/LINKSVC "*title*"
Enter the name of the service title. The quotes must be included. Any title name can be used.

/SERVER:*servername*
This is the name of the computer on which the link service is to be installed.

/LSTYPE:"DLC 802.2 Link Service"
This parameter is used to list the available options for the DLC 802.2 link service. You must type in the exact string as shown above for it to work correctly. The quotes must be included.

/ADAPTERTYPE:*adaptertype*
This parameter specifies the adapter type (using the adapter name) for the link service. Type the name of the adapter. This is an optional parameter and does not need to be defined if there is only one adapter installed. If there are multiple adapters in the computer and this parameter is not specified, it will use the first adapter it finds in the Registry, and only if the adapter has been bound with the DLC protocol.

The adapter name can be located in the registry using the following path:

```
HKEY_LOCAL_MACHINE
   SOFTWARE
      Microsoft
         Windows NT
            CurrentVersion
                NetworkCards
                   number
                      NetRules
```

The value is:

Bindform:REG_SZ: "*short name of adapter*" *yes yes container*

/SAP:hexvalue
Enter the SAP address using a hexadecimal value. For example, an acceptable value is 0x4, or 0xC.

/DISTRIBUTABLE:{ yes | no }
This parameter is used to specify whether the link service will be distributed. The Distributed Link Service feature provides a method for a Host Integration Server 2004 computer to connect with a host using a link service installed on a different Host Integration Server 2004 computer.

VSAM File Transfer

The VSAM File Transfer tool is a command-line utility that supports file transfer to and from mainframe VSAM data sets and PDS/PDSE members using the stream input/output protocol of the IBM Distributed Data Management (DDM) architecture, level 2 and higher.

This utility is implemented as a source DDM requester and interoperates with a specific target DDM server implementation on MVS/ESA and OS/390 called IBM Distributed FileManager. The DDM server is available as a component of IBM Data Facility Storage Management Subsystem (DFSMS), Version 1 Release 2 or higher.

The VSAM File Transfer utility is executed from a command prompt by typing "ddmftp." To open a host session for purposes of file transfer, type "open." You receive the following interactive prompts:

```
DDMFTP> open

host [remote LU] REMOTELU

user USERID

password PASSWORD

dataset [USERID] USERID.DATASET

local LU [LOCAL] LOCALLU

mode [QPCSUPP] MODE
```

You can also batch the commands by typing the following:

DDMFTP> open remotelu=REMOTELU user=USERID password=PASSWORD dataset=USERID.DATASET locallu=LOCALLU mode=MODE

The required elements are remotelu, user, and password. The remaining three elements are defaulted to dataset=USERID, and locallu=LOCAL, and mode=QPCSUPP.

To obtain help, type "help" or "?" at a VSAM File Transfer command prompt.

/!
Execute NT command

/?
Help

/help
Help

/quit
Quit DDMFTP

/bye
Quit DDMFTP

/get
Download file from host

/open
Open host session

/put
Upload file to host

/del
Delete host file

/delete
Delete host file

/close
Close host session

/disconnect
Close host session

/dir
List host files

/ls
List host files
/lcd
Show current local directory
/pwd
Show current host directory
/user
Specify username [and password]
/send
Upload file to host
/recv
Download file from host
/type
Transfer type
/append
Append local file to host file
/hash
Enable/disable hash mark printing
/connect
Open host session
/bell
Beep when command completed
/exit
Quit DDMFTP
/rlen
Set record length
/cd
Change current host directory

Note The APPEND command is not supported in this release.

The VSAM file transfer utility currently does not support PC directory paths containing spaces.

The utility also does not support the '.' and '..' commands in the change directory (CD) command.

To use the VSAM file transfer utility, your mainframe must be running the DFM component of the IBM DFSMS/MVS version 1.2 or later (bundled with the OS/390 release).

Snasvc Reference

This section describes how to use Snasvc to add or remove SNA services.

This section contains:

- Use Snasvc to Add or Remove an SNA Service

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Use Snasvc to Add or Remove an SNA Service

Each Host Integration Server 2004 computer supports up to four SNA Services each of which can support connections, logical units (LUs), and other resources, independent of the other SNA Services. Snasvc is a command-line utility that allows you to add or remove an SNA Service from a given Host Integration Server 2004 computer.

> **Note** Snasvc must be run from a computer on which Host Integration Server 2004 is installed and from the computer you intend to add or remove SNA Services.

Syntax

```
snasvc [options]
```

Options for Snasvc

/?
  Displays a list of available command-line options for Snasvc.
/d
  Enables the delete flag for Snasvc. If the **/d** flag is not specified, Snasvc assumes the specified SNA Service will be added.
2
  Specifies service 2.
3
  Specifies service 3.
4
  Specifies service 4.

Examples

```
snasvc 2
```

Adds service 2 to the current configuration.

```
snasvc 3 /d
```

Removes service 3 from the current configuration.

```
snasvc 2 3 4
```

Adds services 2, 3, and 4 to the current configuration.

```
snasvc 3 4 /d
```

Removes services 3 and 4 from the current configuration.

Sample Host Definitions

This section presents some sample host definitions used for establishing a Microsoft® Host Integration Server 2004 computer connection to IBM S/370 (host) systems. The samples show configuration values for Host Integration Server 2004 computer connections of the following types:

Connection type	Connection use	Host system
Token Ring	3270 emulation	Virtual Telecommunications Access Method (VTAM)
SDLC switched	3270 emulation	VTAM
SDLC leased	3270 emulation	VTAM
X.25	3270 emulation	VTAM
Any type	LU 6.2	Customer Information Control System (CICS)

Note The VTAM listings in this topic omit the column 72-continuation character.

- This section contains:
- Token Ring Definition
- SDLC Definition (for Switched and Leased Lines)
- X.25 Definition

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Token Ring Definition

The following table shows a VTAM definition for a connection between a Host Integration Server 2004 computer and an IBM 9370 host computer across a Token Ring local area network (LAN).

VTAM Token Ring definitions

Name	Description	Parameters
LANODE	VBUILD	TYPE=LAN
R01100	PORT	CUADDR=100,MACADDR=400001701100, LANCON=(5,2),MAXDATA=2012, MAXSTN=32,SAPADDR=04
G01100	GROUP	DIAL=YES,ISTATUS=ACTIVE,LNCTL=SDLC
L01100A	LINE	CALL=INOUT
P01100A	PU	MAXLU=254
L01100B	LINE	CALL=INOUT
P01100B	PU	MAXLU=254
SWLAN	VBUILD	TYPE= SWNET,MAXGRP=5,MAXNO=12
SERVER01	PU	ADDR=C1,IDBLK=05D,IDNUM=00001, ANS=CONTINUE,MAXDATA=265, MAXOUT=7,MAXPATH=7,PACING=0, VPACING=0,SSCPFM=USSSCS, LANACK=(0,0),LANCON=(5,2), LANINACT=4.8,LANRESP=(5,2), LANSDWDW=(7,1),LANSW=YES, MACADDR=4000000000FD,PUTYPE=2, DISCNT=(NO),ISTATUS=ACTIVE, SAPADDR=04
E01100A	PATH	DIALNO=0004400001701100, GRPNM=G01100,GID=1,PID=1,USE=YES
T0110000	LU	LOCADDR=002,DLOGMOD=D4C32782
T0110001	LU	LOCADDR=003,DLOGMOD=D4C32782
T0110002	LU	LOCADDR=004,DLOGMOD=D4C32782
T0110003	LU	LOCADDR=005,DLOGMOD=D4C32782
T0110004	LU	LOCADDR=006,DLOGMOD=LU33286S

The following table defines key parameters for Token Ring.

VTAM parameter descriptions for Token Ring

VTAM parameter	Corresponding Host Integration Server 2004 parameter	Description
IDBLK=	First three digits of local node ID (basic connection setting)	A three-digit hexadecimal value that, together with IDNUM, identifies the Host Integration Server 2004 computer. The values 000 and FFF cannot be used; these values are reserved.
IDNUM=	Last five digits of local node ID (basic connection setting)	A five-digit hexadecimal value that, together with IDBLK, identifies the Host Integration Server 2004 computer.
MAXDATA= (in the PU definition for SERVER01)	Max basic transmission unit (BTU) Length (advanced 802.2 setting)	The maximum length of a BTU sent or received; BTUs are also known as I-frames. Max BTU Length should be less than or equal to MAXDATA.

MACADDR= (in the PORT definition)	Remote Network Address (basic 802.2 setting)	The media access control address, a 12-digit hexadecimal address.
SAPADDR= (in the PU definition)	Remote service access point (SAP) Address (advanced 802.2 setting)	The system access point address, a two-digit hexadecimal number, a multiple of 4, between 04 and EC.
LOCADDR= (in the LU definition)	Local unit (LU) Number	The LU local address at the physical unit (PU). For independent LUs that communicate with a host, the LOCADDR parameter must be set to 0. For dependent LUs with VTAM, the LOCADDR must be at least 2. Also, for dependent LUs, the LU Numbers set in the Host Integration Server 2004 computer must match the LOCADDR values on the host.

The GRPNM value shown in the sample above is a group name; group names must match the label of a VTAM group definition. The DLOGMOD values shown in the sample are the logon mode table entries from the mode table. For descriptions of the group macros used in these samples and a complete listing of default mode table entries, see the documentation for your IBM product.

CICS and VTAM Sample Definitions for LU 6.2

This topic presents sample definitions for CICS (version 1.6) and VTAM (version 3.2) for Host Integration Server 2004 computer connections to an IBM host system for LU 6.2 operation.

To configure a CICS host system for LU 6.2 operation with a Host Integration Server 2004 system, you configure the following information at the host:

- The remote systems with which CICS is able to communicate.
- The name used by VTAM to communicate with each remote system.
- The transaction programs (TPs) available on the CICS system.
- The programming language (PL/I, COBOL, or Assembler) in which each program is written.

This information is configured in CICS and VTAM tables. This topic provides sample definitions that show how to configure CICS for LU 6.2 using these CICS and VTAM tables.

This section contains:

- CICS Tables
- VTAM Definitions

CICS Tables

CICS uses the following tables to define LU 6.2 information:

- Terminal Control Table (TCT)—defines the remote systems to CICS.
- Program Control Table (PCT)—defines the local TPs to CICS.
- Program Processing Table (PPT)—defines the load module characteristics to CICS.

The following sections describe these tables, and include sample definitions to illustrate how they are used.

> **Note** These samples assume there are four TPs residing on CICS written in PL/I with the following names: TRAN0, TRAN1, TRAN2, and TRAN3.

This section contains:

- Terminal Control Table
- Program Control Table
- Program Processing Table

Terminal Control Table

The sample Terminal Control Table (TCT) defines the remote systems to CICS. Each remote system is specified using a DFHTCT definition, which includes both the name by which CICS knows the system (the SYSIDNT field), and the name by which VTAM knows the system (the NETNAME field).

Sample CICS terminal control table entries

Label	Definition	Operands
TP11	DFHTCT	TYPE=SYSTEM ACCMETH=VTAM, FEATURE=SINGLE,TRMTYPE=LUTYPE62, NETNAME=TPLU6207,SYSIDNT=DC11, MODENAM=LU62,CONNECT=AUTO, BUFFER=256,RUSIZE=256, TRMSTAT=(TRANSCEIVE)
TP12	DFHTCT	TYPE=SYSTEM ACCMETH=VTAM, FEATURE=SINGLE,TRMTYPE=LUTYPE62, NETNAME=TPLU6208,SYSIDNT=DC12, MODENAM=LU62,CONNECT=AUTO, BUFFER=256,RUSIZE=256, TRMSTAT=(TRANSCEIVE)
TP13	DFHTCT	TYPE=SYSTEM ACCMETH=VTAM, FEATURE=SINGLE,TRMTYPE=LUTYPE62, NETNAME=TPLU6209,SYSIDNT=DC13, MODENAM=LU62,CONNECT=AUTO, BUFFER=256,RUSIZE=256, TRMSTAT=(TRANSCEIVE)
TP14	DFHTCT	TYPE=SYSTEM ACCMETH=VTAM, FEATURE=SINGLE,TRMTYPE=LUTYPE62, NETNAME=TPLU620A,SYSIDNT=DC14, MODENAM=LU62,CONNECT=AUTO, BUFFER=256,RUSIZE=256, TRMSTAT=(TRANSCEIVE)

See Also

CICS Tables

Program Control Table

The Program Control Table (PCT) defines the local transaction programs (TPs) to CICS. Each TP is specified using a DFHPCT definition that includes the name by which the TP is invoked (the TRANSID field) and the corresponding load module name from the CICS library of TPs.

Sample CICS program control table entries

TP Label	Definition	Operands
TRAN0	DFHPCT	TYPE=ENTRY PROGRAM=TRAN0000, TWASIZE=1000,SPURGE=NO,TPURGE=NO, RSL=00,RSLC=NO,MODENAM=NORMAL, TRANSID=TRAN0
TRAN1	DFHPCT	TYPE=ENTRY PROGRAM=TRAN0001, TWASIZE=1000,SPURGE=NO,TPURGE=NO, RSL=00,RSLC=NO,MODENAM=NORMAL, TRANSID=TRAN1
TRAN2	DFHPCT	TYPE=ENTRY PROGRAM=TRAN0002, TWASIZE=1000,SPURGE=NO,TPURGE=NO, RSL=00,RSLC=NO,MODENAM=NORMAL, TRANSID=TRAN2
TRAN3	DFHPCT	TYPE=ENTRY PROGRAM=TRAN0003, TWASIZE=1000,SPURGE=NO,TPURGE=NO, RSL=00,RSLC=NO,MODENAM=NORMAL, TRANSID=TRAN3

* ****** * PROFILE TO BE USED IN LU6.2 ALLOCATE * ****** *

TP Label	Definition	Operands
	DFHPCT	TYPE=PROFILE, PROFILE=DFHCICSA, INBFMH=ALL,MODENAME=LU62

See Also

CICS Tables

Program Processing Table

The Program Processing Table (PPT) defines the load module characteristics to CICS.

Each load module is defined using the DFHPPT definition, which includes the name of the load module (the PROGRAM field), and the language in which the module has been written. Examples are PL/I, Assembler, or COBOL (the PGMLANG field).

Sample CICS program processing table entries

Definition	Program name	Language
DFHPPT TYPE=ENTRY	PROGRAM=TRAN0000	PGMLANG=PL/I
DFHPPT TYPE=ENTRY	PROGRAM=TRAN0001	PGMLANG=PL/I
DFHPPT TYPE=ENTRY	PROGRAM=TRAN0002	PGMLANG=PL/I
DFHPPT TYPE=ENTRY	PROGRAM=TRAN0003	PGMLANG=PL/I

See Also

CICS Tables

VTAM Definitions

Each remote system must be defined to VTAM in its table of Network Addressable Units, (NAUs), using logical unit (LU) definitions.

If a LOGAPPL parameter is specified on the LU definition naming the CICS system, CICS will attempt to establish a session to that LU whenever it becomes active. This is necessary if TPs residing in CICS do not use the **ALLOCATE** verb with RETURN_CONTROL=WHEN_SESSION_ALLOCATED to establish sessions. There must also be a VTAM mode table definition present for LU 6.2, although CICS does not use the values specified here.

Sample VTAM network control program (NCP) definition for LU 6.2

Label	Operation	Operands
TPPU62	PU	ADDR=C1,IBLK=03E,IDNUM=01A1A, IRETRY=YES,DISCNT=NO,ISTATUS=ACTIVE, MAXDATA=265,SSCPFM=USSSCS, MODETAB=MRNDS,USSTAB=USSNDN1, MAXOUT=7,PASSLIM=7,PUTYPE=2
TPLU6207	LU	LOCADDR=7,DLOGMOD=LU62, USSTAB=USSNOMSG
TPLU6208	LU	LOCADDR=8,DLOGMOD=LU62, USSTAB=USSNOMSG
TPLU6209	LU	LOCADDR=9,DLOGMOD=LU62, USSTAB=USSNOMSG
TPLU620A	LU	LOCADDR=A,DLOGMOD=LU62, USSTAB=USSNOMSG

The following table shows NCP mode table entries for LU 6.2.

Sample NCP mode table entries for LU 6.2

Label	Operation	Operands
	MODETAB	
LU62	MODEENT	LOGMODE=NORMAL
	. . .	
	MODEEND	

> **Note** It is recommended that the mode used by LU 6.2 be listed first, as shown by the LU62 example in the preceding table.

See Also

TP Coding Requirements

TP Coding Requirements

To work with CICS, TPs must be coded to specify a SYSID parameter on the **ALLOCATE** request that matches the defined SYSIDNT parameter configured in the DFHTCT tables. This request must be in the following format:

```
EXEC CICS ALLOCATE SYSID('DC11')
```

The SYSID field must match the SYSIDNT field specified for a CICS program by the DFHTCT definition in the TCT (Terminal Control Table). The TCT then uses the NETNAME parameter to refer to a specific LU in the VTAM table of the NAUs (Network Addressable Units). This parameter is used by the TP to communicate with the remote system.

VTAM Definitions

Sense Codes

This section lists the sense codes used by Microsoft® Host Integration Server 2004

Host Integration Server 2004 sense codes are sent on either a negative response to an outbound data stream or an LUSTAT that notifies the host of a change in the secondary logical unit (LU) state. The sense codes generated by a 3270 emulator program are shown in the following tables.

Negative response sense codes

Value	Meaning
0802	Intervention required (LU 1/LU 3 printer soft error).
0814	Bracket bid reject – RTR forthcoming.
081B	Receiver in transmit mode.
081C	Request not executable (hard error).
0821	Invalid session parameters (negotiable BIND request).
0829	Change direction required.
082B	Presentation space integrity lost.
082D	LU busy (usually local copy print in progress).
082E	Intervention required (local copy print soft error).
082F	Request not executable (local copy print hard error).
0843	WCC print command bit not sent (RQD or RQE, CD, EB).
0863	Referenced character set does not exist.
0871	Read partition state error (SLU in retry state).
1003	Function not supported.
1005	Parameter modifying a control function is invalid.
1007	Category not supported (SSCP data for host printer).

LUSTAT sense codes

Value	Meaning
0001 B000	Host initialized local copy soft error recovery.
081C 0000	Soft error changed to hard error (LU 1/LU 3).
081C B000	Soft error changed to hard error (local copy).
082B 0000	LU session changed from SSCP to PLU (SYSREQ).

Host Print Service Character Translation Table Format

Host Print Service Character Translation Table Format

The character translation table that can be used by the custom code page option of Host Print service is a 512-byte file, split into two 256-byte regions. Bytes 0–255 are the mapping bytes for data from the host; bytes 256–511 map data to the host.

For example, the following illustrates standard translation tables for the 037 EBCDIC code page:

```
   | 00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
---------------------------------------------------

```

Bytes 0-255: Data from Host

Each byte that is received represents a location, that is, a byte offset, in the appropriate table. For example, if the value 0xC1 (the EBCDIC value for the letter A) is received from the host, it is converted to the value in position 0xC1 in the first table; that is, to 0x41 (the ASCII value for the letter A). This is shown in bold in the preceding table.

Similarly, if the letter *Z* (ASCII value 0x5A) is to be transmitted to the host, it is first converted to the value located in position 0x5A in the second table, which is 0xE9 (the EBCDIC value for Z). This is shown in bold in the table below:

```
   | 00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
00| 00 01 02 03 37 2d 2e 2f 16 05 25 0b 0c 0d 0e 0f

```

Bytes 256–511: Data to Host

Currently, only the first table (bytes 0–255) is used by Host Print service. However, the file must be exactly 512 bytes in length, so the final 256 bytes must be present, even if they are set to zero.

http://go.microsoft.com/fwlink/?linkid=29507.

SDK

This software development kit (SDK) section of Microsoft® Host Integration Server 2004 Help provides information for the programmer writing applications for Host Integration Server 2004.

Using Help in a Developer Environment

Microsoft® Host Integration Server 2004 Help contains features that you can use to display the developer documentation in your preferred language and to link between Host Integration Server 2004 Help and Visual Studio 2003 Help.

Using language filtering

The Host Integration Server 2004 .NET Class Reference and COM Object Reference provide signatures and code examples in multiple programming languages. The following tags denote the language-specific information:

- [C#]
- [Visual Basic]
- [C++]
- [JScript]

You can customize your view of the content in the reference pages to display information only in your preferred programming language. To select a custom language, use the Language Filter button in the upper-left corner of the reference page. After it is enabled, the language filtering is persisted until it is changed. When language filtering is enabled on a page, the name of the language follows the title in the blue bar at the top of the page.

Viewing Host Integration Server Help in Visual Studio

You can view Host Integration Server 2004 Help in three ways:

- In Microsoft Visual Studio® .NET 2003. Select **Contents** on the **Help** menu in Visual Studio .NET 2003.
- In the Microsoft Visual Studio .NET 2003 Documentation. Select **Microsoft Visual Studio .NET 2003** from the **Programs** menu.
- In the standalone Microsoft Host Integration Server 2004 Help. Select **Host Integration Server Documentation** from the **Programs, Microsoft Host Integration Server 2004** menu.

If you are developing in Visual Studio .NET, either of the first two methods are recommended. Using either of these methods enables integration between Host Integration Server Help and Visual Studio .NET Help; this integration is extremely useful when navigating class relationships across the documentation sets. If you view Host Integration Server Help outside of Visual Studio .NET, read the following tip to properly render links to Visual Studio .NET.

Linking between Host Integration Server 2004 Help and Microsoft Visual Studio .NET Help

When a member is inherited from the .NET Framework Base Class Library, two links are provided, as shown in the following example:

Finalize (inherited from **System.Object**)	For additional information about the System namespace, see .NET Framework Help available from Visual Studio .NET or go to http://go.microsoft.com/fwlink/?LinkID=9677.

If you are viewing Host Integration Server Help in Visual Studio .NET or in the Visual Studio .NET Documentation, the link in the left column goes to the exact member page. If you are viewing Host Integration Server 2004 Help outside of Visual Studio, use the link in the right column to go to the System namespace page in MSDN Library. Note that the link will not go to the specific member page.

Programmer's Guide

Microsoft® Host Integration Server 2004 provides comprehensive bidirectional services for integrating Microsoft Windows® with legacy systems. Host Integration Server 2004 extends Windows to other platforms by providing interoperability in three areas:

- Application Integration Services
- Data Integration Services
- Network Integration Services

Most of the services provided by Host Integration Server 2004 expose a programming interface, which enables you to extend the functionality of the product and integrate it more tightly in your own environment. This guide describes these interfaces and provides guidance on how to use them.

This section contains:

- Transaction Integrator Programmer's Guide
- Data Integration Programmer's Guide
- Network Integration Programmer's Guide
- Administration and Management Programmer's Guide

Transaction Integrator Programmer's Guide

This section of the Microsoft® Host Integration Server 2004 Software Development Kit (SDK) provides information required to develop software to integrate COM and .NET applications with Customer Information Control System (CICS) and Information Management System (IMS) transactions on IBM mainframe and AS/400 computers.

Transaction Integrator (TI) enables developers to integrate mainframe-based transaction programs (TPs) with component-based Microsoft® Windows® applications. With Transaction Integrator, you can integrate existing mainframe-based TPs with Windows-based COM or distributed COM (DCOM) applications. You may not have to modify your mainframe TP if the business logic is separate from the presentation logic. The wizards available in the TI Designer and TI Manager guide you through the process, step-by-step.

Transaction Integrator is appropriate when you need a synchronous or transactional solution where both systems being integrated are running at all times. For applications only requiring an asynchronous integration solution, a messaging-based solution using the MSMQ-MQSeries Bridge is preferred over Transaction Integrator.

Applications that integrate message queuing and that use MSMQ-MQSeries Bridge in a Host Integration Server 2004 environment can be developed using several different development tools and application programming interfaces including the following:

- C or C++ applications that use the MSMQ-MQSeries Bridge Extensions to extend the MSMQ-MQSeries Bridge.
- Microsoft Visual Basic® applications that use MSMQ-MQSeries Bridge Extensions to extend the MSMQ-MQSeries Bridge.

To use this guide effectively, you should be familiar with the following:

- Microsoft Host Integration Server 2004
- Microsoft Windows® 2000 or later
- Message Queuing
- IBM MQSeries

Depending on the application programming interface and development tools used, you should be familiar with the following:

- Microsoft COM objects
- ASP
- ASP.NET

For API references and other technical information for the Transaction Integrator, see the Transaction Integrator Programmer's Reference in the Programmer's Reference section of the SDK.

For sample code using the Transaction Integrator, see Sample Programs for Transaction Integrator and Transaction Integrator Tutorials in the Samples section of the SDK.

Transaction Integrator Designer

Transaction Integrator (TI) Designer is a graphical user interface for creating TI components, which are annotated type libraries or assemblies. It is a stand-alone program that does not need to be connected to the mainframe. You can use TI Designer to export or import the host data declarations used in mainframe Customer Information Control System (CICS) and Information Management System (IMS) programs or AS/400 programs.

TI Designer is hosted within the Microsoft® Visual Studio® .NET environment. You can use it to generate both Windows®-initiated processing (WIP) and host-initiated processing (HIP) objects. TI Designer also supports COM type libraries and .NET assemblies.

This section contains:

- Installing Transaction Integrator Designer
- Application Development Software Requirements
- Creating a New Transaction Integrator Project
- Using Solution Explorer
- Reporting Errors
- Migrating from Earlier Versions of Host Integration Server

Installing Transaction Integrator Designer

Transaction Integrator (TI) Designer is installed and configured by the Microsoft® Host Integration Server 2004 Installation Wizard. You can install and configure TI Designer at the time you first install Host Integration Server 2004, or you can use the Host Integration Server 2004 Installation Wizard at a later time to add TI Designer. The Host Integration Server 2004 Installation Wizard installs everything you need, including program files, Help files, the CedarBank sample application, and other tools. The TI Project template is automatically installed on your computer at <drive>:/Program Files/Microsoft Host Integration Server/System/Projects/.

> **Note** TI Designer is hosted within the Visual Studio .NET development environment and must be registered in Visual Studio at the time of installation. Be sure that Visual Studio .NET is installed on your computer before you install TI Designer.

To install Transaction Integrator Designer

1. Launch Host Integration Server 2004 Setup and accept all defaults until you reach the **Custom Installation** page.
2. On the **Custom Installation** page, expand the **Application Integration** node.
3. Select **Transaction Integrator Designer** and any other options you want to install.
4. Click **Next**, and then follow the on-screen directions.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Application Development Software Requirements

Use Transaction Integrator (TI) Designer to develop your TI components. A TI component exposes an Automation interface or .NET assembly. To fully support TI Automation servers, use the following additional Windows-based client application software that will call a TI Automation server. If you use these Microsoft tools, keep these requirements in mind:

- To create components with Microsoft® Visual Basic®, use version 5.0 or later. To use all the TI features, such as user-defined types (UDTs), you must use Microsoft Visual Basic version 6.0 or later.
- To create components with Microsoft® Visual C++®, use version 4.2b or later with the Active Template Libraries (ATL) version 1.1 or later. If you use Visual C++ version 4.2, you must have the Win32® software development kit (SDK).
- To create and run Java components, use Microsoft® Visual J++® version 1.0 or later and the Java Virtual Machine installed with Microsoft Internet Explorer version 5.0 or later. You can download the latest version of Internet Explorer from http://go.microsoft.com/fwlink/?LinkId=12773.
- To create Internet applications, use Microsoft Internet Information Server (IIS) version 4.0 or later and Microsoft Internet Explorer version 5.0 or later.

Note If your TI components include recordsets, install the Microsoft Data Access Components (MDAC) on any client computer that uses distributed COM (DCOM) to gain remote access to TI components.

Creating a New Transaction Integrator Project

You can create a new Transaction Integrator (TI) Project within the Visual Studio .NET development environment.

To create a TI Project

1. On the **Start** menu, point to **Programs**, and then click **Microsoft Visual Studio .NET**.
2. On the Visual Studio .NET **File** menu, click **New**, and then click **Project**.
3. Under **Project Types,** select **HIS Projects**.
4. Under **Templates,** select **TI Project**.
5. After **Name**, type the name of the project. The name can be a maximum of 256 Unicode characters.
6. After **Location**, type or browse the location to store the project.

See Also

Using Solution Explorer

Using Solution Explorer

The Visual Studio Solution Explorer provides an organized view of projects and their files, as well as access to available commands and toolbars. The files supported by the project are:

- COM Client-Initiated libraries, which are COM type libraries (.tlb).
- .NET Client-Initiated libraries, which are .NET assemblies.
- Host-Initiated libraries which are Transaction Integrator Metadata (.tim).

To open Solution Explorer

- On the **View** menu, click **Solution Explorer**.

Transaction Integrator Designer

Migrating from Earlier Versions of Host Integration Server

1. Upgrade all your type libraries at once by dragging them into Microsoft Visual Studio® and then clicking **Save All**. Create new REs that have the same characteristics as the old REs using the TI Manager. Associate the updated type libraries with the new REs. This is the easiest upgrade path.
2. Upgrade your type libraries one-at-a-time by opening them in Visual Studio and then clicking **Save As**. Create new REs that have the same characteristics as the old REs using the TI Manager. Associate the updated type libraries with the new REs.
3. Upgrade your type libraries one-at-a-time by creating new type libraries, and then importing the property settings from the old type library. Use TI Manager to create new REs that have the same characteristics as the old REs. Associate the updated type libraries with the new REs. This is the most time-consuming option because each library is created individually.

When a type library is fully upgraded to HIS 2004, three aspects of the old type library may be updated depending on the upgrade process you used. These are:

- Remote environment class
- Library, interface, coclass, and UDT GUIDs
- Default conversion information defined at the library level. The defaults for converting data types are different in TI than in COMTI.

Depending upon your circumstances and the requirements of your applications, you might want to update one, two, or all three aspects.

User Action	TI Actions	Results	When to use
None. Use existing Type Libraries and REs.	No changes are made to: • RE • Type library GUID • Type library default conversions	• Type library and RE is fully functional in both HIS 2004 and HIS 2000. • The properties within the type library and RE can no longer be modified. • New Type libraries created with TI Project cannot be associated with older REs. • Existing COM client works unmodified.	• Initial upgrade to HIS 2004. • Old type libraries and old REs work and do not need to be modified.

Open and **Save**	- Updates the Remote Environment class. No changes are made to: - Type library GUIDs - Default conversions	- The method property **Include Context Parameter** is automatically set to **True**. Client Applications do not need to support the Client Context and work unchanged as Client Context is an optional parameter in the COM environment. In the Visual Studio TI Project, set **Include Context Parameter** to **False** on the method. - Old type libraries are updated the HIS 2004. The updated type library can only be associated with an RE created with TI Manager. - Existing COM client works unmodified.	- When a new RE needs to be created in the HIS 2004 environment. - Using new HIS 2004 RE features. - Using new Client context features (Client Security, Persistent Connections, and so forth). - Moving to the HIS 2004 supported environment. - Programming model stays the same.

Open and **Save As**	• Updates the Remote Environment class. • Generates new type library GUIDS. Save does not. • No changes made to the type library default conversions	The method property **Include Context Parameter** is automatically set to **True**. Client Applications do not need to support the Client Context and work unchanged as Client Context is an optional parameter in the COM environment. In the Visual Studio TI Project, set **Include Context Parameter** to **False** on the method. If you migrate an old type library to a .NET assembly, TI also migrates all Visual Basic version 6.0 Automation data types to Visual Basic .NET data types, including: • Integer to Short • Long to Integer • Currency to Decimal • Recordset to datatable • UDT to Structure Client Applications using the **NewRecordSet** function to create disconnected recordsets must modify the code. The **NewRecordset** function is not supported in .NET. Existing COM Clients that use early binding need to be recompiled because of GUID changes.	• Creating a new instance of the application for side by side operation with HIS 2004 with the intent of extending the application. • Programming model stays the same.
Import	• Updates the Remote Environment class • Updates the GUIDs • Adds HIS 2004 defaults to the new library	• Same results as **Open** and **Save As** • All methods use new library default defined for HIS 2004 • This is the only way to migrate type libraries to Assemblies.	• Same as **Save As** • Programming model change • Target environment change (CICS, IMS, AS/400) • Initiation change (WIP, HIP) • Platform change (COM, .NET)

Introduction to COM and COM+

The Component Object Model (COM) is a binary standard that enables software components to interoperate in a networked environment regardless of the language in which they were developed.

Transaction Integrator (TI) is based on COM, which defines a standard way of handling and reporting errors. (COM is the foundation for COM+.) To understand TI behavior and errors, you need to understand how it uses COM.

Objects and clients are the basic building blocks of COM applications. An object is a piece of software that can do a specific task. A client is software that uses and controls objects.

COM can be compared to business relationships. There are many different businesses that provide their customers (clients) with products and services (objects) that the clients can use and control. COM applications are clients that make use of objects that can do specific tasks. For example, in computer technology, Powerpnt.exe depends on several Microsoft® Office and Microsoft Windows® utility objects to do most of the work involved with editing and presenting a presentation. The Powerpnt.exe is just a client to those utility objects and directs them to their tasks. When you want to open a .ppt file, a dialog box appears, from which you choose the file to open. This dialog box is displayed by a Windows utility object that can display a **File Open** dialog box, rather than by Powerpnt.exe.

Dividing software into clients and objects enables you to use those clients and objects as building blocks that can be combined and reused in many different ways by many different clients, just as standard building materials can be used to construct many different structures.

COM and COM+ are the key technologies that provide the infrastructure that enables clients and objects to work together. Other key COM concepts include methods, interfaces, classes, references, and components, which build on the foundation of clients and objects.

Introduction to COM and COM+

COM+ Defined

Component Services (COM+) consists of the latest version of COM, distributed COM (DCOM), and Microsoft Distributed Transaction Coordinator (DTC), plus additional functionality. With COM+, administrators can deploy and administer COM+ applications through a graphical user interface, or automate administrative tasks using a scripting or programming language. Software developers can use COM+ to visually configure routine component and application behavior, such as security and participation in transactions, and to integrate components into COM+ applications.

To open COM+, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Component Services**. Component Services is also available in Transaction Integrator (TI) Manager as follows: Start **TI Manager** and double-click the **Component Services** folder.

Component Services provides standard application functionality for administration, deployment, security, reliability, and scalability. Component Services simplifies the administrator's work by providing a tool for administering all applications visually through a single user interface.

Introduction to COM and COM+

Component Services Features

Component Services (COM+) builds on COM concepts and adds three major new elements: COM+ applications, increased administrator involvement, and interception. You can gain access to Component Services from within TI Manager.

A COM+ application is a COM component that includes one or more components developed and configured to work together by Component Services to simplify administration of application servers. Each COM+ application unites TI components (type libraries) and COM components with configuration information about how they should be deployed, thus making a single unit for deployment and administration. A wizard helps to deploy COM+ applications. You can easily administer COM+ applications by using Component Services in TI Manager. This feature gives administrators complete control over application server deployment and configuration. COM+ applications also aid in the configuration of an application's presentation tier. Administrators can use Component Services to quickly create application proxies that can be used to configure thousands of client computers.

Component Services expands the role of administrators by empowering administrators to do many tasks that were previously done exclusively by developers. In the application development phase, developers write their own custom type libraries or use TI Designer to create TI component libraries from COBOL transaction programs (TPs). Then developers deploy the TI components in a COM+ application and configure the application settings as needed. The COM+ application is a deployable unit that the developer can pass to the administrator to deploy.

The administrator receives a COM+ application file from a developer, and then uses Component Services to deploy that application on the server computer. Next, the administrator configures permissions to use the application, as well as other settings. Then, the administrator creates an application proxy, which is a file used to configure each client computer in the presentation tier. After using Microsoft® Active Directory® directory service and IntelliMirror® to complete the client configuration, the administrator continues to use Component Services to monitor the application's behavior.

Component Services intercepts all calls from clients to objects, and you can use it to manage objects and their interaction with clients. Because of this interception capability, Component Services governs the interaction between objects and their clients, and does a lot of the work that would be done by objects themselves. You can design objects to do business logic only; Component Services handles everything else by tracking object behaviors and needs and by managing everything the objects do.

The following are the major features of Component Services that are supported by Transaction Integrator (TI):

- **Administration.** You can use the powerful Component Services user interface to administer the application server tier. You can use Component Services to ease deployment, configuration, monitoring, and upgrades. Component Services also gives administrators the ability to use scripts to control all administration.
- **Scalability.** Component Services achieves high scalability by pooling server resources so that when one person is not using them, another person can. When a resource is needed, it is taken from a shared pool. When the resource is no longer needed, it is returned to the pool. Component Services pools many resources, including threads, ODBC connections, OLE DB connections, and COM objects.

  > **Note** TI supports the Microsoft® Windows Server™ 2003 and Windows® 2000 COM+ feature known as object pooling. To enable object pooling for a TI component, right-click the component, and click **Properties**. Then select the **Enable Object Pooling** check box on the **Activation** tab. There are overall system manageability benefits from enabling this feature for TI components because you can then specify the number of instances to be pre-initialized when the application starts by using the **Minimum Pool Size** field. You can also set an upper limit on the number of active instances by using the **Maximum Pool Size** field to prevent the server running Windows Server 2003 or Windows 2000 from flooding the host system.

- **Transaction Support for Reliability and Data Integrity.** Enterprise applications must have high levels of reliability and data integrity. Component Services provides reliability by offering transaction support. That is, either all the actions in a transaction occur, or none of them occurs. If all of the actions cannot take place, Component Services rolls back all of your object's work so that the databases are left in their original state.
- **Security.** Because Component Services acts as an intermediary between clients and objects, it is able to regulate access to application server functionality. By using the Component Services console, the administrator can give different users different access rights to the application.
- **Queued Components.** Component Services is integrated with another feature of Windows called Message Queuing (also known as MSMQ). Message Queuing gives enterprise applications the ability to continue running even when a server is unavailable. Clients can call COM objects when the COM object is currently unavailable, and the call is stored as a message in Message Queuing. After the server is available again, it retrieves the message from the message queue and processes the call to the COM object.

Introduction to COM and COM+

Distributed Applications

Applications that run partly on the Windows platform and partly on the mainframe are known as distributed applications. Transaction Integrator (TI) components support all local and distributed applications that adhere to the Automation specifications and the distributed COM (DCOM) specifications. DCOM supports communication between objects on different computers on a network by handling the low-level details of network protocols. This enables use of distributed programs that consist of multiple processes working together to accomplish a single task. The Distributed Transaction Coordinator (DTC) is the part of Component Services that coordinates external or two-phase transactions.

Automation

Automation is COM-based technology that enables dynamic binding to COM objects at run time. An Automation server is an application that allows its objects, methods, and properties to be controlled by other applications through Automation. An Automation client (also called an Automation controller) is an application that manipulates the objects, methods, and properties of another application (the Automation server) through Automation. An Automation object is an object that is exposed to other applications or programming tools through Automation interfaces.

A Transaction Integrator (TI) component is a type library that exposes an Automation interface. When you deploy a TI component in a COM+ application, you create an Automation server that can be used by any other COM-based application (Automation client). The Automation client application can call the methods on the Automation interface of a TI Automation server (for example, a TI component deployed in a COM+ application) to invoke a CICS or IMS transaction program (TP) on a mainframe host computer.

An Automation client application connects to a TI Automation server application in one of two ways, early binding or late binding:

- Early binding is similar to programming the speed dialer on your phone. You look up the number once, and program it into the phone. After you verify that it is valid, a single button dials the number.
- Late binding is similar to looking up the phone number in a phone book before each call, and then dialing the phone.

Both early binding and late binding produce the intended result. However, the speed dialer (early binding) is more efficient when you make a call, but looking up the number each time (late binding) ensures that the number you are calling is still correct.

In early binding, you declare a variable as an application-defined object type. A type library, object library, or dynamic-link library is then referenced in the Automation client Tools Reference. Early binding is another name for virtual function table binding or vtable binding. A vtable is a data structure that holds the addresses for the methods and properties of each object in an Automation server. The vtable is contained within the referenced library.

Late binding allows you to create an Automation object as an Object or Variant data type. Late binding uses the **IDispatch** interface. **IDispatch** has no preexisting information about the server that it is calling. It assumes during its compile phase that the code is correct. It then attempts at run time to execute the code and trap for run-time errors.

COM Objects

COM objects are entities in memory that can do specific tasks. Each COM object is an instance of a COM class. COM objects are not files, but can manage or represent files. (A COM objects does not usually represent any particular file.) Their lifetimes are short. COM objects are deleted when program execution is terminated.

Introduction to COM and COM+

COM Methods

A COM method is a specific task that a COM object can perform. When a client requests that an object complete a specific task, that client calls a method of the object. For example, Winword.exe (a client) can call the **Spellchecker** method of a **Word.Document** (object) to run a spell-checking session. A TI Automation client application can call a method of an Automation server to run a mainframe transaction program (TP) and return the results.

Windows Script Host COM Client

Introduction to COM and COM+

COM Interfaces

A COM interface is a specific, immutable set of COM methods. COM clients cannot detect the internal workings of the objects they are using. Therefore, it is important for clients and objects to communicate about and agree on the functionality that an object supplies to a client. This agreement, frequently called a contract, is implemented in software by a COM interface.

To facilitate communication, the COM interface supplies a way for clients to query objects whether they implement specific sets of methods. For example, by way of the interface, COM allows a client to query an object whether it implements a set of file management methods, **FileSave** and **FileOpen**. An interface is named by an Interface ID (IID), which is a globally unique identifier (GUID), a 16-byte number. It is a COM rule that an object must either implement an interface or not implement it. There is no in-between state.

COM rules require that all COM objects must implement the **IUnknown** interface. **IUnknown** is used for:

- **Lifetime management.** To determine when objects are no longer in use and thus can be destroyed.
- **Versioning.** To determine which specific interfaces an object supports.

Objects that implement the **IDispatch** interface are scriptable, or Automation compatible; scripting clients such as Windows Script Host (WSH) can use them. Objects that do not implement **IDispatch** cannot be scripted; that is, scripts cannot call them. Objects that do not implement **IDispatch** cannot be Automation servers*;* client applications cannot use their services. In both cases, this inability is due to the clients' need to know certain details about objects before they can call them.

Automation is COM-based technology that enables dynamic binding to COM objects at run time. When a client COM application is compiled, it does not have all the information about the services offered by the Automation servers that it will be using. Later, during run time, the client application uses an Automation server's **IDispatch** interface to find detailed information about the services that the Automation server offers.

After a TI component is associated with a specific remote environment (RE), and then dropped into a COM+ application, that application (or package) becomes an Automation server with an **IDispatch** interface. Then a client COM application can call upon the TI Automation server to operate (automate) a mainframe-based transaction program (TP) and return the results to the calling client COM application.

COM Classes

A COM class is a definition in source code that can be used as a template for creating objects that implement the **IUnknown** interface and expose only their interfaces to clients.

Different objects implement different methods. COM classes ensure that a given client connects to exactly the right kind of object. Because each COM object is an instance of a specific COM class, COM classes actually classify objects. For example, one class of object is the **Word.Document** class. Any object in this class can manage Microsoft Word .doc files.

Each COM class has two identifiers, the programmatic identifier (ProgID) and the class ID (CLSID). When a client tells COM that it needs use an object, the client always specifies a ProgID or CLSID so that COM knows which class of object to create.

A ProgID is a human-readable registry entry that can be associated with a CLSID. You can use the ProgID within programs to create an instance of a COM class. For example, to create an instance of a COM class that has a ProgID of **Component.MyComponent**, use the following Microsoft® Visual Basic® statement:

```
Set Component = CreateObject("Component.MyComponent")
```

A ProgID must not contain more than 39 characters, start with a digit, nor contain any punctuation (including underscores) other than periods. The pieces are separated by periods; no spaces occur within the ProgID. For example, *Word.Document.6* is a valid ProgID. The typical format of a ProgID is:

```
<Library>.<ComponentName>.<VersionNumber>
```

Although the ProgID is human-readable, it should be used only in programs, and not displayed in the user interface. If you need a short displayable string for an object, call **IOleObject::GetUserType**.

A ProgID identifies a class, but with less precision than does a CLSID. The registry entry appears as follows:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Classes\<ProgID> = <CLSID>
```

You can use a ProgID in programming situations where it is not possible to use a CLSID. The ProgID is not guaranteed to be unique, so use them only where name collisions are manageable.

The CLSID is a globally unique identifier (GUID), such as the following that uniquely identifies the COM class:

```
{71AFDE33-F81B-11d2-B12B-00C04F8C2F72}
```

You can generate a GUID with a program such as Uuidgen.exe.

Introduction to COM and COM+

COM Component and TI Component

A COM component is a binary file (.dll or .exe) containing code for creating a COM object and servicing method calls to it. The COM component can contain code for one or more Transaction Integrator (TI) components, class factories, COM classes, registry-entry mechanisms, type libraries, and so on.

COM-based programs and applications are distributed and deployed as COM components. Each COM component uses interfaces to interoperate with each other in much the same way that a person uses an application user interface to interoperate with an application. Each COM interface contains one or more methods.

A TI component is a type library that acts as a proxy for a mainframe transaction program (TP). You can easily change a TI component into a true COM component by deploying it in a COM+ application. TI components all share the same implementation DLLs but are distinguished by their type libraries. Therefore, when you deploy a TI component in a COM+ application, it is the specific type library (.tlb file) that is registered.

The basic unit of distribution for COM is a component. You can deploy COM components on a computer other than your own. This is what distinguishes COM components from COM objects, which reside in memory and thus cannot be copied from computer to computer.

Deploying a COM component is a two-step process. First, copy the component onto the target computer. This is a file copy operation. Then register the component, that is, configure COM to recognize the component. This configuration information is stored in the registry (and in certain cases in a database called regdb.) In TI, registration is automatic. As soon as you drop a TI component into a COM+ application, the resulting TI Automation server is automatically registered on that computer.

Because TI Manager includes Component Services to deploy or remove TI components, TI component deployment is a matter of dragging your TI component into a COM+ application.

Viewing COM Classes, Interfaces, and Methods

Several tools are available for viewing the COM classes, interfaces, and methods that are deployed on your computer:

- **Component Services (COM+) in Windows 2000**

  Component Services (COM+) is a core part of Windows 2000. A class that has not been configured to use Component Services does not show up in Component Services.

- **OLE/COM Object Viewer (OLE View)**

  This tool shows all the deployed classes and gives comprehensive information about each class, with the exception of Component Services configuration information. It is available free at http://go.microsoft.com/fwlink/?LinkId=12793.

- **DCOMCNFG**

  This tool is present on any computer that has distributed COM (DCOM) installed, including all installations of Windows Server™ 2003, Windows® XP Professional, and Windows 2000 Server. DCOMCNFG displays only a subset of the deployed classes, and shows much less information about each class than does OLEVIEW. Its main advantages are that it is automatically installed with DCOM and its graphical user interface (GUI) is less cluttered than the OLEVIEW GUI.

Windows Script Host COM Client

Introduction to COM and COM+

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Windows Script Host COM Client

Microsoft® Windows is filled with utility COM objects that you can use to manage system configuration, users, printers, Active Directory® directory service, and so on. Windows Script Host is a client that controls those Windows objects through scripts. Scripts give administrators much more administrative power than batch (.bat) files afford. The administrator writes a script, a file ending with .vbs or .jvs, with content much like a .bat file. The administrator then double-clicks the script to load Windows Script Host and run the script.

The following is an example of a short Microsoft Visual Basic® Scripting Edition (VBScript) client script. This script has only three lines. The first line establishes a connection to the COM object. The second line calls a method, and the third line displays the result.

```
Set SaySvrObject = CreateObject("Saysvr.Sayclass")
Speech = SaySvrObject.SaySomething
MsgBox Speech
```

In this script:

- **Saysvr.Sayclass** specifies the COM class.
- **CreateObject** is the script's way of requesting that COM give it a reference to the object.
- **SaySvrObject** represents the reference to the object. After this line is completed, the script will have a live reference to the COM object.
- On the right side of the second line, the script uses its SaySvrObject reference to call the **SaySomething** method, which returns a string to the script.
- Speech represents the string returned by the script.
- The third line displays the Speech string in a Message Box.

Introduction to COM and COM+

Data Types

The Transaction Integrator (TI) run-time environment manages the process of converting host data types used by a host-based transaction program (TP) to and from the Automation data and data types used by a Microsoft® Visual Basic® or other Windows®-based programming language.

The topics in this section give you tips for handling different types of data, and they explain how data types are converted and used in both IBM host and Automation programming languages.

TI supports Automation, COM aggregate, and mainframe data types. For a complete listing of the supported data types, see Supported TI Data Types

This section contains:

- Supported TI Data Types
- Data Type Conversion
- Integer Data Type
- Decimal Data Type in Visual Basic
- Variant Data Type
- Recordsets and Datatables
- Arrays
- User-Defined Types (UDTs)
- Transaction Request Messages
- Overriding Settings in the Type Library
- Persistent Connections with the Mainframe

Supported TI Data Types

Transaction Integrator (TI) supports the data types used by COM, .NET, COBOL, and Report Program Generator (RPG).

This section contains:

- Supported Automation Data Types
- Supported COM Aggregate Data Types
- Supported .NET Aggregate Data Types
- Supported COBOL Data Types
- Supported RPG Data Types
- Supported RPG Keywords

Supported Automation Data Types

Automation data types are simple types that you can put into a Variant data type.

1-byte unsigned Integer (BYTE)

An Integer data type that has a positive value ranging from 0 through 255.

2-byte signed Integer

An Integer data type that can be either positive or negative. The most significant bit is the sign bit: 1 for negative values and 0 for positive values. The storage size of the integer is 2 bytes. A 2-byte signed Integer can have a range from –32,768 through 32,767.

4-byte signed Integer

An Integer data type that can be either positive or negative. The most significant bit is the sign bit: 1 for negative values and 0 for positive values. The storage size of a 4-byte signed Integer is 4 bytes. A 4-byte signed Integer can have a range from –2,147,483,648 through 2,147,483,647.

4-byte Real (Single)

A single-precision 32-bit (4-byte) floating-point Real data type (often called a Single). It ranges in value from –3.402823E38 through –1.401298E-45 for negative values, from 1.401298E-45 through 3.402823E38 for positive values, including 0.

8-byte Real (Double)

A double-precision 64-bit (8-byte) floating-point Real data type (often called a Double). It ranges in value from –1.79769313486232E308 through –4.94065645841247E-324 for negative values, from 4.94065645841247E-324 through 1.797693134862325E308 for positive values, including 0.

Boolean

An expression that can be evaluated either true (nonzero) or false (0). (You can use the keywords True and False to supply the values of –1 and 0, respectively.) The field data type Yes/No is Boolean and has the value of –1 for Yes and 0 for No. Several property page settings are Boolean, including Yes/No, True/False, and On/Off.

Variable-length String (BSTR)

A fundamental data type that holds character information. A String value can contain approximately 65,535 bytes (64 KB). It can be fixed-length or variable-length, and it contains one character per byte. Fixed-length Strings are declared to be a specific length. Variable-length Strings can be any length up to 64 KB, less a small amount of storage overhead. A variable length string can range from 0 to approximately 2 billion bytes (characters).

Currency

An 8-byte fixed-point data type that is useful for calculations involving money or for fixed-point calculations in which accuracy is extremely important. This data type is used to store numbers with up to 15 digits to the left of the decimal point and 4 digits to the right. Currency values can range from –922,337,203,685,477.5808 to 922,337,203,685,477.5807.

Date

A data type that is used to store a date, a time, or a date and time as a 64-bit Real number. The value to the left of the decimal point represents a date, and the value to the right of the decimal point represents a time. The Date data type values can range from January 1, 1000 to December 31, 9999.

Decimal

A data type that stores a signed, exact numeric value described as the number of digits appearing before and after a decimal point, with a maximum total of 18 digits.

Supported COM Aggregate Data Types

Array

A set of sequentially indexed elements having the same intrinsic data type. Transaction Integrator (TI) supports an array of any of the Automation data types. Each element of an array has a unique identifying index number. Changes made to one element of an array do not affect the other elements. TI supports multidimensional arrays. However, only the outermost array of a multidimensional array can vary in size; all the other arrays must be fixed in size. For more information, see Arrays.

User-Defined Type (UDT)

A data type that is defined in a program. A UDT can contain any of the Automation data types as well as arrays of those data types, recordsets, and nested UDTs. A UDT generally contains many different data types that are defined by the programming language used. In COBOL, UDTs are called RECORDS as are any declarations that contain lower-level numbers. For more information, see User-Defined Types (UDTs).

Recordset

An Automation object, also known as an ActiveX® Data Object (ADO) recordset, is the equivalent of a fixed or unbounded table that contains simple types in COBOL or report program generator (RPG) data declarations. After you have a recordset object, you can call methods on that object to gain access to its rows. Recordsets supported by TI have disconnected client-side cursors. For more information, see Recordsets and Datatables.

Supported .NET Aggregate Data Types

Datatable

A .NET object that is the equivalent of a fixed or unbounded table that contains simple types in COBOL or Report Program Generator (RPG) data declarations. After you have a **DataTable** object, you can call methods on that object to gain access to its rows. Datatables supported by TI have disconnected, client-side cursors. For more information, see Recordsets and Datatables.

Structures

A user-defined value type. Like a class, structures can contain constructors, constants, fields, methods, properties, indexers, operators, and nested types. Unlike classes, however, structures do not support inheritance.

The distributed program call (DPC) programming model for the AS/400 supports:

- Only single-level .NET structures.
- Arrays of .Net structures.

The DPC programming model for the AS/400 does not support:

- Nesting of structures.
- Arrays within structures.
- Variable sized structures in which the last parameter is a string.

Array

A set of sequentially indexed elements that have the same intrinsic data type. Transaction Integrator (TI) supports an array of any of the .NET data types in this topic. Each element of an array has a unique identifying index number. Changes made to one element of an array do not affect the other elements. TI supports multidimensional arrays. However, only the outermost array of a multidimensional array can vary in size; all the other arrays must be fixed in size. For more information, see Arrays.

COMP-1

A 4-byte, single precision, floating-point Real data type that specifies internal floating-point items. The sign is contained in the first bit of the leftmost byte, and the exponent is contained in the remaining seven bits of that byte. The remaining three bytes hold the mantissa.

COMP-2

An 8-byte, double precision, floating-point Real data type that specifies internal floating-point items. The sign is contained in the first bit of the leftmost byte, and the exponent is contained in the remaining seven bits of the first byte. The remaining seven bytes hold the mantissa.

COMP-3 Packed Decimal

A packed decimal data type that specifies internal decimal items stored in packed decimal format. In the packed decimal format, each byte in a field represents two numeric digits except for the rightmost byte. The rightmost byte holds one digit and the sign. In other words, there are two digits in each character position except for the trailing character position that is occupied by the low-order digit and sign. The item can contain any of the digits from 0 through 9, plus a sign, to represent a value not exceeding 18 decimal digits. For example, the decimal value +123 is represented in two bytes as 0001 0010 0011 1100 in packed decimal format. For more information see, Zoned Decimal or Packed Decimal Data Types.

DISPLAY Zoned Decimal

An unpacked decimal data type that specifies internal decimal items stored in zoned decimal format. Zoned decimal format is synonymous with unpacked decimal format, which is a format for representing numbers where each digit is contained in bits 4 through 7 and the sign is contained in bits 0 through 3 of the least significant byte. Bits 0 through 3 of all bytes other than the least significant byte contain 1s (hex F). For example, the decimal value +123 is represented in three bytes as 1111 0001 1111 0010 1100 0011 in zoned decimal format. For more information see, Zoned Decimal or Packed Decimal Data Types.

DATE and TIME

Specifies a date and time by using group item of two PIC 9(7) COMP-3 Packed Decimal value.

TIME only

Specifies a time by using a PIC 9(7) COMP-3 Packed Decimal value.

DATE only

Specifies a date by using a PIC 9(7) COMP-3 Packed Decimal value.

PIC X

Specifies a single character in an Extended Binary Coded Decimal Interchange Code (EBCDIC) character string. EBCDIC is the native representation for character data on mainframes and AS/400s. Unicode is the native representation for character data on Windows-based platforms.

PIC X No Translation

Specifies a single COBOL character in an EBCDIC character string that is handled as if it were binary data. In other words, there is no translation from EBCDIC to Unicode or from Unicode to EBCDIC.

PIC G

Specifies a double-byte EBCDIC string.

PIC S9(4) COMP (Integer 16-bit)

Specifies an integer that is 16 bits, or 2 bytes, in length.

PIC S9(9) COMP (Integer 32-bit)

Specifies an integer that is 32 bits, or 4 bytes, in length.

Data Type Conversion

The Transaction Integrator (TI) run-time environment automatically converts data types between host-based COBOL or Report Program Generator (RPG) data types and the COM-based Automation data types that a Windows-based programming language like Visual Basic uses. The automatic conversion is based on information that you define in TI Project when you design and create a TI component (type library). This information is stored with the TI component and used by the TI runtime to convert the parameters of a method from the representation understandable by a COM-based or .NET-based programming language into the representation understandable by a host transaction program (TP).

Use TI Project to associate each Automation data type with each COBOL or RPG data type used in the host TP. TI provides default mappings between standard Automation data types and COBOL or RPG data types. You can either accept the default mappings or override the default with other mappings supported by TI. TI Project stores the conversion map in the TI component type library (.tlb) file. This conversion map is used to:

- Handle data moving between the TP and the TI component.
- Convert a TI component into a TP (export the host definition).
- Convert a TP into a TI component (import the host definition).

If a parameter used in a method call is not strictly typed, the TI run-time environment attempts to coerce the data type it receives into the data type it expects. If that coercion is successful, the call proceeds. If it is unsuccessful, an error is returned.

At run time, when a client application uses the TI Automation interface to call a method of the TI Automation server, the TI run-time environment uses the conversion map to handle the actual data conversion of the in and in/out parameters being sent to the mainframe TP. After TI converts the Microsoft® Windows® data, TI reformats the method call as a host system APPC/LU 6.2 or TCP/IP message. Then TI uses Microsoft Host Integration Server 2004 SNA or TCP/IP connectivity to forward the message to the mainframe. When the mainframe TP returns the in/out and out parameters, TI reformats the message for the return to Windows, converts the host data into Windows data, and returns the return value and parameters to the client application.

The choice of language or code page you made in TI Manager when you defined the remote environment (RE) determines which code page is used to convert from UNICODE (on the Automation side) to Extended Binary Coded Decimal Interchange Code (EBCDIC) (on the mainframe side). When you create an RE in TI Manager, you can either select a language to accept the default code page for that language, or select a specific code page.

If you need to convert to different target code pages (if you have, for example, target mainframes in different countries or regions), you need to set up an RE for each target because TI does not support conversions requiring the use of locale.

You can use TI Project to import COBOL or RPG, or to manually enter method descriptions to create Automation methods. When you import COBOL or RPG, each supported COBOL data type has a default Automation type. When you manually create a method, each Automation data type has a default host data type associated with it.

If you do not want to use a default Automation data type, you can use TI Project to change the Automation data type manually. If the new Automation type is compatible with the existing host data type, the existing COBOL or RPG data type is left unchanged. If it is not compatible, the host data type is changed, thus affecting your mainframe program.

This section contains:

Converting Data Types from Automation to OS/390 COBOL

Use the tables in this topic as a guide to specify how you want TI to handle conversions from Automation data types to COBOL data types. For more information about the specific data types, see Supported TI Data Types.

Use the following code key to interpret the codes in the **Possible Conversion Errors** and **Required Property Settings** columns in each table.

Code	Description
r	Range errors possible.
b	Possible loss of precision due to base 2 to base 16 conversion.
p	Possible loss of precision due to picture format scale specification.
m	Mapping errors possible.
f	yyyyddd and hhmmss.
A	You must specify **Truncate**, **Round**, or **Error** under **Error handling** on the **COBOL Definition** tab of the property page.
C	You must specify the precision and scale by filling in the **Digits left** and **Digits right** boxes on the **COBOL Definition** tab of the property page.
D	You must specify the string width by filling in the **Size** box on the **COBOL Definition** tab of the property page.
E	Unicode or EBCDIC mapping information is required, such as a code page.
F	For arrays whose length is less than the maximum specified, you must specify **Size of Filler** under **Trailing filler** on the **COBOL Definition** tab of the property page.
G	You must specify how to deal with strings. Click **Space Padded** or **Null terminated** under **String Delimiting** on the **COBOL Definition** tab of the property page. Then click **Truncate** or **Error** under **Error handling** on the **COBOL Definition** tab of the property page to specify what TI should do if the string is too long.
H	Maximum size is required.
I	Localization is required.
J	Optional SO and SI insertion and deletion is supported.

The following table shows the defaults that TI uses for converting Automation data types to COBOL data types.

Default (occurs unless overridden by developer)

From Automation data type	To OS/390 COBOL data type	Possible conversion errors	Required property settings
1-byte unsigned Integer	PIC X No Translation	None	None
2-byte signed Integer	PIC S9(4) COMP (Integer 16-bit)	None	None
4-byte signed Integer	PIC S9(9) COMP (Integer 32-bit)	None	None
4-byte Real (Single)	COMP-1	br	None
8-byte Real (Double)	COMP-2	br	None
Boolean	PIC S9(4) COMP (Integer 16-bit)	None	None
Variable-length String	PIC X	m	DEG
Currency	COMP-3 Packed Decimal	pr	C
Date (date and time)	COMP-3 Packed Decimal	pf	CI
Date (date only)	COMP-3 Packed Decimal	pf	CI
Date (time only)	COMP-3 Packed Decimal	pf	CI
Decimal	COMP-3 Packed Decimal	pr	C
Array (any data type)	OCCURS fixed TIMES	None	FH

> **Warning** When you convert whole or fractional numbers from Visual Basic Single or Visual Basic Double data types to Packed Decimal or distributed program call (DPC) Zoned Decimal data types, TI is limited to a precision from 1 through 18 digits left of the decimal point (for example, 1.2345678901234567E+17). When you convert fractional numbers Packed Decimal or DPC Zoned Decimal data types, you should convert to Visual Basic Decimal data type.

The following table shows the other supported data type mappings that you can set in TI Project to override the defaults presented in the previous table.

Supported in Transaction Integrator (can be specified by the developer)

From Automation data type	To OS/390 COBOL data type	Possible conversion errors	Required property settings
1-byte unsigned Integer	PIC S9(4) COMP (Integer 16-bit)	None	None
1-byte unsigned Integer	COMP-3 Packed Decimal	None	C
2-byte signed Integer	COMP-3 Packed Decimal	None	C
2-byte signed Integer	DISPLAY Zoned Decimal	None	C
4-byte signed Integer	COMP-3 Packed Decimal	None	C
4-byte signed Integer	DISPLAY Zoned Decimal	None	C
4-byte Real (Single)	PIC S9(4) COMP (Integer 16-bit)	p,r	None
4-byte Real (Single)	PIC S9(9) COMP (Integer 32-bit)	p,r	None
4-byte Real (Single)	COMP-3 Packed Decimal	p,r	C
4-byte Real (Single)	DISPLAY Zoned Decimal	p,r	C
8-byte Real (Double)	PIC S9(4) COMP (Integer 16-bit)	p,r	None
8-byte Real (Double)	PIC S9(9) COMP (Integer 32-bit)	p,r	
8-byte Real (Double)	COMP-3 Packed Decimal	p,r	C
8-byte Real (Double)	DISPLAY Zoned Decimal	p,r	C
Boolean	PIC S9(9) COMP (Integer 32-bit)	None	None
Boolean	COMP-3 Packed Decimal	None	C
Variable-length String	PIC G	m	DEGJ
Currency	PIC S9(?)V9(?) COMP (16-bit)	pr	None
Currency	PIC S9(?)V9(?) COMP (32-bit)	pr	None
Currency	DISPLAY Zoned Decimal	pr	C
Decimal	PIC S9(?)V9(?) COMP (16-bit)	pr	None
Decimal	PIC S9(?)V9(?) COMP (32-bit)	pr	None
Decimal	DISPLAY Zoned Decimal	pr	C
Array (any data type)	OCCURS DEPENDING ON	None	FH

> **Warning** When you convert whole or fractional numbers from Visual Basic Single or Visual Basic Double data types to Packed Decimal or DPC Zoned Decimal data types, TI is limited to a precision of 1 to 18 digits left of the decimal point (for example, 1.2345678901234567E+17).

The following table shows additional supported data type mappings that the TI run-time environment supports.

Supported only by the TI run-time environment

From Automation data type	To OS/390 COBOL data type	Possible conversion errors	Required property settings
1-byte unsigned Integer	PIC S9(9) COMP (Integer 32-bit)	None	None
1-byte unsigned Integer	DISPLAY Zoned Decimal	None	C
Boolean	DISPLAY Zoned Decimal	None	C

No other data type conversions from Automation to COBOL are supported by TI at this time.

> **Note** When the COBOL usage is DISPLAY without a sign and you change the Automation type to String, the COBOL picture is changed to PIC X, which has the same internal data representation. The length remains the same and therefore does not affect your mainframe program.

Converting Data Types from OS/390 COBOL to Automation

Use the tables in this topic as a guide when you set up the way you want Transaction Integrator (TI) to handle conversions from COBOL data types to Automation data types. For more information about the specific data types, see Supported TI Data Types.

Use the following code key to interpret the codes in the **Possible Conversion Errors** and **Required Property Settings** columns in each table.

Code	Description
r	Range errors possible.
b	Possible loss of precision due to base 2 to base 16 conversion.
p	Possible loss of precision due to picture format scale specification.
m	Mapping errors possible.
f	yyyyddd and hhmmss.
A	You must specify **Truncate**, **Round**, or **Error** under **Error handling** on the **COBOL Definition** tab of the property page.
C	You must specify the precision and scale by filling in the **Digits left** and **Digits right** boxes on the **COBOL Definition** tab of the property page.
D	You must specify the string width by filling in the **Size** box on the **COBOL Definition** tab of the property page.
E	Unicode or EBCDIC mapping information is required, such as a code page.
F	For arrays whose length is less than the maximum specified, you must specify **Size of Filler** under **Trailing filler** on the **COBOL Definition** tab of the property page.
G	You must specify how strings should be dealt with. Click **Space Padded** or **Null terminated** under **String Delimiting** on the **COBOL Definition** tab of the property page. Then click **Truncate** or **Error** under **Error handling** on the **COBOL Definition** tab of the property page to specify what TI should do if the string is too long.
H	Maximum size is required.
I	Localization is required.
J	Optional SO and SI insertion and deletion is supported.

The following table shows the defaults that TI uses when you import COBOL source code.

Default (occurs unless overridden by developer)

From OS/390 COBOL data type	To Automation data type	Possible conversion errors	Required property settings
COMP-1	4-byte Real (Single)	b,r	None
COMP-2	8-byte Real (Double)	b,r	None
COMP-3 Packed Decimal	Currency	p	AC
COMP-3 Packed Decimal	Decimal	p	AC
DATE and TIME	Date	None	I
TIME only	Date	None	I
DATE only	Date	None	I
PIC X	Variable-length String	m	DEG
PIC X No Translation	1-byte unsigned Integer	None	None
PIC S9(4) COMP (Integer 16-bit)	2-byte signed Integer	None	None
PIC S9(4) COMP (Integer 16-bit)	Boolean	None	None
PIC S9(9) COMP (Integer 32-bit)	4-byte signed Integer	None	None
OCCURS fixed TIMES	Array	None	None

> **Note** When you convert fractional numbers from Packed Decimal or distributed program call (DPC) Zoned Decimal data types, you should convert to Visual Basic Decimal data type.

For COMP, COMP-3, and DISPLAY numeric COBOL data types, the default is based on the precision and scale shown in the following table. When COBOL uses DISPLAY without a sign and you change the Automation type to String, the COBOL picture is changed to PIC X, which has the same internal data representation. The length remains the same and therefore does not affect your mainframe program.

Precision and scale for OS/390 COBOL	To Automation data type

Precision 1-4, scale 0	2-byte signed Integer
Precision 5-9, scale 0	4-byte signed Integer
Precision 5-7, scale 3-7	4-byte Real
Precision 8-18, scale 3-18	8-byte Real
Precision 1-18, scale 1-2	Currency
Precision 10-18, scale 0	Decimal

The following table shows the other supported data type mappings that you can set in TI Project to override the defaults presented previously in this topic.

Supported in Transaction Integrator (can be specified by the developer)

From OS/390 COBOL data type	To Automation data type	Possible conversion errors	Required property settings
COMP-1	Array	None	None
COMP-2	Array	None	None
COMP-3 Packed Decimal	2-byte signed Integer	p,r	AC
COMP-3 Packed Decimal	4-byte signed Integer	p,r	AC
COMP-3 Packed Decimal	4-byte Real (Single)	p,r	AC
COMP-3 Packed Decimal	8-byte Real (Double)	p	C
COMP-3 Packed Decimal	Boolean	None	None
COMP-3 Packed Decimal	1-byte unsigned Integer	r	None
COMP-3 Packed Decimal	Array	None	None
DISPLAY Zoned Decimal	2-byte signed Integer	p,r	AC
DISPLAY Zoned Decimal	4-byte Real (Single)	p,r	AC
DISPLAY Zoned Decimal	8-byte Real (Double)	p,r	AC
DISPLAY Zoned Decimal	Currency	p,r	AC
DISPLAY Zoned Decimal	Decimal	p,r	AC
DATE and TIME	Array	None	None
TIME only	Array	None	None
DATE only	Array	None	None
PIC X	Array	None	None
PIC X No Translation	Array	None	None
PIC G	Variable-length String	m	DEGJ
PIC G	Array	None	None
PIC S9(4) COMP (Integer 16-bit)	1-byte unsigned Integer	r	None
PIC S9(4) COMP (Integer 16-bit)	Array	None	None
PIC S9(9) COMP (Integer 32-bit)	Boolean	None	None
PIC S9(9) COMP (Integer 32-bit)	1-byte unsigned Integer	r	None
PIC S9(9) COMP (Integer 32-bit)	Array	None	None
PIC S9(?)V9(?) COMP (16-bit)	4-byte Real (Single)	p,r	None
PIC S9(?)V9(?) COMP (16-bit)	8-byte Real (Double)	p,r	None
PIC S9(?)V9(?) COMP (16-bit)	Currency	p,r	None
PIC S9(?)V9(?) COMP (16-bit)	Decimal	p,r	None
PIC S9(?)V9(?) COMP (32-bit)	4-byte Real (Single)	p,r	None
PIC S9(?)V9(?) COMP (32-bit)	8-byte Real (Double)	p,r	None
PIC S9(?)V9(?) COMP (32-bit)	Currency	p,r	None
PIC S9(?)V9(?) COMP (32-bit)	Decimal	p,r	None
OCCURS DEPENDING ON	Array	None	None

> **Note** When you convert fractional numbers from Packed Decimal or DPC Zoned Decimal data types, you should convert to Visual Basic Decimal data type.

The following table shows additional supported data type mappings that the TI run-time environment supports.

Supported only by the TI run-time environment

From OS/390 COBOL data type	To Automation data type	Possible conversion errors	Required property settings
DISPLAY Zoned Decimal	1-byte unsigned Integer	None	AC

DISPLAY Zoned Decimal	4-byte signed Integer	None	AC
DISPLAY Zoned Decimal	Boolean	None	AC

No other data type conversions from COBOL to Automation are supported by TI at this time.

Data Type Conversion

Converting Data Types from Automation to RPG

Use the following table as a guide when you specify the way you want Transaction Integrator (TI) to handle conversions from Automation data types to Report Program Generator (RPG) data types.

TI Project default	RPG data type	Spec-ification	Field length	Field length meaning	Decimal places
Boolean (default)	Integer	I	5	digits	Blank
Boolean	Integer	I	10	digits	Blank
Boolean	Packed	P	3	digits	Blank,0
Byte (default)	Character	A	1	bytes	Blank
Byte	Unsigned	U	3-9	digits	Blank
Byte	Packed	P	3	digits	Blank,0
Byte	Integer	I	3-9	digits	Blank
Currency (default)	Packed	P	1-30	digits	Blank,0-4
Currency	Zoned	S	1-30	bytes	Blank,0-4
Currency	Binary	B	1-4	digits	Blank,0-4
Currency	Binary	B	5-9	digits	Blank,0-4
Date (Date)	*MDY	None	8	bytes	Blank
Date (Date)	*DMY	None	8	bytes	Blank
Date (Date)	*YMD	None	8	bytes	Blank
Date (Date)	*JUL	None	6	bytes	Blank
Date (Date)	*ISO	None	10	bytes	Blank
Date (Date)	*USA	None	10	bytes	Blank
Date (Date)	*EUR	None	10	bytes	Blank
Date (Date)	*JIS	None	10	bytes	Blank
Date (Time)	*HMS	None	8	bytes	Blank
Date (Time)	*ISO	None	8	bytes	Blank
Date (Time)	*USA	None	8	bytes	Blank
Date (Time)	*EUR	None	8	bytes	Blank
Date (Time)	*JIS	None	8	bytes	Blank
Date	Timestamp	Z	Number?	bytes	Blank
Decimal	Float	F	4	Bytes	Blank
Decimal	Float	F	8	Bytes	Blank
Decimal (default)	Packed	P	1-30	digits	Blank,0-30
Decimal	Zoned	S	1-30	bytes	Blank,0-30
Decimal	Binary	B	1-4	digits	Blank,0-4
Decimal	Binary	B	5-9	digits	Blank,0-9
Double (default)	Float	F	8	bytes	Blank
Double [1]	Packed	P	1-30	digits	Blank,0-30
Double [1]	Zoned	S	1-30	bytes	Blank,0-30
Double	Binary	B	1-4	digits	Blank,0-4
Double	Binary	B	5-9	digits	Blank,0-9
Integer (default)	Integer	I	1-5	digits	Blank
Integer	Packed	P	1-30	digits	Blank,0
Integer	Zoned	S	1-30	bytes	Blank,0
Integer	Binary	B	1-5	digits	Blank,0
Long (default)	Integer	I	1-9	digits	Blank
Long	Packed	P	1-30	digits	Blank,0
Long	Zoned	S	1-30	bytes	Blank,0
Long	Binary	B	1-9	digits	Blank,0
Single (default)	Float	F	4	bytes	Blank
Single [1]	Packed	P	1-30	digits	Blank,0-30
Single [1]	Zoned	S	1-30	bytes	Blank,0-30
Single	Binary	B	1-9	digits	Blank,0-9

String (default)	Character	A	1-32755	Bytes==Char	Blank
String	Graphic	G	1-16371	Char	Blank

Warning Note [1] in the preceding table indicates that when you convert whole or fractional numbers from Visual Basic Single or Visual Basic Double data types to Packed Decimal or distributed program call (DPC) Zoned Decimal data types, TI is limited to a precision from 1 through 18 digits to the left of the decimal point (for example, 1.2345678901234567E+17).

Note While TI left-justifies all strings, the RPG MOVE command right-justifies all strings. If you are programming an RPG application, use the MOVEL or EVAL commands to perform the equivalent operation in RPG while manipulating a string.

Converting Data Types from RPG to Automation

Use the following tables as a guide when you set up the way you want Transaction Integrator (TI) to handle conversions from report program generator (RPG) data types to Automation data types. For more information about the specific data types, see Supported TI Data Types.

The following table describes the TI Project property abbreviations used in the data type tables that follow.

Abbreviation	Description
t	Truncate
e	Error
r	Round
sp	Space pad
nt	Null terminate
SO	Add leading shift in
SI	Add trailing shift out
PE	Pack even
TIP	TI Project

Pack even (PE) indicates that the definition specification uses the pack even option for RPG. PE indicates that the precision is an even number of digits when the From and To specification positions are used, which implies a byte count instead of a digit count and which might mean that the high-order digit position is ignored. For example, the following table shows how the number 256 in an RPG packed field is represented in internal memory.

> **Note** For purposes of this example, the number 256 fits in 2 bytes of memory in both the PE and No PE option.

Packed data type option	Byte 1		Byte 2	
	High-order byte high-order nibble	High-order byte low-order nibble	Low-order byte high-order nibble	Low-order byte Sign
No PE	2	5	6	0xf
PE	ignored	5	6	0xf

RPG data type	Spec-ification	RPG field length	TIP data type	TIP default error handling	TIP default field length	TIP default decimals	TIP default string handling
Character	A	1	Byte	None	None	None	None
Character	A	1-32755	String	t,e	80	None	sp,nt
Graphic	G	1-16371	String	t,e	80	None	sp
Binary	B	1-4	Currency	t,r,e	4	2	None

Data Type Conversion

Zoned Decimal or Packed Decimal Data Types

When it imports a host data declaration, Transaction Integrator (TI) converts Zoned Decimal (COBOL numeric PIC with DISPLAY or no USAGE, or RPG S data type) or Packed Decimal data types to Decimal or Currency Automation data types, respectively. Depending on the development application you are using, there might not be an equivalent for Decimal or Currency data types. If this is the case, use one of the following techniques to ensure that the data type works correctly with TI:

- Use language-supplied functions to manipulate the Automation types for Decimal or Currency.
- Within TI Project, if the data type has a fractional component, modify the method's parameter from the Decimal or Currency data type to the Floating Point Binary data type (double or single precision as appropriate). You can substitute a 16-bit or 32-bit binary Integer data type if the data declaration has no fractional component and the number of data declaration digits fits within the expected range.

  Note When you use the Floating Point Binary data type, the likelihood of a data conversion precision problem increases if fractions are involved. TI offers three options to handle data precision errors: Round (default), Truncate, or Error. The double-precision Floating Point Binary data type can handle host data declarations of up to fifteen digits.

Integer Data Type

Binary Integer data types apply to COBOL COMP and Report Program Generator (RPG) Integer data types. Automation data types support only a 16-bit or 32-bit Integer. Therefore, you should ensure that your client application is passing binary integer equivalents to the Transaction Integrator (TI) Automation server.

See Also

Data Types

Decimal Data Type in Visual Basic

If the client application uses Visual Basic 6.0 and includes the DECIMAL data type, the decimal value in Visual Basic must be defined as a Variant, and then assigned a decimal value by the Visual Basic function **CDec**. This must be done for the component to execute properly within the TI component.

The following is an example:

```
Dim xxx as Variant
xxx = CDec(27)
```

If the client application uses Visual Basic .NET, the DECIMAL data type is defined directly.

See Also

Data Types

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Variant Data Type

The type of each element in a message is fixed and defined by the information in the component library. Because mainframe programs do not support the Variant data type, you must fix the type of each parameter at design time in Transaction Integrator (TI) Project. Microsoft Visual Basic Scripting Edition (VBScript), which is often used to create Active Server Pages (ASP) in Web-based applications, supports only the Variant data type. It does not accept declared variables. As a result, if your COM+ client application calls a TI Automation server and passes parameters with Variant data types, the TI run-time environment forces each Variant data type into the type for each parameter as defined in the TI component library.

The Variant data type is not supported in Visual Basic .NET. Visual Basic .NET supports defining data types as objects, and then casting the objects as data types. TI does not support variables defined as objects cast to data types. All method parameters must be defined initially as data types, not objects.

Data Types

Recordsets and Datatables

A recordset is an Automation object that is a fixed-size, bounded, or unbounded table that contains simple rows of host data declarations (data types). A datatable is a .NET object that is identical to a recordset in every regard, except that you cannot use the **NewRecordset** function with datatables. After you have a recordset or datatable object, you can call methods on that object to gain access to its rows.

A recordset or datatable is implemented on top of row sets by Remote Data Service (RDS), which is a part of Microsoft Data Access Components (MDAC) version 2.5. You can use the **RDSServer.DataFactory** object to create a recordset or datatable and use ActiveX® Data Objects (ADO) to update or read the recordset.

A recordset or datatable provides a means of presenting and manipulating tabular data. Currently, recordsets cannot be nested, cannot contain arrays, and cannot contain user-defined types (UDTs).

Support for recordsets and databales enables TI to support what is effectively an array of a structure (or a record, in COBOL terminology) as well as a structure. A structure is represented as a fixed-size recordset or datatable where each column in the row contains a single data element. To deal with mainframe programming issues, TI classifies recordsets and datatables as fixed-size, bounded, or unbounded, in reference to the number of rows contained in the recordset or datatable.

> **Important** The OS/400 distributed program calls (DPC) programming model supports only fixed size recordsets and datatables. The programming model does not support unbounded recordsets and datatables, nor does it support the use of the OCCURS DEPENDING ON clause, or variably-sized recordsets and datatables.

For fixed-size, bounded, and unbounded TI recordsets and datatables, the layout of all rows in a particular recordset is the same and is defined at design time by using TI Project. If a recordset or datatable is an output or return value from the mainframe, TI run-time environment uses the **RDSServer.DataFactory** object to create a recordset or datatable and ADO to fill the recordset or datatable with the rows of data returned from the mainframe program.

Such a recordset is a disconnected recordset with a cursor type of adOpenForwardOnly. To scan the recordset requires calling **MoveFirst** and **MoveNext** to move through the rows. The recordset can be updated in place, but because it is disconnected from the true data source (the data source manipulated by the mainframe program that returned the data), the updates are not propagated to the original data source.

NewRecordset is a function that is supplied automatically for all TI components. This function is called to create a disconnected recordset object that can be passed into a TI method call. **NewRecordset** is provided as a convenience for TI client applications; it is not required to pass a recordset to a TI component's methods. The function can be called only for input or input/output recordset objects. The TI run-time environment creates a recordset object when the parameter is an output recordset object.

This section contains:

- Example Using the New Recordset Call
- Fixed-Size Recordsets
- Bounded Recordsets
- Unbounded Recordsets
- RDS Recordset Requirements for Web Clients
- Recordset Creation When Importing COBOL

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Example Using the New Recordset Call

The following example code uses the **NewRecordset** property to create a new disconnected recordset object, and it passes the object as an input parameter to a Transaction Integrator (TI) method by way of the **IDispatch** interface. The *bstrName* parameter in the **IDispatch** call is the name of the recordset object (for example, **Recordset1**) as specified in TI Project. The call returns the dispatch pointer to an ActiveX® Data Objects (ADO) database recordset object if the call is successful. If the call is not successful, a NULL pointer is returned.

```
IDispatch * NewRecordset(
  BSTR bstrName);

Dim pMyRecord as Object
Dim pMyComponent as Object
Dim varFields(2) as Variant
Dim varValues(2) as Variant
On Error Goto SomeErrorHandler

' Create an instance of the TI object
set pMyComponent = CreateObject("MyComponent.Interface1")

' Create an instance of a recordset object
set pMyRecord = pMyComponent.NewRecordset("Recordset1")

' Fill in some recordset fields
varFields(0) = CStr("member1")
varFields(1) = CStr("member2")
varValues(0) = CInt(99)
varValues(1) = CLng(999)

' Add the recordset fields and values to the recordset object
pMyRecord.AddNew varFields, varValues

' Call the method with the recordset object as a parameter
pMyComponent.Method1(pMyRecord)
```

The TI run-time environment performs some compatibility checks between the structure definition for the recordset in the component library and the recordset object seen at run time. Any incompatibility will result in an Automation exception.

> **Note** Because a recordset cannot be nested, cannot contain arrays, and cannot contain user-defined types (UDTs), a COBOL data structure that is imported into TI Project might be flattened, resulting in an increase in the number of parameters that must be handled on the Automation side.

Fixed-Size Recordsets

Bounded Recordsets

Unbounded Recordsets

RDS Recordset Requirements for Web Clients

Recordset Creation When Importing COBOL

Fixed-Size Recordsets

A fixed-size recordset holds a fixed number of rows that is exactly equal to the maximum number of rows that you specified at design time in Transaction Integrator (TI) Project. A parameter or return value can be defined as a fixed-size recordset for any of the TI programming models.

Among the three possible types of recordsets or datatables (fixed-size, bounded, or unbounded), the TI default is fixed-size.

If the COBOL data declaration contains an OCCURS DEPENDING ON clause, each OCCURS DEPENDING ON clause requires two parameters:

- The size of the OCCURS DEPENDING ON clause.
- The data representation (a single element or a COBOL record) within the OCCURS DEPENDING ON clause.

If the COBOL contains an OCCURS DEPENDING ON clause, when the recordset or datatable is returned to TI and processed at run time, the TI run-time environment looks for the value of the size parameter corresponding to the named parameter (from the OCCURS DEPENDING ON clause). When it sends a fixed-size recordset as an input parameter to the mainframe, the TI run-time environment sets the COBOL size parameter with the actual number of rows in the recordset.

The DPC programming model on the AS/400 platform supports a modified version of OCCURS DEPENDING. By using the OCCURS DEPENDING property to select a parameter to specify size for the array, DPC-invoked programs can receive and send arrays that are partially populated. For example, you might have a structure that is defined to occur 10 times and that you want to return to the client. However, there might be fewer than 10 occurrences that actually contain valid data (for example, if the array was filled from a database table that contained fewer than 10 rows). If you define the array using the OCCURS DEPENDING property, you do not have to fill the remaining occurrences with dummy data. The TI run-time environment will pass only the filled occurrences back to the client.

Bounded Recordsets

Unbounded Recordsets

Using the OCCURS DEPENDING Clause to Define Variable-length Table

Using Variably Sized Rows

Using Bounded Final Fields

RDS Recordset Requirements for Web Clients

Recordset Creation When Importing COBOL

Bounded Recordsets

A recordset that is the last input parameter or the last output parameter in a method can be bounded. This means its actual size (number of rows) can vary from zero up to the maximum number of rows specified at design time. A parameter or return value can be defined as a bounded recordset for all of the Transaction Integrator (TI) programming models except OS/400 distributed program calls (DPCs). The DPC programming model does not support bounded recordsets, datatables, or arrays.

A bounded recordset, datatable, or array must be the last parameter in a particular direction. The last input parameter can be bounded if it is a recordset or an array and there are no following input/output parameters. The last output parameter can be bounded if it is a recordset or an array and there are no following input/output parameters. An input/output parameter can be bounded if it is a recordset or an array and is the final parameter. The mainframe transaction program (TP) is responsible for sending a table of the correct size, depending on the number of elements or rows in use.

Whereas a fixed-size recordset must send the exact number of rows defined as the maximum within the recordset, the number of rows in a bounded recordset can vary from zero to the maximum.

Among the three possible types of recordsets (fixed-size, bounded, or unbounded), the TI default is fixed-size. To change a fixed-size recordset into a bounded recordset within Designer, set the property "variable sized final field" on the method that contains the parameter defined as a recordset to be bounded, to true.

See Also

Example Using the New Recordset Call

Fixed-Size Recordsets

Unbounded Recordsets

RDS Recordset Requirements for Web Clients

Recordset Creation When Importing COBOL

Unbounded Recordsets

The number of rows in an unbounded recordset or datatable is not specified (defined) before run time. A parameter or return value can be defined as an unbounded recordset or datatable for any of the following Transaction Integrator (TI) programming models:

- CICS User Data LU 6.2
- TCP Transaction Request Message User Data
- IMS User Data LU 6.2
- IMS Implicit
- IMS Explicit
- IMS Connect

  Note In the IMS Connect programming model, TI supports only output parameters as unbounded recordsets or datatable. In other words, you cannot send unbounded recordsets or datatables to the host from TI if you are using the IMS Connect model.

An unbounded recordset or datatable is always transmitted to or from the mainframe after all other data. TI supports at most one unbounded input parameter and one unbounded output parameter, and each must be the last parameter in a direction.

To make a fixed size recordset or database unbounded, use the designer to set the **Unbounded** property of the recordset to true. The property **Variable Sized Final Field** on the method associated with the unbounded recordset must be false.

After defining a recordset or datatable as unbounded, the designer **recordset** property class will contain a property called **variably sized rows**. Use this property to determine how the length of the row will be represented.

Unbounded recordsets or datatable that contain variably sized rows must receive the size of the recordset or datatable first, and then receive the data. Therefore, the size of the recordset or datatable must be sent first followed by a second send that contains the data. If TI expects to receive an unbounded recordset or datatable with variably sized rows, CICS must first send the length of the row, and then send the data for that row. These two steps are repeated for each row of the recordset or datatable. TI detects that there is no more data because CICS stops sending and an unbounded recordset or datatable must always be the last parameter sent to TI.

Bounded Recordsets

RDS Recordset Requirements for Web Clients

Recordset Creation When Importing COBOL

RDS Recordset Requirements for Web Clients

If you have a Web-based Automation client application that uses a Remote Data Service (RDS) recordset control (most likely bound to a grid control) to display a table returned from a mainframe transaction program (TP), RDS requires that:

- The returned table be described as a recordset when you import your host data declaration into Transaction Integrator (TI) Project.
- The recordset be the return value from the method. The RDS control uses the HTTP protocol to marshal the recordset from the TI component on the server to the Web browser.

When you import a host data declaration, you must describe the table as a recordset. For more information, see Recordset Creation When Importing COBOL.

When you create the Automation method for your TI component in TI Project, be sure to have the method return the recordset as a return type instead of defining the recordset as a parameter. If you are importing the host code, when TI Project requests that you select the return value item, select the group item level for your table in the host declaration. To manually create a method, first manually describe or import the recordset in TI Project. Then use the **Insert** menu item to add the method that the Web client will call. Select the recordset you just described from the data type submenu list.

There are other properties that you can set on the recordset that is being returned. For details, see the shortcut Help for the **Recordsets** property page.

Recordset Creation When Importing COBOL

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Recordset Creation When Importing COBOL

When you import COBOL in Transaction Integrator (TI) Project, you can choose between two ways to create recordsets and datatables: automatically and explicitly.

When you import COBOL to create or update an Automation method, TI Project automatically creates recordsets and datatables when it encounters a fixed or variable-length table (OCCURS clause). The value for the OCCURS clause's length specifier can be any value greater than or equal to 1. The table must conform to recordset rules, which means that it cannot contain arrays, and it cannot contain nested tables that cannot be flattened.

When you import COBOL to explicitly create or update a recordset or datatable, you can select any group item that conforms to recordset rules. For importing recordsets and datatables, the group item does not need to have an OCCURS clause. If an OCCURS clause is present, it is ignored.

Example

The following COBOL source code was imported using the Import COBOL Wizard. The INVOICES table was selected as the return value for the method.

```
01 CUSTOMER-DATA.
    05 CUSTOMER-NUMBER                PIC 9(9).
    05 INVOICES OCCURS 50 TIMES.
       10 INVOICE-NUMBER              PIC 9(9).
       10 INVOICE-DATE                PIC 9(7) COMP-3.
       10 INVOICE-AMOUNT              PIC S9(13)V9(2) COMP-3.
       10 INVOICE-DESCIPTION          PIC X(40).
    05 LAST-NAME                      PIC X(20).
    05 FIRST-NAME                     PIC X(20).
```

The resulting method was imported as:

```
GetInvoices(lCustomerNumber As Long, strLastName As String, strFirstName As String) As Object
```

The following Visual Basic code demonstrates how to call this method:

```
Dim objCustomer As Object   'Uses late binding
Dim objInvoices As ADODB.Recordset
Dim lCustomerNumber As Long
Dim iRow As Integer
Dim iCol As Integer
Dim strLastName As String
Dim strFirstName As String

'create an instance of the invoicing object
On Error GoTo ErrorHandler1
Set objCustomer = CreateObject("Customer.Invoicing.1")

lCustomerNumber = CLng(txtCustomerNumber)
'See the WebSite folder under the CedarBank Tutorial folder
'for an example of returning recordsets into an RDS
'recordset on a web site

'invoke the GetInvoices method
On Error GoTo ErrorHandler2
Set objInvoices = objCustomer.GetInvoices(lCustomerNumber _
    , strLastName, strFirstName)
'
' Transfer the Recordset data to a variant array in a single operation.
' This is efficient, but may not be suitable for larger Recordsets.
'
Dim Data As Variant
```

```
Data = objInvoices.GetRows
grdInvoices.Rows = UBound(Data, 2) + 1
grdInvoices.Cols = UBound(Data, 1) + 1
For iRow = 0 To UBound(Data, 2)
    grdInvoices.Row = iRow
    For iCol = 0 To UBound(Data, 1)
        grdInvoices.Col = iCol
        grdInvoices.Text = Data(iCol, iRow)
    Next iCol
Next iRow
```

Arrays

Transaction Integrator (TI) supports multidimensional arrays for all programming models except the OS/400 distributed program calls (DPCs). Only the outermost array of a multidimensional array can vary in size. All other arrays must be fixed-sized. For the OS/400 DPC programming model, TI supports only single-dimension arrays.

Arrays in Automation are actually SAFEARRAYs that contain information about their bounds as well as the data for the array elements. SAFEARRAYs are mapped to fixed-size arrays on the mainframe. SAFEARRAYs have a variable size and require custom information to be marshaled to and from fixed-size arrays on the mainframe.

Arrays are created on the mainframe during the import process when a simple data type has one or more OCCURS clauses or DIM keywords. The OCCURS clause can represent a fixed or variable-length table. Although it is possible in COBOL to have nested OCCURS DEPENDING clauses, only the OCCURS DEPENDING length specifier for the outermost table dimension is supported by TI. TI Project ignores nested length specifiers.

The mainframe developer might want to reflect the fixed nature of the array through to the COM object. The error-handling features of the TI run-time environment allow the developer to specify that an exception be raised if an array is not of the expected size. However, the mainframe developer might also want to take advantage of the flexible nature of SAFEARRAYs. TI supports an additional parameter that specifies the actual run-time size of the array. This parameter is supported with the same behavior as the OCCURS DEPENDING ON clause in COBOL. The maximum size of the array remains fixed, but the developer can determine the actual number of elements in the array received from the client.

The following custom information can be associated with either single or multidimensional arrays:

- Maximum size (on each dimension) (Integer: default 10). This value is automatically set to "x" if the COBOL imported into TI Project contains an OCCURS DEPENDING x TIMES clause.
- If the COBOL imported into TI Project contains an OCCURS DEPENDING ON clause, the actual size of the array is associated with the parameter specified by "name".

This section contains:

- Visual Basic and Arrays

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Visual Basic and Arrays

When you develop client applications with Microsoft Visual Basic Scripting Edition (VBScript), you cannot define methods that return arrays. If it is necessary to pass back array information, define an output parameter.

Transaction Integrator (TI) deals with multidimensional arrays in row major order. The outermost dimension of an array in COBOL equates to the leftmost dimension in an array on the Automation side. In Visual Basic, the convention is to use column major order for multidimensional arrays. Therefore, when you access multidimensional arrays in Visual Basic, remember that the array will be row major for TI purposes. This can be a problem if you use Visual Basic functions that deal with multidimensional arrays and expect those arrays to be in column major order. When you access individual array elements, however, this should not be a problem.

> **Warning** Manually re-dimensioning a multidimension array that was generated by TI yields might cause the component to function incorrectly.

> **Note** The Visual Basic command Option Base has no effect on COM SAFEARRAYs, such as those returned as Out or In/Out arrays from TI methods. These SAFEARRAYs always have a base value of 0, regardless of the option base setting.

Example

The following COBOL sample shows a variable-length table:

```
01 UPDATEARRAY-INPUT-AREA.
   05 CUSTOMER-NUMBER                    PIC 9(9) DISPLAY.
   05 LAST-NAME                          PIC X(20).
   05 FIRST-NAME                         PIC X(20).
   05 TABLE-LENGTH                       PIC 9(7) COMP-3.
   05 TABLE OCCURS 10 TIMES
         DEPENDING ON TABLE-LENGTH
         OF UPDATEARRAY-INPUT-AREA
                                         PIC S9(4) COMP.
```

TI Project creates the following method when you import the COBOL sample:

```
UpdateArray(lCustomerNo As Long, strLastName As String, strFirstName As String _
     , lcElements As Long, rgTable() As Integer)
```

The following Visual Basic code shows how to send and receive the table:

```
    Dim objCustomer As Object
    Dim i
    Dim rgTable() As Integer
    Dim lCustomerNo As Long
    Dim strLastName As String
    Dim strFirstName As String
    Dim lcElements As Long

    'create an instance of the invoicing object
    On Error GoTo ErrorHandler1
    Set objCustomer = CreateObject("Customer.Invoicing.1")

    lCustomerNo = 100231001
    strLastName = "Doe"
    strFirstName = "John"

    'Send over 5 elements
    lcElements = 5
    ReDim rgTable(lcElements)
    For i = 0 To lcElements - 1
        rgTable(0) = i
    Next i

    'invoke the UpdateArray method
    On Error GoTo ErrorHandler2
    objCustomer.UpdateArray lCustomerNo, strLastName, strFirstName _
        , lcElements, rgTable

    'lcElements now contains the number of elements returned in rgTable
```

User-Defined Types (UDTs)

In general, a user-defined type (UDT) is equivalent to a structure in C, C++, or Report Program Generator (RPG) records or group item levels in COBOL, and UDTs in Visual Basic. UDTs can contain primitive elements, arrays of elements, recordsets, and nested UDTs.

You can use UDTs to define parameters. A parameter can be defined as a single UDT or as an array of UDTs. Likewise, UDTs can describe a method's return value. A method's return value can be defined as a single UDT or as an array of UDTs. However, you cannot use a UDT to describe a column within a recordset.

TI requires that if you use Visual Basic to build your UDTs, you must use Visual Basic version 6.0 or later.

Before you compile a Visual Basic application that calls a TI component that defines a UDT and that references that UDT within the Visual Basic application, you need to deploy the TI component to register it. If you compile the application before you deploy the TI component or if you fail to deploy the component at all, the Visual Basic client application will not start.

The distributed program call (DPC) programming model for the AS/400 supports:

- Only single-level UDTs and .NET structures.
- Arrays of UDTs and structures.

The DPC programming model for the AS/400 does not support:

- Nesting of UDTs and structures.
- Arrays within UDTs and structures.
- Variable sized UDTs in which the last parameter is a string.

This section contains:

- Requirements for UDT Support in Windows 2000
- Using TI Project to Create UDTs
- Creating UDTs by Importing Host Definitions
- Arrays Defined in UDTs with Visual Basic

Requirements for UDT Support in Windows 2000

When Windows 2000 is installed, Transaction Integrator (TI) offers full functionality. Otherwise, TI restricts the use of user-defined types (UDTs). The functionality offered in this restricted mode is as follows:

- The TI Component Registrar recognizes that it is executing on a computer that does not have Service Pack 4 (SP4) installed. If the registrar is instructed to deploy a component when UDT support is not available, the registrar will search the type library to ensure that there are no UDTs. If UDTs are detected, the component deployment will fail and an error describing this failure will be written to the event log.
- TI Project recognizes that it is executing on a computer that does not have Windows 2000 installed. Although TI Project does not prevent UDTs within component descriptions, it warns users when UDTs are being used on a computer that does not have Windows 2000. Specifically, in TI Project, when the user attempts to save the type library, a UDT warning appears if UDTs are used in the component's description. This warning appears only after the first attempt to save a component description.

Creating UDTs by Importing Host Definitions

Arrays Defined in UDTs with Visual Basic

Using TI Project to Create UDTs

In Microsoft® Visual Studio® Transaction Integrator (TI) Project, you can create a user-defined type (UDT) manually by right-clicking the **User-Defined Type** folder, and then click **Add User-defined Type**. This automatically adds one member field of the type Integer. If only one member field exists in a UDT, you cannot delete that member field; you can only delete the entire UDT. You cannot delete a UDT if it is being used as a type by some other variable in the interface. The name of a UDT cannot be the same as a method name, recordset name, or any reserved names.

To add a member field to a UDT, right-click a previously defined UDT, and then click **Add User-defined Type Member**. A default member is created and can be modified by updating its properties in the **Properties** pane.

In addition to the **Automation** and **COBOL Definition** property pages for UDT member fields, an **Arrays** property page supports defining arrays of member fields, and a **Recordsets** property page supports definition of a maximum row count and options for recordset columns. The rules for arrays of recordsets are the same as for parameters. An OCCURS DEPENDING index must be one of the member fields above the array itself.

In TI Project, you can copy and paste UDT members from and to recordset members.

Requirements for UDT Support in Windows 2000

Creating UDTs by Importing Host Definitions

Arrays Defined in UDTs with Visual Basic

Creating UDTs by Importing Host Definitions

The parser phase of the host import function identifies any group-level clause as a possible user-defined type (UDT). UDTs are created when you specify creating or updating a UDT or as the result of creating a method that contains a UDT. When you create or update a method, there is an additional wizard page following the **Select Return Value** page for specifying that groups of data items are UDTs or recordsets. This page also enables you to cancel the selection of groups of data items as UDTs or recordsets. For backward compatibility, the default data type of a group-level clause is a recordset if the group level has an OCCURS keyword. Also for backward compatibility (that is, updating a method), if there is no OCCURS keyword, the group level is flattened by default.

Requirements for UDT Support in Windows 2000

Using TI Project to Create UDTs

Arrays Defined in UDTs with Visual Basic

Arrays Defined in UDTs with Visual Basic

In Visual Basic, if an array is defined within a user-defined type (UDT), you must re-dimension the array within the UDT before you populate the array. A UDT is a group of data types assigned to a single parameter, which is defined with an alias. In the following example, the UDT is defined within a Transaction Integrator (TI) type library, and not within the Visual Basic client.

The following example presents Visual Basic code that defines an array within a UDT:

```
*** Assign the udt defined within the comti typelib to a variable within the Visual Basic app
lication.
Dim ClientUDT as UDT1
*** assign values to string data type within UDT1
ClientUDT.string = "ABCDEFG"
*** assign size before populating
ReDim ClientUDT.array1(10).
** start assigning values to array within UDT.
ClientUDT.array1(1) = 100
```

Note In an array within a UDT, do not define the array within the Visual Basic client before you perform a re-dimension against the UDT. For all other data types within the UDT, you can immediately populate the values without having to define them within the Visual Basic client data declarations.

Note If you have an output or an in/out array inside a UDT, use a lower bound of zero for all array dimensions. Use zero because type libraries contain information only about array dimensions, not upper and lower bounds. Therefore, Convert has to choose them arbitrarily when it creates the arrays.

Note Report Program Generator (RPG) has additional limitations on the use of UDTs. RPG does not support:

- Nesting more than one level of arrays of UDTs.
- UDTs that contain recordsets within UDTs.

Creating UDTs by Importing Host Definitions

Transaction Request Messages

When you use TCP/IP to communicate with CICS, the client sends the host a transaction request message (TRM) request containing the Transaction Program ID, User ID, Password, and other administrative data to be used by the host. CICS sends the client a TRM reply containing additional administrative data. The data in the TRM is independent from the actual program data to be exchanged with the Transaction Program (TP) on the host.

You can find templates for various TRMs at **\*installation directory*\Microsoft Host Integration Server\system\TIM\MicrosoftTRMDefs.tim**. Use Microsoft Visual Studio .NET 2003 to open the file, and then expand the **User-Defined Types** node. The following TRMs are defined as UDTs:

- TRMIN_MSLink
- TRMOUT_MSLink
- TRMIN_MSCCS
- TRMIN_IBMCCS
- TRMOUT_CCS

You can also find templates for various enhanced listener messages (ELMs) at **\*installation directory*\Microsoft Host Integration Server\system\TIM\MicrosoftELMDefs.tim**. Use Microsoft Visual Studio .NET 2003 to open the file, and then expand the **User-Defined Types** node. The following ELMs are defined as UDTs:

- ELMIN_MSLink
- ELMOUT_MSLink
- ELMIN_MSCCS
- ELMIN_IBMCCS
- ELMOUT_CCS

You can create a TRM or ELM template in COBOL to assist with your programming by exporting the TRM or ELM definition.

To create a TRM template in COBOL

1. Open Microsoft Visual Studio .NET 2003.
2. On the **File** menu, point to **Open**, and then click **File**.
3. In the **Open File** dialog box, navigate to <drive>:\Program Files\Microsoft Host Integration Server\System\TIM\, and then click either **MicrosoftTRMDefs.tim** or **MicrosoftELMDefs.tim**.
4. On the **File** menu, click **Export Host Definition**.
5. In the **Export Host Definition** dialog box, type or select the file name, and then click **Save**.

You can substitute a custom TRM (or ELM) for the default TRM (or ELM) created by the TI runtime. Use the COMTIContext parameter to pass custom context data.

See Also

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Using Custom TRMs and ELMs with COMTIContext

Transaction Integrator (TI) developers can pass custom formatted transaction request messages (TRMs) or enhanced listener messages (ELMs) from a client program to the CICS system and receive custom formatted TRMs or ELMs.

Custom TRMs or ELMs are passed through context data. The context data is contained in the optional *COMTIContext* parameter defined in the client application code and must be the final parameter in the method call. A TRM destined for the host must be defined as a user-defined type (UDT) for the COM model, or a structure for the .NET model. The name of the UDT must begin with the characters TRMIN. A TRM reply from the host must also be defined as a UDT. The name of the UDT must begin with the characters TRMOUT. Examples of valid TRM names are: TRMINMyVeryOwn, TRMINStandard, TRMOUTMyVeryOwn, and TRMOUTStandard.

The type library or structure can contain multiple TRM definitions, but you should include only one TRM for each direction (that is, one TRMIN and one TRMOUT) in the COMTIContext parameter in a single method call. For example, in Visual Basic each COMTIContext array is declared as a single dimension dynamic array of variants (that is, the number of occurrences is not specified).

If you define multiple TRMs for the same direction, the TI run time uses only the first TRM it encounters in the context array. (In some circumstances, the first TRM encountered might not always be the first one that you added to the context array). The TI run time ignores the remaining TRMs in the array until the TRM in use is destroyed. To ensure that the TI run time uses the correct TRM, do not add multiple TRMs intended for the same direction to a context array.

> **Note** The client application that manipulates the Context array must be able to access the appropriate file at run time. If you are using Visual Basic 6.0, the application must be able to access COMTIContext.dll. If you are using Visual Basic .NET, the application must able to access Microsoft.HostIntegration.TI.ClientContext.dll.

> **Note** When you use Visual Basic .NET, the data structure used as a custom TRM must be associated to a parameter within the assembly. Therefore, you must create a dummy method within the assembly, a parameter assigned to the method, and the data structure to be used as the TRM. Failure to do so prevents you from referencing the structure within the Visual Basic .NET application. Associating a UDT to a method was not required in Visual Basic 6.0 because Visual Basic 6.0 allowed referencing of UDTs not associated with methods.

Overriding Settings in the Type Library

If you need to temporarily change certain data sent from the type library to the host, you can override the type library settings without changing the original file. Use the following keywords in combination with the COMTIContext parameter to override the type library setting:

- **REOverride**
- **TPNameOverride**
- **ProgNameOverride**
- **USERID**
- **PASSWORD**
- **IMS_LTERM**
- **TRMIN**
- **RMOUT**

The override remains active until either a new override is set or the override is deleted. Use the **WriteContext** function to set the override and the **DeleteContext** function to delete the override. If you delete the override, the value defaults to the setting in the original type library.

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

Persistent Connections with the Mainframe

Windows-initiated processing (WIP) supports persistent connections over TCP/IP and SNA for the following programming models:

- TCP Transaction Request Message (TRM) Link
- TCP Enhanced Listener Message (ELM) Link
- TCP Transaction Request Message (TRM) User Data
- TCP Enhanced Listener Message (ELM) User Data
- OS/400 DPC
- CICS Link LU 6.2
- CICS User Data LU 6.2

Persistent connections are not supported in the following programming models:

- IMS Implicit
- IMS Explicit
- IMS LU 6.2

Windows Initiated Processing (WIP) Persistent connections allow you to maintain a single TCP connection or SNA conversation over multiple method calls to the host. In Host Integration Server 2000, COMTI had to open and close a connection each time a method call was made to the host. On the mainframe side, CICS had to start and stop a transaction program (TP). In Host Integration Server 2004, persistent connections allow Transaction Integrator (TI) to open a connection for the first method in a group of methods, make all the method calls, and then close the connection. On the mainframe side, CICS starts an instance of the transaction program, keeps the instance active between method calls, and then stops the program after the last call.

One of the major benefits from using persistent connections is that it allows CICS to maintain state across multiple method calls and allows for the use of local variables. Persistent connections are implemented and managed through the COMTIContext.

COMTIContext supports methods that flow to the COM+ or .NET application and updates client status information (**COMTIContext** array) or closes persistent connections.

UpdateContextInfo updates the client’s **COMTIContext** array with information obtained from the COM+ or .NET application object, but with no server object involvement.

ClosePersistentConnection closes persistent connections by contacting the COM+ or .NET application object, but with no server object involvement.

The client can obtain connection state information by calling the **GetConnectionInfo** method that is implemented by the **COMTIContext** object. In the case of a .NET method failure, the client must call **UpdateContextInfo** before it calls **GetConnectionInfo**.

A time-out mechanism reclaims orphaned persistent connections. The new **COMTIContext** keyword **CONNTIMEOUT** takes an integer value specifying, in seconds, how much time elapses before a persistent connection is considered abandoned, and then automatically closed. The timing starts as the client call processing is completed by the COM+ or .NET generic object.

GetConnectionInfo querys the status of a persistent connection. The following shows a COM-based method:

```
       HRESULT GetConnectionInfo (
            [in, out] SAFEARRAY(VARIANT)*COMTIContextArray,
            [out] BOOL* pfConnectionIsPersistent,
            [out] BOOL* pfConnectionIsViable);
```

The following shows the .NET-based equivalent:

```
        GetConnectionInfo (ref object[] contextArray,
            out bool fConnectionIsPersistent,
            out bool fConnectionIsViable).
```

The **COMTIContextArray** parameter is updated to reflect the state of the connection, the **pfConnectionIsPersistent** parameter contains TRUE if the connection is persistent and active, and the **pfConnectionIsViable** parameter contains TRUE if the connection is active.

UpdateContextInfo updates the client's **COMTIContext** array. The following shows a COM-based method:

```
        HRESULT UpdateContextInfo (
            [in, out] SAFEARRAY(VARIANT)*COMTIContextArray);
```

The following shows the .NET-based equivalent:

```
        UpdateContextInfo (ref object[] contextArray).
```

The **COMTIContextArray** parameter is updated to reflect the state of the connection. At a later time other information kept in the COM+ or .NET application might also be returned in the update **COMTIContextArray**.

ClosePersistentConnection closes a persistent connection without the need for a call to the server system. The following shows a COM-based method:

```
        HRESULT ClosePersistentConnection (
            [in, out] SAFEARRAY(VARIANT)*COMTIContextArray);
```

The following shows the .NET-based equivalent:

```
        ClosePersistentConnection (ref object[]COMTIContextArray).
```

The **COMTIContextArray** parameter is updated to reflect the state of the connection.

Using Persistent Connections

To establish a persistent connection, set the **COMTIContext** keyword **CONNTYPE** to **OPEN**. If a call with **CONNTYPE** set to **OPEN** completes successfully, the returned **COMTIContext** array **CONNTYPE** keyword has a value of **USE**.

To make a call and terminate the persistent connection, set the **CONNTYPE** keyword to **CLOSE**. If a call with **CONNTYPE** set to **CLOSE** completes successfully, the returned **COMTIContext** array **CONNTYPE** keyword has a value of **NON-PERSISTENT**.

After you set the **COMTIContext** keyword **CONNTYPE** to **OPEN**, **CONNTYPE** can be set to **USE**. However, this action is not mandatory because it is set to **USE** by default.

All TI objects include the intrinsic methods **ClosePersistentConnect** and **UpdateContextInfo** for use when dealing with persistent connections.

If the method call fails, the **COMTIContext** array cannot be updated and the client should call the intrinsic method **UpdateContextInfo** and then the **GetConnectionInfo** method on the **COMTIContextLib.ContextObject** to obtain updated status of the connection.

You can call **ClosePersistentConnection** at any time to close a persistent connection. The connection will be terminated and there will be no interaction with a server program.

The following Visual Basic 6.0 code sample shows how to use the **OPEN** and **CLOSE** method calls that might return an error. The sample also demonstrates how to determine whether a connection can still be used.

```
Public CtxCount As Long
Public COMTIContext() As Variant
Public ContextObj As COMTIContextLib.ContextObject

Dim fConIsPersistent as Boolean
Dim fConnIsViable as Boolean
Dim varConnType as Variant

Private Sub cmdBalance_Click(fCloseWIthMethod As Boolean)
  On Error GoTo ErrorHandler

OpenCall:
  varConnType = "OPEN"
  ContextObj.WriteContext "CONNTYPE", varConnType, COMTIContext
  lngReturn = objBank.cedrbank(txtName.Text, txtAccount.Text, curRetBalance, COMTIContext)

UseCall:
  lngReturn = objBank.cedrbank(txtName.Text, txtAccount.Text, curRetBalance, COMTIContext)

CloseCall:
  If (fCloseWithMethod) Then
      varConnType = "CLOSE"
      ContextObj.WriteContext "CONNTYPE", varConnType, COMTIContext
      lngReturn = objBank.cedrbank(txtName.Text, txtAccount.Text, curRetBalance, COMTIContext
)
  Else
      COMTIContext = objBank.ClosePersistentConnection
  End-if

  Exit Sub

ErrorHandler:
    COMTIContext  = objBank.UpdateContextInfo  ‘ Optional for COM required for .NET
    ContextObj.GetConnectionInfo (COMTIContext, fConnIsPersistent, fConnIsViable)
    If (fConnIsPersistent = True And fConnIsViable = True) Then
        ‘Continue with the next Use or Close method call is OK
    Else
        ‘Connection is either Non-persistent or no longer viable
        ‘So a Use or Close call is not valid
    End-if
    Exit Sub

End Sub
```

Host and Automation Data

The topics in this section cover issues around working with Windows®-based Automation data and COBOL-based mainframe data.

This section contains:

- Variably-sized Data
- Date and Time Parameters
- Parameter Requirements
- Optional Metadata
- Return Value Positioning
- Data Transfer Options
- Mainframe Character Strings and Code Pages
- Maximum Buffer Sizes for Remote Environments
- Alignment Problems with Generated COBOL
- Filler
- Variable-length Tables and CICS LINK
- Sending Binary Data to the Host

Variably-sized Data

A string or array parameter that is the last parameter in its direction (last of the inputs and in/outs or last of the outputs and in/outs) can be smaller than the maximum size specified, even without an associated actual size. The variable string or array must be a parameter or return value and cannot be contained in a recordset.

If the final field is an array, it can be an array of any type, including a recordset. If there is an unbounded output recordset, it is the only variably-sized data allowed because Transaction Integrator (TI) cannot handle two pieces of the data stream that are variable in size. If COBOL FILLER exists after the last parameter, that parameter cannot be variable in size.

Identify the possibility of variably-sized data at design time in TI Project. In the Designer select the method whose parameter list contains the final field of string to be of variable size, and set the method property "Variable Sized Final Field" to true.

Sending Binary Data to the Host

Date and Time Parameters

Transaction Integrator (TI) converts and formats the **Date** and **Time** parameters exchanged with the host differently, depending on the programming language and the host platform.

You can use TI Project to set or change the properties of the **Date** parameter. The following table shows the formatting and valid separators for each **Host Data Type** in situations where the **Data Type** property of the parameter is set to **Date**.

Data Type Formats and Separators

Host Data Type	Format (default separator)	Valid separators	Length	Notes
DATE and TIME	yyyydddhhmmsss (two packed decimal fields)	None	8	None
DATE only (COBOL only)	yyyyddd (packed decimal)	None	4	(1) (2)
DATE only (RPG only *MDY)	mm/dd/yy	/-.,’&’	8	(5)
DATE only (RPG only *DMY)	dd/mm/yy	/-.,’&’	8	(5)
DATE only (RPG only *YMD)	yy/mm/dd	/-.,’&’	8	(5)
DATE only (RPG only *JUL)	yy/ddd	/-.,’&’	6	(5)
DATE only (RPG only *LONGJUL)	yyyy/ddd	None	8	None
TIME only (COBOL only)	hhmmsss (packed decimal)	None	4	(3) (4)
TIME only (RPG only *HMS)	hh:mm:ss	:.,&	8	None
ISO DATE and TIME	yyyy-mm-dd hh.mm.ss	space	19	None
ISO DATE only	yyyy-mm-dd	-	10	None
ISO TIME only	hh.mm.ss	.	8	None
USA DATE and TIME	mm/dd/yyyy hh:mm AM (or PM)	space	19	None
USA DATE only	mm/dd/yyyy	/	10	None
USA TIME only	hh:mm AM or hh:mm PM	:	8	None
JIS DATE and TIME	yyyy-mm-dd hh:mm:ss	space	19	None
JIS DATE only	yyyy-mm-dd	-	10	None
JIS TIME only	hh:mm:ss	:	8	None
EUR DATE and TIME	dd.mm.yyyy hh.mm.ss	space	19	None
EUR DATE only	dd.mm.yyyy	.	10	None
EUR TIME only	hh.mm.ss	.	8	None
TIMESTAMP	yyyy-mm-dd-hh.mm.ss.mmmm (length 26).	0001-01-01-00.00.00.000000	0001-01-01-00.00.00.000000	None

Where:

ISO = International Standards Organization

USA = IBM USA Standard

EUR = IBM European Standard

JIS = Japanese Industrial Standard Christian Era

> (1) When a date is sent to the host, the host populates a seven-digit COMP-3 data type only with the Julian Date YYYYDDD and no other format.
>
> (2) When a date is received from the host, the **Date** parameter must be packed as a valid Julian Date within a seven-digit COMP-3 data type.
>
> (3) When a time is sent to the host, the host populates a seven-digit COMP-3 data type as HHMMSSS up to 100th of a second. For example, sending 01:12:03 AM populates the COMP-3 data type on the host with 0112030; sending 01:12:003 AM populates the COMP-3 data type on the host with 0112003.

(4) When a time is received from the host, the **Time** parameter must be packed within a seven-digit COMP-3 data type packed as HHMMSSS; data passed under any other format might not return the expected results.

(5) A two-digit year (yy) returned from the host is mapped to a four-digit year (yyyy) as follows:

00 to 39 is mapped as 20xx.

40 to 99 is mapped as 19xx.

Rounding occurs when TI receives the parameter from the host:

- The hour value of time rounds up the day of date.
- The minutes of time rounds up the hour of time.
- The first two digits of seconds influences the value of minutes.
- The third digit of second, or the one 1\100 value of seconds, does not influence the value of minutes. It would just be passed forward to the workstation and displayed.

For example:

- Assigning 1997001 to the host date field and 3701000 to the time field causes the workstation to display 01/02/1997 11:01:00 PM.
- Assigning 1197001 to the host date field and 0101610 to the time field causes the workstation to display 01/01/1997 01:02:01.
- Assigning 1197001 to the host date field and 0101619 to the time field, causes the workstation to display 01/01/1997 01:02:019.

Parameter Requirements

Requirements for the In, In/Out, and Out parameters might affect how you define a Transaction Integrator (TI) component or mainframe transaction program (TP). The In and In/Out parameters are sent to the mainframe-based TP from the TI Automation server. The Out and In/Out parameters are sent from the mainframe-based TP to the TI Automation server.

Best Parameter Order

The way parameters are ordered with regard to inputs and outputs determines the amount of data that must be transmitted, as well as the structure of the mainframe program. If you are creating a Transaction Integrator (TI) component in TI Project without importing COBOL code from a mainframe transaction program, place the parameters in the following order to minimize the amount of data transmitted:

- Input parameters
- Input/output parameters
- Output parameters

However, if you are using a CICS LINK LU 6.2, TCP TRM Link, or TCP ELM Link remote environment (RE) and importing COBOL data declarations into TI Project from an existing mainframe program, place the parameters in the order they appear in the COBOL data structure. In such a case, although the parameters are contained within the COMMAREA data structure, only the part of the COMMAREA containing the last input or input/output parameter is sent to the mainframe. The mainframe program is not affected by this ordering, but less data will be transmitted, especially in the case of small amounts of input data.

Maximum Amount of Parameter Data

The remote environment (RE) you use can affect the maximum possible message size. Programs associated with the CICS LINK LU 6.2, TCP TRM Link, or TCP ELM Link REs are limited by the maximum size of the COMMAREA (32,767 bytes). Therefore, the total byte size of all parameters cannot exceed 32 KB. Programs associated with distributed program call (DPC) are limited to a maximum of 65,500 bytes of user data. This maximum decreases as additional parameters are defined. DPC is limited to a maximum of 35 parameters.

The IMS Using LU 6.2 and CICS Using LU 6.2 REs have message size restrictions that, if exceeded, affect the programming logic in the mainframe program. Therefore, be careful not to exceed the limit if you use either of these REs.

Optional Metadata

As a developer, you can choose to have the Transaction Integrator (TI) run-time environment send and receive metadata to and from the mainframe transaction program (TP), and you can choose the content of that metadata.

> **Note** Metadata is not supported for distributed program call (DPC).

You can send or receive:

- No metadata.
- Only the method name as metadata.
- All metadata including the method name.

The TI run-time environment sends or receives metadata to or from the TP as instructed. Metadata assists the TP in:

- Identifying the format of the metadata (version information).
- Identifying the name of the method used to invoke the TP.
- Reporting detailed error information back to the client.

The metadata is not visible to the Automation client. The metadata is delivered to (or received from) the host TP as part of the request message sent to (or response message received from) the TP.

The metadata set includes the following data:

- TI run-time version.

  A string of characters, such as "Microsoft TI version 1.0.0," that uniquely identifies the TI run-time environment version that generated the request.

- Method name (32-character string) invoked by the client application code.
- Metadata block ID.

  A GUID, in character format, that uniquely identifies this block of exception data. The GUID supports the ability to have additional exception formats in the future and helps to ensure that any data received is valid.

- Variables with no assigned uses to date (reserved):
  - Boolean flag indicating whether the TP is ready to commit.
  - Boolean flag indicating whether the TP is ready to perform additional work.
  - Two Short Integers to hold pieces of the TI run-time environment version number, one Short Integer to hold the major version number and the other to hold the minor version number.
- Exception Block (used only in replies).

  A GUID, in binary format, that uniquely identifies this block of exception data. The GUID allows support of additional exception formats in the future and helps ensure the data received is valid:

  - Boolean flag that indicates whether the TP is ready to commit.
  - Boolean flag that indicates whether the TP is ready to perform additional work.
  - Boolean flag that indicates whether an exception should be returned to the client application. If set, this flag also causes the transaction to quit.
  - 16-bit integer that identifies the error (see the note later in this topic). You can assign this value, along with the 256-character message that describes the error, from the server so that the assigned value is returned when a TI run-time error occurs.
  - 32-bit integer that identifies the context ID in the TP Help file (if any).
  - 256-character message that describes the error. You can assign this value, along with the 16-bit integer that identifies the error from the server, so that the assigned value is returned when a TI run-time error occurs.

Metadata is always located at the beginning of the message.

> **Note** TI error messages have numbers in the range from 0 through 9999. Metadata error message numbers returned from the mainframe can fall within the same range. To distinguish TI error messages from metadata messages returned from the mainframe, TI adds 10000 to the number of any metadata error message returned from the mainframe.

Return Value Positioning

When an Automation method returns control to the calling application, it can return data as the method's value (as distinct from returning data as an output parameter). However, there is no analogous concept when you are dealing with a COBOL or Report Program Generator (RPG) data declaration.

Transaction Integrator (TI) allows you to select one of the data description entries in a data declaration that will be returned to the calling application. When you select an entry as the return value and that entry is not the first entry in the data declaration, the return value is said to be positioned after the parameters.

You can use this feature, for example, when your data declaration describes a table and you need to return a recordset on the Automation side. For example, if you are using Remote Data Service (RDS) to bind to a grid control for a Web application, your Automation method must return the recordset rather than define a parameter that represents an output recordset.

When you import host definitions, the Import COBOL or Import RPG Wizard provides a step that allows you to select data description entries as return values. If you are manually creating a method and you want the method's return value to be placed in a location other than at the front of the data declaration, you can specify the location on the **Advanced** tab of the method properties. Use the **Position return value after the parameter** drop-down list.

Data Transfer Options

You can use various options to transfer data to and from the mainframe transaction program (TP). These options apply to arrays, recordsets, and strings (or variable-length tables and display data in COBOL terms). The topics in this section describe each of the possible data transfer options. Choose the option that optimizes the amount of data to be transferred.

This section contains:

- Using the OCCURS DEPENDING Clause to Define Variable-length Table
- Using Variably Sized Strings
- Using Variably Sized Rows
- Using Bounded Final Fields

Using the OCCURS DEPENDING Clause to Define Variable-length Table

In COBOL, you can use the OCCURS DEPENDING ON syntax to define a variable-length table in a data declaration. The storage for a variable-length table is dynamic, depending on the value in the length specifier variable. The amount of data passed is also dependent on the value in the length specifier variable: Only the number of elements specified are sent or received. The length specifier variable for a variable-length table must be a numeric type, and its direction must match the direction of the variable-length table it controls.

When you import COBOL into Transaction Integrator (TI) Project, and you specify variable-length tables as recordsets, the variable-length tables automatically become arrays or recordset objects whose size is limited by another parameter. The length specifier is exposed on the Automation side as a parameter and must be correctly set when the parameter is being sent to the host application.

To manually indicate that a parameter in a method is the length specifier for an array, first define the length specifier parameter, and then define the array or recordset parameter:

In the parameter property class to be defined as an ODO array, use the Designer to
select the **Is Array** property. After **IsArray** is selected, the **Array Dimensions** and **Occurs depending on** property becomes available.
Define the array's dimensions using the **Array Dimensions** property.
Assign the ODO index to the parameter defined as the ODO array.
Select the index by expanding the property **Occurs depending on**.

You can also manually indicate that a parameter in a method is the length specifier for a recordset parameter.

Follow the same steps as defined earlier; however, change the data type of the parameter from a simple data type to a recordset.

Examples

The following COBOL code shows a variable-length table:

```
01 CUSTOMER-DATA.
   05 CUSTOMER-NUMBER                  PIC 9(9).
   05 LAST-NAME                        PIC X(20).
   05 FIRST-NAME                       PIC X(20).
   05 INVOICE-COUNT                    PIC 9(7) COMP-3.
   05 INVOICES OCCURS 50 TIMES DEPENDING ON INVOICE-COUNT.
      10 INVOICE-NUMBER                PIC 9(10).
      10 INVOICE-DATE                  PIC 9(7) COMP-3.
      10 INVOICE-AMOUNT                PIC S9(13)V9(2) COMP-3.
      10 INVOICE-DESCRIPTION           PIC X(40).
```

The following is the method that is created when the previous COBOL is imported:

```
SendInvoices(lCustomerNo As Long, strLastName As String, strFirstName As String _
    , lcInvoices As Long) As Object
```

The following is an example of Microsoft® Visual Basic® code that calls an imported method:

```
Dim objCustomer As Object   'Uses late binding
Dim objInvoices As ADODB.Recordset
Dim lCustomerNumber As Long
Dim iRow As Integer
Dim iCol As Integer
Dim strLastName As String
Dim strFirstName As String

'create an instance of the invoicing object
On Error GoTo ErrorHandler1
Set objCustomer = CreateObject("Customer.Invoicing.1")
```

```
lCustomerNumber = CLng(txtCustomerNumber)

'See the WebSite folder under the CedarBank tutorial folder
'for an example showing how to return recordsets to an RDS
'recordset on a Web site

'invoke the GetInvoices method
On Error GoTo ErrorHandler2
Set objInvoices = objCustomer.GetInvoices(lCustomerNumber _
    , strLastName, strFirstName)
'
' Transfer the Recordset data to a variant array in a single operation.
' This is efficient, but may not be suitable for larger Recordsets.
'
Dim Data As Variant

Data = objInvoices.GetRows
grdInvoices.Rows = UBound(Data, 2) + 1
grdInvoices.Cols = UBound(Data, 1) + 1
```

Using Variably Sized Strings

When the last input parameter or the last output parameter in a method is a string, that string can be variably sized. Its size can vary from 0 to the maximum number of bytes specified for its length. When the return value is a string and it is positioned after all other output parameters, it can be the variably sized final output field.

The string must be sent or received last if it is to be variably sized. Otherwise, there is no reliable way to determine the end of a variably sized string and the next data item in the buffer. The logic of the host application sends only the data for the part of the string that is needed.

COBOL never sets the variably sized option for strings. To set this property manually, set the **Variable Sized Final Field** property to be variable. The property **Variable Sized Final Field** is subdivided into two parts by direction. Set the direction you want to true.

Example

The following COBOL example has as its last data item a large string that could be optimized by sending only the size of the string:

```
01 CUSTOMER-DATA.
   05 CUST-HEADER.
      10 CUSTOMER-NUMBER              PIC 9(9).
      10 LAST-NAME                    PIC X(20).
      10 FIRST-NAME                   PIC X(20).
   05 COMMENTS                        PIC X(4096).
```

When imported, this COBOL code creates the following method:

```
CustomerInformation(lCustomerNo As Long,_
                    strLastName As String,_
                    strFirstName As String,-
                    strComments As String)
```

The following Visual Basic code calls the method:

```
Dim objCustomer As Object
    Dim lCustomerNo As Long
    Dim strLastName As String
    Dim strFirstName As String
    Dim strComments As String

    lCustomerNo = 100231

    'create an instance of the invoicing object
    On Error GoTo ErrorHandler1
    Set objCustomer = CreateObject("Customer.Invoicing.1")

    'invoke the SetInvoices method
    On Error GoTo ErrorHandler2
    objCustomer.CustomerInformation lCustomerNo, strLastName _
        , strFirstName, strComments
```

Using Variably Sized Rows

When the last column in a record is a string, the row can be variably sized. Its size can vary between zero and the maximum size specified in the picture clause. When you have variably sized rows, your application must explicitly specify the size of each row before the row is sent.

The actual size field is not visible on the Automation side. The Transaction Integrator (TI) run-time environment uses Automation services to determine the size of input data. When the TI run-time environment sends data to the host, it automatically sets the actual size field.

The COBOL Import Wizard never creates a recordset that has variably sized rows. Bring up properties for the recordset that contains the variably sized rows. The **Variable sized rows** property allows user to manually configure this option for a specific recordset. The **Variable sized rows** property offers advanced options. You can specify that the actual row size variable is a half-word or full-word binary. The actual size variable will include itself or will only include the size of the row.

Example

The following COBOL example shows how the host application sends variably sized rows. The length field is included in the row size:

```
01  CUSTOMER-DATA.
    05  CUSTOMER-NUMBER                  PIC 9(9).
    05  LAST-NAME                        PIC X(20).
    05  FIRST-NAME                       PIC X(20).
    05  INVOICE-COUNT                    PIC 9(7) COMP-3.
    05  INVOICES OCCURS 50 TIMES DEPENDING ON INVOICE-COUNT.
        10  INVOICE-DATA.
            15  INVOICE-ROW-SIZE         PIC S9(4) COMP.
             15  INVOICE-NUMBER           PIC 9(10).
             15  INVOICE-DATE             PIC 9(7) COMP-3.
             15  INVOICE-AMOUNT           PIC S9(13)V9(2) COMP-3.
         10  INVOICE-DESCRIPTION          PIC X(4096).
.
.
.
            MOVE LENGTH OF CUSTOMER-DATA TO SEND-LENGTH.
            SUBTRACT LENGTH OF INVOICES FROM SEND-LENGTH.
            EXEC-CICS SEND FROM(CUSTOMER-DATA)
                           LENGTH(SEND-LENGTH)
                           END-EXEC.

            PERFORM VARYING CROW FROM 1 BY 1 UNTIL CROW > INVOICE-COUNT
                INSPECT INVOICE-DESCRIPTION TALLYING INVOICE-ROW-SIZE
                    FOR CHARACTERS BEFORE INITIAL '          '
                ADD LENGTH OF INVOICE-DATA TO INVOICE-ROW-SIZE
                EXEC-CICS SEND FROM(INVOICE-ROW-SIZE)
                               LENGTH(2)
                               END-EXEC
                EXEC-CICS SEND FROM(INVOICES(CROW))
                               LENGTH(INVOICE-ROW-SIZE)
                               END-EXEC
            END-PERFORM.
```

The following COBOL example shows how the host application sends variably-sized rows. The length field is not included in the row size:

```
       01  CUSTOMER-DATA.
          05  CUSTOMER-NUMBER                  PIC 9(9).
          05  LAST-NAME                        PIC X(20).
          05  FIRST-NAME                       PIC X(20).
          05  INVOICE-COUNT                    PIC 9(7) COMP-3.
          05  INVOICE-ROW-SIZE                 PIC S9(4) COMP.
         05  INVOICES OCCURS 50 TIMES DEPENDING ON INVOICE-COUNT.
```

```
             10  INVOICE-DATA.
                  15  INVOICE-NUMBER           PIC 9(10).
                  15  INVOICE-DATE             PIC 9(7) COMP-3.
                  15  INVOICE-AMOUNT           PIC S9(13)V9(2) COMP-3.
              10  INVOICE-DESCRIPTION          PIC X(4096).
.
.
.
            MOVE SIZE OF CUSTOMER-DATA TO SEND-LENGTH.
            SUBTRACT LENGTH OF INVOICES FROM SEND-LENGTH.
            SUBTRACT LENGTH OF INVOICE-ROW-SIZE FROM SEND-LENGTH.
            EXEC-CICS SEND FROM(CUSTOMER-DATA)
                           LENGTH(SEND-LENGTH)
                           END-EXEC.

            PERFORM VARYING CROW FROM 1 BY 1 UNTIL CROW > INVOICE-COUNT
                INSPECT COMMENTS TALLYING INVOICE-ROW-SIZE
                    FOR CHARACTERS BEFORE INITIAL '   '
                ADD LENGTH OF INVOICE-DATA TO INVOICE-ROW-SIZE
                EXEC-CICS SEND FROM(INVOICE-ROW-SIZE)
                               LENGTH(LENGTH OF INVOIVE-ROW-SIZE)
                               END-EXEC

                EXEC-CICS SEND FROM(INVOICES(CROW))
                               LENGTH(INVOICE-ROW-SIZE)
                               END-EXEC
            END-PERFORM.
```

Using the OCCURS DEPENDING Clause to Define Variable-length Table

Using Variably Sized Strings

Using Bounded Final Fields

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Using Bounded Final Fields

When the last input or the last output parameter in a method is an array or recordset, that parameter can be bounded. Its size can vary from 0 to the maximum number of elements or rows specified. The array or recordset must be last to be bounded. Otherwise, there is no reliable way to determine the end of a bounded array or recordset and the beginning of the next field in the buffer. The host application must take care of sending the truncated table.

The Automation client handles this option automatically. The Transaction Integrator (TI) run-time environment sends a truncated amount of data based on the Automation bounds and detects the truncated data and creates the appropriate Automation type when data is received.

The COBOL Import wizard never sets the bounded option for arrays or recordsets. To set this manually for the final parameter in a method, use the Designer to assign a value to the property **Maximum Occurrence**. This field defines the maximum number of rows the recordset may contain. On the method containing the recordset, set the property **Variable Sized Final Field** to true by direction to make the recordset bounded.

If the method contains a recordset that is unbounded, you cannot also specify a bounded or variably-sized final field for that direction. For example, if Parameter1 is an output parameter, and it is an unbounded recordset, the final output parameter cannot be a bounded array or recordset or variably-sized string. When the return value is positioned after all other output parameters, the return value can be the bounded final output field.

Example

The following COBOL example sends only some of the rows in a recordset:

```
01  INVOICE-COUNT                        PIC S9(4) COMP.
01  CUSTOMER-DATA.
    05  CUSTOMER-NUMBER                  PIC 9(9).
    05  LAST-NAME                        PIC X(20).
    05 INVOICES OCCURS 50 TIMES.
               10  INVOICE-NUMBER               PIC 9(10).
               10  INVOICE-DATE                 PIC 9(7) COMP-3.
               10  INVOICE-AMOUNT               PIC S9(13)V9(2) COMP-3.
.
.
.
            MOVE SIZE OF CUSTOMER-DATA TO SEND-LENGTH.
            SUBTRACT LENGTH OF INVOICES FROM SEND-LENGTH.
            EXEC-CICS SEND FROM(CUSTOMER-DATA)
                           LENGTH(SEND-LENGTH)
                           END-EXEC.
            PERFORM VARYING I FROM 1 BY 1 UNTIL I = INVOICE-COUNT
                COMPUTE SEND-LENGTH = LENGTH OF INVOICE-NUMBER +
                                      LENGTH OF INVOICE-DATE +
                                      LENGTH OF INVOICE-AMOUNT
                EXEC-CICS SEND FROM(INVOICES(I))
                               LENGTH(SEND-LENGTH)
                               END-EXEC.
            END-PERFORM.
```

Mainframe Character Strings and Code Pages

When Transaction Integrator (TI) sends data to a mainframe-based transaction program (TP), the TI run-time environment transforms Unicode strings received as parameters, fields, or columns into mainframe character strings. Likewise, when it receives data from a mainframe TP, the TI run-time environment converts the mainframe character strings into Unicode strings to be returned as output values to the calling client application.

TI categorizes these strings of characters sent to and received from the mainframe as follows:

- Extended Binary Coded Decimal Interchange Code (EBCDIC) strings.
- IBM double-byte character set (DBCS) strings.
- Intermixed strings containing both EBCDIC and IBM DBCS strings with the necessary shift-out (SO) and shift-in (SI) characters.

The TI run-time environment determines the type of mainframe character string based on the following information:

- How the parameter, field, or column is defined in the TI component that was built by using TI Project.
- The code page defined for the specific remote environment (RE) that was associated with the active TI Automation server when it was deployed. When you create an RE in TI Manager, you specify a code page for that RE.

This section contains:

- Assign a Different Code Page to a Remote Environment
- IBM DBCS Code Pages
- Mainframe Character Formats
- Padding Mainframe Character Strings with Spaces
- Truncating Undefined Portions of Strings
- Adding Leading SO and Trailing SI Characters

Assign a Different Code Page to a Remote Environment

Use a remote environment (RE) to describe each CICS or IMS mainframe environment. Use Transaction Integrator (TI) Manager to create, modify, and delete REs.

Every RE description includes a property value for the code page that is to be used by the TI run-time environment to convert characters to and from mainframe data representations.

When you create a new RE, TI Manager automatically selects a code page based on the current system locale. However, you can replace this default value with a code page that you select.

As needed, you can use TI Manager to assign a different code page to any RE.

To select a different code page for an RE

1. On the **Start** menu, point to **Programs**, then **Microsoft Host Integration Server 2004**, and then click **TI Manager**.
2. Expand the **Remote Environments** node.
3. Right-click the remote environment to be modified, and then click **Properties**.
4. On the **Locale** tab, clear the check box **Use default code page for the selected locale**.
5. On the **Locale** tab, select the new code page from the **Code page** dropdown list.

Only the code page value is significant to the TI run-time environment when it converts character data. Although you can use the locale displayed on the **Locale** property page to select the code page, the TI run-time environment ignores it and uses only the code page value that is associated with that locale.

IBM DBCS Code Pages

Transaction Integrator (TI) recognizes the following code pages as IBM double-byte character set (DBCS) code pages:

Code page	Description
930	IBM Extend Katakana and IBM Japanese (for Japan)
931	IBM English lower case and IBM Japanese (for Japan)
933	IBM Hungle Extend single-byte and IBM Hungle (for Korea)
935	IBM English single-byte and IBM simplified Chinese (for PRC)
937	IBM English single-byte and IBM traditional Chinese
939	IBM English Extend lower case and IBM Japanese (for Japan)

All other code pages delivered with Microsoft® Host Integration Server 2004 are handled as Extended Binary Coded Decimal Interchange Code (EBCDIC) code pages, which use a single byte to represent a character.

When the TI run-time environment converts UNICODE characters to DBCS characters, it uses standard Microsoft® Windows® NLS code pages.

The following table lists the DBCS code pages and their corresponding NLS code pages.

DBCS code page	NLS code page required by TI
930	932 ANSI Japan
931	932 ANSI Japan
933	949 ANSI Korean
935	936 ANSI Chinese (China, Singapore)
937	950 ANSI Chinese
939	932 ANSI Japan

The list of code pages on the **Locale** property page for a remote environment includes a DBCS code page only if the corresponding NLS code page is loaded on the computer. The following code pages have been added for European support.

Code page	IBM or open systems name	Display name
923	ISO 8859-15 Latin 9 (Euro)	Latin-9 (Euro)
924	IBM Latin - 1/Open System	Latin-1 Open System (Euro)
858	OEM - Multilingual Latin 1 (Euro)	OEM - Multilingual Latin 1 (Euro)
1140	IBM EBCDIC - U.S./Canada (Euro)	U.S./Canada (Euro)
1141	IBM EBCDIC - Germany (Euro)	Germany (Euro)
1142	IBM EBCDIC - Denmark/Norway (Euro)	Denmark/Norway (Euro)

Mainframe Character Formats

Within Transaction Integrator (TI) Project, you can specify the mainframe character format that the TI run-time environment will create when sending data to the mainframe. There are two mainframe character formats supported by TI:

- PIC X(n) COBOL, or RPG A
- PIC G(n) COBOL, or RPG G

When you create string parameters, fields, or columns in TI Project, the PIC X(*n*) or RPG A data type format is selected automatically.

If necessary, you can use the **Properties** command to change the mainframe character format.

If you select the PIC X or RPG A format for a string, the TI run-time environment converts this string to either an Extended Binary Coded Decimal Interchange Code (EBCDIC) character string or an intermixed character string. Specifically, if the TI component you define in TI Project is assigned to a remote environment (RE) with an EBCDIC code page, the TI run-time environment converts a string that has a PIC X or RPG A format into an EBCDIC string. If the TI component's RE identifies a double-byte character set (DBCS) code page, the TI run-time environment converts a string that has a PIC X format as an intermixed string (not supported for RPG).

If you select the PIC G or RPG G format for a string, the TI run-time environment always converts the string into a DBCS string. Therefore, any TI component that uses a string with a PIC G or RPG G format must be assigned to an RE that has a DBCS code page.

If a TI component using a string with a PIC G or RPG G format is assigned to an RE that has an EBCDIC code page, the TI run-time environment reports a conversion error when it attempts to convert the string to or from the PIC G or RPG G format. The TI run-time environment places an error message describing this conversion problem in the Windows Event Log, and it returns an error to the invoking client application.

The following table summarizes how the selection of string format and code page controls the type of character conversion performed by the TI run-time environment.

String format	EBCDIC code page	DBCS code page
PIC X or RPG A	EBCDIC string	Intermixed string
PIC G or RPG G	TI run-time environment reports conversion errors.	DBCS string

String Dimension Values

The meaning of a string's dimension (the *n* part of the PIC X(n) or RPG A(n) and the *n* part of the PIC G(n) or RPG G(n) formats) is based on the character format in use. You specify a string's dimension on the **COBOL Definition** property page in Transaction Integrator (TI) Project.

- The dimension value for a string with a PIC G or RPG G format gives the number of double-byte characters that are used in the mainframe representation of the string. No SO and SI character pair is added when a string with a PIC G or RPG G format is converted.
- The dimension value for a string with a PIC X or RPG A format gives the number of bytes that are used in its mainframe representation. The number of characters that can be placed into or taken from a PIC X or RPG A formatted string varies depending on the number of :
  - Double-byte character set (DBCS) characters, each of which requires two bytes of storage.
  - SO and SI character pairs needed. Each two-byte pair must encapsulate each contiguous stream of DBCS characters.

Developers using TI must take into account this variability in the size of an intermixed string when they specify dimension values in TI Project.

The number of bytes for a string converted using an EBCDIC code page with a PIC X or RPG A format is identical to the number of characters because there are no DBCS characters in the string.

However, for a string converted using a DBCS code page with a PIC X or RPG A format, the actual number of characters that can be placed in a given number of bytes varies. For example, if the conversion to or from UNICODE does not require the use of DBCS characters (that is, no SO and SI character is used in the mainframe string), each character occupies a single byte. However, if

DBCS characters do appear within the mainframe string, the SO and SI character pairs are needed.

How the Import Wizard Defines Strings

When you use Transaction Integrator (TI) Project's Import wizard to import a host definition to create new methods and recordsets, the wizard selects the mainframe character format based on the imported host definition. The following table shows how the wizard maps different COBOL declarations to a string.

COBOL type	Type of string created
PIC X(*n*) or RPG A	String of size *n* bytes
PIC G(*n*) or RPG G	String of size *n* characters

Padding Mainframe Character Strings with Spaces

You can define the properties for a string such that the TI run-time environment adds space characters to pad the mainframe representation of the string instead of depending on a null termination character.

To use either a space character or null termination character

1. In Microsoft® Visual Studio® .NET 2003, right-click the object.
2. On the shortcut menu, click **Properties**.
3. Under **Host Data Type Information** in the **Properties** pane, click **String Delimiting**.
4. Select either **Space** Padded or **Null Terminated**.

The following table describes what happens with each delimiting option (**Space Padded** or **Null terminated**) when converting to the type of string indicated.

Type of string operation	**What happens for each type of string delimiting operation**
Conversion to EBCDIC string	**Space Padded.** The TI run-time environment adds single-byte space characters to the end of the string until all bytes in the PIC X formatted string are filled.
	Null terminated. The TI run-time environment adds a single null character to the end of the string if there is room in the PIC X count for the byte.
Conversion from EBCDIC string	**Space Padded.** The TI run-time environment strips single-byte space characters from the end of the string.
	Null terminated. The TI run-time environment scans from the beginning of the string and stops the conversion at the first null character it encounters in the string.
Conversion to DBCS string	**Space Padded.** The TI run-time environment adds double-byte space characters to the end of the string until all characters in the PIC G formatted string are filled.
	Null terminated. The TI run-time environment adds a double-byte character set (DBCS) null character to the end of the string if there is room in the PIC G count for the bytes.
Conversion from DBCS string	**Space Padded.** The TI run-time environment strips double-byte space characters from the end of the string.
	Null terminated. The TI run-time environment scans from the beginning of the string and stops the conversion at the first DBCS null character it encounters in the string.
Conversion to Intermixed string	**Space Padded.** The TI run-time environment adds single-byte space characters to the end of the string until all bytes in the PIC X formatted string are filled. If the terminating character in the UNICODE string maps to a DBCS character, the TI run-time environment adds an SI character before it adds the space characters.
	Null terminated. The TI run-time environment adds a single byte null character to the end of the string if there is room in the PIC X count. If the terminating character in the UNICODE string maps to a DBCS character, the TI run-time environment adds an SI character before it adds the null character.
Conversion from Intermixed string	**Space Padded.** The TI run-time environment strips the terminating single-byte and double-byte space characters from the end of the string. When it strips the space characters, the TI run-time environment treats any terminating SI character as if it were a space.
	Null terminated. The TI run-time environment scans from the beginning of the string and stops the conversion at the first null character (of either width) it encounters.

Special handling occurs for a string that is last in the host buffer and that is flagged as *last is variable*. For example

- **Space Padded.** Upon conversion to an Extended Binary Coded Decimal Interchange Code (EBCDIC) string, the string is terminated by the length count of the containing buffer, so it contains no additional space characters. Upon conversion from an EBCDIC string, the buffer is considered terminated by the length count of the containing buffer; then the string is examined for blank padding. The host can send this string blank padded beyond the significant data or not blank padded but with the last significant character of the string in the last position in the containing buffer. The space character is determined by the type of string (single, double, or intermixed).
- **Null terminated.** Upon conversion to an EBCDIC string, the string is sent as is. The TI run-time environment checks the length of the string, and then checks that the exact number of characters is sent. In other words, the number of characters

sent is equal to the length of the string. No null terminator or spaces are appended to the end of the string.

The following tables show how string delimiting works when the **String delimiting** property is set to **Space Padded** versus **Null terminated** in combination with the variable size setting. All examples assume the mainframe data declaration as PIC X(5). "b" represents a space,"?" represents unassigned data, and "\0" represents a null.

String delimiting set to Space Padded and variable size not active

Workstation	Direction	Mainframe
ABC\0	To Host	'ABCbb'
ABCb	To Host	'ABCbb'
CBA	From Host	'CBAbb'
CBA\0?	From Host	'CBA\0?'
CBA\0	From Host	'CBA\0b'

String delimiting set to Space Padded and variable size active

Workstation	Direction	Mainframe
ABC\0	To Host	'ABC'
Abb	To Host	'Abb'
CBA	From Host	'CBAbb'
CBA\0?	From Host	'CBA\0?'
CBA\0	From Host	'CBA\0b'

String delimiting set to Null terminated and variable size not active

Workstation	Direction	Mainframe
ABC\0	To Host	'ABC\0?'
ABC	From Host	'ABC\0?'
ABCbb	From Host	'ABCbb'
ABC	From Host	ABC\0\0'

String delimiting set to Null terminated and variable size active

Workstation	Direction	Mainframe
ABC\0	To Host	'ABC\0'
ABC	From Host	'ABC\0?'
ABCbb	From Host	'ABCbb'
ABC	From Host	ABC\0\0'

Truncating Undefined Portions of Strings

You can define the properties for a string such that the Transaction Integrator (TI) run-time environment truncates undefined characters when it converts UNICODE strings to mainframe data representations instead of generating an error message. To do so, click **Truncate** under **Error handling** on the string's **Host Definition** tab (property page) in TI Project.

When truncation is turned on, the TI run-time environment limits the number of characters to the string's previously specified dimension value when it converts a character string to an Extended Binary Coded Decimal Interchange Code (EBCDIC) or double-byte character set (DBCS) character string.

When it converts to intermixed strings, the TI run-time environment ensures that all shift-out (SO) characters have matching shift-in (SI) characters. It adds a terminating SI character when truncation occurs in the middle of a contiguous stream of DBCS characters. Also, the TI run-time environment ensures that it does not leave a partial DBCS character when it adds the SI character.

If blank padding and truncation are specified for a string, the TI run-time environment might need to add an EBCDIC space character after a terminating SI character is added.

Converting Data Types from Automation to OS/390 COBOL

Converting Data Types from OS/390 COBOL to Automation

Adding Leading SO and Trailing SI Characters

For PIC G formatted strings, you can instruct the Transaction Integrator (TI) run-time environment to add a leading shift-out (SO) character and a trailing shift-in (SI) character by selecting the **Add Leading SO and Trailing SI** check box on the string's **COBOL Definition** tab (property page) in TI Project.

If the **Add Leading SO and Trailing SI** check box is selected, the TI run-time environment handles two additional bytes in the mainframe data structure used for describing the double-byte character set (DBCS) string. When it formats a message sent to the mainframe, the TI run-time environment adds the leading SO and trailing SI bytes. When it interprets a message received from the mainframe, the TI run-time environment discards the leading SO and the trailing SI bytes.

The dimension value of the PIC G string always specifies the number of double-byte DBCS characters in the strings, regardless of the presence or absence of the surrounding SO and SI characters.

The use of this automatic SO and SI handling is hidden from the client application. However, the mainframe application must ensure that the appropriate PIC X declarations surround the declaration of the PIC G string.

TI Project generates the appropriate declarations for the surrounding SO and SI bytes, as shown in the following sample code:

```
01     A-SOSI-WRAPPED-DBCS.
       05  LEADING-SO-1                         PIC X.
       05  MY-DBCS-STRING                       PIC G(80).
       05  LEADING-SI-1                         PIC X.
```

The COBOL Import Wizard in TI Project does not set the option to add leading SO and trailing SI bytes. In other words, the COBOL Import Wizard places no significance on the presence of PIC X declarations surrounding a PIC G string. If an existing mainframe transaction program (TP) uses COBOL declarations that contain explicit declarations for SO and SI characters that wrap PIC G strings, you must manually modify the interface created by the COBOL Import Wizard.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Maximum Buffer Sizes for Remote Environments

Both Transaction Integrator (TI) and mainframe applications must be designed not to exceed the following buffer size or transfer limitations:

TCP Transaction Request Message (TRM) Link

The maximum buffer size for input/output is 32767 bytes. This limit is defined by the maximum allowable size of the COMMAREA.

TCP Enhanced Listener Message (ELM) Link

The maximum buffer size for input/output is 32767 bytes. This limit is defined by the maximum allowable size of the COMMAREA.

TCP Transaction Request Message (TRM) User Data

The buffer size for input/output is unlimited.

TCP Enhanced Listener Message (ELM) User Data

The buffer size for input/output is unlimited.

IMS Connect (TCP/IP)

The maximum segment size that TI can send to IMS is 32754 bytes. This limit is defined by the total number of bytes (32767) in an IMS message segment minus the following number of bytes:

- 2 bytes for the LL (Length field).
- 2 bytes for the ZZ (Control Information field).
- 9 bytes for the maximum TRANCODE.

The total amount of data that can be sent to, or received from, an IMS server program using the TCP/IP IMS Connect programming model is unlimited.

IMS Implicit (TCP/IP)

The buffer size for input is from 1 through 32755 bytes. In other words, the IMS Assist Module rejects a request with zero bytes of user data, and the IMS Listener rejects a request with more than 32755 bytes of user data.

The buffer size for output is from 0 through 32755 bytes. The IBM IMS default Listener enforces the limit of 32755 bytes of input/output data. The IBM IMS Assist Module enforces the required minimum of 1 byte of input.

IMS Explicit (TCP/IP)

The buffer size for input/output is unlimited.

OS/400 Distributed Program Calls (DPC)

The total buffer size is 65535 bytes and is reduced by the required headers. The send requires 23 bytes of header.

Each parameter, of either direction, requires 12 bytes of overhead on the send.
Each in\out or out parameter requires 12 bytes of overhead within memory on the return trip.

CICS LINK LU 6.2

The maximum buffer size for input/output is 32767 bytes. This limit is defined by the maximum allowable size of the COMMAREA.

CICS User Data LU 6.2

The buffer size for input/output is unlimited. However, if the size of the input buffer is greater than 32 KB, TI sends the data in multiple chunks of 32 KB. In such a case, the mainframe application must do multiple receives to gather all the input data.

IMS Using LU 6.2

The maximum segment size that TI will send to IMS is 32754 bytes. This limit is defined by the total number of bytes (32767) in an IMS message segment minus the following number of bytes:

- 2 bytes for the LL (Length field).
- 2 bytes for the ZZ (Control Information field).

- 9 bytes for the maximum TRANCODE.

The total amount of data that can be sent to, or received from, an IMS server program that uses LU 6.2 is unlimited.

Alignment Problems with Generated COBOL

COBOL aligns data elements at the 01 level on double-word boundaries. This practice causes a potential problem in CICS non-DPL applications that use TI-generated data declarations along with error metadata. If you code your COBOL application to receive the error metadata and the input parameters in one RECEIVE, the parameters are placed immediately adjacent to the metadata in memory. However, because the error metadata does not end on a double-word boundary, this action puts the parameters 4 bytes ahead of where the COBOL code expects them.

You can prevent this problem. When you click either the **Include method name** or the **Include all information** option under **Meta data** on the **Advanced** tab of a method's property page, verify that the mainframe program issues two RECEIVE commands to handle incoming data for the method. The first RECEIVE pulls in the metadata block, and the second RECEIVE pulls in the data for the method. When COBOL is generated for the method, an additional 01 block is generated for the metadata. When the **Include all information** option is selected, you are also expected to create an additional SEND for the metadata before sending the method data back to the Automation client application.

Host and Automation Data

Filler

This section provides recommendations for handling COBOL-based filler data.

This section contains:

- COBOL FILLER
- TI Application Cannot Reference FILLER
- Using REDEFINES in COBOL
- FILLER Optimization
- FILLER for Discontiguous Output Area and Return Value

COBOL FILLER

If COBOL data declarations imported into Transaction Integrator (TI) Project contain a COBOL FILLER clause or clauses, space is allocated in the message so that the filler is represented correctly for the mainframe program's data alignment. The filler is hidden from the Automation interface.

See Also

TI Application Cannot Reference FILLER

Using REDEFINES in COBOL

FILLER Optimization

FILLER for Discontiguous Output Area and Return Value

TI Application Cannot Reference FILLER

There are at least three possible causes for why the application cannot reference FILLER data:

- Mainframe or COBOL specifics.
- Automation specifics.
- Procedure using TI Project.

The following provides details of these three causes.

Mainframe or COBOL Specifics

When a FILLER keyword is encountered in the import process, the Transaction Integrator (TI) run-time environment adjusts the offset for the position of the data that follows the filler in a send or receive buffer by the length of the filler. This leaves untranslated gaps in the buffers that are sent to (or received from) the host and allows your data to overlay correctly onto the data declaration that describes it.

Automation Specifics

The Automation method does not reference the filler data description entries.

Procedure Using TI Project

The filler that is at the start of a data declaration is associated with a method, recordset, datatable, user-defined type (UDT), or .NET structure. You can view or change filler that is associated with a method from the **Advanced** tab of the method's properties page. To view or change a filler that is associated with a method, recordset, or UDT, right-click the method, recordset, or UDT, and then click **Properties**.

Filler that follows a data description entry is associated with the data description entry (or parameter for methods, column for recordsets, or member for UDTs). You can view or change filler that is associated with a parameter, column, or member from the **COBOL Definitions** tab of the parameter, column, or member properties. When filler follows the data description entry that you have specified as the return value, you can view or change that filler from the **COBOL Definitions** tab of the method's properties.

The following example shows a COBOL data declaration that uses FILLER:

```
01 CUSTOMER-DATA.
   05 CUSTOMER-INFO.
      10 LAST-NAME               PIC X(20).
      10 FIRST-NAME              PIC X(20).
      10 FILLER                  PIC X(12).
   05 DEMOGRAPHICS.
      10 DEMO-AGE                PIC 999.
      10 DEMO-INCOME             PIC S9(9)V99 COMP-3.
      10 DEMO-SEX                PIC X.
      10 DEMO-MSTATUS            PIC X.
      10 FILLER                  PIC X(40).
```

The resulting method is:

```
CustomerDemographics(strLastName As String, strFirstName As String, iAge As Integer _
    , curIncome As Currency, strSex As String, strMStatus As String)
```

The following is an example of the Visual Basic code that calls the method:

```
Dim objCustomer As Object
    Dim strLastName As String
    Dim strFirstName As String
    Dim iAge As Integer
    Dim curIncome As Currency
    Dim strSex As String
    Dim strMStatus As String
```

```
      strLastName = "Doe"
      strFirstName = "John"

      'create an instance of the invoicing object
      On Error GoTo ErrorHandler1
      Set objCustomer = CreateObject("Customer.Invoicing.1")

      'invoke the SetInvoices method
      On Error GoTo ErrorHandler2
      objCustomer.CustomerDemographics strLastName, strFirstName _
          , iAge, curIncome, strSex, strMStatus
```

Filler

Using REDEFINES in COBOL

The COBOL import process in Transaction Integrator (TI) Project recognizes the REDEFINES clause in a data description entry and correctly associates the redefining entries with the redefined entry. You must select one of the redefined or redefining clauses as the entry that represents the data that will be transmitted.

The redefining entries can use less space than the redefined entry. If you select a redefining entry that is smaller than the redefined entry, TI Project automatically adds filler so that the data will correctly overlay the data description when it is sent to the host. If the redefining entry represents a table with multiple fields, the last field contains the filler.

The following COBOL example shows a REDEFINES clause. The redefining clause was selected during import:

```
01 CUSTOMER-DATA.
   05 CUSTOMER-ID                          PIC X(10).
   05 CUSTOMER-ID-PARTS REDEFINES CUSTOMER-ID.
      10 LOCATION                          PIC X(3).
      10 NAME-ABREV                        PIC X(5).
```

The resulting method that is imported is:

```
CreateCustomerID(strLocation As String, strNameAbrev As String)
```

The COBOL generated for this method is:

```
01 CREATECUSTOMERID-INPUT-AREA.
   05 LOCATION              PIC X(3).              INPUT
   05 NAME-ABREV            PIC X(5).              INPUT
   05 FILLER                PIC X(2).              INPUT
```

The FILLER is added to the CUSTOMER-ID redefined area. When this FILLER occurs at the end of send or receive buffers, for performance reasons it is not sent.

The following is an example of Visual Basic code that calls this method:

```
    Dim objCustomer As Object
    Dim strLocation As String
    Dim strNameAbrev As String

    strLocation = "101"
    strNameAbrev = "SPORT"

    'create an instance of the invoicing object
    On Error GoTo ErrorHandler1
    Set objCustomer = CreateObject("Customer.Invoicing.1")

    'invoke the CreateCustomerID method
    On Error GoTo ErrorHandler2
    objCustomer.CreateCustomerID strLocation, strNameAbrev
```

Filler

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

FILLER Optimization

The Transaction Integrator (TI) run-time environment optimizes buffers sent to the host by not sending the bytes corresponding to FILLER that appear at the end of the input data declaration.

In a CICS LU 6.2 environment, use both the MAXLENGTH and NOTRUNCATE options on the RECEIVE statement when the TI run-time environment receives an input area that contains FILLER as the last data item description. However, this requirement does not apply to CICS LINK and IMS transaction programs.

See Also

Filler

FILLER for Discontiguous Output Area and Return Value

If the return value is discontiguous from the output area, you must calculate and manually specify the filler between the return value and the output area.

The following example shows the calculation for the filler from the original COBOL that goes into the Import Wizard (the byte counts on the right are added as an illustration):

```
01  OUTPUT-AREA.
           05  SELECTED-OUTPUT-AREA.
               10  FIELD1                    PIC S9(4)       COMP.     [2 Bytes]
               10  FIELD2                    PIC S9(9)       COMP.     [4 Bytes]
           05  DISCONTIG-UNSELECTED-AREA.
               10  NOTSELECTED               PIC X(10).                 [10 Bytes]
               10  ALSO-NOTSELECTED          PIC S9(9)       COMP.     [4 Bytes]
           05  RETVAL                        PIC S9(9)       COMP.     [4 Bytes]
```

In this case, because the return value follows the output area, filler must be added to the last output parameter. To do this, perform the following steps.

1. Unlock the method.
2. In the details pane, click **FIELD2**.
3. On the **File** menu, click **Properties**, and then click the **COBOL Definition** tab.
4. In the **From Host** box, type 14 as the trailing filler.
5. Click **OK**.

To verify your modified code, in **TI Project**, use the **Export** command on the **File** menu. You can then see your code in Notepad.

The following is the output with the added filler:

```
       01  DISCONTIGCBL-OUTPUT-AREA.
           05  LL                            PIC S9(4) COMP.         OUTPUT     [2 Bytes]
           05  ZZ                            PIC S9(4) COMP.         OUTPUT     [2 Bytes]
           05  FIELD1                        PIC S9(4) COMP.         OUTPUT     [2 Bytes]
           05  FIELD2                        PIC S9(9) COMP.         OUTPUT     [4 Bytes]
           05  FILLER                        PIC X(14).              ADDED     [14 Bytes]
           05  RETVAL                        PIC S9(9) COMP.         OUTPUT     [4 Bytes]
```

Variable-length Tables and CICS LINK

When an OCCURS clause describes a variable-length table in the CICS LINK environment, the storage that the table uses on the host varies depending on the value of the length specifier. COBOL handles this storage automatically on the host, but for Transaction Integrator (TI) to determine where in the buffer to place data sent to the host and where to unpack data from the host, you must give it the value of the length specifier variable on which the table size depends.

Any data that follows a variable-length table must be correctly offset in the buffer immediately following the table, regardless of the maximum length of the table. TI must have the length specifier value for a variable-length table both when it packs the buffer to be sent and when it unpacks the buffer that is received.

If an OCCURS clause describes a variable-length table, you must specify the table and the length specifier that controls the table length as input/output in TI Project. The TI run-time environment must be able to detect the length both when the buffer is sent to the host and when it is received from the host. When you import COBOL or manually create a method that describes a variable-length table in TI Project, this restriction is enforced.

> **Note** Information in this topic also applies to arrays.

Arrays

Using the OCCURS DEPENDING Clause to Define Variable-length Table

Sending Binary Data to the Host

The Transaction Integrator (TI) run-time environment does not translate binary data (Byte in Visual Basic, VT_UI1 in Automation, or unsigned char in C++) when it sends it to the mainframe. Instead, TI copies the binary data unchanged into a PIC X data representation on the mainframe. To define a string of binary data, define it as an array.

Programming Windows-Initiated Processing

This section discusses various issues you need to understand to program Windows-initiated processing components and applications.

This section contains:

- Determine Who Initiated a Transaction
- Use REOverride to Specify RE Programmatically
- Debugging Tips for Visual Basic .NET
- Impersonating Client Application Security Credentials
- Using COMTIIntrinsic in Windows XP Professional

Determine Who Initiated a Transaction

It is helpful to be able to determine who initiated a specific transaction, for example, when you need to track down the history of a transaction failure. You can also use this technique to implement resource or transaction-level, per user, security.

When you select either user-level or package-level security on the **Security** tab of the Transaction Integrator (TI) remote environment (RE) properties page, TI sends security information in the session request to the host. If you deploy the Host Account Mapping database known as the Host Account Cache (HAC) and set up a mapping between each Microsoft® Windows® user and the corresponding host user ID, TI will send that information. Or you can use the **Allow application to override security** option on the **Security** tab, and have the application return any host user ID (and password).

Whether the host does anything with the different user IDs depends mostly on the ATTACHSEC setting for the CICS connection; this corresponds to the APPC LU that TI uses. The default ATTACHSEC setting is **local**, meaning that CICS does not validate the user ID in the session, and CICS runs the transaction in a default host credential. But if you set the ATTACHSEC setting, CICS uses Resource Access Control Facility (RACF) to validate the user ID in the session, and CICS then attaches that user ID to the trusted computing base (TCB) for the transaction as it runs through the mirror transaction into the target mainframe transaction program (TP).

Use REOverride to Specify RE Programmatically

When an application uses a Transaction Integrator (TI) component, the application can be structured to explicitly specify the remote environment (RE) used by the TI run-time environment. When the application specifies the RE, the application identifies the CICS or IMS region where transaction programs (TPs) are executed when they handle method calls to the component.

To programmatically specify an RE, an application uses the **REOverride Context** entry. TI Project automatically adds an optional parameter to a TI object for passing TI context data. The application sets the **REOverride** entry for an object representing a TI component by assigning the name of the RE.

The following Microsoft® Visual Basic® code demonstrates the **REOverride Context** entry:

```
Dim Obj As Object
Dim ConObj AS Object
Dim ContextArray() As Variant

Set ConObj = CreateObject("COMTI.ContextObject")
Set Obj = CreateObject("Your.Object")

ConObj.WriteContext "REOverride", "AltREName", ContextArray

Obj.Method1 parm1, parm2, parm3, ContextArray
Obj.Method2 parm1, parm2, ContextArray
Obj.Method3 parm1, parm2, parm3, parm4, parm5
Obj.Method4 parm1, parm2, parm3, parm4, ContextArray
```

This example (with no error checking) shows how to use **REOverride** to programmatically instruct the TI run-time environment to use a non-default RE named AltREName to handle the calls to Method1, Method2, and Method4. The calls to the three methods are directed to **AltREName** because the client program has set the context name **REOverride** to have the value of **AltREName** and include the optional context parameter **ContextArray**. The call to Method3 is directed to the RE assigned as default to the object because it does not include the optional **ContextArray** context parameter.

This section contains:

- Guidelines for Using REOverride

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Guidelines for Using REOverride

Remote environment (RE) override enables applications to choose which host server environment services Transaction Integrator (TI) requests. The specific algorithm an application uses to select an RE is up to you. For example, an enterprise can use separate CICS or IMS regions to handle requests from different branches. In this case, the application should set the RE to the appropriate value that identifies the region suitable for the current branch.

Use the following guidelines for when to use **REOverride** to set an RE programmatically:

- Avoid hard-coding RE names into applications. Instead, load RE names from a file or database.
- Ensure that applications are structured to handle failures when they attempt to set the RE.
- Structure your application code to use a list of RE names. This practice reduces errors caused by missing REs.
- Ensure that procedures for adding and configuring REs include a mechanism to update REs referenced in the application code.

  Note Use **REOverride** to confirm that administrative and operational tasks do not interfere with application code that sets an RE. Specifically, review when and how REs are deactivated and deleted.

To implement RE selection by using **REOverride**, you must ensure that the TI component starts out with an associated RE instance even though the application will set the RE programmatically. The RE that is currently assigned to the component is used when an application does not explicitly set the RE.

Use REOverride to Specify RE Programmatically

Debugging Tips for Visual Basic .NET

The following are a few other tips that will save some of you from frustrating debugging sessions:

1. When a Transaction Integrator (TI) .NET application is configured to display error numbers (err.number), the number returned is always 0 and not the TI error results. Although TI returns the correct values to COM-Interop and COM-Interop passes the right values to Visual Basic .NET, Visual Basic .NET considers any positive return code to be success and changes it to 0. To work around this problem, configure the .NET application to return an error description (err.description) instead of the error number. The error description provides accurate and useful error information.
2. TI Project parameter type Integer must be defined as a short within Visual Basic .NET.
3. TI Project parameter type Long must be defined as an integer within Visual Basic .NET.
4. A Visual Basic .NET array index begins at 0, the index of TI parameters defined as arrays starts at position 1. Therefore, it is no longer possible to directly align one for one the index of TI parameters defined as arrays with those defined within Visual Basic .NET.
5. Arrays of Decimal data types must be defined as an array of objects, not an array of decimals within Visual Basic .NET. All other arrays of data types can be defined as either an object or data type.
6. A common cause of errors during development of host-initiated processing (HIP) .NET components is forgetting to copy all the required assemblies, including all the dependencies, to the HIP Implementing Assemblies folder.

Impersonating Client Application Security Credentials

If you are using Windows-initiated processing (WIP) and are configuring a remote environment (RE) to use Enterprise Single Sign-On (SSO), you have a choice between using the security credentials of the client application or of the COM server program. You make this choice in Transaction Integrator (TI) Manager on the **Security** tab of the ***remote environment*** **Properties** dialog box. If you select **User credentials**, the COM server impersonates the client's security credentials to access SSO and retrieve the host account information. If you select **COM application or ASP.NET credentials**, the COM server uses its own credentials.

Before the COM server can impersonate the client, however, you must program the client to grant the COM server explicit permission to do the impersonating. You can grant the explicit permission in either of two ways:

- Program the client application to call **CoInitializeSecurity(...)** at the beginning of its lifetime, and then request the **Impersonate access level**:

```
HRESULT hr = CoInitializeSecurity(NULL, -1, NULL, NULL,
             RPC_C_AUTHN_LEVEL_CONNECT, RPC_C_IMP_LEVEL_IMPERSONATE
             NULL, NULL, NULL);
```

- Set the default COM security level on your computer to **Impersonate**.
    1. Click **Start**, point to **Programs**, point to **Microsoft Host Integration Server 2004**, and then click **TI Manager**.
    2. In the TI Manager navigation tree, expand **Component Services**, and then expand **Computers**.
    3. Right-click **My Computer**, and then click **Properties**.
    4. On the **Default Properties** tab, set the **Default Impersonation Level** to **Impersonate**.
    5. Restart your computer so the settings take effect.

The first course of action, adding the **CoInitializeSecurity(...)** call to your application, is the more secure of the two alternatives because it limits the explicit permission to just that client application. The second course of action, changing the default COM security level on your computer, should be chosen only if you are not able to rebuild your client application.

Using COMTIIntrinsic in Windows XP Professional

If you use Explicit Security in your application, you need to be sure that the property **COMTIIntrinsic** is set to **–1**. The property **COMTIIntrinsic** is set to **Off** by default for COM+ in Windows XP Professional. You can use the following Visual Basic script to display and set the **COMTIIntrinsic** value:

```
'Get arguments  ' Set objArgs = WScript.Arguments
 '  if objArgs.Count <> 3 then
 '      WScript.Echo "ComtiSec"
 '      WScript.Echo ""
 '      WScript.Echo "Usage:"
 '      WScript.Echo "ComtiSec [appname], [progid], [value]"
 '      WScript.Echo "[appname]: Name of the application"
 '      WScript.Echo "[progid]:  ProgID of the component to change. Type 'all' for all compon
ents."
 '      WScript.Echo "[value]:   0 for False, 1 for True"
 '      WScript.Quit (0)
 '  end if
   applicationName = "COMTI Utilities"
   componentProgID = "all"
   'ComtiIntrinsics must be set to -1 for comti callback secuity to work.
   ' ComtiIntrinsics = -1 ' This will make Explicit Security work in COM+ on Win XP Pro
   ' ComtiIntrinsics = 0 ' This is the deffault value for COM+ in Win XP Pro
   Set catalog = CreateObject("COMAdmin.COMAdminCatalog.1")
   Set applications = catalog.GetCollection("Applications")
   applications.Populate
   numApplications = applications.Count
   For i = numApplications - 1 To 0 Step -1
       If applications.Item(i).Value("Name") = applicationName Then
           Set application = applications.Item(i)
           Exit For
       End If
   Next
   Set components = applications.GetCollection("Components", application.Value("ID"))
   components.Populate
   numComponents = components.Count
   For i = numComponents - 1 To 0 Step -1
       If components.Item(i).Name = componentProgID Or componentProgID = "all" Then
           Set component = components.Item(i)
           'component.Value("COMTIIntrinsics") = ComtiIntrinsics
      WScript.Echo component.Value("COMTIIntrinsics")
       End If
   Next
   components.SaveChanges
   applications.SaveChanges
   WScript.Echo "Changes All Complete"
```

Note You must clear the **Protection** and **Disable Changes** properties for the COM+ COMTI Utility application before you run the preceding script.

Programming Host-Initiated Processing

This section discusses various issues you need to understand to program host-initiated processing components and applications.

This section contains:

- Connecting HIP Components to Visual Basic Applications

Connecting HIP Components to Visual Basic Applications

A key link in host-initiated processing (HIP) is the connection between the HIP component in Transaction Integrator (TI) and the client application. The connection between the HIP component and the Microsoft® Visual Basic® server DLL is created through matching elements of the HIP type library with elements of the Visual Basic project. The following table shows the relationship between the elements.

HIP Type Library	**Visual Basic Project**
Type Library name	Visual Basic Project name.
Type Library Interface name	Visual Basic Class name.
Type Library Method names	Functions or subroutines within the Visual Basic Class.
Type Library method parameters	Defined one for one within the Visual Basic functions or subroutines with the Visual Basic subroutines and functions.

> **Note** Be sure the Visual Basic server DLL is registered.

If you are using the **Implements** key word within a Visual Basic server, the following additional rules apply:

- The **Visual Basic Implement Compatible Interface** property must be enabled. Set the property on the component *interface* **Properties** page within the TI type library or assembly
- All parameters defined to type library methods must be **Input\Output**. The **Implements** keyword does not support parameters defined as either input or output. All parameters must be defined as input or output.
- The function or subroutine calls must be defined as public, not private, within the Visual Basic class.

Transaction Integrator Security Guide

This section provides information about steps you can take to safeguard Transaction Integrator, your data, and your network when you are programming client or server applications.

This section contains:

- Mainframe Authentication for CICS LINK
- AS/400 Security
- Limitations of User Access Level Sign On
- Using SSO with Host-Initiated Processing
- Using SSO with Encrypted Passwords
- Threat Mitigation within Visual Studio

Mainframe Authentication for CICS LINK

Resource-level authentication is recommended in the CICS region. Due to a restriction imposed by the IBM distributed program link (DPL) protocol, a user ID and password transmitted from the workstation by Transaction Integrator (TI) are ignored and not used for transaction-level authentication. The target CICS region expects, under such circumstances, that authentication has been completed by the application that executes the IBM DPL; for example, a TI application on the PC. (Traditionally, the application that executes an IBM DPL has been another CICS region.)

Instead, for transaction-level authentication, the target CICS region associates the default user ID for the region with the transaction ID of the CICS (Mirror transaction) task and the user ID from the sender is ignored. Unless this practice is taken into consideration, attempts to secure the Mirror transaction can cause an application malfunction because of the failure to authenticate.

Transaction Integrator Security Guide

Using SSO with Host-Initiated Processing

When you use Single Sign-On (SSO) security with host-initiated processing (HIP), the impersonation of user credentials is handled differently depending upon whether you are calling a .NET object or a COM object. If HIP is calling a .NET object, there are no special considerations; the Transaction Integrator (TI) run-time environment impersonates the user account. If HIP is calling a COM object, however, there are special considerations.

Depending on the threading model and registration type of the components, the following actions occur when HIP calls the method of a .COM object when it is impersonating a user account (the one that the host credentials would have been mapped to via SSO):

Threading Model	**Registration**	**Actions**
Single, apartment	Server/Library/No COM+ application	• Server object methods are called under HIP Service/COM+ application configured identity. • Server object methods call **CoImpersonateClient** to start impersonating the user identity. • Optionally, methods can call **CoRevertToSelf**, although that is not necessary because COM will call it anyway after the method returns.
Free, both, neutral	Server COM+ application	• Server object methods are called under HIP Service/COM+ application configured identity. • Server object methods call **CoImpersonateClient** to start impersonating the user identity. • Optionally, methods can call **CoRevertToSelf**, although that is not necessary because COM will call it anyway after the method returns.
Free, both, neutral	Library/No COM+ application	• Server object methods are called under the user identity being impersonated. • Server object method should not call **CoImpersonateClient** or **CoRevertToSelf** because they would fail with RPC_E_CALL_COMPLETE.

If you are programming in Microsoft Visual Basic® 6.0, be sure to include the **CoImpersonateClient** and **CoRevertToSelf** declarations in your programs:

```
Private Declare Function CoImpersonateClient Lib "ole32.dll" () As Long
Private Declare Function CoRevertToSelf Lib "ole32.dll" () As Long
```

Using SSO with Encrypted Passwords

If you are using Single Sign-On (SSO) security, you must determine whether the client application passes plain text passwords or encrypted passwords to the Transaction Integrator (TI) run-time environment. If the passwords are in plain text, SSO accepts the passwords when they are submitted by the TI run-time environment. If the passwords are encrypted, SSO does not accept the passwords, and the call to SSO fails. To avoid failed SSO calls, disable password validation for the SSO affiliate application.

About Programming Single Sign-On

Threat Mitigation within Visual Studio

Product security is a top priority throughout Microsoft development. Beginning with the Microsoft® Windows® Security Push in 2002, Microsoft has invested additional time and resources to developing secure code and detailed instructions for deploying and securing your computing environment. This increased attention to security issues has made Host Integration Server 2004 (HIS 2004) the most secure version in the history of the product.

The HIS 2004 product team conducted a complete threat modeling analysis to identify and mitigate potential areas of concern. A threat model is a security-based analysis that helps you determine the highest-level security risks posed to a product or application and how attacks can manifest themselves.

Although Microsoft has mitigated all known internal security threats to HIS 2004, you should take steps to mitigate threats from elsewhere in your network environment. Threat modeling helps you evaluate the threats to the applications you are writing or running, and thereby reduce the overall risk to your computer system. For more information about threat model analysis, see Chapter 4 “Threat Modeling” in Michael Howard and David LeBlanc, *Writing Secure Code 2nd Edition*, Redmond, WA: Microsoft Press. 2003.

Howard and LeBlanc summarize six categories of possible security threats to your computing environment:

- **Spoofing identity**. Spoofing threats enable an attacker to pose as another user or enable a rogue server to pose as a valid server. An example of user identity spoofing is illegally gaining access and then using another user’s authentication information, such as username and password.
- **Tampering with data**. Data tampering involves malicious modification of data. Examples include unauthorized changes made to persistent data, such as that held in a database, and the alteration of data as it flows between two computers over an open network, such as the Internet.
- **Repudiation**. Repudiation threats are associated with a user who denies that he performed an action without other parties having any way to prove otherwise—for example, a user performs an illegal operation in a system that lacks the ability to trace the prohibited operations.
- **Information disclosure**. Information disclosure threats involve the exposure of information to individuals who are not supposed to have access to it—for example, a user’s ability to read a file that she was not granted access to and an intruder’s ability to read data in transit between two computers.
- **Denial of service**. Denial of service (DoS) attacks deny service to valid users—for example, by making a Web server temporarily unavailable or unusable. You protect against certain types of DoS threats simply to improve system availability and reliability.
- **Elevation of privileges**. In this type of threat, an unprivileged user gains privileged access and thereby has sufficient access to compromise or destroy the entire system. Elevation of privilege threats include situations in which an attacker has effectively penetrated all system defenses and become part of the trusted system itself, a dangerous situation indeed.

Howard and LeBlanc also point out that some threat types can interrelate. For example, it is possible for information disclosure threats to lead to spoofing threats if the user’s credentials are not secured. Similarly, elevation of privilege threats is by far the worst because if someone can become an administrator or root on the target computer, every other threat category becomes a reality. Conversely, spoofing threats might lead to a situation where escalation is no longer needed for an attacker to achieve his goal.

To mitigate threats that originate outside Transaction Integrator (TI) but which can negatively affect TI components and your application, Microsoft recommends that you:

- Protect the TI COM Type Library or .NET Assembly from Unauthorized Access
- Protect the Output from Tracing and Network Monitoring Activities
- Protect the TI Record or Playback Files from Unauthorized Access

Protect the TI COM Type Library or .NET Assembly from Unauthorized Access

To prevent an attacker from viewing or modifying the contents of a Transaction Integrator (TI) COM type library or .NET assembly and then using that information to either create a client application which spoofs the identity of an authorized user or modify the custom properties of the component, you should:

- Place the computer running Visual Studio and TI Designer in a secure location.
- Confirm that the access permissions to Visual Studio, TI Designer, or any other tool used to modify TI type libraries and .NET assemblies are set correctly.
- Store all TI component type libraries and .NET assemblies in a secure directory.
- Confirm that the access permissions are set correctly on all type libraries and .NET assemblies.
- Confirm that the access permissions are set correctly on the directory that contains the type libraries and .NET assemblies.

Protect the Output from Tracing and Network Monitoring Activities

Protect the TI Record or Playback Files from Unauthorized Access

Threat Mitigation within Visual Studio

Protect the Output from Tracing and Network Monitoring Activities

To prevent an attacker from viewing the user credential information that might be stored in trace files or network monitoring files, you should:

- Confirm that only authorized users are allowed to run the SNA TRACE or Microsoft Network Monitoring programs on the computer that is running Transaction Integrator.
- Store all tracing (Tracebits) output files and network monitoring (Netmon) output files in a secure directory.
- Confirm that the access permissions are set correctly on all tracing output files and network monitoring output files.
- Confirm that the access permissions are set correctly on the directory that contains the output files.
- Delete all tracing output files and network monitoring output files as soon as you are done with them.

Protect the TI COM Type Library or .NET Assembly from Unauthorized Access

Protect the TI Record or Playback Files from Unauthorized Access

Threat Mitigation within Visual Studio

Protect the TI Record or Playback Files from Unauthorized Access

To prevent an attacker from either viewing the contents of the Transaction Integrator (TI) record or playback files or replacing those files with ones that could record user data sent to or from the host, you should:

- Store all TI record and playback files in a secure directory.
- Confirm that the access permissions on all record or playback files are set correctly. A user must have administrator rights to be able to record and save a file.
- Confirm that the access permissions are set correctly on the directory that contains the record or playback files are stored.
- Store the record file in a form other than plain text.

Data Integration Programmer's Guide

This section provides information required to develop applications to access data in an environment using Microsoft® Host Integration Server 2004. This section provides documentation for developers about data access, data replication, and data tools.

For API reference and other technical information about data integration, see the Data Integration Programmer's Reference section of the SDK.

For sample code that illustrates data integration, see the Data Integration Samples section of the SDK.

This section contains:

- Introduction to Data Integration
- Data Access Library Programmer's Guide
- Managed Provider Programmer's Guide
- OLE DB Providers Programmer's Guides
- ODBC Driver for DB2 Programmer's Guide
- ActiveX Controls Programmer's Guides
- Using Data Design Tools
- Data Integration Security Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Introduction to Data Integration

This section provides information required to develop applications to access data in an environment using Microsoft® Host Integration Server 2004.

You can develop applications for data integration used in a Host Integration Server 2004 environment using several different development tools and application programming interfaces including the following:

- C or C++ applications that use OLE DB to access AS/400 and VSAM files.
- C or C++ applications that use OLE DB to access IBM Data Base 2 (DB2).
- C, C++, or Microsoft® Visual Basic® applications that use Open Database Connectivity (ODBC) drivers to access IBM DB2.
- Visual Basic applications that use ActiveX® Data Objects (ADO) to access AS/400 and VSAM files.
- Visual Basic applications that use ADO to access IBM DB2 using OLE DB.
- Visual Basic applications that use ADO to access IBM DB2 using ODBC.
- C, C++, or Visual Basic applications that use the Host File Transfer ActiveX control to transfer files to and from MVS, OS/390, AS/400, and AS/36.
- C, C++, or Visual Basic applications that use the Data Queue ActiveX control to access AS/400 data queues.
- Microsoft C++ .NET, Microsoft C#, Microsoft Visual Basic .NET applications that use the Managed Provider for DB2 to access IBM Data Base 2 (DB2).

To use this section effectively, you should be familiar with:

- Microsoft Host Integration Server 2004
- One of the following operating environments:
    - Microsoft Windows Server™ 2003
    - Microsoft Windows XP
    - Microsoft Windows® 2000 Server
- SNA concepts

Depending on the application programming interface and development tools used, you should be familiar with:

- Microsoft COM objects
- Microsoft OLE DB
- Microsoft ADO
- Microsoft ODBC
- Microsoft .NET

This section contains:

- Additional Resources for Data Integration

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Additional Resources for Data Integration

This section does not describe the products, architectures, or standards developed by other companies or organizations.

For information about SNA architecture, see your system network documentation.

The following documents provide additional information about the OLE DB application programming interfaces (APIs):

- Microsoft® Data Access Components (MDAC) Software Development Kit 2.8

The following documents provide additional information about Microsoft ActiveX® Data Objects:

- Microsoft Data Access Components (MDAC) Software Development Kit 2.5

The following documents and publications provide additional information about the Open Database Connectivity (ODBC) standard and ODBC programming:

- Microsoft Data Access Components (MDAC) Software Development Kit 2.5
- Microsoft ODBC 3.0 Software Development Kit and Programmer's Reference
- *Inside ODBC*, written by Kyle Geiger and published by Microsoft Press

Data Access Library Programmer's Guide

This section contains information describing how to access the capabilities of the Data Access Tool using the interface exposed by the Data Access Library.

For API references and other technical information about the Data Access Library, see the Data Access Library Programmer's Reference section of the SDK.

This section contains:

- About the Data Access Library
- Programming with the Data Access Library

About the Data Access Library

This section describes the background for the Data Access Library (DAL), how the different interfaces relate to each other, and what technologies you ought to be familiar with in order to program the DAL.

This section contains:

- Goals for the Data Access Library
- About the Data Access Library Interface
- What You Need to Know Before Programming the Data Access Library
- Supported Platforms for the Data Access Library

Goals for the Data Access Library

The original goal of the Data Access Library (DAL) was to expose an interface that would enable developers to automate lengthy tasks normally performed through the Data Access Tool (DAT) user interface. As development progressed, the Data Access Library grew to include the most common functionality of the DAT.

When Microsoft developers originally created the Data Access Tool (DAT), they realized that some tasks were relatively time-consuming. For example, creating a DB2 data package takes several steps through the DAT user interface. The developers determined that the best way to reduce the time to perform such tasks was to expose a programming interface to the DAT. They determined that in exposing the interface necessary to automate a lengthy procedure, they could expose essentially the entire functionality of the Data Access Tool.

Therefore, the purpose of the Data Access Library interface is to provide a programmatic interface for the Data Access Tool and Data Source Wizard. This is done through a straightforward interface that correlates almost entirely to actions that you can take using the appropriate user interface. Although the Data Access Library provides a subset of the capabilities the user interface exposes, you can automate most of the common tasks for which you would normally use the UI.

About the Data Access Library Interface

The Data Access Library is based around four objects that represent the core functionality of the Data Access Tool (DAT) and Data Source Wizard. The following table describes the core objects for the Data Access Library.

Object	Description
DataAccessControl	Provides access to the options listed on the DAT **Action** menu: testing connections and queries, creating packages, and converting data.
DataAccessSettings	Provides access to the functionality of the Data Source Wizard: describing where information is stored, and controlling the Wizard dialog boxes and warnings.
IConnectionString	Base class for describing the different types of connection strings that the DAT uses.
IHCDItem	Base class for describing the objects that make up a host column description (HCD) file.

In addition to the above objects, the Data Access Library interface has an exception object, possible data types, a callback function triggered when creating packages, and a collection of IHCD items. For more information, see the Data Access Library Programmer's Reference.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

What You Need to Know Before Programming the Data Access Library

The Data Access Library (DAL) is a .NET interface for creating universal data link (.udl) files for Microsoft® Host Integration Server. Therefore, you ought to be familiar with the following concepts and technologies:

- Host Integration Server (HIS) 2004

  The purpose of the DAL is to simplify the creation of .udl files, which HIS then uses to access remote servers through a variety of technologies. As such, you ought to be familiar with the general framework that you will be working with when you use the DAL.

- Data Access Tool (DAT) and Data Access Wizard

  The DAT and the Data Access Wizard are the technologies that allow you to create .udl files and ODBC DSNs through a user interface. Therefore, you ought to be familiar with the standard way in which the technology performs a task before you attempt to perform that task programmatically.

- .NET Framework 1.1

  The Data Access Library was written using Microsoft Visual Studio® .NET 2003 and the .NET Frameworks 1.1. Therefore, in order to successfully use the DAL, you ought to be familiar with the technologies that went into constructing it.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Supported Platforms for the Data Access Library

As a programmatic interface to the Data Access Tool (DAT), the Data Access Library (DAL) is supported by all systems that also support the DAT. In particular, the DAT is supported on the following platforms:

- Microsoft Windows Server™ 2003
- Microsoft Windows XP Professional
- Microsoft® Windows 2000 Server
- Microsoft Windows® 2000 Advanced Server
- Microsoft Windows 2000 Datacenter Server
- Microsoft Windows 2000 Professional

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Programming with the Data Access Library

The main programming tasks for the Data Access Library (DAT) can be considered one of three tasks: creating a connection string, retrieving or modifying data in a connection string, or performing an administrative task.

This section contains:

- Creating a Connection String
- Retrieving Data
- Performing Administrative Tasks

Creating a Connection String

The Data Access Tool can create one of two basic types of connection strings: an OLE DB connection string stored in a universal data link (.udl) file, and an ODBC connection string stored in a data source name (DSN).

This section contains:

- Creating a Connection String for a .udl File
- Creating a Connection String for an ODBC System, User or File DSN

Creating a Connection String for a .udl File

A universal data link (.udl) file is essentially a text file containing the connection string for an OLE DB data source. You can create a .udl file with the appropriate DB2OleDbConnectionString or FileSysOleDbConnectionString constructor, and then save the string to secondary storage with a call to Save. The Data Access Library automatically creates the appropriate .udl file to store the string in, and save the file to disk.

To create a .udl file and associated connection string

1. Create an empty connection string with a call to a connection string constructor.

   Calling the constructor creates a connection string with default settings. These default settings can be set only through the Data Access Tool user interface.

   If you use a file path for a file that currently exists, the system loads the connection string information in that file instead.

   You can determine the default path your system uses for storing .udl files with a call to DataAccessSettings.MakeUDLPath. **DataAccessSettings** also stores the default paths for DSN and HCD files.

2. Add in the relevant connection information to the connection string with a call to the various connection string properties, such as DataSourceName, UserName, or Password. You can also retrieve the full connection string as a text string with a call to GetString, and then save the modified string with SetString.
3. Save the string with a call to the relevant **Save** method, such as **DB2OleDbConnectionString.Save**.

   The system saves the connection string in an .udl file. The system creates the .udl file using the file path passed in the **name** parameter of the constructor. If the file does not contain the full path, the system uses the default path as described in **DataAccessSettings.UDLpath**.

The following code sample describes how to create a .udl file using a new file name, user name, and password.

```
static DB2OleDbConnectionString CreateUDLFile(string FileName, string NameOfUser, string Pass
Word, ref System.Exception myException)
{
   try
   {
      DB2OleDbConnectionString myConnection = new DB2OleDbConnectionString(FileName, false);
      myConnection.UserName = NameOfUser;
      myConnection.Password = PassWord;
      myConnection.Save();
      System.Exception MyEx= new System.Exception(@"Successful Creation", null);
      myException = MyEx;
      return myConnection;

   }
   catch (Exception ex)
   {
      myException = ex;
      return null;
   }
}
```

Retrieving Data

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating a Connection String for an ODBC System, User or File DSN

The other type of data you can create using the Data Access Library is a data source name (DSN). Like a universal data link (UDL) file, a DSN contains the connection information necessary to access a remote database. However, where an .udl file is generally used for an OLEDB database connection, most systems use DSN files for ODBC connections. Further, a DSN does not necessarily have to be a file: a DSN can be a file, a registry-based system DSN, or a registry-based user DSN.

To create a DSN file and associated connection string

1. Call the constructor for DB2OdbcFileConnectionString, DB2OdbcSysConnectionString, or DB2OdbcUserConnectionString.

   Calling the constructor creates a connection string with default settings. These default settings can be set only through the Data Access Tool user interface.

   If you use a file path for a file that currently exists, the system loads the connection string information in that file instead.

2. Fill in the relevant connection string properties with a call to the properties of the object created.

   You can also fill in the connection string with GetString, which returns the connection string as a text string. Once you finish modifying the relevant values, you can return the connection string to the object with a call to SetString.

3. Save the connection string information back into storage with a call to Save.

The following code sample describes how to create a DSN file and associated connection string.

```
static DB2OdbcFileConnectionString CreateUDLFile2(string FileName, string NameOfUser, string
PassWord, ref System.Exception myException)
{
   try
   {
      DB2OdbcFileConnectionString myConnection = new DB2OdbcFileConnectionString(FileName, fa
lse);
      myConnection.UserName = NameOfUser;
      myConnection.Password = PassWord;
      myConnection.Save();
      System.Exception MyEx= new System.Exception(@"Successful Creation", null);
      myException = MyEx;
      return myConnection;

   }
   catch (Exception ex)
   {
      myException = ex;
      return null;

   }
}
```

Configuring a Data Source for the ODBC Driver for DB2

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Retrieving Data

Creating connection string information requires that you create an object that is derived from the **IConnectionString** class, such as DB2OdbcConnectionString or DB2OleDbConnectionString. Once you create the string, you can save, modify, or retrieve information from it using the associated properties.

To retrieve and modify connection string information

1. Create new connection string with a call to the specific type of connection string constructor, using the file path of the .udl file containing the specified connection string.

   Alternately, you can call ReadUDL for the specified **ConnectionString** type. Many of the **ConnectionString** classes also have a **Clone** method that you may wish to use. Note that **Clone** does not load the current instance into active memory, but instead makes a copy that you can later modify and save to disk.

   If you are attempting to retrieve data from a connection string that you currently have an instance of, you can call **Load**. For example, if you recently created a new connection string and called **Save**, you can retrieve the object from storage and into active memory by calling **Load** on the object again.

   If you use a path that describes a file that does not exist, the system creates an .udl new file using the path described.

2. Retrieve the connection data from your current instance using GetString or by accessing the relevant property.

   Using **GetString** enables you to manipulate the connection string as though it were a standard text string. In contrast, accessing the value as a property is usually simpler and safer.

3. When you are finished viewing or manipulating the relevant value, return the value to the object with a call to **SetString** or by setting the appropriate property.
4. Once you are done, save your changes to secondary storage by calling Save.

The following code sample describes how to retrieve, change, and save connection string data.

```
static System.Exception ChangeCommentInUDL(string connString, string newComment)
{
   try
   {
      IConnectionString udl = DB2OleDbConnectionString.ReadUDL(connString);
      udl.Comment = newComment;
      udl.Save();
      System.Exception noException = null;
      return noException;

   }
   catch (System.Exception ex)
   {
      return ex;
   }
}
```

Creating a Connection String

Creating a Connection String for an ODBC System, User or File DSN

Performing Administrative Tasks

The administrative tasks for the Data Access Library refers to the tasks you can perform using the **DataAccessControl** interface. In general, these tasks are those that require you go beyond creating universal data link (UDL) or host column description (HCD) files, and start interacting with the actual data sources.

This section contains:

- Converting Data Source Information
- Creating a DB2 Package
- Testing a Connection
- Running a Sample Query

Converting Data Source Information

Converting a data source enables you to convert DB2 data source information from one provider type to another. Note that this does not change the data source itself, but rather reformats the data source information stored on your system.

To convert data source information

1. Retrieve the connection string for the relevant database using the appropriate call to **ReadUDL**.
2. Create a connection string to the converted database using a call to **DataAccessControl.ConvertTo**, describing the data types of the original data and translated data.
3. Save the data in the new connection string with a call to **IConnectionString.Save**.

The following sample describes how to convert data source information between OLE DB UDLs and ODBC DSNs.

```
IConnectionString ConvertUDLtoODBC(string originalUDL)
{
   try
   {
      IConnectionString udl = DB2OleDbConnectionString.ReadUDL(originalUDL);
      IConnectionString odbcDsn = DataAccessControl.ConvertTo(udl, typeof(DB2OdbcSysConnectio
nString));
      odbcDsn.Save();
      return odbcDsn;
   }
   catch
   {
      return null;
   }
}
```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating a DB2 Package

A DB2 package is a collection of data used by a provider implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester. The provider uses packages to issue SQL statements and call DB2 stored procedures. You can use DataAccessControl.CreatePackages to create these packages.

The create package command creates a Host Integration Server package on a DB2 system.

To create a DB2 package

1. Create a connection string to the targeted database with a call to DB2OleDbConnectionString.ReadUDL.
2. Create the package with **DataAccessControl.CreatePackage**.

The following example describes how to create a package.

```
static void CreatePackage(string myUDL, System.Exception myException)
{
try
   {
      IConnectionString connString = DB2OleDbConnectionString.ReadUDL(myUDL);
      DataAccessControl.CreatePackages(connString, null);
      myException = null;
   }
catch (System.Exception Caught)
   {
      myException = Caught;
   }
}
```

See Also

Creating Packages for Use with the OLE DB Provider for DB2

Creating Packages for Use with the ODBC Driver for DB2

Testing a Connection

Once you have created the appropriate connection string and stored it in a file, you can programmatically test the validity of your connection with a call to DataAccessControl.TestConnection.

To test a connection

1. Create or retrieve the connection string on which you run the sample query.

   For more information about creating and retrieving connection strings, see Creating a Connection String and Retrieving Data.

2. Test the connection with a call to **TestConnection**.

   If successful, **TestConnection** returns the class and version number of the server. Otherwise, the method returns null. Note that you may be required to enter the user name and password. In this case, the **Password** dialog box appears.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Running a Sample Query

One of the final checks you can perform on a created connection string is a simple query that fetches a list of available files and data sources in the target database. Once you create the connection string, you can run this query using DataAccessControl.SampleQuery.

To run a sample query

1. Create or retrieve the connection string on which you run the sample query.

   For more information on creating and retrieving connection strings, see Creating a Connection String and Retrieving Data.

2. Run the sample query with a call to **SampleQuery**.

   If successful, **SampleQuery** returns a data table with the relevant values. Otherwise, the method returns null.

Managed Provider Programmer's Guide

A Managed Provider is a .NET data provider used for connecting Microsoft® Host Integration Server 2004 applications to a database, executing commands, and retrieving results. Those results are processed directly, placed in an ADO.NET **DataSet** to be exposed to the user, combined with data from multiple sources, or accessed remotely between tiers. A Host Integration Server Managed Provider is designed to be lightweight, creating a minimal layer between the data source and your code, and increasing performance without sacrificing functionality.

This section contains:

- Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Managed Provider for DB2 Programmer's Guide

This section describes the general architecture and implementation details of the Managed Provider for DB2. The Managed Provider for DB2 enables a client to connect to a DB2 data source in order to retrieve and modify data, and also serves as a bridge between a DB2 data source and an ADO.NET **DataSet**. The Managed Provider for DB2 implements a subset of the **System.Data** interfaces to enable connection management and query execution.

This section contains:

- About the Managed Provider for DB2
- Using the Managed Provider for DB2

About the Managed Provider for DB2

Microsoft® Host Integration Server (HIS) 2004 includes a Managed Provider to access data from a loosely coupled data source; in this case, a DB2 database. The Managed Provider for DB2 uses two central .NET components to implement this capability: the ADO.NET **DataSet** and the Managed Provider for DB2 itself.

A **DataSet** is an object designed for data access independent of any data source. As a result, it can be used with multiple and differing data sources, used with XML data, or used to manage data local to the application. A **DataSet** contains a collection of one or more **DataTable** objects made up of rows and columns of data, as well as primary key, foreign key, constraint, and relation information about the data in the **DataTable** objects.

In contrast, the Managed Provider for DB2 provides data manipulation and fast, forward-only, read-only access to data. As such, the Managed Provider for DB2 exposes a specific set of objects. The **MSDb2Command** object enables access to DB2 commands to return data, modify data, run stored procedures, and send or retrieve parameter information. The **MsDb2DataReader** provides a high-performance stream of data from the DB2 database. Finally, the **MsDb2DataAdapter** provides the bridge between the **DataSet** object and the DB2 database. **MsDb2DataAdapter** uses **MsDb2Command** objects to execute SQL commands at the data source to both load the **DataSet** with data, and reconcile changes made to the data in the **DataSet** back to the data source.

This section contains:

- Goals for the Managed Provider for DB2
- The .NET Data Provider
- About the ADO.NET DataSet

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Goals for the Managed Provider for DB2

The main goal for the Managed Provider for DB2 is to allow access to loosely coupled data sources using the technologies offered by ADO.NET and the .NET Framework. To implement this goal, the Managed Provider for DB2 was designed as an incremental improvement over the traditional COM-based OLE DB providers. In addition, the Managed Provider for DB2 is optimized for DB2 over the currently-available OLE DB .NET data provider.

Microsoft has offered programming models and tools for developing enterprise data integration solutions for several years. These include the industry-standard ODBC and the COM-based OLE DB. However, developing and deploying ADO-based Web solutions presents a number of issues, including insufficient design tools, diminished performance, limited scalability, and little XML interoperability.

Additionally, the ADO- and OLE DB-based data architecture is based on solutions that require tightly coupled, live connections between application and data tiers. However, the vast majority of Web solutions today require a loosely coupled association between application components and tiers. Also, most modern Web application requirements include the use of XML as the universal Web message and data medium. Remote Data Services (RDS) offered a disconnected recordset between application and presentation tiers. ADO also offered the ability to persist recordsets as XML. However, there was no uniform means of providing asynchronous execution between tiers. In addition, XML recordset persistence was extremely limited.

To make implementation easier and to improve performance, scalability, and XML support, Microsoft offered the .NET Framework and ADO.NET. The .NET Framework offered developers a number of advantages over COM, such as cross-language inheritance, object lifetime management, and language-neutral class libraries as supported by the common language runtime (CLR). The CLR offers application developers with a predictable, managed environment in which to execute their programs. The ADO.NET programming model was designed to provide better performance and scalability the older ADO. ADO.NET is a set of common classes for exposing data services that are implemented by .NET data providers.

Microsoft Visual Studio .NET has shipped two .NET data provider implementations: the first provider accesses Microsoft SQL Server through an application-level protocol called Tabular Data Stream (TDS), and is called the SQL Server .NET Data Provider. The second provider accesses the underlying OLE DB providers, and is called the OLE DB .NET Data Provider.

However, just as the OLE DB Provider for ODBC offers less optimal performance and scalability than a direct OLE DB provider solution, so too does the OLE DB .NET Data Provider offer a less optimal solution than a specific .NET data provider implementation would. In addition, the OLE DB .NET Data provider adds complexity and compatibility issues with an extra layer of indirection. Therefore, Host Integration Server has implemented a .NET data provider for a key enterprise data source: DB2.

Managed Provider for DB2 Programmer's Guide

The .NET Data Provider

In concept, a .NET data provider is similar to an OLE DB provider: the provider runs as an interface between your application and the data source. However, the .NET data provider exposes only a single set of **ADO.NET** interfaces.

This section contains:

- Examining the Core Interface for a Managed Provider for DB2

Examining the Core Interface for a Managed Provider for DB2

A data provider in the .NET Framework serves as a bridge between an application and a data source. The data provider is used to retrieve data from a data source and to reconcile changes to that data back to the data source.

ADO.NET exposes a common model for .NET data provider objects so that a single set of code can be written to work regardless of the .NET data provider. The **Connection**, **Command**, **DataReader**, and **DataAdapter** objects represent the core elements of the .NET data provider model. The following table describes the purpose of these objects, and how they are implemented in the Managed Provider for DB2.

Common model	Managed Provider for DB2	Description
Connection	MsDb2Connection	Responsible for opening, closing, and maintaining a connection to a DB2 host.
Command	MsDb2Command	Manages all parameters that a query may include, which includes both SQL parameters and stored procedure parameters.
DataReader	MsDb2DataReader	A server-side forward-only cursor implementation that inherits form the **IDataReader** and **IDataRecord** interfaces.
DataAdapter	MsDb2DataAdapter	Acts as the gateway between a DB2 host table and a .NET-based data set.

In addition, the Managed Provider for DB2 has several interfaces specific to this implementation. These interfaces deal with exception and event handling, setting up connections to a DB2 host over different types of networks, and passing parameters. For more information, see the Microsoft.HostIntegration.MsDb2Client Namespace.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

About the Relationships between the .NET Provider for DB2 Interfaces

The Managed Provider for DB2 interfaces interact in different ways—with the exception of **MsDb2DataAdapter**, the remaining classes adhere to a rigid parent/child relationship:

- An **MsDb2Connection** can have one **MsDb2Transaction** running, although it can have multiple **MsDb2Commands**.
- An **MsDb2Transaction** can have one or more **MsDb2Commands** running.
- An **MsDb2Command** owns one **MsDb2ParameterCollection**, which stores multiple **MsDb2Parameters**.

  An **MsDb2Command** can also create a single **MsDb2DataReader** for parsing one or more resultsets.

The **MsDb2DataAdapter** takes advantage of all the other **Managed Provider** interfaces. The **MsDb2DataAdapter** serves as the gateway between a host DB2 system and a client-side ADO.NET **DataSet**. The **DataSet** is an important piece of the .NET data framework because it provides a mechanism for caching data in a managed environment and inferring XML schema information, in essence providing a gateway between DB2 data and Microsoft Web Services.

Examining the Core Interface for a Managed Provider for DB2

About the ADO.NET DataSet

The ADO.NET **DataSet** is the object that contains the DB2 data that the Managed Provider for DB2 retrieved from the remote data source. Specifically, the ADO.NET **DataSet** is a local cache of tables, similar to a collection of ADO disconnected recordsets, described in the **System.Data** namespace. In addition, the **DataSet** records the relationships between the tables using keys and constraints. The **DataSet** is central to supporting disconnected, distributed data scenarios with ADO.NET.

Note that the **DataSet** described here is identical to other **DataSets** used in ADO.NET.

This section contains:

- The DataTableCollection
- The DataRelationCollection
- The ExtendedProperties
- XML Support

The DataTableCollection

An ADO.NET **DataSet** contains a collection of zero or more tables represented by **DataTable** objects. The **DataTableCollection** contains all the **DataTable** objects in a **DataSet**.

A **DataTable** is defined in the **System.Data** namespace and represents a single table of memory-resident data. It contains a collection of columns represented by a **DataColumnCollection**, and constraints represented by a **ConstraintCollection**, which together define the schema of the table. A **DataTable** also contains a collection of rows represented by the **DataRowCollection**, which contains the data in the table. Along with its current state, a **DataRow** retains both its current and original versions to identify changes to the values stored in the row.

See Also

About the ADO.NET DataSet

The DataRelationCollection

A **DataSet** contains relationships in its **DataRelationCollection** object. A relationship, represented by the **DataRelation** object, associates rows in one **DataTable** with rows in another **DataTable**. It is analogous to a join path that might exist between primary and foreign key columns in a relational database. A **DataRelation** identifies matching columns in two tables of a **DataSet**.

Relationships enable navigation from one table to another within a **DataSet**. The essential elements of a **DataRelation** are the name of the relationship, the name of the tables being related, and the related columns in each table. Relationships can be built with more than one column per table by specifying an array of **DataColumn** objects as the key columns. When a relationship is added to the **DataRelationCollection**, it may optionally add a **UniqueKeyConstraint** and a **ForeignKeyConstraint** to enforce integrity constraints when changes are made to related column values.

About the ADO.NET DataSet

The ExtendedProperties

The **DataSet** (as well as the **DataTable** and **DataColumn**) has an **ExtendedProperties** property. **ExtendedProperties** is a **PropertyCollection** where you can place customized information, such as the **SELECT** statement that was used to generate the resultset or a date/time stamp of when the data was generated. The **ExtendedProperties** collection is persisted with the schema information for the **DataSet** (as well as the **DataTable** and **DataColumn**).

See Also

About the ADO.NET DataSet

XML Support

The **DataSet** can also persist and reload its contents as XML and its schema as XSD. The **DataSet** has direct support for reading (shredding) and writing data using XML using the .NET Framework **XmlReader** and **XmlWriter**. When writing XML, the output conforms to the W3C XSD schema. XML is a good method of moving data between application tiers. The **XMLDataDocument** can make use of the XML services, such as XSL/T and XPath.

About the ADO.NET DataSet

Using the Managed Provider for DB2

The Managed Provider for DB2 operates in most ways as a normal data provider: you can connect to a DB2 database, execute commands, retrieve data, and use stored procedures.

This section contains:

- Creating a Project in Visual Studio Using the Managed Provider for DB2
- Connecting and Disconnecting to and from a DB2 Database
- Executing Commands in a DB2 Database
- Reading Data from a DB2 Database
- Using Stored Procedures in a DB2 Database
- Obtaining a Single Value from a DB2 Database
- Working with the DataAdapter and the DataSet for a DB2 Database
- Performing Transactions with a DB2 Database
- Performing a Two-Phase Commit Transaction over TCP/IP

Creating a Project in Visual Studio Using the Managed Provider for DB2

You can create a project in Microsoft® Visual Studio® .NET using the Managed Provider for DB2 in the same way you would create any other project. However, while the Managed Provider for DB2 is compatible with versions 1.0 and 1.1 of the .NET Framework, interoperability between the two versions of .NET Framework is limited. The following table describes the different versions of Visual Studio and the .NET Framework you may have installed on your system, and the effects it may have on any new projects you create with the Managed Provider for DB2.

Visual Studio version installed	.NET Framework version installed	New projects using the Managed Provider for DB2
2003	1.1	Reference .NET Framework version 1.1 and work as described.
2002 and 2003	1.0 and 1.1	Projects build in Visual Studio 2002 reference the incorrect .NET Frameworks version. Projects built in Visual Studio 2003 reference .NET Framework 1.1 and function as expected.

When only Visual Studio 2003 and .NET Framework 1.1 are installed, newly created projects function as expected, and reference .NET Framework version 1.1. However, conflicts occur when both Visual Studio 2002 and Visual Studio 2003 or both .NET Framework 1.0 and 1.1 are installed.

Specifically, projects created in Visual Studio 2003 function as expected and reference .NET Framework version 1.1. In contrast, projects created in Visual Studio 2002 only function as expected after redirecting your project to .NET Framework 1.1.

To redirect your Visual Studio 2002 project to .NET Framework version 1.1

1. Remove the version 1.0 references to System, System.Data, and System.Xml.
2. Replace these references with version 1.1 references to System, System.Data, and System.Xml.

   You can browse for the location of these references at <drive>:\Windows\Microsoft.NET\Framework\v1.1.4322\.

Connecting and Disconnecting to and from a DB2 Database

There are two ways to connect and disconnect to a DB2 database. The first and most common way is using an **MsDb2Connection** to open and close the connection. The second method is to access a connection pool.

This section contains:

- Connecting with an MsDb2Connection
- Connecting to a DB2 Connection Pool

Connecting with an MsDb2Connection

The first step to accessing a remote DB2 database is to connect to the database. You must use MsDb2Connection to access an IBM DB2 data source. Once you have connected, you may retrieve, modify, and update information as you wish. Note that connections are not implicitly released when the **MsDb2Connection** falls out of scope or is reclaimed by garbage collection. As such, you must close the connection when you are finished using it. You can close a connection by using either the MsDb2Connection.Close or MsDb2Connection.Dispose.

The following sample describes how to connect to a DB2 database.

```
Public void SampleConnect()
{
   MsDb2Connection myConnection = null;
   Try
   {
      myConnection = new MsDb2Connection(@"file name=HOST.udl ");
      myConnection.Open();
      //perform any necessary tasks here
      myConnection.Close();
   }
finally
   {
      if(myConnection!= null)
         myConnection.Dispose();
   }
}
```

Connecting to a DB2 Connection Pool

Another way to connect to a DB2 database is through a connection pool. Although implemented differently on the server, a connection pool is identical to a tradition ional connection from the perspective of a client application.

A connection pool is a set of one or more connections the server keeps open to service requests from one or more clients. When the client is finished with a connection, the server does not terminate the connection. Instead, the connection is released back into the pool, and can then service another client. Connection pooling is often used in situations where clients will connect, query, and terminate a connection to the server multiple times over the course of a session, such as a database server accessed through the internet.

To connect and disconnect to a DB2 connection pool with HIS

1. Connect to the DB2 server with MsDb2Connection, with the MsDb2Connection.ConnectionPooling set to **true**.
2. Perform your queries as you would with a traditional DB2 connection.
3. Use MsDb2Connection.Close or MsDb2Connection.Dispose to end your session.

   Note that calling **Close** or **Dispose** on a connection from a connection pool does not actually close or dispose the connection. Instead, the server returns the connection to the pool.

The following code sample describes how to connect to a DB2 database using a connection pool.

```
int GetNumberOfOrders()
{
    MsDb2Connection conn = new MsDb2Connection(@"File Name=C:\MyConn.UDL");
    sDb2Command cmd;
    int numOrders = 0;
    conn.ConnectionPooling = true;
    conn.Open();
    cmd = new MsDb2Command("select count(*) from orders", conn);
    numOrders = (int)cmd.ExecuteScalar();
    conn.Close();
    return numOrders;
}
```

Executing Commands in a DB2 Database

After establishing a connection to a data source, you can execute commands and return results from the data source using MsDb2Command. **MsDb2Command** can be created by calling MsDb2Connection.CreateCommand.

MsDb2Command exposes several **Execute** methods you can use. When returning results as a stream of data, use ExecuteReader to return a **DataReader** object. Use ExecuteScalar to return a singleton value. Use ExecuteNonQuery to execute commands that do not return rows.

When using **MsDb2Command** with a stored procedure, you may set MsDb2Command.CommandType to *StoredProcedure*. With a **CommandType** of *StoredProcedure*, you can use the MsDb2Command.Parameters to access input and output parameters and return values. **MsDb2Command.Parameters** can be accessed regardless of the **Execute** method called.

The following example describes how to execute a command in a DB2 database by inserting a row into a database.

```
Public void InsertRow()
{
   MsDb2Connection myConnection = null;
   MsDb2Command myCommand = null;
   try
      {
         string myInsertQuery = "INSERT INTO Customers (CustomerID, CompanyName)
                  Values('NWIND', 'Northwind Traders')";
         myConnection = new MsDb2Connection(@"file name=HOST.udl ");
         myConnection.Open();
         myCommand = new MsDb2Command(myInsertQuery);
         myCommand.Connection = myConnection;
         myCommand.ExecuteNonQuery();
         myConnection.Close();
      }
finally
      {
         if(myCommand!= null)
                  myCommand.Dispose();
         if(myConnection!= null)
                  myConnection.Dispose();
       }
}
```

Reading Data from a DB2 Database

In addition to executing commands on a remote database, you can also retrieve information from the database to view locally.

This section contains:

- Reading Data from the Database
- Retrieving Multiple ResultSets
- Retrieving Schema Information

Reading Data from the Database

You can use MsDb2DataReader to retrieve a read-only, forward-only stream of data from a database. Using **MsDb2DataReader** can increase application performance and reduce system overhead because only one row at a time is ever in memory.

After creating an instance of the MsDb2Command object, you can create an **MsDb2DataReader** by calling MsDb2Command.ExecuteReader to retrieve rows from a data source.

You can use MsDb2DataReader.Read to obtain a row from the results of the query. You access each column of the returned row by passing the name or ordinal reference of the column to **MsDb2DataReader**. However, for best performance, **MsDb2DataReader** provides a series of methods that enable you to access column values in their native data types.

Using the typed accessor methods when the underlying data type is known reduce the amount of type conversion required when retrieving the column value.

MsDb2DataReader also provides a nonbuffered stream of data that enables procedural logic to efficiently process results from a data source sequentially. **MsDb2DataReader** is a good choice when retrieving large amounts of data because the data is not cached in memory.

After you are finished with **MsDb2DataReader**, make sure to call the **Close** method. In addition, output parameters and return values from an MsDb2Command are not available until **MsDb2DataReader** is closed.

Note that the Distributed Relational Data Architecture (DRDA) uses a "." as a decimal point and a "," to separate numerical values. If you are working in a language, such as German, that uses a "," as a decimal point, your may encounter an error when retrieving data from your database. To avoid this error, use **System.Globalization.CultureInfo.InvariantCulture** when calling the **ToString** and **Parse** methods.

The following example describes how to read data from a DB2 database by reading a row from a **SELECT** statement:

```
Public void ReadMyData(string myConnString)
{
   string mySelectQuery = "SELECT OrderID, CustomerID FROM Orders";
   MsDb2Connection myConnection = new MsDb2Connection(myConnString);
   MsDb2Command myCommand = new MsDb2Command(mySelectQuery,myConnection);
   myConnection.Open();
   MsDb2DataReader myReader;
   myReader = myCommand.ExecuteReader();
   //Always call Read before accessing data.
   While (myReader.Read())
   {
       Console.WriteLine(myReader.GetInt32(0) + ", "
       + myReader.GetString(1));
   }
   //always close when done reading.
   myReader.Close();
   //close the connection when done.
   myConnection.Close();
}
```

See Also

Using the Managed Provider for DB2

Retrieving Multiple ResultSets

MsDb2DataReader provides the **NextResult** method to iterate through multiple returned results. The following example describes how to retrieve multiple resultsets.

```
Public void ReadMyData(string myConnString)
{
   string myCallQuery = "CALL MyReports()";
   MsDb2Connection myConnection = new MsDb2Connection(myConnString);
   MsDb2Command myCommand = new MsDb2Command(myCallQuery,myConnection);
   myConnection.Open();
   MsDb2DataReader myReader;
   myReader = myCommand.ExecuteReader();
   do
      {
      //Always call Read before accessing data.
      While (myReader.Read())
         {
         Console.WriteLine(myReader.GetString(0) + " , ", "
                 + myReader.GetString(1));
         }
       }
   while(myReader.NextResult());
   //always call Close when done reading.
   myReader.Close();
   //Close the connection when done with it
   myConenction.Close();
}
```

Using the Managed Provider for DB2

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Retrieving Schema Information

While an MsDb2DataReader is open, you can retrieve schema information about the current resultset using MsDb2DataReader.GetSchemaTable. **GetSchemaTable** returns a **DataTable** populated with rows and columns that contain the schema information for the current resultset. The **DataTable** contains one row for each column of the resultset. Each column of the schema table row maps to a property of the column returned in the resultset, where the **ColumnName** is the name of the property and the value of the column is the value of the property. However, hierarchical rowsets, or "chapters" (OLE DB type DBTYPE_HCHAPTER, ADO type **adChapter**) cannot be retrieved using **MsDb2DataReader**.

See Also

Using the Managed Provider for DB2

Using Stored Procedures in a DB2 Database

A stored procedure is an executable object stored in a database. Calling a stored procedure is similar to invoking an SQL command. Using stored procedures on the data source, instead of executing or preparing a statement in the client application, can provide several advantages, including: higher performance, reduced network overhead, and improved consistency and accuracy.

Stored procedures offer many advantages in data-driven applications. Database operations can be encapsulated in a single command, optimized for best performance, and enhanced with additional security. While a stored procedure can be called by simply passing the stored procedure name followed by parameter arguments as an SQL statement, using MsDb2Command.Parameters enables you to more explicitly define stored procedure parameters as well as to access output parameters and return values.

To call a stored procedure, set MsDb2Command.CommandType to **StoredProcedure**. You can then use **Parameters** to define parameters.

You can create a parameter using the appropriate constructor or by calling **Command.Parameters.Add**. **Parameters.Add** takes as input either constructor arguments or an existing **Parameter** object. When setting the value of a parameter to a **null** value, use **DBNull.Value**.

For parameters other than input parameters, you must set the MsDb2Parameter.Direction property to specify whether the parameter type is **Input**, **Output**, or **InputOutput**.

When using parameters with **MsDb2Command**, the names of the parameters added to the MsDb2ParameterCollection must match the names of the parameter markers in your stored procedure. The Managed Provider for DB2 treats parameters in the stored procedure as named parameters and searches for the matching parameter markers.

The Managed Provider for DB2 does not support named parameters for passing parameters to an SQL statement or a stored procedure called by **CommandType.Text** command. As such, you must use the question mark (?) placeholder, as shown in the following example:

```
SELECT * FROM Customers WHERE CustomerID = ?
```

As a result, the order in which **MsDb2Parameters** are added to the **MsDb2ParametersCollection** must directly correspond to the position of the question mark placeholder for the parameter.

You may need to return information from a database that is not in the form of a table or data stream. For example, you may want to return a single value such as the result of **Count(*)**, **Sum(Price)**, or **Avg(Quantity)**. **Command** provides the capability to return single values using MsDb2Command.ExecuteScalar. **ExecuteScalar** returns the value of the first column of the first row of the resultset as a scalar value.

See Also

Using the Managed Provider for DB2

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Obtaining a Single Value from a DB2 Database

You may need to return database information that is simply a single value rather than in the form of a table or data stream. For example, you may want to return the result of an aggregate function such as **Count(*)**, **Sum(Price)**, or **Avg(Quantity)**. The Command object provides the capability to return single values using the **ExecuteScalar** method. The **ExecuteScalar** method returns as a scalar value the value of the first column of the first row of the resultset.

The following code sample describes how to retrieve a single value from a DB2 database.

```
static void SingleValueConnection()
{
    MsDb2Connection myConnection = null;
    try
    {
//  Obtaining a single value as a database.
        myConnection = new MsDb2Connection(@"file name=HOST.udl ");
        myConnection.Open();
        MsDb2Command myCommand = new MsDb2Command("SELECT Count(*) FROM Orders", myConnection
);
       Int32 count = (Int32)myCommand.ExecuteScalar();
        myConnection.Close();
    }
        catch (Exception exc)
    {
        Console.WriteLine(exc);
        Console.ReadLine();
    }

    finally
    {
        if(myConnection!= null)
            myConnection.Dispose();
    }
} // End SingleValueConnection
```

Working with the DataAdapter and the DataSet for a DB2 Database

The **MsDb2DataAdapter** is the main interface for retrieving and updating the **DataSet**.

This section contains:

- Populating a Managed Provider Dataset from a Data Adapter
- Working with DataAdapter Events
- Updating the DB2 Database with a DataAdapter and the DataSet
- Using Parameters with the DB2 DataAdapter
- Adding Additional Constraints to a DB2 DataSet
- Setting up DataTable and DataColumn Mappings for a DB2 Database

Populating a Managed Provider Dataset from a Data Adapter

A **DataSet** is a memory-resident representation of data that provides a consistent relational programming model independent of the data source. The **DataSet** represents a complete set of data including tables, constraints, and relationships among the tables. Because the **DataSet** is independent of the data source, a **DataSet** can include data local to the application, as well as data from multiple data sources. Interaction with existing data sources is controlled through the MsDb2DataAdapter.

The **MsDb2DataAdapter** is used to retrieve data from a data source and populate tables within a **DataSet**. The **MsDb2DataAdapter** also resolves changes made to the **DataSet** back to the data source. The **MsDb2DataAdapter** uses MsDb2Connection to connect to a data source, and MsDb2Command to retrieve data from and resolve changes to the data source.

MsDb2DataAdapter.SelectCommand is an MsDb2Command object that retrieves data from the data source. Similarly, InsertCommand, UpdateCommand, and DeleteCommand are **MsDb2Command** objects that manage updates to the data in the data source according to modifications made to the data in the **DataSet**. For more information, see Updating the DB2 Database with a DataAdapter and the DataSet.

Working with DataAdapter Events

MsDb2DataAdapter exposes two events you can use to respond to changes made to data at the data source. The following table shows the **MsDb2DataAdapter** events.

Event	**Description**
RowUpdating	An **UPDATE**, **INSERT**, or **DELETE** operation on a row (by a call to one of the **Update** methods) is about to begin.
RowUpdated	An **UPDATE**, **INSERT**, or **DELETE** operation on a row (by a call to one of the **Update** methods) is complete.

RowUpdating is raised before any update to a row from the **DataSet** has been processed at the data source. **RowUpdated** is raised after any update to a row from the **DataSet** has been processed at the data source. As a result, you can use **RowUpdating** to modify update behavior before it happens, to provide additional handling when an update occurs, to retain a reference to an updated row, to cancel the current update and schedule it for a batch process to be processed later, and so on. **RowUpdated** is useful for responding to errors and exceptions that occur during the update. You can add error information to the **DataSet**, as well as retry logic, and so on.

The MsDb2RowUpdatingEventArgs and MsDb2RowUpdatedEventArgs arguments passed to the **RowUpdating** and **RowUpdated** events include: a **Command** property that references the **Command** object being used to perform the update; a **Row** property that references the **DataRow** object containing the updated information; a **StatementType** property for what type of update is being performed; the **TableMapping**, if applicable; and the **Status** of the operation.

You can use the **Status** property to determine if an error has occurred during the operation and, if desired, to control the actions against the current and resulting rows. When the event occurs, the **Status** property equals either **Continue** or **ErrorsOccurred**. The following table shows the values to which you can set the **Status** property in order to control subsequent actions during the update.

Status	**Description**
Continue	Continue the update operation.
ErrorsOccurred	Abort the update operation and throw an exception.
SkipCurrentRow	Ignore the current row and continue the update operation.
SkipAllRemainingRows	Abort the update operation, but do not throw an exception.

Setting the **Status** property to **ErrorsOccurred** causes an exception to be thrown. You can control which exception is thrown by setting the **Errors** property to the desired exception. Using one of the other values for **Status** prevents an exception from being thrown.

Updating the DB2 Database with a DataAdapter and the DataSet

MsDb2DataAdapter.Update is called to resolve changes from a **DataSet** back to the data source. **Update**, like **Fill**, takes as arguments an instance of a **DataSet**, and an optional **DataTable** object or **DataTable** name. The **DataSet** instance is the **DataSet** that contains the changes that have been made, and the **DataTable** identifies the table from which to retrieve the changes.

When you call the **Update** method, the MsDb2DataAdapter analyzes the changes that have been made and executes the appropriate command (**INSERT**, **UPDATE**, or **DELETE**). When the **MsDb2DataAdapter** encounters a change to a **DataRow**, it uses InsertCommand, UpdateCommand, or DeleteCommand to process the change. This enables you to maximize the performance of your ADO.NET application by specifying command syntax at design time and, where possible, through the use of stored procedures. You must explicitly set the commands before calling **Update**. If **Update** is called and the appropriate command does not exist for a particular update (for example, no **DeleteCommand** for deleted rows), an exception will be thrown.

Command parameters can be used to specify input and output values for an SQL statement or stored procedure for each modified row in a **DataSet**. For more information, see Using Parameters with the DB2 DataAdapter.

If your **DataTable** maps to or is generated from a single database table, you can take advantage of the **CommandBuilder** object to automatically generate the **DeleteCommand**, **InsertCommand**, and **UpdateCommand** of the **DataAdapter**.

The **Update** method resolves your changes back to the data source, however other clients may have modified data at the data source since the last time you filled the **DataSet**. To refresh your **DataSet** with current data, use the **DataAdapter** and **Fill** the **DataSet** again. New rows is added to the table, and updated information is incorporated into existing rows.

To handle exceptions that may occur during an **Update**, you can use the **RowUpdated** event to respond to row update errors when they occur (see Working with DataAdapter Events), or you can set **DataAdapter.ContinueUpdateOnError** to **true** before calling **Update**, and respond to the error information stored in the **RowError** property of a particular row when the **Update** is completed.

Note that calling **AcceptChanges** on the **DataSet**, **DataTable**, or **DataRow** causes all **Original** values for a **DataRow** to be overwritten with the **Current** values for the **DataRow**. If the field values that identify the row as unique have been modified, after calling **AcceptChanges,** the **Original** values no longer match the values in the data source.

Using Parameters with the DB2 DataAdapter

The MsDb2DataAdapter has four properties that are used to retrieve data from and update data to the data source. SelectCommand returns data from the data source. The InsertCommand, UpdateCommand, and DeleteCommand are used to manage changes at the data source. **SelectCommand** must be set before calling **Msdb2DataAdapter.Fill**. **InsertCommand**, **UpdateCommand**, or **DeleteCommand** must be set before the **MsDb2DataAdapter.Update** is called, depending on what changes were made to the data in the **DataSet**. For example, if rows have been added, the **InsertCommand** must be set before calling **Update**. When **Update** is processing an inserted, updated, or deleted row, the **MsDb2DataAdapter** uses the respective Command property to process the action. Current information about the modified row is passed to **MsDb2Command** through the **MsDb2ParametersCollection**.

Adding Additional Constraints to a DB2 DataSet

MsDb2DataAdapter.Fill fills a **DataSet** only with table columns and rows from a data source; though constraints are commonly set by the data source, **Fill** does not add this schema information to the **DataSet** by default. To populate a **DataSet** with existing primary key constraint information from a data source, you can either call **MsDb2DataAdapter.FillSchema**, or set **MsDb2DataAdapter.MissingSchemaAction** to *AddWithKey* before calling **Fill**. This ensures that primary key constraints in the **DataSet** reflect those at the data source. Foreign key constraint information is not included and needs to be created explicitly.

Adding schema information to a **DataSet** before filling it with data ensures that primary key constraints are included with the **DataTable** objects in the **DataSet**. As a result, when additional calls to **Fill** the **DataSet** are made, the primary key column information is used to match new rows from the data source with current rows in each **DataTable**, and current data in the tables is overwritten with data from the data source. Without the schema information, the new rows from the data source are appended to the **DataSet**, resulting in duplicate rows.

Note that if a column in a data source is identified as autoincrementing, **FillSchema**, or the **Fill** method with a **MissingSchemaAction** of *AddWithKey*, creates a **DataColumn** with an **AutoIncrement** property set to **true**. However, you need to set the **AutoIncrementStep** and **AutoIncrementSeed** values yourself.

Using **FillSchema** or setting the **MissingSchemaAction** to *AddWithKey* requires extra processing at the data source to determine primary key column information. This additional processing can hinder performance. If you know the primary key information at design time, it is recommended that you specify the primary key column or columns explicitly in order to achieve optimal performance.

If the MsDb2DataAdapter encounters multiple resultsets returned from the SelectCommand, it creates multiple tables in the **DataSet**. The tables is given an incremental default name of TableN, starting with "Table" for Table0. If a table name is passed as an argument to the **FillSchema** method, the tables will be given an incremental default name of TableNameN, starting with "TableName" for TableName0.

Setting up DataTable and DataColumn Mappings for a DB2 Database

An MsDb2DataAdapter contains a collection of zero or more **DataTableMapping** objects in its **TableMappings** property. A **DataTableMapping** provides a master mapping between the data returned from a query against a data source, and a **DataTable**. The **DataTableMapping** name can be passed in place of the **DataTable** name to **MsDb2DataAdapter.Fill**.

A **DataTableMapping** enables you to use column names in a **DataTable** that are different from those in the database. The **MsDb2DataAdapter** uses the mapping to match the columns when the table is updated.

If you do not specify a **TableName** or a **DataTableMapping** name when calling **Fill** or **Update**, the **MsDb2DataAdapter** looks for a **DataTableMapping** named "Table". If that **DataTableMapping** does not exist, the **TableName** of the **DataTable** will be "Table". You can specify a default **DataTableMapping** by creating a **DataTableMapping** with the name of "Table".

In more advanced situations, you may decide that you want the same **MsDb2DataAdapter** to support loading different tables with different mappings. To do this, simply add additional **DataTableMapping** objects.

When **Fill** is passed an instance of a **DataSet** and a **DataTableMapping** name, if a mapping with that name exists, it is used, otherwise a **DataTable** with that name is used.

Note that if a source column name is not supplied for a column mapping or a source table name is not supplied for a table mapping, default names will be automatically generated. If no source column is supplied for a column mapping, the column mapping is given an incremental default name of SourceColumnN, starting with "SourceColumn1". If no source table name is supplied for a table mapping, the table mapping is given an incremental default name of SourceTableN, starting with "SourceTable1".

It is recommended that you avoid the naming convention of "SourceColumnN" when you supply a source column name for a column mapping, or "SourceTableN" when you supply a source table name for a table mapping, because the name you supply may conflict with an existing default column mapping name in the **ColumnMappingCollection** or table mapping name in the **DataTableMappingCollection**. If the supplied name already exists, an exception will be thrown.

If your MsDb2DataAdapter.SelectCommand returns multiple tables, **Fill** automatically generate table names with incremental values for the tables in the **DataSet**, starting with the specified table name and continuing on in the form TableNameN, starting with "TableName1". You can use table mappings to map the automatically generated table name to a name you want specified for the table in the **DataSet**.

Using the Managed Provider for DB2

Performing Transactions with a DB2 Database

Transactions are a group of database operations combined into a logical unit of work, and are used to control and maintain the consistency and integrity of each database despite errors that might occur in the system. A transaction consists of a series of SQL **SELECT**, **INSERT**, **UPDATE**, or **DELETE** statements. If no errors are encountered during a transaction, all modifications in the transaction become a permanent part of the database. If errors are encountered, none of the modifications are made to the database.

For example, in a banking application where funds are transferred from one account to another, one account is credited an amount, and another account is debited the same amount at the same time. Because computers can fail due to power outages, network outages, and so on, it is possible to update a row in one table, but not in the related table. Because the managed provider for DB2 supports the **MsDb2Transaction** object, you can group database operations into a transaction to prevent database inconsistency resulting from these events.

There are three basic commands for transactions: **BEGIN**, **COMMIT**, and **ROLLBACK**. The **BEGIN** statement marks the beginning of a transaction. All procedures attempted after the **BEGIN** statement are considered part of the transaction, which is completed by the **COMMIT** statement, or canceled by the **ROLLBACK** statement.

To perform a transaction

1. Call MsDb2Connection.BeginTransaction to mark the start of the transaction.

   BeginTransaction returns a reference to the transaction. Retain this reference so that you can assign it to commands that are enlisted in the transaction.

2. Assign the transaction to the MsDb2Command.Transaction to be executed.

   If a command is executed on a connection with an active transaction and the **Transaction** object has not been assigned to the **Transaction** property of the Command, an MsDb2Exception will be thrown.

3. Execute the required commands.
4. Call MsDb2Transaction.Commit to complete the transaction, or call MsDb2Transaction.Rollback to cancel the transaction.

The following code sample describes how to perform a transaction.

```
static void TransactionConnection()
{
    MsDb2Connection myConnection new MsDb2Connection(@"file name=HOST.udl ");
    myConnection.Open();
    // Start a local transaction.
    MsDb2Transaction myTrans = myConnection.BeginTransaction();
    // Enlist the command in the current transaction.
    MsDb2Command myCommand = myConnection.CreateCommand();
    myCommand.Transaction = myTrans;
    try
    {
        myCommand.CommandText = "Insert into Region (RegionID, RegionDescription) VALUES (100
, 'Description')";
        myCommand.ExecuteNonQuery();
        myCommand.CommandText = "Insert into Region (RegionID, RegionDescription) VALUES (101
, 'Description')";
        myCommand.ExecuteNonQuery();
        myTrans.Commit();
        Console.WriteLine("Both records are written to database.");
    }
    catch(Exception e)
    {
        try
        {
           myTrans.Rollback();
        }
        catch (MsDb2Exception ex)
        {
            if (myTrans.Connection != null)
            {
                Console.WriteLine("An exception of type " + ex.GetType() +
                        " was encountered while attempting to roll back the transaction.");
                }
            }

            Console.WriteLine("An exception of type " + e.GetType() +
                "was encountered while inserting the data.");
            Console.WriteLine("Neither record was written to database.");
        }
        finally
        {
            Console.ReadLine();
            myConnection.Close();
        }
    } //End TransactionConnection
```

Performing a Two-Phase Commit Transaction over TCP/IP

Two-phase commit (2PC) is a host server-installed protocol that ensures that updates to multiple instances of a database on a network either succeed or fail in their entirety. Host Integration Server 2004 supports 2PC over TCP/IP, enabling you to gain the security of a 2PC connection over the Internet.

Host Integration Server supports 2PC works using three components: the Microsoft Distributed Transaction Coordinator (DTC), the Resync service, and the transaction log. The DTC governs the normal DTC transaction flow: enlist, prepare, commit, and abort. The Resync service coordinates transaction recovery in case of any failure or disconnection, while the transaction log maintains a log of information that is needed in case of recovery.

You can perform a 2PC transaction with ADO.NET and the Managed Provider for DB2 using the **System.EnterpriseServices** namespace. Using a 2PC transaction is automatic. However, you may need to configure your 2PC connection using tools such as the Data Access Tool.

The following code sample describes how to use 2PC in a DB2 transaction.

```
Public class CentralBank : ServicedComponent
{
   public CentralBank()
   {
   }

   public void Transfer(string connString, int fromId, int toId, double amount)
   {
      MsDb2Connection conn = null;
      MsDb2Command cmd = null;
      int rowsAffected = 0;
      try
      {
         conn = new MsDb2Connection(connString);
         conn.Open();

         cmd = new MsDb2Command();
         cmd.Connection = conn;
         cmd.CommandText = "UPDATE ACCOUNTS SET BALANCE = BALANCE + ?
WHERE ID = ?";
         cmd.Parameters.Add("balance", amount);
         cmd.Parameters.Add("toId", toId);
         rowsAffected = cmd.ExecuteNonQuery();
         cmd.Parameters.Clear();
         cmd.CommandText = "UPDATE ACCOUNTS SET BALANCE = BALANCE - ?
WHERE ID = ?";
         cmd.Parameters.Add("balance", amount);
         cmd.Parameters.Add("fromId", fromId);
         rowsAffected = cmd.ExecuteNonQuery();
         ContextUtil.SetComplete();
      }
      catch(MsDb2Exceptionsqlca)
      {
         Console.WriteLine(sqlca.Message);
         ContextUtil.SetAbort();
      }
      finally
      {
         if(cmd != null)
            cmd.Dispose();
         if(conn != null)
         {
            if(conn.State == ConnectionState.Open)
               conn.Close();
            conn.Dispose();
         }
      }
   }
}
```

OLE DB Providers Programmer's Guides

This section of the Microsoft® Host Integration Server 2004 software development kit (SDK) provides information about using the OLE DB providers for AS/400, VSAM, and DB2.

This section contains:

- OLE DB Provider for AS/400 and VSAM Programmer's Guide
- OLE DB Provider for DB2 Programmer's Guide
- ADO Object, Method, Property, and Collection Support for AS/400, VSAM and DB2

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

OLE DB Provider for AS/400 and VSAM Programmer's Guide

The Microsoft® OLE DB Provider for AS/400 and VSAM enables you to directly access record-level data in mainframe VSAM, partitioned data sets (PDSs), and midrange OS/400 files from within an OLE-aware application. The object linking and embedding database (OLE DB) is a standard set of interfaces that provide heterogeneous access to disparate sources of information located anywhere—file systems, e-mail folders, and databases. The OLE DB Provider for AS/400 and VSAM combines the universal data access of OLE DB with the Record-Level Input/Output (RLIO) protocol of the IBM distributed data management (DDM) architecture.

DDM is a set of rules for distributing or extending the data management from one computer to another, such as from a mainframe to an AS/400 computer, or from one of these host computers to a server computer. By combining the OLE DB and DDM architectures, Microsoft enables organizations to preserve their investments in an existing data management infrastructure, while extending universal data access to all enterprise-wide data sources.

For API references and other technical information about the OLE DB provider, see the OLE DB Providers Programmer's Reference section of the SDK.

For sample code using the OLE DB provider, see the OLE DB Provider and ODBC Driver Samples section of the SDK.

This section contains:

- Goals of the OLE DB Provider for AS/400 and VSAM
- OLE DB Environment
- DDM Record-Level Access

- Character Code Conversions

Goals of the OLE DB Provider for AS/400 and VSAM

For the majority of enterprises today, much mission-critical information resides on IBM mainframe and AS/400 computers. This information is stored in records on the OS/400 and VSAM file systems. This information is created, owned, and often accessible by only host-based applications. In the mainframe environment, these applications include CICS and DB2; other commercial applications; and a large number of custom applications written in COBOL, PL/I, and other languages. In the AS/400 environment, these applications include primarily DB2 and commercial applications, plus a large number of custom report program generator (RPG) applications. Not all of these data sources are SQL-accessible. Many of the host data stores contain non-SQL-accessible data that is owned by something other than a traditional relational database management system (RDBMS).

These same enterprises rely on vast networks of personal computers to enable their users to achieve business goals. End users invariably rely on network e-mail, Microsoft® Windows® productivity applications such as Microsoft Office, and personal database programs such as Microsoft Access, to accomplish their daily tasks. It is essential for these same users to incorporate data stored on host systems into their regular correspondence, analysis, and reports.

Available methods of accessing host data do not provide the granular, record-level access required for cost-effective, secure, and meaningful integration of host and personal computer systems. In many cases, end users employ antiquated means of data integration. These methods include copying and pasting data from a terminal emulation screen, retyping information from host application reports, and importing text files containing comma-delimited values that use host EBCDIC-to-computer ASCII file transfer. These methods are not efficient although widely used and are not supported by products from independent software vendors (ISVs).

The challenge is how to provide direct record-level access to this valuable data without going through the host application. Much of the renewed interest in improved access to host data sources is a result of the growth of local intranets, the use of the Internet, and Web technology as a mechanism for delivering information. Fast and inexpensive methods of record-level access are needed to deliver modern, three-tiered information systems during this era of cost-cutting and budget tightening. Additional uses of this direct data access are specific queries and Web-based reporting.

It is common for corporate management to rethink host data storage and the appropriate software used to provide data access. For many organizations, the answer to these issues is in rewriting the arguably outdated host-based business rules with server-based, or even client-based, business logic.

The goal of the Microsoft® OLE DB Provider for AS/400 and VSAM is to provide customers and solution providers with the means to integrate desktop applications with this wealth of data residing on host computers.

OLE DB Environment

Three main roles are performed by software applications in an OLE DB environment:

- **OLE DB Consumer.** The end-user or server-based program that uses (consumes) the OLE DB interfaces. An example is a Web-based component that makes OLE DB calls to integrate host records with a Web-based report.
- **OLE DB Data Provider.** A driver or other program that exposes OLE DB interfaces for use by consumer applications. Data providers translate OLE DB interfaces to a language or commands that the target data source understands. An example is the Microsoft® OLE DB Provider for AS/400 and VSAM, which translates OLE DB interfaces to distributed data management (DDM) commands.
- **OLE DB Service Provider.** An application that both uses (consumes) and exposes OLE DB interfaces. Service providers typically act as proxies for the consumer, retrieving the data through the data provider and offering services to the consumer by manipulating the target data. An example is a query-processing engine.

DDM Record-Level Access

The Microsoft® OLE DB Provider for AS/400 and VSAM provides record-oriented access to host files. There is no need to perform bandwidth-intensive file transfers of entire host files to access data on the host.

The OLE DB interface provided by the OLE DB Provider for AS/400 and VSAM supports the following features:

- Set attributes and a record description of a host file (column information).
- Lock files and records.
- Position to the first record or the last record in a file.
- Navigate to the previous or next record in a file.
- Seek to a record, based on an index.
- Change records in a file.
- Insert new records and delete records in a file.
- Preserve file and record attributes.

The OLE DB Provider for AS/400 and VSAM is a source distributed data management (DDM) requester implementation that can initiate DDM commands to be serviced by a remote host-based target DDM server. On the Microsoft® Windows Server™ 2003 or Windows® 2000 operating system, the Microsoft DDM requester can run as a Windows service. This enables the DDM service to integrate with other host applications using the IBM DDM protocol and DDM servers that are resident on the host. Microsoft-based host software is not required. For more information, see Platforms Supported by the OLE DB Provider for AS/400 and VSAM. IBM offers DDM servers for the most popular host environments.

Providing users with direct record-level access reduces the development time to build and deploy new data integration solutions. Accessing only the target records, as opposed to entire host files, helps ensure data integrity.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Platforms Supported by the OLE DB Provider for AS/400 and VSAM

On the mainframe platform, IBM offers a target distributed data management (DDM) server implementation in IBM Distributed File Manager (DFM), a component of IBM Data Facility Storage Management Subsystem (DFSMS). The Microsoft® OLE DB Provider for AS/400 and VSAM requires DFSMS version 1 release 2 or later for MVS/ESA and OS/390 to support an SNA LU 6.2 connection.

On midrange AS/400 computers, IBM has implemented target DDM servers directly in OS/400. The Microsoft OLE DB Provider for AS/400 and VSAM requires OS/400 Version 3 Release 2 or later to support an SNA LU 6.2 connection. The Microsoft OLE DB Provider for AS/400 and VSAM requires OS/400 Version 4 Release 2 or later to support a TCP/IP connection.

On the AS/400 platform, the OLE DB Provider for AS/400 and VSAM supports physical and logical files with an associated external record description file. For specific limitations, see the *AS/400 DDM User's Guide*.

On the mainframe platform, the OLE DB Provider for AS/400 and VSAM supports the following data set types:

Sequential Access Method (SAM) data sets

- Basic Sequential Access Method data sets (BSAM)
- Queued Sequential Access Method data sets (QSAM)

Virtual Storage Access Method (VSAM) data sets

- Entry-Sequenced Data Sets (ESDS)
- Key-Sequenced Data Sets (KSDS)
- Fixed-Length Relative Record Data Sets (RRDS)
- Variable-Length Relative Record Data Sets (VRRDS)
- Relative Record Data Set (RRDS)
- VSAM Alternate Indexes for ESDS and KSDS data sets

Basic Partitioned Access Method (PDS) data sets

- Partitioned Data Set Extended members (PDSE)
- Partitioned data set (PDS) members
- Read-only support for PDSE directories
- Read-only support for PDS directories

The preceding data set types are supported by IBM DFM/MVS.

The following data set types are not supported by DFM/MVS and cannot be accessed using the OLE DB Provider for AS/400 and VSAM:

- VSAM Linear Data Sets (LDS)
- Generation Data Groups (GDG)
- Generation Data Sets (GDS)
- Basic Direct Access Method data sets (BDAM)
- Indexed Sequential Access Method data sets (ISAM)
- Sequential Data Striping data sets
- OpenEdition MVS Hierarchical File System (HFS) files
- Tape Media

All mainframe data sets accessible through IBM Distributed File Manager must be cataloged in an Intersystem communications function (ICF) catalog and reside on direct access storage devices (DASD).

More information can be found in the Host Integration Server 2004 Installation Guide topic
Hardware and Software Requirements.

The OLE DB Provider for AS/400 and VSAM supplied with Microsoft Host Integration Server 2004 supports the following OLE DB and ADO versions:

- **OLE DB version 2.5.** The Host Integration Server 2004 data access features require the run-time libraries for OLE DB version 2.5. On Windows Server 2003 or Windows 2000, these OLE DB libraries are installed as part of the operating system.

- **ADO version 2.5.** The Microsoft Host Integration Server 2004 data access features require the run-time libraries for ADO version 2.5. On Windows Server 2003 or Windows 2000, these ADO libraries are installed as part of the operating system.

OLE DB version 2.0 or later and ADO version 2.0 or later are required to support indexed record access from an ADO consumer application using the OLE DB Provider for AS/400 and VSAM. Indexed support through OLE DB is supported with OLE DB versions 2.0 and later.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Indexed File Access

The Microsoft® OLE DB Provider for AS/400 and VSAM provides both sequential and indexed file access. Sequential file access is provided for all supported file types on the Platforms Supported by the OLE DB Provider for AS/400 and VSAM.

Indexed file access is provided for the following host file types only:

- Mainframe Virtual Storage Access Method (VSAM) data sets.
  - Key-Sequenced Data Sets (KSDS) only when the keys are unique.
  - Fixed-length Relative Record Data Sets (RRDS) only when the keys are unique.
  - Variable-length Relative Record Data Sets (VRRDS) only when the keys are unique.
- AS/400 files.
  - Logical files.
  - Keyed physical files (externally described to the system).

OLE DB and ADO offer several interfaces that enable indexed file access.

The OLE DB Provider for AS/400 and VSAM supports integrated indexes based on the underlying rowset. OLE DB support for indexed file access using the OLE DB Provider for AS/400 and VSAM is available using the **IRowsetIndex**, **IViewFilter**, and **IViewRowset** interfaces.

For more information about indexes, see Chapter 8, "Indexes" and Chapter 16, "Integrated Indexes" in the *OLE DB Programmer's Reference*. To obtain a list of available indexes in a target AS/400 library, a program can call the OLE DB **IDBSchemaRowset::GetRowset** function of the **Session** object requesting a query type of DBSCHEMA_INDEXES.

ADO support for indexed file access using the OLE DB Provider for AS/400 and VSAM is available using the Find method, Filter property, and Sort property on the ADO **Recordset** object. To obtain a list of available indexes in a target AS/400 library using ADO, a program can call the OpenSchema method on the **Connection** object specifying a *QueryType* of **adSchemaIndexes**.

By default, the OLE DB Provider for AS/400 and VSAM uses a server-based cursor. This means that all indexed file access is based on the cursor located over the host file and not a local computer copy of the host file. If you want to use the many client-based cursor service providers available with the Microsoft® Data Access Components (MDAC), you must configure the provider to use a client-based cursor. For example, a client-based cursor is required when using Remote Data Service (RDS) and the Microsoft® Visual Studio® ADO data-bound controls. However, using these controls, an application can access the host files for read-only purposes. If your application needs to access host files with an intent of both reading and writing, and you require indexed file access, your application should use the OLE DB Provider for AS/400 and VSAM server-based cursor.

File and Record Attributes

By definition, the record description is not part of the record I/O architecture in distributed data management (DDM). Traditionally, applications must embed the record format as part of the application program. This creates a burden on the application and is inconsistent with the existing computer-based data access standards, such as OLE DB and ODBC.

To solve this problem, the Microsoft® OLE DB Provider for AS/400 and VSAM uses an external host column description (HCD) file stored on the computer that enables administrators to describe the host record format. At run time, the OLE DB Provider for AS/400 and VSAM transparently converts the host data to computer data using the local HCD information. Before a user program can view or open a VSAM file using the OLE DB Provider for AS/400 and VSAM, the user program must create a valid record description file or entry for the target VSAM file.

The OLE DB Provider for AS/400 and VSAM includes a Microsoft Management Console (MMC) application designed to enable administrators and developers to easily create these local record description files and the necessary registry settings for data sources. The OLE DB DDM Management application makes it relatively easy to create HCD files without knowing the HCD file format. The Host Column Description file format is documented in the Data Integration Programmer's Reference.

The conversion process occurs in two steps. The host data is converted from host EBCDIC to ASCII data by the DDM dynamic-link library (DLL). The HCD file is used during this step to convert host data types to C data types, which are defined in ODBC and based on the SQL data types defined in the ANSI/ISO SQL-92 standard. The second phase of this conversion occurs in the SNAOLEDB DLL where these SQL C data types are converted to the defined OLE DB data types.

The use of an HCD file is not necessary to describe the record format for data stored in the AS/400 computer because the OLE DB Provider for AS/400 and VSAM automatically detects that the target host system is an AS/400 and uses the appropriate DDM commands to retrieve the record description. If the system administrator or the OLE DB application developer wants to use an HCD file instead of retrieving the AS/400 record description, this behavior can be forced by setting the configuration of the **Host Column Description File** property using Data Links.

Configuring the OLE DB Provider for AS/400 and VSAM

Microsoft® Data Access Components (MDAC) includes Data Links, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Links provide a uniform method of creating persistent OLE DB data source object definitions stored in the form of universal data link (.udl) files. The Microsoft® OLE DB Provider for AS/400 and VSAM normally uses Data Links and .udl files for loading and configuring data sources.

Data Links provide a flexible method for finding and saving connection information to OLE DB data sources.

The Data Source Wizard in the new Microsoft Data Access Tool can help to define .udl files. OLE DB consumer applications, such as Data Transformation Services in Microsoft® SQL Server™ can then use the .udl file to connect to IBM data sources, such as DB2 and the mainframe file system.

To use Microsoft OLE DB Provider for AS/400 and VSAM with an OLE DB consumer application, the user must either create a Microsoft data link (.udl) file and call this from the application, or call the OLE DB provider from within the application using a connection string that includes the provider name and other necessary parameters. If an application accesses VSAM data sets, after configuring a data link, a host data description must also be configured using the Data Descriptions tool.

This section contains:

- Creating Data Links for the OLE DB Provider for AS/400 and VSAM
- Configuring Data Links for the OLE DB Provider for AS/400 and VSAM
- Configuring Data Descriptions
- Converting Existing Data Sources

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating Data Links for the OLE DB Provider for AS/400 and VSAM

Data source information must be configured for each AS/400 or mainframe system data source object that is to be accessed using the OLE DB provider. The default parameters for the OLE DB provider are used as the default values for data sources when these parameters are not configured for each data source.

Microsoft Data Links, a core element of Microsoft Data Access Components (MDAC), provide a uniform method for creating file-persistent OLE DB data source object definitions in the form of universal data link (.udl) files.

The Data Source Wizard in the new Microsoft Data Access Tool can help to define .udl files. OLE DB consumer applications, such as Data Transformation Services in Microsoft SQL Server can then use the .udl file to connect to IBM data sources, such as DB2 and the mainframe file system.

Applications, such as the RowsetViewer sample included with the Microsoft Data Access SDK and the MSDN Platform SDK, can open created .udl files and pass the stored initialization string to the OLE DB Provider for AS/400 and VSAM at run time.

Creating New Data Links for the OLE DB Provider for AS/400 and VSAM

You create new Data Links using the Data Source Wizard from the Data Access Tool.

Browsing Data Links for the OLE DB Provider for AS/400 and VSAM

You can browse data sources using the Data Source Browser window in the Data Access Tool.

To find the physical location of the .udl file associated with a data source, right-click the data source and select **Locate** from the context menu. Windows Explorer appears which will display the location of the file.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring Data Links for the OLE DB Provider for AS/400 and VSAM

To edit the properties of a Data Link file, browse to that file in Windows Explorer, and right-click the file and then click **Data Link Properties**. The **Data Link Properties** dialog box appears with several property tabs:

- **General**
- **Security**
- **Summary**
- **Provider**
- **Connection**
- **Advanced**
- **All**

The **General**, **Security**, and **Summary** tabs provide access to general file information for the .udl file that is available for other files and is not related to the Data Link properties. This information includes file location, file type, file size, file dates, file security permissions for access, and descriptive summary information (description and origin properties and values such as title, subject, and author) for the .udl file. The **General** tab has a text box with the name of the Data Link. This file name must end with the .udl extension if the file is to be recognized as a Data Link file. Note that the **Security** and **Summary** tabs are available on NTFS files systems, and not on the older FAT file systems.

This section contains:

- Provider
- Connection

- All

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Provider

The **Provider** tab enables you to select the OLE DB provider (the provider name string) to be used in this .udl file from a list of possible OLE DB providers. Select the Microsoft OLE DB Provider for AS/400 and VSAM. The parameters and fields displayed by the remaining tabs (**Connection**, **Advanced**, and **All**) are determined by the OLE DB provider that is selected.

Connection

The **Connection** tab enables you to configure the basic properties required to connect to a data source. For the Microsoft OLE DB Provider for AS/400 and VSAM, the connection properties include the following values.

Property	Description
Data Source	This is an optional parameter that can be used to describe the data source.
Network	This drop-down list box enables you to select the type of network connection to be used. The allowable options are **TCP/IP Connection** or **SNA Connection**. If **TCP/IP Connection** is selected, click **More Options**, to open a dialog box for configuring TCP/IP network settings. The parameters you can configure include the IP address of the remote host (or a hostname alias for this computer) and the Network Port (TCP/IP port) used for communication with the host. The default value for the Network Port is 446. The IP address of the host has no default value. If **SNA Connection** is selected (using LU 6.2), click **More Options** to open a dialog box for configuring SNA network settings. The parameters you can configure include: the APPC local LU alias, the APPC remote LU alias, and the APPC mode used for communication with the host. The default value for the APPC mode normally defaults to **QPCSUPP**. The local and remote LU alias fields do not have default values.
	This button enables using the Host Integration Security features providing a to access this OLE DB data source. When this button is selected, the **User name** and **Password** fields are dimmed and become inaccessible. The user name and password fields are set based on the Windows Server 2003 or Windows 2000 logon values. When this button is not selected, the **User name** and **Password** fields must normally contain appropriate values to access data sources on hosts.
User name	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The user must click the button that requires a specific user name and password to be entered.
Password	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The **Blank password** check box is only applicable for a Test Connection. To enter a password, the user needs to clear the **Blank password** check box if it is selected. If **Blank password** is selected, a Test Connection with a blank password does not cause the OLE DB provider to prompt for a password. Optionally, the user can choose to save the password in the .udl file by selecting the **Allow saving password** check box. Users and administrators should be warned that this option saves the authentication information (password) in plain text within the .udl file.
Location	The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM. This parameter is not used when connecting to mainframe systems.

It is possible to connect using a specific user name and password defined on the host system or use the feature (often referred to as Windows integrated security). If a specific user name and password is to be used, this information may need to be saved into the .udl file. The user name and password are saved in plain text in the .udl file. For security reasons in these cases, it is imperative that the .udl file be protected with an access control list (ACL) that restricts access to only authorized users. Saving the user name and password in the data link also forces this .udl file to be updated whenever the password associated with the username is changed. So for a variety of reasons, specifying a user name and password is not the preferred authentication option. Using the Windows integrated security option is the preferred method for authentication.

The **Connection** tab also includes a **Test Connection** button that can be used to test the connection parameters. The connection can only be tested after all of the required parameters are entered. When you click this button, an APPC session or a TCP/IP session attempts to be established to the host using the OLE DB Provider for AS/400 and VSAM.

Advanced

The **Advanced** tab enables you to set the network protection level and access permissions. You can set the protection level from the list box of allowable values. Access permissions are set by selecting the appropriate check boxes. For the Microsoft OLE DB Provider for AS/400 and VSAM, these properties include the values listed in the following table.

Property	**Description**
Host CCSID	The character code set identifier (CCSID) matching the column data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to true, character data is converted based on the column CCSID and default ANSI code page. This parameter defaults to **U.S./Canada (37)**. This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
PC Code Page	The PC Code Page parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the Process Binary as Character check box is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows. This parameter defaults to **Latin 1 (1252)**. This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
Read only	When the Read-only parameter is selected in the **Advanced** tab, the OLE DB Provider for AS/400 and VSAM creates a read-only data source by setting the **Mode** parameter to **Read** (DB_MODE_READ). A user has read access to files and cannot do update operations.
Repair Host Keys	This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This parameter defaults to false. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

All

The **All** tab allows users to configure essentially all of the properties for the data source except for the OLE DB provider. The properties available in the **All** tab include properties that can be configured using the **Connection** and **Advanced** tabs as well as optional detailed properties used to connect to a data source. Some of the properties in the **All** tab are required.

These properties on the **All** tab may be edited by selecting a property from the list displayed and selecting **Edit Value**. This button invokes a dialog box for the specific property containing a Property Description describing the property and a Property Value box for making changes.

For the Microsoft OLE DB Provider for AS/400 and VSAM, these properties include the following values.

Property	Description
Affiliate Application	This property is only used when is enabled. It provides the application name to use when retrieving host credentials from the database.
APPC Local LU Alias	The name of the local LU alias configured on the Host Integration Server 2004 computer. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.
APPC Mode Name	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server 2004 computer configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to **QPCSUPP**. This parameter is equivalent to the DBPROP_SNAOLEDB_APPCMODE OLE DB property ID.
APPC Remote LU Alias	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the name of the remote LU alias configured in the Host Integration Server 2004 computer. This parameter is equivalent to the DBPROP_SNAOLEDB_REMOTELU OLE DB property ID.
Cache Authentication	This parameter determines whether the OLE DB provider caches authentication information such as a password in an internal cache. The value of this property (**true** or **false**) is selected from the drop-down list box. This parameter is not currently supported by the OLE DB provider and defaults to **false**. This parameter is equivalent to the DBPROP_AUTH_CACHE_AUTHINFO OLE DB property ID.
Connect Timeout	The amount of time (in seconds) to wait for initialization to complete. This parameter is not currently supported by the OLE DB provider and defaults to **0**. This parameter is equivalent to the DBPROP_INIT_TIMEOUT OLE DB property ID.
Data Source	The data source is an optional parameter that can be used to describe the data source. This parameter is equivalent to the DBPROP_INIT_DATASOURCE OLE DB property ID.
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.

Encrypt Password	This parameter determines whether special security mechanisms are used to ensure password privacy. The value of this property (true or false) is selected from the drop-down list box. This parameter is not currently supported by the OLE DB provider and defaults to **false**. This parameter is equivalent to the DBPROP_AUTH_ENCRYPT_PASSWORD OLE DB property ID.
Extended Properties	This parameter is a string containing provider-specific, extended connection information. Properties passed through this parameter should be delimited by semicolons and will be interpreted by the provider's underlying network client. The use of this property implies that the OLE DB consumer knows how this string is interpreted and used by the OLE DB provider. This parameter should be used only for provider-specific connection information that cannot be explicitly described through the other property parameters. This parameter is equivalent to the DBPROP_INIT_PROVIDERSTRING OLE DB property ID.
Host CCSID	The character code set identifier (CCSID) matching the data as represented on the host. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the host column CCSID and default ANSI code page. This parameter defaults to **U.S./Canada (37)**. This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
Host Column Description File	The fully qualified file name of the distributed data management (DDM) Host Column Description (HCD) file. This parameter can be a UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the system directory below where the Host Integration Server or Client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.
Impersonation Level	The level of impersonation that the server is allowed to use when impersonating the client. This property applies only to network connections other than Remote Procedure Call (RPC) connections. These impersonation levels are similar to those provided by RPC. The values of this property correspond directly to the levels of impersonation that can be specified for authenticated RPC connections, but can be applied to connections other than authenticated RPC. This parameter can be set to one of the following values: **Anonymous**—The client is anonymous to the server. The server process cannot obtain identification information about the client and cannot impersonate the client. **Delegate**—The process can impersonate the client's security context while acting on behalf of the client. The server process can also make outgoing calls to other servers while acting on behalf of the client. **Identity**—The server can obtain the client's identity. The server can impersonate the client for access control list (ACL) checking, but cannot access system objects as the client. **Impersonate**—The server process can impersonate the client's security context while acting on behalf of the client. This information is obtained when the connection is established, and not on every call. The value of this property is selected from the drop-down list box. This parameter defaults to **Impersonate**. This parameter is equivalent to the DBPROP_INIT_IMPERSONATION_LEVEL OLE DB property ID.
Integrated Security	This parameter is a string containing the name of the authentication service used by the server to identify the user using the identity provided by an authentication domain. For example, for Microsoft Windows Server 2003 or Windows 2000 Integrated Security, this is "SSPI" (for Security Support Provider Interface). If this parameter is a null pointer, the default authentication service should be used. When this property is used, no other DBPROP_AUTH* properties are needed and, if provided, their values are ignored. This parameter is equivalent to the DBPROP_AUTH_INTEGRATED OLE DB property ID.
Locale Identifier	This parameter specifies the locale to be used. OLE DB Provider for AS/400 and VSAM does not support this parameter and defaults to **437**. This parameter is equivalent to the DBPROP_INIT_LCID OLE DB property ID.

Location	The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM. This parameter is not used when connecting to mainframe systems. This parameter is equivalent to the DBPROP_INIT_LOCATION OLE DB property ID.
Mask Password	This parameter indicates whether the password should be sent to the data source or enumerator in a masked form. The value of this property (**true** or **false**) is selected from the drop-down list box. The OLE DB provider does not support this parameter and defaults to **false**. This parameter is equivalent to the DBPROP_AUTH_MASK_PASSWORD OLE DB property ID.
Mode	After a connection is established, this parameter represents a bitmask of the access permissions that will be applied to the data file. As implemented by the OLE DB Provider for AS/400 and VSAM, access permissions apply to host file locks and do not apply to record locks. The allowable values include the following: Read, ReadWrite, Share Deny None, Share Deny Read, Share Deny Write, Share Exclusive, and Write. This parameter can be a combination of zero or more of the following: DB_MODE_READ—Read-only. DB_MODE_WRITE—Write-only. DB_MODE_READWRITE—Read/write (DB_MODE_READ | DB_MODE_WRITE). DB_MODE_SHARE_DENY_READ—Prevents others from opening in read mode. DB_MODE_SHARE_DENY_WRITE—Prevents others from opening in write mode. DB_MODE_SHARE_EXCLUSIVE—Prevents others from opening in read/write mode (DB_MODE_SHARE_DENY_READ | DB_MODE_SHARE_DENY_WRITE). DB_MODE_SHARE_DENY_NONE—Neither read nor write access can be denied to others. This parameter is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Network Address	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting through TCP/IP. This parameter is equivalent to the DBPROP_SNAOLEDB_NETADDRESS OLE DB property ID.
Network Port	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target DDM service access port when connecting through TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. The default value is TCP/IP port 446. This parameter is equivalent to the DBPROP_SNAOLEDB_NETPORT OLE DB property ID.
Network Transport Library	This parameter, which represents the dynamic-link library used for transport, designates whether the provider connects through SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are **TCPIP** or **SNA**. If TCPIP is selected, values for Network Address and Network Port are required. The OLE DB Provider for AS/400 and VSAM does not support TCP/IP connectivity to the mainframe. If SNA is selected, values for APPC Local LU Alias, APPC Mode Name, and APPC Remote LU Alias are required. The value of this property (SNA or TCPIP) is selected from the drop-down list box. This value defaults to **SNA**. This parameter is equivalent to the DBPROP_SNAOLEDB_NETTYPE OLE DB property ID.
Password	A valid user name and password are normally required to access data sources on hosts. The password is case-sensitive and is shown as asterisks in this dialog box for security purposes. Optionally, you can choose to save the password in the .udl file by selecting the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file. This parameter is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.

PC Code Page	Indicates the code page used for character code conversion. This property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the default ANSI code page configured in the Windows operating system. If this parameter is set to **Binary** or **65535**, no character code conversions takes place. This parameter defaults to **Latin 1 (1252)**. This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
Persist Security Info	This parameter indicates whether the data source object is allowed to persist sensitive authentication information such as a password along with other authentication information. Optionally, a user can choose to save the password in the .udl file by selecting the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file. The value of this property (**true** or **false**) is selected from the drop-down list box. This parameter defaults to **false**. This parameter is equivalent to the DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO OLE DB property ID.
Process Binary as Character	This parameter indicates whether to process binary fields (CCSID of 65535) as character data type fields on a per data source basis. The **Host CCSID** and **PC Code Page** values are required input parameters when this parameter is true. The value of this property (true or false) is selected from the drop-down list box. The default for this parameter is **false**; do not process binary fields as character fields. This parameter is equivalent to the DBPROP_SNAOLEDB_BINASCHAR OLE DB property ID.
Protection Level	The level of protection of data sent between client and server. The values of this property correspond directly to the levels of protection that can be specified for authenticated RPC connections. This parameter can be set to one of the following values: DB_PROT_LEVEL_NONE—Performs no authentication of data sent to the server. DB_PROT_LEVEL_CONNECT—Authenticates only when the client establishes the connection with the server. DB_PROT_LEVEL_CALL—Authenticates the source of the data at the beginning of each request from the client to the server. DB_PROT_LEVEL_PKT—Authenticates that all data received is from the client. DB_PROT_LEVEL_PKT_INTEGRITY—Authenticates all data received is from the client and that it has not been changed in transit. DB_PROT_LEVEL_PKT_PRIVACY—Authenticates all data received is from the client, that it has not been changed in transit, and protects the privacy of the data by encrypting it. The value of this property is selected from the drop-down list box. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to the connect level of protection. This parameter is equivalent to the DBPROP_INIT_PROTECTION_LEVEL OLE DB property ID.
Read only	When the Read only parameter is selected in the **Advanced** tab, the OLE DB Provider for AS/400 and VSAM creates a read-only data source by setting the **Mode** parameter to **Read** (DB_MODE_READ). A user has read access to files and cannot do update operations.
Repair Host Keys	This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This parameter defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.

Strict Validation	This parameter indicates whether strict validation should be used and defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This parameter is equivalent to the DBPROP_SNAOLEDB_STRICTVAL OLE DB property ID.
User ID	A valid user name is normally required to access data sources on hosts. This value is case-sensitive. This parameter is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

Configuring Data Descriptions

You use the Data Access Tool to describe the host data file format for mainframe access. Use of the host column description (HCD) files is not required for AS/400 files because by default, the data file format is retrieved automatically from the host.

The data descriptions are stored in a local Host Column Description (HCD) file for each data source.

The following table provides the general parameters or attributes that can be configured describing each column in a data description on the **General** property page.

General parameters	Description
Name	The character string that represents the name of the column. This parameter may be null.
Alias	An optional character string that represents an alias label for the column string name. This parameter may be null.
Comment	An optional character string that represents a comment about the column. This attribute may be null.

The following table provides the data type parameters or attributes that can be configured describing each column in a data description in the **Host** property page.

Host parameters	Description
Type	The data type on the host. The allowed data values for host data type are selected from a drop-down list box. (For allowed values, see Host Data Types.)
Length	Length of the field in bytes. Depending on the selected host type, this parameter may not be editable.
Precision	Total number of decimal digits in the column containing numeric data on the host. Depending on the selected host type, this parameter may not be editable. The only numeric data types that require this information are the PACKED and ZONED data types. For these types, this field cannot be null. It must contain a valid numeric value. For all other host types, this parameter is not editable.
Scale	Number of decimal digits to the right of any decimal point for numeric data on the host. Depending on the selected host type, this parameter may not be editable. The only numeric data types that require this information are the PACKED and ZONED host data types. For these types, this field cannot be null. It must contain a valid numeric value. For all other host types, this parameter is not editable.
CCSID	The character code set identifier (CCSID) used on the host. The allowed data values for host CCSID are selected from a drop-down list box. This parameter defaults to the host CCSID configured for the OLE DB provider and is typically U.S./Canada (37).

The following table describes the parameters contained in the **Local** property page.

Local parameters	Description
Type	Indicates the OLE DB data type on the local computer. The allowed data values for the local data type are selected from a drop-down list box. (For allowed values, see Local OLE DB Data Types.)

The OLE DB provider limits the maximum length character field that can be accessed on an AS/400 computer to 32,745. On mainframes, a limitation of the IBM DFM is that SAM data sets and PDSE members are inaccessible if the fixed record length is greater than 32,760 or variable record lengths are greater than 32,756. DFM also limits all VSAM data sets on a mainframe to have a maximum record length no greater than 32,760. If you attempt to access a character field greater than these lengths on an AS/400 or a mainframe, the attempt will fail and can have unpredictable results.

The CCSID setting used by the OLE DB provider must be set to match the CCSID actually used on the host—otherwise, data loss will occur. Some AS/400 systems default to a CCSID of 937 for enabling double-byte character sets (DBCS).

This section contains:

- Host Data Types
- Local OLE DB Data Types

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to

http://go.microsoft.com/fwlink/?linkid=29507.

Host Data Types

The **Host Type** parameter represents the data type used for this column on the host. The allowed values for **Host Type** that can be selected from the drop-down list box are listed in the following table.

Host Type	Description
Binary	Fixed-length binary data (no character conversion). The length must be specified for this data type.
Character	Fixed-length character data. The length must be specified for this data type.
Date	The date represented as character data in the format yyyy-mm-dd that fits into 10 bytes.
DBCS	Fixed-length character data that can contain only DBCS data. The length must be specified for this data type.
DCBS – Mixed Either	Fixed-length character data that can contain either DBCS or alphanumeric data. The length must be specified for this data type.
DCBS – Mixed Open	Fixed-length character data that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with SHIFT+CTRL characters. The length must be specified for this data type.
DBCS – Variable	Variable-length character data with a prefix of 2 bytes for length that contains only DBCS data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Either	Variable-length character data with a prefix of 2 bytes for length that can contain either DBCS or alphanumeric data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Open	Variable-length character data with a prefix of 2 bytes for length that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with SHIFT+CTRL characters. The maximum possible length for the column containing this data type must be specified.
Double	Floating-point data that fits in 8 bytes (64 bits).
Long	Integer data that fits in 4 bytes (32 bits).
Packed	Packed decimal numeric data where the precision and scale are exactly as specified.
Short	Integer data that fits in 2 bytes (16 bits).
Single	Floating-point data that fits in 4 bytes (32 bits).
Time	The time represented as character data in the format hh:mm:ss that fits into 8 bytes.
Time Stamp	Time stamp represented as characters in the format yyyy-mm-dd hh:mm:ss.ffffff that fits into 19 bytes.
Variable Binary	Variable-length binary data represented as an unsigned character array with a prefix of 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Variable Character	Variable-length character data with a prefix of 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Zoned	Zoned decimal numeric data where the precision and scale are exactly as specified.

> **Note** The floating-point data format assumed by the OLE DB Provider for AS/400 and VSAM depends on the host. For AS/400, the host floating-point data format is assumed to be IEEE. On mainframe hosts, floating-point data types are assumed to be in IBM floating-point formats. Because OLE DB supports the IEEE floating-point format, data conversion errors can occur when converting the extreme values of VSAM floating-point data in IBM format to IEEE floating-point data by the OLE DB provider. These conversion errors occur because the default IBM floating-point formats and the IEEE floating-point format use a different number of bits for the mantissa and exponent when representing a floating-point number.

Local OLE DB Data Types

The **Local Type** represents the OLE DB data type used for this column on the computer. The OLE DB data types are defined in the OLE DB specifications and **#defines** can be found in the Oledb.h file. The allowed values for **Local Type** that can be selected from the drop-down list box are listed in the following table.

Host Type	**Description**
DBTYPE_BYTES	Fixed-length binary data represented as an unsigned char array.
DBTYPE_DBDATE	The OLE DB DBDATE typedef struct as defined in the Oledb.h file.
DBTYPE_DBTIME	The OLE DB DBTIME typedef as defined in the Oledb.h file.
DBTYPE_DBTIMESTAMP	The OLE DB DBTIMESTAMP typedef struct as defined in the Oledb.h file.
DBTYPE_DECIMAL	The OLE DB DECIMAL typedef struct as defined in the Oledb.h file.
DBTYPE_I2	Integer data stored in 2 bytes (16 bits).
DBTYPE_I4	Integer data stored in 4 bytes (32 bits).
DBTYPE_NUMERIC	The OLE DB NUMERIC typedef struct as defined in the Oledb.h file.
DBTYPE_R4	Single precision IEEE floating-point data stored in 4 bytes (32 bits).
DBTYPE_R8	Double precision floating-point data stored in 8 bytes (64 bits).
DBTYPE_STR	Fixed and variable length character data.

Converting Existing Data Sources

The OLE DB management console that was previously used in SNA Server 4.0 and SNA Server 4.0 with Service Pack 1 (SP1) for configuring OLE DB Provider for AS/400 and VSAM data sources has been removed and replaced by Microsoft Data Links and the Data Access Tool. Microsoft Data Links is a component of Microsoft Data Access Components (MDAC) 2.5. On Windows Server 2003 or Windows 2000, MDAC 2.5 is installed as part of the operating system.

Existing registry-based OLE DB Provider for AS/400 and VSAM data sources that were created in SNA Server 4.0 and SNA Server 4.0 SP1 can be converted to .udl files using the Reg2udl tool supplied with Host Integration Server. The Reg2Udl tool is not installed as part of Host Integration Server, but is located on the Host Integration Server 2004 CD in the \Options\Maintenance folder.

When a duplicate .udl file is present in the destination folder, the Reg2udl tool will increment the file name by 1 (Data.udl will become Datat1.udl, for example). This may cause existing applications to fail because the OLE DB Provider for AS/400 and VSAM is looking for the existing name (Data.udl).

Manual conversion of registry-based data sources to .udl files may be necessary in some cases when Setup for Host Integration Server 2004 is used. A version of the Reg2udl tool (for Intel) can be found in the \Support\Utilities folder on the Host Integration Server 2004 CD.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Programming Considerations Using the OLE DB Provider for AS/400 and VSAM

All the Microsoft® OLE DB objects exposed by the Microsoft® OLE DB Provider for AS/400 and VSAM support aggregation. Each OLE DB object has two classes, one that delegates its **IUnknown** calls and one that controls the object as a whole.

The apartment-threading model is supported, allowing multiple threads to access the objects safely. This is the only threading model supported.

When working with the Data Environment (DE) commands within Microsoft® Visual Studio® 6.0, you must use a period (.) as a delimiter when specifying the AS/400 Library or File path. For example, the following is valid syntax when opening the AUTHORS physical file in the PUBS library on an AS/400:

```
EXEC OPEN PUBS.AUTHORS
```

To use the ADO Recordset Find method or the ADO Filter property, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If this method is used on an AS/400 nonkeyed physical file or any other mainframe file type, this method fails.

When using RRDS files, the **Find** method fails when a search is executed using a column name. For example, the following Microsoft® Visual Basic® code will fail on an RRDS file with a column called Area:

```
RecordSet.Find "Area > '1111'", 0, adSearchForward, adBookmarkFirst
```

The error description indicates that a bookmark is invalid.

RRDS files do not have an index based on a column name and the value of the column data, so the syntax to the preceding ADO **Find** method call does not work for RRDS files. In a COBOL program designed to dynamically find a record in an RRDS file, the record position would be passed. For example, for the 75th record in the file, a COBOL program would pass a value of 75. The COBOL program would then use the returned record number and the record length to calculate the position of the first byte of the record in the file.

The SQL command parser of the Data Environment does not accept the forward slash (/) character. The OLE DB Provider for AS/400 and VSAM automatically substitutes a forward slash in place of the period and passes the correctly formatted path to your AS/400 computer.

When using the Data Environment with Microsoft Visual Basic 6.0, it is possible to get the following error when accessing the OLE DB Provider for AS/400 and VSAM:

```
"File is in use by another process. Unspecified error"
```

This error can occur after a data source has been configured for the OLE DB Provider for AS/400 and VSAM using the Data Links property page and a command is added using the Data Environment where the command added is the following:

```
"EXEC OPEN filename"
```

Using the Data Environment and selecting **Run** for this command can result in the preceding error. The Data Environment is opening the file and then trying to open it a second time based on the command to execute without closing the first copy. Depending upon the share options of the data set and the DBPROP_INIT_MODE property set for this data source, this error can occur and the user can be locked out of the AS/400 or VSAM file.

The OLE DB Provider for AS/400 and VSAM does not support the following Microsoft® SQL Server™ features:

- Data Transformation Services (DTS)
- Replication
- Distributed queries as a linked server

When operating on large VSAM files and only querying data on a subset of the records, using the **Filter** property is not desirable because of the performance impact. The entire VSAM file is transferred to the client for filtering. A better solution is to use the server cursor engine and the **Find** method.

The syntax supported by the OLE DB Provider for AS/400 and VSAM for command text is as follows:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 using a 5250 terminal session. For a detailed list of possible commands, see the *OS/400 CL Reference* for your platform.

The syntax supported by the OLE DB Provider for AS/400 and VSAM to open a rowset (table) using command text is as follows:

```
EXEC OPEN FileName
```

where *FileName* represents one of the following host file naming conventions listed in the following table.

Host file type	File naming convention
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned data sets (PDSs)	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILENAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY.FILENAME(MEMBER)

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax used to open a rowset using command text is as follows:

```
EXEC OPEN LIBRARY/FILE("NAMES.DAT")
```

The distributed queries feature of SQL Server is sometimes referred to as the Distributed Query Processor (DQP).

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Record Access and Data Conversion

The design of the OLE DB APIs is similar to the APIs provided by ODBC and other ISAM APIs. The APIs are handle-based. After opening a file, the application can determine the buffer size required to store a row, use the cursor APIs to move, and optionally retrieve one or more rows of data using the row-level binding.

Data is converted to default C data types as defined in ODBC, as illustrated in the following table.

Host data type	**Default C data type**
Binary	unsigned char binary[]
Character	char string[]
Date (in character format)	date struct
Double	Double
Long	Int
Packed	unsigned char number[]
Short	Short
Single	Float
Time (in character format)	time struct
Time Stamp (in character format)	timestamp struct
Variable Binary	unsigned char binary[]
Variable Character	char string[]
Zoned	unsigned char number[]

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example). However, truncation and conversion errors can occur that will not be reported by the OLE DB Provider for AS/400 and VSAM.

The OLE DB Provider for AS/400 and VSAM has a number of other limitations:

- Positive signed floating-point values cannot be read from ZONED DECIMAL fields.
- No floating point values can be inserted into ZONED DECIMAL fields.
- No values can be inserted into single-precision FLOATING POINT fields.
- Positive signed floating-point values cannot be inserted into PACKED DECIMAL fields.
- The ADO **Find** method fails to locate the first record when the key is multiple columns and the first column is a VARCHAR or TIME data type.

You can use the OLE DB Provider for AS/400 and VSAM to access a System/36 computer. However, the automatic mapping from host to client does not occur correctly when you attempt to access the System/36 host. Instead, you must manually map the data types using a host column description (HCD) file. The following table indicates the data types you must map to when accessing a System/36 computer.

Host data type	**OLE DB data type**	**Comments**
Character	DBTYPE_STR	Null-terminated ASCII character string.
Zoned	DBTYPE_STR	The NUMERIC typedef structure defined in OLEDB.H. This is an exact numeric value with a fixed precision and fixed scale.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Record Locking

Distributed data management (DDM) supports record locks so that a requester can perform intended operations on a record without interference from concurrent users. Record locks are used only when the requester opens a file with intent to update the file and specifies that the file is to be shared with another user. Two types of record locks are supported. Record locks are handled automatically by the Microsoft OLE DB Provider for AS/400 and VSAM whenever users call **IRowsetChange::SetData** (in immediate mode) or **IRowsetUpdate** (in the delayed mode). The OLE DB Provider for AS/400 and VSAM locks the record, updates the record, and then releases the lock.

Client Cursor Engines Using the OLE DB Provider for AS/400 and VSAM

The Microsoft Data Access Components (MDAC) supports the option of a client cursor engine. This feature is implemented as part of OLE DB, ADO, and Remote Data Services (RDS). When using ADO, a client cursor is enabled by setting the **CursorLocation** property on the recordset to **adUseClient**.

The OLE DB Provider for AS/400 and VSAM does not support any updating capabilities when used with a client cursor engine. If a client cursor engine is enabled using RDS or ADO, the OLE DB provider cannot be used to update data on the host. The ADO recordset is treated as if it were read-only.

Error Codes Returned by the OLE DB Provider for AS/400 and VSAM

The Microsoft OLE DB Provider for AS/400 and VSAM supports ranges of error codes, as listed in the following table.

Error code range	Source	Definition
1–100	Ddmapi.dll	OLE DB error codes (see OLE DB Provider for AS/400 and VSAM).
256–511	Ddm.dll	IBM DDM documentation.
512–higher	Ddmwappc.dll	Errors specific to the OLE DB Provider for AS/400 and VSAM.

An invalid local LU alias at connect time yields "Network Error" instead of "Invalid Local LU Alias" error. No error is reported when connecting using a nonexistent default library value.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Host Column Description

The Microsoft® OLE DB Provider for AS/400 and VSAM uses a host column description (HCD) file to specify how data on the host is converted by the OLE DB provider. These HCD files are not necessary when used with IBM AS/400 computers because the host data format is automatically determined by the OLE DB provider. When used with AS/400 computers, the OLE DB provider uses default conversions from host data type to OLE DB data types. However, HCD files can be used with AS/400 computers to override the host data format and specify a particular local OLE DB data type to which the data is to be converted.

The following topics describe the host column description file format in detail and provide an example of an HCD file for illustration.

This section contains:

- Host Column Description File Format
- Host Column Description Attributes
- Host Column Description Example File

Host Column Description File Format

The Microsoft® OLE DB Provider for AS/400 and VSAM uses a host column description (HCD) file to describe the format of data files on IBM mainframes and dictate how the data in columns or fields in these files is to be converted by the OLE DB provider. Host column description files can also be used for data on AS/400 computers to override the data format description maintained by the AS/400 host.

The default naming convention for the HCD file is <*data source*>.hcd, where <*data source*> is the remote LU alias, and .hcd is the file extension of the record description file. For example, if the remote LU alias configured on Host Integration Server is named ABC01234, the host column description file would be named ABC01234.hcd as the default. Any name may be used for an HCD file as long as the file extension is .hcd.

All the Virtual Storage Access Method (VSAM) files that have local record descriptions are listed in the [Files] section of the record description file. Each file that is listed in the [Files] section has a record description section, and that section name is the same as the file name. For example, a VSAM file named PUBS/AUTHORS has its record description saved in the [PUBS/AUTHORS] section.

The first key of a record description section is the number of the columns for the file. The syntax is as follows:

```
numcol=<number of columns>
```

Where <*number of columns*> is the actual number of columns described in the section. Each column of a file is described by one key. The naming convention for the key name is as follows:

```
col<column number>
```

For example the ninth column's key is **col9**. Each key has an attribute list that contains eleven concatenated attributes that describe the column. Attributes are separated by semicolons.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Host Column Description Attributes

Attributes are shown in the following table.

Attribute	Field number	Description
Reserved	1	Always zero
Column Name	2	Character string
Alias	3	Character string
Precision	4	Numeric value
Scale	5	Numeric value
Length	6	Numeric value
Host Type	7	Keyword representing the host data type
OLE DB Type	8	Keyword representing the local OLE DB data type
Nullable	9	Y or N
CCSID	10	Numeric value
Title	11	Character string

Column Name

The Column Name attribute is the character string that represents the name of the column. This attribute may be null.

Alias

The Alias attribute is an optional character string that represents an alias label for the column string name. This attribute may be null.

Precision

The Precision attribute is the total number of decimal digits in the column containing numeric data on the host. The only two fixed-point numeric data types that require this information are the NUMERIC and DECIMAL keyword data types, and for these types this field cannot be null and must contain a valid numeric value.

The precision must be set the same as the length attribute for CHAR and BINARY keyword data types, and set to zero for the other types. (Note that under ODBC, the precision was also used to indicate the length of nonnumeric data types including character, date, time, and binary data types.) Precision has no default value and must not be left null.

Scale

The Scale attribute is the number of decimal digits to the right of any decimal point for numeric data on the host. The only two numeric data types that require this information are the NUMERIC and DECIMAL keyword data types, and for these types this field cannot be null and must contain a valid numeric value. For other numeric (the SINGLE and DOUBLE keywords, for example) and nonnumeric data types (binary, character, date, time, and timestamp), the scale should be set to zero. This field must not be left null and must contain a numeric value.

Length

The Length attribute is the total length of the data on the host. This field must not be left empty and must contain a numeric value.

Host Type

The Host Type attribute is a keyword value that represents the data type of the host data. This keyword value is based on standard data types used on AS/400 and VSAM files. If no keyword is entered, this attribute defaults to the BINARY keyword. The following table describes the allowable types for AS/400 and VSAM.

Host type name	Keyword	Comment
Binary	BINARY	Fixed-length binary data (no character code conversions). The length must be specified.
Character	CHAR	Fixed-length character data. The length must be specified.
Date	DATE	The date represented as character data in the format yyyy-mm-dd that fits in 10 bytes.
DBCS	DBCS	Fixed-length character data that can contain only DBCS data.
DCBS – Mixed Either	MIXED_EITHER	Fixed-length character data that can contain either DBCS or alphanumeric data.
DCBS – Mixed Open	MIXED_OPEN	Fixed-length character data that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with SHIFT+CTRL characters.
DBCS – Variable	VARDBCS	Variable-length character data with a prefix of 2 bytes for length that contains only DBCS data. The maximum possible length for the column containing this data type must be specified.

DCBS – Variable Mixed Either	VARMIXED_EITHER	Variable-length character data with a prefix of 2 bytes for length that can contain either DBCS or alphanumeric data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Open	VARMIXED_OPEN	Variable-length character data with a prefix of 2 bytes for length that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with SHIFT+CTRL characters. The maximum possible length for the column containing this data type must be specified.
Double	DOUBLE	Floating-point data that fits in 8 bytes (64 bits).
Long	LONG	Integer data that fits in 4 bytes (32 bits).
Long Variable Binary	LONG VARBINARY	Variable-length binary data represented as an unsigned character array with prefix 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Long Variable Character	LONG VARCHAR	Variable-length character data with a prefix of 2 bytes for the length. The maximum possible length for the column containing this data type must be specified.
Packed	PACKED	Packed decimal numeric data where the precision and scale are exactly as specified.
Short	SHORT	Integer data that fits in 2 bytes (16 bits).
Single	SINGLE	Floating-point data that fits in 4 bytes (32 bits).
Time	TIME	The time represented as character data in the format hh:mm:ss that fits in 8 bytes.
Time Stamp	TIMESTAMP	Timestamp represented as characters in the format yyyy-mm-dd hh:mm:ss.ffffff that fits in 19 bytes.
Variable Binary	VARBINARY	Variable-length binary data represented as an unsigned character array with prefix 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Variable Character	VARCHAR	Variable-length character data with a prefix of 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Zoned	ZONED	Zoned decimal numeric data where the precision and scale are exactly as specified.

Note that the OLE DB provider limits the maximum length character field that can be accessed on an AS/400 computer to 32,745. Attempting to access a character field greater than this length on an AS/400 computer can have unpredictable results and can cause the OLE DB provider to stop responding.

Note that the floating-point data format assumed by the OLE DB Provider for AS/400 and VSAM depends on the host. For AS/400, the host floating-point data format is assumed to be IEEE. On mainframe hosts, floating-point data types are assumed to be in IBM floating-point formats. Because OLE DB supports the IEEE floating-point format, data conversion errors can occur when converting the extreme values of VSAM floating-point data in IBM format to IEEE floating-point data by the OLE DB provider.

Note that the DECIMAL, FLOAT, INTEGER, NUMERIC, REAL, and SMALLINT keywords should not be used in HCD files and should be replaced with the newer keywords as follows:

- The DOUBLE keyword replaces the FLOAT keyword.
- The LONG keyword replaces the INTEGER keyword.
- The PACKED keyword replaces the NUMERIC keyword.
- The SHORT keyword replaces the SMALLINT keyword.
- The SINGLE replaces the REAL keyword.
- The ZONED keyword replaces the DECIMAL keyword.

The Data Descriptions management console snap-in provided with Host Integration Server does not work properly with HCD files containing these older keywords and will give unpredictable results.

OLE DB Type

The OLE DB Type attribute is a keyword that represents the data type of the local personal computer data. This keyword value is based on the standard OLE DB data types as defined in the OLEDB.H header file included with the OLE DB SDK version 1.5 and later. The data structures for the date, time, and timestamp C data types are defined as typedefs in the OLEDB.H header file included with the OLE DB SDK. Similar data types are also used by ODBC. If no keyword is entered, this attribute defaults to the BINARY keyword.

For the decimal and numeric host data types, the OLE DB Type attribute must be set to DBTYPE_STR. These two fixed-point numeric types are currently converted to character data strings by the DDM layer of the Microsoft OLE DB Provider for AS/400 and VSAM. If these host types are converted to any of the defined OLE DB numeric C types, numeric accuracy can be lost.

The allowable types are listed in the following table.

OLE DB type name	Keyword	Comment
DBTYPE_BYTES	BINARY	Fixed-length binary data represented as an unsigned char array.
DBTYPE_DBDATE	DATE	The OLE DB DBDATE typedef struct as defined in the OLEDB.H header file.
DBTYPE_DBTIME	TIME	The OLE DB DBTIME typedef as defined in the OLEDB.H header file.
DBTYPE_DBTIMESTAMP	TIMESTAMP	The OLE DB DBTIMESTAMP typedef struct as defined in the OLEDB.H header file.
DBTYPE_DECIMAL	DECIMAL	The OLE DB DECIMAL typedef struct as defined in the OLEDB.H header file.
DBTYPE_I2	SHORT	Integer data stored in 2 bytes (16 bits).
DBTYPE_I4	LONG	Integer data stored in 4 bytes (32 bits).
DBTYPE_NUMERIC	NUMERIC	The OLE DB NUMERIC typedef struct as defined in the OLEDB.H header file.
DBTYPE_R4	FLOAT	Floating-point data stored in 4 bytes (32 bits).
DBTYPE_R8	DOUBLE	Floating-point data stored in 8 bytes (64 bits).
DBTYPE_STR	CHAR	Character data.
DBTYPE_I1	Not applicable	Not supported (signed tiny integer stored in one byte, 8 bits).
DBTYPE_I8	Not applicable	Not supported (signed long integer stored in eight bytes, 64 bits).
DBTYPE_UI1	Not applicable	Not supported (unsigned tiny integer stored in one byte, 8 bits).
DBTYPE_UI2	Not applicable	Not supported (unsigned short integer stored in two bytes, 16 bits).
DBTYPE_UI4	Not applicable	Not supported (unsigned long integer stored in four bytes, 32 bits).
DBTYPE_UI8	Not applicable	Not supported (unsigned long integer stored in eight bytes, 64 bits).

Nullable

The Nullable attribute indicates whether this field can be a null value. Legal values for this field are Y or N. If this field is empty, the default value for nullable is N. The current version of the OLE DB Provider for AS/400 and VSAM does support nullable fields, so this value must be set to N.

CCSID

The character code set identifier (CCSID) attribute indicates the character set used on the host. If this field is empty, the default value for CCSID is set to EBCDIC US English (37). The CCSID setting used by the OLE DB provider must be set to match the CCSID actually used on the host, otherwise data loss will occur. Note that some AS/400 systems default to a CCSID of 937, rather than 37, for enabling double-byte character sets (DBCS).

If the CCSID is set to 0 or 65535, no character translation will take place when converting character data from the host to the personal computer by the OLE DB provider. The allowable values for CCSID when used with OLE DB Provider for AS/400 and VSAM are listed in the following table.

EBCDIC character set	CCSID value
U.S./Canada	37
Germany	273
Denmark/Norway	277
Finland/Sweden	278
Italy	280
Latin America/Spain	284
United Kingdom	285
France	297
International	500

Note that this value needs to correspond to the CCSID used on the host.

Title

The Title attribute is an optional character string that represents a comment describing the column. This attribute may be null.

Host Column Description Example File

The following is an example for a host column description (HCD) file containing two sample database file descriptions—SAMPLE/ACCOUNTS and PUBS/AUTHORS. The first sample file (SAMPLE/ACCOUNTS) has four columns of data while the second example (PUBS/AUTHORS) has nine columns that must be described.

```
[files]
SAMPLE/ACCOUNTS=1
PUBS/AUTHORS=1

[SAMPLE/ACCOUNTS]
numcol=4
col1=0;CUST_NO;CUST_NO;8;0;0;ZONED;LONG;N;37;;
col2=0;CUST_NAME;CUST_NAME;0;0;40;CHAR;CHAR;N;37;;
col3=0;BALANCE;BALANCE;10;2;0;ZONED;FLOAT;N;37;;
col4=0;LAST_ACC;LAST_ACC;0;0;26;TIMESTAMP;TIMESTAMP;N;37;;

[PUBS/AUTHORS]
NumCol=9
Col1=0;AU_ID;AU_ID;11;0;11;CHAR;CHAR;N;37;;
Col2=0;AU_LNAME;AU_LNAME;0;0;40;VARCHAR;CHAR;N;37;;
Col3=0;AU_FNAME;AU_FNAME;0;0;20;VARCHAR;CHAR;N;37;;
Col4=0;PHONE;PHONE;0;0;12;CHAR;CHAR;N;37;;
Col5=0;ADDRESS;ADDRESS;0;0;40;VARCHAR;CHAR;N;37;;
Col6=0;CITY;CITY;0;0;20;VARCHAR;CHAR;N;37;;
Col7=0;STATE;STATE;2;0;2;CHAR;CHAR;N;37;;
Col8=0;ZIP;ZIP;0;0;5;CHAR;SHORT;N;37;;
Col9=0;CONTRACT;CONTRACT;0;0;9;BINARY;BINARY;N;37;;
```

Conversion from Host to OLE DB Data Types

The external record description for data files residing on mainframes is configured in a host column description (HCD) file using the SNA OLE DB management snap-in. This HCD file is used to convert from host EBCDIC data types to ASCII C data types for the computer in the Distributed Data Management (DDM) dynamic-link library (DLL). These C data types are then mapped to OLE DB data types by the SNAOLEDB DLL.

This section contains:

- Default OLE DB Data Types
- DBDATE
- DBTIME
- DBTIMESTAMP
- DECIMAL
- NUMERIC

Default OLE DB Data Types

The following table indicates the default OLE DB data types that result from the mapping of the host data types by the Microsoft OLE DB Provider for AS/400 and VSAM.

Host data type	**OLE DB data type**	**Comments**
Binary	DBTYPE_BYTES	A fixed-length array of bytes (unsigned char).
Character	DBTYPE_STR	Null-terminated ASCII character string.
Date	DBTYPE_DBDATE	The DBDATE typedef struct defined in OLEDB.H header file.
DBCS	DBTYPE_STR	Null-terminated ASCII character string.
DCBS – Mixed Either	DBTYPE_STR	Null-terminated ASCII character string.
DCBS – Mixed Open	DBTYPE_STR	Null-terminated ASCII character string.
DBCS – Variable	DBTYPE_STR	Null-terminated ASCII character string.
DCBS – Variable Mixed Either	DBTYPE_STR	Null-terminated ASCII character string.
DCBS – Variable Mixed Open	DBTYPE_STR	Null-terminated ASCII character string.
Double	DBTYPE_R8	8-byte floating-point data.
Float	DBTYPE_R8	8-byte floating-point data.
Long Integer	DBTYPE_I4	4-byte signed integer.
Long Variable Binary	DBTYPE_BYTES	A fixed-length array of bytes (unsigned char).
Long Variable Character	DBTYPE_STR	Null-terminated ASCII character string.
Packed	DBTYPE_DECIMAL	The DECIMAL structure typedef defined in OLEDB.H. This is an exact numeric value with a fixed precision and fixed scale.
Real	DBTYPE_R4	4-byte floating-point data.
Short	DBTYPE_I2	2-byte signed integer.
Single	DBTYPE_R4	4-byte floating-point data.
Time	DBTYPE_DBTIME	The DBTIME typedef defined in OLEDB.H header file.
Time Stamp	DBTYPE_DBTIMESTAMP	The DBTIMESTAMP typedef defined in OLEDB.H header file.
Variable Binary	DBTYPE_BYTES	A fixed-length array of bytes (unsigned char).
Variable Character	DBTYPE_STR	Null-terminated ASCII character string.
Zoned	DBTYPE_NUMERIC	The NUMERIC typedef structure defined in OLEDB.H. This is an exact numeric value with a fixed precision and fixed scale.

The host Binary, VarBinary, and Long VarBinary data types are converted to SQL_C_CHAR type by the DDM DLL and mapped to the DBTYPE_BYTES data type by the SNAOLEDB DLL. The host Zoned data type is converted to SQL_C_CHAR type by the DDM DLL and mapped to the DBTYPE_NUMERIC data type by the SNAOLEDB DLL. The host Packed data type is converted to SQL_C_CHAR type by the DDM DLL and mapped to the DBTYPE_DECIMAL data type by the SNAOLEDB DLL.

DBDATE

The **DBDATE** structure typedef is defined as follows:

```
typedef struct tagDBDATE {
    SHORT  year;
    USHORT month;
    USHORT day
} DBDATE;
```

Members

year
The year (0 to 9999) is measured from 0 A.D.

month
The month ranges from 1 to 12 representing January through December.

day
The day ranges from 1 to a maximum of 31, depending on the number of days in the month.

DBTIME

The **DBTIME** structure typedef is defined as follows:

```
typedef struct tagDBTIME {
    USHORT hour;
    USHORT minute;
    USHORT second
} DBTIME;
```

Members

hour
The hour ranges from 0 to 23.

minute
The minute ranges from 0 to 59.

second
The second ranges from 0 to 59.

DBTIMESTAMP

The **DBTIMESTAMP** structure typedef is defined as follows:

```
typedef struct tagDBTIMESTAMP {
    SHORT  year;
    USHORT month;
    USHORT day;
    USHORT hour;
    USHORT minute;
    USHORT second;
    ULONG  fraction
} DBTIMESTAMP;
```

Members

year
The year (0 to 9999) is measured from 0 A.D.

month
The month ranges from 1 to 12 representing January through December.

day
The day ranges from 1 to a maximum of 31, depending on the number of days in the month.

hour
The hour ranges from 0 to 23.

minute
The minute ranges from 0 to 59.

second
The second ranges from 0 to 59.

fraction
The fraction represents billionths of a second ranging from 0 to 999,999,999.

DECIMAL

The **DECIMAL** typedef structure is an exact numeric value with a fixed precision and fixed scale, stored in the same way as in OLE Automation. The **DECIMAL** typedef structure is defined as follows:

```
typedef struct tagDECIMAL {
    USHORT wReserved;
    union {
        struct {
            BYTE scale;
            BYTE sign;
         };
        USHORT signscale;
    };
    ULONG Hi32;
    union {
        struct {
             ULONG Lo32;
             ULONG Mid32;
          };
         ULONGLONG Lo64;
    };
} DECIMAL;
```

Members

wReserved
This member is reserved and should be 0.

scale
Specifies the number of digits to the right of the decimal point and ranges from 0 to 28.

sign
The sign is 0 if positive, 0x80 if negative.

Hi32
The high part of the integer (32-bit aligned).

Mid32
The middle part of the integer (32-bit aligned).

Lo32
The low part of the integer (32-bit aligned).

For example, to specify the number 12.345, the scale is 3, the sign is 0, and the number stored in the 12-byte integer is 12345.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

NUMERIC

The **NUMERIC** typedef structure is an exact numeric value with a fixed precision and fixed scale. The **NUMERIC** typedef structure is defined as follows:

```
typedef struct tagNUMERIC {
    BYTE precision;
    BYTE scale;
    BYTE sign;
    BYTE val[16];
} DB_NUMERIC;
```

Members

precision
The maximum number of digits in base 10.

scale
The number of digits to the right of the decimal point.

sign
The sign is 1 for positive numbers, and 0 for negative numbers.

val
A number stored as a 16-byte scaled integer, with the least significant byte on the left.

For example, to specify the base 10 number 20.003 with a scale of 4, the number is scaled to an integer of 200030 (20.003 shifted by four tens digits), which is 186AA in hexadecimal. The value stored in the 16-byte integer is 5E 0D 03 00 00 00 00 00 00 00 00 00 00 00 00 00, the precision is the maximum precision, the scale is 4, and the sign is 1.

Character Code Conversions

Character code conversions under the OLE DB Provider for AS/400 and VSAM are controlled by a hierarchy of parameters. When connecting to mainframes all of these parameters are controlled on the personal computer. However, when connecting to data sources on the AS/400, parameter settings on the AS/400 as well as parameter settings on the personal computer can be involved.

The character code set identifier (CCSID) used by the host for a data source can be specified in several locations. The Host CCSID setting used by the OLE DB provider must be set to match the CCSID actually used on the host; otherwise data loss will occur. Note that some AS/400 systems default to a CCSID of 937 rather than 37 for enabling double-byte character sets (DBCS).

The following table illustrates the separate hierarchy controlling the Host CCSID parameter on the SNA client, AS/400 host, and mainframe host.

SNA client	**AS/400 host**	**Mainframe host**
SNA OLE DB provider (defaults to U.S./Canada 37)	System (DSPSYSVAL, QCCSID)	None. Determined by the Data Description (HCD file) on the SNA Client.
Data Source (the Host CCSID parameter in the Data Links file describing the Data Source)	User identifier (wrk usrprf)	
Data Description (HCD file)	Job (dspjob, crtjobd)	
	File (dspfd, crtpf)	
	Column (dspffd)	

Note Only those fields in a Data Source that contain character data are affected by the Host CCSID parameters and character conversions.

This section contains:

- Host CCSID and SNA OLE DB Provider
- Host CCSID and Data Source
- Host CCSID and Data Description
- Host CCSID and the Process Binary As Character Parameter

Host CCSID and SNA OLE DB Provider

The Host CCSID setting at the OLE DB provider level defaults to U.S./Canada (37).

Host CCSID and Data Source

The Host CCSID setting at the Data Source level is configured using Data Links for each Data Source. The **Host CCSID** parameter is configured under the **All** tab of the **Data Links** dialog box.

Valid values for the Host CCSID registry setting are any CCSID, including 65535. If the Host CCSID attribute is set to 65535, no character conversion occurs (the data is treated as binary). If the Host CCSID setting at the Data Source level does not exist, the value for Host CCSID defaults to the value at the SNA OLE DB provider level.

Host CCSID and Data Description

A Host CCSID attribute can be applied at the Data Description level. Each column in a host column description (HCD) file can have a Host CCSID attribute that determines how the character data in the column is to be converted. These attributes in the HCD file at the Data Description level should be configured using the SNA OLE DB management console snap-in. (For more information, see Configuring Data Descriptions) Valid values are any CCSID including 65535.

The Host CCSID attribute at the column Data Description level can be any value and may be empty. A Host CCSID value at the Data Description level overrides the value specified at the Data Source and OLE DB provider levels. If the Host CCSID is blank, the value for Host CCSID defaults to the value at the Data Source level. If the Host CCSID attribute is set to 65535, no character conversion occurs (the data is treated as binary).

Host CCSID and the Process Binary As Character Parameter

There is a Data Source parameter configurable using Data Links that affects whether binary data is considered as character data and is converted based on the Host CCSID setting. This **Process Binary As Character** parameter defaults to *false*. If this parameter is *false*, binary data is not treated as character (binary data is not affected by the Host CCSID setting). If this parameter is set to *true*, binary data is converted based on the Host CCSID setting.

This parameter is configured for each Data Source using Data Links under the **All** tab of the **Data Links** dialog box.

OLE DB Provider for DB2 Programmer's Guide

Microsoft® OLE DB Provider for DB2 enables users to access IBM Data Base 2 (DB2) from within an OLE-aware application. The object linking and embedding database (OLE DB) is a standard set of interfaces that provides heterogeneous access to disparate sources of information located anywhere—file systems, e-mail folders, and databases. The OLE DB Provider for DB2 combines the universal data access of OLE DB with the IBM Distributed Relational Database Architecture (DRDA).

Organizations have invested in secure, robust, enterprise-wide data storage and management systems. DRDA is a set of rules for distributing or extending relational data from one computer to another, such as from a personal computer server to an IBM DB2 database server running on a mainframe or an AS/400 computer. By combining the OLE DB and DRDA architectures, Microsoft enables organizations to preserve their investments in existing data management infrastructure, while extending universal data access to all enterprise-wide data sources.

For application programming interface (API) references and other technical information about OLE DB providers, see the OLE DB Providers Programmer's Reference section of the software development kit (SDK).

For sample code using the OLE DB Provider and ODBC Driver, see OLE DB Provider and ODBC Driver Samples section of the SDK.

This section contains:

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Goals of the OLE DB Provider for DB2

Relational database management systems (RDBMS) are one of the major sources of mission-critical information in today's enterprise organizations. Relational database technology enables departments and individual users to save their information in centrally managed database stores that can be easily maintained by the organization's information systems group. Specific query tools designed for accessing relational database systems have added greater flexibility and ease of access to this information.

These same enterprises rely on vast networks of personal computers to enable their users to achieve business goals. End users invariably rely on network e-mail; Microsoft® Windows® productivity applications, such as Microsoft Office; and personal database programs, such as Microsoft Access, to accomplish their daily tasks. It is essential for these same users to incorporate data stored in relational database systems into their regular correspondence, analysis, and reports.

The challenge you have is how to provide access to this valuable data without the effort involved in developing traditional database applications. Much of the renewed interest in improved access to data sources is a result of the growth in the use of Internet and Web technology as mechanisms for delivering information. Fast and inexpensive methods of accessing data stored in RDBMS systems are necessary to deliver modern, three-tiered information systems during this era of cost cutting and budget tightening. Additional uses of this relational database access include specific queries and Web-based reporting.

IBM DB2 is a popular RDBMS for a significant number of enterprise customers. Customers need a cost-effective and manageable means to integrate DB2 with Microsoft SQL Server™, Microsoft Internet Information Services (IIS), and Microsoft Office applications. The goal of the OLE DB Provider for DB2 is to provide customers and solution providers with the means to integrate desktop applications with this wealth of data residing on DB2 database systems.

Distributed Relational Database Architecture

Database technology has enabled departments and individual users to save their information locally—as opposed to centrally managed stores owned by the organization's information systems group. Along with local storage and database query tools comes greater flexibility and ease of access to information. As more databases became distributed, a need emerged for users to access data stored remotely. IBM devised the Distributed Relational Database Architecture (DRDA) to enable their customers to access remote, distributed database systems across hardware platforms.

DRDA supports most dialects of the Structured Query Language (SQL) for access to relational database management systems (RDBMS). SQL is an international standard that defines a standardized language for accessing database management systems (DBMS). DRDA implementations generally support SQL in two ways: static (embedded) SQL, where the SQL commands are embedded directly in the application program and prepared as an extra step in the process of compiling the application; and dynamic or interactive (callable) SQL, where the user passes SQL commands as function calls at run time. One popular IBM implementation of dynamic SQL is the Call Level Interface (CLI). With dynamic SQL or CLI, SQL preparation is not required.

Clients that comply with DRDA are referred to as application requesters (AR) because they request data from the DRDA server. Servers that comply with DRDA are referred to as application servers (AS). Typically, application servers are implemented as the link to the RDBMS. In some cases, products are implemented as both application requesters and application servers.

DRDA supports access to stored procedures on DB2. SQL applications can invoke stored procedures or user-written programs on DB2 using the SQL **CALL** statement.

The OLE DB Provider for DB2 is an application requester implementation that can initiate DRDA commands to be serviced by a remote target DRDA application server represented by IBM DB2. On the Microsoft® Windows Server™ 2003 and Windows® 2000 Server operating systems, the Microsoft DRDA application requester can run as a service. This enables the integration of the DRDA service with other host applications using the IBM DRDA protocols and DRDA servers resident on the host. Microsoft host software is not required. (For more information, see Platforms Supported by the OLE DB Provider for DB2). IBM offers Data Base 2 servers for most popular environments.

Platforms Supported by the OLE DB Provider for DB2

IBM and other software vendors have implemented Distributed Relational Database Architecture (DRDA) support into database systems, such as IBM DB2, and database tools on a wide range of operating systems. DRDA is an open, published, and widely supported protocol, which requires no additional license for development. This makes DRDA appealing to independent software vendors (ISVs), solution providers, large corporate development groups, as well as their customers.

The Microsoft® OLE DB Provider for DB2 is implemented as an IBM DRDA application requester, which means it connects to popular DRDA-compliant DB2 systems.

The Microsoft OLE DB Provider for DB2 can access DB2 systems through SNA LU 6.2 using Microsoft Host Integration Server 2004, and can access DB2 systems directly using TCP/IP.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

OLE DB Provider for DB2 Requirements

You can find more information about hardware and software requirements for the Microsoft® OLE DB Provider for DB2 in the Host Integration Server 2004 Installation Guide topic Hardware and Software Requirements.

When connecting over SNA using LU 6.2, the OLE DB Provider for DB2 requires the following computer-to-host connectivity software:

- Microsoft Host Integration Server 2004
- Microsoft Host Integration Server Client

When connecting to a host system using TCP/IP, the OLE DB Provider for DB2 does not require any special host connectivity software.

The OLE DB Provider for DB2 supports the following OLE DB and ADO versions:

- OLE DB version 2.5. The Host Integration Server 2004 data access features require the run-time libraries for OLE DB version 2.5. These OLE DB libraries are installed as part of the Windows Server 2003 and Windows 2000 operating systems.
- ADO version 2.5. The Microsoft Host Integration Server 2004 data access features require the run-time libraries for ADO version 2.5. On Windows Server 2003 and Windows 2000, these ADO libraries are installed as part of the Windows Server 2003 and Windows 2000 operating systems.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring the OLE DB Provider for DB2

Microsoft® Data Access Components (MDAC) include Data Links, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Links provides a uniform method of creating persistent OLE DB data source object definitions stored in the form of universal data link (.udl) files. The OLE DB Provider for DB2 normally uses Data Links and .udl files for loading and configuring data sources.

The Data Source Wizard in the Microsoft Data Access Tool can help to define .udl files. OLE DB consumer applications, such as Data Transformation Services in Microsoft SQL Server™ can use the .udl files to connect to IBM data sources, such as DB2 and the mainframe file system.

To use Microsoft OLE DB Provider for DB2 with an OLE DB consumer application, the user must either create a Microsoft universal data link (.udl) file and call this from the application, or call the OLE DB provider from within the application using a connection string that includes the provider name and any other needed parameters.

This section contains:

- Creating Data Links for the OLE DB Provider for DB2
- Configuring Data Links for the OLE DB Provider for DB2
- Creating Packages for Use with the OLE DB Provider for DB2

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating Data Links for the OLE DB Provider for DB2

Data source information must be configured for each DB2 system data source object that is to be accessed using the Microsoft® OLE DB Provider for DB2. The default parameters for the OLE DB Provider for DB2 are used as the default values for data sources when these parameters are not configured for each data source.

The Microsoft Data Links, a core element of the Microsoft Data Access Components, provides a uniform method for creating file-persistent OLE DB data source object definitions in the form of universal data link (.udl) files.

The Data Source Wizard in the Microsoft Data Access Tool can help to define .udl files. OLE DB consumer applications, such as Data Transformation Services in Microsoft SQL Server can use the .udl files to connect to IBM data sources, such as DB2 and the mainframe file system.

Creating New Data Links for the OLE DB Provider for DB2

You create new Data Links using the Data Source Wizard from the Data Access Tool.

Browsing Data Sources for the OLE DB Provider for DB2

You can browse data sources using the Data Source Browser window in the Data Access Tool.

To find the physical location of the .udl file associated with a data source, right-click the **DB2 OLE DB UDLs** folder, and then click **Locate** on the context menu. Windows Explorer opens which displays the location of the file.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring Data Links for the OLE DB Provider for DB2

To edit the properties of a universal data link (.udl) file, right-click the file using Windows Explorer and click **Properties**. The **Properties** dialog box appears with property tabs:

- **General**
- **Security**
- **Summary**
- **Provider**
- **Connection**
- **Advanced**
- **All**

The **General**, **Security**, and **Summary** tabs provide access to general file information for the .udl file that is available for other files and is not related to the Data Link properties. This information includes file location, file type, file size, file dates, file security permissions for access, and descriptive summary information (description and origin properties and values such title, subject, and author) for the .udl file. The **General** tab has a text box with the name of the Data Link. This filename must end with the .udl extension if the file is to be recognized as a Data Link file. Note that the **Security** and **Summary** tabs are available on NTFS files systems, and not on the older FAT file systems.

The **Provider**, **Connection**, **Advanced**, and **All** tabs provide access to the Data Link properties that need to be configured to connect to the DB2 system.

The NewSnaDS tool can also be used to open and modify an existing .udl file. The **Data Link Properties** dialog box appears with property tabs.

This section contains:

- Provider
- Connection
- Advanced
- All

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Provider

The **Provider** tab enables you to select the OLE DB provider (the provider name string) to use in the universal data link (.udl) file from a list of possible OLE DB providers. Select **the Microsoft OLE DB Provider for DB2**. The parameters and fields displayed in the remaining tabs (**Connection**, **Advanced**, and **All**) are determined by the OLE DB provider that is selected.

Connection

The **Connection** tab enables you to configure the basic properties required to connect to a data source. The **Connection** tab dialog box contains several sections:

- Data source and Network connectivity
- Authentication
- Database Properties

For the Microsoft OLE DB Provider for DB2, the **Connection** tab includes the following properties for Data source and Network connectivity values.

Property	**Description**
Data source	The data source is an optional property that can be used to describe the data source.
Network	This drop-down list box allows selecting the type of network connection to be used. The allowable options are **TCP/IP Connection** or **APPC Connection**. If **TCP/IP Connection** is selected, click **More Options** (**...**) to open a dialog box for configuring TCP/IP network settings. The properties you can configure include the IP address of the DB2 host (or a hostname alias for this computer) and the Network Port (TCP/IP port) used for communication with the host. The default value for the Network Port is 446. The IP address of the host has no default value. If **APPC Connection** is selected (using SNA LU 6.2), click **More Options** (**...**) to open a dialog box for configuring APPC network settings. The properties you can configure include: the APPC local LU alias, the APPC remote LU alias, and the APPC mode name used for communication with the host. The default value for the APPC mode normally defaults to QPCSUPP. The local and remote LU alias fields do not have default values. The default value for the APPC mode name normally defaults to QPCSUPP. The APPC mode name can be selected from the drop-down list box.

The **Data source** in OLE DB is similar to a Data Source Name (DSN) in ODBC. The data source information is stored in a Microsoft Data Links file and contains the connection information required for the OLE DB Provider for DB2 to access IBM Data Base 2.

For the Microsoft OLE DB Provider for DB2, the **Connection** tab includes the following properties for authentication information:

Property	**Description**
Single sign-on	Click this check box to enable using the Host Integration Server security features providing a Single Sign-On to access this OLE DB data source. When this check box is selected, the **User** name and **Password** fields are dimmed and inaccessible. The user name and password fields are set based on the logon name used for the Windows Server™ 2003 or Windows® 2000 domain logon. When this check box is not selected, the **User** name and **Password** fields must normally contain appropriate values to access data sources on hosts.
User name	A valid user name and password are normally required to access data sources on a host. These values are case-sensitive. Users must not check the **Single sign-on** option if a specific user name and password are to be entered.

Password	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The **Blank password** check box is only applicable for a test connection. To enter a password, the user will need to clear the **Blank password** check box if it is selected. If **Blank password** is selected, a test connection with a blank password does not cause the OLE DB provider to prompt for a password. Optionally, users can choose to save the password in the .udl file by clicking the **Allow saving password** check box. Users and administrators should be warned that this option saves the authentication information (password) in plain text within the .udl file.

The AS/400 computer requires that the **User name** and **Password** properties be in uppercase. When connecting to DB2/400, these parameters must be passed as uppercase strings. When connecting to DB2 on IBM mainframes, the **User name** and **Password** parameters can be in mixed case.

It is possible to connect using a specific user name and password defined in DB2 on the host system or use the Single Sign-On (SSO) feature (often referred to as integrated Windows security). If a specific DB2 user name and password is to be used, this information may need to be saved into the .udl file. The user name and password are saved in plain text in the .udl file. For security reasons in these cases, it is imperative that the .udl file be protected with an access control list (ACL) that restricts access to only authorized users. Saving the user name and password in the data link also forces this .udl file to be updated whenever the password associated with the user name is changed. So for a variety of reasons, specifying a user name and password is not the preferred authentication option. Using the **Single Sign-On** option is the preferred method for authentication.

For the Microsoft OLE DB Provider for DB2, the **Connection** tab includes the following properties for database property values.

Property	Description
Initial catalog	This field is the first entry in the Database section of the **Connection** properties. This OLE DB property is used as the first part of a three-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, one can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE. If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization. This is a required property. This property is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.

Package collection	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. Package names are not restricted and can be uppercase, lowercase, or mixed case. The OLE DB provider creates packages dynamically in the location to which the user points using the Package Collection property. By default, the OLE DB provider will automatically create one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level specified when calling the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as when setting the ADO **IsolationLevel** property on the **Connection** object. A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user with package administrative rights to create a set of packages for use by all users. (For more information, see Creating Packages for Use with the OLE DB Provider for DB2). The OLE DB Provider for DB2 ships with a tool program for use by administrators to create packages. The Data Access Tool is used to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This tool creates a set of packages and grants **EXECUTE** privilege on these packages to the PUBLIC group representing all users on the DB2 system. The packages (for more information, see descriptions under the isoLevel parameter of the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as the ADO IsolationLevel property) created are as follows: AUTOCOMMITTED package (MSNC001 is only applicable on DB2/400) READ UNCOMMITTED package (MSUR001) READ COMMITTED package, (MSCS001) REPEATABLE READ package, (MSRS001) SERIALIZABLE package (MSRR001) Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400. Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be re-created using the Host Integration Server CrtPkg tool to make them compatible with Host Integration Server 2004. The package names changed from SNA Server 4.0. This property is equivalent to the DBPROP_DB2OLEDB_PACKAGECOL OLE DB property ID.
Default schema	The name of the collection where the OLE DB Provider for DB2 looks for catalog information. The Default Schema is the SCHEMA name for the target collection of tables and views. The OLE DB Provider uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the Default Schema is the target AUTHENTICATION (User ID or owner). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, the OLE DB provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Because this default is inappropriate in many cases, it is essential that the Default Schema value in the data source be defined. This property is equivalent to the DBPROP_DB2OLEDB_CATALOGCOL OLE DB property ID.

The **Connection** tab also includes a **Test Connection** button that can be used to test the connection properties. The connection can only be tested after all of the required parameters are entered. When this button is pressed, an APPC session or a TCP/IP session attempts to be established with the host using the OLE DB Provider for DB2.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to

http://go.microsoft.com/fwlink/?linkid=29507.

Advanced

The **Advanced** tab enables users to select the character code set identifier used by the host, the personal C code page used on the client, and some specific options when using the OLE DB Provider for DB2.

For the Microsoft OLE DB Provider for DB2, these properties include the following values.

Property	Description
DBMS Platform	The target DB2 platform property value is used to optimize performance of the OLE DB provider when executing operations such as data conversion. The default value is DB2/MVS.
Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute enables the user to access database objects without fully qualifying the objects using a collection (schema) qualifier. The OLE DB provider sends this value to DB2 using a **SET CURRENT SQLID** statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, no **SET** statement is issued by the OLE DB Provider. This OLE DB property is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to **true**, character data is converted based on the DB2 column CCSID and default ANSI code page. This property defaults to U.S./Canada (37). This property is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.
PC code page	The PC code page property indicates the code page to be used on the computer for character code conversion. This property is required when processing binary data as character data. Unless the **Process binary as character** check box is selected (value is set to **true**), character data is converted based on the default ANSI code page configured in Windows. This property defaults to Latin 1 (1252). This property is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.
Read only	When this option is selected, the OLE DB Provider for DB2 creates a read-only data source by setting the Mode property to Read (DB_MODE_READ). A user has read access to objects such as tables, and cannot do update operations (**INSERT**, **UPDATE**, or **DELETE**, for example). This property defaults to a **Mode** property of Read/Write (DB_MODE_READ/WRITE). This property is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Process binary as character	When this option is selected (property is set to **true**), the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This property defaults to **false**. This property is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.
Distributed transactions	When this option is selected, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and a Host Integration Server 2004 Resync Service. This option requires that an **APPC Connection** is selected as the network transport in the **Connection** tab and Microsoft Transaction Server (MTS) is installed. Note that Host Integration Server 2004 supports 2PC over TCP/IP as well as SNA LU 6.2. This property is equivalent to the DBPROP_DB2OLEDB_UNITSOFWORK OLE DB property ID.

All

The **All** tab enables users to configure essentially all of the properties for the data source except for the OLE DB provider. The properties available in the **All** tab include properties that can be configured using the **Connection** and **Advanced** tabs as well as optional detailed properties used to connect to a data source.

For the Microsoft OLE DB Provider for DB2, these properties include the following values.

Property	Description
Affiliate Application	This property is only used when single sign-on is enabled. It contains the application name to use when retrieving host credentials from the single sign-on database. This property is equivalent to the DBPROP_DB2OLEDB_AFFILIATEAPP OLE DB property ID.
Alternate TP Name	The Alternate Transaction Program (TP) Name property represents the default transaction program name for the DB2 DRDA application server (AS), which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2004 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, the Alternative TP Name is set to 0X07F9F9F9. This property is equivalent to the DBPROP_DB2OLEDB_TPNAME OLE DB property ID.
APPC Local LU Alias	When an **APPC Connection** using SNA LU 6.2 is selected for the Network Transport Library, this field is the name of the local LU alias configured in SNA services. This property is equivalent to the DBPROP_DB2OLEDB_LOCALLU OLE DB property ID.
APPC Mode Name	When an **APPC Connection** using SNA LU 6.2 is selected for the Network Transport Library, this field is the APPC mode and must be set to a value that matches the host configuration and SNA services configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This property normally defaults to QPCSUPP. This property is equivalent to the DBPROP_DB2OLEDB_APPCMODE OLE DB property ID.
APPC Remote LU Alias	When an **APPC Connection** using SNA LU 6.2 is selected for the Network Transport Library, this field is the name of the remote LU alias configured in SNA services. This property is equivalent to the DBPROP_DB2OLEDB_REMOTELU OLE DB property ID.
APPC Security Type	When an **APPC Connection** using SNA LU 6.2 is selected for the Network Transport Library, this field is the security type that is used when allocating an SNA connection. The allowable values are: **Program** (default) and **Same**. This property is equivalent to the DBPROP_DB2OLEDB_APPCSEC OLE DB property ID.

Cache Authentication	This property determines whether the OLE DB provider caches authentication information. This property defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This property is equivalent to the DBPROP_AUTH_CACHE_AUTHINFO OLE DB property ID.
Client Application Name	Use this property to specify a custom application name that the DB2 Network Client (DRDA AR) will pass to the DB2 Server when connecting. When troubleshooting issues, you can use this value to help identify relevant portions within DB2 or system logs. This property is equivalent to the DBPROP_DB2OLEDB_CLIENTAPPNAME OLE DB property ID.
Connection Pooling	This property determines whether connection pooling is used. Connection pooling keeps a connection active after it is closed in case another connection is opened with the same properties. The default value is **False**. This property is equivalent to the DBPROP_DB2OLEDB_CONNPOOLING OLE DB property ID.
Data Source	The data source is an optional property that can be used to describe the data source. This property does not have a default value.
DBMS Platform	The target DB2 platform property value is used to optimize performance of the OLE DB provider when executing operations such as data conversion. The default value is DB2/MVS.
Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute enables the user to access database objects without fully qualifying the objects using a collection (schema) qualifier. The OLE DB provider sends this value to DB2 using a **SET CURRENT SQLID** statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, no **SET** statement is issued by the OLE DB Provider. This OLE DB property is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Default Schema	The name of the collection where the OLE DB Provider for DB2 looks for catalog information. The Default Schema is the SCHEMA name for the target collection of tables and views. The OLE DB Provider uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the Default Schema is the target AUTHENTICATION (User ID or owner). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, the OLE DB Provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Because this default is inappropriate in many cases, it is essential that the Default Schema value in the data source be defined. This property is equivalent to the DBPROP_DB2OLEDB_CATALOGCOL OLE DB property ID.
Extended Properties	This property is a string containing provider-specific, extended connection information. The use of this property implies that the OLE DB consumer knows how this string will be interpreted and used by the OLE DB provider. This parameter should be used only for provider-specific connection information that cannot be explicitly described through the other property values. This property is equivalent to the DBPROP_INIT_PROVIDERSTRING OLE DB property ID.
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page. This property defaults to U.S./Canada (37). This property is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.

Initial Catalog	This OLE DB property is used as the first part of a three-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, one can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE. If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization. This is a required property. This property is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.
Integrated Security	This property determines whether the OLE DB provider uses Host Security Integration (Single Sign-On). When this property is set to SSPI, Single Sign-On is enabled and separate user ID and password parameters are not required. The user name and password fields are set based on the logon name used for the Widows Server 2003 or Windows 2000 domain logon. When this property is null, this Single Sign-On feature is disabled. This property defaults to null (host security integration is disabled) and a user ID and password are required. This property is equivalent to the DBPROP_AUTH_INTEGRATED OLE DB property ID.
Mode	A Mode property is a bitmask specifying access permissions. This bitmask can be a combination of zero or more of the following: DB_MODE_READ—Read-only. DB_MODE_READWRITE—Read/write (DB_MODE_READ | DB_MODE_WRITE). DB_MODE_SHARE_DENY_NONE—Neither read nor write access can be denied to others. DB_MODE_SHARE_DENY_READ—Prevents others from opening in read mode. DB_MODE_SHARE_DENY_WRITE—Prevents others from opening in write mode. DB_MODE_SHARE_EXCLUSIVE—Prevents others from opening in read/write mode (DB_MODE_SHARE_DENY_READ | DB_MODE_SHARE_DENY_WRITE). DB_MODE_WRITE—Write-only. The following values for mode are supported by the OLE DB Provider for DB2: Read (DB_MODE_READ) and Read/Write (DB_MODE_READ/WRITE). This property defaults to Read/Write. When the **Read Only** property is selected in the **Advanced** tab, the OLE DB Provider for DB2 creates a read-only data source by setting the **Mode** property to Read (DB_MODE_READ). A user has read access to objects such as tables, and cannot do update operations (**INSERT**, **UPDATE**, or **DELETE**, for example). This property is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Network Address	When TCP/IP has been selected for the Network Transport Library, this property indicates the IP address of the DB2 host or a hostname alias for this computer. This property is equivalent to the DBPROP_DB2OLEDB_NETADDRESS OLE DB property ID.
Network Port	When TCP/IP has been selected for the Network Transport Library, this property is the TCP/IP port used for communication with the DB2 host. The default value is TCP/IP port 446. This property is equivalent to the DBPROP_DB2OLEDB_NETPORT OLE DB property ID.

Network Transport Library	The network transport dynamic-link library property designates whether the OLE DB Provider for DB2 connects through an APPC connection using SNA LU 6.2 or a TCP/IP connection. The possible values for this property are TCPIP or SNA. The default value for this property is **SNA**. If the default SNA is selected, values for APPC Local LU Alias, APPC Mode Name, and APPC Remote LU Alias are required. If TCPIP is selected, values for Network Address and Network Port are required. This property is equivalent to the DBPROP_DB2OLEDB_NETTYPE OLE DB property ID.
New Password	This property allows an OLE DB connection to change the host password for the user account used for the connection. If this property is set, the account password will be changed to the property value. This property is equivalent to the DBPROP_DB2OLEDB_NEWPWD OLE DB property ID.
Package Collection	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. Package names are not restricted and can be uppercase, lowercase, or mixed case. The OLE DB provider creates packages dynamically in the location to which the user points using the Package Collection property. By default, the OLE DB provider automatically creates one package in the target collection, if one does not exist, at the time the user issues the first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level specified when calling the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as when setting the ADO **IsolationLevel** property on the **Connection** object. A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user with package administrative rights to create a set of packages for use by all users. (For more information, see Creating Packages for Use with the OLE DB Provider for DB2.) The OLE DB Provider for DB2 ships with a tool program for administrators to create packages. You use the Data Access Tool to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This tool creates a set of packages and grants EXECUTE privilege on these packages to the PUBLIC group representing all users on the DB2 system . The packages (for more information, see descriptions under the isoLevel parameter of the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as the ADO IsolationLevel property) created are as follows: AUTOCOMMITTED package (MSNC001 is only applicable on DB2/400) READ UNCOMMITTED package (MSUR001) READ COMMITTED package, (MSCS001) REPEATABLE READ package, (MSRS001) SERIALIZABLE package (MSRR001) Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400. Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2004. The package names changed from SNA Server 4.0. This property is equivalent to the DBPROP_DB2OLEDB_PACKAGECOL OLE DB property ID.
Password	A valid user name and password are normally required to access data sources on hosts. The password is case-sensitive and is displayed as asterisks in this dialog box for security purposes. This property is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.

PC Code Page	The PC Code Page property indicates the code page to be used on the personal computer for character code conversion. This property is required when processing binary data as character data. Unless the Process Binary as Character value is set to **true**, character data is converted based on the default ANSI code page configured in Windows. This property defaults to Latin 1 (1252). This property is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.
Persist Security Info	This property indicates whether the data source object is allowed to persist sensitive authentication information, such as a password along with other authentication information. This property defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This property is equivalent to the DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO OLE DB property ID.
Process Binary as Character	When this property is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This property defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This property is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.
Units of Work	This property indicates whether two-phase commit (distributed unit of work) used for transactions is supported for this data source. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the Host Integration Server 2004 Resync Service. The following values for this property are supported by the OLE DB Provider for DB2: RUW (remote unit of work) DUW (distributed unit of work) This property defaults to RUW. Distributed unit of work (two-phase commit) requires an APPC Connection using SNA LU 6.2 or 2PC over TCP/IP as the network transport. Microsoft Transaction Server (MTS) should also be installed. This property is equivalent to the DBPROP_DB2OLEDB_UNITSOFWORK OLE DB property ID.
User ID	A valid user name is normally required to access data sources on hosts. This value is case-sensitive. This property is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

These properties on the **All** tab may be edited by selecting a property from the list displayed and selecting **Edit Value**. This button invokes a dialog box for the specific property containing a property description describing the property and a property value box for making changes.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating Packages for Use with the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2, which is implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester, uses packages to issue SQL statements and call DB2 stored procedures. There is a provider-specific property that the OLE DB Provider for DB2 uses to identify a location in which to create and store DB2 packages. The OLE DB Provider for DB2 creates packages dynamically in the location to which the user points using the Package Collection property corresponding to the DBPROP_DB2OLEDB_PACKAGECOL property ID of OLE DB. This location may be configured using the **Connection** and **Advanced** tabs using Microsoft Data Links or can be passed as part of the connection string as an attribute keyword and argument. This attribute keyword can be either pkgcol or the long form of this attribute, Package Collection.

There are two package creation options:

1. The OLE DB Provider for DB2 autocreates one package for the currently used isolation level at run time if no package already exists. This autocreate process may fail if the user account does not have authority to create packages.
2. An administrator or user can manually creates all four packages (five packages on DB2/400) for use with all isolation levels and for use by all users (the PUBLIC group on DB2 representing all users) or a specific set of users. The OLE DB Provider for DB2 includes a program for use by users with appropriate administrative privilege that will create these packages and grant access to the PUBLIC group for this purpose.

   Data Access Tool

A shortcut for this tool is added to the **Programs** menu off the **Start** button on the Windows taskbar under the **Host Integration Server\Data Integration** folder with a name of **Data Access Tool**. This shortcut is created when the Microsoft Host Integration Server or the Host Integration Client is first installed and support for Data Access is checked.

This tool creates a set of packages and grants EXECUTE privileges on these packages to the PUBLIC group. The PUBLIC group on DB2 systems is a default group that represents all DB2 users. The following packages are created:

- AUTOCOMMITTED package (MSNC001) is only applicable on DB2/400)
- READ UNCOMMITTED package (MSUR001)
- READ COMMITTED package (MSCS001)
- REPEATABLE READ package (MSRS001)
- SERIALIZABLE package (MSRR001)

Note that the AUTOCOMMITTED package (MSNNC001) is only created on DB2 for OS/400.

The descriptive process name used by the Data Access Tool corresponds with the isolation levels defined in the ANSI SQL standard. The following table indicates how these packages correspond with the terms used by IBM for isolation levels in DB2 documentation.

Package description	**Package name**	**IBM documentation**
AUTOCOMMITTED (Note that this applies only to DB2/400 and does not correspond with an ANSI SQL isolation level)	MSNC001	COMMIT(*NONE) (NC). This isolation level is used in DB2/400 autocommit mode only and has no corresponding isolation level on other DB2 platforms or in ANSI SQL.
READ UNCOMMITTED	MSUR001	UNCOMMITTED READ (UR). This isolation level corresponds with ANSI SQL READ UNCOMMITTED.
READ COMMITTED	MSCS001	CURSOR STABILITY (CS). This isolation level corresponds with ANSI SQL READ COMMITTED.
REPEATABLE READ	MSRS001	READ STABILITY (RS). This isolation level corresponds with ANSI SQL REPEATABLE READ.

SERIALIZABLE	MSRR001	REPEATABLE READ (RR). This isolation level corresponds with ANSI SQL SERIALIZABLE.

Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2004. The package names used by the OLE DB Provider for DB2 on SNA Server 4.0 are not compatible with the OLE DB Provider for DB2 included with Host Integration Server. On SNA Server 4.0, these packages used different names as follows:

```
AUTOCOMMITTED package (SNANC001) only applicable on DB2/400
READ UNCOMMITTED package (SNACH001)
READ COMMITTED package, (SNACS001)
REPEATABLE READ package, (SNARR001)
SERIALIZABLE package (SNAAL001)
```

These isolation levels are described in detail under Support for Isolation Levels Using the OLE DB Provider for DB2. These isolation levels are also described under the OLE DB isoLevel parameter and ADO IsolationLevel property. Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400.

Note that the Data Access Tool creates this set of packages and grants EXECUTE privileges to the PUBLIC group. There may be cases for security reasons where EXECUTE privileges to this set of packages on the DB2 system should be restricted to a different group of users or specific users. In these cases, execution privileges on these created packages need to be modified on the host system.

The Data Access Tool creates all of these packages inside the Collection that is specified in the Package Collection property in the data link file, or in the connection string. If the user does not have the appropriate authority to create packages in the specified Collection, or if the specified Collection does not exist, the OLE DB Provider for DB2 will return an error.

In the case of DB2 on MVS or OS/390, the normal error text returned if the user does not have the appropriate authority would be as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version for
a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -567.
```

In the case of DB2/400, the normal error text returned if the user does not have the appropriate authority would be as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version for
a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -805.
```

In the case of DB2/400, the normal error returned if the collection does not exist would be as follows:

```
Failed to create AUTOCOMMITTED (NC) package.  RETCODE=-99.
SQL Error: Code=-204, State=42704, Error Text= A SQL error has occurred.  Please consult the
documentation for your specific DB2 version for a description of the associated Native Error
and SQL State. SQLSTATE: 42704, SQLCODE: -204
```

There are two authorities required to execute the create package process on MVS using the Data Access Tool:

```
GRANT BINDADD TO <authorization ID>
GRANT CREATE IN COLLECTION <collection ID> TO <authorization ID>
```

The "authorization ID" is the user who needs the permission to create the packages. The "collection ID" is the name of the collection, which the user specifies in the data link file for the Package Collection property. This collection should be a valid collection within the DB2.
If an administrator executes the preceding statements on behalf of a nonprivileged user, this nonprivileged user can then run the CrtPkg tool. Once run, the CrtPkg process creates four sets of packages (one for each of the four isolation levels supported on DB2 for MVS or OS/390) for use by all (PUBLIC) users of the Microsoft data access features.

The following example illustrates this process on DB2 for MVS or DB2 for OS/390.

Grant rights to run the CrtPkg tool to authorization ID WNW999

```
GRANT BINDADD TO WNW999
GRANT CREATE IN COLLECTION MSPKG TO WNW999
```

Run the Data Access Tool using authorization ID WNW999.

To execute the Data Access Tool on DB2/400, a user ID must have one of the following authorities:

- *CHANGE authority on the DB2 collection
- *ALL authority on the DB2 collection

If the user has *USE authority or if the user has *EXCLUDE authority, the Create Package process will fail.

There are several steps required to change user authority on a DB2/400 collection (AS/400 library): From interactive SQL (STRSQL command) while logged on as user with administrative privileges, create a new collection. This command can also be issued using ADO, OLE DB, and ODBC. However, most administrators typically create collections from the AS/400 console because the administrator must be logged on at the console to issue the Command Language (CL) command with which to change the user authority on the collection.

```
CREATE COLLECTION <collection ID>
```

From the AS/400 command console, type the CL WRKOBJ command with the <collection ID> as a parameter.

```
WRKOBJ <collection ID>
```

The "collection ID" is the name of the collection, which the user specifies in the data link file for the Package Collection property. This collection should be a valid collection within DB2. The **Work with objects** dialog box appears. Place the cursor on the *PUBLIC Object Authority line and change the authority from *USE to *ALL.

If an administrator executes the preceding statements on behalf of a nonprivileged user, this nonprivileged user can then run the CrtPkg tool. Once run, the CrtPkg process creates five sets of packages (one for each of the five isolation levels supported on DB2/400) for use by all (PUBLIC) users of the Microsoft data access features. On DB2/400, five packages are created including the AUTOCOMMITTED packages.

The following example illustrates this process on DB2/400.

Grant rights to run the Data Access Tool to authorization ID WNW999

```
CREATE COLLECTION MSPKG
WRKOBJ MSPKG
```

Run the Data Access Tool.

When using the Data Access Tool, if the package collection specified does not exist, DB2 returns SQLCODE -805.

When using auto-create packages, if a package collection is not specified or the package collection does not exist, during the auto-create package process, the consumer application receives SQLSTATE HY000 and SQLCODE -385. The SQLSTATE HY000 is defined as a provider-specific error. The -385 Error Return Code is not a SQLCODE but rather a DDM DRDA AR (DB2 client) return code. This error code is defined as DDM_VALNSPRM with the following associated text string:

```
"The parameter value is not supported by the target system."
```

The OLE DB Provider for DB2 client error codes are defined in the Db2oledb.h file located on the Host Integration Server 2004 CD.

Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2004.

Programming Considerations Using the OLE DB Provider for DB2

The Microsoft® OLE DB Provider for DB2 provides pass-through support for SQL statements. No SQL parsing is provided. The user must know what SQL syntax is supported for the target DB2 implementation. For information about what SQL syntax is supported, see the specific *DB2 SQL Reference and DB2 Application Programming and SQL Guide* for the DB2-specific platform.

The OLE DB Provider for DB2 does not parse the SQL statements to qualify table names. Consequently, users of the OLE DB Provider for DB2 must use either two-part or three-part (fully qualified) object names when naming tables, views, and stored procedures in DB2. A two-part table name would consist of the user ID and table, <UserID>.<Table>. One-part names (just the table name) do not succeed unless the combination of the DB2 collection and schema name correspond directly to the OLE DB User ID. (The OLE DB DBPROPSET_DBINIT property is equal to the OLE DB DBPROP_AUTH_USERID property.)

All the OLE DB objects exposed by the OLE DB Provider for DB2 support aggregation. Each OLE DB object has two classes, one that delegates its **IUnknown** calls and one that controls the object as a whole.

The free-threading model is supported, allowing multiple threads to access the objects safely.

The current implementation of the OLE DB Provider for DB2 services all OLE DB **Session**, **Command**, and **Rowset** objects present in a given instance of the **DataSource** object through a single APPC connection or TCP/IP connection. One implication of this design is that if two **Rowset** objects, each created from a different OLE DB Session object, use explicit commitment control through the **ITransaction** interface, they will interfere with each other. When a **Commit** or **Abort** for one instance is invoked, all work for the DataSource object will be either committed or aborted. This may yield undesirable results. The work around to this problem is to instantiate two instances of the **DataSource** object.

The OLE DB Provider for DB2 does not work with OLE DB Session Pooling.

The OLE DB Provider for DB2 in Microsoft Host Integration Server 2004 supports distributed transactions, DRDA Distributed Unit of Work, and can participate in a distributed transaction coordinated by Microsoft Distributed Transaction Coordinator.

This option requires that the SNA LU 6.2 service is selected as the network transport and Microsoft® Transaction Server (MTS) is installed. The Microsoft OLE DB Provider for DB2 does not support OLE DB automatic transaction enlistment under Microsoft Transaction Server.

The Microsoft Data Access Components (MDAC) support the option of using a client cursor engine. This service component is implemented as part of OLE DB, ADO, and Remote Data Services (RDS). When using ADO, a client cursor is enabled by setting the **CursorLocation** property on the recordset to **adUseClient**. When using the ADO Client Cursor Engine with DB2 for OS/390, you must set the OLE DB Provider for DB2 Auto Commit Mode property in the data link or connection string to FALSE. This is not required when connecting to DB2 for OS/400.

The OLE DB Provider for DB2 included with Host Integration Server 2004 supports updating capabilities when used with a client cursor engine when the following requirements are met:

- To support updates (UPDATE, INSERT, and DELETE) using a client cursor engine, the values in at least one column in the target table must be unique.

When the intent is to update records, DB2 requires that the SQL SELECT statement also include the FOR UPDATE option. For example, to select all records from the AUTHORS table in the DB2 collection called PUBS with intent to update requires the following SQL syntax:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE
```

When using DB2 for MVS V4R1 and DB2 for OS/400 V3R2, there are further requirements to indicate the columns that you intend to update. For example, to update the AU_LNAME and AU_FNAME columns in the PUBS.AUTHORS table, the following SQL syntax must be used:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE OF AU_LNAME, AU_FNAME
```

Support for Isolation Levels Using the OLE DB Provider for DB2

The OLE DB Provider for DB2 provides flexibility in dealing with issues of isolation levels and transaction state. The isolation level for a session can be set using the DBPROP_SESS_AUTOCOMMITISOLEVELS property on a session.

The OLE DB Provider for DB2 supports the following values for the DBPROP_SESS_AUTOCOMMITISOLEVELS and DBPROP_SUPPORTEDTXNISOLEVELS property.

OLE DB property value	Description
DBPROPVAL_TI_BROWSE	This isolation level is the same as DBPROPVAL_TI_READUNCOMMITTED. Note that the OLE DB specification and the OLEDB.H include file defines two macros with the same value.
DBPROPVAL_TI_CHAOS	An undefined value for isolation level. This value is not supported using the OLE DB Provider for DB2.
DBPROPVAL_TI_CURSORSTABILITY	This isolation level is the same as DBPROPVAL_TI_READCOMMITTED. Note that the OLE DB specification and the OLEDB.H include file defines two macros with the same value.
DBPROPVAL_TI_ISOLATED	This isolation level is the same as DBPROPVAL_TI_SERIALIZABLE. Note that the OLE DB specification and the OLEDB.H include file defines two macros with the same value.
DBPROPVAL_TI_READCOMMITTED	When this property is set, it isolates any data read from changes by others and changes made by others cannot be seen. The re-execution of the Read statement is affected by others. This does not support a repeatable read. This is the default value for isolation level. This isolation level is also called Cursor Stability (CS) in IBM DB2 documentation. This isolation level corresponds with the ADO property set to **adXactReadCommitted**.
DBPROPVAL_TI_READUNCOMMITTED	When this property is set, it does not isolate data read from changes by others and changes made by others can be seen. The re-execution of the Read statement is affected by others. This does not support a repeatable read. This isolation level is called Uncommitted Read (UR) in IBM DB2 documentation. This isolation level corresponds with the ADO property set to **adXactReadUncommitted**.
DBPROPVAL_TI_REPEATABLEREAD	When this property is set, it isolates any data read from changes by others and changes made by others cannot be seen. The re-execution of the read statement is affected by others. This supports a repeatable read. This isolation level is called Read Stability (RS) in IBM DB2 documentation. This isolation level corresponds with the ADO property set to **adXactRepeatableRead**.
DBPROPVAL_TI_SERIALIZABLE	When this property is set, it isolates any data read from changes by others and changes made by others cannot be seen. The re-execution of the read statement is not affected by others. This supports a repeatable read. This isolation level is called Repeatable Read (RR) in IBM DB2 documentation. This isolation level corresponds with the ADO property set to **adXactSerializable**.

The isolation level can also be set by calling **ITransactionLocal::StartTransaction** with the appropriate value for the IsoLevel parameter to start a new transaction. Note that the same integer values used for the DBPROP_SESS_AUTOCOMMITISOLEVELS and DBPROP_SUPPORTEDTXNISOLEVELS property values are also used for the *IsoLevel* parameter passed to the **ITransactionLocal::StartTransaction** method. The legal values for the *IsoLevel* parameter are defined in Transact.h while the OLE DB property values for isolation level are defined in OLEDB.h. While the **#define** macro strings used for the OLE DB property values and the *IsoLevel* parameter values differ, the integer values of these macros are the same.

The following table shows the OLE DB property values for isolation level and the equivalent *IsoLevel* parameter passed to **ITransactionLocal::StartTransaction**.

OLE DB isolation level property	OLE DB IsoLevel parameter

DBPROPVAL_TI_BROWSE	ISOLATIONLEVEL_BROWSE
DBPROPVAL_TI_CURSORSTABILITY	ISOLATIONLEVEL_CURSORSTABILITY
DBPROPVAL_TI_ISOLATED	ISOLATIONLEVEL_ISOLATED
DBPROPVAL_TI_READCOMMITTED	ISOLATIONLEVEL_READCOMMITTED
DBPROPVAL_TI_READUNCOMMITTED	ISOLATIONLEVEL_READUNCOMMITTED
DBPROPVAL_TI_REPEATABLEREAD	ISOLATIONLEVEL_REPEATABLEREAD
DBPROPVAL_TI_SERIALIZABLE	ISOLATIONLEVEL_SERIALIZABLE

Nested transactions are not supported by the OLE DB Provider for DB2. If there is already an active transaction on the session (that is, **StartTransaction** has been called with no matching **ITransaction::Commit** or **ITransaction::Abort**), it is not possible to start a new transaction below the current transaction. Calling **ITransactionLocal::StartTransaction** when there is already an active transaction on the session returns XACT_E_XTIONEXISTS.

IBM documents isolation level in DB2 documentation using somewhat different terms. The following table shows how the OLE DB values for isolation level are mapped to the terms used by IBM DB2 for isolation level.

OLE DB isolation level	**IBM DB2 isolation level**
DBPROPVAL_TI_BROWSE	Uncommitted Read (UR)
DBPROPVAL_TI_CURSORSTABILITY	Cursor Stability (CS)
DBPROPVAL_TI_ISOLATED	Repeatable Read (RR)
DBPROPVAL_TI_READCOMMITTED	Cursor Stability (CS)
DBPROPVAL_TI_READUNCOMMITTED	Uncommitted Read (UR)
DBPROPVAL_TI_REPEATABLEREAD	Read Stability (RS)
DBPROPVAL_TI_SERIALIZABLE	Repeatable Read (RR)

Transaction Support Using the OLE DB Provider for DB2

The OLE DB Provider for DB2 included with Host Integration Server 2004 supports distributed transactions. This support is enabled by setting the provider-specific property UNITS OF WORK to DUW, or by selecting the **Distributed transactions** option when configuring a universal data link (.udl) file or Data Source Name (DSN). The current DUW implementation does not have a notion of auto committing transactions so it is recommended to join the transaction through **ITransactionJoin->JoinTransaction** prior to performing work through **ICommandExecute** (or other interfaces). ADO applications do not generally join before starting their work, rather, they rely upon automatic transaction enlistment to enlist in the distributed transaction.

The OLE DB Provider for DB2 included with Host Integration Server 2004 supports DBPROP_MULTIPLECONNECTIONS (the default value is VARIANT_TRUE) for RUW connections. This ensures that no transaction state conflicts across OLE DB session objects (ADO commands or recordsets on a single connection). This feature is a property of DBPROPSET_DATASOURCE. Therefore, you can only set this property after the OLE DB data source or ADO connection objects are created.

If the transaction has been auto-enlisted, the default Transaction Isolation level is used (NC for the AS/400, CS for all other host platforms). If a join is requested (not applicable to ADO applications) after auto-enlistment and work, the isolation level specified on the join may differ from the default. This appears to be acceptable, except when a statement was prepared using one isolation level. The isolation level is then changed through **ITransactionJoin**, and the prepared statement is executed again.

Stored Procedure Support Using the OLE DB Provider for DB2

The OLE DB Provider for DB2 supports calling DB2 stored procedures, returning output parameters, and returning single and multiple result sets.

Distributed Query Support Using the OLE DB Provider for DB2

The OLE DB Provider for DB2 supports remote database access when configured as a linked server to SQL Server using distributed queries. The distributed queries feature of SQL Server is sometimes referred to as the Distributed Query Processor (DQP). SQL Server 2000 supports distributed queries to the OLE DB Provider for DB2 supplied with Host Integration Server 2004.

When using Microsoft SQL Server™ 2000 distributed queries and the OLE DB Provider for DB2 supplied with Host Integration Server 2004, the following OLE DB provider options (displayed in the same order as in the Microsoft® SQL Server™ Enterprise Manager) are supported.

Provider options in SQL Server 2000	**Comments**
Dynamic parameter	SQL Server generates parameterized queries as an optimization for providers that support the '?' parameter marker syntax for parameterized queries in dynamic SQL. This option should not be enabled for the OLE DB Provider for DB2.
Nested queries	SQL Server generates nested queries for providers that support nested **SELECT** queries in the **FROM** clause. Some versions of DB2 have support for nested queries. This option should not be enabled for OLE DB Provider for DB2.
Level zero only	A level zero OLE DB provider is a basic provider that does not support commands, and only level zero OLE DB interfaces are invoked against the provider. The Microsoft OLE DB Provider for DB2 is not a basic provider and uses commands. This option should not be enabled for the OLE DB Provider for DB2.
Allow InProcess	SQL Server enables the OLE DB provider to be instantiated as an in-process server. The default behavior is to instantiate the OLE DB provider outside the SQL Server process. Instantiating the provider outside the SQL Server process protects the SQL Server process from errors in the OLE DB provider. SQL Server requires an in-process server for handling specific types of data including long columns, text, and image data. The OLE DB Provider for DB2 does not currently support the DB2 Large Object (LOB) types. This option may be enabled or disabled for the OLE DB Provider for DB2, but this option is normally unnecessary when using SQL Server 2000.
Non transacted updates	SQL Server disables support for transacted updates if this option is enabled. The Microsoft OLE DB Provider supports transactions, so this option is not appropriate. This option should not be enabled for the OLE DB Provider for DB2.
Index as access path	SQL Server uses the OLE DB Index object with OLE DB providers that support this feature. The OLE DB Provider for DB2 does not currently support the Index object, so this option is not appropriate. This option should not be enabled for the OLE DB Provider for DB2.
Disallow ad hoc accesses	SQL Server uses this option when only an ODBC driver is available. This option should not be enabled for the OLE DB Provider for DB2.

The OLE DB provider options for managing distributed queries can be set using SQL Server Enterprise Manager. In the left pane of SQL Server Enterprise Manager, right-click a SQL Server instance and then select the **Security** tree to define a new linked server or change the properties of an existing linked server. Right-click an existing linked server or create a new linked server. On the **General** tab, select the **Other data source** button and select the OLE DB Provider for DB2 for the **Provider name** from the drop-down list box. Click the **Provider Options** button below the selected OLE DB provider to set the options for distributed queries. Select the appropriate check boxes to enable an option for this linked server. Note that these options operate at the provider level. When the appropriate options are set for the OLE DB Provider for DB2, these settings apply to all linked server definitions using the same OLE DB Provider for DB2.

The OLE DB Provider for DB2 performs data type and code page conversions on behalf of the OLE DB consumer application, in this case the SQL Server Distributed Query Processor. First, the provider converts DB2 numeric and datetime data types to OLE DB numeric and datetime data types. The provider does this on a best-match basis using information provided by DB2 in the DRDA SQL reply data structure for the result set. Second, the provider converts the character data from the DB2 Coded Character Set Identifier (CCSID) to the Windows ANSI code page. For example in the case of an SQL **SELECT** fetch of data from DB2 for

OS/400, the provider converts character data from EBCDIC to UNICODE and UNICODE to ANSI. The source EBCDIC CCSID value comes from the table column descriptor or from the DB2 database if the column CCSID is undefined. The target ANSI code page value comes from the value of the PC Code Page data source property. For example, to convert character data from CCSID 1026, IBM EBCDIC Turkish (Latin-5), to ANSI code page 1254, Turkish, the PC CodePage would need to be set to 1254. OLE DB consumers may convert the data once again from OLE DB to some native data type. In this case, the OLE DB consumer application is a distributed query processor. When using distributed queries, SQL Server does perform numeric and datetime conversions from OLE DB to SQL Server data types.

UNIONs in **SELECT** statements are not supported by the current version of the OLE DB Provider for DB2 when used with distributed queries. For example, the following **SELECT** statement will fail:

```
SELECT * FROM ( SELECT TITLE_ID FROM SNA.TITLE )
```

The SQL parser built into the OLE DB Provider for DB2 does not properly parse these **UNION** statements in a way compatible with DB2. The preceding statement will generate a type 199 error "Keyword FROM not expected. Valid Tokens: LEFT CROSS INNER EXCEPTION." When performing the same query with correlation names added, the error becomes a type 104 error "Token . was not valid. Valid tokens: LEFT CROSS INNER EXCEPTION."

Linked server definitions can also be created or deleted using stored procedures as well as through the SQL Server Enterprise Manager.

When creating linked server definitions, the *@catalog* parameter of the **sp_addlinkedserver** procedure corresponds to the OLE DB provider-specific **Initial Catalog** property. Additionally, when creating linked server definitions, you can use the contents of a universal data link (.udl) file for the *@provstr* parameter value or enter the short provider string keyword arguments (for details, see the ADO ConnectionString property), which are consumed through the OLE DB **DBPROP_INIT_PROVIDERSTRING** (Extended Properties) property.

The following example illustrates how to create a linked server for DB2/MVS using an SNA connection.

```
USE master
GO
EXEC sp_dropserver 'DB2MVS_SNA', 'droplogins'
GO
EXEC sp_addlinkedserver
    @server = 'DB2MVS_SNA',
    @srvproduct = 'Microsoft OLE DB Provider for DB2',
    @provider = 'DB2OLEDB',
    @catalog = 'P390D37',
    @provstr='InitCat=P390D37;NetLib=SNA;LOCALLU=MVSRUS;
       REMOTELU=P390L37;MODENAME=IBMRDB;PkgCol=MSPKG;DefSch=DB2DEMO'
GO
EXEC sp_addlinkedsrvlogin
    @rmtsrvname='DB2MVS_SNA',
    @useself=false,
    @locallogin=NULL,
    @rmtuser='wnw999',
    @rmtpassword='wnw999'
GO
```

The following example illustrates how to create a linked server for DB2/MVS using a TCP/IP connection.

```
USE master
GO
EXEC sp_dropserver 'DB2MVS_IP', 'droplogins'
GO
EXEC sp_addlinkedserver
    @server = 'DB2MVS_IP',
    @srvproduct = 'Microsoft OLE DB Provider for DB2',
    @provider = 'DB2OLEDB',
    @catalog = 'P390D37',
    @provstr='InitCat=P390D37;NetLib=TCPIP;NetAddr=MVSrUS;
        NetPort=446;PkgCol=MSPKG;DefSch=DB2DEMO'
GO
EXEC sp_addlinkedsrvlogin
    @rmtsrvname='DB2MVS_IP',
    @useself=false,
    @locallogin=NULL,
    @rmtuser='wnw999',
    @rmtpassword='wnw999'
GO
```

The following example illustrates several DB2 linked server queries using a TCP/IP connection.

```
/* SELECT using four-part linked server query:   */
/*    <Linked Server>.<Catalog>.<Schema>.<Table> */
SELECT * FROM DB2MVS_IP.P390D37.DB2DEMO.DEPARTMENT
SELECT DEPTNAME FROM DB2MVS_IP.P390D37.DB2DEMO.DEPARTMENT WHERE DEPTNO = 'A00'

/* SELECT using pass-through OPENQUERY with      */
/*     three-part naming convention              */
SELECT * FROM OPENQUERY(DB2MVS_IP,"SELECT * FROM P390D37.DB2DEMO.EMP_ACT")

/* SELECT using pass-through OPENROWSET with     */
/*     two-part naming convention                */
SELECT * FROM OPENROWSET
    (
    'DB2OLEDB',
    'InitCat=P390D37;NetLib=TCPIP;NetAddr=MVSrUS;NetPort=446;
         PkgCol=MSPKG;DefSch=DB2DEMO;User ID=WNW999;Password=WNW999',
    'SELECT * FROM DB2DEMO.EMPLOYEE'
    )
```

The following example illustrates several SQL Server Views to access a DB2 linked server using a TCP/IP connection.

```
/* Create SQL Server View using DB2 linked server query */
USE DB2Demo
GO
DROP VIEW DB2VIEW
GO
CREATE VIEW DB2View
AS
SELECT ORD_ID, ORDERDATE, ORDERSTATUS
    FROM DB2MVS_IP.P390D37.DB2DEMO.ORDERS
GO

/* Access Db2 data using SQL Server View */
SELECT * FROM DB2Demo.dbo.DB2View
```

The following example illustrates the SQL **SELECT**, **UPDATE**, and **DELETE** commands using four-part linked server queries to DB2 over a TCP/IP connection.

```
SELECT * FROM DB2MVS_IP.P390D37.DB2DEMO.CUSTOMERS
INSERT INTO DB2MVS_IP.P390D37.DB2DEMO.CUSTOMERS VALUES (1002,
    'password', 'User', 'DB2Demo', 'One Microsoft Way', 'Redmond',
    '425-882-8080', 'WA', '98052', 'mssna@microsoft.com')
UPDATE DB2MVS_IP.P390D37.DB2DEMO.CUSTOMERS  SET PHONE = '206-882-8080'
    WHERE CUST_ID = 1002
DELETE FROM DB2MVS_IP.P390D37.DB2DEMO.CUSTOMERS WHERE CUST_ID = '1002'
```

The following example illustrates invoking DB2 linked server queries from SQL Server stored procedure.

```
USE DB2Demo
DROP PROCEDURE spGetOrderDetails_DB2MVS_IP

CREATE PROCEDURE spGetOrderDetails_DB2MVS_IP
    @ORDER_ID INT
AS
BEGIN
    SELECT a.*, b.Title, b.SubTitle, b.Author, b.ISBN, b.Weight
```

```
          FROM DB2MVS_IP.P390D37.DB2DEMO.ORDERDETAILS AS a
      INNER JOIN Titles AS b
          ON a.Prod_Id = b.TitleId
          WHERE a.Ord_Id >= @ORDER_ID
  END

  EXEC spGetOrderDetails_DB2MVS_IP 1001
```

For more information about the preceding stored procedures, see the Microsoft SQL Server Books Online.

INSERT, **UPDATE**, and **DELETE** statements when using four-part linked server queries invoke the client cursor engine (CCE). This means that some statements may fail or update incorrect columns. For example, if there is not a unique key column on the target tables or if there are not enough unique values for the CCE to accurately determine which columns to update, the statement may fail. For **INSERT**, **UPDATE**, and **DELETE** linked server queries, there must be either a unique index or unique values.

Using distributed queries, SQL Server returns all rows for the target table locally, and then sorts through results using the client cursor engine to find a unique value (composed of all columns if need be). If the CCE cannot find a unique value, the distributed query fails to perform the **INSERT**, **UPDATE**, or **DELETE** statement.

Using the OLE DB Provider for DB2, SQL Server distributed queries return the incorrect precision for DECIMAL data types when running **OPENQUERY**. The correct precision is returned for DECIMAL data types with using a linked server query.

Query Designer Support Using the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2 supports using the Query Designer that is included with Microsoft SQL Server. When Query Designer is launched from products such as SQL Server Data Transformation Services (DTS), the OLE DB Provider for DB2 is initialized with no provider-specific properties and an invalid property error may be generated.

To work around this problem, create a data link with the provider-specific properties required to connect to the host. These properties are specified in the Extended Properties field on the **All** tab when configuring a data source. Typically, the remote LU Alias, the local LU Alias, and the Default Schema should be specified using either the full property name (APPC Remote LU Alias=REMLU;APPC Local LU Alias;Default Schema=MYLIB) or the short names (RLU=REMLU;LLU;DEFSCH=MYLIB).

Other properties, such as **APPC Mode Name**, may need to be specified if the default values for that property are not acceptable. You should also specify a Default Schema. If a Default Schema is not specified, Query Designer displays all schemas on the remote system (including items such as libraries and collections), which can result in slow performance.

Data Transformation Services Support Using the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2 supports using the Data Transformation Services (DTS) facility provided with Microsoft SQL Server. DTS can be used for file transfer between DB2 and Microsoft SQL Server. There are some special considerations necessary when using DTS and the OLE DB Provider for DB2.

A DB2/400 database member can only be accessed in a SQL statement by using an ALIAS or SYNONYM. For example, if you have several members of a SALES.REVENUE database file, each member storing monthly sales information, you would access one month's data member by using an ALIAS. First, you must create the ALIAS.

```
CREATE ALIAS SALES.REVENUE_JANUARY FOR SALES.REVENUE(JANUARY)
```

Second, you must use this alias when issuing a SQL statement. You can access individual members using an ALIAS in the following SQL statements: SELECT, SELECT INTO, INSERT, UPDATE, and DELETE.

```
SELECT * FROM SALES.REVENUE_JANUARY
```

After the alias is created, you should be able to see the table listed in the systables by issuing the following SQL statement:

```
SELECT * FROM QSYS2.SYSTABLES WHERE TABLE_SCHEMA = 'SALES'
```

The REVENUE_JANUARY table type is "ALIAS". Many OLE DB providers and ODBC drivers do not list an ALIAS as a TABLE when returning catalog schema. Note that DTS does not list the table when using the Microsoft OLE DB Provider for DB2 or the Microsoft ODBC Driver for DB2. If the ALIAS is not listed, utilize the Query option in DTS to specify a SELECT * FROM SALES.REVENUE_JANUARY statement.

Note that it is possible to use the OVRDBF CL command. However, using an override database file has significant overhead, whereas an ALIAS is less demanding on DB2 server resources. Additionally, the OVRDBF command must be issued each time (likely as part of a stored procedure), whereas an ALIAS is persistent.

For more information, see the *DB2/400 IBM SQL Reference Version 4, Document Number SC41-5612-02*.

Microsoft SQL Server Data Transformation Services (DTS) does not automatically create target DB2 tables that can store DBCS or mixed DBCS-SBCS data. When using DTS to move DBCS or mixed data to DB2 as a source, one of the following techniques are recommended:

- Create the target DB2 table ahead of time.
- Edit the CREATE TABLE script within the DTS package to include the required CCSID and FOR MIXED clauses as appropriate for the target DB2 platform and version.

When importing TIME data fields into Microsoft SQL Server using DTS and the OLE DB Provider for DB2, the second field is incorrectly set to a value of **00**. This behavior occurs when the field data type in SQL Server is **Smalldatetime**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

SQL Server Replication Using the OLE DB Provider for DB2

Host Integration Server 2004 supports using the Microsoft OLE DB Provider for DB2 and Microsoft SQL Server Replication.

When using transactional replication, object names such as tables and constraints can be longer in Microsoft SQL Server than in DB2. Therefore, when moving data from Microsoft SQL Server to DB2, one of the following strategies should be used for compatibility:

- Create the Microsoft SQL Server tables and constraints so that the names do not exceed the limits of DB2. (For details, see the DB2 SQL Reference for the target platform and version of DB2.)
- Create the Microsoft SQL Server tables and constraints with names up to the maximum supported by Microsoft SQL Server, and then run ALTER TABLE SQL scripts against the Microsoft SQL Server distribution database after replication has created the publication, but before creating the subscriptions.

For replication to work properly, SQL Server-to-DB2 data type mapping entries must be provided for several data types. These data type mappings must be stored in the Microsoft SQL Server MSdatatype_mappings table in the msdb database. Data type mapping entries must be provided to properly support the CHAR and VARCHAR data types when used to store SBCS character strings or binary data (BINARY and VARBINARY) with replication. The mappings for CHAR and VARCHAR are needed due to the limits for the boundary values using the OLE DB Provider for DB2. The mappings for binary data types are required because binary data is stored as character data using the OLE DB Provider for DB2.

This SQL Server msdb.MSdatatype_mappings table can be updated using a stored procedure that comes with SQL Server. The exec sp_add_datatype_mapping command is a stored procedure that comes with SQL Server. You should run these data mappings in the SQL Query Analyzer (Isqlw.exe). Each line of the exec sp_add_datatype_mapping procedure will add one data mapping to msdb.Msdatatype_mappings.

The Microsoft OLE DB Provider for DB2 when accessing DB2 on all platforms and versions does not support the following Microsoft SQL Server data types with direct mappings. The following is a summary of the limitations.

Microsoft OLE DB Provider for DB2 does not support DB2 GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC data types. Mappings to these DB2 types should be avoided.

Microsoft OLE DB Provider for DB2 does not support DB2 Large Object data types, such as CLOB, DBCLOB, and BLOB, which are used in DB2 Universal Database. Microsoft OLE DB Provider for DB2 does not support the DB2 BIGINT data types, which are used in DB2 Universal Database for Windows NT.

Microsoft SQL Server NCHAR, NVARCHAR, NTEXT, and SYSNAME data types do not map well to supported DB2 data types. The Microsoft SQL Server TIMESTAMP data type should be mapped to a DB2 CHAR FOR BIT DATA data type. The TIMESTAMP data type in SQL Server is used only for the purposes of table logging and not for end-user data. Therefore, you should not map the SQL Server TIMESTAMP data type to the DB2 TIMESTAMP.

The sample mapping table entries map Microsoft SQL Server TEXT and IMAGE to DB2 VARCHAR and DB2 VARCHAR FOR BIT DATA respectively. These Microsoft SQL Server data types can represent up to 2 gigabytes (GB) of data. In contrast, the DB2 VARCHAR data types can hold at most approximately 32 kilobytes (KB) of data. As such, data truncation may occur.

For Microsoft SQL Server data types, MONEY, SMALLMONEY, DECIMAL, and NUMERIC, data values can be replicated to DB2 correctly, but these floating-point data types are mapped to STRING instead of FLOAT. After these data values are replicated to DB2, the string values should be converted back to float before performing calculations. An alternative is to do the calculations and update using SQL Server before replicating these data values over to DB2.

This section contains:

- SQL Replication with DB2 for OS/400
- SQL Replication with DB2 for MVS
- SQL Replication with DB2 UDB for AIX
- SQL Replication with DB2 UDB for Windows NT

SQL Replication with DB2 for OS/400

When used with DB2 for OS/400, run the following commands in a stored procedure:

```
exec dbo.sp_add_datatype_mapping 'DB2/400', 'bit',
    'SMALLINT', 1,  0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'char', 'CHAR', 8000, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'datetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'decimal',
    'DECIMAL', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'double precision',
    'DOUBLE', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'float', 'FLOAT', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'int', 'INT', 10, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'money',
    'DECIMAL', 19, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'numeric',
    'NUMERIC', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'real', 'REAL', 24, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'smalldatetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'smallint',
    'SMALLINT', 5, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'smallmoney',
    'DECIMAL', 10, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'text',
    'VARCHAR', 32739, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'tinyint',
    'SMALLINT', 1, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'uniqueidentifier',
    'CHAR', 38, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'varchar',
    'VARCHAR', 8000, 4, 1
```

SQL Replication with DB2 for MVS

When used with DB2 for MVS, run the following commands:

```
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'bit',
    'SMALLINT', 1,  0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'char', 'CHAR', 254, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'datetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'decimal',
    'DECIMAL', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'double precision',
    'DOUBLE', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'float', 'FLOAT', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'int',
    'INT', 10, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'money',
    'DECIMAL', 19, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'numeric',
    'NUMERIC', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'real', 'REAL', 24, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'smalldatetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'smallint',
    'SMALLINT', 5, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'smallmoney',
   'DECIMAL', 10, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'text',
   'VARCHAR', 4045, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'tinyint',
    'SMALLINT', 1, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'uniqueidentifier',
    'CHAR', 38, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'varchar',
    'VARCHAR', 4045, 4, 1
```

SQL Replication with DB2 UDB for AIX

When used with DB2 Universal Database for AIX, run the following commands:

```
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'bit',
    'SMALLINT', 1,  0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'char',
    'CHAR', 8000, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'datetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'decimal',
    'DECIMAL', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'double precision',
    'DOUBLE', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'float',
    'FLOAT', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'int', 'INT', 10, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'money',
    'DECIMAL', 19, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'numeric',
    'NUMERIC', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'real', 'REAL', 24, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'smalldatetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'smallint',
    'SMALLINT', 5, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'smallmoney',
    'DECIMAL', 10, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'text',
    'VARCHAR', 32739, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'tinyint',
    'SMALLINT', 1, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'uniqueidentifier',
    'CHAR', 38, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'varchar',
    'VARCHAR', 8000, 4, 1
```

SQL Replication with DB2 UDB for Windows NT

When used with DB2 Universal Database for Windows NT, run the following commands:

```
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'bit',
    'SMALLINT', 1,  0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'char', 'CHAR', 8000, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'datetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'decimal',
    'DECIMAL', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'double precision',
    'DOUBLE', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'float', 'FLOAT', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'int', 'INT', 10, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'money',
    'DECIMAL', 19, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'numeric',
    'NUMERIC', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'real', 'REAL', 24, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'smalldatetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'smallint',
    'SMALLINT', 5, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'smallmoney',
    'DECIMAL', 10, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'text',
    'VARCHAR', 32739, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'tinyint',
    'SMALLINT', 1, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'uniqueidentifier',
    'CHAR', 38, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'varchar',
    'VARCHAR', 8000, 4, 1
```

Code Page Support Using the OLE DB Provider for DB2

When creating data links for use with the OLE DB Provider for DB2, the Host character code set identifier (CCSID) should be configured in the data source to match the DB2 data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37) when using the OLE DB Provider for DB2.

Depending on the version of Windows being used, to support specific code page conversions, you may need to install the appropriate National Language Support (NLS) file for your locale.

The appropriate ANSI NLS file for your locale is installed automatically when you install a localized version of Windows Server 2003 or Windows 2000.

The following sections discuss the CCSIDs supported by OLE DB Provider for DB2 in Host Integration Server 2004.

This section contains:

- ANSI Code Page Support Using the OLE DB Provider for DB2
- EBCDIC Code Page Support Using the OLE DB Provider for DB2
- ISO Code Page Support Using the OLE DB Provider for DB2
- DBCS Code Page Support Using the OLE DB Provider for DB2

ANSI Code Page Support Using the OLE DB Provider for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured to use ANSI code pages, for example ANSI 1253 (Greek). Host Integration Server 2004 includes support for some ANSI code pages for purposes of ANSI-to-UNICODE-to-ANSI conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These ANSI code pages can be used when accessing IBM DB2 Universal Database on Windows NT and IBM DB2 ON AIX. (Not all of these ANSI code pages are supported on IBM DB2 Universal Database for AIX.)

The following table shows the ANSI character code set identifiers (CCSIDs) supported by OLE DB Provider for DB2 in Host Integration Server 2004.

Microsoft display name	Microsoft NLS code page	IBM CCSID	Comments
ANSI - Arabic	1256	1256	None.
ANSI - Baltic	1257	1257	None.
ANSI - Cyrillic	1251	1251	None.
ANSI - Central Europe	1250	1250	None.
ANSI - Greek	1253	1253	None.
ANSI - Hebrew	1255	1255	None.
ANSI - Latin I	1252	1252	Support for this code page is normally installed as part of the operating system on Windows Server 2003 or Windows 2000.
ANSI - Turkish	1254	1254	None.
ANSI/OEM - Japanese Shift JIS	932	932	None.
ANSI/OEM - Korean	949	949	None.
ANSI/OEM - Simplified Chinese GBK	936	936	None.
ANSI/OEM - Thai	874	874	None.
ANSI/OEM - Traditional Chinese Big5	950	950	None.
ANSI/OEM - Viet Nam	1258	1258	None.

The Microsoft display name is the name found in the Windows Server 2003 or Windows 2000 definitions for these National Language Support (NLS) files. The Microsoft NLS code page column represents the code page number that is registered and associated with an ANSI-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the OLE DB Provider for DB2. When setting the Host CCSID or PC Code Page attribute or property using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ANSI code page in IBM publications, which for these supported ANSI CCSIDs are the same as the Microsoft CCSID values. IBM lists their ANSI support in publications by referencing the display name which for these ANSI code pages is the same as the Microsoft display name. The OLE DB Provider for DB2 does not recognize or display the IBM CCSID values when configuring data sources using data links. The OLE DB Provider for DB2 maps the Microsoft NLS numbers to ANSI NLS files which correspond with the appropriate IBM CCSID numbers. The OLE DB Provider for DB2, as well as Microsoft ODBC Driver for DB2, pass the corresponding IBM CCSID to the DB2 system at run time even though you configure the provider or driver to use the Microsoft NLS number.

These are the only ANSI pages currently supported by the OLE DB Provider for DB2 in Host Integration Server 2004. IBM supports additional ANSI pages. However, the ANSI code pages listed in the preceding table are the only cases where the Microsoft NLS pages and IBM ANSI code pages (CCSIDs) match.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

EBCDIC Code Page Support Using the OLE DB Provider for DB2

IBM DB2 for MVS, IBM DB2 for OS/390, and IBM DB2 for OS/400 are frequently configured to use EBCDIC code pages, for example EBCDIC 875 (Greek Modern). Host Integration Server 2004 includes support for most EBCDIC code pages for purposes of EBCDIC-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-EBCDIC, and EBCDIC-to-UNICODE-to-EBCDIC conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These EBCDIC code pages can be used when accessing IBM DB2 on a variety of platforms. (Not all of these EBCDIC code pages are supported on all versions of IBM DB2.)

The following table shows the EBCDIC character code set identifiers (CCSIDs) supported by OLE DB Provider for DB2 in Host Integration Server 2004.

Microsoft display name	**Microsoft NLS code page**	**IBM CCSID**	**Comments**
IBM EBCDIC - Arabic	20420	420	None.
IBM EBCDIC - Cyrillic (Russian)	20880	880	None.
IBM EBCDIC - Cyrillic (Serbian, Bulgarian)	21025	1025	None.
IBM EBCDIC - Denmark/Norway	20277	277	None.
IBM EBCDIC - Denmark/Norway (Euro)	1142	1142	None.
IBM EBCDIC - Finland/Sweden	20278	278	None.
IBM EBCDIC - Finland/Sweden (Euro)	1143	1143	None.
IBM EBCDIC - France	20297	297	None.
IBM EBCDIC - France (Euro)	1147	1147	None.
IBM EBCDIC - Germany	20273	273	None.
IBM EBCDIC - Germany (Euro)	1141	1141	None.
IBM EBCDIC - Greek	20423	423	None.
IBM EBCDIC - Greek (Modern)	875	875	None.
IBM EBCDIC - Hebrew	20424	424	None.
IBM EBCDIC - Icelandic	20871	871	None.
IBM EBCDIC - Icelandic (Euro)	1149	1149	None.
IBM EBCDIC - International	500	500	None.
IBM EBCDIC - International (Euro)	1148	1148	None.
IBM EBCDIC - Italy	20280	280	None.
IBM EBCDIC - Italy (Euro)	1144	1144	None.
IBM EBCDIC - Japan English/Kanji (Extended)	939	939	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan English/Kanji (Extended)	5035	5035	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan Katakana/Kanji (Extended)	930	930	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan Katakana/Kanji (Extended)	5026	5026	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japanese	931	931	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Korea (Extended)	933	933	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Latin America/Spain	20284	284	None.
IBM EBCDIC - Latin America/Spain (Euro)	1145	1145	None.
IBM EBCDIC - Multilingual/ROECE (Latin-2)	870	870	None.
IBM EBCDIC - Simplified Chinese (Extended)	935	935	None.
IBM EBCDIC - Thai	20838	838	None.
IBM EBCDIC - Traditional Chinese (Extended)	937	937	Support for this double-byte character set is supplied using TRNSDT.

IBM EBCDIC - Turkish (Latin-3)	20905	905	None.
IBM EBCDIC - Turkish (Latin-5)	1026	1026	None.
IBM EBCDIC - U.S./Canada	037	37	None.
IBM EBCDIC - U.S./Canada (Euro)	1140	1140	None.
IBM EBCDIC - United Kingdom	20285	285	None.
IBM EBCDIC - United Kingdom (Euro)	1146	1146	None.

The Microsoft display name is the name found in the Windows Server 2003 or Windows 2000 definitions for these National Language Support (NLS) files. The Microsoft NLS code page column represents the code page number that is registered and associated with an EBCDIC-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the OLE DB Provider for DB2. When setting the Host CCSID or PC Code Page attribute or property using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the EBCDIC code page in IBM publications. IBM lists their EBCDIC support in publications by referencing the display name which for these EBCDIC code pages is the same as the Microsoft display name. The OLE DB Provider for DB2 does not recognize or display the IBM CCSID values when configuring data sources using data links. The OLE DB Provider for DB2 maps the Microsoft NLS numbers to EBCDIC NLS files which correspond with the appropriate IBM CCSID numbers. The OLE DB Provider for DB2, as well as Microsoft ODBC Driver for DB2, pass the corresponding IBM CCSID to the DB2 system at run time even though you configure the provider or driver to use the Microsoft NLS number.

These are the only EBCDIC pages currently supported by the OLE DB Provider for DB2 in Host Integration Server 2004. IBM supports additional EBCDIC pages. However, the EBCDIC code pages listed in the preceding table are the only cases where the Microsoft NLS pages and IBM EBCDIC code pages (CCSIDs) match.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ISO Code Page Support Using the OLE DB Provider for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured for an ISO code page, for example ISO 819 (Latin I). Host Integration Server 2004 includes support for some ISO code pages for purposes of ISO-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-ISO, and ISO-to-UNICODE-to-ISO conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2.

The following table shows the ISO character code set identifiers (CCSIDs) supported by OLE DB Provider for DB2 in Host Integration Server 2004.

Microsoft display name	Microsoft NLS code page	IBM CCSID	Comments
ISO 8859-1 Latin 1	28591	819	None.
ISO 8859-2 Central Europe	28592	912	None.
ISO 8859-5 Cyrillic	28595	915	None.
ISO 8859-6 Arabic	28596	1089	None.
ISO 8859-7 Greek	28597	813	None.
ISO 8859-8 Hebrew	28598	916	None.
ISO 8859-9 Turkish	28599	920	None.
ISO 6937 Non-Spacing Accent	20269	819	Note that ISO 6937 (CCSID 20269) is not supported by the OLE DB Provider for DB2, but is displayed in the list of configuration options when creating or modifying data sources.
ISO 8859-15 Latin 9 (Euro)	20865	923	NLS Code Page 819 with support for the euro.

The Microsoft National Language Support (NLS) code page column represents the code page number that is registered and associated with an ISO-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the OLE DB Provider for DB2. When setting the Host CCSID or PC Code Page attribute or property using a connection string, use the Microsoft NLS number for this parameter.

The IBM CCSID column represents the CCSID given to the ISO code page in IBM publications. IBM lists their ISO support in publications by referencing the locale name (Bulgaria for ISO8859-5 and 915, for example) rather than using ISO 8859-5 Cyrillic as used by Microsoft. The OLE DB Provider for DB2 does not recognize or display the IBM CCSID values when configuring data sources using data links. The OLE DB Provider for DB2 maps the Microsoft NLS numbers to ISO NLS files which correspond with the appropriate IBM CCSID numbers. The OLE DB Provider for DB2, as well as Microsoft ODBC Driver for DB2, pass the corresponding IBM CCSID to the DB2 system at run time even though you configure the provider or driver to use the Microsoft NLS number.

Note that IBM CCSID 819 is associated with both ISO 8859-1 Latin 1 and ISO 6937 Non-Spacing Accent. It is up to you to choose the standard ISO 8859-1 Latin 1 code page by selecting NLS code page 28591 or the modified code page ISO 6937 Non-Spacing Accent by selecting NLS code page 20269. Note that ISO 6937 Non-Spacing Accent (CCSID 20269) is not currently supported by the OLE DB Provider for DB2, but is displayed in the configuration options when creating or modifying data sources.

IBM CCSID 916 (ISO 8859-8) supports Hebrew visual sort order. IBM CCSID 920 (ISO 8859-8 derivation) supports Hebrew logical sort order. Microsoft supports the logical sort order with NLS 38598.

The OLE DB Provider for DB2 has not been tested using the ISO 8859-8 derivation matching IBM CCSID 920 and does not support this configuration.

These are the only ISO pages currently supported in Host Integration Server 2004. Microsoft supports a number of additional ISO pages. IBM also supports additional ISO pages. However, the code pages listed in the preceding table re the only cases where the Microsoft NLS pages and IBM CCSIDs match.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

DBCS Code Page Support Using the OLE DB Provider for DB2

The OLE DB Provider for DB2 supports Double-Byte Character String (DBCS) data, including conversions between DBCS and ANSI code pages. Conversions between DBCS and ISO code pages are also supported, as are positioned updates against DBCS EBCDIC implementations of DB2.

The DB2 GRAPHIC data types (GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC) are now explicitly supported. These DB2 data types support DBCS (not mixed) data. Mixed data types are supported using CHAR FOR MIXED DATA, VARCHAR FOR MIXED DATA, and LONGVARCHAR FOR MIXED DATA.

Parameterized SQL statements and calling stored procedures when the parameter values contain mixed or DBCS characters are supported.

When performing a SQL statement with inline data, character strings can be prefixed with a ‘G’ or ‘g’ to denote that the data is DBCS and is to be used with a graphic column. Only double-byte characters can be used with a graphic column. For example:

```
CREATE TABLE NAMES (COL1 GRAPHIC(64), COL2 CHAR(64))
INSERT INTO NAMES (COL1, COL2) VALUES (G’DBCS data’, ‘MBCS or SBCS data’)
```

The prefixes ‘n’ (graphic) and ‘gx’ (hexadecimal graphic) are also supported.

Data Conversion Using the OLE DB Provider for DB2

The design of the OLE DB application programming interfaces (APIs) is similar to the APIs provided by ODBC and other ISAM APIs. The APIs are handle-based. After opening a file, the application can determine the buffer size required to store a row, use the cursor APIs to move, and optionally retrieve one or more rows of data using the row-level binding.

Data is converted to default C data types as defined in ODBC and OLE DB illustrated in the following table.

DB2 data type	**Default C data type**	**Comments**
BIGINT	Not applicable.	An 8-byte integer. This data type is converted to DBTYPE_I8 for use by OLE DB. This data type is supported on DB2 UDB only.
BLOB	Not applicable.	A Binary Large Object (BLOB) is a varying-length string that can be up to 2 gigabytes in length. A BLOB is primarily intended to hold binary data. This data type is converted to a DBTYPE_STR for use by OLE DB. This data type is not supported by the OLE DB Provider for DB2.
CHAR (Bit)	char string[]	A fixed length string. This data type is converted to a DBTYPE_BSTR for use by OLE DB.
CHAR (SBCS)	char string[]	A fixed-length SBCS character string. This data type is converted to a DBTYPE_BSTR for use by OLE DB.
CHAR (Mixed Data)	char string[]	A fixed-length mixed character string. This data type is converted to a DBTYPE_BSTR for use by OLE DB.
CLOB	Not applicable.	A Character Large Object (CLOB) is a varying-length string that can be up to 2 gigabytes in length. A CLOB is used to store large single-byte character set data. A CLOB is considered to be a character string. This data type is converted to a DBTYPE_STR for use by OLE DB. This data type is not supported by the OLE DB Provider for DB2.
DATE	date struct	A 10-byte date string. This data type is converted to a DBTYPE_DATE for use by OLE DB.
DEC	unsigned char number[]	A packed decimal number. This data type is converted to a DBTYPE_DECIMAL for use by OLE DB.
DOUBLE	double	An 8-byte double-precision floating point number. This data type is converted to a DBTYPE_R8 for use by OLE DB.
FLOAT	double	An 8-byte double-precision floating point number. This data type is the same as a DOUBLE. This data type is converted to a DBTYPE_R8 for use by OLE DB.
GRAPHIC (DBCS)	unsigned char binary[]	A fixed-length graphic string consisting of a sequence of double byte character string (DBCS) data. This data type is converted to a DBTYPE_WSTR for use by OLE DB.
INTEGER	int	A 4-byte integer ranging in value from -2,147,463,648 to +2,147,483,647. This data type is converted to a DBTYPE_I4 for use by OLE DB.
LONG VARCHAR (Bit)	char string[]	A varying-length character string up to 32,740 characters in length. This data type is converted to a DBTYPE_STR for use by OLE DB.

LONG VARCHAR (SBCS)	char string[]	A varying-length SBCS character string up to 32,740 characters in length. This data type is converted to a DBTYPE_STR for use by OLE DB.
LONG VARCHAR (Mixed)	char string[]	A varying-length mixed-character string. This data type is converted to a DBTYPE_STR for use by OLE DB.
LONG VARGRAPHIC (DBCS)	unsigned char binary[]	A varying-length graphic string consisting of a sequence of double byte character string (DBCS) data ranging up to 16,383 DBCS characters in length. This data type is converted to a DBTYPE_WSTR for use by OLE DB.
SMALLINT	short	A SMALLINT (small integer) is a two-byte integer with a precision of 5 digits ranging from -32,768 to +32,767. This data type is converted to a DBTYPE_I2 for use by OLE DB.
REAL	float	A 4-byte single-precision floating point number. This data type is converted to a DBTYPE_R4 for use by OLE DB.
TIME	time struct	An 8-byte time string. This data type is converted to a DBTYPE_TIME for use by OLE DB. When using ActiveX Data Objects to return data from a DB2 TIME data type, ADO returns a DATETIME value.
TIMESTAMP	timestamp struct	A 26-byte string representing the date, time, and microseconds. This data type is converted to a DBTYPE_DBTIMESTAMP for use by OLE DB.
VARCHAR (Bit)	char string[]	A varying-length character string. The maximum length of the string is dependent on the version and the platform that DB2 is running on. This data type is converted to a DBTYPE_STR for use by OLE DB.
VARCHAR (SBCS)	char string[]	A varying-length character string. The maximum length of the string is dependent on the version and the platform that DB2 is running on. This data type is converted to a DBTYPE_STR for use by OLE DB.
VARCHAR (Mixed)	char string[]	A varying-length character string. The maximum length of the string is dependent on the version and the platform that DB2 is running on. This data type is converted to a DBTYPE_STR for use by OLE DB.
VARGRAPHIC (DBCS)	unsigned char binary[]	A varying-length graphic string consisting of a sequence of double byte character string (DBCS) data. The maximum length of the string is dependent on the version and the platform that DB2 is running on. This data type is converted to a DBTYPE_WSTR for use by OLE DB.

Note that the maximum length of fixed-length CHAR, fixed-length GRAPHIC, VARCHAR, and VARGRAPHIC data types is dependent on the version of DB2 that is being accessed. For example, the maximum length of the CHAR data type on DB2 for OS/390 is 254 characters, while the maximum length of this same host data type is 32,765 on DB2/400.

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example). However, truncation and conversion errors can occur that will not be reported by the OLE DB Provider for DB2.

Using the OLE DB Provider for DB2, certain conversions of strings from EBCDIC to ASCII and then back to EBCDIC are asymmetric, and can result in strings that are different from the original. The EBCDIC specification contains ordinals for which there is no defined character. The OLE DB Provider for DB2 translates all such undefined characters to the question mark character (?). So when ASCII strings containing these characters are converted back to EBCDIC, these undefined characters will be replaced with question marks. To protect EBCDIC strings containing undefined characters, these fields should be tagged as binary strings and mapped by the application.

The ANSI to EBCDIC character conversions affected include the following.

Character value (decimal)	Character value (hexadecimal)	ANSI code page 1252	EBCDIC character after conversion to CCSID 37
128	0x80	Not used	?
130	0x82	Single low quote	?
131	0x83	Latin F with hook	?
132	0x84	Double low quote	?
133	0x85	Ellipsis	?
134	0x86	Dagger	?
135	0x87	Double dagger	?
136	0x88	Per mile	?
137	0x89	S with caron	?
138	0x8A	Left angle	?
139	0x8B	Ligature OE	?
140	0x8C	Not used	?
142	0x8E	Not used	?
145-156	0x91-0x9C		?
158-159	0x9E-0x9F		?

Floating Point Considerations Using the OLE DB Provider for DB2

When real or double (synonymous with float) data is inserted into a DB2 table as a floating point data type, it is stored in scientific notation. For example, FLOAT(1.1) would be stored as +1.10000E+000.

Care must be taken when executing SQL statements to make sure that the proper data type specified in the SQL statement matches the values stored in DB2. For example, the following select statement would match values in DB2 stored as decimal 1.1.

```
SELECT * FROM TEST WHERE C1 = 1.1
```

If the data in DB2 was stored as real numbers, there would not be a match because decimal 1.1 is stored as 1.1, not the representation of +1.10000E+000. When DB2 parses and executes the SQL select statement, it interprets 1.1 as a decimal type. When doing the select query, DB2 does not implicitly do the conversion to floating point. In this case, the SQL statement should explicitly typecast the 1.1 so that DB2 looks for the correct format (the scientific notation format). The select query would look like the following:

```
SELECT * FROM TEST WHERE C1 = REAL(1.1)
```

This will give the results expected. The SQL REAL function will convert the decimal 1.1 to the proper format before DB2 executes the actual select.

Usernames and Passwords Using the OLE DB Provider for DB2

When connecting to remote DB2 systems, most users must be authenticated by the remote system by passing a valid user ID and password.

The AS/400 computer is case-sensitive with regard to user ID and password. The AS/400 only accepts a user ID and password in uppercase. The Microsoft OLE DB Provider for DB2 will force the user ID and password into uppercase when it knows that it is connecting to a DB2/400 system.

The mainframe is not case-sensitive. This means that on mainframe computers, one can enter the user ID and password in any case.

DB2 Universal Database (UDB) for Windows NT is case-sensitive. UDB supports mixed-case passwords. The user must enter the password in the correct mixed case. When entering a user ID, use only the Windows NT user name and do not include the Windows NT domain name.

Two-Phase Commit over TCP/IP Support for the OLE DB Provider for DB2

Two-phase commit (2PC) is a host server-installed protocol that ensures that updates to multiple instances of a database on a network will either succeed or fail in their entirety. Host Integration Server 2004 supports 2PC over TCP/IP, allowing you to gain the security of a 2PC connection over the Internet.

Host Integration Server supports 2PC using three components: the DTC, the Resync Service, and the transaction log. The DTC governs the normal DTC transaction flow: enlist, prepare, commit, and abort. The Resync Service coordinates transaction recovery in case of any failure or disconnection, while the transaction log maintains a log of information that is needed in case of recovery.

You can perform a 2PC transaction with the OLE DB Provider for DB2 using the **ITransactionJoin** interface. However, you may need to configure your 2PC connection using tools such as the OLE DB data links tool.

Troubleshooting the OLE DB Provider for DB2

The Windows Server 2003 and Windows 2000 Event Viewer can be a useful tool for troubleshooting data access in some cases. The OLE DB Provider for DB2 does not issue events. However, when SNA (APPC/LU 6.2) is used for the network transport for the OLE DB Provider for DB2, the low-level SNA APPC transport issues events on the SNA connection.

The Microsoft OLE DB Provider for DB2 supplied with Host Integration Server 2004 has the ability to trace DRDA data flows when used over TCP/IP.

This DB2 tracing capability is accessible from the DB2 Network Library inside the Trace utility. This facility will show the same data as an APPC trace but without the control indicators (for example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the platform software development kit (SDK).

The OLE DB Provider for DB2 can return the following types of errors:

- DB2 SQL errors from the remote database
- Microsoft OLE DB Provider-specific errors
- Errors from the underlying DRDA application requester network client

When the OLE DB Provider for DB2 passes an error code, the best source in which to look up the meaning of the return code is often the SQL Reference or SQL Messages and Codes Reference for the target SQL database. In this case, the target database would be one of the DB2 platforms supported by the Microsoft OLE DB Provider for DB2.

The OLE DB Provider for DB2 maintains an internal integer variable named SQLCODE and an internal 5-byte character string variable named SQLSTATE used to check the execution of SQL statements on DB2. SQLCODE is set by DB2 after each SQL statement is executed. DB2 returns the following values for SQLCODE:

- If SQLCODE = 0, execution was successful.
- If SQLCODE > 0, execution was successful with a warning.
- If SQLCODE < 0, execution was not successful.
- SQLCODE = 100, no data was found. For example, a FETCH statement returned no data because the cursor was positioned after the last row of the result table.

SQLSTATE is also set by DB2 after the execution of each SQL statement. Application programs can check the execution of SQL statements by testing SQLSTATE instead of SQLCODE. SQLSTATE provides application programs with common codes for common error conditions. (The values of SQLSTATE are product-specific only if the error or warning is product-specific.) Furthermore, SQLSTATE is designed so that application programs can test for specific errors or classes of errors.

SQLSTATE values consist of a two-character class code value, followed by a three-character subclass code value. The first character of an SQLSTATE value indicates whether the SQL statement was executed successfully or unsuccessfully (equal to or not equal to zero, respectively). Class code values represent classes of successful and unsuccessful execution conditions. The following SQLSTATE class codes are used by DB2.

Class Code	**Description of Error Class**
00	Successful completion (execution of the SQL statement was successful and did not result in any type of warning or exception condition)
01	Warning
02	No data
07	Dynamic SQL error
08	Connection exception
0A	Feature not supported
0F	Invalid token
21	Cardinality violation
22	Data exception
23	Constraint violation
24	Invalid cursor state
25	Invalid transaction state
26	Invalid SQL statement identifier
2D	Invalid transaction termination
34	Invalid cursor name

39	External function call exception
40	Transaction rollback
42	Syntax error or access rule violation
44	WITH CHECK OPTION violation
51	Invalid application state
53	Invalid operand or inconsistent specification
54	SQL or product limit exceeded
55	Object not in prerequisite state
56	Miscellaneous SQL or product error
57	Resource not available or operator intervention
58	System error

The SQLSTATE value of HY000 is defined as a provider-specific error. An SQLSTATE of 08S01 (connection exception with a subclass code of S01) also indicates a provider-specific error. This means the SQLCODE should be looked up in the driver-specific documentation included with the OLE DB Provider for DB2.

If the SQLSTATE does not indicate a driver-specific error when the OLE DB Provider for DB2 passes back an SQLSTATE of 08S01, it indicates a network error. For example, an SQLCODE of -603 is a provider-specific error that is mapped to DB2OLEDB_COMM_HOST_CONNECT_FAILED in the Ddb2oledb.h include file supplied with the OLE DB Provider for DB2. Errors with an SQLSTATE of 08S01 are documented in the Db2oledb.h include file (the SQLCODE value), which is located on the Host Integration Server 2004 CD in the SDK\Include subdirectory.

The following steps are useful in researching an error. Start by reading the provided error text returned by the OLE DB Provider for DB2. In some cases, the error text provides limited useful information. For example, error text from an SQLCODE of -603 states the following:

```
Test connection failed because of an error in initializing provider.
Could not connect to specified host.
```

The next step is to lookup the SQLSTATE to determine the source of the error. Is the error a DB2 error, a network client error, or an OLE DB provider error? An SQLSTATE of 08S01 is defined as follows:

```
Communication link failure.
```

This definition is intended to inform the user, administrator, or developer that the error is one related to the OLE DB provider's underlying network client.

Unfortunately, many of the SQLSTATE codes returned by the OLE DB Provider for DB2 are DB2 errors and are not documented in the OLE DB Provider for DB2 Help.

The SQLSTATE of HY000 is defined as a provider-specific error. An SQLSTATE of 08S01 also indicates a provider-specific error. This means the SQLCODE should be looked up in the provider-specific documentation included with the OLE DB Provider for DB2.

If the SQLSTATE does not indicate a driver-specific error, the SQLCODE should be looked up in the appropriate DB2 manual for the target platform. For example, an SQLCODE of -603 is documented in Appendix B, "SQLCODEs and SQLSTATEs," in the *AS/400 Advanced Series DB2 for AS/400 SQL Programming, Version 4*, Document Number SC41-5611-00 published by IBM. An SQLCODE of -603 corresponds to SQLSTATE 23515 in the DB2 for OS/400 error code list. For example, the explanation for this SQLCODE is as follows:

```
Unique index cannot be created because of duplicate keys.
```

When the SQLSTATE and the SQLCODE definitions documented in these appendices create a mismatch with the actual errors returned, this usually indicates a provider-specific error condition.

A final step to understand an error is to check the Db2oledb.h file. This file is not installed by the Host Integration Server or Host Integration Client Setup program, but can be found on the Host Integration Server 2004 product CD in the SDK\Include subdirectory. An SQLCODE (for example, -603) can be looked up by searching the right-most column of the Db2oledb.h file for a value near to 603. In this case, one will see a comment "/* -600 */" and can then count down three additional lines to line number 603. The internal error code -603 is defined as follows:

```
DB2OLEDB_COMM_HOST_CONNECT_FAILED
```

This particular error usually indicates a problem with the configuration parameters or the connection string passed.

ADO Object, Method, Property, and Collection Support for AS/400, VSAM and DB2

Microsoft® ActiveX® Data Objects (ADO) version 2.0 defines a number of objects, methods, properties, and collections.

Microsoft OLE DB Provider for AS/400 and VSAM supports the ADO objects, methods, properties, and collections that are appropriate for an OLE DB data provider accessing a non-SQL host file system.

Microsoft OLE DB Provider for DB2 supports the ADO objects, methods, properties, and collections that are appropriate for an OLE DB data provider accessing an SQL database.

Similar support for ODBC can be found in the topic ADO Object Support in the ODBC Driver for DB2.

This section contains:

- ADO Object Support in the OLE DB Provider for AS/400 and VSAM
- ADO Object Support in the OLE DB Provider for DB2

ADO Object Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the Microsoft® ActiveX® Data Objects (ADO) version 2.0 objects that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

ADO object	Support
Collection	Yes, most methods
Command Object	Yes, some methods, some properties, and all collections
Connection Object	Yes, some methods, some properties, and all collections
Error Object	Yes, some properties
Field Object	Yes, all methods, properties, and collections
Parameter Object	No
Recordset Object	Yes, most methods, most properties, and all collections

This section contains:

- ADO Method Support in the OLE DB Provider for AS/400 and VSAM
- ADO Property Support in the OLE DB Provider for AS/400 and VSAM
- ADO Collection Support in the OLE DB Provider for AS/400 and VSAM
- Command Object in the OLE DB Provider for AS/400 and VSAM (ADO)
- Connection Object in the OLE DB Provider for AS/400 and VSAM (ADO)
- Error Object in the OLE DB Provider for AS/400 and VSAM (ADO)
- Field Object in the OLE DB Provider for AS/400 and VSAM (ADO)
- Recordset Object in the OLE DB Provider for AS/400 and VSAM (ADO)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ADO Method Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ActiveX® Data Objects (ADO) version 2.0 object methods that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

ADO object	Method	Support
Collection object	**Append** Method	No
	Clear Method	Yes
	Delete Method	Yes
	Item Method	Yes
	Refresh Method	Yes
Command Object	**CreateParameter** Method	No
	Cancel Method	No
	Execute Method	Yes, but options must be **adCmdText**
Connection Object	**BeginTrans** Method	No
	Cancel Method	No
	Close Method	Yes
	CommitTrans Method	No
	Execute Method	Yes, but options must be **adCmdText**
	Open Method	Yes
	OpenSchema Method	Yes
	RollbackTrans Method	No
Field Object	AppendChunk Method	Yes
	GetChunk Method	Yes
	ReadFromFile Method	No
	WriteToFile Method	No
Parameter Method	**AppendChunk** Method	No
Recordset Object	AddNew Method	Yes
	Cancel Method	No
	CancelBatch Method	Yes
	CancelUpdate Method	Yes
	Clone Method	Yes
	Close Method	Yes
	Delete Method	Yes
	Find Method	Yes
	GetRows Method	Yes
	Move Method	Yes
	MoveFirst Method	Yes
	MoveLast Method	Yes
	MoveNext Method	Yes
	MovePrevious Method	Yes
	NextRecordset Method	No
	Open Method	Yes
	Requery Method	Yes
	Resync Method	No
	Save Method	Yes
	Seek Method	No
	Supports Method	Yes
	Update Method	Yes
	UpdateBatch Method	Yes

Note The **Collection** object is a special case, representing a collection of other ADO objects. These collection objects support several methods:

- **Append** to add an object to a collection
- **Clear** to empty all objects from a collection
- **Delete** to remove a single object from a collection
- **Item** to return a specific member object of a collection by name or ordinal number
- **Refresh** to update the objects in a collection to reflect objects available from and specific to the OLE DB provider

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ADO Property Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ActiveX® Data Objects (ADO) version 2.0 object properties that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

ADO object	Property	Support
Command Object	ActiveConnection Property	Yes
	CommandText Property	Yes
	CommandTimeout Property	No
	CommandType Property	Yes
	Prepared Property	No
	State Property	Yes
Connection Object	Attributes Property	Yes
	CommandTimeout Property	No
	ConnectionString Property	Yes
	ConnectionTimeout Property	No
	CursorLocation Property	Yes
	DefaultDatabase Property	No
	IsolationLevel Property	No
	Mode Property	Yes
	Provider Property	Yes
	State Property	Yes
	Version Property	Yes
Error Object	Description Property	Yes
	HelpContext Property	No
	HelpFile Property	No
	NativeError Property	Yes
	Number Property	Yes
	Source Property	Yes
	SQLState Property	No
Field Object	ActualSize Property	Yes
	Attributes Property	Yes
	DataFormat Property	No
	DefinedSize Property	Yes
	Name Property	Yes
	NumericScale Property	Yes
	OriginalValue Property	Yes
	Precision Property	Yes
	Type Property	Yes
	UnderlyingValue Property	Yes
	Value Property	Yes
Parameter Object	**Attributes** Property	No
	Direction Property	No
	Name Property	No
	NumericScale Property	No
	Precision Property	No
	Size Property	No
	Type Property	No
	Value Property	No
Recordset Object	**AbsolutePage** Property	No
	AbsolutePosition Property	No
	ActiveCommand Property	Yes

	ActiveConnection Property	Yes
	BOF Property	Yes
	Bookmark Property	Yes
	CacheSize Property	Yes
	CursorLocation Property	Yes
	CursorType Property	Yes
	DataMember Property	No
	DataSource Property	No
	EditMode Property	Yes
	EOF Property	Yes
	Filter Property	Yes
	Index Property	No
	LockType Property	Yes
	MarshalOptions Property	No
	MaxRecords Property	No
	PageCount Property	No
	PageSize Property	No
	RecordCount Property	No
	Sort Property	Yes
	Source Property	Yes
	State Property	Yes
	Status Property	Yes
	StayInSync Property	No

ADO Collection Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ActiveX® Data Objects (ADO) version 2.0 object collections that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

ADO object	Collection	Support
Command Object	**Parameters**	No
	Properties	Yes
Connection Object	**Errors**	Yes
	Properties	Yes
Field Object	**Properties**	Yes
Parameter	**Properties**	No
Recordset Object	**Fields**	Yes
	Properties	Yes

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Command Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX® Data Objects (ADO) **Command** object is a definition of a specific command that is executed against an OLE DB data source.

You use **Command** objects to create a **Recordset** object and obtain records, execute a bulk operation, or manipulate the structure of a database. When using Microsoft OLE DB Provider for AS/400 and VSAM, some collections, methods, or properties of a **Command** object may generate an error when called.

The primary purpose of the **Command** object in the context of OLE DB Provider for AS/400 and VSAM is to issue AS/400 command language (CL) commands for execution by the remote OS/400 DDM target server. For a listing of legal distributed data management (DDM) command-line strings, see *AS/400 DDM User's Guide* published by IBM.

The following table lists the **Command** object methods, properties, and collections that the current version of OLE DB Provider for AS/400 and VSAM supports.

Name	**Comment**
Execute Method	Evaluates command text as a text string. (The only supported *Options* parameter for this method is **adCmdText**, which indicates that this is not an SQL command.)
ActiveConnection Property	Sets or returns the information used to establish a connection to a data source. (For more information, see the notes that follow.)
CommandText Property	Sets or returns the command text to be executed.
CommandType Property	Sets or returns the type of command in a **CommandText** property.
State Property	Describes the current state of an object.
Properties collection	Collections of properties on the command.

The **Execute** method executes a command and returns a **Recordset** object, if appropriate. You can use the **Command** object to open tables or execute DDM commands on a remote DDM server. If errors occur, they can be examined with the **Errors** collection on the **Connection** object.

A **Command** object can be created independently of a previously defined **Connection** object by setting the **ActiveConnection** property of the Command object to a valid connection string. ADO still creates a **Connection** object, but it does not assign that object to an object variable. However, if multiple **Command** objects are to be associated with the same connection, the **Connection** object needs to be explicitly created and opened. This assigns the **Connection** object to an object variable. If the **ActiveConnection** property of the **Command** object is not set to this object variable, ADO creates a new **Connection** object for each **Command** object, even if the same connection string is used.

The **ActiveConnection** property associates an open connection with a **Command** object. The **CommandText** property defines the text version of a command. The syntax for the string in the **CommandText** property when used with OLE DB Provider for AS/400 and VSAM is as follows:

```
EXEC COMMAND DDMCmd
```

Where **DDMCmd** represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands enable you to request functions from the OS/400 operating system. Some examples are the **DLTF** (Delete File) or **DSPFFD** (Display File Description) commands. These are the same commands that you could type at the command prompt if you were connected to an AS/400 computer through a 5250 terminal session. For a detailed list of possible commands, see the OS/400 CL Reference for your platform.

The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution to optimize performance. The **CommandType** property must be set to **adCmdText** for use with OLE DB Provider for AS/400 and VSAM.

You can also use the **Command** object to open a data file after a **Connection** object has been opened and the **ActiveConnection** property has been set to this open connection. The **CommandText** property defines the data file to open (an **EXEC OPEN *DataSetName*** statement, for example, where *DataSetName* represents a valid data file or library member on the host). You must set the **CommandType** property to **adCmdText** for use with OLE DB Provider for AS/400 and VSAM. If you open a host data file from a **Command** object, the data file is opened as read-only. This results from the limitation that no argument or option is passed by ADO that supplies a parameter describing whether the data set should be opened as read-only or updateable.

Connection Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX Data Objects (ADO) **Connection** object represents an open connection to an OLE DB data source. The **Provider** property sets the OLE DB provider. You can configure the connection before opening the data source by setting the **ConnectionString** properties. The **Version** property determines the version of the ADO implementation in use.

The **Open** method establishes the physical connection to the data source and the **Close** method terminates the connection. If errors occur, you can examine them with the **Errors** collection.

The following table lists the methods, properties, and collections for the **Connection** object that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

Name	**Comment**
Close Method	Closes a connection to a data source.
Execute Method	Evaluates command text as a table name. (The only supported *Options* parameter for this method is **adCmdTable**.)
Open Method	Opens a connection to a data source and may optionally pass **ConnectionString** parameters with this method. (The only supported *Options* parameter for this method is **adCmdText**.)
OpenSchema Method	Obtains database schema information from the OLE DB provider.
Attributes Method	Indicates one or more characteristics supported for a given **Connection** object.
ConnectionString Property	Contains the information used to establish a connection to a data source. (For more information, see the note that follows.)
CursorLocation property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
Mode Property	Indicates the available permissions for modifying data in a connection.
Provider Property	Sets or returns the name of the provider for a connection.
State Property	Describes the current state of an object.
Version Property	Returns the version number of the ADO implementation in use.
Errors collection	Collections of **Error** objects on the connection.
Properties collection	Collections of properties on the connection.

Note that the information needed to establish a connection to a data source can be set in the **ConnectionString** property or passed as part of the **Open** method. In either case, this information must be in a specific format for use with OLE DB Provider for AS/400 and VSAM or OLE DB Provider for DB2. This information is either a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons.

ADO supports several standard ADO-defined arguments for the **ConnectionString** property, as listed in the following table.

Argument	**Description**
Data Source	Name of the data source for the connection. This argument is optional when using OLE DB Provider for AS/400 and VSAM.
File Name	Name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed and is not supported by OLE DB Provider for AS/400 and VSAM.
Location	The remote database name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	Valid mainframe or AS/400 password to use when opening the connection. Host Integration Server 2004 uses this password to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	Name of the provider to use for the connection. To use OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB." To use OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB."
User ID	Valid mainframe or AS/400 user name to use when opening the connection. Host Integration Server 2004 uses this user name to validate that the user can log on to the target host system and has appropriate access rights to the file.

OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which default to values in the registry. The following table lists these arguments.

Argument	**Description**
BinAsChar	This parameter indicates whether to process binary fields as character fields. (The default is 0; do not process binary fields as character fields.) This parameter is equivalent to the DBPROP_SNAOLEDB_BINASCHAR OLE DB property ID.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If you omit this argument, the default value is U.S./Canada (37). This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.
HCD File Name	The fully qualified file name of the distributed data management (DDM) Host Column Description (HCD) file. This parameter can be a UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the Host Integration Server 2004 system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.
LocalLU	The name of the local logical unit (LU) alias configured in the SNA server. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.
ModeName	The Advanced Program-to-Program Communications (APPC) mode must be set to a value that matches the host configuration and Host Integration Server 2004 configuration. Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes. This parameter is equivalent to the DBPROP_SNAOLEDB_APPCMODE OLE DB property ID.
NetAddr	When you select TCP/IP for the Network Transport Library (NTL), this parameter indicates the IP address of the host. This parameter is equivalent to the DBPROP_SNAOLEDB_NETADDRESS OLE DB property ID.
NetPort	When you select TCP/IP for the NTL, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446. This parameter is equivalent to the DBPROP_SNAOLEDB_NETPORT OLE DB property ID.
NetLib	This parameter determines whether you use TCP/IP or SNA APPC for network communication. The possible values for this parameter are TCPIP or SNA. The default value is SNA. This parameter is equivalent to the DBPROP_SNAOLEDB_NETTYPE OLE DB property ID.
PCCodePage	The character code page to use on the computer. If you omit this argument, the default value is set to Latin 1 (1252). This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
RDB	The remote database name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in the SNA server.
RepairHostKeys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry, The default is **false**. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.
RemoteLU	The name of the remote logical unit (LU) alias configured in the Host Integration Server 2004 computer. This parameter is equivalent to the DBPROP_SNAOLEDB_REMOTELU OLE DB property ID.

StrictVal	This parameter indicates whether strict validation should be used. The default is **false**. This parameter is equivalent to the DBPROP_SNAOLEDB_STRICTVAL OLE DB property ID.

A sample **ConnectionString** for use with OLE DB Provider for AS/400 and VSAM is as follows:

```
Conn.Provider="SNAOLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PCCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

> **Note** The &_ character combination is used for continuing long lines in Visual Basic®.

When opening a connection object in ADO 2.0, you must specify the **Prompt** connection property. For example, the following is valid with ADO 1.5 and ADO 2.0 and prompts the user for **ConnectionString** properties:

```
Conn.ConnectionString = "Provider=SNAOLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

A sample **Open** method call with these parameters is as follows:

```
RS.Open "library/member",Conn,2,1,1
```

The last three parameters to the **Open** method correspond with the *CursorType* (for example, the **adOpenDynamic** enum is 2), *LockType* (for example, the **adLockReadOnly** enum is 1), and *Options* (**adCmdText** is 1, which indicates that the source name should be evaluated as a table name). The *Options* parameter must be set to **adCmdText** (1) when used with a data source name with OLE DB Provider for AS/400 and VSAM.

The allowable values for CCSID when using SNA National Language Support (SNANLS) for character code conversions (the default) are listed in the following table.

EBCDIC character set	CCSID value
Arabic	20420
Binary (No Conversion)	65535
Chinese (Simplified)	935
Chinese (Traditional)	937
Cyrillic (Russian)	20880
Cyrillic (Serbian, Bulgarian)	21025
Denmark/Norway (Euro)	1142
Denmark/Norway	20277
Finland/Sweden (Euro)	1143
Finland/Sweden	20278
France (Euro)	1147
France	20297
Germany (Euro)	1141
Germany	20273
Greek (Modern)	875
Greek	20423
Hebrew	20424
Icelandic (Euro)	1149
Icelandic	20871
International (Euro)	1148
International	500
Italy (Euro)	1144

Italy	20280
Japanese (English-lower)	931
Japanese (Extend English)	939
Japanese (Extend Katakana)	930
Japanese (Katakana)	290
Japanese (Katakana-Kanji)	5026
Japanese (Latin-Kanji)	5035
Korean	933
Latin America/Spain (Euro)	1145
Latin America/Spain	20284
Latin-1 Open System (Euro)	20924
Latin-1 Open System	1047
Multilingual/ROECE (Latin-2)	870
Thai	20838
Turkish (Latin-5)	1026
Turkish	20905
U.S./Canada (Euro)	1140
U.S./Canada	37
United Kingdom (Euro)	1146
United Kingdom	20285

> **Note** SNANLS conversion uses the locale configured for the data sources using data links. For more information on SNANLS, see SNA National Language Support Programmer's Guide.

Error Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX Data Objects (ADO) **Error** object contains details about data access errors pertaining to a single operation involving ADO. You can read the properties of an **Error** object to obtain specific details about each error.

The **Error** object does not support any methods or collections. However, the **Errors** collection supported by other objects provides the standard **Collection** methods (**Clear** and **Delete**). OLE DB Provider automatically appends **Error** objects to the **Errors** collection when they occur.

The following table lists the **Error** object properties that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

Property Name	**Comment**
Description Property	The text of the error alert that is returned based on the minor error code (specific to OLE DB Provider for AS/400 and VSAM) contained in the **Error** object resulting from an error.
NativeError Property	A **Long** integer value of the error code returned by OLE DB Provider for AS/400 and VSAM.
Number Property	The **Long** integer value of the error constant.
Source Property	A **string** that indicates the name of the object or application that originally generated an error.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Field Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX Data Objects (ADO) **Field** object represents a column of data with a common data type. Each **Field** object corresponds to a column in a **Recordset** object.

The following table lists the **Field** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

Name	**Comment**
AppendChunk Method	Appends data to a large text or binary data **Field** object.
GetChunk Method	Returns all or portions of the contents of a large text or binary data **Field** object.
ActualSize Property	Actual length of the value of a field.
Attributes Property	One or more characteristics supported for a given **Field** object.
DefinedSize Property	Defined size of a **Field** object.
Name Property	Name of the **Field** object.
NumericScale Property	Scale of numeric values in a **Field** object for numeric data.
OriginalValue Property	Value of a **Field** object that existed in the record before changes were made.
Precision Property	Degree of precision for numeric values in a **Field** object for numeric data.
Type Property	Operational type or data type for a **Field** object.
UnderlyingValue Property	Current value of a **Field** object.
Value Property	Value assigned to a **Field** object in a **Recordset**.
Properties collection	Collections of properties on the field.

Recordset Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX Data Objects (ADO) **Recordset** object represents the entire set of records from a base table. At any time, the **Recordset** object refers to only one record within the set as the current record.

The following table lists the **Recordset** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

Name	Comment
AddNew Method	Creates a new record for an updateable **Recordset** object.
CancelBatch Method	Cancels a pending batch update.
CancelUpdate Method	Cancels any changes made to a current record or to a new record prior to calling the **UpdateBatch** method.
Clone Method	Creates a duplicate **Recordset** object from an existing **Recordset** object.
Close Method	Closes an open object and any dependent objects.
Delete Method	Deletes the current record in an open **Recordset** object or an object from a collection.
Find Method	Finds the next record to match a condition (ADO 1.5 and later).
GetRows Method	Retrieves multiple records of a **Recordset** into an array.
Move Method	Moves the position of the current record in a **Recordset** object.
MoveFirst Method	Moves to the first record in a specified **Recordset**.
MoveLast Method	Moves to the last record in a specified **Recordset**.
MoveNext Method	Moves to the next record in a specified **Recordset**.
MovePrevious Method	Moves to the previous record in a specified **Recordset**.
Open Method	Opens a cursor on a **Recordset**.
Requery Method	Updates the data in a **Recordset** object by re-executing the query on which the object is based (equivalent to calling the **Close** and **Open** methods in succession).
Save Method	Saves a **Recordset** in a file or **Stream** object.
Seek method	
Supports Method	Determines whether a specified **Recordset** object supports a particular type of function.
Update Method	Saves any changes you make to the current record of a **Recordset** object.
UpdateBatch Method	Writes all pending batch updates to disk.
ActiveCommand Property	Returns the **Command** object that created the specified **Recordset**.
ActiveConnection Property	Sets or returns the **Connection** object that the specified **Recordset** object currently belongs.
BOF Property	Indicates whether the current record position is before the first record in a **Recordset** object.
Bookmark Property	Returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object identified by a valid bookmark.
CacheSize Property	Sets or returns the number of records from a **Recordset** object that are cached locally in memory.
CursorLocation Property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
CursorType Property	Sets or returns the type of cursor used in a **Recordset** object. Only the **adOpenDynamic CursorType** is supported by the current version of OLE DB Provider for AS/400 and VSAM.
EditMode Property	Indicates the editing status of the current record type.
EOF Property	Indicates whether the current record position is after the last record in a **Recordset** object.
Filter Property	Indicates a filter for data in a **Recordset** (revised in ADO 1.5 and later).

LockType Property	Sets or returns the types of locks placed on records during editing. All four lock types (**adLockReadOnly**, **adLockOptimistic**, **adLockPessimistic**, and **adLockBatchOptimistic**) are supported by the OLE DB Provider for AS/400 and VSAM. Note that the OLE DB provider internally maps **adLockPessimistic** to a LockType of **adLockBatchOptimistic**.
Sort Property	Indicates the column names and order to sort data in a **Recordset** object (new property in ADO 1.5 and later).
Source Property	Sets or returns the source (table name or command object) for the data in a **Recordset**.
State Property	Describes the current state of an object.
Status Property	Indicates the status of the current record with respect to batch updates or other bulk operations.
Fields collection	Collections of fields on the **Recordset**.
Properties collection	Collections of properties on the **Recordset**.

The syntax supported by the OLE DB Provider for AS/400 and VSAM to open a recordset (table) using the **Recordset.Open** method is as follows:

```
EXEC OPEN TableName
```

where *TableName* represents one of the host file naming conventions listed in the following table.

Host file type	**File naming convention**
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned Data Sets	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILE.NAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY/FILE.NAME(MEMBER)

Note that if a member of a library contains a dot in the member name, you must surround the member name with double quotes. For example, if the member name is NAMES.DAT, the proper syntax for command text used for the **Recordset.Open** method is:

```
RecordSet.Open "EXEC OPEN LIBRARY/FILE(""NAMES.DAT"")",...
```

You must specify the full path to the mainframe data set. In the preceding example, there are two path elements (LIBRARY/FILE) and one name element (NAMES.DAT).

Whenever a data set is allocated, it is given a unique name composed of one or more segments. Each segment of the data set name is joined by periods and represents a level of qualification. For example, the following data set has four segments that comprise the fully qualified data set name (three path elements and one name element):

```
SAMPLES.DEMO.KSDS.TITLES
```

The high-level qualifier is SAMPLES. The low-level qualifier is TITLES. Each segment can be from 1 through 8 characters in length. (The first character must be alphabetical, and the remainder can be alphanumeric or hyphens.) The full data set name must be no more than 44 characters in length and contain no more than 22 segments.

The Recordset **Bookmark** method is supported for all AS/400 physical and logical files, as well as the following mainframe file types:

- KSDS if the file has a unique key
- RRDS if the file has a unique key

You can use the Recordset **AddNew** method on Entry-Sequenced Data Sets (ESDS) files on the AS/400 only when you are positioned at the end of the **Recordset** object (file). With Alternate Index files on the AS/400, you can use the **AddNew** method to add records when at the end of the **Recordset** object or by key. With Key-Sequenced Data Sets (KSDS) or Fixed-Length Relative Record Data Sets (RRDS) files on the mainframe, the **AddNew** method adds new records by key.

To use the Recordset **Find** method or the **Filter** property, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If you use these methods or properties on an AS/400 non-keyed physical file or any other mainframe file type, the method fails.

The Recordset **Sort** property is used with an open **Recordset** object based on an AS/400 physical file. The **Sort** property enables the user to indicate which logical view to apply to an AS/400 physical file. The logical view must be a valid index specified in the description of the AS/400 physical file. The AS/400 logical file provides the logical view. OLE DB Provider for AS/400 and VSAM responds to the **Sort** property request by first closing the open physical file, and then opening the logical file that points back to the data in the physical file.

The **Recordset Sort** property is only supported on AS/400 hosts. If the user opens a **Recordset** object based on an AS/400 logical file, there is probably no need to use **Recordset**.**Sort**. For performance reasons, applications should be written to open the AS/400 logical file first, because the overhead is so much greater when opening a physical file first.

ADO Object Support in the OLE DB Provider for DB2

The following table summarizes the Microsoft® ActiveX® Data Objects (ADO) version 2.0 objects that the current version of Microsoft OLE DB Provider for DB2 supports.

ADO object	**Support**
Collection	Yes, most methods
Command Object	Yes, some methods, some properties, and all collections
Connection Object	Yes, some methods, some properties, and all collections
Error Object	Yes, some properties
Field Object	Yes, no methods, most properties, and all collections
Parameter Object	Yes, most methods, most properties, and all collections
Recordset Object	Yes, most methods, most properties, and all collections

This section contains:

- ADO Method Support in the OLE DB Provider for DB2
- ADO Property Support in the OLE DB Provider for DB2
- ADO Collection Support in the OLE DB Provider for DB2
- Command Object in the OLE DB Provider for DB2 (ADO)
- Connection Object in the OLE DB Provider for DB2 (ADO)
- Error Object in the OLE DB Provider for DB2 (ADO)
- Field Object in the OLE DB Provider for DB2 (ADO)
- Recordset Object in the OLE DB Provider for DB2 (ADO)

ADO Method Support in the OLE DB Provider for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object methods that the current version of Microsoft OLE DB Provider for DB2 supports.

ADO object	Method	Support
Collection	**Append**	No
	Clear Method	Yes
	Delete Method	Yes
	Item Method	Yes
	Refresh Method	Yes
Command Object	**CreateParameter** Method	Yes
	Cancel Method	No
	Execute Method	Yes
Connection Object	**BeginTrans** Method	Yes
	Cancel Method	No
	Close Method	Yes
	CommitTrans Method	Yes
	Execute Method	Yes
	Open Method	Yes
	OpenSchema Method	Yes
	RollbackTrans Method	Yes
Field Object	**AppendChunk** Method	No
	GetChunk Method	No
	ReadFromFile Method	No
	WriteToFile Method	No
Parameter Object	**AppendChunk** Method	No
Recordset Object	AddNew Method	Yes
	Cancel Method	No
	CancelBatch Method	Yes
	CancelUpdate Method	Yes
	Clone Method	Yes
	Close Method	Yes
	Delete Method	Yes
	Find Method	No
	GetRows Method	Yes
	Move Method	Yes
	MoveFirst Method	Yes
	MoveLast Method	No
	MoveNext Method	Yes
	MovePrevious Method	No
	NextRecordset Method	No
	Open Method	Yes
	Requery Method	Yes
	Resync Method	No
	Save Method	Yes
	Seek Method	No
	Supports Method	Yes
	Update Method	Yes
	UpdateBatch Method	Yes

Note The **Collection** object is a special case, representing a collection of other ADO objects. These collection objects support several methods:

- **Append** to add an object to a collection

- **Clear** to empty all objects from a collection
- **Delete** to remove a single object from a collection
- **Item** to return a specific member object of a collection by name or ordinal number
- **Refresh** to update the objects in a collection to reflect objects available from and specific to the OLE DB provider

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ADO Property Support in the OLE DB Provider for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object properties that the current version of Microsoft OLE DB Provider for DB2 supports.

ADO object	**Property**	**Support**
Command Object	ActiveConnection Property	Yes
	CommandText Property	Yes
	CommandTimeout Property	No
	CommandType Property	Yes
	Prepared Property	Yes
	State Property	Yes
Connection Object	Attributes Property	Yes
	CommandTimeout Property	No
	ConnectionString Property	Yes
	ConnectionTimeout Property	No
	CursorLocation Property	Yes
	DefaultDatabase Property	No
	IsolationLevel Property	Yes
	Mode Property	Yes
	Provider Property	Yes
	State Property	Yes
	Version Property	Yes
Error Object	Description Property	Yes
	HelpContext Property	No
	HelpFile Property	No
	NativeError Property	Yes
	Number Property	Yes
	Source Property	Yes
	SQLState Property	Yes
Field Object	ActualSize Property	Yes
	Attributes Property	Yes
	DataFormat Property	No
	DefinedSize Property	Yes
	Name Property	Yes
	NumericScale Property	Yes
	OriginalValue Property	Yes
	Precision Property	Yes
	Type Property	Yes
	UnderlyingValue Property	Yes
	Value Property	Yes
Parameter Object	**Attributes** Property	Yes
	Direction Property	Yes
	Name Property	Yes
	NumericScale Property	Yes
	Precision Property	Yes
	Size Property	Yes
	Type Property	Yes
	Value Property	Yes
Recordset Object	**AbsolutePage** Property	No
	AbsolutePosition Property	No
	ActiveCommand Property	Yes
	ActiveConnection Property	Yes
	BOF Property	Yes

	Bookmark Property	Yes
	CacheSize Property	Yes
	CursorLocation Property	Yes
	CursorType Property	Yes
	DataMember Property	No
	DataSource Property	No
	EditMode Property	Yes
	EOF Property	Yes
	Filter Property	No
	Index Property	No
	LockType Property	Yes
	MarshalOptions Property	No
	MaxRecords Property	Yes
	PageCount Property	No
	PageSize Property	No
	RecordCount Property	No
	Sort Property	No
	Source Property	Yes
	State Property	Yes
	Status Property	Yes
	StayInSync Property	No

ADO Collection Support in the OLE DB Provider for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object collections that Microsoft OLE DB Provider for DB2 supports.

ADO object	Collection	Support
Command Object	**Parameters** Collection	Yes
	Properties Collection	Yes
Connection Object	**Errors** Collection	Yes
	Properties Collection	Yes
Field Object	**Properties** Collection	Yes
Parameter Object	**Properties** Collection	Yes
Recordset Object	**Fields** Collection	Yes
	Properties Collection	Yes

Command Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Command** object is a definition of a specific command that is to be executed against an OLE DB data source.

You can use **Command** objects to create a **Recordset** object and obtain records, to execute a bulk operation, or to manipulate the structure of a database. When using Microsoft OLE DB Provider for DB2, some collections, methods, or properties of a **Command** object may generate an error when called.

The primary purpose of the **Command** object in the context of OLE DB Provider for DB2 is to issue SQL commands for execution by the remote DB2 target server. Legal SQL commands are documented for the target DB2 platforms in SQL Reference Guides published by IBM.

The following table lists the **Command** object methods, properties, and collections that the current version of OLE DB Provider for DB2 supports.

Name	**Comment**
Execute Method	Evaluates command text (only supported *Options* parameter for this method is **adCmdText**, which indicates that this is an SQL text command).
ActiveConnection Property	Sets or returns the information used to establish a connection to a data source. (For more information, see the notes that follow.)
CommandText Property	Sets or returns the command text to be executed.
CommandType Property	Sets or returns the type of command in a **CommandText** property.
State Property	Describes the current state of an object.
Properties collection	Collections of properties on the command.

The **Execute** method executes a command and returns a **Recordset** object, if appropriate. You can use the **Command** object to open tables or execute SQL commands on a remote DB2 server. If errors occur, you can examine these with the **Errors** collection on the **Connection** object.

You can create a **Command** object independently of a previously defined **Connection** object by setting the **ActiveConnection** property of the **Command** object to a valid connection string. (For the proper syntax, see the **ConnectionString** property of the **Connection** object.) ADO still creates a **Connection** object, but it does not assign that object to an object variable. However, if multiple **Command** objects are to be associated with the same connection, the **Connection** object needs to be explicitly created and opened. This assigns the **Connection** object to an object variable. If the **ActiveConnection** property of the **Command** object is not set to this object variable, ADO creates a new **Connection** object for each **Command** object, even if the same connection string is used.

The **ActiveConnection** property associates an open connection with a **Command** object. The **CommandText** property defines the text version of a command (for example, **SELECT ALL FROM TABLE**). The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution to optimize performance. The **CommandType** property must be set to **adCmdText** for use with OLE DB Provider for DB2.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Connection Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Connection** object represents an open connection to an OLE DB data source. The **Provider** property sets the OLE DB provider to use. The connection can be configured before opening the data source by setting the **ConnectionString** properties. The version of the ADO implementation in use can be determined from the **Version** property.

The physical connection to the data source is established using the **Open** method and terminated with the **Close** method. If errors occur, these can be examined with the **Errors** collection.

The following table lists the **Connection** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for DB2 supports.

Name	**Comment**
Close Method	Closes a connection to a data source.
Execute Method	Evaluates command text.
Open Method	Opens a connection to a data source and may optionally pass **ConnectionString** parameters with this method.
OpenSchema Method	Obtains database schema information from the OLE DB provider.
Attributes Property	One or more characteristics supported for a given **Connection** object.
ConnectionString Property	Contains the information used to establish a connection to a data source. (For more information, see the notes that follow.)
CursorLocation Property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
IsolationLevel Property	Sets or returns the level of isolation for a **Connection** object.
Mode Property	Indicates the available permissions for modifying data in a connection.
Provider Property	Sets or returns the name of the provider for a connection.
State Property	Describes the current state of an object.
Version Property	Returns the version number of the ADO implementation in use.
Errors collection	Collections of **Error** objects on the connection.
Properties collection	Collections of properties on the connection.

You can set the information needed to establish a connection to a data source in the **ConnectionString** property or pass it as part of the **Open** method. In either case, this information must be in a specific format for use with OLE DB Provider for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ADO supports several standard ADO-defined arguments for the **ConnectionString** property as listed in the following table.

Argument	**Description**
Data Source	Name of the data source for the connection. This argument is optional when using OLE DB Provider for DB2.
File Name	Name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed.
Location	The remote database name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	Valid mainframe or AS/400 password to use when opening the connection. This password is used to verify that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.
Provider	Name of the provider to use for the connection. To use OLE DB Provider for DB2, you must set the Provider string to "DB2OLEDB."
User ID	Valid mainframe or AS/400 user name to use when opening the connection. This user name validates that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

The OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the following tables.

The following table lists the arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server 2004.

Argument	Description
BinAsChar	When this parameter is set to **true**, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to **false**.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If you omit this argument, the default value is U.S./Canada (37).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2, SYSIBM, SYSTEM, CURLIB, or USERID depending on platform. This parameter does not have a default value.
InitCat	You use this parameter as the first part of a three-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the **WRKRDBDIRE** command from the console to the OS/400 system. If there is no RDBNAM value, you can create one using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local logical unit (LU) alias configured in Host Integration Server.
ModeName	The Advanced Program-to-Program Communications (APPC) mode must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When you select TCP/IP for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When you select TCP/IP for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether you use TCP/IP or SNA APPC for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the computer. If you omit this argument, the default value is set to Latin 1 (1252).
PkgCol	The name of the Distributed Relational Database Architecture (DRDA) target collection (AS/400 library) where Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB provider creates packages dynamically in the location to which the user points using the Package Collection parameter.

RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The transaction program name when used with SQL/DS.
UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are distributed unit of work (DUW) or remote unit of work (RUW). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

> **Note** Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using OLE DB Provider for DB2 is as follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PcCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

> **Note** The &_ character combination is used for continuing long lines in Visual Basic®.

When opening a connection object in ADO 2.0, you must specify the **Prompt** connection property. For example, the following is valid with ADO 1.5 and ADO 2.0 and will prompt the user for **ConnectionString** properties:

```
Conn.ConnectionString = "Provider=DB2OLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

A sample **Open** method call with these parameters is as follows:

```
RS.Open "Accounting",Conn,0,1,1
```

The last three parameters to the **Open** method correspond with the *CursorType* (for example, the **adOpenForwardOnly** enum is 0), *LockType* (for example, the **adLockReadOnly** enum is 1), and *Options* (**adCmdText** is 1, which indicates that the source name should be evaluated as SQL text). The *Options* parameter must be set to **adCmdText** (1) when used with a data source name with OLE DB Provider for DB2.

The allowable values for the Character Code Set Identifier (CCSID) when using SNA National Language Support (SNANLS) for character code conversions (the default) are listed in the following table.

EBCDIC character set	CCSID value
Arabic	20420
Binary (No Conversion)	65535
Chinese (Simplified)	935
Chinese (Traditional)	937
Cyrillic (Russian)	20880

Cyrillic (Serbian, Bulgarian)	21025
Denmark/Norway (Euro)	1142
Denmark/Norway	20277
Finland/Sweden (Euro)	1143
Finland/Sweden	20278
France (Euro)	1147
France	20297
Germany (Euro)	1141
Germany	20273
Greek (Modern)	875
Greek	20423
Hebrew	20424
Icelandic (Euro)	1149
Icelandic	20871
International (Euro)	1148
International	500
Italy (Euro)	1144
Italy	20280
Japanese (English-lower)	931
Japanese (Extend English)	939
Japanese (Extend Katakana)	930
Japanese (Katakana)	290
Japanese (Katakana-Kanji)	5026
Japanese (Latin-Kanji)	5035
Korean	933
Latin America/Spain (Euro)	1145
Latin America/Spain	20284
Latin-1 Open System (Euro)	20924
Latin-1 Open System	1047
Multilingual/ROECE (Latin-2)	870
Thai	20838
Turkish (Latin-5)	1026
Turkish	20905
U.S./Canada (Euro)	1140
U.S./Canada	37
United Kingdom (Euro)	1146
United Kingdom	20285

Note that the SNA National Language Support (SNANLS) conversion uses the locale configured for the data sources using data links. For more information, see the SDK documentation under the SNA National Language Support Programmer's Guide.

The allowable values for CCSID when using ANSI/OEM for character code conversions are listed in the following table.

ANSI/OEM character set	CCSID value
ANSI - Arabic	1256
ANSI - Baltic	1257
ANSI - Cyrillic	1251
ANSI - Eastern Europe	1250
ANSI - Greek	1253
ANSI - Hebrew	1255
ANSI - Latin I	1252
ANSI - Turkish	1254
ANSI/OEM - Korean (Extended Wansung)	949
ANSI/OEM - Japanese Shift-JIS	932
ANSI/OEM - Simplified Chinese GBK	936
ANSI/OEM - Traditional Chinese Big5	950

ANSI/OEM - Thai	874
ANSI/OEM - Vietnam	1258

Error Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Error** object contains details about data access errors pertaining to a single operation involving ADO. You can read the properties of an **Error** object to obtain specific details about each error.

The **Error** object does not support any methods or collections. However, the **Errors** collection supported by other objects provides the standard **Collection** methods (**Clear** and **Delete**). The OLE DB provider automatically appends **Error** objects to the **Errors** collection when they occur.

The following table lists the **Error** object properties that the current version of Microsoft OLE DB Provider for DB2 supports.

Property Name	**Comment**
Description Property	The text of the error alert that is returned based on the minor error code (specific to the OLE DB Provider for DB2) contained in the **Error** object resulting from an error.
NativeError Property	A **Long** integer value of the error code returned by the OLE DB Provider for DB2.
Number Property	The **Long** integer value of the OLE DB error constant.
Source Property	A string that indicates the name of the object or application that originally generated an error.

Field Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Field** object represents a column of data with a common data type. Each **Field** object corresponds to a column in a **Recordset** object.

The following table lists the **Field** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for DB2 supports.

Name	Comment
ActualSize Property	Actual length of a field's value.
Attributes Property	One or more characteristics supported for a given **Field** object.
DefinedSize Property	Defined size of a **Field** object.
Name Property	Name of the **Field** object.
NumericScale Property	Scale of numeric values in a **Field** object for numeric data.
OriginalValue Property	Value of a **Field** object that existed in the record before changes were made.
Precision Property	Degree of precision for numeric values in a **Field** object for numeric data.
Type Property	Operational type or data type for a **Field** object.
UnderlyingValue Property	Current value of a **Field** object.
Value Property	Value assigned to a **Field** object in a **Recordset**.
Properties collection	Collections of properties on the field.

Recordset Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Recordset** object represents the entire set of records from a base table. At any time, the **Recordset** object refers to only one record within the set as the current record.

The following table lists the **Recordset** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for DB2 supports.

Name	**Comment**
AddNew Method	Creates a new record for an updateable **Recordset** object.
CancelBatch Method	Cancels a pending batch update.
CancelUpdate Method	Cancels any changes made to a current record or to a new record prior to calling the **UpdateBatch** method.
Clone Method	Creates a duplicate **Recordset** object from an existing **Recordset** object.
Close Method	Closes an open object and any dependent objects.
Delete Method	Deletes the current record in an open **Recordset** object or an object from a collection.
GetRows Method	Retrieves multiple records of a **Recordset** into an array.
Move Method	Moves the position of the current record in a **Recordset** object.
MoveFirst Method	Moves to the first record in a specified **Recordset**.
MoveNext Method	Moves to the next record in a specified **Recordset**.
Open Method	Opens a cursor on a **Recordset**.
Requery Method	Updates the data in a **Recordset** object by re-executing the query on which the object is based (equivalent to calling the **Close** and **Open** methods in succession).
Save Method	Saves a **Recordset** in a file or **Stream** object.
Supports Method	Determines whether a specified **Recordset** object supports a particular type of function.
Update Method	Saves any changes you make to the current record of a **Recordset** object.
UpdateBatch Method	Writes all pending batch updates to disk.
ActiveCommand Property	Returns the **Command** object that created the specified **Recordset**.
ActiveConnection Property	Sets or returns the **Connection** object that the specified **Recordset** object currently belongs.
BOF Property	Indicates whether the current record position is before the first record in a **Recordset** object.
Bookmark Property	Returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object identified by a valid bookmark.
CacheSize Property	Sets or returns the number of records from a **Recordset** object that are cached locally in memory.
CursorLocation Property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
CursorType Property	Sets or returns the type of cursor used in a **Recordset** object. The current version of OLE DB Provider for DB2 supports only the **adOpenForwardOnly CursorType**.
EditMode Property	Indicates the editing status of the current record type.
EOF Property	Indicates whether the current record position is after the last record in a **Recordset** object.
LockType Property	Sets or returns the types of locks placed on records during editing. OLE DB Provider for DB2 supports locks of type **adLockReadOnly** and **adLockPessimistic**.
MaxRecords Property	Sets or returns the maximum number of records to return to a **Recordset** from a query.
Source Property	Sets or returns the source (table name or command object) for the data in a **Recordset**.
State Property	Describes the current state of an object.
Status Property	Indicates the status of the current record with respect to batch updates or other bulk operations.
Fields collection	Collections of fields on the **Recordset**.
Properties collection	Collections of properties on the **Recordset**.

ODBC Driver for DB2 Programmer's Guide

The Microsoft® ODBC Driver for DB2 enables users to access IBM Data Base 2 (DB2) from within an ODBC-aware application. ODBC defines a standard set of interfaces that provide access to disparate databases. The ODBC Driver for DB2 combines the data access of ODBC with the underlying Microsoft Distributed Relational Database Architecture (DRDA) application requester also used by the Microsoft OLE DB Provider for DB2. Using this combination of technologies, the ODBC Driver for DB2 can provide database access to IBM's Distributed Relational Database Architecture and IBM DB2.

Organizations have invested in secure, robust, enterprise-wide data storage and management systems. DRDA is a set of rules for distributing or extending relational data from one computer to another, such as a server computer to an IBM DB2 database server running on a mainframe or an AS/400 computer. By combining the ODBC and DRDA architectures, Microsoft allows organizations to preserve their investments in an existing data management infrastructure, while extending data access to all enterprise-wide DB2 data sources.

The ODBC Driver for DB2 can be used interactively or from an application program to issue SQL statements and execute DB2 stored procedures. From Microsoft Excel, users can import DB2 tables into worksheets and use Excel graphing tools to analyze the data. From Microsoft Access, users can import from and export to DB2. With Microsoft Internet Information Services (IIS), developers can publish DB2-stored information to users through a Web browser.

For API reference and other technical information about the ODBC Driver for DB2, see the ODBC Driver for DB2 Programmer's Reference section of the SDK.

For sample code using the OLE DB Provider and ODBC Driver, see the OLE DB Provider and ODBC Driver Samples section of the SDK.

This section contains:

Goals of the ODBC Driver for DB2

Relational database management systems (RDBMS) are one of the major sources of mission-critical information in today's enterprise organizations. Relational database technology enables departments and individual users to save their information in centrally managed database stores that can be maintained by the organization's information systems group.

IBM DB2 is a popular RDBMS for a significant number of enterprise customers. Customers need a cost-effective and manageable means to integrate DB2 with Microsoft® SQL Server™, Microsoft Internet Information Services (IIS), and Microsoft Office applications. The goal of Microsoft ODBC Driver for DB2 is to provide customers and solution providers with the means to integrate desktop database applications with this wealth of data residing on IBM DB2 database systems.

ODBC Driver for DB2 Architecture

The Microsoft® ODBC Driver for DB2 is an ODBC-compliant database driver for Microsoft Windows Server™ 2003 and Windows® 2000 that enables your existing ODBC applications access data residing in IBM DB2 database servers without changing any code. The ODBC Driver for DB2 can connect ODBC-compliant applications with DB2 data sources using the underlying Microsoft Distributed Relational Database Architecture (DRDA) application requester. The ODBC application connects to the ODBC Driver for DB2. These ODBC requests are processed by the underlying Microsoft DRDA application requester. The data is then passed by an SQL interface to the DB2 data store.

The ODBC Driver for DB2 shares the same DRDA application requester that is used by the Microsoft OLE DB Provider for DB2. The DRDA application requester is the network client that provides remote database access to DB2 across an SNA LU 6.2 and TCP/IP network.

The ODBC Driver for DB2 is compliant with the Microsoft Open Database Connectivity (ODBC) specification. ODBC is a specification for an application program interface (API) that enables applications to access multiple database systems using SQL.

Platforms Supported by the ODBC Driver for DB2

The Microsoft® ODBC Driver for DB2 supports popular DB2 platforms supported by the Microsoft OLE DB Provider for DB2 because both use the same underlying Distributed Relational Database Architecture (DRDA) application requester.

The ODBC Driver for DB2 offers network connectivity using SNA APPC LU 6.2 connectivity, as well as native TCP/IP (not reliant on any special IBM or third-party routers).

ODBC Driver for DB2 Requirements

Information about hardware and software requirements for The Microsoft® The ODBC Driver for DB2 can be found in the Host Integration Server 2004

When connecting over SNA using LU 6.2, the ODBC Driver for DB2 requires the following computer-to-host connectivity software:

- Microsoft Host Integration Server 2004
- Microsoft Host Integration Server Client

Note that the The ODBC Driver for DB2 does not require any special host connectivity software when connecting directly to a host system using TCP/IP.

The The ODBC Driver for DB2 supports the following OLE DB and ADO versions:

The ODBC Driver for DB2 supplied with Microsoft Host Integration Server 2004 supports the following ADO version:

- ADO version 2.5. The Microsoft Host Integration Server 2004 data access features require the runtime libraries for ADO version 2.5. On Windows Server 2003 and Windows 2000, these ADO libraries are installed as part of the Windows Server 2003 operating systems or Windows 2000.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring ODBC Data Sources

A data source associates a particular ODBC driver with the data to be accessed through that driver. Data source information must be configured for each DB2 system that is to be accessed using the Microsoft® ODBC Driver for DB2. The default parameters for the ODBC Driver for DB2 are used for the data source only when these parameters are not configured for each data source.

An ODBC data source name (DSN) can be one of the following types:

- User. A data source local to a computer and accessible only by the current user that created the data source.
- System. A data source local to a computer but not dedicated to a specific user, so any user with appropriate privileges can access a system DSN. A System data source is visible to all users on a computer, including Windows NT® services.
- File. A data source stored in a file that can be shared among all users who have the same ODBC drivers installed. These data sources need not be dedicated to a specific user or local to a computer.

User and System data sources are stored in the registry. File data sources are stored as files with a file extension of .dsn. File DSNs can be stored in any location on the file system including remotely mounted shares. By default, File DSNs are stored in the following location:

C:\Program Files\Common Files\ODBC\Data Sources

ODBC data sources can be configured using the **ODBC Data Source Administrator**. On Microsoft® Windows Server™ 2003 and Windows® 2000, a shortcut to the **ODBC Data Source Administrator** is located in the Control Panel under **Administrative Tools** as **Data Sources (ODBC)**. The Data Access Tool provided as part of the ODBC Driver for DB2 enables users to create and modify ODBC data sources. This tool makes calls to the ODBC Data Source Administrator application to provide these functions.

- Using the Microsoft ODBC Driver for DB2 Configuration Dialog Box
- Configuration Property Mappings Between the ODBC Driver for DB2 and the OLE DB Provider for DB2
- ODBC Connection String Attributes

Using the Microsoft ODBC Driver for DB2 Configuration Dialog Box

The **Microsoft ODBC Driver for DB2 Configuration** dialog box contains five tabs, which are described in the following topics.

This section contains:

- General
- Connection
- Security
- Target Database
- Locale

General

The **General** tab enables the user to configure the data source name required to connect to DB2. For the Microsoft® ODBC Driver for DB2 supplied with Host Integration Server 2004, the **General** tab contains the following fields.

Parameter	Comments
Data Source Name	A blank field for specifying the name of the data source. Enter a string that identifies this ODBC data source. The data source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For file data sources, this field is used to name the DSN file, which is stored in C:\Program Files\Common Files\ODBC\Data Sources.
Description	A blank field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.

Connection

The **Connection** tab enables the user to configure the basic attributes required to connect to a data source. For the Microsoft® ODBC Driver for DB2, the **Connection** tab has the following fields.

Parameter	Comments
Network transport	An option button is used to select the network transport. Valid options are **APPC Connection (SNA LU 6.2)** or **TCP/IP Connection**. For the default, **APPC Connection**, the values for APPC local LU alias, APPC remote LU alias, and APPC mode name are required. For **TCP/IP Connection**, the values for IP address and Network port are required.
APPC local LU alias	When **APPC Connection** is selected, this field is the name of the local LU alias configured in Host Integration Server.
APPC remote LU alias	When **APPC Connection** is selected, this field is the name of the remote LU alias configured in Host Integration Server.
APPC mode name	When **APPC Connection** is selected, this field is the APPC mode and must be set to a value that matches the host configuration and SNA service configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). The default is QPCSUPP.
IP address	When **TCP/IP Connection** is selected as the network transport, this field indicates the IP address of the host DB2 server.
Network port	When **TCP/IP Connection** is selected as the network transport, this field indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default is IP port 446.

The **Connection** tab also includes a **Test connection** button that may be used to test the connection parameters. A connection can only be tested after all of the required parameters for the **Connection** tab and other ODBC data source parameters are configured properly. When this button is clicked, a session is established with the remote DB2 system using ODBC Driver for DB2

Security

The **Security** tab enables the user to configure optional attributes used to restrict connections to a data source.

For the Microsoft® ODBC Driver for DB2 in Host Integration Server 2004, the **Security** tab has the following fields.

Parameter	Comments
Authentication	An option button is used to select the type of authentication. Valid options are **Use this username** or **Use single sign on**. For the default **Use this username** option, the value for the user name is required.
Use this username	When this option is selected, authentication is based on the user name entered in the text box. A valid user name is normally required to access data on DB2. A user name can remain optionally in the DSN. The ODBC Driver for DB2 prompts the user at run time to enter a valid password. Additionally, the prompt dialog box enables the user to override the user name that is stored in the DSN.
Use Single Sign-On	An option button to select whether Single Sign-On (SSO) or a specific user name should be used. SSO is an optional Host Security feature. SSO enables the administrator to create data source definitions that isolate the logon process from the end user.

The AS/400 computer is case-sensitive with regard to user IDs and passwords. When connecting to DB2 for OS/400, user names and passwords must be in uppercase. The AS/400 only accepts a DB2 for OS/400 user ID and password in uppercase. If a DB2 for OS/400 connection fails due to incorrect authentication, the ODBC driver resends the authentication, forcing the user ID and password into uppercase.

When connecting to DB2 on IBM mainframes, user names and passwords can be of mixed case. The mainframe is not case-sensitive. The ODBC driver sends these values in uppercase.

DB2 Universal Database (UDB) for Windows Server 2003 or for Windows 2000 is case-sensitive. The user ID is stored in uppercase. The password is stored in mixed case and users must enter the password in the correct case. The ODBC driver sends the password exactly in the case entered by the user. The user ID should contain only the user name, not a combination of the Windows NT® domain name and user name.

It is possible to connect using a specific user name and password defined in DB2 on the host system or use the Single Sign-On feature (often referred to as integrated Windows security). If a specific DB2 user name and password are to be used, this information may need to be saved to a data source name (DSN) file. The user name and password are saved in plain text in the DSN file or to registry keys if a System or User DSN is selected. For security reasons when using File DSNs, it is imperative that the DSN file be protected with an access control list (ACL) that restricts access to only authorized users. System and User DSNs are preferred for security reasons if the locations where these ODBC DSNs are stored in the registry have appropriate security protections. Saving the user name and password in the DSN also forces this DSN to be updated whenever the password associated with the user name is changed. So for a variety of reasons, specifying a user name and password is not the preferred authentication option. Using the **Single Sign-On** option is the preferred method for authentication.

Target Database

The **Target Database** tab enables the user to configure required, as well as optional, attributes used to define the target DB2 system.

For the Microsoft® ODBC Driver for DB2 in Host Integration Server 2004, the **Target Database** tab has the following fields.

Parameter	Comments
Initial catalog	This parameter is used as the first part of a three-part fully qualified DB2 table name. It is referred to by different names depending on the DB2 platform. In DB2 for OS/390 and DB2 for MVS, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 that you need to connect to on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 Installation Manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, a value can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE.
Package collection	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This can be the same as the default schema. The ODBC Driver for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. The ODBC driver creates packages dynamically in the location that the user points to using the Package Collection parameter. By default, the ODBC Driver for DB2 automatically creates one package in the target collection, if one does not exist, at the time the user issues the first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the user ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value specified in the connection. Problems can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), the package is created only for use by this user. This means that other users may be unable to access the required package. The solution is for an administrative user with package administrative rights to create a set of packages for use by all users. (For more information, see Creating Packages for Use with the ODBC Driver for DB2.) The ODBC Driver for DB2 supplied with Host Integration Server 2004 includes the Data Access Tool for use by administrators to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This tool will create a set of packages and grant EXECUTE privilege on these packages to the PUBLIC group representing all users on the DB2 system. The packages (see descriptions under the SQL_ATTR_TXN_ISOLATION connection attribute) created are as follows: AUTOCOMMITTED package (MSNC001 is only applicable on DB2/400) READ UNCOMMITTED package (MSUR001) READ COMMITTED package (MSCS001) REPEATABLE READ package (MSRS001) SERIALIZABLE package (MSRR001) Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400. Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. Note that when upgrading from SNA Server 4.0, any existing SNA Server 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2004. The package names changed from SNA Server 4.0.

Default Schema	The name of the collection where the ODBC Driver for DB2 looks for catalog information. Default schema is the SCHEMA name for the target collection of tables and views. The ODBC driver uses the Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or owner). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, the ODBC driver uses the USER_ID provided at log on. For DB2/400, the driver uses QSYS2 if no collection is found matching the USER_ID value. This default is inappropriate in many cases so it is essential that the Default Schema value in the data source be defined.
DBMS Platform	The target DB2 platform property value is used to optimize performance of the ODBC driver when executing operations such as data conversion. The default value is DB2/MVS.
Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute enables the user to access database objects without fully qualifying the objects using a collection (schema) qualifier. The ODBC driver sends this value to DB2 using a **SET CURRENT SQLID** statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for the default qualifier, no **SET** statement is issued by the ODBC driver. This ODBC connection attribute is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Alternate TP Name	The Alternate Transaction Program (TP) Name property represents the default transaction program name for the DB2 DRDA application server (AS), which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2004 uses the Alternate TP Name in the offline demo configuration (DRDADEMO.UDL). In that case, the Alternative TP Name is set to 0X07F9F9F9.
Distributed transactions	When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the Host Integration Server 2004 Resync Service.
Process binary as character	When this option is checked, it indicates that binary data fields should be processed as characters. This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. For more information, see the Locale tab.

Locale

The **Locale** tab enables the user to configure the parameters used for character conversion between the client and the DB2 server.

For the Microsoft® ODBC Driver for DB2 in Host Integration Server 2004, the **Locale** tab has the following fields.

Parameter	Comments
Host CCSID	The coded character set identifier (CCSID) matching the DB2 data as represented on the remote computer. This property is required when processing binary data as character data. Unless the Process Binary as Character value is set, character data is converted based on the DB2 column CCSID and configured ANSI code page. This parameter defaults to U.S./Canada (37).
PC code page	This parameter indicates the personal computer code page to use. It is required when processing binary data as character data. Unless the Process Binary as Character value is set, character data is converted based on the default ANSI code page configured in Windows. The default value for this property is Latin 1 (1252).

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuration Property Mappings Between the ODBC Driver for DB2 and the OLE DB Provider for DB2

This table compares the configuration parameters used by the ODBC Driver for DB2 and the OLE DB Provider for DB2.

Microsoft ODBC Driver for DB2	Microsoft OLE DB Provider for DB2
General	**General**
Data Source Name	Data Source
Data Source Description	None
Connection	**Connection**
Connection	Network Transport Library
APPC Connection	SNA
TCP/IP Connection	TCPIP
APPC local LU Alias	APPC Local LU Alias
APPC remote LU Alias	APPC Remote LU Alias
APPC mode name	APPC Mode Name
IP address	Network Address
Network port	Network Port
Security	**Security**
Use this username	None
User Name	User ID
Use Single Sign-on	Integrated Security
Affiliate Application	Affiliate Application
Target Database	**Target Database**
Initial catalog	Initial Catalog
Package collection	Package Collection
Default schema	Default Schema
Default qualifier	Default qualifier
DBMS Platform	DBMS Platform
Alternate TP name	Alternate TP Name
Distributed transactions	Distributed transactions
Process binary as character	Process binary as character
Locale	**Locale**
Host CCSID	Host CCSID
PC code page	PC Code Page
Extended	**Extended**
Client Application Name	None
Connection Pooling	None

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ODBC Connection String Attributes

The ODBC **SQLBrowseConnect** and **SQLDriverConnect** functions allow passing in a connection string containing a series of attribute/value pairs to the ODBC Driver Manager to establish a connection with a data source. An example of a connection string is as follows:

```
"DSN=MYDATA;NTL=SNA;LLU=Local;RMU=Remote;RDB=BigData;PC=QSYS2;
DS=QSYS2;RO=false;UID=myname;PWD=Secret"
```

Some ODBC attributes are required as part of the connection string when used with the ODBC Driver for DB2.

The following tables compare the configuration parameters used by the ODBC Driver for DB2 and the ODBC attribute keywords that are supported by the OLE DB Driver for DB2 as part of the passed-in connection string.

For the Microsoft® ODBC Driver for DB2 in Host Integration Server 2004, these attribute keywords compare as follows.

Microsoft ODBC Driver for DB2	ODBC attribute keyword	Comments
General	**General**	**General**
Data Source Name	DSN	Required parameter.
Data Source Description	DESC	None.
Connection	**Connection**	**Connection**
Connection	NTL	Required parameter.
APPC connection	NTL=SNA	None.
TCP/IP connection	NTL=TCPIP	None.
APPC local LU alias	LLU	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA).
APPC remote LU alias	RLU	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA).
APPC mode name	MN	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA).
APPC Security Type	AST	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA). Valid values are “PROGRAM” (the default), or “SAME”.
IP address	NA	Applicable only if TCPIP (a TCP/IP connection) is used for the network transport library (NTL=TCPIP).
Network port	NP	Applicable only if TCPIP (a TCP/IP connection) is used for the network transport library (NTL=TCPIP).
Security	**Security**	**Security**
Use this username	None	None.
User Name	UID	None.
	PWD	The Password parameter is not on the Security tab and is not configurable from the ODBC Administrator tool used to configure ODBC data sources. This parameter can only be preset using the ODBC connection string. Most applications prompt the user for this parameter.
Use single sign-on	None	Not applicable.
Affiliate application	AAP	Applicable only if using single sign-on.
Target Database	**Target Database**	**Target Database**
Initial Catalog	RDB	Required parameter.

Package Collection	PC	Required parameter.
Default Schema	DS	Required parameter.
Default Qualifier	DQ	None.
DBMS Platform	DP	Can be one of the following values: DB2/AS400, DB2/MVS (the default), DB2/6000, or DB2/NT.
Alternate TP Name	TPN	None.
Distributed transactions	RUW	None.
Process binary as character	BAC	None.
Locale	**Locale**	**Locale**
Host CCSID	CCSID	Required parameter.
PC code page	CP	Required parameter.

Creating Packages for Use with the ODBC Driver for DB2

The Microsoft® ODBC Driver for DB2, which is implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester, uses packages to issue SQL statements and call DB2 stored procedures. There is a configuration parameter that the ODBC Driver for DB2 uses to identify a location in which to create and store DB2 packages. The ODBC Driver for DB2 creates packages dynamically in the location to which the user points using the *Package Collection* parameter. This location may be configured using the **Target Database** tab from the Microsoft ODBC Data Source Administrator tool or can be passed as part of the ODBC connection string as an attribute keyword and argument. The attribute keyword for *Package Collection* is PC.

There are two package creation options:

- The ODBC Driver for DB2 autocreates one package for the currently used isolation level at run time if no package already exists. This auto-create process may fail if the user account does not have authority to create packages.
- An administrator or user can manually create all four packages (five packages on DB2/400) for use with all isolation levels and for use by all users (the PUBLIC group on DB2 representing all users) or a specific set of users. The ODBC Driver for DB2 includes a utility program for use by users with appropriate administrative privilege that will create these packages and grant access to the PUBLIC group for this purpose.

However, some users may not have the security level when manually creating packages to GRANT authority to the packages to other users (grant authority to the DB2 PUBLIC group representing all users, for example). This can be a problem if two or more users with different user IDs try to access a single collection of packages. The first user that created the packages will have access to the packages, but the second user likely will not. The Host Integration Server 2004 CD includes a program for use by an administrator or a user with appropriate privileges to create packages. This tool can be run using a privileged user ID to create packages in collections accessed by multiple users. The Data Access Tool can be used to create packages for use with DB2.

This tool creates a set of packages and grants EXECUTE privileges on these packages to the PUBLIC group. The PUBLIC group on DB2 systems is a default group that represents all DB2 users. The following packages are created:

- AUTOCOMMITTED package (MSNC001), only applicable on DB2/400
- READ UNCOMMITTED package (MSUR001)
- READ COMMITTED package (MSCS001)
- REPEATABLE READ package (MSRS001)
- SERIALIZABLE package (MSRR001)

Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400.

The descriptive process name used by the Data Access Tool corresponds with the isolation levels defined in the ANSI SQL standard. The following table indicates how these packages correspond with the terms used by IBM for isolation levels in DB2 documentation.

Package description	Package name	IBM documentation
AUTOCOMMITTED (Note that this applies only to DB2/400 and does not correspond with an ANSI SQL isolation level)	MSNC001	COMMIT(*NONE) (NC). This isolation level is used in DB2/400 autocommit mode only and has no corresponding isolation level on other DB2 platforms or in ANSI SQL.
READ UNCOMMITTED	MSUR001	UNCOMMITTED READ (UR). This isolation level corresponds with ANSI SQL READ UNCOMMITTED.
READ COMMITTED	MSCS001	CURSOR STABILITY (CS). This isolation level corresponds with ANSI SQL READ COMMITTED.
REPEATABLE READ	MSRS001	READ STABILITY (RS). This isolation level corresponds with ANSI SQL REPEATABLE READ.

SERIALIZABLE	MSRR 001	REPEATABLE READ (RR). This isolation level corresponds with ANSI SQL SERIALIZABLE.

Note that when upgrading from SNA Server 4.0, any existing SNA Server 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2004. The package names used by the ODBC Driver for DB2 on SNA Server 4.0 are not compatible with the ODBC Driver for DB2 included with Host Integration Server. On SNA Server 4.0, these packages used different names as follows:

```
AUTOCOMMITTED package (SNANC001) only applicable on DB2/400
READ UNCOMMITTED package (SNACH001)
READ COMMITTED package, (SNACS001)
REPEATABLE READ package, (SNARR001)
SERIALIZABLE package (SNAAL001)
```

These isolation levels are described in detail in Support for Isolation Levels Using the ODBC Driver for DB2. These isolation levels are also described in IsolationLevel Property (ADO). Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400.

Note that the Data Access Tool tool creates this set of packages and grants EXECUTE privileges to PUBLIC. There may be cases for security reasons where EXECUTE privileges to this set of packages should be restricted to a certain group of users or specific users. In these cases, execution privileges on these created packages will need to be modified on the host system.

The Data Access Tool creates all of these packages inside the collection that is specified in the **Package Collection** property in the datalink file, or in the connection string. If the user does not have the appropriate authority to create packages in the specified collection, or if the specified collection does not exist, the ODBC Driver for DB2 returns an error.

In the case of DB2 on MVS or OS/390, the normal error text returned if the user does not have the appropriate authority is as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version for
a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -567.
```

In the case of DB2/400, the normal error text returned if the user does not the appropriate authority is as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version for
a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -805.
```

In the case of DB2/400, the normal error returned if the collection does not exist is as follows:

```
Failed to create AUTOCOMMITTED (NC) package.  RETCODE=-99.
SQL Error: Code=-204, State=42704, Error Text= A SQL error has occurred.  Please consult the
documentation for your specific DB2 version for a description of the associated Native Error
and SQL State. SQLSTATE: 42704, SQLCODE: -204
```

There are two authorities required to execute the create package process on OS/390 or MVS using the Data Access Tool:

```
GRANT BINDADD TO <authorization ID>
GRANT CREATE IN COLLECTION <collection ID> TO <authorization ID>
```

The authorization ID is the user who needs the permission to create the packages. The collection ID is the name of the collection, which the user specifies in the datalink file for the **Package Collection** property. This collection should be a valid collection within the DB2.

If an administrator executes the preceding statements on behalf of a nonprivileged user, this nonprivileged user can then run the Data Access Tool. Once run, the process creates four sets of packages (one for each of the four isolation levels supported on DB2 for MVS or OS/390) for use by all (PUBLIC) users of the Microsoft data access features.

The following example illustrates this process on DB2 for MVS or DB2 for OS/390:

Grant rights to run the Data Access Tool to authorization ID WNW999:

```
GRANT BINDADD TO WNW999
GRANT CREATE IN COLLECTION MSPKG TO WNW999
```

Run the Data Access tool using authorization ID WNW999 .

To execute the Data Access Tool on DB2/400, a user ID must have one of the following authorities:

- *CHANGE authority on the DB2 collection
- *ALL authority on the DB2 collection

If the user only has *USE authority or if the user has *EXCLUDE authority, the Create Package process will fail.

There are several steps required to change user authority on a DB2/400 collection (AS/400 library). From interactive SQL (STRSQL command) while logged in as user with administrative privileges, create a new collection. This command can also be issued using ADO, OLE DB, and ODBC. However, most administrators typically create collections from the AS/400 console because the administrator must be logged in at the console to issue the Command Language (CL) command with which to change the user authority on the collection:

```
CREATE COLLECTION <collection ID>
```

From the AS/400 command console, issue the CL WRKOBJ command with the <collection ID> as a parameter:

```
WRKOBJ <collection ID>
```

The collection ID is the name of the collection, which the user specifies in the datalink file for the Package Collection property. This collection should be a valid collection within DB2. The Work with objects window appears. Place the cursor on the *PUBLIC Object Authority line and change the authority from *USE to *ALL.

If an administrator executes the preceding statements on behalf of a nonprivileged user, this nonprivileged user can run the Data Access Tool. Once run, the process creates five sets of packages (one for each of the five isolation levels supported on DB2/400) for use by all (PUBLIC) users of the Microsoft data access features. On DB2/400, five packages are created including the AUTOCOMMITTED packages.

The following example illustrates this process on DB2/400:

Grant rights to run the Data Access Tool to authorization ID WNW999:

```
CREATE COLLECTION MSPKG
WRKOBJ MSPKG
```

Run the Data Access tool.

When using the create package tool, if the package collection specified does not exist, DB2 returns SQLCODE -805.

When using autocreate packages, if a package collection is not specified or the package collection does not exist, during the autocreate package process, the consumer application receives SQLSTATE HY000 and SQLCODE -385. The SQLSTATE HY000 is defined as a driver-specific error. The -385 Error Return Code is not a SQLCODE but rather a DDM DRDA AR (DB2 client) return code. This error code is defined as DDM_VALNSPRM with the following associated text string:

```
"The parameter value is not supported by the target system."
```

Note that when upgrading from SNA Server 4.0, any existing SNA Server 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2004.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to

http://go.microsoft.com/fwlink/?linkid=29507.

ActiveX Controls Programmer's Guides

This section provides information about how to integrate your applications using the Data Queue and Host File Transfer ActiveX® controls.

For API references and other technical information about ActiveX controls, see the ActiveX Controls Programmer's Reference section in the SDK.

For sample code using ActiveX controls, see the ActiveX Controls Samples section in the SDK.

This section contains:

- Host File Transfer ActiveX Control Programmer's Guide
- Data Queue ActiveX Control Programmer's Guide

Host File Transfer ActiveX Control Programmer's Guide

The Microsoft® Host File Transfer ActiveX® control provides the ability to transfer files between a local computer and an MVS, OS/390, AS/400, or AS/36 host system. Microsoft Host Integration Server 2004 provides this service via a single ActiveX control that depends on other core Host Integration Server DLLs. This extends the ability for a client application to perform file transfer operations from a large number of client development environments.

The Microsoft Host File Transfer ActiveX control uses the record-level input/output (RLIO) protocol of IBM's Distributed Data Management (DDM) architecture to transfer files. The Host File Transfer ActiveX control is implemented as a Distributed Data Management (DDM) source requester, which communicates through APPC LU 6.2 or TCP/IP to a DDM target server.

DDM is a set of rules for distributing or extending data management from one computer to another, such as from a mainframe to an AS/400 computer or from one of these host computers to a server computer. By combining the Microsoft File Transfer ActiveX control and DDM architectures, Microsoft enables organizations to preserve their investments in existing data management infrastructure, while extending universal file transfer to all enterprise-wide data sources.

The information in this section is required to develop applications with Host Integration Server that use ActiveX or COM objects to transfer files from local machines to hosts in a Systems Network Architecture (SNA) environment or over TCP/IP using RLIO and DDM.

This section contains:

- Platforms Supported by the Host File Transfer ActiveX Control
- Configuring Data Descriptions for Host File Transfer
- Registry Settings Used By Host File Transfer
- Object Support Using Host File Transfer
- Programming Considerations Using Host File Transfer

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Platforms Supported by the Host File Transfer ActiveX Control

On the mainframe platform, IBM offers a target DDM server implementation in IBM Distributed File Manager (DFM), a component of IBM Data Facility Storage Management Subsystem (DFSMS).

On the mainframe platform, the Host File Transfer ActiveX control supports the following data set types:

Sequential Access Method (SAM) data sets

- Basic Sequential Access Method data sets (BSAM)
- Queued Sequential Access Method data sets (QSAM)

Basic Partitioned Access Method (PDS) data sets

- Partitioned Data Set Extended members (PDSE)
- Partitioned Data Set members (PDS)

Virtual Storage Access Method (VSAM) data sets

- Entry-Sequenced Data Sets (ESDS)
- Key-Sequenced Data Sets (KSDS)
- Fixed-Length Relative Record Data Sets (RRDS)
- Variable-Length Relative Record Data Sets (VRRDS)
- Relative Record Data Set (RRDS)
- VSAM Alternate Indexes for ESDS and KSDS data sets

The preceding data set types are supported by IBM DFM/MVS. The following data set types are not supported by DFM/MVS and cannot be accessed using the Host File Transfer ActiveX control.

- VSAM Linear Data Sets (LDS)
- Generation Data Groups (GDG)
- Generation Data Sets (GDS)
- Basic Direct Access Method data sets (BDAM)
- Indexed Sequential Access Method data sets (ISAM)
- Sequential Data Striping data sets
- OpenEdition MVS Hierarchical File System (HFS) files
- Tape Media

All mainframe data sets accessible through IBM Distributed File Manager must be cataloged in an Intersystem communications function (ICF) catalog and reside on direct access storage devices (DASD).

More information about hardware and software requirements can be found in the Host Integration Server 2004 Installation Guide topic Hardware and Software Requirements.

Configuring Data Descriptions for Host File Transfer

In order to use the Microsoft® Host File Transfer ActiveX® control to transfer files, a user or client application must describe the data format of the host file to transfer. A host data description is normally configured using the Data Access Tool.

The Data Access Tool contains one high-level object for configuring Host Column Description files:

- **Host Column Descriptions**—Stored in Host Column Description (HCD) files that contain the information required to convert host data types to PC computer data types.

When creating a Data Description for use with the Host File Transfer ActiveX control, the **Use Table for File Transfer** check box must be selected and values must be entered for the following additional parameters:

Parameter	Comment

FieldDelimiter	This value represents the delimiter used to mark the end of one field and the beginning of another within a single record. The position of the field elements within a record is assumed to be absolute as configured and variable-length fields are not supported. This element is used in order to inform the conversion routine to remove this character if it is found at the position within the record as indicated by the Data Description. This parameter is required and has no default value. The comma character "," or tab character "\t" is commonly used with desktop applications as a field separator.
RecordDelimiter	This value represents the character or characters that appear at the ending of a record. This element is used in order to inform the conversion routine to remove this character if it is found in the last position of the record as indicated by the Data Description. This parameter is required and has no default value. The end-of-line character sequence is commonly used as a record delimiter. The carriage return and linefeed character sequence "\n\r" is commonly used with desktop applications. The newline character "\n" is standard for use on UNIX systems and with some desktop applications.
TextQualifier	This value is used in order to allow elements that may contain the **FieldDelimiter** character to be properly parsed by the parsing engine. If this element is enabled on a particular field, then the inclusion of this character at the beginning of the field is an indication to the parsing engine that all characters up to the next instance of the **TextQualifier** should be treated as part of the current field being processed. This parameter has no default value. The single quote or double quote character is sometimes used as a text qualifier to protect a comma character included in a field from being misinterpreted as a field delimiter.

Registry Settings Used By Host File Transfer

The Microsoft® Host File Transfer ActiveX® control uses a number of registry settings for configuration and proper operation. The configuration registry settings are located under the HKEY_LOCAL_MACHINE\Software\Microsoft\SNA Server\CurrentVersion\Setup key. These registry settings include the following subkey:

Subkey	Comment
RootDir	Stores the path to root directory where the Host Integration Server was installed. The system directory below this root directory is the location where the Host File Transfer ActiveX control DLL and other support DLLs are installed.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Object Support Using Host File Transfer

The Microsoft® Host File Transfer ActiveX® control supports a number of standard COM interfaces as well some custom objects and interfaces.

This section contains:

- COM Interface Support Using Host File Transfer
- IEIGFileTransferCtl Object
- IEIGFileTransferCtlEvents Notification

COM Interface Support Using Host File Transfer

The Microsoft Host File Transfer ActiveX control supports a number of standard COM interfaces as well as a single custom interface, **IEIGFileTransferCtl**. The ActiveX control object has the ability to register and de-register itself via standard control mechanisms. Support for a number of standard COM interfaces makes it easy to develop applications using the Host File Transfer ActiveX control with Microsoft Visual Basic® and Microsoft Visual C++® as well as from Microsoft Internet Explorer and Microsoft Access. Supporting a variety of standard COM interfaces also provides different ways for a client to save information.

The following table summarizes the standard COM interfaces supported by the Host File Transfer ActiveX control.

COM interface	Comments
ICategorizeProperties	This interface divides up the properties into an intelligent presentation to the client.
IConnectionPointContainer	None.
IDispatch	A dual interface deriving from **IDispatch** is exposed to provide support and flexibility to clients. Clients that provide support for automation interfaces will utilize the **IDispatch** interface, while more robust clients may use the custom interface. Using the custom interface provides for the greatest execution speed.
IOleControl	None.
IOleInPlaceActiveObject	None.
IOleInPlaceObject	None.
IOleInPlaceObjectWindowless	None.
IOleObject	None.
IOleWindow	None.
IPerPropertyBrowsing	This interface provides support for client browsing of properties in an intelligent manner. This interface exposes to the client property lists used in the population of a dropdown list. This interface is required for the control to be hosted by Microsoft Access.
IPropertyNotifySink	The interface is implemented by a sink object to receive notifications about property changes from an object that supports **IPropertyNotifySink** as an outgoing interface. The client that needs to receive the notifications in this interface (from a supporting connectable object) creates a sink with this interface and connects it to the connectable object through the connection point mechanism.
IPersist	None.
IPersistPropertyBag	This interface is the preferred method of property persisting for Internet Explorer and Visual Basic. Using this interface, persisted properties are stored as a set of name/VARIANT value pairs.
IPersistStorage	This interface stores persistent properties into a structured storage object.
IPersistStreamInit	This interface is responsible for saving the persisted properties in binary form using a stream interface. This is the method used by the Microsoft Visual C/C++ compiler to persist properties.
IProvideClassInfo	None.

IProvideClassInfo2	None.
IQuickActivate	None.
ISupportErrorInfo	This interface is the preferred method to return error indications to scripting clients. Using this interface, error codes and explanation text are returned to the client. This information may be used in order to provide diagnostic information to the user and in cases of failure.
IViewObject	None.
IViewObject2	None.
IViewObjectEx	None.

IEIGFileTransferCtl Object

The Microsoft Host File Transfer ActiveX control supports a number of standard COM interfaces as well as a single custom interface. The **IEIGFileTransferCtl** object supports a number or properties and methods that provide the ability to transfer files to and from MVS, OS/390, AS/400, or AS/36 hosts. The Host File Transfer ActiveX control also supports a set of events notifying a client application of connection status, file transfer status, and error reporting. These events are handled by the client supporting several callback functions and setting these callbacks using the IConnectionPointContainer.

The following IEIGFileTransferCtl object methods are supported by the Microsoft Host File Transfer ActiveX control:

Method name	**Comment**
Cancel method	Terminates a file transfer operation that is already in progress.
Connect method	Establishes a connection to the configured host and reports to the user an indication of the success or failure of the action.
Disconnect method	Terminates an existing connection to a host machine.
GetFile method	Copies a file from host storage to local storage. This method requires the two file names as parameters.
PutFile method	Copies a file from local storage to host storage. This method requires the two file names as parameters.

The following **IEIGFileTransferCtl** object properties are supported by the Microsoft Host File Transfer ActiveX control:

Property name	**Comment**
AppendToEnd property	Sets or returns whether a file transfer should append to the end of a file (eigAnswerYes) if the file exists, or should it overwrite the existing contents replacing the data with the new information (eigAnswerNo). This property defaults to eigAnswerYes (0).
CCSID property	Sets or returns the character code set identifier (CCSID) that must match the data in the file as represented on the remote host computer. This property defaults to U.S./Canada (37).
ConnectionState property	Returns the current state of the connection. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting.
ConnectionType property	Sets or returns the network transport used for this connection. The **ConnectionType** property designates whether the Host File Transfer ActiveX control connects through APPC (SNA LU 6.2) or TCP/IP. The possible values for this parameter are a TCP/IP or an APPC connection using an enumerated value. The default value for this parameter is an APPC (SNA) connection type. If APPC is selected, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required. If TCP/IP is selected, then values for the **NetAddr** and **NetPort** properties are required.
CreateIfNonExisting property	Sets or returns whether a file operation should create a new destination file if one does not already exist (eigAnswerYes). This property defaults to eigAnswerNo (1)
LocalLU property	Sets or returns the Local LU Alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager. This property defaults to the string value of "LOCAL" represented as a BSTR.
ModeName property	Sets or returns the APPC mode. When APPC (LU 6.2 SNA) is selected for the ConnectionType property, this field must bet set to the APPC mode that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This property defaults to the string value of "QPCSUPP" represented as a BSTR.

NetAddr property	Sets or returns the IP address of the host computer. When TCP/IP has been selected for the **ConnectionType** property, this property indicates the IP address of the host. This property can be an IP address or the name representing the host IP address using the Domain Name System (sna.microsoft.com, for example). This property is a string (BSTR) and has no default value.
NetPort property	Sets or returns the TCP/IP port used for communication with the host. When TCP/IP has been selected for the ConnectionType property, this parameter is the TCP/IP port used for communication with the host. The default value for this property is the string (BSTR) "446" representing TCP/IP port 446.
OverwriteHostFile property	Sets or returns whether a file operation request to copy a file that will write over an existing file will fail. When this property is set to eigAnswerNo, a request to write a file over an existing file will fail. This property defaults to eigAnswerNo (1)
Password property	Sets or returns the password used for authentication. A valid user name and password are normally required to access files on a host computer. The password is case sensitive and is normally displayed as asterisks in a dialog box for security purposes. This property is a string (BSTR) and has no default value.
PCCodePage property	Sets or returns the PC codepage The **PCCodePage** property indicates the codepage to be used on the PC for character code conversion. This property defaults to Latin 1 (1252).
RDBName property	Sets or returns the name of the remote database name and the host column description (HCD) file that describes the data types and data conversions used to transfer this file. The HCD file describing the data should be located in the system subdirectory below the root directory where Host Integration Server was installed. Setup defaults to the following location: C:\Program Files\Host Integration Server When TCP/IP is selected for the **ConnectionType** property, the **RDBName** must also match the name of the remote database system.
RemoteLU property	Sets or returns the Remote LU Alias. When APPC (LU 6.2 SNA) is selected for the **ConnectionType** property, this property is the name of the local LU alias configured using SNA Manager. This property is a string (BSTR) has no default value.
UserID property	Sets or returns the user name used for authentication. A valid user name and password are normally required to access files on a host computer. This value is case sensitive. This property is a string (BSTR) and has no default value.

IEIGFileTransferCtlEvents Notification

The Microsoft Host File Transfer ActiveX control also supports a set of events notifying a client application of connection status, file transfer status, and error reporting. These events are handled by the client supporting several callback interfaces and setting these callbacks derived from the standard **IConnectionPointContainer** COM object.

The following IEIGFileTransferCtlEvents notification interface methods are supported by the Microsoft Host File Transfer ActiveX control:

Event notifications	Comment
ConnectionStateChange	This event is fired when the state of a connection has changed. A *ConnectionState* parameter is passed to the client callback function that receives this event method call. This parameter is an eigConnectionStateEnum value representing the new state of the ConnectionState property.
ReportError	This event is used in order to return error conditions that occur during the synchronous processing of methods. This event passes two parameters to the client callback function that receives this event method call. The first parameter is a long value representing an error code. The second parameter is a BSTR string containing a brief text description of the error.
TransferComplete	This event is an indication to the client that the requested transfer operation has completed.
TransferProgress	This event will be fired periodically in order to inform the client of the progress of an unattended file transfer. A *PercentageDone* parameter is passed to the client callback function that receives this event method call. This parameter is a short value representing the percentage complete of the requested operation ranging from 0 to 100. A client application has the option to terminate a file transfer when this event is fired.

Programming Considerations Using Host File Transfer

The Microsoft® Host File Transfer ActiveX® control exposes a dual interface deriving from **IDispatch**. This provides support and flexibility to clients wishing to use the object. Clients that provide support automation interfaces can use the **IDispatch** interface while more robust clients may use the custom interface. Using the custom interface offers the greatest execution speed.

The single-threading model is supported, allowing only single threads to access the objects safely.

The Host File Transfer ActiveX control does not support uploading Direct Relative Record Data Set (RRDS) files on System/36. An error (381) will occur and the following error message will be received.

```
"Target Not Supported"
```

The Host File Transfer ActiveX control also does not support uploading RRDS files with the CreateIfNonExisting property option set to yes on System/36. An error will occur (381) and the following message will be received.

```
"Target Not Supported"
```

If there is existing data in a file on OS/390, setting the OverwriteHostFile and AppendToEnd properties to "no" should cause an error (58) to occur and the following error message should be received.

```
"File contains existing data. Upload not configured to append data - upload aborted"
```

On OS/390, this error is not triggered for sequential or KSDS files. Instead the data is appended to the existing data in the file for sequential files and duplicate records are not appended to KSDS files.

The **AppendToEnd** property and the **OverwriteHostFile** property are mutually exclusive, so it is not possible to enable (set to yes) one of these properties before the opposing property is disabled (set to no). The **AppendToEnd** property takes precedence over the **OverwriteHostFile** property, since **AppendToEnd** defaults to yes and **OverwriteHostFile** defaults to no. Consequently, the order in which these properties are set will affect the outcome. For example, the following order will result in the properties being set correctly:

```
FileTransfer.AppendToEnd = eigAnswerNo         // correctly set to no
FileTransfer.OverwriteHostFile = eigAnswerYes  // correctly set to yes
```

In contrast, setting the properties in the improper order will cause the properties to be set incorrectly as follows:

```
FileTransfer.OverwriteHostFile = eigAnswerYes   // remains at no
// AppendToEnd defaults to eigAnswerYes, so this change is illegal
FileTransfer.AppendToEnd = eigAnswerNo          // correctly set to no
```

In this second case, the **OverwriteHostFile** property cannot be set to yes (enabled) until the **AppendToEnd** property is set to no (disabled).

Using the Data Descriptions tool, setting the Ascending/Descending option on an OS/390 or MVS/ESA key sequenced file has no effect. Using the Host File Transfer ActiveX control, data is always uploaded and downloaded in the ascending key order.

If the **Cancel** method is executed while uploading a file with the **AppendToEnd** property set to yes, this will result in no change to the host file. However, if the **Cancel** method is executed while uploading a file with the **OverwriteHostFile** property set to yes, this will result in an empty host file. The **Cancel** method implies the transfer has been stopped and all the files are at their original values, but this is not really the case when the **OverwriteHostFile** property is set to yes.

This section contains:

- Code Page Support Using Host File Transfer
- Data Conversion Using Host File Transfer
- Usernames and Passwords Using Host File Transfer
- Troubleshooting the Host File Transfer ActiveX Control

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Code Page Support Using Host File Transfer

When using the Host File Transfer ActiveX control, the Host CCSID (character code set identifier) property should be configured to match the data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37) when using the Host File Transfer ActiveX control.

This section contains:

- ISO Code Page Support Using Host File Transfer
- DBCS Code Page Support Using Host File Transfer

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ISO Code Page Support Using Host File Transfer

Microsoft Host Integration Server 2004 includes support for some ISO code pages for purposes of ISO-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-ISO, and ISO-to-UNICODE-to-ISO conversions when using the Host File Transfer ActiveX control. These ISO code pages can be used when accessing host files containing ISO code pages.

Depending on the version of Windows being used, to support ISO-to-UNICODE-to-ANSI (Windows), ANSI-to-UNCODE-to-ISO, and ISO-to-UNICODE-to-ISO code page conversions, you may need to install the appropriate ISO National Language Support (NLS) file for your locale.

On Microsoft Windows® 2000, the appropriate ISO NLS file for your locale is installed automatically when you install a localized version of Windows 2000. On Windows Server™ 2003, the appropriate ISO NLS file for your locale is installed automatically when you install the US-English version.

The following table shows the ISO character code set identifiers (CCSIDs) supported by Host File Transfer ActiveX control in Host Integration Server 2004.

Microsoft display name	Microsoft NLS code page	IBM CCSID	Comments
ISO 8859-1 Latin 1	28591	819	
ISO 8859-2 Central europe	28592	912	
ISO 8859-5 Cyrillic	28595	915	
ISO 8859-6 Arabic	28596	1089	
ISO 8859-7 Greek	28597	813	
ISO 8859-8 Hebrew	28598	916	
ISO 8859-9 Turkish	28599	920	
ISO 6937 Non-Spacing Accent	20269	819	Note that ISO 6937 (CCSID 20269) is not supported by the OLE DB Provider for DB2, but is displayed in the list of configuration options when creating or modifying data sources.
ISO 8859-15 Latin 9 (euro)	20865	923	NLS Code Page 819 with support for the euro.

The Microsoft display name is the name found in the Windows 2000 definitions for these NLS files.

The Microsoft NLS code page column represents the code page number that is registered and associated with an ISO-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when using the Host File Transfer ActiveX control. When setting the Host CCSID or PC Code Page property, use the Microsoft NLS number for this parameter.

The IBM CCSID column represents the CCSID given to the ISO code page in IBM publications. IBM lists their ISO support in publications by referencing the locale name (Bulgaria for ISO8859-5 and 915, for example) rather than simply using ISO 8859-5 Cyrillic as used by Microsoft. The Host File Transfer ActiveX control does not recognize or display the IBM CCSID values.

The Host File Transfer ActiveX control maps the Microsoft NLS numbers to ISO NLS files which correspond with the appropriate IBM CCSID numbers. The Host File Transfer ActiveX control passes the corresponding IBM CCSID to the host system at run time even though you configure this property using the Microsoft NLS number.

> **Note** The IBM CCSID 819 is associated with both ISO 8859-1 Latin 1 and ISO 6937 Non-Spacing Accent. It is up to the user to choose the standard ISO 8859-1 Latin 1 code page by selecting NLS code page 28591 or the modified code page ISO 6937 Non-Spacing Accent by selecting NLS code page 20269.

> **Note** The ISO 6937 Non-Spacing Accent (CCSID 20269) is not currently supported by the Host File Transfer ActiveX control.

IBM CCSID 916 (ISO 8859-8) supports Hebrew "visual sort order". IBM CCSID 920 (ISO 8859-8 derivation) supports Hebrew "logical sort order". Although Microsoft supports the logical sort order with NLS 38598, this NLS file is only distributed with Internet Explorer 5 or Windows 2000.

The Host File Transfer ActiveX control has not been tested using the ISO 8859-8 derivation matching IBM CCSID 920 and does not support this configuration.

These are the only ISO pages currently supported in Host Integration Server 2004. Microsoft supports a number of additional ISO pages. IBM also supports additional ISO pages. However, the code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM CCSIDs match.

DBCS Code Page Support Using Host File Transfer

Support for Double-Byte Character String (DBCS) data is limited using the Host File Transfer ActiveX control. Conversions between DBCS and ANSI code pages are not supported. Conversions between DBCS and ISO code pages are not supported.

Data Conversion Using Host File Transfer

Using the Host File Transfer ActiveX control, host data is converted to default C data types as defined in ODBC and OLE DB and illustrated in the following table:

Host data type **(description in HCD file)**	**Default C data type**	**Comments**
BINARY		A free-form binary data type of specified length. This data type is transferred without being converted.
CHAR	char string[]	A fixed-length string. This data type is converted to a DBTYPE_BSTR for use by Host File Transfer ActiveX control.
DATE	date struct	A 10-byte date string. This data type is converted to a DBTYPE_DATE for use by OLE DB.
DOUBLE	double	An 8-byte double-precision floating-point number. This data type is converted to a DBTYPE_R8 for use by OLE DB.
FLOAT	double	An 8-byte double-precision floating point number. This data type is the same as a DOUBLE. This data type is converted to a DBTYPE_R8 for use by OLE DB.
LONG	int	A 4-byte integer ranging in value from -2,147,463,648 to +2,147,483,647. This data type is converted to a DBTYPE_I4 for use by OLE DB.
LONG VARBINARY	char string[]	A varying-length binary string up to 32,740 bytes in length. This data type is converted to a DBTYPE_STR for use by OLE DB.
LONG VARCHAR	char string[]	A varying-length character string up to 32,740 characters in length. This data type is converted to a DBTYPE_STR for use by OLE DB.
PACKED	unsigned char number[]	A packed decimal number. This data type is converted to a DBTYPE_DECIMAL for use by OLE DB
REAL	float	A 4-byte single-precision floating-point number. This data type is converted to a DBTYPE_R4 for use by OLE DB.
SHORT	short	A SMALLINT (small integer) is a two-byte integer with a precision of 5 digits ranging from -32,768 to +32,767. This data type is converted to a DBTYPE_I2 for use by OLE DB.
SINGLE	float	A 4-byte single-precision floating-point number. This data type is converted to a DBTYPE_R4 for use by OLE DB.
TIME	time struct	An 8-byte time string. This data type is converted to a DBTYPE_TIME for use by OLE DB. When using ActiveX Data Objects to return data from a DB2 TIME data type, ADO returns a DATETIME value.

TIMESTAMP	timestamp struct	A 26-byte string representing the date, time, and microseconds. This data type is converted to a DBTYPE_DBTIMESTAMP for use by OLE DB.
VARBINARY	char string[]	A varying-length binary field. The maximum length of the binary is dependent on the version and the host platform. This data type is transferred without being converted. This data type is converted to a DBTYPE_STR for use by OLE DB.
VARCHAR	char string[]	A varying-length character string. The maximum length of the string is dependent on the version and the host platform. This data type is converted to a DBTYPE_STR for use by OLE DB.
ZONED	unsigned char number[]	A zoned numeric number. This data type is converted to a DBTYPE_NUMERIC for use by OLE DB

> **Note** The maximum length of fixed-length BINARY, fixed-length CHAR, VARBINARY, and VARCHAR data types is dependent on the version of the host software that is being accessed. For example, the maximum length of the CHAR data type on OS/390 is 254 characters, while the maximum length of this same host data type is 32,765 on OS/400.

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example), however truncation and conversion errors can occur that will not be reported by the Host File Transfer ActiveX control.

Using the Host File Transfer ActiveX control, certain conversions of strings from EBCDIC to ASCII and then back to EBCDIC are asymmetric, and can result in strings that are different from the original. The EBCDIC specification contains ordinals for which there is no defined character. The Host File Transfer ActiveX control translates all such undefined characters to the question mark character ("?"). So when ASCII strings containing these characters are converted back to EBCDIC, these undefined characters will be replaced with question marks. To protect EBCDIC strings containing undefined characters, these fields should be tagged as binary strings and mapped by the application.

The ANSI to EBCDIC character conversions affected include the following:

Character value (decimal)	Character value (hexadecimal)	ANSI code page 1252	EBCDIC character after conversion to CCSID 37
128	0x80	Not used	?
130	0x82	Single low quote	?
131	0x83	Latin F with hook	?
132	0x84	Double low quote	?
133	0x85	Ellipsis	?
134	0x86	Dagger	?
135	0x87	Double dagger	?
136	0x88	Per mile	?
137	0x89	S with caron	?
138	0x8A	Left angle	?
139	0x8B	Ligature OE	?
140	0x8C	Not used	?
142	0x8E	Not used	?
145-156	0x91-0x9C		?
158-159	0x9E-0x9F		?

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Usernames and Passwords Using Host File Transfer

When connecting to host systems, most users must be authenticated by the remote system by passing a valid user ID and password.

The AS/400 computer is case-sensitive with regard to user ID and password. The AS/400 only accepts a user ID and password in uppercase. The Microsoft Host File Transfer ActiveX control forces the User ID and Password into uppercase when it knows that it is connecting to an AS/400 system.

The mainframe is not case-sensitive. This means that on mainframe computers, one can enter the user ID and password in any case.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Troubleshooting the Host File Transfer ActiveX Control

The Microsoft Host File Transfer ActiveX control supplied with Host Integration Server 2004 has the ability to trace DRDA data flows when used over TCP/IP.

This tracing capability is accessible from the SNADDM Service tracing inside the Trace tool. This facility will show the same data as an APPC trace but without the control indicators (For example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the Platform SDK.

The Host File Transfer ActiveX control can return the following types of errors:

- Errors from the remote hosts
- Microsoft Host File Transfer-specific errors
- Errors from the underlying DDM application requester network client

Data Queue ActiveX Control Programmer's Guide

A data queue is an AS/400 system object that is used for inter-process communications between multiple programs or jobs. Data queues allow multiple programs to send and receive shared messages via a central repository without first writing the message data to a physical database file. Typically, when a data record is read from the queue, the record is erased from the queue. The advantage of using data queues to share data in comparison with using database files is that data queues require much less file I/O and therefore improve overall system performance.

The Microsoft® Data Queue ActiveX® control provides the ability to access AS/400 data queues. Microsoft Host Integration Server 2004 provides this service via a single ActiveX control that depends on other core Host Integration Server DLLs. Developers can move part or all of their AS/400 applications from an AS/400 computer to a PC platform, while retaining access in the program running on the PC to a remote data queue on the AS/400.

The Data Queue ActiveX control is implemented as a Distributed Data Management (DDM) Application Requester. The Data Queue ActiveX control uses the Data Queue interfaces in the DDM Level 4 architecture, which are extensions to the record-level input/output (RLIO) protocol of IBM's Distributed Data Management architecture.

DDM is a set of rules for distributing or extending data management from one computer to another, such as from a mainframe to an AS/400 computer or from one of these host computers to a server computer. By combining the Microsoft Data Queue ActiveX control and DDM architectures, Microsoft enables organizations to preserve their investments in existing data management infrastructure, while extending universal file and data transfer to all enterprise-wide data sources.

The information in this section is required to develop applications with Host Integration Server 2004 that use ActiveX or COM objects to transfer data from local machines to AS/400 Data Queues in a Systems Network Architecture (SNA) environment.

For information on the platform requirements for the Data Queue ActiveX Control, see the Host Integration Server 2004 Installation Guide topic Hardware and Software Requirements.

This section contains:

- Advantages of Data Queues
- Object Support Using Data Queues
- Programming Considerations Using the Data Queue ActiveX Control

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Advantages of Data Queues

Data queues provide a fast means of inter-process communication, requiring low system overhead and minimal setup. AS/400 Data Queues are designed to provide a flexible, highly efficient, yet temporary means of inter-process communication. Data queues are familiar to most AS/400 programmers as a simple method of passing information to another program.

Data queues provide considerable flexibility to the application programmer. The data queues interfaces require no communications programming and can be used either for connected or disconnected communication. AS/400 and PC applications can be developed using any supported language, yet still communicate with each other. PC programs can communicate with AS/400 programs through a common AS/400 data queue. The use of data queues requires little knowledge of communication and no knowledge of APPC if the programmer utilizes the Microsoft® Data Queue ActiveX® control. The data queue messages are merely described at the record level, allowing the application programmer to define the field-level structure as required.

By default, when one program reads an entry in the queue, the entry is then deleted. Pointers to the queue entries are then updated to reflect the change in the record stack. A data queue can exist with no entries, a single entry, or multiple entries. Multiple concurrent jobs and programs can access data queues.

When receiving data, the requesting application can set a time-out value to wait for data to arrive in the queue. Waits can be applied based on entry of the data record or for a time period (zero seconds to many days in length). A program that reads from a queue need not be running when the queue is created or when records are inserted. A single data queue can support many separate interactive jobs. At regular intervals or at the end of the day, records in the data queue can be persisted to a file by a single automated batch process.

Object Support Using Data Queues

The Microsoft® Data Queue ActiveX® control supports a number of standard COM interfaces as well some custom objects and interfaces.

This section contains:

- COM Interface Support Using Data Queues
- IEIGDataQueueCtl Object
- IEIGDataQueue Object
- IEIGDataQueueItem Object
- IEIGDataQueueCtlEvents Notifications
- IEIGDataQueueEvents Notifications

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

COM Interface Support Using Data Queues

The Microsoft Data Queue ActiveX control supports a number of standard COM interfaces as well as several custom interfaces, **IEIGDataQueueCtl**, **IEIGDataQueue**, and **IEIGDataQueueItem**. The ActiveX control object has the ability to register and de-register itself via standard control mechanisms. Support for a number of standard COM interfaces makes it easy to develop applications using the Data Queue ActiveX control with Microsoft® Visual Basic® and Microsoft Visual C++® as well as from Microsoft Internet Explorer and Microsoft Access. Supporting a variety of standard COM interfaces also provides different ways for a client to save information.

The following table summarizes the standard COM interfaces supported by the Data Queue ActiveX control.

COM interface	Comments
ICategorizeProperties	This interface divides up the properties into an intelligent presentation to the client.
IConnectionPointContainer	
IDispatch	A dual interface deriving from **IDispatch** is exposed to provide support and flexibility to clients. Clients that provide support for automation interfaces will utilize the **IDispatch** interface, while more robust clients may use the custom interface. Using the custom interface provides for the greatest execution speed.
IPerPropertyBrowsing	This interface provides support for client browsing of properties in an intelligent manner. This interface exposes to the client property lists used in the population of a drop-down list. This interface is required for the control to be hosted by Microsoft Access.
IPropertyNotifySink	The interface is implemented by a sink object to receive notifications about property changes from an object that supports **IPropertyNotifySink** as an outgoing interface. The client that needs to receive the notifications in this interface (from a supporting connectable object) creates a sink with this interface and connects it to the connectable object through the connection point mechanism.
IPersist	
IPersistPropertyBag	This interface is the preferred method of property persisting for Internet Explorer and Visual Basic. Using this interface persisted properties are stored as a set of name/VARIANT value pairs.
IPersistStorage	This interface stores persistent properties into a structured storage object.
IPersistStreamInit	This interface is responsible for saving the persisted properties in binary form using a stream interface. This is the method used by the Microsoft Visual C/C++ compiler to persist properties.
ISupportErrorInfo	This interface is the preferred method to return error indications to scripting clients. Using this interface, error codes and explanation text are returned to the client. This information may be used in order to provide diagnostic information to the user and in cases of failure.

Object Support Using Data Queues

IEIGDataQueueCtl Object

The **IEIGDataQueueCtl** object supports a number of properties and methods that provide the ability to connect with a host and communicate with OS/400 Data Queues. The **IEIGDataQueueCtl** also supports a set of events notifying a client application of connection status and error reporting. These events are handled by the client supporting several callback functions and setting these callbacks using the **IConnectionPointContainer**.

The following **IEIGDataQueueCtl** object methods are supported by the Microsoft Data Queue ActiveX control.

Method name	Comment
Connect	Establishes a connection to the configured host and reports to the user an indication of the success or failure of the action.
CreateQueueContainer	Creates an instance of an IEIGDataQueue container object and optionally initializes the QueueName property. The created queue object is assumed to be associated with the connection object that created it for the life of the connection or the life of the queue object.
Disconnect	Terminates an existing connection to a host machine.

The following **IEIGDataQueueCtl** object properties are supported by the Microsoft Data Queue ActiveX control.

Property name	Comment
CCSID	Sets or returns the character code set identifier (CCSID) that must match the data in the AS/400 data queue as represented on the remote host computer. This property defaults to U.S./Canada (37).
ConnectionState	Returns the current state of the connection. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting.
ConnectionType	Sets or returns the network transport used for this connection. The default value for this parameter is SNA. Note that TCP/IP is not supported. If APPC is selected, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required.
LocalLU	Sets or returns the Local LU Alias. When APPC (SNA LU 6.2) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager. This property defaults to the string value of "LOCAL" represented as a BSTR.
ModeName	Sets or returns the APPC mode. When APPC (LU 6.2 SNA) is selected for the **ConnectionType** property, this field must be set to the APPC mode that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This property defaults to the string value of "QPCSUPP" represented as a BSTR.
Password	Sets or returns the password used for authentication. A valid user name and password are normally required to access data on a host computer. The password is case sensitive and is normally displayed as asterisks in a dialog box for security purposes. This property is a string (BSTR) and has no default value.
PCCodePage	Sets or returns the PC code page The PC Code Page property indicates the code page to be used on the PC for character code conversion. This property defaults to Latin 1 (1252).
RemoteLU	Sets or returns the Remote LU Alias. When APPC (LU 6.2 SNA) is selected for the **ConnectionType** property, this property is the name of the remote LU alias configured using SNA Manager. This property is a string (BSTR) and has no default value.

UserID	Sets or returns the user name used for authentication. A valid user name and password are normally required to access data on a host computer. This value is case sensitive. This property is a string (BSTR) and has no default value.

Object Support Using Data Queues

IEIGDataQueue Object

The **IEIGDataQueue** object represents a logical queue and supports a number of properties and methods that provide the ability to communicate with a specific data queue. The QueueName property is the name of the physical queue. All methods and events are related to the queue that is represented by the individual instance of the object. The Data Queue ActiveX control also supports a set of events notifying a client application of connection status, data transfer status, and error reporting. These events are handled by the client supporting several callback functions and setting these callbacks using the **IConnectionPointContainer**.

The following **IEIGDataQueue** object methods are supported by the Microsoft Data Queue ActiveX control.

Method name	**Comment**
AddQueueItem	Adds a record to the current queue.
Cancel	Terminates a request to receive information from the queue that is already in progress.
CancelQueue	Indicates that an application no longer wants to be notified of an incoming queue data item. This can be used to stop pending notifications that were queued as a result of calling **GetQueueItem**.
ClearAll	Removes all items from the queue.
CreateQueue	Creates a data queue.
DeleteQueue	Clears all messages from the queue and then deletes the queue.
GetQueueItem	Retrieves an item from the queue.
QueryAttribute	Requests information on one of the queue's attributes
SetAttribute	Changes the attributes associated with a data queue.
StopQueue	Stops the queue from responding to client requests.

The following **IEIGDataQueue** object property is supported by the Microsoft Data Queue ActiveX control.

Property name	**Comment**
QueueName	This is the name of the data queue this object is associated with.

See Also

Object Support Using Data Queues

IEIGDataQueueItem Object

The **IEIGDataQueueItem** object represents a specific queue item and supports a number of properties and methods.

The following **IEIGDataQueueItem** object method is supported by the Microsoft Data Queue ActiveX control.

Method name	**Comment**
Reset	Resets the queue item properties to default values.

The following **IEIGDataQueueItem** object properties are supported by the Microsoft Data Queue ActiveX control.

Property name	**Comment**
ExtUser	The external job user name.
ExtJobName	The external job name.
ExtJobNumber	The external job number.
InactiveRec	Indicates an Inactive record.
Keyval	The key value.
Message	The queue message.
QItemType	The type of queue item this represents.
Record	The entire queue data.
RecordAttribute	The list of record attributes.
RecCount	The record count.
RecNumber	The record number.
ReplyRequest	Indicates if the reply message should be returned.
UsrProf	The user profile.

Object Support Using Data Queues

IEIGDataQueueCtlEvents Notifications

The **IEIGDataQueueCtl** object of the Microsoft Data Queue ActiveX control also supports a set of events notifying a client application of connection status and error reporting. These events are handled by the client supporting several callback interfaces and setting these callbacks derived from the standard **IConnectionPointContainer** COM object.

The following **IEIGDataQueueCtlEvents** notification interface methods are supported by the Data Queue ActiveX control:

Event notifications	Comment
ConnectionStateChange	This event is fired when the state of a connection has changed. A ConnectionState parameter is passed to the client callback function that receives this event method call. This parameter is an **eigConnectionStateEnum** value representing the new state of the ConnectionState property.
ReportError	This event is fired when an error condition needs to be reported during non-blocking (asynchronous) functions. This event passes two parameters to the client callback function that receives this event method call. The first parameter is a long value representing an error code. The second parameter is a BSTR string containing a brief text description of the error.

See Also

Object Support Using Data Queues

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

IEIGDataQueueEvents Notifications

The **IEIGDataQueue** object of the Microsoft Data Queue ActiveX control also supports a set of events notifying a client application of when transfers are completed, requests are received, and error reporting. These events are handled by the client supporting several callback interfaces and setting these callbacks derived from the standard **IConnectionPointContainer** COM object.

The following **IEIGDataQueueEvents** notification interface methods are supported by the Data Queue ActiveX control:

Event notifications	Comment
ReportError2	This event is fired when an error condition needs to be reported during non-blocking (asynchronous) functions. This event passes two parameters to the client callback function that receives this event method call. The first parameter is a long value representing an error code. The second parameter is a BSTR string containing a brief text description of the error.
RequestReceived	This event is fired when a request is received.
SendComplete	This event is fired as an indication to the client that the requested transfer operation has completed.

Programming Considerations Using the Data Queue ActiveX Control

The Microsoft® Data Queue ActiveX® control exposes a dual interface deriving from **IDispatch**. This provides support and flexibility to clients wishing to use the object. Clients that provide support for automation interfaces can use the **IDispatch** interface while more robust clients may use the custom interface. Using the custom interface offers the greatest execution speed.

The single-threading model is supported, allowing only single threads to access the objects safely.

Asynchronous read operations are not currently supported. The *BlockComplete* parameter of the GetQueueItem method must be set to a value of 0 (eigAnswerYes), indicating that the **GetQueueItem** operation should block until the completion status is known.

This section contains:

- Code Page Support Using Data Queues
- User Names and Passwords Using Data Queues
- Troubleshooting the Data Queue ActiveX Control

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Code Page Support Using Data Queues

When using the Data Queue ActiveX control, the Host CCSID (character code set identifier) property should be configured to match the data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37) when using the Data Queue ActiveX control.

This section contains:

- DBCS Code Page Support Using Data Queues

DBCS Code Page Support Using Data Queues

Support for Double-Byte Character String (DBCS) data is limited using the Data Queue ActiveX control. Conversions between DBCS and ANSI code pages are not supported. Conversions between DBCS and ISO code pages are not supported.

The DB2 GRAPHIC data types (GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC) are not supported. These DB2 data types support DBCS (not mixed) data. Mixed data types are supported using CHAR FOR MIXED DATA, VARCHAR FOR MIXED DATA, and LONGVARCHAR FOR MIXED DATA.

See Also

Code Page Support Using Data Queues

User Names and Passwords Using Data Queues

When connecting to host systems, most users must be authenticated by the remote system by passing a valid User ID and Password.

The AS/400 computer is case-sensitive with regard to user ID and password. The AS/400 only accepts a user ID and password in uppercase. The Microsoft Data Queue ActiveX control forces the user ID and password into uppercase when it knows that it is connecting to an AS/400 system.

Programming Considerations Using the Data Queue ActiveX Control

Using Data Design Tools

The Data Design Tools are a set of technologies exposed in Microsoft® Visual Studio® .NET 2003 that enable you to visually create database connections and queries, browse tables, view data, execute stored procedures, and access other database features. The following table describes the level of support the Server Explorer for Visual Studio .NET 2003 provides for Microsoft® Host Integration Server 2004.

Provider	Visual Studio 2003 data design support
ODBC Driver for DB2	None
OLE DB Provider for DB2	High
Managed Provider for DB2	Low
OLE DB Provider for AS/400 and VSAM	Low
Data Queues	None
File Transfer ActiveX® controls	None

This section contains:

- Using Data Design Tools for the OLE DB Provider for DB2
- Using Data Design Tools for the Managed Provider for DB2
- Using Data Design Tools for the Microsoft OLE DB Provider for AS/400 and VSAM

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Using Data Design Tools for the OLE DB Provider for DB2

The OLE DB Provider for DB2 is the provider that the Microsoft® Visual Studio® .NET 2003 Data Design Tools most heavily support. The following list describes the different Data Design Tools available in Visual Studio .NET 2003, and how they interact with the OLE DB Provider for DB2.

- Database Designer

  With this visual tool, you can design and visualize a DB2 database to which you are connected. When designing a database, you can use the Database Designer to create, edit, or delete tables, columns, keys, indexes, relationships, and constraints. To visualize a database, you can create one or more diagrams illustrating some or all of the tables, columns, keys, and relationships.

- Table Designer

  With this visual tool, you can design and visualize a single table in a DB2 database to which you are connected.

- Query and View Designer

  With this visual tool, you can design a query, view, in-line function, or single-statement stored procedure.

- SQL Editor

  This integrated tool provides a variety of SQL text-editing features.

- Server Explorer

  With this Visual Explorer window, you can view and manipulate data links, database connections, and system resources on any server to which you have network access. Features include the ability to open data connections, log onto servers and display system resources, make database connections, and create data components that describe remote resources for your Visual Studio .NET projects.

- Solution Explorer

  Provides an organized view of your projects and their files as well as ready access to the commands that pertain to them.

See Also

Using Data Design Tools

Using Data Design Tools for the Managed Provider for DB2

The Data Design Tools included in Microsoft® Visual Studio® .NET 2003 do not currently support the Managed Provider for DB2. However, you can partially prototype and design your data connections with System.Data and ADO.NET using the available tools.

To use the Data Design Tools for the Managed Provider for DB2

1. Use the Data Design Tools for the OLE DB Provider for DB2 to outline your data connection.

   The OLE DB Provider for DB2 and the Managed Provider for DB2 are similar enough that the generated scripts and objects can provide a starting point for your Managed Provider for DB2 connection.

2. Manually alter the autogenerated files for use with the Managed Provider for DB2.

See Also

- Using Data Design Tools for the OLE DB Provider for DB2
- Managed Provider for DB2 Programmer's Guide

Using Data Design Tools for the Microsoft OLE DB Provider for AS/400 and VSAM

The Microsoft OLE DB Provider for AS/400 and VASM is a non-SQL command provider. As such, this provider does not integrate well with the Microsoft® Visual Studio® .NET 2003 Data Design Tools. While you can create a data connection from the supplied menus in Visual Studio, very few of the generated scripts and objects are useful for a Microsoft® Host Integration Server 2004 application. Instead, it is recommended that you manually create the connections using the standard programming technologies.

- OLE DB Provider for AS/400 and VSAM Programmer's Guide

Data Integration Security Guide

This topic covers security issues that programmers working with the data integration features of Microsoft® Host Integration Server 2004 should understand.

This section contains:

- Managed Provider Security
- OLE DB Provider for DB 2, AS/400, and VSAM Security
- Host File Transfer Object Security

Managed Provider Security

The following topics discuss security as it applies to the Managed Provider for DB2 section of the Microsoft® Host Integration Server 2004 SDK.

About Managed Provider security for developers

A Managed Provider is a .NET data provider used for connecting Microsoft® Host Integration Server 2004 applications to a database, executing commands, and retrieving results. Those results are either processed directly, or placed in an ADO.NET **DataSet**.

The Managed Provider for DB2 is built on .NET, and because of this it can take advantage of many of the security features that a managed environment provides. This section discusses security features and issues that you should be aware of when using the Managed Provider.

Threats and mitigations for the Managed Provider

Programmers who use the Managed Provider for DB2 should be aware of the following security practices and issues.

Protect components store connection information in plain text

Generic data access components, such as the Data Tools and Data Bound controls in Microsoft Visual Studio® .NET store sensitive DB2 connection data in plain text. This is done to grant third parties easy access to host data when using the control.

Storing connection data in plain text is a security concern because there is the potential for another application or user to read the active memory belonging to the control, and retrieve sensitive information from the plain text stored in the control. You can improve the security of your Host Integration Server application using one or more of the following techniques:

- Store any file known to contain connection information, such as a .UDL file, in a secure location.
- Design your applications so that you release and destroy any components known to store data in plain text as soon as the user is finished with the component.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

OLE DB Provider for DB 2, AS/400, and VSAM Security

The following topics discuss security as it applies to the following sections of Microsoft® Host Integration Server 2004 SDK.

- OLE DB Provider for DB2
- OLE DB Provider for AS/400 and VASM

About OLE DB Provider Security for Developers

These Microsoft® OLE DB providers enable users to access IBM Data Base 2 (DB2) from within an OLE-aware application. The object linking and embedding database (OLE DB) is a standard set of interfaces that provides heterogeneous access to disparate sources of information located anywhere—file systems, e-mail folders, and databases. The OLE DB Provider for DB2 combines the universal data access of OLE DB with the IBM Distributed Relational Database Architecture (DRDA).

This section discusses security features and issues that you should be aware of before programming the OLE DB Provider for DB2.

Single Sign-On

Enterprise Single Sign-On provides services that request and verify your credentials after you log on to the network, and use your credentials to determine the actions that you can perform based on your user rights. Single Sign-On is supported for the OLE DB provider for DB2.

For information on how you can configure Single Sign-On for the OLE DB Providers, see Connection.

Threats and mitigations for the OLE DB Provider

Programmers who use these features should be aware of the following security practices and issues.

Do not use the RowsetViewer sample as a diagnostic tool

The OLE DB RowsetViewer Sample is a sample that is included in the Host Integration SDK sample. In the past it was often used as a diagnostic tool to test data connections. It is rarely used today, and has several security issues. Most developers use the Microsoft® Visual Studio® .NET data design tool Server Explorer. For more information, see Using Data Design Tools.

The Data Access Tool also allows developers and administrators to test connections and sample data without the security risks of the RowsetViewer sample.

The RowsetViewer sample is still included in the SDK for reference purposes, not as a usable tool.

The OLE DB Provider for DB2 stores host configuration data in OLE DB properties collection

The OLE DB Provider for DB2 stores host and PC configuration data in an OLE DB property collection, and then returns this data to the calling program. Your program should not pass this sensitive information on to the end user.

The OLE DB Provider for DB2 DTS and DQP consumers persist configuration data

Generic consumers such as DTS, DQP, Replication, and OLAP persist sensitive host configuration information in the following insecure ways:

- Most SQL Server consumers utilize the SQL Server Repository to store data source information.
- DTS can persist DTS packages (which include data source configuration info) as files (what format?) and VB programs (plain text).

To minimize the risks mentioned above, generic consumers should encrypt sensitive OLE DB connection information using the crypto API (DP, data protection API).

The OLE DB Provider for AS/400 and VSAM stores host configuration data in an OLE DB properties collection

The OLE DB Provider for AS/400 and VSAM stores host and computer configuration data in an OLE DB property collection, and then returns this data to the calling program. Your program should not pass this sensitive information on to the end user.

Use provider-specific connection pooling

It is a best practice to use the provider-specific connection pooling in Host Integration Server 2004 rather than the system provided resource pooling provided by the OLE DB Provider for DB2. This avoids possible security risks in the OLE DB Provider for DB2.

The OLE DB Provider for DB2 DTS and DQP consumers persist configuration data

Generic consumers such as DTS, DQP, Replication and OLAP stores sensitive host configuration information in the following insecure ways:

- Most SQL Server consumers utilize the SQL Server Repository to store data source information.
- DTS can store DTS packages (which include data-source configuration info) as files and VB programs (plain text).

To minimize the risks mentioned above, Generic consumers should encrypt sensitive OLE DB connection information using the crypto API (DP, data protection API).

Host File Transfer Object Security

The Microsoft® Host File Transfer ActiveX® control provides the ability to transfer files between a local computer and an MVS, OS/390, AS/400, or AS/36 host system. Microsoft Host Integration Server 2004 provides this service through a single ActiveX control that depends on other core Host Integration Server DLLs.

This section discusses security features and issues that you should be aware of before you use with the Host File Transfer object in your programs.

Threats and mitigations for the Host File Transfer object

Programmers who use these features should be aware of the following security practices and issues.

Validate input parameters for the Host File Transfer control

You should validate all input parameters before passing them on to the Host File Transfer control.

You should verify all values received from end users before passing values (such as filenames) to the ActiveX control.

The SAM and VSAM data sets, as well as PDS/PDSE members, must be referenced in the host column description (HCD) file the same way as they are referenced in the command text of the OLE DB command object, using the following command text syntax:

```
EXEC OPEN FileName
```

where FileName represents one of the following host file naming conventions:

- Host file type File naming convention
- VSAM Data Sets:

  ```
  DATASETNAME.FILENAME
  ```

- Partitioned Data Sets:

  ```
  DATASETNAME.FILENAME(MEMBER)
  ```

- OS/400 Files:

  ```
  LIBRARY/FILE
  ```

- OS/400 Files:

  ```
  LIBRARY/FILENAME
  ```

- OS/400 File Members:

  ```
  LIBRARY/FILE(MEMBER)
  ```

- OS/400 File Members:

  ```
  LIBRARY.FILENAME(MEMBER)
  ```

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax used to open a rowset using command text is as follows:

```
EXEC OPEN LIBRARY/FILE("NAMES.DAT")
```

Please note that you must utilize the full path to the mainframe data set. In the example below, there are two path elements and one name element to describe the target data set:

```
XXXXX.XXX.XXX
```

Whenever you allocate a data set, it is given a unique name composed of one or more segments. Each segment of a data set name is joined by periods and represents a level of qualification. For example, the following data set has four segments that comprise the fully qualified data set name.

```
WNW999.DEMO.KSDS.TITLES
```

The high-level qualifier is WNW999. The low-level qualifier is TITLES. Each segment can be from 1-8 characters in length (first character must be alphabetic; remainder can be alphanumeric or hyphens). The data set name must be no more than 44 characters in length and contain no more than 22 segments.

Store the HCD files for the Host File Transfer control in a secure location

File Transfer reads host column description (HCD) files at run time as a means to support data conversion from host data types to OLE DB data types. You should store HCD files in a secure location that only the application can access at run time. This ensures that a malicious user may not modify the file to submit embedded commands.

IP-DLC Link Service Programmer's Guide

This section describes how the Internet Protocol–Data Link Control (IP-DLC) link service of Microsoft® Host Integration Server 2004 makes it possible to integrate vital mainframe data and business rules with new e-commerce solutions developed with Microsoft Windows®-based programs. The IP-DLC link service of Host Integration Server 2004 enables you to connect directly to IBM mainframe computers through a pure Transmission Control Protocol/Internet Protocol (TCP/IP) wide area network or local area network.

This section also offers three scenarios for deployment. Two of these scenarios describe migration from Host Integration Server 2000 to Host Integration Server 2004; the third scenario describes a new implementation based on Host Integration Server 2004.

This section contains:

- Transaction Environments Integration
- Fault Tolerance Features
- Security Features
- Common Scenarios
- Define and Set Up the IP-DLC Link Service

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Transaction Environments Integration

IBM CICS and IMS, as well as OS/400, are popular transaction environments on which enterprise-class organizations rely for supporting daily mission-critical operations. For the most part, line-of-business applications are not written in C Programming Language, Microsoft Visual C++®, Visual Basic®, or Visual C#®, rather they are written in COBOL, PLI, and RPG. These applications do not run on the Windows operating system, rather they run on specific-purpose transaction and batch processing environments on IBM VM, VSE, MVS, OS/390, z/OS, and OS/400 mainframe and midrange computing platforms. Host Integration Server 2004 offers a cost-effective and manageable means to integrate vital mainframe data and business rules with new e-commerce Application-to-Application (A2A), Business-to-Business (B2B), and Business-to-Customer(B2C) solutions developed with Microsoft Visual Studio®.

A growing number of enterprises have standardized on TCP/IP across their wide area networks (WANs) and in their branch offices. Host Integration Server 2004 offers an efficient means to reduce dependency on SNA network protocols, while enabling continued value from using Host Integration Server 2004 core SNA services—which require direct SNA or an SNA over IP network connection.

SNA over IP network integration support in Host Integration Server 2004 offers the following advantages:

- Ability to extend mission-critical SNA networks without complex or expensive non-Microsoft software gateways or hardware routers
- Ability to effectively use the Microsoft Windows Server™ 2003 operating system, such as the Microsoft .NET Framework platform and BizTalk® Server, as a viable architecture for developing new enterprise application integration (EAI) solutions

The approach of Host Integration Server 2004 is to provide easy-to-use tools, high-speed connectivity, choice of programming models, flexibility of environments, and cost-effective Windows-based data conversion. The IP-DLC link service of Host Integration Server 2004 enables you to connect directly to IBM mainframe computers through a pure TCP/IP wide area network or local area network (LAN). This approach not only eliminates the disadvantages of parallel, but offers additional scalability and longevity.

Microsoft Host Integration Server 2004 includes a number of technologies that offer various levels of integration from the network layer up to the application layer.

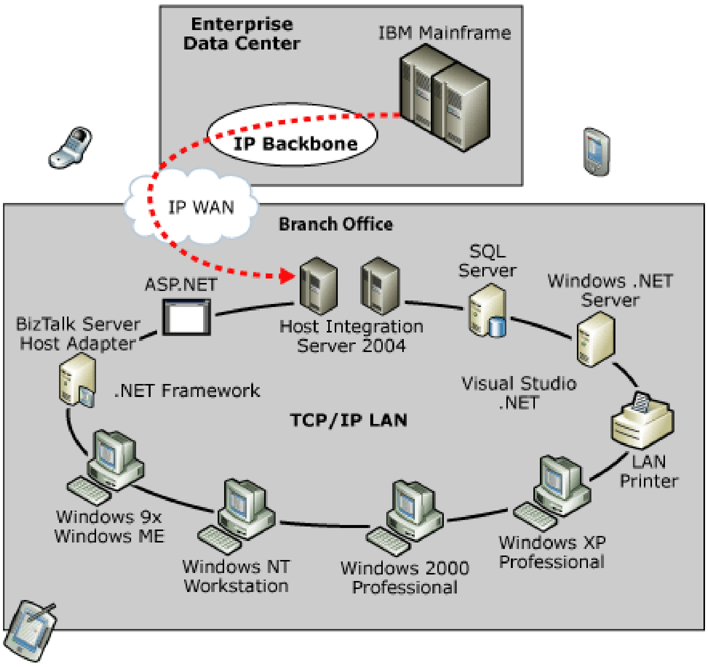
Networking with IP-DLC Link Service

Host Integration Server 2004 offers an efficient means to integrate SNA within data centers, across WANs and in branch offices through a new link service, IP-DLC. IP-DLC link service provides SNA connectivity for applications using dependent and independent sessions over a native IP network.

The IP-DLC link service implements the IP-DLC protocols defined in RFC 2353 and the SNA/APPN HPR Architecture Reference (SNA APPN option set 2009). High Performance Routing (HPR) is an extension of the Advanced Peer-to-Peer Network (APPN) architecture; it provides the following functions:

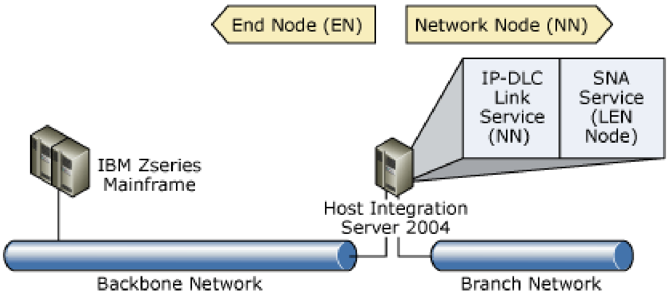
- Rapid Transport Protocol (RTP) minimizes processing cycles and storage requirements for routing network layer packets through intermediate nodes on a session route.
- Automatic Network Routing (ANR) enables APPN networks to automatically reroute sessions if a portion of the originally computed route fails.

The following figure illustrates deploying these new integration solutions across a single LAN-WAN-data center network protocol.



Enterprise Data Center
IBM Mainframe
IP Backbone
IP WAN
Branch Office
ASP.NET
BizTalk Server Host Adapter
Host Integration Server 2004
SQL Server
Windows .NET Server
.NET Framework
TCP/IP LAN
Visual Studio .NET
LAN Printer
Windows 9x Windows ME
Windows NT Workstation
Windows 2000 Professional
Windows XP Professional

The IP-DLC link service acts as a Branch Network Node (BrNN), which combines the functions of a network node and an end node.



End Node (EN)
Network Node (NN)
IP-DLC Link Service (NN)
SNA Service (LEN Node)
IBM Zseries Mainframe
Host Integration Server 2004
Backbone Network
Branch Network

Because the BrNN appears as an end node, it does not receive topology information from the backbone network. Topology information transmits only between network nodes. Thus, the amount of network overhead traffic flowing into the branch network is reduced.

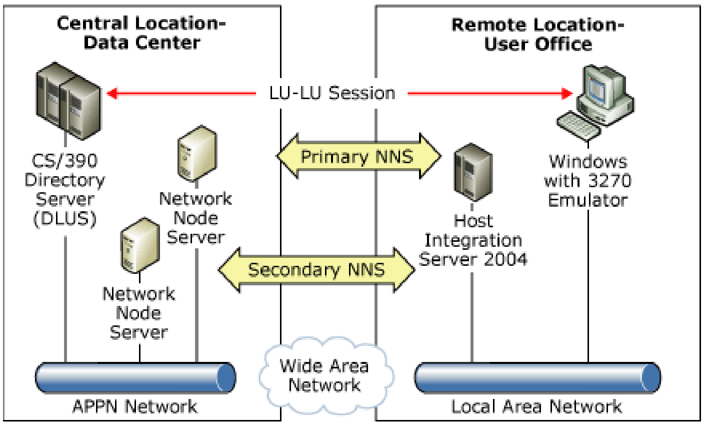
The BrNN registers all resources in the branch with its network node server (NNS) as though they were located on the BrNN itself. This means that the nodes in the backbone network can locate resources in the branch without having to be aware of the separate nodes in the branch.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Fault Tolerance Features

Because the new IP-DLC link service uses the APPN and HPR/IP protocols, it is automatically able to take advantage of a number of fault tolerance features.

A function of HPR is the ability to reroute sessions around a failure in the network, as long as an alternative route exists. To achieve this rerouting, you provide primary and backup NNS to each IP-DLC link service.



Central Location-
Data Center
Remote Location-

CS/390 Directory Server (DLUS)
Network Node Server
Primary NNS
Host Integration Server 2004
Windows with 3270 Emulator
Secondary NNS
Network Node Server
Wide Area Network
APPN Network
Local Area Network

The IBM Parallel Sysplex technology and Multi-Node Persistent Sessions (MNPS) feature together allow mainframe applications to be moved to a different processor with little or no impact to users when system or application failures occur on the mainframe. Parallel Sysplex is a clustering technology that provides high availability, load balancing and scalable growth to the large mainframe environment. MNPS allows sessions to be restarted on another system in a Parallel Sysplex, after a hardware or software failure. (See Networking Implications of S/390 Parallel Sysplex, http://go.microsoft.com/fwlink/?LinkId=38994, for further information.). IP-DLC works with this solution with no specific configuration.

Note The IP-DLC link service cannot provide fault tolerance capabilities to seamlessly handle local adapter failures.

Security Features

The IP-DLC link service takes advantage of the entire Host Integration Server 2004 secure deployment feature set, especially the following:

- A typical IP-DLC link service deployment scenario can use IPSec, a firewall, or a Virtual Private Network (VPN) as a security barrier between the Host Integration Server computer and the remote node. (A VPN is advisable if the HPR/IP link spans an insecure IP network.)
- Incoming frames from IP addresses that are not already defined in Host Integration Server are rejected. This practice isolates the main SNA node service from such attack.
- The IP-DLC link service checks the length of incoming datagrams before it copies the data into internal data areas, and it discards any datagrams that are too long.
- All configuration data—whether from registry entries, COM.cfg, or the SNA node service—is validated for correct value when it is first accessed. Particular consideration is given to validating length to avoid buffer overruns. If errors are found, the IP-DLC link service logs an event and terminates.
- Usage of IPSec/ESP is advisable because it protects all network SNA protocols (LU 6.2, 3270, etc.) within the APPN IP-DLC flow.
- Logical and physical access to Host Integration Server 2004 should be carefully guarded against unauthorized access to IP-DLC internal traces for example.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Common Scenarios

IP-DLC is basically another UDP/IP application (using UDP port 12000 to 12004). IP-DLC networking appears from the application level just like another SNA network protocol.

The following existing Host Integration Server 2004 SNA features are supported over the IP-DLC link service:

- LU types 0, 1, 2, 3, and 6.2 (dependent and independent)
- LUA, FMI, APPC, and CPI-C APIs
- Dynamically defined dependent LUs
- Dynamic local LU, remote LU, and connection configuration
- Incoming and outgoing calls
- Connection activation at server startup, on demand or by administrator
- SNA data compression
- PU concentration with the upstream link over IP-DLC
- NetView RUNCMD/Alerts (The IP-DLC link service does not generate alerts.)

Because the SNA features in the preceding list are supported, the following applications are also supported over the IP-DLC link service:

- Host Integration Server 2004-compatible 3270 emulators
- Host Integration Server 2004-compatible 5250 emulators
- APPC - 3270 Session Viewer (including the Diagnostics tool)
- Print Service
- Data Integration Services
- TN3270 Service
- TN5250 Service
- MSMQ-MQSeries Bridge
- Transaction Integrator

> **Note** If IP-DLC does not limit any of the sockets functionality, some native TCP/IP direct communications can still be used (for example, Transaction Integrator/IMS with IMS Connect) if no SNA-specific function is needed.

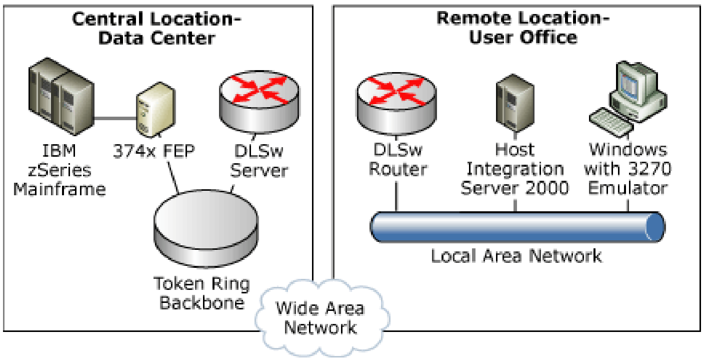
This section contains:

- Scenario 1 Migration: Branch Service Display Session over TN3270
- Scenario 2 Migration: Distributed Architecture Using DLS
- Scenario 3 New Solution: Accessing CICS with Transaction Integrator

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

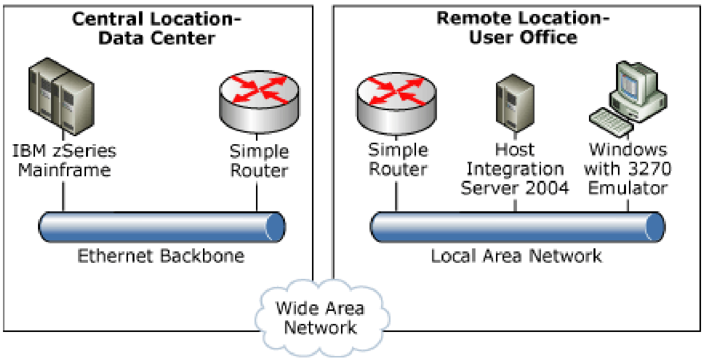
Scenario 1 Migration: Branch Service Display Session over TN3270

With Host Integration Server 2000, DLC traffic is encapsulated by Data Link Switching (DLSw) routers; DLC is still used on the network between the central DLSw router and the mainframe or a communication controller 374x, as shown in the following figure.



Central Location-
Data Center
IBM zSeries Mainframe
374x FEP
DLSw Server
Token Ring Backbone
Wide Area Network
Remote Location-
User Office
DLSw Router
Host Integration Server 2000
Windows with 3270 Emulator
Local Area Network

With Host Integration Server 2004 and IP-DLC, IP is used from end to end. The DLSw routers are no longer involved in SNA. In addition, the DLC protocol can be uninstalled from the computer running Host Integration Server.



Central Location-
Data Center
IBM zSeries Mainframe
Simple Router
Ethernet Backbone
Wide Area Network
Remote Location-
User Office
Simple Router
Host Integration Server 2004
Windows with 3270 Emulator
Local Area Network

The host still uses SNA resources, They are still available on the Windows system. Connections (for example, PU) and display LUs remain the same. Host Integration Server authentication and authorization also are unchanged.

The main steps required to reconfigure Host Integration Server 2004 are:

1. Replace DLC link service with an IP-DLC link service. A new APPN node will be created on the host side identifying the IP-DLC Link service as an end node (EN).
2. Re-create dependent connections in Host Integration Server 2004 and linked with the IP-DLC link service; the local node ID remains the same. Configure new parameters for the DLUS (APPN network ID and SSCPNAME). This PU is dedicated to dependent sessions only; the Remote End parameter should be set as "Host System".
3. Re-create dependents LUs.

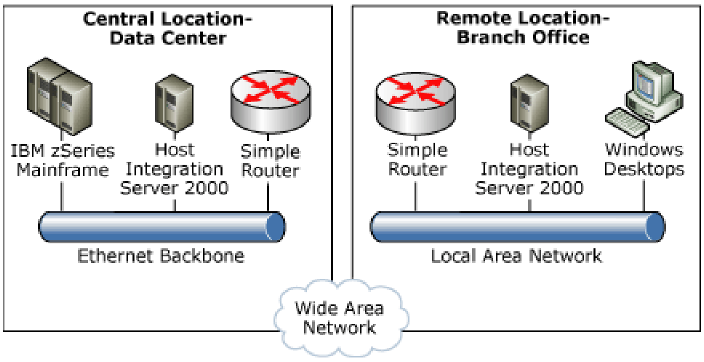
   Note A mainframe connection over OSA Express in QDIO mode is now possible.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Scenario 2 Migration: Distributed Architecture Using DLS

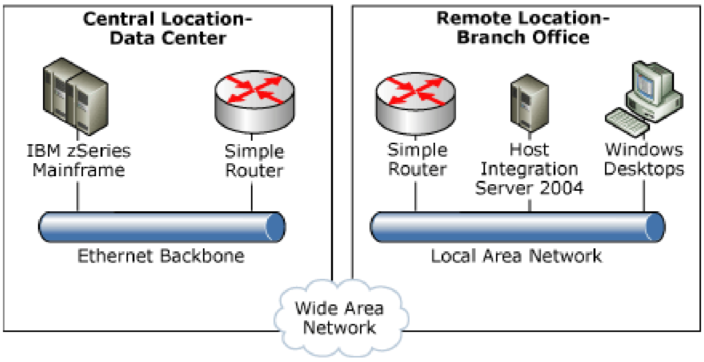
Central office servers equipped with Host Integration Server 2000 connect to the mainframe through DLC over Ethernet or Token ring. Branch office servers equipped with Host Integration Server 2000 are connected to the central server using DLSw link service (also known as SOGA). In our scenario, APPC sessions are in use at the branch.

A good design of a distributed Host Integration Server architecture should be fault tolerant of one central or branch Host Integration Server failure, but the first reason to choose a distributed scenario over a centralized or branch scenario is to manage WAN efficiency and use only TCP/IP on the WAN, as shown in the following figure.



Central Location-
Data Center
IBM zSeries Mainframe
Host Integration Server 2000
Simple Router
Ethernet Backbone
Remote Location-
Branch Office
Simple Router
Host Integration Server 2000
Windows Desktops
Local Area Network
Wide Area Network

With IP-DLC, branch offices equipped with Host Integration Server 2004 can be directly connected to the mainframe using User Datagram Protocol/Internet Protocol (UDP/IP) over the WAN, as shown in the following figure.



Central Location-
Data Center
IBM zSeries Mainframe
Simple Router
Ethernet Backbone
Remote Location-
Branch Office
Simple Router
Host Integration Server 2004
Windows Desktops
Local Area Network
Wide Area Network

The main steps required to reconfigure the Branch Host Integration Server 2004 are:

- Replace the DLC link service with an IP-DLC link service. A new APPN node will be created on the host side identifying the IP-DLC service as an end node (EN).
- Create a new peer connection in Host Integration Server and associate it with the IP-DLC link service; no parameters are needed. This physical unit (PU) is dedicated to independent sessions only. Set the Remote End parameter to "Peer System".
- Local independent sessions logical units (LUs) remain unchanged.
- Associate the remote LUs with the new peer connection.

Optionally, you can deploy the central office Host Integration Server 2004 server to cover a branch office Host Integration Server failure. The Host Integration Server client in the branch can switch over the WAN to use the APPC services provided by the central office Host Integration Server.

> **Note** If DLS traffic has been "firewalled," set new firewall rules to handle HPR-IP protocol and ports: UDP ports 12000 to 12004.

> **Note** If IPSec has been used or should be used to encapsulate (use of AH protocol) or encrypt (use of ESP protocol) traffic between Host Integration Servers, IPSec had to be configured between Host Integration Servers and mainframes. For more information, see the IBM documentation, Communications Server for z/OS V1R2 TCP/IP, Implementation Guide, Volume 7: Security, Chapter 8.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Scenario 3 New Solution: Accessing CICS with Transaction Integrator

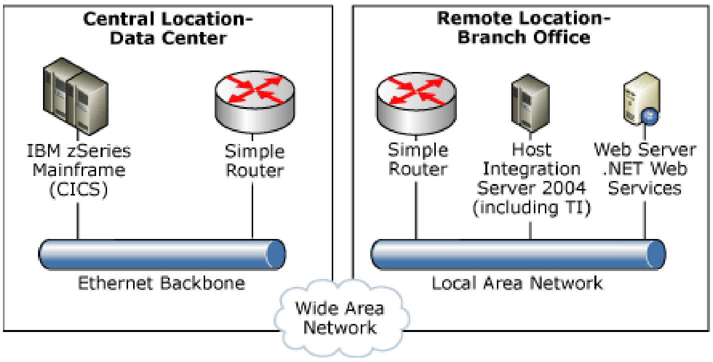
Host Integration Server 2004 Transaction Integrator (TI) integrates the IBM Customer Information Control System (CICS), Information Management System (IMS) transaction programs (TPs), and OS/400 applications with the Component Object Model (COM) and the .NET Framework by:

- Creating interfaces to the CICS, IMS, and OS/400 transaction programs.
- Invoking those transactions on the mainframe or midrange computer (also called the host computer) from a Microsoft Windows–based application.

Because all TI processing is done on the Windows 2000 Server or Windows Server 2003 platform, no TI-related executable code (or "footprint") is required on the mainframe or midrange computer. TI uses SNA (APPC/LU 6.2) and TCP/IP standard communication protocols for all communication between Windows and the host computer.

With IP-DLC link service, you can select the CICS LU 6.2 Link programming model for implementing TI functionality. This choice offers some functions that native TCP/IP does not have:

- Reliable transactions - two phase commit (2PC) over SNA LU 6.2 is supported
- Available mirror TP CSMI for listening on LU 6.2



At the networking level, configure Host Integration Server 2004 with:

- An IP-DLC link service. A new APPN node will be created on the host side identifying the IP-DLC service as an EN.
- Create a peer connection in Host Integration Server 2004 and associated with the IP-DLC link service; no parameters are needed. Set the Remote End parameter to "Peer System".
- A local independent session LU which allows Host Integration Server 2004 for APPC LU-LU conversation with CICS,
- A remote LU identifying the CICS environment (APPLID),
- An APPC mode (or dialog mode).
- The Remote LU and APPC mode may have been defined already; they are not dedicated to Host integration Server 2004.

  Note If IP-DLC is acting as an APPN node, Host Integration Server 2004 can also use an independent session LU that has already been defined.

  Note To provide access to CICS TP, this LU should be known by CICS (value of NETNAME entry in CEDA definition).

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Define and Set Up the IP-DLC Link Service

This section presents suggestions for defining the IP-DLC service and setting up the IP-DLC connection.

This section contains:

- Defining IP-DLC Link Service
- Setting Up IP-DLC Connections

Defining IP-DLC Link Service

One end node should be declared for each IP-DLC link service.

Each IP-DLC link service node definition must use its own CP Name unique on the APPN network. It must use a different CP name from the SNA node service. (This limitation is a consequence of the fact that each IP-DLC link service appears in the APPN network as a separate node and therefore must have a unique node name.)

When host connections or connections to network node servers are established, many remote nodes will accept any network name/CP name pair, provided it is unique. (This is the default case on CS/390 systems.) However, some hosts or network node servers require certain naming conventions or require that the network name/CP name pair be explicitly defined in their configurations. In such cases the user will need to agree with the remote system administrator what network name/CP name to use on the IP-DLC link service. If the link service needs to be defined on the remote system it should be an APPN-style definition.

The following is an example CS/390 APPN-style PU definition for an IP-DLC link service with CP name HIS001.

```
HISPUN20 PU
PUTYPE=2,MAXDATA=1461,ADDR=01,CPNAME=HIS001,CONNTYPE=APPN,
CPCP=YES,MODETAB=DYNAMIC,USSTAB=USSTAB1,HPR=YES"
```

Just as does the LEN, an IP-DLC link requires a connection to an APPN network node server (NNS) in order to participate fully in an APPN network. A network node server is an entry point to an APPN network. NNS provides the distributed directory and routing service for all resources, for example LUs, defined to LEN nodes and end nodes known to the network node server.

The network node server is identified by its IP address, host name, or FQDN DNS name.

> **Note** Multiple IP-DLC link services can be supported—up to one link service for each local IP address on the local Host Integration Server 2004 system. Each IP-DLC link service is tied to a LEN node (for example, SNA Server service) defined to the Host Integration Server computer. Multiple IP-DLC link services can be associated with the same LEN node.

Setting Up IP-DLC Connections

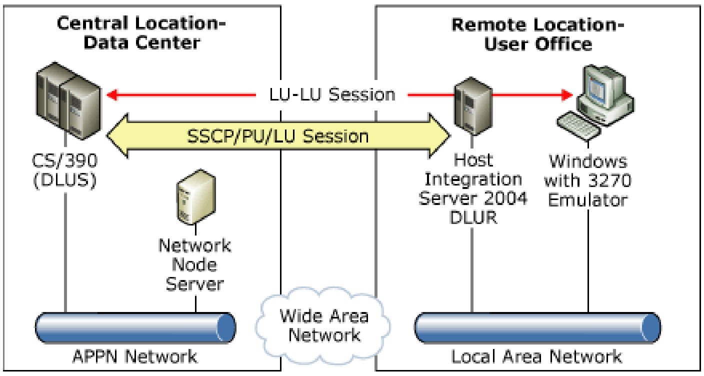
This section describes how to set up IP-DLC connections for dependent and independent LU sessions.

Dependent Sessions

Dependent LU Requester (DLUR) function and dependent LUs, for example 3270 display LUs, are the provider and consumer of dependent LU traffic on an APPN network. Due to the advanced features of HPR this traffic can be routed through intermediate APPN nodes in the APPN network.

DLUR works in conjunction with a dependent LU server (DLUS) at the host. Together, they route sessions across the network from dependent LUs in the APPN network to the DLUS host. The route to the host can span multiple nodes and can take advantage of the APPN network management, dynamic resource location, and route calculation facilities.

IP-DLC works as a DLUR for all or part of dependent connections of one SNA node in Host Integration Server 2004; each dependent connection can have its own primary and backup DLUS defined.



For dependent sessions, each existing PU must be defined as an IP-DLC host connection in Host Integration Server 2004; they are identified by their local node IDs. Each should indicate at least one DLUS server that is identified by the APPN network Name and the SSCPNAME. IP-DLC host connections are dedicated to managing dependent sessions.

> **Note** The NNS and CS/390 must be part of the same reachable APPN network, so that SNA sessions can be activated between them.

Independent Sessions

Remote independent LUs are associated with an IP-DLC peer connection, an internal connection between the SNA node and the IP-DLC link service. All independent LU traffic is routed by the APPN network and can traverse any active IBM Enterprise Extender link. However, all independent session traffic between the IP-DLC link service and the SNA node service flows over the peer IP-DLC connection.

Only one peer connection can be associated with an IP-DLC link service. No parameter is needed to configure this peer connection. IP-DLC peer connections are dedicated to managing independent sessions.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

APPC Programmer's Guide

This section of the Microsoft® Host Integration Server 2004 Developer's Guide provides information about using the Advanced Program-to-Program Communications (APPC) in a distributed processing environment.

For API references and other technical information about APPC, see APPC Programmer's Reference.

For sample code using APPC, see APPC Samples.

This section contains:

- About the APPC Guide
- Introduction to APPC
- About Transaction Programs
- Windows CSV Overview
- Support for APPC Automatic Logon

About the APPC Guide

This section provides information required to develop C-language applications that use Advanced Program-to-Program Communications (APPC) to exchange data in a Systems Network Architecture (SNA) environment.

This section is intended for the developer writing applications that use Common Programming Interface for Communications (CPI-C) to exchange data. It provides conceptual information and detailed reference information.

To use this section effectively, you should be familiar with:

- Microsoft® Host Integration Server 2004
- Microsoft Microsoft Windows Server™ 2003 or Windows® 2000
- SNA concepts

This section contains:

- Operating Systems Support for APPC Development
- Finding Further Information about APPC

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Operating Systems Support for APPC Development

Microsoft® Host Integration Server 2004 supports the development of Advanced Program-to-Program Communications (APPC) applications for Microsoft Windows Server™ 2003 and Microsoft Windows® 2000.

Finding Further Information about APPC

This section does not describe the products, architectures, or standards developed by other companies or organizations.

For more information about SNA and about 3270 information display systems, see the following manuals:

- *IBM 3270 Information Display System: 3274 Control Unit Description and Programmer's Guide*
- *IBM 3270 Information Display System: Color and Programmed Symbols*
- *IBM 3270 Information Display System: 3274 Control Unit Display Station: Operator's Guide*

For background information about logical unit (LU) 6.2, APPC, or the Common Programming Interface for Communications (CPI-C), see the following manuals:

- *IBM Systems Network Architecture: Introduction to APPC*
- *IBM Systems Network Architecture: Transaction Programmer's Reference Manual for LU Type 6.2*
- *IBM SNA: Format and Protocol Reference Manual: Architecture Logic for LU Type 6.2*
- *IBM SNA: Formats*
- *IBM SNA: Technical Overview*
- *IBM SNA: ACF/VTAM Programming for LU Type 6.2*

Introduction to APPC

This section introduces the fundamental concepts of Advanced Program-to-Program Communications (APPC) in a distributed processing environment. These concepts include the following:

- APPC verbs
- Microsoft® Windows® APPC extensions
- Using APPC verbs in C programs
- Operating system considerations

Detailed descriptions of APPC verbs are provided in:

- APPC Management Verbs
- APPC TP Verbs
- APPC Conversation Verbs

APPC is an application programming interface (API) that enables peer-to-peer communications in a Systems Network Architecture (SNA) environment. Through APPC, programs distributed across a network can work together, communicating with each other and exchanging data, to accomplish a single processing task such as querying a remote database, copying a remote file, or sending and receiving electronic mail.

This section contains:

- APPC Verb Overview
- APPC Verb Summary
- Windows APPC Overview
- Using APPC Verbs in C Programs
- Windows Server 2003, Windows XP, and Windows 2000 Considerations

APPC Verb Overview

APPC verbs fall into three categories: management, transaction program (TP), and conversation.

Management Verbs

Management verbs provide management functions. They are:

ACTIVATE_SESSION

CNOS

DEACTIVATE_SESSION

DISPLAY

TP Verbs

TP verbs start and end TPs, and get and set TP properties. They are:

GET_TP_PROPERTIES

SET_TP_PROPERTIES

TP_ENDED

TP_STARTED

Conversation Verbs

Conversation verbs enable TPs to allocate and deallocate conversations, send and receive data, and change conversation states. The conversation verbs are listed in the following table.

Conversation verbs fall into two groups: mapped conversation verbs and basic conversation verbs. The mapped conversation is intended for programs that use the conversation directly. The basic conversation is intended for more complex programs that provide services to other users. In typical situations, end-user TPs use mapped conversations and service TPs use basic conversations.

Mapped conversation verbs can only be issued by a TP in mapped conversations, while basic conversation verbs are reserved for basic conversations. There is one exception to this rule: ALLOCATE can be used to start either a basic or a mapped conversation.

Mapped conversation verbs	Basic conversation verbs
MC_ALLOCATE	ALLOCATE
MC_CONFIRM	CONFIRM
MC_CONFIRMED	CONFIRMED
MC_DEALLOCATE	DEALLOCATE
MC_FLUSH	FLUSH
MC_GET_ATTRIBUTES	GET_ATTRIBUTES
GET_LU_STATUS	GET_LU_STATUS
GET_STATE	GET_STATE
GET_TYPE	GET_TYPE
MC_POST_ON_RECEIPT	POST_ON_RECEIPT
MC_PREPARE_TO_RECEIVE	PREPARE_TO_RECEIVE
RECEIVE_ALLOCATE	RECEIVE_ALLOCATE
MC_RECEIVE_AND_POST	RECEIVE_AND_POST
MC_RECEIVE_AND_WAIT	RECEIVE_AND_WAIT
MC_RECEIVE_IMMEDIATE	RECEIVE_IMMEDIATE
MC_RECEIVE_LOG_DATA	RECEIVE_LOG_DATA
MC_REQUEST_TO_SEND	REQUEST_TO_SEND
MC_SEND_CONVERSATION	SEND_CONVERSATION
MC_SEND_DATA	SEND_DATA
MC_SEND_ERROR	SEND_ERROR
MC_TEST_RTS	TEST_RTS

Mapped and basic verbs have the same functions in their respective types of conversation. For example, **MC_CONFIRM** performs the same function in a mapped conversation that **CONFIRM** performs in a basic conversation.

APPC Verb Summary

This section briefly describes each APPC verb, grouped by function.

Verbs for Starting Conversations

ALLOCATE or MC_ALLOCATE

Issued by the local transaction program (TP). This verb allocates a session between the local logical unit (LU) and a partner LU, and establishes a conversation between the local TP and the partner TP.

ALLOCATE can establish either a basic or a mapped conversation. **MC_ALLOCATE** can start only a mapped conversation. After the conversation is allocated, APPC uses this verb to return a conversation identifier (**conv_id**).

RECEIVE_ALLOCATE

Issued by the partner TP. This verb confirms that the partner TP is ready to begin a conversation with the local TP that issued **ALLOCATE** or **MC_ALLOCATE**. Upon successful execution, this verb returns a TP identifier (**tp_id**) for the partner TP and the **conv_id**.

TP_STARTED

Issued by the local TP. This verb notifies APPC that the local TP is starting. Upon successful execution, this verb returns a **tp_id** for the local TP.

Verbs for Sending Data

CONFIRM or MC_CONFIRM

Sends the contents of the local LU's send buffer and a confirmation request to the partner TP.

FLUSH or MC_FLUSH

Flushes the local LU's send buffer, sending the contents of the buffer to the partner LU and TP. If the send buffer is empty, no action takes place.

PREPARE_TO_RECEIVE or MC_PREPARE_TO_RECEIVE

Changes the state of the conversation from SEND to RECEIVE. Before changing the conversation state, this verb performs the equivalent of **FLUSH**, **MC_FLUSH**, **CONFIRM**, or **MC_CONFIRM**. After this verb has successfully executed, the local TP can receive data.

REQUEST_TO_SEND or MC_REQUEST_TO_SEND

Informs the partner TP that the local TP wants to send data. The local TP must wait until the partner TP issues **PREPARE_TO_RECEIVE**, **MC_PREPARE_TO_RECEIVE**, **RECEIVE_AND_WAIT**, or **MC_RECEIVE_AND_WAIT**, and the conversation state changes to RECEIVE for the partner TP, before the local TP begins sending data.

SEND_DATA or MC_SEND_DATA

Puts data in the local LU's send buffer for transmission to the partner TP.

The data collected in the local LU's send buffer is transmitted to the partner LU and partner TP when one of the following occurs:

- The send buffer fills up.
- The local TP issues **FLUSH**, **MC_FLUSH**, **CONFIRM**, **MC_CONFIRM**, **DEALLOCATE**, **MC_DEALLOCATE**, or another verb that flushes the local LU's send buffer.

Verbs for Receiving Data

POST_ON_RECEIPT or MC_POST_ON_RECEIPT

Issuing this verb allows the application to register to receive a notification when data or status arrives at the local LU without actually receiving it at the same time. This verb can only be issued while in RECEIVE state and it never causes a change in conversation state.

When the TP issues this verb, APPC returns control to the TP immediately. When the specified conditions are satisfied, the Win32® event specified as a parameter is signalled and the verb completes. Then the TP looks at the return code in the verb control block to determine whether or not any data or status notification has arrived at the local LU and issues a **RECEIVE_IMMEDIATE** or **RECEIVE_AND_WAIT** verb to actually receive the data or status notification.

RECEIVE_AND_POST or MC_RECEIVE_AND_POST

Issuing this verb while the conversation is in RECEIVE state changes the conversation state to PENDING_POST and causes the local TP to receive data asynchronously. This allows the local TP to proceed with processing while data is still arriving at the local LU.

Issuing this verb while the conversation is in SEND state flushes the LU's send buffer and changes the conversation state to

PENDING_POST. The local TP then begins to receive data asynchronously.

RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT

Issuing this verb while the conversation is in RECEIVE state causes the local TP to receive any data that is currently available from the partner TP. If no data is available, the local TP waits for data to arrive.

Issuing this verb while the conversation is in SEND state flushes the LU's send buffer and changes the conversation state to RECEIVE. The local TP then begins to receive data.

RECEIVE_IMMEDIATE or MC_RECEIVE_IMMEDIATE

Receives any data that is currently available from the partner TP. If no data is available, the local TP does not wait.

TEST_RTS or MC_TEST_RTS

Determines whether a **REQUEST_TO_SEND** or **MC_REQUEST_TO_SEND** or notification has been received.

Verbs for Confirming Data or Reporting Errors

CONFIRMED or MC_CONFIRMED

Replies to a confirmation request from the partner TP. It informs the partner TP that the local TP has received and processed the data without error.

RECEIVE_LOG_DATA or MC_RECEIVE_LOG_DATA

Issuing this verb allows the user to register to receive the log data associated with an inbound Function Management Header 7 (FMH7) error report. The verb passes a buffer to APPC, and any log data received is placed in that buffer. APPC continues to use this buffer as successive FMH7s arrive until it is provided with another buffer (that is, until the TP issues another **RECEIVE_LOG_DATA** or **MC_RECEIVE_LOG_DATA** specifying a different buffer or no buffer at all).

SEND_CONVERSATION or MC_SEND_CONVERSATION

Issued by the invoking TP, this verb allocates a session between the local LU and partner LU, sends data on the session, and then deallocates the session.

SEND_ERROR or MC_SEND_ERROR

Notifies the partner TP that the local TP has encountered an application-level error.

Verbs for Getting and Setting Information

GET_ATTRIBUTES or MC_GET_ATTRIBUTES

Used by a TP to get the attributes of the conversation.

GET_LU_STATUS

Used to report the status of a particular remote LU.

GET_STATE

Used by a TP to interrogate the state of a particular conversation.

GET_TP_PROPERTIES

Returns attributes of the TP and the current transaction.

GET_TYPE

Used by a TP to determine the conversation type (basic or mapped) of a particular conversation. With this information, the TP can decide whether to issue basic or mapped conversation verbs.

SET_TP_PROPERTIES

Used to set the attributes of the TP and the current transaction.

Verbs that Provide Management Functions

ACTIVATE_SESSION

Activates a session between the local LU and a specified partner LU, using a specified mode.

CNOS (Change Number of Sessions)

Establishes APPC LU 6.2 session limits.

DEACTIVATE_SESSION

Deactivates a particular session, or all sessions on a particular mode.

DISPLAY

Returns configuration information and current operating values for the SNA node.

Verbs for Ending Conversations

DEALLOCATE or MC_DEALLOCATE

Deallocates a conversation between two TPs. Before deallocating the conversation, this verb performs the equivalent of **FLUSH**, **MC_FLUSH**, **CONFIRM**, or **MC_CONFIRM**.

TP_ENDED

Issued by both the local and partner TPs. It notifies APPC that the TP is ending. Issuing this verb also terminates any active conversations.

Windows APPC Overview

The information provided in this guide is source code and executable code compatible with the following implementations of APPC:

- APPC applications based on Microsoft® Host Integration Server 2004 residing on the server or on a client. These applications run on Microsoft® Windows Server™, Windows® XP, and Windows 2000.

Programs written to use this implementation of APPC can exchange data with programs written to use other implementations of APPC that adhere to the SNA LU 6.2 architecture.

The use of the Windows APPC interface on Windows Server 2003 and Windows 2000 causes additional threads to be created within the calling process. These other threads perform interprocess communication with the Host Integration Server 2004 or SNA service over the LAN interface that the client is configured to use (TCP/IP, IPX/SPX, or named pipes, for example).

If an application using Windows APPC is running on Windows Server 2003 and Windows 2000, stopping the SNABASE service causes the application to be unloaded from memory.

This section contains:

- Windows APPC Asynchronous Support
- APPC Verbs and Windows Extensions

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Windows APPC Asynchronous Support

A program that issues a call and does not regain control until the call completes cannot perform any other operations. This type of operation, referred to as blocking, is not suited to a server application designed to handle multiple requests from many clients. Asynchronous call completion returns the initial call immediately so the application can continue with other processes.

Microsoft Host Integration Server 2004 uses the **RegisterWindowsMessage** function for asynchronous support for APPC applications. With "WinAsyncAPPC" as the input string, an application passes a window handle by which it can be notified of verb completion. The application then issues the verb. When the verb completes, a message is posted to the window handle that was passed, notifying the application that the verb is complete.

With the exception of asynchronous RECEIVE_AND_WAIT, MC_RECEIVE_AND_WAIT, RECEIVE_AND_POST, and MC_RECEIVE_AND_POST, which can issue certain other verbs while pending, a conversation can have only one incomplete operation at any time.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

APPC Verbs and Windows Extensions

This topic describes the APPC verbs and Windows extensions that are supported by Host Integration Server 2004:

APPC Verbs

The following APPC verb descriptions contain important features and should be read before using this version of Windows APPC.

ALLOCATE or MC_ALLOCATE

Issued by the invoking transaction program (TP), this verb allocates a session between the local logical unit (LU) and partner LU and (in conjunction with RECEIVE_ALLOCATE) establishes a conversation between the invoking TP and the invokable TP. After this verb executes successfully, APPC generates a conversation identifier (**conv_id**). The **conv_id** is a required parameter for all other APPC conversation verbs.

For a user or group using TPs, 5250 emulators, or APPC applications, you can assign default local and remote LUs. In this case, the field for LU alias is left blank or null and the default LUs are accessed when the user or group member starts an APPC program. For more information about using default LUs, see the Network Integration section of the Microsoft Host Integration Server 2004 Help.

RECEIVE_ALLOCATE

Issued by the invokable TP to confirm that it is ready to begin a conversation with the invoking TP that issued ALLOCATE or MC_ALLOCATE. This must be the first APPC verb issued by the invokable TP. The initial state is RESET. If the verb executes successfully (**primary_rc** is AP_OK), the state changes to RECEIVE.

RECEIVE_AND_POST or MC_RECEIVE_AND_POST

Receives application data and status information asynchronously. This enables the local TP to proceed with processing while data is still arriving at the local LU. RECEIVE_AND_POST and MC_RECEIVE_AND_POST are only supported by the Windows 2000 operating system.

While an asynchronous RECEIVE_AND_POST or MC_RECEIVE_AND_POST is outstanding, the following verbs can be issued:

REQUEST_TO_SEND or MC_REQUEST_TO_SEND

GET_TYPE

GET_ATTRIBUTES or MC_GET_ATTRIBUTES

TEST_RTS or MC_TEST_RTS

DEALLOCATE

SEND_ERROR or MC_SEND_ERROR

TP_ENDED

RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT

Receives any data that is currently available from the partner TP. If no data is currently available, the local TP waits for data to arrive.

RECEIVE_AND_WAIT and MC_RECEIVE_AND_WAIT have been altered to act like RECEIVE_AND_POST and MC_RECEIVE_AND_POST. While an asynchronous RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT is outstanding, the following verbs can be issued:

REQUEST_TO_SEND or MC_REQUEST_TO_SEND

GET_TYPE

GET_ATTRIBUTES or MC_GET_ATTRIBUTES

TEST_RTS or MC_TEST_RTS

DEALLOCATE

SEND_ERROR or MC_SEND_ERROR

TP_ENDED

TP_STARTED

Issued by the invoking TP, this verb notifies APPC that the TP is starting. For a user or group using TPs, 5250 emulators, or APPC applications, you can assign default local and remote APPC LUs. These default LUs are accessed when the user or group member starts an APPC program (a TP, 5250 emulator, or APPC application) and the program does not specify LU aliases. For more information about using default LUs, see the Network Integration section of the Microsoft Host Integration Server 2004 Help.

Limits

Host Integration Server 2004 permits one outstanding Windows APPC asynchronous call per connection and one blocking verb per thread. For example:

```
void ProcessVerbCompletion (WPARAM wParam, LPARAM lParam)
{
    int i;
    for (i = 0; i < nPendingVerbs; i++)
        if (pPendingVerbs[i].hAsync == wParam)
            ProcessVCB( (LPVCB) lParam);
}    . . .
LRESULT CALLBACK SampleWndProc ( ... )
{
    if (msg == uAsyncAPPC) {
        ProcessVerbCompletion(wParam; lParam);
    }
        else switch (msg) {
        case WM_USER:
            if (hAsync = WinAsyncAPPC(hwnd, &vcb))
               pPendingVerbs [nPendingVerbs++].hAsync = hAsync;
            break;
    }
}
WinMain ( ... )
{
    if ( ( WinAPPCStartup ( ...) = = FALSE ) {
    return FALSE ;
    }
    uAsyncAPPC = RegisterWindowsMessage ("WinAsyncAPPC") ;
    while (GetMessage ( ...)  )  {
    ...
    WinAPPCCleanup ( ... )
}
```

> **Note** The exceptions to the rule of one outstanding asynchronous call are RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT. While these verbs are outstanding, certain other verbs can also be called.

Using APPC Verbs in C Programs

This implementation of APPC is available for programs written in Microsoft® C version 5.1 or later. A C program calls APPC through the external function **APPC**. For compatibility with previous versions of Microsoft C, the external function **APPC_C** is also supported.

> **Note** Compilers other than the Microsoft C compiler can also be used to build applications using this implementation of APPC.

This section contains:

- Verb Control Block
- APPC Definition
- Issuing an APPC Verb

Verb Control Block

The only parameter passed to the **APPC** function is the address of a verb control block (VCB). The VCB is a structure made up of variables that:

- Identify the APPC verb to be executed.
- Supply information to be used by the verb.
- Contain information returned by the verb when execution is complete.

Each APPC verb has its own VCB structure, which is declared in the WINAPPC.H header file. For compatibility with earlier versions, the APPC_C.H header file is also supported.

The WINAPPC.H file is supplied as part of the Host Integration Server 2004 Software Development Kit (SDK).

APPC Definition

The prototype definitions of the **APPC** function are as follows:

```
void WINAPI APPC(long);
HANDLE WINAPI WinAsyncAPPC (hWnd, LPAPPC);
```

The verb control block (VCB) address parameter, a 32-bit pointer, is declared as a long integer and thus requires casting from a pointer to a long integer.

Issuing an APPC Verb

The following procedure is required to issue a blocking APPC verb. In the sample code, the verb issued is **MC_SEND_DATA**.

To issue a blocking APPC verb

1. Create a structure variable from the verb control block (VCB) structure that applies to the APPC verb to be issued.

```
#include <winappc.h>
    .
    .
struct mc_send_data  mcsend;
The VCB structures are declared in WINAPPC.H; one of these structures is:
mc_send_data
```

2. Clear (set to zero) the variables within the VCB structure.

```
memset( mcsend, '\0', sizeof( mcsend ) );
```

3. Assign values to the VCB variables that supply information to APPC.

```
mcsend.opcode = AP_M_SEND_DATA;
mcsend.opext = AP_MAPPED_CONVERSATION;
memcpy( mcsend.tp_id, tp_id, sizeof( tp_id ) );
mcsend.conv_id = conv_id;
mcsend.dlen = datalen;
mcsend.dptr = sharebufptr;
```

   The values AP_MAPPED_CONVERSATION and AP_M_SEND_DATA are symbolic constants representing integers. These constants are defined in WINAPPC.H.

4. Invoke the **APPC** function. The only parameter is a pointer to the address of the structure containing the VCB for the desired verb.

```
APPC ( ( long ) (void FAR * ) &mcsend );
```

   Use WinAsyncAPPC if you are running the application under Windows version 3.*x*.

   To call **WinAsyncAPPC**:

```
HANDLE WINAPI WinAsyncAPPC (hWnd, 1pVCB)
```

   When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinAsyncAPPC" as the input string.

5. Use the variables that were returned by APPC.

```
if( mcsend.primary_rc != AP_OK )
/* Do error routine */
    .
    .
    .
```

Windows Server 2003, Windows XP, and Windows 2000 Considerations

This topic summarizes information about developing transaction programs (TPs) using APPC on the following operating systems:

- Microsoft Windows Server™ 2003
- Microsoft Windows XP Professional
- Microsoft® Windows® 2000

Byte ordering

The values of constants defined in WINAPPC.H and WINCSV.H are dependent on the byte ordering of the hardware used. Macros are used to set the constants to the correct value.

By default, Intel little-endian byte ordering is used, with the low byte of a 16-bit value followed by the high byte. However, when defining inline macros, the NON_INTEL_BYTE_ORDER macro used in WINAPPC.H and WINCSV.H will not reverse (flip) the byte order for constants. Non-constant input parameters in verb control blocks (VCBs) (such as lengths, pointers, and so on) are always in the native format.

For example, the primary return code of AP_PARAMETER_CHECK is defined to have a value of 0x0001. Depending on the environment (byte ordering), the constant AP_PARAMETER_CHECK may or may not be 0x0001. Some formats define the value as it appears in memory; others define it as a 2-byte variable. Because you cannot assume that the application always uses provided constants rather than hardwired values, you can define a macro to swap the bytes. The following is an example of using the macro:

```
/* when NON_INTEL_BYTE_ORDER is specified, the APPC_FLIPI macro defined in WINAPPC.H macro b
ecomes */
#define APPC_FLIPI(x)    (x)

/* otherwise this macro flips bytes by defining */
#define APPC_FLIPI(X) APPC_MAKUS(APPC_HI_UC(X),APPC_LO_UC(X))

/* the AP_PARAMETER_CHECK macro is now defined using the APPC_FLIPI macro */
#define AP_PARAMETER_CHECK APPC_FLIPI (0X0001)      /* X '0001' */
```

Events

To receive data asynchronously, an event handle is passed in the semaphore field of the VCB. This event must be in the nonsignaled state when passed to APPC, and the handle must have EVENT_MODIFY_STATE access to the event.

Library names

In order to support the coexistence of Win16 and Win32 API libraries on the same computer, the Win32 DLL names have been changed.

Old DLL names	New DLL names
WINAPPC.DLL	WAPPC32.DLL
WINCSV.DLL	WINCSV32.DLL

The new DLL names should be used for Win32-based applications that are intended to run only on Host Integration Server 2004.

Limits

For Windows Server 2003 and Windows 2000, the number of simultaneous common service verbs (CSVs) allowed per process is 64. Only one of these verbs per thread can be synchronous (blocking).

Using APPC, the maximum number of simultaneous conversations per process is 15,000. Each process supports up to 15,000 simultaneous TPs.

Multiple threads

A TP can have multiple threads that issue verbs. Windows APPC makes provisions for multithreaded Windows-based processes. A process contains one or more threads of execution. All references to threads refer to actual threads in the multithreaded Windows Server 2003 and Windows 2000 environments.

With the exception of RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT, only one conversation verb can be outstanding at a time on any conversation; however, other verbs can be issued for other conversations. This guideline also applies to TP verbs and TPs. Although multiple TP verbs can be issued, only one TP verb can be outstanding at a time on a TP. This applies to both multithreaded applications and single-threaded applications that use asynchronous calls.

Packing

For performance considerations, the VCBs are not packed. VCB structure member elements after the first element are aligned on either the size of the member type or DWORD (4-byte) boundaries, whichever is smaller. As a result, DWORDs are aligned on DWORD boundaries, WORDs are aligned on WORD boundaries, and BYTEs are aligned on BYTE boundaries. This means, for example, that there is a 2-byte gap between the primary and secondary return codes. Therefore, the elements in a VCB should only be accessed using the structures provided.

This option for structure and union member alignment is the default behavior for Microsoft C/C++ compilers. For compatibility with the supplied logical unit application (LUA) libraries, make sure to use an equivalent structure and union member packing option when using other C/C++ compilers or when explicitly specifying a structure alignment option when using Microsoft compilers.

Registering and deregistering applications

All Windows APPC applications must call WinAPPCStartup at the beginning of the session to register the application and WinAPPCCleanup at the end of the session to deregister the application.

All Windows CSV applications must call the Windows SNA extension WinCSVStartup at the beginning of the session to register the application and WinCSVCleanup to deregister the application when the session is finished.

Run-time linking

For a TP to be dynamically linked to APPC at run time, the TP must issue the following calls:

- **LoadLibrary** to load the dynamic-link libraries WINAPPC.DLL or WAPPC32.DLL.
- **GetProcAddress** to specify APPC on all the desired entry points to the DLL such as **APPC**, **WinAsyncAPPC**, **WinAPPCStartup**, and **WinAPPCCleanup**.

For a TP to be dynamically linked to CSV at run time, the TP must issue the following calls:

- **LoadLibrary** to load WINCSV.DLL or WINCSV32.DLL, the dynamic-link libraries for Windows CSV.
- **GetProcAddress** to specify CSV on all the desired entry points to the DLL such as **ACSSVC**, **WinAsyncCSV**, **WinCSVStartup**, and **WinCSVCleanup**.

The TP must issue the **FreeLibrary** call when the APPC or CSV library is no longer required.

Yielding to other components

Because the Windows Server 2003 and Windows 2000 environments are multithreaded, there is no need to yield to other components.

About Transaction Programs

A processing task accomplished by programs using Advanced Program-to-Program Communications (APPC) is called a transaction. Consequently, programs that use APPC are called transaction programs (TP)s. These programs communicate as peers, on an equal (rather than hierarchical) basis. The TPs use APPC verbs to exchange status information and application data. Each TP uses APPC verbs to supply parameters to APPC, which performs the desired function and returns parameters to the TP.

TPs distributed across a local or wide area network perform distributed transaction processing.

This section describes how to write TPs and how to configure the systems on which TPs run. The topics in this section cover the following general areas:

- Understanding fundamental concepts related to TPs
- Designing and coding TPs
- Configuring registry and environment variables for invokable TPs
- Configuring Microsoft® Host Integration Server 2004 to work with your TPs
- Sync Point Level 2 support

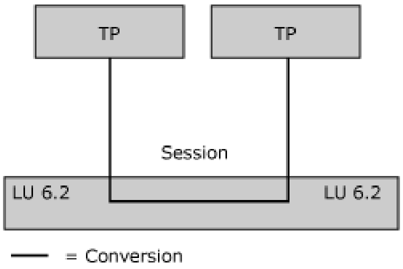
This section contains:

- Communication between TPs
- Designing and Coding TPs
- Configuring Invokable TPs
- Configuring TPs on Host Integration Server
- Arranging TPs Within an SNA Network
- Sync Point Level 2 Support in Host Integration Server

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

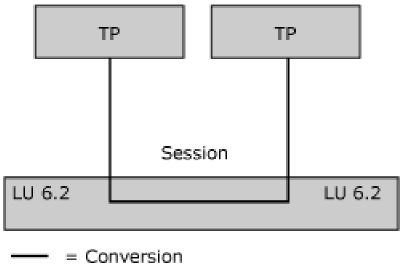
Communication between TPs

Various hardware and software elements in the SNA environment are required for two transaction programs (TPs) to communicate with each other. The following figure shows several fundamental elements.



Each TP is associated with a logical unit (LU) of type 6.2. The LU allows the TP to access the network. Several TPs can be associated with the same LU.

A partner TP can invoke another TP, which, in turn, invokes another TP, and so on. In the following figure, TP A invokes TP B and TP B invokes TP C.



This section contains:

- Fundamental Terms for TPs and LUs
- Sample TPs Illustrating Fundamental Concepts
- Configuring and Controlling TPs
- Creating TPs and Their Supporting Configuration

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Fundamental Terms for TPs and LUs

The following terms describe some fundamental characteristics of transaction programs (TPs) communicating through logical units (LUs):

asynchronous verb

An APPC verb for which the initial function call returns immediately, so that the normal operation of the program is not blocked while processing of the verb completes. For more information, see Receiving Data Asynchronously.

basic conversation

A type of conversation more complex than a mapped conversation and generally used by service TPs (SNA-based programs that provide services to other programs). For more information, see Basic and Mapped Conversations Compared.

conversation

The interaction between TPs carrying out a specific task. Each conversation requires an LU-LU session. A TP can be involved in several conversations simultaneously, as shown with TP B in Communication between TPs.

invokable TP

A TP that can be invoked by another TP. Invokable TPs are usually server-type applications; that is, they work in the same general way that an application such as CICS works. Parameters for an invokable TP are configured through registry or environment variables.

There are several types of invokable TPs:

operator-started invokable TP

A TP that is started manually in preparation for being invoked.

autostarted invokable TP

A TP that is automatically started by APPC when invoked.

queued TP

A TP that, when invoked multiple times, loads once and then queues up subsequent requests to be dealt with one at a time. All operator-started TPs and some autostarted TPs are queued.

nonqueued TP

A TP loaded multiple times, once for every time it is invoked. Some autostarted TPs are nonqueued but no operator-started TPs are nonqueued.

For more information, see Invokable TPs.

invoking TP

A TP that can invoke (that is, initiate a conversation with) other TPs. Invoking TPs are usually client-type applications; that is, they work in the same general way that an emulator works. For more information, see Invoking TPs.

local LU and **local TP**

An LU and TP working together, when viewed as the "home base" for a particular conversation. From this viewpoint, some other LU and TP are seen as the "partner" or "remote" LU and TP.

LU alias

The string that identifies an LU to a TP. The alias can be up to eight characters long.

LU-LU session

The communication between two LUs over a specific connection for a specific amount of time. An LU-LU session is needed for two TPs to interact. One session can be used serially by many pairs of TPs.

An LU 6.2 can have multiple sessions (two or more concurrent sessions with different partner LUs) and parallel sessions (two or more concurrent sessions with the same partner LU).

LUs as well as LU-LU pairs and modes are configured using the SNA Manager on Host Integration Server.

mapped conversation

A type of conversation simpler than a basic conversation and generally used by application TPs (programs that accomplish tasks for end users). The characters **MC_** at the beginning of a verb stand for mapped conversation. For more information, see Basic and Mapped Conversations Compared.

partner LU and **partner TP**, or **remote LU** and **remote TP**

An LU and TP working together, when viewed as being at the far end of a particular conversation.

synchronous verb

An APPC verb that blocks further program operations until the processing of the verb is complete.

http://go.microsoft.com/fwlink/?linkid=29507.

Sample TPs Illustrating Fundamental Concepts

A set of sample transaction programs (TPs) is provided on the Host Integration Server CD-ROM in the \SDK\SAMPLES directory. Included with the sample code in the \SDK\SAMPLES\SNA\TPSETUP directory on the Host Integration Server CD-ROM is TPSETUP, a program that simplifies the setting of registry or environment variables needed by autostarted invokable TPs. Without an interface like that provided by TPSETUP, configuring such variables can be complicated and error-prone. Therefore, it is recommended that you use code like TPSETUP in installation programs for autostarted invokable TPs.

The source code for TPSETUP (INSTALL.C) can be compiled to work in the Microsoft Windows Server™ 2003 and Windows® 2000 environment.

For information about TPSETUP and about the sample TPs, see APPC Samples.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring and Controlling TPs

The following table shows how the characteristics of the transaction programs (TPs) and selection of the logical units (LUs) for a conversation are controlled.

Characteristic	**How controlled**
Type of verb: synchronous or asynchronous	Written into the code. Synchronous verbs use blocking calls; asynchronous verbs avoid blocking calls. See Receiving Data Asynchronously and WinAsyncAPPC.
Type of conversation: basic or mapped	Written into the code. The **MC_** prefix is used on verbs in mapped conversations and omitted on verbs in basic conversations. For two TPs to communicate successfully, both must use the same type of conversation, basic or mapped. See Basic and Mapped Conversations Compared.
Type of TP: invoking or invokable	Written into the code. Invoking TPs start with TP_STARTED, which identifies the invoking TP, and ALLOCATE or MC_ALLOCATE, which identifies the requested invokable TP. Invokable TPs start with RECEIVE_ALLOCATE, which identifies the invokable TP. See Invoking TPs and Invokable TPs.
The local LU alias to be used by an invoking TP	Three options: • Written into the code in TP_STARTED. • Configured (in Host Integration Server Manager as the default local APPC LU for the user who starts the invoking TP. • Configured as a member of the default outgoing local APPC LU pool using the SNA Manager on Host Integration Server 2004. See Configuring Invoking TPs on Host Integration Server.
The invokable TP requested by an invoking TP	Written into the ALLOCATE or MC_ALLOCATE request in the invoking TP.
The LU alias to be used by an invokable TP	Two options: • Written into the invoking TP (not the invokable TP), in ALLOCATE or MC_ALLOCATE. • Configured as the default remote APPC LU for the user who starts the invoking TP. See Configuring Invoking TPs on Host Integration Server and Matching Invoking and Invokable TPs.
Type of autostarted invokable TP: queued or nonqueued	Configured with registry or environment variables. See Configuring Invokable TPs.
Local LU and remote LU aliases	Configured using SNA Manager on Host Integration Server 2004.
The pairing of local and remote LUs, and the mode used for each LU-LU pair	Configured using SNA Manager on Host Integration Server 2004.

Creating TPs and Their Supporting Configuration

The following procedure describes how to create transaction programs (TPs) and set up a supporting configuration.

To create TPs and set up a supporting configuration

1. Write, compile, and link each TP.
2. Place each TP on an appropriate computer.

   For TPs that you start many times or that are started by a user, arrange for the TP to be started easily. That is, for graphical interfaces, create a program icon for starting the TP; for non-graphical interfaces, make sure the TP is in the path.

3. On one or more servers running Host Integration Server, configure logical units (LUs), modes, and LU-LU pairs for use by the TPs.

   For information about how to set up LU-LU pairs to support TPs, see Using Invoking and Invokable TPs.

4. Set any registry or environment variables needed for the invokable TP.

   For autostarted invokable TPs, it is recommended that you use the sample TP configuration program, TPSETUP, for this step. When you write an installation program for autostarted invokable TPs, it is recommended that you include code similar to TPSETUP.

   For information about registry or environment variables, see Configuring Invokable TPs. For information about TPSETUP, see APPC Samples.

5. If the invokable TP is operator-started, start it, or arrange for it to be started when the computer is restarted and then restart the computer.

   If the invokable TP is autostarted, Host Integration Server 2004 will start it when needed.

6. Start the invoking TP.

Designing and Coding TPs

The following topics provide background information about designing and coding transaction programs (TPs).

This section contains:

- Conversation States
- Confirmation Processing
- Receiving Data Asynchronously
- Conversation Security
- Basic and Mapped Conversations Compared
- Using Invoking and Invokable TPs

Conversation States

The state of the conversation (as viewed by a particular TP) governs which APPC verbs the TP can issue at a particular time. For example, a TP cannot issue MC_SEND_DATA if the conversation is not in SEND state for that TP.

The state of a conversation depends on the TP from which it is viewed. A local TP can view a conversation as being in SEND state while the partner TP views the conversation as being in RECEIVE state. A particular TP can be in several conversations, each of which is in a different state.

The possible conversation states are summarized here.

CONFIRM

The TP has received a request for confirmation of receipt of data; it must respond positively or send error information to the partner TP.

CONFIRM_DEALLOCATE

The TP has received a request for confirmation; it must respond positively or send error information. If the TP responds positively, the conversation is automatically deallocated.

CONFIRM_SEND

The TP has received a request for confirmation; it must respond positively or send error information. After responding, the TP can begin to send data.

PENDING_POST

The TP is receiving data asynchronously. The TP can perform other processing not related to this conversation.

RECEIVE

The TP can receive application data and status information from the partner TP. When the conversation is in RECEIVE state, the TP can also send error information and request permission to send data.

RESET

The conversation has not started or has been terminated.

SEND

The TP can send data to the partner TP and request confirmation. When the conversation is in SEND state, the TP can also begin to receive data, which changes the state to RECEIVE.

SEND_PENDING

The TP issued a receive verb and the **what_rcvd** parameter returned by that verb indicated both data received and a status indication of SEND. This only affects the use of the **err_dir** parameter for SEND_ERROR and MC_SEND_ERROR. Otherwise, the state is the same as the SEND state.

This section contains:

- State Checks
- Changing Conversation States

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

State Checks

A state check occurs when a TP issues an APPC verb and the conversation is not in the appropriate state. For example, a state check occurs if a TP issues MC_SEND_DATA while the conversation is in RECEIVE state. When a state check occurs, APPC does not execute the verb; it returns state check information through primary and secondary return codes.

Changing Conversation States

A change in the conversation state can result from:

- A verb issued by the local TP.
- A verb issued by the partner TP.
- An error condition.

The following example shows how APPC verbs can change the state of the conversation from SEND to RECEIVE and from RECEIVE to SEND.

> **Note** Any TP can send or receive data, regardless of whether it is the invoking TP (the TP that started the conversation) or the invokable TP (the TP that responded to a request to start a conversation).

This example shows how APPC verbs can change the conversation state. In this table, each conversation state appears in bold and precedes the APPC verbs that are used while in that state.

Issued by the invoking TP	Issued by the invokable TP
TP_STARTED	
Conversation state: RESET	
MC_ALLOCATE	
(synclevel=AP_CONFIRM_SYNC_LEVL)	
Conversation state: SEND	
MC_SEND_DATA

	(what_rcvd=AP_CONFIRM_DEALLOCATE)
	Conversation state: CONFIRM_DEALLOCATE
	MC_CONFIRMED
Conversation state: RESET	**Conversation state: RESET**
TP_ENDED	TP_ENDED

Initial States

Before the conversation is allocated, the state is RESET for both TPs.

In the example, after the conversation is allocated, the initial state is SEND for the invoking TP and RECEIVE for the invokable TP.

Changing to RECEIVE State

MC_PREPARE_TO_RECEIVE allows a TP to change the conversation from SEND to RECEIVE state. This verb:

- Flushes the local LU's send buffer.
- Sends the AP_CONFIRM_SEND indicator to the partner TP through the **what_rcvd** parameter of a receive verb. This indicator tells the partner TP that an MC_CONFIRMED response is expected before the partner TP can begin to send data.

Confirmation processing is performed when the following conditions are true:

- The **ptr_type** parameter is set to AP_SYNC_LEVEL.
- The synchronization level of the conversation is set to AP_CONFIRM_SYNC_LEVEL.

For more information about confirmation processing, see Confirmation Processing.

> **Note** Issuing MC_RECEIVE_AND_WAIT while the conversation is in SEND state flushes the LU's send buffer and changes the conversation state to RECEIVE. Changing the conversation state in this manner does not support confirmation processing.

Changing to SEND State

MC_REQUEST_TO_SEND informs the partner TP (for which the conversation is in SEND state) that the local TP (for which the conversation is in RECEIVE state) wants to send data. This request is communicated to the partner TP through the **rts_rcvd** parameter of MC_CONFIRM. (The **rts_rcvd** parameter is also returned to MC_SEND_DATA and other verbs.)

When the partner TP issues MC_PREPARE_TO_RECEIVE, the conversation state changes to RECEIVE for the partner TP, making it possible for the local TP to send data.

> **Note** Issuing MC_REQUEST_TO_SEND does not change the state of the conversation. Upon receiving a request to send, the partner TP is not required to change the conversation state; it can ignore the request.

Confirmation Processing

The sequence of events for confirmation processing is as follows:

1. Establish the synchronization level.
2. Send a confirmation request.
3. Receive data and confirmation request.
4. Respond to the confirmation request.
5. Deallocate the conversation.

Using confirmation processing, a TP sends a confirmation request with the data; the partner TP confirms receipt of the data or indicates that an error occurred. Each time the two TPs exchange a confirmation request and response, they are synchronized.

> **Note** Although the example in this section does not show this, any TP can send or receive data, regardless of whether the TP is the invoking TP or the invokable TP.

The following example illustrates confirmation processing.

Issued by the invoking TP	**Issued by the invokable TP**
TP_STARTED	
MC_ALLOCATE	
(synclevel=AP_CONFIRM_SYNC_LEVEL)	
MC_SEND_DATA	
(type=AP_SEND_DATA_CONFIRM)	
	RECEIVE_ALLOCATE
	MC_RECEIVE_AND_WAIT
MC_SEND_DATA	
(type=AP_SEND_DATA_DEALLOC_SYNC_LEVEL)	
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_OK)
	(rtn_status=AP_YES)
	(what_rcvd= AP_DATA_COMPLETE_CONFIRM_DEALLOCATE)
	MC_CONFIRMED
TP_ENDED	TP_ENDED

Establishing the Synchronization Level

The **synclevel** parameter of MC_ALLOCATE determines the synchronization level of the conversation. There are three possible synchronization levels:

- AP_NONE, under which confirmation processing does not occur.
- AP_CONFIRM_SYNC_LEVEL, under which the TPs can request confirmation of receipt of data and respond to requests for confirmation of data.
- AP_SYNCPT, under which the TPs operate under Sync Point Level 2 support for confirmation of receipt of data.

Sending a Confirmation Request

MC_SEND_DATA with type AP_SEND_DATA_CONFIRM has two effects:

- It flushes the local LU's send buffer and sends any data contained in the buffer to the partner TP.
- It sends a confirmation request that the partner TP receives through the **what_rcvd** parameter of a receive verb.

After issuing **MC_SEND_DATA**, the local TP waits for confirmation from the partner TP.

Receiving Data and Confirmation Request

The **what_rcvd** parameter of MC_RECEIVE_AND_WAIT indicates:

- Status of the data received: complete or incomplete.
- Future processing expected of the local TP.

In the example, **what_rcvd** is AP_DATA_COMPLETE_CONFIRM, indicating that the status is complete and a confirmation is requested.

Responding to a Confirmation Request

The partner TP issues MC_CONFIRMED to confirm receipt of data. This frees the local TP to resume processing.

Deallocating the Conversation

MC_SEND_DATA sends a confirmation request with the data when all of the following conditions are true:

- The conversation's synchronization level (established by the **synclevel** parameter of MC_ALLOCATE) is AP_CONFIRM_SYNC_LEVEL.
- The type parameter of **MC_SEND_DATA** is set to AP_SEND_DATA_DEALLOC_SYNC_LEVEL.
- The **what_rcvd** parameter of the final MC_RECEIVE_AND_WAIT is AP_DATA_COMPLETE_CONFIRM_DEALLOCATE, indicating that a confirmation of receipt of data is required before APPC will deallocate the conversation. The local TP waits for this confirmation until the partner TP issues MC_CONFIRMED.

Receiving Data Asynchronously

When using Windows 2000, a TP can receive data asynchronously, without regard to other events occurring within the TP. The following table shows the methods by which a TP can receive data asynchronously. The table also indicates how asynchronous methods can be applied to actions other than receiving data.

Operating system	**Method**
Windows 2000	**Through a Windows message:** Issue **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** with **WinAsyncAPPC**; the application is notified of completion through a **PostMessage** to the defined window handle. This method is not restricted to **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT**, but can be applied to any APPC verb.
Windows 2000	**Through a Win32® event:** Issue **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** with **WinAsyncAPPCEx**; the application is notified of completion through a Win32 event. This method is not restricted to **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT**, but can be applied to any APPC verb.
Windows 2000	With **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST:** Issue the **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST** verb.

The following list gives details about these methods of receiving data asynchronously. For complete information, see the verb descriptions.

RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT with WinAsyncAPPC
: This method enables an application to issue a verb and be notified through a **PostMessage** when the action is complete. To retrieve the message number that will be posted to the window, call **RegisterWindowMessage** with "WinAsyncAPPC" as the input string. Then issue **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** using the **WinAsyncAPPC** entry point.

RECEIVE_AND_WAIT or **MC_RECEIVE_AND_WAIT** with WinAsyncAPPCEx
: This method enables an application to be notified through a Win32 event. This is particularly useful when writing applications that need to service multiple conversations simultaneously. The event must be in the nonsignaled state when passed to APPC, and the handle must have EVENT_MODIFY_STATE access to the event.

RECEIVE_AND_POST or MC_RECEIVE_AND_POST
: When using **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST** with Windows 2000, the application is notified through a Win32 event. The event must be in the nonsignaled state when passed to APPC, and the handle must have EVENT_MODIFY_STATE access to the event.

While receiving data asynchronously, the TP performs tasks not related to this conversation; the TP cannot issue most APPC verbs until notification is received. For information about the verbs that can be issued, see the descriptions of WinAsyncAPPC or WinAsyncAPPCEx.

After a verb has completed asynchronously, check the primary_rc to find out whether the data was received without error.

> **Note** If the initial call to issue the verb returns successfully, the application is guaranteed to be notified (by the applicable method) when the verb completes, regardless of whether the verb is ultimately successful.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Conversation Security

You can use conversation security to require that the invoking TP provide a user identifier and password before APPC will allocate a conversation with the invokable TP. If security is activated, the invoking TP must supply a combination of the user identifier and password as parameters of ALLOCATE or MC_ALLOCATE. Conversation security is activated and configured through registry or environment variables on the computer where the invokable TP is located.

With communication involving more than two TPs, the verification of a user identifier and password can be passed from one TP to another. Suppose that TP A invokes TP B, which requires security information, and TP B in turn invokes TP C, which also requires security information. Through **ALLOCATE** or **MC_ALLOCATE**, TP B can inform TP C that conversation security has already been verified.

For information about the registry or environment variables affecting conversation security, see Configuring Invokable TPs.

Basic and Mapped Conversations Compared

The following table offers some guidelines for choosing between basic and mapped conversations for your TPs. For definitions of basic and mapped conversations, see Fundamental Terms for TPs and LUs.

Characteristic	**Basic conversations**	**Mapped conversations**
Common use	Generally used for service TPs.	Generally used for application TPs.
Partnering	Must be used to communicate with an existing TP that uses basic verbs.	Must be used to communicate with an existing TP that uses mapped verbs.
Sending and receiving method	Before a TP can begin a send operation, it must convert data records into logical records. The TP does this by adding a 2-byte prefix that indicates the length of the record. A TP can send several logical records at one time. When a partner TP receives logical records, it must reconstruct them into usable data records. For more information, see Logical Records Used in Basic Conversations.	A TP sends data one record at a time. Neither the sending TP nor the receiving TP needs to convert data records between different forms.
Abnormal termination	In the DEALLOCATE verb, a TP can indicate whether an error or ABEND (abnormal program termination) was caused by a TP or by a program using the TP.	A TP can indicate an error or ABEND, but cannot tell whether a problem was caused by a TP or by a program using a TP.
	A TP can indicate whether an ABEND was caused by a timeout or by a critical error.	A TP cannot indicate the cause of an ABEND.
Error logging	For an error or ABEND, a TP can send an error message, in the form of a general data stream (GDS) error log variable, to the local log and to the partner LU.	For an error or ABEND, a TP cannot send an error message to the local log or to the partner LU.

This section contains:

- Logical Records Used in Basic Conversations
- An Example of a Mapped Conversation

Logical Records Used in Basic Conversations

Logical records are sent and received in basic conversations only.

A TP can send or receive multiple logical records with a single SEND_DATA or receive verb. The receive verbs are RECEIVE_AND_POST (Windows 2000), RECEIVE_IMMEDIATE, and RECEIVE_AND_WAIT. A TP can also send or receive a logical record in successive portions: beginning, middle, and end.

A logical record is made up of:

- A 2-byte record-length (LL) field.
- A data field that can range in length from 0 bytes through 32765 bytes.

The LL field contains a hexadecimal value that is the length of the data field plus two bytes (for the LL field). For example, if a record contains 228 bytes of application data, the logical record length is 230. The LL field is 0x00E6, the hexadecimal equivalent of 230. If the length of the data field is 0, the value contained in the LL field is 0x0002.

Logical records are sent from or received in a data buffer established by the TP. In the data buffer, the LL field must not be in Intel byte-swapped format. For example, a length of 230 must be 0x00E6, not 0xE600.

The LL field cannot be 0x0000 or 0x0001, which allow less than the two bytes required for the LL field itself. The LL field also cannot be greater than or equal to 0x8000, which is equivalent to decimal 32768 and therefore allows for a data field greater than 32765 or an LL field greater than 2.

Setting the most significant bit of the LL field to 1 indicates that the information contained in the current logical record is continued in the next logical record.

An Example of a Mapped Conversation

For background information about mapped conversations, see Basic and Mapped Conversations Compared.

The following example of a mapped conversation shows the APPC verbs used to start a conversation, exchange data, and end the conversation. APPC verb parameters are in parentheses.

Issued by the invoking TP	Issued by the invokable TP
TP_STARTED	
MC_ALLOCATE	
MC_SEND_DATA	
MC_DEALLOCATE	
TP_ENDED	RECEIVE_ALLOCATE
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_OK)
	(rtn_status=AP_NO)
	(what_rcvd=AP_DATA_COMPLETE)
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_DEALLOC_NORM)
	TP_ENDED

The following paragraphs describe the verbs that are used in a mapped conversation.

Verbs for Starting a Mapped Conversation

To start a mapped conversation, the invoking TP issues the following verbs:

- TP_STARTED, which notifies APPC that the local TP is beginning a conversation.
- MC_ALLOCATE, which requests that APPC establish a conversation between the local TP and the partner TP.

The invokable TP issues RECEIVE_ALLOCATE, which informs APPC that it is ready to begin a conversation with the invoking TP.

Verbs for Sending Data in a Mapped Conversation

MC_SEND_DATA puts one data record (a record containing application data to be transmitted) in the send buffer of the local LU. Data transmission to the partner TP does not happen until one of the following events occurs:

- The send buffer fills up.
- The sending TP issues a verb that forces APPC to flush the buffer and send data to the partner TP.

In the preceding example, the send buffer contains both the data record and the MC_ALLOCATE request (which precedes the data record). Therefore, in the example, MC_DEALLOCATE flushes the buffer, sending the **MC_ALLOCATE** request and data record to the partner TP. Other verbs that flush the buffer are MC_CONFIRM and MC_FLUSH.

Verbs for Receiving Data in a Mapped Conversation

The MC_RECEIVE_AND_WAIT verb allows a TP to receive a data record or status information. If no data is currently available, the TP waits for data to arrive. For Windows 2000 systems, issue **MC_RECEIVE_AND_WAIT** in conjunction with WinAsyncAPPC rather than the blocking version of this call.

In the example, the receiving TP issues **MC_RECEIVE_AND_WAIT** twice. The first time, it issues the verb to receive data. When it finishes receiving the complete data record (**what_rcvd** is AP_DATA_COMPLETE), it issues **MC_RECEIVE_AND_WAIT** again to receive a return code. The return code AP_DEALLOC_NORMAL indicates that the conversation has been deallocated.

> **Note** MC_RECEIVE_IMMEDIATE performs the same function as **MC_RECEIVE_AND_WAIT**, except that it does not wait if data is not currently available from the partner TP. Instead, it returns a no-data-available response to the calling TP.

Verbs for Ending a Mapped Conversation

To end a mapped conversation, one of the TPs issues MC_DEALLOCATE, which causes APPC to deallocate the conversation between the two TPs.

After the conversation has been deallocated, both TPs issue TP_ENDED.

> **Note** A TP can participate in multiple conversations simultaneously. In this case, the TP issues **TP_ENDED** after all conversations have been deallocated.

Using Invoking and Invokable TPs

There are two kinds of TPs: TPs that can invoke (that is, initiate a conversation with) other TPs, and TPs that can be invoked. A TP that can invoke another TP is called an invoking TP, and a TP that can be invoked is called an invokable TP.

The following topics describe how:

- Invoking TPs request invokable TPs.
- Invokable TPs identify themselves to Host Integration Server in preparation for being invoked.
- An invokable TP is matched to an invoking TP's request.

For information about how to configure LUs to support TPs, see Configuring TPs on Host Integration Server and Microsoft Host Integration Server 2004 Help.

This section contains:

- Invoking TPs
- Invoking TPs and Contention
- Invokable TPs
- Subcategories for Invokable TPs
- Matching Invoking and Invokable TPs

Invoking TPs

An invoking TP can be located on any system on the SNA network. An invoking TP identifies itself by issuing TP_STARTED, which specifies the name of the invoking TP and can specify the LU alias that the TP uses. If the LU alias is not specified in **TP_STARTED**, Host Integration Server must be configured to supply it through one of two types of default local LU; otherwise, **TP_STARTED** will fail. For more information, see Configuring Invoking TPs on Host Integration Server.

Next, the invoking TP initiates the invoking process by issuing ALLOCATE or MC_ALLOCATE, in which it specifies the name of the invokable TP, and can also specify the partner LU alias (the LU alias to be used by the invokable TP). If the partner LU is not specified in **ALLOCATE** or **MC_ALLOCATE**, Host Integration Server 2004 must be configured to supply one through the default remote APPC LU assigned to the user who started the invoking TP; otherwise, **ALLOCATE** or **MC_ALLOCATE** will fail. For more information, see Configuring Invoking TPs on Host Integration Server.

After a TP successfully issues an **ALLOCATE** or **MC_ALLOCATE** verb, an allocation request flows. For more information about what happens after an invoking TP requests an invokable TP, see Matching Invoking and Invokable TPs.

Invoking TPs and Contention

The following information applies only to cases where LUs are communicating in complex ways (such as chains of LUs) over multiple sessions. In such cases, two LUs may attempt to allocate a conversation on the same session at the same time. If this happens, one LU must win (the contention winner) and one must lose (the contention loser). The contention-winner LU and the contention-loser LU are determined for each session when the session is established. During that particular session, the contention-loser LU must receive permission from the contention-winner LU before allocating a conversation. In contrast, the contention-winner LU on that session allocates a conversation as needed.

Note that when two LUs are communicating over multiple sessions, one LU can be the contention winner for some of the sessions, and the other LU the contention winner for others.

An invoking TP will operate most efficiently if the number of concurrent **ALLOCATE** or **MC_ALLOCATE** requests that the TP issues is matched by the number of sessions on which the local LU is the contention winner. The choice of contention winner is controlled through the modes configured at the two ends of the communication. The mode is configured using SNA Manager on Host Integration Server 2004. A mode must be configured to work with the mode on the remote system for communication to begin between two LUs. For more information about modes, see Microsoft Host Integration Server 2004 Help.

Invokable TPs

An invokable TP is a TP that can be invoked by another TP. Invokable TPs are written or configured through registry or environment variables to supply their names to Host Integration Server 2004 as a notification that they are available for incoming requests. Invokable TPs can be run on any Host Integration Server 2004 client or server running Windows 2000.

There are two types of invokable TPs:

Operator-started invokable TPs

An operator-started invokable TP must be started by an operator before the TP can be invoked. When the operator-started invokable TP is started, it notifies Host Integration Server 2004 of its availability by issuing a RECEIVE_ALLOCATE verb. The **RECEIVE_ALLOCATE** causes the name of the invokable TP, along with the alias of an associated LU if one has been configured through a registry or environment variable, to be communicated to all the servers running Host Integration Server 2004 in the SNA domain.

Autostarted invokable TPs

An autostarted invokable TP can be started by Host Integration Server 2004 when needed. The TP must be registered through registry entries or environment variables on its local system, so that it can be identified to the SnaBase component of the Host Integration Server 2004 client software. The registered information defines the TP as autostarted and must specify the TP name. The registered information can also specify the local LU alias that the invokable TP will use.

The recommended method for setting registry or environment variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP, or similar code written into your own installation program. For more information about registry or environment variables for invokable TPs, see Configuring Invokable TPs. For information about TPSETUP, see APPC Samples.

If no local LU alias is registered with autostarted TPs, the resulting Host Integration Server 2004 configuration can be more flexible in responding to invoking requests. For more information about such flexible configurations, see TP Name Not Unique; Local LU Alias Unspecified.

After an autostarted invokable TP is started by Host Integration Server 2004, the TP issues RECEIVE_ALLOCATE just as an operator-started TP does. **RECEIVE_ALLOCATE** must provide the TP name that was registered for the TP.

Autostarted TPs must be configured through registry or environment variables to be either queued or nonqueued. All operator-started TPs act as queued TPs.

Queued TPs

If an autostarted TP is configured as queued, or if the TP is operator-started, incoming allocation requests are queued and then sent only when the invokable TP issues **RECEIVE_ALLOCATE**. For autostarted invokable TPs, if a copy of the TP is not yet running, one is started when an incoming allocation request specifies that TP.

> **Note** For Windows 2000, only one copy of a service can be running at any given time; this means that all autostarted TPs that run as services under Windows 2000 must be queued. To write an autostarted TP so it will run under Windows 2000 as a service and also run in a nonqueued way, write a multithreaded program with a **RECEIVE_ALLOCATE** always outstanding.

Nonqueued TPs

If an autostarted TP is configured as nonqueued, a new copy will be started every time an ALLOCATE or MC_ALLOCATE is received for the TP. Nonqueued TPs should process the conversation they have been allocated and then exit, since they will not receive any additional **ALLOCATE** or **MC_ALLOCATE** requests.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Subcategories for Invokable TPs

The following figure shows subcategories for invokable TPs.

Queued or nonqueued	**Application or service**	**Starting method**
Queued	Running as an application or a service	Autostarted or operator-started
Nonqueued	Running as an application	Autostarted

The concept of a TP "running as a service" or "running as an application" is distinct from a service TP or an application TP. Service TP and application TP are SNA terms that describe how a TP is used: either as a supportive service program for other APPC programs, or directly by a user, as an application. For detailed information about services and applications on Windows, see the Microsoft Developer Network (MSDN®) Platform Software Development Kit.

To write an autostarted TP so it will run under Windows as a service and also run in a nonqueued way, write a multithreaded program with a RECEIVE_ALLOCATE always outstanding. See Invokable TPs.

Matching Invoking and Invokable TPs

Each computer running Host Integration Server 2004 maintains a list of available invokable TP names and any LU aliases to be associated with the TP names. This information is obtained as follows:

- For autostarted invokable TPs, registry or environment variables identify a TP name containing a maximum of eight characters, and can specify an associated LU. This information is sent from the client to the server that sponsors the client. A client learns about the domain through a sponsor connection to a server; clients must establish the sponsor connection before proceeding with any other tasks.
- For operator-started invokable TPs, a TP name (with a maximum of 64 characters) is specified with the RECEIVE_ALLOCATE verb. The TP name is truncated to eight characters and sent from the client to the server that sponsors the client, along with the alias of an associated LU if one has been configured through a registry or environment variable.

  > **Note** If you want a TP name to be unique, it is recommended that you limit the name to eight characters or fewer, or make the name unique within the first eight characters. This is because the preliminary routing of allocation requests is carried out using the first eight characters. Although further matching is later carried out between the full TP names specified in ALLOCATE or MC_ALLOCATE and **RECEIVE_ALLOCATE**, it is inefficient to allow the preliminary routing to succeed when in some cases the later matching will fail.

The next step in the matching of invoking and invokable TPs is that the invoking TP issues the **ALLOCATE** or **MC_ALLOCATE** verb. After an invoking TP in a Host Integration Server domain successfully issues this verb, an allocation request flows to the partner LU specified in the **ALLOCATE** or **MC_ALLOCATE** verb, stating the name of the invokable TP that has been requested.

When an allocation request arrives, Host Integration Server compares the requested invokable TP name and LU alias to the list of available invokable TPs (which can include associated LU aliases). The comparison can be modified by registry variables, but by default is carried out as follows:

- Although the TP name requested in the **ALLOCATE** or **MC_ALLOCATE** verb can be as long as 64 characters, any name received through a registry or environment variable is limited to eight characters or less. Therefore, only the first eight characters of TP names are used in comparisons.
- The comparison is carried out first on both the TP name and the LU alias. An invokable TP for which there is a match on both TP name and LU alias will be chosen ahead of a TP for which no LU alias has been configured through a registry or environment variable. A TP for which no LU alias has been configured can be matched with any request that specifies that TP name, since there cannot be a mismatch based on LU alias.
- The comparison of requested and available TP names is carried out in a specific order:
  1. Host Integration Server first checks for operator-started invokable TPs on the local system (the local computer running Host Integration Server 2004).
  2. If no match is found, Host Integration Server checks for autostarted invokable TPs on the local system (the local computer running Host Integration Server 2004).
  3. If no match is found, Host Integration Server checks for operator-started invokable TPs on other Host Integration Server 2004 clients or servers.
  4. If no match is found, Host Integration Server checks for autostarted invokable TPs on other Host Integration Server clients or servers.

This comparison can be modified somewhat by registry entries for the SnaServer service. The entries are called **DloadMatchTPOnly** and **DloadMatchLocalFirst**, and are described in the *Microsoft Host Integration Server 2004 Reference online book*.

If a match is found, Host Integration Server signals the system containing the requested TP to connect to that server running Host Integration Server 2004. If no match is found, Host Integration Server rejects the incoming request.

For suggestions about specific ways to handle TP names and LU aliases, see Arranging TPs Within an SNA Network.

> **Note** Because of the way APPC works, an allocation request will not flow until local data buffers are full, or a confirm or flush verb is issued. This can mean that the allocation request does not flow until some time after the ALLOCATE or MC_ALLOCATE verb is issued. Therefore, any allocation failure caused by the rejection of the allocation request at the partner LU will be observed as the failure of a later verb with one of the allocation failure return codes.

Configuring Invokable TPs

The following topics discuss how to configure invokable transaction programs (TPs) for Microsoft® Host Integration Server 2004 clients.

This section contains:

- Clients Running Windows

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Clients Running Windows

On clients running Microsoft® Windows® 2000, Windows XP, and Windows Server 2003, invokable TPs are configured through the Windows registry.

> **Note** The recommended method for setting registry variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP. Compile INSTALL.C, the source code for TPSETUP, for the Windows environment. When you write an installation program for autostarted invokable TPs, it is recommended that you add code similar to TPSETUP to the installation program. For information about TPSETUP, see APPC Samples.

It is recommended that autostarted invokable TPs be written as Windows services. Be sure to include code like that in TPSETUP in the program that installs your TPs. Among other things, TPSETUP shows how to use the **CreateService** function when installing a TP. For important information about how services work under Windows, see the Microsoft Developer Network (MSDN®) Platform Software Development Kit.

The following table lists the registry entries used for the types of invokable TPs that can be run on Windows clients:

Type of TP	**Location in registry**	**Possible registry entries**
Autostarted invokable TP running as a service	**HKEY_LOCAL_MACHINE** **SYSTEM** **CurrentControlSet** **Services** ***TPName*** (and subkeys)	Registry entries created by the **CreateService** call, including entries that specify the path, display name, and other characteristics of the service. —plus— **Linkage** **OtherDependencies:**REG_MULTI_SZ:SnaBase **Parameters** **SNAServiceType:**REG_DWORD:0x5 **LocalLU:**REG_SZ:*LUalias* **Parameters:**REG_SZ:*ParameterList* **Timeout:**REG_DWORD:*number* **ConversationSecurity:**REG_SZ:{ YES | NO } **AlreadyVerified:**REG_SZ:{ YES | NO }[2] ***Username1:***REG_SZ:*Password1*[2] ... ***UsernameX:***REG_SZ:*PasswordX*[2]
Autostarted invokable TP running as an application	**HKEY_LOCAL_MACHINE** **SYSTEM** **CurrentControlSet** **Services** **SnaBase** **Parameters** **TPs** ***TPName*** Parameters	**SNAServiceType:**REG_DWORD:{ 0x5 | 0x6 } **PathName:**REG_EXPAND_SZ:*path* **LocalLU:**REG_SZ:*LUalias* **Parameters:**REG_SZ:*ParameterList* **TimeOut:**REG_DWORD:*number* **ConversationSecurity:**REG_SZ:{ YES | NO } **AlreadyVerified:**REG_SZ:{ YES | NO }2 ***Username1:***REG_SZ:*Password1*[2] ... ***UsernameX:***REG_SZ:*PasswordX*[2]

Operator-started invokable TP running as a service	**HKEY_LOCAL_MACHINE** **SYSTEM** **CurrentControlSet** **Services** ***TPName*** (and subkeys)	Registry entries created by the **CreateService** call, including entries that specify the path, display name, and other characteristics of the service. —plus— **Linkage** **OtherDependencies:**REG_MULTI_SZ:SnaBase **Parameters** **SNAServiceType:**REG_DWORD:0x1A **LocalLU:**REG_SZ:*LUalias* **Timeout:**REG_DWORD:*number* **ConversationSecurity:**REG_SZ:{ YES | NO } **AlreadyVerified:**REG_SZ:{ YES | NO }[2] ***Username1:***REG_SZ:*Password1*[2] ... ***UsernameX:***REG_SZ:*PasswordX*[2]
Operator-started invokable TP	**HKEY_LOCAL_MACHINE** **SYSTEM** **CurrentControlSet** **Services** **SnaBase** **Parameters** **TPs** ***TPName*** Parameters	**SNAServiceType:**REG_DWORD:0x1A **LocalLU:**REG_SZ:*LUalias* **TimeOut:**REG_DWORD:*number* **ConversationSecurity:**REG_SZ:{ YES | NO } **AlreadyVerified:**REG_SZ:{ YES | NO }2 ***Username1:***REG_SZ:*Password1*[2] ... ***UsernameX:***REG_SZ:*PasswordX*[2]

Notes

APPC Samples

2) **AlreadyVerified** and **Username/Password** entries are used only if **ConversationSecurity** is set to YES.

This section contains:

- Registry Entries for Clients Running Windows 2000
- Example of Windows 2000 Registry Entries for an Invokable TP

Registry Entries for Clients Running Windows 2000

The following list gives details about registry entries for clients running Windows 2000. For each TP type, the applicable variables and their locations are shown in Clients Running Windows.

Registry Entries for TPName on Clients Running Windows 2000

TPName:REG_MULTI_SZ

The name of the transaction program (TP) that is executed. A TP name is up to 64 ASCII characters in length and cannot contain spaces or nulls.

SNA service TPs are a special set of TPs defined by the SNA protocols. Each service TP is a specially-defined function with a special name. An SNA service TP name is represented by up to four EBCDIC bytes; the first byte is a hexadecimal number in the range 0x00 to 0x3F, and the remaining bytes are EBCDIC characters. The first byte defines the function class of the TP. Therefore, to convert a service TP name to an ASCII TP name form, convert the first byte as shown in the following table, and convert the EBCDIC values to ASCII letter equivalents.

First byte of TP name (hexadecimal number)	ASCII character equivalent for WIN.INI
0x07	DDM
0x20	DIA
0x21	SNAD
0x24	FS
0x30	PO
All others	UN

For example, an EBCDIC service TP name of 0x21 0xD7 0xD7 is equivalent to a TP name of SNADPP (0x21 converts to SNAD and each 0xD7 converts to P).

Registry Entries for the TPName Subtree on Clients Running Windows 2000

OtherDependencies:REG_MULTI_SZ:SnaBase

For a TP running as a service, ensures that the SnaBase service will be started before the TP is started. This entry belongs under the **Linkage** subkey.

SNAServiceType:REG_DWORD:{ 0x5 | 0x6 | 0x1A }

Indicates the type of TP. Use a value of 0x5 for an autostarted queued TP, 0x6 for an autostarted nonqueued TP, and 0x1A for an operator-started TP.

Note that the value for an autostarted TP running as a service must be 0x5, because these TPs are always queued, as described in Invokable TPs.

PathName:REG_SZ:*path*

For an autostarted TP running as an application, specifies the path and file name of the TP. The data type of REG_EXPAND_SZ means that the path can contain an expandable data string; for example, %SystemRoot% represents the directory containing the Windows 2000 system files. Note that for a TP running as a service, an equivalent entry is inserted by the **CreateService** call; no additional path entry is needed.

LocalLU:REG_SZ:*LUalias*

Specifies the alias of the local LU to be used when this TP is started on this computer.

Parameters:REG_SZ:*ParameterList*

Lists parameters to be used by the TP. Separate parameters with spaces.

Timeout:REG_DWORD:*number*

Specifies the time, in milliseconds, that a RECEIVE_ALLOCATE will wait before timing out. Specify *number* in decimal; the registry editor converts this to hexadecimal before displaying it. The default is infinity (no limit).

ConversationSecurity:REG_SZ:{ YES | NO }

Indicates whether this TP supports conversation security. The default is NO.

AlreadyVerified:REG_SZ:{ YES | NO }

Indicates whether this TP can be invoked with a user identifier and password that have already been verified. **AlreadyVerified** is ignored if **ConversationSecurity** is set to NO. The default value is NO.

For a diagram of three TPs in a conversation, where the third TP can be invoked with a password that is already verified by the second TP, see Communication between TPs. The following table shows the requirements for using password verification in a chain of TPs.

First TP (invoking TP)	Second TP (invokable TP that confirms password and then invokes another TP)	Third and subsequent TPs (invokable TPs that invoke other TPs)
Does not need registry or environment variables.	**ConversationSecurity** setting must be YES.	**ConversationSecurity** setting must be YES.
Does not need registry or environment variables.	**AlreadyVerified** setting can be YES or NO.	**AlreadyVerified** setting must be YES.
ALLOCATE or MC_ALLOCATE in this TP has a **security** parameter of AP_PGM; as a result, the TP passes along the **user_id** and **pwd** values supplied in **ALLOCATE** or **MC_ALLOCATE**.	**ALLOCATE** or **MC_ALLOCATE** in this TP has a **security** parameter of AP_SAME; as a result, after confirming the user identifier and password, the TP passes along the user identifier and an already-verified flag.	**ALLOCATE** or **MC_ALLOCATE** in this TP has a **security** parameter of AP_SAME; as a result, the TP passes along the user identifier as received, along with the already-verified flag.

If you set **AlreadyVerified** to NO, this TP cannot join in a chain of conversations where password verification is already done. The exception to this is when **ConversationSecurity** is set to NO, in which case the TP could be the final TP in such a chain, since it performs no checking.

If you are configuring a TP that sometimes needs to confirm a password and sometimes accepts an already-verified flag, set **AlreadyVerified** to YES and configure the *UsernameX* variable appropriately. In this case, whenever the TP is invoked without the already-verified flag set, **AlreadyVerified** is ignored; verification is attempted with the user identifier and password configured for the TP.

If you want to have a chain of conversations where the user identifier and password are reverified at every step, carry out the following. For all the TPs, set **ConversationSecurity** to YES, and in each **ALLOCATE** or **MC_ALLOCATE** issued, set the security parameter to AP_PGM and the **pwd** and **user_id** parameters to valid combinations.

If you set **AlreadyVerified** to YES, make sure that **ConversationSecurity** is also set to YES.

Username1:REG_SZ:Password1
...
UsernameX:REG_SZ:PasswordX

Sets one or more user names and passwords to be compared with those sent by the invoking TP. The user name and password can each be as many as 10 characters. Both parameters are case-sensitive.

This variable is ignored if conversation security is not activated or if the password has already been verified, as described for the **AlreadyVerified** entry.

Example of Windows 2000 Registry Entries for an Invokable TP

For an autostarted invokable TP called **BounceTP** and running as a service, the following registry entries might be added to a Windows 2000-based client. The entries would be added to **HKEY_LOCAL_MACHINE\ SYSTEM\ CurrentControlSet\ Services\ SnaBase**, under the subkeys shown in bold type.

> **Note** In the following list, the parameters listed directly under the **BounceTP** key (such as **DisplayName** and **ErrorControl**) are service parameters created when TPSETUP or similar code is run to install the TP. These parameters should be created by TPSETUP or similar code; they should not be set manually. For more information about TPSETUP, see APPC Samples.

BounceTP
DisplayName:REG_SZ:BounceTP
ErrorControl:REG_DWORD:0x1
ImagePath:REG_EXPAND_SZ:c:\sna\system\bouncetp.exe
ObjectName:REG_SZ:LocalSystem
Start:REG_DWORD:0x3
Type:REG_DWORD:0x10

Linkage

OtherDependencies:REG_MULTI_SZ:SnaBase

Parameters

SNAServiceType:REG_DWORD:0x5
LocalLU:REG_SZ:JohnDoe
Parameters:REG_SZ:Arg1 Arg2 Arg3
Timeout:REG_DWORD:0x100
ConversationSecurity:REG_SZ:yes
AlreadyVerified:REG_SZ:no
JohnDoe:REG_SZ:SecretPassword

Security

Security:REG_BINARY:

For an autostarted invokable TP called **BounceTP** running as an application, the following registry entries might be added to a Windows 2000-based client. The entries would be added to **HKEY_LOCAL_MACHINE\SYSTEM\ CurrentControlSet\Services\SnaBase\Parameters\Tps**, under the subkeys shown in bold type.

> **Note** In the following list, the parameters listed under the **BounceTP** key (such as **PathName** and **ConversationSecurity**) are parameters created when TPSETUP or similar code is run to install the TP. These parameters should be created by TPSETUP or similar code; they should not be set manually. For more information about TPSETUP, see APPC Samples.

BounceTP
Parameters

SNAServiceType:REG_DWORD:0x5
PathName:REG_SZ:C:\sna\system\bouncetp.exe
LocalLU:REG_SZ:JohnDoe
Parameters:REG_SZ:Arg1 Arg2 Arg3
Timeout:REG_DWORD:0x100
ConversationSecurity:REG_SZ:yes
AlreadyVerified:REG_SZ:no
JohnDoe:REG_SZ:SecretPassword

Configuring TPs on Host Integration Server

The following topics describe how configuration of invoking and invokable transaction programs (TPs) works on Microsoft® Host Integration Server 2004.

This section contains:

- Configuring Invoking TPs on Host Integration Server
- Configuring Invokable TPs on Host Integration Server

Configuring Invoking TPs on Host Integration Server

For a server running Host Integration Server 2004 to support the beginning of the invoking process (that is, to accept the TP_STARTED and ALLOCATE or MC_ALLOCATE verbs issued by an invoking TP), the following parameters must be configured correctly:

- If the invoking TP specifies in **TP_STARTED** the LU alias that it uses, that LU alias must match a local APPC LU alias on the supporting server running Host Integration Server 2004. If the invoking TP leaves the LU alias blank in **TP_STARTED**, one of two methods for designating a default LU must be carried out on the supporting server running Host Integration Server 2004:
    - Assign a default local APPC LU to the user or group that starts the invoking TP (that is, the user or group logged on at the system from which **TP_STARTED** is issued).
    - Designate one or more LUs as members of the default outgoing local APPC LU pool. The Host Integration Server first attempts to determine the default local APPC LU of the user who started the TP, and then attempts to assign an available LU from the default outgoing local APPC LU pool; if these attempts fail, the Host Integration Server rejects the request.
- In most situations, the supporting Host Integration Server must contain an appropriate connection to another system (host or peer). Sometimes, for testing purposes, the server running Host Integration Server 2004 contains two local LUs paired together (for invoking and invokable TPs that are in the same domain); in this situation, a connection to a host or peer is not necessary.
- If the invoking TP specifies in ALLOCATE or MC_ALLOCATE the partner LU alias, that LU alias must match an LU alias that is paired with the local LU alias specified in TP_STARTED. If the partner LU alias is left unspecified in **ALLOCATE** or **MC_ALLOCATE**, a default remote APPC LU must be assigned to the user who started the invoking TP. The default remote APPC LU is configuring using SNA Manager on Host Integration Server 2004. If the default remote APPC LU is used, it must be paired with the local LU that will be used. Otherwise, **ALLOCATE** or **MC_ALLOCATE** fails.

The preceding parameters support the beginning of the invoking process. For the invoking process to successfully complete, additional parameters must be configured as described in Configuring Invokable TPs on Host Integration Server.

Configuring Invokable TPs on Host Integration Server

For a computer running Host Integration Server 2004 to receive allocation requests from an invoking TP on another system and route those requests to an invokable TP, certain parameters must be configured correctly:

- The Host Integration Server must have a connection to the system from which the invoking TP's request is sent.
- The Host Integration Server must have a remote LU capable of receiving the incoming request. This remote LU can be configured either explicitly or implicitly.

  When configured explicitly, there is an explicit match between a remote LU alias on the Host Integration Server and the alias of the LU that conveys the invoking TP's request.

  When configured implicitly, an implicit incoming remote LU (with its implicit incoming mode) is used. This means that several items must work together. First, the LU alias specified in the incoming request (the LU alias requested for the invokable TP) must match a local LU alias on the Host Integration Server receiving the request. Second, the local LU on the Host Integration Server 2004 server must have an implicit incoming remote LU assigned to it. The properties of the implicit incoming remote LU will be used for that LU-LU session. For more details about how an implicit incoming remote LU works, see Microsoft Host Integration Server 2004 Help.
- Appropriate local LUs must be defined in the Host Integration Server configuration. For descriptions of several ways to set up these local LUs, see Arranging TPs Within an SNA Network.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Arranging TPs Within an SNA Network

If your installation of Microsoft® Host Integration Server contains multiple systems (multiple clients and/or multiple computers running Host Integration Server), you can place a given invokable transaction program (TP) on more than one system. When an invoking request is received in such an installation, there can be a choice of systems on which to run the invokable TP.

You can maintain specific control over this choice or you can allow Host Integration Server to make the choice randomly to distribute the load. To do this, follow the instructions in TP Name Not Unique; Local LU Alias Unspecified.

You can maintain specific control over the choice of system by setting up invokable TPs with unique names, or by setting up each invokable TP to run only with a specific, unique LU alias. With this arrangement, the information provided by the invoking TP (in the **ALLOCATE** or **MC_ALLOCATE** verb) specifies the system on which the invokable TP should run.

You can allow Host Integration Server to make the system choice randomly by setting the **DloadMatchLocalFirst** registry entry to NO and using invokable TPs that leave the local logical unit (LU) alias unspecified. Then, when an incoming request is received, it is routed randomly, rather than preferentially to the local Host Integration Server; in addition, no matter what LU alias is requested for the invokable TP, there cannot be a mismatch. Host Integration Server starts one instance of the requested TP, choosing randomly among the available systems.

This section contains:

- TP Name Unique for Each TP
- TP Name Not Unique; Local LU Alias Unique
- TP Name Not Unique; Local LU Alias Unspecified

TP Name Unique for Each TP

One way to specify the intended system where the invokable TP will run is to use a unique TP name for each invokable TP. In this arrangement, the invoking TP identifies the intended invokable TP (and system) simply by naming the TP. This makes it unnecessary for an invokable TP to specify any LU alias in registry or environment variables.

TP Name Not Unique; Local LU Alias Unique

Another way to specify the intended system where the invokable TP will run is to give the same name to multiple invokable TPs, but associate each TP with a unique local LU alias. To do this, configure each invokable TP (through registry or environment variables) to use a unique local LU alias. Then set up the invoking TPs so that each one is routed not only to the correct TP name but also to the correct partner LU alias for the intended invokable TP.

TP Name Not Unique; Local LU Alias Unspecified

If it does not matter on which system an invokable TP runs, use the same name for multiple invokable TPs and do not specify an LU alias in the registry or environment variables for the TPs. In this situation, there are no associated LU aliases in the list of available invokable TP names on a Host Integration Server. Thus, a request received from an invoking TP cannot cause a mismatch on the LU alias, and will match according to the TP name.

In this situation, if you set the **DloadMatchLocalFirst** registry entry to NO, Host Integration Server randomly routes the request to one of the available TPs. This spreads the processing load among multiple systems and provides hot backup (the ability to take systems online and offline without disrupting service).

Troubleshooting for Invokable TPs

If there are difficulties with starting an invokable TP, there may be a mismatch between the information for the invokable TP, the invoking TP, and/or LUs in the Microsoft® Host Integration Server configuration. That is, there may be a mismatch between the parameters for RECEIVE_ALLOCATE, TP_STARTED, ALLOCATE, or MC_ALLOCATE and/or LU aliases specified in server configuration. LU aliases are configured using SNA Manager on Host Integration Server 2004.

Simplifying APPC Configuration

There are several features in Microsoft® Host Integration Server 2004 that can simplify configuration for APPC:

- The implicit incoming remote LU and the implicit incoming mode, which allow Host Integration Server to accept requests that arrive by unrecognized remote LUs and modes.
- The default local APPC LU and the default remote APPC LU, which allow LU aliases to be associated with user or group names, simplifying the routing of incoming requests and the configuration of client systems.
- The default outgoing local APPC LU pool, which allows LUs to be allocated dynamically to any invoking TP that does not specify a local LU.
- Automatic partnering, which automatically creates LU-LU pairs and assigns modes to the pairs.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Sync Point Level 2 Support in Host Integration Server

The following topics describe additions to Microsoft® Host Integration Server 2004 that enable Sync Point Level 2 support to the LU 6.2 protocol stack.

This section assumes familiarity with the existing Host Integration Server APPC basic and mapped conversation interfaces. It does not attempt to explain the SNA formats and protocols for implementing Sync Point protocols, which are described in *SNA LU6.2 Reference: Peer Protocols* published by IBM (Document SC31-6808-1).

This section contains:

- Sync Point Functional Overview
- Sync Point Support Architecture
- Sync Point Session Support
- Starting Local Sync Point TPs
- Sync Point Conversation Activation
- Sync Point Level 2 Confirm Support
- Sync Point Backout Support
- LUWID, Conversation Correlators, and Session Identifiers
- Configuration Changes for Sync Point Support
- Accepting Incoming Attaches
- Sync Point Examples

Sync Point Functional Overview

The Sync Point support additions to Host Integration Server 2004 allow vendors to provide Sync Point services over LU 6.2 conversations provided by the LU 6.2 protocol stack in Host Integration Server 2004. These additions do not implement the architected Sync Point components and TPs necessary for a complete Sync Point implementation. In particular, the following Sync Point components are not implemented, and must be provided by the vendor.

- Sync Point Services (SPS)
- Conversation-Protected Resource Manager (C-PRM)
- Resynchronization TP

These vendor-supplied components and applications are expected to implement the **SYNCPT** and **BACKOUT** verbs used for Sync Point services. The **SYNCPT** verb is used to synchronize transactions. The **BACKOUT** verb is used to back out of a transaction.

SPS, C-PRM, and the Resynchronization TP are specific components of the SNA Sync Point architecture described in *SNA LU6.2 Reference: Peer Protocols* published by IBM.

Host Integration Server 2004 has been modified to add the features necessary to support these components, namely:

- Additions to the existing APPC API to support implementation of Sync Point verbs.
- Accounting support for Sync Point protocols.
- Modifications to invokable transaction program (TP) initiation.

Changes to the APPC basic and mapped conversation APPC APIs are made so as to ensure backward compatibility with existing APPC applications that adhere strictly to the API.

> **Note** Applications must zero all reserved verb control block (VCB) members before issuing an APPC verb. If this is not done, the application may inadvertently invoke one of the new APPC features.

Sync Point Support Architecture

The Sync Point support provided by Host Integration Server 2004 assumes a particular implementation architecture by the vendor, as follows:

- The vendor provides a communication interface to its own clients requiring Sync Point Services (SPS).
- The vendor API maps its communication and Sync Point requests to the Host Integration Server APPC API.
- The vendor provides a single Microsoft Windows 2000 process, the Transaction Monitor, that is responsible for:
    - Issuing all APPC verbs.
    - Implementing the architected Resynchronization TP.
    - Implementing the architected Conversation-Protected Resource Manager (C-PRM) component of the logical unit (LU).
    - Implementing the architected SPS component of the LU.

  The Transaction Monitor must reside on the same computer as the Host Integration Server containing the LUs for which it is providing Sync Point services. Both incoming and outgoing Sync Point conversations for this Transaction Monitor will be routed through this Host Integration Server 2004 server only.

Detailed descriptions of the three architected Sync Point components can be found in *SNA LU6.2 Reference: Peer Protocols* published by IBM.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Sync Point Session Support

This section discusses support for Sync Point session activation and deactivation in Host Integration Server 2004.

This section contains:

- Sync Point Session Activation
- Sync Point Session Deactivation

Sync Point Session Activation

If Host Integration Server 2004 is to support Sync Point conversations, this must be specified at session activation time. The configuration of Host Integration Server 2004 is modified to allow the system administrator to specify which (if any) local LUs will be used for Sync Point conversations.

The **Local LU Configuration** property page in Host Integration Server contains a new check box. When checked, it indicates that the local LU can participate in Sync Point sessions. Host Integration Server uses this option to determine the parameters it sends on BIND requests and responses.

When Host Integration Server initiates an LU 6.2 session on an LU designated as supporting Sync Point, it sets the synchronization level on BIND requests to indicate that the session can support Sync Point and Backout. If the partner LU also supports Sync Point and Backout, the session is available for conversations requiring Sync Point support. If the partner LU does not support Sync Point, the session will not be used for Sync Point conversations.

Similarly, if the local LU is configured for Sync Point and the partner LU's BIND request indicates that it supports Sync Point, Host Integration Server sends BIND responses specifying that Sync Point is supported. In this case, the session can be used for Sync Point conversations.

Sync Point Session Deactivation

A Sync Point implementation needs to determine whether it has lost connectivity to a partner when establishing Sync Point conversations so that it can know whether or not to resynchronize. To obtain this information, Host Integration Server provides a new APPC verb, GET_LU_STATUS that reports the status of a particular remote LU. The information returned by this verb is as follows:

- Current number of active LU 6.2 sessions between the remote LU and the TP's local LU.
- Whether or not the number of active sessions dropped to zero at any time since this verb was last issued for the remote LU.

Note that the zero sessions indicator is reset to AP_NO each time the verb is issued by any process. It is therefore imperative that only one process issues this verb; otherwise information may be lost.

Starting Local Sync Point TPs

Local TPs are created by issuing the TP_STARTED verb to Host Integration Server. The **TP_STARTED** verb has been modified by adding the new verb control block (VCB) member **syncpoint_rqd** to allow a TP to specify that it requires Sync Point services.

By setting **syncpoint_rqd** to AP_YES, a TP indicates that it requires Sync Point services from Host Integration Server. A value of AP_NO (the default) indicates that Sync Point services are not required.

Since this member cannot be incorporated within the existing **TP_STARTED** VCB, the TP must use a larger VCB structure. To indicate that the VCB is longer than usual, the **opext** member of the VCB must be combined using OR with the value AP_EXTD_VCB before calling APPC.

Conversations started by TPs requiring Sync Point support will be routed only by the Host Integration Server software running on the same computer. They will not be routed to other LAN-attached servers.

Sync Point Conversation Activation

This section discusses support for Sync Point conversation activation in Host Integration Server.

This section contains:

- Locally Initiated Conversations
- Remotely Initiated Conversations
- Already Verified Support
- Presentation Header Support in Data Transfers
- User Control Data
- Implied Forget

Locally Initiated Conversations

Conversations are initiated locally by issuing an ALLOCATE or MC_ALLOCATE verb. The **ALLOCATE** and **MC_ALLOCATE** verbs are modified to support additional parameters required by Sync Point support. The supplied **synclevel** parameter of the **ALLOCATE** and **MC_ALLOCATE** verbs can take on a value of AP_SYNCPT, which specifies that the conversation requested is a Sync Point conversation.

Remotely Initiated Conversations

Applications wishing to receive remotely initiated conversations (incoming Attaches) issue a RECEIVE_ALLOCATE verb. To accommodate Sync Point support, the **RECEIVE_ALLOCATE** verb is modified in a number of ways as follows:

- The returned **sync_level** parameter of the **RECEIVE_ALLOCATE** verb can take on a value of AP_SYNCPT, specifying that the conversation is a Sync Point conversation. The value of the **sync_level** parameter can also be determined by issuing a GET_ATTRIBUTES verb on the new conversation.
- Support is added for the receipt of program initiation parameters (PIP) data by a new parameter to the **RECEIVE_ALLOCATE** verb:

  The **pip_incoming** parameter is set by the application to indicate whether it is willing to accept incoming PIP data, and is returned by Host Integration Server to indicate whether PIP data is available to be received. If the application does not wish to receive PIP data, this member should be set to AP_NO, the default, before issuing the **RECEIVE_ALLOCATE** verb. If it is willing to accept PIP data, this member should be set to AP_YES. On completion of the **RECEIVE_ALLOCATE** verb, this member will be set to AP_YES if PIP data is available to be received by the application and to AP_NO otherwise.

- If PIP data is available, the application can receive it by issuing one of the verbs for receiving data on completion of the RECEIVE_ALLOCATE verb. For basic conversations, these receive verbs include RECEIVE_AND_POST, RECEIVE_AND_WAIT, and RECEIVE_IMMEDIATE. On basic conversations the PIP data will be returned inclusive of the general data stream (GDS) header for PIP data (GDS identifier 0x12F5). For mapped conversations, these receive verbs include MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE. On mapped conversations, Host Integration Server 2004 removes the 4-byte GDS header, and returns the PIP data only.
- For basic conversations, if the application issues a SEND_ERROR, DEALLOCATE, or TP_ENDED verb before the PIP data is received, the PIP data will be discarded. For mapped conversations, if the application issues an MC_SEND_ERROR, MC_DEALLOCATE, or **TP_ENDED** verb before the PIP data is received, the PIP data will be discarded.
- If PIP data is received for a TP that cannot or does not want to receive it, the conversation is rejected with a primary return code of AP_ALLOCATION_ERROR, and a secondary return code of AP_PIP_NOT_ALLOWED.

Already Verified Support

In an implementation where a Host Integration Server application acts as a gateway between an SNA network and a non-SNA network, it is possible that non-Host Integration Server clients of the gateway may require Sync Point Level 2 conversation security. Since the originating client will have validated the relevant user identifier and password, the gateway application should specify conversation security of AP_SAME when starting a conversation on behalf of the client. In this case, however, Host Integration Server assumes that the user identifier to be used has previously been received on an Attach targeted at the TP. In the case of a non-Host Integration Server client this is not the case.

To allow such a gateway to support Sync Point Level 2 conversation security, Host Integration Server provides a new verb, SET_TP_PROPERTIES, which allows the gateway application to set the user identifier for the TP before allocating a conversation with security of AP_SAME. This verb will normally be issued once, immediately after TP_STARTED, to set the user identifier for all the TP's conversations.

Presentation Header Support in Data Transfers

For basic conversations, Sync Point commands are sent by means of presentation headers (PS) across LU 6.2 conversations using the SEND_DATA or MC_SEND_DATA verb. All presentation headers contain length fields that specify a length of 1, which is usually illegal. To support Sync Point conversations, the following modifications are made to the Host Integration Server presentation services component:

- On basic conversations with a **synclevel** of AP_SYNCPT, data transferred specifying a general data stream (GDS) variable length of 1 will not be rejected. If the **synclevel** is not AP_SYNCPT, they will be rejected as before.
- On mapped conversations, PS headers will not be wrapped as mapped conversation application data logical records (with GDS identifier 0x12FF) when they are sent, or have the GDS header stripped off when they are received.
- On mapped conversations, it is the responsibility of the application to provide the complete PS header including the length field. Similarly, the length field will be included in PS header data returned by receive verbs.

To achieve the latter the MC_SEND_DATA verb and the receive verbs (MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE) require modifications as follows:

- A new parameter, **data_type**, is added to the **MC_SEND_DATA** verb. When this is set to AP_APPLICATION (the default, 0x00), the data is sent as application data (GDS identifier 0x12FF) as usual. When it is set to AP_PS_HEADER, the data is sent as described above.
- The following two new values are added for the **what_rcvd** member of the receive verbs to specify that the received data is a PS header:

  AP_PS_HEADER_COMPLETE

  AP_PS_HEADER_INCOMPLETE
- If an application issues a receive verb with **rtn_status** set to AP_YES, Host Integration Server will return status in combination with AP_PS_HEADER_COMPLETE, with the exception of AP_DEALLOCATE_NORMAL and AP_CONFIRM_DEALLOCATE. This is to prevent the conversation being prematurely disconnected from the LU 6.2 session when a COMMIT PS header arrives with the end of conversation indication.

It is the responsibility of the vendor-supplied Sync Point support component to convert these PS headers into the appropriate Sync Point return codes (for example, TAKE_SYNCPT).

User Control Data

For mapped conversations, the MC_SEND_DATA verb and the receive verbs (MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE) are modified to allow applications to send and receive data in user control data general data stream (GDS) variables instead of the regular application data GDS variables. The **MC_SEND_DATA** verb is modified as follows:

- A new parameter, **data_type**, is added. When **data_type** is set to AP_USER_CONTROL_DATA, the data is sent as user control data (GDS identifier 0x12F2). When it is set to AP_APPLICATION (the default), the data is sent as application data (GDS identifier 0x12FF). Note that the APPC library automatically creates the GDS header on behalf of the application for both AP_APPLICATION and AP_USER_CONTROL_DATA data records.
- The mapped conversation receive verbs are modified to allow applications to receive user control data by adding two new values for the **what_rcvd** parameter, as follows:

  AP_USER_CONTROL_DATA_COMPLETE

  AP_USER_CONTROL_DATA_INCOMPLETE

Implied Forget

LU 6.2 Sync Point sessions can use an optimization of the architected message flows known as implied forget. When the protocol specifies that a FORGET presentation header (PS) is required, the next data flow on the session implies that a FORGET has been received, even though it has not. In the normal situation, the TP is aware of the next data flow when data is received or sent on one of its Sync Point conversations.

However it is possible that the last message that flows is caused by the conversation being deallocated. In this case, the TP is unaware when the next data flow on the session occurs. To provide the TP with this notification, the DEALLOCATE and MC_DEALLOCATE verbs are modified to allow the TP to register a callback function which will be called:

- On the first normal flow transmission (request or response) over the session used by the conversation.
- If the session is unbound before any other data flows.
- If the session is terminated abnormally due to a data link control (DLC) outage.

The callback procedure can take any name because the address of the procedure is passed into the APPC DLL.

Note that the **DEALLOCATE** and **MC_DEALLOCATE** verbs will probably complete before the callback routine is called. The conversation is considered to be in RESET state and no further verbs can be issued using the conversation identifier. If the application issues a TP_ENDED verb before the next data flow on the session, the callback routine will not be invoked.

The DEALLOCATE and MC_DEALLOCATE verbs are modified as follows to support implied forget:

- A new member, **callback**, is added to allow the TP to specify the address of the function to call on the next data flow on the session being used by the conversation being deallocated. If this member is NULL, no notification will be provided. A vendor would normally supply this callback function.
- The **DEALLOCATE** and **MC_DEALLOCATE** verbs also contain a correlator member which is returned as one of the parameters when the callback function is invoked. The application can use this parameter in any way (for example, as a pointer to a control block within the application).

Host Integration Server allows TPs to deallocate conversations immediately after sending data by specifying the **type** member in the SEND_DATA and MC_SEND_DATA verbs as AP_SEND_DATA_DEALLOC_FLUSH, AP_SEND_DATA_DEALLOC_SYNC_LEVEL, AP_SEND_DATA_DEALLOC_ABEND, and AP_SEND_DATA_DEALLOC_CONFIRM. However, the **SEND_DATA** and **MC_SEND_DATA** verbs do not contain the implied forget callback function. TPs wishing to receive implied forget notification must issue a DEALLOCATE or MC_DEALLOCATE verb explicitly.

Sync Point Level 2 Confirm Support

The current APPC implementation in Host Integration Server supports conversations with **synclevel** of AP_NONE, AP_CONFIRM_SYNC_LEVEL, or AP_SYNCPT. The DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs specify a **type** member indicating the synchronization level required. This parameter is interpreted as follows:

Allocated synclevel	**Type specified**	**Action performed**
AP_NONE	AP_FLUSH	Action of FLUSH or MC_FLUSH verb before deallocation or change of direction.
AP_NONE	AP_SYNCLEVEL	Action of **FLUSH** or **MC_FLUSH** verb before deallocation or change of direction.
AP_SYNCPT	AP_FLUSH	Action of FLUSH or MC_FLUSH verb before deallocation or change of direction.
AP_SYNCPT or AP_CONFIRM_SYNC_LEVEL	AP_CONFIRM_TYPE	Action of CONFIRM or MC_CONFIRM verb before deallocation or change of direction.
AP_SYNCPT	AP_SYNCLEVEL	It is assumed that a Sync Point implementation built using the APPC API in Host Integration Server implements the defer states appropriately. See the note below.

> **Note** With an allocated **synclevel** of AP_SYNCPT and a specified **type** of AP_SYNCLEVEL, it is assumed that a vendor-supplied Sync Point component implements the defer states appropriately. A vendor-supplied Sync Point system must:

- Intercept DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs on Sync Point Level 2 conversations when type AP_SYNCLEVEL is specified for **synclevel**.
- Maintain the defer state until one of the verbs valid in that state completes.
- On completion of the verb, issue the original **DEALLOCATE**, **MC_DEALLOCATE**, **PREPARE_TO_RECEIVE**, or **MC_PREPARE_TO_RECEIVE** verb to Host Integration Server 2004.

Host Integration Server does not implement the defer states directly. In particular, when a **DEALLOCATE**, **MC_DEALLOCATE**, **PREPARE_TO_RECEIVE**, or **MC_PREPARE_TO_RECEIVE** verb is received with a **type** specified as AP_SYNCLEVEL on a Sync Point conversation, this is treated as if the conversation has a **synclevel** of AP_NONE.

So that Sync Point Level 2 conversations can use confirm type synchronization, the **DEALLOCATE**, **MC_DEALLOCATE**, **PREPARE_TO_RECEIVE**, and **MC_PREPARE_TO_RECEIVE** verbs are modified to support a type member of AP_CONFIRM_TYPE.

The DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs specify a type member indicating the synchronization level required. This parameter is interpreted as follows:

Allocated synclevel	**Type specified**	**Action performed**
AP_NONE	AP_FLUSH	Action of FLUSH or MC_FLUSH verb before deallocation or change of direction.
AP_NONE	AP_SYNCLEVEL	Action of **FLUSH** or **MC_FLUSH** verb before deallocation or change of direction.
AP_CONFIRM_SYNC_LEVEL	AP_FLUSH	Action of **FLUSH** or **MC_FLUSH** verb before deallocation or change of direction.
AP_CONFIRM_SYNC_LEVEL	AP_SYNCLEVEL	Action of CONFIRM or MC_CONFIRM verb before deallocation or change of direction.

Sync Point Backout Support

This section describes back out support for Sync Point conversations.

This section contains:

- Additional Sync Point Return Codes
- Sending Backout on Sync Point Conversations

Additional Sync Point Return Codes

When a remote transaction program (TP) issues a **BACKOUT** verb, the back out is reported to the local TP as a new primary return code value, AP_BACKED_OUT, on the next (current) verb issued. The local TP is provided access to the sense code information contained in the Backout FMH-7 by setting the **secondary_rc** field as follows:

- AP_BO_NO_RESYNC for sense code 0x08240000
- AP_BO_RESYNC for sense code 0x08240001

This new return code will only be supplied on conversations with **synclevel** AP_SYNCPT, and therefore will not be presented to existing applications.

The verbs on which this new return code can be returned are:

CONFIRM

MC_CONFIRM

MC_PREPARE_TO_RECEIVE

MC_RECEIVE_AND_POST

MC_RECEIVE_AND_WAIT

MC_RECEIVE_IMMEDIATE

MC_SEND_DATA

MC_SEND_ERROR

PREPARE_TO_RECEIVE

RECEIVE_AND_POST

RECEIVE_AND_WAIT

RECEIVE_IMMEDIATE

SEND_DATA

SEND_ERROR

Sending Backout on Sync Point Conversations

To send a Backout, an FMH-7 containing a sense code of 0x08240000 or 0x08240001 is sent on the session. This is done using the SEND_ERROR or MC_SEND_ERROR verb. To allow Host Integration Server 2004 to send the appropriate sense data, the **SEND_ERROR** and **MC_SEND_ERROR** verbs are modified as follows:

- A new field, **err_type**, is added to allow the TP to specify the type of error. The default is AP_PROG (0x00), which means existing TPs will continue to work unmodified.
- The **err_type** field in both verbs can take one of two new values, specifying the sense codes to be generated by Host Integration Server 2004:

  AP_BACKOUT_NO_RESYNC for sense code 0x08240000

  AP_BACKOUT_RESYNC for sense code 0x08240001

LUWID, Conversation Correlators, and Session Identifiers

The logical unit-of-work identifier (LUWID), conversation correlators, and session identifiers are important for all Sync Point operations and accounting purposes. The following sections describe how Host Integration Server provides access to these components and, where appropriate, facilities to modify this information.

This section contains:

- Generating and Setting LUWIDs
- Extracting LUWIDs
- Session Identifiers

Generating and Setting LUWIDs

The unit-of-work identifier (LUWID) is used to identify conversations that are part of a single Sync Point transaction. All conversations with the same LUWID are committed (or backed out) at the same time.

Host Integration Server assigns two LUWIDs to a transaction program when the TP is started. For locally started TPs, this is when the TP_STARTED verb is issued. The first LUWID is the TP's protected LUWID. It is used by Host Integration Server 2004 as the LUWID for all **synclevel** AP_SYNCPT conversations allocated by the TP. When the TP issues an ALLOCATE or MC_ALLOCATE verb with a **synclevel** of AP_SYNCPT, Host Integration Server generates an Attach containing the TP's current protected LUWID.

The second LUWID is the TP's unprotected LUWID. It is used on all conversations allocated by the TP with a **synclevel** other than AP_SYNCPT.

For remotely initiated TPs, the incoming Attach may contain an LUWID for the TP—it is mandatory if the conversation has a **synclevel** of AP_SYNCPT. For Sync Point conversations, Host Integration Server saves the LUWID as the TP's protected LUWID and generates a new unprotected LUWID for it. For conversations with a **synclevel** other than Sync Point (AP_SYNCPT), Host Integration Server saves the LUWID as the TP's unprotected LUWID and generates a new protected LUWID.

Host Integration Server generates LUWIDs by concatenating the following:

- The fully qualified name of the local LU, preceded by a single byte indicating its length (exclusive of the length byte).
- A 6-byte LUW instance number, generated from the current date and time (modified to ensure uniqueness if necessary).
- A 2-byte LUW sequence number, initialized to 1.

If the fully qualified LU name component of the LUWID is not 17 bytes long, Host Integration Server does not add any padding between it and the LUW instance number. The application can determine the length of the LUWID, and the offsets within it of the LUW instance number and LUW sequence number, by examining the first byte of the LUWID, which indicates the length of the fully qualified LU name.

When Host Integration Server generates both a protected and an unprotected LUWID for a TP, the unprotected LUWID is created by incrementing the protected LUWID's instance number.

The protected LUWID needs to be changed by a TP for one of four reasons:

- When a transaction is backed out or committed, the LUWID sequence number must be incremented.
- If the transaction tree is split, a new LUWID must be generated for the TP.
- If the application uses multiple logical TPs to implement a transaction, each TP must have the same LUWID (different from that assigned by Host Integration Server).
- If the application is acting as a gateway from a non-SNA environment and LUWIDs are received by a means other than an Attach.

To allow a TP to set or generate new LUWIDs, a new verb, SET_TP_PROPERTIES, is provided by the APPC API. This verb allows the TP to either set its LUWIDs to an existing value, by providing the LUWIDs, or generate new ones and use them from then on. When a new LUWID is generated by Host Integration Server, it is guaranteed to be unique.

Note that it is the responsibility of the application (the Sync Point system component) to transmit the new LUWID PS header to the partner Sync Point system when the protected LUWID is changed. Similarly, when a new LUWID PS header is received, the application must inform the LU by issuing **SET_TP_PROPERTIES**.

Extracting LUWIDs

Both LUWIDs for a particular TP can be determined by issuing the GET_TP_PROPERTIES verb. The **GET_TP_PROPERTIES** verb returns the TP's unprotected LUWID in the **luw_id** field.

If the TP needs to access the protected LUWID, it must combine the **opext** member of the verb control block (VCB) with the value AP_EXTD_VCB using OR before issuing the verb. The protected LUWID will then be returned in the **prot_luw_id** field. If the **opext** field does not contain the AP_EXTD_VCB bit, the verb control block is presumed to end immediately before the **prot_luw_id** field.

The LUWID for a particular conversation can be determined by issuing a GET_ATTRIBUTES or MC_GET_ATTRIBUTES verb on the conversation. These verbs are modified as follows:

- A new field, **luw_id**, is added in which the LUWID is returned. The LUWID returned is the protected one if the conversation was allocated with **synclevel** field of the ALLOCATE or MC_ALLOCATE verb set to Sync Point (AP_SYNCPT); otherwise it is the unprotected one.
- Since the **luw_id** field cannot be incorporated within the existing verb control blocks, the TP must use a larger VCB structure. To indicate that the VCB is longer than usual, the **opext** field of the VCB must be combined with the value AP_EXTD_VCB using OR before calling APPC.
- The **sync_level** field of the **GET_ATTRIBUTES** or **MC_GET_ATTRIBUTES** verb can take an additional value, AP_SYNCPT, when the conversation was allocated with the **synclevel** field of the **ALLOCATE** or **MC_ALLOCATE** verb of Sync Point (AP_SYNCPT).

Session Identifiers

Host Integration Server maintains a unique identification for every LU 6.2 session it has with a remote LU. This 8-byte identifier is generated by Host Integration Server every time it starts a new session (or is received by Host Integration Server when a session is initiated remotely). The Sync Point resynchronization protocols require knowledge of the session identifier.

To provide this, the MC_GET_ATTRIBUTES and the GET_ATTRIBUTES verbs have been modified to return the session identifier of the session over which a particular conversation is allocated. The **MC_GET_ATTRIBUTES** and **GET_ATTRIBUTES** verbs can be used to retrieve this **sess_id** field of the VCB if the **opext** field of the VCB is combined with the value AP_EXTD_VCB using OR before calling APPC.

Configuration Changes for Sync Point Support

A new check box is added to the Local LU Configuration dialog box. When selected, this indicates that the local LU is able to participate in **synclevel** Sync Point sessions. Host Integration Server uses this option to determine the **synclevel** BIND parameters it sends on BIND requests and responses.

This field is added to the Host Integration Server configuration file in a field that is no longer used by Host Integration Server. Existing configurations from earlier versions of Host Integration Server will therefore continue to work unmodified.

Accepting Incoming Attaches

The Sync Point support in Host Integration Server is intended for use only by gateway applications that implement the architected SNA Sync Point components, including Conversation-Protected Resource Manager (C-PRM). In a Sync Point implementation, it is necessary for C-PRM to be aware of all protected conversations, both locally initiated and remotely initiated. This can be achieved in Host Integration Server by C-PRM intercepting the conversation allocation and deallocation verbs and issuing them on behalf of the transaction program (TP). Note that since Host Integration Server does not allow TP or conversation identifiers to be shared across processes, this also means that the process containing C-PRM must also intercept all APPC verbs issued by the client TPs.

For locally initiated TPs, this is straightforward. However for incoming Attaches, the situation is made more complex by the requirement that the RECEIVE_ALLOCATE verb specify the name of the TP to be matched with the Attach.

In some implementations, this will not be an issue, as the gateway will be aware of the names of all the transactions passing through it. To support this situation, the **RECEIVE_ALLOCATE** verb has been enhanced as described in the following topic to permit the gateway to indicate that it can accept Sync Point conversations.

In other implementations, the gateway does not know the names of the transactions passing through it. This is particularly so when the gateway is providing a conversion between SNA and another communications protocol. In this case, Host Integration Server allows the gateway process to register itself as a Sync Point Attach Service, indicating that it is willing to accept incoming Attaches for any Sync Point conversation. In this case, the gateway must be implemented as a Sync Point Attach Manager.

This section contains:

- Sync Point Knows Transaction Names
- Sync Point Attach Manager
- Rejecting Remotely Initiated Conversations

Sync Point Knows Transaction Names

A Sync Point implementation that knows the names of all the transactions that can be supported (for example, through configuration of the gateway) may accept incoming Sync Point conversations by issuing a RECEIVE_ALLOCATE verb specifying the name of the transaction and indicating that it is willing to accept Sync Point conversations.

The **RECEIVE_ALLOCATE** verb was modified to allow a TP to specify that it can accept Sync Point conversations by adding a new **syncpoint_rqd** field to the VCB. When this field is set to AP_YES it indicates that the transaction program can accept Sync Point conversations from Host Integration Server. When this field is set to AP_NO (the default), it indicates that Sync Point conversations are not supported.

Sync Point Attach Manager

Instead of issuing separate RECEIVE_ALLOCATE verbs for each possible transaction name, a Sync Point implementation may instead register as the Sync Point Attach Manager for Host Integration Server. It does so by issuing a **RECEIVE_ALLOCATE** verb specifying a TP name consisting of all 0x00s.

When a Sync Point Attach Manager is registered, the following changes are effected in server's incoming Attach support on Host Integration Server:

- When an Attach message arrives for any TP name on a conversation with the **syncpoint_rqd** field of the VCB set to AP_YES, Host Integration Server 2004 matches it with the application that issued the special **RECEIVE_ALLOCATE** verb registering itself as the Sync Point Attach Manager.
- Any Attach message arriving for the Resynchronization TP (0x06F2) will automatically be routed to the Sync Point Attach Manager.
- If no **RECEIVE_ALLOCATE** has been issued for the Sync Point Attach Manager, or for the specific TP name, Host Integration Server will queue the Attach for a configured period of time. If no **RECEIVE_ALLOCATE** is issued in that time, the Attach will be rejected with a return code of TP_NOT_AVAILABLE_RETRY.
- If a **RECEIVE_ALLOCATE** is matched with the Attach message, the verb is returned to the TP with the **tp_name** field of the VCB set to the TP name contained in the Attach message.

Applications using this feature must adhere to two restrictions:

- All verbs issued on conversations started in this manner must be issued by the same process, as Host Integration Server cannot pass **tp_id**s between processes.
- Only a single process may register as the Sync Point Attach Manager on any server running Host Integration Server 2004. If a second process attempts to register, its **RECEIVE_ALLOCATE** verb will return immediately with the primary return code set to AP_SYNCPOINT_MANAGER_ACTIVE.

Sync Point Attach Manager applications must reside on a Host Integration Server 2004 server. They may not be distributed across Host Integration Server clients. This restriction is imposed to ensure that only a single instance of Sync Point Services (SPS) and Conversation-Protected Resource Manager (C-PRM) exists for each LU on the Host Integration Server (which might not be the case if Sync Point Attach Managers were visible from multiple servers in the Host Integration Server domain).

The structure of the RECEIVE_ALLOCATE verb control block does not require modification to support this function.

Rejecting Remotely Initiated Conversations

In an environment where a Sync Point Attach Manager is receiving all Attach messages as described above, it may be necessary for it to reject an Attach for a particular TP name, either because the TP name is not valid or because there is another problem with the received Attach message. To enable the application to generate the correct return code at the initiating TP, the DEALLOCATE and MC_DEALLOCATE verbs are enhanced with new **deallocate_type** field values in the VCB that allow the application to specify the return code to be sent to the initiating TP. The new values for **deallocate_type** are:

AP_TP_NOT_AVAIL_RETRY

AP_TP_NOT_AVAIL_NO_RETRY

AP_TPN_NOT_RECOGNIZED

AP_PIP_DATA_NOT_ALLOWED

AP_PIP_DATA_INCORRECT

Sync Point Examples

This section contains example verb sequences for implementing the architected Sync Point verbs using the Sync Point facilities provided by Host Integration Server.

In the following figures, TP is the transaction program that requires Sync Point services. Vendor API is the vendor-supplied APPC API. This component provides the SPS and C-PRM components and a mapping between the vendor's APPC syntax and that of Host Integration Server. APPC API is the Host Integration Server APPC basic and mapped conversation interface.

This section contains:

- SYNCPT Verb Issued Locally
- SYNCPT Verb Issued Remotely
- BACKOUT Verb Issued Locally
- BACKOUT Verb Issued Remotely

SYNCPT Verb Issued Locally

This section provides an example verb sequence with a verb issued locally.

1. The transaction program issues a SEND_DATA or MC_SEND_DATA verb depending on whether a basic or mapped conversation is being used.
2. The **SEND_DATA** or **MC_SEND_DATA** VCB is passed transparently through the vendor API to Host Integration Server 2004. When the verb completes, the return code from Host Integration Server 2004 is returned to the transaction program.
3. The transaction program issues a **SYNCPT** verb to the vendor API.
4. The vendor API creates a PREPARE PS header and transmits it by issuing a **SEND_DATA** or **MC_SEND_DATA** verb. For a mapped conversation, the data_type field of the **MC_SEND_DATA** VCB must be set to AP_PS_HEADER.
5. On completion of the **SEND_DATA** or **MC_SEND_DATA** verb, the vendor API issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb.
6. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with the **what_rcvd** field of the VCB with a value of AP_PS_HEADER. The data buffer is filled with the received REQUEST_COMMIT PS header.
7. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued to get send direction. Note that the vendor API can combine these two verbs into a single request by setting the **rtn_status** field of the VCB to AP_YES in order to receive status with data on the first RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT.
8. A COMMITTED PS header is then transmitted using a SEND_DATA or MC_SEND_DATA verb.
9. The Vendor API issues a **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb to receive the FORGET PS header from the remote TP.
10. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued with the **what_rcvd** field of the VCB set to AP_SEND to get send direction (again the **rtn_status RECEIVE_AND_WAIT** field of the VCB can be set to AP_YES to combine these two verbs).
11. When send indication is received, the vendor API returns the **SYNCPT** verb to the local transaction program with an OK return code.

1. The local TP issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb (depending on whether a basic or mapped conversation is being used) to receive data from the remote transaction program. The vendor API passes the verb transparently to Host Integration Server.
2. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with **what_rcvd** = AP_PS_HEADER. The data buffer contains a PREPARE PS header.
3. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued by the vendor API to receive the send indication from the remote TP.
4. The vendor API returns the transaction program's **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb with the **what_rcvd** field of the VCB set to TAKE_SYNCPT.
5. The transaction program issues a **SYNCPT** verb.
6. The vendor API generates a REQUEST_COMMIT PS header and transmits it using a SEND_DATA or MC_SEND_DATA verb. If the conversation is mapped, the **MC_SEND_DATA** verb is issued with the **data_type** field of the VCB set to AP_PS_HEADER.
7. The vendor API then issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb to give the remote TP direction to send.
8. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with the **what_rcvd** field of the VCB set to AP_PS_HEADER. The data buffer contains a COMMITTED PS header.
9. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued to get permission to send.
10. A FORGET PS header is prepared and sent to the remote transaction program.
11. The FORGET is flushed and direction given to the remote transaction program by issuing a PREPARE_TO_RECEIVE or MC_PREPARE_TO_RECEIVE with the **ptr_type** field of the VCB set to AP_FLUSH.
12. When the **PREPARE_TO_RECEIVE** or **MC_PREPARE_TO_RECEIVE** verb completes, the vendor API returns the **SYNCPT** verb to the local transaction program.

BACKOUT Verb Issued Locally

1. The local transaction program issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb (depending on whether a basic or mapped conversation is being used) to receive data from the remote transaction program. The vendor API passes the verb transparently to Host Integration Server.
2. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with the **what_rcvd** field of the VCB set to AP_PS_HEADER. The data buffer contains a PREPARE PS header.
3. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued by the vendor API to receive the send indication from the remote TP.
4. The vendor API returns the transaction program's **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb with the **what_rcvd** field of the VCB set to **TAKE_SYNCPT**.
5. The transaction program issues a **BACKOUT** verb to back out the transaction.
6. The vendor API generates a SEND_ERROR or MC_SEND_ERROR verb of type BACKOUT_RESYNC to send the Backout sense code 0x08240001.
7. The vendor API then issues a CONFIRM or MC_CONFIRM verb to flush the **SEND_ERROR** or **MC_SEND_ERROR** verb and request a response from the remote transaction program.
8. The CONFIRM or MC_CONFIRM verb completes when the remote transaction program issues a CONFIRMED or MC_CONFIRMED verb. The vendor API then returns the **BACKOUT** verb to the local transaction program.

1. The transaction program issues a SEND_DATA or MC_SEND_DATA verb depending on whether a basic or mapped conversation is being used.
2. The **SEND_DATA** or **MC_SEND_DATA** VCB is passed transparently through the vendor API to Host Integration Server. When the verb completes the return code from Host Integration Server is returned to the transaction program.
3. The transaction program issues a **SYNCPT** verb to the vendor API.
4. The vendor API creates a PREPARE PS header and transmits it by issuing a **SEND_DATA** or **MC_SEND_DATA** verb. For a mapped conversation, the data_type field of the **MC_SEND_DATA** VCB must be set to AP_PS_HEADER.
5. On completion of the **SEND_DATA** or **MC_SEND_DATA** verb, the vendor API issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb.
6. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb returns with a return code of AP_BACKED_OUT, indicating that the remote transaction program issued a **BACKOUT** verb.
7. The vendor API issues another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb to receive the Confirm indication.
8. When the verb completes with the **what_rcvd** field of the VCB set to AP_CONFIRM, the vendor API issues a CONFIRMED or MC_CONFIRMED verb to acknowledge the **BACKOUT** verb.
9. The **SYNCPT** verb is returned to the transaction program with a BACKED_OUT return code when the **CONFIRMED** or **MC_CONFIRMED** verb completes.

Windows CSV Overview

Common service verbs (CSVs) are a set of programming functions provided by Microsoft® Host Integration Server 2004. The CSVs provide convert, log, trace, and transfer services to applications.

The CSVs and information presented in this section represent an evolving CSV API that is composed of IBM Extended Services for OS/2 and a set of Microsoft Windows® extensions that allow for registering and deregistering the application, and that provide an asynchronous entry point for TRANSFER_MS_DATA.

This section describes the verbs available to you and explains how to use them with your applications. A detailed description of each verb is provided in the reference portion of the SDK.

The CSVs are as follows:

CONVERT
Converts a character string from ASCII to EBCDIC or from EBCDIC to ASCII.

COPY_TRACE_TO_FILE
Concatenates the contents of the individual application programming interface (API)/link service trace files to form a single trace file.

DEFINE_TRACE
Enables or disables tracing for specific APIs.

GET_CP_CONVERT_TABLE
Creates and returns a 256-byte conversion table to translate character strings from a source code page to a target code page.

LOG_MESSAGE
For OS/2 only, takes a message from a message file, adds specified data to it, and records the message in the error log file. This verb optionally displays the message on the user's screen.

TRANSFER_MS_DATA
Builds a Systems Network Architecture (SNA) request unit (RU) containing Network Management Vector Transport (NMVT) data. The verb can send the NMVT data to NetView for centralized problem diagnosis and resolution. The data is optionally logged in the event log for Windows 2000.

- Issuing a CSV

Host Integration Server Asynchronous Support

Asynchronous call completion returns the initial call immediately so the application can continue with other processes. An application that issues a call and does not regain control until the operation completes is not able to perform any other operations. This type of operation, referred to as blocking, is not suited to a server application designed to handle multiple requests from many clients.

Through **RegisterWindowsMessage** with "WinAsyncCSV" as the string, you pass a window handle by which you will be notified of call completion. You then make your call and when it completes, a message is posted to the window handle that you passed, notifying you that the call is complete.

Before Using Windows CSV

The following Microsoft® Windows® extensions are of particular importance and should be reviewed before using Windows CSV:

WinAsyncCSV

Provides an asynchronous entry point for TRANSFER_MS_DATA only. If used for any other verb, the behavior will be synchronous. Use this extension instead of the blocking version of the verb if you run your application under Microsoft® Windows® version 3.*x*.

When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinAsyncCSV" as the input string. The *wParam* argument contains the asynchronous task handle returned by the original function call. The *lParam* argument contains the original verb control block (VCB) pointer and can be dereferenced to determine the final return code.

If the function returns successfully, a "WinAsyncCSV" message is posted to the application when the operation completes or the conversation is canceled.

WinCSVCleanup

Terminates and deregisters an application from a Windows CSV implementation.

> **Important** An application must call this function to deregister itself from the Windows CSV implementation.

WinCSVStartup

Allows an application to specify the version of Windows CSV required and to retrieve details of the specific CSV implementation.

> **Important** An application must call this function to register itself with a Windows CSV implementation before issuing any further Windows CSV calls.

Creating Specific NetView User Alerts

You can create NetView user alerts for users to send. Users identify the alerts by number; each number corresponds to a specific collection of information or requests that the user wants to send via NetView to a host operator.

Microsoft® Host Integration Server leaves blank fields for the user alert information in the structure that is returned from the sepdcrec function. To create specific user alerts, create appropriate data structures and call the TRANSFER_MS_DATA verb to send the user alert to NetView.

Using CSVs in C Programs

CSVs are available to C applications through the external function **WINCSV**.

Sample Programs

A collection of sample programs is delivered with the Microsoft® Host Integration Server Software Development Kit (SDK) in the \SDK\SAMPLES directory on the Host Integration Server CD. For more information, see APPC Samples.

CSV Verb Control Block

The only parameter passed to the **WINCSV** function is the address of a verb control block (VCB). The VCB is a structure made up of variables that identify the verb to be executed, supply information to be used by the verb, and contain information returned by the verb when execution is complete. Each verb has its own VCB structure, which is declared in the file WINCSV.H.

Bit Ordering

Bit 0 refers to the high-order bit in a byte or word. To set bit 0 on in a byte, use the bitwise **OR** operation (=) with a value of 128.

WINCSV Definition

The prototype definition of the **WINCSV** function is as follows:

```
extern void WINAPI WINCSV (LPCSV);
```

The verb control block (VCB) address parameter, a 32-bit pointer, is declared as a long integer and requires casting from a pointer to a long integer.

WINCSV.H File

Use the **#include** command to include the WINCSV.H file in any application that issues CSVs.

The WINCSV.H file, which is included with the Microsoft® Host Integration Server Software Development Kit (SDK), contains:

- The CSV function prototype.
- The structure declarations for the CSV verb control blocks (VCBs).
- The **#define** statements that substitute meaningful symbolic constants for hexadecimal values supplied to and returned by CSVs.

If a **#define** statement pertains to a hexadecimal value that is longer than one byte, a comment shows how the hexadecimal value is stored in memory.

When setting or testing CSV parameters, use the symbolic constants defined by the WINCSV.H file. When examining trace files or the contents of memory, use the hexadecimal values.

Issuing a CSV

The procedure for issuing a CSV is shown in the following sample code that uses CONVERT.

To issue a CSV

1. Create a structure variable from the verb control block (VCB) structure that applies to the verb to be issued.

   ```
   #include <wincsv.h>
       .
       .
   struct convert  conv_block;
   ```

   The VCB structures are declared in the WINCSV.H file; one of these structures is named **CONVERT**.

2. Clear (set to zero) the variables within the structure.

   ```
   memset( conv_block, '\0', sizeof( conv_block ) );
   ```

   This procedure is not required. However, it helps in debugging and reading the contents of memory. It also eliminates the possibility that future versions of a verb are sensitive to fields that are ignored in the current version.

3. Assign values to the required VCB variables.

   ```
   conv_block.opcode = SV_CONVERT;
   conv_block.direction = SV_ASCII_TO_EBCDIC;
   conv_block.char_set = SV_AE;
   conv_block.len = sizeof(tpstart_name);
   conv_block.source = (LPBYTE) tpstart_name;
   conv_block.target = (LPBYTE) tpstart.tp_name;
   ```

   The values SV_CONVERT, SV_ASCII_TO_EBCDIC, and SV_AE are symbolic constants representing integers. These constants are defined in the WINCSV.H file.

   The character array TPSTART_NAME contains an ASCII string to be converted to EBCDIC and placed in the character array TPSTART.TP_NAME.

4. Invoke the verb. The only parameter is a pointer to the address of the structure containing the VCB for the verb.

   ```
   ACSSVC((LONG) &conv_block);
   ```

   You can also use the following statement:

   ```
   ACSSVC_C((LONG) &conv_block);
   ```

5. Use the values returned by the verb.

   ```
   if( conv_block.primary_rc == SV_OK ) {
   /* other statements */
       .
       .
       .
   ```

Support for APPC Automatic Logon

This section describes the support for automatic logon for Advanced Program-to-Program Communications (APPC) applications available in Microsoft® Host Integration Server 2004. This feature requires specific configuration by the network administrator.

The APPC application must be invoked on the local area network (LAN) side from a client of Host Integration Server 2004. The client must be logged on to a Microsoft Windows Server™ 2003, Microsoft Windows® XP, or Windows 2000 domain.

The client application is coded to use "program" level security, with a special hard-coded APPC user name (MS$SAME) and password (MS$SAME). When this session allocation flows from client to Host Integration Server, the server looks up the host account and password corresponding to the Windows 2000 account under which the client is logged on, and substitutes the host account information into the APPC attach message it sends to the host.

To use this feature for an APPC application, the **user_id** and **pwd** fields in the ALLOCATE or MC_ALLOCATE verbs must be hard-coded to use the string mentioned above, and **security** must be set to AP_PGM.

CPI-C Programmer's Guide

This section of the Microsoft® Host Integration Server 2004 Developer's Guide provides information about developing applications with the Common Programming Interface for Communications (CPI-C).

For API references and other technical information for CPI-C, see the CPI-C Programmer's Reference section of the SDK.

For sample code using CPI-C, see CPI-C Samples section of the SDK.

This section contains:

- Introduction to CPI-C
- CPI-C Call Summary
- Writing CPI-C Applications
- Support for CPI-C Automatic Logon
-

Introduction to CPI-C

Common Programming Interface for Communications (CPI-C) is an application programming interface (API) that enables peer-to-peer communications among programs in a Systems Network Architecture (SNA) environment.

Through CPI-C, programs distributed across a network can work together, communicating with each other and exchanging data, to accomplish a single processing task such as querying a remote database, copying a remote file, or sending and receiving electronic mail.

The CPI-C calls and information presented in this section represent an evolving Microsoft® Windows® CPI-C that is composed of CPI-C version 1.2 and a set of Windows extensions that enable multiple applications and asynchronous call completion.

CPI-C version 1.0 was first introduced to provide a means by which two applications could speak and listen to each other; in other words, have a conversation. A conversation is the logical connection between two programs that enables the programs to communicate with each other. Programs using CPI-C converse with each other by making program calls. These calls are used to establish the full characteristics of the conversation, to exchange data, and to control the information flow between the two programs.

CPI-C version 1.1 includes four new areas of function:

- Support for resource recovery (not supported in Windows CPI-C).
- Automatic parameter conversion.
- Support for communicating with non-CPI-C programs.
- Local and remote transparency.

Built upon CPI-C version 1.1, X/Open CPI-C provided the following:

- Support for nonblocking calls.
- The ability to accept multiple conversations.
- Support for data conversion (beyond parameters).
- Support for security parameters.

CPI-C version 1.2 consolidated CPI-C version 1.1 and X/Open CPI-C and provided all the functions described previously. Windows CPI-C adds to this functionality by providing a set of extensions for asynchronous communication in addition to supporting most features in CPI-C version 1.2 with the exception of the following features:

- Full duplex operation.
- Nonblocking call behavior (as defined in the CPI-C 1.2 specification).
- Some data conversion functions.

For a complete list of unsupported functions, see CPI-C Functions Not Supported.

The use of the Windows CPI-C interface on Microsoft® Windows Server™ 2003 and Windows 2000 causes additional threads to be created within the calling process. These other threads perform interprocess communication with the SNA service over the local area network (LAN) interface that the client is configured to use (TCP/IP, IPX/SPX, or named pipes, for example).

Stopping the SNABASE service causes the application to be unloaded from memory.

Windows CPI-C Asynchronous Support

A program that issues a call and does not regain control until the call completes cannot perform any other operations. This type of operation, referred to as blocking, is not suited to a server application designed to handle multiple requests from many clients. Asynchronous call completion returns the initial call immediately, so the application can continue with other processes.

Windows® Common Programming Interface for Communications (CPI-C) support is related to asynchronous communications and includes the following calls and extensions:

- Set_Processing_Mode
- Specify_Windows_Handle
- Wait_For_Conversation
- WinCPICExtractEvent
- WinCPICIsBlocking
- WinCPICSetBlockingHook
- WinCPICSetEvent
- WinCPICUnhookBlockingHook

Two methods under Microsoft® Windows Server™ 2003 and Windows 2000 are available for asynchronous verb completion:

- Message posting using window handles.
- Waiting for Win32® events.

The traditional method uses messages posted to a window handle to notify an application of verb completion. This method was used in earlier versions of the product to support Windows 3*.x*.

Asynchronous support using message posting is appended to the Set_Processing_Mode call and enables an application to be notified of call completion on a window handle. Calling **RegisterWindowsMessage** with "WinAsyncCPIC" as the string, an application passes a window handle by which the application is notified of call completion. The application then makes the CPI-C call, and when it completes a message is posted to the window handle that was passed, notifying the application that the call is complete.

With the exception of an asynchronous Receive call that can issue certain other calls while pending, a conversation can have only one incomplete operation at any time. For more information about using an asynchronous **Receive** call, see Using Asynchronous Call Completion. In the case of an incomplete operation, the program can issue Wait_For_Conversation to test for its completion or Cancel_Conversation to end the conversation and the incomplete operation.

A second method using Win32 events for notification is supported on Microsoft® Host Integration Server 2004.

If an event has been registered with the conversation using **WinCPICSetEvent**, an application can call the Win32 **WaitForSingleObject** or **WaitForMultipleObjects** function to wait to be notified of the completion of the verb.

The only Windows extension functions required for Windows CPI-C are for initialization (WinCPICStartup) and termination (WinCPICCleanup) purposes. Depending on your application, other Windows extensions for handling asynchronous verb completion can be useful, but they are not required. For an example of how to use Windows CPI-C asynchronous calls and Windows extensions, see Using Asynchronous Call Completion. For a complete description of all Windows CPI-C calls and extensions, see CPI-C Calls and Extensions for the Windows Environment.

Before Using Windows CPI-C

The following Common Programming Interface for Communications (CPI-C) calls and Windows® extensions are of particular importance. You should review them before using Microsoft® Host Integration Server 2004.

> **Note** The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonym. For example, **Set_Processing_Mode** is the pseudonym for a call. The actual function name is **cmspm**.

Set_Processing_Mode (**cmspm**)

Specifies for the conversation whether subsequent calls are returned when the operation they request is complete (blocking) or immediately after the operation is initiated (nonblocking). A program is notified of the completion of nonblocking calls when it issues **Wait_For_Conversation** or through a Windows message sent to a WndProc identified by *hwndNotify* in **Specify_Windows_Handle**. When the processing mode is set for a conversation, it applies to all subsequent calls on the conversation until the mode is set again.

Specify_Windows_Handle (**xchwnd**)

Sets the window handle to which a message is sent on completion of an operation in nonblocking mode.

Wait_For_Conversation (**cmwait**)

Waits for the completion of an operation that was initiated when the processing mode conversation characteristic was set to CM_NON_BLOCKING and CM_OPERATION_INCOMPLETE was returned in the *return_code* parameter. Use **Wait_For_Conversation** when running a background thread or a single-threaded application for Microsoft® Windows Server™ 2003 or Windows 2000. This most likely occurs when porting code from older versions of Host Integration Server and SNA Server.

> **Important** An application can set the processing mode by calling **Set_Processing_Mode**. If the window handle is set to NULL, or this call is never issued, the application must call **Wait_For_Conversation** to be notified when the outstanding operation completes.

When an asynchronous operation is complete, the application's window *hwndNotify* receives the message returned by **RegisterWindowMessage** with "WinAsyncCPIC" as the input string. The *wParam* value contains the conversation return code from the operation that is completing. Its values depend on which operation was originally issued. The *lParam* argument contains the CM_PTR to the conversation identifier specified in the original function call.

WinCPICCleanup

Terminates and unregisters an application from a Windows CPI-C implementation.

> **Important** This function must be called by an application when finished to unregister the application from the Windows CPI-C implementation.

WinCPICExtractEvent

Provides a method for an application to determine the event handle being used for a CPI-C conversation.

WinCPICIsBlocking

Determines if a task is executing while waiting for a previous blocking call to finish. This was used when Windows version 3.*x* went into a **PeekMessageLoop** while allowing Windows to continue. Although a call issued on a blocking function appears to an application as though it blocks, the Windows CPI-C dynamic-link library (DLL) has to relinquish the processor to allow other applications to run. This means that it is possible for the application that issued the blocking call to be re-entered, depending on the messages it receives. In this instance, **WinCPICIsBlocking** can be used to determine whether the application task currently has been re-entered while waiting for an outstanding blocking call to finish.

This extension is intended to provide help to an application written to use the CM_BLOCKING characteristic of the Windows **Specify_Processing_Mode** function. **WinCPICIsBlocking** serves the same purpose as **InSendMessage** in the Windows API.

Older applications that were originally targeted at Windows version 3.*x* and that support multiple conversations must specify CM_NONBLOCKING in **Specify_Processing_Mode** so they can support multiple outstanding operations simultaneously. Applications are still limited to one outstanding operation per conversation in all environments.

> **Note** Windows CPI-C prohibits more than one outstanding blocking call per thread.

WinCPICSetBlockingHook

Allows a Windows CPI-C implementation to block CPI-C function calls by means of a new function. Blocking calls apply only if you do not use asynchronous calls. If a function needs to block, the blocking call is called repeatedly until the original request completes. This allows Windows to continue to run while the original application waits for the call to return. Note that while inside the blocking call, the application can be re-entered. **WinCPICSetBlockingHook** was used by Windows version 3.*x* applications that went into a **PeekMessageLoop** to make blocking calls without blocking the rest of the system.

Note By default, Windows Server 2003 and Windows 2000 do not go into a **PeekMessageLoop**. Rather, they block an event waiting for the call to complete. The only time you need to use **WinCPICSetBlockingHook** for Windows Server 2003 or Windows 2000 is when a single-threaded application for Windows Server 2003 or Windows 2000 shares common source code. In this case, you must explicitly make this call. Contrast this call with **WinCPICIsBlocking** and **WinCPICUnhookBlockingHook**.

WinCPICSetEvent	Associates a Win32® event handle with a verb completion.
WinCPICStartup	Allows an application to specify the version of Windows CPI-C required and to retrieve details of the specific CPI-C implementation.

Important An application must call this function to register itself with a Windows CPI-C implementation before issuing any further Windows CPI-C calls.

WinCPICUnhookBlockingHook	Removes any previous blocking hook that has been installed and reinstalls the default blocking mechanism.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Using Asynchronous Call Completion

With one exception, Microsoft® Host Integration Server permits one outstanding Windows® SNA asynchronous call per connection and one blocking verb per thread. The exception to this is that when issuing an asynchronous Receive call, the following calls can be issued while the **Receive** is outstanding:

- Cancel_Conversation
- Deallocate
- Request_To_Send
- Send_Error
- Test_Request_To_Send_Received

This enables an application, in particular a 5250 emulator, to use an asynchronous **Receive** to receive data. Use of this feature is strongly recommended.

The following example illustrates how to use asynchronous call completion with Host Integration Server:

```
void ProcessVerbCompletion (WPARAM wParam LPARAM lParam)
{
    for ( i = 0; i<nPendingVerbs; i++ )
        if (memcmp  (pPending [i].ConvID, (Conversation_ID) lParam)== 0)
            ProcessCommand  (wParam, lParam);
}

LRESULT CALLBACK SampleWndProc  ( . . .)
{
    if (msg = = uAsyncCPIC ) {
        ProcessVerbCompletion (wParam, lParam);
    }
    else switch  (msg)  {
       case WM_USER:
        Initialize_Conversation (lpConvId, "GORDM", &lError  );
        if  (lError  ! = CM_OK )   {
            ErrorDisplay ( ) ;
            break ;
        }
        Set_Processing_Mode (lpConvId, CM_NON_BLOCKING, &lError  ) ;
        if  ( lError ! = CM_OK )  {
            ErrorDisplay ( ) ;
            break ;
        }
        Allocate  (lpConvId,  &lError )  ;
        switch  (lError )  {
        case CM_OK:
            break ;
        case CM_OPERATION_INCOMPLETE:
            memcopy (pPending [nPending ++].ConvId, lpConvId, sizeof (C) ;
            break ;
        default:
            ErrorDisplay ( ) ;
        }
        break ;
}
WinMain  ( . . . )
{
    if  ( ( WinCPICStartup  ( . . . )  =  =  FALSE  )   {
        return FALSE;
    }
    uAsyncCPIC = RegisterWindowMessage  ("WinAsyncCPIC"");
    Specify_Windows_Handle  (hwndSample) ;
    while  (GetMessage  ( . . . )   )   {
    . . . . .
    }
    WinCPICCleanup  ( . . . )
}
```

For more information about CPI-C calls and Windows extensions, see CPI-C Calls and Extensions for the Windows Environment. For additional information about using CPI-C, see the *IBM Systems Application Architecture Common Programming Interface Communications Reference*, part number SC26-4399-04.

Initial Conversation Characteristics

Common Programming Interface for Communications (CPI-C) maintains a set of internal values called characteristics for each conversation. Some characteristics affect the overall operation of the conversation, such as the conversation type. Others affect the behavior of specific calls, such as the receive type.

Many of these characteristics are initially derived from the side information table (see Side Information for CPI-C Programs) in memory. Initialize_Conversation specifies the symbolic destination name (*sym_dest_name*) associated with the wanted side information table entry.

The following table lists the initial values of the conversation characteristics and tells which call can change a given value.

Characteristic	Initial value set by Initialize_Conversation	Initial value set by Accept_Conversation	Can be changed by
Conversation state	CM_INITIALIZE_STATE	CM_RECEIVE_STATE	Depends on call
Conversation type	CM_MAPPED_ CONVERSATION	The value specified by the invoking program.	Set_Conversation_Type
Deallocate type	CM_DEALLOCATE_ SYNC_LEVEL	CM_DEALLOCATE_ SYNC_LEVEL	Set_Deallocate_Type
Error direction	CM_RECEIVE_ERROR	CM_RECEIVE_ ERROR	Set_Error_Direction
Fill	CM_FILL_LL	CM_FILL_LL	Set_Fill
Log data	Null	Null	Set_Log_Data
Log data length	0	0	Set_Log_Data
Mode name	The mode name contained in the side information. If no *sym_dest_name* is specified, this is a null string.	The mode name for the session on which the conversation startup request arrived.	Set_Mode_Name
Mode name length	Length of mode name. If no *sym_dest_name* is specified, this is zero.	Length of mode name.	Set_Mode_Name
Partner LU name	The partner logical unit (LU) name contained in the side information. If no *sym_dest_name* is specified, this is a single blank.	The partner LU name for the session on which the conversation startup request arrived.	Set_Partner_LU_Name
Partner LU name length	Length of partner LU name. If no *sym_dest_name* is specified, this is 1.	Length of partner LU name.	Set_Partner_LU_Name
Partner program name	The program name contained in the side information. If no *sym_dest_name* is specified, this is a single blank.	Not applicable.	Set_TP_Name
Partner program name length	Length of partner program name. If no *sym_dest_name* is specified, this is 1.	Not applicable.	Set_TP_Name
Password	The password contained in the side information. If no *sym_dest_name* is specified, this is a single blank.	The value specified by the invoking program.	Set_Conversation_Security_Password
Password length	Length of password. If no *sym_dest_name* is specified, this is 1.	Length of password.	Set_Conversation_Security_Password
Prepare-to-receive type	CM_PREP_TO_ RECEIVE_SYNC_ LEVEL	CM_PREP_TO_ RECEIVE_SYNC_ LEVEL	Set_Prepare_To_Receive_Type
Receive type	CM_RECEIVE_AND_ WAIT	CM_RECEIVE_AND_ WAIT	Set_Receive_Type
Return control	CM_WHEN_SESSION_ ALLOCATED	Not applicable.	Set_Return_Control
Security type	The security type contained in the side information.	The value specified by the invoking program.	Set_Conversation_Security_Type
Send type	CM_BUFFER_DATA	CM_BUFFER_DATA	Set_Send_Type

Synchronization level	CM_NONE	The value specified by the invoking program.	Set_Sync_Level
User identifier	The user identifier contained in the side information. If no *sym_dest_name* is specified, this is a single blank.	The value specified by the invoking program.	Set_Conversation_Security_User_ID
User identifier length	Length of user identifier. If no *sym_dest_name* is specified, this is 1.	Length of user identifier.	Set_Conversation_Security_User_ID

Side Information for CPI-C Programs

The information required for two Common Programming Interface for Communications (CPI-C) programs to communicate is stored as a table, called the side information table, in memory. The table is derived from the symbolic destination name (configured in Host Integration Server) and from the Set_CPIC_Side_Information, Extract_CPIC_Side_Information, and Delete_CPIC_Side_Information calls.

The side information is maintained by the system administrator.

If you are developing commercial programs or programs that will be installed on multiple computers within your organization, it is recommended that you include logic that enables a user or system administrator to specify configuration information for each copy of the program.

Each side information entry contains the following fields:

Symbolic destination name

This is the *sym_dest_name* parameter specified by Initialize_Conversation. It is the identifier for the side information entry. The name can be up to eight ASCII characters. See Set_CPIC_Side_Information for the allowed characters.

Partner LU name

This is the name by which the partner logical unit (LU) is known to the local program. It can be an alias of up to eight ASCII characters or a fully qualified network name of up to 17 characters. For the allowed characters, see Set_Partner_LU_Name.

Partner program type and name

These fields indicate whether the partner program is an application transaction program (TP) or an SNA service TP, and provide the partner program name. An application TP name can contain up to 64 ASCII characters. A service TP name can contain up to four characters. For the allowed characters, see Set_TP_Name.

Mode name

This name represents a set of characteristics to be used in an LU-to-LU session. The mode name can contain up to eight ASCII characters. For the allowed characters, see Set_Mode_Name.

Conversation security type

This field indicates whether security will be used and if so, what type.

You can use conversation security to require that the invoking program provides a user identifier and password before CPI-C allocates a conversation with the invoked program.

For an invoked program that in turn invokes another program, the security type can inform the second invoked program that security has already been verified.

For further information about conversation security, see Set_Conversation_Security_Type.

Security user identifier and password

If you intend to use conversation security, a valid combination of user identifier and password is required to access the invoked program. The user identifier and password can be up to 10 ASCII characters. For information about allowed characters, see Set_Conversation_Security_User_ID and Set_Conversation_Security_Password.

Configuration for CPI-C Programs

In addition to maintaining the side information (specified by *sym_dest_name*), the system administrator must define the following entities during configuration:

- Modes
- Local logical units (LUs)
- Partner LUs
- Invokable programs
- User identifiers and passwords

> **Note** For a user or group using transaction programs (TPs), 5250 emulators, or Advanced Program-to-Program Communications (APPC) applications, you can assign a default local APPC LU and a default remote APPC LU. These default LUs are accessed when the user or group member starts an APPC program (TP, 5250 emulator, or APPC application) and the program does not specify LU aliases by leaving the field NULL or filling with blanks.

CPI-C Considerations on Windows Server 2003, Windows XP, and Windows 2000

This topic summarizes information you should keep in mind when you develop programs based on Microsoft® Windows Server™ 2003, Windows® XP, and Windows 2000.

Asynchronous completion notification using message posting

When an asynchronous operation is complete, the application's window *hwndNotify* receives the message returned by **RegisterWindowMessage** with "WinAsyncCPIC" as the input string. The *wParam* value contains the *conversation_return_code* from the operation that is completing. Its values depend on which operation was originally issued. The *IParam* argument contains the CM_PTR to the *conversation_ID* specified in the original function call.

Asynchronous completion notification using Win32® events

When a verb is issued on a nonblocking conversation, it returns CM_OPERATION_INCOMPLETE if it is going to complete asynchronously. If an event has been registered with the conversation, the application can call **WaitForSingleObject** or **WaitForMultipleObjects** to be notified of the completion of the verb. WinCPICExtractEvent allows a Common Programming Interface for Communications (CPI-C) application to determine this event handle. After the verb has completed, the application must call Wait_For_Conversation to determine the return code for the asynchronous verb. The Cancel_Conversation function can be called to cancel an operation and the conversation itself.

It is the responsibility of the application to reset the event, as it is with other APIs.

If no event has been registered, the asynchronous verb completes as it does at present, which is by posting a message to the window that the application has registered with the CPI-C library.

Byte ordering

By default, Intel-byte ordering is used. For inline environments, defining NON_INTEL_BYTE_ORDER does all the required flipping for constants. Nonconstant input parameters in verb control blocks (VCBs)—for example, lengths and pointers—are always in the native format.

Events

To receive data asynchronously, an event handle is passed in the semaphore field of the VCB. This event must be in the nonsignaled state when passed to CPI-C, and the handle must have EVENT_MODIFY_STATE access to the event.

Library name

The Win32® DLL name is WINCPIC32.DLL.

Multiple threads

A transaction program (TP) can have multiple threads that issue verbs. Windows CPI-C makes provisions for multithreaded Windows-based processes. A process contains one or more threads of execution. All references to threads refer to actual threads in a multithreaded Windows environment.

Packing

For performance reasons, the VCBs are not packed. As a result, DWORDs are on DWORD boundaries, WORDs on WORDs, and BYTEs on BYTEs. VCBs should be accessed using the structures provided.

Run-time linking

For a TP to be dynamically linked to CPI-C at run time, the TP must issue:

- **LoadLibrary** to dynamically load WINCPIC.DLL or WINCPIC32.DLL, the libraries for WINCPIC.
- **GetProcAddress** to specify WINCPIC as the desired entry point to the dynamic-link library (DLL).
- **FreeLibrary** when the CPI-C library is no longer required.

Simultaneous conversations

A program can simultaneously participate in as many as 64 conversations per process.

Terminating applications

In Microsoft® Windows Server™ 2003 and Windows® 2000, CPI-C cannot tell when an application terminates. Therefore, if an application must close (for example, it receives a WM_CLOSE message as a result of an ALT+F4 from a user), the application should call WinCPICCleanup.

Yielding to other components

When processing CPI-C and Common Service Verbs (CSV), it may be necessary for the library code to yield to enable another component, such as the SnaBase, to receive messages and pass them to the application. This can be accomplished by using the Windows extensions WinCPICSetBlockingHook and WinCPICUnhookBlockingHook.

WinCPICSetBlockingHook enables a Windows CPI-C implementation to block CPI-C function calls by means of a new function. To call **WinCPICSetBlockingHook**:

```
FARPROC WINAPI WinCPICSetBlockingHook (FARPROC 1pBlockFunc)
```

WinCPICUnhookBlockingHook removes any previous blocking hook that has been installed and reinstalls the default blocking mechanism. To call **WinCPICUnhookBlockingHook**:

```
BOOL WINAPI WinCPICUnhookBlockingHook (void)
```

Operating Systems Support for CPI-C Development

Microsoft® Host Integration Server 2004 supports the development of CPI-C applications for Microsoft® Windows Server™ 2003, Windows XP and Windows® 2000. Support for CPI-C applications is provided only for the Win32® subsystem.

The previous Microsoft SNA Server products also supported the development of CPI-C applications for Microsoft® Windows NT®, Windows 98, Windows 95, Windows 3.*x*, and OS/2. Most CPI-C applications developed for Windows 3.*x* and OS/2 with SNA Server can be used with Host Integration Server 2004.

Finding Further Information about CPI-C

For information about SNA architecture, refer to your system network documentation.

The following topics provide additional information about Microsoft® Host Integration Server 2004 application programming interfaces (APIs) based on SNA architecture:

- About the APPC Guide
- About the LUA Guide

CPI-C Call Summary

This section briefly describes each Common Programming Interface for Communications (CPI-C) call. The features provided by a CPI-C call can be broader than this section indicates. The calls are grouped in categories according to the function they perform. There are calls that start and stop a conversation, send and receive data, get information, and get side information.

This section contains:

- Starting a Conversation
- Sending Data
- Receiving Data
- Confirming Receipt of Data and Reporting Errors
- Getting Information
- Ending a Conversation
- Administering Side Information

Starting a Conversation

The calls in this category are used to start a conversation between two programs.

> **Note** The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Accept_Conversation (**cmaccp**)
Issued by the invoked program to accept the incoming conversation and set certain conversation characteristics. Upon successful execution of this call, Common Programming Interface for Communications (CPI-C) generates a conversation identifier.

Allocate (**cmallc**)
Issued by the invoking program to allocate a conversation with the partner program, using the current conversation characteristics. CPI-C can also start a session between the local logical unit (LU) and partner LU if one does not already exist. The type of conversation allocated depends on the conversation type characteristic—mapped or basic.

Initialize_Conversation (**cminit**)
Issued by the invoking program to obtain a conversation identifier and to set the initial values for the conversation's characteristics. The initial values are derived from side information associated with the symbolic destination name or are CPI-C defaults.

After issuing **Initialize_Conversation**, the invoking program can issue any of the following **Set_** calls to change the initial conversation characteristics. These calls cannot be issued after **Allocate** has been issued.

Call	**Sets**
Set_Conversation_Security_Password (**cmscsp**)	Security password
Set_Conversation_Security_Type (**cmscst**)	Conversation security type
Set_Conversation_Security_User_ID (**cmscsu**)	Security user identifier
Set_Conversation_Type (**cmsct**)	Conversation type
Set_Mode_Name (**cmsmn**)	Mode name
Set_Partner_LU_Name (**cmspln**)	Partner LU name
Set_Return_Control (**cmsrc**)	Return control
Set_Sync_Level (**cmssl**)	Synchronization level
Set_TP_Name (**cmstpn**)	Program name

Sending Data

The following calls are used to send data to the partner program:

> **Note** The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Confirm (**cmcfm**)
Sends the contents of the local logical unit's (LU) send buffer and a confirmation request to the partner program and waits for confirmation.

Flush (**cmflus**)
Sends the contents of the local LU's send buffer to the partner LU (and partner program). If the send buffer is empty, no action takes place.

Prepare_To_Receive (**cmptr**)
Changes the state of the conversation for the local program from SEND to RECEIVE, making it possible for the local program to begin receiving data. Before changing the conversation state, this call performs the equivalent of the **Flush** or **Confirm** call.

Request_To_Send (**cmrts**)
Notifies the partner program that the local program wants to send data. The partner program may or may not act on this request.

Send_Data (**cmsend**)
Puts data in the local LU's send buffer for transmission to the partner program. The data collected in the local LU's send buffer is transmitted to the partner LU (and partner program) when one of the following occurs:

- The send buffer fills up.
- The local program issues a **Flush**, **Confirm**, or Deallocate call or other call that flushes the LU's send buffer. (Some send types, set by **Set_Send_Type**, include flush functionality.)

Set_Prepare_To_Receive_Type (**cmsptr**)
Sets the conversation's prepare-to-receive type, which specifies whether subsequent **Prepare_To_Receive** calls will include **Flush** or **Confirm** functionality. The prepare-to-receive type affects all subsequent **Prepare_To_Receive** calls. It can be changed by reissuing **Set_Prepare_To_Receive_Type**.

Set_Send_Type (**cmsst**)
Sets the conversation's send type. The send type specifies how data will be sent by **Send_Data**. The send type can specify that only data be sent or that, in addition to sending data, Common Programming Interface for Communications (CPI-C) executes the equivalent of **Flush**, **Confirm**, **Prepare_To_Receive**, or Deallocate. The send type value affects all subsequent **Send_Data** calls. It can be changed by reissuing **Set_Send_Type**.

Receiving Data

The following calls or extensions enable a program to receive data from its partner program:

> **Note** The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Receive (**cmrcv**)

Issuing this call while the conversation is in RECEIVE state causes the local program to receive any data that is currently available from the partner program. If no data is available and the receive type is set to CM_RECEIVE _AND_WAIT, the local program waits for data to arrive. If the receive type is set to CM_RECEIVE_IMMEDIATE, the program does not wait.

Issuing this call while the conversation is in SEND or SEND_PENDING state is allowed only if the receive type is set to CM_RECEIVE_AND_WAIT. This flushes the logical unit's (LU) send buffer and changes the conversation state to RECEIVE. The local program then begins to receive data.

Set_Fill (**cmsf**)

Used in a basic conversation, this call sets the conversation's fill type, which specifies whether programs will receive data in the form of logical records or as a specified length of data. This call has an effect only in basic conversations. The fill value affects all subsequent **Receive** calls. It can be changed by reissuing **Set_Fill**.

Set_Processing_Mode (**cmspm**)

Specifies for the conversation whether subsequent calls will be returned when the operation they have requested is complete (blocking) or immediately after the operation is initiated (non-blocking). A program is notified of the completion of non-blocking calls when it issues Wait_For_Conversation or through a Microsoft® Windows® message sent to a WndProc identified by the *hwndNotify* parameter in **Specify_Windows_Handle**.

Set_Receive_Type (**cmsrt**)

Sets the conversation's receive type, which specifies whether a program issuing a **Receive** call will wait for data to arrive if data is not available. The receive type value affects all subsequent **Receive** calls. It can be changed by reissuing **Set_Receive_Type**.

Specify_Windows_Handle (**xchwnd**)

Sets the window handle to which a message is sent on completion of an operation in non-blocking mode. An application can set the processing mode by calling **Set_Processing_Mode**. If the window handle is set to NULL or this call is never issued, then the application must call **Wait_For_Conversation** to be notified when the outstanding operation completes.

WinCPICSetBlockingHook

Allows a Windows Common Programming Interface for Communications (CPI-C) implementation to block CPI-C function calls by means of a new function. This call had to be explicitly issued for Windows version 3.*x* applications to make blocking calls without blocking the rest of the system. Under Windows 2000 and later, this is not necessary.

A Windows CPI-C implementation has a default mechanism by which blocking CPI-C functions are implemented. This function enables the application to execute its own function at blocking time in place of the default function.

Confirming Receipt of Data and Reporting Errors

The following calls confirm receipt of data or report an error:

> **Note** The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Confirmed (**cmcfmd**)

Replies to a confirmation request from the partner program. It informs the partner program that the local program has not detected an error in the received data. Because the program issuing the confirmation request waits for a confirmation, **Confirmed** synchronizes the processing of the two programs.

Send_Error (**cmserr**)

Notifies the partner program that the local program has encountered an application-level error. The local program can use **Send_Error** to inform the partner program of an error encountered in received data, to reject a confirmation request, or to truncate an incomplete logical record it is sending.

Set_Error_Direction (**cmsed**)

Specifies whether a program detected an error while receiving data or while preparing to send data. Error direction is relevant only when a program issues **Send_Error** in SEND_PENDING state—immediately after issuing Receive and receiving data as well as a *status_received* value of CM_SEND_RECEIVED.

Set_Log_Data (**cmsld**)

Used in a basic conversation, this call specifies a log message (log data) and its length to be sent to the partner logical unit (LU). This call has an effect only in basic conversations. If present, log data is sent when **Send_Error** is issued or when the conversation is abnormally deallocated. After the log data is sent, Common Programming Interface for Communications (CPI-C) resets the log data to NULL and the log data length to zero.

Getting Information

The following calls retrieve information about the characteristics of a specified conversation:

> **Note** The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Extract_Conversation_Security_Type (**xcecst**)
Retrieves security type.
Extract_Conversation_Security_User_ID (**cmecsu**)
Retrieves security user identifier.
Extract_Conversation_State (**cmecs**)
Retrieves conversation state.
Extract_Conversation_Type (**cmect**)
Retrieves conversation type.
Extract_Mode_Name (**cmemn**)
Retrieves mode name.
Extract_Partner_LU_Name (**cmepln**)
Retrieves partner LU name.
Extract_Sync_Level (**cmesl**)
Retrieves synchronization level.
Test_Request_To_Send_Received (**cmtrts**)
Determines whether a request-to-send notification has been received from the partner program.

Ending a Conversation

The following calls end a conversation:

> **Note** The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Deallocate (**cmdeal**)
: Deallocates a conversation between two programs. Before deallocating the conversation, this call performs the equivalent of the Flush or Confirm call, depending on the current conversation synchronization level and deallocate type.

Set_Deallocate_Type (**cmsdt**)
: Specifies how the conversation is to be deallocated. The deallocation instructions specified by this call take effect when **Deallocate** is issued or when the send type is set to CM_SEND_AND_DEALLOCATE and Send_Data is issued.

Administering Side Information

The following calls let CPI-C applications add, replace, retrieve, or delete side information entries from memory:

> **Note** The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Delete_CPIC_Side_Information **(xcmdsi)**
Deletes side information entry.
Extract_CPIC_Side_Information **(xcmesi)**
Retrieves side information.
Set_CPIC_Side_Information **(xcmssi)**
Adds or replaces side information entry.

Writing CPI-C Applications

A processing task accomplished by programs using Common Programming Interface for Communications (CPI-C) is called a transaction. Consequently, programs that use CPI-C are called transaction programs (TPs). These programs communicate as peers, on an equal (rather than hierarchical) basis. The TPs use CPI-C calls to exchange status information and application data. Each TP uses CPI-C calls to supply parameters to CPI-C, which performs the preferred function and returns parameters to the TP.

TPs distributed across a local or wide area network perform distributed transaction processing.

This section describes how to write transaction programs using CPI-C and how to configure the systems on which TPs run. The topics in this section cover the following general areas:

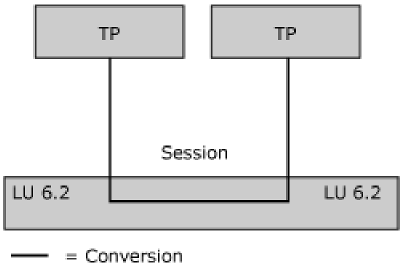
- Understanding fundamental concepts related to TPs.
- Designing and coding TPs.
- Configuring registry and environment variables for invokable TPs.
- Configuring Microsoft® Host Integration Server to work with your TPs.

This section contains:

- Communication Between TPs
- Designing and Coding TPs
- Configuring Invokable TPs
- Configuring Host Integration Server to Support TPs
- Simplifying CPI-C Configuration

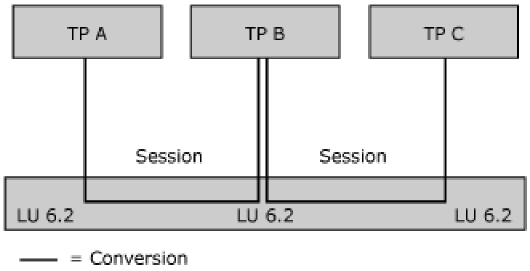
Communication Between TPs

Various hardware and software elements in the SNA environment are required for two transaction programs (TPs) to communicate with each other. The following figure illustrates several fundamental elements.



Each TP is associated with a logical unit (LU) of type 6.2. The LU enables the TP to access the network. Note that several TPs can be associated with the same LU.

A partner TP can invoke another TP, which, in turn, invokes another TP, and so on. In the following figure, TP A invokes TP B, and TP B invokes TP C.



This section contains:

- Fundamental Terms for TPs and LUs
- Sample TPs Illustrating Fundamental Concepts
- Configuring and Controlling TPs
- Creating TPs and Their Supporting Configuration

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Fundamental Terms for TPs and LUs

The following terms describe some fundamental characteristics of transaction programs (TPs) communicating through logical units (LUs):

basic conversation
A type of conversation more complex than a mapped conversation and generally used by service TPs (SNA-based programs that provide services to other programs). For a basic conversation, use Set_Conversation_Type and specify CM_BASIC_CONVERSATION for the *conversation_type*. For more information, see Basic and Mapped Conversations Compared.

conversation
The interaction between TPs carrying out a specific task. Each conversation requires an LU-LU session. A TP can be involved in several conversations simultaneously, as shown with TP B in Communication Between TPs.

invokable TP
A TP that can be invoked by another TP. Invokable TPs are usually server-type applications. That is, they work in the same general way that an IBM CICS application works. Parameters for an invokable TP are configured through registry or environment variables.

There are several types of invokable TPs:

operator-started invokable TP

A TP that is started manually in preparation for being invoked.

autostarted invokable TP

A TP that is automatically started by Common Programming Interface for Communications (CPI-C) when invoked.

queued TP

A TP that, when invoked multiple times, loads once, and then queues up subsequent requests to be dealt with one at a time. All operator-started TPs and some autostarted TPs are queued.

nonqueued TP

A TP loaded multiple times, once for every time it is invoked. Some autostarted TPs are nonqueued but no operator-started TPs are nonqueued.

For more information, see Invokable TPs.

invoking TP
A TP that can invoke (that is, initiate a conversation with) other TPs. Invoking TPs are usually client-type applications. That is, they work in the same general way that an emulator works. For more information see Invoking TPs.

local LU and local TP
An LU and TP working together, when viewed as the home base for a particular conversation. From this viewpoint, some other LU and TP are seen as the partner or remote LU and TP.

LU alias
The string that identifies an LU to a TP. The alias can be up to eight characters long.

LU-LU session
The communication between two LUs over a specific connection for a specific amount of time. An LU-LU session is needed for two TPs to interact. One session can be used serially by many pairs of TPs.

An LU 6.2 can have multiple sessions (two or more concurrent sessions with different partner LUs) and parallel sessions (two or more concurrent sessions with the same partner LU).

LUs are configured through SNA Manager on Microsoft® Host Integration Server 2004. This administration tool is also used to configure LU-LU pairs and modes. The LU and mode configurations control how many sessions a particular LU-LU pair supports.

mapped conversation
A type of conversation simpler than a basic conversation and generally used by application TPs (programs that accomplish tasks for end users). The default for conversation type is mapped. The conversation type can be changed with the Set_Conversation_Type call. For more information, see Basic and Mapped Conversations Compared.

partner LU and partner TP, or remote LU and remote TP
An LU and TP working together, when viewed as being at the far end of a particular conversation.

Sample TPs Illustrating Fundamental Concepts

A set of sample transaction programs (TPs) is provided on the Host Integration Server 2004 CD in the \SDK\Samples\SNA subdirectory. Included with the sample code is TPSETUP, a program that simplifies the setting of registry or environment variables needed by autostarted invokable TPs. Without an interface like that provided by TPSETUP, configuring such variables can be complicated and error-prone. Therefore, it is recommended that you use code like TPSETUP in installation programs for autostarted invokable TPs.

For information about TPSETUP and about the sample TPs, see CPI-C Samples.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring and Controlling TPs

The following table shows how the characteristics of the transaction programs (TPs) and selection of the logical units (LUs) for a conversation are controlled.

Characteristic	How controlled
Type of conversation: basic or mapped.	Written into the code. For two TPs to communicate successfully, both must use the same type of conversation, basic or mapped. The default for conversation type is mapped. The type can be changed with the Set_Conversation_Type call. For more information, see Basic and Mapped Conversations Compared.
Type of TP: invoking or invokable.	Written into the code. Invoking TPs start with Initialize_Conversation and Allocate. Invokable TPs start with Accept_Conversation. For more information, see Invoking TPs and Invokable TPs.
The local LU alias to be used by an invoking TP.	Three options: • Configured with a registry or environment variable. • Configured (using SNA Manager) as the default local APPC LU for the user who starts the invoking TP. • Configured (using SNA Manager) as a member of the default outgoing local APPC LU pool. For more information, see Invoking TPs and SNA Service Configuration.
The symbolic destination name used by an invoking TP.	Written into the code, in Initialize_Conversation.
The invokable (partner) TP requested by an invoking TP.	Specified within the symbolic destination name, which can be configured using SNA Manager.
The LU alias to be used by an invokable TP (the partner LU alias from the point of view of the invoking TP).	Specified within the symbolic destination name, which can be configured through SNA Management using SNA Manager. For more information, see Invoking TPs and SNA Service Configuration and Matching Invoking and Invokable TPs.
Type of autostarted invokable TP: queued or nonqueued.	Configured with registry or environment variables. For more information, see Configuring Invokable TPs.
Local LU and remote LU aliases.	Configured using SNA Manager.
The pairing of local and remote LUs, and the mode used for each LU-LU pair.	Configured using SNA Manager.

Creating TPs and Their Supporting Configuration

The following procedure describes how to create transaction programs (TPs) and set up a supporting configuration.

To create TPs and set up a supporting configuration

1. Write, compile, and link each TP.
2. Place each TP on an appropriate computer.

   For TPs that you start many times or that are started by a user, arrange for the TP to be started easily. That is, for graphical interfaces, create a program icon for starting the TP and for non-graphical interfaces, make sure the TP is in the path.

3. On one or more computers running Host Integration Server, configure logical units (LUs), modes, LU-LU pairs, and a symbolic destination name for use by the TPs.

   For information about how to set up LU-LU pairs to support TPs, see Using Invoking and Invokable TPs.

   For information about symbolic destination names and side information, see Side Information for CPI-C Programs.

4. Set any registry or environment variables needed for the invoking and invokable TPs.

   For autostarted invokable TPs, it is recommended that you use the sample TP configuration program, TPSETUP, for this step. When you write an installation program for autostarted invokable TPs, it is recommended that you include code similar to TPSETUP.

   For information about registry or environment variables, see Configuring Invokable TPs and Invoking TPs. For information about TPSETUP, see CPI-C Samples.

5. If the invokable TP is operator-started, start it, or arrange for it to be started when the computer is restarted, and then restart the computer.

   If the invokable TP is autostarted, Host Integration Server will start it when needed.

6. Start the invoking TP.

Designing and Coding TPs

The following topics provide background information about designing and coding transaction programs (TPs).

This section contains:

- CPI-C Calls in C Programs
- CPI-C and LU 6.2
- Conversation States
- Confirmation Processing
- Conversation Security
- Basic and Mapped Conversations Compared
- Using Invoking and Invokable TPs

CPI-C Calls in C Programs

This implementation of Common Programming Interface for Communications (CPI-C) is available to programs written in Microsoft® C version 6 or later.

The WINCPIC.H header file defines the prototypes for each CPI-C function. Other definitions include:

- Types specifically defined for use by CPI-C parameters.
- The structure of the side information entries.
- Symbolic names defined for integer parameters.

To use CPI-C calls, the C program must include WINCPIC.H and declare the variables to be used in passing parameters on CPI-C calls.

Note that you must define WIN32® before including WINCPIC.H

For example:

```
        #define WIN32
        #include <wincpic.h>
```

Note also that previous operating systems such as Microsoft® Windows® 98, Windows 95 and OS/2 are no longer supported.

In the case of strings, the program must also determine the preferred string length.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

CPI-C and LU 6.2

Common Programming Interface for Communications (CPI-C) applications can communicate with non-CPI-C LU 6.2 applications, such as Advanced Program-to-Program Communications (APPC).

CPI-C supports all functions of logical unit (LU) 6.2 except for the following:

- Sync Point/back out processing
- PIP data
- LOCKS=LONG
- MAP_NAME
- FMH_DATA

Conversation States

The state of the conversation (as viewed by a particular transaction program (TP)) governs which Common Programming Interface for Communications (CPI-C) calls can be made by the TP at a particular time. For example, a TP cannot issue Send_Data if the conversation is not in SEND or SEND_PENDING state for that TP.

The state of a conversation depends on the TP from which it is viewed. A local TP can view a conversation as being in SEND state while the partner TP views the conversation as being in RECEIVE state. A particular TP can be in several conversations, each of which is in a different state.

The possible conversation states are summarized in this topic.

CONFIRM

The TP has received a request for confirmation of receipt of data. It must respond positively or send error information to the partner TP.

CONFIRM_DEALLOCATE

The TP has received a request for confirmation and must respond positively or send error information. If the TP responds positively, the conversation is automatically deallocated.

CONFIRM_SEND

The TP has received a request for confirmation. It must respond positively or send error information. After responding, the TP can begin to send data.

INITIALIZE

The conversation has been initialized successfully.

RECEIVE

The TP can receive application data and status information from the partner TP. When the conversation is in RECEIVE state, the TP can also send error information and request permission to send data.

RESET

The conversation has not started or has been terminated.

SEND

The TP can send data to the partner TP and request confirmation. When the conversation is in SEND state, the TP can also begin to receive data, which can cause the state to change to RECEIVE.

SEND_PENDING

The TP issued a Receive call and received data as well as a send indicator (*status_received* = CM_SEND_RECEIVED), indicating that the TP can begin to send data. This state differs from the SEND state, which occurs when the TP receives data on one **Receive** call and the send indicator on a subsequent **Receive** call.

This section contains:

- State Checks
- Changing Conversation States

State Checks

A state check occurs when a transaction program (TP) issues a Common Programming Interface for Communications (CPI-C) call and the conversation is not in the appropriate state. For example, a state check occurs if a TP issues Send_Data while the conversation is in RECEIVE state. When a state check occurs, CPI-C does not execute the call. It returns state check information through the *return_code* parameter.

Changing Conversation States

A change in the conversation state can result from:

- A call made by the local transaction program (TP).
- A call made by the partner TP.
- An error condition.

The following example shows how Common Programming Interface for Communications (CPI-C) calls can change the state of the conversation from SEND to RECEIVE and from RECEIVE to SEND.

> **Note** Any TP can send or receive data, regardless of whether it is the invoking TP (the TP that started the conversation) or the invokable TP (the TP that responded to a request to start a conversation).

This example shows how CPI-C calls can change the conversation state. In this table, each conversation state appears in bold and precedes the CPI-C calls that are used while in that state.

Issued by the invoking TP	**Issued by the invokable TP**
Conversation state: RESET	
Initialize_Conversation	
Conversation state: INITIALIZE	
Set_Sync_Level	
(sync_level=CM_CONFIRM)	
Allocate	
Conversation state: SEND	
Send_Data	
Prepare_to_Receive	**Conversation state: RESET**
	Accept_Conversation
	Conversation state: RECEIVE
	(status_received= CM_CONFIRM_SEND_RECEIVED)
	Conversation state: CONFIRM_SEND
	Confirm
	Conversation state: SEND
(return_code=CM_OK)	Send_Data
Conversation state: RECEIVE	Confirm
(status_received= CM_CONFIRM_RECEIVED)	
Conversation state: CONFIRM	
Request_To_Send	
Confirmed	
Conversation state: RECEIVE	(return_code=CM_OK)
	(request_to_send_received= CM_REQ_TO_SEND_RECEIVED)
	Prepare_To_Receive
Receive	
(status_received= CM_CONFIRM_SEND_RECEIVED)	
Conversation state: CONFIRM_SEND	
Confirmed	
Conversation state: SEND	(return_code=CM_OK)
	Conversation state: RECEIVE
Send_Data	
Deallocate	
	Receive
	(status_received= CM_CONFIRM_DEALLOC_RECEIVED)

	Conversation state: CONFIRM_DEALLOCATE
	Confirmed
(return_code=CM_OK)	**Conversation state: RESET**
Conversation state: RESET	

Initial States

Before the conversation is allocated, the state is RESET for both TPs.

In the example, after the conversation is allocated, the initial state is SEND for the invoking TP and RECEIVE for the invokable TP.

Changing to RECEIVE State

The Prepare_To_Receive call allows a TP to change the conversation from SEND to RECEIVE state. This call:

- Flushes the local LU's send buffer.
- Sends a CM_CONFIRM_SEND indicator to the partner TP through the *status_received* parameter of a Receive call, because the synchronization level is set to CM_CONFIRM. This indicator tells the partner TP that a Confirmed response is expected before the partner TP can begin to send data.

Changing to SEND State

The Request_To_Send call informs the partner TP (for which the conversation is in SEND state) that the local TP (for which the conversation is in RECEIVE state) wants to send data. This request is communicated to the partner TP through the *request_to_send_received* parameter of the Confirm call. (The *request_to_send_received* parameter is also returned to Send_Data and other calls.)

When the partner TP issues the Prepare_To_Receive call, the conversation state changes to RECEIVE for the partner TP, making it possible for the local TP to send data.

> **Important** Issuing Request_To_Send does not change the state of the conversation. Upon receiving a request to send, the partner TP is not required to change the conversation state. It can ignore the request.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Confirmation Processing

The sequence of events for confirmation processing is as follows:

1. Establish the synchronization level.
2. Send a confirmation request.
3. Receive data and confirmation request.
4. Respond to the confirmation request.
5. Deallocate the conversation.

Using confirmation processing, a transaction program (TP) sends a confirmation request with the data. The partner TP confirms receipt of the data or indicates that an error occurred. Each time the two TPs exchange a confirmation request and response, they are synchronized.

> **Note** Although the example in this section does not show this, any TP can send or receive data, regardless of whether the TP is the invoking TP or the invokable TP.

The following table illustrates the steps involved in confirmation processing.

Step	Issued by the invoking TP	Issued by the invokable TP
1	Initialize_Conversation	
2	Set_Sync_Level (*sync_level*=CM_CONFIRM)	
3	Allocate	
4	Send_Data	
5	Confirm	
6		Accept_Conversation
7		Receive (data_received= CM_COMPLETE_DATA_RECEIVED) (status_received= CM_CONFIRM_RECEIVED)
8		Confirmed
9	(*return_code*=CM_OK)	
10	Send_Data	
11	Deallocate	
12		Receive
13		(status_received= CM_CONFIRM_DEALLOC_RECEIVED)
14		Confirmed
15	(return_code=CM_OK)	

Establishing the Synchronization Level

The Set_Sync_Level call lets you override the default synchronization level of the conversation. The synchronization level is one of the conversation's characteristics. There are two possible synchronization levels:

- CM_CONFIRM, under which the TPs can request confirmation of receipt of data and respond to such requests.
- CM_NONE, the default, under which confirmation processing does not occur.

The Initialize_Conversation call sets the default characteristics of a conversation. There are several calls that begin with **Set_**. These calls let you override the default conversation characteristics.

Sending a Confirmation Request

Issuing the Confirm call has two effects:

- It flushes the local LU's send buffer and sends any data contained in the buffer to the partner TP.
- It sends a confirmation request that the partner TP receives through the *status_received* parameter of a Receive call.

After issuing **Confirm**, the local TP waits for confirmation from the partner TP.

Receiving a Confirmation Request

The *status_received* parameter of the Receive call indicates any future action required by the local TP.

In the example, the first Receive has a *status_received* of CM_CONFIRM_RECEIVED, indicating that a confirmation is required before the partner TP can continue.

Responding to a Confirmation Request

The partner TP issues the Confirmed call to confirm receipt of data. This frees the local TP to resume processing.

Deallocating the Conversation

Because the synchronization level of the conversation is set to CM_CONFIRM, Deallocate sends a confirmation request with the data flushed from the buffer.

For the second Receive call, *status_received* is CM_CONFIRM_DEALLOC_RECEIVED, indicating that the partner TP requires a confirmation, generated by the Confirmed call, before the conversation can be deallocated.

Conversation Security

You can use conversation security to require that the invoking transaction program (TP) provides a user identifier and password before Common Programming Interface for Communications (CPI-C) allocates a conversation with the invokable TP.

For the invoking TP, conversation security is activated and configured (with user identifier and password) through the symbolic destination name in SNA Manager or by the following calls, which override the symbolic destination name:

- Set_Conversation_Security_Type
- Set_Conversation_Security_User_ID
- Set_Conversation_Security_Password

For the invokable TP, conversation security is activated and configured through registry or environment variables on the computer where the invokable TP is located.

With communication involving more than two TPs, the verification of a user identifier and password can be passed from one TP to another. Suppose that TP A invokes TP B, which requires security information, and TP B in turn invokes TP C, which also requires security information. TP B can inform TP C that conversation security has already been verified.

For information about the registry or environment variables affecting conversation security, see Configuring Invokable TPs. For information about symbolic destination names and side information, see Side Information for CPI-C Programs.

Basic and Mapped Conversations Compared

The following table offers some guidelines for choosing between basic and mapped conversations for your transaction programs (TPs). The default for conversation type is mapped. To change to a basic conversation, use Set_Conversation_Type, and specify CM_BASIC_CONVERSATION for the *conversation_type*. For definitions of basic and mapped conversations, see Fundamental Terms for TPs and LUs.

Characteristic	**Basic conversations**	**Mapped conversations**
Common use	Generally used for service TPs.	Generally used for application TPs.
Partnering	Must be used to communicate with an existing TP that uses basic verbs.	Must be used to communicate with an existing TP that uses mapped verbs.
Sending and receiving method	Before a TP can begin a send operation, it must convert data records into logical records. The TP does this by adding a 2-byte prefix that indicates the length of the record. A TP can send several logical records at one time. When a partner TP receives logical records, it must reconstruct them into usable data records. For more information, see Logical Records Used in Basic Conversations.	A TP sends data one record at a time. Neither the sending TP nor the receiving TP needs to convert data records between different forms.
Abnormal termination	In the Deallocate call, a TP can indicate whether an error or ABEND (abnormal program termination) was caused by a TP or by a program using the TP.	A TP can indicate an error or ABEND, but cannot tell whether a problem was caused by a TP or by a program using a TP.
ABEND	A TP can indicate whether an ABEND was caused by a time-out or by a critical error.	A TP cannot indicate the cause of an ABEND.
Error logging	For an error or ABEND, a TP can send an error message, in the form of a general data stream (GDS) error log variable, to the local log and to the partner logical unit (LU).	For an error or ABEND, a TP cannot send an error message to the local log or to the partner LU.

This section contains:

- Logical Records Used in Basic Conversations
- An Example of a Mapped Conversation

Logical Records Used in Basic Conversations

Logical records are sent and received in basic conversations only.

A transaction program (TP) can send or receive multiple logical records with a single Send_Data or Receive call. A TP can also send or receive a logical record in successive portions: beginning, middle, and end.

A logical record is made up of:

- A 2-byte record-length (LL) field.
- A data field that can range in length from 0 bytes through 32765 bytes.

The LL field contains a hexadecimal value that is the length of the data field plus two bytes (for the LL field). For example, if a record contains 228 bytes of application data, the logical record length is 230. The LL field is 0x00E6, the hexadecimal equivalent of 230. If the length of the data field is 0, the value contained in the LL field is 0x0002.

Logical records are sent from or received in a data buffer established by the TP. In the data buffer, the LL field must not be in Intel byte-swapped format. For example, a length of 230 must be 0x00E6, not 0xE600.

The LL field cannot be 0x0000 or 0x0001, which allow less than the two bytes required for the LL field itself. The LL field also cannot be greater than or equal to 0x8000, which is equivalent to decimal 32768 and therefore allows for a data field greater than 32765 or an LL field greater than 2.

Setting the most significant bit of the LL field to 1 indicates that the information contained in the current logical record is continued in the next logical record.

An Example of a Mapped Conversation

The following example of a mapped conversation shows the Common Programming Interface for Communications (CPI-C) calls used to start a conversation, exchange data, and end the conversation. Call parameters are in parentheses.

Issued by the invoking TP	**Issued by the invokable TP**
Initialize_Conversation	
Allocate	
Send_Data	
Deallocate	Accept_Conversation
	Receive
	(data_received=
	CM_COMPLETE_DATA_RECEIVED)
	(*return_code*=
	CM_DEALLOCATED_NORMAL)

The following paragraphs describe the calls that are used in a mapped conversation.

Calls for Starting a Mapped Conversation

To start a conversation, the invoking transaction program (TP) issues the following calls:

- Initialize_Conversation, which requests CPI-C to set the values defining the characteristics of the conversation. The **Initialize_Conversation** call specifies a symbolic destination name that is associated with an entry in a side information table in memory. The side information specifies partner TP, partner LU, mode, security, and so on.
- Allocate, which requests that CPI-C establish a conversation between the invoking TP and the invokable TP.

The invokable TP issues the Accept_Conversation call, which informs CPI-C that it is ready to begin a conversation with the invoking TP.

Calls for Sending Data in a Mapped Conversation

The Send_Data call puts one data record (a record containing application data to be transmitted) in the send buffer of the local logical unit (LU). Data transmission to the partner TP does not happen until one of the following events occurs:

- The send buffer fills up.
- The sending TP makes a call that forces CPI-C to flush the buffer and send data to the partner TP.

In addition to the data record, the send buffer also contains the allocation request (which precedes the data record).

In the preceding example, Deallocate flushes the send buffer, sending the allocation request and data to the partner TP. Other calls that flush the buffer are Confirm and Flush.

Calls for Receiving Data in a Mapped Conversation

The **Receive** call receives the data record and status information from the partner TP. If no data or status information is currently available, the local TP, by default, waits for data to arrive.

The *data_received* parameter of Receive tells the program whether it received data and if so, whether or not the data is complete.

Calls for Ending a Mapped Conversation

To end a conversation, one of the TPs issues Deallocate, which causes CPI-C to deallocate the conversation between the two TPs.

Using Invoking and Invokable TPs

There are two kinds of transaction programs (TPs): TPs that can invoke (that is, initiate a conversation with) other TPs, and TPs that can be invoked. A TP that can invoke another TP is called an invoking TP, and a TP that can be invoked is called an invokable TP.

The following topics describe how:

- Invoking TPs request invokable TPs.
- Invokable TPs identify themselves to the SNA service in preparation for being invoked.
- An invokable TP is matched to an invoking TP's request.

For information about how to configure logical units (LUs) to support TPs, see Configuring Host Integration Server to Support TPs.

This section contains:

- Invoking TPs
- Invoking TPs and Contention
- Invokable TPs
- Subcategories for Invokable TPs
- Matching Invoking and Invokable TPs

Invoking TPs

An invoking transaction program (TP) can be located on any system on the SNA network. An invoking TP identifies itself by issuing Initialize_Conversation, which specifies the name of the invoking TP and the symbolic destination name to be used. A local logical unit (LU) alias can be specified for the invoking TP by using a registry or environment variable, as shown in the following table.

Operating system on computer that contains invoking TP	**Location and name of variable**
Windows 2000, Windows XP and Windows server 2003	Location in Windows 2000 registry: HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services SnaBase Parameters Client <*exename*>:REG_SZ:*localLUalias* Any *exename* registry entries under the Client key represent the file names of Win32 executable files (without the file extension) for any invoking TPs. A REG_SZ value associated with each *exename* registry entry specifies the local LU alias for the invoking TP. For example, the APING.EXE Common Programming Interface for Communications (CPI-C) sample included with the Microsoft® Host Integration Server software development kit (SDK) would have the following registry entry: HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services SnaBase Parameters Client APING:REG_SZ:*localLUalias*

The registry parameter for the local LU alias takes greatest precedence when associating a local LU to an invoking CPI-C application. If a registry value is not configured, two other methods are used to associate a local LU to the CPI-C application.

A local APPC LU can be associated with the user context under which the CPI-C application is running A local APPC LU can be configured by checking the **member of default local APPC LU pool** check box. Of the two possible options, a local LU associated with user context has the higher precedence.

If the local LU alias is not specified in a registry or environment variable, SNA service must be configured to supply it through one of these two types of default local LUs. Otherwise, Initialize_Conversation will fail. For more information, see Invoking TPs and SNA Service Configuration.

Next, the symbolic destination name specified in Initialize_Conversation provides the name of the invokable (or partner) TP and the partner LU alias (the LU alias to be used by the invokable TP). With this information available, the invoking TP can issue the Allocate call.

After a TP successfully issues an Allocate call, an allocation request flows. For more information about what happens after an invoking TP requests an invokable TP, see Matching Invoking and Invokable TPs.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Invoking TPs and Contention

The following information applies only to cases where logical units (LUs) are communicating in complex ways (such as chains of LUs) over multiple sessions. In such cases, two LUs may attempt to allocate a conversation on the same session at the same time. If this happens, one LU must win (the contention winner) and one must lose (the contention loser). The contention-winner LU and the contention-loser LU are determined for each session when the session is established. During that particular session, the contention-loser LU must receive permission from the contention-winner LU before allocating a conversation. In contrast, the contention-winner LU on that session allocates a conversation as needed.

Note that when two LUs are communicating over multiple sessions, one LU can be the contention winner for some of the sessions, and the other LU the contention winner for others.

An invoking transaction program (TP) operates most efficiently if the number of concurrent Allocate requests that the TP issues is matched by the number of sessions on which the local LU is the contention winner. The choice of contention winner is controlled through the modes configured at the two ends of the communication. A mode must be configured to work with the mode on the remote system for communication to begin between two LUs.

Invokable TPs

An invokable transaction program (TP) is a TP that can be invoked by another TP. Invokable TPs are written or configured through registry or environment variables to supply their names to the SNA service as a notification that they are available for incoming requests. An SNA service invokable TP can be run on any computer running Host Integration Server or client.

There are two types of invokable TPs:

Operator-started invokable TPs

An operator-started invokable TP must be started by an operator before the TP can be invoked. When the operator-started invokable TP is started, it notifies the SNA service of its availability by issuing an Accept_Conversation call. The **Accept_Conversation** call causes the name of the invokable TP to be communicated to all the SNA services in the domain, along with the alias of an associated LU if one has been configured through a registry or environment variable.

Autostarted invokable TPs

An autostarted invokable TP can be started by the SNA service when needed. The TP must be registered through registry entries or environment variables on its local system, so that it can be identified to the SnaBase component of the SNA service. The registered information defines the TP as autostarted and must specify the TP name. The registered information can also specify the local LU alias that the invokable TP will use.

The recommended method for setting registry or environment variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP, or similar code written into your own installation program. For more information about registry or environment variables for invokable TPs, see Configuring Invokable TPs. For information about TPSETUP, see CPI-C Samples.

If no local LU alias is registered with autostarted TPs, the resulting SNA service configuration can be more flexible in responding to invoking requests. For more information about such flexible configurations, see TP Name Not Unique; Local LU Alias Unspecified.

After an autostarted invokable TP is started by SNA service, the TP issues Accept_Conversation just as an operator-started TP does. Accept_Conversation must provide the TP name that was registered for the TP.

Autostarted TPs must be configured through registry or environment variables to be either queued or nonqueued. All operator-started TPs act as queued TPs.

Queued TPs

If an autostarted TP is configured as queued, or if the TP is operator-started, incoming allocation requests are queued, and then sent only when the invokable TP issues **Accept_Conversation**. For autostarted invokable TPs, if a copy of the TP is not yet running, one is started when an incoming allocation request specifies that TP.

> **Note** For the Microsoft® Windows Server™ 2003 and Windows 2000 system, only one copy of a service can be running at any given time. This means that all autostarted TPs that run as services under Windows Server 2003 and Windows 2000 must be queued. To write an autostarted TP so it runs under Windows Server 2003 and Windows 2000 as a service and also runs in a nonqueued way, write a multithreaded program with an **Accept_Conversation** always outstanding.

Nonqueued TPs

If an autostarted TP is configured as nonqueued, a new copy will be started every time an Allocate is received for the TP. Nonqueued TPs should process the conversation they have been allocated, and then exit, because they will not receive any additional **Allocate** requests.

Subcategories for Invokable TPs

The following table shows subcategories for invokable transaction programs (TPs).

Queued or nonqueued	Application or service	Starting method
Queued	Running as an application or a service	Autostarted or operator-started
Nonqueued	Running as an application	Autostarted

The concept of a TP running as a service or running as an application is distinct from a service TP or an application TP. Service TP and application TP are SNA terms that describe how a TP is used: either as a supportive service program for other Common Programming Interface for Communications (CPI-C) programs, or directly by a user, as an application. For detailed information about services in Windows Server 2003 and Windows 2000, see the documentation for Windows Server 2003 and Windows 2000.

To write an autostarted TP so it runs under Windows Server 2003 and Windows 2000 as a service and also runs in a nonqueued way, write a multithreaded program with an Accept_Conversation always outstanding. For more information, see Invokable TPs.

To run an autostarted TP as an application under Windows Server 2003 and Windows 2000, make sure the TPSTART program is always started before the TP. For more information, see CPI-C Samples.

Matching Invoking and Invokable TPs

Each SNA service maintains a list of available invokable transaction program (TP) names and any logical unit (LU) aliases to be associated with the TP names. This information is obtained as follows:

- For autostarted invokable TPs, registry or environment variables identify a TP name containing a maximum of eight characters, and can specify an associated LU. This information is sent from the client to the server that sponsors the client. A client learns about the domain through a sponsor connection to a server. Clients must establish the sponsor connection before proceeding with any other tasks.
- For operator-started invokable TPs, a TP name (with a maximum of 64 characters) is specified in Specify_Local_TP_Name. The TP name is truncated to eight characters and sent from the client to the server that sponsors the client, along with the alias of an associated LU if one has been configured through a registry or environment variable.

> **Note** If you want a TP name to be unique, it is recommended that you limit the name to eight characters or fewer, or make the name unique within the first eight characters. This is because the preliminary routing of allocation requests is carried out using the first eight characters. Although further matching is later carried out between the full TP names, it is inefficient to allow the preliminary routing to succeed when in some cases the later matching will fail.

The next step in the matching of invoking and invokable TPs is the creation of a side information table from the parameters in the symbolic destination name. Then the invoking TP issues the Allocate call and an allocation request flows to the partner LU specified in the side information table, stating the name of the invokable TP that has been requested (also listed in the side information table).

When an allocation request arrives, the SNA service compares the requested invokable TP name and LU alias to the list of available invokable TPs (which can include associated LU aliases). The comparison can be modified by registry variables, but by default is carried out as follows:

- Although the TP name requested in the symbolic destination name can be as long as 64 characters, any name received through a registry or environment variable is limited to eight characters or less. Therefore, only the first eight characters of TP names are used in comparisons.
- The comparison is carried out first on both the TP name and the LU alias. An invokable TP for which there is a match on both TP name and LU alias will be chosen ahead of a TP for which no LU alias has been configured through a registry or environment variable. A TP for which no LU alias has been configured can be matched with any request that specifies that TP name, because there cannot be a mismatch based on LU alias.
- The comparison of requested and available TP names is carried out in a specific order:
    1. The SNA service first checks for operator-started invokable TPs on the local system (the local Host Integration Server).
    2. If no match is found, the SNA service checks for autostarted invokable TPs on the local system (the local Host Integration Server).
    3. If no match is found, the SNA service checks for operator-started invokable TPs on other computers running Host Integration Server or clients.
    4. If no match is found, the SNA service checks for autostarted invokable TPs on other computers running Host Integration Server or clients.

This comparison can be modified somewhat by registry entries for the SnaServr service. The entries are called **DloadMatchTPOnly** and **DloadMatchLocalFirst**.

If a match is found, the SNA service signals the system containing the requested TP to connect to that SNA service. If no match is found, the SNA service rejects the incoming request.

For suggestions about specific ways to handle TP names and LU aliases, see Arranging TPs Within an SNA Network.

> **Note** Because of the way Common Programming Interface for Communications (CPI-C) works, an allocation request does not flow until local data buffers are full, or a Confirm or Flush call is made. This may mean that the allocation request does not flow until some time after the Allocate call is made. Therefore, any allocation failure caused by the rejection of the allocation request at the partner LU will be observed as the failure of a later call with one of the allocation failure return codes.

Configuring Invokable TPs

The following topics tell how to configure invokable transaction programs (TPs) for the various Microsoft® SNA service client types.

This section contains:

- Clients Running Windows XP or Windows 2000

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Clients Running Windows XP or Windows 2000

On clients running Microsoft® Windows® XP or Windows 2000, invokable transaction programs (TPs) are configured through the Windows XP or Windows 2000 registry.

> **Note** With Windows XP and Windows 2000, the recommended method for setting registry variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP. Compile INSTALL.C, the source code for TPSETUP, for the Windows XP and Windows 2000 environment. When you write an installation program for autostarted invokable TPs, it is recommended that you add code similar to TPSETUP to the installation program. For information about TPSETUP, see CPI-C Samples.

For clients running Windows XP or Windows 2000, it is recommended that autostarted invokable TPs be written as Windows XP or Windows 2000 services. Be sure to include code like that in TPSETUP in the program that installs your TPs. Among other things, TPSETUP shows how to use the **CreateService** function when installing a TP. For important information about how services work under Windows 2000, see the documentation for Windows 2000.

The following table lists the registry entries used for the types of invokable TPs that can be run on Windows XP or Windows 2000 clients.

Type of TP	**Location in registry**	**Possible registry entries**
Autostarted invokable TP running as a service on Windows XP or Windows 2000 client.	**HKEY_LOCAL_MACHINE** **SYSTEM** **CurrentControlSet** **Services** ***TPName*** (and subkeys)	Registry entries created by the **CreateService** call, including entries that specify the path, display name, and other characteristics of the service. —plus— Linkage OtherDependencies:REG_MULTI_SZ:SnaBase Parameters SNAServiceType:REG_DWORD:0x5 LocalLU:REG_SZ:*LUalias* Parameters:REG_SZ:*ParameterList* Timeout:REG_DWORD:*number* AcceptNames:REG_SZ:*TPNameList* ConversationSecurity:REG_SZ:{ YES | NO } AlreadyVerified:REG_SZ:{ YES | NO } *Username1*:REG_SZ:*Password1* ... *UsernameX*:REG_SZ:*PasswordX* For more information, see the notes following this table.
Autostarted invokable TP running as an application on a Windows XP or Windows 2000 client. CPI-C Samples

AlreadyVerified and Username/Password entries are used only if ConversationSecurity is set to YES.

This section contains:

- Registry Entries for Clients Running Windows XP or Windows 2000
- Example of Registry Entries for Windows XP or Windows 2000

Registry Entries for Clients Running Windows XP or Windows 2000

The following list gives details about registry entries for clients running Windows XP or Windows 2000. For each transaction program (TP) type, the applicable variables and their locations are shown in Clients Running Windows XP or Windows 2000.

OtherDependencies:REG_MULTI_SZ:SnaBase
For a TP running as a service, ensures that the SnaBase service is started before the TP is started. This entry belongs under the **Linkage** subkey.

SNAServiceType:REG_DWORD:{ 0x5 | 0x6 | 0x1A }
Indicates the type of TP. Use a value of 0x5 for an autostarted queued TP, 0x6 for an autostarted nonqueued TP, and 0x1A for an operator-started TP.

Note that the value for an autostarted TP running as a service must be 0x5, because these TPs are always queued, as described in Invokable TPs.

PathName:REG_EXPAND_SZ:*path*
For an autostarted TP running as an application, specifies the path and file name of the TP. The data type of REG_EXPAND_SZ means that the path can contain an expandable data string For example, %SystemRoot% represents the directory containing the Windows 2000 system files. Note that for a TP running as a service, an equivalent entry is inserted by the **CreateService** call. No additional path entry is needed.

LocalLU:REG_SZ:*LUalias*
Specifies the alias of the local LU to be used when this TP is started on this computer.

Parameters:REG_SZ:*ParameterList*
Lists parameters to be used by the TP. Separate parameters with spaces.

Timeout:REG_DWORD:*number*
Specifies the time, in milliseconds, that an Accept_Conversation will wait before timing out. Specify *number* in decimal. The registry editor converts this to hexadecimal before displaying it. The default is infinity (no limit).

AcceptNames:REG_SZ:*TPNameList*
With Windows 2000, used for autostarted TPs only. Lists additional names under which the invokable TP can be invoked. Separate TP names with spaces. The default is none. If an invokable TP does not issue a Specify_Local_TP_Name for each name configured under AcceptNames in the registry, that TP will fail.

ConversationSecurity:REG_SZ:{ YES | NO }
Indicates whether this TP supports conversation security. The default is NO.

AlreadyVerified:REG_SZ:{ YES | NO }
Indicates whether this TP can be invoked with a user identifier and password that have already been verified. **AlreadyVerified** is ignored if **ConversationSecurity** is set to NO.

For a diagram of three TPs in a conversation, where the third TP can be invoked with a password that is already verified by the second TP, see Communication Between TPs. The following table shows the requirements for using password verification in a chain of TPs.

First TP (an invoking TP)	**Second TP (invokable TP that confirms password, and then invokes another TP)**	**Third and subsequent TPs (invokable TPs that invoke other TPs)**
Does not need registry or environment variables.	**ConversationSecurity** setting must be YES.	**ConversationSecurity** setting must be YES.
Does not need registry or environment variables.	**AlreadyVerified** setting can be YES or NO.	**AlreadyVerified** setting must be YES.
Symbolic destination name or **Set_Conversation_ Security_Type** in this TP specifies PROGRAM for the security type. As a result, the TP passes along the user identifier and password supplied in the symbolic destination name (or through calls (1)).	Symbolic destination name or **Set_Conversation_ Security_Type** in this TP specifies SAME for the security type. As a result, after confirming the user identifier and password, the TP passes along the user identifier and an already-verified flag.	Symbolic destination name or **Set_Conversation_ Security_Type** in this TP specifies SAME for the security type. As a result, the TP passes along the user identifier as received, along with the already-verified flag.

Note Set_Conversation_Security_User_ID or **Set_Conversation_Security_Password** overwrites the user identifier and password specified in the symbolic destination name.

If you set **AlreadyVerified** to NO, this TP cannot join in a chain of conversations where password verification is already done. (The exception to this is when **ConversationSecurity** is set to NO, in which case the TP could be the final TP in such a chain, because it performs no checking.)

If you are configuring a TP that sometimes needs to confirm a password and sometimes accepts an already-verified flag, set AlreadyVerified to YES and configure the UsernameX variable appropriately. In this case, whenever the TP is invoked without the already-verified flag set, AlreadyVerified is ignored. Verification is attempted with the user identifier and password configured for the TP.

The default for AlreadyVerified is NO. If you set AlreadyVerified to YES, make sure that ConversationSecurity is also set to YES.

Username1:REG_SZ:*Password1*
...
UsernameX:REG_SZ:*PasswordX*

Sets one or more user names and passwords to be compared with those sent by the invoking TP. The user name and password can each be as many as 10 characters. Both parameters are case-sensitive.

This variable is ignored if conversation security is not activated or if the password has already been verified, as described for the AlreadyVerified entry.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Example of Registry Entries for Windows XP or Windows 2000

For an autostarted invokable transaction program (TP) called **BounceTP** and running as a service, the following registry entries might be added to a client running Windows XP or Windows 2000. The entries would be added to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services**, under the subkeys shown in bold type.

> **Note** In the following list, the parameters listed directly under the **BounceTP** key (such as **DisplayName** and **ErrorControl**) are service parameters created when TPSETUP or similar code is run to install the TP. These parameters should be created by TPSETUP or similar code. They should not be set manually. For more information about TPSETUP, see CPI-C Samples.

BounceTP
  DisplayName:REG_SZ:BounceTP
  ErrorControl:REG_DWORD:0x1
  ImagePath:REG_EXPAND_SZ:c:\sna\system\bouncetp.exe
  ObjectName:REG_SZ:LocalSystem
  Start:REG_DWORD:0x3
  Type:REG_DWORD:0x10

Linkage

OtherDependencies:REG_MULTI_SZ:SnaBase

Parameters

SNAServiceType:REG_DWORD:0x5
LocalLU:REG_SZ:JohnDoe
Parameters:REG_SZ:Arg1 Arg2 Arg3
Timeout:REG_DWORD:0x100
ConversationSecurity:REG_SZ:yes
AlreadyVerified:REG_SZ:no
JohnDoe:REG_SZ:SecretPassword

Configuring Host Integration Server to Support TPs

The following topics describe how the Microsoft® Host Integration Server 2004 configuration works with invoking and invokable transaction programs (TPs.)

This section contains:

- Invoking TPs and SNA Service Configuration
- Invokable TPs and the SNA Service Configuration
- Arranging TPs Within an SNA Network
- Troubleshooting for Invokable TPs

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Invoking TPs and SNA Service Configuration

For an SNA service to support the beginning of the invoking process, the following parameters must be configured correctly:

- If the invoking transaction program (TP) specifies the logical unit (LU) alias that it uses (in a registry or environment variable), that LU alias must match a local Advanced Program-to-Program Communications (APPC) LU alias on the supporting SNA service. If the invoking TP does not specify a local LU alias, one of two methods for designating a default LU must be carried out on the supporting SNA service:
    - Assign a default local APPC LU to the user or group that starts the invoking TP (that is, the user or group logged on at the system from which Initialize_Conversation is issued).

      —or—

    - Designate one or more LUs as members of the default outgoing local APPC LU pool. Host Integration Server or SNA service first attempts to determine the default local APPC LU of the user who started the TP, then attempts to assign an available LU from the default outgoing local APPC LU pool. If these attempts fail, SNA service rejects the request.
- In most situations, the supporting SNA service must contain an appropriate connection to another system (host or peer). Sometimes, for testing purposes, the SNA service contains two local LUs paired together (for invoking and invokable TPs that are in the same domain). In this situation, a connection to a host or peer is not necessary.
- The partner LU alias specified in the symbolic destination name must match an LU alias that is paired with the local LU alias used by the invoking TP.

The preceding parameters support the beginning of the invoking process. For the invoking process to successfully complete, additional parameters must be configured as described in Invokable TPs and the SNA Service Configuration.

Invokable TPs and the SNA Service Configuration

For an SNA service to receive allocation requests from an invoking transaction program (TP) on another system and route those requests to an invokable TP, certain parameters must be configured correctly:

- The SNA service must have a connection to the system from which the invoking TP's request is sent.
- The SNA service must have a remote logical unit (LU) capable of receiving the incoming request. This remote LU can be configured either explicitly or implicitly.

  When configured explicitly, there is an explicit match between a remote LU alias on the SNA service and the alias of the LU that conveys the invoking TP's request.

  When configured implicitly, an implicit incoming remote LU (with its implicit incoming mode) is used. This means that several items must work together. First, the LU alias specified in the incoming request (the LU alias requested for the invokable TP) must match a local LU alias on the SNA service receiving the request. Second, the local LU on the server must have an implicit incoming remote LU assigned to it. The properties of the implicit incoming remote LU will be used for that LU-LU session.

- Appropriate local LUs must be defined in the SNA service configuration. For descriptions of several ways to set up these local LUs, see Arranging TPs Within an SNA Network.

Arranging TPs Within an SNA Network

If your Host Integration Server installation contains multiple systems (clients or SNA services), you can place a given invokable transaction program (TP) on more than one system. When an invoking request is received in such an installation, there can be a choice of systems on which to run the invokable TP. You can maintain specific control over this choice. Alternatively, by following the instructions in TP Name Not Unique; Local LU Alias Unspecified, you can enable SNA service to make the choice randomly to distribute the load.

You can maintain specific control over this choice of system by setting up invokable TPs with unique names, or by setting up each invokable TP to run only with a specific, unique logical unit (LU) alias. With this arrangement, the information provided by the invoking TP (in the symbolic destination name) specifies the system on which the invokable TP should run.

You can allow the SNA service to make the system choice randomly by setting the **DloadMatchLocalFirst** registry entry to NO and using invokable TPs that leave the local LU alias unspecified. Then, when an incoming request is received, it is routed randomly, rather than preferentially to the local server. In addition, no matter what LU alias is requested for the invokable TP, there cannot be a mismatch. SNA service starts one instance of the requested TP, choosing randomly among the available systems.

The following topics describe some of the possible arrangements that can be made for running TPs.

This section contains:

- TP Name Unique for Each TP
- TP Name Not Unique; Local LU Alias Unique
- TP Name Not Unique; Local LU Alias Unspecified

TP Name Unique for Each TP

One way to specify the intended system where the invokable transaction program (TP) will run is to use a unique TP name for each invokable TP. In this arrangement, the invoking TP identifies the intended invokable TP (and system) simply by naming the TP. This makes it unnecessary for an invokable TP to specify any logical unit (LU) alias in registry or environment variables.

TP Name Not Unique; Local LU Alias Unique

Another way to specify the intended system where the invokable transaction program (TP) will run is to give the same name to multiple invokable TPs, but associate each TP with a unique local logical unit (LU) alias. To do this, configure each invokable TP (through registry or environment variables) to use a unique local LU alias. Then set up the invoking TPs so that each one is routed not only to the correct TP name but also to the correct partner LU alias for the intended invokable TP.

TP Name Not Unique; Local LU Alias Unspecified

If it does not matter on which system an invokable transaction program (TP) runs, use the same name for multiple invokable TPs and do not specify a logical unit (LU) alias in the registry or environment variables for the TPs. In this situation, there are no associated LU aliases in the list of available invokable TP names on a computer running Host Integration Server. Thus, a request received from an invoking TP cannot cause a mismatch on the LU alias, and will match according to the TP name.

In this situation, if you set the **DloadMatchLocalFirst** registry entry to NO, the SNA service randomly routes the request to one of the available TPs. This spreads the processing load among multiple systems and provides hot backup (the ability to take systems online and offline without disrupting service).

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Troubleshooting for Invokable TPs

If there are difficulties with starting an invokable transaction program (TP), there may be a mismatch between the information for the invokable TP, the invoking TP, or logical units (LUs) in the SNA service configuration. That is, there may be a mismatch between the symbolic destination parameters, the registry or environment variables, or LU aliases specified in SNA Manager. For details about how to specify LU aliases in SNA Manager, see Invoking TPs and SNA Service Configuration.

Simplifying CPI-C Configuration

There are several features in Microsoft® Host Integration Server 2004 that can simplify configuration for Common Programming Interface for Communications (CPI-C):

- The implicit, incoming remote logical unit (LU) and the implicit, incoming mode which allow SNA service to accept requests that arrive by unrecognized remote LUs and modes.
- The default local Advanced Program-to-Program Communications (APPC) LU and the default remote APPC LU, which allow LU aliases to be associated with user or group names, simplifying the routing of incoming requests and the configuration of client systems.
- The default outgoing local APPC LU pool, which enables LUs to be allocated dynamically to any invoking TP that does not specify a local LU.
- Automatic partnering, which automatically creates LU-LU pairs and assigns modes to the pairs.

Support for CPI-C Automatic Logon

This section describes the support for automatic logon for Common Programming Interface for Communications (CPI-C) applications that is available in Microsoft® Host Integration Server 2004. This feature requires specific configuration by the network administrator. The CPI-C application must be invoked on the local area network (LAN) side from a client of Host Integration Server. The client must be logged into a Microsoft® Windows® domain, and the client application must be running on Microsoft® Windows Server™ 2003, Windows XP, or Windows 2000.).

To use this feature, the CPI-C client application is coded to use program level security, with a special hard-coded user name of MS$SAME and password of MS$SAME. When this session allocation flows from client to SNA services, Host Integration Server looks up the host account and password corresponding to the Windows 2000 account under which the client is logged on, and substitutes the host account information into the APPC attach message it sends to the host.

Use the following function calls to use CPI-C:

- Call the Set_Conversation_Security_Type function with the *conversation_security_type* parameter set to CM_SECURITY_PROGRAM.
- Call the Set_Conversation_Security_User_ID function with the *security_user_ID* parameter set to the MS$SAME string and the *security_user_ID_length* parameter set to 7.
- Call the Set_Conversation_Security_Password function with the *security_password* parameter set to the MS$SAME string and the *security_password_length* parameter set to 7.

LUA Programmer's Guide

This section of the Microsoft® Host Integration Server 2004 Developer's Guide provides the programmatic techniques and procedures for creating applications with the logical unit application (LUA) programming interface.

For API references and other technical information about LUA, see LUA Programmer's Reference.

For sample code using LUA, see LUA Samples.

This section contains:

- About the LUA Guide
- LUA Concepts
- Writing LUA Applications
- Support for LUA Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

About the LUA Guide

This section provides information required to develop C-language applications that use the conventional logical unit application (LUA) programming interface to exchange data in a Systems Network Architecture (SNA) environment.

This implementation of LUA is compatible with the Request Unit Interface (RUI) and the Session Level Interface (SLI) of earlier versions of the LUA for the Microsoft® Windows NT® and Microsoft Windows® 95 operating systems, the Windows graphical environment, and the IBM Extended Services for OS/2 version 1.0.

This section provides conceptual information and detailed reference information.

To use this section effectively, you should be familiar with:

- Microsoft Host Integration Server 2004
- Microsoft Windows Server™ 2003 and Windows 2000 Server
- SNA concepts
- General concepts for the communications software you have installed. (Refer to your product documentation for information.)
- Microsoft Visual C++® version 6.0 or later

This section contains

- Operating Systems Support for LUA Development
- Finding Further Information about LUA

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Operating Systems Support for LUA Development

This section contains information relating to Microsoft® Windows Server 2003 and Windows® 2000 Server.

Microsoft Host Integration Server 2004 supports the development of logical unit application (LUA) applications for Windows Server 2003 and Windows 2000 Server. Support for LUA applications is provided only for the Win32® subsystem.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Finding Further Information about LUA

This section does not provide a detailed explanation of products, architectures, or standards other than those directly pertaining to the Microsoft® Windows® logical unit application (LUA) programming interface. For information about specific operating environments, refer to your system documentation. For information about SNA, refer to your system network documentation.

The following topics provide additional information about Microsoft Host Integration Server application programming interfaces (APIs) based on SNA architecture:

- About the APPC Guide
- APPC Programmer's Guide
- CPI-C Programmer's Guide

For more information about SNA and about 3270 information display systems, see the following manuals:

- *IBM 3270 Information Display System: 3274 Control Unit Description and Programmer's Guide*
- *IBM 3270 Information Display System: Color and Programmed Symbols*
- *IBM 3270 Information Display System: 3274 Control Unit Display Station: Operator's Guide*
- *IBM Systems Network Architecture: Technical Overview*
- *IBM Systems Network Architecture: Concepts and Products*
- *IBM Advanced Communications Function Products Installation Guide*
- *IBM Installation and Resource Definition*
- *IBM 9370 LAN Token Ring Support*
- *IBM SNA Format and Protocol Reference Manual: Architectural Logic*

For background information about logical unit (LU) 6.2, Advanced Program-to-Program Communications (APPC), and/or the Common Programming Interface for Communications (CPI-C), see the following manuals:

- *IBM Systems Network Architecture: Introduction to APPC*
- *IBM Systems Network Architecture: Transaction Programmer's Reference Manual for LU Type 6.2*
- *IBM SNA: Format and Protocol Reference Manual: Architecture Logic for LU Type 6.2*
- *IBM SNA: Formats*
- *IBM SNA: Technical Overview*
- *IBM SNA: ACF/VTAM Programming for LU Type 6.2*

LUA Concepts

The conventional logical unit application (LUA) programming interface is an application programming interface (API) that enables you to write LUA applications to communicate with host applications.

The interface is provided at the request/response unit and session levels, enabling programmable control over the Systems Network Architecture (SNA) messages sent between your communications software and the host. It can be used to communicate with any of the logical unit types 0, 1, 2, or 3 at the host. The application must send the appropriate SNA messages as required by the host.

For example, you can use LUA to write a 3270 emulation program that communicates with a host 3270 application.

This section contains:

- Windows LUA Overview
- LUs and Sessions
- Configuring for LUA
- LUA Verb Summary
- A Sample LUA Communication Sequence

Windows LUA Overview

To provide one common application programming interface (API) to port applications from various operating environments to Microsoft® Windows Server™ 2003 or Windows® 2000 Server, a Windows Systems Network Architecture (SNA) standard was created. As a direct result of this work, Windows logical unit application (LUA) was developed. The LUA verbs, routines, and information presented in this guide represent an evolving Windows LUA that is based on IBM Extended Services for OS/2 version 1.0 and includes a set of Windows extensions.

The use of the Windows LUA interface on Windows Server 2003 or Windows 2000 causes additional threads to be created within the calling process. These other threads perform interprocess communication with the SNA service over the LAN interface that the client is configured to use (for example, TCP/IP, IPX/SPX, or named pipes).

If an application using Windows LUA is running on Windows Server 2003 or Windows 2000, stopping the SNABASE service causes the application to be unloaded from memory.

This section contains:

- Windows LUA Asynchronous Support
- Before Using Windows LUA
- Using LUA and Asynchronous Verb Completion

Windows LUA Asynchronous Support

Asynchronous verb completion returns immediately from issuing an initial verb (before results have been received) so the application can continue with other processes. A program that issues a verb and does not regain control until the operation completes cannot perform any other operations. This synchronous type of operation, called blocking, is not suited to a server application designed to handle multiple requests from many clients.

By design, logical unit application (LUA) is asynchronous and uses semaphores for notification messages. Semaphores work well for Windows Server 2003 or Windows 2000. Windows LUA provides the following functions for issuing the Request Unit Interface (RUI) and Session Level Interface (SLI) verbs:

- RUI
- SLI
- WinRUI
- WinSLI

WinRUI and **WinSLI** provide asynchronous message notification for all Windows-based RUI and SLI verbs, while **RUI** and **SLI** provide support for event notification. Windows version 3.*x* applications use **WinRUI** and **WinSLI** for asynchronous message notification.

Asynchronous support allows you to be notified of verb completion based on a window handle. You can register a window handle using the RegisterWindowsMessage function with "WinRUI" or "WinSLI" as the string. You then issue a verb using the WinRUI or WINSLI function and passing a window handle. When the LUA verb conversation completes, a message is posted to the window handle that you passed, notifying you that the verb is complete.

The only other Windows extension functions required for Windows LUA are for initialization (WinRUIStartup or WinSLIStartup) and termination (WinRUICleanup or WinSLICleanup) purposes. Depending on your application, other Windows extensions may be useful, but they are not required. A complete description of all Windows LUA verbs, routines, and extensions is provided in LUA RUI Verbs, LUA SLI Verbs, and LUA Extensions for the Windows Environment.

Before Using Windows LUA

The following Windows extensions are of particular importance and should be reviewed before using the logical unit application (LUA) application programming interface (API) and this version of Host Integration Server 2004:

- RUI

  Provides event notification for all Request Unit Interface (RUI) verbs. The application must provide a handle to an event in the **lua_post_handle** member of the verb control block (VCB). The event must be in the not-signaled state. When the asynchronous operation is complete, the application is notified through the signaling of the event. Upon signaling of the event, examine the primary return code and secondary return code for any error conditions.

- SLI

  Provides event notification for all Session Level Interface (SLI) verbs. The application must provide a handle to an event in the **lua_post_handle** member of the VCB. The event must be in the not-signaled state. When the asynchronous operation is complete, the application is notified through the signaling of the event. Upon signaling of the event, examine the primary return code and secondary return code for any error conditions.

- WinRUI

  Provides asynchronous notification for all Windows-based RUI verbs. When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinRUI" as the input string. The *lParam* argument of the message contains the address of the VCB being posted as complete. The *wParam* argument of the message is undefined.

  An application must call WinRUIStartup for initialization before calling WinRUI.

- WinRUICleanup

  An application must call this function when finished using RUI verbs to deregister itself from the Windows LUA implementation. This function terminates and deregisters an application from a Windows LUA implementation.

- WinRUIStartup

  An application must call this function to register itself with a Windows LUA implementation before issuing any further Windows LUA calls using RUI verbs. This function allows an application to specify the version of Windows LUA required and to retrieve details of the specific LUA implementation.

- WinSLI

  Provides asynchronous notification for all Windows-based SLI verbs. When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinSLI" as the input string. The *lParam* argument of the message contains the address of the VCB being posted as complete. The *wParam* argument of the message is undefined.

  An application must call WinSLIStartup for initialization before calling WinSLI.

- WinSLICleanup

  An application must call this function when finished using SLI verbs to deregister itself from the Windows LUA implementation. This function terminates and deregisters an application from a Windows LUA implementation.

- WinSLIStartup

  An application must call this function to register itself with a Windows LUA implementation before issuing any further Windows LUA calls using SLI verbs. This function allows an application to specify the version of Windows LUA required and to retrieve details of the specific LUA implementation.

Using LUA and Asynchronous Verb Completion

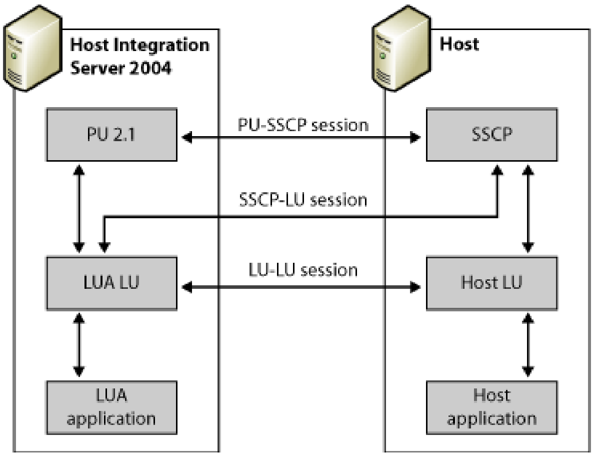
Host Integration Server permits one outstanding Windows SNA asynchronous call per connection and one blocking verb per thread. When the asynchronous verb completes, logical unit application (LUA) does the following for a Windows Server 2003 or Windows 2000 system.

Two types of notification are possible:

- The preferred type is the event method, in which the LUA application issues **WaitForSingleObject/WaitForMultipleObject**.
- The application can also post the "WinRUI"/"WinSLI" notification message to the window handle of the **WinRUI/WinSLI** message.

LUs and Sessions

The following figure shows the SNA components required for logical unit application (LUA) communications.



An LUA application uses a local LU, which uses Microsoft® Host Integration Server to communicate with the host system. There are three progressive sessions when Host Integration Server connects to the host node:

- The PU-SSCP session, between the Host Integration Server physical unit (PU) and the host's system services control point (SSCP). This is used mainly for diagnostic information. LUA communications require only the capabilities of PU 2.0. Host Integration Server provides these capabilities, plus the additional capabilities included in PU 2.1.
- The SSCP-LU session, between the LUA LU at the computer and the SSCP. This is used for controlling the LU.
- The LU-LU session, between the LUA LU at the computer and the host LU. This is used for data transfer between the computer and the host application.

LUA allows applications to send and receive data on the SSCP-LU session and on the LU-LU session. An LUA application can send data on this session using the common service verb TRANSFER_MS_DATA. LUA does not provide access to the PU-SSCP session.

The SSCP and LU sessions each provide two priorities of messages, normal and expedited. Expedited messages take precedence over other messages waiting to be transmitted on the same session. There are four different flows on which a message can be sent or received:

- SSCP session (expedited flow)
- LU session (expedited flow)
- SSCP session (normal flow)
- LU session (normal flow)

The LU session normal flow carries most of the data. The other flows are used only for control purposes.

> **Note** The implementation of LUA in Host Integration Server 2004 does not allow applications to send data on the SSCP expedited flow and does not return data to an application on this flow.

Configuring for LUA

The Microsoft® Host Integration Server 2004 configuration file, which is set up and maintained by the system administrator, contains information that is required for logical unit application (LUA) applications to communicate. An LUA LU is configured by the link service to use a connection to the host, and is given an LU number that matches that of an LU on the host.

The configuration can include LUA LU pools. A pool is a group of LUs with similar characteristics, and it enables an application to use any free LU from the pool. This feature can be used to allocate LUs on a first-come, first-served basis when there are more applications than LUs available, or to provide a choice of LUs on different connections.

The following communications components are configured for use with an LUA application.

Component	Description
Link service	A link service for communicating with the host. This component is normally configured by the setup program during Host Integration Server 2004 installation.
Connection	A connection to the host that uses the link service.
Local node	A local node that owns the connection. This component is configured automatically.
LUA LU	An LUA LU on the local node, configured to use the connection, with an LU number that matches an LU on the host.
LUA LU pool (optional)	If necessary, you can configure more than one LUA LU for the application, and group the LUs into a pool. This means that an application can specify the pool rather than a specific LU when issuing the RUI_INIT verb to start a session. Host Integration Server 2004 uses this name in one of the following ways: • If the name supplied is the name of an LU that is not in a pool, a session is assigned using that LU if it is available (that is, if it is not already in use by an LUA application). • If the name supplied is the name of an LU pool, or the name of any LU within the pool, a session is assigned using the first available LU in the pool (if one is available). Note that this may not be the LU whose name was specified by the RUI_INIT verb.

LUA Verb Summary

Logical unit application (LUA) application programs can establish and use SNA sessions with either the Request Unit Interface (RUI) application programming interface (API) or the Session Level Interface (SLI) API. If an LUA application establishes an SNA session using **RUI_INIT**, it cannot issue any SLI verbs for that session. Likewise, if an LUA application establishes an SNA session using **SLI_OPEN**, it cannot issue any RUI verbs for that session.

Following is a brief summary of each LUA verb or user-supplied routine. Each verb supplies parameters to LUA, which performs the desired function and returns parameters to the application:

RUI_BID
: Allows the application to determine when information from the host is available to be read.

RUI_INIT
: Sets up the SSCP-LU session for an LUA application.

RUI_PURGE
: Cancels an outstanding **RUI_READ**.

RUI_READ
: Receives data or status information sent from the host to the LUA application's LU, on either the SSCP session or the LU session.

RUI_TERM
: Ends the SSCP session for an LUA application. It also terminates the LU session if it is active.

RUI_WRITE
: Sends data to the host on either the SSCP session or the LU session.

SLI_BID
: Notifies the SLI application that a message is waiting to be read using **SLI_RECEIVE**. It also provides the current status of the session to the LUA application.

SLI_BIND_ROUTINE
: An optional, user-supplied exit routine that notifies the LUA application that a BIND request has come from the host. It allows the routine to examine the request and formulate a response.

SLI_CLOSE
: Ends a session opened with **SLI_OPEN**.

SLI_OPEN
: Transfers control of the specified LU to the LUA application. It establishes a session between the SSCP and the specified LU, as well as an LU-LU session.

SLI_PURGE
: Cancels **SLI_RECEIVE** verbs issued with a wait condition.

SLI_RECEIVE
: Receives responses, SNA commands, and data into the buffer of an LUA application. It also provides the current status of the session to the LUA application.

SLI_SEND
: Sends responses, SNA commands, and data from an LUA application to a host LU.

SLI_STSN_ROUTINE
: An optional, user-supplied exit routine that notifies the LUA application that a set and test sequence number (STSN) command has come from the host. It allows the routine to examine the request and formulate a response.

A Sample LUA Communication Sequence

This section illustrates how Request Unit Interface (RUI) and Session Level Interface (SLI) verbs are used for a logical unit application (LUA) communication sequence. The two figures illustrate the LUA verbs used to start a session, to exchange data, and to end the session, as well as the SNA messages sent and received. The arrows indicate the direction in which SNA messages flow.

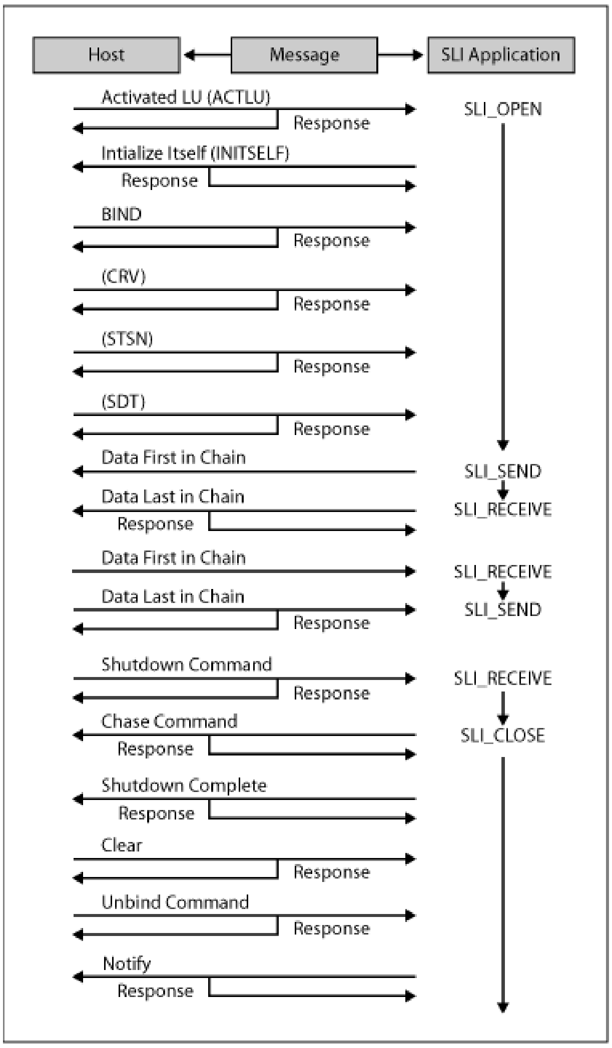
RUITERM

In this example, the application performs the following tasks:

- Issues an RUI_INIT verb to establish the system services control point (SSCP) session. (**RUI_INIT** does not complete until the LUA application has received an ACTLU message from the host and sent a positive response. However, these messages are handled by Microsoft® Host Integration Server 2004 and are not exposed to the LUA application.)
- Sends an INITSELF message to the SSCP to request a BIND and reads the response.
- Reads a BIND message from the host and writes the response. This establishes the LU session.
- Reads an SDT message from the host, which indicates that initialization is complete and data transfer can begin.
- Sends a chain of data consisting of three request/response units (RUs) and reads the response. The last RU indicates that a definite response is required.
- Reads a chain of data consisting of three RUs and writes the response.
- Reads an UNBIND message from the host and writes the response. This terminates the LU session.
- Issues RUI_TERM to terminate the SSCP session. (Host Integration Server 2004 sends a NOTIFY message to the host and waits for a positive response. However, these messages are handled by Host Integration Server 2004 and are not exposed to the LUA application.)

Communication Sequence Using SLI Verbs



Host

In the example shown here, the application performs the following tasks:

- Issues an SLI_OPEN verb to establish the SSCP session.
- Sends an INITSELF message to the SSCP to request a BIND and reads the response.
- Reads a BIND message from the host and writes the response. This establishes the LU session.
- Reads an SDT message from the host, which indicates that initialization is complete and data transfer can begin.

> **Note** INITSELF, BIND, and SDT messages are handled by Host Integration Server 2004 if the application is using SLI. The **SLI_OPEN** does not return until Host Integration Server 2004 has sent an SDT and response.

- Issues SLI_SEND and SLI_RECEIVE to transfer data, SNA commands, or SNA responses between the host and the application.
- Issues SLI_CLOSE to terminate the SSCP session. (Host Integration Server 2004 sends a NOTIFY message to the host and waits for a positive response. However, these messages are handled by Host Integration Server 2004 and are not exposed to the LUA application.)

Writing LUA Applications

The information contained in this section will help you write logical unit application (LUA) application programs for use with Microsoft® Host Integration Server.

This section contains:

- Using LUA Verbs
- LUA VCB Format
- LUA Synchronous and Asynchronous Verb Completion
- Compiling and Linking an LUA Application
- Resetting LUA LUs
- Multiple Processes and Multiple Sessions Using LUA
- Programming Techniques for LUA Pools
- Writing Portable LUA Applications
- LUA System Considerations on Microsoft Windows Server 2003 or Windows 2000
- SNA Considerations Using LUA

Using LUA Verbs

This implementation of logical unit application (LUA) is available to applications written in Microsoft® C++® version 6.0 or later. Applications access all LUA functions on Microsoft Windows™ Server 2003 or Windows® 2000 Server by issuing verbs using the external C functions RUI, SLI, WinRUI, and WinSLI.

Symbolic constants are defined in the WINLUA.H header file for many parameter values. Refer to the WINLUA.H file (contained in the Microsoft Host Integration Server SDK) for a list of LUA constants.

You should use the symbolic constant and not the hexadecimal value when setting values for supplied parameters, or when testing values of returned parameters.

Parameters marked as reserved should always be set to zero.

This section contains:

- RUI and SLI Definitions
- Using an LUA Verb

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

RUI and SLI Definitions

The definitions of the RUI and SLI functions are as follows:

```
void WINAPI RUI(struct LUA_VERB_RECORD FAR * verb);
void WINAPI SLI(struct LUA_VERB_RECORD FAR * verb);
int WINAPI WinRUI(HWND handle, struct LUA_VERB_RECORD FAR * verb);
int WINAPI WinSLI(HWND handle, struct LUA_VERB_RECORD FAR * verb);
```

The WINLUA.H header file supplied with your Host Integration Server SDK includes prototypes of these functions.

The only parameter passed to the **RUI** or **SLI** function is the address of a verb control block (VCB). The VCB is a structure made up of variables that:

- Identify the logical unit application (LUA) verb to be executed.
- Supply information used by the verb.
- Contain information returned by the verb when execution is complete.

The parameters passed to the WinRUI or WinSLI function are a window handle and the address of a VCB. The window handle is used for message notification when the issued verb has completed.

The VCB structure is declared in the WINLUA.H header file. For general VCB information, see LUA VCB Format. For verb-specific VCB information, see the reference documentation for each verb.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Issuing an LUA Verb

The following procedure is required to issue a logical unit application (LUA) verb. In this example, the verb issued is RUI_INIT.

To issue an LUA verb

1. Create a variable for the verb control block (VCB) structure. For example:

   ```
   #include <winlua.h>
           .
           .
   struct LUA_VERB_RECORD rui_init;
   ```

2. The LUA_VERB_RECORD structure is declared in the WINLUA.H header file.
3. Clear (set to zero) the variables within the VCB:

   ```
   memset( &rui_init, 0, sizeof( rui_init) );
   ```

   LUA requires that all reserved parameters, and all parameters not required by the verb being issued, must be set to zero. The simplest way to do this is to set the entire VCB to zeros before setting the parameters required for this particular verb.

4. Assign values to the VCB parameters that supply information to LUA:

   ```
   rui_init.common.lua_verb = LUA_VERB_RUI;
   rui_init.common.lua_verb_length = sizeof(struct LUA_COMMON);
   rui_init.common.lua_opcode = LUA_OPCODE_RUI_INIT;
   memcpy (rui_init.common.lua_luname, "THISLU  ", 8);
   ```

   The values LUA_VERB_RUI and LUA_OPCODE_RUI_INIT are symbolic constants. These constants are defined in the WINLUA.H header file in the Host Integration Server SDK. To ensure portability between different systems, use symbolic constants and not integer values.

5. Invoke LUA. The only parameter is a pointer to the address of the structure containing the VCB for the desired verb.

   ```
   RUI( &rui_init );
   ```

6. Check the asynchronous flag (**rui_init.common.lua_flag2.async**) to determine whether the verb completed asynchronously. If events are being used and the verb did complete asynchronously, wait for the event to complete.

   ```
   if (rui_init.common.lua_flag2.async)
   {
   /* verb will complete asynchronously so continue
   with other processing */
   /* then wait */
   WaitForSingleObject (...)
   }
   ```

   Do not check the return code. It may have changed from LUA_IN_PROGRESS to LUA_OK by the time you check it.

7. Check the variables returned by LUA.

   ```
   if( rui_init.common.lua_prim_rc == LUA_OK )
   {
   /* Init OK */
           .
           .
   }
   else
   {
   ```

```
/* Do error routine */
        .
        .
}
```

LUA VCB Format

The logical unit application (LUA) verb control block (VCB) is called LUA_VERB_RECORD. It is a structure with two parts:

- A structure, LUA_COMMON, which is used for all the LUA verbs.
- A union, LUA_SPECIFIC, which is used only by RUI_BID, SLI_BID, SLI_OPEN, and SLI_SEND.

This section contains:

- LUA_VERB_RECORD
- LUA_COMMON
- LUA_SPECIFIC

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

LUA_VERB_RECORD

The logical unit application (LUA) verb control block (VCB) structure is as follows:

```
typedef struct LUA_VERB_RECORD {
    struct LUA_COMMON common;
    union LUA_SPECIFIC specific;
} LUA_VERB_RECORD;
```

To access parameters in the common part of the VCB, you need to include the structure member name **common**. For example, when using a verb record structure named **Lua_Verb**, you access its **lua_prim_rc** member as **Lua_Verb.common.lua_prim_rc**.

To access parameters in the specific part of the VCB, you need to include the union member name **specific.** For example, when issuing RUI_BID using a verb record structure named **Lua_Verb**, you access its **lua_peek_data** member as **Lua_Verb.specific.lua_peek_data**.

For a complete listing of the structures and related values in the LUA VCB, see LUA Verb Control Blocks.

LUA_COMMON

The following structure lists the common data structure parameters used by all the logical unit application (LUA) verbs.

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *     lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
} LUA_COMMON;
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_RUI for Request Unit Interface (RUI) verbs or LUA_VERB_SLI for Session Level Interface (SLI) verbs. For both of these macros the value is 0x5200.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, for example, LUA_OPCODE_RUI_BID for the RUI_BID verb.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_OPEN and RUI_INIT require this parameter. Other Windows LUA verbs only require this parameter if **lua_sid** is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Specifies the offset from the start of the VCB to the extension list of user-supplied dynamic-link libraries (DLLs). Not used by RUI in Host Integration Server and should be set to zero.

lua_cobol_offset

Offset of the COBOL extension. Not used by LUA in Host Integration Server and should be zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Specifies the length of received buffer for RUI_READ and SLI_RECEIVE. For other RUI and SLI verbs, it is not used and should be set to zero.

lua_data_length

Returned parameter. Specifies the length of data returned in **lua_peek_data** for the RUI_BID verb.

lua_data_ptr

Pointer to the application-supplied buffer that contains the data to be sent for SLI_SEND and RUI_WRITE or that will receive data for **SLI_RECEIVE** and **RUI_READ**. For other RUI and SLI verbs, this parameter is not used and should be set to zero.

lua_post_handle

Supplied parameter. Used under Windows Server 2003 or Windows 2000 if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message sent or received. Various sub parameters are set for write functions and returned for read and bid functions.

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits.

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received. It is set for the write function and returned by the read and bid functions.

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

RU category, two bits.

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1
Supplied parameter. Contains a data structure containing flags for messages supplied by the application. This parameter is used by RUI_BID, RUI_READ, RUI_WRITE, SLI_BID, SLI_RECEIVE, and SLI_SEND. For other LUA verbs, this parameter is not used and should be set to zero.

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

SSCP expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

lua_message_type
Specifies the type of the inbound or outbound SNA commands and data. This is a returned parameter for RUI_INIT and SLI_OPEN and a supplied parameter for SLI_SEND. For other LUA verbs, this variable is not used and should be set to zero.

Possible values are:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIND

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_CLEAR

LUA_MESSAGE_TYPE_CRV

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RQR

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SHUTD

LUA_MESSAGE_TYPE_SIGNAL

LUA_MESSAGE_TYPE_SDT

LUA_MESSAGE_TYPE_STSN

LUA_MESSAGE_TYPE_UNBIND

The SLI receives and responds to the BIND, CRV, and STSN requests through the LUA interface extension routines.

LU_DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2
Returned parameter. Contains flags for messages returned by LUA. This parameter is returned by RUI_BID, RUI_READ, RUI_WRITE, SLI_BID, SLI_RECEIVE, and SLI_SEND. For other LUA verbs this parameter is not used and should be set to zero.

lua_flag2.bid_enable

Indicates that **RUI_BID** was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56
Supplied parameter. Reserved field used by SLI_OPEN and RUI_INIT. For all other LUA verbs, this parameter is reserved and should be set to zero.

lua_encr_decr_option

Field for cryptography options. On **RUI_INIT**, only the following are supported:

- **lua_encr_decr_option** = 0
- **lua_encr_decr_option** = 128

For all other LUA verbs, this parameter is reserved and should be set to zero.

LUA_SPECIFIC

The following union shows the specific data structure that is included for functions that use the **LUA_SPECIFIC** part of a verb control block. The only logical unit application (LUA) verbs that use this union are RUI_BID, SLI_BID, SLI_OPEN, and SLI_SEND.

```
union LUA_SPECIFIC {
    struct SLI_OPEN open;
    unsigned char lua_sequence_number[2];
    unsigned char lua_peek_data[12];
} LUA_SPECIFIC;
```

Members

open
The union member of **LUA_SPECIFIC** used by the **SLI_OPEN** verb.

lua_sequence_number
The union member of **LUA_SPECIFIC** used by the **SLI_SEND** verb. Returned parameter. Sequence number of the RU to the host.

lua_peek_data
The union member of **LUA_SPECIFIC** used by the **RUI_BID** and **SLI_BID** verbs. Returned parameter. Contains up to 12 bytes of the data waiting to be read.

LUA_SPECIFIC.SLI_OPEN

The following structure shows the **SLI_OPEN** fields of the **LUA SPECIFIC** union member for the SLI_OPEN verb.

```
struct SLI_OPEN {
    unsigned char lua_init_type;
    unsigned char lua_resv65;
    unsigned short lua_wait;
    struct LUA_EXT_ENTRY lua_open_extension[3];
    unsigned char lua_ending_delim;
} SLI_OPEN;
```

Members

lua_init_type
  Type of session initiation.
lua_resv65
  Reserved field.
lua_wait
  Secondary retry wait time.
lua_open_extension
  Supplied parameter. Specifies any user-supplied dynamic-link libraries (DLLs) used to process specific LUA messages.
lua_ending_delim
  Extension list delimiter.

LUA_EXT_ENTRY

The following structure shows the **LUA_EXT_ENTRY** fields of the LUA SPECIFIC.SLI_OPEN union member for the SLI_OPEN verb.

```
struct LUA_EXT_ENTRY {
     unsigned char lua_routine_type;
     unsigned char lua_module_name[9];
     unsigned char lua_procedure_name[33];
};
```

Members

lua_routine_type
Extension routine type.
lua_module_name
Extension DLL module name.
lua_procedure_name
Procedure name to call in the extension DLL module.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

LUA Synchronous and Asynchronous Verb Completion

Logical unit application (LUA) verbs can complete execution either synchronously or asynchronously.

Synchronous Verb Completion

When LUA is able to complete all the processing for a verb as soon as it is issued, the verb has completed synchronously. When this happens, the primary return code is set to a value other than LUA_IN_PROGRESS, and the **lua_flag2.async** bit is set to zero.

The value of the **lua_flag2.async** bit should be tested, not the primary return code being not equal to LUA_IN_PROGRESS. (For information about these returned parameters, see individual verb descriptions.)

Asynchronous Verb Completion

Some LUA verbs (for example, RUI_PURGE) complete quickly after local processing. However, most verbs take some time to complete because they require messages to be sent to and received from the local node or the host application.

When LUA must wait for information from the remote LU or from the local node before it can complete a verb, the verb completes asynchronously.

When this happens, the **lua_flag2.async** bit is set to 1. The primary return code is also normally set to LUA_IN_PROGRESS, but this value cannot be relied on. The value of the **lua_flag2.async** bit should be tested. The application can now perform other processing, or wait for notification from LUA that the verb has completed. LUA issues this notification by setting the primary return code to its final value and leaving **lua_flag2.async** set to 1.

When the verb completes, LUA does the following depending on your environment:

- For Windows Server 2003 or Windows 2000, two types of notification are possible. The LUA application either:

  Issues **WaitForSingleObject** or **WaitForMultipleObject**.

  —or—

  Posts the "WinRUI"/"WinSLI" notification message to the window handle of the **WinRUI**/**WinSLI** message.

  The event method using **WaitForSingleObject** or **WaitForMultipleObject** is the preferred way to receive asynchronous notification on Windows Server 2003 or Windows 2000.
- In the Windows environment, it notifies the completion of an asynchronous request by posting the "WinRUI"/"WinSLI" notification message to the window handle of the **WinRUI**/**WinSLI** message. A window handle has been added as the first parameter passed to the WinRUI and WinSLI entry points.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Compiling and Linking an LUA Application

Use the following procedure to compile and link a logical unit application (LUA) application.

To compile and link an LUA application for use with Host Integration Server

- Update the path statement to include the directory containing the LUA application.
- Set any required environmental variables.
- Compile the application, including the WINLUA.H header file provided in the Host Integration Server SDK, to produce the .obj files.
- Link the application with the WINLUA.LIB library to produce an .exe file.

Resetting LUA LUs

Microsoft® Host Integration Server provides a facility for resetting logical unit application (LUA) LUs or forcing off LUA applications, which is useful if an application has become deadlocked or is looping.

The NetView command **deactivate-oldlu** can also be used to reset an LUA LU. These facilities interact with the LUA application as described in the following paragraphs.

When an LUA LU is reset through Host Integration Server or by using the **deactivate-oldlu** command, Host Integration Server sends an UNBIND message to the application (as though the host had issued it).

The UNBIND message sent to the application is 0x32 0x0E, indicating a recoverable LU failure, and is returned to the application on a subsequent RUI_READ. The LU session is terminated, but the system services control point (SSCP) session remains active. (The LU is returned to the same state as if RUI_INIT has just completed.)

Multiple Processes and Multiple Sessions Using LUA

Two processes cannot use the same logical unit application (LUA) session. Only the process that issues RUI_INIT can use the session that is started by the verb. Before another process can use LUA, it must issue **RUI_INIT** to obtain a new session. However, different threads of the same process can issue verbs for the same LUA session.

A single process can simultaneously use more than one LUA session by issuing multiple **RUI_INIT** verbs. Win32® processes support for up to 15,000 sessions for applications based on the Microsoft® Windows Server™ 2003 or Windows® 2000 Server. Each session must use a different LU. Two or more sessions can use the same pool, but the **lua_luname** member (which is either the name of the pool or the name of an LU within the pool) must be different for each **RUI_INIT**.

Two or more instances of the same LUA application can run as different processes, but they must use different LUs. This can be done by using LU pools. The two processes can specify the same pool, but are allocated different LUs from that pool.

Programming Techniques for LUA Pools

When working with a logical unit application (LUA) LU pool, specify the pool name at the beginning of the conversation and then use the **lua_sid** member (not the pool name) with subsequent calls. This is necessary because the **lua_sid** member is a unique identifier, but the pool name is not, because a pool is designed to supply LUs for multiple conversations.

When using RUI_INIT or SLI_OPEN with an LUA pool, specify the pool name with the **lua_luname** member. For subsequent calls in the same conversation, use the **lua_sid** member returned from **RUI_INIT** or **SLI_OPEN** to specify the conversation.

> **Note** On completion of RUI_INIT or SLI_OPEN, the lua_luname member contains the actual name of the LU used. This allows you to create code for a display for the user, showing the actual LU name used in a particular conversation.

Writing Portable LUA Applications

Use the following guidelines for writing logical unit application (LUA) applications that are portable to other environments:

- Use the symbolic constant names for parameter values and return codes, and not the numeric values shown in the WINLUA.H file. (For more information, see the WINLUA.H file in the Microsoft® Host Integration Server SDK.)
- When accessing SNA sense codes in a data buffer, use the symbolic constants rather than the numeric values. This ensures that the byte storage order is correct for your particular system. You should use **memcpy** to set the values, and **memcmp** to test them. For example:

```
memcpy (this_verb.common.lua_data_ptr, LUA_INCORRECT_REQ_CODE, 4);
if (memcmp (this_verb.common.lua_data_ptr,
LUA_INCORRECT_REQ_CODE, 4) == 0)
{
.....
}
```

- Ensure that any parameters shown as reserved are set to zero.
- Set the **lua_verb_length** parameter as described in the verb description.

LUA System Considerations on Microsoft Windows Server 2003 or Windows 2000

This section provides specific information about developing logical unit application (LUA) applications for the following operating systems.

This section contains:

- LUA Considerations on Microsoft Windows Server 2003 or Windows 2000

LUA Considerations on Microsoft Windows Server 2003 or Windows 2000

This topic summarizes information for developing Win32® logical unit application (LUA) applications for Microsoft® Windows™ Server 2003 or Windows® 2000 Server.

Byte ordering

The values of constants defined in the WINLUA.H file are dependent on the byte ordering of the hardware used. Macros are used to set the constants to the correct value.

Currently, the include files in Windows Server 2003 or Windows 2000 to indicate the hardware. These same macros are used by Microsoft® Host Integration Server 2004, along with the Win32 macro, to indicate the byte ordering needs. The macros must be defined in the application or on the command line when building the application.

For example, the primary return code of LUA_PARAMETER_CHECK is defined to have a value of 0x0001. Depending on the environment, the constant LUA_PARAMETER_CHECK may or may not be 0x0001. Some formats define the value as it appears in memory. Others define it as a 2-byte variable. Because it cannot be assumed that an application will always use provided constants rather than hardwired values, a macro can be defined to swap the bytes. The following example shows how the macro can be used:

```
#define LUA_PARAMETER_CHECK LUA_FLIPI (0X0001)
```

Events

To receive data asynchronously, an event handle is passed in the semaphore field of the verb control block (VCB). This event must be in the non-signaled state when passed to LUA, and the handle must have EVENT_MODIFY_STATE access to the event.

Library names

To support the coexistence of Win16 and Win32 API libraries on the same computer, the Win32 dynamic-link library (DLL) names were changed from the names used by Win16 API libraries. Win32 stub DLL libraries using the old names are supplied with Host Integration Server 2004 so that older applications will still run, although these platforms are no longer supported.

Old DLL names	New DLL names
WINRUI.DLL	WINRUI32.DLL
WINSLI.DLL	WINSLI32.DLL

The new DLL names should be used for all new applications intended to run on Host Integration Server 2004.

Load-time linking

To be dynamically linked to LUA at load time, you must do one of the following at link time:

- Insert the following **IMPORTS** statements in the definition (.def) file used to link the application:

  (For RUI)

  ```
  IMPORTS WINRUI.RUI
  IMPORTS WINRUI WinRUI
  IMPORTS WINRUI.WinRUIStartup
  IMPORTS WINRUI.WinRUICleanup
  ```

  (For SLI)

  ```
  IMPORTS WINSLI.SLI
  IMPORTS WINSLI.WinSLI
  IMPORTS WINSLI.WinSLIStartup
  IMPORTS WINSLI.WinSLICleanup
  ```

- Link the application to WINRUI.LIB (for RUI) or WINSLI.LIB (for SLI), which contain the entry-point linkage information.

Multiple threads

An LUA application can have multiple threads that issue verbs. LUA for the Win32 system makes provisions for multithreading processes on Windows Server 2003 or Windows 2000. A process contains one or more threads of execution. All references to threads refer to actual threads in a multithreaded Windows Server 2003 or Windows 2000.

Packing

For performance considerations, the VCBs are not packed. VCB structure member elements after the first element are aligned on either the size of the member type or DWORD boundaries, whichever is smaller. As a result, DWORDs are aligned on DWORD boundaries, WORDs are aligned on WORD boundaries, and BYTEs are aligned on BYTE boundaries. This means, for example, that there is a 2-byte gap between the primary and secondary return codes. Therefore, the elements in a VCB should only be accessed using the structures provided.

This option for structure and union member alignment is the default behavior for Microsoft C/C++ compilers. For compatibility with the supplied LUA libraries, make sure to use an equivalent structure and union member packing option when using other C/C++ compilers or when explicitly specifying a structure alignment option when using Microsoft compilers.

Registering and deregistering applications

All LUA applications for the Windows Server 2003 or Windows 2000 system must call the Windows SNA extension WinRUIStartup or WinSLIStartup at the beginning of the session to register the application and WinRUICleanup or WinSLICleanup at the end of the session to deregister the application.

Restrictions on 3270-style LUs

A Windows Server 2003 or Windows 2000 process cannot access 3270-style LUs from both the function management interface (FMI) and LUA APIs at the same time. However, the process can use the LUA APIs to access LUA LUs while using FMI APIs to access 3270-style LUs.

Run-time linking

For an application to be dynamically linked to LUA at run time, it must issue the following calls:

- **LoadLibrary** to load the specified library module for Windows LUA. That is, WINRUI32.DLL (for RUI), and WINSLI32.DLL (for SLI).
- **GetProcAddress** to retrieve the address of the LUA function entry points exported by the DLL. For RUI, the function entry points are RUI, WinRUI, WinRUIStartup, and WinRUICleanup. For SLI, the function entry points are SLI, WinSLI, WinSLIStartup, and WinSLICleanup.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

SNA Considerations Using LUA

This section explains SNA information you need to consider when writing logical unit application (LUA) applications.

BIND checking

During initialization of the LU session, the host sends to the LUA application a BIND message that contains information such as request/response unit (RU) sizes for use by the LU session. Microsoft® Host Integration Server returns this message to the LUA application on RUI_READ. The LUA application must verify that the parameters specified on the BIND are suitable. The application has the following options:

- It can accept the BIND as it is, by issuing RUI_WRITE containing an OK response to the BIND. No additional BIND data can be sent on the response.
- It can try to negotiate one or more BIND parameters. (This is only permitted if the BIND is negotiable.) To do this, the application issues **RUI_WRITE** containing an OK response, but including the modified BIND as data.
- It can reject the BIND by issuing **RUI_WRITE** containing a negative response, using an appropriate SNA sense code as data.

  Validating the BIND parameters and ensuring that all messages sent are consistent with them is the responsibility of the LUA application. However, the following two restrictions apply:

- Host Integration Server rejects any **RUI_WRITE** that specifies an RU length greater than the size specified on the BIND.
- Host Integration Server requires the BIND to specify that the secondary LU is the contention winner and that error recovery is the responsibility of the contention loser.

> **Note** For SLI, an application must specify that it will use SLI_BIND_ROUTINE on the SLI_OPEN if it will do any BIND checking.

Courtesy acknowledgments

Host Integration Server keeps a record of requests received from the host to correlate any response sent by the application with the appropriate request. When the application sends a response, Host Integration Server correlates the response with the data from the original request, and can then free the storage associated with it.

If the host specifies exception response only (a negative response can be sent but a positive response should not be sent), Host Integration Server must still keep a record of the request in case the application subsequently sends a negative response. If the application does not send a response, the storage associated with this request cannot be freed.

Because of this, Host Integration Server enables the LUA application to issue a positive response to an exception-response-only request from the host. (This is known as a courtesy acknowledgment.) The response is not sent to the host, but is used by LUA to clear the storage associated with the request.

> **Note** The application does not need to send a courtesy acknowledgment for each exception-response-only request. For efficiency, the application can respond less frequently. The node treats a courtesy acknowledgment as an implicit acknowledgment for all prior pending requests.

Distinguishing SNA sense codes from other secondary return codes

A secondary return code that is not a sense code always contains a value of zero in its first two bytes.

An SNA sense code always contains a nonzero value in its first two bytes. The first byte gives the sense code category and the second identifies a particular sense code within that category. (The third and fourth bytes can contain additional information or can be zero.)

Information on SNA sense codes

If you need information about a returned sense code, see

- Status-Error Message
- Error and Sense Codes

Negative responses and SNA sense codes

SNA sense codes can be returned to an LUA application in the following cases:

- When the host sends a negative response to a request from the LUA application, it includes an SNA sense code indicating the reason for the negative response. This is reported to the application on a subsequent RUI_READ or SLI_RECEIVE with the following information.

Sense code	Description
Primary return code	LUA_OK.
Request/response indicator, response type indicator, and sense data included indicator	All set to 1, indicating a negative response that includes sense data.
Data returned	The SNA sense code.

- When Host Integration Server receives invalid data from the host, it generally sends a negative response to the host and does not pass the invalid data to the LUA application. This is reported to the application on a subsequent RUI_READ, SLI_RECEIVE, RUI_BID, or SLI_BID with the following information:

Sense code	Description
Primary return code	LUA_NEGATIVE_RESPONSE.
Secondary return code	The SNA sense code sent to the host.

- In some cases, Host Integration Server detects that data supplied by the host is invalid, but cannot determine the correct sense code to send. In this case, it passes the invalid data in an exception request (EXR) to the LUA application on RUI_READ or SLI_RECEIVE with the following information.

Sense code	Description
Request/response indicator	Set to 0, indicating a request.
Sense data included indicator	Set to 1, indicating that sense data is included. (This indicator is normally used only for a response.)
Message data	A suggested SNA sense code.

  The application must then send a negative response to the message. It can use the sense code suggested by Host Integration Server, or it can alter the sense code.

- Host Integration Server can send a sense code to the application to indicate that data supplied by the application was invalid. This is reported to the application on RUI_WRITE or SLI_SEND with the following information.

Sense code	Description
Primary return code	LUA_UNSUCCESSFUL.
Secondary return code	SNA sense code.

  The sense codes that can be returned as secondary return codes on LUA verbs are listed in the WINLUA.H header file. For this file, see the Host Integration Server or SNA SDK.

Pacing

Pacing is handled by the LUA interface. An LUA application does not need to control pacing and should never set the pacing indicator flag.

If pacing is being used on data sent from the LUA application to the host (determined by the BIND), RUI_WRITE or SLI_SEND may take some time to complete. This is because LUA has to wait for a pacing response from the host before it can send more data.

If an LUA application transfers large quantities of data in one direction, either to the host or from the host (for example, a file transfer application), the host configuration should specify that pacing is used in that direction. This ensures that the node receiving the data is not flooded with data and does not run out of data storage.

Purging data to end of chain

When the host sends a chain of request units to an LUA application, the application can wait until the last RU in the chain is received before sending a response, or it can send a negative response to an RU that is not the last in the chain. If a negative response is sent mid-chain, LUA purges all subsequent RUs from this chain and does not send them to the application.

When LUA receives the last RU in the chain, it indicates this to the application by setting the primary return code of RUI_READ or RUI_BID to LUA_NEGATIVE_RESPONSE with a zero secondary return code.

Note The host can terminate the chain by sending a message such as CANCEL while in mid-chain. In this case, the CANCEL message is returned to the application on RUI_READ. The LUA_NEGATIVE_RESPONSE return code is not used.

Segmentation

Segmentation of RUs is handled by the LUA interface. LUA always passes complete RUs to the application, and the application should pass complete RUs to LUA.

Support for LUA Single Sign-On

This section describes the logical unit application (LUA) support for Single Sign-On using 3270 display sessions that is available in Microsoft® Host Integration Server 2004.

Over 3270 LUs, a Single Sign-On feature for LUA applications is supported to automate the overall logon process. When configured for this feature, Host Integration Server 2004 automatically replaces special keywords in the data stream with the actual host user name and password at appropriate points in the session.

> **Note** Single Sign-On is not supported over LUA logical units (LUs).

To open 3270 LUs from an LUA application using Request Unit Interface (RUI), the **lua_resv56[1]** field must be set to a nonzero value when this verb control block (VCB) is passed to RUI_INIT. To open 3270 LUs from an LUA application using a Session Level Interface (SLI), the **lua_resv56[2]** field must be set to a nonzero value when this VCB is passed to SLI_OPEN. For details, see the reference sections in RUI_INIT and SLI_OPEN.

This section contains:

- Prerequisites for LUA Single Sign-On
- Registry Settings Used for LUA Single Sign-On
- LUA User Name and Password Replacement

Prerequisites for LUA Single Sign-On

In preparation for using Single Sign-On over 3270 logical units (LUs), the system administrator must define a host security domain containing host connections. This host security domain must be initially created or modified to enable the Single Sign-On feature. The system administrator must enable a user's Microsoft® Windows Server™ 2003 or Windows® 2000 Server account in the host security domain and either the administrator or the user must establish a mapped host account for the Windows Server 2003 or Windows 2000 domain user name.

The user must be logged on to a Windows Server 2003 or Windows 2000 domain with a user name and password. Note that this Single Sign-On feature is only supported over 3270 LUs.

Registry Settings Used for LUA Single Sign-On

The logical unit application (LUA) Single Sign-On feature depends on Host Integration Server 2004 scanning 3270 logical units (LUs) used in the logon process for special keywords that are defined in the registry on the computer running Host Integration Server 2004. The values for these special keywords can be defined by the system administrator on the computer running Host Integration Server 2004.

The registry settings used by the LUA Single Sign-On process are located under the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services** registry node. Installed under the **SNASERVR\PARAMETERS** subkey are the following entries:

3270SSOPadByte

This entry should be set to an ASCIIZ string to use as the character for padding replacement text in the user name or password if these strings are shorter than the length of the special tag strings. The default value for this pad character is the ASCII space character.

3270SSOPostReplaceCount

This entry should be set to a DWORD that represents the number of message chains of request/response units (RUs) to scan after replacement of text for user name or password. The default value for this number is 10.

3270SSOPrefix

This entry should be set to an ASCIIZ string to use as the special prefix tag string in combination with the user name and password tags. The default value of this string is MS$.

3270SSOPwdTag

This entry should be set to an ASCIIZ string to use as the special tag string in combination with the **3270SSOPrefix** tag in defining the special host password string that will be replaced. The default value of this string is SAMEP, so the default host password string that is scanned for and replaced is MS$SAMEP. Note that length of the password string that is scanned for (MS$SAMEP, for example) determines the maximum length of the password string that can sent to the host using Single Sign-On. This limit occurs because the password substitution cannot change the length of the data message.

Note that the value of this string must be different from the value of the **3270SSOUserTag** entry for Single Sign-On to function properly.

3270SSOReplaceCount

A DWORD value that affects the time-out value for password substitution. User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the timer expires. By default the timer will be set to 30 seconds, but this behavior can be reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node.

If the **3270SSOReplaceCount** registry entry is defined and the **3270SSOReplaceTimer** registry entry is not defined, the node counts this number of RUs (on PLU-SLU session only) before time-out occurs. If both the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries are defined, the value for **3270SSOReplaceCount** will be used to determine when a time-out will occur. By default, this key is not defined, and the node defaults to a time-out of 30 seconds.

3270SSOReplaceTimer

A DWORD value that affects the time-out value for password substitution. User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the timer expires. By default the timer will be set to 30 seconds, but this behavior can be reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node.

If the **3270SSOReplaceTimer** registry entry is defined and **3270SSOReplaceCount** is not defined, the node uses this value in seconds before time-out occurs. If both the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries are defined, the value for **3270SSOReplaceCount** will be used to determine when a time-out will occur. By default, this key is not defined and the node defaults to a time-out of 30 seconds.

3270SSOUserTag

This entry should be set to an ASCIIZ string to use as the special tag string in combination with the **3270SSOPrefix** tag in defining the special user name string that will be replaced. The default value of this string is SAMEU, so the default user name string that is scanned for and replaced is MS$SAMEU. Note that length of the user name string that is scanned for (MS$SAMEU, for example) determines the maximum length of the user name string that can sent to the host using Single Sign-On. This limit occurs because the user name substitution cannot change the length of the data message.

Note that the value of this string must be different from the value of the **3270SSOPwdTag** entry for Single Sign-On to function properly.

LUA User Name and Password Replacement

The SNA node on the host monitors the inbound session for a replacement sequence consisting of the **3270SSOPrefix** string immediately followed by one of the strings **3270SSOUserTag** or **3270SSOPwdTag**. Thus, the default user name string that would be scanned for and replaced is MS$SAMEU. When this string is found in the inbound session data, the node looks up the corresponding information (host user name in the current host security domain) and overwrites MS$SAMEU with this information. The same process occurs for the password string that would be scanned for and replaced, which defaults to MS$SAMEP.

Note that this operation cannot change the length of the data message. If the actual user name or password that is retrieved from the current host security domain is shorter than the replacement sequence, it is padded out with the first character of the **3270SSOPadByte** string used as a padding character. If the actual host user name or password string is longer than the string that is scanned for, these strings are truncated to the length of the scanned string so that the data message length is not affected.

Note that because the user name and password can be sent in any order, the registry string values for the **3270SSOUserTag** and **3270SSOPwdTag** entries must be different for Single Sign-On to function properly.

The SNA node monitors the SSCP-LU session for these special tag strings at all times and replaces all occurrences of these strings with corresponding looked-up data. On the LU-LU session, the node starts monitoring at start of session (BIND). The node stops monitoring when it has received **3270SSOPostReplaceCount** chains of request/response units (RUs) without seeing a substitution tag. The node will not restart monitoring until it receives an UNBIND–BIND sequence for that session.

Note that the node considers the sequence:

```
BIND, data, UNBIND(BIND FORTHCOMING), BIND …
```

as a continuation of the same LU-LU session and does not restart monitoring on receipt of the second BIND. This sequence is often used by host session managers handing off a session to an application subsystem, and is considered a single terminal session.

User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the node has received **3270SSOPostReplaceCount** chains of RUs without seeing a substitution tag or a timer expires. By default the timer is set to 30 seconds, but this behavior can be reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node. After the timer expires, the node will stop scanning messages for the 3270 replacements strings for the user ID and password. If the replacement strings arrive after the timer expires, the replacement strings will be sent to the host unmodified causing the sign-on to fail. The application will not receive any notification that the timer has expired. The only indication of a problem will likely be that the sign-on to the host session has failed.

> **Note** All strings are specified in the registry in ASCII, but the node translates them to EBCDIC through AE character mapping before scanning for a match.

3270 Emulator Programmer's Guide

This section provides information for independent software vendors who are developing their own 3270 Emulator client software to work with Microsoft® Host Integration Server 2004 or Microsoft SNA Server.

To use this section of the guide effectively, you should be familiar with:

- Host Integration Server 2004
- Microsoft Windows Server™ 2003 or Windows® 2000
- System Network Architecture (SNA) concepts

Operating systems support for 3270 development

Microsoft Host Integration Server 2004 supports the development of 3270 client applications for Windows Server 2003, Windows XP, and Windows 2000.

Network operating systems support for 3270 development

Microsoft Host Integration Server 2004 supports the following network operating systems:

- Native TCP/IP
- Novell NetWare

For API references and other technical information about the 3270 Emulator, see the 3270 Emulator Programmer's Reference section of the SDK.

This section contains:

- Host Integration Server Concepts for 3270 Client Access
- DL-BASE/DMOD Interface
- Function Management Interface
- FMI Status, Error, and Sense Codes
- Configuration Information
- Compiling and Linking 3270 Client Applications
- Support for 3270 Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Host Integration Server Concepts for 3270 Client Access

This section describes some key concepts used in Microsoft® Host Integration Server 2004 when providing 3270 client access. The purpose of this section is to provide information that enables independent software vendors to integrate their 3270 emulators with Host Integration Server. Only the relevant parts of the Host Integration Server 2004 architecture are described.

This section contains:

- Structure of 3270 Client Access Components
- Messages
- LPI Connections

Structure of 3270 Client Access Components

The components of Microsoft® Host Integration Server 2004 that apply to 3270 client access are:

- Local nodes
- Link services
- 3270 emulation program

This section introduces the structure of these components and explains specialized terms.

This section contains:

- Role of the Base
- Localities and DMODs
- Application Localities
- Partners

Role of the Base

The Base is a part of each Host Integration Server gateway component, such as the local 2.1 node or a link service that provides the operating environment for the core functions of that component. It passes messages between components and provides functions common to all components, such as diagnostic tracing.

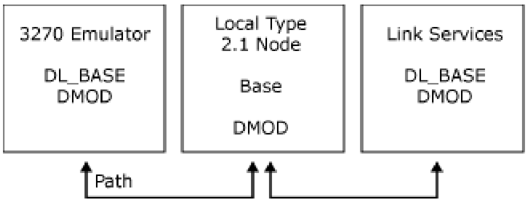
The Base type used with Host Integration Server 3270 emulation programs is DL-BASE. The Host Integration Server DL-BASE supports a single Host Integration Server component or a single user application, and has entry points for initialization, sending messages, receiving messages, and termination.

Localities and DMODs

A Base and the components within it are called a locality. The Host Integration Server system consists of one or more communicating localities, all running Host Integration Server executable programs within the local area network (LAN) Manager domain. For each Host Integration Server system, there is a single configuration file.

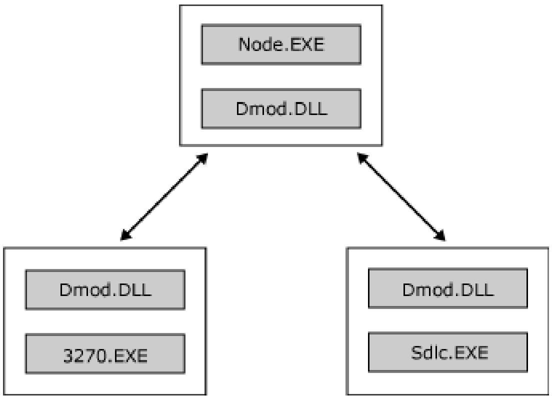
In a system such as Host Integration Server 2004, where the number of localities and their types are not configured in advance, the relationships between the localities are set up dynamically. Localities that can enter and leave a system in this way are called dynamic localities. Dynamic localities can enter or leave the system at any time.

Dynamic localities communicate using the Dynamic Access Module (DMOD) component, which provides the communications facilities needed to pass messages between the Bases. The following figure shows a system consisting of three dynamic localities.



This figure shows a system consisting of three dynamic localities. Dynamic localities can enter or leave this system at any time.

The DMOD is implemented as a dynamic-link library (DLL). The preceding figure can therefore be represented as follows.



To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Application Localities

Applications such as 3270 emulators can enter dynamically into an SNA server system. The application, in conjunction with the Base, acts as a whole locality and communicates with the other localities in the system using a Dynamic Access Module (DMOD).

The topic DL-BASE/DMOD Interface describes the interface to the Base and the DMOD that enables an application to participate in an SNA server system.

Partners

For Host Integration Server components and applications to communicate with each other, it must be possible to identify a partner within a locality. A partner is an addressable component of a locality; that is, code to which messages can be sent. In a Host Integration Server system, there is generally only one partner within a locality (such as a link service or the 3270 emulation program). However, separate functions within the local 2.1 node (such as the 3270 and APPC functions) can be considered to be separate partners.

Messages

Messages are used to pass data between partners in Microsoft® Host Integration Server 2004. This section provides information about message formats.

This section contains:

- Overview of Message Formats
- Buffer Header Format
- Buffer Element Format

Overview of Message Formats

A message always contains fixed-format header information such as a message type and addressing information. It can also contain other header information specific to a particular message type (such as the message subtype) and an indefinite amount of extra data.

Messages are saved in buffers that consist of one header and zero or more elements:

- The header contains the fixed-format information and a pointer to an element. (This pointer is NULL if there are no elements associated with the message.)
- An element contains any extra data for a message and a pointer to another element if the data continues into another element.

Buffer headers and elements are regarded as contiguous (8-bit) byte sequences. Messages of any length can be built by chaining sufficient elements to a header.

The following figure shows a typical message with two elements.

Buffer Header Format

The following table lists the common fields that always occur at the start of a buffer header. These are followed by further fields specific to the particular message. For details about individual message formats, see FMI Message Formats.

Field	Type	Description
nxtqptr	PTRBFHDR	When the buffer is in a queue, this field points to the header of the next buffer in the queue (NULL if it is the last buffer in the queue). When the buffer is not in a queue, this field points to itself. The SNA server buffer management routines use this field to check for buffer corruption.
hdreptr	PTRBFELT	Pointer to the first buffer element in the associated chain of buffer elements. NULL if the message consists only of a buffer header.
numelts	CHAR	Number of buffer elements chained from the header. Zero if the message consists only of a buffer header.
msgtype	CHAR	Message type. For details, see individual message descriptions in FMI Message Formats.
srcl	CHAR	Source locality. For details, see LPI Addresses.
srcp	CHAR	Source partner. For details, see LPI Addresses.
srci	INTEGER	Source index. For details, see LPI Addresses.
destl	CHAR	Destination locality. For details, see LPI Addresses.
destp	CHAR	Destination partner. For details, see LPI Addresses.
desti	INTEGER	Destination index. For details, see LPI Addresses.

> **Note** Fields that occupy two bytes, such as **opresid** in Open(PLU) Request are normally represented with the arithmetically most significant byte in the lowest byte address, irrespective of the normal orientation used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. However, the following fields are exceptions:

- The **srci** and **desti** fields in buffer headers are stored in the local format of the application that assigns them (only the assigning application needs to interpret these values).
- The **startd** and **endd** fields in elements are always stored in low-byte, high-byte orientation (the normal orientation of an Intel processor).

Buffer Element Format

The following table lists the common fields that always occur at the start of a buffer element. The **dataru** field contains information specific to the particular message. For details about individual message formats, see FMI Message Formats.

Field	Type	Description
hdreptr->elteptr	PTRBFELT	Pointer to next buffer element in the chain. NULL if this element is the last or only element in the chain.
hdreptr->startd	INTEGER	Start of valid data in this element. The index into **dataru** of the first byte of valid data.
hdreptr->endd	INTEGER	End of valid data in this element. The index into **dataru** of the last byte of valid data.
hdreptr->trpad	CHAR	Pad byte (reserved).
hdreptr->dataru	CHAR[268]	An array of characters that contains the data for this element. Note that the valid data might not occupy the whole of the element. The **startd** and **endd** fields give the indexes into this array of the start and end of the valid data.

Use the following information to help you interpret the message formats:

- Certain messages are shown as having two elements in the message formats. For example, the Open(PLU) Request has the **CICB** field in the first element and the **BIND RU** in the second element. This indicates that the message consists of two distinct linked element chains. The **elteptr** field in the first element points to the second element.
- Fields that occupy two bytes are represented with the arithmetically most significant byte in the lowest byte address, irrespective of the normal orientation used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. The exceptions to this are the **startd** and **endd** fields in elements, which are always stored in low-byte, high-byte orientation (the normal orientation of an Intel processor).
- The offsets indicated by the **startd** and **endd** fields are expressed in terms of the first byte of **dataru** being offset 1. The first byte of valid data is at **dataru[startd–1]**. For example, if **startd** is 11 and **endd** is 18, **dataru** begins with 10 bytes that are not valid data, followed by 8 bytes of valid data.
- It is possible for an element to arrive with **startd** greater than **endd**. This indicates there is no valid data in **dataru**.

In the sample message format shown in Overview of Message Formats, each element has a **startd** of 13, indicating 12 bytes of padding before the start of the valid data. This leaves room for 256 bytes of data, and so the element data (300 bytes long in this example) requires two elements.

LPI Connections

Partners communicate by passing messages to each other. If two partners want to communicate with each other, a locality partner index (LPI) connection is set up between the two partners. Messages then flow between the partners over this connection. The term LPI connection is explained in LPI Addresses. Note that this is not related to the Microsoft® Host Integration Server concept of a connection between the local node and a remote system.

This section contains:

- Paths and DMODs
- LPI Addresses
- Making Connections

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

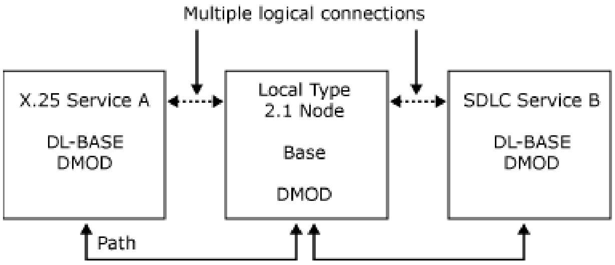
Paths and DMODs

Dynamic Access Modules (DMODs) are responsible for the communication between localities. When the DMODs in two localities can successfully pass messages between them, a path exists between the two localities. A path must exist between two localities before a connection can exist between partners in those localities.

Host Integration Server establishes a path using an appropriate method for the network operating system in use. For example, with Microsoft LAN Manager, a named pipe is used. With NetWare, an SPX connection is used. When the two localities are on the same computer, a local pipe is used. This is implemented using shared buffers to increase performance, but is used by the application in exactly the same way as communication with a remote locality.

The DMOD provides communication between dynamic localities and provides guaranteed in-order delivery of messages flowing over paths between localities. If the DMOD loses its path to another locality, it informs the Base.

The following figure illustrates the paths and connections between an SNA services local node and two 3270 emulation programs. Program A has two connections to the local node (one for each of two sessions). Program B has one connection to the local node.



LPI Addresses

An LPI address is used to identify each end of a connection. It has three components: locality (L), partner (P), and index (I), as described in the following list:

- **Locality** is a 1-byte identifier that uniquely identifies a locality within a system. This locality corresponds to an SNA services component (local node, link service, 3270 emulator, and so on).
- **Partner** is a 1-byte identifier that uniquely identifies a partner within the locality. This is not always used, but can be used to distinguish between parts of a component (for example, the 3270 functions in the local node rather than the Advanced Program-to-Program Communications (APPC) functions).
- **Index** is a 2-byte identifier that uniquely identifies a logical entity within the partner. The meaning and use of this field is defined by the communicating partners. It is used to distinguish multiple connections between the same partners (for example, to identify one of many 3270 sessions between the local node and a particular 3270 emulator). The value of zero should not be used as an index value. Applications must assign unique index values for every active LPI connection with the node.

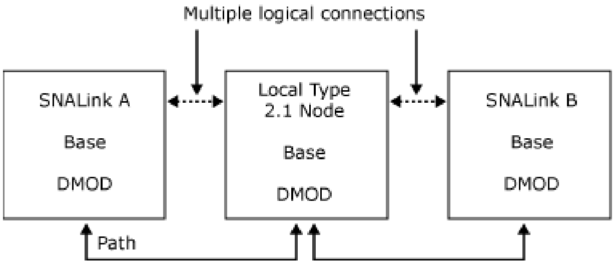
A message flowing over a connection carries a pair of LPIs that identify the source and destination of the message. These are the source LPI and destination LPI of the message. Together they identify the connection on which the message is flowing.

Note More than one connection can exist between any pair of partners. The I values are then used to distinguish the connections. For example, in communications between the local node and a 3270 emulator, the L and P values identify the message as being 3270 data for that local node, and the I value indicates which session the data is intended for.

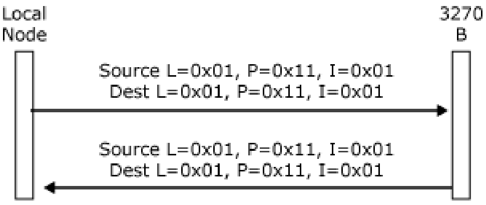
The LPIs are assigned by a combination of the partners and the DMODs when the connection is opened, as described in Making Connections.

Because they are assigned dynamically for each component, the L values are not the same across an entire system. For example, a local 2.1 node locality could be known as locality 4 to one 3270 locality, and locality 6 to a second 3270 locality. However, from the viewpoint of any locality, there exists a unique L value for each remote locality within which a path exists. This L value is used as an index into an internal table that identifies the path to that locality.

The following figures show an example of the L values that could be used between the components shown in Paths and DMODs, and examples of the LPI values that would be used by the local node on messages flowing between the components. (For more information about how the LPI values are assigned and used, see Opening the PLU Connection.)

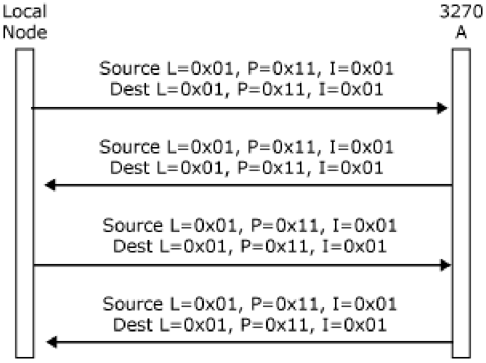


Example L values



Local Node
3270 B
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x11, I=0x01
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x11, I=0x01

L values specified on messages between the local node and 3270 B



Local
Node
3270
A
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x11, I=0x01
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x11, I=0x01
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x11, I=0x01
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x11, I=0x01

LPI values specified on messages flowing on two different connections between the local node and 3270 A

The Base is called by any piece of code that wants to send a message. It uses the destination L value on the message to determine where to send it. When the message reaches the remote locality, the Base in that locality routes it to the appropriate partner if the locality contains more than one partner.

Making Connections

Before messages can flow across a connection, the connection must be established or opened. This is necessary because a partner (P1) does not initially know the locality partner index (LPI) address of the partner with which it wants to communicate. There may not even be a suitable partner with which to communicate.

A component of the Base, known as the Resource Locator, and a message with a type of Open, known as an Open message, are used to establish a connection between partners.

The following procedure outlines how a connection is established. More specific information is available in Function Management Interface.

To establish a connection between partners

1. The Open message has two forms: an Open request and an Open response. The Open request contains information on the type of partner P1 is looking for.

   P1 fills in an Open request and calls the Base with it. Because it does not know the LPI address of its partner, it sets the destination LPI values to zero.

2. The Base cannot forward the Open to a particular partner, because it has no destination LPI address. Therefore it passes the Open to the Resource Locator, which attempts to find a locality that will accept the Open. The Dynamic Access Module (DMOD) has a record of all the localities that could accept this type of Open. The Resource Locator tries each of these localities until the Open is accepted. If no locality is found, the Resource Locator returns a negative response to the Open to inform the sender that no partner could be found.
3. When a remote locality receives an Open, the Base passes the Open to the partner (P2). If P2 can accept the Open, it responds by sending a positive Open response message to P1.
4. The Open response message returned to P1 contains both the source and destination LPI values for the particular connection. At the end of this exchange, both P1 and P2 know each other's addresses and can communicate over the connection.

Note The terms source and destination in the context of LPIs refer to the source and destination of the particular message. When the 3270 emulator builds a message to send to the local 2.1 node, it needs to swap the source and destination LPIs received on the Open response from the local 2.1 node.

For a detailed example of how LPI addresses are assigned during initialization of the system services control point (SSCP) and primary logical unit (PLU) sessions, see Opening the PLU Connection.

DL-BASE/DMOD Interface

This section describes the interface to the Microsoft® Host Integration Server 2004 DL-BASE. It includes a listing of the entry points that an application such as a 3270 emulator can call. These entry points allow messages to be sent to and received from services such as the local 2.1 node.

This section contains:

- About DL-BASE/DMOD
- DL-BASE/DMOD Entry Point Summary
- Sample Code: Initialization and Routing Procedure

About DL-BASE/DMOD

The following topics describe an example in which a 3270 emulator is to be adapted to use Microsoft® Host Integration Server 2004. The emulator needs to communicate with the local 2.1 node.

This section contains:

- Initialization
- Sending Messages
- Receiving Messages
- Opening a Connection
- Termination

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Initialization

The 3270 emulator should initialize the DL-BASE and then call the Dynamic Access Module (DMOD) to obtain the necessary configuration information. This also registers the user name with the DMOD. It can then obtain further system information such as the Host Integration Server version number, if required.

The following table lists the functions involved with this process.

Function	Description
sbpuinit	Initializes the DL-BASE.
sepdcrec	Gets configuration information.
sepdgetinfo	Gets system information.

The **sbpuinit** entry point should always be called before any other DL-BASE/DMOD entry points except SNAGetVersion. For new emulators, **sepdcrec** should be called after **sbpuinit**. (Because of the order of calls used in older emulators, a call to **sepdcrec** before **sbpuinit** is still supported, but this order is not recommended.)

Sending Messages

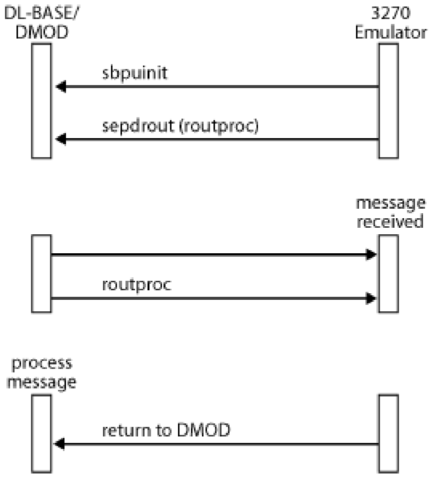
The 3270 emulator inserts a message in a buffer and then calls the DL-BASE to send it. The message contains source and destination locality partner indexes (LPIs), which are set up when the connection is opened. For more information, see LPI Connections.

The application can either obtain a new buffer to contain the message to be sent (using sepdbubl), or reuse a buffer in which it previously received a message. The application is responsible for any buffer it has obtained or in which it has received a message. The application must either use (or reuse) the buffer to send a message or release it (using sepdburl). If the buffer to be reused does not contain the correct number of elements for the message to be sent, the application can obtain additional elements (using sbpibegt) or release existing ones (using sbpiberl). In this case, it must also ensure that the **numelts** field in the buffer header indicates the correct number of elements.

The function used to send the message is sbpusend.

Receiving Messages

The following figure shows the method for receiving messages from the Dynamic Access Module (DMOD).



After DMOD initialization, the 3270 emulator registers the routing procedure by calling sepdrout. When the DMOD receives a message, it calls the 3270 emulator routing procedure, which can then process the message.

With this approach, there is no context switch between the DMOD thread and the 3270 emulator thread. However, the routing procedure must return control to the DMOD quickly. For instance, it cannot suspend waiting for a keyboard input.

The application must determine whether the received message is for this application or for another application. If the message is not for this application, the routing procedure must return, indicating that the message was not processed. If the application processes the message, it is responsible for freeing the buffer when the processing is finished.

In some cases, the routing procedure can process the message to completion. An alternative is for the routing procedure to put the message on an application queue and then clear an application semaphore. The application can then subsequently process the message.

Performance can be improved further by sending a Status-Resource message (to return credit to the local node, enabling it to send further data) from the routing procedure when a message is received, rather than waiting until the message is processed to completion. This usage is illustrated in Sample Code: Initialization and Routing Procedure. For more information about credit and flow control, see Pacing and Chunking.

Note After the application has received a message, the application is responsible for the buffer in which the message was received. The application must either reuse the buffer to send a message (using sbpusend) or release it (using sepdburl). If the buffer to be reused does not contain the correct number of elements for the message to be sent, the application can obtain additional elements (using sbpibegt) or release existing ones (using sbpiberl). In this case, the application must also ensure that the **numelts** field in the buffer header indicates the correct number of elements.

Opening a Connection

Before a locality partner index (LPI) connection can be used to transfer data, it needs to be opened. This is performed by sending Open messages, starting with an Open request. The format of an Open message is defined by the interface being used. For example, the 3270 emulator uses the function management interface (FMI) to communicate with the local 2.1 node.

The interface also defines the initiator of the Open request. In this case, the 3270 emulator sends the Open(SSCP) Request, and the local 2.1 node sends the Open(PLU) Request.

On the **Open(SSCP) Request**, the 3270 emulator sets all the source and destination LPIs to zero, except for the source index, which can be used by the 3270 emulator for internal routing (for example, to distinguish between two sessions).

The DL-BASE and Dynamic Access Module (DMOD) ensure that Open messages are routed to a suitable destination. If a routing procedure is used, it should always first call sbpurcvx to process Open responses. When **sbpurcvx** indicates that it has not processed a received message, and the received message is an Open OK response, the application is informed that the connection was established successfully.

Termination

The 3270 emulator must call sbputerm to free DL-BASE/Dynamic Access Module (DMOD) resources before it terminates.

DL-BASE/DMOD Entry Point Summary

The following table shows entry points divided into the categories DL-BASE, Dynamic Access Module (DMOD), and buffer management, and listed in alphabetical order within each category.

DL-BASE entry points

DL-BASE entry points	Description
sbpuinit	Initializes the DL-BASE.
sbpurcvx	Processes Open from routing procedure.
sbpusend	Sends message.
sbputerm	Terminates.

DMOD entry points

DMOD entry points	Description
routproc	Sample routing procedure.
sepdchnk	Gets the function management interface (FMI) chunk size.
sepdcrec	Gets user and diagnostics records from configuration file.
sepdgetinfo	Gets SNA server system information.
sepdrout	Sets up the routing procedure (Microsoft® Windows Server™ 2003 and Windows® 2000 Server only).

Buffer management entry points

Buffer management entry points	Description
sbpibegt	Gets the buffer element.
sbpiberl	Releases the buffer element.
sepdbubl	Gets the buffer.
sepdburl	Releases the buffer.

> **Note** The standard-call convention (CDECL) is used on Windows Server 2003 and Windows 2000.
>
> **Note** The format of buffer headers and elements is described in Messages. The formats of individual messages contained in buffers are defined in FMI Message Formats.

Sample Code: Initialization and Routing Procedure

This topic contains an outline of source code for receiving messages from the Dynamic Access Module (DMOD).

> **Note** **TRACE*n*()** is a macro used to specify data to be traced. This data can include variable parameters. The value **n** identifies the severity level of the trace. The unmatched parentheses are deliberate. They are resolved by the expansion of the macro.

Function Management Interface

The function management interface (FMI) provides applications with direct access to SNA data flows and information about SNA control flows by means of status messages. This section provides information about the SNA sessions and connections over which FMI messages can flow, and summarizes the messages. The FMI is particularly suited to the requirements of 3270 emulation applications.

This section contains:

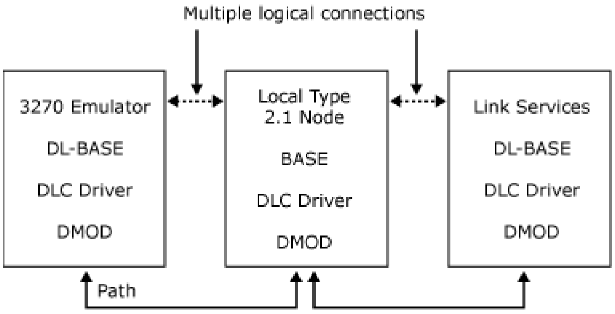
- FMI Concepts
- SSCP Connection
- PLU Connection
- Data Flow
- Status Messages
- FMI Message Summary

FMI Concepts

The local node provides the SNA layers of path control, transmission control, and data flow control (DFC), as well as logical unit (LU) services as shown in the following figure. In terms of the SNA layers, the function management interface (FMI) is between presentation services and DFC. This means that most of the SNA protocol handling is performed by the local node. In particular, the DFC layer of the local node is responsible for the state changes associated with chaining, bracket, and quiesce protocols.

The FMI is defined in terms of the messages that are sent across the interface. Note that this is logically distinct from the definition of the DL-BASE/Dynamic Access Module (DMOD) interface, which defines the mechanism for sending messages between two components in Microsoft® Host Integration Server (for example, between the local node and the 3270 emulator).

The FMI is used by LU types 0, 1, 2, and 3, but not by LU type 6.2. It provides access to the system services control point (SSCP)-LU session as well as the main primary logical unit (PLU)-SLU session. (For more information about these sessions, see Sessions and Connections.) An application can use the FMI to access multiple sessions and hence multiple LUs, simultaneously.



In this example, the 3270 emulator on the client communicates over the local area network (LAN) with the local node on the server by exchanging messages. The content and format of the messages are defined by the FMI. The DMOD is used to transport the messages, but does not interpret them. The local node provides the SNA service for formatting the message. The link service and the data link control (DLC) driver are responsible for transferring data between the local node and the DLC adapter.

This section contains:

- Sessions and Connections
- Application Flags

Sessions and Connections

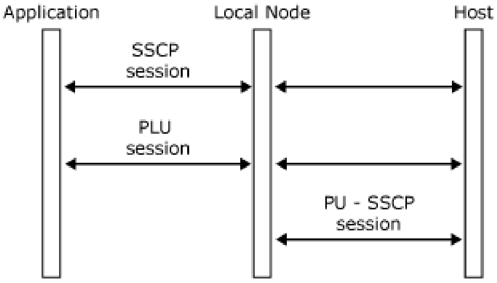
An application using the function management interface (FMI) can communicate with the host on two SNA sessions as described in the following list:

- The system services control point (SSCP) session, between an SNA server logical unit (LU) and the host SSCP, provides information about the activation of the LU and supports communication with the SSCP for commands such as character-coded and field-formatted logon and logoff commands. There is one SSCP session for each SNA server LU.
- The primary logical unit (PLU) session, between an SNA server LU and the host PLU, is the main session for data transfer between the local application and the host application. There is one PLU session for each SNA server LU.

The local node communicates directly with the host on the physical unit (PU)-SSCP session:

- The PU-SSCP session, between the PU (local node) and the host SSCP, supports the reporting of alert information and link statistics to the host SSCP.

The following figure shows the three sessions.

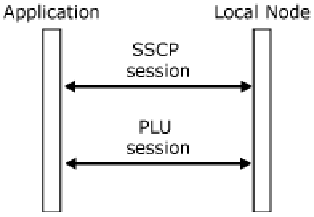


The application can communicate with the local node by means of two locality, partner, index (LPI) sessions. Rather than specifying the session on which a message is to flow, the application sends the message to the local node on one of these connections. The local node then routes it to the appropriate SNA session.

The connections are used as follows:

- The SSCP session is used for the initial startup and logon information for a 3270 session. The Host Integration Server 3270 emulation programs also send network management information, such as user alerts and Response Time Monitor (RTM) statistics, to the local node on this session. For more information about this connection, see SSCP Connection.
- The PLU session is used for the transfer of application data, and for status and flow control messages between the application and the local node. For more information about this connection, see PLU Connection.

The following figure shows these sessions.



These sessions are specific to the local node and the application. Data and status messages passed across a connection result in SNA data and SNA control requests being sent on the appropriate SNA session. Similarly, SNA data and SNA control responses received on an SNA session result in data and control messages being passed to the application on the appropriate connection.

The relationship between the three SNA sessions and the two connections is as follows:

- SNA messages on the SSCP session from the host to the local node result in messages from the local node to the application on the SSCP connection. Messages from the application to the local node on the SSCP connection normally result in SNA messages on the SSCP session from the local node to the host (with the exception of network management information, which results in messages on the PU-SSCP session).
- SNA messages on the PLU session from the host to the local node result in messages from the local node to the application on the PLU connection. Messages from the application to the local node on the PLU connection result in SNA messages on the PLU session from the local node to the host.
- SNA messages on the PU-SSCP session from the local node to the host are generated by messages from the application to the local node on the SSCP connection. When the application sends network management information such as 3270 user

alerts on the SSCP connection, the local node distinguishes it from other data on this connection (which normally corresponds to the SSCP session) and sends the appropriate information about the PU-SSCP session to the host. For more information, see 3270 User Alerts.

Note the distinction between these SNA sessions and 3270 emulation sessions. A 3270 emulator can have more than one 3270 emulation session. For each emulation session, there are separate SSCP and PLU sessions.

Each connection between the application and the local node is opened, managed, and closed separately. This means that an application must maintain a separate internal control block containing the LPI pair, message keys, and state of the connection for each of the SNA sessions associated with each 3270 emulation session. For example, an application using three 3270 emulation sessions, each with an SSCP session and a PLU session, will require six control blocks.

An application identifies the connection (and hence the session) to which a particular message belongs using the LPI pair present in the message. On a received message, the destination index (I) value contains the application's identifier for the connection, and the source I value contains the local node's identifier for the connection. These are reversed for messages sent by the application.

The application selects the LU within the local node that it can use for communications by the relationship in the configuration table between the LU record and APPL record. (For more information, see Opening the SSCP Connection.) The application may be unaware of which LU it accesses if the LUs are arranged within LU groups.

Application Flags

Application flags are included on the following messages:

- All Data messages (both inbound and outbound)
- Status-Acknowledge(Ack) (outbound only)
- Status-Acknowledge(Nack-1) (outbound only)
- All Status-Control messages (both inbound and outbound)

These flags represent key indicators of the state of the session to which the message relates and are closely related (but not always equivalent) to the request header or response header (RH) indicators in the SNA request or response. Note that for inbound messages, applications need to set the flags on **Data** messages and **Status-Control** messages only.

For outbound messages, the local node sets the application flags to reflect the contents of the RH in the corresponding SNA message. The local node performs checks on the SNA message before sending it to the application. Therefore, the application can assume that the RH indicators follow the SNA protocols and need not perform its own checks. The application's task in interpreting the application flags is much simpler than if the local node presented the message with the uninterpreted RH. For example:

- If the application specified the segment delivery option when the primary logical unit (PLU) connection was opened, the end chain indicator (ECI) on an SNA request will occur on the first segment of the last request/response unit (RU) in a chain, but the chain is not complete until the last segment of that RU is received. In this case, the local node manipulates the application flags so that the ECI flag is set in the last segment rather than the first. (For more information, see Opening the PLU Connection.)
- Applications using Transmission Service profile 4 (TS profile 4) on the PLU session can receive the definite response 2 (DR2) RH indicator in combination with definite response 1 (DR1) or exception response (ER) to give RQD2, RQD3, RQE2, and RQE3 requests. The local node interprets the RH indicators and sets the **COMMIT** application flag accordingly.

For inbound Data and Status-Control messages, you should set the application flags to control session characteristics such as chaining, direction control, and brackets. For **Status-Acknowledge** messages, the local node generates an SNA response and sets the RH indicators using information saved from the corresponding request. The application does not need to set the flags on this message.

For information about application flag usage when you are using function management interface (FMI) chunking, see Chunking.

In most cases, the application does not need to use the application flags on Status-Acknowledge(Ack) messages, which derive from the response header indicators on the corresponding response. However, certain applications do require access to the response header flags on responses. For example, transaction-processing applications using TS profile 4 can receive the DR2 flag on responses, which appear as the **COMMIT** flag in the application flags.

Application flag usage on Status-Control (SC) messages is derived from the response header indicators in the corresponding data flow control or session control request unit. Applications may need to be aware of the response header flags for Status-Control messages. For example, LUSTAT request type 6 is a no-op used solely to enable response header flags to be sent when no other request is allowed. The local node delivers the request to the application as a Status-Control(LUSTAT) Request with the relevant application flags set. For summaries of valid request header usage for data flow control request units and of valid response header indicators for SC requests, see *SNA Format and Protocol Reference Manual: Architectural Logic* (IBM publication SC30-3112).

In the summary of the application flags in the table that follows, bits are numbered with bit 0 as the most significant bit in a byte and bit 7 as the least significant. An application flag is set if the relevant bit for the flag is 1 and not set if the bit is 0.

Flag 1 occurs in all messages.

The following table lists the meanings of the individual bits.

Bits in flag 1	**Meaning**
FMHI [bit 0, flag 1] Value: AF_FMH (0x80)	Function management header indicator. Set if a function management header is present in the message, or if the message is a function management data network services (FMD NS) request. Only valid on Data messages. This flag is always set for 3270 user alerts, which are sent on the system services control point (SSCP) connection. For more information, see 3270 User Alerts.

BCI [bit 1, flag 1] Value: AF_BC (0x40)	Begin chain indicator. Set if this message starts a chain. For more information, see Outbound Chaining and Inbound Chaining.
ECI [bit 2, flag 1] Value: AF_EC (0x20)	End chain indicator. Set if this message ends a chain. For more information, see Outbound Chaining and Inbound Chaining.
COMMIT [bit 3, flag 1] Value: AF_COMM (0x10)	Commit indicator. Set if chain carries DR2.
BBI [bit 4, flag 1] Value: AF_BB (0x08)	Begin bracket indicator. Set if chain carries begin bracket (BB). Note that this does not necessarily indicate that the bracket has been initiated. For more information, see Brackets.
EBI [bit 5, flag 1] Value: AF_EB (0x04)	End bracket indicator—set if chain carries end bracket (EB). Note that this does not indicate that the bracket has terminated. For more information, see Brackets .
CDI [bit 6, flag 1] Value: AF_CD (0x02)	Change direction indicator. Set if chain carries change direction (CD). For more information, see Direction.
SDI [bit 7, flag 1] Value: AF_SD (0x01)	System detected error indicator. Set if the local node detects an error in outbound data. For more information, see Outbound Data.

Flag 2 occurs in all messages except **Status-Control(STSN)**, where the indicators included in this byte are not applicable.

The meanings of the individual bits are listed in the following table.

Bits in flag 2	**Meaning**
CODE [bit 0, flag 2] Value: AF_CODE (0x80)	Alternate code indicator. Set if the alternate code set (usually ASCII) is used for this Data message. Note that function management headers are unaffected by the code selection indicator.

ENCRYP [bit 1, flag 2] Value: AF_ENCR (0x40)	Enciphered data indicator. Set to indicate that the information in the **Data** message is enciphered under session level cryptography protocols. You must provide the necessary support for data encryption. The Host Integration Server local node does not support cryptography.
ENPAD [bit 2, flag 2] Value: AF_ENPD (0x20)	Padded data indicator. Set in conjunction with the **ENCRYP** flag to indicate that the data was padded at the end to the next integral multiple of eight bytes before enciphering.
QRI [bit 3, flag 2] Value: AF_QRI (0x10)	Queued response indicator. Set if the response to this request is to be queued in the transmission control and data flow control layers. This flag is only significant for inbound messages.
CEI [bit 4, flag 2] Value: AF_CEI (0x08)	Chain ending indicator. Set on a message corresponding to an outbound SNA request with EC and begin basic information unit (BBIU). This flag is provided solely for the use of SNA server components. Your application should not attempt to use it.
BBIUI [bit 5, flag 2] Value: AF_BBIU (0x04)	Begin basic information unit indicator. Set on a message corresponding to an outbound SNA request with BBIU. This flag is provided for the use of SNA server components and for applications using segment delivery and outbound pacing together. Your application should not attempt to use it. (For more information, see Pacing and Chunking.)
EBIUI [bit 6, flag 2] Value: AF_EBIU (0x02)	End basic information unit indicator. Set on a message corresponding to an outbound SNA request with end basic information unit (EBIU). This flag is provided solely for the use of SNA server components. Your application should not attempt to use it.
RBI [bit 7, flag 2] Value: AF_RBI (0x01)	Real BID indicator. Set on **Status-Control(BID) Request** messages from the local node only. 0x01 indicates that the message is due to an SNA BID RU. 0x00 indicates that the message is due to an outbound function management data (FMD) RU with BB set.

SSCP Connection

The system services control point (SSCP) connection of the application to the local node provides access to the SSCP session between the Microsoft® Host Integration Server secondary logical unit (LU) and the host SSCP.

For simplicity, this section describes the SSCP connection as if an application only uses a single SNA server LU (and therefore a single SSCP connection). In practice, applications can use multiple LUs.

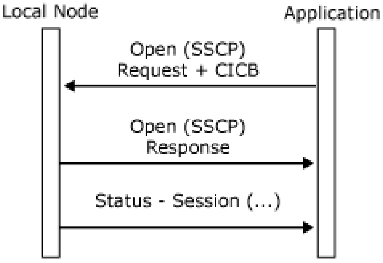
This section contains:

- Opening the SSCP Connection
- Closing the SSCP Connection
- Using the SSCP Session
- RTM Parameters
- 3270 User Alerts

Opening the SSCP Connection

An application gains access to the system services control point (SSCP) session by opening an SSCP connection to the local node. To do this, an application sends an Open(SSCP) Request message to the local node, which responds with an Open(SSCP) Response. The local node follows a positive **Open(SSCP) Response** with a Status-Session message reporting the current state of the SSCP session. (For more information, see Using the SSCP Session.)

The following figure shows the message flow. For a figure showing a more detailed message flow, including locality, partner, index (LPI) values used during initialization of both the SSCP and primary logical unit (PLU) sessions, see Opening the PLU Connection.



This section contains:

- LU Groups
- Resource Location for Open SSCP

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

LU Groups

Note that Host Integration Server supports logical unit (LU) groups. An LU group consists of a number of LUs of the same type, such as 3270 display LUs or logical unit application (LUA) LUs. Any of the LUs in the group can be used for the same task.

If an application sends an Open(SSCP) Request specifying the name of a 3270 display LU group, the local node can select any LU within the group to be used by the application. LUA LU groups are used in the same way, except that the application can specify either the name of the group or the name of any LU within the group to access the group.

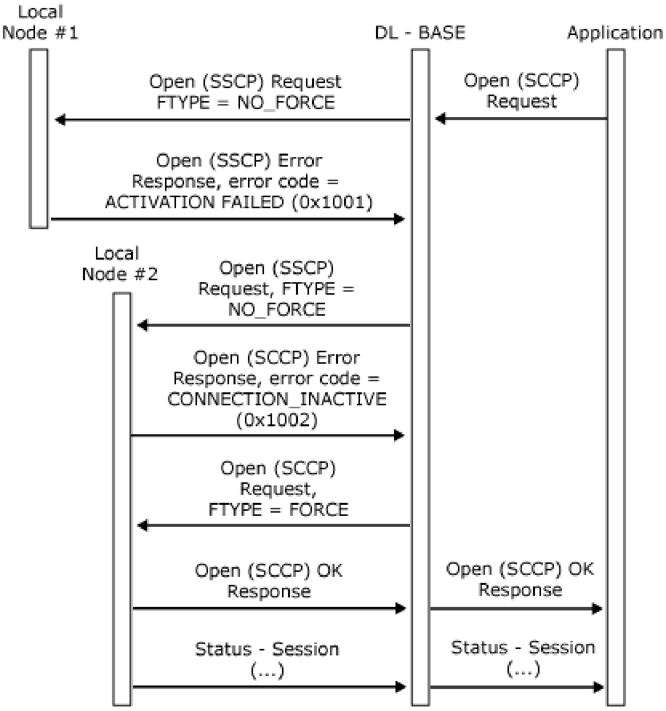
Resource Location for Open SSCP

When attempting to find a free logical unit (LU) across more than one local node, the application does not need to know which local node owns the LU. The DL-BASE is responsible for finding a suitable local node, using the mechanism described. The description is intended to assist in interpreting traces of the message flows involved, and is not needed to write an application

The open force type field in the Open(SSCP) Request specifies either a forced or nonforced Open. If the LU for which the Open is intended does not have an active system services control point (SSCP) session because its link is inactive, a forced Open instructs the local node to attempt to activate the link and the SSCP session. A nonforced Open succeeds only if the SSCP session is already active, and otherwise returns with an error code indicating the state of the LU's connection.

When the application issues the **Open(SSCP) Request**, it does not set the open force type field. The DL-BASE issues a nonforced Open to each node in turn until it finds an LU that already has an active SSCP session. If none of these Opens succeeds, the DL-BASE issues a forced Open to the node that returned the best error code—that is, the one most likely to be able to activate the session.

The sample message flows in the following figure show this process for two local nodes. The DL-BASE tries each in turn, using nonforced Opens. The error code from node #2 indicates that it is more likely to be able to activate the SSCP session than node #1, so the DL-BASE sends a forced Open to node #2. The application is aware only of the first request and its response.



Local Node #1
DL - BASE
Application
Open (SSCP) Request FTYPE = NO_FORCE
Open (SCCP) Request
Open (SSCP) Error Response, error code = ACTIVATION FAILED (0x1001)
Local Node #2
Open (SSCP) Request, FTYPE = NO_FORCE
Open (SCCP) Error Response, error code = CONNECTION_INACTIVE (0x1002)
Open (SCCP) Request, FTYPE = FORCE
Open (SCCP) OK Response
Open (SCCP) OK Response
Status - Session (...)
Status - Session (...)

To enable applications to restart after a disastrous failure (such as terminating the 3270 emulation program), the local node also accepts an Open(SSCP) Request from an application that has failed and has been restarted, providing the same source locality, partner, index (LPI) fields are used. In this case, a **TERM-SELF** message is sent to the host if the LU is bound.

The SNA server LU through which the application communicates is selected by the relationship between the APPL record and the LU or LU group record in the configuration file. The application specifies its name using the source name field on the **Open(SSCP) Request**. The local node fills in the LU or LU group number, selects an unused LU within the LU group (if the association is to an LU group), and informs the application of this LU number on the Open(SSCP) Response.

The **Open(SSCP) Request** specifies the following:

- The source application name.
- A resource identifier that can be used by the application to correlate the Open(PLU) Request that is sent to the application. (For more information, see Opening the PLU Connection.)
- A connection information control block, which specifies the response header usage, checks that the local node should perform for the LU. If the field for a code is set to 0x01, that receive check will be carried out by the data flow control layer of the local node on data arriving from the host. The corresponding send checks are unaffected and are always performed. The connection information control block is provided because these receive checks are optional in SNA. However, it is anticipated that most applications will require all these checks to be performed (all values set to 0x01).
- An indicator that specifies whether the application is to be treated as high or low priority. All SNA server 3270 LUs are marked as high priority (printers do not send significant data inbound). The effect of high priority is to enable data to be

progressed faster to the host when the link is busy.

- An indicator that specifies whether the application is an LUA. This determines whether the local node and the application will communicate using the LUA variant of the function management interface (FMI). (For more information, see FMI Concepts.)
- An indicator that specifies a nonforced or forced Open. This determines whether the local node will attempt to activate the SSCP session if it is not currently active.

The Open(SSCP) Request can fail for one of several reasons, which can be determined from the error codes on the Open(SSCP) Response sent to the application, as detailed in the following list:

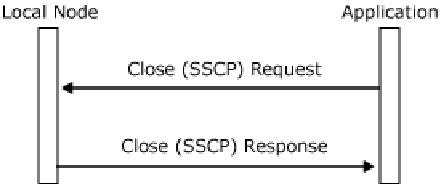
- The local node may still be initializing (retrieving information from the configuration file). In this case, the application can retry immediately.
- The configuration file may not have an entry for the application, or the application record in the configuration file may not point to an LU or LU group record.
- For a nonforced Open, the SSCP session may be inactive.

Closing the SSCP Connection

To close the system services control point (SSCP) connection, an application sends a Close(SSCP) Request to the local node, which responds with a Close(SSCP) Response. The **Close(SSCP) Request** is unconditional. The **Close(SSCP) Response** always reports that the connection was successfully closed. The **Close(SSCP) Response** is provided so that applications can determine when outstanding data and status messages on the session have been delivered.

If the logical unit (LU) is bound, the local node sends a **TERM-SELF** message to the SSCP on behalf of the application to elicit an **UNBIND**. An application that needs to be unbound can issue **Close(PLU)**. (For more information, see Closing the PLU Connection.) Normally, the SSCP connection can be maintained while the application task is active, even if it is idle.

Closing the connection invalidates the locality, partner, index (LPI) pair for the connection, but does not alter the state of the SSCP session. The following figure shows the message flow.



Using the SSCP Session

When the application has opened a system services control point (SSCP) connection, it has access to the SSCP session and can send data to the host SSCP.

This section contains:

- SSCP Session Characteristics
- SSCP Session Status

SSCP Session Characteristics

For SNA type 2.1 nodes, the system services control point (SSCP) session uses function management (FM) profile 0 and Transmission Service profile (TS profile) 1. This combination of profiles provides the following session characteristics:

- The primary and secondary half-sessions both use immediate request mode.
- The primary and secondary half-sessions both use immediate response mode.
- Only definite-response single request unit chains are allowed.
- The maximum request unit size is limited to 256 bytes.
- Data flow control request units are not supported.
- Pacing is not supported.
- Identifiers are used (rather than sequence numbers) on the normal flows.

This implies that the SSCP connection has the following characteristics:

- All Data messages have the acknowledgment required (ACKRQD) field set.
- All Data messages have the begin chain indicator (BCI) and end chain indicator (ECI) application flags set.
- Status-Control messages do not flow on the connection.
- Status-Session messages from the local node to the application only report changes in the activation state of the session.
- The chaining, bracket, confirmation, and recovery protocols (described in PLU Connection) do not apply.

Using the SSCP connection, the application can send and receive **Data** messages corresponding to function management data network services (FMD NS) (session services) requests and FMD data requests. Examples of FMD NS (session services) requests are:

- **INIT-SELF.** Requests from the secondary to the host SSCP requesting that the SSCP assist in the initiation of a session to the host PLU, effectively requesting a **BIND**. (For more information, see Opening the PLU Connection.)
- **TERM-SELF.** Requests from the secondary to the host SSCP requesting that the PLU-SLU session be terminated with an **UNBIND**. (For more information, see Closing the PLU Connection.)
- **Character-coded requests.** Requests such as logon, logoff, or test commands from the secondary display, or a logon prompt from the host application.
- **NOTIFY.** Requests used by the secondary to notify the host SSCP that a device is available after a **BIND** was rejected with sense code 0x0845, for example, where a device emulator supports logical power-off.

The local node sends a **NOTIFY** request to the SSCP on behalf of the LU whenever the application's SSCP connection state changes while the LU is active. A **NOTIFY** (vector key 0x0C with byte 5 set to 0x03), which can act as secondary LU, is sent in the following cases:

- When an Open(SSCP) Request is received when the LU is already active.
- When an ACTLU request is accepted when the SSCP connection is already opened.

A **NOTIFY** (vector key 0x0C with byte 5 set to 0x01), which cannot currently act as secondary LU, is sent in the following cases:

- When an ACTLU is received when the SSCP connection is not open.
- When a Close(SSCP) Request is received when the PLU session is not bound.
- When an **UNBIND** request is received when the SSCP connection is not open.
- When the long response including the **NOTIFY** vector is used for ACTLU requests.

These **NOTIFY** messages can be used by the host in conjunction with the negative response 0x0845 that the local node gives to a **BIND** received when the SSCP connection is not open. (For more information, see Opening the PLU Connection.)

SSCP Session Status

While the system services control point (SSCP) connection is open, the local node reports the initial state and any subsequent changes of state of the SSCP session to the application using Status-Session messages. There are four distinct **Status-Session** status codes that can occur for the SSCP connection:

- **No-Session.** The SSCP session between the SNA server logical unit (LU) and the host SSCP is not active because the SNA server physical unit (PU) or LU is not activated. The **Status-Session** carries a qualifying status code to indicate why the SSCP session is inactive. The application cannot use the SSCP connection to send data to the host SSCP. The qualifiers are:
    - **PU-INACTIVE.** Activate PU (ACTPU) has not been received or Deactivate PU (DACTPU) has been received.
    - **PU-ACTIVE.** ACTPU(COLD) has been received from the SSCP.
    - **PU-REACTIVATED.** ACTPU(COLD) has been received while the PU was active. (The application is not informed if ACTPU(ERP) is received while the PU is active.)
    - **LU-INACTIVE.** ACTLU has not been received, or DACTLU has been received.
- **Link-Error.** The SSCP session between the SNA server LU and the host SSCP is not active, due to a data link control (DLC) error. The **Status-Session** carries a qualifying status code that gives the error code reported by the DLC. The application cannot use the SSCP connection to send data to the host SSCP.

  Note that this session state is reported when the local node is informed that the locality containing the Host Integration Server Synchronous Data Link Control (SDLC) link service has been lost due to a path failure. The qualifier 0x0D is used. The link service will close the link when it is informed of the path error so the application can treat this as an outage.
- **LU-Active.** The SSCP session is active due to the receipt of ACTLU. The application can use the SSCP connection to send data to the host SSCP.
- **LU-Reactivated.** The SSCP session has been reactivated due to the receipt of an ACTLU from the host SSCP. The SSCP connection is still active, but data may have been lost.

For more information, see Status-Session Codes.

RTM Parameters

The Status-RTM message is sent to the application by the local node to indicate the Response Time Monitor (RTM) parameters being used by the host. The host can specify the following parameters:

- Whether RTM measurement is active or inactive.
- Whether local display of RTM data by the application is permitted.
- The definition by which response times are to be measured:
    - Until the first character of a response is written to the screen.
    - Until the keyboard is unlocked.
    - Until the application is allowed to send data. Change direction (CD) or end bracket (EB) is received.
- The boundaries by which response times are to be classified into time bands.
- The initial values of the counters, which indicate how many responses have been received in each time band (as defined by the boundaries).

The local node is responsible for interpreting the response times reported to it by the application, and for sending RTM statistics to the host when required. The application is responsible for measuring the response times and reporting them to the local node. (The application reports response times to the local node using the Status-Acknowledge message. For more information about measuring and reporting response times, see Response Time Monitor Data.)

If the application does not need to provide a local display of RTM data, it only needs to determine whether RTM measurement is active. If active, it needs to determine the definition by which response times are measured. It can ignore the other parameters. If RTM measurement is not active, the application need not measure and report response times.

If the application needs to provide a local display of RTM data, it should use the information from the Status-RTM message to ensure that the local interpretation of response times matches the interpretation used by the host. In particular, it should not display RTM data at all if the **Status-RTM** message indicates that local display is not permitted (or if the **permission to view RTM data** field in the 3270 user configuration record indicates that it is not permitted). The application is responsible for maintaining its own RTM statistics for local display, that is, for classifying the response times according to the boundaries specified by the host and maintaining counts of responses in each category. Although the local node maintains these statistics for sending to the host when required, it does not report them to the application.

> **Note** RTM statistics are maintained for a specific logical unit (LU), not for a specific application's use of that LU. This means that when the **Status-RTM** message is received at start of day, the counters can be nonzero to include a previous use of the LU. The counters are only reset when the host requests the local node to reset them or when the local node sends unsolicited RTM data to the host.

3270 User Alerts

The Host Integration Server 3270 emulation program can send 3270 user alerts to the local node on the system services control point (SSCP) connection. This enables the local node to route each alert to the appropriate host for the 3270 session on which it was sent.

To send a 3270 user alert, the application should send it as a Data message on the SSCP connection. The local node will recognize it as a 3270 user alert if both of the following are true:

- The function management header indicator (FMHI) bit in the application flag is set.
- The first three bytes of the data are 0x41038D, indicating a Network Management Vector Transport (NMVT).

The local node sends the alert to the appropriate host for the 3270 session on which it was received. If a relative time subvector is present (0x42) with increment type 0xEF (sequence), the local node sets the sequence number in each message (starting at one from power-up and incrementing by one for each message sent). Host Integration Server 2004 allows sequence number values up to 2^16. Apart from this, the local node does not alter the contents of the alert.

> **Note** There can be some delay before the application receives a response to the alert. The response is sent on the SSCP connection in the same way as other data on this connection. The application must not send further data on the SSCP connection (including further alerts) until it has received a response to this alert.

PLU Connection

The primary logical unit (PLU) connection of the application to the local node provides access to the PLU session between the Microsoft® Host Integration Server's logical unit (LU) and a PLU in the host.

This section describes how an application opens and closes its PLU connection, and the use of the PLU connection.

For simplicity, this section describes the PLU connection as if an application uses only a single SNA server LU (and therefore a single PLU connection). In practice, applications can use multiple LUs.

This section contains:

- Opening the PLU Connection
- Closing the PLU Connection
- Using the PLU Session
- Outbound Chaining
- Inbound Chaining
- Segment Delivery
- Brackets
- Direction
- Pacing and Chunking
- Confirmation and Rejection of Data
- Shutdown and Quiesce
- Recovery
- Application-Initiated Termination
- LUSTATs
- Response Time Monitor Data

Opening the PLU Connection

The opening of the primary logical unit (PLU) connection is closely associated with the establishment of the PLU session. The local node opens the PLU connection when it receives a **BIND** command from the host for a logical unit (LU) for which an application has previously opened a system services control point (SSCP) connection. Possible sequences are:

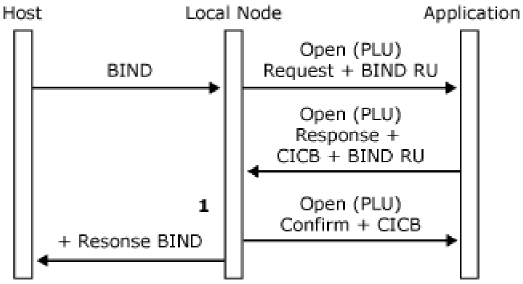
- An application opens its SSCP connection and sends a character-coded logon request or **INIT-SELF** request to the host SSCP. A host PLU subsequently sends a **BIND** request to the SNA server LU, and the local node opens the PLU connection.
- A host PLU sends an unsolicited **BIND** command to the SNA server LU. If the SSCP connection for the LU is open, the local node opens the PLU connection. If the local node is supporting **NOTIFY**, the host can be configured to send a **BIND** when it receives the **NOTIFY** message sent by the local node when the application opens its SSCP connection. (For more information, see SSCP Connection.)
- A host PLU sends a **BIND** command to the SNA server LU. If the SSCP connection for the LU is not open, the local node returns a negative response to the **BIND** request. The sense code used is 0x0845 (**NOTIFY** will be sent). The local node does not open the PLU connection. In this case, the local node sends **NOTIFY** when the SSCP connection is opened. (For more information, see SSCP Connection.)

To successfully open the PLU connection, the local node sends an Open(PLU) Request to the application. The application responds with an Open(PLU) OK Response. Finally the local node sends an Open(PLU) OK Confirm to the application. This exchange of messages opens the PLU connection and establishes the PLU session. It should be noted that a successful PLU opening sequence is a three-way handshake, in comparison to the opening of the SSCP connection, which is a two-way handshake.

The **Open(PLU) Request** is delivered to the application using the SSCP connection for the LU. The **Open(PLU) Request** contains the application name and open resource identifier to allow applications to correlate the PLU and SSCP connections.

The **Open(PLU) Request** indicates the logical unit that the **BIND** request was directed to, references the resource identifier supplied in the Open(SSCP) Request for that LU, and carries the actual **BIND** request/response unit (RU) received from the host. (For more information, see Open(PLU).) It also carries the maximum RU sizes, chunk sizes (if appropriate), and pacing windows for the PLU session, to enable the application to determine the initial credit if it needs to be involved in outbound pacing. (For more information, see Pacing and Chunking.)

The message flow for a successful opening of the PLU connection (on receipt of a nonnegotiable **BIND**) is shown in the following figure. Note that the **BIND** parameters are verified (at [1]) only when the application has supplied the **BIND** check table index as part of the connection information control block (CICB).



The following figure shows the message sequence for the initiation of both the SSCP and PLU sessions, including details of where the Locality Partner Index (LPI) values are assigned. (The application's source P value of 0x12 indicates that it is a 3270 emulator. For more information about how the source LPI values are set, see Open(SSCP) Request.) The message flow shown assumes that the connection to the host is already established and that both the configuration and the **BIND** are valid.

After this message sequence, there are two valid sets of LPI values, one for the SSCP session and one for the PLU session. The application can access either session at any time until **UNBIND** and can use the LPI values to distinguish between received data on the two sessions.

BIND Checking

The Open(PLU) OK Response contains the connection information control block (CICB), which enables the application to customize certain characteristics of the connection and contains information used in **BIND** verification. Note that the local node verifies the **BIND** parameters carried on the **Open(PLU) OK Response**. It does not maintain a copy of the original **BIND** request/response unit (RU) from the host. If the **BIND** is negotiable, the application is permitted to modify the parameters in the **BIND** RU, but if it is nonnegotiable the application should return the **BIND** RU unmodified. A negotiable **BIND** flag is provided in the Open(PLU) Request.

Although many characteristics of the PLU session are determined by the **BIND** parameters, the application can select certain characteristics by specifying fields in the CICB. For more information, see the following table. More detailed information about CICB usage and the effect on the PLU session of selecting various CICB options is given in context in the topics of this section that deal with PLU session characteristics such as chaining and pacing.

The **BIND** is verified using a **BIND** check table entry (whose index is specified in the CICB). The entries in this correspond to the various fields in the **BIND**. The **BIND** check table entries are stored in the configuration file. For example, the **BIND** check table entry can specify that the **BIND** be accepted if the secondary chain response protocol is either "definite response" or "definite or exception response" (byte 5 bits 2 and 3 = B10 or B11). This would be appropriate if the application did not want to send Request Exception (RQE) chains.

Connection information control block usage is shown in the following table.

Field	**Explanation**
Segment delivery option	A value of 0x00 indicates that the local node should perform outbound segment assembly and only deliver complete RUs. A value of 0x01 indicates that the application wants the local node to deliver RU segments. For more information, see Segment Delivery.
Application pacing option	A value of 0x00 indicates that the application requires the local node to handle pacing. A value of 0x01 indicates that the application needs to be involved with outbound pacing through Status-Resource messages. For more information, see Pacing and Chunking.
Application cancel option	A value of 0x00 indicates that the local node should automatically generate CANCEL. A value of 0x01 indicates that the application will generate CANCEL. For more information, see Inbound Chaining.
Application transaction numbers option	A value of 0x00 indicates that the application does not support transaction numbers. A value of 0x01 indicates that the application does support transaction numbers. For more information, see Recovery.
BIND check index	Gives the index of the **BIND** check table entry against which the BIND parameters should be verified. One of the following values should be used: • 0x01 —3270 printer session • 0x02 —3270 display session • 0x10 —LUA (LU type 0) application

The **Open(PLU) Confirm** from the local node to the application indicates whether the **BIND** verification was successful, and if so, supplies the bind information control block (BICB). The BICB summarizes the session **BIND** parameters in a format suitable for high-level languages and effectively defines the characteristics of the PLU session. The application not negotiating the **BIND** should usually not require to examine the **BIND** on the Open(PLU) Request and should use the BICB on the Open(PLU) OK Confirm.

The following table summarizes the fields in the BICB and their correspondence to the parameters in the **BIND** RU. For more detailed information, see the IBM manual *Systems Network Architecture: Formats,* (GA27-3136).

Position on Open(PLU) OK Confirm	**Position in Bind RU [byte, bit]**	**Description**

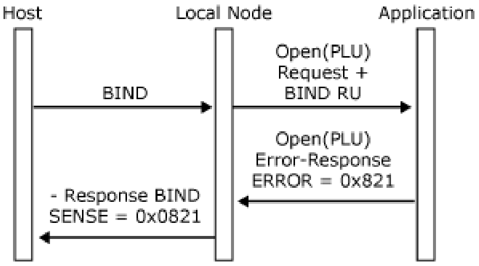
Note 2 0x01 = Bracket reset state is BETB (between-brackets). 0x02 = Bracket reset state is INB (in-bracket).

Note These values are of type INTEGER (all others are of type CHAR).

The opening PLU sequence can fail if the application rejects the Open(PLU) Request (for example, if the **BIND** parameters are unacceptable on a nonnegotiable **BIND**) by sending Open(PLU) Error Response and appropriate sense codes. The local node sends to the host a negative response to the **BIND** request containing the supplied sense codes. The PLU connection is considered to be closed after an **Open(PLU) Error Response**, and the local node does not generate an **Open(PLU) Confirm**. The following figure shows a failure to open the PLU connection (for a nonnegotiable **BIND**), due to the application rejecting the **Open(PLU) Request**.



- The opening PLU sequence can also fail if the **BIND** verification against the **BIND** check table entry specified by the application fails. In this case, the local node does the following: Sends to the host a negative response to the **BIND** request with appropriate sense codes.

- Sends to the application an Open(PLU) Error Confirm with the first word of the sense codes as the first error code and the index of the **BIND** parameter in error as the second error code.

The PLU connection is considered to be closed after the **Open(PLU) Error Confirm**. The following figure shows failure to open the PLU connection due to **BIND** verification failure. Note that error code 2 gives the index in the RU of the **BIND** parameter in error.

Closing the PLU Connection

Either the application or the local node can terminate the primary logical unit (PLU) connection. The criteria for closing are:

- The local node closes the PLU connection if it receives an **UNBIND** request from the host PLU, which terminates the PLU session. If the **UNBIND** type is **BIND forthcoming** (0x02), the local node sets the **BIND**-forthcoming indicator in the Close(PLU) Request, so that the application can reserve any necessary resources.
- The local node closes the PLU connection if it receives a Deactivate Logical Unit (DACTLU) or Deactivate Physical Unit (DACTPU) request from the system services control point (SSCP).
- The local node closes the PLU connection if it receives an outage notification from data link control.
- The local node closes the PLU connection if it detects a critical error in a message from the application, putting the application in a critically failed state. In this case, the local node sends a **TERM-SELF** request to the host to elicit an **UNBIND**.
- The application should close the PLU connection for logical power-off conditions. For example, if its resources are temporarily unavailable, or when the user finishes using the session.

When the local node issues a Close(PLU) Request, the application can determine the reason from the **Close** control field. There may be an associated status message on either the PLU connection (a Status-Acknowledge(Nack-2)) or the SSCP connection (a Status-Session message if the LU has been deactivated).

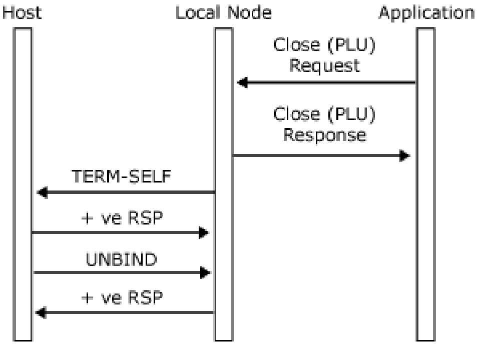
Whether the local node or the application closes the connection, the message is the same. The initiator of the **Close** sequence sends a **Close(PLU) Request** to its partner, which responds with a **Close(PLU) Response**. The **Close(PLU) Request** is unconditional. The **Close(PLU) Response** always reports that the connection was successfully closed.

The **Close(PLU) Response** is provided so that the initiator of the **Close** sequence can determine when outstanding data and status messages have been delivered. To avoid possible race conditions, the application should discard all messages it receives on the PLU connection after issuing a **Close(PLU) Request**, including any **Close(PLU) Request** messages from the local node, until it receives the **Close(PLU) Response**.

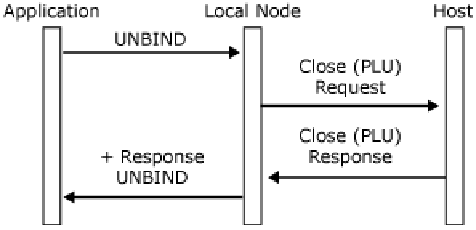
Note that, if the application sends a Close(SSCP) Request while the PLU session is active, the local node will close the PLU connection (as if **Close(PLU) Request** had been sent) as well as the SSCP connection.

The message sequence for an application-initiated **Close** is shown in the following figure. The local node sends a **TERM-SELF** request to the host to elicit an **UNBIND**.

If the host generates an **UNBIND** automatically on receipt of a **TERM-SELF**, the application can view **Close(PLU)** as equivalent to the termination of the PLU-SLU session.



The message flow for a local node-initiated **Close** after receiving an **UNBIND** request from the host is shown in the following figure.



When an application is using the logical unit application (LUA) variant of the FMI, issuing a Close(PLU) Request causes the node to immediately unbind the PLU session by sending an **UNBIND** request to the PLU. The **Close(PLU) Response** is returned to the application on receipt of the **UNBIND** response, as shown in the following figure.

Using the PLU Session

When the primary logical unit (PLU) connection is open, the application has access to the PLU session and can communicate with the host PLU.

This section contains:

- PLU Session Characteristics
- PLU Session Status

PLU Session Characteristics

The local node provides support on the primary logical unit (PLU) session for function management (FM) profiles 2, 3, 4, and 7 and Transmission Service profiles (TS profiles) 2, 3, 4, and 7. Support of these profiles means that the local node supports LU-LU session types 0, 1, 2, and 3. Using the PLU connection, the application can send and receive any FM data that is valid for these LU-LU types.

The protocols appropriate to a particular session are determined by the parameters in the **BIND** request that establishes the session. The **BIND** parameters are reported to the application in the bind information control block (BICB) on the Open(PLU) OK Confirm message. It is the application's responsibility to conform to the session protocols reported in the BICB.

Due to the wide range of **BIND** parameters allowable on a session and the options available to an application in the CICB on the Open(PLU) OK Response, this section does not attempt a complete description of the protocols for a particular session. The remaining topics in this section describe the general protocol characteristics of the PLU session, such as chaining, brackets, and so on.

Most of the protocol descriptions in the remainder of this section are accompanied by figures to illustrate the important features. The figures show:

- The relevant response header flags in SNA requests/responses.
- The sequence number of SNA requests/responses.
- Any sense data (shown as "SENSE=...") on SNA responses or **Data** messages.
- The acknowledgment required (ACKRQD) field in Data and Status-Control messages.
- The relevant application flags in **Data** and **Status-Control** messages. (For more information, see Application Flags.)
- The message key field in **Data** messages.
- Any error codes (shown as "ERROR=...") in Status-Acknowledge or **Status-Control** messages.

For simplicity, it is assumed that all messages are function management data flowing on the same PLU session that:

- Uses half-duplex flip-flop protocols.
- Uses brackets, with reset state of between-bracket.
- Does not use the PLU CICB segment delivery option. (For more information, see Segment Delivery).

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

PLU Session Status

While the primary logical unit (PLU) connection is open, the local node reports any changes of state to the application through Status-Session messages. There is only one **Status-Session** status code that can occur on the PLU connection, which is listed in the following table.

Status code	**Description**
BETB	The PLU session has made the transition from the in-bracket state to the between-bracket state. (For more information, see Brackets.)

Status-Session Codes describes the **Status-Session** status codes.

Outbound Chaining

The local node checks that outbound chains of requests conform to the correct SNA usage, to the chaining usage for the session, and to the current state of the session. The local node will accept valid outbound chains of data from the host if one of the following is true:

- Data traffic is active on a full-duplex session.
- The session is in a state where it can receive data.
- The session is between brackets with neither half-session currently sending, or the session is in contention for a half-duplex contention session. (For more information, see Brackets.)
- The session is waiting for the host to initiate a recovery procedure. For example, the local node has sent a negative response to an outbound chain. (For more information, see Recovery.)

The local node sends a Data message to the application for each outbound request, but note the effects of the application specifying the segment delivery option in the connection information control block. (For more information, see Segment Delivery.) If the application does not specify segment delivery, the begin chain indicator (BCI) and end chain indicator (ECI) application flags in the message header reflect the chaining indicators in the request header of the request.

An outbound chain can terminate in several ways:

- The chain is received complete and without error. All the requests in the chain have been passed to the application as **Data** messages and have been acknowledged where applicable.
- The application detects an error in a Data message while receiving the chain. The application should send a Status-Acknowledge(Nack-1) with associated sense data to the local node, which sends a negative response plus the sense data to the host for the request corresponding to the **Data** message in error. The local node will not purge the remainder of the chain, so the application will see End Chain (EC). Alternatively, the host can terminate the chain with a CANCEL, which is delivered to the application as a **Status-Control(CANCEL)** with ACKRQD set.
- The local node detects an error in a request and presents the application with a system detected error **Data** message to report the premature termination of the chain. This message carries the system detected error indicator (SDI) and ECI application flags, the sense codes for the error, and the ACKRQD indicator. It does not carry user data. When the application responds with Status-Acknowledge(Ack), the local node generates a negative response to the chain using the appropriate sense code. The application can use the reported sense codes to generate diagnostic information for the user. (For example, a 3270 emulator would generate **PROG** check codes.) The local node will purge the remainder of the chain, so the application may not see EC. Alternatively, the host can terminate the chain with a **CANCEL**, which is delivered to the application as a **Status-Control(CANCEL)** with ACKRQD set.
- The host can cancel the chain while sending, by sending the **CANCEL** request. The local node sends a **Status-Control(CANCEL)** message to the application, which the application must acknowledge.

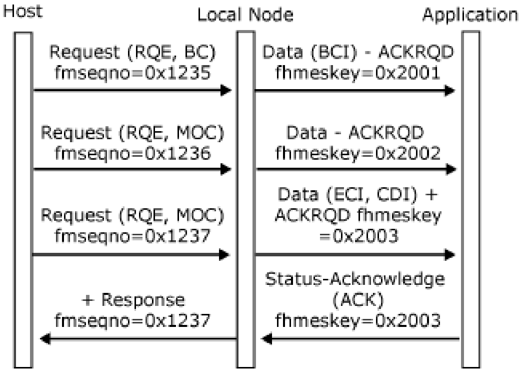
If an error occurs while receiving a chain, and the session uses half-duplex flip-flop protocols, the application must assume an error-recovery-pending state. (For more information, see Recovery.)

For a session using half-duplex flip-flop protocols, if the application flags in the last Data message of the chain have the CDI (change direction) flag set:

- If the chain was received without error, the application has direction.
- If the application rejected any message in the chain, the host retains direction.

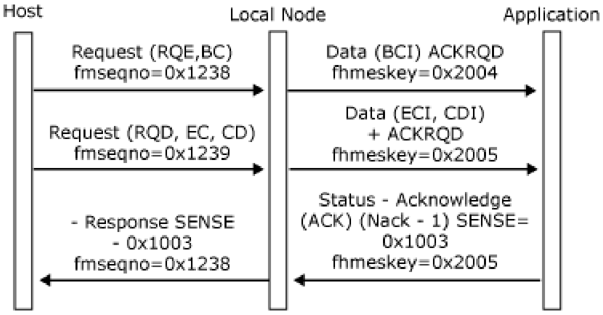
The following four figures illustrate outbound chaining protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

In the first figure, a complete outbound chain is received without error and accepted by the application. Note that after sending **Status-Acknowledge(Ack)**, the application has direction.



Host
Local Node
Application
Request (RQE, BC) fmseqno=0x1235
Data (BCI) - ACKRQD fhmeskey=0x2001
Request (RQE, MOC) fmseqno=0x1236
Data - ACKRQD fhmeskey=0x2002
Request (RQE, MOC) fmseqno=0x1237
Data (ECI, CDI) + ACKRQD fhmeskey =0x2003
+ Response fmseqno=0x1237
Status-Acknowledge (ACK) fhmeskey=0x2003

In the following figure, a complete outbound chain is received without error, but is rejected by the application. Note that even though the chain carried CD, the application does not have direction.



Host
Local Node
Application
Request (RQE,BC) fmseqno=0x1238
Data (BCI) ACKRQD fhmeskey=0x2004
Request (RQD, EC, CD) fmseqno=0x1239

- Response CANCEL fmseqno=0x123D
Status - Control (CANCEL) Ack

Inbound Chaining

The division of application data into Data messages and the control of inbound chaining are the responsibility of the application.

The secondary maximum send request unit size for the session is a parameter in the **BIND** from the host and is available in the bind information control block (BICB) on the Open(PLU) OK Confirm message. The application should ensure that each inbound **Data** message corresponds to a single request unit. It does not contain more data than the maximum request unit size given in the BICB.

The application should use the begin chain indicator (BCI) and end chain indicator (ECI) application flags in the **Data** message headers to control chaining. (For more information, see Application Flags.) The chain is the unit of recovery, and if recoverable errors occur in the chain, the application should assume responsibility for recovery. (For more information, see Recovery.)

An inbound chain can terminate in the following ways:

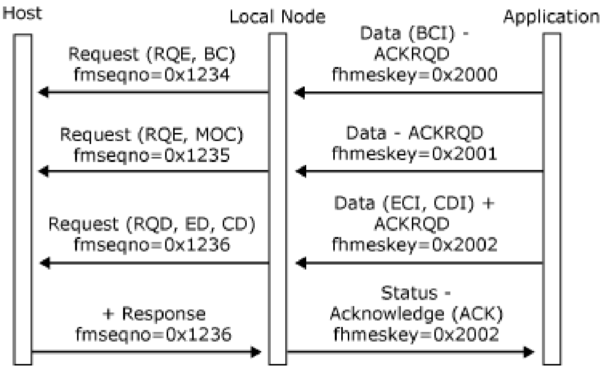
- The complete chain is sent without errors. All the **Data** messages in the chain have been passed to the host. If the session allows the secondary to send definite-response chains, and the application sets the **ACKRQD** field in the last **Data** message of the chain, the application receives a Status-Acknowledge(Ack) from the local node when the host supplies a response.
- The local node detects a critical error in the format of a **Data** message from the application or in the state of the session. The local node rejects the **Data** message with a Status-Acknowledge(Nack-2) containing an error code and closes the PLU connection. Note that the local node will generate an inbound **CANCEL** request before closing the PLU connection. The local node will send a **TERM-SELF** request to the host to elicit an **UNBIND**.
- The host sends a negative response to a request in the chain. The local node sends a Status-Acknowledge(Nack-1) message to the application with the sense codes and sequence number from the negative response. If the host rejects a request that does not carry the ECI application flag, and the application does not specify the application cancel option in the PLU CICB, the local node also generates an inbound CANCEL request. When the application specifies application cancel, it must send EC or **Status-Control(CANCEL)** to terminate the chain. Any subsequent inbound chains are rejected with a noncritical **Status-Acknowledge(Nack-2)**, sense code 0x2002 or 0x2004 (chaining or direction). When the application receives the **Status-Acknowledge(Nack-1)** message, it should stop sending data after this chain for half-duplex flip-flop sessions because the direction has passed to the host. (For more information, see Direction.)
- The application cancels the chain while sending, by sending a **Status-Control(CANCEL)** message to the local node. The local node sends a CANCEL request to the host and sends a **Status-Control(CANCEL)** Acknowledge to the application on receiving a positive response from the host. Responses from the host to requests sent before the **CANCEL** will generate appropriate **Status-Acknowledge** messages to the application if the original Data messages had the **ACKRQD** field set.
- The application closes the PLU connection while sending the chain. The local node sends a **Close(PLU) Response** to the application. Responses from the host to requests sent before the **Close(PLU)** message will not generate **Status-Acknowledge** messages to the application. Note that the local node will also generate an inbound **CANCEL** request and a **TERM-SELF** request to elicit an **UNBIND**.

If the local node detects a noncritical error in the format of a **Data** message from the application or the state of the session, it does not close the PLU connection. Instead, it rejects the **Data** message in error with a **Status-Acknowledge(Nack-2)** containing an appropriate error code. No data is sent to the host.

If an inbound chain terminates with an error, when the session uses half-duplex protocols, the application must assume a receive state. (For more information, see Recovery.)

The following six figures illustrate inbound chaining protocols between the local node and the application, and how those protocols relate to the underlying SNA protocols.

In the first figure, a complete inbound chain is sent without error and accepted by the host. Note that after receiving **Status-Acknowledge(Ack)** the application relinquishes direction to the host.



In the following figure, the local node detects a critical error in the format of the second **Data** message in the chain (**ACKRQD** without the ECI application flag), sends a **Status-Acknowledge(Nack-2)** to the application with the appropriate error code, and closes the PLU connection. Note that the local node only generates the **CANCEL** if the session's function management (FM) profile supports **CANCEL**.

Segment Delivery

If the maximum request/response unit (RU) size for a session (supplied in the **BIND** parameters) allows RUs that are larger than the maximum size of a data link control transmission unit, for example, a Synchronous Data Link Control (SDLC) frame, the local node's path control is responsible for assembling outbound segments into RUs and segmenting inbound RUs where required.

However, certain IBM products (for example, SNA models of the 3270 controllers) do not perform outbound segment assembly, to improve perceived response times at display terminals by displaying each segment as soon as it is received. This feature is referred to as window shading.

The local node allows an application to specify a segment delivery option in the connection information control block (CICB) on the Open(PLU) OK Response. If an application specifies this option, the local node's path control does not assemble outbound segments into complete RUs, and the local node delivers the segments to the application in Data messages. This enables an application emulating a 3270 device to reproduce the perceived response characteristics of the IBM device. In cases where throughput is high, such as 3270 file transfer, segment delivery can give improved performance compared to RU delivery.

Note that there is no comparable feature for inbound data. The application must present **Data** messages containing complete RUs to the local node. Also, there is no support for segment delivery on the system services control point (SSCP) session and connection (where the maximum RU size is limited to 256 bytes).

The local node supports the segment delivery option in such a way that the constraints placed on an application receiving data in either form are identical. If complete RUs are required, the local node rebuilds the RUs from segments in path control. If segments are required, the local node handles all segmentation indicators and modifies processing within its SNA layers to cater for segmented RUs.

All **Data** messages delivered to the application contain application flags, whereas only the first segment in an RU contains a response header (RH). The local node delays the end chain (EC) and change direction (CD) indicators if they occur in the RH of the RU's first segment, and sets the corresponding ECI and CDI application flags in the **Data** message corresponding to the last segment of the RU. Therefore, the **Data** messages corresponding to RU segments have application flags set as if they corresponded to whole RUs. This considerably simplifies the handling of chaining, bracket, and half-duplex protocols for an application using the segment delivery option.

> **Note** EB is not delayed until end basic information unit (EBIU), because the application should use the Status-Session between-brackets message to determine when to enter the between-brackets state.

Brackets

This section primarily describes the bracket protocols between the local node and an application for a session supporting half-duplex flip-flop with brackets.

The local node enforces no bracket protocols for full-duplex sessions. Therefore, messages with begin bracket (BB) are not presented as **Status-Control(BID)** messages, and there are no **Status-Session(BETB)** messages.

The management of this protocol for a generalized application is complex, and there is a significant amount of code in the local node to simplify the application's perception of the protocol. An application is only aware of two states:

- In-bracket
- Between-bracket

The local node, in addition to the states of in-bracket and between-bracket, maintains transient states with a large state transition matrix, or finite-state machine, governing the half-session's state at a particular time.

This section contains:

- Bracket Initiation
- Bracket Termination

Bracket Initiation

While a session is in the between-bracket state, contention exists. Either the application or the host primary logical unit (PLU) can attempt to initiate a bracket, as follows:

- The application initiates a bracket by sending a Data message with the begin bracket indicator (BBI) application flag and **ACKRQD** set while in the between-bracket state. The local node sends a request corresponding to the **Data** message to the host PLU. The application has successfully initiated a bracket and is in the in-bracket state. Flip-flop protocols are now in force until the bracket is terminated.
- The application initiates a bracket by sending a **Status-Control(LUSTAT)** with the BBI application flag set while in the between-bracket state. The local node sends an **LUSTAT** request to the host PLU. The application has successfully initiated a bracket and is in the in-bracket state. Flip-flop protocols are now in force until the bracket is terminated.
- The host PLU sends a **BID** request while in the between-bracket state. The local node sends a **Status-Control(BID)** with **ACKRQD** to the application. (For more information, see Status-Control Message.) The application replies with a **Status-Control(BID) Acknowledge**, to indicate that it is willing to accept a bracket. The local node sends a positive response to the **BID** request. The host PLU has successfully initiated a bracket, and the application's state is in-bracket, with flip-flop protocols applying until the bracket is terminated.
- The host PLU sends data in an RU carrying the BB indicator in the RH while in the between-bracket state. The local node presents this method of initiating a bracket in the same way as if the host PLU had initiated the bracket with **BID**. The local node sends a **Status-Control(BID)** with **ACKRQD** to the application. The application replies with a **Status-Control(BID) Acknowledge** to indicate that it is willing to accept the bracket. The local node sends the Data message corresponding to the RU to the application and sends a positive response to the data RU. The host PLU has successfully initiated a bracket, and the application's state is in-bracket, with flip-flop protocols applying until the bracket is terminated.
- The host PLU sends an **LUSTAT** request carrying the BB indicator in the RH. The local node presents this method of initiating a bracket in the same way as if the host PLU had initiated the bracket with **BID**. The local node sends a **Status-Control(BID)** with **ACKRQD** to the application. The application replies with a **Status-Control(BID) Acknowledge** to indicate that it is willing to accept the bracket. The local node sends a **Status-Control(LUSTAT)** to the application, which requires an acknowledgment. The host PLU has successfully initiated a bracket, and the application's state is in-bracket, with flip-flop protocols applying until the bracket is terminated.
- The host attempts to initiate a bracket using a **BID** request or an RU carrying BB, which the local node sends to the application as a **Status-Control(BID)**, but the application cannot accept the bracket. The application should send a negative **Status-Control(BID)** response with an appropriate sense code. The local node sends a negative response to the BID carrying the sense code supplied by the application. The application's state is still between-bracket. The application should use one of the following sense codes:
  - 0x081B if it has already committed resources for an inbound transfer. For example, a terminal operator has begun typing.
  - 0x0814 if it currently cannot begin a bracket but will notify the host when resources become available. For example, a 3270 printer is being used for local copy in between-bracket printer sharing mode. At a later stage when the resources become available, the application should temporarily reserve the resources and send a **Status-Control(RTR)** to the local node. If the host rejects the **RTR**, the local node returns a **Status-Control(RTR) Negative-Acknowledge-1** response, and the application can release the resources. Otherwise, the host attempts to initiate a bracket that the application must now accept.
- If the application has successfully initiated a bracket, a bracket race may occur due to the host PLU attempting to initiate a bracket. The application gets a **Status-Control(BID) Request**, which it should reject with 0x080B or 0x0813. The application retains direction after race negative responses. (For more information, see Recovery.) The application's bracket state remains as in-bracket.

The application needs to be aware of one further complication in bracket initiation. All the cases relate to sessions whose bracket reset state is between-bracket. A state of contention exists, and either half-session can attempt to begin a bracket.

However, the **BIND** parameters for the session can specify a bracket reset state of in-bracket. If the bracket reset state is in-bracket, one half-session is considered to have already successfully initiated a bracket. Flip-flop protocols will then apply until a **Status-Session(BETB)** is received, at which time the session reverts to a contention state and bracket initiation proceeds as described earlier.

The application must set its bracket state when the PLU connection is opened (on receipt of the Open(PLU) OK Confirm message) and reset it each time the session is reset (after receipt of a **Status-Control(CLEAR) Request**). The appropriate bracket reset state for the session is supplied to the application in the BICB on the Open(PLU) OK Confirm message.

The following six figures illustrate bracket initiation protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

In the first figure, the application initiates a bracket by sending an inbound chain with the BBI application flag set when its state is between-bracket. The application's state is in-bracket until it receives a **Status-Session(BETB)**. (If the application can send RQE chains, a bracket can be opened by sending an RQE chain.)

Bracket Termination

The local node supports bracket termination rule one (conditional) and bracket termination rule two (unconditional), as specified in the **BIND** request. Some sessions only allow bracket termination by one session partner. This is a **BIND** option, supplied in the bind information control block (BICB) on Open(PLU) OK Confirm), and it is the application's responsibility to determine if (and when) it should request bracket termination.

If an application is allowed by its **BIND** to terminate brackets, it does so by setting the End Bracket Indicator (EBI) application flag in an inbound Data or **Status-Control(LUSTAT/CHASE/QC/CANCEL)** message. The bracket is only terminated when the application receives a Status-Session (BETB) from the local node.

If the host terminates a bracket successfully, the local node sends a **Status-Session(BETB)** to the application. Note that the EBI application flag on outbound messages does not indicate bracket termination, but indicates that the corresponding request/response unit (RU) carried End Bracket (EB). The bracket is only terminated when the application receives **Status-Session(BETB)**.

Note that if the application queues data, it should also queue **Status-Session(BETB)** messages. They must not be processed as expedited.

The following two figures illustrate bracket termination protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

In the following figure, the application successfully terminates a bracket by sending an EBI data chain when the application's state is in-bracket, which the host accepts. The local node sends a **Status-Session(BETB)** to indicate that the application's state is now between-bracket.

Direction

When an function management interface (FMI) application is communicating on its primary logical unit (PLU) connection with a normal flow request mode other than full-duplex (that is, half-duplex flip-flop or half-duplex contention), it must obey the SNA direction protocol. These two modes are treated separately.

This section contains:

- Half-Duplex Flip-Flop Direction
- Half-Duplex Contention

Half-Duplex Flip-Flop Direction

The **BIND** used to establish the session carries information about the initial state of the bracket and direction machines. This can be specified in the **BIND** if either of the following conditions are satisfied:

- Brackets are not used.
- Brackets reset state is in-bracket.

If neither of the conditions hold, the initial direction state is contention.

When the direction is specified in the **BIND**, the application should assume the direction state specified in the half-duplex reset state as soon as data can flow. This field can be obtained indirectly by using a **BIND** check index that only accepts a particular direction, or directly by reading the **HDXRSET** field in the bind information control block (BICB) on the Open(PLU) OK Confirm message or by reading the **BIND** on the Open(PLU) Request. For more information about opening the PLU connection, see Opening the PLU Connection.

When in contention state, either the PLU or the application can initiate a bracket. (For more information, see Brackets.) The successful initiator of the bracket obtains direction unless direction is relinquished when opening the bracket by sending Begin Bracket (BB), Begin Chain (BC), End Chain (EC), or Change Direction (CD). Because the secondary is assumed to be the contention winner, the application can assume send state from contention sending BB and rejecting any subsequent **Status-Control(BID) Request** from the local node before receiving **Status-Session(BETB)**. When the application accepts a S**tatus-Control(BID) Request** in contention state, it must assume receive state.

Half-duplex flip-flop direction can change through the following actions:

- Sending or receiving data with the change direction (CD) indicator in the RH, and the corresponding change direction indicator (CDI) flag on the **DATAFMI** and Status-Control messages. Note that CD is only used at the end of a chain (and for applications receiving segments that will be delivered with ECI, EBIUI). Also note that CD is valid on the following normal flow **Status-Control** requests: **LUSTAT**, **CANCEL**, **CHASE** and **QC**.
- Receiving a negative response when the application should assume receive state (error recovery pending state). For more information, see Recovery.
- If the application rejects data from the host carrying CDI, it must remain in receive state.

Providing the FM profile is correct (3, 4, or 7), the application can request direction from the host using a **Status Control(SIGNAL) Request** with CODE1 set to 0x0001. CODE2 is set to a user-defined value.

The following three figures illustrate the direction protocol for applications using the half-duplex flip-flop mode.

In the first figure, the application issues and receives the CD without error.

Half-Duplex Contention

For half-duplex contention, the initial direction state is contention. Half-duplex protocol operates during a chain (only one partner can send), but the direction state normally returns to contention at the end of each chain. The change direction indicator (CDI) in the response header (RH) is thus not required. However, if the CDI is used, direction is reserved for the receiving half-session. Therefore, if the application receives change direction (CD), it should assume send state and not expect to receive data. Conversely, if the application sends CD, it cannot send again until it has received a chain from the host.

In the event of an error being discovered by either half-session, the application must assume receive state, because the host is responsible for recovery.

If both half-sessions attempt to start a chain when the direction state is contention, the race is resolved in favor of the secondary application using a sense code of 0x081B. However, the possible window between the local node and the application means that the local node cannot determine when outbound Request Exception (RQE) data is received by the application. Therefore, if the local node receives data from the application while it determines that the half-duplex contention state is receive, it will reject it with a noncritical NACK-2 (0x2004 direction).

The following two figures illustrate the direction protocol for applications using half-duplex contention mode. The three figures in the previous topic would also be valid although CD does not need to be specified.

In the following figure, the application issues and receives data using half-duplex contention protocol without error.

Pacing and Chunking

The local node supports session pacing inbound and outbound, according to the pacing values in the **BIND** parameters for the session. The application can be involved in outbound pacing through the use of the Status-Resource message. Inbound pacing is handled transparently by the local node and need not concern the application.

This section contains:

- Outbound Pacing
- Chunking

Outbound Pacing

If the application has enough resources to handle outbound data as fast as the network can provide it (for example, a screen), or if a higher level protocol (for example, immediate request mode) constrains the data flow, the application need not be involved in pacing, and it is possible for the local node to handle outbound pacing transparently.

However, certain types of applications may require involvement in outbound pacing. If the application has limited resources (for example, a printer), the application should specify the application pacing option in the connection information control block (CICB) on the Open(PLU) OK Response. (For more information, see Opening the PLU Connection.) The application should also provide the local node with information about the state of these resources initially on the **Open(PLU) OK Response** and periodically using **Status-Resource** messages.

To assist the application in calculating the initial credit field in the **Open(PLU) OK Response**, the local node delivers the pacing window sizes and the primary and secondary maximum request/response unit (RU) sizes on the Open(PLU) Request. The initial credit must be at least as large as the primary to secondary pacing window size. Otherwise, the **BIND** will be rejected and the application will be sent an Open(PLU) Error Confirm message. The local node fills in a suggested initial credit value of one more than the pacing window (to try to avoid stop-start situations).

Note that the local node will also reject the **BIND** if the application specifies that it needs to be involved in pacing (of whatever initial credit), but the **BIND** specifies that there is no outbound pacing.

Only function management data (FMD) requests are part of the credit scheme, so the application must maintain space within its buffer for one Status-Control request per RU in addition to the number of RUs specified by the initial credit count. (A **Status-Control** message takes up 36 bytes.)

Each unit of credit that the application delivers to the local node allows the local node to give the application a single RU (or a single chunk if chunking is being used). Note that if the application is receiving segments, this may correspond to several **DATAFMI** messages. The application can count RUs for the purpose of outbound flow control by using the begin basic information unit (BBIU) and end basic information unit (EBIU) flags.

The application should maintain a credit-used count, which it should report to the local node on Status-Resource messages. The application needs to take the following actions:

- On processing (not receiving) **DATAFMI** messages with EBIU set (corresponding to FMD requests), increment the credit-used count by one.
- On processing **Status-Control** messages and all other messages from the local node, do not increment the credit-used count.
- Periodically report the current credit-used count on a **Status-Resource** message.
- Report the credit-used count when its buffer becomes empty (whatever the last message processed was), unless the credit-used count is zero.
- When the credit-used count is reported to the local node, reset it to zero.

The frequency at which the application provides Status-Resource messages is not architected. However, the local node will only send the application as many Data messages as it has received credit for. When the application's credit-used count reaches the initial credit value, the local node will not send any more data. The application should attempt to send a **Status-Resource** message before this happens, because if the local node cannot send a **Data** message to the application and the host is still sending requests, the local node may not be able to send a pacing response to the host when required, with a consequent degradation of performance.

If the pacing window is small, such as one or two, the application should send a **Status-Resource** after processing each **DATAFMI** message to enable the local node to send the suitable pacing response.

The following figure shows the local node handling outbound pacing when the application is not involved (APPLPAC = 0x00). The pacing window is assumed to be two.

Chunking

Chunking can be thought of as similar to segmentation. (For more information, see Segment Delivery.) The distinction is that segmentation is determined by the communications link between the local node and the remote system, whereas chunking is determined by the communications link between the application and the local node.

The application indicates on the Open(SSCP) Request whether it supports chunking, and, if so, the chunk size in bytes that it wants to use. The local node then uses the request/response unit (RU) size, the chunk size, and the segment size (if applicable) to determine whether chunking is necessary. It then specifies the chunk sizes used for inbound and outbound flow (which need not be the same) on the Open(PLU) Request. These values are specified in units of elements. (For more information, see Messages.) A value of zero for either of these sizes indicates that chunking is not necessary because the chunk size is not the limiting factor. Note that in chunking data, an RU will not be split in the middle of an element. This avoids data copying.

For example, assume that the local node is using an RU size of 8 kilobytes (KB) and segments of 2 KB, and the application's **Open(SSCP) Request** specifies segment delivery and a chunk size of 4 KB. Chunking will be used on inbound data flow (because the chunk size is smaller than the RU size), but is not necessary on outbound data flow (because data will be delivered in segments that are smaller than the chunk size).

If chunking is being used in either direction, all credit values specify the number of chunks that can be sent in that direction, not the number of RUs. Note that the segment delivery option is included on the **Open(SSCP) Request** to enable the local node to calculate the initial chunk credit values on the corresponding PLU connection. The application must also set this option on the **Open(PLU) Response**. If the **Open(SSCP) Request** and the **Open(PLU) Response** have different settings of this option, the setting from the **Open(PLU) Response** will be used. This can mean that the initial credit value used is not appropriate.

If session-level pacing is being used, the local node links this to the chunking credit. In particular, if the application withholds credit, the local node will delay sending a pacing response to the host, thereby applying back pressure to the host. This linkage is handled by the local node and need not concern the application.

Application flags on chunks of RUs are handled in the same way as those on segments. (For more information, see Application Flags and Segment Delivery.) In particular:

- FMHI, BCI, COMMIT, BBI, EBI, CODE, ENCRYP, ENPAD, QRI, and CEI are only set on the first chunk of an RU.
- ECI and CDI are only set on the last chunk of an RU.
- BBIUI is always set on the first chunk of an RU.
- EBIUI is always set on the last chunk of an RU.

Note that EBI is set on the first chunk of the last RU in a bracket and not on the last chunk as might be expected. This is the same behavior as for segment delivery. The application should use the **Status-Session(BETB)** message, not the EBI flag, to determine when a bracket has ended.

Chunks are identified using the segmentation flags BBIUI and EBIUI, and therefore the application cannot distinguish between chunks and segments if both segmentation and chunking are being used outbound. However, there is generally no need for the distinction. The application can perform window shading by displaying each unit of data as it is received, whether the unit of data is a segment or a chunk. (For more information, see Segment Delivery.)

> **Note** Previous versions of this document indicated this as a future feature. The support is enabled in Microsoft Host Integration Server 2004. Applications can test the product version returned on a call to sepdgetinfo for version 1.2 or later before using the chunking system.

In some cases, the RU size used by the local node may be too large for the length of the path between the local node and an FMI application, for example, when using a 16 megabyte (MB) token-ring link, which can support 16 kilobyte (KB) frames. The local node allows an FMI application to specify that data transfer should be in smaller units, called chunks.

Confirmation and Rejection of Data

The following topics describe conditions under which inbound and outbound data is confirmed or rejected.

This section contains:

- Confirmation and Rejection of Inbound Data
- Confirmation and Rejection of Outbound Data

Confirmation and Rejection of Inbound Data

For every SNA chain of data sent or received for which responses are outstanding, such as Request Exception (RQE) or Definite Response Required (RQD), the local node maintains a correlation table entry. If the table entries become depleted, the local node will terminate the session using the most table entries. A Status-Error message (code 0x46) and a Close(PLU) Request are sent to the application, and a **TERM-SELF** message is sent to the host. Table entry shortages (inbound) can be avoided by sending change direction (CD) (for half-duplex) data, or data **ACKRQD,** or any **Status-Control(CHASE)**, or **Status-Control(LUSTAT)** with **ACKRQD**. Outbound shortages can be avoided by sending courtesy acknowledge messages as described in Opening the PLU Connection.

The local node sends chains of data to the host with their chain response mode specified as follows:

1. Definite

   If the application sends a **Data** message to the local node with the **ACKRQD** field set, and the **BIND** parameters specified that the secondary uses definite or definite/exception response mode.

2. Exception

   If the application sends a **Data** message to the local node without the **ACKRQD** field set, and the **BIND** parameters specified that the secondary uses exception or definite/exception response mode.

3. No-Response

   If the application sends a **Data** message to the local node without the **ACKRQD** field set, and the **BIND** parameters specified that the secondary uses no-response mode.

If the setting of **ACKRQD** on a Data message from the application does not reflect the chain response mode specified in the **BIND** parameters, the local node returns a Status-Acknowledge(Nack-2) indicating a noncritical error code. For example, if the application specifies **ACKRQD** but the **BIND** parameters do not permit the local node to send definite response chains.

In case 1, the application receives an acknowledgment to all function management data (FMD) chains it sends to the local node:

- Positive responses from the host are returned to the application as Status-Acknowledge(Ack) messages.
- Negative responses from the host are returned as Status-Acknowledge(Nack-1) messages carrying the SNA sense codes.
- Errors detected by the local node when attempting to send the message are returned as Status-Acknowledge(Nack-2) messages carrying the equivalent error code.

In case 2, the application only receives an acknowledgment of an FMD chain it sends to the local node for:

- Negative responses from the host, which are returned as **Status-Acknowledge(Nack-1)** messages carrying the SNA sense codes.
- Errors detected by the local node when attempting to send the message, which are returned as **Status-Acknowledge(Nack-2)** messages carrying the equivalent error code.

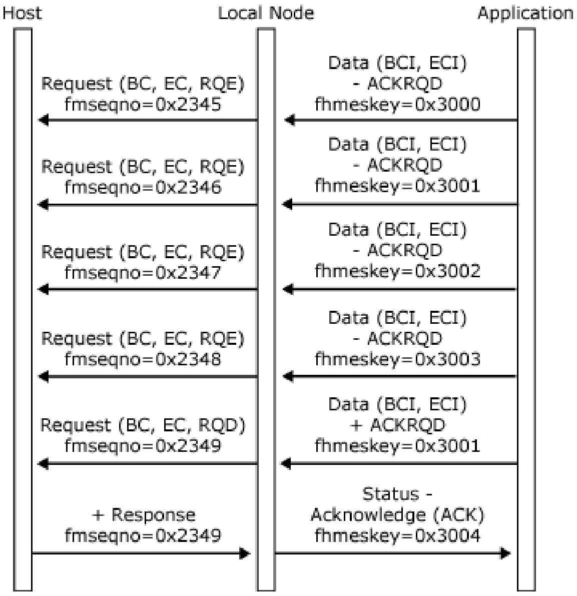
In case 3, the application only receives an acknowledgment of an FMD chain it sends to the local node when the node detects an error in the message and sends the application a **Status-Acknowledge(Nack-2)**. The only dissent that the host can make is to send a subsequent LUSTAT 0x400A (no response not supported) with the sequence number of the request in the sense qualifier field. This is presented to the application as a **Status-Control(LUSTAT)** as usual.

Whenever an application receives a **Status-Acknowledge(Ack)** or **Status-Acknowledge(Nack-1)**, it implicitly confirms receipt by the partner half-session in the host of all previously sent chains.

In case 2, the application does not usually receive such responses from the host to chains it has sent, and in case 3, the application never receives such responses. Therefore, to get the host to confirm receipt of all previously sent chains, the application should issue a **Status-Control(CHASE) Request** with ACKRQD set. This causes the local node to generate an SNA **CHASE** request to the host. The receipt of the response to this CHASE confirms that the host has received this **CHASE** request and all previous chains sent by the application. The local node issues a **Status-Control(CHASE) Acknowledge** to notify the application that this is so.

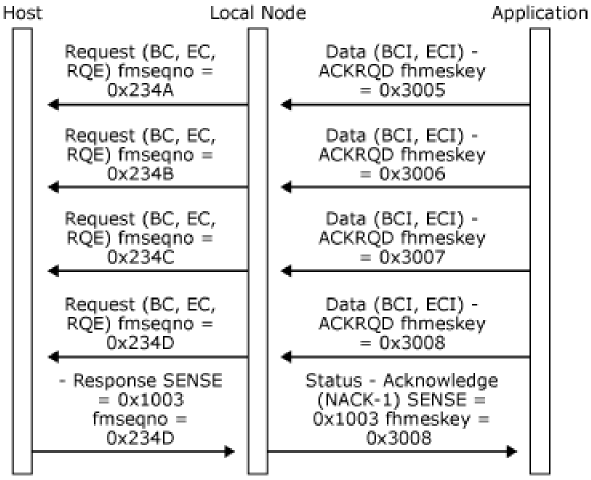
The following three figures illustrate the inbound data confirmation and rejection protocols between the local node and the application, and how those protocols relate to the underlying SNA protocols.

In the first figure, an application sets the **ACKRQD** field in an inbound data chain to get the host to confirm receipt of the chain and all previously sent chains.



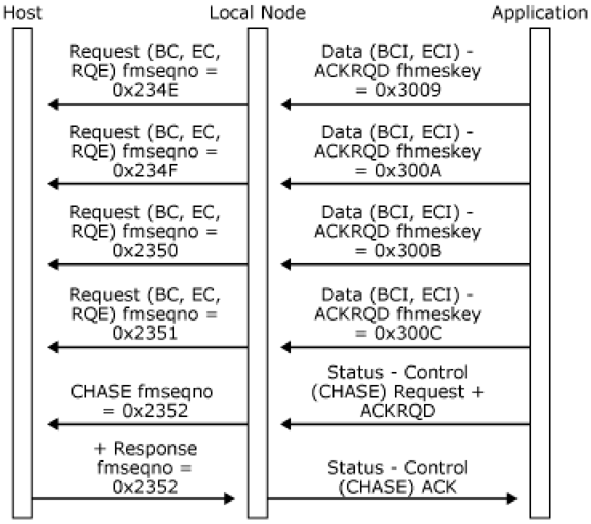
Host
Local Node
Application
Request (BC, EC, RQE) fmseqno=0x2345
Data (BCI, ECI) - ACKRQD fhmeskey=0x3000
Request (BC, EC, RQE) fmseqno=0x2346
Data (BCI, ECI) - ACKRQD fhmeskey=0x3001
Request (BC, EC, RQE) fmseqno=0x2347
Data (BCI, ECI) - ACKRQD fhmeskey=0x3002
Request (BC, EC, RQE) fmseqno=0x2348
Data (BCI, ECI) - ACKRQD fhmeskey=0x3003
Request (BC, EC, RQD) fmseqno=0x2349
Data (BCI, ECI) + ACKRQD fhmeskey=0x3001
+ Response fmseqno=0x2349
Status - Acknowledge (ACK) fhmeskey=0x3004

In the following figure, the **Status-Acknowledge(Nack-1)** rejects the last chain, but confirms receipt by the host of all previously sent data chains.



Host
Local Node
Application
Request (BC, EC, RQE) fmseqno = 0x234A
Data (BCI, ECI) - ACKRQD fhmeskey = 0x3005
Request (BC, EC, RQE) fmseqno = 0x234B
Data (BCI, ECI) - ACKRQD fhmeskey = 0x3006
Request (BC, EC, RQE) fmseqno = 0x234C
Data (BCI, ECI) - ACKRQD fhmeskey = 0x3007
Request (BC, EC, RQE) fmseqno = 0x234D
Data (BCI, ECI) - ACKRQD fhmeskey = 0x3008
- Response SENSE = 0x1003 fmseqno = 0x234D
Status - Acknowledge (NACK-1) SENSE = 0x1003 fhmeskey = 0x3008

In the following figure, the application uses a **Status-Control(CHASE)** to get the host to confirm receipt of the corresponding **CHASE** request and all previously sent chains.



Host
Local Node
Application
Request (BC, EC, RQE) fmseqno = 0x234E
Data (BCI, ECI) - ACKRQD fhmeskey = 0x3009
Request (BC, EC, RQE) fmseqno = 0x234F
Data (BCI, ECI) - ACKRQD fhmeskey = 0x300A
Request (BC, EC, RQE) fmseqno = 0x2350
Data (BCI, ECI) - ACKRQD fhmeskey = 0x300B
Request (BC, EC, RQE) fmseqno = 0x2351
Data (BCI, ECI) - ACKRQD fhmeskey = 0x300C
CHASE fmseqno = 0x2352
Status - Control (CHASE) Request + ACKRQD
+ Response fmseqno = 0x2352
Status - Control (CHASE) ACK

Confirmation and Rejection of Outbound Data

The local node sends chains of data from the host to the application with their **ACKRQD** field set as follows:

- **ACKRQD** set

  If the corresponding SNA request was received specifying definite response, and the **BIND** parameters specify that the primary uses definite or definite/exception chain response mode.

1. **ACKRQD** not set, response mode

   If the corresponding SNA request was received specifying exception response, and the **BIND** parameters specify that the primary uses exception or definite/exception chain response mode.

2. **ACKRQD** not set, no-response mode

   If the corresponding SNA request was received specifying no response, and the **BIND** parameters specify that the primary uses no-response chain response mode.

In case 1, the application should always send an acknowledgment as follows:

- If the application accepts the data, it should return a Status-Acknowledge(Ack) message.
- If the application wants to reject the data, it should return a **Status-Acknowledge(Nack-1)** message carrying the appropriate SNA sense codes.

In case 2, the application should only send an acknowledgment in the following cases:

- If the application wants to reject the data, it should return a **Status-Acknowledge(Nack-1)** message carrying the appropriate SNA sense codes.
- The application can send a courtesy acknowledgement to a Request Exception (RQE) message to clear up correlation data within the local node. (For more information, see Outbound Data.)

In case 3, the application should not send acknowledgments. However, the sending of a **Status-Acknowledge(Ack)** or **Status-Acknowledge(Nack-1)** by the application has no effect. It is discarded.

Whenever an application sends a **Status-Acknowledge(Ack)** or **Status-Acknowledge(Nack-1)** to a received Data message, it implicitly confirms receipt of this and all previously received Data messages.

In case 2, the host can issue a **CHASE** request. The local node sends a **Status-Control(CHASE) Request** with **ACKRQD** set to the application. When the application is in a position to confirm receipt of all outstanding data, it should issue a **Status-Control(CHASE) Acknowledge** message, which the local node converts into a positive response to **CHASE** for the host.

In cases 1 and 2, if the local node detects an error in a received request, it converts the request into a special Data message, which it passes to the application. Regardless of the chain response mode specified for the secondary in the **BIND** parameters, this **Data** message has the following characteristics:

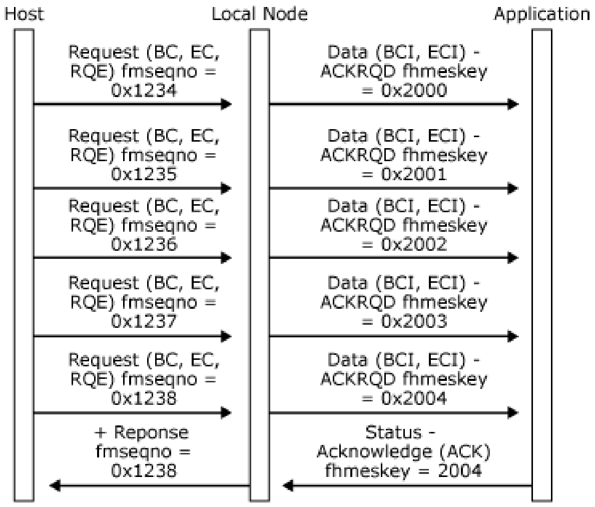
- **ACKRQD** is set. The application must confirm receipt using a Status-Acknowledge(Ack) message.
- The Sense Data Indicator (SDI) application flag is set to indicate that this is a special Data message used to inform the application of an error detected by the local node.
- The End Chain Indicator (ECI) application flag is set to indicate that the received chain has now terminated.
- The first four bytes of the buffer element hold the SNA sense codes detected by the local node that caused the termination.

This mechanism enables:

- The application to reject any previously received **Data** messages.
- The local node to inform the application of any errors it detects in received requests.
- The local node to send negative responses in the correct order.

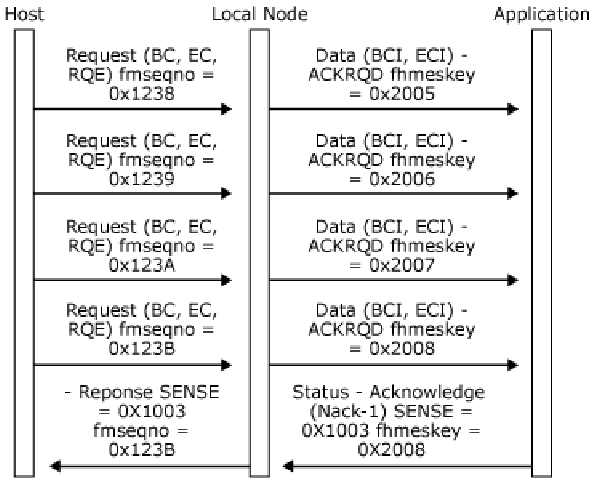
The following three figures illustrate the outbound data confirmation and rejection protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

In the first figure, the host sends a definite response chain to get the application to confirm receipt of the RQD request and all previously sent RQE chains.



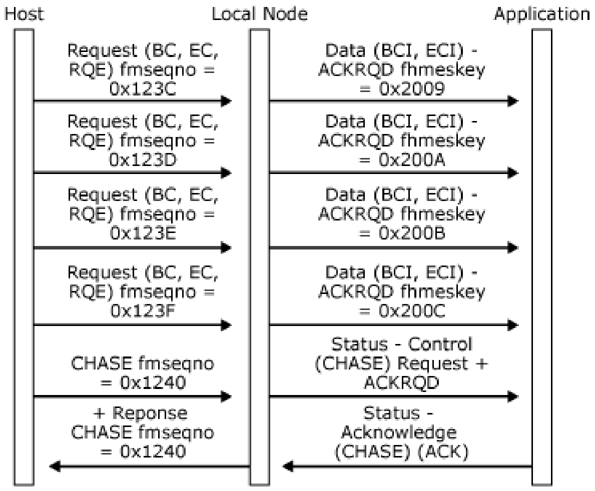
Host
Local Node
Application
Request (BC, EC, RQE) fmseqno = 0x1234
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2000
Request (BC, EC, RQE) fmseqno = 0x1235
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2001
Request (BC, EC, RQE) fmseqno = 0x1236
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2002
Request (BC, EC, RQE) fmseqno = 0x1237
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2003
Request (BC, EC, RQE) fmseqno = 0x1238
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2004
+ Reponse fmseqno = 0x1238
Status - Acknowledge (ACK) fhmeskey = 2004

In the following figure, a **Status-Acknowledge(Nack-1)** from the application rejects the last chain and confirms receipt of all previously sent data chains.



Host
Local Node
Application
Request (BC, EC, RQE) fmseqno = 0x1238
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2005
Request (BC, EC, RQE) fmseqno = 0x1239
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2006
Request (BC, EC, RQE) fmseqno = 0x123A
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2007
Request (BC, EC, RQE) fmseqno = 0x123B
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2008
- Reponse SENSE = 0X1003 fmseqno = 0x123B
Status - Acknowledge (Nack-1) SENSE = 0X1003 fhmeskey = 0X2008

In the following figure, the host sends a **CHASE** request to get the application to confirm receipt of the **CHASE** and all previously sent chains.



Host
Local Node
Application
Request (BC, EC, RQE) fmseqno = 0x123C
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2009
Request (BC, EC, RQE) fmseqno = 0x123D

Shutdown and Quiesce

Both shutdown and quiesce protocols involve a half-session entering a quiesced state, in which it cannot send any more normal flow requests, but must continue to receive and respond to requests from its session partner. The essential differences are that shutdown can only be initiated by the host and only requires that the secondary quiesce as soon as is convenient (usually at the end of a bracket). Quiesce can be initiated by both the host and the application and requires that the recipient quiesce at the end of the chain.

If the application has been quiesced but still attempts to send inbound Data messages, they will be rejected with Status-Acknowledge(Nack-2) messages. The application can, however, continue to generate status messages.

This section contains:

- Shutdown
- Quiesce

Shutdown

The shutdown protocol provides a means for the host application to stop the application from sending any further normal flow requests. This protocol is used when the host application wants to end the session in an orderly manner and is only available for sessions using function management (FM) profile 3 or 4.

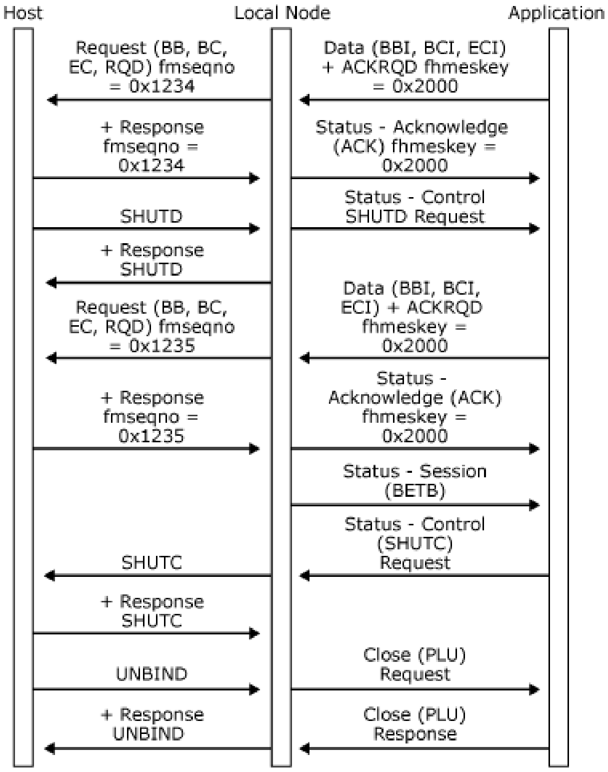
If the local node receives a **SHUTD** request from the host, it issues a **Status-Control(SHUTD) Request** (without **ACKRQD**) to request the application to enter a quiesced state at a convenient time. The application determines what is convenient. For example, it could be after a **Status-Session(BETB)** has been received.

When the application decides it is ready to quiesce, it should issue a **Status-Control(SHUTC) Request** (again without **ACKRQD**) to indicate this transition. The local node will notify the host of this change by sending a **SHUTC** request. The host can continue sending normal flow outbound requests and can subsequently take one of the following actions:

- The host terminates the primary logical unit (PLU) session by sending an **UNBIND** request. The local node closes the PLU connection by sending a Close(PLU) Request to the application. The system services control point (SSCP) session remains active.
- The host abandons the shutdown procedure by sending an **RELQ** request. The local node sends a **Status-Control(RELQ) Request** (with **ACKRQD**) to the application to indicate that it can now resume sending on the PLU session. **RELQ** is only supported on sessions using FM profile 4.
- The host resets the session by sending **CLEAR**, a Transmission Service profile (TS profile) 3 or 4. One of the effects of this is to release the quiesced state. (For more information, see Recovery.)

The following two figures illustrate the shutdown protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

In the following figure, the host sends **SHUTD** while the application is sending in the in-bracket state. The application completes the bracket, sends **Status-Control(SHUTC) Request**, and the host terminates the PLU session by sending **UNBIND**. The local node closes the PLU connection.



Host
Local Node
Application

Status - Acknowledge (ACK) fhmeskey = 0x2004

Quiesce

The quiesce protocol is only supported on sessions using function management (FM) profile 4. The quiesce protocol can be initiated by either half-session.

When an application wants to quiesce its partner half-session in the host, it sends a **Status-Control(QEC) Request** to the local node. The node generates a **QEC** request to the host, which asks the host to quiesce after completing the current outbound chain.

If the host quiesces, it sends a **QC** request, which the local node presents to the application as a **Status-Control(QC) Request** (with **ACKRQD**). The host remains in a quiesced state until the application sends a **Status-Control(RELQ) Request**. The local node sends the **RELQ** request to the host, and the host resumes communications on the primary logical unit (PLU) session.

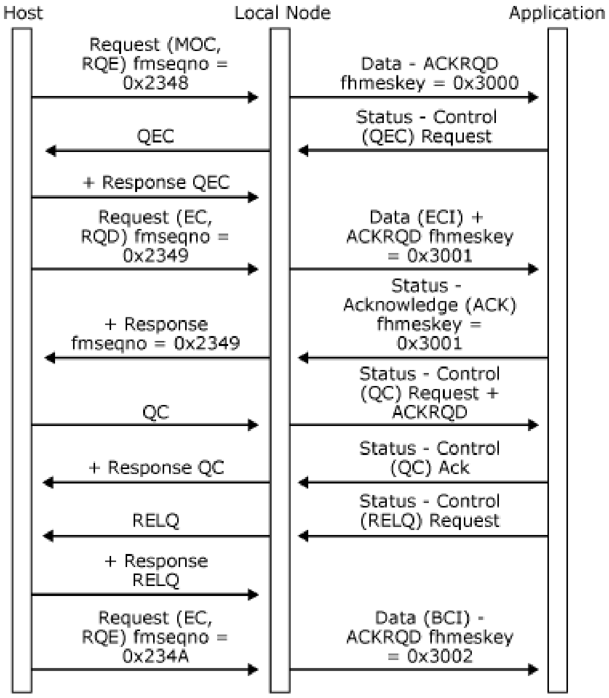
If the attempt to quiesce the host fails, the host responds with a negative **QEC** response, which the local node presents to the application as a **Status-Control(QEC) Negative-Acknowledge-1**.

Conversely, a **Status-Control(QEC) Request** (without **ACKRQD**) is presented to the application if a **QEC** request is received from the host. In this direction, **QEC** cannot be rejected. The local node will always force the application to quiesce after presenting it with a **Status-Control(QEC) Request** by rejecting further attempts to send inbound data. When the application has quiesced, it should send a **Status-Control(QC) Request** to the local node, which sends a **QC** request to the host. The application can subsequently be released by an **RELQ** request from the host, which the local node presents to the application as a **Status-Control(RELQ) Request**.

The receipt of a **CLEAR** or **UNBIND–BIND** sequence, **Close(PLU)–Open(PLU)**, causes the quiesced state to be released.

The following three figures illustrate the quiesce protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

In the first figure, the application quiesces the host and then releases the quiesce.



Host
Local Node
Application
Request (MOC, RQE) fmseqno = 0x2348

Recovery

This section covers a variety of issues pertaining to error recovery:

- Application CANCEL
- Direction after Receiving a Negative Response
- Direction after Sending a Negative Response
- Critical Failure
- RQR and CLEAR
- STSN
- Link Service Failure
- Local Node Failure
- Client Failure

Application CANCEL

One of the parameters on the Open(PLU) OK Response, which the application sends to the local node, specifies whether the application generates **CANCEL** (or **EC**) to terminate an inbound chain that has received a negative response. If this option is not selected, the local node generates a **CANCEL** request when it receives a negative response from the host to an incomplete chain.

Direction after Receiving a Negative Response

Within the local node, error recovery for a half-duplex application (as specified by byte 7 bit 2 of the **BIND**) is assumed to be the responsibility of the host. However, the application must be aware that an error recovery state has been entered to obey the direction protocol.

When an application using half-duplex protocols (flip-flop or contention) receives a negative response to an inbound chain that it sent that does not refer to a race, it must assume receive state. The sense codes used for race conditions that do not require the transition to receive state are listed in the following table.

Sense code	Description
0x080B	Bracket race error
0x081B	Receiver in transmit mode

Direction after Sending a Negative Response

When an application using half-duplex flip-flop protocol sends a negative response to an outbound chain (or sends a Status-Acknowledge(Ack) to a **DATAFMI** message with **SDI** set) that does not refer to a race, the application must assume an error recovery pending state. The sense codes used for race conditions that do not require the transition to error recovery pending state are listed in the following table.

Sense code	Description
0x080B	Bracket race error
0x0813	Bracket bid reject (no RTR forthcoming)
0x0814	Bracket bid reject (RTR forthcoming)
0x081B	Receiver in transmit mode

The application must therefore examine the sense code on an **SDI** message to detect such races.

Error recovery pending state differs from receive state only in one respect: The application can convey sense information to the host using **Status-Control(LUSTAT).** (For more information, see LUSTATs.) The **LUSTAT** must not have the change direction (CD) or end bracket (EB) flags set. (The host already has direction, and the bracket must not be terminated prematurely by the application.) Host Integration Server also enables the function management interface (FMI) application to send **Status-Control(LUSTAT)** in receive state.

An application using the half-duplex contention protocol does not have an error recovery pending state, and must enter contention state whenever it sends a negative response.

> **Note** If the chain is canceled by the host with CD on the **CANCEL** , the application must assume send state.

Critical Failure

When an application makes a protocol error in sending data, the local node rejects the data using a Status-Acknowledge(Nack-2) with a sense code indicating the reason for failure. This message has a critical failure flag that indicates whether the local node has marked the session as unrecoverable. The sense codes are listed in FMI Status, Error, and Sense Codes.

If the error is noncritical, the application can proceed as if the message that caused the error had not been sent. If the error is critical, the local node issues a Close(PLU) Request to the application (providing that the primary logical unit (PLU) connection is open), which means that the application cannot communicate on the PLU-SLU session until an **UNBIND–BIND** sequence is received from the host. The local node also sends a **TERM-SELF** request to the host to elicit an **UNBIND**. Therefore, the application does not need to issue a **LOGOFF** request on the system services control point (SSCP) session.

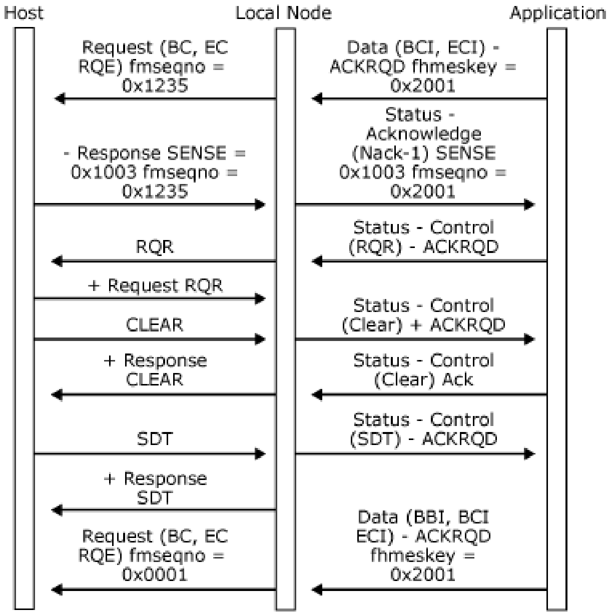
RQR and CLEAR

An application using Transmission Service profile (TS profile) 4 can request the session to be recovered by sending **Status-Control(RQR)**. The local node presents this to the host as an **RQR** request. Note that, if the application has received a critical Status-Acknowledge(Nack-2), this option cannot be taken because the local node will send a Close(PLU) Request immediately following the **Status-Acknowledge(Nack-2)** to the application, and the primary logical unit (PLU) connection will no longer be valid. The **RQR** message requests the host to reset the session by sending a **CLEAR** request, as shown in the following figure.

The receipt of **CLEAR** causes the application to reset its session state to that following the **BIND**, the **Open(PLU)**.

Another way for the application to deal with error conditions is to ask for an **UNBIND** by sending **Status-Control(RSHUTD)**. (For more information, see Application-Initiated Termination.) Note that this may not require the host to supply a new **BIND**, depending on the host configuration. A new SSCP request may be required (such as **LOGON**).

In the following figure, the application requests recovery by issuing **Status-Control(RQR)**. The host sends **CLEAR**, and the application must reset its session to state that it was following the **BIND (Open(PLU))**. In this case, the application is now between brackets and awaiting start data traffic (SDT).



Host

Request (BC, EC RQE) fmseqno = 0x0001
Data (BBI, BCI ECI) - ACKRQD fhmeskey = 0x2001

STSN

Set and test sequence numbers (STSN) are used on sessions with Transmission Service profile (TS profile) 4 for applications to maintain transaction processing sequence numbers between sessions. This enables both partners on the session to discover the amount of data lost after a **CLEAR** or **UNBIND–BIND** sequence.

The **STSN** message is the only one that can reset such transaction processing sequence numbers. **BIND**, **UNBIND**, and **CLEAR** do not affect them.

If the application wants to maintain such transaction numbers, it must specify the **APPLTRAN** option in the Open(PLU) OK Response. The host can send **STSN** after a **BIND** or **CLEAR** before sending **SDT** to set or test the application's transaction numbers. The local node resets its internal session sequence numbers to zero on receipt of **BIND** or **CLEAR**. When the local node receives an **STSN** specifying **SET** (or **SET** and **TEST**) for one half-session, it resets the corresponding internal session sequence number.

Unless both half-session actions are ignore (the action byte is 0x00), the **STSN** request is passed to the application (provided that it specified **APPLTRAN**), with the action byte and the two sequence numbers from the request, as a **Status-Control(STSN)**. (For more information, see Status-Resource.) The application must examine the action byte to determine whether the action is ignore, set, test, or set and test. The application must send a positive response (**Status-Control(STSN) Acknowledge**) to the **STSN**, with the sensed sequence numbers if required (sense or set and test). The local node is responsible for generating the correct result code for the **STSN RSP**.

Note that the application should perform the sense part of **STSN** first (by examining bits 0 and 2 of the action byte for the secondary-to-primary flow and primary-to-secondary flow respectively). The set part of the **STSN** is then performed (by examining bits 1 and 3 of the action byte).

The application should increment its transaction numbers when sending and receiving normal flow request/response units (RUs) from the host. (Note that **Status-Control** messages corresponding to normal flow data flow control (DFC) requests cause the transaction numbers to be incremented.) The sequence number is reported on **DATAFMI** messages and **Status-Acknowledge** messages. The application should be aware that, if a message from the host fails receive checks (and is converted to an **SDI** message), sub-network access protocol (SNAP)-2.1 will purge the remainder of the chain from the host, and the application may miss some sequence numbers. Therefore, the application should reset its primary-to-secondary transaction number from the next outbound data after processing an **SDI** message.

Note that the second application flag byte is not valid for **Status-Control(STSN)**. It is used for the **STSN** control byte.

Link Service Failure

When the server running a link service fails, the local node is informed of this. It treats the problem as a link outage with outage code 0x0D. This is reported to any active 3270 emulation sessions as a communications check code (−+z_nnn). The local node will attempt periodically to reconnect to the link service.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Local Node Failure

If the local node fails, applications are informed of this by the path error return code from the Dynamic Access Module (DMOD) on the sbpurcvx call, or from the routing procedure. All connections that use the destination locality value for which the path error is reported are closed. The application must do the following:

- Clean up resources related to the closed connections, including resetting presentation spaces and displaying a communications check code
  (−+z_nnn) on the status line.
- Attempt to reestablish connection with a local node by reinitiating the resource location process.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Client Failure

If the client computer fails, the local node terminates the application's PLU-SLU session (if it is active) by sending **TERM-SELF**. The system services control point (SSCP) and primary logical unit (PLU) connections are both marked as closed and cannot be reused without being reopened. Internally, the local node treats such a failure in the same way as the receipt of a Close(SSCP) Request from the application.

Application-Initiated Termination

An application on a session with function management (FM) profile 3 or 4 can request termination of the primary logical unit (PLU) session. It should only do so if it has previously ensured that it is in a state where the PLU session can be terminated, that is, between-chain and between-bracket. Terminating the PLU session does not affect the state of the system services control point (SSCP) session.

Note that an application can issue a character coded or field formatted **LOGOFF** command on the SSCP session or send a Close(PLU) Request to get the local node to send **TERM-SELF** on the application's behalf. All of these will elicit an **UNBIND**, either immediately or after session clean-up in the host.

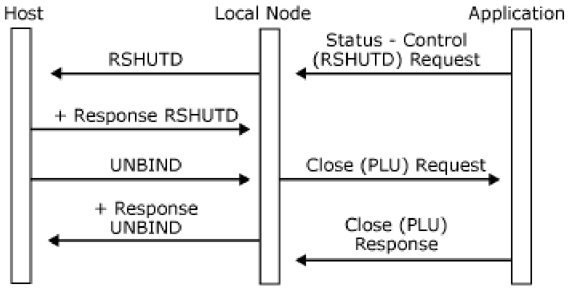
The application requests termination of the PLU session by sending a **Status-Control(RSHUTD) Request** to the local node, which generates an SNA **RSHUTD** request to the host.

After sending the **Status-Control(RSHUTD) Request**, the application must remain capable of accepting and responding to all outbound data it receives. The application can now expect one of two messages, depending on whether the state of the PLU session allows it to be terminated and whether the host wants to terminate the PLU session:

- If the state of the PLU session allows it to be terminated, and the host wants to terminate the PLU session, the host generates a positive response to the **RSHUTD** request, which can be followed by an **UNBIND** request. The local node closes the PLU connection. For more information, see Closing the PLU Connection.
- If the state of the PLU session does not allow it to be terminated (for example, if the session is in-bracket), or the host does not want to terminate the PLU session at this time, the host generates a negative response to the **RSHUTD** request, which the local node presents to the application as a **Status-Control(RSHUTD) Negative-Acknowledge-1** carrying the sense codes supplied on the negative response. This indicates that the request to terminate the PLU session has been rejected by the host, and communication on the PLU session continues unaffected.

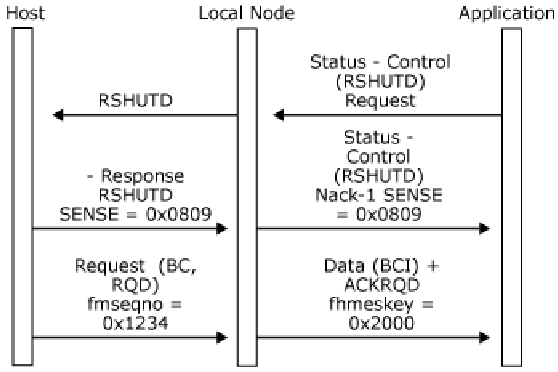
The following two figures illustrate the application-initiated termination protocol between the local node and the application and how this protocol relates to the underlying SNA protocols.

In the first figure, the application requests termination of the PLU session, and the host sends **UNBIND**. The local node closes the PLU connection.



Host
Local Node
Application
Status - Control (RSHUTD) Request
RSHUTD
+ Response RSHUTD
UNBIND
Close (PLU) Request
+ Response UNBIND
Close (PLU) Response

In the following figure, the application requests termination of the PLU session, but the session is not in an appropriate state. The host sends a negative response to the **RSHUTD** request, which the local node presents as **Status-Control(RSHUTD) Negative-Acknowledge-1**. Communication continues on the PLU session.



Host
Local Node
Application
Status - Control (RSHUTD) Request
RSHUTD
Status - Control (RSHUTD) Nack-1 SENSE = 0x0809
- Response RSHUTD SENSE = 0x0809
Request (BC, RQD) fmseqno = 0x1234
Data (BCI) + ACKRQD fhmeskey = 0x2000

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

LUSTATs

The data flow control (DFC) logical unit status **LUSTAT** message is used within SNA to convey four bytes of sense data to the other session partner. It can also be used simply to send a response header (RH) to the other session partner (for example, to open a bracket). (For more information, see the figures in Bracket Initiation.) The message flows on the normal flow and so is subject to direction restrictions. However, it can be sent without end bracket (EB) or change direction (CD) on a half-duplex flip-flop session that is in error recovery pending state. (For more information, see Recovery.)

The local node allows the application to send **Status-Control(LUSTAT) Request** messages at any time that data traffic is active, except while sending data in chain. If the application is in a receiving state (using half-duplex protocol), the **LUSTAT** is queued up and used to provide the sense codes, which are filled into the next outbound request, and the SDI flag is set. The application can therefore present the sense codes for an error state without waiting for the next outbound data if required.

The first byte of sense data must be 0x08 to generate a **DATAFMI** message with **SDI** (to be converted to a negative response). Other **LUSTATs** are left queued on the session until they can be sent.

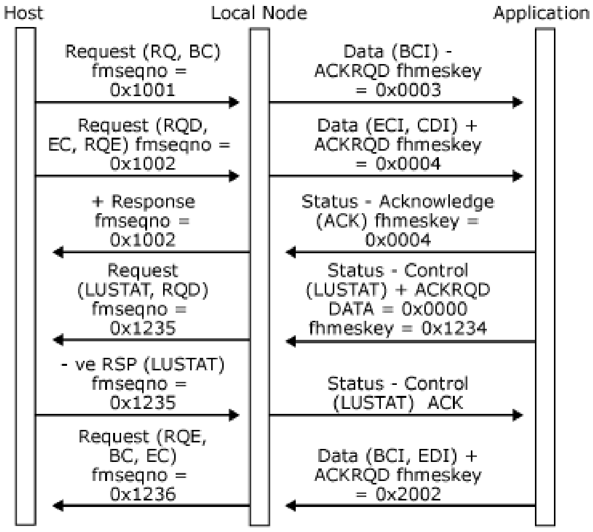
If multiple **Status-Control(LUSTAT)** messages are sent by the application while in a receive state, the local node queues them all. When outbound data has been delivered to the application with **SDI** set, as indicated earlier, and the application has converted it to a Status-Acknowledge(Ack), the local node sends the negative response and the remaining **LUSTATs** (which can now flow because the half-duplex flip-flop state is error recovery pending).

If the application intends to send multiple **Status-Control(LUSTAT)** messages to the host, it is possible that the host will attempt to initiate recovery before the last **LUSTAT** has been sent. In this case, the error recovery chain will be rejected by the next **LUSTAT**.

Note that the application can send **Status-Control(LUSTAT) Request** with or without **ACKRQD**. The local node will map these to **RQD** and **RQE LUSTATs** respectively.

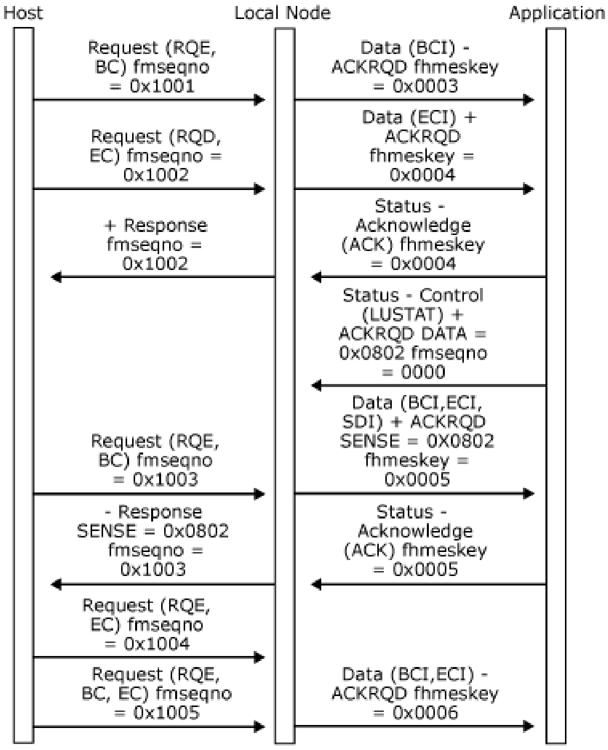
The following three figures illustrate the use of **Status-Control(LUSTAT)** messages by an application using the half-duplex flip-flop mode.

In the first figure, the application issues **Status-Control(LUSTAT)** when it has direction.



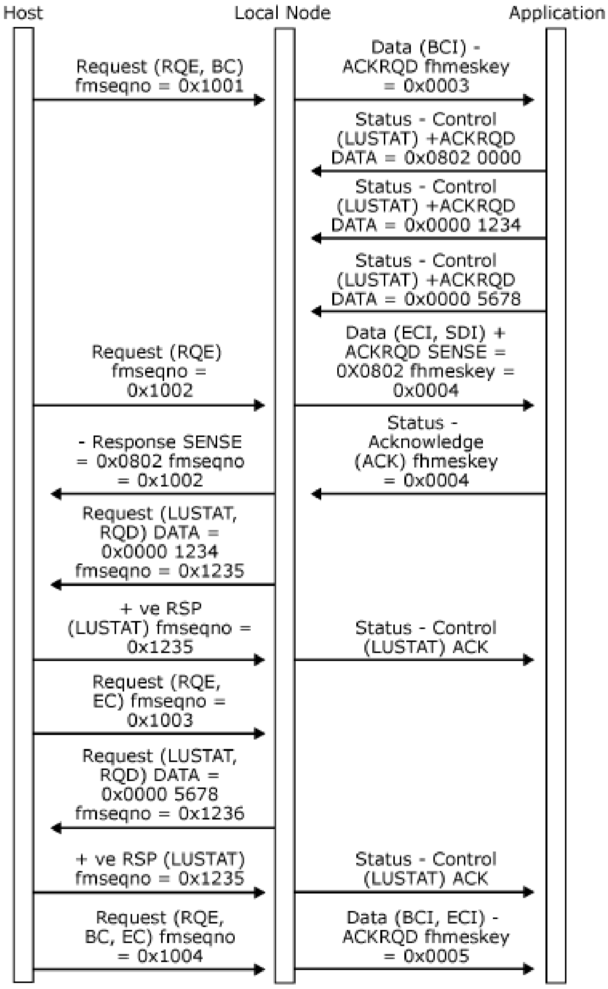
Host
Local Node
Application
Request (RQ, BC) fmseqno = 0x1001
Data (BCI) - ACKRQD fhmeskey = 0x0003
Request (RQD, EC, RQE) fmseqno = 0x1002
Data (ECI, CDI) + ACKRQD fhmeskey = 0x0004
+ Response fmseqno = 0x1002
Status - Acknowledge (ACK) fhmeskey = 0x0004
Request (LUSTAT, RQD) fmseqno = 0x1235
Status - Control (LUSTAT) + ACKRQD DATA = 0x0000 fhmeskey = 0x1234
- ve RSP (LUSTAT) fmseqno = 0x1235
Status - Control (LUSTAT) ACK
Request (RQE, BC, EC) fmseqno = 0x1236
Data (BCI, EDI) + ACKRQD fhmeskey = 0x2002

In the following figure, the application sends **Status-Control(LUSTAT)** request when receiving data between chain. Next, outbound data is delivered with **SDI** set, which gets converted to negative **RSP**.



Host
Local Node
Application
Request (RQE, BC) fmseqno = 0x1001
Data (BCI) - ACKRQD fhmeskey = 0x0003
Request (RQD, EC) fmseqno = 0x1002
Data (ECI) + ACKRQD fhmeskey = 0x0004
+ Response fmseqno = 0x1002
Status - Acknowledge (ACK) fhmeskey = 0x0004
Status - Control (LUSTAT) + ACKRQD DATA = 0x0802 fmseqno = 0000
Data (BCI,ECI, SDI) + ACKRQD SENSE = 0X0802 fhmeskey = 0x0005
Request (RQE, BC) fmseqno = 0x1003
- Response SENSE = 0x0802 fmseqno = 0x1003
Status - Acknowledge (ACK) fhmeskey = 0x0005
Request (RQE, EC) fmseqno = 0x1004
Request (RQE, BC, EC) fmseqno = 0x1005
Data (BCI,ECI) - ACKRQD fhmeskey = 0x0006

In the following figure, the application sends several **Status-Control(LUSTAT)** requests when receiving data in chain. Next, outbound data is delivered with **SDI** set which gets converted to negative response. Subsequent **LUSTATs** are sent to host.



Host
Local Node
Application
Request (RQE, BC) fmseqno = 0x1001

Request (RQE, BC, EC) fmseqno = 0x1004
Data (BCI, ECI) - ACKRQD fhmeskey = 0x0005

Response Time Monitor Data

For a 3270 display application, the local node maintains statistics on host response times—the time it takes the host to respond after the 3270 user presses ENTER or an AID key to send data to the host. These statistics can then be sent to the host for analysis.

The Status-RTM message, sent by the local node to the application, informs the application of the Response Time Monitor (RTM) parameters specified by the host. (For more information, see RTM Parameters.) These parameters specify whether RTM data is to be collected, whether the application is permitted to display RTM statistics locally, the time boundaries by which response times are to be grouped, and the definition of response time. The time can be measured until the first character of the host response reaches the screen, until the keyboard is unlocked, or until the user can send further data (change direction (CD) or end bracket (EB) received by the application).

If the host specifies that response times are to be measured for this session, the application is responsible for measuring response times and for reporting them to the local node. This involves:

- Starting a timer when the user presses the ENTER key or an AID key to send data to the host.
- Stopping the timer when the host's response to the inbound data is received, as defined by the RTM definition specified on the **Status-RTM** message.
- Reporting the response time to the host on the Status-Acknowledge(Ack) message, which acknowledges the host's response. One of the fields on this message specifies the last response time measured by the application, or specifies that no response time is to be reported.
- Optionally displaying the most recent response time as a last transaction time indicator (LTTI) on the 3270 emulation status line.

If the application wants to provide a local display of RTM data, it is responsible for maintaining its own response time statistics. It should use the same definition and boundaries as those specified on the Status-RTM message to ensure that the local data matches the data sent to the host by the local node. Note that the **Status-RTM** message can indicate that a local display of response times is not permitted. In this case, the application should not display either the response times or the LTTI.

Data Flow

The following topics describe data flows between the application and the local node.

This section contains:

- Outbound Data
- Inbound Data
- Inbound Data from LUA Applications

Outbound Data

This section describes the outbound data flows from the local node to the application. The overall structure of the protocols described applies to the system services control point (SSCP) and primary logical unit (PLU) connections, but certain features (such as the use of delayed request mode) are only applicable to the PLU connection.

The local node presents data originating at the host to the application on different connections, depending on the SNA session on which the data flows, as follows:

- Function management data network services (FMD NS) (session services) data and function management data (FMD) originating at the host SSCP and directed to the Host Integration Server logical unit (LU) is sent to the application on the SSCP connection.
- FMD data originating at the host PLU and directed to an SNA server LU is sent to the application on the PLU connection.

For all connections, only FMD requests are presented to the application as Data messages (with message-type = DATAFMI). DFC and session control requests are used to generate **Status-Control** messages. (For more information, see Status-Control Message.)

The local node performs the data flow control state changes required by the response header (RH) indicators in the request, before sending a **Data** message to the application.

The SNA request transmission header (TH) and RH indicators are not available to the application on outbound **Data** messages. Instead, the local node provides application flags in the **Data** message header that reflect the settings of a subset of the RH indicators, but are interpreted by the local node to shield the application from the more obscure aspects of chaining and bracket usage. For a description of the available flags and the way in which the local node uses them on outbound data, see Application Flags.

For outbound data, the first byte is RU[0] for standard function management interface (FMI), and TH[0] for the logical unit application (LUA) variant of FMI.

All Data messages from the local node to an application contain a message key. The local node maintains a unique message key sequence for each outbound data flow to an application. When the local node sends a **Data** message to an application on a particular connection, it places the next message key in the outbound sequence into the message header, sets the application flags, and sends the message to the application. This means that the message key uniquely identifies a **Data** message on a particular connection between the local node and the application. Note that the local node also places message keys on outbound **Status-Control Request** messages.

The acknowledgment protocol enforced by Host Integration Server reflects the chain response protocol and request mode in use on the SNA session, as follows:

- Outbound **RQD** requests generate Data messages with **ACKRQD** set in the message header.
- Outbound **RQE** requests generate **Data** messages without **ACKRQD** set.
- Outbound **RQN** requests generate **Data** messages without **ACKRQD** set.
- If the session uses primary immediate request mode, a **Data** message with **ACKRQD** set must be acknowledged by the application before further **Data** messages will be received.
- If the session uses primary delayed request mode, a **Data** message with **ACKRQD** set need not be immediately acknowledged by the application. **Data** messages will continue to be received.

Note that Host Integration Server enforces the equivalent of immediate response mode for the outbound data acknowledgment protocol for all connections. The application must send acknowledgments in order.

If the local node sets the **ACKRQD** field in the message header of a Data message to the application, it indicates that an acknowledgment to this **Data** message is required. The application acknowledges an outbound **Data** message by sending a **Status-Acknowledge** message to the local node on the same connection, which contains the same message key and sequence number fields as the **Data** message.

On receipt of a Status-Acknowledge(Ack), the local node correlates the message key with outstanding outbound messages and generates an SNA positive response to the appropriate SNA request.

The application should use the Status-Acknowledge(Nack-1) message as a negative acknowledgment. On receipt of a **Status-Acknowledge(Nack-1)**, the local node correlates the message with outstanding outbound messages and generates an SNA negative response plus sense data to the appropriate SNA request. The application supplies the sense data that should accompany the negative response as part of the **Status-Acknowledge(Nack-1)** message and must include the same message key, application flags, and sequence number fields as the **Data** message to which this is a negative acknowledgment.

Status-Control messages caused by expedited-flow requests can be sent at any time and do not affect the sending of positive or negative acknowledgment to normal flow outbound **Data** messages. The fact that they can occur between an outbound **Data** message and the matching **Status-Acknowledge** message is purely coincidental. For details about which **Status-Control** messages correspond to SNA requests, see Status-Control Message.

If errors are detected in the format of a normal flow request from the host or the request is inappropriate for the state of the session, the local node generates an error Data message for the application with the following characteristics:

- The SDI and ECI application flags are set.
- The sense code associated with the error occupies the first four bytes of the **Data** message. (For more information, see Status-Control Message.)
- **ACKRQD** is set.

The application should return a Status-Acknowledge(Ack), and the local node generates a negative response carrying the sense code appropriate to the detected error. This mechanism does the following:

- Informs the application of the detected error.
- Allows the application to respond to any previously received data before the local node sends the negative response to this Data message.

On sessions where the application is receiving a series of RQE chains, the local node will be retaining correlation information for each chain (in case the application wants to send negative responses to any of the chains). If the local node runs out of correlation table entries, it will attempt to allocate more entries and (if this fails) will be forced to terminate sessions. To prevent this, the application should provide **Status-Acknowledge(Ack)** messages for RQE data that it does not want to reject in this case. A response after five consecutive RQE chains should be sufficient. Such messages are referred to as courtesy acknowledgements and do not give rise to a response to the host, but merely free internal correlation data.

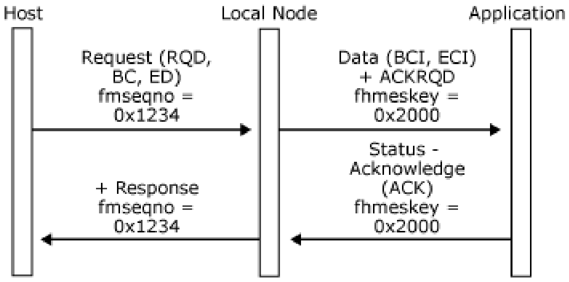
The following six figures illustrate the data acknowledgment protocol enforced between the local node and the application, and show the effects of the application generating positive and negative **Status-Acknowledg**e messages.

The figures show:

- The relevant RH flags in SNA requests/responses.
- The sequence number of SNA requests/responses.
- Any sense data (shown as "SENSE=...") on SNA requests/responses and **Status-Acknowledge** messages.
- The **ACKRQD** field in Data messages.
- The message key field in **Data** messages.

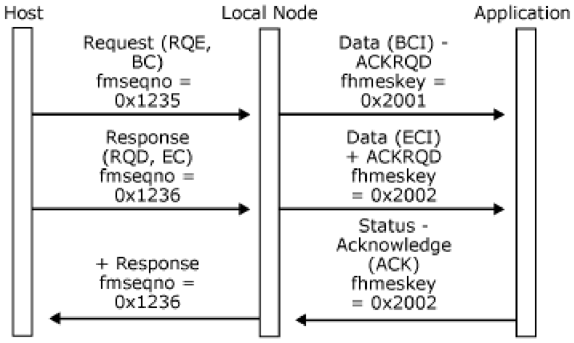
For simplicity, all messages are assumed to be FM data flowing on the same PLU session.

In the following figure, the application accepts a **Data** message corresponding to a definite-response RU.



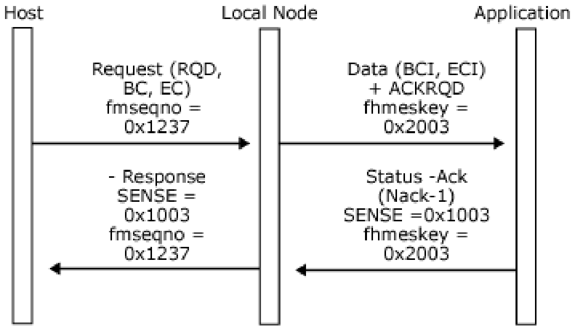
Host
Local Node
Application
Request (RQD, BC, ED) fmseqno = 0x1234
Data (BCI, ECI) + ACKRQD fhmeskey = 0x2000
Status - Acknowledge (ACK) fhmeskey = 0x2000
+ Response fmseqno = 0x1234

In the following figure, the application accepts a **Data** message corresponding to a multi-RU definite-response chain.



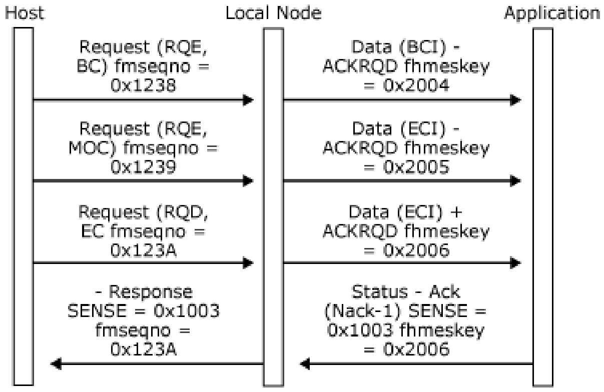
Host
Local Node
Application
Request (RQE, BC) fmseqno = 0x1235
Data (BCI) - ACKRQD fhmeskey = 0x2001
Response (RQD, EC) fmseqno = 0x1236
Data (ECI) + ACKRQD fhmeskey = 0x2002
Status - Acknowledge (ACK) fhmeskey = 0x2002
+ Response fmseqno = 0x1236

In the following figure, the application rejects a **Data** message corresponding to a definite-response chain.



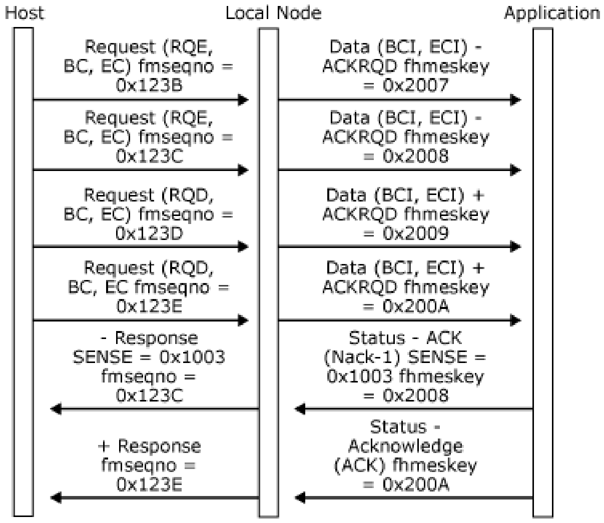
Host
Local Node
Application
Request (RQD, BC, EC) fmseqno = 0x1237
Data (BCI, ECI) + ACKRQD fhmeskey = 0x2003
- Response SENSE = 0x1003 fmseqno = 0x1237
Status -Ack (Nack-1) SENSE =0x1003 fhmeskey = 0x2003

In the following figure, the application rejects a **Data** message corresponding to a multi-RU definite-response chain.



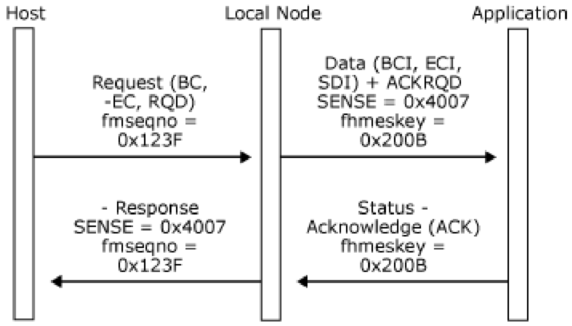
Host
Local Node
Application
Request (RQE, BC) fmseqno = 0x1238
Data (BCI) - ACKRQD fhmeskey = 0x2004
Request (RQE, MOC) fmseqno = 0x1239
Data (ECI) - ACKRQD fhmeskey = 0x2005
Request (RQD, EC fmseqno = 0x123A
Data (ECI) + ACKRQD fhmeskey = 0x2006
- Response SENSE = 0x1003 fmseqno = 0x123A
Status - Ack (Nack-1) SENSE = 0x1003 fhmeskey = 0x2006

In the following figure, the local node enforces immediate response mode. Responses must be sent in sequence. The application rejects the second exception-response chain and accepts the definite-response chain, which implies acceptance of the third exception-response chain.



Host
Local Node
Application
Request (RQE, BC, EC) fmseqno = 0x123B
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2007
Request (RQE, BC, EC) fmseqno = 0x123C
Data (BCI, ECI) - ACKRQD fhmeskey = 0x2008
Request (RQD, BC, EC) fmseqno = 0x123D
Data (BCI, ECI) + ACKRQD fhmeskey = 0x2009
Request (RQD, BC, EC fmseqno = 0x123E
Data (BCI, ECI) + ACKRQD fhmeskey = 0x200A
- Response SENSE = 0x1003 fmseqno = 0x123C
Status - ACK (Nack-1) SENSE = 0x1003 fhmeskey = 0x2008
+ Response fmseqno = 0x123E
Status - Acknowledge (ACK) fhmeskey = 0x200A

In the following figure, the local node detects a chaining error (RQD but not EC) in data destined for the application. (This example requires the receive check 0x4007 to be in force. For more information, see Opening the SSCP Connection.)



Host
Local Node
Application
Request (BC, -EC, RQD) fmseqno = 0x123F
Data (BCI, ECI, SDI) + ACKRQD SENSE = 0x4007 fhmeskey = 0x200B
- Response SENSE = 0x4007 fmseqno = 0x123F
Status - Acknowledge (ACK) fhmeskey = 0x200B

Inbound Data

This section describes inbound data flows from the application to the local node. The overall structure of the protocols described applies to the system services control point (SSCP) and primary logical unit (PLU) connections, but more complex aspects (such as the use of delayed request mode) are only applicable to the PLU connection.

The application can send inbound data on any of the connections, as follows:

- Function management data network services (FMD NS) (session services) and function management data (FMD) character-coded data intended for the host SSCP should be sent to the local node on the SSCP connection.
- FMD data intended for the host PLU should be sent to the local node on the PLU connection.

The application cannot use Data messages to send data flow control (DFC) or session control request messages to the host. Instead it must use **Status-Control** messages. (For details, see Status-Control Message.)

For all connections, the application must fill in certain key fields in the **Data** message's header. In particular it must:

- Set the message-type to **DATAFMI**.
- Allocate a new message key for inbound **Data** messages on this connection.
- Set the **ACKRQD** field if required.
- Set the application flags. (For more information, see Application Flags.)

The **nxtqptr**, **hdreptr** and **numelts** fields in the message header, and the **elteptr** and **startd** fields in the message elements are set up by the Host Integration Server buffer management routines. (For more information, see DL-BASE/DMOD Interface.) The application is responsible for setting the **endd** field.

If the application does not have access to these routines (for example, when the operating environment does not support intertask procedure calls and shared memory), all the fields in the header must be set by the application.

The transmission header (TH) and response header (RH) indicators are not available to the application on inbound Data messages. The application should set the appropriate application flags in the message header to control chaining, direction, and so on. For a description of the available application flags for inbound data and later topics in this section for a description of how the flags are used to control inbound data flows, see Application Flags.

For inbound data, the first byte is RU[0] for standard function management interface (FMI).

The message key supplied by the application in the inbound **Data** message header is used by the local node to indicate which **Data** message on this connection an outbound **Status-Acknowledge** refers to. The application should maintain a unique message key sequence for the inbound data flow on each connection it has with the local node, so that the application can use the message key to correlate inbound **Data** messages and outbound **Status-Acknowledge** messages on the connection. Note that the application must also provide a message key on **Status-Control Request** messages to differentiate between multiple **RQE LUSTAT** messages.

The inbound data acknowledgment protocol reflects the secondary chain response protocol and request mode in use on the session, as follows:

- Inbound Data messages with **ACKRQD** set in the header generate **RQD** requests.
- Inbound **Data** messages without **ACKRQD** set in the header generate **RQE** or **RQN** requests depending on the chain response protocol.
- The application should only set **ACKRQD** on **Data** messages that have the end chain indicator (ECI) application flag set.
- If the session specifies that the secondary uses immediate request mode, the application can still send further **Data** messages after sending data with **ACKRQD** set, even though it has not received a **Status-Acknowledge** message for that **Data** message. The messages are queued within the local node and are progressively sent as positive responses are received.
- If the session specifies that the secondary uses delayed request mode, after sending a **Data** message with **ACKRQD** set, the application can continue to send **Data** messages.

If the application sets the **ACKRQD** field in the message header of a Data message, it indicates that it requires an acknowledgment to this **Data** message. The local node acknowledges an inbound **Data** message by sending a **Status-Acknowledge** message to the application on the same connection and using the same message key as the **Data** message. (For an illustration, see the first figure at the end of this topic.)

The local node processes inbound **Data** messages from the application through its internal state computers, assigns the correct SNA sequence number or an identifier for this flow, and sends the data in a request to the host. The chain-response type of the request depends on whether **ACKRQD** was set in the **Data** message and the session parameters.

The local node maps a positive response from the host to a Status-Acknowledge(Ack) to the application. The application can use the message key in the **Status-Acknowledge** to correlate the acknowledgment with the original **Data** message. Therefore, receipt of a **Status-Acknowledge(Ack)** for a particular **Data** message implies that the local node has received a positive SNA response from the host to the inbound SNA request. (For an illustration, see the second figure at the end of this topic.)

Note that responses are absorbed on the SSCP-PU session.

Note that outbound Status-Acknowledge(Ack) messages contain application flags and a sequence number. The application flags reflect the RH indicators in the response. The sequence number is the SNA sequence number from the response, and provides a mechanism for applications using Transmission Service profile (TS profile) 4 to track the SNA secondary sequence number corresponding to a unit of work.

The local node maps a negative response from the host to a Status-Acknowledge(Nack-1) message to the application. The application can use the message key in the **Status-Acknowledge** to correlate the negative acknowledgment with the original **Data** message. The outbound **Status-Acknowledge(Nack-1)** message contains the SNA sense codes and sequence number from the negative response. (For an illustration, see the third and fourth figures at the end of this topic.)

If the local node detects an error in the format of an inbound **Data** message, or the **Data** message is not appropriate to the current state of the session, it sends a Status-Acknowledge(Nack-2) to the application containing an error code. (For a list of error codes, see Error and Sense Codes.) The local node does not send a request to the host corresponding to the **Data** message in error and does not advance the SNA sequence number for the session. The application can use any message key in its next inbound **Data** message (assuming the error does not cause a critical failure).

An example of a serious chaining error, where the application sends a **Data** message with **ACKRQD** but without ECI in the application flags, is shown in the last figure at the end of this topic. Note that after detecting this particular error, the local node marks the application's connection as critically failed, closes the connection, and sends a **TERM-SELF** request to the SSCP to elicit an **UNBIND**. (For more information, see Recovery.)

Inbound **Status-Control** messages, which cause the generation of expedited-flow requests, can be sent at any time and do not affect the sending of a positive or negative acknowledgment to inbound **Data** messages. For details about which **Status-Control** messages correspond to SNA expedited-flow requests, see Status-Control Message.

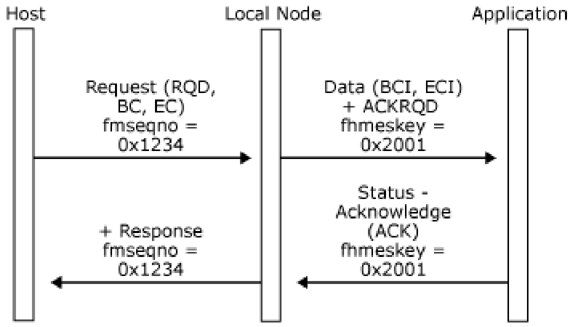
The following five figures illustrate examples of the inbound data acknowledgment protocols (and the underlying SNA protocols) for different chain-response types and secondary session request modes.

The figures show:

- The **ACKRQD** field on Data messages.
- The message key on **Data** messages.
- Any relevant application flags on **Data** messages.
- Error codes (shown as "ERROR=...") on **Data** messages.
- Relevant RH flags on SNA requests/responses.
- Sequence numbers on SNA requests/responses.
- Sense codes (shown as "SENSE=....") on SNA requests/responses.

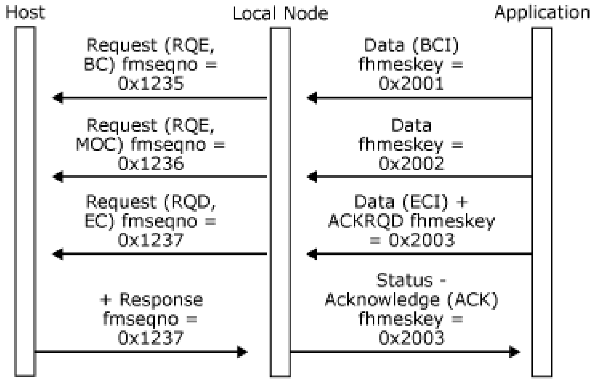
For simplicity, all messages are assumed to be flowing on the same PLU session.

In the following figure, the application successfully sends a **Data** message.



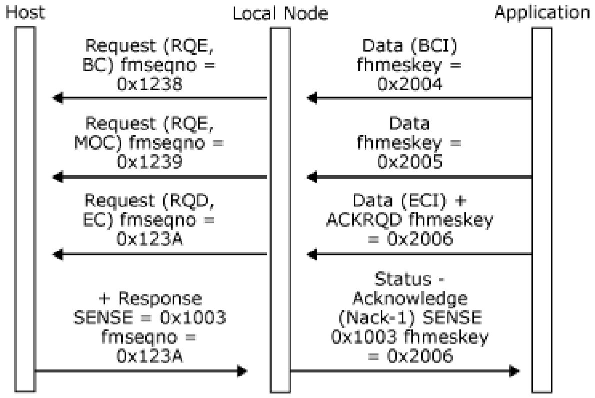
Host
Local Node
Application
Request (RQD, BC, EC) fmseqno = 0x1234
Data (BCI, ECI) + ACKRQD fhmeskey = 0x2001
Status - Acknowledge (ACK) fhmeskey = 0x2001
+ Response fmseqno = 0x1234

In the following figure, the application successfully sends a chain of **Data** messages.



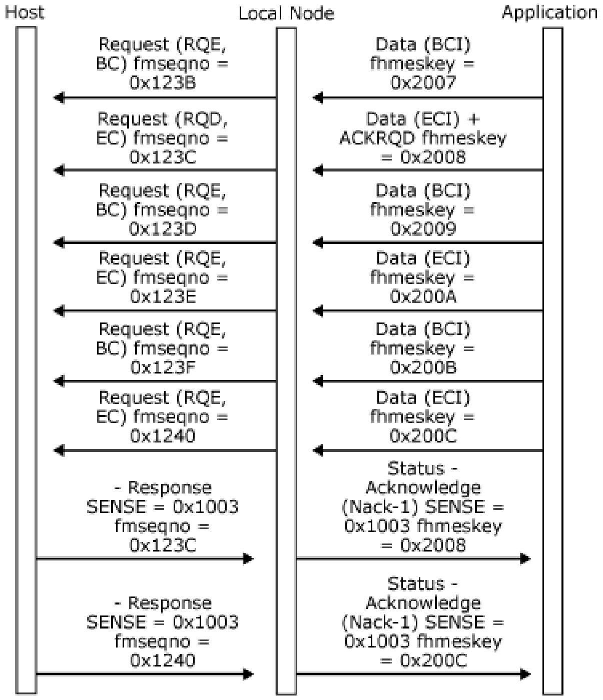
Host
Local Node
Application
Request (RQE, BC) fmseqno = 0x1235
Data (BCI) fhmeskey = 0x2001
Request (RQE, MOC) fmseqno = 0x1236
Data fhmeskey = 0x2002
Request (RQD, EC) fmseqno = 0x1237
Data (ECI) + ACKRQD fhmeskey = 0x2003
+ Response fmseqno = 0x1237
Status - Acknowledge (ACK) fhmeskey = 0x2003

In the following figure, the host rejects a chain of **Data** messages.



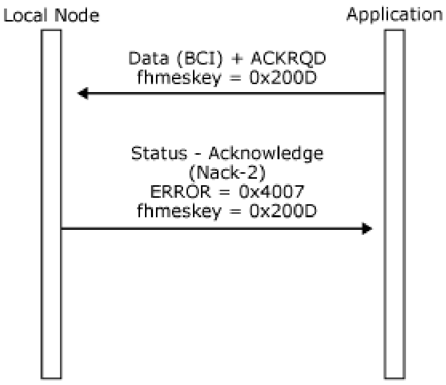
Host
Local Node
Application
Request (RQE, BC) fmseqno = 0x1238
Data (BCI) fhmeskey = 0x2004
Request (RQE, MOC) fmseqno = 0x1239
Data fhmeskey = 0x2005
Request (RQD, EC) fmseqno = 0x123A
Data (ECI) + ACKRQD fhmeskey = 0x2006
+ Response SENSE = 0x1003 fmseqno = 0x123A
Status - Acknowledge (Nack-1) SENSE 0x1003 fhmeskey = 0x2006

In the following figure, the host rejects the first definite-response chain and rejects the third exception-response chain on a delayed request session. Note that the negative response to the third chain implies a positive response to the second chain.



Host
Local Node
Application
Request (RQE, BC) fmseqno = 0x123B
Data (BCI) fhmeskey = 0x2007
Request (RQD, EC) fmseqno = 0x123C
Data (ECI) + ACKRQD fhmeskey = 0x2008
Request (RQE, BC) fmseqno = 0x123D
Data (BCI) fhmeskey = 0x2009
Request (RQE, EC) fmseqno = 0x123E
Data (ECI) fhmeskey = 0x200A
Request (RQE, BC) fmseqno = 0x123F
Data (BCI) fhmeskey = 0x200B
Request (RQE, EC) fmseqno = 0x1240
Data (ECI) fhmeskey = 0x200C
- Response SENSE = 0x1003 fmseqno = 0x123C
Status - Acknowledge (Nack-1) SENSE = 0x1003 fhmeskey = 0x2008
- Response SENSE = 0x1003 fmseqno = 0x1240
Status - Acknowledge (Nack-1) SENSE = 0x1003 fhmeskey = 0x200C

In the following figure, the local node detects the application's invalid use of **ACKRQD** without the ECI application flag on a **Data** message. Note that no data is sent to the host. However, because the error is critical, the local node will send a **TERM-SELF** message to the SSCP.



Local Node
Application
Data (BCI) + ACKRQD
fhmeskey = 0x200D
Status - Acknowledge
(Nack-2)
ERROR = 0x4007
fhmeskey = 0x200D

Inbound Data from LUA Applications

The local node performs certain checks on data supplied by a client application before sending it to the host and rejects it with a Status-Acknowledge(Nack-2) message if the checks fail. It does not return any acknowledgment to the application if the data passes the checks (although the host may do so later).

If the client application is providing a logical unit application (LUA) API, the design of the API may require that an LUA verb sending data inbound to the application does not complete until the local node has checked the data. Because of this, the local node will always respond to a client application that uses the LUA variant of the function management interface (FMI), after it has completed its send checking of the inbound message. This allows the client application to complete processing of the LUA verb and return control to the LUA application program.

If the inbound message passed the local node's send checks and will be sent to the host, the local node sends a Status-Acknowledge(ACKLUA) message to the client application to indicate this. The client application can then complete the LUA verb processing with an OK return code. Note that the **Status-Acknowledge(ACKLUA)** message does not imply that the data was successfully sent to the host or that the host received it. It may later be followed by a Status-Acknowledge(Nack-1) message indicating that the host rejected the data.

If the inbound message fails the local nodes send checking, a Status-Acknowledge(Nack-2) message will be returned as for non-LUA client applications. The client application can then report this to the LUA application program by a non-OK return code to the LUA verb that sent the message.

If the client application is providing an LUA API, it should therefore wait for either **Status-Acknowledge(ACKLUA)** or **Status-Acknowledge(Nack-2)** to determine whether to return an OK or error return code to the LUA send verb. If this dependence on the local node's send checks is not required, the client application can ignore the **Status-Acknowledge(ACKLUA)** message.

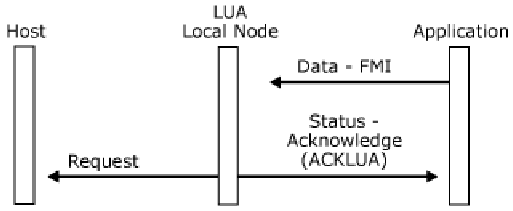
Note that there are certain race conditions in which the local node cannot complete its send checks before replying to the client application. In these cases, the local node returns a Status-Acknowledge(ACKLUA), but may subsequently send a Status-Acknowledge(Nack-2) if it detects an error during the remaining send checks. The client application may therefore receive a **Status-Acknowledge(ACKLUA)** followed by a **Status-Acknowledge(Nack-2)** for the same inbound message.

In the transmission header (TH) for the LUA variant of FMI, the expedited flow indicator (EFI), the destination-address field (DAF), and the origin-address field (OAF) are used. Other fields (including the sequence number field) are ignored. In the RH for the LUA variant of FMI, all fields except the queued-response indicator (QRI) and pacing indicator (PI) are used.

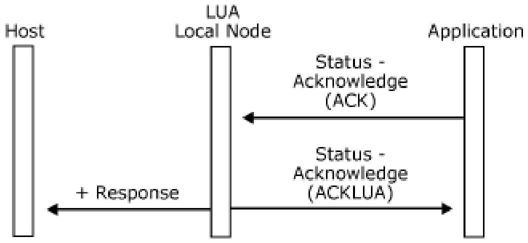
For inbound data, the first byte is TH[0] for the LUA variant of FMI.

The following three figures illustrate the **Status-Acknowledge(ACKLUA)** acknowledgment protocol for different messages that the application can send.

In the first figure, the application sends a **Data** message that passes the local node's send checks.



In the following figure, the application sends a **Status-Acknowledge(Ack)** message that passes the local node's send checks.



In the following figure, the application sends a **Status-Acknowledge(Nack-1)** message that passes the local node's send checks.

Status Messages

The local node uses status messages to provide the application with information about the state of its sessions and to give the application control, in association with the host system services control point (SSCP) and primary logical unit (PLU), over the progress of the session. The status messages are designed to allow the application to use all the protocols allowed in the function management (FM) and Transmission Service profiles (TS profiles) supported by the Microsoft® Host Integration Server local node.

Most applications only need to use a subset of the available status messages. For example, a 3270 device emulator would not require the status messages used in quiesce protocols.

This section contains:

- Status-Acknowledge Message
- Status-Control Message
- Status-Error Message
- Status-Resource Message
- Status-Session Message
- Status-RTM Message

Status-Acknowledge Message

Status-Acknowledge messages are the basic mechanism used to enforce inbound and outbound data acknowledgment protocols on all connections. For details about the use of **Status-Acknowledge** messages, see Outbound Data and Inbound Data.

For a 3270 emulation application, **Status-Acknowledge** messages sent from the application to the local node (acknowledging outbound data from the host) can also carry information about host response times. This allows the local node to maintain response time statistics for sending to the host when required. For details, see Response Time Monitor Data.

Status-Control Message

Status-Control messages provide access to session control and data flow control protocols on the primary logical unit (PLU) session using the PLU connection. They are not used on the other connections. **Status-Control** messages map directly to the equivalent SNA session control and data flow control request/response units (RUs).

All **Status-Control** messages that correspond to SNA requests on the normal flow with the exception of LUSTAT-sent Request Exception (RQE), and **Status-Control** messages corresponding to **CLEAR** and **STSN** request on the expedited flow, have the **ACKRQD** (acknowledgment required) field set. **Status-Control** messages that correspond to SNA requests on the expedited flow (with the exception of **CLEAR** and **STSN**) do not have the **ACKRQD** field set by the local node. However, the application can set **ACKRQD** when sending these **Status-Control** messages. The last figure in this topic summarizes which **Status-Control** requests always have **ACKRQD** set.

If a **Status-Control** request has **ACKRQD** set in the message header, the recipient must supply a **Status-Control** response (**Acknowledge, Negative-Acknowledge-1** or **Negative-Acknowledge-2**) before the sender sends further Data messages or further **Status-Control** requests on the flow. The sender can still send **Status-Control** responses, **Status-Acknowledge**, **Status-Error**, and **Status-Resource** messages on the flow. This applies to both normal and expedited flows and all request modes (including delayed-request mode). The message key received on the request must be returned on the response. (This is to allow multiple **RQE LUSTAT** messages to be outstanding.) The local node increments the message key on **Status-Control** requests and **DATAFMI** messages that it sends to the application on the PLU connection.

For the logical unit application (LUA) variant of the function management interface (FMI), the message key field is used in a different way, as follows:

- For inbound expedited flow requests, the local node sets the SNA sequence number to the value supplied by the application in the message key field. The application must ensure that this field is set to the correct sequence number.
- For inbound **Status-Control** responses, the local node sets the SNA sequence number to the value supplied by the application in the message key field. The application must ensure that this field is set to the sequence number of the request for which a response is being sent.

Except in the case of **Status-Control(LUSTAT)**, if a **Status-Control** request does not have **ACKRQD** set, the application should not reply, because a positive response has already been sent by the local node.

For example, if the application sends a **Status-Control(QC) Request** with **ACKRQD** set (corresponding to an SNA request on the normal flow), this blocks further data and **Status-Control** requests corresponding to the inbound normal flow until the **Status-Control(QC)** response is received. It does not block other messages on the normal flow, or messages on the expedited flow. For example, the application could still send **Status-Control(SIGNAL)**.

The receipt of the **Status-Control** response implies an acknowledgment to all outstanding messages (including **Data** messages) on the flow.

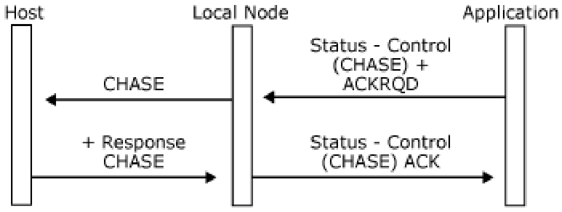
The use of **ACKRQD** on **Status-Control** messages effectively enforces definite-response and immediate request mode. This is appropriate for:

- **Status-Control** messages that correspond to the SNA requests **CLEAR** and **STSN** (because the expedited flow is **RQD**).
- **Status-Control** messages corresponding to all the **DFC** requests (which are **RQD**) except **LUSTAT** (which can be **RQE**).

The application can set **ACKRQD** on **Status-Control** requests that correspond to SNA requests on the expedited flow, even where **ACKRQD** is not required. For example, when an application is signaling for direction (for example, a 3270 emulator with a terminal operator repeatedly pressing the ATTN key), it can generate multiple **Status-Control(SIGNAL) Request** messages, which would adversely affect the performance of other users. The application can set **ACKRQD** on the first **Status-Control(SIGNAL) Request** and ignore events that would cause further **Status-Control(SIGNAL) Request** messages until the **Status-Control(SIGNAL) Response** is received from the local node.

The message flows in the following six figures show outbound and inbound **Status-Control** sequences with and without **ACKRQD** and the corresponding SNA RUs.

In the first figure, the application sends **Status-Control(CHASE)**.



Host
Local Node

The following table summarizes the **Status-Control** requests supported by the local node and SNA session control (SC) and data flow control (DFC) requests. For each **Status-Control** request, the table gives:

- The SNA category of the corresponding SNA request (SC or DFC).
- The flow used by the corresponding SNA request (normal or expedited).
- The TS or FM profiles on which the corresponding SNA request is supported.
- The directions for which it is valid (NODE <–> APPL).

- Whether it requires **ACKRQD**. Note that the application can set ACKRQD on a Status-Control request that does not require it.
- The hexadecimal code used in the control-type field of the Status-Control message. (For more information, see FMI Message Formats.)

Status-Control	SNA RQ flow	TS profile	FM profile	Direction node–appl	ACKRQD	Code
CLEAR	SC,Exp	2,3,4	–	–>	ACKRQD	CCLEAR (0x01)
SDT	SC,Exp	3,4	–	–>	–	CSDT (0x02)
RQR	SC,Exp	4	–	<–	–	CRQR (0x03)
STSN	SC,Exp	4	–	–>	ACKRQD	CSTSN (0x04)
CANCEL	DFC,Norm	–	3,4,7	<–>	ACKRQD	CCANCEL (0x10)
LUSTAT	DFC,Norm	–	3,4,7	<–>	–	CLUSTAT (0x11)
SIGNAL	DFC,Exp	–	3,4,7	<–>	–	CSIGNAL (0x12)
RSHUTD	DFC,Exp	–	3,4,7	<–	–	CRSHUTD (0x13)
BID	DFC,Norm	–	3,4	–>	ACKRQD	CBID (0x14)
CHASE	DFC,Norm	–	3,4	<–>	ACKRQD	CCHASE (0x15)
SHUTC	DFC,Exp	–	3,4	<–	–	CSHUTC (0x16)
SHUTD	DFC,Exp	–	3,4	–>	–	CSHUTD (0x17)
RTR	DFC,Norm	–	3,4	<–	ACKRQD	CRTR (0x18)
QC	DFC,Norm	–	4	<–>	ACKRQD	CQC (0x20)
QEC	DFC,Exp	–	4	<–>	–	CQEC (0x21)
RELQ	DFC,Exp	–	4	<–>	–	CRELQ (0x22)

The requests in the following table are used only with LUA. (For more information, see FMI Concepts.)

Status-Control	SNA RQ flow	TS profile	FM profile	Direction node–appl	ACKRQD	Code
CRV	SC,Exp	3,4	–	–>	ACKRQD	CCRV (0x05)
BIS	DFC,Norm	–	18	<–>	ACKRQD	CBIS (0x19)
SBI	DFC,Exp	–	18	<–>	ACKRQD	CSBI (0x1A)

The use of particular **Status-Control** messages is described in following topics of this section, in the context of PLU session protocols such as chaining, brackets, recovery, and so on.

For the formats of **Status-Control** messages, see Status-Control.

This section contains:

- Status-Control (ACKLUA) Message

Status-Control (ACKLUA) Message

When a logical unit application (LUA) application sends a **Status-Control** message inbound to the local node, the LUA verb used to send the message cannot complete until the local node acknowledges the message. Because of this, the local node will always respond to the LUA application after it has completed its send checking of the inbound message. If the inbound message passes the local node's send checks, and the corresponding SNA message will be sent to the host, the local node sends a Status-Control(...) ACKLUA message to the application to indicate this. Note that the **ACKLUA** message does not imply that the SNA message was successfully sent to the host, or that the host received it.

The format of the **Status-Control(...) ACKLUA** message is explained in Status-Control(...) ACKLUA. Note that the use of the message key field in **Status-Control(...) ACKLUA** is different from other **Status-Control** messages. It contains the sequence number from the transmission header (TH) of the **Status-Control** message sent by the LUA application, not the message key.

If the inbound message fails the local nodes send checking, a Status-Control(...) Negative-Acknowledge-2 message will be returned as for non-LUA applications. (This is then reported to the LUA application by a non-OK return code to the LUA verb that sent the message.)

The following three figures illustrate the **ACKLUA** acknowledgment protocol for different messages that the application can send.

In the first figure, the application sends a **Status-Control(...) Request** message that passes the send checks of the local node.

Status-Error Message

Status-Error messages flow from the local node to the application to report request reject and response header (RH) usage error conditions for:

- Errors in outbound expedited data flow control (DFC) requests.
- Errors in outbound session control (SC) requests.
- Errors in inbound responses.

The **Status-Error** message contains four bytes of error code information that contain the appropriate SNA sense codes for the detected error. For a list of error codes, see Error and Sense Codes.

Status-Resource Message

Status-Resource messages flow between an application and the local node to enable the local node to pace the primary logical unit (PLU) session of the application. They provide the local node with an indication of the buffer resources available at the application to receive outbound messages. With this information, the local node can determine when to send a pacing response. (For more information, see Pacing and Chunking.)

> **Note** Flow control is an option. Inbound pacing is handled by the local node, transparently to the application, and outbound pacing can be handled similarly. This is appropriate when only a limited number of messages flows from end-to-end of the SNA session between definite responses, such as with a 3270 screen.

Status-Session Message

Status-Session messages always flow from the local node to the application and provide information about changes in the state of the session. There are separate **Status-Session** flows for each connection between the application and the local node.

The local node uses only one **Status-Session** message on the primary logical unit (PLU) connection. This is the **Status-Session(BETB)** message, used to report when the PLU session returns to the between-bracket state after the application or the PLU initiated a bracket. (For more information, see Brackets.)

The local node reports the activation and deactivation states of the system services control point (SSCP) session and PU-SSCP session using **Status-Session** messages. For example, it reports the receipt of an **ACTLU** request from the host SSCP using a **Status-Session (LU-Active)** message on the SSCP connection. (For more information, see SSCP Connection.)

By providing **Status-Session** messages rather than requiring the application to interpret the relevant information in the SNA request, the local node shields the application from decisions affecting conditional state transitions and from the necessity for a detailed understanding of SNA protocols.

A **Status-Session** message contains a status code, and for some status codes, an additional status code that qualifies the meaning of the primary status code. For example, the Link-Error status code, which occurs on the SSCP connection, is qualified by a status code that reports the link outage code supplied by the data link control layer of the local node. Applications such as 3270 device emulators use the qualifying status codes to display communications check codes (−+z_nnn) on the status line of the display.

The **Status-Session** codes are summarized in Status-Session Codes.

Status-RTM Message

The Status-RTM message is used by the local node to inform the application of the Response Time Monitor (RTM) parameters being used by the host. It flows from the local node to the application on the system services control point (SSCP) connection and is sent only for 3270 display logical units (LUs), or LUs in a pool of display LUs.

The **Status-RTM** message is sent at the following times:

- After the OK response to the Open(SSCP) Request message, to inform the application of the initial RTM parameters.
- When the RTM counters are reset, either due to a request from the host or when the local node sends unsolicited RTM data to the host.
- When any of the RTM parameters are changed by the host.

For more information about the use of the **Status-RTM** message, see RTM Parameters. For more information about how the application supplies RTM data to the local node, see Response Time Monitor Data.

FMI Message Summary

This section lists each of the messages used at the function management interface (FMI) and gives a reference to a topic in the section where each message is described. The formats of the messages are given in FMI Message Formats.

For each message the direction of flow is indicated. IN means from the application to the local node, and OUT means from the local node to the application. The connection on which the message flows is also given.

Message	Direction	Connection	Reference
Open(SSCP) Request	IN	SSCP	Opening the SSCP Connection
Open(SSCP) Response	OUT	SSCP	Opening the SSCP Connection
Open(SSCP) Error Response	OUT	SSCP	Opening the SSCP Connection
Open(PLU) Request	OUT	PLU	Opening the PLU Connection

Status-Control(SBI) Ack	IN/OUT	PLU	Status-Control Message
Status-Control(SBI) Nack-1	IN/OUT	PLU	Status-Control Message

FMI Status, Error, and Sense Codes

This section lists the function management interface (FMI) status codes, error codes, and sense codes used on **Open** messages, **Status** messages, and **Data** messages with the system detected error indicator (SDI) set.

This section contains:

- Status-Session Codes
- Error and Sense Codes

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Status-Session Codes

For the status codes used on Status-Session messages, the following table lists:

- The value for the status code.
- The valid qualifying codes (if any) and their values.
- On which sessions the combinations of primary and qualifying status codes can occur.

For an overall description of the role of the **Status-Session** message, see Status-Session Message. The individual codes are discussed in SSCP Connection and PLU Connection.

Status code	Value	Qualifying code	Value	Usage
STNOSESS (no session)	0x01	STPUINAC STPUACT STPUREAC STLUINAC	0x10 0x03 0x04 0x11	SSCP SSCP SSCP SSCP
STLINERR (link error)	0x02	DLC ERROR	(See Note 1)	SSCP
STLUACT (LU active)	0x05	-	-	SSCP
STLUREAC (LU reactivated)	0x06	-	-	SSCP
STBETB (between brackets)	0x07	-	-	PLU

> **Note** The qualifying status code supplied on a **Status-Session** link error is the error code supplied by the data link control layer of the local node.
>
> **Status-Session** link error code 20 is generated by the node rather than by the link service. It indicates that the link service is not yet available, but is being activated. Ignore this error code during session activation. Otherwise, all **Status-Session** link errors (including 20) will cause the emulator to send a **Close(SSCP)**. When the emulator receives the Close(SSCP) Response, it will start again and send a new **Open(SSCP)**.
>
> **Note** The session status identifier is obsolete. It was used by the Microsoft® SNA Server OS/2 and Microsoft MS-DOS®-based 3270 emulators. Its value was obtained by adding 484 (decimal) to the qualifying status code shown in the preceding table.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Error and Sense Codes

This section describes the error and sense codes that are reported to the application in the following messages:

- Error Codes for Open(SSCP) Error Response
- Error Codes for Open(PLU) Error Confirm
- Error Codes for Nack-2 Messages
- Error Codes for Status-Error Messages
- Sense Codes for SDI Messages

Where the reported codes are SNA sense codes, a more complete description is given in Chapter 8 of the IBM document *Systems Network Architecture: Reference Summary* (GA27-3136). These SNA sense codes are also documented in Microsoft Host Integration Server 2004 Help.

In addition, the local node delivers negative responses from the host as **Status-Acknowledge(Nack-1)** and **Status-Control(...) Negative-Acknowledge-1**, which can have any SNA sense code.

Application designers should note that error codes listed here that are specific to Host Integration Server always have an initial byte value of 0x00, and therefore can be easily distinguished from SNA sense codes, which have nonzero initial bytes.

The error codes are listed in topics for each type of message with an indication of the reason for the error.

This section contains:

- Error Codes for Open Messages
- Error Codes for Nack-2 Messages
- Error Codes for Status-Error Messages
- Sense Codes for SDI Messages

Error Codes for Open Messages

The possible error codes for **Open(SSCP) Error Response** and **Open(PLU) Error Confirm** are shown in the following topics.

This section contains:

- Error Codes for Open(SSCP) Error Response
- Error Codes for Open(PLU) Error Confirm

Error Codes for Open(SSCP) Error Response

The following table gives the values for error code 1 and error code 2 that can be returned on the **Open(SSCP) Error Response**.

Error code 1	**Description**	**Error code 2**	**Description**
0	No servers found.	CSRENOSR (0)	No servers found.
0x0053	Logical unit (LU) not verified.	CSRECBSH (3)	LU not verified.
0x0055	System services control point (SSCP) connection already open.	CSRECBSH (3)	Control block / resource shortage.
0x0057	No LU in group free.		
0x0812	No free session control block available.		
0x1001	A connection activation failed recently.		
0x1002	The connection is inactive.		
0x1008	The link service is active remotely. This error return code is not supported by this level of Host Integration Server.		
0x1009	The SNA server is active, but the connection on which the requested LU is defined is not active.		
0x100B	The connection is in the process of activating as the result of another **Open(SSCP)** or operator activation or recovery from an outage.		
0x1010	The connection is active, but an activate physical unit (ACTPU) has not yet been received.		
0x1011	The connection is active, but an activate logical unit (ACTLU) has not yet been received.		
0x0063	Unrecognized Open request.	CSRESERV (1)	Service not present.
0x0A0E	LU/LU group not found in configuration.		

Note The error code 1 values 0x1001 to 0x1011 are returned when the Open(SSCP) Request specifies a nonforced Open. They do not indicate errors, but indicate that the LU-SSCP session is not active. The application can retry the **Open(SSCP) Request** specifying a forced Open, in which case the local node will attempt to activate the connection if possible.

Error Codes for Open(PLU) Error Confirm

The following table gives the values for error code 1 that can be returned on the Open(PLU) Error Confirm message. Error code 2 is zero, except when error code 1 is 0x0821. In this case it contains the byte offset in the **BIND** where the **BIND** failed to match the **BIND** check table.

Error code	Description
0x0051	Fewer than two buffer elements were present on **Open(PLU) Response**.
0x0052	System services control point (SSCP) connection is no longer active.
0x0821	**BIND** checking failed: error code 2 gives byte offset in **BIND** at which the error occurred.

Error Codes for Nack-2 Messages

The possible error codes delivered to the function management interface (FMI) application on Status-Acknowledge(Nack-2) and Status-Control(...) Negative-Acknowledge-2 messages are tabulated in the following table. A **Nack-2** is delivered to the application in response to data that is sent in error (or a Status-Control(...) Request that is in error). The data has not been sent to the host. The table indicates whether the error is critical, applying to the primary logical unit (PLU) connection only. If the error is critical, the critical failure indicator will be set in the message, and the application will receive a Close(PLU) Request as the next message.

All Nack-2 messages have the second word of information as 0x0000.

Error / Sense code	**Critical YES/NO**	**Description**
0x0040	YES	No buffer element on DATAFMI message.
0x0042	YES	DATAFMI message sent when no credit.
0x0043	YES	Invalid status-control for Transmission Service profile (TS profile).
0x0044	YES	Invalid status-control from application.
0x004A	YES	Half-duplex (HDX) contention and -QR,-BB,EB, or BKTFSM in pending-term-session.
0x0809	YES	Mode inconsistency.
0x1002	YES	Request/response unit (RU) length error.
0x1003	YES	Function not supported, invalid function management (FM) profile.
0x2002	NO	Chaining error.
0x2003	NO	Bracket error.
0x2004	NO	Direction error.
0x2005	YES	Data traffic reset.
0x2006	YES	Data traffic quiesced.
0x200D	YES	Response owed before sending request (half-duplex).
0x4003	YES	Begin bracket (BB) not allowed.
0x4004	YES	End bracket (EB) not allowed.
0x4006	YES	Exception response not allowed.
0x4007	YES	Definite response not allowed.
0x4009	YES	Change direction (CD) not allowed.
0x400A	YES	No-response not allowed.
0x400B	YES	Chaining not supported.
0x400C	YES	Brackets not supported.
0x400D	YES	CD not supported.
0x400F	YES	Incorrect use of FI.
0x4014	YES	Incorrect use of DR1, DR2, ER.
0x8005	NO	System services control point (SSCP) data sent when logical unit (LU) inactive.

Error Codes for Status-Error Messages

The possible error codes delivered to the function management interface (FMI) application on Status-Error messages are tabulated in the following table. A **Status-Error** message is delivered to the application in one of several cases, as shown in the following list:

- The local node detects an error in a response sent from the application (as a **Status-Acknowledge** or **Status-Control Ack/Nack-1** message).
- The local node detects an error in some data from the host that will not be delivered to the application as an system detected error indicator (SDI) message (such as an expedited flow request).
- The application sends an invalid **Status** message.

For inbound responses, the **Status-Error** codes have first byte 0x00. When the application is in error, the table indicates whether the error is critical, applying to the primary logical unit (PLU) connection only. If the error is critical, the application will receive a Close(PLU) Request as the next message.

The sense codes beginning with 0x40 will only be delivered if the corresponding receive check has been enabled in the connection information control block (CICB) on the Open(SSCP) Request from the application.

Where the sense code is marked with the * symbol, the second word of sense information carries the request code of the expedited flow request that was in error (for example 0x00C9 for SIGNAL).

Error / Sense code	Critical YES/NO	Description
0x0008	NO	Negative response already sent to this chain.
0x0040	YES	Invalid **Status** message from application.
0x0046	YES	Session failure due to correlation table shortage.
0x0050	YES	Invalid sequence number on Status-Ack.
0x0053	YES	Application may not send status control (**STSN**) negative acknowledge if it supports transaction numbers.
0x0056	YES	**Status-Ack** sent when previous RQD chains are outstanding. (For more information, see Outbound Data.)
0x0801	NO	Message received when pacing count is zero.
0x0805	NO	**BIND** from another PLU when already bound.
0x0809 *	NO	Mode inconsistency (**QEC** or **SHUTD**).
0x0815	NO	**BIND** from same PLU when already bound.
0x0821	NO	Incorrect **ACTLU** type (SSCP connection).
0x1003 *	NO	Wrong profile/network control request/invalid session control message.
0x2005	NO	Data traffic reset.
0x2007	NO	Data traffic not reset (**STSN** after **SDT**).
0x4009 *	NO	Change direction (CD) not allowed.
0x400B *	NO	Chaining not supported.
0x400C *	NO	Brackets not supported.
0x400F *	NO	Incorrect use of FI.
0x4011 *	NO	Incorrect use of request/response unit (RU) category.
0x4014 *	NO	Incorrect use of definite response 1 (DR1), definite response 2 (DR2), exception response (ER).

Sense Codes for SDI Messages

When the local node detects an error in a normal flow request from the host, the message is converted into a **DATAFMI** message with the system detected error indicator (SDI) set to inform the application and to allow data to be processed serially. The application must convert the message to a Status-Acknowledge(Ack) to allow the local node to send the required negative response to the host. The possible error codes delivered to the function management interface (FMI) application on such SDI messages are tabulated in the following table.

The sense codes beginning with 0x40 will only be delivered if the corresponding receive check has been enabled in the connection information control block (CICB) on the Open(SSCP) Request from the application. If a receive check has been disabled, the message can still be converted to an SDI message. For example, a message with begin bracket (BB), -begin chain (BC) would fail as 2002 or 2003 if 4003 were disabled.

When the application uses a **Status-Control(LUSTAT) Request** to reject outbound data, the sense codes supplied by the application will be present on the SDI message generated by the local node. For more information, see LUSTATs.

Sense code	**Description**
0x0809	Mode inconsistency.
0x080B	Bracket race error.
0x081B	Contention race condition.
0x1003	Incorrect FM profile for request.
0x2001	Sequence number error.
0x2002	Chaining error.
0x2003	Bracket error.
0x2004	Direction error.
0x2006	Data traffic quiesced.
0x4003	BB not allowed.
0x4004	End bracket (EB) not allowed.
0x4006	Exception response not allowed.
0x4007	Definite response not allowed.
0x4009	Change direction (CD) not allowed.
0x400B	Chaining not supported.
0x400C	Brackets not supported.
0x400D	CD not supported.
0x400F	Incorrect use of FI.
0x4011	Incorrect use of RU category.
0x4014	Incorrect use of definite response 1 (DR1), definite response 2 (DR2), exception response (ER).

Configuration Information

To obtain information about the Microsoft® Host Integration Server 3270 configuration, the application uses the calls listed in the following table.

Function	**Description**
sepdcrec	Returns a data structure that contains the 3270 user record for this user and the diagnostics record from the running configuration file.
sepdgetinfo	Returns general information about the version of Host Integration Server currently running, such as the release level, the network operating system, and the directory of the running configuration file.

If the return code from **sepdcrec** indicates that no 3270 user record was found for this user, the emulation program should terminate and not allow the user to use 3270 emulation. The Host Integration Server error message COM0438 is provided to log this error.

This section contains:

- 3270 User Record Format
- Diagnostics Record Format
- Creating NetView User Alerts

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

3270 User Record Format

The format of the 3270 user record is shown below. The first structure definition is a logical unit (LU)/session information record, which includes details of a 3270 LU; the second is the 3270 user record, which includes a number of LU/session information records.

Note that the user record is not a fixed length, because the number of LU/session information records in the remap list is variable. The structures used below are provided simply as a template to allow you to map to the correct offset in the record.

```
typedef struct tecwrksd {
    UCHAR   cwshost[9];
    USHORT  cwsestyp;
    USHORT  cwsmodov;
    USHORT  cwspad;
} TECWRKSD;
```

Members

cwshost[9]
LU/pool name accessed.
cwsestyp
Session type (M2, M3, M4, M5, printer).
cwsmodov
Whether the user has override permission.
cwspad
Two bytes of padding.

```
typedef struct tecwrkus {
    USHORT   cwlen;
    USHORT   cwtype;
    UCHAR    cwname[21];
    UCHAR    cwremark[26];
    UCHAR    cwstylef[9];
    USHORT   cwvewrtm;
    USHORT   cwalert;
    USHORT   cwchghan;
    USHORT   cwmaxses;
    USHORT   cwnumrec;
    TECWRKSD cwsesdat[10];
    USHORT   cwmodisf;
    UCHAR    cwstatus;
    UCHAR    cwpad;
    USHORT   cwnumrmp;
    TECWRKSD cwremap[1];
} TECWRKUS;
```

Members

cwlen
Length of record.
cwtype
Type of record.
cwname[21]
User name.
cwremark[26]
Comment field.
cwstylef[9]
Initial style file name.
cwvewrtm
Whether user can view Response Time Monitor (RTM) information.
cwalert
Whether user has ALERT permission.
cwchghan

Whether user can change LU/pool name accessed.

cwmaxses
Maximum number of active sessions (1–10).

cwnumrec
Number of sessions for user.

cwsesdat[10]
Session information records.

cwmodisf
Permission to modify initial style.

cwstatus
Status byte: user or group.

cwpad
One byte of padding.

cwnumrmp
Number of LUs/pools in remap list.

cwremap[1]
LU/pool remap list.

For Windows 2000

Microsoft® Host Integration Server permits configuration of more than 10 sessions per user when used with clients running Microsoft Windows® 2000. The first 10 sessions are placed in the **cwsesdat** array with **cwnumrec** set to 10 and the remainder are placed in the location of the remap list. The **cwnumrmp** member indicates the number of **TECWRKSD** structures in the remap list. Note that this permits **cwmaxses** to be greater than **cwnumrec**.

The following "Members" list explains the meaning of each field in the structures and indicates how the application should use each field. For more information about Host Integration Server 3270 configuration, see Configuration Information.

Members

cwshost
The name (up to eight characters) of the LU or LU pool that this session is configured to use. The application specifies this name on the Open(SSCP) Request.

cwsestyp
The LU type (display or printer) of the LU used by this session and (if it is a display LU or a pool of display LUs) the screen model. The possible values are:

- CERTMOD2 (0) Model 2 display (24 by 80)
- CERTMOD3 (1) Model 3 display (32 by 80)
- CERTMOD4 (2) Model 4 display (43 by 80)
- CERTMOD5 (3) Model 5 display (27 by 132)
- CERTPRNT (4) Host printer

The application should use this value to distinguish between display and printer sessions and to set the appropriate screen model for display sessions.

cwsmodov
TRUE if the user has permission to override the screen model for display sessions—that is, to change the session to use a different screen model from the one configured. If this value is **FALSE**, the user should not be permitted to change the screen model. This field is not used for printer sessions and should not be checked.

cwlen
The length of the 3270 user record (this is variable because it contains a variable number of LU/session records in the remap list). The application should use this value to locate the start of the next 3270 user record when searching for the correct record.

cwtype
Identifies this as a 3270 user record.

cwname
The Local Area Network (LAN) Manager user name, or other identifying name, of the 3270 user (up to 20 characters). The application uses this to search for the correct 3270 user record.

cwremark
An optional comment field (up to 25 characters), used in the configuration program to give more information about the user (for example, the user's full name).

cwstylef
The name (up to eight characters) of the default style file used by this user (a file containing the user's 3270 customization

settings, used by the Host Integration Server 3270 emulation programs). This field can be used to identify the equivalent file for your 3270 emulator, if appropriate.

If this field is blank, no style file is used and the 3270 emulator should revert to its default settings (unless overridden by a style file specified by the user).

cwvewrtm
TRUE if this user is permitted to view a display of RTM statistics for his or her 3270 sessions. If this field is **FALSE**, the application should not display RTM statistics and should not display a last transaction time indicator (LTTI) on the status line of display sessions. For more information about the use of Response Time Monitor (RTM), see Diagnostics Record Format.

cwalert
TRUE if the user is permitted to send NetView user alerts. If this field is **FALSE**, the user should not be permitted to send alerts. For more information about the use of alerts, see Diagnostics Record Format.

cwchghan
TRUE if the user is permitted to remap a 3270 session to use a different LU (in which case it can be changed to use any LU in the remap list—see **cwremap**). If this field is **FALSE**, the application should not allow the user to remap sessions.

cwmaxses
The maximum number of active sessions permitted to this user. If the number of sessions configured (see **cwnumrec**) is greater than this, the user must not be allowed to activate more sessions at a time than this field specifies.

cwnumrec
The total number of sessions configured for this user. The user record always contains 10 LU/session records (see **cwsesdat**), but only this number of the records will be used—the remainder will be filled with zeros.

cwsesdat
Ten LU/session records. Some of these records can be filled with zeros, indicating that they are unused (**cwnumrec** gives the number of sessions that are used). The application should list, and allow the user to use, only the sessions that have valid session records here.

cwmodisf
TRUE if the user is permitted to modify the initial 3270 customization. If this field is **FALSE**, the application should use the customization defined by **cwstylef** (if specified); the user should not be allowed to make changes to this style, or to override it by loading a different style file.

cwstatus
Indicates whether the user name in this record is a LAN Manager user name or group name. The least significant bit of this byte is **CERTGRUP (1)** for a group, and **zero** for a user. Other bits are not used.

cwpad
Pad byte—not used by the application.

cwnumrmp
The number of LU/session records in the remap list (see **cwremap**).

cwremap
The list of LU/session records, which indicates the LUs to which the user can remap sessions (if any). If the user is not permitted to remap sessions (see **cwchghan**), this list is not used and should not be checked by the application.

Diagnostics Record Format

The format of the Diagnostics record is shown below. The first structure definition is an Alert information record, which includes details of a 3270 NetView user alert; the second is the Diagnostics record, which includes a number of Alert information records.

```
typedef struct tedalert {
    UCHAR    dalrtnam[53];
    UCHAR    daparam1[33];
    UCHAR    daparam2[33];
    UCHAR    daparam3[33];
} TEDALERT;
```

The following "Members" list explains the meaning of each field in the structures that is relevant to the application and indicates how the application should use each field. Fields that are not included in the list are used by other Microsoft® Host Integration Server components and need not concern the application; in particular, the network management connection name and the times at which RTM data is sent to the host are handled by the local node on behalf of the application.

Note that the application should determine whether the user is permitted to send NetView user alerts and/or view RTM data (see 3270 User Record Format). It should not display the appropriate information, as described below, if the user does not have permission to use that information. The host can also override whether the application is permitted to send and/or to display RTM data (for more information, see RTM Parameters).

For more information about how the application uses the RTM parameters, see RTM Parameters, Response Time Monitor Data, and Status-RTM.

Members

dalrtnam[53]
The description (up to 52 characters) of the alert corresponding to a particular alert number. The application should display this information to help the user determine which alert to send.

daparam1[33]
The descriptions (each up to 32 characters) of up to three parameters.

daparam2[33]
Required for the alert; depending on the specific alert.

daparam3[33]
One or more of these descriptions can be blank, indicating that the parameter is not used. For each of these descriptions that is not blank, the application should display this string to prompt the user for the appropriate parameter.

```
typedef struct tediagns {
    USHORT   dilen;
    USHORT   ditype;
    UCHAR    dinetmgt[9];
    USHORT   disrtmco;
    USHORT   disrtmub;
    USHORT   diwruldr;
    USHORT   dirtmth1;
    USHORT   dirtmth2;
    USHORT   dirtmth3;
    USHORT   dirtmth4;
    TEDALERT dialerts[20];
    UCHAR    diaudit[128];
    UCHAR    dierror[128];
    USHORT   diaudlev;
    UCHAR    dipad[16];
} TEDIAGNS;
```

Members

dilen
Length of record.

ditype
Type of record.

dinetmgt[9]
Network management connection name.

disrtmco
Send Response Time Monitor (RTM) data at counter overflow.
disrtmub
Send RTM data at UNBIND.
diwruldr
The definition by which response times are to be measured. The application should measure the response time from the time the user presses ENTER or an AID key to send data to the host, until one of the following events as defined by this field:

CERTWRIT (0)

The first host data reaches the 3270 display.

CERTUNLK (1)

The host unlocks the user's keyboard.

CERTDIRE (2)

The host gives the application direction so that the user can send further data.

Note that the host can override these definitions; for more information, see RTM Parameters.

dirtmth1
The thresholds that define the bands into which response times are to be classified. Note that the host can override these definitions; for more information, see RTM Parameters.
dirtmth2
RTM threshold #2.
dirtmth3
RTM threshold #3.
dirtmth4
RTM threshold #4.
dialerts[20]
Up to 20 alert records that define the alerts that Host Integration Server users can send to a host. There are always 20 records, but some of these can be blank, indicating that they are not used. The application should display the descriptions of any nonblank alerts together with the alert number (from 1 to 20) defined by the position of the alert record in this array.
diaudit[128]
Audit log file name.
dierror[128]
Error log file name.
diaudlev
Default audit level.
dipad[16]
16 bytes of padding.

Creating NetView User Alerts

You can create NetView user alerts for users to send. Users identify the alerts by number. Each number corresponds to a specific collection of information or requests that the user wants to send through NetView to a host operator.

Microsoft® Host Integration Server leaves blank fields for the user alert information in the structure that is returned from sepdcrec. To create specific user alerts, create appropriate data structures and call the TRANSFER_MS_DATA common service verb to send the user alert to NetView.

Compiling and Linking 3270 Client Applications

This section describes the 3270 client samples included with Microsoft® Host Integration Server 2004. The samples are located in the \SDK\Samples\SNA folder on the Host Integration Server 2004 CD.

This section lists and explains the header files and libraries needed to develop 3270 client applications for use with Host Integration Server 2004 client applications. It also provides information about compiling and linking the 3270 client applications.

This section contains:

- Building the 3270 Client Samples
- Client Interface Files for 3270 Applications
- 3270 Include Files
- Compiler Options for 3270 Applications
- Linking 3270 Client Applications

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Building the 3270 Client Samples

When installed from the Microsoft® Host Integration Server CD, all the 3270 client samples are built in a similar way, as described in this section. First, set the environment variables listed in the following table.

Variable	Description
ISVLIBS	The directory containing the Host Integration Server 2004 LIB files for Microsoft Windows® 2000.
ISVINCS	The directory containing the Host Integration Server 2004 header files.
SAMPLEROOT	The root directory where the sample code provided as part of the SDK has been installed on a local hard disk.

For example, after copying the contents of the SDK folder on the Host Integration Server 2004 CD to C:\SNASDK, use the following lines to set the variables:

```
ISVLIBS=C:\SNASDK\Lib
ISVINCS=C:\ SNASDK\Include
SAMPLEROOT=C:\SNASDK\Samples\SNA
```

Next, run NMAKE on the .mak file in each subdirectory below this root directory containing the actual sample source code. For example, for APING and APINGD, change to the Samples\aping directory and type the following:

nmake -f makeping.mak

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Client Interface Files for 3270 Applications

The files listed in the following table are required to build 3270 client applications for use with Microsoft® Host Integration Server.

File	Description
FMI.H	Main header file containing the definitions of buffer and message formats, function prototypes for the DL-BASE/DMOD interface calls, and constant definitions.
TRACE.H	Definitions of the logging and tracing macros.
FMISTR32.LIB	Function Management Interface (FMI) string library for use with Microsoft Windows® 2000.
SNACLI.LIB	Main interface library for developing 3270 client applications on Windows 2000.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

3270 Include Files

To compile the application, the header files FMI.H and TRACE.H are required. In addition, one of the standard operating system header files may be required. To include the required files, use the following lines in your application:

```
#include <fmi.h>
#include <trace.h>
```

Compiler Options for 3270 Applications

When compiling the 3270 client application, the compiler options listed in the following table are required.

Option	Explanation
/c	Compile only, without linking. Linking is normally done as a separate phase to include the required Microsoft® Host Integration Server libraries.
/D NOTRC	The NOTRC macro specifies that internal tracing should not be compiled into the application. The **/D NOTRC** option should be used for building a final system (internal tracing should not be included because it will degrade performance and require more memory and resources). For a development system, you may want to compile with internal tracing; if so, remove the **/D NOTRC** option.
/D WIN32_SUPPORT /D MSWIN_SUPPORT, /D OS2_SUPPORT, /D DOS_SUPPORT	These macros are used in the header files FMI.H and TRACE.H supplied with SNA services to support variants of the client interface for the different operating systems supported. One of these options must be defined, depending on the operating system for which the application is intended.

/Gzs	c:	Use **stdcall** calling conventions on i386/i486 and Pentium class processors.
	S:	Remove stack check calls.

The compiler flags listed in the following table are required, but any of the valid options for each flag may be used, as appropriate to your application.

Flag	Description
/A	Compiler model (Does not apply to Microsoft Windows® 2000)
/O	Optimization
/W	Warning level

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

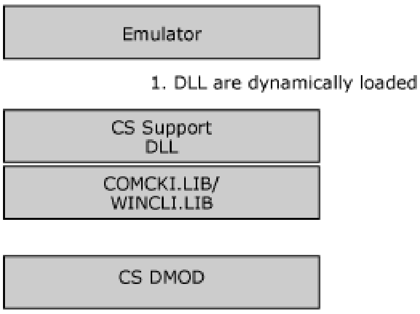
Linking 3270 Client Applications

This topic describes how to link 3270 client applications using different platforms.

The SNACLI.LIB library must be linked with the application.

The DMOD is implemented as a DLL. SNACLI.LIB contains import definitions for the APIs in the DLL, and some global variables required for the logging and tracing macros.

It is possible to create a DLL that is dynamically loaded when the user starts a session for an LU. In this case, to make the log and trace macros available, the application structure needs to be as shown in the following figure.



Emulator
1. DLL are dynamically loaded
CS Support DLL
COMCKI.LIB/ WINCLI.LIB
CS DMOD

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Support for 3270 Single Sign-On

This section describes the support for Single Sign-On for 3270 display sessions that is available in Microsoft® Host Integration Server 2004.

Over 3270 LUs, a Single Sign-On feature is supported to automate the overall logon process. When configured for this feature, Host Integration Server automatically replaces special keywords in the data stream with the actual host user name and password at appropriate points in the session.

This section contains:

- Prerequisites for 3270 Single Sign-On
- Registry Settings Used for 3270 Single Sign-On
- 3270 User Name and Password Replacement

Prerequisites for 3270 Single Sign-On

In preparation for using 3270 Single Sign-On, the system administrator must define a host security domain containing host connections. This host security domain must be initially created or modified to enable the Single Sign-On feature. The system administrator must enable a user's Microsoft® Windows Server™ 2003 or Microsoft Windows® 2000 account in the host security domain and either the administrator or the user must establish a mapped host account for the Microsoft® Windows Server™ 2003 or Windows 2000 domain user name.

The user must be logged on to a Microsoft® Windows Server™ 2003 or Windows 2000 domain with a user name and password. Note that this Single Sign-On feature is only supported over 3270 LUs.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Registry Settings Used for 3270 Single Sign-On

The 3270 Single Sign-On feature depends on Microsoft® Host Integration Server scanning 3270 logical units (LUs) used in the logon process for special keywords that are defined in the registry on the computer running Host Integration Server. The values for these special keywords can be defined by the system administrator on the computer running Host Integration Server.

The registry settings used by the 3270 Single Sign-On process are located under the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services** registry node. The following entries are installed under the **SNASERVR\PARAMETERS** subkey:

3270SSOPadByte

This entry should be set to an ASCIIZ string to use as the character for padding replacement text in the user name or password if these strings are shorter than the length of the special tag strings defined below. The default value for this pad character is the ASCII space character.

3270SSOPostReplaceCount

This entry should be set to a DWORD that represents the number of message chains of RUs to scan after replacement of text for user name or password. The default value for this number is 10.

3270SSOPrefix

This entry should be set to an ASCIIZ string to use as the special prefix tag string in combination with the user name and password tags. The default value of this string is MS$.

3270SSOPwdTag

This entry should be set to an ASCIIZ string to use as the special tag string in combination with the **3270SSOPrefix** tag in defining the special host password string that will be replaced. The default value of this string is SAMEP, so the default host password string that is scanned for and replaced is MS$SAMEP. Note that length of the password string that is scanned for (MS$SAMEP, for example) determines the maximum length of the password string that can sent to the host using Single Sign-On. This limit occurs because the password substitution cannot change the length of the data message.

Note that the value of this string must be different from the value of the **3270SSOUserTag** entry for Single Sign-On to function properly.

3270SSOReplaceCount

A DWORD value that affects the time-out value for password substitution. User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the timer expires. By default the timer will be set to 30 seconds, but this behavior can reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node.

If the **3270SSOReplaceCount** registry entry is defined and the **3270SSOReplaceTimer** registry entry is not defined, the node counts this number of RUs (on PLU-SLU session only) before time-out occurs. If both the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries are defined, the value for **3270SSOReplaceCount** will be used to determine when a time-out will occur. By default, this key is not defined and the node defaults to a time-out of 30 seconds.

3270SSOReplaceTimer

A DWORD value that affects the time-out value for password substitution. User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the timer expires. By default the timer will be set to 30 seconds, but this behavior can reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node.

If the **3270SSOReplaceTimer** registry entry is defined and **3270SSOReplaceCount** is not defined, the node uses this value in seconds before time-out occurs. If both the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries are defined, the value for **3270SSOReplaceCount** will be used to determine when a time-out will occur. By default, this key is not defined and the node defaults to a time-out of 30 seconds.

3270SSOUserTag

This entry should be set to an ASCIIZ string to use as the special tag string in combination with the **3270SSOPrefix** tag in defining the special user name string that will be replaced. The default value of this string is SAMEU, so the default user name string that is scanned for and replaced is MS$SAMEU.

Note that length of the user name string that is scanned for (MS$SAMEU, for example) determines the maximum length of the username string that can sent to the host using Single Sign-On. This limit occurs because the user name substitution cannot change the length of the data message.

Note that the value of this string must be different from the value of the **3270SSOPwdTag** entry for Single Sign-On to function properly.

3270 User Name and Password Replacement

The SNA node on the host monitors the inbound session for a replacement sequence consisting of the **3270SSOPrefix** string immediately followed by one of the strings **3270SSOUserTag** or **3270SSOPwdTag**. Thus, the default user name string that would be scanned for and replaced is MS$SAMEU. When this string is found in the inbound session data, the node looks up the corresponding information (host user name in the current host security domain) and overwrites MS$SAMEU with this information. The same process occurs for the password string that would be scanned for and replaced, which defaults to MS$SAMEP.

Note that this operation cannot change the length of the data message. If the actual user name or password that is retrieved from the current host security domain is shorter than the replacement sequence, it is padded out with the first character of the **3270SSOPadByte** string used as a padding character. If the actual host user name or password string is longer than the string that is scanned for, these strings are truncated to the length of the scanned string so that the data message length is not affected.

Note that since the user name and password can be sent in any order, the registry string values for the **3270SSOUserTag** and **3270SSOPwdTag** entries must be different for Single Sign-On to function properly.

The SNA node monitors the SSCP-LU session for these special tag strings at all times and replaces all occurrences of these strings with corresponding looked-up data. On the LU-LU session, the node starts monitoring at start of session (BIND). The node stops monitoring when it has received **3270SSOPostReplaceCount** chains of request/response units (RUs) without seeing a substitution tag. The node will not restart monitoring until it receives an UNBIND–BIND sequence for that session.

Note that the node considers the sequence:

```
BIND, data, UNBIND(BIND FORTHCOMING), BIND …
```

As a continuation of the same LU-LU session and does not restart monitoring on receipt of the second BIND. This sequence is often used by host session managers handing off a session to an application subsystem, and is considered a single terminal session.

User IDs and passwords will be substituted in each chain on the system services control LU-SSCP and PLU-SLU sessions until the node has received **3270SSOPostReplaceCount** chains of RUs without seeing a substitution tag or a timer expires. By default the timer is set to 30 seconds, but this behavior can reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node. After the timer expires, the node will stop scanning messages for the 3270 replacements strings for the user ID and password. If the replacement strings arrive after the timer expires, the replacement strings will be sent to the host unmodified causing the Single Sign-On to fail. The application will not receive any notification that the timer has expired. The only indication of a problem will likely be that the Single Sign-On to the host session has failed.

Note that all strings are specified in the registry in ASCII, but the node translates them to Extended Binary Coded Decimal Interchange Code (EBCDIC) through AE character mapping before scanning for a match.

SNA Internationalization Programmer's Guide

This section describes the features available in Microsoft® Host Integration Server 2004 for supporting international languages and different national language character sets.

The SNANLS API uses the language support features provided with Microsoft Windows® 2000 and Microsoft Windows XP. SNANLS supports European languages that use single-byte encoding, as well as East Asian languages that use double-byte or Unicode encoding.

For API references and other technical information about SNA Internationalization, see
SNA Internationalization Programmer's Reference.

This section contains:

- SNA National Language Support Programmer's Guide

SNA National Language Support Programmer's Guide

The SNA National Language Support (SNANLS) API standardizes the way in which national languages and locales are supported. SNANLS handles string conversion necessary for supporting a wide range of host and code pages. Components such as the Host Print service and Shared Folders service use SNANLS API to convert strings from EBCDIC to ANSI and from ANSI to EBCDIC.

The SNANLS API is the standard means to convert strings in Microsoft® Host Integration Server 2004. SNANLS presents a single interface to applications that need strings converted from one code page to another. These conversions may be EBCDIC-to-ANSI, ANSI-to-EBCDIC, EBCDIC-to-OEM code pages, OEM-to-EBCDIC, EBCDIC-to-ISO code pages, and ISO-to-EBCDIC. Additionally, SNANLS supports the broadest possible range of host and PC code page conversions.

SNANLS provides a uniform interface for programmers, hiding the details and difficulties of string conversion. SNANLS supports both SBCS and DBCS conversions. Two other lower-level APIs handle the actual string conversion. For SBCS conversions, SNANLS uses the system-provided Win32® NLS API that is resident on Microsoft Server™ 2003, Windows® XP, and Windows 2000.

For DBCS conversions, SNANLS uses the **TrnsDT** API. The **TrnsDT** API is installed with Host Integration Server 2004.

SNANLS is supported on Windows Server™ 2003, Windows XP, and Microsoft Windows 2000.

This section contains:

- National Language Support in Windows Server 2003, Windows XP, and Windows 2000

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

National Language Support in Windows Server 2003, Windows XP, and Windows 2000

National Language Support (NLS) provides a standardized method of supporting multiple international locales, code pages, input methods, sort orders, and number/currency/time/date formats.

The Win32® NLS API provides developers with a way to access system-provided Unicode-to-ANSI and ANSI-to-Unicode conversion services. Microsoft® Windows Server™ 2003, Windows® XP, and Windows 2000 supply EBCDIC-to-Unicode and Unicode-to-EBCDIC translation tables for all of the popular host code pages.

The SNANLS API leverages the existing work done to support the NLS API on Server™ 2003, Windows® XP, and Windows 2000. Microsoft Host Integration Server 2004 takes advantage of these EBCDIC-to-Unicode-to-ANSI and ANSI-to-Unicode-to-EBCDIC code page conversion services.

Currently, the Win32 NLS API only supports SBCS EBCDIC code pages. However, future versions of the NLS API will support DBCS EBCDIC. SNANLS currently uses TrnsDT for DBCS conversions.

SNA Print Server Data Filter Programmer's Guide

The Host Print service of Microsoft® Host Integration Server 2004 provides server-based 3270 and 5250 printer emulation, enabling host applications to print to Local Area Network (LAN) printers supported by Microsoft Windows Server™ 2003 or Microsoft Windows® 2000 Server and Novell NetWare. This section introduces the SNA Print Server Data Filter API (sometimes referred to as the Print Exit API). This API can be used to extend the capabilities of the Host Print service in Host Integration Server 2004.

The user can provide a print data filter DLL that will be called by Host Print service when a print job is initiated, when data is sent to the printer, and when the print job is completed. This print data filter DLL can:

- Send data to the printer when a job starts (print a banner page, for example).
- Perform special processing on the data to be printed.
- Send data to the printer upon print job completion (print a trailer page, for example).

SNADIS Programmer's Guide

This section enables original equipment manufacturers (OEMs) and adapter vendors who are developing their own SNALink software to work with Microsoft® Host Integration Server 2004 SNA Services.

SNALink software must be written as a Microsoft® Windows® 2000 device driver. For information about writing Windows 2000 device drivers, see the Windows 2000 Device Driver Kit (DDK).

This section provides the following information:

- Internal concepts of Host Integration Server 2004 that are required to integrate new communications adapters into the server environment.
- Definitions of the interfaces used by Host Integration Server 2004 to communicate with SNALinks.
- Information about using the configuration and diagnostics features included in Host Integration Server 2004.
- Instructions for compiling and linking the SNALink support software.

The network operating systems currently supported by Host Integration Server 2004 include Microsoft LAN Manager (as implemented in Microsoft Windows 2000) and TCP/IP. Future versions of Host Integration Server may support other network operating systems. Because of this, it is recommended that you develop link support that is independent of the network operating system.

For API references and other technical materials for programming SNALink applications, see the SNADIS Drivers Programmer's Reference section of the SDK.

This section contains:

- SNALink Concepts in Host Integration Server
- The SNALink Interface
- SNALink Configuration Information
- The Data Link Control Interface
- Setup Information
- Compiling and Linking a SNALink
- Synchronous Dumb Card Interface
- SNA Modem Status Interface
- SNA Performance Monitor Interface

SNALink Concepts in Host Integration Server

This section describes key concepts used in the SNALink feature of Microsoft® Host Integration Server 2004. Because the purpose of this section is to enable original equipment manufacturers (OEMs) and adapter vendors to develop link support software to integrate their hardware adapters into a Host Integration Server 2004 system, only the relevant parts of the Host Integration Server 2004 architecture are described.

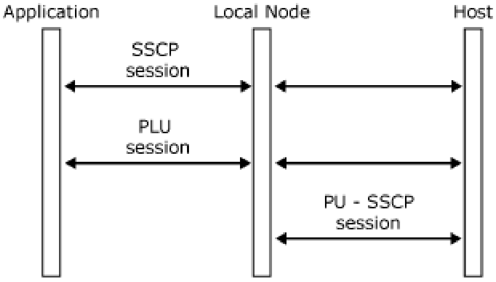
This section contains:

- Overview of SNALink
- SNALink Configuration and Management
- Structure of SNALink Components
- Messages
- LPI Connections

Overview of SNALink

A Microsoft® Host Integration Server 2004 SNALink must implement an SNA-compatible data transport mechanism capable of connecting the local type 2.1 node to remote host (PU4/5) or peer (PU2.1) systems.

The local node provides the SNA layers of path control, transmission control, data flow control, and logical unit (LU) services. The following figure shows an example of a Host Integration Server 2004 system.



The local node uses the data link control (DLC) interface to communicate with a SNALink. This interface is defined in The Data Link Control Interface. The SNALink and the DLC driver are responsible for transferring data between the path control layer of the node and the DLC adapter.

The routing of messages that flow between Host Integration Server 2004 components is handled by the SnaBase and Dynamic Access Module (DMOD) components. For details about how to send and receive messages, see The SNALink Interface.

SNALink Configuration and Management

The configuration information for a Microsoft® Host Integration Server 2004 system is stored in two forms:

- A centralized configuration file containing details of logical units (LUs), physical units (PUs), and connections.
- Entries in the Microsoft® Windows Server™ 2003 or Windows® 2000 registry containing configuration information for the SNALinks supported on that computer. This information contains parameters required by Host Integration Server 2004, and any other parameters that independent hardware vendor (IHV) code may require.

A Host Integration Server SNALink is defined when a Host Integration Server system is installed. A SNALink can support only one physical connection from the server. If a single adapter is capable of supporting multiple physical connections, Host Integration Server requires multiple SNALinks to be configured.

To reconfigure a server's SNALink support (for example, after installing a new adapter), the administrator uses either the Windows Network Control Panel applet or the Host Integration Server setup program. For further information about how this operates, see Setup Information.

All other configuration of a Host Integration Server system is performed using SNA Manager. As part of the configuration process, logical connections to remote PUs are associated with one or more SNALinks.

All configured SNALinks are automatically started when the Host Integration Server system is started. At this stage, the SNALink performs any initialization required, and then waits for instructions from local nodes.

When a connection is activated, either from SNA Manager or automatically (for example, in response to a 3270 user's request for a session with a remote host), the SNALink receives an Open(LINK) message from the local node. The SNALink should then perform whatever action is required to initiate that connection. This can involve dialing a telephone number for a switched Synchronous Data Link Control (SDLC) connection or bringing up level 2 on an X.25 link and sending a CALL packet.

If the IHV wants the same physical adapter to be available for use by multiple SNALinks (for example, a dumb SDLC card can be used to communicate using SDLC or X.25 protocols), the SNALink should not attempt to access the hardware until it has received an **Open(LINK)** message from the local node.

Structure of SNALink Components

The components of SNALink are:

- Local nodes
- SNALinks
- 3270 emulators

This section introduces the structure of these components and explains terms used to refer to the structure.

This section contains:

- Role of the Base
- Localities and DMODs
- Component Localities
- Partners
- SNALink Structure

Role of the Base

The Base is a part of each Microsoft® Host Integration Server 2004 component, such as the local 2.1 node or a link service that provides the operating environment for that component. It passes messages between components and provides functions common to all components, such as diagnostic tracing.

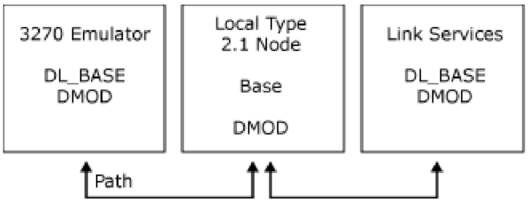
The Link Base is the type of Base used by Host Integration Server SNALink. The Base has entry points for initialization, sending messages, receiving messages, and termination.

Localities and DMODs

A Base and its components (that is, a Host Integration Server 2004 executable program) is called a **locality**. The Host Integration Server system therefore consists of one or more communicating localities (all the running Host Integration Server 2004 executable programs within the LAN Manager domain). For each Host Integration Server system, there is a central configuration file. In addition, each Host Integration Server computer maintains configuration information about the SNALinks it supports.

In a system such as Host Integration Server, where the number of localities and their types are not configured in advance, the relationships between the localities are set up dynamically as individual localities come and go. Localities that can enter and leave a system in this way are called **dynamic localities**.

Dynamic localities communicate using the Dynamic Access Module (DMOD) component, which provides the communications facilities needed to pass messages between the Bases. This is illustrated in the following figure.



This figure shows a system consisting of three dynamic localities. Dynamic localities can enter or leave this system at any time.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Component Localities

SNALinks can enter dynamically into a Host Integration Server 2004 system. The SNALink, in conjunction with the Base, acts as a whole locality and communicates with the other localities in the system using a Dynamic Access Module (DMOD).

The SNALink Interface topic describes the interface to the Base and the DMOD that allows a SNALink (or any other Host Integration Server 2004 component) to participate in a Host Integration Server 2004 system.

Partners

For Host Integration Server 2004 components and applications to communicate with each other, it must be possible to identify a partner within a locality. A partner is an addressable component of a locality; that is, code to which messages can be sent. In a Host Integration Server system, there is generally only one partner within a locality (such as an SNALink or the 3270 emulation program). However, separate functions within the local 2.1 node (such as the 3270 and Advanced Program-to-Program Communications (APPC) functions) can be considered to be separate partners.

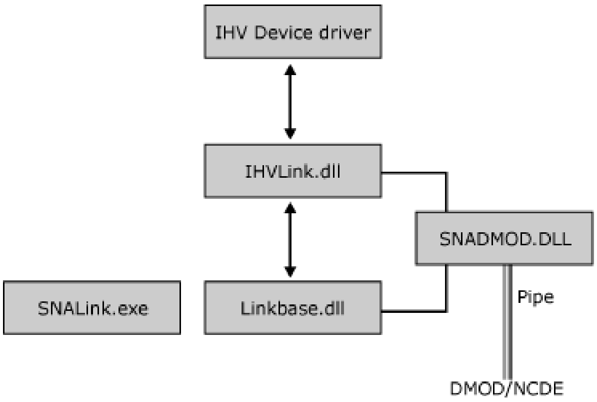
SNALink Structure

A Host Integration Server 2004 SNALink consists of the following:

- The link-specific protocol code provided by the independent hardware vendor (IHV)
- A Base
- A Dynamic Access Module (DMOD)

The DMOD, Base, and the IHV link-specific component of a Host Integration Server SNALink are implemented as dynamic-link libraries (DLLs). The executable component SNALINK.EXE is used to start a SNALink. SNALINK.EXE determines (from the Host Integration Server configuration) which link support DLL (for example, IHVLINK.DLL) is required and dynamically loads it before entering the Base scheduler.

The following figure shows the executable structure of a SNALink.



To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Messages

Messages are used to pass data between partners in the Microsoft® Host Integration Server 2004 system. This section provides information about message structure and formats.

This section contains:

- Overview of Message Formats
- Buffer Header Format
- Buffer Element Format

Overview of Message Formats

A message always contains fixed-format header information such as a message type and addressing information. It can also contain other header information specific to a particular message type (such as the message subtype) and an indefinite amount of extra data.

Messages are saved in buffers that consist of one header and zero or more elements:

- The header contains the fixed-format information and a pointer to an element. (This pointer will be NULL if there are no elements associated with the message.)
- An element contains any extra data for a message and a pointer to another element if the data continues into another element.

Buffer headers and elements are regarded as contiguous (8-bit) byte sequences. Messages of any length can be built up by chaining sufficient elements to a header.

The following figure shows a typical message with two elements.

Buffer Header Format

This topic lists the common fields that always occur at the start of a buffer header. These are followed by further fields specific to the particular message. For details of individual message formats, see SNADIS Message Formats.

Field	Type	Description
PTRBFHDR	nxtqptr	When the buffer is in a queue, this field points to the header of the next buffer in the queue (NULL if it is the last buffer in the queue). When the buffer is not in a queue, this field points to itself. The Host Integration Server 2004 buffer management routines use this to check for buffer corruption.
PTRBFELT	hdreptr	Pointer to the first buffer element in the associated chain of buffer elements; NULL if the message consists only of a buffer header.
CHAR	numelts	Number of buffer elements chained from the header. Zero if the message consists only of a buffer header.
CHAR	msgtype	Message type. For more information, see individual message descriptions in SNADIS Message Formats.
CHAR	srcl	Source locality. For more information, see LPI Addresses.
CHAR	srcp	Source partner. For more information, see LPI Addresses.
INTEGER	srci	Source index. For more information, see LPI Addresses.
CHAR	destl	Destination locality. For more information, see LPI Addresses.
CHAR	destp	Destination partner. For more information, see LPI Addresses.
INTEGER	desti	Destination index. For more information, see LPI Addresses.

> **Note** Fields that occupy two bytes, such as **opresid** in the Open(LINK) request, are normally represented with the arithmetically most significant byte in the lowest byte address, irrespective of the normal orientation used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. However, the following fields are exceptions:

- The **srci** and **desti** fields in buffer headers are stored in the local format of the application that assigns them (only the assigning application needs to interpret these values).
- The **startd** and **endd** fields in elements are always stored in low-byte, high-byte orientation (the normal orientation of an Intel processor).

Buffer Element Format

This topic lists the common fields that always occur at the start of a buffer element. The **dataru** field contains information specific to the particular message. For details about individual message formats, see SNADIS Message Formats.

Field	**Type**	**Description**
PTRBFELT	hdreptr–>elteptr	Pointer to next buffer element in the chain. NULL if this element is the last or only element in the chain.
INTEGER	hdreptr–>startd	Start of valid data in this element. The index into *dataru* of the first byte of valid data.
INTEGER	hdreptr–>endd	End of valid data in this element. The index into *dataru* of the last byte of valid data.
CHAR	hdreptr–>trpad	Pad byte (reserved).
CHAR[SNANBEDA]	hdreptr–>dataru	An array of characters that contains the data for this element. Note that the valid data might not occupy the whole of the element. The **startd** and **endd** fields give the indexes into this array of the start and end of the valid data. The constant SNANBEDA is defined in SNA_DLC.H as 268.

The following information will help you to interpret the message formats:

- Fields that occupy two bytes are represented with the arithmetically most significant byte in the lowest byte address, irrespective of the normal orientation used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. The exceptions to this are the **startd** and **endd** fields in elements, which are always stored in low-byte, high-byte orientation (the normal orientation of an Intel processor).
- The offsets indicated by the **startd** and **endd** fields are expressed in terms of the first byte of dataru being offset 1; the first byte of valid data is at **dataru(startd–1)**. For example, if **startd** is 11 and **endd** is 18, **dataru** begins with 10 bytes that are not valid data, followed by 8 bytes of valid data.

In the example message format illustrated in Overview of Message Formats, each element has a **startd** of 13, indicating 12 bytes of padding before the start of the valid data. This leaves room for 256 bytes of data, and hence the element data (300 bytes long in this example) requires two elements.

LPI Connections

Partners communicate by passing messages to each other. If two partners want to communicate with each other, a locality, partner, index (LPI) connection is set up between the two partners. Messages then flow between the partners over this connection. The term "LPI connection" is explained in LPI Addresses. Note that this is not related to the Microsoft® Host Integration Server 2004 concept of a connection between the local node and a remote system.

This section contains:

- Paths and DMODs
- LPI Addresses
- Making Connections

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

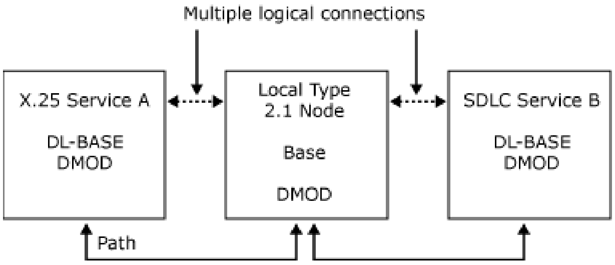
Paths and DMODs

Dynamic Access Modules (DMODs) are responsible for the communication between localities. When the DMODs in two localities can successfully pass messages between them, a path is said to exist between the two localities. A path must exist between two localities before a connection can exist between partners in those localities.

In Host Integration Server 2004, a path is implemented using reliable LAN connections (named pipes, SPX, TCP, VINES IP)—one LAN connection for each path. When the two localities are on the same computer, a local pipe is used. This is implemented using shared buffers to increase performance, but is used by the application in exactly the same way as communication with a remote locality.

The DMOD provides communication between dynamic localities and provides guaranteed in-order delivery of messages flowing over paths between localities. If the DMOD loses its path to another locality, it informs the Base.

The following figure illustrates the paths and connections between a Host Integration Server local node and two SNALinks. X.25 service A has two connections to the local node (one for each of two virtual circuits); SDLC service B has one connection to the local node.



LPI Addresses

A locality, partner, index (LPI) address is used to identify each end of a connection. It has three components: locality (L), partner (P), and index (I).

- **Locality** is a 1-byte identifier that uniquely identifies a locality within a system. This locality corresponds to a Host Integration Server 2004 component (local node, SNALink, 3270 emulator, and so on).
- **Partner** is a 1-byte identifier for the type of service. Each type of service has a unique value. A Host Integration Server local type 2.1 node has a defined value of 0x11. A Host Integration Server emulator has a defined product identifier of 0x12. A Host Integration Server link service (X.25. SDLC, Token Ring, Ethernet, or Channel, for example) has a defined value of 0x16.
- **Index** is a 2-byte identifier that uniquely identifies a logical entity within the product. The meaning and use of this field is defined by the communicating services. It is used to distinguish multiple connections between the same services (for example, to identify one of many virtual circuits available from an X.25 SNALink). The value of zero should not be used as an index. Applications must assign unique index values for every active LPI connection within the node.

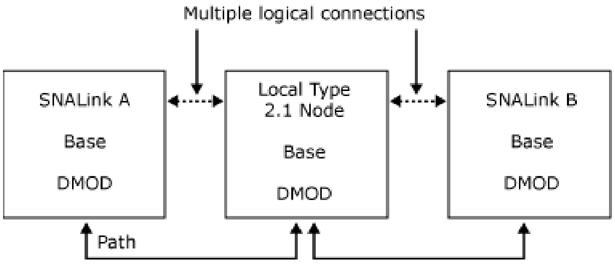
A message flowing over a connection carries a pair of LPIs, identifying the source and destination of the message. These are the source LPI and destination LPI of the message. Together they identify the connection on which the message is flowing.

Note that more than one connection can exist between any pair of services. The Index values are then used to distinguish the connections. For example, in communications between the local node and a SNALink, the L and P values identify the message as being data link control (DLC) data for that local node, and the I value indicates which connection the data is intended for.

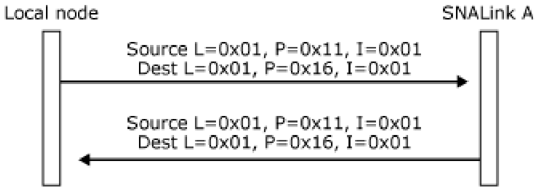
The LPIs are assigned by a combination of the products and the Dynamic Access Modules (DMODs) when the connection is opened, as described in Making Connections.

Because they are assigned dynamically for each component, the L values are not the same across a whole system. For example, a local 2.1 node locality could be known as locality 4 to one SNALink locality and locality 6 to a second SNALink locality. However, from the viewpoint of any locality, there exists a unique L value for each remote locality within which a path exists. This L value is used as an index into an internal table that identifies the path to that locality.

The following three figures show an example of the L values that could be used between the components shown in Paths and DMODs, and examples of the LPI values that would be used by the local node on messages flowing between the components.

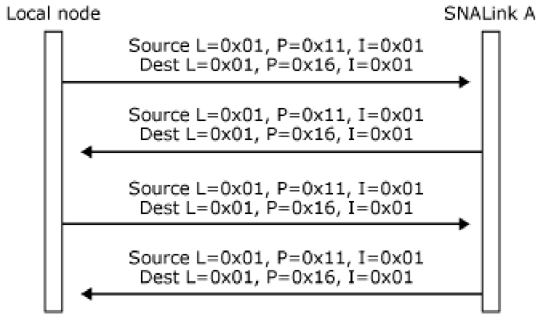


The following figure shows L values specified on messages between the local node and SNALink A.



Local node
SNALink A
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x16, I=0x01
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x16, I=0x01

The following figure shows LPI values specified on messages flowing on two different connections between the local node and SNALink A.



Local node
SNALink A
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x16, I=0x01
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x16, I=0x01
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x16, I=0x01
Source L=0x01, P=0x11, I=0x01
Dest L=0x01, P=0x16, I=0x01

The Base is called by any piece of code that wants to send a message. It uses the destination L value on the message to determine where to send it. When the message gets to the remote locality, the Base in that locality routes it to the appropriate service if the locality contains more than one service.

Making Connections

Before messages can flow across connections, the connections must be established, or opened. This is necessary because a service does not initially know the locality, partner, index (LPI) address of the service with which it wants to communicate. There may not even be a suitable service for it to communicate with.

When a local node wants to communicate with an SNALink, it attempts to open a connection by sending an **Open(LINK)** request to the SNALink. This message will have LPI values already set up by the Base, which the SNALink should save for referencing the connection in the future.

The data link control (DLC) interface does not permit the SNALink to issue an Open request.

The SNALink Interface

The SNALink interface specifies how an Independent Hardware Vendor (IHV) link DLL fits into the SNA link service architecture provided by the Base/DMOD interface. This section describes the SNALink interface, the entry points that an IHV link DLL can call, and those functions that a link service must provide to the Base/DMOD interface. These entry points allow messages to be sent to and received from the local 2.1 node.

This section contains:

- Process Structure and Scheduling
- SNALink Initialization
- SNALink Termination
- Sending Messages
- The Dispatcher
- Receiving Messages
- The Work Manager
- Base/DMOD and SNALink Entry Point Summary
- Sample Code for SNALinkDispatchProc

Process Structure and Scheduling

The primary thread of execution within a Microsoft® Host Integration Server 2004 SNALink is under the complete control of the Base. The Base schedules the SNALink by calling predefined entry points, which the IHV link support code must provide.

The IHV link support code can spawn extra threads of execution; however, the Base is not reentrant. The IHV code must ensure that only a single thread is executing within the Base at any moment in time.

The recommended SNALink structure uses the dispatcher to handle messages received from the local node and the work manager to process data received from the link. These routines and the way in which they are scheduled are described in The Dispatcher and The Work Manager respectively.

SNALink Initialization

When the SNALink is loaded into memory, the Base/DMOD performs all initialization required by the Microsoft® Host Integration Server 2004 system, including announcing availability of the new SNALink to other Host Integration Server 2004 components.

When this has been completed, the Base/DMOD calls the SNALinkInitialize function, which must be provided by the IHV link support code.

SNALinkInitialize is called with a parameter that is a handle to the global Base event. This handle should be saved by the SNALink and used to signal the Base when an event occurs (for example, when data is received from the link).

The **SNALinkInitialize** function should also:

- Read in the Host Integration Server 2004 configuration information for the SNALink. For details, see SNALink Configuration Information.
- Set up any required data structures.
- Register with the driver that provides the support for the hardware adapter, initializing this if necessary.

If initialization fails for any reason (for example, if an associated driver is not installed), the function should report the failure to the administrator by calling **SNAReportStatus**.

SNALink Termination

When a critical error occurs, forcing abnormal termination of the SNALink, the IHV code must ensure that all active connections are cleanly terminated, using whatever protocols are appropriate for the link type in use. For example, an X.25 SNALink would send a CLEAR packet on all active VCs and possibly take down level 2.

This should be performed using the process detach facility of the Win32® API function **DLLEntryPoint** .

Sending Messages

The SNALink should build a message in a buffer, and then call the Base to send it. The message contains source and destination LPIs, which are set up when the connection is opened. For more information, see LPI Connections.

The SNALink can either obtain a new buffer to contain the message to be sent (using SNAGetBuffer) or reuse one in which it has previously received a message. The application is responsible for any buffer that it has obtained or in which it has received a message. It must either use (or reuse) the buffer to send a message or release it (using SNAReleaseBuffer). If a buffer to be reused does not contain the correct number of elements for the message to be sent, the application can obtain additional elements (using SNAGetElement) or release existing ones (using SNAReleaseElement). It is the application's responsibility to maintain the **numelts** field in the message header.

The function used to send a message to the node is SNASendMessage.

The Dispatcher

Whenever a Base event occurs, the Base calls the link support code dispatcher function SNALinkDispatchProc to handle the event. The term Base event in this context means:

- A message arriving from a local 2.1 node.
- A Base timer tick occurring—this relatively slow event happens approximately every five seconds.
- Losing contact with a local 2.1 node (for example, the machine being powered down).

The **SNALinkDispatchProc** function should examine parameters passed to it by the Base to determine why it has been called (for details, see Sample Code for SNALinkDispatchProc) and call an appropriate function to handle the event. When the event has been processed, control returns to the Base scheduler.

Receiving Messages

The Base calls the SNALink dispatcher function SNALinkDispatchProc when a message is available for it.

Note that after the application receives a message, it is responsible for the buffer in which the message was received. It must either reuse the buffer to send a message (using SNASendMessage) or release it (using SNAReleaseBuffer). If the buffer to be reused does not contain the correct number of elements for the message to be sent, the application can obtain additional elements (using SNAGetElement) or release existing ones (using SNAReleaseElement).

The Work Manager

When no work is currently outstanding, the Base thread of execution sleeps, waiting for an event or for a maximum period of five seconds. SNALinks should signal the Base when an event occurs (such as data arriving on the link) by setting the Base global event. A handle to this event is passed on the SNALinkInitialize call.

When the Base is rescheduled, it calls the SNALink work manager function SNALinkWorkProc. This function should handle any link events that have occurred.

A common use of this function is in an SNALink where there is a single thread that handles the protocol of the link and also multiple threads suspended on synchronous calls to a driver read function. When data is received from the link, it is placed on an internal queue, and the driver sets the global Base event. This causes the Base to be scheduled, and **SNALinkWorkProc** is called. **SNALinkWorkProc** then removes messages from the queues and passes them to the Base to be sent to the local node.

Base/DMOD and SNALink Entry Point Summary

The following tables show entry points divided into the categories SNALink, buffer management, and Base/DMOD, and listed in alphabetic order within each category.

SNALink entry points

Entry point	Description
SNALinkDispatchProc	Dispatcher.
SNALinkInitialize	Initialize SNALink.
SNALinkTerminate	Terminate SNALink.
SNALinkWorkProc	Work manager.

Buffer management entry points

Entry point	Description
SNAGetBuffer	Get buffer.
SNAGetElement	Get buffer element.
SNAReleaseBuffer	Release buffer.
SNAReleaseElement	Release buffer element.

Base/DMOD entry points

Entry point	Description
SNAGetLinkName	Get the name of the SNALink.
SNASendAlert	Send a preformatted NMVT alert to NetView.
SNASendMessage	Send a message to the node.

The following functions are defined in SNALink Configuration Information:

Entry point	Description
SNAGetConfigValue	Get a named item of configuration information.
SNAGetSystemInfo	Get Microsoft® Host Integration Server 2004 system information.

> **Note** Standard calling conventions [WINAPI] are used for all entry points including those provided by the IHV SNALink.

The format of buffer headers and elements is described in Messages. The formats of individual messages contained in buffers are defined in SNADIS Message Formats.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Sample Code for SNALinkDispatchProc

This section contains outline source code for the link dispatcher function SNALinkDispatchProc.

```
/***********************************************************************/
/* First, include the SNA service header files                        */
/***********************************************************************/
#include <sna_dlc.h>
#include <sna_cnst.h>
#include <trace.h>

/***********************************************************************/
/* The link dispatcher routine - SNALinkDispatchProc                   */
/***********************************************************************/
VOID SNALinkDispatchProc (msgptr, function, locality)
PTRBFHDR msgptr;
INTEGER  function;
INTEGER  locality;
{
  INTEGER     discard_buff;
  COM_ENTRY("Ldisp");
  if (msgptr != NULL)
  {
    TRACE4()"received message from local node"));
    discard_buff = FALSE;
    switch (msgptr->msgtype)
    {
      case OPENMSG:
             /* process the OPEN message */
             break;
      case CLOSEMSG:
             /* process the CLOSE message */
             break;
      case DLCDATA:
             /* Data to be sent on link */
             break;
      case DLCSTAT:
             /* Switch on the subtype of the message */
             switch (msgptr->dshdr.dstype)
             {
               case STRESRCE :
                      /* call flow control processor */
                      break;
               case DLCSDXID:
                      /* call XID processor */
                      break;
               default:
                      discard_buff = TRUE;
                      break;
             }
             break;
      default:
             discard_buff = TRUE;
             break;
    }
    if (discard_buff)
    {
      /* message has not been processed, so simply discard */
      SNAReleaseBuffer(msgptr);
      msgptr = NULL;
    }
  }
  else if (function == SBLOST)
  {
    /* Lost contact with local node 'locality'  */
    /* Terminate all connections on this node (matching destl-value) */
    }
    else if (function == SBTICK)
    {
      /* 5 second timer tick */
    }
    COM_EXIT;
  }
```

SNALink Configuration Information

The configuration information for all SNALinks on a computer is stored hierarchically, referenced by the SNALink name.

The entry for each SNALink must include certain fields that are required by the Microsoft® Host Integration Server 2004 system. These are listed in the following table.

Required field	**Description**
TYPE	The type of the SNALink. Acceptable values for TYPE are: SDLC, X25, TOKENRING, TCPIP, FRAMERELAY, CHANNEL, ISDN, ETHERNET.
LINKMODULE	The name of the IHV DLL that provides the protocol code.

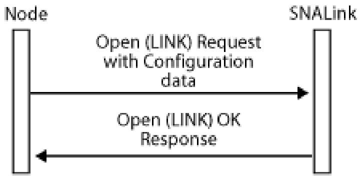
The remainder of the configuration information consists of entries of the form PARAMETER = VALUE. Parameters can be set to either an integer or a string.

Examples of possible parameters that may be required by an SNALink are as follows:

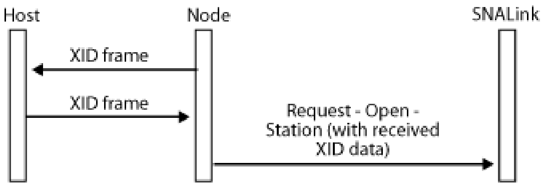
- PortNumber = 3
- LineType = SWITCHED
- L3PacketSize = 128
- T1Timeout = 30

Note that to support more than one port on a multiport adapter, you must define multiple SNALinks. It is not possible to configure a single SNALink to support more than one physical link.

The following figure shows a sample configuration for a computer with two SNALinks—SDLC1 and X25HOST.



End-to-end connection established



The configuration information is accessed using API calls that Host Integration Server 2004 provides.

The IHV Setup utility must write the configuration information for each SNALink supported. See Setup Information for information about how this should be performed.

This section contains:

- Accessing Configuration Information

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Accessing Configuration Information

The following table lists the calls the SNALink uses to obtain its configuration information.

Call	Description
SNAGetConfigValue	Returns the value of a named configuration parameter.
SNAGetSystemInfo	Returns general information on the version of SNA server currently running, such as the release level, and the network operating system.

If the return code from **SNAGetConfigValue** indicates that the specified configuration parameter is not available, or if the information returned is invalid, it is the SNALink's responsibility to decide what action to take. If appropriate, an error message could be logged.

It is strongly recommended that the SNALink read all required configuration parameters at initialization time (when SNALinkInitialize is called by the Base). This safeguards against the configuration information changing while the link service is running.

> **Note** Standard calling conventions (WINAPI) are used for all entry points, including those provided by the IHV SNALink.

The Data Link Control Interface

The data link control (DLC) interface defines the interface between the local 2.1 node and an SNALink. The DLC interface is defined in terms of the messages that are sent across the interface. Note that this is logically distinct from the definition of the Base/Dynamic Access Module (DMOD) interface, which defines the API used to send messages between two components in Microsoft® Host Integration Server 2004 (for example, between the local node and an SNALink).

DLC messages are exchanged between the local node and an SNALink across LPI connections. For details, see Structure of SNALink Components.

The local node uses the DLC interface to:

- Activate DLC connections.
- Exchange format 0 or format 3 XIDs for station activation.
- Exchange DLC information frames.
- Handle DLC error notification.

This section contains:

- Supported Configurations
- Opening a Connection
- DLC Information Transfer
- Closing a Connection
- Incoming Call Support
- SDLC Multipoint Connections

Supported Configurations

The 2.1 node supports the full range of station roles:

- Primary data link control (DLC) stations
- Secondary DLC stations
- DLC station role negotiation

For Synchronous Data Link Control (SDLC) connections, the node allows:

- Leased lines configured as:
    - Secondary point-to-point
    - Primary point-to-point or multipoint
    - Negotiable point-to-point
- Switched lines (point-to-point only) with:
    - Remote physical unit (PU) identification through XID exchange
    - Auto dial (with suitable hardware support)
    - Incoming call support

For X.25 and 802.2, the node also supports:

- Multiple connections over one physical link
- Incoming calls with validation of caller's address

In addition, for X.25, the node supports permanent virtual circuits (PVCs) and switched virtual circuits (SVCs).

Opening a Connection

The 2.1 node is capable of supporting multiple connections through one or more SNALinks. For each connection, the node opens two Locality Partner Index (LPI) connections to the SNALink:

- LINK LPI connection to handle activation and deactivation of the connection.
- STATION LPI connection to transfer data to and from the remote station.

The one exception to this rule is the case of primary multipoint connections where there is a single LINK LPI connection and multiple STATION LPI connections. This special case is described in SDLC Multipoint Connections.

The following messages flow over the data link control (DLC) interface and are used to activate a connection to a remote station.

Message	Description
Open(LINK) Request	• Flows from node to DLC over LINK connection. • Opens the LINK LPI connection between the node and the SNALink. • Provides configuration data for the SNALink. • Provides link connection data such as Token Ring address for the remote station.
Open(LINK) Response	• Flows from DLC to node over LINK connection. • Reports whether the SNALink has accepted the **Open(LINK) Request**. • Returns certain link-specific configuration parameters to the local node. • Can be an OK Response or an Error Response.
Request-Open-Station	• Flows from DLC to node over LINK connection. • Passes an XID received from the SNALink up to the node. • Indicates that the SNALink has received a mode setting command, such as SNRM over SDLC, or SABME over 802.2.
Send-XID	• Flows from node to DLC over LINK connection. • Passes an XID from the node to the SNALink to be sent out over the link to the remote station.
Open(STATION) Request	• Flows from node to DLC over STATION connection. • Opens the STATION LPI connection between the node and the SNALink. • Specifies certain station-specific configuration information.
Open(STATION) OK Response –or– Open(STATION) Error Response	• Flows from DLC to node over STATION connection. • Acknowledges **Open(STATION) Request**.
Station-Contacted	• Flows from DLC to node over STATION connection. • Informs the local node that the link is now ready for data transfer.

The use of these messages in activating various types of connections is described throughout the rest of this section. For information about the format of the messages, see SNADIS Message Formats.

The name of the Request-Open-Station message is historical. In earlier versions of the DLC interface, the higher-level software (such as the local node) always sent an **Open(STATION) Request** in response to this message—hence the name Request-Open-Station. However, now that multiple XIDs can be exchanged before the link is activated, the **Open(STATION) Request** is only sent at the end of the XID exchange.

The Request-Open-Station message now has two distinct semantic meanings:

- A Receive-XID
- A Receive-Set-Mode

This section contains:

- Opening the LINK LPI Connection

- Activating a Host Connection
- Activating a Peer Connection
- Opening the STATION LPI Connection
- Node Identification and Signaling Information
- XID Retries
- Multiple Connections

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Opening the LINK LPI Connection

The local node attempts to activate a connection:

- During system initialization if the connection is configured as initially active.
- If the system administrator manually activates the connection.
- If a 3270 or logical unit (LU) 6.2 session is requested when there is no active connection to support the LU, and the connection is configured to be activated on demand.

For each connection to be activated, the local node opens a LINK Locality Partner Index (LPI) connection by sending an Open(LINK) Request to the SNALink. This message contains configuration data such as:

- Synchronous Data Link Control (SDLC) line type: leased, switched.
- Operational role: primary, secondary, or negotiable.
- Time-out values.
- Retry limit values.
- Line speed.
- Half-duplex/full-duplex.
- 802.2 remote service access point (SAP) address.
- X.25 facility data.

For incoming calls, the local node primes the SNALink by opening the LINK LPI connection, but does not perform an activation sequence at this stage. For details, see Incoming Call Support.

The local node also inserts the first XID frame to be used (where applicable) and link connection data to be used on a switched link. The link connection data can be:

- A telephone number for a manual or autodial modem (in this case, the SNALink software could dial the required number or send a message to the operator specifying the number to be dialed).
- The media access control (MAC) address of the remote station.
- The X.25 remote data terminal equipment (DTE) address.

Finally, the **Open(LINK)** contains various time-out values that should be used by the SNALink when setting up protocol timers. For more information, see Open(LINK) Request and Open(LINK) Response.

The SNALink should return an **Open(LINK) OK Response** if:

- Its internal control blocks are successfully initialized.
- Its device driver has installed correctly.
- Its link hardware is successfully initialized.

The SNALink should not wait for an end-to-end connection before giving an **Open(LINK) Response**.

If the SNALink has successfully initialized, it should return an **Open(LINK) OK Response** immediately, supplying the required link-specific configuration information to the node (such as the maximum BTU size it can support). The local node uses this information during XID negotiation with the remote station.

If the SNALink cannot initialize successfully, it responds with an **Open(LINK) Error Response** containing an error code. The error is logged and the local node notifies the system operator before retrying the link activation.

If an XID is supplied on the **Open(LINK) Request**, this should be sent when the end-to-end connection is established for a primary or negotiable link. Note that the supplied XID can be a NULL XID, which has a zero length. Hence, it is important that the XID field is examined rather than checking for a zero XID length. An XID will be supplied for all connections except primary leased connections (which could be multipoint).

When an SNALink receives an XID frame from the remote station, it is passed to the local node in a Request-Open-Station message on the LINK LPI connection.

If the SNALink fails to receive any frames from the remote station, it generates an Outage message as described in Closing a Connection.

The following figure shows the **Open(LINK) Request** and **Open(LINK) Response**, followed by an exchange of XIDs.

Activating a Host Connection

A host connection can be activated over a leased Synchronous Data Link Control (SDLC) line, X.25, 802.2, or a switched SDLC line. This section describes the activation procedures for each type of connection.

This section contains:

- Leased SDLC Line (No XIDs Exchanged), Channel Adapter
- X.25, 802.2, or Switched SDLC Line (XIDs Exchanged)

Leased SDLC Line (No XIDs Exchanged), Channel Adapter

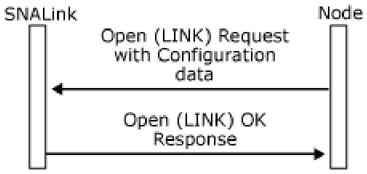
For a connection to a host computer using a leased Synchronous Data Link Control (SDLC) line, the SNALink receives a set normal response mode (SNRM) when the end-to-end connection is established. The SNALink responds with an unnumbered acknowledgement (UA) and informs the local node that the connection is ready for data transfer. This is done with the Request-Open-Station message with the Rcv-Set-Mode flag set.

The node then opens the STATION Locality Partner Index (LPI) connection with the Open(STATION) message. If the SNALink has an available control block, it responds with an **Open(STATION) OK Response**. This is followed by a Station-Contacted message.

A channel connection is treated the same way as a leased secondary SDLC connection. Each channel connection is associated with a channel subaddress in the range 0x00 to 0xFF. The SNA service node sends the channel link service an Open(LINK) Request for each configured channel connection when the connection is activated. The link service should expect to receive multiple **Open(LINK) Requests**, one for each supported subchannel address.

Note that the Request-Open-Station message flows on the LINK LPI connection, whereas the Station-Contacted message flows on the STATION LPI connection.

The message flow for a leased line is shown in the following figure.



SNALink
Node

Request - Open - Station (Rcv-Set-Mode)
Open (Station) Request
Open (Station) Response
Station - Contacted

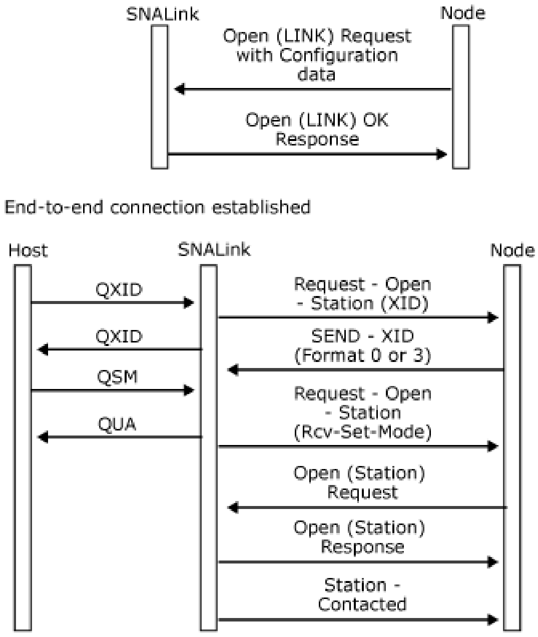
To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

X.25, 802.2, or Switched SDLC Line (XIDs Exchanged)

The initial sequence for a host connection over X.25, 802.2, or a switched Synchronous Data Link Control (SDLC) line is similar to the sequence over a leased line. The only difference is that exchange identifications (XIDs) are exchanged before the host (or front-end processor) sends a mode-setting command such as set mode (QSM) on an X.25 qualified logical link control (QLLC) link.

When the SNALink receives an XID, it is passed to the local node on a Request-Open-Station message (on the LINK Locality Partner Index (LPI) connection). The local node then passes the data link control (DLC) a Send-XID message (also on the LINK LPI connection) containing the XID to be sent to the host. The host typically checks the node identifier in this XID and, if it is valid, sends the mode-setting command.

The sequence is shown in the following figure.



SNALink
Node
Open (LINK) Request with Configuration data
Open (LINK) OK Response
End-to-end connection established
Host
SNALink
Node
QXID
QXID
QSM
QUA
Request - Open - Station (XID)
SEND - XID (Format 0 or 3)
Request - Open - Station (Rcv-Set-Mode)
Open (Station) Request
Open (Station) Response
Station - Contacted

At the link level, a mode-setting command is required to enter the information transfer state. For an SDLC link, this is a set normal response mode (SNRM). For an X.25 QLLC link, this is a QSM. For an 802.2 link, it is set asynchronous balanced mode extended (SABME). If the SNALink acknowledges the command (with a UA/QUA) immediately, it needs to buffer any data that arrives on the link in the short window before the Open(STATION) Request arrives from the local node. The alternative is to wait for the **Open(STATION) Request** before sending the UA/QUA response.

For switched connections using SDLC modems, the Open(LINK) Request contains dial digits for manual or auto-dial modems. It is the responsibility of the SNALink to handle the management of these devices. For X.25 and 802.2 connections, the **Open(LINK) Request** contains the address of the remote station.

The SNALink should initiate the dialing procedure when it receives the **Open(LINK) Request**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Activating a Peer Connection

For a peer connection, there is an activation sequence that involves the two stations exchanging format 3 exchange identification (XID) frames. As part of this sequence, the two stations agree on their link roles. They also exchange information relating to the link level connection, such as the maximum frame size supported.

The node passes XIDs to the SNALink over the LINK LPI connection using the Send-XID message. The SNALink returns received XIDs to the local node over the LINK LPI connection using the Request-Open-Station message.

Fixed Link Roles and Negotiable Link Roles show examples of XID exchange for the two cases:

- The link roles are explicitly configured for the two stations.
- The link roles of both stations are negotiable.

Points to note are:

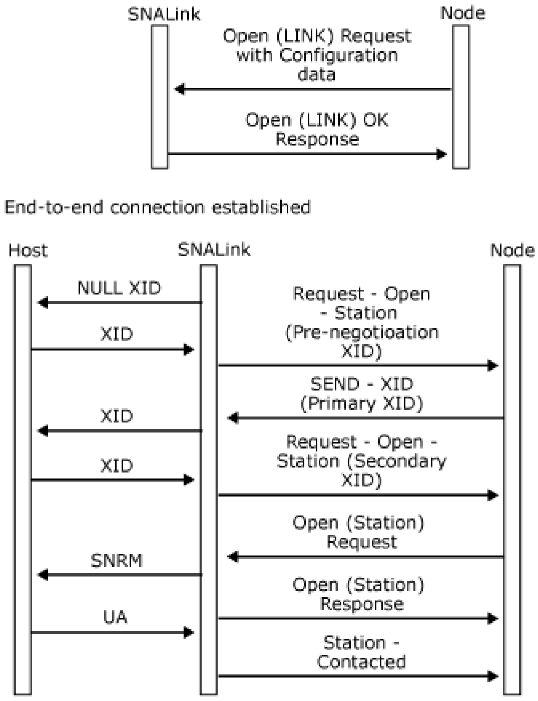
- The Open(LINK) Request is supplied with a NULL XID that is sent when the end-to-end connection is established.
- After the first NULL XID, all XIDs are format 3.
- If both stations are set up to be negotiable, the station with the higher node identifier becomes the primary.
- If both stations are negotiable and have the same node identifier, both stations produce randomized node identifiers that are compared as before.

This section contains:

- Fixed Link Roles
- Negotiable Link Roles

Fixed Link Roles

The following figure shows the sequence of messages for a peer connection where the local end is configured as the primary station and the remote end is configured as the secondary.



SNALink
Node
Open (LINK) Request with Configuration data
Open (LINK) OK Response
End-to-end connection established
Host
SNALink
Node
NULL XID

SNRM
Open (Station) Request
UA
Open (Station) Response
Station - Contacted

local node identifier	= 0x05D11111
remote node identifier	= 0x05D22222

The following summaries the rules that the SNALink must follow when supporting exchange identification (XID) exchange, and in particular XID role negotiation:

- If an XID is supplied in the Open(LINK) Request, it must be transmitted as soon as the end-to-end connection is established for primary or negotiable links.
- All XIDs received from the remote station must be passed to the local node in a Request-Open-Station message.
- An XID received from the local node in a Send-XID message must be transmitted immediately.
- XID transmissions must be retried until an XID is received from the remote station. For half-duplex links, the retry time-out should be randomized to prevent repeated XID clashes.
- When a mode-setting command, such as set normal response mode (SNRM), QSM, or set asynchronous balanced mode extended (SABME), is received before the station has been opened, a Request-Open-Station must be sent to the local node with the Rcv-Set-Mode flag on.
- When the local node sends an Open(STATION) message, the link should examine it to determine its link role (that is, primary or secondary).
- A secondary station should send a Station-Contacted message after receiving and responding to the **Open(STATION)** message.
- For a primary station, the mode-setting command should be sent when the **Open(STATION)** message is received. The Station-Contacted message should be sent to the local node when this command has been acknowledged by the secondary station (for instance, an unnumbered acknowledgement (UA) received on an Synchronous Data Link Control (SDLC) link).

If the local node detects an error during role negotiation, such as both physical units (Pus) configured as primary, it sends out an XID containing an error vector. The vector is appended to the end of the normal XID data. The vector number specified is 0x22, and the vector data specifies that the data link control (DLC) role field is in error.

After sending the error XID, the local node sends a **Close(LINK)** message to terminate the connection (see Closing a Connection).

The following table is a matrix of the possible combinations of station link roles and shows the eventual role of the local station.

	Local Station			
Remote Station		**Primary**	**Secondary**	**Negotiable**
	Primary	Fail	Secondary	Secondary
	Secondary	Primary	Fail	Primary
	Negotiable	Primary	Secondary	Either*

*The station with the higher node identifier becomes the primary.

Opening the STATION LPI Connection

After receiving a Request-Open-Station (RQOS) message, the local node sends an Open(STATION) message to the SNALink when:

- The station is configured as secondary (or has negotiated to secondary), and the RQOS message has the Rcv-Set-Mode flag on, indicating that the SNALink has received a mode-setting command such as set normal response mode (SNRM).
- The station is configured as primary (or has negotiated to primary), the RQOS message contains a secondary exchange identification (XID), and the local station has sent at least one negotiation-proceeding XID.

The Open(STATION) Request contains the link index that was on the Open(LINK) Request. This field is used to correlate the LINK and STATION LPI connections for SNALinks that support multiple connections, such as X.25, 802.2, and channel.

This **Open(STATION) Request** contains configuration data for the link station, such as the Synchronous Data Link Control (SDLC) address of the adjacent link station (0x00 for secondary stations, 0x01 to 0xFE for primary stations).

The SNALink should use this address field for determining the local station's role. If it is set to 0x00, the local station is a secondary station. Otherwise, the local station is the primary station. This field has this meaning even when the address is not used because of the link type (such as 802.2).

See Open(STATION) Request for the format of this message.

If the station cannot be initialized (perhaps due to a lack of resources), the SNALink responds with an Open(STATION) Error Response containing the appropriate error code.

Node Identification and Signaling Information

For information about the role an SNALink plays in node identification, see Incoming Call Support.

When exchange identifications (XIDs) are exchanged, there are two mechanisms for identifying the remote station:

- The node identifier on received XIDs.
- The data link control (DLC) defined address; for example, the media access control (MAC) address. This is known as signaling information.

The presence of signaling information depends on the type of the SNALink. For instance, there is no signaling information over a Synchronous Data Link Control (SDLC) link, but there is signaling information over X.25 and 802.2. The SNALink passes signaling information to the local node on the Request-Open-Station message by appending it after the XID.

If signaling information is present, the local node checks it against the configured value in the dial-digits record of the Host Integration Server 2004 configuration file. For incoming call support, this allows the local node to determine the connection that is to be activated. For a fuller description of incoming calls, see Incoming Call Support.

If there is no signaling information, the local node compares the control point (CP) name on the received XID with the remote control point name in the configuration.

If the remote station is identified correctly, XID exchange proceeds as detailed in Activating a Peer Connection. However, if there is a mismatch, the local node sends an XID (in the Send-XID message) containing an error vector followed by a Close(LINK) Request, as shown in the following figure.

Close (LINK) Request
Close (LINK) Response

XID Retries

When the local node specifies that the SNALink is to send an exchange identification (XID), either by supplying it on the Open(LINK) Request or by sending it on a Send-XID message, it is the responsibility of the SNALink to perform any retries.

XIDs need to be retried because:

- The remote station has not been started yet.
- Frames may be lost on the line due to noise.

Synchronous Data Link Control (SDLC) SNALinks should implement a contact time-out and a retry limit—values for these are provided on the Open(LINK) message. The time-out specifies how often the XID should be retried, and the retry limit specifies how many XIDs should be sent before abandoning the connection activation and sending an Outage message to the local node. The SNALink should stop retrying the XID when one of the following occurs:

- It receives an XID from the remote station.
- An Open(STATION) message is received from the node.
- A mode-setting command is received on the link.

Multiple Connections

For 802.2 and X.25 links, multiple connections can use the same physical link supported by a single instance of the SNALink software.

For each connection to a remote station, there is a LINK LPI connection and a STATION LPI connection (this is different from Synchronous Data Link Control (SDLC) multipoint as described in SDLC Multipoint Connections). Hence, there can be multiple pairs of LPI connections between a local node and an SNALink. For each connection, the local node issues an Open(LINK) Request and, after exchange identification (XID) exchange, an Open(STATION) Request.

The local node is configured with a maximum number of connections that can be active at any one time. In addition, each potential connection is configured with the address of the remote station. This information is required when activating a connection, and is included in the **Open(LINK) Request** for an outgoing connection.

DLC Information Transfer

When the local node has opened the LINK and STATION LPI connections and received a Station-Contacted message from the SNALink for a remote station, it can exchange data using the data link control (DLC) interface with the physical unit (PU) and associated logical units (LUs) at the remote station.

Data messages are contained within buffers. The transmission header (TH) of the SNA path information unit is contained within the buffer header. The request/response header (RH), if present, and request/response unit (RU) are contained within one or more buffer elements. The TH is contained in the buffer header for historical reasons. Typically, this will be copied by the SNALink into the element before **startd**, to keep the entire frame in contiguous memory locations. For a description of the DLC-Data message format, see DLC-Data.

Note that all data messages to a specified remote station flow on the associated DLC STATION LPI connection, and not on the controlling DLC LINK LPI connection.

This section contains:

- DLC Flow Control

DLC Flow Control

The flow of data messages at the data link control (DLC) interface for each link station is flow controlled. For each direction of flow, there is an initial credit of messages that can be transmitted.

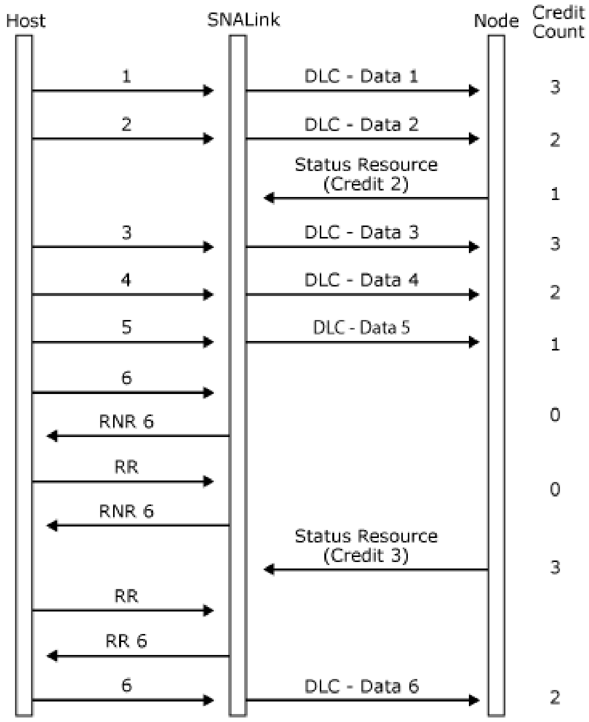
Flow control is maintained by initial specification on the Open(STATION) Request and Open(STATION) OK Response messages, and by the sending of DLC Status-Resource messages to give more credit periodically.

The sender maintains a count of credit, starting at the initial value set on the **Open(STATION)**, which is decremented for each DLC-Data message sent. When the credit count reaches zero, no more DLC-Data messages can be sent until more credit is received.

For flow in a given direction, the amount of credit is specified by the recipient of the data, because the recipient has to do any queuing. The initial credit values are passed on the Open(STATION) message (on the request for flow from the SNALink to the local node and on the response for flow from the local node to the SNALink).

The initial credit for the flow from the SNALink to the local node is determined by the node. The initial credit for the flow from the local node to the SNALink is set by the SNALink software—a suggested value is 16.

If the SNALink runs out of credit to send to the local node, it should either queue the data or discard it and send no acknowledgment. It should also start sending receive not ready (RNR), for example, when polled by a primary station. An example message flow with an Synchronous Data Link Control (SDLC) SNALink is shown in the following figure with an initial credit of 3. When the SNALink runs out of credit, it does not acknowledge any further frames and starts sending RNR.



For flow control from the local node to the SNALink, when the node runs out of credit, it queues the data and applies back pressure on sessions using that station. There is thus end-to-end flow control in this direction, independent of any SNA pacing that may be in force.

The SNALink gives credit to the local node for the messages that have been transmitted, not for the messages for which acknowledgments have been sent. The amount of data queuing in the SNALink is kept down most of the time because frames will usually be acknowledged.

Flow control for the flow of data from the local node to the SNALink is shown in the following figure, where the initial credit is assumed to be 2.

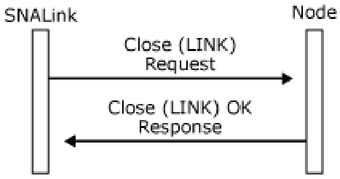
Closing a Connection

The local node closes a connection to a remote station:

- If the system administrator manually deactivates the connection.
- If the connection is configured as on-demand and no 3270 or LU 6.2 sessions are active.
- If an outage has been reported by the SNALink.

The local node closes a connection by sending a Close(LINK) message. The SNALink then takes some action, such as lowering Data Terminal Ready (DTR) on an Synchronous Data Link Control (SDLC) link or issuing a DLC_CLOSE_STATION on a 802.2 connection. It then replies with a **Close(LINK) OK Response** as shown in the following figure.

The case of multipoint connections is slightly different and is considered in SDLC Multipoint Connections. The following topics discuss point-to-point connections.



This section contains:

- Outages
- Connection Retries

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

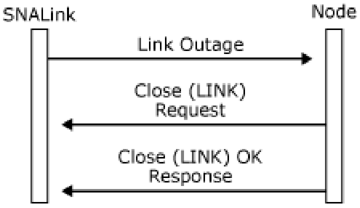
Outages

If the SNALink detects a link or station failure, it reports the failure by sending an Outage message to the node on either the LINK or STATION LPI connection depending on whether it is a link or station outage. Generally, a station outage indicates a problem at the remote station, and a link outage indicates a local or line problem.

When the local node receives an Outage message, it:

- Logs an error containing the outage code.
- Cleans up each session using the connection and informs applications of the failure (for instance, with a Comm Check code on a 3270 emulator).
- Sends a Close(LINK) Request to the SNALink.

On receipt of the **Close(LINK) Request**, the SNALink should clear up its internal resources for the connection and send back a Close(LINK) Response.



There is a special case when the node loses contact with the SNALink software. In this case, the node is notified of this event (a lost locality) and performs outage processing apart from sending messages to the SNALink.

The outage codes are not distinguished by the node, but they are logged. For the sake of consistency across SNALink implementations, the values listed in the following topics should be used.

This section contains:

- SDLC Outage Codes
- 802.2 Outage Codes
- X.25 Outage Codes

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

SDLC Outage Codes

The following table describes Synchronous Data Link Control (SDLC) outage codes.

Outage code	Description
0x0D	Internally generated for SNALink lost locality.
0x11	Data set ready (DSR) failure.
0x12	Clear to send (CTS) failure.
0x14	Data carrier detect (DCD) failure.
0x24	Nonproductive receive retry limit exceeded.
0x25	Idle time-out retry limit exceeded.
0x29	Connection problem. subqual = 0x00I-frame retransmission subqual nonzeroXID retransmission
0x2D	Abnormal modem response.
0x2E	Write time-out retry exceeded.
0xA0	Exchange identification (XID) exchange failed on multidrop line. Subqual is address of secondary station.
0x15	Discontact (DISC) received.
0x23	Receive buffer overrun.
0x2C	Invalid command received. subqual = 0x03invalid N(R) subqual = 0x04invalid or unsupported command/response subqual = 0x05excess I-field
0x80	Disconnect mode (DM) received in information transfer state.
0x81	Discontact retry limit exceeded.
0x82	Contact retry limit exceeded.
0x83	Poll retry limit exceeded.
0x84	No response retry limit exceeded.
0x85	Remote busy retry limit exceeded.
0x86	Frame reject (FRMR) received. subqual = 0x00no reason given subqual = 0x03invalid N(R) subqual = 0x04invalid or unsupported command/response subqual = 0x05excess I-field
0x87	Invalid frame received. subqual = 0x03invalid N(R) invalid or unsupported command/response subqual = 0x05excess I-field
0x88	Request Initialization Mode (RIM) received.
0x89	Request Disconnect (RD) received.

802.2 Outage Codes

The following table describes 802.2 outage codes.

Outage code	Description
0x29	Remote node not active.
0xAB	The set asynchronous balanced mode extended (SABME) received while connection active.
0xAC	Frame reject (FRMR) sent.
0xAD	FRMR received.
0xAE	Discontact (DISC)/disconnect mode (DM) received.
0xAF	Link lost.

X.25 Outage Codes

The following table describes X.25 outage codes.

Outage code	Description
0x37	Loss of a virtual circuit.
0x60	Switched virtual circuit (SVC) cleared down by remote station or network.
0x61	Permanent virtual circuit (PVC) has been reset by remote station or network.
0x62	Attempt to connect to remote station through SVC failed.

Connection Retries

If an initially active or operator-started connection is closed because of an outage, the node periodically tries to reopen the connection. This can be stopped by manually deactivating the connection. This retry mechanism is also used when the node attempts to open a connection but the SNALink software has not yet been started. On-demand connections are not retried automatically by the node, but will be retried if the user attempts to reactivate a session using the connection.

Note that this connection retry timer is totally separate from the timers specified on the Open(LINK) Request.

Incoming Call Support

The local node allows an SNALink to be set up to support incoming calls. In this mode of operation, the node primes the SNALink by sending an Open(LINK) Request, but the SNALink does not attempt to activate the link until it receives an exchange identification (XID) from a remote station.

The SNALink recognizes an **Open(LINK) Request** for an incoming call by the absence of a connection name in the destination name field (this field is filled with ASCII blanks).

For incoming calls, **Open(LINK) Request** requires an immediate response from the SNALink, just as in the case of an **Open(LINK) Request** for an outgoing call.

For a Synchronous Data Link Control (SDLC) SNALink, there can be only one **Open(LINK)** outstanding. However, 802.2 and X.25 allow the possibility of multiple connections being handled through a single SNALink. In these cases, for each configured connection that is primed to await incoming calls, the local node will send an **Open(LINK)** with a blank connection name to the SNALink.

When an incoming call is received by the SNALink, the received XID should be passed to the local node on any LPI connection that is primed for incoming calls. The LPI connection selected must then be used for all future messages relating to that incoming call.

It is not necessary for the SNALink to perform validation of incoming calls—this will be performed by the local node. However, if required, the SNALink can choose to validate calls before passing them to the node. A common example of this is to ensure that only X.25 calls with a specific local address are passed through to the local node.

The following figure shows incoming call support with an SNALink that supports two connections. A remote station calls in and uses connection A. The node sets up connection B for incoming calls but then needs to open connection C. Because the SNALink only supports two connections, connection B is closed.

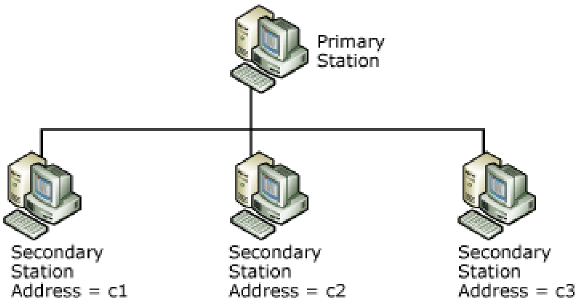
SDLC Multipoint Connections

The node can support primary multipoint (also known as multi-dropped) links, at both the primary and secondary end. Multipoint is a special configuration for a Synchronous Data Link Control (SDLC) leased link where a single SDLC line at the primary station can be used to communicate with up to 16 secondary stations. Special hardware is required to fan out the primary line so that there is a physical connection to each secondary station. The following figure shows an example with three secondary stations.



Primary Station
Secondary Station Address = c1
Secondary Station Address = c2
Secondary Station Address = c3

The SDLC address of the secondary station is used to route frames to and from the individual secondary stations. Hence, the SNALink at the secondary station needs to check the SDLC address as the primary sends all frames to all secondary stations. The SNALink at the secondary station should only accept frames with its SDLC address—the other frames should be ignored.

From the viewpoint of the node at a secondary station, the message flow at the data link control (DLC) interface is as for a point-to-point connection (described in Opening a Connection). The node need have no knowledge that this is a multipoint connection.

The primary end has to handle the special processing required for multipoint connections. The remainder of this section concentrates on the primary station.

At the primary end, there are the following LPI connections:

- One LINK LPI connection.
- A STATION LPI connection for each active secondary station.

Because the exchange identification (XID) exchange is carried out using the single LINK LPI connection, the Request-Open-Station and Send-XID messages always specify the station address of the secondary station that the XID has arrived from or is going to. Note that no XID is supplied on the Open(LINK) Request.

Each STATION LPI connection has different values of I, the index. After the station has been activated, data messages flow on the STATION LPI connection rather than the LINK LPI connection.

If the XID exchange fails because the secondary is failing to reply to the XID, the SNALink generates a special variant of link Outage message. Ideally, the SNALink would give a station Outage message, but this is not possible because the STATION LPI connection is not yet open. Instead, the SNALink generates a link Outage message with code 0xA0 and a subqualifier that is the SDLC address of the station.

When the stations are activated on a multipoint link, the majority of messages flow across the STATION LPI connections. If a connection to a particular secondary station is to be closed (because the operator deactivates it, for instance), the node issues a Close(STATION) Request. The SNALink replies with a Close(STATION) Response to the node and sends a Discontact (DISC) frame to the secondary station.

The SNALink can generate both station and link Outage messages. If the problem only affects a particular station, such as not responding to polls, the link generates a station Outage message and the node closes the station with a **Close(STATION) Request**. The SNALink responds with a **Close(STATION) Response**.

If the problem affects the link as a whole, such as the line being disconnected from the primary SDLC adapter, the SNALink generates a link Outage message and the node sends a Close(LINK) Request. The SNALink responds with a Close(LINK) Response.

Whenever the node receives a **Close(STATION) Response**, it checks to see if any stations are still active on the multipoint link. If not, a **Close(LINK) Request** is sent. The SNALink responds with a **Close(LINK) Response**. The following figure shows the message flows for outage processing. It shows a multipoint connection with two secondary stations (the full XID exchange is not shown).

Setup Information

This section describes the integrated link service installation provided with Microsoft® Host Integration Server 2004.

In Host Integration Server 2004, SNA Manager is used to install and configure link services. Host Integration Server 2004 uses the Microsoft System Installer (MSI) and MSI packages for the installation of the Host Integration Server software. Link services from independent hardware vendors (IHVs) are not included in the main Host Integration Server MSI packages. IHV link services are installed using a separate IHV-provided MSI package.

A sample IHV link service using the generic Synchronous Data Link Control (SDLC) link service that illustrates IHV link service installation is included in the Host Integration Server software development kit (SDK). The SDK samples are installed on your computer when the SDK option is selected during installation of Host Integration Server software. These sample files are also located on the Host Integration Server 2004 CD under the SDK\Samples\IHVLInks subdirectory. Host Integration Server 2004 does not support the earlier .inf-based link service setup procedure.

This section contains:

- Setup Registry Architecture
- Integrated Link Service Setup on Host Integration Server 2004

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Setup Registry Architecture

There are two main subtrees in the Microsoft® Windows® 2000 registry where information is kept relevant to Microsoft® Host Integration Server 2004: the **SOFTWARE** tree and the **SYSTEM** tree. Both of these are subtrees of **HKEY_LOCAL_MACHINE**. The **SOFTWARE** tree contains generic information about independent hardware vendor (IHV) link services, and the **SYSTEM** tree contains information about the individual components of those services. While reading the following topics, it may be helpful to view examples of what is being discussed by inspecting the registry of an existing system with several of the built-in link services installed.

This section contains:

- Product Entries
- Service Entries

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Product Entries

All of the information relevant to the product as a whole resides in the registry under the key **SOFTWARE\Microsoft**. Each product or link support has an entry whose name consists of the product name and version separated by an underscore. This key contains most of the information about the product, such as the script name and option name that control it and the service name for that particular instance.

Each instance key must also have a NetRules key. This key contains all of the information for the Network Control Panel Applet bindings.

The Host Integration Server Setup writes the path of the root directory of the computer's Host Integration Server tree into the key:

SOFTWARE\Microsoft\SNA Server\CurrentVersion\Setup\RootDir

Service Entries

Each instance of a component appears to the system as a unique service. These services must be created using the Service Control Manager (SCM). The SCM creates a registry entry for each service under **SYSTEM\CurrentControlSet\Services**. This key contains all of the service-specific information.

The top-level service key contains information that the SCM uses to control the service. This includes the type of service that this key represents, how it should be started, what sort of error handling should be used, the path to the executable image, and so on. All information in this key should be handled by the SCM. Each service key also contains two subkeys—the Linkage key and the Parameters key.

The Linkage key is used by the Network Control Panel Applet to store binding information. The Parameters key contains information that is relevant to Host Integration Server 2004 Setup, such as the name of the DLL responsible for handling a link service. All information in this key should be handled by Host Integration Server 2004 Server Setup. The Parameters key contains another key, ExtraParameters, which is used for any IHV-specific information, including component-specific parameters and other information not required by the main SNA Server Setup program.

Integrated Link Service Setup on Host Integration Server 2004

In Microsoft® Host Integration Server 2004, the SNA Manager supports installation and configuration of link services. Host Integration Server 2004 uses the Microsoft System Installer (MSI) and MSI packages for the installation of the Host Integration Server software. Link services from independent hardware vendors (IHVs) are not included in the main Host Integration Server MSI packages. IHV link services are installed using a separate IHV-provided MSI package. For an example of this process, install the DLC, 802.2, or IBM Synchronous Data Link Control (SDLC) link service in Host Integration Server.

IHV MSI Packages contain two types of features:

- Features that can be installed and used independently of Microsoft Host Integration Server 2004.
- Features that require Microsoft Host Integration Server 2004 to function.

Features that can be installed and used independently of Microsoft Host Integration Server 2004 include drivers, utilities, and applications that can run without Host Integration Server support. These features should be represented in the package as one or more features in the MSI Select Features dialog box. (For more information, see the Generic Link Service sample feature "Generic Link Service" from the Generic.msi Feature table.) Generic.msi can be found in the Host Integration Server 2004 SDK on the CD and in the install directory at the following address: SDK\Samples\IHVLinks\Packages\Generic.msi.

Features that require Microsoft Host Integration Server 2004 include drivers, utilities, and applications that require Host Integration Server to function. These features should be represented in the package as one or more features in the MSI Select Features dialog box. These features should be hidden if Host Integration Server is not installed on the computer. (For more information, see the Generic Link Service sample feature "Host Integration Server Support" from the Generic.msi feature table.)

Properties can be equated to a variable (either global or local) in a high-level programming language such as C or C++. Properties can be used as a placeholder for informational text, or as values used during an installation. (For more information, see the property SERVER_INSTALLED in the custom action source code GenSet.cpp, and the Condition table entry in the Generic.msi package.)

Custom Actions provide a method of extending the capabilities of MSI. Functions not supported in MSI, can be custom written, and invoked from within a sequence table or directly from a dialog control event. (For more information, see the Custom Actions SetHISPath and GetHISData in the GenSet.cpp source file.)

Launch Conditions provide a method of preventing an install from launching. The sample MSI package included with the Host Integration Server SDK does not use a launch condition, however, if your package requires Host Integration Server to be installed for your features to function, you should include a launch condition that fails the installation if Host Integration Server is not detected.

The Condition table provides a method of controlling the layout of the features listed in the select feature dialog box. The sample MSI package uses the Condition table to hide the "Host Integration Server Support" if Host Integration Server is not detected in the installation.

For Host Integration Server to control the installed state of IHV features that require Host Integration Server to be installed, the following registry keys must be included in the package for each separate feature which requires Host Integration Server to be installed.

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SnaBase\IHVSupport\<ihv key>
<feature table entry 1> : REG_SZ : <product code 1>
<feature table entry 2> : REG_SZ : <product code 2>
.
.
.
<feature table entry n> : REG_SZ : <product code n>
```

Where:

<feature table entry x> specifies an entry in the feature table (not title).

<product code x> specifies the package product code.

Note that feature table entries must be unique. Product codes may or may not be unique depending on the number of packages provided by an IHV. One package may have several Host Integration Server dependent features and therefore should list each feature separately.

These registry keys should be installed by the feature rather than globally by the package.

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SnaBase\LinkServicesInstalled
<Link Service Name> : REG_SZ : <Link Service Configuration Dll name>
```

Target paths specify a directory where files will be installed. An MSI package will contain one or more target paths.

The sample package contains two features:

- Generic Link Service
- Host Integration Server Support

The Generic Link Service is not dependent on Host Integration Server. This feature installs the following:

- gencfg.exe into the <Generic Link Service> directory.
- generic.sys driver into the %windir%\system32\drivers directory.
- generic.inf into the %windir%\inf directory

Host Integration Server Support is dependent on Host Integration Server. This feature installs the following:

- gendtct.dll into the HIS\system directory.
- generic.dll into the HIS\system\hwsetup\i386 directory.

This feature contains the following entry in the condition table to hide the feature if Host Integration Server is not detected

```
HIS_RELATED_FEATURE  0  SERVER_INSTALLED="NO"
```

See dialog snapshots later in this topic for layout of features with and without Host Integration Server installed:

Adds:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SnaBase\LinkServicesInstalled
Generic Link Service : REG_SZ : GENERIC.DLL

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SnaBase\IHVSupport\GenericLinkService
HIS_RELATED_FEATURE : REG_SZ : {FDF11E0E-3BFF-4B0F-89BD-E4E1FB979E4D}
```

The sample package uses one custom action DLL with two entry points:

```
SetHISPath
GetHISData
```

The **SetHISPath** entry sets the target path to the Host Integration Server 2004 install directory.

The **GetHISData** entry sets the MSI property SERVER_INSTALLED to "YES" if Host Integration Server is installed and sets the MSI property SERVER_INSTALLED to "NO" if Host Integration Server is not installed.

The sample contains two target paths:

```
INSTALLDIR
INSTALLDIR1
```

The INSTALLDIR target path specifies the installation directory for the features that are not dependent on Host Integration Server. It can be set using the **browse** button in the **Select Features** dialog box when the Generic Link Service feature is currently selected.

The INSTALLDIR1 target path specifies the directory where Host Integration Server is installed. This target path is set by the custom action SetHISPath.

The IHVUtil.exe tool can be used to verify the Host Integration Server dependent interfaces. If the tool is launched after the IHV package is installed, all Host Integration Server dependent features should show up in the dialog box. Executing Remove from the dialog box should remove the Host Integration Server dependent feature as well as remove it from the dialog box.

Note that the sample provided can also be tested using the SNA Manager. While the sample does not actually function, it will appear as an installed link service.

This section contains:

- Integrated Link Service Configuration and Reconfiguration on Host Integration Server 2004
- Constructing an Integrated Link Service DLL on Host Integration Server 2004

Integrated Link Service Configuration and Reconfiguration on Host Integration Server 2004

In Microsoft Host Integration Server 2004, the initial configuration functions are performed by your configuration DLL running in the context of SNA Manager.

After your link service has been created, SNA Manager must be able to locate its configuration DLL when the operator wishes to reconfigure the link service. To support this feature, when your configuration DLL initially creates the link service, it must put a new value in the registry of the target server as follows:

SYSTEM\CurrentControlSet\Services\<yourLinkService>\Parameters

DLLName: REG_SZ: <configDllName>

where:

<configDllName> is the file name and extension of the configuration DLL, for example, IBMSDCFG.DLL. No path is specified in the value.

This value replaces **InfName**, which was used in SNA Server 2.*x* to name the path to the .inf file.

Since SNA Manager can be running on a management workstation remote from the target server, the configuration DLL must be able to create configuration information on the target server. Host Integration Server loads the appropriate configuration DLL over the network from \<snaRoot>\SYSTEM\HWSETUP\<cpu> on the target server as needed.

> **Note** There is an alternate way of locating the link service configuration DLL (linkcfg) if the link services from the vendor were not included with the released Host Integration Server CD.
>
> Depending on the setup tool used by the vendor, the vendor's setup software may not be able to read the registry and locate the directory where link services should be installed. To resolve this problem, the SNA Manager scans the **LinkServicesInstalled** key prior to making the call to the link service configuration DLL. The SNA Manager checks for a % character in the configDllName and if it exists, configDllName will be interpreted differently than just the name of the configuration DLL. The following example illustrates this case:
>
> Under the **SYSTEM\CurrentControlSet\Services\<yourLinkService>\Parameters key**
>
> **DLLName: REG_SZ: "share\%s\<relative path and DLL Name>**
>
> If a %s string is found, \\ServerName will be prepended and the CPU architecture string (i386) will be substituted for %s.

Constructing an Integrated Link Service DLL on Host Integration Server 2004

Microsoft Host Integration Server 2004 provides an enhanced method for installing integrated link services that allows for remote setup and administration of new link services, as well as support for setup and configuration using a command-line tool. This feature is based on the link service provider supplying a setup and configuration DLL exporting a specific list of functions. A developer must follow certain standards for using this SNA link service configuration DLL (linkcfg) and set various keys and values as registry settings to be used by Host Integration Server for link service configuration.

To support vendors using these setup and configuration features, Host Integration Server includes the source code for a sample generic Synchronous Data Link Control (SDLC) link service configuration DLL. Also included for use by developers is the source code to a library of utility functions (lnktools) that are commonly useful when implementing the linkcfg DLL. This sample code and the documentation that follows can be used as a guideline for vendors developing similar link service configuration DLLs for their hardware. This sample source code is located on the Host Integration Server CD in the \SDK\SAMPLES\IHVLinks subdirectory. Sample include files, C++ files, resource files, makefiles, and project files are included for use with Microsoft® Visual C++® version 6.0 and later.

This section contains:

- Components of an Integrated Link Service Configuration DLL on Host Integration Server 2004
- Contents of IHVLinks Sample Kit on Host Integration Server

Components of an Integrated Link Service Configuration DLL on Host Integration Server 2004

The link service configuration DLL (linkcfg) must export the following functions.

Exported function	Purpose
CommandLineAdd	Called from **LinkCfg** to parse command-line input.
ConfigureLinkService	Called from SNA Manager to add or modify a link service.
ConfigureLinkServiceEx	Called from SNA Manager to add or modify a link service, returning a configuration buffer to be added to the configuration file.
DisplayHelpInfo	Returns a buffer containing command-line syntax for this type of link service.
RemoveLinkService	Called from SNA Manager to remove a link service.
RemoveAllLinkServices	Called from Setup to remove all instances of this link service.

The sample linkcfg.cpp DLL is written in C++ using the Microsoft Foundation Classes (MFC) and uses a single property sheet with two property pages as follows:

- The card configuration property page implementation is in the cardcfg.cpp and cardcfg.h files. This property page is concerned with configuring various hardware properties (interrupt, DMA channel, and I/O address, for example) of the link service hardware.
- The connection mode property sheet implementation is in the mode.cpp and mode.h files. This property page is concerned with configuring mode information (link service name, link service title, Synchronous Data Link Control (SDLC) line type, for example) for the link service.

The two property pages are linked to the link service property sheet in linkcfg.cpp within the **ConfigureLS** routine. This function is called by the exported **ConfigureLinkService** and **ConfigureLinkServiceEx** routines in linkcfg.cpp. An actual link service configuration DLL developed from these sources may require more property pages depending on the information needed to configure the actual link service DLL.

The registry.h include file used by linkcfg.cpp contains a global definition of the registry entries required for the sample generic SDLC link service. The values in this structure will be modified to contain the actual information specified by the user. This structure is added to the registry when a new link service is configured, and this structure is removed when a link service is deleted. The registry values that a developer must modify include the Link Registry Base entry (LINKSERVICE is used in the sample include file), the name of the device driver root (GenSdlc is used in the sample include file and source code), and various software and service registry settings appropriate for the target link service.

Several of the exported link service DLL functions use a configuration buffer, the CONFIG_BUFFER structure defined in linkcfg.h. The format of any CONFIG_BUFFER used by developers must match the structure format of this sample file for the first three parameters. Other parameters may differ for a developer's version of the CONFIG_BUFFER structure based on the target link service.

The sample link service configuration DLL calls a set of general utility functions that are not specific to any target link service. These utility functions are included in the lnktools library (lnktool.cpp) that is linked in as an OBJ file. This lnktools library includes the following utility functions that are useful in developing link service configuration DLLs.

Utility function	Purpose
AddPerfmonCounters	Add Perfmon counters for this link service.
bCreateService	Create a service on a computer.
bDeleteService	Delete a service on a computer.
bStopService	Stop a service running on a computer.
CheckForExistingLinkService	Check to see if a link service of this type exists with this title.
ConvertHexStringToDWORD	Convert a hexadecimal string to a DWORD value.
ExtractNextParameter	Get the next parameter from a buffer.
fAddRegistryEntry	Add a new registry value to the registry.
fCanWeAdministerRemoteBox	Determine if the user has administrative privileges on the remote computer.
fConnectRegistry	Connect to a remote computer's registry and return a handle to the remote registry.
fDisconnectRegistry	Disconnect from a remote computer's registry.
fFindAndReplaceString	Find and replace a substring within a string.
fFindString	Determine if a string exists within a string buffer.

fFindStringInMultiSZ	Find a string in a REG_MULTI_SZ string list and return entire string.
fQueryRegistryValue	Query a value from the registry.
fRegistryKeyExists	Test whether a registry key exists.
fRemoveRegistryEntry	Remove a registry key.
fRemoveRegistryValue	Remove a registry value.
fStringCompare	Determine if two strings compare.
LoadStringResource	Load a string from the string resource.
ParseNextField	Return the next field from a string.
RemovePerfmonCounters	Remove Perfmon counters for this link service.
ReturnString	Return a pointer to a string resource string.

The sample source code for a generic SDLC link service configuration DLL (linkcfg) includes several functions that may be useful as sample code when developing link service configuration DLLs for other hardware. The following functions are included in the linkcfg.cpp source code that may be of use as examples.

Utility function	**Purpose**
bDetectNetworkCard	Detect the remote network card and return the card settings buffer for the sample generic SDLC link service.
bLastGenericDFTLinkService	Check for the last generic SDLC link service for the sample generic SDLC link service. This routine is used to determine if the GENSDLC Device Driver (if one exists) can be removed.
ConfigureLS	The common link service configuration function used by the sample generic SDLC link service.
fAddAllRegistryValues	Add all registry values for the sample generic SDLC link service.
fAddClassAndBindformRegistries	Add the class and bindform registry entries for the sample generic SDLC link service. The bindform and class registry entries can only exist for the first link service of this type.
fEnumerateEventLogSources	Enumerate the Event Log sources registry value for the sample generic SDLC link service.
fRemoveAllRegistryValues	Remove all registry values for the sample generic SDLC link service.
fReplaceAllRegistryValues	Replace all user-provided information in the registry data for the sample generic SDLC link service.
fReplaceRegistryData	Replace global registry data for the sample generic SDLC link service.
fReplaceRegistryKeyName	Replace global registry structure strings for the registry key name for the sample generic SDLC link service.
fSetupGlobalValues	Create or update all user-provided information in the registry data structure for the sample generic SDLC link service.
InitializeGlobalStructure	Initialize link service data contained in the global data structure for the sample generic SDLC link service.

Contents of IHVLinks Sample Kit on Host Integration Server

The sample source code for a generic Synchronous Data Link Control (SDLC) integrated link configuration MSI package that illustrates an integrated independent hardware vendor (IHV) link service installation are included on the Microsoft Host Integration Server 2004 CD. These sample programs are located in the \SDK\Samples\IHVLinks subdirectory on the Host Integration Server 2004 CD. These files are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the Host Integration Server Software Development Kit (SDK) option is selected. These samples are installed in the SDK\Samples\IHVLinks subdirectory below where the Host Integration Server SDK software is installed (C:\Program Files\Microsoft Host Integration Server\SDK, by default).

These sample files include the following directories.

Directory	Description
LinkServ	Directories used in creating the IHVLinks sample generic SDLC link service configuration and detection DLLs.
LinkServ\Build	A file containing the normal COFF base address for a link service configuration DLL (linkcfg).
LinkServ\Detect	The source code to the sample generic SDLC link service detection DLL.
LinkServ\Linkcfg	The source code to the sample generic SDLC link service configuration DLL. The link service configuration DLL must export specific functions. A definitions (.DEF) file must be used so that exported function names are not decorated by the compiler and linker.
LinkServ\LnkTools	The source code to a collection of library routines used by the generic SDLC link service configuration DLL.
LinkServ\NT5INF	An INF file that can be used with the generic SDLC link service.
Setup	Directories used in creating the IHVLinks sample generic SDLC link service setup and setup test tools.
Setup\Bins	The compiled generic MSI package containing the generic SDLC link service driver, configuration and detection DLLs, and configuration tool.
Setup\CASource	This directory contains the source code used for the custom actions in setup. The GetHISData custom action sets the MSI property SERVER_INSTALLED to "YES" if Host Integration Server 2000 is installed, otherwise the property is set to "NO". This custom action is used to disable Host Integration Server 2004 dependent features from the installation directory if not installed. The SetHISPath custom action sets the target directory INSTALLDIR1 to the installation directory where Host Integration Server 2004 was installed. This custom action is used to set the destination directory for the link service configuration DLLs.
Setup\Package	The sample GENERIC.MSI SDLC link service package ready for installation and testing.
Setup\Tools	The source code for various utility functions and tools that can be used to test your integrated link service MSI package.

This sample source code is included for your reference. The communication between workstation management station and Host Integration Server is performed by RPCSVC.EXE, the SNA remote procedure call (RPC) service.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Compiling and Linking a SNALink

This section provides information about compiling and linking a SNALink for use with the Microsoft® Host Integration Server 2004. This section also lists and explains the header files and libraries need to build a SNALink.

This section contains:

- Host Integration Server 2004 DLC Header Files
- Included Files
- Required Exports
- Compiler Options
- Linking

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Host Integration Server 2004 DLC Header Files

The following files are required to build a Microsoft® Host Integration Server 2004 SNALink:

File	**Description**
SNA_DLC.H	Main header file containing the definitions of buffer and message formats.
SNA_CNST.H	Function prototypes for the Base/DMOD interface calls and constant definitions.
TRACE.H	Definitions of the logging and tracing macros.
IHVLINK.LIB	Main library for the SNADIS interface.

Included Files

To compile a SNALink, the header files SNA_DLC.H, SNA_CNST.H and TRACE.H are required. In addition, one of the standard operating system header files may be required. To include the required files, the following lines should be used in your application:

```
#include <sna_dlc.h>
#include <sna_cnst.h>
#include <trace.h>
```

> **Note** The TRACE.H include file is required to enable SNA tracing and use of the Microsoft® Host Integration Server 2004 Trace viewer utility.

Required Exports

The IHV link support DLL must export the following entry points:

- SNALinkInitialize
- SNALinkWorkProc
- SNALinkDispatchProc

These are called by the Base scheduler when the SNALink is invoked.

Compiler Options

When compiling the SNALink DLL, the following compiler options are required:

Option	Explanation
/c	Compile only, without linking. Linking is done as a separate phase to include the required Microsoft® Host Integration Server 2004 libraries.
/D NOTRC	The NOTRC macro specifies that internal tracing should not be compiled into the application. The /D NOTRC option should be used for building a final system (internal tracing should not be included because it will degrade performance and occupancy). For a development system, you may want to compile with internal tracing; if so, remove the /D NOTRC option.
/D WIN32_SUPPORT	The macro WIN32_SUPPORT is used in the header files SNA_DLC.H, SNA_CNST.H, and TRACE.H to support variants of the DLC interface for Microsoft Windows® 2000.
/Gzs	**z**: Use stdcall conventions . **s**: Remove stack check calls.

The following compiler flags are required, but any of the valid options for each flag may be used, as appropriate to your application:

/O	Optimization
/W	Warning level

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Linking

The IHVLINK.LIB library must be linked with the application. It contains the Base, DMOD imports, and diagnostics routines. The DMOD and the Base are implemented as DLLs.

> **Note** The Microsoft® Host Integration Server 2004 library only contains the external references for the corresponding DLLs, which are part of the main Host Integration Server 2004 product.

Synchronous Dumb Card Interface

This section describes the interface to the synchronous dumb card device driver used by the Synchronous Data Link Control (SDLC) and X.25 SNALinks that Microsoft® Host Integration Server 2004 supplies. The interface provides a simple but flexible mechanism for transferring frames of data through a dumb synchronous communications card (such as the IBM MPCA card).

This interface is intended primarily for independent hardware vendors (IHVs) who want to provide drivers for their own dumb cards that are directly compatible with SDLC and X.25 SNALinks. It can also be used by Independent Hardware Vendors (IHVs) who intend to write their own SNALinks and want to ensure that their drivers conform to the standard Host Integration Server 2004 model.

This section contains:

- Driver Interface
- I/O Request Packets

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Driver Interface

Application software running on Microsoft® Windows Server™ 2003 or Windows® 2000 normally does not interact directly with device drivers. Usually, the operating system itself controls the interface to underlying device drivers on behalf of the application. For example, Disk I/O consists of sequences of driver requests generated by a file system, as a result of an application making file system requests.

By contrast, in the Microsoft® Host Integration Server 2004 device driver model, synchronous dumb cards are controlled directly by the SNALink using input and output control (IOCTL) commands. This mechanism enables the SNALink to pass raw control packets to the driver without any intervention from the operating system.

This is achieved by issuing an Open request with a file name that identifies the device driver. The operating system detects the fact that this file is a driver and passes an OPEN I/O request packet to the driver. The user application is returned a handle that can be used to reference the driver.

The IBMSYNC driver creates various device names. During setup, the configuration for adapters in the computer is saved in the registry. When the driver starts, it reads this data and creates the device names for all the adapters that are found.

The following table lists the device names that the IBMSYNC driver can create.

Device name	**Description**
\Device\IBMSDLC	Standard IBM Synchronous Data Link Control (SDLC) adapter.
\Device\MPCA_1	IBM MPCA 1 adapter. This adapter has a switch set on it to enforce MPCA 1 operation. This adapter is the primary MPCA adapter in the computer and supports direct memory access (DMA) interrupt mode.
\Device\MPCA_2	IBM MPCA 2 adapter. This adapter has a switch set on it to enforce MPCA 2 operation. This adapter is the secondary MPCA adapter in the computer and supports only interrupt mode.
\Device\SYNC_*x*	Generic adapter (for example, Microgate). The letter *x* is 1 (for the primary adapter) or 2 (for the secondary adapter).
\Device\MPAA_S*x*	IBM MPAA adapter, where *x* represents the number of the MCA slot where the adapter is installed in the computer. This number is a value from 1 through 8.
\Device\SYNC_S*x*	Generic MPAA adapter (for example, the Microgate MPAA adapter). The letter *x* represents the number of the MCA slot where the adapter is installed in the computer. This number is a value from 1 through 8.

Subsequent IOCTL calls using **DeviceIOControl** made by the SNALink using the driver handle cause the operating system to pass an IOCTL I/O request packet to the driver. The driver therefore sees IOCTL requests from the SNALink as a series of I/O request packets passed to it by the operating system.

The Host Integration Server 2004 dumb card interface uses the following operating system calls:

- **OpenFile**
- **DeviceIOControl**
- **CloseFile**

DeviceIOControl allows free-format information to be passed to the driver. The dumb card interface uses its own format of information to pass all requests to the driver (with the exception of Open and Close requests, which are handled differently by the operating system).

This section contains:

- Architecture Overview

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Architecture Overview

This section describes how information is transferred between the driver and the SNALink.

This section contains:

- Interface Record
- Event Signaling
- Link Characteristics

Interface Record

Status information is transferred between the driver and the SNALink using a buffer known as the interface record.

The driver allocates this buffer when it starts and maintains the information in it while it is running. The contents of this buffer are copied to an SNALink buffer by using an IOCTL call of type **READ_INTERFACE_RECORD**.

Event Signaling

The device driver notifies the SNALink whenever an event occurs (such as a frame being received from the line) by setting an event.

The SNALink provides the driver with a handle to this event (or semaphore) at the start of day by issuing an IOCTL call of type **SET_EVENT_HANDLE**.

Link Characteristics

Before the driver can transfer any data, it needs information about the link. This includes the following:

- The frame size.
- The station address to listen on (if required).
- Details of hardware selectable options, such as SDLC/HDLC, Internal/External clocking, and so on.

For more details of these options, refer to the topic Function 0x42: Set Link Characteristics.

I/O Request Packets

All I/O requests are passed to the driver by Microsoft® Windows Server™ 2003 or Windows® 2000 using the standard IRP structure. For more details about this, refer to the Windows Server 2003 or Windows 2000 Device Driver Kit.

I/O request packets are defined in terms of C structures. The relevant fields are accessed as follows:

Field name	Description
IRP.CurrentStackLocation -> MajorFunction	Defines the IRP as an IOCTL.
IRP.IoStatus	Status codes upon completion of request.
IRP.CurrentStackLocation -> IoControlCode	The IOCTL function code.

IoControlCode identifies the function to be performed and **IoStatus** is the mechanism for returning result codes to the SNALink. The structure **IoStatus** is defined as follows:

IoStatus.Status

A standard Windows Server 2003 or Windows 2000 result code (for example, STATUS_INVALID_PARAMETER) as defined in the Windows Server 2003 or Windows 2000 header file NTSTATUS.H.

IoStatus.Information

For successful read-frame IOCTLs, the length of the received buffer (can be zero if no data available). Additional error information, as defined in the header file SECLINK.H.

This section contains:

- Initialization
- OPEN Call
- CLOSE Call
- IOCTL Command Summary
- Equates and Structure Layouts

Initialization

Device drivers under Windows Server 2003 or Windows 2000 should perform all initialization required at the start of day when they are loaded by Windows Server 2003 or Windows 2000. Configuration information for device drivers is stored in the Configuration Registry under Windows Server 2003 or Windows 2000. For more details, refer to the documentation supplied with the Windows Server 2003 or Windows 2000 Device Driver Kit.

The SNALinks for dumb cards are implemented by the following files:

SDLC SNALink
  SNAroot\SYSTEM\IBMSDLC.DLL
X.25 SNALink
  SNAroot\SYSTEM\IBMX25.DLL

To bind to one of these, an installation script should mention the appropriate DLL in the IHVDLL registry entry that the script creates for the link service.

OPEN Call

The **OPEN** call has no parameters. It grants access to the driver from a particular process. The driver ensures that only one **OPEN** is accepted by the link at any one time. When **OPEN** is processed, the driver attempts to reserve access to hardware resources such as interrupt vectors. The **OPEN** is rejected if this fails.

After a successful **OPEN** request, the driver expects to receive the following IOCTL commands:

- **SET_EVENT_HANDLE**
- **SET_INTERFACE_RECORD**
- **SET_LINK_CHARACTERISTICS**

Of these, the first two can be performed in any order, but both should be issued before calling **SET_LINK_CHARACTERISTICS**.

When these three calls have been successfully performed by the SNALink, the driver is ready for information transfer.

CLOSE Call

The **CLOSE** call has no parameters. It performs the logical converse of **OPEN**. Resources are released back to the operating system when a **CLOSE** is performed.

IOCTL Command Summary

The parameters to the IOCTL request packet are stored in the following fields in the associated I/O request packet (IRP).

IRP.CurrentStackLocation -> IOControlCode	**Function code**
IRP.SystemBuffer	Address of parameter buffer (if used)
IRP.CurrentStackLocation -> InputBufferLength	Length of parameter buffer
IRP.UserBuffer	Address of data buffer
IRP.CurrentStackLocation -> OutputBufferLength	Length of data buffer

Note that under Windows Server 2003 or Windows 2000, the operating system reserves the lower four bits of the IOCTL function codes to determine the method used to map the various buffers passed on the **DeviceIoControl** function call into the driver address space. The various options available to device driver writers are:

Low nibble	**IOCTL definition**
0	METHOD_BUFFERED
1	METHOD_IN_DIRECT
2	METHOD_OUT_DIRECT
3	METHOD_NEITHER

For further details of the memory mapping performed by these various options, refer to the Windows Server 2003, Windows 2000, or Windows DDK documentation.

For a driver function code of ZZ, using memory mapping code M, the IOCTL code passed on the **DeviceIoControl** function call is 0xZZM.

The function codes are set out as shown in the table later in this topic. Note that all other function codes will be returned with the error ERROR_INVALID_DEVICE_REQUEST in the field **IoStatus.Status**. The Windows Server 2003 or Windows 2000 I/O System validates the address and length of the areas passed as parameter and data packets. If the address validation fails, an exception will be raised.

All requests must return immediately. In general, they are simple, immediate operations, but in the case of Transmit Frame and Receive Frame, the driver must not suspend the calling SNALink thread while waiting for I/O to complete—a relevant return code should be sent instead, allowing the SNALink to retry.

The complete list of functions is as follows.

Function	**Function code**	**Windows Server 2003 or Windows 2000 IOCTL code**
Function 0x41: Set Event/Semaphore Handle	0x41	0x410
Function 0x42: Set Link Characteristics	0x42	0x420
Function 0x43: Set V24 Output Status	0x43	0x430
Function 0x44: Transmit Frame	0x44	0x441
Function 0x45: Abort Transmitter	0x45	0x450
Function 0x46: Abort Receiver	0x46	0x460
Function 0x47: Off-Board Load	0x47	0x470
Function 0x61: Get/Set Interface Record	0x61	0x613
Function 0x62: Get V24 Status	0x62	0x622
Function 0x63: Receive Frame	0x63	0x632
Function 0x64: Read Interface Record	0x64	0x642

In the function descriptions in the following topics, the bit-numbering convention is: The bits in a byte are numbered 0 through 7, where bit 0 is the least significant and bit 7 is the most significant.

> **Note** There is no function for the controlling autodialer across the synchronous dumb card interface. This autodial feature is implemented in the link service itself. The Microsoft link services that support the synchronous dumb card interface first perform the dial operation by sending the dial string containing the server-stored number to a COM port rather than the SDLC chip, and then sending a command to the device driver to raise DTR through a Set V24 Output Status IOCTL.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Equates and Structure Layouts

Many standard operating system device driver error codes are used (for example, "invalid function"), together with a new set of device driver-specific errors. Return codes below 0x80 reflect serious failures.

SNA Modem Status Interface

This section describes the interface to the modem status used by Synchronous Data Link Control (SDLC) and X.25 SNALinks that Microsoft® Host Integration Server 2004 supplies. This interface provides a set of simulated modem lights to show modem status. The modem status interface is intended primarily for the Microgate cards with internal modems, but can be used with any SDLC or X.25 link service to show the modem status.

This interface is intended primarily for independent hardware vendors (IHVs) who wish to provide drivers for their own dumb cards that are directly compatible with SDLC and X.25 SNALinks that Host Integration Server 2004 provides. It can also be used by IHVs who intend to write their own SNALinks but who wish to ensure that their drivers conform to the standard Host Integration Server 2004 model.

This section includes the following topics:

SNA Device Driver Interface to Modem Status

Supporting Modem Status in an SNA Link Service

Modem API Summary

DevIoctl Definitions to Support SNA Modem Status

SNA Device Driver Interface to Modem Status

There are three interfaces from which modem status can be gathered:

- The SNADIS Dumb Card Interface **GetV24Status** IOCTL call that reports the status of the Ring Indicator (DRI), Carrier Detect (DCD), Clear To Send (CTS), and Data Set Ready (DSR) signal lines.
- The SNADIS Dumb Card Interface **SetV24Status** IOCTL call that sets the status of the Data Terminal Ready (DTR) and Request To Send (RTS) signal lines.
- The SNADIS Dumb Card Interface receive and transmit IOCTL calls, used to set the operating mode of the device driver.

Whenever one of the first two interfaces indicates a modem line is high, the corresponding light in the display is lit. However, the transmit and receive IOCTL calls cannot provide a definitive statement as to whether the card is receiving data, only that it is ready to receive data. To work around this limitation and to have the modem lights give a reasonable indication of ordinary data throughput, the following mechanism is recommended:

Simulate the receive and transmit lights with counters and track the number of frames received and transmitted for each link service. The display application uses this information to control the flashing of the receive and transmit lights.

The other topics in this section describe the changes that must be made to the link service for supporting the modem status interface and the interface provided to the display application. Microsoft® Host Integration Server 2004 comes with an application that displays the modem status.

Supporting Modem Status in an SNA Link Service

The implementation of a link service that supports the modem status requires the following:

- A call to the SNA Modem interface to initialize the SNA Modem data structures.
- Modification of the SNA Modem structures as the status changes, as reported by the **DevIoctl** calls.

Independent hardware vendors (IHVs) who use the Microsoft® Host Integration Server 2004 SDLC link service and who fully implement the SNADIS interface do not need to make any changes to use the modem status feature. However, IHVs should check that the status returned by **DevIoctl** calls from their device driver conforms to the requirements described later.

IHVs who provide both the device driver and link service need to implement the code in their link service that initializes the SNA Modem API and updates the modem status information.

Modem API Summary

To simplify the task for independent hardware vendors (IHVs) who want to use this feature, four new entry points have been added to SNALINK.DLL. An IHV who uses these must be linking with IHVLINK.LIB, a stub library that contains the exports library for SNALINK.DLL. This API enables the IHV to simply maintain the contents of a MODEM_STATUS structure. The underlying SNALINK library code handles the communication of this information to the modem lights application.

The modem status functions are as follows.

Function	Description
SNAModemInitialize	Initializes the communication path to the SNA Modem application.
SNAModemAddLink	Adds an SNA link.
SNAModemDeleteLink	Deletes the resources associated with a link.
SNAModemTerminate	Terminates an SNA link.

DevIoctl Definitions to Support SNA Modem Status

The **SNA DevIoctl** interface is modified to update the MODEM_STATUS structure for a link each time a modem status change is detected or caused by a **GetV24** or **SetV24** IOCTL call. Code is manually added to the link service to track the number of frames received and transmitted.

The **DevIoctl** changes are highlighted as follows.

```
#define SETV24STATUS                                              \
         NtDeviceIoControlFile(seldrvrh,NULL,NULL,NULL,&IoStatus, \
                               IoctlCodeSetV24,NULL,0L,           \
                               &pInterfaceRecord->V24Out,1L);     \
         if (SavedIROut != (InterfaceRecord.V24Out &              \
                            (MASK_DTR | MASK_RTS)    ))           \
         {                                                        \
           SavedIROut = (pInterfaceRecord->V24Out &               \
                         (MASK_DTR | MASK_RTS)    );              \
           pSharedMem->V24Out = pInterfaceRecord->V24Out;         \
         }

#define GETV24STATUS(rc)                                          \
         rc |= NtDeviceIoControlFile(seldrvrh,NULL,NULL,NULL,     \
               &IoStatus,IoctlCodeGetV24,NULL,0L,NULL,0L);        \
         rc |= READINTERFACERECORD;                               \
         if (SavedIRIn != (InterfaceRecord.V24In &                \
                     (MASK_CTS | MASK_DSR | MASK_DCD| MASK_DRI))) \
         {                                                        \
             SavedIRIn = (InterfaceRecord.V24In &                 \
                     (MASK_CTS | MASK_DSR | MASK_DCD| MASK_DRI)); \
             pSharedMem->V24In = InterfaceRecord.V24In;           \
         }
```

pSharedMem is a pointer to the MODEM_STATUS structure for this link service.

V24In and *V24Out* are of type char and are used to notify the display application when status changes, not each time it is read or set.

SNA Performance Monitor Interface

This section describes the interface for performance monitoring (Perfmon) used by SNADIS links that Microsoft® Host Integration Server 2004 supplies. This interface is provided to simplify the integration of SNADIS-compliant link services with the Microsoft Windows® 2000 System Monitor applications. It provides a common look-and-feel to all link service performance counters exported by SNADIS links, independent of the vendor and link transport (channel, Twinax, SDLC, X.25, TR, E/Net, and so on).

The performance monitoring statistics maintained for an SNA link service are stored in a series of ADAPTERCOUNTER structures that are members of an ADAPTERPERFDATA structure. These structures are defined in the SEMFPERF.H header file.

Three API entry points are exported from IHVLINK.DLL (and the IHVLINK.LIB import library) that are used by the Perfmon API. These functions should be called in the order noted below at link service initialization time.

To support performance monitoring, an SNA Link driver first calls SNAInitLinkPerfmon to initialize data structures used by the Perfmon application. This call should be followed with a call to the function SNAGetLinkPerfArea, which returns a shared mutex handle and a pointer to the shared data area for the **ADAPTERPERFDATA** structure used by the Perfmon application to store the link statistics. This handle and shared memory data area parameter are the returned values from **SNAInitLinkPerfmon**. Finally, the SNAGetPerfValues function is called to fill in the *ServiceNameIndex* and *FirstCounterIndex* fields so that the Perfmon application knows where to get the descriptions of the performance counters from the registry.

After these three calls have been made, the SNA link driver simply maintains the count members in the **ADAPTERCOUNTER** structures that make up the **ADAPTERPERFDATA** structure, incrementing the count member whenever data is received, connections fail, and other events occur. The Perfmon application accesses these counters to display Host Integration Server 2004 performance monitoring data statistics.

Network Integration Security Guides

The network integration features of Microsoft® Host Integration Server 2004 fall into several areas. Each area has a Security guide.

This section contains:

- APPC Programmer's Security Guide
- CPI-C Programmer's Security Guide
- LUA Programmer's Security Guide
- SNA Print Server Data Filter Programmer's Security Guide

APPC Programmer's Security Guide

The following topics discuss security as it applies to the APPC section of the Microsoft® Host Integration Server 2004 SDK.

About APPC security for developers

This section discusses security practices and issues that apply to C-language applications that you write to use Advanced Program-to-Program Communications (APPC) to exchange data in a Systems Network Architecture (SNA) environment.

Conversation Security

- Owners of APPC transaction programs may want to allow only a limited set of users to start the program. APPC provides a mechanism, called APPC conversation security, where the client transaction program supplies credentials to the server to gain access to the program. You can find more information on conversation security in the section: APPC Security.

Several APPC verbs create a connection with a remote LU. When creating a connection with a remote LU, credentials may be required to establish access. The **security** parameter controls conversation security, and the **pwd** and **user_id** parameters specify the information used to validate the user on the host.

Conversational security is documented in the topic Conversation Security, and in the reference pages for the following APPC verbs:

- ALLOCATE
- MC_ALLOCATE
- SEND_CONVERSATION
- MC_SEND_CONVERSATION

Session Security configuration using SNACFG

You can use the utility SNACFG to set session security for a remote LU. Possible values are none, use a plaintext key, and use a scrambled key.

Automatic Login

The configuration of Host Integration Server 2004 to support automatic login is discussed in the topic Support for CPI-C Automatic Logon.

Setting the service key with CNOS

You can specify a master or service key using the **key** parameter when changing the number of sessions with the CNOS verb. This is a plaintext parameter, and is valid if the keylock feature has been secured.

CPI-C Programmer's Security Guide

The following topics discuss security as it applies to the CPI-C section of the Microsoft® Host Integration Server 2004 SDK.

About CPI-C security for developers

The Common Programming Interface for Communications (CPI-C) is a platform-independent API designed to simplify the use APPC verbs, and has many of the same issues and features as APPC.

This section discusses security practices and issues that apply to C-language applications that you write to use CPI-C to exchange data between a Host Integration Server system and a computer or computers in a Systems Network Architecture (SNA) environment.

Session Security configuration using SNACFG

You can use the utility SNACFG to set session security for a remote LU. Possible values are none, use a plaintext key, and use a scrambled key.

Conversation Security in CPI-C

Conversation security in CPI-C controls who can connect to a remote LU. You can find more information in the topic Conversation Security.

A programmer controls conversation security using the Set_Conversation_Security_Type call and sets user credentials using the Set_Conversation_Security_User_ID and Set_Conversation_Security_Password call from the CPI-C SDK.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

LUA Programmer's Security Guide

The following topics discuss security as it applies to the LUA section of the Microsoft® Host Integration Server 2004 SDK.

About LUA security for developers

LUA presents a simple API that enables programmatic control over the SNA messages. LUA has a simple structure, but exposes a complex data stream, that associated with SNA messages.

Since LUA is a low-level interface, the programmer must be especially vigilant on security issues.

Threats and mitigations for LUA

Programmers who use this feature should be aware of the following security practices and issues.

The data stream between Host Integration Server and the Mainframe is not encrypted.

LUA provides no encryption for the data stream between Host Integration Server and the Mainframe.

SNA Print Server Data Filter Programmer's Security Guide

The following topics discuss security as it applies to the APPC section of the Microsoft® Host Integration Server 2004 SDK.

Threats and mitigations for SNA Print Server Data Filter

Programmers who use the SNA Print Server Data Filter should be aware of the following security issue.

Store DLLs in a secure location

The DLLs which support the SNA Print Server Data Filter API can be configured by an administrator or developer. Because of this, the DLLs should be stored in a secure location. The default installation directory is secure. If this location is customized, by an administrator or developer, the new location should also be secured.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Administration and Management Programmer's Guide

The following section describes how to use Windows® Management Instrumentation (WMI) to programmatically manage different tasks for Microsoft® Host Integration Server.

This section contains:

- About WMI and HIS
- Using WMI with HIS

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

About WMI and HIS

Windows® Management Instrumentation (WMI) is a component of the Microsoft® Windows operating system that provides management information and control in an enterprise environment. In the context of Microsoft Host Integration Server, WMI provides a programming and scripting interface for four major administrative tasks: configuration, run-time control, health monitoring, and trace capturing.

This section contains:

- About WMI and the Host Integration Server Architecture
- What You Can Do to Administer HIS with WMI
- What You Need to Know Before Programming for WMI and HIS
- Supported Platforms for Administering with WMI

About WMI and the Host Integration Server Architecture

The architecture of the Windows® Management Instrumentation (WMI) technology includes management applications, managed objects, providers, and the management infrastructure.

Management Applications

A management application is a Microsoft® Windows-based application or service that processes or displays data from a managed object. A management application can perform a variety of tasks in a Host Integration Server (HIS) environment, such as configuring servers running HIS, measuring performance, reporting outages, and correlating data. The management application is what you will probably be creating using this Programmer's Guide.

Managed Objects

A managed object represents a logical or physical enterprise component. A managed object is modeled in WMI using the Common Information Model (CIM), and is accessed by a management application through the WMI programming interface. A managed object in the HIS 2004 environment can be any component of the system, from a link service device driver communicating with hardware to software configuration information about users and connected logical units (LUs).

WMI Providers

A WMI provider is a COM object that exposes an interface to a managed object. The WMI providers supplied with HIS 2004 use the WMI COM API to supply the WMI repository with data from HIS managed objects, to handle requests on behalf of HIS management applications, and to generate notifications of events.

Management Infrastructure

The management infrastructure is made up of WMI and the CIM repository. WMI lets users handle communications between management applications and providers. Users store their static data in the CIM repository. Applications and providers communicate through WMI using a common application programming interface (COM API). The COM API, which supplies event notification and query processing services, is available in the C and C++ programming languages.

The CIM repository holds static management data. Static data is data that does not regularly change. WMI also supports dynamic data, which is data that must be generated on demand because it changes frequently. Data can be placed in the CIM repository by WMI or network administrators. Information can be placed in the CIM repository using either the managed object format (MOF) language and the MOF Compiler or the WMI COM APIs. The WMI providers supplied with HIS 2004 use both mechanisms.

Management applications can access the COM API directly to interact with WMI and the CIM repository to make management requests of HIS 2004. Applications can also use other access methods such as Open Database Connectivity (ODBC) and HTML to make these requests. An ODBC driver for WMI is included with Windows 2000. The protocol used for communication between local and remote components is Distributed Component Object Model (DCOM).

What You Can Do to Administer HIS with WMI

The Windows® Management Instrumentation (WMI) providers for Host Integration Server (HIS) are designed as programming and scripting administration interfaces. As such, these providers are optimized to perform get and set information, and to start and stop services. The following section describes what components of HIS you can administer with WMI, and what tasks you can perform on those components.

This section contains:

- What Administrative Tasks You Can Perform on HIS with WMI
- What Sections of HIS You Can Administer with WMI

What Administrative Tasks You Can Perform on HIS with WMI

With the Windows Management Instrumentation (WMI) providers for Host Integration Server (HIS) you can administer a variety of components on HIS. However, any administration you perform on HIS through WMI is performed through the following tasks:

- Logging on to WMI

  Like most providers, you must first log on to the WMI provider to use it. Therefore, the WMI providers expose the logon and security interfaces. For more information, see Logging On to HIS through a WMI Provider.

- Getting and setting information

  Most of the tasks you will do through WMI will be checking information about different HIS services. You can also set information. For more information, see Accessing an HIS Property through WMI.

- Calling methods

  The methods exposed on the WMI providers for HIS are designed mainly to administer various HIS services. You can administer these HIS services by calling the relevant **Start**, **Stop**, **Pause**, or **Cancel** method through the relevant provider. For more information, see Calling an HIS Method through WMI.

What Sections of HIS You Can Administer with WMI

Host Integration Server (HIS) 2004 is included with Windows Management Instrumentation (WMI) providers that grant administrative access to the following areas:

- Rolling out, configuring, and restoring services

  The SNA Provider WMI Programmer's Reference and SNA Trace Provider WMI Programmer's Reference providers expose information regarding the Setup and rollout procedures for HIS. You can use instances of classes such as **MsSna_LinkService** to set up and administer link services, and the classes derived from **MsSna_Config** to configure your system. For more information, see Configuring HIS with WMI.

- Starting and stopping services and connections

  The **WmiSna** provider exposes the **MsSna_Server**, **MsSna_Service**, and **MsSna_Connection** classes. These classes and their derived classes let you add an SNA service, start and stop services, pause services, and start and stop connections. For more information, see Controlling Services and Connections with WMI.

- Health monitoring

  The **WmiSnaStatus** provider exposes information regarding the SNA service status. **WmiSnaStatus** uses a variety of classes derived from **MsSnaStatus_Event** to describe changes in different parts of your system. For more information, see Health Monitoring for HIS with WMI.

- Trace capturing

  The **WmiSnaTrace** provider supports classes and instances derived from the **MsHisTrace_Config** class, which displays information regarding different configuration files. **WmiSnaTrace** also supports the **MsHisTrace_Event**, which describes an event that occurs whenever a trace is triggered. For more information, see HIS Trace Capturing with WMI.

Additionally, Microsoft Windows 2000 includes several standard WMI providers, such as a registry provider, for accessing information from the system registry. Windows 2000 also supplies a Windows 2000 Event Log provider that enables applications to receive notifications of Windows 2000 and HIS 2004 events and to access the information stored in the Windows 2000 event log. Third-party vendors can create custom providers to interact with managed objects specific to their environment.

What You Need to Know Before Programming for WMI and HIS

To use this guide effectively, you should be familiar with the following:

- Microsoft® Host Integration Server 2004
- SNA concepts
- Windows Management Instrumentation (WMI)
- Microsoft Windows Server™ 2003 operating systems, Windows® XP Professional, Windows 2000 Server

Depending on the API and development tools used, you should also be familiar with the following languages:

- WMI COM/DCOM APIs
- WMI Query Language
- WMI schema and MOF file syntax
- Windows Script Host
- Microsoft Visual Basic® .NET
- Visual Basic for Applications
- Visual Basic Scripting Edition
- JScript®
- Microsoft ODBC
- Microsoft ADO
- Active Server Pages

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Supported Platforms for Administering with WMI

Microsoft Windows Management Instrumentation (WMI) is included as part of Microsoft® Windows Server® 2003, Windows® XP, and Windows 2000. For use with Host Integration Server (HIS), the WMI Software Development Kit version 1.1 or later can be installed on one of the following operating systems:

- Microsoft Windows Server 2003
- Microsoft Windows XP Professional
- Microsoft Windows 2000 Server
- Microsoft Windows 2000 Advanced Server
- Microsoft Windows 2000 Datacenter Server

Windows Script Host (WSH) is installed by default with Windows 2000.

Complete information about WSH is available as part of the Windows 2000 MSDN® Platform SDK.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Using WMI with HIS

There are two main types of programming tasks described in this section: basic tasks and advanced tasks. A basic task is one of the tasks common to most every Windows® Management Instrumentation (WMI) application: logging on to WMI, getting and setting properties, and calling methods. The advanced tasks are those built on the basic tasks, and describe the tasks for which the developers incorporated WMI into Microsoft® Host Integration Server (HIS). Additionally, this section discusses common problems that you may experience when installing and programming WMI for HIS, and solutions to those problems.

This section contains:

- Installing WMI on HIS
- Basic WMI Tasks for HIS
- Advanced WMI Tasks for HIS
- Programming Considerations for Using WMI with HIS

Installing WMI on HIS

Host Integration Server (HIS) 2004 should automatically install the relevant files for you to use the relevant Windows Management Instrumentation (WMI) interfaces. However, you may have to modify the location of certain managed object format (MOF) files if you want to use WMI on remote servers, and you may have to modify certain security settings if you want to have WMI work correctly as well.

This section contains:

- Installing WMI Providers on an HIS Server
- Upgrading to Windows Server 2003 with HIS and WMI
- Setting ASP Security for HIS and WMI

Installing WMI Providers on an HIS Server

Microsoft Host Integration Server (HIS) 2004 provides several Windows Management Instrumentation (WMI) providers. The managed object format (MOF) files used by HIS are installed in the System directory below where HIS is installed. The default location for these files is in the following subdirectory:

> C:\Program Files\Microsoft Host Integration Server\System

To use or view these MOF files on other computers (a computer with the Administration client or end-user client, for example) to develop applications, these MOF files must be copied from the HIS computer. These MOF files document the WMI providers supplied with HIS and the class identifiers (CLSIDs), classes, properties, and methods supported by these providers.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Upgrading to Windows Server 2003 with HIS and WMI

Windows Server 2003 interacts with WMI providers differently than previous editions of the operating system. One change is how the operating system handles the credentials under which the provider is hosted. If you upgraded your HIS computer to Windows Server 2003, you may have to recompile the HIS WMI namespace using updated Windows Server 2003 MOF files. Recompiling with the new MOF files should let you use WMI on Windows Server 2003.

To recompile the HIS WMI namespace for Windows Server 2003

- Use the following syntax on the command prompt:

  Mofcomp -class:forceupdate mof filename

  The following examples show how to recompile each MOF file:

  ```
  Mofcomp -class:forceupdate  wmiHIS_xp.mof
  Mofcomp -class:forceupdate wmiHIS_xp.mof
  Mofcomp -class:forceupdate wmisnastatus_xp.MOF
  Mofcomp -class:forceupdate wmisnatrace_xp.mof
  Mofcomp -class:forceupdate wmisna_xp.mof
  ```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Setting ASP Security for HIS and WMI

WMI scripting using Active Server Pages (ASP) is enabled automatically on Microsoft® Windows® 2000. For the correct security setting for ASP on Windows 2000, it is recommended that you set **Anonymous Authentication** to **Off** and enable **Integrated Windows Authentication** in the Internet Information Services (IIS) configuration for directories with ASP files used with Host Integration Server (HIS). To access HIS configuration and status information, an application or user must have the appropriate administrative rights, which are not available with anonymous authentication. Use the following procedure on Windows 2000 to correctly configure security using ASP.

To configure security using ASP

1. Open the IIS (point to **Start**, **Administrative Tools**, **Services**, and then click **IIS Admin Service** or point to **Start**, **Settings**, **Control Panel**, **Administrative Tools**, **Services**, and then click **IIS Admin Service**).
2. Move to the directory where the ASP files reside.
3. Right-click the directory, and then click **Properties**.
4. When the next dialog box appears, on the **Directory Security** tab, in the **Anonymous Authentication** section, click **Edit**.
5. When the next dialog box appears, clear the **Anonymous Authentication** check box, select **Integrated Windows Authentication**, and then click **OK** to save these settings.

This sets that particular directory to use **Integrated Windows Authentication** instead of **Anonymous Authentication** without affecting any of your other directories. If there are other ASP files that require or allow **Anonymous Authentication** you may want to create a new directory in which you can turn off **Anonymous Authentication** and store the WMI ASPs there. Any script that calls **ExecMethod** from an ASP page should be set up to use **Integrated Windows Authentication** to verify the user trying to run the script.

Additionally, when using a "REFRESH" variable on a Web page and the page is being used to start and stop SNA service through ASP scripting, the Web browser client (Internet Explorer, for example) should set the **Every visit to the page** option, as shown in the following procedure.

To use a Web browser client to start and stop SNA services through ASP scripting

1. Click **Start**, point to **Programs**, and then click **Internet Explorer**.
2. In Internet Explorer, on the **Tools** menu, click **Internet Options**.
3. In the **Internet Options** dialog box, on the **General** tab, in the **Temporary Internet file** section, click **Settings**.
4. In the **Settings** dialog box, in the **Check for newer versions of stored pages** section, make sure that the option **Every visit to the page** is selected.
5. Click **OK**.

If this change is not made on the Web browser client, some ASP scripts do not run correctly because Internet Explorer is caching older results.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Basic WMI Tasks for HIS

Regardless of what you may want to do with WMI, most actions you will perform with WMI are one of the following: logging on to WMI, getting or setting WMI properties, or calling WMI methods.

This section contains:

- Logging On to HIS through a WMI Provider
- Accessing an HIS Property through WMI
- Calling an HIS Method through WMI

Logging On to HIS through a WMI Provider

The first step that you must perform when you create a WMI application or script is to log on to WMI and set the security for your application. You can perform this action either by using the **SWbemLocator** locator object, or with a moniker.

To connect to WMI using SWbemLocator

1. Retrieve a locator object with a call to **CreateObject**.
2. Log on to the namespace with a call to **ConnectServer**.
3. Set the impersonation level with a call to **Security._ImpersonationLevel**.
4. Implement your task.

The following code sample shows how to connect to WMI using **SWbemLocator**:

```
    Set WmiLocator = CreateObject("WbemScripting.SWbemLocator")
    Set WmiNameSpace = WmiLocator.ConnectServer("","root\MicrosoftHIS","", "","", "",0,Nothin
g)

    if Err = 0 then
        'Retrieve the SNA_LU_Lua class
        Set ServerClass = WmiNamespace.Get("MsSNA_LuLua")
        Set Path = ServerClass.Path_
        ServerClass.Security_.impersonationLevel = 3
        Set LU3270 = ServerClass.Instances_
```

Another way you can connect to WMI is by using a moniker. A moniker is essentially a compact version of the above lines of code, and contains the WMI namespace and other connection information.

To connect to WMI using a moniker

1. Call **GetObject** with a moniker in the input parameter.
2. Implement your task.

The following example shows how to connect to WMI using a moniker:

```
    set objService = GetObject("winmgmts:root/microsofthis")
```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Accessing an HIS Property through WMI

Getting and setting an instance is one of the most common retrieval procedures you are most likely to perform on Host Integration Server (HIS) using WMI. You can retrieve an instance using the **GetObject** method, and modify it using the various **Put_** methods.

This section contains:

- Retrieving an Instance
- Retrieving Multiple Instances
- Modifying or Updating an Instance

Retrieving an Instance

You can retrieve a local copy of the instance with a call to **GetObject** with the object path of the instance. The following example shows how to retrieve an IPDLC connection using WMI:

```
Set ObjClass = Namespace.Get("MsSna_ConnectionIpDlc")
```

Besides retrieving a single instance, you can also retrieve collections of WMI instances by querying the WMI database with a **SELECT** statement.

Retrieving Multiple Instances

You can retrieve a local copy of the collection with a call to **ExecQuery**. After you have retrieved an instance, you can modify and update the instance. The following example shows how to retrieve a collection:

```
Set colItems = objWMIService.ExecQuery("Select * from MSSnaStatus_Connection")
```

Modifying or Updating an Instance

After you have retrieved an instance, you can modify your local copy and update your changes to the server.

To modify or update an instance

1. Retrieve a local copy of the object with a call to **GetObject**.
2. If necessary, view the properties of the object with a call to the **Properties_** method.

   Although not required, you may want to know the value of the property before you change it.

3. Make any changes to the object properties with a call to the **SWbemProperty.Value** method.

   The **Value** method changes only the local copy. To save your changes to WMI, you must put the complete copy back in the WMI repository.

4. Put the object back in the WMI repository with a call to the **SWbemObject.Put_** or **SWbemObject.PutAsync_** methods.

   As the names imply, **Put_** updates synchronously while **PutAsync_** updates asynchronously. Either method copies over the original instance with your modified instance. However, to take advantage of asynchronous processing, you must create a **SWbemSink** object.

   The following example shows how to update an instance:

```
    Set ObjClass  = Namespace.Get("MsSna_LinkService_IpDlc")
' Create new link service instance
    Set NewInst   = ObjClass.SpawnInstance_
    ' Set instance properties
    NewInst.NetworkName = Left(strComputerName, 8)
    NewInst.CPName = "IPDLCLS"
    NewInst.NodeID = "05D.FFFFF"
    NewInst.AddressType = 2
    NewInst.LocalAddress = Trim(strLocalAddress)
    NewInst.LENNode = strLenNode
    NewInst.PrimaryNNS = strPrimaryNNS
    if (strBackupNNS <> Empty) then
        NewInst.BackupNNS = strBackupNNS
    end if
    ' Commit the instance
    NewInst.Put_
```

Calling an HIS Method through WMI

You have two options when calling methods through WMI: you may call a WMI method, or a provider method. A WMI method is supported by the WMI infrastructure, and provides general services such as query support or log on access. For example, Logging On to HIS through a WMI Provider and Accessing an HIS Property through WMI describe calling the **GetObject** and **ExecQuery** WMI methods. In contrast, a provider method is supported by the provider, and is unique to each service. Most HIS provider methods deal with controlling services. For example, the **WmiSna** provider supports the **MsSna_ServiceSNA** class, which in turn supports the **Start**, **Stop**, **Pause**, and **Resume** methods. The actual process of calling a WMI method or a provider method is the same as calling any other COM or scripting interface.

Advanced WMI Tasks for HIS

An advanced Windows Management Instrumentation (WMI) task is a task that uses the basic WMI programming tasks to perform an activity specific to Host Integration Server (HIS). Generally, an advanced task deals with setting up HIS on a server, controlling a service or connection, or monitoring an aspect of your enterprise.

This section contains:

- Configuring HIS with WMI
- Controlling Services and Connections with WMI
- Health Monitoring for HIS with WMI
- HIS Trace Capturing with WMI

Configuring HIS with WMI

One of the reasons WMI is implemented in HIS is to help in configuring and updating different technologies in your enterprise. As an extended sample, this section describes how to configure an IP-DLC link service. This sample is a command prompt script that takes as input the host you want to go against and configures an IP--DLC link service and independent session connection to the host.

To configure an IP-DLC link service

1. Retrieve the command prompt instructions.
2. If necessary, retrieve the adapter name.
3. Create the link service.
4. Create the independent session.

The following code sample describes how to configure an IP-DLC link service. The following table describes the relevant command prompt switches:

Command line switch	Description
-p	PrimaryNNS: the Primary Network Node Server
-b	(Optional) BackupNNS: Backup Network Node Server
-d	(Optional) device: Overrides the adapter name discovered
-l	(Optional) LenNode: Used to configure the LEN node (default is 1st)

```
       On Error Resume   Next
   'Declarations and Constants
       Dim strPrimaryNNS
       Dim strBackupNNS
       Dim strLocalAddress
       Dim strLenNode
       Dim strComputerName
       Dim wshEnvProc
   'Defaults
       strPrimaryNNS = ""
       strBackupNNS = ""
       strLocalAddress = ""
       strLenNode = "SNA Service"
   'Get the command line
       Set objArgs = WScript.Arguments
       For I = 0 to objArgs.Count - 1
          select case objArgs(I)
           Case "-p"
               I = I + 1
               strPrimaryNNS = objArgs(I)
           case "-b"
               I = I + 1
               strBackupNNS = objArgs(I)
           case "-d"
               I = I + 1
               strLocalAddress = objArgs(I)
           case "-l"
               I = I + 1
               strLenNode = objArgs(I)
           case else
               Wscript.Echo "Script Usage: "
               Wscript.Echo " -p Primary NNS (Required)"
               Wscript.Echo " -b Backup NNS (Optional)"
               wscript.echo " -d Device Name (Optional)"
               wscript.echo " -l Len Node (Optional)"
               return
          end select
       Next
   'NNS parameter is required
       if strPrimaryNNS = "" then
          Wscript.Echo "Please supply the -p (PrimaryNNS) parameter"
          return
```

```
    end if
'See if we need to get a device
    if strLocalAddress = "" then
       GetAdapterName()
    end if
' Two methods for creating the link service and independent session connection
    CreateIPDLCLinkService
    CreateIndependentSession
```

This section contains:

- Retrieving an Adapter Name
- Creating a Link Service
- Creating an Independent Session
- Handling Errors While Creating a Link Service

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Retrieving an Adapter Name

One of the tasks you must perform when setting up an IPDLC connection is to retrieve the name of the adapter you are connecting with.

To retrieve an adapter name

1. Connect to the namespace on the local computer using **GetObject**.
2. Retrieve the name of the adapter using **ExecMethod** with **GetAllNetworkAdapters** as the method to execute.

The following example shows how to retrieve the name of the first adapter on a system:

```
Private Sub GetAdapterName()
   Dim objService, outParam, objSD, MyArray, nArray
   set objService = GetObject("winmgmts:root/microsofthis")
   set outParam = objService.Execmethod("MsSna_LinkService_IPDLC",
"GetAllNetworkAdapters")
   objSD = Join(outParam.Adapters, ",")
   MyArray = Split(objSD, ",")
   nArray = Ubound(MyArray)
   if nArray < 0 then
      strLocalAddress = ""
   else
      strLocalAddress = MyArray(0)  'default to first one
   end if
End Sub
```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating a Link Service

Another task you may want to perform when setting up an IPDLC connection is to create the link service.

To create a link service

1. Connect to the namespace on the local computer using **GetObject**.
2. Create the new link service instance using **SpawnInstance**.
3. Set the properties of the new link service.
4. Commit the new instance to memory using the **Put_** method.

The following example shows how to create a new link service:

```
private Sub CreateIPDLCLinkService
    on error resume next
' Connect to the namepsace on the local machine
    Set Namespace = GetObject("Winmgmts:root\MicrosoftHIS")
    Set ObjClass  = Namespace.Get("MsSna_LinkService_IpDlc")
' Create new link service instance
    Set NewInst   = ObjClass.SpawnInstance_
    ' Set instance properties
    NewInst.NetworkName = Left(strComputerName, 8)
    NewInst.CPName = "IPDLCLS"
    NewInst.NodeID = "05D.FFFFF"
    NewInst.AddressType = 2
    NewInst.LocalAddress = Trim(strLocalAddress)
    NewInst.LENNode = strLenNode
    NewInst.PrimaryNNS = strPrimaryNNS
    if (strBackupNNS <> Empty) then
        NewInst.BackupNNS = strBackupNNS
    end if
    ' Commit the instance
    NewInst.Put_
    if Err.Number <> 0 then
        PrintWMIErrorThenExit Err.Description, Err.Number
        Wscript.Echo "Link Service Creation Failed " & Err.Description
    Else
        Wscript.Echo "Link Serice Created Successfully"
    end if
End Sub
```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating an Independent Session

After you have created the link service, you need to create an independent session to use.

To create an independent session

1. Create the "Independent Sessions Connection" record.
2. Validate that the session was created.
3. Define the properties of the new connection.

The following code sample shows how to create an independent session:

```
Private Sub CreateIndependentSession
    On error resume next
'Create the Independent Sessions Connection record.
    Set Namespace = GetObject("Winmgmts:root\MicrosoftHIS")
'Validate that the instance was created
    strQuery = "select * from MsSna_LinkService_IpDlc"
    ' this is our instance
    Set instset = Namespace.ExecQuery(strQuery)
    if ( instset.Count<>1) Then
        wscript.echo "No instances found for the link service query " & strQuery
    End If
    For each inst_ in instSet
        Set Inst = inst_ ' This is our new instance
    Next ' end of query workaround
    ' define independent sessions connection
    Set ObjClass = Namespace.Get("MsSna_ConnectionIpDlc")
    Set IndepConn = ObjClass.SpawnInstance_
    IndepConn.Activation = 0
    IndepConn.Adapter = "SNAIP1"
    IndepConn.AllowIncoming = TRUE
    IndepConn.BackupDLUSCPName = ""
    IndepConn.BackupDLUSNetName = ""
    IndepConn.BlockId = "05D"
    IndepConn.Comment = ""
    IndepConn.CompressionLevel = 0
    IndepConn.DLURRetryDelay = 0
    IndepConn.DLURRetryLimit = 0
    IndepConn.DLURRetryType = 0
    IndepConn.DynamicLuDef = TRUE
    IndepConn.IndepSess = TRUE
    IndepConn.LocalControlPoint = ""
    IndepConn.LocalNetName = ""
    IndepConn.Name = Inst.Name
    IndepConn.NodeId = "FFFFF"
    IndepConn.PartnerConnectionName = ""
    IndepConn.PeerRole = 1
    IndepConn.PrimDLUSCPName = ""
    IndepConn.PrimDLUSNetName = ""
    IndepConn.RemoteAddress = ""
    IndepConn.RemoteBlockId = ""
    IndepConn.RemoteControlPoint = ""
    IndepConn.RemoteEnd = 1
    IndepConn.RemoteNetName = ""
    IndepConn.RemoteNodeId = ""
    IndepConn.RetryDelay = 0
    IndepConn.RetryLimit = 0
    IndepConn.Service = strComputerName
    IndepConn.XIDFormat = 1
    IndepConn.Put_
    if Err.Number <> 0 then
        PrintWMIErrorThenExit Err.Description, Err.Number
    End If
End Sub
```

Creating a Link Service

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Handling Errors While Creating a Link Service

As with most scripts, you need to write functions to handle any errors. This error handler scans the Windows Management Instrumentation (WMI) error queue for any relevant error information and posts and displays the error to the user.

The following sample shows how to handle errors while you are creating a link service:

```
Sub PrintWMIErrorThenExit(strErrDesc, ErrNum)
    On Error Resume Next
    Dim objWMIError : Set objWMIError =    CreateObject("WbemScripting.SwbemLastError")
    wscript.echo TypeName(objWMIError)

    If ( TypeName(objWMIError) = "Empty" ) Then
    wscript.echo strErrDesc & " (HRESULT: " & Hex(ErrNum) & ")."
    Else
    wscript.echo "Extended error information:"
    wscript.echo objWMIError.Description
    Set objWMIError = nothing
    End If
    Exit sub
End Sub
```

Controlling Services and Connections with WMI

Another task that Windows Management Instrumentation (WMI) can perform is accessing services and connections throughout Host Integration Server (HIS). Two common procedures in this realm are displaying the status of all current connections, and retrieving information about a specified connection.

This section contains:

- Displaying Connection Status
- Retrieving Connection Information

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Displaying Connection Status

Retrieving the status of a connection is a common task that you might want to perform with WMI.

To display the status of a connection

1. Connect to the namespace using **GetObject** with a moniker in the parameter.
2. Enumerate **MsSnaStatus_Connections** using **ExecQuery**.
3. Display error codes if necessary.

The following example shows how to display the status of all the connections defined in Host Integration Server (HIS):

```
Private Function DisplayConnectionStatus ()
'Variables
   Dim objWMIService, colItems, iCounter, objItem, _
       strReport
'Connect to the namespace
   Set objWMIService = GetObject("winmgmts:\\" & strComputer & "\root\microsofthis")
'Enumerate the Class
   Set colItems = objWMIService.ExecQuery("Select * from MSSnaStatus_Connection")
   iCounter = colItems.Count
   if Err.Number = 0 then
      For Each objItem in colItems
         strReport = "Connection " & objItem.Name & " status is " & objItem.StatusText
         Wscript.Echo strReport
         strReport = ""
      Next
   else
      Wscript.Echo "An error occurred enumerating instances for status " & Err.Number & " " &
Err.Description
   End If
   DisplayConnectionStatus = true
End Function
```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Retrieving Connection Information

Another common task you may want to perform with Windows Management Instrumentation (WMI) for Host Integration Server (HIS) is retrieving information regarding a connection.

To retrieve connection information

1. Connect to the namespace using **GetObject** with a moniker in the parameter.
2. Retrieve all connection information objects using **ExecQuery**.
3. Display the information as appropriate.

The following code sample shows how to retrieve information about an SDLC connection:

```
On Error Resume Next
strComputer = "."
Set objWMIService = GetObject("winmgmts:\\" & strComputer & "\root\MicrosoftHIS")
Set colItems = objWMIService.ExecQuery("Select * from MsSna_ConnectionSdlc",,48)
For Each objItem in colItems
    Wscript.Echo "Activation: " & objItem.Activation
    Wscript.Echo "Adapter: " & objItem.Adapter
    Wscript.Echo "AllowIncoming: " & objItem.AllowIncoming
    Wscript.Echo "BlockId: " & objItem.BlockId
    Wscript.Echo "Comment: " & objItem.Comment
    Wscript.Echo "CompressionLevel: " & objItem.CompressionLevel
    Wscript.Echo "DialData: " & objItem.DialData
    Wscript.Echo "DynamicLuDef: " & objItem.DynamicLuDef
    Wscript.Echo "LocalControlPoint: " & objItem.LocalControlPoint
    Wscript.Echo "LocalNetName: " & objItem.LocalNetName
    Wscript.Echo "MaxBtu: " & objItem.MaxBtu
    Wscript.Echo "Name: " & objItem.Name
    Wscript.Echo "NodeId: " & objItem.NodeId
    Wscript.Echo "PartnerConnectionName: " & objItem.PartnerConnectionName
    Wscript.Echo "PeerRole: " & objItem.PeerRole
    Wscript.Echo "RemoteBlockId: " & objItem.RemoteBlockId
    Wscript.Echo "RemoteControlPoint: " & objItem.RemoteControlPoint
    Wscript.Echo "RemoteEnd: " & objItem.RemoteEnd
    Wscript.Echo "RemoteNetName: " & objItem.RemoteNetName
    Wscript.Echo "RemoteNodeId: " & objItem.RemoteNodeId
    Wscript.Echo "RetryDelay: " & objItem.RetryDelay
    Wscript.Echo "RetryLimit: " & objItem.RetryLimit
    Wscript.Echo "SdlcContactLimit: " & objItem.SdlcContactLimit
    Wscript.Echo "SdlcContactTO: " & objItem.SdlcContactTO
    Wscript.Echo "SdlcDataRate: " & objItem.SdlcDataRate
    Wscript.Echo "SdlcDuplex: " & objItem.SdlcDuplex
    Wscript.Echo "SdlcEncoding: " & objItem.SdlcEncoding
    Wscript.Echo "SdlcIdleLimit: " & objItem.SdlcIdleLimit
    Wscript.Echo "SdlcIdleTO: " & objItem.SdlcIdleTO
    Wscript.Echo "SdlcLeasedLine: " & objItem.SdlcLeasedLine
    Wscript.Echo "SdlcMultiPrimary: " & objItem.SdlcMultiPrimary
    Wscript.Echo "SdlcPollAddress: " & objItem.SdlcPollAddress
    Wscript.Echo "SdlcPollLimit: " & objItem.SdlcPollLimit
    Wscript.Echo "SdlcPollRate: " & objItem.SdlcPollRate
    Wscript.Echo "SdlcPollTO: " & objItem.SdlcPollTO
    Wscript.Echo "SdlcStandby: " & objItem.SdlcStandby
    Wscript.Echo "SdlcSwitchTO: " & objItem.SdlcSwitchTO
    Wscript.Echo "Service: " & objItem.Service
    Wscript.Echo "StatusText: " & objItem.StatusText
    Wscript.Echo "XIDFormat: " & objItem.XIDFormat
Next
```

Health Monitoring for HIS with WMI

Health monitoring refers to viewing the current status of different aspects of Host Integration Server (HIS) through the **WmiSnaStatus** provider. You can access **WmiSnaStatus** provider in the same manner as you would any other instance and method provider. You use **ExecQuery** to query for the relevant information, and then display the information to screen or write the information to a log file. Some **WmiSnaStatus** classes also have methods that let you start and stop related services.

To monitor the health of HIS with WMI

1. Connect to the namespace using **GetObject** with a moniker in the parameter.
2. Retrieve the object representing the SNA Status provider using **ExecQuery**.
3. Use the information gathered from the **ExecQuery** as appropriate.

You can see an example of health monitoring in the Displaying Connection Status code sample.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

HIS Trace Capturing with WMI

Trace capturing refers to the process of viewing trace logs. For Host Integration Server (HIS), this typically refers to collating data stored in trace log objects into a single file and saving it to a specified location. You can capture SNA trace information in the same manner as you would retrieve any other information from WMI. You use **ExecQuery** to make a call to the relevant object, and then write the information to the location you want.

To capture a trace

1. Connect to the namespace using **GetObject** with a moniker in the parameter.
2. Retrieve the objects representing the SNA Application using **ExecQuery**.

   The core functionality of capturing a trace can be described in the following code:

   ```
   Set colItems = objWMIService.ExecQuery("Select * from MsHisTrace_SNAApplication",,48)
   Set colItems = objWMIService.ExecQuery("Select * from MsHisTrace_SNABase",,48)
   ```

   Everything else in this sample is to support logging to a file.

The following code sample shows how to capture a trace:

```
On Error Resume Next
strComputer = "."
Dim iCounter
'Initialize
    CreateLogFile
    Set objWMIService = GetObject("winmgmts:\\" & strComputer & "\root\MicrosoftHIS")

'Validate TraceSnaApplication
    iCounter = 0
    Set colItems = objWMIService.ExecQuery("Select * from MsHisTrace_SNAApplication",,48)
For Each objItem in colItems
    Wscript.Echo "APPCTrace: " & objItem.APPCTrace
    Wscript.Echo "CPICTrace: " & objItem.CPICTrace
    Wscript.Echo "CSVTrace: " & objItem.CSVTrace
    Wscript.Echo "EnabledTraces: " & objItem.EnabledTraces
    Wscript.Echo "InternalMessageTrace: " & objItem.InternalMessageTrace
    Wscript.Echo "LU62Trace: " & objItem.LU62Trace
    Wscript.Echo "LUATrace: " & objItem.LUATrace
    Wscript.Echo "T3270Trace: " & objItem.T3270Trace
    iCounter = iCounter + 1
Next

if iCounter > 0 then
    Wscript.Echo "Number of Instances found " & iCounter
else
    Wscript.Echo "No Instances Found"
End If

    iCounter = 0
    Set colItems = objWMIService.ExecQuery("Select * from MsHisTrace_SNABase",,48)
For Each objItem in colItems
    Wscript.Echo "EnabledTraces: " & objItem.EnabledTraces
    Wscript.Echo "InternalMessageTrace: " & objItem.InternalMessageTrace
    Wscript.Echo "LU62Trace: " & objItem.LU62Trace
    Wscript.Echo "T3270Trace: " & objItem.T3270Trace
    iCounter = iCounter + 1
Next

if iCounter > 0 then
    Wscript.Echo "Number of Instances found " & iCounter
else
    Wscript.Echo "No Instances Found"
End If
```

Programming Considerations for Using WMI with HIS

The following section discusses various issues that you need to know about when programming Windows Management Instrumentation (WMI) with Host Integration Server (HIS).

This section contains:

- Using HIS and WMI on a Backup Server
- Using Duplicate LU Pools with HIS and WMI

Using HIS and WMI on a Backup Server

There are some restrictions on using Windows Management Instrumentation (WMI) and Host Integration Server (HIS) 2004 regarding connections to backup servers. The Snabase works to synchronize the information in the COM.CFG configuration file on the primary server across all backup servers. Each backup server has a local copy of the COM.CFG file from this synchronization process. WMI has a limitation that it will not attempt to read the local backup server's copy of COM.CFG if the primary server is alive. This request will always be forwarded to the primary server.

A client that connects to a WMI provider running on a backup server cannot retrieve any information or make configuration changes. This is a limitation of DCOM which does not permit impersonation outside the local computer. When a client on one computer connects to a WMISNA provider on another computer that is a backup server, the client is using DCOM to connect to the backup HIS computer. When the WMI provider on the backup server tries to access the COM.CFG file from the primary server, this is not allowed by DCOM because the application is trying to impersonate the user across the computer boundary.

You can work around this limitation on Windows 2000 using delegation.

The limitation against accessing a remote COM.CFG file does not apply when the primary server is down. In this case the server will fail-over to a backup and use replicated copies.

Using Duplicate LU Pools with HIS and WMI

A VBScript ImportExport sample program written in Microsoft Visual Basic® Scripting Edition (VBScript) is provided as part of the Host Integration Server (HIS) SDK. This tool enables configuration information from HIS to be exported and saved to a text file using Windows Management Instrumentation (WMI) in MOF format. This text file can also be changed and imported using this sample program to change configuration information.

A potential problem using WMI can occur with duplicate LU pools that can be illustrated using this sample program. Typically, exporting and re-importing the MOF file would not create duplicates. However, the HIS WMI provider allows pool-to-workstation association instances to be duplicated because, by design, duplicates of this type of object are allowed. You can associate the same pool to the same workstation or user multiple times. This is used by emulators to create more sessions for clients. Therefore, you cannot identify one such association from another. The WMISNA provider, WMISNA.DLL, always creates new associations of these types, even if an association with the same pair (Pool, Wks) already exists. This object type is allowed only in this specific case. However, this can create a problem for applications developed using WMI (the Import/Export sample, for example) if the application does not know not to create the duplicates.

The follow sequence illustrates this issue using the ImportExport sample:

1. Use SNA Manager to create a pool workstation association.
2. Export the SNA configuration to a MOF file using the ImportExport utility.
3. Import that same MOF file again using the ImportExport utility.
4. Duplicate pool-workstation associations are created.

The result is that if a client uses the import/export sample or a similar application developed using WMI on a HIS configuration that has pool-to-workstation associations, then the number of associations will effectively double after running the sample. The workaround using the ImportExport sample would be as follows:

1. Export the configuration to a MOF file.
2. Remove the pool to workstation associations from the MOF file that was just created.
3. Re-import the MOF file.

When importing the configuration from one domain to another using the ImportExport sample or a similar application developed using WMI, then step 2 should be ignored. Typically, WMI applications should copy an existing configuration to a blank configuration file so this condition does not occur.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Messaging Programmer's Guide

This section of the Microsoft® Host Integration Server 2004 SDK describes the extensions and components that make up Microsoft MSMQ-MQSeries Bridge.

For general information about developing for MSMQ-MQSeries Bridge, see Messaging Programmer's Reference.

For sample programs illustratating MSMQ-MQSeries Bridge, see Messaging Samples.

This section contains:

- MSMQ-MQSeries Bridge Programmer's Guide

MSMQ-MQSeries Bridge Programmer's Guide

The MSMQ-MQSeries Bridge provides the ability to send and receive messages between Microsoft® Message Queuing (also known as MSMQ) and IBM MQSeries easily and efficiently. The MSMQ-MQSeries Bridge Extensions enable a programmer to develop and control how these message transfers will occur and how properties of a message are translated.

The main programming issues when using the MSMQ-MQSeries Bridge Extensions fall into three areas:

- Queue addressing
- Message conversion
- Limitations to specific API functions

Queue addressing deals with how to specify the name of an MQSeries destination queue in an MSMQ API call, or the name of an MSMQ destination queue in an MQSeries API call. Message conversion deals with how the MSMQ-MQSeries Bridge converts MSMQ message properties to MQSeries message data structures, and how the MSMQ-MQSeries Bridge converts MQSeries message data structures to MSMQ properties. These topics are covered in detail in separate sections below. Limitations to the MSMQ-MQSeries Bridge Extensions are discussed in detail in the section on programming considerations.

This section contains:

- Platforms Supported by MSMQ-MQSeries Bridge Extensions
- Queue Addressing Using MSMQ-MQSeries Bridge
- Converting Messages Using MSMQ-MQSeries Bridge
- MSMQ-MQSeries Bridge Extensions Mechanism
- Programming Considerations Using MSMQ-MQSeries Bridge Extensions
- Registry Settings Used By MSMQ-MQSeries Bridge Extensions

Platforms Supported by MSMQ-MQSeries Bridge Extensions

The MSMQ-MQSeries Bridge Extensions can access message queues on IBM MQSeries systems through SNA LU 6.2 or TCP/IP using Microsoft® Host Integration Server 2004 and MSMQ-MQSeries Bridge:

On Windows 2000, The MSMQ-MQSeries Bridge requires that Message Queuing (also known as MSMQ) be set up as a Message Queuing server, not a workgroup, with routing enabled. MSMQ-MQSeries Bridge Manager, which is used to configure and manage MSMQ-MQSeries Bridge, can be installed on any of the platforms supported by Host Integration Server 2004.

For more information on platforms supported by the MSMQ-MQSeries Bridge, see the Host Integration Server 2004 Installation Guide topic Hardware and Software Requirements.

Queue Addressing Using MSMQ-MQSeries Bridge

This section explains how to specify the name of an MQSeries destination queue in a Message Queuing (also known as MSMQ) call, or the name of a Message Queuing destination queue in an MQSeries call. This information is needed to specify the destination queue where you are sending a message.

This section contains:

- Addressing an MQSeries Queue in Message Queuing
- Sending a Message Queuing Message to an MQSeries Queue
- Addressing a Message Queuing Queue in MQSeries
- Sending a Message to a Message Queuing Queue in MQSeries

Addressing an MQSeries Queue in Message Queuing

In Message Queuing, address MQSeries queues as if they are on the Message Queuing network. For the Message Queuing computer name, specify the MQSeries Queue Manager name. For the Message Queuing queue name, specify the MQSeries queue name.

For example, if the MQSeries Queue Manager is MQS1, and the queue name is **MQS_QUEUE4**, the Message Queuing path name is **MQS1\MQS_QUEUE4**.

Sending a Message Queuing Message to an MQSeries Queue

To send a message to an MQSeries queue, you follow the normal Message Queuing (also known as MSMQ) procedure, which is to determine the Message Queuing format name corresponding to the path name. More precisely, you must determine the format name of the Message Queuing foreign queue representing the MQSeries queue. If the foreign queue does not already exist, you can create it and determine its format name by calling **MQCreateQueue**. If the foreign queue already exists, you can call **MQPathNameToFormatName**, or you can determine the format name in Message Queuing Explorer.

Call **MQOpenQueue** with the format name argument to open the queue for send access.

Call **MQSendMessage** and specify the destination queue handle returned by **MQOpenQueue**.

In the MSMQ-to-MQSeries direction, MSMQ-MQSeries Bridge sends transacted messages using the MSMQ to MQS message pipe and untransacted messages using the MSMQ to MQS transactional message pipe.

Addressing a Message Queuing Queue in MQSeries

There are two ways to address a Message Queuing (also known as MSMQ) queue from MQSeries:

- By the Message Queuing format name
- By the Message Queuing path name

By either method, you specify the name in the object descriptor (MQOD structure) of the MQSeries message.

Note MSMQ-MQSeries Bridge supports the following types of format names:

```
PUBLIC=<GUID>
PRIVATE=<machine GUID>\<file number>
DIRECT=OS:<Path name>
```

Converting Messages Sent from MQSeries to Message Queuing

Sending a Message to a Message Queuing Queue in MQSeries

To send a message from MQSeries to Message Queuing (also known as MSMQ), you specify the Message Queuing format or path name of the destination queue in the object descriptor. Call **MQOPEN** to open the queue. Call **MQPUT** or **MQPUT1** to send the message.

The addressing syntax enables you to send a message by either MQS->Message Queuing message pipe or MQS->Message Queuing transactional message pipe.

Converting Messages Using MSMQ-MQSeries Bridge

This section describes how the MSMQ-MQSeries Bridge converts Message Queuing (also known as MSMQ) message properties to MQSeries message data structures and how MQSeries data structures are converted to Message Queuing message properties.

When the MSMQ-MQSeries Bridge transmits a message, it converts the message properties between the Message Queuing and MQSeries formats. When equivalent properties exist in the two systems, the MSMQ-MQSeries Bridge assigns the property values directly. For example, the Message Queuing **messagebody** property is converted to the MQSeries **messagebuffer**. The Message Queuing **messagebodylength** is converted to the MQSeries **messagebufferlength**.

When partially equivalent properties exist in the two systems, the MSMQ-MQSeries Bridge assigns the properties according to conversion rules. For example, the MQSeries property **MQMD.Report** is converted to the Message Queuing properties **PROPID_M_ACKNOWLEDGE** and **PROPID_M_JOURNAL**.

When a property has no equivalent, the MSMQ-MQSeries Bridge either ignores the property or assigns a default value. For example, the Message Queuing property **PROPID_M_AUTH_LEVEL** refers to a specific Message Queuing authentication method that is not supported by MQSeries. In a message sent from Message Queuing to MQSeries, this property is ignored. In a message received by Message Queuing from MQSeries, the MSMQ-MQSeries Bridge assigns the Message Queuing default value to the property.

You can supplement or override the conversions described here using the Message Queuing message extension property (**PROPID_M_EXTENSION**). For information about overriding the default conversions, see Using Message Extensions.

When you send a message from Message Queuing to IBM MQSeries, MSMQ-MQSeries Bridge converts the Message Queuing message properties to an MQSeries data structure. To do this, MSMQ-MQSeries Bridge maps the various message properties of the Message Queuing message as nearly as possible to equivalent MQSeries fields. The following sections describe the conversion rules by which this is done.

This section contains:

- Converting Messages Sent from Message Queuing to MQSeries
- Converting Messages Sent from MQSeries to Message Queuing

Converting Messages Sent from Message Queuing to MQSeries

The information in this section applies to messages that you send from Message Queuing (also known as MSMQ) to MQSeries. For messages sent from MQSeries to Message Queuing, see Converting Messages Sent from MQSeries to Message Queuing.

This section contains two main subsections, which provide essentially the same information but from complementary points of view.

The first section describes the conversion rules from the sender's point of view, and explains how MSMQ-MQSeries Bridge converts each Message Queuing property that you include in a message.

The second section explains the rules from the receiver's point of view. This section describes how MSMQ-MQSeries Bridge builds a complete MQSeries message containing all the needed fields, whether or not they have exact Message Queuing equivalents.

You can supplement or override the conversions described in this section by using the Message Queuing message extension property (**PROPID_M_EXTENSION**).

This section contains:

- Converting Message Queuing Properties
- Building an MQSeries Message

Converting Message Queuing Properties

This topic explains how MSMQ-MQSeries Bridge converts the Message Queuing (also known as MSMQ) properties that you include in a message to MQSeries. For information about MQSeries fields that have no Message Queuing equivalents, see Building an MQSeries Message.

This section contains:

- Message Body (PROPID_M_BODY)
- Queue Format Names (PROPID_M_..._QUEUE)
- Message Class (PROPID_M_CLASS)
- Message Expiration (PROPID_M_TIME...)
- Message Acknowledgment (PROPID_M_ACKNOWLEDGE)
- Other Message Queuing Properties with Equivalent Properties
- Unconverted Properties
- Transaction Properties

Message Body (PROPID_M_BODY)

The Message Queuing (also known as MSMQ) message body is equivalent to the MQPUT or MQGET message buffer of MQSeries. The length of the MQPUT buffer is the Message Queuing message body size.

The following table lists the Message Queuing properties and the MQSeries fields to which they are converted.

Message Queuing property	Converted to MQSeries field
PROPID_M_BODY	Message buffer
PROPID_M_BODY_SIZE	Message buffer length

Queue Format Names (PROPID_M_..._QUEUE)

Each Message Queuing (also known as MSMQ) message contains the format name of a destination queue, and optionally the format names of response or administration queues. The MSMQ-MQSeries Bridge converts the names to the equivalent MQSeries object and Queue Manager names.

If a message contains both a response queue and an administration queue, MSMQ-MQSeries Bridge ignores the administration queue.

The following table lists the Message Queuing properties and the MQSeries fields to which they are converted.

Message Queuing properties	Converted to MQSeries fields
PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN	MQOD.ObjectName and MQOD.ObjectQMgrName
PROPID_M_RESP_QUEUE and PROPID_M_RESP_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr
PROPID_M_ADMIN_QUEUE and PROPID_M_ADMIN_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr

Message Class (PROPID_M_CLASS)

MSMQ-MQSeries Bridge converts the Message Queuing (also known as MSMQ) message class (PROPID_M_CLASS) to the MQSeries message type and feedback. It translates the message class values according to the following table.

Value of Message Queuing property	**Converted to MQSeries value**	
PROPID_M_CLASS	MQMD.MsgType	MQMD.Feedback
MQMSG_CLASS_NORMAL	MQMT_REQUEST or MQMT_DATAGRAM	MQFB_NONE
MQMSG_CLASS_ACK_REACH_QUEUE	MQMT_REPORT	MQFB_COA
MQMSG_CLASS_ACK_RECEIVE		MQFB_COD
MQMSG_CLASS_NACK_RECEIVE_TIMEOUT		MQFB_EXPIRATION
MQMSG_CLASS_NACK_REACH_QUEUE_TIMEOUT		MQFB_EXPIRATION
MQMSG_CLASS_NACK_Q_EXCEED_QUOTA		MQRC_Q_FULL
MQMSG_CLASS_NACK_ACCESS_DENIED		MQRC_NOT_AUTHORIZED
MQMSG_CLASS_NACK_ERROR		MQFB_APPL_TYPE_ERROR
Any other value		MQFB_NONE

> **MQMSG_CLASS_NORMAL** is converted to **MQMD_REQUEST** if the message includes a response queue (**PROPID_M_RESP_QUEUE**) or if **PROPID_M_RESP_QUEUE** is missing, NULL, or an empty string.

Message Expiration (PROPID_M_TIME...)

Message Queuing (also known as MSMQ) provides two message expiration properties, **PROPID_M_TIME_TO_REACH_QUEUE** and **PROPID_M_TIME_TO_BE_RECEIVED**, both in units of seconds. MQSeries provides a single expiration field, **MQMD.Expiry**, whose units are tenths of a second.

MSMQ-MQSeries Bridge converts the values as listed in the following table.

Value of Message Queuing properties PROPID_M_TIME_TO_REACH_QUEUE and PROPID_M_TIME_TO_BE_RECEIVED	**Converted to MQSeries value of MQMD.Expiry**
Both values are INFINITE	MQEI_UNLIMITED
One or both values are not INFINITE	Ten times the smaller of the two Message Queuing values

> **Note** Message Queuing typically interprets **INFINITE** as 90 days. In practice, the MSMQ-MQSeries Bridge does not apply the **INFINITE** conversion because Message Queuing decrements the values slightly during transmission. If you need an **MQMD.Expiry** value of exactly **MQEI_UNLIMITED**, you should send this value in the message extension.

Message Acknowledgment (PROPID_M_ACKNOWLEDGE)

MSMQ-MQSeries Bridge supports the Message Queuing (also known as MSMQ) and MQSeries acknowledgment mechanisms. You can send a Message Queuing message to MQSeries and receive an automatic acknowledgment from the MQSeries Queue Manager.

To do this, set the Message Queuing acknowledgment property (**PROPID_M_ACKNOWLEDGE**) to a value that requests an acknowledgment. Also specify the administration or response queue name (**PROPID_M_ADMIN_QUEUE** or **PROPID_M_RESP_QUEUE**), to which the acknowledgment is sent. For more information about queue format names, see Queue Format Names (PROPID_M_..._QUEUE).

MSMQ-MQSeries Bridge converts the acknowledgment property to the MQSeries **MQMD.Report** field, as listed in the following table. When MQSeries receives the message, it returns the appropriate acknowledgment through MSMQ-MQSeries Bridge.

Value of Message Queuing property PROPID_M_ACKNOWLEDGE	Converted to MQSeries value of MQMD.Report
MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE	MQRO_EXCEPTION | MQRO_COA
MQMSG_ACKNOWLEDGMENT_FULL_RECEIVE	MQRO_EXCEPTION | MQRO_EXPIRATION | MQRO_COD
MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE	MQRO_EXCEPTION
MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE	MQRO_EXCEPTION | MQRO_EXPIRATION
MQMSG_ACKNOWLEDGMENT_NONE	MQRO_NONE

If both PROPID_M_ACKNOWLEDGE and PROPID_M_JOURNAL are included in a Message Queuing message, the value of the MQSeries **MQMD.Report** field is computed by a bitwise or of the values converted from the two Message Queuing properties. For more information about other Message Queuing properties, see Other Message Queuing Properties with Equivalent Properties.

If the **MSMQ_PROPID_M_ACKNOWLEDGE** property has a value of **MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE**, the value of MQSeries **MQMD.Report** field is computed by a bitwise or **of MQRO_EXCEPTION** and **MQRO_COA**.

If the **MSMQ_PROPID_M_ACKNOWLEDGE** property has a value of **MQMSG_ACKNOWLEDGMENT_FULL_RECEIVE**, the value of MQSeries MQMD.Report field is computed by a bitwise or of **MQRO_EXCEPTION**, **MQRO_EXPIRATION**, and **MQRO_COD**.

If the Message Queuing **PROPID_M_ACKNOWLEDGE** property has a value of **MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE**, the value of MQSeries MQMD.Report field is computed by a bitwise or of **MQRO_EXCEPTION** and **MQRO_EXPIRATION**.

Other Message Queuing Properties with Equivalent Properties

The following Message Queuing (also known as MSMQ) properties have MQSeries equivalents. The MSMQ-MQSeries Bridge converts the values of each property as listed in the table.

> **Note** To save space in the table, the prefixes PROPID_M_ and MQMD are omitted from the Message Queuing property names and the MQSeries field names, respectively. For example, the first row of data means that **PROPID_M_BODY_TYPE** is converted to MQMD.Format.

Message Queuing property		**Converted to MQSeries**	
PROPID_M_	**Value**	MQMD	**Value**
BODY_TYPE	VT_BSTR Any other value	Format	MQFMT_STRING MQFMT_NONE
CORRELATIONID	Value (20 bytes)	CorrelId	"FQ2Q" + value
DELIVERY	MQMSG_DELIVERY_ RECOVERABLE EXPRESS	Persistence	MQPER_ PERSISTENT NOT_PERSISTENT
JOURNAL	MQMSG_ DEADLETTER MQMSG_JOURNAL MQMSG_JOURNAL_NONE	Reporta	MQRO_ DEAD_LETTER_Q (Ignored) DISCARD_MSG
LABEL LABEL_LEN	Value	ApplIdentityData	Value (MQCHAR32)
MSGID	Value (20 bytes)	MsgId	"FQ2Q" + value
PRIORITY	0 1 2 3 4 5 6 7	Priority	1 3 4 5 6 7 8 9
SENTTIME	Seconds since Jan. 1, 1970	PutDate PutTime	YYYMMDD format HHMMSSTH format

If both **PROPID_M_ACKNOWLEDGE** and **PROPID_M_JOURNAL** are included in a Message Queuing message, the **MQSeries MQMD.Report** field is computed by a bitwise or of the values converted from the two Message Queuing queuing properties.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Unconverted Properties

The following Message Queuing (also known as MSMQ) properties have no equivalents in MQSeries. The MSMQ-MQSeries Bridge ignores these properties and does not transmit them to MQSeries:

- **PROPID_M_APPSPECIFIC**
- **PROPID_M_ARRIVEDTIME**
- **PROPID_M_AUTH_LEVEL**
- **PROPID_M_AUTHENTICATED**
- **PROPID_M_CONNECTOR_TYPE**
- **PROPID_M_DEST_SYMM_KEY**
- **PROPID_M_DEST_SYMM_KEY_LEN**
- **PROPID_M_ENCRYPTION_ALG**
- **PROPID_M_HASH_ALG**
- **PROPID_M_PRIV_LEVEL**
- **PROPID_M_PROV_NAME**
- **PROPID_M_PROV_NAME_LEN**
- **PROPID_M_PROV_TYPE**
- **PROPID_M_SECURITY_CONTEXT**
- **PROPID_M_SENDER_CERT**
- **PROPID_M_SENDER_CERT_LEN**
- **PROPID_M_SENDERID**
- **PROPID_M_SENDERID_LEN**
- **PROPID_M_SENDERID_TYPE**
- **PROPID_M_SIGNATURE**
- **PROPID_M_SIGNATURE_LEN**
- **PROPID_M_SRC_MACHINE_ID**
- **PROPID_M_TRACE**
- **PROPID_M_VERSION**

Transaction Properties

The following Message Queuing (also known as MSMQ) properties are not converted to MQSeries fields or values:

- **PROPID_M_XACT_STATUS_QUEUE**
- **PROPID_M_XACT_STATUS_QUEUE_LEN**

For more information about transactions, see Transaction Support Using MSMQ-MQSeries Bridge.

Building an MQSeries Message

This section explains how the MSMQ-MQSeries Bridge builds a complete MQSeries message, including all needed fields whether or not they have Message Queuing (also known as MSMQ) equivalents. The conversion to MQSeries fields from Message Queuing properties is listed from the MQSeries perspective.

For information about these same conversion rules from the Message Queuing perspective, see Converting Message Queuing Properties.

This section contains:

- Message Buffer
- Object Descriptor (MQOD)
- Message Descriptor (MQMD)

Message Buffer

The MQPUT or MQGET message buffer of MQSeries is equivalent to the message body property of Message Queuing (also known as MSMQ). The length of the MQPUT buffer is the Message Queuing message body size.

The following table lists the MQSeries fields and the Message Queuing properties from which they are converted.

MQSeries fields	**Converted from Message Queuing property**
Message buffer	PROPID_M_BODY
Message buffer length	PROPID_M_BODY_SIZE

Object Descriptor (MQOD)

The MSMQ-MQSeries Bridge retrieves the MQSeries object descriptor fields from the Message Queuing (also known as MSMQ) format name of the destination queue.

The following table lists the MQSeries fields and the Message Queuing properties from which they are converted.

MQSeries fields	Converted from Message Queuing property
MQOD.ObjectName and MQOD.ObjectQMgrName	PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN

Message Descriptor (MQMD)

Some fields of the MQSeries message descriptor have no equivalent in Message Queuing (also known as MSMQ). The MSMQ-MQSeries Bridge assigns default values to these fields. Alternatively, you can pass explicit values of the MQMD fields using the Message Queuing message extension property (**PROPID_M_EXTENSION**).

The following table lists the MQSeries fields and the default value assigned by MSMQ-MQSeries Bridge.

MQSeries MQMD fields	Default value assigned by MSMQ-MQSeries Bridge
MQMD.AccountingToken	MQACT_NONE
MQMD.CodeCharSetId	MQCCSI_Q_MGR
MQMD.Encoding	MQENC_NATIVE
MQMD.PutApplName	NULL
MQMD.PutApplType	NULL
MQMD.StrucId	MQMD_STRUC_ID
MQMD.Version	MQMD_VERSION_1

Some fields of the MQSeries message descriptor have no equivalent in Message Queuing and the MSMQ-MQSeries Bridge does not assign default values to these fields. You can assign explicit values for these MQMD fields using the Message Queuing message extension property (**PROPID_M_EXTENSION**).

The following table lists the MQSeries fields for which no default value is assigned by MSMQ-MQSeries Bridge.

MQSeries MQMD fields	Default value assigned by MSMQ-MQSeries Bridge
MQMD.UserIdentifier	No default value is assigned

Many of the MQMD fields are equivalent to one or more Message Queuing properties. The conversion rules are listed in the following table.

You can override the conversion rules by passing explicit MQMD values in the Message Queuing message extension property.

To save space in the table, the prefix MQMD. is omitted from the MQSeries field names. For example, the first row of data means that MQMD.ApplIdentityData is built from the Message Queuing properties **PROPID_M_LABEL** and **PROPID_M_LABEL_LEN**.

MQSeries MQMD field	MQSeries MQMD field value	Converted from Message Queuing property
ApplIdentity	Value (MQCHAR32)	The value of PROPID_M_LABEL and PROPID_M_LABEL_LEN
CorrelId	"FQ2Q" + value	The value of PROPID_M_CORRELATIONID (20 bytes)
Expiry	MQEI_UNLIMITED	Both PROPID_M_TIME_TO_BE_RECEIVED and PROPID_M_TIME_TO_REACH_QUEUE have value of INFINITE
Expiry	10 times the smaller of the two Message Queuing values	PROPID_M_TIME_TO_BE_RECEIVED or PROPID_M_TIME_TO_REACH_QUEUE have a value that is not INFINITE
Feedback	MQFB_EXPIRATION	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_RECEIVE_TIMEOUT
Feedback	MQFB_APPL_TYPE_ERROR	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_REACH_QUEUE_TIMEOUT
Feedback	MQRC_Q_FULL	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_Q_EXCEED_QUOTA
Feedback	MQRC_NOT_AUTHORIZED	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_ACCESS_DENIED
Feedback	MQFB_COA	PROPID_M_CLASS has a value of MQMSG_CLASS_ACK_REACH_QUEUE
Feedback	MQFB_COD	PROPID_M_CLASS has a value of MQMSG_CLASS_ACK_RECEIVE
Feedback	MQFB_NONE	PROPID_M_CLASS has any other value
Format	MQFMT_STRING	PROPID_M_BODY_TYPE has a value of VT_BSTR
Format	MQFMT_NONE	PROPID_M_BODY_TYPE has any other value
MsgId	"FQ2Q" + value	The value of PROPID_M_MSGID (20 bytes)
MsgType	MQMT_DATAGRAM	PROPID_M_CLASS has a value of MQMSG_CLASS_NORMAL
MsgType	MQMT_REQUESTREPORT	PROPID_M_CLASS has any other value
Persistence	MQPER_PERSISTENT	PROPID_M_DELIVERY has a value of MQMSG_DELIVERY_RECOVERABLE
Persistence	MQPER_NOT_PERSISTENT	PROPID_M_DELIVERY has a value of MQMSG_DELIVERY_EXPRESS
Priority	1	PROPID_M_PRIORITY has a value of 0

Priority	3	PROPID_M_PRIORITY has a value of 1
Priority	4	PROPID_M_PRIORITY has a value of 2
Priority	5	PROPID_M_PRIORITY has a value of 3
Priority	6	PROPID_M_PRIORITY has a value of 4
Priority	7	PROPID_M_PRIORITY has a value of 5
Priority	8	PROPID_M_PRIORITY has a value of 6
Priority	9	PROPID_M_PRIORITY has a value of 7
PutDate	YYYMMDD format	The date from the Message Queuing PROPID_M_SENTTIME property which has a value of seconds since January 1, 1970
PutTime	HHMMSSTH format	The time from the Message Queuing PROPID_M_SENTTIME property which has a value of seconds since January 1, 1970
ReplyToQ	Retrieved from Message Queuing format name	The Message Queuing format name from PROPID_M_RESP_QUEUE if this property is included and is not NULL or an empty string
ReplyToQ	Retrieved from Message Queuing format name	The Message Queuing format name from PROPID_M_ADMIN_QUEUE if PROPID_M_RESP_QUEUE is not included or is NULL or an empty string
ReplyToQMgr	Retrieved from Message Queuing format name	The Message Queuing format name from PROPID_M_RESP_QUEUE if this property is included and is not NULL or an empty string
ReplyToQMgr	Retrieved from Message Queuing format name	The Message Queuing format name from PROPID_M_ADMIN_QUEUE if PROPID_M_RESP_QUEUE is not included or is NULL or an empty string
Report	MQRO_EXCEPTION|COA	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
Report	MQRO_EXCEPTION|EXPIRATION|COD	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_FULL_RECEIVE
Report	MQRO_EXCEPTION	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
Report	MQRO_EXCEPTION|EXPIRATION	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
Report	MQRO_NONE	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_NONE
Report	MQRO_DEAD_LETTER_Q	PROPID_M_JOURNAL has a value of MQMSG_DEADLETTER
Report	The Message Queuing value is ignored	PROPID_M_JOURNAL has a value of MQMSG_JOURNAL
Report	MQRO_DISCARD_MSG	PROPID_M_JOURNAL has a value of MQMSG_JOURNAL_NONE

In practice, the MSMQ-MQSeries Bridge does not assign **MQEI_UNLIMITED** as value for MQMD.Expiry because Message Queuing interprets INFINITE values typically as 90 days and decrements them slightly during transmission. To assign an MQMD.Expiry value of exactly **MQEI_UNLIMITED**, send this value in the message extension.

The MSMQ-MQSeries Bridge assigns **MQMT_DATAGRAM** as value for MQMD.MsgType if the Message Queuing **PROPID_M_RESP_QUEUE** is missing, NULL, or an empty string. Otherwise a value of **MQMT_REQUEST** is assigned to MQMD.MsgType.

If both **PROPID_M_ACKNOWLEDGE** and **PROPID_M_JOURNAL** are included in a Message Queing message, MQMD.Report is computed by a bitwise or of the values converted from the two Message Queuing properties.

Converting Messages Sent from MQSeries to Message Queuing

When you send a message from IBM MQSeries to Microsoft® Message Queuing (also known as MSMQ), the MSMQ-MQSeries Bridge converts the message from an MQSeries data structure to a Message Queuing message property. o do this, MSMQ-MQSeries Bridge maps the various data fields of the MQSeries message as nearly as possible to equivalent Message Queuing message properties.

This section describes the conversion rules by which this is done. The information in this section applies to messages that you send from MQSeries to Message Queuing. For messages sent from Message Queuing to MQSeries, see Converting Messages Sent from Message Queuing to MQSeries.

The section contains two main subsections, which provide essentially the same information, but from complementary points of view. The first section describes the conversion rules from the sender's point of view, and explains how the MSMQ-MQSeries Bridge converts each MQSeries field that you include in a message. The second section explains the rules from the receiver's point of view. Use this section to learn how MSMQ-MQSeries Bridge builds a complete Message Queuing message containing all the needed properties, whether or not they have exact MQSeries equivalents.

Besides the conversions described in this section, the MSMQ-MQSeries Bridge transmits the original MQSeries message descriptor fields in the Message Queuing message extension property (**PROPID_M_EXTENSION**).

This section contains:

- Converting MQSeries Fields
- Building a Message Queuing Message

Converting MQSeries Fields

This section explains how the MSMQ-MQSeries Bridge converts the fields of an MQSeries message to Message Queuing (also known as MSMQ). For information about Message Queuing properties that have no MQSeries equivalents, see Building a Message Queuing Message.

This section contains:

- Message Buffer
- Object Descriptor (MQOD)
- Character Substitutions in Object Descriptor Conversion
- Format Name Method of Object Descriptor Conversion
- Path Name Method of Object Descriptor Conversion
- Queue Alias Method of Object Descriptor Conversion
- Examples of Object Descriptor Conversion
- Message Descriptor (MQMD)
- MQMD.Report Field
- MQMD.MsgType and MQMD.Feedback Fields
- MQMD.ReplyToQ and MQMD.ReplyToQMgr Fields
- Unconverted MQSeries MQMD Fields

Message Buffer

The MQGET or MQPUT buffer of MQSeries is equivalent to the message body property of Message Queuing (also known as MSMQ).

The following table lists the MQSeries fields and the Message Queuing properties to which they are converted.

MQSeries fields	**Converted to Message Queuing property**
Message buffer	PROPID_M_BODY
Message buffer length	PROPID_M_BODY_SIZE

Object Descriptor (MQOD)

The MSMQ-MQSeries Bridge converts the MQSeries remote Queue Manager and queue names to the Message Queuing (also known as MSMQ) destination queue name. The MQSeries fields are interpreted as a Message Queuing format name or path name.

The following table lists the MQSeries fields and the Message Queuing properties that they are converted to.

MQSeries fields	**Converted to Message Queuing property**
MQOD.ObjectName and MQOD.ObjectQMgrName	PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN

Character Substitutions in Object Descriptor Conversion

Certain characters are supported in Message Queuing (also known as MSMQ) format names, but not in MQSeries names. When you assign the MQSeries MQOD.ObjectName, the MSMQ-MQSeries Bridge performs character substitutions to the Message Queuing format names. The following table lists special characters in MQSeries names and what MSMQ-MQSeries Bridge converts these characters to in Message Queuing format names.

Characters in MQSeries MQOD field names	Characters substituted in Message Queuing format names
/ (forward slash))	: (colon) or \ (backslash)
_ (underscore)	- (hyphen) or = (equal)
P_ (at start of MQOD.ObjectName)	PRIVATE=

The MSMQ-MQSeries Bridge converts the characters back when it transmits the MQSeries message to Message Queuing. The characters are interpreted according to context to generate a legal Message Queuing name. For example, MSMQ-MQSeries Bridge converts the format name:

```
DIRECT_OS/MACHINE2/QUEUE4
```

to the following:

```
DIRECT=OS:MACHINE2\QUEUE4.
```

Note that this character substitution is only for format names, not for computer or path names. If you want to address Message Queuing path names, do not include hyphens or other characters not supported by MQSeries. For example, the path name:

```
MACHINE2\MY-QUEUE
```

is legal in Message Queuing, but you cannot specify the hyphen character in MQSeries.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Format Name Method of Object Descriptor Conversion

Subject to the following conditions, the MSMQ-MQSeries Bridge interprets the MQSeries MQOD.ObjectName field as the format name of the Message Queuing (also known as MSMQ) destination queue:

- The MQOD.ObjectQMgrName is an MQSeries alias for a Message Queuing computer.
- The MQOD.ObjectName begins with PUBLIC_, P_, or DIRECT_OS/.

If these conditions apply, the MSMQ-MQSeries Bridge converts the MQSeries MQOD.ObjectName to the Message Queuing format name of the destination queue using one of the following methods based on the value of **MQOD.ObjectName**:

```
PUBLIC=<GUID>
PRIVATE=<machine GUID>\<file number>
DIRECT=OS:<path name>.
```

If you know the globally unique identifier (GUID) of the destination queue, the PUBLIC=<GUID> syntax gives better performance than the DIRECT=OS:<path name> syntax. Also note that nontransacted private queues are supported only on the computer running the MSMQ-MQSeries Bridge.

Path Name Method of Object Descriptor Conversion

If the conditions for the format name method do not hold, the MSMQ-MQSeries Bridge interprets MQOD.ObjectQMgrName\MQOD.ObjectName as a Message Queuing (also known as MSMQ) path name. The remote Queue Manager name must be an alias for a computer running Message Queuing that you have previously defined in MQSeries.

For example, if MQOD.ObjectQMgrName is MACHINE2 and MQOD.ObjectName is QUEUE4, the MSMQ-MQSeries Bridge sends the message to a Message Queuing queue having the path name MACHINE2\QUEUE4.

The MSMQ-MQSeries Bridge determines the Message Queuing format name corresponding to this path name to forward the message.

> **Note** The MQSeries name fields are limited to 48 characters each. If the path name is longer than this, use the format name method instead.

Queue Alias Method of Object Descriptor Conversion

Optionally, you can address a Message Queuing (also known as MSMQ) queue using an MQSeries queue alias. If you use this method, set MQOD.ObjectName to the queue alias. Leave MQOD.ObjectQMgrName blank, or set it to the MQSeries Queue Manager where the transmission queue is located.

Examples of Object Descriptor Conversion

In the following examples, you want to send a message to a Message Queuing (also known as MSMQ) destination having the following identifiers:

```
Machine name = MACHINE2
Queue name = QUEUE4
GUID = A56F41B4-9869-11D0-AF8F-0000E8D1C3A7
```

MSMQ-MQSeries Bridge is installed on a computer called BRIDGEMQ1. You have defined the aliases BRIDGEMQ1 and BRIDGEMQ1% for this computer in MQSeries. In the MSMQ-MQSeries Bridge Manager, you have configured BRIDGEMQ1 for MQS->Message Queuing message pipe and BRIDGEMQ1% for MQS->Message Queuing transactional message pipe.

You may address a message to this queue in any of the following ways:

Format name method

Using the format name method and MQS->Message Queuing message pipe, the MQSeries name would become:

```
MQOD.ObjectQMgrName = "BRIDGEMQ1"
MQOD.ObjectName = "PUBLIC_A56F41B4_9869_11D0_AF8F_0000E8D1C3A7"
```

- or -

```
MQOD.ObjectQMgrName = "BRIDGEMQ1"
MQOD.ObjectName = "DIRECT_OS/MACHINE2/QUEUE4"
```

Using the format name method and MQS->Message Queuing transactional message pipe, the MQSeries name would become:

```
MQOD.ObjectQMgrName = "BRIDGEMQ1%"
MQOD.ObjectName = "PUBLIC_A56F41B4_9869_11D0_AF8F_0000E8D1C3A7"
```

- or -

```
MQOD.ObjectQMgrName = "BRIDGEMQ1%"
MQOD.ObjectName = "DIRECT_OS/MACHINE2/QUEUE4"
```

Optionally, you can define the MQSeries aliases MACHINE2 and MACHINE2% for the Message Queuing destination computer. You now have two additional ways to address the queue.

Using the path name method and MQS->Message Queuing message pipe, the MQSeries name would become:

```
MQOD.ObjectQMgrName = "MACHINE2"
MQOD.ObjectName = "QUEUE4"
```

Using the path name method and MQS->Message Queuing transactional message pipe, the MQSeries name would become:

```
MQOD.ObjectQMgrName = "MACHINE2%";
MQOD.ObjectName = "QUEUE4"
```

In yet another option, you can define the MQSeries aliases QUEUE4 and QUEUE4% for the Message Queuing destination queues. If you do this, you can address the queue using the following syntax.

Using the queue alias method and normal service, the MQSeries name would become:

```
MQOD.ObjectQMgrName = ""
MQOD.ObjectName = "QUEUE4"
```

Using the queue alias method and high service, the MQSeries name would become:

```
MQOD.ObjectQMgrName = ""
MQOD.ObjectName = "QUEUE4%"
```

Message Descriptor (MQMD)

The MSMQ-MQSeries Bridge converts most of the MQSeries field values to Message Queuing (also known as MSMQ) property values.

MQMD.Report Field

The MSMQ-MQSeries Bridge supports the MQSeries and Message Queuing (also known as MSMQ) acknowledgment mechanisms. You can send a Message Queuing message to MQSeries and receive an automatic acknowledgment from the Message Queuing Queue Manager.

To do this, set the MQMD.Report field of the MQSeries message to a value that requests an acknowledgment. Also set the MQMD.ReplyToQ and MQMD.ReplyToQMgr fields, which specify where the acknowledgment is sent.

The MSMQ-MQSeries Bridge converts MQMD.Report to the Message Queuing acknowledgment property. When Message Queuing receives the message, it returns the appropriate acknowledgment thorough the MSMQ-MQSeries Bridge.

The MSMQ-MQSeries Bridge also supports the MQSeries and Message Queuing dead letter mechanism. For this purpose, MSMQ-MQSeries Bridge converts the MQMD.Report values to the Message Queuing journaling property.

The conversions are listed in the following table.

Value of MQSeries field MQMD.Report	**Converted to Message Queuing property and value**
MQRO_NONE	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NONE
MQRO_EXCEPTION	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
MQRO_EXCEPTION_WITH_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
MQRO_EXCEPTION_WITH_FULL_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
MQRO_EXPIRATION	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
MQRO_EXPIRATION_WITH_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
MQRO_EXPIRATION_WITH_FULL_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
MQRO_COA	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
MQRO_COA_WITH_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
MQRO_COA_WITH_FULL_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
MQRO_DEAD_LETTER_Q	The value of PROPID_M_JOURNAL is set to MQMSG_DEADLETTER
MQRO_DISCARD_MSG	The value of PROPID_M_JOURNAL is set to MQMSG_JOURNAL_NONE
MQRO_NEW_MSG_ID	(Not converted)
MQRO_PASS_MSG_ID	(Not converted)
MQRO_COPY_MSG_ID_TO_CORREL_ID	(Not converted)
MQRO_PASS_CORREL_ID	(Not converted)

> **Note** For these report values, the MSMQ-MQSeries Bridge duplicates part or all of the message buffer in the Message Queuing message extension (**PROPID_M_EXTENSION**). The increased message size may degrade performance.

MQMD.MsgType and MQMD.Feedback Fields

The values of the MQSeries MQMD.MsgType and MQMD.Feedback fields are converted to the Message Queuing (also known as MSMQ) message class property.

The conversions are listed in the following table based on the value of MQMD.MsgType when MQMD.Feedback is MQFB_NONE.

Value of MQSeries MQMD.MsgType	Converted to value of Message Queuing PROP_M_CLASS
MQMT_SYSTEM_FIRST	MQMSG_CLASS_NORMAL
MQMT_SYSTEM_LAST	MQMSG_CLASS_NORMAL
MQMT_DATAGRAM	MQMSG_CLASS_NORMAL
MQMT_REQUEST	MQMSG_CLASS_NORMAL
MQMT_REPLY	MQMSG_CLASS_NORMAL
MQMT_APPL_FIRST	MQMSG_CLASS_NORMAL
MQMT_APPL_LAST	MQMSG_CLASS_NORMAL

The conversions are listed in the following table based on the value of MQMD.Feedback when MQMD.MsgType is MQMT_REPORT.

Value of MQSeries MQMD.Feedback	Converted to value of Message Queuing PROP_M_CLASS
MQFB_EXPIRATION	MQMSG_CLASS_NACK_RECEIVE_TIMEOUT
MQFB_COA	MQMSG_CLASS_ACK_REACH_QUEUE
MQFB_COD	MQMSG_CLASS_ACK_RECEIVE
MQFB_APPL_TYPE_ERROR	MQMSG_CLASS_NACK_ERROR
MQFB_DATA_LENGTH_ZERO	MQMSG_CLASS_NACK_ERROR
MQFB_DATA_LENGTH_NEGATIVE	MQMSG_CLASS_NACK_ERROR
MQFB_DATA_LENGTH_TOO_BIG	MQMSG_CLASS_NACK_ERROR
MQFB_BUFFER_OVERFLOW	MQMSG_CLASS_NACK_ERROR
MQFB_LENGTH_OFF_BY_ONE	MQMSG_CLASS_NACK_ERROR
MQFB_NONE	(Not converted)
MQFB_SYSTEM_FIRST	(Not converted)
MQFB_SYSTEM_LAST	(Not converted)
MQFB_APPL_FIRST	(Not converted)
MQFB_APPL_LAST	(Not converted)
MQFB_TM_ERROR	(Not converted)
MQFB_IIH_ERROR	(Not converted)
MQFB_NOT_AUTHORIZED_FOR_IMS	(Not converted)
MQFB_IMS_ERROR	(Not converted)
MQFB_IMS_FIRST	(Not converted)
MQFB_IMS_LAST	(Not converted)
MQFB_QUIT	(Not supported)
MQRC_NOT_AUTHORIZED	MQMSG_CLASS_NACK_ACCESS_DENIED
MQRC_Q_FULL	MQMSG_CLASS_NACK_Q_EXCEED_QUOTA
MQRC_PERSISTENT_NOT_ALLOWED	MQMSG_CLASS_NACK_ERROR
MQRC_MSG_TOO_BIG_FOR_Q_MGR	MQMSG_CLASS_NACK_ERROR
MQRC_MSG_TOO_BIG_FOR_Q	MQMSG_CLASS_NACK_ERROR
MQRC_PUT_INHBITED	(Not converted)

MQMD.ReplyToQ and MQMD.ReplyToQMgr Fields

The MSMQ-MQSeries Bridge converts the MQSeries ReplyToQMgr and ReplyToQ fields to a Message Queuing (also known as MSMQ) format name. The name is assigned both to the response queue property and to the administration queue property of the new Message Queuing message.

The MSMQ-MQSeries Bridge interprets the **ReplyToQMgr** and the **ReplytoQ** fields in the same way as the destination queue name.

If MQMD.ReplyToQMgr is the MSMQ-MQSeries Bridge computer name and MQMD.ReplyToQ begins with PUBLIC_, P_, or DIRECT_OS/, MSMQ-MQSeries Bridge interprets MQMD.ReplyToQ as a Message Queuing format name.

Otherwise, the MSMQ-MQSeries Bridge interprets MQMD.ReplyToQMgr\MQMD.ReplyToQ as a Message Queuing path name and determines the Message Queuing format name.

The following table lists the MQSeries fields and the Message Queuing properties to which they are converted.

MQSeries fields	Converted to Message Queuing property
MQOD.ReplyToQMgr and MQOD.ReplyToQ	PROPID_M_RESP_QUEUE
MQOD.ReplyToQMgr and MQOD.ReplyToQ	PROPID_M_ADMIN_QUEUE (same value as PROPID_M_RESP_QUEUE)

Other MQMD Fields

The following table lists the conversions of additional MQMD fields, in addition to the ones described previously, to Message Queuing properties.

> **Note** To save space in the table, the prefixes MQMD and PROPID_M_ are omitted from the MQSeries field names and the Message Queuing property names, respectively. For example, the first row of data means that MQMD.ApplIdentityData is converted to **PROPID_M_LABEL** and **PROPID_M_LABEL_LEN**.

MQSeries field		**Converted to Message Queuing**	
MQMD.	**Value**	**PROPID_M_**	**Value**
ApplIdentityData	Value (MQCHAR32)	LABEL	Value
CorrelId	Value (MQBYTE24)	CORRELATIONID	Last 20 bytes of value
Expiry	MQEI_UNLIMITED Value > 0 (tenths of seconds)	TIME_TO_BE_RECEIVED	INFINITE Value/10 (seconds)
Format	MQFMT_STRING Any other value	BODY_TYPE	VT_BSTR Not converted
Persistence	MQPER_ PERSISTENT NOT_PERSISTENT	DELIVERY	MQMSG_DELIVERY_ RECOVERABLE EXPRESS
Priority	0, 1 2, 3 4 5 6 7 8 9	PRIORITY	0 1 2 3 4 5 6 7
UserIdentifier	Value	SENDERID	SID value (if the user is registered in Windows 2000 Not converted (if the user is not registered)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to

http://go.microsoft.com/fwlink/?linkid=29507.

Unconverted MQSeries MQMD Fields

The following MQSeries fields have no equivalents in Message Queuing (also known as MSMQ). The MSMQ-MQSeries Bridge ignores these fields and does not transmit them to Message Queuing.

Like all MQMD fields, MSMQ-MQSeries Bridge stores the fields in the Message Queuing message extension property:

- MQMD.AccountingToken
- MQMD.ApplOriginData
- MQMD.BackoutCount
- MQMD.Encoding
- MQMD.MsgId
- MQMD.PutApplName
- MQMD.PutApplType
- MQMD.PutDate
- MQMD.PutTime
- MQMD.StrucId

When the value of MQMD.CodeCharSetID is **MQCCSI_Q_QMG**, the MSMQ-MQSeries Bridge ignores this field and does not transmit it to Message Queuing. When the value of MQMD.CodeCharSetID is **MQCCSI_Q_QMG**, The MSMQ-MQSeries Bridge does not support this value.

When the value of MQMD.Version is **MQPMO_VERSION_1**, the MSMQ-MQSeries Bridge ignores this field and does not transmit it to Message Queuing.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Building a Message Queuing Message

This section explains how the MSMQ-MQSeries Bridge builds a complete Message Queuing (also known as MSMQ) message, including all needed properties, whether or not they have MQSeries equivalents.

Message Body (PROPID_M_BODY)

The Message Queuing (also known as MSMQ) message body is equivalent to the MQPUT or MQGET message buffer of MQSeries. The length of the MQPUT buffer is the Message Queuing message body size.

The following table lists the Message Queuing properties and the MQSeries fields from which they are converted.

Message Queuing property	Converted from MQSeries field
PROPID_M_BODY	Message buffer
PROPID_M_BODY_SIZE	Message buffer length

Queue Format Names (PROPID_M_..._QUEUE)

MSMQ-MQSeries Bridge retrieves the Message Queuing (also known as MSMQ) format names of the destination, response, and administration queues from the MQSeries queue and Queue Manager names.

The following table lists the Message Queuing properties and the MQSeries fields from which they are converted.

Message Queuing properties	Converted from MQSeries fields
PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN	MQOD.ObjectName and MQOD.ObjectQMgrName
PROPID_M_RESP_QUEUE and PROPID_M_RESP_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr
PROPID_M_ADMIN_QUEUE and PROPID_M_ADMIN_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr

Message Class (PROPID_M_CLASS)

The MSMQ-MQSeries Bridge assigns the Message Queuing (also known as MSMQ) message class based on the MQSeries MQMD.MsgType and MQMD.Feedback values. For detailed information, see MQMD.MsgType and MQMD.Feedback Fields.

The following table lists the Message Queuing properties and the MQSeries fields from which they are converted.

Message Queuing properties	Converted from MQSeries fields
PROPID_M_CLASS	MQMD.MsgType and MQMD.Feedback

Message Expiration (PROPID_M_TIME...)

The MSMQ-MQSeries Bridge converts the MQSeries MQMD.Expiry value (in tenths of seconds) to the Message Queuing (also known as MSMQ) **PROPID_M_TIME_TO_BE_RECEIVED** (in seconds). If MQMD.Expiry is set to **MQEI_UNLIMITED**, the value of Message Queuing **PROPID_M_TIME_TO_BE_RECEIVED** is set to INFINITE. For other values of MQMD.Expiry greater than zero, the value of Message Queuing **PROPID_M_TIME_TO_BE_RECEIVED** is converted by dividing MQMD.Expiry by 10. The MSMQ-MQSeries Bridge does not set **PROPID_M_TIME_TO_REACH_QUEUE**.

Value of Message Queuing properties	Converted from MQSeries fields
PROPID_M_TIME_TO_BE_RECEIVED	MQMD.Expiry

Message Acknowledgment and Journaling (PROPID_M_ACKNOWLEDGE, PROPID_M_JOURNAL)

The Message Queuing (also known as MSMQ) message acknowledgment and journaling are converted from values of MQMD.Report.

Message Queuing property	Converted from MQSeries
PROPID_M_ACKNOWLEDGE PROPID_M_JOURNAL	MQMD.Report

Other Message Queuing Properties (PROPID_M_...)

Some Message Queuing (also known as MSMQ) properties have no equivalent in MQSeries. The MSMQ-MQSeries Bridge assigns values to these properties as listed in the following table.

Message Queuing property	**Value assigned by MSMQ-MQSeries Bridge**
PROPID_M_APPSPECIFIC	None
PROPID_M_AUTH_LEVEL	Default
PROPID_M_CONNECTOR_TYPE	None
PROPID_M_DEST_QUEUE	Default
PROPID_M_DEST_QUEUE_LEN	Default
PROPID_M_DEST_SYMM_KEY	None
PROPID_M_ENCRYPTION_ALG	None
PROPID_M_HASH_ALG	None
PROPID_M_MSGID	Assigned by Message Queuing
PROPID_M_PRIV_LEVEL	Default
PROPID_M_PROV_NAME	None
PROPID_M_PROV_TYPE	None
PROPID_M_SECURITY_CONTEXT	Default
PROPID_M_SENDER_CERT	Default
PROPID_M_SENTTIME	Time when MSMQ-MQSeries Bridge transmits the message to Message Queuing
PROPID_M_SIGNATURE	None
PROPID_M_SRC_MACHINE_ID	GUID of the MSMQ-MQSeries Bridge machine
PROPID_M_TRACE	Default
PROPID_M_VERSION	0x0010

Equivalent Message Queuing Properties

The following Message Queuing (also known as MSMQ) properties have MQSeries equivalents. The MSMQ-MQSeries Bridge converts the values of each property as listed in the table.

> **Note** To save space in the table, the prefixes PROPID_M_ and MQMD. are omitted from the Message Queuing property names and the MQSeries field names, respectively. For example, the first row of data means that PROPID_M_BODY_TYPE is converted from MQMD.Format.

Message Queuing property		**Converted from MQSeries**	
PROPID_M_	**Value**	**MQMD.**	**Value**
BODY_TYPE	VT_BSTR Not converted (default)	Format	MQFMT_STRING Any other value
CORRELATIONID	Last 20 bytes of value	MsgId	Value (MQBYTE24)
DELIVERY	MQMSG_DELIVERY_ RECOVERABLE EXPRESS	Persistence	MQPER_ PERSISTENT NOT_PERSISTENT
LABEL LABEL_LEN	Value	ApplIdentityData	Value (MQCHAR32)
PRIORITY	0 1 2 3 4 5 6 7	Priority	0, 1 2, 3 4 5 6 7 8 9

SENDERID SENDERID_TYPE	SID value MQMSG_SENDERID_TYPE_SID Not converted MQMSG_SENDERID_TYPE_NONE	UserIdentifier	Value, if the user is registered in Windows 2000 If the user is not registered in Windows 2000

MSMQ-MQSeries Bridge Extensions Mechanism

Besides the automatic conversion of Microsoft® Message Queuing (also known as MSMQ) and IBM MQSeries messages, the MSMQ-MQSeries Bridge provides a mechanism for sending and receiving explicit MQSeries field values. The MSMQ-MQSeries Bridge Extension Property API supports the message extension property (**PROPID_M_EXTENSION**) of the Message Queuing server. The message extension property provides a way for applications to attach any type of data—in essence, custom properties—to a Message Queuing message.

Similar to the Message Queuing message body property (**PROPID_M_BODY**), the message extension can have any length. However, the message extension has a defined structure that lets an application label its data with a globally unique identifier (GUID) code. Applications can attach multiple extension fields, each labeled with its own GUID and all included in a single message extension property. This is done using the Message Queuing message extension property (**PROPID_M_EXTENSION**).

This section contains:

- Data Structure of a Message Extension
- How MSMQ-MQSeries Bridge Creates a Message Extension
- How MSMQ-MQSeries Bridge Converts a Message Extension
- Using Message Extensions
- Programming a Message Extension
- MSMQ-MQSeries Bridge Extension Property API

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Data Structure of a Message Extension

A message extension is a Message Queuing (also known as MSMQ) message property of arbitrary length. The property symbol of a message extension is **PROPID_M_EXTENSION** and its type indicator is VT_UI1|VT_VECTOR. A message extension is a sequential buffer containing any number of Message Queuing extension fields.

Each extension field comprises three subfields, as listed in the following table.

Subfield	Length of subfield (bytes)	Description
GUID	16	A GUID identifier, typically of the application that created the extension field.
Length	4	The length of the data subfield in bytes.
Data	Value of the length subfield	Any data that is part of the message extension.

For use with the MSMQ-MQSeries Bridge, the GUID identifier is set to the MSMQ-MQSeries Bridge GUID value.

The Message Queuing message extension length property, **PROPID_M_EXTENSION_LEN**, is of type indicator VT_UI4 and represents the overall size in bytes of all message extensions attached to a message. Message Queuing sets the message extension length automatically when you send a message. When you receive or peek at a message, you can look into the message extension length to detect whether the message contains any message extension fields and to determine the necessary receive buffer size.

The MSMQ-MQSeries Bridge Extension API functions work with an alternative data representation for a message extension, called an **EP** object. An **EP** object contains the same fields and subfields as a message extension, but in a format adapted for programming.

How MSMQ-MQSeries Bridge Creates a Message Extension

When the MSMQ-MQSeries Bridge processes a message from MQSeries, it creates a **PROPID_M_EXTENSION** property, which it includes in the message that it transmits to Message Queuing (also known as MSMQ).

This section contains:

- MQMD Extension Field
- Error Extension Field
- Other Extension Fields

MQMD Extension Field

Ordinarily, the message extension contains a single extension field with the following structure:

- The MSMQ-MQSeries Bridge globally unique identifier (GUID) code is stored in the GUID subfield of the extension.
- The size of MQMD is stored in the length subfield of the extension.
- The MQMD is copied byte-for-byte into the data buffer of the extension.

The MSMQ-MQSeries Bridge GUID is the value of the sg_MSMQExtMQMD constant which is defined in the Mqsrext.h include file found in the SDK\Include subdirectory.

The MQMD extension has the following GUID for MQMD version 2.

```
static const GUID sg_MSMQExtMQMDE =
{ 0x18ae68f5, 0x989b, 0x11d3,
    { 0x8d, 0xf9, 0x0, 0x0, 0xf8, 0x1a,  0xea, 0x1f }
};
```

Error Extension Field

If the MSMQ-MQSeries Bridge encounters an MQSeries error when it transmits a message from Message Queuing (also known as MSMQ), it records the error in the extension property and places the message on the dead letter queue.

To do this, the MSMQ-MQSeries Bridge adds an extension property to the Message Queuing message, if it does not already exist. Within the extension property, MSMQ-MQSeries Bridge creates an extension field containing the following data:

- The globally unique identifier (GUID) subfield contains a MSMQ-MQSeries Bridge error GUID (different from the GUID used for MQMD).
- The length subfield contains the value 4.
- The data subfield contains a reason code, identical to the codes returned by the MQSeries function MQPUT.

The MSMQ-MQSeries Bridge error GUID is the value of the sg_MSMQExtReasonCode constant, which is defined in the Mqsrext.h include file found in the SDK\Include subdirectory.

If wanted, a Message Queuing application can read messages from the dead letter queue and interpret the reason codes.

Other Extension Fields

If you send an MQSeries message having certain values of MQMD.Report, the MSMQ-MQSeries Bridge adds a second extension field to the new Message Queuing (also known as MSMQ) message. This field is for internal use only, not for use in your applications. The MSMQ-MQSeries Bridge distinguishes the Report extension field from the MQMD and error extension fields by labeling them with different globally unique identifiers (GUIDs).

For more information about other extension fields, see Converting Messages Sent from MQSeries to Message Queuing.

How MSMQ-MQSeries Bridge Converts a Message Extension

If you send a Message Queuing (also known as MSMQ) message including a message extension to MQSeries, the MSMQ-MQSeries Bridge converts the extension in the following way:

- The MSMQ-MQSeries Bridge looks for an extension field identified by the MSMQ-MQSeries Bridge GUID. If it finds one, it reads the MQMD structure from the extension field.
- MSMQ-MQSeries Bridge ignores any other extension fields that may be present in the message extension.
- MSMQ-MQSeries Bridge includes the MQMD structure that it reads from the extension field in the new MQSeries message.

The MQMD structure in the message extension overrides the default MQMD conversions, which are described in Converting Messages Sent from Message Queuing to MQSeries.

A few exceptions to these rules are described in the following sections.

This section contains:

- Sender and User Identifiers
- Version Identifiers

Sender and User Identifiers

MSMQ-MQSeries Bridge reads the value of **MQMD.UserIdentifier** stored in the message extension and assigns the value to the **MQMD.UserIdentifier** field in the new MQSeries message.

Version Identifiers

MQSeries uses the following fields for version identification:

- **MQMD.StrucId**
- **MQMD.Version**

When the MSMQ-MQSeries Bridge converts a message extension, it confirms that the values of these fields are for a version of MQSeries that the Bridge supports. If they are not, MSMQ-MQSeries Bridge places the message on the dead letter queue and does not transmit it to MQSeries.

For more information about the supported versions of MQSeries, see Platforms Supported by MSMQ-MQSeries Bridge Extensions. For more information about the permitted values of the version identification fields, see Converting Messages Sent from Message Queuing to MQSeries.

Using Message Extensions

This section suggests a few ways that you can use the message extension property in your messaging applications.

This section contains:

- Sending an MQSeries Message to Message Queuing
- Sending a Message Queuing Message to MQSeries

Sending an MQSeries Message to Message Queuing

MSMQ-MQSeries Bridge stores the complete MQMD structure of an MQSeries message in a Message Queuing (also known as MSMQ) message extension. A Message Queuing application can read the extension and retrieve the original MQMD structure.

In this way, a Message Queuing application can retrieve the original values of every MQMD field, regardless of the MSMQ-MQSeries Bridge conversions.

Sending a Message Queuing Message to MQSeries

When you send a Message Queuing (also known as MSMQ) message to MQSeries, you can include a message extension. This can be an extension that you originally received from MQSeries, or one that you created yourself. MSMQ-MQSeries Bridge reads the message extension and uses it to set the MQMD fields of the converted message that it sends to MQSeries.

You can use this feature for two purposes:

- To override the default conversions described in the section Converting Messages Sent from Message Queuing to MQSeries
- To supplement the default conversions by assigning MQMD fields that have no Message Queuing equivalent.

The following are some examples of fields that have no equivalents or only partial equivalents (different permitted values or length) among the Message Queuing message properties:

- **MQMD.AccountingToken**
- **MQMD.ApplOriginData**
- **MQMD.CorrelId**
- **MQMD.MsgId**
- **MQMD.MsgType**
- **MQMD.PutApplName**
- **MQMD.PutApplType**
- **MQMD.ReplyToQ**
- **MQMD.ReplyToQMgr**
- **MQMD.Report**

Suppose you want to send a message to an MQSeries application including an MQMD.MsgType value of MQMD_REPLY. The default message conversions provide no way to set this particular value. You can send the value by storing an MQMD data structure in a message extension.

Programming a Message Extension

In a Message Queuing (also known as MSMQ) application, you can program a message extension containing an arbitrary number of extension fields. For use with MSMQ-MQSeries Bridge, build the extension according to the following specifications.

It is recommended that you use MSMQ-MQSeries Bridge Extension Property API to construct the extension with the required syntax. Create a **PROPID_M_EXTENSION** property containing at least one extension field.

Store the MSMQ-MQSeries Bridge globally unique identifier (GUID) code in the GUID subfield of exactly one extension field. The GUID is the value of the sg_MSMQExtMQMD constant, which is defined in the Mqsrext.h include file of the Extension Property API. Store the size of MQMD in the length subfield. Copy a complete MQMD structure byte-for-byte into the data buffer subfield.

When you send the message to MQSeries, the MSMQ-MQSeries Bridge converts the extension field identified by the MSMQ-MQSeries Bridge GUID. Any other extension fields are ignored.

MSMQ-MQSeries Bridge Extension Property API

The MSMQ-MQSeries Bridge Extension Property API is recommended for programming and working with message extensions. The API provides a library of functions that help you create and interpret message extensions. The MSMQ-MQSeries Bridge Extension Property API is supplied as part of the Host Integration Server SDK.

Your Message Queuing (also known as MSMQ) applications can use the API to do the following:

- Read message extensions that you receive from MQSeries
- Create or modify message extensions that you send to MQSeries
- Read or create message extensions for any other Message Queuing messaging purpose

The MSMQ-MQSeries Bridge Extension Property API enables you to create and work with the Message Queuing message extension property. This section provides a few guidelines for using the API functions.

The MSMQ-MQSeries Bridge Extension Property API operates directly on the EP representation of a message extension. In particular, the API functions support the following programming approach:

- Creating or deleting an **EP** object.
- Creating, finding, reading, writing, or deleting extension fields in an **EP** object.
- Converting an **EP** object to a message extension. (**PROPID_M_EXTENSION**) that you can send in a Message Queuing message.
- Converting a message extension that you received in a Message Queuing message to an **EP** object.

You cannot send an **EP** object directly in a Message Queuing message. You must first convert it to a message extension (**PROPID_M_EXTENSION**).

To use the message extension API, include the MSMQext.h header file in your applications. This header files contains constants and function prototypes for the Extension Property API functions. This header file is located in the SDK\Include directory on the Host Integration Server CD and is installed when the SDK package is selected.

If you are using the API in conjunction with MSMQ-MQSeries Bridge, also include the Mqsrext.h header file located in the SDK\Include directory. This file defines the GUID that labels the extension fields.

The Extension Property API functions are handle-based. The following is a summary of the MSMQ-MQSeries Bridge Extension Property API functions. For complete details, see the individual function descriptions in MSMQ-MQSeries Bridge Extensions Reference.

Function	Description
EPAdd	Adds a new extension field to an **EP** object.
EPClose	Frees the extension handle and associated memory of an **EP** object.
EPDelete	Deletes an extension field from an **EP** object.
EPDeleteAll	Deletes all extension fields or all extensions fields matching a specific GUID from an **EP** object.
EPGet	Positions to and optionally retrieves a requested extension field from an **EP** object, storing the GUID, length, and data subfields in separate variables. **EPGet** can also be used to locate extension fields containing a specified GUID.
EPGetBuffer	Converts an **EP** object to a message extension and packs the message extension into the supplied buffer.
EPOpen	Creates an **EP** object and optionally unpacks the supplied message extension buffer into it.
EPUpdate	Writes new data to an existing extension field of an **EP** object.

Programming Considerations Using MSMQ-MQSeries Bridge Extensions

The limitations of specific API functions result from the fact that MSMQ-MQSeries Bridge transmits messages, not API calls, between queuing systems. The MSMQ-MQSeries Bridge transmits messages across the MSMQ-MQSeries interface. The MSMQ-MQSeries Bridge does not transmit API calls across the interface. Thus, Microsoft® Message Queuing (also known as MSMQ) API calls operate only within the Message Queuing environment, and MQSeries API calls operate only within the MQSeries environment. This principle limits the ways in which you can create and access queues.

All Message Queuing API functions operate only within the Message Queuing environment, up to and including foreign computers and queues. For example, you can use the following functions:

- **MQLocateBegin**, **MQLocateNext**, and **MQLocateEnd** to search for foreign queues
- **MQGetMachineProperties**, **MQGetPrivateComputerInformation**, **MQGetQueueProperties**, and **MQGetQueueSecurity** functions to retrieve the properties of foreign queues
- **MQOpenQueue** to open a foreign queue
- **MQSetQueueProperties** and **MQSetQueueSecurity** to set the properties of foreign queues
- **MQCloseQueue** to close a foreign queue

When creating a queue, you can call the Message Queuing function **MQCreateQueue** to create a foreign queue representing an MQSeries queue, but you cannot create the actual MQSeries queue itself. Similarly, you cannot create a Message Queuing queue by calling the MQSeries function **MQOPEN**.

To communicate across the MSMQ-MQSeries interface, your Message Queuing and MQSeries applications should each create their own queues. Alternatively, you can use administration tools such as the Message Queuing Manager or the MQSeries command interface to create the queues.

For proper message delivery, you must ensure that the destination queue for each message actually exists.

You can use the Message Queuing **MQPathNameToFormatName** function to determine a Message Queuing format name for an MQSeries queue. The format name actually refers to the Message Queuing foreign queue. The MSMQ-MQSeries Bridge processes the format name that it finds in a message and directs the message to the MQSeries queue.

When opening a queue, a call to the Message Queuing function **MQOpenQueue** opens the foreign queue, not the MQSeries queue itself. The MSMQ-MQSeries Bridge opens the MQSeries queue as necessary when it transmits a message. If you are sending messages to more that one MQSeries queue, you must open each one separately using its own Message Queuing format name.

In the opposite direction, the MQSeries function **MQOPEN** opens the transmission queue for the Message Queuing computer. The MSMQ-MQSeries Bridge opens the Message Queuing queue when it transmits a message.

When sending a Message Queuing message to a foreign queue with MQSendMessage, Message Queuing delivers the message to the connector queue in the MSMQ-MQSeries Bridge computer. The MSMQ-MQSeries Bridge converts and transmits the message to MQSeries queue. MQSeries delivers a message sent by **MQPUT** to a transmission queue. The MSMQ-MQSeries Bridge reads the message from the MQSeries transmission queue. After converting the message from MQSeries to Message Queuing message properties, MSMQ-MQSeries Bridge transmits the message to the destination Message Queuing queue.

When receiving a message, the MSMQ-MQSeries Bridge does not transmit receive requests across the MSMQ-MQSeries interface. A Message Queuing application can receive a message only from a native Message Queuing queue (the **MQReceiveMessage** function). An MQSeries application can receive only from a native MQSeries queue (the **MQGET** function).

When sending a message from MQSeries to Message Queuing, if you want the MQSeries message to have a value for MQMD.ApplIdentityData, you need the set both of the following:

- Set the **Open** option with **MQOO_SET_IDENTITY_CONTEXT**
- Set the **Put** option with **MQPMO_SET_IDENTITY_CONTEXT**

When a message is retrieved from Message Queuing, the MSMQ-MQSeries Bridge will have converted the Message Queuing **PROPID_M_LABEL** and **PROPID_M_LABEL_LEN** properties from the MQSeries MQMD.ApplIdentityData field value.

The MQMDE extension has the following GUID for MQMD version 2.

```
static const GUID sg_MSMQExtMQMDE =
{ 0x18ae68f5, 0x989b, 0x11d3,
      { 0x8d, 0xf9, 0x0, 0x0, 0xf8, 0x1a,  0xea, 0x1f }
  };
```

This section contains:

- Transaction Support Using MSMQ-MQSeries Bridge
- Security Using MSMQ-MQSeries Bridge
- Troubleshooting MSMQ-MQSeries Bridge Extensions

Transaction Support Using MSMQ-MQSeries Bridge

The MSMQ-MQSeries Bridge supports both Message Queuing (also known as MSMQ) and MQSeries transactions. The procedure for sending a group of transacted messages is similar in either direction, from Message Queuing to MQSeries or from MQSeries to Message Queuing. Your application should follow these three basic procedures:

- Open a transaction
- Send the messages
- Commit the transaction

At this point, the group of messages reaches the Message Queuing connector queue or the MQSeries transmission queue. Only then does the MSMQ-MQSeries Bridge transmit the messages to the other messaging system. If your application stops the transaction instead of committing, MSMQ-MQSeries Bridge does not handle the messages at all.

Even after you commit a transaction, it is still possible that MSMQ-MQSeries Bridge cannot transmit all the messages. This may occur, for example, if some of the messages are addressed to queues that do not exist in the recipient messaging system. MSMQ-MQSeries Bridge places any undeliverable messages on its dead letter queue.

In the Message Queuing-to-MQSeries direction, the MSMQ-MQSeries Bridge sends transacted messages by a transactional message pipe and untransacted messages by regular message pipe. In the MQSeries-to-Message Queuing direction, MQS->Message Queuing message pipe, and MQS->Message Queuing transactional message pipe do not depend on transaction status.

Security Using MSMQ-MQSeries Bridge

Message authentication and message body encryption are supported from the Message Queuing (also known as MSMQ) sending application up to MSMQ-MQSeries Bridge. Authentication and message body encryption from MSMQ-MQSeries Bridge to MQSeries, or from MQSeries to Message Queuing, are not currently supported.

Troubleshooting MSMQ-MQSeries Bridge Extensions

The MSMQ-MQSeries Bridge generally ignores warnings that it receives from Message Queuing (also known as MSMQ) or MQSeries, but errors are not ignored. Where possible, the MSMQ-MQSeries Bridge transmits messages despite any warnings.

If the MSMQ-MQSeries Bridge is unable to transmit a message to Message Queuing or MQSeries, it places the message on one of its dead letter queues. This can happen, for example, if a message contains an unsupported Message Queuing or MQSeries version identifier or if MSMQ-MQSeries Bridge encounters an error in the recipient messaging system.

The dead letter queues are Message Queuing queues located on the MSMQ-MQSeries Bridge computer. There are two dead letter queues used for this purpose with the following names.

Dead letter queue names	Comments
MQBridge dead letter	Used for untransacted messages when errors occur.
MQBridge xact dead letter	Used for transacted messages when errors occur.

Note that these are different from the Message Queuing and MQSeries dead letter queues, where the messaging systems place expired or incorrectly addressed messages.

You can determine whether there are messages on the dead letter queues using the MSMQ-MQSeries Bridge Manager.

If the MSMQ-MQSeries Bridge cannot deliver a message to MQSeries, it records the error in the extension property **PROPID_M_EXTENSION** of the original Message Queuing message and places the message on the dead letter queue. This extension property can be examined to determine the nature of the error encountered.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Registry Settings Used By MSMQ-MQSeries Bridge Extensions

The MSMQ-MQSeries Bridge Extensions uses a number of registry settings for configuration and proper operation. The configuration registry settings are located under the **HKEY_LOCAL_MACHINE\Software\Microsoft\SNA Server\CurrentVersion\Setup** key. These registry settings include the subkeys listed in the following table.

Subkey	Comment
RootDir	Stores the path to the root directory where the Host Integration Server was installed. The system directory below this root directory is the location where the MSMQ-MQSeries Bridge Extensions dynamic link library (DLL) and other support DLLs are installed.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Single Sign-On Programmer's Guide

This section provides information about Enterprise Single Sign-On (SSO) technology.

For API references and other technical information about SSO, see the Single Sign-On Programmer's Reference section of the SDK.

This section contains:

- About Programming Single Sign-On
- Programming with Enterprise Single Sign-On

About Programming Single Sign-On

A business process that relies on several different applications is likely to face the challenge of dealing with several different security domains. Accessing an application on a Microsoft® Windows® operating system may require one set of security credentials, while accessing an application on an IBM mainframe may require different credentials. Dealing with this profusion of credentials is hard for users, and it can pose an even greater challenge for automating processes. To address this problem, Microsoft Host Integration Server 2004 includes Enterprise Single Sign-On (SSO).

SSO provides a way to map a Windows user ID to non-Windows user credentials. This service can simplify business processes that use applications on diverse systems.

To use SSO, an administrator defines affiliated applications, each of which represents a non-Windows system or application. An affiliated application might be a Customer Information Control System (CICS) application running on an IBM mainframe, an SAP ERP system running on Unix, or any other kind of software. Each of these applications has its own mechanism for authentication, and so each requires its own unique credentials.

SSO stores an encrypted mapping between the Windows user ID of a user and the associated credentials for one or more affiliated applications. These linked pairs are stored in a Credentials database. SSO uses the Credentials database in two ways. The first way, called Windows-initiated Single Sign-On, uses the user ID to determine to which affiliated applications the user has access. For example, a Windows user account may be linked with credentials that grant access to a DB2 database running on a remote AS/400 server. The second way, called host-initiated Single Sign-On, acts in reverse: determining what remote applications have access to a specified user ID, and the privileges that go with that account. For example, a remote application may be linked with credentials that grant access to a user account that has administration privileges on a Windows network.

Note that SSO also includes administration tools to perform various operations. All operations performed on the Credential database are audited; for example, tools are provided that enable an administrator to monitor these operations and set various audit levels. Other tools enable an administrator to disable a particular affiliated application, turn on and off an individual mapping for a user, and perform other functions. There is also a client program that enables end users to configure their own credentials and mappings.

One of the administrative requirements for Single Sign-On is that your local system must be aware of the credentials necessary to log onto a remote system. Similarly, the remote system must be aware of the credentials on your local system. Thus, when you update your credentials, such as when you update your password on your local machine, you must also inform the remote systems that you have done so. The component you design that synchronizes passwords across an enterprise is called a password sync adapter.

This section contains:

- About the Single Sign-On Interface
- About Single Sign-On Applications
- What you Need To Know Before Programming Single Sign-On
- Supported Platforms for Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

About the Single Sign-On Interface

The Single Sign-On (SSO) interface was originally created for Microsoft® BizTalk® Server 2004, and as such still exists in the BizTalk namespace. The following table describes the .COM and .NET interfaces that make up the Single Sign-On interface.

.NET	COM	Description
ISSOAdmin	ISSOAdmin	Sets up and maintains the SSO server database. This database contains the names and descriptions of the various affiliated applications currently exposed on the enterprise.
ISSOConfigStore	ISSOConfigStore	Gets and sets information in the SSO configuration store.
ISSOLookup1	ISSOLookup1	Enables you to look up the external credentials on a specified application for the current user.
ISSOLookup2	ISSOLookup2	As above, but also enables you to look up the Windows® credentials for a specified external user.
ISSOMapper	ISSOMapper	Mainly acts as a set of **Get** methods to expose the properties of **ISSOAdmin** and **ISSOMapping**, but also enables you to set the external credentials for the current user for a specified application.
ISSOMapping	ISSOMapping	Creates and maintains the map between users and affiliated applications.
ISSOTicket	ISSOTicket	Creates the ticket that contains the appropriate security information. This ticket is then sent on with the appropriate message from your application.

In addition, Microsoft Host Integration Server supports the Password Sync Helper (PS Helper) component. You can use PS Helper when designing password synchronization components. The following table describes the COM interface exposed by PS Helper.

COM Object	Description
ISSONotification	Handles password changes to and from non-Windows operating systems.
SExternalAccount	Describes an external account.
SPasswordChange	Describes a password change.
SPasswordChangeComplete	Describes the completion of a password change.
SStatus	Describes an error or event.
SAdapterInGroup	Describes the adapters in a given group.
SAdapter	Describes a specific adapter.

About Single Sign-On Applications

From a programming perspective, you will write two different kinds of applications using Single Sign-On: a traditional Single Sign-On application that uses the Single Sign-On interface to interact with remote applications, and a password sync adapter that uses the Password Sync (PS) Helper interface to synchronize passwords across your enterprise.

This section contains:

- About Traditional Single Sign-On Applications
- About Password Sync Adapters

About Traditional Single Sign-On Applications

The Single Sign-On programming architecture contains a mapping component exists to map between applications and users, a lookup component enables you to look up credentials for a specified use, and an administration component enables you to perform administrative tasks. The main difference is that you are creating an application that uses many of the features that an administrator maintains.

Mapping

Mapping is the process of linking a specified user with a specified application. You can map between affiliate applications and users using ISSOMapping and ISSOMapper. With **ISSOMapping**, you can create, delete, enable, and disable mappings. With **ISSOMapper**, you can get and set mapping data for the current user. For more information about how to programmatically perform mapping, see Mapping Single Sign-On Credentials and Determining Current Single Sign-On Access.

Lookup

The core of the Single Sign-On programming interface is the ability to look up credentials for specified users. You can look up credentials using ISSOLookup1 and ISSOLookup2. **ISSOLookup1** enables you to look up the credentials of a local user for a remote affiliate application. In contrast, **ISSOLookup2** also enables you to look up the credentials of a remote user for a local affiliate application. The former is necessary for a traditional Single Sign-On application, while the latter is useful when writing a host-initiated Single Sign-On application. For information on how to programmatically look up credentials for both local and remote users, see Logging on to a Remote or Local Application.

Administration

You can perform many of the administrative capabilities programmatically through ISSOAdmin Interface and ISSOConfigStore. Such tasks include Configuring Single Sign-On and Creating and Describing an Application to Single Sign-On.

Communication and ticketing

Your application will most likely issue messages so that your user can communicate with a remote application. To communicate with a remote application securely, you will need to issue and redeem an SSO ticket. You can actually issue and redeem tickets programmatically using the techniques described in Issuing and Redeeming a Single Sign-On Ticket.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

About Password Sync Adapters

A password sync adapter is a component that propagates password changes to and from a non-Windows system. A password sync adapter is similar to a traditional Single Sign-On application, with several differences: they are administered using a specialized interface, they are described using a specialized XML format in the configuration store, and Microsoft Host Integration Server uses a specialized feature to organize adapters in the configuration store.

This section contains:

- About Password Sync Programming Architecture
- About Adapter Programming Administration
- About Adapter Programming Configuration
- About Adapter Groups and Group Adapters

About Password Sync Programming Architecture

A password sync adapter uses a pull model for interacting with the rest of the Enterprise Single Sign-On system: that is, the adapter actively receives password changes from the Enterprise Single Sign-On (ENTSSO) service as well as the non-Windows system. Similarly, the adapter pushes password changes received from one system to the other. With this model, your adapter interacts with three architectural components: the ENTSSO architecture, the Password Sync (PS) Helper component, and a specified non-Windows system.

Enterprise Single Sign-On architecture

ENTSSO is the service that implements the Enterprise Single Sign-On technology, and runs as a local service on the same system as your adapter. Therefore, communication between the adapter and ENTSSO is always local. However, a password sync adapter runs in a separate process from the ENTSSO service.

ENTSSO uses the configuration store to store configuration information for an adapter. The Application Users account of a configuration store application corresponds to the access account. When an adapter calls into ENTSSO, ENTSSO checks that the adapter is within the configured access account for that adapter. The access account must be a (local or domain) group account.

Because ENTSSO stores information about an adapter, the adapter can identify itself to ENTSSO by its adapter name. The adapter name corresponds to the configuration store application name and the configuration store identifier used to store the adapter properties. Therefore, adapters only must know their adapter name (configured at adapter installation time) to access configuration information and to correctly identify themselves to the ENTSSO system at run time.

Password Sync Helper

Password Sync (PS) Helper is a COM component provided by ENTSSO. PS Helper runs in-process with the password sync adapter, and exposes the ISSONotification Interface. Your adapter can call **ISSONotification** to communicate with the ENTSSO service. The PS Helper passes communications to and from ENTSSO using encrypted (packet privacy) lighweight remote procedure call (LRPC). While the communications are mainly for password updates, you can also use **ISSONotification** to pass other types of notifications between the adapter and ENTSSO. Because PS Helper runs as a singleton value per process, it is possible for multiple adapters to call the same PS Helper object from within the same adapter process. For more information on using PS Helper programmatically, see Synchronizing a Password.

Non-Windows system

The non-Windows system is the remote computer your adapter interacts with. How you interact with the non-Windows system is up to you. However, you will likely use Transaction Integrator to do so. For more information on Transaction Integrator and writing applications that interact with remote host systems, see the Transaction Integrator Programmer's Guide.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

About Adapter Programming Administration

An adapter is a special type of configuration store application: that is, an adapter is a component that shares a namespace with other Single Sign-On and configuration store applications. Therefore, you can access information about an adapter using ISSOConfigStore. However, you do not perform administrative functions on an adapter, such as creating, updating and deleting the adapter, using ISSOAdmin Interface. Instead, you administer an adapter through ISSONotification. The reason for a specialized adapter administration interface is so that Host Integration Server 2004 can coordinate other activities with the configuration store.

See Also

About Adapter Programming Configuration

About Adapter Groups and Group Adapters

About Adapter Programming Configuration

Every type of password sync adapter has different configuration requirements, depending on what non-Windows system you design the adapter for. Like affiliate applications, you can use the Enterprise Single Sign-On configuration store to store configuration properties centrally and securely. As with other configuration store applications, an administrator can use the Enterprise Single Sign-On management user interface to locate and read an XML file that describes the configuration properties for your adapter. The management tools use the XML file to render a property page to gather the required property values, for the specified adapter. You can also use ISSOConfigStore to load and read a XML name/value combinations to and from the configuration store, or you can use the SSOPS tool. You can also use the Enterprise Single Sign-On administration tools to enable and disable an adapter. On initial creation, an adapter is disabled.

About Adapter Groups and Group Adapters

An adapter group is an administration mechanism you can use to collect and organize a set of adapters. In contrast, a group adapter is a component that services all adapters in an adapter group. For example, you may write a set of adapters that all use the same COM component to transmit password synchronizations over TCP/IP. Your set of adapters is called the adapter group, while the component that services them all is called a group adapter. Adapter groups are described in the configuration store. You can retrieve information and updates on an adapter group using ISSONotification.ReceiveNotification.

A group adapter has the same name as the adapter group. Other than the naming restriction, a group adapter is otherwise identical to a normal adapter. For example, a group adapter can have can have independent access groups and configuration properties, as described by its configuration file. A group adapter will most likely be on the same computer as any adapters in the adapter group. However, this is not currently enforced. Likewise all adapters in the same adapter group may be expected to be on the same computer.

Using InitializeAdapter, you can access and initialize a group adapter during startup. When you initialize a group adapter, Host Integration Server 2004 informs the group adapter of all adapters in the adapter group on the current system. In addition, HIS will send notifications to the group adapter any time an adapter is added, deleted, enabled, or disabled in the adapter group. However, the group adapter does not receive any password change notifications.

Adapter groups and group adapters are optional using the Administration tool.

What you Need To Know Before Programming Single Sign-On

In order to user the Single Sign-On Programming Guide effectively, you should be familiar with the following:

- Microsoft® Host Integration Server 2004, including how to set up and administer Single Sign-On.
- Microsoft Windows Server ™ 2003, Microsoft Windows® XP, or Microsoft Windows 2000 Server operating systems. You should be particularly familiar with Windows Security features.
- Administrative features of Enterprise Single Sign-On, especially how to perform administrative actions using the user interface.

Depending on the API and development used, you should also be familiar with the following interfaces:

- COM
- .NET Framework and the common language runtime
- Windows Networking, and in particular how to send and receive tickets

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Supported Platforms for Single Sign-On

Enterprise Single Sign-On ships with Microsoft® Host Integration Server 2004, and as such is supported by all platforms that support it as well.

- Microsoft Windows Server™ 2003
- Microsoft Windows XP Professional
- Microsoft Windows® 2000 Server
- Microsoft Windows 2000 Advanced Server
- Microsoft Windows 2000 Datacenter Server
- Microsoft Windows 2000 Professional

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Programming with Enterprise Single Sign-On

Enterprise Single Sign-On (SSO) is a technology implemented in the Enterprise Single Sign-On service (ENTSSO) that enables users to access multiple remote services without having to work their way through additional sign-on screens.

This section contains:

- Determining Current Single Sign-On Access
- Configuring Single Sign-On
- Creating and Describing an Application to Single Sign-On
- Mapping Single Sign-On Credentials
- Logging on to a Remote or Local Application
- Issuing and Redeeming a Single Sign-On Ticket
- Synchronizing a Password

Determining Current Single Sign-On Access

One of the first tasks you may need to perform for a user is to determine what affiliated applications have already been set up for the current user. You can perform this query with a call to ISSOMapper.GetApplications.

To query the Single Sign-On database for the application affiliated with the current user

1. Create a new instance of ISSOMapper.

   In general, **ISSOMapper** is an interface designed to retrieve information from SSO. You will most likely be using **ISSOMapper** in many similar queries.

2. Retrieve all of the applications affiliated with the current user with a call to **ISSOMapper.GetApplications**.

   ISSOMapper.GetApplications automatically returns only the affiliated applications of the current user.

The following code sample describes how to query the Single Sign-On (SSO) database.

```
private static string[] Applications=null;
. . .
public static string[] GetCurrentUserApplications()
{
   if(Applications==null)
   {
      string[] descs;
      string[] contacts;
      ISSOMapper mapper=new ISSOMapper();
      mapper.GetApplications(out Applications, out descs, out contacts);
   }
   return Applications;
}
```

Configuring Single Sign-On

Before accessing Single Sign-On (SSO), you should make sure that Single Sign-On is set correctly for the current user. For most configurations, you are using one of two interfaces. ISSOAdmin Interface is the general administration interface that enables you to create new affiliation applications. However, using the ISSOAdmin.GetGlobalInfo and UpdateGlobalInfo, you can set a variety of flags and administration values. One possible task, as described below, is ensuring that SSO ticketing has been enabled.

To enable ticketing

1. Create a new instance of **ISSOAdmin**.
2. Retrieve the current settings through **ISSOAdmin.GetGlobalInfo**.

   If necessary, you may wish to confirm that the flags are set to the correct values at this point.

3. Change any relevant flags using **ISSOAdmin.UpdateGlobalInfo**.

   In this particular case, all the flags are being set to validate and enable tickets. Note that Microsoft Host Integration Server currently supports only the SSO_FLAG_ENABLED. For a complete listing of all the available flags for SSO, see Enterprise Single Sign-On Flags.

The following example describes how to enable ticketing using Single Sign-On.

```
public static bool EnableTickets()
{
   try
   {
      ISSOAdmin admin=new ISSOAdmin();
      int flags=0;
      int appDeleteMax=-1;
      int mappingDeleteMax=-1;
      int ntpLookupMax=-1;
      int xplLookupMax=-1;
      int ticketTimeout=-1;
      int cacheTimeout=-1;
      string secretServer=null;
      string ssoAdminGroup=null;
      string affiliateAppMgrGroup=null;
      // Get current default settings
      admin.GetGlobalInfo(out flags, out appDeleteMax, out mappingDeleteMax, out ntpLookupMax
, out xplLookupMax, out ticketTimeout, out cacheTimeout, out secretServer, out ssoAdminGroup,
out affiliateAppMgrGroup);
      // Update global settings
      admin.UpdateGlobalInfo(SSOFlag.SSO_FLAG_ALLOW_TICKETS | SSOFlag.SSO_FLAG_VALIDATE_TICKE
TS, SSOFlag.SSO_FLAG_ALLOW_TICKETS | SSOFlag.SSO_FLAG_VALIDATE_TICKETS, ref appDeleteMax, ref
mappingDeleteMax, ref ntpLookupMax, ref xplLookupMax, ref ticketTimeout, ref cacheTimeout, nu
ll, null, null);
   }
   catch
   {
      return false;
   }
return true;
}
```

Creating and Describing an Application to Single Sign-On

Another common administrative task you may need to perform is adding an affiliate application into the Single Sign-On (SSO) database. Adding an affiliate application to the SSO database enables you to associate users and credentials with the affiliated application. Note that creating an affiliated application requires administrative privileges, and can be done through the user interface as well.

To create and describe an application in the SSO database

1. Create a new ISSOAdmin object.
2. Create a new application with a call to ISSOAdmin.CreateApplication.
3. Add the relevant fields describing the application with a call to ISSOAdmin.CreateFieldInfo.

   It is during this step that you tell the database that an application has users and associated passwords.

4. Push the newly created description out to the server with a call to ISSOAdmin.UpdateApplication.
5. Purge the local cache for the changes you made using a call to ISSOAdmin.PurgeCacheForApplication.

   Purging the local cache is a security measure that prevents having the names and passwords that you describe in step three to exist in an unsecured location.

The following sample describes how to create an application and add field information.

```
  public static bool AddApplication(string name, string admins, string users)
      {
         try
         {
            ISSOAdmin admin=new ISSOAdmin();
            // Create application
            admin.CreateApplication(name, "SSO Sample Application", "administrator@ssoaffilia
teapplication.com", users, admins, SSOFlag.SSO_WINDOWS_TO_EXTERNAL | SSOFlag.SSO_FLAG_ALLOW_T
ICKETS | SSOFlag.SSO_FLAG_VALIDATE_TICKETS, 2);
            // Add fields
            admin.CreateFieldInfo(name, "User Id", SSOFlag.SSO_FLAG_NONE);
            admin.CreateFieldInfo(name, "Password", SSOFlag.SSO_FLAG_FIELD_INFO_MASK);
            // Enable application
            admin.UpdateApplication(name, null, null, null, null, SSOFlag.SSO_FLAG_ENABLED, S
SOFlag.SSO_FLAG_ENABLED);
            // Purge changes
            admin.PurgeCacheForApplication(name);
         }
         catch
         {
            return false;
         }
         return true;
      }
```

Mapping Single Sign-On Credentials

Once you know you have affiliated applications in your Single Sign-On (SSO) database, you can map the credentials for a user to that application. Mapping the credentials of the current user to an affiliated application requires you use a combination of the ISSOMapper and ISSOMapping interfaces.

To map between an affiliated application and user credentials

1. Create new instances of **ISSOMapper** and **ISSOMapping**.
2. Set the **ISSOMapping** properties to the relevant values.

   The relevant properties for **ISSOMapping** are the Microsoft® Windows® domain name of the user, the Windows user name, the name of the affiliated application, and the logon name the user goes by for the affiliated application.

3. Make sure the mapping exists using a call to ISSOMapping.Create.

   Calling **ISSOMapping.Create** propagates the local copy of mapping out to the SSO server.

4. Set the credentials on the mapping with a call to ISSOMapper.SetExternalCredentials.

   It is necessary to set the credentials with a separate call due to security reasons.

5. Enable the mapping with a call to ISSOMapping.Enable.

   Calling **ISSOMapping.Enable** exposes your created map to the enterprise. Without calling this step, your map would remain private on the server, and thus unusable.

The following sample describes how to add mapping between a specified SSO application and a user.

```
public static bool AddMapping(string application, string user, string XU, string XP)
{
   try
   {
      // Set mapping
      ISSOMapper mapper=new ISSOMapper();
      ISSOMapping mapping=new ISSOMapping();
     string username=user.Substring(user.IndexOf('\\')+1);
      string userdomain=user.Substring(0, user.IndexOf('\\'));
      mapping.WindowsDomainName=userdomain;
      mapping.WindowsUserName=username;
      mapping.ApplicationName=application;
      mapping.ExternalUserName=XU;
      mapping.Create(0);
      // Set credentials
      string[] credentials=new string[]{XP};
      mapper.SetExternalCredentials(application, XU, ref credentials);
      mapping.Enable(0);
   }
   catch
   {
      return false;
   }
   return true;
      }
```

Logging on to a Remote or Local Application

After you have finished setting affiliate credentials for your user, you can use Enterprise Single Sign-On service (ENTSSO) to provide access to applications. If the user is local, you can use ENTSSO to retrieve credentials for a non-Windows application. In contrast, if the user is remote, you can use ENTSSO to retrieve credentials for a local application.

This section contains:

- Logging a Local User on to a non-Windows Application
- Logging a Remote User on to a Local Application

Logging a Local User on to a non-Windows Application

Once you have set up your user with an affiliate application, you can use Single Sign-on to access the external user name and credentials of the current user. Using these credentials, you can then use Transaction Integrator (TI) to log your user on to the affiliate application running on a host server.

To log a local user on to a host application

1. Receive the request to log the current user on to an application running on the host server.

   It is your responsibility to determine how the current user requests to be logged on to a host application.

2. Retrieve the credentials for the current user using ISSOLookup1.GetCredentials or ISSOLookup2.GetCredentials.

   You must supply the name of the host application along with any relevant flags. **GetCredentials** returns the associated username and credentials for the host application.

   Note that you may use either **ISSOLookup1** or **ISSOLookup2**. The only difference is that ISSOLookup2 also has a method for logging a remote user on to a local windows application.

3. Use the external user name and credentials to log on to the host application.

   It is your responsibility to determine how to use the credentials to log on to the host application. However, you will most likely use a Transaction Integrator (TI) interface.

See Also

Logging a Remote User on to a Local Application

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Logging a Remote User on to a Local Application

The other main feature of Enterprise Single Sign-On service (ENTSSO) is supporting a host-initiated process (HIP). ENTSSO interacts with HIP when a remote user attempts to access a local Windows resource. Using Host Integration Sever 2004 and ENTSSO, you can receive the request from the host user and request access to the local Windows application.

To log a remote user on to a local Windows application

1. Receive the request from the remote user.

   It is your responsibility to determine how to retrieve a request from the remote user. Most likely, you will use a Transaction Integrator (TI) interface, but that is not strictly necessary.

2. Request that the remote user be given access to the specified affiliate application, using IssoLookup2.LogonExternalUser.

   LogonExternalUser passes in the name of the application the external user wishes to access, the name of the user, the associated credentials for the user, and any relevant flags. If successful, **LogonExternalUser** will return a Windows handle.

   Note that the remote user must already be identified in the Single Sign-On database, be associated with an affiliate application, and have his credentials on file. Otherwise, **LogonExternalUser** will return an error.

   You can keep the user names and credentials up to date using Password Sync.

3. Use the Windows handle returned from **LogonExternalUser** to grant access to your remote user.

   To continue keeping your application secure, you can use SSO to issue and redeem tickets. For more information, see Issuing and Redeeming a Single Sign-On Ticket.

   As with the original request to log on, it is your responsibility to determine how the remote host will use the Windows handle.

See Also

Logging a Local User on to a non-Windows Application

Issuing and Redeeming a Single Sign-On Ticket

Once you have linked together a user and an affiliate application, you can issue tickets to ensure security while maintaining communications. Single Sign-On ticketing works as other ticketing technologies: prior to sending the message off, you append the SSO ticket to the message as a string. The server receives your message, decodes the ticket, and uses the information as appropriate. The server then acknowledges that it received the message by sending a return ticket, which you can decode and redeem.

To issue a Single Sign-On ticket

1. Create a new ticket object with a call to ISSOTicket.
2. Issue the ticket with a call to SSOTicket.IssueTicket.

   IssueTicket does not currently accept any valid parameters. Therefore, you must assign the returned encoded string only to the relevant message. The affiliate application you send the message to uses the encoded SSO ticket to determine to what parts of the application you have access.

To redeem an Single Sign-On ticket

1. Create a new ticket object with a call to **SSOTicket**.
2. Redeem the ticket with a call to SSOTicket.RedeemTicket or IBTSTicket.ValidateAndRedeemTicket.

The following code sample describes how to redeem an SSO ticket using **IBTSTicket**.

```
public class SSOResult
    {
        private string userName;
        private string[] result;
        public SSOResult (IBaseMessage message, string affiliateApplication)
        {
            string   userName = null;
            string[] result   = null;
            IBTSTicket ticket = new IBTSTicket();
            result = ticket.ValidateAndRedeemTicket(
                message,
                affiliateApplication,
                0,
                out userName);
            this.userName = userName;
            this.result   = result;
        }
        public string UserName
        {
            get { return userName; }
        }
        public string[] Result
        {
            get { return result; }
        }
    }
```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Synchronizing a Password

Synchronizing a password is performed through a password sync adapter. A password sync adapter is an application you create that is registered with the configuration store. This application ought to be capable of communicating with a specific, remote, non-Windows system, and should also be capable of instructing that system to update password information.

This section contains:

- Creating a Password Sync Adapter
- Registering and Configuring a Password Sync Adapter

Creating a Password Sync Adapter

A password sync (PS) adapter is an application that uses the Password Sync Helper component to pass notifications to and from Enterprise Single Sign-On (SSO). Note that although the PS Helper component exposes a COM interface, your adapter does not necessarily have to be a COM component. You can design your adapter as a stand-alone process, a COM+ application, or a Windows service.

To create a password sync adapter

1. Inform Enterprise Single Sign-On service (ENTSSO) that your provider is active using ISSONotification.InitializeAdapter.

   InitializeAdapter informs ENTSSO that a provider (usually the same provider that is making the call) is currently turned on, and therefore will be communicating password updates to and from the system. You can also use **InitializeAdapter** to activate other resources such as group adapters.

2. Send password updates to ENTSSO using ISSONotification.SendNotification.

   It is up to you to determine how you receive password updates from your non-Windows system: most likely, you will be using a Transaction Integrator (TI) interface. Once you have received the update, you can pass the information on to ENTSSO using **SendNotification**. Note that **SendNotification** is not limited to sending password updates: the architecture of **SendNotification** allows you to send other types of notifications as well.

3. Request password updates from ENTSSO using ISSONotification.ReceiveNotification.

   Because the password sync adapter is a pull technology, ENTSSO will never call your adapter. Instead, your adapter will periodically call **ReceiveNotification** to see if any password updates are available. You can choose to set the WAIT flag on **ReceiveNotification**. Setting WAIT will block the thread until a notification is available.

   Note that ENTSSO delivers a password change to your adapter in plain text. It is the responsibility of the adapter to protect that password information against incorrect disclosure. It is also the responsibility of the adapter to protect itself against spoofing or attacks from other invalid sources, including spoofing of the Password Sync Helper component.

   Once you receive a password update from ENTSSO through the *pReceiveNotification* parameter, you must pass this information on to your non-Windows system. As with **SendNotification**, it is up to you to determine the best means of communicating with the remote server. Most likely however, you will use a variation of Transaction Integrator (TI).

4. Turn off your adapter using ISSONotification.ShutdownAdapter.

   ShutdownApplication should be the last method called by an adapter, and indicates that the adapter will no longer be sending or receiving password updates to ENTSSO.

   Note that ENTSSO buffers any password changes a user makes while the adapter is shut down, up to a buffer size limit.

See Also

COM Mapper Programmer's Reference

Registering and Configuring a Password Sync Adapter

Once you are finished creating your password sync adapter, you must load your adapter on to a system. Further, you must inform Enterprise Single Sign-On and the configuration store that your application is a password sync adapter. You must register with the configuration store for security purposes: your adapter will request updates to passwords and other credentials. Therefore, ENTSSO must know that a given adapter is allowed to ask for such permissions.

To register and use a password sync adapter

- Register your adapter with the configuration store using the **ssops** tool.

  Using **ssops**, you load an XML configuration file that describes your application to Enterprise Single Sign-On.

Programmer's Reference

This section of the Microsoft® Host Integration Server 2004 software development kit (SDK) provides reference information for the programmer writing applications for Host Integration Server 2004.

This section contains:

- Transaction Integrator Programmer's Reference
- Data Integration Programmer's Reference
- Network Integration Programmer's Reference
- Administration and Management Programmer's Reference
- Messaging Programmer's Reference
- Security Programmer's Reference

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Transaction Integrator Programmer's Reference

This section of the Microsoft® Host Integration Server 2004 Programmer 's Reference describes the objects, methods, properties, controls, and other interfaces that enable you to integrate Host Integration Server technologies into your application.

For general information about programming for Transaction Integrator, see the Transaction Integrator Programmer's Guide section of the SDK.

For sample code using Transaction Integrator, see the Transaction Integrator Samples section of the SDK.

This section contains:

- COMTIContext Interface
- COMTIContext Keywords
- TI Component Properties
- Standard Transaction Request and Reply Messages
- CICS Enhanced Listener Request and Reply Messages
- Microsoft Concurrent Server

COMTIContext Interface

Use the **ICOMTIContext** interface to add, remove, and query information in the Transaction Integrator (TI Context). The following methods implement the **ICOMTIContext** interface:

- ClearAllContext
- ClosePersistentConnection
- CountContext
- DeleteContext
- GetConnectionInfo
- QueryContextInfo
- ReadContext
- UpdateContextInfo
- WriteContext

ClearAllContext

Use the **ClearAllContext** method to remove all the entries in a TI Context array.

```
HRESULT ClearAllContext (
[in] SAFEARRAY(VARIANT)*    prgContextArray
    );
```

Parameters

prgContextArray
This SAFEARRAY parameter contains the TI Context that is to be cleared.

Return Codes

S_OK
The method call completed successfully.
E_INVALIDARG
One or more of the parameters passed are invalid.
E_FAIL
An internal processing error occurred.

See Also

ClosePersistentConnection

CountContext

DeleteContext

GetConnectionInfo

QueryContextInfo

ReadContext

UpdateContextInfo

WriteContext

Persistent Connections with the Mainframe

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ClosePersistentConnection

Use the **ClosePersistentConnection** method to close the persistent connection by contacting the COM+ or .NET application object without the need for a call to the server object.

```
HRESULT ClosePersistentConnection (
[in, out] SAFEARRAY(VARIANT)*COMTIContextArray
    );
```

Parameters

COMTIContextArray
This SAFEARRAY contains the state of the connection.

Return Codes

S_OK
The method call completed successfully.
E_INVALIDARG
One or more of the parameters passed are invalid.
E_FAIL
An internal processing error occurred.

ClearAllContext

CountContext

DeleteContext

GetConnectionInfo

QueryContextInfo

ReadContext

UpdateContextInfo

WriteContext

Persistent Connections with the Mainframe

CountContext

Use the **CountContext** method to acquire a count of the entries in a TI Context array.

```
HRESULT CountContext (
[in] SAFEARRAY(VARIANT)*    prgContextArray,
[out] ULONG*                pulContextEntriesCount
    );
```

Parameters

prgContextArray
  This SAFEARRAY parameter contains TI Context entries that are passed to and returned from COM+ objects.
pulContextEntriesCount
  Upon successful completion of the call, this integer parameter contains a count of the number of entries in the specified TI Context array.

Return Codes

S_OK
  The method call completed successfully.
E_INVALIDARG
  One or more of the parameters passed are invalid.
E_FAIL
  An internal processing error occurred.

DeleteContext

Use the **DeleteContext** method to remove an entry in a TI Context array.

```
HRESULT DeleteContext (
[in] BSTR                       bstrContextEntryName,
[in,out] SAFEARRAY(VARIANT)*    prgContextArray
    );
```

Parameters

bstrContextEntryName
This string parameter contains the name of the TI Context entry to be removed.
prgContextArray
This SAFEARRAY parameter contains the TI Context entries that are passed to and returned from COM+ objects.

Return Codes

S_OK
The method call completed successfully.
E_INVALIDARG
One or more of the parameters passed are invalid.
E_FAIL
An internal processing error occurred.

GetConnectionInfo

Use the **GetConnectionInfo** method to query the state of the persistent connection.

```
HRESULT GetConnectionInfo (
[in] SAFEARRAY(VARIANT)*COMTIContextArray,
[out] BOOL* pfConnectionIsPersistent,
[out] BOOL* pfConnectionIsViable
    );
```

Parameters

COMTIContextArray
This SAFEARRAY contains the state of the connection.
pfConnectionIsPersistent
This BOOL parameter is set to TRUE if the connection is persistent and active.
pfConnectionIsViable
This BOOL parameter is set to TRUE if the connection is active.

Return Codes

S_OK
The method call completed successfully.
E_INVALIDARG
One or more of the parameters passed are invalid.
E_FAIL
An internal processing error occurred.

QueryContextInfo

Use the **QueryContextInfo** method to acquire a count of the entries in a TI Context array, the names of the context entries, and the data types of the context entries.

```
HRESULT QueryContextInfo (
[in, out] SAFEARRAY(VARIANT)*   prgContextArray,
[out] ULONG*                    pulContextEntriesCount,
[out] SAFEARRAY(BSTR)*          prgContextNameArray,
[out] SAFEARRAY(SHORT)*         prgContextTypeArray
    );
```

Parameters

prgContextArray
This SAFEARRAY parameter contains the TI Context entries that are passed to and returned from COM+ objects.
pulContextEntriesCount
Upon successful completion of the call, this integer parameter contains a count of the entries in the specified TI Context array.
prgContextNameArray
This SAFEARRAY of strings parameter contains the TI Context entry names.
prgContextTypeArray
This SAFEARRAY of integers parameter contains the TI Context entry data types.

Return Codes

S_OK
The method call completed successfully.
E_INVALIDARG
One or more of the parameters passed are invalid.
E_FAIL
An internal processing error occurred.

ReadContext

Use the **ReadContext** method to acquire the value of an entry in a TI Context array.

```
HRESULT ReadContext (
[in] BSTR                   bstrContextEntryName,
[out] VARIANT*              pvarContextEntryValue,
[in] SAFEARRAY(VARIANT)*    prgContextArray
    );
```

Parameters

bstrContextEntryName
This string parameter contains the name of the TI Context entry to be retrieved.
pvarContextEntryValue
This VARIANT parameter contains the value of the context entry identified by bstrContextEntryName.
prgContextArray
This SAFEARRAY parameter contains the TI Context entries that are passed to and returned from COM+ objects.

Return Codes

S_OK
The method call completed successfully.
E_INVALIDARG
One or more of the parameters passed are invalid.
E_FAIL
An internal processing error occurred.

UpdateContextInfo

Use the **UpdateContextInfo** method to update the client **COMTIContext** array with the current state of the connection.

```
HRESULT UpdateContextInfo (
[in, out] SAFEARRAY(VARIANT)*COMTIContextArray
    );
```

Parameters

COMTIContextArray
This SAFEARRAY contains the state of the connection.

Return Codes

S_OK
The method call completed successfully.
E_INVALIDARG
One or more of the parameters passed are invalid.
E_FAIL
An internal processing error occurred.

WriteContext

Use the **WriteContext** function to add or replace an entry in a TI Context array.

```
HRESULT WriteContext (
[in] BSTR                     bstrContextEntryName,
[in] VARIANT                  varContextEntryValue,
[in, out] SAFEARRAY(VARIANT)   prgContextArray
    );
```

Parameters

bstrContextEntryName
This string parameter contains the name under which the TI Context entry will be stored and accessed. Some context entry names are predefined by Microsoft. You are free to define your own (although there is no way to deal with such in the COM+ application).
varContextEntryValue
This VARIANT parameter contains the value to be stored for the context entry identified by bstrContextEntryName.
prgContextArray
This SAFEARRAY parameter contains the TI Context entries that are passed to and returned from COM+ objects.

Return Codes

S_OK
The method call completed successfully.
E_INVALIDARG
One or more of the parameters passed are invalid.
E_FAIL
An internal processing error occurred.

COMTIContext Keywords

Use the COMTIContext keywords as commands to override the contents of a transaction request message (TRM).

This section contains:

- REOverride
- TPNameOverride
- ProgNameOverride
- USERID
- PASSWORD
- IMS_LTERM
- TRMIN
- TRMOUT
- CONNTIMEOUT
- CONNTYPE

REOverride

Use the **REOverride** keyword to override the type library assignment of the method call to a remote environment (RE) and to assign the call to a newly specified RE. The COMTIContext context name is **REOverride**; the value must be a valid remote environment name.

See Also

TPNameOverride

ProgNameOverride

USERID

PASSWORD

IMS_LTERM

TRMIN

TRMOUT

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

TPNameOverride

Use the **TPNameOverride** keyword to override the transaction ID assigned within the type library and to specify the new transaction ID to be sent to the host. The COMTIContext context name is **TPNameOverride**; the value must be a string that contains a valid mainframe transaction ID.

See Also

REOverride

ProgNameOverride

USERID

PASSWORD

IMS_LTERM

TRMIN

TRMOUT

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

ProgNameOverride

Use the **ProgNameOverride** keyword to override the program name assigned within the type library and to specify a different program name to be sent to the host. The COMTIContext context name is **ProgNameOverride**; the value must be a string that contains a valid mainframe program name.

See Also

REOverride

TPNameOverride

USERID

PASSWORD

IMS_LTERM

TRMIN

TRMOUT

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

USERID

Use the **USERID** keyword, combined with **PASSWORD**, to provide explicit security without the need for a callback. The COMTIContext context name is **USERID**; the value must be a string that contains a valid mainframe security user ID.

See Also

REOverride

TPNameOverride

ProgNameOverride

PASSWORD

IMS_LTERM

TRMIN

TRMOUT

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

PASSWORD

Use the **PASSWORD** keyword, combined with **USERID**, to provide explicit security without the need for a callback. The COMTIContext context name is **PASSWORD**; the value must be a string that contains a valid mainframe security password.

REOverride

TPNameOverride

ProgNameOverride

USERID

IMS_LTERM

TRMIN

TRMOUT

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

IMS_LTERM

Use the **IMS_LTERM** to override the default LTERM that an Information Management Systems (IMS) connect call uses while processing the host transaction within IMS. The COMTIContext context name is **IMS_LTERM**, and its value must be from one through eight alphanumeric characters.

> **Note** If the **IMS_LTERM** is assigned more than eight characters, the **IMS_LTERM** value is not passed to the host transaction and the host transaction continues to use the system provided default LTERM.

REOverride

TPNameOverride

ProgNameOverride

USERID

PASSWORD

TRMIN

TRMOUT

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

TRMIN

Use the **TRMIN** keyword to override the default transaction request message (TRM) containing the transaction program ID, user ID, password, and other administrative data sent to the host. The COMTIContext context name is **TRMIN**. The TRM must be defined as a user-defined type (UDT), and the name of that UDT must begin with the characters TRMIN.

See Also

TPNameOverride

ProgNameOverride

USERID

PASSWORD

IMS_LTERM

TRMOUT

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

TRMOUT

Use the **TRMOUT** keyword to override the default transaction request message (TRM) containing the transaction program ID, user ID, password, and other administrative data sent from the host. The COMTIContext context name is **TRMOUT**. The TRM must be defined as a user-defined type (UDT), and the name of that UDT must begin with the characters TRMOUT.

See Also

TPNameOverride

ProgNameOverride

USERID

PASSWORD

IMS_LTERM

TRMIN

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

CONNTIMEOUT

Use the CONNTIMEOUT keyword to reclaim orphaned persistent connections. **CONNTIMEOUT** takes an integer value specifying, in seconds, how long to wait before a persistent connection is considered abandoned and then automatically closed. The timing starts as the client call processing is completed by the COM+ or .NET generic object.

TPNameOverride

ProgNameOverride

USERID

PASSWORD

IMS_LTERM

TRMIN

Using Custom TRMs and ELMs with COMTIContext

Sample Client Application That Passes a Custom TRM

CONNTYPE

CONNTYPE

Use the CONNTYPE keyword to establish a persistent connection by setting **CONNTYPE** to **OPEN**. If a call with **CONNTYPE** set to **OPEN** completes successfully, the returned **COMTIContext** array **CONNTYPE** keyword has a value of **USE**. To make a call and terminate the persistent connection, set the **CONNTYPE** keyword to **CLOSE**. If a call with **CONNTYPE** set to **CLOSE** completes successfully, the returned **COMTIContext** array **CONNTYPE** keyword has a value of **NONPERSISTENT**.

TI Component Properties

In the Microsoft® Visual Studio® .NET 2003 environment, Transaction Integrator (TI) component properties appear and are edited in the **Properties** pane. When you select an entity in the Visual Studio tree view or list view, its properties appear in categories in the **Properties** pane. When you select multiple items, the intersection of their properties appear to allow for bulk edit.

> **Warning** The properties of the TI components are not intended to be set or changed programmatically. Setting or changing the properties programmatically may cause the component to function incorrectly.

Standard Transaction Request and Reply Messages

To support the TCP transaction request message (TRM) Link programming model and the TCP TRM User Data programming model, Transaction Integrator (TI) supports two variations of the CICS Standard Listener TRM.

This section contains:

- TRM Format for the TCP TRM Link Programming Model
- TRM Format for the TCP TRM User Data Programming Model

TRM Format for the TCP TRM Link Programming Model

This topic describes the format and content of the transaction request message (TRM) used by the TCP TRM Link programming model.

Request Message

The following table shows the contents of the request message.

TranID	Comma	Client in data
4	1	35

TranID
Transaction ID of the Concurrent Server to be started by the Listener.

Comma
A comma (,) separates the transaction ID from the Client in data.

Client in data
35 bytes of data used by the CICS TCP/IP security exit and passed to the Concurrent Server in the transaction initiation message (TIM).

Client in data for Microsoft Security Exit format

The following code block describes the format of the client in data for the Microsoft security exit.

```
struct CLIENT_IN_DATA {
   BYTE    bUserID[8];
   BYTE    bPassword[8];
   BYTE    bLinkToName[8];
   USHORT  usCommareaLen;
   BYTE    bReserved[9];
} UNALIGNED;
```

Client in data for IBM Security Exit format

The following code block describes the format of the client in data for the IBM security exit.

```
struct CLIENT_IN_DATA2 {
   BYTE    bSecFlag;
   BYTE    bPassword[8];
   BYTE    bUserID[8];
   BYTE    bLinkToName[8];
   USHORT  usCommareaLen;
   BYTE    bReserved[8];
} UNALIGNED;
```

Reply Message

The following table shows the contents of the reply message.

TRM reply msg length	Formatted field length	Formatted field code	*Data*
4	4	1	*0-n*

Note The formatted field length, formatted field code, and data can be repeated multiple times in a single message.

TRM reply msg length
The total length of the TRM reply message. This length is the sum of all the lengths of the formatted fields that follow in the message and does not include the length of the TRM reply msg length field itself.

Formatted field length
The total length of the formatted field. This length is the length of the individual formatted field that follows in the message and does not include the length of the Formatted field length itself.

Formatted field code
A 1-byte code that describes the information passed from the Concurrent Server back to the client.

Data

This area contains 0 or more bytes of information that is associated with a specific formatted field. The length of the data is determined by the formula (formatted field length minus the size of formatted field code).

Normal codes

The following table shows the meaning of the normal codes.

Code	Type	Meaning
0x01	Info	Version ID for Microsoft® Transaction Integrator Concurrent Server
0x02	Info	User Data

Error codes

The following table shows the meaning of the error codes.

Code	Type	Meaning
0x03	Error	Invalid ProgID
0x04	Error	Invalid TranID
0x05	Error	Inquiry Failed
0x06	Error	Inquiry Status
0x07	Error	Execution OK
0x08	Error	Program ABEND
0x09	Error	Execution Failed
0x0A	Error	Invalid TRM

For more information about the format of the TRM, see the TRM definition file at <drive>:\Program Files\Microsoft Host Integration Server\System\TIM\MicrosoftTRMDefs.tim. Use Microsoft Visual Studio® .NET 2003 to view the file.

ELM Format for the TCP ELM Link Programming Model

Enhanced Listener CICS Administration

Enhanced Listener CICS Administration

The following code defines a CICS Enhanced Listener. There are several new keywords available for use with the Enhanced Listener. The parameter definitions describe how these new Listener configuration values are used for support the TI Enhanced Listener feature.

```
      EZACICD TYPE=LISTENER,  Listener record definition               X
             FORMAT=ENHANCED,  Enhanced Listener                       X
             APPLID=XYZ12345,  Application ID of CICS region           X
             TRANID=CSKM,      Transaction name for Listener           X
             PORT=1234,        Port number for Listener                X
             IMMED=YES,        Listener starts up at initialization?   X
             NUMSOCK=50,       Number of sockets supported by Listener X
             ACCTIME=30,       Timeout value for Accept                X
             GIVTIME=30,       Timeout value for Givesocket            X
             REATIME=30,       Timeout value for Read                  X
             CSTRAN=MSCS,      Name of child server transaction        X
             CSSTTYPE=KC,       Child server startup type              X
             CSDELAY=000000,   Child server delay interval             X
             MSGLEN=35,        Length of input message                 X
             PEEKDATA=NO,       Peek option                            X
             MSGFORM=EBCDIC,   Output message format                   X
```

CSTRANID

This parameter is specific to the enhanced version of the Listener and specifies the default child server transaction that the Listener starts.

For enhanced listener message (ELM) Link support, this value should be set to MSCS to conform to the samples that Microsoft delivers with the product. The MSCS transaction code should be associated with the mscmtics.cbl program that supports the Standard and Enhanced Listener protocols. Otherwise, this parameter is the transaction ID that will be executed for each request made to the designated port.

CSSTTYPE

This parameter is specific to the enhanced version of the Listener and specifies the default start method for the child server task. This parameter can be overridden by the security/transaction exit. Possible values are IC, KC, and TD.

IC

Indicates that the child server task is started using EXEC CICS START with the value specified by CSDLYINT (or an overriding value from the security/transaction exit) as the delay interval.

KC

Indicates that the child server task is started using EXEC CICS START with no delay interval.

TD

Indicates that the child server task is started using the EXEC CICS WRITEQ TD command, which uses transient data to trigger the child server task.

CSDLYINT

This parameter is specific to the enhanced version of the Listener and is applicable only if CSSTTYPE is IC. It specifies the delay interval to be used on the EXEC CICS START command, in the form hhmmss (hours/minutes/seconds).

MSGFORM

This parameter is specific to the enhanced version of the Listener and indicates whether an error message returned to the client should be in ASCII or Extended Binary Coded Decimal Interchange Code (EBCDIC) format. ASCII is the default. MSGFORM is displayed as MSGFORMat on the IBM-supplied CICS Transaction screens.

For TI Enhanced Listener support, this value must be set to EBCDIC.

MSGLEN

This parameter is specific to the enhanced version of the Listener and specifies the length of the data to be received from the client by the Listener. The valid range is from 0 through 999. If the value is 0, the Listener does not read in any data from the client.

For TI Enhanced Listener support, this value must be the size of the ELM that is delivered. The size of the ELM is 35.

PEEKDATA

This parameter is specific to the enhanced version of the Listener and applies only if MSGLEN is not 0.

A value of NO indicates that the Listener performs a normal read of the client data. The child server application accesses this data in the data area-2 portion of the transaction initiation message (TIM).

A value of YES indicates that the Listener reads the data using the Peek option. The data remains queued in TCP/IP and the child server applications read it in rather than accessing it through the TIM.

For TI Enhanced Listener support, this value must be set to NO. Setting this value to NO instructs the Enhanced Listener to read the ELM (35 bytes) and place it in the TIM in the data area-2 field.

The mscmtics.cbl Concurrent Server uses the information in this area to determine what server program to link to.

ELM definition file at <drive>:\Program Files\Microsoft Host Integration Server\System\TIM\MicrosoftELMDefs.tim. Use Microsoft Visual Studio® .NET 2003 to view the file.

Microsoft Concurrent Server

The MSCS transaction (program mscmtics.cbl) samples support both the Standard and the Enhanced Listener. The transaction program can be started by either the Enhanced or Standard Listener.

Each listener passes a unique transaction initiation message (TIM) to the transaction program when the Concurrent Server is started. The Standard Listener formats and passes the TIM shown in the following code sample. The length of this TIM is 72 bytes.

```
01  TRANSACTION-INITIATION-MESSAGE.
    05  GIVE-TAKE-SOCKET    PIC 9(8) COMP.
    05  LSTN-NAME           PIC X(8).
    05  LSTN-SUBNAME        PIC X(8).
    05  CLIENT-IN-DATA      PIC X(35).
    05  FILLER              PIC X(1).
    05  SOCKADDR-IN-PARM.
        15 SIN-FAMILY       PIC 9(4) COMP.
        15 SIN-PORT         PIC 9(4) COMP.
        15 SIN-ADDRESS      PIC 9(8) COMP.
        15 SIN-ZERO         PIC X(8).
```

The Enhanced Listener formats and passes the TIM shown in the following code sample. The length of this TIM is 189 bytes.

```
01  TRANSACTION-INITIATION-MESSAGE.
    05  GIVE-TAKE-SOCKET    PIC 9(8) COMP.
    05  LSTN-NAME           PIC X(8).
    05  LSTN-SUBNAME        PIC X(8).
    05  CLIENT-IN-DATA      PIC X(35).
    05  FILLER              PIC X(1).
    05  SOCKADDR-IN-PARM.
        15 SIN-FAMILY       PIC 9(4) COMP.
        15 SIN-PORT         PIC 9(4) COMP.
        15 SIN-ADDRESS      PIC 9(8) COMP.
        15 SIN-ZERO         PIC X(8).
    05  FILLER              PIC X(80).
    05  DATA-AREA-2-LEN     PIC 9(4) COMP.
    05  DATA-AREA-2         PIC X(35).
```

The mscmtics.cbl sample Concurrent Server can determine whether the Standard or the Enhanced Listener was used by evaluating the length of the TIM received.

In a scenario where the Enhanced Listener started the Microsoft Concurrent Server, the mscmtics.cbl program looks at the Client-in-data that is contained in the ELM found in the TIM data area-2 field. The Client-in-data contains the name of the CICS Server program to be executed and the length of the request data to be received from the client. The following code sample shows the contents of this data area.

```
       01 CLIENT-IN-DATA                      PIC X(35).
       01 FILLER REDEFINES CLIENT-IN-DATA.
          05 CID-USERID                       PIC X(8).
          05 CID-PASSWORD                     PIC X(8).
          05 CID-LINK-TO-PROG                 PIC X(8).
          05 CID-COMMAREA-LEN                 PIC S9(4) COMP.
          05 CID-DATA-LEN                     PIC S9(8) COMP.
          05 CID-VERSION                      PIC X.
             88 CID-VERSION-1                 VALUE X'00'.
             88 CID-VERSION-2                 VALUE X'01'.
          05 CID-FLAGS                        PIC X(2).
             88 CID-FLAGS-PERSISTENT-NONE     VALUE X'0001'.
             88 CID-FLAGS-PERSISTENT-OPEN     VALUE X'0002'.
             88 CID-FLAGS-PERSISTENT-USE      VALUE X'0004'.
             88 CID-FLAGS-PERSISTENT-CLOSE    VALUE X'0008'.
          05 CID-RESERVED                     PIC X.
          05 CID-FORMAT                       PIC X.
             88 CID-FORMAT-NOTSET             VALUE X'00'.
             88 CID-FORMAT-MS                 VALUE X'01'.
```

```
                88 CID-FORMAT-IBM              VALUE X'02'.

Data Integration Programmer's Reference

This section of the Microsoft® Host Integration Server 2004 Developer's Guide describes the objects, methods, properties, controls, and other interfaces that enable you to integrate data into your Host Integration Server application.

For general information about programming for data integration, see Data Integration Programmer's Guide section of the SDK.

For sample code using data integration, see Data Integration Samples section of the SDK.

This section contains:

- OLE DB Providers Programmer's Reference
- ODBC Driver for DB2 Programmer's Reference
- Managed Provider for DB2 Programmer's Reference
- Data Access Library Programmer's Reference

OLE DB Providers Programmer's Reference

The OLE DB specification version 2.0 defines a number of objects and interfaces.

Microsoft® OLE DB Provider for AS/400 and VSAM supports the OLE DB objects and interfaces appropriate for an OLE DB data provider accessing a non-SQL host file system.

Microsoft OLE DB Provider for DB2 supports the OLE DB objects and interfaces appropriate for an OLE DB data provider accessing an SQL database.

This section also provides a comparison of the objects and interfaces supported by OLE DB Provider for AS/400 and VSAM and OLE DB Provider for DB2.

> **Note** Do not use double or real columns when specifying **UPDATE** or **DELETE** statements on the MsDb2DataAdapter. These rows will not be found and will throw the concurrency violation exception.

OLE DB Object Support Comparison

The following table compares the OLE DB version 2.0 objects that are supported by the current version of Microsoft® OLE DB Provider for AS/400 and VSAM and Microsoft OLE DB Provider for DB2.

OLE DB object	OLE DB Provider for AS/400 and VSAM	OLE DB Provider for DB2
Command	Yes, most interfaces	Yes, most interfaces
CustomErrorObject	No	Yes, all interfaces
DataSource	Yes, most interfaces	Yes, some interfaces
Enumerator	No	No
ErrorObject	Yes, all interfaces	Yes, all interfaces
ErrorRecord	Yes, all interfaces	Yes, all interfaces
Index	Yes, all interfaces	No
MultipleResults	No	No
Rowset	Yes, most interfaces	Yes, some interfaces
Session	Yes, some interfaces	Yes, some interfaces
Transaction	No	Yes, some interfaces
TransactionOptions	No	Yes, all interfaces
View	Yes, all interfaces	No

OLE DB Interface Support Comparison

The following table compares the OLE DB version 2.0 interfaces that are supported by the current version of Microsoft® OLE DB Provider for AS/400 and VSAM and Microsoft OLE DB Provider for DB2.

Object	Interface	OLE DB Provider for AS/400 and VSAM	OLE DB Provider for DB2
Command	**IAccessor**	Yes	Yes
	IColumnsInfo	Yes	Yes
	IColumnsRowset	No	No
	ICommand	Yes	Yes
	ICommandPersist	No	No
	ICommandPrepare	No	Yes
	ICommandProperties	Yes	Yes
	ICommandText	Yes	Yes
	ICommandWithParameters	No	Yes
	IConvertType	Yes	Yes
	ISupportErrorInfo	Yes	Yes
CustomErrorObject	**IErrorLookup**	No	Yes
	ISQLErrorInfo	No	Yes
DataSource	**IDBAsynchStatus**	No	No
	IConnectionPointContainer	No	No
	IDBCreateSession	Yes	Yes
	IDBDataSourceAdmin	No	No
	IDBInfo	No	Yes

	IViewRowset	Yes	No
	IViewSort	Yes	No

OLE DB Object Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the OLE DB version 2.0 objects that are supported by the current version of Microsoft® OLE DB Provider for AS/400 and VSAM.

OLE DB object	**Support**
Command Object	Yes, most interfaces
CustomErrorObject	No
DataSource Object	Yes, most interfaces
Enumerator	No
ErrorObject Object	Yes, all interfaces
ErrorRecord Object	Yes, all interfaces
Index Object	Yes, all interfaces
MultipleResults	No
Rowset Object	Yes, most interfaces
Session Object	Yes, some interfaces
Transaction	No
TransactionOptions	No
View Object	Yes, all interfaces

This section contains:

- OLE DB Interface Support in the OLE DB Provider for AS/400 and VSAM
- Command Object (OLE DB Provider for AS/400 and VSAM)
- DataSource Object (OLE DB Provider for AS/400 and VSAM)
- ErrorObject Object (OLE DB Provider for AS/400 and VSAM)
- ErrorRecord Object (OLE DB Provider for AS/400 and VSAM)
- Index Object (OLE DB Provider for AS/400 and VSAM)
- Rowset Object (OLE DB Provider for AS/400 and VSAM)
- Session Object (OLE DB Provider for AS/400 and VSAM)
- View Object (OLE DB Provider for AS/400 and VSAM)
- OLE DB Property Support in the OLE DB Provider for AS/400 and VSAM

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

OLE DB Interface Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the OLE DB version 2.0 interfaces that are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM.

Object	**Interface**	**Support**
Command Object	**IAccessor**	Yes
	IColumnsInfo	Yes
	IColumnsRowset	No
	ICommand	Yes
	ICommandPersist	No
	ICommandPrepare	No
	ICommandProperties	Yes
	ICommandText	Yes
	ICommandWithParameters	No
	IConvertType	Yes
	ISupportErrorInfo	Yes
CustomErrorObject	**IErrorLookup**	No
	ISQLErrorInfo	No
DataSource Object	**IDBAsynchStatus**	No
	IDBConnectionPointContainer	No
	IDBCreateSession	Yes
	IDBDataSourceAdmin	No
	IDBInfo	No
	IDBInitialize	Yes
	IDBProperties	Yes
	IPersist	Yes
	IPersistFile	Yes
	ISupportErrorInfo	Yes
Enumerator	**IDBInitialize**	No
	IDBProperties	No
	IParseDisplayName	No
	ISourcesRowset	No
	ISupportErrorInfo	No
ErrorObject Object	**IErrorRecords**	Yes
ErrorRecord Object	**IErrorInfo**	Yes
Index Object	**IAccessor**	Yes
	IColumnsInfo	Yes
	IConvertType	Yes
	IRowset	Yes
	IRowsetChange	Yes
	IRowsetFind	Yes
	IRowsetIdentity	Yes
	IRowsetIndex	Yes
	IRowsetInfo	Yes
	IRowsetLocate	Yes
	IRowsetRefresh	Yes
	IRowsetScroll	Yes
	IRowsetUpdate	Yes
	IRowsetView	Yes
	ISupportErrorInfo	Yes
MultipleResults	**IMultipleResults**	No

	ISupportErrorInfo	No
Rowset Object	**IAccessor**	Yes
	IChapteredRowset	Yes
	IColumnsInfo	Yes
	IColumnsRowset	Yes
	IConnectionPointContainer	No
	IConvertType	Yes
	IDBAsynchStatus	No
	IRowset	Yes
	IRowsetChange	Yes
	IRowsetChapterMember	No
	IRowsetFind	Yes
	IRowsetIdentity	Yes
	IRowsetIndex	Yes
	IRowsetInfo	Yes
	IRowsetLocate	Yes
	IRowsetRefresh	Yes
	IRowsetScroll	No
	IRowsetUpdate	Yes
	IRowsetView	Yes
	ISupportErrorInfo	Yes
Session Object	**IAlterIndex**	No
	IAlterTable	No
	IDBCreateCommand	Yes
	IDBSchemaRowset	Yes
	IGetDataSource	Yes
	IIndexDefinition	No
	IOpenRowset	Yes
	ISessionProperties	Yes
	ISupportErrorInfo	Yes
	ITableDefinition	No
	ITransaction	No
	ITransactionJoin	No
	ITransactionLocal	No
	ITransactionObject	No
Transaction	**IConnectionPointContainer**	No
	ISupportErrorInfo	No
	ITransaction	No
TransactionOptions	**ISupportErrorInfo**	No
	ITransactionOptions	No
View Object	**IAccessor**	Yes
	IColumnsInfo	Yes
	ISupportErrorInfo	Yes
	IViewChapter	Yes
	IViewFilter	Yes
	IViewRowset	Yes
	IViewSort	Yes

Command Object (OLE DB Provider for AS/400 and VSAM)

The **Command** object is created by an OLE DB consumer, or by a service provider on behalf of a consumer. A **Command** object is used to execute a distributed data management (DDM)-specific command on a remote DDM server. The **Command** object currently supports executing Command Language commands on AS/400 DDM servers.

It is important not to confuse a command, which is an OLE COM object, and its command text, which is a string. Commands are generally used for data definition, such as creating a table or granting privileges, and data manipulation, such as updating or deleting rows. A special case of data manipulation using the **Command** object is opening a rowset (a table).

Before a consumer can use a command, it must determine if commands are supported. To do this, the consumer calls **QueryInterface** for **IDBCreateCommand** on a session. If this interface is exposed, the provider supports commands. To create a command, the consumer then calls **IDBCreateCommand::CreateCommand** on the session. A single session can be used to create multiple commands.

When the command is first created, it does not contain a command text. The consumer sets the command text with **ICommandText::SetCommandText**. Because the text command syntax is provider-specific, the consumer passes the globally unique identifier (GUID) of the syntax to use. For use with Microsoft OLE DB Provider for AS/400 and VSAM, the GUID is DBGUID_DBSQL. Note that under OLE DB Provider for AS/400 and VSAM, this GUID does not signify that the text command is a superset of ANSI SQL. The level at which the provider supports ANSI SQL is specified by the DBPROP_SQLSUPPORT property. This property is a bitmask specifying the level of support for SQL. OLE DB Provider for AS/400 and VSAM sets this property to DBPROPVAL_SQL_NONE, indicating that SQL is not supported.

The syntax supported by OLE DB Provider for AS/400 and VSAM for command text is as follows:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands enable you to request functions from the OS/400 operating system. Some examples are the Delete File (DLTF) or Display File Description DSPFFD) commands. These are the same commands that could be issued at the command prompt if you were connected to an AS/400 through a 5250 terminal session. For a detailed list of possible commands, see the OS/400 CL reference for your platform.

The syntax supported by OLE DB Provider for AS/400 and VSAM to open a rowset (table) using command text is as follows:

```
EXEC OPEN FileName
```

where *FileName* represents one of the following host file naming conventions listed in the following table.

Host file type	File naming convention
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned Data Sets	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILENAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY.FILENAME(MEMBER)

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax used to open a rowset using command text is as follows:

```
EXEC OPEN LIBRARY/FILE("NAMES.DAT")
```

To execute the command, the consumer calls **ICommand::Execute**. If the command text specifies the command to open a rowset, (an **EXEC OPEN** command), **Execute** instantiates the rowset and returns an interface pointer to it.

The following interfaces of the **Command** object are supported by the current version of OLE DB Provider for AS/400 and VSAM:

- **IAccessor**
- **IColumnsInfo**
- **ICommand**
- **ICommandProperties**

- **ICommandText**
- **IConvertType**
- **ISupportErrorInfo**

DataSource Object (OLE DB Provider for AS/400 and VSAM)

The **DataSource** object is created by an OLE DB consumer. The **DataSource** object contains the knowledge and ability to connect to an IBM mainframe or AS/400 computer over Advanced Program-to-Program Communications (APPC) and LU 6.2 (through Microsoft Host Integration Server 2004) or over TCP/IP. The **DataSource** object is used to create one or more **Session** objects.

The following interfaces of the **DataSource** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IDBCreateSession**
- **IDBInitialize**
- **IDBProperties**
- **IPersist**
- **IPersistFile**
- **ISupportErrorInfo**

ErrorObject Object (OLE DB Provider for AS/400 and VSAM)

The **ErrorObject** object is created by any interface on any SNA OLE DB object. The **ErrorObject** object is used to retrieve additional information when an error occurs.

The following interface of the **ErrorObject** object is supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IErrorRecords**

The **IErrorRecords** interface returns **ErrorRecord** objects with detailed information about the error that occurred.

ErrorRecord Object (OLE DB Provider for AS/400 and VSAM)

The **ErrorRecord** object is created by calling the **IErrorRecord** interface on the **ErrorObject** object. An **ErrorObject** is created on any interface on any SNA OLE DB object when an error occurs. The **ErrorRecord** object is used to retrieve additional information when an error occurs.

The following interface of the **ErrorRecord** object is supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IErrorInfo**

OLE DB interface methods return error information in two ways. The error code returned by an interface method, known as the **return code**, indicates the overall success or failure of a method. Error records provide detailed information about the error, such as a text description of the error, the globally unique identifier (GUID) of the interface that defined the error, and provider-specific error information. Error objects in OLE DB are an extension of the error objects in Automation. They use many of the same mechanisms, and can be used as Automation error objects.

OLE DB error return codes are of type HRESULT. There are two general classes of return codes: success and warning codes, and error codes.

Success and warning codes begin with S_ or DB_S_ and indicate that the method successfully completed. The standard OLE DB error codes are defined in the OLEDBERR.H include file.

If the return code is other than S_OK or S_FALSE, it is likely that an error occurred from which the method was able to recover. For example, **IRowset::GetNextRows** returns DB_S_ENDOFROWSET when it is unable to return the requested number of rows due to reaching the end of the rowset. If a single warning condition occurs, the method returns the code for that condition. If multiple warning conditions occur, the method describes the hierarchy of warning return codes indicating which warning code should be returned when given a choice between multiple warning return codes.

Error codes begin with E_ or DB_E_ and indicate that the method failed completely and was unable to do any useful work. For example, **GetNextRows** returns E_INVALIDARG when the pointer in which it is to return a pointer to an array of row handles (*prghRows*) is null. An exception to this is that some of the methods that return DB_E_ERRORSOCCURRED allocate memory in which to return additional information about these errors. Consumers must free this memory. For information about which methods allocate memory in this case, see the methods that return DB_E_ERRORSOCCURRED. Although error codes can indicate run-time errors, such as running out of memory, they generally indicate programming errors. If multiple errors occur, the code that is returned is provider-specific. If both errors and warnings occur, the method fails and returns an error code.

All methods can return S_OK, E_FAIL, and E_OUTOFMEMORY. The E_OUTOFMEMORY code applies only to those methods which allocate memory that is returned to the consumer. In some cases, the E_OUTOFMEMORY code might be eliminated by calling the method requesting fewer returned values, such as fewer rows from **GetNextRows**.

Index Object (OLE DB Provider for AS/400 and VSAM)

An OLE DB index, also known as an **index rowset**, is a rowset built over an index in a data source. It is generally used in conjunction with a rowset built over a base table in the same data source. Each row of the index rowset contains a bookmark that points to a row in the base-table rowset. Thus, an OLE DB consumer can traverse the index rowset and use it to access rows in the base-table rowset.

Indexes are created using the index interfaces of the **Rowset** object. Index rowsets allow an application to read records efficiently by means of a key.

The following index interfaces of the **Rowset** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM when applied to AS/400 keyed physical files, AS/400 logical files, VSAM KSDS files with unique keys, and VSAM RRDS files with unique keys:

- **IAccessor**
- **IColumnsInfo**
- **IConvertType**
- **IRowset**
- **IRowsetChange**
- **IRowsetFind**
- **IRowsetIdentity**
- **IRowsetIndex**
- **IRowsetInfo**
- **IRowsetLocate**
- **IRowsetRefresh**
- **IRowsetScroll**
- **IRowsetUpdate**
- **IRowsetView**
- **ISupportErrorInfo**

OLE DB Provider for AS/400 and VSAM supports integrated indexes using the **IRowsetIndex** interface based on the underlying rowset.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Rowset Object (OLE DB Provider for AS/400 and VSAM)

Rowset objects are created by **Session** objects. The **Rowset** object exposes data in tabular format.

The following interfaces of the **Rowset** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IAccessor**
- **IChapteredRowset**
- **IColumnsInfo**
- **IColumnsRowset**
- **IConvertType**
- **IRowset**
- **IRowsetChange**
- **IRowsetFind**
- **IRowsetIdentity**
- **IRowsetIndex**
- **IRowsetInfo**
- **IRowsetLocate**
- **IRowsetRefresh**
- **IRowsetUpdate**
- **IRowsetView**
- **ISupportErrorInfo**

> **Note** The **IRowsetFind** interface is only supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM when applied to AS/400 keyed physical files, AS/400 logical files, VSAM KSDS files with unique keys, and VSAM RRDS files with unique keys.

Session Object (OLE DB Provider for AS/400 and VSAM)

The **Session** object is created by a **DataSource** object. The **Session** object is used to create one or more **Rowset** objects.

The following interfaces of the **Session** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IDBCreateCommand**
- **IDBSchemaRowset**
- **IGetDataSource**
- **IOpenRowset**
- **ISessionProperties**
- **ISupportErrorInfo**

Consumers can get information about a data store without knowing its structure by using the **IDBSchemaRowset** methods. The methods on this interface can be used to retrieve advanced schema information. OLE DB Provider for AS/400 and VSAM organizes this information into a set of schemas that contain tables for each schema. These schema rowsets are identified by globally unique identifiers (GUIDs).

The following schema rowset GUIDs are supported by OLE DB Provider for AS/400 and VSAM:

- DBSCHEMA_COLUMNS
- DBSCHEMA_INDEXES
- DBSCHEMA_PROVIDER_TYPES
- DBSCHEMA_TABLES

The following table lists these GUIDs and the columns for which restrictions can be specified on the schema rowset when using OLE DB Provider for AS/400 and VSAM. The number of restriction columns for each schema rowset are defined as constants prefixed with CRESTRICTIONS_ in the OLE DB header files. Restriction values are treated as literals rather than as search patterns. For example, the restriction value "A_C" matches "A_C" but not "ABC".

GUID	Number of restrictions	Restriction columns
DBSCHEMA_COLUMNS	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME COLUMN_NAME
DBSCHEMA_INDEXES	5	TABLE_CATALOG TABLE_SCHEMA INDEX_NAME TYPE TABLE_NAME
DBSCHEMA_PROVIDER_TYPES	2	DATA_TYPE BEST_MATCH
DBSCHEMA_TABLES	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME TABLE_TYPE

The **IDBSchemaRowset** interface allows an application to pass at run time the target library of a partitioned data set (PDS), a dataset, or a member name when using the **IDBSchemaRowset:GetSchemas** function to retrieve the schema.

This following example illustrates using a target library to retrieve a table schema:

```
hr = pIDBSchemaRowset->GetRowset(
        NULL,                         // punkOuter
        DBSCHEMA_TABLES,              // schema IID
         2L,                          // # of restrictions
         rgRestrictions,              // array of restrictions
         IID_IRowset,                 // rowset interface
         0L,                          // # of properties
         NULL,                        // properties
         (IUnknown**)&pIRowset);      // rowset pointer
```

The variable *rgRestrictions* is an array containing two restriction values. The first array entry is VT_EMPTY and the second array entry is the target library name.

View Object (OLE DB Provider for AS/400 and VSAM)

The **View** object is created on a **Rowset** object. The **View** object is used to expose simple operations, such as sorting and filtering a rowset by applying a view. Views can be applied when opening a **Rowset** object or applied to an existing **Rowset** object.

The following interfaces of the **View** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM when applied to AS/400 keyed physical files, AS/400 logical files, VSAM KSDS files with unique keys, and VSAM RRDS files with unique keys:

- **IAccessor**
- **IColumnsInfo**
- **ISupportErrorInfo**
- **IViewChapter**
- **IViewFilter**
- **IViewRowset**
- **IViewSort**

OLE DB Property Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the provider-specific OLE DB version 2.0 properties in the SNAOLEDB_DBPROPSET_DBINIT property set that are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM.

OLE DB Property ID	Description
DBPROP_SNAOLEDB_APPCMODE	When logical unit (LU) 6.2 (SNA) is selected for the Network Transport Library (DBPROP_SNAOLEDB_NETTYPE), this property is the Advanced Program-to-Program Communications (APPC) mode and must be set to a value that matches the host configuration and SNA server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This VT_BSTR type property normally defaults to QPCSUPP.
DBPROP_SNAOLEDB_BINASCHAR	This property indicates whether to process binary fields (Character Code Set Identifier or CCSID of 65535) as character data type fields on a per data source basis. The host CCSID and PC Code Page values are required input parameters when this parameter is true. This VT_BOOL type property defaults to VARIANT_FALSE, do not process binary fields as character fields.
DBPROP_SNAOLEDB_HCDPATH	The fully qualified file name of the distributed data management (DDM) host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This VT_BSTR type property is required when connecting to mainframe systems and is optional when connecting to OS/400.
DBPROP_SNAOLEDB_HOSTCCSID	The CCSID matching the data as represented on the host. This property is required when processing binary data as character data. Unless the DBPROP_SNAOLEDB_BINASCHAR property is set to **true**, character data is converted based on the host column CCSID and default ANSI code page. This VT_I4 property defaults to U.S./Canada (37).
DBPROP_SNAOLEDB_LIBRARY	The default AS/400 library to be accessed. This VT_BSTR property is not required for mainframe access and is optional when connecting to AS/400 files.
DBPROP_SNAOLEDB_LOCALLU	When LU 6.2 (SNA) is selected for the Network Transport Library, this property is the name of the local LU alias configured in the SNA server.
DBPROP_SNAOLEDB_NETADDRESS	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting through TCP/IP.

DBPROP_SNAOLEDB_NETPORT	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target DDM service access port when connecting by using TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. The default value for the VT_BSTR type property is 446.
DBPROP_SNAOLEDB_NETTYPE	This property which represents the dynamic link library used for transport designates whether the provider connects by using SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCP/IP or SNA. If TCP/IP is selected, values for Network Address (DBPROP_SNAOLEDB_NETADDRESS) and Network Port (DBPROP_SNAOLEDB_NETPORT) are required. TCP/IP connectivity to the mainframe is not supported by OLE DB Provider for AS/400 and VSAM. If SNA is selected, values for APPC Local LU Alias (DBPROP_SNAOLEDB_LOCALLU), APPC Mode Name (DBPROP_SNAOLEDB_APPCMODE), and APPC Remote LU Alias (DBPROP_SNAOLEDB_REMOTELU) are required. This value for this VT_BSTR property defaults to SNA.
DBPROP_SNAOLEDB_PCCODEPAGE	The PC Code Page property ID indicates the code page to be used on the computer for character code conversion. This property is required when processing binary data as character data. Unless DBPROP_SNAOLEDB_BINASCHAR is set to true, character data is converted based on the default ANSI code page configured in Windows. If this parameter is set to Binary or 65535, no character code conversions will take place. The default value for this VT_I4 type property is 1252 (Latin-1).
DBPROP_SNAOLEDB_REMOTELU	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_SNAOLEDB_NETTYPE), this property ID is the name of the remote LU alias configured in the SNA server.
DBPROP_SNAOLEDB_REPAIRKEY	This property ID provides for repair of invalid key offsets received from OS/400 when keys have been defined using the Digital Data System (DDS) "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This VT_BOOL type property defaults to VARIANT_FALSE.
DBPROP_SNAOLEDB_STRICTVAL	This property indicates whether strict validation should be used. This VT_BOOL type property defaults to VARIANT_FALSE.

OLE DB Object Support in the OLE DB Provider for DB2

The following table summarizes the OLE DB version 2.0 objects that are supported by the current version of Microsoft® OLE DB Provider for DB2.

OLE DB object	**Support**
Command Object	Yes, most interfaces
CustomErrorObject	Yes, all interfaces
DataSource Object	Yes, some interfaces
Enumerator	No
ErrorObject Object	Yes, all interfaces
ErrorRecord Object	Yes, all interfaces
Index	No
MultipleResults	No
Rowset Object	Yes, some interfaces
Session Object	Yes, some interfaces
Transaction Object	Yes, some interfaces
TransactionOptions	Yes, all interfaces
View	No

OLE DB Interface Support in the OLE DB Provider for DB2

The following table summarizes the OLE DB version 2.0 interfaces that are supported by the current version of Microsoft OLE DB Provider for DB2.

Object	**Interface**	**Support**
Command Object	**IAccessor**	Yes
	IColumnsInfo	Yes
	IColumnsRowset	No
	ICommand	Yes
	ICommandPersist	No
	ICommandPrepare	Yes
	ICommandProperties	Yes
	ICommandText	Yes
	ICommandWithParameters	Yes
	IConvertType	Yes
	ISupportErrorInfo	Yes
CustomErrorObject Object	**IErrorLookup**	Yes
	ISQLErrorInfo	Yes
DataSource Object	**IDBAsynchStatus**	No
	IConnectionPointContainer	No
	IDBCreateSession	Yes
	IDBDataSourceAdmin	No
	IDBInfo	Yes
	IDBInitialize	Yes
	IDBProperties	Yes
	IPersist	Yes
	IPersistFile	Yes
	ISupportErrorInfo	Yes
Enumerator	**IDBInitialize**	No
	IDBProperties	No
	IParseDisplayName	No
	ISourcesRowset	No
	ISupportErrorInfo	No
ErrorObject Object	**IErrorRecords**	Yes
ErrorRecord Object	**IErrorInfo**	Yes
Index	**IAccessor**	No
	IColumnsInfo	No
	IConvertType	No
	IRowset	No
	IRowsetChange	No
	IRowsetFind	No
	IRowsetIdentity	No
	IRowsetIndex	No
	IRowsetInfo	No
	IRowsetLocate	No
	IRowsetRefresh	No
	IRowsetScroll	No
	IRowsetUpdate	No
	IRowsetView	No
	ISupportErrorInfo	No
MultipleResults	**IMultipleResults**	No
	ISupportErrorInfo	No
Rowset Object	**IAccessor**	Yes

	IChapteredRowset	No
	IColumnsInfo	Yes
	IColumnsRowset	No
	IConnectionPointContainer	No
	IConvertType	Yes
	IDBAsynchStatus	No
	IRowset	Yes
	IRowsetChange	Yes
	IRowsetChapterMember	No
	IRowsetFind	No
	IRowsetIdentity	No
	IRowsetIndex	No
	IRowsetInfo	Yes
	IRowsetLocate	No
	IRowsetRefresh	No
	IRowsetScroll	No
	IRowsetUpdate	Yes
	IRowsetView	No
	ISupportErrorInfo	Yes
Session Object	**IAlterIndex**	No
	IAlterTable	No
	IDBCreateCommand	Yes
	IDBSchemaRowset	Yes
	IGetDataSource	Yes
	IIndexDefinition	No
	IOpenRowset	Yes
	ISessionProperties	Yes
	ISupportErrorInfo	Yes
	ITableDefinition	No
	ITransaction	Yes
	ITransactionJoin	No
	ITransactionLocal	Yes
	ITransactionObject	Yes
Transaction Object	**IConnectionPointContainer**	No
	ISupportErrorInfo	Yes
	ITransaction	Yes
TransactionOptions	**ISupportErrorInfo**	Yes
	ITransactionOptions	Yes
View	**IAccessor**	No
	IColumnsInfo	No
	ISupportErrorInfo	No
	IViewChapter	No
	IViewFilter	No
	IViewRowset	No
	IViewSort	No

Command Object (OLE DB Provider for DB2)

The **Command** object is created by an OLE DB consumer, or by a service provider on behalf of a consumer. A **Command** object is used to execute a distributed data management (DDM)-specific command on a remote DDM server. The **Command** object currently supports executing Command Language commands on AS/400 DDM servers.

It is important not to confuse a command, which is an OLE COM object, and its command text, which is a string. Commands are generally used for data definition, such as creating a table or granting privileges, and data manipulation, such as updating or deleting rows. A special case of data manipulation using the **Command** object is the creation of rowsets based on DB2 tables. When using the command text with DB2/400 on the AS/400 computer, table names specified in a command are by default passed as uppercase. If a table name uses mixed case, the table name must be passed in a quoted string.

Before a consumer can use a command, it must determine if commands are supported. To do this, the consumer calls **QueryInterface** for **IDBCreateCommand** on a session. If this interface is exposed, the provider supports commands. To create a command, the consumer then calls **IDBCreateCommand::CreateCommand** on the session. A single session can be used to create multiple commands.

When the command is first created, it does not contain a command text. The consumer sets the command text with **ICommandText::SetCommandText**. Because the text command syntax is provider-specific, the consumer passes the globally unique identifier (GUID) of the syntax to use. For use with Microsoft OLE DB Provider for DB2, the GUID is DBGUID_DBSQL. Note that under OLE DB Provider for DB2, this GUID signifies that the text command is a superset of ANSI SQL. The level at which the provider supports ANSI SQL is specified by the DBPROP_SQLSUPPORT property. This property is a bitmask specifying the level of support for SQL.

The syntax supported by OLE DB Provider for DB2 for command text is as Entry-Level ANSI SQL 92 (with some exceptions based on the DB2 server host platform).

Legal SQL commands are documented in the following publications published by IBM:

- *AS/400 Advanced Series: DB2 for AS/400 SQL Reference Version 4* (Document Number SC41-5612-00)
- *DB2 for OS/390 Version 5: SQL Reference* (Document Number SC26-8966)

To execute the command, the consumer calls **ICommand::Execute**. If the command text specifies the command to open a rowset, **Execute** instantiates the rowset and returns an interface pointer to it.

The following interfaces of the **Command** object are supported by the current version of OLE DB Provider for DB2:

- **IAccessor**
- **IColumnsInfo**
- **ICommand**
- **ICommandPrepare**
- **ICommandProperties**
- **ICommandText**
- **ICommandWithParameters**
- **IConvertType**
- **ISupportErrorInfo**

When using the **ICommand** object, Microsoft OLE DB Provider for DB2 cannot derive parameter type information from the data store. The OLE DB client application must supply the native parameter type information through **ICommandWithParameters::SetParameterInfo** function. The OLE DB provider uses the type information specified by **SetParameterInfo** to determine how to convert parameter data from the type supplied by the consumer (as indicated by the wType value in the binding structure) to the native type used by the data store. When the consumer specifies a data type with known precision, scale, and size values, any information supplied by the consumer for precision, scale, or size is ignored by OLE DB Provider for DB2.

The information that the consumer supplies must be correct and must be supplied for all parameters. OLE DB Provider for DB2 cannot verify the supplied information against the parameter metadata, although the OLE DB provider can determine that the specified values are legal values for the provider. The result of executing a command using incorrect parameter information or passing parameter information for the wrong number of parameters is undefined. For example, if the parameter type is **LONG** and the consumer specifies a type indicator of DBTYPE_STR in **ICommandWithParameters::SetParameterInfo**, OLE DB Provider for DB2 converts the data to a string before sending it to the data store. Because the data store is not expecting a **LONG**, this will likely result in an error.

CustomErrorObject Object (OLE DB Provider for DB2)

The **CustomErrorObject** object is created by a **Command** object when a command error occurs. The **CustomErrorObject** object is used to retrieve additional information when an error occurs.

The following interfaces of the **CustomErrorObject** object are supported by the current version of Microsoft OLE DB Provider for DB2:

- **IErrorLookup**
- **ISQLErrorInfo**

DataSource Object (OLE DB Provider for DB2)

The **DataSource** object is created by an OLE DB consumer. The **DataSource** object contains the knowledge and ability to connect to DB2 over Advanced Program-to-Program Communications (APPC) and LU 6.2 (through Microsoft Host Integration Server 2004) or over TCP/IP. The **DataSource** object is used to create one or more **Session** objects.

The following interfaces of the **DataSource** object are supported by the current version of Microsoft OLE DB Provider for DB2:

- **IDBCreateSession**
- **IDBInfo**
- **IDBInitialize**
- **IDBProperties**
- **IPersist**
- **IPersistFile**
- **ISupportErrorInfo**

ErrorObject Object (OLE DB Provider for DB2)

The **ErrorObject** object is created by any interface on any DB2 OLE DB object. The **ErrorObject** object is used to retrieve additional information when an error occurs.

The following interface of the **ErrorObject** object is supported by the current version of Microsoft OLE DB Provider for DB2:

- **IErrorRecords**

The **IErrorRecords** interface returns **ErrorRecord** objects with detailed information on the error that occurred.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ErrorRecord Object (OLE DB Provider for DB2)

The **ErrorRecord** object is created by calling the **IErrorRecord** interface on the **ErrorObject** object. An **ErrorObject** is created on any interface on any SNA OLE DB object when an error occurs. The **ErrorRecord** object is used to retrieve additional information when an error occurs.

The following interface of the **ErrorRecord** object is supported by the current version of Microsoft OLE DB Provider for DB2:

- **IErrorInfo**

OLE DB interface methods return error information in two ways. The error code returned by an interface method, known as the **return code**, indicates the overall success or failure of a method. Error records provide detailed information about the error, such as a text description of the error, the globally unique identifier (GUID) of the interface that defined the error, and provider-specific error information. Error objects in OLE DB are an extension of the error objects in Automation. They use many of the same mechanisms, and can be used as Automation error objects.

OLE DB error return codes are of type HRESULT. There are two general classes of return codes: success and warning codes, and error codes.

Success and warning codes begin with S_ or DB_S_ and indicate that the method successfully completed. The standard OLE DB error codes are defined in the OLEDBERR.H include file.

If the return code is other than S_OK or S_FALSE, it is likely that an error occurred from which the method was able to recover. For example, **IRowset::GetNextRows** returns DB_S_ENDOFROWSET when it is unable to return the requested number of rows due to reaching the end of the rowset. If a single warning condition occurs, the method returns the code for that condition. If multiple warning conditions occur, the method describes the hierarchy of warning return codes, indicating which warning code should be returned when given a choice between multiple warning return codes.

Error codes begin with E_ or DB_E_ and indicate that the method failed completely and was unable to do any useful work. For example, **GetNextRows** returns E_INVALIDARG when a null pointer in which the OLE DB provider returns a pointer to an array of row handles (*prghRows*). An exception to this is that some of the methods that return DB_E_ERRORSOCCURRED allocate memory to return additional information about these errors. Consumers must free this memory. For information about which methods allocate memory in this case, see the methods that return DB_E_ERRORSOCCURRED.

Although error codes can indicate run-time errors, such as running out of memory, they generally indicate programming errors. If multiple errors occur, the code that is returned is provider-specific. If both errors and warnings occur, the method fails and returns an error code.

All methods can return S_OK, E_FAIL, and E_OUTOFMEMORY. The E_OUTOFMEMORY code applies only to those methods which allocate memory that is returned to the consumer. In some cases, the E_OUTOFMEMORY code might be eliminated by calling the method requesting fewer returned values, such as fewer rows from **GetNextRows**.

Rowset Object (OLE DB Provider for DB2)

Rowset objects are created by **Session** objects. The **Rowset** object exposes data in tabular format.

The following interfaces of the **Rowset** object are supported by the current version of Microsoft OLE DB Provider for DB2.

- **IAccessor**
- **IColumnsInfo**
- **IConvertType**
- **IRowset**
- **IRowsetChange**
- **IRowsetInfo**
- **IRowsetUpdate**
- **ISupportErrorInfo**

Session Object (OLE DB Provider for DB2)

The **Session** object is created by a **DataSource** object. The **Session** object is used to create one or more **Rowset** objects.

The following interfaces of the **Session** object are supported by the current version of Microsoft OLE DB Provider for DB2:

- **IDBCreateCommand**
- **IDBSchemaRowset**
- **IGetDataSource**
- **IOpenRowset**
- **ISessionProperties**
- **ISupportErrorInfo**
- **ITransaction**
- **ITransactionLocal**
- **ITransactionObject**

Consumers can get information about a data store without knowing its structure by using the **IDBSchemaRowset** methods. The methods on this interface can be used to retrieve advanced schema information. OLE DB Provider for DB2 organizes each DB2 database server in a set of schemas that contain tables for each schema. These schema rowsets are identified by globally unique identifiers (GUIDs).

The following schema rowset GUIDs are supported by OLE DB Provider for DB2:

- DBSCHEMA_COLUMNS
- DBSCHEMA_INDEXES
- DBSCHEMA_PRIMARY_KEYS
- DBSCHEMA_PROCEDURES
- DBSCHEMA_PROCEDURE_PARAMETERS
- DBSCHEMA_PROVIDER_TYPES
- DBSCHEMA_TABLES

The following table lists these GUIDs and the columns for which restrictions can be specified on the schema rowset when using OLE DB Provider for DB2. The number of restriction columns for each schema rowset are defined as constants prefixed with CRESTRICTIONS_ in the OLE DB header files. Restriction values are treated as literals rather than as search patterns. For example, the restriction value "A_C" matches "A_C" but not "ABC".

GUID	Number of restrictions	Restriction columns
DBSCHEMA_COLUMNS	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME COLUMN_NAME
DBSCHEMA_INDEXES	4	TABLE_CATALOG TABLE_SCHEMA INDEX_NAME TABLE_NAME
DBSCHEMA_PRIMARY_KEYS	3	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME
DBSCHEMA_PROCEDURES	4	PROCEDURE_CATALOG PROCEDURE_SCHEMA PROCEDURE_NAME PROCEDURE_TYPE
DBSCHEMA_PROCEDURE_PARAMETERS	4	PROCEDURE_CATALOG PROCEDURE_SCHEMA PROCEDURE_NAME PARAMETER_NAME
DBSCHEMA_PROVIDER_TYPES	2	DATA_TYPE BEST_MATCH

DBSCHEMA_TABLES	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME TABLE_TYPE

Note that the TYPE restriction on the DBSCHEMA_INDEXES GUID is not supported by OLE DB Provider for DB2.

The PROCEDURE_SCHEMA restriction on the DBSCHEMA_PROCEDURE GUID and the DBSCHEMA_PROCEDURE_PARAMETERS GUID is not supported when connecting to DB/2 on OS/390 platforms.

Transaction Object (OLE DB Provider for DB2)

The **Transaction** object is created by a **Session** object. The **Transaction** object is used to manage transactions on one or more **Rowset** objects.

The following interfaces of the **Transaction** object are supported by the current version of Microsoft OLE DB Provider for DB2:

- **ISupportErrorInfo**
- **ITransaction**

The current implementation of OLE DB Provider for DB2 services all OLE DB **Session**, **Command**, and **Rowset** objects present in a given instance of the **DataSource** object through a single Advanced Program-to-Program Communications (APPC) conversation or TCP/IP connection. One implication of this design is that if two **Rowset** objects, each created from a different OLE DB **Session** object, use explicit commitment control through the **ITransaction** interface, they will interfere with each other. When a **Commit** or **Abort** for one instance is invoked, all work for the **DataSource** object will be either committed or aborted. This may yield undesirable results. The work around to this problem is to instantiate two instances of the **DataSource** object.

OLE DB Property Support in the OLE DB Provider for DB2

OLE DB Provider for DB2 included with Host Integration Server 2004 supports a different set of provider-specific properties than the earlier OLE DB Provider for DB2 supplied with SNA Server 4.0. The sections below provide information about provider-specific and standard OLE DB properties supported by the current and the previous version of OLE DB provider.

This section contains:

- OLE DB Provider-Specific Property Support in the OLE DB Provider for DB2
- OLE DB Data Source Property Support in the OLE DB Provider for DB2

OLE DB Provider-Specific Property Support in the OLE DB Provider for DB2

The following table summarizes the provider-specific OLE DB version 2.0 properties in the DB2OLEDB_DBPROPSET_DBINIT property set that are supported by the version of Microsoft OLE DB Provider for DB2 included with Host Integration Server 2004.

OLE DB Property ID	Description
DBPROP_DB2OLEDB_APPCMODE	When logical unit (LU) 6.2 (SNA) is selected for the Network Transport Library (DBPROP_DB2OLEDB_NETTYPE), this property is the Advanced Program-to-Program Communications (APPC) mode and must be set to a value that matches the host configuration and SNA server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This VT_BSTR type property normally defaults to QPCSUPP.
DBPROP_DB2OLEDB_BINASCHAR	This property indicates whether to process binary fields (Character Code Set Identifier or CCSID of 65535) as character data type fields on a per data source basis. The host CCSID and PC Code Page values are required input parameters when this parameter is true. This VT_BOOL type property defaults to VARIANT_FALSE, do not process binary fields as character fields.
DBPROP_DB2OLEDB_CATALOGCOL	The name of the collection where OLE DB Provider for DB2 looks for catalog information. This is the default schema, the "SCHEMA" name for the target collection of tables and views. This property is the Data Schema value when configuring data sources. OLE DB Provider for DB2 uses this default schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the default schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the default schema is the target COLLECTION name. For DB2 Universal Database (UDB), the default schema is the SCHEMA name. If the user does not provide a VT_BSTR value for DBPROP_DB2OLEDB_CATALOGCOL, the OLE DB provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Because these values for the default schema are inappropriate in many cases, it is essential that the Default Schema value in the data source be defined.
DBPROP_DB2OLEDB_HOSTCCSID	The CCSID matching the data as represented on the host. This property is required when processing binary data as character data. Unless the DBPROP_DB2OLEDB_BINASCHAR property ID is set to **true**, character data is converted based on the host column CCSID and default ANSI code page. This VT_I4 type property defaults to 37 (U.S./Canada).
DBPROP_DB2OLEDB_LOCALLU	When LU 6.2 (SNA) is selected for the Network Transport Library, this property is the name of the local LU alias configured in the SNA server. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_NETADDRESS	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting by using TCP/IP. This VT_BSTR type property defaults to SNA.

DBPROP_DB2OLEDB_NETPORT	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target DDM service access port when connecting by using TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. This VT_BSTR type property defaults to 446.
DBPROP_DB2OLEDB_NETTYPE	This property, which represents the dynamic-link library used for transport, designates whether the provider connects through SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCPIP or SNA. If TCPIP is selected, values for Network Address (DBPROP_DB2OLEDB_NETADDRESS) and Network Port (DBPROP_DB2OLEDB_NETPORT) are required. If SNA is selected, values for APPC Local LU Alias (DBPROP_DB2OLEDB_LOCALLU, APPC), Mode Name (DBPROP_DB2OLEDB_APPCMODE), and APPC Remote LU Alias (DBPROP_DB2OLEDB_REMOTELU) are required. This VT_BSTR type property defaults to SNA.
DBPROP_DB2OLEDB_PACKAGECOL	The name of the Distributed Relational Database Architecture (DRDA) target collection (AS/400 library) where Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be the same as the Default Schema (DBPROP_DB2OLEDB_DEFAULTSCH). Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. OLE DB Provider for DB2 will create packages dynamically in the location to which the user points using this property ID. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_PCCODEPAGE	The PC Code Page property ID indicates the code page to be used on the computer for character code conversion. This property is required when processing binary data as character data. Unless DBPROP_DB2OLEDB_BINASCHAR is set to true, character data is converted based on the default ANSI code page configured in Windows. If this parameter is set to Binary or 65535, no character code conversions will take place. This VT_I4 type property defaults to 1252 (Latin 1).
DBPROP_DB2OLEDB_PLATFORM	The target DB2 platform property value is used to optimize performance of the OLE DB provider when executing operations such as data conversion. The following values for this property are supported by OLE DB Provider for DB2: • DB2/MVS • DB2/NT • DB2/6000 • DB2/400 This VT_BSTR property has a default value of DB2/MVS.
DBPROP_DB2OLEDB_QUALIFIERCOL	The name of the schema (collection/owner) used to fully qualify unqualified object names. Note that this attribute allows the user to access database objects without fully qualifying the object using a collection (schema) qualifier. The OLE DB provider sends this value to DB2 using a **SET CURRENT SQLID** statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, no **SET** statement is issued by the ODBC driver. This OLE DB property is only valid when connecting to DB2 for MVS (OS/390, z/OS). This VT_BSTR type property has a default value of “”.
DBPROP_DB2OLEDB_REMOTELU	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_DB2OLEDB_NETTYPE), this property is the name of the remote LU alias configured in the SNA server. This VT_BSTR type property has no default value.

DBPROP_DB2OLEDB_TPNAME	This property represents the default transaction program (TP) name for the DB2 DRDA application server (AS), which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2004 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, this property is set to 0X07F9F9F9. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_UNITSOFWORK	This property indicates whether two-phase commit (distributed unit of work) used for transactions is supported for this data source. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and SNA LU 6.2 Resync Service. The following values for this property are supported by OLE DB Provider for DB2: • Remote unit of work (RUW) • Distributed unit of work (DUW) This VT_BSTR type property has a default value of RUW. Distributed unit of work (two-phase commit) works only with DB2 for OS/390 v5R1 or later. This option also requires that the SNA LU 6.2 service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

OLE DB Data Source Property Support in the OLE DB Provider for DB2

The following table summarizes the standard OLE DB version 2.0 data source properties from the DBPROP_DATASOURCE property set that are supported by the version of Microsoft OLE DB Provider for DB2 included with Host Integration Server 2004,

OLE DB Property ID	**Comments**
DBPROP_CURRENTCATALOG	The name of the current catalog. This property is derived from the *Initial Catalog* parameter when configuring data sources. An application can use the CATALOGS schema rowset to enumerate catalogs. This VT_BSTR type property defaults to the value configured in the data source for *Initial Catalog*.

ODBC Driver for DB2 Programmer's Reference

The Microsoft® ODBC Driver for DB2 enables users to access IBM Data Base 2 (DB2) from within an ODBC-aware application. ODBC defines a standard set of interfaces that provide access to disparate databases. This section provides reference material needed to program for the ODBC Driver for DB2.

For general information about programming for the ODBC Driver for DB2, see the ODBC Driver for DB2 Programmer's Guide section of the SDK.

For sample code using OLE DB Provider and ODBC Driver, see the OLE DB Provider and ODBC Driver Samples section of the SDK.

This section contains:

- Programming Considerations Using the ODBC Driver for DB2
- ODBC Conformance
- ADO Object, Method, Property, and Collection Support for AS/400, VSAM and DB2

Programming Considerations Using the ODBC Driver for DB2

The Microsoft® ODBC Driver for DB2 provides passthrough support for SQL statements. No SQL parsing is provided. The user must know what SQL syntax is supported for the target DB2-implementation. For information on what SQL syntax is supported, see the specific DB2 SQL Reference and DB2 Application Programming and SQL Guide for the specific platform.

The ODBC Driver for DB2 does not parse the SQL statements to qualify table names. Consequently, users of the ODBC Driver for DB2 must use either two-part or three-part (fully qualified) object names when naming tables, views, and stored procedures in DB2. A two-part table name would consist of the user ID and table, <UserID>.<Table>. One-part names (just the table name) will not succeed unless the combination of the DB2 collection and schema name correspond directly to the ODBC User ID

The Microsoft ODBC Driver for DB2 does not insert the correct value for the fraction when using a parameterized insert with the TIMESTAMP data type.

Microsoft Data Access Components (MDAC) supports the option of using a client cursor engine. This service component is implemented as part of OLE DB, ADO, and Remote Data Services (RDS). When using ADO, a client cursor is enabled by setting the **CursorLocation** property on the recordset to **adUseClient**. When using the ADO Client Cursor Engine with DB2 for OS/390, the developer must configure the ODBC Driver for DB2 Auto Commit Mode property in the DSN or connection string to **FALSE**. This is not required when connecting to DB2 for OS/400.

The ODBC Driver for DB2 included with Host Integration Server 2004 supports updating capabilities when used with a client cursor engine and the following requirements are met:

- To support updates (UPDATE, INSERT, and DELETE), the values in at least one column in the target table must be unique.
- The Auto Commit parameter must be set to **FALSE** when configuring the data source or when this parameter is passed as part of a connection string.

Previous versions of the ODBC Driver for DB2 do not support any updating capabilities when used with a client cursor engine. In other words, if a client cursor engine is enabled using RDS or ADO, the ODBC Driver for DB2 cannot be used to update data on the host. The ADO recordset is treated as if it were read-only. When using the ADO Client Cursor Engine with DB2 for OS/390, the developer must configure the ODBC Driver for DB2 Auto Commit parameter in the data source or connection string to FALSE. This is not required when connecting to DB2 for OS/400.

When the intent is to update records with a server-side cursor, DB2 requires that the SQL **SELECT** statement also include the FOR UPDATE option. For example, to select all records from the AUTHORS table in the DB2 collection called PUBS with intent to update requires the following SQL syntax:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE
```

When using DB2 for MVS V4R1 and DB2 for OS/400 V3R2, there are further requirements to indicate the columns that you intend to update. For example, to update the AU_LNAME and AU_FNAME columns in the PUBS.AUTHORS table, the following SQL syntax must be used:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE OF AU_LNAME, AU_FNAME
```

The Microsoft ODBC Driver for DB2 provides support for distributed transactions and DRDA Distributed Unit of Work, and can participate in a distributed transaction coordinated by Microsoft Distributed Transaction Coordinator. This feature is only available when connecting to one of the following across an LU 6.2 network connection:

- DB2 for OS/390 V5R1 or later.
- DB2 for DB2/400 V4R3 or later.

This option also requires that the SNA LU 6.2 service is selected as the network transport and Microsoft Transaction Server (MTS) is installed. The Microsoft ODBC Driver for DB2 does not support automatic transaction enlistment under Microsoft Transaction Server.

Applications should not commit or roll back transactions by executing **COMMIT** or **ROLLBACK** statements using the **SQLExecute** or **SQLExecDirect** ODBC functions. The effects of doing this are undefined, and the ODBC Driver for DB2 no longer knows when a transaction is active. Applications should call the **SQLEndTran** ODBC function instead.

Microsoft Visual Studio .NET 2003 offers a number of ADO data-bound controls, including a data grid and the ADO Data control. When using these ADO data controls, the developer must set the **CursorLocation** property on the recordset to **adUseClient**. Additionally, when using these ADO data controls with DB2 for OS/390, you must set the ODBC Driver for DB2 Auto Commit parameter in the data source or connection string to **FALSE**.

You can use Microsoft® Query (MSQUERY) supplied with Microsoft Excel and Microsoft Office to access ODBC data sources using the ODBC Driver for DB2. When a data of a column defined with TIMESTAMP data type is updated using Microsoft Query, the microseconds portion of the TIMESTAMP is not updated properly. The result is that updating any TIMESTAMP value using Microsoft Query will cause the loss of fractional seconds.

The Microsoft ODBC Driver for DB2 is not supported for use with the Microsoft ODBC .NET Data Provider. When accessing DB2 from ADO.NET, use the Microsoft OLE DB Provider for DB2 in conjunction with the Microsoft OLE DB .NET Data Provider.

This section contains:

Stored Procedure Support Using the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 supports calling DB2 stored procedures, returning output parameters and single and multiple result sets.

Support for Isolation Levels Using the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 provides flexibility in dealing with issues of isolation levels and transaction state. The ODBC **SQLSetConnectAttr** function is used to set the isolation level that is to be used for a connection. This function would be called with the attribute parameter set to SQL_ATTR_TXN_ISOLATION and the *ValuePtr* parameter pointing to an integer value indicating the isolation level requested. This integer value is a 32-bit bitmask that sets the transaction isolation level for the current connection.

The allowable values for isolation level (the *ValuePtr* parameter when calling **SQLSetConnectAttr**) can be determined by calling **SQLGetInfo** with InfoType equal to SQL_TXN_ISOLATION_OPTION. The following table list the allowable values for isolation level using the ODBC Driver for DB2 supplied with Host Integration Server.

ODBC Isolation Level Attribute	Description
SQL_TXN_READ_COMMITTED	When this attribute value is set, it isolates any data read from changes by others and changes made by others by others cannot be seen. The re-execution of the read statement is affected by others. This does not support a repeatable read. This is the default value for isolation level This isolation level is also called Cursor Stability (CS) in IBM DB2 documentation.
SQL_TXN_READ_UNCOMMITTED	When this attribute value is set, it does not isolate data read from changes by others and changes made by others by others can be seen. The re-execution of the read statement is affected by others. This does not support a repeatable read. This isolation level is called Uncommitted Read (UR) in IBM DB2 documentation.
SQL_TXN_REPEATABLE_READ	When this attribute value is set, it isolates any data read from changes by others and changes made by others cannot be seen. The re-execution of the read statement is affected by others. This supports a repeatable read. This isolation level is called Read Stability (RS) in IBM DB2 documentation.
SQL_TXN_SERIALIZABLE	When this attribute value is set, it isolates any data read from changes by others and changes made by others by others cannot be seen. The re-execution of the read statement is not affected by others. This supports a repeatable read. This isolation level is called Repeatable Read (RR) in IBM DB2 documentation.

The SQL_ATTR_TXN_ISOLATION attribute can be set only if there are no open transactions on the connection. An application must call **SQLEndTran** to commit or roll back all open transactions on a connection, before calling **SQLSetConnectAttr** with this option.

Some connection attributes support substitution of a similar value if the data source does not support the value specified in *ValuePtr*. In such cases, the driver returns SQL_SUCCESS_WITH_INFO and SQLSTATE 01S02 (Option value changed). To determine the substituted value, an application calls **SQLGetConnectAttr**.

Code Page Support Using the ODBC Driver for DB2

When creating data sources or file DSNs for use with the ODBC Driver for DB2, the Host character code set identifier (CCSID) should be configured in the data source to match the DB2 data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37).

On Windows 2000, the appropriate ANSI NLS file for your locale is installed automatically when you install a localized version of Windows 2000.

The following sections discuss the character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2004.

This section contains:

- ANSI Code Page Support Using the ODBC Driver for DB2
- EBCDIC Code Page Support Using the ODBC Driver for DB2
- ISO Code Page Support Using the ODBC Driver for DB2
- DBCS Code Page Support Using the ODBC Driver for DB2

ANSI Code Page Support Using the ODBC Driver for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured to use ANSI code pages, for example ANSI 1253 (Greek). Host Integration Server 2004 includes support for some ANSI code pages for purposes of ANSI-to-UNICODE-to-ANSI conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These ANSI code pages can be used when accessing IBM DB2 Universal Database on Windows NT and IBM DB2 ON AIX (not all of these ANSI code pages are supported on IBM DB2 Universal Database for AIX).

The following table shows the ANSI character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2004.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
ANSI - Arabic	1256	1256	
ANSI - Baltic	1257	1257	
ANSI - Cyrillic	1251	1251	
ANSI - Central Europe	1250	1250	
ANSI - Greek	1253	1253	
ANSI - Hebrew	1255	1255	
ANSI - Latin I	1252	1252	Support for this codepage is normally installed as part of the operating system on Windows 2000.
ANSI - Turkish	1254	1254	
ANSI/OEM - Japanese Shift JIS	932	932	
ANSI/OEM - Korean	949	949	
ANSI/OEM - Simplified Chinese GBK	936	936	
ANSI/OEM - Thai	874	874	
ANSI/OEM - Traditional Chinese Big5	950	950	
ANSI/OEM - Viet Nam	1258	1258	

The Microsoft Display Name is the name found in the Windows 2000 definitions for these NLS files. The Microsoft NLS Code Page column represents the code page number that is registered and associated with an ANSI-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the ODBC Driver for DB2. When setting the Host CCSID or PC Code Page parameter using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ANSI code page in IBM publications, which for these supported ANSI CCSIDs are the same as the Microsoft CCSID values. IBM lists their ANSI support in publications by referencing the display name which for these ANSI code pages is the same as the Microsoft display name. The ODBC Driver for DB2 does not recognize or display the IBM CCSID values when configuring data sources. The ODBC Driver for DB2 maps the Microsoft NLS numbers to ANSI NLS files which correspond with the appropriate IBM CCSID numbers. The Microsoft ODBC Driver for DB2 passes the corresponding IBM CCSID to the DB2 system at run time even though you configure the driver to use the Microsoft NLS number.

These are the only ANSI pages currently supported by the ODBC Driver for DB2 in Host Integration Server 2004 and in SNA Server 4.0 with Service Pack 3 or later. IBM supports additional ANSI pages, however, the ANSI code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM ANSI code pages (CCSIDs) match.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

EBCDIC Code Page Support Using the ODBC Driver for DB2

IBM DB2 for MVS, IBM DB2 for OS/390, and IBM DB2 for OS/400 are frequently configured to use EBCDIC code pages, for example EBCDIC 875 (Greek Modern). Host Integration Server 2004 includes support for most EBCDIC code pages for purposes of EBCDIC-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-EBCDIC, and EBCDIC-to-UNICODE-to-EBCDIC conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These EBCDIC code pages can be used when accessing IBM DB2 on a variety of platforms (not all of these EBCDIC code pages are supported on all versions of IBM DB2).

The following table shows the EBCDIC character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2004.

Microsoft Display Name	**Microsoft NLS Code Page**	**IBM CCS ID**	**Comments**
IBM EBCDIC - Arabic	20420	420	
IBM EBCDIC - Cyrillic (Russian)	20880	880	
IBM EBCDIC - Cyrillic (Serbian, Bulgarian)	21025	1025	
IBM EBCDIC - Denmark/Norway	20277	277	
IBM EBCDIC - Denmark/Norway (Euro)	1142	1142	
IBM EBCDIC - Finland/Sweden	20278	278	
IBM EBCDIC - Finland/Sweden (Euro)	1143	1143	
IBM EBCDIC - France	20297	297	
IBM EBCDIC - France (Euro)	1147	1147	
IBM EBCDIC - Germany	20273	273	
IBM EBCDIC - Germany (Euro)	1141	1141	
IBM EBCDIC - Greek	20423	423	
IBM EBCDIC - Greek (Modern)	875	875	
IBM EBCDIC - Hebrew	20424	424	
IBM EBCDIC - Icelandic	20871	871	
IBM EBCDIC - Icelandic (Euro)	1149	1149	
IBM EBCDIC - International	500	500	
IBM EBCDIC - International (Euro)	1148	1148	
IBM EBCDIC - Italy	20280	280	
IBM EBCDIC - Italy (Euro)	1144	1144	
IBM EBCDIC - Japan English/Kanji (Extended)	939	939	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan English/Kanji (Extended)	5035	5035	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan Katakana/Kanji (Extended)	930	930	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan Katakana/Kanji (Extended)	5026	5026	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japanese	931	931	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Korea (Extended)	933	933	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Latin America/Spain	20284	284	
IBM EBCDIC - Latin America/Spain (Euro)	1145	1145	
IBM EBCDIC - Multilingual/ROECE (Latin-2)	870	870	
IBM EBCDIC - Simplified Chinese (Extended)	935	935	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Thai	20838	838	
IBM EBCDIC - Traditional Chinese (Extended)	937	937	Support for this double-byte character set is supplied using TRNSDT.

IBM EBCDIC - Turkish (Latin-3)	20905	905	
IBM EBCDIC - Turkish (Latin-5)	1026	1026	
IBM EBCDIC - U.S./Canada	037	37	
IBM EBCDIC - U.S./Canada (Euro)	1140	1140	
IBM EBCDIC - United Kingdom	20285	285	
IBM EBCDIC - United Kingdom (Euro)	1146	1146	

The Microsoft Display Name is the name found in the Windows 2000 definitions for these NLS files. The Microsoft NLS Code Page column represents the code page number that is registered and associated with an EBCDIC-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the ODBC Driver for DB2. When setting the Host CCSID or PC Code Page parameter using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the EBCDIC code page in IBM publications. IBM lists their EBCDIC support in publications by referencing the display name which for these EBCDIC code pages is the same as the Microsoft display name. The ODBC Driver for DB2 does not recognize or display the IBM CCSID values when configuring data sources using data links. The ODBC Driver for DB2 maps the Microsoft NLS numbers to EBCDIC NLS files which correspond with the appropriate IBM CCSID numbers. The Microsoft ODBC Driver for DB2 passes the corresponding IBM CCSID to the DB2 system at run time even though you configure the driver to use the Microsoft NLS number.

These are the only EBCDIC pages currently supported by the ODBC Driver for DB2 in Host Integration Server 2004 and in SNA Server 4.0 with Service Pack 3 or later. IBM supports additional EBCDIC pages; however, the EBCDIC code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM EBCDIC code pages (CCSIDs) match.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ISO Code Page Support Using the ODBC Driver for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured for an ISO code page, for example ISO 819 (Latin I). Host Integration Server 2004 includes support for some ISO code pages for purposes of ISO-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-ISO, and ISO-to-UNICODE-to-ISO conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These ISO code pages can be used when accessing IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX.

The following table shows the ISO character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2004.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
ISO 8859-1 Latin 1	28591	819	
ISO 8859-2 Central Europe	28592	912	
ISO 8859-5 Cyrillic	28595	915	
ISO 8859-6 Arabic	28596	1089	
ISO 8859-7 Greek	28597	813	
ISO 8859-8 Hebrew	28598	916	
ISO 8859-9 Turkish	28599	920	
ISO 6937 Non-Spacing Accent	20269	819	Note that ISO 6937 (CCSID 20269) is not supported by the ODBC Driver for DB2, but is displayed in the list of configuration options when creating or modifying data sources.
ISO 8859-15 Latin 9 (Euro)	20865	923	NLS Code Page 819 with support for the euro.

The ///Microsoft Display Name is the name found in the Windows 2000 definitions for these NLS files.

The Microsoft NLS Code Page column represents the code page number that is registered and associated with an ISO-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the ODBC Driver for DB2. When setting the Host CCSID or PC Code Page attribute/property using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ISO code page in IBM publications. IBM lists their ISO support in publications by referencing the locale name (Bulgaria for ISO 8859-5 and 915, for example) rather than simply using ISO 8859-5 Cyrillic as used by Microsoft. The ODBC Driver for DB2 does not recognize or display the IBM CCSID values when configuring data sources. The ODBC Driver for DB2 maps the Microsoft NLS numbers to ISO NLS files which correspond with the appropriate IBM CCSID numbers. The Microsoft ODBC Driver for DB2 passes the corresponding IBM CCSID to the DB2 system at run time even though you configure the driver to use the Microsoft NLS number.

Note that IBM CCSID 819 is associated with both ISO 8859-1 Latin 1 and ISO 6937 Non-Spacing Accent. It is up to the user to choose the standard ISO 8859-1 Latin 1 code page by selecting NLS code page 28591 or the modified code page ISO 6937 Non-Spacing Accent by selecting NLS code page 20269. Note that ISO 6937 Non-Spacing Accent (CCSID 20269) is not currently supported by the ODBC Driver for DB2, but is displayed in the configuration options when creating or modifying data sources.

IBM CCSID 916 (ISO 8859-8) supports Hebrew "visual sort order". IBM CCSID 920 (ISO 8859-8 derivation) supports Hebrew "logical sort order". Although Microsoft supports the logical sort order with NLS 38598, this NLS file is only distributed with Internet Explorer 5 or Windows 2000. The ODBC Driver for DB2 has not been tested using the ISO 8859-8 derivation matching IBM CCSID 920 and does not support this configuration.

These are the only ISO pages currently supported in Host Integration Server 2004 and in SNA Server 4.0 with Service Pack 3 or later. Microsoft supports a number of additional ISO pages. IBM also supports additional ISO pages. However, the code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM CCSIDs match.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

DBCS Code Page Support Using the ODBC Driver for DB2

The ODBC Provider for DB2 supports Double-Byte Character String (DBCS) data, including conversions between DBCS and ANSI code pages. Conversions between DBCS and ISO code pages are also supported, as are positioned updates against DBCS EBCDIC implementations of DB2.

The DB2 GRAPHIC data types (GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC) are now explicitly supported. These DB2 data types support DBCS (not mixed) data. Mixed data types are supported using CHAR FOR MIXED DATA, VARCHAR FOR MIXED DATA, and LONGVARCHAR FOR MIXED DATA.

Parameterized SQL statements and calling stored procedures when the parameter values contain Mixed or DBCS characters are supported.

When performing a SQL statement with inline data, character strings can be prefixed with a 'G' or 'g' to denote that the data is DBCS and is to be used with a graphic column. Only double-byte characters can be used with a graphic column. For example:

```
CREATE TABLE NAMES (COL1 GRAPHIC(64), COL2 CHAR(64))
INSERT INTO NAMES (COL1, COL2) VALUES (G’DBCS data’, ‘MBCS or SBCS data’)
```

The prefixes 'n' (graphic) and 'gx' (hexadecimal graphic) are also supported.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Data Conversion Using the ODBC Driver for DB2

The design of ODBC APIs is similar to other ISAM APIs. The APIs are handle-based. After opening a file, the application can determine the buffer size required to store a row, use the cursor APIs to move, and optionally retrieve one or more rows of data using the row-level binding.

Data is converted to default SQL data types, as defined in ODBC. The following table lists these conversions.

DB2 data type	Default SQL Data Type	Exposed as Native Type in SQLGetTypeInfo	Comments
BIGINT			An 8-byte integer. This data type is supported on DB2 UDB only.
BLOB			A Binary Large Object (BLOB) is a varying-length string that can be up to 2 gigabytes in length. A BLOB is primarily intended to hold binary data. This data type is not supported by the ODBC Driver for DB2.
CHAR (BIT)	SQL_BINARY	No	A fixed length (double-byte only) character string.
CHAR (SBCS)	SQL_CHAR	Yes	A fixed-length SBCS character string.
CHAR (MIXED)	SQL_CHAR	No	A fixed-length mixed (single and double-byte) character string.
CLOB			A Character Large Object (CLOB) is a varying-length string that can be up to 2 gigabytes in length. A CLOB is used to store large single-byte character set data. A CLOB is considered to be a character string. This data type is not supported by the ODBC Driver for DB2.
DATE	SQL_TYPE_DATE	Yes	A 10-byte date string. This data type is converted to an SQL_DATE for use by ODBC.
DBCLOB			A Double-Byte Character Large Object (DBCLOB) is a varying-length string of double-byte characters that can be up to 2 gigabytes in length (1,073,741,823 double-byte characters). A DBCLOB is used to store large double-byte character set data. A DBCLOB is considered to be a graphic string. It is not supported by the ODBC Driver for DB2.
DECIMAL	SQL_DECIMAL	Yes	A packed decimal number.
DOUBLE	SQL_DOUBLE	Yes	An 8-byte double-precision floating point number.
FLOAT	SQL_FLOAT	Yes	An 8-byte double-precision floating point number. This data type is the same as a DOUBLE.
GRAPHIC (DBCS)	SQL_CHAR	No	A fixed-length graphic string consisting of a sequence of double byte (DBCS only) character string data.
INTEGER	SQL_INTEGER	Yes	A 4-byte integer with a precision of 10 digits ranging in value from -2,147,463,648 to +2,147,483,647.
LONG VARCHAR (BIT)	SQL_BINARY	No	A varying-length (double-byte only) character string.
LONG VARCHAR (SBCS)	SQL_CHAR	No	A varying-length SBCS character string.
LONG VARCHAR (MIXED)	SQL_CHAR	No	A varying-length mixed-character (single and double-byte) string.

LONG VARGRAPHIC (DBCS)	SQL_LONGVARCHAR	No	A varying-length graphic string consisting of a sequence of double byte (DBCS only) character string data.
SMALLINT	SQL_SMALLINT	Yes	A SMALLINT (small integer) is a two-byte integer with a precision of 5 digits ranging from -32,768 to +32,767.
REAL	SQL_REAL	Yes	A 4-byte single-precision floating point number.
TIME	SQL_TYPE_TIME	Yes	An 8-byte time string. When using ActiveX Data Objects to return data from a DB2 TIME data type, ADO returns a DATETIME value.
TIMESTAMP	SQL_TYPE_TIMESTAMP	Yes	A 26-byte string representing the date, time, and microseconds.
VARCHAR (BIT)	SQL_BINARY	No	A varying-length (double-byte only) character string.
VARCHAR (SBCS)	SQL_CHAR	Yes	A varying-length character string.
VARCHAR (MIXED)	SQL_CHAR	No	A varying-length mixed (single and double-bye) character string.
VARGRAPHIC (DBCS)	SQL_VARCHAR	No	A varying-length graphic string consisting of a sequence of double byte (DBCS only) character string data.

Not all platforms and versions of DB2 support all of the above-referenced data types. Consult your IBM SQL Reference for the specific target and platform and version of DB2.

The ODBC Driver for DB2 exposes only selected DB2 data types as native types in the ODBC catalog function **GetTypeInfo**. For example, the driver does not expose LONG CHARACTER or VARYING LONG CHARACTER types. Rather these types are exposed as CHARACTER and VARYING CHARACTER respectively. Also, the driver exposes CHARACTER FOR SBCS DATA, CHARACTER FOR MIXED DATA, and CHARACTER FOR BIT DATA as CHARACTER. The driver exposes VARYING CHARACTER FOR SBCS DATA, VARYING CHARACTER FOR MIXED DATA, and VARYING CHARACTER FOR BIT DATA as VARYING CHARACTER. However, the ODBC Driver for DB2 returns these LONG and VARYING LONG data types if one reads a table with these data types. For example, when reading a table with a variable character string of length greater than 254 bytes, the ODBC Driver for DB2 returns a LONG VARCHAR.

The maximum length of the DB2 character and graphic string data types is dependent on the DB2 platform and version. For example, a CHAR type on DB2 for OS/390 V5R1 has a maximum length of 254 bytes, whereas a CHAR type on DB2/400 V4R4 has a maximum length of 32,766 bytes.

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example), however truncation and conversion errors can occur that will not be reported by the ODBC Driver for DB2.

For more information on support for the DB2 character data types of subtype MIXED using the ODBC Driver for DB2, see Code Page Support Using the ODBC Driver for DB2.

Using the ODBC Driver for DB2, certain conversions of strings from EBCDIC to ASCII and then back to EBCDIC are asymmetric, and can result in strings that are different from the original. The EBCDIC specification contains ordinals for which there is no defined character. The ODBC Driver for DB2 translates all such undefined characters to the question mark character ("?"). So when ASCII strings containing these characters are converted back to EBCDIC, these undefined characters are replaced with question marks. To protect EBCDIC strings containing undefined characters, these fields should be tagged as binary strings and mapped by the application.

The affected ANSI-to-EBCDIC character conversions include the following:

Character value (decimal)	**Character value (hexadecimal)**	**ANSI code page 1252**	**EBCDIC character after conversion to CCSID 37**

128	0x80	Not used	?
130	0x82	Single low quote	?
131	0x83	Latin F with hook	?
132	0x84	Double low quote	?
133	0x85	Ellipsis	?
134	0x86	Dagger	?
135	0x87	Double dagger	?
136	0x88	Per mile	?
137	0x89	S with caron	?
138	0x8A	Left angle	?
139	0x8B	Ligature OE	?
140	0x8C	Not used	?
142	0x8E	Not used	?
145-156	0x91-0x9C		?
158-159	0x9E-0x9F		?

Floating Point Considerations Using the ODBC Driver for DB2

When real or double (synonymous with float) data is inserted into a DB2 table as a floating point data type, it is stored in scientific notation. For example, FLOAT(1.1) would be stored as +1.10000E+000.

Care must be taken when executing SQL statements to make sure that the proper data type specified in the SQL statement matches the values stored in DB2. For example, the following select statement would match values in DB2 stored as decimal 1.1:

```
SELECT * FROM TEST WHERE C1 = 1.1
```

If the data in DB2 was stored as real numbers, there would not be a match since decimal 1.1 is stored as 1.1, not the representation of +1.10000E+000. When DB2 parses and executes the SQL **SELECT** statement, it interprets 1.1 as a decimal type. When doing the **SELECT** query, DB2 does not implicitly do the conversion to floating point. In this case, the SQL statement should explicitly typecast the 1.1 so that DB2 looks for the correct format (the scientific notation format). The **SELECT** query would look like the following:

```
SELECT * FROM TEST WHERE C1 = REAL(1.1)
```

This will give the expected results. The SQL **REAL** function converts the decimal 1.1 to the proper format before DB2 executes the actual select.

Usernames and Passwords Using the ODBC Driver for DB2

When connecting to remote DB2 systems, most users must be authenticated by the remote system by passing a valid user ID and password.

The AS/400 computer is case-sensitive with regard to user ID and password; it accepts them only in uppercase. The ODBC Driver for DB2 automatically converts the user ID and password into uppercase when connecting to a DB2 for OS/400 system.

The mainframe is not case-sensitive; the user ID and password is acceptable in lowercase or uppercase.

DB2 Universal Database (UDB) for Windows NT is case-sensitive; it supports mixed case passwords. Users must enter a password in the correct mixed case. When entering a user ID, use only the Windows NT user name and not the Windows NT domain name.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to
http://go.microsoft.com/fwlink/?linkid=29507.

Errors Returned by the ODBC Driver for DB2

The ODBC Driver for DB2 generates errors in the following areas:

- ODBC Driver Manager
- Microsoft ODBC Driver for DB2
- DRDA Application Requester network client

The ODBC Driver Manager is a shared library that establishes connections with ODBC drivers, submits requests to ODBC drivers, and returns results to applications. An ODBC Driver Manager error has the following format:

```
[vendor] [ODBC DLL] message
```

For example:

```
[Microsoft] [ODBC DLL] Driver does not support this function.
```

If you encounter this type of error, check the last ODBC call the application made for possible problems. For further information on ODBC Driver Manager errors, contact your ODBC application vendor or refer to the ODBC documentation available from Microsoft Press.

An error reported by the Microsoft ODBC Driver for DB2 has the following format:

```
[Microsoft] [ODBC Driver for DB2] message
```

For example:

```
[Microsoft] [ODBC Driver for DB2] Invalid precision specified.
```

If you encounter this type of error is, check the last ODBC call the application made for possible problems. For further information on ODBC Driver errors, contact your ODBC application vendor or refer to the ODBC documentation available from Microsoft Press.

When using the Microsoft ODBC Driver for DB2, data source refers to the target database. An error that occurs in the data source is returned with the data source name and in the following format:

```
[Microsoft] [ODBC Driver for DB2] [data_source] message
```

For example, an ODBC application may receive the following message from a DB2 data source running on an IBM mainframe:

```
[Microsoft] [ODBC Driver for DB2] [DB2] DB2-0919: specified length too long for CHAR column
```

If you encounter this type of error, the application attempted to perform an operation not supported by the DB2 database system. Check the DB2 database system documentation for more information or consult your database administrator.

Two-Phase Commit over TCP/IP Support Using the ODBC Driver for DB2

Two-phase commit (2PC) is a host server-installed protocol that ensures that updates to multiple instances of a database on a network either succeed or fail in their entirety. Host Integration Server 2004 supports 2PC over TCP/IP, allowing you to gain the security of a 2PC connection over the Internet.

Host Integration Server supports 2PC works using three components: the DTC, the Resync Service, and the transaction log. The DTC governs the normal DTC transaction flow: enlist, prepare, commit, and abort. The Resync service coordinates transaction recovery in case of any failure or disconnection, while the transaction log maintains a log of information that is needed in case of recovery.

You can perform a 2PC transaction with the ODBC Driver for DB2 using **SQLSetConnAttr**. Using a 2PC transaction is automatic. However, you may need to configure your 2PC connection using tools such as ODBC Connection Manager.

Troubleshooting the ODBC Driver for DB2

The Windows 2000 Event Viewer can be a useful tool for troubleshooting data access in some cases. The ODBC Driver for DB2 does not issue events. However, when SNA (APPC/LU 6.2) is used for the network transport for the ODBC Driver for DB2, the low-level SNA APPC transport issues events on the SNA connection.

The ODBC Driver for DB2 supplied with Host Integration Server 2004 has the ability to trace DRDA data flows when used over TCP/IP. This capability is accessible from the SNADB2 Service tracing inside the Trace utility shipped with Host Integration Server 2004.

This facility shows the same data as an APPC trace but without the control indicators (for example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the Win32 SDK.

When the ODBC Driver for DB2 passes an error code, the best source in which to look-up the meaning of the return code is often the SQL Reference or SQL Messages and Codes Reference for the target SQL database. In this case, the target database is one of the DB2 platforms supported by the ODBC Driver for DB2.

The ODBC Driver for DB2 maintains an internal integer variable named SQLCODE and an internal 5-byte character string variable named SQLSTATE used to check the execution of SQL statements on DB2. SQLCODE is set by DB2 after each SQL statement is executed. DB2 returns the following values for SQLCODE:

- If SQLCODE = 0, execution was successful.
- If SQLCODE > 0, execution was successful with a warning.
- If SQLCODE < 0, execution was not successful.
- SQLCODE = 100, "no data" was found. For example, a **FETCH** statement returned no data because the cursor was positioned after the last row of the result table.

SQLSTATE is also set by DB2 after the execution of each SQL statement. Application programs can check the execution of SQL statements by testing SQLSTATE instead of SQLCODE. SQLSTATE provides application programs with common codes for common error conditions (the values of SQLSTATE are product-specific only if the error or warning is product-specific). Furthermore, SQLSTATE is designed so that application programs can test for specific errors or classes of errors.

SQLSTATE values consist of a two-character class code value, followed by a three-character subclass code value. The first character of an SQLSTATE value indicates whether the SQL statement was executed successfully or unsuccessfully (equal to or not equal to zero, respectively). Class code values represent classes of successful and unsuccessful execution conditions. The following table describes SQLSTATE class codes used by DB2.

Class Code	Description of Error Class
00	Successful completion. Execution of the SQL statement was successful and did not result in any type of warning or exception condition.
01	Warning
02	No data
07	Dynamic SQL error
08	Connection exception
0A	Feature not supported
0F	Invalid token
21	Cardinality violation
22	Data exception
23	Constraint violation
24	Invalid cursor state
25	Invalid transaction state
26	Invalid SQL statement identifier
2D	Invalid transaction termination
34	Invalid cursor name
39	External function call exception
40	Transaction rollback
42	Syntax error or access rule violation
44	WITH CHECK OPTION violation
51	Invalid application state

53	Invalid operand or inconsistent specification
54	SQL or product limit exceeded
55	Object not in prerequisite state
56	Miscellaneous SQL or product error
57	Resource not available or operator intervention
58	System error

The SQLSTATE value of HY000 is defined as a driver-specific error. An SQLSTATE of 08S01 (connection exception with a subclass code of S01) also indicates a driver-specific error. This means the SQLCODE should be looked up in the driver-specific documentation included with the ODBC Driver for DB2.

If the SQLSTATE does not indicate a driver-specific error when the ODBC Driver for DB2 passes back an SQLSTATE of 08S01, it indicates a network error. For example, an SQLCODE of -603 is a driver-specific error that is mapped to DB2OLEDB_COMM_HOST_CONNECT_FAILED in the db2oledb.h include file supplied with the ODBC Driver for DB2. Errors with an SQLSTATE of 08S01 are documented in the db2oledb.h include file (the SQLCODE value) which is located on the Host Integration Server 2004 CD in the SDK\Include subdirectory.

The following steps are useful in researching an error. Start by reading the provided error text returned by the ODBC Driver for DB2. In some cases, the error text may provide limited information. For example, error text from an SQLCODE of -603 reads:

```
Test connection failed because of an error in initializing driver.
Could not connect to specified host.
```

The next step is to lookup the SQLSTATE to determine the source of the error. Is the error a DB2 error, a network client error, or an ODBC Driver error? An SQLSTATE of 08S01 is defined as follows:

```
Communication link failure.
```

This definition is intended to inform the user, administrator, or developer that the error is one related to the ODBC driver's underlying network client.

Unfortunately, many of the SQLSTATE codes returned by the ODBC Driver for DB2 are DB2 errors and are not documented in the ODBC Driver for DB2 Help.

The SQLSTATE of HY000 is defined as a driver-specific error. An SQLSTATE of 08S01 also indicates a driver-specific error. In this case, you should look up the SQLCODE in the driver-specific documentation included with the ODBC Driver for DB2.

If the SQLSTATE does not indicate a driver-specific error, you should look up the SQLCODE in the appropriate DB2 manual for the target platform. For example, an SQLCODE of -603 is documented in Appendix B, "SQLCODEs and SQLSTATEs," in the *AS/400 Advanced Series DB2 for AS/400 SQL Programming, Version 4*, document number SC41-5611-00 published by IBM. An SQLCODE of -603 corresponds to SQLSTATE 23515 in the DB2 for OS/400 error code list. For example, the explanation for this SQLCODE is:

```
Unique index cannot be created because of duplicate keys.
```

When the SQLSTATE and the SQLCODE definitions documented in these appendixes create a mismatch with the actual errors returned, it usually indicates a driver-specific error condition.

A final step in understanding an error is to check the db2oledb.h file. This file is not installed by Setup for the Host Integration Client 2000, but is located on the CD-ROM for in the SDK\Include folder. An SQLCODE (for example, -603) can be found by searching the rightmost column of the db2oledb.h file for a value near to 603. For instance, locate the comment "/* -600 */" and then count down three additional lines to line number 603. The internal error code -603 is defined as follows:

```
DB2OLEDB_COMM_HOST_CONNECT_FAILED.
```

This particular error usually indicates a problem with the configuration parameters or the connection string passed.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ODBC Conformance

The Microsoft® ODBC Driver for DB2 supports ODBC 2.*x* and ODBC 3.*x* functions. SQL grammar conformance varies, depending on the version of the DB2 database that is accessed. The following sections list the ODBC functions and attributes supported by the Microsoft ODBC Driver for DB2.

This section contains:

- Support for ODBC 2 Core Functions
- Support for ODBC 2 Level 1 Functions
- Support for ODBC 2 Level 2 Functions
- Support for ODBC 3 Functions
- Support for ODBC Connection Attributes
- Support for ODBC Statement Attributes

Support for ODBC 2 Core Functions

The following table lists the ODBC 2.*x* Core functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 2.*x* Core Functions	Functions Supported by the Microsoft ODBC Driver for DB2
SQLAllocConnect	Yes
SQLAllocEnv	Yes
SQLAllocStmt	Yes
SQLBindCol	Yes
SQLCancel	Yes
SQLColAttributes	Yes
SQLConnect	Yes
SQLDescribeCol	Yes
SQLDisconnect	Yes
SQLError	Yes
SQLExecDirect	Yes
SQLExecute	Yes
SQLFetch	Yes
SQLFreeConnect	Yes
SQLFreeEnv	Yes
SQLFreeStmt	Yes
SQLGetCursorName	Yes
SQLNumResultCols	Yes
SQLPrepare	Yes
SQLRowCount	Yes
SQLSetCursorName	Yes
SQLSetParam	In ODBC 2.0, the ODBC 1.0 **SQLSetparam** function was replaced by **SQLBindParameter**
SQLTransact	Yes

Support for ODBC 2 Level 1 Functions

The following table lists the ODBC 2.*x* level 1 functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 2.*x* level 1 functions	Functions supported by the Microsoft ODBC Driver for DB2
SQLBindParameter	Yes
SQLColumns	Yes
SQLDriverConnect	Yes
SQLGetConnectOption	Yes
SQLGetData	Yes
SQLGetFunctions	Yes
SQLGetInfo	Yes
SQLGetStmtOption	Yes
SQLGetTypeInfo	Yes
SQLParamData	Yes
SQLPutData	Yes
SQLSetConnectOption	Yes
SQLSetStmtOption	Yes
SQLSpecialColumns	Yes
SQLStatistics	Yes
SQLTables	Yes

Support for ODBC 2 Level 2 Functions

The following table lists the ODBC 2.*x* level 2 functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 2.*x* level 2 functions supported	**Functions supported by the Microsoft ODBC Driver for DB2**
SQLBrowseConnect	No
SQLColumnPrivileges	No
SQLDataSources	Yes. This function is actually supported by the ODBC Driver Manager
SQLDescribeParam	No
SQLDrivers	Yes. This function is actually supported by the ODBC Driver Manager
SQLExtendedFetch	Yes, but supports forward scrolling only
SQLForeignKeys	No
SQLMoreResults	Yes
SQLNativeSQL	Yes
SQLNumParams	Yes
SQLParamOptions	Yes
SQLPrimaryKeys	Yes, but SQL grammar conformance varies depending on the version of the DB2 database that is accessed
SQLProcedureColumns	Yes
SQLProcedures	Yes
SetPos	Yes
SQLSetScrollOptions	Yes
SQLTablePrivileges	No

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Support for ODBC 3 Functions

The following table lists the ODBC 3.0 functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 3.0 functions	Functions supported by the Microsoft ODBC Driver for DB2
SQLAllocHandle	Yes
SQLBulkOperations	No
SQLCloseCursor	Yes
SQLColAttribute	Yes
SQLCopyDesc	Yes
SQLEndTran	Yes
SQLFetchScroll	Yes, but supports forward scrolling only
SQLFreeHandle	Yes
SQLGetConnectAttr	Yes
SQLGetDescField	Yes
SQLDescRec	Yes
SQLGetDiagField	Yes
SQLGetDiagRec	Yes
SQLGetEnvAttr	Yes
SQLGetStmtAttr	Yes
SQLRowCount	Yes
SQLSetConnectAttr	Yes
SQLSetDescField	Yes
SQLSetDescRec	Yes
SQLSetEnvAttr	Yes
SQLSetStmtAttr	Yes

Support for ODBC Connection Attributes

The following table lists the ODBC connection attributes support using the Microsoft ODBC Driver for DB2. Note that the connection attributes in this list use the ODBC Version 3.0 attribute names, rather than the older ODBC 1.0 names.

ODBC connection attribute	ODBC version	Attribute supported by the Microsoft ODBC Driver for DB2
SQL_ATTR_ACCESS_MODE	1.0	Yes
SQL_ATTR_ASYNC_ENABLE	3.0	No
SQL_ATTR_AUTO_IPD	3.0	No
SQL_ATTR_AUTOCOMMIT	1.0	Yes
SQL_ATTR_CONNECTION_DEAD	3.5	No
SQL_ATTR_CONNECTION_TIMEOUT	3.0	No
SQL_ATTR_CURRENT_CATALOG	2.0	Yes
SQL_ATTR_ENLIST_IN_DTC	3.0	Yes
SQL_ATTR_ENLIST_IN_XA	3.0	No
SQL_ATTR_LOGIN_TIMEOUT	1.0	No
SQL_ATTR_METADATA_ID	3.0	No
SQL_ATTR_ODBC_CURSORS	2.0	Yes, handled by ODBC Driver Manager
SQL_ATTR_PACKET_SIZE	2.0	No
SQL_ATTR_QUIET_MODE	2.0	Yes
SQL_ATTR_TRACE	1.0	Yes, handled by ODBC Driver Manager
SQL_ATTR_TRACEFILE	1.0	Yes, handled by ODBC Driver Manager
SQL_ATTR_TRANSLATE_LIB	1.0	No
SQL_ATTR_TRANSLATE_DLL	1.0	No
SQL_ATTR_TRANSLATE_OPTION	1.0	No
SQL_ATTR_TXN_ISOLATION	1.0	Yes

Support for ODBC Statement Attributes

The following table lists the ODBC statement attribute support using the Microsoft ODBC Driver for DB2. Note that the statement attributes in this list use the ODBC Version 3.0 attribute names, rather than the older ODBC 1.0 names.

ODBC statement attribute	ODBC version	Attribute supported by the Microsoft ODBC Driver for DB2
SQL_ATTR_APP_PARAM_DESC	3.0	Yes
SQL_ATTR_APP_ROW_DESC	3.0	Yes
SQL_ATTR_ASYNC_ENABLE	1.0	No
SQL_ATTR_CONCURRENCY		No
SQL_ATTR_CURSOR_SCROLLABLE	3.0	No
SQL_ATTR_CURSOR_SENSITIVITY	3.0	No
SQL_ATTR_CURSOR_TYPE	1.0	Yes, but the ODBC Driver for DB2 supports a forward scrolling only cursor type
SQL_ATTR_ENABLE_AUTO_IPD	3.0	No
SQL_ATTR_FETCH_BOOKMARK_PTR	3.0	No
SQL_ATTR_IMP_PARAM_DESC		Yes, handled by ODBC Driver Manager
SQL_ATTR_IMP_ROW_DESC		Yes, handled by ODBC Driver Manager
SQL_ATTR_KEYSET_SIZE	1.0	No
SQL_ATTR_MAX_LENGTH	1.0	No
SQL_ATTR_MAX_ROWS	1.0	No
SQL_ATTR_METADATA_ID	3.0	Yes
SQL_ATTR_NOSCAN	1.0	Yes
SQL_ATTR_PARAM_BIND_OFFSET_PTR	3.0	Yes
SQL_ATTR_PARAM_BIND_TYPE	3.0	Yes
SQL_ATTR_PARAM_OPERATION_PTR	3.0	Yes
SQL_ATTR_PARAM_STATUS_PTR	3.0	Yes
SQL_ATTR_PARAMS_PROCESSED_PTR	3.0	Yes
SQL_ATTR_PARAMSET_SIZE	3.0	Yes
SQL_ATTR_QUERY_TIMEOUT	1.0	No
SQL_ATTR_RETRIEVE_DATA	1.0	No
SQL_ATTR_ROW_ARRAY_SIZE	3.0	Yes
SQL_ATTR_ROW_BIND_OFFSET_PTR	3.0	Yes
SQL_ATTR_ROW_BIND_TYPE	1.0	Yes
SQL_ATTR_ROW_NUMBER	1.0	No
SQL_ATTR_ROW_OPERATION_PTR	3.0	No
SQL_ATTR_ROW_STATUS_PTR	3.0	Yes
SQL_ATTR_ROWS_FETCHED_PTR	3.0	Yes
SQL_ATTR_SIMULATE_CURSOR	1.0	No
SQL_ATTR_USE_BOOKMARKS	1.0	No

ADO Object Support in the ODBC Driver for DB2

The following table summarizes the Microsoft® ActiveX® Data Objects (ADO) version 2.0 objects that are supported by the current version of the Microsoft Open Database Connectivity (ODBC) Driver for DB2.

ADO object	Support
Collection	Yes, most methods
Command Object	Yes, some methods, some properties, and all collections
Connection Object	Yes, some methods, some properties, and all collections
Error Object	Yes, some properties
Field Object	Yes, no methods, most properties, and all collections
Parameter Object	Yes, most methods, most properties, and all collections
Recordset Object	Yes, most methods, most properties, and all collections

The **Parameter** object will be supported by a later version of the ODBC Driver for DB2. For more information about ADO object support, see ADO Object Support in the OLE DB Provider for AS/400 and VSAM and ADO Object Support in the OLE DB Provider for DB2.

This section contains:

- ADO Method Support in the ODBC Driver for DB2
- ADO Property Support in the ODBC Driver for DB2
- ADO Collection Support in the ODBC Driver for DB2
- Command Object in the ODBC Driver for DB2 (ADO)
- Connection Object in the ODBC Driver for DB2 (ADO)
- Error Object in the ODBC Driver for DB2 (ADO)
- Field Object in the ODBC Driver for DB2 (ADO)
- Recordset Object in the ODBC Driver for DB2 (ADO)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ADO Method Support in the ODBC Driver for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object methods that are supported by the current version of the Microsoft ODBC Driver for DB2.

ADO object	Method	Support
Collection Object	**Append** Method	No
	Clear Method	Yes
	Delete Method	Yes
	Item Method	Yes
	Refresh Method	Yes
Command Object	**CreateParameter** Method	Yes
	Cancel Method	No
	Execute Method	Yes
Connection Object	**BeginTrans** Method	Yes
	Cancel Method	No
	Close Method	Yes
	CommitTrans Method	Yes
	Execute Method	Yes
	Open Method	Yes
	OpenSchema Method	Yes
	RollbackTrans Method	Yes
Field Object	**AppendChunk** Method	No
	GetChunk Method	No
	ReadFromFile Method	No
	WriteToFile Method	No
Parameter Object	**AppendChunk** Method	No
Recordset Object	AddNew Method	Yes
	Cancel Method	No
	CancelBatch Method	Yes
	CancelUpdate	Yes
	Clone Method	Yes
	Close Method	Yes
	Delete Method	Yes
	Find Method	No
	GetRows Method	Yes
	Move Method	Yes
	MoveFirst Method	Yes
	MoveLast Method	Yes, when using a client-side cursor only
	MoveNext Method	Yes
	MovePrevious Method	Yes, when using a client-side cursor only
	NextRecordset Method	No
	Open Method	Yes
	Requery Method	Yes
	Resync Method	No
	Save Method	Yes
	Seek Method	No
	Supports Method	Yes
	Update Method	Yes
	UpdateBatch Method	Yes

Note The **Collection** object is actually a special case, representing a collection of other ADO objects. These collection objects support several methods:

- **Append** to add an object to a collection.

- **Clear** to empty all objects from a collection.
- **Delete** to remove a single object from a collection.
- **Item** to return a specific member object of a collection by name or ordinal number.
- **Refresh** to update the objects in a collection to reflect objects available from and specific to the ODBC Driver.

ADO Property Support in the ODBC Driver for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object properties that are supported by the current version of Microsoft ODBC Driver for DB2.

ADO object	Property	Support
Command Object	ActiveConnection Property	Yes
	CommandText Property	Yes
	CommandTimeout Property	No
	CommandType Property	Yes
	Prepared Property	Yes
	State Property	Yes
Connection Object	Attributes Property	Yes
	CommandTimeout Property	No
	ConnectionString Property	Yes
	ConnectionTimeout Property	No
	CursorLocation Property	Yes
	DefaultDatabase Property	No
	IsolationLevel Property	Yes
	Mode Property	Yes
	Provider Property	Yes
	State Property	Yes
	Version Property	Yes
Error Object	Description Property	Yes
	HelpContext Property	No
	HelpFile	No
	NativeError Property	Yes
	Number Property	Yes
	Source Property	Yes
	SQLState Property	Yes
Field Object	ActualSize Property	Yes
	Attributes Property	Yes
	DataFormat Property	No
	DefinedSize Property	Yes
	Name Property	Yes
	NumericScale Property	Yes
	OriginalValue Property	Yes
	Precision Property	Yes
	Type Property	Yes
	UnderlyingValue Property	Yes
	Value Property	Yes
Parameter Object	**Attributes** Property	Yes
	Direction Property	Yes
	Name Property	Yes
	NumericScale Property	Yes
	Precision Property	Yes
	Size Property	Yes
	Type Property	Yes
	Value Property	Yes
Recordset Object	**AbsolutePage** Property	No
	AbsolutePosition Property	No
	ActiveCommand Property	Yes
	ActiveConnection Property	Yes
	BOF Property	Yes

	Bookmark Property	Yes
	CacheSize Property	Yes
	CursorLocation Property	Yes
	CursorType Property	Yes
	DataMember Property	No
	DataSource Property	No
	EditMode Property	Yes
	EOF Property	Yes
	Filter Property	No
	Index Property	No
	LockType Property	Yes
	MarshalOptions Property	No
	MaxRecords Property	Yes
	PageCount Property	No
	PageSize Property	No
	RecordCount Property	No
	Sort Property	No
	Source Property	Yes
	State Property	Yes
	Status Property	Yes
	StayInSync Property	No

ADO Collection Support in the ODBC Driver for DB2

The following table summarizes the Microsoft® ActiveX® Data Objects (ADO) version 2.0 object collections that are supported by the current version of the Microsoft ODBC Driver for DB2.

ADO object	Collection	Support
Command Object	**Parameters** Property	Yes
	Properties Property	Yes
Connection Object	**Errors** Property	Yes
	Properties Property	Yes
Field Object	**Properties** Property	Yes
Parameter	**Properties** Property	Yes
Recordset Object	**Fields** Property	Yes
	Properties Property	Yes

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Command Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Command** object is a definition of a specific command that is to be executed against an Open Database Connectivity (ODBC) Driver data source.

Command objects can be used to create a **Recordset** object and obtain records, execute a bulk operation, or manipulate the structure of a database. When using the Microsoft ODBC Driver for DB2, some collections, methods, or properties of a **Command** object can generate an error when called.

The primary purpose of the **Command** object in the context of the ODBC Driver for DB2 is to issue SQL commands for execution by the remote DB2 target server. Legal SQL commands are documented for the target DB2 platforms in SQL Reference Guides published by IBM.

The following table lists the **Command** object methods, properties, and collections that are supported by the current version of the ODBC Driver for DB2.

Name	**Comment**
Execute Method	Evaluates command text (only supported *Options* parameter for this method is **adCmdText**, which indicates that this is an SQL text command).
ActiveConnection Property	Sets or returns the information used to establish a connection to a data source (see notes following).
CommandText Property	Sets or returns the command text to be executed.
CommandType Property	Sets or returns the type of command in a **CommandText** property.
State Property	Describes the current state of an object.
Properties collection	Collections of properties on the command.

The **Execute** method executes a command and returns a **Recordset** object, if appropriate. The **Command** object can be used to open tables or execute SQL commands on a remote DB2 server. If errors occur, you can examine them with the **Errors** collection on the **Connection** object.

You can create a **Command** object independently of a previously defined **Connection** object by setting the **ActiveConnection** property of the **Command** object to a valid connection string (for the proper syntax, see the **ConnectionString** property of the **Connection** object). ADO still creates a **Connection** object, but it does not assign that object to an object variable. However, if multiple **Command** objects are to be associated with the same connection, the **Connection** object should be explicitly created and opened. This assigns the **Connection** object to an object variable. If the **ActiveConnection** property of the **Command** object is not set to this object variable, ADO creates a new **Connection** object for each **Command** object, even if the same connection string is used.

The **ActiveConnection** property associates an open connection with a **Command** object. The **CommandText** property defines the text version of a command (**SELECT ALL FROM TABLE**, for example). The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution to optimize performance. The **CommandType** property must be set to **adCmdText** for use with the ODBC Driver for DB2.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Connection Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Connection** object represents an open connection to an Open Database Connectivity (ODBC) data source. The **Provider** property sets the ODBC Driver to use. Setting the **ConnectionString** properties configures the connection before opening the data source. The **Version** property determines the version of the ADO implementation in use.

The **Open** method establishes the physical connection to the data source and the **Close** method terminates the connection. If errors occur, these can be examined with the **Errors** collection.

The following table lists the **Connection** object methods, properties, and collections that are supported by the current version of the Microsoft ODBC Driver for DB2.

Name	**Comment**
Close Method	Closes a connection to a data source.
Execute Method	Evaluates command text.
Open Method	Opens a connection to a data source and can optionally pass **ConnectionString** parameters with this method.
OpenSchema Method	Obtains database schema information from the ODBC Driver.
Attributes Property	One or more characteristics supported for a given **Connection** object.
ConnectionString Property	Contains the information used to establish a connection to a data source (see notes following this table).
CursorLocation property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
IsolationLevel Property	Sets or returns the level of isolation for a **Connection** object.
Mode Property	Indicates the available permissions for modifying data in a connection.
Provider Property	Sets or returns the name of the provider for a connection.
State Property	Describes the current state of an object.
Version Property	Returns the version number of the ADO implementation in use.
Errors collection	Collections of **Error** objects on the connection.
Properties collection	Collections of properties on the connection.

The information needed to establish a connection to a data source can be set in the **ConnectionString** property or passed as part of the **Open** method. In either case, this information must be in a specific format for use with the ODBC Driver for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. The following table list the supported ADO-defined arguments for the **ConnectionString** property.

Argument	**Description**
Data Source	A required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file that is stored in the Program Files\Common Files\ODBC\Data Sources directory.
File Name	Name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed.
Location	The remote database name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	Valid mainframe or AS/400 password for use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database.
Provider	Name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".
User ID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database.

The ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the following tables. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2004 differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The following table describes the arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server 2004.

Argument	**Description**
BAC	When the *BinAsChar* parameter is set to **true** (1), the ODBC Driver for DB2 treats binary data type fields (with a Code Character Set Identifier (CCSID) of 65535) as character data type fields on a per-data source basis. The **CCSID** and **PCCodePage** values are required input parameters.
CCSID	The CCSID matching the DB2 data as represented on the remote computer. The **CCSID** property is required when processing binary data as character data. Unless the **BinAsChar** value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character *Code Page* to use on the computer. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Microsoft® Windows®. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The *Default Schema* parameter is the name of the collection where the ODBC Driver for DB2 looks for catalog information. The *Default Schema* parameter is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses *Default Schema* to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the *Default Schema* is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the *Default Schema* is the target COLLECTION name. For DB2 Universal Database (UDB), the *Default Schema* is the SCHEMA name. If the user does not provide a value for *Default Schema*, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the **Default Schema** value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote logical unit (LU) alias configured in Host Integration Server.
MN	When SNA is used for the Network Transport Library (NTL), the **Mode Name** field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to *QPCSUPP*.
NA	When TCP/IP is used for the NTL, the *Network Address* parameter indicates the IP address or the hostname alias of the host DB2 server.

NP	When TCP/IP is used for the NTL, the *Network Port* parameter indicates the TCP/IP port used for communication with the target DB2 Distributed Relational Database Architecture (DRDA) service. The default value is TCP/IP port 446.
NTL	The *Network Transport Library* parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for **NetAddr** and **NetPort** are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the *Package Collection* parameter.
PDS	The *Provider Data Source* is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the *Parameter* parameter.
RDB	The *Remote Database Name* parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 Installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The **RDBNAM** value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no **RDBNAM** value, then a value can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
TPN	The *Transaction Program (TP) Name* parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2004 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, the alternative TP Name is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the *User ID* parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are distributed unit of work (DUW) or remote unit of work (RUW). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the ODBC Driver for DB2 is as follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "UID=USERNAME;PWD=password",&_
  "LLU=LOCAL;RLU=DATABASE",&_
  "MN=QPCSUPP;CCSID=37;CP=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note The &_ character combination is used for continuing long lines in Visual Basic.

When opening a connection object in ADO 2.0, you must specify the *Prompt* connection property. For example, the following syntax is valid with ADO 1.5 and ADO 2.0 and prompts the user for **ConnectionString** properties, as shown in the following code:

```
Conn.ConnectionString = "Provider=DB2OLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

A sample **Open** method call with these parameters is as follows:

```
RS.Open "Accounting",Conn,0,1,1
```

The last three parameters to the **Open** method correspond with the *CursorType* (the **adOpenForwardOnly** enum is 0, for example), *LockType* (the **adLockReadOnly** enum is 1, for example), and *Options* (**adCmdText** is 1, which indicates that the source name should be evaluated as SQL text). The *Options* parameter must be set to **adCmdText** (1) when used with a data source name with ODBC Driver for DB2.

The following table describes the allowable values for CCSID when using SNA National Language Support (SNANLS) for character code conversions (the default).

EBCDIC character set	CCSID value
Arabic	20420
Binary (No Conversion)	65535
Chinese (Simplified)	935
Chinese (Traditional)	937
Cyrillic (Russian)	20880
Cyrillic (Serbian, Bulgarian)	21025
Denmark/Norway (euro)	1142
Denmark/Norway	20277
Finland/Sweden (euro)	1143
Finland/Sweden	20278
France (euro)	1147
France	20297
Germany (euro)	1141
Germany	20273
Greek (Modern)	875
Greek	20423
Hebrew	20424
Icelandic (euro)	1149
Icelandic	20871
International (euro)	1148
International	500
Italy (euro)	1144
Italy	20280
Japanese (English-lower)	931
Japanese (Extend English)	939
Japanese (Extend Katakana)	930
Japanese (Katakana)	290
Japanese (Katakana-Kanji)	5026

Japanese (Latin-Kanji)	5035
Korean	933
Latin America/Spain (euro)	1145
Latin America/Spain	20284
Latin-1 Open System (euro)	20924
Latin-1 Open System	1047
Multilingual/ROECE (Latin-2)	870
Thai	20838
Turkish (Latin-5)	1026
Turkish	20905
U.S./Canada (euro)	1140
U.S./Canada	37
United Kingdom (euro)	1146
United Kingdom	20285

Note that the SNANLS conversions use the locale configured for the data sources using data links. For more information, see SNA National Language Support Programmer's Guide.

The following table describes the allowable values for CCSID when using ANSI/OEM for character code conversions.

ANSI/OEM character set	CCSID value
ANSI - Arabic	1256
ANSI - Baltic	1257
ANSI - Cyrillic	1251
ANSI - Eastern Europe	1250
ANSI - Greek	1253
ANSI - Hebrew	1255
ANSI - Latin I	1252
ANSI - Turkish	1254
ANSI/OEM - Korean (Extended Wansung)	949
ANSI/OEM - Japanese Shift-JIS	932
ANSI/OEM - Simplified Chinese GBK	936
ANSI/OEM - Traditional Chinese Big5	950
ANSI/OEM - Thai	874
ANSI/OEM - Vietnam	1258

Error Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Error** object contains details about data access errors pertaining to a single operation involving ADO. You can read the properties of an **Error** object to obtain specific details about each error.

The **Error** object does not support any methods or collections; however, the **Errors** collection supported by other objects provides the standard **Collection** methods (**Clear** and **Delete**). **Error** objects are automatically appended to the **Errors** collection by the Open Database Connectivity (ODBC) Driver when they occur. The following table lists the **Error** object properties that are supported by the current version of the Microsoft® ODBC Driver for DB2.

Property Name	**Comment**
Description Property	The text of the error alert that is returned based on the minor error code (specific to the ODBC Driver for DB2) contained in the **Error** object resulting from an error.
NativeError Property	A **Long** integer value of the error code returned by the ODBC Driver for DB2.
Number Property	The **Long** integer value of the ODBC error constant.
Source Property	A **string** that indicates the name of the object or application that originally generated an error.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Field Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Field** object represents a column of data with a common data type. Each **Field** object corresponds to a column in a **Recordset** object.

The following table lists the **Field** object methods, properties, and collections that are supported by the current version of Microsoft ODBC Driver for DB2.

Name	**Comment**
ActualSize Property	Actual length of a field's value.
Attributes Property	One or more characteristics supported for a given **Field** object.
DefinedSize Property	Defined size of a **Field** object.
Name Property	Name of the **Field** object.
NumericScale Property	Scale of numeric values in a **Field** object for numeric data.
OriginalValue Property	Value of a **Field** object that existed in the record before changes were made.
Precision Property	Degree of precision for numeric values in a **Field** object for numeric data.
Type Property	Operational type or data type for a **Field** object.
UnderlyingValue Property	Current value of a **Field** object.
Value Property	Value assigned to a **Field** object in a **Recordset**.
Properties collection	Collections of properties on the field.

Recordset Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Recordset** object represents the entire set of records from a base table. At any time, the **Recordset** object refers to only one record within the set as the current record.

The following table lists the **Recordset** object methods, properties, and collections that are supported by the current version of the Microsoft ODBC Driver for DB2.

Name	**Comment**
AddNew Method	Creates a new record for an updateable **Recordset** object.
CancelBatch Method	Cancels a pending batch update.
CancelUpdate Method	Cancels any changes made to a current record or to a new record prior to calling the **UpdateBatch** method.
Clone Method	Creates a duplicate **Recordset** object from an existing **Recordset** object.
Close Method	Closes an open object and any dependent objects.
Delete Method	Deletes the current record in an open **Recordset** object or an object from a collection.
GetRows Method	Retrieves multiple records of a **Recordset** into an array.
Move Method	Moves the position of the current record in a **Recordset** object.
MoveFirst Method	Moves to the first record in a specified **Recordset**.
MoveLast Method	Moves to the last record in a specified **Recordset**. This method is only supported when using a client-side cursor.
MoveNext Method	Moves to the next record in a specified **Recordset**.
MovePrevious Method	Moves to the previous record in a specified **Recordset**. This method is only supported when using a client-side cursor.
Open Method	Opens a cursor on a **Recordset**.
Requery Method	Updates the data in a **Recordset** object by re-executing the query on which the object is based (equivalent to calling the **Close** and **Open** methods in succession).
Save Method	Saves a **Recordset** in a file or **Stream** object.
Supports Method	Determines whether a specified **Recordset** object supports a particular type of function.
Update Method	Saves any changes you make to the current record of a **Recordset** object.
UpdateBatch Method	Writes all pending batch updates to disk.
ActiveCommand Property	Returns the **Command** object that created the specified **Recordset**.
ActiveConnection Property	Sets or returns the **Connection** object that the specified **Recordset** object currently belongs.
BOF Property	Indicates whether the current record position is before the first record in a **Recordset** object.
Bookmark Property	Returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object identified by a valid bookmark.
CacheSize Property	Sets or returns the number of records from a **Recordset** object that are cached locally in memory.
CursorLocation Property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
CursorType Property	Sets or returns the type of cursor used in a **Recordset** object. Only the **adOpenForwardOnly CursorType** is supported by the current version of the ODBC Driver for DB2.
EditMode Property	Indicates the editing status of the current record type.
EOF Property	Indicates whether the current record position is after the last record in a **Recordset** object.
LockType Property	Sets or returns the types of locks placed on records during editing. The ODBC Driver for DB2 supports locks of type **adLockReadOnly** and **adLockPessimistic**.
MaxRecords Property	Sets or returns the maximum number of records to return to a **Recordset** from a query.
Source Property	Sets or returns the source (table name or command object) for the data in a **Recordset**.
State Property	Describes the current state of an object.

Status Property	Indicates the status of the current record with respect to batch updates or other bulk operations.
Fields collection	Collections of fields on the **Recordset**.
Properties collection	Collections of properties on the **Recordset**.

Managed Provider for DB2 Programmer's Reference

The Managed Provider for DB2 enables users to access IBM Data Base 2 (DB2) from within a managed code application, and serves as a bridge between a DB2 data source and an ADO **DataSet**. This section provides the reference material needed to program the Managed Provider for DB2.

For general information about programming for the Managed Provider for DB2, see the Managed Provider Programmer's Guide.

This section contains:

- Microsoft.HostIntegration.MsDb2Client Namespace

Microsoft.HostIntegration.MsDb2Client Namespace

The **Microsoft.HostIntegration.MsDb2Client** namespace contains functions designed to be used for accessing DB2 databases using Microsoft® Host Integration Server 2004 technologies.

Namespace hierarchy

Classes

Class	Description
MsDb2Command	Manages all parameters that a query might have which includes both SQL parameters and stored procedure parameters.
MsDb2Connection	Responsible for opening, closing, and maintaining a connection to a DB2 host.
MsDb2DataAdapter	Acts as the gateway between a DB2 host table and a .NET-based data set.
MsDb2DataReader	A server-side forward-only cursor implementation that inherits from the **IDataReader** and **IDataRecord** interfaces.
MsDb2Exception	The exception thrown when the underlying provider returns a warning or error for a DB2 data source.
MsDb2NetworkProperties	An abstract base class for defining network-specific connection properties to a DB2 host.
MsDb2NetworkPropertiesAPPC	Defines the network-specific connections for connecting to a DB2 host using the APPC protocol.
MsDb2NetworkPropertiesTCP	Defines the network-specific connection properties for connecting to a DB2 host using the TCP/IP protocol.
MsDb2Parameter	Represents a placeholder for a parameter in a SQL command.
MsDb2ParameterCollection	A strongly-typed collection of **MsDb2Parameters**.
MsDb2RowUpdatedEventArgs	Provides data for the **RowUpdated** event.
MsDb2RowUpdatingEventArgs	Provides data for the **RowUpdating** event.
MsDb2Transaction	An implementation of the **IDbTransaction** interface.

Delegates

Delegate	Description
MsDb2RowUpdatedEventHandler	Represents the method that handles the **RowUpdated** event of an **MsDb2DataAdapter**.
MsDb2RowUpdatingEventHandler	Represents the method that handles the **RowUpdating** event of an **OleDbDataAdapter**.

Enumerations

Enumeration	Description
DBMSPlatform	The target DB2 platform property value to optimize performance of the OLEDB provider when executing operations such as data conversions.
MsDb2Type	Specifies the data type of a field, a property, or an **MsDb2Parameter**.
UnitsOfWorkType	The type of transaction supported by the provider. Currently only remote unite of work is supported.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

DBMSPlatform Enumeration

Specifies the target DB2 platform to optimize the Managed Provider when executing operations, such as data conversions.

VB

```
<Serializable>
Public Enum DBMSPlatform
[C#]
[Serializable]
public enum DBMSPlatform
[C++]
[Serializable]
__value public enum DBMSPlatform
[JScript]
public
   Serializable
enum DBMSPlatform
```

Members

The following table describes the different target DB2 platforms for which to optimize. The default value is DB2VMS.

Member name	Description
DB2MVS	MVS
DB2AS400	AS400
DB2NT	Windows NT 4.0
DB26000	6000

Requirements

Namespace: Microsoft.HostIntegration.MsDb2Client

Platforms: Windows 2000, Windows XP Professional, Windows Server 2003 family

Assembly: Microsoft.Hostintegration.Msdb2client (in Microsoft.Hostintegration.Msdb2client.dll)

See Also

Microsoft.HostIntegration.MsDb2Client Namespace Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command Class

Manages all parameters that a query might have, including both SQL parameters and stored procedure parameters.

For a list of all members of this type, see MsDb2Command Members.

System.Object
  Microsoft.HostIntegration.MsDb2Client.MsDb2Command

VB

```
Public Class MsDb2Command
   Implements IDbCommand, IDisposable
[C#]
public class MsDb2Command : IDbCommand, IDisposable
[C++]
public __gc class MsDb2Command : public IDbCommand, IDisposable
[JScript]
public class MsDb2Command implements IDbCommand, IDisposable
```

Thread Safety

Any public static (**Shared** in Microsoft® Visual Basic®) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

MsDB2Command is an implementation of the **IDbCommand** interface. An **MsDb2Command** represents a single query to a DB2 host system. These queries can be any DML, DDL, or stored procedure statement formatted for the specific DB2 platform. The **MsDb2Command** class does not perform any pre-parsing to verify the SQL statement. As **MsDb2Command** is a single SQL statement per command, there is no batch mode.

An **MsDB2Command** instance belongs to a single transaction running on a single connection.

An **Ms2Db2Command** can become "dirty" if it has been prepared, and there is a change to a piece of the command structure. If a change is made, the command must be re-prepared to account for the changes. **MsDb2Command** has a private dirty flag that will determine when to re-prepare a command. Events that make a command dirty include:

- All changes to parameters, excluding the value (such as precision, scale, type, and so on)
- Changes to the number of parameters
- Changes to the **CommandText**
- Changes to the **CommandType**

Requirements

Namespace: Microsoft.HostIntegration.MsDb2Client

Platforms: Microsoft® Windows Server 2003, Windows® XP Professional, Windows 2000 Server

Assembly: Microsoft.Hostintegration.Msdb2client (in Microsoft.Hostintegration.Msdb2client.dll)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command Members

For background and overview information, see MsDb2Command overview.

Public Constructors

MsDb2Command Constructor	Overloaded. Initializes a new instance of the **MsDb2Command** class.

Public Properties

CommandText	Gets or sets the command value sent to the DB2 system.
CommandTimeout	Gets or sets the amount of time to wait before the command execution times out.
CommandType	Gets or sets the type of command the **CommandText** property stores.
Connection	Gets or sets the connection that owns the command.
Parameters	Gets the collection of parameters that belong to this particular command.
Transaction	Gets or sets the owning transaction of the command.
UpdatedRowSource	Gets or sets how command results are applied to the DataRow when used by **MsDb2DataAdapter.Update**.

Public Methods

Cancel	Preempts an executing command and causes a transition rollback of the results have been partially retrieved.
CreateParameter	Creates and returns a new **MsDb2Parameter**.
Dispose	Releases the resources used by the current instance.
Equals (inherited from **System.Object**)	Determines whether two **Objects** are equal.
ExecuteNonQuery	Executes an SQL statement against the Connection and returns the number of rows affected.
ExecuteReader	Overloaded. Executes a query that expects some sort of forward-only resultset cursor.
ExecuteScalar	Executes a query that returns a resultset and returns the object value of row 1, column 1.
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
Prepare	Prepares a query command for execution.
ToString (inherited from **System.Object**)	Returns a **String** that represents the current **Object**.

Protected Methods

Finalize	Overridden. Enables an **Object** to attempt to free resources and perform other cleanup operations before the **Object** is reclaimed by the garbage collection. In Microsoft® Visual C#® and Visual C++®, finalizers are expressed using destructor syntax.
MemberwiseClone (inherited from **System.Object**)	Creates a shallow copy of the current object.

MsDb2Command Constructor

For background and overview information, see MsDb2Command overview.

Overload List

[Visual Basic] Public Sub New()

[C#] public MsDb2Command();

[C++] public: MsDb2Command();

[JScript] public function MsDb2Command();

[Visual Basic] Public Sub New(System.String)

[C#] public MsDb2Command(System.String);

[C++] public: MsDb2Command(System.String);

[JScript] public function MsDb2Command(System.String);

[Visual Basic] Public Sub New(System.String, MsDb2Connection)

[C#] public MsDb2Command(System.String, MsDb2Connection);

[C++] public: MsDb2Command(System.String, MsDb2Connection*);

[JScript] public function MsDb2Command(System.String, MsDb2Connection);

[Visual Basic] Public Sub New(System.String, MsDb2Connection, MsDb2Transaction)

[C#] public MsDb2Command(System.String, MsDb2Connection, MsDb2Transaction);

[C++] public: MsDb2Command(System.String, MsDb2Connection*, MsDb2Transaction*);

[JScript] public function MsDb2Command(System.String, MsDb2Connection, MsDb2Transaction);

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Command Constructor ()

Initializes a new instance of the MsDb2Command class.

VB

```
Public Sub New()
[C#]
public MsDb2Command();
[C++]
public: MsDb2Command();
[JScript]
public function MsDb2Command();
```

Remarks

The default constructor initializes any fields to their default values. The following table describes the initial values for an instance of **MsDb2Command**.

Properties	Initial Value
CommandText	Empty string ("")
CommandTimeout	30
CommandType	**Text**
Connection	null

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide | MsDb2Command Constructor Overload List

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command Constructor (System.String)

Initializes a new instance of the MsDb2Command class.

VB

```
Public Sub New( _
   ByVal cmdText As String _
)
[C#]
public MsDb2Command(
   string cmdText
);
[C++]
public: MsDb2Command(
   String* cmdText
);
[JScript]
public function MsDb2Command(
   cmdText : String
);
```

Parameters

cmdText
The text of the query.

Remarks

The following table describes the initial values for an instance of MsDb2Command.

Properties	Initial Value
CommandText	*cmdText*
CommandTimeout	30
CommandType	**Text**
Connection	null

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Constructor (System.String, MsDb2Connection)

initializes a new instance of the MsDb2Command class using the specified command text and connection.

VB

```
Public Sub New( _
   ByVal cmdText As String, _
   ByVal connection As MsDb2Connection _
)
[C#]
public MsDb2Command(
   string cmdText,
   MsDb2Connection connection
);
[C++]
public: MsDb2Command(
   String* cmdText,
   MsDb2Connection* connection
);
[JScript]
public function MsDb2Command(
   cmdText : String,
   connection : MsDb2Connection
);
```

Parameters

cmdText
The text of the query.
connection
The MsDb2Connection that represents a connection to the database source.

Remarks

The following table describes the initial values for an instance of **MsDb2Command**.

Properties	Initial Value
CommandText	*cmdText*
CommandTimeout	30
CommandType	**Text**
Connection	The value contained in the *connection* parameter.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2Command Constructor (System.String, MsDb2Connection, MsDb2Transaction)

Initializes a new instance of the MsDb2Command class using the specified command text, connection, and transaction.

VB

```
Public Sub New( _
   ByVal cmdText As String, _
   ByVal connection As MsDb2Connection, _
   ByVal txn As MsDb2Transaction _
)
[C#]
public MsDb2Command(
   string cmdText,
   MsDb2Connection connection,
   MsDb2Transaction txn
);
[C++]
public: MsDb2Command(
   String* cmdText,
   MsDb2Connection* connection,
   MsDb2Transaction* txn
);
[JScript]
public function MsDb2Command(
   cmdText : String,
   connection : MsDb2Connection,
   txn : MsDb2Transaction
);
```

Parameters

cmdText
  The text of the query.
connection
  An MsDb2Connection representing a connection to the data source.
txn
  The transaction in which the **MsDb2Command** executes.

Remarks

The following table describes the initial values for an instance of **MsDb2Command**.

Properties	**Initial Value**
CommandText	*cmdText*
CommandTimeout	30
CommandType	**Text**
Connection	The value contained in the *connection* parameter.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2Command Properties

This section lists the properties of the **MsDb2Command** class. For a complete list of **MsDb2Command** class members, see MsDb2Command Members.

Public Properties

CommandText	Gets or sets the command value sent to the DB2 system.
CommandTimeout	Gets or sets the amount of time to wait before the command execution times out.
CommandType	Gets or sets the type of command the **CommandText** property stores.
Connection	Gets or sets the connection that owns the command.
Parameters	Gets the collection of parameters that belong to this particular command.
Transaction	Gets or sets the owning transaction of the command.
UpdatedRowSource	Gets or sets how command results are applied to the DataRow when used by **MsDb2DataAdapter.Update**.

MsDb2Command Class | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.CommandText Property

Gets or sets the command value sent to the DB2 system.

VB

```
Public Overridable Property CommandText As String  Implements _
   IDbCommand.CommandText
[C#]
public virtual string CommandText {get; set;}
[C++]
public: __property virtual String* get_CommandText();
public: __property virtual void set_CommandText(String*);
[JScript]
public function get CommandText() : String;
public function set CommandText(String);
```

Property Value

The command value sent to the DB2 system. The default is an empty string.

Implements

IDbCommand.CommandText

Exceptions

Exception Type	Condition
InvalidCommandText	The command text is null or empty.

Remarks

The value of **CommandText** is dependent on the *CommandValue* field. The **CommandText** can include a stored procedure name, a table name, or SQL statement text. When **CommandText** is changed, the _dirty flag is set.

When CommandType is set to **StoredProcedure**, CommandText should be set to the name of the stored procedure. The user may be required to use escape character syntax if the stored procedure name contains any special characters. The command executes this stored procedure when you call one of the Execute methods.

When **CommandType** is set to **TableDirect**, **CommandText** should be set to the name of the table or tables to be accessed. The user may be required to use escape character syntax if any of the tables named contain any special characters. All rows and columns of the named table or tables will be returned when you call one of the Execute methods.

You cannot set Connection, CommandType and **CommandText** if the current connection is performing an execute or fetch operation.

The Managed Provider for DB2 not support named parameters for passing parameters to an SQL statement or a stored procedure called by an **MsDb2Command** when **CommandType** is set to **Text**. In this case, the question mark (?) placeholder must be used, as in the following example:

```
SELECT * FROM Customers WHERE CustomerID = ?
```

As a result, the order in which an MsDb2Parameter is added to the MsDb2ParameterCollection must directly correspond to the position of the question mark placeholder for the parameter.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace |

Managed Provider for DB2 Programmer's Guide

MsDb2Command.CommandTimeout Property

Gets or sets the amount of time to wait before the command execution times out.

VB

```
Public Overridable Property CommandTimeout As Integer  Implements _
   IDbCommand.CommandTimeout
[C#]
public virtual int CommandTimeout {get; set;}
[C++]
public: __property virtual int get_CommandTimeout();
public: __property virtual void set_CommandTimeout(int);
[JScript]
public function get CommandTimeout() : int;
public function set CommandTimeout(int);
```

Property Value

The time (in seconds) to wait for the command to execute. The default is 30 seconds

Implements

IDbCommand.CommandTimeout

Property Value

Integer containing the amount of time to wait before the command execution times out.

Exceptions

Exception Type	Condition
InvalidCommandTimeout	Timeout was attempted to be set to a negative value.

Remarks

A value of 0 indicates no limit, and should be avoided in a **StoredProcedure** because an attempt to execute a command waits indefinitely.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.CommandType Property

Gets or sets the type of command the **CommandText** property stores.

VB

```
Public Overridable Property CommandType As CommandType  Implements _
   _
   IDbCommand.CommandType
[C#]
public virtual CommandType CommandType {get; set;}
[C++]
public: __property virtual CommandType get_CommandType();
public: __property virtual void set_CommandType(CommandType);
[JScript]
public function get CommandType() : CommandType;
public function set CommandType(CommandType);
```

Property Value

One of the CommandType values. The default is **Text**.

Implements

IDbCommand.CommandType

Property Value

CommandType containing the type of command the **CommandText** property stores.

Exceptions

Exception Type	Condition
InvalidCommandType	The **CommandType** value is not a value listed above.

Remarks

When you set **CommandType** to **StoredProcedure**, you should set CommandText to the name of the stored procedure. The command executes this stored procedure when you call one of the Execute methods.

The Connection, CommandType and CommandText cannot be set if the current connection is performing an execute or fetch operation.

The Managed Provider for DB2 does not support named parameters for passing parameters to an SQL statement or a stored procedure called by an **MsDb2Command** when **CommandType** is set to **Text**. In this case, the question mark (?) placeholder must be used, as in the following example:

```
SELECT * FROM Customers WHERE CustomerID = ?
```

As a result, the order in which an MsDb2Parameter is added to the MsDb2ParameterCollection must directly correspond to the position of the question mark placeholder for the parameter.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to

http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.Connection Property

Gets or sets the connection that owns this command.

VB

```
Public Overridable Property Connection As IDbConnection  Implements _
   _
   IDbCommand.Connection
[C#]
public virtual IDbConnection Connection {get; set;}
[C++]
public: __property virtual IDbConnection* get_Connection();
public: __property virtual void set_Connection(IDbConnection*);
[JScript]
public function get Connection() : IDbConnection;
public function set Connection(IDbConnection);
```

Property Value

IdbConnection containing the connection that owns this command. The default value is a null reference (**Nothing** in Microsoft Visual Basic).

Implements

IDbCommand.Connection

Remarks

You cannot set the **Connection**, CommandType and CommandText if the current connection is performing an execute or fetch operation.

If you set **Connection** while a transaction is in progress and the Transaction property is not null, an **InvalidOperationException** is generated. If the **Transaction** is not null and the transaction has already been committed or rolled back, **Transaction** is set to null.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.Parameters Property

Gets the collection of parameters that belong to this particular command.

VB

```
Public ReadOnly Property Parameters As MsDb2ParameterCollection
[C#]
public MsDb2ParameterCollection Parameters {get;}
[C++]
public: __property MsDb2ParameterCollection* get_Parameters();
[JScript]
public function get Parameters() : MsDb2ParameterCollection;
```

Property Value

The parameters of the SQL statement or stored procedure. The default is an empty collection.

Remarks

The Managed Provider for DB2 does not support named parameters for passing parameters to an SQL statement or a stored procedure called by an MsDb2Command when CommandType is set to **Text**. In this case, the question mark (?) placeholder must be used. For example:

```
SELECT * FROM Customers WHERE CustomerID = ?
```

As a result, the order in which an MsDb2Parameter is added to the MsDb2ParameterCollection must directly correspond to the position of the question mark placeholder for the parameter.

If the parameters in the collection do not match the requirements of the query to be executed, an error may result.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.Transaction Property

Gets or sets the owning transaction of the command.

VB

```
Public Property Transaction As MsDb2Transaction
[C#]
public MsDb2Transaction Transaction {get; set;}
[C++]
public: __property MsDb2Transaction* get_Transaction();
public: __property void set_Transaction(MsDb2Transaction*);
[JScript]
public function get Transaction() : MsDb2Transaction;
public function set Transaction(MsDb2Transaction);
```

Property Value

IdBTransaction containing the owning transaction of this command. The default value is a null reference (**Nothing** in Visual Basic).

Exceptions

Exception Type	Condition
InvalidTransactionProperty	The property value is null.

Remarks

Changing the transaction of the command causes a rollback of the current transaction.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.UpdatedRowSource Property

Gets or sets how command results are applied to the DataRow when used by **MsDb2DataAdapter**.

VB

```
Public Overridable Property UpdatedRowSource As UpdateRowSource  _
   Implements IDbCommand.UpdatedRowSource
[C#]
public virtual UpdateRowSource UpdatedRowSource {get; set;}
[C++]
public: __property virtual UpdateRowSource get_UpdatedRowSource();
public: __property virtual void
   set_UpdatedRowSource(UpdateRowSource);
[JScript]
public function get UpdatedRowSource() : UpdateRowSource;
public function set UpdatedRowSource(UpdateRowSource);
```

Property Value

One of the UpdateRowSource values. The default is Both unless the command is automatically generated. Then the default is None.

Implements

IDbCommand.UpdatedRowSource

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Methods

This section lists the methods of the **MsDb2Command** class. For a complete list of **MsDb2Command** class members, see MsDb2Command Members.

Public Methods

Cancel	Preempts an executing command and causes a transition rollback of the results have been partially retrieved.
CreateParameter	Creates and returns a new **MsDb2Parameter**.
Dispose	Releases the resources used by the **Component**.
Equals (inherited from **System.Object**)	Determines whether two **Objects** are equal.
ExecuteNonQuery	Executes an SQL statement against the Connection and returns the number of rows affected.
ExecuteReader	Overloaded. Executes a query that expects some sort of forward-only resultset cursor.
ExecuteScalar	Executes a query that returns a resultset and returns the object value of row 1, column 1.
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
Prepare	Prepares a query command for execution.
ToString (inherited from **System.Object**)	Returns a **String** that represents the current **Object**.

Protected Methods

Finalize	Overridden. Enables an **Object** to attempt to free resources and perform other cleanup operations before the **Object** is reclaimed by garbage collection. In Microsoft® Visual C#® and Visual C++®, finalizers are expressed using destructor syntax.
MemberwiseClone (inherited from **System.Object**)	Creates a shallow copy of the current Object.

MsDb2Command Class | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.Cancel Method

Preempts an executing command and causes a transaction rollback if the results have been partially retrieved

VB

```
Public Overridable Sub Cancel() Implements IDbCommand.Cancel
[C#]
public virtual void Cancel();
[C++]
public: virtual void Cancel();
[JScript]
public function Cancel();
```

Implements

IDbCommand.Cancel

Remarks

If there is nothing to cancel, nothing happens. However, if there is a command in process, and the attempt to cancel fails, no exception is generated.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.CreateParameter Method

Creates and returns a new **MsDb2Parameter**.

VB

```
Public Function CreateParameter() As MsDb2Parameter
[C#]
public MsDb2Parameter CreateParameter();
[C++]
public: MsDb2Parameter* CreateParameter();
[JScript]
public function CreateParameter() : MsDb2Parameter;
```

Return Value

A new MsDb2Parameter.

Remarks

CreateParameter does not add the parameter to the internally stored **MsDb2ParameterCollection**. To do so, you must manually call **Parameters.Add()**.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.Dispose Method

Releases the resources used by the current instance.

VB

```
Public Overridable Sub Dispose() Implements IDisposable.Dispose
[C#]
public virtual void Dispose();
[C++]
public: virtual void Dispose();
[JScript]
public function Dispose();
```

Implements

IDisposable.Dispose

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.ExecuteNonQuery Method

Executes a Data Definition Language (DDL) or Distributed Data Management (DDM) statement that does not expect a resultset.

VB

```
Public Overridable Function ExecuteNonQuery() As Integer Implements _
   _
   IDbCommand.ExecuteNonQuery
[C#]
public virtual int ExecuteNonQuery();
[C++]
public: virtual int ExecuteNonQuery();
[JScript]
public function ExecuteNonQuery() : int;
```

Return Value

The number of rows affected.

Implements

IDbCommand.ExecuteNonQuery

Exceptions

Exception Type	Condition
InvalidOperationException	The connection does not exist, or the connection is not open.

Remarks

Output parameters are suitable. The return value is the number of rows affected.

You can use the **ExecuteNonQuery** to perform catalog operations (for example, querying the structure of a database or creating database objects such as tables), or to change the data in a database without using a **DataSet** by executing UPDATE, INSERT, or DELETE statements.

Although the **ExecuteNonQuery** does not return any rows, any output parameters or return values mapped to parameters are populated with data.

For UPDATE, INSERT, and DELETE statements, the return value is the number of rows affected by the command. For all other types of statements, the return value is -1.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Command.ExecuteReader Method

Executes a query that expects some sort of forward-only result set cursor.

Overload List

[Visual Basic] Overloads Public Function ExecuteReader() As MsDb2DataReader

[C#] public MsDb2DataReader ExecuteReader();

[C++] public: MsDb2DataReader* ExecuteReader();

[JScript] public function ExecuteReader() : MsDb2DataReader;

[Visual Basic] Overloads Public Function ExecuteReader(System.Data.CommandBehavior) As MsDb2DataReader

[C#] public MsDb2DataReader ExecuteReader(System.Data.CommandBehavior);

[C++] public: MsDb2DataReader* ExecuteReader(System.Data.CommandBehavior);

[JScript] public function ExecuteReader(System.Data.CommandBehavior) : MsDb2DataReader;

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Command.ExecuteReader Method ()

Executes a query that expects some sort of forward-only resultset cursor.

VB

```
Overloads Public Function ExecuteReader() As MsDb2DataReader
[C#]
public MsDb2DataReader ExecuteReader();
[C++]
public: MsDb2DataReader* ExecuteReader();
[JScript]
public function ExecuteReader() : MsDb2DataReader;
```

Return Value

An MsDb2DataReader object.

Remarks

In addition, the queries can include stored procedures, **SELECT** statements, and schema fetches. Calling **ExecuteReader** with these types of queries is the same as calling **ExecuteReader(CommandBehavior.Default)**.

When CommandType is set to **StoredProcedure**, CommandText should be set to the name of the stored procedure. The command executes this stored procedure when you call **ExecuteReader**. While the MsDb2DataReader is in use, the associated MsDb2Connection is busy serving the **MsDb2DataReader**. While in this state, no other operations can be performed on the **MsDb2Connection** other than closing it. This is the case until the **Close** method of the **MsDb2DataReader** is called.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide | MsDb2Command.ExecuteReader Overload List

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.ExecuteReader Method (System.Data.CommandBehavior)

Executes a query that expects some sort of forward-only resultset cursor using the specified behavior.

VB

```
Overloads Public Function ExecuteReader( _
   ByVal behavior As CommandBehavior _
) As MsDb2DataReader
[C#]
public MsDb2DataReader ExecuteReader(
   CommandBehavior behavior
);
[C++]
public: MsDb2DataReader* ExecuteReader(
   CommandBehavior behavior
);
[JScript]
public function ExecuteReader(
   behavior : CommandBehavior
) : MsDb2DataReader;
```

Parameters

behavior
The command behavior of the execution.

Remarks

The queries executed by **ExecuteReader** can include stored procedures, **SELECT** statements, and schema fetches.

The following is a list of possible values for *behavior***.**

- CloseConnection
- Default
- KeyInfo
- SchemaOnly
- SequentialAccess
- SingleResult
- SingleRow

When you specify **SingleRow** with **ExecuteReader**, the Managed Provider for DB2 performs binding using the OLE DB **IRow** interface if it is available. Otherwise, it uses the **IRowset** interface. If your SQL statement is expected to return only a single row, specifying **SingleRow** can also improve application performance.

When CommandType is set to **StoredProcedure**, CommandText should be set to the name of the stored procedure. The command executes this stored procedure when you call **ExecuteReader**.

The MsDb2DataReader supports a special mode that enables large binary values to be read efficiently. For more information, see the **SequentialAccess** setting for **CommandBehavior**.

While the **MsDb2DataReader** is in use, the associated **MsDb2Connection** is busy serving the **MsDb2DataReader**. While in this state, no other operatons can be performed on the MsDb2Connection other than closing it. This is the case until the **Close** method of the **MsDb2DataReader** is called.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide | MsDb2Command.ExecuteReader Overload List

MsDb2Command.ExecuteScalar Method

Executes a query that returns a result set and returns the object value of row 1, column 1.

VB

```
Public Overridable Function ExecuteScalar() As Object Implements _
   IDbCommand.ExecuteScalar
[C#]
public virtual object ExecuteScalar();
[C++]
public: virtual Object* ExecuteScalar();
[JScript]
public function ExecuteScalar() : Object;
```

Return Value

The first column in the first row in the resultset.

Implements

IDbCommand.ExecuteScalar

Remarks

Calling **ExecuteScalar** is semantically equivalent to the following code:

```
IDbDataReader reader = cmd.ExecuteReader();
reader.Read();
object value = reader.GetValue(0);
```

Use **ExecuteScalar** to retrieve a single value (for example, an aggregate value) from a data source. This requires less code than using **ExecuteReader**, and then performing the operations necessary to generate the single value using the data returned by an MsDb2DataReader.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Command.Finalize Method

Allows an **Object** to attempt to free resources and perform other cleanup operations before the **Object** is reclaimed by the garbage collection.

[C#] In C#, finalizers are expressed using destructor syntax.

[C++] In C++, finalizers are expressed using destructor syntax.

VB

```
Overrides Protected Sub Finalize()
[C#]
~MsDb2Command();
[C++]
~MsDb2Command();
[JScript]
protected override function Finalize();
```

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.IDbCommand.ExecuteReader Method (System.Data.CommandBehavior)

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

VB

```
Private Function ExecuteReader( _
   ByVal behavior As CommandBehavior _
) As IDataReader Implements IDbCommand.ExecuteReader
[C#]
IDataReader IDbCommand.ExecuteReader(
   CommandBehavior behavior
);
[C++]
private: IDataReader* IDbCommand::ExecuteReader(
   CommandBehavior behavior
);
[JScript]
private function IDbCommand.ExecuteReader(
   behavior : CommandBehavior
) : IDataReader;
```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Command.Prepare Method

Prepares a query command for execution.

VB

```
Public Overridable Sub Prepare() Implements IDbCommand.Prepare
[C#]
public virtual void Prepare();
[C++]
public: virtual void Prepare();
[JScript]
public function Prepare();
```

Remarks

Prepare improves efficiency when the command is executed more than once, but with different parameter values. If the _dirty flag is set inside the **MsDb2Command**, then the command must be re-prepared (but this can be done internally).

If CommandType is set to **TableDirect**, **Prepare** does nothing. If **CommandType** is set to **StoredProcedure**, the call to **Prepare** should succeed, although it may result in a no-op.

Before you call **Prepare**, specify the data type of each parameter in the statement to be prepared. For each parameter that has a variable length data type, you must set the **Size** property to the maximum size needed. **Prepare** returns an error if these conditions are not met.

If you call an Execute method after calling **Prepare**, any parameter value that is larger than the value specified by the **Size** property is automatically truncated to the original specified size of the parameter, and no truncation errors are returned.

Output parameters (whether prepared or not) must have a user-specified data type. If you specify a variable length data type, you must also specify the maximum **Size**.

Implements

IDbCommand.Prepare

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2Command Class | MsDb2Command Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection Class

Opens, closes, and maintains a connection to a DB2 host.

For a list of all members of this type, see MsDb2Connection Members.

System.Object
  Microsoft.HostIntegration.MsDb2Client.MsDb2Connection

VB

```
Public Class MsDb2Connection
   Implements IDbConnection, IDisposable
[C#]
public class MsDb2Connection : IDbConnection, IDisposable
[C++]
public __gc class MsDb2Connection : public IDbConnection,
   IDisposable
[JScript]
public class MsDb2Connection implements IDbConnection, IDisposable
```

Thread Safety

Any public static (**Shared** in Microsoft® Visual Basic®) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

An **MsDb2Connection** object represents a unique connection to a data source. In the case of a client/server database system, it is equivalent to a network connection to the server. Depending on the functionality supported by the native OLE DB provider, some collections, methods, or properties of an **MsDb2Connection** object may not be available.

When you create an instance of **MsDb2Connection**, all properties are set to their initial values. For a list of these values, see the MsDb2Connection constructor.

If the **MsDb2Connection** goes out of scope, it is not closed. Therefore, you must explicitly close the connection by calling Close or Dispose.

To deploy high-performance applications, you need to use connection pooling. When you use the MsDb2 .NET Data Provider, you do not need to enable connection pooling because the provider manages this automatically.

If a fatal MsDb2Exception (for example, a SQL Server severity level of 20 or greater) is generated by the method executing an MsDb2Command, the **MsDb2Connection**, the connection may be closed. However, the user can reopen the connection and continue.

An application that creates an instance of the **MsDb2Connection** object can require all direct and indirect callers to have adequate permission to the code by setting declarative or imperative security demands. **MsDb2Connection** makes security demands using the **MsDb2Permission** object. Users can verify that their code has adequate permissions by using the **MsDb2PermissionAttribute** object. Users and administrators can also use the Code Access Security Policy Tool (Caspol.exe) to modify security policy at the computer, user, and enterprise levels.

Unlike other .NET providers, the Managed Provider for DB2 enables you to open multiple **MsDb2DataReaders** on a single **MsDb2Connection**.

Requirements

Namespace: Microsoft.HostIntegration.MsDb2Client

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Assembly: Microsoft.Hostintegration.Msdb2client (in Microsoft.Hostintegration.Msdb2client.dll)

MsDb2Connection Members

See MsDb2Connection overview for more information.

Public Constructors

MsDb2Connection Constructor	Overloaded. Initializes a new instance of the **MsDb2Connection** class.

Public Properties

BinaryAsCharacter	Gets or sets a value that determines if the provider treats binary data type fields (with a character code set identifier (CCSID) of 65535) as character data type fields on a per-data source basis.
ConnectionPooling	Gets or sets a value that determines if the application connects to the server using a traditional connection or a connection pool.
ConnectionString	Gets or sets the connection string to connect to the data source.
Database	Gets or sets the name of the database to which **MsDb2Connection** connects.
DBMSPlatform	Gets or sets the target DB2 platform the Managed Provider is optimized for.
DefaultSchema	Gets or sets the default database schema used.
HostCCSID	Gets or sets the character code set identifier (CCSID) that must match the data in the file as represented on the remote host computer.
NetworkProperties	Gets or sets network-specific connection properties.
PackageCollection	Gets or sets the name of the DRDA target collection (AS/400 library) where the provider should store and bind DB2 packages.
Password	Gets or sets the password used to connect to the database.
PCCodepage	Gets or sets the code page to be used on the local machine.
State	Gets the status of the **MsDb2Connection**.
UnitsOfWork	Gets or sets the type of transaction supported by the provider.
UserName	Gets or sets the name of the user connecting to the database.

Public Methods

BeginTransaction	Overloaded. Begins a transaction context using the wanted **IsolationLevel**.
ChangeDatabase	Enables users to change the database that the connection is accessing.
Close	Closes the connection with the remote host.
CreateCommand	Creates a new command that can be executed.
Dispose	Releases the resources used by the **Component**.
Equals (inherited from **System.Object**)	Determines if two **Objects** are equal.
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
Open	Opens the connection with the remote host.
ToString (inherited from **System.Object**)	Returns a **String** that represents the current **Object**.

Protected Methods

Finalize	Overridden. Allows an **Object** to attempt to free resources and perform other cleanup operations before the **Object** is reclaimed by garbage collection. In Microsoft® Visual C#® and Visual C++®, finalizers are expressed using destructor syntax.
MemberwiseClone (inherited from **System.Object**)	Creates a shallow copy of the current **Object**.

MsDb2Connection Constructor

Initializes a new instance of the **MsDb2Connection** class.

Overload List

[Visual Basic] Public Sub New()

[C#] public MsDb2Connection();

[C++] public: MsDb2Connection();

[JScript] public function MsDb2Connection();

[Visual Basic] Public Sub New(System.String)

[C#] public MsDb2Connection(System.String);

[C++] public: MsDb2Connection(System.String);

[JScript] public function MsDb2Connection(System.String);

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Connection Constructor ()

Initializes a new instance of the MsDb2Connection class.

VB

```
Public Sub New()
[C#]
public MsDb2Connection();
[C++]
public: MsDb2Connection();
[JScript]
public function MsDb2Connection();
```

Remarks

The default constructor initializes any fields to their default values. The following table describes the default values for a new instance of **MsDb2Connection**.

Properties	Initial Values
ConnectionString	Empty string ("")
Database	Empty string ("")
DataSource	Empty string ("")

You can change the value for these properties only by using ConnectionString.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection Constructor (System.String)

Initializes a new instance of the MsDb2Connection class using the specified connection string.

VB

```
Public Sub New( _
   ByVal connectionString As String _
)
[C#]
public MsDb2Connection(
   string connectionString
);
[C++]
public: MsDb2Connection(
   String* connectionString
);
[JScript]
public function MsDb2Connection(
   connectionString : String
);
```

Parameters

connectionString
The connection string that provides the parameters for the connection.

Exceptions

Exception Type	Condition
InvalidPropertyValue	The connection string is invalid.

Remarks

The default constructor initializes any fields to their default values. The following table describes the default values for a new instance of **MsDb2Connection**.

Properties	Initial Values
ConnectionString	*connectionString*
Database	Empty string ("")
DataSource	Empty string ("")

You can change the value for these properties only by using ConnectionString.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2Connection Properties

This section lists the properties of the **MsDb2Connection** class. For a complete list of **MsDb2Connection** class members, see MsDb2Connection Members.

Public Properties

BinaryAsCharacter	Gets or sets a value that determines if the provider treats binary data type fields (with a character code set identifier (CCSID) of 65535) as character data type fields on a per-data source basis.
ConnectionPooling	Gets or sets a value that determines if the application connects to the server using a traditional connection or a connection pool.
ConnectionString	Gets or sets the connection string to connect to the data source.
Database	Gets or sets the name of the database to which **MsDb2Connection** connects.
DBMSPlatform	Gets or sets the target DB2 platform for which the Managed Provider is optimized.
DefaultSchema	Gets or sets the default database schema used.
HostCCSID	Gets or sets the character code set identifier (CCSID) that must match the data in the file as represented on the remote host computer.
NetworkProperties	Gets or sets network-specific connection properties.
PackageCollection	Gets or sets the name of the DRDA target collection (AS/400 library) where the provider should store and bind DB2 packages.
Password	Gets or sets the password used to connect to the database.
PCCodepage	Gets or sets the code page to be used on the local computer.
State	Gets the status of the **MsDb2Connection**.
UnitsOfWork	Gets or sets the type of transaction supported by the provider.
UserName	Gets or sets the name of the user connecting to the database.

See Also

MsDb2Connection Class | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Connection.BinaryAsCharacter Property

Gets or sets a value that determines if the provider treats binary data type fields (with a character code set identifier (CCSID) of 65535) as character data type fields on a per-data source basis.

VB

```
Public Property BinaryAsCharacter As Boolean
[C#]
public bool BinaryAsCharacter {get; set;}
[C++]
public: __property bool get_BinaryAsCharacter();
public: __property void set_BinaryAsCharacter(bool);
[JScript]
public function get BinaryAsCharacter() : Boolean;
public function set BinaryAsCharacter(Boolean);
```

Value

true to treat binary data type fields as character data on a per-data source basis; otherwise, **false**. The default value is **false**.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.ConnectionPooling Property

Gets or sets a value that determines if the application connects to the server using a traditional connection or a connection pool.

C#

```
public bool ConnectionPool {get; set;}
[C++]
public: __property bool get_ConnectionPool();
public: __property void set_ConnectionPool(bool);
[JScript]
public function get ConnectionPool() : Boolean;
public function set ConnectionPool(Boolean);
```

Value

true to connect to the DB2 server using a connection pool; otherwise, **false**. The default value is **false**.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.ConnectionString Property

Gets or sets the connection string to connect to the data source.

VB

```
Public Overridable Property ConnectionString As String  Implements _
   _
   IDbConnection.ConnectionString
[C#]
public virtual string ConnectionString {get; set;}
[C++]
public: __property virtual String* get_ConnectionString();
public: __property virtual void set_ConnectionString(String*);
[JScript]
public function get ConnectionString() : String;
public function set ConnectionString(String);
```

Value

The connection string to connect to the data source.

Remarks

The format of the connection string follows the attribute=value pair listing similar to Open Database Connectivity (ODBC) and OLE DB connection strings. The connection string is parsed in the managed environment so that the proper fields can be extracted for a uniform call to the distributed relational database architecture (DRDA AR). The default value is an empty string.

Exceptions

Exception type	Condition
InvalidPropertyException	A property name/value pair is invalid.
InvalidConnectionPropertySet	User tried to set the value while the connection was not closed.

Implements

IDbConnection.ConnectionString

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.Database Property

Gets or sets the name of the database to which **MsDb2Connection** connects.

VB

```
Public Overridable Property Database As String  Implements _
   IDbConnection.Database
[C#]
public virtual string Database {get; set;}
[C++]
public: __property virtual String* get_Database();
public: __property void set_Database(String*);
[JScript]
public function get Database() : String;
public function set Database(String);
```

Implements

IDbConnection.Database

Value

The name of the database to which **MsDb2Connection** connects. The default value is an empty string.

Remarks

Database is set in the connection string.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.DBMSPlatform Property

Gets or sets the target DB2 platform for which the Managed Provider is optimized.

VB

```
Public Property DBMSPlatform As DBMSPlatform
[C#]
public DBMSPlatform DBMSPlatform {get; set;}
[C++]
public: __property DBMSPlatform get_DBMSPlatform();
public: __property void set_DBMSPlatform(DBMSPlatform);
[JScript]
public function get DBMSPlatform() : DBMSPlatform;
public function set DBMSPlatform(DBMSPlatform);
```

Value

The DB2 platform the Managed Provider is optimized for.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.DefaultSchema Property

Gets or sets the default database schema to be used.

VB

```
Public Property DefaultSchema As String
[C#]
public string DefaultSchema {get; set;}
[C++]
public: __property String* get_DefaultSchema();
public: __property void set_DefaultSchema(String*);
[JScript]
public function get DefaultSchema() : String;
public function set DefaultSchema(String);
```

Value

The default database schema to use.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection.HostCCSID Property

Gets or sets the character code set identifier (CCSID) that must match the data in the file as represented on the remote host computer.

VB

```
Public Property HostCCSID As Integer
[C#]
public int HostCCSID {get; set;}
[C++]
public: __property int get_HostCCSID();
public: __property void set_HostCCSID(int);
[JScript]
public function get HostCCSID() : int;
public function set HostCCSID(int);
```

Value

The character code set identifier (CCSID) that must match the data in the file as represented on the remote host computer.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Connection.NetworkProperties Property

Gets or sets network-specific connection properties.

VB

```
Public Property NetworkProperties As MsDb2NetworkProperties
[C#]
public MsDb2NetworkProperties NetworkProperties {get; set;}
[C++]
public: __property MsDb2NetworkProperties* get_NetworkProperties();
public: __property void set_NetworkProperties(MsDb2NetworkProperties*);
[JScript]
public function get NetworkProperties() : MsDb2NetworkProperties;
public function set NetworkProperties(MsDb2NetworkProperties);
```

Value

MsDb2NetworkProperties containing the network properties of the connection.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.PackageCollection Property

Gets or sets the name of the DRDA target collection (AS/400 library) where the Managed Provider should store and bind DB2 packages.

VB

```
Public Property PackageCollection As String
[C#]
public string PackageCollection {get; set;}
[C++]
public: __property String* get_PackageCollection();
public: __property void set_PackageCollection(String*);
[JScript]
public function get PackageCollection() : String;
public function set PackageCollection(String);
```

Value

The name of the DRDA target collection.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection.Password Property

Gets or sets the password used to connect to the database.

VB

```
Public Property Password As String
[C#]
public string Password {get; set;}
[C++]
public: __property String* get_Password();
public: __property void set_Password(String*);
[JScript]
public function get Password() : String;
public function set Password(String);
```

Value

The password used to connect to the database.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection.PCCodepage Property

Gets or sets the code page to be used on the local computer.

VB

```
Public Property PCCodepage As Integer
[C#]
public int PCCodepage {get; set;}
[C++]
public: __property int get_PCCodepage();
public: __property void set_PCCodepage(int);
[JScript]
public function get PCCodepage() : int;
public function set PCCodepage(int);
```

Value

The code page for the local computer.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2Connection.State Property

Gets the status of the **MsDb2Connection**.

VB

```
Public Overridable ReadOnly Property State As ConnectionState  _
   Implements IDbConnection.State
[C#]
public virtual ConnectionState State {get;}
[C++]
public: __property virtual ConnectionState get_State();
[JScript]
public function get State() : ConnectionState;
```

Implements

IDbConnection.State

Value

The duration in seconds to wait before the connection times out.

Remarks

State is set in the connection string.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection.UnitsOfWork Property

Gets or sets the type of transaction supported by the Managed Provider.

VB

```
Public Property UnitsOfWork As UnitsOfWorkType
[C#]
public UnitsOfWorkType UnitsOfWork {get; set;}
[C++]
public: __property UnitsOfWorkType get_UnitsOfWork();
public: __property void set_UnitsOfWork(UnitsOfWorkType);
[JScript]
public function get UnitsOfWork() : UnitsOfWorkType;
public function set UnitsOfWork(UnitsOfWorkType);
```

Value

UnitsOfWorkType containing the units of work.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.UserName Property

Gets or sets the name of the user connecting to the database.

VB

```
Public Property UserName As String
[C#]
public string UserName {get; set;}
[C++]
public: __property String* get_UserName();
public: __property void set_UserName(String*);
[JScript]
public function get UserName() : String;
public function set UserName(String);
```

Value

The user name.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2Connection Methods

This section lists the methods of the **MsDb2Connection** class. For a complete list of **MsDb2Connection** class members, see MsDb2Connection Members.

Public Methods

BeginTransaction	Overloaded. Begins a transaction context using the wanted **IsolationLevel**.
ChangeDatabase	Enables users to change the database that the connection is accessing.
Close	Closes the connection with the remote host.
CreateCommand	Creates a new command that can be executed.
Dispose	Releases the resources used by the **Component**.
Equals (inherited from **System.Object**)	Determines if two **Objects** are equal.
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
Open	Opens the connection with the remote host.
ToString (inherited from **System.Object**)	Returns a **String** that represents the current **Object**.

Protected Methods

Finalize	Overridden. Enables an **Object** to attempt to free resources and perform other cleanup operations before the **Object** is reclaimed by garbage collection. In Microsoft® Visual C#® and Visual C++®, finalizers are expressed using destructor syntax.
MemberwiseClone (inherited from **System.Object**)	Creates a shallow copy of the current **Object**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.BeginTransaction Method

Begins a transaction context using the wanted **IsolationLevel**.

Overload List

[Visual Basic] Overloads Public Function BeginTransaction() As MsDb2Transaction

[C#] public MsDb2Transaction BeginTransaction();

[C++] public: MsDb2Transaction* BeginTransaction();

[JScript] public function BeginTransaction() : MsDb2Transaction;

[Visual Basic] Overloads Public Function BeginTransaction(System.Data.IsolationLevel) As MsDb2Transaction

[C#] public MsDb2Transaction BeginTransaction(System.Data.IsolationLevel);

[C++] public: MsDb2Transaction* BeginTransaction(System.Data.IsolationLevel);

[JScript] public function BeginTransaction(System.Data.IsolationLevel) : MsDb2Transaction;

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Connection.BeginTransaction Method ()

Begins a transaction context using the default isolation level.

VB

```
Overloads Public Function BeginTransaction() As MsDb2Transaction
[C#]
public MsDb2Transaction BeginTransaction();
[C++]
public: MsDb2Transaction* BeginTransaction();
[JScript]
public function BeginTransaction() : MsDb2Transaction;
```

Exceptions

Exception Type	Condition
OpenConnectionRequired	Connection is not yet open.
ParallelTransactionNotSupport	Attempt to begin two transactions at once.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide | MsDb2Connection.BeginTransaction Overload List

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.BeginTransaction Method (System.Data.IsolationLevel)

Begins a transaction context using the specified isolation level.

VB

```
Overloads Public Function BeginTransaction( _
   ByVal level As IsolationLevel _
) As MsDb2Transaction
[C#]
public MsDb2Transaction BeginTransaction(
   IsolationLevel level
);
[C++]
public: MsDb2Transaction* BeginTransaction(
   IsolationLevel level
);
[JScript]
public function BeginTransaction(
   level : IsolationLevel
) : MsDb2Transaction;
```

Return Value

IsolationLevel describing the current isolation level.

Exceptions

Exception Type	Condition
OpenConnectionRequired	Connection is not yet open.
InvalidIsolationLevel	The isolation level is invalid. Some levels are invalid because there is no .NET to Distributed Data Management (DDM) conversion, and some because some isolation levels are not permitted on certain platforms. Isolation Level UR is forbidden on OS/390.

Remarks

The following table describes the possible values for *IsolationLevel* and the associated DRDA AR values and **ConnectionAttribute** values.

.NET Isolation level	DRDA AR Value	ConnectionAttribute
Chaos	n/a	n/a
ReadCommitted	IsolationCS	SQL_TXN_READ_COMMITED
ReadUncommitted	IsolationCHG	SQL_TXN_READ_UNCOMMITED
RepeatableRead	IsolationALL	SQL_TXN_REPEATABLE_READ
Serializable	IsolationRR	SQL_TXN_SERIALIZABLE
Unspecified	n/a	n/a
n/a	IsolationNC	n/a Must be AS/400 + AutoCommit = TRUE to get this.

Parameters

level
The wanted **IsolationLevel**.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide | MsDb2Connection.BeginTransaction Overload List

MsDb2Connection.ChangeDatabase Method

Enables users to change the database that the connection is accessing using the specified database name.

VB

```
Public Overridable Sub ChangeDatabase( _
   ByVal dbName As String _
) Implements IDbConnection.ChangeDatabase
[C#]
public virtual void ChangeDatabase(
   string dbName
);
[C++]
public: virtual void ChangeDatabase(
   String* dbName
);
[JScript]
public function ChangeDatabase(
   dbName : String
);
```

Parameters

dbName
The new database name to which to connect.

Implements

IDbConnection.ChangeDatabase

Exceptions

Exception Type	Condition
OpenConnectionRequired	The connection is not open.
InvalidPropertyValue	The **dbName** is null or empty.

Remarks

Using **ChageDatabase** requires all open **MsDb2Commands**, **MsDb2DataAdapters**, and **MsDb2DataReaders** be closed or declared invalid.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.Close Method

Closes the connection with the remote host.

VB

```
Public Overridable Sub Close() Implements IDbConnection.Close
[C#]
public virtual void Close();
[C++]
public: virtual void Close();
[JScript]
public function Close();
```

Implements

IDbConnection.Close

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.CreateCommand Method

Creates a new command that can be executed.

VB

```
Public Function CreateCommand() As MsDb2Command
[C#]
public MsDb2Command CreateCommand();
[C++]
public: MsDb2Command* CreateCommand();
[JScript]
public function CreateCommand() : MsDb2Command;
```

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2Connection Class | MsDb2Connection Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Connection.Dispose Method

Releases the resources used by the **Component**.

VB

```
Public Overridable Sub Dispose() Implements IDisposable.Dispose
[C#]
public virtual void Dispose();
[C++]
public: virtual void Dispose();
[JScript]
public function Dispose();
```

Implements

IDisposable.Dispose

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2Connection.Finalize Method

Enables an **Object** to attempt to free resources and perform other cleanup operations before the **Object** is reclaimed by the garbage collection.

[C#] In C#, finalizers are expressed using destructor syntax.

[C++] In C++, finalizers are expressed using destructor syntax.

VB

```
Overrides Protected Sub Finalize()
[C#]
~MsDb2Connection();
[C++]
~MsDb2Connection();
[JScript]
protected override function Finalize();
```

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2Connection.Open Method

Opens the connection with the remote host.

VB

```
Public Overridable Sub Open() Implements IDbConnection.Open
[C#]
public virtual void Open();
[C++]
public: virtual void Open();
[JScript]
public function Open();
```

Implements

IDbConnection.Open

Exceptions

Exception Type	Condition
NoConnectionString	No connection string.
ConnectionAlreadyOpen	Connection is already in the open state.
HostNotAvailableException	The host is not available.
InvalidPropertyException	One or more of the properties in the connection was invalid.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2DataAdapter Class

Acts as the gateway between a DB2 host table and a .NET-based data set.

For a list of all members of this type, see MsDb2DataAdapter Members.

System.Object
  System.MarshalByRefObject
    System.ComponentModel.Component
      System.Data.Common.DataAdapter
        System.Data.Common.DbDataAdapter
          Microsoft.HostIntegration.MsDb2Client.MsDb2DataAdapter

VB

```
Public Class MsDb2DataAdapter
   Inherits DbDataAdapter
   Implements IDbDataAdapter
[C#]
public class MsDb2DataAdapter : DbDataAdapter, IDbDataAdapter
[C++]
public __gc class MsDb2DataAdapter : public DbDataAdapter,
   IDbDataAdapter
[JScript]
public class MsDb2DataAdapter extends DbDataAdapter implements
   IDbDataAdapter
```

Thread Safety

Any public static (**Shared** in Microsoft® Visual Basic®) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

The **MsDb2DataAdapter** serves as a bridge between a **DataSet** and data source for retrieving and saving data. The **MsDb2DataAdapter** provides this bridge by using **Fill** to load data from the data source into the **DataSet**, and using **Updat**e to send changes made in the **DataSet** back to the data source.

When the **MsDb2DataAdapter** fills a **DataSet**, it creates the necessary tables and columns for the returned data if they do not already exist. However, primary key information is not included in the implicitly created schema unless the **MissingSchemaAction** property is set to **AddWithKey**. You may also have the **MsDb2DataAdapter** create the schema of the **DataSet**, including primary key information, before filling it with data using **FillSchema**. Note that some OLE DB providers, including the **MSDataShape** provider, do not return base table or primary key information. As a result, the **MsDb2DataAdapter** cannot properly set the **PrimaryKey** property on any created **DataTable**. In such cases you should explicitly specify primary keys for tables in the **DataSet**.

The **MsDb2DataAdapter** also includes the **SelectCommand**, **InsertCommand**, **DeleteCommand**, **UpdateCommand**, and **TableMappings** properties to facilitate the loading and updating of data.

When you create an instance of **MsDb2DataAdapter**, properties are set to their initial values. For a list of these values, see the **MsDb2DataAdapter** constructor.

> **Note** Do not use double or real columns when specifying UPDATE or DELETE statements on the **MsDb2DataAdapter**: These rows will not be found and will throw the concurrency violation exception.

Requirements

Namespace: Microsoft.HostIntegration.MsDb2Client

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Assembly: Microsoft.Hostintegration.Msdb2client (in Microsoft.Hostintegration.Msdb2client.dll)

MsDb2DataAdapter Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataAdapter Members

MsDb2DataAdapter overview

Public Constructors

MsDb2DataAdapter Constructor	Overloaded. Initializes a new instance of the **MsDb2DataAdapter** class.

Public Properties

AcceptChangesDuringFill (inherited from **System.Data.Common.DataAdapter**)	Gets or sets a value indicating whether **AcceptChanges** is called on a **DataRow** after it is added to the **DataTable**.
Container (inherited from **System.ComponentModel.Component**)	Gets the **IContainer** that contains the Component.
ContinueUpdateOnError (inherited from **System.Data.Common.DataAdapter**)	Gets or sets a value that specifies whether to generate an exception, or the row in error when an error is encountered during a row update.
DeleteCommand	Gets or sets an SQL statement or stored procedure for deleting records from the data set.
InsertCommand	Gets or sets an SQL statement or stored procedure used to insert new records into the data source.
MissingMappingAction (inherited from **System.Data.Common.DataAdapter**)	Determines the action to take when incoming data does not have a matching table or column.
MissingSchemaAction (inherited from **System.Data.Common.DataAdapter**)	Determines the action to take when existing **DataSet** schema does not match incoming data.
SelectCommand	Gets or sets an SQL statement or stored procedure used to select records in the data source.
Site (inherited from **System.ComponentModel.Component**)	Gets or sets the **ISite** of the Component.
TableMappings (inherited from **System.Data.Common.DataAdapter**)	Gets a collection that provides the master mapping between a source table and a **DataTable**.
UpdateCommand	Gets or sets an SQL statement or stored procedure used to update records in the data source.

Public Methods

CreateRowUpdatedEvent	Creates a new instance of the MsDb2RowUpdatedEventArgs class.
CreateRowUpdatingEvent	Creates a new instance of the MsDb2RowUpdatingEventArgs class.
CreateObjRef (inherited from **System.MarshalByRefObject**)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose (inherited from **System.ComponentModel.Component**)	Overloaded. Releases the resources used by the **Component**.
Equals (inherited from **System.Object**)	Overloaded. Determines whether two **Object** instances are equal.
Fill (inherited from **System.Data.Common.DbDataAdapter**)	Overloaded. Adds or refreshes rows in the **DataSet** to match those in an ADO **Recordset** or **Record** object.
FillSchema (inherited from **System.Data.Common.DbDataAdapter**)	Overloaded. Overridden. Adds a **DataTable** to a **DataSet** and configures the schema to match that in the data source.
GetFillParameters (inherited from **System.Data.Common.DbDataAdapter**)	Overridden. Gets the parameters set by the user when executing an SQL SELECT statement.
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from **System.MarshalByRefObject**)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
InitializeLifetimeService (inherited from **System.MarshalByRefObject**)	Obtains a lifetime service object to control the lifetime policy for this instance.
OnRowUpdated	Raises the **RowUpdated** event using a **RowUpdatedEventArgs** object.
OnRowUpdating	Raises the **RowUpdating** event using a **RowUpdatingEventArgs**.

ToString (inherited from **System.ComponentModel.Component**)	Returns a String that represents the current **Object**.
Update (inherited from **System.Data.Common.DbDataAdapter**)	Overloaded. Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the **DataSet**.

Public Events

Disposed (inherited from **System.ComponentModel.Component**)	Adds an event handler to listen to the **Disposed** event on the component.
FillError (inherited from **System.Data.Common.DbDataAdapter**)	Returned when an error occurs during a fill operation.
RowUpdated	Occurs during **Update** after a command is executed against the data source. The attempt to update is made, so the event fires.
RowUpdating	Occurs during **Update** before a command is executed against the data source. The attempt to update is made, so the event fires.

MsDb2DataAdapter Constructor

Initializes a new instance of the **MsDb2DataAdapter** class.

Overload List

[Visual Basic] Public Sub New()

[C#] public MsDb2DataAdapter();

[C++] public: MsDb2DataAdapter();

[JScript] public function MsDb2DataAdapter();

[Visual Basic] Public Sub New(MsDb2Command)

[C#] public MsDb2DataAdapter(MsDb2Command);

[C++] public: MsDb2DataAdapter(MsDb2Command*);

[JScript] public function MsDb2DataAdapter(MsDb2Command);

[Visual Basic] Public Sub New(System.String, MsDb2Connection)

[C#] public MsDb2DataAdapter(System.String, MsDb2Connection);

[C++] public: MsDb2DataAdapter(System.String, MsDb2Connection*);

[JScript] public function MsDb2DataAdapter(System.String, MsDb2Connection);

[Visual Basic] Public Sub New(System.String, System.String)

[C#] public MsDb2DataAdapter(System.String, System.String);

[C++] public: MsDb2DataAdapter(System.String, System.String);

[JScript] public function MsDb2DataAdapter(System.String, System.String);

See Also

MsDb2DataAdapter Class | MsDb2DataAdapter Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataAdapter Constructor ()

Initializes a new instance of the MsDb2DataAdapter class.

VB

```
Public Sub New()
[C#]
public MsDb2DataAdapter();
[C++]
public: MsDb2DataAdapter();
[JScript]
public function MsDb2DataAdapter();
```

Remarks

The default constructor initializes any fields to their default values. The following table describes the default values of **MsDb2DataAdapter**.

Properties	Initial Value
MissingMappingAction	**MissingMappingAction.Passthrough**
MissingSchemaAction	**MissingSchemaAction.Add**

You can change the value of any of these properties through a separate call to the relevant property.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataAdapter Class | MsDb2DataAdapter Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide | MsDb2DataAdapter Constructor Overload List

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter Constructor (MsDb2Command)

Initializes a new instance of the MsDb2DataAdapter class.

VB

```
Public Sub New( _
   ByVal selectCommand As MsDb2Command _
)
[C#]
public MsDb2DataAdapter(
   MsDb2Command selectCommand
);
[C++]
public: MsDb2DataAdapter(
   MsDb2Command* selectCommand
);
[JScript]
public function MsDb2DataAdapter(
   selectCommand : MsDb2Command
);
```

Parameters

selectCommand
An **MsDb2Command** that is a SELECT statement or stored procedure. This **MsDb2Command** is set as the **SelectCommand** property of the **MsDb2DataAdapter**.

Remarks

This version of the constructor sets the **SelectCommand** property to the value specified in the *selectCommand* parameter.

The following table describes the default values of **MsDb2DataAdapter**.

Properties	Initial Value
MissingMappingAction	**MissingMappingAction.Passthrough**
MissingSchemaAction	**MissingSchemaAction.Add**

You can change the value of any of these properties through a separate call to the relevant property.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataAdapter Class | MsDb2DataAdapter Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide | MsDb2DataAdapter Constructor Overload List

MsDb2DataAdapter Constructor (System.String, MsDb2Connection)

Initializes a new instance of the MsDb2DataAdapter class.

VB

```
Public Sub New( _
   ByVal selectCommandText As String, _
   ByVal selectConnection As MsDb2Connection _
)
[C#]
public MsDb2DataAdapter(
   string selectCommandText,
   MsDb2Connection selectConnection
);
[C++]
public: MsDb2DataAdapter(
   String* selectCommandText,
   MsDb2Connection* selectConnection
);
[JScript]
public function MsDb2DataAdapter(
   selectCommandText : String,
   selectConnection : MsDb2Connection
);
```

Parameters

selectCommandText
A String that is an SQL SELECT statement or stored procedure to be used as the **CommandText** of the **SelectCommand** property of the **MsDb2DataAdapter**.

selectConnection
An **MsDb2Connection** that represents the connection.

Remarks

This implementation of the **MsDb2DataAdapter** opens and closes an MsDb2Connection if it is not already open. This can be useful in an application that must call the **Fill** method for two or more **MsDb2DataAdapter** objects. If the **MsDb2Connection** is already open, you must explicitly call **Close** or **Dispose** to close it.

The following table describes the default values of **MsDb2DataAdapter**.

Properties	**Initial Value**
MissingMappingAction	**MissingMappingAction.Passthrough**
MissingSchemaAction	**MissingSchemaAction.Add**

You can change the value of any of these properties through a separate call to the relevant property.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter Constructor (System.String, System.String)

Initializes a new instance of the MsDb2DataAdapter class.

VB

```
Public Sub New( _
   ByVal selectCommandText As String, _
   ByVal selectConnectionString As String _
)
[C#]
public MsDb2DataAdapter(
   string selectCommandText,
   string selectConnectionString
);
[C++]
public: MsDb2DataAdapter(
   String* selectCommandText,
   String* selectConnectionString
);
[JScript]
public function MsDb2DataAdapter(
   selectCommandText : String,
   selectConnectionString : String
);
```

Parameters

selectCommandText
A **String** that is a SQL SELECT statement or stored procedure to be used as the **CommandText** of the **SelectCommand** property of the **MsDb2DataAdapter**.
selectConnectionString
The connection string.

Remarks

The following table describes the default values of **MsDb2DataAdapter**.

Properties	Initial Value
MissingMappingAction	**MissingMappingAction.Passthrough**
MissingSchemaAction	**MissingSchemaAction.Add**

You can change the value of any of these properties through a separate call to the relevant property.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2DataAdapter Properties

This section lists the properties of the **MsDb2DataAdapter** class. For a complete list of **MsDb2DataAdapter** class members, see MsDb2DataAdapter Members.

Public Properties

AcceptChangesDuringFill (inherited from **System.Data.Common.DataAdapter**)	Gets or sets a value indicating whether **AcceptChanges** is called on a **DataRow** after it is added to the **DataTable**.
Container (inherited from **System.ComponentModel.Component**)	Gets the **IContainer** that contains the **Component**.
ContinueUpdateOnError (inherited from **System.Data.Common.DataAdapter**)	Gets or sets a value that specifies whether to generate an exception, or the row in error when an error is encountered during a row update.
DeleteCommand	Gets or sets an SQL statement or stored procedure for deleting records from the data set.
InsertCommand	Gets or sets an SQL statement or stored procedure used to insert new records into the data source.
MissingMappingAction (inherited from **System.Data.Common.DataAdapter**)	Determines the action to take when incoming data does not have a matching table or column.
MissingSchemaAction (inherited from **System.Data.Common.DataAdapter**)	Determines the action to take when existing **DataSet** schema does not match incoming data.
SelectCommand	Gets or sets an SQL statement or stored procedure used to select records in the data source.
Site (inherited from **System.ComponentModel.Component**)	Gets or sets the **ISite** of the **Component**.
TableMappings (inherited from **System.Data.Common.DataAdapter**)	Gets a collection that provides the master mapping between a source table and a **DataTable**.
UpdateCommand	Gets or sets an SQL statement or stored procedure used to update records in the data source.

MsDb2DataAdapter Class | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter.DeleteCommand Property

Gets or sets an SQL statement or stored procedure for deleting records from the data set.

VB

```
Public Shadows Property DeleteCommand As MsDb2Command
[C#]
public new MsDb2Command DeleteCommand {get; set;}
[C++]
public: __property MsDb2Command* get_DeleteCommand();
public: __property void set_DeleteCommand(MsDb2Command*);
[JScript]
public hide function get DeleteCommand() : MsDb2Command;
public function set DeleteCommand(MsDb2Command);
```

Property Value

An **MsDb2Command** used during **Update** to delete records in the data source that correspond to deleted rows in the **DataSet**.

Remarks

During **Update**, if this property is not set and primary key information is present in the **DataSet**, the **DeleteCommand** can be generated automatically if you set the **SelectCommand** property and use the **MsDb2CommandBuilder**. Then, any additional commands that you do not set are generated by the **MsDb2CommandBuilder**. This generation logic requires key column information to be present in the **DataSet**.

When **DeleteCommand** is assigned to a previously created **MsDb2Command**, the **MsDb2Command** is not cloned. The **DeleteCommand** maintains a reference to the previously created **MsDb2Command** object.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter.InsertCommand Property

Gets or sets an SQL statement or stored procedure used to insert new records into the data source.

VB

```
Public Shadows Property InsertCommand As MsDb2Command
[C#]
public new MsDb2Command InsertCommand {get; set;}
[C++]
public: __property MsDb2Command* get_InsertCommand();
public: __property void set_InsertCommand(MsDb2Command*);
[JScript]
public hide function get InsertCommand() : MsDb2Command;
public function set InsertCommand(MsDb2Command);
```

Property Value

An **MsDb2Command** used during **Update** to insert records in the data source that correspond to new rows in the **DataSet**.

Remarks

During **Update**, if this property is not set and primary key information is present in the **DataSet**, the **InsertCommand** can be generated automatically if you set the **SelectCommand** property and use the **MsDb2CommandBuilder**. Then, any additional commands that you do not set are generated by the **MsDb2CommandBuilder**. This generation logic requires key column information to be present in the **DataSet**.

When **InsertCommand** is assigned to a previously created MsDb2Command, the **MsDb2Command** is not cloned. The **InsertCommand** maintains a reference to the previously created **MsDb2Command** object.

If execution of this command returns rows, these rows may be added to the **DataSet** depending on how you set the **UpdatedRowSource** property of the **MsDb2Command** object.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter.SelectCommand Property

Gets or sets an SQL statement or stored procedure used to select records in the data source. .

VB

```
Public Shadows Property SelectCommand As MsDb2Command
[C#]
public new MsDb2Command SelectCommand {get; set;}
[C++]
public: __property MsDb2Command* get_SelectCommand();
public: __property void set_SelectCommand(MsDb2Command*);
[JScript]
public hide function get SelectCommand() : MsDb2Command;
public function set SelectCommand(MsDb2Command);
```

Property Value

An **MsDb2Command** that is used during **Fill** to select records from data source for placement in the **DataSet**.

Remarks

When **SelectCommand** is assigned to a previously created **MsDb2Command**, the **MsDb2Command** is not cloned. The **SelectCommand** maintains a reference to the previously created **MsDb2Command** object.

If the **SelectCommand** does not return any rows, no tables are added to the **DataSet**, and no exception is raised.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter.UpdateCommand Property

Gets or sets an SQL statement or stored procedure used to update records in the data source.

VB

```
Public Shadows Property UpdateCommand As MsDb2Command
[C#]
public new MsDb2Command UpdateCommand {get; set;}
[C++]
public: __property MsDb2Command* get_UpdateCommand();
public: __property void set_UpdateCommand(MsDb2Command*);
[JScript]
public hide function get UpdateCommand() : MsDb2Command;
public function set UpdateCommand(MsDb2Command);
```

Property Value

An **MsDb2Command** used during **Update** to update records in the data source that correspond to modified rows in the **DataSet**.

Remarks

During **Update**, if this property is not set and primary key information is present in the **DataSet**, the **UpdateCommand** can be generated automatically if you set the **SelectCommand** property and use the **MsDb2CommandBuilder**. Then, any additional commands that you do not set are generated by the **MsDb2CommandBuilder**. This generation logic requires key column information to be present in the **DataSet**.

When **UpdateCommand** is assigned to a previously created **MsDb2Command**, the **MsDb2Command** is not cloned. The **UpdateCommand** maintains a reference to the previously created **MsDb2Command** object.

If execution of this command returns rows, these rows may be merged with the **DataSet** depending on how you set the **UpdatedRowSource** property of the **MsDb2Command** object.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2DataAdapter Methods

This section lists the methods of the **MsDb2DataAdapter** class. For a complete list of **MsDb2DataAdapter** class members, see MsDb2DataAdapter Members.

Public Methods

CreateRowUpdatedEvent	Creates a new instance of the MsDb2RowUpdatedEventArgs class.
CreateRowUpdatingEvent	Creates a new instance of the MsDb2RowUpdatingEventArgs class.
CreateObjRef (inherited from **System.MarshalByRefObject**)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose (inherited from **System.ComponentModel.Component**)	Overloaded. Releases the resources used by the **Component**.
Equals (inherited from **System.Object**)	Overloaded. Determines whether two **Object** instances are equal.
Fill (inherited from **System.Data.Common.DbDataAdapter**)	Overloaded. Adds or refreshes rows in the **DataSet** to match those in an ADO **Recordset** or **Record** object.
FillSchema (inherited from **System.Data.Common.DbDataAdapter**)	Overloaded. Overridden. Adds a **DataTable** to a **DataSet** and configures the schema to match that in the data source.
GetFillParameters (inherited from **System.Data.Common.DbDataAdapter**)	Overridden. Gets the parameters set by the user when executing an SQL SELECT statement.
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from **System.MarshalByRefObject**)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
InitializeLifetimeService (inherited from **System.MarshalByRefObject**)	Obtains a lifetime service object to control the lifetime policy for this instance.
OnRowUpdated	Raises the **RowUpdated** event using a **RowUpdatedEventArgs** object.
OnRowUpdating	Raises the **RowUpdating** event using a **RowUpdatingEventArgs**.
ToString (inherited from **System.ComponentModel.Component**)	Returns a String that represents the current **Object**.
Update (inherited from **System.Data.Common.DbDataAdapter**)	Overloaded. Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the **DataSet**.

MsDb2DataAdapter Class | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataAdapter.CreateRowUpdatedEvent Method

Creates a new instance of the MsDb2RowUpdatedEventArgs class.

This member overrides **DbDataAdapter.CreateRowUpdatedEvent**.

VB

```
Overrides Protected Function CreateRowUpdatedEvent( _
   ByVal dataRow As DataRow, _
   ByVal command As IDbCommand, _
   ByVal statementType As StatementType, _
   ByVal tableMapping As DataTableMapping _
) As RowUpdatedEventArgs
[C#]
protected override RowUpdatedEventArgs CreateRowUpdatedEvent(
   DataRow dataRow,
   IDbCommand command,
   StatementType statementType,
   DataTableMapping tableMapping
);
[C++]
protected: RowUpdatedEventArgs* CreateRowUpdatedEvent(
   DataRow* dataRow,
   IDbCommand* command,
   StatementType statementType,
   DataTableMapping* tableMapping
);
[JScript]
protected override function CreateRowUpdatedEvent(
   dataRow : DataRow,
   command : IDbCommand,
   statementType : StatementType,
   tableMapping : DataTableMapping
) : RowUpdatedEventArgs;
```

Parameters

dataRow
The **DataRow** used to update the data source.
command
The command executed during the **Update**.
statementType
Whether the command is an UPDATE, INSERT, DELETE, or SELECT statement.
tableMapping
A **DataTAbleMapping** object.

Return Value

A new instance of the MsDb2RowUpdatedEventArgs class.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataAdapter Class | MsDb2DataAdapter Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter.CreateRowUpdatingEvent Method

Creates a new instance of the MsDb2RowUpdatingEventArgs class.

This member overrides **DbDataAdapter.CreateRowUpdatingEvent**.

VB

```
Overrides Protected Function CreateRowUpdatingEvent( _
   ByVal dataRow As DataRow, _
   ByVal command As IDbCommand, _
   ByVal statementType As StatementType, _
   ByVal tableMapping As DataTableMapping _
) As RowUpdatingEventArgs
[C#]
protected override RowUpdatingEventArgs CreateRowUpdatingEvent(
   DataRow dataRow,
   IDbCommand command,
   StatementType statementType,
   DataTableMapping tableMapping
);
[C++]
protected: RowUpdatingEventArgs* CreateRowUpdatingEvent(
   DataRow* dataRow,
   IDbCommand* command,
   StatementType statementType,
   DataTableMapping* tableMapping
);
[JScript]
protected override function CreateRowUpdatingEvent(
   dataRow : DataRow,
   command : IDbCommand,
   statementType : StatementType,
   tableMapping : DataTableMapping
) : RowUpdatingEventArgs;
```

Parameters

dataRow
The **DataRow** that updates the data source.
command
The command to execute during the **Update**.
statementType
Whether the command is an UPDATE, INSERT, DELETE, or SELECT statement.
tableMapping
A **DataTableMapping** object.

Return Value

Creates a new instance of the MsDb2RowUpdatingEventArgs class.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter.OnRowUpdated Method

Raises the **RowUpdated** event using a **RowUpdatedEventArgs** object.

VB

```
Overrides Protected Sub OnRowUpdated( _
   ByVal value As RowUpdatedEventArgs _
)
[C#]
protected override void OnRowUpdated(
   RowUpdatedEventArgs value
);
[C++]
protected: void OnRowUpdated(
   RowUpdatedEventArgs* value
);
[JScript]
protected override function OnRowUpdated(
   value : RowUpdatedEventArgs
);
```

Parameters

value
A **RowUpdatedEventArgs** that contains the event data.

Remarks

Raising an event invokes the event handler through a delegate.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataAdapter Class | MsDb2DataAdapter Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter.OnRowUpdating Method

Raises the **RowUpdating** event using a **RowUpdatingEventArgs**.

VB

```
Overrides Protected Sub OnRowUpdating( _
   ByVal value As RowUpdatingEventArgs _
)
[C#]
protected override void OnRowUpdating(
   RowUpdatingEventArgs value
);
[C++]
protected: void OnRowUpdating(
   RowUpdatingEventArgs* value
);
[JScript]
protected override function OnRowUpdating(
   value : RowUpdatingEventArgs
);
```

Parameters

value
A **RowUpdatingEventArgs** that contains the event data.

Remarks

Raising an event invokes the event handler through a delegate.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataAdapter Class | MsDb2DataAdapter Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataAdapter Events

This section lists the events of the **MsDb2DataAdapter** class. For a complete list of **MsDb2DataAdapter** class members, see MsDb2DataAdapter Members.

Public Events

⚡Disposed (inherited from **System.ComponentModel.Component**)	Adds an event handler to listen to the **Disposed** event on the component.
⚡FillError (inherited from **System.Data.Common.DbDataAdapter**)	Occurs when an error occurs during a fill operation.
⚡RowUpdated	Occurs during **Update** after a command is executed against the data source. The attempt to update is made, so the event fires.
⚡RowUpdating	Occurs during **Update** before a command is executed against the data source. The attempt to update is made, so the event fires.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataAdapter.RowUpdated Event

Occurs during **Update** after a command is executed against the data source. The attempt to update is made, so the event fires.

VB

```
Public Event RowUpdated As MsDb2RowUpdatedEventHandler
[C#]
public event MsDb2RowUpdatedEventHandler RowUpdated;
[C++]
public: __event MsDb2RowUpdatedEventHandler* RowUpdated;
```

[JScript] In JScript, you can handle the events defined by a class, but you cannot define your own.

Event Data

The event handler receives an argument of type MsDb2RowUpdatedEventArgs containing data related to this event. The following **MsDb2RowUpdatedEventArgs** properties provide information specific to this event.

Property	Description
Command	Gets the MsDb2Command executed when Update is called.
Errors (inherited from **System.Data.Common.RowUpdatedEventArgs**)	Gets any errors generated by the .NET data provider when the **Command** was executed.
RecordsAffected (inherited from **System.Data.Common.RowUpdatedEventArgs**)	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row (inherited from **System.Data.Common.RowUpdatedEventArgs**)	Gets the **DataRow** sent through an **Update**.
StatementType (inherited from **System.Data.Common.RowUpdatedEventArgs**)	Gets the type of SQL statement executed.
Status (inherited from **System.Data.Common.RowUpdatedEventArgs**)	Gets the **UpdateStatus** of the **Command**.
TableMapping (inherited from **System.Data.Common.RowUpdatedEventArgs**)	Gets the **DataTableMapping** sent through an **Update**.

Remarks

When using **Update**, there are two events that occur per data row updated. The order of execution is as follows:

1. The values in the **DataRow** are moved to the parameter values.
2. The **OnRowUpdating** event is raised.
3. The command executes.
4. If the command is set to **FirstReturnedRecord**, then the first returned result is placed in the **DataRow**.
5. If there are output parameters, they are placed in the **DataRow**.
6. The **OnRowUpdated** event is raised.
7. **AcceptChanges** is called.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataAdapter Class | MsDb2DataAdapter Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataAdapter.RowUpdating Event

Occurs during **Update** before a command is executed against the data source. The attempt to update is made, so the event fires.

VB

```
Public Event RowUpdating As MsDb2RowUpdatingEventHandler
[C#]
public event MsDb2RowUpdatingEventHandler RowUpdating;
[C++]
public: __event MsDb2RowUpdatingEventHandler* RowUpdating;
```

[JScript] In JScript, you can handle the events defined by a class, but you cannot define your own.

Event Data

The event handler receives an argument of type MsDb2RowUpdatingEventArgs containing data related to this event. The following **MsDb2RowUpdatingEventArgs** properties provide information specific to this event.

Property	**Description**
Command	Gets or sets the **MsDb2Command** to execute when performing the Update.
Errors (inherited from **System.Data.Common.RowUpdatingEventArgs**)	Gets any errors generated by the .NET data provider when the **Command** executes.
Row (inherited from **System.Data.Common.RowUpdatingEventArgs**)	Gets the **DataRow** to send through an **Update**.
StatementType (inherited from **System.Data.Common.RowUpdatingEventArgs**)	Gets the type of SQL statement to execute.
Status (inherited from **System.Data.Common.RowUpdatingEventArgs**)	Gets the **UpdateStatus** of the **Command**.
TableMapping (inherited from **System.Data.Common.RowUpdatingEventArgs**)	Gets the **DataTableMapping** to send through the **Update**.

Remarks

When using **Update**, there are two events that occur per data row updated. The order of execution is as follows:

1. The values in the **DataRow** are moved to the parameter values.
2. The **OnRowUpdating** event is raised.
3. The command executes.
4. If the command is set to **FirstReturnedRecord**, then the first returned result is placed in the **DataRow**.
5. If there are output parameters, they are placed in the **DataRow**.
6. The **OnRowUpdated** event is raised.
7. **AcceptChanges** is called.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataAdapter Class | MsDb2DataAdapter Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader Class

Describes a server-side forward-only cursor implementation that inherits from the **IDataReader** and **IDataRecord** interfaces.

For a list of all members of this type, see MsDb2DataReader Members.

System.Object
  Microsoft.HostIntegration.MsDb2Client.MsDb2DataReader

VB

```
Public Class MsDb2DataReader
   Implements IDataReader, IDisposable, IDataRecord
[C#]
public class MsDb2DataReader : IDataReader, IDisposable,
   IDataRecord
[C++]
public __gc class MsDb2DataReader : public IDataReader,
   IDisposable, IDataRecord
[JScript]
public class MsDb2DataReader implements IDataReader, IDisposable,
   IDataRecord
```

Thread Safety

Any public static (**Shared** in Microsoft® Visual Basic®) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

To create an **MsDb2DataReader**, you must call MsDb2Command.ExecuteReader, rather than directly using a constructor.

Unlike other .NET providers, the Managed Provider for DB2 allows you to open multiple **MsDb2DataReaders** on a single MsDb2Connection.

Changes made to a **ResultSet** by another process or thread while data is being read may be visible to the user of the **MsDb2DataReader**. However, the precise behavior is timing-dependent.

IsClosed and RecordsAffected are the only properties that you can call after the **MsDb2DataReader** is closed. Though the **RecordsAffected** property may be accessed at any time while the **MsDb2DataReader** exists, always call Close before returning the value of **RecordsAffected** to ensure an accurate return value.

Requirements

Namespace: Microsoft.HostIntegration.MsDb2Client

Platforms: Microsoft® Windows Server™ 2003 , Windows® XP Professional, Windows 2000 Server

Assembly: Microsoft.Hostintegration.Msdb2client (in Microsoft.Hostintegration.Msdb2client.dll)

MsDb2DataReader Members

MsDb2DataReader overview

Public Properties

Depth	Gets a value indicating the depth of nesting for the current row.
FieldCount	Gets the number of columns in the current row.
IsClosed	Gets a value that indicates whether the data reader is closed.
Item	Overloaded. Gets the value of a column in its native format. In Microsoft® Visual C#®, this property is the indexer for the **MsDb2DataReader** class.
RecordsAffected	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

Public Methods

Close	Closes the current instance.
Dispose	This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.
Equals (inherited from **System.Object**)	Determines whether two **Object** instances are equal.
GetBoolean	Gets the value of the specified column as a Boolean.
GetByte	Gets the value of the specified column as a byte.
GetBytes	Gets a stream of bytes from the specified column offset into the buffer as an array starting at the given buffer offset.
GetChar	Gets the value of the specified column as a character.
GetChars	Gets a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.
GetData	This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.
GetDataTypeName	Gets the name of the source data type.
GetDateTime	Gets the value of the specified column as a **DateTime** object.
GetDecimal	Gets the value of the specified column as a **Decimal** object.
GetDouble	Gets the value of the specified column as a double-precision floating point number.
GetFieldType	Gets the **Type** that is the data type of the object.
GetFloat	Gets the value of the specified column as a single-precision floating point number.
GetGuid	Gets the value of the specified column as a globally-unique identifier (GUID).
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetInt16	Gets the value of the specified column as a 16-bit signed integer.
GetInt32	Gets the value of the specified column as a 32-bit signed integer.
GetInt64	Gets the value of the specified column as a 64-bit signed integer.
GetName	Gets the name of the specified column.
GetOrdinal	Gets the column ordinal, given the name of the column.
GetSchemaTable	Returns a **DataTable** that describes the column metadata of the **MsDb2DataReader**.
GetString	Gets the value of the specified column as a string.
GetTimeSpan	Gets the value of the specified column as a **TimeSpan** object.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
GetValue	Gets the value of the column at the specified ordinal in its native format.
GetValues	Gets all the attribute columns in the current row.
IsDBNull	Gets a value indicating whether the column contains nonexistent or missing values.
NextResult	Advances the data reader to the next result, when reading the results of batch SQL statements.
Read	Advances the **MsDb2DataReader** to the next record

ToString (inherited from **System.Object**)	Returns a String that represents the current **Object**.

Protected Methods

Finalize (inherited from **System.Object**)	Frees resources before the **MsDb2DataReader** is reclaimed by the Garbage Collector. In Microsoft® Visual C#® and Visual C++®, finalizers are expressed using destructor syntax.
MemberwiseClone (inherited from **System.Object**)	Creates a shallow copy of the current **Object**.

MsDb2DataReader Properties

This section lists the properties of the **MsDb2DataReader** class. For a complete list of **MsDb2DataReader** class members, see MsDb2DataReader Members.

Public Properties

Depth	Gets a value indicating the depth of nesting for the current row.
FieldCount	Gets the number of columns in the current row.
IsClosed	Indicates whether the data reader is closed.
Item	Overloaded. Gets the value of a column in its native format. In Microsoft® Visual C#®, this property is the indexer for the **MsDb2DataReader** class.
RecordsAffected	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

MsDb2DataReader Class | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataReader.Depth Property

Gets a value indicating the depth of nesting for the current row.

VB

```
Public Overridable ReadOnly Property Depth As Integer  Implements _
   IDataReader.Depth
[C#]
public virtual int Depth {get;}
[C++]
public: __property virtual int get_Depth();
[JScript]
public function get Depth() : int;
```

Property Value

The depth of nesting for the current row.

Implements

IDataReader.Depth

Remarks

The outermost table has a length of zero.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.FieldCount Property

Gets the number of columns in the current row.

VB

```
Public Overridable ReadOnly Property FieldCount As Integer  _
   Implements IDataRecord.FieldCount
[C#]
public virtual int FieldCount {get;}
[C++]
public: __property virtual int get_FieldCount();
[JScript]
public function get FieldCount() : int;
```

Property Value

When not positioned in a valid **RecordSet**, 0; otherwise the number of columns in the current record. The default is -1.

Implements

IDataRecord.FieldCount

Remarks

After executing a query that does not return rows, **FieldCount** returns 0.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.IsClosed Property

Gets a value that indicates whether the data reader is closed.

VB

```
Public Overridable ReadOnly Property IsClosed As Boolean  _
   Implements IDataReader.IsClosed
[C#]
public virtual bool IsClosed {get;}
[C++]
public: __property virtual bool get_IsClosed();
[JScript]
public function get IsClosed() : Boolean;
```

Property Value

true if the **MsDb2DbDataReader** is closed; otherwise, **false**.

Implements

IDataReader.IsClosed

Remarks

IsClosed and **RecordsAffected** are the only properties that you can call after the **MsDb2DataReader** is closed.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataReader.Item Property

Gets the value of a column in its native format.

[C#] In C#, this property is the indexer for the **MsDb2DataReader** class.

Overload List

[Visual Basic]
Overloads Public Overridable Default ReadOnly Property Item(System.Int32) As Object Implements IDataRecord.Item

[C#] public virtual object this[System.Int32] {get;}

[C++] public: __property virtual Object* get_Item(System.Int32);

[JScript] MsDb2DataReader.Item (System.Int32)

[Visual Basic]
Overloads Public Overridable Default ReadOnly Property Item(System.String) As Object Implements IDataRecord.Item

[C#] public virtual object this[System.String] {get;}

[C++] public: __property virtual Object* get_Item(System.String);

[JScript] MsDb2DataReader.Item (System.String)

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataReader.Item Property (System.Int32)

Gets the value of the specified column in its native format given the column ordinal.

[C#] In C#, this property is the indexer for the **MsDb2DataReader** class.

VB

```
Overloads Public Overridable Default ReadOnly Property Item( _
   ByVal i As Integer _
) As Object  Implements IDataRecord.Item
[C#]
public virtual object this[
   int i
] {get;}
[C++]
public: __property virtual Object* get_Item(
   int i
);
[JScript]
returnValue = MsDb2DataReaderObject.Item(i);
-or-
returnValue = MsDb2DataReaderObject(i);
```

[JScript] In JScript, you can use the default indexed properties defined by a type, but you cannot explicitly define your own. However, specifying the **expando** attribute on a class automatically provides a default indexed property whose type is **Object** and whose index type is **String**.

Arguments [JScript]

i
  The column ordinal.

Parameters [Visual Basic, C#, C++]

i
  The column ordinal.

Property Value

The value of the specified column in its native format.

Implements

IDataRecord.Item

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide | MsDb2DataReader.Item Overload List

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.Item Property (System.String)

Gets the value of the specified column in its native format given the column name.

[C#] In C#, this property is the indexer for the **MsDb2DataReader** class.

VB

```
Overloads Public Overridable Default ReadOnly Property Item( _
   ByVal name As String _
) As Object  Implements IDataRecord.Item
[C#]
public virtual object this[
   string name
] {get;}
[C++]
public: __property virtual Object* get_Item(
   String* name
);
[JScript]
returnValue = MsDb2DataReaderObject.Item(name);
-or-
returnValue = MsDb2DataReaderObject(name);
```

[JScript] In JScript, you can use the default indexed properties defined by a type, but you cannot explicitly define your own. However, specifying the **expando** attribute on a class automatically provides a default indexed property whose type is **Object** and whose index type is **String**.

Arguments [JScript]

name
The column name.

Parameters [Visual Basic, C#, C++]

name
The column name.

Property Value

The value of the specified column in its native format.

Implements

IDataRecord.Item

Remarks

A case-sensitive lookup is performed first. If it fails, a second case-insensitive search is made.

This method is kana-width insensitive.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide | MsDb2DataReader.Item Overload List

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.RecordsAffected Property

Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

VB

```
Public Overridable ReadOnly Property RecordsAffected As Integer  _
   Implements IDataReader.RecordsAffected
[C#]
public virtual int RecordsAffected {get;}
[C++]
public: __property virtual int get_RecordsAffected();
[JScript]
public function get RecordsAffected() : int;
```

Implements

IDataReader.RecordsAffected

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Methods

This section lists the methods of the **MsDb2DataReader** class. For a complete list of **MsDb2DataReader** class members, see MsDb2DataReader Members.

Public Methods

Close	Closes the **MsDb2DataReader** object.
Dispose	This member supports the .NET Framework infrastructure and is not intended to be used directly from your code
Equals (inherited from **System.Object**)	Determines whether two **Object** instances are equal.
GetBoolean	Gets the value of the specified column as a **Boolean**.
GetByte	Gets the value of the specified column as a byte.
GetBytes	Reads a stream of bytes from the specified column offset into the buffer as an array starting at the given buffer offset.
GetChar	Gets the value of the specified column as a character.
GetChars	Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.
GetData	This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.
GetDataTypeName	Gets the name of the source data type.
GetDateTime	Gets the value of the specified column as a **DateTime** object.
GetDecimal	Gets the value of the specified column as a **Decimal** object.
GetDouble	Gets the value of the specified column as a double-precision floating point number.
GetFieldType	Gets the Type that is the data type of the object.
GetFloat	Gets the value of the specified column as a single-precision floating point number.
GetGuid	Gets the value of the specified column as a globally unique identifier (GUID).
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetInt16	Gets the value of the specified column as a 16-bit signed integer.
GetInt32	Gets the value of the specified column as a 32-bit signed integer.
GetInt64	Gets the value of the specified column as a 64-bit signed integer.
GetName	Gets the name of the specified column.
GetOrdinal	Gets the column ordinal, given the name of the column.
GetSchemaTable	Returns a DataTable that describes the column metadata of the **MsDb2DataReader**.
GetString	Gets the value of the specified column as a string.
GetTimeSpan	Gets the value of the specified column as a **TimeSpan** object.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
GetValue	Gets the value of the column at the specified ordinal in its native format.
GetValues	Gets all the attribute columns in the current row.
IsDBNull	Gets a value indicating whether the column contains nonexistent or missing values.
NextResult	Advances the data reader to the next result, when reading the results of batch SQL statements.
Read	Advances the **MsDb2DataReader** to the next record.
ToString (inherited from **System.Object**)	Returns a **String** that represents the current **Object**.

MsDb2DataReader Class | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataReader.Close Method

Closes the **MsDb2DataReader** object.

VB

```
Public Overridable Sub Close() Implements IDataReader.Close
[C#]
public virtual void Close();
[C++]
public: virtual void Close();
[JScript]
public function Close();
```

Implements

IDataReader.Close

Remarks

You must explicitly call the Close method when you are through using the **MsDb2DataReader** to use the associated MsDb2Connection for any other purpose.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.Dispose Method

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

VB

```
Public Overridable Sub Dispose() Implements IDisposable.Dispose
[C#]
public virtual void Dispose();
[C++]
public: virtual void Dispose();
[JScript]
public function Dispose();
```

Implements

IDisposable.Dispose

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetBoolean Method

Gets the value of the specified column as a **Boolean**.

VB

```
Public Overridable Function GetBoolean( _
   ByVal i As Integer _
) As Boolean Implements IDataRecord.GetBoolean
[C#]
public virtual bool GetBoolean(
   int i
);
[C++]
public: virtual bool GetBoolean(
   int i
);
[JScript]
public function GetBoolean(
   i : int
) : Boolean;
```

Parameters

i

The zero-based column ordinal.

Return Value

Implements

IDataRecord.GetBoolean

Remarks

No conversions are performed, therefore the data retrieved must already be a **Boolean** or an exception is generated.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetByte Method

Gets the value of the specified column as a byte.

VB

```
Public Overridable Function GetByte( _
   ByVal i As Integer _
) As Byte Implements IDataRecord.GetByte
[C#]
public virtual byte GetByte(
   int i
);
[C++]
public: virtual unsigned char GetByte(
   int i
);
[JScript]
public function GetByte(
   i : int
) : Byte;
```

Parameters

i
The zero-based column ordinal.

Return Value

The value of the specified column as a byte.

Implements

IDataRecord.GetByte

Remarks

No conversions are performed; therefore the data retrieved must already be a byte.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetBytes Method

Reads a stream of bytes from the specified column offset into the buffer as an array starting at the given buffer offset.

VB

```
Public Overridable Function GetBytes( _
   ByVal i As Integer, _
   ByVal fieldOffset As Long, _
   ByVal buffer() As Byte, _
   ByVal bufferoffset As Integer, _
   ByVal length As Integer _
) As Long Implements IDataRecord.GetBytes
[C#]
public virtual long GetBytes(
   int i,
   long fieldOffset,
   byte[] buffer,
   int bufferoffset,
   int length
);
[C++]
public: virtual __int64 GetBytes(
   int i,
   __int64 fieldOffset,
   unsigned char buffer __gc[],
   int bufferoffset,
   int length
);
[JScript]
public function GetBytes(
   i : int,
   fieldOffset : long,
   buffer : Byte[],
   bufferoffset : int,
   length : int
) : long;
```

Parameters

i
The zero-based column ordinal.
fieldOffset
The index within the field from which to begin the read operation.
buffer
The buffer into which to read the stream of bytes.
bufferoffset
The index for buffer to begin the read operation.
length
The maximum length to copy into the buffer.

Return Value

The actual number of bytes read.

Implements

IDataRecord.GetBytes

Remarks

GetBytes returns the number of available bytes in the field. In most cases this is the exact length of the field. However, the number returned may be less than the true length of the field if **GetBytes** has already been used to obtain bytes from the field. This may be the case, for example, when the MsDb2DataReader is reading a large data structure into a buffer. For more information, see the **SequentialAccess** setting for **CommandBehavior**.

If you pass a buffer that is a null reference (**Nothing** in Visual Basic), **GetBytes** returns the length of the field in bytes.

No conversions are performed; therefore the data retrieved must already be a byte array.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetChar Method

Gets the value of the specified column as a character.

VB

```
Public Overridable Function GetChar( _
   ByVal i As Integer _
) As Char Implements IDataRecord.GetChar
[C#]
public virtual char GetChar(
   int i
);
[C++]
public: virtual __wchar_t GetChar(
   int i
);
[JScript]
public function GetChar(
   i : int
) : Char;
```

Parameters

i

The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetChar

Remarks

No conversions are performed; the data retrieved must already be a character.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetChars Method

Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.

VB

```
Public Overridable Function GetChars( _
   ByVal i As Integer, _
   ByVal fieldoffset As Long, _
   ByVal buffer() As Char, _
   ByVal bufferoffset As Integer, _
   ByVal length As Integer _
) As Long Implements IDataRecord.GetChars
[C#]
public virtual long GetChars(
   int i,
   long fieldoffset,
   char[] buffer,
   int bufferoffset,
   int length
);
[C++]
public: virtual __int64 GetChars(
   int i,
   __int64 fieldoffset,
   __wchar_t buffer __gc[],
   int bufferoffset,
   int length
);
[JScript]
public function GetChars(
   i : int,
   fieldoffset : long,
   buffer : Char[],
   bufferoffset : int,
   length : int
) : long;
```

Parameters

i
The zero-based column ordinal.
fieldoffset
The index within the row from which to begin the read operation.
buffer
The buffer into which to copy data.
bufferoffset
The index for buffer to begin the read operation.
length
The number of characters to read.

Return Value

The actual number of characters read.

Implements

IDataRecord.GetChars

Remarks

GetChars returns the number of available characters in the field. In most cases this is the exact length of the field. However, the number returned may be less than the true length of the field if **GetChars** has already been used to obtain characters from the field. This may be the case, for example, when the **MsDb2DataReader** is reading a large data structure into a buffer. For more information, see the **SequentialAccess** setting for **CommandBehavior**.

If you pass a buffer that is a null reference (**Nothing** in Visual Basic), **GetChars** returns the length of the field in characters.

No conversions are performed; therefore the data retrieved must already be a character array.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2DataReader.GetData Method

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

VB

```
Public Function GetData( _
   ByVal i As Integer _
) As MsDb2DataReader
[C#]
public MsDb2DataReader GetData(
   int i
);
[C++]
public: MsDb2DataReader* GetData(
   int i
);
[JScript]
public function GetData(
   i : int
) : MsDb2DataReader;
```

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataReader.GetDataTypeName Method

Gets the name of the source data type.

VB

```
Public Overridable Function GetDataTypeName( _
   ByVal i As Integer _
) As String Implements IDataRecord.GetDataTypeName
[C#]
public virtual string GetDataTypeName(
   int i
);
[C++]
public: virtual String* GetDataTypeName(
   int i
);
[JScript]
public function GetDataTypeName(
   i : int
) : String;
```

Parameters

i
The zero-based column ordinal.

Return Value

The name of the host data type.

Implements

IDataRecord.GetDataTypeName

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetDateTime Method

Gets the value of the specified column as a **DateTime** object.

VB

```
Public Overridable Function GetDateTime( _
   ByVal i As Integer _
) As DateTime Implements IDataRecord.GetDateTime
[C#]
public virtual DateTime GetDateTime(
   int i
);
[C++]
public: virtual DateTime GetDateTime(
   int i
);
[JScript]
public function GetDateTime(
   i : int
) : DateTime;
```

Parameters

i

The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetDateTime

Remarks

No conversions are performed; the data retrieved must already be a **DateTime** object.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetDecimal Method

Gets the value of the specified column as a **Decimal** object.

VB

```
Public Overridable Function GetDecimal( _
   ByVal i As Integer _
) As Decimal Implements IDataRecord.GetDecimal
[C#]
public virtual decimal GetDecimal(
   int i
);
[C++]
public: virtual Decimal GetDecimal(
   int i
);
[JScript]
public function GetDecimal(
   i : int
) : Decimal;
```

Parameters

i
  The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetDecimal

Remarks

No conversions are performed; the data retrieved must already be a **Decimal** object.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetDouble Method

Gets the value of the specified column as a double-precision floating point number.

VB

```
Public Overridable Function GetDouble( _
   ByVal i As Integer _
) As Double Implements IDataRecord.GetDouble
[C#]
public virtual double GetDouble(
   int i
);
[C++]
public: virtual double GetDouble(
   int i
);
[JScript]
public function GetDouble(
   i : int
) : double;
```

Parameters

i

The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetDouble

Remarks

No conversions are performed; the data retrieved must already be a double-precision floating point number.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetFieldType Method

Gets the **Type** that is the data type of the object.

VB

```
Public Overridable Function GetFieldType( _
   ByVal i As Integer _
) As Type Implements IDataRecord.GetFieldType
[C#]
public virtual Type GetFieldType(
   int i
);
[C++]
public: virtual Type* GetFieldType(
   int i
);
[JScript]
public function GetFieldType(
   i : int
) : Type;
```

Parameters

i

The zero-based column ordinal.

Return Value

The **Type** that is the data type of the object.

Implements

IDataRecord.GetFieldType

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetFloat Method

Gets the value of the specified column as a single-precision floating point number.

VB

```
Public Overridable Function GetFloat( _
   ByVal i As Integer _
) As Single Implements IDataRecord.GetFloat
[C#]
public virtual float GetFloat(
   int i
);
[C++]
public: virtual float GetFloat(
   int i
);
[JScript]
public function GetFloat(
   i : int
) : float;
```

Parameters

i
The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetFloat

Remarks

No conversions are performed; the data retrieved must already be a single-precision floating point number.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetGuid Method

Gets the value of the specified column as a globally unique identifier (GUID).

VB

```
Public Overridable Function GetGuid( _
   ByVal i As Integer _
) As Guid Implements IDataRecord.GetGuid
[C#]
public virtual Guid GetGuid(
   int i
);
[C++]
public: virtual Guid GetGuid(
   int i
);
[JScript]
public function GetGuid(
   i : int
) : Guid;
```

Parameters

i
The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetGuid

Remarks

No conversions are performed; the data retrieved must already be a globally unique identifier.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetInt16 Method

Gets the value of the specified column as a 16-bit signed integer.

VB

```
Public Overridable Function GetInt16( _
   ByVal i As Integer _
) As Short Implements IDataRecord.GetInt16
[C#]
public virtual short GetInt16(
   int i
);
[C++]
public: virtual short GetInt16(
   int i
);
[JScript]
public function GetInt16(
   i : int
) : Int16;
```

Parameters

i

The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetInt16

Remarks

No conversions are performed; the data retrieved must already be a 16-bit signed integer.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetInt32 Method

Gets the value of the specified column as a 32-bit signed integer.

VB

```
Public Overridable Function GetInt32( _
   ByVal i As Integer _
) As Integer Implements IDataRecord.GetInt32
[C#]
public virtual int GetInt32(
   int i
);
[C++]
public: virtual int GetInt32(
   int i
);
[JScript]
public function GetInt32(
   i : int
) : int;
```

Parameters

i

The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetInt32

Remarks

No conversions are performed; the data retrieved must already be a 32-bit signed integer.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetInt64 Method

Gets the value of the specified column as a 64-bit signed integer.

VB

```
Public Overridable Function GetInt64( _
   ByVal i As Integer _
) As Long Implements IDataRecord.GetInt64
[C#]
public virtual long GetInt64(
   int i
);
[C++]
public: virtual __int64 GetInt64(
   int i
);
[JScript]
public function GetInt64(
   i : int
) : long;
```

Parameters

i

The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetInt64

Remarks

No conversions are performed; the data retrieved must already be a 64-bit signed integer.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetName Method

Gets the name of the specified column.

VB

```
Public Overridable Function GetName( _
   ByVal i As Integer _
) As String Implements IDataRecord.GetName
[C#]
public virtual string GetName(
   int i
);
[C++]
public: virtual String* GetName(
   int i
);
[JScript]
public function GetName(
   i : int
) : String;
```

Parameters

i
The zero-based column ordinal.

Return Value

The name of the specified column.

Implements

IDataRecord.GetName

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetOrdinal Method

Gets the column ordinal, given the name of the column.

VB

```
Public Overridable Function GetOrdinal( _
   ByVal name As String _
) As Integer Implements IDataRecord.GetOrdinal
[C#]
public virtual int GetOrdinal(
   string name
);
[C++]
public: virtual int GetOrdinal(
   String* name
);
[JScript]
public function GetOrdinal(
   name : String
) : int;
```

Parameters

name
The name of the column.

Return Value

The zero-based column ordinal.

Implements

IDataRecord.GetOrdinal

Remarks

GetOrdinal performs a case-sensitive lookup first. If it fails, a second case-insensitive search is made.

GetOrdinal is kana-width insensitive.

Because ordinal-based lookups are more efficient than named lookups, it is inefficient to call **GetOrdinal** within a loop. Save time by calling **GetOrdinal** once and assigning the results to an integer variable for use within the loop.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetSchemaTable Method

Returns a data table that describes the column metadata of the **MsDb2DataReader**.

VB

```
Public Overridable Function GetSchemaTable() As DataTable _
   Implements _
   IDataReader.GetSchemaTable
[C#]
public virtual DataTable GetSchemaTable();
[C++]
public: virtual DataTable* GetSchemaTable();
[JScript]
public function GetSchemaTable() : DataTable;
```

Implements

IDataReader.GetSchemaTable

Remarks

The **GetSchemaTable** method maps to the OLE DB IColumnsRowset::GetColumnsRowset method, and returns metadata about each column in the following order:

DataReader Column	OLE DB Column ID	Description
ColumnName	DBCOLUMN_NAME	The name of the column; this might not be unique. If this cannot be determined, a null value is returned. This name always reflects the most recent renaming of the column in the current view or command text.
ColumnOrdinal	DBCOLUMN_NUMBER	The ordinal of the column. This is zero for the bookmark column of the row, if any. Other columns are numbered starting with one. This column cannot contain a null value.
ColumnSize	DBCOLUMN_COLUMNSIZE	The maximum possible length of a value in the column. For columns that use a fixed-length data type, this is the size of the data type.
NumericPrecision	DBCOLUMN_PRECISION	If **DbType** is a numeric data type, this is the maximum precision of the column. The precision of columns with a data type of DBTYPE_DECIMAL or DBTYPE_NUMERIC depends on the definition of the column. If DbType is not a numeric data type, this is a null value.
NumericScale	DBCOLUMN_SCALE	If **DbType** is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the number of digits to the right of the decimal point. Otherwise, this is a null value.
DataType	None	Maps to the .NET Framework type of the column.
ProviderType	DBCOLUMN_TYPE	The indicator of the column's data type. If the data type of the column varies from row to row, this must be DBTYPE_VARIANT. This column cannot contain a null value.
IsLong	DBCOLUMNFLAGS_ISLONG	The provider sets DBCOLUMNFLAGS_ISLONG if the column contains a Binary Long Object (BLOB) that contains very long data. The definition of very long data is provider-specific. The setting of this flag corresponds to the value of the IS_LONG column in the PROVIDER_TYPES rowset for the data type.

AllowDBNull	DBCOLUMNFLAGS_ISNULLABLE	The provider sets DBCOLUMNFLAGS_ISNULLABLE if the consumer can set the column to a null value, or if the provider cannot determine whether or not the consumer can set the column to a null value. A column may contain null values, even if it cannot be set to a null value.
IsReadOnly	DBCOLUMNFLAGS_WRITE	**true** if the column can be modified; otherwise **false**. The column is assumed to be writable if the provider has set either the DBCOLUMNFLAGS_WRITE or DBCOLUMNFLAGS_WRITEUNKNOWN flag.
IsRowVersion	DBCOLUMNFLAGS_ISROWID	The provider sets DBCOLUMNFLAGS_ISROWID if the column contains a persistent row identifier that cannot be written to, and has no meaningful value except to identity the row.
IsUnique	DBCOLUMN_ISUNIQUE	VARIANT_TRUE: No two rows in the base table-the table returned in **BaseTableName**-can have the same value in this column. **IsUnique** is guaranteed to be VARIANT_TRUE if the column constitutes a key by itself or if there is a constraint of type UNIQUE that applies only to this column. VARIANT_FALSE: The column can contain duplicate values in the base table. The default of this column is VARIANT_FALSE.
IsKey	DBCOLUMN_KEYCOLUMN	VARIANT_TRUE: The column is one of a set of columns in the rowset that, taken together, uniquely identify the row. The set of columns with **IsKey** set to VARIANT_TRUE must uniquely identify a row in the rowset. There is no requirement that this set of columns is a minimal set of columns. This set of columns may be generated from a base table primary key, a unique constraint or a unique index. VARIANT_FALSE-The column is not required to uniquely identify the row.
IsAutoIncrement	DBCOLUMN_ISAUTOINCREMENT	VARIANT_TRUE: The column assigns values to new rows in fixed increments. VARIANT_FALSE: The column does not assign values to new rows in fixed increments. The default of this column is VARIANT_FALSE.
BaseSchemaName	DBCOLUMN_BASESCHEMANAME	The name of the schema in the data store that contains the column. A null value if the base schema name cannot be determined. The default of this column is a null value.
BaseCatalogName	DBCOLUMN_BASECATALOGNAME	The name of the catalog in the data store that contains the column. A null value if the base catalog name cannot be determined. The default of this column is a null value.
BaseTableName	DBCOLUMN_BASETABLENAME	The name of the table or view in the data store that contains the column. A null value if the base table name cannot be determined. The default of this column is a null value.
BaseColumnName	DBCOLUMN_BASECOLUMNNAME	The name of the column in the data store. This might be different than the column name returned in the **ColumnName** column if an alias was used. A null value if the base column name cannot be determined or if the rowset column is derived, but not identical to, a column in the data store. The default of this column is a null value.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataReader.GetString Method

Gets the value of the specified column as a string.

VB

```
Public Overridable Function GetString( _
   ByVal i As Integer _
) As String Implements IDataRecord.GetString
[C#]
public virtual string GetString(
   int i
);
[C++]
public: virtual String* GetString(
   int i
);
[JScript]
public function GetString(
   i : int
) : String;
```

Parameters

i

The zero-based column ordinal.

Return Value

The value of the specified column.

Implements

IDataRecord.GetString

Remarks

No conversions are performed; the data retrieved must already be a string.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetTimeSpan Method

Gets the value of the specified column as a **TimeSpan** object.

VB

```
Public Function GetTimeSpan( _
   ByVal i As Integer _
) As TimeSpan
[C#]
public TimeSpan GetTimeSpan(
   int i
);
[C++]
public: TimeSpan GetTimeSpan(
   int i
);
[JScript]
public function GetTimeSpan(
   i : int
) : TimeSpan;
```

Parameters

i
  The zero-based column ordinal.

Return Value

The value of the specified column.

Remarks

No conversions are performed; the data retrieved must already be a **TimeSpan** object.

Call **IsDBNull** to check for null values before calling this method.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.GetValue Method

Gets the value of the column at the specified ordinal in its native format.

VB

```
Public Overridable Function GetValue( _
   ByVal i As Integer _
) As Object Implements IDataRecord.GetValue
[C#]
public virtual object GetValue(
   int i
);
[C++]
public: virtual Object* GetValue(
   int i
);
[JScript]
public function GetValue(
   i : int
) : Object;
```

Parameters

i
  The zero-based column ordinal.

Return Value

The value to return.

Implements

IDataRecord.GetValue

Remarks

This method returns **DBNull** for null database columns.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataReader.GetValues Method

Gets all the attribute columns in the current row.

VB

```
Public Overridable Function GetValues( _
   ByVal values() As Object _
) As Integer Implements IDataRecord.GetValues
[C#]
public virtual int GetValues(
   object[] values
);
[C++]
public: virtual int GetValues(
   Object* values __gc[]
);
[JScript]
public function GetValues(
   values : Object[]
) : int;
```

Parameters

values

An array of **Object** into which to copy the attribute columns.

Return Value

The number of instances of **Object** in the array.

Implements

IDataRecord.GetValues

Remarks

For most applications, the **GetValues** method provides an efficient means for retrieving all columns, rather than retrieving each column individually.

You can pass an **Object** array that contains fewer than the number of columns contained in the resulting row. Only the amount of data the **Object** array holds is copied to the array. You can also pass an **Object** array whose length is more than the number of columns contained in the resulting row.

This method returns **DBNull** for null database columns.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2DataReader.IDataRecord.GetData Method

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

VB

```
Private Function GetData( _
   ByVal ordinal As Integer _
) As IDataReader Implements IDataRecord.GetData
[C#]
IDataReader IDataRecord.GetData(
   int ordinal
);
[C++]
private: IDataReader* IDataRecord::GetData(
   int ordinal
);
[JScript]
private function IDataRecord.GetData(
   ordinal : int
) : IDataReader;
```

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2DataReader.IEnumerable.GetEnumerator Method

This member supports the .NET Framework infrastructure and is not intended to be used directly from your code.

VB

```
Private Function GetEnumerator() As IEnumerator Implements _
IEnumerable.GetEnumerator
[C#]
IEnumerator IEnumerable.getEnumerator();
 [C++]
private: IEnumerator* IEnumerable::GetEnumerator();
 [JScript]
private function IEnumerable.GetEnumerator() : IEnumerator;
```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.IsDBNull Method

Gets a value indicating whether the column contains nonexistent or missing values.

VB

```
Public Overridable Function IsDBNull( _
   ByVal i As Integer _
) As Boolean Implements IDataRecord.IsDBNull
[C#]
public virtual bool IsDBNull(
   int i
);
[C++]
public: virtual bool IsDBNull(
   int i
);
[JScript]
public function IsDBNull(
   i : int
) : Boolean;
```

Parameters

i
  The zero-based column ordinal.

Return Value

true if the specified column value is equivalent to **DBNull**; otherwise, **false**.

Implements

IDataRecord.IsDBNull

Remarks

Call this method to check for null column values before calling the typed get methods (for example, **GetByte**, **GetChar**, and so on) to avoid raising an error.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.NextResult Method

Advances the data reader to the next result, when reading the results of batch SQL statements.

VB

```
Public Overridable Function NextResult() As Boolean Implements _
   IDataReader.NextResult
[C#]
public virtual bool NextResult();
[C++]
public: virtual bool NextResult();
[JScript]
public function NextResult() : Boolean;
```

Return Value

true if there are more resultsets; otherwise, **false**.

Implements

IDataReader.NextResult

Remarks

Used to process multiple results, which can be generated by executing batch SQL statements.

By default, the data reader is positioned on the first result.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

See Also

MsDb2DataReader Class | MsDb2DataReader Members | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MsDb2DataReader.Read Method

Advances the **MsDb2DataReader** to the next record.

VB

```
Public Overridable Function Read() As Boolean Implements _
   IDataReader.Read
[C#]
public virtual bool Read();
[C++]
public: virtual bool Read();
[JScript]
public function Read() : Boolean;
```

Return Value

true if there are more rows; otherwise, **false**.

Implements

IDataReader.Read

Remarks

The default position of the **MsDb2DataReader** is prior to the first record. Therefore, you must call **Read** to begin accessing any data.

While the **MsDb2DataReader** is in use, the associated **MsDb2Connection** is busy serving it until you call **Close**.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsDb2Exception Class

The exception that is thrown when the underlying provider returns a warning or error for a DB2 data source. This class cannot be inherited.

For a list of all members of this type, see MsDb2Exception Members.

System.Object
  System.Exception
    Microsoft.HostIntegration.MsDb2Client.MsDb2Exception

VB

```
Public Class MsDb2Exception
   Inherits Exception
[C#]
public class MsDb2Exception : Exception
[C++]
public __gc class MsDb2Exception : public Exception
[JScript]
public class MsDb2Exception extends Exception
```

Thread Safety

Any public static (**Shared** in Microsoft® Visual Basic®) members of this type are safe for multithreaded operations. Any instance members are not guaranteed to be thread safe.

Remarks

This class is created whenever the DB2 .NET Data Provider encounters an error generated from the server. (Client side errors are thrown as standard URT exceptions.) **MsDb2Exception** always contains at least one instance of **MsDb2Error**.

If the severity of the error is too great, the server may close the **MsDb2Connection**. However, the user can reopen the connection and continue.

Requirements

Namespace: Microsoft.HostIntegration.MsDb2Client

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Assembly: Microsoft.Hostintegration.Msdb2client (in Microsoft.Hostintegration.Msdb2client.dll)

MsDb2Exception Members

MsDb2Exception overview

Public Properties

HelpLink (inherited from **System.Exception**)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from **System.Exception**)	Gets the **Exception** instance that caused the current exception.
Message (inherited from **System.Exception**)	Overridden. Gets the text describing the error.
Source (inherited from **System.Exception**)	Overridden. Gets the name of the DB2 provider that generated the error.
StackTrace (inherited from **System.Exception**)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from **System.Exception**)	Gets the method that throws the current exception.

Public Methods

Argument	Overloaded. Contains the arguments for the exception.
Equals (inherited from **System.Object**)	Overloaded. Determines whether two **Object** instances are equal.
GetBaseException (inherited from **System.Exception**)	When overridden in a derived class, returns the **Exception** that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from **System.Exception**)	See **Exception.GetObjectData**.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
InvalidOperation	Describes the invalid operation that caused the exception to occur.
NullReference	Describes the null reference that caused the exception to occur.
Security	Describes the security violation that caused the exception to occur.
ToString	Overridden. Creates and returns a string representation of the current exception.
TypeLoad	Describes the type-loading failure that caused the exception.

See Also

MsDb2Exception Class | Microsoft.HostIntegration.MsDb2Client Namespace | Managed Provider for DB2 Programmer's Guide

MsDb2Exception Methods

This section lists the methods of the **MsDb2Exception** class. For a complete list of **MsDb2Exception** class members, see MsDb2Exception Members.

Public Methods

Argument	Overloaded. Contains the arguments for the exception.
Equals (inherited from **System.Object**)	Overloaded. Determines whether two Object instances are equal.
GetBaseException (inherited from **System.Exception**)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from **System.Object**)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from **System.Exception**)	See **Exception.GetObjectData**.
GetType (inherited from **System.Object**)	Gets the **Type** of the current instance.
InvalidOperation	Describes the invalid operation that caused the exception to occur.
NullReference	Describes the null reference that caused the exception to occur.
Security	Describes the security violation that caused the exception to occur.
ToString	Overridden. Creates and returns a string representation of the current exception.
TypeLoad	Describes the type-loading failure that caused the exception.

Managed Provider for DB2 Programmer's Guide

MsDb2Exception.Argument Method (System.String, System.Exception)

Returns the arguments for the exception, using the error text and inner exception.

VB

```
Overloads Protected Shared Function Argument( _
   ByVal error As String, _
   ByVal inner As Exception _
) As Exception
[C#]
protected static Exception Argument(
   string error,
   Exception inner
);
[C++]
protected: static Exception* Argument(
   String* error,
   Exception* inner
);
[JScript]
protected static function Argument(
   error : String,
   inner : Exception
) : Exception;
```

Parameters

error
Text describing the error.
inner
The exception instance that caused the current exception.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server
