

Supplementary figure 1: Distribution of fungal divisions among sampling sites (L = litter, H = humic horizon, S = summer, W = winter, 1 = site one, 2 = site two, 3 = site three)

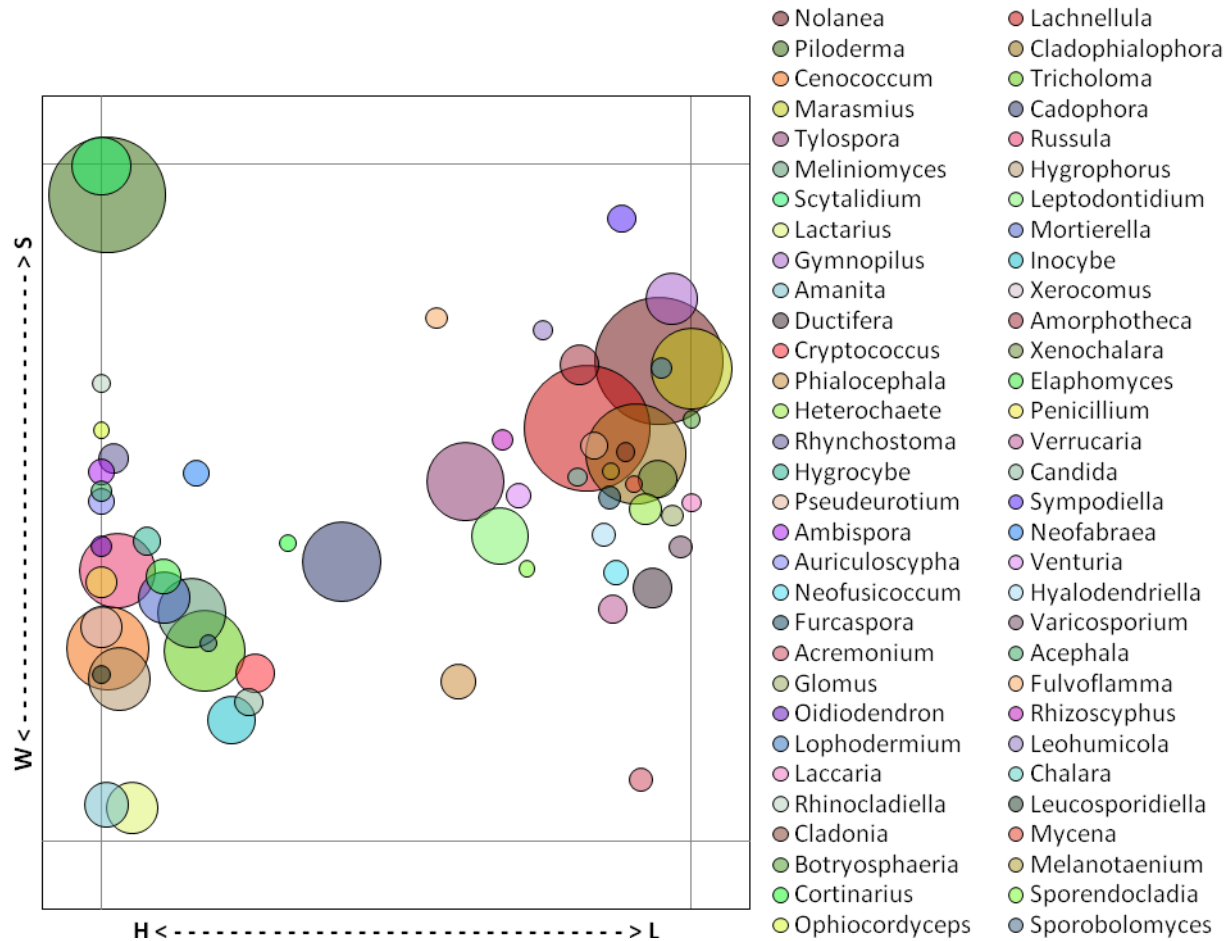

Notes to supplementary figures 2-13: Distribution of fungal sequences among horizons and seasons.

The S/W ratio indicates the relative abundance of certain taxon in the summer and is thus counted as the relative abundances in the LS + HS divided by the sum of LS + HS + LW + HW. The L/H indicates the preference of the taxon for the litter and soil and is calculated in the similar way. The position in the bottom left corner corresponds to exclusive occurrence in the soil in winter while that in the upper right corner indicates exclusive occurrence in the litter in summer. W = winter, S = summer, H = humus, L = litter

Supplement figure 2: 2D graph of genera with relative abundance over 20.

Most abundant genera of total fungal community

Supplement figure 3: 2D graph Basidiomycota

Supplement figure 4: 2D graph Agaricomycetes

Supplement figure 5: 2D graph Agaricales

Supplement figure 6: 2D graph Ascomycota

Supplement figure 7: 2D graph Dothideomycetes

Supplement figure 8: 2D graph Eurotiomycetes

Supplement figure 9: 2D graph Lecanoromycetes

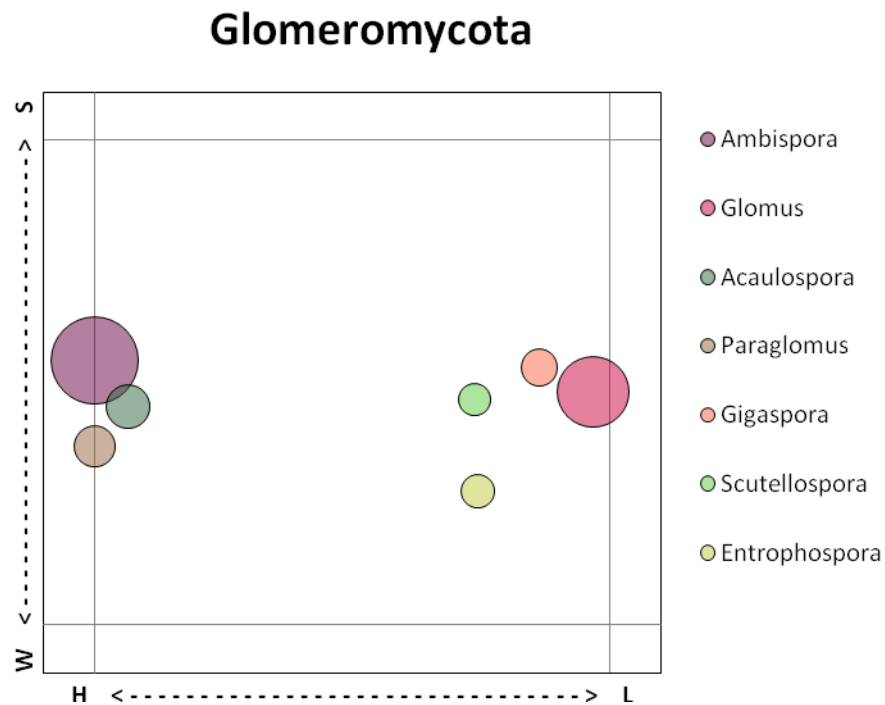

Supplement figure 10: 2D graph Sordariomycetes

Supplement figure 11: 2D graph Helotiales

Supplement figure 12: 2D graph Glomeromycota

Supplement figure 13: 2D graph Chytridiomycota

Supplement figure 14: 2D graph of genera that used to be in phylum Zygomycota

Supplementary figure 15: BioNJ phylogenetic tree based on *cbh1* sequences of 56 most abundant OTUs. Sequences in green are cloned *cbh1* of fungi isolated by growing method from the *P.abies* needles or gained from fungal collection according to Štrusová *et al.* (2012). Sequences are marked according horizon and the season they were found in. Red circle represents LS, orange HS, green LW and blue HW

Supplementary figure 16: BioNJ phylogenetic tree based on protein *Cbh1* sequences. Sequences in green are cloned *cbhI* of fungi isolated by growing method from the *P.abies* needles or gained from fungal collection based on Štrusová (2012). Sequences are marked based on horizon and the season they were found in.

Supplementary figure 17: BioNJ phylogenetic tree based on ITS sequences of most abundant genera (over 1%). Sequences are marked based on horizon and the season they were found in. The branch of cluster 43 was shortened 4x of the length of phylogenetic distance standard at the bottom.

Supplementary table 1: Overview of statistical analyses of fungal genera with relative abundances over 20. LS, HS, LW, HW represents sums of relative abundance in each horizon and season. Canoco, Anova and Stamp are three statistics used to test significance of environmental influences on species. In the last column are percentages of PlutoF taxonomic hit, which can be the range if there were more than 1 OTUs merged into the genera or by single number when genus is based on data from 1 OTU.
