After you run the application, you must drop a request message that conforms to the schema for invoking the **Customer Interface** concurrent program. For example, the request message to invoke the **Customer Interface** concurrent program is:

```
<RACUST xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/ConcurrentPrograms/AR">
  <Description>Customer Interface Program</Description>
  <StartTime></StartTime>
  <CREATE_RECIPROCAL_CUSTOMER>Yes</CREATE_RECIPROCAL_CUSTOMER>
  <ORG_ID>203</ORG_ID>
</RACUST>
```

Note

The request message for invoking a concurrent program requires some optional parameters such as SetOptions, SetPrintOptions, and SetRepeatOptions. The request message provided here does not contain these optional parameters. For information on the complete request message, including optional parameters, see [Message Schemas for Concurrent Programs](#).

The orchestration consumes the message, passes it on to the Oracle E-Business Suite, and receives a response. The response message is saved at the other file location specified as part of the orchestration. The response for the Customer Interface concurrent program resembles the following:

```
<?xml version="1.0" encoding="utf-8"?>
<RACUSTResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/ConcurrentPrograms/AR">
  <RACUSTResult>2794708</RACUSTResult>
</RACUSTResponse>
```

The response from the Oracle E-Business Suite contains a request ID. The orchestration extracts the request ID from the response message, constructs a message to invoke the **Get_Status** concurrent program, and passes it to the Oracle E-Business Suite to execute the **Get_Status** concurrent program. After the response is received for the **Get_Status** concurrent program, it is copied to the same file location as the first response. The response for the **Get_Status** concurrent program resembles the following:

```
<?xml version="1.0" encoding="utf-8" ?>
<GetStatusForConcurrentProgramResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/ConcurrentPrograms/AR">
  <GetStatusForConcurrentProgramResult>true</GetStatusForConcurrentProgramResult>
  <Phase>Pending</Phase>
  <Status>Standby</Status>
  <DevPhase>PENDING</DevPhase>
  <DevStatus>STANDBY</DevStatus>
  <Message>null</Message>
</GetStatusForConcurrentProgramResponse>
```

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the binding file. After you generate a binding file, you can import the configuration settings from the file, so that you do not need to create items such as send ports and receive ports for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

[Developing BizTalk Applications](#)

Invoking Request Sets in Oracle E-Business Suite Using BizTalk Server

Microsoft BizTalk Adapter for Oracle E-Business Suite enables you to execute request sets in Oracle E-Business Suite. Request sets are divided into one or more stages, and each stage contains a set of reports and concurrent programs. For more information on how the adapter supports request sets, see [Operations on Request Sets](#). For information about the structure of SOAP messages for invoking request sets, see [Message Schemas for Request Sets](#).

Prerequisites

You must have completed the steps in [Before You Develop BizTalk Applications](#).

How to Invoke Request Sets in Oracle E-Business Suite

Performing an operation on Oracle E-Business Suite using the Oracle E-Business adapter with BizTalk Server involves procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To invoke a request set, these tasks are:

- Create a BizTalk project, and generate schema for the request set you want to invoke.
- Create messages in the BizTalk project for sending and receiving messages to and from Oracle E-Business Suite.
- Create an orchestration to invoke the request set.
- Build and deploy the BizTalk project.
- Configure the BizTalk application by creating physical send and receive ports.
- Start the BizTalk application.

This topic provides instructions to perform these tasks.

Generating Schema

This topic demonstrates how to invoke a request set, by invoking the **Function Security Reports** (friendly name) request set from the **Application Object Library** application. The actual name of the request set is **FNDRSSUB43**. This request set is available with the default Oracle E-Business Suite application. This request set returns a request ID.

Hence, in this topic, we generate schema for the **FNDRSSUB43** request set. See [Retrieving Metadata for Oracle E-Business Suite Operations in Visual Studio](#) for more information about how to generate schema.

Defining Messages and Message Types

The schema that you generated earlier describes the “types” required for the messages in the orchestration. A message is typically a variable, the type for which is defined by the corresponding schema. You must now create messages for the orchestration, and link them to schemas that you generated in the previous step.

In this orchestration you must create two messages—one to send message to invoke the request set and another to receive a response for the request set.

To create messages and link to schema

1. Add an orchestration to the BizTalk project. From Solution Explorer, right-click the BizTalk project name, point to **Add**, and then click **New Item**. Type a name for the BizTalk orchestration, and then click **Add**.
2. Open the Orchestration View window of the BizTalk project, if it is not already open. To do so, click **View**, point to **Other Windows**, and then click **Orchestration View**.
3. In Orchestration View, right-click **Messages**, and then click **New Message**.
4. Right-click the newly created message, and then select **Properties Window**.
5. In the **Properties** pane for the **Message_1**, do the following:

Use this	To do this
Identifier	Type Request
Message Type	From the drop-down list, expand Schemas , and then select <i>RequestSet.OracleEBSBindingRequestSets_FND.FNDRSSUB43</i> , where RequestSet is the name of your BizTalk project. OracleEBSBindingRequestSets is the schema generated for invoking the FNDRSSUB43 request set.

6. Repeat step 3 to create a message. In the **Properties** pane for the new message, do the following:

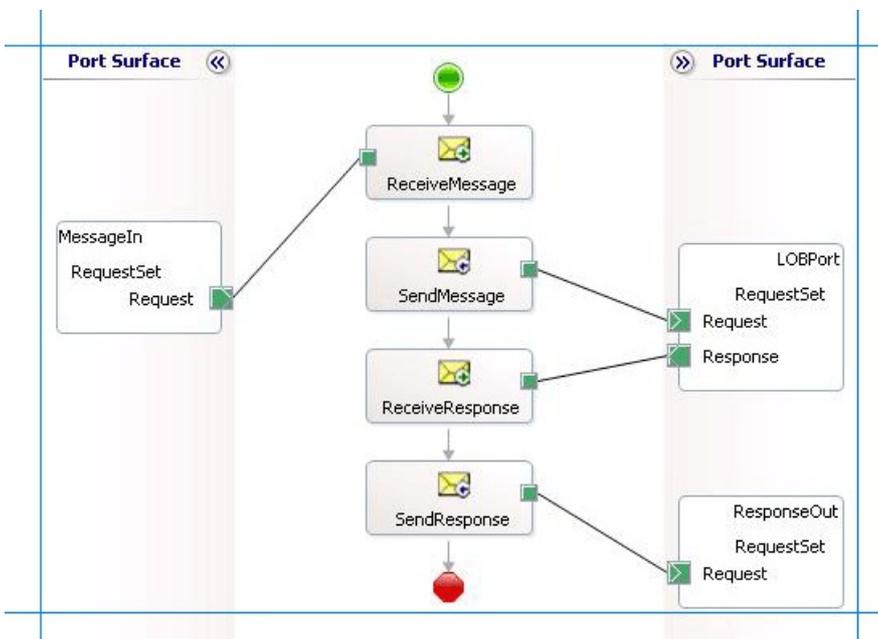

Use this	To do this
Response	<i>RequestSet.OracleEBSBindingRequestSets_FND.FNDRSSUB43Response</i>

Setting up the Orchestration

You must create a BizTalk orchestration to use BizTalk Server for invoking request sets in Oracle E-Business Suite. In this orchestration, you will be dropping a request message at a defined receive location. The orchestration consumes this message and passes it on to Oracle E-Business Suite to invoke the **FNDRSSUB43** request set. The response for the request set is received from Oracle and is saved at another location. A typical orchestration to invoke a request set would contain:

- Send and Receive shapes to send messages to Oracle E-Business Suite and receive responses.
- A one-way receive port to receive request messages to send to Oracle E-Business Suite.
- A two-way send port to send request messages to Oracle E-Business Suite and receive responses.
- A one-way send port to send the responses from Oracle E-Business Suite to a folder.

A sample orchestration to invoke a request set resembles the following:

Adding Message Shapes

Specify the following properties for each of the message shapes. The names listed in the *Shape* column are the names of the message shapes as displayed in the preceding orchestration.

Shape	Shape Type	Properties
-------	------------	------------

ReceiveMessage	Receive	<ul style="list-style-type: none"> • Set Name to <i>ReceiveMessage</i> • Set Activate to <i>True</i>
SendMessage	Send	<ul style="list-style-type: none"> • Set Name to <i>SendMessage</i>
ReceiveResponse	Receive	<ul style="list-style-type: none"> • Set Name to <i>ReceiveResponse</i> • Set Activate to <i>False</i>
SendResponse	Send	<ul style="list-style-type: none"> • Set Name to <i>SendResponse</i>

Adding Ports

Make sure you specify the following properties for each of the logical ports. The names listed in the *Port* column are the names of the ports as displayed in the orchestration.

Port	Properties
MessageIn	<ul style="list-style-type: none"> • Set Identifier to <i>MessageIn</i> • Set Type to <i>MessageInType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Receive</i>
LOBPort	<ul style="list-style-type: none"> • Set Identifier to <i>LOBPort</i> • Set Type to <i>LOBPortType</i> • Set Communication Pattern to <i>Request-Response</i> • Set Communication Direction to <i>Send-Receive</i>
ResponseOut	<ul style="list-style-type: none"> • Set Identifier to <i>ResponseOut</i> • Set Type to <i>ResponseOutType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Send</i>

Specify Messages for Action Shapes and Connect to Ports

The following table specifies the properties and their values to be set to specify messages for action shapes and linking them to the ports. The names listed in the *Shape* column are the names of the message shapes as displayed in the previous orchestration.

Shape	Properties
ReceiveMessage	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>MessageIn.RequestSet.Request</i>

SendMessage	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>LOBPort.RequestSet.Request</i>
ReceiveResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>LOBPort.RequestSet.Response</i>
SendResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>ResponseOut.RequestSet.Request</i>

After you have specified these properties, the message shapes and ports are connected and your orchestration is complete.

You must now build the BizTalk solution and then deploy it to a BizTalk Server. For more information, see <http://go.microsoft.com/fwlink/?LinkId=102359>.

Configuring the BizTalk Application

After you have deployed the BizTalk project, the orchestration you created earlier is listed under the Orchestrations pane in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. For more information about configuring an application, see <http://go.microsoft.com/fwlink/?LinkID=196961>.

Configuring an application involves:

- Selecting a host for the application.
- Mapping the ports that you created in your orchestration to physical ports in the BizTalk Server Administration console. For this orchestration you must:
 - Define a location on the hard disk and a corresponding file port where you will drop a request message. The BizTalk orchestration will consume the request message and send it to the Oracle E-Business Suite.
 - Define a location on the hard disk and a corresponding file port where the BizTalk orchestration will drop the response message containing the response from Oracle E-Business Suite.
 - Define a physical WCF-Custom or WCF-OracleEBS send port to send messages to Oracle E-Business Suite. You must also specify the action in the send port. For information about how to create send ports, see [Manually Configuring a Physical Port Binding to the Oracle E-Business Adapter](#).

To invoke request sets using the Oracle E-Business adapter, you must set the right application context in which the operation is invoked. The Oracle E-Business adapter provides certain binding properties to specify the application context for any operation. You must set these binding properties on the WCF-Custom or WCF-OracleEBS port used for invoking request sets.

- If the **ClientCredentialType** binding property is set to **Database**, then you must specify the following binding properties to set the applications context.

Binding Property	Value

OracleUserName	Specify the name of an Oracle E-Business Suite user. The Oracle E-Business adapter does not preserve the case of the value that you enter for the OracleUserName binding property when it connects to Oracle E-Business Suite. The user name is passed to Oracle E-Business Suite using the standard rules of SQL*Plus. However, if you want the case of the user name to be preserved or if you want to enter a user name containing special characters, you must specify the value within double quotes.
OraclePassword	The password for the Oracle E-Business Suite user. The Oracle E-Business adapter does not preserve the case of the value that you enter for the OraclePassword binding property when it connects to Oracle E-Business Suite. The password is passed to Oracle E-Business Suite using the standard rules of SQL*Plus. However, if you want the case of the password to be preserved or if you want to enter a password containing special characters, you must specify the value within double quotes.
OracleEBSResponsibilityName	The responsibility associated with the Oracle E-Business Suite user.

- If the **ClientCredentialType** binding property is set to **EBusiness**, you must have already specified Oracle E-Business credentials while establishing the connection. In such a case you must only specify value for the **OracleEBSResponsibilityName** binding property.

For more information about the different binding properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For more information on how the adapter supports setting the application context, see [Setting Application Context](#).

Note

You can set the application context either by specifying the binding properties or by setting the message context properties exposed by the Oracle E-Business adapter. For instructions on how to set the binding properties, see [Specifying Binding Properties](#). For instructions on how to set the application context using message context properties, see [Set the Application Context Using Message Context Properties](#).

Note

Generating the schema using the Consume Adapter Service BizTalk Project Add-in also creates a binding file that contains information about the ports and the actions to be set for those ports. You can import this binding file from the BizTalk Server Administration console to create send ports (for outbound calls) or receive ports (for inbound calls). For more information, see [Configuring a Physical Port Binding Using a Port Binding File](#).

Starting the Application

You must start the BizTalk application for invoking the request sets. For instructions on starting a BizTalk application, see <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The FILE receive port to receive request messages for the orchestration is running.
- The FILE send port to receive the response messages from the orchestration is running.
- The WCF-Custom or WCF-OracleEBS send port to invoke the **FNDRSSUB43** request set is running.
- The BizTalk orchestration for the operation is running.

Executing the Operation

After you run the application, you must drop a request message that conforms to the schema for invoking the **FNDRSSUB43** request set. For example, the request message to invoke the **FNDRSSUB43** request set is:

```
<FNDRSSUB43 xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSets/FND">
  <StartTime></ StartTime>
  <All_x0020_Requests_x0020_in_x0020_the_x0020_Set_STAGE10>
    <FNDMNAV xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSetStage/FND/FNDRSSUB43">
      <Responsibility xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSetConcurrentProgram/FND/FNDRSSUB43/STAGE10/FND">System Administrator</Responsibility>
      <ns3:Application xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSetConcurrentProgram/FND/FNDRSSUB43/STAGE10/FND"></ns3:Application>
    </ns2:FNDMNAV>
    <ns2:FNDMMNNU xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSetStage/FND/FNDRSSUB43">
      <ns3:Responsibility xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSetConcurrentProgram/FND/FNDRSSUB43/STAGE10/FND">System Administrator</ns3:Responsibility>
      <ns3:Application xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSetConcurrentProgram/FND/FNDRSSUB43/STAGE10/FND"></ns3:Application>
    </ns2:FNDMMNNU>
    <ns2:FNDMNFUN xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSetStage/FND/FNDRSSUB43">
      <ns3:Responsibility xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSetConcurrentProgram/FND/FNDRSSUB43/STAGE10/FND">System Administrator</ns3:Responsibility>
      <ns3:Application xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSetConcurrentProgram/FND/FNDRSSUB43/STAGE10/FND"></ns3:Application>
    </ns2:FNDMNFUN>
  </ns0:All_x0020_Requests_x0020_in_x0020_the_x0020_Set_STAGE10>
</ns0:FNDRSSUB43>
```

Note

The request message for invoking a request set requires some optional parameters such as SetRelClassOptions, SetPrintOptions, SetRepeatOptions, and SetNlsOptions. The request message provided here does not contain these optional parameters. For information on the complete request message, including optional parameters, see [Message Schemas for Request Sets](#).

The orchestration consumes the message, passes it on to the Oracle E-Business Suite, and receives a response. The response message is saved at the other file location specified as part of the orchestration. The response for the **FNDRSSUB43** request set resembles the following:

```
<?xml version="1.0" encoding="utf-8"?>
<FNDRSSUB43Response xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/RequestSets/FND">
  <FNDRSSUB43Result>2543208</FNDRSSUB43Result>
</FNDRSSUB43Response>
```

The response from the Oracle E-Business Suite contains a request ID. Request ID '0' denotes that the final submit operation on the request set failed. In such a case, you can specify other optional parameters in the request message, such as ContinueOnFail, to find out the reason of failure and to debug further.

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the binding file. Once you generate a binding file, you can import the configuration settings from the file, so that you do not need to create items such as send ports and receive ports for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

[Developing BizTalk Applications](#)

Performing ExecuteReader, ExecuteScalar, or ExecuteNonQuery Operations Using BizTalk Server

The Oracle E-Business adapter exposes generic operations such as **ExecuteNonQuery**, **ExecuteReader**, and **ExecuteScalar**. You can use these operations to execute any SQL statement on Oracle database. These operations differ based on the kind of response you get for the SQL statement. For more information about how the adapter supports these operations, see [Support for ExecuteNonQuery, ExecuteReader, and ExecuteScalar Operations](#).

This topic demonstrates how to perform an **ExecuteReader** operation using the Oracle E-Business adapter with BizTalk Server. You can follow the same set of procedures described in this topic to perform **ExecuteNonQuery** and **ExecuteScalar** operations.

How to Invoke ExecuteReader operation on Oracle Database

Performing an operation on a Oracle database by using Oracle E-Business adapter with BizTalk Server involves procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To invoke the **ExecuteReader** operation on Oracle database, these tasks are:

1. Create a BizTalk project, and generate schema for the **ExecuteReader** operation.
2. Create messages in the BizTalk project for sending and receiving messages from Oracle database.
3. Create an orchestration to invoke the operation on Oracle database.
4. Build and deploy the BizTalk project.
5. Configure the BizTalk application by creating physical send and receive ports.
6. Start the BizTalk application.

This topic provides instructions to perform these tasks.

Generating Schema

This topic demonstrates how to invoke the **ExecuteReader** operation on an Oracle database using the Oracle E-Business adapter with BizTalk Server. The **ExecuteReader** operation takes any SQL statement as a parameter and returns the result set for the operation as an array of DataSet. For this topic, we execute a SELECT statement on ACCOUNTACTIVITY table using the **ExecuteReader** operation. The ACCOUNTACTIVITY table is created by running the scripts provided with the samples. For more information about the script, see [Samples](#).

To demonstrate how to invoke **ExecuteReader** operation, schema is generated for the **ExecuteReader** operation. You must create a BizTalk project and use the Consume Adapter Service Add-in to generate the schema. For more information about how to generate schemas, see [Retrieving Metadata for Oracle E-Business Suite Operations in Visual Studio](#).

Defining Messages and Message Types

The schema that you generated earlier describes the "types" required for the messages in the orchestration. A message is typically a variable, the type for which defined by the corresponding schema. You must now create messages for the orchestration and link them to schemas you generated in the previous step.

To create messages and link to schema

1. Add an orchestration to the BizTalk project. From Solution Explorer, right-click the BizTalk project name, point to **Add**, and then click **New Item**. Type a name for the BizTalk orchestration, and then click **Add**.
2. Open the Orchestration View window of the BizTalk project, if it is not already open. To do so, click **View**, point to **Other Windows**, and then click **Orchestration View**.
3. In Orchestration View, right-click **Messages**, and then click **New Message**.
4. Right-click the newly created message, and then select **Properties Window**.
5. In the **Properties** pane for the **Message_1**, do the following:

Use this	To do this
Identifier	Type Request
Message Type	From the drop-down list, expand Schemas , and then select <i>Execute_Reader.GenericOperation.ExecuteReader</i> , where <i>Execute_Reader</i> is the name of your BizTalk project. <i>GenericOperation</i> is the schema generated for the ExecuteReader operation.

6. Repeat step 2 to create a new message. In the **Properties** pane for the new message, do the following:

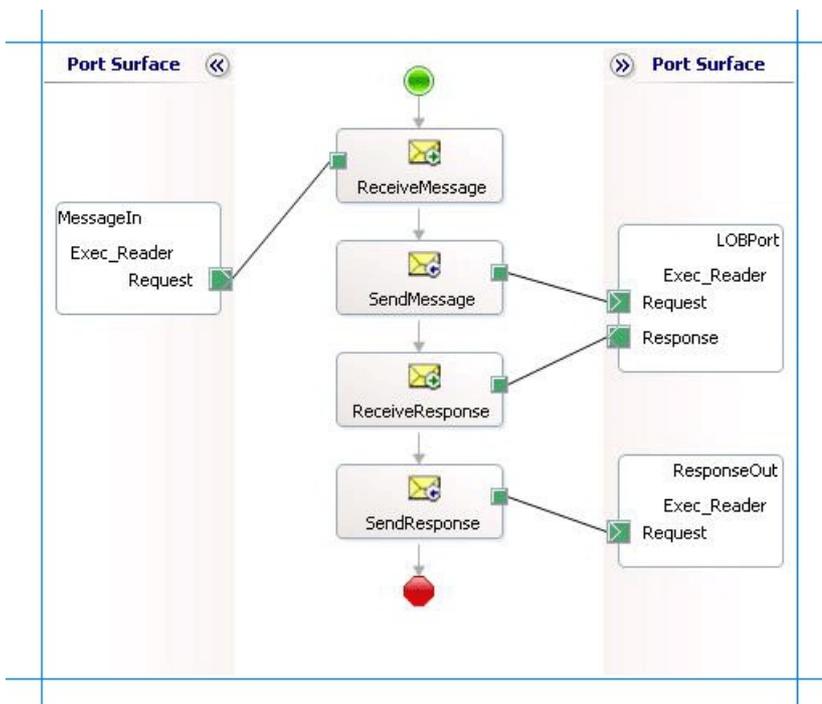

Use this	To do this
Identifier	Type Response
Message Type	From the drop-down list, expand Schemas , and then select <i>Execute_Reader.GenericOperation.ExecuteReaderResponse</i> .

Setting up the Orchestration

You must create a BizTalk orchestration to use BizTalk Server for performing an operation on Oracle database. In this orchestration, you drop a request message at a defined receive location. The Oracle E-Business adapter consumes this message and passes it on to Oracle database. The response from Oracle database is saved to another location. A typical orchestration for invoking generic operations such as **ExecuteReader** would contain:

- Send and Receive shapes to send and receive messages from an Oracle database.
- A two-way receive port to send and receive messages from an Oracle database.
- A one-way send port to send response from Oracle database to a folder.

A sample orchestration for invoking an **ExecuteReader** operation resembles the following:

Adding Message Shapes

You need to configure the following properties for each of the message shapes. The names listed in the Shape column correspond to the names of the message shapes as displayed in the just-mentioned orchestration.

Shape	Shape Type	Properties
-------	------------	------------

ReceiveMessage	Receive	<ul style="list-style-type: none"> • Set Name to <i>ReceiveMessage</i> • Set Activate to <i>True</i>
SendMessage	Send	<ul style="list-style-type: none"> • Set Name to <i>SendMessage</i>
ReceiveResponse	Receive	<ul style="list-style-type: none"> • Set Name to <i>ReceiveResponse</i> • Set Activate to <i>False</i>
SendResponse	Send	<ul style="list-style-type: none"> • Set Name to <i>SendResponse</i>

Adding Ports

For each of the logical ports, configure the properties in the table below. The names listed in the Port column correspond to the names of the ports as displayed in the orchestration.

Port	Properties
MessageIn	<ul style="list-style-type: none"> • Set Identifier to <i>MessageIn</i> • Set Type to <i>MessageInType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Receive</i>
LOBPort	<ul style="list-style-type: none"> • Set Identifier to <i>LOBPort</i> • Set Type to <i>LOBPortType</i> • Set Communication Pattern to <i>Request-Response</i> • Set Communication Direction to <i>Send-Receive</i>
ResponseOut	<ul style="list-style-type: none"> • Set Identifier to <i>ResponseOut</i> • Set Type to <i>ResponseOutType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Send</i>

Specify Messages for Action Shapes and Connect Them to Ports

The following table specifies the property values to specify messages for action shapes and to link the messages to the ports. The names listed in the **Shape** column correspond to the names of the message shapes as displayed in the orchestration diagram earlier.

After you have configured these properties, the message shapes and ports are connected, and your orchestration is complete.

Then, you must now build the BizTalk solution and deploy it to BizTalk Server. For more information, see <http://go.microsoft.com/fwlink/?LinkId=102359>.

Shape	Properties
-------	------------

ReceiveMessage	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>MessageIn.Exec_Reader.Request</i>
SendMessage	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>LOBPort.Exec_Reader.Request</i>
ReceiveResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>LOBPort.Exec_Reader.Response</i>
SendResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>ResponseOut.Exec_Reader.Request</i>

Configuring the BizTalk Application

After you have deployed the BizTalk project, the orchestration you created earlier is listed under the **Orchestrations** pane in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. For more information about configuring an application, see <http://go.microsoft.com/fwlink/?LinkID=196961>.

Configuring an application involves:

- Selecting a host for the application.
- Mapping the ports that you created in your orchestration to physical ports in the BizTalk Server Administration console. For this orchestration you must:
 - Define a location on the hard disk and a corresponding file port where you will drop a request message. The BizTalk orchestration will consume the request message and send it to the Oracle database.
 - Define a location on the hard disk and a corresponding file port where the BizTalk orchestration will drop the response message containing the response from the Oracle database.
 - Define a physical WCF-Custom or WCF-OracleEBS send port to send messages to the Oracle database. You must also specify the action in the send port. For information about how to create send ports, see [Manually Configuring a Physical Port Binding to the Oracle E-Business Adapter](#).

◆ Important

As part of generic operations, if you are executing operations on objects, for example stored procedures, functions, interface tables, or interface views, which belong to an Oracle E-Business Suite application, you must set the application context by specifying the requisite binding properties. For more information about setting the application context, see [Setting Application Context](#).

You can set the application context either by specifying the binding properties or by setting the message context properties exposed by the Oracle E-Business adapter. For instructions on how to set the binding properties, see [Specifying Binding Properties](#). For instructions on how to set the application context using message context properties, see [Set the Application Context Using Message Context Properties](#).

📌 Note

Generating the schema using the Consume Adapter Service BizTalk Project Add-in also creates a binding file that contains information about the ports and the actions to be set for those ports. You can import this binding file from the BizTalk Server Administration console to create send ports (for outbound calls) or receive ports (for inbound calls). For more information, see [Configuring a Physical Port Binding Using a Port Binding File](#).

Starting the Application

You must start the BizTalk application before invoking **ExecuteReader** operation on Oracle database. For instructions on starting a BizTalk application, see <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The FILE receive port to receive request messages for the orchestration is running.
- The FILE send port to receive the response messages from the orchestration is running.
- The WCF-Custom or WCF-OracleEBS send port to send messages to Oracle database is running.
- The BizTalk orchestration for the operation is running.

Executing the Operation

After you run the application, you must drop a request message to the FILE receive location. The schema for the request message must conform to the schema for the **ExecuteReader** operation you generated earlier. For example, the request message to execute a SELECT statement using an **ExecuteReader** operation is:

```
<ExecuteReader xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/GenericOperation/">
  <Query>SELECT * FROM ACCOUNTACTIVITY</Query>
</ExecuteReader>
```

See Message Schemas for ExecuteReader, ExecuteScalar, and ExecuteNonQuery Operations for more information about the request message schema for invoking an **ExecuteReader** operation using the Oracle E-Business adapter.

The orchestration consumes the message and sends it to the Oracle database. The response from the Oracle database is saved at the other FILE location defined as part of the orchestration. The response for the **ExecuteReader** operation contains a result set as a DataSet. For example, the response from the Oracle database for the preceding request message is:

```
<?xml version="1.0" encoding="utf-8" ?>
<ExecuteReaderResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/GenericOperation/">
  <ExecuteReaderResult>
    <xs:schema id="NewDataSet" xmlns:xs="http://www.w3.org/2001/XMLSchema" xmlns:msdata="urn:schemas-microsoft-com:xml-msdata">
      <xs:element msdata:IsDataSet="true" name="NewDataSet">
        <xs:complexType>
          <xs:sequence>
            <xs:element minOccurs="0" maxOccurs="unbounded" name="NewTable">
              <xs:complexType>
                <xs:sequence>
                  <xs:element minOccurs="0" name="TID" type="xs:decimal" />
                  <xs:element minOccurs="0" name="ACCOUNT" type="xs:decimal" />
                  <xs:element minOccurs="0" name="AMOUNT" type="xs:decimal" />
                  <xs:element minOccurs="0" name="DESCRIPTION" type="xs:string" />
                  <xs:element minOccurs="0" name="TRANSDATE" type="xs:dateTime" />
                  <xs:element minOccurs="0" name="PROCESSED" type="xs:string" />
                </xs:sequence>
              </xs:complexType>
            </xs:element>
          </xs:sequence>
        </xs:complexType>
      </xs:element>
    </xs:schema>
    <diffgr:diffgram xmlns:diffgr="urn:schemas-microsoft-com:xml-diffgram-v1">
```

```
<NewDataSet xmlns="">
  <NewTable>
    <TID>1</TID>
    <ACCOUNT>100001</ACCOUNT>
    <AMOUNT>500</AMOUNT>
    <DESCRIPTION />
    <TRANSDATE>2008-08-04T13:04:20</TRANSDATE>
    <PROCESSED>n</PROCESSED>
  </NewTable>
  <NewTable>
    .....
    .....
  </NewTable>
  .....
  .....
</NewDataSet>
</diffgr:diffgram>
</ExecuteReaderResult>
</ExecuteReaderResponse>
```

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the binding file. After you generate a binding file, you can import the configuration settings from the file, so that you do not need to create items such as the send ports and receive ports for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

Polling Oracle E-Business Suite Using BizTalk Server

You can configure the Oracle E-Business adapter to receive polling-based messages from Oracle database. The adapter provides two ways of polling the Oracle database:

- **Using SELECT statements.** You can specify a simple SELECT statement to poll the Oracle database. The adapter executes the SELECT statement at specified intervals and returns the result to the adapter clients.
- **Using stored procedures.** You can specify a stored procedure to poll the Oracle database. The adapter executes the stored procedure at specified intervals and returns the result to the adapter clients.

The key difference in the two approaches is the way adapter clients specify a polling statement that the adapter uses to poll the Oracle database. While the polling statement for the first approach is a simple SELECT statement, the polling statement for the stored procedure approach is a request message that executes the stored procedure. Adapter clients specify the polling statement, for either approach, for the **PollingInput** binding property. For more information about the binding properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#).

The topics in this section provide instructions on how to poll using a SELECT statement and a stored procedure.

In This Section

- [Polling Using SELECT Statement](#)
- [Polling Using Stored Procedures](#)

[Developing BizTalk Applications](#)

Polling Using SELECT Statement

You can configure the Oracle E-Business adapter to receive periodic data-change messages by using a SELECT statement to continuously poll the interface tables, interface views, tables and views in Oracle E-Business Suite. You can specify a SELECT statement as a polling statement that the adapter executes periodically to poll Oracle E-Business Suite. You can also specify a post-poll PL/SQL code block that the adapter executes after the polling statement is executed.

To enable polling, you must specify certain binding properties on the WCF-Custom or WCF-OracleEBS receive port. For more information about how the adapter supports polling, see [Support for Inbound Calls Using Polling](#). For information about the structure of the SOAP message for polling operations, see [Message Schemas for the Polling Operations](#).

Configuring a Polling Operation with Oracle E-Business Suite Adapter Binding Properties

The following table summarizes the Oracle E-Business adapter binding properties that you use to configure the adapter to receive data change messages. You must specify these binding properties while configuring the receive port in BizTalk Server Administration console.

Binding Property	Description
InboundOperationType	Specifies whether you want to perform Polling or Notification inbound operation. Default is Polling .
PolledDataAvailableStatement	Specifies the SQL statement that the adapter executes to determine whether any data is available for polling. Only if a record is available, the SELECT statement you specify for the PollingInput binding property will be executed.
PollingInterval	Specifies the interval, in seconds, at which the Oracle E-Business adapter executes the statement specified for the PolledDataAvailableStatement binding property. The default is 30 seconds. The polling interval determines the time interval between successive polls. If the statement is executed within the specified interval, the adapter sleeps for the remaining time in the interval.
PollingInput	Specifies the polling statement. To poll using a SELECT statement, you must specify a SELECT statement for this binding property. The default is null. You must specify a value for PollingInput binding property to enable polling. The polling statement is executed only if there is data available for polling, which is determined by the PolledDataAvailableStatement binding property.
PollingAction	Specifies the action for the polling operation. You can determine the polling action for a specific operation from the metadata you generate for the operation using the Consume Adapter Service Add-in.
PostPollStatement	Specifies a statement block that is executed after the statement specified by the PollingInput binding property is executed.
PollWhileDataFound	Specifies whether the Oracle E-Business adapter ignores the polling interval and continuously executes the polling statement, if data is available in the table being polled. If no data is available in the table, the adapter reverts to execute the polling statement at the specified polling interval. Default is false.

For a more complete description of these properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For a complete description of how to use the Oracle E-Business adapter to poll the Oracle database, read further.

How This Topic Demonstrates Polling

In this topic, to demonstrate how the Oracle E-Business adapter supports receiving data change messages using SELECT statements, create a BizTalk project and generate schema for the **Poll** operation for table you want to poll. In this topic, we generate schema for the **Poll** operation for the **MS_SAMPLE_EMPLOYEE** interface table in the **Application Object Library**

application. This table is created when you run the `create_apps_artifacts.sql` script provided with the samples to create these objects in Oracle E-Business Suite.

Next, we will use content-based routing (CBR) in BizTalk Server to configure an application with a receive port that will receiving polling messages from the **MS_SAMPLE_EMPLOYEE** interface table, and then route it to a send port. In this case, we will create a filter on the send port that checks the receive location specified, and the message is routed to the send port.

To demonstrate a polling operation, we do the following:

- Specify a SELECT statement for the **PolledDataAvailableStatement** binding property to determine where the interface table being polled (`MS_SAMPLE_EMPLOYEE`) has any data. In this example, you can set this binding property as:

```
SELECT COUNT (*) FROM MS_SAMPLE_EMPLOYEE
```

This ensures that the adapter executes the polling statement only when the `MS_SAMPLE_EMPLOYEE` interface table has some records.

- Specify a SELECT statement for the **PollingInput** binding property. This statement retrieves all the rows in the `MS_SAMPLE_EMPLOYEE` interface table. In this example, you can set this binding property as:

```
SELECT * FROM MS_SAMPLE_EMPLOYEE FOR UPDATE
```

Note

For information about the FOR UPDATE clause used in the SELECT statement, see [Specifying a FOR UPDATE Clause in the Polling Statement](#).

- Specify a DELETE statement as part of the **PostPollStatement** binding property. This statement will delete all data from `MS_SAMPLE_EMPLOYEE` interface table. In this example, you can set this binding property as:

```
DELETE FROM MS_SAMPLE_EMPLOYEE
```

Once this happens, the next time the statement specified for **PollingInput** will be executed, it will not fetch any data.

- Until more data is added to the `MS_SAMPLE_EMPLOYEE` interface table, you will not get any polling messages. So, you must repopulate the `MS_SAMPLE_EMPLOYEE` interface table with new records. You can do so by running the `insert_apps_data.sql` script provided with the samples. After you run this script, the next polling operation will fetch the new records inserted into the table.

How to Receive Data-change Messages from Oracle E-Business Suite

Performing an operation on Oracle database using Oracle E-Business adapter with BizTalk Server involves the following procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To configure the adapter to poll Oracle E-Business Suite using a SELECT statement, these tasks are:

1. Create a BizTalk project, and generate schema for the **Poll** operation for the interface table you want to poll.
2. Build and deploy the BizTalk project.
3. Configure the BizTalk application by creating receive and send ports. Additionally, add filter on the send port so that it checks the receive location specified in the receive port, and the polling message is routed to the send port.

Important

For inbound polling scenarios you must always configure a one-way receive port. Two-way receive ports are not supported for inbound operations.

4. Start the BizTalk application.

This topic provides instructions to perform these tasks.

Sample Based On This Topic

A sample, `PollingUsingSelectStatement`, based on this topic is also provided with the BizTalk Adapter Pack. For more information, see [Samples](#).

Generating Schema

You must generate the schema for the **Poll** operation on the `MS_SAMPLE_EMPLOYEE` interface table in the **Application Object Library** application. Perform the following tasks while generating the schema using the Consume Adapter Service Add-in.

- Select the contract type as **Service (Inbound operation)**.
- Generate schema for the **Poll** operation on the `MS_SAMPLE_EMPLOYEE` interface table. You can select the operation and the interface table either from the **Application-Based View** node or the **Artifact -Based View** node.

For more information about how to generate schema, see [Browsing, Searching, and Retrieving Metadata for Oracle E-Business Operations](#).

Building and Deploying the BizTalk Project

You must now build the BizTalk solution, and deploy it to a BizTalk Server. For information about deploying the solution to BizTalk Server, see <http://go.microsoft.com/fwlink/?LinkId=107182>.

Configuring the BizTalk Application

After you have deployed the BizTalk project, the application is listed under the **Applications** node in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. As part of configuring the application, you must create a receive port and a send port in the application, and then add filter to the send port so that all the messages from the receive port are routed to the send port.

Configuring an application involves:

- Selecting a host for the application.
- Creating receive and send ports.

Creating a Receive Port

You must create a WCF-Custom or WCF-OracleEBS one-way receive port, which polls Oracle using the SELECT statement specified for the **PollingInput** binding property. For information about how to create receive ports, see [Manually Configuring a Physical Port Binding to the Oracle E-Business Adapter](#). While creating the receive port, ensure you specify the following binding properties.

For Polling

Binding Property	Value
InboundOperationType	Set this to Polling .
PolledDataAvailableStatement	For this example, set this binding property to: <pre>SELECT COUNT (*) FROM MS_SAMPLE_EMPLOYEE</pre>
PollingAction	Retrieve the polling action from the schema generated for the Poll operation on <code>MS_SAMPLE_EMPLOYEE</code> interface table. For this example, set this binding property to InterfaceTables/Poll/FND/APPS/MS_SAMPLE_EMPLOYEE .

PollingInput	<p>For this binding property, specify a SELECT statement to retrieve all records from the MS_SAMPLE_EMPLOYEE interface table. For this example, set this binding property to:</p> <pre data-bbox="280 185 1501 264">SELECT * FROM MS_SAMPLE_EMPLOYEE FOR UPDATE</pre>
PostPollState ment	<p>Specify the post-poll statement to delete all data from the MS_SAMPLE_EMPLOYEE interface table. For this example, set this binding property to:</p> <pre data-bbox="280 398 1501 477">DELETE FROM MS_SAMPLE_EMPLOYEE</pre>

For Setting Application Context

If you are performing operation on Oracle E-Business Suite artifacts, you must specify values for the appropriate binding properties to set the application context. For more information about application context and the binding properties required for setting application context, see [Setting Application Context](#).

For this example, specify appropriate values for the **oracleUserName**, **oraclePassword**, and **oracleEBSResponsibility** binding properties.

Note

We recommend configuring the transaction isolation level and the transaction timeout while performing inbound operations using the Oracle E-Business adapter. You can do so by adding the service behavior while configuring the receive port. For instruction on how to add the service behavior, see [Configure Transaction Isolation Level and Transaction Timeout](#).

Creating a Send Port

Define a location on the hard disk and create a corresponding FILE send port where BizTalk Server will drop the messages from Oracle. These messages will be in response to the polling statement that you specify for the receive port. For information about how to create send ports, see [Manually Configuring a Physical Port Binding to the Oracle E-Business Adapter](#).

You must also add a filter on the send port to route messages from the receive location. To add filter to the send port:

1. Double-click the send port to open the **Send Port Properties** dialog box.
2. In the **Send Port Properties** dialog box, click the **Filters** tab.
3. Specify the following values:
 - In the **Property** list, click **BTS.ReceivePortName**.
 - In the **Operator** list, click **=**.
 - In the **Value** field, specify the receive port name.
4. In the **Send Port Properties** dialog box, click **OK**.

Starting the Application

You must start the BizTalk application for polling Oracle E-Business Suite. For instructions on starting a BizTalk application, see <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The WCF-Custom or WCF-OracleEBS one-way receive port, which polls Oracle using the SELECT statement specified for the **PollingInput** binding property, is running.
- The FILE send port, which receives messages from Oracle database, is running.

Executing the Operation

After you run the application, the following set of actions take place, in the same sequence:

- The adapter executes the **PolledDataAvailableStatement** which returns a positive value indicating the adapter to execute the statement specified for **PollingInput** binding property.
- The adapter executes the SELECT statement for the **PollingInput** binding property and returns all the rows in the MS_SAMPLE_EMPLOYEE interface table. The response from Oracle E-Business Suite resembles the following:

```
<?xml version="1.0" encoding="utf-8" ?>
<Poll xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/InterfaceTables/FND/APPS/M
S_SAMPLE_EMPLOYEE">
  <DATA>
    <SelectRecord xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/TableViewRecor
d/APPS/MS_SAMPLE_EMPLOYEE">
      <EMP_NO>10002</EMP_NO>
      <NAME>JEFF PRICE</NAME>
      <DESIGNATION>MANAGER</DESIGNATION>
      <SALARY>25000</SALARY>
      <JOIN_DATE>2007-12-15T00:00:00</JOIN_DATE>
    </SelectRecord>
    <SelectRecord xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/TableViewRecor
d/APPS/MS_SAMPLE_EMPLOYEE">
      <EMP_NO>10003</EMP_NO>
      <NAME>DON HALL</NAME>
      <DESIGNATION>ACCOUNTANT</DESIGNATION>
      <SALARY>12000</SALARY>
      <JOIN_DATE>2005-10-29T00:00:00</JOIN_DATE>
    </SelectRecord>
    ...
    <SelectRecord xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/TableViewRecor
d/APPS/MS_SAMPLE_EMPLOYEE">
      ...
    </SelectRecord>
    ...
  </DATA>
</Poll>
```

- The adapter executes the post-poll statement, which deletes all the data from MS_SAMPLE_EMPLOYEE interface table.
- After the polling interval, the adapter again executes **PolledDataAvailableStatement**. Because the MS_SAMPLE_EMPLOYEE interface table has no records now, **PolledDataAvailableStatement** does not return a positive value and hence the adapter does not execute the statement specified for the **PollingInput** binding property. As a result, adapter client does not get any polling message.
- The adapter client will not get any more polling messages until some records are explicitly inserted into the MS_SAMPLE_EMPLOYEE interface table. To insert more records, you can run the insert_apps_data.sql script provided with the samples. After you run this script, the next time **PolledDataAvailableStatement** is executed, it returns a positive value. As a result, the adapter executes the polling statement and adapter clients again receive a polling message.

Note

The Oracle E-Business adapter will continue to poll until you explicitly disable the receive port from the BizTalk Server Administration console.

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the bindings file. Once you generate a bindings file, you can import the configuration settings from the file so that you do not need to create the send ports and receive ports. For more information about binding files, see [Reusing Adapter Bindings](#).

[Polling Oracle E-Business Suite Using BizTalk Server](#)

Polling Using Stored Procedures

You can configure the Oracle E-Business adapter to receive periodic data-change messages by using stored procedures to continuously poll the Oracle database. You can specify a stored procedure as a polling statement that the adapter executes periodically to poll the Oracle database.

To enable polling, you must specify certain binding properties on the WCF-Custom or WCF-OracleEBS receive port. For more information about how the adapter supports polling, see [Support for Inbound Calls Using Polling](#). For information about the structure of the SOAP message for polling operations, see [Message Schemas for the Polling Operations](#).

Configuring a Polling Operation with Oracle E-Business Adapter Binding Properties

The following table summarizes the Oracle E-Business adapter binding properties that you use to configure the adapter to receive data-change messages. You must specify these binding properties while configuring the WCF-Custom or WCF-OracleEBS receive port in the BizTalk Server Administration console.

Binding Property	Description
InboundOperationType	Specifies whether you want to perform a Polling or Notification inbound operation. Default is Polling .
PolledDataAvailableStatement	Specifies the SQL statement that the adapter executes to determine whether any data is available for polling. Only if a record is available, the stored procedure you specified for the PollingInput binding property will be executed.
PollingInterval	Specifies the interval, in seconds, at which the Oracle E-Business adapter executes the statement specified for the PolledDataAvailableStatement binding property. The default is 30 seconds. The polling interval determines the time interval between successive polls. If the statement is executed within the specified interval, the adapter sleeps for the remaining time in the interval.
PollingInput	Specifies the polling statement. To poll using a stored procedure, you must specify the entire request message for this binding property. The request message must be the same that you send to the adapter for invoking the stored procedure as an outbound operation. The default is null. You must specify a value for PollingInput binding property to enable polling. The polling statement is executed only if there is data available for polling, which is determined by the PolledDataAvailableStatement binding property.
PollingAction	Specifies the action for the polling operation. You can determine the polling action for a specific operation from the metadata you generate for the operation using the Consume Adapter Service Add-in.
PostPollStatement	Specifies a statement block that is executed after the statement specified by the PollingInput binding property is executed.
PollWhileDataFound	Specifies whether the Oracle E-Business adapter ignores the polling interval and continuously executes the polling statement, if data is available in the table being polled. If no data is available in the table, the adapter reverts to execute the polling statement at the specified polling interval. Default is false.

For a more complete description of these properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For a complete description of how to use the Oracle E-Business adapter to poll the Oracle database, read the following sections.

How This Topic Demonstrates Polling

In this topic, to demonstrate how the Oracle E-Business adapter supports receiving data change messages using stored procedures, create a BizTalk project and generate schema for the stored procedure you want to use to poll the Oracle database. In this topic, we use the GET_ACTIVITYS stored procedure to poll the ACCOUNTACTIVITY table. This stored procedure is

available with the ACCOUNT_PKG package. You can run the SQL scripts provided with the samples to create these objects in the database.

Note

The orchestration in this topic polls the ACCOUNTACTIVITY table, which is a base database table created by running the scripts provided with the samples. You must perform similar procedures as described in this topic to poll any other table, including interface tables.

To demonstrate a polling operation, we do the following:

- Specify a SELECT statement for the **PolledDataAvailableStatement** binding property to determine where the table being polled (ACCOUNTACTIVITY) has any data. In this example, you can set this binding property as:

```
SELECT COUNT (*) FROM ACCOUNTACTIVITY
```

This ensures that the adapter executes the polling statement only when the ACCOUNTACTIVITY table has some records.

- Execute a stored procedure, GET_ACTIVITYS, by providing the request message as part of the **PollingInput** binding property. This stored procedure will retrieve all the rows in the ACCOUNTACTIVITY table and you will get a response message from the adapter.
- EXECUTE a PL/SQL block as part of the **PostPollStatement** binding property. This statement will move all data from ACCOUNTACTIVITY table to another table in the database. Once this happens, the next time **PollingInput** will be executed, it will not fetch any data and hence the GET_ACTIVITYS stored procedure will return an empty response message.
- Until more data is added to the ACCOUNTACTIVITY table, you will continue to get empty response messages. So, you must repopulate the ACCOUNTACTIVITY table with new records. You can do so by running the more_activity_data.sql script provided with the samples. After you run this script, the next polling operation will fetch the new records inserted into the table.

How to Receive Data-change Messages from Oracle

Performing an operation on Oracle database using Oracle E-Business adapter with BizTalk Server involves the following procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To configure the adapter to poll Oracle database using a stored procedure, these tasks are:

1. Create a BizTalk project, and generate schema for the stored procedure you want to use for polling.
2. Create a message in the BizTalk project for receiving messages from Oracle database.
3. Create an orchestration to receive messages from Oracle database and save them to a folder.
4. Build and deploy the BizTalk project.
5. Configure the BizTalk application by creating physical send and receive ports.

Important

For inbound polling scenarios you must always configure a one-way receive port. Two-way receive ports are not supported for inbound operations.

6. Start the BizTalk application.

This topic provides instructions to perform these tasks.

Sample Based On This Topic

A sample, `PollingUsingStoredProc`, based on this topic is also provided with the BizTalk Adapter Pack. For more information, see [Samples](#).

Generating Schema

You must generate the schema for the `GET_ACTIVITYS` operation. Perform the following tasks while generating the schema using the Consume Adapter Service Add-in.

- Select the contract type as **Service (Inbound operation)**.
- Generate schema for the **GET_ACTIVITYS** procedure.

For more information about how to generate schema, see [Browsing, Searching, and Retrieving Metadata for Oracle E-Business Operations](#).

Defining Messages and Message Types

The schema that you generated earlier describes the "types" required for the messages in the orchestration. A message is typically a variable, the type for which is defined by the corresponding schema. Once the schema is generated, you must link it to the messages from the Orchestration view of the BizTalk project.

For this topic, you must create one message to receive messages from Oracle.

Perform the following steps to create messages and link them to schema.

To create messages and link to schema

1. Add an orchestration to the BizTalk project. From the Solution Explorer, right-click the BizTalk project name, point to **Add**, and then click **New Item**. Type a name for the BizTalk orchestration and then click **Add**.
2. Open the orchestration view window of the BizTalk project, if it is not already open. Click **View**, point to **Other Windows**, and then click **Orchestration View**.
3. In the **Orchestration View**, right-click **Messages**, and then click **New Message**.
4. Right-click the newly created message, and then select **Properties Window**.
5. In the **Properties** pane for **Message_1**, do the following:

U s e t h is	To do this
Id e nt ifi er	Type Receive .

From the drop-down list, expand **Schemas**, and select *Polling.OracleEBSBindingSchema*, where *Polling* is the name of your BizTalk project. *OracleEBSBindingSchema* is the response schema generated for the **GET_ACTIVITYS** stored procedure.

Important

Because polling is a one way operation, the schema generated by the adapter does not contain a response node, and hence there is only one root node in the schema. If you use such schemas for a message type, you must identify the schema by the filename of the generated schema. For example, if you create schema for a two-way operation, the nodes in the schema file with a name *OracleEBSBindingSchema* may look like "Request" and "Response". If you want to create a message in the orchestration that maps to the request schema, you can identify the schema in the list by looking for *OracleEBSBindingSchema.Request*. However, in the case of polling operation, because the only node is "Poll", it is not easy to identify the schema you want to map to because schemas with single nodes are not listed as <schemafilename>.<rootnodename>. Instead, such schemas are listed by only the filename. In such a case, the only way to identify the schema is by the schema filename, for example, *OracleEBSBindingSchema*.

The Consume Adapter Service Add-in generates schema for both inbound and outbound operations for the GET_ACTIVITYS stored procedure. You must use the schema for inbound operation to:

- Map the message created as part of the orchestration.
- To retrieve the action you must specify for the **PollingAction** binding property at run-time.

You must use the schema for the outbound operation to get the request message you must specify as part of the **PollingInput** binding property.

Setting up the Orchestration

You must create a BizTalk orchestration to use BizTalk Server for receiving polling-based data-change messages from Oracle. In this orchestration, the adapter receives the response by executing the stored procedure for which you specified the request message as part of the **PollingInput** binding property. The response message for the stored procedure is saved to a FILE location. A typical orchestration for polling Oracle database would contain:

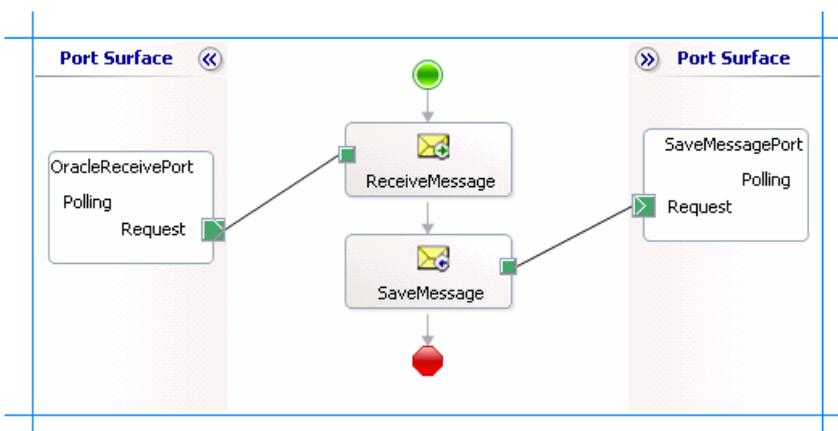

- Receive and Send shapes to receive messages from Oracle and send to a FILE port, respectively.
- A one-way receive port to receive messages from Oracle database.

Important

For inbound polling scenarios you must always configure a one-way receive port. Two-way receive ports are not supported for inbound operations.

- A one-way send port to send polling responses from Oracle database.

A sample orchestration resembles the following.

Adding Message Shapes

Make sure you specify the following properties for each of the message shapes. The names listed in the Shape column are the

names of the message shapes as displayed in the just-mentioned orchestration.

Shape	Shape Type	Properties
ReceiveMessage	Receive	<ul style="list-style-type: none"> • Set Name to <i>ReceiveMessage</i> • Set Activate to <i>True</i>
SaveMessage	Send	<ul style="list-style-type: none"> • Set Name to <i>SaveMessage</i>

Adding Ports

Make sure you specify the following properties for each of the logical ports. The names listed in the Port column are the names of the ports as displayed in the orchestration.

Port	Properties
OracleReceivePort	<ul style="list-style-type: none"> • Set Identifier to <i>OracleReceivePort</i> • Set Type to <i>OracleReceivePortType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Receive</i>
SaveMessagePort	<ul style="list-style-type: none"> • Set Identifier to <i>SaveMessagePort</i> • Set Type to <i>SaveMessagePortType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Send</i>

Specify Messages for Action Shapes and Connect to Ports

The following table specifies the properties and their values that you should set to specify messages for action shapes and to link the messages to the ports. The names listed in the Shape column are the names of the message shapes as displayed in the orchestration mentioned earlier.

Shape	Properties
ReceiveMessage	<ul style="list-style-type: none"> • Set Message to <i>Receive</i> • Set Operation to <i>OracleReceivePort.Polling.Request</i>
SaveMessage	<ul style="list-style-type: none"> • Set Message to <i>Receive</i> • Set Operation to <i>SaveMessagePort.Polling.Request</i>

After you have specified these properties, the message shapes and ports are connected and your orchestration is complete.

You must now build the BizTalk solution and deploy it to a BizTalk Server. For more information, see "Building and Running Orchestrations" at <http://go.microsoft.com/fwlink/?LinkId=102359>.

Configuring the BizTalk Application

After you have deployed the BizTalk project, the orchestration you created earlier is listed under the **Orchestrations** pane in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. For more information about configuring an application, see "How to Configure an Application" at

<http://go.microsoft.com/fwlink/?LinkID=196961>.

Configuring an application involves:

- Selecting a host for the application.
- Mapping the ports that you created in your orchestration to physical ports in the BizTalk Server Administration console. For this orchestration you must:
 - Define a location on the hard disk and a corresponding FILE port where the BizTalk orchestration will drop the messages from Oracle. These messages will be in response to the polling statement that you specify for the receive port.
 - Define a physical WCF-Custom or WCF-OracleEBS one-way receive port. This port polls the Oracle database. For information about how to create receive ports, see [Manually Configuring a Physical Port Binding to the Oracle E-Business Adapter](#). Make sure you specify the following binding properties for the receive port.

Binding Property	Value
Inbound OperationType	Set this to Polling .
PolledDataAvailableStatement	<p>For this example, set this binding property to:</p> <pre>SELECT COUNT (*) FROM ACCOUNTACTIVITY</pre> <p>This ensures that the adapter executes the polling statement only when the ACCOUNTACTIVITY table has some records.</p>
Polling Action	Retrieve the polling action from the schema generated for the inbound message for the GET_ACTIVITY_S procedure. For this example, set this binding property to PollingPackageApis/APPS/ACCOUNT_PKG/GET_ACTIVITIES .
PollingInput	<p>For this binding property, specify the request message to invoke the GET_ACTIVITY_S stored procedure. You can get the request message from the schema for the outbound operation generated by the Consume Adapter Service Add-in. You must provide the entire XML message as an input for this binding property. For this example, set this binding property to:</p> <pre><GET_ACTIVITYS xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/PackageApis/APPS/ACCOUNT_PKG"> <INRECS>OPEN ? FOR SELECT * FROM ACCOUNTACTIVITY</INRECS> </GET_ACTIVITYS></pre> <p>The GET_ACTIVITY_S stored procedure takes an input REF CURSOR as parameter.</p>
PostPollStatement	<p>Specify the post-poll statement to move all data from ACCOUNTACTIVITY table to another table. For this example, set this binding property to:</p> <pre>BEGIN ACCOUNT_PKG.PROCESS_ACTIVITY(); END;</pre>

For more information about the different binding properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#).

◆ Important

If you are polling an interface table, you must set the application context by specifying the requisite binding properties. For more information about setting the application context see [Setting Application Context](#).

📌 Note

We recommend configuring the transaction isolation level and the transaction timeout while performing inbound operations using the Oracle E-Business adapter. You can do so by adding the service behavior while configuring the WCF-Custom or WCF-OracleEBS receive port. For instruction on how to add the service behavior, see [Configure Transaction Isolation Level and Transaction Timeout](#).

Starting the Application

You must start the BizTalk application for polling Oracle database. For instructions on starting a BizTalk application, see <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The WCF-Custom or WCF-OracleEBS one-way receive port, which polls Oracle using the stored procedure specified for the **PollingInput** binding property, is running.
- The FILE send port, which receives messages from Oracle database, is running.
- The BizTalk orchestration for the operation is running.

Executing the Operation

After you run the application, the following set of actions take place, in the same sequence:

- The adapter executes the **PolledDataAvailableStatement** which returns a positive value indicating the adapter to execute the statement specified for **PollingInput** binding property.
- The adapter executes the GET_ACTIVITYS stored procedure specified for the **PollingInput** binding property and returns all the rows in the ACCOUNTACTIVITY table. The response from Oracle database resembles the following:

```
<?xml version="1.0" encoding="utf-8" ?>
<GET_ACTIVITYS xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/PollingPackageApis/APPS/ACCOUNT_PKG">
  <OUTRECS>
    <OUTRECSRecord xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/ReferencedRecordTypes/APPS/ACCOUNT_PKG/GET_ACTIVITYS/APPS/GET_ACTIVITYS">
      <TID>1</TID>
      <ACCOUNT>100001</ACCOUNT>
      <AMOUNT>500</AMOUNT>
      <DESCRIPTION />
      <TRANSDATE>2008-06-21T15:52:19</TRANSDATE>
      <PROCESSED>n</PROCESSED>
    </OUTRECSRecord>
    <OUTRECSRecord xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/ReferencedRecordTypes/APPS/ACCOUNT_PKG/GET_ACTIVITYS/APPS/GET_ACTIVITYS">
      .....
      .....
    </OUTRECSRecord>
    .....
    .....
  </OUTRECS>
</GET_ACTIVITYS>
```

- The adapter executes the post-poll statement, which moves all the data from ACCOUNTACTIVITY table to another table.
- After the polling interval, the adapter again executes **PolledDataAvailableStatement**. Because ACCOUNTACTIVITY table has no records now, **PolledDataAvailableStatement** does not return a positive value and hence the adapter does not execute the statement specified for the **PollingInput** binding property. As a result, adapter client does not get any polling message.
- The adapter client will not get any more polling messages until some records are explicitly inserted into the ACCOUNTACTIVITY table. To insert more records, you can run the more_activity_data.sql script provided with the samples. After you run this script, the next time **PolledDataAvailableStatement** is executed, it returns a positive value. As a result, the adapter executes the polling statement and adapter clients again receive a polling message.

Note

The Oracle E-Business adapter will continue to poll until you explicitly disable the receive port from the BizTalk Server Administration console.

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the bindings file. Once you generate a bindings file, you can import the configuration settings from the file so that you do not need to create the send ports and receive ports for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

Receiving Database Change Notifications Using BizTalk Server

You can configure the Oracle E-Business adapter to receive database change notification messages from Oracle E-Business Suite. You can specify a SELECT statement that the adapter uses to register for notifications with Oracle E-Business Suite. The adapter receives a notification message when the result set for the SELECT statement, registered for notification, changes. For more information about how the adapter supports notification, see [Receiving Database Change Notifications](#).

Following are some scenarios in which you can configure the Oracle E-Business adapter with BizTalk Server to receive notifications from Oracle E-Business Suite:

- Adapter clients get only “incremental” notification, for example, only for those changes that were made to a database table since the last notification.
- If a large number of rows are inserted into a database table, the adapter clients can configure multiple receive locations to load-balance receiving notifications.

After the adapter clients receive a notification message, they can perform specific tasks based on the kind of notification received. For example, a BizTalk orchestration can be designed in such a way that it performs one set of tasks if an insert notification is received and another set of tasks if an update notification is received.

Caution

If there is a network outage between the Oracle database and the adapter client, the notifications will not be sent to the adapter clients for the changes done on the Oracle database during the period of network outage, and thereafter. Therefore, you must use the Polling operation instead of the Notification operation for critical scenarios.

The topics in this section provide information on how to configure the adapter for each of these scenarios. To start getting notifications from Oracle E-Business Suite using the Oracle E-Business adapter, you must specify certain binding properties. For more information about the binding properties related to notifications, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For more information about structure of notification messages, see [Message Schemas for the Notification Operation](#).

For receiving notifications from Oracle E-Business Suite, make sure:

- You use the adapter to connect to Oracle database version 10.2 or later. Oracle database versions prior to 10.2 do not support notifications.
- The **change notification** privilege is required for receiving database change notifications. To configure this privilege, connect to Oracle database using administrative privileges and then type the following command on the SQL prompt.

```
grant change notification to <user name>
```

- Decide on a TCP port you want ODP.NET to use for receiving database change notifications from Oracle database. Add that port to Windows Firewall exceptions list. For instructions on how to add ports to Windows Firewall exceptions list, see <http://go.microsoft.com/fwlink/?LinkID=196959>. You must provide the same port number for the **NotificationPort** binding property. For more information about the binding property, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#).

Considerations for Receiving Database Change Notifications Using the Adapter

This topic provides some considerations and best practices that you must keep in mind while using the Oracle E-Business adapter to receive database notifications from an Oracle database.

Considerations While Using the Adapter to Receive Notifications

You must consider the following while using the Oracle E-Business adapter to receive query notifications.

- The Oracle E-Business adapter simply passes on the notification, which it receives from the Oracle database, to the adapter clients. The adapter does not distinguish between the notifications for different operations, i.e., the adapter does not have any information whether a particular notification is for an Insert operation or an Update operation.
- The notification message for an operation is not affected by the number of records affected by that operation. For example, irrespective of the number of records inserted in an Oracle database table, the adapter clients receive only one notification message.
- We recommend that the adapter client application contain the logic to interpret the kind of notification received from the Oracle database. The adapter client applications can do so by extracting the information in the **<Info>** element of the received notification message. Here's an example of a notification message received for an Insert operation.

```
<?xml version="1.0" encoding="utf-8" ?>
<Notification xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/">
  <Details>
    <NotificationDetails>
      <ResourceName>SCOTT.ACCOUNTACTIVITY</ResourceName>
      <Info>1</Info>
      <QueryId>0</QueryId>
    </NotificationDetails>
  </Details>
  <Info>Insert</Info>
  <ResourceNames>
    <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">SCOTT.AC
COUNTACTIVITY</string>
  </ResourceNames>
  <Source>Data</Source>
  <Type>Change</Type>
</Notification>
```

Notice the value within the **<Info>** element. This value provides information on the operation for which the notification message was received. Your application should have the functionality to extract the value within the **<Info>** element and then based on the value, perform subsequent tasks. The topic [Processing Notification Messages to Perform Specific Tasks](#) has instructions on how to extract the value within the **<Info>** element.

- Ideally, after the client application receives a notification, it should update the record for which the notification is already received so that the subsequent notifications are not for the same record. For example, consider an **ACCOUNTACTIVITY** table that has a **Processed** column. For all new records inserted into the **ACCOUNTACTIVITY** table, the value in the **Processed** column is always 'n'. For example, after an insert operation, the records in the **ACCOUNTACTIVITY** table will look like the following:

Account Transaction ID	Processed
10001	n

To get notifications for the newly inserted record, the adapter client will set the **NotificationStatement** binding property as:

```
SELECT * FROM SCOTT.ACCOUNTACTIVITY WHERE PROCESSED = 'n'
```

After, receiving the notification, the client application must set the value of the **Processed** column to 'y' so that the notification statement does not operate on the record that was already notified for. So, to achieve this, the client application must perform an Update operation on the **ACCOUNTACTIVITY** table. After the Update operation, the same record in the **ACCOUNTACTIVITY** table will look like the following:

Account Transaction ID	Processed
10001	y

Interestingly, the Update operation will again send a notification to the adapter client and the whole process will be repeated again. So, the client application must have the required logic to discard such unwanted notifications.

- If the **NotifyOnListenerStart** binding property is true, the adapter will send a notification to the adapter client every time the receive location starts. For more information on how to use the binding property and interpret the notification message, see [Receiving Database Change Notifications After a Receive Location Breakdown](#).

Typical Orchestration for Receiving Notifications

This section outlines the typical orchestration flow for receiving notifications using the Oracle E-Business adapter.

1. The first thing that the orchestration must do is to check the kind of notification received. The things to check for are:
 - Whether the notification was received for the receive location restart.
 - Whether the notification was received for an operation on a database table, such as Insert, Update, or Delete.

The orchestration must include an **Expression** shape, and within that an xpath query, to decide what kind of message is received.

2. After the notification type is available, the orchestration must include a decision block to perform specific actions based on the type of notification received. To achieve this, the orchestration must include a **Decide** shape. The **Decide** shape consists of a **Rule** block and an **Else** block. Within the **Rule** block, you must specify the condition and then include orchestration shapes to perform certain operations if the condition is met. Within the **Else** block, you must include orchestration shapes to perform certain operations if the condition is *not* met.

The preceding recommendations are described in detail in [Processing Notification Messages to Perform Specific Tasks](#).

[Receiving Database Change Notifications Using BizTalk Server](#)

Processing Notification Messages to Perform Specific Tasks

You can use the Oracle E-Business adapter to receive notifications for changes to the Oracle database tables. However, the adapter only sends you a notification that some records were inserted, updated, or deleted in a certain database table. Any post-processing on those records must be handled by the client applications themselves. This topic presents a scenario-based description on how to process the records in the table based on the kind of notification received from the Oracle database.

Scenarios for Performing Subsequent Actions After Receiving Notification

Following are a couple of scenarios in which the adapter clients must perform certain post-notification tasks.

- **Scenario 1.** Consider a scenario where the adapter client must perform certain tasks based on the kind of notification you receive from the Oracle database. For example, the client application must update the records in table "A" if records are inserted in table "B". Similarly, the client application must delete records from table "A" if records are deleted from table "B".

In this scenario, from the notification message received, the adapter clients must extract the type of notification to decide whether the notification was for an insert operation or a delete operation. Once the notification type is ascertained, the adapter clients must perform subsequent actions to insert or update the relevant tables.

- **Scenario 2.** Consider a scenario where the receive location that receives notification messages for changes to a table goes down. While the receive location is down, some records are added to the table. However, for these records the adapter client does not receive any notification. When the receive location is back up, the adapter notifies the client by sending a specific message, and then the client application must look for all the records that were inserted in the database table while the receive location was down.

In this scenario, from the notification message received, the adapter clients must extract the information regarding whether the notification is for a change to a database table or for the receive location starting. If the notification is for the receive location starting, the adapter clients must implement the logic to process the records that might have been inserted, updated, or deleted while the receive location was down.

Note

These are just some example scenarios that are listed for a better understanding of how to use the notification feature in the Oracle E-Business adapter. However, the basic set of tasks required to extract the type of notification received will be similar for all scenarios. This topic provides instructions on how to extract the type of notification from a notification message.

How This Topic Demonstrates Receiving Notification Messages

In this topic, to demonstrate how to process notification messages to perform subsequent tasks, we consider a basic scenario where an adapter client uses BizTalk application to receive notification messages for changes to the ACCOUNTACTIVITY table. After the notification is received, the client filters the type of notification received and performs subsequent action. To demonstrate a very basic scenario, let us consider that the adapter client copies the notification messages to different folders based on the kind of notification received. Therefore:

- If the notification message is for an Insert or Update operation, the adapter client copies the message to C:\TestLocation\UpsertNotification folder.
- If the notification message is for any other operation, for example Delete, the adapter client copies the message to C:\TestLocation\OtherNotificaion folder.

To achieve this as part of a BizTalk application, the orchestration must contain the following:

- A one-way receive port to receive notification messages.
- An Expression shape that contains an xpath query to extract the information about the kind of notification message received.

- A Decide shape to include a decision block in the orchestration. In this decision block, the application decides on what subsequent operations to perform based on the notification message received.
- Two one-way send ports that finally receive the notification messages.

Configuring Notifications with the Oracle E-Business Adapter Binding Properties

The following table summarizes the Oracle E-Business adapter binding properties that you use to configure receiving notifications from Oracle E-Business Suite. You must specify these binding properties when configuring the receive port in the BizTalk Server Administration console.

Note	
You may choose to specify these binding properties when generating the schema for the Notification operation, even though it is not mandatory. If you do so, the port binding file that the Consume Adapter Service Add-in generates as part of the metadata generation also contains the values you specify for the binding properties. You can later import this binding file in the BizTalk Server Administration console to create the WCF-custom or WCF-OracleEBS receive port with the binding properties already set. For more information about creating a WCF-custom or WCF-OracleEBS port using the binding file, see Configuring a Physical Port Binding Using a Port Binding File .	

Binding Property	Description
InboundOperationType	Specifies the inbound operation that you want to perform. To receive notification messages, set this to Notification .
NotificationPort	Specifies the port number that ODP.NET must open to listen for database change notification from Oracle database.
NotificationStatement	Specifies the SELECT statement used to register for query notifications. The adapter gets a notification message only when the result set for the specified SELECT statement changes.
NotifyOnListenerStart	Specifies whether the adapter sends a notification to the adapter clients when the listener is started.

For a more complete description of these properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For a complete description of how to use the Oracle E-Business adapter to receive notifications from Oracle E-Business Suite, read further.

How to Receive Notification Messages from Oracle E-Business Suite

Performing an operation on Oracle E-Business Suite using the Oracle E-Business adapter with BizTalk Server involves the procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To configure the adapter to receive notification messages, these tasks are:

1. Create a BizTalk project, and then generate schema for the **Notification** inbound operation. Optionally, you can specify values for the **InboundOperationType**, **NotificationPort**, and **NotificationStatement** binding properties.
2. Create a message in the BizTalk project for receiving notification from Oracle E-Business Suite.
3. Create an orchestration as described in the preceding section.
4. Build and deploy the BizTalk project.
5. Configure the BizTalk application by creating physical send and receive ports.

Note	
For inbound operations, like receiving notification messages, you must only configure a one-way WCF-Custom or WCF-OracleEBS receive port. Two-way receive ports are not supported for inbound operations.	

6. Start the BizTalk application.

This topic provides instructions to perform these tasks.

Generating Schema

You must generate the schema for the **Notification** inbound operation. For more information about how to generate the schema, see [Retrieving Metadata for Oracle E-Business Suite Operations in Visual Studio](#).

Perform the following tasks when generating the schema. Skip the first step if you do not want to specify the binding properties at design-time.

1. Specify a value for **InboundOperationType**, **NotificationPort**, and **NotificationStatement** binding properties while generating the schema. For more information about this binding property, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For instructions on how to specify binding properties, see [Specifying Binding Properties](#).
2. Select the contract type as **Service (Inbound operations)**.
3. Generate schema for the **Notification** operation.

Defining Messages and Message Types

The schema that you generated in the previous section describes the "types" required for the messages in the orchestration. A message is typically a variable, the type for which is defined by the corresponding schema. After the schema is generated, you must link it to the messages from the Orchestration view of the BizTalk project.

For this topic, you must create one message to receive notifications from the Oracle database.

Perform the following steps to create messages and link them to schema.

To create messages and link to schema

1. Add an orchestration to the BizTalk project. From the Solution Explorer, right-click the BizTalk project name, point to **Add**, and then click **New Item**. Type a name for the BizTalk orchestration and then click **Add**.
2. Open the orchestration view window of the BizTalk project, if it is not already open. Click **View**, point to **Other Windows**, and then click **Orchestration View**.
3. In the **Orchestration View**, right-click **Messages**, and then click **New Message**.
4. Right-click the newly created message, and then select **Properties Window**.
5. In the **Properties** pane for **Message_1**, do the following:

Use this	To do this
Identifier	Type NotifyReceive .
Message Type	From the drop-down list, expand Schemas , and select <i>Process_Notification.OracleEBSBinding.Notification</i> , where <i>Process_Notification</i> is the name of your BizTalk project. <i>OracleEBSBinding</i> is the schema generated for the Notification operation.

Setting up the Orchestration

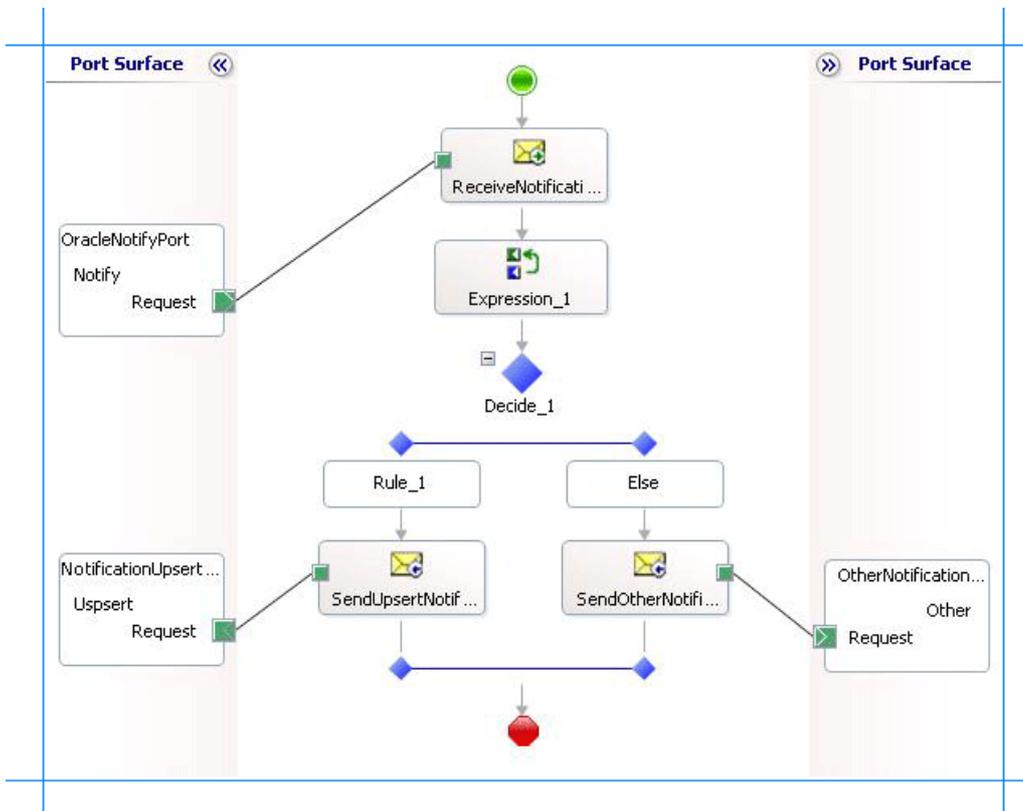

You must create a BizTalk orchestration to use BizTalk Server for receiving notification messages from the Oracle database and then performing tasks based on the type of notification received. In this orchestration, the adapter receives the notification message based on the SELECT statement specified for the **NotificationStatement** binding property. The xpath query specified within the Expression shape extracts the type of notification into a variable, say **NotificationType**. The Decide shape uses the value in this variable to decide on the kind of notification received and takes the appropriate "path" to perform subsequent operations. As mentioned in the preceding section, the orchestration will perform the following operations based on the kind of notification message received.

- If the notification message is for an Insert or Update operation, the adapter client copies the message to C:\TestLocation\UpsertNotification folder.
- If the notification message is for any other operation, for example Delete, the adapter client copies the message to C:\TestLocation\OtherNotificaiton folder.

So, your orchestration must contain the following:

- A one-way receive port to receive notification messages.
- An Expression shape that contains an xpath query to extract the kind of notification received.
- A Decide shape to include a decision block in the orchestration. In this decision block, the application decides on what subsequent operations to perform based on the notification message received.
- Two one-way send ports that finally receive the notification messages.
- Receive shape.

A sample orchestration resembles the following:

Adding Message Shapes

Make sure you specify the following properties for each of the message shapes. The names listed in the **Shape** column are the names of the message shapes as displayed in the orchestration diagram.

Shape	Shape Type	Properties
ReceiveNotification	Receive	<ul style="list-style-type: none"> • Set Name to <i>ReceiveNotification</i> • Set Activate to <i>True</i>

Adding an Expression Shape

The purpose of including an Expression shape in the orchestration is to have an xpath query to extract the kind of notification message received. Before creating an xpath query, let us look at the format of a notification message. A typical notification message resembles the following:

```
<?xml version="1.0" encoding="utf-8" ?>
<Notification xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/">
  <Details>
    <NotificationDetails>
      <ResourceName>SCOTT.ACCOUNTACTIVITY</ResourceName>
      <Info>1</Info>
      <QueryId>0</QueryId>
    </NotificationDetails>
  </Details>
  <Info>Insert</Info>
  <ResourceNames>
    <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">SCOTT.ACCOUNT
ACTIVITY</string>
  </ResourceNames>
  <Source>Data</Source>
  <Type>Change</Type>
</Notification>
```

As you see, the information about the type of the notification is available within the `<Info>` tag, within the parent `<Notification>` tag. So, as part of this expression shape you must:

- Create a variable that contains the value within the `<Info>` tag and set its type to `System.String`. For more information about creating variables, see <http://go.microsoft.com/fwlink/?LinkId=102357>.

For this topic, name the variable as **NotificationType**.

- Create an xpath query to extract the value from the `<Info>` tag. The xpath query will resemble the following:

```
NotificationType = xpath(NotifyReceive, "string(/*[local-name()='Notification']/*[local
-name()='Info']/text())");
```

In this xpath query, **NotifyReceive** is the message you created for receiving notification messages. The excerpt within the `string` function indicates that the query must extract the value within the `<Info>` tag, which in turn is within the `<Notification>` tag. Finally, the value extracted by the query is assigned to the **NotificationType** variable.

Adding a Decide Shape

The purpose of adding a Decide shape is to include a decision block in the orchestration to decide what subsequent operations to perform based on the kind of notification message received. The decision is made on the basis of the value of the **NotificationType** variable. In this topic, the orchestration makes a decision based on the kind of notification message received. So, the condition in the Rule shape is specified as follows:

```
NotificationType.Equals("Insert") | NotificationType.Equals("Update")
```

This condition suggests that if the value for **NotificationType** variable is Insert or Update, the orchestration will perform one set of tasks. If the value of **NotificationType** variable is anything else, the orchestration will perform other set of tasks.

As mentioned in the preceding sections, to demonstrate a simple approach, the orchestration will copy messages to different folders based on the notification message type. So, within the Rule and Else blocks, you must add Send shapes to send the messages to different ports. For this topic, name the Send shape in the Rule block as **SendUpsertNotification** and the Send shape in the Else block as **SendOtherNotification**.

Adding Ports

You must now add the following logical ports to the orchestration:

- One-way receive port to receive notification messages from the Oracle database.
- One-way send port to send notification messages for Insert and Update operations to a specific folder.
- One-way send port to send notification messages for any other operations to a specific folder.

Make sure you specify the following properties for each of the logical ports. The names listed in the **Port** column are the names of the ports as displayed in the orchestration diagram shown earlier in this topic.

Port	Properties
OracleNotifyPort	<ul style="list-style-type: none"> • Set Identifier to <i>OracleNotifyPort</i> • Set Type to <i>OracleNotifyPortType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Receive</i>
NotificationUpsertPort	<ul style="list-style-type: none"> • Set Identifier to <i>NotificationUpsertPort</i> • Set Type to <i>NotificationUpsertPortType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Send</i>
OtherNotificationPort	<ul style="list-style-type: none"> • Set Identifier to <i>OtherNotificationPort</i> • Set Type to <i>OtherNotificationPortType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Send</i>

Specify Messages for Action Shapes and Connect to Ports

The following table specifies the properties and their values that you should set to specify messages for action shapes and to link the messages to the ports. The names listed in the **Shape** column are the names of the message shapes as displayed in the orchestration diagram shown earlier in this topic.

Shape	Properties
ReceiveNotification	<ul style="list-style-type: none"> • Set Message to <i>NotifyReceive</i> • Set Operation to <i>OracleNotifyPort.Notify.Request</i>
SendUpsertNotification	<ul style="list-style-type: none"> • Set Message to <i>NotifyReceive</i> • Set Operation to <i>NotificationUpsertPort.Upsert.Request</i>
SendOtherNotification	<ul style="list-style-type: none"> • Set Message to <i>Select</i> • Set Operation to <i>OtherNotificationPort.Other.Request</i>

After you have specified these properties, the message shapes and ports are connected and your orchestration is complete.

You must now build the BizTalk solution and deploy it to a BizTalk Server. For more information, see "Building and Running Orchestrations" at <http://go.microsoft.com/fwlink/?LinkId=102359>.

Configuring the BizTalk Application

After you have deployed the BizTalk project, the orchestration you created earlier is listed under the **Orchestrations** pane in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. For more information about configuring an application, see "How to Configure an Application" at <http://go.microsoft.com/fwlink/?LinkID=196961>.

Configuring an application involves:

- Selecting a host for the application.
- Mapping the ports that you created in your orchestration to physical ports in the BizTalk Server Administration console. For this orchestration you must:
 - Define a physical WCF-Custom or WCF-OracleEBS one-way receive port. This port listens for notifications coming from Oracle E-Business Suite. For information about how to create receive ports, see [Manually Configuring a Physical Port Binding to the Oracle E-Business Adapter](#). Make sure you specify the following binding properties for the receive port.

◆Important
 You do not need to perform this step if you specified the binding properties at design-time. In such a case, you can create a WCF-custom or WCF-OracleEBS receive port, with the required binding properties set, by importing the binding file created by the Consume Adapter Service Add-in. For more information see [Configuring a Physical Port Binding Using a Port Binding File](#).

Binding Property	Value
InboundOperationType	Set this to Notification .
NotificationPort	<p>Specifies the port number that ODP.NET must open to listen for database change notification from Oracle database. Set this to the same port number that you must have added to the Windows Firewall exceptions list. For instructions on how to add ports to Windows Firewall exceptions list, see http://go.microsoft.com/fwlink/?LinkID=196959.</p> <p>◆Important If you set this to the default value of -1, you will have to completely disable Windows Firewall to receive notification messages.</p>
NotificationStatement	<p>Set this to:</p> <pre style="border: 1px solid black; padding: 5px; margin: 5px 0;">SELECT TID,ACCOUNT,PROCESSED FROM SCOTT.ACCOUNTACTIVITY WHERE PROCESSED = 'n'</pre> <p>📌Note You must specify the table name along with the schema name. For example, SCOTT.ACCOUNTACTIVITY.</p>
NotifyOnListenerStart	Set this to True .

For more information about the different binding properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#).

◆Important

If you are configuring notifications for an interface table, you must set the application context by specifying the requisite binding properties. For more information about setting the application context see [Setting Application Context](#).

Note

We recommend configuring the transaction isolation level and the transaction timeout while performing inbound operations using the Oracle E-Business adapter. You can do so by adding the service behavior while configuring the WCF-Custom or WCF-OracleEBS receive port. For instruction on how to add the service behavior, see [Configure Transaction Isolation Level and Transaction Timeout](#).

- Define a location on the hard disk and a corresponding file port where the BizTalk orchestration will drop the notification messages from the Oracle database for Insert and Update operations. Configure this port to drop notification messages to the folder C:\TestLocation\UpsertNotification.
- Define a location on the hard disk and a corresponding file port where the BizTalk orchestration will drop the notification messages from the Oracle database for all other operations. Configure this port to drop notification messages to the folder C:\TestLocation\OtherNotification.

Starting the Application

You must start the BizTalk application for receiving notification messages from the Oracle database and for performing the subsequent Select and Update operations. For instructions on starting a BizTalk application, see "How to Start an Orchestration" at <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The WCF-Custom or WCF-OracleEBS one-way receive port, which receives the notification messages from the Oracle database is running.
- The two FILE send ports, which receive messages from Oracle database, are running.
- The BizTalk orchestration for the operation is running.

Executing the Operation

After you start the BizTalk orchestration, the following set of actions take place:

- Because the **NotifyOnListenerStart** binding property is set to **True**, you receive the following message:

```
<?xml version="1.0" encoding="utf-8" ?>
<Notification xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/">
  <Info>ListenerStarted</Info>
  <Source>OracleEBSBinding</Source>
  <Type>Startup</Type>
</Notification>
```

Note that the value in the `<Info>` tag is "ListenerStarted". Hence, this message is received in C:\TestLocation\OtherNotification folder.

- Insert a record in the ACCOUNTACTIVITY table. You will receive a notification message resembling the following:

```
<?xml version="1.0" encoding="utf-8" ?>
<Notification xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/">
  <Details>
    <NotificationDetails>
      <ResourceName>SCOTT.ACCOUNTACTIVITY</ResourceName>
```

```

    <Info>1</Info>
    <QueryId>0</QueryId>
  </NotificationDetails>
</Details>
<Info>Insert</Info>
<ResourceNames>
  <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">SCOTT.AC
COUNTACTIVITY</string>
</ResourceNames>
<Source>Data</Source>
<Type>Change</Type>
</Notification>

```

Note that the value in the `<Info>` tag is "Insert". Hence, this message is received in C:\TestLocation\UpsertNotification folder.

- Update a record in the ACCOUNTACTIVITY table. You will receive a notification message resembling the following:

```

<?xml version="1.0" encoding="utf-8" ?>
<Notification xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/">
  <Details>
    <NotificationDetails>
      <ResourceName>SCOTT.ACCOUNTACTIVITY</ResourceName>
      <Info>32</Info>
      <QueryId>0</QueryId>
    </NotificationDetails>
  </Details>
<Info>Update</Info>
<ResourceNames>
  <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">SCOTT.AC
COUNTACTIVITY</string>
</ResourceNames>
<Source>Data</Source>
<Type>Change</Type>
</Notification>

```

Note that the value in the `<Info>` tag is "Update". Hence, this message is received in C:\TestLocation\UpsertNotification folder.

- Delete a record from the ACCOUNTACTIVITY table. You will receive a notification message resembling the following:

```

<?xml version="1.0" encoding="utf-8" ?>
<Notification xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/">
  <Details>
    <NotificationDetails>
      <ResourceName>SCOTT.ACCOUNTACTIVITY</ResourceName>
      <Info>16</Info>
      <QueryId>0</QueryId>
    </NotificationDetails>
  </Details>
<Info>Delete</Info>
<ResourceNames>
  <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">SCOTT.AC
COUNTACTIVITY</string>
</ResourceNames>
<Source>Data</Source>
<Type>Change</Type>

```

```
</Notification>
```

Note that the value in the `<Info>` tag is "Delete". Hence, this message is received in C:\TestLocation\OtherNotification folder.

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the binding file. Once you generate a binding file, you can import the configuration settings from the file, so that you do not need to create the send ports and receive ports for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

Performing Complex Operations After Receiving Notification Messages

For simplicity and better understanding, the orchestration in this topic copies messages to different folders based on the notification type. However, in real-world scenarios you might want to perform more complex operations. You can perform similar procedures as provided in this topic and build on them to perform the operations you wish. For example, you can change the orchestration to insert records in another table if you get a notification message for an Insert operation on the ACCOUNTACTIVITY table. In such a case, you can make appropriate changes within the Decide shape.

[Receiving Database Change Notifications Using BizTalk Server](#)

Receiving Database Change Notifications Incrementally Using BizTalk Server

◆ Important

For the sake of brevity, this topic only describes how to receive notifications incrementally. In business scenarios, the orchestration must ideally include the logic to extract the kind of notification message received and then perform any subsequent operations. In other words, the orchestration described in this topic must be built on top of the orchestration described in [Processing Notification Messages to Perform Specific Tasks](#).

This topic demonstrates how to configure the Oracle E-Business adapter to receive incremental query notification messages from Oracle. To demonstrate incremental notifications, we consider a table, ACCOUNTACTIVITY, with a "Processed" column. When a new record is inserted to this table, the value of the "Processed" column is set to 'n'. You can configure the adapter to receive incremental notifications by doing the following:

- Register for notifications using a SELECT statement that retrieves all records that have "Processed" column as 'n'. You can do so by specifying the SELECT statement for the **NotificationStatement** binding property.
- For rows which have been notified for, update the "Processed" column to 'y'.

This topic demonstrates how to create a BizTalk orchestration and configure a BizTalk application to achieve this.

Configuring Notifications with the Oracle E-Business Adapter Binding Properties

The table below summarizes the Oracle E-Business adapter binding properties that you use to configure receiving notifications from Oracle E-Business Suite. You must specify these binding properties while configuring the receive port in the BizTalk Server Administration console.

📌 Note

You may choose to specify these binding properties when generating the schema for the **Notification** operation, even though it is not mandatory. If you do so, the port binding file that the Consume Adapter Service Add-in generates as part of the metadata generation also contains the values you specify for the binding properties. You can later import this binding file in the BizTalk Server Administration console to create the WCF-custom or WCF-OracleEBS receive port with the binding properties already set. For more information about creating a receive port using the binding file, see [Configuring a Physical Port Binding Using a Port Binding File](#).

Binding Property	Description
InboundOperationType	Specifies the inbound operation that you want to perform. To receive notification messages, set this to Notification .
NotificationPort	Specifies the port number that ODP.NET must open to listen for database change notification from Oracle database.
NotificationStatement	Specifies the SELECT statement used to register for query notifications. The adapter gets a notification message only when the result set for the specified SELECT statement changes.
NotifyOnListenerStart	Specifies whether the adapter sends a notification to the adapter clients when the listener is started.

For a more complete description of these properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For a complete description of how to use the Oracle E-Business adapter to receive notifications from Oracle E-Business Suite, read further.

How This Topic Demonstrates Receiving Notification Messages

In this topic, to demonstrate how the Oracle E-Business adapter supports receiving incremental database change notification

messages from Oracle E-Business Suite, we will configure the adapter to receive notifications for changes to the ACCOUNTACTIVITY table. Let us assume that the ACCOUNTACTIVITY table has columns "TID", "Account", and "Processed". Whenever a new record is added, the value of the "Processed" column is set to 'n'. So, to get incremental notifications you will have to do the following tasks as part of the BizTalk orchestration:

- Get notification for all records where "Processed" is 'n'. You can do this by specifying a SELECT statement as a notification statement.
- After the notification is received for a certain record, set "Processed" to 'y'. You can do this by executing a stored procedure, PROCESS_RECORDS, which updates the "Processed" column.

To demonstrate receiving incremental notifications, we do the following:

- Generate schema for the **Notification** (inbound operation), and **PROCESS_RECORDS** (outbound operation) on the ACCOUNTACTIVITY table.
- Create an orchestration that has the following:
 - A receive location to receive notification messages. You can configure for notification by specifying the SELECT statement as:

```
SELECT TID,ACCOUNT,PROCESSED FROM SCOTT.ACCOUNTACTIVITY WHERE PROCESSED = 'n'
```

Note

You must specify the table name along with the schema name. For example, SCOTT.ACCOUNTACTIVITY.

- A send port to update the rows for which notification has already been sent. You will execute the PROCESS_RECORDS stored procedure on this port to set the value of "Processed" column to 'y' for the records for which notification is received.

Note that this operation must be executed after receiving the notification messages so that the processed rows are updated. To do away with the overhead of waiting to get the notification response and then manually dropping a request message to execute the PROCESS_RECORDS procedure, you will generate the request message for PROCESS_RECORDS procedure within the orchestration itself. You can do so by using the **Construct Message** shape within an orchestration.

How to Receive Notification Messages from Oracle E-Business Suite

Performing an operation on Oracle E-Business Suite using Oracle E-Business adapter with BizTalk Server involves the procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To configure the adapter to receive notification messages, these tasks are:

1. Create a BizTalk project, and then generate schema for the **Notification** (inbound operation) and **PROCESS_RECORDS** procedure (outbound operation) on the ACCOUNTACTIVITY table. Optionally, you can specify values for the **InboundOperationType**, **NotificationPort**, and **NotificationStatement** binding properties.
2. Create a message in the BizTalk project for receiving notification from Oracle E-Business Suite.
3. Create messages in the BizTalk project for executing the PROCESS_RECORDS stored procedure and receiving response messages.
4. Create an orchestration that does the following:
 - Receives notification message from Oracle E-Business Suite.
 - Creates a message to execute the PROCESS_RECORDS procedure.

- Sends this message to Oracle E-Business Suite to select and update the records and receive a response.

5. Build and deploy the BizTalk project.
6. Configure the BizTalk application by creating physical send and receive ports.

Note

For inbound operations, like receiving notification messages, you must only configure a one-way WCF-Custom or WCF-OracleEBS receive port. Two-way receive ports are not supported for inbound operations.

7. Start the BizTalk application.

This topic provides instructions to perform these tasks.

Generating Schema

You must generate the schema for the **Notification** operation and **PROCESS_RECORDS** procedure. See [Retrieving Metadata for Oracle E-Business Suite Operations in Visual Studio](#) for more information about how to generate the schema. Perform the following tasks when generating the schema. Skip the first step if you do not want to specify the binding properties at design-time.

1. Specify a value for **InboundOperationType**, **NotificationPort**, and **NotificationStatement** binding properties while generating the schema. For more information about this binding property, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For instructions on how to specify binding properties, see [Specifying Binding Properties](#).
2. Select the contract type as **Service (Inbound operations)**.
3. Generate schema for the **Notification** operation.
4. Select the contract type as **Client (Outbound operations)**.
5. Generate schema for the **PROCESS_RECORDS** procedure. This procedure is available under the **ACCOUNT_PKG** package.

Defining Messages and Message Types

The schema that you generated earlier describes the "types" required for the messages in the orchestration. A message is typically a variable, the type for which is defined by the corresponding schema. Once the schema is generated, you must link it to the messages from the Orchestration view of the BizTalk project.

For this topic, you must create three messages—one to receive notifications from the Oracle E-Business Suite, one to execute the **PROCESS_RECORDS** procedure, and one to receive the response for the procedure.

Perform the following steps to create messages and link them to schema.

To create messages and link to schema

1. Add an orchestration to the BizTalk project. From the Solution Explorer, right-click the BizTalk project name, point to **Add**, and then click **New Item**. Type a name for the BizTalk orchestration and then click **Add**.
2. Open the orchestration view window of the BizTalk project, if it is not already open. Click **View**, point to **Other Windows**, and then click **Orchestration View**.
3. In the **Orchestration View**, right-click **Messages**, and then click **New Message**.
4. Right-click the newly created message, and then select **Properties Window**.
5. In the **Properties** pane for **Message_1**, do the following:

Use this	To do this
Identifier	Type NotifyReceive .
Message Type	From the drop-down list, expand Schemas , and select <i>OracleNotifyIncremental.OracleEBSBinding.Notification</i> , where <i>OracleNotifyIncremental</i> is the name of your BizTalk project. <i>OracleEBSBinding</i> is the schema generated for the Notification operation.

6. Repeat step 3 to create two new messages. In the **Properties** pane for the new message, do the following:

Set Identifier to	Set Message Type to
Procedure	<i>OracleNotifyIncremental.OracleEBSBinding1.PROCESS_RECORDS</i> , where <i>OracleEBSBinding1</i> is the schema generated for the PROCESS_RECORDS procedure.
ProcedureResponse	<i>OracleNotifyIncremental.OracleEBSBinding1.PROCESS_RECORDSResponse</i>

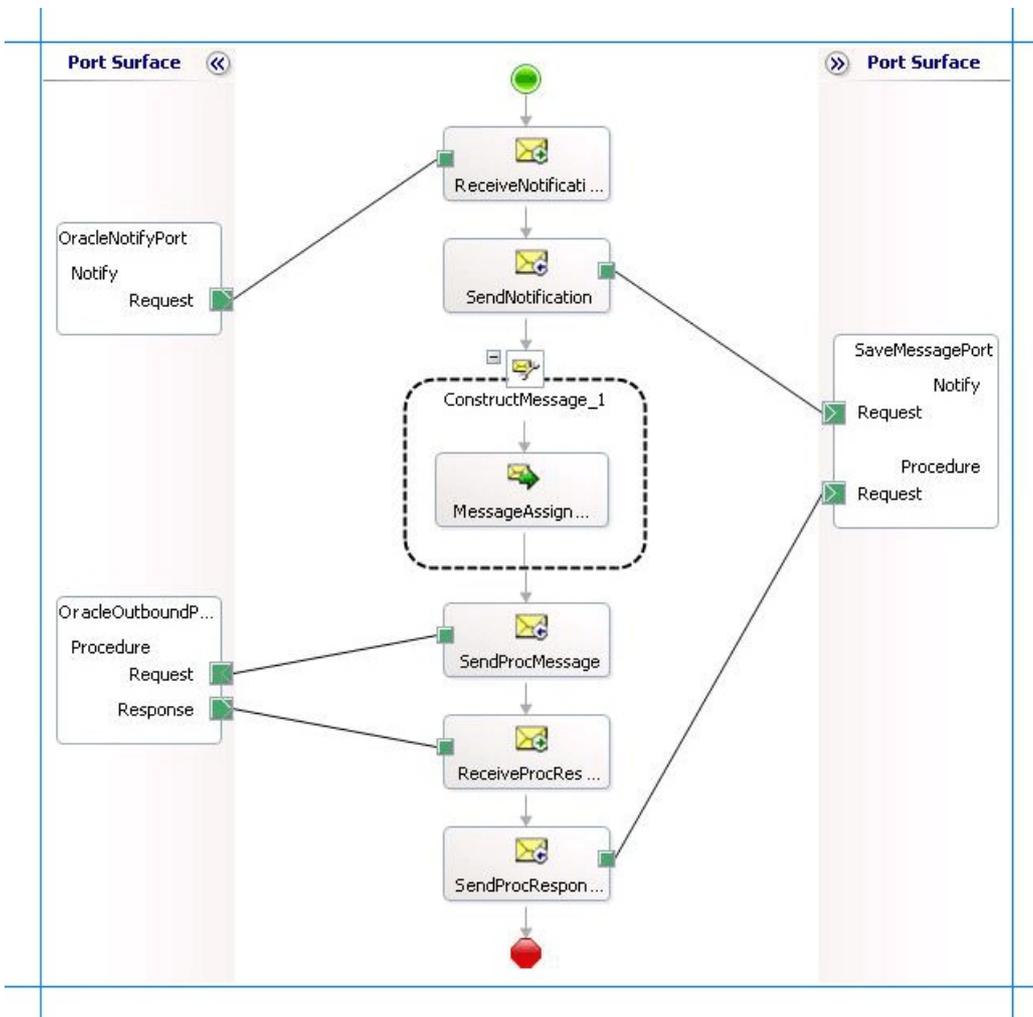

Setting up the Orchestration

You must create a BizTalk orchestration to use BizTalk Server for receiving notification messages from Oracle E-Business Suite and then updating the rows for which notification was received. In this orchestration, the adapter receives the notification message based on the SELECT statement specified for the **NotificationStatement** binding property. The notification message is received at a FILE location. Once the response is received, the orchestration constructs a message to invoke the PROCESS_RECORDS procedure, which updates the rows for which notification is received. The response for this message is also received at the same FILE location.

So, your orchestration must contain the following:

- A one-way WCF-Custom or WCF-OracleEBS receive port to receive notification messages.
- A two-way WCF-Custom or WCF-OracleEBS send port to send messages to execute the PROCESS_RECORDS procedure.
- A **Construct Message** shape to construct messages, to execute PROCESS_RECORDS procedure, within the orchestration.
- A FILE send port to save the notification message and the response for the PROCESS_RECORDS procedure.
- Receive and send shapes.

A sample orchestration resembles the following.

Adding Message Shapes

Make sure you specify the following properties for each of the message shapes. The names listed in the Shape column are the names of the message shapes as displayed in the just-mentioned orchestration.

Shape	Shape Type	Properties
ReceiveNotification	Receive	<ul style="list-style-type: none"> Set Name to <i>ReceiveNotification</i> Set Activate to <i>True</i>
SaveNotification	Send	<ul style="list-style-type: none"> Set Name to <i>SaveNotification</i>
SendProcMessage	Send	<ul style="list-style-type: none"> Set Name to <i>SendProcMessage</i>
ReceiveProcResponse	Receive	<ul style="list-style-type: none"> Set Name to <i>ReceiveProcResponse</i>
SaveProcResponse	Send	<ul style="list-style-type: none"> Set Name to <i>SaveProcResponse</i>

Adding Construct Message Shape

You can use the **Construct Message** shape to generate a request message within the orchestration to execute the PROCESS_RECORDS procedure. To do so, you must add a **Construct Message** shape and within that a **Message Assignment** shape to your orchestration. For this example, the **Message Assignment** shape invokes code that generates a message that is sent to Oracle E-Business Suite to execute the procedure. The **Message Assignment** shape also sets the action for the message to be sent to Oracle E-Business Suite.

For the construct message shape, set the **Message Constructed** property to **Procedure**.

The code to generate the response could be part of the same Visual Studio solution as your BizTalk project. A sample code for

generating a response message looks like this.

```
namespace MessageCreator
{
    public class MessageCreator
    {
        private static XmlDocument Message;
        private static string XmlFileLocation;
        private static string ResponseDoc;

        public static XmlDocument XMLMessageCreator()
        {
            XmlFileLocation = "C:\\\\TestLocation\\MessageIn";
            try
            {
                ResponseDoc = (Directory.GetFiles(XmlFileLocation, "*.xml", SearchOption.To
                pDirectoryOnly))[0];
            }
            catch (Exception ex)
            {
                Console.WriteLine("Trying to get XML from: " + XmlFileLocation);
                Console.WriteLine("EXCEPTION: " + ex.ToString());
                throw ex;
            }
            //Create Message From XML
            Message = new XmlDocument();
            Message.PreserveWhitespace = true;
            Message.Load(ResponseDoc);
            return Message;
        }
    }
}
```

For the above code excerpt to be able to generate a request message, you must have an XML request message (for the PROCESS_RECORDS procedure) in the location specified for the `XmlFileLocation` variable.

Note

After you build the project, `MessageCreator.dll` will be created in the project directory. You must add this DLL to the global assembly cache (GAC). Also, you must add the `MessageCreator.dll` as a reference in the BizTalk project.

Add the following expression to invoke this code from the **Message Assignment** shape and to set the action for message. To add an expression, double-click the **Message Assignment** shape to open the Expression Editor.

```
Procedure = MessageCreator.MessageCreator.XMLMessageCreator();
Procedure(WCF.Action) = "PackageApis/SCOTT/ACCOUNT_PKG/PROCESS_RECORDS";
```

Adding Ports

Make sure you specify the following properties for each of the logical ports. The names listed in the Port column are the names of the ports as displayed in the orchestration.

Port	Properties
OracleNotifyPort	<ul style="list-style-type: none">Set Identifier to <i>OracleNotifyPort</i>Set Type to <i>OracleNotifyPortType</i>Set Communication Pattern to <i>One-Way</i>Set Communication Direction to <i>Receive</i>

SaveMessagePort	<ul style="list-style-type: none"> • Set Identifier to <i>SaveMessagePort</i> • Set Type to <i>SaveMessagePortType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Send</i> • Create an operation <i>Notify</i>. This operation is used for notification messages. • Create an operation <i>Procedure</i>. This operation is used for select response messages.
OracleOutboundPort	<ul style="list-style-type: none"> • Set Identifier to <i>OracleOutboundPort</i> • Set Type to <i>OracleOutboundPortType</i> • Set Communication Pattern to <i>Request-Response</i> • Set Communication Direction to <i>Send-Receive</i>

Specify Messages for Action Shapes and Connect to Ports

The following table specifies the properties and their values that you should set to specify messages for action shapes and to link the messages to the ports. The names listed in the Shape column are the names of the message shapes as displayed in the orchestration mentioned earlier.

Shape	Properties
ReceiveNotification	<ul style="list-style-type: none"> • Set Message to <i>NotifyReceive</i> • Set Operation to <i>OracleNotifyPort.Notify.Request</i>
SaveNotification	<ul style="list-style-type: none"> • Set Message to <i>NotifyReceive</i> • Set Operation to <i>SaveMessagePort.Notify.Request</i>
SendProcMessage	<ul style="list-style-type: none"> • Set Message to <i>Procedure</i> • Set Operation to <i>OracleOutboundPort.Procedure.Request</i>
ReceiveProcResponse	<ul style="list-style-type: none"> • Set Message to <i>ProcedureResponse</i> • Set Operation to <i>OracleOutboundPort.Procedure.Response</i>
SaveProcResponse	<ul style="list-style-type: none"> • Set Message to <i>ProedureResponse</i> • Set Operation to <i>SaveMessagePort.Procedure.Request</i>

After you have specified these properties, the message shapes and ports are connected and your orchestration is complete.

You must now build the BizTalk solution and deploy it to a BizTalk Server. For more information, see "Building and Running Orchestrations" at <http://go.microsoft.com/fwlink/?LinkId=102359>.

Configuring the BizTalk Application

After you have deployed the BizTalk project, the orchestration you created earlier is listed under the **Orchestrations** pane in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. For more information about configuring an application, see "How to Configure an Application" at <http://go.microsoft.com/fwlink/?LinkID=196961>.

Configuring an application involves:

- Selecting a host for the application.
- Mapping the ports that you created in your orchestration to physical ports in the BizTalk Server Administration console. For this orchestration you must:
 - Define a physical WCF-Custom or WCF-OracleEBS one-way receive port. This port listens for notifications coming from Oracle E-Business Suite. For information about how to create receive ports, see [Manually Configuring a Physical Port Binding to the Oracle E-Business Adapter](#). Make sure you specify the following binding properties for the receive port.

◆Important
 You do not need to perform this step if you specified the binding properties at design-time. In such a case, you can create a receive port, with the required binding properties set, by importing the binding file created by the Consume Adapter Service Add-in. For more information see [Configuring a Physical Port Binding Using a Port Binding File](#).

Binding Property	Value
InboundOperationType	Set this to Notification .
NotificationPort	<p>Specifies the port number that ODP.NET must open to listen for database change notification from Oracle database. Set this to the same port number that you must have added to the Windows Firewall exceptions list. For instructions on how to add ports to Windows Firewall exceptions list, see http://go.microsoft.com/fwlink/?LinkID=196959.</p> <p>◆Important If you set this to the default value of -1, you will have to completely disable Windows Firewall to receive notification messages.</p>
NotificationStatement	<p>Set this to:</p> <pre>SELECT TID,ACCOUNT,PROCESSED FROM SCOTT.ACCOUNTACTIVITY WHERE PROCESSED = 'n'</pre> <p>📌Note You must specify the table name along with the schema name. For example, SCOTT.ACCOUNTACTIVITY.</p>
NotifyOnListenerStart	Set this to True .

For more information about the different binding properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#).

◆Important

If you are configuring notifications for an interface table, you must set the application context by specifying the requisite binding properties. For more information about setting the application context see [Setting Application Context](#).

Note

We recommend configuring the transaction isolation level and the transaction timeout while performing inbound operations using the Oracle E-Business adapter. You can do so by adding the service behavior while configuring the WCF-Custom or WCF-OracleEBS receive port. For instruction on how to add the service behavior, see [Configure Transaction Isolation Level and Transaction Timeout](#).

- Define a physical WCF-Custom or WCF-OracleEBS send port to send messages to Oracle E-Business Suite to execute the PROCESS_REOCRDS procedure. You must also specify the action in the send port.
- Define a location on the hard disk and a corresponding file port where the BizTalk orchestration will drop the messages from Oracle E-Business Suite. These will be the notification messages received from Oracle E-Business Suite and messages for the PROCESS_RECORDS procedure you execute through the WCF-Custom or WCF-OracleEBS send port.

Starting the Application

You must start the BizTalk application for receiving notification messages from Oracle E-Business Suite and for executing the PROCESS_RECORDS procedure. For instructions on starting a BizTalk application, see "How to Start an Orchestration" at <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The WCF-Custom or WCF-OracleEBS one-way receive port, which receives the notification messages from Oracle E-Business Suite is running.
- The WCF-Custom or WCF-OracleEBS send port to execute the PROCESS_RECORDS procedure is running.
- The FILE send port, which receives messages from Oracle E-Business Suite, is running.
- The BizTalk orchestration for the operation is running.

Executing the Operation

Assume that the ACCOUNTACTIVITY table already has some records. Also, make sure the XML message to execute PROCESS_RECORDS procedure is available at C:\TestLocation\Messageln. The XML file should resemble the following:

```
<PROCESS_RECORDS xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/PackageApis/SCOTT/ACCOUNT_PKG" />
```

Once the BizTalk orchestration is started, the following set of actions take place, in the same sequence:

- The adapter receives a notification message that resembles the following:

```
<?xml version="1.0" encoding="utf-8" ?>
<Notification xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/">
  <Info>ListenerStarted</Info>
  <Source>OracleEBSBinding</Source>
  <Type>Startup</Type>
</Notification>
```

This message notifies that the receive port for receiving the notification messages is started. Note that the value for the <Info> element is "ListnerStarted".

- The adapter executes the PROCESS_RECORDS procedure. The next response from Oracle E-Business Suite is for the procedure.

```

<?xml version="1.0" encoding="utf-8" ?>
<PROCESS_RECORDSResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Package
Apis/SCOTT/ACCOUNT_PKG">
  <TABLE_DATA>
    <xs:schema id="NewDataSet" xmlns:xs="http://www.w3.org/2001/XMLSchema" xmlns:msdat
a="urn:schemas-microsoft-com:xml-msdata">
      <xs:element msdata:IsDataSet="true" name="NewDataSet">
        <xs:complexType>
          <xs:sequence>
            <xs:element minOccurs="0" maxOccurs="unbounded" name="NewTable">
              <xs:complexType>
                <xs:sequence>
                  <xs:element minOccurs="0" name="TID" type="xs:decimal" />
                  <xs:element minOccurs="0" name="ACCOUNT" type="xs:decimal" />
                  <xs:element minOccurs="0" name="PROCESSED" type="xs:string" />
                </xs:sequence>
              </xs:complexType>
            </xs:element>
          </xs:sequence>
        </xs:complexType>
      </xs:element>
    </xs:schema>
    <diffgr:diffgram xmlns:diffgr="urn:schemas-microsoft-com:xml-diffgram-v1">
      <NewDataSet xmlns="">
        <NewTable>
          <TID>1</TID>
          <ACCOUNT>100001</ACCOUNT>
          <PROCESSED>n</PROCESSED>
        </NewTable>
        <NewTable>
          .....
          .....
        </NewTable>
        .....
        .....
      </NewDataSet>
    </diffgr:diffgram>
  </TABLE_DATA>
</PROCESS_RECORDSResponse>

```

This is the response for the SELECT statement execute as part of the PROCESS_RECORDS procedure.

- The PROCESS_RECORDS procedure also updates the rows to set PROCESSED to 'y'. Hence, the adapter receives another notification for the Update operation.

```

<?xml version="1.0" encoding="utf-8" ?>
<Notification xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/">

```

```

<Details>
  <NotificationDetails>
    <ResourceName>SCOTT.ACCOUNTACTIVITY</ResourceName>
    <Info>32</Info>
    <QueryId>0</QueryId>
  </NotificationDetails>
</Details>
<Info>Update</Info>
<ResourceNames>
  <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">SCOTT.AC
COUNTACTIVITY</string>
</ResourceNames>
<Source>Data</Source>
<Type>Change</Type>
</Notification>

```

Note that the `Info` element contains "Update".

- After the second notification, the adapter again executes the `PROCESS_RECORDS` procedure. However, now because there are no records where `PROCESSED` column is set to 'n', the procedure returns an empty response resembling the following.

```

<?xml version="1.0" encoding="utf-8" ?>
<PROCESS_RECORDSResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Package
Apis/SCOTT/ACCOUNT_PKG">
  <TABLE_DATA>
    <xs:schema id="NewDataSet" xmlns:xs="http://www.w3.org/2001/XMLSchema" xmlns:msdat
a="urn:schemas-microsoft-com:xml-msdata">
      <xs:element msdata:IsDataSet="true" name="NewDataSet">
        <xs:complexType>
          <xs:sequence>
            <xs:element minOccurs="0" maxOccurs="unbounded" name="NewTable">
              <xs:complexType>
                <xs:sequence>
                  <xs:element minOccurs="0" name="TID" type="xs:decimal" />
                  <xs:element minOccurs="0" name="ACCOUNT" type="xs:decimal" />
                  <xs:element minOccurs="0" name="PROCESSED" type="xs:string" />
                </xs:sequence>
              </xs:complexType>
            </xs:element>
          </xs:sequence>
        </xs:complexType>
      </xs:element>
    </xs:schema>
    <diffgr:diffgram xmlns:diffgr="urn:schemas-microsoft-com:xml-diffgram-v1">
      <NewDataSet xmlns="" />
    </diffgr:diffgram>
  </TABLE_DATA>
</PROCESS_RECORDSResponse>

```

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the binding file. Once you generate a binding file, you can import the configuration settings from the file, so that you do not need to create the send ports and receive ports for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

Other Resources

Receiving Database Change Notifications On Multiple Receive Locations

Consider a scenario where you have multiple receive locations created as part of different BizTalk applications configured to receive query notifications for the same table (e.g. ACCOUNTACTIVITY) in the same database. If a hundred records are inserted into the same table, all the receive locations will get the notification message. To effectively receive notifications across multiple receive locations, you can call operations from your BizTalk application in such a way that if a notification is received by one receive location, the other receive location does not get the same notification. So, you can effectively load-balance notifications received on multiple locations.

The tasks required to set up an orchestration to load-balance receiving notifications are same as that for [Receiving Database Change Notifications Incrementally Using BizTalk Server](#). This topic lists the only the difference between the two approaches.

Load-Balancing Query Notifications Across Multiple Receive Locations

Like in the topic [Receiving Database Change Notifications Incrementally Using BizTalk Server](#), you configured incremental notifications by executing a PROCESS_RECORDS procedure. To configure load-balancing, you could execute a stored procedure that deletes the records that have been notified for. For example, consider a stored procedure NOTIFY_LOAD_BALANCE with the following definition:

```
PROCEDURE NOTIFY_LOAD_BALANCE (TABLE_DATA OUT SYS_REFCURSOR) IS
  var int;
BEGIN
  SELECT TID INTO var FROM ACCOUNTACTIVITY WHERE ROWNUM = 1 FOR UPDATE;
  OPEN TABLE_DATA FOR SELECT * FROM ACCOUNTACTIVITY WHERE TID = var;
  DELETE FROM ACCOUNTACTIVITY WHERE TID = var;
END NOTIFY_LOAD_BALANCE;
```

When you execute this stored procedure as part of the BizTalk application, the record for which notification is already received gets deleted. So, the other receive location gets notification for the next record.

Here are the high-level steps you must perform to configure load-balancing for receiving notifications.

1. Create schema for **Notification** (inbound operation) and **NOTIFY_LOAD_BALANCE** procedure (outbound operation).
2. Add an orchestration and add three messages for receiving notification, executing the procedure, and getting response for the procedure.
3. Create an orchestration by adding Send and Receive shapes, Construct Message shape, and ports. You can use the same sample code for constructing a message to invoke the NOTIFY_LOAD_BALANCE stored procedure. Note that while performing the operation in BizTalk Server Administration console, you must have the request message for the NOTIFY_LOAD_BALANCE procedure in the location C:\TestLocation\MessageIn. You do so because the code snippet you invoke as part of the orchestration created in [Receiving Database Change Notifications Incrementally Using BizTalk Server](#) creates a request message based on the request XML present in C:\TestLocation\MessageIn.
4. Build and deploy the application. To demonstrate load-balancing, you must deploy this orchestration at least on two different computers that have BizTalk Server and Oracle E-Business adapter installed.
5. In the BizTalk Server Administration console on both the computers, specify the following binding properties for the WCF-Custom or WCF-OracleEBS receive location:

Binding Property	Value

InboundOperationType	Set this to Notification .
NotificationPort	<p>Specifies the port number that ODP.NET must open to listen for database change notification from Oracle database. Set this to the same port number that you must have added to the Windows Firewall exceptions list. For instructions on how to add ports to Windows Firewall exceptions list, see http://go.microsoft.com/fwlink/?LinkID=196959.</p> <p> Important If you set this to the default value of -1, you will have to completely disable Windows Firewall to receive notification messages.</p>
NotificationStatement	<p>Set this to:</p> <pre>SELECT TID,ACCOUNT,PROCESSED FROM SCOTT.ACCOUNTACTIVITY WHERE PROCESSED = 'n'</pre> <p> Note You must specify the table name along with the schema name. For example, SCOTT.ACCOUNTACTIVITY.</p>
NotifyOnListenerStart	Set this to True .

6. Start the BizTalk application.
7. To start receiving notifications, insert a hundred records into the ACCOUNTACTIVITY table. While doing so, make sure the request XML for invoking the NOTIFY_LOAD_BALANCE procedure is available in C:\TestLocation\MessageIn.
8. Monitor the location (on both the computers) where the BizTalk application will be dropping the notification messages. You will notice that of the hundred records inserted, one location gets notifications for some records while the other location gets notification for the remaining records. Together, both the locations will get notification for all the hundred records.

[Receiving Database Change Notifications Using BizTalk Server](#)

Receiving Database Change Notifications After a Receive Location Breakdown

Consider a scenario where you have a BizTalk application that receives database change notification messages when changes are made to the ACCOUNTACTIVITY table. If the receive location configured as part of the BizTalk application breaks down, and simultaneously records are added into the ACCOUNTACTIVITY table, you will not receive notifications for the recently added records. You will also not know when the receive location is available again. The Oracle E-Business adapter exposes a binding property, **NotifyOnListenerStart**, that you can configure to get a notification that the receive location has recovered. You can specify the following values for the **NotifyOnListenerStart** binding property:

- Set this property to **True**, to receive a notification informing that the receive location is available, as soon as the receive location recovers.
- Set this property to **False**, to not receive a notification informing that the receive location is available, after the receive location recovers.

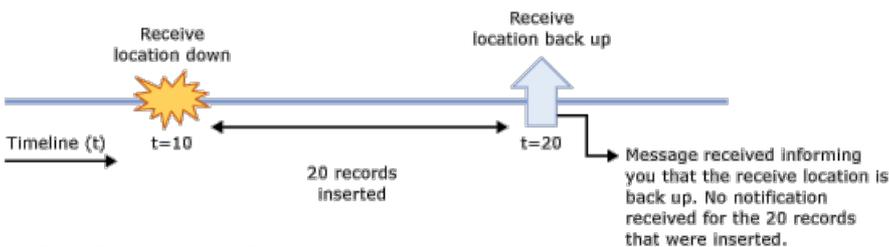

Default is **True**.

Configuring the Oracle E-Business Adapter Behavior

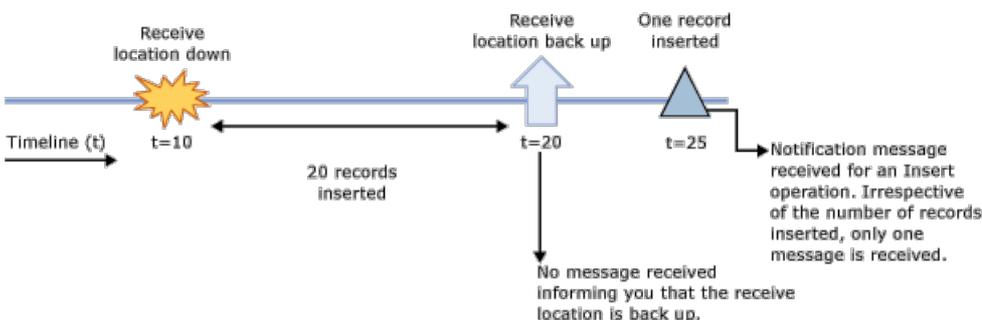

For either of the approaches, you do not need to perform any specific tasks while generating metadata or while configuring the BizTalk application. You only need to set the **NotifyOnListenerStart** binding property accordingly on the WCF-Custom or WCF-OracleEBS receive location. To create the BizTalk application, you must perform the same set of tasks as described in [Receiving Database Change Notifications Incrementally Using BizTalk Server](#). However, when configuring the BizTalk application using BizTalk Server, you can try changing the value of **NotifyOnListenerStart** binding property and see the difference in the two configurations.

The following figure demonstrates how the notifications are received based on the value of the **NotifyOnListenerStart** binding property.

NotifyOnListenerStart = True

NotifyOnListenerStart = False

Note that in the first scenario, when the **NotifyOnListenerStart** is set to **True** and records are inserted into the database table while the receive location was down, the adapter only sends you a notification message when the receive location comes up. The adapter does not perform any operation to process the records that were inserted while the receive location was down. The adapter client must implement the relevant logic in their application to process the records that were inserted while the receive location was down.

Developing Applications By Using the WCF Service Model

Windows Communication Foundation (WCF) provides a programming model called the WCF service model to connect to the Microsoft BizTalk Adapter for Oracle E-Business Suite. The service model was added to WCF to address, in part, some of the limitations of the WCF channel programming model.

The WCF service model uses familiar .NET paradigms to hide the complexities of exchanging SOAP message over a channel. The service model accomplishes this simplification by reading the entire SOAP message into memory before copying the information into .NET data structures. Loading long messages into memory may not be practical for some applications. In these cases, developers should use the WCF channel model. For more information about using the WCF channel model, see [Developing Applications by Using the WCF Channel Model](#).

At the lowest level, the WCF presents the WCF channel model in which clients invoke operations on a service by exchanging SOAP messages over a channel established between client and service endpoints. The WCF channel model exposes data types and methods that enable you to operate directly on the WCF channel architecture. The WCF channel model provides you with direct control over the contents of the SOAP messages you create and over the way both your application and the Oracle E-Business adapter consume them. However, creating well-formed SOAP messages to send over a channel and validating the reply messages returned can be a detailed and exacting task.

The WCF service model uses proxy classes to invoke operations on a target service or to receive operations from a client. The Oracle E-Business adapter exposes the Oracle E-Business Suite as a WCF service on which you can invoke operations.

- The proxy class used to invoke operations on a target service is called a WCF client class. This class models the operations exposed by a service as .NET methods with strongly-typed parameters. By using the WCF service model, you can invoke the operations exposed by the Oracle E-Business adapter as .NET methods on the WCF client. For more information about WCF clients, see "WCF Client Overview" at <http://go.microsoft.com/fwlink/?LinkId=91458>

You can use either of the following tools to generate a WCF client class and associated helper code from the service metadata that the Oracle E-Business adapter exposes:

- **The ServiceModel Metadata Utility Tool (svcutil.exe)**, which ships with WCF.
- **The Add Adapter Service Reference Visual Studio Plug-in**, which ships with the Oracle E-Business adapter and is integrated with the Visual Studio design experience. This tool presents a standard Microsoft Windows interface that provides powerful browsing and searching capabilities on operations that the adapter exposes. For more information about how to generate a WCF client, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).

Overview of Using the WCF Service Model with the Adapter

The Microsoft BizTalk Adapter for Oracle E-Business Suite exposes an Oracle E-Business Suite system as a WCF service. To perform operations on Oracle E-Business Suite artifacts, for example to invoke a stored procedure, you invoke an operation on the adapter, which, in turn, performs the operation on the Oracle E-Business Suite. Your code acts as a client to the WCF service presented by the adapter.

In the Windows Communication Foundation (WCF) service model, the service contract that exists between a client and a service is represented as a .NET interface, and operations are represented as methods on this interface. The Oracle E-Business adapter and WCF provide tools that enable you to generate this interface for targeted operations from the metadata that the adapter exposes. These tools also create a WCF client class that can be used to invoke the operations exposed in the service interface. A client application can call the methods of the WCF client class to invoke operations on the adapter.

The following section explains how to use the WCF service model to invoke operations with a WCF client.

Invoking Operations on the Oracle E-Business Suite with a WCF Client

To use the WCF service model to invoke operations on the Oracle E-Business adapter, you must first generate a WCF client class for the target operations. You can then create an instance of this class, a WCF client, and call its methods to perform these operations on the Oracle E-Business Suite.

To invoke operations on the Oracle E-Business adapter

1. Generate a WCF client class and helper code. Use the Add Adapter Service Reference Visual Studio Plug-in or the ServiceModel Metadata Utility Tool (svcutil.exe) to generate a WCF client class targeted at Oracle E-Business Suite artifacts with which you want to work. For more information about how to generate a WCF client, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).
2. Create a WCF client instance and configure the WCF client. Configuring the WCF client involves specifying the binding and endpoint address (connection URI) that the client will use. You can do this either imperatively in code or declaratively in configuration. The following code creates a WCF client that targets the **Customer Interface** concurrent program in the **Receivables** application in the Oracle E-Business Suite. It also sets the credentials for the Oracle E-Business Suite. The WCF client is initialized from configuration.

```
ConcurrentPrograms_ARClient client = new ConcurrentPrograms_ARClient("OracleEBSBinding
_ConcurrentPrograms_AR"); //picking the binding and address from app.config

client.ClientCredentials.UserName.UserName = "myuser";
client.ClientCredentials.UserName.Password = "mypassword";
```

Note

You can either specify the client binding and endpoint address in the code or declare it in the app.config configuration file. The preceding code snippet uses the latter. For more information on how to use either approaches, see [Specifying a Client Binding for the Oracle E-Business Suite](#).

3. Open the WCF client.

```
client.Open();
```

4. Invoke methods on the WCF client created in step 2 to perform operations on the Oracle E-Business Suite. The following code invokes the **Customer Interface** concurrent program in the **Receivables** application in the Oracle E-Business Suite.

```
string Result = client.RACUST(null, null, null, description, null, recipro_cust, org_id);
```

RACUST is the actual name of the Customer Interface concurrent program. **Customer Interface** is the friendly name of the concurrent program.

5. Close the WCF client.

```
client.Close();
```

Metadata and the WCF Service Model

In the WCF service model, you use the Add Adapter Service Reference Visual Studio Plug-in or the ServiceModel Metadata Utility Tool (svcutile.exe) to do the following:

- Generate a service contract—the WCF service contract—through which your code can receive operations from the adapter. This .NET interface represents the service contract for target operations.
- Generate proxy classes—the WCF client class—through which your code can invoke operations on the adapter.
- Annotated classes that represent the supporting message contracts, operation contracts, and data contracts for the service contract.

For help in understanding the structure of this generated code, see "Understanding Generated Client Code" at <http://go.microsoft.com/fwlink/?LinkId=98365>. This topic specifically describes code that svcutil.exe generates, but its content is also applicable to the code that the Add Adapter Service Reference Plug-in generates.

For information about how to generate a WCF client class or WCF service contract for target operations and about the differences between svcutil.exe and the Add Adapter Service Reference Plug-in, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).

[Developing Applications By Using the WCF Service Model](#)

Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts

You can use the Add Adapter Service Reference Visual Studio Plug-in to generate a WCF client class or a WCF service contract (interface) targeted at selected operations on Oracle E-Business Suite artifacts. You can also use the ServiceModel Metadata Utility Tool (svcutil.exe) to generate the WCF client class or WCF service contract; however, the Add Adapter Service Reference Plug-in exposes the functionality of the ServiceModel Metadata Utility Tool through a standard Microsoft Windows interface. It also provides browse and search capabilities that are not available with the svcutil.exe tool, and it generates a configuration file based on the binding properties that you select when you connect to the Oracle E-Business Suite.

Generating a Client Class by Using the Add Adapter Service Reference Plug-in

Perform the following steps to generate a WCF client class by using the Add Adapter Service Reference Plug-in.

To generate a WCF client class

1. In Visual Studio Solution Explorer, right-click your project, and then click **Add Adapter Service Reference**.
2. After the **Add Adapter Service Reference** dialog box opens, follow the steps in [Retrieving Metadata for Oracle E-Business Suite Operations in Visual Studio](#) to connect to the Oracle E-Business Suite and browse and search for operations. To create a WCF client class for the operations that you select, be sure that **Client (Outbound operations)** is selected from the **Select contract type** drop-down list (this is the default).
3. After you select all of the operations that you want to target, click **OK** to generate the WCF client class.

The Add Adapter Service Reference Plug-in adds two files to your project:

- **OracleEBSBindingClient.cs**. This file contains the generated WCF client class and helper code for the operations that you selected.
- **app.config**. This file contains a binding configuration and client endpoint configurations. These configurations are based on the selections you made when you configured the binding and connection for the Add Adapter Service Reference Plug-in.

Important

While using the Add Adapter Service Reference Visual Studio Plug-in, if you do not specify a value for a binding property of type string and whose default value is null then that binding property will not be available in the app.config file. You must manually add the binding property and its value in the app.config file, if required.

Generating a WCF Service Contract by Using the Add Adapter Service Reference Plug-in

The adapter exposes inbound operations to enable Oracle E-Business Suite to send messages to an adapter client. For such operations you must generate a WCF service contract. This section provides information on how to generate a service contract for inbound operations exposed by the adapter.

Perform the following steps to generate a WCF service contract by using the Add Adapter Service Reference Plug-in.

To generate a WCF service contract for inbound operations

1. In Visual Studio Solution Explorer, right-click your project, and then click **Add Adapter Service Reference**.
2. After the **Add Adapter Service Reference** dialog box opens, follow the steps in [Retrieving Metadata for Oracle E-Business Suite Operations in Visual Studio](#) to connect to the Oracle E-Business Suite. There are several binding properties and a URI property that you may want to set when you connect to the Oracle E-Business Suite.
3. After you have connected to the Oracle E-Business Suite, select **Service (Inbound operations)** from the **Select contract type** drop-down list.
4. In the **Select a category** box, browse to the inbound operation for which you want to generate the service contract. For example, for **Notification** operation, click the root node (*/*), select **Notification** from the **Available categories and operations** box, and then click **Add**. For instructions on how to browse for inbound operations, see

5. To generate the WCF service contract for the operation, click **OK**.

The Add Adapter Service Reference Plug-in adds three files to your project:

- **OracleEBSBindingInterface.cs**. This file contains the generated WCF service contract (interface) and helper code for the inbound operation.
- **OracleEBSBindingService.cs**. This file contains a class that implements the interface defined in OracleDBBindingInterface.cs. You can implement the business logic that processes the records returned by the inbound operation.
- **app.config**. This file contains a binding configuration, endpoint behaviors, and service endpoint configuration that are based on the selections you made when you configured the binding and connection for the Add Adapter Service Reference Plug-in.

◆ Important

While using the Add Adapter Service Reference Visual Studio Plug-in, if you do not specify a value for a binding property of type string and whose default value is null then that binding property will not be available in the app.config file. You must manually add the binding property and its value in the app.config file, if required.

Using svcutil.exe to Generate a WCF Client Class or a WCF Service Contract

You can use svcutil.exe to generate a WCF client class or a WCF service interface for your application. You must configure svcutil.exe to use it with the Oracle E-Business adapter.

Svcutil.exe generates the WCF client class or WCF service contract in an output file. The default file name is output.cs. You must manually include this file in your Visual Studio project. For more information about svcutil.exe, see <http://go.microsoft.com/fwlink/?LinkId=139432>.

Specifying a Client Binding for the Oracle E-Business Suite

After you have generated the WCF client class, you can create a WCF client (instance) and invoke its methods to consume the Oracle E-Business adapter.

To create the WCF client, you must specify an endpoint address and a binding. The endpoint address must contain a valid Oracle E-Business Suite connection URI, and the binding must be an instance of an Oracle E-Business Suite binding (**OracleEBSBinding**). For more information about the Oracle E-Business Suite connection URI, see [Establishing a Connection to the Oracle E-Business Suite](#). We recommend that you do not specify the user credentials as part of the connection URI. You may instead use the **ClientCredentials** property of the WCF client, as explained in this topic.

You can specify the Oracle E-Business Suite binding and the endpoint address in your code or in a configuration file. When you use the Add Adapter Service Reference Visual Studio Plug-in to generate the WCF client class, a configuration file (app.config) is also created for your project. This file contains configuration settings that reflect the binding properties and connection information (except credentials) that you specified when you connected to the Oracle E-Business Suite with the Add Adapter Service Reference Plug-in.

Specifying the Binding and Endpoint Address in Code

The following code shows how to create a WCF client by specifying the binding and endpoint address in code using the **ClientCredentials** property of the WCF client.

```
//Create an Oracle EBS binding and set the binding properties
OracleEBSBinding binding = new OracleEBSBinding();
binding.OracleUserName = "myOracleEBSUser";
binding.OraclePassword = "myOracleEBSPassword";
binding.OracleEBSResponsibilityName = "Responsibility";
binding.OracleEBSOrganizationId = "204";

//Create the client endpoint
EndpointAddress address = new EndpointAddress("oracleebs://<oracleebs_instance_name>");

//Create the client and specify the credentials
ConcurrentPrograms_ARClient client = new ConcurrentPrograms_ARClient(binding,address);
client.ClientCredentials.UserName.UserName = "myuser";
client.ClientCredentials.UserName.Password = "mypassword";

//Open the client
client.Open();
```

Specifying the Binding and Endpoint Address in a Configuration File

The following code shows how to create a WCF client by specifying the binding and endpoint address in an app.config file.

```
//Create the client by specifying the endpoint name in the app.config. In this case, the binding properties
//must also be specified in the app.config.
ConcurrentPrograms_ARClient client = new ConcurrentPrograms_ARClient("OracleEBSBinding_ConcurrentPrograms_AR");

//Specify the credentials
client.ClientCredentials.UserName.UserName = "myuser";
client.ClientCredentials.UserName.Password = "mypassword";

client.Open();
```

The following XML shows the configuration file created for the **Customer Interface** concurrent program by the Add Adapter Service Reference Plug-in. This file contains the client endpoint configuration referenced in the preceding example.

```
<?xml version="1.0" encoding="utf-8"?>
<configuration xmlns="http://schemas.microsoft.com/.NetConfiguration/v2.0">
  <system.serviceModel>
    <bindings>
```

```

    <oracleEBSBinding>
      <binding openTimeout="00:05:00" name="OracleEBSBinding" closeTimeout="00:01
:00"
      Database"
        receiveTimeout="00:10:00" sendTimeout="00:01:00" clientCredentialType="
ge="false"
        inboundOperationType="Polling" metadataPooling="true" statementCachePur
statementCacheSize="10" pollWhileDataFound="false" pollingInterval="30"
useOracleConnectionPool="true" minPoolSize="1" maxPoolSize="100"
incrPoolSize="5" decrPoolSize="1" connectionLifetime="0" acceptCredenti
alsInUri="false"
        useAmbientTransaction="true" notifyOnListenerStart="true"
        notificationPort="-1" dataFetchSize="65536" longDatatypeColumnSize="325
12"
        skipNilNodes="true" maxOutputAssociativeArrayElements="32"
        enableSafeTyping="false" insertBatchSize="20" useSchemaInNameSpace="tru
e"
        enableBizTalkCompatibilityMode="true">
        <mlsSettings language="" dateFormat="" dateLanguage="" numericCharacter
s=""
        sort="" territory="" comparison="" currency="" dualCurrency=""
        iSOCurrency="" calendar="" lengthSemantics="" nCharConversionExcept
ion="true"
        timeStampFormat="" timeStampTZFormat="" timeZone="" />
      </binding>
    </oracleEBSBinding>
  </bindings>
<client>
  <endpoint address="oracleEBS://EBS-70-12/" binding="oracleEBSBinding"
    bindingConfiguration="OracleEBSBinding" contract="ConcurrentPrograms_AR"
    name="OracleEBSBinding_ConcurrentPrograms_AR" />
</client>
</system.ServiceModel>
</configuration>

```

If a project has more than one WCF client, there will be multiple client endpoint entries defined in the configuration file. Each WCF client entry will have a unique name based on its binding configuration and target Oracle E-Business Suite artifact. If you connect multiple times to create the WCF clients in your project, multiple binding configuration entries will be created, one for each connection. These binding configuration entries will be named in the following manner: OracleEBSBinding, OracleEBSBinding1, and so on. Each client endpoint entry created during a specific connection will reference the binding entry created during that connection.

[Developing Applications By Using the WCF Service Model](#)

Performing Insert, Update, Delete, or Select Operations on Interface Tables and Views Using the WCF Service Model

The Oracle E-Business adapter discovers a set of basic Insert, Select, Update, and Delete operations on interface tables. By using these operations, you can perform simple Insert, Select, Update, and Delete statements qualified by a WHERE clause on a target interface table. This topic provides instructions on how to perform these operations using the WCF service model.

Note

The Oracle E-Business adapter supports only Select operations on interface views.

For more information about how the adapter supports these operations, see [Operations on Interface Tables and Interface Views](#).

About the Examples Used in this Topic

The example in this topic performs operations on the MS_SAMPLE_EMPLOYEE interface table. The table is created by running the script provided with the samples. For more information about samples, see [Samples](#). A sample, **Interface_Table_Ops**, which is based on this topic, is also provided with the Oracle E-Business adapter samples.

The WCF Client Class

The name of the WCF client generated for the basic operations that the Oracle E-Business adapter discovers is based on the name of the table or view, as listed in the following table.

Artifact	WCF Client Name
Interface tables	InterfaceTables_[APP_NAME]_[SCHEMA]_[TABLE_NAME]Client
Interface views	InterfaceViews_[APP_NAME]_[SCHEMA]_[VIEW_NAME]Client

[APP_NAME] = Actual name of the Oracle E-Business Suite application; for example, FND.

[SCHEMA] = Collection of artifacts; for example, APPS.

[TABLE_NAME] = The name of the table; for example, MS_SAMPLE_EMPLOYEE.

[VIEW_NAME] = The name of the view; for example, MS_SAMPLE_EMPLOYEE_View.

Method Signature for Invoking Operations on Tables

The following table shows the method signatures for the basic operations on an table. The signatures are the same for a view, except that the view namespace and name replace those of the table.

Operation	Method Signature
Insert	string Insert(InsertRecord[] RECORDSET);
Select	SelectRecord[] Select(string COLUMN_NAMES, string FILTER);
Update	string Update(UpdateRecord RECORDSET, string FILTER);
Delete	string Delete(string FILTER);

As an example, the following code shows the method signatures for a WCF client class generated for the Delete, Insert, Select and Update operations on the MS_SAMPLE_EMPLOYEE interface table under the default APPS schema.

```
public partial class InterfaceTables_FND_APPMS_MS_SAMPLE_EMPLOYEEClient : System.ServiceModel
1.ClientBase<InterfaceTables_FND_APPMS_MS_SAMPLE_EMPLOYEE>, InterfaceTables_FND_APPMS_SAMP
LE_EMPLOYEE {
    public SelectRecord[] Select(string COLUMN_NAMES, string FILTER);
```

```

public string Insert(InsertRecord[] RECORDSET);

public string Update(UpdateRecord RECORDSET, string FILTER);

public string Delete(string FILTER);
}

```

In this snippet, **InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEEClient** is the name of the WCF class in the OracleEBSBindingClient.cs generated by the Add Adapter Service Reference Plug-in.

Parameters for Table Operations

This section provides the parameters required by each table operation

Select Operation

COLUMN_NAMES	FILTER
A comma-delimited list of column names in the target; for example, "EMP_NO, DESIGNATION". The column list specifies the columns of the target that should be returned in the result set. Columns not specified in the column list will be set to their .NET default values in the returned record set. For nullable columns, this value is null .	The contents of a WHERE clause that specifies the target rows of the query; for example, "Designation = 'Manager'". You can set this parameter to null to return all rows of the target.

The return value for a Select operation is a strongly-typed result set that contains the specified columns and rows.

Insert Operation

Insert operation type	RECORDSET
Multiple record	A collection of INSERTRECORDS that should be inserted into the table.

The return value for an Insert operation is the number of rows inserted.

Update Operation

RECORDSET	FILTER
A collection of records that should be updated in the table.	The contents of a WHERE clause that specifies the target rows of the query; for example, "Designation = 'Manager'". You can set this parameter to null to return all rows of the target.

The return value for an Update operation is the number of rows updated.

Delete Operation

The Delete operation takes as input a WHERE clause that specifies the rows to be deleted. The return value for a Delete operation is the number of rows deleted.

Creating a WCF Client to Invoke Operations on Interface Tables and Interface Views

The generic set of actions required to perform an operation on Oracle E-Business Suite using a WCF client involves a set of tasks described in [Overview of Using the WCF Service Model with the Adapter](#). This section describes how to create a WCF client to invoke basic Insert, Select, Update, Delete operations on an interface table.

To create a WCF client to perform operations on tables

1. Create a Visual C# project in Visual Studio. For this topic, create a console application.
2. Generate the WCF client class for the Insert, Select, Update, and Delete operation on the MS_SAMPLE_EMPLOYEE interface table. For more information about generating a WCF client class, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).

Important

Before generating the WCF client class, make sure you set the **EnableBizTalkCompatibilityMode** binding property to false.

3. In the Solution Explorer, add reference to `Microsoft.Adapters.OracleEBS` and `Microsoft.ServiceModel.Channels`.

4. Open the Program.cs file and add the following namespaces:

- `Microsoft.Adapters.OracleEBS`
- `System.ServiceModel`

5. Open the Program.cs file and create a client as described in the snippet below.

```
OracleEBSBinding binding = new OracleEBSBinding();
EndpointAddress address = new EndpointAddress("oracleebs://ebs_instance_name");
InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEEClient client = new InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEEClient(binding, address);
```

In this snippet, `InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEEClient` is the WCF client defined in `OracleEBSBindingClient.cs`. This file is generated by the Add Adapter Service Reference Plug-in.

Note

In this snippet, you explicitly specify the binding and endpoint address in your application code. You can use these values from the application configuration file, `app.config`, also generated by the Add Adapter Service Reference Plug-in. For more information on the different ways of specifying client binding, see [Specifying a Client Binding for the Oracle E-Business Suite](#).

6. Set the credentials for the client.

```
client.ClientCredentials.UserName.UserName = "myuser";
client.ClientCredentials.UserName.Password = "mypassword";
```

7. Because you are performing an operation on an interface table, you must set the application context. In this example, to set the application context, you specify the **OracleUserName**, **OraclePassword**, and **OracleEBSResponsibilityName** binding properties. For more information about application context, see [Setting Application Context](#).

```
binding.OracleUserName = "myOracleEBSUserName";
binding.OraclePassword = "myOracleEBSPassword";
binding.OracleEBSResponsibilityName = "myOracleEBSResponsibility";
```

8. Open the client as described in the snippet below:

```
try
{
    Console.WriteLine("Opening Client...");
    client.Open();
}
catch (Exception ex)
{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}
```

9. Invoke the Insert operation on the `MS_SAMPLE_EMPLOYEE` table.

```
Console.WriteLine("The application will insert a record in the MS_SAMPLE_EMPLOYEE interface table");

// The date values cannot contain time zone information. Hence, you must use
// DateTimeKind.Unspecified to not include the time zone information.
```

```

DateTime date = new DateTime(DateTime.Now.Ticks, DateTimeKind.Unspecified);

string result;

InsertRecord[] recordSet = new InsertRecord[1];

EMP_NO__COMPLEX_TYPE emp_no = new EMP_NO__COMPLEX_TYPE();
emp_no.Value = "10007";

NAME__COMPLEX_TYPE name = new NAME__COMPLEX_TYPE();
name.Value = "John Smith";

DESIGNATION__COMPLEX_TYPE desig = new DESIGNATION__COMPLEX_TYPE();
desig.Value = "Manager";

SALARY__COMPLEX_TYPE salary = new SALARY__COMPLEX_TYPE();
salary.Value = "500000";

JOIN_DATE__COMPLEX_TYPE doj = new JOIN_DATE__COMPLEX_TYPE();
doj.Value = date;

recordSet[0] = new InsertRecord();
recordSet[0].EMP_NO = emp_no;
recordSet[0].NAME = name;
recordSet[0].DESIGNATION = desig;
recordSet[0].SALARY = salary;
recordSet[0].JOIN_DATE = doj;

try
{
    result = client.Insert(recordSet);
}
catch (Exception ex)
{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}

Console.WriteLine("Number of records inserted= " + result);
Console.WriteLine("Press any key to continue...");
Console.ReadLine();

```

You can replace the preceding code snippet to perform Select, Update, or Delete operations as well. You can also append the code snippets to perform all operation in a single application. For code snippets on how to perform these operations, see [Select Operation](#), [Update Operation](#), and [Delete Operation](#) respectively.

10. Close the client as described in the snippet below:

```

client.Close();
Console.WriteLine("Press any key to exit...");
Console.ReadLine();

```

11. Build the project and then run it. The application inserts a record in the MS_SAMPLE_EMPLOYEE table.

Select Operation

The following code shows a Select operation that targets the MS_SAMPLE_EMPLOYEE interface table. The Select operation selects the last record inserted into the table. The returned record is written to the console.

```

Console.WriteLine("The application will now select the last inserted record");
SelectRecord[] selectRecords;
try
{
    selectRecords = client.Select("?", "WHERE EMP_NO LIKE 10007");
}
catch (Exception ex)
{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}

Console.WriteLine("The details of the newly added employee are:");
Console.WriteLine("*****");
for (int i = 0; i < selectRecords.Length; i++)
{
    Console.WriteLine("Employee ID      : " + selectRecords[i].EMP_NO);
    Console.WriteLine("Employee Name    : " + selectRecords[i].NAME);
    Console.WriteLine("Employee Designation : " + selectRecords[i].DESIGNATION);
    Console.WriteLine("Employee Salary    : " + selectRecords[i].SALARY);
    Console.WriteLine();
}
Console.WriteLine("*****");
Console.WriteLine("Press any key to continue ...");
Console.ReadLine();

```

Update Operation

The following code shows an Update operation that targets the MS_SAMPLE_EMPLOYEE interface table.

```

Console.WriteLine("The application will now update the employee name in the newly inserted
record");
string recordsUpdated;
UpdateRecord updateRecordSet = new UpdateRecord();
updateRecordSet.NAME = "Tom Smith";
updateRecordSet.DESIGNATION = "Accountant";

try
{
    recordsUpdated = client.Update(updateRecordSet, "WHERE EMP_NO LIKE 10007");
}
catch (Exception ex)
{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}

Console.WriteLine("No of records updated: " + recordsUpdated);
Console.WriteLine("Press any key to continue...");
Console.ReadLine();

```

Delete Operation

The following code shows a Delete operation that targets the MS_SAMPLE_EMPLOYEE interface table.

```

Console.WriteLine("The sample will now delete the record that it first inserted");
string deletedRecords;
try
{
    deletedRecords = client.Delete("WHERE EMP_NO LIKE 10007");
}
catch (Exception ex)
{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}
Console.WriteLine("No of records deleted: " + deletedRecords);

```

```
Console.WriteLine("Press any key to exit...");  
Console.ReadLine();
```

[Developing Applications By Using the WCF Service Model](#)

Performing Operations on Tables with Large Data Types Using the WCF Service Model

The Oracle E-Business adapter enables adapter clients to perform operations on interface tables and views with large data types such as BLOB, CLOB, NCLOB, and BFILE.

- For columns of type BLOB, CLOB, and NCLOB, the adapter enables clients to read as well as update data. The adapter exposes `Read_<LOBColumnName>` and `Update_<LOBColumnName>` operations to read and update data respectively, where `<LOBColumnName>` is the name of column with large data type. If there is more than one column with large data type in a single interface table, the adapter exposes as many read and update operations for that interface table.
- For columns of type BFILE, adapter clients can only read data. The adapter exposes `Read_<LOBColumnName>` operation to read data from columns of BFILE type. If there is more than one column with large data type in a single interface table, the adapter exposes as many read operations for the interface table.

For more information about these operations, see [Operations on Interface Tables, Interface Views, Tables, and Views That Contain LOB Data](#).

About the Examples Used in this Topic

The example in this topic updates a BLOB column (PHOTO) in the CUSTOMER database table and then retrieves the data from the same column. The table is created by running the script provided with the samples. For more information about samples, see [Samples](#). A sample, **LargeDataTypes_ServiceModel**, which is based on this topic, is also provided with the Oracle E-Business adapter samples.

Note
This topic lists detailed tasks for updating and reading columns of large data types in a base database table. You must perform the same set of tasks for updating and reading columns of large data types in an interface table.

The WCF Client Class

The name of the WCF client generated for the operations on tables with large data types by the Oracle E-Business adapter is based on the name of the table, as listed in the following table.

Artifact	WCF Client Name
Interface tables	InterfaceTables_[APP_NAME]_[SCHEMA]_[TABLE_NAME]Client

[APP_NAME] = Actual name of the Oracle E-Business Suite application; for example, FND.

[SCHEMA] = Collection of artifacts; for example, APPS.

[TABLE_NAME] = The name of the table; for example, MS_SAMPLE_EMPLOYEE.

[VIEW_NAME] = The name of the view; for example, MS_SAMPLE_EMPLOYEE_View.

Method Signature for Invoking Operations on Tables

The following table shows the method signatures for the basic operations on a table. The signatures are the same for a view, except that the view namespace and name replace those of the table.

Operation	Method Signature
<code>Update_<column_name></code>	<code>public void Update_<column_name>(string FILTER, byte[] DATA);</code>
<code>Read_<column_name></code>	<code>public System.IO.Stream Read_<column_name>(string FILTER);</code>

As an example, the following code shows the method signatures for a WCF client class generated for the `Update_PHOTO` and `Read_PHOTO` operations on the CUSTOMER database table under the APPS schema.

```
public partial class Tables_APPSCUSTOMERClient : System.ServiceModel.ClientBase<Tables_APP
```

```

S_CUSTOMER>, Tables_APPS_CUSTOMER {
    public void Update_PHOTO(string FILTER, byte[] DATA);
    public System.IO.Stream Read_PHOTO(string FILTER);
}

```

In this snippet, **Tables_APPS_CUSTOMERClient** is the name of the WCF class in the OracleEBSBindingClient.cs generated by the Add Adapter Service Reference Plug-in. Update_PHOTO and Read_PHOTO are methods that can be invoked to update and read columns of large data types in a table.

Parameters for Table Operations

This section provides the parameters required by the Update_<column_name> and Read_<column_name> operation.

Operation name	Parameters
Update_<column_name>	<p>Requires the following parameters:</p> <ul style="list-style-type: none"> • <code>string FILTER</code>. This parameter must contain the where clause that denotes the record for which data has to be updated. For example, "WHERE Name='Mindy Martin'". • <code>byte[] DATA</code>. Contains a byte array of data to be update in a column of large data type.
Read_<column_name>	<p>Requires the following parameters:</p> <ul style="list-style-type: none"> • <code>string FILTER</code>. This parameter must contain the where clause that denotes the record from which the data has to be read. For example, "WHERE Name='Mindy Martin'".

Creating a WCF Client to Invoke Operations on Tables with Columns of Large Data Types

The generic set of actions required to perform an operation on Oracle E-Business Suite using a WCF client involves a set of tasks described in [Overview of Using the WCF Service Model with the Adapter](#). This section describes how to create a WCF client to invoke Update_PHOTO and Read_PHOTO operations on a CUSTOMER database table.

To create a WCF client

1. Create a Visual C# project in Visual Studio. For this topic, create a console application.
2. Generate the WCF client class for the Update_PHOTO and Read_PHOTO operations on the CUSTOMER database table. For more information about generating a WCF client class, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).

Important

Before generating the WCF client class, make sure you set the **EnableBizTalkCompatibilityMode** binding property to false.

3. In the Solution Explorer, add reference to `Microsoft.Adapters.OracleEBS` and `Microsoft.ServiceModel.Channels`, `System.Transactions`.
4. Open the Program.cs file and add the following namespaces:
 - `Microsoft.Adapters.OracleEBS`
 - `System.ServiceModel`
 - `System.Transactions`
 - `System.IO`

- Open the Program.cs file and create a client as described in the snippet below.

```
Tables_APPS_CUSTOMERClient client = new Tables_APPS_CUSTOMERClient("OracleEBSBinding_ables_APPS_CUSTOMER");

client.ClientCredentials.UserName.UserName = "<Enter user name here>";
client.ClientCredentials.UserName.Password = "<Enter password here>";
```

In this snippet, `Tables_APPS_CUSTOMERClient` is the WCF client defined in `OracleEBSBindingClient.cs`. This file is generated by the Add Adapter Service Reference Plug-in.

Note

In this snippet, you use the binding and endpoint address from the configuration file `app.config`. You can also explicitly specify these values in your code. For more information on the different ways of specifying client binding, see [Specifying a Client Binding for the Oracle E-Business Suite](#).

- Set the credentials for the client.

```
client.ClientCredentials.UserName.UserName = "myuser";
client.ClientCredentials.UserName.Password = "mypassword";
```

Important

In this example, you are performing operations on a database table. However, if you are performing operations on an interface table, you must set the application context by specifying appropriate values for the **OracleUserName**, **OraclePassword**, and **OracleEBSResponsibilityName** binding properties. You must specify these binding properties before opening the client. For more information about application context, see [Setting Application Context](#).

- Open the client as described in the snippet below:

```
try
{
    Console.WriteLine("Opening Client...");
    client.Open();
}
catch (Exception ex)
{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}
```

- Invoke the `Update_PHOTO` operation on the `CUSTOMER` table.

The `Update_PHOTO` operation requires a byte array for the data to be updated. In this code snippet, you use the `FileStream` class to create a byte array for a photo, `SamplePhoto.jpg`. For this application to work, the file must be copied to the project's `bin` directory.

Important

The `Update_PHOTO` operation must be performed in a transaction, so the **UseAmbientTransaction** binding property must be set to **true** and the `Update_PHOTO` operation must be performed within a transaction scope. You can set the **UseAmbientTransaction** binding property either in the `app.config` or by explicitly setting it in your application as `binding.UseAmbientTransaction = true`. Note that if you are specifying the binding property explicitly in the code, you must do so before opening the client.

```

byte[] photo;

using (FileStream fs = new FileStream("SamplePhoto.jpg", FileMode.Open))
{
    try
    {
        Console.WriteLine("Reading the photo");
        int count = 0;
        photo = new byte[fs.Length];
        while ((count += fs.Read(photo, count, (int)((fs.Length - count) > 4096) ? 40
96 : fs.Length - count))) < fs.Length) ;
    }
    catch(Exception ex)
    {
        Console.WriteLine("Exception: " + ex.Message);
        throw;
    }
}

Console.WriteLine("Updating data for the 'PHOTO' column");
// Invoking the Update_PHOTO operation inside a transaction scope
using (TransactionScope tx = new TransactionScope())
{
    string filter = "WHERE Name='Mindy Martin'";
    client.Update_PHOTO(filter, photo);
    tx.Complete();
}

```

9. Invoke the Read_PHOTO operation on the CUSTOMER table.

The Read_PHOTO gives the output in the form of System.IO.Stream. The adapter client must implement the FileStream class to read the data from Read_PHOTO operation. After the Read_PHOTO operation is complete, a file PhotoCopy.jpg is copied under the project's bin directory.

```

using (FileStream fs = new FileStream("PhotoCopy.jpg", FileMode.Create))
{
    Console.WriteLine("Reading photo data");
    String ReadFilter = "WHERE NAME='Mindy Martin'";
    Stream photoStream = client.Read_PHOTO(ReadFilter);
    Console.WriteLine("Photo data read -- writing to PhotoCopy.jpg");

    int count;
    int length = 0;
    byte[] buffer = new byte[4096];
    while ((count = photoStream.Read(buffer, 0, 4096)) > 0)
    {
        fs.Write(buffer, 0, count);
        length+=count;
    }
    Console.WriteLine("{0} bytes written to PhotoCopy.jpg", length);
}

Console.WriteLine("Photo updated and read back -- Hit <RETURN> to end");
Console.ReadLine();

```

10. Close the client as described in the snippet below:

```
client.Close();  
Console.WriteLine("Press any key to exit...");  
Console.ReadLine();
```

11. Build the project and then run it. The application updates the PHOTO column of the CUSTOMER table and then reads the content of the PHOTO column.

[Developing Applications By Using the WCF Service Model](#)

Invoking Concurrent Programs in Oracle E-Business Suite Using the WCF Service Model

Oracle E-Business Suite exposes concurrent programs that you can execute to perform specific operations on Oracle applications. Each Oracle application has a set of standard concurrent programs (that are same across all operations) and certain concurrent programs that are specific to an Oracle application. The Oracle E-Business adapter exposes all concurrent programs as operations that adapter clients can invoke. For more information about how the adapter supports concurrent programs, see [Operations on Concurrent Programs](#).

Note

For the concurrent programs that do not expose their metadata, the Oracle E-Business adapter exposes 100 optional parameters for each of these concurrent programs. To invoke these concurrent programs successfully, the user must consult the Oracle E-Business Suite documentation to figure out the parameters for a concurrent program that require a value, and then specify them. An example of such a concurrent program is **Journal Import** (actual name: **GLLEZL**) in the **General Ledger** application.

About the Examples Used in this Topic

The example in this topic invokes the **MS_SAMPLE_COPY_EMP_DATA** concurrent program, followed by the **Get_Status** concurrent program to know the status of the first concurrent program. These concurrent programs are invoked from the **Application Object Library** application. The **MS_SAMPLE_COPY_EMP_DATA** is created by running the script provided with the samples. For more information about samples, see [Samples](#). A sample, **ConcurrentProgram_ServiceModel**, which is based on this topic, is also provided with the Oracle E-Business adapter samples.

The WCF Client Class

The name of the WCF client generated for invoking the concurrent programs by the Oracle E-Business adapter is listed in the following table.

Artifact	WCF Client Name
Concurrent Program	ConcurrentPrograms_[APP_NAME]Client

[APP_NAME] = Actual name of the Oracle E-Business Suite application; for example, FND.

Method Signature for Invoking Concurrent Programs

The following table shows the method signature for the concurrent programs.

Operation	Method Signature
Concurrent program	public <return type> <Concurrent_program_name>(param 1, param 2, ...)

As an example, the following code shows the method signatures for a WCF client class generated for the **MS_SAMPLE_COPY_EMP_DATA** and **Get_Status** concurrent programs.

```
public partial class ConcurrentPrograms_FNDClient : System.ServiceModel.ClientBase<ConcurrentPrograms_FND>, ConcurrentPrograms_FND {

    public string MS_SAMPLE_COPY_EMP_DATA(schemas.microsoft.com.OracleEBS._2008._05.Options.SetOptions SetOptions,
        schemas.microsoft.com.OracleEBS._2008._05.Options.SetPrintOptions SetPrintOptions,
        schemas.microsoft.com.OracleEBS._2008._05.Options.SetRepeatOptions SetRepeatOptions,
        string Description, string StartTime);

    public bool GetStatusForConcurrentProgram(string RequestId, out string Phase, out string Status,
        out string DevPhase, out string DevStatus, out string Message);
}
```

In this snippet, **ConcurrentPrograms_FNDClient** is the name of the WCF class in the OracleEBSBindingClient.cs generated by the Add Adapter Service Reference Plug-in. **MS_SAMPLE_COPY_EMP_DATA** is the name of the method to invoke the

concurrent program. **GetStatusForConcurrentProgram** is the name of the method to invoke the concurrent program to get the status of the first concurrent program.

Note

GetStatusForConcurrentProgram is the actual name of the **Get_Status** concurrent program.

Creating a WCF Client to Invoke Concurrent Programs

The generic set of actions required to perform an operation on Oracle E-Business Suite using a WCF client involves a set of tasks described in [Overview of Using the WCF Service Model with the Adapter](#). This section describes how to create a WCF client to invoke the **MS_SAMPLE_COPY_EMP_DATA** and **Get_Status** concurrent programs.

To create a WCF client

1. Create a Visual C# project in Visual Studio. For this topic, create a console application.
2. Generate the WCF client class for the **MS_SAMPLE_COPY_EMP_DATA** and **Get_Status** concurrent programs. For more information about generating a WCF client class, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).

Important

Before generating the WCF client class, make sure you set the **EnableBizTalkCompatibilityMode** binding property to false.

3. In the Solution Explorer, add reference to `Microsoft.Adapters.OracleEBS` and `Microsoft.ServiceModel.Channels`.
4. Open the Program.cs file and add the following namespaces:

- `Microsoft.Adapters.OracleEBS`
- `System.ServiceModel`

5. Open the Program.cs file and create a client as described in the snippet below.

```
OracleEBSBinding binding = new OracleEBSBinding();
EndpointAddress address = new EndpointAddress("oracleebs://ebs_instance_name");
ConcurrentPrograms_FNDClient client = new ConcurrentPrograms_FNDClient(binding, address);
```

In this snippet, `ConcurrentPrograms_FNDClient` is the WCF client defined in `OracleEBSBindingClient.cs`. This file is generated by the Add Adapter Service Reference Plug-in.

Note

In this snippet, you explicitly specify the binding and endpoint address in your application code. You can also use these values from the application configuration file, `app.config`, also generated by the Add Adapter Service Reference Plug-in. For more information on the different ways of specifying client binding, see [Specifying a Client Binding for the Oracle E-Business Suite](#).

6. Set the credentials for the client.

```
client.ClientCredentials.UserName.UserName = "myuser";
client.ClientCredentials.UserName.Password = "mypassword";
```

7. Because you are invoking concurrent programs in an Oracle E-Business Suite application, you must set the application context. In this example, to set the application context, you specify the **OracleUserName**, **OraclePassword**, and **OracleEBSResponsibilityName** binding properties. For more information about application context, see [Setting Application Context](#).

```
binding.OracleUserName = "myOracleEBSUserName";
binding.OraclePassword = "myOracleEBSPassword";
binding.OracleEBSResponsibilityName = "myOracleEBSResponsibility";
```

8. Open the client as described in the snippet below:

```
try
{
    Console.WriteLine("Opening Client...");
    client.Open();
}
catch (Exception ex)
{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}
```

9. Invoke the **MS_SAMPLE_COPY_EMP_DATA** and **Get_Status** concurrent programs.

```
string RequestID;
bool Result;
string Phase;
string Status;
string DevPhase;
string DevStatus;
string Message;

try
{
    Console.WriteLine("Invoking the MS_SAMPLE_COPY_EMP_DATA concurrent program");
    RequestID = client.MS_SAMPLE_COPY_EMP_DATA(null, null, null, null, null);
    Console.WriteLine("The request ID generated for the concurrent program is : " + RequestID);
    Console.WriteLine("*****");
    Console.WriteLine("\nWaiting for 60 seconds for the concurrent program to be complete");
    System.Threading.Thread.Sleep(60000);
    Console.WriteLine("\nInvoking the Get_Status concurrent program");
    Result = client.GetStatusForConcurrentProgram(RequestID, out Phase, out Status, out DevPhase, out DevStatus, out Message);
    Console.WriteLine("\nResult is : " + Result);
    Console.WriteLine("Phase is : " + Phase);
    Console.WriteLine("Status is : " + Status);
    Console.WriteLine("DevPhase is : " + DevPhase);
    Console.WriteLine("DevStatus is : " + DevStatus);
    Console.WriteLine("Message is : " + Message);
    Console.WriteLine("*****");
    Console.WriteLine("\nHit <RETURN> to end");
    Console.ReadLine();
}
catch (Exception ex)
{
    Console.WriteLine("Exception : " + ex);
    throw;
}
```

10. Close the client as described in the snippet below:

```
client.Close();
```

11. Build the project and then run it. The application invokes the **MS_SAMPLE_COPY_EMP_DATA** and returns a request ID. The ID is then passed to the **Get_Status** concurrent program, which finally provides the status of the **MS_SAMPLE_COPY_EMP_DATA** column program.

[Developing Applications By Using the WCF Service Model](#)

Invoking Request Sets in Oracle E-Business Suite Using the WCF Service Model

Microsoft BizTalk Adapter for Oracle E-Business Suite enables you to execute request sets in Oracle E-Business Suite. Request sets are divided into one or more stages, and each stage contains a set of reports and concurrent programs. For more information about how the adapter supports request sets, see [Operations on Request Sets](#).

The WCF Client Class

The name of the WCF client generated for invoking the request sets by the Oracle E-Business adapter is listed in the following table.

Artifact	WCF Client Name
Request Set	RequestSets_[APP_NAME]Client

[APP_NAME] = Actual name of the Oracle E-Business Suite application; for example, SQLAP.

Method Signature for Invoking Request Sets

The following table shows the method signature for request sets.

Operation	Method Signature
Request Set	public <return type> <request set name>(param 1, param 2, ...)

As an example, the following code shows the method signatures for a WCF client class generated for the **reqset_singlestage** request set.

Note
This is a custom request set and might not be available on your Oracle E-Business Solution instance.

```
public partial class RequestSets_SQLAPClient : System.ServiceModel.ClientBase<RequestSets_S
QLAP>, RequestSets_SQLAP{

    public string REQSTG(
        schemas.microsoft.com.OracleEBS._2008._05.Options.SetRelClassOptions SetRelClassOptio
ns,
        schemas.microsoft.com.OracleEBS._2008._05.Options.SetPrintOptions SetPrintOptions,
        schemas.microsoft.com.OracleEBS._2008._05.Options.SetRepeatOptions SetRepeatOptions,
        schemas.microsoft.com.OracleEBS._2008._05.Options.SetNlsOptions SetNlsOptions,
        string StartTime,
        schemas.microsoft.com.OracleEBS._2008._05.RequestSetStage.SQLAP.REQSTG.set1 set1_set1
    );
}
```

In this snippet, **RequestSets_SQLAPClient** is the name of the WCF class in the OracleEBSBindingClient.cs generated by the Add Adapter Service Reference Plug-in. **REQSTG** is the name of the method to invoke the request set.

Creating a WCF Client to Invoke Request Sets

The generic set of actions required to perform an operation on Oracle E-Business Suite using a WCF client involves a set of tasks described in [Overview of Using the WCF Service Model with the Adapter](#). This section describes how to create a WCF client to invoke the **reqset_singlestage** request set.

To create a WCF client

1. Create a Visual C# project in Visual Studio. For this topic, create a console application.
2. Generate the WCF client class for the **reqset_singlestage** request set. For more information about generating a WCF client class, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).

Important

Before generating the WCF client class, make sure you set the **EnableBizTalkCompatibilityMode** binding property to false.

3. In the Solution Explorer, add reference to `Microsoft.Adapters.OracleEBS` and `Microsoft.ServiceModel.Channels`.
4. Open the Program.cs file and add the following namespaces:

- `Microsoft.Adapters.OracleEBS`
- `System.ServiceModel`

5. Open the Program.cs file and create a client as described in the snippet below.

```
OracleEBSBinding binding = new OracleEBSBinding();
EndpointAddress address = new EndpointAddress("oracleebs://ebs_instance_name");
RequestSets_SQLAPClient client = new RequestSets_SQLAPClient(binding, address);
```

In this snippet, `RequestSets_SQLAPClient` is the WCF client defined in `OracleEBSBindingClient.cs`. This file is generated by the Add Adapter Service Reference Plug-in.

Note

In this snippet, you explicitly specify the binding and endpoint address in your application code. You can also use these values from the application configuration file, `app.config`, also generated by the Add Adapter Service Reference Plug-in. For more information about the different ways of specifying client binding, see [Specifying a Client Binding for the Oracle E-Business Suite](#).

6. Set the credentials for the client.

```
client.ClientCredentials.UserName.UserName = "myuser";
client.ClientCredentials.UserName.Password = "mypassword";
```

7. Because you are invoking request sets in an Oracle E-Business Suite application, you must set the application context. In this example, to set the application context, you specify the **OracleUserName**, **OraclePassword**, and **OracleEBSResponsibilityName** binding properties. For more information about application context, see [Setting Application Context](#).

```
binding.OracleUserName = "myOracleEBSUserName";
binding.OraclePassword = "myOracleEBSPassword";
binding.OracleEBSResponsibilityName = "myOracleEBSResponsibility";
```

8. Open the client as described in the snippet below:

```
try
{
    Console.WriteLine("Opening Client...");
    client.Open();
}
catch (Exception ex)
{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}
```

9. Invoke the **reqset_singlestage** request set.

```

string RequestID;

schemas.microsoft.com.OracleEBS._2008._05.RequestSetStage.SQ LAP.REQSTG.set1 param =
    new schemas.microsoft.com.OracleEBS._2008._05.RequestSetStage.SQ LAP.REQSTG.set1();

param.INS PARAMPROG = new schemas.microsoft.com.OracleEBS._2008._05.RequestSetConcurren
tProgram.SQ LAP.REQSTG.set1.SQ LAP1.INS PARAMPROG();
param.INS PARAMPROG.p_id = "123";
param.INS PARAMPROG.p_name = "MyName";

try
{
    Console.WriteLine("Invoking the reqset_singlestage request set");
    RequestID = client.REQSTG(null, null, null, null, null, param);
    Console.WriteLine("The request ID generated for the request set is : " + RequestID
);
    Console.WriteLine("*****");
    Console.WriteLine("\nHit <RETURN> to end");
    Console.ReadLine();
}
catch (Exception ex)
{
    Console.WriteLine("Exception : " + ex);
    throw;
}

```

10. Close the client as described in the snippet below:

```
client.Close();
```

11. Build the project and then run it. The application invokes the **reqset_singlestage** request set and returns a request ID, which is written to the console.

[Developing Applications By Using the WCF Service Model](#)

Performing ExecuteReader, ExecuteScalar, or ExecuteNonQuery Operations Using WCF Service Model

The Oracle E-Business adapter exposes generic operations such as **ExecuteNonQuery**, **ExecuteReader**, and **ExecuteScalar**. You can use these operations to execute any statement on Oracle E-Business Suite. These operations differ based on the kind of response you get for the statement. For more information about how the adapter supports these operations, see [Support for ExecuteNonQuery, ExecuteReader, and ExecuteScalar Operations](#).

This topic demonstrates how to perform an **ExecuteReader** operation using the Oracle E-Business adapter using the WCF service model. You can follow the same set of procedures described in this topic to perform **ExecuteNonQuery** and **ExecuteScalar** operations.

About the Examples Used in this Topic

The example in this topic performs an **ExecuteReader** operation to perform a SELECT operation on the MS_SAMPLE_EMPLOYEE interface table. The table is created by running the script provided with the samples. For more information about samples, see [Samples](#). A sample, **ExecuteReader**, which is based on this topic, is also provided with the Oracle E-Business adapter samples.

The WCF Client Class

The name of the WCF client generated for invoking generic operations (ExecuteNonQuery, ExecuteReader, or ExecuteScalar) using the Oracle E-Business adapter is listed in the following table.

Operations	WCF Client Name
ExecuteNonQuery, ExecuteReader, or ExecuteScalar	GenericOperation_Client

Method Signature for Invoking Generic Operations

The following table shows the signature for the method exposed to invoke the generic operations.

Operation	Method Signature
ExecuteNonQuery	int ExecuteNonQuery(string Query, string[] OutputRefCursorNames, out System.Data.DataSet[] OutputRefCursors)
ExecuteReader	System.Data.DataSet ExecuteReader(string Query)
ExecuteScalar	string ExecuteScalar(string Query)

As an example, the signature for the generic operation methods is shown in the following code snippet.

```
public partial class GenericOperation_Client : System.ServiceModel.ClientBase<GenericOperation_>, GenericOperation_ {
    public int ExecuteNonQuery(string Query, string[] OutputRefCursorNames, out System.Data.DataSet[] OutputRefCursors);
    public System.Data.DataSet ExecuteReader(string Query);
    public string ExecuteScalar(string Query);
}
```

In this snippet,

- `GenericOperation_Client` is the name of the class. This class is used to create a client to invoke the generic operation, `ExecuteReader`.
- `public System.Data.DataSet ExecuteReader(string Query)` is the method that you invoke to perform a SELECT statement on the MS_SAMPLE_EMPLOYEE interface table.

Creating a WCF Client to Invoke an ExecuteReader Operation

The generic set of actions required to perform an operation on Oracle E-Business Suite using a WCF client involves a set of

tasks described in [Overview of Using the WCF Service Model with the Adapter](#). This section describes how to create a WCF client to invoke the **ExecuteReader** operation.

To create a WCF client to invoke ExecuteReader operation

1. Create a Visual C# project in Visual Studio. For this topic, create a console application.
2. Generate the WCF client class for the **ExecuteReader** generic operation. This operation is available under the root node when you connect to the Oracle E-Business Suite using the Add Adapter Service Reference Plug-in. For more information about generating a WCF client class, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).

Important

Before generating the WCF client class, make sure you set the **EnableBizTalkCompatibilityMode** binding property to false.

3. In the Solution Explorer, add reference to `Microsoft.Adapters.OracleEBS` and `Microsoft.ServiceModel.Channels`.
4. Open the Program.cs file and add the following namespaces:

- `Microsoft.Adapters.OracleEBS`
- `System.ServiceModel`

5. In the Program.cs file, create a client as described in the snippet below.

```
OracleEBSBinding binding = new OracleEBSBinding();
EndpointAddress address = new EndpointAddress("oracleebs://ebs-72-11");
GenericOperation_Client client = new GenericOperation_Client(binding, address);
```

In this snippet, `GenericOperation_Client` is the WCF client defined in `OracleEBSBindingClient.cs`. This file is generated by the Add Adapter Service Reference Plug-in.

Note

In this snippet, you explicitly specify the binding and endpoint address in your application code. You can use these values from the application configuration file, `app.config`, also generated by the Add Adapter Service Reference Plug-in. For more information about the different ways of specifying client binding, see [Specifying a Client Binding for the Oracle E-Business Suite](#).

6. Set the credentials for the client.

```
client.ClientCredentials.UserName.UserName = "myuser";
client.ClientCredentials.UserName.Password = "mypassword";
```

7. Because you are performing an operation on an interface table, you must set the application context. In this example, to set the application context, you specify the **OracleUserName**, **OraclePassword**, and **OracleEBSResponsibilityName** binding properties. For more information about application context, see [Setting Application Context](#).

```
binding.OracleUserName = "myOracleEBSUserName";
binding.OraclePassword = "myOracleEBSPassword";
binding.OracleEBSResponsibilityName = "myOracleEBSResponsibility";
```

8. Open the client as described in the snippet below:

```
try
{
```

```

        Console.WriteLine("Opening Client...");
        client.Open();
    }
    catch (Exception ex)
    {
        Console.WriteLine("Exception: " + ex.Message);
        throw;
    }
}

```

9. Invoke the **ExecuteReader** operation for performing the SELECT operation on MS_SAMPLE_EMPLOYEE table. Before you invoke the ExecuteReader operation, you must add the `System.Data` namespace to your code.

```

string query = "SELECT * FROM MS_SAMPLE_EMPLOYEE";
DataSet ds = client.ExecuteReader(query);

Console.WriteLine("Invoking the SELECT statement using ExecuteReader");
Console.WriteLine("*****");
foreach (DataTable tab in ds.Tables)
{
    foreach (DataRow row in tab.Rows)
    {
        Console.WriteLine("The details of the employee are: ");
        for (int i = 0; i < tab.Columns.Count; i++)
        {
            Console.WriteLine(row[i]);
        }
        Console.WriteLine();
    }
}
Console.WriteLine("*****");
Console.ReadLine();

```

10. Close the client as described in the snippet below:

```

client.Close();
Console.WriteLine("Press any key to exit...");
Console.ReadLine();

```

11. Build the project and then run it. All the records in the MS_SAMPLE_EMPLOYEE table are displayed on the console.

[Developing Applications By Using the WCF Service Model](#)

Polling Oracle E-Business Suite Using the WCF Service Model

You can configure the Oracle E-Business adapter to receive polling-based messages from the Oracle database. The adapter provides two ways of polling the Oracle database:

- **Using SELECT statements.** You can specify a simple SELECT statement to poll the Oracle database. The adapter executes the SELECT statement at specified intervals and returns the result to the adapter clients.
- **Using stored procedures.** You can specify a stored procedure to poll the Oracle database. The adapter executes the stored procedure at specified intervals and returns the result to the adapter clients.

The key difference in the two approaches is the way adapter clients specify a polling statement that the adapter uses to poll the Oracle database. While the polling statement for the first approach is a simple SELECT statement, the polling statement for the stored procedure approach is a request message that executes the stored procedure. Adapter clients specify the polling statement, for either approach, for the **PollingInput** binding property. For more information about the binding properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#).

The topics in this section provide instructions on how to poll using a SELECT statement and a stored procedure.

[Developing Applications By Using the WCF Service Model](#)

Polling Using SELECT Statement Using the WCF Service Model

You can configure the Oracle E-Business adapter to receive periodic data-change messages by using a SELECT statement to continuously poll the interface tables, interface views, tables and views in Oracle E-Business Suite. You can specify a SELECT statement as a polling statement that the adapter executes periodically to poll Oracle E-Business Suite. You can also specify a post-poll PL/SQL code block that the adapter executes after the polling statement is executed.

To enable polling, you must specify certain binding properties as described in this topic. For more information about how the adapter supports polling, see [Support for Inbound Calls Using Polling](#).

Configuring a Polling Operation with Oracle E-Business Suite Adapter Binding Properties

The following table summarizes the Oracle E-Business adapter binding properties that you use to configure the adapter to receive data change messages. You must specify these binding properties while running the polling application.

Binding Property	Description
InboundOperationType	Specifies whether you want to perform Polling or Notification inbound operation. Default is Polling .
PolledDataAvailableStatement	Specifies the SQL statement that the adapter executes to determine whether any data is available for polling. Only if a record is available, the SELECT statement you specify for the PollingInput binding property will be executed.
PollingInterval	Specifies the interval, in seconds, at which the Oracle E-Business adapter executes the statement specified for the PolledDataAvailableStatement binding property. The default is 30 seconds. The polling interval determines the time interval between successive polls. If the statement is executed within the specified interval, the adapter sleeps for the remaining time in the interval.
PollingInput	Specifies the polling statement. To poll using a SELECT statement, you must specify a SELECT statement for this binding property. The default is null. You must specify a value for PollingInput binding property to enable polling. The polling statement is executed only if there is data available for polling, which is determined by the PolledDataAvailableStatement binding property.
PollingAction	Specifies the action for the polling operation. You can determine the polling action from the service interface generated for the operation using the Add Adapter Service Reference Visual Studio Plug-in.
PostPollStatement	Specifies a statement block that is executed after the statement specified by the PollingInput binding property is executed.
PollWhileDataFound	Specifies whether the Oracle E-Business adapter ignores the polling interval and continuously executes the polling statement, if data is available in the table being polled. If no data is available in the table, the adapter reverts to execute the polling statement at the specified polling interval. Default is false.

For a more complete description of these properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For a complete description of how to use the Oracle E-Business adapter to poll the Oracle database, read further.

How This Topic Demonstrates Polling

In this topic, to demonstrate how the Oracle E-Business adapter supports receiving data change messages using SELECT statements, you poll the **MS_SAMPLE_EMPLOYEE** interface table in the **Application Object Library** application. This table is created when you run the create_apps_artifacts.sql script provided with the samples to create these objects in Oracle E-Business Suite.

To demonstrate a polling operation, we do the following:

- Specify a SELECT statement for the **PolledDataAvailableStatement** binding property to determine where the interface table being polled (MS_SAMPLE_EMPLOYEE) has any data. In this example, you can set this binding property as:

```
SELECT COUNT (*) FROM MS_SAMPLE_EMPLOYEE
```

This ensures that the adapter executes the polling statement only when the MS_SAMPLE_EMPLOYEE interface table has some records.

- Specify a SELECT statement for the **PollingInput** binding property. This statement retrieves all the rows in the MS_SAMPLE_EMPLOYEE interface table. In this example, you can set this binding property as:

```
SELECT * FROM MS_SAMPLE_EMPLOYEE FOR UPDATE
```

Note

For information about the FOR UPDATE clause used in the SELECT statement, see [Specifying a FOR UPDATE Clause in the Polling Statement](#).

- Specify a DELETE statement as part of the **PostPollStatement** binding property. This statement will delete all data from MS_SAMPLE_EMPLOYEE interface table. In this example, you can set this binding property as:

```
DELETE FROM MS_SAMPLE_EMPLOYEE
```

After this happens, the next time the statement specified for **PollingInput** will be executed, it will not fetch any data.

- Until more data is added to the MS_SAMPLE_EMPLOYEE interface table, you will not get any polling messages so you must repopulate the MS_SAMPLE_EMPLOYEE interface table with new records. You can do so by running the insert_apps_data.sql script provided with the samples. After you run this script, the next polling operation will fetch the new records inserted into the table.

Configuring Polling in the WCF Service Model

To poll an interface table using the Oracle E-Business adapter with the WCF service model, you must:

- Generate a WCF service contract (interface) for the **Poll** operation on the MS_SAMPLE_EMPLOYEE interface table. To do this, you could use the Add Adapter Service Reference Plug-in.
- Implement a WCF service from this interface.
- Host this WCF service using a service host (**System.ServiceModel.ServiceHost**).

About the Examples Used in this Topic

The examples in this topic poll the MS_SAMPLE_EMPLOYEE interface table. A script to generate the table is supplied with the samples. For more information about the samples, see [Samples](#). A sample, **SelectPolling_ServiceModel**, which is based on this topic, is also provided with the Oracle E-Business adapter samples.

The WCF Service Contract and Class

You can use the Add Adapter Service Reference Plug-in to create a WCF service contract (interface) and supporting classes for the **Polling** operation. For more information about generating a WCF service contract, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).

The WCF Service Contract (Interface)

The following code shows the WCF service contract (interface) generated for the **Poll** operation on MS_SAMPLE_EMPLOYEE

interface table.

```
[System.CodeDom.Compiler.GeneratedCodeAttribute("System.ServiceModel", "3.0.0.0")]
[System.ServiceModel.ServiceContractAttribute(Namespace="http://schemas.microsoft.com/Oracl
eEBS/", ConfigurationName="InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEE")]
public interface InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEE {

    // CODEGEN: Generating message contract since the wrapper namespace (http://schemas.mic
rosoft.com/Oracl
eEBS/2008/05/InterfaceTables/FND/APPS/MS_SAMPLE_EMPLOYEE) of message Poll
// does not match the default value (http://schemas.microsoft.com/Oracl
eEBS/)
[System.ServiceModel.OperationContractAttribute(IsOneWay=true, Action="InterfaceTables/
Poll/FND/APPS/MS_SAMPLE_EMPLOYEE")]
    void Poll(Poll request);
}
```

The Message Contracts

Following is the message contract for the **Poll** operation on MS_SAMPLE_EMPLOYEE interface table.

```
[System.Diagnostics.DebuggerStepThroughAttribute()]
[System.CodeDom.Compiler.GeneratedCodeAttribute("System.ServiceModel", "3.0.0.0")]
[System.ServiceModel.MessageContractAttribute(WrapperName="Poll", WrapperNamespace="http://
schemas.microsoft.com/Oracl
eEBS/2008/05/InterfaceTables/FND/APPS/MS_SAMPLE" +
    "_EMPLOYEE", IsWrapped=true)]
public partial class Poll {

    [System.ServiceModel.MessageBodyMemberAttribute(Namespace="http://schemas.microsoft.com
/Oracl
eEBS/2008/05/InterfaceTables/FND/APPS/MS_SAMPLE" +
        "_EMPLOYEE", Order=0)]
    public schemas.microsoft.com.Oracl
eEBS._2008._05.TableViewRecord.APPS.MS_SAMPLE_EMPLOYE
E.SelectRecord[] DATA;

    public Poll() {
    }

    public Poll(schemas.microsoft.com.Oracl
eEBS._2008._05.TableViewRecord.APPS.MS_SAMPLE_EM
PLOYEE.SelectRecord[] DATA) {
        this.DATA = DATA;
    }
}
```

WCF Service Class

The Add Adapter Service Reference Plug-in also generates a file that has a stub for the WCF service class implemented from the service contract (interface). The name of the file is OracleEBSBindingService.cs. You can insert the logic to process the **Poll** operation directly into this class. The following code shows the WCF service class generated by the Add Adapter Service Reference Plug-in.

```
namespace OracleEBSBindingNamespace {

    public class OracleEBSBindingService : InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEE {

        // CODEGEN: Generating message contract since the wrapper namespace (http://schemas
.microsoft.com/Oracl
eEBS/2008/05/InterfaceTables/FND/APPS/MS_SAMPLE_EMPLOYEE) of message Po
ll
// does not match the default value (http://schemas.microsoft.com/Oracl
eEBS/)
        public virtual void Poll(Poll request) {
            throw new System.NotImplementedException("The method or operation is not implem
ented.");
        }
    }
}
```

Receiving Inbound Messages for the Poll Operation Using a SELECT Statement

This section provides instructions on how to write a .NET application to receive inbound polling messages using the Oracle E-Business adapter.

To receive polling messages using a SELECT statement

1. Use the Add Adapter Service Reference Plug-in to generate a WCF service contract (interface) and helper classes for the **Poll** operation on the MS_SAMPLE_EMPLOYEE interface table. For more information, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#). You can optionally specify the binding properties while generating the service contract and helper classes. This guarantees that they are properly set in the generated configuration file.
2. Implement a WCF service from the interface and helper classes generated in step 1. The **Poll** method of this class can throw an exception to abort the polling transaction, if an error is encountered processing the data received from the **Poll** operation; otherwise the method does not return anything. You must attribute the WCF service class as follows:

```
[ServiceBehavior(InstanceContextMode = InstanceContextMode.Single)]
```

Within the **Poll** method, you can implement your application logic directly. This class can be found in OracleEBSBindingService.cs. This code in this example sub-classes the **OracleEBSBindingService** class. In this code, the polling message received and is written to the console.

```
[ServiceBehavior(InstanceContextMode = InstanceContextMode.Single)]

public class PollingService : OracleEBSBindingNamespace.OracleEBSBindingService
{
    public override void Poll(Poll request)
    {
        Console.WriteLine("\nNew Polling Records Received");
        Console.WriteLine("*****");
        Console.WriteLine("Emp No\tName\tDesignation\tSalary");
        for (int i = 0; i < request.DATA.Length; i++)
        {
            Console.WriteLine("{0}\t{1}\t{2}\t{3}",
                request.DATA[i].EMP_NO,
                request.DATA[i].NAME,
                request.DATA[i].DESIGNATION,
                request.DATA[i].SALARY);
        }
        Console.WriteLine("*****");
        Console.WriteLine("\nHit <RETURN> to stop polling");
    }
}
```

3. You must implement the following class to avoid passing credentials as part of the URI. In the latter part of the application, you will instantiate this class to pass on the credentials.

```
class PollingCredentials : ClientCredentials, IServiceBehavior
{
    public void AddBindingParameters(ServiceDescription serviceDescription, ServiceHostBase serviceHostBase, Collection<ServiceEndpoint> endpoints, BindingParameterCollection bindingParameters)
    {
        bindingParameters.Add(this);
    }

    public void ApplyDispatchBehavior(ServiceDescription serviceDescription, ServiceHostBase serviceHostBase)
    { }
}
```

```

    public void Validate(ServiceDescription serviceDescription, ServiceHostBase serviceHostBase)
    { }

    protected override ClientCredentials CloneCore()
    {
        ClientCredentials clone = new PollingCredentials();
        clone.UserName.UserName = this.UserName.UserName;
        clone.UserName.Password = this.UserName.Password;
        return clone;
    }
}

```

4. Create an **OracleEBSBinding** and configure the polling operation by specifying the binding properties. You can do this either explicitly in code or declaratively in configuration. At a minimum, you must specify the **InboundOperationType**, **PolledDataAvailableStatement**, **PollingInput**, and **PollingAction** binding properties.

```

OracleEBSBinding binding = new OracleEBSBinding();
binding.InboundOperationType = InboundOperation.Polling;
binding.PolledDataAvailableStatement = "SELECT COUNT (*) FROM MS_SAMPLE_EMPLOYEE";
binding.PollingInput = "SELECT * FROM MS_SAMPLE_EMPLOYEE FOR UPDATE";
binding.PollingAction = "InterfaceTables/Pol/FND/APPS/MS_SAMPLE_EMPLOYEE";
binding.PostPollStatement = "DELETE FROM MS_SAMPLE_EMPLOYEE";

```

5. Because you are polling an interface table, you must also set the applications context. For more information about application context and the binding properties required for setting application context, see [Setting Application Context](#).

```

binding.OracleUserName = "myOracleEBSUserName";
binding.OraclePassword = "myOracleEBSPassword";
binding.OracleEBSResponsibilityName = "myOracleEBSResponsibility";

```

6. Specify Oracle E-Business Suite credentials by instantiating the **PollingCredentials** class you created in Step 3.

```

PollingCredentials credentials = new PollingCredentials();
credentials.UserName.UserName = "<Enter user name here>";
credentials.UserName.Password = "<Enter password here>";

```

7. Create an instance of the WCF service created in step 2.

```

// create service instance
PollingService service = new PollingService();

```

8. Create an instance of **System.ServiceModel.ServiceHost** by using the WCF service and a base connection URI. The base connection URI cannot contain the inbound ID, if specified. You must also pass the credentials here.

```

// Enable service host
Uri[] baseUri = new Uri[] { new Uri("oracleebs://ebs_instance_name") };
ServiceHost serviceHost = new ServiceHost(service, baseUri);
serviceHost.Description.Behaviors.Add(credentials);

```

9. Add a service endpoint to the service host. To do this:

- Use the binding created in step 4.
- Specify a connection URI that contains credentials and, if required, an inbound ID.

- Specify the contract as "InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEE" to poll the MS_SAMPLE_EMPLOYEE interface table.

```
// Add service endpoint: be sure to specify InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEE as the contract
Uri ConnectionUri = new Uri("oracleebs://ebs_instance_name");
serviceHost.AddServiceEndpoint("InterfaceTables_FND_APPS_MS_SAMPLE_EMPLOYEE", binding, ConnectionUri);
```

10. To receive polling data, open the service host. The adapter will return data whenever the query returns a result set.

```
// Open the service host to begin polling
serviceHost.Open();
```

11. To terminate polling, close the service host.

◆ Important

The adapter will continue to poll until the service host is closed.

```
serviceHost.Close();
```

Example

The following example shows a polling application that polls the MS_SAMPLE_EMPLOYEE interface table. The **PollingInput** property contains the select statement that reads all the data from the MS_SAMPLE_EMPLOYEE table and the post poll statement deletes all the data from the same table. The first polling message gives all the records from the MS_SAMPLE_EMPLOYEE interface table. Subsequent polling messages will not contain any records because the post poll statement deletes the records. Until more data is added to the MS_SAMPLE_EMPLOYEE interface table, you will not get any polling messages. So, you must repopulate the MS_SAMPLE_EMPLOYEE interface table with new records. You can do so by running the insert_apps_data.sql script provided with the samples. After you run this script, the next polling operation will fetch the new records inserted into the table. The adapter will continue to poll until you close the service host by pressing <RETURN>.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using Microsoft.Adapters.OracleEBS;
using Microsoft.ServiceModel.Channels;
using System.ServiceModel;
using System.ServiceModel.Description;
using System.ServiceModel.Channels;
using System.Collections.ObjectModel;

namespace SelectPolling_ServiceModel
{
    [ServiceBehavior(InstanceContextMode = InstanceContextMode.Single)]

    public class PollingService : OracleEBSBindingNamespace.OracleEBSBindingService
    {
        public override void Poll(Poll request)
        {
            Console.WriteLine("\nNew Polling Records Received");
            Console.WriteLine("*****");
            Console.WriteLine("Emp No\tName\tDesignation\tSalary");
            for (int i = 0; i < request.DATA.Length; i++)
            {
                Console.WriteLine("{0}\t{1}\t{2}\t{3}",
                    request.DATA[i].EMP_NO,
```

```

        request.DATA[i].NAME,
        request.DATA[i].DESIGNATION,
        request.DATA[i].SALARY);
    }
    Console.WriteLine("*****");
    Console.WriteLine("\nHit <RETURN> to stop polling");
}
}

class PollingCredentials : ClientCredentials, IServiceBehavior
{
    public void AddBindingParameters(ServiceDescription serviceDescription, ServiceHost
Base serviceHostBase, Collection<ServiceEndpoint> endpoints, BindingParameterCollection bin
dingParameters)
    {
        bindingParameters.Add(this);
    }

    public void ApplyDispatchBehavior(ServiceDescription serviceDescription, ServiceHos
tBase serviceHostBase)
    { }

    public void Validate(ServiceDescription serviceDescription, ServiceHostBase service
HostBase)
    { }

    protected override ClientCredentials CloneCore()
    {
        ClientCredentials clone = new PollingCredentials();
        clone.UserName.UserName = this.UserName.UserName;
        clone.UserName.Password = this.UserName.Password;
        return clone;
    }
}

class Program
{
    static void Main(string[] args)
    {
        ServiceHost serviceHost = null;
        try
        {
            Console.WriteLine("Sample started...");
            Console.WriteLine("Press any key to start polling...");
            Console.ReadLine();

            OracleEBSBinding binding = new OracleEBSBinding();
            binding.InboundOperationType = InboundOperation.Polling;
            binding.PolledDataAvailableStatement = "SELECT COUNT (*) FROM MS_SAMPLE_EMP
LOYEE";

            binding.PollingInput = "SELECT * FROM MS_SAMPLE_EMPLOYEE FOR UPDATE";
            binding.PollingAction = "InterfaceTables/Poll/FND/APPS/MS_SAMPLE_EMPLOYEE";
            binding.PostPollStatement = "DELETE FROM MS_SAMPLE_EMPLOYEE";
            binding.OracleUserName = "myOracleEBSUserName";
            binding.OraclePassword = "myOracleEBSPassword";
            binding.OracleEBSResponsibilityName = "myOracleEBSResponsibility";

            // This URI is used to specify the address for the ServiceEndpoint
            // It must contain the InboundId that was used to generate
            // the WCF service callback interface
            Uri ConnectionUri = new Uri("oracleEBS://ebs_instance_name");

            // This URI is used to initialize the ServiceHost. It cannot contain
            // an InboundID; otherwise, an exception is thrown when
            // the ServiceHost is initialized.
            Uri[] baseUri = new Uri[] { new Uri("oracleEBS://ebs_instance_name") };

            PollingCredentials credentials = new PollingCredentials();

```

Polling Using Stored Procedures Using the WCF Service Model

You can configure the Oracle E-Business adapter to receive periodic data-change messages by using stored procedures to periodically poll the Oracle database. You can specify a stored procedure as a polling statement that the adapter executes periodically to poll the Oracle database.

To enable polling, you must specify certain binding properties as described in this topic. For more information about how the adapter supports polling, see [Support for Inbound Calls Using Polling](#).

Configuring a Polling Operation with Oracle E-Business Adapter Binding Properties

The following table summarizes the Oracle E-Business adapter binding properties that you use to configure the adapter to receive data-change messages. You must specify these binding properties while running the polling application.

Binding Property	Description
InboundOperationType	Specifies whether you want to perform a Polling or Notification inbound operation. Default is Polling .
PolledDataAvailableStatement	Specifies the SQL statement that the adapter executes to determine whether any data is available for polling. Only if a record is available, the stored procedure you specified for the PollingInput binding property will be executed.
PollingInterval	Specifies the interval, in seconds, at which the Oracle E-Business adapter executes the statement specified for the PolledDataAvailableStatement binding property. The default is 30 seconds. The polling interval determines the time interval between successive polls. If the statement is executed within the specified interval, the adapter sleeps for the remaining time in the interval.
PollingInput	Specifies the polling statement. To poll using a stored procedure, you must specify the entire request message for this binding property. The request message must be the same that you send to the adapter for invoking the stored procedure as an outbound operation. The default is null. You must specify a value for PollingInput binding property to enable polling. The polling statement is executed only if there is data available for polling, which is determined by the PolledDataAvailableStatement binding property.
PollingAction	Specifies the action for the polling operation. You can determine the polling action from the service interface generated for the operation using the Add Adapter Service Reference Visual Studio Plug-in.
PostPollStatement	Specifies a statement block that is executed after the statement specified by the PollingInput binding property is executed.
PollWhileDataFound	Specifies whether the Oracle E-Business adapter ignores the polling interval and continuously executes the polling statement, if data is available in the table being polled. If no data is available in the table, the adapter reverts to execute the polling statement at the specified polling interval. Default is false.

For a more complete description of these properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For a complete description of how to use the Oracle E-Business adapter to poll, read the following sections.

How This Topic Demonstrates Polling

In this topic, to demonstrate how the Oracle E-Business adapter supports receiving data change messages using stored procedures, you use the GET_ACTIVITYS stored procedure to poll the ACCOUNTACTIVITY table in the Oracle database. This stored procedure is available with the ACCOUNT_PKG package. You can run the SQL scripts provided with the samples to create these objects in the database.

Note

The example in this topic polls the ACCOUNTACTIVITY table, which is a base database table created by running the scripts provided with the samples. You must perform similar procedures as described in this topic to poll any other table, including interface tables.

To demonstrate a polling operation, we do the following:

- Specify a SELECT statement for the **PolledDataAvailableStatement** binding property to determine where the table being polled (ACCOUNTACTIVITY) has any data. In this example, you can set this binding property as:

```
SELECT COUNT (*) FROM ACCOUNTACTIVITY
```

This ensures that the adapter executes the polling statement only when the ACCOUNTACTIVITY table has some records.

- Execute a stored procedure, GET_ACTIVITYS, by providing the request message as part of the **PollingInput** binding property. This stored procedure will retrieve all the rows in the ACCOUNTACTIVITY table and you will get a response message from the adapter.
- Execute a PL/SQL block as part of the **PostPollStatement** binding property. This statement will move all data from ACCOUNTACTIVITY table to another table in the database. After this happens, the next time **PollingInput** is executed, it will not fetch any data and hence the GET_ACTIVITYS stored procedure will return an empty response message.
- Until more data is added to the ACCOUNTACTIVITY table, you will continue to get empty response messages so you must repopulate the ACCOUNTACTIVITY table with new records. You can do so by running the more_activity_data.sql script provided with the samples. After you run this script, the next polling operation will fetch the new records inserted into the table.

Configuring Polling in the WCF Service Model

To poll using stored procedures with the Oracle E-Business adapter with the WCF service model, you must:

- Generate a WCF service contract (interface) for the stored procedure using which you are going to poll. For this example, you must generate the WCF service contract for the **GET_ACTIVITYS** stored procedure as an inbound operation. To do this, you could use the Add Adapter Service Reference Plug-in.
- Implement a WCF service from this interface.
- Host this WCF service using a service host (**System.ServiceModel.ServiceHost**).

About the Examples Used in this Topic

The examples in this topic poll the ACCOUNTACTIVITY database table using the GET_ACTIVITYS stored procedure. A script to generate the table and the stored procedure is supplied with the samples. For more information about the samples, see [Samples](#). A sample, **StoredProcPolling_ServiceModel**, which is based on this topic, is also provided with the Oracle E-Business adapter samples.

The WCF Service Contract and Class

You can use the Add Adapter Service Reference Plug-in to create a WCF service contract (interface) and supporting classes for the **GET_ACTIVITYS** inbound operation. For more information about generating a WCF service contract, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#).

The WCF Service Contract (Interface)

The following code shows the WCF service contract (interface) generated for the **GET_ACTIVITYS** inbound operation.

```
[System.CodeDom.Compiler.GeneratedCodeAttribute("System.ServiceModel", "3.0.0.0")]  
[System.ServiceModel.ServiceContractAttribute(Namespace="http://schemas.microsoft.com/OracleEBS/", ConfigurationName="PollingPackageApis_APPS_ACCOUNT_PKG")]
```

```

public interface PollingPackageApis_APPS_ACCOUNT_PKG {

    // CODEGEN: Generating message contract since the wrapper namespace (http://schemas.microsoft.com/OracleEBS/2008/05/PollingPackageApis/APPs/ACCOUNT_PKG) of message GET_ACTIVITYS
    // does not match the default value (http://schemas.microsoft.com/OracleEBS/)
    [System.ServiceModel.OperationContractAttribute(IsOneWay=true, Action="PollingPackageApis/APPs/ACCOUNT_PKG/GET_ACTIVITYS")]
    void GET_ACTIVITYS(GET_ACTIVITYS request);
}

```

The Message Contracts

Following is the message contract for the **GET_ACTIVITYS** inbound operation.

```

[System.Diagnostics.DebuggerStepThroughAttribute()]
[System.CodeDom.Compiler.GeneratedCodeAttribute("System.ServiceModel", "3.0.0.0")]
[System.ServiceModel.MessageContractAttribute(WrapperName="GET_ACTIVITYS", WrapperNamespace="http://schemas.microsoft.com/OracleEBS/2008/05/PollingPackageApis/APPs/ACCOUNT_PK" + "G", IsWrapped=true)]
public partial class GET_ACTIVITYS {

    [System.ServiceModel.MessageBodyMemberAttribute(Namespace="http://schemas.microsoft.com/OracleEBS/2008/05/PollingPackageApis/APPs/ACCOUNT_PK" + "G", Order=0)]
    public schemas.microsoft.com.OracleEBS._2008._05.RecordTypes.APPs.ACCOUNT_PKG.GET_ACTIVITYS.OUTRECSRecord[] OUTRECS;

    public GET_ACTIVITYS() {
    }

    public GET_ACTIVITYS(schemas.microsoft.com.OracleEBS._2008._05.RecordTypes.APPs.ACCOUNT_PKG.GET_ACTIVITYS.OUTRECSRecord[] OUTRECS) {
        this.OUTRECS = OUTRECS;
    }
}

```

WCF Service Class

The Add Adapter Service Reference Plug-in also generates a file that has a stub for the WCF service class implemented from the service contract (interface). The name of the file is OracleEBSBindingService.cs. You can insert the logic to process the **GET_ACTIVITYS** operation directly into this class. The following code shows the WCF service class generated by the Add Adapter Service Reference Plug-in.

```

namespace OracleEBSBindingNamespace {

    public class OracleEBSBindingService : PollingPackageApis_APPS_ACCOUNT_PKG {

        // CODEGEN: Generating message contract since the wrapper namespace (http://schemas.microsoft.com/OracleEBS/2008/05/PollingPackageApis/APPs/ACCOUNT_PKG) of message GET_ACTIVITYS
        // does not match the default value (http://schemas.microsoft.com/OracleEBS/)
        public virtual void GET_ACTIVITYS(GET_ACTIVITYS request) {
            throw new System.NotImplementedException("The method or operation is not implemented.");
        }
    }
}

```

Receiving Inbound Messages For Polling Using a Stored Procedure

This section provides instructions on how to write a .NET application to receive inbound polling messages using the Oracle E-Business adapter.

To receive polling messages using a stored procedure

1. Use the Add Adapter Service Reference Plug-in to generate a WCF service contract (interface) and helper classes for the

GET_ACTIVITYS inbound operation. For more information, see

[Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#). You can optionally specify the binding properties while generating the service contract and helper classes. This guarantees that they are properly set in the generated configuration file.

2. Implement a WCF service from the interface and helper classes generated in step 1. The **GET_ACTIVITYS** method of this class can throw an exception to abort the polling transaction, if an error is encountered processing the data received from the **GET_ACTIVITYS** operation; otherwise the method does not return anything. You must attribute the WCF service class as follows:

```
[ServiceBehavior(InstanceContextMode = InstanceContextMode.Single)]
```

Within the **GET_ACTIVITYS** method, you can implement your application logic directly. This class can be found in OracleEBSBindingService.cs. This code in this example sub-classes the **OracleEBSBindingService** class. In this code, the polling message received and is written to the console.

```
[ServiceBehavior(InstanceContextMode = InstanceContextMode.Single)]

public class PollingService : OracleEBSBindingNamespace.OracleEBSBindingService
{
    public override void GET_ACTIVITYS(GET_ACTIVITYS request)
    {
        Console.WriteLine("\nNew Polling Records Received");
        Console.WriteLine("*****");
        Console.WriteLine("Tx Id\tAccount\tAmount\tProcessed");
        for (int i = 0; i < request.OUTRECS.Length; i++)
        {
            Console.WriteLine("{0}\t{1}\t{2}\t{3}",
                request.OUTRECS[i].TID,
                request.OUTRECS[i].ACCOUNT,
                request.OUTRECS[i].AMOUNT,
                request.OUTRECS[i].PROCESSED);
        }
        Console.WriteLine("*****");
        Console.WriteLine("\nHit <RETURN> to stop polling");
    }
}
```

3. You must implement the following class to avoid passing credentials as part of the URI. In the latter part of the application, you will instantiate this class to pass on the credentials.

```
class PollingCredentials : ClientCredentials, IServiceBehavior
{
    public void AddBindingParameters(ServiceDescription serviceDescription, ServiceHostBase serviceHostBase, Collection<ServiceEndpoint> endpoints, BindingParameterCollection bindingParameters)
    {
        bindingParameters.Add(this);
    }

    public void ApplyDispatchBehavior(ServiceDescription serviceDescription, ServiceHostBase serviceHostBase)
    { }

    public void Validate(ServiceDescription serviceDescription, ServiceHostBase serviceHostBase)
    { }
}
```

```

protected override ClientCredentials CloneCore()
{
    ClientCredentials clone = new PollingCredentials();
    clone.UserName.UserName = this.UserName.UserName;
    clone.UserName.Password = this.UserName.Password;
    return clone;
}
}

```

4. Create an **OracleEBSBinding** and configure the polling operation by specifying the binding properties. You can do this either explicitly in code or declaratively in configuration. At a minimum, you must specify the **InboundOperationType**, **PolledDataAvailableStatement**, **PollingInput**, and **PollingAction** binding properties.

```

OracleEBSBinding binding = new OracleEBSBinding();
binding.InboundOperationType = InboundOperation.Polling;
binding.PolledDataAvailableStatement = "SELECT COUNT (*) FROM ACCOUNTACTIVITY";
binding.PollingInput = "<GET_ACTIVITYYS xmlns='http://schemas.microsoft.com/OracleEBS/2008/05/PackageApis/APPS/ACCOUNT_PKG'><INRECS>OPEN ? FOR SELECT * FROM ACCOUNTACTIVITY</INRECS></GET_ACTIVITYYS>";
binding.PollingAction = "PollingPackageApis/APPS/ACCOUNT_PKG/GET_ACTIVITYYS";
binding.PostPollStatement = "BEGIN ACCOUNT_PKG.PROCESS_ACTIVITY(); END;";

```

Note

Note that the value for the **PollingInput** binding property contains the request message for invoking the **GET_ACTIVITYYS** stored procedure as an outbound operation.

Important

In this example, because you are polling a database table, you do not need to set the applications context. However, if you were polling an interface table, you must set the applications context by specifying the **OracleUserName**, **OraclePassword**, and **OracleEBSResponsibilityName** binding properties. For more information about application context, see [Setting Application Context](#).

5. Specify Oracle E-Business Suite credentials by instantiating the **PollingCredentials** class you created in Step 3.

```

PollingCredentials credentials = new PollingCredentials();
credentials.UserName.UserName = "<Enter user name here>";
credentials.UserName.Password = "<Enter password here>";

```

6. Create an instance of the WCF service created in step 2.

```

// create service instance
PollingService service = new PollingService();

```

7. Create an instance of **System.ServiceModel.ServiceHost** by using the WCF service and a base connection URI. The base connection URI cannot contain the inbound ID, if specified. You must also pass the credentials here.

```

// Enable service host
Uri[] baseUri = new Uri[] { new Uri("oracleEBS://ebs_instance_name") };
ServiceHost serviceHost = new ServiceHost(service, baseUri);
serviceHost.Description.Behaviors.Add(credentials);

```

8. Add a service endpoint to the service host. To do this:

- Use the binding created in step 4.

- Specify a connection URI that contains credentials and, if required, an inbound ID.
- Specify the contract as "PollingPackageApis_APPS_ACCOUNT_PKG" to poll the MS_SAMPLE_EMPLOYEE interface table.

```
// Add service endpoint: be sure to specify PollingPackageApis_APPS_ACCOUNT_PKG as the
contract
Uri ConnectionUri = new Uri("oracleebs://ebs_instance_name");
serviceHost.AddServiceEndpoint("PollingPackageApis_APPS_ACCOUNT_PKG", binding, Connect
ionUri);
```

9. To receive polling data, open the service host. The adapter will return data whenever the query returns a result set.

```
// Open the service host to begin polling
serviceHost.Open();
```

10. To terminate polling, close the service host.

◆ Important

The adapter will continue to poll until the service host is closed.

```
serviceHost.Close();
```

Example

The following example shows a polling application that polls the ACCOUNTACTIVITY database table using the GET_ACTIVITYS stored procedure. The **PollingInput** binding property contains the request message to invoke the GET_ACTIVITYS stored procedure that reads all the data from the ACCOUNTACTIVITY table and the post poll statement moves all the data from ACCOUNTACTIVITY to ACTIVITYHISTORY table.

The first polling message gives all the records from the ACCOUNTACTIVITY table. Subsequent polling messages will not contain any records because the post poll statement deletes the records. Until more data is added to the ACCOUNTACTIVITY table, you will not get any polling messages so you must repopulate the ACCOUNTACTIVITY table with new records. You can do so by running the more_activity_data.sql script provided with the samples.

After you run this script, the next polling operation will fetch the new records inserted into the table. The adapter will continue to poll until you close the service host by pressing <RETURN>.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using Microsoft.Adapters.OracleEBS;
using Microsoft.ServiceModel.Channels;
using System.ServiceModel;
using System.ServiceModel.Description;
using System.ServiceModel.Channels;
using System.Collections.ObjectModel;

namespace StoredProcPolling_ServiceModel
{
    [ServiceBehavior(InstanceContextMode = InstanceContextMode.Single)]

    public class PollingService : OracleEBSBindingNamespace.OracleEBSBindingService
    {
        public override void GET_ACTIVITYS(GET_ACTIVITYS request)
        {
            Console.WriteLine("\nNew Polling Records Received");
        }
    }
}
```

```

Console.WriteLine("*****");
Console.WriteLine("Tx Id\tAccount\tAmount\tProcessed");
for (int i = 0; i < request.OUTRECS.Length; i++)
{
    Console.WriteLine("{0}\t{1}\t{2}\t{3}",
        request.OUTRECS[i].TID,
        request.OUTRECS[i].ACCOUNT,
        request.OUTRECS[i].AMOUNT,
        request.OUTRECS[i].PROCESSED);
}
Console.WriteLine("*****");
Console.WriteLine("\nHit <RETURN> to stop polling");
}
}

class PollingCredentials : ClientCredentials, IServiceBehavior
{
    public void AddBindingParameters(ServiceDescription serviceDescription, ServiceHost
Base serviceHostBase, Collection<ServiceEndpoint> endpoints, BindingParameterCollection bin
dingParameters)
    {
        bindingParameters.Add(this);
    }

    public void ApplyDispatchBehavior(ServiceDescription serviceDescription, ServiceHos
tBase serviceHostBase)
    { }

    public void Validate(ServiceDescription serviceDescription, ServiceHostBase service
HostBase)
    { }

    protected override ClientCredentials CloneCore()
    {
        ClientCredentials clone = new PollingCredentials();
        clone.UserName.UserName = this.UserName.UserName;
        clone.UserName.Password = this.UserName.Password;
        return clone;
    }
}

class Program
{
    static void Main(string[] args)
    {
        ServiceHost serviceHost = null;
        try
        {
            Console.WriteLine("Sample started...");
            Console.WriteLine("Press any key to start polling...");
            Console.ReadLine();

            OracleEBSBinding binding = new OracleEBSBinding();
            binding.InboundOperationType = InboundOperation.Polling;
            binding.PolledDataAvailableStatement = "SELECT COUNT (*) FROM ACCOUNTACTIVI
TY";
            binding.PollingInput = "<GET_ACTIVITYS xmlns='http://schemas.microsoft.com/
OracleEBS/2008/05/PackageApis/APPS/ACCOUNT_PKG'><INRECS>OPEN ? FOR SELECT * FROM ACCOUNTACT
IVITY</INRECS></GET_ACTIVITYS>";
            binding.PollingAction = "PollingPackageApis/APPS/ACCOUNT_PKG/GET_ACTIVITYS"
;
            binding.PostPollStatement = "BEGIN ACCOUNT_PKG.PROCESS_ACTIVITY(); END;";

            // This URI is used to specify the address for the ServiceEndpoint
            // It must contain the InboundId that was used to generate
            // the WCF service callback interface
            Uri ConnectionUri = new Uri("oracleebs://ebs_instance_name");

```

Receiving Database Change Notifications Using the WCF Service Model

This topic demonstrates how to configure the Oracle E-Business adapter to receive query notification messages from an Oracle database. To demonstrate notifications, consider a table, ACCOUNTACTIVITY, with a "Processed" column. When a new record is inserted to this table, the value of the Status column is set to "n." You can configure the adapter to receive notifications by registering for notifications using a SQL statement that retrieves all records that have "Processed" column as "n." You can do so by specifying the SQL statement for the **NotificationStatement** binding property. After the adapter client receives the notification, it can contain the logic to do any subsequent tasks on the Oracle database. In this example, for the sake of simplicity, the adapter client lists all the records in the table that have the "Processed" column as "n."

Configuring Notifications with the Oracle E-Business Adapter Binding Properties

The table below summarizes the Oracle E-Business adapter binding properties that you use to configure receiving notifications from Oracle E-Business Suite. You must specify these binding properties while running the .NET application to receive notifications.

Binding Property	Description
InboundOperationType	Specifies the inbound operation that you want to perform. To receive notification messages, set this to Notification .
NotificationPort	Specifies the port number that ODP.NET must open to listen for database change notification from Oracle database.
NotificationStatement	Specifies the Select statement used to register for query notifications. The adapter gets a notification message only when the result set for the specified Select statement changes.
NotifyOnListenerStart	Specifies whether the adapter sends a notification to the adapter clients when the listener is started.

For a more complete description of these properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For a complete description of how to use the Oracle E-Business adapter to receive notifications from Oracle E-Business Suite, read the remainder of this topic.

Configuring Notifications Using the WCF Service Model

To receive the notifications using the WCF service model, you must:

- Generate a WCF service contract (interface) for the **Notification** operation from the metadata exposed by the adapter. To do this, you could use the Add Adapter Service Reference Plug-in.
- Generate a WCF client for the **Select** operation on the ACCOUNTACTIVITY table. To do this, you could use the Add Adapter Service Reference Plug-in.
- Implement a WCF service from this interface.
- Host this WCF service using a service host (**System.ServiceModel.ServiceHost**).

About the Examples Used in this Topic

The examples in this topic receives notification for the ACCOUNTACTIVITY table. A script to generate the table is supplied with the samples. For more information about the samples, see [Samples](#). A sample, **Notification_ServiceModel**, which is based on this topic, is also provided with the Oracle E-Business adapter samples.

The WCF Service Contract and Class

You can use the Add Adapter Service Reference Plug-in to create a WCF service contract (interface) and supporting classes for the **Notification** operation. For more information about generating a WCF service contract, see

The WCF Service Contract (Interface)

The following code shows the WCF service contract (interface) generated for the **Notification** operation.

```
[System.CodeDom.Compiler.GeneratedCodeAttribute("System.ServiceModel", "3.0.0.0")]
[System.ServiceModel.ServiceContractAttribute(Namespace="http://schemas.microsoft.com/OracleEBS/", ConfigurationName="Notification_")]
public interface Notification_ {

    // CODEGEN: Generating message contract since the wrapper namespace (http://schemas.microsoft.com/OracleEBS/2008/05/Notification/) of message Notification
    // does not match the default value (http://schemas.microsoft.com/OracleEBS/)
    [System.ServiceModel.OperationContractAttribute(IsOneWay=true, Action="Notification")]
    void Notification(Notification request);
}
```

The Message Contracts

Following is the message contract for the Notification operation.

```
[System.Diagnostics.DebuggerStepThroughAttribute()]
[System.CodeDom.Compiler.GeneratedCodeAttribute("System.ServiceModel", "3.0.0.0")]
[System.ServiceModel.MessageContractAttribute(WrapperName="Notification", WrapperNamespace="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/", IsWrapped=true)]
public partial class Notification {

    [System.ServiceModel.MessageBodyMemberAttribute(Namespace="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/", Order=0)]
    public schemas.microsoft.com.OracleEBS._2008._05.Notification.NotificationDetails[] Details;

    [System.ServiceModel.MessageBodyMemberAttribute(Namespace="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/", Order=1)]
    public string Info;

    [System.ServiceModel.MessageBodyMemberAttribute(Namespace="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/", Order=2)]
    public string[] ResourceNames;

    [System.ServiceModel.MessageBodyMemberAttribute(Namespace="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/", Order=3)]
    public string Source;

    [System.ServiceModel.MessageBodyMemberAttribute(Namespace="http://schemas.microsoft.com/OracleEBS/2008/05/Notification/", Order=4)]
    public string Type;

    public Notification() {
    }

    public Notification(schemas.microsoft.com.OracleEBS._2008._05.Notification.NotificationDetails[] Details, string Info, string[] ResourceNames, string Source, string Type) {
        this.Details = Details;
        this.Info = Info;
        this.ResourceNames = ResourceNames;
        this.Source = Source;
        this.Type = Type;
    }
}
```

WCF Service Class

The Add Adapter Service Reference Plug-in also generates a file that has a stub for the WCF service class implemented from the service contract (interface). The name of the file is OracleEBSBindingService.cs. You can insert the logic to process the **Notification** operation directly into this class. The following code shows the WCF service class generated by the Add Adapter

```

namespace OracleEBSBindingNamespace {

    public class OracleEBSBindingService : Notification_ {

        // CODEGEN: Generating message contract since the wrapper namespace (http://schemas
        .microsoft.com/OracleEBS/2008/05/Notification/) of message Notification
        // does not match the default value (http://schemas.microsoft.com/OracleEBS/)
        public virtual void Notification(Notification request) {
            throw new System.NotImplementedException("The method or operation is not implem
            ented.");
        }
    }
}

```

Receiving Query Notifications Using WCF Service Model

This section provides instructions on how to write a .NET application to receive query notifications using the Oracle E-Business adapter.

To receive query notifications

1. Use the Add Adapter Service Reference Plug-in to generate a WCF client for **Select** operation on the **ACCOUNTACTIVITY** table. You will use this client to perform Select operations after receiving a notification message. Add a new class, TableOperation.cs, to your project and add the following code snippet to perform a Select operation.

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace Notification_ServiceModel
{
    class TableOperation
    {
        public void TableOp()
        {
            ////////////////////////////////////////////////////////////////////
            // CREATING THE CLIENT AND SETTING CLIENT CREDENTIALS
            ////////////////////////////////////////////////////////////////////

            Tables_APPS_ACCOUNTACTIVITYClient client = new Tables_APPS_ACCOUNTACTIVITY
            Client();

            client.ClientCredentials.UserName.UserName = "<Enter user name here>";
            client.ClientCredentials.UserName.Password = "<Enter password here>";

            ////////////////////////////////////////////////////////////////////
            // OPENING THE CLIENT
            ////////////////////////////////////////////////////////////////////
            try
            {
                Console.WriteLine("Opening the client ...");
                client.Open();
            }
            catch (Exception ex)
            {
                Console.WriteLine("Exception: " + ex.Message);
                throw;
            }
        }
    }
}

```

```

////////////////////////////////////
////////////////////////////////////
// SELECTING THE LAST INSERTED VALUES
////////////////////////////////////
////////////////////////////////////
Console.WriteLine("The application will now select the last inserted recor
d");

        schemas.microsoft.com.OracleEBS._2008._05.TableViewRecord.APPS.ACCOUNTACTI
VITY.SelectRecord[] selectRecords;

        try
        {
            selectRecords = client.Select("", "WHERE PROCESSED = 'n'");
        }
        catch (Exception ex)
        {
            Console.WriteLine("Exception: " + ex.Message);
            throw;
        }

        Console.WriteLine("The details of the newly added records are:");
        Console.WriteLine("*****");
        for (int i = 0; i < selectRecords.Length; i++)
        {
            Console.WriteLine("Transaction ID   : " + selectRecords[i].TID);
            Console.WriteLine("Account ID       : " + selectRecords[i].ACCOUNT);
            Console.WriteLine("Processed Status : " + selectRecords[i].PROCESSED);
            Console.WriteLine();
        }
        Console.WriteLine("*****");
    }
}
}
}

```

2. Use the Add Adapter Service Reference Plug-in to generate a WCF service contract (interface) and helper classes for the **Notification** operation.

For more information, see [Generating a WCF Client or a WCF Service Contract for Oracle E-Business Solution Artifacts](#). You can optionally specify the binding properties while generating the service contract and helper classes. This guarantees that they are properly set in the generated configuration file.

3. Implement a WCF service from the interface and helper classes generated in step 2. The **Notification** method of this class can throw an exception to abort the operation, if an error is encountered processing the data received from the **Notification** operation; otherwise the method does not return anything. You must attribute the WCF service class as follows:

```
[ServiceBehavior(InstanceContextMode = InstanceContextMode.Single)]
```

Within the **Notification** method, you can implement your application logic directly. This class can be found in OracleEBSBindingService.cs. This code in this example sub-classes the **OracleEBSBindingService** class. In this code, the notification message received is written to the console. Additionally, the **TableOp** method within the **TableOperation** class is invoked to perform the Select operation.

```
[ServiceBehavior(InstanceContextMode = InstanceContextMode.Single)]

public class NotificationService : OracleEBSBindingNamespace.OracleEBSBindingService
{

```

```

public override void Notification(Notification request)
{
    Console.WriteLine("\nNew Notification Received");
    Console.WriteLine("*****");
    Console.WriteLine(request.Info);
    Console.WriteLine(request.Source);
    Console.WriteLine(request.Type);
    Console.WriteLine("*****");

    TableOperation Ops = new TableOperation();
    Ops.TableOp();
}
}

```

4. You must implement the following class to pass credentials for the Oracle E-Business Suite. In the latter part of the application, you will instantiate this class to pass on the credentials.

```

class NotificationCredentials : ClientCredentials, IServiceBehavior
{
    public void AddBindingParameters(ServiceDescription serviceDescription, ServiceHostBase serviceHostBase, Collection<ServiceEndpoint> endpoints, BindingParameterCollection bindingParameters)
    {
        bindingParameters.Add(this);
    }

    public void ApplyDispatchBehavior(ServiceDescription serviceDescription, ServiceHostBase serviceHostBase)
    { }

    public void Validate(ServiceDescription serviceDescription, ServiceHostBase serviceHostBase)
    { }

    protected override ClientCredentials CloneCore()
    {
        ClientCredentials clone = new NotificationCredentials();
        clone.UserName.UserName = this.UserName.UserName;
        clone.UserName.Password = this.UserName.Password;
        return clone;
    }
}

```

5. Create an **OracleEBSBinding** and configure the adapter to receive query notifications by specifying the binding properties. You can do this either explicitly in code or declaratively in configuration. At a minimum, you must specify the **InboundOperationType** and **NotificationStatement** binding properties.

```

OracleEBSBinding binding = new OracleEBSBinding();
binding.InboundOperationType = InboundOperation.Notification;
binding.NotificationStatement = "SELECT TID,ACCOUNT,PROCESSED FROM APPS.ACCOUNTACTIVITY WHERE PROCESSED = 'n'";
binding.NotifyOnListenerStart = true;
binding.NotificationPort = 10;

```

◆ Important

The value for the **NotificationPort** binding property must be set to the same port number that you must have added to the Windows Firewall exceptions list. For instructions on how to add ports to Windows Firewall exceptions list, see <http://go.microsoft.com/fwlink/?LinkID=196959>.

◆ Important

If you do not set the **NotificationPort** binding property, the adapter will assume the default value of -1 for this binding property. In such a case, you will have to completely disable Windows Firewall to receive notification messages.

- Specify Oracle E-Business Suite credentials by instantiating the **NotificationCredentials** class you created in Step 4.

```
NotificationCredentials credentials = new NotificationCredentials();
credentials.UserName.UserName = "<Enter user name here>";
credentials.UserName.Password = "<Enter password here>";
```

- Create an instance of the WCF service created in step 3.

```
// create service instance
NotificationService service = new NotificationService();
```

- Create an instance of **System.ServiceModel.ServiceHost** by using the WCF service and a base connection URI. You must also specify the credentials here.

```
// Enable service host
Uri[] baseUri = new Uri[] { new Uri("oracleebss://ebs_instance_name") };
ServiceHost serviceHost = new ServiceHost(service, baseUri);
serviceHost.Description.Behaviors.Add(credentials);
```

- Add a service endpoint to the service host. To do this:

- Use the binding created in step 5.
- Specify a connection URI that contains credentials and, if required, an inbound ID.
- Specify the contract as "Notification_".

```
// Add service endpoint: be sure to specify Notification_ as the contract
Uri ConnectionUri = new Uri("oracleebss://ebs_instance_name?");
serviceHost.AddServiceEndpoint("Notification_", binding, ConnectionUri);
```

- To receive notification message, open the service host.

```
// Open the service host to begin receiving notifications
serviceHost.Open();
```

- To stop receiving notifications, close the service host.

```
serviceHost.Close();
```

Example

The following example shows a .NET application to receive notification messages for the ACCOUNTACTIVITY table.

Note

The following code snippet instantiates a **TableOperation.cs** class and invokes the **TableOp** method. The class and the method are described in Step 1.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using Microsoft.Adapters.OracleEBS;
using Microsoft.ServiceModel.Channels;
using System.ServiceModel;
using System.ServiceModel.Description;
using System.ServiceModel.Channels;
using System.Collections.ObjectModel;

namespace Notification_ServiceModel
{
    [ServiceBehavior(InstanceContextMode = InstanceContextMode.Single)]

    public class NotificationService : OracleEBSBindingNamespace.OracleEBSBindingService
    {
        public override void Notification(Notification request)
        {
            Console.WriteLine("\nNew Notification Received");
            Console.WriteLine("*****");
            Console.WriteLine(request.Info);
            Console.WriteLine(request.Source);
            Console.WriteLine(request.Type);
            Console.WriteLine("*****");

            TableOperation Ops = new TableOperation();
            Ops.TableOp();
        }
    }

    class NotificationCredentials : ClientCredentials, IServiceBehavior
    {
        public void AddBindingParameters(ServiceDescription serviceDescription, ServiceHost
        Base serviceHostBase, Collection<ServiceEndpoint> endpoints, BindingParameterCollection bin
        dingParameters)
        {
            bindingParameters.Add(this);
        }

        public void ApplyDispatchBehavior(ServiceDescription serviceDescription, ServiceHos
        tBase serviceHostBase)
        { }

        public void Validate(ServiceDescription serviceDescription, ServiceHostBase service
        HostBase)
        { }

        protected override ClientCredentials CloneCore()
        {
            ClientCredentials clone = new NotificationCredentials();
            clone.UserName.UserName = this.UserName.UserName;
            clone.UserName.Password = this.UserName.Password;
            return clone;
        }
    }

    class Program
    {
```

```

static void Main(string[] args)
{
    ServiceHost serviceHost = null;
    try
    {
        Console.WriteLine("Sample started...");
        Console.WriteLine("Press any key to start receiving notifications...");
        Console.ReadLine();

        OracleEBSBinding binding = new OracleEBSBinding();
        binding.InboundOperationType = InboundOperation.Notification;
        binding.NotificationStatement = "SELECT TID,ACCOUNT,PROCESSED FROM APPS.ACCO
OUNTACTIVITY WHERE PROCESSED = 'n'";
        binding.NotifyOnListenerStart = true;
        binding.NotificationPort = 10;

        // This URI is used to specify the address for the ServiceEndpoint
        // It must contain the InboundId that was used to generate
        // the WCF service callback interface
        Uri ConnectionUri = new Uri("oracleebs://ebs_instance_name");

        // This URI is used to initialize the ServiceHost. It cannot contain
        // an InboundID; otherwise,an exception is thrown when
        // the ServiceHost is initialized.
        Uri[] baseUri = new Uri[] { new Uri("oracleebs://ebs_instance_name") };

        NotificationCredentials credentials = new NotificationCredentials();
        credentials.UserName.UserName = "<Enter user name here>";
        credentials.UserName.Password = "<Enter password here>";

        Console.WriteLine("Opening service host...");
        NotificationService service = new NotificationService();
        serviceHost = new ServiceHost(service, baseUri);
        serviceHost.Description.Behaviors.Add(credentials);
        serviceHost.AddServiceEndpoint("Notification_", binding, ConnectionUri);
        serviceHost.Open();
        Console.WriteLine("Service host opened...");
        Console.WriteLine("Waiting for notification...");

        Console.WriteLine("\nHit <RETURN> to stop receiving notification");
        Console.ReadLine();
    }
    catch (Exception e)
    {
        Console.WriteLine("Exception :" + e.Message);
        Console.ReadLine();

        /* If there is an error it will be specified in the inner exception */
        if (e.InnerException != null)
        {
            Console.WriteLine("InnerException: " + e.InnerException.Message);
            Console.ReadLine();
        }
    }
    finally
    {
        // IMPORTANT: you must close the ServiceHost to stop polling
        if (serviceHost.State == CommunicationState.Opened)
            serviceHost.Close();
        else
            serviceHost.Abort();
    }
}
}
}
}

```

[Developing Applications By Using the WCF Service Model](#)

Developing Applications by Using the WCF Channel Model

You can use the Windows Communication Foundation (WCF) channel model to consume the Microsoft BizTalk Adapter for Oracle E-Business Suite by sending XML messages directly over a channel instance created with the Oracle EBS Binding.

One advantage of using the WCF channel model over using the strongly-typed classes and methods that the WCF service model exposes is that the channel model provides more fine-grained control over the operations that you perform on the Oracle E-Business Suite. This control comes from the fact that in the WCF channel model, you directly control the contents of the messages that you send over the channel.

In certain scenarios, this extra level of control can be beneficial. For example, when you use the WCF channel model to perform an Update operation on a table, you can selectively update columns in the target rows by omitting columns from the update template that you pass in the message. The only columns that are required are those with "nillable=false" in the WSDL. The update method exposed by a WCF client uses a strongly-typed record parameter for the template that includes every column in the table schema.

The topics in this section explain how to perform operations on the Oracle E-Business adapter by using the WCF channel model.

Overview of Using the WCF Channel Model with the Adapter

To invoke operations on the Microsoft BizTalk Adapter for Oracle E-Business Suite, your code acts as a WCF client and sends outbound operations to the adapter. In the WCF channel model, your code invokes operations on the adapter by sending a request message over a channel.

To invoke inbound operations, such as receiving polling-based data-changed messages using the **Poll** operation provided by the adapter, your code acts as a WCF service and receives the inbound operation from the adapter. In other words, your code receives a request message from the adapter over a channel.

The topics in this section provide an overview of using the Oracle E-Business adapter with the WCF channel model.

WCF Channel Model Overview

Clients and services communicate by exchanging SOAP messages. The WCF channel model is a low-level abstraction of this message exchange. It provides interfaces and types that enable you to send and receive messages by using a layered protocol stack called a channel stack. Each layer of the stack is composed of a channel, and each channel is created from a WCF binding. At the lowest layer is the transport channel. The transport channel implements the underlying transport mechanism between a service and a client and presents each message to the higher layers (and ultimately the consuming application) as a **System.ServiceModel.Message**. The WCF **Message** class is an abstraction of a SOAP message. WCF provides several channel interfaces, called channel shapes, that model the basic SOAP message exchange patterns, such as request-reply or one-way. A WCF transport binding provides an implementation of one or more channel shapes that higher layers can use to send and receive messages. For more information about the WCF channel model, see "Channel Model Overview" at <http://go.microsoft.com/fwlink/?LinkId=82614>.

The Oracle E-Business adapter is a WCF custom transport binding that exposes an Oracle E-Business Suite artifact as a WCF service.

Supported Channel Shapes for the Oracle E-Business Suite Adapter

The adapter implements the following WCF channel shapes:

- **IRequestChannel (System.ServiceModel.Channels.IRequestChannel)**. The **IRequestChannel** interface implements the client side of a request-reply message exchange. You can use an **IRequestChannel** to perform operations for which you want to consume a response, for example to perform a SELECT query on an interface table.
- **IOutputChannel (System.ServiceModel.Channels.IOutputChannel)**. This shape implements the client side of a one-way message exchange. You can use an **IOutputChannel** to invoke an operation for which you do not need to consume a response, for example to call a procedure that has no OUT parameters.

◆ Important

All underlying calls by the adapter to the Oracle client are synchronous. This includes calls to the Oracle client that are the result of operations invoked over an **IOutputChannel**. When you use an **IOutputChannel**, the adapter discards the response received from the Oracle client.

- **IInputChannel (System.ServiceModel.Channels.IInputChannel)**. This shape implements the service side of a one-way message exchange. You use an **IInputChannel** to receive inbound messages from the adapter.

Like any WCF binding, the Oracle E-Business adapter uses a factory pattern to provide channels to application code. You use a **Microsoft.Adapters.OracleEBSBinding** object to create instances of:

- **System.ServiceModel.ChannelFactory<IRequestChannel>** to provide **IRequestChannel** channels you can use to invoke request-response operations on the adapter.
- **System.ServiceModel.ChannelFactory<IOutputChannel>** to provide **IOutputChannel** channels you can use to invoke one-way operations on the adapter.
- **System.ServiceModel.IChannelListener<IInputChannel>** to provide **IInputChannel** channels you can use to receive inbound messages from the adapter.

Creating Messages for the Oracle Enterprise Business Solution in the WCF Channel Model

In WCF the **System.ServiceModel.Channels.Message** class provides an in memory representation of a SOAP message. You create a **Message** instance by invoking the static **Message.Create** method.

There are two important parts to the SOAP message that you must specify when you create a **Message** instance to send to the Oracle E-Business adapter.

- The message action is a string that is part of the SOAP message header. The message action identifies the operation that should be invoked on the Oracle E-Business Suite. The following shows the message action specified to invoke the **Customer Interface** concurrent program under the **Receivables** application in Oracle E-Business Suite:

`ConcurrentPrograms/AR/RACUST`.

- The message body contains the parameter data for the operation. The message body is composed of well-formed XML that corresponds to the message schema expected by the Oracle E-Business adapter for the requested operation. The following message body specifies a request message to invoke the **Customer Interface** concurrent program.

```
<RACUST xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/ConcurrentPrograms/AR">
  <Description>Customer Interface Program</Description>
  <StartTime></StartTime>
  <CREATE_RECIPROCAL_CUSTOMER>Yes</CREATE_RECIPROCAL_CUSTOMER>
  <ORG_ID>203</ORG_ID>
</RACUST>
```

For information about the Oracle E-Business adapter message schemas and message actions for operations, see [Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#).

The **Create** method is overloaded and offers many different options for providing the message body. The following code shows how to create a **Message** instance by using an **XmlReader** to supply the message body. In this code, the message body is read from a file.

```
XmlReader readerIn = XmlReader.Create("ConcProgRequest.xml");
Message messageIn = Message.CreateMessage(MessageVersion.Default,
    "ConcurrentPrograms/AR/RACUST",
    readerIn);
```

where, `ConProgRequest.xml` contains the request message.

◆ Important

You must provide a message action in your **Message** instance. This is typically done when the **Message** instance is created.

[Developing Applications by Using the WCF Channel Model](#)

Creating a Channel

In the WCF channel model, you invoke operations on the Oracle E-Business Suite and receive the results by exchanging SOAP messages with the Microsoft BizTalk Adapter for Oracle E-Business Suite over a WCF channel.

- You invoke operations (outbound operations) by using either an **IRequestChannel** or an **IOutputChannel** to send messages to the adapter.
- You receive messages for inbound operations over an **IInputChannel**.

The topics in this section provide information about how to create and configure channel shapes that are used for inbound and outbound operations.

Creating Outbound (Client) Channels

You can use either an **IRequestChannel** or an **IOutputChannel** to invoke operations on the Oracle E-Business Suite. In either case, you first create a **System.ServiceModel.ChannelFactory** using the appropriate interface. You then use the factory to create the channel. After you have created the channel you can use it to invoke operations on the adapter.

To create and open an outbound channel

1. Create and initialize an instance of **ChannelFactory** for the desired channel shape by using an endpoint and a binding. The endpoint specifies an Oracle E-Business Suite connection URI and the binding is an instance of **OracleEBSBinding**.
2. Provide Oracle E-Business Suite credentials for the channel factory by using the **Credentials** property.
3. Open the channel factory.
4. Get an instance of the channel by invoking the **CreateChannel** method on the channel factory.
5. Open the channel.

You can specify the binding and endpoint address in your code or from configuration.

Specifying the Binding and Endpoint Address in Code

The following code example shows how to create an **IRequestChannel** by specifying the binding and endpoint address in code. The code to create an **IOutputChannel** is the same except that you must specify an **IOutputChannel** interface for the **ChannelFactory** and channel type.

```
// Create binding -- set binding properties before you open the factory.
OracleEBSBinding binding = new OracleEBSBinding();

// Create address
EndpointAddress address = new EndpointAddress("oracleebs://<oracleebs_instance_name>/");

// Create channel factory from binding and address.
ChannelFactory<IRequestChannel> factory =
    new ChannelFactory<IRequestChannel>(binding, address);

// Specify credentials.
factory.Credentials.UserName.UserName = "myuser";
factory.Credentials.UserName.Password = "mypassword";

// Open factory
factory.Open();

// Get channel and open it.
IRequestChannel channel = factory.CreateChannel();
channel.Open();
```

Specifying the Binding and Endpoint Address in Configuration

The following code example shows how to create a channel factory from a client endpoint specified in configuration.

```

// Create channel factory from configuration.
ChannelFactory<IRequestChannel> factory =
new ChannelFactory<IRequestChannel>("MyRequestChannel");

// Specify credentials.
factory.Credentials.UserName.UserName = "myuser";
factory.Credentials.UserName.Password = "mypassword";

// Open the factory.
factory.Open();

// Get a channel and open it.
IRequestChannel channel = factory.CreateChannel();
channel.Open();

```

The Configuration Settings

The following code shows the configuration settings used for the preceding example. The contract for the client endpoint must be "System.ServiceModel.Channels.IRequestChannel" or "System.ServiceModel.Channels.IOutputChannel" depending on the kind of channel shape that you want to create.

```

<?xml version="1.0" encoding="utf-8"?>
<configuration xmlns="http://schemas.microsoft.com/.NetConfiguration/v2.0">
  <system.serviceModel>
    <bindings>
      <oracleEBSBinding>
        <binding openTimeout="00:05:00" name="OracleEBSBinding" closeTimeout="00:01:00"
Database"
receiveTimeout="00:10:00" sendTimeout="00:01:00" clientCredentialType="
inboundOperationType="Polling" metadataPooling="true" statementCachePur
ge="false"
statementCacheSize="10" pollWhileDataFound="false" pollingInterval="30"

incrPoolSize="5" decrPoolSize="1" connectionLifetime="0" acceptCredenti
alsInUri="false"
useAmbientTransaction="true" notifyOnListenerStart="true"
notificationPort="-1" dataFetchSize="65536" longDatatypeColumnSize="0"
skipNilNodes="true" maxOutputAssociativeArrayElements="32"
enableSafeTyping="false" insertBatchSize="20" useSchemaInNameSpace="tru
e"
enableBizTalkCompatibilityMode="true" enablePerformanceCounters="false"
>
        <mlsSettings language="" dateFormat="" dateLanguage="" numericCharacter
s=""
sort="" territory="" comparison="" currency="" dualCurrency=""
ISOCurrency="" calendar="" lengthSemantics="" nCharConversionExcept
ion="true"
timestampFormat="" timeStampTZFormat="" timeZone="" />
      </binding>
    </oracleEBSBinding>
  </bindings>
  <client>
    <endpoint address="oracleEBS://oracle_ebs_instance/" binding="oracleEBSBinding"
bindingConfiguration="OracleEBSBinding" contract="System.ServiceModel.Chann
els.IRequestChannel"
name="MyRequestChannel" />
  </client>
</system.serviceModel>
</configuration>

```

Creating Inbound (Service) Channels

You configure the Oracle E-Business adapter to poll the Oracle database tables and views by setting binding properties on an instance of **OracleEBSBinding**. You then use this binding to build a channel listener from which you can get an **IInputChannel** channel to receive inbound operations from the adapter.

To create and open an `IInputChannel` to receive messages for inbound operations

1. Create an instance of **OracleEBSBinding**.
2. Set the binding properties required for the inbound operation. For example, for a polling operation, at a minimum you must set the **InboundOperationType**, **PolledDataAvailableStatement**, **PollingAction**, and the **PollingInput** binding properties to configure the Oracle E-Business adapter to poll the Oracle database.
3. Create a binding parameter collection using the **BindingParameterCollection** class and set the credentials.
4. Create a channel listener by invoking **BuildChannelListener<IInputChannel>** method on the **OracleEBSBinding**. You specify the Oracle connection URI as one of the parameters to this method.
5. Open the listener.
6. Get an **IInputChannel** channel by invoking the **AcceptChannel** method on listener.
7. Open the channel.

The following code shows how to create a channel listener and get an **IInputChannel** to receive messages for inbound operations from the adapter.

◆ Important

The Oracle E-Business adapter only supports one-way receive. So, you must use **IInputChannel** to receive messages for inbound operations from Oracle E-Business Suite.

```
// Create a binding: specify the InboundOperationType, the PolledDataAvailableStatement, the
// the PollingInput binding properties.
OracleEBSBinding binding = new OracleEBSBinding();
binding.InboundOperationType = InboundOperation.Polling;
binding.PolledDataAvailableStatement = "SELECT COUNT (*) FROM MS_SAMPLE_EMPLOYEE";
binding.PollingAction = "InterfaceTables/Poll/FND/APPS/MS_SAMPLE_EMPLOYEE";
binding.PollingInput = "SELECT * FROM MS_SAMPLE_EMPLOYEE FOR UPDATE";

// Create a binding parameter collection and set the credentials
ClientCredentials credentials = new ClientCredentials();
credentials.UserName.UserName = "myuser";
credentials.UserName.Password = "mypassword";

BindingParameterCollection bindingParams = new BindingParameterCollection();
bindingParams.Add(credentials);

// Get a listener from the binding and open it.
Uri connectionUri = new Uri("oracleebs://oracle_ebs_instance/");
IChannelListener<IInputChannel> listener = binding.BuildChannelListener<IInputChannel>(conn
ectionUri, bindingParams);
listener.Open();

// Get a channel from the listener and open it.
IInputChannel channel = listener.AcceptChannel();
channel.Open();
```

[Developing Applications by Using the WCF Channel Model](#)

Performing an Insert Operation on an Interface Table Using the WCF Channel Model

The Oracle E-Business adapter discovers a set of Insert, Select, Update, and Delete operations on Oracle E-Business Suite interface tables. By using these operations, you can perform simple Insert, Select, Update, and Delete statements qualified by a Where clause on a target interface table. This topic provides instructions on how to perform an Insert operation on an interface table using the WCF channel model.

For more information on how the adapter supports these operations, see [Operations on Interface Tables and Interface Views](#). For more information about how to perform operations on Oracle E-Business Suite using the WCF Channel model, see [Overview of Using the WCF Channel Model with the Adapter](#).

About the Examples Used in this Topic

The example in this topic performs operations on the MS_SAMPLE_EMPLOYEE interface table. The table is created by running the script provided with the samples. For more information about samples, see [Samples](#). A sample, **InsertOperation**, which is based on this topic, is also provided with the Oracle E-Business adapter samples.

The Insert Message

To perform operations on the Oracle E-Business Suite using the WCF channel model, you must have the request message specific to the operation. The request message to perform an Insert operation on the MS_SAMPLE_EMPLOYEE interface table resembles the following:

```
<Insert xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/InterfaceTables/FND/APPS/MS_S
AMPLE_EMPLOYEE">
  <RECORDSET>
    <InsertRecord xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/TableViewRecord/APP
S/MS_SAMPLE_EMPLOYEE">
      <EMP_NO>10050</EMP_NO>
      <NAME>John Smith</NAME>
      <DESIGNATION>Manager</DESIGNATION>
      <SALARY>500000</SALARY>
      <JOIN_DATE>1999-05-31</JOIN_DATE>
    </InsertRecord>
  </RECORDSET>
</Insert>
```

This request message inserts a record with following details:

```
Employee Number = 10050
Name = Tom Smith
Designation = Manager
Salary = 500000
```

You must copy the message to a file, e.g. InsertRequest.xml. This file is used in this example to send the request message to Oracle E-Business Suite using the Oracle E-Business adapter. For more information about the message schema for operations on table, see [Message Schemas for Insert, Update, Delete, and Select Operations](#).

Creating a WCF Channel Application

This section provides instructions on how to create a WCF channel application to perform an Insert operation on the MS_SAMPLE_EMPLOYEE interface table.

To create a WCF channel application for inserting records into the table

1. Create a Visual C# project in Visual Studio. For this topic, create a console application.
2. In the Solution Explorer, add reference to `Microsoft.Adapters.OracleEBS`, `Microsoft.ServiceModel.Channels`, `System.ServiceModel`, and `System.Runtime.Serialization`.
3. Open the Program.cs file and add the following namespaces:
 - `Microsoft.Adapters.OracleEBS`

- Microsoft.ServiceModel.Channels
- System.ServiceModel
- System.ServiceModel.Channels
- System.Xml

4. Create the binding and endpoint.

```
OracleEBSBinding binding = new OracleEBSBinding();
EndpointAddress address = new EndpointAddress("oracleebs://ebs_instance_name");
```

5. Because you are performing an operation on an interface table, you must set the application context. In this example, to set the application context, you specify the **OracleUserName**, **OraclePassword**, and **OracleEBSResponsibilityName** binding properties. For more information about application context, see [Setting Application Context](#).

```
binding.OracleUserName = "myOracleEBSUserName";
binding.OraclePassword = "myOracleEBSPassword";
binding.OracleEBSResponsibilityName = "myOracleEBSResponsibility";
```

6. Create and open the channel factory. This application sends request message to Oracle E-Business Suite and receives a response, hence you must implement the IRequestChannel interface.

```
ChannelFactory<IRequestChannel> factory = new ChannelFactory<IRequestChannel>(binding,
address);
factory.Credentials.UserName.UserName = "<Enter user name here>";
factory.Credentials.UserName.Password = "<Enter password here>";
factory.Open();
```

7. Create and open the channel.

```
IRequestChannel channel;
try
{
    channel = factory.CreateChannel();
    channel.Open();
}
catch (Exception ex)
{
    Console.WriteLine("Exception :" + ex.Message);
    throw;
}
```

8. Create and send the request message.

```
XmlReader readerIn;
try
{
    readerIn = XmlReader.Create("InsertRequest.xml");
    Console.WriteLine("Reader created");
}
catch (Exception ex)
```

```

{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}
Message messageIn;
Message messageOut;
try
{
    messageIn = Message.CreateMessage(MessageVersion.Default, "InterfaceTables/Insert/F
ND/APPS/MS_SAMPLE_EMPLOYEE", readerIn);
    messageOut = channel.Request(messageIn);
}
catch (Exception ex)
{
    Console.WriteLine("Exception: " + ex.Message);
    throw;
}

```

While creating the request message, you must specify the message action that indicates the action that the adapter performs on the interface table. To perform an Insert operation on the MS_SAMPLE_EMPLOYEE table, the message action is `InterfaceTables/Insert/FND/APPS/MS_SAMPLE_EMPLOYEE`. For information about how you can determine the message action for various operations on tables, see [Message Schemas for Insert, Update, Delete, and Select Operations](#).

9. Get the response message.

```

XmlReader readerOut = messageOut.GetReaderAtBodyContents();
XmlDocument doc = new XmlDocument();
doc.Load(readerOut);
doc.Save("C:\\Response.xml");

```

10. Close the message, channel, and channel factory.

```

messageOut.Close();
channel.Close();
factory.Close();

```

11. Build the project. After building the project, you must copy the request message, `InsertRequest.xml`, at the same location as your project executable. Typically, this location is `\\bin\\Debug\\` under your project directory.
12. Run the application. The response message, `Response.xml`, is saved at the location you specified in the application. The response message contains the number of records inserted and resembles the following:

```

<InsertResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/InterfaceTables/
FND/APPS/MS_SAMPLE_EMPLOYEE">
  <InsertResult>1</InsertResult>
</InsertResponse>

```

The value "1" denotes that a single record is inserted into the MS_SAMPLE_EMPLOYEE table.

Polling Using SELECT Statement Using the WCF Channel Model

You can configure the Oracle E-Business adapter to receive periodic data-change messages by using a SELECT statement to continuously poll the interface tables, interface views, tables and views in Oracle E-Business Suite. You can specify a SELECT statement as a polling statement that the adapter executes periodically to poll Oracle E-Business Suite. You can also specify a post-poll PL/SQL code block that the adapter executes after the polling statement is executed.

To enable polling, you must specify certain binding properties as described in this topic. For more information about how the adapter supports polling, see [Support for Inbound Calls Using Polling](#).

Configuring a Polling Operation with Oracle E-Business Suite Adapter Binding Properties

The following table summarizes the Oracle E-Business adapter binding properties that you use to configure the adapter to receive data change messages. You must specify these binding properties while running the polling application.

Binding Property	Description
InboundOperationType	Specifies whether you want to perform Polling or Notification inbound operation. Default is Polling .
PolledDataAvailableStatement	Specifies the SQL statement that the adapter executes to determine whether any data is available for polling. Only if a record is available, the SELECT statement you specify for the PollingInput binding property will be executed.
PollingInterval	Specifies the interval, in seconds, at which the Oracle E-Business adapter executes the statement specified for the PolledDataAvailableStatement binding property. The default is 30 seconds. The polling interval determines the time interval between successive polls. If the statement is executed within the specified interval, the adapter sleeps for the remaining time in the interval.
PollingInput	Specifies the polling statement. To poll using a SELECT statement, you must specify a SELECT statement for this binding property. The default is null. You must specify a value for PollingInput binding property to enable polling. The polling statement is executed only if there is data available for polling, which is determined by the PolledDataAvailableStatement binding property.
PollingAction	Specifies the action for the polling operation. You can determine the polling action from the service interface generated for the operation using the Add Adapter Service Reference Visual Studio Plug-in.
PostPollStatement	Specifies a statement block that is executed after the statement specified by the PollingInput binding property is executed.
PollWhileDataFound	Specifies whether the Oracle E-Business adapter ignores the polling interval and continuously executes the polling statement, if data is available in the table being polled. If no data is available in the table, the adapter reverts to execute the polling statement at the specified polling interval. Default is false.

For a more complete description of these properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For a complete description of how to use the Oracle E-Business adapter to poll the Oracle database, read the remainder of this topic.

How This Topic Demonstrates Polling

In this topic, to demonstrate how the Oracle E-Business adapter supports receiving data change messages using SELECT statements, you poll the **MS_SAMPLE_EMPLOYEE** interface table in the **Application Object Library** application. This table is created when you run the create_apps_artifacts.sql script provided with the samples to create these objects in Oracle E-Business Suite.

To demonstrate a polling operation, we do the following:

- Specify a SELECT statement for the **PolledDataAvailableStatement** binding property to determine where the interface table being polled (MS_SAMPLE_EMPLOYEE) has any data. In this example, you can set this binding property as:

```
SELECT COUNT (*) FROM MS_SAMPLE_EMPLOYEE
```

This ensures that the adapter executes the polling statement only when the MS_SAMPLE_EMPLOYEE interface table has some records.

- Specify a SELECT statement for the **PollingInput** binding property. This statement retrieves all the rows in the MS_SAMPLE_EMPLOYEE interface table. In this example, you can set this binding property as:

```
SELECT * FROM MS_SAMPLE_EMPLOYEE FOR UPDATE
```

Note

For information about the FOR UPDATE clause used in the SELECT statement, see [Specifying a FOR UPDATE Clause in the Polling Statement](#).

- Specify a DELETE statement as part of the **PostPollStatement** binding property. This statement will delete all data from MS_SAMPLE_EMPLOYEE interface table. In this example, you can set this binding property as:

```
DELETE FROM MS_SAMPLE_EMPLOYEE
```

After this happens, the next time the statement specified for **PollingInput** will be executed, it will not fetch any data.

- Until more data is added to the MS_SAMPLE_EMPLOYEE interface table, you will not get any polling messages so you must repopulate the MS_SAMPLE_EMPLOYEE interface table with new records. You can do so by running the insert_apps_data.sql script provided with the samples. After you run this script, the next polling operation will fetch the new records inserted into the table.

Consuming the Polling Request Message

The adapter invokes the polling operation on your code to poll the Oracle E-Business Suite. That is, the adapter sends a polling request message that you receive over an `IInputChannel` channel shape. The polling request message contains the result set of the query specified by the **PollingInput** binding property. You can consume the polling message in one of two ways:

- To consume the message using node-value streaming, you must call the **WriteBodyContents** method on the response message and pass it an **XmlDictionaryWriter** that implements node-value streaming.
- To consume the message using node streaming, you can call **GetReaderAtBodyContents** on the response message to get an **XmlReader**.

About the Examples Used in this Topic

The examples in this topic poll the MS_SAMPLE_EMPLOYEE interface table. A script to generate the table is supplied with the samples. For more information about the samples, see [Samples](#). A sample, **SelectPolling_ChannelModel**, which is based on this topic, is also provided with the Oracle E-Business adapter samples.

Receiving Inbound Messages for Polling Operation Using the WCF Channel Model

This section provides instructions on how to write a .NET application (channel model) to receive inbound polling messages using the Oracle E-Business adapter.

To receive polling messages from the adapter

1. Create a Microsoft Visual C#® project in Visual Studio. For this topic, create a console application.

2. In the Solution Explorer, add reference to `Microsoft.Adapters.OracleEBS`, `Microsoft.ServiceModel.Channels`, `System.ServiceModel`, and `System.Runtime.Serialization`.

3. Open the Program.cs file and add the following namespaces:

- `Microsoft.Adapters.OracleEBS`
- `System.ServiceModel`
- `System.ServiceModel.Description`
- `System.ServiceModel.Channels`
- `System.Xml`

4. Specify a connection URI. For more information about the adapter connection URI, see [The Oracle E-Business Suite Connection URI](#).

```
Uri ConnectionUri = new Uri("oracleebs://ebs_instance_name");
```

5. Create an instance of **OracleEBSBinding** and set the binding properties required to configure polling. At a minimum you must set the **InboundOperationType**, **PolledDataAvailableStatement**, **PollingInput**, and **PollingAction** binding properties. For more information about binding properties used to configure polling, see [Support for Inbound Calls Using Polling](#).

```
OracleEBSBinding binding = new OracleEBSBinding();  
binding.InboundOperationType = InboundOperation.Polling;  
binding.PolledDataAvailableStatement = "SELECT COUNT (*) FROM MS_SAMPLE_EMPLOYEE";  
binding.PollingInput = "SELECT * FROM MS_SAMPLE_EMPLOYEE FOR UPDATE";  
binding.PollingAction = "InterfaceTables/Poll/FND/APPS/MS_SAMPLE_EMPLOYEE";  
binding.PostPollStatement = "DELETE FROM MS_SAMPLE_EMPLOYEE";
```

6. Because you are polling an interface table, you must also set the applications context. For more information about application context and binding properties required for setting application context, see [Setting Application Context](#).

```
binding.OracleUserName = "<Enter user name here>";  
binding.OraclePassword = "<Enter password here>";  
binding.OracleEBSResponsibilityName = "<Enter responsibility here>";
```

7. Create a binding parameter collection and set the credentials.

```
ClientCredentials credentials = new ClientCredentials();  
credentials.UserName.UserName = "<Enter user name here>";  
credentials.UserName.Password = "<Enter password here>";  
  
BindingParameterCollection bindingParams = new BindingParameterCollection();  
bindingParams.Add(credentials);
```

8. Create a channel listener and open it. You create the listener by invoking **BuildChannelListener<IInputChannel>** method on the **OracleEBSBinding**.

```
IChannelListener<IInputChannel> listener = binding.BuildChannelListener<IInputChannel>  
(connectionUri, bindingParams);  
listener.Open();
```

9. Get an **IInputChannel** channel by invoking the **AcceptChannel** method on the listener and open it.

```
IInputChannel channel = listener.AcceptChannel();
channel.Open();
```

10. Invoke **Receive** on the channel to get the next inbound message from the adapter.

```
Message message = channel.Receive();
```

11. Consume the result set returned by the inbound operation. You can consume the message using either an **XmlReader** or an **XmlDictionaryWriter**.

```
XmlReader reader = message.GetReaderAtBodyContents();
```

12. Close the channel when you have completed processing the request.

```
channel.Close()
```

◆Important

You must close the channel after you have finished processing the inbound operation. Failure to close the channel may affect the behavior of your code.

13. Close the listener when you are finished receiving data-changed messages.

```
listener.Close()
```

◆Important

Closing the listener does not close channels created using the listener. You must explicitly close each channel created using the listener.

Example

The following example shows a polling application that polls the MS_SAMPLE_EMPLOYEE interface table. The **PollingInput** property contains the select statement that reads all the data from the MS_SAMPLE_EMPLOYEE table and the post poll statement deletes all the data from the same table. The polling message is written to C:\PollingOutput.xml.

Subsequent polling messages will not contain any records until more data is added to the MS_SAMPLE_EMPLOYEE interface table. You can do so by running the insert_apps_data.sql script provided with the samples. After you run this script, the next polling operation will fetch the new records inserted into the table. The adapter will continue to poll until you close the service host by pressing <RETURN>.

```
using System;
using Microsoft.Adapters.OracleEBS;
using System.ServiceModel;
using System.ServiceModel.Description;
using System.ServiceModel.Channels;
using System.Xml;

namespace SelectPolling_ChannelModel
{
    class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("Sample started. This sample will poll 5 times and will perfo
```

```

rm the following tasks:");
    Console.WriteLine("Press any key to start polling...");
    Console.ReadLine();
    IChannelListener<IInputChannel> listener = null;

    IInputChannel channel = null;

    try
    {
        TimeSpan messageTimeout = new TimeSpan(0, 0, 30);

        OracleEBSBinding binding = new OracleEBSBinding();
        binding.InboundOperationType = InboundOperation.Polling;
        binding.PolledDataAvailableStatement = "SELECT COUNT (*) FROM MS_SAMPLE_EMP
LOYEE";
        binding.PollingInput = "SELECT * FROM MS_SAMPLE_EMPLOYEE FOR UPDATE";
        binding.PollingAction = "InterfaceTables/Poll/FND/APPS/MS_SAMPLE_EMPLOYEE";
        binding.PostPollStatement = "DELETE FROM MS_SAMPLE_EMPLOYEE";
        binding.OracleUserName = "<Enter user name here>";
        binding.OraclePassword = "<Enter password here>";
        binding.OracleEBSResponsibilityName = "<Enter responsibility here>";

        Uri ConnectionUri = new Uri("oracleebs://ebs_instance_name?");

        ClientCredentials credentials = new ClientCredentials();
        credentials.UserName.UserName = "<Enter user name here>";
        credentials.UserName.Password = "<Enter password here>";

        BindingParameterCollection bindingParams = new BindingParameterCollection()
;
        bindingParams.Add(credentials);

        listener = binding.BuildChannelListener<IInputChannel>(ConnectionUri, bindi
ngParams);
        listener.Open();

        channel = listener.AcceptChannel();
        channel.Open();

        Console.WriteLine("Channel and Listener opened...");
        Console.WriteLine("\nWaiting for polled data...");
        Console.WriteLine("Receive request timeout is {0}", messageTimeout);

        // Poll five times with the specified message timeout
        // If a timeout occurs polling will be aborted
        for (int i = 0; i < 5; i++)
        {
            Console.WriteLine("Polling: " + i);
            Message message = null;
            XmlReader reader = null;
            try
            {
                //Message is received so process the results
                message = channel.Receive(messageTimeout);
            }
            catch (System.TimeoutException toEx)
            {
                Console.WriteLine("\nNo data for request number {0}: {1}", i + 1, t
oEx.Message);
                continue;
            }
            // Get the query results using an XML reader
            try
            {
                reader = message.GetReaderAtBodyContents();
            }

```

Using the Oracle E-Business Adapter with Microsoft Office SharePoint Server

Most line-of-business (LOB) applications have proprietary interfaces that are accessible to relatively few people with the required subject matter expertise. However, because information workers need relevant information at all levels in an organization, the subject matter experts have to export required data into more familiar applications, like Microsoft Excel, for information workers to consume the information.

The new collection of Microsoft Office client applications and features bridges this gap by bringing backend business data into the most common interface for information workers, Microsoft Office. Microsoft Office client applications seamlessly present data from LOB applications through interfaces familiar to information workers. One example is the Business Data Catalog in Microsoft Office SharePoint Server.

About Business Data Catalog

The Business Data Catalog is a new integration component in Microsoft Office SharePoint Server 2007 and later. The Business Data Catalog is a shared service and surfaces business data from backend applications via databases and Web services, without the need for writing any code. It is a metadata repository that defines business entities like customers, invoices, and purchase orders. Once defined, clients can use these entities.

The Business Data Catalog provides a Business Data Catalog Definition Editor to help you author application definition files for the Business Data Catalog in Microsoft Office SharePoint Server 2007 and later. Using the Business Data Catalog Definition Editor, you can create and edit metadata for business applications.

For more information about the Business Data Catalog, see "Business Data Catalog" at <http://go.microsoft.com/fwlink/?LinkId=103882>.

Using the Oracle E-Business Adapter to Integrate the Oracle E-Business Suite with the Business Data Catalog and Microsoft Office SharePoint Server

The Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK includes the WCF LOB Adapter Service Development Wizard, which generates a WCF service for specific LOB artifacts. This WCF service is hosted in a hosting environment such as Microsoft Internet Information Services (IIS). The Business Data Catalog Definition Editor uses the URL where the WCF service is hosted to get the Web Services Description Language (WSDL) for the WCF service. Using the WSDL, the Business Data Catalog Definition Editor extracts the methods available to the WCF service. These methods can be used to establish entities and the association between the entities.

The Business Data Catalog Definition Editor helps you create an application definition file (an XML file) that Microsoft Office SharePoint Server can consume. Once the application definition file is imported to Microsoft Office SharePoint Server, you can create Web Parts to present the information from enterprise applications. For more information, see "Creating Web Parts" in Step 3: Create a SharePoint Application to Retrieve Data from Oracle E-Business Suite in [Tutorial: Presenting Data from Oracle E-Business Suite on a SharePoint Site](#).

Tutorial

To demonstrate how to use the Oracle E-Business adapter with Microsoft Office SharePoint Server, the BizTalk Adapter Pack includes a tutorial that provides step-by-step instructions to present data from Oracle E-Business Suite on a SharePoint site. See [Tutorial: Presenting Data from Oracle E-Business Suite on a SharePoint Site](#).

Considerations While Using the Oracle-Business Adapter with Microsoft Office SharePoint Server

This topic contains information about the issues you might encounter while using the Microsoft BizTalk Adapter for Oracle E-Business Suite with Microsoft Office SharePoint Server, along with resolutions. The issues are divided into two categories:

- General issues
- Issues involving custom Web Parts

General Issues

This section contains issues that have no resolution.

Issue 1: The simple type data returned by the WCF service is not displayed

Explanation: Microsoft Office SharePoint Server expects the data returned by the WCF service to be of DataSet or Collection type only. If the data returned by the WCF service is of simple type, Microsoft Office SharePoint Server does not display the data.

Resolution: No resolution. It is a known limitation with Microsoft Office SharePoint Server.

Issue 2: An error message is displayed if the data returned by the WCF service is NULL

Explanation: If the data returned by the WCF service is a NULL value, Microsoft Office SharePoint Server displays an error message. For example, suppose you are using the Business Data List Web Part for the **Finder** method instance, and are searching for customers in Oracle E-Business Suite based on a search expression. The search expression that you specified fetches a NULL value. In this case, Microsoft Office SharePoint Server will display an error message.

Resolution: No resolution. It is a known limitation with Microsoft Office SharePoint Server.

Issue 3: An array of simple type returned by the WCF service is not displayed

Explanation: If the data returned by the WCF service is an array of simple type, Microsoft Office SharePoint Server does not display the data. Moreover, when you execute a method instance in Business Data Catalog Definition Editor that returns an array of simple type, the following error message is displayed: "Backend system adapter returned a structure incompatible with the corresponding metadata (MethodInstance, Parameter or TypeDescriptor)."

Resolution: No resolution. It is a known limitation with Microsoft Office SharePoint Server and Business Data Catalog Definition Editor.

Issue 4: Cannot import an application definition file that contains a complex type parameter having more than 300 fields

Explanation: Microsoft Office SharePoint Server cannot import an application definition file that has more than 300 fields in the complex type parameter returned by the WCF service, and displays an error message if you try to do so. This is due to the limitation of Microsoft Office SharePoint Server of not being able to display more than 300 fields of a complex type parameter.

Resolution: Use the Business Data Catalog Definition Editor to limit the number of fields of the complex type parameter to less than or equal to 300. Depending on your requirement, you can delete the fields of the complex type parameter in the Business Data Catalog Definition Editor that you do not require to be displayed in Microsoft Office SharePoint Server. Alternatively, you can also export the application definition file from Business Data Catalog Definition Editor with all the fields, and then modify the application definition file in a notepad or any XML authoring application to delete the fields that are not required in order to limit the number of fields to 300.

Issues Involving Custom Web Parts

This section contains issues that require the use of custom Web Part for a resolution. For detailed information about using a custom Web Part to resolve issues that might come up while working with Oracle E-Business adapter and Microsoft Office SharePoint Server, see [How Do I Use a Custom Web Part?](#).

Issue 1: Limitation with displaying a single record in Microsoft Office SharePoint Server based on multiple values

Explanation: If you want to display a single record in Microsoft Office SharePoint Server based on multiple values (input parameters) from Oracle E-Business Suite, you cannot use any of the three Web Parts (Business Data List, Business Data Item, and Business Data Related List) specified in Step 3: Create a SharePoint Application to Retrieve Data from Oracle E-Business Suite in [Tutorial: Presenting Data from Oracle E-Business Suite on a SharePoint Site](#).

Resolution: You must use a custom Web Part to do this. For information about using a custom Web Part, see [How Do I Use a Custom Web Part?](#). In "Step 1: Create a Custom Web Part" of that topic, you can use the following code sample in step 5. The following code sample takes BankCountry and BankKey as the input parameters, and then displays them as a single record in Microsoft Office SharePoint Server.

```
namespace CustomWebPart
{
    public class CustomWebPart : WebPart
    {
        private string displayText = "Hello World!";

        [WebBrowsable(true), Personalizable(true)]
        public string DisplayText
        {
            get { return displayText; }
            set { displayText = value; }
        }
        protected override void Render(System.Web.UI.HtmlTextWriter writer)
        {
            string BankCountry = "US";
            string BankKey = "134329042";

            /**Step 1: Get the required entity and method.***/

            LobSystem newSystem = ApplicationRegistry.GetLobSystems()["BAPI_BANK_GETDETAIL"
]; // Name specified in application definition file
            LobSystemInstance newSystemInstance = newSystem.GetLobSystemInstances()["BAPI_B
ANK_GETDETAIL_Instance"]; // Name specified in application definition file
            Entity CategoryEntity = newSystem.GetEntities()["Entity"]; // Name specified in
application definition file
            Method newMethod = CategoryEntity.GetMethods()["BAPI_BANK_GETDETAIL"]; // Name
specified in application definition file
            MethodInstance methodInstance = newMethod.GetMethodInstances()["MethodInstance"
]; // Name specified in application definition file

            /**Step 2: Get the list of input parameters.***/

            Object[] args = methodInstance.GetMethod().CreateDefaultParameterInstances(meth
odInstance); //Get the default values of the input parameters.
            Object[] ArgsInput = new Object[args.Length];

            /**Step 3: Assign them required values.***/

            Type t = null;
            char[] myString = BankCountry.ToCharArray();
            String s = new String(myString);
            t = s.GetType();
            ArgsInput[0] = Activator.CreateInstance(t, myString);

            myString = BankKey.ToCharArray();
            s = new String(myString);
            t = s.GetType();
            ArgsInput[1] = Activator.CreateInstance(t, myString);

            /**Step 4: Execute the particular method instance using the required value.***/

            IEntityInstance IE = (IEntityInstance)CategoryEntity.Execute(methodInstance, ne
wSystemInstance, ref ArgsInput); //Method instance of type Specific Finder is being used he
re.

            /**Step 5: Display the output on the custom Web Part in Microsoft Office SharePoint Server
.***/

            writer.Write("<table>");
            writer.Write("<tr>");
            foreach (Field f in CategoryEntity.GetFinderView().Fields)
            {
```

```

        writer.Write("<td>");
        writer.Write(IE[f]);
        writer.Write("</td>");
    }
    writer.Write("</tr>");
    writer.Write("</table>");
}
}

```

Note

The application definition file must contain the **Specific Finder** method instance. A **Specific Finder** method finds a specific record based on an identifier. For information about creating a **Specific Finder** method instance, see "Requirement 2: Retrieve Details for a Specific Customer from the List of Customers" in

[Step 2: Create an Application Definition File for the Oracle E-Business Suite Artifacts](#) in [Tutorial: Presenting Data from Oracle E-Business Suite on a SharePoint Site](#).

Issue 2: Cannot specify values to array elements

Explanation: If the input parameter of the WCF service is an array, you cannot specify values to the array elements using filters that are defined in the application definition file created using the Business Data Catalog Definition Editor. It implies that you cannot use the Business Data List or Business Data Item Web Part in Microsoft Office SharePoint Server to specify values for these input parameters (elements of array) to the WCF service. This is because of the way arrays are defined in the application definition file.

Resolution: Use a custom Web Part to assign values to array elements. For information about using a custom Web Part, see [How Do I Use a Custom Web Part?](#). For example, you can use the following code sample in step 3 in "Issue 1: Limitation with displaying a single record in Microsoft Office SharePoint Server based on multiple values" to assign values to array elements.

```

/**Assign required values to parameters of type array.***/
/**Assumption is that the ith parameter of Method is of type Array and all the simple type
elements in the array are of string type.***/

    Type t = asm.GetType(args[i].GetType().ToString()); // Get type of the parameter
    Type TElement = t.GetElementType(); // Getting type of element of array
    int index = 5; //Size of Array
    Array ElementArray = Array.CreateInstance(TElement, index); //Creating an array
of length: index

    for (int ind = 0; ind < index; ind++)
    {
        //Creating an instance of an element of array
        object ElementType = Activator.CreateInstance(TElement);
        FieldInfo[] FI = ElementType.GetType().GetFields();
        for (int f = 0; f < FI.Length; f++)
        {
            ElementType.GetType().GetFields()[f].SetValue(ElementType, (Object)"ElementValue");
        }
        ElementArray.SetValue(ElementType, ind);
    }

    ArgsInput[i] = (object)ElementArray; // As shown in sample, ArgsInput is fed as
input while executing Method Instance

```

Issue 3: Limitation with specifying NULL values to complex type parameters

Explanation: If you do not specify any value for a complex type parameter from a Web Part in Microsoft Office SharePoint Server, NULL should be passed on as the value for the complex type parameter to the WCF service. However, a non-NULL value is passed for the complex type parameter, and NULL is passed for its children elements (of simple type). This causes a mismatch between the expected message schema and the message schema that is passed on to the WCF service. As a result, the Oracle E-Business adapter might display an error message.

Note

To find out the default value of a complex type parameter when no value is passed from a Web Part in Microsoft Office SharePoint Server, use step 2 in the code sample mentioned in "Issue 1: Limitation with displaying a single record in Microsoft Office SharePoint Server based on multiple values."

Resolution: Use a custom Web Part to assign a NULL value to the complex type parameter. For information about using a custom Web Part, see [How Do I Use a Custom Web Part?](#).

How Do I Use a Custom Web Part?

This section provides information about using a custom Web Part with Microsoft Office SharePoint Server. To use a custom Web Part, you must do the following:

1. Create a custom Web Part
2. Deploy the custom Web Part to a SharePoint portal
3. Configure the SharePoint portal to use the custom Web Part

Before You Begin

Before you create a custom Web Part:

- Publish the Oracle E-Business Suite artifacts as a WCF service. For more information, see [Step 1: Use the Oracle E-Business Adapter to Create and Publish a WCF Service in Tutorial: Presenting Data from Oracle E-Business Suite on a SharePoint Site.](#)
- Create an application definition file for the Oracle E-Business Suite artifacts using the Business Data Catalog in Microsoft Office SharePoint Server. For more information, see [Step 2: Create an Application Definition File for the Oracle E-Business Suite Artifacts in Tutorial: Presenting Data from Oracle E-Business Suite on a SharePoint Site.](#)

Step 1: Create a custom Web Part

To create a custom Web Part using Visual Studio, do the following:

1. Start Visual Studio 2010, and then create a project.
2. In the **New Project** dialog box, from the **Project types** pane, select **Visual C#**. From the **Templates** pane, select **Class Library**.
3. Specify a name and location for the solution. For this topic, specify **CustomWebPart** in the **Name** and **Solution Name** boxes. Specify a location, and then click **OK**.
4. Add a reference to the System.Web component into the project. Right-click the project name in **Solution Explorer**, and then click **Add Reference**. In the **Add Reference** dialog box, select **System.Web** in the **.NET** tab, and then click **OK**. The System.Web component contains the required namespace of System.Web.UI.WebControls.WebParts.
5. Add the required code based on your issue in the project. For the code sample that is relevant to a certain issue, see "Issues Involving Custom Web Parts" in [Considerations While Using the Oracle-Business Adapter with Microsoft Office SharePoint Server.](#)
6. Build the project. On successful build of the project, a .dll file, CustomWebPart.dll, will be generated in the <project folder>/bin/Debug folder.
7. **Only for 64-bit computer:** Sign the CustomWebPart.dll file with a strong name before performing the following steps. Otherwise, you will not be able to import, and hence use the CustomWebPart.dll in the SharePoint portal in "Step 3: Configure the SharePoint Portal to use the custom Web Part." For information about how to sign an assembly with a strong name, see <http://go.microsoft.com/fwlink/?LinkId=197169>.

Step 2: Deploy the custom Web Part to a SharePoint Portal

You must do the following to make the CustomWebPart.dll file (custom Web Part) that is created in "Step 1: Create a custom Web Part" of this topic usable on the SharePoint portal:

- **Copy the CustomWebPart.dll file to the bin folder of the SharePoint Portal:** Microsoft Office SharePoint Server creates portals under the <root drive>:\inetpub\wwwroot\wss\VirtualDirectories folder. A folder is created for each portal, and can be identified with the port number. You must copy the CustomWebPart.dll file created in “Step 1: Create a custom Web Part” of this topic to the <root drive>:\inetpub\wwwroot\wss\VirtualDirectories\<Port_Number>\bin folder. For example, if the port number of your SharePoint portal is 13614, you must copy the CustomWebPart.dll file to the <root drive>:\inetpub\wwwroot\wss\VirtualDirectories\13614\bin folder.

 **Tip**

Another way to find the folder location of your SharePoint portal is by using the **Internet Information Services (IIS) Manager** window (**Start > Run > inetmgr**). Locate your SharePoint portal in the **Internet Information Services (IIS) Manager** window ([computer_name] > Web Sites > [Portal-Name]), right-click, and then click **Properties** in the shortcut menu. In the properties dialog box of the SharePoint portal, click the **Home Directory** tab, and then select the **Local path** box.

- **Add the Safe Control Entry in the web.config File:** Because the CustomWebPart.dll file will be used on different computers and by multiple users, you must declare the file as “safe.” To do so, open the web.config file located in the SharePoint portal folder at <root drive>:\inetpub\wwwroot\wss\VirtualDirectories\<Port_Number>. Under the <SafeControls> section of the web.config file, add the following safe control entry:

- **On 32-bit computer:**

```
<SafeControl Assembly="CustomWebPart" Namespace="CustomWebPart" TypeName="*" Safe="True" />
```

- **On 64-bit computer:**

```
<SafeControl Assembly="CustomWebPart, Version=1.0.0.0, Culture=neutral, PublicKeyToken=<PUBLICKEYTOKEN_OF_CustomWebPart.dll>" Namespace="CustomWebPart" TypeName="*" Safe="True" />
```

Save the web.config file, and then close it.

Step 3: Configure the SharePoint portal to use the custom Web Part

You need to add the custom Web Part to the Microsoft Office SharePoint Server Web Part Gallery, so that you can use it on your SharePoint portal. To do so:

1. Start SharePoint 3.0 Central Administration. Click **Start**, point to **All Programs**, point to **Microsoft Office Server**, and then click **SharePoint 3.0 Central Administration**.
2. In the left navigation pane, click the name of the Shared Service Provider (SSP) to which you want to add the custom Web Part.
3. On the Shared Services Administration page, in the upper-right corner, click **Site Actions**, and then click **Create**.
4. On the Site Settings page, click **Web Parts** under the **Galleries** column.
5. On the Web Part Gallery page, to add the custom Web Part to the gallery, click **New**. At this point the custom Web Part is not available in the Web Part Gallery page.
6. On the New Web Parts page, locate **CustomWebPart** (name of the custom Web Part) in the list, select the check box on the left, and then click **Populate Gallery** on the top of the page. This will add the **CustomWebPart** entry in the Web Part Gallery page.

Now you can use the custom Web Part (**CustomWebPart**) to create Web Parts in your SharePoint portal. The custom Web

Part (**CustomWebPart**) will appear under the **Miscellaneous** section in the Add Web Parts page.

[Using the Oracle E-Business Adapter with Microsoft Office SharePoint Server](#)

Samples

Samples for Microsoft BizTalk Adapter for Oracle E-Business Suite are categorized into:

- BizTalk Server samples
- WCF service model samples
- WCF channel model samples
- Microsoft Office SharePoint Server samples

The samples are available at <http://go.microsoft.com/fwlink/?LinkID=196854>. The SQL scripts for creating the interface tables, concurrent programs, tables, and packages used in the samples are also available along with the samples for the Oracle E-Business adapter.

The following tables contain the names and descriptions of the samples for the Oracle E-Business adapter.

BizTalk Server Samples

Sample Directory Name	Description
InterfaceTableInsert	Demonstrates how to insert records into an interface table in Oracle E-Business Suite using Oracle E-Business adapter.
ConcurrentProgram	Demonstrates how to invoke a concurrent program in Oracle E-Business Suite using the Oracle E-Business adapter.
RequestSet	Demonstrates how to invoke a request set in Oracle E-Business Suite using the Oracle E-Business adapter.
MsgContextProperty	Demonstrates how to use the message context properties exposed by the Oracle E-Business adapter to set application context to perform operations on artifacts in Oracle E-Business Suite using the Oracle E-Business adapter.
OracleEBS_CompositeOperation	Demonstrates how to perform composite operations in Oracle E-Business Suite using the Oracle E-Business adapter.
OracleNotifyIncremental	Demonstrates how to receive "incremental" query notification messages from Oracle using the Oracle E-Business adapter.
PollingUsingSelectStatement	Demonstrates how to configure a polling query using a SELECT statement and receive the results using the Oracle E-Business adapter.
PollingUsingStoredProc	Demonstrates how to configure a polling query using a stored procedure and receive the results using the Oracle E-Business adapter.

WCF Service Model Samples

Sample Directory Name	Description
ConcProgram_ServiceModel	Demonstrates how to invoke concurrent programs in Oracle E-Business Suite using the adapter.
ExecuteReader	Demonstrates how to invoke an ExecuteReader operation on Oracle E-Business Suite using the adapter.

Interface_Table_Ops	Demonstrates how to perform operations on interface tables in Oracle E-Business Suite using the adapter.
LargeDataTypes_ServiceModel	Demonstrates how to perform operations on tables with columns of large data types in Oracle E-Business Suite using the adapter.
Notification_ServiceModel	Demonstrates how to receive notifications from databases behind Oracle E-Business Suite using the adapter.
SelectPolling_ServiceModel	Demonstrates how to use a SELECT statement to poll an interface table in Oracle E-Business Suite using the adapter.
StoredProcPolling_ServiceModel	Demonstrates how to use a stored procedure to poll tables in Oracle E-Business Suite using the adapter.

WCF Channel Model Samples

Sample Directory Name	Description
InsertOperation	Demonstrates how to perform an Insert operation on an interface table in Oracle E-Business Suite using the adapter.
SelectPolling_ChannelModel	Demonstrates how to use a SELECT statement to poll an interface table in Oracle E-Business Suite using the adapter.

Microsoft Office SharePoint Server Samples

Sample Directory Name	Description
MOSS_Sample	Demonstrates how to use the Oracle E-Business adapter to create a Windows Communication Foundation (WCF) service from Oracle E-Business Suite artifacts, and then use the WCF service to display data in Microsoft Office SharePoint Server using a Business Data List Web Part.

[Development](#)

Configure Transaction Isolation Level and Transaction Timeout

While performing inbound operations (Polling and Notification) using the Microsoft BizTalk Adapter for Oracle E-Business Suite with BizTalk Server, you should appropriately configure the transaction isolation level and the transaction timeout values. To do this:

1. Start the BizTalk Server Administration console.
2. In the console tree, expand the **BizTalk Group**, and then expand **Applications**.
3. Expand the BizTalk application that you have deployed after generating the metadata using the Oracle E-Business adapter.
4. Right-click **Receive Ports**, point to **New**, and then click **One-way Receive Port**.
5. In the **Receive Port Properties** dialog box, on the **General** tab, type a name for the receive port.
6. In the left pane of the **Receive Port Properties** dialog box, click **Receive Locations**, and then click **New** in the right pane to define a new receive location.
7. In the **Receive Location Properties** dialog box, click **WCF-Custom** in the **Type** list.
8. Click **Configure** adjacent to the **Type** list.
9. In the **WCF-Custom Transport Properties** dialog box, click the **Behavior** tab.
10. In the **Behavior** list, right-click **ServiceBehavior**, and click **Add extension**.
11. In the **Select Behavior Extension** dialog box, select **oracleEBSAdapterInboundTransactionBehavior**, and click **OK**.
12. In the left pane of the **WCF-Custom Transport Properties**, select the **oracleEBSAdapterInboundTransactionBehavior** service under **ServiceBehavior**.
13. In the right pane of the **WCF-Custom Transport Properties**, specify appropriate values for the **transactionIsolationLevel** and **transactionTimeout** parameters. You can select any of the following transaction isolation levels: **Serializable**, **RepeatableRead**, **ReadCommitted**, **ReadUncommitted**, **Snapshot**, **Chaos**, and **Unspecified**. For information about these transaction isolation levels, see the **Members** section at <http://go.microsoft.com/fwlink/?LinkId=126983>.

◆ Important

Oracle E-Business Suite supports only the following two transaction isolation levels: ReadCommitted and Serializable.

14. Click **OK** in the **WCF-Custom Transport Properties** dialog box.
15. Click **OK** in the open dialog boxes to save the changes.

Set the Application Context Using Message Context Properties

To perform operations on Oracle E-Business Suite artifacts using the Oracle E-Business adapter, you must set the application context appropriately. You can set the application context in the following ways:

- By specifying the binding properties that the adapter exposes. For more information, see [Setting Application Context](#).
- By using message context properties that the adapter exposes. You must consider the following when setting the application context by using message context properties.
 - You can set values only for **ApplicationShortName**, **OrganizationID**, **ResponsibilityKey**, and **ResponsibilityName** by using message context properties. For the user name and password, you must use the binding properties. The value specified for the **ResponsibilityKey** message context property overrides the value specified for the **ResponsibilityName** message context property.
 - If you set the application context using both the binding properties and message context properties, the values specified for message context properties take precedence and override the values specified for the binding properties. However, for example, if you specify the application short name as a message context property, and the organization ID and responsibility name as binding properties, only the value for the application short name is taken from the message context property. The rest are picked from the relevant binding properties.

Why use message context properties over binding properties to set the application context? If you set the application context using binding properties, the WCF-Custom send port for the Oracle E-Business adapter can be used only for the specific organization ID, responsibility, and application that you specified for the binding properties. On the contrary, if you use the message context property, you can configure a "generic" WCF-Custom send port, and set the application context at the message level.

Adapter clients must set the message context properties on the message that is sent to Oracle E-Business Suite to invoke an operation on Oracle E-Business Suite. The messages in BizTalk Server are immutable. Hence, clients must first create a message from the existing message, and then set the message context properties on the new message. For the procedure described in this section, assume that the existing message is called **Request**, and the new message is called **New_Request**.

To set the message context properties for BizTalk applications

1. Open the BizTalk project in Visual Studio.
2. In Solution Explorer, right-click **References**, and then click **Add References**.
3. In the **Add Reference** dialog box, click the **Browse** tab, and then browse to the location where the BizTalk property schema DLL for the Oracle E-Business adapter is available.

This DLL, `Microsoft.Adapters.OracleEBS.BiztalkPropertySchema.dll`, is installed by the BizTalk Adapter Pack at `<installation drive>\Program Files\Microsoft BizTalk Adapter Pack\bin`.
4. Select the DLL, and then click **Add**.
5. In the BizTalk orchestration, add a message, **New_Request**. For the **Message Type** property, make sure you select the same type as the existing request message.
6. Before the Send shape using which the message is sent to the send port, add a Construct Message shape and within that, a Message Assignment shape.
7. Double-click the Message Assignment shape to open **BizTalk Expression Editor**.
8. In **BizTalk Expression Editor**, add the following, and then click **OK**:

```
New_Request = Request;
New_Request(Microsoft.Adapters.OracleEBS.BiztalkPropertySchema.ApplicationShortName) =
"AR";
New_Request(Microsoft.Adapters.OracleEBS.BiztalkPropertySchema.ResponsibilityKey) = "R
ECEIVABLES_VISION_OPERATIONS";
```

```
New_Request(Microsoft.Adapters.OracleEBS.BiztalkPropertySchema.ResponsibilityName) = "
Receivables, Vision Operations (USA)";
New_Request(Microsoft.Adapters.OracleEBS.BiztalkPropertySchema.OrganizationId) = "204"
;
```

◆ Important

The value specified for the **ResponsibilityKey** message context property overrides the value specified for the **ResponsibilityName** message context property.

9. Make sure further processing of the orchestration is done by using the **New_Request** message.
10. Before you can deploy this orchestration in BizTalk Server, you must add the assembly reference for `Microsoft.Adapters.OracleEBS.BiztalkPropertySchema.dll` in the BizTalk application where you will be deploying the orchestration. To deploy an assembly in BizTalk Server:
 - a. Start the BizTalk Server Administration console.
 - b. In the console tree, expand **BizTalk Group**, then expand **Applications**, and then the application to which you want to add a BizTalk assembly.
 - c. Right-click **Resources**, point to **Add**, and then click **BizTalk Assemblies**.
 - d. In the **Add Resources** dialog box, click **Add**, navigate to the folder containing the BizTalk assembly file, which is `<installation drive>\Program Files\Microsoft BizTalk Adapter Pack\bin`. Select the `Microsoft.Adapters.OracleEBS.BiztalkPropertySchema.dll` file, and then click **Open**.
 - e. On the **Options** tab, specify the options for installing the BizTalk assembly to the global assembly cache (GAC), and then click **OK**.

Setting the Language for Performing Operations

The Oracle E-Business adapter supports the Multi-Language Support (MLS) feature of Oracle E-Business Suite, and allows you to specify a language while performing operations. The adapter exposes the **Language** message context property to specify a language for performing operations.

The value specified for the **Language** message context property overrides the value of the **Language** binding property under the **MlsSettings** binding property. For more information about the **MlsSettings** binding property, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#).

Troubleshooting

The BizTalk Adapter Pack uses or depends on several Microsoft technologies, including but not limited to the Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK, Microsoft Visual Studio, and Microsoft .NET Framework 3.5 SP1 or .NET Framework 4. The BizTalk Adapter Pack is built on top of the WCF LOB Adapter SDK, which in turn requires the .NET Framework 3.5 SP1 or .NET Framework 4. The adapters can be consumed either by writing applications using Visual Studio or by creating BizTalk applications. For issues related to each of these technologies and products, see the respective documentation.

This section provides information about troubleshooting the BizTalk Adapter Pack, including:

- Enabling tracing to diagnose issues with the adapters.
- Handling installation and operational issues that you might encounter when working with the adapters, including probable cause and a resolution.
- Using performance counters to gauge adapter performance.
- Handling exceptions and errors, including probable cause, and a resolution.

In This Section

- [Diagnostic Tracing and Message Logging](#)
- [Troubleshooting Installation Issues](#)
- [Troubleshooting Operational Issues](#)
- [Using Performance Counters](#)
-

Diagnostic Tracing and Message Logging

Diagnostic tracing helps to effectively diagnose problems that you might encounter when using the adapters. This topic provides information about the following three types of tracing supported with Microsoft BizTalk Adapter for Oracle E-Business Suite:

- Oracle server-side tracing using a client identifier.
- WCF tracing between the adapter client and the adapter.
- WCF tracing within the adapter.

Oracle Server Side Tracing Using a Client Identifier

Oracle allows you to perform server-side tracing for the operations performed by client applications on the Oracle database. Because requests from client applications can be routed to different database sessions, it becomes difficult to trace the origin of the request. However, Oracle facilitates end-to-end application tracing using client identifiers. The Oracle E-Business adapter exposes the **OracleConnectionClientId** binding property that allows you to specify the client identifier at the design time for the connection used by the adapter to connect to Oracle. The adapter client identifier helps you in selective tracing of the operations performed by the adapter client on Oracle, and also allows you to filter and view the Oracle server traces based on the client identifier. For information about how you can enable tracing for client identifiers in Oracle, see <http://go.microsoft.com/fwlink/?LinkId=135746>.

WCF Tracing Between the Adapter Client and the Adapter

Adapter clients can enable WCF tracing to trace issues between the adapter client and the adapter. WCF tracing is used to trace the input XML that comes from the adapter client by using the WCF service model and is useful in diagnosing serialization issues. WCF tracing is not used for the WCF channel model or for output messages from the adapter to the adapter client. You can activate WCF tracing for BizTalk applications and WCF service model applications by adding an excerpt to the respective configuration files. Also, you can enable tracing both at design-time and run-time.

- **Tracing at design-time.** For the design-time experience, you may use the Add Adapter Service Reference Plug-in, Consume Adapter Service Add-in, or the Add Adapter Metadata Wizard. All these tools can be used from Visual Studio. So, to enable tracing for the design-time experience, you must add the excerpt to the devenv.exe.config file located in `<installation drive>\Program Files\Microsoft Visual Studio <version>\Common7\IDE`.
- **Tracing at run-time.** For run-time tracing, you must add the excerpt depending on the application you are using.
 - For a BizTalk Server applications, you must add the excerpt to the BizTalk configuration file, typically `BTSNTSvc.exe.config`. For BizTalk Server 2010, this file is available typically under `<installation drive>\Program Files\Microsoft BizTalk Server 2010`.
 - For a WCF service model .NET application, you must add the excerpt to the app.config file of your project.

To enable WCF tracing, add the following excerpt within the `<configuration>` tag.

```
<system.diagnostics>
  <sources>
    <source name="System.ServiceModel" switchValue="Verbose">
      <listeners>
        <add name="xml" />
      </listeners>
    </source>
    <source name="System.ServiceModel.MessageLogging"
      switchValue="Verbose, ActivityTracing">
      <listeners>
        <add name="xml" />
      </listeners>
    </source>
  </sources>
</system.diagnostics>
```

```

    <source name="System.Runtime.Serialization" switchValue="Verbose">
      <listeners>
        <add name="xml" />
      </listeners>
    </source>
  </sources>
  <sharedListeners>
    <add name="xml" type="System.Diagnostics.XmlWriterTraceListener"
      traceOutputOptions="LogicalOperationStack"
      initializeData="C:\log\WCFTrace.svclog" />
  </sharedListeners>
  <trace autoflush="true" />
</system.diagnostics>
<system.serviceModel>
  <diagnostics>
    <messageLogging
      logEntireMessage="true"
      logMalformedMessages="false"
      logMessagesAtServiceLevel="true"
      logMessagesAtTransportLevel="false"/>
  </diagnostics>
</system.serviceModel>

```

This saves the WCF traces to C:\log\WCFTrace.svclog. For more information about WCF tracing, see "Tracing" at <http://go.microsoft.com/fwlink/?LinkId=91242>.

◆ Important

Make sure you mitigate potential security threats of exposing sensitive business data that can be caused when enabling tracing. For recommendations, see [Best Practices](#).

WCF Tracing Within the Adapter

The adapters log different categories of useful information to the trace file such as errors, warnings, and information messages. Such information is useful in understanding the process flow within the adapter and diagnosing issues with the adapter. You can activate the WCF LOB Adapter SDK and adapter tracing for BizTalk applications and WCF service model applications by adding an excerpt to the respective configuration files. Also, you can enable tracing both at design-time and run-time.

- **Tracing at design-time.** For the design-time experience, you may use the Add Adapter Service Reference Plug-in, Consume Adapter Service Add-in, or the Add Adapter Metadata Wizard. All these tools can be used from Visual Studio. So, to enable tracing for the design-time experience, you must add the excerpt to the devenv.exe.config file located in <installation drive>\Program Files\Microsoft Visual Studio <version>\Common7\IDE.
- **Tracing at run-time.** For run-time tracing, you must add the excerpt depending on the application you are using.
 - For a BizTalk Server applications, you must add the excerpt to the BizTalk configuration file, typically BTSNTSvc.exe.config. For BizTalk Server 2006 R2, this file is available typically under <installation drive>\Program Files\Microsoft BizTalk Server 2006. For BizTalk Server 2010, this file is available typically under <installation drive>\Program Files\Microsoft BizTalk Server 2010.
 - For a WCF service model .NET application, you must add the excerpt to the app.config file of your project.

To enable WCF LOB Adapter SDK and adapter tracing, add the following excerpt within the <configuration> tag.

```

<system.diagnostics>
  <sources>
    <source name="Microsoft.ServiceModel.Channels" switchValue="Error">
      <listeners>
        <add name="xml" />
      </listeners>
    </source>
    <source name="Microsoft.Adapters.OracleEBS" switchValue="Information">
      <listeners>

```

```
        <add name="xml" />
    </listeners>
</source>
</sources>
<sharedListeners>
    <add name="xml" type="System.Diagnostics.XmlWriterTraceListener"
traceOutputOptions="LogicalOperationStack"
        initializeData="C:\log\AdapterTrace.svclog" />
</sharedListeners>
<trace autoflush="true" />
</system.diagnostics>
```

This saves the WCF traces to C:\log\AdapterTrace.svclog.

Viewing the Traces

You can use the Windows Communication Foundation (WCF) Service Trace Viewer tool to view the traces. For more information about the tool, see "Using Service Trace Viewer for Viewing Correlated Traces and Troubleshooting" at <http://go.microsoft.com/fwlink/?LinkId=91243>.

Configuring Tracking for BizTalk Applications

The BizTalk Server Administration console lets you configure various tracking options for items such as send ports and receive ports. The tracking configuration settings enable you to track inbound and outbound event data, message properties, message bodies, and orchestrations. For more information about configuring tracking for BizTalk applications, see the "Configuring Tracking Using the BizTalk Server Administration Console" at <http://go.microsoft.com/fwlink/?LinkId=106851>.

You can also use Health and Activity Tracking (HAT) to view historical or tracked data. For more information, see "Viewing Historical or Tracked Data Using HAT" at <http://go.microsoft.com/fwlink/?LinkId=106852>.

[Troubleshooting](#)

Troubleshooting Installation Issues

This topic was last updated on: June 05, 2009

Installation of the Microsoft BizTalk Adapter Pack copies the product binaries on the computer and registers the bindings for each adapter. This section discusses using troubleshooting techniques to resolve installation errors.

Logging Messages for Setup Actions

The BizTalk Adapter Pack setup program performs the standard task of installing the BizTalk Adapter Pack. Additionally, the setup also performs certain custom actions such as registering the adapter bindings. You can log messages for both the standard as well as custom actions that the setup performs.

- The BizTalk Adapter Pack setup installs the adapter-specific files using an MSI. Therefore, the logging for the setup is the standard MSI logging. For more information about logging for an MSI, see <http://go.microsoft.com/fwlink/?LinkId=196953>.
- All logs for the custom actions that the setup program performs are available at %TEMP%\adaptersetup.log. If the tracing to the log file fails, the traces are also available in the event log.

Known Issues

The following are the most common errors you might encounter when installing the BizTalk Adapter Pack, along with their probable cause and resolution.

- [Setup fails to register adapter bindings](#)
- [Error while using the Consume Adapter Service add-in or Add Adapter Service Reference plug-in on a 64-bit installation](#)
- [Invalid binding error while configuring Oracle E-Business Suite adapter ports in BizTalk Server Administration Console on a 64-bit installation](#)

Setup fails to register adapter bindings

Problem

The Microsoft BizTalk Adapter Pack setup wizard fails to register the adapter bindings, but proceeds with the adapter installation.

Cause

This might result due to problems with Windows Communication Foundation (WCF) installation, Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK installation, or the machine.config file being corrupt. The adapter bindings are written to the machine.config file.

Resolution

You should manually register the Oracle E-Business adapter binding.

To register the adapter binding

1. Navigate to the machine.config file on the computer. For example, on a 32-bit platform, the machine.config is available under <system drive>:\WINDOWS\Microsoft.NET\Framework\<version>\CONFIG.

In this path, <version> is the version of the .NET Framework. For example, for Microsoft .NET Framework 3.5 SP1, the version will be v2.0.50727.

2. Open the file by using a text editor.

3. To register the Oracle E-Business adapter binding:

- a. Search for the element "system.serviceModel" and add the following under it:

```
<client>
  <endpoint binding="oracleEBSBinding" contract="IMetadataExchange" name="oracleebs" />
</client>
```

- b. Search for the element "bindingElementExtensions" under system.serviceModel\extensions.

- c. Look for the missing Oracle E-Business adapter binding. Add the following section under the "bindingElementExtensions" node.

For Oracle E-Business adapter, add:

```
<add name="oracleEBSAdapter" type="Microsoft.Adapters.OracleEBS.OracleEBSBindingElementExtension
```

```
Element, Microsoft.Adapters.OracleEBS, Version=<version>, Culture=neutral, PublicKeyToken=<public key>" />
```

- d. Search for the element "bindingExtensions" under system.serviceModel\extensions.
- e. Look for the missing Oracle E-Business adapter binding. Add the following section under the "bindingExtensions" node.

For Oracle E-Business adapter, add:

```
<add name="oracleEBSBinding" type="Microsoft.Adapters.OracleEBS.OracleEBSBindingCollectionElement, Microsoft.Adapters.OracleEBS, Version=<version>, Culture=neutral, PublicKeyToken=<public key>" />
```

Note

For information about how to determine the public key and the version, see [Determining the Public Key and Version](#).

4. Save and close the machine.config file.

Determining the Public Key and Version

Perform the following steps to determine the public key for Oracle E-Business adapter.

To determine the public key

1. Navigate to the Windows directory, typically C:\WINDOWS\assembly.
2. Right-click the DLL for which you want the public key and the version, and then select **Properties**. The following table lists the name of the DLL for Oracle E-Business adapter.

Adapter	Name of the DLL
Oracle E-Business adapter	Microsoft.Adapters.OracleEBS

3. On the **General** tab, the value against the **Public Key Token** label specifies the public key for the DLL. Similarly, value against the **Version** label specifies the version number for the DLL.
4. Copy the public key, and then click **Cancel**.

Error while using the Consume Adapter Service add-in or Add Adapter Service Reference plug-in on a 64-bit installation

Problem

Using the Add Adapter Service Reference Visual Studio Plug-in or the Consume Adapter Service BizTalk Project Add-in from Visual Studio on a 64-bit computer running 64-bit version of the BizTalk Adapter Pack results in the following error:

```
No valid adapters are installed on this machine
```

Cause

The Oracle E-Business adapter is a WCF custom binding, which is registered under System.ServiceModel in the machine.config file. A 64-bit platform has two machine.config files, one used by the 32-bit applications and the other used by the 64-bit applications. So, when you install the 64-bit version of the BizTalk Adapter Pack, the setup wizard registers the bindings in the 64-bit version of the machine.config file. However, Visual Studio runs as a 32-bit process and hence when you launch the Consume Adapter Service Add-in from Visual Studio, the plug-in checks for the bindings in the 32-bit version of the machine.config file and fails giving an error.

Resolution

- Install both the 32-bit and 64-bit versions of the BizTalk Adapter Pack on a 64-bit WCF LOB Adapter SDK installation.

Important

You must only have a 64-bit WCF LOB Adapter SDK installation. Side-by-side installation of 32-bit and 64-bit WCF LOB Adapter SDK on a single computer is not supported.

- Install both the 32-bit and 64-bit versions of the Oracle Data Access Components for Oracle Client 11.1.0.6 with Patch Set 11.1.0.7.

Note

To make sure your application works with the most recent version of ODP.NET, you must have the "policy DLLs" installed on the computer and registered in the GAC. For more information, see "Oracle Data Provider for .NET FAQ" at <http://go.microsoft.com/fwlink/?LinkId=92834>.

Invalid binding error while configuring Oracle E-Business Suite adapter ports in BizTalk Server Administration Console on a 64-bit installation

Problem

When you try to configure a port for the adapter in BizTalk Server Administration console, you get the following error:

```
"Unable to create binding configuration element for editing. Check the values of the BindingType and BindingConfiguration properties.  
(Microsoft.Biztalk.Adapter.Wcf.Converters.CreateBindingException) Unable to get binding type for binding extension "oracleEBSBinding".  
Verify the binding extension is registered in machine.config."
```

Cause

The Oracle E-Business adapter is a WCF custom binding, which is registered under System.ServiceModel in the machine.config file. A 64-bit platform has two machine.config files, one used by the 32-bit applications and the other used by the 64-bit applications. So, when you install the 64-bit version of the BizTalk Adapter Pack, the setup wizard registers the bindings in the 64-bit version of the machine.config file. However, BizTalk Server Administration console runs as a 32-bit process and hence when you configure a port for the adapter, it checks for the bindings in the 32-bit version of the machine.config file and fails giving an error.

Resolution

- Install both the 32-bit and 64-bit versions of the BizTalk Adapter Pack on a 64-bit WCF LOB Adapter SDK installation.

Important

You must only have a 64-bit WCF LOB Adapter SDK installation. Side-by-side installation of 32-bit and 64-bit WCF LOB Adapter SDK on a single computer is not supported.

- Install both the 32-bit and 64-bit versions of the Oracle Data Access Components for Oracle Client 11.1.0.6 with Patch Set 11.1.0.7.

Note

To make sure your application works with the most recent version of ODP.NET, you must have the "policy DLLs" installed on the computer and registered in the GAC. For more information, see "Oracle Data Provider for .NET FAQ" at <http://go.microsoft.com/fwlink/?LinkId=92834>.

Troubleshooting Operational Issues

This topic was last updated on: June 05, 2009

This section discusses using troubleshooting techniques to resolve operational errors that you might encounter when using Microsoft BizTalk Adapter for Oracle E-Business Suite.

Enabling Tracing

For more information about tracing support in the Oracle E-Business adapter, [Diagnostic Tracing and Message Logging](#).

Known Issues

The following are the most common errors you might encounter when using the BizTalk Adapter Pack, along with their probable cause and resolution.

- [Error in loading the adapter bindings](#)
- [The Oracle E-Business Suite adapter does not display in the list of adapters in BizTalk Server Administration console](#)
- [Error while performing operations on the Oracle E-Business Suite](#)
- [BizTalk process might crash due to an incorrect Oracle client version when a request message is dropped at the receive location](#)
- [Adapter might throw an overflow exception on executing an operation](#)
- [Adapter might throw an arithmetic overflow exception on executing an ExecuteScalar operation](#)
- [Adapter client might throw the following exception on executing an operation: "Could not retrieve user id, responsibility id, application id. Check if correct values were passed in."](#)
- [Error with RootNode TypeName in BizTalk Projects](#)
- [Invalid binding warning when using the adapter in Visual Studio 2010](#)
- [BizTalk Server throws an exception if you use more than one Notification schema in the same application or use the Notification schema across multiple applications on the same host](#)
- [Timeout Exception while browsing Oracle E-Business Suite Artifacts in Visual Studio](#)
- [Memory usage and thread count increases when using the adapter in a transacted inbound operation](#)

Error in loading the adapter bindings

Problem

When you try to start the Add Adapter Service Reference Visual Studio Plug-in or the Consume Adapter Service BizTalk Project Add-in, you get the following error:

```
There was an error loading the binding, <binding name>, from your system configuration.ConfigurationErrorsException: Exception has been thrown by the target of an invocation.
```

Cause

When you try to start the Add Adapter Service Reference Plug-in or the Consume Adapter Service Add-in, WCF loads the adapter bindings for all the installed adapters. In turn, the adapter bindings are dependent on the specific client software for the enterprise application. You might face this issue for one or both of the following reasons:

- The required LOB client software is not installed on the computer where you installed the adapter.
- You did a Typical or Complete installation of the adapter, which installs all the adapters contained in the BizTalk Adapter Pack. However, the LOB client libraries might be installed for only one enterprise application. As a result, the GUI fails to load the bindings for the other adapters.

Resolution

- Make sure that the required LOB client versions are installed on the computer where you installed the BizTalk Adapter Pack. For information about the supported client versions, see the installation guide available at <installation drive>\Program Files\Microsoft BizTalk Adapter Pack.
- Make sure you do a custom installation of the adapters to install only the adapter you need.

The Oracle E-Business Suite adapter does not display in the list of adapters in BizTalk Server Administration console

Problem

Unlike the earlier version of the adapters shipped with BizTalk Server, the Oracle E-Business adapter shipped with BizTalk Adapter Pack does not show up in the list of adapters in the BizTalk Server Administration console.

Cause

The latest Oracle E-Business adapter is a WCF custom binding. So, although the BizTalk Server Administration console displays the WCF-Custom adapter, it does not display the WCF custom bindings and hence, does not display the WCF-based Oracle E-Business adapter.

Resolution

You can explicitly add the Oracle E-Business adapter to the BizTalk Server Administration console by following the steps mentioned in [Adding the Oracle E-Business Suite Adapter to BizTalk Server Administration Console](#).

Error while performing operations on the Oracle E-Business Suite

Problem

The adapter gives the following error when performing any operation on the Oracle E-Business Suite using BizTalk Server.

- **For BizTalk Server 2010**

```
System.ArgumentNullException: Value cannot be null.
```

Cause

The WCF action for the message is not specified. WCF requires a SOAP action to be specified for every operation, which informs the adapter about the operation to be performed on the LOB application.

Resolution

Specify the SOAP action in the send port or as a message context property in a BizTalk orchestration. For instructions, see [Specifying SOAP Action](#). See [Technical Reference](#) to see a list of actions for each operation.

BizTalk process might crash due to an incorrect Oracle client version when a request message is dropped at the receive location

Problem

After a request message is dropped at a receive location defined in a BizTalk orchestration, the orchestration consumes the message and BizTalk host (BTSNTSvc.exe) crashes and restarts.

Cause

Installing the Oracle client adds the reference to the latest client assemblies in the PATH variable. Also, the references to the most recent installation of the Oracle client assembly precede the reference to the existing client assemblies. So, if the most recent Oracle client installation is not of a supported client version, BizTalk host crashes and then restarts.

For example, assume that the supported Oracle client 11.1.0.7 is already installed on the computer and the PATH variable has the following reference:

```
C:\oracle\product\11.1.0\client_1\bin;
```

If an unsupported Oracle client, for example 10.2.0.3, is installed on the same computer, the PATH variable will have the following reference:

```
C:\oracle\product\10.2.0\db_2\bin;C:\oracle\product\11.1.0\client_1\bin;
```

Note that the unsupported client version is referenced before the supported version and hence BizTalk host crashes. If there are more than one BizTalk hosts running, then the one hosting the adapter crashes.

Resolution

If more than one Oracle client is installed on the same computer, make sure the supported Oracle client version is referenced before the other Oracle client versions in the PATH variable. For example, if the supported Oracle client version is 11.1.0.7, the reference in the PATH variable must look like:

```
C:\oracle\product\11.1.0\client_1\bin;C:\oracle\product\10.2.0\db_2\bin;
```

Adapter might throw an overflow exception on executing an operation

Problem

Using the adapter, if you try to perform an operation containing Oracle numeric data types inside DataSets or weakly-typed REF CURSORS, the adapter might throw an overflow exception.

Cause

This happens if you supply a large value for the Oracle numeric data type inside DataSets or weakly-typed REF CURSORS that cannot fit into the respective .NET type.

Resolution

If you want to pass large values for the Oracle numeric data type inside DataSets or weakly-typed REF CURSORS, you must enable safe typing by setting the value of the **EnableSafeTyping** binding property to **true**. Enabling safe typing exposes the Oracle numeric data type inside DataSets or weakly-typed REF CURSORS as strings.

Adapter might throw an arithmetic overflow exception on executing an ExecuteScalar operation

Problem

Using the adapter, if you try to execute a SELECT statement in an ExecuteScalar operation that retrieves a large number, the adapter throws the following exception: "System.OverflowException: Arithmetic operation resulted in an overflow."

Cause

This happens due to the known limitation of ExecuteScalar operation in ODP.NET. ODP.NET tries to fit in the data into the .NET Decimal data type, and if the result is too large to fit in the .NET Decimal type, the exception is thrown.

Resolution

Use TO_CHAR() in the SELECT statement in the ExecuteScalar operation to convert the returned data as string.

Adapter client might throw the following exception on executing an operation: "Could not retrieve user id, responsibility id, application id. Check if correct values were passed in."

Problem

The adapter clients might throw this exception if you are performing operations on Oracle E-Business Suite artifacts (interface tables, interface views, concurrent programs, and request sets).

Cause

This happens if you supply an incorrect combination of Oracle user name, password, and responsibility name while performing operations on interface tables, interface views, concurrent programs, and request sets. The Oracle E-Business adapter requires these values in order to set the application context for these artifacts. For more information about setting application context, see [Setting Application Context](#).

Resolution

You must specify a correct combination of the Oracle user name, password, and responsibility to appropriately set application context for an Oracle E-Business Suite artifact. To specify values for Oracle user name and password, you must use the **OracleUserName** and **OraclePassword** binding properties. To specify value for the Oracle responsibility, you can either use the **OracleEBSResponsibilityName** binding property or message context property.

Error with RootNode TypeName in BizTalk Projects

Problem

In a BizTalk project in Visual Studio, if the schemas generated from the Consume Adapter Service Add-in contains invalid characters or reserved words for the **RootNode TypeName** property, the following error will occur while compiling the project:

```
Node <node reference> - Specify a valid .NET type name for this root node.  
The current .NET type name of this root node is invalid (it is a reserved BizTalk Keyword or is an invalid C# identifier).
```

Resolution

1. Right-click the root node referenced in the error and select **Properties**.
2. For the **RootNode TypeName** property, remove any illegal characters or reserved words, for example, dot (.).

Invalid binding warning when using the adapter in Visual Studio 2010

Problem

When you use the adapter to create an application in Visual Studio 2010 and you open the configuration file (app.config) generated by the adapter, you see a warning similar to the following:

```
The element 'bindings' has invalid child element 'oracleEBSBinding'. List of possible elements expected: 'basicHttpBinding, customBinding, ...'
```

Cause

This warning appears because the Oracle E-Business adapter binding, `oracleEBSBinding`, is not a standard binding shipped with the Windows Communication Foundation (WCF).

Resolution

You can safely ignore this warning.

BizTalk Server throws an exception if you use more than one Notification schema in the same application or use the Notification schema across multiple applications on the same host

Problem

BizTalk Server throws an XLANG exception or an exception stating that the application cannot locate the document specification because multiple schemas matched the message type.

Cause

This happens because of either of the following:

- You have generated more than one Notification schema in a BizTalk Server project, deployed it to a BizTalk Server application, and then ran the application to receive notifications from the Oracle database. Because the Notification schemas are common, there is a conflict between the schemas that are deployed in the BizTalk Server application.
- In case of multiple projects, you have generated a Notification schema for each of the BizTalk Server projects, deployed each project to a separate BizTalk Server application on the same host, and then ran an application or applications to receive notifications from the Oracle database. Because the schemas and assemblies are accessible across the applications in BizTalk Server, there is a conflict between the common schemas deployed under various BizTalk Server applications and assemblies.

Resolution

Use a single Notification schema file for a BizTalk Server application. If you need to use the Notification schema in multiple BizTalk Server applications on the same host, create an application containing a single Notification schema, and then use the notification schema from all other applications in BizTalk Server.

Timeout Exception while browsing Oracle E-Business Suite Artifacts in Visual Studio

Problem

While browsing Oracle E-Business Suite artifacts in a Visual Studio project using the Add Adapter Metadata Wizard, Add Adapter Service Reference Plug-in, or Consume Adapter Service Add-in you might encounter a timeout exception.

Cause

This might happen if the server hosting the Oracle E-Business Suite is slow, server is located at a remote location, or the schema you are looking under has a large number of artifacts.

Resolution

You can either choose to increase the value of the **SendTimeout** binding property or provide a search expression in the **Search in category** text box to reduce the number of artifacts that the adapter retrieves.

For more information about specifying binding properties, see [Specifying Binding Properties](#). For more information about searching artifacts in Oracle E-Business Suite, see [Browsing, Searching, and Retrieving Metadata for Oracle E-Business Operations](#).

Memory usage and thread count increases when using the adapter in a transacted inbound operation

Problem

In a transacted inbound operation, such as Polling, **if there is no data available in the table being polled** and the adapter continues to poll, over a period of time you experience an increase in the memory usage and the thread count.

Cause

If there is no data available in the table being polled, after every receive timeout cycle, Windows Communication Foundation (WCF) spawns a new thread to continue the polling operation. Hence, the thread count and memory usage increases over a period of time. However, if the table being polled has some data, the same thread continues to perform all subsequent polls.

Resolution

We recommend setting the **ReceiveTimeout** to the maximum possible value, which is 24.20:31:23.6470000 (24 days) so that a new thread is spawned only every 24 days. This will ensure that the memory usage and thread count does not grow too much too soon.

For more information about the **ReceiveTimeout** binding property, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). For instructions on specifying binding properties, see [Specifying Binding Properties](#).

Note

When using the adapter with BizTalk Server, setting the timeout to a large value does not impact the functionality of the adapter.

[Troubleshooting](#)

Using Performance Counters

Microsoft BizTalk Adapter Pack clients can use performance counters to gauge the performance of the adapters. The BizTalk Adapter Pack setup program creates the performance counter category **BizTalk .NET Adapter for Oracle E-Business Suite** along with installing the BizTalk Adapter Pack.

The LOB Time (Cumulative) Performance Counter

The **BizTalk .NET Adapter for Oracle E-Business Suite** category has one performance counter called the "LOB Time (Cumulative)." This performance counter denotes the time, in milliseconds, that the LOB client library takes to complete an action that the adapter initiates. The Oracle E-Business adapter creates an instance of the performance counter in any of the following patterns:

```
<process id>:<app domain id>:<oracle data source>:<string>
```

Where "string" could be:

- Connection.Open
- Connection.Close
- Metadata
- Message action. For example, if the action is `InterfaceTables/Insert/FND/APPS/MS_SAMPLE_EMPLOYEE` then the string will be `InterfaceTables.Insert.FND.APPS.MS_SAMPLE_EMPLOYEE`.

The Oracle data source is the same as specified in the connection URI.

The performance counter is initialized only after the adapter makes the first call to the Oracle database. Also, the `InstanceLifetime` property of the performance counter is set to 'Process', which means that the performance counter ceases to exist as soon as the program that creates the counter terminates. For more information about the `InstanceLifetime` property, see <http://go.microsoft.com/fwlink/?LinkId=104181>.

Note

The precision of the LOB Time (Cumulative) performance counter is 16 milliseconds.

Enabling Performance Counters

The performance counters can be enabled or disabled by setting the binding property **EnablePerformanceCounters**. To enable performance counters, set the **EnablePerformanceCounters** binding property to **True**. To disable performance counters, set **EnablePerformanceCounters** to **False**. By default, **EnablePerformanceCounters** is set to **False**.

Performance Counters and the WCF LOB Adapter SDK

Changing the value of the **EnablePerformanceCounters** binding property also changes the value of the corresponding performance counter for the WCF LOB Adapter SDK. Also, the binding property for the WCF LOB Adapter SDK is static, whereas that for the BizTalk Adapter Pack is dynamic. Therefore, if there are two instances of the Oracle E-Business adapter binding in the AppDomain, and the **EnablePerformanceCounters** binding property is set to **True** in one and **False** in the other, the adapter-specific performance counter will be enabled in one and disabled in the other. However, because the binding property for WCF LOB Adapter SDK is static, it will either be set to **True** or **False** depending on what value was specified last.

Technical Reference

This section covers technical reference information about Microsoft BizTalk Adapter for Oracle E-Business Suite.

In This Section

- [Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)
- [Glossary](#)

Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite

The Microsoft BizTalk Adapter for Oracle E-Business Suite is a Windows Communication Foundation (WCF) custom binding. It exposes operations that applications can invoke on it and that it can, in turn, invoke on applications. These operations are invoked by sending SOAP messages over a channel. If a response is required, it is returned in a SOAP message over the same channel.

As a WCF service, the Oracle E-Business adapter exposes metadata for its operations and data types by using standard WCF mechanisms. The sections in this topic describe the XML structure of the messages and data types that the Oracle E-Business adapter uses.

[Technical Reference](#)

Basic Oracle Data Types

This topic describes how the Microsoft BizTalk Adapter for Oracle E-Business Suite surfaces basic Oracle data types.

Supported Oracle Data Types

The Oracle E-Business adapter supports safe typing for some Oracle data types. When safe typing is enabled, these data types are represented as strings. You configure safe typing by enabling the **EnableSafeTyping** binding property (disabled by default). For more information about the Oracle E-Business adapter binding properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#).

Note

Safe typing is not supported if data types are inside User Defined Types (UDTs).

The following table shows how the Oracle data types are surfaced with safe typing disabled (**EnableSafeTyping** is **false**). Oracle data types that are affected by the **EnableSafeTyping** binding property are marked with an asterisk (*).

Oracle Data Type	XSD type	.NET type	Comments
BFile	input: xsd:string output: xsd:base64Binary	String Byte[]	BFile data type is not supported inside complex types (such as RecordType, TableType, UDT, and VArray).
Blob	xsd:base64Binary	Byte[]	-
Char	xsd:string	String	-
Clob	xsd:string	String	-
Date* (No safe typing if inside an UDT)	xsd:dateTime	DateTime	<p>Date values cannot contain time zone information (UTC or UTC offsets):</p> <ul style="list-style-type: none"> • xsd:dateTime values must not contain UTC or UTC offsets • DateTime.Kind must be DateTimeKind.Unspecified <p>If time zone information is specified, the adapter throws an XmlReaderParsingException exception with a message that indicates the field.</p> <p>Note</p> <p>The Oracle E-Business adapter exposes Oracle Date data type as xsd:dateTime instead of xsd:date because:</p> <ul style="list-style-type: none"> • Oracle Date data type can also contain time value. • There is no .NET equivalent for xsd:date.

Float**	xsd:float if prec <=7 xsd:double if prec >7 and <=15 xsd:string if prec >15	Float Double String	You must specify the value consistent with the format specified for the decimal character and group separator in the NumericCharacters binding property under the MlsSettings binding property. If no value is specified for the NumericCharacters binding property, the adapter uses the MLS settings for the ODP.NET client on the same computer where the adapter is installed.
IntervalDS	xsd:string xsd:duration if inside an UDT	String TimeSpan if inside an UDT	The adapter returns the IntervalDS data as a string using the OracleIntervalDS.ToString method. The value should be expressed in Oracle native format: Day HH:MI:SSxFF (for example, "5 15:30:12.99").
IntervalYM	xsd:string xsd:long if inside an UDT	String Long if inside an UDT	The adapter returns the IntervalYM data as a string using the OracleIntervalYM.ToString method. The value should be expressed in Oracle native format: Year-Month; for example, "1-2" (1 year and 2 months).
Long	xsd:string	String	Starting with the Oracle database 9i release, the LONG data type is deprecated. Oracle recommends using the Large Object (LOB) data types instead. Therefore, when performing operations on the Oracle database using the Oracle Database adapter, we recommend using Oracle database artifacts that operate on LOB data types and not the LONG data type.
LongRaw	xsd:base64Binary	Byte[]	-
NChar	xsd:string	String	-
NClob	xsd:string	String	-
Number**	xsd:decimal if prec <=28 xsd:string if prec >28	Decimal String	-
NVarchar2	xsd:string	String	-

Raw	xsd:base64Binary	Byte[]	
RowID	xsd:string	String	-
TimeStamp* (No safe typing if inside an UDT)	xsd:dateTime if prec <= 7 xsd:string if prec > 7	DateTime String	<p>When exposed as string (prec > 7), the value should be expressed in Oracle NLS_TIMESTAMP_FORMAT. You can specify the string format for TimeStamp data types in the TimeStampFormat binding property under the MlsSettings binding property. If no value is specified for the TimeStampFormat binding property, the adapter uses the MLS settings for the ODP.NET client on the same computer where the adapter is installed.</p> <p>TimeStamp values cannot contain time zone information (UTC or UTC offsets):</p> <ul style="list-style-type: none"> • xsd:dateTime values must not contain UTC or UTC offsets • DateTime.Kind must be DateTimeKind.Unspecified <p>If time zone information is specified, the adapter throws an XmlReaderParsingException exception with a message that indicates the field.</p>
TimeStampLTZ	xsd:string	String	<p>TimeStampLTZ is not supported inside UDTs.</p> <p>Outside an UDT: The value should be expressed in Oracle NLS_TIMESTAMP_TZ_FORMAT. You can specify the string format for TimeStampLTZ data types in the TimeStampTZFormat binding property under the MlsSettings binding property. If no value is specified for the TimeStampTZFormat binding property, the adapter uses the MLS settings for the ODP.NET client on the same computer where the adapter is installed.</p>
TimeStampTZ	xsd:string xsd:dateTime if inside an UDT	String DateTime if inside an UDT	<p>Outside an UDT: The value should be expressed in Oracle NLS_TIMESTAMP_TZ_FORMAT. You can specify the string format for TimeStampTZ data types in the TimeStampTZFormat binding property under the MlsSettings binding property. If no value is specified for the TimeStampTZFormat binding property, the adapter uses the MLS settings for the ODP.NET client on the same computer where the adapter is installed.</p>
Decimal**	xsd:decimal if prec <= 28 xsd:string if prec > 28	Decimal String	-
Varchar2	xsd:string	String	-
BinaryFloat**	xsd:float if prec <= 7 xsd:string if prec > 7	Float String	<p>You must specify the value consistent with the format specified for the decimal character and group separator in the NumericCharacters binding property under the MlsSettings binding property. If no value is specified for the NumericCharacters binding property, the adapter uses the MLS settings for the ODP.NET client on the same computer where the adapter is installed.</p>

Binary Double**	xsd:double if prec <= 15 xsd:string if prec > 15	Double String	-
Binary Integer*	xsd:integer	Int32	
Boolean	xsd:boolean	Nullable boolean	
XMLTYPE	xsd:string	String	Supported for top level procedure parameters. Reserved XML characters like '<', '>' must be replaced with their entity representation (&lt; , &gt;) when developing applications in BizTalk, and when using WCF channel Model. This is not required in the case of WCF Service Model.

*The way in which these Oracle data types are surfaced is affected by the **EnableSafeTyping** binding property.

The way in which these Oracle numeric data types inside DataSets and weakly-typed REF CURSORS are surfaced is affected by the **EnableSafeTyping binding property.

◆ Important
<ul style="list-style-type: none"> The maximum length of the value in an Oracle data type in the Oracle E-Business adapter is bound by the maximum length of the value supported by ODP.NET for the Oracle data type. The Oracle E-Business adapter internally treats the Oracle numeric data types inside UDTs as .NET Decimal. However, in general (that is outside UDTs), the Oracle E-Business adapter internally treats the Oracle numeric data types as OracleDecimal.

Safe Typing Enabled

The following table shows how the Oracle data types that are affected by safe typing are changed when the **EnableSafeTyping** binding property is **true**.

📌 Note
Oracle data types that are not in this table are surfaced in the same way whether safe typing is enabled or disabled.

Oracle Data Type	XML Schema Type	.NET Type	Comment

Date	xs	St	The value should be expressed in Oracle NLS_DATE_FORMAT. You can specify the format for the Date data types in the DateFormat binding property under the MlsSettings binding property. If no value is specified for the DateFormat binding property, the adapter uses the MLS settings for the ODP.NET client on the same computer where the adapter is installed.
TimeStamp	xs	St	The value should be expressed in Oracle NLS_TIMESTAMP_FORMAT. You can specify the string format for TimeStamp data types in the TimeStampFormat binding property under the MlsSettings binding property. If no value is specified for the TimeStampFormat binding property, the adapter uses the MLS settings for the ODP.NET client on the same computer where the adapter is installed.

◆ Important

If safe typing is enabled, the Oracle numeric data types inside DataSets and weakly-typed REF CURSORS are always exposed as strings.

Validation

The Oracle E-Business adapter performs no explicit validation on the values that you specify for Oracle data types. However, depending on the Oracle data type and whether safe typing is enabled or disabled, implicit validation may be performed:

- When de-serializing between the XML passed in a message and the .NET types that are used internally by the adapter.
- By ODP.NET for some data types.

[Technical Reference](#)

[Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)

Message Schemas for Insert, Update, Delete, and Select Operations

The Microsoft BizTalk Adapter for Oracle E-Business Suite surfaces basic Insert, Update, Delete, and Select operations for each interface table in Oracle E-Business Suite and each table in the underlying database. The adapter also surfaces the Select operation for each interface view in Oracle E-Business Suite and each view in the underlying database. These operations perform the appropriate SQL statement qualified by a WHERE clause. The Oracle E-Business adapter uses strongly-typed records and record sets in these operations.

Message Structure for Basic Operations

The following table shows the XML message structure for the basic operations exposed by the Oracle E-Business adapter on Oracle E-Business Suite interface tables and interface views and on the underlying database tables and views. The target object for an operation is specified in the message action and also appears in the target namespace.

 Note
See attribute descriptions after table.

Operation	XML Message	Description	SQL Executed by the Adapter
Insert	<pre><Insert xmlns="[VERSION]/InterfaceTables/[SCHEMA]/[APP_NAME]/[INTERFACETABLE_NAME]"> <RECORDSET> <InsertRecord> <[FIELD1_NAME] InlineValue="value">[value1]</[FIELD1_NAME]> <[FIELD2_NAME] InlineValue="value">[value2]</[FIELD2_NAME]> ... </InsertRecord> </RECORDSET> </Insert></pre>	The value for the InlineValue attribute, if specified, overrides the value of an element.	<pre>INSERT INTO TABLE_NAME (FIELD1_NAME, FIELD2_NAME, ...) VALUES (value1, value2, ...);</pre>
Insert Response	<pre><InsertResponse xmlns="[VERSION]/InterfaceTables/[SCHEMA]/[APP_NAME]/[INTERFACETABLE_NAME]"> <InsertResult>[rows inserted]</InsertResult> </InsertResponse></pre>	The number of rows inserted is returned in the InsertResult element.	--

Select	<pre><Select xmlns="[VERSION]/InterfaceTables/[SCHEMA]/[APP_NAME]/[INTERFACETABLE_NAME]"> <COLUMN_NAMES>[COLUMN_list]</COLUMN_NAMES> <FILTER>WHERE_clause</FILTER> </Select></pre>	<p>A SELECT query is performed on the target table using the WHERE clause specified in the FILTER element. The result set contains the columns in the comma-separated list of column names specified in the COLUMN_NAMES element.</p> <p>◆ Important This is the only operation that is applicable for interface views and database views.</p>	<pre>SELECT COLUMN_list FROM TABLE_NAME WHERE WHERE_clause;</pre>
Select Response	<pre><SelectResponse xmlns="[VERSION]/InterfaceTables/[SCHEMA]/[APP_NAME]/[INTERFACETABLE_NAME]"> <SelectResult> <SelectRecord> <[FIELD1_NAME]>value1</[FIELD1_NAME]> <[FIELD2_NAME]>value2</[FIELD2_NAME]> ... </SelectRecord> </SelectResult> </SelectResponse></pre>	<p>The result set generated by the SELECT query.</p>	<pre>--</pre>
Update	<pre><Update xmlns="[VERSION]/InterfaceTables/[SCHEMA]/[APP_NAME]/[INTERFACETABLE_NAME]"> <RECORDSET> <[FIELD1_NAME]>value1</[FIELD1_NAME]> <[FIELD2_NAME]>value2</[FIELD2_NAME]> ... </RECORDSET> <FILTER>WHERE_clause</FILTER> </Update></pre>	<p>Rows that match the where clause specified in the FILTER element are updated to the values specified in the RECORDSET. Only the columns that are specified in the RECORDSET element are updated in each matching row.</p>	<pre>UPDATE [TABLE_NAME] SET [FIELD1_NAME] = value1, [FIELD2_NAME] = value2, ... WHERE WHERE_clause;</pre>
Update Response	<pre><UpdateResponse xmlns="[VERSION]/InterfaceTables/[SCHEMA]/[APP_NAME]/[INTERFACETABLE_NAME]"> <UpdateResult>[rows inserted]</UpdateResult> </UpdateResponse></pre>	<p>The number of rows updated is returned in the UpdateResult element.</p>	<pre>--</pre>

Delete	<pre><Delete xmlns="[VERSION]/InterfaceTables/[SCHEMA]/[APP_NAME]/[INTERFACETABLE_NAME]"> <FILTER>WHERE_clause</FILTER> </Delete></pre>	Rows matching the WHERE clause specified by the FILTER element are deleted.	DELETE FROM [TABLE_NAME] WHERE WHERE_clause;
Delete Response	<pre><DeleteResponse xmlns="[VERSION]/InterfaceTables/[SCHEMA]/[APP_NAME]/[INTERFACETABLE_NAME]"> <DeleteResult>[rows deleted]</DeleteResult> </DeleteResponse></pre>	The number of rows deleted is returned in the DeleteResult element.	

Attribute descriptions:

[VERSION] = The message version string; for example, http://schemas.microsoft.com/OracleEBS/2008/05.

[SCHEMA] = Collection of Oracle artifacts; for example, SCOTT.

[APP_NAME] = Application short name.

[INTERFACETABLE_NAME] = Name of the interface table.

[FIELD1_NAME] = Table field name.

[COLUMN_list] = Comma-separated list of columns.

[WHERE_clause] = WHERE_clause for the SELECT statement used for the operation; for example, ID > 10.

◆ Important

The message structure for the basic operations on interface views, database tables, and database views is the same as that on interface tables, but the namespace for the operation specifies an interface view, database table, or database view rather than an interface table.

Message Actions for Basic Operations

The following table shows the message actions that the Oracle E-Business adapter uses for the basic operations on the interface tables and interface view in Oracle E-Business Suite, and the tables and views in the underlying database. The Oracle E-Business adapter uses the interface table, interface view, database table, or database view specified in the message action to determine the target of the operation.

📌 Note

See entity descriptions after table.

Operation	Message Action	Example
Insert	<p>Applications: InterfaceTables/Insert/[SHORT_NAME]/[APP_NAME]/[TABLE_NAME]</p> <p>Database: Tables/Insert/[SCHEMA]/[TABLE_NAME]</p>	<p>Applications: InterfaceTables/Insert/SQLGL/GL/GL_ALLOC_HISTORY</p> <p>Database: Tables/Insert/GL/GL_ALLOC_HISTORY</p>

Insert Response	<p>Applications: InterfaceTables/Insert/[SHORT_NAME]/[APP_NAME]/[TABLE_NAME]/response</p> <p>Database: Tables/Insert/[SCHEMA]/[TABLE_NAME]/response</p>	<p>Applications: InterfaceTables/Insert/SQLGL/GL/GL_ALLOC_HISTORY/response</p> <p>Database: Tables/Insert/GL/GL_ALLOC_HISTORY/response</p>
Select	<p>Applications: InterfaceTables/Select/[SHORT_NAME]/[APP_NAME]/[TABLE_NAME]</p> <p>Database: Tables/Select/[SCHEMA]/[TABLE_NAME]</p>	<p>Applications: InterfaceTables/Select/SQLGL/GL/GL_ALLOC_HISTORY</p> <p>Database: Tables/Select/GL/GL_ALLOC_HISTORY</p>
Select Response	<p>Applications: InterfaceTables/Select/[SHORT_NAME]/[APP_NAME]/[TABLE_NAME]/response</p> <p>Database: Tables/Select/[SCHEMA]/[TABLE_NAME]/response</p>	<p>Applications: InterfaceTables/Select/SQLGL/GL/GL_ALLOC_HISTORY/response</p> <p>Database: Tables/Select/GL/GL_ALLOC_HISTORY/response</p>
Update	<p>Applications: InterfaceTables/Update/[SHORT_NAME]/[APP_NAME]/[TABLE_NAME]</p> <p>Database: Tables/Update/[SCHEMA]/[TABLE_NAME]</p>	<p>Applications: InterfaceTables/Update/SQLGL/GL/GL_ALLOC_HISTORY</p> <p>Database: Tables/Update/GL/GL_ALLOC_HISTORY</p>
Update Response	<p>Applications: InterfaceTables/Update/[SHORT_NAME]/[APP_NAME]/[TABLE_NAME]/response</p> <p>Database: Tables/Update/[SCHEMA]/[TABLE_NAME]/response</p>	<p>Applications: InterfaceTables/Update/SQLGL/GL/GL_ALLOC_HISTORY/response</p> <p>Database: Tables/Update/GL/GL_ALLOC_HISTORY/response</p>
Delete	<p>Applications: InterfaceTables/Delete/[SHORT_NAME]/[APP_NAME]/[TABLE_NAME]</p> <p>Database: Tables/Delete/[SCHEMA]/[TABLE_NAME]</p>	<p>Applications: InterfaceTables/Delete/SQLGL/GL/GL_ALLOC_HISTORY</p> <p>Database: Tables/Delete/GL/GL_ALLOC_HISTORY</p>
Delete Response	<p>Applications: InterfaceTables/Delete/[SHORT_NAME]/[APP_NAME]/[TABLE_NAME]/response</p> <p>Database: Tables/Delete/[SCHEMA]/[TABLE_NAME]/response</p>	<p>Applications: InterfaceTables/Delete/SQLGL/GL/GL_ALLOC_HISTORY/response</p> <p>Database: Tables/Delete/GL/GL_ALLOC_HISTORY/response</p>

Entity descriptions:

- [SCHEMA] - Collection of Oracle artifacts (for example, GL).
- [TABLE_NAME] - Name of the table (for example, GL_ALLOC_HISTORY).

◆ Important

The message action for the Select operation on an interface view is the same as that for the interface table, except that "InterfaceViews" replaces "InterfaceTables." Similarly, the message action for the Select operation on a database view is the same as that for the database table, except that "Views" replaces "Tables."

[Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)

Message Schemas for Stored Procedures, Functions, and PL/SQL APIs

The Microsoft BizTalk Adapter for Oracle E-Business Suite surfaces the underlying Oracle database stored procedures, functions, and PL/SQL APIs (stored procedures and functions within a package) as operations. This section describes the message structure and actions used to invoke stored procedures, functions, and PL/SQL APIs.

Message Structure of Stored Procedures, Functions, and PL/SQL APIs

The operations surfaced for functions and stored procedures follow a request-response message exchange pattern. The following table shows the structure of these request and response messages.

 Note
See entity descriptions after the table.

Operation	XML Message	Description
Stored Procedure Request	<pre><[SP_NAME] xmlns="[VERSION]/Procedures/[SCHEMA]"> <[PRM1_NAME]>value1</[PRM1_NAME]> <[PRM2_NAME]>value2</[PRM2_NAME]> ... </[SP_NAME]></pre>	Supports Oracle IN and IN OUT parameters in the message body
Stored Procedure Response	<pre><[SP_NAME]Response xmlns="[VERSION]/Procedures/[SCHEMA]"> <[PRM1_NAME]>value1<[PRM1_NAME]> <[PRM2_NAME]>value2</[PRM2_NAME]> ... </[SP_NAME]Response></pre>	Supports Oracle OUT and IN OUT parameters in the message body
Function Request	<pre><[FN_NAME] xmlns="[VERSION]/Functions/[SCHEMA]"> <[PRM1_NAME]>value1</[PRM1_NAME]> <[PRM2_NAME]>value2</[PRM2_NAME]> ... </[FN_NAME]></pre>	Supports Oracle IN and IN OUT parameters in the message body
Function Response	<pre><[FN_NAME]Response xmlns="[VERSION]/Functions/[SCHEMA]"> <[FN_NAME]Result>return_value</[FN_NAME]Result> <[PRM1_NAME]>value1</[PRM1_NAME]> <[PRM2_NAME]>value2</[PRM2_NAME]> ... </[FN_NAME]Response></pre>	Supports Oracle OUT and IN OUT parameters in the message body The function return value is returned in the <[FN_NAME]Result> element. This is the first element in the response message. It comes before any parameters.

PL/SQL API Request	<pre><[SP_NAME] xmlns="[VERSION]/PackageApis/[SCHEMA]/[PACKAGE_NAME]/[SP_NAME]"> <[PRM1_NAME]>value1</[PRM1_NAME]> <[PRM2_NAME]>value2</[PRM2_NAME]> ... </[SP_NAME]></pre>	Same as Function or Stored Procedure
Packaged Procedure or Function Response	<pre><[SP_NAME]Response xmlns="[VERSION]/PackageApis/[SCHEMA]/[PACKAGE_NAME]/[SP_NAME]"> <[PRM1_NAME]>value1</[PRM1_NAME]> <[PRM2_NAME]>value2</[PRM2_NAME]> ... </[SP_NAME]Response></pre>	Same as Function or Stored Procedure

Entity descriptions:

[VERSION] = <http://schemas.microsoft.com/OracleEBS/2008/05>.

[SCHEMA] = Collection of Oracle artifacts; for example, SCOTT.

[SP_NAME] = The stored procedure to be executed; for example, SP_INSERT.

[FN_NAME] = The function to be executed; for example, FN_GETID.

[PRM1_NAME] = The name of the Oracle parameter. See the Description column for supported parameter directions for each message.

[PACKAGE_NAME] = The name of the package that contains the targeted procedure or function.

The Oracle database supports overloading for stored procedures and functions. The Oracle E-Business adapter supports this capability by appending an overload string to the target namespace for each overloaded artifact. The value of this string is "overload1" for the first overload, "overload2" for the second overload, and so on. The following example shows the message structure for two overloaded stored procedures.

```
Stored Procedure Overload 1:
<[SP_NAME] xmlns="[VERSION]/PackageApis/[SCHEMA]/[PACKAGE_NAME]/[SP_NAME]/overload1">
  <[PRM1_NAME]>value1</[PRM1_NAME]>
  <[PRM2_NAME]>value1</[PRM2_NAME]>
  ...
</[SP_NAME]>

Stored Procedure Overload 2:
<[SP_NAME] xmlns="[VERSION]/PackageApis/[SCHEMA]/[PACKAGE_NAME]/[SP_NAME]/overload2">
  <[PRM1_NAME]>value1</I_[PRM1_NAME]>
  <[PRM2_NAME]>value1</I_[PRM2_NAME]>
  ...
</[SP_NAME]>
```

Message Actions of Stored Procedures, Functions, and PL/SQL APIs

The Oracle E-Business adapter uses the following message actions for stored procedure, function, and PL/SQL API operations.

Note
See entity descriptions after the table.

Message	Action	Example
---------	--------	---------

Stored Procedure Request	Procedures/[SCHEMA]/[SP_NAME]	Procedures/SCOTT/SP_INSERT
Stored Procedure Response	Procedures/[SCHEMA]/[SP_NAME]/response	Procedures/SCOTT/SP_INSERT/response
Function Request	Functions/[SCHEMA]/[FN_NAME]	Functions/SCOTT/FN_GETID
Function Response	Functions/[SCHEMA]/[FN_NAME]/response	Functions/SCOTT/FN_GETID/response
PL/SQL API Request	[SCHEMA]/Package/[PACKAGE_NAME]/[SP_NAME]	SCOTT/Package/CUSTOMER/SP_INSERT
Packaged Stored Procedure Response	[SCHEMA]/Package/[PACKAGE_NAME]/[SP_NAME]/response	SCOTT/Package/CUSTOMER/SP_INSERT/response
Packaged Function Request	[SCHEMA]/Package/[PACKAGE_NAME]/[FN_NAME]	SCOTT/Package/CUSTOMER/FN_GETID
Packaged Function Response	[SCHEMA]/Package/[PACKAGE_NAME]/[FN_NAME]/response	SCOTT/Package/CUSTOMER/FN_GETID/response
Overloaded Stored Procedure Request	[SCHEMA]/Procedure/[SP_NAME]/[OVERLOAD]	SCOTT/Procedure/SP_INSERT/overload1
Overloaded Stored Procedure Response	[SCHEMA]/Procedure/[SP_NAME]/[OVERLOAD]/response	SCOTT/Procedure/SP_INSERT/overload1/response

Entity descriptions:

[SCHEMA] = Collection of Oracle artifacts; for example, SCOTT.

[SP_NAME] = The stored procedure to be executed; for example, SP_INSERT.

[FN_NAME] = The function to be executed; for example, FN_GETID.

[PACKAGE_NAME] = The name of the package that contains the targeted procedure or function.

[OVERLOAD] = The Overload parameter. The possible values are overload1, overload2, and so on.

[Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)

Message Schemas for Concurrent Programs

The Microsoft BizTalk Adapter for Oracle E-Business Suite surfaces concurrent programs as operations. Along with the concurrent programs exposed as operations, the Oracle E-Business adapter also surfaces the following three standard operations: Get_Status, Wait_For_Request, and Submit_Request. For information about these operations related to concurrent programs, see [Operations on Concurrent Programs](#).

Message Structure of Concurrent Program Operations

The operations surfaced for concurrent programs follow a request-response message exchange pattern. The following table shows the structure of these request and response messages.

 Note
See entity descriptions after the table.

Operation	XML Message	Description
-----------	-------------	-------------

[Concurrent_Program_Name]
Request

```
<?xml version="1.0" encoding="utf-8" ?>  
<[Concurrent_Program_Name] xmlns="[VERSION]"/>  
  <SetOptions>  
    <Implicit>[value]</Implicit>  
    <Protected>[value]</Protected>  
    <Language>[value]</Language>  
    <Territory>[value]</Territory>  
    <ContinueOnFail>[value]</ContinueOnFail>  
  </SetOptions>  
  <SetPrintOptions>  
    <Printer>[value]</Printer>  
    <Style>[value]</Style>  
    <Copies>[value]</Copies>  
    <SaveOutput>[value]</SaveOutput>  
    <PrintTogether>[value]</PrintTogether>  
    <ContinueOnFail>[value]</ContinueOnFail>  
  </SetPrintOptions>  
  <SetRepeatOptions>  
    <RepeatTime>[value]</RepeatTime>  
    <RepeatInterval>[value]</RepeatInterval>  
    <RepeatUnit>[value]</RepeatUnit>  
    <RepeatType>[value]</RepeatType>  
    <RepeatEndTime>[value]</RepeatEndTime>  
    <ContinueOnFail>[value]</ContinueOnFail>  
  </SetRepeatOptions>  
  <Description>[value]</Description>  
  <StartTime><[value]</StartTime>  
  <[CONCURRENT_PROGRAM_ARGUMENT1]>[value]</[CONCURRENT_PROGRAM_ARGUMENT1]>  
  <[CONCURRENT_PROGRAM_ARGUMENT2]>[value]</[CONCURRENT_PROGRAM_ARGUMENT2]>  
  ...  
</[Concurrent_Program_Name]>
```

- The [Concurrent_Program_Name] operation takes five standard parameters: *SetOptions*, *SetPrintOptions*, *SetRepeatOptions*, *Description*, and *StartTime*.
- The *ContinueOnFail* parameter indicates whether the concurrent request submission should continue in case the parent parameter (*SetOptions*, *SetPrintOptions*, or *SetRepeatOptions*) fails, or whether it should throw an exception. You can specify **True** (continue) or **False** (throw an exception).
- For detailed information about each parameter, see [Operations on Concurrent Programs](#).

<p>[Concurrent_Program_Name] Response</p>	<pre><?xml version="1.0" encoding="utf-8" ?> <[Concurrent_Program_Name]Response xmlns="[VERSION]/ConcurrentPrograms/[APP_SHORT_NAME]"> <[Concurrent_Program_Name]Result>[value] </[Concurrent_Program_Name]Result> </[Concurrent_Program_Name]Response></pre>	<p>The response from Oracle E-Business Suite contains a concurrent request ID.</p>
<p>Get_Status Request</p>	<pre><?xml version="1.0" encoding="utf-8" ?> <GetStatusForConcurrentProgram xmlns="[VERSION]/ConcurrentPrograms/[APP_SHORT_NAME]"> <RequestId>[value] </RequestId> </GetStatusForConcurrentProgram></pre>	<p>This Get_Status request message takes the request ID of a concurrent program as an input.</p>
<p>Get_Status Response</p>	<pre><?xml version="1.0" encoding="utf-8" ?> <GetStatusForConcurrentProgramResponse xmlns="[VERSION]/ConcurrentPrograms/[APP_SHORT_NAME]"> <GetStatusForConcurrentProgramResult>[value] </GetStatusForConcurrentProgramResult> <Phase>[value] </Phase> <Status>[value] </Status> <DevPhase>[value] </DevPhase> <DevStatus>[value] </DevStatus> <Message>[value] </Message> </GetStatusForConcurrentProgramResponse></pre>	<p>This Get_Status response message returns the request phase/status and the completion message of a concurrent program.</p> <p>For detailed information about each parameter, see Operations on Concurrent Programs.</p>

Wait_For_Request Request	<pre><?xml version="1.0" encoding="utf-8" ?> <WaitForRequestForConcurrentProgram xmlns=" [VERSION]/ConcurrentPrograms/[APP_SHORT_NAME]"> <RequestId>[value]</RequestId> <Interval>[value]</Interval> <MaxWait>[value]</MaxWait> </WaitForRequestForConcurrentProgram></pre>	For detailed information about each parameter, see Operations on Concurrent Programs .
Wait_For_Request Response	<pre><?xml version="1.0" encoding="utf-8" ?> <WaitForRequestForConcurrentProgramResponse xmlns=" [VERSION]/ConcurrentPrograms/[APP_SHORT_NAME]"> <WaitForRequestForConcurrentProgramResult>[value]</WaitForRequestForConcurrentProgramResult> <Phase>[value]</Phase> <Status>[value]</Status> <DevPhase>[value]</DevPhase> <DevStatus>[value]</DevStatus> <Message>[value]</Message> </WaitForRequestForConcurrentProgramResponse></pre>	This Wait_For_Request response message returns the request phase/status and the completion message of a concurrent program. For detailed information about each parameter, see Operations on Concurrent Programs .

Submit_Req
uest Re
quest

```
<?xml version="1.0" encoding="utf-8" ?>
<SubmitRequestForConcurrentProgram xmlns="
[VERSION]/ConcurrentPrograms/[APP_SHORT_NAME]">
  <SetOptions>
    <Implicit>[value]
  </Implicit>
    <Protected>[value]
  </Protected>
    <Language>[value]
  </Language>
    <Territory>[value]
  </Territory>
    <ContinueOnFail>[value]
  </ContinueOnFail>
  </SetOptions>
    <SetPrintOptions>
      <Printer>[value]
    </Printer>
      <Style>[value]
    </Style>
      <Copies>[value]
    </Copies>
      <SaveOutput>[value]
    </SaveOutput>
      <PrintTogether>[value]
    </PrintTogether>
      <ContinueOnFail>[value]
    </ContinueOnFail>
    </SetPrintOptions>
    <SetRepeatOptions>
      <RepeatTime>[value]
    </RepeatTime>
      <RepeatInterval>[value]
    </RepeatInterval>
      <RepeatUnit>[value]
    </RepeatUnit>
      <RepeatType>[value]
    </RepeatType>
      <RepeatEndTime>[value]
    </RepeatEndTime>
      <ContinueOnFail>[value]
    </ContinueOnFail>
    </SetRepeatOptions>

    <Program>[value]
  </Program>
    <Description>[value]
  </Description>
    <StartTime>[value]
  </StartTime>
    <Arguments>[array_of_strings]
  </Arguments>
</SubmitRequestForConcurrentProgram>
```

For detailed information about each parameter, see [Operations on Concurrent Programs](#).

Submit_Request Response	<pre><?xml version="1.0" encoding="utf-8" ?> <SubmitRequestForConcurrentProgramResponse xmlns="[VERSION]/ConcurrentPrograms/[APP_SHORT_NAME]"> <SubmitRequestForConcurrentProgramResult>[value]</SubmitRequestForConcurrentProgramResult> </SubmitRequestForConcurrentProgramResponse></pre>	If the submit request completes successfully, the response message returns the concurrent request ID. Otherwise, it returns "0".
-------------------------	--	--

Entity descriptions:

[VERSION] = <http://schemas.microsoft.com/OracleEBS/2008/05>

[APP_SHORT_NAME] = Application short name

[CONCURRENT_PROGRAM_ARGUMENT] = Argument expected by the concurrent program as defined in Oracle E-Business Suite

Message Actions for Concurrent Programs

The Oracle E-Business adapter uses the following message actions for concurrent programs.

Note
See entity descriptions after the table.

Message	Action	Example
[Concurrent_Program_Name] Request	ConcurrentPrograms/[APP_SHORT_NAME]/[CONCURRENT_PROGRAM_SHORT_NAME]	ConcurrentPrograms/SQLGL/ADSFINS
[Concurrent_Program_Name] Response	ConcurrentPrograms/[APP_SHORT_NAME]/[CONCURRENT_PROGRAM_SHORT_NAME]/response	ConcurrentPrograms/SQLGL/ADSFINS/response
Get_Status Request	ConcurrentPrograms/[APP_SHORT_NAME]/GetStatusForConcurrentProgram	ConcurrentPrograms/SQLGL/GetStatusForConcurrentProgram
Get_Status Response	ConcurrentPrograms/[APP_SHORT_NAME]/GetStatusForConcurrentProgram/response	ConcurrentPrograms/SQLGL/GetStatusForConcurrentProgram/response
Wait_For_Request Request	ConcurrentPrograms/[APP_SHORT_NAME]/WaitForRequestForConcurrentProgram	ConcurrentPrograms/SQLGL/WaitForRequestForConcurrentProgram
Wait_For_Request Response	ConcurrentPrograms/[APP_SHORT_NAME]/WaitForRequestForConcurrentProgram/response	ConcurrentPrograms/SQLGL/WaitForRequestForConcurrentProgram/response
Submit_Request Request	ConcurrentPrograms/[APP_SHORT_NAME]/SubmitRequestForConcurrentProgram	ConcurrentPrograms/SQLGL/SubmitRequestForConcurrentProgram
Submit_Request Response	ConcurrentPrograms/[APP_SHORT_NAME]/SubmitRequestForConcurrentProgram/response	ConcurrentPrograms/SQLGL/SubmitRequestForConcurrentProgram/response

Entity descriptions:

[APP_SHORT_NAME] = Application short name

[CONCURRENT_PROGRAM_SHORT_NAME] = Concurrent Program short name

[Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)

Message Schemas for Request Sets

Each request set in an Oracle application in Oracle E-Business Suite is surfaced as an operation in Microsoft BizTalk Adapter for Oracle E-Business Suite.

Message Structure of Request Set Operation

The operations surfaced for request set follow a request-response message exchange pattern. The following table shows the structure of these request and response messages.

 Note
See entity descriptions after the table.

Operation	XML Message	Description
[Request_Set_Name] Request	<pre><?xml version="1.0" encoding="utf-8" ?> <[Request_Set_Name] xmlns="[VERSION]/RequestSets/[APP_SHORT_NAME]/"> <SetRelClassOptions> <Application> [value]</Application> <ClassName>[value]</ClassName> <CancelOrHold>[value]</CancelOrHold> <StaleDate>[value]</StaleDate> <ContinueOnFail>[value]</ContinueOnFail> </SetRelClassOptions> <SetPrintOptions> <Printer>[value]</Printer> <Style>[value]</Style> <Copies>[value]</Copies> <SaveOutput>[value]</SaveOutput> <PrintTogether>[value]</PrintTogether> <ContinueOnFail>[value]</ContinueOnFail> </SetPrintOptions> <SetRepeatOptions> <RepeatTime>[value]</RepeatTime> <RepeatInterv</pre>	<ul style="list-style-type: none"> • The [Request_Set_Name] operation takes five standard parameters: <i>SetRelClassOptions</i>, <i>SetPrintOptions</i>, <i>SetRepeatOptions</i>, <i>SetNlsOptions</i>, and <i>StartTime</i>. • The <i>ContinueOnFail</i> parameter indicates whether the request set submission should continue or throw an exception in case the parent parameter (<i>SetRelClassOptions</i>, <i>SetPrintOptions</i>, <i>SetRepeatOptions</i> or <i>SetNlsOptions</i>) fails. You can specify True (continue) or False (throw an exception). • For detailed information about each parameter, see Operations on Request Sets.

	<pre> al>[value]</RepeatInterval> <RepeatUnit>[value]</RepeatUnit> <RepeatType>[value]</RepeatType> <RepeatEndTime>[value]</RepeatEndTime> <ContinueOnFail>[value]</ContinueOnFail> </SetRepeatOptions> <SetNlsOptions> <Language>[value]</Language> <Territory>[value]</Territory> <ContinueOnFail>[value]</ContinueOnFail> </SetNlsOptions> <StartTime><[value]</StartTime> <[CONCURRENT_PROGRAM_NAME1]>[value]</[CONCURRENT_PROGRAM_NAME1]> <[CONCURRENT_PROGRAM_NAME2]>[value]</[CONCURRENT_PROGRAM_NAME2]> ... </[Request_Set_Name]> </pre>	
[Request_Set_Name] Response	<pre> <?xml version="1.0" encoding="utf-8" ?> <[Request_Set_Name]Response xmlns=" [VERSION]/RequestSets/[APP_SHORT_NAME]"> <[Request_Set_Name]Result>[value] </[Request_Set_Name]Result> </[Request_Set_Name]Response> </pre>	The response from Oracle E-Business Suite contains a concurrent request ID.

Entity descriptions:

[VERSION] = <http://schemas.microsoft.com/OracleEBS/2008/05>

[CONCURRENT_PROGRAM_NAME] = Concurrent program included in the request set.

Message Actions for Request Sets

The Oracle E-Business adapter uses the following message actions for request sets.

Note
See entity descriptions after the table.

Message	Action	Example
Request Set request	RequestSets/[APP_SHORT_NAME]/[REQUESTSET_SHORT_NAME]	RequestSets/SQLGL/FNDRSSUB965
Request Set response	RequestSets/[APP_SHORT_NAME]/[REQUESTSET_SHORT_NAME]/response	RequestSets/SQLGL/FNDRSSUB965/response

Entity descriptions:

[APP_SHORT_NAME] = Application short name.

[REQUESTSET_SHORT_NAME] = Request Set short name.

[Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)

Message Schemas for Special LOB Operations

The Read_<LOBColName> and Update_<LOBColName> operations are surfaced for tables and views that contain LOB columns, where <LOBColName> is the LOB column in the table or view. These operations enable you to read or write the LOB data as a stream of base64Binary-encoded data. They operate on a single column of LOB data in a single row.

For an overview of the Read_<LOBColName> and Update_<LOBColName> operations and of the Oracle LOB data types supported, see [Operations on Interface Tables, Interface Views, Tables, and Views That Contain LOB Data](#).

Message Structure of LOB Data-Type Operations

The following table shows the structure of the request and response messages for the Read_<LOBColName> and Update_<LOBColName> operations. The target table for the operation is specified in the message action and also appears in the target namespace.

Note
See entity descriptions after the table.

Operation	XML Message	Description
Read_<LOBColName>	<pre><Read_[LOBColName] xmlns="[VERSION]/Tables/[SCHEMA]/[TABLE_NAME]"> <FILTER>[WHERE_clause]</FILTER> </Read_[LOBColName]></pre>	The LOB data in the row that matches the where clause specified in the FILTER element is returned. The where clause should match only a single row. If there is more than one matching row, the Oracle E-Business adapter will throw an exception.
Read_<LOBColName> Response	<pre><Read_[LOBColName]Response xmlns="[VERSION]/Tables/[SCHEMA]/[TABLE_NAME]"> <Read_[LOBColName]Result> [LOB_DATA] </Read_[LOBColName]Result> </Read_[LOBColName]Response></pre>	The LOB data is returned as a stream of base64Binary encoded data.
Update_<LOBColName>	<pre><Update_[LOBColName] xmlns="[VERSION]/Tables/[SCHEMA]/[TABLE_NAME]"> <FILTER>[WHERE_clause]</LOB_COLUMN> <DATA>[Value]</DATA> </Update_[LOBColName]></pre>	<p>The LOB data in the row that matches the where clause specified in the FILTER element is updated with the data in the <DATA> element. The where clause should match only a single row. If there is more than one matching row, the Oracle E-Business adapter throws an exception.</p> <p>Note While updating BLOB columns, the <DATA> element must always contain a base64 encoded value. For CLOB and NCLOB, the <DATA> element can have string values.</p>

Update_<LOBColName> Response	<pre><Update_[LOBColName]Response xmlns="[VERSION]/Tables/[SCHEMA]/[TABLE_NAME]"> </Update_[LOBColName]Response></pre>	An empty response is returned.
------------------------------	--	--------------------------------

Entity descriptions:

[VERSION] = The message version string; for example, "http://schemas.microsoft.com/OracleEBS/2008/05".

[SCHEMA] = Collection of Oracle artifacts; for example, SCOTT.

[TABLE_NAME] = The table that contains the targeted LOB column; for example, CUSTOMER.

[LOBCol_Name] = The name of a LOB column; for example, Photo.

[WHERE_clause] = An Oracle database SELECT statement WHERE clause that matches a single row; for example, ID = 1.

[LOB_DATA] = The LOB column data in base64Binary type.

<p>Important</p>
<p>The message structure for the Read_<LOBColName> and Update_<LOBColName> operations on views is the same as that on tables except that the namespace for the operation specifies a view rather than a table: <ReadLOB xmlns = "[VERSION]/Views/[SCHEMA]/[VIEW_NAME]">.</p>

Message Actions for LOB Data-Type Operations

The following table shows the message actions that are used by the Oracle E-Business adapter for the Read_<LOBColName> and Update_<LOBColName> operations on tables. The Oracle E-Business adapter uses the table name and the LOB column name specified in the message action to determine the target table and LOB column for the operation.

<p>Note</p>
<p>See entity descriptions after the table.</p>

Operation	Action	Example
Read_<LOBColName>	Tables/ReadLOB/[SCHEMA]/[TABLE_NAME]/[LOBColName]	Tables/ReadLOB/SCOTT/CUSTOMER/Photo
Read_<LOBColName> Response	Tables/ReadLOB/[SCHEMA]/[TABLE_NAME]/[LOBColName]/response	Tables/ReadLOB/SCOTT/CUSTOMER/Photo/response
Update_<LOBColName>	<p>For BLOB:</p> <p>Tables/UpdateBLOB/[SCHEMA]/[TABLE_NAME]/[LOBColName]</p> <p>For CLOB and NCLOB:</p> <p>Tables/UpdateCLOB/[SCHEMA]/[TABLE_NAME]/[LOBColName]</p>	<p>For BLOB:</p> <p>Tables/UpdateBLOB/SCOTT/CUSTOMER/Photo/</p> <p>For CLOB and NCLOB:</p> <p>Tables/UpdateCLOB/SCOTT/CUSTOMER/Photo1/</p>
Update_<LOBColName> Response	<p>For BLOB:</p> <p>Tables/UpdateBLOB/[SCHEMA]/[TABLE_NAME]/[LOBColName]/response</p> <p>For CLOB and NCLOB:</p> <p>Tables/UpdateCLOB/[SCHEMA]/[TABLE_NAME]/[LOBColName]/response</p>	<p>For BLOB:</p> <p>Tables/UpdateBLOB/SCOTT/CUSTOMER/Photo/response</p> <p>For CLOB and NCLOB:</p> <p>Tables/UpdateCLOB/SCOTT/CUSTOMER/Photo1/response</p>

Entity descriptions:

[SCHEMA] = Collection of Oracle artifacts; for example, SCOTT.

[TABLE_NAME] = The table that contains the targeted LOB column; for example, CUSTOMER. (The SCOTT.CUSTOMER table is installed by a SQL script included in the samples.)

[LOBCol_Name] = The name of a LOB column; for example, Photo.

◆ Important

The message action for Read_<LOBColName> and Update_<LOBColName> operations on views is similar to that used for tables, except that action for the operation specifies a view rather than a table: Views/ReadLOB/[SCHEMA]/[VIEW_NAME]/[LOBColName].

[Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)

Message Schemas for the Polling Operations

The Microsoft BizTalk Adapter for Oracle E-Business Suite surfaces various inbound operations related to polling depending on the target object in Oracle E-Business Suite. For interface tables, interface views, tables, and views, a single Poll operation is surfaced whereas you can have multiple custom polling operations for PL/SQL APIs, functions, and stored procedures.

You configure the polling operations by setting binding properties in the Oracle E-Business adapter. For more information about these binding properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). You set the **PollingStatement** binding property to specify a SQL statement, stored procedure, function or a procedure within a package for the polling query. The result set of this query is returned as data to your code in the polling operation.

Message Structure for the Polling Operations

The following table shows the XML message structure for the various polling operations.

Note
See entity descriptions after the table.

Operation	Target Object	XML Message	Description
Poll	<ul style="list-style-type: none"> Interface Tables Interface Views Tables Views 	<pre><?xml version="1.0" encoding="utf-8" ?> <Poll xmlns="[Version]/[TargetObject]/[Schema]/[TargetObjectName]"> <DATA> <SelectRecord> <Column1>[Value]</Column1> <Column2>[Value]</Column2> ... </SelectRecord> </DATA> </Poll></pre>	<p>For example, the XML message for the Poll operation on Interface Tables will be as follows:</p> <pre><?xml version="1.0" encoding="utf-8" ?> <Poll xmlns="[Version]/InterfaceTables/[Schema]/[InterfaceTableName]"> <DATA> <SelectRecord> <Column1>[Value]</Column1> <Column2>[Value]</Column2> ... </SelectRecord> </DATA> </Poll></pre>

<p>[CustomPollingOperation]</p>	<ul style="list-style-type: none"> • PL/SQL APIs • Stored Procedures • Functions 	<p>PL/SQL APIs</p> <pre><?xml version="1.0" encoding="utf-8" ?> <[CustomPollingOperation] xmlns="[Version]/PollingPackageAPis/[Schema]/[PL/SQL API]"> <[CustomPollingOperation]Result>[Value]</[CustomPollingOperation]Result> </[CustomPollingOperation]></pre> <p>Functions</p> <pre><?xml version="1.0" encoding="utf-8" ?> <[CustomPollingOperation] xmlns="[Version]/PollingFunctions/[Schema]"> <[CustomPollingOperation]Result> <COL1>[Value]</COL1> <COL2>[Value]</COL2> ... </[CustomPollingOperation]Result> </[CustomPollingOperation]></pre> <p>Stored Procedures</p> <pre><?xml version="1.0" encoding="utf-8" ?> <[CustomPollingOperation] xmlns="[Version]/PollingFunctions/[Schema]"> <[CustomPollingOperation]Result> <PRM1>[Value]</PRM1> <PRM2>[Value]</PRM2> ... </[CustomPollingOperation]Result> </[CustomPollingOperation]></pre>	<p>The structure of the result set in the polling operation is determined by the data type of the elements in the target object.</p>
---------------------------------	---	---	--

Entity descriptions:

[Version] = <http://schemas.microsoft.com/OracleEBS/2008/05>.

[CustomPollingOperation] = Name of the custom polling operation.

[Schema] = Name of the Oracle schema. For example, SCOTT.

[PL/SQL API] = Name of the PL/SQL API on which a custom polling operation is performed.

[Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)

Message Schemas for the Notification Operation

The Microsoft BizTalk Adapter for Oracle E-Business Suite surfaces the Notification operation to receive database change notifications from the underlying database in Oracle E-Business Suite.

You configure the Notification operation by setting binding properties in the Oracle E-Business adapter. For more information about the Notification-related binding properties, see [Working with BizTalk Adapter for Oracle E-Business Suite Binding Properties](#). You set the **NotificationStatement** binding property to specify a SELECT statement for the query notification.

Message Structure for the Notification Operation

The following table shows the XML message structure for the Notification operation.

Operation	XML Message	Description
Notification	<pre><?xml version="1.0" encoding="utf-8" ?> <Notification xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Notification"> <Info>Value</Info> <Source>Value</Source> </Notification> <Type>Value</Type> </Notification></pre>	<p>This is the inbound message that is sent by Oracle E-Business Suite to the adapter clients. In the message:</p> <ul style="list-style-type: none"> • The <code><Info></code> tag indicates the reason for the notification. For example, an "insert" value in this tag indicates that data has been inserted in one or more of the tables referenced in the notification statement. • The <code><Source></code> tag indicates the source for the notification. For example, a "data" value in this tag indicates a change in the data in a referenced object. Similarly, an "object" value in this tag indicates a change in a referenced object. • The <code><Type></code> tag indicates the type of data change. For example, an "Update" value in the <code><Type></code> tag indicates that the results of the query have been updated.

Message Action for the Notification Operation

The message action for the notification operation is "Notification."

[Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)

Message Schemas for the ExecuteNonQuery, ExecuteReader, and ExecuteScalar Operations

The Microsoft BizTalk Adapter for Oracle E-Business Suite exposes the ExecuteNonQuery, ExecuteReader, and ExecuteScalar outbound operations at the root level to execute any arbitrary SQL statements or PL/SQL blocks in Oracle E-Business Suite.

For more information about:

- These operations, see [Support for ExecuteNonQuery, ExecuteReader, and ExecuteScalar Operations](#).
- Performing these operations using the Oracle E-Business adapter, see [Performing ExecuteReader, ExecuteScalar, or ExecuteNonQuery Operations Using BizTalk Server](#).

Message Structure for the ExecuteNonQuery, ExecuteReader, and ExecuteScalar Operations

The messages in these operations follow a request-response message exchange pattern, and the following table shows the structure of these request and response messages.

Note
See entity descriptions after the table.

Operation	XML Message
ExecuteNonQuery Request	<pre><?xml version="1.0" encoding="utf-8" ?> <ExecuteNonQuery xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/GenericOperation/ "> <Query>[PL/SQL block]</Query> <OutputRefCursorNames> <string>[stringvalue1]</string> <string>[stringvalue2]</string> ... </OutputRefCursorNames> </ExecuteNonQuery></pre>
ExecuteNonQuery Response	<pre><?xml version="1.0" encoding="utf-8" ?> <ExecuteNonQueryResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/GenericOperation/ "> <ExecuteNonQueryResult>[value]</ExecuteNonQueryResult> <OutputRefCursors> <DataSet> <Any>[value]</Any> <Any>[value]</Any> ... </DataSet> </OutputRefCursors> </ExecuteNonQueryResponse></pre>
ExecuteReader Request	<pre><?xml version="1.0" encoding="utf-8" ?> <ExecuteReader xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/GenericOperation/ "> <Query>[PL/SQL block]</Query> </ExecuteReader></pre>

ExecuteReader Response	<pre><?xml version="1.0" encoding="utf-8" ?> <ExecuteReaderResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/GenericOperation/ "> <ExecuteReaderResult> <Any>[value]</Any> <Any>[value]</Any> ... </ExecuteReaderResult> </ExecuteReaderResponse></pre>
ExecuteScalar Request	<pre><?xml version="1.0" encoding="utf-8" ?> <ExecuteScalar xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/GenericOperation/ "> <Query>[PL/SQL block]</Query> </ExecuteScalar></pre>
ExecuteScalar Response	<pre><?xml version="1.0" encoding="utf-8" ?> <ExecuteScalarResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/GenericOperation/ "> <ExecuteScalarResult>[value]</ExecuteScalarResult> </ExecuteScalarResponse></pre>

Entity descriptions:

[PL/SQL block] = The entire PL/SQL block to be executed.

[stringvalue1] = A value in the array of strings.

Message Action for the ExecuteNonQuery, ExecuteReader, and ExecuteScalar Operations

The following table shows the message actions that are used by the ExecuteNonQuery, ExecuteReader, and ExecuteScalar operations.

Operation	Action
ExecuteNonQuery Request	GenericOp/ExecuteNonQuery
ExecuteNonQuery Response	GenericOp/ExecuteNonQuery/response
ExecuteReader Request	GenericOp/ExecuteReader
ExecuteReader Response	GenericOp/ExecuteReader/response
ExecuteScalar Request	GenericOp/ExecuteScalar
ExecuteScalar Response	GenericOp/ExecuteScalar/response

Message Schemas for the Composite Operation

The Microsoft BizTalk Adapter for Oracle E-Business Suite enables you to execute composite operations in Oracle E-Business Suite. A composite operation can contain multiple operations, and in any order. For information about which operations can be included in a composite operation, see [Support for Composite Operations](#).

For information about how to perform composite operations using the Oracle E-Business adapter, see [Performing Composite Operations on Oracle Database by Using BizTalk Server](#).

Message Structure for the Composite Operation

Since a composite operation contains multiple individual operations; the message structure of a composite operation contains message structures of the individual operations. The composite operation message follows a request-response message exchange pattern.

The following table shows the structure of the request and response messages of a composite operation that contains an Insert operation, a packaged stored procedure that does not take any input parameters, and a Delete operation.

Note
See entity descriptions after the table.

Operation	XML Message
Composite Operation Request	<pre> <?xml version="1.0" encoding="utf-8" ?> <Request xmlns="http://[PROJECT_NAME].[COMPOSITE_SCHEMA_NAME]"> <Insert xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Tables/[SCHEMA]/[TABLE_NAME]"> <Recordset> <InsertRecord> <[FIELD1_NAME]>[value1]</[FIELD1_NAME]> <InlineValue>[value]</InlineValue> <[FIELD2_NAME]>[value2]</[FIELD2_NAME]> <InlineValue>[value]</InlineValue> ... <InsertRecord> </RECORDSET> </Insert> <[SP_NAME] xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/PackageApis/[SCHEMA]/[APP_NAME]" /> <Delete xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/Tables/[SCHEMA]/[TABLE_NAME]"> <FILTER>[WHERE_clause]</FILTER> </Delete> </Request> </pre>

Composite Operation Response	<pre> <?xml version="1.0" encoding="utf-8" ?> <RequestResponse xmlns="http://[PROJECT_NAME].[COMPOSITE_SCHEMA_NAME]"> <InsertResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/T ables/[SCHEMA]/[TABLE_NAME]"> <InsertResult>[value]</InsertResult> </InsertResponse> <[SP_NAME]Response xmlns="http://schemas.microsoft.com/OracleEBS/2008/0 5/Procedures/[SCHEMA]"> <[PRM1_NAME]>value1<[PRM1_NAME]> <[PRM2_NAME]>value2<[PRM2_NAME]> ... </[SP_NAME]Response> <DeleteResponse xmlns="http://schemas.microsoft.com/OracleEBS/2008/05/T ableOp/[SCHEMA]/[TABLE_NAME]"> <DeleteResult>[value]</DeleteResult> </DeleteResponse> </RequestResponse> </pre>
------------------------------	---

Entity descriptions:

[PROJECT_NAME] = Name of the BizTalk project that contains the composite operation schema.

[COMPOSITE_SCHEMA_NAME] = Name of the composite operation schema given by the user.

[SCHEMA] = Collection of Oracle artifacts; for example, SCOTT.

[TABLE_NAME] = Name of the table; for example, EMPLOYEE.

[FIELD1_NAME] = Table field name; for example, NAME.

[SP_NAME] = The packaged stored procedure to be executed; for example, ADD_EMP_DETAILS.

[APP_NAME] = Name of the Oracle Application that contains the packaged stored procedure.

[PRM1_NAME] = The name of the Oracle parameter in the packaged stored procedure.

Message Action for the Composite Operation

The message action for the composite operation is "CompositeOperation."

[Messages and Message Schemas for BizTalk Adapter for Oracle E-Business Suite](#)

Glossary

The following terms and definitions are used in Microsoft BizTalk Adapter for Oracle E-Business Suite Help.

Microsoft BizTalk Adapter Pack Glossary

[A](#) [B](#) [C](#) [D](#) [E](#) [F](#) [G](#) [H](#) [I](#) [J](#) [K](#) [L](#) [M](#) [N](#) [O](#) [P](#) [Q](#) [R](#) [S](#) [T](#) [U](#) [V](#) [W](#) [X](#) [Y](#) [Z](#)

A

Term	Definition
adapter	A WCF-based component that helps exchange messages between applications (for example, a line-of-business system) and BizTalk Server. The adapter consists of design-time components and run-time components for receive and send operations.
adapter client	An application that interacts with a line-of-business (LOB) system through the adapter.

B

Term	Definition
binding	A process by which software components and layers are linked together. When a network component is installed, the binding relationships and dependencies for the components are established. Binding allows components to communicate with each other. In BizTalk Server, an established mapping between an orchestration adapter-agnostic endpoint (port or role link) and physical adapter-specific endpoints (send/receive ports or party).
BizTalk Server	Connects diverse software. BizTalk Server enables you to create and modify process logic that uses that software. BizTalk Server also enables information workers to monitor running processes, interact with trading partners, and perform other business-oriented tasks.

C

Term	Definition
channel	A concrete implementation of a binding element. The binding represents the configuration, and the channel is the implementation associated with that configuration. Therefore, there is a channel associated with each binding element. Channels stack on top of each other to create the concrete implementation of the binding: the channel stack.
connection URL	A string that identifies a resource in a distributed environment. Adapters use a connection Uniform Resource Identifier (URI) that contains the information necessary to establish a connection with the LOB system.
contract	Specifies the collection and structure of messages required to access the operations offered by the service.

D

Term	Definition
data manipulation language (DML)	The subset of SQL statements that is used to retrieve and manipulate data. DML statements typically start with SELECT, INSERT, UPDATE, or DELETE.
design-time experience	Procedures and operations that a developer performs during design time; for example, using the Consumer Adapter Service BizTalk Project Add-in to retrieve message schemas.

E

Term	Definition
------	------------

endpoint address	A network address that identifies the location of a Windows Communication Foundation (WCF) service endpoint. For an adapter, the endpoint address is expressed as a connection Uniform Resource Identifier (URI) that contains location and connection parameters. The adapter can use these to establish a connection to the underlying line-of-business (LOB) system.
Enterprise Single Sign-on system	An SSO database, a master secret server, and one or more Enterprise Single Sign-On (SSO) servers. These servers do the mapping between the Windows and non-Windows credentials, look up the credentials in the SSO database, and are used for administering the SSO system. The SSO database is also used as a configuration store to hold custom configuration data for adapters.
Extensible Markup Language	A markup language designed to describe data. XML tags are not predefined.

G

Term	Definition
GAC	See global assembly cache.
global assembly cache (GAC)	A machine-wide code cache that stores assemblies specifically installed to be shared by many applications on the computer. Applications deployed in the global assembly cache must have a strong name.

H

Term	Definition
Health and Activity Tracking (HAT)	A user interface that enables specified data to be tracked. This interface can be used to monitor the health of the BizTalk Server farm and to track and view specific events and messages.

I

Term	Definition
inbound operation	An operation that is invoked by a line-of-business (LOB) system on the adapter.

M

Term	Definition
metadata	In WCF, refers to a description of the contract exposed by a service. This is known as the service description and is expressed in a WSDL document. The metadata exposed by an adapter describes the (interface to) the operations that it can perform on the underlying LOB system.
Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK	The specifications for building BizTalk adapters using open standards based on Web services.

O

Term	Definition
one-way	A message exchange pattern (MEP) in which the sender sends a message, but no response is returned by the receiver. In BizTalk Server, MEPs are referred to as communication patterns.
outbound operation	An operation that is invoked by the adapter on the line-of-business system (LOB).
output.cs	The default output file created by the ServiceModel Metadata Utility tool (svcutil.exe).

P

Term	Definition
polling	A technique that device drivers use to find out from multiple devices whether they contain data to transmit. The devices are polled one at a time.

proxy	In WCF, refers to a managed-code object that implements the service contract exposed by a service. The WCF service model is based on the use of such proxies. In the WCF service model, the service contract is expressed as a .NET interface.
-------	--

R

Term	Definition
request-reply	A message exchange pattern (MEP) in which the sender sends a request message and expects a response message from the receiver. In BizTalk Server, MEPs are referred to as communication patterns. Depending on the messaging technology and the direction of the request message (inbound or outbound), this pattern is also called request-reply or solicit-response.
runtime experience	Procedures and operations performed by a developer during run time or when deploying a solution; for example, creating a physical port binding from the BizTalk Server Administration console.

S

Term	Definition
schema	The structure for a message. A schema can contain multiple subschema.
ServiceModel Metadata Utility Tool (svcutil.exe)	A command-line utility that is included with WCF. It is used to create service model proxy code from the service description (metadata) that is exposed by a WCF service such as an adapter. For outbound operations, the tool creates a WCF client class and helper code; for inbound operations, the tool creates a WCF service contract and helper code.
Simple Object Access Protocol	See SOAP.
SOAP	A simple, XML-based protocol for exchanging structured and type information in decentralized, distributed environments. WCF is based on the exchange of SOAP messages between clients and services to invoke operations and return results.
SOAP message	A well-formed XML document. It should use the SOAP envelope and SOAP encoding namespaces and include an optional XML declaration, followed by a SOAP envelope (the root element), which is made up of an optional SOAP header and a SOAP message body.
SQL Server Integration Services (SSIS)	A component that is used to import, export, and transform data from different data sources. Previously called data transformation service (DTS).
SSIS	See SQL Server Integration Services.
SSO	See Enterprise Single Sign-on system.
strongly-typed data	A data set or result set that is bound to an underlying object type. Each row in a strongly-typed XML data set is composed of typed, named elements that correspond to fields of the underlying object type.
svcutil.exe	See ServiceModel Metadata Utility Tool.

U

Term	Definition
Uniform Resource Identifier (URI)	See connection URI

W

Term	Definition
------	------------

WCF	See Windows Communication Foundation
WCF channel model	A programming model that relies on several interfaces and other types. Channels provide a low-level programming model for sending and receiving messages.
WCF client	A client-application construct that exposes the service operations as methods. You can use the Add Adapter Service Reference Visual Studio Plug-in or the ServiceModel Metadata Utility Tool to generate a WCF client class from the metadata exposed by an adapter.
WCF LOB Adapter SDK	See Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK
WCF service contract	A managed-code representation of the service contract. It is expressed as an interface in which classes and methods are attributed to define the service, operation, message, and data contracts used to communicate with a service. You can use the ServiceModel Metadata Utility tool or the Add Adapter Service Reference Visual Studio Plug-in to generate a WCF service contract from the metadata exposed by an adapter. You implement the WCF service contract to receive operations from an LOB system.
WCF service model	A WCF programming model in which a service is represented as a managed code object. The operations exposed by the service are represented as methods with strongly-typed data.
weakly-typed data	A data set or result set that is not bound to an underlying object type. Each row in a weakly-typed XML data set is composed of a collection of generic columns in which attributes describe the name and type of each element.
Web services	A unit of application logic providing data and services to other applications. Applications access XML Web services using standard Web protocols and data formats such as HTTP, XML, and SOAP, independent of how each XML Web service is implemented. XML Web services combine the best aspects of component-based development and the Web , and are a cornerstone of the Microsoft .NET programming model.
Web Services Description Language (WSDL)	An XML-based language that describes a service as a set of endpoints that operate on messages. The WSDL document describes the service contract, operation contracts, message contracts, and data contracts that a client must use to interface with the service.
Windows Communication Foundation (WCF)	A Microsoft service-oriented communication infrastructure. The framework inherently provides clients with a service programming model and a channel programming model for finer control of message exchanges.
WSDL	See Web Services Description Language.

X

Term	Definition
XML	See Extensible Markup Language.
XML Schema definition language (XSD)	A schema language. An XML Schema defines the elements, attributes, and data types that comply with the World Wide Web Consortium (W3C) XML Schema Part 1: Structures Recommendation for the XML Schema Definition Language. The W3C XML Schema Part 2: Datatypes Recommendation is the recommendation for defining data types that are used in XML schemas. The XML Schema definition language enables you to define the structure and data types for XML messages.
XSD	See XML Schema definition language.

Class Library

Namespaces

Namespace
Microsoft.Adapters.OracleEBS
Microsoft.Adapters.OracleEBS.BiztalkPropertySchema

Microsoft.Adapters.OracleEBS Namespace

Classes

Class	Description
MlsSettings	Multiple Language System Settings configuration element
OracleEBSAdapter	The Binding Element for the Oracle E-Business Suite Adapter.
OracleEBSBinding	Represents the Oracle E-Business Suite WCF Binding.
OracleEBSBindingCollectionElement	Represents the StandardBindingCollectionElement for the Oracle E-Business Suite Adapter.
OracleEBSBindingConfigurationElement	Represents the StandardBindingElement for the Oracle E-Business Suite Adapter.
OracleEBSBindingElementExtensionElement	Enables the configuration of the Oracle E-Business Suite Adapter Binding from an application configuration file.
OracleEBSConnectionUri	Builds the Uniform Resource Identifier (URI) for establishing connection to the Oracle E-Business Suite and essentially the underlying Oracle database.
OracleEBSInboundTransactionBehavior	

Enumerations

Enumeration	Description
ClientCredential	The set of credentials that are specified while establishing a connection with the Oracle E-Business Suite.
InboundOperation	The Inbound Operation to be performed.
OracleServiceType	

ClientCredential Enumeration

The set of credentials that are specified while establishing a connection with the Oracle E-Business Suite.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

MlsSettings.ToString Method

Creates a string representation of the current MlsSettings configuration element.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration  
Public Overrides Function ToString As String
```

C#

```
public override string ToString ()
```

C++

```
public:  
virtual String^ ToString () override
```

J#

```
public String ToString ()
```

JScript

```
public override function ToString () : String
```

Return Value

The current MlsSettings configuration element as a string.

Thread Safety Any public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

MlsSettings Properties

Public Properties (see also [Protected Properties](#))

	Name	Description
	Calendar	Gets or sets the calendar used in the management license settings.
	Comparison	Gets or sets the comparison used in the management license settings.
	Currency	Gets or sets the currency used in the management license settings.
	DateFormat	Gets or sets the date format used in the used in the management license settings.
	DateLanguage	Gets or sets the date format used in the management license settings.
	DualCurrency	Gets or sets the dual currency used in the management license settings.
	ElementInformation	(inherited from ConfigurationElement)
	ISOCurrency	Gets or sets the ISO currency used in the management license settings.
	Language	Gets or sets the language used in the management license settings.
	LengthSemantics	Gets or sets the length semantics used in the management license settings.
	LockAllAttributesExcept	(inherited from ConfigurationElement)
	LockAllElementsExcept	(inherited from ConfigurationElement)
	LockAttributes	(inherited from ConfigurationElement)
	LockElements	(inherited from ConfigurationElement)
	LockItem	(inherited from ConfigurationElement)
	NCharConversionException	Gets or sets whether the specified object is a national character conversion exception.
	NumericCharacters	Gets or sets the numeric characters used in the management license settings.
	Sort	Gets or sets the sort order used in the management license settings.
	Territory	Gets or sets the territory used in the management license settings.
	TimeStampFormat	Gets or sets the time stamp format used in the management license settings.
	TimeStampTZFormat	Gets or sets the time stamp time zone format used in the management license settings.
	TimeZone	Gets or sets time zone used in the management license settings.

Protected Properties

	Name	Description
	ElementProperty	(inherited from ConfigurationElement)
	EvaluationContext	(inherited from ConfigurationElement)
	Item	Overloaded. (inherited from ConfigurationElement)
	Properties	Overridden. Gets the properties used in the management license settings.

C#

```
[ConfigurationPropertyAttribute("nCharConversionException", DefaultValue=true)]
public bool NCharConversionException { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"nCharConversionException", DefaultValue=true)]
public:
virtual property bool NCharConversionException {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
public final boolean get_NCharConversionException ()

/** @property */
public final void set_NCharConversionException (boolean value)
```

JScript

```
public final function get NCharConversionException () : boolean
public final function set NCharConversionException (value : boolean)
```

Property Value

<languageKeyword>True</languageKeyword> if the specified object is a national conversion exception; otherwise, <languageKeyword>>false</languageKeyword>. The default value is <languageKeyword>>true</languageKeyword>.

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSAdapter Members

The Binding Element for the Oracle E-Business Suite Adapter.

The following tables list the members exposed by the [OracleEBSAdapter](#) type.

Public Constructors

Name	Description
OracleEBSAdapter	Initializes a new instance of the OracleApps class

Top

Public Properties (see also [Protected Properties](#))

Name	Description
 AcceptCredentialsInUri	Gets or sets whether the connection URI can contain user credentials for the data base.
 ApplicationShortName	Gets or sets the application short name.
 ClientCredentialType	Gets or sets the client credential type.
 ConnectionLifetime	Gets or sets the maximum duration in seconds of a connection.
 DataFetchSize	Gets or sets the amount of data in bytes that data provider fetches from the result set in one server round trip.
 DecrPoolSize	Gets or sets the number of connections that are closed when an excessive amount of established connections are not in use.
 EnableBizTalkCompatibilityMode	Gets or sets whether the BizTalk compatibility mode is enabled.
 EnablePerformanceCounters	Gets or sets whether to enable the WCF LOB Adapter SDK performance counters and the Oracle Database adapter LOB Latency performance counter.
 EnableSafeTyping	Gets or sets whether enables or disables safe typing.
 GeneratedUserTypesAssemblyFilePath	Gets or sets the name and path of the DLL that the adapter generates.
 GeneratedUserTypesAssemblyKeyFilePath	Gets or sets the name and path of the key file that the adapter uses to create a strongly-typed assembly.
 InboundOperationType	Gets or sets the inbound operation type.
 IncrPoolSize	Gets or sets the number of new connections to be created when a new connection is requested and there are no available connections in the connection pool.
 InsertBatchSize	Gets or sets the batch size for multiple record Insert operations.
 LongDatatypeColumnSize	Gets or sets the maximum size in bytes of an Oracle long data type column. Obsolete.
 ManualAddressing	(inherited from TransportBindingElement)
 MaxBufferPoolSize	(inherited from TransportBindingElement)
 MaxOutputAssociativeArrayElements	Gets or sets the size of the associative array that the adapter creates when performing operations that return an associative array in the response.
 MaxPoolSize	Gets or sets the maximum number of connections in the connection pool.
 MaxReceivedMessageSize	(inherited from TransportBindingElement)
 MetadataPooling	Gets or sets whether data provider caches metadata information for executed queries.
 MinPoolSize	Gets or sets the minimum number of connections in the connection pool.
 MlsSettings	Gets or sets the Multiple Language System Settings configuration element.
 NotificationPort	Gets or sets the port number that must open to listen for database change notification from Oracle database.
 NotificationStatement	Gets or sets the SELECT statement used to register for getting notifications from Oracle database.
 NotifyOnListenerStart	Gets or sets whether the specified object notifies on listener start.
 OracleConnectionClientId	Gets or sets the Oracle connection client identifier.
 OracleEBSOrganizationId	Gets or sets the Oracle EBS organization identifier.
 OracleEBSResponsibilityKey	Gets or sets the Oracle EBS responsibility key.
 OracleEBSResponsibilityName	Gets or sets the Oracle EBS responsibility name.
 OraclePassword	Gets or sets the Oracle password.
 OracleUserName	Gets or sets the Oracle user name.

 PolledDataAvailableStatement	Gets or sets the polled data available statement.
 PollingAction	Gets or sets the action for the polling operation.
 PollingInput	Gets or sets the polling input.
 PollingInterval	Gets or sets the transacted polling interval, that is, the interval in seconds at which the Oracle Database adapter executes the polling statement against the Oracle database.
 PollWhileDataFound	Gets or sets whether the specified object continuously poll data when it is available.
 PostPollStatement	Gets or sets the PL/SQL block that is executed after the polling statement and before the /POLLINGSTMT message is sent to the consumer.
 Scheme	Overridden. Gets the scheme used in the adapter.
 SkipNilNodes	Gets or sets whether the Oracle Database adapter will skip inserting or updating values for nodes that are marked as ?nil? in the request XML.
 StatementCachePurge	Gets or sets whether the data provider statement cache associated with a connection is purged.
 StatementCacheSize	Gets or sets the maximum number of statements that can be cached by each data provider connection.
 TransactedReceiveEnabled	(inherited from Adapter)
 UseAmbientTransaction	Gets or sets whether the Oracle Database adapter performs the operations using the transaction context provided by the caller.
 UseOracleConnectionPool	Gets or sets whether to use the Oracle connection pool.
 UserAssembliesLoadPath	Gets or sets the path where the assemblies will be loaded.
 UseSchemaInNameSpace	Gets or sets whether the schema name is included in the xml namespace for operations and their associated types.

[Top](#)

Protected Properties

Name	Description
 Namespace	Overridden. Gets the namespace used for the adapter.
 Settings	(inherited from Adapter)

[Top](#)

Public Methods (see also [Protected Methods](#))

Name	Description
 BuildChannelFactory	(inherited from Adapter)
 BuildChannelListener	(inherited from Adapter)
 CanBuildChannelFactory	(inherited from Adapter)

OracleEBSAdapter.BuildConnectionFactory Method

Initializes a channel factory for producing channels of a specified type from the specified object.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

Protected Overrides Function BuildConnectionFactory ( _
    connectionUri As ConnectionUri, _
    clientCredentials As ClientCredentials, _
    context As BindingContext _
) As IConnectionFactory
```

C#

```
protected override IConnectionFactory BuildConnectionFactory (
    ConnectionUri connectionUri,
    ClientCredentials clientCredentials,
    BindingContext context
)
```

C++

```
protected:
virtual IConnectionFactory^ BuildConnectionFactory (
    ConnectionUri^ connectionUri,
    ClientCredentials^ clientCredentials,
    BindingContext^ context
) override
```

J#

```
protected IConnectionFactory BuildConnectionFactory (
    ConnectionUri connectionUri,
    ClientCredentials clientCredentials,
    BindingContext context
)
```

JScript

```
protected override function BuildConnectionFactory (
    connectionUri : ConnectionUri,
    clientCredentials : ClientCredentials,
    context : BindingContext
) : IConnectionFactory
```

Parameters

connectionUri

The connection for the unified resource identifier.

clientCredentials

The client credentials

context

The specified context.

Return Value

The channel factory.

OracleEBSAdapter Properties

Public Properties (see also [Protected Properties](#))

Name	Description
 AcceptCredentialsInUri	Gets or sets whether the connection URI can contain user credentials for the data base.
 ApplicationShortName	Gets or sets the application short name.
 ClientCredentialType	Gets or sets the client credential type.
 ConnectionLifetime	Gets or sets the maximum duration in seconds of a connection.
 DataFetchSize	Gets or sets the amount of data in bytes that data provider fetches from the result set in one server round trip.
 DecrPoolSize	Gets or sets the number of connections that are closed when an excessive amount of established connections are not in use.
 EnableBizTalkCompatibilityMode	Gets or sets whether the BizTalk compatibility mode is enabled.
 EnablePerformanceCounters	Gets or sets whether to enable the WCF LOB Adapter SDK performance counters and the Oracle Database adapter LOB Latency performance counter.
 EnableSafeTyping	Gets or sets whether enables or disables safe typing.
 GeneratedUserTypesAssemblyFilePath	Gets or sets the name and path of the DLL that the adapter generates.
 GeneratedUserTypesAssemblyKeyFilePath	Gets or sets the name and path of the key file that the adapter uses to create a strongly-typed assembly.
 InboundOperationType	Gets or sets the inbound operation type.
 IncrPoolSize	Gets or sets the number of new connections to be created when a new connection is requested and there are no available connections in the connection pool.
 InsertBatchSize	Gets or sets the batch size for multiple record Insert operations.
 LongDatatypeColumnSize	Gets or sets the maximum size in bytes of an Oracle long data type column. Obsolete.
 ManualAddressing	(inherited from TransportBindingElement)
 MaxBufferPoolSize	(inherited from TransportBindingElement)
 MaxOutputAssociativeArrayElements	Gets or sets the size of the associative array that the adapter creates when performing operations that return an associative array in the response.
 MaxPoolSize	Gets or sets the maximum number of connections in the connection pool.
 MaxReceivedMessageSize	(inherited from TransportBindingElement)
 MetadataPooling	Gets or sets whether data provider caches metadata information for executed queries.
 MinPoolSize	Gets or sets the minimum number of connections in the connection pool.
 MlsSettings	Gets or sets the Multiple Language System Settings configuration element.
 NotificationPort	Gets or sets the port number that must open to listen for database change notification from Oracle database.
 NotificationStatement	Gets or sets the SELECT statement used to register for getting notifications from Oracle database.
 NotifyOnListenerStart	Gets or sets whether the specified object notifies on listener start.
 OracleConnectionClientId	Gets or sets the Oracle connection client identifier.
 OracleEBSOrganizationId	Gets or sets the Oracle EBS organization identifier.
 OracleEBSResponsibilityKey	Gets or sets the Oracle EBS responsibility key.
 OracleEBSResponsibilityName	Gets or sets the Oracle EBS responsibility name.
 OraclePassword	Gets or sets the Oracle password.
 OracleUserName	Gets or sets the Oracle user name.
 PolledDataAvailableStatement	Gets or sets the polled data available statement.
 PollingAction	Gets or sets the action for the polling operation.
 PollingInput	Gets or sets the polling input.
 PollingInterval	Gets or sets the transacted polling interval, that is, the interval in seconds at which the Oracle Database adapter executes the polling statement against the Oracle database.
 PollWhileDataFound	Gets or sets whether the specified object continuously poll data when it is available.

 PostPollStatement	Gets or sets the PL/SQL block that is executed after the polling statement and before the /POLLINGSTMT message is sent to the consumer.
 Scheme	Overridden. Gets the scheme used in the adapter.
 SkipNilNodes	Gets or sets whether the Oracle Database adapter will skip inserting or updating values for nodes that are marked as ?nil? in the request XML.
 StatementCachePurge	Gets or sets whether the data provider statement cache associated with a connection is purged.
 StatementCacheSize	Gets or sets the maximum number of statements that can be cached by each data provider connection.
 TransactedReceiveEnabled	(inherited from Adapter)
 UseAmbientTransaction	Gets or sets whether the Oracle Database adapter performs the operations using the transaction context provided by the caller.
 UseOracleConnectionPool	Gets or sets whether to use the Oracle connection pool.
 UserAssembliesLoadPath	Gets or sets the path where the assemblies will be loaded.
 UseSchemaInNamespace	Gets or sets whether the schema name is included in the xml namespace for operations and their associated types.

Protected Properties

	Name	Description
 Namespace		Overridden. Gets the namespace used for the adapter.
 Settings		(inherited from Adapter)

OracleEBSAdapter.AcceptCredentialsInUri Property

Gets or sets whether the connection URI can contain user credentials for the database.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

Public Property AcceptCredentialsInUri As Boolean
```

C#

```
public bool AcceptCredentialsInUri { get; set; }
```

C++

```
public:
virtual property bool AcceptCredentialsInUri {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final boolean get_AcceptCredentialsInUri ()

/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final void set_AcceptCredentialsInUri (boolean value)
```

JScript

```
CompilerGeneratedAttribute
public final function get AcceptCredentialsInUri () : boolean

CompilerGeneratedAttribute
public final function set AcceptCredentialsInUri (value : boolean)
```

Property Value

<languageKeyword>True</languageKeyword> if use the Oracle connection URI can contain user credentials for the Oracle database; otherwise, <languageKeyword>>false</languageKeyword>.

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSAdapter.DecrPoolSize Property

Gets or sets the number of connections that are closed when an excessive amount of established connections are not in use.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

Public Property DecrPoolSize As Integer
```

C#

```
public int DecrPoolSize { get; set; }
```

C++

```
public:
virtual property int DecrPoolSize {
    int get () sealed;
    void set (int value) sealed;
}
```

J#

```
/** @property */
public final int get_DecrPoolSize ()

/** @property */
public final void set_DecrPoolSize (int value)
```

JScript

```
public final function get DecrPoolSize () : int

public final function set DecrPoolSize (value : int)
```

Property Value

The number of connections that are closed.

Thread Safety Any public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

Platforms

Development Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

Target Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of

Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

OracleEBSAdapter.EnableBizTalkCompatibilityMode Property

Gets or sets whether the BizTalk compatibility mode is enabled.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration  
  
Public Property EnableBizTalkCompatibilityMode As Boolean
```

C#

```
public bool EnableBizTalkCompatibilityMode { get; set; }
```

C++

```
public:  
virtual property bool EnableBizTalkCompatibilityMode {  
    bool get () sealed;  
    void set (bool value) sealed;  
}
```

J#

```
/** @property */

OracleEBSAdapter.MetadataPooling Property

Gets or sets whether data provider caches metadata information for executed queries.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

Public Property MetadataPooling As Boolean
```

C#

```
public bool MetadataPooling { get; set; }
```

C++

```
public:
virtual property bool MetadataPooling {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final boolean get_MetadataPooling ()

/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final void set_MetadataPooling (boolean value)
```

JScript

```
CompilerGeneratedAttribute
public final function get MetadataPooling () : boolean

CompilerGeneratedAttribute
public final function set MetadataPooling (value : boolean)
```

Property Value

<languageKeyword>True</languageKeyword> if the data provider caches metadata information for executed queries; otherwise, <languageKeyword>>false</languageKeyword>.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

OracleEBSAdapter.MinPoolSize Property

Gets or sets the minimum number of connections in the connection pool.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

Public Property MinPoolSize As Integer
```

C#

```
public int MinPoolSize { get; set; }
```

C++

```
public:
virtual property int MinPoolSize {
    int get () sealed;
    void set (int value) sealed;
}
```

J#

```

OracleEBSAdapter.UseOracleConnectionPool Property

Gets or sets whether to use the Oracle connection pool.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

Public Property UseOracleConnectionPool As Boolean
```

C#

```
public bool UseOracleConnectionPool { get; set; }
```

C++

```
public:
virtual property bool UseOracleConnectionPool {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final boolean get_UseOracleConnectionPool ()

/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final void set_UseOracleConnectionPool (boolean value)
```

JScript

```
CompilerGeneratedAttribute
public final function get UseOracleConnectionPool () : boolean

CompilerGeneratedAttribute
public final function set UseOracleConnectionPool (value : boolean)
```

Property Value

<languageKeyword>True</languageKeyword> if use the Oracle connection pool; otherwise, <languageKeyword>>false</languageKeyword>.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

OracleEBSAdapter.UserAssembliesLoadPath Property

Gets or sets the path where the assemblies will be loaded.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

Public Property UserAssembliesLoadPath As String
```

C#

```
public string UserAssembliesLoadPath { get; set; }
```

C++

```
public:
virtual property String^ UserAssembliesLoadPath {
String^ get () sealed;
void set (String^ value) sealed;
}
```

J#

```
/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final String get_UserAssembliesLoadPath ()

/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final void set_UserAssembliesLoadPath (String value)
```

JScript

```
CompilerGeneratedAttribute
public final function get UserAssembliesLoadPath () : String

CompilerGeneratedAttribute
public final function set UserAssembliesLoadPath (value : String)
```

Property Value

The path where the assemblies will be loaded.

[OracleEBSBinding Members](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBinding Members

Represents the Oracle E-Business Suite WCF Binding.

The following tables list the members exposed by the [OracleEBSBinding](#) type.

Public Constructors

Name	Description
OracleEBSBinding	Overloaded. Initializes a new instance of the OracleEBSBinding class.

Top

Public Properties

Name	Description
 AcceptCredentialsInUri	Gets or sets whether the connection URI can contain user credentials for the data base.
 ApplicationShortName	Gets or sets the application short name.
 AssuresOrderedDelivery	(inherited from AdapterBinding)
 ClientCredentialType	Gets or sets the client credential type.
 CloseTimeout	(inherited from Binding)
 ConnectionLifetime	Gets or sets the maximum duration in seconds of a connection.
 ConnectionUriType	Overridden. Gets the type of the specific ConnectionUri.
 DataFetchSize	Gets or sets the amount of data in bytes that data provider fetches from the result set in one server round trip.
 DecrPoolSize	Gets or sets the number of connections that are closed when an excessive amount of established connections are not in use.
 DefaultXsdFileNamePrefix	(inherited from AdapterBinding)
 EnableBizTalkCompatibilityMode	Gets or sets whether the BizTalk compatibility mode is enabled.
 EnablePerformanceCounters	Gets or sets whether to enable the WCF LOB Adapter SDK performance counters and the Oracle Database adapter LOB Latency performance counter.
 EnableSafeTyping	Gets or sets whether enables or disables safe typing.
 GeneratedUserTypesAssemblyFilePath	Gets or sets the name and path of the DLL that the adapter generates.
 GeneratedUserTypesAssemblyKeyFilePath	Gets or sets the name and path of the key file that the adapter uses to create a strongly-typed assembly.
 InboundOperationType	Gets or sets the inbound operation type.
 IncrPoolSize	Gets or sets the number of new connections to be created when a new connection is requested and there are no available connections in the connection pool.
 InsertBatchSize	Gets or sets the batch size for multiple record Insert operations.
 LongDatatypeColumnSize	Gets or sets the maximum size in bytes of an Oracle long data type column. Obsolete.
 MaxOutputAssociativeArrayElements	Gets or sets the size of the associative array that the adapter creates when performing operations that return an associative array in the response.
 MaxPoolSize	Gets or sets the maximum number of connections in the connection pool.
 MessageVersion	(inherited from Binding)
 MetadataPooling	Gets or sets whether data provider caches metadata information for executed queries.
 MinPoolSize	Gets or sets the minimum number of connections in the connection pool.
 MlsSettings	Gets or sets the Multiple Language System Settings configuration element.
 Name	(inherited from Binding)
 Namespace	(inherited from Binding)
 NotificationPort	Gets or sets the port number that must open to listen for database change notification from Oracle database.
 NotificationStatement	Gets or sets the SELECT statement used to register for getting notifications from Oracle database.
 NotifyOnListenerStart	Gets or sets whether the adapter sends a notification message to the adapter clients, informing that the receive location is running, when the listener starts.
 OpenTimeout	(inherited from Binding)
 OracleConnectionClientId	Gets or sets the Oracle connection client identifier.

 OracleEBSOrganizationId	Gets or sets the Oracle EBS organization identifier.
 OracleEBSResponsibilityKey	Gets or sets the Oracle EBS responsibility key.
 OracleEBSResponsibilityName	Gets or sets the Oracle EBS responsibility name.
 OraclePassword	Gets or sets the Oracle password.
 OracleUserName	Gets or sets the Oracle user name.
 PolledDataAvailableStatement	Gets or sets the polled data available statement.
 PollingAction	Gets or sets the action for the polling operation.
 PollingInput	Gets or sets the polling input.
 PollingInterval	Gets or sets the transacted polling interval, that is, the interval in seconds at which the Oracle Database adapter executes the polling statement against the Oracle database.
 PollWhileDataFound	Gets or sets whether the specified object continuously poll data when it is available.
 PostPollStatement	Gets or sets the PL/SQL block that is executed after the polling statement and before the /POLLINGSTMT message is sent to the consumer.
 QueuedDelivery	(inherited from AdapterBinding)
 ReceiveTimeout	(inherited from Binding)
 Scheme	Overridden. Gets the scheme of the binding.
 SendTimeout	(inherited from Binding)
 SkipNilNodes	Gets or sets whether the Oracle Database adapter will skip inserting or updating values for nodes that are marked as ?nil? in the request XML.
 StatementCachePurge	Gets or sets whether the data provider statement cache associated when a connection is purged.
 StatementCacheSize	Gets or sets the maximum number of statements that can be cached by each data provider connection.
 SupportsCertificateAuthentication	(inherited from AdapterBinding)
 SupportsMetadataBrowse	Overridden. Gets a value that indicates whether the binding supports metadata browsing.
 SupportsMetadataGet	Overridden. Gets a value that indicates whether the binding supports metadata retrieval.
 SupportsMetadataSearch	Overridden. Gets a value that indicates whether the binding supports metadata search.
 SupportsUserNameAuthentication	(inherited from AdapterBinding)
 SupportsWindowsAuthentication	(inherited from AdapterBinding)
 UseAmbientTransaction	Gets or sets whether the Oracle Database adapter performs the operations using the transaction context provided by the caller.
 UseOracleConnectionPool	Gets or sets whether to use the Oracle connection pool.
 UserAssembliesLoadPath	Gets or sets the path where the assemblies will be loaded.
 UseSchemaInNamespace	Gets or sets whether the schema name is included in the xml namespace for operations and their associated types.

 SupportsMetadataBrowse	Overridden. Gets a value that indicates whether the binding supports metadata browsing.
 SupportsMetadataGet	Overridden. Gets a value that indicates whether the binding supports metadata retrieval.
 SupportsMetadataSearch	Overridden. Gets a value that indicates whether the binding supports metadata search.
 SupportsUserNameAuthentication	(inherited from AdapterBinding)
 SupportsWindowsAuthentication	(inherited from AdapterBinding)
 UseAmbientTransaction	Gets or sets whether the Oracle Database adapter performs the operations using the transaction context provided by the caller.
 UseOracleConnectionPool	Gets or sets whether to use the Oracle connection pool.
 UserAssembliesLoadPath	Gets or sets the path where the assemblies will be loaded.
 UseSchemaInNameSpace	Gets or sets whether the schema name is included in the xml namespace for operations and their associated types.

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBinding.AcceptCredentialsInUri Property

Gets or sets whether the connection URI can contain user credentials for the database.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<CategoryAttribute("Security")> _
<BrowsableAttribute(True)> _
Public Property AcceptCredentialsInUri As Boolean
```

C#

```
[CategoryAttribute("Security")]
[BrowsableAttribute(true)]
public bool AcceptCredentialsInUri { get; set; }
```

C++

```
[CategoryAttribute(L"Security")]
[BrowsableAttribute(true)]
public:
virtual property bool AcceptCredentialsInUri {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final boolean get_AcceptCredentialsInUri ()

/** @property */
/** @attribute CompilerGeneratedAttribute() */
public final void set_AcceptCredentialsInUri (boolean value)
```

JScript

```
CompilerGeneratedAttribute
public final function get AcceptCredentialsInUri () : boolean

CompilerGeneratedAttribute
public final function set AcceptCredentialsInUri (value : boolean)
```

Property Value

<languageKeyword>True</languageKeyword> if use the Oracle connection URI can contain user credentials for the Oracle database; otherwise, <languageKeyword>>false</languageKeyword>.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not

guaranteed to be thread safe.

public final int get_NotificationPort ()

/** @property */
public final void set_NotificationPort (int value)
```

JScript

```
public final function get NotificationPort () : int

public final function set NotificationPort (value : int)
```

Property Value

The port number that must open to listen for database change notification from Oracle database.

Thread Safety Any public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

OracleEBSBinding.PollingInterval Property

Gets or sets the transacted polling interval, that is, the interval in seconds at which the Oracle Database adapter executes the polling statement against the Oracle database.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<BrowsableAttribute(True)> _
<BindingPropertyDirectionAttribute(True, False)> _
<CategoryAttribute("Polling")> _
Public Property PollingInterval As Integer
```

C#

```
[BrowsableAttribute(true)]
[BindingPropertyDirectionAttribute(true, false)]
[CategoryAttribute("Polling")]
public int PollingInterval { get; set; }
```

C++

```
[BrowsableAttribute(true)]
[BindingPropertyDirectionAttribute(true, false)]
[CategoryAttribute(L"Polling")]
public:
virtual property int PollingInterval {
    int get () sealed;
    void set (int value) sealed;
}
```

J#

```
/** @property */
public final int get_PollingInterval ()

/** @property */
public final void set_PollingInterval (int value)
```

JScript

```
public final function get PollingInterval () : int

public final function set PollingInterval (value : int)
```

Property Value

The transacted polling interval.

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingConfigurationElement Members

Represents the StandardBindingElement for the Oracle E-Business Suite Adapter.

The following tables list the members exposed by the [OracleEBSBindingConfigurationElement](#) type.

Public Constructors

Name	Description
OracleEBSBindingConfigurationElement	Overloaded.

Top

Public Properties (see also [Protected Properties](#))

Name	Description
 AcceptCredentialsInUri	Gets or sets whether the connection URI can contain user credentials for the data base.
 ApplicationShortName	Gets or sets the application short name.
 ClientCredentialType	Gets or sets the client credential type.
 CloseTimeout	(inherited from StandardBindingElement)
 ConnectionLifetime	Gets or sets the maximum duration in seconds of a connection.
 DataFetchSize	Gets or sets the amount of data in bytes that data provider fetches from the result set in one server round trip.
 DecrPoolSize	Gets or sets the number of connections that are closed when an excessive amount of established connections are not in use.
 ElementInformation	(inherited from ConfigurationElement)
 EnableBizTalkCompatibilityMode	Gets or sets whether the BizTalk compatibility mode is enabled.
 EnablePerformanceCounters	Gets or sets whether to enable the WCF LOB Adapter SDK performance counters and the Oracle Database adapter LOB Latency performance counter.
 EnableSafeTyping	Gets or sets whether enables or disables safe typing.
 GeneratedUserTypesAssemblyFilePath	Gets or sets the name and path of the DLL that the adapter generates.
 GeneratedUserTypesAssemblyKeyFilePath	Gets or sets the name and path of the key file that the adapter uses to create a strongly-typed assembly.
 InboundOperationType	Gets or sets the inbound operation type.
 IncrPoolSize	Gets or sets the number of new connections to be created when a new connection is requested and there are no available connections in the connection pool.
 InsertBatchSize	Gets or sets the batch size for multiple record Insert operations.
 LockAllAttributesExcept	(inherited from ConfigurationElement)
 LockAllElementsExcept	(inherited from ConfigurationElement)
 LockAttributes	(inherited from ConfigurationElement)
 LockElements	(inherited from ConfigurationElement)
 LockItem	(inherited from ConfigurationElement)
 LongDatatypeColumnSize	Gets or sets the maximum size in bytes of an Oracle long data type column. Obsolete.
 MaxOutputAssociativeArrayElements	Gets or sets the size of the associative array that the adapter creates when performing operations that return an associative array in the response.
 MaxPoolSize	Gets or sets the maximum number of connections in the connection pool.
 MetadataPooling	Gets or sets whether data provider caches metadata information for executed queries.
 MinPoolSize	Gets or sets the minimum number of connections in the connection pool.
 MlsSettings	Gets or sets the Multiple Language System Settings configuration element.
 Name	(inherited from StandardBindingElement)
 NotificationPort	Gets or sets the port number that must open to listen for database change notification from Oracle database.
 NotificationStatement	Gets or sets the SELECT statement used to register for getting notifications from Oracle database.
 NotifyOnListenerStart	Gets or sets whether the adapter sends a notification message to the adapter clients, informing that the receive location is running, when the listener starts.
 OpenTimeout	(inherited from StandardBindingElement)

 OracleConnectionClientId	Gets or sets the Oracle connection client identifier.
 OracleEBSOrganizationId	Gets or sets the Oracle EBS organization identifier.
 OracleEBSResponsibilityKey	Gets or sets the Oracle EBS responsibility key.
 OracleEBSResponsibilityName	Gets or sets the Oracle EBS responsibility name.
 OraclePassword	Gets or sets the Oracle password.
 OracleUserName	Gets or sets the Oracle user name.
 PolledDataAvailableStatement	Gets or sets the polled data available statement.
 PollingAction	Gets or sets the action for the polling operation.
 PollingInput	Gets or sets the polling input.
 PollingInterval	Gets or sets the transacted polling interval, that is, the interval in seconds at which the Oracle Database adapter executes the polling statement against the Oracle database.
 PollWhileDataFound	Gets or sets whether the specified object continuously poll data when it is available.
 PostPollStatement	Gets or sets the PL/SQL block that is executed after the polling statement and before the /POLLINGSTMT message is sent to the consumer.
 ReceiveTimeout	(inherited from StandardBindingElement)
 SendTimeout	(inherited from StandardBindingElement)
 SkipNilNodes	Gets or sets whether the Oracle Database adapter will skip inserting or updating values for nodes that are marked as ?nil? in the request XML.
 StatementCachePurge	Gets or sets whether the data provider statement cache associated when a connection is purged.
 StatementCacheSize	Gets or sets the maximum number of statements that can be cached by each data provider connection.
 UseAmbientTransaction	Gets or sets whether the Oracle Database adapter performs the operations using the transaction context provided by the caller.
 UseOracleConnectionPool	Gets or sets whether to use the Oracle connection pool.
 UserAssembliesLoadPath	Gets or sets the path where the assemblies will be loaded.
 UseSchemaInNameSpace	Gets or sets whether the schema name is included in the xml namespace for operations and their associated types.

OracleEBSBindingConfigurationElement Properties

Public Properties (see also [Protected Properties](#))

Name	Description
 AcceptCredentialsInUri	Gets or sets whether the connection URI can contain user credentials for the data base.
 ApplicationShortName	Gets or sets the application short name.
 ClientCredentialType	Gets or sets the client credential type.
 CloseTimeout	(inherited from StandardBindingElement)
 ConnectionLifetime	Gets or sets the maximum duration in seconds of a connection.
 DataFetchSize	Gets or sets the amount of data in bytes that data provider fetches from the result set in one server round trip.
 DecrPoolSize	Gets or sets the number of connections that are closed when an excessive amount of established connections are not in use.
 ElementInformation	(inherited from ConfigurationElement)
 EnableBizTalkCompatibilityMode	Gets or sets whether the BizTalk compatibility mode is enabled.
 EnablePerformanceCounters	Gets or sets whether to enable the WCF LOB Adapter SDK performance counters and the Oracle Database adapter LOB Latency performance counter.
 EnableSafeTyping	Gets or sets whether enables or disables safe typing.
 GeneratedUserTypesAssemblyFilePath	Gets or sets the name and path of the DLL that the adapter generates.
 GeneratedUserTypesAssemblyKeyFilePath	Gets or sets the name and path of the key file that the adapter uses to create a strongly-typed assembly.
 InboundOperationType	Gets or sets the inbound operation type.
 IncrPoolSize	Gets or sets the number of new connections to be created when a new connection is requested and there are no available connections in the connection pool.
 InsertBatchSize	Gets or sets the batch size for multiple record Insert operations.
 LockAllAttributesExcept	(inherited from ConfigurationElement)
 LockAllElementsExcept	(inherited from ConfigurationElement)
 LockAttributes	(inherited from ConfigurationElement)
 LockElements	(inherited from ConfigurationElement)
 LockItem	(inherited from ConfigurationElement)
 LongDatatypeColumnSize	Gets or sets the maximum size in bytes of an Oracle long data type column. Obsolete.
 MaxOutputAssociativeArrayElements	Gets or sets the size of the associative array that the adapter creates when performing operations that return an associative array in the response.
 MaxPoolSize	Gets or sets the maximum number of connections in the connection pool.
 MetadataPooling	Gets or sets whether data provider caches metadata information for executed queries.
 MinPoolSize	Gets or sets the minimum number of connections in the connection pool.
 MlsSettings	Gets or sets the Multiple Language System Settings configuration element.
 Name	(inherited from StandardBindingElement)
 NotificationPort	Gets or sets the port number that must open to listen for database change notification from Oracle database.
 NotificationStatement	Gets or sets the SELECT statement used to register for getting notifications from Oracle database.
 NotifyOnListenerStart	Gets or sets whether the adapter sends a notification message to the adapter clients, informing that the receive location is running, when the listener starts.
 OpenTimeout	(inherited from StandardBindingElement)
 OracleConnectionClientId	Gets or sets the Oracle connection client identifier.
 OracleEBSOrganizationId	Gets or sets the Oracle EBS organization identifier.
 OracleEBSResponsibilityKey	Gets or sets the Oracle EBS responsibility key.
 OracleEBSResponsibilityName	Gets or sets the Oracle EBS responsibility name.
 OraclePassword	Gets or sets the Oracle password.
 OracleUserName	Gets or sets the Oracle user name.
 PolledDataAvailableStatement	Gets or sets the polled data available statement.

 PollingAction	Gets or sets the action for the polling operation.
 PollingInput	Gets or sets the polling input.
 PollingInterval	Gets or sets the transacted polling interval, that is, the interval in seconds at which the Oracle Database adapter executes the polling statement against the Oracle database.
 PollWhileDataFound	Gets or sets whether the specified object continuously poll data when it is available.
 PostPollStatement	Gets or sets the PL/SQL block that is executed after the polling statement and before the /POLLINGSTMT message is sent to the consumer.
 ReceiveTimeout	(inherited from StandardBindingElement)
 SendTimeout	(inherited from StandardBindingElement)
 SkipNilNodes	Gets or sets whether the Oracle Database adapter will skip inserting or updating values for nodes that are marked as ?nil? in the request XML.
 StatementCachePurge	Gets or sets whether the data provider statement cache associated when a connection is purged.
 StatementCacheSize	Gets or sets the maximum number of statements that can be cached by each data provider connection.
 UseAmbientTransaction	Gets or sets whether the Oracle Database adapter performs the operations using the transaction context provided by the caller.
 UseOracleConnectionPool	Gets or sets whether to use the Oracle connection pool.
 UserAssembliesLoadPath	Gets or sets the path where the assemblies will be loaded.
 UseSchemaInNameSpace	Gets or sets whether the schema name is included in the xml namespace for operations and their associated types.

Protected Properties

	Name	Description
	BindingElementType	(inherited from StandardBindingElement)
	ElementProperty	(inherited from ConfigurationElement)
	EvaluationContext	(inherited from ConfigurationElement)
	Item	Overloaded. (inherited from ConfigurationElement)
	Properties	(inherited from StandardBindingElement)

OracleEBSBindingConfigurationElement.AcceptCredentialsInUri Property

Gets or sets whether the connection URI can contain user credentials for the database.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<CategoryAttribute("Security")> _
<BrowsableAttribute(False)> _
<ConfigurationPropertyAttribute("acceptCredentialsInUri")> _
Public Property AcceptCredentialsInUri As Boolean
```

C#

```
[CategoryAttribute("Security")]
[BrowsableAttribute(false)]
[ConfigurationPropertyAttribute("acceptCredentialsInUri")]
public bool AcceptCredentialsInUri { get; set; }
```

C++

```
[CategoryAttribute(L"Security")]
[BrowsableAttribute(false)]
[ConfigurationPropertyAttribute(L"acceptCredentialsInUri")]
public:
virtual property bool AcceptCredentialsInUri {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
public final boolean get_AcceptCredentialsInUri ()

/** @property */
public final void set_AcceptCredentialsInUri (boolean value)
```

JScript

```
public final function get AcceptCredentialsInUri () : boolean

public final function set AcceptCredentialsInUri (value : boolean)
```

Property Value

<languageKeyword>True</languageKeyword> if use the Oracle connection URI can contain user credentials for the Oracle database; otherwise, <languageKeyword>>false</languageKeyword>.

[OracleEBSBindingConfigurationElement Members](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingConfigurationElement.MinPoolSize Property

Gets or sets the minimum number of connections in the connection pool.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<ConfigurationPropertyAttribute("minPoolSize")> _
<CategoryAttribute("OracleConnectionPool")> _
Public Property MinPoolSize As Integer
```

C#

```
[ConfigurationPropertyAttribute("minPoolSize")]
[CategoryAttribute("OracleConnectionPool")]
public int MinPoolSize { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"minPoolSize")]
[CategoryAttribute(L"OracleConnectionPool")]
public:
virtual property int MinPoolSize {
    int get () sealed;
    void set (int value) sealed;
}
```

J#

```
/** @property */
public final int get_MinPoolSize ()

/** @property */
public final void set_MinPoolSize (int value)
```

JScript

```
public final function get MinPoolSize () : int
public final function set MinPoolSize (value : int)
```

Property Value

The minimum number of connections in the connection pool.

Thread Safety Any public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

Platforms

Development Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the

Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

Target Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

public class OracleEBSBindingElementExtensionElement extends BindingElementExtensionElement
```

Remarks

The Microsoft BizTalk Adapter for Oracle E-Business Suite surfaces several binding properties. By setting these properties, you can control some of the adapter's behavior while interfacing with Oracle E-Business Suite or with the Oracle database.

[OracleEBSBindingElementExtensionElement Members](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingElementExtensionElement Members

Enables the configuration of the Oracle E-Business Suite Adapter Binding from an application configuration file.

The following tables list the members exposed by the [OracleEBSBindingElementExtensionElement](#) type.

Public Constructors

Name	Description
OracleEBSBindingElementExtensionElement	Initializes a new instance of the OracleEBSBindingElementExtensionElement class.

Top

Public Properties (see also [Protected Properties](#))

Name	Description
 AcceptCredentialsInUri	Gets or sets a value that indicates whether the Oracle E-Business Suite connection URI is allowed to contain credentials.
 ApplicationShortName	Gets or sets the short name for an Oracle E-Business Suite application.
 BindingElementType	Overridden. Gets the binding element type.
 ClientCredentialType	Gets or sets the sets of credentials to specify when establishing a connection to Oracle E-Business Suite. The possible values are Database or EBusiness.
 ConfigurationElementName	(inherited from ServiceModelExtensionElement)
 ConnectionLifetime	Gets or sets the maximum duration in seconds of a connection.
 DataFetchSize	Gets or sets the amount of data in bytes the ODP.NET fetches from the result set in one server round trip.
 DecrPoolSize	Gets or sets the number of connections that are closed when an excessive amount of established connections are not in use.
 ElementInformation	(inherited from ConfigurationElement)
 EnableBizTalkCompatibilityMode	Gets or sets a value that indicates how the adapter generates schema for a DataSet.
 EnablePerformanceCounters	Gets or sets a value that indicates whether to enable the WCF LOB Adapter SDK performance counters and the Oracle Database adapter LOB Latency performance counter.
 EnableSafeTyping	Gets or sets a value that indicates whether to enable or disable safe typing, that is, how the adapter surfaces certain Oracle data types.
 GeneratedUserTypesAssemblyFilePath	Gets or sets the name and path of the DLL that the adapter generates, while generating metadata, containing all UDTs that are used in the metadata.
 GeneratedUserTypesAssemblyKeyFilePath	Gets or sets the name and path of the key file that the adapter uses to create a strongly-typed assembly.
 InboundOperationType	Gets or sets the manner how the adapter receives messages from Oracle E-Business Suite. The possible values are Polling or Notification.
 IncrPoolSize	Gets or sets the number of new connections to be created when a new connection is requested and there are no available connections in the ODP.NET connection pool.
 InsertBatchSize	Gets or sets the batch size for multiple record Insert operations.
 LockAllAttributesExcept	(inherited from ConfigurationElement)
 LockAllElementsExcept	(inherited from ConfigurationElement)
 LockAttributes	(inherited from ConfigurationElement)
 LockElements	(inherited from ConfigurationElement)
 LockItem	(inherited from ConfigurationElement)
 LongDatatypeColumnSize	Gets or sets the maximum size in bytes of an Oracle long data type column. Obsolete.
 MaxOutputAssociativeArrayElements	Gets or sets the size of the associative array that the adapter creates when performing operations that return an associative array in the response.
 MaxPoolSize	Gets or sets the maximum number of connections in an ODP.NET connection pool.
 MetadataPooling	Gets or sets a value that indicates whether ODP.NET caches metadata information for executed queries.

 MinPoolSize	Gets or sets the minimum number of connections in an ODP.NET connection pool.
 MlsSettings	Gets or sets the settings for multi-language support (MLS) specific options.
 NotificationPort	Gets or sets the port number that ODP.NET must open to listen for database change notification from Oracle database.
 NotificationStatement	Gets or sets the SELECT statement used to register for getting notifications from Oracle database.
 NotifyOnListenerStart	Gets or sets a value that indicates whether the adapter sends a notification message to the adapter clients, informing that the receive location is running, when the listener starts.
 OracleConnectionClientId	Gets or sets the client identifier (ID) for the connection used by the adapter to connect to Oracle.
 OracleEBSOrganizationId	Gets or sets the organization ID to which an Oracle E-Business Suite application belongs.
 OracleEBSResponsibilityKey	Gets or sets the responsibility key associated with the Oracle E-Business Suite user.
 OracleEBSResponsibilityName	Gets or sets the name of the responsibility associated with the Oracle E-Business Suite user.
 OraclePassword	Gets or sets the password credential for an Oracle database user or an Oracle E-Business Suite user.
 OracleUserName	Gets or sets the user name credential for an Oracle database user or an Oracle E-Business Suite user.
 PolledDataAvailableStatement	Gets or sets the SELECT statement executed to determine whether any data is available for polling for a specific table.
 PollingAction	Gets or sets the action for the polling operation.
 PollingInput	Gets or sets the polling statement.
 PollingInterval	Gets or sets the interval in seconds at which the Oracle Database adapter executes the polling statement against the Oracle database.
 PollWhileDataFound	Gets or sets a value that indicates whether the Oracle Database adapter ignores the polling interval and continuously polls the Oracle database, if data is available in the table being polled.
 PostPollStatement	Gets or sets a PL/SQL block that is executed after the polling statement and before the /POLLINGSTMT message is sent to the consumer.
 SkipNilNodes	Gets or sets a value that indicates whether the Oracle Database adapter will skip inserting or updating values for nodes that are marked as ?nil? in the request XML.
 StatementCachePurge	Gets or sets a value that indicates whether the ODP.NET statement cache associated with a connection is purged when the connection is returned to the connection pool.
 StatementCacheSize	Gets or sets the maximum number of statements that can be cached by each ODP.NET connection.
 UseAmbientTransaction	Gets or sets a value that indicates whether the Oracle Database adapter performs the operations using the transaction context provided by the caller.
 UseOracleConnectionPool	Gets or sets a value that indicates whether to use the ODP.NET connection pool.
 UserAssembliesLoadPath	Gets or sets the name of the DLLs, separated by a semi-colon, which the adapter creates while generating metadata.
 UseSchemaInNameSpace	Gets or sets a value that indicates whether the schema name is included in the XML namespace for operations and their associated types.

[OracleEBSBindingElementExtensionElement Members](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingElementExtensionElement Properties

Public Properties (see also [Protected Properties](#))

Name	Description
 AcceptCredentialsInUri	Gets or sets a value that indicates whether the Oracle E-Business Suite connection URI is allowed to contain credentials.
 ApplicationShortName	Gets or sets the short name for an Oracle E-Business Suite application.
 BindingElementType	Overridden. Gets the binding element type.
 ClientCredentialType	Gets or sets the sets of credentials to specify when establishing a connection to Oracle E-Business Suite. The possible values are Database or EBusiness.
 ConfigurationElementName	(inherited from ServiceModelExtensionElement)
 ConnectionLifetime	Gets or sets the maximum duration in seconds of a connection.
 DataFetchSize	Gets or sets the amount of data in bytes the ODP.NET fetches from the result set in one server round trip.
 DecrPoolSize	Gets or sets the number of connections that are closed when an excessive amount of established connections are not in use.
 ElementInformation	(inherited from ConfigurationElement)
 EnableBizTalkCompatibilityMode	Gets or sets a value that indicates how the adapter generates schema for a DataSet.
 EnablePerformanceCounters	Gets or sets a value that indicates whether to enable the WCF LOB Adapter SDK performance counters and the Oracle Database adapter LOB Latency performance counter.
 EnableSafeTyping	Gets or sets a value that indicates whether to enable or disable safe typing, that is, how the adapter surfaces certain Oracle data types.
 GeneratedUserTypesAssemblyFilePath	Gets or sets the name and path of the DLL that the adapter generates, while generating metadata, containing all UDTs that are used in the metadata.
 GeneratedUserTypesAssemblyKeyFilePath	Gets or sets the name and path of the key file that the adapter uses to create a strongly-typed assembly.
 InboundOperationType	Gets or sets the manner how the adapter receives messages from Oracle E-Business Suite. The possible values are Polling or Notification.
 IncrPoolSize	Gets or sets the number of new connections to be created when a new connection is requested and there are no available connections in the ODP.NET connection pool.
 InsertBatchSize	Gets or sets the batch size for multiple record Insert operations.
 LockAllAttributesExcept	(inherited from ConfigurationElement)
 LockAllElementsExcept	(inherited from ConfigurationElement)
 LockAttributes	(inherited from ConfigurationElement)
 LockElements	(inherited from ConfigurationElement)
 LockItem	(inherited from ConfigurationElement)
 LongDatatypeColumnSize	Gets or sets the maximum size in bytes of an Oracle long data type column. Obsolete.
 MaxOutputAssociativeArrayElements	Gets or sets the size of the associative array that the adapter creates when performing operations that return an associative array in the response.
 MaxPoolSize	Gets or sets the maximum number of connections in an ODP.NET connection pool.
 MetadataPooling	Gets or sets a value that indicates whether ODP.NET caches metadata information for executed queries.
 MinPoolSize	Gets or sets the minimum number of connections in an ODP.NET connection pool.
 MlsSettings	Gets or sets the settings for multi-language support (MLS) specific options.
 NotificationPort	Gets or sets the port number that ODP.NET must open to listen for database change notification from Oracle database.
 NotificationStatement	Gets or sets the SELECT statement used to register for getting notifications from Oracle database.

 NotifyOnListenerStart	Gets or sets a value that indicates whether the adapter sends a notification message to the adapter clients, informing that the receive location is running, when the listener starts.
 OracleConnectionClientId	Gets or sets the client identifier (ID) for the connection used by the adapter to connect to Oracle.
 OracleEBSOrganizationId	Gets or sets the organization ID to which an Oracle E-Business Suite application belongs.
 OracleEBSResponsibilityKey	Gets or sets the responsibility key associated with the Oracle E-Business Suite user.
 OracleEBSResponsibilityName	Gets or sets the name of the responsibility associated with the Oracle E-Business Suite user.
 OraclePassword	Gets or sets the password credential for an Oracle database user or an Oracle E-Business Suite user.
 OracleUserName	Gets or sets the user name credential for an Oracle database user or an Oracle E-Business Suite user.
 PolledDataAvailableStatement	Gets or sets the SELECT statement executed to determine whether any data is available for polling for a specific table.
 PollingAction	Gets or sets the action for the polling operation.
 PollingInput	Gets or sets the polling statement.
 PollingInterval	Gets or sets the interval in seconds at which the Oracle Database adapter executes the polling statement against the Oracle database.
 PollWhileDataFound	Gets or sets a value that indicates whether the Oracle Database adapter ignores the polling interval and continuously polls the Oracle database, if data is available in the table being polled.
 PostPollStatement	Gets or sets a PL/SQL block that is executed after the polling statement and before the /POLLINGSTMT message is sent to the consumer.
 SkipNilNodes	Gets or sets a value that indicates whether the Oracle Database adapter will skip inserting or updating values for nodes that are marked as ?nil? in the request XML.
 StatementCachePurge	Gets or sets a value that indicates whether the ODP.NET statement cache associated with a connection is purged when the connection is returned to the connection pool.
 StatementCacheSize	Gets or sets the maximum number of statements that can be cached by each ODP.NET connection.
 UseAmbientTransaction	Gets or sets a value that indicates whether the Oracle Database adapter performs the operations using the transaction context provided by the caller.
 UseOracleConnectionPool	Gets or sets a value that indicates whether to use the ODP.NET connection pool.
 UserAssembliesLoadPath	Gets or sets the name of the DLLs, separated by a semi-colon, which the adapter creates while generating metadata.
 UseSchemaInNameSpace	Gets or sets a value that indicates whether the schema name is included in the XML namespace for operations and their associated types.

Protected Properties

Name	Description
 ElementProperty	(inherited from ConfigurationElement)
 EvaluationContext	(inherited from ConfigurationElement)
 Item	Overloaded. (inherited from ConfigurationElement)
 Properties	Overridden. Gets the collection of configuration properties.

[OracleEBSBindingElementExtensionElement Class](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingElementExtensionElement.AcceptCredentialsInUri Property

Gets or sets a value that indicates whether the Oracle E-Business Suite connection URI is allowed to contain credentials.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<ConfigurationPropertyAttribute("acceptCredentialsInUri", DefaultValue:=False)> _
Public Property AcceptCredentialsInUri As Boolean
```

C#

```
[ConfigurationPropertyAttribute("acceptCredentialsInUri", DefaultValue=false)]
public bool AcceptCredentialsInUri { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"acceptCredentialsInUri", DefaultValue=false)]
public:
virtual property bool AcceptCredentialsInUri {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
public final boolean get_AcceptCredentialsInUri ()

/** @property */
public final void set_AcceptCredentialsInUri (boolean value)
```

JScript

```
public final function get AcceptCredentialsInUri () : boolean

public final function set AcceptCredentialsInUri (value : boolean)
```

Property Value

<languageKeyword>>true</languageKeyword> if the Oracle E-Business Suite connection URI is allowed to contain credentials, otherwise <languageKeyword>>false</languageKeyword>. The default is <languageKeyword>>false</languageKeyword>.

Remarks

By default, the Oracle Database adapter throws an exception when the Oracle database credentials are specified in the connection URI. This is because these credentials are represented as plain text in the connection URI, and this poses a security risk.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

Platforms

Development Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

OracleEBSBindingElementExtensionElement.EnableBizTalkCompatibilityMode Property

Gets or sets a value that indicates how the adapter generates schema for a DataSet.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration
<ConfigurationPropertyAttribute("enableBizTalkCompatibilityMode", DefaultValue:=True)> _
Public Property EnableBizTalkCompatibilityMode As Boolean
```

C#

```
[ConfigurationPropertyAttribute("enableBizTalkCompatibilityMode", DefaultValue=true)]
public bool EnableBizTalkCompatibilityMode { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"enableBizTalkCompatibilityMode", DefaultValue=true)]
public:
virtual property bool EnableBizTalkCompatibilityMode {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingElementExtensionElement.EnableSafeTyping Property

Gets or sets a value that indicates whether to enable or disable safe typing, that is, how the adapter surfaces certain Oracle data types.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<ConfigurationPropertyAttribute("enableSafeTyping", DefaultValue:=False)> _
Public Property EnableSafeTyping As Boolean
```

C#

```
[ConfigurationPropertyAttribute("enableSafeTyping", DefaultValue=false)]
public bool EnableSafeTyping { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"enableSafeTyping", DefaultValue=false)]
public:
virtual property bool EnableSafeTyping {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
public final boolean get_EnableSafeTyping ()

/** @property */
public final void set_EnableSafeTyping (boolean value)
```

JScript

```
public final function get EnableSafeTyping () : boolean

public final function set EnableSafeTyping (value : boolean)
```

Property Value

<languageKeyword>true</languageKeyword> if the safe typing is enabled, otherwise <languageKeyword>>false</languageKeyword>. The default is <languageKeyword>>false</languageKeyword>.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

[OracleEBSBindingElementExtensionElement Class](#)

[OracleEBSBindingElementExtensionElement Members](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingElementExtensionElement.InsertBatchSize Property

Gets or sets the batch size for multiple record Insert operations.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<ConfigurationPropertyAttribute("insertBatchSize", DefaultValue:=20)> _
Public Property InsertBatchSize As Integer
```

C#

```
[ConfigurationPropertyAttribute("insertBatchSize", DefaultValue=20)]
public int InsertBatchSize { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"insertBatchSize", DefaultValue=20)]
public:
virtual property int InsertBatchSize {
    int get () sealed;
    void set (int value) sealed;
}
```

J#

```
/** @property */
public final int get_InsertBatchSize ()

/** @property */
public final void set_InsertBatchSize (int value)
```

JScript

```
public final function get InsertBatchSize () : int
public final function set InsertBatchSize (value : int)
```

Property Value

The batch size for multiple record Insert operations. The default is 20.

Remarks

The Oracle E-Business adapter batches the specified number of records into a single ODP.NET call. A well-chosen value for InsertBatchSize can greatly improve adapter performance for multiple record Insert operations.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not

guaranteed to be thread safe.

Reference

[OracleEBSBindingElementExtensionElement Class](#)

[OracleEBSBindingElementExtensionElement Members](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingElementExtensionElement.MetadataPooling Property

Gets or sets a value that indicates whether ODP.NET caches metadata information for executed queries.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<ConfigurationPropertyAttribute("metadataPooling", DefaultValue:=True)> _
Public Property MetadataPooling As Boolean
```

C#

```
[ConfigurationPropertyAttribute("metadataPooling", DefaultValue=true)]
public bool MetadataPooling { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"metadataPooling", DefaultValue=true)]
public:
virtual property bool MetadataPooling {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
public final boolean get_MetadataPooling ()

/** @property */
public final void set_MetadataPooling (boolean value)
```

JScript

```
public final function get MetadataPooling () : boolean

public final function set MetadataPooling (value : boolean)
```

Property Value

<languageKeyword>true</languageKeyword> when metadata pooling is enabled, otherwise <languageKeyword>>false</languageKeyword>. The default is <languageKeyword>true</languageKeyword>.

Remarks

Caching this information improves performance; however, if changes to the underlying Oracle artifacts occur on the Oracle system, this pooled metadata will be out of sync. This might cause operations performed on the Oracle system to return unexpected exceptions.

Thread Safety Any public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingElementExtensionElement.MinPoolSize Property

Gets or sets the minimum number of connections in an ODP.NET connection pool.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration  
  
<ConfigurationPropertyAttribute("minPoolSize", DefaultValue:=1)> _  
Public Property MinPoolSize As Integer
```

C#

```
[ConfigurationPropertyAttribute("minPoolSize", DefaultValue=1)]  
public int MinPoolSize { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"minPoolSize", DefaultValue=1)]  
public:  
virtual property int MinPoolSize {  
    int get () sealed;  
    void set (int value) sealed;  
}
```

J#

```
/** @property */  
public final int get_MinPoolSize ()  
  
/** @property */  
public final void set_MinPoolSize (int value)
```

JScript

```
public final function get MinPoolSize () : int  
public final function set MinPoolSize (value : int)
```

Property Value

The minimum number of connections in an ODP.NET connection pool. The default is one.

Thread Safety Any public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

Platforms

Development Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the

Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

Target Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

OracleEBSBindingElementExtensionElement.MlsSettings Property

Gets or sets the settings for multi-language support (MLS) specific options.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<ConfigurationPropertyAttribute("mIsSettings", DefaultValue:=Nothing)> _
Public Property MIsSettings As MIsSettings
```

C#

```
[ConfigurationPropertyAttribute("mIsSettings", DefaultValue=null)]
public MIsSettings MIsSettings { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"mIsSettings", DefaultValue=nullptr)]
public:
virtual property MIsSettings^ MIsSettings {
    MIsSettings^ get () sealed;
    void set (MIsSettings^ value) sealed;
}
```

J#

```
/** @property */

OracleEBSBindingElementExtensionElement.NotificationPort Property

Gets or sets the port number that ODP.NET must open to listen for database change notification from Oracle database.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<BindingPropertyDirectionAttribute(True, False)> _
<ConfigurationPropertyAttribute("notificationPort", DefaultValue:=-1)> _
<CategoryAttribute("Notification")> _
Public Property NotificationPort As Integer
```

C#

```
[BindingPropertyDirectionAttribute(true, false)]
[ConfigurationPropertyAttribute("notificationPort", DefaultValue=-1)]
[CategoryAttribute("Notification")]
public int NotificationPort { get; set; }
```

C++

```
[BindingPropertyDirectionAttribute(true, false)]
[ConfigurationPropertyAttribute(L"notificationPort", DefaultValue=-1)]
[CategoryAttribute(L"Notification")]
public:
virtual property int NotificationPort {
    int get () sealed;
    void set (int value) sealed;
}
```

J#

```
/** @property */
public final int get_NotificationPort ()

/** @property */
public final void set_NotificationPort (int value)
```

JScript

```
public final function get NotificationPort () : int

public final function set NotificationPort (value : int)
```

Property Value

The port number that ODP.NET must open to listen for database change notification from Oracle database. The default is -1, which signifies that ODP.NET uses a valid, random, unused port number.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

[OracleEBSBindingElementExtensionElement Class](#)

[OracleEBSBindingElementExtensionElement Members](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingElementExtensionElement.OracleConnectionClientId Property

Gets or sets the client identifier (ID) for the connection used by the adapter to connect to Oracle.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration
<ConfigurationPropertyAttribute("oracleConnectionClientId", DefaultValue:=Nothing)> _
Public Property OracleConnectionClientId As String
```

C#

```
[ConfigurationPropertyAttribute("oracleConnectionClientId", DefaultValue=null)]
public string OracleConnectionClientId { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"oracleConnectionClientId", DefaultValue=nullptr)]
public:
virtual property String^ OracleConnectionClientId {
String^ get () sealed;
void set (String^ value) sealed;
}
```

J#

```
/** @property */
public final String get_OracleConnectionClientId ()

/** @property */
public final void set_OracleConnectionClientId (String value)
```

JScript

```
public final function get OracleConnectionClientId () : String
public final function set OracleConnectionClientId (value : String)
```

Property Value

The client ID for the connection used by the adapter to connect to Oracle.

Remarks

This is useful if you have enabled Oracle server-side tracing, and want to selectively trace the operations for a particular client ID. This also allows you to filter and view the Oracle server traces based on a client ID.

OracleEBSBindingElementExtensionElement.PolledDataAvailableStatement Property

Gets or sets the SELECT statement executed to determine whether any data is available for polling for a specific table.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<BindingPropertyDirectionAttribute(True, False)> _
<ConfigurationPropertyAttribute("polledDataAvailableStatement", DefaultValue:=Nothing)> _
Public Property PolledDataAvailableStatement As String
```

C#

```
[BindingPropertyDirectionAttribute(true, false)]
[ConfigurationPropertyAttribute("polledDataAvailableStatement", DefaultValue=null)]
public string PolledDataAvailableStatement { get; set; }
```

C++

```
[BindingPropertyDirectionAttribute(true, false)]
[ConfigurationPropertyAttribute(L"polledDataAvailableStatement", DefaultValue=nullptr)]
public:
virtual property String^ PolledDataAvailableStatement {
String^ get () sealed;
void set (String^ value) sealed;
}
```

J#

```
/** @property */
public final String get_PolledDataAvailableStatement ()

/** @property */
public final void set_PolledDataAvailableStatement (String value)
```

JScript

```
public final function get PolledDataAvailableStatement () : String

public final function set PolledDataAvailableStatement (value : String)
```

Property Value

The SELECT statement executed to determine whether any data is available for polling for a specific table.

OracleEBSBindingElementExtensionElement.PollingAction Property

Gets or sets the action for the polling operation.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<BindingPropertyDirectionAttribute(True, False)> _
<ConfigurationPropertyAttribute("pollingAction", DefaultValue:=Nothing)> _
Public Property PollingAction As String
```

C#

```
[BindingPropertyDirectionAttribute(true, false)]
[ConfigurationPropertyAttribute("pollingAction", DefaultValue=null)]
public string PollingAction { get; set; }
```

C++

```
[BindingPropertyDirectionAttribute(true, false)]
[ConfigurationPropertyAttribute(L"pollingAction", DefaultValue=nullptr)]
public:
virtual property String^ PollingAction {
String^ get () sealed;
void set (String^ value) sealed;
}
```

J#

```
/** @property */
public final String get_PollingAction ()

/** @property */
public final void set_PollingAction (String value)
```

JScript

```
public final function get PollingAction () : String
public final function set PollingAction (value : String)
```

Property Value

The action for the polling operation.

Remarks

You can determine the polling action for a specific operation from the metadata you generate for the operation using the Consume Adapter Service Add-in.

OracleEBSBindingElementExtensionElement.SkipNilNodes Property

Gets or sets a value that indicates whether the Oracle Database adapter will skip inserting or updating values for nodes that are marked as ?nil? in the request XML.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<ConfigurationPropertyAttribute("skipNilNodes", DefaultValue:=True)> _
<CategoryAttribute("Run Time Behavior")> _
Public Property SkipNilNodes As Boolean
```

C#

```
[ConfigurationPropertyAttribute("skipNilNodes", DefaultValue=true)]
[CategoryAttribute("Run Time Behavior")]
public bool SkipNilNodes { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"skipNilNodes", DefaultValue=true)]
[CategoryAttribute(L"Run Time Behavior")]
public:
virtual property bool SkipNilNodes {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
public final boolean get_SkipNilNodes ()

/** @property */
public final void set_SkipNilNodes (boolean value)
```

JScript

```
public final function get SkipNilNodes () : boolean

public final function set SkipNilNodes (value : boolean)
```

Property Value

<languageKeyword>>true</languageKeyword> if the adapter will skip passing values for nodes that are marked as 'nil';
 <languageKeyword>>false</languageKeyword> if the adapter explicitly passes a null value for these nodes. The default is
 <languageKeyword>>false</languageKeyword>.

Remarks

This binding property is applicable for inserting or updating records in a table and for RECORD type parameters in stored procedures.

```
/** @property */
public final boolean get_UseAmbientTransaction ()

/** @property */
public final void set_UseAmbientTransaction (boolean value)
```

JScript

```
public final function get UseAmbientTransaction () : boolean

public final function set UseAmbientTransaction (value : boolean)
```

Property Value

<languageKeyword>true</languageKeyword> if the adapter always performs the operations in a transaction context, otherwise <languageKeyword>>false</languageKeyword>. The default is <languageKeyword>true</languageKeyword>.

Remarks

Not performing operations in a transactional context is advisable only for operations that do not make changes to the database. For operations that update data in the database, we recommend setting the binding property to true otherwise you might either experience message loss or duplicate messages depending on whether you are performing inbound or outbound operations.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

Platforms

Development Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

Target Platforms

OracleEBSBindingElementExtensionElement.UseOracleConnectionPool Property

Gets or sets a value that indicates whether to use the ODP.NET connection pool.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration
<ConfigurationPropertyAttribute("useOracleConnectionPool", DefaultValue:=True)> _
Public Property UseOracleConnectionPool As Boolean
```

C#

```
[ConfigurationPropertyAttribute("useOracleConnectionPool", DefaultValue=true)]
public bool UseOracleConnectionPool { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"useOracleConnectionPool", DefaultValue=true)]
public:
virtual property bool UseOracleConnectionPool {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
public final boolean get_UseOracleConnectionPool ()

/** @property */
public final void set_UseOracleConnectionPool (boolean value)
```

JScript

```
public final function get UseOracleConnectionPool () : boolean
public final function set UseOracleConnectionPool (value : boolean)
```

Property Value

<languageKeyword>true</languageKeyword> if the ODP.NET connection pool is used, otherwise <languageKeyword>>false</languageKeyword>. The default is <languageKeyword>true</languageKeyword>.

[OracleEBSBindingElementExtensionElement Class](#)

[OracleEBSBindingElementExtensionElement Members](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSBindingElementExtensionElement.UseSchemaInNameSpace Property

Gets or sets a value that indicates whether the schema name is included in the XML namespace for operations and their associated types.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<ConfigurationPropertyAttribute("useSchemaInNameSpace", DefaultValue:=True)> _
Public Property UseSchemaInNameSpace As Boolean
```

C#

```
[ConfigurationPropertyAttribute("useSchemaInNameSpace", DefaultValue=true)]
public bool UseSchemaInNameSpace { get; set; }
```

C++

```
[ConfigurationPropertyAttribute(L"useSchemaInNameSpace", DefaultValue=true)]
public:
virtual property bool UseSchemaInNameSpace {
    bool get () sealed;
    void set (bool value) sealed;
}
```

J#

```
/** @property */
public final boolean get_UseSchemaInNameSpace ()

/** @property */
public final void set_UseSchemaInNameSpace (boolean value)
```

JScript

```
public final function get UseSchemaInNameSpace () : boolean

public final function set UseSchemaInNameSpace (value : boolean)
```

Property Value

<languageKeyword>true</languageKeyword> if the schema name is included in the XML namespace, otherwise <languageKeyword>>false</languageKeyword>. The default is <languageKeyword>true</languageKeyword>.

Remarks

The advantage of not having scheme name included in the namespace is that if there is a table with same name in two different schemas then the same XML can be used to perform the simple SQL operations (Insert, Update, Delete, Select) on both tables.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

OracleEBSConnectionUri Members

Builds the Uniform Resource Identifier (URI) for establishing connection to the Oracle E-Business Suite and essentially the underlying Oracle database.

The following tables list the members exposed by the [OracleEBSConnectionUri](#) type.

Public Constructors

Name	Description
OracleEBSConnectionUri	Overloaded. Initializes a new instance of the OracleEBSConnectionUri class.

Top

Public Properties

Name	Description
 DataSourceName	Gets or sets the Oracle data source name.
 PortNumber	Gets or sets the Oracle Net listener port.
 SampleUriString	Overridden. Gets formatted URI string.
 SecureUriString	(inherited from ConnectionUri)
 ServerAddress	Gets or sets the name or IP address of the server on which the Oracle E-Business Suite is running.
 ServiceName	Gets or sets the Oracle database service name.
 ServiceType	Gets or sets the Oracle service type. The possible values are Dedicated or Shared.
 Uri	Overridden. Gets or sets the connection URI.

Top

Public Methods (see also [Protected Methods](#))

Name	Description
 Equals	Overloaded. (inherited from Object)
 GetAttributes	(inherited from ConnectionUri)
 GetClassName	(inherited from ConnectionUri)
 GetComponentName	(inherited from ConnectionUri)
 GetConverter	(inherited from ConnectionUri)
 GetDefaultEvent	(inherited from ConnectionUri)
 GetDefaultProperty	(inherited from ConnectionUri)
 GetEditor	(inherited from ConnectionUri)
 GetEvents	Overloaded. (inherited from ConnectionUri)
 GetHashCode	(inherited from Object)
 GetProperties	Overloaded. (inherited from ConnectionUri)

Gets or sets the name or IP address of the server on which the Oracle E-Business Suite is running.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<CategoryAttribute("Connect Descriptor")> _
Public Property ServerAddress As String
```

C#

```
[CategoryAttribute("Connect Descriptor")]
public string ServerAddress { get; set; }
```

C++

```
[CategoryAttribute(L"Connect Descriptor")]
public:
property String^ ServerAddress {
String^ get ();
void set (String^ value);
}
```

J#

```
/** @property */
/** @attribute CompilerGeneratedAttribute() */
public String get_ServerAddress ()

/** @property */
/** @attribute CompilerGeneratedAttribute() */
public void set_ServerAddress (String value)
```

JScript

```
CompilerGeneratedAttribute
public function get ServerAddress () : String

CompilerGeneratedAttribute
public function set ServerAddress (value : String)
```

Property Value

The name or IP address of the server on which the Oracle E-Business Suite is running.

Thread Safety Any public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

Platforms

Development Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of

Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

Target Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

OracleEBSConnectionUri.ServiceName Property

Gets or sets the Oracle database service name.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<CategoryAttribute("Connect Descriptor")> _
Public Property ServiceName As String
```

C#

```
[CategoryAttribute("Connect Descriptor")]
public string ServiceName { get; set; }
```

C++

```
[CategoryAttribute(L"Connect Descriptor")]
public:
property String^ ServiceName {
String^ get ();
void set (String^ value);
}
```

J#

```
/** @property */

public String get_ServiceName ()

/** @property */
/** @attribute CompilerGeneratedAttribute() */
public void set_ServiceName (String value)
```

JScript

```
CompilerGeneratedAttribute
public function get ServiceName () : String

CompilerGeneratedAttribute
public function set ServiceName (value : String)
```

Property Value

The Oracle database service name.

Thread Safety Any public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

Platforms

Development Platforms

The 32-bit and 64-bit editions of Windows Server 2003 R2 (except the Web Editions); The 32-bit and 64-bit editions of

Windows Server 2003 with SP2 (except the Web Edition); The 32-bit and 64-bit editions of Windows Server 2008 (except the Web Editions); The 32-bit and 64-bit editions of Windows Vista Ultimate, Enterprise, and Business editions; The 32-bit and 64-bit editions of Windows XP Professional with SP3; Windows Small Business Server 2003 with SP1 or SP2; Windows Small Business Server 2008

Target Platforms

[OracleEBSConnectionUri Class](#)

[OracleEBSConnectionUri Members](#)

[Microsoft.Adapters.OracleEBS Namespace](#)

OracleEBSConnectionUri.ServiceType Property

Gets or sets the Oracle service type. The possible values are Dedicated or Shared.

Namespace: Microsoft.Adapters.OracleEBS

Assembly: Microsoft.Adapters.OracleEBS (in microsoft.adapters.oracleebs.dll)

Syntax

VB

```
'Declaration

<CategoryAttribute("Connect Descriptor")> _
Public Property ServiceType As OracleServiceType
```

C#

```
[CategoryAttribute("Connect Descriptor")]
public OracleServiceType ServiceType { get; set; }
```

C++

```
[CategoryAttribute(L"Connect Descriptor")]
public:
property OracleServiceType ServiceType {
OracleServiceType get ();
void set (OracleServiceType value);
}
```

J#

```
/** @property */
/** @attribute CompilerGeneratedAttribute() */
public OracleServiceType get_ServiceType ()

/** @property */
/** @attribute CompilerGeneratedAttribute() */
public void set_ServiceType (OracleServiceType value)
```

JScript

```
CompilerGeneratedAttribute
public function get ServiceType () : OracleServiceType

CompilerGeneratedAttribute
public function set ServiceType (value : OracleServiceType)
```

Property Value

One of the enumeration values of the [OracleServiceType](#). The default is Dedicated.

Remarks

A dedicated service uses a dedicated server process to serve only one user process. A shared service uses a shared server process that can serve multiple user processes.

Thread SafetyAny public static (**Shared** in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

	Samples Samples demonstrating how to use the Microsoft BizTalk Adapter for Siebel eBusiness Applications.
	Community Resources Information about how to get assistance with the BizTalk Adapter Pack.

Getting Started

This section provides an overview of the adapter, prerequisites, and topics for users who are new to the Microsoft BizTalk Adapter Pack. It discusses the features of Microsoft BizTalk Adapter for Siebel eBusiness Applications and the different operations that can be performed on the Siebel system using the adapter.

What is an adapter? An adapter is a software component that enables you to send and receive messages to and from a line-of-business (LOB) system. The primary design goal of adapters is to facilitate the exchange of business documents between trading partners. Because each business system may adhere to specific document formats and protocols, the adapter must use a delivery mechanism that conforms to commonly recognized standards and protocols.

The adapters can be divided into two broad categories:

- **LOB adapters.** Such adapters provide a service-oriented programming model to access LOB systems—for example, adapters for SAP or Siebel.
- **Data adapters.** Such adapters provide a service-oriented programming model to access databases—for example, an adapter for the Oracle database or SQL Server.

There are five adapters in the BizTalk Adapter Pack:

- Microsoft BizTalk Adapter for SQL Server (the SQL adapter)
- Microsoft BizTalk Adapter for Oracle E-Business Suite (the Oracle E-Business adapter)
- Microsoft BizTalk Adapter for Oracle Database (the Oracle Database adapter)
- Microsoft BizTalk Adapter for mySAP Business Suite (the SAP adapter), including .NET Framework Data Provider for mySAP Business Suite (Data Provider for SAP)
- Microsoft BizTalk Adapter for Siebel eBusiness Applications (the Siebel adapter), including .NET Framework Data Provider for Siebel eBusiness Applications (Data Provider for Siebel)

Note

The Siebel adapter is not available for 64-bit platforms.

If you do not already know how you want to use the Siebel adapter at your company, it is recommended that you start by exploring the features and functionality of the adapter described in [Overview of BizTalk Adapter for Siebel eBusiness Applications](#).

In This Section

- [Common Developer Tasks](#)
- [Understanding BizTalk Adapter for Siebel eBusiness Applications](#)
- [Siebel Adapter Tutorials](#)
- [Community Resources](#)
- [Frequently Asked Questions](#)

Prerequisite Skills and Knowledge

The potential users for the BizTalk Adapter Pack are:

- Developers who directly program to the adapters.
- IT professionals who consume the adapters using other integration platforms like Microsoft BizTalk Server and other tools.
- Independent software vendors (ISVs) who build solutions on top of the adapters.

The prerequisite skills and knowledge required for each role are detailed below.

Prerequisites for Developers

A developer using Microsoft BizTalk Adapter for Siebel eBusiness Applications must be at least moderately experienced with the use of:

- Microsoft Visual Studio 2010, with the development of .NET solutions
- Programming with the .NET Framework 3.5 SP1 and .NET Framework 4
- Programming with the Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK
- Extensible Markup Language (XML)
- XML Schema definition (XSD) language
- Web Services Description Language (WSDL)

Prerequisites for IT Professionals

An IT professional using the Siebel adapter must be at least moderately experienced with the use of:

- SQL Server Integration Services (SSIS)
- Microsoft BizTalk Server 2010
- Windows SharePoint Services

Prerequisites for ISVs

ISVs using the Siebel adapter must be at least moderately experienced with:

- The internal workings and concepts of Siebel to be able to build applications on top of the adapters
- The .NET Framework 3.5 SP1 and .NET Framework 4
- The WCF LOB Adapter SDK

Understanding BizTalk Adapter for Siebel eBusiness Applications

The BizTalk Adapter Pack enables service-oriented programmatic access in order to interact with an external system. The adapters provide the following advantages to clients:

- **Consistent design-time experience.** The adapters provide a common and user-friendly design time experience for browsing, searching, and retrieving metadata of LOB artifacts.
- **Varied programming options.** The adapters provide a choice of programming model including Windows Communication Foundation (WCF) channel model, WCF service model, ADO.NET, Web services, or BizTalk supported models.
- **Uniform experience across LOBs.** The adapters standardize on using the WCF and Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK and hence provide a uniform experience of gaining access to any LOB system.

As mentioned, the adapters are built on top of the Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK. The WCF LOB Adapter SDK provides a common basis for building integration adapters that a variety of client applications such as BizTalk Server and Microsoft Office can consume. The WCF LOB Adapter SDK aligns the adapter strategy with the Microsoft Services strategy by exposing integration adapters as Windows Communication Foundation (WCF) channels. For more information about the WCF LOB Adapter SDK, see the WCF LOB Adapter SDK documentation. The documentation is installed along with the WCF LOB Adapter SDK, typically under <installation drive>:\Program Files\WCF LOB Adapter SDK\Documents.

To perform operations on a Siebel system, adapter clients must have access to business services exposed by the Siebel system. A Siebel application exposes data as business components and business objects. A Siebel *business component* is a logical entity that associates columns from one or more tables into a single structure. A Siebel *business object* implements a business model by tying together a set of interrelated business components. With the Microsoft BizTalk Adapter for Siebel eBusiness Applications, adapter clients can surface Siebel business objects and business components.

The Siebel adapter also includes the .NET Framework Data Provider for Siebel eBusiness Applications (Data Provider for Siebel). The Data Provider for Siebel provides an ADO interface to a Siebel system by extending ADO.NET interfaces.

This section discusses the features of the Siebel adapter and the Data Provider for Siebel.

Overview of BizTalk Adapter for Siebel eBusiness Applications

The Microsoft BizTalk Adapter for Siebel eBusiness Applications exposes the Siebel system as a WCF service. Adapter clients can perform operations on the Siebel system by exchanging SOAP messages with the adapter. The adapter consumes the WCF message and makes appropriate calls to the Siebel system to perform the operation. The adapter returns the response from the Siebel system back to the client in the form of SOAP messages.

The Siebel adapter surfaces metadata of Siebel artifacts (business components, business services) that describes the structure of a SOAP message in the form of WSDL. The Siebel adapter uses the Add Adapter Service Reference Visual Studio Plug-in and Consume Adapter Service BizTalk Project Add-in to enable adapter clients to retrieve metadata for operations and generates programming artifacts that can be used in your programming solution.

The Siebel adapter uses the Siebel COM Data Control to access the Siebel system. The Siebel COM Data Control comes bundled with the Siebel Web client. Hence, make sure you have the Siebel Web client installed on the same computer as the Siebel adapter. You can use the Siebel adapter to communicate with the Siebel system in the following ways:

- By developing BizTalk applications. See [Developing BizTalk Applications](#).
- By using the WCF service model. See [Developing Applications by Using the WCF Service Model](#).
- By using the WCF channel model. See [Developing Applications by Using the WCF Channel Model](#).

How Does the Adapter Connect to a Siebel System?

The Siebel adapter requires adapter clients to provide a connection string, called the connection Uniform Resource Identifier (URI), to connect to a Siebel system. With a connection URI, adapter clients can specify connection parameters to connect to an external system. For more information about the connection URI, see [Establishing a Connection to the Siebel System](#).

Make sure you comply with the security guidelines when establishing a connection with the Siebel system. For more information about security guidelines, see [Security and Protection](#).

Concepts

[Overview of BizTalk Adapter for Siebel eBusiness Applications](#)

How Does the Adapter Surface Siebel Metadata?

The Siebel adapter surfaces metadata from the Siebel system that describes the message structure for communicating with a Siebel system using the adapter. The Siebel adapter supports two interfaces for retrieving metadata.

- MetadataExchange provided by Windows Communication Foundation (WCF). WCF provides a metadata-exchange endpoint for all WCF bindings, which enables clients to get metadata from the Siebel system.
- IMetadataRetrievalContract provided by the Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK, which supports the metadata browsing and searching capabilities of the adapter.

The goal of the Microsoft BizTalk Adapter for Siebel eBusiness Applications is to expose the Siebel system as a WCF service. The adapter surfaces Siebel artifacts (business objects and business services) as operations that adapter clients can invoke.

Adapter clients can browse, search, and retrieve metadata by using the WCF service model, by using the WCF channel model, or by creating a BizTalk project in Visual Studio. When using the WCF service model, you must use the Add Adapter Service Reference Visual Studio Plug-in to generate the proxy classes for performing operations on the Siebel system. When using a BizTalk project, you must use the Consume Adapter Service BizTalk Project Add-in to generate metadata for the operations that you want to perform on the Siebel system. For more information about browsing, searching, and retrieving metadata using the Add Adapter Service Reference Plug-in or the Consume Adapter Service Add-in, see [Retrieving Metadata for Siebel Operations in Visual Studio](#).

Browsing Metadata

The Siebel adapter enables adapter clients to browse the business objects and business services exposed by the Siebel system. As part of the metadata browse operation, the adapter categorizes the artifacts into multiple logical levels and exposes a hierarchical view of metadata to the adapter clients. Metadata from a Siebel system is categorized under the following nodes:

- **Business Objects.** This node contains the business objects in a Siebel system, which is a logical collection of business components. The business objects are further categorized as business components. At the lowest level of the hierarchy are the operations that you can invoke on the business components.
- **Business Services.** This node contains the business services exposed by a Siebel system. A Siebel business service is a collection of business service methods or functions that can be directly invoked in the Siebel system.

For more information about how the metadata is categorized, see [Metadata Node IDs](#).

Searching Metadata

The Siebel adapter enables adapter clients to search metadata in a Siebel system. It does this by using valid Siebel search expressions compatible with Siebel's LIKE operator on the [Name] field of the Siebel repository business component used for metadata browsing. The following table lists the Siebel artifacts and the metadata hierarchy under which they can search.

Artifact	Searches under the node in the GUI
Business Object	/Business Objects
Business Component	/Business Objects/Business Object Name
Business Service	/Business Services

The following table lists the special characters that can be used for search and their interpretation by the Siebel adapter.

Special character	Interpretation
? (question mark)	Matches exactly one character. For example, A? matches AB, AC, AD

* (asterisk)	Matches zero or more characters. For example, A* matches A, AB, ABC.
--------------	---

Retrieving Metadata

When retrieving metadata, the Siebel adapter can extract metadata under a schema, including all or a subset of business objects or business services with the respective operation parameters. It presents the entities from the Siebel system as element names in XML. The Siebel adapter enables adapter clients to retrieve metadata for the Siebel system, including detailed metadata characteristics:

- For business components, the Siebel adapter retrieves such items as the business object name, business component name, the field names, data types, field lengths, mandatory field, optional field, and picklist field. The adapter also retrieves the operations possible on the business component such as INSERT, UPDATE, DELETE, and QUERY.
- For business service methods, the Siebel adapter retrieves such items as the business service name, the method name (same as operation), method parameters, and parameter data types.

For more information about retrieving the metadata, see [Retrieving Metadata for Siebel Operations in Visual Studio](#).

What Operations Can be Performed Using the Adapter?

Adapter clients can perform operations on the Siebel system by either:

- Creating BizTalk projects.
- Using the WCF channel model.
- Using the WCF service model.

The Siebel adapter exposes operations that applications can invoke on it and that it can, in turn, invoke on applications. These operations are invoked by sending SOAP messages over a channel. If a response is required, it is returned in a SOAP message over the same channel. For information about the message structure and the SOAP action associated with each operation, see [Messages and Message Schemas for BizTalk Adapter for Siebel eBusiness Applications](#).

This section provides information about the operations supported on the Siebel system using the Siebel adapter.

Note

The Siebel adapter does not support receiving inbound calls from a Siebel system.

Concepts

[Overview of BizTalk Adapter for Siebel eBusiness Applications](#)

Operations on Business Components

A Siebel business component is a logical entity that associates columns from one or more database tables into a single structure. Adapter clients can perform the following operations on the Siebel business components by using the adapter:

- **Insert.** Adapter clients can insert one or more records into a business component.
- **Query.** Adapter clients can query one or more records from a business component. This operation takes the following parameters as input:
 - SearchExpr: Contains a search expression. All records under a specified business component are compared against this search expression, and matching records are returned to the adapter client.
 - SortSpec: If there are multiple records that match the search expression, this specification determines the order in which records are returned. This parameter is optional.
 - QueryFields: Enables adapter clients to retrieve values for only a subset of fields in returned records. This parameter is optional.

Note

The Siebel adapter supports using original names in the QueryField parameter in the Query operation on the business component

- **Update.** Adapter clients can update one or more records in a business component.
- **Delete.** Adapter clients can delete one or more records in a business component by specifying a set of IDs or by providing a search expression.

Note

In addition to other parameters the Query, Update, and Delete operations also take a ViewMode parameter. This parameter takes an integer that determines the access permissions of the user. For more information about the ViewMode parameter and the other parameters for these operations, see the request message for business component operations under [Message Schemas for Business Component Operations](#).

For information about:

- Performing operations on business components using BizTalk Server, see [Performing Operations on Business Components Using BizTalk Server](#).
- Performing operations on business components using the WCF service model, see [Performing Operations on Business Components by Using the WCF Service Model](#).
- Performing Operations on business components using the WCF channel model, see [Performing Operations on Business Components by Using the WCF Channel Model](#).
- Performing operations on business components using message structures and SOAP actions, see [Message Schemas for Business Component Operations](#).

Operations on Business Components with MVG Fields

A Siebel business component can also retrieve fields from other business components using joins or multivalued groups (MVG). In addition to the Insert, Query, Update, and Delete operations that are surfaced for all business components, adapter clients can perform the following operations on the Siebel business components by using the adapter:

- **Associate.** Adapter clients can associate records by specifying search expressions for parent and child records. This is applicable only for business components with MVG fields. The search expressions should filter exactly one record for both the parent and child business components.
- **Disassociate.** Adapter clients can dissociate records by specifying search expressions for parent and child records. This is applicable only for business components with MVG fields. The search expressions must filter exactly one record for both the parent and child business components.
- **Query_[MVG_Child_Business_Comp].** Adapter clients can query the child records that are associated with a parent record by specifying the parent record and the MVG field name. This is applicable only for business components with MVG fields.

 **Note**

In addition to other parameters, these operations also take a ViewMode parameter. This parameter takes an integer that determines the access permissions of the user. For more information about the ViewMode parameter and the other parameters for these operations, see the request message for business component operations under [Message Schemas for Business Component Operations](#).

For more information about:

- Performing these operations on business components using BizTalk Server, see [Performing Operations on Business Components with MVG Fields Using BizTalk Server](#).
- Performing these operations on business components using WCF service model, see [Performing Operations on Business Components with MVG Fields by Using the WCF Service Model](#).
- Message structures and SOAP actions for these operations, see [Message Schemas for Business Component Operations](#).

Operations on Business Components with Picklist Fields

Picklist field types in business components constitute a collection of values from which users can pick specific values to pass to the Siebel system. The Siebel adapter supports operations on a business component with picklist fields. The operations on business components containing picklist fields are the same as operations on any other business component, as described in the preceding paragraph. However, depending on the kind of picklist, the input values to the business component may vary. For more information about picklists and their types, refer to Siebel documentation.

One of the picklist types, static bounded picklists, are surfaced by the adapters as an enumerated picklist type in the metadata generated by the adapter at design time. This contains a static set of values that must be specified for the picklist type at run time. While specifying a value for a static bounded picklist, you must always specify a value that belongs to the set.

The message structure to perform operations on business components with picklist fields is similar to the message structures for operations on any other business component, as described in [Message Schemas for Business Component Operations](#).

For more information about:

- Message structures for business components containing picklist fields, see [Message Schema for Picklist Operations](#).
- Performing operations on a business component that contains picklist fields, see [Performing Operations on Business Components with Picklist Fields Using BizTalk Server](#).

[What Operations Can be Performed Using the Adapter?](#)

Operations on Business Services

A Siebel business service is a collection of business methods that can be directly invoked in Siebel. Whereas business components and business objects are associated to specific data and tables in Siebel, business services invoke the objects to perform specific tasks.

The Siebel adapter surfaces the business service methods as operation names and supports IN, OUT, and INOUT parameters. For example, the Siebel adapter surfaces the **ATPRunCheck** method as an operation. This method belongs to the **ATP** business service.

Certain conditions that the Siebel adapter imposes while using the Siebel business services:

- If a Siebel business service method takes an argument that does not have the data type specified, the adapter exposes the argument as TEXT.
- A Siebel business service method argument can be of the following types:
 - String (exposed as xsd:string)
 - Number (exposed as xsd:decimal)
 - Date (exposed as xsd:DateTime, with pattern facet indicating that time part must be set to 00:00:00)
 - Hierarchy (exposed as xsd:string)
 - Integration Object (exposed as xsd:string)

Also, the business service method verifies whether the value passed for an argument complies with the corresponding type. So, if a business service method accepts or returns values that do not comply with the corresponding argument type, the adapter may throw an exception. If the adapter does succeed in invoking the business service method, the schema validation may fail.

For information about:

- Performing operations on business services using BizTalk Server, see [Invoking Business Service Methods Using BizTalk Server](#).
- Message structures and SOAP actions to perform operations on business services, see [Message Schemas for Business Service Operations](#).

[What Operations Can be Performed Using the Adapter?](#)

Other Features Supported by the Adapter

In addition to the features discussed throughout the topics of [Overview of BizTalk Adapter for Siebel eBusiness Applications](#), the Siebel adapter provides the following features that are useful for adapter clients:

- **Support for configuring adapters using binding properties.** Adapter clients can configure the Siebel adapter by specifying certain binding properties while generating the metadata. For more information, see [Working with BizTalk Adapter for Siebel Binding Properties](#).
- **Support for null values for operation parameters.** The Siebel adapter enables adapter clients to provide null values for business object operation parameters using the XSD "nillable" attribute. The adapter does not pass fields with null values to the Siebel system.
- **Support for XML data streaming.** Adapter clients can stream data from or to the Siebel adapter by using the **XMLReader** or **XMLWriter** interfaces.
- **Support for dynamic ports in BizTalk Server.** Through the BizTalk WCF-Custom adapter, the Siebel adapter supports a dynamic port that enables dynamic routing of messages from BizTalk Server based on the message context properties. For more information, see [Configuring Dynamic Ports](#).
- **Support for message versioning.** The Siebel adapter supports message versioning. This enables support for different message schemas in future releases of the BizTalk Adapter Pack. For more information, see [Message Versioning Support](#).
- **Support for performance counters.** The Siebel adapter supports WCF-based performance counters that adapter clients can use. For more information about performance counters, see [Using Performance Counters](#).

Note

This feature does not provide backward compatibility with the earlier versions of the adapter.

- **Support for encoding XML element names.** The Siebel adapter presents entities from enterprise applications as element names in XML. Underscores are the only special characters that can be included in the element names. Therefore, underscores are used to encode element names with special characters. For example, `emp$name` is encoded to `emp_x0024_name`.

New Features in the Siebel Adapter

This section lists the new features in Microsoft BizTalk Adapter for Siebel eBusiness Applications.

New Features in the Siebel Adapter

The following are the new features introduced in this release of the Siebel adapter.

Technology-Related Features

Feature	Comment
Support for using the Siebel adapter with Microsoft Office SharePoint Server (MOSS)	You can use the adapters to present data from the Siebel system onto a MOSS portal. For more information, see Using the Siebel Adapter with Microsoft Office SharePoint Server .

Operations-Related Features

Feature	Comment
Support for ASSOCIATE operation on business components	Adapter clients can associate records by specifying search expressions for parent and child records. This is applicable only for business components with multivalued group (MVG) fields. Note that the search expressions should filter exactly one record for both the parent and child business components.
Support for DISSOCIATE operation on business components	Adapter clients can dissociate records by specifying search expressions for parent and child records. This is applicable only for business components with multivalued group (MVG) fields. Note that the search expressions must filter exactly one record for both the parent and child business components.
Support for multivalued link queries	Adapter clients can query the child records associated with a parent record by specifying the parent record and the multivalued field name. This is applicable only for business components with multivalued group (MVG) fields.

Other Features

Feature	Comment
New way of using the adapter in BizTalk Server	The Siebel adapter can be used in BizTalk either as a WCF-Custom port or a WCF-Siebel port. If you want to use the Siebel adapter through a WCF-Custom port, you do not need to add the WCF-Custom port to the BizTalk Server Administration console because the WCF-Custom port is added to the BizTalk Server Administration console by default. However, if you want to use the Siebel adapter through a WCF-Siebel port, you must first add the WCF-Siebel adapter to the BizTalk Server Administration console. For more information, see Adding the Siebel Adapter to BizTalk Server Administration Console .

[Understanding BizTalk Adapter for Siebel eBusiness Applications](#)

Limitations of BizTalk Adapter for Siebel eBusiness Applications

The following are known limitations of the Microsoft BizTalk Adapter for Siebel eBusiness Applications:

- The Siebel adapter is not compatible with Microsoft BizTalk Adapter 2.0 for Siebel eBusiness Applications, the previous release of the adapter. The current release of the adapter does not support sending and receiving messages that have schemas generated by using the earlier version of the adapter.

Note

You can modify the BizTalk projects for previous version of the Siebel adapter to use the new WCF-based Siebel adapter. For more information, see [Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#).

- The Siebel adapter does not support workflow objects.
- The Siebel adapter does not validate the format in which a client passes a time value to the Siebel system. Adapter clients must make sure that the value specified for a date and time field adheres to a format in which the Siebel system expects.
- The Siebel adapter does not perform schema validation. For example, a field of length 30 can take values with length 100, if allowed by the Siebel system. It can also lead to a loss of data in certain scenarios because the data that the client inserts through business objects might not necessarily be the data that is actually written to the database. Adapter clients must explicitly validate the input against the schema that is surfaced by the adapter. However, the Siebel adapter does validate that all required fields (for business components) or arguments (for business services) are specified.
- The Siebel adapter expects the time values to be specified in standard Siebel format—that is HH:MM:SS. Time values that are specified in any other format will produce an error, and the Siebel adapter throws a `TargetSystemException`.
- In certain scenarios, the Siebel application might or might not throw an error message. For example, a search operation using an expression might either throw an exception or return zero records. Accordingly, the Siebel adapter might throw a `TargetSystemException` or get an empty XML as the output.
- While retrieving data from the Siebel system using the WCF service model, the Siebel adapter does not deserialize XMLs having more than 65536 nodes. Make sure the output XML has nodes less than or equal to 65536. You can work around this limitation by modifying the app.config file for your application. For instructions, see [Troubleshooting Operational Issues](#).
- The Siebel adapter retrieves the maximum length for a field from the business component layer, as opposed to the database layer. So, if you try to insert a value that complies with the maximum length of the database column, but which is greater than the maximum length of the corresponding field for a business component, the value written to the database might be different from the value you wanted to enter.
- While performing batch operations (Insert, Update, and Delete), the Siebel adapter throws an error if the first operation results in an error. However, if the first operation succeeds and any of the subsequent operations fail, the adapter does not throw an error but rather returns the IDs for records that correspond to the successful operations in the output. Adapter clients must explicitly verify whether all the operations have been successful.
- Due to issues with timeout handling by the underlying Siebel client API, the Siebel adapter does not support command and connection timeout.
- Consider a scenario where user "A" generates the metadata for an operation in Siebel. Another user "B", having lesser privileges than user "A," will be able to access the metadata. The Siebel adapter does not perform any checks to validate whether user "B" must get access to the metadata. However, because of insufficient privileges, user "B" might not be able to execute any operation on the Siebel system by using the metadata.

- The Siebel adapter does not support specifying a connection URI that has special characters for any of the parameter values. For each parameter value that contains special characters, make sure you replace the special characters with the corresponding values, as specified by the URI encoding standards.
- When using the adapters with BizTalk Server, if the credentials on the WCF-Custom send port are incorrect, the request messages are not processed. After you specify the correct credentials, the message is sent to the Siebel system, and a response is received. However, the response message is not available to the out port. In such scenarios, you might need to restart the host instance.

About the Data Provider for Siebel

This section lists the various uses of the .NET Framework Data Provider for Siebel eBusiness Applications (Data Provider for Siebel). For instructions about how to use the Data Provider for Siebel, see [Using the .NET Framework Data Provider for Siebel eBusiness Applications](#).

The Data Provider for Siebel is built on top of the Microsoft BizTalk Adapter for Siebel eBusiness Applications. You can use the Data Provider for Siebel in the following ways:

- To write an ADO.NET client to connect to the Siebel system. The Data Provider for Siebel exposes certain classes that enable you to interface with the provider.
- To perform a SELECT query on a Siebel business component.
- To perform an EXEC query on a Siebel business service.
- To use the Data Provider for Siebel with SQL Server Integration Services (SSIS).

See [Using the .NET Framework Data Provider for Siebel eBusiness Applications](#) for information about:

- The ADO.NET interfaces extended by the Data Provider for Siebel
- The connection string to connect to a Siebel system
- Syntax for the SELECT and EXEC statements
- Using the Data Provider for Siebel with SSIS

In This Section

- [Limitations of the Data Provider for Siebel](#)

Limitations of the Data Provider for Siebel

The following are known limitations of the .NET Framework Data Provider for Siebel eBusiness Applications:

- The Data Provider for Siebel supports alias names for tables in the SELECT clause, but not in the WHERE clause.
- The Data Provider for Siebel fails to create a table with column names that have the special character, "]". You can escape the special character by including another closing square bracket. So, you should include"]]" instead of "]".
- Due to issues with timeout handling by the underlying Siebel client API, the Data Provider for Siebel does not support command and connection timeout.
- The Data Provider for Siebel does not support asynchronous command behavior.
- When used with a SQL Server Integration Services (SSIS) project, the Data Provider for Siebel fails to retrieve data for columns that contain values with more than 8000 characters. This is due to an SSIS restriction according to which:
 - Values greater than 4000 characters in SSIS variable are not supported.
 - Values greater than 4000 wide characters are not supported.
 - Values greater than 8000 single-byte characters are not supported.
- The EXEC operation will not be functional while using the .NET Framework Data Provider for Siebel eBusiness Applications with SQL Server Integration Services (SSIS). So, for example, adapter clients will not be able to execute a business service in Siebel (using Data Provider for Siebel) while using the data providers with SSIS.

Siebel Adapter Tutorials

The first of the Siebel adapter tutorials contains a step-by-step demonstration of how to present data from a Siebel system on a Microsoft SharePoint portal. The second Siebel adapter tutorial contains detailed instructions on how to migrate BizTalk projects created using the previous version of the Siebel adapter to use the WCF-based Siebel adapter.

Also, the topics in the [Developing BizTalk Applications](#) section provide detailed instructions on how to use the Siebel adapter with BizTalk Server.

In This Section

[Getting Started](#)

Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site

This tutorial provides detailed instructions on using the Siebel adapter with Microsoft Office SharePoint Server to present business data from a Siebel system on a SharePoint portal. To demonstrate how to use the Siebel adapter with Office SharePoint Server, we create an application in Office SharePoint Server to retrieve a list of customer accounts from the Siebel repository using the Siebel adapter.

To extract this information from the Siebel system, the example invokes the Query method on the **Account** business components.

Note

Before proceeding with the tutorial, make sure you have installed all the prerequisites for using the Siebel adapter with Office SharePoint Server. For more information about the prerequisites, see the BizTalk Adapter Pack installation guide, typically installed at <installation drive>:\Program Files\Microsoft BizTalk Adapter Pack\Documents.

In This Section

- [Step 1: Publish the Siebel Business Component Operations as a WCF Service](#)
- [Step 2: Create an Application Definition File for Siebel Business Component Operations](#)
- [Step 3: Create a SharePoint Application to Retrieve Data from Siebel](#)
- [Step 4: Test Your SharePoint Application](#)

[Siebel Adapter Tutorials](#)

Step 1: Publish the Siebel Business Component Operations as a WCF Service

Step 1

Time to complete: 10 minutes

Objective: You can use the WCF Adapter Service Development Wizard to generate a WCF service that can be hosted in a hosting environment such as Internet Information Services (IIS) or Windows Process Activation Service (WAS). This topic demonstrates how to use the wizard to generate a WCF service file.

Prerequisites

Before running the wizard, install the following:

- Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK either with the **Complete** option or the **Custom** option (and choosing **Tools** within this option). This installs the Visual Studio template for the WCF Adapter Service Development Wizard.
- Microsoft BizTalk Adapter for Siebel eBusiness Applications
- The required Siebel client.

For more information about these prerequisites, see the BizTalk Adapter Pack installation guide. The installation guide is typically installed at <installation drive>\Program Files\Microsoft BizTalk Adapter Pack\Documents.

To publish the Siebel Business Components as a WCF Service

1. Start Visual Studio, and then create a project.
2. In the **New Project** dialog box, from the **Project types** pane, select **Visual C#**. From the **Templates** pane, select **WCF Adapter Service**.

Alternatively, from the **Project types** pane, expand **Visual C#**, and then select **Web**. From the **Templates** pane, select **WCF Adapter Service**.

 **Note**

If you installed Visual Studio 2010 with the Web Development component, the **WCF Adapter Service** template is also available from the **New Website** option.

3. Specify a name and location for the solution, and then click **OK**. The WCF Adapter Service Development Wizard starts.
4. On the Welcome page, click **Next**.
5. On the Choose Operations page, specify a connection string to connect to the Siebel system. To do so:
 - a. In the **Select a binding** list, click **siebelBinding**, and then click **Configure**.
 - b. In the **Configure Adapter** dialog box, click the **Security** tab.
 - c. In the **Client credential type** list, select **Username**, and then specify the user name and password to connect to the Siebel system.
 - d. Click the **URI Properties** tab, and then specify values for the connection parameters. For more information about the connection URI for the Siebel adapter, see [The Siebel System Connection URI](#).

 **Note**

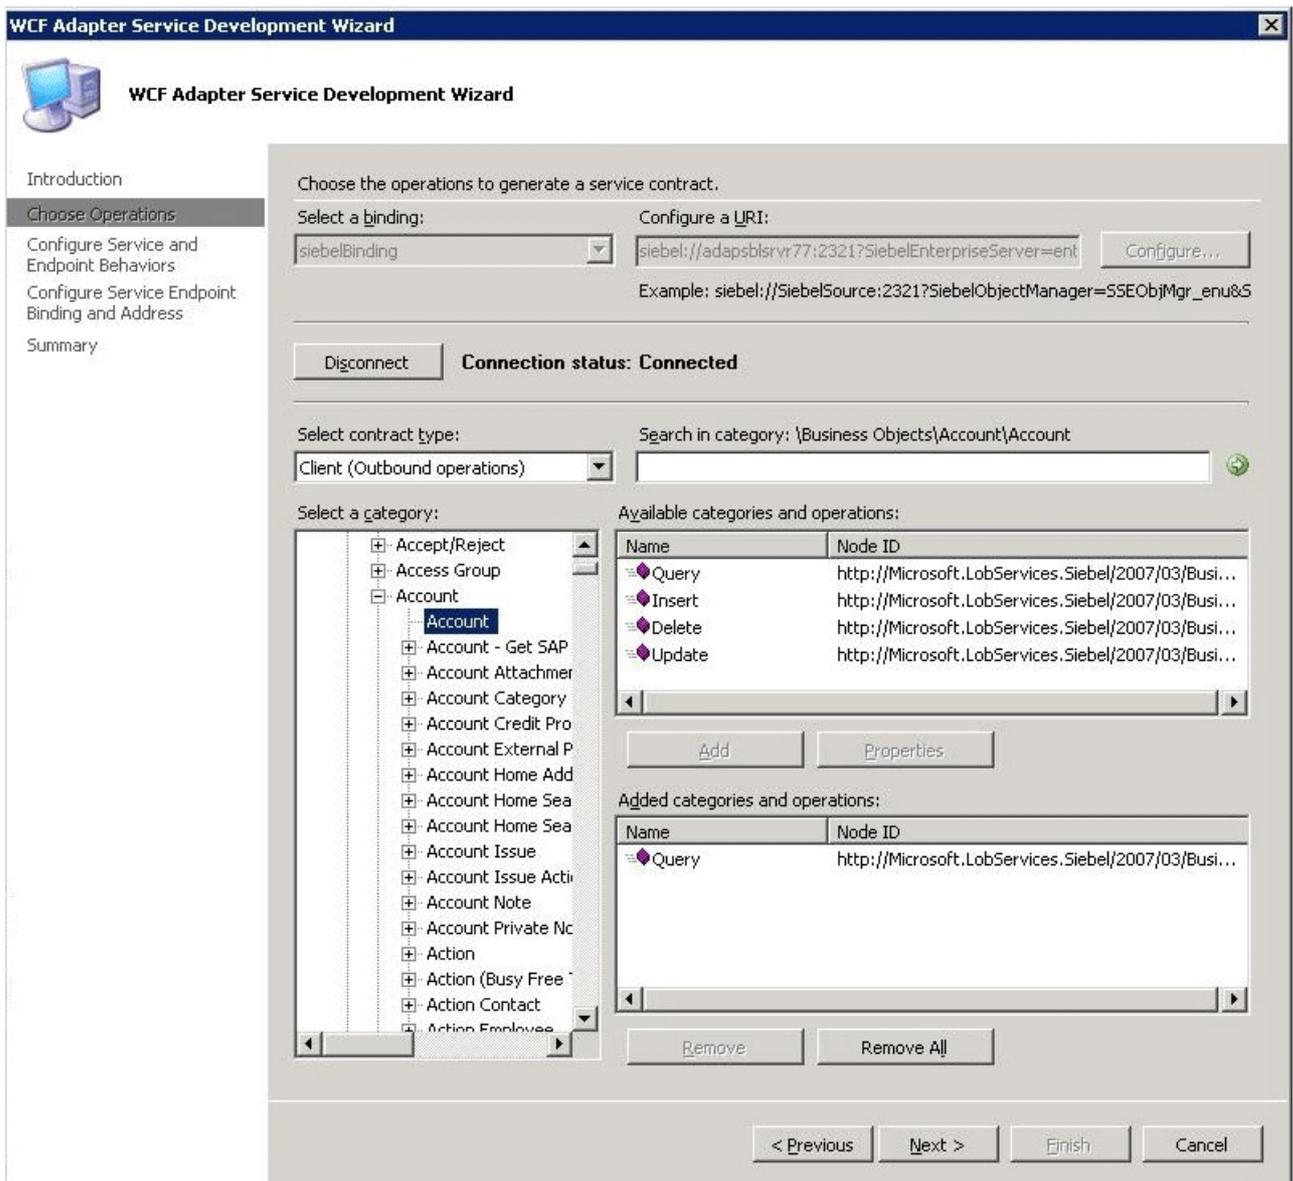

If the connection parameters contain any reserved characters (such as XML special characters), you must specify them as-is in the **URI Properties** tab, that is, without using any escape characters. However, if you specify the URI directly in the **Configure a URI** field and the connection parameters contain reserved characters, you must specify the connection parameters using proper escape characters.

- e. Click the **Binding Properties** tab, and then specify values for the binding properties, if any, required for the operations you want to target.

For more information about binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).

- f. Click **OK**, and then click **Connect**. After the connection is established, the connection status is shown as **Connected**.

- 6. On the Choose Operations page, in the **Select contract type** list, click **Client (Outbound operations)**.
- 7. In the **Select a category** box, expand the Siebel **Business Objects** node to see the list of business objects in the Siebel repository. For this example, do the following:
 - a. Expand the **Account** business object, and then click the **Account** business component.
 - b. In the **Available categories and operations** box, select the **Query** operation, and then click **Add**. The selected operation is listed in the **Added categories and operations** box.

- 8. On the Choose Operations page, click **Next**

8. On the Choose Operations page, click **Next**.

9. On the Configure Service and Endpoint Behaviors page, specify values to configure the service and endpoint behavior.

a. In the **Service Behavior Configuration** box, specify values for the following:

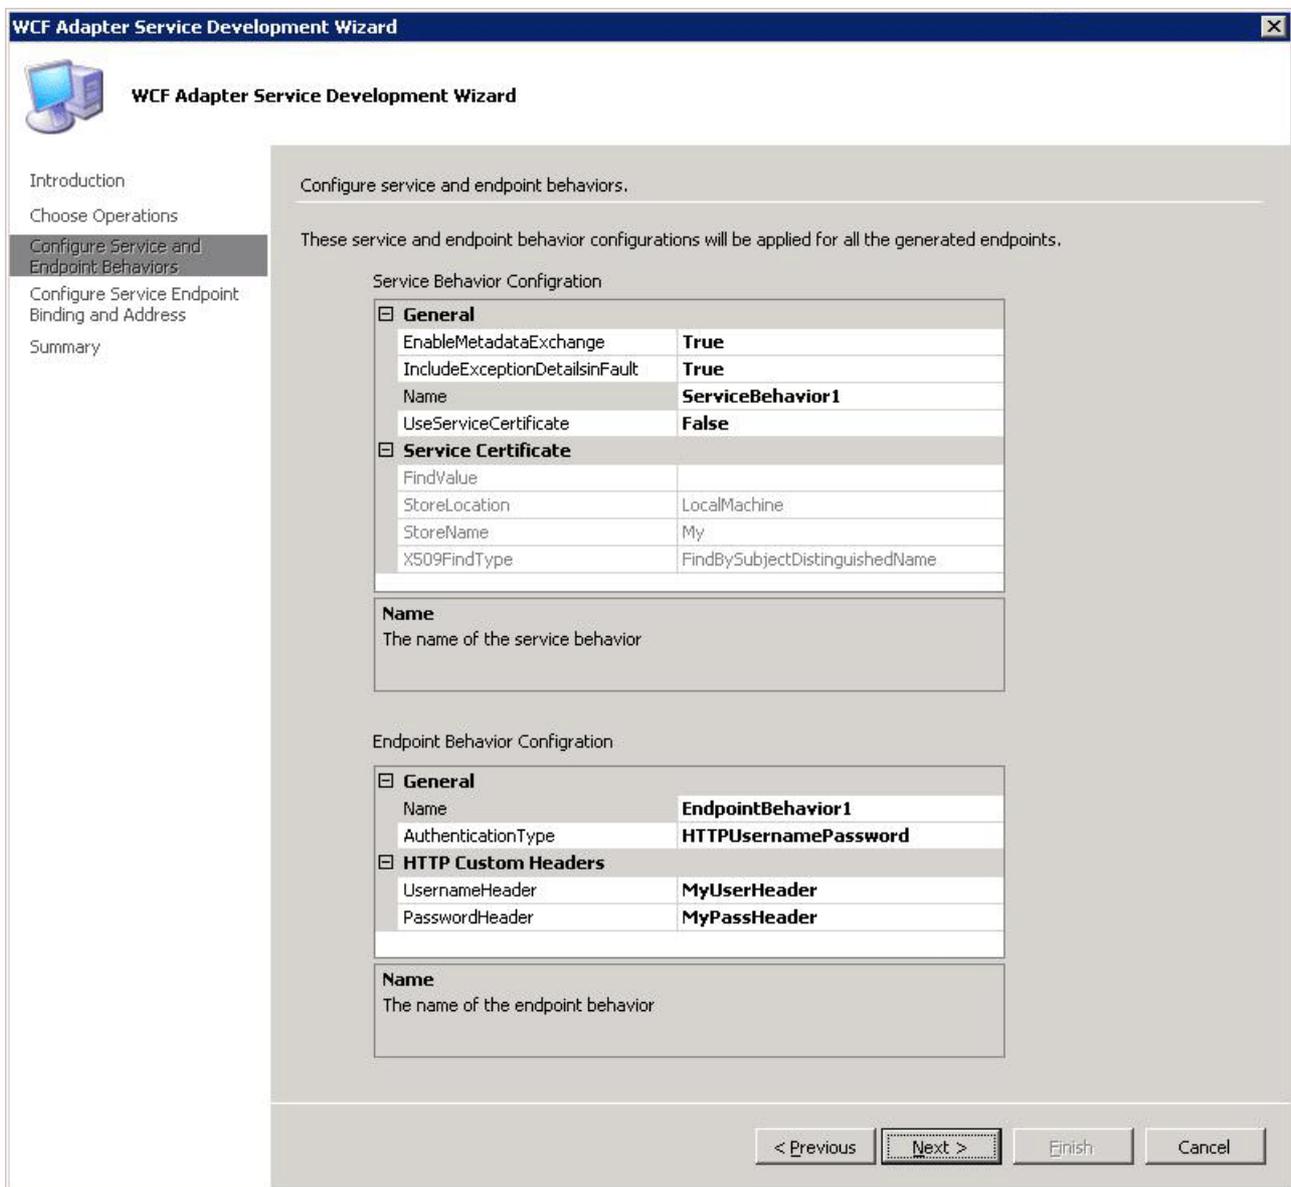

For the property	Specify the value
EnableMetadataExchange	Set this to True to create a metadata exchange endpoint. By setting this to True , you make the service metadata available using standardized protocols, such as WS-Metadata Exchange (MEX) and HTTP/GET requests. Default is False .
IncludeExceptionDetailsInFault	Set this to True to include managed exception information in detail of SOAP faults returned to the client for debugging purposes. Default is False .
Name	Name for the service behavior configuration.
UseServiceCertificate	Specifies whether you want to use the message level security mode of WCF. Default is True . For this tutorial, you must set this to False .
FindValue	A string that specifies the value to search for in the X.509 certificate store.  Note Specify a value for this property only if UseServiceCertificate is set to True .
StoreLocation	A value that specifies the location of the certificate store that the service can use to validate the client's certificate.  Note Specify a value for this property only if UseServiceCertificate is set to True .
StoreName	Name of the X.509 certificate store to open.  Note Specify a value for this property only if UseServiceCertificate is set to True .
X509FindType	The type of X.509 search to be executed.  Note Specify a value for this property only if UseServiceCertificate is set to True .
 Note	
For more information about the certificates and the associated properties, see "X509ClientCertificateCredentialsElement Properties" at http://go.microsoft.com/fwlink/?LinkId=103771 .	

b. In the **Endpoint Behavior Configuration** box, specify values for the following:

For the property	Specify the value

Authentication Type	<ul style="list-style-type: none"> • Set this to ClientCredentialUserNamePassword to enable the clients to specify the user name and password while consuming the WCF service. • Set this to HTTPUserNamePassword to enable clients to specify user name and password as part of the HTTP header. • Set this to Auto to first enable clients to specify credentials through the ClientCredential interface. If this fails, clients can pass credentials as part of the HTTP header. <p>Default is Auto. For Microsoft Office SharePoint Server to consume the WCF service, you should set this as HTTPUserNamePassword.</p>
Name	Specify a name for the endpoint behavior configuration.
UsernameHeader	<p>Name for the user name header. For this example, specify MyUserHeader. For more information about HTTP headers, see "Support for Custom HTTP and SOAP Headers" at http://go.microsoft.com/fwlink/?LinkId=106692.</p> <p> Note You must specify a value for this property if the Authentication Type is set to HTTPUserNamePassword. If Authentication Type is set to Auto, this property is optional.</p>
PasswordHeader	<p>Name for the password header. For this example, specify MyPassHeader. For more information about HTTP headers, see "Support for Custom HTTP and SOAP Headers" at http://go.microsoft.com/fwlink/?LinkId=106692.</p> <p> Note You must specify a value for this property if the Authentication Type is set to HTTPUserNamePassword. If Authentication Type is set to Auto, this property is optional.</p>

The following figure shows the Configure Service and Endpoint Behaviors page with the specified values.

10. On the Configure Service and Endpoint Behaviors page, click **Next**.
11. On the Configure Service Endpoint Binding and Address page, the **Select a contract to configure** box lists the contracts for the Siebel business components for which you selected the operations on the Choose Operations page. The **Operations under the selected contract** box displays the operations you selected for each artifact on the Choose Operations page.
12. In the **Configure the address and binding for the contract** box, specify values for the following:

For the property	Specify the value
Binding Configuration	<p>The wizard only supports basic HTTP binding. So, the binding configuration field is automatically populated to <code>System.ServiceModel.Configuration.BasicHttpBindingElement</code>.</p> <p>Click the ellipsis button (...) to change the properties for HTTP binding. To use a secure communication channel, you must always set the Mode property to Transport. The wizard sets the default value for the Mode property as Transport.</p> <p>For more information about the other bindings exposed, see "BasicHttpBindingElement Members" at http://go.microsoft.com/fwlink/?LinkId=103773.</p>
Endpoint Name	Specify an endpoint name for the contract.

The other fields on this page are automatically populated based on the values you specified in the earlier pages.

Click **Apply**. Perform this step for all the contracts displayed under the **Select a contract to configure** box.

Note

If you do not specify any values on this page, the default values are accepted for all the contracts.

The following figure shows the Configure Service Endpoint Binding and Address page with the specified values.

The screenshot shows the 'WCF Adapter Service Development Wizard' window. The left sidebar contains a navigation pane with the following steps: Introduction, Choose Operations, Configure Service and Endpoint Behaviors, **Configure Service Endpoint Binding and Address** (highlighted), and Summary. The main area is titled 'Configure the service endpoint binding and address.' It features two sections: 'Select a contract to configure:' with a list box containing 'BusinessObjects_Account_Account_Operation' (checked), and 'Operations under the selected contract BusinessObjects_...' with a list box containing 'Query'. Below these is a section titled 'Configure the address and binding for the contract BusinessObjects_Account_Account_Operation' containing a table with expandable sections: 'Binding Properties' (BindingConfiguration: System.ServiceModel.Configuration.BasicHttpBinding), 'Endpoint Details' (EndpointBehaviorConfiguration: EndpointBehavior1, EndpointName: AccountEndPoint), and 'Service Details' (ServiceBehaviorConfiguration: ServiceBehavior1, ServiceName: BusinessObjects_Account_Account_OperationClient). At the bottom of this section is an 'EndpointName' field with the label 'Endpoint name'. An 'Apply' button is located below the table. At the bottom of the wizard are four buttons: '< Previous', 'Next >', 'Finish', and 'Cancel'.

Binding Properties	
BindingConfiguration	System.ServiceModel.Configuration.BasicHttpBinding

Endpoint Details	
EndpointBehaviorConfiguration	EndpointBehavior1
EndpointName	AccountEndPoint

Service Details	
ServiceBehaviorConfiguration	ServiceBehavior1
ServiceName	BusinessObjects_Account_Account_OperationClient

EndpointName
Endpoint name

13. On the Configure Service Endpoint Binding and Address page, click **Next**. The Summary page lists a tree structure of the contracts for the selected Siebel business components and, under that, the operations selected for each business component.
14. Review the summary, and then click **Finish**.
15. The wizard creates a WCF service and adds the following files to the Visual Studio project:
 - a. .svc file. This is the WCF service file. The wizard generates one file for each contract.
 - b. Web.config file.
 - c. Service code (.cs file).
16. Publish the WCF service.
 - a. Make sure SSL is enabled for Internet Information Services (IIS). For instructions on how to enable SSL for IIS, see <http://go.microsoft.com/fwlink/?LinkId=197170>.
 - b. Right-click the project in Solution Explorer, and then click **Publish**.

- c. In the **Publish Web** dialog box, specify a URL for the WCF service. For example:

```
https://<computer_name>/Siebel_Account/
```

- d. From the **Copy** box, click **All project files**.

- e. Click **Publish**.

17. Verify that the WCF service is published successfully.

- Start the IIS Microsoft Management Console. Click **Start**, point to **Administrative Tools**, and then click **Internet Information Services**.
- Navigate to the node where you published the service. For the **Siebel_Account** service, navigate to **Internet Information Services** > <Computer Name> > **Web Sites** > **Default Web Site** > **Siebel_Account**.
- On the right pane, right-click the BusinessObjects_Account_Account_Operation.svc file, and then click **Browse**.
- The Web page shows up with the URL for retrieving the WSDL. You may want to test metadata retrieval using the svcutil command. For example, the command to retrieve metadata for the Siebel_Account service is:

```
svcutil.exe https://localhost/Siebel_Account/BusinessObjects_Account_Account_Operation.svc?wsdl
```

Next Steps

You now have a WCF service for the Siebel business component. Use the Business Data Catalog Definition Editor to create an application definition file for the Siebel business component operations. See [Step 2: Create an Application Definition File for Siebel Business Component Operations](#) for instructions. The application definition file identifies where the LOB data is stored and the format in which it is stored.

See Also

Other Resources

[Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site](#)

Step 2: Create an Application Definition File for Siebel Business Component Operations

Time to complete: 15 minutes

Objective: The Business Data Catalog exposes and incorporates data from line-of-business (LOB) applications into portals. To incorporate this data into your portal site, you must build an application definition file that Microsoft Office SharePoint Server can consume.

The Business Data Catalog Definition Editor tool enables you to create an application definition file for the Business Data Catalog. This tool automatically generates the XML for the definition file. Therefore, you do not have to manually create the file in an XML editor.

The purpose of the Microsoft Office SharePoint Server application that you are creating is to perform a Query operation on the Account business component to retrieve a list of records. To achieve this, you must complete a set of tasks in the Business Data Catalog Definition Editor. This topic provides instructions on how to perform these tasks.

Prerequisites

- You must have the Business Data Catalog Definition Editor installed as part of the Microsoft Office SharePoint Server 2007 SDK. You can download the SDK from <http://go.microsoft.com/fwlink/?LinkId=104130>.
- You should have published the WCF service, as described in [Step 1: Publish the Siebel Business Component Operations as a WCF Service](#).

Creating an Application Definition File

This section provides step-by-step instructions to create an application definition file for the WCF service.

Connect to the WCF Service, and Create Entities

You must connect to the WCF service to extract the Web Services Description Language (WSDL) for the service. From the WSDL, the Business Data Catalog Definition Editor extracts the methods. These methods can be used to create entities. For this example, you must create one entity for the Query operation on the Account business component.

To connect to the WCF service, and create entities

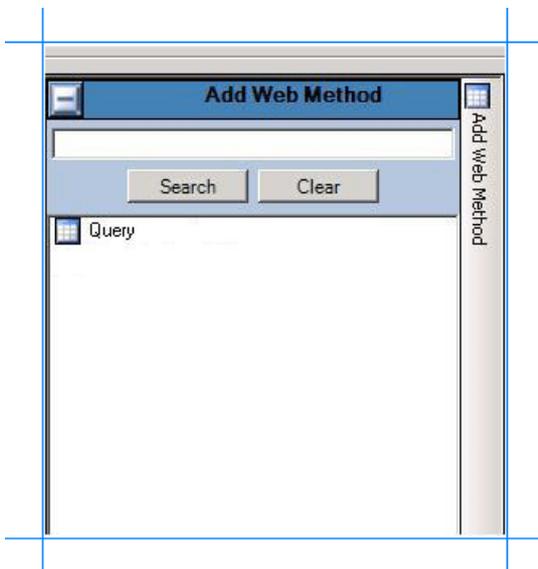

1. Start the Business Data Catalog Definition Editor. On the **Start** menu, click **Microsoft Business Data Catalog Definition Editor**.
2. In the tool, click **Add LOB System**.
3. In the Add LOB System window, click **Connect to Webservice**.
4. In the URL box, type the URL for the WCF service. The URL must be in the following format:

```
https://<computer_name>/Siebel_Account/BusinessObjects_Account_Account_Operation.svc?wsdl
```

where, BusinessObjects_Account_Account_Operation.svc is the service file created for the Siebel contract.

The URL that you must type is available when you test whether the WCF service is published successfully, as described in [Step 1: Publish the Siebel Business Component Operations as a WCF Service](#).

5. Click **Connect**.
6. Click the **Add Web Method** tab to see the operations you selected in the WCF Adapter Service Development Wizard. You will see the **Query** method.

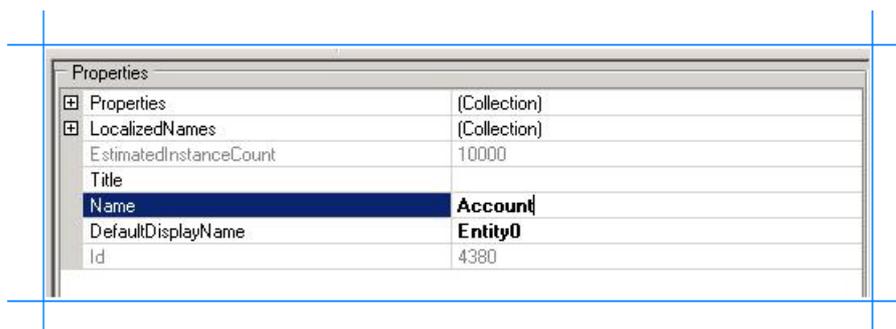

7. Drag the **Query** method to the design surface and then click **OK**.
8. In the **Enter the name for the LOB System** dialog box, type a name in the **LOB System Name** box. For this example, type **Siebel_Account**, and then click **OK**. An entity, **Entity0**, is created in the Business Data Catalog Definition Editor.

◆Important

The Business Data Catalog Definition Editor tool does not handle enumerated data types. So, the Business Data Catalog Definition Editor tool imports the fields till it encounters an enumerated data type and ignores the remaining fields. The Business Data Catalog Definition Editor tool also gives an error. You can ignore this error and proceed by clicking OK. You can manually add the required fields in the application definition file at a later stage.

9. Change the entity names to use more friendly names. For this example, change **Entity0** to **Account**.
 - a. Expand the **Siebel_Account** node, and then expand the **Entities** node.
 - b. Select the **Entity0** node.
 - c. In the Properties pane, type **Account** in the **Name** field.

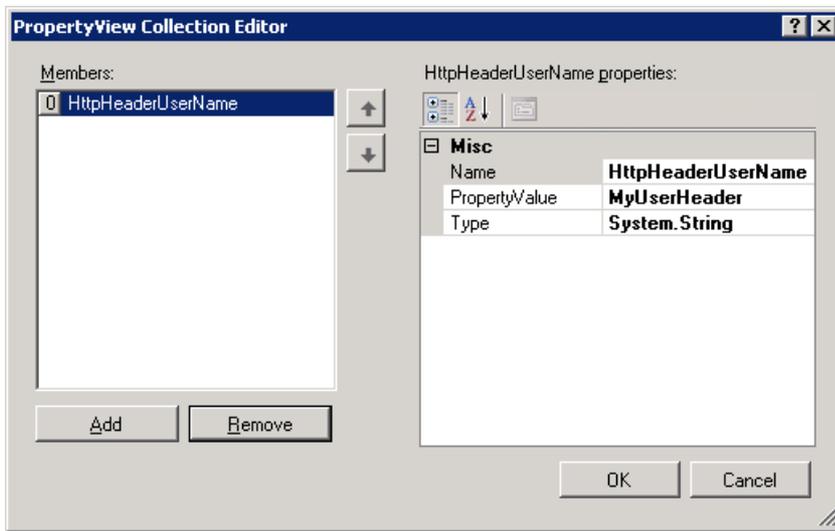

Specify User Name and Password Headers for Methods

When creating a WCF service for the selected business component operations in the Siebel system, you specified user name and password headers as part of the endpoint behavior configuration ([Step 1: Publish the Siebel Business Component Operations as a WCF Service](#)). You must specify the same values for the method properties.

To specify user name and password headers for the Query method

1. In the Metadata Objects pane, expand the **Account** node, and then expand the **Methods** node.
2. Click the **Query** node, and in the Properties pane click the ellipsis (...) button against the **Properties** field.
3. In the PropertyView Collection Editor dialog box, click **Add**, and in the Properties pane, type **HTTPHeaderUserName** for the **Name** field. Similarly, type **MyUserHeader** for the **PropertyValue** field. Select **System.String** for the **Type** field.

4. In the PropertyView Collection Editor window, click **Add**, and in the Properties pane, type **HttpHeaderPassword** for the **Name** field. Similarly, type **MyPassHeader** for the **PropertyValue** field. Select **System.String** for the **Type** field.
5. Click **OK**.

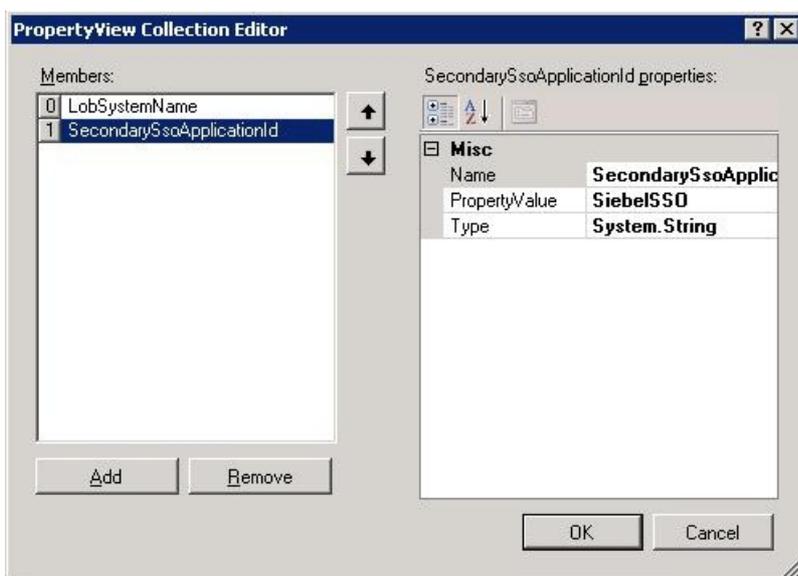

Set up Single Sign-On for Connecting to a Siebel System

After you have finished performing all the procedures in this topic, you will have created an application definition XML that can be imported into a SharePoint application. From the application, you will invoke the Siebel business component operations (exposed as Web methods) to retrieve relevant data from the Siebel system. To enable this, you must create a mapping between a user in the Siebel system and the user in the SharePoint application. You create this mapping in SharePoint Central Administration Web site after you have imported the application definition XML.

However, to create the mapping you must set a property **SecondarySsoApplicationId** in the Business Data Catalog Definition Editor.

To set the SecondarySsoApplicationId property

1. In the Metadata Objects pane, expand the **Siebel_Account** node, and then expand the **Instances** node.
2. Click **Siebel_Account_Instance** and in the Properties pane click the ellipsis (...) button against the **Properties** field.
3. In the PropertyView Collection Editor window, click **Add**, and in the Properties pane, type **SecondarySsoApplicationId** for the **Name** field. Similarly, type **SiebelSSO** for the **PropertyValue** field. Select **System.String** for the **Type** field.

4. Click **OK**.

Requirement: Perform a Query Operation on the Account Business Component

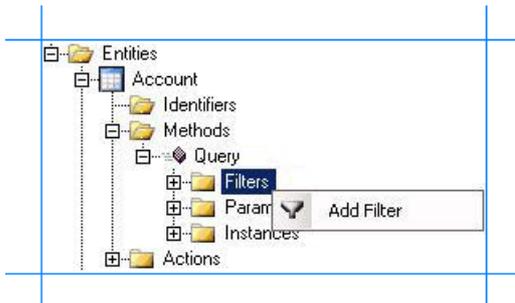

The first requirement of this example is to create an application definition that can be used to perform a Query operation on the Account business component. To achieve this requirement, you must perform the following set of tasks:

- In the Query method, create a filter, and map it to the parameter on which the Query operation is performed. For the Account business component, you will perform a query using the **SearchExpr** parameter. So, you will map the filter to the **SearchExpr** parameter.
- Create a Finder method instance for the Query method. A Finder method retrieves a list of records based on a filter.

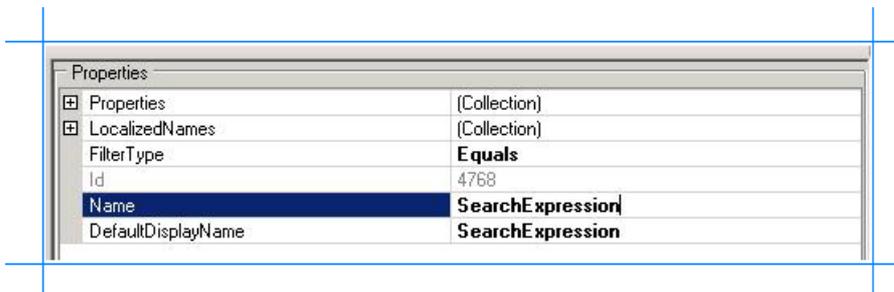

To create a filter, and map it to the SearchExpr parameter

1. Create a filter for the Query method.

- In the Metadata Objects pane, expand the **Account** node, and then expand the **Methods** node.
- Expand the Query method, right-click **Filters**, and then click **Add Filter**.

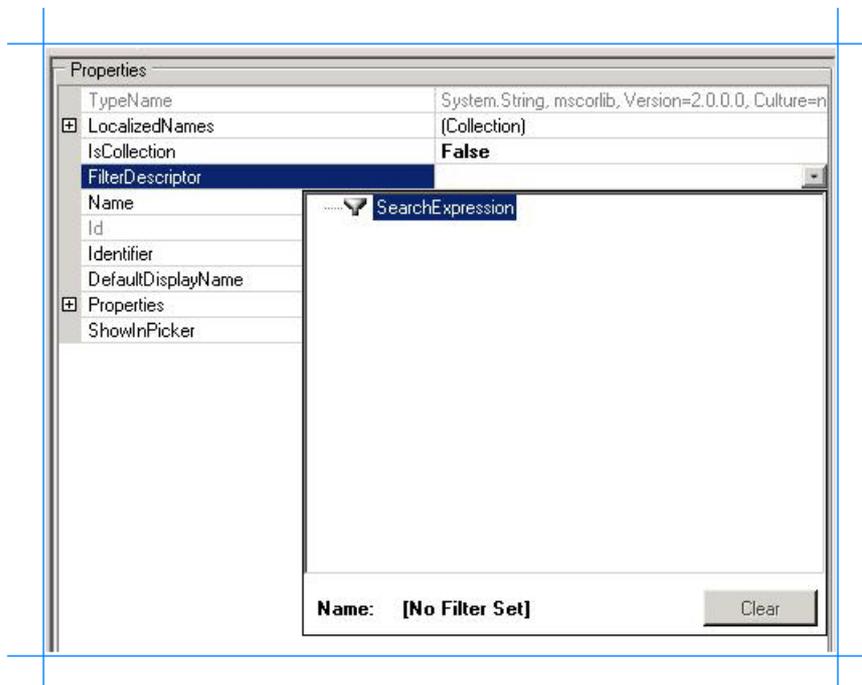

- In the Properties pane, type **SearchExpression** for the **Name** field.
- For the **FilterType** property, select **Equals**.

2. Map the filter to the **SearchExpr** parameter in the Query method.

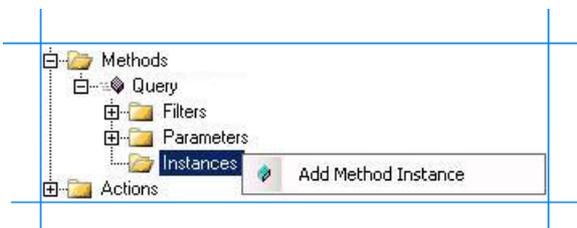

- In the Metadata Objects pane, expand the **Account** node, and then expand the **Methods** node.
- Expand the Query method, and then expand the **Parameters** node.
- Expand the **AccountQueryInputRecord** node, and then expand the second **AccountQueryInputRecord** node.
- Click the **SearchExpr** node and in the Properties pane, select **SearchExpression** from the **FilterDescriptor** list.

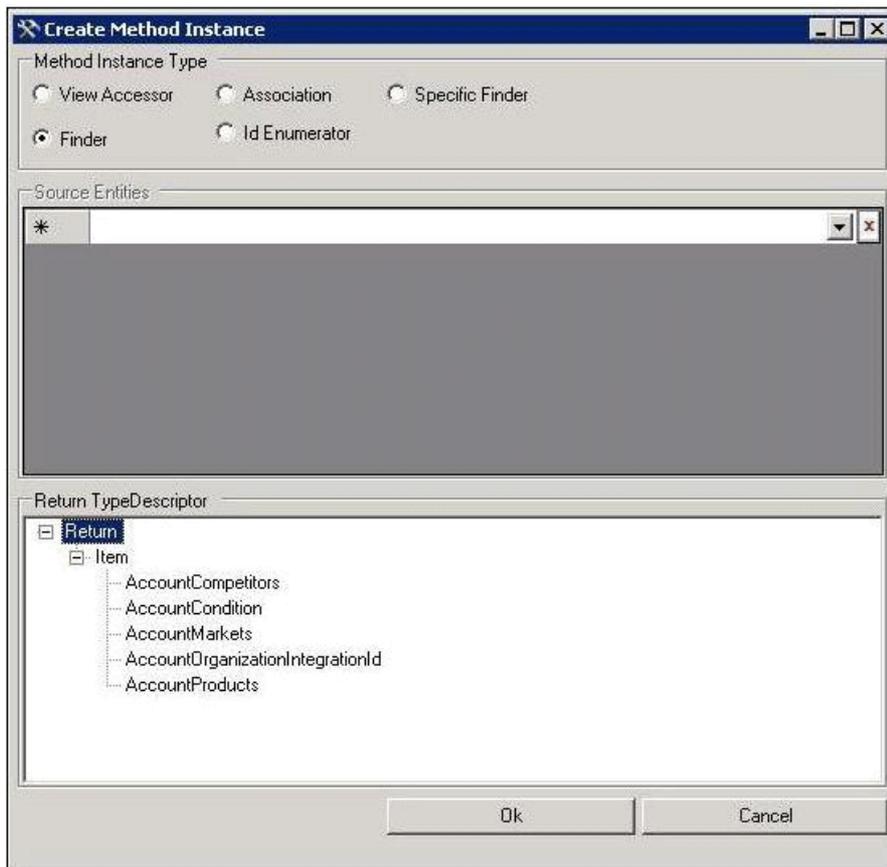

Important
 The **AccountQueryInputRecord** also contains a **QueryFields** node, which in turn contains an **Item** node. You must delete the **Item** node, otherwise the Query operation on the Account business component might not give the desired results. To delete the **Item** node, right-click the node, and then select **Delete**.

To create a Finder method instance for Query method

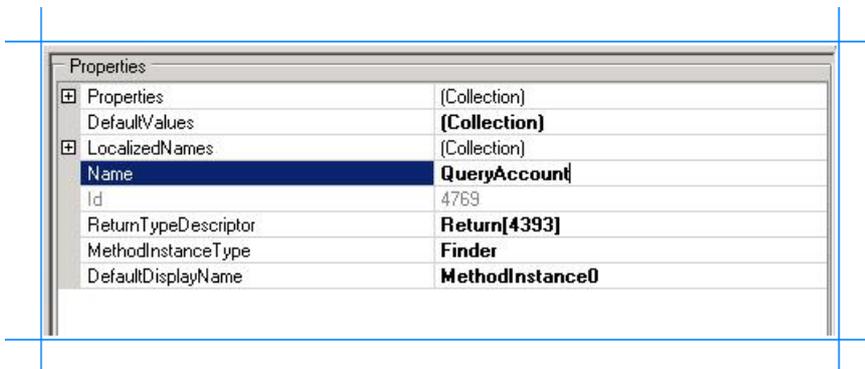

1. In the Metadata Objects pane, expand the **Account** node, and then expand the **Methods** node.
2. Expand the **Query** node, right-click **Instances**, and then click **Add Method Instance** to open the Create Method Instance window.

3. In the Create Method Instance window, click **Finder** for the **Method Instance Type**.
4. Click **Return** from **Return TypeDescriptor** section.

5. Click **OK**.
6. In the Properties pane, type **QueryAccount** for the **Name** field.

Remove the Parameters of System.Nullable Type

The return parameters for Query function may contain parameters that are of System.Nullable type. Due to the presence of these parameters in the application definition, you might get an error while presenting Siebel data on a SharePoint portal. So, you must remove the parameters of System.Nullable type from the application definition.

Also, for each parameter of System.Nullable type, the Business Data Catalog Definition Editor creates another parameter of System.Boolean type, and appends "Specified" to the parameter name. For example, the parameter AccountRole is of System.Nullable type. So, the Business Data Catalog Definition Editor adds an AccountRoleSpecified parameter to the list of parameters. You must remove such parameters as well.

Note

You can see the parameter type by selecting the parameter in the Business Data Catalog Definition Editor, and looking at the value for the **TypeName** property in the Properties pane.

Note

You can skip this step if the application does not contain any parameters of System.Nullable type.

To remove the parameters of System.Nullable type for the Query method

1. In the Metadata Objects pane, expand the **Account** node, and then expand the **Methods** node.
2. Expand the **Query** node, and then expand the **Parameters** node.
3. Expand the **Return** node, and then expand the second **Return** node.
4. Right-click the parameter you want to delete, and then select **Delete**.
5. In the dialog box, click **OK**.

Export the Application Definition to a File

You have now created an application definition that contains the Siebel system instance metadata. You must export this definition to an XML file, which can be imported into Microsoft Office SharePoint Server.

To export the application definition to a file

1. Right-click the **Siebel_Account** node in the Metadata Objects pane, and then click **Export**.
2. Save the file as Siebel_Account.xml.

Modify the Application Definition File to Include Specific Parameters

As mentioned earlier in this topic, the Business Data Catalog Definition Editor tool does not handle enumerated data types. The Business Data Catalog Definition Editor tool imports the fields till it encounters an enumerated data type and ignores the remaining fields. So, certain fields that you want in your application might be omitted. You can manually edit the application definition file to include those fields.

Note

You must make sure the parameters you are adding are present in the .cs file generated by the WCF Adapter Service Development Wizard in [Step 1: Publish the Siebel Business Component Operations as a WCF Service](#).

In this application definition file, you will add or remove return parameters for the **QueryAccount** method.

To modify the application definition file

1. Open the application definition file, Siebel_Account.xml, by using Visual Studio or any other editor.
2. Modify the application definition file to replace the parameters for the **QueryAccount** method.
 - a. Within the application definition file, search for the following:

```
<TypeDescriptor TypeName="BDC.AccountQueryRecord,Siebel_Account" Name="Item">
```

- b. Within the <TypeDescriptors> tag, replace the existing <TypeDescriptor> elements with the following:

```
<TypeDescriptor TypeName="System.String, mscorlib, Version=2.0.0.0, Culture=neutral, PublicKeyToken=<token>" Name="Id" />
<TypeDescriptor TypeName="System.String, mscorlib, Version=2.0.0.0, Culture=neutral, PublicKeyToken=<token>" Name="Country" />
<TypeDescriptor TypeName="System.String, mscorlib, Version=2.0.0.0, Culture=neutral, PublicKeyToken=<token>" Name="Name" />
<TypeDescriptor TypeName="System.String, mscorlib, Version=2.0.0.0, Culture=neutral, PublicKeyToken=<token>" Name="Location" />
```

- c. Save and close the file.

Tip

You can import the updated application definition file back in the Business Data Catalog Definition Editor tool to see the newly added fields. However, before importing you will have to remove the existing "Siebel_Account" application from the Business Data Catalog Definition Editor tool.

Next Steps

You must now create a SharePoint application to retrieve data from a Siebel system. See [Step 3: Create a SharePoint Application to Retrieve Data from Siebel](#) for instructions.

See Also

Other Resources

[Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site](#)

Step 3: Create a SharePoint Application to Retrieve Data from Siebel

Time to complete: 15 minutes.

Objective: You must now take the application definition file you created by using the Business Data Catalog Definition Editor, and import it into Office SharePoint Server.

Prerequisites

- You should have created an application definition file, as described in [Step 2: Create an Application Definition File for Siebel Business Component Operations](#).
- The Microsoft Single Sign-on service must be running.

How to Create a SharePoint Application

Creating a SharePoint application involves the following steps:

- Create a single sign-on (SSO) application in SharePoint
- Create a Shared Services Provider (SSP)
- Import the application definition file
- Create a Web Part page, and add Web Parts

Creating an SSO Application in SharePoint

To access the data in a Siebel system from a SharePoint application, you must set up an SSO application that maps a SharePoint user to a Siebel user. Creating an SSO application in SharePoint involves the following steps:

1. **Manage server settings for single sign-on.** In this step, you specify a user account that can manage and set up the single sign-on service. You can do so from the Manage Server Settings page. This option is available from the SharePoint Central Administration console. For more information about this step, refer to the "Configure Single Sign-On for Office SharePoint Server 2007" section at <http://go.microsoft.com/fwlink/?LinkId=105291>.
2. **Manage settings for enterprise application definitions.** In this step, you configure the settings for the enterprise application definition. You can do so from the Manage Settings for Enterprise Application Definitions page. This option is available from the SharePoint Central Administration console.
 - a. On Central Administration, on the top navigation bar, click **Operations**.
 - b. On the Operations page, in the **Security Configuration** section, click **Manage settings for single sign-on**.
 - c. On the Manage Settings for Single Sign-On page, in the **Enterprise Application Definition Settings** section, click **Manage settings for enterprise application definitions**.
 - d. On the Manage Enterprise Application Definitions page, provide values for the **Display name**, **Application name**, and the **Contact e-mail address** fields.

◆ Important

For the **Application name** field, make sure you specify the same SSO application name that you specified for the **SecondarySsoApplicationId** variable while creating the application definition file, as described in [Step 2: Create an Application Definition File for Siebel Business Component Operations](#).

e. Leave the other fields as default, and click **OK**.

3. **Manage account information for enterprise application definitions.** In this step, you enable individual users or groups to connect to an enterprise application from SharePoint. Essentially, in this step you map an individual user or group to a user in the LOB system. You also specify the credentials to connect to the LOB system. You can do so from Manage Account Information for Enterprise Application Definitions page. This option is available from the SharePoint Central Administration console. For more information about this step, refer to the "Manage account information for an enterprise application definition" section at <http://go.microsoft.com/fwlink/?LinkId=105291>.

Creating a Shared Services Provider

An SSP is a logical grouping of shared services and their supporting resources. You can create an SSP using the SharePoint Central Administration console.

You must define a Web site while creating an SSP. Remember the port number and the site address you create. You will import the Business Data Catalog application definition to this site.

For more information about creating an SSP, see "Chapter overview: Create and configure Shared Services Providers" at <http://go.microsoft.com/fwlink/?LinkId=105119>.

Importing the Application Definition File

You must now import the application definition file into the SSP.

To import the application definition file

1. Start SharePoint 3.0 Central Administration. Click **Start**, point to **All Programs**, point to **Microsoft Office Server**, and then click **SharePoint 3.0 Central Administration**.
2. In the left navigation pane, click the name of the SSP to which you want to import the application definition.
3. In the **Business Data Catalog** section, click **Import application definition**.
4. On the Import Application Definition page that opens, browse to Siebel_Account.xml, select the file, and then click **Open**.
5. Click **Import**.
6. Click **OK**.

After importing the application, you can see your application by going to the **View Applications** link. Click the application name to see the entities in the application.

Creating Web Parts

You must now create Web Parts in your SharePoint site to view and manage the business data that will be extracted from the Siebel system. Web Parts are reusable components that can contain any kind of Web-based information, including analytical, collaborative, and database information.

In this tutorial, Web Parts are created for the method instances that were created in Business Data Catalog Definition Editor. Office SharePoint Server provides different kinds of Web Parts for specific use. For the Finder method instance, we will use the **Business Data List** Web Part. This Web Part enables you to specify a search expression to perform a query on the Account business component. For this tutorial, we call this the **Query Accounts** Web Part.

This section provides instructions to create these Web Parts. For more information about creating Web Parts, see the Microsoft Office SharePoint Server 2007 document ("Customize business data lists, Web Parts, and sites") at <http://go.microsoft.com/fwlink/?LinkId=104131>.

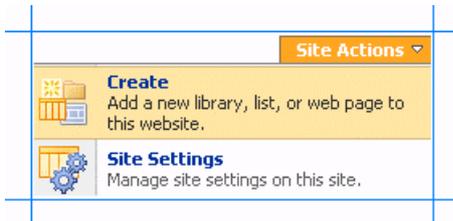

The Web Parts will be added to a single Web Part page. You must create a Web Part page before adding the Web Parts. For this tutorial, the Web Part page is called **Siebel Account**.

Creating a Web Part Page

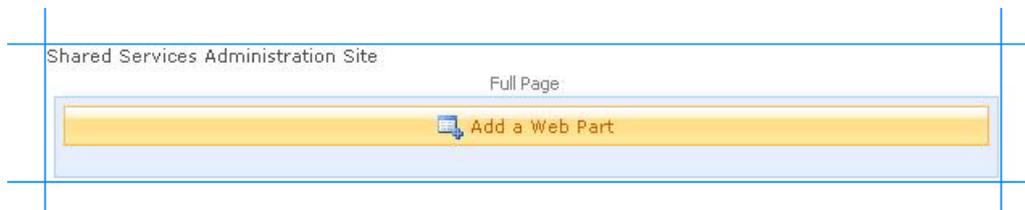

This section provides instructions to create a Web Part page.

To create a web part page

1. Start SharePoint 3.0 Central Administration. Click **Start**, point to **All Programs**, point to **Microsoft Office Server**, and click **SharePoint 3.0 Central Administration**.
2. In the left navigation pane, click the name of the SSP to which you want to import the application definition.
3. On the Shared Services Administration page, from the top right-hand corner, click **Site Actions**, and then click **Create**.

4. On the Create page, under the **Web Pages** section, click **Web Part Page**.
5. In the New Web Part page, do the following:
 - a. In the **Name** field, specify a name for the page. For this tutorial, specify the name as **Siebel Account**.
 - b. Select the **Overwrite if file already exists** check box, if you want to overwrite old pages with the same name as the page you create.
 - c. In the **Layout** section, from the **Choose a Layout Template** box, select a layout for the Web Part page. For this tutorial, select **Full Page, Vertical**.
 - d. In the **Save Location** section, in the **Document Library** list, select **Form Templates**.
 - e. Click **Create**. The following figure shows a Web Part page after it is just created.

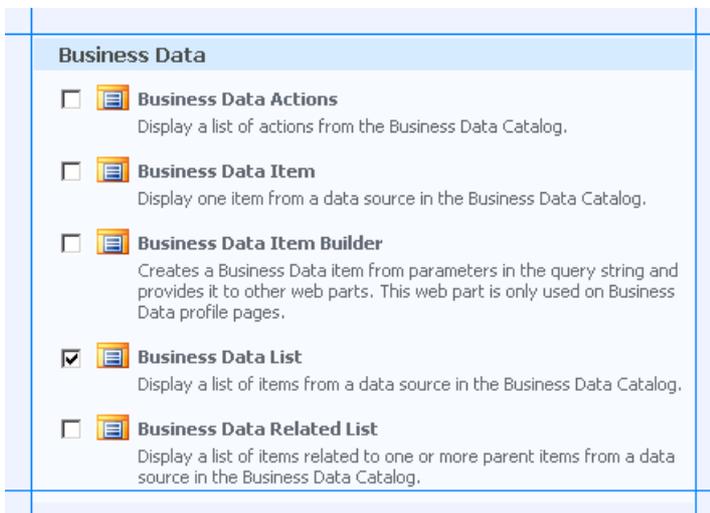

You must now add the different Web Parts to this page.

Adding a Business Data List Web Part

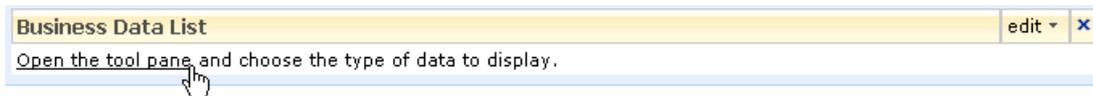

You must now add a Business Data List Web Part to the Web Part page. Using this Web Part, you will query the Account business component using a search expression. This Web Part corresponds to the Finder method instance (QueryAccount) you created in the Business Data Catalog Definition Editor.

To add a Business Data List Web Part

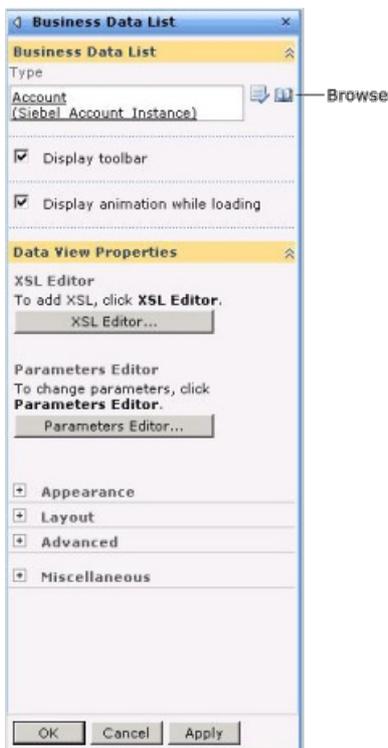

1. In the **Siebel Account** page, in the **Header** section, click **Add a Web Part**.
2. In the **Add Web Parts** dialog box, in the **Business Data** section, select the **Business Data List** check box, and then click **Add**.

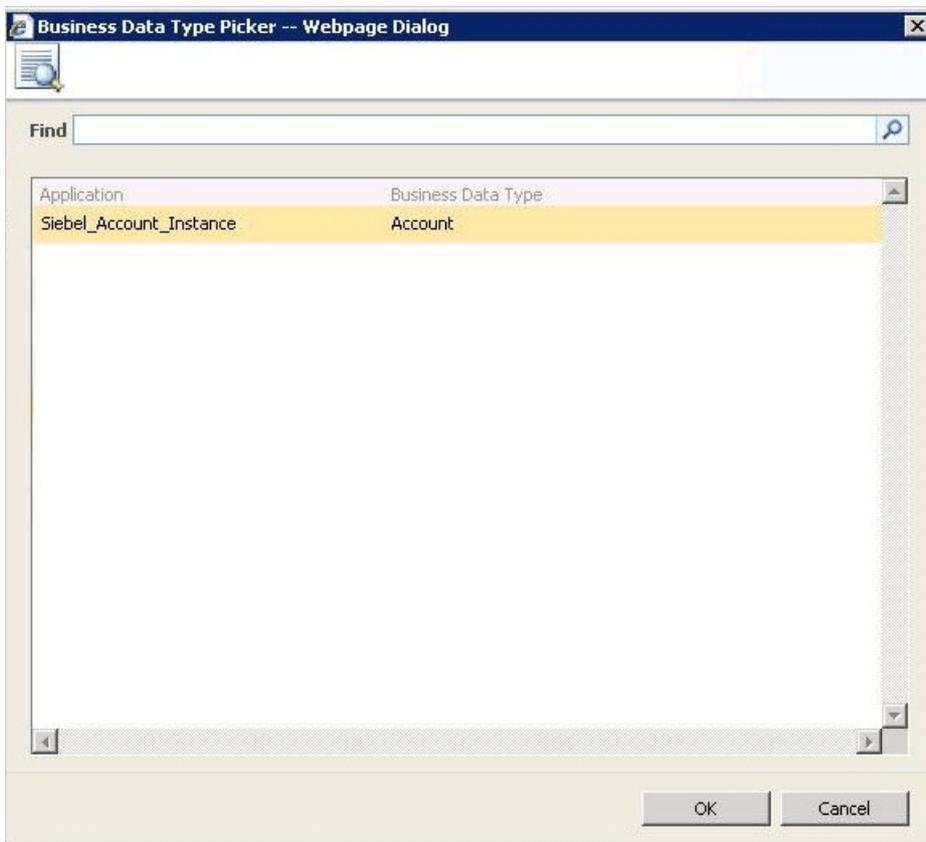

- In the newly added Business Data List Web Part, click the **Open the tool pane** link.

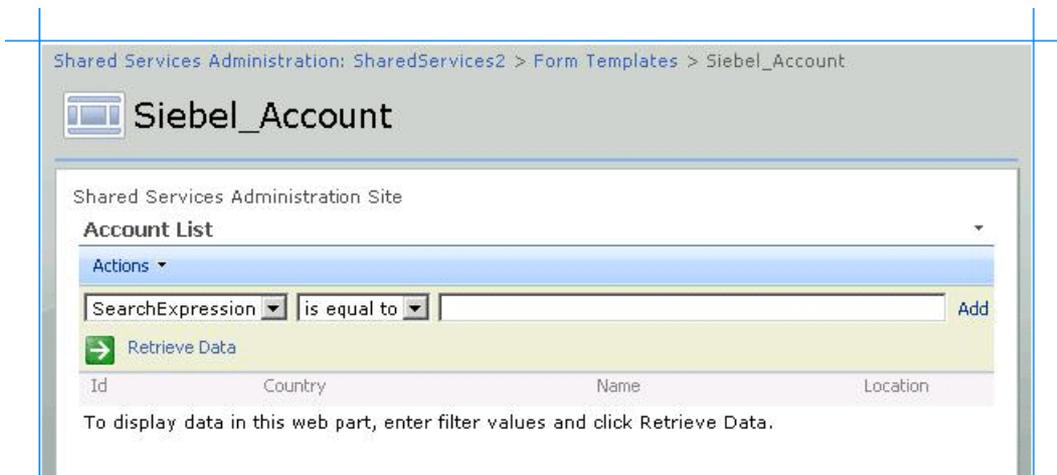

- The Business Data List tool pane opens in the right pane. In the **Business Data List** section, for the **Type** field, click the **Browse** button.

- In the **Business Data Type Picker** dialog box, select the **Siebel_Account_Instance** application, and then click **OK**.

6. Expand the **Appearance** node, and in the **Title** field, specify a title for the Web Part. For this Web Part, specify **Account List**.
7. In the Business Data List tool pane, click **Apply**, and then click **OK**. The Business Data List Web Part now looks like the following:

Note
 You can also change the order in which the parameter columns appear. You can do so by clicking the **Edit View** link towards the right corner of the Web Part.

8. Click **Exit Edit Mode** from the top right corner of the page.

Next Steps

Test the SharePoint application by retrieving data from a Siebel system. See [Step 4: Test Your SharePoint Application](#).

See Also

Other Resources

[Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site](#)

Step 4: Test Your SharePoint Application

Time to complete: 5 minutes.

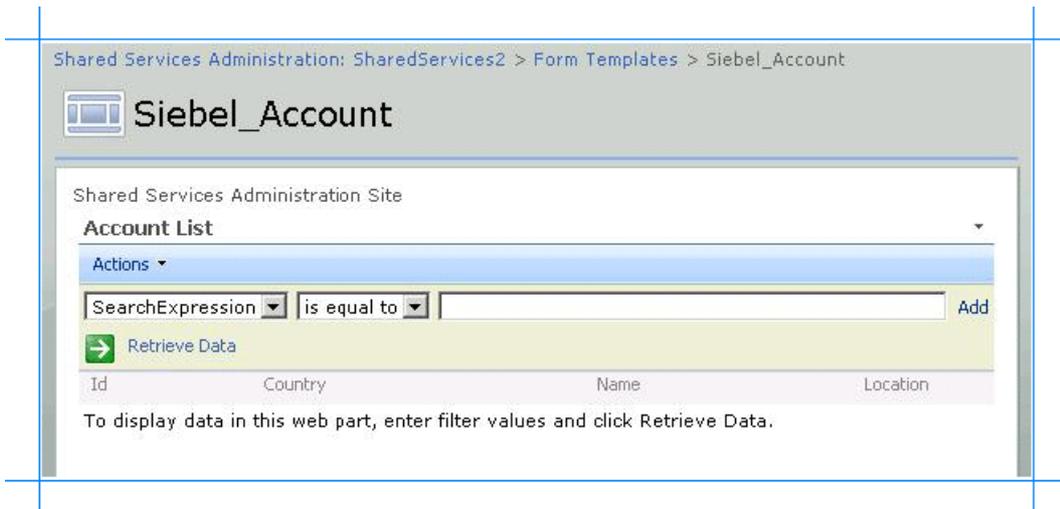

Objective: After you have added Web Parts in the SharePoint site and created an application, you must test the application by retrieving some data from the Siebel system. This section provides instructions on how to use the application to retrieve the data from the Siebel system.

Prerequisites

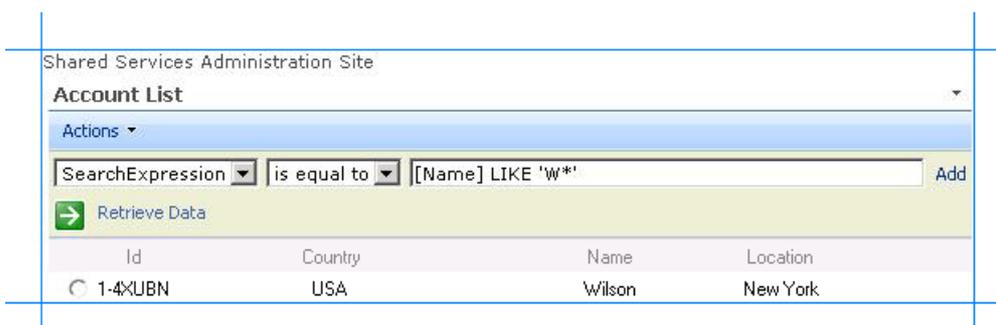

You should have created the Web Part page containing the appropriate Web Parts to retrieve business data. See [Step 3: Create a SharePoint Application to Retrieve Data from Siebel](#).

To test the SharePoint application

1. Start SharePoint 3.0 Central Administration. Click **Start**, point to **All Programs**, point to **Microsoft Office Server**, and then click **SharePoint 3.0 Central Administration**.
2. In the left navigation pane, click the name of the SSP under which you created the application.
3. In the left pane, click **View All Site Content**. From the right pane, click **Form Templates**.
4. In the **Form Category** list, click **Siebel Account**. You specified this name while creating the Web Part page. The following figure shows the Web Part page that you created.

5. Query the Account business component based on a search string. For example, specify the search expression `[Name] LIKE 'W*'`. To do so:
 - a. In the **Account List** section, from the first list, select **SearchExpression**, and then select **is equal to**.
 - b. In the text field, type **[Name] LIKE 'W*'**.
 - c. Click **Retrieve Data** link, or press ENTER. The following figure shows the records retrieved from the Siebel system that satisfy the search criteria.

Other Resources

[Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site](#)

Tutorial 2: Migrating BizTalk Projects

The previous version of the Siebel adapter that shipped with Microsoft BizTalk Server differs from the WCF-based Siebel adapter in many aspects, including:

- The design-time experience of creating a BizTalk project.
- The metadata retrieval experience.
- Schema file name and namespace.
- Data type mappings.
- The operations that can be performed using the adapter.
- Physical port configuration in the BizTalk Server Administration console

These differences are explained in the topics within [Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#).

However, you can make changes to the BizTalk project created using the previous version of the adapter and make it work with the WCF-based Siebel adapter.

This tutorial provides instructions on the changes you should make to the existing BizTalk project created using the previous version of the adapter.

Note

In this tutorial, for the sake of brevity, the previous version of the Siebel adapter will be referred to as vPrev Siebel adapter. Similarly, a BizTalk project that uses the vPrev Siebel adapter will be referred to as vPrev BizTalk project.

Sample Used for the Tutorial

This tutorial is based upon a sample (Siebel_BussComp_Migration) that demonstrates how to migrate a vPrev BizTalk project that performs an Insert operation on the Account Siebel business component. The sample is provided with Microsoft BizTalk Adapter Pack. For more information, see [Samples](#).

Prerequisites

- You must have a vPrev BizTalk project. This tutorial involves a BizTalk project that performs an Insert operation on the Account business component.
- You must have a request message to perform an Insert operation on the Account business component using the vPrev Siebel adapter. The request message must conform to the schema of the Insert operation generated using the vPrev Siebel adapter.
- You must have completed the steps in [Before You Develop BizTalk Applications](#).

Understanding a BizTalk Project Created Using the Previous Version of the Adapter

The key constituents of a vPrev BizTalk project created are:

- **BizTalk orchestration.** This is a simple orchestration that picks request messages from a file location, sends the request message to the Siebel system using a Siebel send-receive port, receives the response, and saves it to another file location.
- **Schema for the operation you wish to perform on the Siebel business component.** This tutorial involves a BizTalk project that performs an Insert operation on the Account business component. The schema generated for the Account business component is AccountService_Account_x5d.xsd. This schema is generated using the vPrev Siebel adapter.

Note

Unlike the WCF-based Siebel adapter, the vPrev Siebel adapter does not support generating metadata for specific operations on a business component. By default, the adapter generates schema for all the operations supported on the business component. For more such differences between the vPrev Siebel adapter and the WCF-based Siebel adapter, see [Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#).

- **Request message.** The request message to perform an Insert operation on the Account business component. The schema of the request message conforms to the schema of the Insert operation as surfaced by the vPrev Siebel adapter.

How to Migrate a BizTalk Project Created Using the Previous Version of the Adapter

The goal of this migration tutorial is to enable you to send a request message, which conforms to schema generated by the vPrev Siebel adapter, using a WCF-Custom port that can only process messages conforming to the WCF-based Siebel adapter. So, in short, the migration exercise involves configuring the WCF-Custom port to process messages that do not conform to the WCF-based Siebel adapter's schema.

However, to be able to configure the WCF-Custom port appropriately, you must perform the following tasks:

- Generate metadata for the Insert operation on the Account business component using the WCF-based Siebel adapter.
- Map the request message for performing an Insert operation using the vPrev Siebel adapter to a request message for performing an Insert operation using the WCF-based Siebel adapter.
- Map the response message received using the WCF-based Siebel adapter to the response message for the vPrev Siebel adapter.
- Create a WCF-Custom Siebel send-receive port in the BizTalk Server Administration console.
- Configure the WCF-Custom port to use the request and response mappings.

In This Section

- [Step 1: Modify the vPrev BizTalk Project](#)
- [Step 2: Configure the Orchestration in BizTalk Server Administration Console](#)
- [Step 3: Test the Migrated Application](#)

See Also

Other Resources

[Siebel Adapter Tutorials](#)

Step 1: Modify the vPrev BizTalk Project

Step 1

Time to complete: 10 minutes

Objective: In this step, you make the following changes to the existing vPrev BizTalk project:

- Generate metadata for the Insert operation on the Account business component using the WCF-based Siebel adapter.
- Map the request message for performing an Insert operation using the vPrev Siebel adapter to a request message for performing an Insert operation using the WCF-based Siebel adapter.
- Map the response message received using the WCF-based Siebel adapter to the response message for the vPrev Siebel adapter.

Prerequisite

- You must have a vPrev BizTalk project to perform an Insert operation on the Account business component in the Siebel system.

To modify the vPrev BizTalk project

1. Generate metadata for the Insert operation on the Account business component using the WCF-based Siebel adapter. You can use the Consume Adapter Service BizTalk Project Add-in to generate metadata.

For instructions on how to generate metadata, see [Retrieving Metadata for Siebel Operations in Visual Studio](#). After the schema is generated, a file with the name similar to *SiebelBindingSchema.xsd* is added to the BizTalk project. This file contains the schema for sending a message to perform the Insert operation on the Account business component using the WCF-based Siebel adapter.

2. Generating the metadata for the Insert operation also creates a port binding file. In the next step, this binding file will be used to create a WCF-Custom send port to send messages to the Siebel system. The SOAP action for the operation is also set to the operation for which you generated metadata. For example, if you generate metadata for the Insert operation, the operation name in the SOAP action on the send port will be "Insert". However, the operation name on the logical send port that you create as part of the orchestration could be different, for example, "Operation_1". As a result, when you send messages to the Siebel system using the send port, you get an error. To prevent this, make sure the operation name on the logical send port in your orchestration is the same as the operation name for which you generated metadata.

So, in case of this tutorial, because you generate metadata for the Insert operation, change the name of the logical send port operation to "Insert".

3. For the request message, map the schema generated using vPrev Siebel adapter to the schema generated using the WCF-based Siebel adapter.

- a. Add a BizTalk mapper to the BizTalk project. Right-click the BizTalk project, point to **Add**, and click **New Item**.

In the **Add New Item** dialog box, from the left pane, select **Map Files**. From the right pane, select **Map**. Specify a name for the map, such as **RequestMap.btm**. Click **Add**.

- b. From the Source Schema pane, click **Open Source Schema**.

- c. In the **BizTalk Type Picker** dialog box, expand the project name, expand **Schemas**, and select the schema for the request message for the vPrev Siebel adapter. For this tutorial, select *Siebel_BussComp_Migration.AccountService_Account_x5d*. Click **OK**.

- d. In the **Root Node for Source Schema** dialog box, select *Insert*, and then click **OK**.

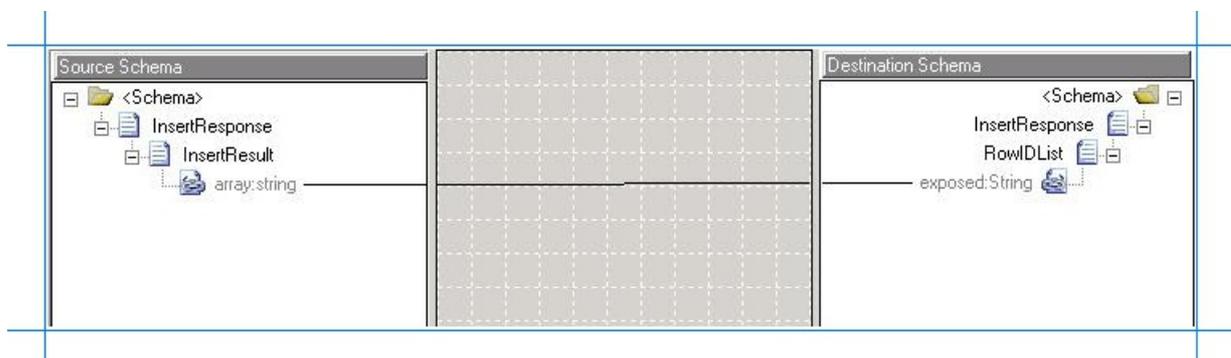

- e. From the Destination Schema pane, click **Open Destination Schema**.
- f. In the **BizTalk Type Picker** dialog box, expand the project name, expand **Schemas**, and select the schema for the request message for the WCF-based Siebel adapter. For this tutorial, select *Siebel_BussComp_Migration.SiebelDBBindingSchema*, and then click **OK**.
- g. In the **Root Node for Target Schema** dialog box, select *Insert*, and then click **OK**.
- h. Map the following elements in both the schemas: **Currency_Code**, **Current_Volume**, **Customer_Account_Group**, **Location**, **Main_Phone_Number**, **Name**, **Party_Name**, **Primary_Address_Id**,
- i. Save the map.

4. For the response message, map the schema generated using the vPrev Siebel adapter to the schema generated using the WCF-based Siebel adapter.

- a. Add a BizTalk mapper to the BizTalk project. Right-click the BizTalk project, point to **Add**, and click **New Item**.

In the Add New Item dialog box, from the left pane, select **Map Files**. From the right pane, select **Map**. Specify a name for the map, such as **ResponseMap.btm**. Click **Add**.

- b. From the Source Schema pane, click **Open Source Schema**.
- c. In the **BizTalk Type Picker** dialog box, expand the project name, expand **Schemas**, and select the schema for the response message for the WCF-based Siebel adapter. For this tutorial, select *Siebel_BussComp_Migration.SiebelDBBindingSchema*. Click **OK**.
- d. In the **Root Node for Source Schema** dialog box, select *InsertResponse* and click **OK**.
- e. From the Destination Schema pane, click **Open Destination Schema**.
- f. In the **BizTalk Type Picker** dialog box, expand the project name, expand **Schemas**, and select the schema for the response message for the vPrev Siebel adapter. For this tutorial, select *Siebel_BussComp_Migration.AccountService_Account_x5d*. Click **OK**.
- g. In the **Root Node for Target Schema** dialog box, select *InsertResponse* and click **OK**.
- h. Map the **array:string** element in the source schema to the **exposed:string** element in the destination schema, as illustrated in the following figure.

- i. Save the map.

- 5. Save and build the BizTalk solution. Right-click the solution, and then click **Build Solution**.
- 6. Deploy the solution. Right-click the solution, and then click **Deploy Solution**.

Next Steps

Create a WCF-custom send port and configure it to use the maps you created in this step, as described in [Step 2: Configure the Orchestration in BizTalk Server Administration Console](#).

See Also

Concepts

[Tutorial 2: Migrating BizTalk Projects](#)

Step 2: Configure the Orchestration in BizTalk Server Administration Console

Time to complete: 10 minutes

Objective: In this step, you perform the following tasks:

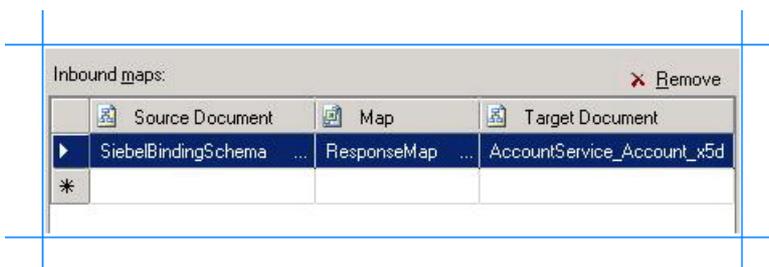

- Create a WCF-Custom send-receive port to send and receive messages from the Siebel system using the Siebel adapter. Configure this port to use the maps you created in the previous step.
- Configure the orchestration you deployed in the last step to use the WCF-Custom port.

Prerequisite

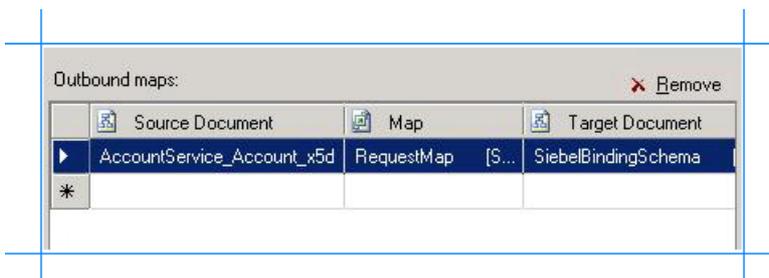

- You must have deployed the BizTalk orchestration for which you want to configure the WCF-Custom port.

To create a WCF-Custom port

1. When you generate schema for an operation on the Siebel system using Consume Adapter Service BizTalk Project Add-in, a binding file is also added to the BizTalk project. You can import this binding file into your BizTalk application to create a WCF-Custom send-receive port. For instructions on importing a binding file, see [Importing Bindings](#).
2. After you import the binding file, a send port is created under the **Send Ports** folder in the BizTalk Server Administration console.
3. Right-click the WCF-Custom port, and then click **Properties**.
4. From the left pane of the send port properties dialog box, click the **General** tab. From the right pane, click **Configure**.
5. In the **WCF-Custom Transport Properties** dialog box, click the **Credentials** tab and specify the credentials to connect to a Siebel system.
6. Click **OK**.
7. From the left pane of the send port properties dialog box, click **Inbound Maps**. From the right pane, click the field under the **Map** column, and from the drop-down select **ResponseMap**.

8. From the left pane of the send port properties dialog box, click **Outbound Maps**. From the right pane, click the field under the **Map** column, and from the drop-down select **RequestMap**.

9. Click **OK**.

To configure the BizTalk application

1. In the BizTalk Server Administration console, expand **BizTalk Group**, expand **Applications**, and expand the BizTalk Application where the orchestration is deployed.
2. Right-click the BizTalk application, and then select **Configure**.
3. From the left pane, click the orchestration to configure. From the right pane, from the **Host** drop-down list, select a BizTalk host instance.
4. Under the **Bindings** box, map the logical ports of the BizTalk orchestration to the physical ports in the BizTalk Server Administration console.
 - a. Select the file port where you will drop a request message. The BizTalk orchestration will consume the request message and send it to the Siebel system.
 - b. Select the file port where the BizTalk orchestration will drop the response message containing the response from the Siebel system.
 - c. Select the WCF-Custom send port you created earlier in this topic.
 - d. Click **OK**.

For more information about configuring an application, see "How to Configure an Application" at <http://go.microsoft.com/fwlink/?LinkId=102360>.

Next Steps

You have now completed migration of your vPrev BizTalk project to a BizTalk project that sends messages to the Siebel system using the WCF-based Siebel adapter. You must now test the migrated BizTalk application by sending a request message to invoke the Insert operation on the Account business component, as described in [Step 3: Test the Migrated Application](#).

See Also

Concepts

[Tutorial 2: Migrating BizTalk Projects](#)

Step 3: Test the Migrated Application

Time to complete: 5 minutes

Objective: In this step, you will test the migrated application by performing an Insert operation on the Account business component. To do this, you drop a request message that conforms to the schema generated using the vPrev Siebel adapter.

Prerequisites

- Configure the BizTalk application by mapping the logical ports in the BizTalk orchestration to physical ports in the BizTalk Server Administration console.
- Configure the BizTalk application to use the WCF-Custom send port for the WCF-based Siebel adapter.

To test the migrated application

1. From the Siebel_BussComp_Migration folder, copy the AccountInsert.xml request message. This request message conforms to the schema generated by the vPrev Siebel adapter. Using the outbound map, the WCF-Custom send port converts this to conform to the schema for the WCF-based Siebel adapter and sends it to the Siebel system.

```
<Insert xmlns="http://schemas.microsoft.com/[Siebel://Business Objects/Account/Account
 ]">
  <AccountInsertRecordSet>
    <AccountInsertRecord xmlns="http://schemas.microsoft.com/Business_Objects">
      <Currency_Code>USD</Currency_Code>
      <Customer_Account_Group>Sold-To-Party</Customer_Account_Group>
      <Location>Location_1</Location>
      <Main_Phone_Number>012345678</Main_Phone_Number>
      <Name>John_Smith</Name>
      <Party_Name>Party_Name_1</Party_Name>
      <Primary_Address_Id></Primary_Address_Id>
    </AccountInsertRecord>
  </AccountInsertRecordSet>
</Insert>
```

2. Paste the request message to the folder mapped to the file receive location.
3. The orchestration consumes the request message and sends it to the Siebel system. The response from the Siebel system is received in the schema that conforms with the schema of the WCF-based Siebel adapter. Using the inbound map, the WCF-Custom send port converts this to the schema for the vPrev Siebel adapter. The response from the Siebel system is saved to the other file location defined as part of the orchestration. The response for the preceding request message is:

```
<?xml version="1.0" encoding="utf-8"?>
<ns0:InsertResponse xmlns:ns0="http://schemas.microsoft.com/[Siebel://Business Objects
 /Account/Account]" xmlns:exposed="http://schemas.microsoft.com" xmlns:Business_Objects
 ="http://schemas.microsoft.com/Business_Objects">
  <ns0:RowIDList>
    <exposed:String>1-8EWWZ</exposed:String>
  </ns0:RowIDList>
</ns0:InsertResponse>
```

Community Resources

There are two principal sources of information from Microsoft about the BizTalk Adapter Pack:

- The documentation and samples installed with the BizTalk Adapter Pack.
- The Microsoft BizTalk Adapter Pack forums.

BizTalk Adapter Pack Documentation

You can install the BizTalk Adapter Pack documentation when you install the BizTalk Adapter Pack. (For information about how to install the BizTalk Adapter Pack, see the BizTalk Adapter Pack installation guide. The installation guide is typically available under <installation drive>:\Program Files\Microsoft BizTalk Adapter Pack\Documents.) The core documentation covers the concepts and procedures required to use the BizTalk Adapter Pack.

After you install the BizTalk Adapter Pack, you can access the documentation through the **Microsoft BizTalk Adapter Pack** program group on the Start menu.

BizTalk Adapter Pack Samples

This BizTalk Adapter Pack release provides samples demonstrating how to use the adapters with:

- BizTalk Server.
- The Windows Communication Foundation (WCF) channel model.
- The WCF service model.
- The .NET Framework Data Provider for Siebel eBusiness Applications (Data Provider for Siebel).

In addition, migration samples are provided.

The samples are available at <http://go.microsoft.com/fwlink/?LinkID=196854>.

BizTalk Adapter Pack Forums

You can post your queries about the BizTalk Adapter Pack on the forums.

Resource	Location
BizTalk Adapter Pack Forums	http://go.microsoft.com/fwlink/?LinkId=87695

Getting Assistance with the BizTalk Adapter Pack

Should you encounter any issues with the BizTalk Adapter Pack, you must mention the product ID (PID) for the BizTalk Adapter Pack in all communications with Microsoft Support. The PID is available in a file, pid.txt, installed by the setup wizard, typically under <installation drive>:\Program Files\Microsoft BizTalk Adapter Pack\Documents.

The end-user license agreement (EULA) for the BizTalk Adapter Pack is available in a file, EULA.rtf, installed by the setup wizard, typically under <installation drive>:\Program Files\Microsoft BizTalk Adapter Pack.

Frequently Asked Questions

The following are some frequently asked questions (FAQs) related to Microsoft BizTalk Adapter for Siebel eBusiness Applications.

What are the supported Siebel server versions?

The Siebel adapter can be used to connect to Siebel system with the following versions:

- Siebel 7.5 (7.5.3.17 + Quick Fix 7.5.3.17[16285]QF0H05)
- Siebel 7.7 (7.7.2.10)
- Siebel 7.8 (7.8.2.8)
- Siebel 8.0 (8.0.0.2)

What are the supported Siebel client versions?

The Siebel adapter supports the following Siebel client version:

- Siebel Web Client 7.5
- Siebel Web Client 7.7
- Siebel Web Client 7.8
- Siebel Web Client 8.0

What are the supported BizTalk versions for the BizTalk Adapter Pack?

The BizTalk Adapter Pack is supported with Microsoft BizTalk Server 2010.

In which user context should the setup be run?

You must always run the BizTalk Adapter Pack setup wizard under a user context with administrative privileges on the computer.

Does the Microsoft BizTalk Adapter Pack support tracing?

Microsoft BizTalk Adapter Pack enables adapter clients to activate WCF tracing and adapter specific tracing. For more information about tracing see [Diagnostic Tracing and Message Logging](#).

Where are the trace files stored?

The trace files are stored at a location specified by the adapter clients. The adapter clients can specify a location for storing the files while enabling tracing. For more information about tracing see [Diagnostic Tracing and Message Logging](#).

How do I view the traces?

You can use the Windows Communication Foundation (WCF) Service Trace Viewer tool to view the traces. For more information about the tool see <http://go.microsoft.com/fwlink/?LinkId=91243>.

Are performance counters available for the adapters?

The BizTalk Adapter Pack provides a "LOB Time (Cumulative)" performance counter to measure the time, in milliseconds, that the LOB client library takes to complete an action that the adapter initiates. For more information about performance counters see [Using Performance Counters](#).

How do I enable performance counters for adapters?

The performance counters can be enabled or disabled by setting the binding property **EnablePerformanceCounters**. Set **EnablePerformanceCounters** binding property to **True** to enable performance counters. To disable performance counters, set **EnablePerformanceCounters** to **False**. By default, **EnablePerformanceCounters** is set to **False**.

Planning and Architecture

This section describes:

- The architecture of end-to-end solutions that use the Siebel adapter to operate on a Siebel system.
- The internal architecture of the Siebel adapter.

An understanding of the Siebel adapter architecture can help you:

- Understand the relationship between the Siebel adapter and the Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK.
- Understand security boundaries, so that you can improve data security in your solution.
- Understand the Siebel adapter binding properties.
- Troubleshoot installation issues.

In This Section

- [Architecture for BizTalk Adapter for Siebel eBusiness Applications](#)
- [BizTalk Adapter for Siebel eBusiness Applications and the WCF LOB Adapter SDK](#)

Architecture for BizTalk Adapter for Siebel eBusiness Applications

The Microsoft BizTalk Adapter for Siebel eBusiness Applications is built on top of the Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK and runs on top of the WCF LOB Adapter SDK run time. The WCF LOB Adapter SDK provides a software framework and tooling infrastructure that the Siebel adapter employs to provide a rich set of features to users and adapter clients.

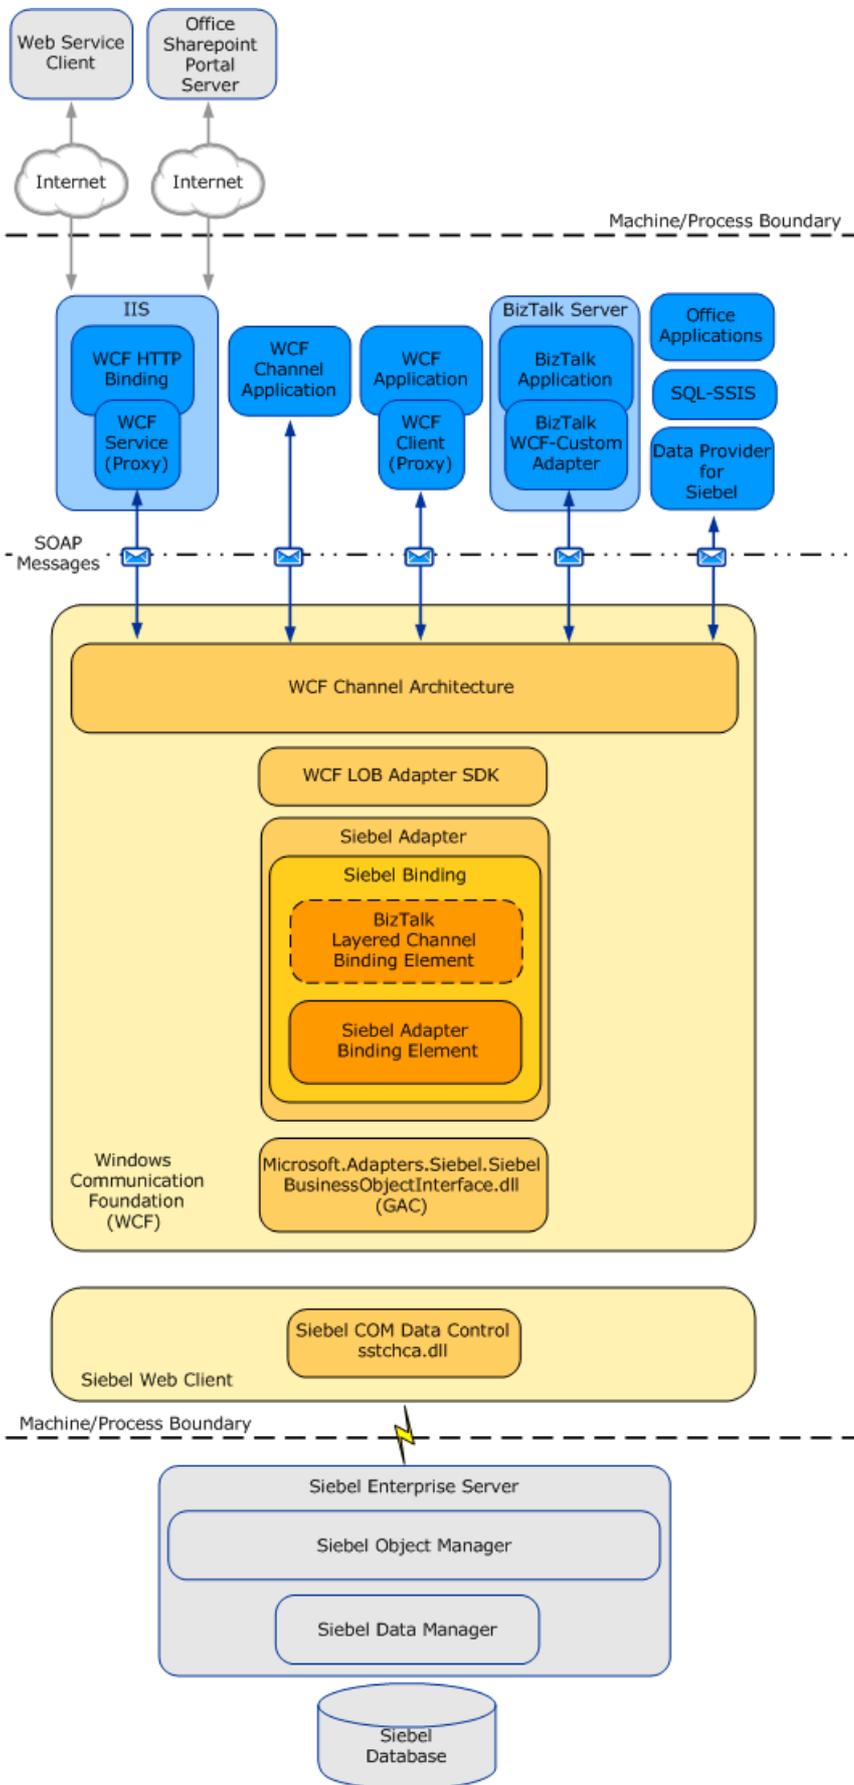

The Siebel adapter is a WCF custom binding. This binding contains a single custom transport binding element that enables communication with a Siebel system. The Siebel adapter is wrapped by the WCF LOB Adapter SDK run time and is exposed to applications through the WCF channel architecture.

The Siebel COM Data Control

The Siebel adapter connects with the Siebel system through the Siebel COM Data Control library (sstchca.dll) and the Microsoft.Adapters.Siebel.SiebelBusinessObjectInterface.dll library. The Siebel COM Data Control is a component of the Siebel Web Client. For information about how to install the Siebel Web Client on your computer, see [Installing the BizTalk Adapter Pack](#).

The Siebel COM Data Control interfaces enable an external client like the Siebel adapter to connect and communicate with a Siebel Application Object Manager on a Siebel Enterprise Server. The Siebel Object Manager and Siebel Enterprise Server as well as other connection parameters are specified in the Siebel adapter connection URI. For more information about the connection URI, see [The Siebel System Connection URI](#).

The following figure shows the end-to-end architecture for solutions that are developed by using the Siebel adapter.

Consuming the Adapter

The Siebel adapter exposes the Siebel system as a WCF service to client applications. To perform operations and access data on the Siebel system, client applications exchange SOAP messages with the Siebel adapter through WCF channels. The preceding figure shows four ways in which the Siebel adapter can be consumed.

- Through a WCF channel model application. A WCF channel model application performs operations on the Siebel system by using the WCF channel model to exchange SOAP messages directly with the Siebel adapter. For more information about developing solutions for the Siebel adapter by using the WCF channel model, see

Developing Applications by Using the WCF Channel Model.

- Through a WCF service model application. A WCF service model application calls methods on a WCF client to perform operations on the Siebel system. A WCF client models the operations exposed by the Siebel adapter as .NET methods. You can use the WCF LOB Adapter SDK or the ServiceModel Metadata Utility Tool (svcutil.exe) to create a WCF client class from metadata exposed by the Siebel adapter. For more information about the WCF service model and the Siebel adapter, see [Developing Applications by Using the WCF Service Model](#).
- Through a BizTalk receive location or send port that is configured to use the Microsoft BizTalk WCF-Custom adapter. The WCF-Custom adapter enables the use of WCF extensibility features. By using the WCF-Custom adapter you can select and configure the Siebel Binding and the behavior for the receive location or send port. BizTalk transactions are supported by the BizTalk Layered Channel Binding Element, which can be loaded by setting a binding property on the Siebel Binding. For more information about how to use the Siebel adapter in BizTalk Server solutions, see [Developing BizTalk Applications](#).
- Through an IIS-hosted Web service. In this scenario, a WCF service proxy generated by using the adapter is hosted in IIS using the standard WCF Http Binding. This exposes the service contract as a Web service to external users. IIS automatically hosts the adapter at run time, which, in turn, communicates with the Siebel system.

The Siebel adapter and the Siebel COM Data Control library are always hosted in-process with the application or service that consumes the adapter.

The Siebel Adapter and WCF

WCF presents a programming model based on the exchange of SOAP messages over channels between clients and services. These messages are sent between endpoints exposed by a communicating client and service. An endpoint consists of:

- An *endpoint address*, which specifies the location at which messages are received.
- A *binding*, which specifies the communication protocols that are used to exchange messages.
- A *contract*, which specifies the operations and data types that are exposed by the endpoint.

A binding consists of one or more binding elements that stack on top of each other to define how messages are exchanged with the endpoint. At a minimum, a binding must specify the transport and encoding that are used to exchange messages with the endpoint. Message exchange between endpoints occurs over a channel stack that is composed of one or more channels. Each channel is a concrete implementation of one of the binding elements in the binding that is configured for the endpoint. For more information about WCF and the WCF programming model, see the WCF Help documentation at <http://go.microsoft.com/fwlink/?LinkId=89726>.

The Microsoft BizTalk Adapter for Siebel eBusiness Applications exposes a WCF custom binding, the Siebel Binding (**Microsoft.Adapters.Siebel.SiebelBinding**). By default, this binding contains a single custom transport binding element, the Siebel Adapter Binding Element (**Microsoft.Adapters.Siebel.SiebelAdapter**), which enables operations on a Siebel system. When using the Siebel adapter with BizTalk Server, you can set the **EnableBizTalkCompatibilityMode** binding property to load a custom binding element—the BizTalk Layered Channel Binding Element—on top of the Siebel Adapter Binding Element. The BizTalk Layered Channel Binding Element is implemented internally by the Siebel adapter and is not exposed outside the Siebel Binding.

Microsoft.Adapters.Siebel.SiebelBinding (the Siebel Binding) and **Microsoft.Adapters.Siebel.SiebelAdapter** (the Siebel Adapter Binding Element) are public classes and are also exposed to the configuration system. Because the Siebel Adapter Binding Element is exposed publicly, you can build your own custom WCF bindings capable of extending the functionality of the Siebel adapter. For example, you could implement a custom binding to support Enterprise Single Sign-on (SSO) in WCF channel or service model programming. The reasons for doing this are to either:

- Aggregate database operations into a single multifunction operation.
- Perform schema transformation between operations that are implemented by a custom application and operations on the Siebel system.

[Planning and Architecture](#)

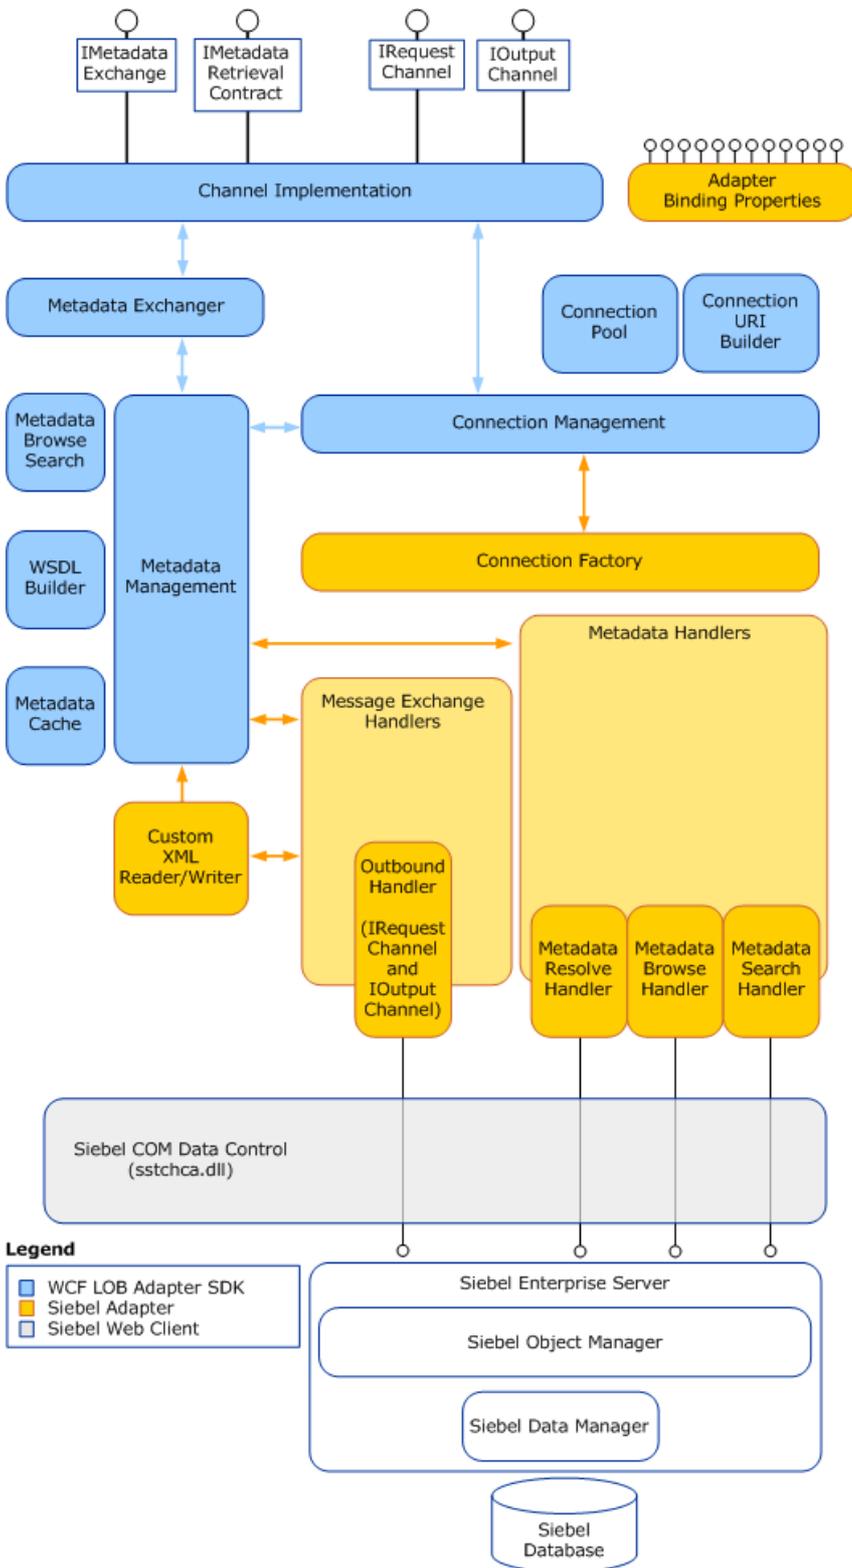

[Understanding BizTalk Adapter for Siebel eBusiness Applications](#)

BizTalk Adapter for Siebel eBusiness Applications and the WCF LOB Adapter SDK

The Microsoft BizTalk Adapter for Siebel eBusiness Applications implements a set of core components that:

- Leverage functionality provided by the Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK.
- Provide connectivity to the Siebel system through the Siebel COM Data Control library (sstchca.dll).

The WCF LOB Adapter SDK is the software layer through which the Siebel adapter interfaces with WCF; Siebel COM Data Control is the layer through which the Siebel adapter interfaces with the Siebel system. The following figure shows the relationships between the internal components of the Siebel adapter and between these components and the Siebel COM Data Control.

Other Resources

[Planning and Architecture](#)

Security and Protection

The Siebel system often contains sensitive business information such as customer account details. Applications that use the Microsoft BizTalk Adapter for Siebel eBusiness Applications to access and modify this information either locally or across a distributed network might inadvertently expose it to access by unauthorized actors, unless efforts are made to protect and secure the data during transmission. Data protection and security are usually thought of in the following terms:

- *Authorization* controls access to a resource based on the identity of the requester.
- *Authentication* provides mechanisms for verifying the identity of a requester.
- *Data confidentiality* provides mechanisms for protecting the privacy of data through encryption.
- *Data integrity* provides mechanisms to digitally sign data, so that the receiver can ensure that the data has not been altered in-transit.

Another important area of concern is the user-name password credentials that you supply to the Siebel adapter. The adapter uses these credentials to open connections to the Siebel system. These credentials can be supplied in the connection URI; however, because the user name and password are clear text, the Siebel adapter provides alternative methods that you can use to supply these credentials in a more secure manner.

The topics in this section provide guidelines to help you better secure the solutions that you develop with the Siebel adapter.

In This Section

- [Security Considerations Between the Siebel System and the Adapter](#)
- [Security Considerations When Using the Adapter with BizTalk Server](#)
- [Security Considerations When Programming on the Adapter](#)
- [Best Practices](#)

Security Considerations Between the Siebel System and the Adapter

The Siebel adapter can support rsa or mscrypto encryption on the data that it exchanges with the Siebel system. You configure the encryption mode through a query string parameter in the connection URI. For more information about the Siebel connection URI, see [The Siebel System Connection URI](#). For more information about rsa and mscrypto encryption support by Siebel, see the Siebel documentation.

Specifying an encryption mode can help to ensure privacy of data exchanged between the adapter and the Siebel system; however, the Siebel adapter does not provide mechanisms that support authorization, authentication or data integrity on such exchanges. If these issues are a concern in your environment, you must provide a security mechanism to help mitigate them.

One possible mechanism for helping to provide more security across the network is Internet Protocol Security (IPsec). IPsec is a framework of open standards for protecting communications over Internet Protocol (IP) networks. For more information about IPsec and about using IPsec with Microsoft products, see the Microsoft TechNet article "IPsec" at <http://go.microsoft.com/fwlink/?LinkID=196851>.

The Siebel adapter supports authorization and authentication on the connections that it establishes with the Siebel system through user name password credentials that you supply. The Siebel adapter uses these credentials to authenticate the user on the Siebel system when it opens a connection. These credentials provide a level of authorization on the Siebel system for the connection. The Siebel adapter provides a number of methods through which you can supply these credentials. For information about how to more securely provide Siebel credentials in BizTalk solutions, see [Security Considerations When Using the Adapter with BizTalk Server](#). For information about how to more securely provide Siebel system credentials in programming solutions, see [Security Considerations When Programming on the Adapter](#).

Note

The credentials used by the Siebel adapter to establish a connection to the Siebel system do not provide message-level or transport-level authentication or authorization for data traveling across the network. They are only used to open a connection and authenticate the user on the Siebel system.

[Security and Protection](#)

Security Considerations When Using the Adapter with BizTalk Server

When you configure a send port or a receive port (location) by using the BizTalk Server Administration console, or when you use the Consume Adapter Service BizTalk Project Add-in to retrieve message schemas for a BizTalk solution, you must provide credentials for the Siebel system. It is important to supply these credentials in a secure way to help prevent them from being revealed to potentially malicious actors. This topic discusses how to most securely supply credentials for the Microsoft BizTalk Adapter for Siebel eBusiness Applications for BizTalk Server solutions.

A more general discussion of security in the context of BizTalk solutions is an expansive topic and is beyond the scope of this documentation. For information about how you can make your BizTalk solutions more secure, see the "Security and Protection" topic in the BizTalk Server Help documentation at <http://go.microsoft.com/fwlink/?LinkID=101135>.

How Do I Protect Credentials When I Use the Consume Adapter Service BizTalk Project Add-in?

When you use the Consume Adapter Service Add-in to retrieve message schemas for a BizTalk solution, you must supply a user name and password for the Siebel system. You should only do this from the **Security** tab on the **Configure Adapter** dialog box. This ensures that your credentials will not be displayed in the **Uri** field of the Consume Adapter Service Add-in dialog box, where anyone with access to your computer screen can read them. For more information about how to retrieve message schemas by using the Consume Adapter Service Add-in, including how to enter a user name and password for the Siebel system, see [Retrieving Metadata for Siebel Operations in Visual Studio](#).

How Do I Protect Credentials When I Configure a Send Port or a Receive Location?

BizTalk solutions use the Microsoft BizTalk WCF-Custom adapter to consume WCF services. The Siebel adapter is a WCF custom binding that enables clients to consume the Siebel system as if it were a WCF service. BizTalk solutions consume the Siebel adapter through send ports and receive locations that are configured to use the WCF-Custom adapter, which is, in turn, configured to use the Siebel adapter as its transport. For more information about how to configure send ports and receive ports (receive locations), including how to configure the WCF-Custom adapter, see [Manually Configuring a Physical Port Binding to the Siebel Adapter](#).

You configure the Siebel system credentials from the **Credentials** tab of the **WCF-Custom Transport Properties** dialog box for send ports or from the **Other** tab of the **WCF-Custom Transport Properties** dialog box for receive locations. Because the WCF-Custom adapter supports Enterprise Single Sign-On (SSO), you can choose to provide either a user name and password or an SSO affiliate application on either of these tabs. The following topics discuss both options.

User Name Password Credentials

You should only supply a user name and password from the **Credentials** tab (for send ports) or the **Other** tab (for receive locations) in the **WCF-Custom Transport Properties** dialog box. This ensures the following:

- Your credentials will not be displayed in the **Uri** field of the dialog box. This prevents those who have access to your screen (or who have permissions that enable them to view the send port or receive location properties) from seeing your credentials.
- Your password will not be written to the binding file if you export the send port or receive port binding. This prevents anyone with access to the file from viewing your password.

Enterprise Single Sign-On and SSO Affiliate Applications

You can configure the WCF-Custom adapter to use Enterprise Single Sign-on (SSO) to get the credentials for the Siebel system. SSO uses a database and a master secret to encrypt and store user credentials. It also provides services to map Microsoft Windows accounts to secondary credentials that are used to access a back-end system. By using SSO, you can map a Windows account to a user name and password on the Siebel system.

SSO uses *affiliate applications* and *SSO mappings* to map credentials to the back-end system. An affiliate application is a logical entity in SSO that refers to a system or an application that requires secondary credentials. An SSO mapping is associated with an affiliate application. It maps a Windows account to the secondary credentials used by that account to access the affiliate system or application. An SSO mapping can be associated with a Windows user account or with a group.

To use SSO with the Siebel adapter, you must do the following.

1. Create an affiliate application in SSO to hold the user name password credentials for the Siebel system. This step is often

performed by someone with special types of SSO administrative privileges.

2. Create a user or group mapping for the affiliate application that maps your Windows account to the user name and password that are used to establish a connection with the Siebel system. Depending on your installation, a user might be able to perform this step or it might require someone with special types of SSO administrative privileges.

Note

When configured for SSO, the WCF-Custom adapter uses services provided by SSO to get the Siebel user name and password from the SSO database. It provides these (unencrypted) to the Siebel adapter, so that the adapter can open a connection to the Siebel system. SSO provides no encryption or protection across the connection between the Siebel adapter and the Siebel system.

For information about how to use SSO, including information about how to create affiliate applications and SSO mappings, see the "Using SSO" topic in the BizTalk Server Help documentation at <http://go.microsoft.com/fwlink/?LinkId=103052>. For more general information about SSO, see the "Implementing Enterprise Single Sign-On" topic in the BizTalk Server Help documentation at <http://go.microsoft.com/fwlink/?LinkId=103054>.

The AcceptCredentialsInUri Binding Property

The Siebel adapter surfaces the **AcceptCredentialsInUri** binding property. This property determines whether Siebel system credentials are permitted in the connection URI. By default, **AcceptCredentialsInUri** is **false** and the Siebel adapter throws an exception if credentials are included in the URI.

This property is surfaced because there are certain programming scenarios that require the credentials to be present in the connection URI. This should never be the case when you are configuring a send port or a receive location, or when you are using the Consume Adapter Service Add-in to retrieve message schemas from the Siebel adapter. It is recommended that you do not set **AcceptCredentialsInUri** to **true**. For more information about the Siebel adapter binding properties, see Working with [Working with BizTalk Adapter for Siebel Binding Properties](#).

The **AcceptCredentialsInUri** binding property is not available in BizTalk Server in the **Binding** tab while configuring a WCF-Custom or WCF-Siebel send port. To set the value of the **AcceptCredentialsInUri** binding property, you must open the adapter bindings file (XML file) that is created after you have generated metadata using the Consume Adapter Service Add-in, and then locate this binding property in the file. Specify an appropriate value for this binding property, save the binding file, and then import the binding file in BizTalk Server. See [Importing Bindings](#) for instructions.

Security Considerations When Programming on the Adapter

How Do I Protect Credentials When I Use the Add Adapter Service Reference Visual Studio Plug-in?

When you use the Add Adapter Service Reference Plug-in to create a WCF client, you must supply a user name and password for the Siebel system. You should only do this from the **Security** tab on the **Configure Adapter** dialog box. By entering the Siebel credentials from the **Security** tab instead of directly into the **Uri** field, you ensure the following:

- The credentials will not be displayed in the **Uri** field of the Add Adapter Service Reference Plug-in dialog box where anyone with access to your computer screen can read them.
- The credentials will not appear in the configuration file that the Add Adapter Service Reference Plug-in generates.

For more information about how to generate a WCF client by using the Add Adapter Service Reference Plug-in, including how to enter a user name and password for the Siebel system, see [Retrieving Metadata for Siebel Operations in Visual Studio](#).

What Are Best Practices for Setting Credentials in Code?

WCF provides the **ClientCredentials** class to help you configure the credentials that a client communication object, such as a **ChannelFactory**, uses to authenticate itself with a service. By using the **ClientCredentials** class, you ensure that WCF takes whatever authentication mechanisms are specified in that object's channel stack and applies them to the exchange between your client and the service.

Because the Siebel adapter is hosted in-process with its consuming application, it is not imperative to use the **ClientCredentials** class to set credentials on the client communication objects that the consuming application uses. It is, however, considered good practice to do so.

The Siebel adapter encourages the use of the **ClientCredentials** class through the **AcceptCredentialsInUri** binding property. This property specifies whether the adapter will accept the user name and password for the Siebel system in the connection URI. **AcceptCredentialsInUri** defaults to **false**, which means that the adapter will throw an exception if the connection URI contains credentials. You can set **AcceptCredentialsInUri** to **true** to supply credentials in the connection URI. In fact, you must do this in certain cases; for example, when you use the ServiceModel Metadata Utility Tool (svcutil.exe) to generate a WCF client class for Siebel system artifacts.

The following example shows how to use the **Credentials** class to set credentials for the Siebel system on a **ChannelFactory**.

```
// Create binding and endpoint
SiebelBinding binding = new SiebelBinding();
EndpointAddress endpointAddress = new EndpointAddress("siebel://Siebel_server:1234?SiebelObjectManager=obj_mgr&SiebelEnterpriseServer=entserver&Language=enu ");

// Create the channel factory
ChannelFactory<IRequestChannel> factory = new ChannelFactory<IRequestChannel>(binding, endpointAddress);

// Set user name and password
factory.Credentials.UserName.UserName = "YourUserName";
factory.Credentials.UserName.Password = "YourPassword";

// Open the channel factory
factory.Open();
```

The following example shows how to use the **ClientCredentials** class to set credentials for the Siebel system on a WCF client.

```
// Initialize a new client for the SQLEXECUTE operation from configuration
BusinessObjects_Account_Account_OperationClient accountAccountClient = new BusinessObjects_Account_Account_OperationClient ("SiebelBinding_BusinessObjects_Account_Account_Operation");

// Set user name and password
accountAccountClient.ClientCredentials.UserName.UserName = "YourUserName";
accountAccountClient.ClientCredentials.UserName.Password = "YourPassword";
```

```
// Open the client
accountAccountClient.Open();
```

How Can I Provide for More Secure Data Exchange Across Process Boundaries?

The Siebel adapter is hosted in-process with the application or service that consumes it. Because the adapter is hosted in-process with the consumer, there is no need to provide security on messages exchanged between the consumer and the Siebel adapter. However, if the consuming application or service sends messages that contain sensitive database information across a process boundary to another service or client, you should take measures to provide adequate protection for this data in your environment. Windows Communication Foundation (WCF) provides many options for helping to secure messages sent between clients and services. For more information about helping to secure messages sent between clients and services in WCF, see "Securing Services and Clients" at <http://go.microsoft.com/fwlink/?LinkId=89725>. For more general information about security features that WCF provides, see "Windows Communication Foundation Security" at <http://go.microsoft.com/fwlink/?LinkId=89726>.

[Security and Protection](#)

Best Practices

This section provides best practices that you should follow to more completely protect sensitive data when you use or develop applications that consume the Microsoft BizTalk Adapter for Siebel eBusiness Applications.

Security Best Practices for the Connection between the Siebel Adapter and the Siebel System

- The Siebel adapter supports mscrypto or rsa encryption on the data exchanged between the adapter and the Siebel system. To help ensure the privacy of the data that is exchanged between the adapter and the Siebel system, you should enable one of these encryption modes.
- The Siebel adapter does not provide mechanisms to help ensure data integrity or to provide for authentication and authorization on the data that is exchanged between it and the Siebel system. You must provide such mechanisms, if these concerns exist in your environment.
- Do not provide user name password credentials for the Siebel system in the connection URI. See the remainder of this topic for alternative methods of providing credentials to the Siebel adapter.

For more information, see [Security Considerations Between the Siebel System and the Adapter](#).

Security Best Practices for Consuming the Siebel Adapter with BizTalk Server

- Do not provide user name password credentials for the Siebel system in the connection URI.
- When you use the Consume Adapter Service Add-in, enter the user name password credentials for the Siebel system from the **Security** tab of the **Configure Adapter** dialog box.
- When you configure the BizTalk WCF-Custom adapter for the Siebel adapter on a send port, enter the user name password credentials for the Siebel system from the **Credentials** tab of the **Configure WCF Custom Transport** dialog box.
- When you configure the BizTalk WCF-Custom adapter for the Siebel adapter on a receive location, enter the user name password credentials for the Siebel system from the **Other** tab of the **Configure WCF Custom Transport** dialog box.

For more information, see [Security Considerations When Using the Adapter with BizTalk Server](#).

Security Best Practices for Consuming the Siebel Adapter with Programming Solutions

- It is sometimes necessary to provide the user name password credentials for the Siebel system in the connection URI; however, if possible, you should avoid doing this.
- When you use the Add Adapter Service Reference Visual Studio Plug-in, enter the user name password credentials for the Siebel system from the **Security** tab of the **Configure Adapter** dialog box.
- In WCF Channel Model programming, use the **Credentials** property on the channel factory to set the user name password credentials for the Siebel system.
- In WCF Service Model programming, use the **ClientCredentials** property on the WCF client to set the user name password credentials for the Siebel system.
- If an application that consumes the Siebel adapter sends messages that contain sensitive database information across a process boundary to another service or client, ensure that these messages have sufficient security measures applied to provide adequate data protection in your environment.

For more information see, [Security Considerations When Programming on the Adapter](#).

Security Best Practices for Hosting the Siebel Adapter in IIS

- Hosting the Siebel adapter in Microsoft Internet Information Services (IIS) as a Web service exposes operations surfaced by the Siebel adapter to Web clients. These operations might involve exchanging sensitive data over the Internet, so you should take measures to help ensure that this data is as secure as possible.

WCF provides two standard bindings for HTTP transport: the **BasicHttpBinding** provides basic HTTP transport with no security mechanisms; the **WSHttpBinding** supports both transport-level and message-level security mechanisms.

You can either use the **BasicHttpBinding** over an HTTPS connection, or use the **WSHttpBinding** to help protect your data. The WCF LOB Adapter SDK includes the WCF LOB Adapter Service Development Wizard to generate WCF services for LOB artifacts. This wizard only supports use of **BasicHttpBinding**.

You can also develop a custom HTTP binding to leverage additional security mechanisms that your environment provides. For more information about the security features that WCF provides, see "Securing Services and Clients" at <http://go.microsoft.com/fwlink/?LinkId=89725>.

Security Best Practices for WCF Diagnostic Tracing and Message Logging

WCF supports diagnostic tracing and message logging. You configure diagnostic tracing and message logging either through configuration files or by using Windows Management Instrumentation (WMI). Depending on the configuration options you set, WCF diagnostic tracing or message logging can emit sensitive information to log files, where it could potentially be exposed to observation by unauthorized users.

Follow the recommendations provided in the WCF documentation to mitigate potential security threats exposed by enabling these features. At a minimum, you should observe the following best practices for diagnostic tracing and message logging:

- Do not enable "verbose" or "information" tracing in a production environment. This may lead to performance degradation. However, you must enable "warning" and "error" tracing in a production environment. If you enable tracing, you must take proper security measures to protect your data. See the WCF documentation for more information.
- Ensure that log files and configuration files are protected by access control lists (ACLs).

The following warnings apply specifically to the messages that are exchanged between a client application and the Siebel adapter:

- WCF diagnostic tracing can log the header (but not the body) of messages exchanged with the Siebel adapter. Because the message action is in the message header, this reveals the operations invoked on the Siebel adapter by the client.
- If WCF message logging is enabled and **logMessagesAtServiceLevel** is **true**, the message header (but not the message body) of messages exchanged between the adapter client and the Siebel adapter are logged. Because the message action is in the message header, this reveals the operations that the client invoked on the Siebel adapter. If **logEntireMessage** is also **true**, the message body will be logged. This can reveal sensitive database information.

For more information about improving security when you enable diagnostic tracing, see "Security Concerns and Useful Tips for Tracing" at <http://go.microsoft.com/fwlink/?LinkId=89796>. For more information about improving security when you enable message logging, see "Security Concerns for Message Logging" at <http://go.microsoft.com/fwlink/?LinkId=89797>.

Development

The Microsoft BizTalk Adapter for Siebel eBusiness Applications is a Windows Communication Foundation (WCF) custom binding. Client applications can consume the Siebel adapter to invoke operations on Siebel artifacts. The Siebel adapter can be consumed:

- Through a physical port binding in a BizTalk Server solution.
- By invoking methods on an instance of a client proxy.
- As a hosted WCF service.
- By sending SOAP messages over a channel instance in code that uses the WCF channel model.
- Through an ADO.NET interface.

The following table:

- Lists the different operations that can be performed on a Siebel system using the Siebel adapter.
- Indicates which of the approaches (BizTalk Server, WCF service model, WCF channel model, or ADO.NET interface) can be used to perform the operations.
- Provides links to more information about performing the task using the chosen approach.

- [Samples](#)

Establishing a Connection to the Siebel System

The Microsoft BizTalk Adapter for Siebel eBusiness Applications is a Windows Communication Foundation (WCF) custom binding. As such, it enables communication to a Siebel system through a WCF endpoint address. In WCF the endpoint address identifies the network location of a service and is typically expressed as a Uniform Resource Identifier (URI). The Siebel adapter expresses this location as a connection URI, which contains properties that the Siebel adapter uses to establish a connection to the Siebel system. You must specify a connection URI when you:

- Create a channel factory or a channel listener using the WCF channel model, or create a WCF client or service host using the WCF service model.
- Create a physical port binding in a BizTalk Server solution.
- Use the Add Adapter Service Reference Visual Studio Plug-in to generate a WCF client class, or WCF service interface for a WCF service model solution.
- Use the Consume Adapter Service BizTalk Project Add-in to retrieve message schemas from the Siebel adapter for a BizTalk Server solution.
- Use the ServiceModel Metadata Utility tool (svcutil.exe) to generate a WCF client class, or WCF service interface for a WCF service model solution.

The topics in this section describe how to establish a connection between the Microsoft BizTalk Adapter for Siebel eBusiness Applications and the Siebel system by providing you with:

- Information about the connection properties and the structure of the Siebel connection URI.
- Links to topics that show how to establish a connection by using the Siebel adapter.

In This Section

- [The Siebel System Connection URI](#)

Concepts

[Development](#)

The Siebel System Connection URI

The Microsoft BizTalk Adapter for Siebel eBusiness Applications connection URI contains properties that the adapter uses to establish a connection to the Siebel system.

This topic provides information about the Siebel connection URI and also provides links to other topics that explain how to specify a connection URI in different programming scenarios.

Connection URI for the Siebel Adapter

A typical WCF endpoint address URI is represented as follows:

```
scheme://userinfoparams@hostinfoparams?query_string
```

The endpoint address URI contains the following components:

- scheme is the scheme name.
- userinfoparams is a name-value collection of parameters required for user authentication by the endpoint.
- hostinfoparams is information required to establish the connection to the host; for example, a path.
- query_string is an optional name-value collection of parameters delimited by a question mark (?).

The Siebel connection URI follows this general format and is implemented as follows:

```
siebel://Username=[USER_NAME];Password=[PASSWORD]@[SERVER]:[PORT]?SiebelObjectManager=[SIEBEL_OBJECT_MANAGER_NAME]&SiebelEnterpriseServer=[SERVER_NAME]&Language=[LANGUAGE]&Transport=[TRANSPORT]&Encryption=[ENCRYPTION]&Compression=[COMPRESSION]&SiebelServer=[SIEBEL_SERVER_NAME]&SiebelRepository=[SIEBEL_REPOSITORY_NAME]
```

The following sections describe the properties implemented for each component of the Siebel connection URI.

The Scheme for the Siebel Connection URI

The scheme for the Siebel connection URI is "siebel".

User Information in the Siebel Connection URI

By default, the Siebel adapter throws an exception when Siebel system credentials are specified in the connection URI. This is because these credentials are represented as plain text, which poses an inherent security risk. You can set the **AcceptCredentialsInUri** binding property to control whether the connection URI can contain credentials. If the **AcceptCredentialsInUri** property is **false**, the Siebel adapter throws an exception if the connection URI contains credentials; if the property is **true**, no exception is thrown.

◆ Important

Due to the inherent security risks posed by passing credentials in strings as plain text, it is best not to specify Siebel system credentials in the connection URI.

There are several ways to supply Siebel system credentials without specifying them in the connection URI.

- In code, you can set the **ClientCredentials** property on the appropriate object.
- When you use the Add Adapter Service Reference Plug-in or the Consume Adapter Service Add-in, you can enter the credentials by selecting the **Security** tab of the **Configure Adapter** dialog box.
- When you specify a send port or receive location binding in a BizTalk Server solution, you can enter the credentials by selecting the **Security** tab of the appropriate dialog box.

The user information (userinfoparams) in the Siebel connection URI is represented as a name-value collection of parameters required for user authentication. The following table describes these parameters.

Property	Description
User name	The user name on the Siebel system; this value is case-sensitive. You must set the AcceptCredentialsInUri binding property to true to specify the user name and password in the connection URI.  Note The Siebel adapter preserves the case of the value that you enter for the user name when it opens a connection on the Siebel system.
Password	The password for the user on the Siebel system; this value is case-sensitive. You must set the AcceptCredentialsInUri binding property to true to specify the user name and password in the connection URI.  Note The Siebel adapter preserves the case of the value that you enter for the password when it opens a connection on the Siebel system.

Host Information in the Siebel Connection URI

The Siebel host information (hostinfoparams) specifies the address of the Siebel system in the following format: [SERVER]:[PORT]. Depending on the Siebel server version, the Siebel host information takes different values:

- **For Siebel version 7.5 and earlier**, the host information parameter takes the name of the computer on which Siebel gateway server is installed and the Siebel gateway port number.
- **For Siebel version 7.7 and later**, the host information parameter takes the name of the computer on which the Siebel server is installed and the Siebel connection broker port number.

Important

When you use the Add Adapter Service Reference Visual Studio Plug-in or the Consume Adapter Service BizTalk Project Add-in to connect to a Siebel system, the host information must be provided for the "SiebelGateway" connection property.

Query Information in the Siebel Connection URI

The query information (query_string) in the Siebel connection URI is used to specify additional connection properties.

Property	Description
SiebelObjectManager	The name of the Siebel object manager on the enterprise server. This parameter is required.
SiebelEnterpriseServer	The name of the Siebel Enterprise Server. This parameter is required.
Language	The language of the object manager. This parameter is optional. If it is not specified, the Siebel adapter supplies a default value (enu).
Transport	The transport; only tcpip is supported. This parameter is optional. If it is not specified, the Siebel system supplies a default value (tcpip).
Encryption	The type of encryption to use between the Siebel adapter and the Siebel system. Supported values are none, mscrypto, or rsa. This parameter is optional. If it is not specified, the Siebel system supplies a default value (none).
Compression	The compression algorithm to use between the Siebel adapter and the Siebel system. Supported values are none or zlib. This parameter is optional. If it is not specified, the Siebel system supplies a default value (zlib).

SiebelServer	The Siebel server. Required for all Siebel 7.5 server connections (7.5.2, 7.5.3, etc.); otherwise, do not set this parameter.
SiebelRepository	The Siebel repository. Required if more than one repository exists on the server; otherwise, optional.  Note If more than one repository exists on the server, you must specify a target repository in the SiebelRepository parameter.

For more information about the Siebel parameters that are set in the query information, see your Siebel documentation.

Using Reserved Characters in the Connection URI

The Siebel adapter does not support specifying a connection URI that has special characters for any of the parameter values. If the connection parameter values contain special characters, make sure you do one of the following:

- If you are specifying the URI in Visual Studio using Add Adapter Service Reference Plug-in or Consume Adapter Service Add-in, you must specify them as-is in the **URI Properties** tab, that is, without using any escape characters. If you specify the URI directly in the **Configure a URI** field and the connection parameters contain reserved characters, you must specify the connection parameters using proper escape characters.
- If you are specifying the URI while creating a send or receive port in BizTalk Server Administration console, and the connection parameters contain reserved characters, you must specify the connection parameters using proper escape characters.

Using the Connection URI to Connect to the Siebel System

The following is a sample Siebel connection URI.

```
siebel://Username=YourUserName;Password=YourPassword@Siebel_server:1234?SiebelObjectManager=obj_mgr&SiebelEnterpriseServer=entserver&Language=enu
```

Note

This sample URI contains the Siebel system credentials; you must set the **AcceptCredentialsInUri** binding property to **true** to use a connection URI that contains credentials.

For information about how to establish a connection to the Siebel system (including setting connection properties) when you:

- Use the Consume Adapter Service BizTalk Project Add-in or the Add Adapter Service Reference Visual Studio Plug-in, see [Retrieving Metadata for Siebel Operations in Visual Studio](#).
- Configure a send port or receive port (location) in a BizTalk Server solution, see [Manually Configuring a Physical Port Binding to the Siebel Adapter](#).
- Use the WCF channel model in a programming solution, see [Creating a Channel](#).
- Use the WCF service model in a programming solution, see [Configuring a WCF Client for a Siebel System](#).
- Use the WCF ServiceModel Metadata Utility Tool (svcutil.exe), see [Using the ServiceModel Metadata Utility Tool with the BizTalk Adapter for Siebel eBusiness Applications](#).

Retrieving Metadata for Siebel Operations in Visual Studio

The Microsoft BizTalk Adapter for Siebel eBusiness Applications provides two Visual Studio components that you can use to help you develop solutions using the adapter.

- The Consume Adapter Service BizTalk Project Add-in is available in BizTalk Server projects. You use the Consume Adapter Service Add-in to generate message schemas (XSDs) for operations that you want to target in your BizTalk solution. For more information about developing solutions with BizTalk Server, see [Developing BizTalk Applications](#).
- The Add Adapter Service Reference Visual Studio Plug-in is available in non-BizTalk programming projects. You use the Add Adapter Service Reference Plug-in to generate a WCF client class or a WCF service callback interface when you develop solutions using the WCF service model. For more information about developing solutions with the WCF service model, see [Developing Applications by Using the WCF Service Model](#).

Both of these Visual Studio components simplify development by:

- Providing a Microsoft Windows interface through which you can browse and search for operations that you want to use in your solution.
- Retrieving metadata exposed by the adapter for these target operations.
- Converting that metadata, which is expressed as a Web Services Description Language (WSDL) document by the adapter, into a form that you can use in your solution (XSD message schemas for BizTalk projects or a .NET object representation of a service contract for the WCF service model) and adding it to your project.

This section provides instructions about how to use the Consume Adapter Service Add-in and the Add Adapter Service Reference Plug-in.

In This Section

- [Connecting to the Siebel System in Visual Studio](#)
- [Browsing, Searching, and Retrieving Metadata for Siebel Operations](#)

[Development](#)

Connecting to the Siebel System in Visual Studio

This section provides instructions about how to use the Consume Adapter Service Add-in, the Add Adapter Metadata Wizard, and the Add Adapter Service Reference Plug-in.

- The **Consume Adapter Service BizTalk Project Add-in** is available in BizTalk Server projects and is installed as part of the WCF LOB Adapter SDK installation. You use the Consume Adapter Service Add-in to generate message schemas (XSDs) for operations that you want to target in your BizTalk solution. For more information about developing solutions with BizTalk Server, see [Developing BizTalk Applications](#).
- The **Add Adapter Metadata Wizard** is available in the BizTalk Server projects and is installed as part of the BizTalk Server installation. You use the Add Adapter Metadata Wizard to generate message schemas (XSDs) for operations that you want to target in your BizTalk solution. For more information about developing solutions with BizTalk Server, see [Developing BizTalk Applications](#).

Note

Because the Siebel adapter is exposed both as a WCF-Custom binding and as BizTalk adapter, you can use either the Consume Adapter Service Add-in or the Add Adapter Metadata Wizard from a BizTalk project to connect to a Siebel system.

- The **Add Adapter Service Reference Visual Studio Plug-in** is available in non-BizTalk programming projects. You use the Add Adapter Service Reference Plug-in to generate a WCF client class or a WCF service callback interface when you develop solutions using the WCF service model. For more information about developing solutions with the WCF service model, see [Developing Applications by Using the WCF Service Model](#).

To use the Consume Adapter Service BizTalk Project Add-in, Add Adapter Metadata Wizard, or the Add Adapter Service Reference Visual Studio Plug-in, you must first connect to the Siebel system. All three methods present a dialog box through which you configure a connection by setting the following:

- **Connection parameters.** These are the parameters that are used to build the connection URI such as the name of the Siebel Enterprise Server.
- **User name password credentials for the Siebel system.** These are used to authenticate you on the Siebel system when the connection is established. You must specify a user name and password.
- **Binding properties.** Binding properties are optional and whether you specify them depends primarily on whether you target operations that require specific binding properties to be set.

At a minimum, when you configure the connection to the Siebel system, you only have to specify binding properties and connection parameters that are needed to establish the connection and that affect the metadata returned by the Siebel adapter for the operations you want to target. However, you might also want to specify values for any additional binding properties and connection parameters that will be used at run time. This is because:

- The Consume Adapter Service Add-in creates a BizTalk port binding file from the binding properties and connection parameters that you specify when you configure the connection and adds this file to your project.
- The Add Adapter Service Reference Plug-in creates an app.config file from the binding properties and connection properties that you specify when you configure the connection and adds this file in your project directory.

In This Section

[Retrieving Metadata for Siebel Operations in Visual Studio](#)

Connecting to the Siebel System in Visual Studio Using Consume Adapter Service Add-in

The Consume Adapter Service BizTalk Project Add-in is installed when you install WCF LOB Adapter SDK. The Consume Adapter Service Add-in loads all the WCF-Custom bindings installed on the computer. To connect to a Siebel system using the WCF-based Siebel adapter in a BizTalk project, you must use the **siebelBinding**.

Connecting to a Siebel System Using Consume Adapter Service Add-in

Perform the following steps to connect to a Siebel system using the Consume Adapter Service Add-in.

To connect to a Siebel system

1. To connect using the Consume Adapter Service Add-in in a BizTalk solution:
 - a. Create a BizTalk project using Visual Studio.
 - b. Right-click the project in Solution Explorer, point to **Add**, and then click **Add Generated Items**.
 - c. In the **Add Generated Items** dialog box, do the following:

Use this	To do this
Categories	Click Consume Adapter Service .
Templates	Click Consume Adapter Service .

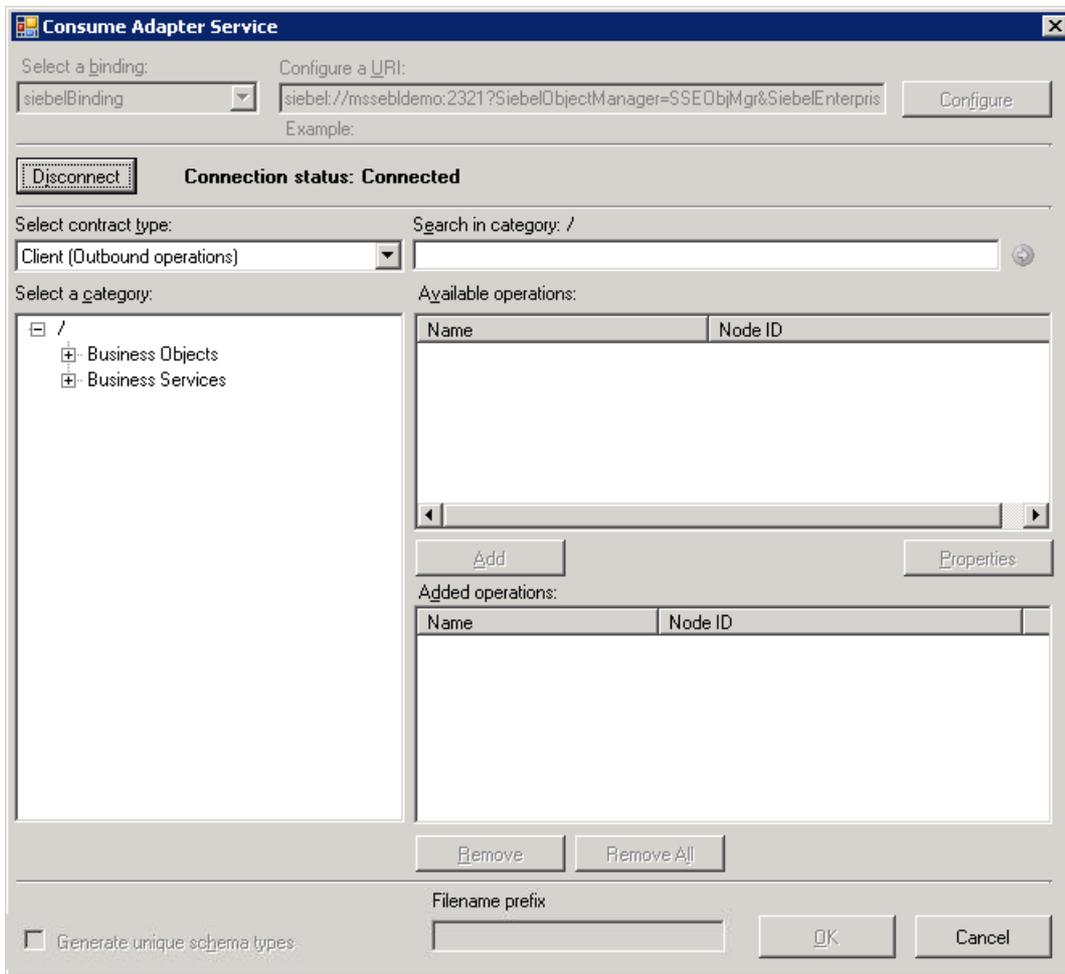

- d. Click **Add**. The Consume Adapter Service Add-in opens.
2. From the **Select a binding** drop-down list, select **siebelBinding**, and then click **Configure**.
 3. In the **Configure Adapter** dialog box, click the **Security** tab, and from the **Client credential type** drop-down list box, select **Username**.
 4. Specify the user name and password to connect to the Siebel system.
 5. Click the **URI Properties** tab, and specify values for the connection parameters. For more information about the connection URI for the Siebel adapter, see [The Siebel System Connection URI](#).

Note

If the connection parameters contain any reserved characters, you must specify them as-is in the **URI Properties** tab, that is, without using any escape characters. However, if you specify the URI directly in the **Configure a URI** field and the connection parameters contain reserved characters, you must specify the connection parameters using proper escape characters.

6. Click the **Binding Properties** tab, and then specify values for the binding properties, if any, required by the operations you want to target. For more information about binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).
7. Click **OK**.
8. Click **Connect**. Once the connection is established, the connection status is shown as **Connected**.

The following figure shows the Consume Adapter Service Add-in immediately after the connection is established.

The Consume Adapter Service Add-in displays different nodes containing various operations that can be performed on the Siebel system. For example, the **Business Objects** node contains all the business objects and business components that can be invoked on the Siebel system. Similarly, the **Business Services** node contains all the business services in the Siebel system you connected to. For more information about these nodes, see [Metadata Node IDs](#).

Connecting to the Siebel System in Visual Studio Using Add Adapter Metadata Wizard

The Siebel adapter is also exposed as a BizTalk adapter and hence, you can use the Add Adapter Metadata Wizard to generate schema for the operations you want to perform on the Siebel system using the adapter.

Connecting to a Siebel System Using Add Adapter Metadata Wizard

Perform the following steps to connect to a Siebel system using the Add Adapter Metadata Wizard.

To connect to a Siebel system

1. To connect using the Add Adapter Metadata Wizard in a BizTalk solution:
 - a. Create a BizTalk project using Visual Studio.
 - b. Right-click the project in Solution Explorer, point to **Add**, and then click **Add Generated Items**.
 - c. In the **Add Generated Items** dialog box, do the following:

Use this	To do this
Categories	Click Consume Adapter Service .
Templates	Click Consume Adapter Service .

- d. Click **Add**. The Add Adapter Metadata Wizard opens.
- e. In the Add Adapter Metadata Wizard, select WCF-Siebel. Select the computer on which BizTalk Server is installed and the name of the BizTalk database.

◆ Important
If you already have a WCF-Siebel port configured in BizTalk, select the port from the Port list.

- f. Click **Next**.
2. From the **Select a binding** drop-down list, select **siebelBinding**, and then click **Configure**.
 3. In the **Configure Adapter** dialog box, click the **Security** tab, and from the **Client credential type** drop-down list box, select **Username**.
 4. Specify the user name and password to connect to the Siebel system.
 5. Click the **URI Properties** tab, and specify values for the connection parameters. For more information about the connection URI for the Siebel adapter, see [The Siebel System Connection URI](#).

📌 Note
If the connection parameters contain any reserved characters, you must specify them as-is in the URI Properties tab, that is, without using any escape characters. However, if you specify the URI directly in the Configure a URI field and the connection parameters contain reserved characters, you must specify the connection parameters using proper escape characters.

6. Click the **Binding Properties** tab, and then specify values for the binding properties, if any, required by the operations you want to target. For more information about binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).

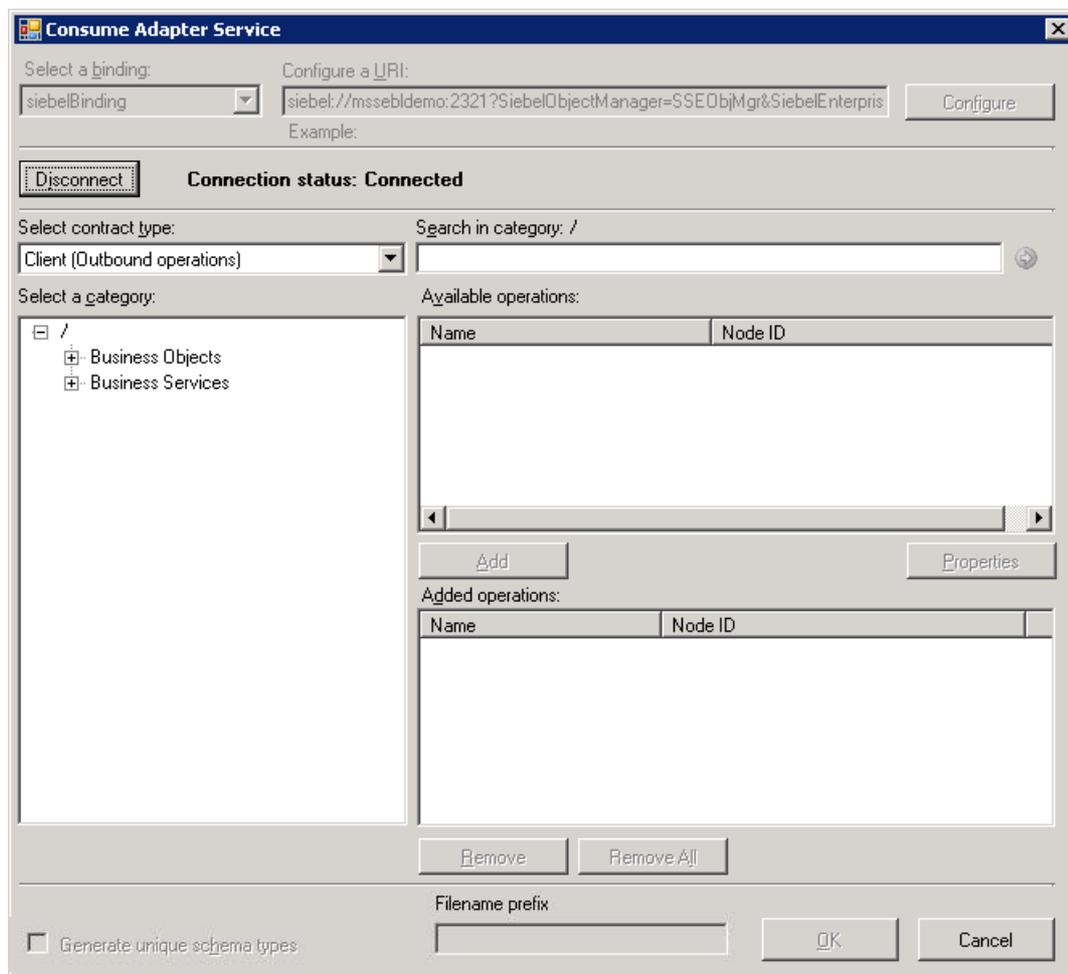

📌 Note

If you are generating metadata using Add Adapter Metadata Wizard and you selected an existing WCF-Siebel send port, you need not specify the binding properties. The binding properties are picked from the send port configuration. However, you may choose to specify the binding properties that are required at design-time, if any. In such case, the new values for binding properties will be used at design-time while generating the metadata. However, at run-time the values specified for binding properties in the send port configuration will be applicable.

7. Click **OK**.

8. Click **Connect**. Once the connection is established, the connection status is shown as **Connected**.

The following figure shows the Consume Adapter Service Add-in immediately after the connection is established.

The Consume Adapter Service Add-in displays different nodes containing various operations that can be performed on the Siebel system. For example, the **Business Objects** node contains all the business objects and business components that can be invoked on the Siebel system. Similarly, the **Business Services** node contains all the business services in the Siebel system you connected to. For more information about these nodes, see [Metadata Node IDs](#).

Connecting to the Siebel System in Visual Studio Using Add Adapter Service Reference Plug-in

To connect to a Siebel system using the Siebel adapter in a .NET programming solution, you must use the Add Adapter Service Reference Visual Studio Plug-in. This topic provides instructions on how to use the Add Adapter Service Reference Plug-in.

Connecting to a Siebel System Using Add Adapter Service Reference Plug-in

Perform the following steps to connect to a Siebel system using the Add Adapter Service Reference Plug-in.

To connect to a Siebel system

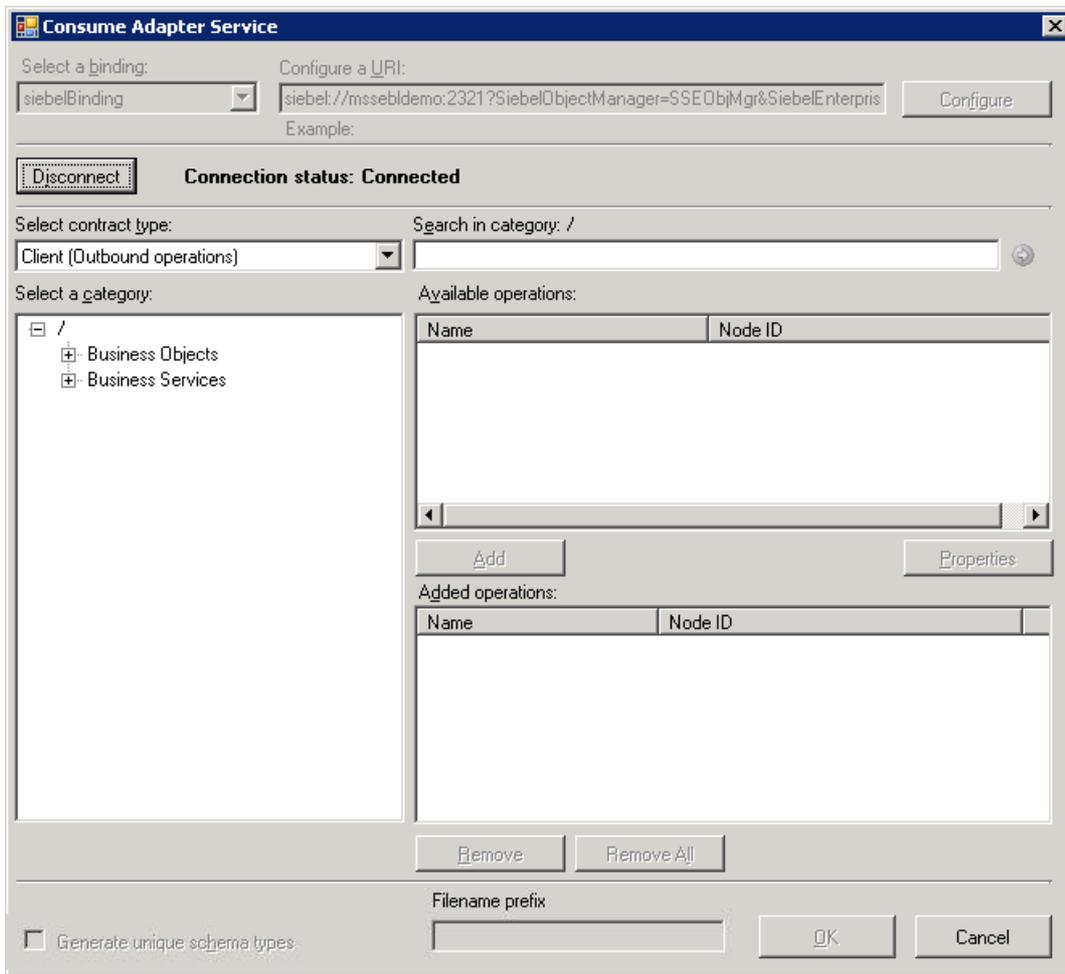

1. To connect using the Consume Adapter Service Add-in in a BizTalk solution:
 - a. Create a BizTalk project using Visual Studio.
 - b. Right-click the project in Solution Explorer, and then click **Add Adapter Service Reference**. The Add Adapter Service Reference Plug-in opens.
2. From the **Select a binding** drop-down list, select **siebelBinding**, and then click **Configure**.
3. In the **Configure Adapter** dialog box, click the **Security** tab, and from the **Client credential type** drop-down list box, select **Username**.
4. Specify the user name and password to connect to the Siebel system.
5. Click the **URI Properties** tab, and specify values for the connection parameters. For more information about the connection URI for the Siebel adapter, see [The Siebel System Connection URI](#).

Note

If the connection parameters contain any reserved characters, you must specify them as-is in the **URI Properties** tab, that is, without using any escape characters. However, if you specify the URI directly in the **Configure a URI** field and the connection parameters contain reserved characters, you must specify the connection parameters using proper escape characters.

6. Click the **Binding Properties** tab, and then specify values for the binding properties, if any, required by the operations you want to target. For more information about binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).
7. Click **OK**.
8. Click **Connect**. Once the connection is established, the connection status is shown as **Connected**.

The following figure shows the Consume Adapter Service Add-in immediately after the connection is established. The graphical user interface is same for the Add Adapter Service Reference Plug-in.

The Add Adapter Service Reference Plug-in displays different nodes containing various operations that can be performed on the Siebel system. For example, the **Business Objects** node contains all the business objects and business components that can be invoked on the Siebel system. Similarly, the **Business Services** node contains all the business services in the Siebel system you connected to. For more information about these nodes, see [Metadata Node IDs](#).

Browsing, Searching, and Retrieving Metadata for Siebel Operations

This section provides information about how to use the Consume Adapter Service BizTalk Project Add-in, the Add Adapter Metadata Wizard, and the Add Adapter Service Reference Visual Studio Plug-in. By using these Visual Studio components, you can:

- Browse for operations for which to retrieve metadata.
- Search for operations for which to retrieve metadata.
- Add message schemas for selected operations and port binding configuration files to a BizTalk Server project when using the Consume Adapter Service Add-in.
- Add a WCF client class or a WCF service contract (interface) for selected operations and a configuration file (app.config) to a non-BizTalk programming project when using the Add Adapter Service Reference Plug-in.

Note

The Consume Adapter Service Add-in, the Add Adapter Metadata Wizard, and the Add Adapter Service Reference Plug-in present essentially the same interface when you browse and search for operations, so all three components are covered in the same topics.

Prerequisites

You must connect to a Siebel system before you can browse, search, or retrieve metadata for target operations. For information about how to connect to a Siebel system when you use the Consume Adapter Service Add-in, the Add Adapter Metadata Wizard, or the Add Adapter Service Reference Plug-in, see [Connecting to the Siebel System in Visual Studio](#).

Browsing Metadata

While browsing metadata using the Consume Adapter Service Add-in, the Add Adapter Metadata Wizard, or Add Adapter Service Reference Plug-in, the Siebel adapter surfaces:

- Operations that can be performed on Siebel business components such as Insert, Query, Update, and Delete.
- Business service methods that can be invoked by the adapter clients.

Note

By using the Consume Adapter Service Add-in, the Add Adapter Metadata Wizard, or Add Adapter Service Reference Plug-in, you can browse category and operation nodes using a Windows interface.

For more information about browsing Siebel metadata, see [How Does the Adapter Surface Siebel Metadata?](#)

Perform the following steps to browse metadata of a Siebel system using the Consume Adapter Service Add-in or Add Adapter Service Reference Plug-in.

To browse metadata in a Siebel system

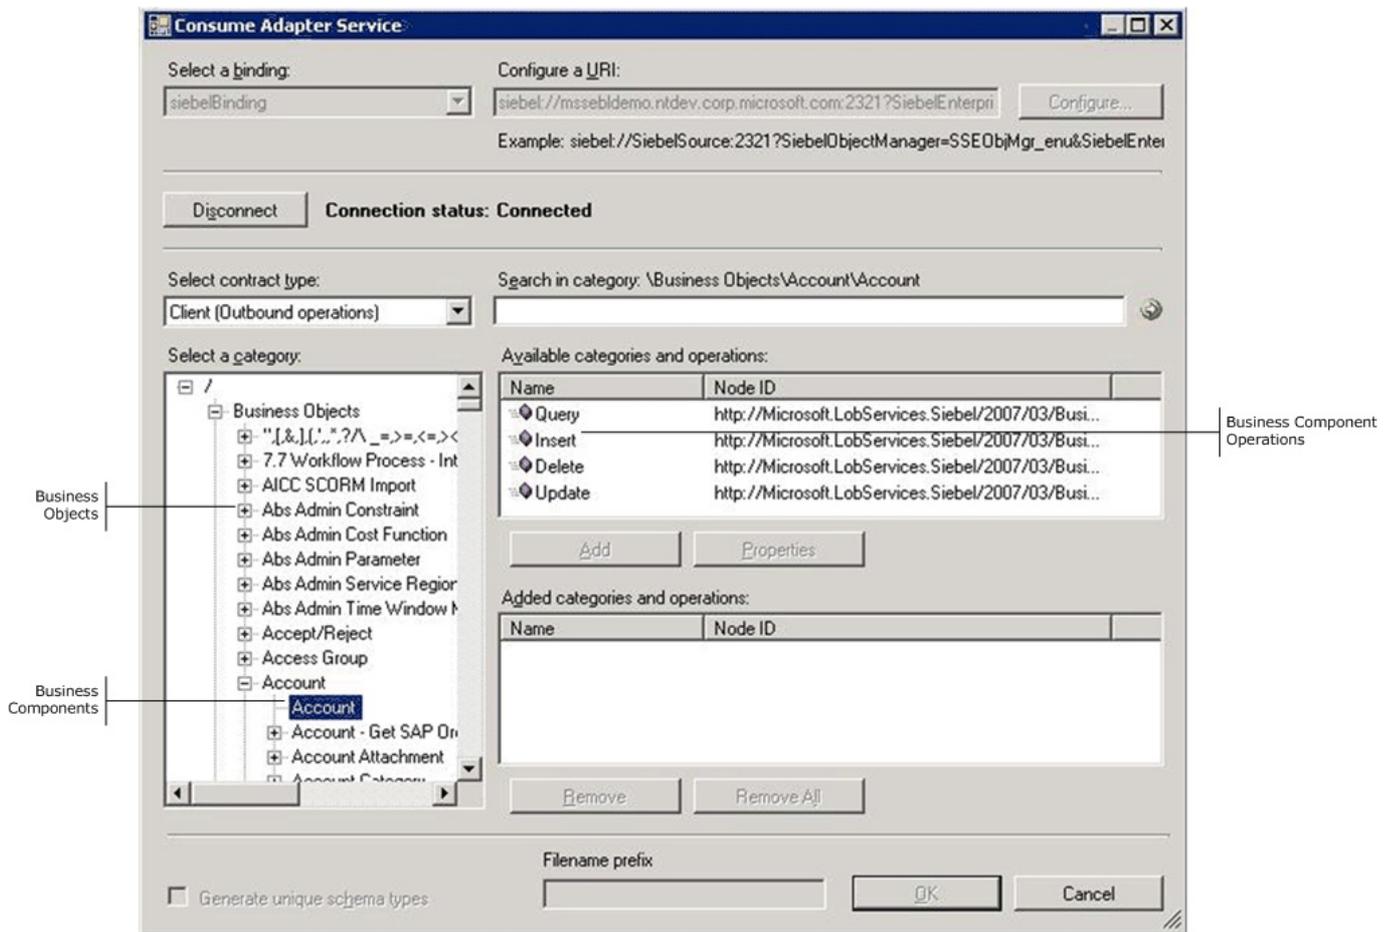

1. Connect to a Siebel system using the Consume Adapter Service Add-in, Add Adapter Metadata Wizard, or Add Adapter Service Reference Plug-in. See [Connecting to the Siebel System in Visual Studio](#) for instructions.
2. From the **Select contract type** drop-down list, select the type of contract based on whether you will be performing inbound or outbound operations using the adapter.
3. The **Select a category** box lists the **Business Objects** and **Business Services** nodes. Click the **Business Objects** node to see a list of business objects in the **Available categories and operations** box. Alternatively, you can see the list of business objects by expanding the **Business Objects** node.

Tip

You can directly go to the "immediate" category node or subcategory nodes in the tree, by typing the name of the artifact in while the focus is on the tree view in the **Select a category** box. For example, to jump to the **Account** business object, keep the focus on the **Business Objects** node, and then type **Account**.

4. Click the business objects to see the list of business components for a particular business object. Alternatively, you can see the list of business components by expanding a business object.
5. Click the business components to see the list of operations supported for the particular business component.

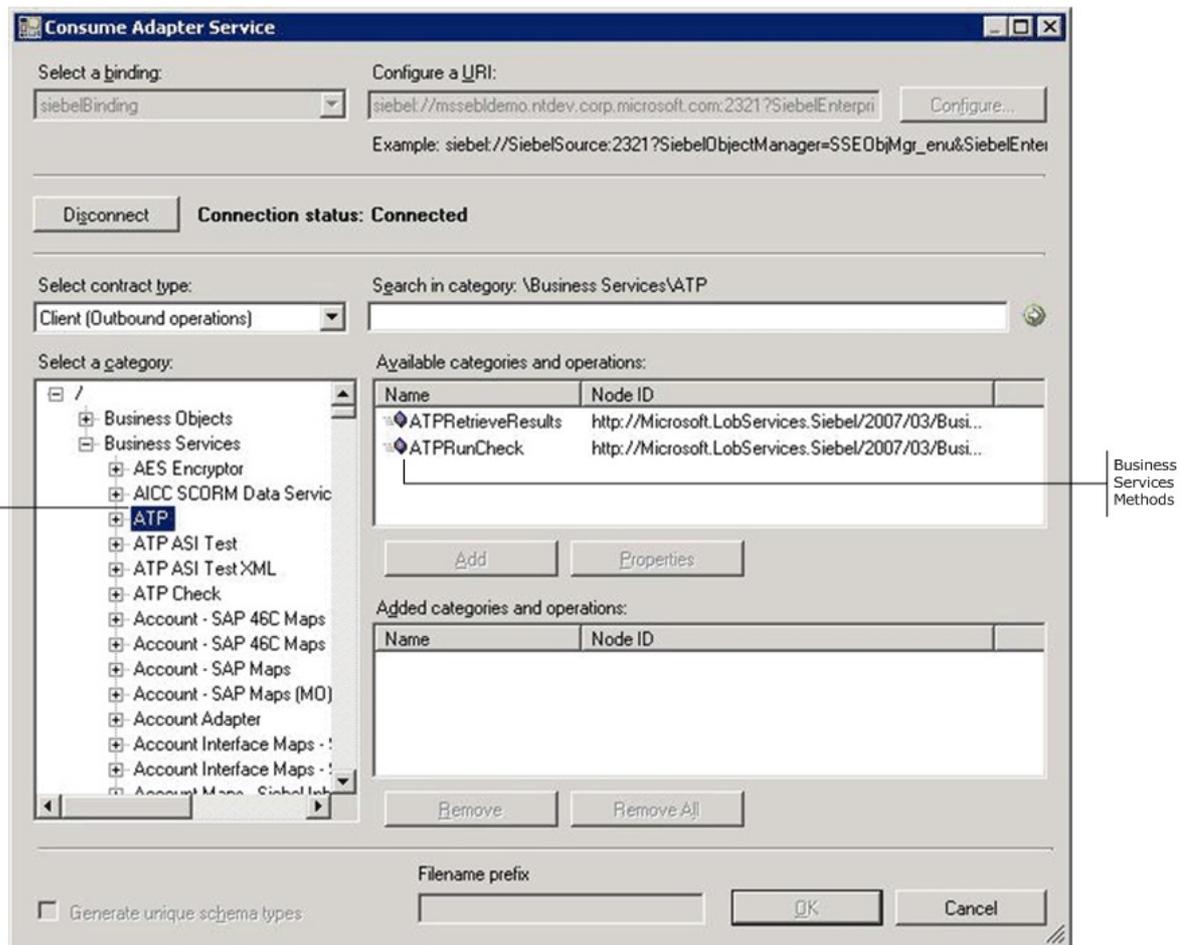

The following figure shows the Consume Adapter Service Add-in, which lists the business object, the business components, and the supported operations.

6. Click the **Business Services** node to see a list of business services in the **Available categories and operations** box. Alternatively, you can see the list of tables by expanding the **Business Services** node.

7. Click the business services to see the list of corresponding business service methods.

The following figure shows the Consume Adapter Service Add-in, which lists the business services and the corresponding business service methods.

Searching Metadata

While searching Siebel metadata using Add Adapter Service Reference Plug-in, Add Adapter Metadata Wizard, or Consume Adapter Service Add-in, the Siebel adapter:

- Supports wildcard and escape characters.
- Enables search immediately under the node at which the search operation is performed. For example, to search for a business service, you must be searching under \Business Services.

The following table lists the special characters that can be used for search and their interpretation by the Siebel adapter.

Special character	Interpretation
? (question mark)	Matches exactly one character For example, A? matches AB, AC, AD.
* (asterisk)	Matches zero or more characters. For example, A* matches A, AB, ABC.

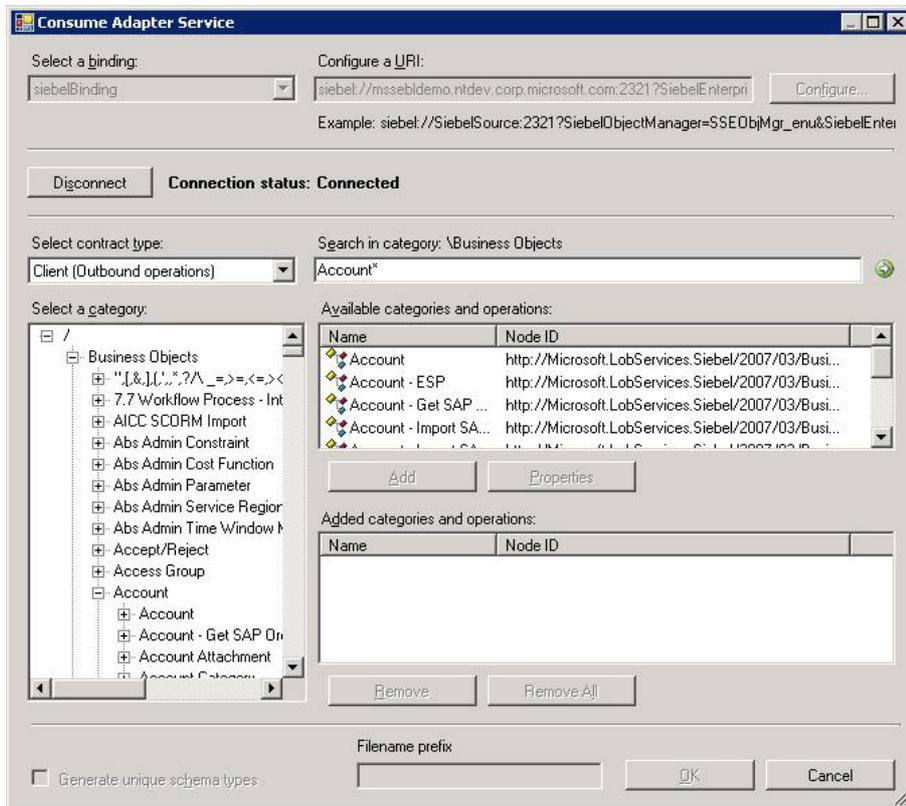

Perform the following steps to search metadata in a Siebel system using the Consume Adapter Service Add-in or Add Adapter Service Reference Plug-in.

To search metadata in a Siebel system

1. Connect to a Siebel system using the Consume Adapter Service Add-in, Add Adapter Metadata Wizard, or Add Adapter Service Reference Plug-in. See [Connecting to the Siebel System in Visual Studio](#) for instructions.
2. From the **Select contract type** drop-down list, select the **Client (Outbound operations)** contract.
3. In the **Select a category** box, click the **Business Object** node.
4. To search for a particular business object, click the **Business Objects** node in the **Search in category** text box and enter a search expression. For example, to search for business objects that have names beginning with "Account", type **Account*** in the text box.
5. Click the button with the right-arrow icon to start the search. After the search is complete, the **Available categories and operations** box lists the business objects that satisfy the search criteria.
6. To search for a particular business component under a business object, click a business object and in the **Search in category** text box enter a search expression. For example, to search for business components that have names beginning with "Account", type **Account*** in the text box.

7. Click the button with the right-arrow icon to start the search. After the search is complete, the **Available categories and operations** box lists the business components that satisfy the search criteria.
8. To search particular operations for a business component, click a business component and in the **Search in category** text box enter a search expression. For example, to search for operations having names starting with "Query", type **Query*** in the text box.
9. Click the button with the right-arrow icon to start the search. After the search is complete, the **Available categories and operations** box lists the business components that satisfy the search criteria.

The following figure shows the Consume Adapter Service Add-in, which lists the search result.

Perform a similar procedure to search under the **Business Service** node.

Generating Schema for BizTalk projects

You can use the Consume Adapter Service Add-in or the Add Adapter Metadata Wizard to generate schema for selected Siebel artifacts. Once you have browsed and searched for the artifacts you want to invoke, you can generate schema for those artifacts and send messages, conforming to the schema, to Siebel.

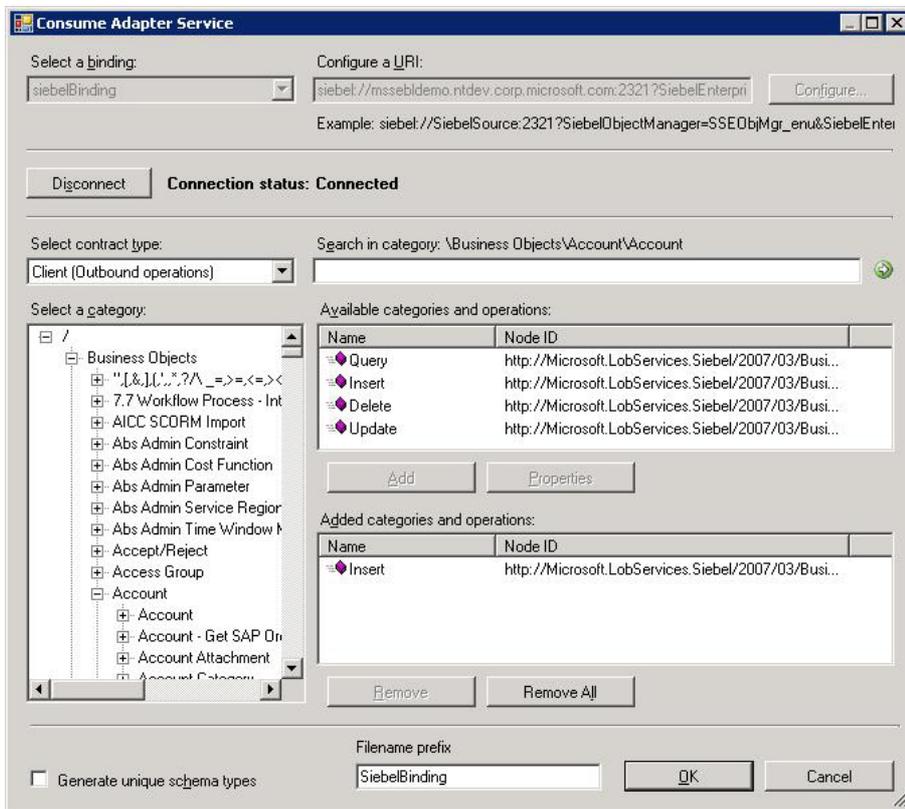

Note

You can select category nodes to return all the operations in that category's sub-tree—for example, you can select a business component (to generate schema for all the operations in the business component) or a select specific operations on a business component (for example, Insert and Delete) to generate schema for only those operations. For more information about the nodes, see [Metadata Node IDs](#).

To generate schema for Siebel artifacts

1. Connect to a Siebel system using the Consume Adapter Service Add-in or the Add Adapter Metadata Wizard. See [Connecting to the Siebel System in Visual Studio](#) for instructions.
2. From the **Select contract type** drop-down list, select the **Client (Outbound operations)** contract.
3. In the **Select a category** box, expand the business object or business service node.
4. In the **Available categories and operations** box, select the business components or business services or the corresponding operations for which you want to generate metadata, and then click **Add**. The selected functional areas or operations are listed in the **Added categories and operations** box.

The following figure shows the Consume Adapter Service Add-in, which lists the selected operations.

If you want to generate schema for multiple operations, there may be some duplicate element definitions among these schema that may cause failure in compiling the BizTalk project. For example, consider a scenario where you generate schema for an operation "Op1". The schema for "Op1" contains a parameter of complex data type "CT1". After generating the schema for "Op1" you close the Consume Adapter Service Add-in and re-open it to generate schema for another operation "Op2". Assume that "Op2" also contains a parameter of complex data type "CT1". After you exit the Consume Adapter Service Add-in and compile the project, you will get compilation errors because the complex data type "CT1" is defined twice in different XSD files. In such situations, we recommend the following:

- Generate schema for all the operations in a single run of Consume Adapter Service Add-in. This ensures that the Consume Adapter Service Add-in generates only one definition for the complex data type "CT1".
- If you want to generate schema for multiple operations across different runs of Consume Adapter Service Add-in, make sure you select the **Generate unique schema types** check box so that the generated XSD files contain unique namespaces for the complex data type "CT1".

5. Click **OK**. The schema file is saved with an .xsd extension at the same location as the BizTalk project.

By default, the files are created with the naming convention "SiebelBindingSchema<n>.xsd", where 'n' can be 1, 2, and so on, depending on the number of schema files created. Alternatively, you can provide a custom name to the schema files by entering a name in the **Filename prefix** text box. The Consume Adapter Service Add-in now creates schema files with the naming convention <file name prefix>Schema<n>.xsd.

Note

The Consume Adapter Service Add-in also creates a binding file (an XML file) containing the binding properties that you specified when generating the schema for an operation and the SOAP action to invoke the operation. You can import this binding file in the BizTalk Server Administration console to create a WCF-Custom port with the connection URI, binding properties, and the SOAP action set. For more information, see [Configuring a Physical Port Binding Using a Port Binding File](#).

6. On the **File** menu, click **Save All**.

Generating a WCF Client Using the Add Adapter Service Reference Plug-in

You can use the Add Adapter Service Reference Plug-in to generate WCF client code for outbound operations on a Siebel system.

To generate a WCF client

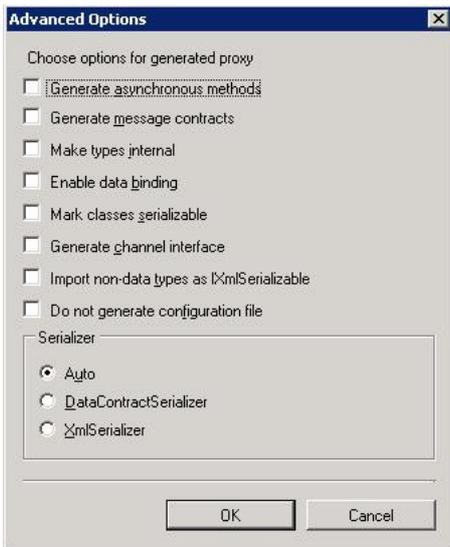

1. In the Add Adapter Service Reference Plug-in, from the **Select contract type** drop-down list, select **Client (Outbound operations)**.
2. In the **Select a category** box, expand the business object or business service node.
3. In the **Available categories and operations** box, select the business components, business services, or the corresponding operations for which you want to generate a WCF client, and then click **Add**. The selected functional areas or operations are listed in the **Added categories and operations** box. You can select any node that is listed in the **Available categories and operations** box. If you select a category node, then all of the operations available under that node and its sub-nodes will be selected.

Important

Depending on the categories and operations that you select, more than one WCF client class may be generated. For more information, see [Generating a WCF Client for Siebel Artifacts](#).

4. For most scenarios the default serialization options are sufficient; however, if needed, you can control several aspects about the code that is generated and the type of serializer that is used. To set these options:
 - a. To open the **Advanced Options** box, click **Advanced Options**.
 - b. In the **Advanced Options** box under **Choose options for generated proxy**, select the options that you want. For example, you can select whether asynchronous methods are generated for the WCF client, or you can disable the generation of a configuration file.
 - c. Under **Serializer**, select the serializer that should be used.

The following figure shows the **Advanced Options** box with the default selections (**Auto** is selected for the serializer and no other options are selected).

The options that you can configure in the **Advanced Options** box are equivalent to some of the options available when you use the ServiceModel Metadata Utility Tool (svcutil.exe). For more information about these options, see "ServiceModel Metadata Utility Tool (Svcutil.exe)" at <http://go.microsoft.com/fwlink/?LinkId=99821>.

5. Click **OK**. The Add Adapter Service Reference Plug-in saves the WCF client class and helper code for the operations and categories that you have selected in your project directory. By default, a configuration file is also saved. For more information, see [Generating a WCF Client for Siebel Artifacts](#).

Working with BizTalk Adapter for Siebel Binding Properties

The Microsoft BizTalk Adapter for Siebel eBusiness Applications surfaces several binding properties that enable you to control some of its run-time and design-time behavior. This section describes these binding properties and provides links to topics that explain how you can set them.

The Siebel Adapter Binding Properties

The following table shows the Siebel adapter binding properties grouped by category. The category refers to the node under which each binding property appears in the dialog boxes that are presented by different applications to configure the adapter (or binding).

Binding Property	Category	Description	.NET Type
EnableBizTalkCompatibilityMode	General	Specifies whether the BizTalk Layered Channel Binding Element should be loaded. Set this to True to load the binding element. Otherwise, set this to False . When using the adapters from BizTalk Server, you must always set the property to True . When using the adapters from Visual Studio, you must always set the property to False .	bool (System.Boolean)
Name	General	Specifies the name of the file generated by the Add Adapter Service Reference Visual Studio Plug-in to hold the WCF client class. The Add Adapter Service Reference Plug-in forms the file name by appending "Client" to the value of the Name property. The default is "SiebelBinding"; for this value, the generated file will be named "SiebelBindingClient".	string
CloseTimeout	General	Specifies the WCF connection close timeout. The default is 1 minute.	System.DateTime
OpenTimeout	General	Specifies the WCF connection open timeout. The default is 1 minute.	System.DateTime
ReceiveTimeout	General	Specifies the WCF message receive timeout. The default is 10 minutes.	System.DateTime
SendTimeout	General	Specifies the WCF message send timeout. The default is 1 minute.	System.DateTime
EnableConnectionPooling	Connection	Specifies whether the Siebel adapter connection pool is enabled. The default is true , which specifies that the connection pool is enabled.	bool (System.Boolean)

IdleConnectionTimeout	Connection	Specifies the Siebel adapter idle connection timeout. When a connection is idle for a period that exceeds this timeout, the connection will be disposed. The default is 1 minute.	System.Data.Time
MaxConnectionsPerSystem	Connection	Specifies the maximum number of connections in the Siebel adapter connection pool. The default is 5. MaxConnectionsPerSystem is a static property within an application domain. This means that when you change MaxConnectionsPerSystem for one binding instance in an application domain, the new value applies to all objects created from all binding instances within that application domain.	int (System.Int32)
EnablePerformanceCounters	Diagnostics	Specifies whether the WCF LOB Adapter SDK performance counters and the Siebel adapter LOB Latency performance counter are enabled. The default is true ; performance counters are enabled. The Siebel adapter LOB Latency performance counter measures the total time the adapter spends in making calls to the Siebel system.	boolean (System.Boolean)
LogData	Diagnostics	Specifies whether to capture business data in traces. The default is false ; business data is not captured.	boolean (System.Boolean)
AcceptCredentialsInUri	Not surfaced by the Consume Adapter Service Add-in or the Add Adapter Service Reference Plug-in.	Specifies whether the Siebel connection URI can contain user credentials for the Siebel system. The default is false , which disables user credentials in the connection URI. If AcceptCredentialsInUri is false and the connection URI contains user credentials, the Siebel adapter throws an exception. You can set AcceptCredentialsInUri to true if you must specify credentials in the URI. For more information, see The Siebel System Connection URI .	boolean (System.Boolean)

How Do I Set Siebel Binding Properties?

You can set the Siebel binding properties when you configure a connection to a Siebel system. For information about how to set binding properties when you:

- Use the Consume Adapter Service BizTalk Project Add-in or the Add Adapter Service Reference Visual Studio Plug-in, see [Connecting to the Siebel System in Visual Studio](#).

◆ Important

While using the Consume Adapter Service Add-in or the Add Adapter Service Reference Plug-in, if you do not specify a value for a binding property of type string and whose default value is null then that binding property will not be available in the binding file (an XML file) or the app.config file respectively. You must manually add the binding property and its value in the binding file or the app.config file, if required.

- Configure a send port or receive port (location) in a BizTalk Server solution, see [Manually Configuring a Physical Port Binding to the Siebel Adapter](#).
- Use the WCF channel model in a programming solution, see [Creating a Channel](#).
- Use the WCF service model in a programming solution, see [Configuring a WCF Client for a Siebel System](#).
- Use the WCF ServiceModel Metadata Utility Tool (svcutil.exe), see [Using the ServiceModel Metadata Utility Tool with the BizTalk Adapter for Siebel eBusiness Applications](#).

Concepts
[Development](#)

Developing BizTalk Applications

Developing BizTalk applications involves creating a BizTalk project in Visual Studio and using the Consume Adapter Service BizTalk Project Add-in to generate XML schema. Once you have generated the schema, you can either use Content-Based Routing (CBR) or create BizTalk orchestrations to send and receive messages that conform to the generated schema.

CBR can be used in scenarios where the messages being sent to a Siebel system do not require any intensive processing. For example, if you know that the receive port will be receiving messages only of a certain type, you can add a filter to the send port to route the messages matching the filter expression to the send port.

In BizTalk orchestrations, you create send and receive ports to send and receive messages to and from the WCF-Custom adapter, which in turn sends the messages to BizTalk Server. This section provides information about using BizTalk orchestrations to perform operations on a Siebel system using the Siebel adapter. The Siebel adapter in turn uses the WCF-Custom adapter that can interact with a WCF binding.

◆ Important

To use the Siebel adapter with Microsoft BizTalk Server, you must always set the **EnableBizTalkCompatibilityMode** binding property to **True**. For instructions about how to set the binding properties, see [Specifying Binding Properties](#).

◆ Important

Unlike the earlier version of the adapters shipped with BizTalk Server, the Siebel adapter shipped with BizTalk Adapter Pack does not show up in the list of adapters in the BizTalk Server Administration console. This is because the latest Siebel adapter is a WCF custom binding. So, while the BizTalk Server Administration console displays the WCF-Custom adapter, it does not display the WCF custom bindings and hence, does not display the WCF-based Siebel adapter.

Also, to generate metadata you must use the Consume Adapter Service BizTalk Project Add-in and not the Add Adapter Metadata Wizard, as used for the previous version of the adapter. For instructions on using the Consume Adapter Service Add-in, see [Retrieving Metadata for Siebel Operations in Visual Studio](#). For more such differences between the adapter versions, see [Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#).

Before You Develop BizTalk Applications

This section provides information about certain prerequisites tasks that you must perform before developing BizTalk applications using the Siebel adapter. The section also lists some BizTalk Server tools that will be used to develop BizTalk applications.

In This Section

- [Create a Strong-Name Key File](#)
- [Learn About BizTalk Server Tools](#)

Create a Strong-Name Key File

You must create a strong name key file to build projects in Microsoft Visual Studio. A strong name consists of the project's identity — its simple text name, version number, and culture information (if provided) — plus a public key and a digital signature. The strong name key file contains the public key and the private key.

Important

You must create one strong name key file, one time before developing a BizTalk application.

To create a strong name key file

1. Click **Start**, point to **All Programs**, point to **Microsoft Visual Studio 2010**, point to **Visual Studio Tools**, and then click **Visual Studio Command Prompt (2010)**.
2. At the command prompt navigate to the location where you want to create the key file. For example, type **cd C:\Sample**, and then press ENTER.
3. At the command prompt, type **sn -k <key file name>.snk**, and then press ENTER.

Note

You should receive a message at the command prompt stating that the key pair was written to the strong-name key file.

4. At the command prompt, type **exit**, and then press ENTER.

[Before You Develop BizTalk Applications](#)

Learn About BizTalk Server Tools

The topics on how to use the Siebel adapter in [Developing BizTalk Applications](#) assume that you have working knowledge of a number of BizTalk Server tools. You will use the following tools to develop BizTalk applications using Siebel adapter:

- Microsoft Visual Studio 2010.
- Orchestration Designer
- Pipeline Designer
- BizTalk Mapper
- BizTalk Server Administration console

Prerequisites

You must install BizTalk Server before you can access the BizTalk Server tools.

BizTalk Server Tools

The following table provides you with a list of top-level topics that explain how to use each of the listed tools.

Tool	Topics in BizTalk Server Documentation
Visual Studio	<ul style="list-style-type: none"> • Using Visual Studio (http://go.microsoft.com/fwlink/?LinkId=107180) • Working with BizTalk Projects (http://go.microsoft.com/fwlink/?LinkId=107181) • Deploying BizTalk Assemblies from Visual Studio into a BizTalk Application (http://go.microsoft.com/fwlink/?LinkId=107182) <p>Learn more about Visual Studio:</p> <ul style="list-style-type: none"> • Introduction to Solutions, Projects, and Items (http://go.microsoft.com/fwlink/?LinkId=58503) • Solution Explorer Concepts (http://go.microsoft.com/fwlink/?LinkId=58504)
Orchestration Designer	<ul style="list-style-type: none"> • Creating Orchestrations Using Orchestration Designer (http://go.microsoft.com/fwlink/?LinkId=107184)
Pipeline Designer	<ul style="list-style-type: none"> • Creating Pipelines Using Pipeline Designer (http://go.microsoft.com/fwlink/?LinkId=107185)
BizTalk Mapper	<ul style="list-style-type: none"> • Creating Maps Using BizTalk Mapper (http://go.microsoft.com/fwlink/?LinkId=107186)
BizTalk Server Administration console	<ul style="list-style-type: none"> • Using the BizTalk Server Administration Console (http://go.microsoft.com/fwlink/?LinkId=107187)

Tasks

[Create a Strong-Name Key File](#)

Other Resources

Building Blocks for Developing BizTalk Applications

Performing operations on a Siebel system using Siebel adapter involves two set of activities: design-time activities and run-time activities. To perform operations on a Siebel system by using the Siebel adapter with BizTalk Server, you must perform a set of design-time and run-time tasks using Visual Studio and BizTalk Server Administration console respectively. This section provides an overview of these tasks. All the topics in this section, which demonstrate how to perform specific operations on a Siebel system using BizTalk Server, are modeled on these high-level tasks.

Design-time Tasks

The WCF LOB Adapter SDK provides capability to browse, search, and retrieve the Siebel metadata for business components and business services in the form of XML Schema definition languages (XSDs) using the Consume Adapter Service BizTalk Project Add-in or Add Adapter Metadata Wizard. The XSDs are specific to the operation you wish to perform on the Siebel system and the Consume Adapter Service Add-in or Add Adapter Metadata Wizard is available only when you create a BizTalk Project. At design time you may need to perform the following tasks.

- Create BizTalk project and generate schema.** To start with, you must create a BizTalk project in Microsoft Visual Studio and generate the schema for the business components or the business services you will invoke in the Siebel system. For example, if you want to insert a record into the Account business component, you must generate the metadata for the Insert operation for the Account business component. In this step you use the Consume Adapter Service Add-in or Add Adapter Metadata Wizard to generate the schema. For more information, see [Retrieving Metadata for Siebel Operations in Visual Studio](#).
- Set up an orchestration.** Once you have generated the schema, you must set up an orchestration by using the Orchestration Designer. For a basic orchestration, you add the Send and Receive shapes along with the Send and Receive logical ports. In the later steps, you will map these logical ports to physical ports by using the BizTalk Server Administration console. The orchestration uses these ports to pick up messages sent by an adapter client. The orchestration then passes the messages to the Siebel system. Once a response is received from the Siebel system, the orchestration passes the response to the adapter client.
- Create messages and link to schema.** In your orchestration, you must create messages that will be mapped to the schema you generated in the first step. Typically, you would create a request and a response message. These messages are mapped to corresponding request and response schemas.
- Map message shapes to messages and ports.** In your orchestration, you must now map each shape you added in the second step to messages you created in the third step. You must also map a message shape to the port on which that message will be sent.

For example, if the first shape in your orchestration is a Receive shape that will receive a message, you will map this shape to a "request" message and the port that sends the request message.

- Build and deploy the BizTalk project.** After you have set up the orchestration and mapped messages, ports, and schemas you must build the BizTalk solution. For building a project in Visual Studio, you will need an assembly key file. After you successfully build the solution, you must deploy the solution.

Note

More detailed description of these high level tasks, including procedural information is provided under the topics that follow.

Once the solution is deployed, your design time tasks are accomplished. You must now perform the run time tasks.

Run-time Tasks

- Configure the application.** The BizTalk project you deployed at design time will show up in the BizTalk Server Administration console as an orchestration. You must configure this orchestration by mapping the logical ports you created at design time to physical ports that you must now create using the BizTalk Server Administration console.

On the physical ports, you must specify an "action" or "action mapping". This action corresponds to the operation you

want to perform on the Siebel system. You need to set the action if you are not using dynamic actions. For more information about dynamic actions, see the BizTalk Server Help documentation at <http://go.microsoft.com/fwlink/?LinkID=101130>.

- **Start the application.** After the application is configured, you must start the application, and drop input messages at a defined file location. The orchestration consumes the input messages and passes them to the Siebel system and receives a response. This response will be available to you at another defined file location.

To accomplish these high-level design-time and run-time tasks, you must also perform other tasks. For example, when you use the Consume Adapter Service BizTalk Project Add-in or Add Adapter Metadata Wizard to generate the schema, you must specify a connection URI to connect to the Siebel system. This section provides information on such repetitive tasks that you must perform as you develop BizTalk applications by using the Siebel adapter.

In This Section

- [Adding the Siebel Adapter to BizTalk Server Administration Console](#)
- [Specifying the Connection URI](#)
- [Specifying Credentials for the Siebel System](#)

- [Reusing Adapter Bindings](#)

Adding the Siebel Adapter to BizTalk Server Administration Console

The Siebel adapter can be used in BizTalk either as a WCF-Custom port or a WCF-Siebel port. If you want to use the Siebel adapter through a WCF-Custom port, you do not need to add the WCF-Custom port to the BizTalk Server Administration console because the WCF-Custom port is added to the BizTalk Server Administration console by default. However, if you want to use the Siebel adapter through a WCF-Siebel port, you must first add the WCF-Siebel adapter to the BizTalk Server Administration console.

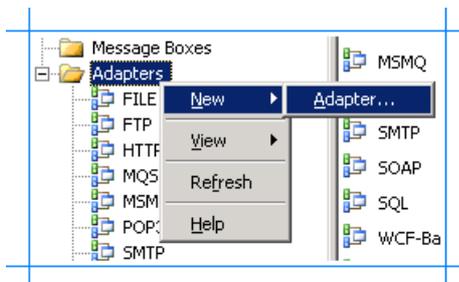

This topic provides instructions on how to add the WCF-Siebel adapter to the BizTalk Server Administration console.

◆ Important

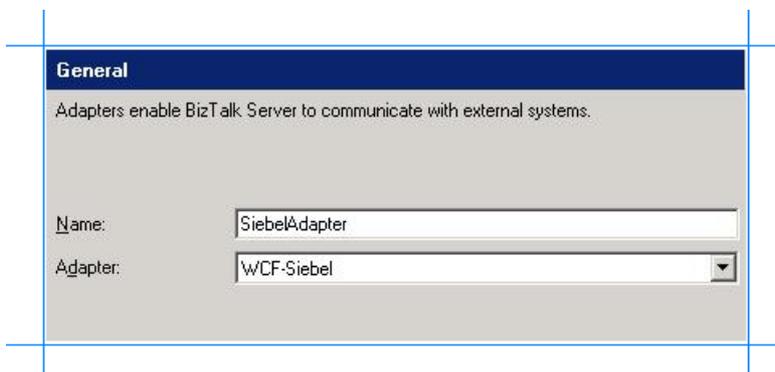

You need not perform these tasks if you want to configure a WCF-Custom port for the Siebel adapter.

To add the Siebel Adapter

1. Start the BizTalk Server Administration console.
2. In the console tree, expand the **BizTalk Group**, expand **Platform Settings**, and then click **Adapters**.
3. Right-click **Adapters**, point to **New**, and click **Adapter**.

4. In the **Adapter Properties** dialog box, specify a name for the adapter and from the **Adapter** list, select **WCF-Siebel**.

5. Click **OK**.

Tasks

[Building Blocks for Developing BizTalk Applications](#)

Specifying the Connection URI

A connection URI is a connection string to connect to a Siebel system. The connection URI contains various parameters required to establish connection with a Siebel system. You must specify this connection URI both at the design time and the run time. At design time, you must specify the URI to connect to the Siebel system to generate the metadata. At run time, you must specify the URI to connect to the Siebel system to perform operations.

Specifying Connection URI at Design Time

For design time, you must specify the connection URI using the Consume Adapter Service Add-in or the Add Adapter Metadata Wizard.

To specify connection URI using Consume Adapter Service Add-in

1. Right-click your BizTalk project, point to **Add**, and then select **Add Generated Items**.
2. In the **Add Generated Items** dialog box, do the following:

Use this	To do this
Categories	Click Consume Adapter Service .
Templates	Click Consume Adapter Service .

3. To start the **Consume Adapter Service** dialog box, click **Add**.
4. In the **Consume Adapter Service** dialog box, from the **Select a binding** drop-down list select **siebelBinding**, and click **Configure**.
5. In the **Configure Adapter** dialog box, click the **Security** tab. From the **Client credential type** drop-down list box, select **Username** and specify the user name and password to connect to the Siebel system.
6. In the **Configure Adapter** dialog box, click the **URI Properties** tab and specify values for different parameters. For more information about the connection URI for the Siebel adapter, see [The Siebel System Connection URI](#).
7. In the **Configure Adapter** dialog box, click the **Binding Properties** tab and specify the binding values, if any, which are required to be specified before generating the schema. For more information about binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).
8. Click **OK**.

To specify connection URI using Add Adapter Metadata Wizard

1. Right-click your BizTalk project, point to **Add**, and then select **Add Generated Items**.
2. In the **Add Generated Items** dialog box, do the following:

Use this	To do this
Categories	Click Add Adapter .
Templates	Click Add Adapter Metadata .

3. Click **Add**. The Add Adapter Metadata Wizard opens.
4. In the Add Adapter Wizard, select **WCF-Siebel**. Select the computer on which BizTalk Server is installed and the name of the BizTalk database.

◆ Important
If you already have a WCF-Siebel port configured in BizTalk, select the port from the Port list.

5. Click **Next**.
6. In the **Consume Adapter Service** dialog box, from the **Select a binding** drop-down list select **siebelBinding**, and click

Configure.

7. In the **Configure Adapter** dialog box, click the **Security** tab. From the **Client credential type** drop-down list box, select **Username** and specify the user name and password to connect to the Siebel system.
8. In the **Configure Adapter** dialog box, click the **URI Properties** tab and specify values for different parameters. For more information about the connection URI for the Siebel adapter, see [The Siebel System Connection URI](#).
9. In the **Configure Adapter** dialog box, click the **Binding Properties** tab and specify the binding values, if any, which are required to be specified before generating the schema. For more information about binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).

Note

If you selected an existing WCF-Siebel send port, you need not specify the binding properties. The binding properties are picked from the send port configuration. However, you may choose to specify the binding properties that are required at design-time, if any. In such case, the new values for binding properties will be used at design-time while generating the metadata. However, at run-time the values specified for binding properties in the send port configuration will be applicable.

10. Click **OK**.

Specifying Connection URI at Run Time

For run time, you must specify the URI as part of the WCF-Custom or WCF-Siebel port configuration in the BizTalk Server Administration Console.

To specify connection URI for the WCF-Custom port

1. Start the BizTalk Server Administration console.
2. In the console tree, expand **BizTalk Group**, then expand **Applications**, and then expand the application under which you want to create a port, and then click **Send Ports**. In the right pane, you can choose to create a port or select an existing port.
3. In the port properties dialog box, from the **Type** drop-down list, select **WCF-Custom**, and then click **Configure**.
4. In the **WCF-Custom Transport Properties** dialog box, click the **General** tab.
5. In the **Address (URI)** text box, specify the connection URI to connect to the Siebel system. For more information about the connection URI for the Siebel adapter, see [The Siebel System Connection URI](#).
6. In the **WCF-Custom Transport Properties** dialog box, click the **Binding** tab. From the **Binding Type** drop-down list, select **siebelBinding**.
7. To create a send port, in the **WCF-Custom Transport Properties** dialog box, click the **Credentials** tab and do one of the following:
 - a. Select the **Do not use Single Sign-On** option, and specify the user name and password to connect to a Siebel system.
 - b. Select the **Use Single Sign-On** option, and specify an affiliate ESSO application.
8. Click **OK**.

To specify connection URI for the WCF-Siebel port

1. Start the BizTalk Server Administration console.
2. Add the WCF-Siebel adapter to the BizTalk Server Administration console. For instructions, see [Adding the Siebel Adapter to BizTalk Server Administration Console](#).
3. In the console tree, expand **BizTalk Group**, then expand **Applications**, and then expand the application under which you want to create a port, and then click **Send Ports**. In the right pane, you can choose to create a port or select an existing port.
4. In the port properties dialog box, from the **Type** drop-down list, select the WCF-Siebel adapter you added earlier, and

then click **Configure**.

5. In the transport properties dialog box, click the **General** tab.
6. Click the **Configure** button and provide values for the connection parameters. For more information about the connection URI for the Siebel adapter, see [The Siebel System Connection URI](#).
7. In the transport properties dialog box, click the **Binding** tab and specify values for binding properties.
8. To create a send port, in the **WCF-Custom Transport Properties** dialog box, click the **Credentials** tab and do one of the following:
 - a. Select the **Do not use Single Sign-On** option, and specify the user name and password to connect to a Siebel system.
 - b. Select the **Use Single Sign-On** option, and specify an affiliate ESSO application.
9. Click **OK**.

Tasks

[Building Blocks for Developing BizTalk Applications](#)

Specifying Credentials for the Siebel System

The Siebel adapter requires the adapter clients to provide client credentials. The adapter uses these credentials to authenticate the user with the Siebel system and to establish a connection.

Adapter clients can provide the client credentials either at design time or run time. At design time, credentials are required to generate the metadata. At run time, credentials are required to perform operations on the Siebel system. This section provides information about specifying client credentials at design time and run time.

Specifying Client Credentials at Design Time

For design time, you must specify the credentials using the Consume Adapter Service Add-in or the Add Adapter Metadata Wizard.

To specify client credentials using Consume Adapter Service Add-in

1. Right-click your BizTalk project, point to **Add**, and then select **Add Generated Items**.
2. In the **Add Generated Items** dialog box, do the following:

Use this	To do this
Categories	Click Consume Adapter Service .
Templates	Click Consume Adapter Service .

3. To start the **Consume Adapter Service** dialog box, click **Add**.
4. In the **Consume Adapter Service** dialog box, from the **Select a binding** list, select **siebelBinding**, and then click **Configure**.
5. In the **Configure Adapter** dialog box, click the **Security** tab and from the **Client credential type** drop-down list box, select **Username** and specify the user name and password to connect to the Siebel system.
6. Click **OK**.

To specify client credentials using Add Adapter Metadata Wizard

1. Right-click your BizTalk project, point to **Add**, and then select **Add Generated Items**.
2. In the **Add Generated Items** dialog box, do the following:

Use this	To do this
Categories	Click Add Adapter .
Templates	Click Add Adapter Metadata .

3. Click **Add**. The Add Adapter Metadata Wizard opens.
4. In the Add Adapter Wizard, select **WCF-Siebel**. Select the computer on which BizTalk Server is installed and the name of the BizTalk database.

◆ Important
If you already have a WCF-Siebel port configured in BizTalk, select the port from the Port list.

5. Click **Next**.
6. In the **Consume Adapter Service** dialog box, from the **Select a binding** list, select **siebelBinding**, and then click **Configure**.
7. In the **Configure Adapter** dialog box, click the **Security** tab and from the **Client credential type** drop-down list box, select **Username** and specify the user name and password to connect to the Siebel system.

8. Click **OK**.

Specifying Client Credentials at Run Time

For run time, you must specify the client credentials as part of the WCF-Custom or WCF-Siebel port configuration in the BizTalk Server Administration console.

To specify credentials for the WCF-Custom port

1. Start the BizTalk Server Administration console.
2. In the console tree, expand **BizTalk Group**, then expand **Applications**, and then expand the application under which you want to create a port, and then click **Send Ports**. In the right pane, you can choose to create a port or select an existing port.
3. In the port properties dialog box, from the **Type** drop-down list, select **WCF-Custom**, and then click **Configure**.
4. For a send port, in the **WCF-Custom Transport Properties** dialog box, click the **Credentials** tab and do one of the following:
 - Select the **Do not use Single Sign-On** option, and specify the user name and password to connect to a Siebel system.
 - Select the **Use Single Sign-On** option, and specify an affiliate ESSO application.
5. Click **OK**.

Note

BizTalk Adapter Pack also supports the Enterprise Single Sign-On (ESSO) system. ESSO is only applicable in the BizTalk scenario, in which the WCF adapter is aware of ESSO affiliate applications. For more information about security with respect to BizTalk Server, see [Security Considerations When Using the Adapter with BizTalk Server](#).

To specify credentials for the WCF-Siebel port

1. Start the BizTalk Server Administration console.
2. Add the WCF-Siebel adapter to the BizTalk Server Administration console. For instructions, see [Adding the Siebel Adapter to BizTalk Server Administration Console](#).
3. In the console tree, expand **BizTalk Group**, then expand **Applications**, and then expand the application under which you want to create a port, and then click **Send Ports**. In the right pane, you can choose to create a port or select an existing port.
4. In the port properties dialog box, from the **Type** drop-down list, select the WCF-Siebel port you added earlier, and then click **Configure**.
5. For a send port, in the transport properties dialog box, click the **Credentials** tab and do one of the following:
 - Select the **Do not use Single Sign-On** option, and specify the user name and password to connect to a Siebel system.
 - Select the **Use Single Sign-On** option, and specify an affiliate ESSO application.
6. Click **OK**.

Note

BizTalk Adapter Pack also supports the Enterprise Single Sign-On (ESSO) system. ESSO is only applicable in the BizTalk scenario, in which the WCF adapter is aware of ESSO affiliate applications. For more information about security with respect to BizTalk Server, see [Security Considerations When Using the Adapter with BizTalk Server](#).

Tasks

Specifying Binding Properties

The Siebel adapter surfaces several binding properties that enable you to control some of its behavioral characteristics. This section provides information about setting the binding properties from Visual Studio (design time) and from the BizTalk Server Administration Console (run time). At design time, you must specify the binding properties to generate schema for specific operations. At run time, you must specify the binding properties as part of the send port for sending messages to the Siebel system.

For information about the binding properties, including a list of binding properties for Siebel adapter, see [Working with BizTalk Adapter for Siebel Binding Properties](#).

Specifying Binding Properties at Design Time

For design time, you must specify the binding properties from the Consume Adapter Service Add-in or the Add Adapter Metadata Wizard dialog box.

To specify binding properties using Consume Adapter Service Add-in

1. Right-click your BizTalk project, point to **Add**, and then select **Add Generated Items**.
2. In the **Add Generated Items** dialog box, do the following:

Use this	To do this
Categories	Click Consume Adapter Service .
Templates	Click Consume Adapter Service .

3. To start the **Consume Adapter Service** dialog box, click **Add**.
4. In the **Consume Adapter Service** dialog box, from the **Select a binding** drop-down list select **siebelBinding**, and click **Configure**.
5. In the **Configure Adapter** dialog box, click the **Binding Properties** tab and specify the binding values, if any, which are required to be specified before generating the schema. For more information about binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).
6. Click **OK**.

To specify binding properties using Add Adapter Metadata Wizard

1. Right-click your BizTalk project, point to **Add**, and then select **Add Generated Items**.
2. In the **Add Generated Items** dialog box, do the following:

Use this	To do this
Categories	Click Add Adapter .
Templates	Click Add Adapter Metadata .

3. Click **Add**. The Add Adapter Metadata Wizard opens.
4. In the Add Adapter Wizard, select **WCF-Siebel**. Select the computer on which BizTalk Server is installed and the name of the BizTalk database.

◆ Important
If you already have a WCF-Siebel port configured in BizTalk, select the port from the Port list.

5. Click **Next**.
6. In the **Consume Adapter Service** dialog box, from the **Select a binding** drop-down list select **siebelBinding**, and click **Configure**.

7. In the **Configure Adapter** dialog box, click the **Binding Properties** tab and specify the binding values, if any, which are required to be specified before generating the schema. For more information about binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).

 **Note**

If you selected an existing WCF-Siebel send port, you need not specify the binding properties. The binding properties are picked from the send port configuration. However, you may choose to specify the binding properties that are required at design-time, if any. In such case, the new values for binding properties will be used at design-time while generating the metadata. However, at run-time the values specified for binding properties in the send port configuration will be applicable.

8. Click **OK**.

Specifying Binding Properties at Run Time

For run time, you must specify the binding properties as part of the WCF-Custom or the WCF-Siebel port configuration in the BizTalk Server Administration console.

To specify binding properties for the WCF-Custom port

1. Start the BizTalk Server Administration console.
2. In the console tree, expand **BizTalk Group**, then expand **Applications**, and then expand the application under which you want to create a port, and then click **Send Ports**. In the right pane, you can choose to create a port or select an existing port.
3. In the **Port Properties** dialog box, from the **Type** drop-down list, select **WCF-Custom**, and then click **Configure**.
4. In the **WCF-Custom Transport Properties** dialog box, click the **Binding** tab.
5. From the **Binding Type** drop-down list, select **siebelBinding**.
6. In the **Configuration** box, specify the values for the different binding properties and click **OK**.

To specify binding properties for the WCF-Siebel port

1. Start the BizTalk Server Administration console.
2. Add the WCF-Siebel adapter to the BizTalk Server Administration console. For instructions, see [Adding the Siebel Adapter to BizTalk Server Administration Console](#).
3. In the console tree, expand **BizTalk Group**, then expand **Applications**, and then expand the application under which you want to create a port, and then click **Send Ports**. In the right pane, you can choose to create a port or select an existing port.
4. In the **Port Properties** dialog box, from the **Type** drop-down list, select the WCF-Siebel port you added earlier, and then click **Configure**.
5. In the transport properties dialog box, click the **Binding** tab and specify values for the binding properties.
6. Click **OK**.

Tasks

[Building Blocks for Developing BizTalk Applications](#)

Specifying SOAP Action

To perform any operation on the Siebel system using the WCF-based Siebel adapter, adapter users must specify a SOAP action. The SOAP action communicates to the adapter what action should be performed. You can specify the SOAP action either at design time or at run time. However, if you specify the SOAP action both at design time and run time, the action you specified at design time will be overridden.

For more information about specifying SOAP action, see <http://go.microsoft.com/fwlink/?LinkId=102063>.

Specifying SOAP Action at Design Time

For design time, you must specify the SOAP action as part of orchestration by including an expression shape.

To specify SOAP action at design time

1. In the BizTalk orchestration include an Expression shape by dragging it from the **BizTalk Orchestration** toolbox.
2. Double-click the **Expression** shape to open the BizTalk Expression Editor.
3. Specify the action in the BizTalk Expression Editor. For example:

```
OutboundMessage(WCF.Action)="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert"
```

For more information about **Expression** shape and the BizTalk Expression Editor, see <http://go.microsoft.com/fwlink/?LinkId=102064>.

Specifying SOAP Action at Run Time

For run time, you must specify the SOAP action as part of the WCF-Custom or WCF-Siebel port properties dialog box.

To specify a SOAP action for the WCF-Custom port

1. Start the BizTalk Server Administration console.
2. In the console tree, expand **BizTalk Group**, then expand **Applications**, and then click **Send Ports**. In the right pane, you can choose to create a port or select an existing port.
3. In the port properties dialog box, from the **Type** drop-down list, select **WCF-Custom**, and then click **Configure**.
4. In the **WCF-Custom Transport Properties** dialog box, click the **General** tab.
5. In the **Action** text box, specify the SOAP action for the operation. You can specify the action in the following ways:

- **By using the single action format.** Use this format if the WCF-Custom port sends and receive messages for a single operation. For example:

```
http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert
```

- **By using the action mapping format.** Use this format if a single WCF-Custom port sends and receives messages for more than one operation. For example, if a single WCF-Custom port sends and receives messages for Op1 (to perform an Insert operation on Account business component) and Op2 (to perform an Update operation on Account business component), the SOAP action can be specified in the following manner:

```
<BtsActionMapping>
  <Operation Name="Op1" Action="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert " />
  <Operation Name="Op2" Action="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Update " />
</BtsActionMapping>
```

This approach provides greater flexibility in terms of specifying a set of actions and hence enabling messages

belonging to different action types to flow through the same port.

The format for the SOAP action is different for each operation. For more information about action format for each operation, see individual topics under [Technical Reference](#).

To specify a SOAP action for the WCF-Siebel port

1. Start the BizTalk Server Administration console.
2. Add the WCF-Siebel adapter to the BizTalk Server Administration console. For instructions, see [Adding the Siebel Adapter to BizTalk Server Administration Console](#).
3. In the console tree, expand **BizTalk Group**, then expand **Applications**, and then click **Send Ports**. In the right pane, you can choose to create a port or select an existing port.
4. In the port properties dialog box, from the **Type** drop-down list, select the WCF-Siebel adapter you add earlier, and then click **Configure**.
5. In the port properties dialog box, click the **General** tab.
6. In the **Action** text box, specify the SOAP action for the operation. You can specify the action in the following ways:
 - **By using the single action format.** Use this format if the WCF-Custom port sends and receive messages for a single operation. For example:

```
http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert
```

- **By using the action mapping format.** Use this format if a single WCF-Custom port sends and receives messages for more than one operation. For example, if a single WCF-Custom port sends and receives messages for Op1 (to perform an Insert operation on Account business component) and Op2 (to perform an Update operation on Account business component), the SOAP action can be specified in the following manner:

```
<BtsActionMapping>  
  <Operation Name="Op1" Action="http://Microsoft.LobServices.Siebel/2007/03/Busine  
ssObjects/Account/Account/Insert " />  
  <Operation Name="Op2" Action="http://Microsoft.LobServices.Siebel/2007/03/Busine  
ssObjects/Account/Account/Update " />  
</BtsActionMapping>
```

This approach provides greater flexibility in terms of specifying a set of actions and hence enabling messages belonging to different action types to flow through the same port.

The format for the SOAP action is different for each operation. For more information about action format for each operation, see individual topics under [Technical Reference](#).

[Building Blocks for Developing BizTalk Applications](#)

Manually Configuring a Physical Port Binding to the Siebel Adapter

This section provides information about configuring the Microsoft BizTalk Adapter for Siebel eBusiness Applications as a WCF custom binding by using the BizTalk Server Administration console. After deploying the adapter, you will be able to send and receive messages from the Siebel system by using the BizTalk Server Administration Console. The steps for deploying the adapter vary depending on the direction of communication between BizTalk Server and Siebel adapter. You may choose to configure a Send or a Send-Receive port. Your choices are summarized in the following table:

Port direction	Communication pattern	Direction of communication to choose from
Send	One-way	I will always be sending messages on this port.
Send-Receive	Request-response	I will be sending a request and receiving a response.

For more information, see the BizTalk Server Help documentation at <http://go.microsoft.com/fwlink/?LinkID=101130>.

Note

Receive ports are not supported because the Siebel adapter does not enable inbound operations from the Siebel system.

Note

You can also configure the WCF-Custom send ports by importing a binding configuration file that is created by the Consume Adapter Service Add-in as part of metadata generation. For instructions on configuring ports using this binding file, see [Configuring a Physical Port Binding Using a Port Binding File](#).

In This Section

- [Configuring a Port Using the WCF-Custom Adapter](#)
- [Configuring a Port Using the WCF-Siebel Adapter](#)

[Building Blocks for Developing BizTalk Applications](#)

Configuring a Port Using the WCF-Custom Adapter

This topic provides instructions on how to configure WCF-Custom send ports to perform outbound operations on a Siebel system using the Siebel adapter.

Prerequisites

To perform the procedures in this topic, you must be logged on with an account that is a member of the BizTalk Server Administrators or BizTalk Operators group. For more detailed information about permissions, see BizTalk Server documentation at <http://go.microsoft.com/fwlink/?LinkID=101130>.

Deploying Adapters for Sending Messages to a Siebel System

Perform the following steps to configure a WCF-Custom send port for sending messages to a Siebel system using the BizTalk Server Administration console.

To deploy adapters for sending messages to a Siebel system

1. Start the BizTalk Server Administration console.
2. In the console tree, expand **BizTalk Group**, and then expand **Applications**.
3. Expand the application under which you wish to deploy the Siebel adapter.
4. Right-click **Send Ports**, point to **New**, and point to a type of port you want to configure depending on the mode of communication between BizTalk Server and the Siebel system.
5. In the **Send Port Properties** dialog box, on the **General** tab, type a name for the send port.
6. From the **Type** drop-down list, select **WCF-Custom** and click **Configure**.
7. In the **WCF-Custom Transport Properties** dialog box, do the following:
 - a. Click the **General** tab and in the **Address (URI)** field specify the connection URI to connect to a Siebel system. For more information about the connection URI, see [The Siebel System Connection URI](#).
 - b. On the **General** tab, in the **Action** text box, type the action for the operation. See individual topics in [Technical Reference](#) for a list of actions for each operation. For example, the action to invoke the Insert operation on the Account business component is:

```
http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert
```
 - c. Click the **Binding** tab and from the **Binding Type** drop-down list, select **siebelBinding**. You can also specify the different binding properties exposed by the Siebel adapter. For more information, see [Working with BizTalk Adapter for Siebel Binding Properties](#).
 - d. Click the **Credentials** tab and do one of the following:
 - Select the **Do not use Single Sign-On** option, and specify the user name and password to connect to a Siebel system.
 - Select the **Use Single Sign-On** option, and specify an affiliate ESSO application.
8. From the **Send handler** drop-down list, select **BizTalkServerApplication**.

For more information about security with respect to BizTalk Server, see [Security Considerations When Using the Adapter with BizTalk Server](#).

e. To return to the **Send Port Properties** dialog box, click **OK**.

9. If you chose Static One-Way Send Port in step 4, specify a send pipeline. From the **Send pipeline** drop-down list, select the pipeline corresponding to XMLTransmit.
10. If you chose Static Solicit-Response Port in step 4, specify send and receive pipelines.
 - a. From the **Send pipeline** drop-down list, select the pipeline corresponding to XMLTransmit.
 - b. From the **Receive pipeline** drop-down list, select the pipeline corresponding to XMLReceive.
11. Click **OK**.

Configuring a Port Using the WCF-Siebel Adapter

This topic provides instructions on how to configure WCF-Siebel send ports to perform outbound operations on a Siebel system using the Siebel adapter.

Prerequisites

To perform the procedures in this topic, you must be logged on with an account that is a member of the BizTalk Server Administrators or BizTalk Operators group. For more detailed information about permissions, see BizTalk Server documentation at <http://go.microsoft.com/fwlink/?LinkID=101130>.

Deploying Adapters for Sending Messages to a Siebel System

Perform the following steps to configure a WCF-Siebel send port for sending messages to a Siebel system using the BizTalk Server Administration console.

To deploy adapters for sending messages to a Siebel system

1. Start the BizTalk Server Administration console.
2. Add the WCF-Siebel adapter to the BizTalk Server Administration console. For instructions, see [Adding the Siebel Adapter to BizTalk Server Administration Console](#).
3. In the console tree, expand **BizTalk Group**, and then expand **Applications**.
4. Expand the application under which you wish to deploy the Siebel adapter.
5. Right-click **Send Ports**, point to **New**, and point to a type of port you want to configure depending on the mode of communication between BizTalk Server and the Siebel system.
6. In the **Send Port Properties** dialog box, on the **General** tab, type a name for the send port.
7. From the **Type** drop-down list, select the WCF-Siebel adapter you added earlier and click **Configure**.
8. In the transport properties dialog box, do the following:
 - a. Click the **General** tab, click the **Configure** button, and provide values for the connection parameters. For more information about the connection URI, see [The Siebel System Connection URI](#).
 - b. On the **General** tab, in the **Action** text box, type the action for the operation. See individual topics in [Technical Reference](#) for a list of actions for each operation. For example, the action to invoke the Insert operation on the Account business component is:

```
http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert
```

- c. Click the **Binding** tab and specify values for the binding properties. For more information, see [Working with BizTalk Adapter for Siebel Binding Properties](#).
- d. Click the **Credentials** tab and do one of the following:
 - Select the **Do not use Single Sign-On** option, and specify the user name and password to connect to a Siebel system.
 - Select the **Use Single Sign-On** option, and specify an affiliate ESSO application.

For more information about security with respect to BizTalk Server, see [Security Considerations When Using the Adapter with BizTalk Server](#).

- e. To return to the **Send Port Properties** dialog box, click **OK**.

9. From the **Send handler** drop-down list, select **BizTalkServerApplication**.
10. If you chose Static One-Way Send Port in step 5, specify a send pipeline. From the **Send pipeline** drop-down list, select the pipeline corresponding to XMLTransmit.
11. If you chose Static Solicit-Response Port in step 5, specify send and receive pipelines.
 - a. From the **Send pipeline** drop-down list, select the pipeline corresponding to XMLTransmit.
 - b. From the **Receive pipeline** drop-down list, select the pipeline corresponding to XMLReceive.
12. Click **OK**.

[Manually Configuring a Physical Port Binding to the Siebel Adapter](#)

Configuring a Physical Port Binding Using a Port Binding File

When you use the Consume Adapter Service BizTalk Project Add-in to generate metadata for a Siebel artifact, other than the schema files, the Consume Adapter Service Add-in also generates a port binding file. You can import this binding file into your BizTalk application to create a physical send port. For instructions on importing binding files, see [Importing Bindings](#). If you import this binding file, you do not have to manually create a physical send port.

◆ Important

While using the Consume Adapter Service Add-in, if you do not specify a value for a binding property of type string and whose default value is null then that binding property will not be available in the binding file. You must manually add the binding property and its value in the binding file, if required.

Creating a port using the port binding file always creates a two-way send port. If you want to create one-way port, you can create it manually by following the procedure mentioned in [Manually Configuring a Physical Port Binding to the Siebel Adapter](#). Or, you can follow the workarounds documented in this topic to modify the port binding file to create one-way ports.

◆ Important

Using the Add Adapter Metadata Wizard does not create a port binding file using which you can create a WCF-Siebel port. However, you could make some changes to the port binding file generated by the Consume Adapter Service Add-in and use it to create a WCF-Siebel port. For more information, see [Configuring a WCF-Siebel Port Using the Port Binding File Generated Using Consume Adapter Service Add-in](#).

Following are some key points that you must understand with respect to the binding file generated by the Consume Adapter Service Add-in:

- The files are created with a specific naming convention. If you generated metadata for outbound operations, that is to send messages to the Siebel system, the name of the file is `WcfSendPort_SiebelBinding_Custom.bindinginfo.xml`.
- The file contains information about the binding configuration, the binding type, the endpoint URI, and the port action based on the operations for which metadata was generated. When you import this binding file to create a port, all the relevant information required to configure a physical port is automatically set on the port.

◆ Important

By default, the action on the send port is mapped to the operation name for which you generate metadata. For example, if you generate metadata for Insert operation on the Account Business component, the action on the port is set to `<Operation Name="Insert" Action="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert " />`. However, the operation name on the logical send port you create in the BizTalk orchestration might not be the same. You must ensure that the operation name in the logical port (in the BizTalk orchestration) and the physical send port (in BizTalk Server Administration console) are the same. If not, you will receive an error while sending messages to the Siebel system through the send port.

- You only need to provide the credentials for the port to connect to the Siebel system. While the binding file does retain the username with which to connect, for security reasons the binding file does not contain the password.

Key Considerations for Using the Port Binding File

- When you import the binding file, you might get a dialog message informing that the BizTalk application name in the binding file does not match the application name to which you are importing the binding file. You can safely ignore this message and continue.
- The binding file also contains names of ports and receive locations. If the BizTalk application to which you are importing the binding file creates a port or a receive location that has the same name as an already existing port in the same BizTalk application, you will get an error. You must manually edit the bindings file to specify a unique name for the ports or receive locations.

- By default, the port binding file always contains definitions for two-way send ports. When you import this file in a BizTalk application, it creates a two-way send port. However, you may have an orchestration that has a one-way send port. So, when you configure such an orchestration and use the port created by importing the binding file, the port is not available in the list. This happens because the logical port you created as part of the orchestration is a one-way port while the physical port created in the orchestration is a two-way port. In such cases, you can edit the bindings file to make the following changes:

For this	Do this
<p>To edit the port bindings file to configure a one-way send port</p>	<ol style="list-style-type: none"> In the following excerpt, change the value of IsTwoWay property to false. Originally, this is set to true. <div data-bbox="695 533 1495 651" style="border: 1px solid black; padding: 5px; margin: 10px 0;"> <pre><SendPort Name="port_name" IsStatic="true" IsTwoWay="false" BindingOption="0"></pre> </div> Comment out the following excerpts: <div data-bbox="695 741 1495 1070" style="border: 1px solid black; padding: 5px; margin: 10px 0;"> <pre><ReceivePipeline Name="Microsoft.BizTalk.DefaultPipelines.XMLReceive" FullyQualifiedName="Microsoft.BizTalk.DefaultPipelines.XMLReceive, Microsoft.BizTalk.DefaultPipelines, Version=3.0.1.0, Culture=neutral, PublicKeyToken=token" Type="1" TrackingOption="None" Description="" /></pre> </div> <div data-bbox="695 1093 1495 1178" style="border: 1px solid black; padding: 5px; margin: 10px 0;"> <pre><ReceivePipelineData xsi:nil="true" /></pre> </div>

Configuring a WCF-Siebel Port Using the Port Binding File Generated Using Consume Adapter Service Add-in

The Consume Adapter Service Add-in also creates a port binding file that you can import in BizTalk Server Administration console. You can use the same port binding file to also create the BizTalk WCF-Siebel port in BizTalk Server Administration console. However, before creating WCF-Siebel port you must perform the following tasks to modify the port binding file.

1. Open the port binding file in a text editor.
2. Search and replace "WCF-Custom" with the name with which you added the WCF-Siebel adapter in BizTalk Server Administration console. For example, if you added the WCF-Siebel adapter as "SiebelAdapter", replace "WCF-Custom" with "SiebelAdapter".
3. Search for the "ConfigurationClsid" attribute, and replace the existing value of the attribute with "7971A78D-AE8F-42B4-834D-3A957FD945E9".
4. Save and close the binding file.
5. Import the binding file in BizTalk Server Administration console. For instructions on how to import the binding file, see [Importing Bindings](#).

[Building Blocks for Developing BizTalk Applications](#)

Configuring Dynamic Ports

In BizTalk Server, you can configure dynamic ports for a WCF-Custom adapter. Because Siebel adapter is a WCF-based adapter, you can dynamically configure a port for the Siebel adapter by using message context properties.

For the Siebel adapter, the URI, action, and binding might be determined from a property on an incoming message, and then specified in the **Expression** shape, as shown in the following example:

```
Request2=Request1;
Request2(WCF.Action)="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert";
Request2(WCF.BindingType)="siebelBinding";
Request2(WCF.UserName)="YourUserName";
Request2(WCF.Password)="YourPassword";
SendPort(Microsoft.XLANGs.BaseTypes.Address)="siebel://mySiebelServer:1234?SiebelObjectManager=SSEObjMgr&SiebelEnterpriseServer=myEnterpriseServer&Language=enu";
SendPort(Microsoft.XLANGs.BaseTypes.TransportType)="WCF-Custom";
```

Note

If you are using a WCF-Siebel adapter in BizTalk Server Administration console, you can also specify the transport type as `SendPort(Microsoft.XLANGs.BaseTypes.TransportType)="SiebelAdapter"`, where **SiebelAdapter** is the name with which you added the WCF-Siebel adapter in BizTalk Server Administration console.

In the preceding example:

- Request2 message is being created from Request1 message. Both the messages map to an operation schema, which is generated using the Consume Adapter Service BizTalk Project Add-in.
- SendPort is the name of the logical send port in the BizTalk orchestration.

The Expression shape is part of the BizTalk orchestration. When you deploy the orchestration, the WCF-Custom send port is also created.

For more information on configuring dynamic ports, see <http://go.microsoft.com/fwlink/?LinkId=106735>.

[Building Blocks for Developing BizTalk Applications](#)

Reusing Adapter Bindings

A binding creates a mapping between a logical endpoint, such as an orchestration port or a role link, and a physical endpoint, such as a send and receive port or party. This enables communication between different components of a BizTalk business solution. You can create bindings by using the BizTalk Server Administration console.

What Is a Binding File?

A binding file is an XML file that contains binding information for each BizTalk orchestration in the scope of a BizTalk assembly, application, or group. The binding file describes what host each orchestration is bound to and its trust level as well as the settings for each send port, receive port, receive location, and party that has been configured. You can generate binding files and then apply the bindings they contain to an assembly, application, or group to avoid needing to manually configure bindings in different deployment environments.

For more information about bindings and binding files, see the BizTalk Server documentation at <http://go.microsoft.com/fwlink/?LinkID=101130>.

A binding file is not automatically generated for a BizTalk assembly, application, or group, but you can generate a binding file by exporting bindings, as described in [Exporting Bindings](#). You can then import the binding file into an application or group, as described in [Importing Bindings](#).

In This Section

- [Exporting Bindings](#)
- [Importing Bindings](#)

Exporting Bindings

This section describes how to export bindings for a BizTalk application into an XML file. You can then import the bindings from the XML file into another BizTalk application. Importing bindings overwrites any existing bindings of the same name in the application. You can also add bindings to an application, which does not overwrite existing bindings. The bindings that you add do not take effect until you import the application.

Prerequisites

To perform the procedures in this topic, you must be logged on with an account that is a member of the BizTalk Server Administrators or BizTalk Operators group. For more detailed information about permissions, see BizTalk Server documentation at <http://go.microsoft.com/fwlink/?LinkID=101130>.

To export bindings using the BizTalk Server Administration console

1. Start the BizTalk Server Administration console.
2. In the console tree, expand **BizTalk Group**, and then expand **Applications**.
3. Right-click the application whose bindings you want to export, point to **Export**, and then click **Bindings**.
4. On the Export Bindings page, in **Export to file**, type the absolute path of the .xml file to which to export the bindings.

Example: **C:\Bindings\Application1Bindings.Binding1.xml**

5. Ensure that **Export all bindings from the current application** is selected.
6. To export all party information for the group, select the **Export Global Party information** check box.
7. Click **OK**.

The bindings are exported into an XML file in the location that you specified.

[Reusing Adapter Bindings](#)

Importing Bindings

This topic describes how to use the BizTalk Server Administration console to import bindings into a BizTalk application from an XML file.

Prerequisites

To perform the procedures in this topic, you must be logged on with an account that is a member of the BizTalk Server Administrators or BizTalk Operators group. For more detailed information about permissions, see BizTalk Server documentation at <http://go.microsoft.com/fwlink/?LinkID=101130>.

To import bindings using the BizTalk Server Administration console

1. Start the BizTalk Server Administration console.
2. In the console tree, expand **BizTalk Group**, and then expand **Applications**.
3. Right-click the application into which you want to import bindings, point to **Import**, and then click **Bindings**.
4. Click the binding file and click **Open**.

The artifacts in the binding file are written to the application. They display in appropriate folders of the application

Performing Operations on Business Components Using BizTalk Server

The Siebel adapter surfaces operations that can be invoked on a business component. The operations on business components can be categorized as:

- Standard operations on business components. These include Insert, Query, Update, and Delete. This topic discusses how to perform these operations using BizTalk Server.
- Operations on business components containing multivalued group fields. These include the standard operations as well as Associate, Disassociate, Query_[MVG_Child_Business_Comp]. For more information about performing these operations, see [Performing Operations on Business Components with MVG Fields Using BizTalk Server](#)
- Operations on business components containing picklist fields. For more information about performing these operations, see [Performing Operations on Business Components with Picklist Fields Using BizTalk Server](#).

For more information about how the Siebel adapter supports operations on business components, see [Operations on Business Components](#). For more information about the structure of SOAP messages for performing these operations, see [Message Schemas for Business Component Operations](#).

How to Perform Operations on a Business Component

Performing an operation on a Siebel system using the Siebel adapter with BizTalk Server involves procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To perform an operation on a business component, these tasks are:

1. Create a BizTalk project and generate schema for operation you want to invoke on the business component.
2. Create messages in the BizTalk project for sending and receiving messages from the Siebel system.
3. Create an orchestration to invoke an operation in the Siebel system.
4. Build and deploy the BizTalk project.
5. Configure the BizTalk application by creating physical send and receive ports.
6. Start the BizTalk application.

This topic provides instructions to perform these tasks.

Sample Based On This Topic

A sample, SiebelAccount, based on this topic is also provided with the BizTalk Adapter Pack. For more information, see [Samples](#).

Generating Schema

In this topic, to demonstrate how to invoke operations on a business component, schema are generated for the Insert operation in the Account business component. See [Retrieving Metadata for Siebel Operations in Visual Studio](#) for more information about how to generate schema.

Defining Messages and Message Types

The schema that you generated earlier describes the "types" required for the messages in the orchestration. A message is typically a variable, the type for which is defined by the corresponding schema. You must link the schema you generated in the first step to the messages from the Orchestration view of the BizTalk project.

For this topic, you must create two messages—one to send a request to the Siebel system and the other to receive a response.

Perform the following steps to create messages and link them to the schema:

To create messages and link to schema

1. Open the orchestration view the BizTalk project, if not already open. Click **View**, point to **Other Windows**, and click **Orchestration View**.
2. In the **Orchestration View**, right-click **Messages**, and then click **New Message**.
3. Right-click the newly create message and select **Properties Window**.
4. In the **Properties** pane for **Message_1**, do the following:

Use this	To do this
Identifier	Type Request .
Message Type	From the drop-down list, expand Schemas , and select <i>SiebelAccount.SiebelBindingSchema.Insert</i> , where <i>SiebelAccount</i> is the name of your BizTalk project. <i>SiebelBindingSchema</i> is the schema generated for invoking the <i>Insert</i> operation on <i>Account</i> business component.

5. Repeat the previous step to create a new message. In the **Properties** pane for the new message, do the following:

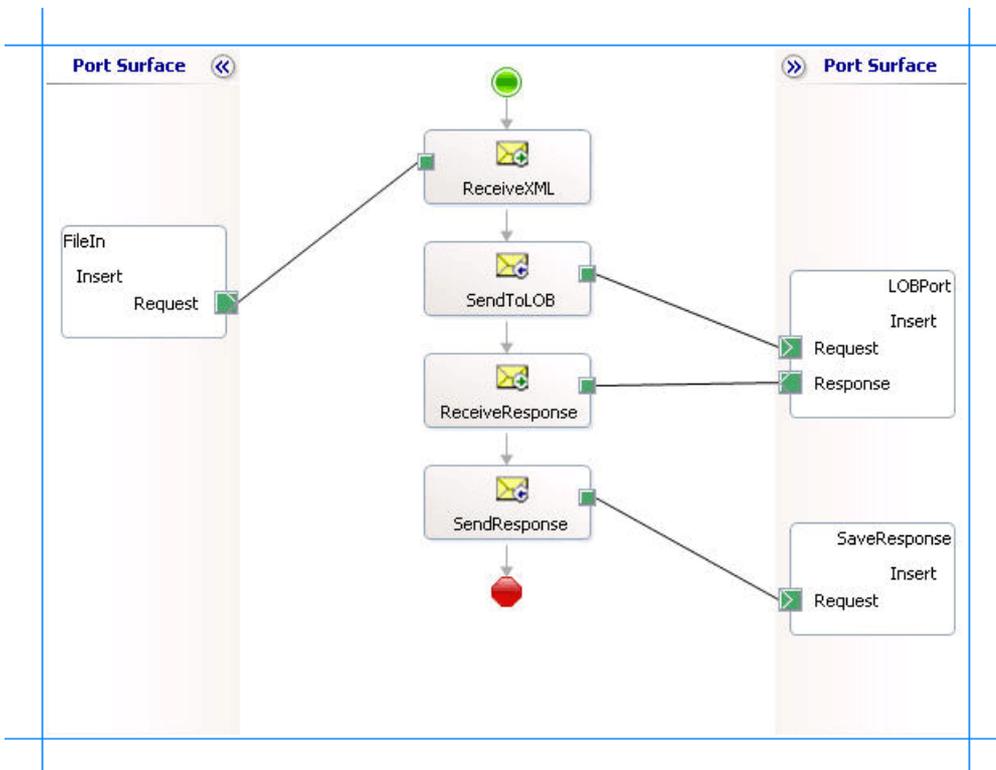

Use this	To do this
Identifier	Type Response .
Message Type	From the drop-down list, expand Schemas , and select <i>SiebelAccount.SiebelBindingSchema.InsertResponse</i> .

Setting up the Orchestration

You must create a BizTalk orchestration to use BizTalk Server for performing an operation on a Siebel business component. In this orchestration, you drop a request message at a defined receive location. The Siebel adapter consumes this message and passes it on to the Siebel system. The response from the Siebel system is saved to another location. A typical orchestration for performing operations on Siebel business components would contain:

- Send and receive shapes to send messages to Siebel and receive responses.
- A one-way receive port to receive request messages to send to Siebel.
- A two-way send port to send request messages to Siebel and receive responses.
- A one-way send port to send the responses from Siebel to a folder.

A sample orchestration for the *Insert* operation on an *Account* business component resembles the following:

Adding Message Shapes

Make sure you specify the following properties for each of the message shapes. The names listed in the *Shape* column are the names of the message shapes as displayed in the orchestration above.

Shape	Shape Type	Properties
ReceiveXML	Receive	<ul style="list-style-type: none"> Set Name to <i>ReceiveXML</i> Set Activate to <i>True</i>
SendToLOB	Send	<ul style="list-style-type: none"> Set Name to <i>SendToLOB</i>
ReceiveResponse	Receive	<ul style="list-style-type: none"> Set Name to <i>ReceiveResponse</i> Set Activate to <i>False</i>
SendResponse	Send	<ul style="list-style-type: none"> Set Name to <i>SendResponse</i>

Adding Ports

Make sure you specify the following properties for each of the logical ports. The names listed in the *Port* column are the names of the ports as displayed in the orchestration.

Port	Properties
FileIn	<ul style="list-style-type: none"> Set Identifier to <i>FileIn</i> Set Type to <i>FileInType</i> Set Communication Pattern to <i>One-Way</i> Set Communication Direction to <i>Receive</i>

LOBPort	<ul style="list-style-type: none"> • Set Identifier to <i>LOBPort</i> • Set Type to <i>LOBPortType</i> • Set Communication Pattern to <i>Request-Response</i> • Set Communication Direction to <i>Send-Receive</i>
SaveResponse	<ul style="list-style-type: none"> • Set Identifier to <i>SaveResponse</i> • Set Type to <i>SaveResponseType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Send</i>

Specify Messages for Action Shapes and Connect to Ports

The following table specifies the properties and their values to be set to specify messages for action shapes and linking them to the ports. The names listed in the *Shape* column are the names of the message shapes as displayed in the orchestration above.

Shape	Properties
ReceiveXML	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>FileIn.Insert.Request</i>
SendToLOB	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>LOBPort.Insert.Request</i>
ReceiveResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>LOBPort.Insert.Response</i>
SendResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>SaveResponse.Insert.Request</i>

After you have specified these properties, the message shapes and ports are connected and your orchestration is complete.

You must now build the BizTalk solution and deploy it to a BizTalk Server. For more information, see <http://go.microsoft.com/fwlink/?LinkId=102359>.

Configuring the BizTalk Application

After you have deployed the BizTalk project, the orchestration you created earlier is listed under the **Orchestrations** pane in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. For more information about configuring an application, see <http://go.microsoft.com/fwlink/?LinkId=102360>.

Configuring an application involves:

- Selecting a host for the application.
- Mapping the ports that you created in your orchestration to physical ports in the BizTalk Server Administration console. For this orchestration you must:

- Define a location on the hard disk and a corresponding file port where you will drop a request message. The BizTalk orchestration will consume the request message and send it to the Siebel system.
- Define a location on the hard disk and a corresponding file port where the BizTalk orchestration will drop the response message containing the response from the Siebel system.
- Define a physical WCF-Custom or WCF-Siebel send port to send messages to the Siebel system. You must also specify the action in the send port. For information about how to create ports, see [Manually Configuring a Physical Port Binding to the Siebel Adapter](#).

Note

Generating the schema using the Consume Adapter Service BizTalk Project Add-in also creates a binding file containing information about the ports and the actions to be set for those ports. You can import this binding file from the BizTalk Administration Console to create send ports (for outbound calls). For more information, see [Configuring a Physical Port Binding Using a Port Binding File](#).

Starting the Application

You must start the BizTalk application for performing an *Insert* operation on the *Account* business component in Siebel. For instructions on starting a BizTalk application, see <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The FILE receive port to receive request messages for the orchestration is running.
- The FILE send port to receive the response messages from the orchestration is running.
- The WCF-Custom or WCF-Siebel send port to send messages to the Siebel system is running.
- The BizTalk orchestration for the operation is running.

Executing the Operation

After you run the application, you must drop the request message to the FILE receive location. The schema of the request message must conform to the schema of the Insert operation (on Account business component) you generated earlier. For example, the request message to insert a record in the Account business component is:

```
<Insert xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Operation">
  <ArrayOfAccountInsertRecord>
    <AccountInsertRecord xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects">
      <Currency_x0020_Code>usd</Currency_x0020_Code>
      <Current_x0020_Volume>9</Current_x0020_Volume>
      <Customer_x0020_Account_x0020_Group>Sold-To Party</Customer_x0020_Account_x0020_Group>
    >
      <Location>Location_1</Location>
      <Main_x0020_Phone_x0020_Number>4256543212</Main_x0020_Phone_x0020_Number>
      <Name>Name_Surname</Name>
      <Party_x0020_Name>test_party</Party_x0020_Name>
      <Primary_x0020_Address_x0020_Id>1212 street</Primary_x0020_Address_x0020_Id>
    </AccountInsertRecord>
  </ArrayOfAccountInsertRecord>
</Insert>
```

See [Message Schemas for Business Component Operations](#) for more information about the schema for the request message.

The orchestration consumes the request message and passes it to the Siebel system. The response from the Siebel system is saved at the other FILE location defined as part of the orchestration. For example, the response from Siebel system for the

above request message is:

```
<?xml version="1.0" encoding="utf-8"?>
<InsertResponse xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/
Account/Operation">
  <InsertResult>
    <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">1-8ANYV</stri
ng>
  </InsertResult>
</InsertResponse>
```

Possible Exceptions

For information about the exceptions you might encounter while performing an operation on business component using BizTalk Server, see [Exceptions and Error Handling](#).

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the binding file. Once you generate a bindings file, you can import the configuration settings from the file so that you do not need to create the send ports, receive ports, etc. for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

[Developing BizTalk Applications](#)

Performing Operations on Business Components with MVG Fields Using BizTalk Server

This section provides instructions on performing operation on a business component containing multi-value fields. To demonstrate an end-to-end operation on such business components, you need to perform:

- An INSERT operation on a parent business component
- An INSERT operation on a child business component
- An ASSOCIATE operation on the multi-value links between the parent and child business component
- A Query_[MVG_Child_Business_Comp] operation on a record of parent business component

For more information about how the Siebel adapter supports operations on business components, see [Operations on Business Components](#). For more information about the structure of SOAP messages for performing these operations, see [Message Schemas for Business Component Operations](#).

How to Perform Operations on a Business Component with Multi-value Fields?

Performing an operation on a Siebel system using the Siebel adapter with BizTalk Server involves procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To perform an operation on a business component, these tasks are:

1. Create a BizTalk project and generate schema for all the operations you want to invoke on the business component. As described earlier, to perform operations on a business component with multi-value fields, you must generate schema for Insert operation on the parent and child business components, Associate operation on the multi-value links between the parent and child business components, and a Query operation on the parent business component.
2. Create messages in the BizTalk project for sending and receiving messages from the Siebel system.
3. Create orchestration to invoke the different operations in the Siebel system.
4. Build and deploy the BizTalk project.
5. Configure the BizTalk application by creating physical send and receive ports.
6. Start the BizTalk application.

This topic provides instructions to perform these tasks.

Sample Based On This Topic

A sample, MVLDemo, based on this topic is also provided with the BizTalk Adapter Pack. For more information, see [Samples](#).

Generating Schema

In this topic, to demonstrate how to associate the parent business component, **Account** to a child business component, **Contact**, we will generate the schema for the following:

- INSERT operation on the **Account** business component. See [Performing Operations on Business Components Using BizTalk Server](#).
- INSERT operation on the **Contact** business component.
- ASSOCIATE operation on the **Account** business component.
- QUERY_CONTACT operation on the **Account** business component.

See [Retrieving Metadata for Siebel Operations in Visual Studio](#) for more information about how to generate schema.

Defining Messages and Message Types

The schema that you generated earlier describes the "types" required for the messages in the orchestration. A message is typically a variable, the type for which is defined by the corresponding schema. You must link the schema you generated in the first step to the messages from the Orchestration view of the BizTalk project.

For this topic, you must create four sets of request and response messages, one for each operation you will invoke on the Siebel system. Each set must have a request message and a response message. As an example, the following procedure provides instructions to create a request and response message for the Associate operation. You must perform similar steps to create messages for other operations.

Perform the following steps to create messages and link them to the schema:

To create messages and link to schema

1. Open the orchestration view the BizTalk project, if not already open. Click **View**, point to **Other Windows**, and click **Orchestration View**.
2. In the **Orchestration View**, right-click **Messages**, and then click **New Message**.
3. Right-click the newly create message and select **Properties Window**.
4. In the **Properties** pane for **Message_1**, do the following:

Use this	To do this
Identifier	Type AccountAssociate_Request .
Message Type	From the drop-down list, expand Schemas , and select <i>MVLDemo.SiebelBindingSchema.Associate</i> , where <i>MVLDemo</i> is the name of your BizTalk project. <i>SiebelBindingSchema</i> is the schema generated for the invoking the <i>Associate</i> operation on <i>Account</i> business component.

5. Repeat the previous step to create a new message. In the **Properties** pane for the new message, do the following:

Use this	To do this
Identifier	Type AccountAssociate_Response .
Message Type	From the drop-down list, expand Schemas , and select <i>MVLDemo.SiebelBindingSchema.AssociateResponse</i> .

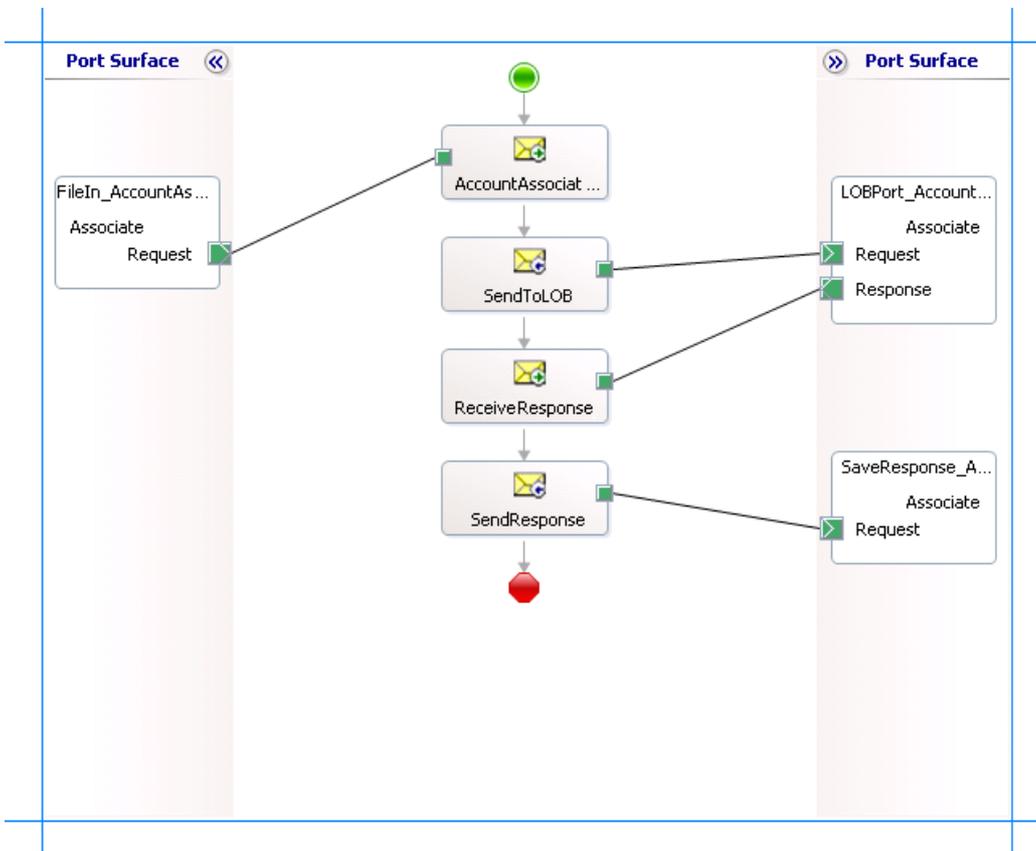

Setting up the Orchestrations

You must now set up orchestrations to use BizTalk Server for performing operations on the Account and Contact business components.

- Set up an orchestration to perform an INSERT operation on the **Account** business component. See [Performing Operations on Business Components Using BizTalk Server](#).
- Set up an orchestration to perform an INSERT operation on the **Contact** business component. This is similar to the INSERT operation on the **Account** business component.
- Set up an orchestration to perform an ASSOCIATE operation on the **Account** business component.
- Set up an orchestration to perform a QUERY_CONTACT operation on the **Account** business component.

This topic will demonstrate how to set up an orchestration for the ASSOCIATE operation on the **Account** business component. You must perform similar tasks to set up the remaining orchestrations as well.

The orchestration for the ASSOCIATE operation on the Account business component looks like:

The following section provides information on how to set up this orchestration by dropping message shapes, ports, linking messages to schemas, etc. You must perform similar tasks to set up the other orchestrations as well.

Adding Message Shapes

Make sure you specify the following properties for each of the message shapes. The names listed in the *Shape* column are the names of the message shapes as displayed in the orchestration above.

Shape	Shape Type	Properties
AccountAssociateXML	Receive	<ul style="list-style-type: none"> Set Name to <i>AccountAssociateXML</i> Set Activate to <i>True</i>
SendToLOB	Send	<ul style="list-style-type: none"> Set Name to <i>SendToLOB</i>
ReceiveResponse	Receive	<ul style="list-style-type: none"> Set Name to <i>ReceiveResponse</i> Set Activate to <i>False</i>
SendResponse	Send	<ul style="list-style-type: none"> Set Name to <i>SendResponse</i>

Adding Ports

Make sure you specify the following properties for each of the logical ports. The names listed in the *Port* column are the names of the ports as displayed in the orchestration.

Port	Properties
------	------------

FileIn_AccountAssociate	<ul style="list-style-type: none"> • Set Identifier to <i>FileIn_AccountAssociate</i> • Set Type to <i>FileInAccountAssociateType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Receive</i>
LOBPort_AccountAssociate	<ul style="list-style-type: none"> • Set Identifier to <i>LOBPort_AccountAssociate</i> • Set Type to <i>LOBPortAccountAssociateType</i> • Set Communication Pattern to <i>Request-Response</i> • Set Communication Direction to <i>Send-Receive</i>
SaveResponse_AccountAssociate	<ul style="list-style-type: none"> • Set Identifier to <i>SaveResponse_AccountAssociate</i> • Set Type to <i>SaveResponseAccountAssociateType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Send</i>

Specify Messages for Action Shapes and Connect to Ports

The following table specifies the properties and their values to be set to specify messages for action shapes and linking them to the ports. The names listed in the *Shape* column are the names of the message shapes as displayed in the orchestration above.

Shape	Properties
AccountAssociateXML	<ul style="list-style-type: none"> • Set Message to <i>AccountAssociate_Request</i> • Set Operation to <i>FileIn_AccountAssociate.Associate.Request</i>
SendToLOB	<ul style="list-style-type: none"> • Set Message to <i>AccountAssociate_Request</i> • Set Operation to <i>LOBPort_AccountAssociate.Associate.Request</i>
ReceiveResponse	<ul style="list-style-type: none"> • Set Message to <i>AccountAssociate_Response</i> • Set Operation to <i>LOBPort_AccountAssociate.Associate.Response</i>
SendResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>SaveResponse_AccountAssociate.Associate.Request</i>

After you have specified these properties, the message shapes and ports are connected and your orchestration is complete.

You must now build the BizTalk solution and deploy it to a BizTalk Server. For more information, see <http://go.microsoft.com/fwlink/?LinkId=102359>.

Configuring the BizTalk Application

After you have deployed the BizTalk project, the orchestration you created earlier is listed under the **Orchestrations** pane in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. For more information about configuring an application, see <http://go.microsoft.com/fwlink/?LinkId=102360>.

Configuring an application involves:

- Selecting a host for the application.
- Mapping the ports that you created in your orchestration to physical ports in the BizTalk Server Administration console. For this orchestration you must:
 - Define a location on the hard disk and a corresponding file port where you will drop a request message. The BizTalk orchestration will consume the request message and send it to the Siebel system. You can have the same port for all the four orchestrations.
 - Define a location on the hard disk and a corresponding file port where the BizTalk orchestration will drop the response message containing the response from the Siebel system. You can have the same port for all the four orchestrations.
 - Define physical WCF-Custom or WCF-Siebel send ports to send messages to the Siebel system. You must also specify the action in the send port. For information about how to create ports, see [Manually Configuring a Physical Port Binding to the Siebel Adapter](#). You must have different ports for all the four orchestrations.

Note

Generating the schema using the Consume Adapter Service BizTalk Project Add-in also creates a binding file containing information about the ports and the actions to be set for those ports. You can import this binding file from the BizTalk Administration Console to create send ports (for outbound calls). For more information, see [Configuring a Physical Port Binding Using a Port Binding File](#).

Starting the Application

You must start the BizTalk application for associating a parent business component to the child business component. For instructions on starting a BizTalk application, see <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The FILE receive port to receive request messages for the orchestration is running.
- The FILE send port to receive the response messages from the orchestration is running.
- The four WCF-Custom or WCF-Siebel send ports, one each for sending messages to the Siebel system, are running
- The four BizTalk orchestrations for the different operations are running

Executing the Operation

You must drop the request messages to the FILE receive port. The schema for the request messages must conform to the schema you generated earlier in the topic. See [Message Schemas for Business Component Operations](#) for more information about the schema for the request message for different operations. You must drop the request messages in the following order:

- Drop a request message to insert a record into the **Account** business component. The request message will be similar to the one dropped for inserting a record in the Account business component in the topic [Performing Operations on Business Components Using BizTalk Server](#). The orchestration consumes the message and sends it to the Siebel system. The response from the Siebel system is saved at the other FILE location defined as part of the orchestration.
- Drop a request message to insert a record into the **Contact** business component. The request message will be similar to

the one dropped for inserting a record in the Account business component in the topic [Performing Operations on Business Components Using BizTalk Server](#). The orchestration consumes the message and sends it to the Siebel system. The response from the Siebel system is saved at the other FILE location defined as part of the orchestration.

- Drop a request message to perform an ASSOCIATE operation on the **Account** business component. This will associate the parent and child business components based on the search expression and the name of the multi-valued field you specify in the input XML. Note that:
 - The parent search expression in the ASSOCIATE operation must match a unique record in the parent table.
 - The child search expression in the ASSOCIATE operation must match a unique record in the child table.

For example, the request message to perform an Associate operation on the Account business component is:

```
<Associate xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Operation">
  <ViewMode>3</ViewMode>
  <ParentSearchExpr>[Name] LIKE "SampleName1"</ns0:ParentSearchExpr>
  <ParentMVGField>Bill To First Name</ns0:ParentMVGField>
  <ChildSearchExpr>[First Name] LIKE "SampleName2"</ns0:ChildSearchExpr>
</Associate>
```

The orchestration consumes the message and sends it to the Siebel system. The response from the Siebel system is saved at the other FILE location defined as part of the orchestration. For example, the response for the above request message is:

```
<?xml version="1.0" encoding="utf-8"?>
<AssociateResponse xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Operation">
  <AssociateResult>
    <ChildID xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects">1-8A009</ChildID>
    <ParentID xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects">1-8ANZ5</ParentID>
  </AssociateResult>
</AssociateResponse>
```

- Drop a request message to perform a QUERY_CONTACT operation on the **Account** business component. For example, the request message for a QUERY_CONTACT operation is:

```
<Query_Contact xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Operation">
  <ViewMode>3</ViewMode>
  <ParentSearchExpr>[Name] LIKE "SampleName1"</ParentSearchExpr>
  <ParentMVGField>Bill To First Name</ParentMVGField>
  <ContactQueryInputRecord>
    <SearchExpr xmlns:ns1="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects">[Id] LIKE '*'</SearchExpr>
  </ContactQueryInputRecord>
</Query_Contact>
```

The orchestration consumes the message and sends it to the Siebel system. The response from the Siebel system is saved at the other FILE location defined as part of the orchestration.

See [Message Schemas for Business Component Operations](#) for more information about the schema for the request message.

Possible Exceptions

For information about the exceptions you might encounter while performing an operation on business component with multivalued fields using BizTalk Server, see [Exceptions and Error Handling](#).

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the bindings file. Once you generate a bindings file, you can import the configuration settings from the file so that you do not need to create the send ports, receive ports, etc. for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

[Developing BizTalk Applications](#)

Performing Operations on Business Components with Picklist Fields Using BizTalk Server

A Siebel picklist field type constitutes a collection of possible values from which client may specify a certain value to be passed onto the Siebel system. In other words, a picklist field contains a list of accepted values for a field. For more information about picklist and their types, refer to Siebel documentation. For more information about how the Siebel adapter supports operations on business components with picklist fields, see [Operations on Business Components](#).

When you generate metadata for a business component containing a static bounded picklist field (a type of picklist), the accepted values for the picklist are also published as part of the metadata. If you are inserting a value into a picklist field, you must specify a value that is published in the metadata.

How to Perform Operations on Business Components with Picklist Fields?

Performing an operation on a Siebel system using the Siebel adapter with BizTalk Server involves procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To perform an operation on a business component with picklist field, these tasks are:

1. Create a BizTalk project and generate schema to perform an operation on a business component containing picklist fields.
2. Create messages in the BizTalk project for sending and receiving messages from the Siebel system.
3. Create orchestration to invoke an operation in the Siebel system.
4. Build and deploy the BizTalk project.
5. Configure the BizTalk application by creating physical send and receive ports.
6. Start the BizTalk application.

This topic provides instructions to perform these tasks.

Sample Based On This Topic

A sample, SiebelPicklist, based on this topic is also provided with the BizTalk Adapter Pack. For more information, see [Samples](#).

Generating Schema

In this topic, to demonstrate how to invoke operations on business components with picklist fields, we will generate schema for the **Insert** operation for the **Account** business component. The **Account** business component has a static picklist, *Survey Type*.

See [Retrieving Metadata for Siebel Operations in Visual Studio](#) for more information about how to generate schema.

When you generate the metadata for the Insert operation for the **Account** business component, you get a separate .xsd file containing the picklist fields and their possible values. Note that the .xsd contains only the values for the static picklists, including *Survey Type*.

Defining Messages and Message Types

The schema that you generated earlier describes the "types" required for the messages in the orchestration. A message is typically a variable, the type for which is defined by the corresponding schema. You must link the schema you generated in the first step to the messages from the Orchestration view of the BizTalk project.

For this topic, you must create two messages—one to send a request to the Siebel system and the other to receive a response.

Perform the following steps to create messages and link them to the schema:

To create messages and link to schema

1. Open the orchestration view the BizTalk project, if not already open. Click **View**, point to **Other Windows**, and click **Orchestration View**.

- In the **Orchestration View**, right-click **Messages**, and then click **New Message**.
- Right-click the newly create message and select **Properties Window**.
- In the **Properties** pane for **Message_1**, do the following:

Use this	To do this
Identifier	Type Request .
Message Type	From the drop-down list, expand Schemas , and select <i>SiebelPicklist.SiebelBindingSchema.Insert</i> , where <i>SiebelPicklist</i> is the name of your BizTalk project. <i>SiebelBindingSchema</i> is the schema generated for invoking the <i>Insert</i> operation on <i>Account</i> business component.

- Repeat the previous step to create a new message. In the **Properties** pane for the new message, do the following:

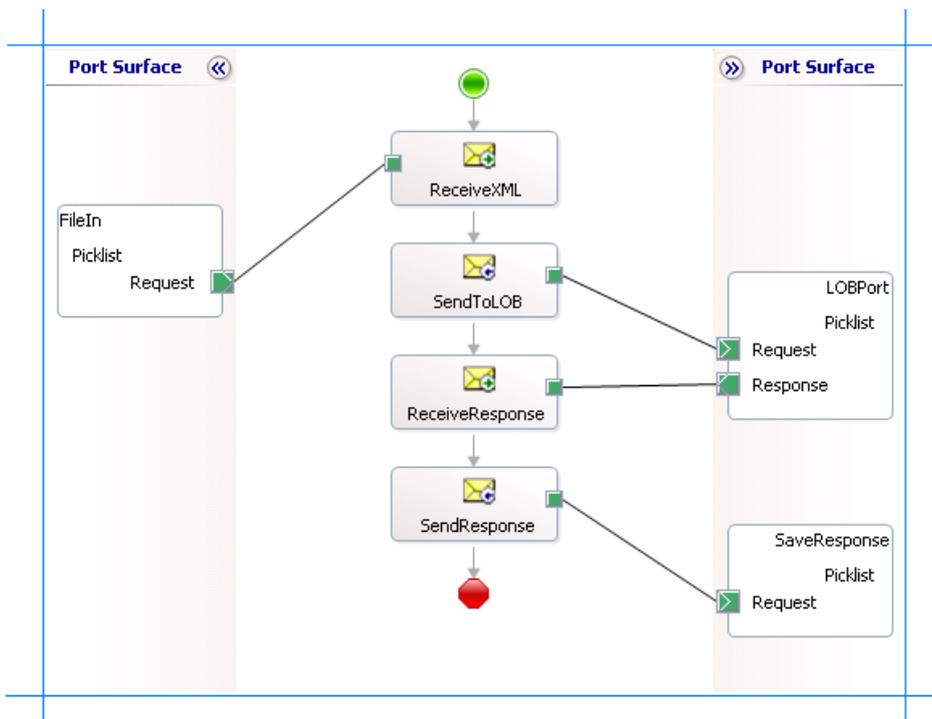

Use this	To do this
Identifier	Type Response .
Message Type	From the drop-down list, expand Schemas , and select <i>SiebelPicklist.SiebelBindingSchema.InsertResponse</i> .

Setting up the Orchestration

You must create a BizTalk orchestration to use BizTalk Server for performing an Insert operation on a Siebel business component with picklist fields. In this orchestration, you drop a request message at a defined receive location. The Siebel adapter consumes this message and passes it on to the Siebel system. The response from the Siebel system is saved to another location. A typical orchestration for performing operations on Siebel business components would contain:

- Send and receive shapes to send messages to Siebel and receive responses.
- A one-way receive port to receive request messages to send to Siebel.
- A two-way send port to send request messages to Siebel and receive responses.
- A one-way send port to send the responses from Siebel to a folder.

A sample orchestration for the *Insert* operation on an *Account* business component resembles the following:

Adding Message Shapes

Make sure you specify the following properties for each of the message shapes. The names listed in the *Shape* column are the names of the message shapes as displayed in the orchestration above.

Shape	Shape Type	Properties
ReceiveXML	Receive	<ul style="list-style-type: none">Set Name to <i>ReceiveXML</i>Set Activate to <i>True</i>
SendToLOB	Send	<ul style="list-style-type: none">Set Name to <i>SendToLOB</i>
ReceiveResponse	Receive	<ul style="list-style-type: none">Set Name to <i>ReceiveResponse</i>Set Activate to <i>False</i>
SendResponse	Send	<ul style="list-style-type: none">Set Name to <i>SendResponse</i>

Adding Ports

Make sure you specify the following properties for each of the logical ports. The names listed in the *Port* column are the names of the ports as displayed in the orchestration.

Port	Properties
FileIn	<ul style="list-style-type: none">Set Identifier to <i>FileIn</i>Set Type to <i>FileInType</i>Set Communication Pattern to <i>One-Way</i>Set Communication Direction to <i>Receive</i>
LOBPort	<ul style="list-style-type: none">Set Identifier to <i>LOBPort</i>Set Type to <i>LOBPortType</i>Set Communication Pattern to <i>Request-Response</i>Set Communication Direction to <i>Send-Receive</i>
SaveResponse	<ul style="list-style-type: none">Set Identifier to <i>SaveResponse</i>Set Type to <i>SaveResponseType</i>Set Communication Pattern to <i>One-Way</i>Set Communication Direction to <i>Send</i>

Specify Messages for Action Shapes and Connect to Ports

The following table specifies the properties and their values to be set to specify messages for action shapes and linking them to the ports. The names listed in the *Shape* column are the names of the message shapes as displayed in the orchestration above.

Shape	Properties
-------	------------

ReceiveXml	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>FileIn.Picklist.Request</i>
SendToLOB	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>LOBPort.Picklist.Request</i>
ReceiveResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>LOBPort.Picklist.Response</i>
SendResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>SaveResponse.Picklist.Request</i>

After you have specified these properties, the message shapes and ports are connected and your orchestration is complete.

You must now build the BizTalk solution and deploy it to a BizTalk Server. For more information, see <http://go.microsoft.com/fwlink/?LinkId=102359>.

Configuring the BizTalk Application

After you have deployed the BizTalk project, the orchestration you created earlier is listed under the **Orchestrations** pane in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. For more information about configuring an application, see <http://go.microsoft.com/fwlink/?LinkId=102360>.

Configuring an application involves:

- Selecting a host for the application.
- Mapping the ports that you created in your orchestration to physical ports in the BizTalk Server Administration console. For this orchestration you must:
 - Define a location on the hard disk and a corresponding file port where you will drop a request message. The BizTalk orchestration will consume the request message and send it to the Siebel system.
 - Define a location on the hard disk and a corresponding file port where the BizTalk orchestration will drop the response message containing the response from the Siebel system.
 - Define a physical WCF-Custom or WCF-Siebel send port to send messages to the Siebel system. You must also specify the action in the send port. For information about how to create ports, see [Manually Configuring a Physical Port Binding to the Siebel Adapter](#).

Note

Generating the schema using the Consume Adapter Service BizTalk Project Add-in also creates a binding file containing information about the ports and the actions to be set for those ports. You can import this binding file from the BizTalk Administration Console to create send ports (for outbound calls). For more information, see [Configuring a Physical Port Binding Using a Port Binding File](#).

Starting the Application

You must start the BizTalk application for performing an *Insert* operation on the *Account* business component in Siebel. For instructions on starting a BizTalk application, see <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The FILE receive port to receive request messages for the orchestration is running.
- The FILE send port to receive the response messages from the orchestration is running.
- The WCF-Custom or WCF-Siebel send port to send messages to the Siebel system is running
- The BizTalk orchestration for the operation is running

Executing the Operation

You must drop the request message to the FILE receive location. The schema of the request message must conform to the schema you generated earlier in this topic. See [Message Schemas for Business Component Operations](#) for more information about the schema for the request messages.

To insert a value to the picklist field, look at the generated schema to determine the list of acceptable values for the picklist. Make sure the request message has an element to insert value to the picklist field. For example, the request message must contain the following element to insert value to the *Survey Type* picklist.

```
<Survey_x0020_Type>1</Survey_x0020_Type>
```

Here, "1" is an acceptable value for the Survey Type pick list.

An example request message that contains a picklist parameter is:

```
<Insert xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/
Operation">
  <ArrayOfAccountInsertRecord>
    <AccountInsertRecord xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects
">
      <Currency_x0020_Code>usd</Currency_x0020_Code>
      <Current_x0020_Volume>9</Current_x0020_Volume>
      <Customer_x0020_Account_x0020_Group>Sold-To Party</Customer_x0020_Account_x0020_Group
>
      <Location>Location_1</Location>
      <Main_x0020_Phone_x0020_Number>4256543212</Main_x0020_Phone_x0020_Number>
      <Name>Name_Surname</Name>
      <Party_x0020_Name>test_party</Party_x0020_Name>
      <Primary_x0020_Address_x0020_Id>1212 street</Primary_x0020_Address_x0020_Id>
      <Survey_x0020_Type>1</Survey_x0020_Type>
    </AccountInsertRecord>
  </ArrayOfAccountInsertRecord>
</Insert>
```

The orchestration consumes the request message and passes it to the Siebel system. The response from the Siebel system is saved at the other FILE location defined as part of the orchestration.

Note

You may also try an insert an invalid value for the picklist. In that case, you must get a `TargetSystemException`.

Possible Exceptions

For information about the exceptions you might encounter while performing an operation on business component with picklist fields using BizTalk Server, see [Exceptions and Error Handling](#).

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the bindings file. Once you generate a bindings file, you can import the configuration settings from the file so that you do not need to create the send ports, receive ports, etc. for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

Invoking Business Service Methods Using BizTalk Server

A Siebel business service is a collection of business methods that can be directly invoked in Siebel. For more information about how the Siebel adapter supports invoking business services in a Siebel system, see [Operations on Business Services](#). For more information about the structure of SOAP messages for performing business service operations, see [Message Schemas for Business Service Operations](#).

How to Invoke Business Services?

Performing an operation on a Siebel system using the Siebel adapter with BizTalk Server involves procedural tasks described in [Building Blocks for Developing BizTalk Applications](#). To invoke a business service, these tasks are:

1. Create a BizTalk project and generate schema for the business service method you want to invoke.
2. Create messages in the BizTalk project for sending and receiving messages from the Siebel system.
3. Create orchestration to invoke a business service method in the Siebel system.
4. Build and deploy the BizTalk project.
5. Configure the BizTalk application by creating physical send and receive ports.
6. Start the BizTalk application.

This topic provides instructions to perform these tasks.

Sample Based On This Topic

A sample, BusinessService, based on this topic is also provided with the BizTalk Adapter Pack. For more information, see [Samples](#).

Generating Schema

In this topic, to demonstrate how to invoke a business service method, we will generate schema for the **Execute** method exposed by the **TimeStamp** business service. See [Retrieving Metadata for Siebel Operations in Visual Studio](#) for more information about how to generate schema.

Defining Messages and Message Types

The schema that you generated earlier describes the "types" required for the messages in the orchestration. A message is typically a variable, the type for which is defined by the corresponding schema. You must link the schema you generated in the first step to the messages from the Orchestration view of the BizTalk project.

For this topic, you must create two messages—one to send a request to the Siebel system and the other to receive a response.

Perform the following steps to create messages and link them to the schema:

To create messages and link to schema

1. Open the orchestration view the BizTalk project, if not already open. Click **View**, point to **Other Windows**, and click **Orchestration View**.
2. In the **Orchestration View**, right-click **Messages**, and then click **New Message**.
3. Right-click the newly create message and select **Properties Window**.
4. In the **Properties** pane for **Message_1**, do the following:

Use this	To do this
Identifier	Type Request .

Message Type	From the drop-down list, expand Schemas , and select <i>BusinessService.SiebelBindingSchema.Execute</i> , where <i>BusinessService</i> is the name of your BizTalk project. <i>SiebelBindingSchema</i> is the schema generated for invoking the <i>Execute</i> business service method.
--------------	--

5. Repeat the previous step to create a new message. In the **Properties** pane for the new message, do the following:

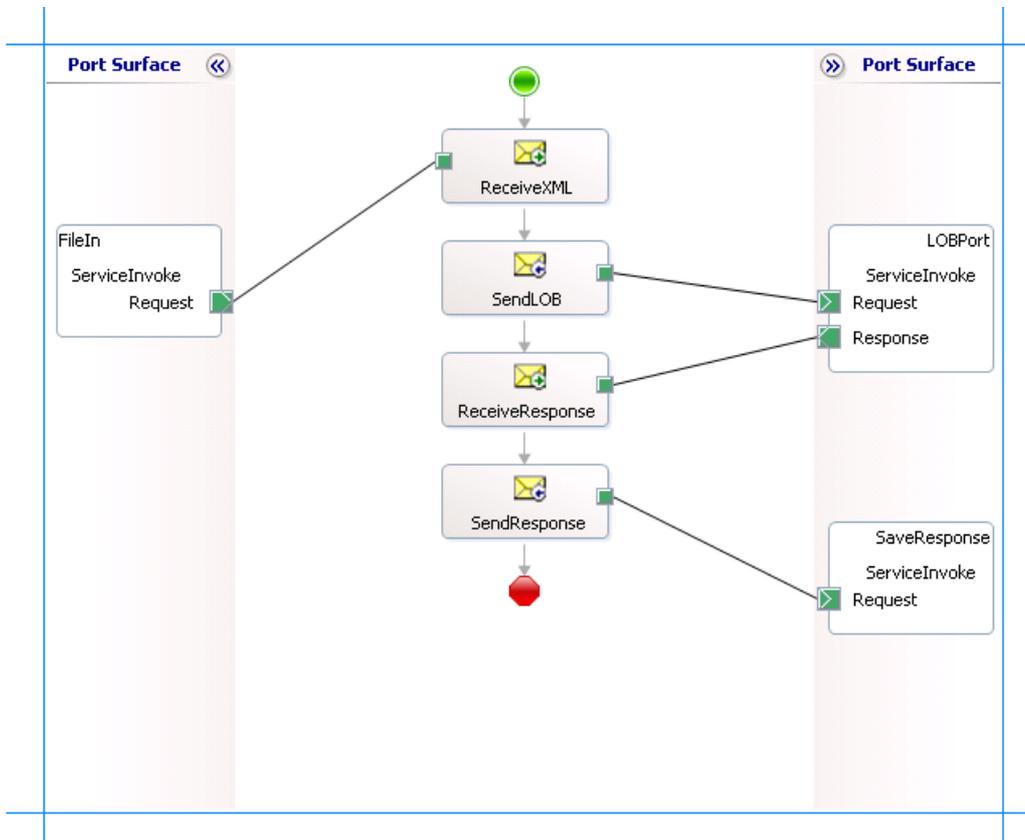

Use this	To do this
Identifier	Type Response .
Message Type	From the drop-down list, expand Schemas , and select <i>BusinessService.SiebelBindingSchema.ExecuteResponse</i> .

Setting up the Orchestration

You must create a BizTalk orchestration to use BizTalk Server for invoking a business service. In this orchestration, you drop a request message at a defined receive location. The Siebel adapter consumes this message and passes it on to the Siebel system. The response from the Siebel system is saved to another location. A typical orchestration for invoking Business Service methods would contain:

- Send and receive shapes to send messages to Siebel and receive responses.
- A one-way receive port to receive request messages to send to Siebel.
- A two-way send port to send request messages to Siebel and receive responses.
- A one-way send port to send the responses from Siebel to a folder.

A sample orchestration for calling the *Execute* method for the *TimeStamp* business service resembles the following:

Adding Message Shapes

Make sure you specify the following properties for each of the message shapes. The names listed in the *Shape* column are the names of the message shapes as displayed in the orchestration above.

Shape	Shape Type	Properties
-------	------------	------------

ReceiveXML	Receive	<ul style="list-style-type: none"> • Set Name to <i>ReceiveXML</i> • Set Activate to <i>True</i>
SendToLOB	Send	<ul style="list-style-type: none"> • Set Name to <i>SendToLOB</i>
ReceiveResponse	Receive	<ul style="list-style-type: none"> • Set Name to <i>ReceiveResponse</i> • Set Activate to <i>False</i>
SendResponse	Send	<ul style="list-style-type: none"> • Set Name to <i>SendResponse</i>

Adding Ports

Make sure you specify the following properties for each of the logical ports. The names listed in the *Port* column are the names of the ports as displayed in the orchestration.

Port	Properties
FileIn	<ul style="list-style-type: none"> • Set Identifier to <i>FileIn</i> • Set Type to <i>FileInType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Receive</i>
LOBPort	<ul style="list-style-type: none"> • Set Identifier to <i>LOBPort</i> • Set Type to <i>LOBPortType</i> • Set Communication Pattern to <i>Request-Response</i> • Set Communication Direction to <i>Send-Receive</i>
SaveResponse	<ul style="list-style-type: none"> • Set Identifier to <i>SaveResponse</i> • Set Type to <i>SaveResponseType</i> • Set Communication Pattern to <i>One-Way</i> • Set Communication Direction to <i>Send</i>

Specify Messages for Action Shapes and Connect to Ports

The following table specifies the properties and their values to be set to specify messages for action shapes and linking them to the ports. The names listed in the *Shape* column are the names of the message shapes as displayed in the orchestration above.

Shape	Properties
ReceiveXML	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>FileIn.ServiceInvoke.Request</i>

SendToLOB	<ul style="list-style-type: none"> • Set Message to <i>Request</i> • Set Operation to <i>LOBPort.ServiceInvoke.Request</i>
ReceiveResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>LOBPort.ServiceInvoke.Response</i>
SendResponse	<ul style="list-style-type: none"> • Set Message to <i>Response</i> • Set Operation to <i>SaveResponse.ServiceInvoke.Request</i>

After you have specified these properties, the message shapes and ports are connected and your orchestration is complete.

You must now build the BizTalk solution and deploy it to a BizTalk Server. For more information, see <http://go.microsoft.com/fwlink/?LinkId=102359>.

Configuring the BizTalk Application

After you have deployed the BizTalk project, the orchestration you created earlier is listed under the **Orchestrations** pane in the BizTalk Server Administration console. You must use the BizTalk Server Administration console to configure the application. For more information about configuring an application, see <http://go.microsoft.com/fwlink/?LinkId=102360>.

Configuring an application involves:

- Selecting a host for the application.
- Mapping the ports that you created in your orchestration to physical ports in the BizTalk Server Administration console. For this orchestration you must:
 - Define a location on the hard disk and a corresponding file port where you will drop a request message. The BizTalk orchestration will consume the request message and send it to the Siebel system.
 - Define a location on the hard disk and a corresponding file port where the BizTalk orchestration will drop the response message containing the response from the Siebel system.
 - Define a physical WCF-Custom or WCF-Siebel send port to send messages to the Siebel system. You must also specify the action in the send port. For information about how to create ports, see [Manually Configuring a Physical Port Binding to the Siebel Adapter](#).

Note

Generating the schema using the Consume Adapter Service BizTalk Project Add-in also creates a binding file containing information about the ports and the actions to be set for those ports. You can import this binding file from the BizTalk Administration Console to create send ports (for outbound calls). For more information, see [Configuring a Physical Port Binding Using a Port Binding File](#).

Starting the Application

You must start the BizTalk application for executing the *Execute* method on the *TimeStamp* business service in Siebel. For instructions on starting a BizTalk application, see <http://go.microsoft.com/fwlink/?LinkId=102387>.

At this stage, make sure:

- The FILE receive port to receive request messages for the orchestration is running.
- The FILE send port to receive the response messages from the orchestration is running.

- The WCF-Custom or WCF-Siebel send port to send messages to the Siebel system is running.
- The BizTalk orchestration for the operation is running.

Executing the Operation

You must drop the request message to the FILE receive location. The schema of the request message must confirm to the schema you generated earlier in this topic. See [Message Schemas for Business Service Operations](#) for more information about the schema for invoking a business service. For example, the request message to invoke the *Execute* method on the *TimeStamp* business service is:

```
<Execute xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessServices/TimeStamp/Operation" />
```

The orchestration consumes the request message and passes it to the Siebel system. The response from the Siebel system is saved at the FILE send location. The response for the above request message is:

```
<?xml version="1.0" encoding="utf-8"?>
<ExecuteResponse xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessServices/TimeStamp/Operation">
  <ExecuteResult>
    <Time xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessServices/TimeStamp">2007-11-25T20:42:11.0000000</Time>
  </ExecuteResult>
</ExecuteResponse>
```

Possible Exceptions

For information about the exceptions you might encounter while performing an operation on business service using BizTalk Server, see [Exceptions and Error Handling](#).

Best Practices

After you have deployed and configured the BizTalk project, you can export configuration settings to an XML file called the bindings file. Once you generate a bindings file, you can import the configuration settings from the file so that you do not need to create the send ports, receive ports, etc. for the same orchestration. For more information about binding files, see [Reusing Adapter Bindings](#).

[Developing BizTalk Applications](#)

Invoking Business Service Methods with Integration Objects

The Siebel adapter enables adapter clients to invoke business service methods that work with integration objects. These business services typically have IN, OUT, or IN OUT parameters of "hierarchy" data type to send or receive integration object data.

The Siebel adapter exposes these hierarchical types as strings. These string values are essentially an XML string encapsulated in an XML CDATA section. The XML string is compatible with the XML schema of the integration object the adapter client is trying to send or receive.

Sample Based On This Topic

A sample, `SiebelAdapterIntegrationObjects`, based on this topic is also provided with the BizTalk Adapter Pack. For more information, see [Samples](#).

Creating an Orchestration to Invoke Business Service Methods with Integration Objects

Creating an orchestration to invoke a business service method that takes integration object parameters is similar to the orchestration to invoke any other business service, as described in [Invoking Business Service Methods Using BizTalk Server](#).

The difference lies in the request message that you drop for the orchestration. This difference is because of the following:

- The schema for the request message is different because you invoke a different business service.
- The request message contains the XML string for the integration object. This XML is encapsulated in a CDATA section. You must first generate the schema for the integration object and then create an XML that conforms to the schema. This XML must be passed within the CDATA section of the request message sent to the adapter.

After you have generated the XML that conforms to the integration object schema and included it in the request message, you must drop the request message at a FILE location, just like you do for any other orchestration. Look for the response message in the other FILE location.

Request and Response Messages for Invoking Business Service with Integration Objects

As mentioned before, the only difference for invoking a business service that takes integration object parameters is the request message sent to the adapter. This section provides instructions on the steps you must perform to create the request message.

For better understanding, take a Siebel business service 'EAI Siebel Adapter' as an example. The 'EAI Siebel Adapter' business service operates on a Siebel integration object, 'Sample Account'. You must perform the following tasks to create the request message to invoke a method exposed by the 'EAI Siebel Adapter' business service:

- **Generate the schema for the EAI Siebel Adapter business service.** You must use the Consume Adapter Service Add-in to generate the schema. Once you generate the schema, generate the XML that conforms to the schema.
- **Generate the schema for the integration object.** Use Siebel Tools to generate schema for an integration object. From the Siebel Tools interface, select the integration object, for example, Sample Account, and click **Generate Schema**. While generating the schema, make sure:
 - The **Select a Business Service from the list** drop-down has the value "EAI XML XSD Generator".
 - The **Select an envelope type from the list** drop-down has the value "Siebel Message Envelope".

For more information, see the Siebel documentation.

- **Create an XML message that conforms to schema of the integration object.** A sample XML message generated for the 'Sample Account' integration object looks like:

```
<?xml version="1.0" encoding="UTF-16"?>
<SiebelMessage MessageId="" IntObjectName="Sample Account" MessageType="Integration Object" IntObjectFormat="Siebel Hierarchical">
  <ListOfSampleAccount>
```

```

<Account>
  <CurrencyCode>USD</CurrencyCode>
  <Location>Redmond</Location>
  <Name>IntegrationObjectTest</Name>
</Account>
</ListOfSampleAccount>
</SiebelMessage>

```

- **Pass this XML message as the value for the CDATA element in the request message for the business service method.** A sample request message that contains the preceding XML message within a CDATA element looks like the following. This sample request is to invoke the Insert method for the 'EAI Siebel Adapter' business service.

```

<Insert xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessServices/EAI_x0020_
Siebel_x0020_Adapter/Operation">
  <InsertRequestRecord />
  <InsertInOutRecord>
    <SiebelMessage xmlns="http://Microsoft.LobServices.Siebel/2007/03/BusinessServices

Developing Applications by Using the WCF Service Model

WCF provides a programming model called the WCF service model, which, in part, helps address some of the limitations of another programming model—the WCF channel model.

At the lowest level, the Windows Communication Foundation (WCF) presents the WCF channel model in which clients invoke operations on a service by exchanging SOAP messages over a channel established between client and service endpoints. The WCF channel model exposes data types and methods that enable you to operate directly on the WCF channel architecture. The WCF channel model provides you with direct control over the contents of the SOAP messages you create and over the way both your application and the Siebel adapter consume them. However, creating well-formed SOAP messages to send over a channel and validating the reply messages returned can be a detailed and exacting task.

The WCF service model, however, involves the use of proxy classes to invoke operations on a target service or to receive operations from a client. The Siebel adapter exposes the Siebel system as a WCF service on which you can invoke operations.

- The proxy class used to invoke operations on a target service is called a WCF client class. This class models the operations exposed by a service as .NET methods with strongly-typed parameters. By using the WCF service model, you can invoke the operations exposed by the Siebel adapter as .NET methods on the WCF client. For more information about WCF clients, see "WCF Client Overview" at <http://go.microsoft.com/fwlink/?LinkId=91458>.

You use tools to generate a WCF client class and associated helper code from the service metadata that the Siebel adapter exposes. You can use either of the following tools:

- The ServiceModel Metadata Utility Tool (svcutil.exe), which ships with WCF
- The Add Adapter Service Reference Visual Studio Plug-in, which ships with the Siebel adapter

The Add Adapter Service Reference Plug-in is integrated with the Visual Studio design experience and presents a standard Microsoft Windows interface that provides powerful browsing and searching capabilities on operations exposed by the adapter. For more information about how to generate a WCF client, see [Generating a WCF Client for Siebel Artifacts](#)

Why Choose the WCF Service Model or the WCF Channel Model?

Because it presents a model that is familiar to .NET programmers and hides the underlying complexities of SOAP message exchange over a channel, the WCF service model is often the best choice to develop programming solutions for the Siebel adapter. However, there are scenarios in which the WCF channel model might be a better choice. For example, serializing and de-serializing between the XML representation of objects in a SOAP message and the .NET types used to represent them in the WCF service model involves reading the entire message into memory.

The WCF channel model provides support for XML node-level streaming on all operations. In node-level streaming, only each node of the XML message is held in memory at any one time. For certain operations, for example, if you are performing queries that return large result sets, the WCF channel model might be a better choice for your application. For more information about using the WCF channel model, see [Developing Applications by Using the WCF Channel Model](#).

The topics in this section contain information, procedures, and examples to help you create and use the WCF service model to develop applications by using the Siebel adapter.

Overview of Using the WCF Service Model with the Adapter

The Microsoft BizTalk Adapter for Siebel eBusiness Applications exposes a Siebel system as a WCF service. To perform operations on Siebel system artifacts, for example to invoke a method of a Siebel business service, you invoke an operation on the adapter, which, in turn, performs the operation on the Siebel system. Your code therefore acts as a client to the WCF service presented by the adapter.

In the Windows Communication Foundation (WCF) service model, the service contract that exists between a client and a service is represented as a .NET interface, and operations are represented as methods on this interface. The Siebel adapter and WCF provide tools that enable you to generate this interface for targeted operations from the metadata that the adapter exposes. These tools also create a WCF client class that can be used to invoke the operations exposed in the service interface. A client application can call the methods of the WCF client class to invoke operations on the adapter.

The following section explains how to use the WCF service model to invoke operations with a WCF client.

Invoking Operations on the Siebel System with a WCF Client

To use the WCF service model to invoke operations on the Siebel adapter, you must first generate a WCF client class for the target operations. You can then create an instance of this class, a WCF client, and call its methods to perform these operations on the Siebel system.

To invoke operations on the Siebel adapter

1. Generate a WCF client class and helper code. Use the Add Adapter Service Reference Visual Studio Plug-in or the ServiceModel Metadata Utility Tool (svcutil.exe) to generate a WCF client class targeted at the Siebel system artifacts with which you want to work. For more information about how to generate a WCF client, see [Generating a WCF Client for Siebel Artifacts](#).
2. Create a WCF client instance and configure the WCF client. Configuring the WCF client involves specifying the binding and endpoint address (connection URI) that the client will use. You can do this either imperatively in code or declaratively in configuration. For more information about how to configure the WCF client, see [Configuring a WCF Client for a Siebel System](#). The following code creates a WCF client that targets the Siebel TimeStamp business service. It also sets the credentials for the Siebel system. The WCF client is initialized from configuration.

```
BusinessServices_TimeStamp_OperationClient client =
    new BusinessServices_TimeStamp_OperationClient("SiebelBinding_BusinessServices_Tim
eStamp_Operation");

client.ClientCredentials.UserName.UserName = "YourUserName";
client.ClientCredentials.UserName.Password = "YourPassword";
```

3. Open the WCF client.

```
client.Open();
```

4. Invoke methods on the WCF client created in step 2 to perform operations on the Siebel system. The following code invokes the **Execute** method of the WCF client to invoke the **Execute** method of the TimeStamp business service on the Siebel system.

```
// Create a parameter to hold the results and then invoke the Execute method of the Ti
meStamp business service.
microsoft.lobservices.siebel._2007._03.BusinessServices.TimeStamp.ExecuteResponseReco
rder;
er = client.Execute();
```

5. Close the WCF client.

```
client.Close();
```

For more information about invoking Siebel business service methods, see [Invoking Business Service Methods by Using the WCF Service Model](#)

[Developing Applications by Using the WCF Service Model](#)

Metadata and the WCF Service Model

In the WCF service model, you use the Add Adapter Service Reference Visual Studio Plug-in or the ServiceModel Metadata Utility Tool (svcutile.exe) to generate a proxy class—the WCF client class—through which your code can invoke operations on the Microsoft BizTalk Adapter for Siebel eBusiness Applications.

These tools use the metadata exposed by the adapter to generate:

- An annotated .NET interface that represents the service contract for target operations. This interface is called the WCF service contract.
- Annotated classes that represent the supporting message contracts, operation contracts, and data contracts for the service contract.
- A WCF client class whose methods can be used to invoke the service methods (operations) exposed by the WCF service contract.

For help in understanding the structure of this generated code, see "Understanding Generated Client Code" at <http://go.microsoft.com/fwlink/?LinkId=98365>. This topic specifically describes code that svcutil.exe generates, but its content is also applicable to the code that the Add Adapter Service Reference Plug-in generates.

For information about how to generate a WCF client class for target operations and about the differences between svcutil.exe and the Add Adapter Service Reference Plug-in, see [Generating a WCF Client for Siebel Artifacts](#)

See Also

Concepts

[Developing Applications by Using the WCF Service Model](#)

Generating a WCF Client for Siebel Artifacts

You can use the Add Adapter Service Reference Visual Studio Plug-in to generate a WCF client class targeted at selected operations on Siebel artifacts. You can also use the ServiceModel Metadata Utility Tool (svcutil.exe) to generate the WCF client class; however, the Add Adapter Service Reference Plug-in exposes the functionality of the ServiceModel Metadata Utility Tool through a standard Microsoft Windows interface. It also provides browse and search capabilities that are not available with the svcutil.exe tool, and generates a configuration file based on the binding properties that you select when you connect to the Siebel system.

Generating a WCF Client Class by Using the Add Adapter Service Reference Plug-in

Perform the following steps to generate a WCF client class by using the Add Adapter Service Reference Plug-in.

To generate a WCF client class

1. In Visual Studio Solution Explorer, right-click your project, and then click **Add Adapter Service Reference**.
2. After the **Add Adapter Service Reference** dialog box opens, follow the steps in [Retrieving Metadata for Siebel Operations in Visual Studio](#) to connect to the Siebel system and browse and search for operations. To create a WCF client class for the operations that you select, be sure that **Client (Outbound operations)** is selected from the **Select contract type** drop-down list (this is the default).
3. After you select all of the operations that you want to target, click **OK** to generate the WCF client class.

The Add Adapter Service Reference Plug-in adds two files to your project:

- The WCF client code file. This file contains the generated WCF client class and helper code for the operations that you selected. The first time you run the Add Adapter Service Reference Visual Studio Plug-in it will generate this file with the default name **SiebelBindingClient.cs**. If you run it again, the next file it generates will be called **SiebelBindingClient1.cs**. The number suffix will increase by 1 for every new file you generate. You can also change the default prefix **SiebelBinding** by entering a different prefix in the **Filename prefix** field of the Add Adapter Service Reference Visual Studio Plug-in before selecting **OK** to generate the file.
- **App.config**. This file contains a binding configuration and client endpoint configurations that are based on the selections you made when you configured the connection for the Add Adapter Service Reference Plug-in. For more information about the contents of the app.config file, see [Configuring a WCF Client for a Siebel System](#).

◆ Important

While using the Add Adapter Service Reference Plug-in, if you do not specify a value for a binding property of type string and whose default value is null then that binding property will not be available in the app.config file. You must manually add the binding property and its value in the app.config file, if required.

Generating a WCF Client Class by Using svcutil.exe

You can use svcutil.exe to generate a WCF client class for your application. You must configure svcutil.exe to use it with the Microsoft BizTalk Adapter for Siebel eBusiness Applications. For more information about configuring and using svcutil.exe with the Siebel adapter, see [Using the ServiceModel Metadata Utility Tool with the BizTalk Adapter for Siebel eBusiness Applications](#).

Svcutil.exe generates the WCF client class in an output file with a default file name of output.cs. You must manually include this file in your Visual Studio project.

Concepts

[Developing Applications by Using the WCF Service Model](#)

Configuring a WCF Client for a Siebel System

After you have generated the WCF client class, you can create a WCF client (instance) and invoke its methods to consume the Siebel adapter. For information about how to generate the WCF client class and helper code for operations that the Microsoft BizTalk Adapter for Siebel eBusiness Applications exposes, see [Generating a WCF Client for Siebel Artifacts](#).

To create the WCF client, you must specify an endpoint address and a binding. The endpoint address must contain a valid Siebel connection URI, and the binding must be an instance of a Siebel Binding (**SiebelBinding**). For more information about the Siebel connection URI, see [Connecting to the Siebel System in Visual Studio](#).

You can specify the Siebel Binding and the endpoint address in your code or in a configuration file. When you use the Add Adapter Service Reference Visual Studio Plug-in to generate the WCF client class, a configuration file (app.config) is also created for your project. This file contains configuration settings that reflect the binding properties and connection information (except credentials) that you specified when you connected to the Siebel system with the Add Adapter Service Reference Plug-in.

Specifying the Binding and Endpoint Address in Code

The following code shows how to create a WCF client by specifying the binding and endpoint address in code. It is good practice to specify the Siebel credentials by using the **ClientCredentials** property of the WCF client rather than in the connection URI supplied for the endpoint address.

```
// A WCF client that targets the TimeStamp business service is created
// by using a binding object and endpoint address
SiebelBinding sblBinding = new SiebelBinding();
EndpointAddress sblAddress = new EndpointAddress("siebel://Siebel_server:1234?SiebelObjectM
anager=obj_mgr&SiebelEnterpriseServer=ent_server&Language=enu");

BusinessServices_TimeStamp_OperationClient client =
    new BusinessServices_TimeStamp_OperationClient(sblBinding, sblAddress);

client.ClientCredentials.UserName.UserName = "SADMIN";
client.ClientCredentials.UserName.Password = "SADMIN";

client.Open();
```

Specifying the Binding and Endpoint Address in a Configuration File

The following code shows how to create a WCF client by specifying the binding and endpoint address in an app.config file.

```
// A WCF client that targets the TimeStamp business service is created
// by specifying the client endpoint information in app.config
BusinessServices_TimeStamp_OperationClient client =
    new BusinessServices_TimeStamp_OperationClient("SiebelBinding_BusinessServices_TimeStam
p_Operation");

client.ClientCredentials.UserName.UserName = "SADMIN";
client.ClientCredentials.UserName.Password = "SADMIN";

client.Open();
```

The App.config File

The following XML shows the configuration file created for the TimeStamp business service by the Add Adapter Service Reference Plug-in. This file contains the client endpoint configuration referenced in the preceding example.

```
<?xml version="1.0" encoding="utf-8"?>
<configuration xmlns="http://schemas.microsoft.com/.NetConfiguration/v2.0">
  <system.serviceModel>
    <bindings>
      <siebelBinding>
        <binding name="SiebelBinding" closeTimeout="00:01:00" openTimeout="00:01:00"
receiveTimeout="00:10:00" sendTimeout="00:01:00" enableBizTalkCompatibi
```

```

lityMode="false"
        enablePerformanceCounters="false" enableConnectionPooling="true"
        maxConnectionsPerSystem="5" idleConnectionTimeout="00:01:00"
        acceptCredentialsInUri="false" />
    </siebelBinding>
</bindings>
<client>
    <endpoint address="siebel://Siebel_server:1234?SiebelObjectManager=obj_mgr&
SiebelEnterpriseServer=ent_server&Language=enu"
        binding="siebelBinding" bindingConfiguration="SiebelBinding"
        contract="BusinessServices_TimeStamp_Operation" name="SiebelBinding_Busines
sServices_TimeStamp_Operation" />
    </client>
</system.serviceModel>
</configuration>

```

If a project has more than one WCF client, there will be multiple client endpoint entries defined in the configuration file. Each WCF client entry will have a unique name based on its binding configuration and target Siebel artifact; for example, "SiebelBinding_BusinessServices_TimeStamp_Operation ". If you connect multiple times to create the WCF clients in your project, multiple binding configuration entries will be created, one for each connection. These binding configuration entries will be named in the following manner: SiebelBinding, SiebelBinding1, SiebelBinding2, and so on. Each client endpoint entry created during a specific connection will reference the binding entry created during that connection.

Performing Operations on Business Components by Using the WCF Service Model

You can create a WCF client that targets a Siebel business component. You can then use the WCF client to perform Insert, Update, Query, Delete, Associate, Dissociate, and child record query operations on the business component on the Siebel system. Siebel business objects are surfaced under the Business Objects node in the Add Adapter Service Reference Visual Studio Plug-in. The business components that compose each business object are surfaced under the node corresponding to that object. You can follow the steps in [Overview of Using the WCF Service Model with the Adapter](#) to generate a WCF client for a business component that targets specific operations and use the client to invoke these operations on the business component.

Note

This topic provides information about performing basic operations (Insert, Update, Query, Delete) on business components. For more information about performing Associate, Dissociate, and child record query operations, see [Performing Operations on Business Components with MVG Fields by Using the WCF Service Model](#)

The following code uses a WCF client to perform Insert, Update, and Delete operations on a record in the Account business component of the Account business object. Between each operation, a Query operation is performed to verify the results. The WCF client in this example is initialized from a configuration file that is generated by the Add Adapter Service Reference Plug-in. For an example of a generated configuration file, see [Configuring a WCF Client for a Siebel System](#).

```
using System;
using System.Collections.Generic;
using System.Text;

using System.ServiceModel;
using microsoft.lobservices.siebel._2007._03.BusinessObjects;
using microsoft.lobservices.siebel._2007._03;

namespace Business_Component_Operations
{
    class Program
    {
        static void Main(string[] args)
        {
            BusinessObjects_Account_Account_OperationClient client = null;

            try
            {
                client = new BusinessObjects_Account_Account_OperationClient("SiebelBinding
_BusinessObjects_Account_Account_Operation");
                client.ClientCredentials.UserName.UserName = "YourUserName";
                client.ClientCredentials.UserName.Password = "YourPassword";

                Console.WriteLine("Opening connection to " + client.Endpoint.Address.Uri.Host);

                client.Open();
                AccountInsertRecord[] air = new AccountInsertRecord[1];
                air[0] = new AccountInsertRecord();
                Random r = new Random();
                int count = r.Next();

                air[0].Name = "Anil" + count.ToString();
                Console.WriteLine("Inserting " + air[0].Name + " ...");
                client.Insert(air);

                //Query for the record.
                Console.WriteLine("Querying to check inserted record ...");
                AccountQueryInputRecord aqir = new AccountQueryInputRecord();
```

```

short viewmode = new short(); viewmode = 3;
string[] fields = new string[2];
fields[0] = "Name";
fields[1] = "Id";
aqir.QueryFields = fields;
aqir.SearchExpr = "[Name] LIKE \"Anil*\"";
AccountQueryRecord[] aqr = client.Query(viewmode, aqir);
Console.WriteLine(aqr.Length + " records returned");
string[] ids = new string[1];
AccountUpdateRecord[] aur = new AccountUpdateRecord[1];
aur[0] = new AccountUpdateRecord();
foreach (AccountQueryRecord rec in aqr)
{
    Console.WriteLine("Name: " + rec.Name);
    Console.WriteLine("Id: " + rec.Id);
    Console.WriteLine("");
    ids[0] = rec.Id;
    aur[0].Name = rec.Name;
    aur[0].Id = rec.Id;
}

//Update it.

aur[0].Name = "Anil" + count.ToString() + "modified";
Console.WriteLine("Update the record to " + aur[0].Name + " ...");
client.Update(viewmode, aur);
//query again
aqr = client.Query(viewmode, aqir);
Console.WriteLine(aqr.Length + " records returned");
foreach (AccountQueryRecord rec in aqr)
{
    Console.WriteLine("Name: " + rec.Name);
    Console.WriteLine("Id: " + rec.Id);
    Console.WriteLine("");
}

//Delete it.
Console.WriteLine("Deleting record ...");
client.Delete(viewmode, ids, "");

//Check again.
Console.WriteLine("Check that " + aur[0].Name + " is not present");
aqr = client.Query(viewmode, aqir);

Console.WriteLine(aqr.Length + " records returned");
foreach (AccountQueryRecord rec in aqr)
{
    Console.WriteLine(rec.Name);
    Console.WriteLine(rec.Id);
}

// Wait for <RETURN> to end sample.
Console.WriteLine("\nHit <RETURN> to finish");
Console.ReadLine();
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
}
finally
{
    // Close the client.
    if (client != null)
    {
        if (client.State == CommunicationState.Opened)

```

```
        client.Close();
    else
        client.Abort();
    }
}
}
```

[Developing Applications by Using the WCF Service Model](#)

Invoking Business Service Methods by Using the WCF Service Model

You can create a WCF client that targets methods of Siebel business services. You can then use the WCF client to invoke these methods on the Siebel system. Siebel business services are surfaced under the Business Services node in the Add Adapter Service Reference Visual Studio Plug-in. The methods exposed by each business service are surfaced under the node corresponding to that service. You can follow the steps in [Overview of Using the WCF Service Model with the Adapter](#) to generate a WCF client for a business service and to use it to invoke the service's methods.

The following code uses a WCF client to invoke the **Execute** method of the TimeStamp business service. The time stamp, which is returned in the local time of the Siebel server, is then written to the console. The WCF client in this example is initialized from a configuration file generated by the Add Adapter Service Reference Plug-in. For an example of a generated configuration file, see [Configuring a WCF Client for a Siebel System](#).

```
using System;
using System.Collections.Generic;
using System.Text;

using System.ServiceModel;
using microsoft.lobservices.siebel._2007._03.BusinessServices.TimeStamp;

namespace Business_Service
{
    class Program
    {
        static void Main(string[] args)
        {
            BusinessServices_TimeStamp_OperationClient client = null;

            try
            {
                client =
                    new BusinessServices_TimeStamp_OperationClient("SiebelBinding_Business
Services_TimeStamp_Operation");

                client.ClientCredentials.UserName.UserName = "YourUserName";
                client.ClientCredentials.UserName.Password = "YourPassword";
                client.Open();

                ExecuteResponseRecord er = client.Execute();
                Console.WriteLine(er.Time);

                Console.WriteLine("\nHit <RETURN> to finish");
                Console.ReadLine();
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
            finally
            {
                // Close the client.
                if (client != null)
                {
                    if (client.State == CommunicationState.Opened)
                        client.Close();
                    else
                        client.Abort();
                }
            }
        }
    }
}
```

}

- [Performing Operations on Business Components by Using the WCF Channel Model](#)

Creating a Channel

This section demonstrates how to create a channel for direct messaging with Siebel by providing and consuming XML messages.

```
//create a channel factory, capable of sending a request to Siebel and receiving a reply (I
RequestChannel)
IChannelFactory<IRequestChannel> factory = binding.BuildChannelFactory<IRequestChannel>(new
BindingParameterCollection());

//open factory
factory.Open();

//obtain a channel from the factory by specifying the address you want to connect to
IRequestChannel irc = factory.CreateChannel(address);

//open the channel
irc.Open();

//perform operations
.....
.....
.....

//close the channel
irc.Close();

//close the factory
factory.Close();
```

Once you have created the channel, you can use that channel to perform operations on Siebel.

Performing Operations on Business Components by Using the WCF Channel Model

This section demonstrates how to perform operations on Siebel using the channel created in [Creating a Channel](#).

```
// create binding
SiebelBinding binding = new SiebelBinding();

//set up an endpoint address
EndpointAddress address = new EndpointAddress("siebel://Username=myuser;Password=mypass@mysiebelserver:1234?SiebelObjectManager=SSEObjMgr&SiebelEnterpriseServer=ent771&Language=enu");

//create request channel factory
IChannelFactory<IRequestChannel> factory = binding.BuildChannelFactory<IRequestChannel>(new BindingParameterCollection());

//open factory
factory.Open();

//create request channel using endpoint
IRequestChannel channel = factory.CreateChannel(address);

//open the channel
channel.Open();

// send request message and receive reply
System.Xml.XmlReader readerIn = System.Xml.XmlReader.Create(inputXml);
System.ServiceModel.Channels.Message messageIn = System.ServiceModel.Channels.Message.CreateMessage(MessageVersion.Default, action, readerIn);
System.ServiceModel.Channels.Message messageOut = channel.Request(messageIn);

// get response XML from SOAP message
System.Xml.XmlReader readerOut = messageOut.GetReaderAtBodyContents();

// save output file
XmlDocument doc = new XmlDocument();
doc.Load(readerOut);
doc.Save(outputXml);
Console.WriteLine("XML written out to {0}", outputXml);

// close the channel and the factory
channel.Close();
factory.Close();
```

Using the .NET Framework Data Provider for Siebel eBusiness Applications

This section provides instructions on using the .NET Framework Data Provider for Siebel eBusiness Applications (Data Provider for Siebel). This section provides information about:

- The connection string to connect to a Siebel system using an ADO.NET client.
- The syntax for SELECT and EXEC statements.
- Using the Data Provider for Siebel with SSIS.
- The ADO.NET interfaces that the Data Provider for Siebel extends.

In This Section

- [Extending ADO.NET Interfaces](#)
- [The Data Provider for Siebel Connection String](#)

[Using the .NET Framework Data Provider for Siebel eBusiness Applications](#)

SiebelClientFactory

An ADO.NET client accesses the Data Provider for Siebel using generic ADO.NET classes and interfaces. To enable this feature, the Data Provider for Siebel inherits the **System.Data.Common.DbProviderFactory** class. The client program consumes the client as follows:

```
DbProviderFactory factory = DbProviderFactories.GetFactory("Microsoft.Data.SiebelClient");  
DbConnection connection = factory.CreateConnection();
```

An alternative approach is as follows:

```
SiebelClientFactory factory = SiebelClientFactory.Instance;  
DbConnection connection = factory.CreateConnection();
```

SiebelClientFactory exists in the namespace Microsoft.Data.SiebelClient.

Supported Members

SiebelClientFactory extends **System.Data.Common.DbProviderFactory**. The following table provides a description of the members that **SiebelClientFactory** overrides.

Name	Description
Instance	This is a member variable. It provides a singleton instance of SiebelClientFactory.
CreateCommand()	Creates an instance of SiebelCommand.
CreateConnection()	Creates an instance of SiebelConnection.
CreateConnectionStringBuilder()	Creates an instance of SiebelConnectionStringBuilder.
CreateParameter()	Creates an instance of SiebelParameter.

[Extending ADO.NET Interfaces](#)

SiebelConnection

The Data Provider for Siebel accesses the underlying Siebel adapter `Binding`, the `ConnectionFactory`, and `Channel` to connect to the Siebel system. The Data Provider for Siebel implements the `DbConnection` class to support the preceding features.

Using an instance of `Microsoft.Data.SiebelClient.SiebelClientFactory`, a client program can obtain an instance of the `System.Data.Common.DbConnection` class to connect to the Siebel system.

```
//In this example, factory is an instance of SiebelClientFactory
DbConnection connection = factory.CreateConnection();
```

Alternatively, the following approach can be used to create a connection:

```
SiebelConnection connection = new SiebelConnection();
connection.ConnectionString = connectionString;
```

The `SiebelConnection` class inherits from `DbConnection`. It exists in the namespace `Microsoft.Data.SiebelClient`.

Supported Properties

The `SiebelConnection` class supports the following `DbConnection` properties.

Name	Get/Set	Description
ConnectionString	Get and Set	Gets or sets the string used to open the connection.
Database	Get	Gets the name of the current database after a connection is opened, or the database name specified in the connection string before the connection is opened. This should be the Siebel repository name.
DataSource	Get	Gets the name of the Siebel gateway for this connection.
ServerVersion	Get	In the current version of Data Provider for Siebel, this property returns a hard-coded value, which does not present the actual version of the Siebel server.
State	Get	Gets a string that describes the state of the connection. This can contain three possible values: OPEN, BROKEN, or CLOSED.

Supported Methods

The `SiebelConnection` class supports the following `DbConnection` methods.

Name	Description
CreateDbCommand	This protected method provides a new <code>DbCommand</code> instance.
ChangeDatabase	This public method is not supported, and will throw an exception if called.
Open	Opens a connection with the Siebel system by creating a WCF channel.
Close	Closes a connection with the Siebel system by closing a WCF channel.
CreateCommand	Creates a command object.

See Also

Other Resources

SiebelCommand

After establishing a connection with the Siebel system, the Data Provider for Siebel parses the Siebel command strings and command parameters provided by the ADO.NET client and maps the command into a WCF request message. The Data Provider for Siebel then sends the request to the Siebel adapter and obtains the response XML and the body contents from the adapter. The Data Provider for Siebel then uses the `XMLDataReader` to retrieve the relational data from the XML body.

Using an instance of `Microsoft.Data.SiebelClient.SiebelClientFactory`, a client program can obtain an instance of the `System.Data.Common.DbCommand` class to construct a Siebel command.

```
//In this example, factory is an instance of SiebelClientFactory
DbCommand command = factory.CreateCommand();
```

Alternatively, the following approach can be used to create a command:

```
//Here connection is an instance of SiebelConnection
SiebelCommand cmd = (SiebelCommand) connection.CreateCommand();
cmd.CommandText = "SELECT [Name] as MyName, [City], [Country] from Account.Account WHERE Name LIKE '3Com*' OPTION 'ViewMode 1'";
```

The `SiebelCommand` class inherits from `DbCommand`. It exists in the namespace `Microsoft.Data.SiebelClient`.

Supported Properties

The **SiebelCommand** class supports the following `DbCommand` *protected* properties:

Name	Get/Set	Description
DbConnection	Get and Set	This should contain the underlying <code>DbConnection</code> instance from which this <code>DbCommand</code> instance is obtained.
DbParameterCollection	Get	Gets the collection of <code>DbParameter</code> objects.

`SiebelCommand` also supports the following `DbCommand` *public* properties:

Name	Get/Set	Description
CommandText	Get and Set	This contain the SQL statement that the ADO.NET client wishes to execute.
CommandType	Get and Set	Only <code>CommandType.Text</code> is supported.
Connection	Get and Set	This uses the <code>DbConnection</code> member.
Parameters	Get	This uses the <code>DbParameterCollection</code> member.
◆ Important		
The <code>SiebelCommand</code> class ignores the <code>CommandTimeout</code> , <code>DesignTimeVisible</code> , and <code>DbTransaction</code> properties.		

Supported Methods

The Data Provider for Siebel supports the following `DbCommand` *protected* methods:

Name	Description
CreateDbParameter	Creates a new <code>DbParameter</code> instance.
ExecuteDbDataReader	This executes the SELECT and EXEC commands and returns a <code>DbDataReader</code> .

`SiebelCommand` also supports the following `DbCommand` *public* methods:

Name	Description
CreateParameter	Creates a new <code>DbParameter</code> instance through <code>CreateDbParameter()</code> .
ExecuteReader	Executes <code>CommandText</code> against the <code>Connection</code> and returns <code>DbDataReader</code> through <code>ExecuteDbDataReader()</code> .
Prepare	This parses the <code>CommandText</code> and builds the SQL command parse tree.

[Extending ADO.NET Interfaces](#)

SiebelParameter

The Data Provider for Siebel provides a `DbParameter` implementation to enable an ADO.NET client to specify parameters for a particular command. Using an instance of the `System.Data.Common.DbCommand` class of the Data Provider for Siebel, a client program can obtain an instance of the `System.Data.Common.DbParameter` class.

```
//In this example, command is an instance of DbCommand
DbParameter param = command.CreateParameter();
```

Alternatively, the following approach can be used:

```
//Here command is an instance of SiebelCommand
SiebelParameter param = (SiebelParameter) command.CreateParameter();
param.ParameterName = "@Time";
```

The `SiebelParameter` class inherits from `DbParameter`. It exists in the namespace `Microsoft.Data.SiebelClient`.

Supported Properties

The `SiebelParameter` class supports the following `DbParameter` *public* properties:

Name	Get/Set	Description
DbType	Get and Set	Data type of the parameter. See Basic Siebel Data Types .
Direction	Get and Set	The following values are supported: <ul style="list-style-type: none"> • <code>ParameterDirection.Input</code> • <code>ParameterDirection.Output</code> • <code>ParameterDirection.InputOutput</code>
IsNullable	Get and Set	The property is not supported, and will throw an exception if called.
ParameterName	Get and Set	The Data Provider for Siebel supports this property for an ADO.NET client to specify the parameter name.
Value	Get and Set	The Data Provider for Siebel represents parameter values as strings.

Supported Data Types

The following table summarizes the simple Siebel field types that Data Provider for Siebel supports. For more detailed coverage, see [Basic Siebel Data Types](#).

Siebel Field Type	.NET Type	XML Schema Type
DTYPE_BOOL	Boolean	xsd:boolean
DTYPE_CURRENCY	Decimal	xsd:decimal
DTYPE_DATE	DateTime	xsd:dateTime
DTYPE_DATETIME	DateTime	xsd:dateTime

DTYPE_UTCDATETIME	DateTime	xsd:dateTime
DTYPE_ID	String	xsd:string
DTYPE_INTEGER	Integer	xsd:int
DTYPE_NOTE	String	xsd:string
DTYPE_NUMBER	Decimal	xsd:decimal
DTYPE_PHONE	String	xsd:string
DTYPE_TEXT	String	xsd:string
DTYPE_TIME	DateTime	xsd:dateTime

Supported Methods

The `SiebelParameter` class does not override any special methods in `DbParameter`.

[Extending ADO.NET Interfaces](#)

SiebelConnectionStringBuilder

The Data Provider for Siebel provides a `DbConnectionStringBuilder` implementation to enable SQL Server Integration Services (SSIS) and Visual Studio explorer tools environments to get the connection properties of the Data Provider for Siebel and display them in the form of a GUI driven by the PropertyGrid.

To create a `SiebelConnectionStringBuilder`, use the following approach:

```
//In this example, factory is an instance of SiebelClientFactory
SiebelConnectionStringBuilder bldr = (SiebelConnectionStringBuilder)factory.CreateConnectio
nStringBuilder();
bldr.ConnectionString = connstr;
```

Or, simply:

```
SiebelConnectionStringBuilder bldr = new SiebelConnectionStringBuilder();
```

To see the keys and values supported as part of the `DbConnectionStringBuilder`, see [The Data Provider for Siebel Connection String](#).

See Also

Other Resources

[Extending ADO.NET Interfaces](#)

DbDataReader

The Data Provider for Siebel provides a `DbDataReader` leveraging the XML Data Reader. This provides the consumer of the Siebel data source the ability to read a forward-only stream of rows.

Supported Properties

The Data Provider for Siebel supports the following `DbDataReader` properties.

Name	Get/Set	Description
HasRows	Get	This property is not supported, and will throw an exception if accessed.
IsClosed	Get	Gets a value indicating whether the <code>DbDataReader</code> is closed.
RecordsAffected	Get	Gets a value indicating whether the <code>DbDataReader</code> contains one or more rows.
Item(Int32)	Get	Gets the value of the specified column as an instance of <code>Object</code> . Use the ordinal number for the desired column when invoking this indexer.
Item(String)	Get	Gets the value of the specified column as an instance of <code>Object</code> . Use the name of the desired column when invoking this indexer.

Supported Methods

The Data Provider for Siebel supports the following `DbDataReader` methods.

Name	Description
GetSchemaTable	<p>Returns a <code>DataTable</code> that describes the column metadata of the <code>DbDataReader</code>. The schema column attributes supported by the Data Provider for Siebel are:</p> <ul style="list-style-type: none"> • ColumnName • ColumnOrdinal • .NET DataType • Length • Precision (if available) • Scale (if available) • AllowDBNull • LocalName • Extended LocalName • Namespace
GetString	Gets the value of the specified column as an instance of <code>String</code> .
GetValue	Gets the value of the specified column as an instance of <code>String</code> .

isDBNull	Gets a value that indicates whether the column contains nonexistent or missing values.
NextResult	The Siebel Data Provider always returns a single result set; hence this call fully exhausts the current result set before returning false .
Read	Advances the reader to the next record in a result set. It returns true if it succeeds, and false if the reader has no more records left.
Close	Closes the <code>DbDataReader</code> object.  Caution When you are done using the <code>DbDataReader</code> object, you must close it, in order to free up the Siebel COM library objects. Otherwise, the client application's memory and handle usage will go up.

[Extending ADO.NET Interfaces](#)

The Data Provider for Siebel Connection String

The .NET Framework Data Provider for Siebel eBusiness Applications (Data Provider for Siebel) uses the Siebel adapter to access the Siebel system. The Siebel adapter in turn uses the Siebel COM Data Control library to access the Siebel system. The Siebel COM Data Control comes bundled with the Siebel Web client.

To establish connectivity to a Siebel system, ADO.NET clients must specify the Siebel connection properties that are encoded into a database connection string. This is required because the Data Provider for Siebel implements **DbConnection** to access the underlying Siebel adapter binding.

The connection string to connect to a Siebel system using the Data Provider for Siebel contains the following properties.

Property	Description
Password	The password for the user on the Siebel system; this value is case-sensitive.  Note The Data Provider for Siebel preserves the case of the value that you enter for the password when it opens a connection on the Siebel system.
Username	The user name on the Siebel system; this value is case-sensitive.  Note The Data Provider for Siebel preserves the case of the value that you enter for the user name when it opens a connection on the Siebel system.
Compression	The compression algorithm to use between the Data Provider for Siebel and the Siebel system. Supported values are none or zlib . This parameter is optional. If it is not specified, the Siebel system supplies a default value (zlib).
Encryption	The type of encryption to use between the Data Provider for Siebel and the Siebel system. Supported values are none , mscrypto , or rsa . This parameter is optional. If it is not specified, the Siebel system supplies a default value (none).
Language	The language of the object manager. An example value is enu . This parameter is required.
SiebelEnterpriseServer	The name of the Siebel Enterprise Server. This parameter is required.
SiebelGateway	Consists of the Siebel server IP and port. For example, Siebel_Server:1234.
SiebelObjectManager	The name of the Siebel object manager on the enterprise server. This parameter is required.
SiebelRepository	The Siebel repository. Required if more than one repository exists on the server; otherwise, optional.  Note If more than one repository exists on the server, you must specify a target repository in the SiebelRepository parameter.
SiebelServer	The Siebel server. Required for all Siebel 7.5 server connections; otherwise, do not set this parameter.
Transport	The transport; only tcPIP is supported. This parameter is optional. If it is not specified, the Siebel system supplies a default value (tcPIP).

For example:

```
Username=YourUserName;Password=YourPassword;SiebelGateway=Siebel_Server:1234;SiebelObjectMa  
nager=obj_mgr;SiebelEnterpriseServer=ent_server;Language=enu;SiebelRepository=siebel_rep
```

Concepts

[Using the .NET Framework Data Provider for Siebel eBusiness Applications](#)

Syntax for a SELECT Statement

Using the Data Provider for Siebel, ADO.NET clients can perform a SELECT query on Siebel business components by specifying a WHERE clause that represents a valid Siebel search specification. The syntax for the SELECT statement is:

```
SELECT
<column name 1> AS <column alias 1>,
<column name 2> AS <column alias 2>,
...
FROM
<Business object name>.<Business component name> AS <table alias>
WHERE
<filter condition>
OPTION
'ViewMode <value>'
```

In the above syntax, the ViewMode option corresponds to the Siebel system View Modes, which is a filtering mechanism to restrict the set of records that match the query. For the allowed set of values, see the Siebel documentation.

Note

If the field names in the WHERE clause contain special characters or empty spaces, make sure you always enclose the field names within square brackets.

Note

In SELECT queries containing alias names with special characters, make sure you include the alias names within square brackets.

Note

The Data Provider for Siebel supports alias names for tables in the SELECT clause but not in the WHERE clause.

Searching and Sorting Data Using the Data Provider for Siebel

The Data Provider for Siebel supports a filter condition in SQL statements based on the search specifications supported by the Siebel system.

The rules for the search specification are:

- Standard comparison operators must be used to compare a field to a constant, or one field to another field. These include =, !=, >, <, >=, and <=.

Example: [Revenue] > 5000

- String constants must be enclosed in double quotation marks, and the string values must be case-sensitive.

Example: [Type] != "COST LIST"

- The logical operators AND, OR, and NOT must be used to negate or combine expressions. Case sensitivity is ignored in these operators; for example, "and" is the same as "AND".

Example: [Competitor] IS NOT NULL and [Competitor] != "N"

- A field name in a search specification must be enclosed in square brackets.

Example: [Conflict Id] = 0

- The LIKE operator may be used to create text string comparison expressions in which a field is compared to a constant, or a field to another field and a match on only the first several characters is required. The wildcard characters "*" and "?" must be used to indicate any number of characters, and a single character, respectively.
- ADO.NET clients can specify original Siebel business objects, business components, and business component field names. These names must be enclosed in square brackets if they contain any special characters or white space. Examples of queries that are supported are:

```
SELECT [Name], [Postal Code] FROM Account.Account where [Postal Code] != '11065'  
SELECT [Name], [Postal Code], Id From Account.Account where [Postal Code] != '60626' O  
rder BY Id ASC, Name DESC  
SELECT * FROM [Admin Price List].[Price Book Items]
```

The Data Provider for Siebel supports sort specifications in SQL statements based on the sort specification supported by Siebel. The rules for the sort specification are:

- Use commas to separate field names in a sort specification; for instance, Name, Location
- To indicate that a field in the list sorts in descending order, include (DESC) after the field name, as in "Start Date (DESC)." If no sort order is specified, ascending order is used. To explicitly specify ascending order, use the keyword (ASC).
- The sort specification expression must be 255 characters or less.

See Also

Concepts

[Using the .NET Framework Data Provider for Siebel eBusiness Applications](#)

Syntax for an EXEC Statement

Using the Data Provider for Siebel, ADO.NET clients can also perform an EXEC operation on the Siebel adapter. The syntax for the EXEC statement is:

```
EXEC
<Business Service name>.<Business Service method>
<value 1..n>,
@parameter 1..n [OUTPUT],
@parameter 1..n = <value>
```

In the preceding syntax, <value 1..n> represents a set of unnamed parameters. These are hard-coded values. They usually represent IN parameters. They can also represent INOUT parameters. However, if a hard-coded value is used for an INOUT parameter, the output value associated with that parameter cannot be retrieved after the EXEC statement is executed.

The @parameter 1..n syntax represents a set of named parameters, which can be IN, INOUT, or OUT parameters. The output parameters must be followed by the **OUTPUT** keyword.

Note

The **OUTPUT** keyword must only be used with OUT parameters and not with INOUT parameters.

To specify parameter values inline, use the @parameter 1..n = <value> syntax.

All parameters must be comma-separated.

The following are examples of EXEC statements:

```
EXEC ExtractDataService.Echo @In, @InOut, @Out OUTPUT
EXEC ExtractDataService.Echo 'InputValue', @InOut, @Out OUTPUT
EXEC ExtractDataService.Echo @InOut, @Out OUTPUT, @In='InputValue'
EXEC ExtractDataService.Echo 'InputValue', @Out OUTPUT, @InOut='InputValue'
```

Note

Every parameter name (like @In in the preceding example) must match the corresponding argument name in the Siebel Business Service method.

[Using the .NET Framework Data Provider for Siebel eBusiness Applications](#)
[Performing a SELECT Query on Business Components](#)

Using the Data Provider for Siebel with SSIS

You can use the .NET Framework Data Provider for Siebel eBusiness Applications (Data Provider for Siebel) along with SQL Server Integration Services (SSIS) to import data from a Siebel system into SQL Server database tables, flat files, or other compatible destination types. Specifically, you can create an SSIS package that can be executed to import this data.

To import data into the SQL Server database, use the SQL Server Import and Export Wizard, and provide a SELECT query to specify the data to be imported. The query must conform to the semantics supported by the Data Provider for Siebel. For more information about the grammar for a SELECT query for the Data Provider for Siebel, see [Syntax for a SELECT Statement](#).

Note

The Data Provider for Siebel does not support using an EXEC statement with SSIS.

You can start the SQL Server Import and Export wizard either from the SQL Server Management Studio or from an Integration Service project in Visual Studio. This section provides instructions on running the wizard from both the SQL Server Management Studio and Visual Studio interfaces.

Importing Siebel Data by Using SQL Server Management Studio

This section provides information about how to use SQL Server Management Studio to import data from a Siebel system into a SQL Server database. It also provides instructions on how to create and execute an SSIS package to import this data.

Prerequisites

Before performing the procedures provided in this topic, make sure:

- The Data Provider for Siebel is installed on the computer.
- SQL Server Business Intelligence Development Studio is installed on the computer.

Importing Data by Using SQL Server Management Studio

Perform the following steps to import data from Siebel system using Data Provider for Siebel with SQL Server Management Studio.

To import data by using SQL Server Management Studio

1. Start the SQL Server Management Studio.
2. In the **Connect to Server** dialog box, specify the values to connect to a SQL Server database, and then click **Connect**. Microsoft SQL Server Management Studio opens.
3. In Object Explorer, expand the SQL Server name, expand **Databases**, and right-click the database into which you will be exporting the tables from the Siebel system. From the context menu, point to **Tasks**, and then click **Import Data**. This starts the SQL Server Import and Export Wizard.
4. Read the information on the Welcome screen, and then click **Next**.
5. In the **Choose a Data Source** dialog box, from the **Data Source** drop-down list, select **.NET Framework Data Provider for Siebel eBusiness Applications**. Specify values for the different connection properties for the Data Provider for Siebel connection string. For more information about the connection string properties, see [The Data Provider for Siebel Connection String](#).

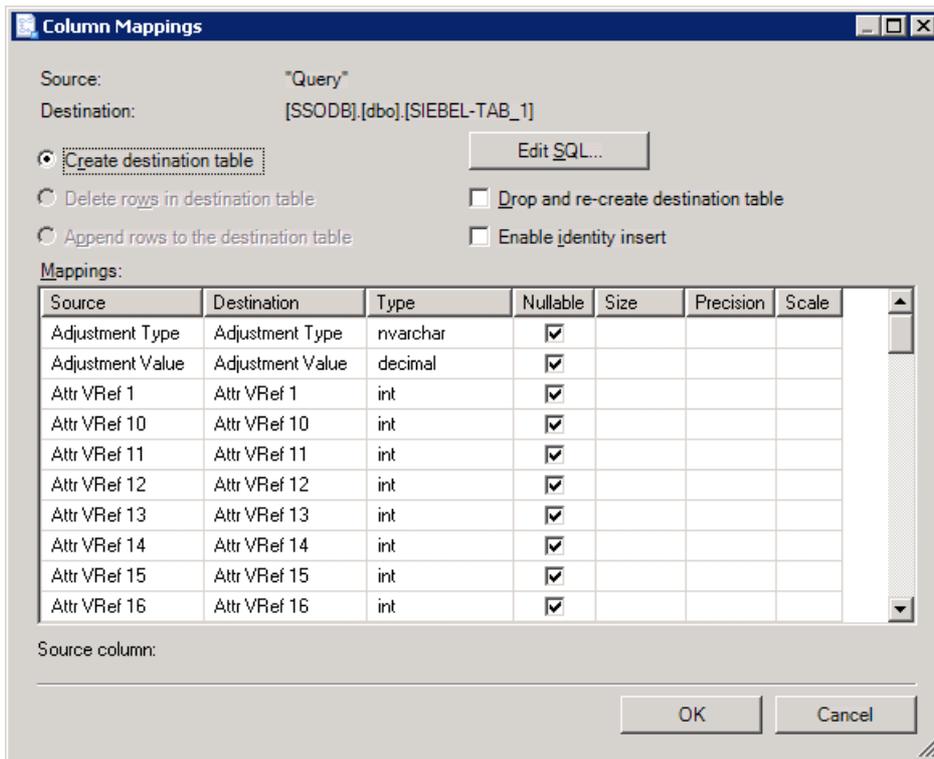

Click **Next**.

6. In the **Choose a Destination** dialog box:
 - a. From the **Destination** drop-down list, select **SQL Native Client**.
 - b. From the **Server name** drop-down list, select a SQL Server name.
 - c. Select an authentication mode.
 - d. From the **Database** drop-down list, select the database to which you want to import the Siebel table.
 - e. Click **Next**.
7. In the **Specify Table Copy or Query** dialog box, choose the **Write a query to specify the data to transfer** option.
8. In the **Provide a Source Query** dialog box, specify a SELECT query to filter the data to be imported into the SQL Server. For more information about the grammar for a SELECT query for the Data Provider for Siebel, see [Syntax for a SELECT Statement](#).

Click the **Parse** button to validate the query, click **OK** in the pop-up dialog box, and then click **Next**.

9. In the **Select Source Tables and Views** dialog box, select the check box against the source and destination tables. The source is the query you specified to retrieve data from Siebel. The destination is the table that will be created in the SQL Server database.

10. The wizard creates a default mapping between the source and destination table fields. However, you can change the mappings according to your requirement. To change the field mappings, click **Edit Mappings**.

11. In the **Column Mappings** dialog box, you can:

- Change the names of columns in the destination table.
- Ignore certain columns in the destination table.
- Change the data type for fields in destination table.
- Change other field attributes such as nullable, size, precision, and scale.

When you are finished, click **OK**.

12. In the **Select Source Tables and Views** dialog box, click **Next**.

13. In the **Save and Execute Package** dialog box:

- Select the **Execute immediately** check box to execute the query.
- Select the **Save SSIS Package** check box to save the query as a package and execute it later. If you chose to save the package, you must also specify whether you want to save the package in the SQL Server or the file system.
- From the **Package protection level** drop-down list, select a protection level for the package and specify credentials where required.
- Click **Next**.

If you chose to save the package, proceed to the next step. Otherwise, skip to step 15.

14. In the **Save SSIS Package** dialog box, specify the following:

- The name for the package
- The description for the package

- If you chose to save the package to a SQL Server, select a SQL Server from the **Server name** drop-down list.
- If you chose to save the package to the file system, specify the name and location of the file in the **File name** text box.

When you are finished, click **Next**.

15. In the **Complete the Wizard** dialog box, review the summary of actions that the wizard will perform, and then click **Finish**.
16. In the **Performing Operations** dialog box, the wizard starts executing tasks to import the information from Siebel into a SQL Server database table. The status for each task is displayed in the wizard.
17. After all the tasks are successfully executed, click **Close**. If a task fails, see the corresponding error message, fix the issue, and rerun the wizard.

Running the SSIS Package

If you chose to save the SSIS package, you can run it to retrieve the most recent information from the Siebel system. This section provides information about how to run the package if you chose to save it to the file system.

To run the package from Windows Explorer

1. From **Windows Explorer**, navigate to the location where you saved the package, and double-click the package.
2. In the **Execute Package Utility** dialog box, click **Execute**. The **Package Execution Progress** dialog box displays the progress of the different tasks.
3. After all the tasks are successfully executed, click **Close**.
4. In the **Execute Package Utility** dialog box, click **Close**.

For more information about running packages, see "Running Packages" at <http://go.microsoft.com/fwlink/?LinkId=94972>. For any other information related to SSIS packages, see "Package How-to Topics (SSIS)" at <http://go.microsoft.com/fwlink/?LinkId=94973>.

Verifying the Results

After executing the package, you must verify the results by going to the SQL Server database to which the Siebel data is imported. Executing the package should have created a table in the destination database. This table should be populated with the values from the Siebel table.

Importing Siebel Data by Using Visual Studio

This section provides information about how to use Microsoft Visual Studio to import data from a Siebel system into a SQL Server database. It also provides instructions on how to create and execute an SSIS package to import this data.

Prerequisites

Before performing the procedures provided in this topic, make sure:

- The Data Provider for Siebel is installed on the computer.
- Microsoft Visual Studio 2010 is installed on the computer.

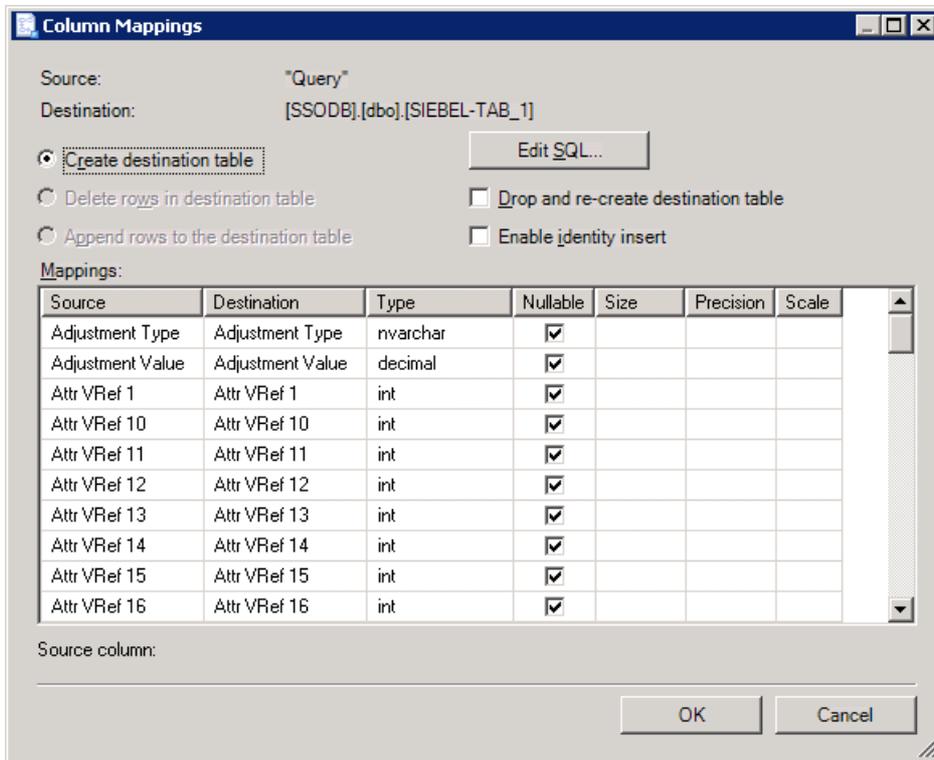

Importing Data by Using Visual Studio

Perform the following steps to import data using Data Provider for Siebel in Visual Studio.

To import data by using Visual Studio

1. Start Visual Studio and create an Integration Service project.
2. From the **Project** menu, select **SSIS Import and Export Wizard**. This starts the SQL Server Import and Export Wizard.
3. Read the information on the Welcome screen, and then click **Next**.
4. In the **Choose a Data Source** dialog box, from the **Data Source** drop-down list select **.NET Framework Data Provider for Siebel eBusiness Applications**. Specify values for the different connection properties for the Data Provider for Siebel connection string. For more information about the connection string properties, see [The Data Provider for Siebel Connection String](#).
Click **Next**.
5. In the **Choose a Destination** dialog box:
 - a. From the **Destination** drop-down list, select **SQL Native Client**.
 - b. From the **Server name** drop-down list, select a SQL Server name.
 - c. Select an authentication mode.
 - d. From the **Database** drop-down list, select the database to which you want to import the Siebel table.
 - e. Click **Next**.
6. In the **Specify Table Copy or Query** dialog box, choose the **Write a query to specify the data to transfer** option.
7. In the **Provide a Source Query** dialog box, specify a SELECT query to filter the data to be imported into the SQL Server. For more information about the grammar for a SELECT query for the Data Provider for Siebel, see [Syntax for a SELECT Statement](#).
8. To validate the query, click the **Parse** button, click **OK** in the pop-up dialog box, and then click **Next**.
9. In the **Select Source Tables and Views** dialog box, select the check box against the source and destination tables. The source is the query you specified to retrieve data from Siebel. The destination will be the table that will be created in the SQL Server database.
10. The wizard creates a default mapping between the source and destination table fields. However, you can change the mappings according to your requirement. To change the field mappings, click **Edit Mappings**.
11. In the **Column Mappings** dialog box, you can:
 - Change the names of columns in the destination table.

- Ignore certain columns in the destination table.
- Change the data type for fields in destination table.
- Change other field attributes such as nullable, size, precision, and scale.
- Click **OK**.

12. In the **Select Source Tables and Views** dialog box, click **Next**.
13. In the **Complete the Wizard** dialog box, review the summary of actions that the wizard will perform, and then click **Finish**.
14. In the **Performing Operations** dialog box, the wizard starts executing tasks to import the information from Siebel into a SQL Server database table. The status for each task is displayed in the wizard.
15. After all the tasks are successfully executed, click **Close**. If a task fails, see the corresponding error message, fix the issue, and rerun the wizard.
16. The wizard adds an SSIS package to your Integration Service project. Save the Integration Service project.

Running the SSIS Package

Once the package is created within an Integration Service project, you can execute it to import data from a Siebel system into a SQL Server database. Perform the following steps to import Siebel data by executing the package.

To run the package from Visual Studio

1. Navigate to the SSIS package in Solution Explorer.
2. Right-click the package name, and then select **Execute Package**.

For more information about running packages, see "Running Packages" at <http://go.microsoft.com/fwlink/?LinkId=94972>. For any other information related to SSIS packages, see "Package How-to Topics (SSIS)" at <http://go.microsoft.com/fwlink/?LinkId=94973>.

Verifying the Results

After executing the package, you must verify the results by logging on to the SQL Server and navigating to the database to which the Siebel data is imported. Executing the package should have created a table in the destination database. This table should be populated with the values from the Siebel table.

Tasks

[Using the Data Provider for Siebel with SSIS](#)

Using the Siebel Adapter with Microsoft Office SharePoint Server

Most line-of-business (LOB) applications have proprietary interfaces that are accessible to relatively few people with the required subject matter expertise. However, because information workers need relevant information at all levels in an organization, the subject matter experts have to export required data into more familiar applications, like Microsoft Excel, for information workers to consume the information.

The new collection of Microsoft Office client applications and features bridges this gap by bringing backend business data into the most common interface for information workers, Microsoft Office. Microsoft Office client applications seamlessly present data from LOB applications through interfaces familiar to information workers. One example is the Business Data Catalog in Microsoft Office SharePoint Server.

In This Section

- [About Business Data Catalog](#)
- [Using the Siebel Adapter to Integrate the Siebel System with the Business Data Catalog and Microsoft Office SharePoint Server](#)
- [Considerations While Using the Siebel Adapter with Microsoft Office SharePoint Server](#)
- [How Do I Use a Custom Web Part?](#)

About Business Data Catalog

The Business Data Catalog is a new integration component in Microsoft Office SharePoint Server 2007 and later. The Business Data Catalog is a shared service and surfaces business data from backend applications via databases and Web services, without the need for writing any code. It is a metadata repository that defines business entities like customers, invoices, and purchase orders. Once defined, clients can use these entities.

The Business Data Catalog provides a Business Data Catalog Definition Editor to help you author application definition files for the Business Data Catalog in Microsoft Office SharePoint Server 2007 and later. Using the Business Data Catalog Definition Editor, you can create and edit metadata for business applications.

For more information about the Business Data Catalog, see "Business Data Catalog" at <http://go.microsoft.com/fwlink/?LinkId=103882>.

[Using the Siebel Adapter with Microsoft Office SharePoint Server](#)

Using the Siebel Adapter to Integrate the Siebel System with the Business Data Catalog and Microsoft Office SharePoint Server

The Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK includes the WCF LOB Adapter Service Development Wizard, which generates a WCF service for specific LOB artifacts. This WCF service is hosted in a hosting environment such as Microsoft Internet Information Services (IIS). The Business Data Catalog Definition Editor uses the URL where the WCF service is hosted to get the Web Services Description Language (WSDL) for the WCF service. Using the WSDL, the Business Data Catalog Definition Editor extracts the methods available to the WCF service. These methods can be used to establish entities and the association between the entities.

The Business Data Catalog Definition Editor helps you create an application definition file (an XML file) that Microsoft Office SharePoint Server can consume. Once the application definition file is imported to Microsoft Office SharePoint Server, you can create Web Parts to present the information from enterprise applications. For more information, see "Creating Web Parts" in [Step 3: Create a SharePoint Application to Retrieve Data from Siebel](#) in [Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site](#).

Tutorial

To demonstrate how to use the Siebel adapter with Microsoft Office SharePoint Server, the BizTalk Adapter Pack includes a tutorial that provides step-by-step instructions to present data from a Siebel system on a SharePoint site. See [Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site](#).

[Using the Siebel Adapter with Microsoft Office SharePoint Server](#)

Considerations While Using the Siebel Adapter with Microsoft Office SharePoint Server

This topic contains information about the issues you might encounter while using the Microsoft BizTalk Adapter for Siebel eBusiness Applications with Microsoft Office SharePoint Server, along with resolutions. The issues are divided into two categories:

- General issues
- Issues involving custom Web Parts

General Issues

This section contains issues that either have no resolution or requires you to modify the application definition file for the resolution.

Issue 1: The simple type data returned by the WCF service is not displayed

Explanation: Microsoft Office SharePoint Server expects the data returned by the WCF service to be of DataSet or Collection type only. If the data returned by the WCF service is of simple type, Microsoft Office SharePoint Server does not display the data.

Resolution: No resolution. It is a known limitation with Microsoft Office SharePoint Server.

Issue 2: An error message is displayed if the data returned by the WCF service is NULL

Explanation: If the data returned by the WCF service is a NULL value, Microsoft Office SharePoint Server displays an error message. For example, suppose you are using the Business Data List Web Part for the **Finder** method instance, and are searching for customers in the Siebel system based on a search expression. The search expression that you specified fetches a NULL value. In this case, Microsoft Office SharePoint Server will display an error message.

Resolution: No resolution. It is a known limitation with Microsoft Office SharePoint Server.

Issue 3: An array of simple type returned by the WCF service is not displayed

Explanation: If the data returned by the WCF service is an array of simple type, Microsoft Office SharePoint Server does not display the data. Moreover, when you execute a method instance in Business Data Catalog Definition Editor that returns an array of simple type, the following error message is displayed: "Backend system adapter returned a structure incompatible with the corresponding metadata (MethodInstance, Parameter or TypeDescriptor)."

Resolution: No resolution. It is a known limitation with Microsoft Office SharePoint Server and Business Data Catalog Definition Editor.

Issue 4: Cannot import an application definition file that contains a complex type parameter having more than 300 fields

Explanation: Microsoft Office SharePoint Server cannot import an application definition file that has more than 300 fields in the complex type parameter returned by the WCF service, and displays an error message if you try to do so. This is due to the limitation of Microsoft Office SharePoint Server of not being able to display more than 300 fields of a complex type parameter.

Resolution: Use the Business Data Catalog Definition Editor to limit the number of fields of the complex type parameter to less than or equal to 300. Depending on your requirement, you can delete the fields of the complex type parameter in the Business Data Catalog Definition Editor that you do not require to be displayed in Microsoft Office SharePoint Server. Alternatively, you can also export the application definition file from Business Data Catalog Definition Editor with all the fields, and then modify the application definition file in a notepad or any XML authoring application to delete the fields that are not required in order to limit the number of fields to 300.

Issues Involving Custom Web Parts

This section contains issues that require the use of custom Web Parts for resolution. For detailed information about using a custom Web Part to resolve issues that might come up while working with Siebel adapter and Microsoft Office SharePoint Server, see [How Do I Use a Custom Web Part?](#).

Issue 1: Index of an enumerator is displayed instead of the value for the enum data type

Explanation: If a Business Data List or Business Data Item Web Part in Microsoft Office SharePoint Server contains data of enum type (a distinct type consisting of a set of named constants called the enumerators), the index of the enumerator is

displayed instead of its value in Microsoft Office SharePoint Server. This is because the Business Data List and Business Data Item Web Parts incorrectly print the values of the enum type data to the SharePoint portal.

Resolution: Use a custom Web Part to print the value of the enumerator instead of the index. For information about using a custom Web Part, see [How Do I Use a Custom Web Part?](#). For example, you can use the following code sample in your Web part to print the correct values of enum type data on Microsoft Office SharePoint Server.

```
namespace CustomWebpart
{
    public class CustomWebPart : WebPart
    {
        private string displayText = "Hello World!";

        [WebBrowsable(true), Personalizable(true)]
        public string DisplayText
        {
            get { return displayText; }
            set { displayText = value; }
        }
        protected override void Render(System.Web.UI.HtmlTextWriter writer)
        {
            string SearchExpr = "[Address Name] LIKE \"*\";";
            object ElementType = null;

            /**Step 1: Get the required entity and method.***/

            LobSystem newSystem = ApplicationRegistry.GetLobSystems()["WebServiceLobSystem"]; // Name specified in application definition file
            LobSystemInstance newSystemInstance = newSystem.GetLobSystemInstances()["Siebel_Instance"]; // Name specified in application definition file
            Entity CategoryEntity = newSystem.GetEntities()["Siebel_Method_Name"]; // Name specified in application definition file
            Method newMethod = CategoryEntity.GetMethods()["Query"]; // Name specified in application definition file
            MethodInstance methodInstance = newMethod.GetMethodInstances()["MethodInstance0"]; // Name specified in application definition file

            /**Step 2: Get the list of input parameters.***/
            Object[] args = methodInstance.GetMethod().CreateDefaultParameterInstances(methodInstance); // Get default value of the input parameter
            Object[] ArgsInput = new Object[args.Length];

            /**Step 3: Assign them required values.***/

            //Assigning values to a complex type parameter. Index of this parameter is 3rd in args array.
            /** Complex Type Parameter is defined as follows:
            <Parameter Direction="In" Name="BusinessAddressQueryInputRecord">
            <TypeDescriptor TypeName="BDC.BusinessAddressQueryInputRecord,WebServiceLobSystem" Name="BusinessAddressQueryInputRecord">
            <TypeDescriptors>
            <TypeDescriptor TypeName="System.String, ..." Name="SearchExpr"></TypeDescriptor>
            <TypeDescriptor TypeName="System.String, ..." Name="SortSpec"></TypeDescriptor>
            <TypeDescriptor TypeName="System.String[], ..." IsCollection="true" Name="QueryFields"></TypeDescriptor>
            </TypeDescriptors>
            </TypeDescriptor>
            </Parameter>
            * We are assigning value to Parameter SearchExpr. ***/

            Assembly asm = Assembly.GetAssembly(args[2].GetType());
            Type t = asm.GetType(args[2].GetType().ToString()); // Get type of the parameter

            FieldInfo[] FI = t.GetFields();
            ElementType = Activator.CreateInstance(t);
        }
    }
}
```

```
        ElementType.GetType().GetFields()[f].SetValue(ElementType, (Object)"ElementValue");
    }
    ElementArray.SetValue(ElementType, ind);
}

ArgsInput[i] = (object)ElementArray; // As shown in sample, ArgsInput is fed as
input while executing Method Instance
```

Issue 3: Limitation with specifying NULL values to complex type parameters

Explanation: If you do not specify any value for a complex type parameter from a Web Part in Microsoft Office SharePoint Server, NULL should be passed on as the value for the complex type parameter to the WCF service. However, a non-NULL value is passed for the complex type parameter, and NULL is passed for its children elements (of simple type). This causes a mismatch between the expected message schema and the message schema that is passed on to the WCF service. As a result, the Siebel adapter might display an error message.

Note

To find out the default value of a complex type parameter when no value is passed from a Web Part in Microsoft Office SharePoint Server, use step 2 in the code sample mentioned in "Issue 1: Index of an enumerator is displayed instead of the value for the enum data type."

Resolution: Use a custom Web Part to assign a NULL value to the complex type parameter when no value is specified from a Web Part in Microsoft Office SharePoint Server. For information about using a custom Web Part, see [How Do I Use a Custom Web Part?](#)

Issue 4: Limitation with displaying a single record in Microsoft Office SharePoint Server based on multiple values

Explanation: If you want to display a single record in Microsoft Office SharePoint Server based on multiple values (input parameters) from a Siebel system, you cannot use any of the three Web Parts (Business Data List, Business Data Item, and Business Data Related List) specified in [Step 3: Create a SharePoint Application to Retrieve Data from Siebel](#) in [Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site](#).

Resolution: You must use a custom Web Part to do this. For information about using a custom Web Part, see [How Do I Use a Custom Web Part?](#) For example, in step 3 in "Issue 1: Index of an enumerator is displayed instead of the value for the enum data type" you can modify the code to provide values for more than one parameter instead of providing input to a single business component parameter.

How Do I Use a Custom Web Part?

This section provides information about using a custom Web Part with Microsoft Office SharePoint Server. To use a custom Web Part, you must do the following:

1. Create a custom Web Part
2. Deploy the custom Web Part to a SharePoint portal
3. Configure the SharePoint portal to use the custom Web Part

Before You Begin

Before you create a custom Web Part:

- Publish the Siebel artifacts as a WCF service. For more information, see [Step 1: Publish the Siebel Business Component Operations as a WCF Service](#) in [Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site](#).
- Create an application definition file for the Siebel artifacts using the Business Data Catalog in Microsoft Office SharePoint Server. For more information, see [Step 2: Create an Application Definition File for Siebel Business Component Operations](#) in [Tutorial 1: Presenting Data From a Siebel System on a SharePoint Site](#).

Step 1: Create a custom Web Part

To create a custom Web Part using Visual Studio, do the following:

1. Start Visual Studio 2010, and then create a project.
2. In the **New Project** dialog box, from the **Project types** pane, select **Visual C#**. From the **Templates** pane, select **Class Library**.
3. Specify a name and location for the solution. For this topic, specify **CustomWebPart** in the **Name** and **Solution Name** boxes. Specify a location, and then click **OK**.
4. Add a reference to the System.Web component into the project. Right-click the project name in **Solution Explorer**, and then click **Add Reference**. In the **Add Reference** dialog box, select **System.Web** in the **.NET** tab, and then click **OK**. The System.Web component contains the required namespace of System.Web.UI.WebControls.WebParts.
5. Add the required code based on your issue in the project. For the code sample that is relevant to a certain issue, see "Issues Involving Custom Web Parts" in [Considerations While Using the Siebel Adapter with Microsoft Office SharePoint Server](#).
6. Build the project. On successful build of the project, a .dll file, CustomWebPart.dll, will be generated in the *<project folder>/bin/Debug* folder.

Step 2: Deploy the custom Web Part to a SharePoint Portal

You must do the following to make the CustomWebPart.dll file (custom Web Part) that is created in "Step 1: Create a custom Web Part" of this topic usable on the SharePoint portal:

- **Copy the CustomWebPart.dll file to the bin folder of the SharePoint Portal:** Microsoft Office SharePoint Server creates portals under the *<root drive>:\Inetpub\wwwroot\wss\VirtualDirectories* folder. A folder is created for each portal, and can be identified with the port number. You must copy the CustomWebPart.dll file created in "Step 1: Create a custom Web Part" of this topic to the *<root drive>:\Inetpub\wwwroot\wss\VirtualDirectories\<Port_Number>\bin* folder. For example, if the port number of your SharePoint portal is 13614, you must copy the CustomWebPart.dll file to the *<root drive>:\Inetpub\wwwroot\wss\VirtualDirectories\13614\bin* folder.

Tip

Another way to find the folder location of your SharePoint portal is by using the **Internet Information Services (IIS) Manager** window (**Start > Run > inetmgr**). Locate your SharePoint portal in the **Internet Information Services (IIS) Manager** window ([*computer_name*] > Web Sites > [*Portal-Name*]), right-click, and then click **Properties** in the shortcut menu. In the properties dialog box of the SharePoint portal, click the **Home Directory** tab, and then select the **Local path** box.

- **Add the Safe Control Entry in the web.config File:** Because the CustomWebPart.dll file will be used on different computers and by multiple users, you must declare the file as "safe." To do so, open the web.config file located in the SharePoint portal folder at <root drive>:\inetpub\wwwroot\wss\VirtualDirectories\<Port_Number>. Under the <SafeControls> section of the web.config file, add the following safe control entry:

```
<SafeControl Assembly="CustomWebPart" Namespace="CustomWebPart" TypeName="*" Safe="True" />
```

Save the web.config file, and then close it.

Step 3: Configure the SharePoint Portal to use the custom Web Part

You need to add the custom Web Part to the Microsoft Office SharePoint Server Web Part Gallery, so that you can use it on your SharePoint portal. To do so:

1. Start SharePoint 3.0 Central Administration. Click **Start**, point to **All Programs**, point to **Microsoft Office Server**, and then click **SharePoint 3.0 Central Administration**.
2. In the left navigation pane, click the name of the Shared Services Provider (SSP) to which you want to add the custom Web Part.
3. On the **Shared Services Administration** page, in the upper-right corner, click **Site Actions**, and then click **Create**.
4. On the **Site Settings** page, click **Web Parts** under the **Galleries** column.
5. On the **Web Part Gallery** page, to add the custom Web Part to the gallery, click **New**. At this point the custom Web Part is not available in the **Web Part Gallery** page.
6. On the **New Web Parts** page, locate **CustomWebPart** (name of the custom Web Part) in the list, select the check box on the left, and then click **Populate Gallery** on the top of the page. This will add the **CustomWebPart** entry in the **Web Part Gallery** page.

Now you can use the custom Web Part (**CustomWebPart**) to create Web Parts in your SharePoint portal. The custom Web Part (**CustomWebPart**) will appear under the **Miscellaneous** section in the **Add Web Parts** page.

[Using the Siebel Adapter with Microsoft Office SharePoint Server](#)

Samples

Samples for Microsoft BizTalk Adapter for Siebel eBusiness Applications are categorized into:

- BizTalk Server samples
- WCF service model samples
- Data Provider for Siebel samples
- Migration samples

The samples are available at <http://go.microsoft.com/fwlink/?LinkID=196854>.

The following list contains the names and descriptions of the samples for the Siebel adapter.

BizTalk Server Samples

Sample Directory Name	Description
BusinessService	Demonstrates how to invoke a business service in Siebel using the Siebel adapter.
MVLDemo	Demonstrates how to work with multivalued links (MVLs) in Siebel using the Siebel adapter.
SiebelAccount	Demonstrates how to insert records into the Account business component in Siebel using the Siebel adapter.
SiebelAdapterIntegration Objects	Demonstrates how to invoke a business service in Siebel, which works with Integration Objects, using the Siebel adapter.
SiebelPicklist	Demonstrates how to insert values of picklist types into a Siebel business component using the Siebel adapter.

WCF Service Model Samples

Sample Directory Name	Description
AccountInsertDelete	Demonstrates how to perform Insert, Update, Delete, and Query operations on a Siebel business component. The sample inserts a record into the Account business component of the Account business object, updates the record, and finally deletes it. Before and after each operation a Query operation is performed on the business component to verify the results.
Business Services	Demonstrates how to invoke a Siebel business service method, TimeStamp, and displays the results to the console.
MVL	Demonstrates how to work with multivalued links in a Siebel business component by using the Associate, Dissociate, and child query operations. The sample displays all contacts associated with an account. It also shows how to Associate and Dissociate a contact from an account.

Data Provider for Siebel Sample

Sample Directory Name	Description
siebel ado	Demonstrates how to use the .NET Framework Data Provider for Siebel eBusiness Applications.

Migration Sample

Sample Directory Name	Description
-----------------------	-------------

Siebel_Buss_Comp	Demonstrates how to use a BizTalk project created using the previous version of the Siebel adapter and make it work with the WCF-based Siebel adapter.
------------------	--

Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter

The previous version of the Siebel adapter that shipped with Microsoft BizTalk Server differs from Microsoft BizTalk Adapter for Siebel eBusiness Applications in many aspects, including:

- The design-time experience of creating a BizTalk project.
- The metadata retrieval experience.
- Schemas.
- Data type mappings.
- The operations that can be performed using the adapter.
- Physical port configuration in the BizTalk Server Administration console.

This section discusses the differences between the versions.

Note

The Siebel adapter is a WCF-based adapter and can be used with BizTalk Server, the WCF service model, or the WCF channel model. The earlier version of the adapter, however, can be used only with BizTalk Server.

Therefore, this section talks about version differences in terms of using the adapter with BizTalk Server. For information about how to use the adapter with the WCF service model or WCF channel model, see

[Overview of BizTalk Adapter for Siebel eBusiness Applications](#).

In This Section

- [Differences in the Design-time Experience](#)
- [Differences in Metadata Retrieval Experience](#)
- [Differences in the Schema File Name and Namespace](#)
- [Differences in Data Type Mapping](#)
- [Differences in Operations Surfaced for the Siebel Artifacts](#)
- [Differences in Physical Port Configuration in the BizTalk Server Administration Console](#)
- [Migration Tutorials and Sample](#)

Differences in the Design-time Experience

The design-time experience for using the adapters includes creating a BizTalk project in Visual Studio and then generating metadata for the operations you want to perform on the Siebel system using the adapter. This section discusses how the design-time experience differs between the two adapter versions.

Design-time Experience for the Previous Version of the Adapter

The design-time experience using the previous version of the adapter involves the following steps:

1. **Add the Siebel adapter to the BizTalk Server Administration console.** Installing the adapter does not add the adapter to the console. You must add the adapter in the BizTalk Server Administration console under BizTalk Server Administration > BizTalk Group > Platform Settings > Adapters.

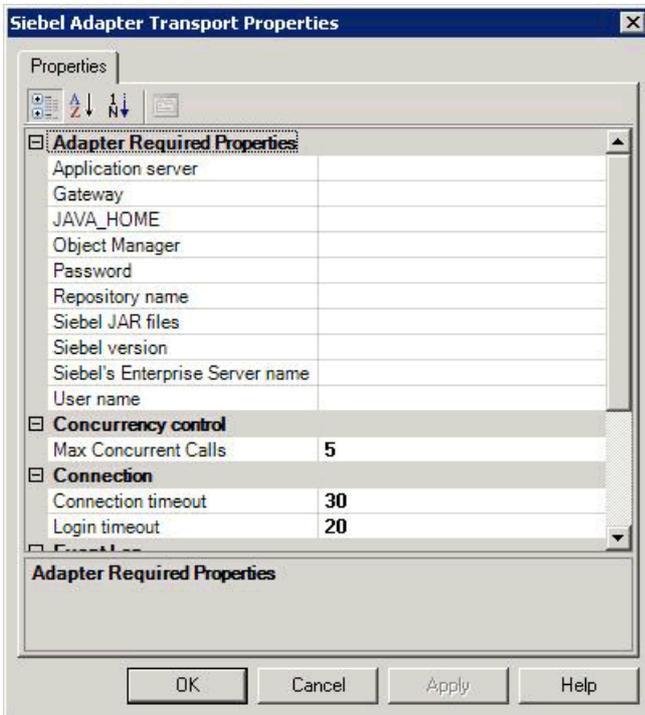

2. **Add a physical send port.** To retrieve metadata from a Siebel system, the previous version of the adapter requires you to configure a physical send port in BizTalk Server Administration console, before you create a BizTalk project.

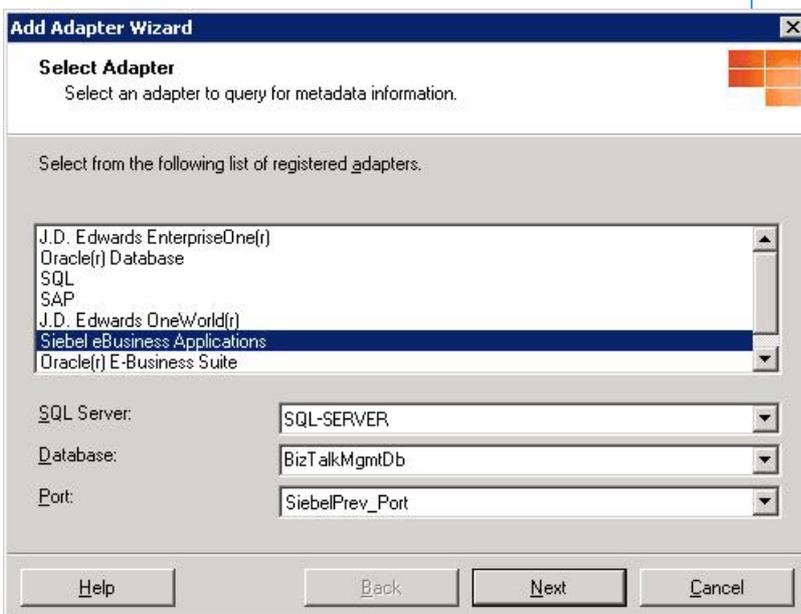

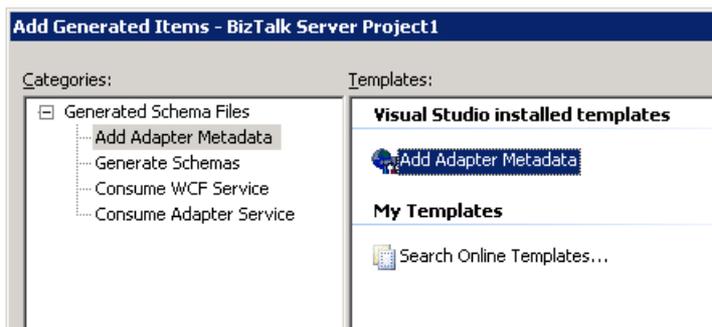

You can configure a send port under BizTalk Server Administration > BizTalk Group > BizTalk Applications > [Your Application] > Send Ports. For the send port, you must specify the connection properties to connect to the Siebel system.

The key connection properties to connect to a Siebel system using the previous version of the adapter are:

- **Without Enterprise SSO:** User name, Password, Gateway, Object Manager, repository name, Siebel Enterprise Server name, Affiliate Application (set to none).
- **With Enterprise SSO:** ESSO affiliate application configured in the SSO Administration console, all other parameters mentioned above (except user name and password).

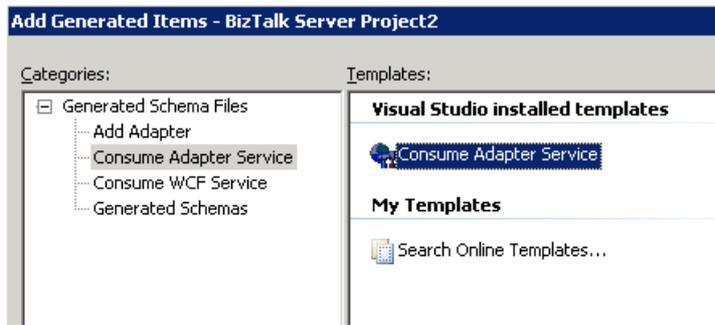

3. **Generate metadata.** Create a BizTalk project in Visual Studio. Right-click the BizTalk project and select Add > Add Generated Items > Add Adapter Metadata.

Design-time Experience for the New WCF-based Adapter

The design-time experience using the WCF-based Siebel adapter involves the following steps:

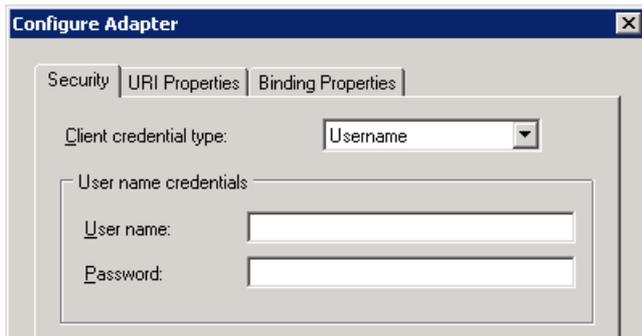

1. **Create a BizTalk project.** Create a BizTalk project in Visual Studio. Right-click the BizTalk project and select Add > Add Generated Items > Consume Adapter Service.

Note

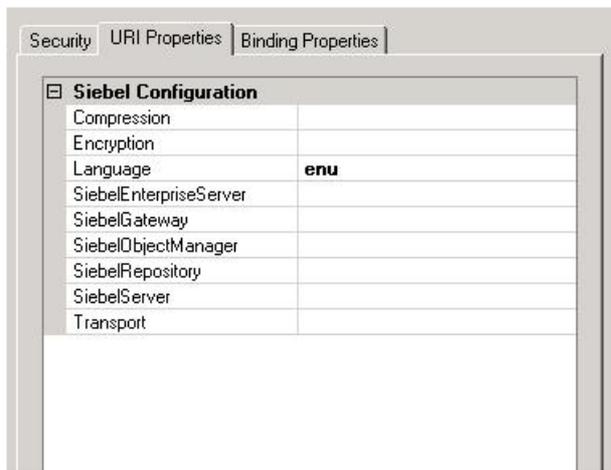

Note that WCF-based Siebel adapter does not require you to configure a physical BizTalk port for the design-time experience.

2. **Connect to the Siebel system.** In the Consume Adapter Service BizTalk Project Add-in, select the binding for Siebel (siebelBinding) and click **Configure** to start the Configure Adapter dialog box. You must specify the different connection properties in this dialog box to connect to the Siebel system.

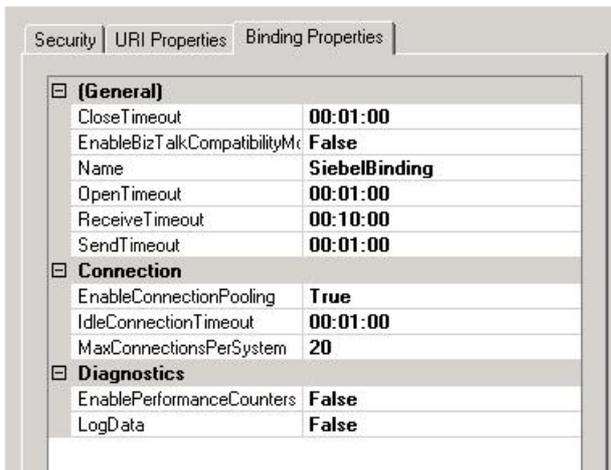

The key connection properties to connect to a Siebel system using the WCF-based Siebel adapter are:

- **Siebel Object Manager.** The name of the Siebel Object Manager on the enterprise server.
- **Siebel Enterprise Server.** The name of the Siebel Enterprise Server.
- **Siebel server.** The Siebel server. Required for all Siebel 7.5 server connections (7.5.2, 7.5.3, etc.); otherwise, do not set this parameter.
- **User name.** The user name on the Siebel system; this value is case-sensitive.
- **Password.** The password for the user on the Siebel system; this value is case-sensitive.
- **Language.** The language of the object manager.

For more information about the connection properties, see [The Siebel System Connection URI](#).

3. **Specify binding properties.** The WCF-based Siebel adapter is essentially a custom WCF binding that includes different binding properties. These binding properties govern the behavior of the adapter. These properties can be set both at design time (when generating the metadata) and at run time (when sending messages to the Siebel system).

For more information about the binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).

Key Differences in Design-time Experience

The following table lists the key differences in the design-time experience for the two versions of the adapter.

Previous version of the Siebel adapter	WCF-based Siebel adapter
Add the adapter to the BizTalk Server Administration console under Platform Settings > Adapters .	The WCF-based Siebel adapter is a WCF custom binding and is configured as specific binding type of the WCF-Custom adapter. The BizTalk Server Administration console already contains the WCF-Custom adapter under Platform Settings > Adapters .
Create a physical send port to connect to the Siebel system at design time.	There is no need to configure a send port.
Use the Add Adapter Metadata option to connect to the Siebel system and retrieve metadata.	Use the Consume Adapter Service option to connect to the Siebel system and retrieve metadata.
There is no option to configure the adapter behavior during design time (using binding properties) to control metadata generation.	Set binding properties to configure the adapter behavior during design time to control metadata generation.

[Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#)

Differences in Metadata Retrieval Experience

Once you have connected to the Siebel system from the BizTalk project in Visual Studio, you can generate metadata to perform operations on Siebel business components or invoke Siebel business service methods. The steps involved in generating the metadata in the previous version of the Siebel adapter differ from those in the WCF-based Microsoft BizTalk Adapter for Siebel eBusiness Applications. This section discusses the differences.

Metadata Retrieval Experience for the Previous Version of the Adapter

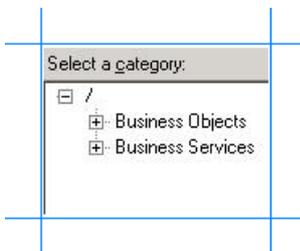

- Metadata categories.** The previous version of the adapter surfaces two categories: **Business Objects** and **Business Services**. All the business objects and their constituent business components are surfaced under **Business Objects** node. Similarly, all the business services are surfaced under the **Business Services** node. However, no operations (Insert, Query, Delete) are surfaced for the business components. Similarly, the Business Services node does not surface the different business service methods for a particular business service.

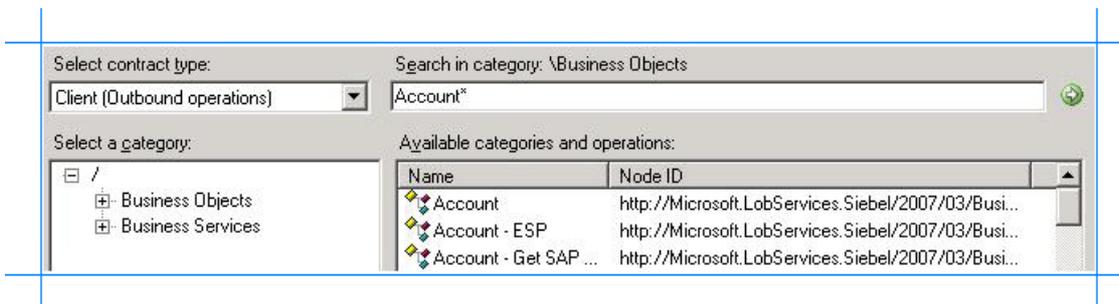

- Searching for Siebel artifacts.** The previous version of the adapter does not support searching for Siebel artifacts. You need to browse through the entire tree exposed by the adapter to find the artifact you are looking for.

Metadata Retrieval Experience for the WCF-based Adapter

- Contract type.** The WCF-based Siebel adapter only supports the contract type **Client (Outbound Operations)**. So, adapter clients can only perform outbound operations on the Siebel system. That is, adapter clients can invoke operations in the Siebel system. From a BizTalk user perspective, the contract type basically indicates the direction of message flow between BizTalk Server and the adapter. The Siebel adapter does not support inbound operations via a BizTalk Receive port.
- Metadata Categories.** The WCF-based Siebel adapter surfaces two categories: **Business Objects** and **Business Services**. All the business objects and their constituent business components are surfaced under **Business Objects** node. All operations supported on the business components are also surfaced. All the business services are surfaced under the Business Services node. The methods for a particular business service are also surfaced as operations.

- Searching for Siebel artifacts.** With the WCF-based Siebel adapter you can specify a search expression after selecting a relevant category node. For example, to search for a business object, click the Business Objects node and specify a search expression (with the same syntax as the Siebel query search expression). Note that the search expressions are case-sensitive. For more information about searching Siebel metadata using the WCF-based Siebel adapter, see [How Does the Adapter Surface Siebel Metadata?](#)

- BizTalk port binding file.** Generating schema for the WCF-based Siebel adapter using the Consume Adapter Service BizTalk Project Add-in also creates a BizTalk port binding file. You can import this file into a BizTalk application to configure a WCF-Custom port. The file essentially contains the physical port configuration including the binding configuration, the binding type, the endpoint URI, and the port action based on the operations for which metadata was generated. This makes it significantly easier to create physical WCF-Custom ports for the project. For more information, see [Configuring a Physical Port Binding Using a Port Binding File](#).

Key Differences in Metadata Retrieval Experience

The following table lists the key differences in the metadata retrieval experience for the two versions of the adapter.

Previous version of the Siebel adapter	WCF-based Siebel adapter
No operations are surfaced under the Business Objects and Business Services node.	The Business Objects node surfaces the business objects, business components, and the operations (Insert, Query, Delete) that can be performed on the business components. Business Services node surfaces the business nodes along with the business service methods.
Search is not supported.	Search is supported for Siebel artifacts using search expression with the same syntax as the Siebel query search expression.
No differentiation between inbound and outbound operations	Outbound operations are surfaced under the Client (Outbound Operations) category. Inbound operations are not supported

[Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#)

Differences in the Schema File Name and Namespace

The previous version of the adapter generates metadata for Siebel artifacts differently than the current version. This section discusses these differences including:

- File naming convention.
- Target namespace.

Schema File Name and Namespace for the Previous Version of the Adapter

- **File naming convention.** The previous version of the adapter generates schema files with names containing the name of the Siebel artifact. For example, generating the metadata for the Account business component creates a file with the name AccountService_Account_x5d.xsd.
- **Target namespace of the schema.** The following table lists the target namespace of the schemas generated by the previous version of the adapter.

Siebel artifact	Target namespace
Business Component	http://schemas.microsoft.com/[Siebel://Business Objects/{Business_Object}/{Business_Component}]
Business Service	http://schemas.microsoft.com/[Siebel://Business Services/{Business_Service}]

In the preceding table, the text in parentheses { } are placeholders to present the convention for the namespace. The actual namespace contains the appropriate values.

Schema File Name and Namespace for the WCF-based Adapter

- **File naming convention.** By default, the WCF-based Siebel adapter generates schema files with names containing the name of the binding, for example, SiebelBindingSchema1.xsd. However, the Consume Adapter Service BizTalk Project Add-in provides the option of specifying a custom file name while generating the schema. For more information about how to retrieve the schema, see [Retrieving Metadata for Siebel Operations in Visual Studio](#).
- **Target namespace of the schema.** The following table lists the target namespace of the schemas generated by the WCF-based Siebel adapter.

Siebel artifact	Target namespace
Business Component	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/{Business_Object}/{Business_Component}/Operation
Business Service	http://Microsoft.LobServices.Siebel/2007/03/BusinessServices/{Business_Service}

In the preceding table, the text in parentheses { } are placeholders to present the convention for the namespace. The actual namespace contains the appropriate values.

[Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#)

Differences in Data Type Mapping

The two versions of the adapter differ in how the Siebel data type maps to the XSD date type. This section lists the data type mapping for Siebel artifacts in both versions of the adapter.

Data Type Mapping for Siebel Artifacts

The following table lists the mapping between the Siebel data types and XSD data types for Siebel artifacts for both the adapter versions. For more information about data type mapping for WCF-based Siebel adapter, see [Basic Siebel Data Types](#).

Siebel data type	XSD mapping for previous version of the adapter	XSD mapping for WCF-based adapter (for Beta 2 release)	XSD mapping for WCF-based adapter (for Nov CTP release)
DTYPE_BOOL	xsd:boolean	xsd:boolean	xsd:boolean
DTYPE_CURRENCY	xsd:string with pattern	xsd:decimal	xsd:decimal
DTYPE_DATE	xsd:date	xsd:dateTime	xsd:dateTime with pattern or xsd:string
DTYPE_DATE TIME	xsd:dateTime	xsd:dateTime or xsd:string	xsd:dateTime or xsd:string
DTYPE_ID	xsd:string	xsd:string	xsd:string
DTYPE_INTEGER	xsd:int	xsd:int	xsd:int
DTYPE_NOTE	xsd:string	xsd:string	xsd:string
DTYPE_NUMBER	xsd:int	xsd:decimal	xsd:decimal
DTYPE_PHONE	xsd:string	xsd:string	xsd:string
DTYPE_TEXT	xsd:string	xsd:string	xsd:string
DTYPE_TIME*	xsd:time	xsd:string	xsd:dateTime with pattern or xsd:string
DTYPE_UTCDATETIME	xsd:dateTime	xsd:dateTime	xsd:dateTime or xsd:string

* The supported date pattern for the November CTP release was `(0001-01-01)T(\d\d:\d\d:\d\d)(.*)`. For the Release Candidate (RC) and RTM release, the supported date pattern is changed to `(1753-01-01)T(\d\d:\d\d:\d\d)(.*)`. All other data type mappings remain unchanged.

[Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#)

Differences in Operations Surfaced for the Siebel Artifacts

The two versions of the adapter differ in the operations they expose for the Siebel artifacts. This section lists the differences in:

- Operations on business components.
- Operations on business services.

For more information about the operations supported by the WCF-based Siebel adapter, see [What Operations Can be Performed Using the Adapter?](#)

Operations on Business Components

The following table lists the operations surfaced for business components by both versions of the adapter.

Operation for previous version of the adapter	Description	Operation for WCF-based adapter	Description
Insert	Inserts one or more records into the business component.	Insert	Inserts one or more records into the business component.
InsertEx	Inserts one or more records into the business component with ViewMode support and business component preloading.		
Query	Queries records from a business component based on search and sort specifications.	Query	Queries records from a business component based on search and sort specifications, query fields, and ViewMode.
QueryWithViewMode	Queries records from a business component based on search and sort specifications with support for ViewMode.		
QueryEx	Same as QueryWithViewMode and includes business component preloading.		
QueryEx2	Same as QueryEx.		
Update	Updates one or more records in the business component.	Update	Updates one or more records in the business component with support for ViewMode.
UpdateEx	Updates one or more records in the business component with ViewMode support and business component preloading.		
Delete	Delete one or more records in the business component	Delete	Delete one or more records in the business component based on record ID or search expression and with support for ViewMode
DeleteEx	Delete one or more records in the business component with ViewMode support and business component preloading		

Operations on Business Services

- The previous version of the adapter does not surface any operations for the business service.

- The WCF-based Siebel adapter surfaces business service methods as operations that adapter clients can invoke.

[Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#)

Differences in Physical Port Configuration in the BizTalk Server Administration Console

To use the previous version of the Siebel adapter or the WCF-based Siebel adapter with BizTalk Server, you need to configure physical ports in the BizTalk Server Administration console. This section lists the differences in configuring a physical port for both versions of the adapter.

Configuring a Physical Port for the Previous Version of the Siebel Adapter

You can configure a send port to send messages to the Siebel using the previous version of the adapter. You must provide values for the configuration properties available for the send port.

Note

You cannot configure a receive port for the previous version of the Siebel adapter.

Configuring a Physical Port for the WCF-based Siebel Adapter

For the WCF-based Siebel adapter, you do not necessarily have to create a port manually. You have the option of configuring a physical port automatically by importing a port binding file that is generated while you generate metadata for any operation using the Consume Adapter Service BizTalk Project Add-in. The file essentially contains the physical port configuration including the binding configuration, the binding type, the endpoint URI, and the port action based on the operations for which metadata was generated. For more information, see [Configuring a Physical Port Binding Using a Port Binding File](#).

Several other considerations that make a physical port configuration for WCF-based Siebel adapter different from the previous version of the Siebel adapter are:

- The port type for WCF-based Siebel adapter is "WCF-Custom." So, with respect to BizTalk Server, this port uses custom WCF configurations and, primarily, a custom WCF binding. Because the WCF-based Siebel adapter is essentially a custom WCF binding, it can be used in BizTalk Server via the WCF-Custom port.
- A BizTalk WCF-Custom send port requires an "Action" to be specified in the port. This is the WCF action that is sent on the message by BizTalk before it gets to the binding. The WCF action conveys to the adapter:
 - The operation the adapter client wants to perform.
 - The Siebel artifact on which the user wants to perform the operation.

Adapter clients can specify this action in various ways. For more information on specifying an action, see [Specifying SOAP Action](#).

- BizTalk WCF-Custom send ports include binding information that, in turn, includes a binding type and binding properties for that binding type. This is a key configuration that ties the WCF-Custom port to a WCF-based Siebel adapter. For the WCF-based Siebel adapter, binding type is **siebelBinding**.
- The binding configuration properties that govern how an adapter behaves while generating metadata or while sending messages to the Siebel system. The adapter users must be aware of which binding property to set for a specific operation performed by the adapter. For more information about the binding properties, see [Working with BizTalk Adapter for Siebel Binding Properties](#).
- The configurations under the **Messages** tab in the **WCF-Custom Transport Properties** dialog box enable adapter users to alter the message that is sent or received using the WCF-Custom port. While sending messages (from BizTalk to the adapter), users can choose to send the message body or use a template to transform the XML message to a different message structure before sending it to the adapter (the WCF custom binding). While receiving messages (from the adapter to BizTalk), users can choose to get the entire SOAP envelope, the body contents of the SOAP message, or a specific node value in the incoming message referenced by an XPath query expression.

[Migrating BizTalk Projects Created Using the Previous Version of the Siebel Adapter](#)

Troubleshooting

The BizTalk Adapter Pack uses or depends on several different Microsoft technologies including but not limited to Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK, Microsoft Visual Studio, and the Microsoft .NET Framework 3.5 SP1/.NET Framework 4. The BizTalk Adapter Pack is built on top of the WCF LOB Adapter SDK, which in turn requires .NET Framework 3.5 SP1 and .NET Framework 4. The adapters can be consumed either by writing applications using Visual Studio or by creating BizTalk applications. For issues related to each of these technologies and products, refer to the respective documentation.

This section provides information about troubleshooting the BizTalk Adapter Pack, including:

- Enabling tracing to diagnose issues with the adapters.
- Handling installation and operational issues that you might encounter when working with the adapters, including probable cause, and a resolution.
- Using performance counters to gauge adapter performance.
- Handling exceptions and errors, including probable cause, and a resolution.

In This Section

- [Diagnostic Tracing and Message Logging](#)
- [Troubleshooting Installation Issues](#)
- [Troubleshooting Operational Issues](#)
- [Troubleshooting Performance Issues](#)
- [Troubleshooting Issues with the Data Provider for Siebel](#)
- [Using Performance Counters](#)
- [Exceptions and Error Handling](#)

Diagnostic Tracing and Message Logging

Adapter clients can enable diagnostic tracing to effectively diagnose problems encountered while using the adapters. Adapter clients can activate tracing at three different levels:

- Between the adapter client and the adapter
- Within the adapter
- Between the adapter and the line-of-business (LOB) application

This section provides information about activating tracing at these levels.

Tracing Between the Adapter Client and the Adapter

Adapter clients can enable WCF tracing to trace issues between the adapter client and the adapter. WCF tracing is used to trace the input XMLs coming from the adapter client using the WCF service model and is useful in diagnosing serialization issues. WCF tracing is not used for the WCF channel model or for output messages from the adapter to the adapter client. You can activate WCF tracing for BizTalk applications and WCF service model applications by adding an excerpt to the respective configuration files. Also, you can enable tracing both at design-time and run-time.

- **Tracing at design-time.** For the design-time experience, you may use the Add Adapter Service Reference Plug-in, Consume Adapter Service Add-in, or the Add Adapter Metadata Wizard. All these tools can be used from Visual Studio. So, to enable tracing for the design-time experience, you must add the excerpt to the devenv.exe.config file located in `<installation drive>\Program Files\Microsoft Visual Studio <version>\Common7\IDE`.
- **Tracing at run-time.** For run-time tracing, you must add the excerpt depending on the application you are using.
 - For a BizTalk Server applications, you must add the excerpt to the BizTalk configuration file, typically `BTSNTSvc.exe.config`. For BizTalk Server 2010, this file is available typically under `<installation drive>\Program Files\Microsoft BizTalk Server 2010`.
 - For a WCF service model .NET application, you must add the excerpt to the `app.config` file of your project.

To enable WCF tracing, you must add the following excerpt within the `<configuration>` tag.

```
<system.diagnostics>
  <sources>
    <source name="System.ServiceModel" switchValue="Verbose">
      <listeners>
        <add name="xml" />
      </listeners>
    </source>
    <source name="System.ServiceModel.MessageLogging"
      switchValue="Verbose, ActivityTracing">
      <listeners>
        <add name="xml" />
      </listeners>
    </source>
    <source name="System.Runtime.Serialization" switchValue="Verbose">
      <listeners>
        <add name="xml" />
      </listeners>
    </source>
  </sources>
  <sharedListeners>
    <add name="xml" type="System.Diagnostics.XmlWriterTraceListener"
      traceOutputOptions="LogicalOperationStack"
      initializeData="C:\log\WCFTrace.svclog" />
  </sharedListeners>
```

```

<trace autoflush="true" />
</system.diagnostics>
<system.serviceModel>
  <diagnostics>
    <messageLogging
      logEntireMessage="true"
      logMalformedMessages="false"
      logMessagesAtServiceLevel="true"
      logMessagesAtTransportLevel="false"/>
    </diagnostics>
  </system.serviceModel>

```

This saves the WCF traces to C:\log\WCFTrace.svclog. For more information about WCF tracing, see <http://go.microsoft.com/fwlink/?LinkId=91242>.

◆ Important

Make sure you mitigate potential security threats of exposing sensitive business data by enabling tracing. For recommendations see [Best Practices](#).

Tracing Within the Adapter

The adapters in the BizTalk Adapter Pack log different categories of useful information to the trace file such as errors, warnings, and information. Such information is useful in understanding the process flow within the adapter and diagnosing issues with the adapter. You can activate WCF LOB Adapter SDK and adapter tracing for BizTalk applications and WCF service model applications by adding an excerpt to the respective configuration files. Also, you can enable tracing both at design-time and run-time.

- **Tracing at design-time.** For the design-time experience, you may use the Add Adapter Service Reference Plug-in, Consume Adapter Service Add-in, or the Add Adapter Metadata Wizard. All these tools can be used from Visual Studio. So, to enable tracing for the design-time experience, you must add the excerpt to the devenv.exe.config file located in *<installation drive>*:\Program Files\Microsoft Visual Studio *<version>*\Common7\IDE.
- **Tracing at run-time.** For run-time tracing, you must add the excerpt depending on the application you are using.
 - For a BizTalk Server applications, you must add the excerpt to the BizTalk configuration file, typically BTSNTSvc.exe.config. For BizTalk Server 2010, this file is available typically under *<installation drive>*:\Program Files\Microsoft BizTalk Server 2010.
 - For a WCF service model .NET application, you must add the excerpt to the app.config file of your project.

To enable WCF LOB Adapter SDK and adapter tracing, you must add the following excerpt within the `<configuration>` tag:

```

<system.diagnostics>
  <sources>
    <source name="Microsoft.ServiceModel.Channels" switchValue="Error">
      <listeners>
        <add name="xml" />
      </listeners>
    </source>
    <source name="Microsoft.Adapters.Siebel" switchValue="Information">
      <listeners>
        <add name="xml" />
      </listeners>
    </source>
  </sources>
  <sharedListeners>
    <add name="xml" type="System.Diagnostics.XmlWriterTraceListener"
      traceOutputOptions="LogicalOperationStack"
      initializeData="C:\log\AdapterTrace.svclog" />
  </sharedListeners>
  <trace autoflush="true" />
</system.diagnostics>

```

This would save the WCF traces to C:\log\AdapterTrace.svclog.

Tracing Between the Adapter and the LOB Application

You must enable tracing for communication between the adapter and the LOB application to diagnose issues you suspect within the LOB application. Adapters also depend on LOB tracing (client/server side) to get access to this information. The specifics of turning on LOB tracing are excluded from this document.

Additionally, the Siebel adapter provides a binding property (**LogData**), which if set to **True** and if the trace level is set to **Verbose**, the Siebel adapter logs the information flow between the adapter and the Siebel system. This information is logged along with the adapter traces in the same trace file.

For more information about this binding property, see [Working with BizTalk Adapter for Siebel Binding Properties](#).

Viewing the Traces

You can use the Windows Communication Foundation (WCF) Service Trace Viewer tool to view the traces. For more information about the tool, see <http://go.microsoft.com/fwlink/?LinkId=91243>.

Configuring Tracking for BizTalk Applications

The BizTalk Administration Console enables you to configure various tracking options for things such as send ports, receive ports. The tracking configuration settings enable you to track inbound/outbound event data, message properties, message bodies, and orchestrations. For more information about configuring tracking for BizTalk applications, see "Configuring Tracking Using the BizTalk Server Administration Console" at <http://go.microsoft.com/fwlink/?LinkId=106851>.

You can also use Health and Activity Tracking (HAT) to view historical tracked data. For more information, see "Viewing Historical or Tracked Data Using HAT" at <http://go.microsoft.com/fwlink/?LinkId=106852>.

[Troubleshooting](#)

Troubleshooting Installation Issues

This topic was last updated on: June 05, 2009

The Microsoft BizTalk Adapter Pack installation copies the product binaries on the computer and registers the bindings for each adapter. This section discusses troubleshooting techniques to resolve installation errors.

Setup Logging

The BizTalk Adapter Pack setup program performs the standard task of installing the BizTalk Adapter Pack. Additionally, the setup also performs certain custom actions such as registering the adapter bindings. You can log messages for both the standard as well as custom actions performed by the setup.

- The BizTalk Adapter Pack setup installs the adapter specific files using an MSI. Hence, the logging for the setup will be the standard MSI logging.
- Logs for the custom actions performed by the setup program are available at %TEMP%\adaptersetup.log. If the tracing to the log file fails, the traces are also available in the event log.

Known Issues

Following are the most common errors you may encounter while installing the BizTalk Adapter Pack, their probable cause, and resolution.

- [Setup fails to register adapter bindings](#)

Setup fails to register adapter bindings

Problem

The Microsoft BizTalk Adapter Pack setup wizard fails to register the Siebel adapter binding or the Data Provider for Siebel, but proceeds with the adapter installation.

Cause

This might result due to problems with WCF installation, Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK installation, or the machine.config being corrupt. The adapter bindings are written to the machine.config file.

Resolution

You should manually register the Siebel adapter binding and Data Provider for Siebel.

To register the adapter binding or the data provider

1. Navigate to the machine.config file on the computer. For example, on a 32-bit platform, the machine.config is available under <system drive>:\WINDOWS\Microsoft.NET\Framework\<version>\CONFIG.

In this path, <version> is the version of the .NET Framework. For example, for Microsoft .NET Framework 3.5 SP1, the version will be v2.0.50727.

2. Open the file using a text editor.
3. To register the Siebel adapter binding:
 - a. Search for the element "system.serviceModel" and add the following under it:

```
<client>
  <endpoint binding="siebelBinding" contract="IMetadataExchange" name="siebel" />
</client>
```

- b. Search for the element "bindingElementExtensions" under system.serviceModel\extensions.

- c. Look for the missing Siebel adapter binding. Add the following section under the "bindingElementExtensions" node.

For Siebel adapter, add:

```
<add name="siebelAdapter" type="Microsoft.Adapters.Siebel.SiebelAdapterExtensionElement,Microsoft.Adapters.Siebel, Version=<version>, Culture=neutral, PublicKeyToken=<public key>" />
```

- d. Search for the element "bindingExtensions" under system.serviceModel\extensions.

- e. Look for the missing Siebel adapter binding. Add the following sections under the "bindingExtensions" node.

For Siebel adapter, add:

```
<add name="siebelBinding" type="Microsoft.Adapters.Siebel.SiebelAdapterBindingSection,Microsoft.Adapters.Siebel, Version=<version>, Culture=neutral, PublicKeyToken=<public key>" />
```

Note

For information about how to determine the public key, see [Determining the Public Key and Version](#).

- 4. To register the Data Provider for Siebel:

- a. Search for the element DbProviderFactories under the system.data node.
- b. Look for the missing Data Provider for Siebel. Add the following section under the DbProviderFactories node.

For Data Provider for Siebel, add:

```
<add name="SiebelClient Data Provider" invariant="Microsoft.Data.SiebelClient" description=".NET Framework Data Provider for Siebel eBusiness Applications" type="Microsoft.Data.SiebelClient.SiebelProviderFactory,Microsoft.Data.SiebelClient, Version=<version>, Culture=neutral, PublicKeyToken=<public key>" />
```

- 5. Save and close the machine.config file.

Determining the Public Key and Version

Perform the following steps to determine the public key for Siebel adapter or Data Provider for Siebel.

To determine the public key

1. Navigate to the Windows directory, typically C:\WINDOWS\assembly.
2. Right-click the DLL for which you want the public key and select **Properties**. The following table lists the name of the DLLs for each adapter and provider.

Adapter/ADO Provider	Name of the DLL
Siebel adapter	Microsoft.Adapters.Siebel
Data Provider for Siebel	Microsoft.Data.SiebelClient

3. On the **General** tab, the value against the **Public Key Token** label specifies the public key for the DLL. Similarly, value against the **Version** label specifies the version number for the DLL.
4. Copy the public key, and then click **Cancel**.

Troubleshooting Operational Issues

This topic was last updated on: June 05, 2009

This section provides a centralized location for information about operational issues you might encounter when using the Microsoft BizTalk Adapter for Siebel eBusiness Applications.

Enabling Tracing

For information about tracing support in the Siebel adapter, see [Diagnostic Tracing and Message Logging](#).

Known Issues

The following are some issues and recommended solutions that you might encounter while using the Siebel adapter.

- [Error in loading the adapter bindings](#)
- [The Siebel adapter does not display in the list of adapters in BizTalk Server Administration console](#)
- [Error while connecting to the Siebel system](#)
- [Error while retrieving XMLs with more than 65536 nodes](#)
- [Error while specifying a connection URI for a WCF-Custom port in BizTalk](#)
- [Error while performing operation on the Siebel system](#)
- [XmlReaderParsingException due to an incorrect operation name in the specified action](#)
- [Application using the Siebel adapter does not terminate](#)
- [Siebel adapter may hang if the Siebel server is restarted](#)
- [The adapter does not recognize the action on the physical port even though you use the binding file generated by the Consume Adapter Service add-in to create the ports](#)
- [Siebel adapter does not handle Siebel objects with XML encoded strings in the name](#)
- [Error with RootNode TypeName in BizTalk Projects](#)
- [Invalid binding warning when using the adapter in Visual Studio 2010](#)

Error in loading the adapter bindings

Problem

When you try to start the Add Adapter Service Reference Visual Studio Plug-in or the Consume Adapter Service BizTalk Project Add-in, the GUI gives the following error:

```
There was an error loading the binding, <binding name>, from your system configuration.ConfigurationErrorsException: Exception has been thrown by the target of an invocation.
```

Cause

When you start the Add Adapter Service Reference Plug-in or the Consume Adapter Service Add-in, WCF loads the adapter bindings for all the installed adapters. In turn, the adapter bindings are dependent on the specific enterprise application client software. So, you could face this issue for one or both of the following reasons:

- The required LOB client software is not installed on the computer where you installed the adapter.
- You did a "Typical" or "Complete" installation of the adapter, which installs all the adapters in the BizTalk Adapter Pack. However, the client libraries might be installed for only one enterprise application. As a result, the GUI fails to load the bindings for the other adapters.

Resolution

- Make sure the required client versions are installed on the computer where you installed the BizTalk Adapter Pack.
- Make sure you do a custom installation of the adapters to install only the adapter you need.

The Siebel adapter does not display in the list of adapters in BizTalk Server Administration console

Problem

Unlike the earlier version of the adapters that shipped with BizTalk Server, the Siebel adapter that shipped with BizTalk Adapter Pack does not show up in the list of adapters in the BizTalk Server Administration console.

Cause

The latest Siebel adapter is a WCF custom binding. So, although the BizTalk Server Administration console displays the WCF-Custom adapter, it does not display the WCF custom bindings and hence, does not display the WCF-based Siebel adapter.

Resolution

You can explicitly add the Siebel adapter to the BizTalk Server Administration console by following the steps mentioned in [Adding the Siebel Adapter to BizTalk Server Administration Console](#).

Error while connecting to the Siebel system

Problem

The Add Adapter Service Reference Plug-in or the Consume Adapter Service Add-in gives the following error when you try to connect to the Siebel system:

```
Connecting to the system LOB has failed. Retrieving the COM class factory for component with CLSID {ID} failed due to the following error: 80040154
```

Cause

The Siebel Web client might not be installed on the computer.

Resolution

Make sure the supported version of the Siebel Web client is installed on the computer. Refer to the installation guide for supported client and server versions for Siebel. The installation guide is available at <system drive>\Program Files\Microsoft BizTalk Adapter Pack\Documents.

Error while retrieving XMLs with more than 65536 nodes

Problem

The adapter gives the following error while retrieving XML output that has more than 65536 nodes.

```
Maximum number of items that can be serialized or deserialized in an object graph is '65536'.Change the object graph or increase the MaxItemsInObjectGraph quota.
```

Cause

The adapter cannot serialize and deserialize an object with more than 65536 items.

Resolution

You can fix this issue by setting the `maxItemsInObjectGraph` parameter. You can set this in any of the following two ways:

- Set this parameter by changing the `maxItemsInObjectGraph` parameter in the `ServiceBehavior` attribute on your service class.
- Add the following to your application's `app.config` file.

```
<behaviors>
  <endpointBehaviors>
    <behavior name="NewBehavior">
      <dataContractSerializer maxItemsInObjectGraph="65536000" />
    </behavior>
  </endpointBehaviors>
</behaviors>
```

A sample `app.config` will look like:

```
<?xml version="1.0" encoding="utf-8"?>
<configuration>
  <system.serviceModel>
    <behaviors>
      <endpointBehaviors>
        <behavior name="NewBehavior">
          <dataContractSerializer maxItemsInObjectGraph="65536000" />
        </behavior>
      </endpointBehaviors>
    </behaviors>
    <client>
      <endpoint behaviorConfiguration="NewBehavior" binding="siebelBinding"
        contract="IOutboundContract" name="siebel_ICalculator" />
    </client>
  </system.serviceModel>
</configuration>
```

Error while specifying a connection URI for a WCF-Custom port in BizTalk

Problem

BizTalk Server gives the following error when you specify a connection URI to connect to the Siebel system.

```
Error saving properties.
(System.ArgumentException) The specified address is invalid.
(System.ArgumentException) Invalid address;
"<connection URI>" is not a well-formed absolute uri.
```

Cause

The connection URI does not adhere to the standard encoding format. For example, the value for a parameter might contain a space.

Resolution

Make sure the connection URI you specify adheres to the standard encoding format. For example, a blank space must be replaced by "%20".

Error while performing operation on the Siebel system

Problem

The adapter gives the following error when performing any operation on the Siebel system using BizTalk Server.

- For BizTalk Server 2010

```
System.ArgumentNullException: Value cannot be null.
```

Cause

The WCF action for the message is not specified. WCF requires a SOAP action to be specified for every operation, which informs the adapter about the operation to be performed on the LOB application.

Resolution

Specify the SOAP action in the send port or as a message context property in a BizTalk orchestration. For instructions, see [Specifying SOAP Action](#). See [Technical Reference](#) to see a list of actions for each operation.

XmlReaderParsingException due to an incorrect operation name in the specified action

Problem

The BizTalk Server Administration console gives the following error when sending messages to a Siebel system:

```
Microsoft.ServiceModel.Channels.Common.XmlReaderParsingException: Invalid argument:
<BtsActionMapping xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <Operation Name="operation_name" Action="<action>" />
</BtsActionMapping>
```

Cause

If you configure a WCF-Custom port by importing the port binding file created by the Consume Adapter Service BizTalk Project Add-in, the action in the port is specified in the following format:

```
<BtsActionMapping>
  <Operation Name="Op1" Action="http://MyService/Svc/Op1" />
</BtsActionMapping>
```

In the preceding format, the operation name is governed by the operation you chose while generating the schema. For example, if you generated schema for a Query operation on a Siebel business component, the operation name in the action will be "Query". However, the operation name in the logical port created in the BizTalk orchestration in Visual Studio might be different.

Resolution

Make sure the operation names in both the logical port (in the BizTalk orchestration in Visual Studio) and the physical port (in BizTalk Server Administration console) are the same.

Application using the Siebel adapter does not terminate

Problem

An application that uses the Siebel adapter with Siebel client version 7.5 does not terminate.

Cause

This is because of a Siebel client issue where the process does not terminate when logging off from a Siebel server.

Resolution

Make sure you have the patch 7.5.3.17 installed for the Siebel server, along with the quick fix QF0H05.

Siebel adapter may hang if the Siebel server is restarted

Problem

If the Siebel server is restarted while the Siebel adapter is sending a message to the Siebel server using, the Siebel adapter may hang.

Resolution

Restart the BizTalk application host instance. To do so from the BizTalk Server Administration console, in the console tree expand **BizTalk Group**, expand **Platform Settings**, and then click **Host Instances**. From the right pane, right-click the host name, and then select **Restart**.

The adapter does not recognize the action on the physical port even though you use the binding file generated by the Consume Adapter Service add-in to create the ports

Problem

After you use the Consume Adapter Service Add-in to generate schema for a specific operation on the Siebel system, the add-in also creates a port binding file. You can import this binding file using the BizTalk Server Administration console to create physical ports in BizTalk Server. However, when you send messages to the Siebel system using such ports, the adapter fails to understand the action specified on the port and gives an error similar to the following:

```
Microsoft.ServiceModel.Channels.Common.UnsupportedOperationException: Incorrect Action
<BtsActionMapping xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <Operation Name="op_name" Action="<action>" />
</BtsActionMapping>. Correct the specified Action, or refer to the documentation on the allowed formats for the Actions.
```

Cause

When you create logical ports in a BizTalk orchestration, you specify certain names for the operations on those ports or you just use the default names like Operation_1, Operation_2, etc. However, in the binding file generated by the Consume Adapter Service Add-in, the operation name is same as the name of the operation for which you generate metadata. For example, if you generate metadata for Insert operation on the Account business component, the action will be set to the following:

```
<Operation Name="Insert" Action="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert" />
```

When you import the binding file, the same action is set on physical port. So, the operation names on the logical port (Operation_1, Operation_2, etc) do not match the operation names specified in the action on the physical port, resulting in an error.

Resolution

Make sure the operation name in the logical port is the same as the operation name specified as part of the action in the physical port. Do one of the following:

- Change the operation name in the logical port in BizTalk orchestration from Operation_1, etc. to the operation for which you generate metadata, for example Insert.
- Change the operation name in the action on the physical port to the operation name in the logical port. For example, you could change the action in the physical port to resemble the following:

```
<Operation Name="Operation_1" Action="http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert" />
```

Siebel adapter does not handle Siebel objects with XML encoded strings in the name

Problem

The Siebel adapter cannot perform operations involving Siebel objects (business objects, business components, business services, picklist, methods, fields, arguments, etc) that have XML encoded strings in their name. For example, the Siebel adapter will not be able to invoke a business service method with the name Time_x0020_Stamp.

Resolution

Make sure the Siebel objects do not contain XML encoded strings in their name.

Error with RootNode TypeName in BizTalk Projects

Problem

In a BizTalk project in Visual Studio, if the schemas generated from the Consume Adapter Service Add-in contains invalid characters or reserved words for the **RootNode TypeName** property, the following error will occur while compiling the project:

```
Node <node reference> - Specify a valid .NET type name for this root node.  
The current .NET type name of this root node is invalid (it is a reserved BizTalk Keyword or is an invalid C# identifier).
```

Resolution

1. Right-click the rood node referenced in the error and select **Properties**.
2. For the **RootNode TypeName** property, remove any illegal characters or reserved words, for example, dot (.

Invalid binding warning when using the adapter in Visual Studio 2010

Problem

When you use the adapter to create an application in Visual Studio 2010 and you open the configuration file (app.config) generated by the adapter, you see a warning similar to the following:

```
The element 'bindings' has invalid child element 'siebelBinding'. List of possible elements expected: 'basicHttpBinding, custom Binding, ...
```

Cause

This warning appears because the Siebel adapter binding, `siebelBinding`, is not a standard binding shipped with the Windows Communication Foundation (WCF).

Resolution

You can safely ignore this warning.

Troubleshooting Performance Issues

This topic was last updated on: June 05, 2009

This section discusses using troubleshooting techniques to resolve performance issues that you might encounter when using Microsoft BizTalk Adapter for Siebel eBusiness Applications.

Known Issues

The following are the most common performance issues you might encounter when using the Siebel adapter, along with their probable cause and resolution.

- [Slowdown or stall in throughput when using the adapter with BizTalk Server](#)

Slowdown or stall in throughput when using the adapter with BizTalk Server

Problem

When using the Siebel adapter with BizTalk Server, the number of messages sent or received by the adapter slows down or comes to a stall.

Cause

The **EnableBizTalkCompatibilityMode** binding property is not set on the WCF-Custom send or receive port in BizTalk Server Administration console.

Resolution

Set the **EnableBizTalkCompatibilityMode** binding property to True. For more information about this property, see [Working with BizTalk Adapter for Siebel Binding Properties](#). For instructions on how to set a binding property, see [Specifying Binding Properties](#).

Troubleshooting Issues with the Data Provider for Siebel

This topic was last updated on: June 05, 2009

This section discusses using troubleshooting techniques to resolve errors that you might encounter when using the .NET Framework Data Provider for Siebel eBusiness Applications (Data Provider for Siebel).

Known Issues

The following are the most common errors you might encounter when using Data Provider for Siebel, along with their probable cause and resolution.

- [Data Provider for Siebel may give "component 'DataReader Source' \(380\)" error](#)

Data Provider for Siebel may give "component 'DataReader Source' (380)" error

Problem

While performing a SELECT query on a Siebel business component, the Data Provider for Siebel may give a "component 'DataReader Source' (380)" error.

Cause

The Data Provider for Siebel gives this error if the value received from the Siebel system for a parameter exceeds the maxLength property for the parameter.

[Troubleshooting](#)

Using Performance Counters

BizTalk Adapter Pack clients can use the performance counters to gauge the performance of the adapters. The BizTalk Adapter Pack setup program creates the performance counter category "Microsoft BizTalk Adapter for Siebel eBusiness Applications" along with the Adapter Pack installation.

The LOB Time (Cumulative) Performance Counter

The **BizTalk .NET Adapter for Siebel** category has one performance counter called "LOB Time (Cumulative)". This performance counter denotes the time, in milliseconds, that the LOB client library takes to complete an action that the adapter initiates. The Siebel adapter creates an instance of the performance counter for each action, for a specific Siebel server name. The instances are created in the following pattern:

```
<process id>:<app domain id>:<endpoint id>:<action id>
```

In case of the Siebel adapter, the endpoint id is the name of the Siebel server, as specified in the connection URI. The action id could be any action performed by the Siebel adapter such as Login, Logoff, Metadata, <business component name>. <operation>, <business service name>.<business service method>. If the preceding naming convention results in a name that exceeds 127 characters only the action ID is displayed in the following format:

```
:::<action id>
```

If :::<action id> also exceeds 127 characters, it is trimmed down to 127 characters.

The performance counter is initialized only after the adapter makes the first call to the Siebel system. Also, the **InstanceLifetime** property of the performance counter is set to 'Process', which means that the performance counter ceases to exist as soon as the program that creates the counter terminates. For more information about the **InstanceLifetime** property, see "PerformanceCounter.....InstanceLifetime Property" at <http://go.microsoft.com/fwlink/?LinkId=104181>.

Note

The precision of the LOB Time (Cumulative) performance counter is 16 milliseconds.

Enabling Performance Counters

The performance counters can be enabled or disabled by setting the binding property **EnablePerformanceCounters**. Set **EnablePerformanceCounters** binding property to **True** to enable performance counters. To disable performance counters, set **EnablePerformanceCounters** to **False**. By default, **EnablePerformanceCounters** is set to **False**.

Performance Counters and the WCF LOB Adapter SDK

Changing the value of the **EnablePerformanceCounters** binding property changes the value of the corresponding performance counter for WCF LOB Adapter SDK. Also, the binding property for the WCF LOB Adapter SDK is static, whereas that for the BizTalk Adapter Pack is dynamic. Hence, if there are two instances of the Siebel adapter binding in the AppDomain, and the **EnablePerformanceCounters** binding property is set to **True** in one and **False** in the other, the adapter-specific performance counter will be enabled in one and disabled in the other. However, because the binding property for the WCF LOB Adapter SDK is static, it will either be set to **True** or **False**, depending on what value was specified last.

Exceptions and Error Handling

This section lists the exceptions thrown by the Microsoft BizTalk Adapter for Siebel eBusiness Applications. These can contain:

- An inner exception, which is a system exception that the .NET Framework throws
- An LOB exception that the LOB client library throws.

For more information about the inner exception, refer to the respective .NET Framework or Siebel documentation. The exception also contains a detailed error message that helps in resolving the problem. Note that the list of exceptions mentioned here is not comprehensive.

Exception	Possible Cause/Error Description
ConnectionException	The adapter throws this exception if it is unable to establish a connection or close an existing connection to a Siebel system.
CredentialsException	The adapter throws this exception if the adapter client does not specify a user name or password to connect to a Siebel system.
MetadataException	The adapter throws this exception if it fails to retrieve metadata for Siebel artifacts.
XmlReaderParsingException	The adapter throws this exception if the input information provided by the adapter clients to invoke an operation in the Siebel system, is either incomplete or incorrect.
XmlReaderGenerationException	The adapter throws this exception if it is unable to generate output for an operation executed in a Siebel system.
TargetSystemException	The adapter throws this exception if the Siebel COM API, which the adapter uses to interface with the Siebel system, throws an exception. The inner exception contains the exception thrown by the Siebel COM API.

Messages and Message Schemas for BizTalk Adapter for Siebel eBusiness Applications

The Microsoft BizTalk Adapter for Siebel eBusiness Applications is a Windows Communication Foundation (WCF) custom binding. It exposes operations that applications can invoke on a Siebel system. These operations are invoked by sending SOAP messages over a channel. If a response is required, it is returned in a SOAP message over the same channel.

As a WCF service, the Siebel adapter exposes metadata for its operations and data types by using standard WCF mechanisms. The sections in this topic describe the XML structure of the messages and data types that the Siebel adapter uses.

In This Section

Basic Siebel Data Types

This section describes how Siebel data types are supported on the Microsoft BizTalk Adapter for Siebel eBusiness Applications.

Supported Siebel Data Types

The following table shows the Siebel data types that the Siebel adapter supports and how they are represented by the adapter for BizTalk (XSD type) and in the WCF service model (.NET type). For the types marked with an asterisk, see the note following the table.

Data Type	XSD type	.NET type	Description
DTYPE_BOOLEAN	xsd:boolean	Boolean	-
DTYPE_CURRENCY	xsd:decimal	Decimal	-
DTYPE_DATE*	xsd:dateTime*	DateTime	<p>The value must not be Coordinated Universal Time (UTC).</p> <ul style="list-style-type: none"> For xsd:dateTime, values are expected to follow this pattern: "(\\d\\d\\d\\d-\\d\\d-\\d\\d)T(00:00:00)(.*)". For DateTime objects, DateTime.Kind must be DateTimeKind.Unspecified. <p>The time component will be ignored by the adapter.</p> <p>For outbound messages, the adapter performs a runtime validation to ensure that the value specified is not UTC (z or UTC offset). If that validation fails, the adapter throws an exception.</p> <p>When this type is exposed as xsd:string (based on rules explained below):</p> <ul style="list-style-type: none"> The format is determined by the underlying database. No runtime validation is performed on the value.
DTYPE_DATETIME*	xsd:dateTime*	DateTime	<p>The value can contain both date and time components and must not be UTC.</p> <ul style="list-style-type: none"> For DateTime objects, DateTime.Kind must be DateTimeKind.Unspecified. <p>For outbound messages, the adapter performs a run-time validation to ensure that these conditions are met; if the validation fails, the adapter throws an exception.</p> <p>When this type is exposed as xsd:string (based on rules explained below):</p> <ul style="list-style-type: none"> The format is determined by the underlying database. No run-time validation is performed on the value.
DTYPE_ID	xsd:string	String	-
DTYPE_INTEGER	xsd:int	Int32	-

DTYPE_NUMBER	xsd:string	String	-
DTYPE_NUMBER	xsd:decimal	Decimal	-
DTYPE_PHONE	xsd:string	String	-
DTYPE_TEXT	xsd:string	String	-
DTYPE_TIME	xsd:dateTime*	Date Time	<p>The value must not be UTC.</p> <ul style="list-style-type: none"> For xsd:dateTime, values are expected to follow this pattern: (1753-01-01)T(\d\d:\d\d:\d\d)(.*)". For DateTime objects, DateTime.Kind must be DateTimeKind.Unspecified. <p>For outbound messages, the adapter performs a runtime validation to ensure that the value specified is not UTC (z or UTC offset). If that validation fails, the adapter throws an exception.</p> <p>When this type is exposed as xsd:string (based on the rules explained below):</p> <ul style="list-style-type: none"> The format is determined by the underlying database. No run-time validation is performed on the value.
DTYPE_UTC_DATETIME	xsd:dateTime*	Date Time	<p>The value can contain both date and time components and must be UTC.</p> <ul style="list-style-type: none"> For xsd:dateTime, the value must be expressed in UTC ('Z' notation or UTC offset). For DateTime objects DateTime.Kind must be DateTimeKind.Utc. <p>For outbound messages, the adapter performs a run-time validation to ensure that these conditions are met; if the validation fails, the adapter throws an exception.</p> <p>When this type is exposed as xsd:string (based on rules explained below):</p> <ul style="list-style-type: none"> The format is determined by the underlying database. No run-time validation is performed on the value.

The following are the Business Service method argument types:

Date

The same as DTYPE_DATE.

Number

The same as DTYPE_NUMBER.

String

The same as DTYPE_TEXT.

Hierarchy

Corresponds to XSD type xsd:string, and to .Net type String. In XML messages, this has to be placed in a CDATA node.

Integration Object

The same as Hierarchy.

*The adapter determines whether to use `xsd:dateTime` or `xsd:string` to represent `DTYPE_DATE`, `DTYPE_DATETIME`, `DTYPE_TIME`, and `DTYPE_UTCDATETIME` fields in business components in the following manner.

1. If the business component field has one of the preceding data types, the adapter will expose it as the `xsd:dateTime` type (in .Net this maps to the `DateTime` type).
2. If the business component field has no data type, the adapter will expose it as `xsd:string` (in .Net this maps to the `String` type).

Supported Facets for the XML Schema Types

The Siebel adapter supports the following facets for the XML schema types.

Siebel Type	Facet
DTYPE_BOOL	None
DTYPE_CURRENCY	Precision (22), Scale
DTYPE_DATE	(\d\d\d\d-\d\d-\d\d)T(00:00:00)(.*)
DTYPE_DATETIME	None
DTYPE_ID	MaxLength (15)
DTYPE_INTEGER	Precision (22)
DTYPE_NOTE	MaxLength (16384)
DTYPE_NUMBER	Precision (22), Scale
DTYPE_PHONE	MaxLength (40)
DTYPE_TEXT	MaxLength (2048)
DTYPE_TIME	(1753-01-01)T(\d\d:\d\d:\d\d)(.*)
DTYPE_UTCDATETIME	None

The following are some rules that govern how and when the facets, and their values, are published:

If the `Length` attribute of the field is set to a value greater than zero and less than or equal to the maximum value (specified in parentheses in the preceding table):

- The `Precision` facet is published as follows:
 - If the `Precision` attribute is set for the field, the same value is published as `Precision` facet.
 - If the `Precision` attribute is not set for the field, the `Length` value is published as the `Precision` facet.
- The `Scale` facet is published only if both:
 - The `Precision` attribute has been published
 - The `Scale` attribute is set for the field to a value greater than zero and less than the value published as part of the

Precision facet

- The MaxLength facet is the value specified for the Length attribute. This is picked up from the field definition repository. In case the length is not specified in the field definition repository, the value specified in parentheses in the preceding table gets published.

Special Cases Related to Siebel Data Types

The following rules affect the business component field facets based on the context of the operation in which they are used. These rules are applicable for INSERT and UPDATE operations only. For QUERY operations, all business component fields are exposed to the user.

Business component field marked as REQUIRED in Siebel

Even if a business component field is marked as REQUIRED in the Siebel system but the pre-default or post-default values are set for the field, Siebel adapter marks the field as OPTIONAL. Hence if a user provides a value to be inserted or updated, the adapter processes that value. If no value is provided, Siebel uses the pre-default/post-default values.

Business component field NOT marked as READ ONLY in Siebel

If a business component field is NOT marked as READ ONLY, the Siebel adapter exposes it as a writable field. However, there are a couple of exceptions to this rule. These are:

- If the business component field is a **Calculated** field in Siebel, it will not appear in the Insert or Update operations because Siebel will automatically take care of **Calculated** fields.
- If the business component field is obtained through an explicit join (table join on another table), it is generally read only. However Siebel allows data to be written to this field if it is a picklist field. Hence, if the business component field is from an explicit join and the field is NOT a picklist field, then it will NOT appear in the Insert or Update operations because adapter clients cannot write data into such fields.

Data type of a field not specified in the Business Component

If the data type of a field is not specified in the Business Component, the Siebel adapter exposes the field metadata using the following heuristics.

- If the field is a special field (i.e. picklist or join), the Siebel adapter will look up the mapped field in the destination Business Component. If that field has a type associated with it, the Siebel adapter will expose that as the type of the field. However, if that type is DTYPE_DATE, DTYPE_TIME, DTYPE_DATETIME, or DTYPE_UTCDATETIME, the Siebel adapter will expose the field as the xsd:string type. If the mapped field doesn't have an associated type, the Siebel adapter will expose the original field as the xsd:string type.
- If the field is not a picklist or join field, the Siebel adapter will expose it as the xsd:string type.

Data type, field length, or precision of a parent business component is not available

If the data type, length, or field precision of a parent business component (a business component that has a child business component based on picklists or MVLs), the Siebel adapter obtains the information about the data type, length, precision, and scale from the picklist business component or the MVL business component.

[Messages and Message Schemas for BizTalk Adapter for Siebel eBusiness Applications](#)

Message Schemas for Business Component Operations

Message Schemas for Siebel Business Component Operations

The following table lists the message schemas for the operations exposed by the Siebel adapter on Siebel business components.

Operation	XML Structure	Description
Insert	<p>Insert message:</p> <pre><Insert xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation"> <ArrayOf[BC]InsertRecord> <[BC]InsertRecord> <[FIELD1_NAME]>value1</[FIELD1_NAME]> <[FIELD2_NAME]>value2</[FIELD2_NAME]> ... </[BC]InsertRecord> ... </ArrayOf[BC]InsertRecord> </Insert></pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[BO] = Name of the business object; for example, Account.</p> <p>[BC] = Name of the business component; for example, Account.</p> <p>[FIELD1_NAME] = Business component field name; for example, Account_x0020_Status.</p> <p>Insert response message:</p> <pre><InsertResponset xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation"> <InsertResult> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[ID1]</string> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[ID2]</string> ... </InsertResult> </InsertResponse></pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03"</p> <p>[BO] = Name of the business object; for example, Account.</p> <p>[BC] = Name of the business component; for example, Account.</p> <p>[ID] = Record ID; for example, 42-6ODBL.</p>	<p>Inserts one or more records into a business component.</p> <p>The response contains the record IDs of all records inserted.</p> <p>If at least one insertion is successful, then no exception is thrown and the response will contain the IDs of the successfully inserted records. However, if all insertions fail, an exception will be thrown (XmlReaderParsingException or TargetSystemException).</p>

<p>Query message:</p>	<pre> <Query xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation"> <ViewMode>[View_mode]</ViewMode> <[BC]QueryInputRecord> <SearchExpr>[Search_expr]</SearchExpr> <SortSpec>Sort_spec</SortSpec> <QueryFields> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[Field1_name]</string> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[Field2_name]</string> ... </QueryFields> </[BC]QueryInputRecord> </Query> </pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[View_mode] = View mode to apply. This is an optional parameter. See the Siebel documentation for an explanation of possible values.</p> <p>[Search_expr] = Siebel search expression; for example, [Name] LIKE "3Com*".</p> <p>[Sort_spec] = Siebel sort specification; for example, Name (DESC), Location.</p> <p>[FIELD1_NAME] = Business component field name; for example, Account Status.</p> <p>Query response message:</p> <pre> <QueryResponse xmlns=" [VERSION]/BusinessObjects/[BO]/[BC]/Operation"> <QueryResult> <[BC]QueryRecord> <[FIELD1_NAME]>value1</[FIELD1_NAME]> <[FIELD2_NAME]>value2</[FIELD2_NAME]> ... </[BC]QueryRecord > </QueryResult> </QueryResponse> </pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[BO] = Name of the business object; for example, Account.</p> <p>[BC] = Name of the business component; for example, Account.</p> <p>[FIELD1_NAME] = Business component field name; for example, Account_x0020_Status.</p>	<p>Queries one or more records from the target business component. The Query operation takes the following parameters:</p> <p><SearchExpr> All records under the target business component are compared against the search expression and matching records are returned.</p> <p><SortSpec> The sort specification determines the order in which records that match the search expression are returned. This parameter is optional.</p> <p><QueryFields> A list of field names that specifies the fields in the target business component that should be retrieved by the query operation. Only the fields in this list are returned in each record. Each field should be specified by using the original name of the field in the business component, not the XML-encoded name; for example, "First Name" instead of "First_x0032_Name". This parameter is optional. If query fields are not specified, then all fields are returned.</p>
-----------------------	---	---

Update message:	<pre> <Update xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation"> <ViewMode>[View_mode]</ViewMode> <ArrayOf[BC]UpdateRecord> <[BC]UpdateRecord> <[FIELD1_NAME]>value1</[FIELD1_NAME]> <[FIELD2_NAME]>value2</[FIELD2_NAME]> ... <Id>[Record_ID]</Id> </[BC]UpdateRecord> ... </ArrayOf[BC]UpdateRecord> </Update> </pre>	<p>Update one or more records specified by a list of update records.</p> <p>Each update record contains a list of the fields to be updated and a single, mandatory <Id> element that identifies the record to be updated.</p> <p>The response contains a list of the record IDs of all of the records updated.</p> <p>If at least one update is successful, then no exception is thrown and the response will contain the IDs of the successfully updated records. However, if all updates fail, an exception will be thrown (XmlReader ParsingException or TargetSystemException).</p>
	<p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[BO] = Name of the business object; for example, Account.</p> <p>[BC] = Name of the business component; for example, Account.</p> <p>[View_mode] = View mode to apply when querying the records that need to be updated. This is an optional parameter. See the Siebel documentation for an explanation of possible values.</p> <p>[FIELD1_NAME] = Business component field name; for example, Account_x0020_Status.</p> <p>[Record_ID] = Record ID of a record to be updated; for example, 42-60DBL.</p> <p>Update response message:</p> <pre> <UpdateResponse xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation"> <UpdateResult> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[ID1]</string> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[ID2]</string> ... </UpdateResult> </UpdateResponse> </pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[BO] = Name of the business object; for example, Account.</p> <p>[BC] = Name of the business component; for example, Account.</p> <p>[ID] = Record ID; for example, 42-60DBL.</p>	

Delete message:	<pre> <Delete xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation"> <ViewMode>[View_mode]</ViewMode> <Id> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[ID1]</string> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[ID2]</string> ... </Id> <SearchExpr>Search_expr</SearchExpr> </Delete> </pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[BO] = Name of the business object; for example, Account.</p> <p>[BC] = Name of the business component; for example, Account.</p> <p>[View_mode] = View mode to apply when querying the records that need to be deleted. This is an optional parameter. See the Siebel documentation for an explanation of possible values.</p> <p>[ID] = Record ID; for example, 42-6ODBL.</p> <p>Search_expr = Siebel search expression; for example, [Name] LIKE "3Com*".</p> <p>Delete response message</p> <pre> <DeleteResponse xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation"> <DeleteResult> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[ID1]</string> <string xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">[ID2]</string> ... </DeleteResult> </DeleteResponse> </pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[BO] = Name of the business object; for example, Account.</p> <p>[BC] = Name of the business component; for example, Account.</p> <p>[ID] = Record ID; for example, 42-6ODBL.</p>	<p>Delete one or more records matching a set of record IDs or a search expression.</p> <p>◆ Important The Delete operation takes either a search expression or a set of record IDs. You cannot specify both parameters in the same Delete operation.</p> <p>The response contains a list of the record IDs of all of the rows deleted.</p> <p>If at least one deletion is successful, then no exception is thrown and the response will contain the IDs of the successfully deleted records. However, if all deletions fail, an exception will be thrown (XmlReaderParsingException or TargetSystemException).</p>
Associate message:	<pre> <Associate xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation"> <ViewMode>[View_mode]</ViewMode> <ParentSearchExpr>Parent_search</ParentSearchExpr> <ParentMVGField>Field_name</ParentMVGField> <ChildSearchExpr>Child_search</ChildSearchExpr> </Associate> </pre> <p>The Associate operation is surfaced only for business components with multi-value group (MVG) fields. It associates records by specifying search expressions for parent and child records.</p> <p>The Associate operation:</p> <ul style="list-style-type: none"> • Associates a selected parent business component record with one selected child business component record 	

[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".

[BO] = Name of the business object; for example, Account.

[BC] = Name of the business component; for example, Account.

[View_mode] = View mode to apply to the query for parent and child business component records. If a value is specified, that value will be applied to both the parent search and the child search. This is an optional argument. For an explanation of possible values, see the Siebel documentation.

[Par_search] = Search expression matching exactly one parent business component record; for example, [Id] LIKE AB-12345.

[Chld_search] = Search expression matching exactly one child business component record that will be associated with the parent business component record; for example, [Id] LIKE CD-12345.

[Field_name] = Multi-value group field name of the parent business component; for example, 'Bill To First Name' in the Account business component.

Associate response message:

```
<AssociateResponse xmlns=
"[VERSION]/BusinessObjects/[BO]/[BC]/Operation">
  <AssociateResult>
    <ChildID>[CHILD_ID]</
ChildID>
    <ParentID>[PARENT_ID]
</ParentID>
  </AssociateResult>
</AssociateResponse>
```

[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".

[BO] = Name of the business object; for example, Account.

[BC] = Name of the business component; for example, Account.

[CHILD_ID] = Child Record ID; for example, 42-6ODBL.

[PARENT_ID] = Parent Record ID; for example, 42-6ODBL.

- Establishes a 1:1 association. one parent record will be associated with one child record
- Multiple 1:1 associations should be made for a 1:N association and multiple 1:N associations should be made for a M:N association

Please note:

- The parent search expression must match a unique record in the parent table.
- The child search expression must match a unique record in the child table.

The return value contains the record ID of the associated child row and the record ID of the associated parent row. If the parent search expression or the child search expression returns more than one matching record, an exception will be thrown.

Di Dissociate message:

The Dissociate operation is surfaced onl

```
<Dissociate xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation">
  <ViewMode>[View_mode]</ViewMode>
  <ParentSearchExpr>Par_search</ParentSearchExpr>
  <ParentMVGField>Field_name</ParentMVGField>
  <ChildSearchExpr>Chld_search</ChildSearchExpr>
</Dissociate>
```

[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".

[BO] = Name of the business object; for example, Account.

[BC] = Name of the business component; for example, Account.

[View_mode] = View mode to apply to the query for parent and child business component records. If a value is specified, that value will be applied to both the parent search and the child search. This is an optional argument. For an explanation of permissible values, see the Siebel documentation.

[Par_search] = Search expression matching exactly one parent business component record; for example, [Id] LIKE AB-12345.

[Chld_search] = Search expression matching exactly one child business component record that will be dissociated with the parent business component record; for example, [Id] LIKE CD-12345.

[Field_name] = Multi-value group field name of the parent business component; for example, 'Bill To First Name' in the Account business component.

Dissociate response message:

```
<DissociateResponse xmlns="[VERSION]/BusinessObjects/[BO]/[BC]/Operation">
  <DissociateResult>
    <ChildID>[CHILD_ID]</ChildID>
    <ParentID>[PARENT_ID]</ParentID>
  </DissociateResult>
</DisocciateResponse>
```

[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".

y for business components with multi-value group (MVG) fields. It dissociates records by specifying search expressions for parent and child records.

The Dissociate operation:

- Dissociates a selected parent business component record with one selected child business component record
- Establishes a 1:1 dissociation. one parent record will be dissociated with one child record
- Multiple 1:1 dissociations should be made for a 1:N dissociation and multiple 1:N dissociations should be made for a M:N dissociation

Note that the child search expression must match a unique record among the associated records with parent records that match the parent search expression.

◆ Important

There is a difference in the child search expression for ASSOCIATE and DISSOCIATE operations. In an ASSOCIATE operation, the child search expression searches all records in the child business component. In a DISSOCIATE operation, the child search expression searches only those records in the child business component that are associated with records in the parent business component, where the parent records match the parent search expression.

The return value contains the record ID of the dissociated child record and the record ID of the dissociated parent record. If the parent search expression or the child search expression returns more than one matching record, an exception will be thrown.

<p>ices.Siebel/2007/03".</p> <p>[BO] = Name of the business object; for example, Account.</p> <p>[BC] = Name of the business component ; for example, Account.</p> <p>[CHILD_ID] = Child Record ID; for example, 42-6ODBL.</p> <p>[PARENT_ID] = Parent Record ID; for example, 42-6ODBL.</p>	
<p>Query_[MVG_Child_Business_Comp] message:</p> <pre> <Query_[CHILD_BC] xmlns=" BusinessObjects/[BO]/[BC] /Operation"> <ViewMode>View_mode</ViewMode> <ParentSearchExpr>Par_search</ParentSearchExpr> <ParentMVGField>Field_name</ParentMVGField> <[CHILD_BC]QueryInputRecord> <SearchExpr>Chld_search </SearchExpr> <QueryFields> <string>field1</string> <string>field2</string> ... </QueryFields> </[CHILD_BC]QueryInputRecord> </Query_[CHILD_BC]> </pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[BO] = Name of the business object; for example, Account.</p> <p>[BC] = Name of the business component ; for example, Account.</p> <p>[View_mode] = View mode to apply; can be 0 to 9. This is an optional parameter. See the Siebel documentation for an explanation of these possible values.</p> <p>[CHILD_BC] = Name of the child business component associated with the parent business component's MVG field; for example, Contact (for the Account parent business component).</p> <p>[Par_search] = Search expression matching 1 parent business component record; for example, [Id] LIKE AB-12345.</p>	<p>This operation is exposed for business components with MVG fields.</p> <p>It queries the child records associated with a parent record that is associated with a MVG field in the parent business component.</p>

[Field_name] = Multi-value group field name of the Parent business component; for example, 'Bill To First Name' in the Account business component'.

[Chld_search] = Search expression matching 1 or more child business component records; for example, [Id] LIKE CD-12345.

[field1], [field2], and so on = Query fields in the child business component. A list of field names that specifies the fields in the child business component that should be retrieved by the operation. Only the fields in this list are returned in each record. Each field should be specified by using the original name of the field in the child business component, not the XML encoded name; for example, "First Name" instead of "First_x0032_Name". This parameter is optional.

Query_[MVG_Child_Business_Comp] response message:

```
<Query_[CHILD_BC]Response
xmlns="[VERSION]/Business
Objects/[BO]/[BC]/Operati
on">
  <Query_[CHILD_BC]Result
  >
    <[CHILD_BC]QueryRecor
d>
      <[FIELD1_NAME]>valu
e1</[FIELD1_NAME]>
      <[FIELD2_NAME]>valu
e2</[FIELD2_NAME]>
      ...
    </[CHILD_BC]QueryReco
rd >
  </QueryResult>
</QueryResponse>
```

[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".

[BO] = Name of the business object; for example, Account.

[BC] = Name of the business component; for example, Account.

[FIELD1_NAME] = business component field name; for example, Account_x0020_Status.

[CHILD_BC] = Name of the child business component associated with the parent business component's MVG field; for example, Contact (for the Account parent business component).

The following table shows the SOAP action for each of the Siebel business component operations. Only the actions for the request messages are shown, the action for the response message is formed by appending "/response" to the request message action; for example, "http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert/response".

Operation	Action	Example
Insert	[VERSION]/BusinessObjects/[BO]/[BC]/Insert	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert
Query	[VERSION]/BusinessObjects/[BO]/[BC]/Query	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Query
Update	[VERSION]/BusinessObjects/[BO]/[BC]/Update	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Update
Delete	[VERSION]/BusinessObjects/[BO]/[BC]/Delete	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Delete
Associate	[VERSION]/BusinessObjects/[BO]/[BC]/Associate	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Associate
Dissociate	[VERSION]/BusinessObjects/[BO]/[BC]/Dissociate	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Dissociate
Query_[CHILD_BC]	[VERSION]/BusinessObjects/[BO]/[BC]/Query_[CHILD_BC]	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Query_Contact

[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".

[BO] = Business object name; for example, Account.

[BC] = Business component name; for example, Account.

Name of the child business component associated with the parent business component's MVG field; for example, Contact (for the Account parent business component).

You must explicitly specify the message action when you consume the Siebel adapter in a BizTalk Server solution or by using the Windows Communication Foundation (WCF) channel model. For more information, see [Development](#).

Siebel Business Component WCF Client Methods

The following table shows the WCF service model method signatures that are generated by the Add Adapter Service Reference Visual Studio Plug-in for Siebel business components.

Operation	WCF Service Model Method
Insert	<code>string[] client.Insert([BC]InsertRecord[] ArrayOf[BC]InsertRecord);</code>
	[BC] = Name of business component; for example, Account.
Query	<code>[BC]QueryRecord[] client.Query(System.Nullable<short> ViewMode, [BC]QueryInputRecord [BC]QueryInputRecord);</code>
	[BC] = Name of business component, for example, Account.
Update	<code>string[] client.Update(System.Nullable<short> ViewMode, [BC]UpdateRecord[] ArrayOf[BC]UpdateRecord);</code>
	[BC] = Name of business component; for example, Account.

Delete	<code>string[] client.Delete(System.Nullable<short> ViewMode, string[] Id, string SearchExpr);</code>
Associate	<code>ParentChildRecord client.Associate(System.Nullable<short> ViewMode, string ParentSearchExpr, string ParentMVGField, string ChildSearchExpr);</code>
Dissociate	<code>ParentChildRecord client.Dissociate(System.Nullable<short> ViewMode, string ParentSearchExpr, string ParentMVGField, string ChildSearchExpr);</code>
Query_[MVG Child Business Comp]	<code>[CHILD_BC]QueryRecord[] client.Query_[CHILD_BC](System.Nullable<short> ViewMode short ViewMode, string ParentSearchExpr, string ParentMVGField, [CHILD_BC]QueryInputRecord [CHILD_BC]QueryInputRecord);</code>
	[CHILD_BC] = Name of the child business component associated with the parent business component's MVG field; for example, Contact (for the Account parent business component).

[Messages and Message Schemas for BizTalk Adapter for Siebel eBusiness Applications](#)

Message Schemas for Business Service Operations

A Siebel business service is a collection of business methods that can be directly invoked on a Siebel system. The Siebel adapter surfaces the business methods of a Siebel business service as operations.

Message Schemas for Siebel Business Service Method Operations

The following table shows the message schemas for Siebel business service method operations surfaced by the Siebel adapter.

Operation	XML Structure	Description
-----------	---------------	-------------

<p>[Business Service Method Name]</p>	<p>Business Service Method Request message:</p> <pre> <[METHOD_NAME] xmlns="[VERSION]/BusinessServices/[Business Service]/Operation"> <[METHOD_NAME]RequestRecord> <[I_PRM1_NAME]>value1</[I_PRM1_NAME]> <[I_PRM2_NAME]>value2</[I_PRM2_NAME]> ... </[METHOD_NAME]RequestRecord> <[METHOD_NAME]InOutRecord> <[IO_PRM1_NAME]>value1</[IO_PRM1_NAME]> <[IO_PRM2_NAME]>value2</[IO_PRM2_NAME]> ... </[METHOD_NAME]InOutRecord> </[METHOD_NAME]> </pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[Business Service] = The name of business service; for example, ExtractDataService.</p> <p>[METHOD_NAME] = The name of the business service method; for example, ExecuteNext.</p> <p>[I_PRM_NAME] = Names of IN parameters.</p> <p>[IO_PRM_NAME] = Names of IN OUT parameters.</p> <p>Business Service Method Response message:</p> <pre> <[METHOD_NAME]Response xmlns="[VERSION]/BusinessServices/[Business Service]/Operation"> <[METHOD_NAME]Result> <[O_PRM1_NAME]>value1</[O_PRM1_NAME]> <[O_PRM2_NAME]>value2</[O_PRM2_NAME]> ... </[METHOD_NAME]Result> <[METHOD_NAME]InOutRecord> <[IO_PRM1_NAME]>value1</[IO_PRM1_NAME]> <[IO_PRM2_NAME]>value2</[IO_PRM2_NAME]> ... </[METHOD_NAME]InOutRecord > </[METHOD_NAME]Response> </pre> <p>[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".</p> <p>[Business Service] = Name of business service; for example, ExtractDataService.</p> <p>[METHOD_NAME] = Name of the business service method; for example, ExecuteNext.</p> <p>[O_PRM_NAME] = Names of OUT parameters.</p> <p>[IO_PRM_NAME] = Names of INOUT parameters.</p> <p>◆ Important The IN OUT and OUT parameters are always marked as optional in the metadata, even if they required by the Siebel system. So, if a parameter is marked as optional in the metadata but required by the Siebel system, the adapter throws the <code>TargetSystemException</code> as received from Siebel and not the <code>XmlReaderParsingException</code>.</p>	<p>The Siebel business service method is surfaced as an operation name.</p> <ul style="list-style-type: none"> • IN, IN OUT and OUT parameters are supported. • Hierarchical types are surfaced as strings. The Siebel adapter does not validate the values passed for these strings. If these values do not conform to the schemas expected by the Siebel system, a run-time exception will be generated.
---------------------------------------	---	--

Message Actions for Siebel Business Service Method Operations

The following table shows how the SOAP action for a Siebel Business Service method is formed. Only the action for the request message is shown, the action for the response message is formed by appending "/response" to the request message action; for example, "[VERSION]/BusinessServices/ExtractDataService/ExecuteNext/response".

Operation	Action	Description
[Business_Service_METHOD_NAME]	[VERSION]/BusinessServices/[Business Service]/[Business_Service_METHOD_NAME]	[VERSION]/BusinessServices/ExtractDataService/ExecuteNext

[VERSION] = The message version string; for example, "http://Microsoft.LobServices.Siebel/2007/03".

[Business Service] = The name of business service; for example, ExtractDataService.

[Business_Service_METHOD_NAME] = The name of the business service method; for example, ExecuteNext.

You must explicitly specify the message action when you consume the Siebel adapter in a BizTalk Server solution or by using the WCF channel model. For more information, see [Development](#).

Siebel Business Service WCF Client Methods

The following table shows the WCF service model method signature that is generated by the Add Adapter Service Reference Visual Studio Plug-in for Siebel business services methods.

Operation	WCF Service Model Method
[Business_Service_METHOD_NAME]	[Business_Service_METHOD_NAME]ResponseRecord client.[Business_Service_METHOD_NAME]([Business_Service_METHOD_NAME]RequestRecord);
	[Business_Service_METHOD_NAME] = Business service method name; for example, ExecuteNext.

Message Schema for Picklist Operations

Picklists are special field types in business components. They represent a collection of values from which a user may pick a single value for assignment. Picklists are of different types. For more information about picklists and their types, refer to Siebel documentation.

One of the picklist types, static bounded picklists, are surfaced by the adapters as an enumerated picklist type in the metadata generated by the adapter at design time. This contains a static set of values that must be specified for the picklist type at run time. While specifying a value for a static bounded picklist, you must always specify a value that belongs to the set.

The following sample shows the schema of a static bounded picklist type:

```
<element name="[FIELD_NAME]RequiredPickListType" nillable="true" type="ns1:[FIELD_NAME]RequiredPickListType" />
<simpleType name="[FIELD_NAME]RequiredPickListType">
  <restriction base="string">
    <enumeration value="value1" />
    <enumeration value="value2" />
    ...
  </restriction>
</simpleType>
```

[FIELD_NAME] = Picklist field name in the business component

The following represents the proxy experience of a static bounded picklist type:

```
[BC]InsertRecord[] insertRecs = new [BC]InsertRecord[1];
insertRecs[0] = new [BC]InsertRecord();
insertRecs[0].[BC_STATIC_PICKLIST_FIELD] = [BC_PICKLIST_FIELD_NAME]OptionalPickListType.value1;
```

[BC_STATIC_PICKLIST_FIELD] = A static bounded picklist field in the BC

Message Versioning Support

The Microsoft BizTalk Adapter for Siebel eBusiness Applications supports versioning by including a version string component in the message actions, namespaces, and node IDs surfaced for operations. The current version is <http://Microsoft.LobServices.Siebel/2007/03>. This means that for an Insert operation on an Account business object in the Siebel repository, the Insert operation surfaced by the adapter has the following:

- Node ID: <http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert>
- Message action: <http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert>
- Namespace: <http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Operation>

 **Note**

This feature does not provide backward compatibility with the earlier versions of the adapter.

Metadata Node IDs

Siebel Node IDs

The Siebel adapter surfaces Siebel system artifacts in a hierarchical manner. The following table describes the node types and node IDs for Siebel artifacts surfaced by the Siebel adapter.

Artifact	Node Type	Node Id	Example	Description
Business Objects (All Business Objects)	CATEGORY	[VERSION]/BusinessObjects	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects	Returns all business objects.
Business Object (BO)	CATEGORY	[VERSION]/BusinessObjects/[BO]	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account	Returns all business components associated with the specified business object.
Business Component (BC)	CATEGORY	[VERSION]/BusinessObjects/[BO]/[BC]	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account	Returns all operations associated with the specified business component.
Insert	OPERATION	[VERSION]/BusinessObjects/[BO]/[BC]/Insert	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert	Returns the Insert operation for the specified business component.
Query	OPERATION	[VERSION]/BusinessObjects/[BO]/[BC]/Query	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Query	Returns the Query operation for the specified business component.
Update	OPERATION	[VERSION]/BusinessObjects/[BO]/[BC]/Update	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Update	Returns the Update operation for the specified business component.
Delete	OPERATION	[VERSION]/BusinessObjects/[BO]/[BC]/Delete	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Delete	Returns the Delete operation for the specified business component.
Associate	OPERATION	[VERSION]/BusinessObjects/[BO]/[BC]/Associate	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Associate	Returns the Associate operation for the specified business component.
Dissociate	OPERATION	[VERSION]/BusinessObjects/[BO]/[BC]/Dissociate	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Dissociate	Returns the Dissociate operation for the specified business component.
Query_[MVG Child Business Component]	OPERATION	[VERSION]/BusinessObjects/[BO]/[BC]/Query_[MVG Child Business Component]	http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Query_Contact	Returns the Query operation for the child business component.
Business Services	CATEGORY	[VERSION]/BusinessServices	http://Microsoft.LobServices.Siebel/2007/03/BusinessServices	Returns all business services.
Business Service	CATEGORY	[VERSION]/BusinessServices/[Business Service]	http://Microsoft.LobServices.Siebel/2007/03/BusinessServices/ATP	Returns all business methods for the specified business service.

Business Service Method	OPERATION	[VERSION]/BusinessServices/[Business Service Method]	http://Microsoft.LobServices.Siebel/2007/03/BusinessServices/ATP/ATPRunCheck	Returns the specified business service method.
-------------------------	-----------	--	--	--

[VERSION] = The version string; for example http://Microsoft.LobServices.Siebel/2007/03.

[BO] = A Siebel business object; for example, Account.

[BC] = A business component; for example, Account.

[Business Service] = A Siebel business service; for example, ATP.

[Business Service Method] = A method of a business service; for example, DismissAlarm.

[MVG Child Business Component] = A multi-value group child business component; for example, Contact.

Metadata Search and Node IDs

Metadata search is a powerful feature that the Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK surfaces as part of its **MetadataRetrievalContract** interface. The Siebel adapter leverages this feature to support searching the following Siebel artifacts.

Artifact	Node Id	Description
Business Object	[VERSION]/BusinessObjects	Return business objects that match the search expression.
Business Component	[VERSION]/BusinessObjects/[BO]	Return business components that match the search expression.
Business Service	[VERSION]/BusinessServices	Return business services that match the search expression.
Business Service Method	[VERSION]/BusinessServices/[Business Service]	Return business service methods that match the search expression.

[VERSION] = The version string; for example http://Microsoft.LobServices.Siebel/2007/03.

[BO] = A Siebel Business Object; for example, Account.

[Business Service] = A Siebel Business Service; for example, ATP.

For valid search expressions, refer to the Siebel documentation.

Note
The Siebel adapter only supports searches at the level below the currently selected node. For example, when BusinessObjects is selected, A* is a supported search, but A*/A* is not.

Metadata Retrieval and Node IDs

The Siebel adapter captures the following characteristics for each type of artifact.

Artifact	Metadata Characteristics
----------	--------------------------

Business Component	<ul style="list-style-type: none"> • Business component name • Business component field names • Business component field data types mapped to simple/complex WSDL types • Business component field length mapped to facet maxLength • Business component mandatory field mapped to facet minOccurs = 1 • Business component optional field mapped to facet minOccurs = 0 • Business component picklist field mapped to a Picklist complex type in WSDL • Business component static bounded picklist to contain an enumerated list of values • Business component field NULL constraint mapped to facet isNillable = true • Business component operations <ul style="list-style-type: none"> • INSERT • QUERY • UPDATE • DELETE • ASSOCIATE • DISSOCIATE • QUERY_[MVG Child Business Comp] for each child business component with which the business component has an m:n relationship
Business Service Method	<ul style="list-style-type: none"> • Business Service name • Method name • Method is the operation • Method parameter names • Method parameter data types mapped to WSDL types • Method parameter direction mapped to WSDL parameter direction • Method parameter order mapped to element sequence

For detailed information about the format of the metadata that the Siebel adapter exposes for specific artifacts and operations on the Siebel system, see [Messages and Message Schemas for BizTalk Adapter for Siebel eBusiness Applications](#).

Using the ServiceModel Metadata Utility Tool with the BizTalk Adapter for Siebel eBusiness Applications

You can use the ServiceModel Metadata Utility Tool (svcutil.exe) to generate a WCF client class for operations that the Microsoft BizTalk Adapter for Siebel eBusiness Applications exposes. After you run svcutil.exe to generate a WCF client class, you can include the generated file in your code and create instances of the WCF client class to perform operations on the Siebel system.

Using svcutil.exe requires you to supply a connection URI that contains credentials. Because, by default, the Siebel adapter disables credentials in the connection URI, you must configure svcutil.exe to use a non-default binding for the Siebel adapter. You can also configure other binding properties in the non-default binding.

The following sections show you how to configure svcutil.exe and how to use svcutil.exe to generate WCF client code with the Siebel adapter.

Configuring svcutil.exe for the Siebel Adapter

To configure svcutil.exe to use a non-default binding, you must create a local copy of svcutil.exe and then create or modify a local copy of the svcutil.exe.config configuration file.

To configure svcutil.exe for a non-default binding

1. Create a folder, and copy svcutil.exe into the new folder. You can typically find svcutil.exe at the Windows SDK installation location, specifically, C:\Program Files\Microsoft SDKs\Windows\v6.0\Bin.
2. Create a file named svcutil.exe.config in the new folder.
3. Add a binding and a client endpoint to the svcutil.exe.config file. You must run svcutil.exe from the new folder to ensure that the correct configuration is used.

Important

The name attribute of the client endpoint must specify the scheme used in the connection URI. This value is case-sensitive.

```
<configuration>
  <system.serviceModel>
    <client>
      <!-- the name should match the required scheme of the Metadata Exchange endpoint
      and the contract should be "IMetadataExchange" -->
      <endpoint name="siebel"
        binding="siebelBinding"
        bindingConfiguration="SiebelBinding"
        contract="IMetadataExchange" />
    </client>
    <bindings>
      <siebelBinding>
        <binding name="SiebelBinding" acceptCredentialsInUri="true" />
      </siebelBinding>
    </bindings>
  </system.serviceModel>
</configuration>
```

Note

You can set any of the binding properties of the Siebel adapter in the binding configuration.

For more information about configuring a non-default binding for svcutil.exe, see the "Custom Secure Metadata Endpoint" topic in the WCF documentation at <http://go.microsoft.com/fwlink/?LinkId=96077>.

Creating a WCF Client Class with svcutil.exe

To use svcutil.exe to generate WCF client code for the Siebel adapter, you must supply a connection URI that specifies an **IMetadataExchange** (mex) endpoint and the operation or operations for which you want svcutil.exe to generate code. You must also specify connection credentials for the Siebel system in the connection URI.

Note

Before you can use svcutil.exe with the Siebel adapter, you must configure it to use a non-default binding; for information about how to do this, see [Configuring svcutil.exe for the Siebel Adapter](#).

You specify a mex endpoint and target operations in the Siebel adapter connection URI in the following manner:

- You must include the "wsdl" parameter in the query_string. If it is the first parameter in the query_string, it is specified just after the question mark (?). If it is not the first parameter, it should be preceded with an ampersand (&).
- You must follow the "wsdl" parameter by one or more "op" parameters. Each "op" parameter is preceded by an ampersand (&) and specifies the node ID of a target operation.

The following two examples show how to target various operations by using svcutil.exe.

This example creates a WCF client class for an insert operation on the ACCOUNT\ACCOUNT Business Object.

```
.\svcutil "siebel://Username=YourUserName;Password=YourPassword@Siebel_server:1234?
SiebelEnterpriseServer=ent_server&SiebelObjectManager=obj_mgr&Language=enu&wsdl&op=http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert"
```

This example creates a WCF client class for both an insert operation and a delete operation on the ACCOUNT\ACCOUNT Business Object.

```
.\svcutil " siebel://Username=YourUserName;Password=YourPassword@Siebel_server:1234?
SiebelEnterpriseServer=ent_server&SiebelObjectManager=obj_mgr&Language=enu&wsdl&op=http://Microsoft.LobServices.Siebel/2007/03/BusinessObjects/Account/Account/Insert&op
```

Important

You must place the connection URI in quotation marks on the command line. Otherwise, svcutil.exe attempts to retrieve metadata for operations that the Siebel adapter does not support. The results of such an attempt are undefined.

By default, svcutil.exe places the generated code in the output.cs file; however, you can change the name of the output file and many other options that svcutil.exe uses by setting command-line switches.

Svcutil.exe does not provide the capability to search for operations (for example, by using wildcard characters). You must explicitly specify node IDs for the specific operations you want to target. You cannot specify node IDs that refer only to categories. For more information about the node IDs that the Siebel adapter surfaces, see [Metadata Node IDs](#).

The Add Adapter Service Reference Visual Studio Plug-in provides advanced browse and search capabilities that can greatly simplify generating a WCF client class. For more information about the Add Adapter Service Reference Plug-in, see [Generating a WCF Client for Siebel Artifacts](#).

Glossary

The following terms and definitions are used in Microsoft BizTalk Adapter for Siebel eBusiness Applications Help.

Microsoft BizTalk Adapter Pack Glossary

[A](#) [B](#) [C](#) [D](#) [E](#) [F](#) [G](#) [H](#) [I](#) [J](#) [K](#) [L](#) [M](#) [N](#) [O](#) [P](#) [Q](#) [R](#) [S](#) [T](#) [U](#) [V](#) [W](#) [X](#) [Y](#) [Z](#)

A

adapter	A WCF-based component that helps exchange messages between applications (for example, a line-of-business system) and BizTalk Server. The adapter consists of design-time components and run-time components for receive and send operations.
adapter client	Refers to an application that is interacting with a line-of-business (LOB) system through the adapter.

B

binding	A process by which software components and layers are linked together. When a network component is installed, the binding relationships and dependencies for the components are established. Binding allows components to communicate with each other. In BizTalk Server, an established mapping between an orchestration adapter-agnostic endpoint (port or role link) and physical adapter-specific endpoints (send/receive ports or party).
BizTalk Server	Connects diverse software. BizTalk Server enables you to create and modify process logic that uses that software. BizTalk Server also enables information workers to monitor running processes, interact with trading partners, and perform other business-oriented tasks.

C

channel	A concrete implementation of a binding element. The binding represents the configuration, and the channel is the implementation associated with that configuration. Therefore, there is a channel associated with each binding element. Channels stack on top of each other to create the concrete implementation of the binding: the channel stack.
connection URI	A string that identifies a resource in a distributed environment. Adapters use a connection Uniform Resource Indicator (URI) that contains the information necessary to establish a connection with the LOB system.
contract	Specifies the collection and structure of messages required to access the operations offered by the service.

D

design-time experience	Procedures and operations that a developer performs during design time; for example, using the Consume Adapter Service BizTalk Project Add-in to retrieve message schemas.
------------------------	--

E

endpoint address	A network address that identifies the location of a Windows Communication Foundation (WCF) service endpoint. For an adapter, the endpoint address is expressed as a connection Uniform Resource Identifier (URI) that contains location and connection parameters. The adapter can use these to establish a connection to the underlying line-of-business (LOB) system.
Enterprise Single Sign-on system	An SSO database, a master secret server, and one or more Enterprise Single Sign-On (SSO) servers. These servers do the mapping between the Windows and non-Windows credentials, look up the credentials in the SSO database, and are used for administering the SSO system. The SSO database is also used as a configuration store to hold custom configuration data for adapters.

Extensible Markup Language	A markup language designed to describe data. XML tags are not predefined.
----------------------------	---

G

GAC	See global assembly cache.
global assembly cache (GAC)	A machine-wide code cache that stores assemblies specifically installed to be shared by many applications on the computer. Applications deployed in the global assembly cache must have a strong name.

H

Health and Activity Tracking (HAT)	A user interface that enables specified data to be tracked. This interface can be used to monitor the health of the BizTalk server farm and to track and view specific events and messages.
------------------------------------	---

I

inbound operation	An operation that is invoked by a line-of-business (LOB) system on the adapter.
-------------------	---

M

metadata	Information, such as location, time, message size, and/or exception information.
Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK	The specifications for building BizTalk adapters using open standards based on Web services.

O

one-way	A message exchange pattern (MEP) in which the sender sends a message, but no response is returned by the receiver. In BizTalk Server, MEPs are referred to as communication patterns.
outbound operation	An operation that is invoked by the adapter on the line-of-business system (LOB).
output.cs	The default output file created by the ServiceModel Metadata Utility tool (svcutil.exe).

P

picklist	A field in a business component whose value is typically constrained to one of a set of values (akin to enumeration).
proxy	In WCF, refers to a managed-code object that implements the service contract exposed by a service. The WCF service model is based on the use of such proxies. In the WCF service model, the service contract is expressed as a .NET interface.

R

request-reply	A message exchange pattern (MEP) in which the sender sends a request message and expects a response message from the receiver. In BizTalk Server, MEPs are referred to as communication patterns. Depending on the messaging technology and the direction of the request message (inbound or outbound), this pattern is also called request-reply or solicit-response.
runtime experience	Procedures and operations performed by a developer during run time or when deploying a solution; for example, creating a physical port binding from the BizTalk Server Administration console.

S

schema	The structure for a message. A schema can contain multiple subschema.
--------	---

ServiceModel Metadata Utility tool	A command-line utility that is included with WCF. It is used to create service model proxy code from the service description (metadata) that is exposed by a WCF service such as an adapter. For outbound operations, the tool creates a WCF client class and helper code; for inbound operations, the tool creates a WCF service contract and helper code.
Siebel business component	Associates logically related columns from one or more tables into a single structure.
Siebel business object	Represents a logical grouping of business components.
Siebel business service	A collection of business service methods or functions that can be directly invoked in the Siebel system.
Siebel COM Data Control library	Contains interfaces that enable an external client like the Siebel adapter to connect and communicate with a Siebel Application Object Manager on a Siebel server.
Simple Object Access Protocol	See SOAP.
SOAP	A simple, XML-based protocol for exchanging structured and type information in decentralized, distributed environments. WCF is based on the exchange of SOAP messages between clients and services to invoke operations and return results.
SOAP message	A well-formed XML document. It should use the SOAP envelope and SOAP encoding namespaces and include an optional XML declaration, followed by a SOAP envelope (the root element), which is made up of an optional SOAP header and a SOAP message body.
SQL Server Integration Services	A component that is used to import, export, and transform data from different data sources. Previously called data transformation service (DTS).
SSIS	See SQL Server Integration Services.
SSO	See Enterprise Single Sign-on system.
strongly-typed data	A data set or result set that is bound to an underlying object type. Each row in a strongly-typed XML data set is composed of typed, named elements that correspond to fields of the underlying object type.
svcutil	See ServiceModel Metadata Utility tool.

U

Uniform Resource Identifier (URI)	See connection URI.
-----------------------------------	---------------------

W

WCF	See Windows Communication Foundation.
WCF channel model	A programming model that relies on several interfaces and other types. Channels provide a low-level programming model for sending and receiving messages.

WCF client	A client-application construct that exposes the service operations as methods. You can use the Add Adapter Service Reference Visual Studio Plug-in or the ServiceModel Metadata Utility Tool to generate a WCF client class from the metadata exposed by an adapter.
WCF LOB Adapter SDK	See Microsoft Windows Communication Foundation (WCF) Line of Business (LOB) Adapter SDK.
WCF service contract	A managed-code representation of the service contract. It is expressed as an interface in which classes and methods are attributed to define the service, operation, message, and data contracts used to communicate with a service. You can use the ServiceModel Metadata Utility tool or the Add Adapter Service Reference Visual Studio Plug-in to generate a WCF service contract from the metadata exposed by an adapter. You implement the WCF service contract to receive operations from an LOB system.
WCF service model	A WCF programming model in which a service is represented as a managed code object. The operations exposed by the service are represented as methods with strongly-typed data.
weakly-typed data	A data set or result set that is not bound to an underlying object type. Each row in a weakly-typed XML data set is composed of a collection of generic columns in which attributes describe the name and type of each element.
Web services	A unit of application logic providing data and services to other applications. Applications access XML Web services using standard Web protocols and data formats such as HTTP, XML, and SOAP, independent of how each XML Web service is implemented. XML Web services combine the best aspects of component-based development and the Web , and are a cornerstone of the Microsoft .NET programming model.
Web Services Description Language	An XML-based language that describes a service as a set of endpoints that operate on messages. The WSDL document describes the service contract, operation contracts, message contracts, and data contracts that a client must use to interface with the service.
Windows Communication Foundation (WCF)	A Microsoft service-oriented communication infrastructure. The framework inherently provides clients with a service programming model and a channel programming model for finer control of message exchanges.
WSDL	See Web Services Description Language.
WS-Metadata Exchange (MEX) endpoint	An endpoint exposed by a WCF service, such as an adapter, that implements the IMetadataExchange interface. A WS-Metadata Exchange endpoint can be used to retrieve a service description (WSDL) for operations exposed by an adapter on the target system.

X

XML	See Extensible Markup Language.
XML Schema definition language (XSD)	A schema language. An XML Schema defines the elements, attributes, and data types that comply with the World Wide Web Consortium (W3C) XML Schema Part 1: Structures Recommendation for the XML Schema Definition Language. The W3C XML Schema Part 2: Datatypes Recommendation is the recommendation for defining data types that are used in XML schemas. The XML Schema definition language enables you to define the structure and data types for XML messages.
XSD	See XML Schema definition language.

SiebelBindingConfigElement Constructor ()

Initializes a new instance of the [SiebelBindingConfigElement](#) Class.

Namespace: Microsoft.Adapters.Siebel

Assembly: Microsoft.Adapters.Siebel (in microsoft.adapters.siebel.dll)

Syntax

VB

```
'Declaration  
Public Sub New
```

C#

```
public SiebelBindingConfigElement ()
```

C++

```
public:  
SiebelBindingConfigElement ()
```

J#

```
public SiebelBindingConfigElement ()
```

JScript

```
public function SiebelBindingConfigElement ()
```

RemarksThe default constructor initializes any fields to their default values.

SiebelConnectionUri.SiebelGateway Property

Namespace: Microsoft.Adapters.Siebel

Assembly: Microsoft.Adapters.Siebel (in microsoft.adapters.siebel.dll)

Syntax

VB

```
'Declaration

<DescriptionAttribute("Machine name and port number (For e.g. SiebelServer:2321)")> _
<CategoryAttribute("Siebel Configuration")> _
<BrowsableAttribute(True)> _
Public Property SiebelGateway As String
```

C#

```
[DescriptionAttribute("Machine name and port number (For e.g. SiebelServer:2321)")]
[CategoryAttribute("Siebel Configuration")]
[BrowsableAttribute(true)]
public string SiebelGateway { get; set; }
```

C++

```
[DescriptionAttribute(L"Machine name and port number (For e.g. SiebelServer:2321)")]
[CategoryAttribute(L"Siebel Configuration")]
[BrowsableAttribute(true)]
public:
property String^ SiebelGateway {
String^ get ();
void set (String^ value);
}
```

J#

```
/** @property */
public String get_SiebelGateway ()

/** @property */
public void set_SiebelGateway (String value)
```

JScript

```
public function get SiebelGateway () : String

public function set SiebelGateway (value : String)
```

SiebelCommand Constructor ()

Initializes a new instance of the [SiebelCommand](#) Class.

Namespace: Microsoft.Data.SiebelClient

Assembly: Microsoft.Data.SiebelClient (in microsoft.data.siebelclient.dll)

Syntax

VB

```
'Declaration  
Public Sub New
```

C#

```
public SiebelCommand ()
```

C++

```
public:  
SiebelCommand ()
```

J#

```
public SiebelCommand ()
```

JScript

```
public function SiebelCommand ()
```

RemarksThe default constructor initializes any fields to their default values.
