Introduction

A minimum in the second potential well of deformed nuclei was predicted[1] and the associated shell gaps are illustrated in the harmonic oscillator potential shell energy surface calculations shown in figure 1[2,3]. A strong superdeformed minimum in ^{152}Dy was predicted for β_2~0.65[4,5,6]. Subsequently, a discrete set of γ-ray transitions in ^{152}Dy was observed[7] and assigned to the predicted superdeformed band. Extensive research at several laboratories has since focused on searching for other mass regions of large deformation[8-12]. A new generation of γ-ray detector arrays (Gammasphere, Eurogam, and GASP) is already producing a wealth of information about the mechanisms for feeding and deexciting superdeformed bands. These bands have been found in three distinct regions near A=130, 150, and 190. This research extends upon previous work in the actinide region near A=240 where fission (shape) isomers were identified and also associated with the second potential well[13]. Quadrupole moment measurements for selected cases in each mass region are consistent with assigning the bands to excitations in the second local minimum.

As part of our committment to maintain nuclear structure data as current as possible in the Evaluated Nuclear Structure Reference File (ENSDF)[14] and the *Table of Isotopes*[15], we have updated the information on superdeformed nuclear bands. As of April, 1994, we have compiled data from 86 superdeformed bands and 46 fission isomers identified in 73 nuclides for this report. Partial data for superdeformed bands and fission isomers are shown in the band drawings.

For each nuclide there is a complete level table listing both normal and superdeformed band assignments; level energy, spin, parity, half-life, magnetic moments, decay branchings; and the energies, final levels, relative intensities, multipolarities, and mixing ratios for transitions deexciting each level. Mass excess, decay energies, and proton and neutron separation energies are also provided from the evaluation of Audi and Wapstra [16].

For superdeformed bands we provide the following quantities.

Level energies: For SD bands, since the absolute level energies are not yet known, only relative values are given. In the drawings the SD bands are shown with a common baseline for convenient display of multiple bands in a nucleus.

Level half-lives: Measured values are quoted in the tables only.

Level spins: The spin value is generally given only for the first member of the SD band. This value is typically suggested by the authors and has some uncertainty (~1-2 $\hbar$) associated with it. Since linking to normal states is unobserved, except for tentative assignments in ^{133,135}Nd, there is no direct confirmation of these spins. The cascading transitions are all assumed as E2 which is consistent with angular correlation data and short level half-lives in several cases. The parities are not shown because of insufficient evidence at this time.

γ-ray energies: The energies are adopted from the most complete set of data for each band. We have not averaged values because uncertainties are not usually available. Typical energy uncertainties range from 0.1-0.3 keV for intense transitions to 2 kev for weaker γ-rays.

γ-ray intensities: The values given are relative intensities normalized to 1.0 for the most intense transition in the cascade. These values are generally read off of the intensity figures in the papers. Correction for internal conversion is assumed to have been applied. When more than one measurement exists, the most complete set of intensities has been chosen. Absolute intensities can be obtained by multiplying the relative intensities by the %-feeding in Table I.

Moments: Transition Quadrupole moments for SD states are deduced from Doppler broadening of γ-rays. The SD quadrupole moment is typically an average value for the band corresponding to the intrinsic (transition) moment. For fission isomers the quadrupole moments are also intrinsic. The values appear in the summary tables only.

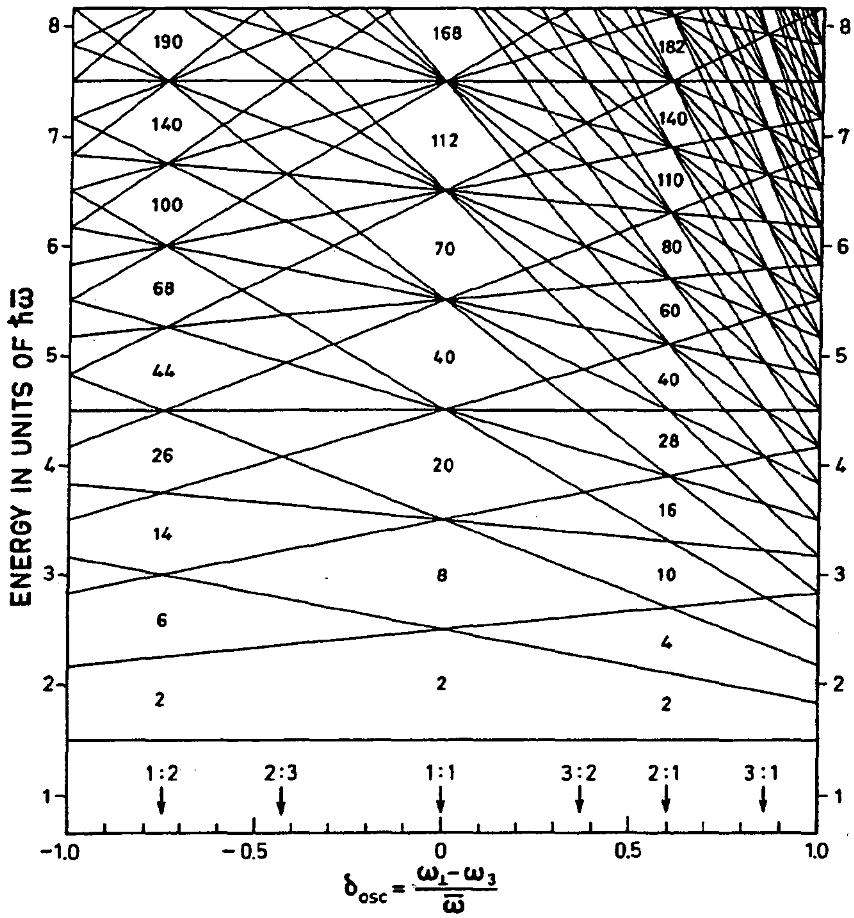

Figure 1. Single-particle level energies calculated for an axially symmetric harmonic oscillator (from reference 2).

The following calculated quantities[17,18] are provided (E_γ in MeV):

Rotational frequency:

$$\hbar\omega(J)=\frac{E_\gamma((J+2)\rightarrow J)+(E_\gamma(J\rightarrow(J-2))}{4}\ MeV$$

Kinetic moment of inertia†:

$$I_1(J)=\frac{2J-1}{E_\gamma(J\rightarrow(J-2))}\hbar^2\ MeV^{-1}$$

Dynamic moment of inertia:

$$I_2(J)=\frac{4}{E_\gamma((J+2)\rightarrow J)-E_\gamma(J\rightarrow(J-2))}\hbar^2\ Mev^{-1}$$

We have not attempted to label bands according to particle or intruder configurations or according to their isospectral behavior. The reader is referred to the original papers for information about reactions populating these bands and fission isomers. References with keyword abstracts have been provided from the Nuclear Structure Reference (NSR) file[19]. They are divided into three sections for superdeformed band experiment, superdeformed band theory, and fission isomers. The theoretical references before 1986 were not completely scanned for superdeformation.

We express our gratitude to the many nuclear data evaluators for creating the ENSDF file and to the staff at the National Nuclear Data Center at Brookhaven National Laboratory for maintaining ENSDF. Many useful suggestions were provided by members of the high-spin physics group at Lawrence Berkeley Laboratory. Special recognition should go to S.Y. Frank Chu, J.A. Cizewski, J.D. Garrett, and J.C. Waddington for their detailed comments and suggestions.
