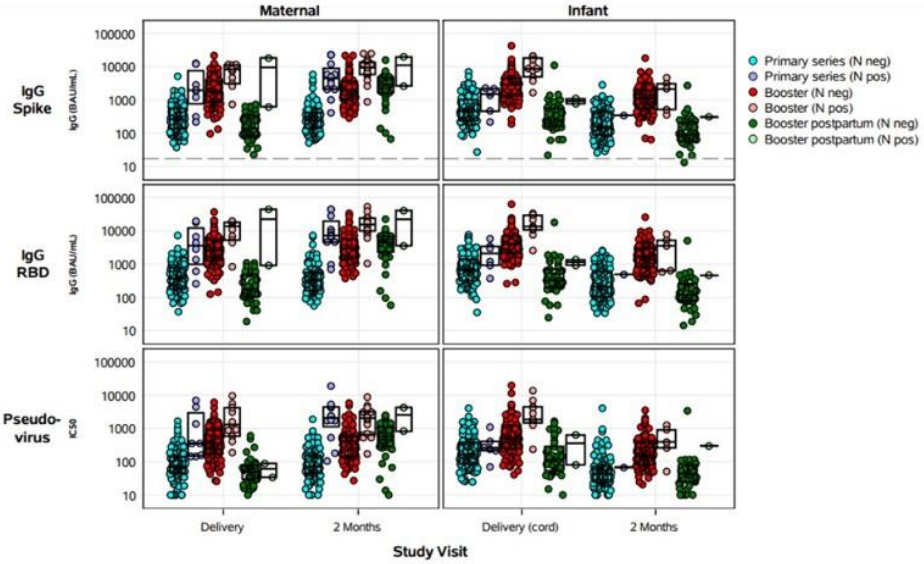
Backgrounds: The durability of immunity following COVID-19 vaccination during pregnancy or postpartum and the protection afforded by a booster dose are not well characterized. We measured immune responses in mothers and infants following maternal primary and booster COVID-19 mRNA vaccination during pregnancy or postpartum.
Methods: Prospective multicenter cohort study of participants enrolled after receipt of a primary 2-dose, or booster COVID-19 mRNA vaccination during pregnancy or a booster dose within 6-weeks postpartum. SARS-CoV-2 binding (IgG), live, and pseudovirus neutralizing antibody (nAb) titers were measured to Spike and RBD. Immune responses were compared between primary and booster vaccine recipients in maternal sera and cord blood at delivery, and maternal and infant sera at 2-months postpartum. Maternal infection status was assessed by medical history and detection of N-protein IgG.

Results:



110 maternal/infant dyads received a primary 2-dose series of either Pfizer or Moderna mRNA vaccine during pregnancy; 104 maternal/infant dyads received a booster vaccination during pregnancy, and 39 maternal/infant dyads received a postpartum booster. Maternal booster vaccination during pregnancy resulted in significantly higher GMT of Spike and RBD IgG, and pseudovirus nAb at delivery and 2-months postpartum in both mothers and infants compared with primary 2-dose series in pregnancy alone ($p<0.01$ for all comparisons). An increase in maternal titers was also seen at 2-months for mothers boosted postpartum. Similarly, maternal booster vaccination during pregnancy resulted in significantly higher live neutralizing antibodies to prototype, Omicron BA.1 and BA.5 strains in mothers and infants at delivery and 2-months post-delivery, compared to primary 2-dose vaccination ($p<0.01$ for all comparisons). Maternal infection increased GMT but numbers are low to evaluate impact.
Conclusions/Learning Points: Our data supports booster vaccination during pregnancy for optimal protection for the mother and newborn (through 2-months) against SARS-CoV2.

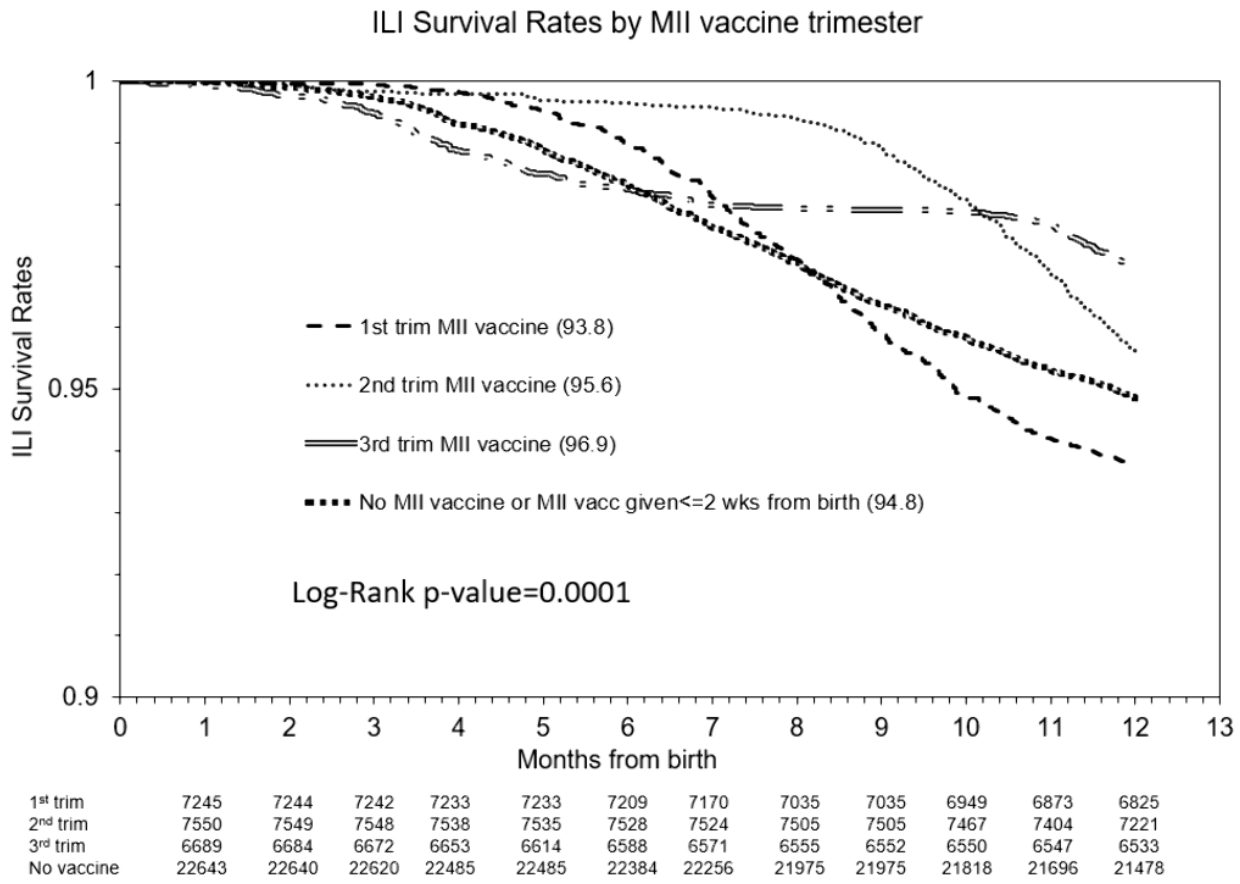
RISK OF INFLUENZA LIKE ILLNESS AMONG INFANTS BASED ON TIMING OF MATERNAL INFLUENZA VACCINE ADMINISTRATION DURING PREGNANCY

Joint Symposium
JOINT SYMPOSIUM: PIDS-ESPID: MATERNAL VACCINES AND INFANT PROTECTION: CURRENT EVIDENCE AND PRACTICES IN EUROPE AND THE U.S

Anne-Marie Rick[1], Helen D'Agostino[2], Judith Martin[1], G.K Balasubramani[2]
[1]University of Pittsburgh, Pediatrics, Pittsburgh, United States of America, [2]University of Pittsburgh, Epidemiology, Pittsburgh, United States of America

Backgrounds: Infants ≤12 months are at high risk of influenza. Maternal influenza immunization (MII) during pregnancy can protect infants from influenza, however, duration of protection and how it relates to vaccine timing during pregnancy is not well understood.
Methods: We used electronic health records from a retrospective cohort of mother-infant pairs of infants born January 1, 2012 to December 31, 2019 who received longitudinal care within a health system. We identified children ≤12 months with ILI based on a composite of influenza laboratory testing, influenza diagnosis codes, oseltamivir prescriptions and respiratory illness with objective fever. We compared Kaplan-Meier survival curves and hazard ratios (HR) for ILI by trimester of MII for all infants 0-12 months with logrank tests and multivariable cox regression, respectively. On secondary cox regression analysis, we analyzed ILI in infants 0-<6 months and ≥6-12 months separately.
Results: Of the 44,132 mother-infant pairs included, 4.9% (n=2163) of infants ≤12 months had ILI. 51.3% of women were unvaccinated for influenza during pregnancy, 48.7% were vaccinated (16.4% 1st trimester, 17.1% 2nd trimester, 15.2% 3rd trimester). Infants exposed to 3rd trimester vaccine were least likely to have ILI during the first year with 96.9% survival (Figure 1) and adjusted HR (aHR) 0.58 (95%CI: 0.5-0.67). However, these effects are age dependent as 1st and 2nd trimester vaccines significantly reduced HR for ILI among infants 0-6 months (aHR:0.61; 95%CI:0.48-0.78 and aHR:0.21;95CI:0.14-0.31, respectively) but not among infants 6-12 months. These time dependent changes are also reflected in the survival
curves.



1st trim	7245	7244	7242	7233	7233	7209	7170	7035	7035	6949	6873	6825
2nd trim	7550	7549	7548	7538	7535	7528	7524	7505	7505	7467	7404	7221
3rd trim	6689	6684	6672	6653	6614	6588	6571	6555	6552	6550	6547	6533
No vaccine	22643	22640	22620	22485	22485	22384	22256	21975	21975	21818	21696	21478

Conclusions/Learning Points: There are vast differences in protection from ILI during the first year based on timing of MII during pregnancy, which could have significant implications for administration of maternal and infant influenza vaccines warranting additional investigation.

O0003 / #2033

LINKS2HEALTHIERBUBS: A POPULATION-BASED LINKED RECORD STUDY EVALUATING POTENTIAL 'BLUNTING' EFFECTS OF MATERNAL PERTUSSIS VACCINATION ON CHILDHOOD VACCINE EFFECTIVENESS

Joint Symposium
JOINT SYMPOSIUM: PIDS-ESPID: MATERNAL VACCINES AND INFANT PROTECTION: CURRENT EVIDENCE AND PRACTICES IN EUROPE AND THE U.S

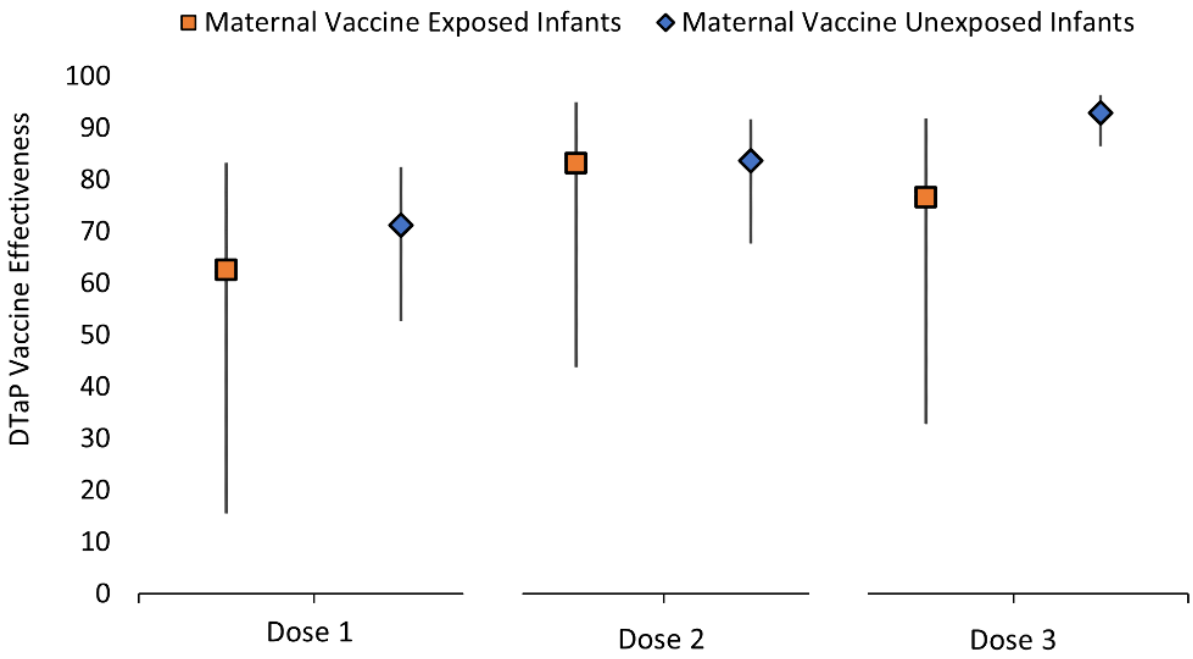
Backgrounds: Maternal pertussis immunisation is recommended to prevent infant infection; however, maternal antibodies may 'blunt' infant's responses to primary vaccination. Limited population-based data have evaluated these effects.
Methods: Links2HealthierBubs is a population-based cohort study using probabilistically linked administrative health records for mothers and their infants born in Northern Territory or Queensland between August 2014 and December 2017 (i.e., initial years of maternal pertussis vaccination programs). We used immunisation data to define the age of receipt of the primary three-dose series of infant DTaP-containing vaccine; infants were defined as exposed to maternal vaccine if mothers had a record of dTpa during pregnancy. We compared rates of pertussis infection by DTaP dose using Cox proportional hazard models with infant age as the underlying time scale and doses of DTaP as the time-varying exposure. DTaP vaccine effectiveness (VE) was estimated as one minus the hazard ratio (HR) and adjusted for child covariates. To evaluate potential 'blunting,' we included maternal vaccination as an effect modifier and compared rates of pertussis at each DTaP dose by maternal vaccination status.
Results: Among 171,840 mother-infant pairs, 87.3% of maternal vaccine-exposed and 76.6% of unexposed infants completed the three-dose series of infant DTaP. VE was similar by exposure status at first and second doses of DTaP but was lower at the third DTaP dose among exposed children (76.5% versus 92.9%; P=0.002); however, pertussis incidence after third dose was similar (20.7 vs. 23.1 cases per 100,000 infants, respectively) and the relative rate of pertussis infection was comparable between maternal vaccine groups (aHR 0.70; 95% CI 0.61,
3.39).



Conclusions/Learning Points: Our data show that maternally vaccinated infants are not more prone to pertussis infection after completing the primary series of DTaP-containing vaccine.

O0004 / #1408

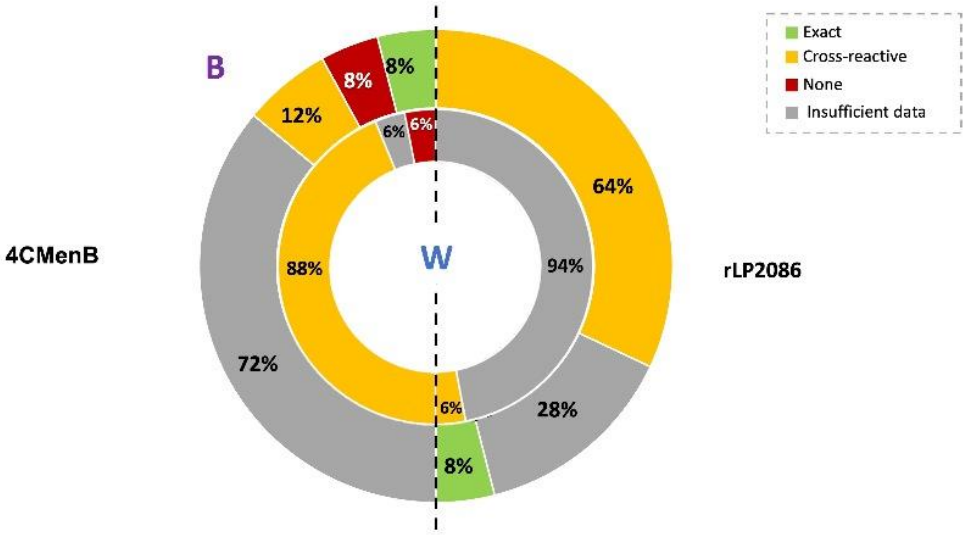
WHOLE GENOME SEQUENCING OF INVASIVE NEISSERIA MENINGITIDIS ISOLATED IN CHILDREN IN CHILE FROM 2016 TO 2019

Parallel Symposium
PARALLEL SYMPOSIUM: WHAT DOES THE FUTURE HOLD FOR NEISSERIA?

Cindy Arteta Acosta[1], Rodolfo Villena[2,3], Jorge Fernández[4], Maria Elena Santolaya[2,5]
[1]Universidad de Chile, Doctoral And Postgraduate Studies, Santiago, Chile, [2]Universidad de Chile, Infectious Diseases, Santiago, Chile, [3]Hospital Exequiel González Cortés, Infectious Diseases Unit, Santiago, Chile, [4]Instituto de Salud Publica de Chile, Molecular Genetic, Santiago, Chile, [5]Hospital Dr Luis Calvo Mackenna, Infectious Disease, Santiago, Chile

Backgrounds: The whole-genome sequencing (WGS) and bioinformatics tools have contributed to enhanced epidemiological surveillance and the impact of vaccination strategies. The aim of this study was to perform a genomic analysis and to evaluate the potential protection provided by two meningococcal vaccines (4CMenB and rLP2086).
Methods: Forty-two meningococcal genomes isolated from pediatric patients between 2016-2019 were obtained in fastaformat by the Public Health Institute of Chile. De novo assembly genomes were scanned by the BIGSdb platform to assign clonal complex (cc), molecular typing, BAST profile, vaccine antigens, and estimate vaccination coverage using MenDeVAR index.
Results: Serogroups classification were MenB 25 (59.5%), MenW 16 (38%), and MenC 1 (2.3%). For capsular genogrouping, 11 isolates contained serogroup-specific genes in cps locus, 8 were MenB and 3 were MenW. Many of the isolates were assigned to cc11 (39%), followed by cc41/44 (36.5%), and the most prevalent molecular typing were W:P1.5,2:F1-1:cc11 (33.3%) and B:P1.19,13-1:F1-18:cc41/44 (23.8%). The BAST-2 profile was present in 48% of the genomes (all cc11), and 13 new BAST profiles were identified in 16 bacteria. A 26% of genomes had peptide vaccine sequence FHbp-22, NHBA-29, NadA-6, PorA VR1-5, PorA VR2-2. The MenDeVAR index values showed that 80% (20/25) of MenB isolates had any type of vaccination coverage: 20% (5/25) by 4CMenB, and 72% (18/25) by rLP2086. A 72% and 28% of MenB had insufficient coverage data by 4CMenB and rLP2086, respectively. MenW cross-reactivity was 87.5% (14/16) by 4CMenB, and 6.2% (1/16) isolates by rLP2086. Figure 1

Figure 1. **Vaccination coverage of *N. meningitidis* serogroups B and W isolated in children in Chile from 2016 to 2019, using MenDeVAR index**



Conclusions/Learning Points: WGS analysis of meningococcus from Chile belong to the hypervirulent cc, having a molecular typing different from other countries. New recombinant MenB vaccines might afford for a variable protection against MenB and MenW.

USE OF EXPANDED NEISSERIA MENINGITIDIS SEROGROUP B (MENB) PANELS WITH THE SERUM BACTERICIDAL ANTIBODY (SBA) ASSAY IN THE EVALUATION OF MENB VACCINE EFFECTIVENESS

Parallel Symposium
PARALLEL SYMPOSIUM: WHAT DOES THE FUTURE HOLD FOR NEISSERIA?

Woo Yun Sohn[1], Ray Borrow[2], Federico Martinon-Torres[3], Veronique Abitbol[4], Anar Andani[5], Scott Preiss[1], Alessandro Muzzi[6], Larua Serino[6]
[1]GSK, Medical Affairs, Rockville, United States of America, [2]UKHSA, Meningococcal Reference Lab, Manchester, United Kingdom, [3]Hospital Clínico Universitario de Santiago, Translational Pediatrics And Infectious Diseases, Santiago de Compostela, Spain, [4]GSK, Medical Affairs, Rueil-Malmaison, France, [5]GSK, Medical Affairs, Wavre, Belgium, [6]GSK, Preclinical, Sienna, Italy

Backgrounds: Measurement of MenB vaccine effectiveness (VE) is complicated by diversity in antigen expression among MenB strains. Since using the classical human complement SBA assay (hSBA) against all circulating strains is not feasible, a new assay is required to assess VE against a large panel of disease-causing strains.
Methods: The characteristics of two methods for predicting MenB VE are discussed: hSBA using endogenous complement in each vaccinees' serum (enc-hSBA) against a panel of MenB isolates (110-strain), and classical hSBA using exogenous complement (exc-hSBA) against 14 (4+10) MenB strains.
Results: Enc-hSBA provides a binary assessment of killing activity elicited by vaccine-specific antibodies in individual vaccinees' sera, bypassing the need to identify suitable human complement. It accounts for inter-subject variability in bactericidal killing and synergistic effects of multiple MenB vaccine antigens. It was qualified using 110 representative disease-causing MenB strains, randomly selected from a 442-strain US panel, representing ~89% of strains circulating globally and 95% of US strains, including the most prevalent clonal complexes and genetic variants of MenB vaccine antigens. Exc-hSBA 4+10 is a titre-based measure of killing activity of the bivalent MenB-FHbp vaccine via hSBA against four primary and 10 additional MenB strains selected following evaluation of factor H-binding protein (fHbp) sequence diversity and expression in 1263/1814 strains. These 14 strains represent ~80% of circulating strains in the US and Europe.
Conclusions/Learning Points: Use of the hSBA against expanded MenB strain panels in VE assessments helps account for diverse circulating MenB strains. With a large panel of randomly selected strains and the vaccinee's own complement, the enc-hSBA assay aims to measure VE under conditions that are as close as possible to real-world settings.

COMPARISON OF 6 DOSES OF INTRAPLEURAL FIBRINOLYTIC THERAPY VS CONVENTIONAL 3 DOSES, IN CHILDREN WITH EMPYEMA- A PILOT RANDOMIZED CONTROLLED TRIAL

Joint Symposium
JOINT SYMPOSIUM: ERS-ESPID: PAEDIATRIC PNEUMONIA - MOLECULAR MICROBIOLOGY AND CLINICAL MANAGEMENT

Bisman Singh
Post Graduate Institute of Medical Education and Research, Pediatrics, Chandigarh, India

Backgrounds: Childhood pneumonia continues to be a significant public health problem, and nearly 10% pneumonias are complicated by parapneumonic effusions, with 1% progressing to empyema. In addition to appropriate antibiotic therapy, there is ample evidence supporting intrapleural fibrinolytic therapy. There is also limited evidence suggesting that six doses of intrapleural streptokinase may be superior to the conventional three doses. However, there is no well designed trial comparing six versus three doses delivered over the same period of time.
Methods: Children(<12y old) with empyema(standard definition) were randomised to Group A:Intrapleural streptokinase 15000 U/kg/dose, twice daily for 3 days(total 6 doses); or Group B:Intrapleural streptokinase 15000 U/kg/dose, once daily for 3 days(total 3 doses).The outcomes assessed were volume of fluid drained, duration of fever, respiratory distress, hospitalization, radiological evidence of collection after therapy completion, and need for surgical intervention.
Results: A total of 32 patients was enrolled. At the end of 3 days of fibrinolytics, the total fluid drained was higher among those who received 6 doses, median(IQR) in ml being 367(266-850), compared to those who received 3 doses, median(IQR) in ml being 195(142-422), p value 0.02.The mean(SD) duration of fever was shorter in children who received 6 doses,compared to three doses: 2.3(0.8) days vs 5.7(1.6) respectively, p 0.04. Similarly the mean(SD) duration of respiratory distress was significantly shorter in children who received 6 doses SK, compared to three doses: 2.2(0.9) days,vs 6.3(1.9) days p 0.03. There were no differences however, in the duration of hospitalization, intercostal drainage, cost of therapy. There were no significant adverse effects, or other situations necessitating cessation or deferment of streptokinase doses.
Conclusions/Learning Points: Six doses of intrapleural streptokinase appears superior to the conventional three doses in children with empyema; with comparable safety.

O0007 / #1185

THE DYNAMICS OF HOSPITALIZATIONS FOR COMMUNITY-ACQUIRED ALVEOLAR PNEUMONIA (CAAP) IN CHILDREN UNDER 24 MONTHS DURING THE FIRST AND SECOND COVID-19 PANDEMIC-YEARS

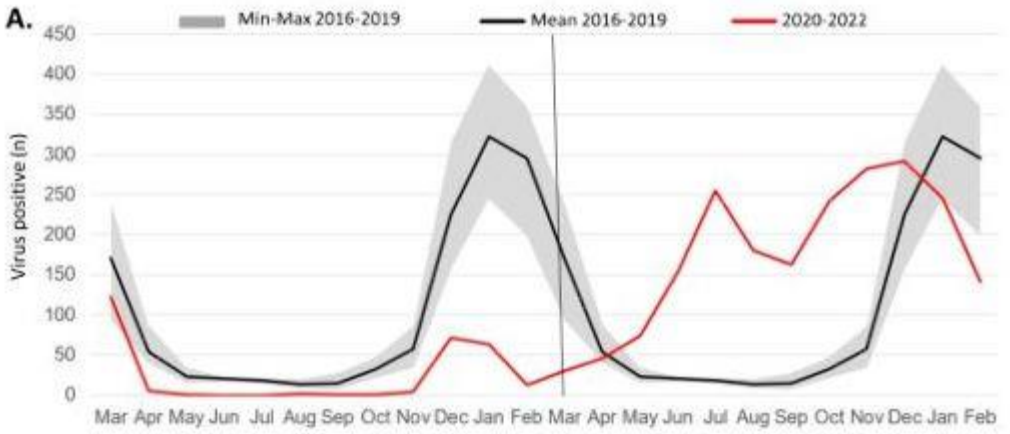
Joint Symposium
JOINT SYMPOSIUM: ERS-ESPID: PAEDIATRIC PNEUMONIA - MOLECULAR MICROBIOLOGY AND CLINICAL MANAGEMENT

Dana Danino[1,2], Bart Van Der Beek[3], Shalom Ben-Shimol[1,2], David Greenberg[1,2], Ron Dagan[3]
[1]Ben Gurion University, Faculty Of Health Sciences, Beer Sheva, Israel, [2]Soroka University Medical Center, Pediatric Infectious Disease Unit, Beer Sheva, Israel, [3]Ben-Gurion University of the Negev Faculty of Health Sciences, The Shraga Segal Dept. Of Microbiology, Immunology And Genetics, Beer Sheva, Israel

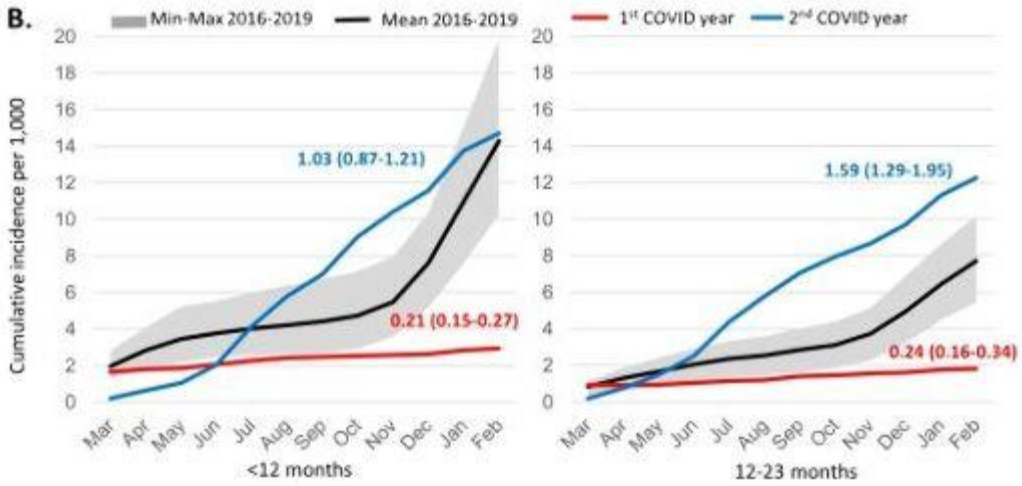
Backgrounds: We have previously demonstrated that the seasonal activity of specific respiratory viruses (RSV/hMPV/influenza/parainfluenza, termed here "LRI-viruses") contributed a major attributable factor in hospitalization for CAAP (CAAP-HOSP) in young children, during the first COVID-19 pandemic year, temporary disappearance of these viruses resulted in a dramatic reduced CAAP-HOSP in <24m old children. During the second pandemic year, both LRI-viruses and CAAP-HOSP reemerged. We evaluated the yearly cumulative rates for CAAP-HOSP in children <12m and 12-23m in parallel to the LRI-viruses during the first and second pandemic years.
Methods: This is an ad-hoc analysis, based on data from prospective surveillance on viral activity and CAAP-HOSP in southern Israel in 2016-2022 (Dagan, medRxiv 2022, doi: https://doi.org/10.1101/2022.09.06.22279606). Cumulative monthly incidence rates during first and second pandemic years were compared to those during 2016-2019 (pre-pandemic).
Results: During the pre-pandemic period, the cumulative incidence of CAAP-HOSP in children <12m was 1.9 (95%CI, 1.5:2.3) times higher than that in 12-23m (Figure 1B). In general, dynamics in cumulative rates for each age group followed LRI-virus activity in the community (Figure 1A+B). In the first pandemic year, cumulative rates of CAAP-HOSP were reduced by 79.5% (95%CI, 72.8; 84.6) and 76.4% (95%CI, 66.1; 83.6) in children <12m and 12-23m, respectively. In contrast, during the second pandemic year cumulative rates returned to expected in the <12m, but exceeded the expected rates in the 12-23m group. When the cohort of <12m, enrolled during the first pandemic year, was followed for the two successive pandemic years, their 2-year cumulative CAAP-HOSP rate remained significantly lower than expected. (Figure

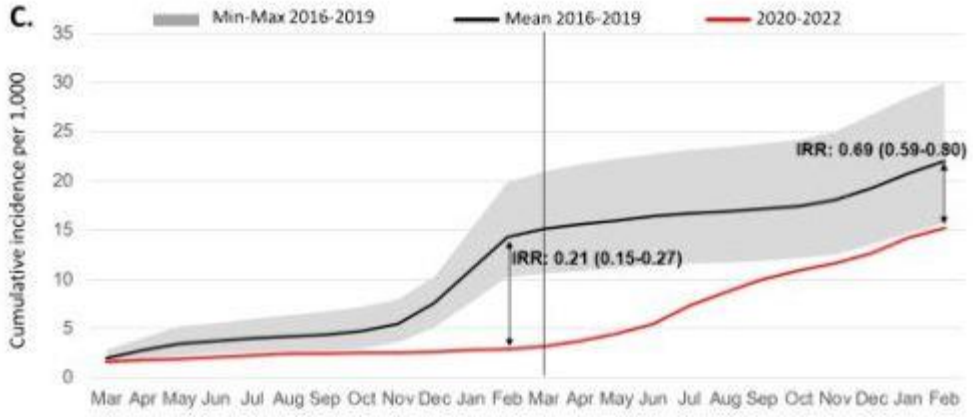
Figure 1:

Dynamics of monthly LRI-virus activity, mean March 2016 through February 2019 *vs.* March 2020 through February 2022, in children <5 years of age, southern Israel



Cumulative monthly CAAP incidence rates, mean March 2016 through February 2019 *vs.* March 2020 through February 2022, in children <24 months of age





1C)

Conclusions/Learning Points: The major variations of LRI-virus activity observed during the first two years of the COVID-19 pandemic resulted in parallel dynamics in CAAP-HOSP in children <24m in southern Israel.

Backgrounds: Between September 2022 and January 2023, UK-based paediatricians noted an increase in cases of invasive group A Streptococcal infections (iGAS);with 343 cases and 29 deaths reported. These cases have occurred outside of the usual seasonality of this pathogen and included an unusually high proportion of pneumonias with parapneumonic effusion.
Methods: Case series of 24 children admitted to 3 UK hospitals between 20th October and 16th December 2022, with microbiologically confirmed/high clinical suspicion of group A streptococcal pneumonia with parapneumonic effusion. Pseudonymised clinical data obtained from medical records.
Results: Median patient age was 4 years, only 9(38%) female, and 20(83%) previously healthy. Commonest presenting features were fever, cough, difficulty breathing, rash and lethargy. Fifteen(63%) children had healthcare professional review prior to admission. Sixteen(67%) children had viral co-infection detected at admission(see Table 1). Twenty-two(92%) children had unilateral pneumonia with parapneumonic effusion, 2(8%) children had bilateral pneumonia with effusion. Twenty children(83%) had chest drain inserted, 15(63%) also requiring urokinase. Two children later required VATS. Nine cases had culture data available; no macrolide resistance was detected. Duration of fever after admission was prolonged (median 12 days). Intravenous antibiotic courses varied in length (7-42 days; median 15), with each child receiving 2-5 different

drugs.

Conclusions/Learning Points: Children presented with initial symptoms which would be difficult to distinguish from viral infection, illustrated by the frequency of contact with medical services prior to admission. Many cases occurred with co-existent respiratory viral infections, a previously well-recognised risk with influenza A and VZV. The variance in intravenous treatment length highlights the limited available antibiotic guidance. Prolonged fever in many cases induced escalation to broad-spectrum

antibiotics (for a pathogen universally penicillin-sensitive). MDT discussion is encouraged and national data collection underway to standardise future management.

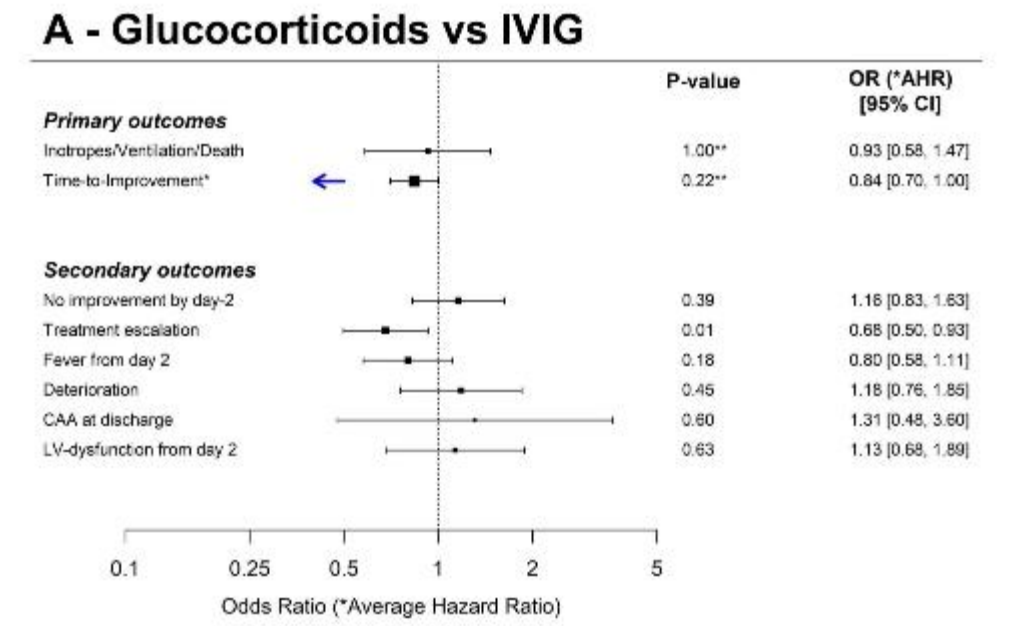
Backgrounds: Intravenous immunoglobulin (IVIG) and/or glucocorticoids are currently the recommended initial treatment for Multisystem Inflammatory System in Children (MIS-C). Evidence comparing their use, individually or in combination, is limited.
Methods: We collected clinical data and outcomes for MIS-C patients from paediatricians around the world, as part of the "Best Available Treatment Study" to evaluate different immunomodulatory treatments. Inverse probability weighting was used to compare primary treatments with IVIG, glucocorticoids, or combined therapy (IVIG+G), using IVIG as reference treatment, adjusting for baseline differences in treatment groups. Primary outcomes were: a composite of inotropic or ventilator support from the second day after treatment initiation, or death; and time-to-improvement on an ordinal clinical severity scale. Extensive secondary outcomes were also studied.
Results: After exclusions 2009 children from 39 countries were enrolled at 121 sites with clinically diagnosed MIS-C, between May 2020 and April 2022. 680 patients received primary treatment with IVIG; 487 glucocorticoids; and 698 IVIG+G. No significant differences in primary outcomes were seen between treatment groups: adjusted odds ratios relative to IVIG for ventilation, inotropic support or death were 1.09 (95% confidence interval [CI] 0.75-1.58) for IVIG+G, and 0.93 (95% CI: 0.58-1.47) for glucocorticoids alone (fig1). Adjusted average hazard ratios for time-to-improvement were 1.04 (95% CI: 0.91-1.20) and 0.84 (95% CI: 0.70-1.00) respectively. Treatment escalation was less frequent for IVIG+G and glucocorticoids vs IVIG. Persistent fever was less common with IVIG+G. Coronary artery aneurysm occurrence and resolution did not differ significantly between

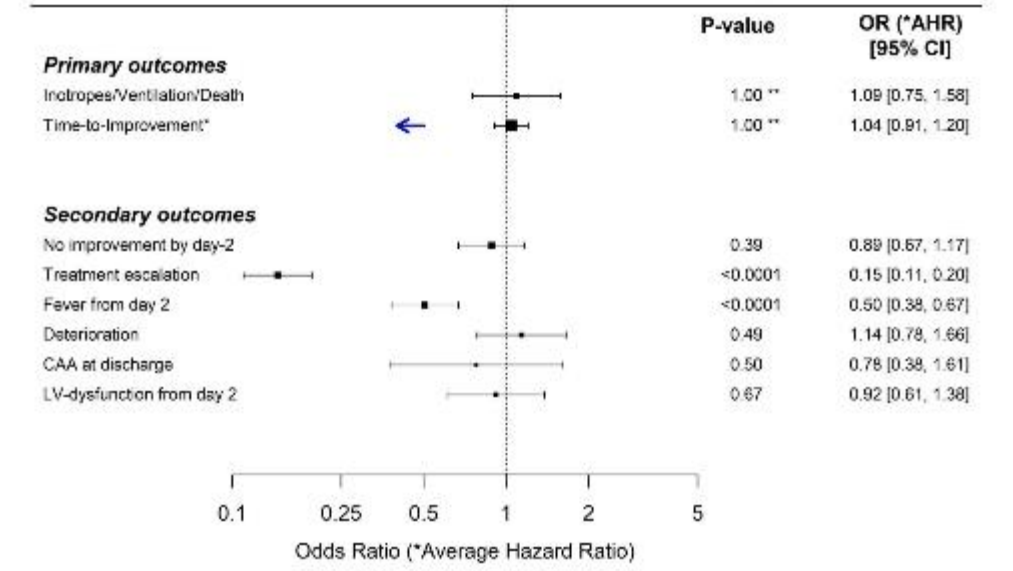
Figure 1 | Forest plots for primary and secondary outcomes

*Shown are outcomes for persons with suspected MIS-C who received steroids alone (Panel A) or IVIG plus steroids (Panel B) compared with those who received IVIG alone (reference group, indicated by an odds ratio or average hazard ratio of 1.00). Displayed values are adjusted odds ratios (or average hazard ratios for time-to-event analysis, indicated by *). Values to the right of the dotted line indicate superiority of IVIG alone, except for time to event analysis, where values to the left indicate superiority of IVIG alone (indicated by blue arrow).*

***Indicates p-values correction for multiple hypothesis testing using the Benjamini-Hotb procedure across all primary outcomes*

Abbreviations: IVIG: Intravenous immunoglobulin; IVIG+S: IVIG and Steroids; OR: Odds-ratio; AHR: Average Hazard Ratio; CAA: Coronary Artery Aneurysms; LV: Left ventricular





treatments.

Conclusions/Learning Points: Initial treatment with either glucocorticoids or IVIG alone appears to be an acceptable alternative to combined therapy for MIS-C, supporting the adoption of glucocorticoids monotherapy as initial treatment, in view of the cost and limited availability of IVIG in many countries.

O0010 / #470

DEVELOPMENT OF A PREDICTIVE MODEL FOR CARDIAC DYSFUNCTION IN PEDIATRIC MIS-C PATIENTS: RELEVANCE OF LABORATORY BIOMARKERS

Parallel Symposium
PARALLEL SYMPOSIUM: COVID-19 IN CHILDREN: PIMS-TS

Guliz Erdem[1], Brendan Galdo[1], Steve Rust[2], Brent Merryman[2], Diego Cruz Vidal[3], Roshini Abraham[4]
[1]Nationwide Children's Hospital, Information Science, Columbus, OH, United States of America, [2]Nationwide Children's Hospital, Information Science, Columbus, United States of America, [3]Nationwide Children's Hospital, Pediatrics, Division Of Infectious Diseases., Columbus, United States of America, [4]Nationwide Children's Hospital, Information Science, Columbus OH, United States of America

Backgrounds: We developed a preliminary predictive algorithm for left ventricular systolic dysfunction (LVSD) or coronary artery anomalies (CAA) in patients with MIS-C.
Methods: Laboratory and clinical data were collected by retrospective chart review during a 21-month period. Laboratory data included absolute lymphocyte count (ALC), albumin (ALB), sedimentation rate (SED), C-reactive protein (CRP), procalcitonin (PROCAL), d-dimer, fibrinogen (FIBR), ferritin (FERR), IL-6, lymphocyte subsets (TBNK). The Spearman correlation between the variables was assessed. Changes across time was determined using spline regression. A regularized logistic regression model was created to predict LVSD and CAA within 24 hours of admission. The performance of this predictive model was assessed using repeated cross-validation.
Results: Of 160 children with MIS-C, 69 (43%) had LVSD and 27 (17%) had CAA. The time-based analysis found univariate differences in mean ALB, ALC, CRP, FIBR, PROCAL at specific time-points with vs. without LVSD. Differences in CRP, FIBR, PROCAL were notable early on with the mean difference being observed in the first 24 hours. We found differences in mean FERR, d-dimer levels for CAA patients. The best LVSD predictive model performed well with mean cross-validated AUC of 0.78. The predictive biomarkers selected by the LVSD model included: CRP, PROCAL, FIBR, SED, IL6, absolute NK cell count. The best model for CAA performed poorly with mean cross-validated AUC of 0.57.
Conclusions/Learning Points: We used machine-learning methods to construct mathematical models and identified widely available biomarkers to successfully predict systolic dysfunction in MIS-C patients. Highest risks of systolic dysfunction were with higher peak CRP, PROCAL, FIBR early on; and lower ALB and ALC at days 2 and 3 post-admission. Patients with CAA had higher FERR, d-dimer levels, but the effect sizes were small making them less relevant as predictive biomarkers.

O0011 / #1778

CORONARY ANEURYSMS IN MULTIINFLAMMATORY SYNDROME (MIS-C): TREATMENTS PREVENTING THEM, AND RISK FACTORS

Parallel Symposium
PARALLEL SYMPOSIUM: COVID-19 IN CHILDREN: PIMS-TS

Backgrounds: Multisystem inflammatory syndrome in children (MIS-C) can complicate with coronary aneurysms (CAA). We aimed to investigate if treatments given for the MIS-C can prevent the development of CAA. Secondary aims included to find baseline risk factors associated with the development of aneurysms.
Methods: This is an ESPID-nested, multicenter, collaborative, retrospective-prospective cohort study, including hospitalized pediatric patients (0-18 years) from 2 national cohorts of MIS-C (Poland and Spain), and a regional cohort (Catalonia). Clinical and laboratory variables potentially associated with CAA and treatments administered prior to the diagnosis of aneurysms were analyzed univariate logistic model for the treatments and a Cox regression model for the variables associated with CAA considering treatment a time dependent covariate. Ethic committees approved the study.
Results: 872 patients with MIS-C were included, 520 (59.6%) from Poland, 248 (28.4%) from Spain, and 104 (11.9%) from Catalonia. Prior to the diagnosis of aneurysms (or if no aneurysms, during the admission), patients received either steroids (n=85, 9%), or IVIG (n=145, 16%), or both (n=549, 63%), or both plus biological agent (n=12, 1.3%), or none (n=81, 9%). Aneurysms were diagnosed in 67 (7.7%) patients. The variables associated with the risk of CAA were younger age (HR, 1.33; CI95%:1.08-1.63), criteria for KD (HR, 9.4; CI95%:1.39-64.3), and lower hemoglobin (HR, 2.39; CI95%:1.23-4.65). In the univariable logistic model, not receiving treatment increased the risk of CAA compared to steroids (OR, 14.5; CI95%, 4.0-93), IVIG (OR, 6.9; CI95%, 2.9-18.3), and steroids+IVIG (OR 4.9; CI95%, 2.7-9.04). Biological agents added no benefit (OR 3.8; CI95%, 0.6-72).
Conclusions/Learning Points: Risk factors for the development of aneurysms included younger age, KD criteria, and lower hemoglobin. All treatments prevented aneurysms compared to no treatment. In this analysis, no treatment showed any benefit compared to the others.

EFFICACY AND SAFETY OF TAKEDA'S TETRAVALENT DENGUE VACCINE CANDIDATE (TAK-003) AFTER 4.5 YEARS OF FOLLOW-UP: RESULTS FROM PARTICIPANTS IN BRAZIL

Joint Symposium
JOINT SYMPOSIUM: ARBOVIRAL DISEASES - A LATIN AMERICAN PERSPECTIVE

Denise Abud[1], Shibadas Biswal[2], Eric Lloyd[2], Vianney Tricou[3], Nicolas Folschweiller[3]
[1]Takeda, Medical Affairs Vaccines, São Paulo, Brazil, [2]Takeda, Vaccines Business Unit, Cambridge, United States of America, [3]Takeda, Vaccine Business Unit, Zurich, Switzerland

Backgrounds: Dengue is a major public problem in Brazil; therefore, an effective vaccine against dengue is needed to reduce the disease burden. An ongoing, long-term phase 3 trial has evaluated the efficacy and safety of Takeda's tetravalent dengue vaccine candidate (TAK-003) on children/adolescents across eight dengue-endemic countries. We present the results of 4.5 years of follow-up, including a subgroup analysis of participants from Brazil.
Methods: TIDES (NCT02747927) is a multicenter, double-blind, placebo-controlled trial of TAK-003 among 20,099 healthy children/adolescents aged ≥4 to ≤16 years at enrolment across Asia and Latin America. Participants were randomized 2:1 to receive two doses of TAK-003/placebo, subcutaneously, three months apart. Safety was evaluated, and participants were under active febrile illness surveillance for symptomatic dengue. A serotype-specific RT-PCR was used to identify virologically confirmed dengue (VCD).
Results: Overall, 20,071 participants received ≥1 dose of TAK-003/placebo; 91% completed the 54-month post-vaccination follow-up; 27.7% were seronegative at baseline. In total, 27,684 febrile illnesses were reported. Of these, 5.8 % placebo and 2.5% TAK-003 participants had VCD. The vaccine efficacy (VE) to 4.5 years of follow-up was 61.2% (95% CI 56.0–65.8) against VCD (64.2% for baseline seropositive and 53.5% for baseline seronegative participants) and 84.1% (95% CI 77.8–88.6) against hospitalization. Overall, there were slightly more serious adverse events in the placebo group. In Brazil, 1,773 participants received ≥1 dose of TAK-003/placebo. VE was 82.2% (61.8–91.8) against VCD; 2 participants in the placebo group were hospitalized versus 0 in the TAK-003 group.
Conclusions/Learning Points: TAK-003 was well tolerated and efficacious against dengue fever over 4.5 years in children/adolescents. The analyses from the Brazil subgroup were consistent with the overall results. Support: Study and medical writing support was funded by Takeda.

EFFICACY AND SAFETY OF BUTANTAN-DV LIVE-ATTENUATED TETRAVALENT DENGUE VACCINE OVER TWO YEARS IN A PHASE 3 CLINICAL TRIAL

Joint Symposium
JOINT SYMPOSIUM: ARBOVIRAL DISEASES - A LATIN AMERICAN PERSPECTIVE

Monica Cintra[1], Jose Moreira[1], Elizabeth Patino[1], Patricia Emilia Braga[1], Patricia Carneiro[1], Lucas Alves[1], Juliana Tenorio[1], Esper Kallas[1,2], Mauricio Nogueira[3], Alejandra Esteves-Jaramillo[4], Tulin Shekar[4], Jung-Jin Lee[4], Julieta Macey[4], Sabrina Gozlan Kelner[4], Beth-Ann Coller[4], Fernanda Castro Boulos[1]
[1]Instituto Butantan, , San Paulo, Brazil, [2]Hospital das Clínicas da Faculdade de Medicina, Usp-sp, Sao Paulo, Brazil, [3]Faculdade de Medicina de Sao Jose do Rio Preto, Famerp, Sao Paulo, Brazil, [4]Merck & Co., Inc., Rahway, United States of America

Backgrounds: Butantan-DV is a live-attenuated tetravalent dengue vaccine produced by Instituto Butantan analogous to TV003 developed by the US National Institutes of Health. We assessed the efficacy and safety of Butantan-DV in participants ages 2-59.
Methods: Participants were stratified by age (2-6, 7-17, and 18-59 years old) and randomized 2:1 to receive a single dose of Butantan-DV or placebo in an ongoing, phase III, double-blind trial conducted in 16 sites across Brazil, with projected five years follow-up (NCT02406729). The primary objectives were to describe the safety up to Day 21 and to evaluate vaccine efficacy (VE) to prevent symptomatic virologically confirmed dengue (VCD) by RT-PCR after Day 28 postvaccination to any dengue virus (DENV) serotype and regardless of participants' baseline serostatus. VE was assessed through the first 2 years of follow-up. Safety was evaluated as the frequency of participants with solicited (local and systemic) vaccine-related adverse events (AEs). Secondary objectives, VE by baseline serostatus and by serotype, were also evaluated.
Results: 16,235 participants were enrolled and received Butantan-DV (n=10,259) or placebo (n=5,976) between 2016 and 2019. Non-serious, solicited systemic vaccine-related AEs were observed in a slightly higher proportion of participants receiving Butantan-DV (58.3%) compared to placebo (45.6%) within 21 days postvaccination. The overall 2-year VE was 79.6% (95% CI:70.0%-86.3%). Regarding baseline serostatus, overall VE was 73.6% (95% CI:57.6%-83.7%) in dengue-naïve participants and 89.2% (95% CI:77.6%-95.6%) in dengue-experienced participants. Serotype-specific VE was 89.5% (95% CI:78.7%-95.0%) against DENV1 and 69.6% (95% CI:50.8%-81.5%) against DENV2. No cases of DENV3 or DENV4 were observed during the first 2 years.
Conclusions/Learning Points: A single dose of Butantan-DV was generally well tolerated and efficacious against DENV1 and DENV2 symptomatic VCD, regardless of baseline serostatus, through the first 2 years of follow-up.

O0014 / #1934

SIGNIFICANTLY LOWER INFECTION FATALITY RATES ASSOCIATED WITH SARS-COV-2 OMICRON INFECTION IN CHILDREN: ACTIVE, PROSPECTIVE NATIONAL SURVEILLANCE, JANUARY-MARCH 2022, ENGLAND

Parallel Symposium
PARALLEL SYMPOSIUM: LEARNING FROM COVID

Erjola Hani[1], Marta Bertran[2], Annabel Powell[1], Hannah Williams[1], Paul Birrell[1], Daniela Deangelis[3], Mary Ramsay[2], Godwin Oligbu[4], Shamez Ladhani[2,5,6]
[1]UK Health Security Agency, Immunisations And Vaccine Preventable Diseases, London, United Kingdom, [2]UK Health Security Agency, Immunisations And Vaccine Preventable Diseases Division, London, United Kingdom, [3]University of Cambridge, Department Of Primary Care And Public Health, Cambridge, United Kingdom, [4]NHS Scotland, Nhs, Scotland, United Kingdom, [5]St George's, University of London, Centre For Neonatal And Paediatric Infection, London, United Kingdom, [6]UK Health Security Agency, Respiratory And Vaccine Preventable Bacteria Reference Unit, London, United Kingdom

Backgrounds: Children and young people (CYP) have a very low risk of severe or fatal COVID-19, especially when compared to adults. Detailed follow-up of COVID-19 deaths in CYP in England between 01 March 2020 and 31 December 2021 showed 91% of deaths occurred within 30 days of testing, mainly in CYP with severe and/or life-limiting underlying conditions. We extended our previous analysis to include deaths during the first Omicron variant wave, when the BA1/BA.2 subvariants were circulating in England.
Methods: CYP aged <20 years who died within 30 days of laboratory-confirmed SARS-CoV-2 infection between 01 January 2022 and 31 March 2022 in England were followed up in detail, using national databases, surveillance questionnaires, post-mortem reports, and clinician interviews. Infections were estimated through real-time, nowcasting modelling.
Results: Out of 46 deaths within 30 days of COVID-19 during the 3-month follow-up period, 11 (23.9%) were due to COVID-19. All deaths followed a primary COVID-19 infection, seven (66%) were male, six were White (55%) and eight (73%) had underlying comorbidities, including four with severe neurodisabilities. All but one were hospitalised. Over the 3-month surveillance period, SARS-CoV-2 was responsible for 1.0% (10/1,003) of all deaths in CYP aged <20 years. The infection fatality rate (IFR) was lower than that of the previous study period overall (0.1/100,000 vs. 0.7/100,000) and for all age groups. IFR during the Omicron wave was lower than in the first pandemic wave (1.0/100,000; 21/2,062,780), alpha (0.8/ 100,000; 15/1,980,140) and delta (0.7/100,000; 81/11,629,407) waves.
Conclusions/Learning Points: Despite very large infections during the Omicron wave, COVID-19 deaths remained extremely are in CYP with IFR being lower during Omicron than all preceding waves. Most fatalities involved CYP with severe comorbidities, especially neurodisabilities, similar to previous variant waves.

Backgrounds: Variants of SARS-CoV-2 have emerged over the course of the COVID-19 pandemic, resulting in changes in transmissibility and pathogenicity in adults. The implications for COVID-19 severity in children world-wide are unclear.
Methods: Clinical data from hospitalised children (<18 years) who were SARS-CoV-2 PCR positive were

obtained from 9 countries during three time frames: T1 ancestral cohort; T2 pre-Omicron cohort; and T3 Omicron cohort. Age groups were aligned with the vaccine age groups: < 6 months, 6 months to < 5 years and 5 to <18 years. Site-specific estimates were calculated, modelling the relative risk (RR) of each clinical outcome by age category, and combined in a meta-analysis. Children with an incidental positive test were excluded.
Results: Of the 31,785 children included, 5,438 (17.1%) were categorized in the T1 ancestral cohort, 15,205 (47.8%) in the T2 pre-Omicron cohort and 11,142 (35.1%) in the T3 Omicron cohort. In children < 5 years of age over the pandemic, there was a reduction in ICU admission (T3 vs T1: RR 0.56, 95% CI, 0.42-0.75; [children <6 months], RR 0.61, 95% CI, 0.47–0.79 [6 months – < 5 years]), but not ventilation or oxygen support. In contrast, ICU admission (T3 versus T1: RR, 0.39, 95% CI, 0.32–0.48), ventilation (T3 versus T1: RR, 0.37, 95% CI, 0.27–0.51) and oxygen therapy (T3 versus T1: RR, 0.47, 95% CI, 0.32-0.7) all decreased in those aged 5 to <18 years old. The results were consistent when restricted to data from unvaccinated children aged 5 to <18 years.
Conclusions/Learning Points: These data reveal that COVID-19 severity assessed by ICU admission, ventilation and oxygen support decreased over time for children aged 5-18 years, whereas ventilation and oxygen support did not decline in hospitalised children < 5 years.

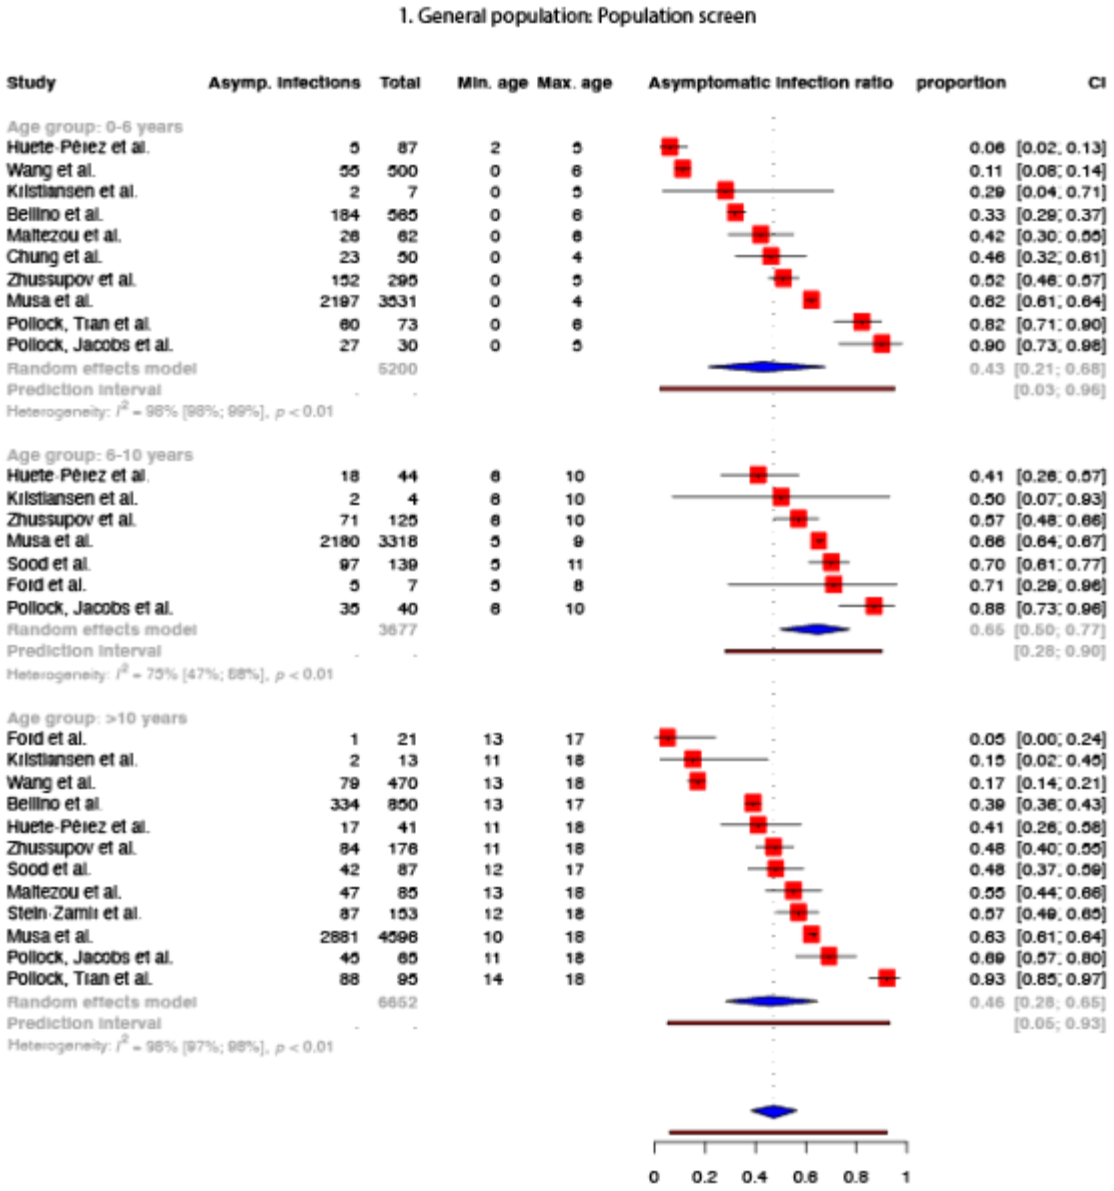
TWO-THIRDS OF SARS-COV-2 INFECTED SCHOOL-AGE CHILDREN ARE ASYMPTOMATIC: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 48 352 CHILDREN

Parallel Symposium
PARALLEL SYMPOSIUM: LEARNING FROM COVID

Ágoston Jánosi[1], Réka Garai[2], Regina Molnár[3], Tamás Kói[4], Marcell Imrei[1], Fanni Dembrovszky[1], Katalin Müller[5], Ibolya Túri[6], Andrea Harnos[1], Péter Hegyi[1], Andrea Párniczky[1]
[1]Semmelweis University, Centre For Translational Medicine, Budapest, Hungary, [2]Semmelweis University, 1st Department Of Pediatrics, Budapest, Hungary, [3]Semmelweis University, Faculty Of Medicine, Budapest, Hungary, [4]Budapest University of Technology and Economics, Department Of Stochastics, Institute Of Mathematics, Budapest, Hungary, [5]Heim Pál National Pediatric Institute, Department Of Gastroenterology, Budapest, Hungary, [6]Semmelweis University, András Pető Faculty, Budapest, Hungary

Backgrounds: Evidence shows that asymptomatic SARS-CoV-2 infected people are just as contagious as their symptomatic counterparts, therefore they play a key role in transmission. Knowing the prevalence of asymptomatic COVID-19 in children is of paramount importance in understanding the transmission potential of SARS-CoV-2 in school and community settings.
Methods: We conducted a systematic review and meta-analysis of studies (Medline, Embase, Central) containing information about the prevalence of PCR confirmed asymptomatic COVID-19 in children until 14th October 2021. We calculated risk ratios and performed one-stage dose-response random effect meta-analysis to assess the effect of age on asymptomatic infections. Pooled prevalences of asymptomatic paediatric COVID-19 by subgroups, risk ratios of different age groups and dose-response analysis of age were our main outcomes. Subgroups were created by screening strategies, age and by Healthcare Access and Quality (HAQ) index.
Results: We included 153 articles with 48 352 children's data from 58 countries. The pooled prevalence of asymptomatic SARS-CoV-2 infection in the general pediatric population was 45% (CI: 34-57%) with the highest prevalence among 6-10 years of age: 65% (CI: 50-77%). The subgroup analysis of different screening strategies identified contact tracing as the most common (43,78% of the studies) protective approach worldwide. Meanwhile, in a population of newborns with SARS-CoV-2 infected mothers, the prevalence of asymptomatic COVID-19 was 69% (CI: 58-



78%).

Conclusions/Learning Points: Around half of all SARS-CoV-2 infected children and more than two third of newborns of affected mothers are asymptomatic. Re-evaluating protective strategies and everyday medical practice – particularly in the shadow of poorly diagnosable post-COVID cases - considering the proportion of asymptomatic children is crucial, with particular attention to vaccination, which can protect society, also vulnerable groups even from the severe disease acquired from asymptomatic children.

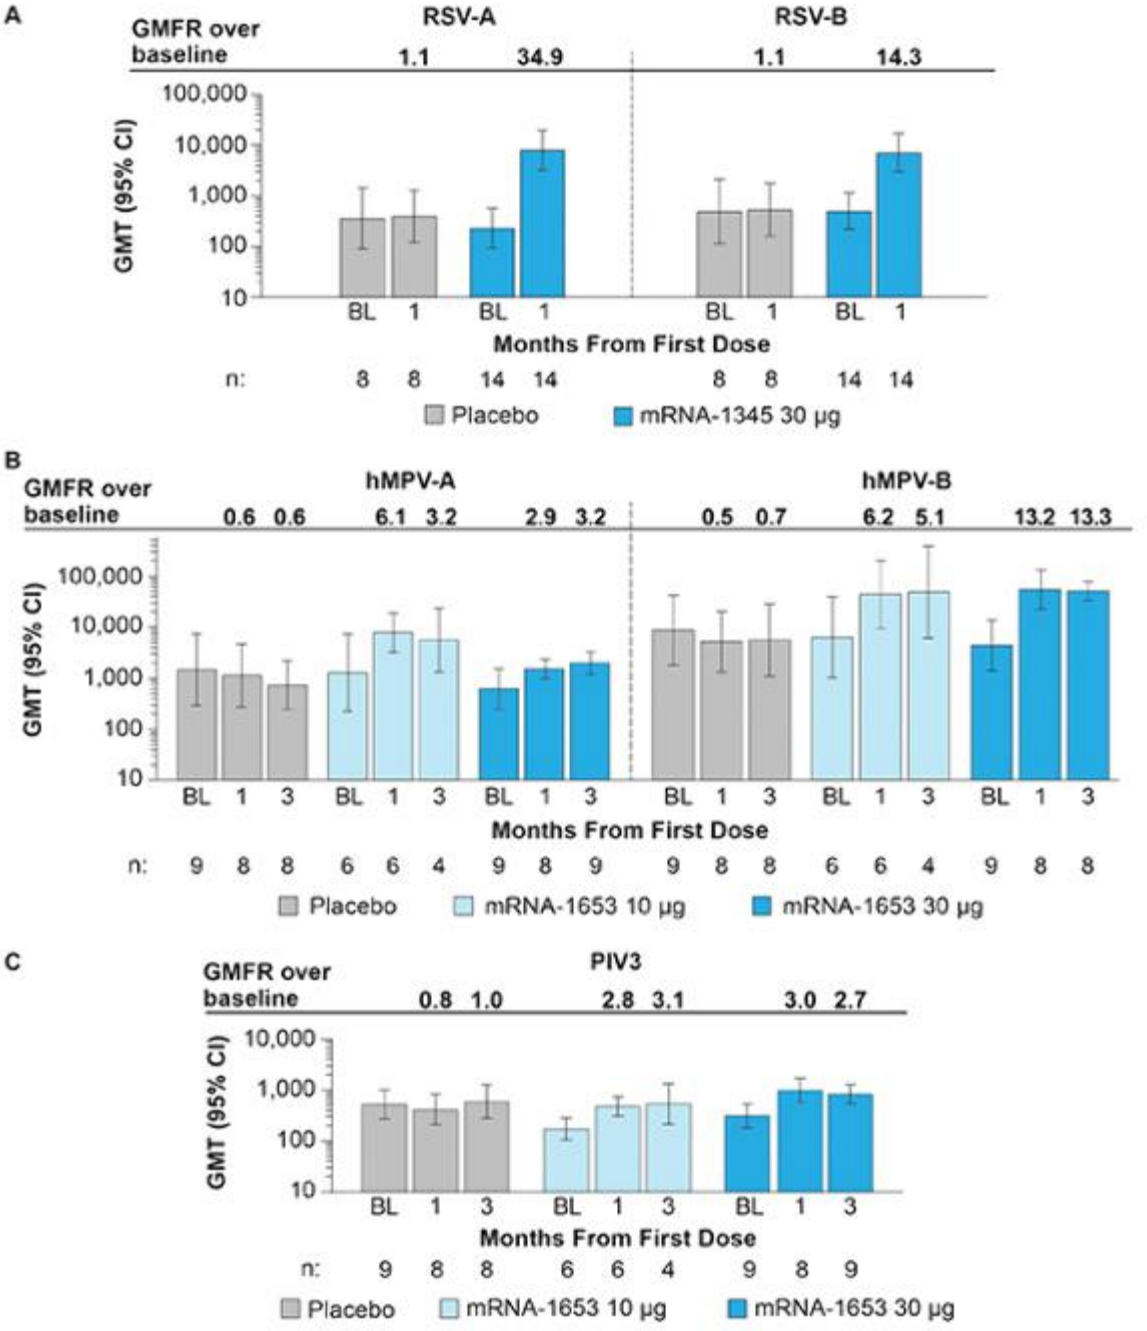
SAFETY/IMMUNOGENICITY OF 2 INVESTIGATIONAL MRNA VACCINES, A RESPIRATORY SYNCYTIAL VIRUS VACCINE AND A HUMAN METAPNEUMOVIRUS AND PARAINFLUENZA VIRUS TYPE 3 COMBINATION VACCINE IN YOUNG CHILDREN

Parallel Symposium
PARALLEL SYMPOSIUM: NEW WAYS TO MAKE BETTER VACCINES

Matthew Snape[1], Sabine Schnyder Ghamloush[2], Grace L. Chen[3], Rakesh Dhar[4], Runa Mithani[2], Vinicius Righi[2], Louie Morsy[2], Sophia Lu[5], Archana Kapoor[6], Bethany Girard[6], Laila El Asmar[2], Christine A. Shaw[2]
[1]Moderna, Inc., Pediatric And Maternal Development, Cambridge, United States of America, [2]Moderna, Inc., Infectious Disease, Cambridge, United States of America, [3]Moderna, Inc., Infectious Disease Development, Cambridge, United States of America, [4]Moderna, Inc., Pharmacovigilance, Cambridge, United States of America, [5]Moderna, Inc., Statistics & Programming, Cambridge, United States of America, [6]Moderna, Inc., Clinical Biomarkers, Cambridge, United States of America

Backgrounds: Respiratory syncytial virus (RSV), human metapneumovirus (hMPV), and parainfluenza virus type 3 (PIV3) are common respiratory illnesses in children. Two investigational vaccines, mRNA-1345, encoding the RSV prefusion stabilized F glycoprotein, and mRNA-1653, encoding the hMPV and PIV3 F glycoproteins, are in clinical trials.
Methods: Two Phase 1, randomized, observer blind, placebo-controlled trials in children (aged 12-59 months) assessed the safety and immunogenicity of mRNA-1345 (NCT04528719) and mRNA-1653 (NCT04144348). In the mRNA-1345 trial, RSV-seropositive children (n=26) were randomized to receive 3 doses of mRNA-1345 (30 µg) or placebo 2 months apart. In the mRNA-1653 trial, hMPV- and PIV3-seropositive children (n=27) were randomized to receive 2 doses of mRNA-1653 (10 or 30 µg) or placebo 2 months apart. Interim data through Month (M) 1 for mRNA-1345 and M3 for mRNA-1653 are presented.
Results: mRNA-1345 and mRNA-1653 were well-tolerated; the most frequently reported local solicited adverse reaction (SAR) was injection site pain (mRNA-1345, 53.3%; placebo, 30.0% and mRNA-1653, 44.4%-60.0%; placebo, 12.5%-30.0%); systemic SARs were mostly grade 1 or 2 (mRNA-1345, 53.3%; placebo, 40.0% and mRNA-1653, 33.3%-55.6%; placebo, 12.5%-60.0%). One mRNA-1345 injection boosted RSV-A and RSV-B neutralizing antibody (nAb) geometric mean titers (GMTs) at M1 (geometric mean fold rise [GMFR] over baseline: RSV-A=34.9; RSV-B=14.3; Figure). One mRNA-1653 injection boosted hMPV and PIV3 nAb GMTs at M1 (GMFRs: hMPV-A=2.9-6.1; hMPV-B=6.2-13.2; PIV3=2.8-3.0); a second injection did not further increase GMTs at M3 (GMFRs: hMPV-A=3.24 for both dose levels; hMPV-B=5.1-13.3; PIV3=2.7-3.1). In both trials, antibody responses were prefusion F-

Figure. Serum neutralizing antibody titers in seropositive children*: (A) RSV-A and RSV-B, (B) hMPV-A and hMPV-B, and (C) PIV3.



*In the mRNA-1345 trial, dose 1 was administered at baseline; in the mRNA-1653 trial, dose 1 was administered at baseline and dose 2 was administered at Month 2.

BL, baseline; CI, confidence interval; GMFR, geometric mean fold rise; GMT, geometric mean titer; hMPV, human metapneumovirus; PIV3, parainfluenza virus type 3; RSV, respiratory syncytial virus.

biased.

Conclusions/Learning Points: mRNA-1345 and mRNA-1653 were well-tolerated and boosted RSV and hMPV plus PIV3 nAbs, respectively, in seropositive children aged 12-59 months, supporting continued development of these vaccines and the development of a combination RSV and hMPV vaccine.

IMMUNOGENICITY AND SAFETY OF DIFFERENT MF59-ADJUVANTED H5N1 (AH5N1) INFLUENZA VACCINE FORMULATIONS IN HEALTHY PEDIATRIC SUBJECTS

Parallel Symposium
PARALLEL SYMPOSIUM: NEW WAYS TO MAKE BETTER VACCINES

Airi Põder[1], Esther Van Twuijver[2], Matthew Hohenboken[3], Eve Versage[3]
[1]Clinical Research Center, Clinical Research, Tartu, Estonia, [2]CSL Seqirus, Clinical Development, Amsterdam, Netherlands, [3]CSL Seqirus, Clinical Development, Waltham, United States of America

Backgrounds: A randomized, observer-blind, dose-ranging study evaluated the safety and immunogenicity of MF59-adjuvanted H5N1 vaccine formulations in healthy children.
Methods: 420 subjects 6 months to < 9yrs, were equally randomized to receive 2 doses of one of 6 different vaccine formulations including either 1.875, 3.75, or 7.5 µg H5N1 antigen combined with 0.125 mL (50%) or 0.25 mL (100% [versus adult dosage]) MF59, three weeks apart, stratified into 2 age cohorts (6 to <36 months and 3 to <9 years of age). HI and MN assays measured antibody responses against the homologous H5N1 (A/turkey/Turkey/1/2005) strain at baseline (Day 1), and 3 weeks after the 1st (Day 22) and 3 weeks (Day 43) and 6 months after the 2nd vaccination (Day 202).
Results: All vaccine formulations elicited strong homologous immune responses after the second vaccination, with a trend towards higher responses in subjects receiving the 100% MF59-adjuvanted vaccine formulations at Day 43 and at Day 202. No clear effect of the H5N1 antigen dose on immune responses was observed with both MF59 dosages. These immunogenicity patterns were observed in the entire study population and in both age cohorts. No patterns in frequency or severity of solicited or unsolicited adverse events were observed with increasing H5N1 antigen or MF59-adjuvant content.
Conclusions/Learning Points: Both the HI and MN responses indicate a 2-dose series of MF59-adjuvanted H5N1 vaccine, 3 weeks apart, achieves antibody levels likely to provide protection in children 6 months to 9 years of age. Although all formulations were highly immunogenic with a favorable safety profile, the vaccine formulations with higher MF59 content were associated with a greater magnitude and persistence of immune responses, while not associated with increased reactogenicity.

LIVE-ATTENUATED RESPIRATORY SYNCYTIAL VIRUS VACCINE FOR THE PREVENTION OF RSV DISEASE: PH1/2 RESULTS SHOW PROMISING SAFETY, IMMUNOGENICITY AND INFECTIVITY

Parallel Symposium
PARALLEL SYMPOSIUM: NEW WAYS TO MAKE BETTER VACCINES

Scott Gallichah[1], Olubukola T Idoko[2], Sanie Sesay[2], Sophie Pallardy[2], Haritha Adhikarla[3]
[1]Sanofi, R&d, Toronto, Canada, [2]Sanofi, R&d, Merieux, France, [3]sanofi, R&d, swiftwater, United States of America

Backgrounds: After decades of research a paediatric vaccine for RSV is not yet available. Early trials with live attenuated vaccine candidates suggest promise for paediatric vaccination and have not been linked to the risk of enhanced disease noted with formalin inactivated candidates.
Methods: The ongoing Sanofi-sponsored Phase I/II trial (NCT04491877) evaluated a live-attenuated RSV vaccine, which was co-developed in partnership with NIH under a CRADA and license agreement, in 6-18mo infants and toddlers in the US and South America (Chile and Honduras). In this trial, the safety, immunogenicity and infectivity of two formulations administered intranasally was assessed in sequential cohorts (N=259). Participants received two administrations of the candidate or placebo two months apart and provided blood samples at baseline and up to at least 5 months post the second vaccine administration (and/or end of RSV season) to assess immunogenicity. Vaccine viral shedding was assessed 7 days post each vaccine formulation administration. Safety follow up lasted 5 months after the second vaccine administration or to the end of the RSV season, whichever was greater.
Results: The results show that the vaccine was well tolerated with no safety concerns identified after 1 and 2 administrations of either formulation. The vaccine virus shedding and immunogenicity results from the interim data analysis are promising and demonstrate strong take of the vaccine with a high degree of recipients showing shedding of the virus and the development of neutralizing antibodies.
Conclusions/Learning Points: The current results indicate that the live-attenuated RSV vaccine is safe and immunogenic and support the future development of the candidate.

STAPHYLOCOCCUS AUREUS CAUSING PEDIATRIC INVASIVE INFECTIONS IN PORTUGAL ARE A DIVERSE POPULATION WITH LOW REPRESENTATION OF MRSA AND IMPORTANT VIRULENCE GENES

Joint Symposium
JOINT SYMPOSIUM: ESCMID-ESPID: STAPHYLOCOCCI PERSISTING AND PERISHING

Marcos Pinho[1], Yenine Martins[1], Paula Correia[2], Catarina Gouveia[3], Fernanda Rodrigues[4], José Melo-Cristino[1], Mário Ramirez[1], . The Portuguese Study Group Of Invasive Pneumococcal Disease Of The Pediatric Infectious Diseases Society[1], . Study Group Of Pediatric Staphylococcal Disease In Portugal[1]
[1]Faculdade de Medicina da Universidade de Lisboa, Instituto De Microbiologia, Lisbon, Portugal, [2]Hospital Professor Doutor Fernando da Fonseca, Paediatrics, Amadora, Portugal, [3]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatric Infectious Diseases Unit, Lisbon, Portugal, [4]Centro Hospitalar e Universitário de Coimbra, Hospital Pediátrico, Coimbra, Portugal

Backgrounds: We aimed at identifying the Staphylococcus aureus lineages causing pediatric (<18 yrs) invasive infections (piSA) in Portugal, evaluating antimicrobial susceptibility and the distribution of virulence genes.
Methods: A total of 205 isolates were recovered from blood (n=180), synovial fluid (n=12) or other normally sterile fluids/tissues (n=13) in 10 Portuguese hospitals in 2015-2020. Genomic sequences (Illumina) were obtained for all isolates. Multilocus sequence typing (MLST), virulence and antimicrobial resistance genes were identified. Antimicrobial susceptibility to fourteen antimicrobial agents was determined by disk diffusion or E-test, following EUCAST guidelines.
Results: Isolates belonged to 36 sequence types (STs) grouped into 17 CCs and one singleton (Simpson's index of diversity ± 95% confidence interval, 0.899 ± 0.015). CC398 (16.6%), CC30 (16.1%), CC5 (13.7%) and CC45 (10.7%) were the most frequent CCs. Overall penicillin resistance was 87.3% and methicillin-resistant (MRSA) strains accounted for 17.1% (n=35) of the isolates, with SCCmec types IV (n=17), VI (n=8) and II (n=8). MRSA isolates belonged to CCs 5 (51.4%), 22 (31.4%), 8 (11.4%), 72 and 152 (2.9% each). Resistance to other antimicrobial agents included erythromycin (29.8%), norfloxacin (15.1%), fusidic acid (7.3%) and gentamicin (6.8%). Panton-Valentine leucocidin (PVL) genes were detected in 10 (4.9%) isolates, including two MRSA. Toxic shock syndrome toxin-1 gene was found in 15.6% (n=32) of the isolates while exfoliative toxins ETA (2.9%) and ETB (2.4%) genes were carried by a minority of isolates.
Conclusions/Learning Points: S. aureus causing piSA in Portugal showed considerable diversity, albeit representing widely disseminated lineages. While most isolates were resistant to penicillin, only a minority were MRSA, with CC5 and CC22 dominating among this group. Despite the severity of some cases, PVL, ETA or ETB genes were present in <5% of isolates.

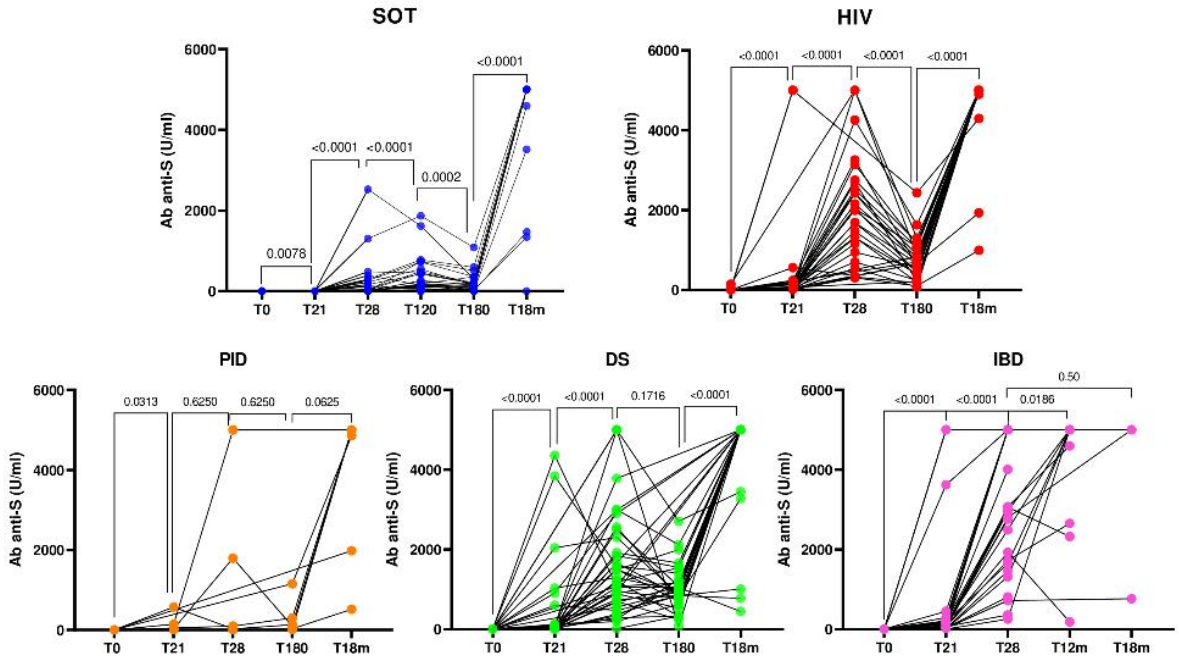
Backgrounds: Little is known about the longevity of COVID19 vaccine-induced protection in vulnerable populations. Our analysis aims to evaluate the persistence of humoral immunity following BNT162B2 mRNA COVID-19 vaccination in 5 cohorts of vulnerable children and young adults: solid organ transplant recipients (SOT), ART-treated perinatally HIV-infected (HIV), Down Syndrome (DS), Inflammatory Bowel Disease (IBD), primary immunodeficiency (PID).
Methods: Longitudinal blood samples were collected on the day of vaccination (T0), 21-days (T21), 28-days (T28), 6-months (T180), and 12-months and/or 18-months (T18m) after the priming dose. Anti–SARS-CoV-2 S1 receptor-binding domain antibodies were assessed at each time point. Booster shot and SARS-CoV-2 infection occurring between the second dose and the first booster were monitored via the regional registry.
Results:



At T18m, 106 patients were included in our analysis: 24 SOTs, 28 DS, 32 HIV, 15 IBDs, 7 PID. Among

them, 99/106 got the booster shot at T180. The serological data overall showed a decrease in Ab at T180 in SOT, HIV and DS. However, 98/99 of booster-vaccinated individuals have significantly increased ab titers at T18m compared to T180 ($p < 0.05$ in SOTs, HIVs and DSs, and not statistically significant in PID and IBD). Only one SOT remained non-responder after 1 booster dose and SARS-CoV-2 infection.
Conclusions/Learning Points: According to our analysis, the vaccination schedule adopted for vulnerable population was able to provide long-term humoral immunity (18 months). Whereas a decreasing trend was observed 6 months after vaccination, booster shots provided at 12 months were able to restore vaccine induced Ab. These data further show that timing of immunization and boosters are crucial in these populations and additional data are needed to pursue a personalized vaccination approach in immune compromised adolescents and young adults.

EFFECTIVENESS OF BNT162B2 AND CORONAVAC AGAINST PEDIATRIC COVID-19-ASSOCIATED HOSPITALIZATION AND MODERATE-TO-SEVERE DISEASE

Oral Presentations Session
ORAL PRESENTATION SESSION 01: COVID VACCINES

Jaime Rosa Duque, Daniel Leung, Ka Man Yip, Derek Lee, Hung-Kwan So, Wilfred Wong, Yu Lung Lau
The University of Hong Kong, Department Of Paediatrics And Adolescent Medicine, Hong Kong, Hong Kong PRC

Backgrounds: Vaccine effectiveness (VE) of BNT162b2 and CoronaVac against COVID-19-associated hospitalization and moderate-to-severe disease due to SARS-CoV-2 Omicron BA.2 for pediatric populations that had low exposure to prior SARS-CoV-2 variants needs to be further clarified. This can be studied from the 1.36 million vaccine doses that had been administered to 766,601 of 953,400 children and adolescents in Hong Kong (HK) since March 2021 to April 2022.
Methods: Using an ecological design leveraging HK vaccination coverage statistics and public hospital records, this study investigated the VE for children aged 3-11 years and adolescents aged 12-18 years at the population level during the Omicron BA.2 wave from January to April 2022.
Results: VE against COVID-19-associated hospitalization for children was 65.3% for 1 dose of BNT162b2 and 13.0% and 86.1% for 1 and 2 doses of CoronaVac, respectively. For adolescents, VE against COVID-19-associated hospitalization was 60.2% and 82.4% after 1 and 2 doses of BNT162b2 and 30.8% and 90.7% after 1 and 2 doses of CoronaVac, respectively. Protection against moderate-to-severe disease for aged 3-18 was high, with VE of 93.1% and 95.8% after 2 doses of BNT162b2 and CoronaVac, respectively. No COVID-19-associated hospitalization or moderate-to-severe disease occurred for 68,565 children and adolescents who received their third dose. Estimated hospitalizations of children and adolescents averted by vaccination were 68 and 999, respectively, and were 45 and 147 for moderate-to-severe cases.
Conclusions/Learning Points: BNT162b2 or CoronaVac provide substantial protection from COVID-19-associated hospitalization and moderate-to-severe disease due to a SARS-CoV-2 variant of concern.

Backgrounds: This was the first study to investigate the reactogenicity and immunogenicity of heterologous or fractional dose COVID-19 vaccine regimens in adolescents.
Methods: A phase II, single-blind, multi-centre, randomised-controlled trial recruited across seven UK sites from September to November 2021, with follow-up visits to August 2022. Healthy 12-to-16 years olds were randomised (1:1:1) to either 30µg BNT162b2 (BNT-30), 10µg BNT162b2 (BNT-10), or NVX-CoV2373 (NVX), eight weeks after a first 30µg dose of BNT162b2. The primary outcome was solicited systemic reactions one week after vaccination. Secondary outcomes included immunogenicity and safety. 'Breakthrough infection' analyses were exploratory.
Results: 148 participants were recruited (median age 14 years, 30% anti-nucleocapsid IgG seropositive pre-second dose). Reactions were mostly mild-to-moderate, with lower rates in BNT-10 recipients. Compared to BNT-30, at 28 days post-second dose anti-spike antibody responses were similar for NVX (geometric mean ratio (GMR) 1.09, 95% confidence interval (CI): 0.84,1.42) and significantly lower for BNT-10 (GMR 0.78 95% CI: 0.61, 0.99). For Omicron BA.1 and BA.2 neutralising antibody (NAb) titres, GMR compared to BNT-30 at day 28 were similar for BNT-10 [1.0 (95% CI 0.65, 1.54), 1.02 (95% CI 0.71, 1.48)] respectively, but higher for NVX [1.7 (95% CI 1.07, 2.69), 1.43 (0.96 – 2.12)]. Amongst SARS-CoV-2 infection naïve participants, NVX participants had an 89% reduction in the risk of a self-reported 'breakthrough infection' compared to BNT-30 (hazard ratio (HR) 0.11, 95% CI: 0.01, 0.86). BNT-10 recipients were significantly more likely to have a 'breakthrough infection' compared to BNT-30 (HR 2.14, 95% CI: 1.02, 4.51).
Conclusions/Learning Points: The enhanced performance of the heterologous schedule using NVX-CoV2373 against the Omicron SARS-CoV-2 variant suggests this mRNA prime and protein-subunit-boost schedule may provide a greater breadth of protection than the licensed homologous schedule.

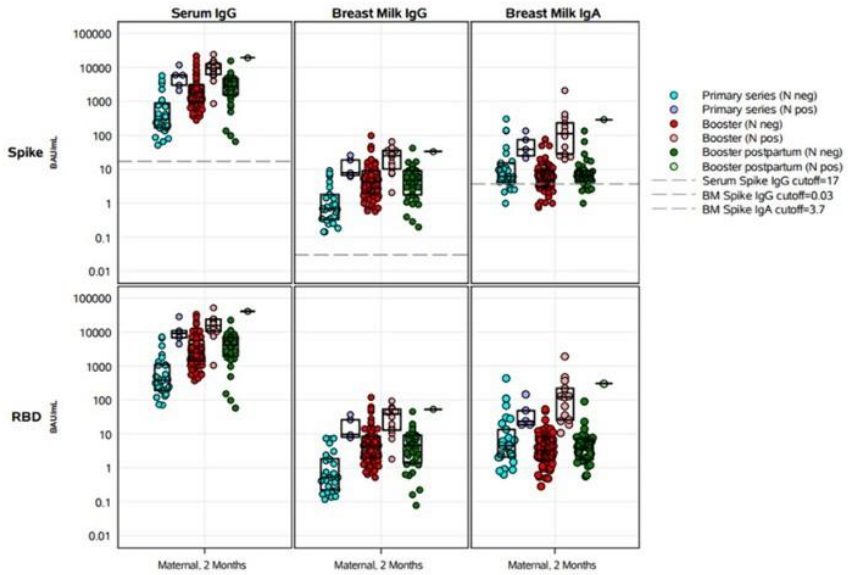
Backgrounds: The immune profile of breastmilk following primary vs. booster COVID-19 vaccination during pregnancy or post-partum and its potential for protection are not well characterized.
Methods: Prospective multicenter cohort study of participants enrolled after receipt of a primary 2-dose, or booster COVID-19 mRNA vaccination during pregnancy or a booster dose within 6 weeks postpartum. Maternal blood and breastmilk samples were collected at 2-months postpartum in this substudy. IgG and IgA binding antibodies to Spike and RBD of SARS-COV-2 in breastmilk were compared in primary vs. booster vaccine recipients. The correlation between maternal Spike IgG and breastmilk Spike IgG and IgA was assessed. Maternal infection status was assessed by medical history and detection of N-protein IgG.
Results: The study included 32 mother-infant dyads with primary 2-dose vaccination during pregnancy, 82 dyads with booster vaccination during pregnancy and 36 dyads with maternal booster within 6 weeks postpartum. The majority of infants were born at term (≥90%) and most (≥85%) were breastfeeding at 2 months postpartum. Spike and RBD IgG and IgA were present in breastmilk in all study groups. Higher IgG GMT were measured in those who received a booster vaccination either during pregnancy or postpartum, compared with primary 2-dose vaccination during pregnancy. Maternal infection increased GMT in breastmilk but numbers were low to evaluate impact. A significant positive correlation was observed between maternal serum IgG titers and breastmilk IgG and IgA at 2-months postpartum, regardless of vaccine regimen. The Spearman correlation between maternal sera and breastmilk antibodies was higher with breastmilk IgG (r=0.79-0.9596) than with breastmilk IgA (r=0.42-0.52).



Conclusions/Learning Points: Results support the potential protective effect of breastmilk antibodies in nursing infants of mothers who are vaccinated or boosted with COVID-19 mRNA vaccines during pregnancy or postpartum.

IMMUNOGENICITY AND REACTOGENICITY OF BNT162B2 MRNA COVID-19 VACCINE AMONG CHILDREN PREVIOUSLY INFECTED WITH SARS-COV-2

Oral Presentations Session
ORAL PRESENTATION SESSION 01: COVID VACCINES

Wanatpreeya Phongsamart[1], Yarlanphol Thirakulnanchai[1], Keswadee Lapphra[1], Orasri Wittawatmongkol[1], Supattra Rungmaitree[1], Alan Maleesatharn[1], Sansnee Senawong[2], Kulkanya Chokephaibulkit[3]
[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Department Of Pediatrics, Bangkok, Thailand, [2]Faculty of Medicine Siriraj Hospital, Mahidol University, Department Of Immunology, Bangkok, Thailand, [3]Faculty of Medicine Siriraj Hospital, Mahidol University, Siriraj Institute Of Clinical Research, Bangkok, Thailand

Backgrounds: The immunogenicity of vaccination among children previously infected with SARS-CoV-2 is limited studied.
Methods: Children aged 5-11 years with confirmed SARS-CoV2 infection were randomly assigned to receive BNT162b2 vaccine at full-dose (10 micrograms) or half-dose (5 micrograms). Anti-spike receptor binding domain (RBD) IgG, and neutralizing (NT) antibody against ancestor and omicron BA.5 variant were measured at 3 (+/- 1week) weeks after vaccination. Solicited adverse events (AEs) were recorded for 7 days following vaccination.
Results: 183 children were enrolled, median age (IQR) of 8.5 (7.2-10.1) years. One participant withdrew. Overall, anti- RBD antibody was higher among children who had infections at >3 months prior compared to those at 1-3 months prior. The full-dose group provided higher antibody levels compared to half-dose; however, the significant different was found only among the children infected at 1-3 months prior.

Duration from previous infection	Anti-spike RBD IgG(AU/mL) GMT (95%CI)		
	Before vaccination (N=182)	After Vaccination (N=177)	p-value
1-3 months			
Full-dose	165.4 (110.7-248.2)	9469.0 (8319.6-10777.1)	<0.001
Half-dose	142.3 (90.0-225.0)	6255.7 (5183.0-7550.5)	<0.001
p-value	0.621	<0.001	
>3 months			
Full-dose	200.2 (121.6-329.5)	17691.6 (12823.0-24408.8)	<0.001
Half-dose	187.6 (128.0-275.0)	16750.8 (11448.4-24509.1)	<0.001
p-value	0.836	0.824	

The NT against ancestral virus [GMT(95%CI) 826.0 (600.3-1136.7) vs 122.3 (93.7-159.6); p<0.001] and omicron BA.5 [GMT(95%CI) 165.1 (128.8-211.7) vs 75.7 (58.1-98.7); p<0.001] were higher among children who had infection at >3 months prior than those at 1-3 months prior, respectively. The most common AEs were pain (33.5%), myalgia (18.1%), and headache (9.9%); no myocarditis/pericarditis or serious AEs.
Conclusions/Learning Points: Delaying vaccination after 3 months from infection provided better immunogenicity than earlier vaccination. Half dose of BNT162b2 mRNA

COVID-19 vaccine may be an alternative regimen for children with prior SARS-CoV-2 infection >3 months.

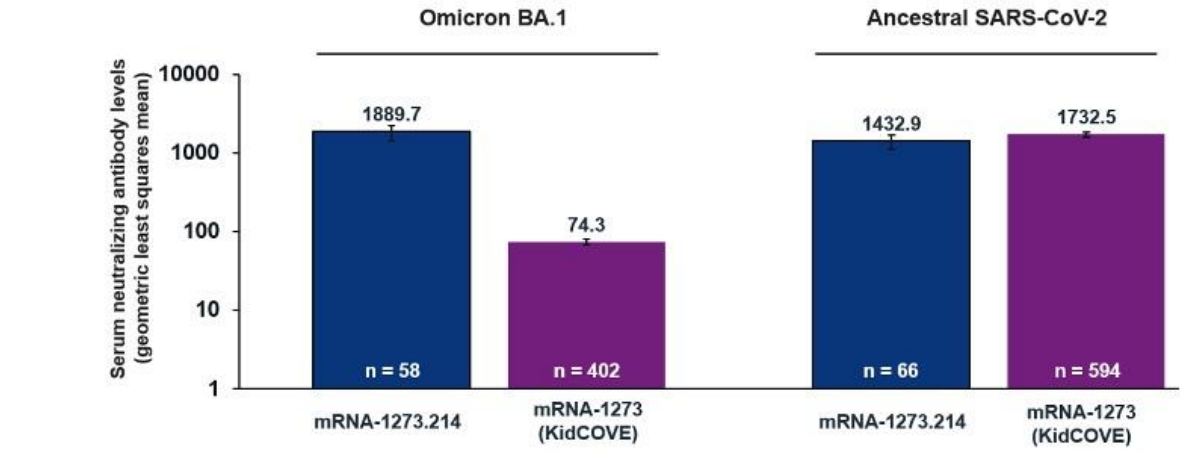
SAFETY, REACTOGENICITY, AND IMMUNOGENICITY OF MRNA-1273.214 PRIMARY SERIES AND BOOSTER VACCINATION IN INDIVIDUALS AGED 6 MONTHS TO LESS THAN 6 YEARS: INTERIM RESULTS FROM A PHASE 3, OPEN-LABEL TRIAL

Oral Presentations Session
ORAL PRESENTATION SESSION 01: COVID VACCINES

Avika Dixit[1], Richard Bennett[2], Kashif Ali[3], Robert Clifford[4], Rosanne Poston[1], Kelly Hautzinger[1], Anne Yeakey[5], Bethany Girard[1], Wen Zhou[1], Weiping Deng[1], Honghong Zhou[1], Sabine Schnyder Ghamloush[1], Jacqueline Miller[1], Rituparna Das[1]
[1]Moderna, Inc., Clinical Development, Cambridge, United States of America, [2]Clinical Research Partners LLC, Clinical Development, Richmond, United States of America, [3]Texas Center for Drug Development, Clinical Development, Houston, United States of America, [4]Coastal Pediatric Research, Clinical Development, Charleston, United States of America, [5]BioPoint Contracting, Pharmacovigilance, Wake Forest, United States of America

Backgrounds: The bivalent mRNA-1273.214 vaccine, containing mRNAs encoding the spike glycoproteins of the SARS-CoV-2 Wuhan-Hu-1 isolate and the omicron B.1.1.529 BA.1 subvariant, was previously evaluated in a phase 2/3 study as a second booster in adults who received the mRNA-1273 primary series plus a first booster. Herein, we present interim results from a study evaluating mRNA-1273.214 as a primary series in children.
Methods: This ongoing, phase 3, open-label trial evaluated the safety, reactogenicity, and immunogenicity of mRNA-1273.214 (25 µg) as a 2-dose primary series administered 28 days apart (Part 1) in SARS-CoV-2 vaccine-naive individuals aged 6 months to <6 years (NCT05436834). Effectiveness of mRNA-1273.214 was inferred based on immune responses against BA.1 and ancestral SARS-CoV-2 at 28 days after dose 2 compared with those induced by the mRNA-1273 (25 µg) primary series among participants of the same age group from the phase 3 KidCOVE study. Immunogenicity comparisons were based on geometric mean ratio (GMR; mRNA-1273.214 vs mRNA-1273) of neutralizing antibodies (nAbs).
Results: A total of 179 participants (median age, 3 [IQR 1-3] years) were included in this interim analysis of mRNA-1273.214 (dose 1, 179; dose 2, 142). mRNA-1273.214 was generally well-tolerated and no safety concerns were identified. Irritability/crying and pain were the most frequently reported solicited adverse reactions. Superiority of the nAb response against omicron BA.1 (GMR, 25.4 [95% CI, 20.1-32.1]) and non-inferiority against the ancestral strain (GMR, 0.83 [95% CI, 0.67-1.02]) were demonstrated following mRNA-1273.214 compared with mRNA-1273
(Figure).

Figure. Serum neutralizing antibodies against SARS-CoV-2 at 28 days after dose 2 of mRNA-1273.214 or mRNA-1273



Geometric mean ratio (95% CI)	25.4 (20.1-32.1)	0.83 (0.67-1.02)

Immunogenicity was assessed in the per-protocol immunogenicity population, including participants aged 6 months to <6 years regardless of baseline SARS-CoV-2 status. Superiority against omicron BA.1 was declared if the lower bound of the 95% CI of the geometric mean ratio (ratio of the geometric least squares mean serum antibody values for mRNA-1273.214 vs mRNA-1273 at 28 days after dose 2) was >1. Non-inferiority against ancestral SARS-CoV-2 was declared if the lower bound of the 95% CI of the geometric mean ratio (ratio of the geometric least squares mean serum antibody values for mRNA-1273.214 vs mRNA-1273 at 28 days after dose 2) was >0.667.

Conclusions/Learning Points: A 2-dose primary series of the bivalent mRNA-1273.214 vaccine had no new safety concerns and elicited immune responses against omicron BA.1 that were superior to mRNA-1273 in children aged 6 months to <6 years.

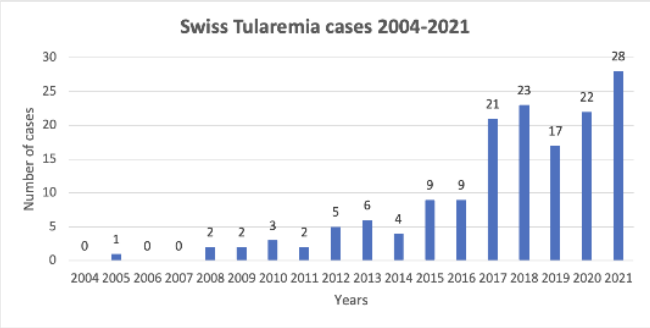
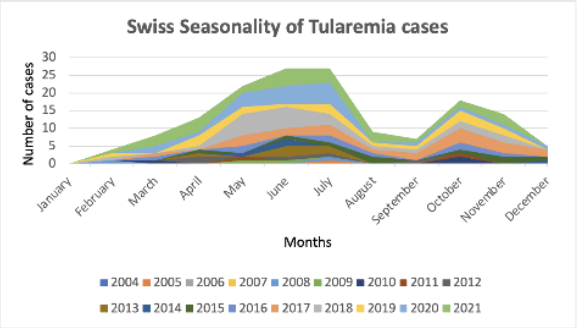
PAEDIATRIC TULAREMIA IN EUROPE – TWO COUNTRIES: DIFFERENT VECTORS AND EPIDEMIOLOGY

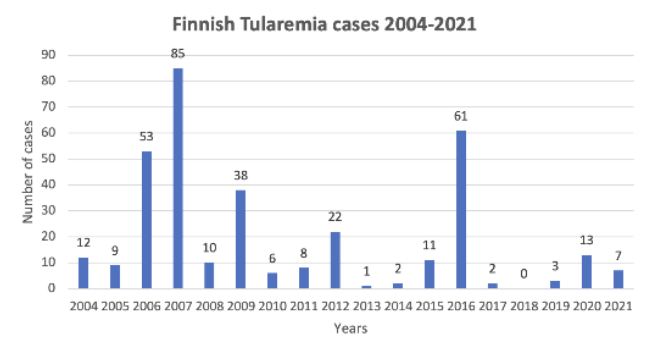
Oral Presentations Session
ORAL PRESENTATION SESSION 02: MISCELLANEOUS I

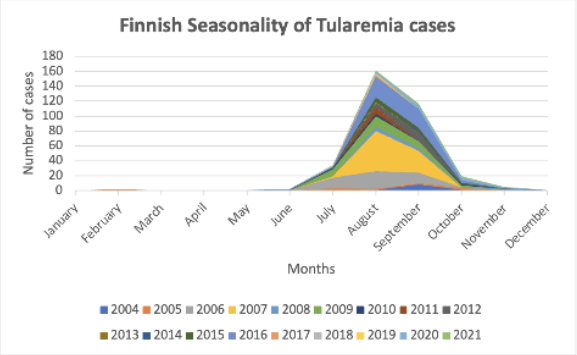
Patrizia Schmid[1], Oona Sanaksenaho[2], Ulla Koskela[3], Tytti Pokka[3], Ekkehardt Altpeter[4], Anton Labutin[4], Terhi Tapiainen[2,3,5], Michael Buettcher[1,6,7]
[1]University of Lucerne, Faculty Of Health Sciences And Medicine, Lucerne, Switzerland, [2]Oulu University Hospital, Department Of Pediatrics And Adolescent Medicine, Oulu, Finland, [3]University of Oulu, Research Unit Of Clinical Medicine And Medical Research Centre Oulu, Oulu, Finland, [4]Swiss Federal Office of Public Health, Transmissible Infections, Bern, Switzerland, [5]University of Oulu, Biocenter Oulu, Oulu, Finland, [6]University Children's Hospital Basel, Paediatric Pharmacology And Pharmacometrics, Basel, Switzerland, [7]Children's Hospital Lucerne, Paediatric Infectious Diseases, Lucerne, Switzerland

Backgrounds: Paediatric data on tularemia, an emerging zoonosis, are scarce. In Europe the Francisella tularensis holarctica subtype is primarily responsible for tularemia syndromes in children. We characterize the epidemiological differences of tularemia in children in Finland and in Switzerland
Methods: We compared datasets from nationwide register-based cohorts from two European countries. Paediatric data (<15 years of age) from 2004-2021 were retrieved from the Swiss (CH) and Finnish (FI) national public health surveillance reporting systems, including a cohort from the Oulu catchment area, a tularemia hotspot in Finland.
Results: We recorded 497 (343 FI; 154 CH) cases, 40% (N=201) of cases were in females. Main vectors were ticks in CH and mosquitoes in FI. In FI, the highest annual incidence was seen in 2007 with the annual incidences of 10.2 in 0-4y, 10.1 in 5-9y, and 8.2 in the 10-14 year age groups. In CH, the annual incidence increased from 0 to 1.7 per100 000 per year for the <15y age group. In FI, outbreaks occurred regularly every few years, whereas a steady increasing annual incidence was observed in CH. In FI infections peaked in late summer (August and September), while CH recorded two epidemiological peaks (June to July and October) (Fig.1.). In both cohorts the most common clinical manifestations were ulceroglandular or glandular tularemia followed by rare oropharyngeal, pulmonary, oculoglandular, middle ear, abdominal, and typhoidal manifestations.









Conclusions/Learning Points: The CH and FI surveillance cohorts revealed clear differences in the epidemiology of paediatric tularaemia, specifically in regards to main transmission vector and incidence peak variation. In CH, the reasons for the observed increasing incidence of pediatric tularemia are unknown.

CLINICAL CHARACTERISTICS AND SEROLOGICAL PROFILES OF LYME DISEASE IN CHILDREN: A RETROSPECTIVE COHORT STUDY IN SWITZERLAND, 2006–2020

Oral Presentations Session
ORAL PRESENTATION SESSION 02: MISCELLANEOUS I

Beat Greiter[1], Semjon Sidorov[1], Roland Martin[2], Rheinhard Zbinden[3], Christoph Berger[1], Patrick M. Meyer Sauteur[1]
[1]University Children's Hospital Zurich, Division Of Pediatric Infectious Diseases And Hospital Epidemiology, Zurich, Switzerland, [2]University Hospital Zurich & University of Zurich, Neuroimmunology And Multiple Sclerosis Research Section, Zurich, Switzerland, [3]University of Zurich, Institute Of Medical Microbiology, Zurich, Switzerland

Backgrounds: Lyme disease (LD) is the most common tickborne disease in the northern hemisphere caused by the bacteria Borrelia burgdorferi (Bb). Although classical characteristics of LD are well-known, the diagnosis and treatment are often delayed, particularly in children. The aim of this study was to better describe clinical characteristics and serological profiles which allow for early and reliable diagnosis of LD in children.
Methods: This is a retrospective cohort study of children, 0–17 years of age, diagnosed with LD according to current guidelines at University Children's Hospital Zurich from January 1, 2006–December 31, 2020.
Results: In total, 469 children diagnosed with LD were included. LD presented in 171 (36.5%) patients with skin manifestations (including erythema migrans and borrelial lymphocytoma), in 190 patients (40.5%) with Lyme neuroborreliosis (LNB), and in 108 (23.0%) patients with Lyme arthritis (Figure, Panel A). Seasonal variations were observed in patients with skin manifestations and LNB (high prevalence in May–October), but not in patients with Lyme arthritis (Figure, Panel B). The median age was 8.0 years (IQR 5.5 - 10.5), but there were significant differences in age between patients with different manifestations (Figure, Panel C). Patients with Lyme arthritis showed more pronounced systemic inflammation compared to other manifestations. Significant differences were observed in specificity and magnitude of Bb-specific serum antibody responses among LD manifestation groups (Figure, Panel D).
Conclusions/Learning Points: This is one of the largest and most detailed studies for LD in Europe. It presents new observations regarding the differences in epidemiology and immune responses between various manifestations of LD in children, which we will investigate in more detail in an upcoming

prospective LD study.

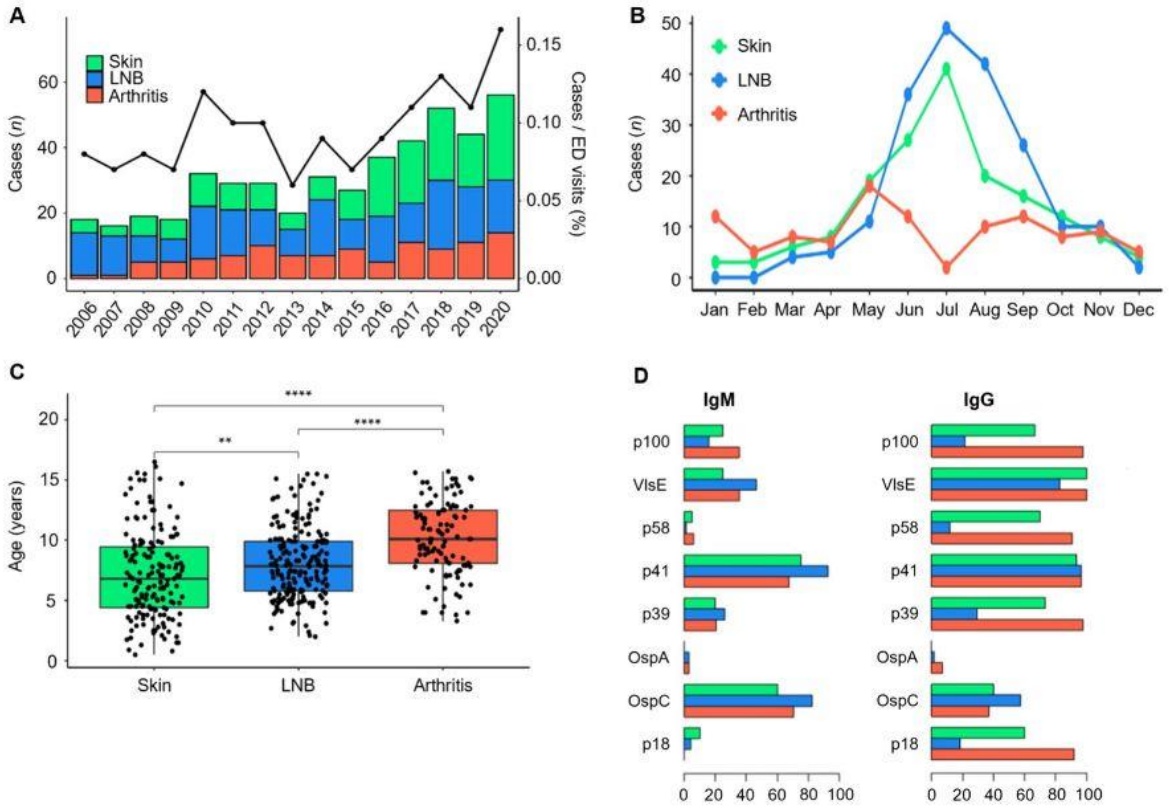

Figure. (A) Incidence per year, (B) Seasonal changes in number of cases, (C) Age differences, and (D) Serum antibody responses among different manifestations of Lyme disease. Abbreviations: ED, emergency department; LNB, Lyme neuroborreliosis.

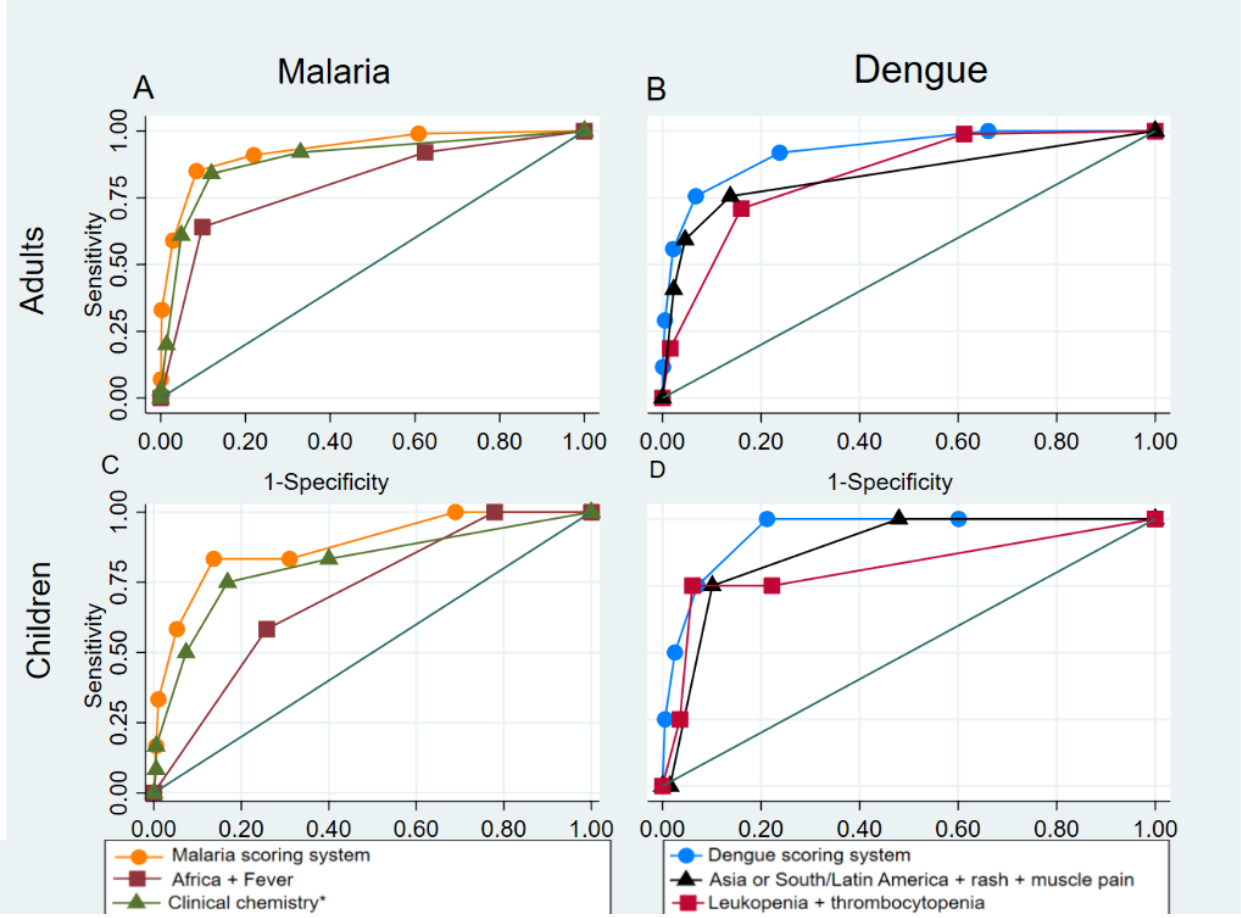
SCORING SYSTEMS FOR PREDICTION OF MALARIA AND DENGUE FEVER IN NON-ENDEMIC AREAS AMONG TRAVELERS ARRIVING FROM TROPICAL AND SUB-TROPICAL AREAS

Oral Presentations Session
ORAL PRESENTATION SESSION 02: MISCELLANEOUS I

Donya Satarvandi[1,2], Suzanne Van Der Werff[1,3], Pontus Nauclér[1,4], Helena Hildenwall[5,6,7], Klara Sondén[8,9]
[1]Karolinska Institute, Department Of Medicine, Solna, Stockholm, Sweden, [2]Karolinska University Hospital, Children's Hospital Of Astrid Lindgren, Solna, Sweden, [3]Karolinska Institute, Department Of Infectious Diseases, Solna, Sweden, [4]Karolinska Institute, Department Of Infectious Diseases, Stockholm, Sweden, [5]Karolinska Institute, Department Of Global Public Health,, Stockholm, Sweden, [6]Karolinska Institute, Department Of Clinical Science, Intervention And Technology (clintec), Huddinge, Sweden, [7]Karolinska University Hospital, Children's Hospital Of Astrid Lindgren, Stockholm, Sweden, [8]Public Health Agency of Sweden, Department Of Microbiology, Solna, Sweden, [9]Karolinska Institute, Department Of Medicine, Solna, Solna, Sweden

Backgrounds: Fever is a common symptom among travelers returning from tropical/subtropical areas, and to promptly distinguish severe illnesses from self-limiting febrile syndromes is important, but can be challenging due to unspecific clinical presentation
Methods: A cross sectional study enrolling adults and children who sought care at Karolinska University Hospital, Stockholm, Sweden with fever within two months following return from travel to a tropical/subtropical area. Prospective and retrospective data was collected on symptoms and laboratory parameters. Two separate scoring systems for malaria and dengue were developed based on forward stepwise regressions with combination of clinical indicators.
Results: In total, 2113 adults aged 18-94 and 202 children aged 1-17 were included during 2015-2020, with 112 (4.8%) cases of malaria and 90 (3.9%) cases of dengue. In the scoring systems ranging from 0-7 points depending on the following predictors mentioned, scores of ≥3 points predicted a high odds ratio (OR) for dengue in adults 42.7 (95% CI 25.3–71.9) and children 39.4 (95% CI 3.8–404.2), as well as for malaria, OR adults 61.4 (95% CI 34.7–108.7) vs. OR children 31.5 (95% CI 6.5–152.1). Malaria was predominantly diagnosed in patients presenting with thrombocytopenia (2p), anemia (1p), lymphocytopenia (1p), neutropenia (1p), and fever ≥39.5 °C (1p) after visiting sub-Saharan Africa (1p). Leukopenia (2p), thrombocytopenia (1p), muscle pain (1p) and rash (1p) after traveling to Asia or South/Latin America (1p) indicated high probability of dengue. Figure: ROC-curve of the scoring systems



*Clinical chemistry = Thrombocytopenia, anemia, lymphocytopenia, neutropenia

Conclusions/Learning Points: The scoring systems provide a novel tool for structured assessment of tropical fever patients and highlight clinical signs associated with a potential severe etiology and indicate the need for microbial investigation.

UKRAINIAN CHILD MIGRANTS' AND WAR REFUGEES' HOSPITAL ADMISSIONS : EVIDENCE FROM THE POLISH NATIONWIDE GENERAL HOSPITAL MORBIDITY STUDY, 2014-2022

Oral Presentations Session
ORAL PRESENTATION SESSION 02: MISCELLANEOUS I

Katarzyna Lewtak[1,2], Anna Poznańska[3], Dorota Kleszczewska[4], Anna Dzielska[5], Joanna Bogusz[6]
[1]Medical University of Warsaw, Department Of Social Medicine And Public Health, Warsaw, Poland, [2]National Institute of Public Health NIH - NRI, Department Of Health Promotion And Prevention Of Chronic Diseases, Warsaw, Poland, [3]National Institute of Public Health NIH - NRI, Department Of Population Health Monitoring And Analysis, Warsaw, Poland, [4]Institute of Mother and Child Foundation, Institute Of Mother And Child Foundation, Warsaw, Poland, [5]Institute of Mother and Child, Department Of Child And Adolescent Health, Warsaw, Poland, [6]National Institute of Public Health NIH - NRI, Department Of Epidemiology, Warsaw, Poland

Backgrounds: Millions of Ukrainian children have fled to other countries because of the Russian war. The aim of the study was to assess changes in the frequency and structure of hospitalizations among Ukrainian child migrants and refugees in Poland after the outbreak of the war.
Methods: The study was based on the analysis of hospital admission data of Ukrainian children under the age of 18, which were collected in the Nationwide General Hospital Morbidity Study. Two periods were analyzed: before the war (01.01.2014-23.02.2022) and after (24.02.2022-31.05.2022) its outbreak.
Results: In the study period, 1515 Ukrainian children were hospitalized in Poland, 644 of whom (42.3%) were admitted to hospitals after 24 February 2022. Before Russia's invasion of Ukraine the average of 0.3 child/day was admitted to hospital, and since the war started this number increased to 6.7 patients a day. Prior to the war, the most frequently reported hospital events among the Ukrainian migrant children were factors influencing health status and contact with health services (Z00-Z99) – 30.5%, certain conditions originating in the perinatal period (P00-P96) – 18.3%, and diseases of the blood and blood-forming organs and certain disorders involving the immune mechanism (D50-D89) – 8.2%. Since the beginning of the war, the incidence of health problems among Ukrainian child refugees has changed dramatically, with infectious and parasitic diseases (A00-B99) being the most common – 42.0%, followed by abnormal clinical and lab findings (R00-R99) – 16.2%, and diseases of the respiratory system (J00-J99) – 10.5%.
Conclusions/Learning Points: Studies on the health condition of child war refugees and the use of health services by them are of key importance for health policy and strategic planning of healthcare in the host countries.

NEONATAL INVASIVE CANDIDIASIS (NIC) IN LOW- AND MIDDLE-INCOME COUNTRIES (LMICS): BURDEN OF DISEASE AND CASE FATALITY.

Oral Presentations Session
ORAL PRESENTATION SESSION 02: MISCELLANEOUS I

Daniel Hsiang-Te Tsai[1,2], Ian Chang-Yen Wu[1,2,3], Ling-Fang Chang[4,5], Marie Jen-Huey Lu[6], Brishti Debnath[2], Adilia Warris[7], Mike Sharland[2], Yingfen Hsia[2,8], Laura Ferreras-Antolin[2,7,9]
[1]National Cheng Kung University, School Of Pharmacy And Institute Of Clinical Pharmacy And Pharmaceutical Sciences, College Of Medicine, Tainan, Taiwan, [2]St George's, University of London, Centre For Neonatal And Paediatric Infection, London, United Kingdom, [3]National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Department Of Pharmacy, Tainan, Taiwan, [4]National Yang-Ming Chiao Tung University, Institute Of Public Health, School Of Medicine, Taipei, Taiwan, [5]Taipei Veterans General Hospital, Department Of Pharmacy, Taipei, Taiwan, [6]National Yang Ming Chiao Tung University School of Pharmaceutical Science, Department Of Pharmacy, Taipei, Taiwan, [7]University of Exeter, Mrc Centre Medical Mycology, Exeter, United Kingdom, [8]Queen's University Belfast, School Of Pharmacy, Belfast, United Kingdom, [9]St. George's University Hospital NHS Foundation Trust, Paediatrics, London, United Kingdom

Backgrounds: Candida spp. are an important cause of neonatal infections. The real burden of NIC in LMICs has been poorly described and is likely underreported. We performed a systematic review and meta-analysis to evaluate the burden of this infection together with the case-fatality rates (CFR) in LMICs.
Methods: The systematic review included all articles published (excluding case reports, opinion pieces, conference proceedings, review articles and systematic reviews) about microbiologically confirmed NIC in LMICs until April 2022. No language restrictions applied. We performed a meta-analysis to estimate pooled incidence rates and CFR. Results were stratified by WHO region and risk of NIC (high-risk defined as <1500 gr birth-weight or <28 weeks gestational age).
Results: 465 articles were included, with 10,928 NIC cases from 36 LMICs. The distribution by WHO region was: 3976 (36.4%) Western Pacific; 3512 (32.1%) Africa; 1346 (12.3%) Southeast Asia; 989 (9.1%) Eastern Mediterranean; 813 (7.4%) Latin America; 292 (2.7%) Europe. 119 articles were included to estimate incidence rates and 98 articles for CFR. The incidence rate for mixed population (no exclusively high-risk neonates) was 3% (95% confidence interval [CI] 2-3%). Regional differences were observed, with the highest incidence rate reported in Southeast Asia (6% [95% CI, 3-10%]). A higher incidence rate was observed in high-risk neonates (8% [95% CI, 6-10%]). Overall, the CFR was 19% (95% CI, 16%-22%,). Sensitivity analysis showed a higher CRF after excluding articles published in Chinese language, 28% (95% CI, 23%-33%).
Conclusions/Learning Points: There was marked variation in incidence of NIC in LMICs. Compared to the published CFR in high income countries, CFR was higher in LMICs. Our data reveal that target neonatal studies focusing on prevention and management in these settings are urgently needed.

O0032 / #488

ASSOCIATIONS WITH SEVERITY IN MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN

Oral Presentations Session
ORAL PRESENTATION SESSION 03: COVID 19 AND MIS-C

Harsita Patel[1], Clare Wilson[1], Andrew Mcardle[1], Ortensia Vito[1], Samuel Channon-Wells[1], Eleanor Seaby[1], Priyen Shah[1], Claire Broderick[1], Giselle D'Souza[1], Tisham De[1], Elizabeth Whittaker[1,2], Aubrey Cunnington[1], Myrsini Kaforou[1], Jethro Herberg[1], Michael Levin[1]
[1]Imperial College London, Section Of Paediatrics, Infectious Disease, London, United Kingdom, [2]Department of Paediatric Infectious Diseases, St Mary's Hospital, Imperial College Nhs Healthcare Trust, London, United Kingdom

Backgrounds: Multisystem Inflammatory Syndrome in children (MIS-C) varies in severity with complications including cardiac involvement (54%), shock (60%) and multi-organ dysfunction requiring intensive care (71%). Early identification of children at risk of severe disease and cardiac involvement would help clinical management.
Methods: 1315 patients recruited through the BATS study were categorized into four severity categories: mild (no support), moderate (1 of oxygen, NIV, fluid bolus), severe (invasive ventilation or vasoactive treatment) or very severe (invasive ventilation and vasoactive treatment, or ECMO, RRT, death). Previously described physiological scores (incorporating cardiovascular, respiratory and neurological parameters) and a novel laboratory score, incorporating markers associated with MIS-C, were calculated: [CRP+ [(40-albumin) x 10] + (neutrophils x 10) + [(3- lymphocyte count) x 20] + (400 - platelet count) + [(150 – Hb) x 2] + troponin + ferritin + (lactate x 10)]. A combined physiological-laboratory score was calculated. Individual clinical and laboratory variables and these scores were evaluated for association with severity.
Results: In an adjusted model, age ($p<0.001$), sex ($p<0.001$), self-reported ethnicity ($p<0.001$-0.02), respiratory distress ($p<0.001$), gastrointestinal symptoms ($p<0.001$ for ³3), and ³3 neurological symptoms ($p<0.001$) were independently associated with severe or very severe disease. Blood marker trends significantly ($p<0.01$-0.0001) associated with severe or very severe disease include increased neutrophils, CRP, ferritin, d-dimer, troponin and lactate and decreased haemoglobin, lymphocytes, platelets, and albumin. The total physiological, laboratory and combined scores associated with severe disease at baseline (all $p<0.0001$; AUC 0.87, 0.78 and 0.91 respectively Figure 1) and 48-hours (all $p<0.005$, AUC 0.67, 0.76 and 0.79
respectively).

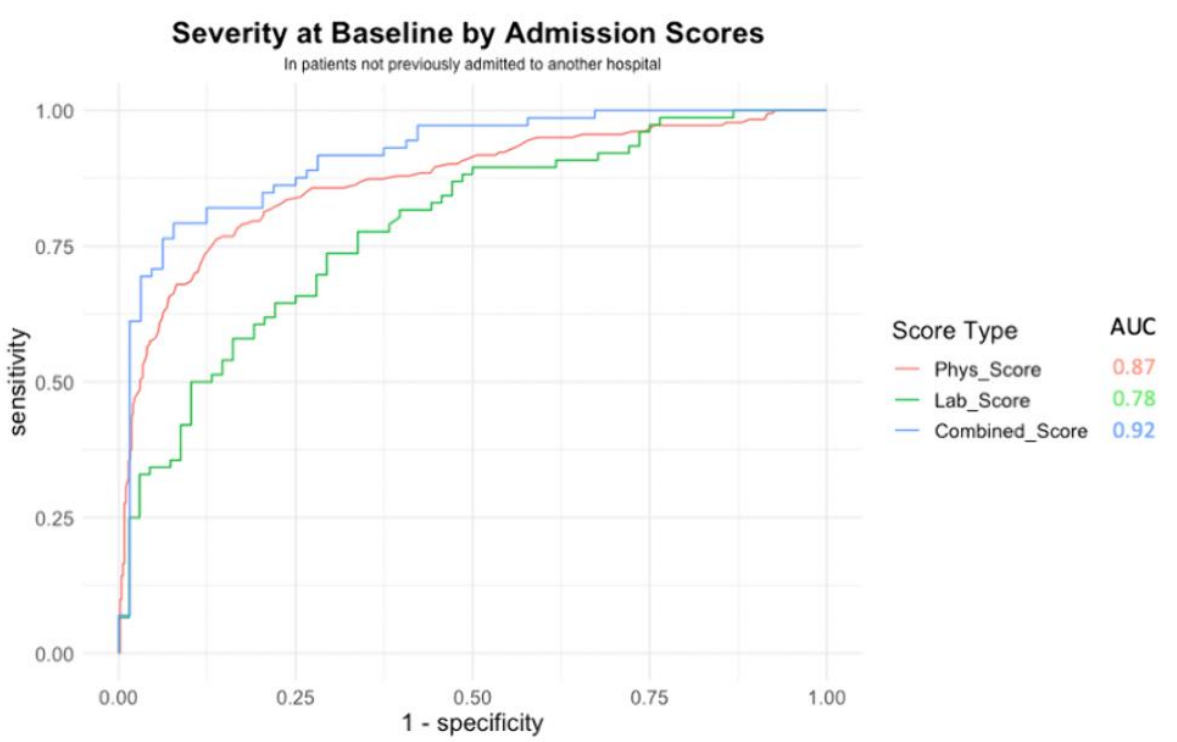

Figure 1: Receiving operator curves demonstrating predictive value of the physiological score, laboratory score and combined physiological-laboratory score for severity at baseline

Conclusions/Learning Points: We have shown individual and combined clinical and laboratory markers associate with severe disease at admission and 48-hours in children presenting to hospital with MIS-C. This is being externally validated.

HEALTHCARE RESOURCE UTILIZATION AND COSTS ASSOCIATED WITH ACUTE COVID IN PEDIATRIC PATIENTS MANAGED IN THE COMMUNITY OR HOSPITAL SETTING IN ENGLAND: A POPULATION-BASED STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 03: COVID 19 AND MIS-C

Jingyan Yang[1], Kathleen Andersen[2], Kiran Rai[3], Maya Reimbaeva[4], Leah Mcgrath[2], Carmen Tsang[5], Theo Tritton[3], Poppy Payne[5], Bethany Backhouse[3], Tendai Mugwagwa[6], Kevin Naicker[7], Diana Mendes[6], Tamuno Alfred[4], Mary Araghi[5], Robert Wood[3], Jennifer Nguyen[8]
[1]Pfizer Inc., Patient Health And Impact, New York, United States of America, [2]Pfizer Inc., Real World Evidence Center Of Excellence, New York, United States of America, [3]Adelphi Real World, Real World Evidence, Bollington, United Kingdom, [4]Pfizer Inc., Biostatistics, New York, United States of America, [5]Pfizer Ltd., Real-world Evidence, Tadworth, United Kingdom, [6]Pfizer Ltd., Health & Value, Tadworth, United Kingdom, [7]Pfizer Ltd., Medical Affairs, Tadworth, United Kingdom, [8]Pfizer Inc., Medical Affairs, New York, United States of America

Backgrounds: The COVID pandemic severely affected the UK healthcare system. We aimed to describe patient demographic and clinical characteristics, healthcare resource utilization and costs associated with acute COVID in pediatrics in England.
Methods: This population-based retrospective study used linked Clinical Practice Research Datalink (CPRD Aurum) and Hospital Episode Statistics (HES) data to identify persons aged 1-17 years who were: 1) hospitalized (admitted within 12 weeks of a positive COVID-19 PCR test between August 2020 - March 2021) and 2) non-hospitalized (positive test between August 2020 - January 2022 and managed in the community). Costs were calculated using 2021 UK healthcare reference costs.
Results: We identified 564,704 COVID cases. More cases were observed in older age groups for non-hospitalized & hospitalized cohorts (1-4 years: 7% and 25%; 5-11 years: 46% and 35%; 12-17 years: 47% and 40%, respectively). Among non-hospitalized & hospitalized cohorts, 2% and 20%, respectively, were considered high risk for severe COVID using COVID immunization priority groups in the UK HSA's Green Book. For the hospitalized cohort (n=60), median inpatient stay was 2 days for each age group. No cases aged < 12 received mechanical ventilation. Median (IQR) costs (critical care cost excluded) for a finished consultant episode with COVID as a primary diagnosis per-patient were £1,444 (£4,604) for ages 1-4, £1,471 (£4,604) ages 5-11 and £3,746 (£4604) ages 12-17. The majority (>90%) of non-hospitalized cases did not seek GP care in the 12 weeks after COVID diagnosis. Of those with at least 1 GP visit, the median healthcare costs in the non-hospitalized cohort for each age group was £15.
Conclusions/Learning Points: The COVID pandemic resulted in substantial healthcare resource allocation and costs among the pediatrics, driven largely by in-hospital stays.

Backgrounds: Amongst children, differences in the presentation and disease severity of SARS-CoV-2 lineages are not well understood. We aimed to determine the absolute and relative hospital burden of severe paediatric COVID-19 in Canada by age group and lineage.
Methods: Data were collected during two national surveillance studies: the Canadian Paediatric Surveillance Program (April 2020–May 2021) and Canadian Immunization Monitoring Program, ACTive (June 2021–May 2022). Children <17 years old hospitalized for COVID-19 (excluding incidental SARS-CoV-2) at one of thirteen sentinel paediatric hospitals were included. SARS-CoV-2 lineages were classified as "Ancestral", "pre-Delta" (Alpha, Beta, or Gamma), "Delta", or "Omicron" based on genetic sequencing or the predominant lineage across Canada at the time of hospitalization. Severe disease was defined as intensive care, ventilatory, or hemodynamic support requirements, organ system complications, or death.
Results: Among 1357 hospitalized children, median age at hospitalization was highest for Delta (3.0 years, interquartile range 0.2–11.1) and lowest for Omicron (1.3 years, interquartile range 0.3–5.4; p<0.001). COVID-19 vaccination (≥1 doses) was received by <5 pre-Delta (<4.8%), six Delta (3.4%), and 98 Omicron cases (11.9%). Among unvaccinated patients (n=1251; Table), severe COVID-19 was most common for Delta (34.3%) versus other lineages (24.0% ancestral, 22.3 pre-Delta, 24.8% Omicron; p=0.049). Differences were most pronounced for children aged <5 years, with Delta more often leading to intensive care and ventilation (21.6% and 15.7%) than other lineages (9.8–13.9%, p=0.053; 7.0–9.6%, p=0.03). The absolute number of hospitalizations among children aged <12 years during Omicron waves was greater than all other waves

combined.

Table. Disease severity of unvaccinated children with COVID-19, by timing of hospitalization.

[1]Descriptive statistics are presented as frequency and proportions, or medians and interquartile ranges. [2]Unadjusted comparisons were conducted using χ^2 and Fisher's exact tests; multivariable comparisons to be conducted upon completion of case reporting.

Conclusions/Learning Points: While Delta lineages were relatively more severe, substantially more children were hospitalized during Omicron waves. The epidemiologic differences between SARS-CoV-2 lineages may guide future planning for vaccination and health system resource planning.

Backgrounds: In Australia the Paediatric Active Enhanced Disease Surveillance (PAEDS) program monitors children hospitalised with severe disease across seven tertiary referral hospitals. In 2020, this network expanded its surveillance to include hospitalised COVID-19 cases. In addition to case surveillance that monitors severe or complicated disease, serosurveillance studies are important to determine population infection rates. Serosurveys that utilise residual sera systematically under-sample children because they present to health care infrequently or have minimal blood collected. During the COVID-19 pandemic, novel, population representative sampling approaches for serosurveillance were needed.
Methods: PAEDS SARS-CoV-2 surveillance program was expanded to include serosurveillance of children aged 0-19 years undergoing an anaesthetic procedure (e.g. for day surgery, trauma or other reason). Recruitment occurred from 3 November to 12 March 2021 (pre-vaccination rollout) and from 8 June 2022 to 31 August 2022 (vaccination recommended for ≥ 5 years). Samples were tested for anti-spike antibodies in 2021 and anti-spike and -nucleocapsid antibodies in 2022.
Results: We collected 3995 samples (1689 in 2020-21 and 2045 in 2022). Participants broadly reflected geographic and socio-economic status population distributions. Seroprevalence of anti-spike antibody increased from <0.6% (7/1689) to 90% (1833/2045) and anti-nucleocapsid seroprevalence was 64% (1309/2046) in 2022. Of those unvaccinated in 2022 (1,170), 961 (82%) had anti-spike antibodies detected and 739 (63%) anti-nucleocapsid antibodies detected. Children with pre-existing medical conditions had a lower prevalence of anti-nucleocapsid antibodies (59%) compared to those without medical conditions (67%).
Conclusions/Learning Points: Using a collaborative and well-established research network, we were able to recruit nearly 4000 children for the purpose of understanding SARS-CoV-2 paediatric seroprevalence in Australia, across 2 years. Our methodology shows promise as an efficient, acceptable and representative approach to paediatric serosurveys.

O0036 / #920

HOUSEHOLD TRANSMISSION AND CLINICAL FEATURES OF SARS-COV-2 POSITIVE AND NEGATIVE RESPIRATORY TRACT INFECTIONS DURING THE COVID-19 PANDEMIC: A COHORT STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 03: COVID 19 AND MIS-C

Jaakko Ahti[1], Laura Toivonen[1], Helena Ollila[2], Lauri Ivaska[1], Krista Salo-Tuominen[3], Tytti Vuorinen[4], Johanna Lempainen[1], Ville Peltola[1]
[1]University of Turku, Department Of Paediatrics And Adolescent Medicine, Turku, Finland, [2]Turku University Hospital, Turku Clinical Research Centre, Turku, Finland, [3]Turku University Of Applied Sciences, Laboratory, Turku, Finland, [4]Turku University Hospital, Department Of Clinical Microbiology, Turku, Finland

Backgrounds: There is a lack of comparative data for the transmission of respiratory infections positive and negative for SARS-CoV-2 in households with children.
Methods: We followed all respiratory tract infections in 700 participants from 175 households from June 2020 through April 2022. Daily symptoms were monitored by weekly electronic questionnaires. SARS-CoV-2 PCR tests were performed for symptomatic participants, and twice with a one-week interval for household members of positive participants. Clinical features and secondary attack rates (SAR), based on the onset of symptoms, were compared between SARS-CoV-2 positive and negative respiratory infections.
Results: Of 700 participants, 376 (54%) were children (median age, 11.1 years) and 324 (46%) adults. The majority (90%) of SARS-CoV-2 infections occurred from January through April 2022 when Omicron BA.1 and BA.2 were the dominant variants. Fever (51%) and cough (67%) were more common in SARS-CoV-2 positive infections compared to SARS-CoV-2 negative infections (18% and 43%, respectively; P <0.001 for both). Transmission occurred more often in SARS-CoV-2 positive households (84/117, 72%) than in SARS-CoV-2 negative households (280/603, 46%, P <0.001). The SAR for SARS-CoV-2 positive and negative infections was 44% and 24%, respectively (P <0.001). In SARS-CoV-2 positive infections, SAR was similar for the child (42%) and adult (46%; P = 0.43) index cases whereas in SARS-CoV-2 negative infections, SAR was higher for the child (27%) than for adult index cases (19%; P <0.001).
Conclusions/Learning Points: Compared to SARS-CoV-2 negative respiratory infections, SARS-CoV-2 positive infections presented with more severe symptoms and were transmitted more efficiently in households with children. Transmission of SARS-CoV-2 was similar for adult and child index cases, whereas transmission of SARS-CoV-2 negative infections was higher for child index cases.

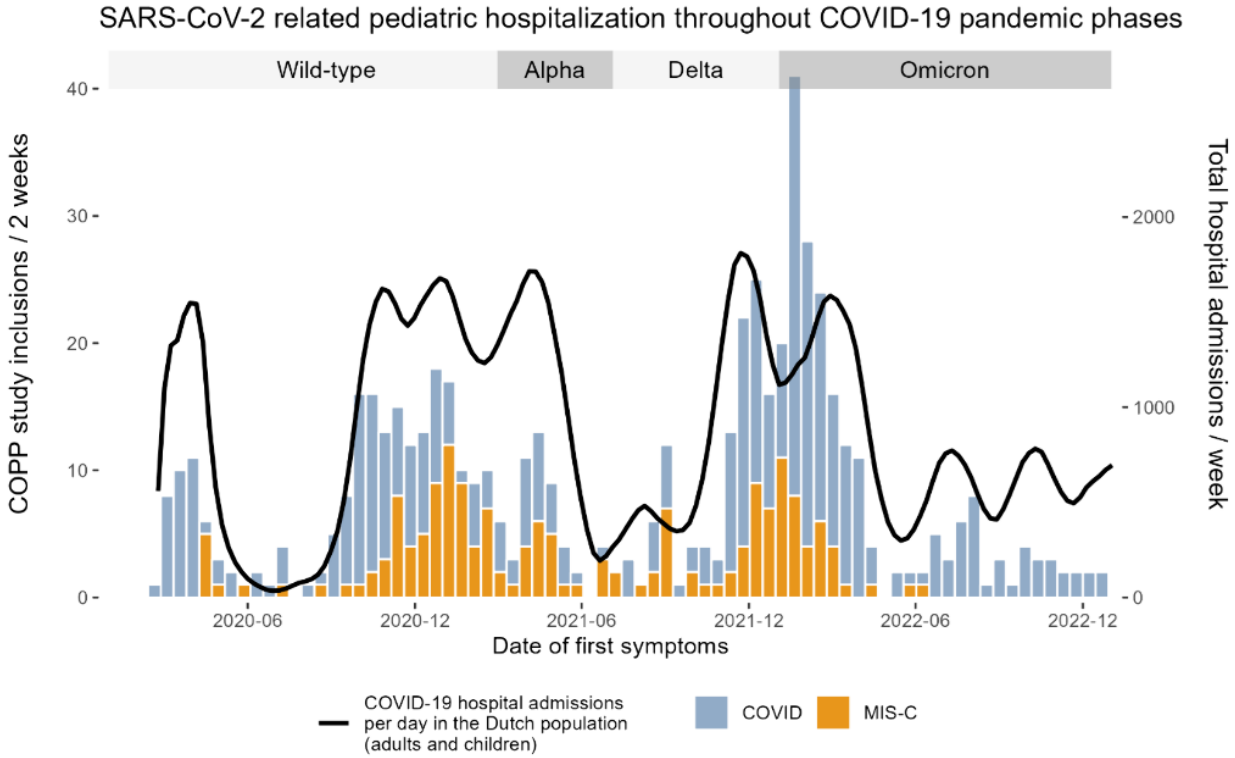
Backgrounds: Pandemic preparedness is key to reduction of morbidity and mortality in future pandemics. Real-life data reporting throughout the outbreak of a new disease has a major impact on policy making decisions.
Methods: This real-life hospital-based multicenter, prospective cohort study with online real-time reporting was active from March 2020 until December 2022. Children under 18 years of age with acute COVID-19 or Multisystem Inflammatory Syndrome in Children (MIS-C) presenting in 42 hospitals in the Netherlands, and two Caribbean hospitals (Curaçao and Surinam) were eligible to participate. Longitudinal incident rates and risk factors for severe disease were determined. In total, 589 children were included.
Results: The incidence rate as well as the severity for both acute pediatric COVID-19 and MIS-C were strongly reduced during the Omicron wave compared to the Wild-type, Alpha, and Delta waves. After June 2023, when pediatric seroprevalence approached 100%, a strong reduction of severe pediatric acute COVID-19 and MIS-C was observed. 125/415 (30%) patients with acute COVID-19 infection needed supplemental oxygen therapy and 31 (7.5%) patients required intensive care unit (ICU) admission. Higher age, cardiac and respiratory rate at initial hospital visit, and a positive medical history were predictors for severe disease in pediatric COVID-19. For MIS-C, 93/174 (53%) patients meeting the WHO criteria were admitted to ICU and 66 (40%) required inotropic medication. Low blood pressure, higher respiratory rate, cardiac and renal involvement were predictors for severe disease in MIS-C.



Conclusions/Learning Points: Our study shows that real-time reporting of accurate and high quality data is feasible and impacts clinical and public health decision making. The reporting framework of our consortium is readily accessible for future SARS-COV-2 waves and other emerging (pediatric) infectious diseases.

STREPTOCOCCUS PYOGENES IN CHILDREN WITH PARAPNEUMONIC PLEURAL EFFUSIONS AND PLEURAL EMPYEMA (PPE/PE) - PATIENT CHARACTERISTICS AND SUBTYPE DISTRIBUTION (ESPED STUDY, 2010-2020)

Oral Presentations Session
ORAL PRESENTATION SESSION 04: MISCELLANEOUS II

Eva-Lotta Tanzberger[1], Andrea Streng[1], Patricia Niekler[1], Johannes Forster[2], Christoph Schoen[2], Mark Van Der Linden[3], Johannes Liese[1]
[1]University Hospital of Wuerzburg, Department Of Pediatrics, Wuerzburg, Germany, [2]University Hospital of Wuerzburg, Institute Of Hygiene And Microbiology, Wuerzburg, Germany, [3]University Hospital RWTH Aachen, National Reference Center For Streptococci, Department Of Medical Microbiology, Aachen, Germany

Backgrounds: Streptococcus pyogenes (Spy) is the second most common pathogen of PPE/PE in children in Germany after S. pneumoniae (Liese 2018). Spy subtypes (emm-types) are classified by sequence typing of the M-protein (Imöhl 2017). We analyzed patient characteristics and emm-types in children with Spy-associated PPE/PE.
Methods: From October 2010 - June 2020, all hospitalized children <18 years of age with pneumonia-associated PPE/PE persisting for more than 7 days or requiring drainage were registered by the German Surveillance Unit for Rare Pediatric Diseases (ESPED). Spy detected from blood culture or pleural fluid (culture/PCR) were recorded. Supplemental eubacterial 16S-rDNA-PCR from pleural fluid was offered and Spy from available samples were subtyped.
Results: During 10 study years (SY), 210 children with Spy-associated PPE/PE were registered (median age 3 years [IQR 1-5]; 49% male; 19% with chronic conditions); the annual incidence increased from 0.045 (SY1) to 0.329 (SY10) per 100,000 children. Median length of hospital stay was 17 days (IQR 14-22); 176 (84%) children received intensive care treatment (median length 7 days [IQR 4-12]); 19% received thoracoscopy and 6% open thoracotomy. Two children (1%) died; 30 (14%) showed confirmed/possible sequelae. Spy was detected from blood culture in 27/183 (15%) and/or from pleural fluid in 198/206 (96%) samples. 35 of 71 submitted samples with Spy could be subtyped; most common was emm1 (29/35; 83%), followed by emm12 (3/35; 9%) and emm3, emm68, and emm75 (1/35 [3%] each).
Conclusions/Learning Points: The incidence of Spy-associated PPE/PE increased 7.3-fold from 2010 to 2020. In Germany, the proportion of PPE/PE-associated emm1 was 83% (29/35); higher than in children in Spain (14/27; 52%; Sanchez-Encinales 2019) and comparable to France (17/22; 77%; Bellulo 2016).

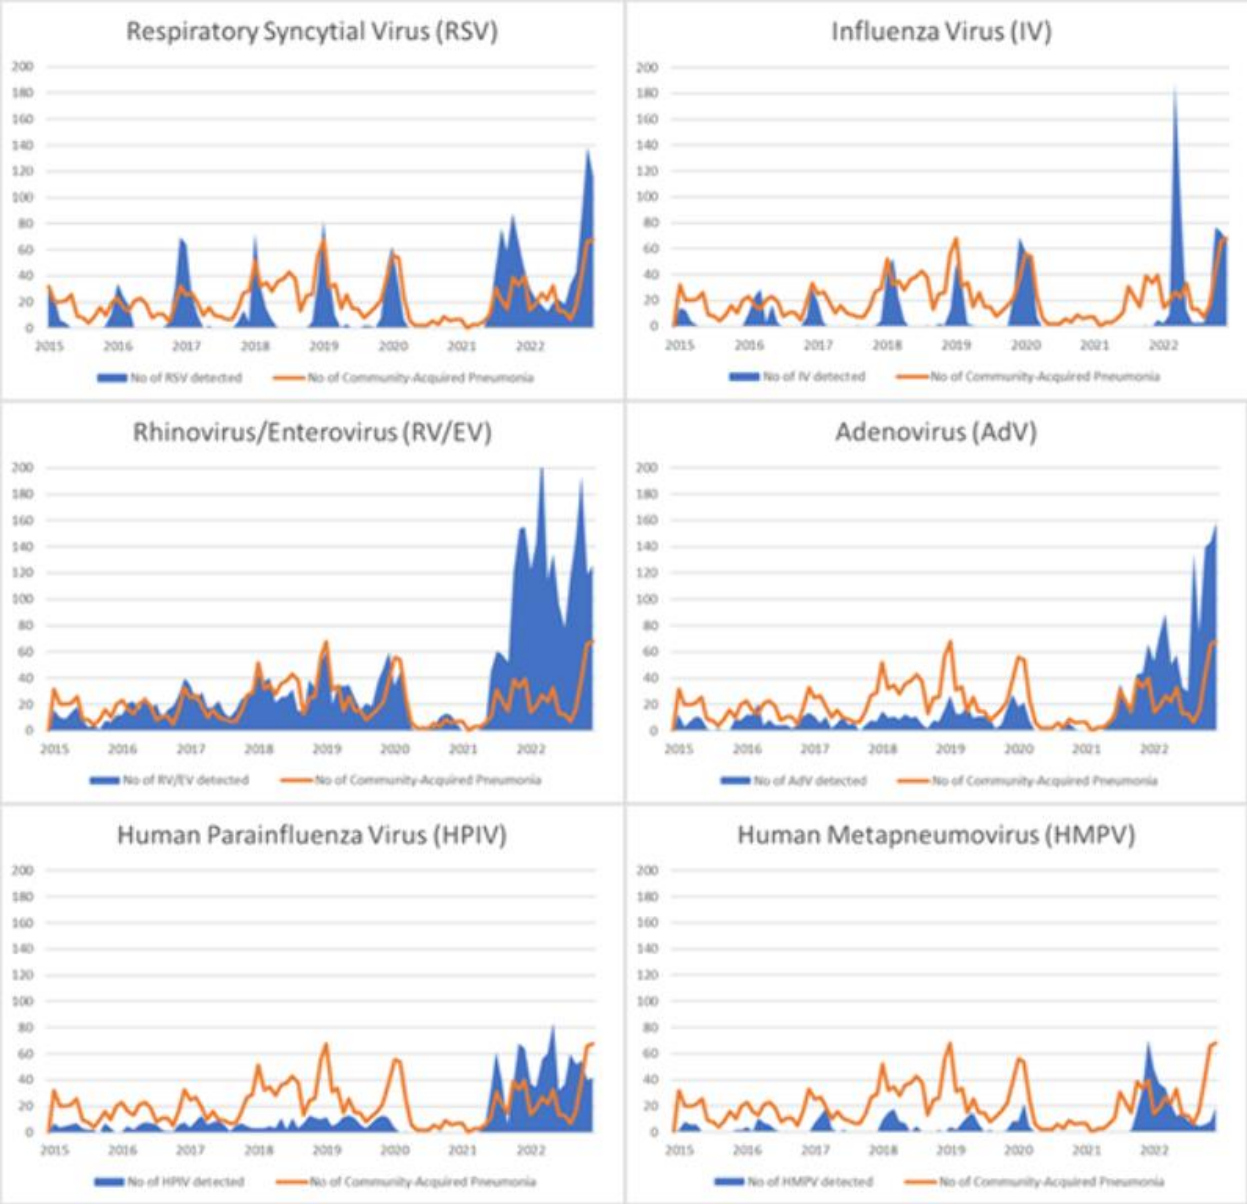
O0039 / #1416

THE LINK BETWEEN RESPIRATORY VIRUSES AND COMMUNITY-ACQUIRED PNEUMONIA (CAP)

Oral Presentations Session
ORAL PRESENTATION SESSION 04: MISCELLANEOUS II

Miguel Lucas[1], Mariana Costa[1], Lia Gata[1], João Pereira Vaz[2], Lurdes Correia[2], Fernanda Rodrigues[1,3]
[1]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Clinical Pathology Service, Coimbra, Portugal, [3]Universidade de Coimbra, Faculty Of Medicine, Coimbra, Portugal

Backgrounds: During the first year of the COVID-19 pandemic, there was a very important reduction in CAP diagnoses in children. The association of CAP with nasopharyngeal colonization by pneumococcus and respiratory viruses (RV) is known. Recent studies have shown no change in colonization characteristics during the pandemic, suggesting that CAP reduction was associated with decreased RV circulation. Given that the resurgence of these viruses occurred at different times, the aim of this study was to evaluate their impact on CAP diagnoses in an emergency service (ES) of a paediatric hospital.
Methods: Observational, retrospective, descriptive study, performed in a tertiary paediatric hospital that has received an average of 60 000 children/year. The analysis of the data from ES episodes, from January 2015 to December 2022, included: - all CAP diagnostic codes (ICD-9: 481 pneumococcal pneumonia; 482 other bacterial pneumonia; 4828 pneumonia due to other specified bacteria; 4829 unspecified bacterial pneumonia and ICD-10: J13 pneumococcal pneumonia; J159 unspecified bacterial pneumonia; J181 lobar pneumonia, unspecified organism); - all positive PCR tests (FilmArray respiratory panel) for RV.
Results: The distributions of CAP diagnoses and positive PCR tests for each RV, throughout the years are presented in figure 1. FIGURE 1. Number of various respiratory viruses detected by PCR and number of Community-Acquired Pneumonia cases by year, 2015-
2022



Conclusions/Learning Points: The pre-pandemic data suggest a link between seasonality of respiratory viral infections and the incidence of CAP. Data throughout the pandemic, with the resurgence of different RV at different times, suggest a stronger link between CAP and RSV than with Influenza. These findings support the concept that interventions to control RV could prevent a large proportion of CAP cases.

SHIFTS OF INFECTIOUS DISEASE PROFILE DUE TO WAR IN UKRAINE

Oral Presentations Session
ORAL PRESENTATION SESSION 04: MISCELLANEOUS II

Alina Zaretska
Odessa National Medical University, Children Infectious Diseases, Odesa, Ukraine

Backgrounds: Russian military invasion of Ukraine brings life-threatening risks for people, especially children. Not only the weapon affection but also the absence of access to hygiene, adequate nutrition, vaccination, and medical care on time. As a result, the poor statistic (couldn't cover occupated territory) uncovered the morbidity shifts, for instance, the infectious one.
Methods: The morbidity reports of different age people from all regions of Ukraine were analyzed for 11 months in 2022 and compared with the appropriate data in 2021.
Results: Acute intestinal infections (AII) with detected etiology were 41,99 per 100,000 population, which on 10,1% higher than in 2021, with the highest level of enteritis caused by rotavirus (12,97 per 100,000 population - 49,1% higher than in 2021). Despite our fears, officially, we had no cases of Cholera in Ukraine in 2022. Also, AII without detection of etiology was diagnosed (51,91 per 100,000 population), but their level was almost the same as it was in 2021 (3,1%). The level of acute respiratory infection in 2022 was 11081,26 per 100,000 population which is less if compared with 2021 to 38,0%. At the same time, the morbidity of Influenza was 10,92 per 100,000 population, which on 23,8% higher than in 2021. The situation with SARS-CoV2 morbidity changed very fast and achieved 15,87 per 100,000 population. Isolated cases of tularemia (1), listeriosis (2), rabies (2), and diphtheria (2) and in 12 people were detected as carriers of causative agents of non-toxigenic strains of diphtheria. Being the one of important life-threatening factors in case of war the Tetanus was diagnosed generally in 12 people. As a fact, the number of detection of scabies and pediculosis was less than in the previous 2021.
Conclusions/Learning Points: Despite a lot of risks and decreased public health response (destroyed medical and public health infrastructure, vaccination distribution) there are no threateningly increased levels of global health diseases in Ukraine.

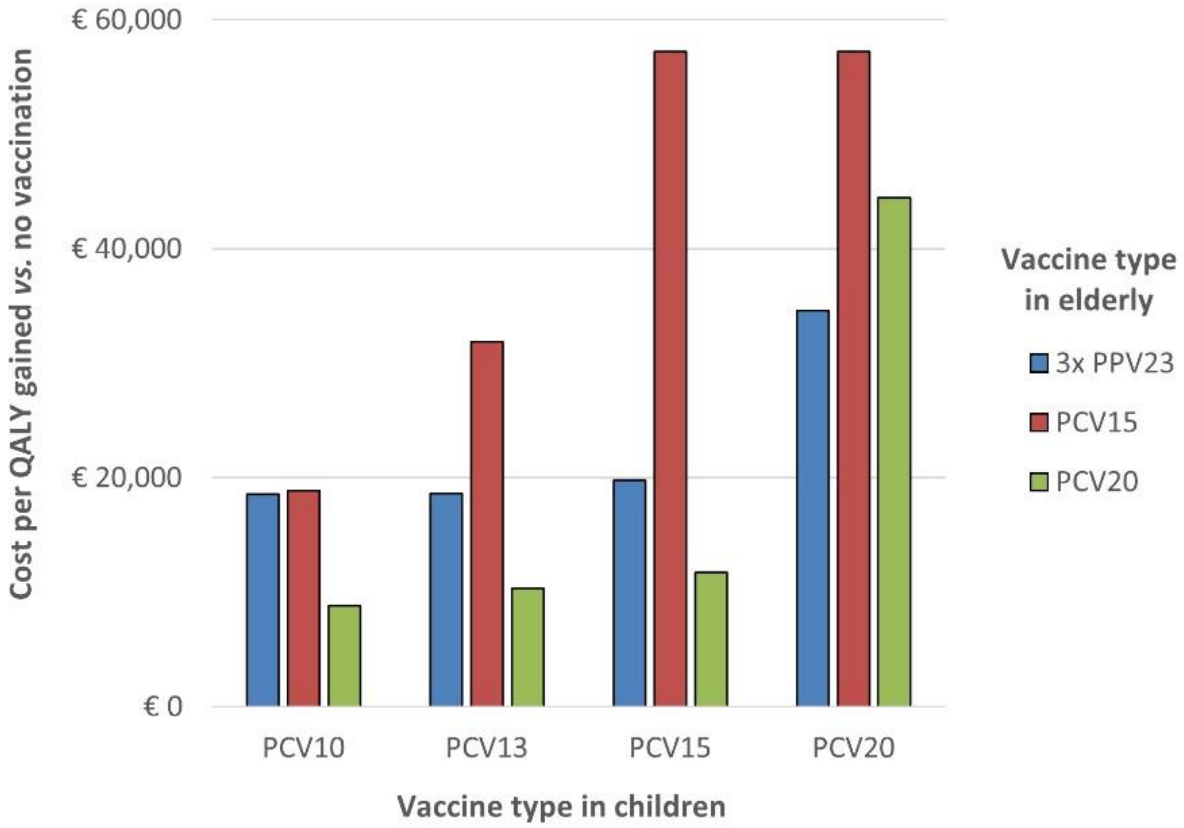
THE POTENTIAL IMPACT OF THE USE OF HIGHER-VALENT PNEUMOCOCCAL CONJUGATE VACCINES IN CHILDREN ON THE COST-EFFECTIVENESS OF PNEUMOCOCCAL VACCINATION IN ELDERLY

Oral Presentations Session
ORAL PRESENTATION SESSION 04: MISCELLANEOUS II

Pieter De Boer, Cornelius Van Werkhoven, Albert Jan Van Hoek, Mirjam Knol, Lieke Sanders, Jacco Wallinga, Hester De Melker, Anneke Steens
National Institute for Public Health and the Environment, Centre For Infectious Diseases, Epidemiology And Surveillance, Bilthoven, Netherlands

Backgrounds: New 15-valent and 20-valent pneumococcal conjugate vaccines (PCV15 and PCV20) are developed for use in children and adults. Current pediatric programs with PCV10 and PCV13 have shown to induce replacement of vaccine serotypes with non-vaccine serotypes, potentially mitigating the impact of elderly pneumococcal vaccination programs. We assessed the potential impact of higher-valent PCVs in children on the cost-effectiveness of different elderly pneumococcal vaccination strategies.
Methods: A static model parameterized for the Netherlands was used to estimate the cost-effectiveness of 23-valent pneumococcal polysaccharide vaccine (PPV23, every 5 years), PCV15 and PCV20 compared to no vaccination, in a cohort of 65-year-olds, over a time-horizon of 15 years. We assumed that herd protection reduced the disease burden from serotypes added to the pediatric vaccine in elderly by 80% (except serotype 3, no effect), and that this reduction in disease burden in elderly was completely offset by an increase in disease burden from serotypes not included in the pediatric vaccine.
Results: With PCV10-13 in children, PCV20 was the economically most attractive strategy for elderly (Figure 1, lowest cost per QALY gained compared to no vaccination). Higher-valent paediatric vaccines worsened the cost-effectiveness of the elderly vaccination programs, with the increase in cost per QALY depending on the extent of overlap between serotypes covered by the pediatric vaccine and the elderly vaccine. With implementation of PCV20 in children, the economically most attractive vaccination strategy for elderly changed from PCV20 to
PPV23.

Figure 1: Cost-effectiveness of elderly vaccination



Conclusions/Learning Points: The vaccine choice for pediatric pneumococcal programs affects the cost-effectiveness and optimal vaccine choice of elderly pneumococcal programs. Policy decisions on how to reduce the burden of pneumococcal disease in the entire population should be informed by combined economic evaluations for children- and elderly vaccination.

O0042 / #681

ASSESSING THE BURDEN OF BRONCHIOLITIS AND RESPIRATORY SYNCYTIAL VIRUS 15 DAYS AND 6 MONTHS FOLLOWING A PRIMARY CARE VISIT, FRANCE, 2021-2022

Oral Presentations Session
ORAL PRESENTATION SESSION 04: MISCELLANEOUS II

Alexis Rybak[1], Corinne Levy[1], Camille Jung[2], Stéphane Béchet[1], Christophe Batard[1], Fréderic Hassid[3], François Vie Le Sage[3], Jean François Salaun[3], Fabienne Cahn-Sellem[3], Mathieu Bangert[4], Rolf Kramer[4], Robert Cohen[1]
[1]ACTIV, Infectious Disease, Créteil, France, [2]CHI Créteil, Crc, Créteil, France, [3]AFPA, Pediatrics, Créteil, France, [4]Sanofi, Medical, Lyon, France

Backgrounds: Although the role of respiratory syncytial virus (RSV) in hospitalizations of infants for bronchiolitis is well known, its burden in outpatient settings is not sufficiently assessed. In the context of possible implementation of future generalized RSV prophylaxis, our study aimed to provide a baseline of the attributable burden of bronchiolitis in outpatient settings.
Methods: 46 pediatricians participating in the OURSYN study between February 2021 and September 2022 enrolled children <2 years old with a first episode of bronchiolitis. For each patient, a nasopharyngeal swab was taken for rapid diagnostic testing for RSV. Parents were called 15 days and 6 months after enrollment to complete a standardized follow-up questionnaire.
Results: Among the 753 children enrolled (mean age 8±5.7 months), 6.9% were preterm and 38.1% attended day care center. No significant differences in socio demographic characteristics were reported according to the RSV test result. RSV+ bronchiolitis cases had significantly more hospitalization, need for emergency department (ED) visits, parental leave and decreased food intake 15 days after outpatient visit compared to RSV- bronchiolitis
cases.

N (%)	RSV+ N=332 (44)	RSV- N=421 (56)	Total 753	p
15-day follow-up	**230 (69.3)**	**304 (72.4)**	**534 (71.0)**	**0.35**
Hospitalization	32 (14.2)	23 (7.6)	55 (10.4)	0.01
Need for ED visit	37 (16.6)	29 (9.9)	66 (12.8)	0.02
Parental leave	93 (46.7)	87 (35.1)	180 (40.3)	0.01
Need for new outpatient visit	81 (35.7)	127 (42.0)	208 (39.3)	0.14
Persistent wheezing	59 (28.1)	91 (33.3)	150 (31.1)	0.22
Persistent cough	101 (47.9)	137 (50.6)	238 (46.4)	0.56
Decreased food intake	56 (27.1)	40 (14.8)	96 (20.1)	0.001
6-month follow-up	**175 (52.7)**	**213 (50.7)**	**388 (51.6)**	**0.59**
Hospitalization	10 (6.1)	9 (4.7)	19 (5.4)	0.55
Need for ED visit	28 (16.3)	39 (19.2)	67 (17.9)	0.46
Parental leave	38 (24.5)	51 (28.3)	89 (26.9)	0.43
Need for new outpatient visit	164 (93.7)	197 (92.5)	361 (93.0)	0.64

Conclusions/Learning Points: Our study shows that the 15-day follow-up for outpatient children with RSV, which accounted for almost half of children with bronchiolitis, had a more severe disease with higher impact on parents and medical care. By contrast, the 6-month follow-up did not show any differences between the RSV+ and the RSV- groups. Our baseline data highlight that RSV prevention could greatly reduce the burden of bronchiolitis in outpatient settings.

Background: Congenital CMV (cCMV) is one of the leading causes of non-genetic hearing loss and neurologic impairment in children. We describe long-term outcomes of infants with cCMV in a European cohort (cCMVnet) according to cranial MRI findings at birth.
Methods: A multicentric study was performed within cCMVnet cohort in children with MRI and cranial US (cUS) performed in the first 3 months of life. Presence of hearing loss (HL), motor impairment (paresis/spasticity), epilepsy and/or visual impairment during follow-up were evaluated.
Results: 349 children with available MRI were included, 60.2% infants had abnormalities in MRI and 56.4% in cUS. Follow-up visit was available in 240 children, with a median follow-up of 26.5 [13.5–40.2] months. 84 (35%) children showed sequelae in the last evaluation: 75(31.2%) had hearing loss, 10(4.1%) epilepsy, 24(10%) motor impairment and 6(2.5%) visual impairment. Univariate analysis of prognostic factors is listed in table 1. Eighteen children developed Delayed Onset of HL (DOHL) (18/170; 10.5%), this was associated with abnormalities in MRI (p=0.05) (ventriculomegaly (p=0.032)) and physical examination at birth (p=0.003),but was not associated with abnormalities in cUS (p=0.5). In multivariate analysis abnormal physical examination at birth (OR: 4.0 95%IC:2.1– 7.8), ventriculomegaly in MRI (OR: 5.2 95%IC: 2.1–13.0), and white matter abnormalities (WMA) in MRI and in cUS (OR: 2.8 95%IC:1.5–5.4 and OR: 3.4 ;95%IC:1.2 – 9.5 respectively) were associated with

sequelae.

Conclusions/Learning Points: In this large European cohort, sequelae were associated with abnormalities in birth physical examination, brain MRI and cUS. Abnormalities in MRI were also associated with DOHL, which could have prognostic importance. Large cohort studies are essential to define risk factors for sequelae in cCMV infection. We encourage all ESPID members to enroll their patients in cCMVnet.

Lurie Children's Hospital of Chicago, Pediatrics (emergency Medicine), Chicago, United States of America, [2]Children's Hospital of Colorado, Emergency And Hospital Medicine, Aurora, United States of America, [3]Royal Children's Hospital, Paediatric Emergency Medicine, Melbourne, Australia, [4]Starship Children's Hospital, Children's Emergency Department, Auckland, New Zealand, [5]Cincinnati Children's Hospital Medical Center, Pediatric Emergency Medicine, Cincinnati, United States of America, [6]Biocruces Bizkaia Health Research Institute, Hospital Universitario Cruces, Pediatric Emergency Medicine, Bilbao, Spain, [7]Boston Children's Hospital, Pediatric Emergency Medicine, Boston, United States of America, [8]Children's Hospital of Eastern Ontario, Paediatric Emergency Medicine, Ottowa, Canada, [9]UC Davis, Emergency Medicine And Pediatrics, Davis, United States of America

Backgrounds: Elevation of certain host biomarkers are associated with disease severity in adults with community-acquired pneumonia (CAP). There are conflicting data, however, about these associations in children. We evaluated the association of white blood cell (WBC), absolute neutrophil counts (ANC), C-reactive protein (CRP), and procalcitonin (PCT) with development of severe outcomes in children with CAP.
Methods: We performed a prospective cohort study of children 3 months to 14 years with CAP in 69 emergency departments (ED) globally in the Pediatric Emergency Research Network (PERN). Blood biomarkers were obtained at the discretion of the treating clinician. The primary outcome was disease severity: mild (discharged home), moderate (hospitalized, but not meeting severe criteria), or severe (ICU>24 hours, positive-pressure ventilation, vasopressors, chest drainage, ECMO, death within 7 days).
Results: Of 2540 enrolled children, WBC was obtained in 1004, ANC in 1007, CRP in 792, and PCT in 152 children. There were no significant differences in median WBC or ANC across severity categories (Table). Increasing CRP and PCT concentrations were significantly associated with more severe disease. In multivariable analyses adjusting for age, antibiotic use for the current illness, fever duration and viral pathogen detection, CRP and PCT were associated with more severe outcomes. No biomarker had sufficient sensitivity, specificity, or discriminatory capacity; however, CRP and PCT had better diagnostic performance (per AUC) for severe disease compared with the WBC and
ANC.

Table. Blood Biomarkers and Disease Severity in Children with CAP

Median [Interquartile Range] Across Severity Levels							
	Mild	**Moderate**	**Severe**	**p-value***			
WBC (1000/uL)	11.3 [7.5, 16.5]	12.4 [8.6, 17.9]	11.6 [7.5, 17.7]	0.07			
ANC (1000/uL)	6.9 [4.3, 12.4]	7.9 [4.9, 12.9]	7.9 [5, 13]	0.1			
CRP (mg/dL)	3.1 [1, 7]	5.1 [1.9, 13.1]	18.5 [6.2, 27]	<0.001			
PCT (ng/mL)	0.25 [0.13, 2.3]	0.97 [0.23, 6]	3.5 [0.48, 10.8]	0.03			
Diagnostic Performance							
		Mild vs. Moderate/Severe Disease			**Mild/Moderate vs. Severe Disease**		
	aOR**	**Sensitivity**	**Specificity**	**AUC**	**Sensitivity**	**Specificity**	**AUC**
WBC>15	1.3 (0.98,1.72)	37 (33.7,40.5)	69.9 (63.5,75.7)	0.534 (0.5,0.569)	41.1 (31.1,51.6)	65.1 (61.9,68.1)	0.531 (0.479,0.583)
WBC>20	1.12 (0.79,1.59)	17.4 (14.8,20.2)	83.8 (78.4,88.4)	0.506 (0.479,0.533)	18.9 (11.6,28.3)	83.1 (80.5,85.4)	0.51 (0.469,0.551)
ANC>10	1.22 (0.93,1.62)	37.7 (34.3,41.2)	67.9 (61.3,74)	0.528 (0.492,0.563)	38 (28.1,48.8)	63.7 (60.5,66.8)	0.509 (0.456,0.561)
CRP>2	1.91 (1.36,2.67)	74.2 (70.6,77.6)	37.7 (30.2,45.6)	0.559 (0.518,0.601)	85.7 (75.3,92.9)	29.6 (26.2,33.1)	0.576 (0.532,0.621)
CRP>6	2.33 (1.68,3.22)	48.2 (44.2,52.2)	66.7 (58.8,73.9)	0.574 (0.533,0.615)	75.7 (64,85.2)	57.9 (54.2,61.5)	0.668 (0.614,0.722)
PCT>0.5	2.9 (1.29,6.53)	64.1 (55.1,72.3)	65.2 (42.7,83.6)	0.646 (0.538,0.754)	71.4 (41.9,91.6)	41.6 (33.3,50.3)	0.565 (0.436,0.695)
PCT>2	2.62 (1.15,6)	41.4 (32.8,50.4)	73.9 (51.6,89.8)	0.577 (0.475,0.678)	64.3 (35.1,87.2)	63.5 (54.9,71.6)	0.639 (0.503,0.775)

*p-values calculated by Kruskal-Wallis rank sum test comparing mild, moderate, and severe for each biomarker

**Each biomarker was included individually in ordinal regression models and adjusted for age, duration of fever, prior antibiotic use for the current illness, and viral detection

Conclusions/Learning Points: Conclusions: None of the blood biomarkers examined can be used in isolation to predict severe outcomes in children with CAP. However, CRP and PCT are more strongly associated with moderate and severe disease than are WBC and ANC, which have limited discriminatory ability.

Backgrounds: Nearly half of infants with a symptomatic respiratory syncytial virus (RSV) infection do not seek medical attention. Current focus on medically-attended RSV infections therefore underrepresents the true burden of RSV on society. To capture the population burden of RSV, we assessed the clinical and societal burden of non-medically attended RSV infections in healthy term-born infants during the first year of life.
Methods: The RESCEU study is a prospective, observational birth cohort study that enrolled healthy term-born infants (n=9164) between 2017 and 2020 in five European countries. We performed active RSV surveillance in a nested cohort (n=993) until the age of one year. During an RSV episode, parents kept a diary of symptoms, medicine use, healthcare resource use, and family impact.
Results: A total of 102 infants with a non-medically attended RSV episode were included. Median duration of any respiratory symptoms and moderate-severe respiratory symptoms were 14 days (IQR 4) and 5 days (IQR 3.5) respectively. Cough was the most common respiratory symptom (97.1%) and persisted for a median of 11 days (IQR 6). Commonly reported non-respiratory symptoms were feeding difficulties (69.6%), vomiting (54.9%) and fever (51.0%). Medicine use was reported in 53.9% of episodes. More than half of parents noted impairment in usual daily activities (58.9%) for a median duration of 5 days (IQR 8), and nearly a quarter (24.5%) reported absenteeism from work.
Conclusions/Learning Points: Even when medical attendance is not required, RSV infection in infancy poses a significant burden to infants, families and society at large. These findings are important for policymakers when deciding on the implementation of RSV immunoprophylaxis or maternal vaccination in a national immunization program.

PHARMACOKINETICS, SERUM-NEUTRALIZING ACTIVITY, AND EFFICACY FROM A PHASE 1B/2A INFANT STUDY OF CLESROVIMAB (MK-1654), AN RSV- NEUTRALIZING MONOCLONAL ANTIBODY

Oral Presentations Session
ORAL PRESENTATION SESSION 05: RESPIRATORY INFECTIONS

Brian Maas[1], Radha Railkar[1], Xin Cao[1], Farina Hellman[1], Sinoeun Touch[1], Andrea Krick[1], Luzelena Caro[1], Jingxian Chen[1], Nele Plock[2], S. Y. Amy Cheung[2], Brad Roadcap[1], Jeffrey Sachs[1], Kalpit Vora[1], Antonios Aliprantis[1], Andrew Lee[1]
[1]Merck & Co., Inc., Research, Rahway, United States of America, [2]Certara, Research, Princeton, United States of America

Backgrounds: Clesrovimab is an investigational RSV-neutralizing monoclonal antibody targeting site IV of the RSV F fusion protein for the prevention of RSV lower respiratory tract infection in infants.
Methods: This phase 1b/2a double-blind, randomized, placebo-controlled study evaluated the safety, tolerability, pharmacokinetics (PK), and serum neutralizing antibody (SNA) titers of clesrovimab in pre-term (born 29-35 weeks gestational age) and full-term infants. The study randomized 181 infants 2 weeks to 8 months of age in a 4:1 ratio within five separate panels (pre-term: 20, 50, 75 or 100-mg, full-term: 100mg) to receive a single intramuscular dose of clesrovimab or placebo. Blood samples were collected to quantify clesrovimab serum concentrations and SNA titers. Exploratory efficacy analyses were conducted for RSV-associated medically attended lower respiratory tract infection (MALRI), RSV-associated acute respiratory Infection (ARI, which encompasses upper and lower respiratory tract infection) and RSV-associated hospitalization through day 150 post-administration.
Results: The half-life of clesrovimab was approximately 42 days. A linear relationship was observed between increasing concentrations of clesrovimab and increasing SNA. The efficacy of a 100 mg dose of clesrovimab vs. placebo was 80.6% (95% CI: -141.2%, 99.6%) against RSV-associated MALRI and 71.6% (95% CI: -97.8%, 97.4%) against RSV-associated ARI from days 1 to 150 post-administration. Three infants who received placebo were hospitalized with RSV infection while no RSV-associated hospitalizations were observed in infants receiving any dose of clesrovimab from days 1 to 150 post-administration (Table 1).

Table 1: Efficacy through Day 150, Full Analysis Set

		Clesrovimab		Placebo		
RSV-Associated Clinical Endpoint		Participants	Cases	Participants	Cases	Observed Efficacy %, (95% CI) ‡
MALRI	100 mg Vs. placebo	64	1	38	3	80.6 (-141.2, 99.6)
MALRI	Combined* dose group Vs. placebo	143	3	38	3	74.2 (-92.9, 96.5)
ARI	100 mg Vs. placebo	64	2	38	4	71.6 (-97.8, 97.4)
ARI	Combined* dose group Vs. placebo	143	8	38	4	48.7 (-132.8, 86.3)
Hospitalization	100 mg Vs. placebo	64	0	38	3	100 (-39.4, 100)
Hospitalization	Combined* dose group Vs. placebo	143	0	38	3	100 (37.9, 100)

*Combined 20, 50, 75 and 100mg dose groups

‡ Estimated based on the exact binomial method proposed by Chan and Bohidar

Conclusions/Learning Points: While subject to limitations of small sample size, these results support the efficacy of clesrovimab against RSV-associated upper and lower respiratory tract infection and hospitalization and warrant continued evaluation in ongoing phase 3 studies.

Backgrounds: Bronchiolitis is a major source of morbimortality among young children worldwide. Non-pharmaceutical interventions (NPIs) implemented to reduce the spread of SARS-CoV-2 may have had an important impact on bronchiolitis outbreaks, as well as major societal consequences. Discriminating between their respective impacts would help define optimal public health strategies against bronchiolitis. We aimed to assess the respective impact of each NPI on bronchiolitis outbreaks in 14 European countries.
Methods: We conducted a quasi-experimental interrupted time-series analysis based on a multicentre international study. All children diagnosed with bronchiolitis presenting to the paediatric emergency department of one of the 27 centres from January 2018 to March 2021 were included. We assessed the association between each NPI and change in the bronchiolitis trend over time by seasonally adjusted multivariable quasi-Poisson regression modelling.
Results: In total, 42,916 children were included. We observed an overall cumulative 78% reduction (95%CI [-100;-54], p<0.0001) in bronchiolitis cases following NPI implementation. The decrease varied between countries from -97% (95%CI [-100;-47], p=0.0005) to -36% (95%CI [-79;+07], p=0.105). Full lockdown (IRR 0.21, 95%CI [0.14;0.30], p<0.001), secondary-school closure (IRR 0.33, 95%CI [0.20;0.52], p<0.0001), wearing a mask indoors (IRR 0.49, 95%CI [0.25;0.94], p=0.034), and teleworking (IRR 0.55, 95%CI [0.31;0.97], p=0.038) were independently associated with reducing bronchiolitis.
Conclusions/Learning Points: Several NPIs were associated with a reduction of bronchiolitis outbreaks, including full lockdown, school closure, teleworking and facial masking. Some of these public health interventions may be considered to further reduce the global burden of bronchiolitis.

O0048 / #2116

HOW DID THE UK COVID-19 LOCKDOWNS DISRUPT THE SEASONALITY AND AGE STRUCTURE OF RESPIRATORY SYNCYTIAL VIRUS TRANSMISSION?

Oral Presentations Session
ORAL PRESENTATION SESSION 05: RESPIRATORY INFECTIONS

Zoe Hancock[1], Peter Muir[2], Paul North[2], Philip Williams[2], Adam Finn[1], Robin Marlow[3]
[1]Bristol Royal Hospital for Children, Bristol Children's Vaccine Centre, Bristol, United Kingdom, [2]UKHSA, South West Regional Laboratory, Bristol, United Kingdom, [3]Bristol Royal Hospital For Children, Paediatric Emergency Department, Bristol, United Kingdom

Backgrounds: The UK's COVID-19 lockdowns also interrupted the transmission of other childhood infections. We investigated how the seasonality, age dynamics and severity of respiratory syncytial virus (RSV) infections were affected over the following two seasons compared to a 'normal' pre-pandemic year.
Methods: Bristol Royal Hospital for Children is the only paediatric hospital for a population of 180,000 children in the South-West of England. All admissions with respiratory symptoms are routinely screened using a viral PCR panel. We retrospectively extracted the RSV results of all acute admissions for 2019-2022, extracting their age, diagnosis and length of stay.
Results: With no RSV epidemic in 2020, post-lockdown there was a large out of season outbreak in early 2021, a smaller outbreak in early 2022 followed by a more typical (still ongoing) winter. Post lockdown, there was a significant increase in age (p=<0.001), length of stay was increased for <12m, decreased for 12-24m but unchanged for
>24m.

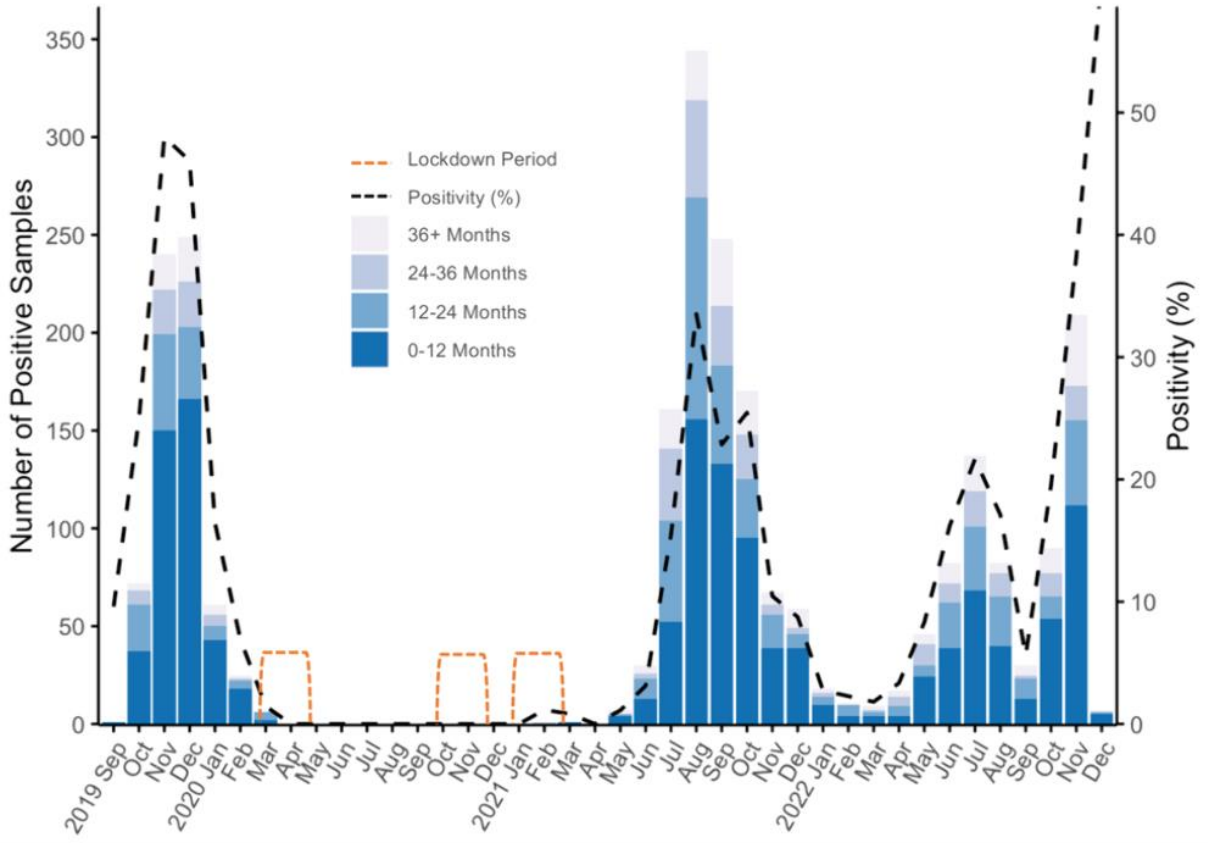

Table 1			
Year	Season	Number of Admissions	Median Age (months)
2019/20	Sep-Mar	591	7.4
2020	Apr-Mar	1	6.9
2021/22	Apr-Mar	1003	12.5
2022-23	Mar-ongoing	655	11.8

Conclusions/Learning Points: Changes in age dynamics and length of stay were observed after the UK's COVID-19 lockdown with sustained increase in RSV infection age post-pandemic but changes in length of stay suggesting potential milder disease in the children for whom RSV infection had been delayed. This natural experiment shifting age of infection for a cohort may provide useful modelling parameters for estimating the potential effects of passive immunity through long lasting monoclonal antibodies.

SUSTAINED IMPORTANCE OF STREPTOCOCCUS PNEUMONIAE AMONG PEDIATRIC COMPLICATED PNEUMONIA IN PORTUGAL (2019-22)

Oral Presentations Session
ORAL PRESENTATION SESSION 05: RESPIRATORY INFECTIONS

Joana Gomes-Silva, Catarina Silva-Costa, Marcos Pinho, Ana Friães, Mário Ramirez, José Melo-Cristino, . The Portuguese Group For The Study Of Streptococcal Infections, . The Portuguese Study Group Of Invasive Pneumococcal Disease Of The Pediatric Infectious Diseases Society
Faculdade de Medicina de Lisboa, Instituto De Microbiologia, Lisboa, Portugal

Backgrounds: To improve the etiological diagnosis of culture-negative pediatric complicated pneumonia (PCP), we expanded our real-time PCR assay to include other bacterial agents and evaluate potential changes in etiology after 7 years of near universal use of 13-valent conjugate pneumococcal vaccine (PCV13).
Methods: We collected 156 culture-negative pleural fluid and empyema samples from children (<18 years), in 62 hospitals in Portugal, from January 2019 to December 2022. Our assay included Streptococcus pneumoniae, Streptococcus pyogenes, Staphylococcus aureus, Mycoplasma pneumoniae, Haemophilus influenzae, Mycobacterium tuberculosis and Streptococcus agalactiae. For S. pneumoniae cases we performed molecular serotyping.
Results: Overall, 78 samples were negative for all bacteria tested (50.0%). Among the remaining 78 samples, the majority was positive for S. pneumoniae (n=64, 41.0%). S. pyogenes was found in 7 samples (4.49%), S. aureus in 5 samples (3.20%), H. influenzae in 2 samples (1.28%), and M. pneumoniae in 1 sample (0.64%). We did not detect M. tuberculosis nor S. agalactiae. In 2 samples, we detected the presence of DNA from both S. pneumoniae and another species: S. aureus (n=1) and H. influenzae (n=1). Among the pneumococcal samples, 44 were serotype 3 (56.4%), 5 were serotype 8 (6.41%), 2 were serotype 14 (2.56%) and serotypes 15A, 16F, 19A, 19F and 6C/6D were detected in 1 sample each (1.28% each). The remaining were negative for all serotypes tested (4.49%).
Conclusions/Learning Points: After two decades of pneumococcal conjugate vaccine use, S. pneumoniae is still responsible for most culture-negative PCPs, with PCV13 serotype 3 responsible for most cases. Expanding the molecular diagnostic panel to other species allowed the identification of the etiology of only an additional 9.62% of cases, suggesting that bacteria other than S. pneumoniae remain infrequent despite PCV13 use.

Backgrounds: We aimed to estimate the proportion of children hospitalized for influenza whose illness was complicated by bloodstream infection, describe their clinical course, and identify factors associated with bloodstream infection.
Methods: We performed active surveillance for laboratory-confirmed influenza hospitalizations among children ≤16 years old at the 12 Canadian Immunization Monitoring Program Active hospitals, from 2010 to 2021. Factors associated with bloodstream infection were identified using multivariable logistic regression analyses.
Results: Among 9,179 laboratory-confirmed influenza hospital admissions, bloodstream infection occurred in 87 children (0.9%). Streptococcus pyogenes (22%), Staphylococcus aureus (18%), and Streptococcus pneumoniae (17%) were the most common bloodstream infection pathogens identified. Children with cancer (adjusted odds ratio [aOR] 2.78, 95% confidence interval [CI] 1.23-5.63), a laboratory-confirmed non-bloodstream bacterial infection (aOR 14.1, 95% CI 8.04-24.3), or radiographically-confirmed pneumonia (aOR 1.87, 95% CI 1.17-2.97), were more likely to experience a bloodstream infection, whereas children with chronic lung disorders were less likely (aOR 0.41, 95% CI 0.19-0.80). Disease severity markers such as ICU admission (aOR 2.11, 95% CI 1.27-3.46), mechanical ventilation (aOR 2.84, 95% CI 1.63-4.80) and longer hospital length of stay (aOR 1.02, 95% CI 1.01-1.03) were associated with bloodstream infection. Bloodstream infection also increased the odds of death (aOR 13.0, 95% CI 4.84-29.1) after adjustment for age, influenza virus type and the presence of ≥ 1 at-risk chronic condition.
Conclusions/Learning Points: Bloodstream infections, although infrequent, are associated with ICU admission, mechanical ventilation, increased hospital length of stay, and in-hospital mortality, thus requiring increased levels of care among pediatric influenza hospitalizations.

Backgrounds: Respiratory syncytial virus (RSV) respiratory tract infection (RTI) is estimated to cause >100,000 deaths per year globally in children. In England it is estimated that 53% of RTI admissions in children <5 are caused by RSV. Nirsevimab was recently licensed in the UK for prevention of RSV Lower RTI in children. This study will provide granular data on the burden of RSV in primary care and hospitals in the UK. This unique study will provide data to inform policy decisions on which children should be immunised, at what age, and when in the season.
Methods: A prospective observational study in primary and hospital healthcare settings in Cheshire, Merseyside and Bristol, UK to estimate RSV incidence among children <3 years with RTI symptoms (target n=2000), Dec 2021 - March 2023 (ISRCTN:41075797). Nasal swabs collected from n=723 children <3 years old from December 2021–August 2022, tested on multiplex respiratory viral panel using Biofire/ Panther systems. This study is funded by a collaborative agreement with Sanofi / AstraZeneca.
Results: Overall RSV positivity was 49% in hospital and 16% in primary healthcare settings. RSV point prevalence was highest in Summer 2022 (compared to Winter 2021-22 and Spring 2022) and in hospital settings compared to primary care. Point prevalence of RSV was highest in <1yr olds.
Conclusions/Learning Points: As expected, the highest burden of RSV was found in infants <1 year but is significantly higher in other age groups post COVID-19 pandemic. The seasonality of RSV infection has been perturbed due to COVID-19 pandemic. This is the first prospective RSV swab data from primary care; importantly it suggests a large and previously unknown RSV disease burden in primary care. This data may be used to inform future immunisation programmes.

O0052 / #2015

GROUP A STREPTOCOCCUS: A RETURN TO PRE-PANDEMIC INCIDENCE BUT NO REBOUND IN PORTUGAL

Oral Presentations Session
ORAL PRESENTATION SESSION 05: RESPIRATORY INFECTIONS

Joana Oliveira[1], Ana Rita Jesus[1], Lia Gata[1], Lurdes Correia[2], Fernanda Rodrigues[1]
[1]Centro Hospitalar e Universitário de Coimbra, Hospital Pediátrico, Coimbra, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Clinical Pathology Service, Coimbra, Portugal

Backgrounds: A number of European countries reported an increase in the number of cases of invasive Group A Streptococcus (iGAS) disease among children <10 years of age, and in some cases also Scarlet Fever, seen during 2022, particularly since September 2022, with no newly emerging gene sequence types identified. The aim of this study was to evaluate the current epidemiological situation of non-invasive GAS infection in a paediatric tertiary centre, where iGAS remains very rare.
Methods: We performed an observational descriptive study in a paediatric tertiary centre that admits an average of 60 000 children/year, from January 2015 to December 2022 including all: - positive rapid antigen test for GAS; - ICD9 and ICD10 codes for Scarlet Fever and Streptococcal tonsillitis; - iGAS diagnoses.
Results:

	2015	2016	2017	2018	2019	2020	2021	2022
Number of children seen in Emergency Service/year	61 012	64 971	62 124	63 656	65 360	39 567	51 927	71 261
Number of rapid antigen tests for GAS	2974	3215	3513	3623	3814	1261	1297	2886
Number of positive rapid antigen tests for GAS (%)	1099 (37%)	1104 (34%)	1354 (39%)	963 (27%)	1166 (31%)	273 (22%)	105 (8%)	601 (21%)
Number of iGAS infections	1	4	7	1	2	0	0	3

Total number and monthly distribution of positive rapid antigen test for GAS, Scarlet Fever and Streptococcal Tonsillitis diagnoses are shown in the figure. In the pre-pandemic years (2015-2019) GAS infection presented with 2 peaks (May-June and November-December). After the first two years of the COVID-19 pandemic with a very reduced incidence, in 2022 there was a progressive rise, returning to the pre-pandemic numbers and seasonality. The number of iGAS cases remain small and unchanged.
Conclusions/Learning Points: In 2022, the distribution of GAS infections has returned to the pre-pandemic pattern. Up to date, iGAS infections remain rare and currently no more frequent than in a typical year, unlike the situation reported in some European countries. These epidemiological data will be continuously assessed.

O0053 / #77

INCIDENCE, SEVERITY AND CLINICAL CHARACTERISTICS OF LOWER RESPIRATORY TRACT INFECTIONS IN CHILDREN BEFORE AND AFTER LOCKDOWN – A RETROSPECTIVE COHORT STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 05: RESPIRATORY INFECTIONS

Marjolijn Nagelkerke[1], Matthijs Kruizinga[1], Mirjam Van Veen[1], Jolita Bekhof[2]
[1]Juliana Children's Hospital, Pediatrics, Den Haag, Netherlands, [2]Isala Hospital, Pediatrics, Zwolle, Netherlands

Backgrounds: SARS-CoV-2 public health measures reduced the incidence of pediatric lower respiratory tract infections (LRTIs) in 2020. An interseasonal surge in pediatric LRTI's occurred after relaxation of restrictions. We aimed to compare characteristics and disease severity of children presenting with LRTI's before, during, and after COVID-19 lockdown.
Methods: All LRTI presentations in a large pediatric hospital in the Netherlands between 2019 and 2021 were included. Parameters were compared between 2019 and 2020 and between 2019 and 2021. Variables included demographic characteristics, condition upon ED arrival, diagnosis, applied treatment, and clinical follow-up.
Results: Patients in 2020 were older compared to 2019 (median age 2.0 (IQR 0.8-4.5) years versus 1.3 (IQR 0.5-3.5) years, p <0.001). In 2021, median age was lower (1.1 (IQR 0.4-2.5) years, p = 0.003) and there was a larger proportion of bronchiolitis cases (64% versus 48% in 2019, p < 0.001). Oxygen saturation at presentation was lower in 2021 (17.0% <90% versus 12.6% in 2019) and admission rate was higher (58.4% versus 48.5%, p = 0.001). Both in 2020 and 2021, a larger proportion of children presented with co-occurring symptoms of obstructive lung disease compared to 2019 (20.6% in 2019 to 30% in 2020 (p = 0.003) and 29.5% in 2021 (p <0.001).
Conclusions/Learning Points: Children presenting with LRTIs in 2021 seem to have a more severe clinical phenotype, possibly explained by immunity debt after COVID-19 lockdown, stricter referral policy or changes in healthcare seeking behavior. Future research is needed to evaluate long-term consequences of growing up during lockdown.

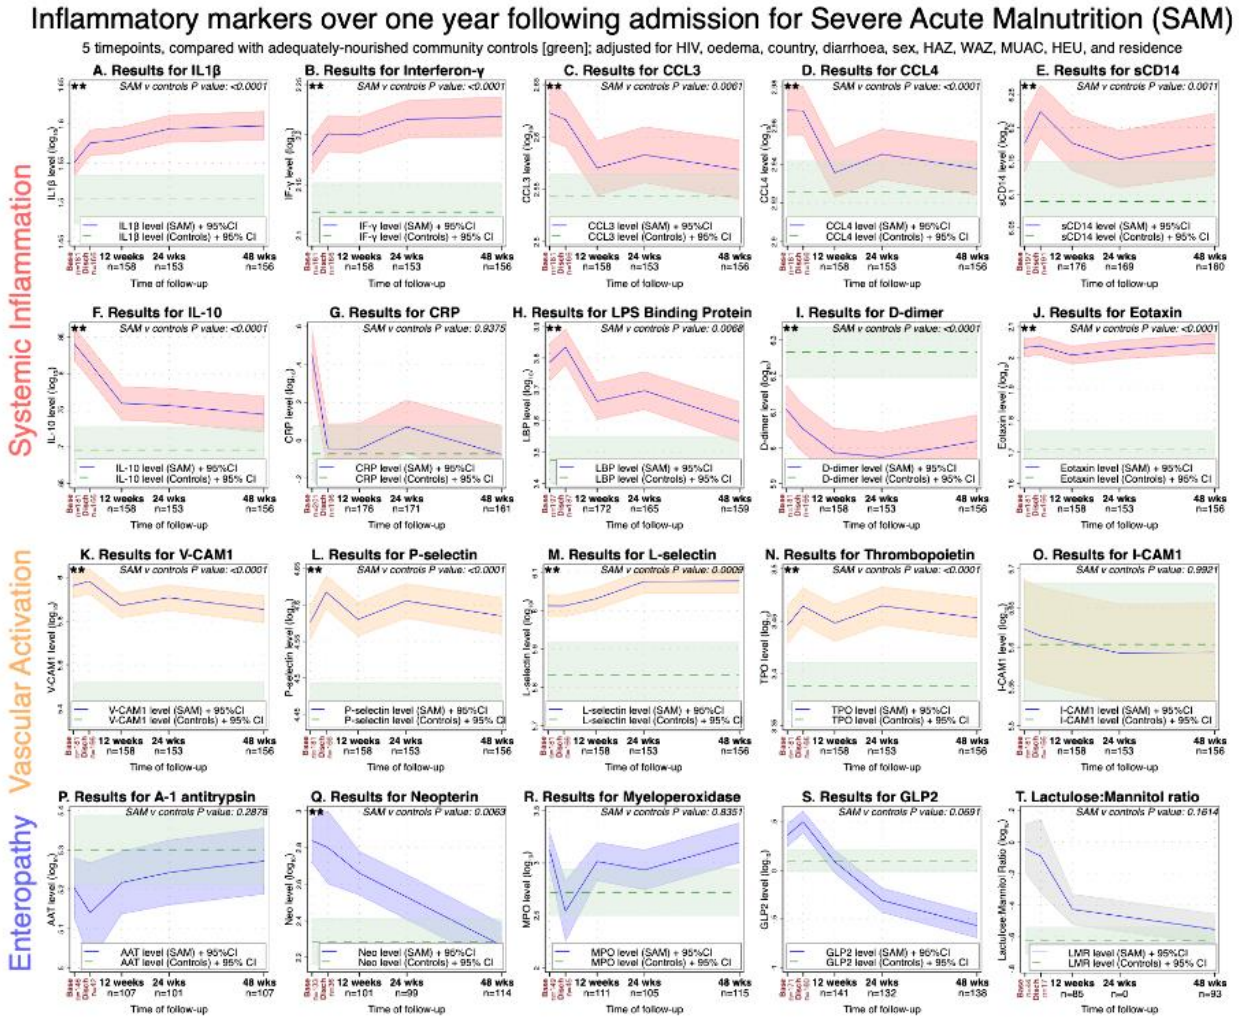
O0054 / #518

CHILDREN ADMITTED WITH SEVERE MALNUTRITION HAVE HIGHER INFLAMMATORY MARKERS, FURTHER EXACERBATED BY HIV; THESE REMAIN HIGHER OVER ONE-YEAR POST-DISCHARGE DESPITE NUTRITIONAL RECOVERY

Oral Presentations Session
ORAL PRESENTATION SESSION 06: GLOBAL HEALTH & HIV

Jonathan Sturgeon[1], Joice Tome[1], Cherlynn Dumbura[1], Florence Majo[1], Deophine Ngosa[2], Kuda Mutasa[1], Kanekwa Zyambo[2], Ellen Besa[2], Kanta Chandwe[2], Chanda Kapoma[2], Benjamin Mwapenya[1], Kusum Nathoo[3], Claire Bourke[4], Robert Ntozini[1], Bernard Chasekwa[1], Melanie Smuk[4], Mutsa Bwakura[5], Beatrice Amadi[2], Paul Kelly[2], Andrew Prendergast[1]
[1]Zvitambo Institute for Maternal and Child Health Research, Na, Harare, Zimbabwe, [2]University of Zambia, School Of Medicine, Lusaka, Zambia, [3]University of Zimbabwe, School Of Medicine, Harare, Zimbabwe, [4]Queen Mary University of London, Centre For Genomics And Child Health, London, United Kingdom, [5]University of Zimbabwe, Paediatrics, Harare, Zimbabwe

Backgrounds: Severe acute malnutrition (SAM) is the most high-risk form of undernutrition, particularly when children require hospitalisation for complications. It is a multisystem disease with high inpatient mortality, matched by a similar rate in the year post-discharge, frequently attributed to infections, particularly in children with HIV. However, we lack understanding of the underlying pathogenesis.
Methods: A prospective cohort study enrolled 262 children admitted with SAM across 3 hospitals in Zimbabwe/Zambia. They were followed up for 48 weeks post-discharge, with biospecimens taken at baseline, discharge, 12 weeks, 24 weeks, and 48 weeks. 173 adequately-nourished community-control children were recruited to assess normal values. A proteomic analysis examined 34 markers of inflammation in blood/stool at each timepoint, with significance adjusted for multiple-hypothesis testing.
Results: Children admitted with SAM have higher baseline inflammation compared with controls in multiple compartments: higher systemic inflammation (LBP, IL-8, IL1ra), endothelial activation (VCAM-1, P-selectin, L-selectin, eotaxin), and reduced placental growth factor. Children with SAM and HIV had higher inflammatory markers over children with SAM alone, including CRP, TNFa, IL-6, IL-33, IL-10, IL-2, and IL-1ra. Systemic, vascular, and intestinal inflammation does not resolve over one-year post-discharge despite phenotypic recovery from acute malnutrition, with 15/17 systemic inflammatory biomarkers, and 4/5 vascular inflammatory markers remaining higher over community controls (Figure 1). Following principal components analysis, children with higher systemic inflammation and lower epidermal growth factor had a greater risk of death/readmission to hospital.



Conclusions/Learning Points: Few studies have longitudinally examined the longitudinal pathophysiology of children following SAM. Our study highlights the high hidden need of these children after discharge, with ongoing systemic and vascular inflammation; this may represent a state of functional immunosuppression, with levels predicting ongoing mortality, frequently due to infection, despite their nutritional recovery.

Backgrounds: Invasive Group B streptococcus (GBS) is considered a common infectious cause of stillbirth and 0-90-day deaths. We examined stillbirths and 0-90-day deaths to investigate the role of GBS using post-mortem minimally invasive tissue sampling (MITS) in children from seven LMICs participating in Child Health and Mortality Prevention Surveillance (CHAMPS).
Methods: From December 2016-December 2021, post-mortem specimens collected by MITS within 24-48hours of death were investigated. Laboratory diagnostic tests included microbial culture of blood and cerebrospinal fluid, real-time PCR by TaqMan Array Card on blood, cerebrospinal fluid, nasopharyngeal swabs, and lung tissue and histopathological investigation of lungs, liver, placenta, and brain. Data collection included clinical record review and family interview using standardized verbal autopsy. Expert panels reviewed all information and assigned causes of death per WHO recommendations.

Results: We evaluated 2,966 deaths, including stillbirths (n=1,332), deaths within the first 24-hours (0-<24h; n=597), early-neonatal deaths (1d-<7d; n=593) and 7-90-day deaths (n=454). GBS was detected in post-mortem specimens in 11% (327/2,966) of deaths; it was part of causal chain of death for 2.7% (79/2,966; range 0.3% in Sierra Leone to 7.2% in South Africa), including 2.3% (31/1,322) of stillbirths, 4.7% (28/597) of deaths within the first 24-hours, 1.9% (11/593) of early-neonatal deaths and 2.0% (9/454) of 7–90-day deaths. Among GBS-attributed deaths, 49% weighed <2500grams at birth. Other infections in the causal pathway were found in 32.9% (26/79) of GBS deaths; and common pathogens were Escherichia coli 42% (11/26) and Klebsiella pneumoniae 27% (7/26).
Conclusions/Learning Points: Our findings confirm that GBS is an important and possibly underestimated cause of stillbirth and 0-90-day deaths in LMICs. These findings add to the substantial body of literature calling for better prevention options including maternal vaccination for GBS in high-mortality rate settings.

O0056 / #2265

PATHWAYS AND MORTALITY OF UNDER 5 CHILDREN IDENTIFIED AS SEVERE CASES WITH ROUTINE PULSE OXIMETRY USED INTO THE INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS GUIDELINES AT PRIMARY HEALTH CENTERS IN WEST AFRICA, JUNE 2021 TO JUNE 2022

Oral Presentations Session
ORAL PRESENTATION SESSION 06: GLOBAL HEALTH & HIV

Backgrounds: The Integrated Management of Childhood Illness (IMCI) guidelines for children under5 is a symptom-based algorithm, adapted for resources-limited countries at primary health center (PHC) level. To improve the diagnosis and care-management of severe cases with hypoxemia, the AIRE project, UNITAID-funded, has implemented the routine Pulse Oximeter (PO) use into IMCI consultations at PHCs in Burkina Faso, Guinea, Mali and Niger. This study purpose was to describe the care pathway and mortality of children with serious illness.
Methods: In 16 PHCs (4/country), all under5 children attending IMCI consultations and classified as severe cases were enrolled in a prospective short cohort study with 14-Days of follow-up, with parental consent.
Results: From June 2021 to June 2022, 39,360 children attended IMCI consultations at the research PHCs. Among the 3,163 identified as severe cases, 1998 were followed of whom 499 (25%) were referred to district hospital (DH) while 1470 (73.5%) were treated at PHC and 29 (1.5%) were not referred and treated at PHC. The D14-mortality rate was at 4.7% (95/1998 - 95% CI: 3.9-5.8). It was significantly different among children managed at hospital level with 14.8% (74/499-95% CI: 11.8-18.3) and those treated at PHC level with 1.3% (19/1470-95%CI: 0.8-2.0). Hypoxemia was detected in 141 children of whom 128 (91%) was treated at DH vs 13 (9%) at PHC. Their D14-mortality rate was at 26.2% (37/141; 95%CI: 19.2-34.3); 24.8% (35/141; 95%CI: 17.9-32.8) for referred children vs 1.4% (2/141; 95%CI: 0.2-5) for those treated at PHC.
Conclusions/Learning Points: Unexpectedly, referral of severe case to hospital is not systematic even for hypoxemia. The D14-mortality rate remain high especially at hospital level. The health Care Worker training, the practice of IMCI and the proper transfer of severe case remain challenges in West African

[1]ISGlobal - Barcelona Institute for Global Health, Maternal, Child And Reproductive Health, Barcelona, Spain, [2]ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, Immunology. Malaria Laboratory, Barcelona, Spain, [3]Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Moçambique., Maternal, Child And Reproductive Health, Manhiça, Mozambique, [4]Centro de Investigação em Saúde de Manhiça, Data Centre, Manhiça, Mozambique

Backgrounds: Pertussis is a highly contagious and potentially severe respiratory disease. HIV and malaria may affect immunity against childhood pathogens. We aimed to evaluate the effect of HIV and malaria in pregnancy on maternal and infant immunity against pertussis and on placental antibody transfer.
Methods: A prospective cohort study was conducted in pregnant women attending ANC and their infants in Mozambique. Peripheral and cord blood samples were collected from women and from infants at 1 and 9 months of age for antibody assays (Luminex). Maternal HIV serostatus was assessed. Peripheral/placental P. falciparum infection in pregnancy was assessed by microscopy/molecular/histological methods. Efficiency in placental transfer was determined through cord-to-mother ratio of antibodies against pertussis toxin (PT), pertactin (PRN) and fimbriae 2/3 (FIM).
Results: A total of 278 mother-infant pairs were enrolled, 101 mothers were HIV-infected and 40 mothers malaria-infected. Geometric mean (GM) antibody levels to PT, PRN and FIM were significantly lower at birth (cord) in infants born to HIV-infected mothers compared to HIV-uninfected; conversely, antibodies were higher in infants born to malaria-infected women compared to uninfected. HIV-infected women showed reductions in placental transfer (PT 13.1%, p=0.01; PRN 14.5%, p=<0.01; and FIM 10.9%, p=0.12) compared to HIV-uninfected. A trend towards reduction in antibody transfer was observed in malaria-infected women (PT 9.5%, p=0.15; PRN 5.2%, p=0.37; and FIM 16.9%, p=0.06) compared to uninfected. In multivariate analyses, maternal HIV infection (p<0.01), maternal anaemia (p<0.01) and a high maternal viral load (p=0.03) were associated with impaired placental transfer.
Conclusions/Learning Points: Maternal HIV is associated with lower mother-infant transfer of pertussis antibodies. An effect towards impaired placental transfer is also observed in pregnant women with malaria. Preventive interventions against pertussis may require to target HIV- and malaria-infected mothers and their infants.

ASSESSING THE USE OF NEONATAL BLOODSTREAM INFECTION GUIDELINES IN TWO SUB-SAHARAN AFRICAN COUNTRIES: WHAT IS USED AND WHAT IS USEFUL?

Oral Presentations Session
ORAL PRESENTATION SESSION 06: GLOBAL HEALTH & HIV

Felicity Fitzgerald[1], Nushrat Khan[2], Gwendoline Chimhini[3], Gloria Zailani[4], Deliwe Nkhoma[5], Samuel Neal[6], Mario Cortina Borja[2], Leyla Larsson[7], Tim Hull-Bailey[2], Emma Wilson[2], Katharina Kranzer[8], Hannah Gannon[2], Marcia Mangiza[9], Simbarashe Chimhuya[3], Michelle Heys[2], Msandeni Chiume[4]
[1]Imperial College London, Infectious Diseases, London, United Kingdom, [2]UCL, Ucl Gos Institute Of Child Health, London, United Kingdom, [3]University of Zimbabwe, Paediatrics, Harare, Zimbabwe, [4]Kamuzu Central Hospital, Paediatrics, Lilongwe, Malawi, [5]Neotree, Malawi, Lilongwe, Malawi, [6]University of Edinburgh, Neonatology, Edinburgh, United Kingdom, [7]LUDWIG MAXIMILIANS UNIVERSITY, Paediatrics, munich, Germany, [8]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom, [9]Ministry of Health and Child Care, Paediatrics, Harare, Zimbabwe

Backgrounds: Neonatal sepsis is a major cause of neonatal mortality in low-resource settings. In the frequent absence of microbiological diagnostics, clinical guidelines used to prescribe antibiotics prioritise sensitivity over specificity. We assessed how neonatal sepsis guidelines were used in two Zimbabwean hospitals (Sally Mugabe Central Hospital, SMCH; and Chinhoyi Provincial Hospital, CPH), and one Malawian hospital (Kamuzu Central Hospital, KCH).
Methods: Utilising routine data collected using the digital quality improvement tool Neotree, we retrospectively reviewed concordance of national and World Health Organization (WHO) guideline recommendation for commencement of antibiotics for suspected sepsis with clinicians' contemporaneous decisions. We compared clinical features and outcomes of neonates that would have received antibiotics as per guideline versus those who actually received them.
Results: From January 2021 to June 2022, data were collected on 10,868 neonates, 6045 admitted to SMCH, 1094 to CPH and 3729 to KCH (Table, 10,690 included in analysis). At all sites, complete implementation of national guideline recommendation to commence antibiotics would result in a large increase in prescription rates at admission: from 2253 (38%) to 3727 (63%) neonates at SMCH, from 472 (44%) to 852 (79%) at CPH, and 1519 (41%) to 3043 (82%) at KCH. Clinical features of sepsis were similarly distributed between both groups, but the case fatality rate was lower in the group not prescribed antibiotics despite guideline recommendation(Table). Complete implementation of WHO guidelines would lead to an increase in antibiotic prescription to 91% at SMCH, 88% at CPH, and 77% in KCH, Malawi

Table

Numbers of neonates admitted to facilities eligible for antibiotics as per national guidelines, comparing case fatality rates between those who received and did not receive antibiotics

Site	Total	Sepsis predicted (%)	% of eligible who received antibiotics	CFR of those who met criteria and received antibiotics (per 1,000)	CFR of those not receiving antibiotics despite meeting criteria	Fisher's exact test
SMCH (Zimbabwe)	5878	63%	49%	273	175	p<0.001
CPH (Zimbabwe)	1081	79%	54%	225	180	p=0.097
KCH (Malawi)	3728	82%	43%	246	215	p=0.048

SMCH: Sally Mugabe Central Hospital, Zimbabwe
CPH: Chinhoyi Provincial Hospital, Zimbabwe
KCH: Kamuzu Central Hospital, Malawi
CFR: Case Fatality Rate

Conclusions/Learning Points: Guidelines for bloodstream infection are inconsistently used, with clinicians using other features to triage neonates most in need of antibiotics. Work is needed to derive clinical diagnostic algorithms that are used and useful in low-resource settings.

O0059 / #2488

POPULATION PHARMACOKINETIC MODELLING OF CEFTRIAXONE IN CEREBROSPINAL FLUID IN CHILDREN: SHOULD WE BE USING ONCE OR TWICE DAILY DOSING FOR MENINGITIS?

Oral Presentations Session
ORAL PRESENTATION SESSION 06: GLOBAL HEALTH & HIV

Floyd Wang[1], Alison Boast[2], Gena Gonis[3], Amanda Di Carlo[3], Brett Mcwhinney[4], Jacobus Ungerer[4], Alice Lei[2], Joseph Standing[1], Amanda Gwee[2]
[1]Great Ormond Street Hospital for Children, Pharmacy Department, London, United Kingdom, [2]Murdoch Children's Research Institute, Infectious Diseases Group, Melbourne, Australia, [3]Royal Children's Hospital, Microbiology, Melbourne, Australia, [4]Pathology Queensland, Chemical Pathology, Brisbane, Australia

Background: International guidelines for bacterial meningitis in children recommend intravenous ceftriaxone 50mg/kg (max 2g) twice daily or 100mg/kg (max 4g) once daily, with the decision regarding the dose frequency determined by the prescriber. We investigated the cerebrospinal fluid (CSF) penetration of ceftriaxone in children and evaluated whether one dosing regimen is superior to another.
Methods: Serum and CSF samples from children aged 0-18 years treated with ceftriaxone were collected if there was excess sample left after clinical tests were performed and unbound ceftriaxone concentrations determined. A population pharmacokinetic (popPK) model was developed using non-linear mixed effects modelling. Once- and twice-daily dosing regimens were simulated and the probability of target attainment (PTA) of achieving CSF concentrations above the MIC of common meningitis pathogens for 100% of the dosing interval determined.
Results: Overall, 17 serum and 87 CSF samples were collected from 98 children (median age 1.9 years (range 0.2-18.5). The final two-compartment serum-CSF model included a post-menstrual age maturation function with weight scaling on clearance, intercompartmental clearance and volume of distribution. The median serum:CSF penetration was 15.5%. Both dosing regimens achieved a PTA >90% for bacteria with MICs of <1mg/L. However, for an MIC of 1 mg/L (i.e. E. coli), only the once-daily dosing regimen achieved a PTA >90%. For Staphylococcus aureus (MIC 4 mg/L), neither dosing regimen was sufficient.
Conclusions/Learning Points: This is the first paediatric serum:CSF popPK model of ceftriaxone. Our findings support a ceftriaxone dosing regimen of 100mg/kg once daily as empirical treatment for meningitis. Neither regimen achieved the pharmacodynamic target for S. aureus.

A PHASE III OPEN-LABEL, RANDOMIZED, CONTROLLED STUDY TO EVALUATE IMMUNOGENICITY AND SAFETY OF NOPV2 AT DIFFERENT INTERVALS OF ADMINISTRATION IN INFANTS IN DOMINICAN REPUBLIC

Oral Presentations Session
ORAL PRESENTATION SESSION 06: GLOBAL HEALTH & HIV

Ricardo Rüttimann[1], Luis Rivera Mejia[2], Lourdes Peña Mendez[3], Sonia Mazara[2], Nadia Rosario[3], Katy Rodriguez[2], Laura Rivera[2], Gabriela Aguirre[4], Chris Gast[5], Ananda Bandyopadhyay[6]
[1]FIDEC, Vaccines, Buenos Aires, Argentina, [2]HUMNSA, Neonatology, Santo Domingo, Dominican Republic, [3]Clinica Jimilian, Pediatrics, Santo Domingo, Dominican Republic, [4]FIDEC, Vaccines, Miami, United States of America, [5]Gast, Statistics, Sammamish, United States of America, [6]BMGF, Polio, Seattle, United States of America

Background: In November 2020, the WHO prequalification program issued an Emergency Use Listing authorization for novel OPV type 2 (nOPV2) to allow rollout of the vaccine in countries affected by circulating vaccine-derived poliovirus type 2 (cVDPV2) outbreaks. It is important to investigate the option of shorter interval administration of nOPV2 in vaccination campaigns for prompt interruption of outbreaks.
Methods: The primary objective of the study was to determine if the seroconversion (SC) rate to poliovirus type 2 (PV2), 28 days following 2 doses of nOPV2 given at 1 week or 2 weeks, is non-inferior to the standard 4-week interval administration in infants. Incidence of serious adverse events (SAE), important medical events (IME), solicited and unsolicited mild, moderate and severe adverse events (AEs) were also evaluated.
Results: 905 infants, 6 to 8 weeks old from Dominican Republic, were randomized with a 1:1:1 ratio to receive 2 doses of nOPV2 to the following groups: A: 302, 1 week apart, B: 300, 2 weeks apart, and C (control group): 303, 4 weeks apart. SC rates were 87.5% (CI95% 83.2-91.1), 91.8% (88.1-94.7), 95.5% (92.5-97.6) in group A, B and C respectively. Incidence of SAEs and IMEs were similar across groups and no causal association to the vaccination was reported.
Conclusions/Learning Points: Shorter intervals could be an option for nOPV2 administration in order to optimize immunization campaigns.

O0061 / #2512

OUTCOMES OF THE TREATMENT WITH SOFOSBUVIR/VELPATASVIR IN PATIENTS AGED 6 TO 18 YEARS WITH CHRONIC HEPATITIS C: RESULTS OF THE PANDAA-PED STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 06: GLOBAL HEALTH & HIV

Maria Pokorska-Śpiewak[1,2], Ewa Talarek[1,2], Małgorzata Aniszewska[1,2], Magdalena Pluta[1,2], Anna Dobrzeniecka[2], Magdalena Marczyńska[1,2], Giuseppe Indolfi[3]
[1]Medical University of Warsaw, Department Of Children's Infectious Diseases, Warsaw, Poland, [2]Regional Hospital of Infectious Diseases in Warsaw, Department Of Pediatric Infectious Diseases, Warsaw, Poland, [3]Meyer Children's University of Florence, Department Of Neurofarba, Firenze, Italy

Background: In this non-commercial, open-label, non-randomized clinical trial PANDAA-PED we analyzed the efficacy and safety of a fixed-dose pangenotypic regimen sofosbuvir/velpatasvir (SOF/VEL) in children and adolescents aged 6 to 18 years with chronic hepatitis C virus (HCV) infection.
Methods: Fifty patients qualified for the 12-week treatment were divided into two weight groups: 15 children weighting between 17 and <30 kg received a fixed dose of 200/50 mg of SOF/VEL (tablet) once daily, and 35 patients weighting ≥ 30 kg were treated with a fixed dose of 400/100 mg SOF/VEL. The primary endpoint of the study was efficacy defined as sustained viral response (undetectable HCV RNA using an real-time polymerase chain reaction, RT-PCR method) at 12 weeks posttreatment (SVR12).
Results: Median age of the participants was 10 (interquartile range, IQR 8 – 12) years, 47 were infected vertically, 3 patients were previously ineffectively treated with pegylated interferon and ribavirin. Thirty-seven participants were infected with HCV genotype 1, 10 with HCV genotype 3, and the remaining 3 with genotype 4. There was no case of cirrhosis. SVR12 was 100%. There were 33 reported adverse events (AEs) possibly or probably related to the administration of SOF/VEL, all of them were mild or moderate. Children presenting with AEs were older compared to these without AEs: median age 12 (9.5 – 13) vs. 9 (8 – 11) years, respectively (p = 0.008). The most commonly reported symptoms were headache (18%), abdominal pain (16%), and asthenia (12%).
Conclusions/Learning Points: Results of the PANDAA-PED study indicated a 100% effectiveness of a 12-week therapy with SOF/VEL in children aged 6 to 18 years with chronic HCV infection and its good safety profile, in particular in younger patients.

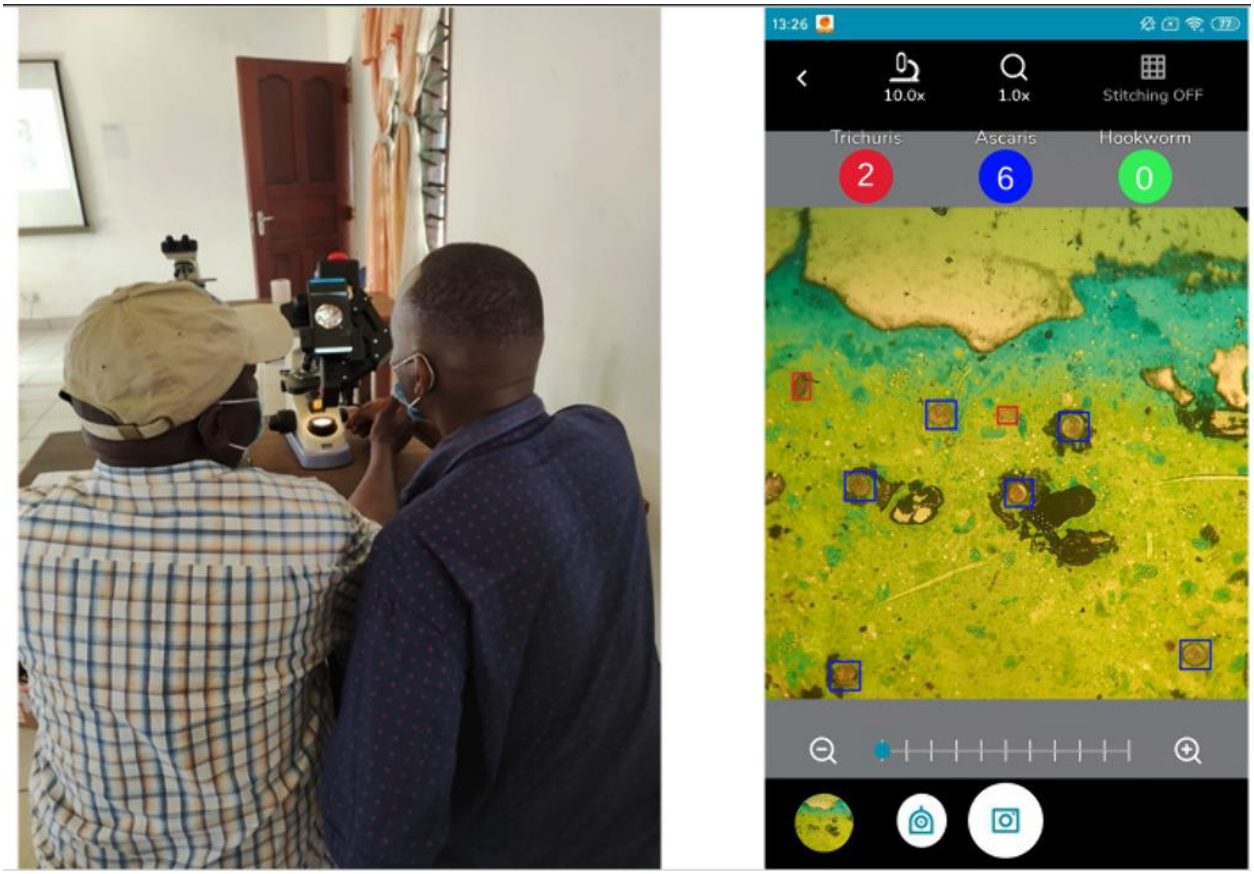
[1]Spotlab, R&d, Madrid, Spain, [2]ETSI Telecomunicación, Universidad Politécnica De Madrid & Ciber-bbn, Madrid, Spain, [3]ESACIPAC, Kenya Medical Research Institution (kemri), Nairobi, Kenya, [4]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic-universitat De Barcelona, Barcelona, Spain

Background: Soil-transmitted helminthiasis (STH), a neglected tropical disease (NTD), affects 1.5 billion people. Although the Kato-Katz technique is the recommended diagnostic method, it has decreased sensitivity and is labour-intensive. To address these issues, a methodology was created and piloted to digitize samples, train and deploy an artificial intelligence (AI) model which runs in real-time on a smartphone for the detection and quantification of Ascaris lumbricoides, Trichuris trichiura and hookworm.
Methods: 1347 stool samples from 5-15-year-old children (Kwale, Kenya) were collected and analyzed by 8 experts with an AI (SSD-MobileNet V2 network) app on smartphones coupled to an optical microscope. The AI model was improved through an iterative methodology in 2 weeks with 4 versions. To iteratively improve the AI model, images were uploaded to a telemedicine platform. Labeled images were used to train a new version of the model, which was deployed on smartphones for the next day's campaign.
Results: The final model, trained with 679 images and 1685 labels, achieved 87.27% precision and 84.72% recall on a validation set of 311 images and 553 labels.
Conclusions/Learning Points: This experiment showed the possibility of human-AI feedback loops to support the work performed by lab technicians close to the point-of-care. The methodology demonstrated the feasibility of carrying out these studies leveraging the latest artificial intelligence tools in a real-world setting without the need for connectivity or expensive equipment. The use of AI could support the WHO's 2030 control and elimination targets for
NTDs.



Funding: EU's Horizon 2020 program (grant No 881062), the Comunidad de Madrid's predoctoral grant IND2019/TIC-17167, and the THRiVE consortium's postdoctoral training fellowship, funded by the Wellcome Trust.

A. Rotman Laboratories, Toronto, Canada, [4]ISGlobal, Medicine, Barcelona, Portugal, [5]ISGlobal (Barcelona Institute for Global Health), Campus Clínic, Barcelona, Spain, [6]ISGlobal, Hospital Clínic, Barcelona, Spain, [7]Barcelona Institute for Global Health (ISGlobal), Campus Clínic, Barcelona, Spain, [8]Centro de Investigacao em Saude de Manhica, Cism, Moz, Mozambique

Background: Despite potent antimalarials, the mortality rate of pediatric severe malaria remains high. Peroxisome proliferator-activated receptor gamma agonists have been shown to act on several pathways implicated in the pathogenesis of severe malaria, including the angiopoietin (Angpt) Tie-2 axis. We tested the hypothesis that adjunctive rosiglitazone treatment would reduce levels of circulating Angpt-2 and improve outcomes of Mozambican children with severe malaria.
Methods: A randomized, double-blind placebo-controlled trial of rosiglitazone versus placebo as adjunctive treatment to artesunate in children with severe malaria was conducted. A 0.045 mg/kg/dose of rosiglitazone or matching placebo were administered, in addition to standard of malaria care, twice a day for four days. The primary endpoint was the rate of decline of Angpt-2 over 96h. Secondary outcomes included the longitudinal dynamics of the Angpt-2/Angpt-1 ratio over 96h, parasite clearance kinetics, clinical outcomes, and safety metrics.
Results: One hundred eighty children were enrolled; 91 were assigned to rosiglitazone and 89 to placebo. Children that received rosiglitazone had a steeper rate of decline of Angpt-2 over the first 96h of hospitalization compared to children that received placebo; however, the trend was not significant ($P = 0.288$). A similar non-significant trend was observed for the Angpt-2/Angpt-1 ratio ($P = 0.347$). All other secondary and safety outcomes were similar between groups ($P > 0.05$).
Conclusions/Learning Points: Adjunctive rosiglitazone at this dosage was safe and well tolerated but did not significantly affect the longitudinal kinetics of circulating Angpt-2. The results of our study do not discount the potential utility of rosiglitazone in a larger clinical trial as an adjunctive therapy with different doses and routes of administration for pediatric severe malaria. Moreover, the Angpt-Tie2 pathway remains a valid target for adjunctive malaria therapies.

Backgrounds: The Congenital CMV Network (cCMVnet) is a European initiative promoting international collaboration, research and educational activities in cCMV. In 2020 the Network established the European cCMV registry collecting data on epidemiology, clinical characteristics, long term sequelae and treatment of infants born with cCMV. An online virtual clinic has also been initiated, a forum for clinicians to review complex cases and treatment strategies.

Methods: From February 2021, via an online platform, monthly virtual clinics were established (last Wednesday of the month). A standardized slide set is available for case presentations including: history, clinical and laboratory data, imaging, treatment, and clinical questions for discussion (usually around 20 minutes per case).

Results: Sixteen monthly virtual clinics have run so far, reviewing 64 patients. Approximately 40 clinicians across multiple specialties (general paediatrics, neonatology, paediatric infectious diseases, audiology, obstetrics, ENT, virology) and countries (including Spain, UK, Greece, Germany, Estonia, Iceland, Denmark) have attended each clinic. Recommendations from the cCMVnet steering committee and other experts in the field were provided, and summarised in anonymised feedback. Issues discussed include management of preterm infants with cCMV (12 cases), treatment options when cCMV is diagnosed after the neonatal period (11), treatment related side effects (5), brain MRI imaging considerations(8), deranged liver function during treatment(4), hearing impairment(4).

Conclusions/Learning Points: Overall, this educational activity received highly positive verbal feedback from the participants. The clinic highlights the gaps in treatment guidelines and the urgent need for further clinical research. Our future plan is to create a bank of anonymised complex cCMV cases available as a training tool. Anyone wishing to discuss a case, please contact ccmvnet@gmail.com.

EARLY NEUROIMAGING FINDINGS AND NEURODEVELOPMENTAL OUTCOMES OF CHILDREN WITH CCMV

Oral Presentations Session
ORAL PRESENTATION SESSION 07: NEONATAL & CONGENITAL

Valeria Rubinacci[1], Manuela Martin Bejarano[2], Roberto Pedrero[3], Noelia Medina[4], Raquel Lara Tomé[4], Ana Martinez De Aragòn[5], Constanza Liebana[5], Sara Vila[6], Noemi Núñez Enamorado[6], Ana Camacho[6], Joaquín De Vergas[7], Ángela Manzanares[8], Serena Villaverde[8], Berta Zamora[2], Daniel Blázquez-Gamero[8]
[1]Hospital 12 de Octubre, Madrid- University of Milan, Milan, Pediatric Infectious Diseases, Madrid, Spain, [2]Hospital 12 de Octubre, Madrid, Spain, Pediatrics, Madrid, Spain, [3]Instituto de Investigación Hospital 12 de Octubre, Unidad De Ensayos Clínicos Pediátricos, Madrid, Spain, [4]Universidad Complutense de Madrid, Pediatrics, Madrid, Spain, [5]Hospital 12 de Octubre, Madrid, Spain, Radiology, Madrid, Spain, [6]Hospital 12 de Octubre, Madrid, Spain, Neuropaediatrics, Madrid, Spain, [7]Hospital 12 de Octubre, Madrid, Spain, Ent, Madrid, Spain, [8]12 de Octubre University Hospital, Pediatric Infectious Diseases, Madrid, Spain

Backgrounds: Congenital CMV (cCMV) is one of the leading non-genetic causes of pediatric sensorineural hearing loss (SNHL) and neurocognitive impairment. We aim to study the prevalence of anomalies in cUS and MRI and their possible association with SNHL and neurodevelopment.
Methods: Retrospective study performed in a prospective cohort of 32 pediatric patients with cCMV infection. Clinical and neurological examination with Bayley-III Neurodevelopmental Scale, neuro-imaging and hearing evaluation by auditory brainstem responses were performed.
Results: At birth, anomalies in cUS were detected in 12 (38.7%) patients being lenticulostriate vasculopathy (n=7), subependymal cysts (n=7) and white matter abnormalities (WMA) the most frequent findings. MRI resulted abnormal in 18 (60%) patients, most of them with WMA (n=9) and periventricular cysts (n=3). SNHL was present in 6 patients, all of which had abnormal cUS and MRI. Last follow-up visit was performed at 23.4 [IQR 11.4-26.2] months of age. Mean Bayley z-scores in cognitive combined IQ, combined language and combined motor scales were within the normal range (-0.2,-0.7,-0.8).When evaluating the presence of WMA in cUS we found relevant differences in expressive language Z scores (-0.9 vs 0; p=0.005). For calcifications in cUS, differences were seen in expressive language (-1 vs 0;p=0.018) and in fine and gross motor Z scores (-1 vs -0.1 and -1.7 vs -0.2; p = 0.048 and 0.05, respectively). We did not find significant differences when evaluating WMA and calcifications in MRI.
Conclusions/Learning Points: In cUS but not in MRI, children with WMA showed worse results in expressive language, and children with calcifications in expressive language and in fine and gross motor z-scores. Higher sensitivity of MRI allows to detect milder WMA not associated with worse Bayley z-scores. All patients with SNHL had abnormal neuroimaging.

O0066 / #429

PREDICTION OF C-REACTIVE PROTEIN DYNAMICS DURING MEROPENEM TREATMENT IN NEONATES AND INFANTS

Oral Presentations Session
ORAL PRESENTATION SESSION 07: NEONATAL & CONGENITAL

Hiie Soeorg[1], Helgi Padari[2], Mari-Liis Ilmoja[3], Koit Herodes[4], Karin Kipper[4], Irja Lutsar[1], Tuuli Metsvaht[2], Neomero Consortium[5]
[1]University of Tartu, Department Of Microbiology, Tartu, Estonia, [2]Tartu University Hospital, Pediatric Intensive Care Unit, Tartu, Estonia, [3]Tallinn Children's Hospital, Pediatric Intensive Care Unit, Tallinn, Estonia, [4]University of Tartu, Institute Of Chemistry, Tartu, Estonia, [5]Fondazione Penta Onlus, Neomero, Padova, Italy

Backgrounds: Sepsis is major cause of mortality in neonates/infants. C-reactive protein (CRP) has been proposed to inform on the effect of antibiotic treatment. We aimed to develop a joint pharmacokinetic-pharmacodynamic model of CRP and meropenem in neonates/infants and evaluate its performance to predict CRP dynamics.
Methods: Data from neonates/infants in two previous studies in two Estonian NICUs (a meropenem PK study in VLBW neonates (Padari et al. 2012), the NeoMero studies (Lutsar et al. 2020, Germovsek et al. 2018)) were analysed. Turnover, effect compartment and transit compartment models of CRP as a function of meropenem concentration or cumulative area under the curve (AUC) were evaluated. The percentage of neonates/infants was calculated in whom the ratio of the 5th treatment day CRP to peak value was predicted with error of <0.2 ($P_{0.2}$).
Results: From 60 neonates/infants (median (range) gestational age 27.6 (22.6-40.9) weeks; postnatal age 13 (2-89) days) 351 CRP concentrations (maximum value 65.5 (13-358.4) mg/L) were collected. Turnover model of CRP as a function of meropenem cumulative AUC provided the best fit. The EC50 (AUC inducing half maximum meropenem effect) was smaller in neonates/infants in the NeoMero studies, allowing other earlier antibiotic treatment for up to 24 hours, and larger if S. aureus/enterococci were cultured in the blood/CSF (Figure). Considering the CRP peak within 72 (48) hours of the start of treatment and using data available at 0, 24, 48 and 72 hours after the start of treatment, $P_{0.2}$ was 69.7%, 63.6%, 72.7%, 75.8% (63.6%, 57.6%, 72.7%, 78.8%),
respectively.

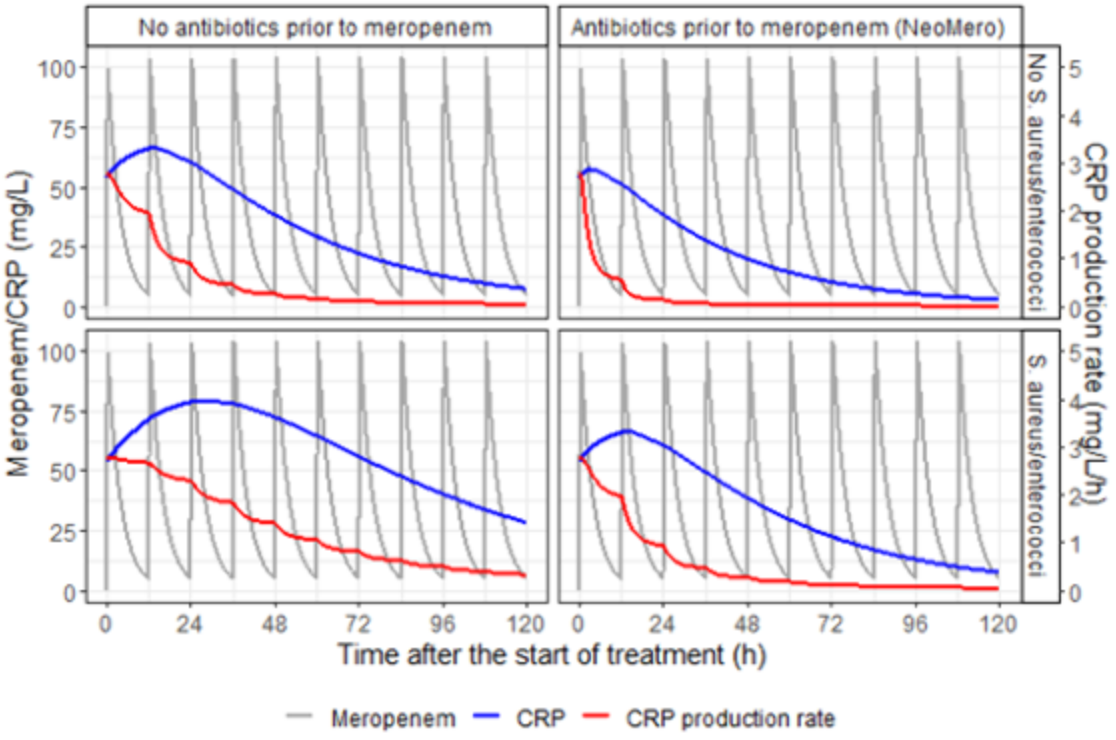

Figure. Meropenem (grey) and C-reactive protein (blue) concentration (mg/L) and CRP production rate (mg/L/h) (red) during meropenem treatment with 20 mg/kg q12h in a neonate with weight of 846 g and initial CRP 54 mg/L.

The equation describing C-reactive protein (CRP) dynamics: $\frac{\mathbf{dCRP}}{\mathbf{dt}} = \mathbf{K}_{in} \cdot \left(1 - \frac{AUC^{H}}{EC_{50}^{H} + AUC^{H}}\right) \cdot \left(1 - \frac{\mathbf{CRP}}{\mathbf{POP_{max}}}\right) - \mathbf{K_{out}} \cdot \mathbf{CRP}$

$\mathbf{EC_{50}=565.5 \cdot (0.36)^{NM} \cdot (2.81)^{S.a./ent.} \cdot e^{\eta 2}}$ mg·h/L (**NM** – if the neonate/infant was included in the NeoMero studies then NM=1, otherwise NM=0; **S.a./ent** – if *S. aureus* or enterococci were cultured in the blood/CSF, then S.a./ent=1, otherwise S.a./ent=0; $\eta_2 \sim N(0,1.09)$) – meropenem cumulative area under the curve (AUC) that produces half maximum CRP inhibition; **H=2.22** – slope function; $\mathbf{K_{out}=0.03}$ mg/L/h – rate of CRP elimination; $\mathbf{K_{in}=2.77 \cdot (CRP_0/35.8) \cdot e^{\eta 1}}$ mg/L/h (**CRP_0** – CRP value prior to the start of meropenem treatment; $\eta_1 \sim N(0, 0.84)$) – maximum rate of CRP production; $\mathbf{POP_{max}=358.4}$ mg/L – maximum value of CRP in the population.

Conclusions/Learning Points: Pharmacokinetic-pharmacodynamic model of meropenem and CRP can predict CRP dynamics with acceptable accuracy in most neonates/infants. The relationship between meropenem exposure and its effect is influenced by causative agent and prior other antibiotic therapy.

CHANGING EPIDEMIOLOGY OF GROUP B STREPTOCOCCAL INFECTIONS AMONG NEONATES IN PORTUGAL: 2005-2019 SURVEILLANCE

Oral Presentations Session
ORAL PRESENTATION SESSION 07: NEONATAL & CONGENITAL

Milani Rodrigues[1], José Melo-Cristino[2], Mário Ramirez[1], Elisabete Martins[1], . The Portuguese Group For The Study Of Streptococcal Infections[2]
[1]Instituto de Medicina Molecular, Instituto De Microbiologia, Lisboa, Portugal, [2]Faculdade de Medicina da Universidade de Lisboa, Instituto De Microbiologia, Lisboa, Portugal

Backgrounds: Group B streptococci(GBS) remains a leading cause of neonatal invasive disease despite prophylactic approaches.
Methods: We characterized 301 GBS isolates from neonatal invasive infections in Portugal. Information on serotype, multilocus sequence type(MLST), surface proteins, pilus island(PI) profiles, and antimicrobial resistance determining genes was obtained from PCR and Sanger sequencing for 218 isolates (2005-2015) and from Illumina high-throughput sequencing, after data analysis by mapping/de novo assembly approaches, for 83 isolates (2016-2019).
Results: Serotypes III(60%), Ia(20%), Ib(9%) V(4%), II(3%), IV(1%) and VI(0.7%), VIII(0.3%) and IX(0.3%) representing 9 clonal complexes(CC) were found. CC17 included 51% of all isolates, mostly III/ST17/rib/PI-1+PI-2b, associated with late-onset disease(LOD)(P=0.02). Serotype Ib, representing mostly Ib/ST1/alp3/PI-1+PI-2a, increased in the study period(P<0.05). Macrolide resistance increased(P<0.05), associated with the ermB gene, being overrepresented among serotype Ib isolates(P<0.001) and in CC1(P<0.001). While representatives of CC17 were mostly susceptible to macrolides, we identified a recent sub-lineage characterized by the loss of PI-1(CC17/PI-2b), simultaneously resistant to macrolides, lincosamides, tetracycline, and aminoglycosides (high-level resistance).
Conclusions/Learning Points: The stability and dominance of a few genetic lineages among GBS recovered from neonatal invasive infections in Portugal, namely the hypervirulent ST17/III/rib/PI-1+PI-2b, which remains responsible for the majority of infections, suggests it is extremely well adapted to this niche. The emergence of the Ib/CC1 lineage had been mostly restricted to non-pregnant adult disease and was the major driver of the increase in macrolide resistance in invasive adult infections in Portugal. The expansion of the Ib/CC1 lineage in this collection may suggest a shift in the serotypes and clones causing neonatal disease, which may impact the vaccine formulations currently under development. The emergence of a macrolide resistant CC17 sub-lineage is puzzling given the decrease in macrolide consumption in Portugal.

GROUP B STREPTOCOCCUS DETECTION IN NON-PREGNANT FEMALES TO EVALUATE CONCEPT DETECTION TEST FOR MATERNAL CARRIAGE

Oral Presentations Session
ORAL PRESENTATION SESSION 07: NEONATAL & CONGENITAL

Emelie Alsheim[1], A. Toby Jenkins[2], Naing Thet[2], Maisem Laabei[3]
[1]University of Bath, Department Of Chemistry, Bath, United Kingdom, [2]University of Bath, Chemistry, Bath, United Kingdom, [3]University of Bath, Life Sciences, Bath, United Kingdom

Backgrounds: Group B Streptococcus (GBS) cause severe infection and sepsis in neonates, with high mortality and sequelae. Maternal vaginal carriage allows for transmission to the foetus either during pregnancy or intrapartum. Neonatal infection can be difficult to diagnose, and few countries offer maternal screening to detect GBS carriage during pregnancy. Current guidelines dictate that maternal screening should occur in gestation week 35-37. With GBS being a transient coloniser, this means the maternal carriage status may have shifted from the point of screening to the point of labour.
Methods: We have developed a test for GBS carriage, which could be used intrapartum on the mother, or postpartum on the neonate, using lipid vesicles lysed by GBS virulence factors. To test the potential utility of the sensor, a small pilot healthy human study was conducted, recruiting 100 non-pregnant female participants, over the age of 18 to detect GBS carriage (REACH, EP 22 072). Participants donated two swabs, one of which is tested using our novel detection test, and the other is used for standard microbiological detection of GBS.
Results:

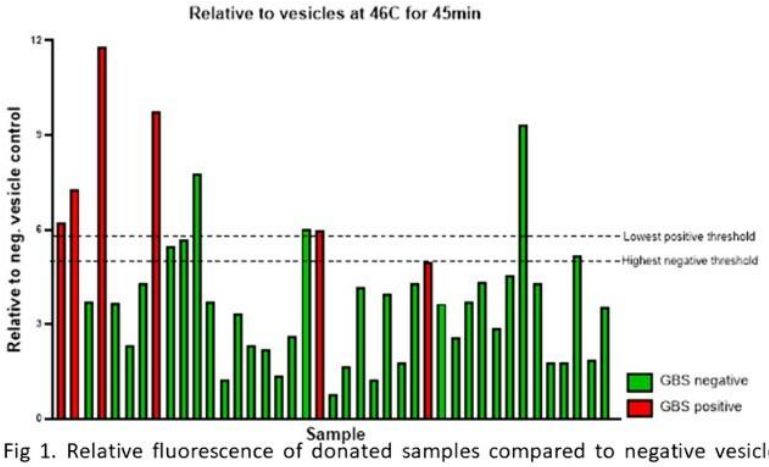

Fig 1. Relative fluorescence of donated samples compared to negative vesicle control. Green colour is GBS negative, red is GBS positive. Highest negative threshold is set at 5, with lowest positive threshold set at 5.8, n = 42.

At time of writing (January, 2023), 42 participants has been enrolled, GBS carriage rate in the study was found to be 14.3%, as confirmed by the clinical microbiology ECM (Enriched Culture Medium) test. Current test sensitivity (TP/TP+FN) was found to be 83%; specificity (TN/TN+FP) is 91% (Figure 1).
Conclusions/Learning Points: This test has potential for cost effective, rapid detection of maternal and neonatal GBS carriage, without the need of advanced equipment.

MATERNAL VAGINAL MICROBES AND EARLY-ONSET NEONATAL INFECTION IN A RESOURCE-LIMITED, HIGH-DISEASE BURDEN SETTING; A NESTED-CASE CONTROL STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 07: NEONATAL & CONGENITAL

Maryke Nielsen[1], Charlotte Van Der Veer[2], Vita Nyasulu[2], Bridget Freyne[3], Baleke Ndamala[2], Queen Dube[1], Kondwani Kawaza[1], Josephine Langton[1], Luis Gadama[4], Stephen Gordon[5], Enitan Carrol[6], Neil French[6], David Lissauer[2]
[1]Queen Elizabeth Central Hospital, Paediatrics, Blantyre, Malawi, [2]Malawi-Liverpool Wellcome Trust, Maternal And Child Health, Blantyre, Malawi, [3]Children Health Ireland Crumlin and Temple Street hospitals, Infectious Disease And Immunology, Dublin, Ireland, [4]Queen Elizabeth Central Hospital, Obstetrics, Blantyre, Malawi, [5]Liverpool School of Tropical Medicine, Clinical Sciences, Blantyre, Malawi, [6]University of Liverpool, Institute Of Infection, Veterinary And Ecological Sciences, Liverpool, United Kingdom

Backgrounds: Early Onset Neonatal Infection (EO-NI) has traditionally been associated with Gram-positive bacteria such as Streptococcus agalactiae (GBS). The roles of other suspected EO-NI causative micro-organisms (referred to as pathobionts) are incompletely understood. Disruption in the transmission of beneficial micro-organisms (e.g. lactobacilli) due to maternal vaginal dysbiosis may increase the infant's vulnerability to infection with hospital-associated opportunistic pathobionts. Our aim was to assess whether a Lactobacillus-deficient microbiome and/or carriage of pathobionts associates with EO-NI.
Methods: Vaginal swabs were collected prospectively in a maternal/neonatal cohort and nested case-control study at the Queen Elizabeth Central Hospital, Blantyre, Malawi. Extracted DNA was sequenced on the Illumina HiSeq platform using the 16srRNA V4 region. Data analysis and taxonomy assignment were done using DADA2 and the SILVA 16S reference database respectively. Relative abundances of key bacterial taxa were summarized into clinically relevant bacterial groups.
Results: A total of 544 samples (n=62 cases, n=150 matched controls, n=332 cohort) collected between May 2019 and March 2020, were successfully sequenced. Overall, the median relative abundance of Lactobacillus spp and bacterial vaginosis (BV) associated bacteria was 55.4% and 24.0% respectively and this did not significantly differ between cases and controls. Cases had a higher median relative abundance of pathobionts (0.4% vs 0.2%) compared to controls but not significantly so (p=0.401). Overall, mothers of infants with low birth weight (<2500g) had a higher median relative abundance of BV-associated bacteria compared with mothers of normal-weight infants (34.9% vs 20.6%; p=0.017). Additionally, Lactobacillus spp. dominance (>90% relative abundance) associated with normal birth weight (>2500g; p=0.037).
Conclusions/Learning Points: The maternal vaginal levels of lactobacilli and pathobionts did not significantly associate with EO-NI. Mothers of low-birthweight infants had lower levels of lactobacilli and higher levels of BV-associated bacteria.

DAPTOMYCIN USE FOR PERSISTENT COAGULASE NEGATIVE STAPHYLOCOCCAL (CONS) BACTEREMIA IN A NEONATAL INTENSIVE CARE UNIT, CASE SERIES 2011-2022

Oral Presentations Session
ORAL PRESENTATION SESSION 07: NEONATAL & CONGENITAL

Eleni Papachatzi[1], Despoina Gkentzi[2], Sotiris Tzifas[1], Theodore Dassios[1], Gabriel Dimitriou[1,2]
[1]University Hospital of Patras, Neonatal Intensive Care Unit, Patras, Greece, [2]University Hospital of Patras, Department Of Paediatrics, Patras, Greece

Backgrounds: During the last two decades the incidence of late onset sepsis (LOS) has increased due to improved survival of premature neonates. Persistent bacteremia (PB) in LOS is defined as two or more positive blood cultures obtained on different calendar days during the same infectious episode. Although rare, PB should be treated aggressively in order to prevent adverse outcomes. Daptomycin, a lipopeptide antibiotic, has been used in neonates with persistent CoNS bacteremia with promising results.
Methods: In this retrospective, observational, case series study we present data of neonates, treated with daptomycin, during the period 2011 - 2022, in the Neonatal Intensive Care Unit (NICU) University General Hospital of Patras, Greece.
Results: There were 12 patients included in the study and 66.7% (8/12) were male. Median gestational age and mean birthweight were 32 weeks (IQR 31-34) and 1840±867.4 grams, respectively. 70% (7/10) were delivered by emergency cesarean section and 60% (6/10) were intubated at birth. Antibiotic course, duration of treatment and causative pathogens are shown in figure 1. Decision to start daptomycin (6mg/kg/dose twice daily) was taken on day 10 (IQR 7-15) of infection. None of the infants had focal complications or meningitis. No renal, hepatic, muscular or gastrointestinal adverse events were observed. 8% (1/12) developed seizures while on treatment with daptomycin (intracranial hemorrhage and meningitis were excluded). 91.6% (11/12) of infants were discharged and 8% (1/12) passed away due to multiple prematurity complications.
Conclusions/Learning Points: Daptomycin monotherapy showed an adequate cure rate in premature neonates with persistent CoNS bacteremia in a tertiary NICU. In our study, daptomycin was effective and well tolerated; the safety profile, however, needs to be confirmed in larger studies and randomised controlled

trials.

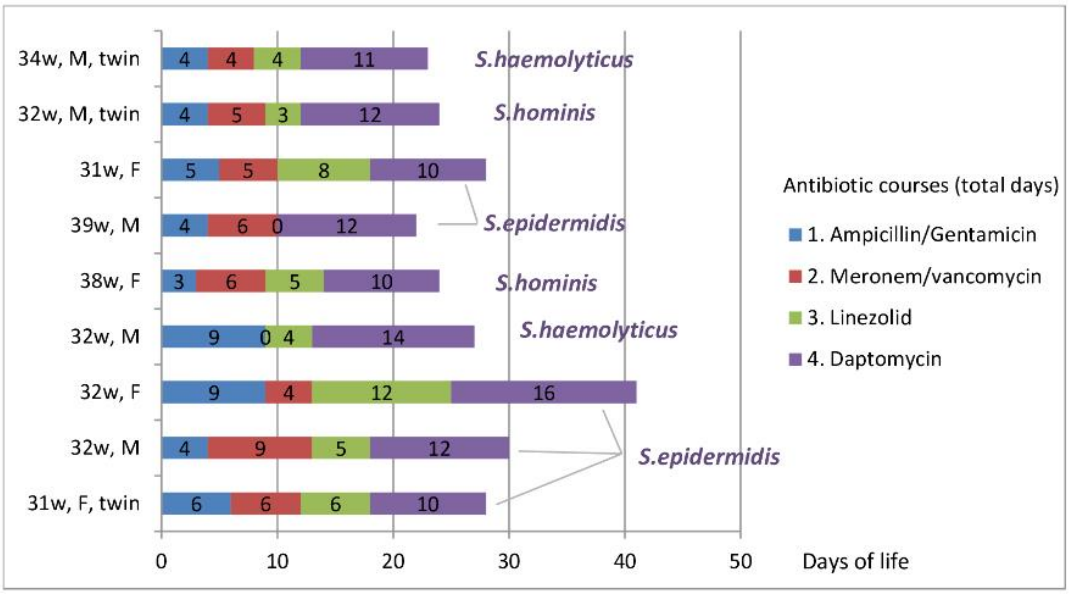

Figure 1. Antibiotic course, total days of treatment and causative pathogen (per patient per course). Courses 1,2 were empiric and courses 3,4 were targeted. Y axis corresponds to days of life.

Backgrounds: Congenital CMV (cCMV) is the main cause of non-genetic childhood hearing loss (HL). Evidence for treatment in asymptomatic/mildly symptomatic cCMV (A/mild cCMV) is still lacking. We describe hearing outcomes at 24 months of age for infants with A/mild cCMV, depending on whether or not they received antiviral treatment.
Methods: A multicenter study was performed in an European cohort. Included children had an asymptomatic or mild cCMV infection (A/mild cCMV). A/mild cCMV was defined as the presence of all of the following: normal physical examination (excluding SGA), with normal ALT and platelets (ALT <80 U/L, platelets >100,000 cs/mm3), absence of HL at birth and with normal or non-severe findings in cranial imaging (venticulostriated vasculopathy, germinolysis, caudothalamic or subependymal cysts and/or focal/multifocal white matter abnormalities). Main outcome was presence of HL at 24 months of age, defined as a hearing thresholds over 25 dB in any ear (by ABR).
Results: 196 were included. 68/196(34.7%) received antiviral treatment (figure 1). Children treated with antivirals had lower gestational age, lower birth weight, smaller head circumference, and maternal primary infection was less frequent. Most infants with mild abnormalities in imaging were treated. Nine patients (4.6%) developed HL at 24 months. In the HL group 2 of 9 patients presented minor abnormalities in MRI and received antiviral treatment. At 24 months, HL was similar in treated versus non-treated infants (4.6% vs 6.3%;
p=0.6).

TABLE 1: Clinical and imaging variables according to treatment group

	All Population (N = 196)	Treated children (N = 68)	Non treated children (N = 128)	p-value
Male, n (%)	91 (46.4)	34 (50.0)	57 (44.5)	0.465
Age at diagnosis (days), mean (SD) [N = 192]	1.9 (2.72)	2.4 (3.16)	1.6 (2.41)	0.034
Gestational age at delivery (weeks), mean (sd) [N =186]	37.6 (2.5)	36.8 (3.02)	38.1 (2.06)	**0.008**
Birth Weight (gr), mean (sd) [N = 169]	2880.4 (753.16)	2597.0 (832.88)	3040.5(655.74)	**<0.001**
Birth head circumference (cm), mean (sd) [N = 128]	33.1 (2.64)	32.3 (2.87)	33.7 (2.33)	**0.003**
ALT (GPT) (U/L), mean (sd) [N = 116]	20.6 (12.79)	19.8(14.3)	21.3 (11.54)	0.175
Platelets (cs/mm3), mean (sd) [N = 135]	276077.5 (96669.3)	247320.8 (107390)	277302.6(89157.5)	0.326
Maternal primary infection, n (%)	109 (62.6)	26 (42.6)	83 (73.5)	**<0.001**
Congenital CMV diagnosis first 21 days, n (%)	130 (66.3)	44 (64.7)	86 (67.2)	0.504
Child first cranial ultrasound findings, n (%)				
Child first cranial ultrasound abnormal	20 (11.6)	13 (21.3)	7 (6.3)	**0.003**
Lenticulostriate Vasculopathy	11 (6.2)	9 (14.5)	2 (1.7)	**0.001**
Caudothalamic / Subependymal Cysts /germinolysis	6 (3.4)	3 (4.8)	3 (2.6)	0.434
Child first cranial MRI findings, n (%)				
Child first cranial MRI abnormal	16 (8.7)	13 (21.3)	3 (2.5)	<0.001
White matter abnormalities (focal/multifocal)	12 (6.1)	9 (13.2)	3 (2.3)	0.002
Caudothalamic / Subependymal Cysts /germinolysis	4 (2.0)	4 (5.9)	0 (0.0)	0.006
Hearing loss 24 MONTHS (>25 dB in at least one ear)	**9 (4.6)**	**3 (4.6)**	**6 (6.3)**	**0.658**

Conclusions/Learning Points: One third of children with asymptomatic/mild cCMV were treated with antivirals. At 24 months the incidence of HL was similar among treated and untreated children. Larger numbers, and longer follow up is required to ascertain whether early treatment is protective at older ages, highlighting the importance of the CCMVNET international registry.

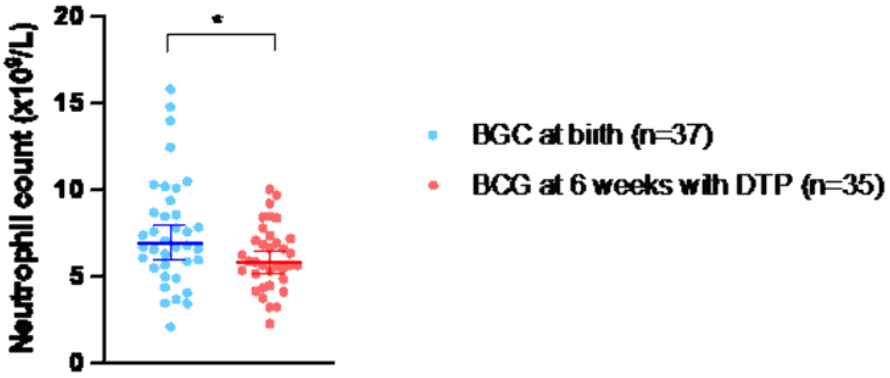
DOES BCG VACCINATION PROTECT INFANTS FROM HETEROLOGOUS INFECTIONS BY INDUCING EMERGENCY GRANULOPOIESIS? A SECONDARY ANALYSIS OF TWO RANDOMISED CONTROLLED TRIALS.

Oral Presentations Session
ORAL PRESENTATION SESSION 07: NEONATAL & CONGENITAL

Johanna Kellett Wright[1], Beatrice Nassanga[2], Ebrima Sise[3], Emily Webb[4], Hazel Dockrell[5], Alison Elliott[6], Stephen Cose[5], Sarah Prentice[6]
[1]London School of Hygiene and Tropical Medicine, Faculty Of Infectious And Tropical Diseases, London, United Kingdom, [2]MRC/UVRI and LSHTM Uganda Research Unit, Mrc/uvri, Entebbe, Uganda, [3]London School of Hygiene & Tropical Medicine (LSHTM), Medical Research Council (mrc) Unit The Gambia, Serrekunda, Gambia, [4]London School of Hygiene and Tropical Medicine, Department Of Infectious Disease Epidemiology, London, United Kingdom, [5]London School of Hygiene and Tropical Medicine, Department Of Infection Biology, London, United Kingdom, [6]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom

Backgrounds: BCG vaccination protects neonates against non-tuberculous heterologous infections and death in high-morbidity countries. The mechanisms underlying these non-specific beneficial effects are incompletely understood. BCG-induced emergency granulopoiesis protects newborn mice against polymicrobial sepsis, but the evidence for a BCG-induced rise in granulocytes in human neonates is limited.
Methods: BCG-induced emergency granulopoiesis was investigated using full blood counts collected during two randomised controlled trials of differing BCG vaccination timings conducted in 120 Gambian and 240 Ugandan neonates. Neutrophil counts determined by automatic counter were available from Gambian infants at birth, days of life (DOL)1-3 and from Ugandan infants at birth, DOL5-9 and at age 6- and 10-weeks (+/-7 days). Comparisons between BCG-vaccinated and naïve infants in both studies, as well as early (birth) vs. delayed (at 6-weeks) BCG-vaccination in Ugandan infants, were conducted using linear regression.
Results: No significant differences in granulocyte/neutrophil counts were found at most short and longer-term post-intervention blood-sampling time-points, when comparing BCG-vaccinated with BCG-naïve Gambian and Ugandan infants. However, BCG-vaccinated female infants had a significant increase in neutrophils between baseline and DOL2-3 compared to BCG-naïve female infants (1.37 vs. 0.70 fold-change, p=0.006). Male infants showed the opposite trend (0.62 vs.1.11 fold-change, p=0.07, interaction by sex p=0.01). Infants BCG-vaccinated at birth had higher neutrophils 1-day after non-specific stimulation from their second dose of primary immunisations compared to infants who received BCG at 6-weeks (GMR 1.17 (1.00-1.36), p=0.05, Figure
1).

Neutrophil count 1 day after EPI vaccinations at 10 weeks



Effect more pronounced in boys (GMR 1.27 (1.03–1.61))

Conclusions/Learning Points: We did not find strong evidence for BCG-induced emergency granulopoiesis in Ugandan and Gambian infants, to explain BCG's non-specific effects. The possibility of a sex-differential effect of BCG on acute neutrophil production, and enhancement of neutrophil responses following exposure to heterologous stimuli should be explored in prospective studies.

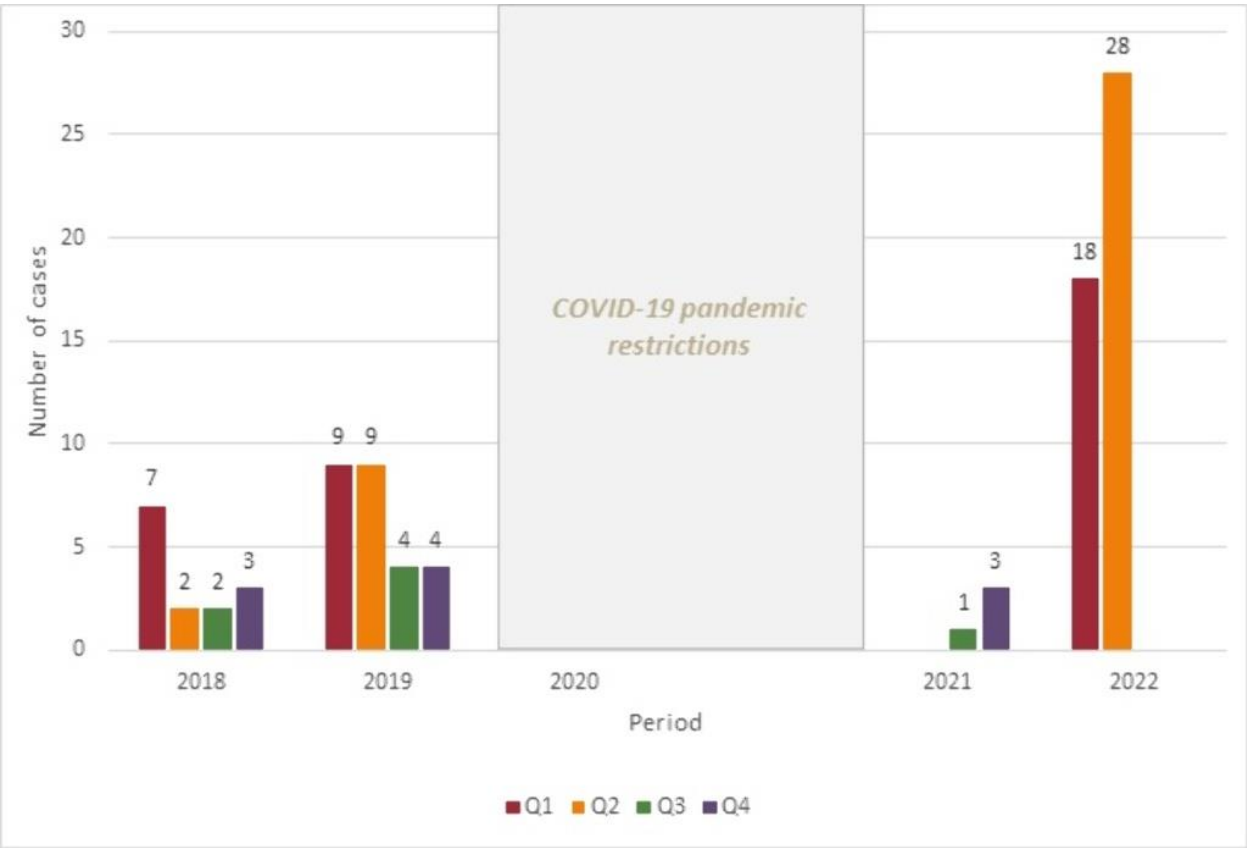
INCREASE IN INVASIVE GROUP A STREPTOCOCCAL INFECTIONS IN CHILDREN IN THE NETHERLANDS, A SURVEY AMONG 7 HOSPITALS IN 2022

Oral Presentations Session
ORAL PRESENTATION SESSION 08: PUBLIC HEALTH

Evelien Van Kempen[1], Patricia Bruijning-Verhagen[2], Dorine Borensztajn[3], Clementien Vermont[4], Marjolijn Quaak[4], Jo-Anne Janson[5], Ianthe Maat[6], Kim Stol[7], Bart Vlaminckx[8], Jantien Wieringa[9], Nina Van Sorge[10], Mirjam Van Veen[11], Navin Boeddha[12]
[1]Juliana Children's Hospital - HagaHospital, Pediatrics, the Hague, Netherlands, [2]Utrecht University Medical Center, Pediatrics, Utrecht, Netherlands, [3]Noordwest Ziekenhuis, Kindergeneeskunde, Alkmaar, Netherlands, [4]Erasmus MC - Sophia Children's Hospital, Department Of Pediatric Infectious Diseases And Immunology, Rotterdam, Netherlands, [5]Maastricht University Medical Center, Pediatrics, Maastricht, Netherlands, [6]Radboud University Medical Center, Microbiology, Nijmegen, Netherlands, [7]Amalia Children's Hospital - Radboud University Medical Center, Pediatrics, Nijmegen, Netherlands, [8]St Antonius Hospital, Microbiology, Nieuwegein, Netherlands, [9]Haaglanden Medical Center, Pediatrics, The Hague, Netherlands, [10]Amsterdam University Medical Center, Department Of Medical Microbiology And Infection Prevention, Amsterdam, Netherlands, [11]Juliana Children's Hospital -HagaHospital, Pediatrics, the Hague, Netherlands, [12]Maasstad Hospital, Pediatrics, Rotterdam, Netherlands

Backgrounds: Since early 2022, pediatricians in the Netherlands have observed a rise in pediatric cases of severe invasive group A streptococcal (iGAS) disease, including several deaths. National surveillance also reported an increase in the following iGAS clinical presentations: necrotizing fasciitis and toxic shock syndrome. However, other clinical presentations of iGAS are not systematically recorded. Aim was to determine whether case numbers were indeed elevated compared to the pre-COVID-19 period and to gain more insight into the spectrum of clinical presentations and disease severity.
Methods: We performed a survey regarding microbiology confirmed pediatric iGAS cases in seven Dutch hospitals. Cases were included between 01-07-2021 and 30-06-2022 (i.e. P2), to capture recent trends, and compared to cases from pre-COVID-19 years 01-01-2018 - 31-12-2019 (i.e. P1). Aggregated data were collected on age-category, year-quarter, clinical diagnosis, coinciding or preceding influenza or varicella infection and outcome (mortality, PICU admission).
Results: In P2 (12 months), 61 pediatric iGAS cases were reported (5.1/month) versus 56 cases in P1 (24 months, 2.3/month). A 3-fold increase occurred early 2022, most pronounced in <5-year olds. Main diagnosis in P1 was sepsis (26%), compared to pneumonia with empyema (28%) in P2. No cases of necrotizing fasciitis were reported in P1, while in P2 this clinical presentation represented 11% of diagnoses. PICU admission occurred in 21% of cases in P1 and in 32% of cases in P2. One death was reported in P1 (1/39; 3%) versus 5/57 (9%) in
P2.



Conclusions/Learning Points: There is a substantial surge in pediatric iGAS cases in the Netherlands since early 2022, some with fatal outcome, that requires further evaluation. Clinicians and parents should be vigilant and aware of unusual pediatric presentations such as necrotizing fasciitis.

TIME AND SPACE KDETS: KAWASAKI DISEASE EXPOSURES IN TIME AND SPACE TO VIRUSES

Oral Presentations Session
ORAL PRESENTATION SESSION 08: PUBLIC HEALTH

Rana Sawires[1], Hazel Clothier[2], David Burgner[2], Michael Fahey[3], Jim Buttery[2]
[1]Monash University, Paediatrics, Clayton, Australia, [2]Murdoch Children's Research Institute, Health Informatics, Melbourne, Australia, [3]Monash Children's Hospital, Neurology, Clayton, Australia

Backgrounds: Kawasaki disease is an uncommon vasculitis affecting children less than five years old. The aetiology remains poorly understood, although preceding infective triggers are widely suggested. We aimed to determine whether Kawasaki disease incidence was related to community respiratory virus circulation and to describe viral associations prior to and during the COVID-19 pandemic. SNOTWATCH is a de-identified ecologic analysis platform capturing population level multiplex polymerase chain reaction (PCR) molecular diagnostic results together with hospital encounters. We used this platform to investigate the associations between respiratory viruses and Kawasaki disease at a population level in both time and space.
Methods: Spatiotemporal associations between Kawasaki disease across Victoria, Australia, and nine respiratory viruses (adenovirus, SARS-CoV-2 (severe acute respiratory syndrome-coronavirus-2), hMPV (human metapneumovirus), influenza A, influenza B, parainfluenza, picornavirus, parechovirus and RSV (respiratory syncytial virus)) detected at two large hospital networks from July 2011- November 2021 were studied through Poisson regression analysis.
Results: Results from 153,153 multiplex PCR tests and 1,081 Kawasaki disease presentations demonstrated an association of Kawasaki disease with hMPV (1.52 risk ratio (RR), 99%CI 1.27-1.82) and RSV (1.43 RR, 99%CI 1.17-1.73) before the COVID-19 pandemic, and no associations observed during the pandemic with community lockdowns used extensively in Victoria to limit viral transmission.
Conclusions/Learning Points: With a large sample size and the granularity of a spatiotemporal analysis, our findings confirm the importance of understanding viral circulation patterns and their implications for paediatric health outcomes. If these results are confirmed, with successful RSV vaccine phase 3 clinical trials already reported and hMPV vaccine clinical trials underway, the possibility of Kawasaki disease being at least partially vaccine-preventable is an exciting prospect.

O0075 / #1911

THE PREVALENCE AND BURDEN OF EPSTEIN-BARR VIRAL CO-INFECTION IN UK YOUTH LIVING WITH PERINATALLY ACQUIRED HIV.

Oral Presentations Session
ORAL PRESENTATION SESSION 08: PUBLIC HEALTH

Rachel Savage[1], Helen Payne[1], Tan.B Huat[1], Niamh Donaldson[1], Hana Jadayel[2], Elizabeth Whittaker[1], Sarah Fidler[3], Caroline Foster[2]
[1]Paediatric Infectious Diseases, Imperial College, London, United Kingdom, [2]Imperial College Healthcare NHS Trust, Paediatric Infectious Diseases, London, United Kingdom, [3]Infectious Diseases, Imperial College, London, United Kingdom

Backgrounds: Considerable evidence implicates co-infecting Epstein-Barr virus (EBV) as a driver of B-cell lymphoproliferation in people living with HIV. Yet, the prevalence and burden of EBV in youth living with perinatally acquired HIV (YLWPaHIV) is underrepresented, despite their increased risk of lymphoma.
Methods: EBV co-infection was determined in a cohort (N=48) of virally HIV-suppressed (<80 copies/mL) YLWPaHIV by quantifying EBNA1 IgG in plasma (ELISA), and EBV-DNA in saliva (PCR), and PBMCs (ddPCR) at a single time point. Seropositivity was explored alongside clinical data, including, $CD4^+$ and $CD8^+$ T-cell counts, histories of HIV-suppression, and duration ART treatment. Flow cytometric and LUMINEX assays measured immune activation and inflammation associated with lymphoma development.
Results: In this cohort (male 60%, black ethnicity 82%, median and [IQR]: age 23 [20-28], $CD4^+$ count 652 cells/mL [540-848], age of ART initiation 7 [2-12], lifetime HIV-supressed 69% [48-88%]), EBV seropositivity was 92%, with salivary EBV-DNA detected in 42%. Participants with detectable cell-associated EBV-DNA [30%] had shorter durations of lifetime HIV-suppressed [**P=0.0065] and reduced $CD4^+$:$CD8^+$ ratios [**P=0.0049], compared to those with undetectable cell-associated EBV-DNA. Higher measurements of EBNA1 IgG and cell-associated EBV-DNA negatively correlated with delayed ART initiation during childhood [*P=0.0107, r=-0.3854; *P=0.0148, r=-0.6947; respectively]. When investigating B-cell activation, greater Ki67 [*P=0.0319] and B-lymphocyte-induced maturation protein-1 (latent to lytic switch inducer) [*P=0.0089] expression was seen in late memory B-cells of those with undetectable salivary EBV-DNA (latent), compared to detectable.
Conclusions/Learning Points: Our study highlights a correlation between EBV suppression and YLWPaHIV's duration of ART treatment and duration of life HIV-suppressed. Associations between latent and reactivated states of EBV infection, immune activation and inflammation, and clinical outcomes must be investigated in larger YLWPaHIV cohorts to better understand the burden of co-infection.

RISK FACTORS FOR SEVERE RESPIRATORY SYNCYTIAL VIRUS INFECTION DURING THE FIRST YEAR OF LIFE: DEVELOPMENT AND VALIDATION OF A CLINICAL PREDICTION MODEL

Oral Presentations Session
ORAL PRESENTATION SESSION 08: PUBLIC HEALTH

Pekka Vartiainen[1,2], Sakari Jukarainen[2], Samuel Rhedin[3,4], Alexandra Prinz[2], Tuomo Hartonen[2], Andrius Vabalas[2], Essi Viippola[2], Rodosthenis Rodosthenous[2], Sara Kuitunen[2], Aoxing Liu[2], Cecilia Lundholm[3], Awad Smew[3], Emma Osvald[3,5], Emmi Helle[1,6,7], Markus Perola[8], Catarina Almqvist[3,5], Santtu Heinonen[1,2], Andrea Ganna[2]
[1]Helsinki University Hospital, Pediatric Research Centre, Helsinki, Finland, [2]University of Helsinki, Institute Of Molecular Medicine In Finland (fimm), Helsinki, Finland, [3]Karolinska Institutet, Department Of Medical Epidemiology And Biostatistics, Stockholm, Sweden, [4]South General Hospital, Sachs' Children And Youth Hospital, Stockholm, Sweden, [5]Karolinska University Hospital, Pediatric Allergy And Pulmonology Unit At Astrid Lindgren Children's Hospital, Stockholm, Sweden, [6]Faculty of Medicine, University of Helsinki, Stem Cells And Metabolism Research Program, Helsinki, Finland, [7]The Hospital for Sick Children, University of Toronto, Department Of Paediatrics, Labatt Family Heart Centre, Toronto, Canada, [8]Finnish Institute for Health and Welfare (THL), Population Health Unit, Helsinki, Finland

Backgrounds: Novel immunisation methods against respiratory syncytial virus (RSV) are emerging, but our knowledge of risk factors for severe RSV disease is insufficient for their optimal targeting. Our aim was to screen comprehensive registry data with machine learning methods to identify predictors for RSV hospitalisation before 1 year of age, and develop a clinical prediction model for targeting RSV immunoprophylaxis.
Methods: Using nationwide healthcare and population registries from Finland and Sweden, we studied infants born between 6/1997 - 5/2020 (n=2.8 million) and their parents and siblings. Based on data-driven screening, we created a 16-variable logistic regression model and compared it to a machine learning (XGboost) model including all 1509 variables.
Results: We identified several novel predictors for RSV hospitalisation, most notably esophageal malformations (adjusted odds ratio (aOR) 3.11, 95% confidence interval 1.86 - 5.19) and lower-complexity congenital heart defects (CHD, aOR 1.43, 1.25 - 1.63), in addition to known predictors such as severe CHD (aOR 2.89, 2.28 - 3.65). In validation data, the clinical prediction model's C-statistic was 0.766 (0.742 - 0.789) in Finland and 0.737 (0.710 - 0.763) in Sweden. The prediction model performed equally to the machine learning model in Finland (C-statistic 0.771, 0.754 - 0.788). Calibration varied according to epidemic intensity, but average calibration was good. In the top 10% of infants having the highest predicted risk for RSV hospitalisation, the immunisation would have had a number-needed-to-treat of 23 in Finland and 40 in Sweden in preventing hospitalisations, assuming 60% effectiveness.
Conclusions/Learning Points: The identified predictors and the prediction model can be used in guiding RSV immunoprophylaxis in infants. The breadth of the associated variables warrants further research to study their mechanisms.

RISK OF MENINGOCOCCAL DISEASE IN PRETERM COMPARED TO TERM INFANTS: THE RESULTS OF THE IMPS STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 08: PUBLIC HEALTH

Anna Calvert[1], Anna Mensah[2], Christine Jones[3], Helen Campbell[2], Kirsty Le Doare[1], Paul Heath[1], Shamez Ladhani[1,2]
[1]St George's, University of London, Centre For Neonatal And Paediatric Infection, London, United Kingdom, [2]UK Health Security Agency, Immunisation And Vaccine Preventable Diseases Division, London, United Kingdom, [3]University Hospital Southampton NHS Foundation Trust, Nihr Southampton Clinical Research Facility And Biomedical Research Centre, Southampton, United Kingdom

Backgrounds: Invasive meningococcal disease (IMD) is most common in the first year of life and immunity relies on complement and antibody mediated killing. Because of their immature immunity, preterm infants may be at increased risk of IMD and may present differently compared to term infants. This study explored the incidence, clinical characteristics and outcomes of IMD in infants less than one year of age in England.
Methods: This was a retrospective analysis of IMD cases in infants in England during 01 September 2015 to 31 August 2020. Cases were identified through national surveillance conducted by the UK Health Security Agency.
Results: There were 393 IMD cases over the five-year period and 274 (67.7%) were due to meningococcal serogroup B. Gestational age was available for 92.4% (n=363) of infants, including 87.6% (n=318) born at term and 12.4% (n=45) premature (<37 weeks gestation). Overall IMD incidence was 12.4/100,000 infants, but was higher in those born prematurely (18.2/100,000) compared to those born at term (10.9/100,000; incidence rat ratio, 1.66; 95%CI; 1.58-1.72). There were no differences in clinical presentation or course of illness between term and preterm infants. At least one sequelae was reported in 36.8% preterm compared to 19.6% term infants (p=0.02).
Conclusions/Learning Points: We found an increased incidence of IMD in preterm infants, no difference in presentation or clinical course between term and preterm infants, but at least one sequelae was reported in significantly more preterm infants compared with term infants.

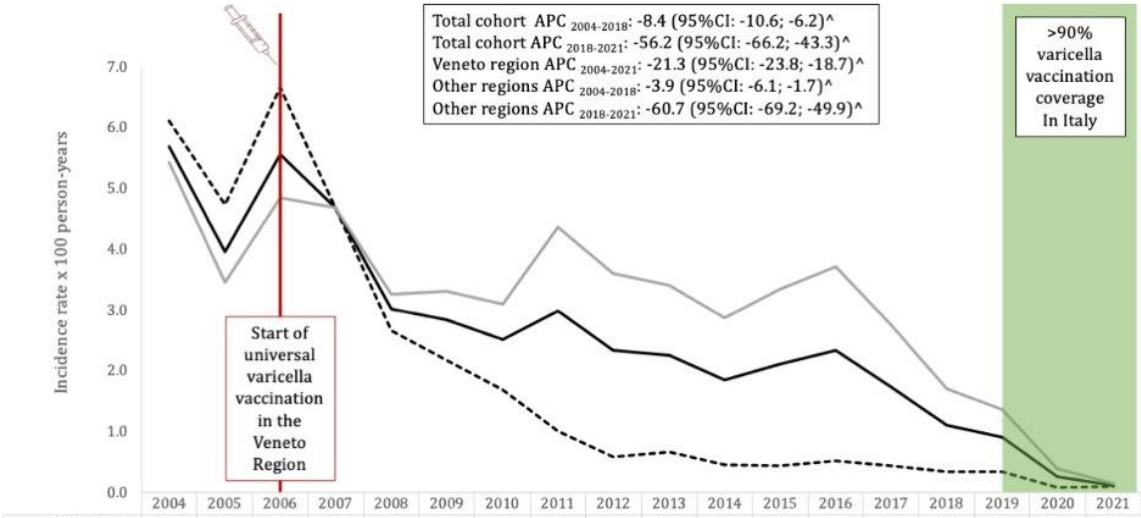
RESIDUAL BURDEN OF VARICELLA IN A HIGH VACCINATION COVERAGE AREA: A POPULATION DATABASE ANALYSIS IN ITALY (2004-2021)

Oral Presentations Session
ORAL PRESENTATION SESSION 08: PUBLIC HEALTH

Elisa Barbieri[1], Silvia Cocchio[2], Patrizia Furlan[2], Antonio Scamarcia[3], Luigi Cantarutti[3], Carlo Giaquinto[1], Vincenzo Baldo[2]
[1]University of Padova, Division Of Paediatric Infectious Diseases, Department For Women And Children's Health, Padova, Italy, [2]University of Padua, Department Of Public Health, Padua, Italy, [3]Societa' Servizi Telematici, Pedianet, Padova, Italy

Backgrounds: Routine childhood immunization has dramatically reduced varicella incidence. In Italy, universal varicella vaccination (VV) was included in the national immunization calendar in 2017, even if some regions offered VV before. VV coverage reached 90% in 2019, with differences between Italian regions. Due to limitations in electronic health record databases in capturing varicella episodes, we aimed to assess the burden of varicella disease in the pediatric population using a primary-care database.
Methods: Data from a comprehensive database including 161 family pediatricians in Italy (Pedianet) was analyzed. Incidence rates (IR) of varicella (ICD-9-CM code 052, 052.0–52.9) were evaluated in subjects <15 years of age between January 2004 and December 2021 by calendar year and region. Subjects were followed up from 2004, or the enrollment date, until the end of assistance or the study period or the date of varicella. Comorbidities and complications were recorded. Significant trends over the years were assessed as average annual percent changes (APC) using the joint-point regression.
Results: 440,567 children were included in the study. 64,434 varicella index cases were recorded. Nationwide, the IR decreased annually by 8.4% from 5.7 in 2004 to 1.1 x 100 person-years in 2018 and by 56.2% from 1.1 in 2018 to 0.1 in 2021. Following the VV implementation in 2006 in Veneto Region, the IR significantly decreased, ranging from 6.1 in 2004 to 0.1x 100 person-years in 2021 (Figure1).

Figure 1. Annual IR of varicella in the Veneto region and the total cohort. Pedianet, 2004-2021



Children with gastroenterological and immune diseases had higher IR (3.5 and 3.3 x 100 person-years, respectively) than the overall cohort.

Conclusions/Learning Points: This retrospective and comprehensive analysis further confirmed that the implementation of universal VV programs drastically reduces the IR of varicella.

O0079 / #1258

POST-PANDEMIC WINTER TRENDS IN INVASIVE PNEUMOCOCCAL DISEASE IN ENGLAND

Oral Presentations Session
ORAL PRESENTATION SESSION 08: PUBLIC HEALTH

Marta Bertran[1], Erjola Hani[1], Seyi Eletu[2], Joshua D'Aeth[2], David Litt[2], Norman Fry[2], Shamez Ladhani[1]
[1]UK Health Security Agency, Immunisations And Vaccine Preventable Diseases Division, London, United Kingdom, [2]UK Health Security Agency, Respiratory And Vaccine Preventable Bacteria Reference Unit, London, United Kingdom

Backgrounds: The COVID-19 pandemic and its related social distancing restrictions were associated with large declines in invasive pneumococcal disease (IPD) cases. With the easing of restrictions, cases in children increased above pre-pandemic levels during the first post-pandemic year (2021/2022), especially in 1–4-year-olds. In adults, however, cases remained below 45% compared to pre-pandemic years.
Methods: We conduct enhanced surveillance of IPD cases received through routine laboratory notifications of IPD cases in England and provide a national reference laboratory service for confirmation and serotyping at the UK Health Security Agency. Here we report winter trends in the post-pandemic period.
Results: Overall, there were 1,764 IPD cases during July to December 2022. Cases in children <15 years were lower (n=150) compared to the same period in the previous year (n=203) but similar to the three-year pre-pandemic average for this time period (2017-2019; n=157). In adults, there were 1,614 IPD cases during July to December 2022 vs an average of 2,381 between July-December of the previous three pre-pandemic years and 1,488 cases between July-December 2021.
Conclusions/Learning Points: Cases in children appeared to have returned to pre-pandemic levels in the latest winter period, despite large increases in circulating respiratory viruses. Adult cases also appear to have stabilised but remain substantially below pre-pandemic levels.

PAEDIATRIC HEPATITIS CLUSTERS IN VICTORIA AUSTRALIA: EXPLORING POTENTIAL RESPIRATORY VIRAL ASSOCIATIONS

Oral Presentations Session
ORAL PRESENTATION SESSION 08: PUBLIC HEALTH

Rana Sawires[1], Joshua Osowicki[2], Hazel Clothier[3], Michael Fahey[4], Jim Buttery[3]
[1]Monash University, Paediatrics, Clayton, Australia, [2]The Royal Children's Hospital, General Medicine, Infectious Diseases Unit, Parkville, Australia, [3]Murdoch Children's Research Institute, Health Informatics, Melbourne, Australia, [4]Monash Children's Hospital, Neurology, Clayton, Australia

Backgrounds: Beginning in early 2022, clusters of severe paediatric hepatitis were reported in Europe and the USA. To date, no cause has been identified, although human adenovirus 41 has been proposed in a proportion of cases. We examined population data over 11 years for hepatitis clusters in Victoria, Australia, and whether any were spatiotemporally associated with community transmission of common respiratory viruses.
Methods: The Victorian Agency for Health Information (VAHI) collates, analyses and shares health data from public hospitals across the Australian state of Victoria (population 6.5 million). Data are stored by ICD-10-AM codes and hepatitis cases were identified using a broad set of relevant codes which included hepatitis without a specific aetiological agent. Only paediatric hepatitis cases (<20 years old) were included. Nine respiratory viruses (adenovirus, SARS-CoV-2 (severe acute respiratory syndrome-coronavirus-2), hMPV (human metapneumovirus), influenza A, influenza B, parainfluenza, picornavirus, parechovirus and RSV (respiratory syncytial virus)) detected at two large hospital networks were included. We used SaTScan™ to analyse clusters of paediatric hepatitis and respiratory adenoviruses in Victoria. Negative binomial regression analysis was performed to determine associations between hepatitis and respiratory viruses across Victoria between 1 July 2011 and 30 June 2022.
Results: Several positive associations were observed in Victoria between paediatric hepatitis clusters and respiratory viruses in our spatiotemporal analysis, including with picornaviruses. A positive association was not found with respiratory adenoviruses or SARS-CoV-2. Increased hepatitis clusters were observed in 2021 and 2022, as noted internationally.
Conclusions/Learning Points: These findings suggest that the current severe hepatitis outbreak is a novel phenomenon that requires further etiological investigation. Common circulating respiratory viral pathogens appear to be associated with paediatric hepatitis, and the robust association with picornaviruses warrants further investigation, including by subtype—rhinoviruses and enteroviruses.

Backgrounds: Since the first reports in April 2022 of hepatitis of unknown aetiology occurring in UK children, over 1000 cases have been reported worldwide, including 278 cases in the UK, with the majority younger than 6 years old.
Methods: Using a combination of genomic, transcriptomic, proteomic and immunohistochemical methods, we undertook investigation of 38 cases, 67 age-matched immunocompetent controls and 21 immunocompromised comparator subjects, performing HAdV or AAV2 whole viral genome sequencing in a further 34 controls.
Results: We detected high levels of adeno-associated virus 2 (AAV2) DNA in liver, blood, plasma or stool from 27/28 cases. We found low levels of Adenovirus (HAdV) and Human Herpesvirus 6B (HHV-6B), in 23/31 and 16/23 respectively of the cases tested. In contrast, AAV2 was infrequently detected at low titre in blood or liver from control children with HAdV, even when profoundly immunosuppressed. AAV2, HAdV and HHV-6 phylogeny excluded emergence of novel strains in cases. Histological analyses of explanted livers showed enrichment for T-cells and B-lineage cells. Proteomic comparison of liver tissue from cases and healthy controls, identified increased expression of HLA class 2, immunoglobulin variable regions and complement proteins. HAdV and AAV2 proteins were not detected in the livers. Instead, we identified AAV2 DNA complexes reflecting both HAdV and HHV-6B-mediated replication.
Conclusions/Learning Points: We hypothesize, that high levels of AAV2 replication products aided by HAdV and in the most severe cases also by HHV-6B may have triggered immune-mediated hepatic disease in genetically and immunologically predisposed children.

Backgrounds: Nirsevimab is a monoclonal antibody with an extended half-life that is licensed in the UK and EU to protect infants against lower respiratory tract infection (LRTI) due to respiratory syncytial virus (RSV) during their first RSV season. In this pragmatic trial conducted in the UK, France, and Germany (EudraCT 2022-000099-20), we evaluated nirsevimab for the prevention of hospitalization due to RSV-associated LRTI in infants. Here we report the preliminary results.
Methods: We individually randomised infants (≥29 weeks gestational age) in an open label 1:1 ratio to receive a single intramuscular injection of nirsevimab (<5 kg 50 mg; ≥5 kg 100 mg), or no intervention (standard of care) before or during the RSV season. Following a single physical visit participants were monitored remotely for RSV LRTI hospitalization (primary endpoint, defined as treating physician decision to admit to in-patient care with confirmed RSV) and/or very severe RSV LRTI (secondary endpoint, defined as SpO2 <90% and oxygen supplementation). Efficacy will be evaluated through the RSV season. Adverse events (AEs) will be monitored for 365 days.
Results: At the time of the primary analysis, 8058 infants were randomized, 4037 in nirsevimab group and 4021 in the no intervention group. Of these, 3916 (48.6%), 1912 (23.7%) and 2230 (27.7%) were ≤3.0, >3.0 and ≤6.0, and >6.0 months of age Efficacy against RSV LRTI hospitalization was 83.21% (95% CI: 67.77%, 92.04%) and 75.71% (32.75%, 92.91%) against very severe RSV LRTI.
Conclusions/Learning Points: A single dose of nirsevimab given before or during the RSV season protected infants against RSV LRTI hospitalization and very severe RSV LRTI in a pragmatic clinical trial conducted in real-world settings.

Backgrounds: TAK-003, a tetravalent dengue vaccine, demonstrated efficacy and safety against symptomatic and hospitalized dengue in a long-term phase 3 study. As a robust cell-mediated immune (CMI) response is important for immunity, this open-label phase 2 study evaluated T-cell responses to TAK-003 in healthy 4- to 16-year-old participants in dengue-endemic regions (NCT02948829).
Methods: 200 participants were enrolled to receive TAK-003 at Days 1 and 90. Dengue serostatus was tested at baseline (seropositivity: reciprocal neutralizing antibody [NAb; MNT_{50}] titer ≥10 for ≥1 serotype). The primary endpoint was CMI response rate at Day 120 (defined as interferon-gamma [IFN-γ] enzyme-linked immunospot response >3 times baseline and ≥5 spots per well). Peptide pools for non-structural (NS) proteins NS1, NS3, and NS5 matching DENV-1, -2, -3, and -4 were used for stimulation. Secondary endpoints included further evaluation of CMI, NAb responses and safety. Participants were followed up to 3 years post-second vaccination.
Results: CMI response rate against any peptide pool at Day 120 was 86.1% (seropositive participants: 82.0%; seronegative participants: 91.8%) and remained stable through Day 270. CMI response rate at Day 120 to peptide pools matching DENV-1, -2, -3, and -4 were 64.7%, 85.0%, 69.2%, and 63.6%, respectively, and remained elevated through Day 270. Multifunctional (secretion of ≥2 cytokines among IFN-γ, interleukin-2 and tumor necrosis factor-α) CD4+ and CD8+ T-cell responses were observed, independent of baseline serostatus. NAb titers and seropositivity rates remained high against all four DENV serotypes through Year 3. TAK-003 was well-tolerated with no important safety risks identified.
Conclusions/Learning Points: TAK-003 elicited multifunctional, cross-reactive T-cell responses against all four DENV serotypes, irrespective of participant baseline serostatus, in 4- to 16-year-old participants living in dengue-endemic regions.

Backgrounds: Serogroups A/B/C/W/Y cause nearly all invasive meningococcal disease (IMD). This study evaluated safety and noninferiority of seroresponses of a pentavalent MenABCWY vaccine compared with the licensed vaccines MenB-fHbp and MenACWY-CRM.
Methods: This phase 3, observer-blinded, active-controlled study randomized 10–25-year-olds (2:1; n=2431), stratified according to prior ACWY vaccination history, to receive MenABCWY (Months 0,6) or MenB-fHbp (Months 0,6) and MenACWY-CRM (Month 0). Immunogenicity evaluations utilized serum bactericidal assays with human complement (hSBA) against serogroup A/C/W/Y strains and 4 diverse, vaccine-heterologous serogroup B (MenB) strains. Noninferiority was achieved if the lower bounds of the 95% CIs for the differences in percentages of participants achieving ≥4-fold titer rises over baseline (ie, seroresponses) or hSBA titers ≥lower limit of quantitation (LLOQ) for all strains combined (ie, composite response; MenB only) in the MenABCWY versus MenB-fHbp + MenACWY-CRM groups was >−10%. Safety was also evaluated.
Results:

Table. Percentages of Participants Achieving ≥4-fold Rises in hSBA Titer from Baseline or Composite Response

MenA/MenC/MenW/MenY Endpoint Strain	ACWY-Naive: MenABCWY + Saline n[a]/N[b] (%) (95% CI[c])	ACWY-Naive: MenB-fHbp + MenACWY-CRM n[a]/N[b] (%) (95% CI[c])	ACWY-Naive: Difference[d] ([MenABCWY + Saline] − [MenB-fHbp + MenACWY-CRM]) (95% CI[e])	ACWY-Experienced: MenABCWY + Saline n[a]/N[b] (%) (95% CI[c])	ACWY-Experienced: MenB-fHbp + MenACWY-CRM n[a]/N[b] (%) (95% CI[c])	ACWY-Experienced: Difference[d] ([MenABCWY + Saline] − [MenB-fHbp + MenACWY-CRM]) (95% CI[e])
≥4-fold rise in hSBA titer from baseline[f] to 1 month after MenABCWY Dose 1 or a single MenACWY-CRM dose						
MenA	484/498 (97.0) (95.1, 98.3)	242/254 (95.3) (91.9, 97.5)	1.7 (−1.0, 5.3)	416/439 (94.8) (92.2, 96.7)	220/227 (96.9) (93.7, 98.8)	−2.2 (−5.2, 1.4)

MenB Endpoint Strain (fHbp variant) or time point	ACWY-Naive and ACWY-Experienced Combined: MenABCWY + Saline n[a]/N[b] (%) (95% CI[c])	MenB-fHbp + MenACWY-CRM n[a]/N[b] (%) (95% CI[c])	Difference[d] ([MenABCWY + Saline] − [MenB-fHbp + MenACWY-CRM]) (95% CI[e])
≥4-fold rise in hSBA titer from baseline[f] to 1 month after Dose 2			
PMB80 (A22)	646/778 (83.0) (80.2, 85.6)	313/396 (79.0) (74.7, 82.9)	4.0 (−0.7, 8.9)
PMB2001 (A56)	771/807 (95.5) (94.3, 97.2)	378/400 (94.5) (91.8, 96.5)	1.1 (−1.0, 4.3)
PMB2948 (A24)	567/833 (68.1) (64.8, 71.2)	239/418 (57.2) (52.3, 62.0)	10.9 (5.2, 16.6)
PMB2707 (A44)	731/845 (86.5) (84.0, 88.7)	332/419 (79.2) (75.0, 83.0)	7.3 (2.9, 11.9)
Composite hSBA response [hSBA titer ≥LLOQ for all 4 MenB strains]			
Baseline[f]	10/812 (1.2) (0.6, 2.3)	8/403 (2.0) (0.9, 3.9)	-
1 Month after Dose 2	591/755 (78.3) (75.2, 81.2)	263/383 (68.7) (63.8, 73.3)	9.6 (4.2, 15.2)

fHbp=factor H binding protein; hSBA=serum bactericidal activity assay using human complement; LLOQ=lower limit of quantitation; LOD=limit of detection; MenA, MenB, MenC, MenW, and MenY=*Neisseria meningitidis* serogroup A, serogroup B, serogroup C, serogroup W, and serogroup Y; MenABCWY=pentavalent serogroups A, B, C, W, Y vaccine; MenACWY-CRM= quadrivalent meningococcal CRM conjugate vaccine; MenB-fHbp=bivalent rLP2086.

LLOQ=1:8 for all MenA, MenC, MenW, and MenY serogroups and A56, B24, and B44; LLOQ=1:16 for A22.

4-fold increase is defined as follows: (1) For participants with a baseline hSBA titer <LOD (1:4), a response is defined as an hSBA titer ≥1:16. (2) For participants with a baseline hSBA titer ≥LOD and <LLOQ, a response is defined as an hSBA titer ≥4 times the LLOQ. (3) For participants with a baseline hSBA titer ≥LLOQ, a response is defined as an hSBA titer ≥4 times the baseline titer.

[a]n=number of participants who achieved the endpoint noted.

[b]N=number of participants with valid and determinate hSBA titers for the specified strain at both the specified time point and baseline (≥4-fold responses) or number of participants with valid and determinate hSBA results for all 4 strains (composite hSBA response).

[c]Exact 2-sided CI based upon the observed proportion of participants, using the Clopper and Pearson method.

[d]Difference in proportions ([MenABCWY + saline] − [MenB-fHbp − MenACWY-CRM]) expressed as a percentage.

[e]2-sided CI (based on Miettinen and Nurminen) for the difference in proportions, expressed as a percentage.

[f]Baseline is defined as the blood draw prior to Dose 1.

Seroresponses were noninferior for 1 (ACWY-naive, 62.9%–97.0%; ACWY-experienced, 93.4%–97.4%) or 2 (ACWY-naive, 93.3%–97.8%; ACWY-experienced, 93.0%–97.1%) MenABCWY doses compared with 1 MenACWY-CRM dose (ACWY-naive, 52.4%–95.3%; ACWY-experienced, 93.7%–96.9%), regardless of ACWY experience (Table). For serogroup B, seroresponses for each test strain 1 month after MenABCWY Dose 2 (68.1%–95.9%) and percentages with composite responses (78.3%) were noninferior to MenB-fHbp after Dose 2 (57.2%–94.5% and 68.7%, respectively; Table). Reactogenicity,

which was mostly mild to moderate in severity, and adverse events were reported at similar frequencies across groups; no reactogenicity events led to study withdrawal.
Conclusions/Learning Points: MenABCWY administered on a 0-,6-month schedule induced robust, noninferior immune responses against all 5 serogroups compared with concomitantly administered MenB-fHbp and MenACWY-CRM and was safe and well tolerated. These findings support use of MenABCWY to simplify protection against IMD and potentially raise MenB vaccination rates. Funded by Pfizer.

EFFECTIVENESS, IMMUNOGENICITY AND SAFETY OF A PENTAVALENT MENINGOCOCCAL ABCWY VACCINE IN ADOLESCENTS AND YOUNG ADULTS: RESULTS FROM A PHASE 3, RANDOMIZED, CONTROLLED CLINICAL STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 09: VACCINES

Terry Nolan[1,2], Peter Silas[3], Arnold Willemsen[4], Chiranjiwi Bhusal[4], Daniella Toneatto[5], . The Quintet Study Group[6]
[1]Peter Doherty Institute for Infection & Immunity, Infectious Diseases, Melbourne, Australia, [2]Murdoch Children's Research Institute, Virgo, Parkville, Australia, [3]Wee Care Pediatrics, Pediatrics, Syracuse, United States of America, [4]GSK, Statistics, Amsterdam, Netherlands, [5]GSK, Neisseria, Siena, Italy, [6]., ., Multiple Cities, Australia

Background: A meningococcal (Men) serogroups ABCWY vaccine could provide a practical approach towards broad protection against invasive meningococcal disease.
Methods: The effectiveness, immunogenicity and safety of an investigational MenABCWY vaccine and licensed 4CMenB and MenACWY-CRM vaccines were compared. In the observer-blind study (NCT04502693), 3651 healthy individuals aged 10–25 years were randomized (5:5:9:1) to receive 4CMenB (3-dose schedule: 0-2-6 months), 4CMenB (2-dose schedule: 0-6 months), investigational MenABCWY vaccine (2-dose schedule: 0-6 months) or MenACWY-CRM (1 dose: 0 month; control). Primary objectives of the MenABCWY analyses included demonstration of vaccine effectiveness (VE), using enc-hSBA (human serum bactericidal antibody assay using endogenous complement in each vaccinee's serum) against a panel of 110 diverse invasive meningococcal serogroup B (MenB) strains, with 2 approaches: test-based (percentages of samples without bactericidal serum activity against MenB strains post-last MenABCWY dose vs post-MenACWY dose) and responder-based (percentage of participants whose sera kill ≥70% strains at 1 month post-last dose). Other primary objectives included demonstrations of the non-inferiority of effectiveness of MenABCWY vs 4CMenB, immunological non-inferiority of MenABCWY vs MenACWY-CRM in MenACWY vaccine-naïve individuals, and safety.
Results: The 2-dose MenABCWY schedule met the pre-defined criteria for success for both VE endpoints. The non-inferiority of effectiveness of MenABCWY vs 2-dose 4CMenB and immunological non-inferiority vs 1-dose MenACWY were also demonstrated (see table). The safety profile of MenABCWY was in line with that of 4CMenB, with no safety concerns.

VE, and effectiveness and immunological non-inferiority of investigational MenABCWY vaccine

Test-based VE[1]	**Samples without bactericidal serum activity, %**			
	MenABCWY, N=25,715	**MenACWY, N=4374**	**Relative risk (95% CI)**	**MenABCWY VE, % (95% CI)**
	17.4	79.0	0.22 (0.21, 0.23)	77.9 (**76.6**, 79.2)
Responder-based VE[2]				84.1 (**81.4**, 86.5) N=817 (subjects)

Effectiveness non-inferiority[3]	**Samples with bactericidal serum activity, % (95% CI)**		**Group difference, % (95% CI)**
	MenABCWY, N=25,715	**4CMenB (0–2 M), N=27,569**	
	82.5 (82.1, 83.0)	83.1 (82.7, 83.6)	-0.6 (**-1.3**, 0.0)

Immunological non-inferiority[4]	**MenABCWY**		**MenACWY (control)**		
	Subjects, N	**% with 4-fold rise in hSBA titre (95% CI)**	**Subjects, N**	**% with 4-fold rise in hSBA titre (95% CI)**	**Group difference, % (95% CI)**
MenA	1170	97.0 (95.9, 97.9)	112	85.7 (77.8, 91.6)	11.3 (**5.9**, 19.0)
MenC	1189	97.2 (96.1, 98.1)	114	50.0 (40.5, 59.5)	47.2 (**38.1**, 56.3)
MenW	1185	97.0 (95.9, 97.9)	115	61.7 (52.2, 70.6)	35.3 (**26.9**, 44.5)
MenY	1196	96.7 (95.6, 97.7)	119	69.7 (60.7, 77.8)	27.0 (**19.4**, 35.8)

CI, confidence interval; hSBA, human serum bactericidal antibody assay; M, study month; N, number of samples or subjects; VE, vaccine effectiveness

[1] Percentages of samples without bactericidal serum activity by enc-hSBA against MenB strain panel at 1 M post-last MenABCWY dose vs post-MenACWY dose. Relative risk = percentage of samples without bactericidal serum activity in MenABCWY group / percentage in control MenACWY group. **Test-based VE demonstrated with lower limit (LL) of 2-sided 95% CI >65%**

[2] Percentage of participants whose sera kill ≥70% strains by enc-hSBA against MenB strain panel at 1 M post-last dose. **Responder-based VE demonstrated with LL of 2-sided 95% CI >65%**

[3] Percentages of samples with bactericidal serum activity by enc-hSBA against MenB strain panel at 1 M post-last MenABCWY dose and post-2 4CMenB doses (group that received third dose at M 6). **Effectiveness non-inferiority demonstrated with LL of 2-sided 95% CI for group difference above -5%**

[4] Percentages of MenACWY vaccine-naïve participants with 4-fold rise in hSBA titres against serogroups A, C, W, Y at 1 M post-last MenABCWY dose and 1 M post-MenACWY dose. **Immunological non-inferiority demonstrated with LL of 2-sided 95% CI for group difference above -10%**

Conclusions/Learning Points: The investigational MenABCWY vaccine is effective against a panel of 110 diverse invasive MenB strains and its safety profile is acceptable. Two MenABCWY doses given 6 months apart are non-inferior to 2 doses of 4CMenB and 1 dose of MenACWY in 10–25 year-old individuals.

PHASE 3 SAFETY AND IMMUNOGENICITY STUDY OF A 20-VALENT PNEUMOCOCCAL CONJUGATE VACCINE (PCV20) ADMINISTERED IN A 3-DOSE INFANT IMMUNIZATION SERIES

Oral Presentations Session
ORAL PRESENTATION SESSION 09: VACCINES

Piotr Korbal[1], Jacek Wysocki[2], Noor Tamimi[3], Mary Kline[3], Jelena Drozd[3], Lanyu Lei[4], Yahong Peng[3], Peter Giardina[4], William Gruber[4], Daniel Scott[3], Wendy Watson[3]
[1]University Hospital No. 2 im. Dr Jana Biziela, Neonatology, Bydgoszcz, Poland, [2]Poznan University of Medical Sciences, Department Of Preventive Medicine, Swiecickiego, Poland, [3]Pfizer Inc, Vaccine Research And Development, Collegeville, United States of America, [4]Pfizer Inc, Vaccine Research And Development, Pearl River, United States of America

Backgrounds: Pneumococcal conjugate vaccines have reduced vaccine-type pneumococcal disease. This study assessed PCV20, which contains the components of the 13-valent pneumococcal conjugate vaccine (PCV13) and 7 additional conjugates in a 3-dose infant immunization series.
Methods: This phase 3 study (NCT04546425) was conducted in Europe and Australia. Infants (randomized 1:1) received 3 doses of PCV20 or PCV13 at ages 2–3, 4–5, and 11–12 months. Primary objectives included noninferiority of PCV20 to PCV13 based on serotype-specific immunoglobulin G (IgG) geometric mean ratios (GMRs; 2-fold noninferiority criterion) 1 month after Doses 2 and 3, and participants (%) with predefined IgG concentrations 1 month after Dose 2 (10% noninferiority criterion). The 7 additional serotypes in the PCV20 group were compared with the lowest result in the PCV13 group for the noninferiority evaluation. Dose 2 primary objectives were included based on scientific advice from the Committee for Medicinal Products for Human Use. The totality of immunogenicity data was assessed for serotypes missing noninferiority. Safety assessments included local reactions, systemic events, and adverse events.
Results: Of 1207 participants (PCV20, n=603; PCV13, n=604), 1173 (97.2%) completed all visits. Nineteen of 20 serotypes met statistical noninferiority criterion for IgG GMR 1 month after Dose 3; serotype 6B narrowly missed (lower 95% bound=0.48). After Dose 2, 16 serotypes met noninferiority for ≥1 of the immunogenicity objectives. Functional responses were elicited by PCV20 after Doses 2 and 3; booster responses were observed after Dose 3. The overall safety profile of PCV20 was similar to PCV13.
Conclusions/Learning Points: A 3-dose infant series of PCV20 had a safety profile similar to PCV13 and elicited responses expected to protect against pneumococcal disease due to the 20 vaccine serotypes.

Backgrounds: Immunization during pregnancy (IP) has proven effective in preventing pertussis in young infants but causes blunting of the infants' pertussis vaccine responses. We aimed to evaluate the blunting effect of IP on quantity and functionality of infants' anti-pertussis toxin (PT) IgG antibodies after primary pertussis vaccination.
Methods: We used a prospective, interventional, open-label controlled study design to evaluate the effect of immunization with tetanus-diphtheria-acellular pertussis (Tdap) vaccine at 30-35 weeks of pregnancy on DTaP vaccine responses of the infants. Geometric mean concentration (GMC) of anti-PT IgG antibodies and titer of PT neutralizing antibodies (PTNAs) were determined in infants born to vaccinated mothers in comparison with infants born to unvaccinated mothers at 6 months of age. Antibody concentrations of filamentous hemagglutinin, pertactin, diphtheria toxin, and tetanus toxin were also determined. Infants received their primary DTaP vaccines at 3 and 5 months of age.
Results: In total, 69 mother-infant pairs completed the study, 47 mothers and infants in the immunization during pregnancy group (Arm1), and 22 mothers and infants in the control group (Arm2). At six months of age, GMC (95% CI) of anti-PT IgG antibodies was 68 IU/ml (56-83) in Arm1 and 142 IU/ml (99-204) in Arm2. Infants in Arm1 had a higher PTNA titer than Arm2 in cord blood 178 (126-252) vs 40 (23-70) and at 3 months of age 65 (48-88) vs 28 (18-43), but equal at 6 months of age 113 (90-143) vs 117 (80-169), respectively. However, the fold increase of PTNAs from 3 to 6 months was 1.75 in Arm1 and 4.13 in Arm2 ($p < 0.001$).
Conclusions/Learning Points: IP seems to blunt more infants' anti-PT IgG antibody responses to pertussis vaccines than PTNA capacity by 6 months.

Backgrounds: Pertussis is an acute respiratory tract infection caused by the bacterium Bordetella pertussis (Bp). Although maternal vaccination programs protect against disease in early life, their effect on the infant's subsequent response to primary pertussis vaccination is not fully understood.
Methods: The Gambian Pertussis Study (GaPS), performed as part of the PERISCOPE consortium, is a randomised, double-blind controlled clinical trial in pregnant women, exploring the impact of aP vaccination in pregnancy on the immunogenicity in infants randomized to receive either an aP or wP vaccine. In an immunological sub study, we analyzed vaccine-induced nasal antibody responses to Bp, measuring antibody binding to wildtype Bp bacteria (Bp_wt) and an isogenic Bp deletion mutant that lacks all aP vaccine antigens.
Results: Our results show that infants born to mothers vaccinated with aP during pregnancy have significantly higher nasal IgG binding levels to Bp_wt prior to primary vaccination compared to infants born to mothers vaccinated with a control (tetanus-toxoid) vaccine. Subsequent primary vaccination of infants with wP results in significantly higher nasal IgG binding compared to aP, both at 5 and 9 months of age. At 9 months of age, aP-vaccinated infants born to mothers vaccinated with aP during pregnancy had significantly lower nasal IgG levels compared to the three other groups.
Conclusions/Learning Points: Our study demonstrates that maternal vaccination results in increased nasal antibody levels in infants, and furthermore identifies clear differences in nasal antibodies induced after primary aP versus wP vaccination. Clinical significance of the findings remains to be established.

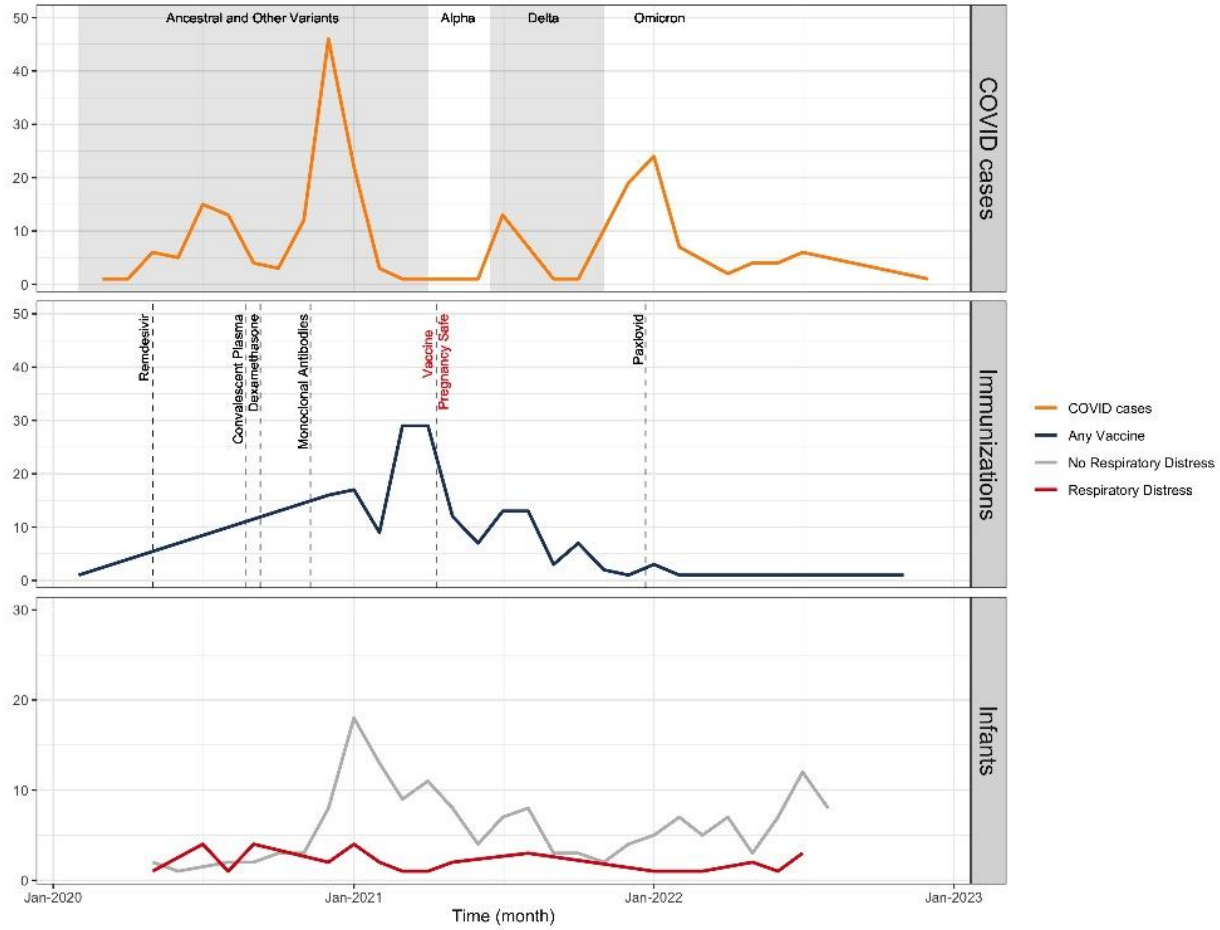
[1]University of California, Los Angeles, David Geffen School Of Medicine, Los Angeles, United States of America, [2]University of California, Los Angeles, Pediatrics, Los Angeles, United States of America, [3]UCLA David Geffen School of Medicine, Department Of Medicine, Division Of Infectious Diseases, Los Angeles, United States of America, [4]University of California, Los Angeles, Institute Of The Environment And Sustainability, Los Angeles, United States of America, [5]University of California, Los Angeles, Obstetrics And Gynecology, Los Angeles, United States of America, [6]UCLA Neonatology, Medicine, Los Angeles, United States of America, [7]UCLA David Geffen School of Medicine, Department Of Pediatrics, Division Of Pediatric Infectious Diseases, Los Angeles, United States of America

Backgrounds: Respiratory Distress (RD) has been reported in SARS CoV-2-exposed uninfected (SEU) term neonates born to women with COVID-19 during pregnancy. Prior studies suggest that prenatal exposure may activate an inflammatory cascade in the newborn's airway. However, associations of maternal COVID-19 vaccination on neonatal RD remain unknown.
Methods: We recruited a longitudinal cohort of pregnant women with confirmed SARS-CoV-2 during pregnancy and their infants in Los Angeles, CA. Maternal disease severity was defined by NIH criteria. We explored multifactorial associations between maternal COVID-19 parameters and infant RD.
Results: Twenty-nine of 227 women (13%) had severe/critical COVID-19; 199 infants born between 4/2021 to 8/2022 had neonatal data available with 17% (n=34) diagnosed with RD. Of these, 38% (n=14) were full-term and none tested positive for SARS CoV-2. 17% of infants (n=34) in the cohort were premature. Causes of RD included: Respiratory Distress Syndrome (47%), Transient Tachypnea of the Newborn (16%), and infectious etiologies (16%). 157 mothers (69%) were unvaccinated with severe/critical disease present in 16% (n=23), whereas only 4% of vaccinated mothers (n=3) had severe/critical disease. Neonatal RD was associated with maternal disease severity (OR:4.5, 95%CI:1.49-13.10), prematurity (OR:15.41, 95%CI:6.55-38.07), and absence of maternal COVID immunization (OR:3.74, 95% CI:1.47-11.49). RD was not associated with trimester of COVID-19 in pregnancy (OR:1.03, 95%CI:0.49-2.18) nor maternal race/ethnicity (OR:0.91, 95%CI:0.39-2.23). After adjusting for prematurity, OR of RD in neonates born to unvaccinated women was 4.25 (95%CI:1.2-20.7). When pregnant women received > 1 mRNA vaccine dose prior to infection, OR of neonatal RD was 0.33 (95%CI:0.1-0.96), a 67%
decline.

FIGURE 1: Maternal COVID cases, maternal immunizations, and cases of infant respiratory distress over time



Conclusions/Learning Points: Unusually high rates of RD were observed in SEU infants born to women with COVID-19 during pregnancy. Maternal vaccination against COVID-19 reduced maternal disease severity and frequency of neonatal RD.

O0090 / #1801

CO-ADMINISTRATION OF VACCINES AGAINST ROTAVIRUS AND GROUP B MENINGOCOCCUS IS ASSOCIATED WITH AN INCREASED ROTAVIRUS VACCINATION COVERAGE: A 5-YEAR RETROSPECTIVE POPULATION STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 09: VACCINES

Andrea Lo Vecchio[1], Sara Maria Scarano[1], Pietro Buono[2], Alessandro Scoppa[2], Chiara Amato[1], Valerio Colecchia[1], Alfredo Guarino[1]
[1]University of Naples, Federico II, Department Of Translational Medical Sciences - Section Of Pediatrics, Naples, Italy, [2]General Directorate for Health, Department Of Maternal And Child Health, Naples, Italy

Backgrounds: In Italy Rotavirus vaccination (RVV) coverage is scattered and suboptimal. The narrow time frame to complete the schedule is a major barrier to vaccine uptake, and co-administration with other vaccines may potentially increase the coverage. We aimed at studying the impact on RVV coverage of the co-administration of RVV and Meningococcal Group B vaccines (MenB), a practice often applied although not included into product labels.
Methods: Regional Vaccination Registry was used to conduct a retrospective cohort study in children born in Campania Region (January 2016-December 2020) and receiving vaccines scheduled in the first year of life.
Results: A total of 224.110 children were enrolled during the study period. Overall, 60.614 (27.0%) completed the RVV schedule, with a progressive increase over time (from 1.15% in 2016 to 56.92% in 2020), in parallel with MenB/RVV co-administration (from 0.7% in 2016 to 46.85% in 2020). Monovalent RVV schedule (2-doses) was completed in 91.1% of children compared to pentavalent RVV Schedule (3-doses) in 81.3% ($p<0.00001$). Children receiving RVV/MenB co-administration had a significant higher chance to complete RV schedule compared to those receiving RVV alone during a specific appointment (94.78% vs 72.26%, Prevalence Ratio -PR- 1.275, 95%IC 1.245-1.295 $p<0.00001$). The positive effect of RVV/MenB co-administration was more evident for children receiving pentavalent RVV (PR 1.288) than monovalent RVV (PR 1.115), this evidence was confirmed when adjusted for confounding variables (i.e.year of vaccination, local health district,gender).
Conclusions/Learning Points: Although still far from the target, RVV coverage has increased in recent years in Campania Region. Co-administration with MenB vaccine may aid in achieving this goal, especially for pentavalent RVV. Further safety data are needed to support co-administration as a key tool to increase coverage.

A COMMUNITY BASED TRIAL FOR ASSESSING THE UPTAKE OF CHILDHOOD VACCINES THROUGH COMMUNITY MOBILIZATION AND AN INNOVATIVE CONDITIONAL COLLECTIVE COMMUNTIY INCENTIVE

Oral Presentations Session
ORAL PRESENTATION SESSION 09: VACCINES

Jai Das
Aga Khan University, Global Health And Development, Karachi, Pakistan

Backgrounds: Despite the decline in under-five mortality by over 60% in the last three decades, majority of the child mortality is still attributable to communicable and infectious diseases that are not only preventable but also treatable.
Methods: The interventions were formally evaluated prospectively in a three-arm cluster randomized controlled trial to evaluate the impact of community engagement and demand creation strategy, involving conditional community-based incentives(CCI) on uptake of childhood immunizations and sanitation and hygiene behaviors in a rural setting of Pakistan: community mobilization and Incentivization (CMI); community mobilization only (CM); and control group. The CCI were an innovative strategy as it involved serial incremental targets of collective improvement in community behavior related to improvement in the coverage of a composite indicator of fully immunized children (FIC), and sanitation index (SI). The evaluation was done by an independent data collection and analysis team at baseline and end line This trial is registered with ClinicalTrials.gov, number NCT03594279
Results: At the end of the two-year intervention, 59.16% children were fully immunized in the CMI group, 43.7% in the CM, and 46.57% in the control group; SI in the CMI group was a mean of 10.15 (9.73, 10.57), followed by CM group 9.32 (8.91, 9.73) and the control group 8.93 (8.47, 9.38); The multivariate results suggest that there was a significant improvement in the CMI group for FIC (relative risk (RR) 1.27,95%confidenceinterval (CI)1.02-1.58), total SI (β:0.99,95%CI:0.13-1.85) and exclusive-breastfeeding (RR:1.79,95%CI:1.39-2.29), a significant decrease in prevalence of diarrhea (RR:0.65:95%CI:0.46-0.94).
Conclusions/Learning Points: Despite the challenges associated with the strategy of community mobilization and CCI, CMI was effective in increasing the coverage of essential interventions and can be an effective strategy for behavior change, enhanced acceptance and improve coverage of recommended health interventions.

Backgrounds: To ensure applicability of EUCAST breakpoints, antimicrobials should not be used at lower doses than listed in EUCAST dosing tables. However, a paediatric minimal dosing table has not yet been developed and its development is complicated by a lack of high-quality pharmacokinetic (PK) study data to inform adequate dosing. Allometric scaling is commonly accepted as an empiric pharmacokinetic scaling approach for paediatric patients down to an age of approximately one year.
Methods: Adult target attainment was calculated for a 70kg-person using, where possible, the same parameters as for EUCAST breakpoint setting. For paediatric body weights of 10, 20, 30 and 40 kg, target attainment was calculated using PK parameters scaled from adults using theory-based allometry. The taskforce selected schedules based on ≥80% relative target attainment (but preferentially 100%) compared to adults over all modelled body weights, low frequency of dosing where possible and consistency with adult EUCAST recommendations. Where adult-equivalent target attainment cannot be expected with commonly acceptable dosing schedules, plans were made for future review of alternative (i.e. observed in high-quality PK studies) evidence for adequate target attainment.
Results: For most beta-lactams, adult-equivalent target attainment can likely be achieved with dosing schedules within the accepted range. Table 1 shows minimum dosing for commonly used beta-lactams with highlights where suggested doses are higher than used in most

Agent	Standard Dosage (in mg/kg BW)	High Dosage (in mg/kg BW)	Max. daily dose
Penicillins			
Benzylpenicillin	32.5 x 4	30 x 6	14.4g
Ampicillin	40 x 4	75 x 4	15g
Amoxicillin IV	35 x 3	50 x 6	12g
Amoxicillin PO	15 x 2	27 x 3	3g
Amoxicillin-clavulanic acid IV	37 x 3	37 x 4	8g
Amoxicillin-clavulanic acid PO (8:1 or 7:1)	15 x 2	30 x 3	8g
Piperacillin-tazobactam	80 x 4	100 x 4 3hr inf	16g
Phenoxymethylpenicillin	15 x 4	none	3.6g
Cloxacillin IV	17 x 6	none	12g
Cloxacillin PO	under review	none	6g
Flucloxacillin IV	12.5 x 4	none	12g
Flucloxacillin PO	20 x 4	none	3g
Cephalosporins			
Cefalexin	under review	none	6g
Cefazolin	23 x 2	50 x 3	6g
Cefotaxime	50 x 3	50 x 4	12g
Ceftazidime	50 x 3	100 x 3	6g
Ceftriaxone	50 x 1	80 x 1	4g
Cefuroxime IV	50 x 3	50 x 4	4.5g
Cefuroxime PO	under review	under review	1g
Carbapenems			
Meropenem	40 x 3	30 x 3 3hr inf	4.5g

recommendations.

Conclusions/Learning Points: Using allometric scaling accounts for differences in metabolism resulting in non-linear dependency of drug clearance on body weight and does not correct for differences in maturation. Findings from allometric scaling provide a first basis for discussion with the aim to develop a EUCAST dosing table for children.

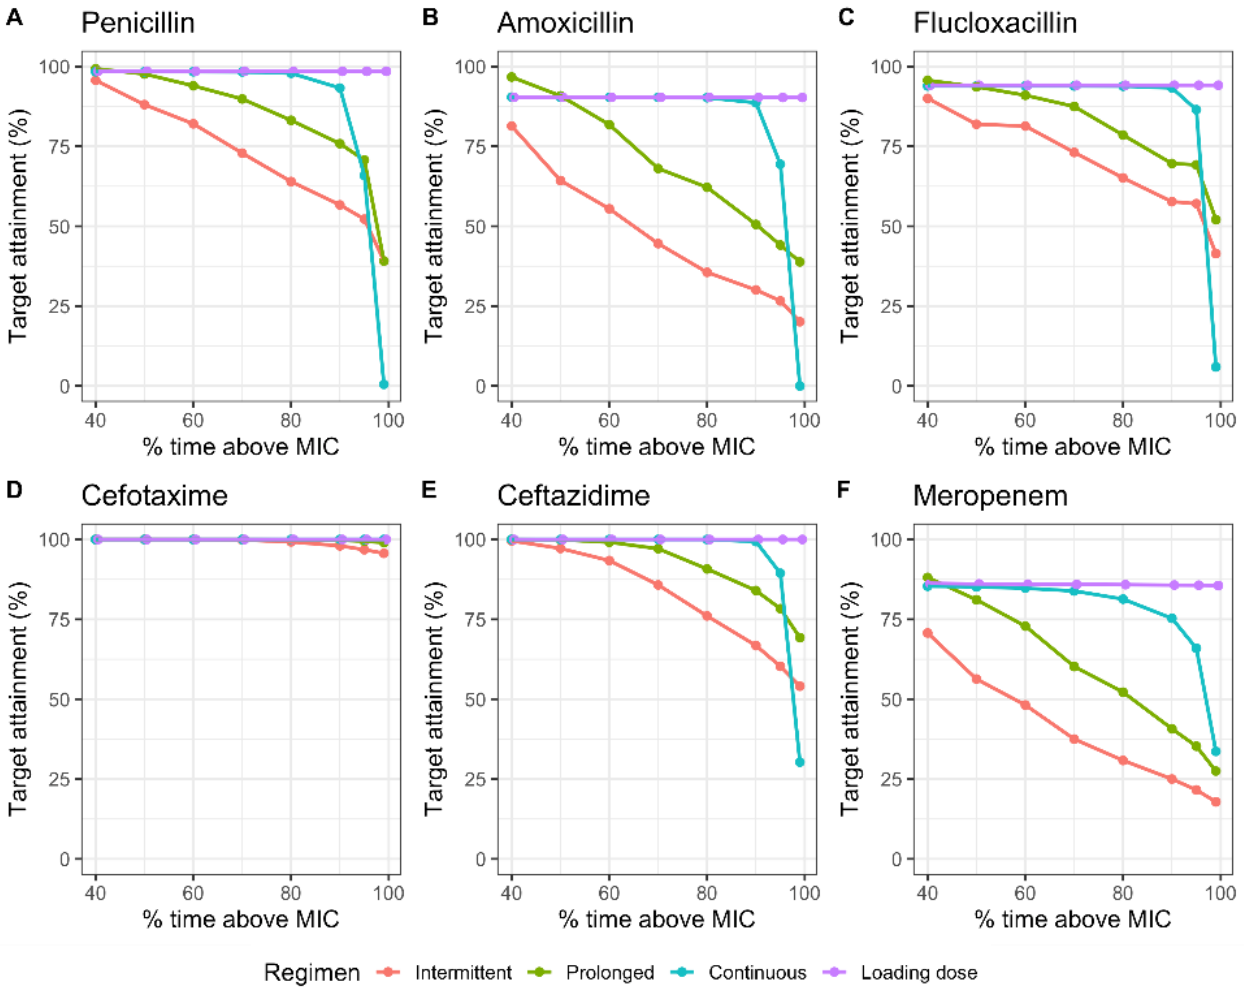
OPTIMIZATION OF BETA-LACTAM DOSING REGIMENS IN NEONATAL INFECTIONS - CONTINUOUS AND EXTENDED ADMINISTRATION VERSUS INTERMITTENT ADMINISTRATION

Oral Presentations Session
ORAL PRESENTATION SESSION 10: ANTIMICROBIALS & ANTIBIOTIC STEWARDSHIP & MICROBIOME

Matthijs Kruizinga, Leo Wewerinke, Anne De Grauw, Mirjam Van Veen, Emiel Leegwater, Bert Storm
Juliana Children's Hospital, Pediatrics, Den Haag, Netherlands

Backgrounds: Neonatal infections and especially neonatal sepsis are a major cause of morbidity and mortality. The cornerstone of treatment of neonatal infections are beta-lactam antibiotics. Clinical success of antibiotics is dependent on the use of safe and effective dosing regimens. However, despite the common use of these antibiotics, it is currently unknown which beta-lactam dosing regimens are optimal. In this pharmacokinetic-pharmacodynamic simulation study, we aimed to compare the treatment with continuous versus intermittent infusion of β-lactam antibiotics for neonates with infectious diseases.
Methods: We selected population pharmacokinetic models of penicillin G, amoxicillin, flucloxacillin, cefotaxime, ceftazidime and meropenem and performed a Mote Carlo simulation with 30 000 neonates. Four different dosing regimens were simulated, intermittent infusion in 30 minutes, prolonged infusion in four hours, continuous infusion and continuous infusion with a loading dose. The first 48 hours of therapy were simulated. The primary endpoint was 90% probability of target attainment (PTA) for 100% $\int T > MIC$.
Results: For all antibiotics except cefotaxime, continuous infusion with a loading dose resulted in a higher PTA compared to other dosing regimens (Figure 1). Sufficient exposure using continuous infusion (PTA>90%) with a loading dose was reached for amoxicillin (90.3%), penicillin G (PTA 98.4%), flucloxacillin (PTA 94.3%), cefotaxime (PTA 100%) and ceftazidime (PTA 100%). Higher meropenem (PTA 85.5%) doses might be needed to treat severe infections in neonates. Ceftazidime and cefotaxime dose might be unnecessary high, as even with dose reductions a PTA>90% was retained.



Conclusions/Learning Points: Continuous infusion with a loading dose leads to a higher PTA compared to continuous, intermittent or prolonged infusion and can improve antibiotic treatment in neonates. Our models suggest continuous infusion treatment as preferable in neonatal infections, instead of the currently used intermittent dosing regimen.

Backgrounds: Optimisation of antimicrobial stewardship is key to tackling antimicrobial resistance (AMR). We described patterns of empiric antibiotic use in European paediatric Emergency Departments (EDs) and characterised appropriateness and consistency of prescribing.
Methods: Febrile children attending ED with suspected infection and venepuncture for diagnostics tests were recruited to the BIVA study in PERFORM (Personalised Risk assessment in Febrile illness to

Optimise Real-life Management), and cases were phenotyped using the validated PERFORM probability algorithm. Empiric systemic antibiotic use was determined in view of assigned final ‘bacterial’ or ‘viral’ phenotype. Antibiotics were classified according to WHO AWaRe (Access, Watch, Reserve).
Results: Of 2130 participating children, 1549 (72.7%) were assigned a ‘bacterial’ and 581 (27.3%) a ‘viral’ phenotype. A total of 1318 (85.1%) patients with a ‘bacterial’ and 269 (46.3%) with a ‘viral’ phenotype were prescribed empiric antibiotics during the first two days of admission. Of all patients treated with antibiotics, the majority (87.8% in ‘bacterial’ and 87.0% in ‘viral’ group) received parenteral antibiotics. The top three antibiotics prescribed were third-generation cephalosporins, penicillins and penicillin/beta-lactamase inhibitor combinations. 61.0% in the ‘bacterial’ and 80.3% patients in the ‘viral’ group receiving antibiotics had ≥ one WHO Watch antibiotic prescribed. The proportion of Watch antibiotic use was similar in initial and final syndrome classifications.
Conclusions/Learning Points: Differentiating bacterial from viral aetiology in febrile illness on initial ED presentation remains challenging, resulting in over-prescription of antibiotics. Of note, a significant proportion of patients with a final ‘viral’ phenotype received systemic antibiotics during admission, predominantly classified as WHO Watch. Rapid and accurate point-of-care tests in the ED differentiating between bacterial and viral aetiology, could significantly improve antimicrobial stewardship, and help stem the rising tide of AMR. Funding: EU H2020 programme, GA No 66830

SUCCESS OF AMOXICILLIN ORAL CHALLENGES IN CHILDREN AT LOW RISK OF ALLERGY REQUIRING ANTIBIOTIC IN THE EMERGENCY DEPARTMENT

Oral Presentations Session
ORAL PRESENTATION SESSION 10: ANTIMICROBIALS & ANTIBIOTIC STEWARDSHIP & MICROBIOME

Evelyne Doyon Trottier[1], Gervais Camille[2], Roy Hélène[3], Buithieu Maria[4], Des Roches Anne[5], Pellerin Stéphanie[1], Ovetchkine Philippe[6], Luc Panetta[6,7]
[1]CHU Sainte-Justine, Pediatric Emergency Department, Montreal, Canada, [2]McGill University, Faculty Of Medicine And Health Sciences, Montreal, Canada, [3]CHU Sainte Justine, Pharmacy, Montreal, Canada, [4]CHU Sainte Justine, Pediatric, Montreal, Canada, [5]CHU Sainte Justine, Pediatric Allergology, Montreal, Canada, [6]CHU Sainte Justine, Pediatric Infectious Disease, Montreal, Canada, [7]Hôpital Femme Mère Enfant - Hospices Civils de Lyon, Emergency - Pediatric Infectious Disease, Bron, France

Backgrounds: Up to 10% of children are labelled as penicillin allergic, requiring the use of suboptimal antibiotics. The aim of this study was to assess the success of the oral amoxicillin challenges in our emergency department (ED).
Methods: This is an ongoing prospective observational study conducted at a tertiary care pediatric hospital. Children considered at low risk of penicillin allergy (https://www.inesss.qc.ca) and requiring amoxicillin were prescribed an amoxicillin challenge on a pre-written order set. In the absence of a reaction, patients were discharged with an amoxicillin prescription. Parents were contacted one month after the challenge to assess for late onset reactions.
Results: Since June 2021, 70 children underwent an amoxicillin challenge in the ED. The most frequent discharge diagnoses were otitis media (65%). The challenge was successful in the ED for 69/70 (99%) patients. Sixty-two (89%) patients were successfully contacted for a follow up phone call. In total, 7/62 (11%) of the children had a reported reaction: one (1%) child had an immediate reaction in the ED, while 6/62 (10%) had a rash 1 to 61 days after the first dose of antibiotics. No severe reactions were reported. A correlation between the amoxicillin administration and the delayed reaction was considered less likely for 3/6 patients because of the later onset of symptoms (28-61 days). The three other patients were considered not to have a penicillin allergy after formal assessment at the allergy clinic.
Conclusions/Learning Points: Using a standardized pre-written order set for an amoxicillin challenge in the ED allowed 99% of participating children to be discharged safely with an amoxicillin prescription, and rapidly remove the label of “penicillin allergy”. Despite about 10% of the children presenting a rash after discharge, none were considered to have a late onset reaction after follow-up.

ANTIBIOTIC USE AND ECONOMIC BURDEN OF VARICELLA INFECTION AMONG PEDIATRIC PATIENTS: A RETROSPECTIVE COHORT ANALYSIS OF REAL-WORLD DATA IN FRANCE

Oral Presentations Session
ORAL PRESENTATION SESSION 10: ANTIMICROBIALS & ANTIBIOTIC STEWARDSHIP & MICROBIOME

Stephanie Kujawski[1], Caroline Casey[2], Herve Haas[3], Amisha Patel[2], Christina Diomartari[2], Victoria Banks[2], Tim Holbrook[2], Manjiri Pawaskar[1]
[1]Merck & Co., Inc., Center For Observational And Real-world Evidence, Rahway, United States of America, [2]Adelphi Real World, Observational Research, Bollington, United Kingdom, [3]Centre Hospitalier Princesse Grace, Paediatrics And Neonatalogy, Monaco, Monaco

Backgrounds: Although varicella is considered a mild disease, varicella-related complications are often treated with antibiotics or antivirals. The extent to which these antimicrobial agents are used in the management of varicella in France is not well documented. This study assessed antibiotics and antivirals use in the management of varicella in France.
Methods: A retrospective cohort study using electronic medical records from general practitioners (GPs) and specialist consultations in France (Cegedim Strategic Data-Longitudinal Patient Database [CSD-LPD]) was conducted. Children <18 years of age with a first varicella diagnosis during January 2014 to December 2018 with 3-month follow-up available were included. Descriptive analyses were performed to assess varicella-related complications, medication use and healthcare resource (HCRU) costs in the 3-month follow-up period.
Results: 48,027 children were included. Mean age at diagnosis was 3.73 years [SD 2.41] and 52.4% were male. 15.3% (n=7,369) children had ≥1 varicella-related complication. Top complications were ear, nose, and throat conditions (38.0%, n=2,798), respiratory infections (36.0%, n=2,642) and ophthalmic infections (20.4%, n=1,502). 25.1% (n=12,045) were prescribed an antibiotic, with 18.7% (n=8,982) prescribed systemic antibiotics and 9.5% (n=4,545) non-systemic antibiotics. Only 2.2% were prescribed antivirals. The most prescribed antibiotic was amoxicillin (51.7%, n=6,231/12,025). Higher proportions of patients with varicella-related complications were prescribed antibiotics compared with those without complications (68.1% vs. 17.3%). Annualized varicella-related medication and HCRU costs were €333,465, with €53,001 attributed to medication costs, €249,192 attributed to GP and €31,272 to specialist consultation costs.
Conclusions/Learning Points: A considerable proportion of children with varicella experienced complications and were treated with antibiotics in France. Varicella management is associated with significant medication and HCRU costs. Varicella poses significant clinical and economic burden in France.

METAGENOMIC ANALYSIS OF THE NEONATAL INTESTINAL RESISTOME

Oral Presentations Session
ORAL PRESENTATION SESSION 10: ANTIMICROBIALS & ANTIBIOTIC STEWARDSHIP & MICROBIOME

Stefano Leo[1], Omer Faruk Cetiner[2], Laure Pittet[3], Nicole Messina[3], Laurent Falquet[4], Nigel Curtis[3], Petra Zimmermann[1]
[1]University of Fribourg, Community Health, Faculty Of Science And Medicine, Fribourg, Switzerland, [2]Istanbul University, Istanbul Faculty Of Medicine, Istanbul, Turkey, [3]University of Melbourne, Paediatrics, Melbourne, Australia, [4]University of Fribourg, Department Of Biology, Fribourg, Switzerland

Backgrounds: The intestinal microbiome forms a major reservoir for antibiotic resistance genes (ARGs). Little is known about the neonatal intestinal resistome.
Methods: Shotgun metagenomics was used to analyse the resistome and factors that influence the abundance of ARG in stool samples collected at one week of age from 393 healthy, term-born neonates without direct antibiotic exposure.
Results: Overall, 913 ARGs belonging to 27 classes were identified. The most abundant ARGs were those conferring resistance to tetracyclines, quaternary ammonium compounds, and macrolide-lincosamide-streptogramin-B. Phylogenetic composition was strongly associated with the resistome composition. Other factors that were associated with the abundance of ARGs were delivery mode, gestational age, birth weight, feeding method and antibiotics in the last trimester of pregnancy. Sex, ethnicity, probiotic use during pregnancy, and intrapartum antibiotics had little effect on the abundance of ARGs.
Conclusions/Learning Points: Even in the absence of antibiotic exposure, the neonatal intestine harbours a high abundance and variety of ARGs.

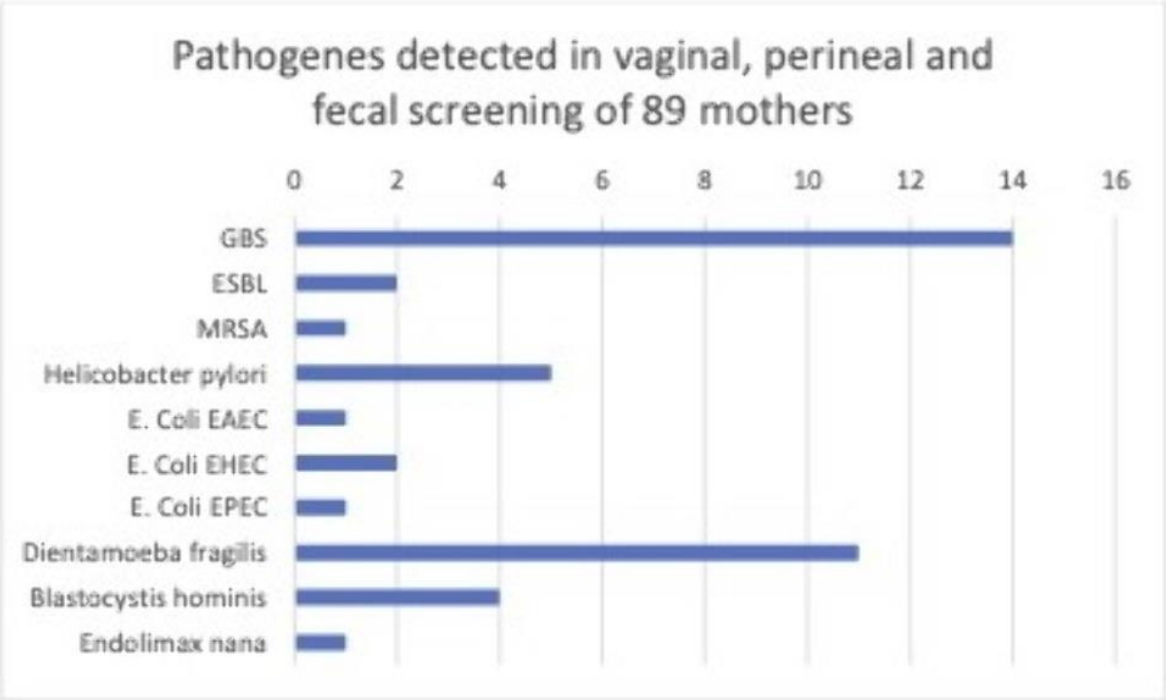
CESAREAN SECTION AND INTESTINAL FLORA OF THE NEWBORN - FINDINGS OF FECAL SCREENING BEFORE TRANSFER OF MATERNAL FECAL MICROBIOME

Oral Presentations Session
ORAL PRESENTATION SESSION 10: ANTIMICROBIALS & ANTIBIOTIC STEWARDSHIP & MICROBIOME

Noora Carpén[1], Sture Anderssom[1], Timo Hytinantti[1], Vedran Stefanovic[1], Kaija-Leena Kolho[2], Anne Salonen[3], Willem De Vos[3,4], Otto Helve[1,5]
[1]Helsinki University, Helsinki University Hospital, Helsinki, Finland, [2]University of Helsinki, Helsinki University Hospital, Helsinki, Finland, [3]University of Helsinki, Human Microbiome Research Program, Helsinki, Finland, [4]Wageningen University, Laboratory Of Microbiology, Wageningen, Netherlands, [5]Finnish Institute for Health and Welfare, Health Security, Helsinki, Finland

Backgrounds: Normal microbial colonization process from the mother to the newborn is disrupted by birth by caesarean section (CS). We assess, whether in CS-delivered infants, the intestinal microbiome could be successfully and safely normalized by postnatal oral transfer of maternal fecal microbiome (FMT). In this double-blinded randomized placebo-controlled trial, we assess the difference in heterogeneity of the intestinal microbiome between the transplant and placebo groups from birth to 24 months of age. Safety of the transplant is of crucial concern and the transplant is screened thoroughly. Here, we present findings from screening of fecal transplants from healthy mothers.
Methods: 100 healthy pregnant women scheduled for elective CS are recruited. After screening and randomization, within two hours of delivery, the newborns are given 3.5 mg of the transplant from their own mothers or placebo mixed in mother's milk. Screening is performed according to European guidelines that have been adapted for the use of FMT to newborn infants.
Results: We have recruited 89 mothers. All mothers were asymptomatic, no prescribed courses of antibiotics or travelling outside the European Union region within three months of screening. 38 (43%) were found positive in our screening tests (Figure 1). 30 infants have received the transplant/placebo without any noticeable side effects.



Conclusions/Learning Points: The maternal screening of fecal, perineal, and vaginal samples is crucial for safety of the transplant process. Our positivity rate of 43% underlines the importance of rigorous screening. Recruitment continues until end of January 2023. Our primary outcome measurement is assessed when the study subjects are 3 months of age, approximately 5/2023. Reference for the protocol: Carpen N et al, BMC Pediatrics, 2022, https://doi.org/10.1186/s12887-022-03609-3

EXPLORING THE ROLE OF THE HOST NASOPHARYNGEAL MICROBIOTA ON HOST RESPONSE TO RSV INFECTION UTILISING OXFORD NANOPORE SEQUENCING

Oral Presentations Session
ORAL PRESENTATION SESSION 10: ANTIMICROBIALS & ANTIBIOTIC STEWARDSHIP & MICROBIOME

James Kavanagh[1], Alex Shaw[2], Andrew Mcardle[3], Heather Jackson[4], Myrsini Kaforou[4], Michael Levin[4]
[1]St Mary's Hospital, Imperial College London, Paediatric Infectious Diseases, London, United Kingdom, [2]Imperial College London, School Of Public Health, Department Of Medicine, London, United Kingdom, [3]Imperial College London, Faculty Of Medicine, Department Of Infectious Disease, Section Of Paediatric Infectious Disease, London, United Kingdom, [4]Imperial College London, Department Of Infectious Disease, London, United Kingdom

Backgrounds: Distinguishing between bacterial and viral infections is aided by host markers of inflammation, such as elevated levels of C-reactive protein (CRP). However, markers of inflammation are not specific to bacterial infections. Patients with respiratory syncytial virus (RSV) frequently demonstrate inflammatory marker levels overlapping those of bacterial infections. Given the significant role the nasopharyngeal (NP) microbiota has in determining respiratory health, it is possible these systemic inflammation responses in patients with viral infections are influenced by the patients' respiratory microbiota.
Methods: The nasopharyngeal microbiota of paediatric RSV patients with an inflammatory response indicative of a bacterial infection and those with a typical viral-like inflammatory response were profiled. Throat swabs were collected as part of the PERFORM study (GA No. 668303); DNA was extracted and sequenced using Oxford Nanopore 16S to create profiles at the genus and species level. Statistical models were employed to contrast the sequencing profiles between children with RSV response indicative of a bacterial infection and those with a typical viral-like inflammatory response.
Results: Using average-linkage hierarchical clustering and random forest analysis, we assessed the correlation of NP microbiota profiles with existing blood marker data. Microbiota profiles showed significant differences between patients with typical viral-like inflammatory responses to RSV (n=25) and those with high inflammatory responses (n=9). Further analysis is being conducted to identify taxa that are prominent in determining the difference in these two groups.
Conclusions/Learning Points: Identifying prominent taxa in determining the microbiota profiles of RSV patients with a typical inflammatory response compared to those with a high inflammatory response can elucidate the mechanisms in these responses. This work is expected to improve our understanding of RSV pathogenesis in children and optimise the use of host-based diagnostics for RSV infections.

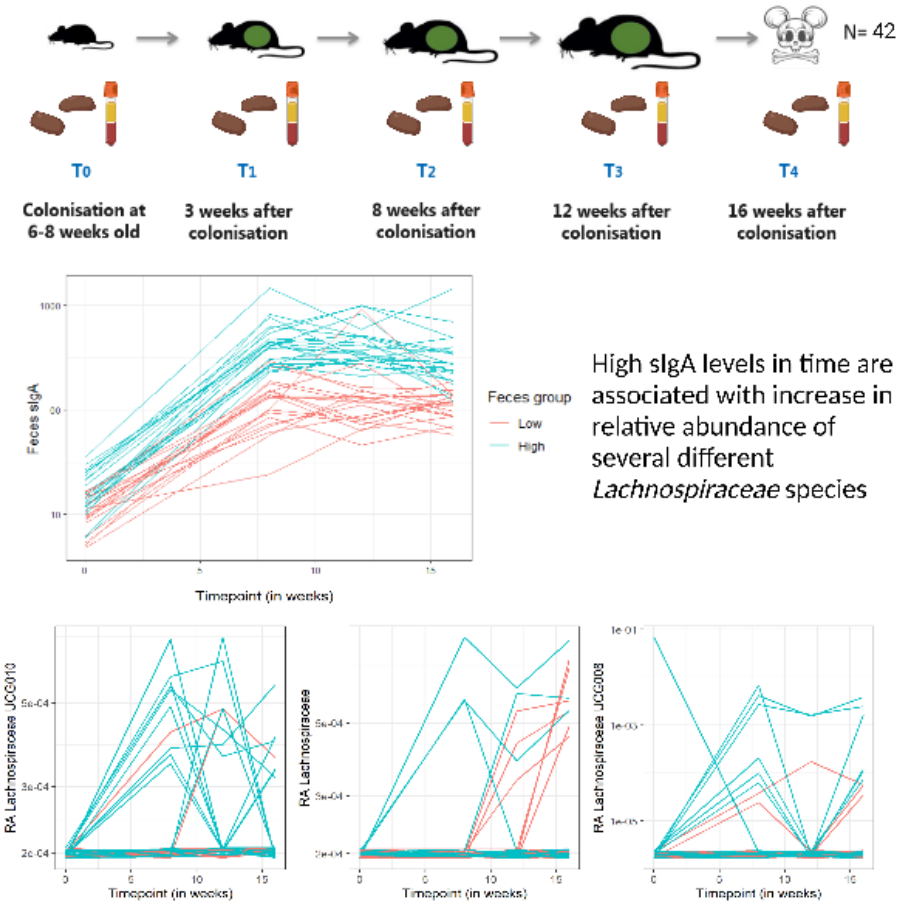
Backgrounds: IgA deficiency is common in young children, with recurrent respiratory tract infections (rRTIs) as the most common clinical manifestation. While the exact etiology of IgA deficiency remains unknown, germ-free mouse experiments have shown that IgA production starts after microbial colonization. We investigated the intestinal microbiota of children with IgA deficiency and its influence on IgA induction.
Methods: We collected serum and feces from children <7 years with rRTIs with and without IgA deficiency (-2SD below age-normalized IgA levels), without recent antibiotic use. Microbiota composition was determined by 16S-rRNA-sequencing and IgA antibody concentrations were measured with ELISA. We collected serum and feces samples upon colonization of germ-free mice, using oral gavage, at baseline and after 3, 8, 12 and 16 weeks (Figure) to analyse the fecal microbiota composition in relation to serum and fecal IgA levels.
Results:

Figure: Germ-free mice inoculated with feces from children <7 years with recurrent respiratory tract infections with and without IgA deficiency



We included 82 children with rRTIs of whom 38% had an IgA deficiency. Microbiota composition of IgA deficient children differed significantly, as compared to symptomatic controls (PERMANOVA R^2 2.2%, p=0.01, corrected for age). In 42 mice colonized with microbiotas from children with rRTIs, we found a strong induction of IgA levels between baseline and 8 weeks, which stabilized around 12 weeks. Several members of the Lachnospiraceae family were associated with IgA induction in both serum and feces (Figure).

Conclusions/Learning Points: The altered microbiota composition in young IgA deficient children compared to symptomatic controls suggests that the microbiota might play a role in IgA deficiency in early life. Examining the IgA inducing role of the microbiota from pediatric patients in germ-free mice revealed that members of the Lachnospiraceae family were able to induce IgA levels. This study reveals the microbial dynamics of IgA production using pediatric fecal samples.

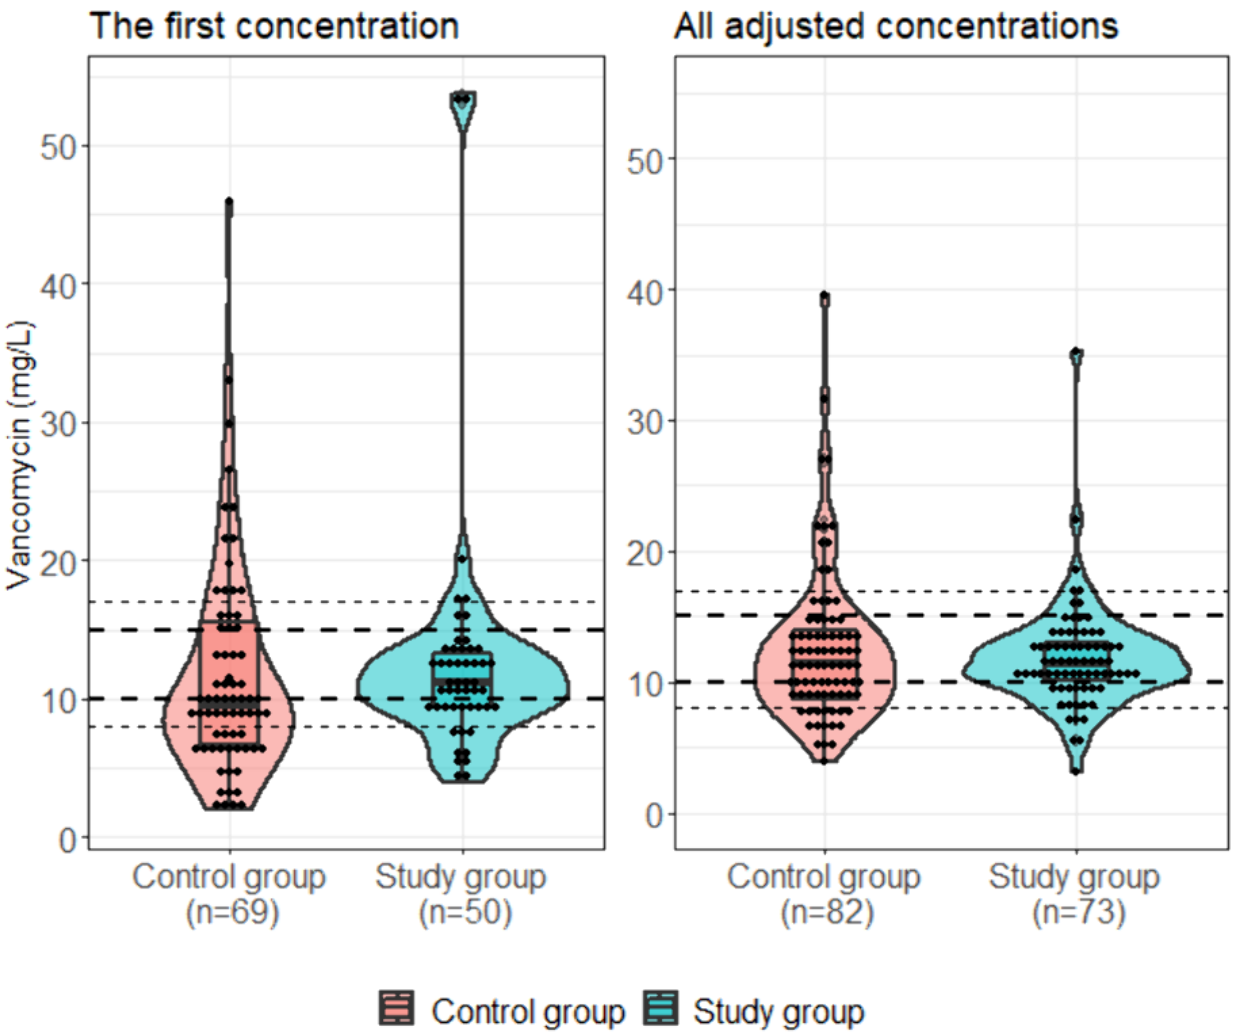
PROSPECTIVE VALIDATION OF MODEL-INFORMED PRECISION DOSING OF VANCOMYCIN IN NEONATES AND INFANTS

Oral Presentations Session
ORAL PRESENTATION SESSION 10: ANTIMICROBIALS & ANTIBIOTIC STEWARDSHIP & MICROBIOME

Riste Kalamees[1], Hiie Soeorg[2], Tuuli Metsvaht[3], Irja Lutsar[2]
[1]Tartu University Hospital, Clinic Of Anaesthesiology And Intensive Care, Tartu, Estonia, [2]University of Tartu, Department Of Microbiology, Tartu, Estonia, [3]Tartu University Hospital, Pediatric Intensive Care Unit, Tartu, Estonia

Backgrounds: Therapeutic target of vancomycin, frequently trough concentration (C_{tr}) of 10-15mg/l, is achieved in <30% of neonates/infants with standard dosing. We aimed to prospectively validate whether model-informed precision dosing (MIPD) improves vancomycin therapeutic target attainment (TA) in neonates/infants compared with conventional dosing.
Methods: This prospective clinical trial included neonates/infants with late-onset sepsis treated with vancomycin from three NICUs in Estonia between 29.05.2019-16.06.2021. Neonates/infants treated with conventional dosing of vancomycin between 01.01.2016-31.05.2019 served as control group. In the study group, initial dose to achieve steady-state C_{tr}10-15mg/l was based on population predictions from pharmacokinetic model by Zhao et al. 2013. Thereafter dose was adjusted every 36-48h based on measured C_{tr} value(s). The percentage of neonates/infants attaining the optimization target ($PTA\%_{10\text{-}15mg/l}$) and clinically acceptable target of C_{tr}8-17mg/l ($PTA\%_{8\text{-}17mg/l}$) was compared between the groups.
Results: Neonates/infants in the study group (n=48, with 50 episodes) had smaller GA (median (range) 26.6 (23-41.3) vs 27.3 (23-41.1) weeks; p=0.003), but similar PNA (9.5 (3-69) vs 10 (1-66) days) compared with controls (n=66, with 85 episodes). C_{tr}-s in the study group were more often within the optimization target compared with the control group (Figure).
$PTA\%_{10\text{-}15mg/l}$ improved from 26.1% in the study group to 50% in the control group (p=0.007) for the first and 40.2% to 56.2% (p=0.04) for all adjusted concentrations; $PTA\%_{8\text{-}17mg/l}$ accordingly from 47.8% to 76% (p=0.002) and from 68.3% to 84.9% (p=0.01). Compared with the control group, the study group had similar average daily doses (26.1 (10-59.4) vs 24.8 (15-67.7) mg/kg/d, respectively), nephrotoxicity (none had acute kidney injury) and ototoxicity (failed otoacoustic emissions in 8.3% vs 20%) rates.



Conclusions/Learning Points: Individualized dosing with MIPD software significantly improves the achievement of vancomycin target in neonates/infants, without increasing the risk of side effects.

[1]Erasmus MC - Sophia Children's Hospital, General Pediatrics, Rotterdam, Netherlands, [2]Radboud University Medical Center, Laboratory Of Medical Immunology, Nijmegen, Netherlands, [3]Imperial College London, Department Of Infectious Diseases, London, United Kingdom, [4]Imperial College London, Department Of Infectious Disease, London, United Kingdom, [5]University of Otago Christchurch, Department Of Pediatrics, Christchurch, New Zealand, [6]Wilhelmina Children's Hospital, Pediatric Infectious Diseases And Immunology, Utrecht, Netherlands, [7]Franciscus Gasthuis & Vlietland, Pediatrics, Rotterdam, Netherlands, [8]Erasmus MC - Sophia Children's Hospital, Department Of Pediatric Infectious Diseases And Immunology, Rotterdam, Netherlands

Backgrounds: Distinguishing bacterial from viral infections based on clinical signs and symptoms in febrile children attending the Emergency Department (ED) is challenging. The addition of biomarkers contributes to the diagnostic process. Therefore, the aim of this study is to determine a novel combination of host protein biomarkers and to assess its performance in distinguishing bacterial from viral infection in febrile children attending EDs.
Methods: A literature search was performed to identify blood protein biomarkers able to distinguish bacterial and viral infections (May 2015-May 2019). We selected seven protein biomarkers: PCT, TRAIL, IL-4, IL-6, IP-10, IFN-gamma and LCN2. These were measured in blood plasma using a bead-based immunoassay in children with a confirmed bacterial or viral infection attending seven EDs in the Netherlands, recruited as part of the PERFORM project (https://www.perform2020.org/). We used generalized linear modelling to classify bacterial and viral infections, and applied a previously developed feature selection algorithm to select the optimal combination of proteins. Additionally, we performed a subgroup analysis of this protein signature in patients with CRP < 60 mg/L, representing a clinically challenging diagnostic group.
Results: 102 children were included (N=67 definite bacterial; N=35 definite viral). Individual performance of the seven biomarkers in classifying bacterial versus viral infections ranged from 60.8%-74.5% AUC. TRAIL, LCN2 and IL-6 were identified as the best 3-protein signature with an AUC of 86% (95%CI 71.3%-100%). In 57 patients with CRP levels < 60 mg/L, in which CRP would not be able to classify, the 3-protein signature had an AUC of 85.1% (95%CI 75.3%-94.9%).
Conclusions/Learning Points: We demonstrate a promising novel combination of three host protein biomarkers; TRAIL, LCN2 and IL-6, which performs well in classifying bacterial and viral infections in febrile children in emergency care.

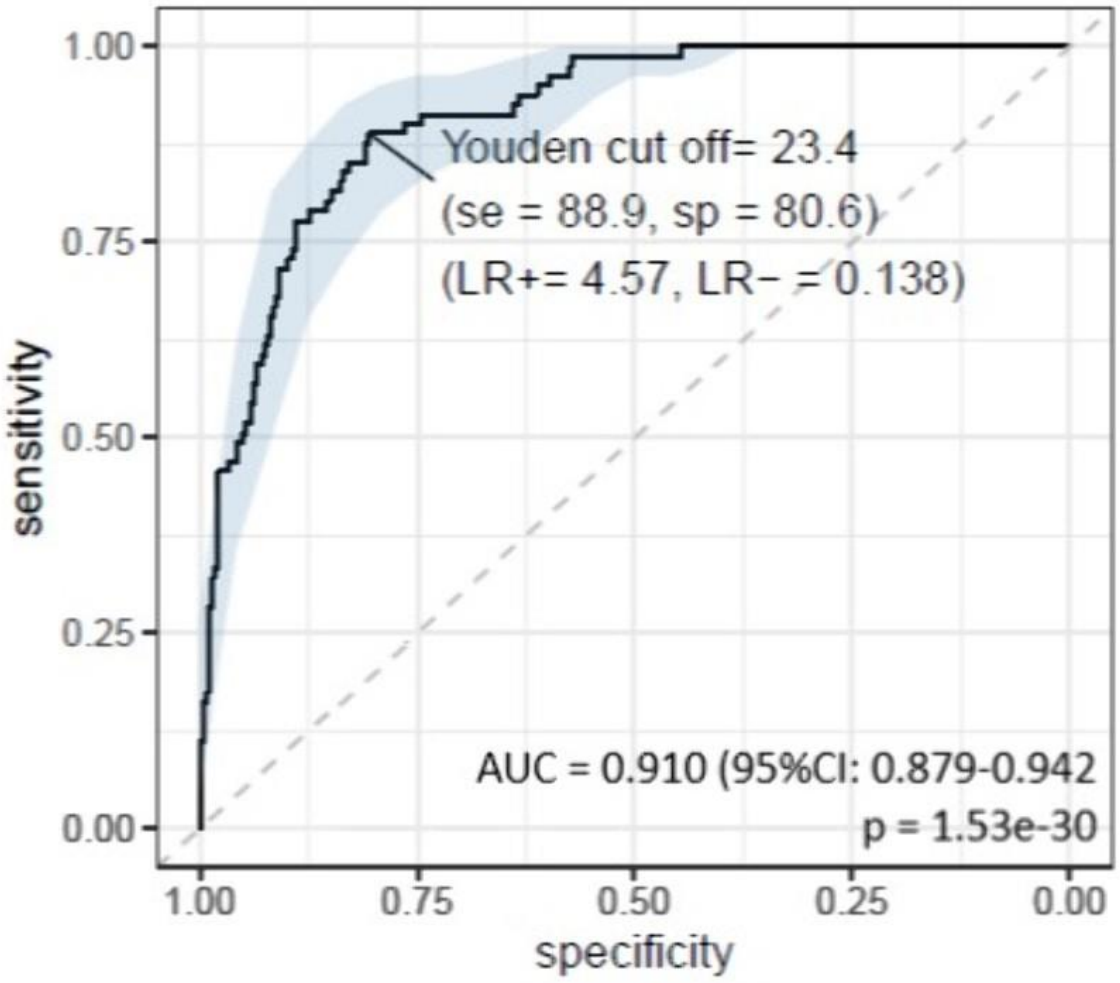
THE DIAGNOSTIC KAWASAKI DISEASE GENE EXPRESSION PROFILING (KIDS-GEP) CLASSIFIER HAS A GOOD PERFORMANCE IN BOTH COMPLETE AND INCOMPLETE KAWASAKI DISEASE PATIENTS

Oral Presentations Session
ORAL PRESENTATION SESSION 11: BIOMARKERS & DIAGNOSTICS

Rowan Kuiper[1], Chisato Shimizu[2], Daphne Huigh[1], Adriana Tremoulet[2], Deniz Lehnert[1], Daniëlle Van Keulen[1], Michael Levin[3], Jane Burns[2]
[1]SkylineDx, Skylinedx, Rotterdam, Netherlands, [2]Rady Children's Hospital and University of California San Diego, Department Of Pediatrics, La Jolla, United States of America, [3]Imperial College London, Department Of Infectious Disease, London, United Kingdom

Backgrounds: Kawasaki disease (KD) is a systemic vasculitis that can result in coronary artery aneurysms (CAA). Treatment with intravenous immunoglobulin (IVIG) is effective against CAA, but should be started as early as possible within the first 10 illness days. Diagnosing KD can be challenging, especially in patients with incomplete KD, who present with fewer clinical signs but have similar CAA risks. Studies showed that up to 1 in 6 KD patients are diagnosed after 10 illness days. In this study, we retrospectively investigate if the previously described KiDs-GEP classifier, a blood-based 12-gene host response classifier that aids diagnosis of KD, identifies both complete and incomplete KD patients in an independent US cohort.
Methods: We performed the KiDs-GEP classifier in 81 KD patients (14.8% incomplete KD) and 324 febrile controls who had ≥1 clinical criterion for KD. Blood samples were obtained within the first 7 illness days and before IVIG treatment. All patients were under 18 years of age and diagnosed between 2010 and 2019 at Rady Children's Hospital in San Diego.
Results: The KiDs-GEP classifier distinguished KD patients from febrile controls with an area under the curve of 0.910, a sensitivity of 88.9% and a specificity of 80.6%. In the subset of complete and incomplete KD patients, the sensitivity was 88.4% and 91.7%,
respectively.



Conclusions/Learning Points: The KiDs-GEP classifier correctly identified 88.9% of KD patients in the first week of illness and performed similarly for complete and incomplete KD patients. These results indicate that the KiDs-GEP classifier can be a valuable tool to aid early diagnosis of KD.

[1]Erasmus MC, Pediatrics, Rotterdam, Netherlands, [2]Maasstad Hospital, Pediatrics, Rotterdam, Netherlands, [3]Academic Hospital Paramaribo, Pediatrics, Paramaribo, Suriname, [4]Catholic University Of Health And Allied Sciences, Department Of Medicine, Mwanza, Tanzania, [5]University Hospital Berne, Pediatric Emergency Department, Bern, Switzerland, [6]Bristol Royal Hospital for Children, Department Of Paediatric Accident And Emergency, Bristol, United Kingdom, [7]Swiss Tropical and Public Health Institute, Digital And Global Health Unit, Allschwil, Switzerland, [8]University of Edinburgh, Child Life And Health, Edinburgh, United Kingdom, [9]LSHTM, Medical Research Council Unit The Gambia At Lshtm, Fajara, Gambia

Backgrounds: In acute care settings, early recognition of children at risk of serious illness is essential in preventing morbidity and mortality, particularly in low- and middle-income countries (LMICs). This study aimed to validate the Emergency Department-Paediatric Early Warning Score (ED-PEWS), a simple score solely based on vital parameters, for the recognition of high urgency in febrile children in LMICs.
Methods: This observational study is based on previously collected clinical data from diverse (primary care to academic) acute care settings in LMICs. This analysis was restricted to children presenting with fever, but other inclusion criteria and study periods (2010-2021) varied. We simulated the ED-PEWS, consisting of patient age, consciousness, work of breathing, respiratory rate, oxygen saturation, heart rate, and capillary refill time, based on the available vital parameters upon ED presentation. Performance was assessed by the area under the curve (AUC), sensitivity, and specificity (previously defined cut-offs < 6 and ≥ 15). The outcome measure was for each setting a composite marker of high urgency.
Results: In total, 9,254 visits of febrile children were included from four settings: Gambia rural (n=6,567), Gambia urban (n=501), Suriname (n=590), and Tanzania (n=1,596). Performance was highest in Gambia urban (0.80 (95%CI 0.70-0.89)), and lowest in Tanzania (0.62 (95%CI 0.55-0.67)). The low-urgency cut-off showed a high sensitivity in all settings ranging from 0.93 (95%CI 0.89-0.95) to 1.00 (95%CI 0.97-1.00). The high-urgency cut-off showed a specificity ranging from 0.71 (95%CI 0.66-0.75) to 0.95 (95%CI 0.94-0.95). ED-PEWS performance was better than the local triage systems.
Conclusions/Learning Points: The ED-PEWS, or at least components, appear to have potential in improving the identification of high urgency children presenting with febrile conditions in LMICs.

EXHALED BREATH ANALYSIS: A PROMISING TRIAGE TEST FOR TUBERCULOSIS IN YOUNG CHILDREN - KENYA

Oral Presentations Session
ORAL PRESENTATION SESSION 11: BIOMARKERS & DIAGNOSTICS

Else Bijker[1], Walter Mchembere[2], Jan-Willem Gerritsen[3], Henny Oord[3], Jonathan Smith[4], Kimberly Mccarthy[4], Eleanor Click[4], Kevin Cain[4], Rinn Song[1]
[1]University of Oxford, Paediatrics, Oxford, United Kingdom, [2]Kenya Medical Research Institute, Center For Global Health Research, Kisumu, Kenya, [3]The eNose Company, Enose B.v., Zutphen, Netherlands, [4]Division of Global HIV and Tuberculosis, Centers For Disease Control And Prevention, Atlanta, United States of America

Backgrounds: The diagnosis of paediatric pulmonary tuberculosis (TB) is difficult, especially in young infants who cannot expectorate sputum spontaneously. Breath testing has shown promise in diagnosing respiratory tract infections of various aetiologies in adults and children, but data on paediatric TB are limited.
Methods: We performed a prospective cross-sectional study in Kisumu, Kenya. We recruited children younger than five years with symptoms and/or chest radiography findings suggestive of TB (2013-2015). Xpert MTB/RIF and culture were done on multiple samples as microbiological reference standard. Children were clinically classified (confirmed, unconfirmed, or unlikely TB) according to international criteria. We analysed exhaled-breath measurements of volatile organic compounds conducted with a hand-held battery-powered nose device (Aeonose, The eNose Company, Zutphen, The Netherlands). For data analysis, machine learning with artificial neural networks (ANN) was applied using samples classified as positive (confirmed TB) or negative (unlikely TB) to predict TB diagnoses. Sensitivity, specificity, positive and negative predictive value (PPV, NPV), and their 95% confidence intervals (CI) were used to assess accuracy.
Results: Breath analysis was performed in 124 children: 22 (18%) had confirmed TB, 40 (32%) had unconfirmed TB, and 62 (50%) had unlikely TB. The area under the curve of the optimal model was 0.73. At a sensitivity of 86% (CI 62-96%), this resulted in a specificity of 42% (95% CI 30-55%), NPV of 90% (CI 71-97%) and PPV of 35% (CI 23-49%). Using the trained ANN, 40 unconfirmed TB cases that were not part of the training set were classified, labelling 26 children as positive and 14 as negative.
Conclusions/Learning Points: Exhaled breath analysis shows promise as a triage test for TB in young children, although the WHO target product characteristics were not met.

Backgrounds: Early detection of children with suspected infection requiring surgical intervention is challenging but crucial to improve outcome. Archetypal surgical infections are increasingly managed conservatively, suggesting research and guidance revision is required. Aims Identify factors associated with surgical management of paediatric febrile illness Independently analyse three syndromes with high surgical intervention incidence and potential clinical impact: suppurative central nervous system (CNS) infection, septic arthritis, and appendicitis.
Methods: Prospective data collection of patients with suspected infection, requiring venepuncture, presenting to the Emergency Department (2016-2019) within Personalised-Risk-Assessment-in-Febrile-Illness-to-Optimise Real-Life-Management (PERFORM). Logistic regression was used to identify features associated with surgical intervention.
Results: 52 potential risk factors and 15 outcome variables were analysed in 4931 episodes. When adjusted for confounding, surgical intervention (n=431) was associated with: older age (OR 1.06 (95%CI 1.03-1.08)), recent surgery (OR 1.98 (95%CI 1.08-3.60)), gastrointestinal comorbidity (OR 1.37 (95%CI 1.10-2.18)), circulatory support requirement (OR 2.37 (95%CI 1.66-3.38)), severe vomiting (OR 1.70 (95%CI 1.16-2.48)), and neutrophilia (OR 1.01 (95%CI 1.01-1.02)). Surgical patients were more likely to have bacterial infection (OR 5.70 (95%CI 4.54-7.16)). There were no presentation differences between treatment groups in suppurative CNS infection (n=10) and septic arthritis (n=28), and lower than hypothesised surgical incidence rates (50%, 72% respectively). In appendicitis (n=105), we observed minimal presentation differences and no outcome differences.
Conclusions/Learning Points: Older age, gastrointestinal comorbidities, recent surgery, vomiting, neutrophilia, and circulatory support are associated with surgical intervention. Non-surgical treatment

remains divisive for some infections, but appears justified in appendicitis, where surgical intervention is utilised unsystematically with no differences in outcome variables.Older age, gastrointestinal comorbidities, recent surgery, vomiting, neutrophilia, and circulatory support are associated with surgical intervention. Non-surgical treatment remains divisive for some infections, but appears justified in appendicitis, where surgical intervention is utilised unsystematically with no differences in outcome variables.

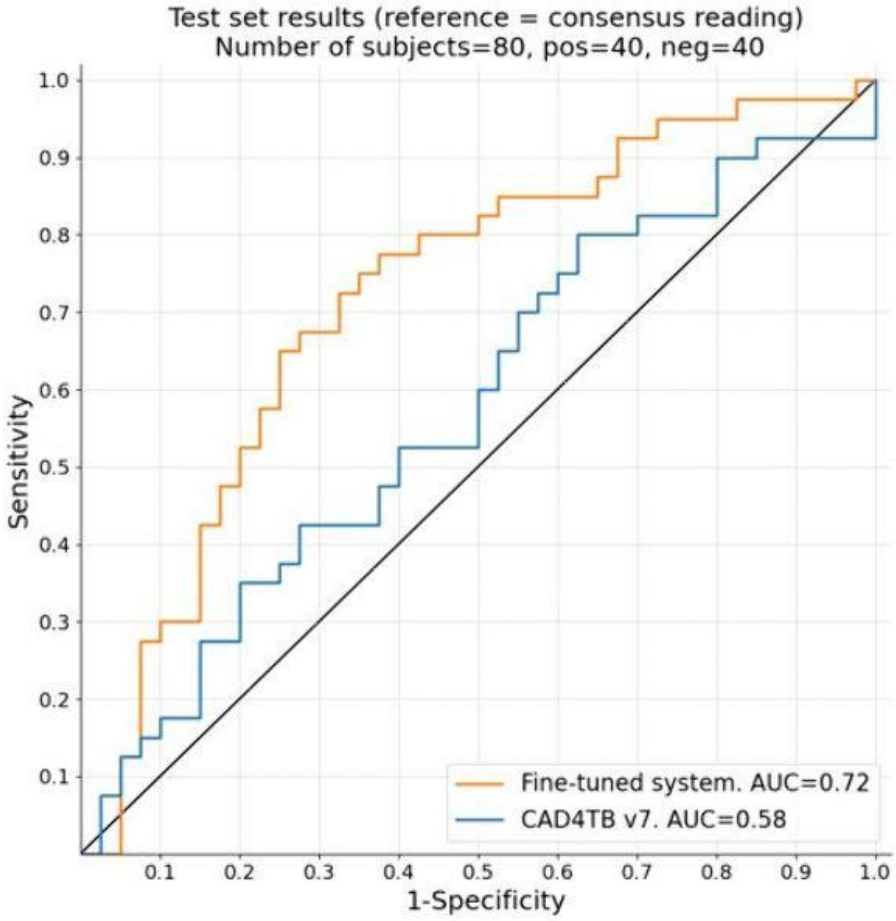
OPTIMISING COMPUTER AIDED DETECTION TO IDENTIFY PULMONARY TUBERCULOSIS ON CHEST X-RAY IN SOUTH AFRICAN CHILDREN

Oral Presentations Session
ORAL PRESENTATION SESSION 11: BIOMARKERS & DIAGNOSTICS

Megan Palmer[1], James Seddon[2], Marieke Van Der Zalm[1], Anneke Hesseling[1], Pierre Goussard[3], H Schaaf[1], Julie Morrison[3], Bram Van Ginneken[4], Jaime Melendez[5], Elisabetta Walters[1,6], Keelin Murphy[4]
[1]Stellenbosch University, Desmond Tutu Tb Centre, Paediatrics And Child Health, Cape Town, South Africa, [2]Imperial College London, Department Of Infectious Diseases, London, United Kingdom, [3]Stellenbosch University, Department Of Paediatrics And Child Health, Cape Town, South Africa, [4]Radboud University Medical Centre, Diagnostic Image Analysis Group, Nijmegen, Netherlands, [5]Delft Imaging, Delft, Nijmegen, Netherlands, [6]Newcastle-upon-Tyne, Nhs Foundation Trust, Newcastle, United Kingdom

Backgrounds: There is a reliance on clinical algorithms, which include chest x-ray, to diagnose paediatric TB. Computer aided detection (CAD) for tuberculosis on chest x-ray shows promise in adults. We aimed to measure and optimise an adult CAD system, CAD4TB, to identify radiological features of tuberculosis on chest x-ray in children with presumptive tuberculosis.
Methods: We used chest x-rays from 620 children <13 years enrolled in a tuberculosis diagnostic study in South Africa. A panel of human expert readers classified each chest x-ray as ‘tuberculosis’ or ‘not tuberculosis’ to establish a radiological reference read. Of the 525 chest x-rays included, 80 (40 with a reference of ‘tuberculosis’ and 40 with ‘not tuberculosis’) were allocated to an independent test set. The remainder made up the training set. The performance of CAD4TB to identify ‘tuberculosis’ versus ‘not tuberculosis’ on chest x-ray against the radiological reference read was calculated. The CAD4TB software was then fine-tuned using the training set. We compared the performance of the fine-tuned model to the original model.
Results:

Figure 1. Receiver operating characteristic curves illustrating the performance of CAD4TB v7.0 before and after fine-tuning (reference standard is the radiological read established by a panel of expert readers)



Results The area under the receiver operating characteristic curve (AUC) of the original CAD4TB model was 0.58. After fine-tuning the AUC improved to 0.72 (p=0.0016). Fig 1.

Conclusions/Learning Points: In this first-ever description of CAD to identify tuberculosis on chest x-ray in children, we demonstrated a significant improvement in CAD4TB's performance after fine-tuning with paediatric chest x-rays. We recommend replicating the described methods using a larger chest x-ray dataset from a diverse population and evaluating the role of CAD within treatment-decision algorithms for paediatric tuberculosis.

Backgrounds: Approximately 1.2 million children develop tuberculosis (TB) disease annually, resulting in 230,000 deaths. Microbiological diagnosis of TB remains challenging in children. Gene expression signatures in blood may offer a fast, reliable, non-sputum-based diagnostic test. However, gene expression signatures in adult populations underperform in children, while the few paediatric studies focus on specific countries. We undertook a multi-country gene expression signature discovery study to identify an accurate signature for paediatric TB.
Methods: Whole blood was collected from 571 children presenting to healthcare facilities in South Africa, Malawi, Kenya and The Gambia between 2008 and 2018 with suspected TB. Cases included pulmonary or extra-pulmonary TB, with or without HIV-infection; 264 (48%) had microbiologically confirmed TB and 307 (52%) other respiratory diseases (OD). RNA extraction and RNA-sequencing were done on blood samples collected at enrolment. Quality control, batch correction and normalisation were performed on the data prior to differential expression and feature selection analyses in R.
Results: Amongst 571 children (48 [18.1-93.8] median [IQR] age in months; 219 HIV-infected), differential expression analysis identified 178 candidate biomarker genes. A feature selection algorithm with cross-validation (using a training-test split at 80:20) performed on the 178 genes, identified a 6-gene signature to distinguish TB from OD with an AUC of 91.2%, sensitivity of 80.0% and specificity of 92.2%. Cross-platform validation by RT-qPCR showed an AUC of 88.3% regardless of HIV status, and 90.2% in the HIV-uninfected participants, and was followed by RT-qPCR validation on independent cohorts that had not been used for discovery.
Conclusions/Learning Points: A 6-gene signature met the minimum WHO Target Product Profile criteria for a non-sputum-based test for paediatric TB, which can be used to develop a novel, rapid and inexpensive point-of-care test for childhood TB.

Background: Meningitis is a life-threatening condition that requires prompt diagnosis and urgent treatment. Signs and symptoms at presentation are unspecific, especially among young infants and newborns, justifying the need for lumbar punctures (LP) to obtain cerebrospinal fluid (CSF) for ruling out or confirming meningitis. In high-income settings, more than 95% of the LPs are negative and up to 45% traumatic. The aim of this study is to validate a novel transfontanellar ultrasound-based technique to screen for meningitis, designed to non-invasively count white blood cells (WBC) in the CSF using deep learning (DL) models, to correctly classify patients according to their WBC count in CSF.
Methods: In three Spanish University Hospitals, we prospectively recruited patients under one year of age, with a not-yet closed fontanelle and a LP performed within the preceding 24h due to suspected meningitis (2021-2023). Images showing the backscatter pattern from the CSF were obtained using a customized ultrasonic probe, working at a central frequency of 20MHz and a spatial resolution below 10 mm. A DL model was trained to classify the CSF patterns according to the white blood cells count values obtained through the LP (gold standard comparator), setting a 30 cells/mL threshold to define meningitis and controls.
Results: We recruited 16 participants on which 17 LPs were performed (one patient with meningitis had 2), 7 resulting positive for meningitis and 10 with a negative result. The device showed a sensitivity of 100% and a specificity of 90%, with only one non-meningitis case misclassified.
Conclusions/Learning Points: Our device based on ultrasound and DL shows an exciting potential as a non-invasive rapid automated screening tool to accurately rule out or confirm meningitis, and spare up to 90% of LPs in patients without meningitis.

[1]Imperial College London, Department Of Infectious Disease, London, United Kingdom, [2]University of California San Diego, Infectious Disease, La Jolla, United States of America, [3]Rady Children's Hospital and University of California San Diego, La Jolla, California, Department Of Pediatrics, La Jolla, United States of America, [4]University of Melbourne, Microbioloogy And Immunology, Melbourne, Australia

Background: Kawasaki disease (KD) remains an important childhood problem worldwide. Although treatment with immunoglobulin and other immunomodulators reduces the risk of coronary artery aneurysms, diagnosis and treatment is often delayed because clinicians cannot easily distinguish KD from other febrile conditions. There is an urgent need for a diagnostic test. We aimed to identify protein biomarkers as the basis for a diagnostic test for KD.
Methods: Patients with KD (n=38), MIS-C (n=79), bacterial (n=43), and viral (n=40) infections were recruited to the NIH-funded PREVAIL study and the EU-funded PERFORM/DIAMONDS studies. Patients were phenotyped using a standardised algorithm. The plasma proteomes were characterised for patients using the SomaScan assay, a targeted proteomic method that measures over 7,000 proteins. Feature selection was performed to identify a diagnostic signature for distinguishing between KD and other infections and inflammatory conditions. Using an independent SomaScan dataset, the levels of the proteins included in the diagnostic signature were explored in patients with KD compared to healthy controls.
Results: Through feature selection and differential abundance analysis, a four-protein signature was identified which distinguished KD from MIS-C, bacterial and viral infections with an AUC of 94.9% (95% confidence-interval: 90.4%-99.4%). High performance was observed for each of the sub-comparisons (KD vs. MIS-C/KD vs. bacterial/KD vs. viral), with AUCs consistently over 93%. Three of these proteins were measured in the independent SomaScan dataset, and all three showed concordant directions of change between KD and healthy controls.
Conclusions/Learning Points: Despite the clinical similarities between KD and other infectious and inflammatory conditions, there are key differences in protein abundance profiles that can be used in diagnostic contexts. It will be necessary for the proteins reported here to undergo further validation prior to development into tests with clinical utility.

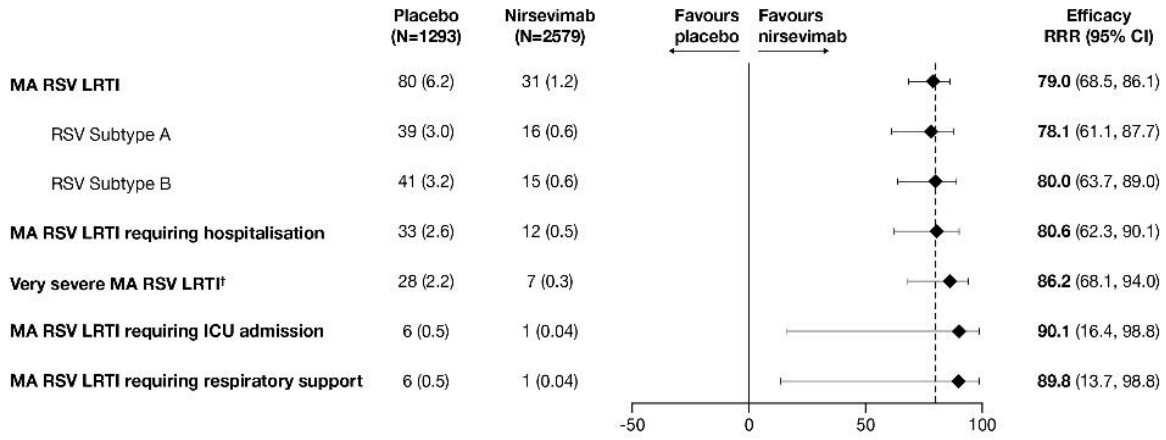
Background: Nirsevimab, a monoclonal antibody with extended half-life, is authorised in the European Union and Great Britain for preventing respiratory syncytial virus (RSV) lower respiratory tract disease in neonates and infants entering their first RSV season. We report an updated post hoc pooled efficacy analysis of the authorised dose of nirsevimab against RSV by severity and subtype through 150 days post-dose in healthy term and preterm infants ≥29 weeks gestational age (wGA).
Methods: Data were pooled from two double-blind, randomised trials: Phase 2b (infants ≥29 to <35 wGA; NCT02878330) and Phase 3 MELODY following enrolment completion (infants ≥35 wGA; NCT03979313). Data were analysed for all participants who received the authorised dose of nirsevimab (infants <5 kg, 50 mg; ≥5 kg, 100 mg) before their first RSV season. Efficacy is calculated as relative risk reduction versus placebo.
Results: Overall, 3872 participants received nirsevimab (n=2579) or placebo (n=1293). Demographics were similar across treatments. Nirsevimab demonstrated an efficacy of 79.0% (95% confidence interval [CI] 68.5, 86.1) against medically attended (MA) RSV lower respiratory tract infection (LRTI), 80.6% (95% CI 62.3, 90.1) against cases requiring hospitalisation, 86.2% (95% CI 68.1, 94.0) against very severe disease, 90.1% (95% CI 16.4, 98.8) against cases requiring ICU admission and 89.8% (95% CI 13.7, 98.8) against cases requiring respiratory support (Figure). Consistent efficacy against MA RSV LRTI was also observed across RSV subtypes and participant subgroups (by age at randomisation, sex, ancestry, weight or geographical region).
Conclusions/Learning Points: In a large, pooled analysis of healthy term and preterm infants ≥29 wGA who received the authorised dose of nirsevimab prior to their first RSV season, nirsevimab demonstrated consistent efficacy across severities and subtypes of MA RSV LRTI, including subpopulations, through 150 days post-

dose.

Figure. Pooled analysis of the efficacy of nirsevimab in reducing varying severities of MA RSV LRTI across the Phase IIb and Phase III MELODY studies*



Dashed line refers to 80% RRR. RRR and its corresponding 95% CI (mid-p adjusted) were estimated based on an exact conditional method using PROC GENMOD with no strata.

*For all participants who received the authorised dose of nirsevimab (infants <5 kg, 50 mg; ≥5 kg, 100 mg).

†Defined as those cases of hospitalisation for MA RSV LRTI that required supplemental oxygen or intravenous fluids.

CI, confidence interval; ICU, intensive care unit; LRTI, lower respiratory tract infection; MA, medically attended; RRR, relative risk reduction; RSV, respiratory syncytial virus.

UNPRECEDENTED HIGH RATES OF GROUP A STREPTOCOCCUS NASOPHARYNGEAL CARRIAGE IN INFANTS AND TODDLERS IN FRANCE, 2022-2023

Oral Presentations Session
ORAL PRESENTATION SESSION 12: LATE BREAKING

Robert Cohen[1], Philippe Bidet[2], Emmanuelle Varon[3], Stéphane Béchet[1,4], Jean François Delobbe[5], Jérémie Cohen[6], Stéphane Bonacorsi[4], Corinne Levy[4]
[1]ACTIV, Pediatric, Créteil, France, [2]Robert Debré Hospital, Microbiology, Paris, France, [3]Centre Hospitalier intercommunal de Créteil (CHIC), National Reference Center For Pneumococci, Créteil, France, [4]ACTIV, Infectious Disease, Créteil, France, [5]AFPA, Pediatrics, Créteil, France, [6]Necker Hospital, Pediatrics, paris, France

Background: Like many countries, France faced a major increase in invasive Group A Streptococcal infection (iGAS) and scarlet fever during the fall and winter of 2022-2023. Whether the current peak of iGAS correlates with high rates of GAS transmission and carriage and the community remains poorly investigated.
Methods: Since 2006, from October to June of each year, in a prospective nasopharyngeal (NP) carriage study, 90 pediatricians throughout France have enrolled more than 900 children per year, aged 6 to 24 months with acute otitis media. GAS strains were identified by colony morphology, Gram staining, beta-hemolysis on blood agar, and mass spectrometry.
Results: GAS was scarce during the first NP study years, 0.3% (3/894) in 2006, and 0.6% in 2016 (6/942); no GAS strain was isolated during the other years. However, among the 552 children (mean age ± SD: 13.1 ± 4.9 months) enrolled between October 2022 and January 2023, 49 GAS were isolated (49/552, 8.9%; study ongoing). GAS was frequently associated with other otopathogens (41/49, 83.7%), most often Haemophilus influenzae (27/49, 55.1%), Moraxella catarrhalis (23/49, 46.9%) and Streptococcus pneumoniae (15/49, 30.6%). For 30/49 (61%) GAS strains, emm-typing was performed by multiplex PCR. The distribution of emm-typing was emm-type 12 (46.7%), followed by emm-type 1 (23.3%), emm-type 4 (10.0%), emm-type 75 (10.0%), emm-type 28 (6.7%) and emm-type 89 (3.3%).
Conclusions/Learning Points: Our data of our well-established surveillance showed a 15-times increase in GAS carriage in 2022-2023 compared to previous years. It likely indicates a greater GAS circulation even in young children, several months after the relaxation of non-pharmaceutical COVID-19 mitigation interventions. The recent surge in iGAS correlates with high rates of GAS carriage in infants and toddlers in the community.

PEDIATRIC SEVERE INVASIVE STREPTOCOCCAL A INFECTIONS: FRENCH NATION-WIDE PICUS COHORT STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 12: LATE BREAKING

Camille Bréhin[1], Guillaume Le Balle[2], Lionel Berthomieu[2], Claire Poyart[3], Isabelle Parent Du Chatelet[4], Jean-Paul Guthman[4], Stéphane Leteurtre[5], Yves Gillet[6], Etienne Javouhey[7]
[1]CHU de Toulouse, Hôpital Des Enfants, Toulouse, France, [2]CHU Toulouse, Hôpital Des Enfants, Toulouse, France, [3]Assistance Publique des Hôpitaux de Paris, Centre National De Référence, Paris, France, [4]Santé Publique France, Santé Publique France, Saint Maurice, France, [5]Hôpital Jeanne de Flandre, Rénimation Pédiatrique, LooS, France, [6]Hôpital Femme Mère Enfant - Hospices Civils de Lyon, Emergency - Pediatric Infectious Disease, Bron, France, [7]Hôpital Femme mère enfant, Réanimation Pédiatrique, BRON, France

Background: An increase Group A Streptococcus (iGAS) infections has been observed in France and other European countries since September 2022. The French Pediatric Intensive Care, the French Pediatric Infectious Diseases expert's groups and the French national public health agency have launched a nationwide alert to describe the most severe cases.
Methods: Patients with iGAS hospitalized in Pediatric Intensive Care Unit (PICU) were included retrospectively and prospectively from September 1, 2022 to January 31 in French PICUs via the PICURe network. Epidemiological, bacteriological and clinical data were collected from confirmed (positive GAS in culture, PCR or antigen in sterile media) and probable (positive GAS antigen in non sterile media with clinical presentation) cases. Molecular analysis included the determination of the emm gene and superantigen profile.
Results: During the studied period, 37 PICUs have declared 129 children with severe iGAS infections (103 confirmed and 26 probable cases). Median age was 3.4 years (IQR: 1.2-6). The predominant clinical presentation was severe respiratory forms with 50% (64/129) of children presenting with pleuropneumonia. No severe cutaneous forms occurred. A viral co-infection was observed in 53% of patients (69/129). Blood culture was positive in 27% of cases. Among the 129 patients, 11 died (8.5%). A total of 21 invasive isolates (from blood, pleural fluid, synovial fluid, and cerebrospinal fluid) were anlysed at the national reference center for streptococci. The predominant type was M1 (13 isolates). Each emm type was associated with one or more exotoxin gene profiles.
Conclusions/Learning Points: An increase incidence of severe iGAS in children is confirmed in France. Physicians must be alerted to severe iGAS and evoke them especially in a child presenting a severe respiratory picture, in order to adapt the treatment.

O0114 / #2684

SURGE IN LOWER RESPIRATORY TRACT INVASIVE GROUP A STREPTOCOCCUS INFECTIONS IN CHILDREN DURING WINTER 2022

Oral Presentations Session
ORAL PRESENTATION SESSION 12: LATE BREAKING

Rebecca Guy[1], Lucy Findlater[2], Katie Wrenn[3], Alicia Demirjian[1,4,5], Juliana Coelho[1], Colin Brown[1], Theresa Lamagni[1]
[1]UK Health Security Agency, Hcai, Fungal, Amr, Amu And Sepsis, London, United Kingdom, [2]UK Health Security Agency, Field Service South East And London, London, United Kingdom, [3]UK Health Security Agency, Rapid Investigation Team, Field Service, London, United Kingdom, [4]Evelina London Children's Hospital, Paediatric Infectious Diseases, London, United Kingdom, [5]King's College London, Faculty Of Life Sciences & Medicine, London, United Kingdom

Background: Following low incidence of invasive group A Streptococcus (iGAS) infections during the COVID-19 pandemic, increases were noted in England during 2022. In November 2022, increases in unusual lower respiratory tract infection (LRTI) iGAS (including empyema) in children <15y were notified by paediatricians. We look in more depth at the reports of iGAS LRTI presentation in children.
Methods: Laboratory-confirmed iGAS notification data for children <15y in England between October 2022 and January 2023 were linked to a range of UK Health Security Agency surveillance databases. Cases were investigated by demographic, clinical presentation, emm type, respiratory virus co-infection and 7-day all-cause mortality.
Results: In the four-month window, 236 cases of LRTI iGAS were recorded, 56% occurring in December 2022. Fifty-five per-cent (129) were male with a median age of 4y (inter-quartile range 2y-6y). Ethnicity was known in 61% cases (143), of which 71% were 'White' (101) and 18% (26) were 'Asian/Asian British'. Cases were distributed across all regions of England. Fifty-one per-cent of cases had a pleural fluid specimen (120). Strain typing (available for 133 cases) identified 74% (98) as emm1.0, and 17% (22) as emm12.0. Respiratory virus co-infections were identified in 42% of cases (99; 28% >1 co-infection); 42% cases with co-infection recorded human metapneumovirus and 34% respiratory syncytial virus. A total of 35 deaths (all-cause <7d iGAS diagnosis) were reported.
Conclusions/Learning Points: iGAS infections in children, particularly LRTI, showed a marked increase in late 2022, potentially reflecting reduced exposure during the COVID-19 pandemic. Whilst the excess numbers of cases and deaths seen in 2022 may equate to those prevented during the pandemic, the transmission intensity and rapidity had a detrimental effect on healthcare-service delivery, antimicrobial supply, and fuelled public concern.

UPSURGE OF PEDIATRIC INVASIVE STREPTOCOCCUS PYOGENES (GROUP A STREPTOCOCCUS) INFECTIONS IN PORTUGAL DOMINATED BY M1UK AND EMM12 LINEAGES

Oral Presentations Session
ORAL PRESENTATION SESSION 12: LATE BREAKING

Catarina Gouveia[1], Ana Carvalho[1], Fernanda Rodrigues[2], Luís Varandas[1], Paula Bajanca-Lavado[3], Célia Bettencourt[3], Joana Gomes-Silva[4], Mário Ramirez[4], José Melo-Cristino[4], Ana Friães[4], . The Portuguese Group For The Study Of Streptococcal Infections[5], . Portuguese Study Group Of Pediatric Invasive Streptococcal Disease[6]
[1]Hospital Dona Estefânia - Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal, Paediatric Infectious Diseases Department, Lisbon, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Hospital Pediátrico, Coimbra, Portugal, [3]Instituto Nacional de Saúde Dr. Ricardo Jorge, Laboratório Nacional De Referência A Infeções Respiratórias, Departamento De Doenças Infeciosas, Lisbon, Portugal, [4]Faculdade de Medicina, Universidade de Lisboa, Instituto De Microbiologia, Instituto De Medicina Molecular, Lisbon, Portugal, [5]Faculdade de Medicina de Lisboa, Instituto De Microbiologia, Lisboa, Portugal, [6]Multiple Hospitals, Microbiologia, Multiple Cities, Portugal

Background: Multiple countries have recently issued alerts regarding an ongoing rise of invasive infections caused by Group A Streptococcus (iGAS). This study reports the most recent epidemiological and molecular surveillance data of pediatric iGAS in Portugal.
Methods: Demographic and clinical characteristics of pediatric (<18 yrs) iGAS between 1-Sep-2022 and 28-Feb-2023 were recorded as part of an ongoing national prospective surveillance. The emm type, multilocus sequence type (ST), and number of $M1_{UK}$-characteristic SNPs were obtained from whole-genome sequencing data of all available isolates (n=19).
Results: We recorded 39 confirmed iGAS cases (GAS identified in a normally sterile site) and 2 probable cases [streptococcal toxic shock syndrome (STSS) and GAS identified in a nonsterile site]. The median age was 3.0 years (IQR 2-6 years), 56% females. The most frequent diagnoses were pneumonia (42%), bacteraemia without focus (25%), osteoarticular infection (21%), sepsis (15%), and STSS (13%), with one death. The case fatality rate (CFR), ICU admission, and length of stay were similar to previous years. The most common lineage was emm1-ST28 (n=8, of which 7 presented the 27 $M1_{UK}$-characteristic SNPs), followed by emm12-ST36/242 (n=6), emm89-ST101 (n=2), emm4-ST39, emm22-ST46, and emm87-ST62 (n=1 each).
Conclusions/Learning Points: Between Sep-2022 and Feb-2023, the 41 paediatric iGAS cases in Portugal were significantly more numerous than in the same period of pre-pandemic years (2014-2020; average 11.8 cases, 95% confidence interval 8.4-15.2), with no increase in the CFR. This upsurge is not associated with an emerging new lineage but with multiple lineages previously circulating in Portugal, with a clear dominance of the $M1_{UK}$ sub-lineage and emm12 (68%). In contrast to recent reports from Denmark, the speC gene was not detected in any emm1 isolate.

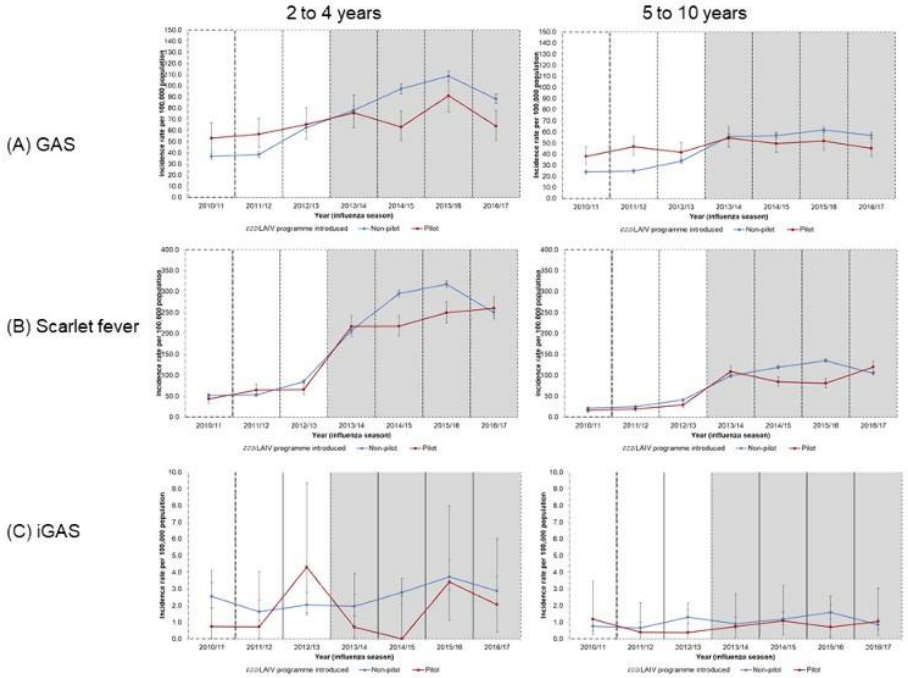
O0116 / #2452

EPIDEMIOLOGICAL IMPACT OF THE PAEDIATRIC LIVE ATTENUATED INFLUENZA VACCINE (LAIV) PROGRAMME ON GROUP A STREPTOCOCCUS (GAS) INFECTIONS IN ENGLAND

Oral Presentations Session
ORAL PRESENTATION SESSION 12: LATE BREAKING

Mary Anissa Sinnathamby[1], Fiona Warburton[1], Rebecca Guy[2], Nick Andrews[1], Theresa Lamagni[1], Conall Watson[1], Jamie Lopez-Bernal[1]
[1]UK Health Security Agency, Uk Health Security Agency, London, United Kingdom, [2]UK Health Security Agency, Hcai, Fungal, Amr, Amu And Sepsis, London, United Kingdom

Background: Group A Streptococcus (GAS) infections, including invasive disease (iGAS) are secondary bacterial infections associated with influenza infections. The universal paediatric live attenuated influenza vaccine (LAIV) programme introduced in England from the 2013/14 influenza season was incrementally implemented, introducing cohorts of children annually from 2-16 years. Additionally, a series of geographically discrete pilot areas offered the LAIV to all pre- and primary- school age children. This differential roll-out of the programme allowed for the impact assessment of the programme on the incidence rates of GAS infections among pilot and non-pilot areas.
Methods: Cumulative incidence rate ratios (IRRs) of GAS, scarlet fever (SF) and iGAS, comparing pilot and non-pilot areas were estimated using Poisson regression, within each season by age-group. The overall effect of the pilot programme between the pre- (2010/11-2012/13 seasons) and post-introduction (2013/14- 2016/17 seasons) periods was assessed using negative binomial regression by comparing the pre-/post- programme changes in incidence between pilot/non-pilot areas (rIRR = ratio of IRR).
Results: Reductions in IRRs of GAS and SF were observed within most post-LAIV programme seasons, among the 2-4 and 5-10 years. Significant reductions were seen among 5-10 years (rIRR of 0.57 (95% CI: 0.45 to 0.71; p-value: <0.001); 2-4 years (rIRR of 0.62 (95% CI:0.43 to 0.90; p-value: 0.011) and 11-16 years (rIRR of 0.63 (95% CI: 0.43 to 0.90; p-value: 0.018) for GAS infections when assessing the overall effect of the programme. A non-significant reduction was also seen for iGAS in 2–4-year-olds (rIRR of 0.58 (95% CI: 0.21 to 1.65; p-value=0.31)).



Conclusions/Learning Points: Our findings highlight the paediatric LAIV programme reducing the incidence of GAS and iGAS infections among children and support attaining high uptake of childhood influenza vaccination.

1 AND 2 YEAR MULTIDISCIPLINARY FOLLOW-UP OF PAEDIATRIC INFLAMMATORY MULTISYSTEM SYNDROME (PIMS-TS) PATIENTS AT A UK TERTIARY PAEDIATRIC HOSPITAL: A RETROSPECTIVE COHORT STUDY

Oral Presentations Session
ORAL PRESENTATION SESSION 12: LATE BREAKING

Sarah Johnson[1], Justin Penner[1], Richard Issitt[2,3], Karlie Grant[1], Ashwin Pandey[1], Laura Kmentt[1], Dimitrios Champsas[4], Omar Abdel-Mannan[4], Kim Mckenzie[5], Zoe Berger[6], Rebecca Arnold[6], Yael Hacohen[4], Karyn Moshal[1]
[1]Great Ormond Street Hospital, Paediatric Infectious Diseases, London, United Kingdom, [2]Great Ormond Street Hospital, Perfusion Department, London, United Kingdom, [3]Great Ormond Street Hospital, Digital Research Environment, London, United Kingdom, [4]Great Ormond Street Hospital, Paediatric Neurology, London, United Kingdom, [5]Great Ormond Street Hospital, Rheumatology And Chronic Pain Team In Physiotherapy, London, United Kingdom, [6]Great Ormond Street Hospital, Psychological Medicine, London, United Kingdom

Background: PIMS-TS was first observed in spring of 2020. Six-month follow-up was reassuring, but it was unknown whether long-term sequelae would be experienced or whether different variants would affect clinical phenotypes/outcomes.
Methods: Children (<18 years) meeting the Royal College of Paediatrics and Child Health diagnostic criteria for PIMS-TS were followed by a multidisciplinary team at six weeks, six months, one and two years. PIMS-TS waves were determined by the corresponding prevalence of primary circulating SARS-CoV-2 variant (>50%).
Results: 160 children were included (wave one=45; wave two=79 and wave three=36). 59% (96) were male with a median age of 10.1 years (IQR 7.9-12.6). Symptoms were similar across all waves. Days of hospitalisation decreased with time (10.7 days wave one vs1 vs 1.8 days wave two+three). More patients were ventilated in wave one (12, 7, 2 respectively). Inotropic support was received in the majority of wave two (86%), vs 40% in wave one and 47% in wave three. Inflammatory markers normalised by six weeks and continued to be normal up to two years in all patients except one. There were no PIMS-TS relapses. 11 patients remain under follow-up: cardiology-5, gastroenterology-5, nephrology-1. The main symptoms reported at 1-2 year included abdominal pain (n=5) and myalgia (n=2). All patients required a graduated home exercise programme and were offered supportive psychology and intensive inpatient rehabilitation.
Figure 1: Heatmap showing symptoms by chronological order of admission

Conclusions/Learning Points: PIMS-TS patients have a sustained recovery after the initial, severe acute episode. Across waves, symptoms were similar, length of stay reduced and less intubation was required. This may have reflected greater insights into treatment rather than severity.

Background: In response to a national mpox outbreak in England, children exposed to a confirmed mpox case were offered Modified Vaccinia Ankara–Bavaria Nordic (MVA-BN), a third-generation smallpox vaccine, for post-exposure prophylaxis. We assessed the safety and reactogenicity, as well as humoral and cellular immune responses, following the first reported use of MVA-BN in children.
Methods: Children receiving MVA-BN for post-exposure prophylaxis were followed-up after vaccination and requested to complete a post-vaccination questionnaire and have blood tests at one and three months post-vaccination.
Results: Between June 01 and November 30, 2022, 87 children had one MVA-BN dose and none developed any serious adverse events or developed mpox disease after vaccination. Their median age was 5 years, (IQR 5-9, range 0-14). Of the 45 children with complete questionnaires, 16 (36%) reported no symptoms, 18 (40%) reported local reaction only and 11 (24%) reported systemic symptoms with or without local reactions. Seven children provided a first blood sample and five provided a second at a median of six and 15 weeks post-vaccination, respectively. All children had poxvirus IgG antibodies with levels well-above the cut-off limit. Assessment of reactivity to 27 recombinant VACV and mpox virus proteins showed humoral antigen recognition, primarily to mpox virus antigens B6, B2, and VACV antigen B5, with waning of humoral responses observed between the two timepoints. All children demonstrated robust T-cell responses to whole ModifiedVaccinia Ankara (MVA) virus and a select pool of conserved pan-Poxviridae peptides. A balanced CD4+ and CD8+ T cell response was evident at 6 weeks, which was retained at 15 weeks post-vaccination.
Conclusions/Learning Points: A single dose of MVA-BN for post-exposure prophylaxis was well-tolerated in children and induced robust antibody and cellular immune responses up to 15 weeks after vaccination.

Background: The epidemiology of influenza during the COVID-19 pandemic showed atypical features. We aimed to describe the pre-pandemic epidemiologic characteristics and clinical outcomes of pediatric influenza hospitalizations, comparing them to those of the 2021-2022 season.
Methods: Analysis of data from a national active surveillance program evaluating influenza-related hospitalizations in children aged 0-16 years was conducted from 2012-2022 by the Canadian Immunization Monitoring Program, ACTive, which covers ~90% of national tertiary-care pediatric beds. Key epidemiologic, clinical, and severe outcomes data from the 2012-2020 period was compared to data from 2021-2022. Adjustment for multiple comparisons was not done.
Results: A total of 8271 influenza hospitalizations (43% females, median age=3 years [IQR=1.2-6.5]) were recorded, of whom, 72% were caused by influenza A. Overall, 7944 hospitalizations occurred during 2012-2020 (average/season=827.1), 0 in 2020-21, and 327 in 2021-2022. By comparing the 2012-2020- and 2021-2022-time frames, a higher number of subjects aged >=10 years in 2021-2022 (18% vs 12.2%, p=0.001) and a higher number of cases aged 6-23 months in 2012-2020 (24.5% vs 19%, p=0.018) were noticed. While the proportion of children with comorbidities was similar (45.4% vs 45%, 2012-2020 and 2021-2022, respectively), the types of comorbidities between periods differed (table). Neurological influenza manifestations were lower during 2021-2022 (7.3% vs 11.4%,p=0.018). Seventeen percent and 11% of children required ICU admission in the 2012-2020 and 2021-2022 periods, respectively (p=0.003). A greater proportion of patients required ventilatory support during 2012-2020 (10.2% vs 3.7%, p<0.001). Forty-four deaths (average/season=5.5) were recorded in 2012-2020, compared to one death in 2021-2022 with no difference in the mortality rate per season
(p=0.69).

TABLE.

§ All influenza included: Influenza A and B coinfections, only influenza A, and only influenza B

Underlying disorders included also the following diseases (2021-2022 vs 2012-2020 time frames): Chronic heart disease (2.1% vs 3.6%, p=0.656), Chronic renal disease (1.8% vs 2.2%, p=0.646), Inherited and acquired immunodeficiency (0.3% vs 1.7%, p=0.055), Chronic anemia (0.9% vs 1.4%, p=0.630). Categories were not mutually exclusive.

* Chronic lung disorder (i.e., asthma, bronchopulmonary dysplasia, and cystic fibrosis). Morbid obesity: body max index (BMI) greater than 95% for their age. Immunosuppression (i.e., due to underlying disease or therapy). Haemoglobinopathy (i.e., sickle cell disease).

Conclusions/Learning Points: The flu epidemiology shifted during the COVID-19 pandemic without cases in the first season and then older and less severe in the second season.

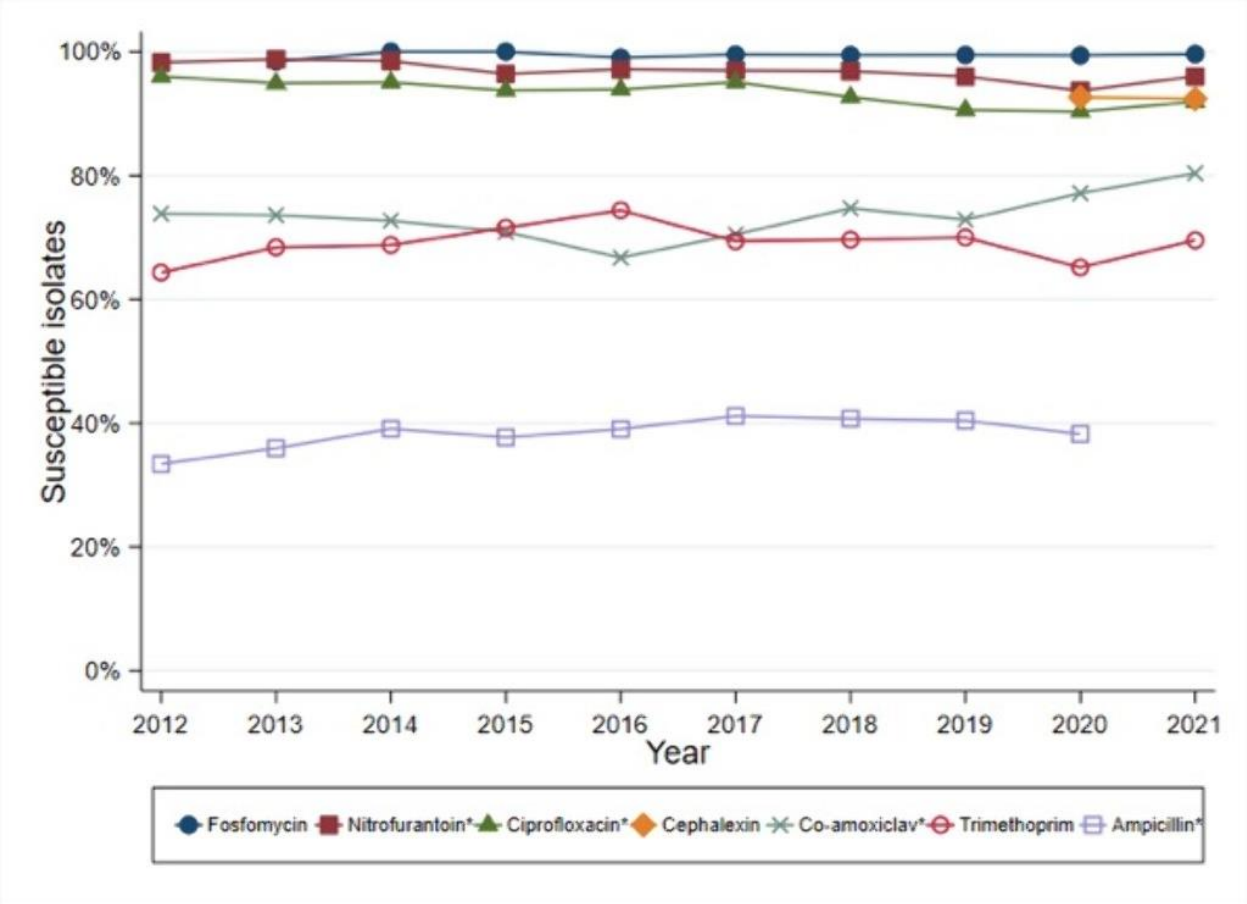
PD0001 / #847

TURNING THE TIDE - INCREASING SUSCEPTIBILITY TO CO-AMOXICLAV IN ESCHERICHIA COLI URINARY TRACT INFECTION - A TEN-YEAR REVIEW OF SUSCEPTIBILITY TRENDS AND CLINICAL MANAGEMENT

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Sean Whelan[1], Sarah Kyne[2], Andrew Dore[2], Mark Glynn[2], Edina Moylett[2], Martin Cormican[1,3]
[1]Galway University Hospital, Division Of Medical Microbiology, Galway, Ireland, [2]Galway University Hospital, Department Of General Paediatrics, Galway, Ireland, [3]University of Galway, Discipline Of Bacteriology, Galway, Ireland

Backgrounds: Escherichia coli is the predominant pathogen in paediatric urinary tract infection (UTI). Previous local, national and international studies have demonstrated increasing antimicrobial resistance (AMR), including to co-amoxiclav. We sought to examine the AMR patterns of urinary E.coli isolates, and to review treatment and outcomes of a hospitalised subset of patients.
Methods: E.coli isolated from patients aged ≤14 from 2012-2021 from a single Irish hospital were analysed. Trends in susceptibility were assessed for statistical significance. A retrospective chart review was performed on inpatients ≥2 months 2016-2021 with upper UTI to review treatment and outcomes. Treatment was compared to institutional guidance (co-amoxiclav and gentamicin).
Results: E.coli accounted for 71.2% of significant isolates (9,314). Susceptibility to co-amoxiclav significantly increased over time, from 66.7% to 80.4% between 2016-2021. Trends were similar in the subset of admitted patients with confirmed E.coli UTI. Susceptibility to gentamicin decreased in recent years, from 93.8% to 79.7% since 2017. Of 222 admitted clinical cases reviewed, 45.5% were treated with both co-amoxiclav and gentamicin as-per-guideline, and 39.2% treated with co-amoxiclav alone. The proportion receiving both agents increased over the study period. In this admitted cohort, 25.6% of isolates were non-susceptible to co-amoxiclav alone, while only 1% were non-susceptible to both co-amoxiclav and gentamicin. 9% of patients were treated with co-amoxiclav and despite non-susceptible isolates clinically improved, and were
discharged.



Conclusions/Learning Points: Co-amoxiclav susceptibility among E.coli isolates increased significantly over the study period. This was temporally associated with national and local stewardship measures to reduce co-amoxiclav use, and suggests potential reversal of previous trends of increasing AMR. Conversely, reducing susceptibility to gentamicin is concerning and requires monitoring. Non-adherence to guideline, associated with an increased risk of treatment with non-susceptible agents, decreased over the study period.

PD0002 / #676

USE OF CEFIDEROCOL IN THE MANAGEMENT OF CHILDREN WITH INFECTION OR COLONISATION WITH MULTIDRUG-RESISTANT GRAM-NEGATIVE BACTERIA

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Hanna Schmid[1], Li-An Brown[2], Bairavi Indrakumar[3], James Hatcher[2], Alaisdair Bamford[1,4]
[1]Great Ormond Street Hospital for Children NHS Foundation Trust, Paediatric Infectious Diseases, London, United Kingdom, [2]Great Ormond Street Hospital for Children NHS Foundation Trust, Department Of Microbiology, Laboratory Medicine, London, United Kingdom, [3]Great Ormond Street Hospital for Children NHS Foundation Trust, Pharmacy Department, London, United Kingdom, [4]UCL Great Ormond Street Institute of Child Health, Paediatric Infectious Diseases, London, United Kingdom

Backgrounds: Cefiderocol is a novel siderophore cephalosporin, representing a treatment option for infections with multidrug-resistant Gram-negative bacteria (MDR-GNB). Clinical data on paediatric use is limited.
Methods: All treatment episodes with cefiderocol in paediatric inpatients at Great Ormond Street Hospital, London, UK in 2021/2022 were retrospectively identified through pharmacy dispensing data and reviewed for demographics, indications, targeted organisms, dosing, outcome and tolerability.
Results: Fifteen episodes of cefiderocol use were recorded in 12 children, aged between 0.4-15.6 years (median 3.4y, weight 4-60kg), half of whom were immunocompromised. Nine episodes represented serious/invasive infections with MDR-GNB, including Stenotrophomonas maltophilia, Acinetobacter baumanii, Pseudomonas aeruginosa and Pseudomonas putida. Treated conditions were pulmonary, bloodstream and skin infections. Median treatment duration was 11 days with clinical response seen in 5/9 cases. All but one patient had co-infections, and all received co-administration of other antimicrobials. In a further 5 episodes, cefiderocol was either empirically or prophylactically administered, in view of known colonisation with MDR-GNB. Overall 30-day mortality was 17%, with cause of death primarily attributed to underlying disease. Tolerability was favourable, with mild transaminitis and purple urine discoloration noted in one case each, neither leading to treatment discontinuation. One patient developed desquamating skin changes while on treatment with cefiderocol, which were later attributed to graft-versus-host disease but led to early discontinuation.
Conclusions/Learning Points: We present the largest cohort of children treated with cefiderocol. Specific clinical response to its therapeutic use remains difficult to assess, given the complex nature of the patient cohort and isolation of multiple infecting/colonising organisms with co-administration of other antimicrobials. A lower 30-day mortality was demonstrated, when compared to literature reviewing adult cases, and good tolerability. Further research is needed to evaluate cefiderocol as a treatment option in paediatric MDR-GNB infection.

PD0003 / #1071

PREDISPOSING FACTORS AND CLINICAL FEATURES OF FLUCLOXACILLIN-INDUCED HEPATOTOXICITY AMONG CHILDREN.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Stefan Coombs[1], Laure Pittet[2], Kailey Tang[3], Amanda Gwee[3,4,5]
[1]The Royal Children's Hospital Melbourne, Pharmacy Department, Flemington Rd, Australia, [2]University of Melbourne, Paediatrics, Melbourne, Australia, [3]The University of Melbourne, Department Of Paediatrics, Melbourne, Australia, [4]Murdoch Children's Research Institute, Infectious Diseases Group, Melbourne, Australia, [5]The Royal Children's Hospital Melbourne, Infectious Diseases Unit, Melbourne, Australia

Backgrounds: Flucloxacillin-induced hepatotoxicity is well-established in adults. However, there are few paediatric studies of flucloxacillin-induced hepatotoxicity despite this drug being among the most commonly prescribed in children. We aimed to determine the incidence of flucloxacillin-induced hepatotoxicity in children receiving IV therapy as well as identify risk factors for this adverse drug reaction.
Methods: Retrospective audit of children admitted to the Royal Children's Hospital over a 24-month period (2019-2021). Patients were included if they were aged between 0-18 years and: (i) received IV flucloxacillin and had liver function tests determined prior to and within 60-days of the start of therapy; and (ii) if the IV flucloxacillin treatment course was at least 24-hours.
Results: Overall, the incidence of hepatotoxicity was 66/394 (17%). Of those with hepatotoxicity, the median age was 1.1 years (range 0.3-11.9), 43 (65%) received ≥2 concomitant hepatotoxic medications and 23 (35%) were receiving total parental nutrition. The median timing of onset of hepatotoxicity after commencement of flucloxacillin was 4 days (range 2-7). Severe hepatotoxicity (CTCAE ≥ grade 3) occurred in 9/66 (14%) for bilirubin, 13/66 (20%) for alanine transaminase and 10/66 (15%) for gamma-glutamyl transferase. Predisposing factors for hepatotoxicity were increasing age (OR 1.06 per additional year, 95%CI 1.01-1.10, p=0.02) with adolescents aged 12-18 years having the highest risk (OR 5.10, 95%CI 2.02-12.85, p=0.001), and ≥2 concomitant hepatotoxic medications (OR 2.51, 95% CI 1.02-6.18, p=0.05). The median time to resolution of hepatotoxicity after cessation of flucloxacillin was 5 days (range 2-10).
Conclusions/Learning Points: In children, older patients and those receiving two or more concomitant hepatotoxic medications are at greater risk of flucloxacillin-induced hepatotoxicity.

FREQUENCY AND FACTORS ASSOCIATED WITH INAPPROPRIATE ANTIBIOTIC PRESCRIPTIONS DURING INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS (IMCI) CONSULTATIONS AMONG CHILDREN AGED 2-59 MONTHS IN PRIMARY HEALTH CENTERS BURKINA FASO, GUINEA, AND MALI, JUNE 2021 TO FEBRUARY 2022

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Désiré Néboua[1], Cédric Besnier[2], Emelyne Gres[2], Gildas Boris Hedible[2], Bokol Lucie Peters[2], Sarah Louart[3], Valéry Ridde[4], Valeriane Leroy[2]
[1]ALIMA (The Alliance for International Medical Action), Aire Project, Dakar, Burkina Faso, [2]Inserm, Umr1295, TOULOUSE, France, [3]ALIMA, Aire Project, Dakar, Senegal, [4]IRD, Ceped, Paris, France

Backgrounds: In low-income countries, data assessing appropriateness of antibiotic prescriptions is scarce, mainly hospital-based. We analyzed antibiotic prescriptions and correlates of inappropriate prescriptions in children attending IMCI consultations in primary health centers (PHCs) in three West African countries (Burkina Faso, Guinea and Mali), as part of the AIRE project, held with NGO' support (ALIMA, Solthis, Terre des hommes).
Methods: A multicenter cross-sectional study of all children aged 2-59 months seen as outpatients who received an IMCI consultation in four public PHCs per country was conducted between June 2021 and February 2022. Those eligible for Pulse Oximetry measurement were included with parent's consent. A standardized algorithm was developed based on national IMCI guidelines to define inappropriate antibiotic prescriptions based on the non-proprietary name of antibiotic prescribed: either the antibiotic wasn't recommended but prescribed (over-prescription), or it was recommended but not prescribed (missed treatment opportunity). In Mali, correlates of over antibiotic prescriptions were analyzed using mixed-effects logistic regression models with a random effect on the inclusion site.
Results: Among the 6,796 children included, a significant proportion of IMCI consultations (65.5%) resulted in the prescription of >1 antibiotic. Over-prescription and missed opportunity for antibiotic concerned 36% and 19% of children respectively. In Mali, young age (2-11 months), household density >5 persons vs <5 (aOR:1.64;95% CI: 1.21-2.21), hypoxemia (SpO2<90%) (aOR:2.47;95% CI: 1.01-6.06) and previous antibiotherapy (aOR:0.81;95% CI: 0.65-0.99) were independently associated with over-prescription for the sub-population of IMCI simple and moderate cases (N=776).
Conclusions/Learning Points: The frequency of inappropriate antibiotic prescriptions was high in under-5 in the three countries. Understanding the determinants of inappropriate antibiotic prescribing will enable health authorities and policy makers to design relevant interventions to promote a better rational use of antibiotics in PHC in Africa

[1]Dr. von Hauner Children's Hospital, Paediatric Infectious Diseases, Munich, Germany, [2]Frauenhofer Institute for Molecular Biology and Applied Ecology (IME), Branch For Bioresources, Giessen, Germany, [3]Justus-Liebig-University of Giessen, University, Giessen, Germany, [4]Institute for Medical Information Processing, Biometry, and Epidemiology, Ibe, München, Germany, [5]Pettenkofer School of Public Health, Psph, Munich, Germany, [6]German Center for Infection Research (DZIF), Partner Site Giessen-marburg-langen, Giessen, Germany, [7]German Center for Infection Research (DZIF), Partner Site Munich, Munich, Germany

Backgrounds: Antimicrobial resistance (AMR) and multi-drug-resistant gram-negativ (MRGN) pathogens are an increasing threat to health care. Patients with chronic pulmonary disease, like cystic fibrosis (CF), are particularly vulnerable and depend heavily on effective antibiotic therapy. We evaluated antimicrobial activity of recently licensed drugs ceftazidime-avibactam (CZA), ceftolozane-tazobactam (C/T) and cefiderocol (FDC) as well as two novel preclinical antibiotics, darobactin B (DAR B) and B9 (DAR B9), against clinical Pseudomonas aeruginosa isolates from CF patients.
Methods: Between 2006 and 2018, 66 MRGN P. aeruginosa samples were obtained from CF patients at a paediatric tertiary care hospital in Munich, Germany. Antimicrobial susceptibility to CZA, C/T, and FDC was determined by gradient diffusion testing using Etest Strips (Liofilchem, Roseto degli Abruzzi, Italy). Minimum inhibitory concentrations (MIC in µg/mL) were determined. Antimicrobial activity was assessed as MIC still showing efficacy in 50% or 90% of isolates. Antipseudomonal activity of darobacin B and B9 was assessed by micro-broth-dilution assays. MIC was defined as lowest concentration inhibiting growth by at least 80% relative to the growth control.
Results: Of 66 investigated P. aeruginosa isolates, 53% were resistant to CZA, 49% to C/T and 30% to FDC, including 52 isolates obtained from CF patients prior to market introduction of CZA and C/T. Both novel preclinical compounds performed better (CZA and C/T) or in close range to the licensed drugs (FDC).
Conclusions/Learning Points: Our results highlight the necessity of global consistency in antibiotic stewardship to prevent AMR from further impairing the potency of antibiotics. Since resistance to CZA, C/T and FDC may be due to pre-existing resistance mechanisms there is an urgent need to support the development of novel antimicrobials, preferably with a new mode of action such as darobactin B and B9.

PD0006 / #726

ANTIMICROBIAL RESISTANCE OF STREPTOCOCCUS PNEUMONIAE ISOLATES CAUSING INVASIVE PNEUMOCOCCAL DISEASE IN 17 HOSPITALS OF COLOMBIA.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Backgrounds: Invasive Pneumococcal Disease (IPD) is a cause of morbidity and mortality in children. Some Streptococcus pneumoniae isolates are resistant to antibiotics used for IPD, such as beta-lactams and macrolides. Increased resistance has been reported in Colombia.
Methods: A descriptive study in pediatric patients with IPD admitted in 10 hospitals of Bogotá, and 4 hospitals of Cali, 2 of Medellin and 1 of Cartagena in 2017-2022. Data on serotype(Spn) and resistance were obtained.(preliminary data).
Results: 344 cases of IPD were found. Susceptibility profile information was obtained for 320(93%) isolates; 290(90.7%) were non-meningeal (NM) and 30(9.3%) meningeal (M). Regarding non-meningeal, 21.3% were penicillin-resistant, and 7.5% showed intermediate susceptibility; 10.3% were resistant to ceftriaxone and 12% had intermediate susceptibility. Meningeal isolates showed 40% resistance to penicillin, 10% resistance to ceftriaxone, and 6.6% intermediate susceptibility. Resistance to macrolides was 50.3%, to clindamycin 36.8%, and to trimethoprim sulfa 37.8%. All isolates were susceptible to vancomycin. Only 25% of the isolates were susceptible to all antibiotics; 22.5% were multi-resistant. The serotype most resistant to penicillin was 19A (34.3%), 23,9% was associated with multiresistance and only 8,3% were susceptible to all antibiotics.
Conclusions/Learning Points: An increase in antibiotic resistance is observed in relation to previous reports associated with emergence of multiresistant S. pneumoniae serotype 19A. Colombia changed to PCV 13 in July 2022. The impact of the vaccine change needs to be monitored.

PD0007 / #1099

ANTIMICROBIAL RESISTANCE ISLANDS: A NEW WEAPON FOR PATHOGENS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Samantha Mccarlie, Robert Bragg
University of the Free State, Microbiology & Biochemistry, Bloemfontein, South Africa

Backgrounds: In the fight against antimicrobial resistance, very little is known about, microbial resistance to disinfectants and antiseptics. How resistance to disinfectants develops and how this resistance is transferred between bacteria is largely unknown. Genomic islands are portions of the bacterial genetic code where resistance genes can be found grouped together. These resistance genes converge together and then mobilise as a unit, transferrable within a microbial population. An increasing number of hospital-acquired infections and outbreaks by Serratia marcescens prompted research into Serratia sp. HRI, an isolate with high antimicrobial resistance capabilities. Specifically, whether resistance islands harbouring multiple resistance genes could be found.
Methods: Genomic island prediction software (IslandViewer4) and bioinformatic gene annotation programs (RAST, psi-BLAST, PGAP) were used to find any resistance islands and identify any antimicrobial resistance genes in the highly resistant Serratia sp. HRI.
Results: Bioinformatic analysis revealed 9 resistance islands, containing both antibiotic and biocide/disinfectant resistance genes. A number of genes encoding for multidrug efflux pumps belonging to the MFS, ABC and DMT efflux families were found. Antibiotic resistance islands containing genes macrolide, erythromycin (emrE) and biclomycin resistance were identified. In addition, two genomic islands were identified harbouring disinfectant resistance genes (smr).
Conclusions/Learning Points: Numerous resistance islands are present within the highly resistant bacterium and can contribute to both antibiotic and disinfectant resistance. The presence of both antibiotic and disinfectant resistance genes within one bacterium is a major cause for concern as eradication of this isolate in a healthcare setting would be a great challenge. Serratia marcescens is an important emerging pathogen in hospitals. This work shows that these pathogens are capable of resistance to antibiotics and disinfectants simultaneously and that these resistance genes are on highly transferable genetic elements.

PD0008 / #377

COMPARATIVE EFFECT OF FOUR ANTIMALARIAL TREATMENTS ON HAEMATOCRIT IN CHILDREN IN SOUTHWEST OF NIGERIA

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Zacchaeus Olofin[1,2], Adebola Orimadegun[3], Catherine Falade[1,4]
[1]University of Ibadan, Pharmacology And Therapeutics, Ibadan, Nigeria, [2]Bowen University, Pharmacology And Therapeutics, Iwo, Nigeria, [3]University of Ibadan, Institute Of Child Health, Ibadan, Nigeria, [4]University of Ibadan, Institute For Advanced Medical Research And Training, Ibadan, Nigeria

Backgrounds: Anaemia in malaria has both central (dyserythropoiesis) and peripheral causes (phagocytosis of both infected and uninfected erythrocytes and haemolysis). Some antimalarial drugs also cause intravascular hemolysis leading to anemia. However, it is often difficult to disentangle the anemia effect of malaria from its treatments.
The aim of this study was carried out to compare the change in hematocrit following four antimalarial treatments.
Methods: Data were extracted from 313 case record forms of children that met the eligibility criteria aged 3-119 months enrolled in antimalarial clinical trials in Southwest Nigeria between 1998 and 2014. Change in haematocrit level from baseline through 28 days follow up period were compared among children treated with artemether-lumefantrine (82), artovaquone-proguanil (41), artesunate-amodiaquine (156) and chloroquine (34). Repeated measures analysis was done by fitting a general linear model (GLM).
Results: The median age of the study population was 25 months and 54% were males. The mean differences (95% CI) in haematocrit from baseline were 4.7 (95% CI = 3.6, 5.8), 4.4 (95% CI = 2.7, 6.0), 3.8 (95% CI = 3.0, 4.7) and 2.4 (95% CI = 0.5, 4.4), for artemether-lumefantrine, artovaquone-proguanil and artesunate-amodiaquine and chloroquine, respectively. Using the general lineal model, repeated measure analysis showed that there were significant differences in the mean haematocrit level over the 28-day follow-up among the four treatment groups ($p<0.05$).
Conclusions/Learning Points: All children experienced increases in haematocrit after treatment, with artesunate-amodiaquine appearing to result in a greater increase in haematocrit than other antimalarial drugs.

PD0009 / #148

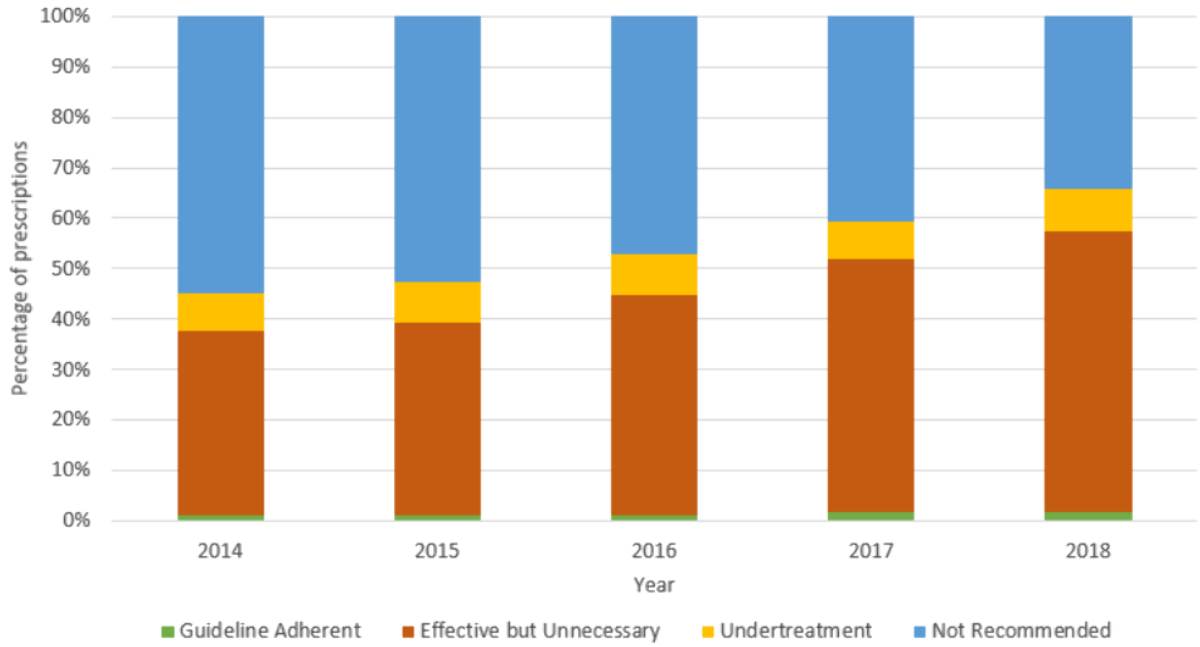
QUALITY OF ANTIBIOTIC PRESCRIBING FOR PEDIATRIC COMMUNITY-ACQUIRED PNEUMONIA IN OUTPATIENT CARE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Ariana Saatchi[1], Manon Haverkate[1], Jennifer Reid[2], Salimah Shariff[2], Marcus Povitz[3], David Patrick[4,5], Michael Silverman[6], Andrew Morris[7], James Mccormack[1], Fawziah Marra[1], Fawziah Lalji[1]
[1]University of British Columbia, Faculty Of Pharmaceutical Sciences, Vancouver, Canada, [2]ICES Western, Lawson Health Research Institute, London, Canada, [3]University of Calgary, Department Of Medicine, Calgary, Canada, [4]British Columbia Centre for Disease Control, Bccdc, Vancouver, Canada, [5]University of British Columbia, School Of Population And Public Health, Vancouver, Canada, [6]University of Western Ontario, Faculty Of Medicine, London, Canada, [7]University Health Network and University of Toronto, Sinai Health System, Toronto, Canada

Backgrounds: Antibiotics remain the primary treatment for community acquired pneumonia (CAP), however rising rates of antimicrobial resistance may jeopardize their future efficacy. With higher rates reported in the youngest populations, effective treatment courses for pediatric pneumonia are of paramount importance. This study is the first to examine the quality of pediatric antibiotic use by agent, dose and duration.
Methods: A retrospective cohort analysis included all outpatient physician visits for pediatric CAP (aged < 19 years) in the province of British Columbia, between January 1 2014 to December 31 2018. Relevant practice guidelines were identified, and treatment recommendations were extracted. Categories of prescribing included: guideline adherent, effective but unnecessary, undertreatment, and not recommended. Proportions of attributable-antibiotic use were examined by prescribing category, and then stratified by age and sex.
Results: A total of 40,527 episodes of pediatric CAP were identified. Of those, 31,347 (77.3%) resulted in an antibiotic prescription. Amoxicillin is the recommended treatment for pediatric CAP, accounting for 48% of all prescriptions. The majority (83.6%) of amoxicillin use was “effective but unnecessary”, with 2.8% fully “guideline adherent”. Excessive durations were the hallmark of “effective but unnecessary” prescriptions (97.1%), while excessive average daily dose was present in 48.9%. A remaining 13.5% was classified as “undertreatment”, wherein sub-therapeutic dosing was the leading determinant. Overall, 98.6% of antibiotic use for pediatric CAP was not adherent, by agent, dose and/or duration.

Figure 1. Percentage of outpatient antibiotic use for paediatric CAP by category of prescription quality by year



Conclusions/Learning Points: This study is the first in Canada to examine prescribing quality for paediatric CAP by agent, dose and duration. Promoting the use of first-line agents, and shifting prescribing to reflect evidence-based shorter treatment courses are targets for paediatric stewardship. Study results highlight the importance of examining the quality of prescriptions across other common indications.

PD0010 / #1691

IMPACT OF A HOSPITAL ANTIMICROBIAL STEWARDSHIP PROGRAM ON THE TREATMENT OF ACUTE HEMATOGENOUS BONE AND JOIN INFECTIONS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Marta Agüera[1], María Ríos-Barnes[2], David Moreno Romo[3], Anna Gamell Fulla[4], Victoria Fumado[5], Eneritz Velasco Arnaiz[4]
[1]Hospital Sant Joan de Deu, Paediatrics, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Deu, Infectious And Imported Diseases, Pediatric Unit, Esplugues de Llobregat, Spain, [3]Hospital Sant Joan de Deu, Orthopaedic Surgery And Traumatology, Esplugues de Llobregat, Barcelona, Spain, [4]Hospital Sant Joan de Deu, Infectious Diseases, Esplugues de Llobregat, Barcelona, Spain, [5]Saint John of God Hospital, Pediatrics Infectious Diseases, Esplugues de Llobregat, Spain

Backgrounds: Antimicrobial stewardship programmes(ASP) contribute to reducing unnecessarily prolonged antimicrobial courses. We aimed to describe the impact of a hospital ASP on the antibiotic treatment of acute hematogenous bone and joint infections(BJI) from 2017 in children in a tertiary referral hospital. ASP also changed first-line empiric antibiotics in the local protocol in June 2020 (from third generation-cephalosporin+cloxacillin combination to cefuroxime in <5 years old and from cloxacillin/6h to cefazolin/8h in ≥5 years old).
Methods: Unicentric retrospective study comparing pediatric patients(0-18 years) with acute hematogenous BJI admitted to a tertiary hospital in Barcelona(Spain) one year before (2016, period 1[P1]) and six years after (2017-22, period 2[P2]) the implementation of a multifaceted ASP with prospective audit as a primary strategy. Demographic and clinical characteristics and antibiotic treatment before and after ASP implementation and protocol change are described and compared.
Results: Figure 1 shows the main demographic and clinical characteristics of the 225 patients included. The length of parenteral antibiotic treatment(LPA) and the length of hospital stay(LOS) were significantly lower in P2 (median[IQR] days, P1: 9 [7-15] vs P2: 7 [5-8]; p=0.003; and P1: 9 [7-16] vs P2: 7 [5-9]; p=0.005, respectively), also in cases with positive blood culture (median[IQR] days of LPA and LOS, P1: 15 [10-20] vs P2: 9 [7-12], p=0.030 and p=0.049, respectively).
After June 2020, 3rd generation of cephalosporin use decreased in patients <5 years old (61/91 [67%] vs 4/38 [10%] cases; p<0.001). In patients ≥5 years-old cloxacillin utilization decreased (50/63 [79%] vs 5/32 [15%]), and cefazolin use increased (4/63 [6%] vs 18/32 [56%])
(p<0.001).

Figure 1. Demographic and clinical characteristics of patients with acute hematogenous BJI during period 1 (2016) and period 2 (2017-2022). We used Chi-squared and F-Fisher tests to compare categorical variables and U-Mann-Whitney test to cpmapre quantitative variables. Data are shown as number (percentatge) or median (IQR).

	Period 1 (2016) n= 24	Period 2 (2017-2022) n= 201	p-value
Age (years)	2.2 (1.4-10.5)	3.2 (1.4-10.8)	0.713

OM	13 (54.2%)	114 (56.7%)	
OA	3 (12.5%)	13 (6.5%)	
Sequelae after antibiotic	0 (0%)	12 (6%)	0.369

IQR: interquartile range; ESG: erythrocyte sedimentation rate; CRP: C reactive protein; SAMS: *Staphylococcus aureus methicillin-sensible*; SAMR: *Staphylococcus aureus methicillin-resistant*; SA: septic arthritis; OM: osteomyelitis; OA: osteoarthritis. *Period 1: n=13; period 2: n=118. **Period 1: n= 24, Period 2: n=196; ^Period 1: n=9, Period 2: n=101.

Conclusions/Learning Points: After ASP implementation, the use of generation cephalosporin, the length of parenteral antibiotic treatment and hospital stay in children with acute hematogenous BJI were safely reduced.

PD0011 / #1769

QUALITY AND QUALITY USE OF ANTIBIOTICS TO TREAT BLOODSTREAM INFECTIONS IN HOSPITAL-ADMITTED CHILDREN UNDER-FIVE IN A LOW-RESOURCE FIELD SETTING

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Bieke Tack[1,2,3], Daniel Vita[4], Emmanuel Ntangu[5], Japhet Ngina[5], Pathy Mukoko[6], Dina Vangeluwe[7], Jaan Toelen[3,8], Karel Allegaert[8,9,10], Octavie Lunguya[11,12], Raffaella Ravinetto[13], Jan Jacobs[1,2]
[1]Institute of Tropical Medicine, Department Of Clinical Sciences, Antwerp, Belgium, [2]KU Leuven, Department Of Microbiology, Immunology And Transplantation, Leuven, Belgium, [3]University Hospitals Leuven, Department Of Pediatrics, Leuven, Belgium, [4]Saint Luc Hôpital Général de Référence Kisantu, Internal Medicine, Kisantu, Congo, [5]Saint Luc Hôpital Général de Référence Kisantu, Paediatrics, Kisantu, Congo, [6]Saint Luc Hôpital Général de Référence Kisantu, Pharmacy, Kisantu, Congo, [7]Médecins Sans Vacances, Pharmacy, Mechelen, Belgium, [8]KU Leuven, Department Of Development And Regeneration, Leuven, Belgium, [9]KU Leuven, Department Of Pharmaceutical And Pharmacological Sciences, Leuven, Belgium, [10]Erasmus University Medical Center Rotterdam, Department Of Hospital Pharmacy, Rotterdam, Netherlands, [11]Institut National de Recherche Biomédicale, Department Of Microbiology, Kinshasa, Congo, [12]University Teaching Hospital of Kinshasa, Department Of Medical Biology, Kinshasa, Congo, [13]Institute of Tropical Medicine, Department Of Public Health, Antwerp, Belgium

Backgrounds: Quality-assured, appropriate antibiotics are essential for treatment of bloodstream infection, but are challenging in low-resource settings. In children admitted to Kisantu district hospital (DR Congo), we report field observations on quality and quality use of antibiotics (excluding appropriate antibiotic choice and ingredient quality).
Methods: Children under-five with suspected bloodstream infection were enrolled in a cohort study (01/08/2021 – 31/07/2022, NCT04850677). Treatment was documented until day 3, and until discharge for non-typhi Salmonella bloodstream infection. We performed a standardized visual inspection of antibiotics.
Results: Antibiotics were administered to 98.4% (1838/1867) of children. In only 61.7% (1135/1838) children, treatment was initiated on the admission day. Most frequent initial antibiotics were ceftriaxone (84.3%, 1550/1838) and cefotaxime (11.7%, 216/1838). Ciprofloxacin and azithromycin were used to treat third-generation cephalosporin resistant non-typhi Salmonella infections. Oral ciprofloxacin suspension was out-of-stock for 12-months nationwide. Minimum one prescribed dose was missed in 2.9% (67/2300) of prescriptions, most (46/67) for cefotaxime, due to failure to administer cefotaxime every 6 hours outside the twice-daily routine administration rounds (43/46). In 77.6% of prescriptions, calculated doses were not feasible to administer (e.g. gentamicin prescription 7.5mg/kg/dose for 8.9kg child = 66.75mg = 1.67ml). In 20.6% (37/180) of intravenous ciprofloxacin prescriptions, administered versus prescribed doses differed >16%, due to inaccurate aliquoting of multidose vials (Fig1). For 21/21 prescriptions of azithromycin tablets, unscored tablets were split and crushed, hampering accurate dosing. In oral suspensions, dosing accuracy was impaired by lack of instructions for reconstitution, tools to measure reconstituting volumes, and dosing devices (Fig1). Furthermore, access to safe (sterile) water was
limited.

Figure 1. Poor quality and quality use of antibiotics in a field setting:
A. Multidose use of a single-dose perfusion vial with inaccurate aliquoting of the vial indicated with tape.
B. Poorly packaged powder for suspension with absent instructions for reconstitution & absent dosing device.
C. Splitting an unscored tablet in four & crushing it to administer it to a 12 month old infant.
D. Administering the "dissolved" crushed powder to a 12 month old infant.
E. Inhomogenous suspension & caking of reconstituted powder.

Conclusions/Learning Points: Challenges for quality and quality use of antibiotics were delayed prescribing, inaccurate dosing, stock-outs and lack of formulations adapted to a pediatric, low-resource setting.

PD0012 / #2508

BENCHMARKING CROSS-SITE ANTIBIOTIC CONSUMPTION IN PAEDIATRIC HAEMATOLOGY-ONCOLOGY INPATIENTS WITH ROUTINELY COLLECTED ELECTRONIC PRESCRIBING DATA: A PILOT STUDY IN TWO UK TERTIARY UNITS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 01: ANTIMICROBIALS (STATION 01)

Samuel Channon-Wells[1], Caroline Herin[1], Ismail Elbeshlawi[1], Juliet Gray[2], Sanjay Patel[2], Stephane Paulus[1]
[1]Oxford Children's Hospital, Oxford University Hospitals NHS Foundation Trust, Department Of Paediatrics, Oxford, United Kingdom, [2]University Hospital Southampton NHS Foundation Trust, Department Of Paediatrics, Southampton, United Kingdom

Background: Systematic antimicrobial consumption data in paediatric inpatients is lacking, both in quantity and quality. Our pilot study demonstrates how the use of routinely collected electronic prescribing data can bridge this gap in a high-risk paediatric population.
Methods: We conducted an observational study comparing intravenous antibiotic use at two UK paediatric Haematology-Oncology units in Oxford and Southampton from 2018-2022. Monthly Days-of-Therapy (DOT) per 100-patient-days (PD) for intravenous antibiotics were extracted from antimicrobial surveillance systems at each site. We report total and specific antibiotic consumption. Linear regression and autoregressive moving average models were used to estimate trends.
Results: The total patient-days included were 18,505 for Oxford and 24,427 for Southampton. Median monthly DOT-per-100-PD for total intravenous antibiotic consumption at each site were similar (25.9 and 29.4). Total antibiotic consumption declined at both sites during the study period, with estimated annual yearly reduction in DOT-per-100-PD of 2.7 (95% confidence interval (CI): 0.7-4.7) for Oxford and 3.9 (95% CI: 2.2-5.6) for Southampton. Median intravenous consumption was similar for Carbapenems, Piperacillin/tazobactam and Aminoglycosides, whilst Ceftriaxone and Teicoplanin use demonstrated approximately threefold relative difference in median monthly consumption between sites. Meropenem, Piperacillin/tazobactam, Teicoplanin, Vancomycin and Gentamicin all demonstrated a statistically significant reduction in use over time at either one or both sites, and was most marked for Piperacillin/tazobactam and Vancomycin (Figure
1).

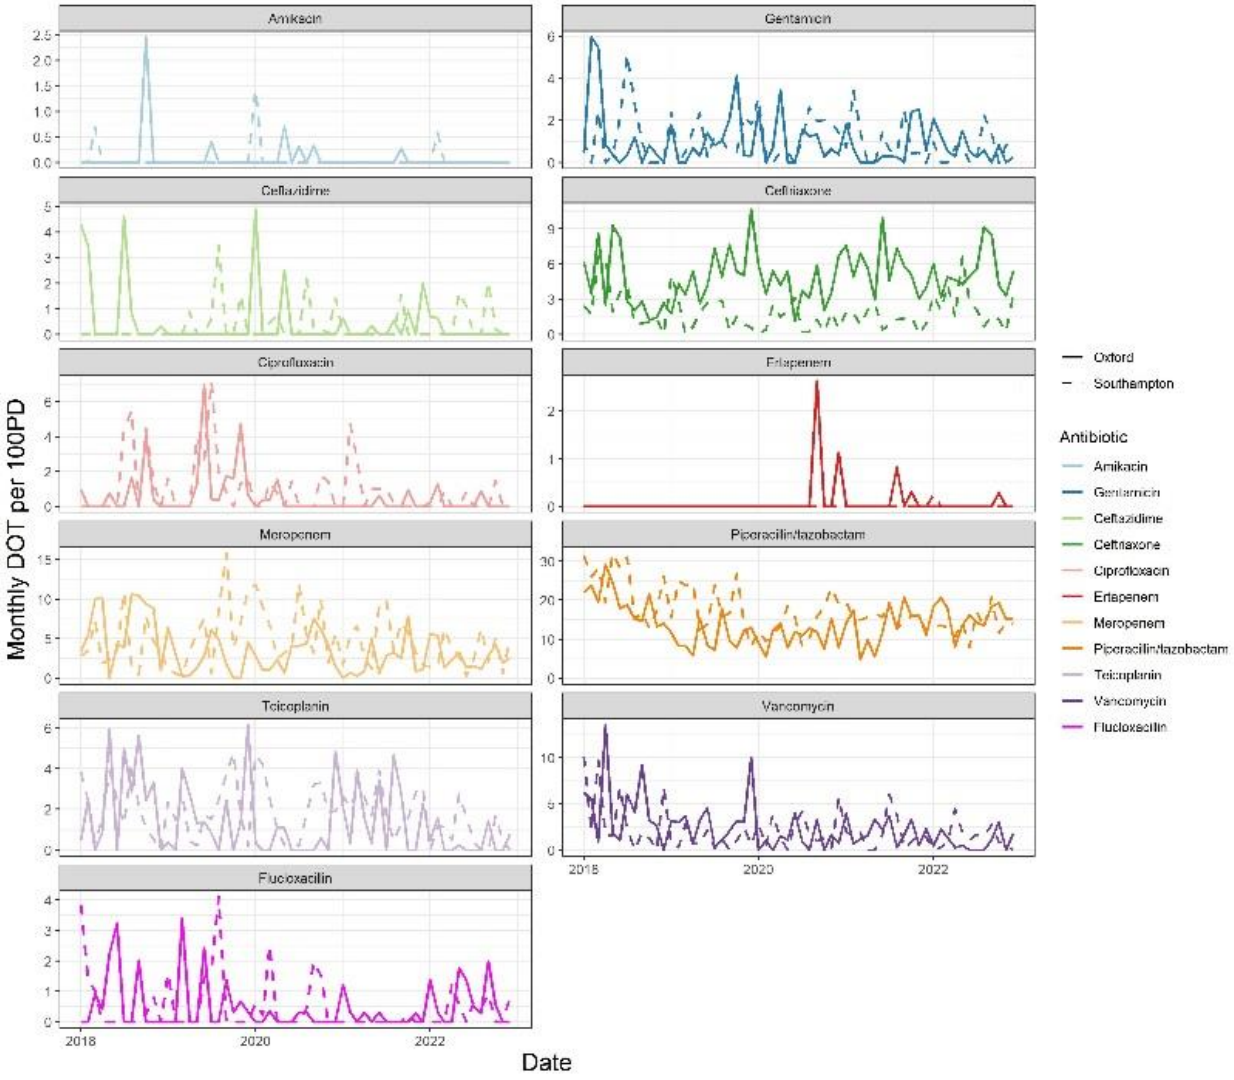

Figure 1: Monthly DOT-per-100-PD across the entire study period, separated by each antimicrobial and site. Solid line indicates results from Oxford site, and dashed line indicates results from Southampton site.

Conclusions/Learning Points: Routinely collected electronic prescribing records provide granular benchmarking data of antibiotic use in paediatric Haematology-Oncology patients across different sites. This approach can highlight areas to target antimicrobial stewardship interventions and evaluate their impact. This methodology should be rolled out more widely to establish a national framework for consumption reporting, and can be applied to other high-risk paediatric groups, including neonatal and paediatric intensive care units.

PD0013 / #2152

THE ADDED VALUE OF USING PULSE OXIMETER ROUTINELY INTO THE INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS GUIDELINES TO BETTER IDENTIFY AND MANAGE SEVERE CASES AMONG CHILDREN UNDER-5 YEARS OLD IN WEST AFRICA, JUNE 2021 TO JUNE 2022

E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Gildas Boris Hedible[1], Désiré Neboua[2], Lucie Peters Bokol[1], Gildas Anago[2], Zineb Zair[1], Severin Lenaud[3], Honorat Agbeci[1], Abdoul Guaniyi Sawadogo[4], Desire G Kargougou[5], Bertrand Meda[6], Jacques Seraphin Kolie[7], Sarah Louart[2], Valéry Ridde[8], Valeriane Leroy[1]
[1]Inserm, Umr1295, TOULOUSE, France, [2]ALIMA, Hq, Dakar, Senegal, [3]PACCI, Data Management, TOULOUSE, Côte d'Ivoire, [4]Terre des Hommes, Health Service, Ouagadougou, Burkina Faso, [5]ALIMA, Health Service, BAMAKO, Mali, [6]SOLTHIS, Health Service, Ouagadougou, Burkina Faso, [7]ALIMA, Health Service, CONAKRY, Guinea, [8]IRD, Ceped, Dakar, Senegal

Backgrounds: The Integrated Management of Childhood Illness (IMCI) guidelines for children under 5 is a symptom-based algorithm adapted to the primary health center (PHC) level in resource-limited countries. Hypoxemia is a life-threatening event often underdiagnosed clinically. The AIRE project, UNITAID-funded, has implemented routine use of Pulse Oximeter (PO) into IMCI consultations at PHCs in Burkina Faso, Guinea, Mali and Niger. We measured the added value of IMCI+PO use to improve the diagnosis and care-management of hypoxemia.
Methods: In 16 AIRE PHC research sites (4/country), all children aged 0-59 months attending IMCI consultations, except those aged 2-59 months classified as green without cough or breathing difficulties were eligible for PO use, and enrolled in a cross-sectional study with parental consent. Severe cases were followed-up during 14 days.
Results: From June 2021 to June 2022, 39,360 children attended IMCI consultations at the research PHCs, of whom 31,600 (80.2%) was eligible for PO use. Overall, 9,8% were identified as severe cases using IMCI alone (3,103/31,600; 95%CI: 9.5–10.2); and 60 cases newly identified. Prevalence of severe case using IMCI+PO was at 10% (3,103+60)/31,600; 95%CI: 9.7–10.3). Overall +1.9% (60/3,103; 95%CI: 1.5-2.5) were detected using PO alone. This added value was heterogeneous between countries: +0.9% (95%CI: 0.1-3.4), +0.3% (95%CI: 0.09-0.9), +3.2% (95%CI: 2.3-4.2), +2.9% (95%CI: 1.4-5.2), in BF, Guinea, Mali, Niger, respectively. Among the 60 additional severe cases identified only with PO, 25 of them were included and followed, 21 (84%) were transferred to district hospital but only 11 (44%) received an oxygen therapy.
Conclusions/Learning Points: The added value of IMCI+PO was estimated globally to +2% to better identify severe cases, with a similar effect except in Guinea and Burkina Faso. Their appropriate management remains challenging for West African governments.

PD0014 / #457

INCREASED RISK OF LONG-TERM SEQUELAE FOLLOWING CHILDHOOD BACTERIAL MENINGITIS IN SWEDEN: 1987-2021

E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Salini Mohanty[1], Urban Johansson Kostenniemi[2], Sven Arne Silfverdal[3], Stina Salomonsson[4], Federico Iovino[5], Eric Sarpong[6], Goran Bencina[7], Gustaf Bruze[8]
[1]Merck & Co. Inc., Center For Observational And Real World Evidence (core), Rahway, United States of America, [2]Umeå University, Department Of Clinical Microbiology, Umeå, Sweden, [3]Umeå University, Department Of Clinical Sciences, Umeå, Sweden, [4]MSD Sweden, Center For Observational And Real World Evidence (core), Stockholm, Sweden, [5]Karolinska Institute, Department Of Neuroscience, Stockholm, Sweden, [6]Merck & Co. Inc., Real-world Data Analytics & Innovation, Rahway, United States of America, [7]MSD Spain, Center For Observational And Real World Evidence (core), Madrid, Spain, [8]Karolinska Institutet, Department Of Medicine, Solna, Stockholm, Sweden

Backgrounds: Survivors of bacterial meningitis are at risk for long-term disabling sequelae. The objective of this study was to describe the frequency and severity of sequelae following childhood bacterial meningitis in Sweden.
Methods: This is a matched cohort study of individuals diagnosed with bacterial meningitis in childhood (<18 years) between 1987 and 2021. Cases of bacterial meningitis were matched with controls regarding sex, birth year, and place of residence. Post-meningitis sequelae were identified in the nationwide Swedish National Patient Register (cognitive disabilities, seizures, hearing loss, motor function disorders, visual disturbances, behavioral disorders, and intracranial structural injury) and further stratified by three major causes of bacterial meningitis (Streptococcus pneumoniae, Neisseria meningitidis, and Haemophilus influenzae).
Results: The cohort included 3,623 individuals diagnosed with bacterial meningitis in childhood (cases) and 32,607 matched general population controls. The mean age at diagnosis was 4.1 years and median follow-up time was 23.7 years. Cases had a higher cumulative incidence of all seven sequelae relative to the controls. The highest absolute risk of sequelae was found for visual disturbances, hearing loss, and behavioral disorders. The estimated hazard ratios (HRs) for sequelae showed a significant increased risk for cases relative to controls for all categories of sequelae. The estimated adjusted HR (95% confidence intervals) showed a largest relative risk for intracranial structural injury 29.4 (18.3-47.4), seizures 4.76 (4.01-5.65), and motor function disorders 4.70 (3.94-5.60) (Table 1). The adjusted HRs for cognitive disabilities, seizures, hearing loss, motor function disorders, visual disturbances, and intracranial structural injury were significantly higher for Streptococcus pneumoniae compared to Haemophilus influenzae and compared to Neisseria
meningitidis.

Table 1: Risk for Sequelae: Adjusted* Hazard Ratios (HR)

	Events		Rate (per 100,000 person-years)		HR (95%CI)
	Bacterial Meningitis (n=3623)	Controls (n=32,607)	Bacterial Meningitis (n=3623)	Controls (n=32,607)	
Cognitive Disability	265	610	352	86.6	3.3 (2.8-3.8)
Seizures	249	398	332	56.4	4.8 (4.0-5.7)
Hearing Loss	461	961	635	137	4.1 (3.7-4.6)
Motor Function Disorders	263	354	351	50.1	4.7 (3.9-5.6)
Visual Disturbances	478	1523	654	219	2.3 (2.0-2.5)
Behavioral Disorders	370	2315	494	335	1.4 (1.3-1.6)
Intracranial Structural Injury	214	58	284	8.16	29.4 (18.3-47.4)

* Adjusted for age at the index date, the index year, sex, education of mother, education of father, birth characteristics (5-minute Apgar score, birth weight, head circumference), and seven pre-existing condition (malignancies, perinatal complications, psychiatric disorders, central nervous system disease, congenital di traumatic injuries, and operations in the nervous system).

Conclusions/Learning Points: The results highlight the increased risk for long-term disabling sequelae among individuals in Sweden diagnosed with childhood bacterial meningitis, particularly pneumococcal meningitis.

PD0015 / #746

SUSTAINED HERD PROTECTION AGAINST INVASIVE PNEUMOCOCCAL DISEASE (IPD) IN YOUNG INFANTS, 10 YEARS POST PCV7/PCV13 IMPLEMENTATION WITH A 2+1 DOSE SCHEDULE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Ron Dagan[1], Bart Van Der Beek[1], Orli Megged[2], Shalom Ben-Shimol[3,4], Meirav Mor[5]
[1]Ben-Gurion University of the Negev Faculty of Health Sciences, The Shraga Segal Dept. Of Microbiology, Immunology And Genetics, Beer Sheva, Israel, [2]Shaare Zedek Medical Center, Pediatric Infectious Diseases, Jerusalem, Israel, [3]Ben Gurion University, Faculty Of Health Sciences, Beer Sheva, Israel, [4]Soroka University Medical Center, Pediatric Infectious Disease Unit, Beer Sheva, Israel, [5]Schneider Children's Medical Center, Infectious Disease Unit, Petah Tikva, Israel

Backgrounds: PCV7 and PCV13 were implemented in the Israeli infant immunization plan using a 2+1 schedule (2, 4, 12m) in 2009 and 2010, respectively. Despite the wide adoption of the 2+1 schedule globally, head-to-head studies comparing this schedule with the originally licensed 3+1 schedule were not done, resulting in still prevailing doubts about whether the 2+1 and 3+1 schedules provide similar indirect protection. To assess the extent of indirect (herd) protection from PCV13-vaccinated children to non-immunized/partially immunized infants, we compared the annual IPD rates in the late PCV13 period (2016-2019) vs. the pre-PCV period (2004-2008) in children <4m (scheduled for ≤1 dose), 4-6m (immediate post-dose 2), 7-12m (a few months post-dose 2), and 13-23m (post-dose 3 [booster dose]).
Methods: The methodology of the nationwide IPD prospective study in children (the IsraNIP program) was previously described (Ben-Shimol, CID 74:1639-1649, 2022). There were 286,500, 311,500, and 367,900 children <24 months in Israel in 2004, 2009, and 2019 respectively. PCV13 serotypes (VT13), non-VT13, and total IPD incidence rates in the late-PCV13 (2016-2019) vs. pre-PCV (2004-2008) period were calculated for each age group.
Results:

		Pre-PCV (2004-2008)	Late-PCV (2016-2019)	IRR* Late vs. Pre
Children <4 months				
	VT13	20.8 ± 7.9	1.6 ± 1.1	0.08 (0.03-0.26)
	non-VT13	3.4 ± 3.9	7.7 ± 0.9	2.26 (0.81-6.26)
	Total	24.2 ± 6.9	9.3 ± 0.5	0.38 (0.21-0.68)
Children 4-6 months				
	VT13	12.3 ± 1.5	0.9 ± 0.6	0.09 (0.02-0.68)
	non-VT13	2.4 ± 0.9	5.7 ± 1.8	2.01 (0.63-6.42)
	Total	14.7 ± 2.0	6.6 ± 1.5	0.44 (0.22-0.89)
Children 7-12 months				
	VT13	49.4 ± 2.9	1.6 ± 1.3	0.03 (0.01-0.11)
	non-VT13	8.2 ± 2.6	17.9 ± 3.9	2.22 (1.14-4.29)
	Total	57.6 ± 3.4	19.6 ± 4.9	0.34 (0.23-0.50)
Children 13-23 months				
	VT13	82.7 ± 4.8	1.5 ± 0.3	0.02 (0.01-0.06)
	non-VT13	6.3 ± 2.2	25.4 ± 3.4	4.09 (2.00-8.35)
	Total	89.3 ± 2.8	26.9 ± 3.1	0.30 (0.22-0.42)

* Incidence Rate Ratio

The incidence rate ratio of IPD caused by VT13 during the late PCV13 vs. pre-PCV period for children <4m, 4-6m, 7-12m, and 13-23m were 0.08, 0.09, 0.03, and 0.02, respectively (Table). Reductions for all age groups scheduled to be post-dose 2 exceeded 95%, with no significant difference between the groups scheduled to be post-dose 2 vs. the post-booster group.

Conclusions/Learning Points: The 2+1 PCV13 schedule was highly protective for those not completely vaccinated, with similar rates of VT13 IPD, suggesting that the high impact of the 2+1 schedule is similar to that of the 3+1 schedule.

PD0016 / #701

SARS-COV-2 PANDEMIC INDUCED CHANGES IN SEROYPE PREVALENCE AMONG CHILDREN WITH INVASIVE PNEUMOCOCCAL DISEASE (IPD) IN GERMANY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Mark Van Der Linden, Andreas Itzek
University Hospital RWTH Aachen, National Reference Center For Streptococci, Department Of Medical Microbiology, Aachen, Germany

Backgrounds: Infant PCV vaccination was universally recommended in Germany in 2006. SARS-CoV-2 reached Germany at the beginning of March 2020. Here, we present data on the serotype distribution of invasive IPD cases among children under the age of 18 years, before and during the pandemic.
Methods: IPD in children in Germany has been monitored since 1997. Isolates were serotyped using the Neufeld Quellung reaction.
Results: From June 2020-March 2021, only 55 cases were reported, compared to 189 cases in the same period one year earlier. From June 2021-March 2022 case numbers increased to 169, and in the current season 137 cases have been reported thus far (June 2022-January 2023). Serotype distributions in June 2019-March 2020, June 2021-March 2022 and June 2022-Jan 2023, were similar but differed from June 2020-March 2021. Prevalence of serotypes 3 and 8 was strongly reduced, serotypes 10A, 15C, 23A and 23B increased. Serotype 24F strongly decreased only during June 2021-March 2022. PCV13-serotype prevalence was 23.8% (PCV15: 32.3%, PCV20: 55.0%) in June 2019-March 2020, and decreased to 7.3% (9.1%, 30.9%) in June 2020-March 2021. After June 2021, PCV13 prevalence increased to 35.8% (40.1%, 56.2%). This increase was most prevalent among children 2-4y. (47.1%, 51.0%, 56.7%) and 5-17y. (42.9%, 47.6%, 69.0%). Among children 0-1y., PCV13 prevalence reduced to pre-pandemic levels (13.6%). Most prevalent PCV13 serotypes were 3 and 19A.
Conclusions/Learning Points: During the SARS-CoV-2 pandemic IPD case numbers were strongly reduced. Due to non-pharmaceutical interventions (NPI) numbers of reported IPD cases decreased till June 2021, when NPI were relieved and numbers quickly increased to pre-pandemic levels. Serotypes 3 and 8 were less prevalent, 10A, 15C, 23A and 23B increased. After June 2021, higher numbers of PCV13-type IPD were observed among older children.

PD0017 / #878

EPIDEMIOLOGY OF BLOODSTREAM INFECTIONS AND ASSOCIATION WITH CARBAPENEM-RESISTANT COLONIZATION IN PEDIATRIC ONCOLOGY PATIENTS: FIVE-YEAR RESULTS OF A TWO-CENTER STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Violetta Magdalini Darda[1], Elias Iosifidis[1], Maria Kourti[1], Charalambos Zarras[2], Angeliki Kassomenaki[3], Paraskevi Mantza[3], Efthymia Protonotariou[3], Lemonia Skoura[3], Athanassios Tragiannidis[4], Emmanuel Hatzipantelis[4], Asimina Galli-Tsinopoulou[4], Eugenia Papakonstantinou[5], Emmanuel Roilides[1]
[1]Hippokration, 3 Rd Department Pediatrics, School Of Medicine, Faculty Of Health Sciences, Aristotle University Of Thessaloniki, Thessaloniki, Greece, [2]Ippokratio, Microbiology Department, Thessaloniki, Greece, [3]AHEPA, Microbiology Department, Thessaloniki, Greece, [4]AHEPA, Children's & Adolescent's Hematology-oncology Unit, 2nd Department Of Pediatrics, Thessaloniki, Greece, [5]Ippokratio, Pediatric Oncology Department, Thessaloniki, Greece

Backgrounds: Bloodstream infections (BSI) can be life-threatening, especially caused by carbapenem-resistant (CR) isolates, due to restricted therapeutic options. The association between CR-colonization and CR-BSI has been described mainly in adults. The aim of this study was to assess the epidemiology of BSI and its correlation to CR gut colonization in pediatric oncology patients.
Methods: Patients (≤16 years) treated in two pediatric oncology centers between 2018 and 2022 were retrospectively screened for BSI and CR colonization. The patients with BSI, those with CR-colonization, and those that were CR-colonized and developed BSI were recorded. All blood and colonization isolates were recorded. Logistic regression between BSIs due to Gram-negative or other bacteria among CR-colonized patients was performed.
Results: A total of 372 patients were hospitalized during the study period. Females were 52.2% and the median age was 5 (IQR:7.5) years. Sixty-two (16.7%) patients were found CR-carriers. Seventy-three (19.6%) patients acquired BSI of which 4 (5.5%) were due to CR isolate. The majority (75%) of patients with CR-BSI were CR-carriers (similar antimicrobial susceptibility testing). Gram-negative bacteria predominated (65.8%) compared to Gram-positive pathogens (30.1%). Three fungemias (4.1%) were also noted. Twenty-one (43.8%) patients with Gram-negative BSI were CR-carriers, compared to 5 (20%) with other BSIs (OR: 3.11, 95%CI: 1.06-10.59). Escherichia coli was the most frequent (35.4%) Gram-negative bacteria, whereas Staphylococcus aureus was the most frequent Gram-positive bacteria (47.4% of Gram-positive isolates, MRSA: 33.3%).
Conclusions/Learning Points: Gram-negative bacteria were the most frequently isolated pathogens in pediatric oncology patients with BSI. CR-carriers are three times more likely to acquire Gram-negative BSI and CR-BSI, compared to non-CR carriers. These findings could help to choose the appropriate use of empirical antibiotic treatment according to the local epidemiology.

PD0018 / #926

INVASIVE PNEUMOCOCCAL DISEASE IN CHILDREN: EPIDEMIOLOGIC AND CLINICAL TRENDS DURING THE COVID-19 PANDEMIC.

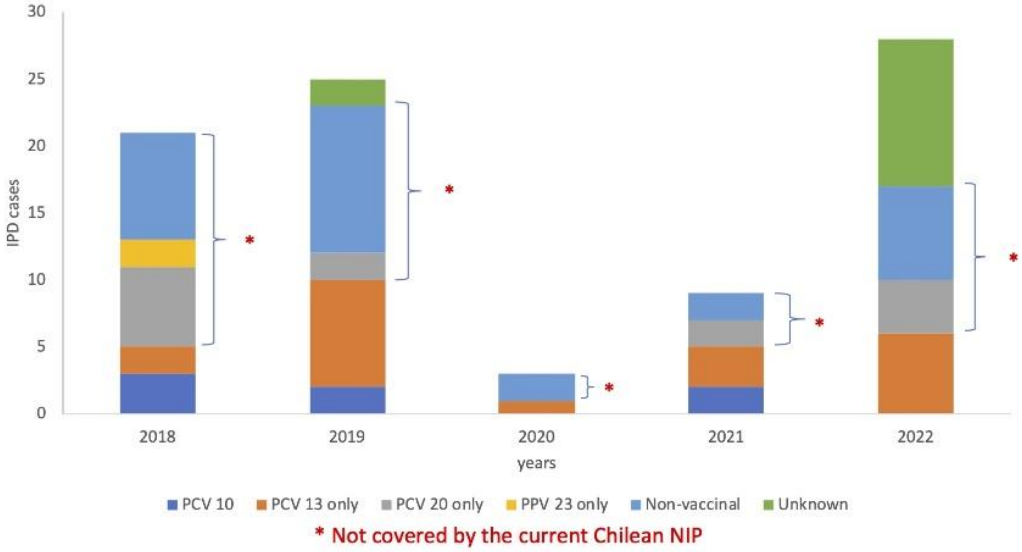
E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Giannina Izquierdo[1,2], Carolina Rivacoba[1], Marcela Zuñiga[2,3], Dona Benadoff[2,4], Javiera Albornoz[2], Paula Chavez[2], Paula Leal[1], Rodolfo Villena[1,2]
[1]Hospital Exequiel González Cortés, Infectious Diseases Unit, Santiago, Chile, [2]Faculty of Medicine, Universidad de Chile, Department Of Pediatrics, Santiago, Chile, [3]Hospital Roberto del Río, Infectious Diseases Unit, Santiago, Chile, [4]Hospital Roberto del Río, Laboratorio De Microbiología, Santiago, Chile

Backgrounds: During the Covid-19 pandemic many countries experienced a significant reduction of Invasive Pneumococcal Disease (IPD). A risk of rebound after the lifting of restrictions has been suggested. The aim of this study is to describe the epidemiological and clinical trend of IPD in the pre and postSARS-CoV-2 periods.
Methods: Descriptive study of IPD cases, admitted at 3 tertiary pediatric hospitals in Santiago, Chile, during preSARS-CoV-2 (2018–2019) and postSARS-CoV-2 (2020-2022) periods. Epidemiologic, clinic and microbiologic data were obtained from clinical and microbiological records, Public Health Institute and National Immunization Program (NIP).
Results: 86 cases were reported, 47 pre and 39 postSARS-CoV-2 respectively with a significant reduction in 2020. Median age 26 months (p25-75 12.7-57), 59% males. The most frequent diagnoses were: complicated/bacteremic pneumonia (40.6%), bacteremia (19,7%), septic shock (15.1%) and meningitis (4,6%).Median length of hospitalization: 7.5 days (p25-75 4-15), PICU admission: 43%; 30 days-CFR: 3.5%. There was no difference between the pre and postSARS-CoV-2 periods regarding number of IPD cases (Figure 1), PICU admission and 30 days-CFR, as the proportion of meningitis, bacteremia and septic shock, except for an increase trend of complicated pneumonias. Pneumococcal serotype identification occurred in 73 cases (85%); being 19A (16,4%), 24F (13,6%) and 3 (10,9%) the most prevalent. Included in PCV-10: 9,5%; PCV-13 only: 27,4% and PCV-20 only: 19%. Non-vaccinal serotypes: 41%. 57% of cases occurred in fully vaccinated subjects, and vaccine failure was evidenced in 8 cases (comorbidities: 50% 71%: 2+1 schedule), without deaths.
Conclusions/Learning Points: Significant reductions in IPD were observed during the postSARS-CoV-2 period, but sustained increase has been evidenced after restrictions were eased. Despite non-vaccinal serotypes being predominant, a high vaccine coverage is of paramount importance to maintain population

protection.

Figure 1. IPD cases by serotypes, Chile 2018-2022



PD0019 / #1602

ACUTE LOWER TRACT INFECTION IN HOSPITALIZED PATIENTS: 2022 INFLUENZA SEASON IN ARGENTINA. A MULTICENTER STUDY.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Angela Gentile[1], Maria Del Valle Juarez[1], Gabriela Ensinck[2], Oscar Lopez[3], Lucía Romero Bollon[1], Tatiana Fernandez[4], Andres Gioiosa[4], Gustavo Lazarte[2], Silvina Lobertti[2], Andrea Graboviezki[3], Silvia Villordo[3], Gabriela Gregorio[4]
[1]Ricardo Gutierrez Children's Hospital, Epidemiology, Buenos Aires, Argentina, [2]Vilela Children's Hospital, Infectious Disease, Rosario, Argentina, [3]Hospital Pediátrico “Fernando Barreyro”, Pediatrics, Posadas, Argentina, [4]Hospital Nacional “Prof. Alejandro Posadas”, Pediatrics, Buenos Aires, Argentina

Backgrounds: Respiratory disease is 3rd cause of death in Argentina. Influenza vaccine is mandatory for children between 6-24 months. Objectives: to describe the clinical and epidemiologic patterns of ALRI and influenza (IF) infection in four Argentina different regions.
Methods: A prospective, multicenter cross-sectional study of patients admitted for ALRI in Buenos Aires province, Buenos Aires city, Rosario and Misiones between January and December 2022. Virological diagnosis was made by real time-PCR or Film Array. A multivariate analysis was performed to found independent predictors (IP) of influenza infections factors comparing with others viruses.
Results: A total of 1,636 ALRI were included; 98.2% tested (1606) and 70,9% (1139) had positive results. Viral distribution: RSV 27.8%, Rhinovirus 21.1% Metapneumovirus 13.5%; Influenza 8.7 %[(60% type A, 40% type B (Victoria)], Parainfluenza 8.7%, Adenovirus 5.2%; SARS-CoV-2 5%; Picornavirus 2.1%. Median age:11 months (RI=5-30mo). ALRI lethality: 0.6% (9/1606): Influenza: 2.2% (3/139); Rhinovirus: 0.6% (2/339); Metapneumovirus: 0.5% (1/217). Influenza (n=139) showed a bimodal pattern (EW9-14 late summer; EW38-45 spring). Median age:27 months (IR:7-71 months). Age distribution:<6 months (20.1%), 6-23 months (31%), 2-4 yrs. (17.3%), >5 yrs. (31.7%). Influenza vaccination coverage (6-24 months):28.7% (over 512 vaccination cards evaluated). Most frequent clinical feature was consolidated pneumonia(76.3%); 10.8% were born preterm, 60.4% had comorbidities; 10.4% required AVM and 11.8% CAFO. From 6-24 months influenza cases (n=43), 40 had vaccination card and only 20% had complete schedule. Influenza infection independent predictors: pneumonia as clinical presentation [OR:3,6 (CI95%=2,3-5,4) p<0,001] and malnourishment [OR:2,5 (IC95%=1,2-5,3) p=0,0139].
Conclusions/Learning Points: 62% of IF cases had less than 5 years (group involved in transmission). Influenza had the highest lethality rate. Vaccine coverage was low.

PD0020 / #1623

IMMUNE RESPONSES TO VACCINATION IN HIV VERTICALLY-INFECTED PATIENTS: A LONG TERM EVALUATION.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Annachiara Zin[1], Daniele Mengato[2], Andrea Francavilla[3], Lorenzo Chiusaroli[1], Carlo Giaquinto[1], Daniele Donà[1], Osvalda Rampon[1]
[1]University of Padua, Division Of Pediatric Infectious Diseases, Department Of Women's And Children's Health, Padua, Italy, [2]University Hospital of Padua, Hospital Pharmacy Department, Padua, Italy, [3]University of Padua, Unit Of Biostatistics, Epidemiology And Public Health, Department Of Cardiac, Thoracic, Vascular Sciences And Public Health, Padua, Italy

Backgrounds: Despite successful antiretroviral therapy (ART), people living with HIV are at risk of suboptimal vaccine response, exposing this vulnerable population to common vaccine-preventable diseases.
Methods: This was a cross-sectional observational study investigating humoral responses to vaccination in HIV-vertically infected patients. We analyzed the seroprotection rate at specific time points since primary immunization for diphtheria, tetanus, measles, mumps, rubella, varicella and hepatitis B, reviewing the serological analysis and medical records available for each patient from 2004 to 2022. Only vaccinated patients were included in the study, and booster doses were excluded. Associations between vaccine outcome and predictive factors were analyzed.
Results: 82 vertically-infected patients were included; all were on ART with a median age of 24 years (IQR 16-29) at enrollment. Two years after the last vaccine dose, the seroprotection rate was 71% for diphtheria, 79% for tetanus and measles, 67% for mumps, 87% for rubella and 54% for varicella. After five years, 50-70% of patients maintain protective antibodies, dropping to 50-58% after ten years. After 20 years, protection is < 30% for all vaccines, except for rubella (47%). Seroprotection for hepatitis B is the lowest: only 60%, 37%, 24% and 7.5% maintained protective IgG titre after, respectively, 2-5-10 and 20 years since vaccination. Patients who maintained protective antibody levels over time were younger, started ART by 12 months, and were fully vaccinated after being started on ART ($p<0.05$).
Conclusions/Learning Points: In this small-size population of HIV vertically-infected patients, seroprotection to vaccination was lower and less durable than expected in the general population. Therefore, periodic seroprotection monitoring and revaccination are crucial in managing these patients. Early initiation of ART seems to create the most favorable conditions for optimizing vaccination outcomes.

PD0021 / #1700

DETECTION AND MOLECULAR CHARACTERIZATION OF HUMAN PARECHOVIRUS IN RESPIRATORY INFECTIONS IN LOMBARDY (NORTHERN ITALY), FROM AUGUST TO DECEMBER 2022

E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Laura Pellegrinelli, Arlinda Seiti, Cristina Galli, Valeria Primache, Giovanni Anselmi, Emanuela Matteucci, Sandro Binda, Elena Pariani
UNIVERSITY OF MILAN, Department Of Biomedical Sciences For Health, MILAN, Italy

Backgrounds: Human Parechovirus (HPeV) is generally associated with mild respiratory and/or gastrointestinal infection. However, it may occasionally cause severe disease such as meningitis, encephalitis and acute flaccid paralysis, particularly in young children. This study aimed at: 1) detecting and investigating the role of HPeV in respiratory infections in Lombardy from August to December 2022; 2) molecularly characterizing HPeV strains.
Methods: Nasal-pharyngeal swabs (NPSs) were collected from influenza-like illness (ILI) paediatric outpatients (0-14 years) in the framework of the Italian influenza surveillance network (InfluNet&RespiVirNet) and from acute respiratory infections (ARI) outpatients in the framework of RSV surveillance study (RSVComNet). NPSs were collected from August 1, to December 30, 2022. All NPSs were tested by real-time RT-PCR targeting the untranslated region of HPeV. The VP1/VP3 region (nt 2159-2458) of all HPeV-positive samples was sequenced.
Results: 832 NPSs were collected from as many ILI (n=733) and ARI (n=99) cases. HPeV was detected in 5.7% (n=48) of NPSs: 4.6% (34/733) collected from ILIs, and 14.1% (14/99) from ARIs. The median age of HPeV-positive cases was 1 year (IQR: 2.25 years). HPeV was identified from week 37-2022 to week 50-2022 peaking in week 48-2022. 87.5% (42/48) of HPeV-positive cases were children ≤4 years. In 93.8% of HPeV-positive samples another respiratory virus was detected. 40% (19/48) of HPeV strains were sequenced and their molecular characterization revealed that: 10% (2/19) were subtype 1, 16% (3/19) subtype 3, 21% (4/19) subtype 5, and 53% (10/19) subtype 6.
Conclusions/Learning Points: In our series, HPeV was detected in nearly 6% of cases, mainly in children ≤4 years with ARI. In most samples HPeV was detected with another respiratory virus. Molecular characterization of detected strains showed the co-circulation of several subtypes, with HPeV-6 being the predominant.

THE OUTPATIENT AND INPATIENT PEDIATRIC POPULATION OF MANHIÇA DISTRICT THROUGH A GENDER LENS: A 17-YEAR RETROSPECTIVE STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 02: PUBLIC HEALTH I (STATION 02)

Núria Balanza[1], Sara Ajanovic[1], Aura Hunguana[2], Rosauro Varo[1], Justina Bramugy[2], Arsenio Nhacolo[2], António Sitoe[2], Llorenç Quintó[1], Sozinho Acácio[2], Khátia Munguambe[2], Inacio Munduapege Mandomando[2], Charfudin Sacoor[2], Caterina Guinovart[1], Quique Bassat[1]
[1]Barcelona Institute for Global Health (ISGlobal), Campus Clínic, Barcelona, Spain, [2]Centro de Investigação em Saúde de Manhiça, -, Manhiça, Mozambique

Backgrounds: Gender-based health inequalities in the pediatric population have been previously reported in different countries, especially in South Asia, but data are scarce in others regions like sub-Saharan Africa. In this study we analyzed whether girls differ over boys with respect to health-seeking behavior, clinical management, and outcomes in the district of Manhiça, Mozambique.
Methods: Retrospective analysis of data collected through the Manhiça morbidity surveillance system on all pediatric visits to seven outpatient clinics (>1.1 million) and all admissions (>41,000) to the Manhiça District Hospital between 2004-2020. Minimum community-based incidences rates (MCBIRs) of outpatient visits and hospital admissions were estimated using demographic surveillance system data. Data were stratified by age groups (<3 months, 3-59 months, 5-9 years, and 10-<15 years) and calendar years.
Results: Girls represented a slightly lower overall percentage of pediatric outpatient visits (49.2%) and hospital admissions (45.1%) than boys. Girls accounted for 50.3% of children <15 years old living in the study area during the study period. Consequently, MCBIRs of outpatient visits and hospital admission were also marginally lower in girls. Both groups reported similar number of days with symptomatology before arriving to a health post or being admitted to the hospital. Severity traits at presentation tented to be more frequent among male outpatients and inpatients, although patterns changed by age group. The hospital case fatality rate in girls was 4.2% and in boys it was 4.1%.
Conclusions/Learning Points: We did not find important differences in terms of access to health system and outcomes between boys and girls. More in-depth research focused on potential differences according to syndrome or specific diseases is warranted to continue evaluating whether inherent gender biases may affect health outcomes.

Backgrounds: Varicella is still a ubiquitous disease of childhood in the UK, whilst highly effective and safe vaccines have been routinely used in other countries for more than 20 years. UK assessments of varicella vaccines did not meet the National Institute for Health and Care Excellence cost utility threshold, in part due to limited data quantifying the quality of life (QoL) lost in children.
Methods: We carried out a prospective multicentre observational study recruiting families while their child was suffering with acute chickenpox infection or secondary complications. We included both cases admitted to hospital and community cases. Quality of life was assessed using standard tools: EQ5D-5L + CHU9 for children and EQ5D-5L for both carers. In hospitalised patients, assessments were carried out daily until discharge, weekly for 1 month then a follow-up at six months. In the community arm, assessments were daily until back to normal health.
Results: Between 2018 and 2022 we recruited 128 hospitalised and 68 community cases. In children the mean Quality Adjusted Life Year (QALY) loss was 38.7 (36.2-40.2)/1000 hospitalised and 5.8 (5.5-6.6)/1000 community cases. Primary carers lost 20.4(19.2-22.1)/1000 hospitalised or 2.1(2.0-2.4)/1000 community cases. Secondary carers lost 16.9(15.9-18.6)/1000 hospitalised and 0.6 (0.3-0.7)/1000 community cases. Mean length of hospital stay was 4.5days (IQR 1-4.8) but total length of illness in hospitalised cases was a median of 30 days (IQR 23-37).
Conclusions/Learning Points: This detailed prospective assessment of QoL loss from chickenpox has found it to be 1.5 times larger for community cases and 10 times larger for hospitalised children than that used in previous economic assessments and has also demonstrated substantial QALY loss for both primary and secondary carers. These data can be used to help parameterise new assessments of UK varicella vaccine cost utility.

PD0024 / #1793

A PHASE 3 TRIAL EVALUATING THE SAFETY AND IMMUNOGENICITY OF A 20-VALENT PNEUMOCOCCAL CONJUGATE VACCINE IN HEALTHY CHILDREN 15 MONTHS THROUGH 17 YEARS OF AGE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 03: VACCINES (STATION 03)

Jay Meyer[1], Peter Silas[2], G. Laïssa Ouedraogo[3], Kathleen Mcelwee[3], Georgina Keep[4], James Trammel[3], Yahong Peng[3], Ingrid Scully[5], William Gruber[5], Daniel Scott[3], Wendy Watson[3]
[1]Meridan Clinical Research, Meridan Clinical Research, Lincoln, United States of America, [2]Wee Care Pediatrics, Pediatrics, Syracuse, United States of America, [3]Pfizer Inc, Vaccine Research And Development, Collegeville, United States of America, [4]Pfizer UK, Vaccine Research And Development, Hurley, United Kingdom, [5]Pfizer Inc, Vaccine Research And Development, Pearl River, United States of America

Backgrounds: A 20-valent pneumococcal conjugate vaccine (PCV20) was developed to extend protection against pneumococcal disease. Safety and immunogenicity findings are reported for PCV20 in children 15 months through 17 years of age.
Methods: This phase 3, single-arm study (NCT04642079) enrolled healthy US children (≥15 to <24 months, ≥2 to <5 years, ≥5 to <10 years, ≥10 to <18 years of age) to receive a single dose of PCV20. Children <5 years of age had ≥3 PCV13 doses before enrolment. Local reactions and systemic events were collected for 7 days; adverse events (AEs) and serious AEs (SAEs) were collected for 1 and 6 months, respectively. Immunoglobulin G (IgG) concentrations and opsonophagocytic activity (OPA) titers to vaccine serotypes were measured in sera before and 1 month after vaccination.
Results: 831 study participants were vaccinated (201–216 per cohort). Local reactions and systemic events were predominantly mild/moderate in intensity. Pain at injection site was the most common local reaction reported across all age groups. AE frequencies ranged from 4.4% in the oldest age cohort to 23.9% in the youngest; headache and muscle pain (older age cohorts), fatigue (≥2 to <5 years of age), and irritability (≥15 to <24 months of age) were the most common. SAEs were uncommon. IgG geometric mean fold-rises (GMFRs) from before to 1 month after PCV20 for the 7 additional serotypes and the PCV13 serotypes ranged from 10.5–1847.7 and 2.9–127.9, respectively, and OPA GMFRs ranged from 11.5–983.6 and 2.8–147.9, respectively, across age cohorts.
Conclusions/Learning Points: PCV20 had a satisfactory safety profile and immune responses with the potential to extend the benefit for the 7 additional vaccine serotypes in children 15 months through 17 years of age.

PD0025 / #2129

PERSISTENCE OF HSBA TITERS ELICITED BY A PENTAVALENT MENABCWY VACCINE AND IMMUNOGENICITY, SAFETY, AND TOLERABILITY OF A BOOSTER DOSE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 03: VACCINES (STATION 03)

James Peterson[1], Daniel Drazan[2], Beth Moughan[3], Jason Maguire[3], Lefteris Zolotas[4], Roger Maansson[3], Robert O'Neill[5], Paula Peyrani[6], Luis Jodar[6], William Gruber[5], Annaliesa Anderson[5], Johannes Beeslaar[4]
[1]J Lewis Research, General Practice, Salt Lake City, United States of America, [2]General Practice for Children and Adolescents, Pediatrics, Jindrichuv Hradec, Czech Republic, [3]Pfizer, Vaccine Research And Development, Collegeville, United States of America, [4]Pfizer, Vaccine Research And Development, Hurley, United Kingdom, [5]Pfizer, Vaccine Research And Development, Pearl River, United States of America, [6]Pfizer, Vaccines/antivirals And Evidence Generation, Collegeville, United States of America

Backgrounds: Comprehensive protection of adolescents and young adults against meningococcal disease requires protection from serogroups A/B/C/W/Y. Previous results demonstrated safety and immunogenicity of a primary series of a MenABCWY vaccine composed of 2 licensed vaccines, MenB-fHbp and MenACWY-TT. We report persistence of immune responses from that study and safety and immunogenicity of a booster dose.
Methods: This active-controlled study randomized 10–25-year-olds stratified according to prior ACWY vaccination history to receive MenABCWY (Months 0,6) and saline (Month 0) or MenB-fHbp (Months 0,6) and MenACWY-CRM (Month 0). Booster doses of the assigned vaccine were administered 4 years later. Immune responses during the 48 months after primary vaccination and 1 month after booster were evaluated in serum bactericidal activity assays using human complement (hSBA) against serogroup A/C/W/Y strains and 4 diverse, vaccine-heterologous MenB strains. Safety was evaluated.
Results: During the 48 months after primary vaccination, 62.0%–100% of ACWY-naive MenABCWY recipients and 38.1%–95.2% of ACWY-naive MenACWY-CRM recipients had hSBA titers ≥1:8 (lower limit of quantitation [LLOQ]) for serogroups A/C/W/Y; respective percentages among ACWY-experienced participants were 98.7%–100% and 89.7%–100% (Figure). Percentages of participants with MenB hSBA titers ≥LLOQ (1:8 for A56, B24, and B44 strains; 1:16 for A22 strain) declined initially before plateauing, generally remaining higher than baseline through 48 months. After the booster, 100% of participants achieved hSBA titers ≥1:8 for serogroups A/C/W/Y (Figure). For MenB strains, percentages of participants achieving hSBA titers ≥LLOQ were higher postbooster than after the primary series. Postbooster reactogenicity events were similarly frequent across groups; no safety concerns were identified.

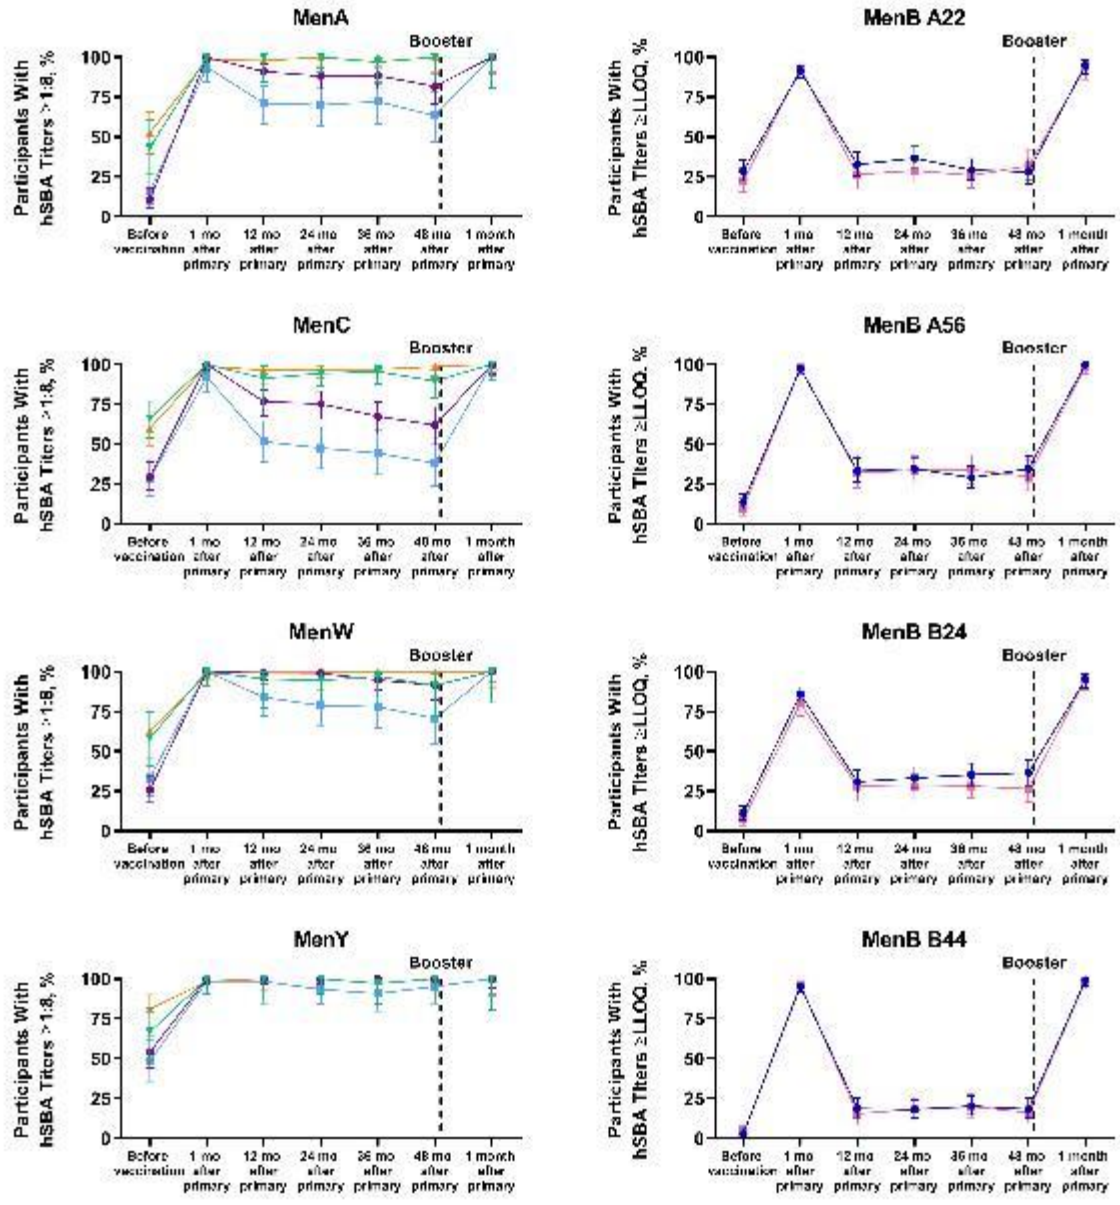

Figure. Percentages of participants in each group achieving hSBA titers ≥1:8 (MenA, MenC, MenW, and MenY) or ≥LLOQ (MenB) at each time point. Error bars represent 95% CIs. LLOQ=1:16 for A22 and 1:8 for A56, B24, and B44 (more stringent than the accepted correlate of protection of ≥1:4). MenB strains are indicated by the vaccine-heterologous fHbp variants they express. Data for all prebooster time points use the mITT population: ACWY-naive MenABCWY–saline n=70-112; ACWY-naive MenB-fHbp+MenACWY-CRM, n=41-64; ACWY-experienced MenABCWY+saline, n=40-100; ACWY-experienced MenB-fHbp+MenACWY-CRM, n=22-72; combined MenABCWY–saline, n=138-212; combined MenB-fHbp+MenACWY-CRM, n=85-136. Data for 1 month after booster used the booster-evaluable immunogenicity population: ACWY naive MenABCWY–saline, n=60; ACWY naive MenB-fHbp+MenACWY-CRM, n=37; ACWY experienced MenABCWY+saline, n=39-73; ACWY-experienced MenB-fHbp+MenACWY-CRM, n=17-51; combined MenABCWY+saline, n=122-126; combined MenB-fHbp+MenACWY-CRM, n=61-66. fHbp=factor H binding protein; hSBA=serum bactericidal activity assay using human complement; LLOQ=lower limit of quantitation; MenA, MenB, MenC, MenW, and MenY=Neisseria meningitidis serogroup A, serogroup B, serogroup C, serogroup W, and serogroup Y; MenABCWY=pentavalent serogroups A, B, C, W, Y vaccine; MenACWY-CRM=quadrivalent meningococcal CRM conjugate vaccine; MenB-fHbp=bivalent rLP2086; rLP2086=recombinant lipidated, non-surface-exposed, factor H binding protein 2086 antigen.

Conclusions/Learning Points: A single MenABCWY vaccine combining MenB-fHbp and MenACWY-TT was safe, well-tolerated, demonstrated immunopersistence, and induced immunologic memory regardless of ACWY history, offering early and boostable protection throughout adolescence. Funded by Pfizer.

Backgrounds: Sanofi set out to design a large international multicentre trial further evaluating the efficacy of nirsevimab in preventing RSV LRTI hospitalisations in infants (EudraCT 2022-000099-20). The impact of the COVID-19 pandemic on clinical and research capacity required a novel approach to conventional industry-sponsored studies.
Methods: Sanofi and academic investigators worked together to design and deliver a feasible trial that prioritized the minimisation of burden on families, site staff and health systems. This was achieved through: i) Study design and protocol based on researcher, clinician and public advice; ii) Use of digital systems including patient-facing documentation and, where possible, e-consent; iii) Family friendly patient information sheets; iv) Ensuring Clinical Research Organisation (CRO) and study systems supported family and researcher experience. Data capture included digital health record interrogation and remote participant follow-up. To expedite trial set up, the UK, French and German public health regulatory agencies were consulted to identify potential obstacles. Weekly study management meetings of lead investigators, Sponsor and CRO (LabCorp) continued throughout the trial.
Results: The trial opened at over 250 sites, supported by National Institute of Health Research infrastructure (UK), the PEDSTART network (France) and NETSTAP e.V.(Germany). At abstract submission, >5000 infants have been recruited. The single primary outcome was RSV hospitalization based on clinician decision and this was met within 11 months of protocol approval and within 4 months of trial opening.
Conclusions/Learning Points: We demonstrated the success of redefined relationships between a pharmaceutical company, academic investigator groups and a CRO by successfully setting up and delivering at speed a large industry-sponsored trial designed with families and researchers in mind. Participants and researchers are more likely to take part in studies that make taking part easy.

PD0027 / #716

EFFECTIVENESS OF THE 10- AND 13-VALENT PNEUMOCOCCAL CONJUGATE VACCINES (PCVS) TO PREVENT SEROTYPE 19A INVASIVE PNEUMOCOCCAL DISEASE (IPD) IN QUEBEC, CANADA. A CANADIAN IMMUNIZATION RESEARCH NETWORK (CIRN) STUDY.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 03: VACCINES (STATION 03)

Philippe De Wals
Laval University, Social And Preventive Medicine-criucpq, Québec, Canada

Backgrounds: In the province of Quebec, a childhood pneumococcal immunization program was implemented in December 2004 and 2+1 PCV7 doses were offered to low-risk infants at 2, 4 and 12 months of age. PCV7 was replaced by PCV10 in 2009, by PCV13 in 2011, by PCV10 in 2018 and by a mixed schedule (MS) consisting of 2 PCV10 + 1 PCV13 doses in 2020 with no catch-up in all instances. Objective was to assess the effectiveness (VE) of different schedules to prevent serotype 19A IPD.
Methods: IPD cases in children 2–59 months during the years 2009–2021 were identified throughout mandatory IPD notification and laboratory surveillance data. Parents were interviewed and immunization records reviewed. VE was estimated by the indirect cohort method, using 19A IPD cases and non-vaccine serotype IPD controls within multivariate logistic regression models.
Results: 214 19A IPD cases and 395 IPD controls were analyzed. VE for at least one dose was 64% [11%-86%] for PCV10 and 71% [35%-87%] for PCV13. VE for 3 doses was 80% [37%-94%] for PCV10, 79% [46%-92%] for PCV13 and 88% [58%-97%] for MS. VE tended to be lower after 2 doses only: 43% [-70%-81%] for PCV10, 52% [-52%-80%] for PCV13. Protection provided by a 2+1 PCV10 schedule tended to be of shorter duration compared to a 2+1 PCV13 schedule or a MS, the latter two schedules having similar waning protection curves over time.
Conclusions/Learning Points: A 2+1 PCV10 schedule seems to provide less robust protection against 19A IPD than a 2+1 PCV13 or MS, the latter two seeming almost equivalent. When PCV10 can be obtained at lower cost than PCV13, a mixed 2 PCV10 + 1 PCV13 schedule may be economically attractive.

PD0028 / #2124

PENTAVALENT MENABCWY MENINGOCOCCAL VACCINE ADMINISTERED ON A 0-,12-MONTH SCHEDULE IS SAFE AND WELL-TOLERATED AND PROVIDES A HIGH DEGREE OF PROTECTIVE IMMUNITY IN HEALTHY ADOLESCENTS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 03: VACCINES (STATION 03)

Jake Jones[1], Mary Tipton[2], Lefteris Zolotas[3], Jason Maguire[4], Kelly Belanger[5], Beth Moughan[4], Yanping Liu[4], Roger Maansson[4], Robert O'Neill[5], Paul Balmer[4], Paula Peyrani[4], Johannes Beeslaar[3]
[1]Wasatch Pediatrics, Pediatrics, Murray, United States of America, [2]CopperView Medical Center, Pediatrics, South Jordan, United States of America, [3]Pfizer, Vaccine Research And Development, Hurley, United Kingdom, [4]Pfizer, Vaccine Research And Development, Collegeville, United States of America, [5]Pfizer, Vaccine Research And Development, Pearl River, United States of America

Backgrounds: Neisseria meningitidis serogroups A/B/C/W/Y cause the vast majority of meningococcal disease globally, with disease incidence highest among infants and adolescents. Safety and immunogenicity of a pentavalent MenABCWY vaccine have been previously reported for a 2-dose, 0-,6-month schedule. This study assessed the safety and immunogenicity of extended interval dosing schedules of MenABCWY.
Methods: In this phase 2b, observer-blinded study, meningococcal vaccine-naive 11–14-year-olds were randomized 1:1 to receive MenABCWY (Month 0,12) or MenABCWY (Month 0,36). Here we report results for the Month 0,12 schedule. Immune responses were evaluated by serum bactericidal activity assays using human complement (hSBA) for serogroups A/C/W/Y and 4 diverse, vaccine-heterologous serogroup B (MenB) test strains. Endpoints included percentages of participants achieving seroprotective hSBA titers (ie, ≥lower limit of quantitation [LLOQ]; 1:16 [A22 strain] or 1:8 [other strains], more stringent than the 1:4 correlate of protection) and ≥4-fold rises from baseline in hSBA titers (ie, seroresponses). Safety was also evaluated.
Results: Among the 121 MenABCWY recipients, 96.6%–100.0% and 99.1%–100.0% achieved seroprotective hSBA titers for each of the MenB test strains and serogroups A/C/W/Y, respectively, at 1 month after the second dose (Table). At this time point, 92.9%–100.0% and 98.2%–99.1% of participants achieved seroresponses for the MenB test strains and A/C/W/Y serogroups, respectively, and 96.4% had hSBA titers ≥LLOQ for all 4 MenB strains combined (ie, composite response; Table). Related adverse events were mostly attributable to reactogenicity-type events, with no safety concerns identified.

Table. Percentages of Participants with Seroprotective hSBA Titers[a]						
Serogroup/strain	Before First Dose			1 Month After Second Dose		
	N[b]	n[c] (%)	(95% CI)[d]	N[b]	n[c] (%)	(95% CI)[d]
MenB strain[e]						
A22	114	8 (7.0)	(3.1, 13.4)	113	112 (99.1)	(95.2, 100.0)
A56	116	3 (2.6)	(0.5, 7.4)	115	115 (100.0)	(96.8, 100.0)
B24	116	2 (1.7)	(0.2, 6.1)	113	111 (98.2)	(93.8, 99.8)
B44	116	1 (0.9)	(0.0, 4.7)	116	112 (96.6)	(91.4, 99.1)
All MenB strains combined (composite response)	–	–	–	110	106 (96.4)	(91.0, 99.0)
MenA	116	8 (6.9)	(3.0, 13.1)	116	115 (99.1)	(95.3, 100.0)
MenC	115	11 (9.6)	(4.9, 16.5)	116	115 (99.1)	(95.3, 100.0)
MenW	114	19 (16.7)	(10.3, 24.8)	115	115 (100.0)	(96.8, 100.0)
MenY	113	37 (32.7)	(24.2, 42.2)	114	114 (100.0)	(96.8, 100.0)

fHbp=factor H binding protein; hSBA=serum bactericidal assay using human complement; LLOQ=lower limit of quantitation; MenA, MenB, MenC, MenW, and MenY=*Neisseria meningitidis* serogroup A, serogroup B, serogroup C, serogroup W, and serogroup Y.

[a]Seroprotective titers were defined as titers ≥LLOQ, where LLOQ=1:16 for A22; 1:8 for A56, B24, and B44; and 1:8 for MenA, MenC, MenW, and MenY.

[b]N=number of participants with valid and determinate hSBA titers for the specified strain at the given sampling time point. These values are used as the denominators for the percentage calculations.

[c]n=number of participants achieving the defined hSBA titer for the specified strain at the given sampling time point.

[d]Exact 2-sided confidence intervals based on the observed proportion of participants, using the Clopper and Pearson method.

[e]MenB strains are indicated by the vaccine-heterologous fHbp variants they express.

Conclusions/Learning Points: MenABCWY administered on a 2-dose, 0-,12-month schedule is well tolerated, with a safety profile consistent with that of a 0-,6-month schedule, and induces robust bactericidal responses for all 5 serogroups. Funded by Pfizer.

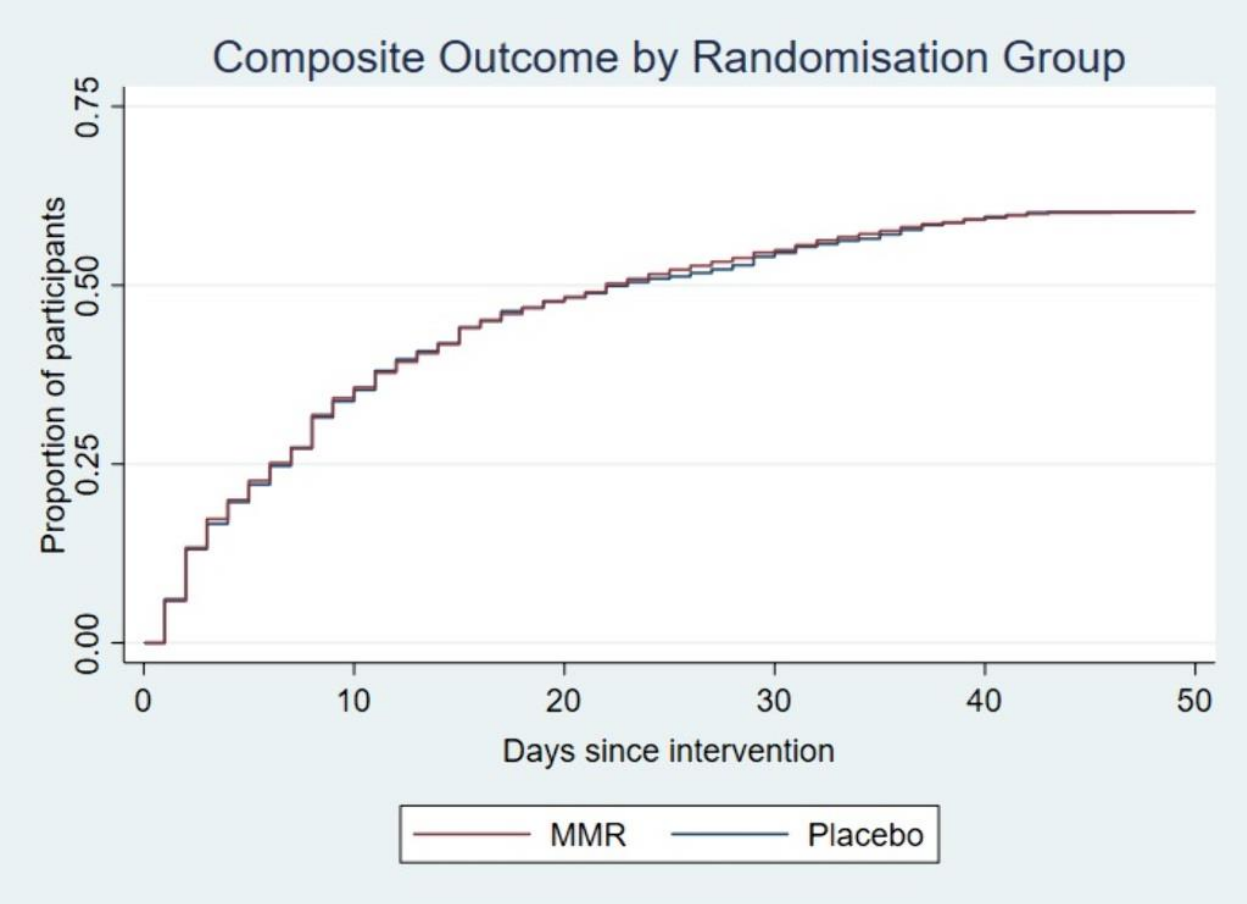
MEASLES-MUMPS-RUBELLA (MMR) VACCINATION AT 6 MONTHS OF AGE: REACTOGENICITY AND SERIOUS ADVERSE EVENTS IN A PLACEBO-CONTROLLED RANDOMIZED TRIAL

E-Poster Discussion
E-POSTER DISCUSSION SESSION 03: VACCINES (STATION 03)

Dorthe Vittrup[1], Andreas Jensen[2], Michelle Malon[2], Anne Zimakoff[2], Jesper Sørensen[2], Jannet Svensson[1], Lone Graff Stensballe[2]
[1]Herlev Hospital, Dept. For Children And Adolescents, Herlev, Denmark, [2]Rigshospitalet, Dept. For Children And Adolescents, Copenhagen E, Denmark

Backgrounds: Measles is a highly contagious viral disease that can be effectively prevented by vaccination. However, measles case numbers are increasing in all WHO regions. In 2019 vaccine hesitancy was named one of the ten biggest health threats by WHO. To accommodate hesitancy, high quality RCTs are important to document safety. MMR vaccines are well-tolerated and well investigated in children above twelve months of age, but little is known about MMR vaccines in infants less than twelve months of age and especially in infants less than nine months of age.
Methods: In this double-blind placebo-controlled RCT, 6540 healthy infants were randomized 1:1 to receive either M-M-R VaxPro or placebo (solvent only) at five to seven months of age. Parents were asked to fill out a diary card if any untoward event happened regardless of the suspected cause. Study personnel called the parents six weeks after randomization and registered all reported events. Data were analyzed using Cox regression stratified by sex, prematurity and site since the randomization was stratified by these factors.
Results: Data was successfully collected for 99% of the population (N=6465). Mean follow-up was 44.5 days. Hazard ratio (HR) between randomization groups was 1.00 (95% CI 0.94-1.07) regarding any non-severe reaction following MMR (composite outcome, see figure). No symptom-specific outcome differed significantly between randomization groups either. Severe adverse events (SAE) occurred in 25 individuals (16 MMR, 9 placebo, HR 1.77 (95% CI 0.78-4.01)), but all were deemed unrelated to intervention.



Conclusions/Learning Points: MMR vaccination at 5-7 months of age was associated with little to no increased risk of short-term adverse reactions and SAEs.

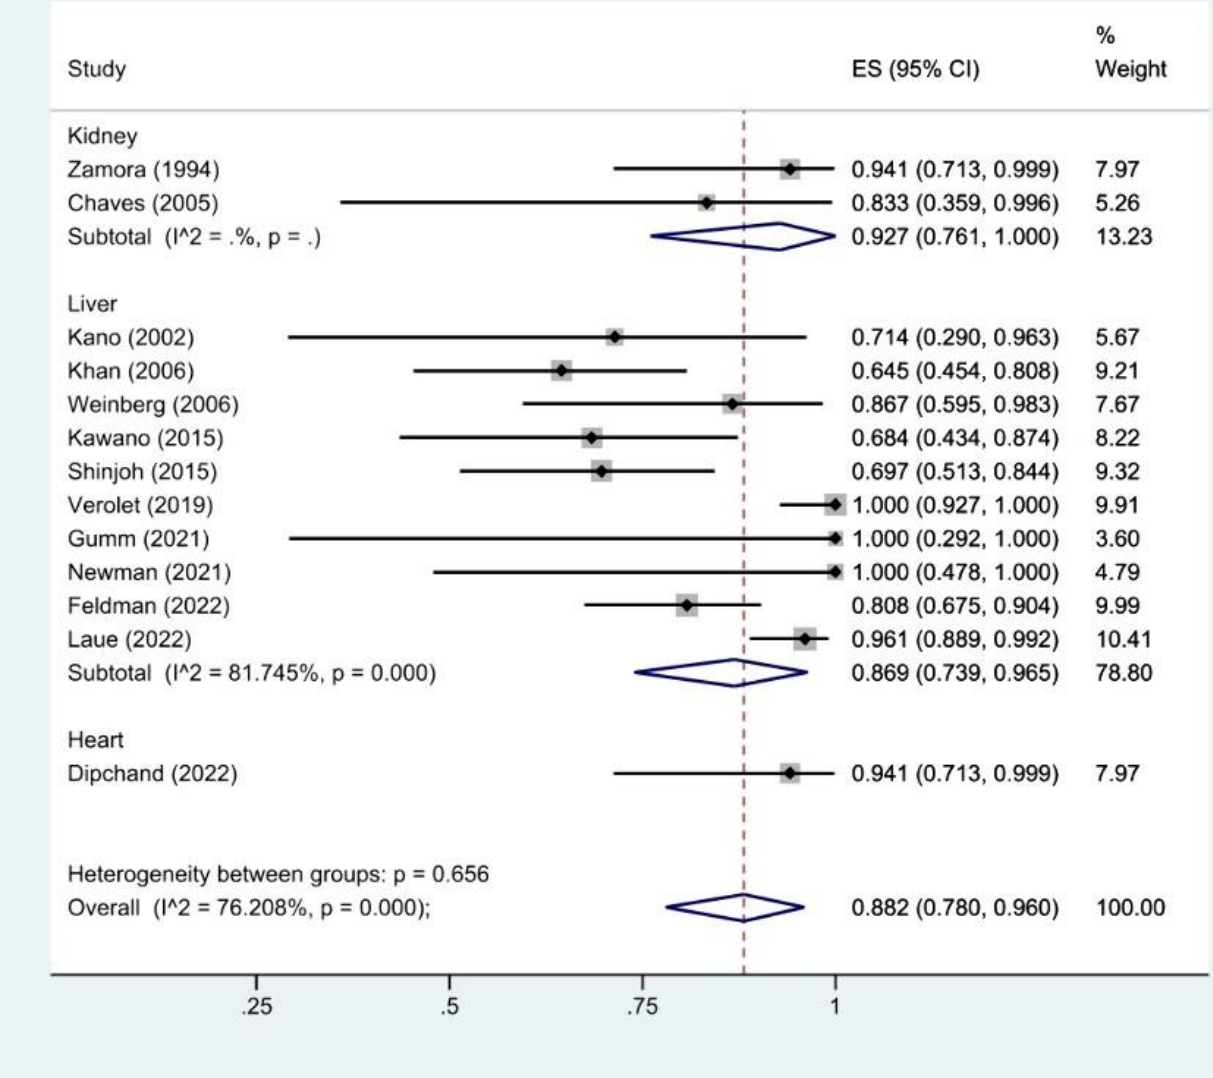
SAFETY AND IMMUNOGENICITY OF THE LIVE-ATTENUATED VARICELLA VACCINE IN SOLID ORGAN TRANSPLANT RECIPIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 03: VACCINES (STATION 03)

Pierre-Philippe Piche-Renaud[1], Erika Lee[2], Catherine Ji[3], Jenny Huang[4], Elizabeth Uleryk[5], Chia Wei Teoh[6], Shaun Morris[1], Karina Top[7], Julia Upton[8], Manav Vyas[9], Upton Allen[1]
[1]Hospital for Sick Children, Division Of Infectious Diseases, Toronto, Canada, [2]St. Michael's Hospital, Division Of Clinical Immunology And Allergy, Toronto, Canada, [3]University of Toronto, Department Of Family And Community Medicine, Toronto, Canada, [4]University of Toronto, Department Of Medicine, Toronto, Canada, [5]E.M. Uleryk Consulting, E.m. Uleryk Consulting, Toronto, Canada, [6]The Hospital for Sick Children, Nephrology, Toronto, Canada, [7]Dalhousie University, Department Of Pediatrics,, Halifax, Canada, [8]The Hospital for Sick Children, Immunology, Toronto, Canada, [9]University of Toronto, Neurology, Toronto, Canada

Backgrounds: Recent recommendations in solid organ transplant (SOT) recipients have been more permissible on the use of the live-attenuated varicella vaccine (LAVV) if certain eligibility criteria are respected. The purpose of this study was to synthesize the available evidence on the immunogenicity, safety and effectiveness of the LAVV when administered in the post-transplant period.
Methods: Medline and EMBASE were searched using predefined terms to identify relevant studies. Included articles reported varicella vaccine administration in the post-transplant period in children and adults. Pooled proportion of transplant recipients who seroconverted, who developed vaccine-strain varicella and who had vaccine failure (varicella disease) were generated.
Results: After screening and full-text review, nineteen articles (15 studies and 4 case reports) were included in the review. The articles reported on 715 SOT recipients who received the LAVV in the post-transplant period, with 330 (46.2%) having immunological investigations performed after vaccination. The pooled proportion of vaccinees who seroconverted was 88.2% (95% confidence interval 78.0%-96.0%, n=283/330) and was comparable between liver, kidney and heart transplant recipients, although most studies reported on liver transplant recipients (Figure). The pooled proportion of vaccinees who developed vaccine-strain varicella was 0% (0%-1.2%, n=13/635) and the pooled proportion of vaccine failure was 0.8% (0%-4.9%, n=8/279). Most studies followed clinical guidelines for administering live-attenuated vaccines with criteria that could include being at least one-year post-transplant, two months post-rejection episode, and on low-dose immunosuppressive
medications.



Conclusions/Learning Points: Varicella vaccination in transplant recipients was overall safe in the included studies, with few cases of vaccine-strain induced varicella or vaccine failure, and while it was immunogenic, the proportion of people who seroconverted was lower than that seen in the general population. Our data support varicella vaccination in select solid organ transplant recipients.

Backgrounds: PCV20 was developed to expand protection for pneumococcal disease. It contains the components of PCV13 plus conjugates for 7 additional serotypes. Reported here are findings from a trial describing the safety of PCV20 in infants.
Methods: In this phase 3, multi-country, double-blind study (NCT04379713), healthy infants born at ≥34 weeks gestation were randomized 2:1 to receive 4 doses of PCV20 or PCV13 at 2, 4, 6, and 12–15 months of age. The primary objective evaluated the tolerability and safety of PCV20. Safety assessments included local reactions and systemic events within 7 days after each vaccination, adverse events (AEs) from Dose 1 to 1 month after Dose 3 and from Dose 4 to 1 month after Dose 4, and serious adverse events (SAEs) from Dose 1 through 6 months after the last dose.
Results: Participants (99.5%) received ≥1 dose of PCV20 (n=1006) or PCV13 (n=505) and 91.7% received all doses. Frequencies of local reactions and systemic events after each dose were generally similar in the PCV20 and PCV13 groups, with most reported as mild or moderate. The most common local reaction was injection site pain (PVC20, 24.7%–40.5%; PVC13, 26.8%–42.0%), and irritability (PVC20, 54.8%–68.2%; PVC13, 54.7%–68.5%) was the most common systemic event. Frequencies of AEs were 29.6% and 27.6% through 1 month after Dose 3 and 15.1% and 15.8% from Dose 4 through 1 month after Dose 4, in the PVC20 and PVC13 groups, respectively. SAEs were reported in 4.4% of the PCV20 group and 5.6% of the PCV13 group; none were related to the vaccines.
Conclusions/Learning Points: PVC20 administered as a 4-dose series had a tolerability and safety profile similar to PVC13.

PD0032 / #306

SAFETY PROFILE OF FOUR-COMPONENT SEROGROUP B MENINGOCOCCAL VACCINE (4CMENB) ACROSS CLINICAL TRIALS AND POST-LICENSURE SURVEILLANCE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 03: VACCINES (STATION 03)

Woo Yun Sohn[1], Rafik Bekkat-Berkani[1], Silvia Cenci[2], Emilia Occhipinti[2], Helen Marshall[3], Gary Marshall[4,5], James Conway[6], Victoria Abbing-Karahagopian[7]
[1]GlaxoSmithKline, Global Medical Affairs, Rockville, United States of America, [2]GlaxoSmithKline, Safety Department, Siena, Italy, [3]Women's and Children's Health Network and Adelaide Medical School and Robinson Research Institute, The University Of Adelaide, Adelaide, Australia, [4]Norton Children's and University of Louisville School of Medicine, Pediatrics Infectious Diseases, Louisville, United States of America, [5]Norton Children's Hospital and University of Louisville School of Medicine, Pediatrics Infectious Diseases, Louisville, United States of America, [6]University of Wisconsin School of Medicine and Public Health, Clinical Sciences Center, Department Of Pediatrics, Madison, United States of America, [7]GlaxoSmithKline Vaccines, Epidemiology, Amsterdam, Netherlands

Backgrounds: The most serious consequence of Neisseria meningitidis infection is invasive meningococcal disease (IMD) which has a fatality rate of 4–20%, depending on age and serogroup (overall estimated at 8%). In developed countries, Neisseria meningitidis serogroup B is the most common cause of IMD. The vaccine 4CMenB (Bexsero®), administered to prevent IMD caused by serogroup B, is approved in >50 countries and currently utilised in 10 national immunisation programmes (NIPs).
Methods: 4CMenB safety data were reviewed from published clinical trials, global surveillance studies and post-marketing experience generated over 9 years of use.
Results: Data from 229 publications were reviewed, together with spontaneous reports in the GSK database. 4CMenB was generally well tolerated across clinical trials involving ~9000 recipients. In these trials, there was a higher incidence of short-term fever in infants following coadministration of 4CMenB with routine vaccines versus routine vaccines administered alone. No safety concerns have arisen in enhanced surveillance assessments following the introduction of 4CMenB into the UK NIP, for which coadministration with routine vaccines is recommended. Kawasaki disease, which was reported in clinical trials and initially considered a concern, was not linked to 4CMenB in longitudinal surveillance studies. Febrile convulsions were reported in small numbers of recipients during clinical trials and surveillance studies, with incidence comparable with those reported following other routine vaccines. These findings have been corroborated by post-licensure spontaneous adverse event reporting after >74 million doses were distributed globally.
Conclusions/Learning Points: No safety concerns for 4CMenB emerged following the review of clinical evidence, post-licensure pharmacovigilance and real-world experience. Overall, the data have confirmed a favourable benefit–risk profile for 4CMenB.

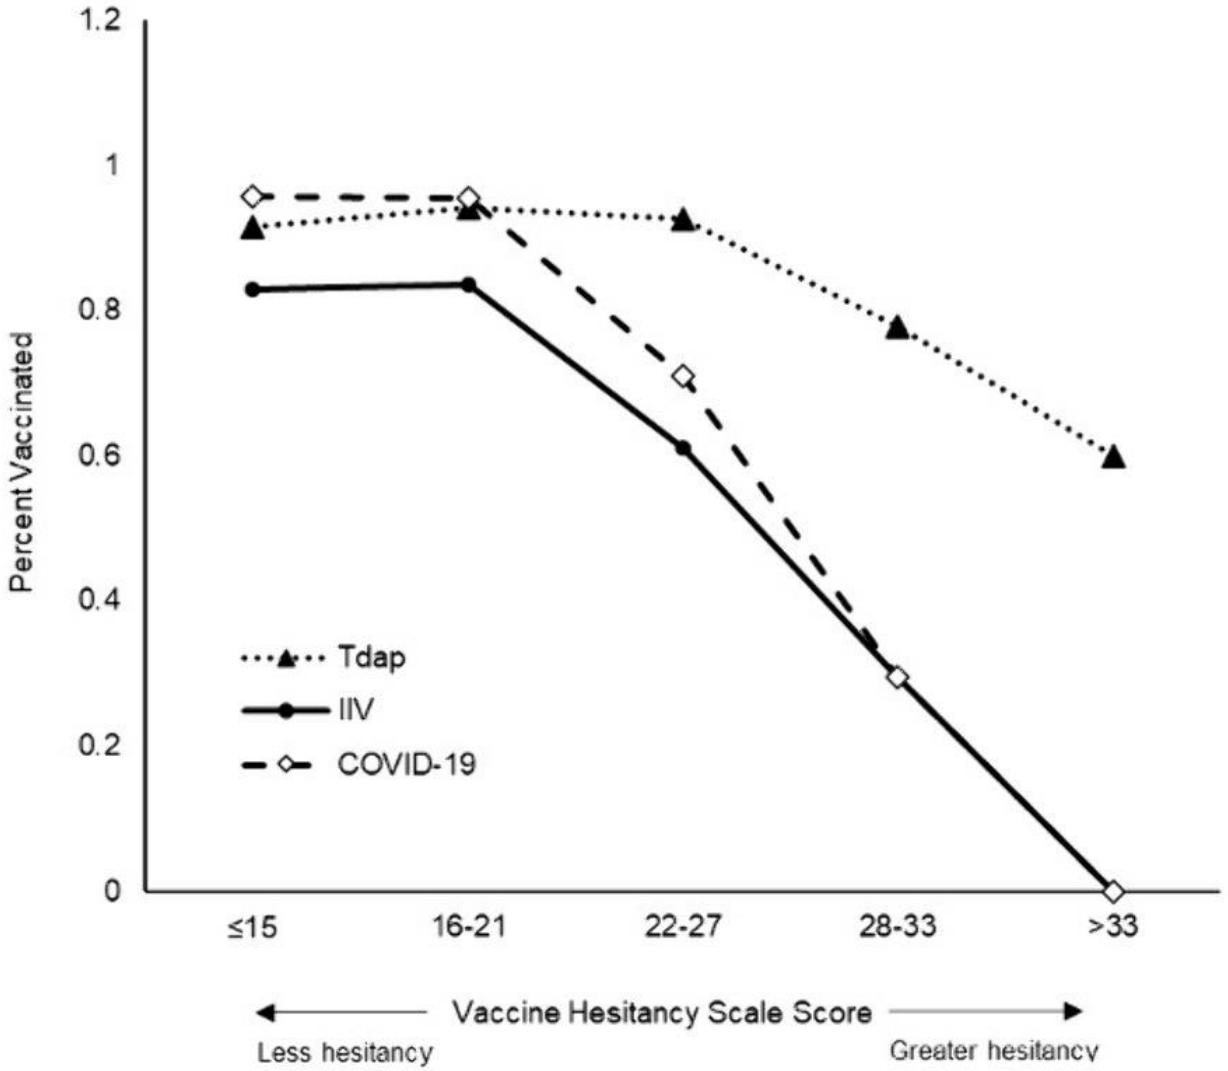
PD0033 / #669

MEASURING HESITANCY TOWARD MATERNAL VACCINES: DEVELOPMENT OF A MATERNAL VACCINE HESITANCY SCALE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 03: VACCINES (STATION 03)

Jeannette Comeau[1], Marie-Claude Couture[2], Ning Yan Gu[3], Tasmiah Nuzhath[4], Annette Regan[5]
[1]Dalhousie University, Department Of Pediatrics, Division Of Infectious Diseases, Halifax, Canada, [2]University of San Francisco, School Of Nursing And Health Professions, San Francisco, United States of America, [3]University of San Francisco, School Of Nursing And Health Professions, Sacramento, United States of America, [4]Texas A&M University, School Of Public Health, College Station, United States of America, [5]University of San Francisco, School Of Nursing And Health Professions, Orange, United States of America

Backgrounds: Maternal immunization offers protection against severe vaccine-preventable diseases to newborns. However, uptake of vaccines during pregnancy remains suboptimal, and despite extensive research on determinants and predictors of maternal vaccination, there is currently no tool to measure hesitancy toward vaccination during pregnancy.
Methods: We analyzed data from a national cross-sectional survey of 872 US adults 18-49 years of age who had given birth during the past 6 months. Participants self-reported uptake of influenza, Tdap, and COVID-19 vaccines during their most recent pregnancy and completed the adult Vaccine Hesitancy Scale (aVHS). The aVHS is a scale initially developed by the SAGE Working Group on Vaccine Hesitancy and recently modified for application to adult vaccines, with higher scores indicating greater hesitancy to vaccines. We performed confirmatory factor analysis using structural equation modeling with maximum likelihood estimators. We examined mean aVHS scores for both vaccinated and unvaccinated respondents. We also compared vaccination rates for each vaccine by aVHS quintile.
Results: Confirmatory factor analysis indicated moderate fit of the aVHS among postpartum adults (Standardized Root Mean Residual [SRMR] = 0.063; Tucker-Lewis Index = 0.856), which modestly improved after removing item 5 (SRMR 0.052; Tucker-Lewis Index = 0.882). The mean aVHS score was 20.1 (range: 9 to 41) and was lower for vaccinated compared to unvaccinated respondents for COVID-19 vaccine (-5.8) and influenza vaccine (-3.7), and less so for Tdap vaccine (-2.0). We observed lower uptake of influenza and COVID-19 vaccines associated with higher aVHS scores and weaker declines in the uptake of Tdap vaccine
(Figure).



Conclusions/Learning Points: Currently available tools for measuring vaccine hesitancy in adults do not perform optimally for all vaccines recommended during pregnancy. A tool specifically designed to measure hesitancy toward maternal vaccines is needed.

PD0034 / #1542

IMPACT OF POLICY MAKERS' DECISIONS ON INVASIVE MENINGOCOCCAL B DISEASE VACCINATION UPTAKE IN FRANCE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 03: VACCINES (STATION 03)

Robert Cohen[1], Alain Martinot[2], Joel Gaudelus[3], Alina Gruber[4], Lilya Mediouni[4], Maxime Denigot[5], Patricia Gelin[6], Jean-Paul Stahl[7]
[1]CHI Créteil, Unité Court Séjour Petits Nourrissons, Créteil, France, [2]Université de Lille, CHU Lille, Ulr 2694-metrics, Lille, France, [3]Université Paris XIII, Faculté De Médecine, Bobigny, France, [4]GSK, Medical Affairs, Rueil-Malmaison, France, [5]IDM-Families, Market Research, Issy-les-Moulineaux, France, [6]IDM-Families, Ceo, Issy-les-Moulineaux, France, [7]Université Grenoble Alpes, Faculté De Médecine, La Tronche, France

Backgrounds: In France, vaccination against invasive meningococcal B (MenB) disease is recommended since June 2021 and reimbursed since April 2022 for all infants from 2 months to 2 years. This vaccination is not mandatory, unlike those against 11 diseases included in the national immunization program up to 2 years. Through the 'Vaccinoscopie' study, we measured the impact of the new policy on mothers' attitude towards MenB vaccination and on the vaccine coverage rate (VCR).
Methods: Vaccinoscopie is a French annual survey conducted since 2008. The online standardized questionnaire was carried out from September 09,2022 to October 10,2022 on a representative sample of 1500 mothers of infants aged 0–35 months.
Results: Nearly 88% of mothers perceived MenB vaccination as essential/useful. Compared to 2021, the proportion of mothers aware of this vaccination increased from 54.3% to 67.9% in 2022 ($p<0.05$). This increase was greater in mothers whose child was followed in maternal and infant protection (40.2% vs 71.1%, $p<0.05$). About 82% of mothers would vaccinate their child aged 0–23 months against MenB if recommended by a healthcare professional (HCP), mentioning the recommendation/reimbursement beforehand. VCR increased from 5.9% to 19.4% ($p<0.05$) for at least 1 dose in children aged 12–23 months, and from 4.9% to 30.1% in children aged 2–11 months ($p<0.05$) (2021 vs 2022). VCR progressed the least in infants followed by general practitioners.
Conclusions/Learning Points: These results confirm the positive impact of MenB vaccine recommendation and reimbursement on its uptake in France. However, its VCR is still low compared to mandatory vaccinations. As for other vaccines, mothers' acceptance and HCPs' adherence are also key success factors. Communication and education on MenB vaccination must be reinforced to improve the uptake, especially among general practitioners.

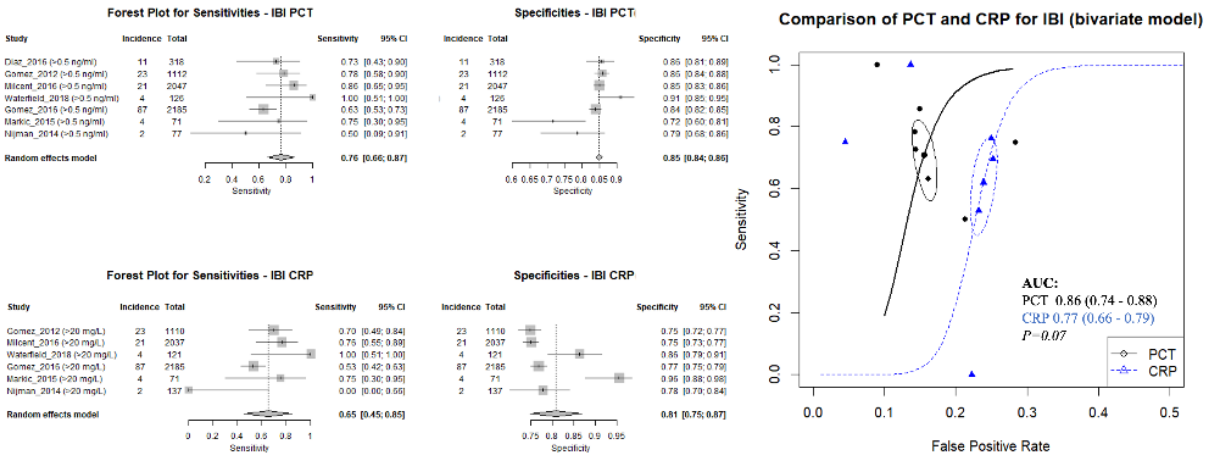
PD0035 / #585

THE DIAGNOSTIC TEST ACCURACY OF PROCALCITONIN (PCT) AND C-REACTIVE PROTEIN (CRP) IN THE DETECTION OF BACTERIAL INFECTIONS IN FEBRILE INFANTS LESS THAN 90 DAYS OF AGE. A SYSTEMATIC REVIEW AND META-ANALYSIS.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 04: DIAGNOSTICS AND BIOMARKERS (STATION 04)

Hannah Norman-Bruce[1], Etimbuk Umana[2], Clare Mills[1], Hannah Mitchell[3], Lisa Mcfetridge[3], David Mccleary[1], Thomas Waterfield[1]
[1]Queen's University Belfast, Wwiem, Belfast, United Kingdom, [2]Queen's University Belfast, Wwiem, Belfast, Ireland, [3]Queen's University Belfast, School Of Mathematics, Belfast, United Kingdom

Backgrounds: Procalcitonin (PCT) and C-reactive protein (CRP) are widely used biomarkers in the assessment of febrile infants under 90 days of age. In Europe and the USA, PCT is typically favoured whereas CRP is favoured in the UK. The aim of this systematic review and meta-analysis is to report the test accuracy of PCT and CRP in identifying young infants with invasive and serious bacterial infections (SBI/IBI).
Methods: This systematic review and meta-analysis was registered with PROSPERO and the protocol written adherent to PRISMA-P standards. The full protocol is available as an open access publication. An electronic search of MEDLINE, EMBASE, Web of Science and The Cochrane Library was conducted. Eligible studies were selected and assessed for quality and generalisably using GRADE and QUADAS-2 tools. Data were extracted using a standardised data extraction tool. Pooled sensitivities and specificities and area under the curve(AUC) were calculated incorporating a range of cut-off values.
Results: 13 studies, involving 7497 participants, were included in the meta-analysis. The pooled sensitivity/specificity of PCT(>0.5ng/ml) to detect IBI was 0.76/0.85 and CRP(>20mg/L) was 0.65/0.81respectively. For SBI, the pooled sensitivity/specificity of PCT was 0.52 /0.91 and CRP was 0.67/0.85 respectively. The AUC for diagnosis of IBI [0.86 for PCT, 0.77 for CRP, p=0.07] and SBI [0.83 for PCT , 0.82 for CRP, p=0.95]. The optimal cut-off value for PCT was 0.4ng/ml(IBI) and 0.17ng/ml(SBI). The optimal cut-off value for CRP was 12.4mg/L(IBI) and 17.6mg/L(SBI).



Conclusions/Learning Points: This review and meta-analysis is the largest review of its type including over 7000 infants. The AUC for PCT and CRP for identifying infants with IBI and SBI was not statistically different. This suggests that PCT is not superior to CRP as a biomarker in this age group.

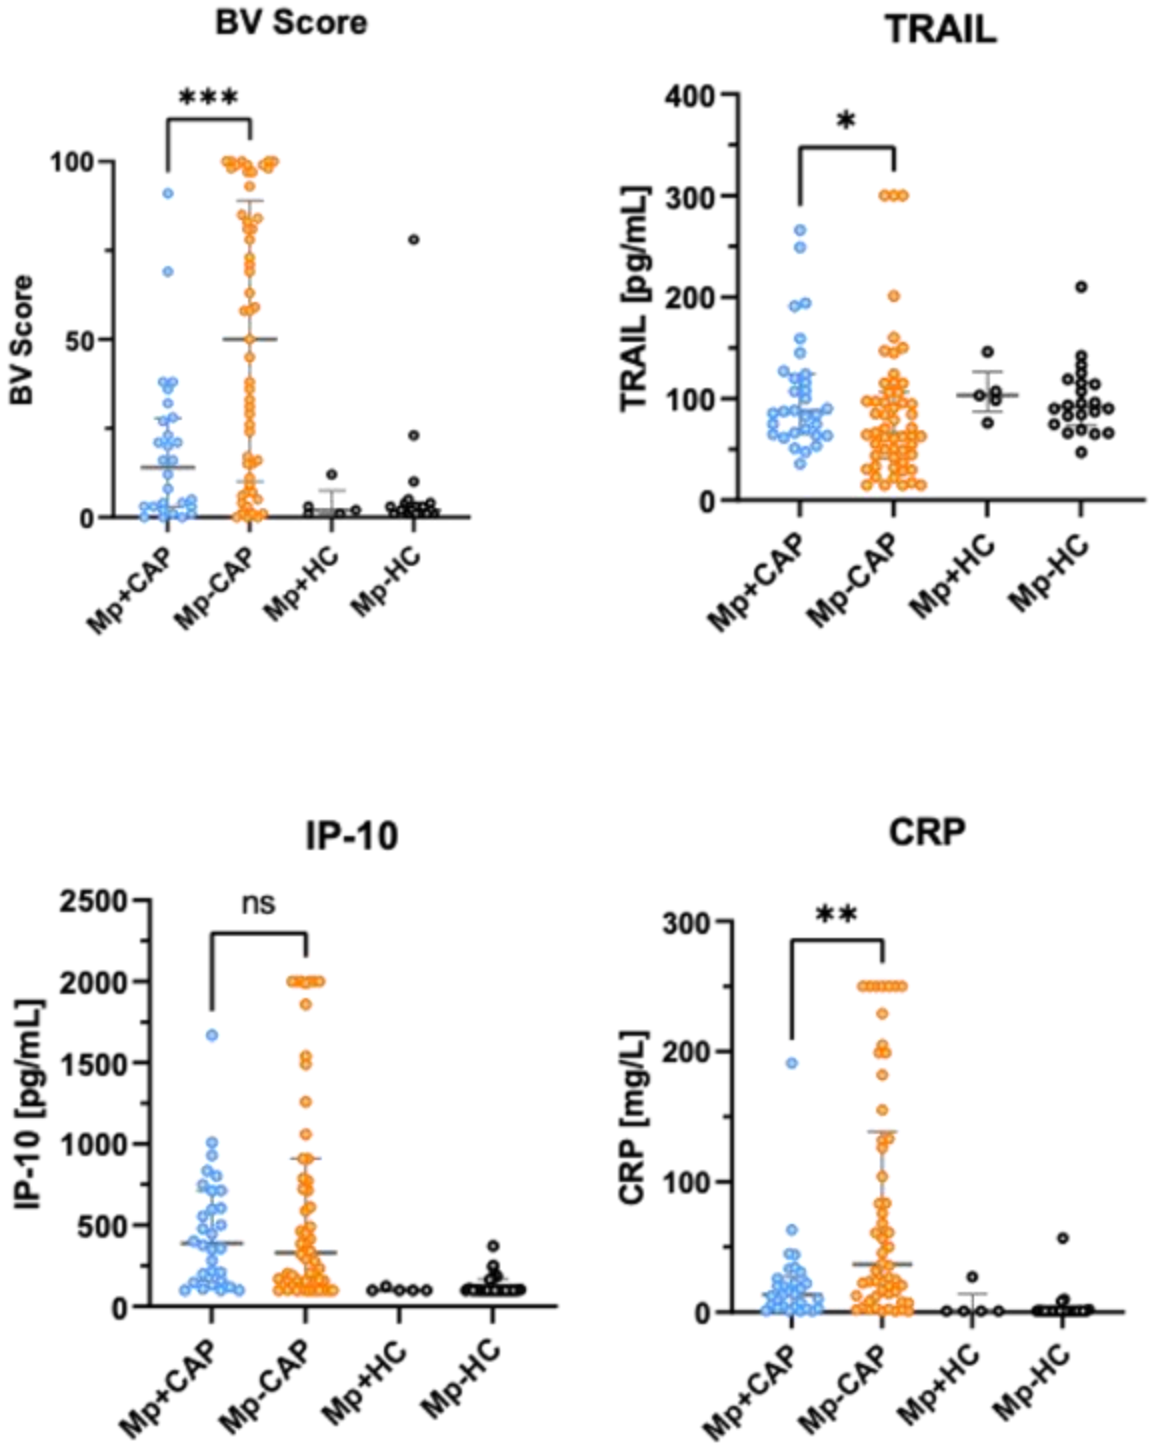
PD0036 / #1118

COMBINATORIAL HOST-RESPONSE BIOMARKER SIGNATURE (BV SCORE) AND ITS SUBANALYTES TRAIL, IP-10, AND CRP IN CHILDREN WITH MYCOPLASMA PNEUMONIAE PCR-POSITIVE COMMUNITY-ACQUIRED PNEUMONIA

E-Poster Discussion
E-POSTER DISCUSSION SESSION 04: DIAGNOSTICS AND BIOMARKERS (STATION 04)

Cihan Papan[1,2], Semjon Sidorov[3], Beat Greiter[3], Nina Bühler[2], Sören Becker[2], Patrick Sauteur[3]
[1]University Hospital Bonn, Institute For Hygiene And Public Health, Bonn, Germany, [2]Saarland University, Centre For Infectious Diseases, Institute Of Medical Microbiology And Hygiene, Homburg, Germany, [3]University Children's Hospital Zurich, Division Of Infectious Diseases And Hospital Epidemiology, Zürich, Switzerland

Backgrounds: Novel host-response biomarkers to differentiate between bacterial and viral aetiology in children with respiratory infections have previously shown high diagnostic accuracies. However, their expression in Mycoplasma pneumoniae (Mp) infections has been understudied. Due to its distinctive microbiological characteristics, we hypothesized that levels of combinatorial host-response biomarker signature (BV score) and its subanalytes TRAIL, IP-10, and CRP in Mp PCR-positive community-acquired pneumonia (CAP) would differ from the levels found in Mp PCR-negative CAP.
Methods: This is a post-hoc analysis of a previously published cohort of paediatric CAP patients. Mp PCR-results were confirmed with the measurement of Mp-specific IgM antibody-secreting cells (ASCs) by enzyme-linked immunospot (ELISpot) assay, which differentiated between Mp infection and carriage. We analysed BV scores (ranging 0-100, with 0-34 being suggestive of viral aetiology, and 66-100 indicating bacterial aetiology), TRAIL (pg/mL), IP-10 (pg/mL), and CRP (mg/L) serum levels. Measurements were performed using Liaison MeMed BV on a Liaison XL. We compared biomarker levels between Mp PCR-positive CAP (Mp+CAP) and Mp PCR-negative CAP (Mp-CAP).
Results: Of 83 CAP patients, 29 were Mp PCR-positive; among 25 healthy controls, five were Mp PCR-positive (carriers). BV scores were lower (median 16.0, interquartile range [IQR] 3.0-28.0 vs. 54.0, IQR 12.0-84.8; p=0.0006), while TRAIL levels were higher (87.5, IQR 66.5-124.0 vs. 65.5, IQR 42.5-103.9; p=0.02) in Mp+CAP compared with Mp-CAP patients. CRP were lower among Mp+CAP patients (13.9, IQR 4.5-25.9 vs. 36.7, IQR 13.0-132.8; p=0.003), while IP-10 levels were comparable between the two groups (400.0, IQR 160.0-711.0 vs. 331.0, IQR 154.3-878.8; p=0.94). Figure 1 displays the distribution of measurements including healthy
controls.



Conclusions/Learning Points: BV scores in Mp+CAP yielded atypically low, viral levels. Our findings show that novel biomarkers can have limitations for atypical bacteria which underscores the role of microbiological testing to guide targeted antibacterial treatment.

PD0037 / #1163

MMP-13/TIMP-3 RATIO DIFFERENTIATES BETWEEN TICK-BORNE ENCEPHALITIS AND LYME NEUROBORRELIOSIS IN CHILDREN

E-Poster Discussion
E-POSTER DISCUSSION SESSION 04: DIAGNOSTICS AND BIOMARKERS (STATION 04)

Kacper Toczylowski[1], Dawid Lewandowski[1], Diana Martonik[2], Marta Sawicka[1], Ewa Bojkiewicz[1], Marta Wozinska[1], Artur Sulik[1]
[1]Medical University of Bialystok, Department Of Pediatric Infectious Diseases, Bialystok, Poland, [2]Medical University of Bialystok, Department Of Infectious Diseases And Hepatology, Bialystok, Poland

Backgrounds: Tick-borne encephalitis (TBE) and Lyme neuroborreliosis (LNB) are frequent causes of meningitis in children in northeastern Poland. The diagnosis of TBE and LNB is based on serological tests, which are time-consuming, not always readily available and might produce false results. Differentiation between these two tick-borne diseases is crucial in tailoring treatment plans. It has been previously shown that matrix metalloproteinases (MMPs) play crucial roles in the pathophysiology of various diseases, including neuroinfections. We therefore aimed at comparing serum profiles of MMPs in children with TBE and LNB in order to identify possible biomarkers of these diseases.
Methods: Serum samples were collected from 21 children hospitalized with TBE and 21 children with LNB. We measured pre-treatment concentrations of 5 different MMPs (MMP-1, MMP-3, MMP-7, MMP-8, MMP-13), their inducers (TNF-α, IL-6 and EMMPRIN), and 4 inhibitors of MMPs (TIMP 1-4).
Results: Children with TBE had significantly elevated MMP-7 (3402.4± 1530.2 vs. 1666.3± 514.6 pg/mL; p<0.001), MMP-8 (20468.4± 14982.8 vs. 8787.7± 5281.6 pg/mL; p=0.002), MMP-13 (1394.5± 468.8 vs. 396.6± 350.8 pg/mL; p<0.001), TNF-α (13.8 ±14.0 vs. 6.8±5.2 pg/mL; p=0.037), and IL-6 (20.1±16.7 vs. 8.8±6.1 pg/mL; p=0.006). Total serum concentration of MMP inhibitors (the sum of 4 TIMPs) was lower in TBE compared to LNB (267210.3±52086.0 vs. 384301.3±91282.0 pg/mL; p<0.001). MMP-13/TIMP-3 ratio equal to or higher than 0.02 differentiated TBE from LNB with 92% sensitivity and 93% specificity (AUC, 0.933; 95%CI, 0.81-1.0; p<0.001).
Conclusions/Learning Points: TBE in children is characterized by stronger systemic inflammatory response compared to LNB. We found that MMP-13/TIMP-3 ratio differentiates between these two infections with high accuracy. Previously, MMP-13 was shown to increase brain endothelium permeability. This remarkable upregulation of MMP-13 that we found possibly reflects significant involvement of the brain tissue in TBE.

PD0038 / #1213

EFFICACY OF XPERT MTB/RIF ULTRA IN COMPARISION TO XPERT MTB/RIF ASSAY FOR DIAGNOSIS OF TUBERCULOSIS IN INDIAN CHILDREN

E-Poster Discussion
E-POSTER DISCUSSION SESSION 04: DIAGNOSTICS AND BIOMARKERS (STATION 04)

Meenakshi Dey, Maithili Joshi, Ira Shah
Bai Jerbai Wadia Hospital for Children, Pediatric Infectious Diseases, mumbai, India

Backgrounds: To evaluate the efficacy of Xpert MTB/RIF Ultra (Xpert Ultra) in comparision to Xpert MTB/RIF assay for diagnosis of Tuberculosis in Indian Children.
Methods: This is a retrospective study done in children upto 18 years of age with bacteriological (TB MGIT culture positive for mycobacterium tuberculosis) or clinically confirmed TB as per World Health Organization (WHO) case definition between January 2021 to January 2022. Sensitivity and Specificity of Xpert MTB/RIF Ultra (Xpert Ultra) and Xpert MTB/RIF assay was determined in both pulmonary (PTB) and extrapulmonary (EPTB) samples. 70 samples were subjected to Xpert Ultra and 63 samples were subjected to Xpert MTB /RIF assay. All samples were sent for TB MGIT culture.
Results: Sensitivity,specificity, Positive predictive value (PPV),Negative predictive value (NPV) and accuracy of Ultra as compared to TB MGIT culture for diagnosis of MTB was 80.6%,40.6%,60.4%,65%,61.8% respectively.Sensitivity, specificity, PPV,NPV and accuracy of Xpert MTB/RIF assay as compared to TB MGIT culture for diagnosis of MTB was 89.2%,40%,68.7%,71.4%,69.3% respectively.The sensitivity, specificity, PPV, NPV and accuracy of Xpert ultra for detection of rifampicin resistance against the diagnostic efficacy by TB culture was 92.9%, 80.0%, 86.7%, 88.9% and 87.5% respectively.The sensitivity, specificity, PPV, NPV and accuracy of Xpert MTB/RIF assay for detection of rifampicin resistance against the diagnostic efficacy by TB culture was 100.0%, 90.9%, 81.8%, 100.0% and 93.5% respectively.5 samples were tested for both Xpert MTB/RIF assay and Xpert ultra.All these 5 samples detected M.Tb by Xpert Ultra, however among these 5 samples Xpert MTB/RIF assay did not detect M.Tb in 2 samples.

Table 1: Results of Xpert Ultra, Xpert MTB/RIF assay and TB MGIT culture for detection of mycobacterium tuberculosis (MTB) and for detection of rifampicin resistance (RR).

	Xpert Ultra (n=70)	Xpert MTB/RIF (n=63)	TB MGIT culture (n=128)
MTB positive	48 (70.6%)	48 (77.4%)	71 (57.1%)
Rifampicin resistance	16 (33.2%)	27 (56.1%)	34 (52.3%)
Pulmonary (gastric lavage,BAL,sputum) samples positive for MTB	21 (out of 26 - 80.7%)	20 (out of 21 - 95.2%)	27 (out of 47- 57.4%)
Pulmonary samples positive for MTB			
1. Gastric lavage	11 (out of 13 – 84.6%)	11 (100%)	12 (out of 24 – 50%)
2. BAL	4 (out of 7 – 57.14%)	4 (out of 5 - 80%)	5 (out of 11 – 45.45%)
3. Sputum	6 (100%)	6 (100%)	10 (out of 12- 83.33%)
Extra pulmonary samples positive for MTB	28 (out of 43 – 65.11%)	28 (out of 41 – 68%)	46 (out of 84 – 54.7%)
EPTB samples positive for MTB			
Lymph node	11(out of 14 -78.57%)	5 (out of 8 – 62.5%)	14 (out of 22-63.63%)
Pleural fluid	0 (out of 4 – 0%)	2 (out of 2 -100%)	1 (out of 6 – 16.66%)
CSF	6 (out of 7 -85.71%)	3(out of 5 -60%)	2 (out of 9 -22.22%)
Ascitic fluid	0 (out of 4)	0 (out of 2)	1 (out of 6- 16.66%)
Biopsy sample	4 (out of 6- 66.66%)	7(out of 12- 58.33%)	13 (out of 18-72.26%)
Pus	5 (out of 5-100%)	9 (out of 9-100%)	14 (out of 14-100%)

Note = MTB=mycobacterium tuberculosis, BAL bronchoalveolar lavage

Conclusions/Learning Points: Xpert Ultra was not statistically superior to Xpert MTB/RIF assay for the diagnosis of TB in Indian children.

PD0039 / #1460

VALIDITY OF GENE XPERT MTB/RIF ASSAY AS A DIAGNOSTIC TOOL IN THE DETECTION OF TUBERCULAR MENINGITIS IN CHILDREN

E-Poster Discussion
E-POSTER DISCUSSION SESSION 04: DIAGNOSTICS AND BIOMARKERS (STATION 04)

Gajanand Singh Tanwar[1], Vikas Gurjar[1], Renu Agrawal[1], Priya Tanwar[2]
[1]S. P. Medical College,, Pediatrics, BIKANER, India, [2]SP Medical College, Pediatrics, BIKANER, India

Backgrounds: Tubercular meningitis (TBM) is more challenging to diagnose than other types of bacterial meningitis due to frequent atypical and varied clinical presentation, inadequate clinical sample with conventional cerebrospinal fluid culture based diagnosis and paucibacillary nature of the biological samples, which frequently results in a delay or deprivation of treatment. Role of PCR based Gene-Xpert MTB/RIF test in diagnosing TBM is yet to be validated so far. The aim of this prospective study was to evaluate the role of CSF Gene XPERT (CBNAAT) in diagnosis of tuberculous meningitis (TBM) and determine its sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV).
Methods: This prospective study enrolled 44 clinically suspected TBM patients admitted in a calendar year (2021-22). Clinical, radiological evaluation and conventional tests were done. CSF samples were subjected to routine CSF analysis, MGIT culture and CBNAAT. Children on anti-tuberculous therapy were excluded from study.
Results: The mean age of the study population was 6.4 (±3.4) years. Male to female ratio was 1:1.3. Meningeal signs were present in 54.5% children. Neurological deficits were present in 47.3%. Most common brain imaging findings were communicating hydrocephalus (47.7%) followed by meningeal enhancement (38.6%) and basal exudates (31.8%). AFB was present in direct microscopy in only 1(2.3%) case, positive growth on culture in 5 (11.4%) cases and positive Gene-Xpert test in 7 (16.0%) cases. Gene XPERT showed sensitivity, specificity, PPV, NPV and diagnostic accuracy of 42.7%, 92.5%, 76.7%, 80.4% and 88.2% respectively as compared to culture considering as gold standard. One child was rifampicin resistant.
Conclusions/Learning Points: Despite of low sensitivity of CSF Gene-Xpert (42.7%) in this study, positive result not only confirm speedy diagnosis of tuberculous meningitis but also reveal about rifampicin sensitivity status.

PD0040 / #2150

A LATERAL FLOW TEST FOR RAPID IDENTIFICATION OF PAEDIATRIC VIRAL INFECTION BASED ON HOST RESPONSE MRNA TRANSCRIPTS.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 04: DIAGNOSTICS AND BIOMARKERS (STATION 04)

Ruth Reid[1], Jaidan Cheema[1], Rebecca Womersley[1], Jesus Rodriguez-Manzano[2], Myrsini Kaforou[1], Pantelis Georgiou[3], Jethro Herberg[1], Michael Levin[1]
[1]Imperial College London, Paediatric Infectious Disease, London, United Kingdom, [2]Imperial College London, Department Of Infectious Disease, London, United Kingdom, [3]Imperial College, Electrical And Electronic Engineering, London, United Kingdom

Backgrounds: The current diagnostic pathway for identifying the cause of infection has several limitations. The clinical features of infection overlap, and diagnostic tests are expensive and lack discriminatory power. Infections can be defined by their unique host-response transcriptomic profile but there are no available cheap, quick, and accurate test platforms that leverage published host transcript signatures. We aimed to develop a lateral flow assay to detect and quantify the mRNA transcript IFI44L, a biomarker for viral infection.
Methods: An RT-LAMP nucleic acid lateral flow assay was developed for the detection of IFI44L and PPIB (housekeeping gene) by modifying primers for lateral flow (see figure for detailed explanation). 6 whole blood samples were collected from febrile children with viral (4) or bacterial (2) infection. mRNA was extracted using the Dynabeads mRNA direct kit from 300 µl of PAXgene stabilised blood (equating to <100 µl of whole blood). RT-LAMP was carried out for 30 minutes at 63 °C and 1 µl of each product was added to a universal lateral flow strip. Bands were quantified using a lateral flow reader. Results were normalised against the lateral flow control and the housekeeping
gene.

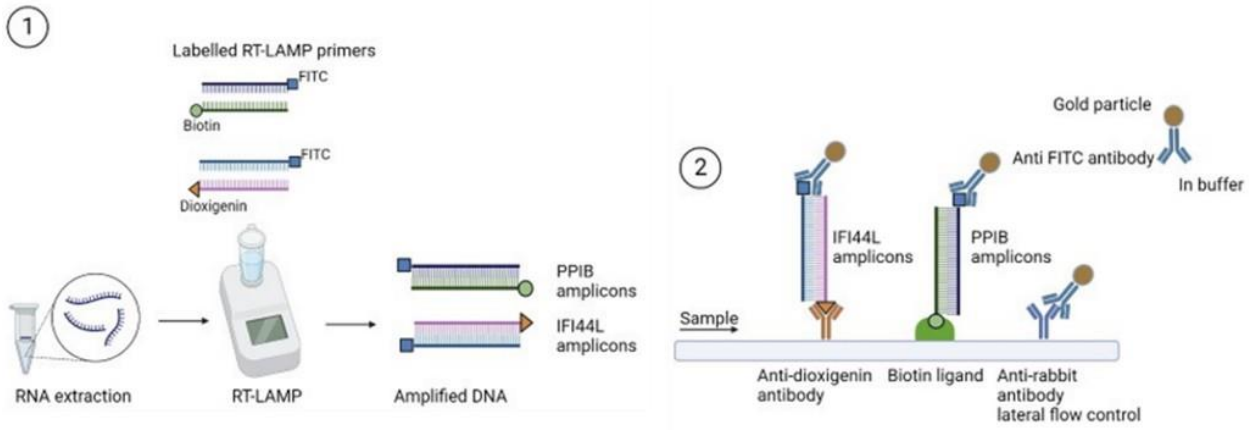


Figure: Binding of the amplified product to a specified band of the lateral flow strip is mediated by biotin-streptavidin (IFI44L) and dioxygenin-antidioxygenin (PPIB). The amplified product also contains FITC – this is required for visualisation via antiFITC gold nanoparticles contained in the lateral flow buffer. This causes the characteristic red colour change. Binding to the lateral flow strip only occurs when the specific target has amplified, as both biotin/dioxygenin and FITC are required to produce a colour change.

Results: The limit of detection was 100 copies/µl. Normalised median (95% CI) expression levels for bacterial and viral patients were 0.416, (0.145 – 1.008), n=2; and 0.723, (0.469 – 0.976), n=4, respectively. p=0.18.
Conclusions/Learning Points: These results suggest feasibility of a lateral flow test to detect and quantify host-response transcripts from whole blood. Such an approach would enable low-cost, laboratory-free, rapid diagnosis of childhood febrile illness, based on a point-of-care technology that leverages host transcript diagnostic signatures, and is suitable for use across a range of clinical settings.

PD0041 / #2183

METHODS FOR TRANSFERRING AN ELISA ONTO A SEMICONDUCTOR MICROCHIP FOR RAPID DIAGNOSTICS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 04: DIAGNOSTICS AND BIOMARKERS (STATION 04)

Natasha Walker[1,2], Lewis Keeble[1], Diego Estrada-Rivadeneyra[2], Shea Hamilton[2], Michael Levin[2], Pantelis Georgiou[1], Nicolas Moser[1]
[1]Imperial College, Electrical And Electronic Engineering, London, United Kingdom, [2]Imperial College, Department Of Infectious Disease, London, United Kingdom

Backgrounds: Rapidly differentiating between bacterial and viral infection is essential in treatment selection and clinical outcomes. Using lab-on-chip technology to quantify host protein biomarkers has the potential to enable connected and portable diagnostics at point-of-care. The aim of this proof-of-concept study was to transfer an enzyme-linked immunosorbent assay (ELISA) onto a semiconductor platform to assess the biocompatibility of the assay on the chip surface.
Methods: We designed and optimised a colorimetric ELISA for C-reactive protein (CRP). We used a complementary metal-oxide-semiconductor (CMOS) microchip integrating thousands of electrochemical sensors with a silicon nitride surface. Four chips were treated with oxygen plasma to add hydroxyl groups. We functionalised the surface for covalent antibody binding using silane chemistry i.e. 3-(Aminopropyl)triethoxysilane (APTES) and glutaraldehyde. Monoclonal capture antibodies specific to CRP (2µg/mL) were immobilised on the surface and incubated with recombinant CRP at concentrations of 250pg/mL, 500pg/mL and 1000pg/mL. One chip was incubated with buffer solution as a negative control. We validated the assay's functionality through a colorimetric readout. The colorimetric difference between the CRP concentrations were assessed using MATLAB as a colour processing software.
Results: The ELISA standard curve detected CRP at concentrations between 31.25pg/mL and 1000pg/mL. There were significant variations in colour intensity as quantified by the image processing algorithm between the three concentrations and the negative control after 30 minutes. This showed the successful translation of the ELISA onto the silicon nitride surface.
Conclusions/Learning Points: This study demonstrated the biocompatibility of a CRP-ELISA on a CMOS-based rapid diagnostic platform. These results will be used in further studies using this electrochemical platform to offer real-time and rapid detection of host proteins.

PD0042 / #1024

ARE CHILDREN WITH PROLONGED FEVER AT A HIGHER RISK FOR SERIOUS ILLNESS? A PROSPECTIVE OBSERVATIONAL STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 04: DIAGNOSTICS AND BIOMARKERS (STATION 04)

Backgrounds: A prolonged fever is considered a warning sign for serious infection in the NICE childhood fever management guidelines. We aimed to describe the characteristics and clinical outcomes of children with fever >=5 days presenting to emergency departments (EDs) and compare these to children with a shorter duration of fever.
Methods: Design: Prospective observational study, embedded in PERFORM study Setting: 12 European EDs Patients: Consecutive febrile children <18 years between January 2017-April 2018. Interventions: Children with fever >=5 days and their risks for serious bacterial infection (SBI) were compared with children with fever <5 days, including diagnostic accuracy of non-specific symptoms, warning signs, and C-reactive protein (mg/L). Main outcome measures: SBI and other non-infectious serious illness
Results: 3778/35705 (10.6%) of febrile children had fever ³5 days. Incidence of SBI in children with fever ³5 days was higher than in those with fever <5 days (8.4% vs. 5.7%). Triage urgency, lifesaving interventions and intensive care admissions were similar for fever ³5 days and <5 days. Several warning signs had good rule in value for SBI with specificities >0.90, but were observed infrequently (range: 0.4%-17%). Absence of warning signs was not sufficiently reliable to rule out SBI (sensitivity 0.92 (95% CI 0.87-0.95), negative LR 0.34 (0.22-0.54)). CRP <20mg/L was useful for ruling out SBI (negative LR 0.16 (0.11-0.24)). There were 66 cases (1.7%) of non-infectious serious illnesses, including 21 cases of Kawasaki Disease (0.6%), 28 inflammatory conditions (0.7%) and 4 malignancies.
Conclusions/Learning Points: Children with prolonged fever have a higher risk of SBI, warranting a careful clinical assessment and diagnostic work up. Warning signs of SBI occurred infrequently, but if

present, increased the likelihood of SBI. Although rare, clinicians should consider important non-infectious causes of prolonged fever.

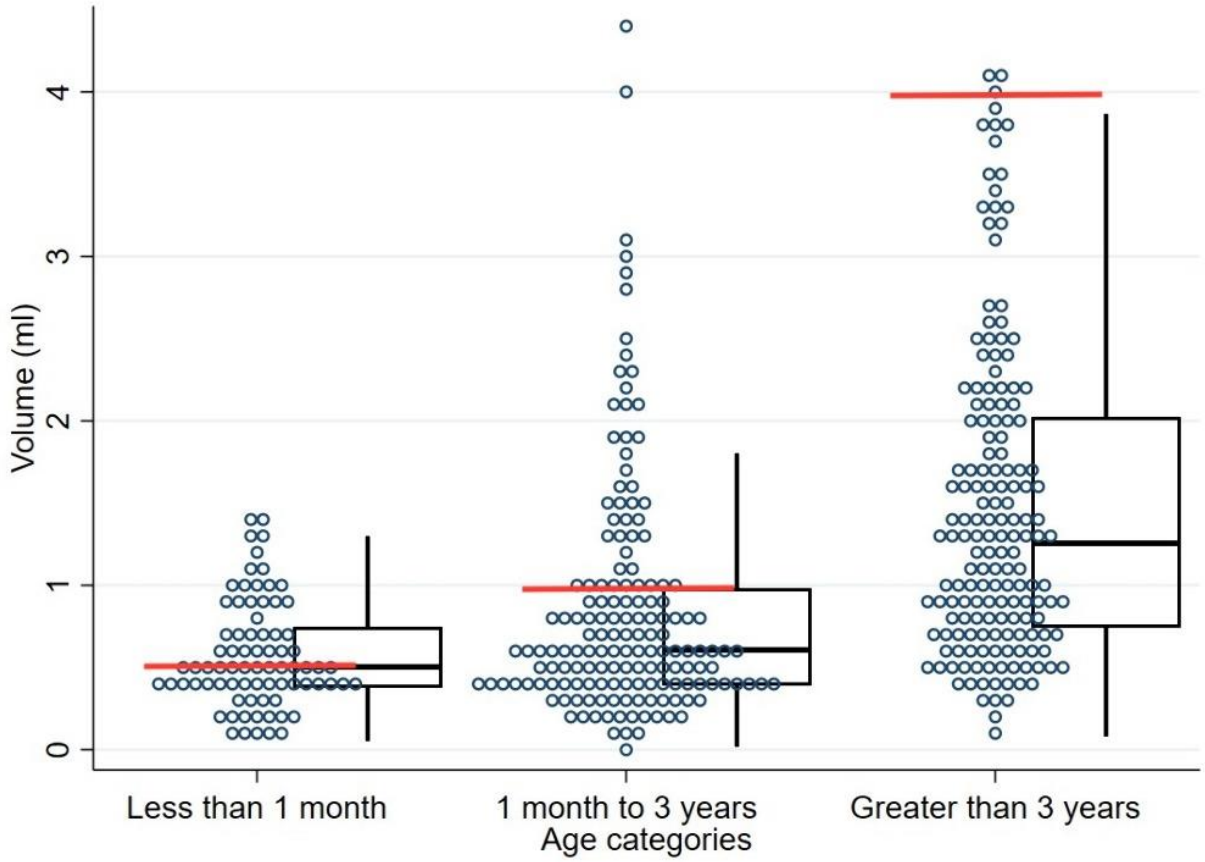
PD0043 / #2181

MAKING BLOOD CULTURES COUNT - AN AUDIT OF PAEDIATRIC BLOOD CULTURE VOLUMES AND QUALITY IMPROVEMENT STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 04: DIAGNOSTICS AND BIOMARKERS (STATION 04)

Sean Whelan[1], Conor Mulrooney[1], Frank Moriarty[2], Martin Cormican[1]
[1]Department of Clinical Microbiology, Galway University Hospital, Galway, Ireland, [2]RCSI University of Medicine and Health Sciences, School Of Pharmacy And Biomolecular Sciences, Dublin, Ireland

Backgrounds: Blood cultures [BCs] are the gold standard for the diagnosis of serious bacterial infection in children. It has been demonstrated the major determinant of BC sensitivity and specificity is the volume of blood inoculated into the BC bottle. Our aim was to review our BC inoculant volumes, design an intervention to improve volumes, and monitor the impact of this intervention.
Methods: The study was carried out in a single institution with paediatric and neonatal departments. All BD BACTEC™ Peds Plus™ bottles were weighed pre and post- sampling, and inoculated blood-volumes were calculated. Clinical details, including age, weight, and indication were recorded from patient notes. As per manufacturer instructions, 0.5ml is the minimum acceptable volume, while 1ml+ is the recommended volume. Age-specific recommendations were also assessed.
Results: Over a four-month period, 402 BC bottles had inoculant volumes calculated, 64 from NICU and 338 from Paediatrics. Among NICU samples, the median volume was 0.49ml [IQR 0.37,0.74], with 51.5%<0.5ml and 90.6%<1ml. Amongst paediatric samples, the median volume inoculated was 0.85ml [0.491,1.600], with 25.1% <0.5ml, and 58.6% <1ml. Overall, using age-based criteria, only 20.5% were adequately filled [see Figure]. Thirty-five BCs were positive, 10 likely contaminants, of which 9 had volumes <1ml, while of 25 significant positive cultures, 80% had volumes >1ml.



Conclusions/Learning Points: There was widespread underfilling of BC volumes in our institution, with many bottles critically underfilled. Consequently, in many cases while BCs have been sent, no meaningful test had been performed, risking missing bacteraemia. Trends whereby smaller volumes were associated with contaminants, and higher volumes associated with true positives were noted. Education sessions, policy implementation, regular feedback on performance are all currently underway, with ongoing volume assessment, and this pre/post intervention comparison will be presented.

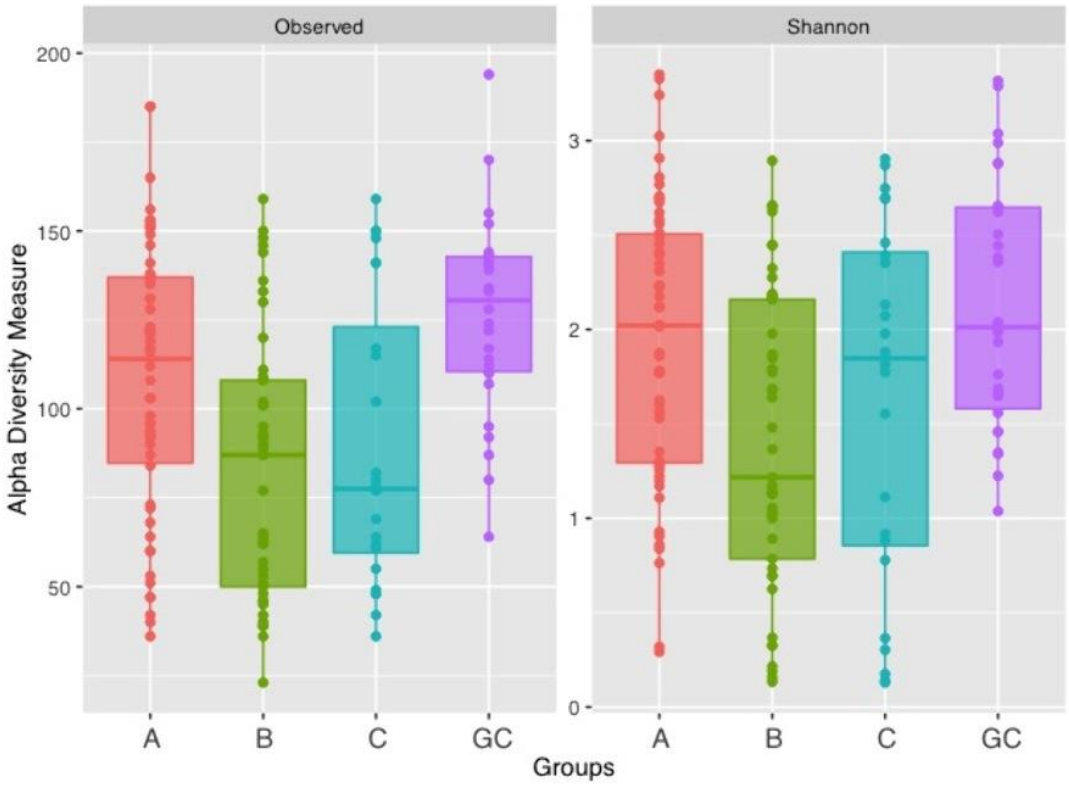
PD0044 / #2120

DYNAMIC OF RESPIRATORY MICROBIOTA IN CHILDREN UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) BEFORE, DURING AND AFTER TREATMENT

E-Poster Discussion
E-POSTER DISCUSSION SESSION 05: MYCOBACTERIA & IMMUNO COMPROMISED HOST (STATION 05)

Juan Pablo Torres[1,2], Mariana Izquierdo[3], Veronica De La Maza[3], Paula Catalan[4], Julia Palma[4], Salome Rivera[2], Romina Valenzuea[3], Maria Elena Santolaya[3], Mauricio Farfan[5]
[1]Instituto Sistemas Complejos de Ingenieria, Isci, Santiago, Chile, [2]Faculty of Medicine, Universidad de Chile, Department Of Pediatrics, Division Of Pediatric Infectious Diseases,, Santiago, Chile, [3]Faculty of Medicine, Universidad de Chile, Department Of Pediatrics, Division Of Pediatric Infectious Diseases, Santiago, Chile, [4]Hospital Calvo Mackenna, Unidad De Trasplante De Medula Osea, Santiago, Chile, [5]Faculty of Medicine, Universidad de Chile, Department Of Pediatrics, Santiago, Chile

Backgrounds: Respiratory microbiota can play a key role in virus-bacteria interactions in respiratory infections, especially in immunocompromised children. The dynamic changes after HSCT and the possible role in the severity of infections is unknown. Our aim was to determine the dynamics of the composition of the respiratory microbiota in children undergoing HSCT before, during and after treatment.
Methods: Prospective cohort study, children≤18 years with cancer and HSCT admitted at Hospital Calvo-Mackenna,Chile (September-2017 to January-2022). Nasopharyngeal samples were obtained at: Group-A:2-4 weeks prior to HSCT;Group-B:day 0 of HSCT and Group-C:3 months after HSCT. Sequencing of the full length 16S rRNA using the PacBio Sequel was performed. Raw sequences were processed (Mothur-software) and data were analyzed with RStudio program. A control group(CG) of children without HSCT was included.
Results:



110 children(149 samples) were enrolled (Group-A=54/Group-B=45/Group-C=24/CG=26). We found a smaller number of taxa and diversity value (Shannon-index) for Group-B compared to Group-A and GC($p<0.05$). By Redundancy Analysis we observed differences in community structure between these 4 groups($p=0.001$). For all groups, Firmicutes was the predominant Phylum, followed by Proteobacteria and Bacteroidota. An increase of Firmicutes and a decrease of Proteobacteria were found in Group-B compared to Group-A and CG. We found Staphylococcus in children from Groups A-B-C compared to CG. Group-B had a smaller amount of Neisseria, Haemophilus and Granulicatella compared to groups A and GC.

Conclusions/Learning Points: To our knowledge, this is the first report on the dynamics of the respiratory microbiota in children undergoing HSCT. Significant changes were found at the level of diversity, community structure and bacterial genera. Dynamics of the microbiota could be relevant in the susceptibility and/or severity of respiratory infection after HSCT, however more studies are needed (ANID-PIA/ApoyoAFB220003;FONDECYT Grant 1171795).

DIFFERENTIAL CLINICAL CHARACTERISTICS BETWEEN CHILDREN WITH TUBERCULOUS MENINGITIS (TBM) AND OTHER FEBRILE NEUROLOGICAL ILLNESSES IN AFRICAN CENTRES PARTICIPATING IN A TBM TREATMENT SHORTENING TRIAL (SURE)

E-Poster Discussion
E-POSTER DISCUSSION SESSION 05: MYCOBACTERIA & IMMUNO COMPROMISED HOST (STATION 05)

Susan Abarca Salazar[1,2,3], Vivian Mumbiro[4], Ennie Chidziva[4], Lisa Nkole[5], Christina Zulu[5], Joyce Lungu[5], Chimuka Tembo[5], Rogers Owori[6], Nancy Nabukeera[6], Juliet Nyiramugisha[6], Hiroyuki Moriuchi[1], Suzanne Anderson[2], Diana Gibb[2], Hilda Mujuru[7], Chishala Chabala[5], Veronica Mulenga[5], Eric Wobudeya[6], Sabrina Kitaka[6], Robin Basu Roy[2]
[1]Nagasaki University, School Of Tropical Medicine And Global Health, Nagasaki, Japan, [2]University College London, Mrc Clinical Trials Unit, LONDON, United Kingdom, [3]London School of Hygiene and tropical Medicine, Clinical Research, London, United Kingdom, [4]University of Zimbabwe Clinical Research Centre, Department Of Paediatrics At Sally Mugabe Hospital, Harare, Zimbabwe, [5]University of Zambia, School Of Medicine And University Teaching Hospital, Lusaka, Zambia, [6]University of Uganda, Mujhu Research Collaboration, Kampala, Uganda, [7]University of Zimbabwe, Paediatrics, Harare, Zimbabwe

Backgrounds: Tuberculosis meningitis (TBM) has a high risk of mortality and sequelae in children. Early diagnosis and treatment lead to improved survival; however, available tests are neither sensitive nor rapid enough to confirm TBM. We aim to identify and validate novel biomarkers to diagnose TBM in children.
Methods: Participants: 29 days to 18 years old with suspected central nervous system infections identified as part of the screening of the SURE trial in Zambia, Zimbabwe and Uganda are classified as TBM case or non-TBM control. Data from May to December 2022 were analysed using Chi-square and t-tests with RStudio.
Results::

Variables	TBM (n = 30)	Non-TBM (n = 55)	Total (n = 85)	p
age (years), median (IQR)	4.25 (0.75, 7.2)	1.5 (0.43, 6.25)	2 (0.6, 6.5)	0.191
disease onset (days), median (IQR)	14 (7, 21)	4 (2.5, 7)	7 (3, 13.25)	< 0.001
impaired consciousness, n (%)	25 (86)	18 (38)	43 (57)	< 0.001
focal neurological signs, n (%)	18 (62)	4 (9)	22 (29)	< 0.001
pGCS, median (IQR)	8 (5.25, 12.75)	14 (11, 15)	13 (8.75, 15)	0.002
CSF WBC (cells/mm3), n (%) 5-100 >100	5 (18) 5 (18)	3 (8) 5 (14)	8 (12) 10 (15)	0.374
CSF protein (mg/dL) median (IQR)	105 (36.6, 238)	30 (19.5, 42)	39.5 (24, 108.75)	< 0.001
CSF glucose <2.5 mmol/L, n (%)	9 (36)	1 (4)	10 (20)	0.005

Conclusions/Learning Points: Children with TBM diagnosis have a longer illness duration and more serious neurological signs than controls. This study is nested in the largest ever clinical trial in paediatric TBM, therefore has a unique chance to contribute well-characterised samples to evaluate novel diagnostics to identify TBM cases.

PD0046 / #1004

CLINICAL, IMMUNOLOGICAL AND SOCIAL OUTCOME FOLLOWING TRANSITION TO ADULT CARE OF HIV-INFECTED PATIENTS – 10 YEARS CASUISTIC FROM A TERTIARY PAEDIATRIC UNIT

E-Poster Discussion
E-POSTER DISCUSSION SESSION 05: MYCOBACTERIA & IMMUNO COMPROMISED HOST (STATION 05)

Carolina Fraga[1], Vanessa Costa[1], Joanna Ashworth[1], Carla Teixeira[2], Alexandre Fernandes[2], Laura Marques[2]
[1]Centro Materno-Infantil do Norte, Centro Hospitalar Universitario do Porto, Pediatrics Department, Porto, Portugal, [2]Centro Materno-Infantil do Norte, Centro Hospitalar e Universitário do Porto, Infectious Diseases And Immunodeficiencies Unit, Paediatric Department, Porto, Portugal

Backgrounds: Transition to adult care is a challenging period for HIV-infected young people, with increased risk of noncompliance and non-retention in care.
Methods: Clinical, immunological and social evaluation was assessed in HIV-infected patients participating in a transition program to adult care from 2012-2022 in a Tertiary Paediatric Centre. A post transition questionnaire was applied to patients with >1 year follow-up in adult care.
Results: Forty-six patients participated in the transition program and was completed in 23 (50%); of these, 61% were female with median age at transition of 18.5 (16-21) years and infection occurred by mother-to-child transmission in 91%. Median follow-up time at adult care: 6 (0.5-11) years. After transition, 2 patients were lost to follow-up (8.7%), and 30% missed at least one appointment per year. Seventeen patients (73%) changed ART (mostly simplification). Viral load and CD4 count evolution weren't different pre-transition and during follow-up (Table). New AIDS diagnosis occurred in 1 patient; no deaths recorded. Three patients (13%) have graduated in university, 70% are employed, and 17% have children, all uninfected. Biological parent death occurred in 52%. Most adults knew viral load and ART regimen (60% and 70%, respectively) but didn't know last CD4 count (90%). Transition was reported as harder than expected by 40%. Communication issues were the most relevant difficulty. The major advantage identified was higher autonomy.

CD4 count and viral load evolution

	Pre-transition n=23	**1-year-after n=21**	**5-years-after n=15**
Undetectable viral load	74%	65%	73%
CD4 count <200/mm3	8%	0%	13%

Conclusions/Learning Points: The majority of transitioned HIV-infected patients were retained in adult care and no deaths occurred. Most were virally suppressed with CD4 counts >500/mm3 1-5 years after transition. The majority are employed. Transition programs improve outcomes in HIV-infected young adults.

PD0047 / #787

POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER FOLLOWING PEDIATRIC INTESTINAL TRANSPLANT: AN OLD FOE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 05: MYCOBACTERIA & IMMUNO COMPROMISED HOST (STATION 05)

Harry Mystakelis[1], Nada Yazigi[2], Khalid Khan[2], Bernadette Vitola[2], Stuart Kaufman[2], Cal Matsumoto[2], Udeme Ekong[2]
[1]Medstar Georgetown University Hospital, Pediatrics, Washington, United States of America, [2]MedStar Georgetown Transplant Institute, Transplant Institute, Washington, United States of America

Backgrounds: Our center previously reported a post- transplant lymphoproliferative disorder (PTLD) rate following pediatric intestinal transplantation of 10%. Given improvements in the management of immunosuppression (IS) over the past decade, we evaluated if improvements in IS would change PTLD rate.
Methods: A single-center retrospective review of pediatric intestinal transplant between January 1, 2012 and December 31, 2022 was performed. PTLD was diagnosed using WHO classification criteria and confirmed with biopsy and PET/CT when available. Recipient characteristics, interventions and outcomes were assessed.
Results: 86 intestinal transplants were performed in 85 recipients. 40 patients received an isolated intestinal transplant and 46 received a composite transplant of intestine, liver, and pancreas. Of the 86 recipients, Epstein Barr Virus (EBV) viremia was observed in 33; 12 developed PTLD (14%); (6F, 6M); 10 had EBV+ PTLD. Median age at transplantation for the entire study cohort was 28(IQR:15-54)-months, while the median age at transplant of patients with PTLD was 35.5(IQR:15.5-122.3)-months (p=0.19). The median duration from transplant at PTLD diagnosis was 8(IQR 3-29)-months. All patient were on tacrolimus and prednisone with a median tacrolimus level of 9(6.5-14)ng/ml prior to PTLD diagnosis. There was no significant difference in PTLD rate between isolated intestine and composite transplant recipients(p=0.75). Treatment consisted of Rituximab, two patients received EBV cytotoxic T cell therapy, and 3 received systemic chemotherapy. 19 patients died during the observation period (22%). Four patients diagnosed with PTLD died during the observation period (36%) (p= 0.28). Lastly, 15 patients with EBV viremia received Rituximab. None progressed to PTLD.

Clinical Characteristics	No PTLD	PTLD[1]
Total Patients	73	12
Age at Transplant[2] (IQR)	28 (14.25-47.75)	31 (16-120.5)
Gender (%Male)	69	50
Composite Transplant	40	6
Isolated Intestinal Transplant	34	6
Survival (%)	80%	75%
EBV positivity (%)	31%	83%
Rituximab Administration for EBV Viremia**(#)	18	10
EBV copie/sml at time of rituximab/PTLD (IQR)	6,000 (3,000-21,775)	5,100 (900-5,3275)
Time post transplant for peak EBV Viremia/PTLD (IQR)[2]	13(1-57)	8.5 (2.5-27.5)
PET/CT (#)	8	11

[1] One patient was excluded due to relapsed PTLD from previous transplant prior to 2012
[2] Months

Conclusions/Learning Points: PTLD rate remains unchanged despite improvements in immunosuppression and occurs early post intestinal / composite transplant. Early use of B cell reducing therapy with Rituximab during EBV viremia may halt progression to PTLD.

PD0048 / #439

PAEDIATRIC OUTPATIENT PARENTERAL ANTIMICROBIAL THERAPY (P-OPAT): A COLLABORATIVE STUDY FROM THE P-OPAT UK NETWORK TO DESCRIBE THE ROLE OF P-OPAT IN ANTIFUNGAL THERAPY.

E-Poster Discussion

E-POSTER DISCUSSION SESSION 05: MYCOBACTERIA & IMMUNO COMPROMISED HOST (STATION 05)

Beatrice Zanetti[1], Katja Doerholt[2], Sanjay Patel[3], Helen Green[3], Jaroslava Alam[1], Beatriz Keith Antojado[1], The Uk Popat Network[1], Laura Ferreras Antolín[1]
[1]St. George's Hospital, Paediatric Infectious Disease, London, United Kingdom, [2]Institute for Infection and Immunity, Saint George's, Centre For Neonatal And Paediatric Infection, London, United Kingdom, [3]University Hospital Southampton, Paediatric Infectious Diseases, Southampton, United Kingdom

Backgrounds: There has been an increase in the paediatric population considered at risk for invasive fungal infections. Many of those will need antifungal prophylaxis or treatment for long periods. Whereas oral formulations are the preferred option in the community; different circumstances might require intravenous (iv) formulations. pOPAT has been successfully used in the UK mainly for antibiotics. Our aim was to describe the use and outcomes of pOPAT for antifungals.
Methods: Retrospective cohort study collecting data on children 0- 18 years from Oct 2017-May 2022 who used pOPAT services for iv antifungal prophylaxis or treatment at two pOPAT centres in the UK.
Results: 29 patients were included, representing 2% of total pOPAT patients during the study period. Median age was 5 years (IQR 3-13). Almost all had an underlying condition 28/29 (96.5%); dominated by haemato-oncology and transplant patients 22/29 (75.9%). 8/29 (27.6%) required antifungals for prophylaxis whilst 21/29 (72.4%) received them for treatment. 75.8% (22/29) were on a single antifungal agent while under pOPAT. Liposomal amphotericin B was the commonest antifungal prescribed (22/29 cases [75.9%]); followed by caspofungin (7/29 [24.1%]) and in one case, fluconazole (3.4%). Antifungals were delivered mainly by community nurses 19/29 (65.5%), followed by pOPAT clinics 11/29 (37.9%). Favourable outcomes (completion of pOPAT therapy with no antimicrobial change, no adverse events, cure of infection and no readmission) were achieved in 18/29 (62.0%) cases. De-escalation to orals happened in 20.7% (6/29) patients.
Conclusions/Learning Points: The study proves that pOPAT can be a safe system to deliver iv antifungals when oral formulations are not indicated,especially to prevent long hospital admissions for oncology patients.Patients tend to have good outcomes with minimal drug-related events. Further investigation and structured national recommendations are required.

THE BURDEN OF CHILDHOOD TUBERCULOSIS IN COUNTRIES THAT MAINTAIN UNIVERSAL BCG VACCINATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 05: MYCOBACTERIA & IMMUNO COMPROMISED HOST (STATION 05)

Joana Valente Dias[1,2], Luís Varandas[3,4,5], Luzia Gonçalves[6,7], Benjamin Kagina[8]
[1]Hospital Beatriz Ângelo, Paediatrics Department, Loures, Portugal, [2]Universidade Nova de Lisboa, Instituto De Higiene E Medicina Tropical, Lisbon, Portugal, [3]Centro Hospitalar Universitário Lisboa Central, Hospital Dona Estefânia, Lisbon, Portugal, [4]Universidade Nova de Lisboa, Instituto de Higiene e Medicina Tropical, Global Health And Tropical Medicine, Lisbon, Portugal, [5]Universidade Nova de Lisboa, Nova Medical School, Lisbon, Portugal, [6]Universidade de Lisboa, Centro De Estatística E Aplicações, Lisbon, Portugal, [7]Universidade Nova de Lisboa, Instituto De Higiene E Medicina Tropical, Global Health And Tropical Medicine, Lisbon, Portugal, [8]University of Cape Town, School Of Public Health & Family Medicine, Vaccines For Africa Initiative, Cape Town, South Africa

Backgrounds: Historically, childhood tuberculosis has been neglected, particularly in low-resource settings. However, tuberculosis disease in children significantly contributes to the global burden of tuberculosis and remains an important cause of global childhood morbidity and mortality.
Methods: A systematic review of research published between 2000 and 2020, in three databases (PubMed, Web of Science and SciELO), was carried out to characterise childhood tuberculosis in countries that maintain universal BCG vaccination. Studies reporting relevant epidemiological data, with a particular focus on disease outcomes, regarding children between 0 and 14 years old, were selected. Random effects meta-analysis was performed in R software.
Results: We identified 1806 references from database searching and, after screening for inclusion criteria, 35 articles reporting relevant epidemiological data from 24 countries were selected. Among children with tuberculosis, the overall proportion of unfavourable outcomes was 19.52% (95% confidence interval (CI) 14.44-25.84) and the pooled case fatality ratio was 6.06% (95% CI 4.34-8.40). A higher proportion of deaths was observed among children between 0 and 4 years old (6.56%, 95% CI 4.91-8.71) if compared to older children (4.61%, 95% CI 3.06-6.90). Pooled prevalence of HIV infection among tested children was 21.30% (CI 95% 11.89-35.17) and TB/HIV co-infected children presented a higher case fatality ratio (15.09%, 95% CI 7.86-27.02) when compared to HIV negative children (4.16%, 95% CI 2.00-8.44). The overall proportion of MDR-TB was 8.14% (95% CI 4.64-13.90).
Conclusions/Learning Points: Although limited by heterogeneity, our findings suggest a significant proportion of unfavourable outcomes, including death, particularly in younger children with tuberculosis and TB/HIV co-infected children. Therefore, global efforts to close remaining gaps, such as underreporting, underdiagnosis and inadequate treatment, should be intensified if we aim to effectively tackle the burden of childhood tuberculosis.

Backgrounds: Tuberculous meningitis (TBM) in children causes significant mortality and neurological disability. Shorter and optimal treatment regimens with better neurological outcomes are an important research priority. We describe updated recruitment and baseline characteristics of children recruited into the largest ever paediatric TBM treatment trial.
Methods: SURE is a factorial phase III RCT evaluating the non-inferiority for mortality of shorter intensive 6-month (high-dose rifampicin/isoniazid, pyrazinamide, levofloxacin) vs standard 12- month antituberculosis treatment and superiority of aspirin vs placebo on neurological disability. 400 children aged <18 years with TBM are being enrolled in 3 African and 2 Asian countries.
Results: Between 3 March 2021 and 31 December 2022, 157 children (females [45%], median age 4.0 years [IQR 1.0 – 9.5]) were enrolled. Five [3%] are HIV infected with one on ART before randomisation. 28 (18%) reported history of TB contact in the preceding year. Common symptoms were: fever (147, 94%), lack of playfulness/energy (122, 78%), poor feeding/appetite (107, 68%) for median duration 15 (IQR 9,27), 14 (7,22) and 14 (7, 21) days respectively. Seizures, focal neurological signs and hydrocephalus were present in 72 (46%), 56 (36%) and 47 (32%) respectively. Eleven required VP shunts, 3 external ventricular drains and 15 were managed medically. At enrolment, 71 (45%), 60 (38%) and 26 (17%) were TBM stage I, II and III respectively.
Conclusions/Learning Points: The SURE trial has recruited 157/400 children, despite diagnostic challenges and severe disruptions caused by COVID; most children were TBM stage II/III. Follow-up for each child will be for 18 months. Several sub-studies are planned/ongoing, including evaluation of new diagnostic techniques. [Update of data presented at 5th TBM 'Closed' International Consortium Meeting, August 2022]

PD0051 / #687

INTEGRASE INHIBITORS IN CHILDREN AND ADOLESCENTS: CLINICAL USE AND RESISTANCE

Backgrounds: Although integrase inhibitor (INI)-based regimens are now the first-line choice for all people living with HIV, experience among children and adolescents is still scarce. We describe the characteristics and outcomes of a paediatric/adolescent cohort on INI-based ART.
Methods: Retrospective analysis of HIV-infected patients below 18 years of age who started an INI-based regimen from 2007 to 2019, enrolled in the Spanish National Adult (CoRIS) and Paediatric (CoRISpe) cohorts. Resistance mutations were identified by the Stanford HIV Drug Resistance Database.
Results: Overall, 318 INI-based regimens were implemented in 288 patients [53.8% female; median age at start of 14.3 years (IQR 12.0–16.3)]. Most were born in Spain (69.1%), vertically infected (87.7%) and treatment experienced (92.7%). The most frequently prescribed INI was dolutegravir (134; 42.1%), followed by raltegravir (110; 34.6%) and elvitegravir (73; 23.0%). The median exposure was 2.0 years (IQR 1.1–3.0). The main reasons to start an INI-based therapy were treatment simplification (54.4%) and virological failure (34.3%). In total, 103 (32.4%) patients interrupted their regimen: 14.5% for simplification and 8.5% due to virological failure. Most subjects who received dolutegravir (85.8%) and elvitegravir (83.6%) did not interrupt their regimen and maintained undetectable viral load. There were only five virological failures with dolutegravir and three with elvitegravir. There were no interruptions related to adverse events. Seven patients with virological failure presented major resistance mutations to INIs; none of them were on
dolutegravir.

Table. Seven patients under virological failure carrying resistance viruses to integrase inhibitors among those with available integrase sequence.

Legend Table 3: ART, antiretroviral therapy; VL, viral load; HIV-1 RNA copies/milliliter plasma); INI, integrase inhibitors; Major DRM to INI, drug resistance mutations to INI according to Stanford v9.0. More information in https://hivdb.stanford.edu/dr-summary/resistance-notes/INSTI/. **Aa code**: A, Alanine; E, Glutamic acid; G, Glycine; H, Histidine; K, Lysine; N, Asparagine; Q, Glutamine; R, Arginine; S, Serine; Y, Tyrosine. 3TC, lamivudine; ABC, abacavir; DRV, darunavir; DTG, dolutegravir; EVGc, elvitegravir-cobicistat; FTC, emtricitabine; IN, HIV-1 integrase protein; INI, IN inhibitors; MRV, maraviroc; RAL, raltegravir; T20, enfuvirtide; TAF, tenofovir alafenamide; TDF, tenofovir disoproxil fumarate; TMC 125, etravirine; TPVr, tipranavir-ritonavir.

Patient	Age (years-old)	ART at failure	VL at failure (copies/mL)	Major DRM to INI	Salvage ART	VL after 6 months (copies/mL)
1	11.9	ABC 3TC RAL	41,800	N155H	TAF FTC EVGc	Undetectable
2	12.9	TPVr MRV RAL	36,671	E138K, S147G, Q148R	DRV T20 DTG	Undetectable
3	10.0	ABC 3TC RAL	5,501	Q148R	ABC 3TC DTG	Undetectable
4	15.4	DRVr TMC125 RAL	36,500	G140S, Q148H, E138A	TDF FTC EVGc	13,900
5	16.8	TDF FTC DRV EVGc	124,000	G140S, Q148H, E138K	3TC DRV DTG	Undetectable
6	16.0	DRVr TMC125 RAL	47,938	Y143R	TDF FTC DRVr TMC125 DTG	Undetectable
7	13.5	TAF FTC EVGc	34,800	E92Q, N155H	TAF FTC DRV	Undetectable

Conclusions/Learning Points: INI-based regimens were effective and safe for HIV treatment in children and adolescents. Dolutegravir and elvitegravir presented an excellent profile, and most patients achieved and maintained viral suppression.

Backgrounds: Low rates of postnatal retention in HIV care and viral suppression have been reported in women living with HIV (WLWH) despite viral suppression at delivery. At the same time, postpartum follow-up is of crucial importance in light of the increasing support offered in many resource-rich countries including Switzerland to WLWH choosing to breastfeed their infant, if optimal scenario criteria are met.
Methods: We longitudinally investigated retention in HIV care, viral suppression, and infant follow-up in a prospective multicentre HIV cohort study of WLWH in the optimal scenario who had a live birth between January 2000 and December 2018. Risk factors for adverse outcomes in the first years postpartum were assessed using logistic and proportional hazard models.
Results: Overall, WLWH were retained in HIV care for at least six months after 94·2% of the deliveries (694/737). Late start of combination antiretroviral therapy (cART) during the third trimester was found to be the main risk factor for failure of retention in HIV care (crude OR 3·79; 95% CI, 1·21-9·96; p = 0·011). Among mothers on combination antiretroviral therapy (cART) until at least one year after delivery, 4·4% (26/591) experienced viral failure, with illicit drugs use being the most important risk factor (HR, 13·1; 95% CI, 2·44-70·1; p = 0·003). The main risk factors for not following the recommendations regarding infant follow-up were substance use (adjusted OR, 1·90; 95% CI, 1·01 - 3·56; p = 0·046) and maternal depression (OR, 3·47; 95% CI, 1·15-10·35; p = 0·024).
Conclusions/Learning Points: Several modifiable risk factors for adverse postpartum outcome, such as late treatment initiation, substance use, and depression, were identified. These factors should be addressed in HIV care of all WLWH, especially those opting to breastfeed in resource-rich countries.

NONTUBERCULOUS MYCOBACTERIAL PULMONARY INFECTIONS IN CHILDREN.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 05: MYCOBACTERIA & IMMUNO COMPROMISED HOST (STATION 05)

Alejandra Coccolo Góngora[1], Marina Ascunce Abad[1], Yasmina Mozo Del Castillo[2], Paula Rodríguez-Molino[3], Fernando Baquero-Artigao[3], Carlos Toro Rueda[4], Cristina De Manuel Gómez[5], Marta Ruiz De Valbuena[5], Paloma Garcia Clemente[4], Cristina Calvo[3], Carlos Grasa[3], Ana Méndez-Echevarría[3], Talia Sainz[3], Dolores Corral Sanchez[2], David Bueno Sánchez[2], Luisa Sisini[2], Antonio Pérez-Martínez[2], Teresa Del Rosal[3]
[1]La Paz Universitary Hospital, Paediatrics, Madrid, Spain, [2]La Paz University Hospital, Paediatric Haemato-oncology, Madrid, Spain, [3]La Paz Universitary Hospital, Pediatric Infectious Diseases, Madrid, Spain, [4]La Paz University Hospital, Microbiology, Madrid, Spain, [5]La Paz University Hospital, Paediatric Pulmonology, Madrid, Spain

Backgrounds: Nontuberculous mycobacterial (NTM) infections are increasing in immunocompromised patients and those with chronic lung diseases, such as cystic fibrosis (CF). Nevertheless, limited paediatric data are available.
Methods: Retrospective, tertiary-centre study including all paediatric patients (aged 0-18 years) with microbiological isolation of NTM in bronchoalveolar lavage or sputum, between 2013-2022.
Results: We included 40 patients (median age of 13.3 years [IQR 10.9-15.5]). CF was the most frequent underlying disease (n=16, 40%), followed by recipients of hematopoietic stem cell transplant (n=10, 25%). Four patients (10%) did not have any pre-existing medical condition. Thirteen patients (32.5%) had lymphopenia. Seven patients (17.5%) met the 2020 ATS/IDSA diagnostic criteria for NTM pulmonary disease. There were 5 patients who did not meet the criteria but were treated because of clinical and radiological findings and underlying medical conditions. The other 28 isolates were interpreted as colonizations and did not develop disease despite not being treated (median follow-up: 3.2 years [IQR 0.5-5.5]). The most common NTM species were Mycobacterium avium (n= 16, 40%), Mycobacterium intracellulare (n=7, 17.5%) and Mycobacterium abscessus (n=6, 15%). The latter was the most frequent pathogen in CF patients (n=5, 31%). Drug-resistance was tested in 27 isolates (Table). All treated patients received combined antibiotic therapy (median number of drugs used: 3.5 [IQR 3-4], median duration of treatment: 12 months [IQR 2-13.5]). No surgical treatment was needed. Nine patients died during follow-up due to underlying disease. NTM infection might have contributed to two deaths.

	***M. abscessus* (n=6)** Sensitive/tested isolates	***M. avium* complex (n=18)** Sensitive/tested isolates	***p***
Clarithromycin	2 / 6	18 / 18	0.054
Ciprofloxacin	0 / 5	0 / 1	1
Amikacin	6 / 6	1 / 1	1
Linezolid	2 / 3	1 / 1	1

Table. Antimicrobial susceptibility patterns of tested isolates.

Conclusions/Learning Points: NTM respiratory infections affect mainly children with CF or immunodeficiency. Most NTM isolates from respiratory samples are colonizations. The most frequent pathogens are members of the Mycobacterium avium complex. Mycobacterium abscessus is emerging in CF patients and is associated with high antimicrobial resistance.

[1]Great Ormond Street Hospital, Paediatric Infectious Diseases, London, United Kingdom, [2]Great Ormond Hospital for Children, Microbiology, Virology And Infection Control, London, United Kingdom, [3]Great Ormond Street Hospital, Department Of Neurology, London, United Kingdom, [4]Great Ormond Street Hospital, Radiology, London, United Kingdom, [5]Bartshealth NHS trust, Virology, London, United Kingdom, [6]UCL Great Ormond Street Institute of Child Health, Paediatric Virology, London, United Kingdom, [7]University College London, Institute Of Child Health, London, United Kingdom

Background: Atypical or complex paediatric neurological presentations are common clinical conundrums and often remain undiagnosed despite extensive investigations. This is particularly pronounced in immunocompromised patients. The application of multidisciplinary teams (MDT) has been successful in conditions with broad ranging diagnostic possibilities. Here we show that clinical metagenomics (CMg) is a valuable adjunct diagnostic tool to be used by neuro-infection MDTs.
Methods: We included patients referred to the Great Ormond Street Hospital neuro-infection MDT where diagnostic uncertainty remained, despite a standardised comprehensive set of investigations, and subsequently referred for untargeted CMg on brain tissue and/or CSF. In a retrospective review, two clinicians independently assessed whether the CMg results in conjunction with the MDT resulted in a change of patient clinical management.
Results: 60 undiagnosed patients met the inclusion criteria. We detected the causative pathogen by CMg in 15/60 (25%), with 13 positives in 36 patients known to be immunocompromised. CMg results, even when negative, informed patient care, resulting in changes in clinical management in 43/56 (77%). Six patients had unexpected findings of pathogens not identified on prior samples. In four patients, the pathogen was found solely in the brain and was absent from all other specimens, including CSF.
Conclusions/Learning Points: CMg is particularly useful when conventional diagnostic techniques for meningoencephalopathy are exhausted and proved to be a necessary diagnostic tool for immunosuppressed patients when diagnostic uncertainty remained. CMg provided increased reassurance against an infective aetiology prior to recommending immunosuppression. Specialised MDTs should advocate for early brain biopsies and routine CMg in undiagnosed complex neurological cases affecting immunocompromised patients.

PD0055 / #2622

DISCRIMINATION OF TUBERCULOSIS INFECTION AND DISEASE USING CYTOKINE RESPONSE TO NOVEL M. TUBERCULOSIS ANTIGENS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 05: MYCOBACTERIA & IMMUNO COMPROMISED HOST (STATION 05)

Nora Fritschi[1], Begoña Santiago García[2], Thomas Sutter[3], Julia Vogt[4], Nicole Ritz[1]
[1]University Children Hospital Basel and University Basel, Department Of Clinical Reserach, Basel, Switzerland, [2]Gregorio Marañon Hospital, Gregorio Marañon Hospital, Madrid, Spain, [3]ETH Zurich, . Department Of Computer Science, Zurich, Switzerland, [4]ETH Zurich, Department Of Computer Science, Basel, Switzerland

Background: Interferon-γ release assays (IGRA) have limited sensitivity in children with tuberculosis (TB) disease and do not distinguish TB infection from disease. The diagnostic performance of tests using novel stimulatory antigens and additional cytokines to distinguish TB infection from disease is the aim of this study.
Methods: In this prospective, multicentre, diagnostic study in Switzerland children < 18 years of age with TB infection, disease, or TB exposed non-infected were included. Whole blood was stimulated with ESAT-6/CFP-10 and 5 novel M. tuberculosis antigens and the following cytokines were analysed: TNF-α, sCD40L, IP-10, IL-6, IL-2, IL-1RA, IL-17, IL-13, IL-10, IFN-γ and GM-CSF. Descriptive statistics and machine learning algorithms including random forest (with 4-fold cross validation) were used to find most discriminative cytokine/antigen pairs.
Results: In total 107 children were included, of which 24 (22%) children had TB disease, and 28 (26%) TB infection. Median age was 8.9 (IQR 3.4-12.1) years and 60 (56%) were female. The stimulatory antigens ESAT-6/ CFP-10, Rv2346/47c-and Rv2031c-induced the largest difference in cytokine concentration in children with TB disease or infection versus exposed non-infected children (Figure 1). To distinguish children with TB disease or infection from exposed non-infected children a random forest model performed with an area under the curve (AUC) of 0.89 (+/- 0.07) and the most informative cytokine/antigen pairs were IL-2/ESAT-6/CFP-10, IP-10/RC2346/47 and IP-10/ Rv2031c. To distinguish children with TB disease from children with TB infection the model performed with an AUC of 0.72 (+/- 0.17) and most informative cytokine/antigen pairs were IL2/Rv0081, IFN-γ/Rv2431 and IL-17/RV0081.

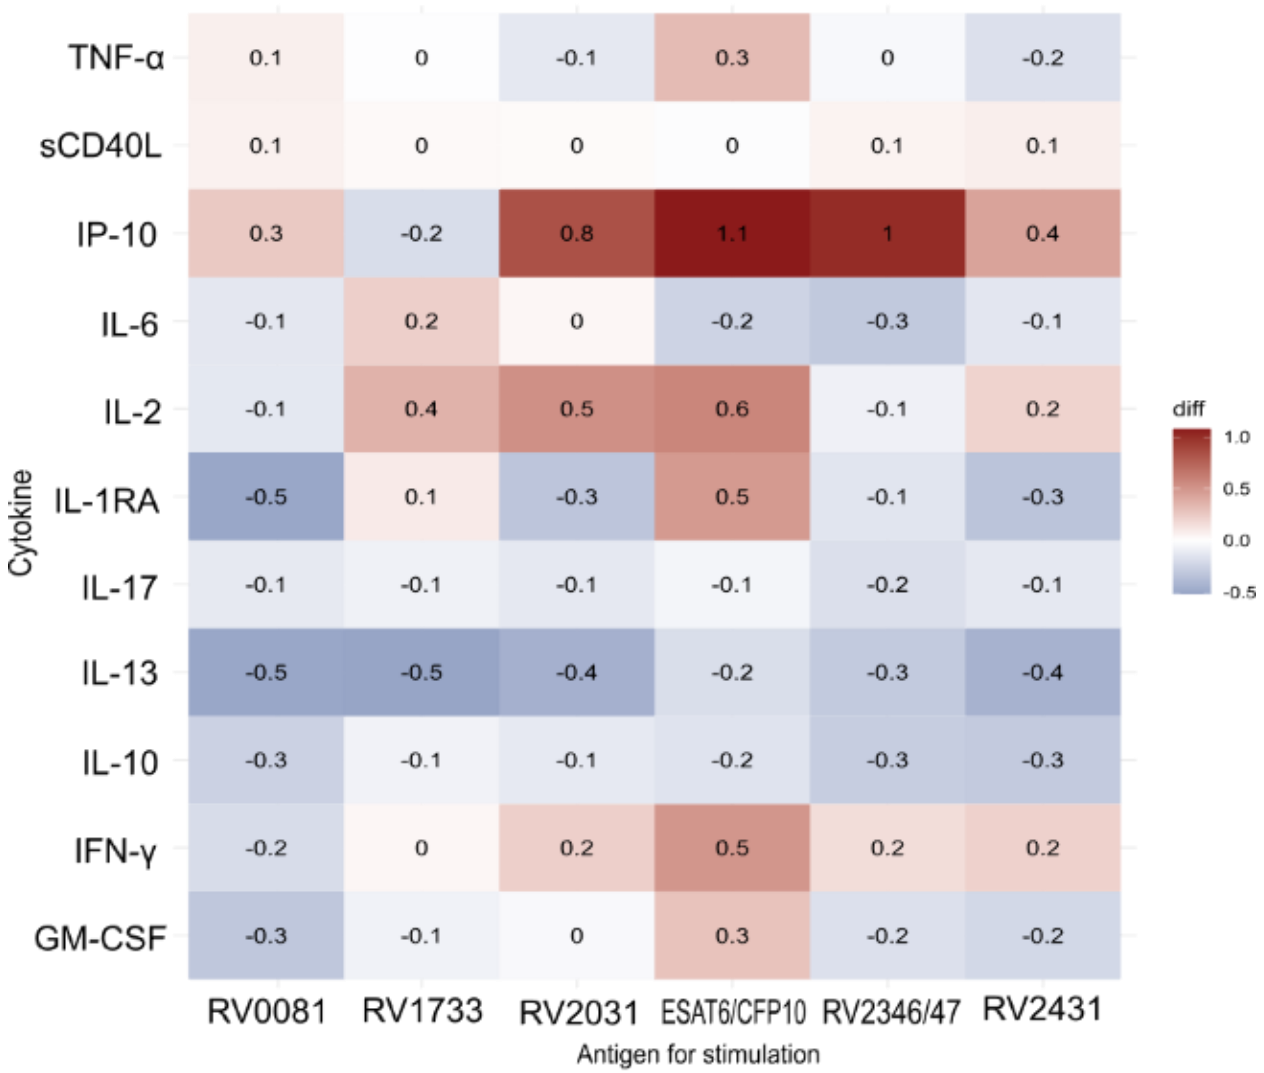

Figure 1: The mean of every antigen-cytokine pair in the groups of children with TB disease or infection and exposed children was calculated, and the difference is displayed in this figure.

Conclusions/Learning Points: This study confirms that novel cytokine-antigen pairs improve sensitivity compared to commercially available IGRAs. The discriminatory potential for these cytokine/antigen pairs to distinguish TB infection and disease is not yet optimal.

PD0056 / #324

UNDERSTANDING THE BURDEN OF RSV IN NEWBORNS AND CHILDREN DURING THEIR FIRST RSV SEASON IN PORTUGAL, 2015-2018

E-Poster Discussion
E-POSTER DISCUSSION SESSION 06: RESPIRATORY INFECTIONS (STATION 06)

Teresa Bandeira[1], Mafalda Carmo[2], Hugo Lopes[3], Catarina Gomes[4], Cátia Marques[4], Mathieu Bangert[5], Fernanda Rodrigues[6], Gustavo Januário[6], Teresa Tomé[7], Inês Azevedo[8]
[1]Centro Hospitalar Universitário Lisboa Norte, Faculdade de Medicina, Universidade De Lisboa, Caml, Lisbon, Portugal, [2]IQVIA, Real World Evidence Solutions, Barcelona, Spain, [3]IQVIA, Healthcare, Lisbon, Portugal, [4]Sanofi, Medical, Lisbon, Portugal, [5]Sanofi, Medical, Lyon, France, [6]Centro Hospitalar e Universitário de Coimbra, Hospital Pediátrico, Coimbra, Portugal, [7]Centro Hospitalar Universitário Lisboa Central, Pediatria, Lisbon, Portugal, [8]Faculdade de Medicina, Universidade do Porto, Centro Hospitalar Universitário S. João, Epiunit, Instituto De Saúde Pública, Porto, Portugal

Backgrounds: The EMA's recent approval of the first immunization for the broad infant population to prevent lower respiratory tract disease during their first RSV season calls for a better understanding on RSV's burden in this population.
Methods: We reviewed anonymized administrative data of hospitalizations potentially related to RSV in infants aged <12 months from 2015-2018, covering all public hospital discharges in mainland Portugal. Three case definitions were considered: (a) RSV-specific, (b) (a) plus unspecified acute bronchiolitis (RSV-specific & Bronchiolitis), and (c) (b) plus unspecified ALRI (RSV-specific & ALRI). Children hospitalized during epidemic seasons (November-March) were split into four cohorts according to birth date: born during RSV season (November-March); born until 3 months before RSV season (August-October); born until 7 months before RSV season (April-July); or children who have already gone through a prior RSV season since birth.
Results: A total of 6,183 RSV-specific hospitalizations were registered during epidemic seasons 2015/2016 to 2017/2018 in children aged <12 months, increasing to 11,020 for RSV-specific & ALRI hospitalizations. Hospitalizations per 1,000 infants/per season were 23.8, 38.8, and 42.3 for RSV-specific, RSV-specific & Bronchiolitis, and RSV-specific & ALRI definitions. The majority of hospitalized infants had been born outside of the RSV epidemic season (Table 1). Children without registered underlying medical conditions always accounted for over 95% of hospitalizations. Length-of-stay, severity markers and mean hospitalization costs per patient were always higher in children born during RSV season, potentially related to their age. Annual direct costs of €2.1 million were estimated for RSV-specific hospitalizations—rising to €3.8 million for RSV-specific &
ALRI.

Table 1. Potential RSV-associated hospitalizations during RSV season in children aged <12 months, per RSV case definition and time of birth (season 2015/16 to 2017/18[a])

ALRI - Acute lower respiratory infection; IMV - Invasive mechanical ventilation; NIV – Non-invasive ventilation; RSV - Respiratory syncytial virus.

(a) Epidemic season includes cases from November to March (both inclusive).

(b) Includes only RSV-specific diagnosis (ICD10 codes: J21.0, J12.1, J20.5 and B97.4, ICD9 codes: 079.6; 466.11, 480.1).

(c) Includes RSV-specific and acute bronchiolitis without specific virus identification diagnosis (previous ICD10 codes, plus J21.8, J21.9; or previous ICD9 codes, plus 466.19)

(d) Includes RSV-specific and other ALRI without specific virus identification diagnosis (previous ICD10 codes, plus J12.8, J12.9, J18.0, J18.8, J18.9, J21.8, J21.9, J20.8, J20.9, J22, or previous ICD9 codes, plus 466.0; 519.8; 480.3; 480.8, 480.9; 487.0; 485; 486)

(e) Percentage of cases within each RSV case definition according to time of birth

(f) The following risk factors were considered: heart disease, neuromuscular disorders, bronchopulmonary dysplasia, Down syndrome, immunodeficiency, congenital anomalies of respiratory system, congenital musculoskeletal anomalies, and cystic fibrosis. Prematurity, low birth weight and exposure to tobacco were separately assessed as they do could not be adequately assessed in the present study

(g) The created respiratory severity marker, combines the following procedures and diagnosis: supplementary oxygen therapy, hypoxemia, invasive and noninvasive ventilation and respiratory failure

Conclusions/Learning Points: Most infants hospitalized for RSV were otherwise healthy and experiencing their first RSV season, supporting the use of RSV protective options for the broad infant population.

Backgrounds: In children, respiratory infections such as SARS-CoV-2, respiratory syncytial virus, and influenza share similar clinical signs and symptoms. To distinguish between those viruses when epidemics overlap in time, the use of triple tests could be useful. The performance of the triple rapid antigen test from self-collected anterior nasal swabs (Covid Viro All-inn Triplex) has not been assessed in real-life. We aimed to compare this testing method (Triplex test) to the reverse transcription polymerase chain reaction (RT-PCR) from nasopharyngeal swabs.
Methods: From October 2022 to December 2022, we performed a manufacturer-independent cross-sectional, prospective, multicenter study involving 2 pediatric department in Jean-Verdier hospital in Bondy, France and Princess Grace hospital in Monaco. Two swabs of children less than 15 years old with respiratory symptoms were collected (a self-collected anterior nasal swab for the Triplex test and a nasopharyngeal swab for the RT-PCR).
Results: We included 164 children (median age, 1.4 years; mean age ± SD 2.7±3.5 years). The sensitivity of the triplex test compared to RT-PCR was 85.7% (95%CI 57.2; 98.2), 78.7% (95%CI 66.3; 88.1), and 82.4% (95%CI 65.5; 93.2), for SARS-CoV-2, RSV, and influenza A, respectively. The specificity was always 100% for each
virus.

Triplex	PCR+ N	PCR - N	Sensitivity IC95%	Specificity CI95%	LR- CI95%	VPP CI95%	VPN CI95%	Accuracy CI95%
SARS+	12	0	85.7	100	0.14	100	98.7	98.8
SARS-	2	150	[57.2;98.2]	[97.6;100]	[0.39;0.52]	[73.5;100]	[95.3;99.8]	[95.7;99.9]
RSV+	48	0	78.7	100	0.21	100	88.5	91.9
RSV-	13	100	[66.3;88.1]	[96.4;100]	[0.13;0.35]	[92.6;100]	[81.1;93.7]	[86.6;95.6]
Influenza A+	28	0	82.4	100	0.17	100	95.6	96.4
Influenza A-	6	131	[65.5;93.2]	[97.2;100]	[0.09;0.4]	[87.7;100]	[90.7;98.4]	[92.3;98.7]

Conclusions/Learning Points: If our data suggest that the sensitivity of the triple test is not yet optimal, the speed of the result (15 minutes) for 3 viruses could improves the management of children with respiratory infections when epidemics of Covid, Flu and RSV overlap in time. Contrary to nasopharyngeal samples, the nasal self-collected test is less discomfort for the child.

PD0058 / #1164

SEASONAL EPIDEMICS AND MACROLIDE RESISTANCE OF CHILDHOOD MYCOPLASMA PNEUMONIAE RESPIRATORY INFECTIONS IN TAIWAN, 2017-2022

E-Poster Discussion
E-POSTER DISCUSSION SESSION 06: RESPIRATORY INFECTIONS (STATION 06)

Tsung-Hua Wu[1], Chun-Yi Lee[2], Fang-Ching Liu[3], Hui-Hsien Pan[4], Yu-Ping Fang[2]
[1]Show Chwan Memorial Hospital, Department Of Pediatrics, Changhua, Taiwan, [2]Chang Bing Show Chwan Memorial Hospital, Department Of Pediatrics, Changhua, Taiwan, [3]Jen-Ai Hospital, Department Of Pediatrics, Taichung, Taiwan, [4]Chung Shan Medical University Hospital, Department Of Pediatrics, Taichung, Taiwan

Backgrounds: Mycoplasma pneumoniae (Mp) is a common pathogen of childhood respiratory tract infections (RTIs), and macrolide resistance is a growing concern, especially in Asia. This study aimed to delineate the circulation pattern and the dynamic change of macrolide resistance of childhood Mp RTIs in Taiwan.
Methods: In this multicenter study, we prospectively enrolled 456 hospitalized children with RTIs and positive serological Mp immunoglobulin M test between March 2017 and December 2022. Oropharyngeal swabs were obtained for Mp culture. All Mp isolates were further analyzed by macrolide resistance and multilocus sequence typing analysis.
Results: In total, 186 out of 456 enrolled children were culture proven Mp RTIs. Mp infections were detected throughout whole year in Taiwan and mainly occurred from March to September, i.e., from spring and summer seasons. The overall macrolide resistance rate of Mp strains was 39.8% (74/186), but changes dynamically. The resistance rate increased in 2017-2020 and peaked at 85.7% in 2020. However, the rate plummeted down to 18.2% in 2021 and 0% in 2022 during COVID-19 period. Regarding sequence types (STs), ST3 (52.6%) was the most prevalent type, followed by ST17 (35.1%). ST3 (24 of 33, 72.7%) was predominant among macrolide-resistant strains ($p = 0.006$).
Conclusions/Learning Points: Mp infection has characteristic seasonal epidemics in Taiwan. Macrolide-resistant Mp infections have prevailed in Taiwan between 2017 and 2020 but declined sharply during COVID-19 pandemic. ST3 and ST17 are the two prevailing Mp sequence types in Taiwan, and ST3 is strongly associated with macrolide resistance. It is warranted to keep monitoring the evolving molecular epidemiology of Mp infection at local and global level.

PD0059 / #698

RESPIRATORY SYNCYTIAL VIRUS CIRCULATION ACCORDING TO THE EPIDEMIC PERIOD AMONG OUTPATIENT CHILDREN WITH BRONCHIOLITIS IN THE COVID-19 PANDEMIC ERA

E-Poster Discussion
E-POSTER DISCUSSION SESSION 06: RESPIRATORY INFECTIONS (STATION 06)

Alexis Rybak[1], Corinne Levy[1], Camille Jung[2], Stéphane Béchet[1], Nathalie Gelbert[3], Andreas Werner[3], Mathieu Bangert[4], Rolf Kramer[4], Robert Cohen[1]
[1]ACTIV, Infectious Disease, Créteil, France, [2]CHI Créteil, Crc, Créteil, France, [3]AFPA, Pediatrics, Créteil, France, [4]Sanofi, Medical, Lyon, France

Backgrounds: Before the COVID-19 pandemic, regular annual epidemics of bronchiolitis due to respiratory syncytial virus (RSV) were observed in the winter season which led the surveillance networks to focus on this period. With the pandemic, RSV activity was impacted by non-pharmaceutical interventions which led to unusual virus circualtion, the aim of our study was to assess the proportion of RSV positive children among ambulatory children with bronchiolitis during and outside the bronchiolitis epidemic periods.
Methods: Among 8 different regions in France 37 pediatricians participated in the OURSYN study between February 2021 and May 2022. Children <2 years old with a first episode of bronchiolitis were prospectively enrolled. For each patient, a single nasopharyngeal swab was taken for rapid diagnostic testing for RSV, SARS-CoV-2 and influenza. We matched each patient to the weekly regional bronchiolitis epidemic level defined by the French public health institute: no epidemic, pre or post-epidemic and epidemic.
Results: During the study period, 984 outpatients <2 years old with bronchiolitis were included among which 437/984 (44.4%) had a positive RSV test, 11/979 (1.1%) were positive for influenza A and/or B, and 26/979 (2.7%) for SARS-CoV-2. RSV positivity rate was 28.9% (76/263, CI95% [23.8; 34.7]) for children presenting a bronchiolitis during the non-epidemic period compared to 45.2% (28/62, CI95% [33.4; 57.5]) during the pre- or post-epidemic period and 50.5% (333/659, CI95% [46.7; 54.3]) during the epidemic period.
Conclusions/Learning Points: RSV was the most common cause for bronchiolitis in <2 years old. Our study suggests that a continuous RSV circulation may have occured in outpatients in the COVID-19 pandemic era. Further surveillance is needed to monitor RSV circulation post COVID and inform immunoprophylaxis against RSV.

PD0060 / #1327

DESCRIBING RSV PHENOTYPES AND SEASONS: HOW CAN WE PROGRESS?

E-Poster Discussion
E-POSTER DISCUSSION SESSION 06: RESPIRATORY INFECTIONS (STATION 06)

Côme Horvat[1], Dominique Ploin[2]
[1]Hopital Femme-Mere-Enfant, Pediatric Emergency Ward, Bron, France, [2]Hôpital Femme Mère Enfant - Hospices Civils de Lyon, Emergency - Infectious Disease, Bron, France

Backgrounds: Respiratory Syncytial Virus (RSV) causes a seasonal epidemic pediatric respiratory burden in temperate countries. COVID-19 pandemic non-pharmaceutical-interventions impacted the epidemic pattern and cases incidence. Most studies rely on hospitalization and lack a univocal clinical score. We propose new tools for RSV clinical phenotype description and season comparison.
Methods: Two observational studies were based in the pediatric tertiary care center of a French urban area: a pre-COVID-19 study based on a birth cohort from 2013 to 2019, and a per-COVID-19 study based on hospitalizations from 2019 to 2022. Medical files were extensively reviewed. Literature-described hospitalization risk factors were explored with a multivariate analysis. 4 clinical phenotypes were based on the WHO severity score: neurological (unconscious, apneas), respiratory (SpO2<93%), digestive (inability to feed), and no organ insufficiency. Seasonal comparison was performed between 2019-20 and per-COVID-19 seasons. RSV-season-length (RSL) was the number of days including the central-95%-cases. RSV-season-burden was assessed with Length-of-Stay (LOS) and Length-of-Ventilation (LOV) Areas Under the Curve (AUC).
Results: Perinatal risk factors for hospitalization were birth during the two months before or the month after the epidemic onset, prematurity, male sex, multiparity, and cesarean delivery. In the pre-COVID-19 cohort, 16% had no risk factors and presented no neurological or respiratory phenotype. Clinical phenotype comparison identified in 2021-22 more respiratory insufficiencies in older children with more chronic bronchopulmonary disease. In 2019-20, 2020-21, and 2021-22 respectively, RSL were 115, 166, and 200 days, LOS-AUC were 2582, 1274, and 3246 children-days, and LOV-AUC were 525, 293, and 674 children-days.
Conclusions/Learning Points: Perinatal risk factors can guide prevention strategies. RSL help comparing temporal distribution. Clinical phenotypes and hospital resources consumption could be useful tools to monitor the impact of future interventions on hospital burden.

PD0061 / #1409

VIRAL CO-DETECTIONS AS A RISK FACTOR FOR SEVERE RESPIRATORY SYNCYTIAL VIRUS INFECTIONS?

E-Poster Discussion
E-POSTER DISCUSSION SESSION 06: RESPIRATORY INFECTIONS (STATION 06)

Backgrounds: Respiratory syncytial virus (RSV) causes the majority of lower respiratory tract infections (LRTI) in infants, and viral co-detections are reported in up to 10-30% cases of hospitalized LRTI patients. However, the clinical significance of viral co-infections is unclear. This study aims to compare clinical outcomes of RSV-related LRTI hospitalized patients with/without co-detections by other respiratory viruses.
Methods: Data from hospitalized children diagnosed with RSV-related LRTI (October 2021-November 2022) were analyzed. Respiratory samples were collected from 13 secondary and 4 tertiary hospitals of the COPEDICAT network (https://www.copedicat.cat/) in Catalonia (Spain). All respiratory viruses' laboratory-confirmation was performed by a real-time multiplex RT-PCR-based assay (Allplex Respiratory Panel Assay, Seegene, South Korea).
Results: Among data collected from 636 children, 289 (45.4%) tested positive for RSV. RSV was co-detected with other respiratory viruses in 116 patients (40.1%). Overall, median age was 17 months (IQR 5-29), 52.9% were male and 29.6% had comorbidities. No demographic differences were observed between mono- and co-infected cases. In the bivariable analysis, single RSV infections had longer median intensive care unit (ICU) stay (7 versus 4 days, p=0.03), higher requirements of respiratory support with a higher proportion of patients requiring mechanical ventilation (4.1% versus 0%, p=0.016), but slightly less severe clinical score at admission (18.6% versus 21.5%, p=0.06) compared with cases with co-detections. Antibiotic prescription was higher in the co-infection group (41.7% versus 22.3%, p=0.014). In the multivariable analysis, these differences were not statistically significant but a severe clinical score at admission remained associated with RSV co-detections (OR=2.95; CI 95%: 1.00-8.68, p=0.049).
Conclusions/Learning Points: RSV co-detections in children were not associated with a worse clinical evolution after admission despite being associated with a higher severity clinical score at admission.

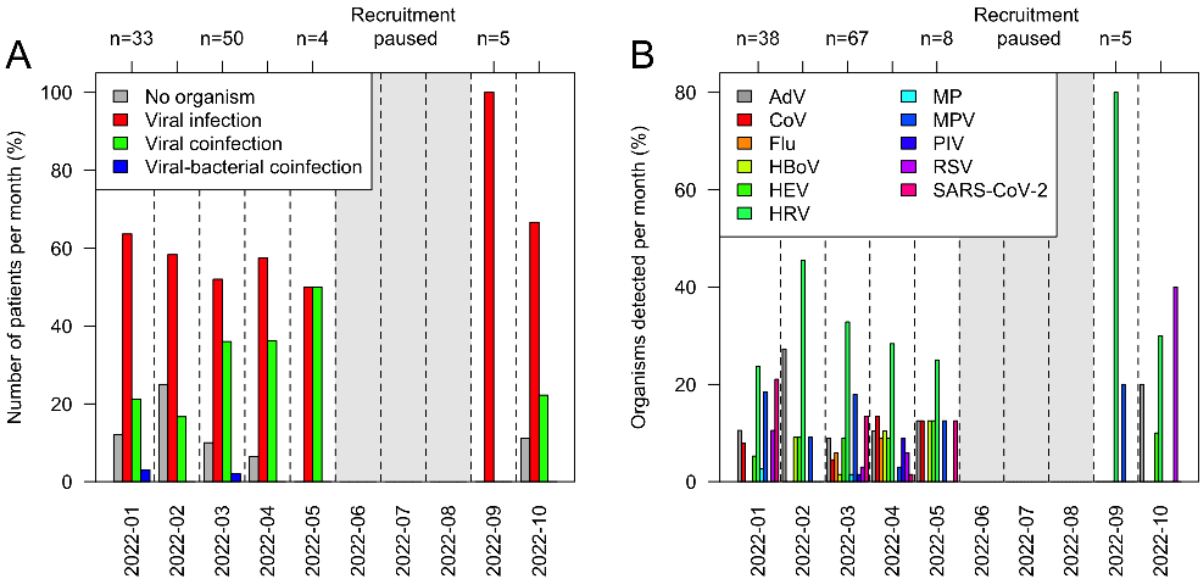
Backgrounds: SARS-CoV-2 pandemic has modified the epidemiology of respiratory viruses. The aim of RHEDI is to describe the burden of RSV and other acute respiratory infections (ARI) at Emergency Departments (ED) of Spain & Portugal in infants≤ 2 years of age. RSV season in Iberia usually runs October-to-March.
Methods: Prospective, hospital-based surveillance in ED of eight hospitals in Spain& Portugal covering six metropolitan areas. 2.000 children <2 years with ARI or otitis media attending ED will be recruited as of 8 subjects/week/site, 50% of them with LRTI. Allplex™-multiplex panel and SARS-Cov-2 will be performed in all subjects. Preliminary results of the pandemic months is reported.
Results: RHEDI surveillance started in Jan-2022. Due to impact of the pandemic, it was paused in Apr-2022 and resumed in Sep-2022. As of 22-nov-2022, 256 children were recruited. No organism was detected in 12.1% (n=31) of patients, 59.0% (n=151) suffered viral mono-infection, and 28.1% (n=72) viral coinfection and 0.8% (n=2) with viral+bacterial coinfection. The most common organisms detected were rhinovirus(n=94), adenovirus (n=35), metapneumovirus (n=34), SARS-CoV-2 (n=34), and RSV (n=24). Among all combinations, the most common microbiologic scenarios were: monoinfection with rhinovirus (18.0%, n=46), metapneumovirus (9.0%, n=23), SARS-CoV-2 (7.0%, n=18) or RSV (5.1%, n=13), while the most common viral coinfections were adenovirus+rhinovirus (4.3%, n=11), rhinovirus+SARS-CoV-2 (2.0%, n=5) and enterovirus+rhinovirus (2.0%, n=5). No differences regarding to microbiological status were observed considering clinical syndrome LRTI vs URTI (Fisher's test P-value=0.332) or hospitalization (Fisher's test P-value=0.508).



Conclusions/Learning Points: During the pandemic period, infants attending ED with ARI more frequently had rhinovirus, adenovirus, metapneumovirus, and SARS-CoV-2. RSV and influenza were less frequently detected than usually expected. RHEDI design is sensible to assess ARI burden in ED.

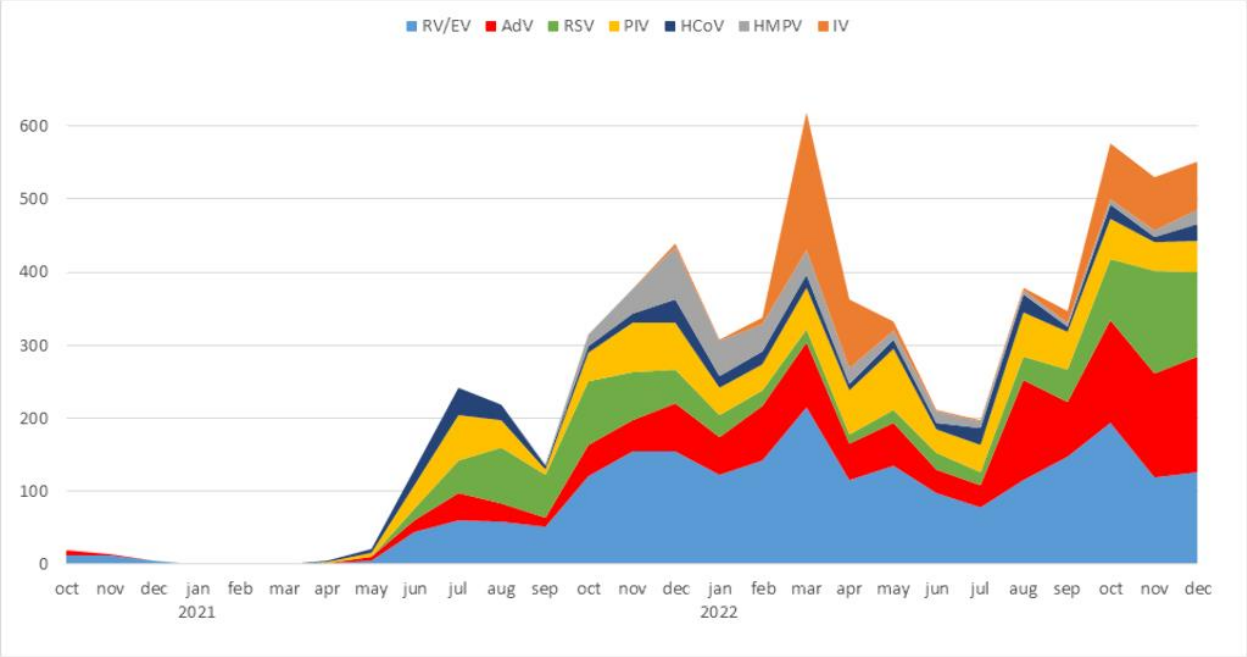
PD0063 / #1710

BEYOND THE COVID-19 PANDEMIC - THE HETEROGENEOUS RETURN OF THE RESPIRATORY VIRUSES

E-Poster Discussion
E-POSTER DISCUSSION SESSION 06: RESPIRATORY INFECTIONS (STATION 06)

Miguel Lucas[1], Mariana Costa[1], Joana Sousa[1], Ana Manuela Silva[1], João Pereira Vaz[2], Lurdes Correia[2], Lia Gata[1], Fernanda Rodrigues[1,3]
[1]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Clinical Pathology Service, Coimbra, Portugal, [3]Universidade de Coimbra, Faculty Of Medicine, Coimbra, Portugal

Backgrounds: COVID-19 did not displace all respiratory viruses in the same way, with persistent circulation for rhinovirus/enterovirus and adenovirus, although at lower levels. The reasons for these differences are probably multifactorial: including tropism to the lower respiratory tract vs the upper tract, duration of the infectious period, sensitivity to hydroalcoholic solutions, amongst others. The aim of this study was to characterize the resurgences of different respiratory viruses.
Methods: Observational, retrospective, descriptive study, performed in a tertiary paediatric hospital, that receives an average of 60 000 children/year in the Emergency Service, with analysis of all cases with a positive PCR in nasopharyngeal samples (FilmArray respiratory panel: RSV, Adenovirus (AdV), Rhinovirus/Enterovirus (RV/EV), Parainfluenza virus (PIV), Human coronavirus (HCoV), Human metapneumovirus (HMPV) and Influenza virus (IV)), collected as part of routine testing.
Results: The pattern of resurgences of the different viruses is presented (figure): RSV, PIV and HCoV appeared first, followed by HMPV 6 months later and IV 10 months later. FIGURE 1. Number of various respiratory viruses detected by PCR, in each month, from October 2020 to December 2022



Conclusions/Learning Points: The pattern of resurgences of the different enveloped seasonal viruses was quite heterogeneous, especially for RSV and IV. These differences should be better understood to help to predict events in future viral epidemics or pandemics.

DIFFERENTIAL HOST TRANSCRIPTOMIC RESPONSE TO VIRAL AND BACTERIAL PNEUMONIAS: A MULTI-COHORT STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 06: RESPIRATORY INFECTIONS (STATION 06)

Sandra Viz Lasheras[1], Alberto Gómez-Carballa[1], Jacobo Pardo-Seco[2], Sara Pischedda[1], Irene Rivero Calle[1], Myrsini Kaforou[3], Heather Jackson[3], Dominic Habgood-Coote[3], Michael Levin[3], Antonio Salas[1,4], Federico Martinon-Torres[1], Euclids Consortium[1], Perform Consortium[5]
[1]Instituto de Investigación Sanitaria de Santiago, Genetics, Vaccines And Infections Research Group (genvip), Santiago de Compostela, Spain, [2]Instituto de Investigación Sanitaria de Santiago, Grupo De Investigación En Genética, Vacunas, Infecciones Y Pediatría (genvip), Santiago de Compostela, Spain, [3]Imperial College London, Department Of Infectious Disease, London, United Kingdom, [4]Unidade de Xenética, Instituto de Ciencias Forenses, Facultade De Medicina, Universidade De Santiago De Compostela, Santiago de Compostela, Spain, [5]Paediatric Infectious Diseases, Imperial College, London, United Kingdom

Backgrounds: Pneumonia is one of the largest causes of death in children younger than 5 years old outside the neonatal period. Pneumonia can be caused by a wide variety of micro-organisms. Diagnosis remains challenging and is based on clinical or microbiological criteria that are often inaccurate, slow and remain unreliable for therapy and prognosis. We investigate host transcriptomic biomarkers in blood from children with viral and bacterial pneumonia and healthy controls, aiming at identifying a gene-expression signature that could help diagnosis and management of the disease.
Methods: RNA-seq data was obtained from blood of patients and controls. Data normalisation and differential expression (DE) analysis were carried out using DESeq2. We used the Reactome and GO pathway database to examine biological pathways associated with the DE genes (DEG) in pneumonia patients vs. controls and in children with a bacterial infection vs. children with viral infections. We investigated a minimum specific transcript signature to differentiate between viral/bacterial pneumonia using Parallel Regularised Regression Model Search.
Results: We identified several DEGs in the comparisons controls vs. pneumonia and viral vs. bacterial pneumonias. Functional enrichment analysis showed pathways significantly altered mostly related to the immune system response in both comparisons. Preliminary findings show a minimum host transcriptomic signature allowing to differentiate viral from bacterial pneumonias.
Conclusions/Learning Points: We found different mechanisms and genes involved in the specific response to bacterial and viral pneumonia. Our results suggest that host transcriptomic signatures could be helpful to stratify severe pneumonia condition according to its bacterial or viral origin and contribute to reduce unnecessary antibiotic prescriptions in children with respiratory infections.

PD0065 / #1134

SYSTEMATIC LITERATURE REVIEW OF THE EFFECTIVENESS AND IMPACT OF PCV13 FOR CHILDREN WITH OTITIS MEDIA

E-Poster Discussion
E-POSTER DISCUSSION SESSION 06: RESPIRATORY INFECTIONS (STATION 06)

Kyla Hayford[1], Iwona Pustulka[2], Carol Forbes[3], Liping Huang[4], Adriano Arguedas[5], Alejandro Cane[5], Maria Tort[6], Heather Sings[5]
[1]Pfizer, Global Medical Affairs, Toronto, Canada, [2]Evidera, Evidence Synthesis, Warsaw, Poland, [3]Evidera, Evidence Synthesis, London, United Kingdom, [4]Pfizer, Global Value & Evidence, New York, United States of America, [5]Pfizer, Medical And Scientific Affairs, Collegeville, United States of America, [6]Pfizer, Us Medical Affairs, Collegeville, United States of America

Backgrounds: Otitis media (OM) is one of the most common childhood illnesses and associated with a high number of ambulatory medical visits and antimicrobial prescriptions. The introduction of 13-valent pneumococcal conjugate vaccine (PCV13) was associated with reductions in all-cause OM, Streptococcus pneumoniae (Spn) OM, and vaccine-type (VT-OM) through direct and indirect protection, but estimates are difficult to compare due to use of different endpoints and study designs.
Methods: A systematic literature review (SLR) was conducted to summarize direct vaccine effectiveness and impact of PCV13 against OM in children, based on studies and conference abstracts published from January 2000 to February 2022. Studies were grouped by study design (effectiveness, impact) and endpoint (all-cause OM, Spn OM, VT-OM).
Results: Four studies reported direct vaccine effectiveness (VE) of PCV13 (Table). VE against PCV13-type OM was 62% (non-significant), 77.4%, and 86.4%. Two studies also demonstrated 86% and 67.7% VE against the 6 PCV13-nonPCV7 serotypes. Eleven studies estimated pre-post impact of PCV13 on all-cause or Spn OM, of which 4 studies from Israel also estimated impact against PCV13-type OM compared to PCV7 period (range 89-97%). No significant differences in impact against PCV7 serotypes and the additional PCV13-nonPCV7 were observed. Statistically significant PCV13 impact against all-cause OM outcomes was observed in all but one study (range: -1.7 to 80%), but impact varied substantially by age group, case definition, and comparison period. In comparison, VE and impact on Spn OM and VT-OM results were less variable.
Conclusions/Learning Points: Using PCV13 in paediatric immunization programs has contributed to

substantial direct vaccine effectiveness and population-level impact against otitis

Table. Effectiveness and Impact of PCV13 vaccination versus paediatric all-cause, Spn, and vaccine-type OM

Author, year	N (age, country)	Vaccine, schedule (comparator)	Endpoint (design, estimand)	Vaccine Type Outcomes VE (95%CI) p-value	All Cause Outcomes

RESPIRATORY ILLNESS AND WEEKLY VIRAL INFECTIONS DURING A WINTER SEASON IN A PROSPECTIVE COHORT OF YOUNG CHILDREN; PRELIMINARY RESULTS OF 2021/2022

E-Poster Discussion
E-POSTER DISCUSSION SESSION 06: RESPIRATORY INFECTIONS (STATION 06)

Emma Van Westrhenen[1], Patricia Bruijning-Verhagen[2], Marieke Hoog[1], Marc Bonten[1], Michiel Van Boven[3], Rob Schuurman[4]
[1]UMC Utrecht, Julius Centre Infectious Diseases, Utrecht, Netherlands, [2]Utrecht University Medical Center, Pediatrics, Utrecht, Netherlands, [3]RIVM, Rivm, Bilthoven, Netherlands, [4]UMC Utrecht, Medical Microbiology, Utrecht, Netherlands

Backgrounds: To detect patterns of respiratory viral (co-)infections and illness in healthy young children and to explore viral interactions. We report results on the first of two study periods.
Methods: A random selection of children <5 years were invited from the Dutch population registry. Participants were prospectively followed for 16 consecutive weeks each between October 2021 and May 2022. Nasal swabs were collected weekly and tested by multiplex PCR for common respiratory viruses. Symptoms were logged daily by parents. Frequency of virus infections and co-infections as well as median duration of PCR positivity per infection were calculated. Virus-virus interactions were explored in an observed versus expected co-detection analysis including viruses detected ≥10 times in our cohort.
Results: Mean age of 79 participants was 20 months (range: 3-43) and 44.3% were female. Among 8618 diary days ≥1 respiratory symptom was reported in 53.0%. Participants experienced on average 3.8 respiratory illness episodes (range: 0–8) and 5 different virus infections (range: 2-8) during follow-up. Of 1199 nasal swabs, 63.9% contained ≥1 virus and 21.9% ≥2 viruses (Figure 1A and B). Most viruses were detected on average for 1 week, except for SARS-CoV-2 and rhinovirus (1-2 weeks). In co-detection analysis, rhinovirus associated negatively with coronavirus OC43 (OR: 0.6; 95% CI 0.4 – 0.9) and positively with adenovirus (OR: 2.1; 95% CI 1.5 –

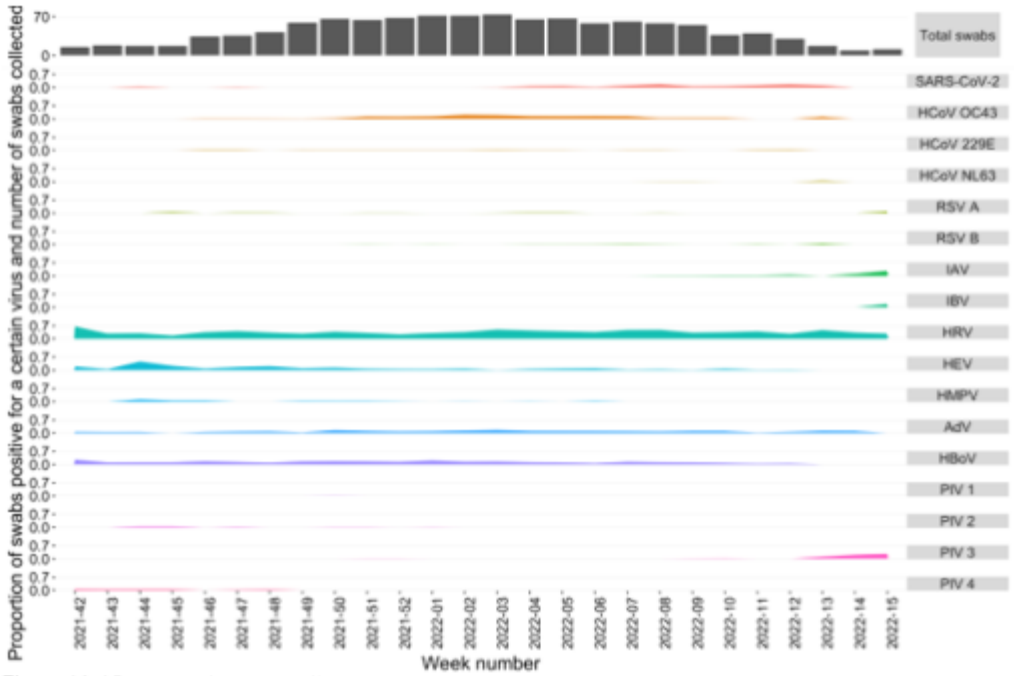

Figure 1A: Virus prevalence over time

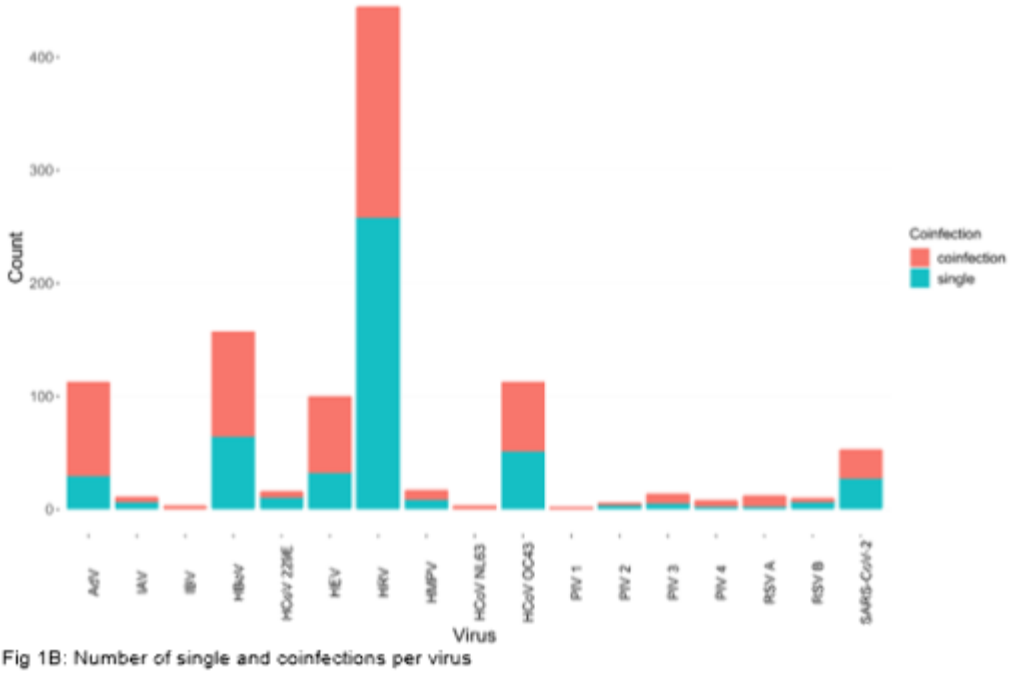

Fig 1B: Number of single and coinfections per virus

AdV = adenovirus. IAV = influenza A virus. IVB = influenza B virus. HBoV = human bocavirus. HCoV 229E = human coronavirus 229E. HEV = human enterovirus. HRV = human rhinovirus. HMPV = human metapneumovirus. HCoV NL63 = human coronavirus NL63. HCoV OC43 = human coronavirus. PIV 1= parainfluenza virus 1. PIV 2 = parainfluenza virus 2. PIV 3 = parainfluenza virus 3. PIV 4 = parainfluenza virus 4. RSV A = respiratory syncytial virus A. RSV B = respiratory syncytial virus B. SARS-CoV-2 = severe acute respiratory syndrome coronavirus 2.

3.2).

Conclusions/Learning Points: Our preliminary data confirm very high prevalence of viral infections in young children during the respiratory season and viral interactions with rhinovirus. As data accumulate, interactions between other respiratory viruses and associations with illness severity will be further quantified.

PD0067 / #1407

THE ESTIMATION OF LONG-COVID PREVALENCE AND LONG-TERM PERSISTENCE IN ITALIAN CHILDREN AFTER COVID-9 COMPARED TO UN-INFECTED SUBJECTS: AN ANALYSIS USING A PEDIATRIC PRIMARY CARE DATABASE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 07: COVID-19 (STATION 01)

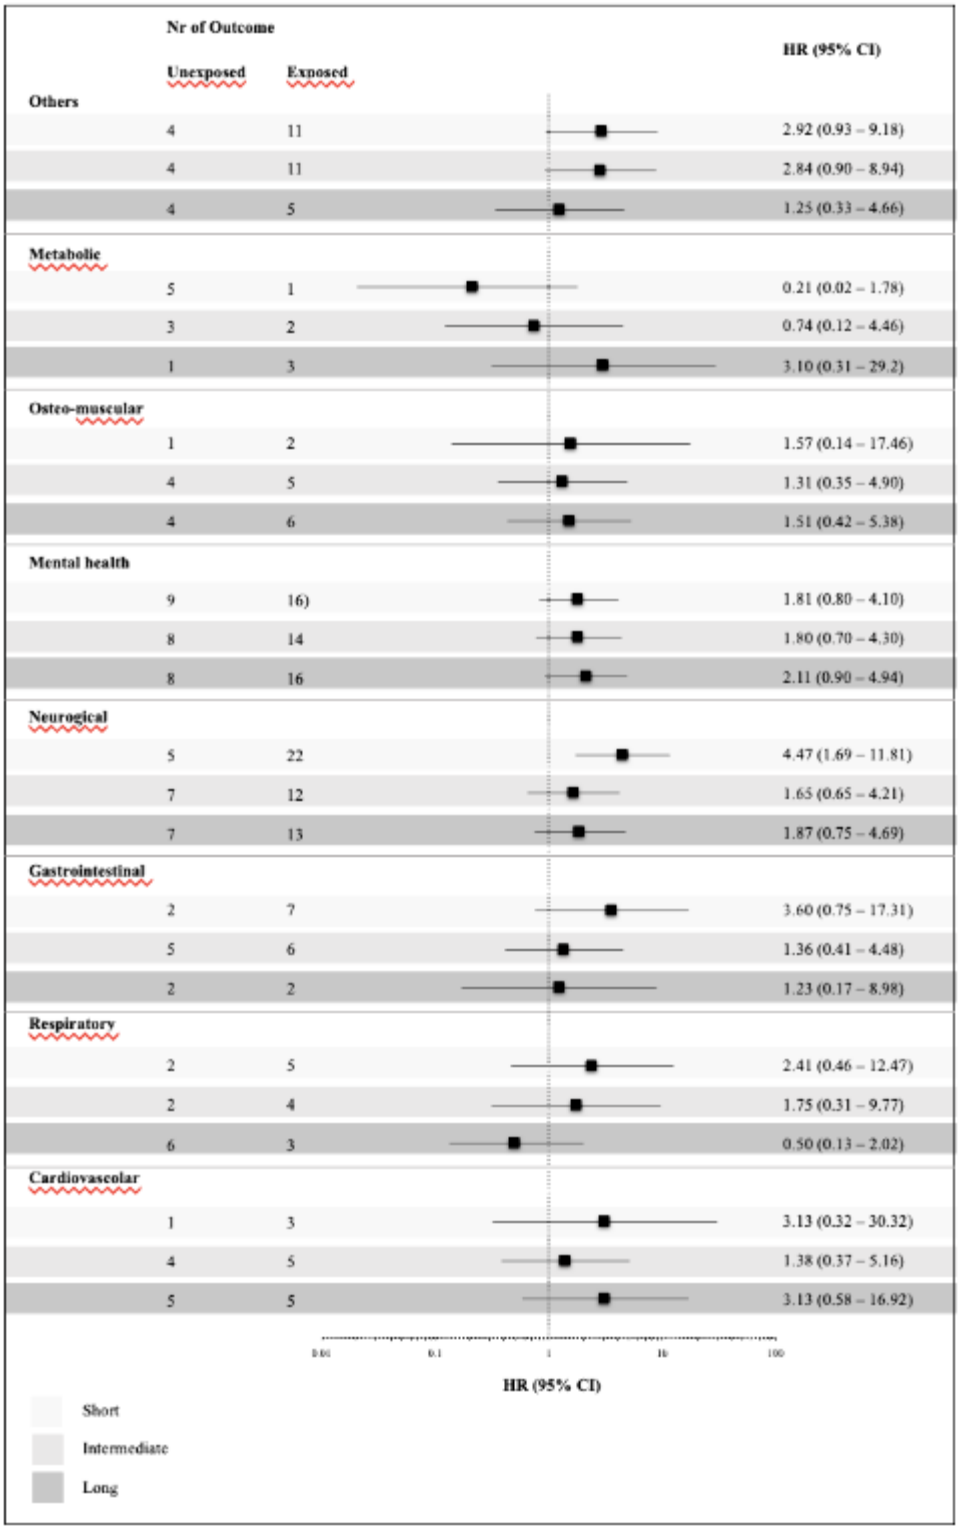
[1]University of Padova, Division Of Pediatric Infectious Diseases, Department For Women's And Children's Health, Padova, Italy, [2]University of Padova, Division Of Paediatric Infectious Diseases, Department For Women And Children's Health, Padova, Italy, [3]University of Milano Bicocca, Department Of Statistics And Quantitative Methods, Division Of Biostatistics, Epidemiology And Public Health, Laboratory Of Healthcare Research And Pharmacoepidemiology, Milano, Italy, [4]Societa' Servizi Telematici, Pedianet, Padova, Italy, [5]University of Oslo, Pharmacoepidemiology And Drug Safety Research Group, Department Of Pharmacy, And Pharmatox Strategic Research Initiative, Oslo, Norway, [6]Medical Research Council, Paediatrics, London, United Kingdom

Backgrounds: Children may suffer from the long-COVID syndrome; however, evidence on disease prevalence and long-term persistence is still heterogeneous. This study aims to determine the prevalence of long-COVID and the short, medium-, and long-term symptoms' persistence in previously SARS-CoV-2 exposed and unexposed children.
Methods: A retrospective nested-cohort study was conducted on children aged 0-14 years. Data were retrieved from an Italian pediatric primary-care database linked to the Veneto region's hospitalization and COVID-19 registries. Children with a positive nasal pharyngeal swab (NPS) (exposed) were matched 1:1 with children with a negative NPS (unexposed). Starting the index date, which was defined as the first positive NPS, symptoms were recorded across three time periods (short [index date+28days - index date+28+90], medium [index date+28+91 - index date+28+180], and long-term [index date+28+181 - end of follow-up]. Cox proportional hazard regression was performed to identify the risk of new diseases.
Results: A total of 3,312 children (52% female), including 1,656 exposed and 1,656 unexposed, were evaluated from Feb-2020 to Nov-2021. Overall, we found a significantly higher risk of mental health (HR 1.81, 95%CI=1.10-2.99), neurology (2.38, 95%CI=1.39-4.07), and other conditions, including skin rashes (1.98, 95%CI=1.04-3.79) in exposed compared to unexposed. According to the 3 time periods, cardiovascular, respiratory, and gastro-enteric diseases decreased over time. Conversely, an increasing trend of metabolic sequelae was observed from the short- to the long-term period



(figure).

Conclusions/Learning Points: We found an overall increased risk of long-COVID in children exposed up to 21 after infection. However, cardiovascular, pulmonary, and gastroenteric sequelae showed a slight decrease across time, suggesting possible improvement of tissue injuries. Further studies, evaluating the long-term sequelae in children who experienced COVID-19 in the Omicron era are needed to confirm our findings.

PD0068 / #318

RISK OF SEVERE COVID-19 IN PEDIATRIC SOLID ORGAN TRANSPLANT RECIPIENTS – BIG DATA CONVERGENCE STUDY IN KOREA

E-Poster Discussion
E-POSTER DISCUSSION SESSION 07: COVID-19 (STATION 01)

Jiman Kang[1], Minsun Kang[2], Minyoung Kim[3], Young-Eun Kim[4], Yoonkyung Choi[4], Jaehyun Seong[5], Min Jin Go[5], Kyungmin Huh[6], Jaehun Jung[2]

Backgrounds: Solid organ transplant recipients (SOTRs) are a representative high-risk population for severe COVID-19, but the actual risk has not been well established in the pediatric SOT population. We evaluated the relative risk of severe COVID-19 in pediatric SOTRs.
Methods: A newly constructed K-COV-N (Korea Disease Control and Prevention Agency-COVID19-National Health Insurance Service) cohort was used. From January 2008 to January 2020, children who received SOT in Korea were selected. Thereafter, pediatric SOTR with COVID-19 (<18 years) until March 2022 were included. For comparison, propensity score matching using a greedy nearest neighbor algorithm was performed for age, gender, pediatric comorbidity index (PCI), and year of infection. Logistic regression was also performed. Severe COVID-19 was defined as a case requiring mechanical respiratory support or prolonged hospitalization (≥6 days).
Results: Of the 955 pediatric SOTRs in Korea, 206 were infected with SARS-CoV-2. The median age at the time of COVID-19 was 11 years (IQR, 8 to 14 years), and 48% were male. Liver transplantation was the most common (72%), followed by kidney transplantation (20%), heart transplantation (7%), and lung transplantation (0.5%). After matching, 205 were included in the pediatric SOT group and 803 were included in the non-SOT group. Fifteen cases of severe COVID-19 were identified. The SOT group had a 3.6-fold higher risk of severe COVID-19 than the non-SOT group (95%CI, 1.1 to 11.7, P=0.03). Among SOTRs infected with SARS-CoV-2, age under 5 years old, high PCI score, and pre-omicron period were identified as risk factors for severe COVID-19.
Conclusions/Learning Points: Pediatric SOTRs are at higher risk of severe COVID-19 compared to the non-SOT population. To prevent severe COVID-19 in these high-risk children, more aggressive prevention strategies, such as extending the vaccination age, are needed.

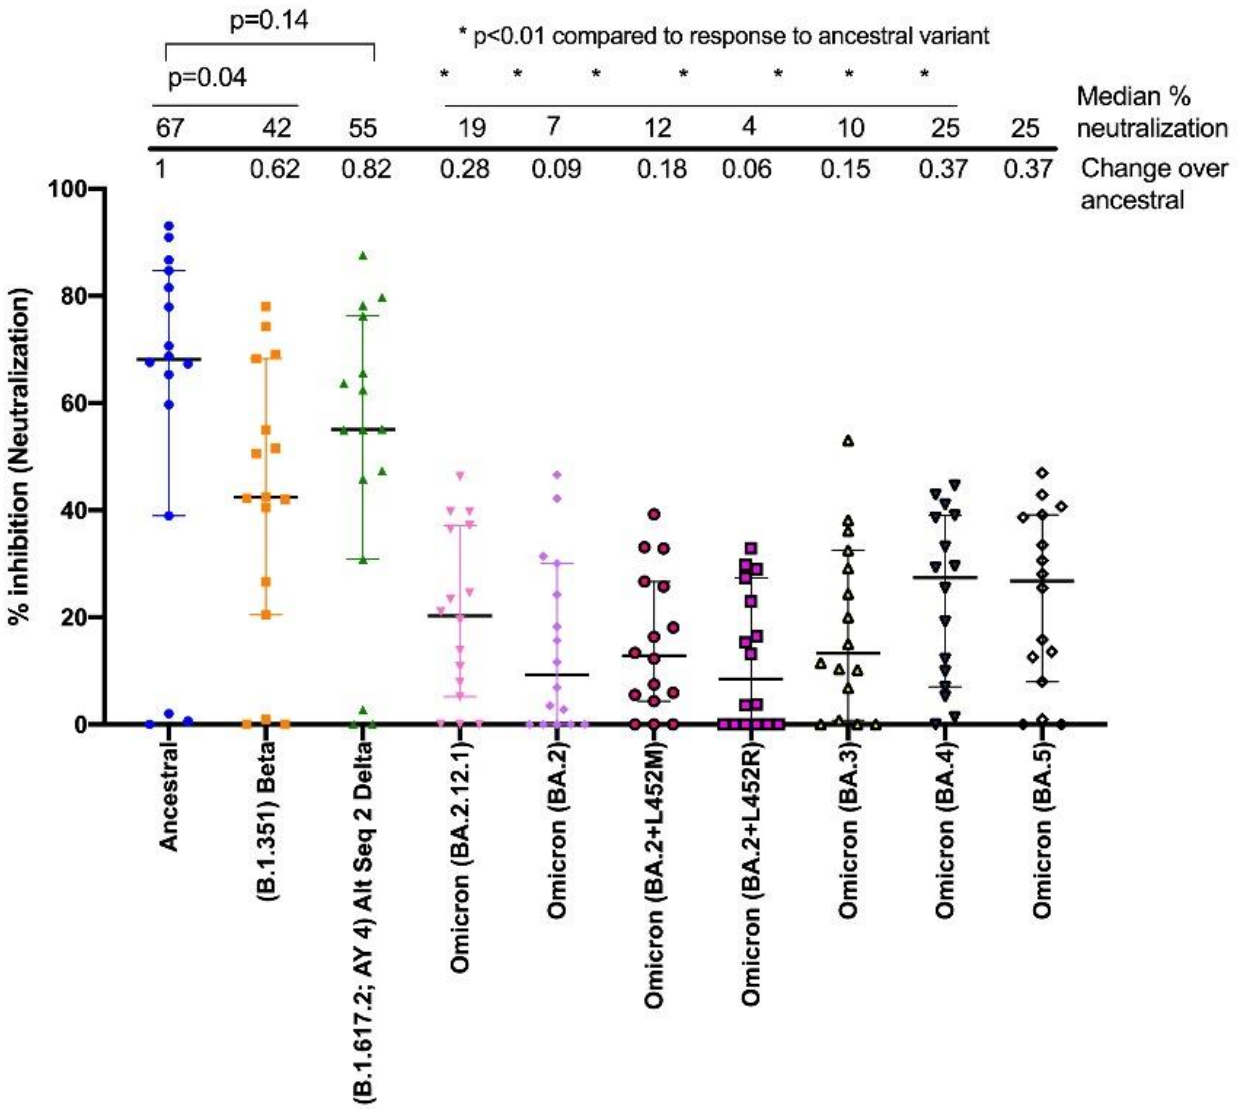
Backgrounds: The ability of SARS-CoV-2 variants of concern to escape from mRNA-vaccine in 5 to 11 years children, regardless of their immune status, is not clearly defined.
Methods: Children from 5 to 11 years vaccinated with Pfizer/BioNTech-BNT162B2 were recruited in December 2021. Sera were obtained at 1 (+1m) and 6 months (+6m) after full vaccination: 2 doses for healthy-participants (HP), 3 for immunosuppressed-participants (ISP). Neutralizing activity for ancestral, beta (B.1.351), delta (B.1.617.2) and omicron variants (BA2.12.1, BA.2, BA.2+L452M, BA.2+L452R, BA.3, BA.4, BA.5) was analyzed.
Results: 30 participants (23-HP, 7-ISP) were enrolled. Of them, 14 (4 ISP), had anti-N antibodies at +1m. All 30 sera were analyzed for neutralization +1m after full vaccination. Median neutralizing activity was: ancestral 67% (IQR, 59-81), beta 42% (16-51), delta 55% (45-65), BA2.12.1 19% (8-24), BA.2 7% (9-18), BA.2+L452M 12% (4-18), BA.2+L452R 4% (0-16), BA.3 10% (1-29), BA.4 25% (10-33), BA.5 25% (12-33). We found differences between ancestral vs. delta ($p=0.04$) and vs. all omicron variants ($p<0.01$). No differences in neutralizing capacities were observed between HP and ISP. (Figure 1). 13 HP were studied +6m after full vaccination; 1/13 (8%) had COVID-19 and further 6/13 (47%) increased anti-N during omicron wave. Neutralizing activity was: ancestral 21% (17-25) ($p=0.02$ vs. +1 month), beta 9% (7-17), delta 14% (10-19), BA2.12 6% (2-7), BA.2 0% (0-3), BA.2+L452M 0.5% (1-4), BA.2+L452R 3% (1-5), BA.3 7.1% (4-11), BA.4 7.7% (5-10), BA.5 6.5% (5-8). Response to omicron variants was also lower than to ancestral at +6m
($p=0.01$).



Conclusions/Learning Points: Neutralizing activity after BNT162B2 was high for ancestral, beta and delta at +1m but low at +6m. No differences between HP and a limited number of ISP children were observed. Response to omicron was low at all time points.

COVID-19 VACCINE CANADIAN WEBSITES FOR CAREGIVERS OF CHILDREN AGED 5-11 YEARS: A COMPREHENSIVE REVIEW OF QUALITIES AMONG DIFFERENT OFFICIAL ORGANIZATIONS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 07: COVID-19 (STATION 01)

Costanza Di Chiara[1], Pierre-Philippe Piche-Renaud[2,3], Elahe Karimi-Shahrbabak[1], Sarah Abu Fadaleh[1], Brooke Lowe[4], Joelle Peresin[1], Lauren Tailor[1,4], Nikki Wong[5], Katie Lee[5], Daniel Farrar[1], Shaun Morris[1,2,3,4]
[1]Hospital for Sick Children, Centre For Global Child Health And Child Health Evaluative Sciences, Toronto, Canada, [2]Hospital for Sick Children, Division Of Infectious Diseases, Toronto, Canada, [3]University of Toronto, Department Of Pediatrics, Faculty Of Medicine, Toronto, Canada, [4]University of Toronto, Dalla Lana School Of Public Health, Toronto, Canada, [5]University of Toronto, Faculty Of Medicine, Toronto, Canada

Backgrounds: High-quality health information is crucial to mitigate COVID-19 vaccine hesitancy. This study aims to evaluate the content, reliability, readability, and understandability/actionability of Canadian official organizations' websites.
Methods: From March 21 to April 22, 2022, a review of online Canadian public-facing academic pediatric hospitals, government, public health authorities, and selected professional organizations' websites on SARS-CoV-2 vaccines was conducted by two authors, and a third author resolved discrepancies. Inclusion criteria were: i) targeting caregivers of children aged 5–11 years; ii) written in English or French; iii) formatting as online webpages, FAQs, posters/infographics, and/or videos. Exclusion criteria and site mapping were used to screen and identify primary and secondary weblinks. A content checklist was used to assess key topics; reliability, readability, and understandability/actionability were appraised using JAMA Benchmark, Flesch-Kincaid Grade Level (FKGL), and Patient Education Material Assessment Tool (PEMAT) for printable (p)/audiovisual (av) materials, respectively. Descriptive statistics were performed using Fisher exact and Anova tests.
Results: Among 1046 websites, mapping identified 43 primary and 141 secondary webpages suitable for analysis. The comprehensive content means score was 12.7±3.6, without differences between organizations. Among 43 primary resources, the total average percentage score was 86.6±13.8 for JAMA and 8.9±1.6 for FKGL, respectively. Thirty-three sources scored as not difficult to read. According to organization types, no differences were founded in reliability and readability. Almost all resources achieved understandable scores. Conversely, only 16.3% of the printable and 84.2% of the audiovisual resources were recorded as actionable, with significant differences among organizations (Table).

Table 1. Quality of online resources for caregivers of information on SARS-COV-2 vaccinations for children aged 5-11 years between different types of organization

Backgrounds: Paediatric post-COVID is much rarer than its adult counterpart yet can take a heavy toll. To understand the scope of the problem, we executed a longitudinal observational population study in COVID-19 positive and negative children.
Methods: We recruited children ≤ 18 years who were attending one of our national testing centres between April 2021 and September 2022. All children were asked to complete questionnaires on the day of inclusion and at 1, 3, 6, and 12 months after, irrespective of their test outcome. We compared prevalence of complaints and assessed what variables were related to persisting complaints at 3 months with a multivariate model.
Results: In total, data were obtained from 1175 children at baseline, 780 at 1 month, 574 at 3 months, 418 at 6 months, and 129 at 12 months (Table 1). A significantly higher proportion SARS-CoV-2 test-positive children reported complaints at 3 months compared to test-negative children (15% vs 2.3%; p:< 0.001). The prevalence at 3 months was lower in 0–6-year-olds (11%) compared to 13-18 year olds (25%). Prevalence dropped at 6 months to 5.9% vs 1.6% in the control group, and no difference between groups was observed at 12 months. At 3 months, fatigue was the most common complaint (9.6% vs 1.9% positive vs negative group; p < 0.001), dropping to 4.9% vs 0.5% at 6 months (positive vs negative group; p: 0.002). In a multivariate model, ageusia (p< 0.01, OR: 0.13), diarrhoea (p: 0.02, 0.24), and headache (p: 0.03, OR: 0.50) at onset were negatively associated with sequelae at 3 months.

Table 1: Post COVID complaints

	Negative	Positive	p*
Persistent Complaints (3 months)			
n	257	260	
Yes	6 (2.3%)	39 (15%)	< 0.001
Fatigue	5 (1.9%)	25 (9.6%)	< 0.001
Headache	1 (0.4%)	15 (5.8%)	< 0.001

‡ Chi-squared test

Conclusions/Learning Points: Our study reveals that COVID-19 infections in children can lead to persistent complaints, but with a decrease over time, shedding light on the prevalence and burden of paediatric post-COVID complaints.

PD0072 / #1900

CLINICAL FEATURES OF SARS-COV-2 INFECTION IN CHILDREN AND ADOLESCENTS WHO EXPERIENCED COVID-19 ACROSS PARENTAL, DELTA, AND OMICRON WAVES IN ITALY: A PROSPECTIVE OBSERVATIONAL STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 07: COVID-19 (STATION 01)

Costanza Di Chiara[1], Riccardo Boracchini[2], Giulia Sturniolo[1], Alessia Barbieri[1], Marica De Pieri[1], Cecilia Liberati[1], Sandra Cozzani[1], Anna Cantarutti[2], Daniele Donà[1], Carlo Giaquinto[1]
[1]University of Padova, Division Of Pediatric Infectious Diseases, Department For Women's And Children's Health, Padova, Italy, [2]University of Milano Bicocca, Laboratory Of Healthcare Research & Pharmacoepidemiology, Unit Of Biostatistics, Epidemiology And Public Health, Department Of Statistics And Quantitative Methods, Milan, Italy

Backgrounds: COVID-19 features changed with the Omicron variant of concern (VOC) in adults. This study aims to describe COVID-19 symptoms in children and adolescents during the Parental, Delta, and Omicron waves.
Methods: A single-centre, prospective observational study was conducted on individuals aged 0-20 years attending the University Hospital of Padua (Italy) from March 2020 to November 2022. Confirmed COVID-19 cases were defined by positive SARS-CoV-2 molecular detection and/or serology; patient/family symptoms and virological positivity were considered to determine the infection onset. Variables were summarized using descriptive statistics and compared among VOCs and age classes using the appropriate test.
Results: A total of 509 cases (46% female, median age eight years [IQR:4-12]) were studied. Three-hundred-eighty-seven, 52, and 70 subjects experienced COVID-19 during the Parental, Delta, and Omicron waves, respectively. Only 26/509 underwent a breakthrough infection. Most subjects developed an asymptomatic (26%) or mild (71%) disease. Overall, the most frequent symptoms were fever (47%) and rhinitis (21%), which showed a significant increasing trend from the Parental to Omicron waves ($p<0.001$). Conversely, diarrhea was commonest during the Parental and Delta variants ($p=0.03$). Strytifing symptoms according to age classes, fever, rhinitis, and skin rashes were higher in infants/toddlers; conversely, asthenia and headache were more frequent in children older than five years (table). Symptoms' duration was similar across different VOCs; conversely, symptoms' numbers varied according to age classes
($p<0.0001$).

Table. Clinical manifestation of COVID-19 in the study population (N=509) overall, and statified according to age classes and SARS-CoV-2 variant of concern

‡Cochran-Armitage Trend Test, Chi-Squared test, and Kruskal-Wallis test as appropriate

Conclusions/Learning Points: This study showed differences in COVID-19 clinical presentation among infants, children, and adolescents, and confirmed Omicron infection is more likely to be associated with upper respiratory symptoms. However, further population-based studies are needed to support these findings. In addition, active surveillance will play a crucial role in assessing the disease severity of future VOCs.

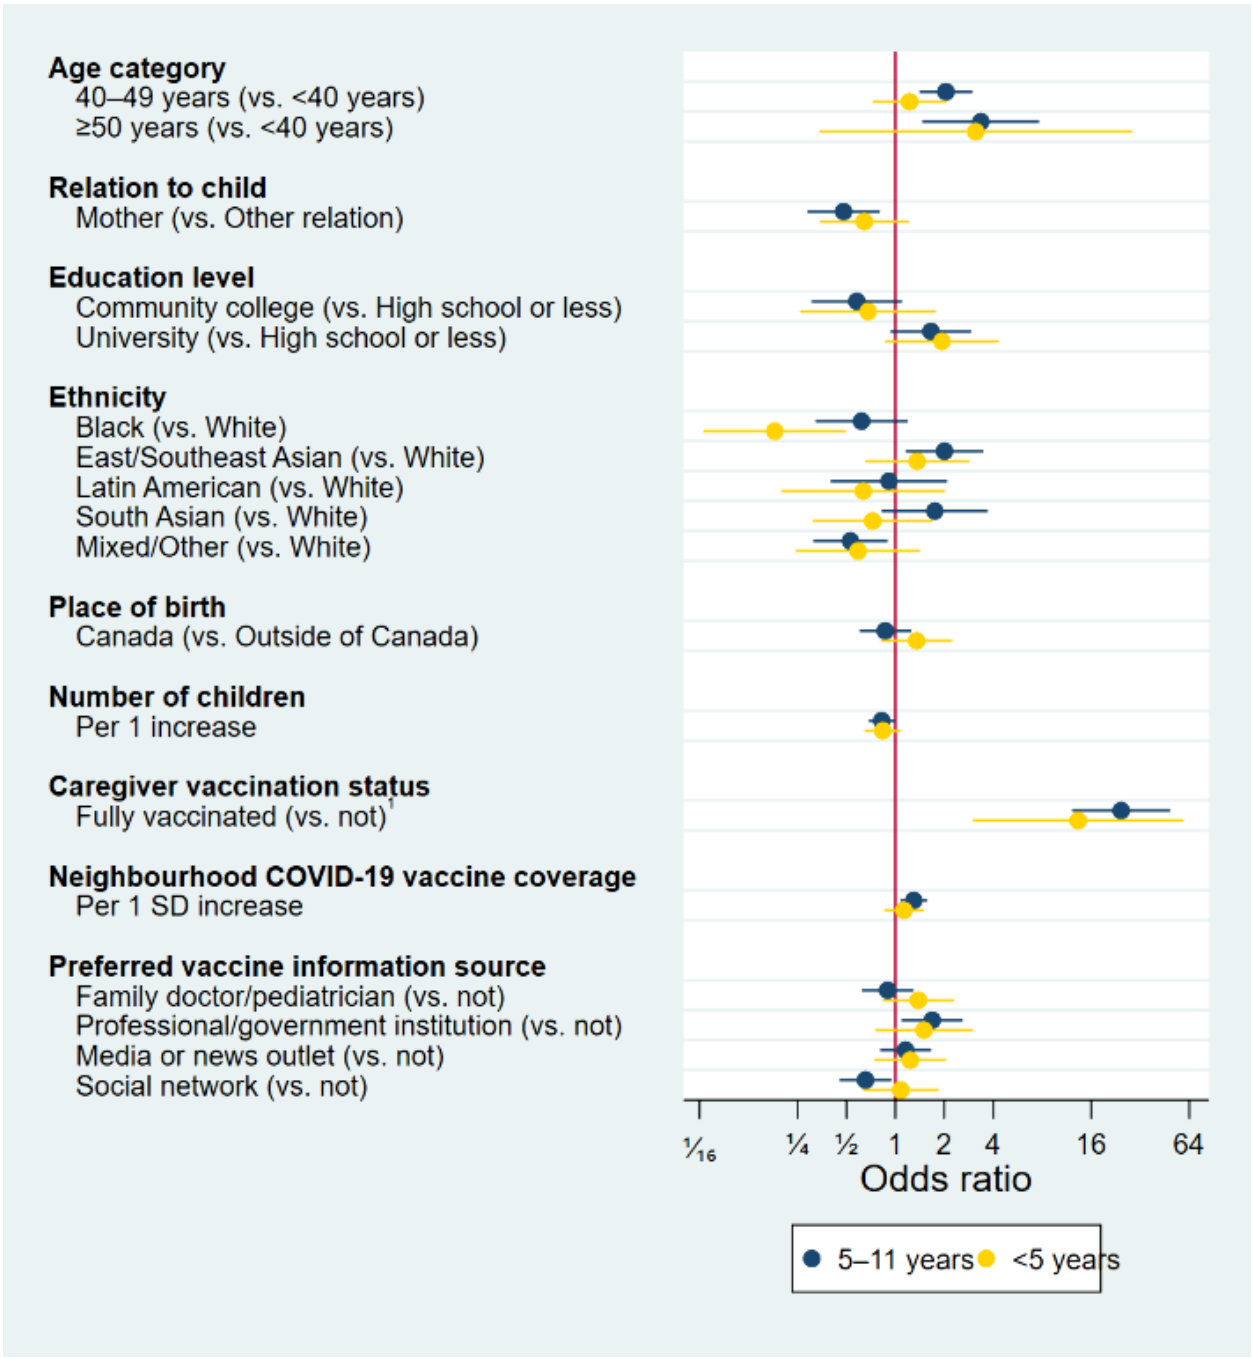
PD0073 / #1489

SARS-COV-2 VACCINE ACCEPTANCE AND UPTAKE AMONG CAREGIVERS OF CHILDREN OF DIFFERENT AGE GROUPS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 07: COVID-19 (STATION 01)

Pierre-Philippe Piche-Renaud[1], Costanza Di Chiara[2], Elahe Karimi-Shahrbabak[3], Sarah Abu Fadaleh[3], Daniel Farrar[4], Shaun Morris[5]
[1]Hospital for Sick Children, Division Of Infectious Diseases, Toronto, Canada, [2]University of Padua, Paediatric Infectious Diseases, Padua, Italy, [3]Hospital for Sick Children, Centre For Global Child Health And Child Health Evaluative Sciences, Toronto, Canada, [4]Hospital for Sick Children, Centre For Global Child Health, Toronto, Canada, [5]The Hospital for Sick Children, University of Toronto, Pediatric Infectious Diseases, Toronto, Canada

Backgrounds: Although vaccination against SARS-CoV-2 is recommended in Canada for all children aged more than 6 months old, uptake remains low in younger children. This study aimed to assess and compare vaccine uptake and acceptance among caregivers of children of all ages, and identify factors associated with SARS-CoV-2 vaccine uptake and acceptance.
Methods: A multi-language self-administered survey was sent to caregivers through more than 600 schools and two community health centers in the Greater Toronto Area from April 5th to July 4th, 2022. Caregivers of children ≥5 years old (yo) were asked to report on their child's vaccine status, and caregivers of children <5yo were asked about their intention to vaccinate. Univariate logistic regressions were employed to determine and compare odds ratios of vaccine uptake or acceptance by caregiver or children characteristics.
Results: In total, 1,223 caregivers answered the survey. 253 caregivers had at least one <5yo child, 807 had at least one 5-11yo child and 522 had at least one 12-17yo child. 618 caregivers (76.6%) reported that their children 5-11yo were vaccinated, and 461 caregivers (88.3%) reported that their children 12-17yo were vaccinated ($p<0.001$). 658 caregivers (81.7%) of children 5-11yo were vaccine acceptant or reported that their child was already vaccinated, versus 148 caregivers (58.5%) of children <5yo who were vaccine acceptant ($p<0.001$). Characteristics associated with vaccine uptake and acceptance are reported in the Figure. Odds ratios of vaccine uptake and acceptance were comparable across age groups for most
characteristics.



Age category
40–49 years (vs. <40 years)
≥50 years (vs. <40 years)
Relation to child
Mother (vs. Other relation)
Education level
Community college (vs. High school or less)
University (vs. High school or less)
Ethnicity

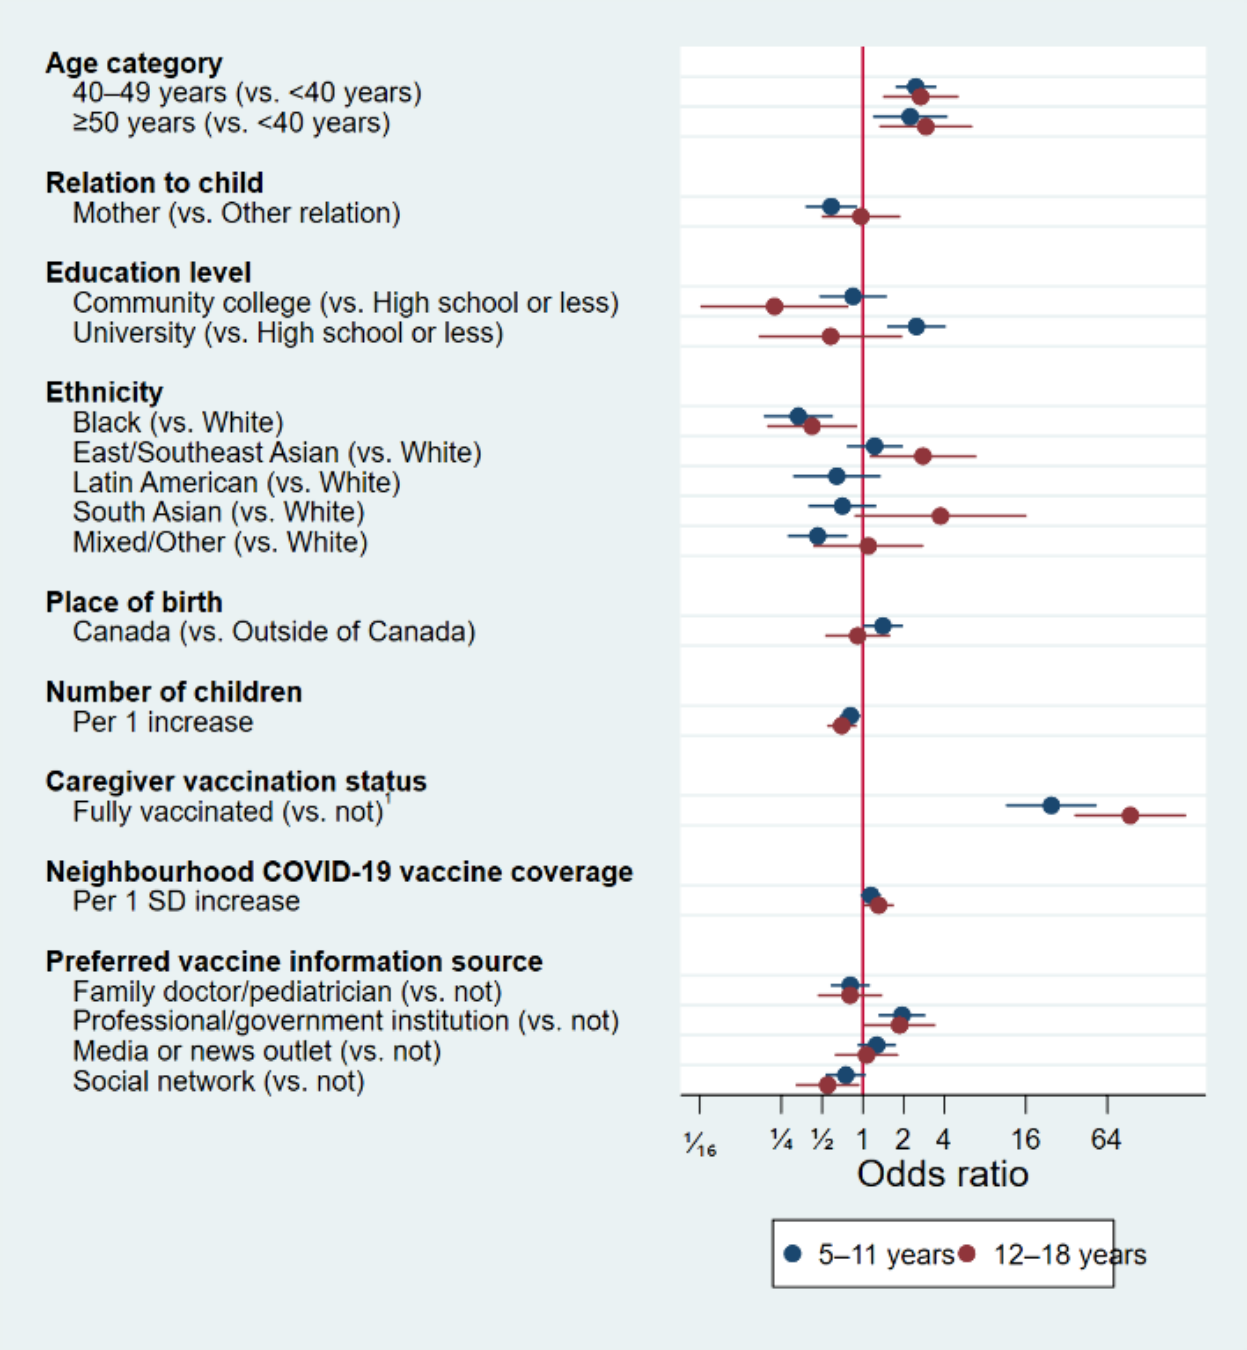
Social network (vs. not)
1/16
¼
½
1
2
4
16
64
Odds ratio
5–11 years
<5 years



Conclusions/Learning Points: SARS-CoV-2 vaccine acceptance was found to be lower amongst caregivers of younger children. Characteristics associated with vaccine uptake and acceptance were identified, which can inform targeted interventions to support vaccine uptake, especially in younger age groups.

PD0074 / #1676

RISK OF INVASIVE BACTERIAL INFECTION (IBI) AND URINARY TRACT INFECTION (UTI) IN FEBRILE INFANTS 90 DAYS AND YOUNGER WITH CONCURRENT SARS-COV-2 (COVD19) INFECTION.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 07: COVID-19 (STATION 01)

Etimbuk Umana, Hannah Norman-Bruce, Clare Mills, Thomas Waterfield, Febrile Infants Diagnostic Assessment And Outcome Study Group
Queen's University Belfast, Wwiem, Belfast, United Kingdom

Backgrounds: There is variable literature on the rates of IBI and UTI in febrile infants (<90days) when viral panels are positive for SARS-CoV-2 (COVD19). We aimed to assess the rates of IBI and UTI in febrile infants presenting to emergency departments across the UK with concurrent COVD19 infection.
Methods: The FIDO study is large prospective multicentre observational study looking at the evaluation of febrile infant on behalf of the Paediatric Emergency UK and Ireland (PERUKI) network. It is currently collecting data from 27 sites across the UK. Infants up to 90 days of age attending between 01/08/2022 - 16/01/2023 were screened for inclusion. Infants with a recorded fever (≥38°C) prior to presentation were eligible for inclusion. There were no exclusion criteria. Disposition outcomes and rates of IBI and UTI were reported for infants with positive COVID19.
Results: Of the 240 patients undergoing viral panel testing, 40 (17%) were COVID19 positive. The median age for the COVID19 cohort was 48 days (IQR: 30 – 60) with females making up 55%. The median absolute neutrophil count was 3.7x109/L (IQR: 2.2 – 5.7) while the median C-reactive protein was 9mg/L (IQR: 2 – 23). About 90% underwent bloods, 68% urinalysis and culture, and 40% had a lumbar puncture performed in the COVID19 cohort. Of the 40 patients, 5 (12.5%) were discharged home directly from ED. In the entire cohort of patient undergoing viral testing (240) the UTI rate was 8.3% and IBI rate was 3.8%. However, no patient with positive COVID19 test had UTI or IBI.
Conclusions/Learning Points: In this study, the concurrent risk of IBI and UTI in patients with positive COVID19 status was negligible. We would advocate a tailored approach to the management of these patients.

PD0075 / #1787

HUMORAL AND CELL-MEDIATED IMMUNE RESPONSES IN HIV-VERTICALLY TRANSMITTED YOUNG PATIENTS AFTER A THIRD BOOSTER DOSE OF BNT162B2 MRNA SARS-COV-2 VACCINE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 07: COVID-19 (STATION 01)

Claudia Vanetti[1], Marta Stracuzzi[2], Elisa Crivellaro[2], Federica Cicilano[1], Micaela Garziano[1], Claudio Fenizia[3], Mario Clerici[4], Gianvincenzo Zuccotti[5], Vania Giacomet[2], Daria Trabattoni[1]
[1]Università degli Studi di Milano, Department Of Biomedical And Clinical Sciences, Milan, Italy, [2]Università degli Studi di Milano, Pediatric Infectious Disease, Luigi Sacco Hospital, Milan, Italy, [3]Università degli Studi di Milano, Department Of Pathophysiology And Transplantation, Milan, Italy, [4]IRCCS, Fondazione Don Carlo Gnocchi, Milan, Italy, [5]Università degli Studi di Milano, Department Of Pediatrics, V. Buzzi Children's Hospital, Milan, Italy

Backgrounds: Data on the efficacy and the duration of protection of a third booster dose of mRNA SARS-CoV-2 vaccine, and the role of a previous natural SARS-CoV-2-infection in enhancing the efficacy of vaccination in people living with vertically-transmitted HIV (PLWH) are still scarce.
Methods: We analyzed the SARS-CoV-2-specific neutralizing antibody activity (NA) against the European (EU, lineage B.1), the Delta (D) and the Omicron (Omi) strains and the SARS-CoV-2-specific cell-mediated responses in 29 ART-treated HIV-vertically-transmitted individuals (PLWH) vaccinated with three doses of BNT162b2-mRNA vaccine. Patients were stratified based on a previous history of COVID-19 (SPIV or SV). Analyses were performed at T0-before vaccination, T2-before the third dose-and T3-3 months after the third dose. Results were compared with those obtained in 27 BNT162b2-mRNA-vaccinated healthy controls (HC).
Results: Significantly higher NA against EU and D were observed at T2 in SPIVs compared to the SV groups ($p=0.05$). At T3, this discrepancy was lost as NA against all variants was generally increased. Focusing on B-cell subsets, we observed increased switched-plasmablasts at T2 and T3 compared to T0 in SPIV PLWH. Differently from NA, T-cell response was maintained high at T2 and T3. SV and SPIV PLWH mounted a SARS-CoV-2-specific T-cell memory overtime. CD4+ and CD8+IFN-γ+ secreting T-cells frequencies were boosted further by the third dose, principally in the SV ($p<0.05$ T3 vs T0). Overall, in HCs the magnitude of response was higher compared to the PLWH groups. Particularly, SPIV HCs displayed significantly higher percentages of CD8+IFN-γ+secreting T-cells compared to the PLWH respective group at T3 ($p<0.01$).
Conclusions/Learning Points: BNT162b2-mRNA vaccine is effective even in ART-treated PLWH. The third dose is crucial in generating humoral and cellular-mediated responses against all variants considered, independently from a previous SARS-CoV-2 natural infection.

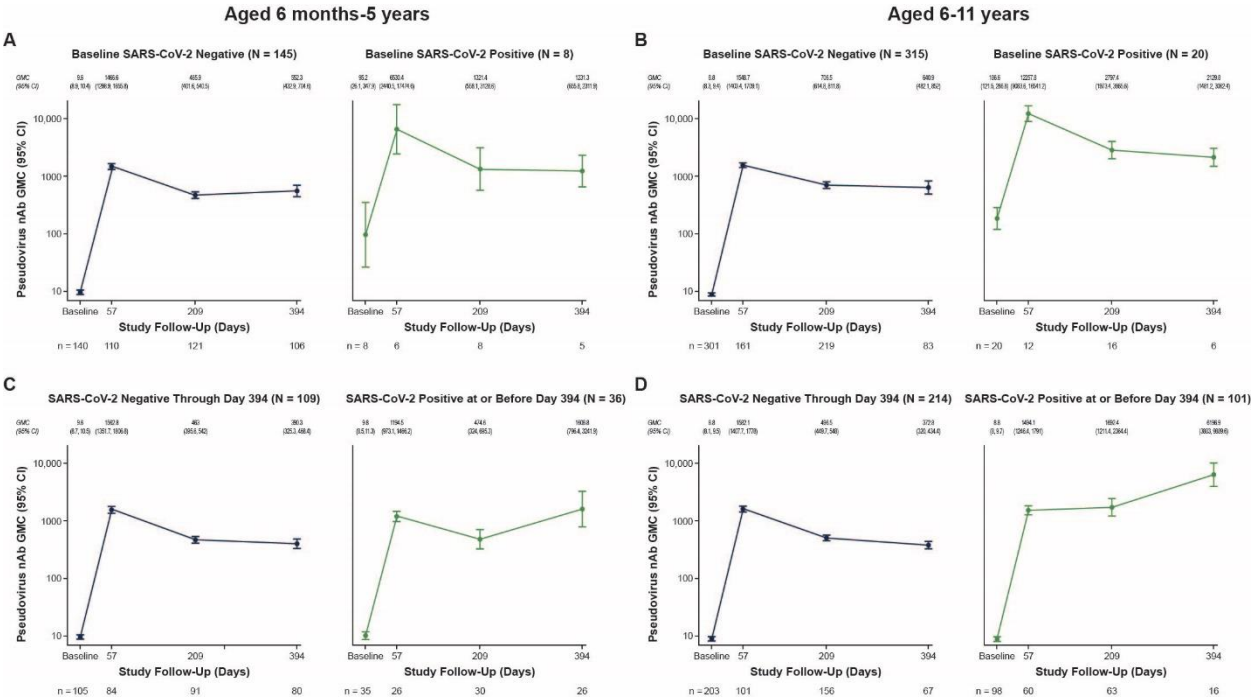
MRNA-1273 PRIMARY SERIES INDUCES DURABLE NEUTRALIZING ANTIBODY RESPONSES IN CHILDREN 6 MONTHS TO 11 YEARS OF AGE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 07: COVID-19 (STATION 01)

Sabine Schnyder Ghamloush[1], Christina Rostad[2], C. Buddy Creech[3], Vladimir Berthaud[4], Weiping Deng[1], Xiaoping Zhao[1], Jialin Qu[1], Honghong Zhou[1], Mollie Brown[1], Roxanne Kelly[1], Bethany Girard[5], Rituparna Das[1]
[1]Moderna, Inc., Clinical Development, Cambridge, United States of America, [2]Emory University School of Medicine and Children's Healthcare of Atlanta, Paediatrics, Atlanta, United States of America, [3]Vanderbilt University Medical Center, Paediatric Infectious Diseases, Nashville, United States of America, [4]Meharry Medical College – Clinical and Translational Research Center, Infectious Diseases, Nashville, United States of America, [5]Moderna, Inc., Infectious Diseases, Cambridge, United States of America

Background: KidCOVE is a phase 2/3 study conducted to evaluate the safety, reactogenicity, immunogenicity, and efficacy of mRNA-1273 in healthy children 6 months-11 years of age (NCT04796896). Here, we present the 1-year durability of immune responses after receipt of the mRNA-1273 primary series.
Methods: Participants received the 2-dose mRNA-1273 primary series (25 µg [6 months-5 years] or 50 µg [6-11 years]) administered 28 days apart. Immunogenicity was assessed by measuring neutralizing antibodies (nAb) against ancestral SARS-CoV-2 at 1 month (Day 57), 6 months (Day 209), and 12 months (Day 394) after dose 2. Geometric mean concentrations (GMCs) with 95% confidence intervals (CIs) at time points up to Day 394 were summarized by participant SARS-CoV-2 status (as determined by anti-nucleocapsid antibodies and/or RT-PCR) at baseline and up to Day 394.
Results: In baseline SARS-CoV-2–negative participants <6 years of age (n=145) and 6-11 years of age (n=315), durable nAb responses against ancestral SARS-CoV-2 were observed at Day 209 (6 months; Figure; GMC [95% CI], <6 years: 466 [402-541]; 6-11 years: 707 [615-812]) and Day 394 (12 months; GMC [95% CI], <6 years: 522 [433-705]; 6-11 years: 641 [482-852]). nAb responses persisted among participants without any evidence of SARS-CoV-2 infection through Day 394. Participants with evidence of post-baseline infection (positive SARS-COV-2 status at or before Day 394) had higher or similar nAb levels at Day 394 than at Day
57.



Conclusions/Learning Points: A 2-dose mRNA-1273 primary series induced durable nAb responses to ancestral SARS-CoV-2 through 12 months after vaccination in children 6 months-11 years of age. These data suggest durable protection afforded by mRNA-1273 in this age group and may inform the selection of appropriate booster intervals.

PD0077 / #363

RISK FACTORS FOR POST-COVID-19 CONDITION (LONG COVID) IN CHILDREN: A PROSPECTIVE COHORT STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 07: COVID-19 (STATION 01)

Danilo Buonsenso, Rosa Morello, Francesco Mariani, Piero Valentini
Fondazione Policlinico Universitario A. Gemelli IRCCS, Pediatrics, Roma, Italy

Backgrounds: Adults and children can develop post-Covid-19 condition (PCC) (also often referred as Long Covid) after SARS-CoV-2 infection. However, methodological limitations of available pediatric studies included small sample size, substantial heterogeneity in outcome definitions, short follow-up duration, and did not account for SARs-CoV-2 vaccination variant in the subsequent risk of developing Long Covid.
Methods: A prospective cohort study of children (from birth to 18 years of life) previously diagnosed with microbiologically confirmed SARS-CoV-2 infection. . Children were assessed in person at a referral pediatric post-covid clinic in Rome, Italy, 3-6-12-18 months following acute infection. PCC was defined as persistence of otherwise unexplained symptoms for at least three months after initial infection. [
Results: 1243 children were included (575 (46,3%) females, median age 7,25 years (4-10,3). 294 (23%)patients were diagnosed with PCC at three months, of them 268 (91%) had subsequent follow-up: 143/268 (53%) of patients remained symptomatic at six months, 38/268 (14%) at twelve months, and 15 (6%) at eighteen months. The following risk factors were associated with PCC: older age ((>10 years) (OR 3,79; 95%CI 2,87 - 5,01), comorbidities (OR 1,73; 95%CI 1,21 - 2,48), and hospitalization during the acute phase (OR 2,62; 95%CI 1,21 – 5,67). In multivariate logistic regression, compared to the Omicron variant, all other variants were significantly associated with PCC at 3 and 6 months. Vaccines were associated with a reduced but not statistically significant risk of developing persistent symptoms
Conclusions/Learning Points: Children with previous hospitalizations, comorbidities, and older age are at higher risk of PCC. However, most children tend to improve over time, particularly those infected during Omicron wave. We did not find strong protective effect of vaccination status on PCC development.

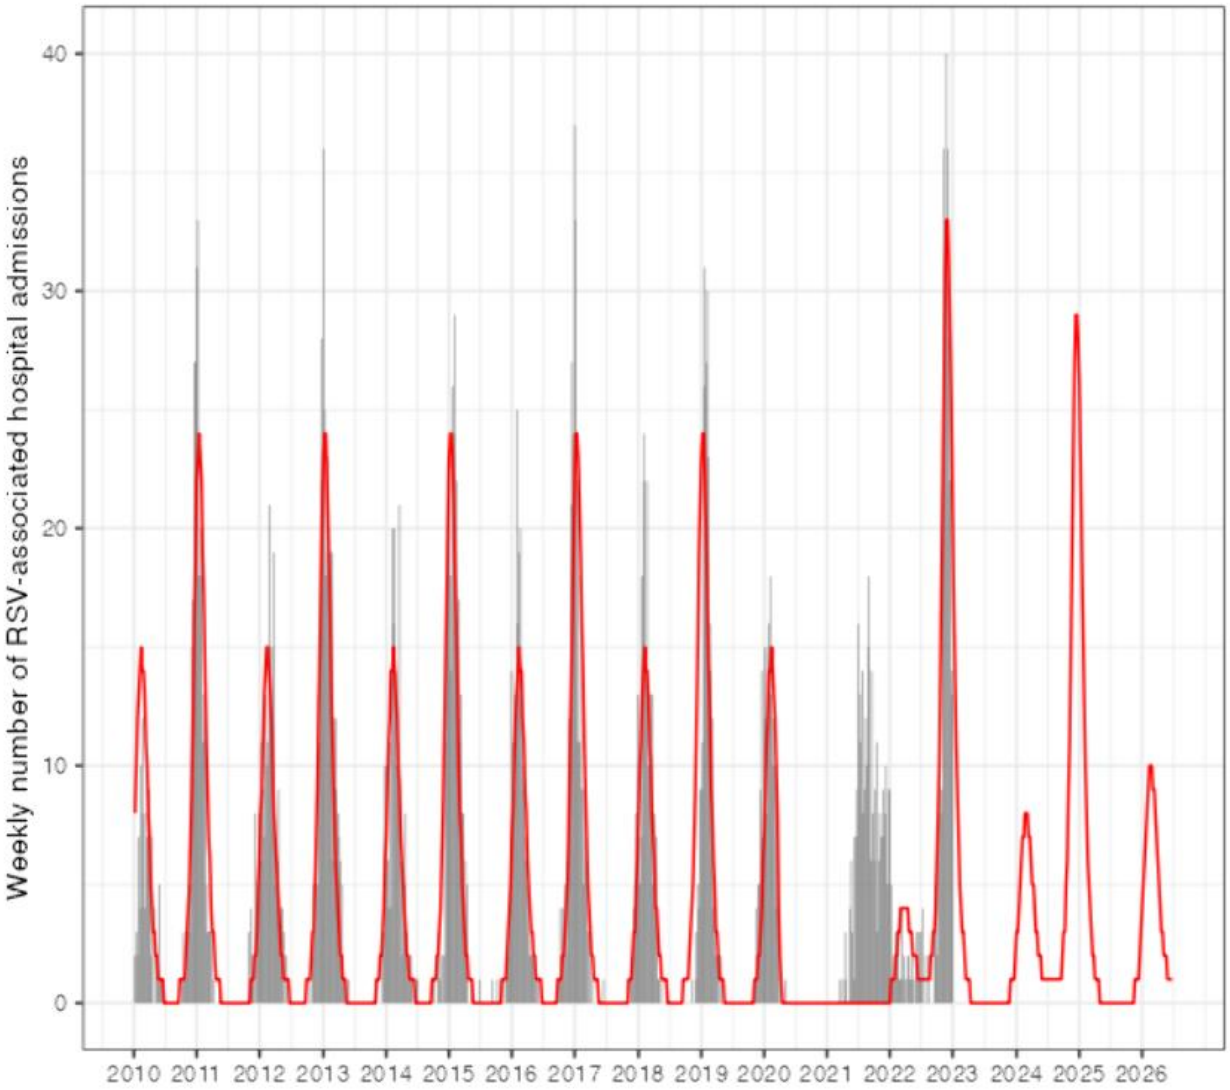
[1]Inselspital, Bern University Hospital, Department Of Paediatrics. Division Of Paediatric Infectious Diseases, Bern, Switzerland, [2]Inselspital, Bern University Hospital, Department Of Paediatrics, Division Of Paediatric Pneumology And Allergology, Bern, Switzerland, [3]University of Bern, Institute For Infectious Diseases, Bern, Switzerland, [4]Swiss Group for Clinical Cancer Research, Statistics, Bern, Switzerland

Backgrounds: Respiratory syncytial virus (RSV) is the most important cause of bronchiolitis and pneumonia in children younger than 5 years worldwide. In western countries, RSV is estimated to cause about 20% of lower respiratory tract infections in children, with most of the disease burden occurring in children younger than 1-year-old. A distinct alternating pattern of minor and major seasons of RSV infection has been reported in several North and central European countries, as well as in some parts of North America. Here we report on >20 years data of hospital admissions due to RSV at a tertiary paediatric centre in Switzerland and the impact of non-pharmaceutical interventions (NPI) during the SARS-CoV-2 pandemic.
Methods: We implemented a susceptible-infected-recovered-susceptible (SIRS) dynamic transmission model with waning immunity described by a series of ordinary differential equations to model RSV epidemiology.
Results: From December 1997 until December 2022, 5083 children with RSV infection were admitted to the University Children's Hospital Bern. Before the COVID-19 pandemic, we observed an alternating cycle of minor and major seasons (figure). While no child was hospitalised with RSV infection in winter 2020/2021, we observed an out-of-season increase in the number of hospital admissions in summer 2021. A SIRS model captured the previous local epidemiology well with a root-mean-square-error of 3.61, compared to weekly case numbers (figure). Modelling the impact of COVID-19 associated NPI on RSV epidemiology failed to capture the out-of season increase in summer, but correctly predicted a larger than usual season in 2022/2023. According to the model, it may take several years to return to the previous epidemiology.



Conclusions/Learning Points: A simple mathematical model captured RSV epidemiology, including features of the changed disease dynamics following COVID-19-associated NPI, at the University Children's Hospital Bern.

PD0079 / #492

CAREGIVER PRODUCTIVITY LOSS AND ECONOMIC BURDEN ASSOCIATED WITH PEDIATRIC PNEUMOCOCCAL DISEASE IN THIRTEEN COUNTRIES

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

Xiuyan Li[1], Sophie Warren[1], Mark Rozenbaum[2], Johnna Perdrizet[1]
[1]Pfizer Inc, Global Value & Evidence, New York, United States of America, [2]Pfizer, Health Economics And Outcomes Research, Capelle aan den IJssel, Netherlands

Backgrounds: Studies estimating the economic burden of pediatric pneumococcal disease often include direct medical costs and omit indirect non-medical costs. This study aims to quantify caregiver productivity losses due to pediatric pneumococcal disease and associated economic burden attributable to serotypes in licensed pneumococcal conjugate vaccines (PCVs), the 10-, 13-, and 15-valent (PCV10, PCV13, and PCV15), and in an investigational PCV, the 20-valent (PCV20).
Methods: Using a decision-analytic model, a human capital approach was adopted to estimate the indirect non-medical economic burden for caregivers of children <5 years with pneumococcal disease. The monetary value of caregiver productivity loss was measured by its opportunity cost of losing paid income. Thirteen countries were included, of which 5 have PCV10 national immunization programs (NIPs) (Austria, Finland, Netherlands, New Zealand, and Sweden) and 8 have PCV13 NIPs (Australia, Canada, France, Germany, Italy, South Korea, Spain, and United Kingdom). Input parameters were derived from published literature. Costs were inflated to 2021 values in United States dollars.
Results: PCV20 serotypes contributed to a substantial non-medical economic burden, amounting to over $173 million across 13 countries annually (Figure 1), of which $80.6 million was PCV20-unique serotypes. Country-specific productivity losses varied by the current PCV included in the NIP. For PCV10 NIPs, economic burden attributed to serotypes was mainly caused by PCV13-unique serotypes; and in PCV13 NIPs, largely caused by PCV20-unique serotypes.

Figure 1: Annual estimated lost of productivity due to clinical burden attributable to PCV serotypes in children < 5 years in 13 selected countries

Annual total indirect costs (million USD)*	PCV10 NIPs					PCV13 NIPs							
	AUT	FIN	NLD	NZL	SWE	AUS	CAN	FRA	DEU	ITA	KOR	ESP	GBR
PCV10-serotypes	$ 0.70	$ 0.05	$ 0.09	$ 0.07	$ 0.09	$ 1.47	$ 1.30	$ 3.56	$ 5.37	$ 2.68	$ 0.61	$ 3.39	$ 0.25
PCV13-serotypes	$ 3.72	$ 3.06	$ 1.17	$ 0.52	$ 0.38	$ 6.41	$ 6.14	$ 8.06	$ 17.34	$ 4.33	$ 4.56	$ 8.56	$ 1.83
PCV15-serotypes	$ 3.95	$ 3.21	$ 1.52	$ 0.74	$ 0.46	$ 7.58	$ 11.93	$ 12.45	$ 26.32	$ 5.96	$ 4.86	$ 10.61	$ 3.01
PCV20-serotypes	$ 4.88	$ 3.53	$ 2.95	$ 1.49	$ 0.70	$ 9.08	$ 17.56	$ 20.75	$ 55.23	$ 14.77	$ 15.80	$ 17.93	$ 8.51

Abbreviations: AUS = Australia; AUT = Austria; CAN = Canada; DEU = Germany; ESP = Spain; FIN = Finland; FRA = France; GBR = United Kingdom; ITA = Italy; KOR = South Korea; NIP = national immunization program; NLD = Netherlands; NZL = New Zealand; PCV = Pneumococcal conjugate vaccine; SWE = Sweden.
*The model inputs derived for caregivers in each country included: 1) Missed workdays: the number of workdays missed per event of childhood invasive pneumococcal disease (IPD), acute otitis media (AOM), inpatient pneumonia, and outpatient pneumonia; 2) Proportion of caregivers missing work: the proportion of caregivers reporting missed workdays from paid employment, assuming only one caregiver per infected child would miss work; 3) Serotype-specific incidence: the annual clinical burden of respective pneumococcal disease outcome attributable to PCV serotypes reported in Wasserman et al (2021); and 4) Indirect non-medical costs: the indirect cost per disease case, estimated by the mean workdays missed multiplying the unit costs of productivity loss (average daily wage). Annual cost estimates accross the countries are reported in Million United States Dollars (USD).

Conclusions/Learning Points: The non-medical economic burden is possibly greater, given only the monetary value associated with missed workdays from paid employment were accounted for in our estimates. Results demonstrate the importance of including indirect costs when estimating the total burden associated with PCV serotypes and the potential addressable economic burden associated with higher-valent PCVs.

PD0080 / #867

MODELLING THE PUBLIC HEALTH IMPACT OF ROUTINE PEDIATRIC VACCINATION FOR THE PREVENTION OF CYTOMEGALOVIRUS AND CONGENITAL CYTOMEGALOVIRUS AT THE POPULATION-LEVEL

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

Ashley Davis[1], Cameron Cook[1], Jonathan Graham[1], John Diaz-Decaro[2], Evan Myers[3], Philip Buck[4]
[1]RTI Health Solutions, Health Economics, Research Triangle Park, United States of America, [2]Moderna, Inc., Epidemiology, Cmv Vaccine, Cambridge, United States of America, [3]Duke University Medical Center, Department Of Obstetrics And Gynecology, Durham, United States of America, [4]Moderna, Inc., Health Economics And Outcomes Research, Cambridge, United States of America

Backgrounds: Cytomegalovirus (CMV) infection in healthy individuals is often mild or asymptomatic; however, a pregnant woman can pass CMV to her newborn, resulting in congenital cytomegalovirus (cCMV), the major infectious cause of sensorineural hearing loss in infants born in developed countries. There are no prophylactic vaccines currently available to prevent CMV.
Methods: A dynamic transmission model was developed to evaluate the incremental impact of routine pediatric CMV vaccination in the US population, compared to no vaccination. We modelled an initial 1-year catch-up vaccination of children aged 6 months to 3 years, then only newly eligible children aged 6 months were vaccinated in subsequent years. Two vaccine coverage scenarios were modelled: 100% and 50% coverage. Using conservative assumptions, efficacy against primary infection for the 2-dose vaccine regimen was 70% in the first 2 years then waned to zero over the next 5 years; no efficacy was assumed against non-primary infection. Health outcomes included CMV infections (primary and non-primary) and cCMV cases (symptomatic cCMV, neonatal death, and cCMV-related stillbirth) averted. Sensitivity analyses assessed the robustness of parameter estimates.
Results: Based on 100% pediatric vaccination coverage in the US population, we expected a mean annual reduction of 12,712 cCMV cases (including 1,213 symptomatic cCMV cases). In the 50% pediatric vaccination coverage scenario, a mean annual reduction of 12,375 cCMV cases (including 1,181 symptomatic cCMV cases) was expected (see Table 1).
Conclusions/Learning Points: There is substantial public health benefit associated with utilization of an effective CMV vaccine in US children due to the potential reduction in CMV transmission. Several model parameters were based on assumptions and robust evidence generation is needed. Furthermore, the efficacy and durability of a licensed vaccine are unknown and will be important

considerations.

Table 1. Mean Annual Results (Undiscounted) for Pediatric CMV Vaccination Versus No Vaccination in the US Population

	100% CMV Vaccination Coverage			50% CMV Vaccination Coverage		
	Vaccination	**No Vaccination**	**Difference**	**Vaccination**	**No Vaccination**	**Difference**

PD0081 / #1056

MENINGOCOCCAL PEDIATRIC COST OF ILLNESS IN ARGENTINA. IMPACT ON PATIENTS WITH SEQUELAE.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

Norberto Giglio[1], Paula Micone[2], Mariana Coelho[3], Hernan Sanguinetti[1], Angela Gentile[1]
[1]Hospital de ninos Ricardo Gutiérrez, Epidemiology, Ciudad Autonoma de Buenos Aires, Argentina, [2]Hospital de Agudos Carlos Durand, Obstetrician, Ciudad Autonoma de Buenos Aires, Argentina, [3]FIPEC, Chagas, CABL, Argentina

Backgrounds: Meningococcal disease continues to be a cause of morbidity and mortality in the pediatric population .Long term sequelae reach up to 20% to 50%.Health systems are forced to allocate significant budgets for the management of severe cases. The aim of this study was to estimate the total costs of meningococcal disease among pediatric population in Argentina.
Methods: Decision tree/ Markov model was adapted for Argentina including 5 squeals:Dermatological (skin sarring), Musculoskeletal or amputation, Neurological, Hearing loss and Visual. Resources identification and utilization rate were taken from literature validated from expert opinion. Unit costs were obtained from Buenos Aires Hospital de Niños Ricardo Gutierrez health care tariff charge September 2021. The perspective of public sector was adopted based on a time horizon of 15 years discounted at 5% annually.According to uncertainties related to sequelae cost, we have added scenarios of maximum and minimum severity in order to be able to estimate the wide range of costs.
Results: Infants newborns cohort 2019 in Argentina was 625,4419 with a meningococcal incidence 13.2/100,000 in under one year old.Clinical Acute manifestations of meningococcemia showed, meningococcemia with meningitis 37%, meningitis 29,8%, meningococcemia 16%, others 17%. Sequelae Distribution: Dermatological (skin scarring) 22% (13% major, 87% minor); Musculoskeletal or Amputations 8 %(50% major,50% minor) Neurological 42% (50% major, 50%minor) , Hearing Loss 25 % (50% major,50% minor) and Visual 3%(2% major 98% minor).Meningococcal cost was estimated in Acute Cost, Cohort 83 cases; 396,517 USD (376,589-416,400), Sequelae 38 cases 986,374 USD total per 15 year and 10 deaths.
Conclusions/Learning Points: Meningococcal cost of illnes (acute and cronic) per cohort was estimated in 1,382,891 USD where the chronic sequelaes represent 71% of the total cost of meningococcal diseaes in Argentina

PD0082 / #1242

COST-EFFECTIVENESS OF A 20-VALENT PEDIATRIC PNEUMOCOCCAL CONJUGATE VACCINE COMPARED WITH A 15-VALENT PNEUMOCOCCAL CONJUGATE VACCINE IN ITALY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

Roberto Di Virgilio[1], Alessandra Pagliaro[2], Raffaella Iantomasi[2], Michele Wilson[3], Cheryl Mcdade[3], Giorgio Lorenzo Colombo[4], Emanuele Amodio[5], Vania Giacomet[6], Eva Agostina Montuori[2], Sophie Warren[7], Johnna Perdrizet[7]
[1]Pfizer Italia, Health Economics And Outcomes Research, Rome, Italy, [2]Pfizer Italia, Medical Affairs Vaccines, Rome, Italy, [3]RTI Health Solutions, Health Economics, Research Triangle Park, United States of America, [4]University of Pavia, Department Of Drug Sciences, Pavia, Italy, [5]University of Milan, Department Of Biomedical And Clinical Sciences “l. Sacco”, Unit Of Paediatric Infectious Disease, Milan, Italy, [6]University of Palermo, Promotion Of Health, Maternal-child, Internal Medicine And Specialist Of Excellence “g. D'alessandro", Palermo, Italy, [7]Pfizer Inc, Global Value & Evidence, New York, United States of America

Backgrounds: Pneumococcal disease represents a substantial heath and economic burden in Italy. The 13-valent pneumococcal conjugate vaccine (PCV13) has been part of the pediatric national immunization program (NIP) since 2010. The 15-valent (PCV15) and the 20-valent (PCV20) conjugate vaccines, may become available in Italy in 2023 and 2024, respectively. The objective of this study is to determine the cost-effectiveness of switching from PCV13 to PCV15 compared with switching to PCV20 in Italy’s paediatric NIP.
Methods: A decision-analytic model was developed to estimate the cost-effectiveness of switching from PCV13 to PCV20 in 2024 compared with switching to PCV15 in 2023 over a 5-year time horizon from a payer perspective. Published Italian age and serotype-specific invasive pneumococcal disease (IPD) incidence data for 2008-2019 were used to project future incidence. Projections of non-invasive disease incidence were assumed to vary proportionally with IPD. Vaccine prices were obtained from local sources and direct medical costs were collected from published literature. The model estimated disease cases, direct medical costs, quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratio (ICER) for each vaccination strategy.
Results: Switching from PCV13 to PCV20 in 2024 was estimated to avert an additional 626 IPD cases, 49,375 otitis media (OM) cases, 7,951 inpatient, non-bacteremic (NB) pneumonia cases, and 1,074 deaths over 5 years compared with switching to PCV15 in 2023. PCV20 also gained an additional 1,251 QALYs and saved the health system €1,692,829 in total direct medical costs despite higher vaccine acquisition costs (Table 1). As such, PCV20 was dominant (more effective and cost-saving) compared to PCV15.

Table 1. Cost-effectiveness Results Over 5 Year Time Horizon

Outcomes	PCV15	PCV20	Incremental
Disease cases			
Bacteremia	2,635	2,227	-408
Meningitis	1,409	1,191	-218
Inpatient NB pneumonia	53,298	45,346	-7,952
OM	596,971	547,597	-49,374
Total	654,313	596,361	-57,952
Deaths			
IPD	880	745	-135
Inpatient NB pneumonia	6,410	5,470	-940
Total	7,290	6,215	-1,075
Costs (€)			
Vaccine	€ 279,148,313	€ 321,965,462	€ 42,817,149
IPD	€ 24,339,938	€ 20,629,102	-€ 3,710,835
Inpatient NB Pneumonia	€ 202,145,317	€ 172,530,516	-€ 29,614,801
OM	€ 123,462,219	€ 112,277,878	-€ 11,184,341
Total	€ 629,095,787	€ 627,402,958	-€ 1,692,829
Outcomes			
Life years	159,542,739	159,544,255	1,516
QALYs	118,334,929	118,336,180	1,251
ICER			PCV20 dominant (cost-saving)

Abbreviations: IPD = invasive pneumococcal disease, defined as bacteremia and meningitis; NB = non-bacteremic; OM = otitis media; PCV = pneumococcal conjugate vaccines; QALY = quality-adjusted life year; ICER = incremental cost-effectiveness ratio.

Note: The cost-effectiveness analysis was run for two scenarios over a 5-year time horizon from a payer perspective, (1) switching from PCV13 to PCV15 in 2023 and (2) switching from PCV13 to PCV20 in 2024.

Conclusions/Learning Points: Despite a one-year delay in implementation, switching to PCV20 instead of PCV15 is expected to result in substantially greater public health and economic benefit in Italy.

PD0083 / #1263

A COST-EFFECTIVENESS ANALYSIS COMPARING THE 20-VALENT PNEUMOCOCCAL CONJUGATE VACCINE VERSUS THE 15-VALENT PNEUMOCOCCAL CONJUGATE VACCINE FOR CHILDREN IN GREECE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

Vasiliki Kossyvaki[1], Myrto Barmpouni[2], Michele Wilson[3], Sophie Warren[4], Johnna Perdrizet[4]
[1]Pfizer Hellas, Medical Affairs Vaccines, Athens, Greece, [2]Pfizer Hellas, Health Economics And Outcomes Research, Athens, Greece, [3]RTI Health Solutions, Health Economics, Research Triangle Park, United States of America, [4]Pfizer Inc, Global Value & Evidence, New York, United States of America

Backgrounds: Since June 2010, the 13-valent pneumococcal conjugate vaccine (PCV13) has been included in Greece's pediatric national immunization program (NIP). The 15-valent (PCV15) and the 20-valent (PCV20), may become available in Greece in 2023 and 2024, respectively. The objective of this study is to determine the cost-effectiveness of switching from PCV13 to PCV15 compared with switching to PCV20 in Greece's paediatric NIP.
Methods: A decision-analytic model was used to compare the cost-effectiveness of switching from PCV13 to PCV15 in 2023 or to PCV20 in 2024, over a 10-year time horizon from a payer perspective. The model used recently published age and serotype-specific invasive pneumococcal disease (IPD) epidemiological data from Greece and historical IPD incidence trends from the United States (US) to project future incidence. US data were used for non-invasive disease incidence given similar epidemiology and no local data. Future projections of non-invasive disease incidence were assumed to vary proportionally with IPD. Vaccine costs were obtained from the Greek Drug Positive List in which the published price of PCV20 is lower than that of PCV15. Direct medical costs were compiled from published literature and official sources such as Diagnosis Related Group tariffs. Projected outcomes included disease cases, direct costs, quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratio (ICER) for each vaccination strategy.
Results: Switching from PCV13 to PCV20 in 2024 could avert an additional 175 IPD cases, 46,897 otitis media cases, 8,114 pneumonia cases, and 285 deaths over 10 years across all ages. PCV20 is cost-saving compared to PCV15 and could reduce healthcare spending by over €53 million (Table 1).

Table 1. Results on cost-effectiveness of switching from PCV13 to PCV15 or PCV20 in Greece's paediatric NIP

Outcomes	PCV15	PCV20	Incremental
Disease cases			
Bacteremia	3,050	2,893	-157
Meningitis	346	329	-18
Inpatient pneumonia	97,325	91,969	-5,356
Outpatient pneumonia	246,633	243,875	-2,758
Simple OM	531,839	488,480	-43,359
Complex OM	43,394	39,857	-3,537
Total	922,587	867,403	-55,184
Deaths			
IPD	320	308	-13
Inpatient pneumonia	5,794	5,522	-272
Total	6,114	5,830	-285
Costs (EUR)			
Vaccine	154,517,434	152,383,563	-2,133,871
IPD	10,716,699	10,197,435	-519,264
Pneumonia	637,780,626	605,631,585	-32,149,041
OM	248,230,693	229,363,818	-18,866,875
Total	1,051,245,452	997,576,402	-53,669,050
Outcomes			
Life years	90,773,552	90,774,291	739
QALYs	72,495,355	72,496,112	757
ICER			**PCV20 dominant (cost-saving)**

Abbreviations: IPD = invasive pneumococcal disease; OM = otitis media; NIP = national immunization program; PCV = pneumococcal conjugate vaccines; QALY = quality-adjusted life year.
Note: The cost-effectiveness analysis was run for two scenarios over a 10-year time horizon from a payer perspective, (1) switching from PCV13 to PCV15 in 2023 and (2) switching from PCV13 to PCV20 in 2024.

Conclusions/Learning Points: Even if implemented one year later than PCV15, PCV20 could have greater public health and economic impact compared to PCV15.

PD0084 / #2703

RESULTS FROM THE IMPLEMENTATION OF A NATIONWIDE SURVEILLANCE NETWORK OF RESPIRATORY SYNCYTIAL VIRUS IN CHILDREN < 2 YEARS OLD IN PORTUGAL

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

Aryse Melo[1], Ana Torres[2], Miguel Lança[1], Vânia Gaio[2], Ana Paula Rodrigues[2], Raquel Guiomar[1], Teresa Bandeira[3], Inês Azevedo[4]
[1]National Institute of Health Doutor Ricardo Jorge, Infectious Diseases, Portugal, Portugal, [2]National Institute of Health Doutor Ricardo Jorge, Epidemiology, Portugal, Portugal, [3]Centro Hospitalar Universitário Lisboa Norte, Faculdade de Medicina, Universidade De Lisboa, Caml, Lisbon, Portugal, [4]Centro Hospitalar Universitário São João, Paediatrics, Lisbon, Portugal

Background: Human respiratory syncytial virus (RSV) is associated with substantial morbidity and mortality in infants, young children and the elderly. Monoclonal antibodies (MAb) therapy is available to prevent severe disease in infants, nevertheless, there is a global effort in the development of vaccines and a new generation of MAb. RSV surveillance is essential to estimate the burden of RSV infection, evaluate the impact of preventive measures and support public health decisions. Following European recommendations, a nationwide hospital-based RSV sentinel network denominated VIGIRSV was set up in Portugal. This work aims to describe the implementation of VIGIRSV and report preliminary results.
Methods: VIGIRSV was implemented in 2021 with the initiative of the National Institute of Health Doutor Ricardo Jorge (INSA) and the Portuguese Paediatrics Society (SPP), during 2023, a network of 20 hospitals collaborate in the surveillance. The surveillance is based on the recruitment of children <2 year-old hospitalized ≥24 hours, due to an Acute Respiratory Infection (ARI). At recruitment, the paediatrician fills out a clinical questionnaire, and biological samples are collected for laboratory diagnosis. RSV positive samples are forwarded to INSA for virological analyses such as genetic characterization of the virus.
Results: Preliminary results from the first 2 years of surveillance are presented in table 1 and show an early RSV activity with high intensity in the 2022/23 season. VIGIRSV´s results integrate the weekly "Epidemiological surveillance bulletin of Influenza and other respiratory viruses" available at https://www.insa.min-saude.pt/category/informacao-e-cultura-cientifica/publicacoes/atividade-gripal/, as well as the surveillance at European
level.

Table 1. Results obtained from the first 2 years of the nationwide hospital-based RSV sentinel network (VIGIRSV), in Portugal.

Season	*2021/2022*	*2022/2023**
Number of RSV cases	270	497
Number ARI admissions	733	692
Proportion of admissions of ARI by RSV (%)	36.8	71.8
Maximum Incidence rate (week)	91,7 (W43/21)	136.4 (W45/2022)
*Proportion of RSV positive children with co-morbidities (%)***	7.4	3.2
Proportion of RSV positive children with low weight at birth (%)	14.8	13.8
*Proportion of RSV severe cases (%)****	10.7	10.7
Proportion of RSV positive preterm	15.7	12.7
Number of genetic characterized samples	225	211

* up to week 9/2023; ** children with trisomy 21, cardiac disease, pulmonary disease, neuromuscular disease, immunodeficiency, velocardiofacial syndrome or dermatitis; *** severe cases: children admitted in Intensive Care Units or needing ventilation.

Conclusions/Learning Points: The maintenance of such important surveillance is possible due to the effort of distinct organizations and professionals. Data from the VIGIRSV are being used to implement prevention/therapeutic measures for severe disease risk groups, by health decision makers.

PD0085 / #2467

AN INTERCOUNTRY COMPARISON OF THE IMPACT OF THE PAEDIATRIC LIVE ATTENUATED INFLUENZA VACCINE (LAIV) PROGRAMME ACROSS THE UK AND THE REPUBLIC OF IRELAND (ROI), 2010-2017

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

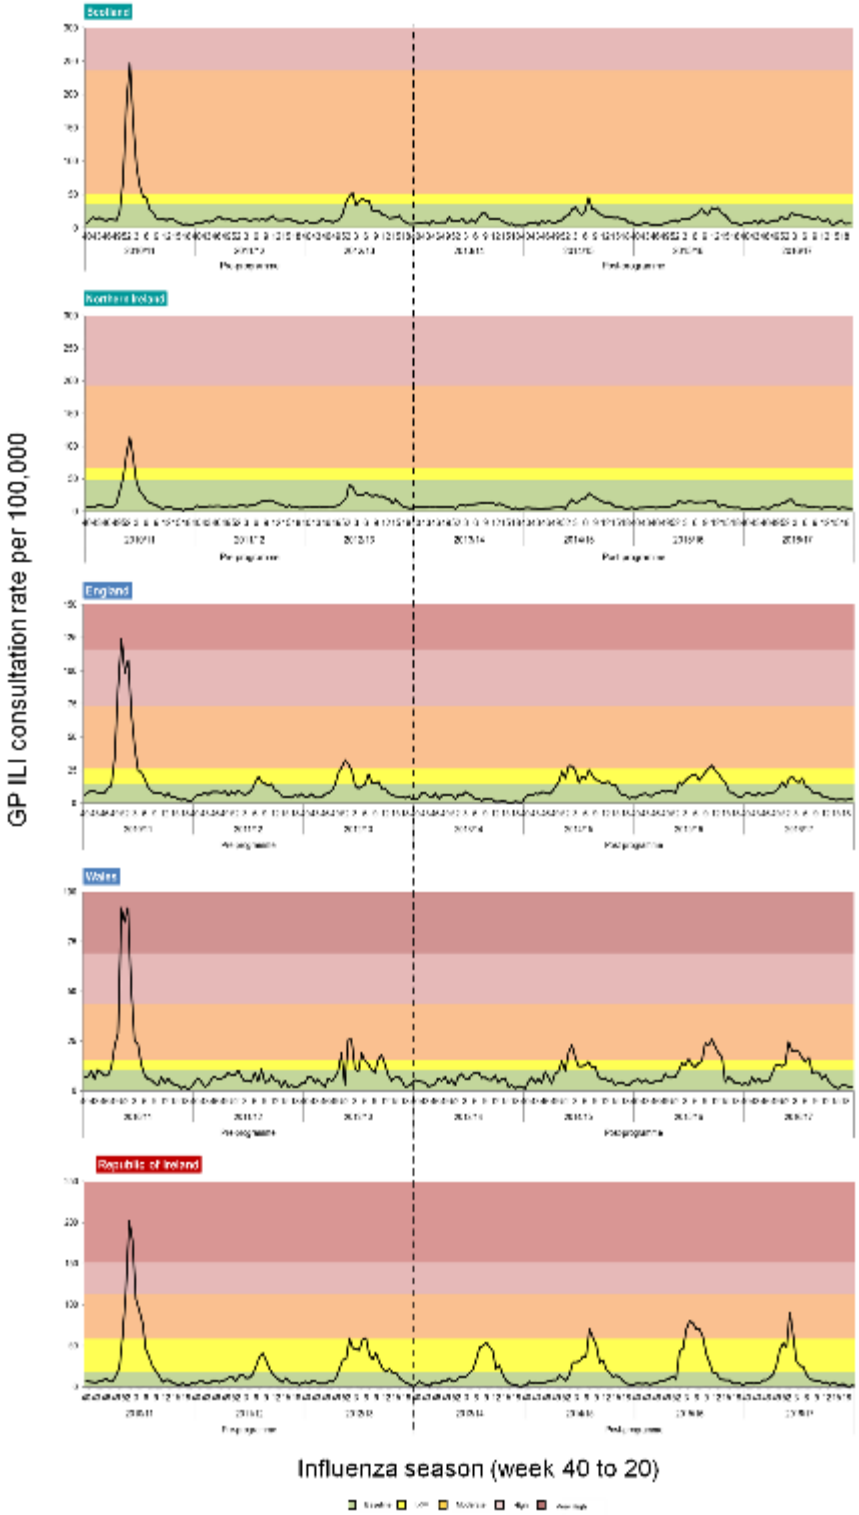
[1]UK Health Security Agency, Uk Health Security Agency, London, United Kingdom, [2]Public Health Scotland, Public Health Scotland, Glasgow, United Kingdom, [3]Public Health Wales, Public Health Wales, Cardiff, United Kingdom, [4]Public Health Agency - Northern Ireland, Public Health Agency - Northern Ireland, Belfast, United Kingdom, [5]Health Service Executive-Health Protection Surveillance Centre, Health Service Executive-health Protection Surveillance Centre, Dublin, Ireland, [6]Royal College of General Practitioners (RCGP) Research and Surveillance Centre (RSC), Royal College Of General Practitioners (rcgp) Research And Surveillance Centre (rsc), London, United Kingdom, [7]University of Surrey, University Of Surrey, London, United Kingdom, [8]University of Oxford, University Of Oxford, Oxford, United Kingdom

Background: The United Kingdom commenced the roll-out of a universal paediatric live attenuated influenza vaccine (LAIV) in 2013/14 programme following evidence of projected population benefits on children themselves and the wider population. In 2013/14, the LAIV vaccine was offered to all 2–3-year-olds in the UK. Since 2014/15, all pre-school and primary school children in Scotland and Northern Ireland have been offered the vaccine. England and Wales incrementally introduced the programme with additional school age cohorts being vaccinated each season. The Republic of Ireland (ROI) had no universal paediatric programme before 2017.
Methods: The potential epidemiological population impact of vaccinating primary school aged children across the five countries up to the 2016/17 influenza season was assessed by comparing rates of primary care influenza-like illness consultations, confirmed influenza intensive care unit (ICU) admissions, and all-cause excess mortality using standardised methods. To further quantify the impact, a scoring system was developed where each weekly rate/z-score was scored and summed across each influenza season according to the weekly respective threshold experienced in each country.
Results: Results highlight ILI consultations rates in the four seasons post-programme breached baseline thresholds once or not at all in Scotland and Northern Ireland; in three out of the four seasons in England and Wales and in all four seasons in ROI. No differences were observed in the seasons post-programme introduction between countries in rates of ICU and excess mortality, although reductions in influenza-related mortality were seen. The scoring system also reflected similar results



overall.

Conclusions/Learning Points: Findings of this study suggest that LAIV vaccination of primary school age children is associated with population-level benefits, particularly in reducing infection incidence in primary care.

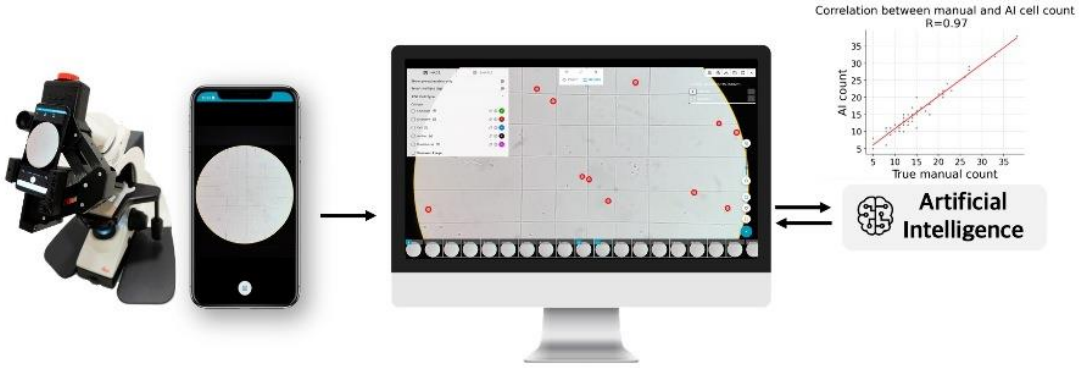
ARTIFICIAL INTELLIGENCE-BASED SYSTEM FOR AUTOMATED CELL COUNTING IN NEONATAL CEREBROSPINAL FLUID ANALYSIS: A REMOTE QUALITY CONTROL AND DIGITAL DIAGNOSTIC TOOL

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

David Bermejo-Peláez[1], Houssain Tligui[2], Sara Arias[3], Lin Lin[1,4], Elena Dacal[1], Ramon Vallés-López[1], Alexander Vladimirov[1], Carla Caballero[1], Daniel Cuadrado[1], Jaime García-Villena[1], Oscar Darias[1], Sobha El Ftouh[2], Rachid Babi[2], Khalid Bounagua[2], Chaymae El Abbass[5], Najat Amalik[5], Imane Zizi[5], Ilham Ouardighi[5], Lamya Elyazigi5[5], Amina Barkat[5], Rosauro Varo[3], Núria Balanza[3], Sara Ajanovic[3], Rita Quesada-Diez[6], Javier Jimenez[6], Quique Bassat[3], Miguel Luengo-Oroz[1]
[1]Spotlab, R&d, Madrid, Spain, [2]Centre Hospitalier Universitaire IBN Sina de Rabat, Laboratoire De Recherche, Rabat, Morocco, [3]ISGlobal, Hospital Clínic - Universitat De Barcelona, Barcelona, Spain, [4]ETSI Telecomunicación, Universidad Politécnica De Madrid & Ciber-bbn, Madrid, Spain, [5]Centre National de Référence en Néonatalogie et en Nutrition, Université Mohammed V De Rabat, Rabat, Morocco, [6]New Born Solutions, R&d, Barcelona, Spain

Background: Meningitis significantly contributes to neonatal morbidity and mortality. Patients with suspected meningitis require lumbar puncture and cell counting in cerebrospinal fluid (CSF). Manual cell counting in hemocytometer chambers is a laborious, time-consuming, error-prone task, which often requires high expertise. We present a pilot study using digital and AI tools to improve reliability and automatize this task.
Methods: We present a simple and accessible digital system to digitize CFS samples using a 3D-printed adapter coupled to a conventional microscope, store and analyze samples remotely in a web telemedicine platform supported by artificial intelligence (AI) algorithms to automatically perform cell counting. The developed AI model uses a convolutional encoder–decoder network to segment cells in images and postprocesses the output for final cell count using computer vision techniques.
Results: 18 CSF samples (neonates <28 days old) were acquired at the Rabat Children's Hospital (Morocco) and digitized resulting in a total of 1,800 microscopy field-of-view images which were made available for remote analysis via the web platform. A preliminary AI model for cell counting was validated based on 54 Malassez chamber field-of-view images from 4 CSF samples that were manually analyzed by experienced technicians. The AI algorithm correlated with manual cell count with a Pearson coefficient of 0.97.
Conclusions/Learning Points: The proposed system allows digitalization and remote CSF analysis and quality control, enabling expert personnel to analyze samples from areas with less expertise. AI algorithms can provide objective, reliable analysis while eliminating potential errors of manual counting. Future work involves multi-centric field validation of the system, the analysis of a higher number of samples, and finer cell type differentiation. The system is versatile, improving diagnostic accuracy for cell count-reliant

diseases.



1. Sample digitization **2.** Expert can analyze the sample remotely **3.** AI automatically detects cells

MYCOPLASMA PNEUMONIAE BEYOND THE COVID-19 PANDEMIC: OUT OF OFFICE!

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

Patrick M. Meyer Sauteur[1], Michael M. Beeton[2], Esgmac Maps Study Group[3]
[1]University Children's Hospital Zurich, Division Of Infectious Diseases And Hospital Epidemiology, Zurich, Switzerland, [2]Cardiff Metropolitan University, Microbiology And Infection Research Group, Department Of Biomedical Sciences, Cardiff, United Kingdom, [3]ESGMAC Mycoplasma pneumoniae Surveillance (MAPS) study group, (www.escmid.org/research_projects/study_groups/study_groups_g_n/mycoplasma_and_chlamydia), Zurich, Switzerland

Background: Mycoplasma pneumoniae (Mp) is a major bacterial cause of respiratory tract infection. We established a collaborative global network on behalf of the ESCMID Study Group for Mycoplasma and Chlamydia Infections (ESGMAC) to assess the effect of nonpharmaceutical interventions (NPIs) against COVID-19 on the transmission of Mp. Data collected through this network showed a significantly reduced incidence of Mp in the first year (1.69%) and second year (0.70%) after the implementation of NPIs in March 2020, compared with previous years (8.61%; 2017–2020). We used this network to prospectively track Mp as of the third year to alert to the resurgence of Mp.
Methods: The ESGMAC Mycoplasma pneumoniae Surveillance (MAPS) study aims to prospectively collect Mp detections on a monthly basis from April 1, 2022. Demographic characteristics and laboratory information of participating sites are detailed in previous publications (Eurosurveillance: PMID 35551702 and Lancet Microbe: PMID 35964636).
Results: Data from 45 sites from 23 countries in Europe, Asia, America, and Oceania were received from April 1, 2022 to February 28, 2023. The mean incidence by PCR during this 11-month-period was 0.83% (SD 2.68). Overall, Mp was detected in 130 (0.09%) of 136,999 tests. The global distribution of Mp detections was as follows: detections were reported from Europe (n=87/130 total detections, 66.92%) and Asia (n=41/130, 31.54%), but not Oceania and America (except for Cuba, n=2/130, 1.54%).
Conclusions/Learning Points: These data show an ongoing absence of Mp globally. We do not know when Mp will reappear; however, when it does, an exceptionally large wave of infections could occur as a result of reduced exposure. Continuous surveillance by the ESGMAC MAPS study will help to alert to the resurgence of Mp.

FACTORS ASSOCIATED WITH DEATH FROM SEVERE ACUTE RESPIRATORY SYNDROME CAUSED BY INFLUENZA IN CHILDREN AND ADOLESCENTS IN BRAZIL: POPULATION STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 08: PUBLIC HEALTH II (STATION 02)

Richarlisson Morais[1,2], Patrícia Shimabukuro[3], Isis Arruda[2], Thayna Gonçalves[4], Rodrigo Zerbinati[5], Simone Giannecchini[6], Kelvin To[7], Paulo Henrique Braz-Silva[5], Monica Taminato[2]
[1]Federal University of Uberlandia, Technical School Of Health, Uberlandia, Brazil, [2]Federal University of Sao Paulo, Paulista Nursing School, Sao Paulo, Brazil, [3]Federal University of Uberlandia, Paulista Nursing School, Sao Paulo, Brazil, [4]Federal University of Uberlandia, Medical School, Uberlandia, Brazil, [5]University of Sao Paulo, Institute Of Tropical Medicine Of Sao Paulo, Sao Paulo, Brazil, [6]University of Florence, Department Of Experimental And Clinical Medicine, Florence, Italy, [7]University of Hong Kong, Faculty Of Medicine, Hong Kong, China

Background: Severe Acute Respiratory Syndrome (SARS) is an infectious respiratory syndrome that can be caused by various etiological agents that infect the respiratory tract, including the influenza virus. SARS can progress to complications, leading to an increased risk of admission to the Intensive Care Unit (ICU) with the use of mechanical ventilation and even death, especially in more vulnerable populations such as the pediatric population.
Methods: A cross-sectional population study using secondary data from the Brazilian Ministry of Health. Children and adolescents under the age of 18 diagnosed with Influenza by RT-PCR and those with case progression (death/discharge) recorded from all regions of Brazil from 02/16/20 to 01/29/22 were included. To identify the factors associated with the death of cases of SARS caused by Influenza in children and adolescents in Brazil.
Results: 1,139 children and adolescents with SARS caused by Influenza were included. Of these, 49 had death as the outcome. There was a predominance of male sex (56.1%) and brown ethnicity (47.2%). Hospitalization was required in 97.2%, with 22.5% in intensive care. There was a significant association between the variable investigating Influenza vaccination and the outcome, as all participants with unfavorable outcomes were not vaccinated (<0.009). According to logistic regression, those of brown ethnicity have a 2.6 (p=0.003) higher risk of death, and for each unit increase in age, there is an 11.5% (p=0.001) increase in the chance of death.
Conclusions/Learning Points: The results evidenced the factors associated with death. All participants who had the outcome of death were not vaccinated, and among those vaccinated, all survived the SARS. This reinforces the need to encourage adherence to vaccination and propose changes in public policies to make Influenza vaccines available to the entire population.

PD0089 / #1011

COMPARISON OF IMMUNE RESPONSES THROUGH MULTIPARAMETRIC T-CELL CYTOKINE EXPRESSION PROFILE BETWEEN CHILDREN WITH CONVALESCENT COVID-19 OR MULTISYSTEM INFLAMMATORY SYNDROME

E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Backgrounds: The activated T-cell-mediated immunological pathways that cause Multisystem Inflammatory Syndrome (MIS-C) after SARS-CoV-2 infection in children remain under investigation. The aim of this study is to prospectively compare T-cell cytokine expression profile between children with convalescent COVID-19 or MIS-C.
Methods: Peripheral blood mononuclear cells (PBMCs) from fresh, non-defrost, whole peripheral blood were isolated from unvaccinated children with acute MIS-C (MIS-C_A) before immunosuppression, unvaccinated convalescent MIS-C (one month after syndrome onset, MIS-C_C), unvaccinated convalescent COVID-19 (one month after hospitalization) and unvaccinated healthy controls. Cells were stimulated using SARS-CoV-2-Spike antigenic peptides mix. Cells were stained with fluorochrome monoclonal antibodies against 8 surface markers (CD3, CD4, CD8, CD14, CD19, CD137, CD197, CD45RA) and 6 intracellular markers (IL-4, IL-2, IL-17, IFN-γ, TNF-α, Granzyme B). Stained cell preparations were analyzed using 13-colour Flow Cytometry (DX Flex, Beckman Coulter). Flow cytometric analysis was performed using Kaluza 2.1 Software and statistical analysis using SAS Software.
Results: Twenty children (4 MIS-C_A, 4 MIS-C_C, 8 post-COVID-19 and 4 controls) with median age (IQR) 11.5 (7.25-14) years were included in the study. From the comparison of the flow cytometry analysis of the 14 markers of MIS-C_A with the other 3 groups (MIS-C_C, post-COVID-19 and controls), statistically significant differences were identified for: 1. $CD4^+$IL-17 [293.0 (256.4-870.9) vs 50.7 (8.4-140.5); P:0.034, vs 96.7 (89.2-135.4); P:0.029 and vs 8.7 (0.0-82.4); P:0.033, respectively], 2. $CD8^+$IL-17 [335.2 (225.8-429.9) vs 78.0 (31.9-128.9 vs 84.1(0.0-204.6) vs 33.2 (0.0-114.6); P:0.05, respectively] 3. $CD8^+$IFN-γ [162.2 (91.6-273.4) vs 30.3 (0.0-92.8); P:0.077, vs 41.5 (0.0-77.4); P:0.028 vs 36.6 (11.2-97.3); P:0.078, respectively].
Conclusions/Learning Points: Children with acute MIS-C were identified to highly activate T-cells for IL-17 and IFN-γ production compared to COVID-19 and controls and could be possible immunological biomarkers for MIS-C_A detection.

PD0090 / #2243

FUNCTIONAL IMMUNE RESPONSES AFTER IMMUNE-MODULATORY THERAPY FOR PIMS-TS.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Helen Payne[1], Sarah Johnson[2], Katherine Longbottom[3], Harsita Patel[1], Arnold Awuah[4], Alison Kent[2], Karlie Grant[2], Kimberly Gilmour[4], Alaisdair Bamford[2], Elizabeth Whittaker[1]
[1]Paediatric Infectious Diseases, Imperial College, London, United Kingdom, [2]Great Ormond Street Hospital, Paediatric Infectious Diseases And Immunology, London, United Kingdom, [3]Imperial College NHS Healthcare Trust, Paediatric Infectious Diseases, London, United Kingdom, [4]Great Ormond Street Hospital, Paediatric Immunology And Lab Sciences, London, United Kingdom

Backgrounds: Although the immunophenotype of children with paediatric inflammatory multisystem syndrome temporally associated with SARS-CoV2 (PIMS-TS) is relatively well-characterised, less is known about the medium-term impact of PIMS-TS, and the immunomodulatory therapy used to manage it, on functional immune responses.
Methods: Blood samples were taken from follow-up visits at 6-12 weeks (V1) and 6 months (V2) in children post-admission with PIMS-TS. Lymphocyte subsets, immunoglobulins G, A and M, vaccine antibody assays and T-cell stimulation with phytohemagglutinin and COVID peptides were performed. These findings were analysed alongside clinical data from admission and follow-up.
Results: 26 children, median age 10.9 (IQR 8.5-11.6) years, were recruited from June 2021 to March 2022 (Table 1). Cardiac recovery was 100%, however 89% of children at V1 and 54% at V2 had at least 1 medical concern. Immunological blood tests done in 100% at V1 and 54% at V2 demonstrated 65% and 40% of results, respectively, were outside the expected range. High levels of gamma-delta T-cells (median 13, range 8-19%, normal <5%) were seen in 30% at V1, persisting at V2. Both T-cell stimulation assays were suppressed or absent in 40% at V1 compared to controls, but resolved at V2. There was no significant difference in presenting features, investigation findings or management in those with or without an immunological abnormality, however 75% of children with infections or rashes during follow-up had raised gamma-delta T-
cells.

Presentation	Med [IQR], n (%)	Investigations	Med [IQR], n (%)	Management	Med [IQR], n (%)
Admission age (yrs)	10.9 [8.5-11.6]	Plts, min	175 [96-335]	Antibiotic	26 (100%)
Fever (days)	6 [5-6]	Lymph, min	1.0 [0.7-1.3]	Total antibiotic days	5 [5-7]
COVID contact	20 (77%)	CRP, max	205 [97-298]	LMWH	23 (88%)
Rash	16 (61.5%)	Fibrinogen, min	3.8 [2.3-5.7]	Aspirin	23 (88%)
Red eyes	14 (54%)	Ferritin, max	.062 [602-1744	PPI	26 (100%)
Mucosal inflammation	3 (11.5%)	ALT, max	52 [37-104]	Fluid.resus	18 (69%)
Gastro symptoms	21 (81%)	Albumin, min	26 [22-29]	Inotropes	16 (62%)
Neurological symptoms	8 (31%)	Troponin, max	147 [54-548]	Inotropes (days)	1 (0.5-7)
Respiratory symptoms	12 (46%)	COVID PCR positive	1 (4.5%)	Ventilation	5 (19%)
Oxygen requirement	8/11 (73%)	COVID serology positive	20/20 (100%)	Ventilation (days)	1 [1-4]
CVS symptoms	17 (65%)	Bacteria co-infection	3 (12%)	IVIG	12 (46%)
No significant PMH	22 (85%)	Viral co-infection	2 (8%)	IVIG dose 2g/kg	11 (92%)
		ECHO LVEF%	49 [44-59]	IV MTP	20 (77%)
		ECHO abnormal	16 (62%)	MTP 10mg/kg	18 (90%)
		CXR abnormal	7 (26%)	MTP (days)	85% (3 days)
		EEG abnormal	3 (11%)	Steroid weaning	18 (90%)
		Abdo scan abnormal	9 (35%)	Both IVIG & MTP	8 (31%)

Conclusions/Learning Points: Immunological abnormalities, such as raised gamma-delta T-cells and suppressed proliferative responses, are common in children recovering from PIMS-TS, and it is important to consider this when advising families regarding infection risk exposure and when to reinitiate vaccinations. The long-term impact of raised gamma-delta T-cells is uncertain and further observation is required.

PD0091 / #1516

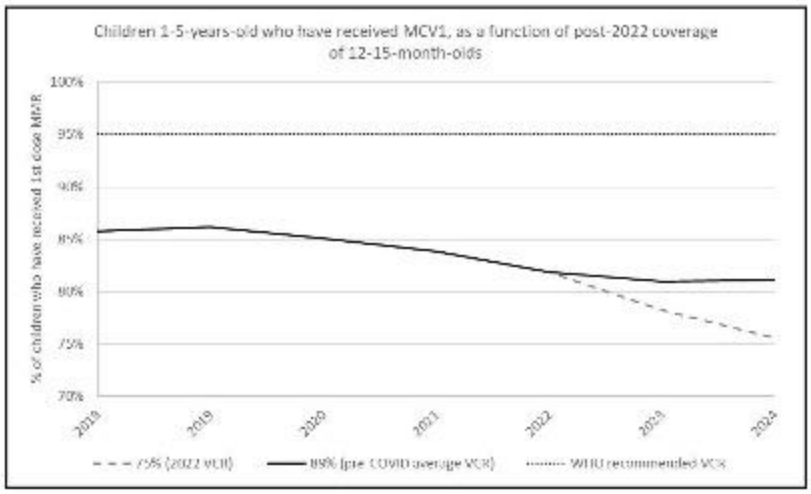
IMPACT OF COVID-19 PANDEMIC ON MEASLES IMMUNIZATION RATES IN SERBIA

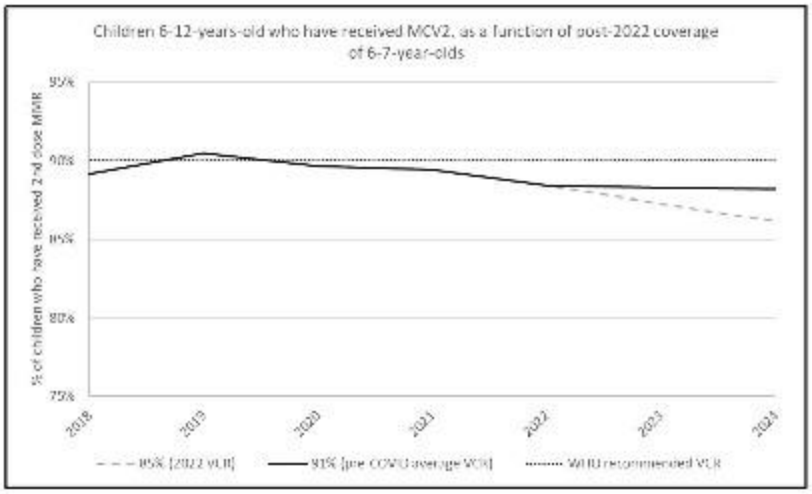
E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Colleen Burgess[1], Bogdan Lisul[2], Manjiri Pawaskar[1], Tanaz Petigara[1], Janice Murtagh[3], Milena Kanazir[4], Goranka Loncarevic[4], Cristina Carias[1]
[1]Merck & Co., Inc., Center For Observational And Real-world Evidence, Rahway, United States of America, [2]MSD d.o.o., Global Medical Affairs See, Belgrade, Serbia, [3]MSD, Global Medical And Scientific Affairs, Dublin, Ireland, [4]Institute of Public Health of Serbia “Dr Milan Jovanovic Batut”, Center For Prevention And Disease Control, Belgrade, Serbia

Backgrounds: Measles vaccination coverage of > 95% is required to ensure herd immunity. The COVID-19 pandemic negatively impacted pediatric immunization programs globally, including in Serbia. We calculated pre- and post-pandemic 1st and 2nd dose measles, mumps and rubella (MMR) vaccine coverage rates (VCRs) and estimated catch-up rates to return to pre-pandemic levels of coverage.
Methods: Annual planned and administered doses among children 12-15 months and 6-7 years old were used to calculate average annual 1st and 2nd dose MMR VCRs for all children aged 1-5 years (12 – 71 months) and 6-12 years (72 – 143 months), respectively, in the pre-pandemic (2011-2019) and pandemic (2020-2022) periods, and to project the VCR for the post-pandemic (2023-2024) period. Doses administered in 2020-2022 were compared to the pre-pandemic average to calculate missed doses during the pandemic. The number of months required to administer missed doses were estimated using monthly catch-up rates of 5-30%.
Results: Annual 1st (2nd) dose VCRs during the pandemic years declined from 88% (92%) to 75% (86%) from 2019 to 2021. If annual 1st (2nd) dose VCR remains at 2022 levels, the percent of all children aged 1-5 (6-12) years having received the 1st (2nd) MMR dose drops from 85% (90%) in 2020 to 76% (86%) in 2024 (figure 1). During pandemic years, ~25,000 1st doses and ~12,000 2nd MMR doses were missed. Catching up missed 1st (2nd) doses is estimated to take 131 (52) months at 75% (85%) VCR with 5% catch-up

Figure 1: (A) Annual 1st dose MMR vaccine coverage rate (VCR) among 1-5-year-olds, and (B) Annual 2nd dose MMR VCR among 6-12-year-olds.





VCR (Vaccine Coverage Rate).
The different lines correspond to VCR per year under two scenarios for the birth cohort's VCR in 2023 and 2024: 2022 VCR and pre-COVID average VCR. The WHO recommended VCR is also presented as a reference. VCR was retrieved from the Institute of Public Health of Serbia and calculated as the ratio between administered and planned vaccines. VCR data for 2023 and 2024 was assumed to be equal to projected 2022 or the pre-COVID average.
The VCR for the second dose is higher since there is a higher number of planned and administered vaccines to include catch-up campaigns.

rates.

Conclusions/Learning Points: Estimated 1st and 2nd dose MMR VCRs for children 1-5 and 6-12 years old respectively will continue to decline without catch-up. Catching up missed doses requires sustained efforts and is important to prevent future outbreaks.

PD0092 / #1494

COVID-19 AND MIS-C TREATMENT IN CHILDREN – RESULTS FROM AN INTERNATIONAL SURVEY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Daniele Donà[1], Chiara Minotti[1], Martina Penazzato[2], Tiziana Masini[2], Marieke Van Der Zalm[3], Ali Judd[4], Carlo Giaquinto[1], Marc Lallemant[5]
[1]University of Padua, Paediatric Infectious Diseases, Padua, Italy, [2]World Health Organization, World Health Organization, Geneva, Switzerland, [3]Stellenbosch University, Desmond Tutu Tb Centre, Paediatrics And Child Health, Cape Town, South Africa, [4]University College of London, Mrc Clinical Trials Unit, London, United Kingdom, [5]Chiang Mai University, Faculty Of Associated Medical Sciences, Chiang Mai, Thailand

Backgrounds: Although COVID-19 infection is generally mild in children, comorbidities can lead to increased disease severity and higher hospitalization rates. Most COVID-19-specific and MIS-C treatment products have no pediatric indication, and children have been mostly excluded from clinical trials. In addition, access to specific drugs is not always universal. Treating physicians' experiences are important to understand which drugs should be promoted for development and availability to children.
Methods: A standardized questionnaire was designed to understand the drugs used to treat COVID-19 and MIS-C in children globally.
Results: Seventy-three physicians from 29 countries participated. Steroids were used by 75.6% of responders; among antivirals, remdesivir was prescribed by 48.6% of responders, nirmatrelvir + ritonavir and molnupinavir by 7.2%, monoclonal antibodies by 27.1%. For MIS-C, steroids were prescribed by 79.1% of responders, intravenous immunoglobulins by 69.6%, acetylsalicylic acid by 50%, and anakinra by 28.2 %. The use of these products depended on their pediatric approval and availability in the country or hospital, notably with limited access to some antivirals and most monoclonal antibodies in Africa, South America, South-East Asia, and eastern Europe. Other aspects guiding drug use were the clinical presentation and age of the child, the product labeling, and perceived benefits or side effects.
Conclusions/Learning Points: This international survey offers insight into the established practice for treating pediatric COVID-19 worldwide. Off-label use is widespread due to the paucity of clinical evaluation under 12 years and 40 kg, though generally determining clinical benefits and being relatively safe, even in young children. However, access to care, including medicine availability, differs widely globally. Antivirals and monoclonal antibodies might benefit from the acceleration of clinical development and informed pediatric indication to increase the worldwide availability of safe and effective pediatric formulations.

PD0093 / #1959

THE SOLUBLE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR (SUPAR) AS A SEVERITY BIOMARKER IN CHILDREN WITH ACUTE COVID-19 OR MULTISYSTEM INFLAMMATORY SYNDROME (MIS-C)

E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Magdalini Louka[1], Elizabeth-Barbara Tatsi[2], Sofia Vassiliu[1], George Theoharis[3], Kalliopi Straka[4], Filippos Filippatos[2], Vasiliki Syriopoulou[2], Athanasios Michos[1]
[1]National and Kapodistrian University of Athens, First Department Of Pediatrics, Infectious Diseases And Chemotherapy Research Laboratory , 'aghia Sophia' Children's Hospital, ATHENS, Greece, [2]National and Kapodistrian University of Athens, First Department Of Pediatrics, Infectious Diseases And Chemotherapy Research Laboratory, Medical School, Athens, Greece, [3]National and Kapodistrian University of Athens, First Department Of Pediatrics,'aghia Sophia' Children's Hospital, ATHENS, Greece, [4]Agia Sophia Children's Hospital, Pediatric Intensive Care Unit, Athens, Greece

Backgrounds: Elevated soluble urokinase plasminogen activator receptor (suPAR) has been associated with a poor prognosis in serious infections. The aim of this study was to evaluate the clinical value of suPAR in children with acute COVID-19 or multisystem inflammatory syndrome (MIS-C).
Methods: Serum suPAR was measured using the suPARnostic® AUTO Flex enzyme-linked immunosorbent assay in hospitalized children with COVID-19, MIS-C in acute and convalescent phase, bacterial or viral pneumonia in acute phase and healthy controls.
Results: Overall, 211 children with mean (±SD) age 6.9±4.96 years were tested; Children with COVID-19 59(28%), MIS-C 36(17%), pneumonia 78(37%) and healthy controls 38(18%). In acute phase levels of suPAR (mean±SD) were; MIS-C: 8.11±2.80 ng/ml, COVID-19: 4.91±1.90ng/ml, pneumonia: 4.25±1.44ng/ml and controls: 2.09±0.47 ng/ml (P<0.001). Children with acute COVID-19 and severe or moderate clinical presentation had higher values than those with mild symptoms: 5.79±1.58 vs 5.40±1.94 vs 3.19±0.73 ng/ml respectively (P< 0.001). In the MIS-C group, children hospitalized in the intensive care unit (ICU) and in need of mechanical ventilation had higher suPAR than those with who were not admitted to an ICU: 9.32±3.06 vs 7.13±2.19 ng/ml respectively (P=0.023). In children with COVID-19 or MIS-C there was correlation between suPAR values and length of hospitalization (r_s=0.418, P<0.001). No difference in suPAR levels was observed between COVID-19 and MIS-C children in convalescent phase.
Conclusions/Learning Points: The findings suggest that suPAR may be a valuable biomarker of disease severity in children with COVID-19 or MIS-C. This could facilitate the identification of children in need of intensive anti-inflammatory treatment as it has been shown in adults. More studies on suPAR levels in pediatric patients and the effect of immunomodulatory therapies may further clarify the clinical significance of this biomarker.

PD0094 / #2164

EXPLORING PARENTAL HESITANCY TO COVID-19 VACCINATION FOR CHILDREN 5-11 YEARS OLD

E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Giovanni Autore[1], Cristiano Rosafio[2], Simonetta Partesotti[3], Michele Fiore[4], Francesco Antodaro[2], Andrea Bergomi[3], Cosimo Neglia[1], Alberto Argentiero[1], Nicola Principi[5], Stefano Zona[6], Susanna Esposito[1]
[1]Pediatric Clinic, Medicine And Surgery, University Of Parma, Parma, Italy, [2]Local Health Agency of Modena, Primary Care Pediatricians, Modena, Italy, [3]Primary Health Care Department, Local Health Agency Of Modena, Modena, Italy, [4]Primary Care Pediatricians, Local Health Agency Of Genoa, Genoa, Italy, [5]University of Milan, Medicine And Surgery, Milan, Italy, [6]Health Direction, Local Health Agency Of Modena, Modena, Italy

Backgrounds: Vaccines are safe and effective measures to prevent pediatric infectious diseases. However, hesitancy still limits vaccination coverage for several diseases including COVID-19. The aim of the study was to investigate the characteristics and reasons for parental hesitancy to COVID-19 vaccination for children 5-11 years old.
Methods: This study analyzed questionnaires compiled anonymously by parents of children aged 5-11 years from 12/15/2021 to 01/15/2022 in Italy. Data collection used the Crowd Signal online platform. The socio-economic and demographic characteristics of responders were investigated. Perceptions of risk associated with COVID-19, degree of pediatric vaccination awareness and vaccine-related fear were assessed as scores based on answers to specific questions. Factors associated with vaccine hesitancy were investigated by univariate and multivariate logistic analysis.
Results: In a total of 3433 questionnaires, a favorable judgment was expressed in 1459 (42.5%) cases, uncertainty in 1223 (35.6%) cases and hesitancy/reluctance in 751 (21.9%) cases. Age < 40 years, female gender, annual income < €28,000 and more than one child aged 5-11 years were associated with doubtful or contrary opinions ($p<0.01$). Higher school education and residence in southern regions were significantly associated with lower hesitancy ($p<0.001$). The multivariate analysis confirmed these findings and added that uncertainty was significantly associated with lower awareness of vaccines and COVID-19 and greater fear of vaccinations. Hesitancy was associated with less knowledge and greater fear about pediatric vaccines ($p<0.05$ for all associations).
Conclusions/Learning Points: COVID-19 vaccination for children is associated with significant parental uncertainty and hesitancy. The perception of the infection and the awareness of vaccination safety seem to be the main factors on which it is possible to intervene to increase vaccination coverage.

Backgrounds: The relationship between COVID-19 and URT microbiota have been investigated mainly in the adult population. We explored the URT microbiota profile of children affected by COVID-19, compared to healthy controls.
Methods: Nasopharyngeal swabs (NPS) of COVID-19 patient between March-September 2020 were collected at the admission (T0), at 72 h to 7 days (T1) and at the discharge (T2). URT microbiota profile was investigated by 16S rRNA targeted-metagenomics. The Kruskal–Wallis test was applied to compare taxonomic differences between ASVs of COVID-19 patients and healthy subjects (CTRLs). Multiple machine learning (ML) models were exploited.
Results: The URT microbiota in COVID-19 patients (N=71) was characterized by reduction of alfa-diversity compared to CTRLs (p-value <0.001). In the URT microbiota of COVID-19 children an increase of Streptococcus, Veillonella, Burkholderia, Gemella, Haemophilus, Enterococcus and a decrease of Faecalibacterium, Akkermansia, Ruminococcaceae, Blautia, Bacteroides were reported compared to CTRLs (FDR < 0.001). Exploiting ML models for URT microbiota biomarker associated to COVID-19 patients identified: Enterococcus, Pseudomonas, Streptococcus, Capnocytopagha, Tepidiphilus, Porphyromonas, Staphylococcus, Veillonella. No significant differences were found comparing the URT microbiota profile of COVID-19 patients at three times point. We compared URT microbiota of COVID-19 children based on SARS-CoV-2 viral load in NPS: we did not observe any significance differences among patients with high (CT < 25), medium (CT 25-30) and low (CT > 30) viral load suggesting an effect of SARS-CoV-2 on the URT microbiota regardless the viral load.
Conclusions/Learning Points: This evidence provide a specific characterization of the URT microbiota of pediatric COVID-19 resulting independent from the SARS-CoV-2 viral load. Our data suggest that the URT microbiota of COVID-19 patients may have a signature since the first days of infection with no changes during the course of the disease.

PD0096 / #2288

DELIVERY OF A COVID-19 VACCINE TO THE SKIN USING A HIGH DENSITY-MICROARRAY PATCH (HD-MAP)

E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Robert Booy[1], Chris Mcmillan[2], David Muller[2]
[1]uni of sydney, Institute Of Id, Sydney, Australia, [2]uni of QLd, Id, brisbane, Australia

Backgrounds: SARS-CoV-2 has infected hundreds of millions globally and resulted in perhaps 20 million deaths to date, with ongoing waves of infection in communities despite relatively high vaccination rates. We still face many challenges in the rollout of vaccines and subsequent boosting of initial protective immune responses. A high-density microarray patch (HD-MAP) has been developed by the University of Queensland and Vaxxas that can deliver vaccines to the skin, with possible dose sparing and high thermostability
Methods: This presentation will cover the background HD-MAP technology and its application to COVID-19 vaccine development. We have used the HD-MAP to deliver a SARS-CoV-2 spike subunit vaccine directly to the skin of mice to examine protective efficacy. Human trials are underway
Results: We have shown that the vaccine, dry-coated on the patch is thermostable, and delivery of spike via HD-MAP induces higher cellular and antibody immune responses than traditional needle delivery, with serum able to potently neutralize clinically relevant isolates including alpha, beta, delta and omicron lineages. Finally, a single dose of HD-MAP-delivered spike provided complete protection from a lethal virus challenge,
Conclusions/Learning Points: ,We have demonstrated that HD-MAP delivery of a SARS-CoV-2 vaccine has the potential to significantly impact the ongoing COVID-19 pandemic.

PD0097 / #1294

PARENT ATTITUDES TOWARDS COVID-19 VACCINATION AND VACCINATION RATE AMONG PRE-SCHOOL CHILDREN BEFORE GENERAL VACCINE RECOMMENDATION FOR CHILDREN 5 YEARS OF AGE OR OLDER

E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Elena Hick[1], Géraldine Engels[1], Katharina Hecker[1], Johannes Forster[2], Christoph Härtel[1], Oliver Kurzai[2], Nicole Töpfner[3], Johannes Liese[1], Andrea Streng[1]
[1]University Hospital Wuerzburg, Department Of Paediatrics, Wuerzburg, Germany, [2]University Hospital of Wuerzburg, Institute Of Hygiene And Microbiology, Wuerzburg, Germany, [3]University Hospital Dresden, Department Of Paediatrics, Dresden, Germany

Backgrounds: On November 26th, 2021, COVID-19 vaccine was EU-licensed for administration in children aged ≥ 5 years. On May 24th, 2022, the German Advisory Board on Vaccinations (STIKO) recommended general vaccination for children aged ≥ 5 years. We evaluated parent attitudes on COVID-19 vaccination and vaccination rate in pre-school children before general recommendation.
Methods: Parent attitudes towards COVID-19 child vaccination, child vaccination status and previous PCR-confirmed SARS-CoV-2 infection were collected questionnaire-based for children aged 2-6 years attending day care centers in Würzburg (Germany) in July 2022.
Results: Of 356 participating children, 53 (14.9%) were vaccinated against COVID-19; 50/53 (94.3%) between Nov 2021 and May 2022. Median age was 6 years (IQR 5-6) in vaccinated and 4 years (IQR 3-5) in unvaccinated children. Vaccination rates were 2.6% (6/223) in 2-4-year-old and 35.9% (47/131) in 5-6-year-old children; 9.4% of vaccinated and 10.0% of unvaccinated children had a chronic disease; 7/53 (13.2%) were vaccinated off-label. Among 299 parents of unvaccinated children, 35.1% were willing to vaccinate their child, 18.4% were unwilling, and 46.5% were undecided. Parents with a migration background were more often unwilling (34.5%) compared to parents without (13.1%; p=0.001). Previous SARS-CoV-2 infection of the unvaccinated child (131/298; 44.0%) had no impact on the parents' willingness for future vaccination (p=0.424). Parents of unvaccinated children declared the availability of an age-adjusted vaccine (51.2%), STIKO recommendation (46.2%) and pediatrician recommendation (42.5%) as the most important factors for COVID-19 child vaccination.
Conclusions/Learning Points: Even before general recommendation, 36% of 5-6-year-old children were vaccinated against COVID-19, indicating high parental acceptance of the age-adjusted vaccine. Additional efforts are necessary to increase vaccination acceptance in parents with a migration background.

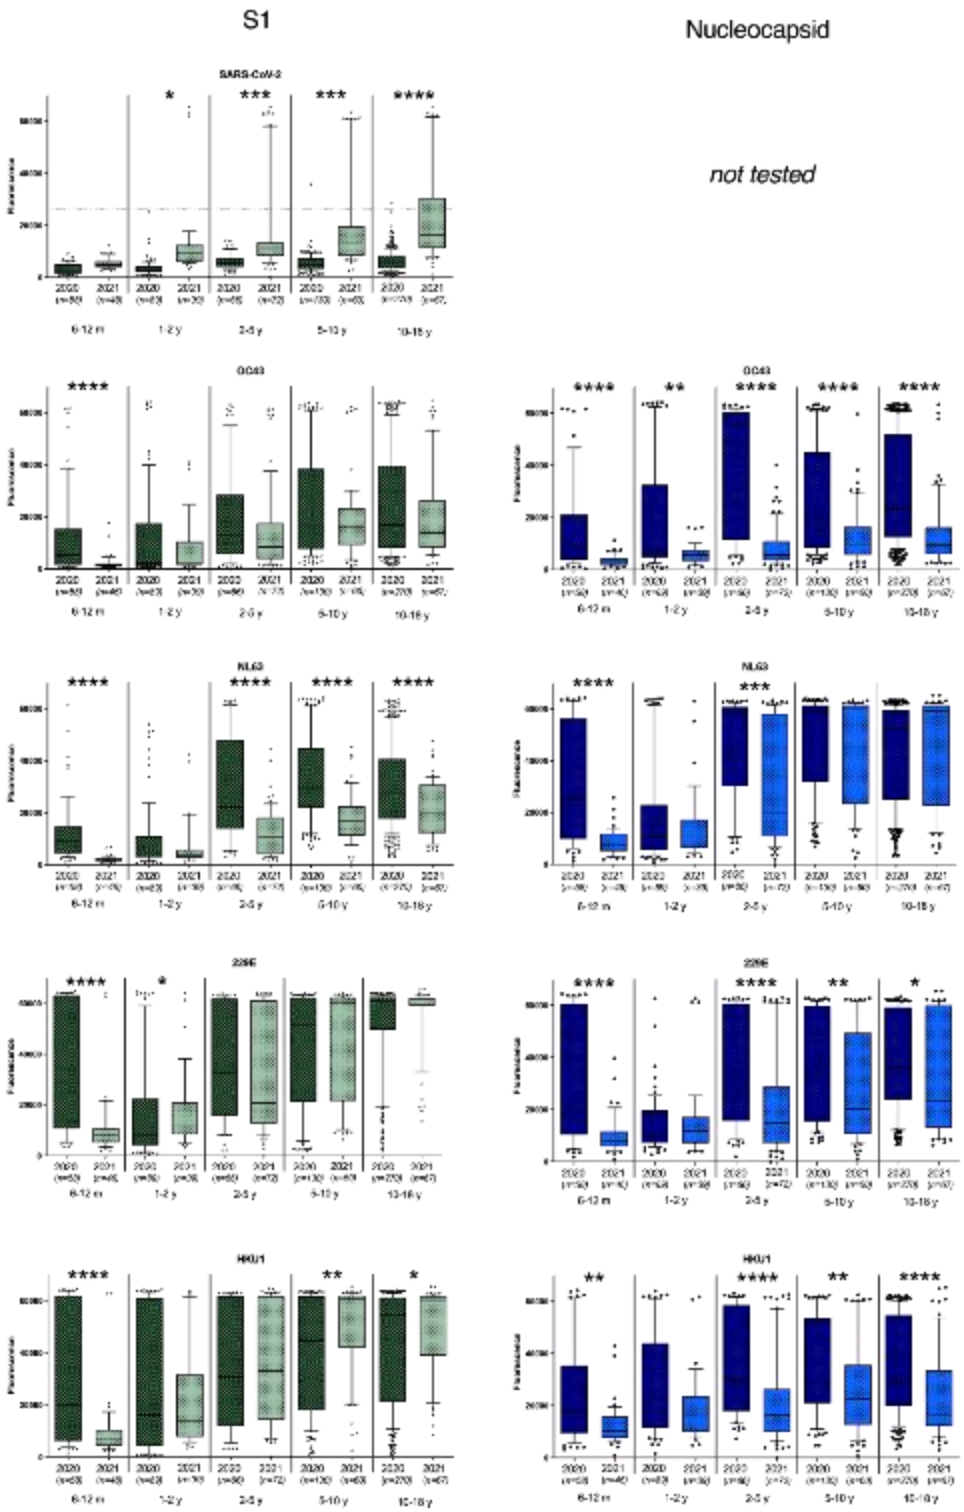
PD0098 / #1208

REDUCED SEASONAL CORONAVIRUS ANTIBODY RESPONSES IN CHILDREN FOLLOWING COVID-19 MITIGATION MEASURES, THE NETHERLANDS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Reina Sikkema[1], Erwin De Bruin[2], Christian Ramakers[3], Robbert Bentvelsen[4], Wentoa Li[5], Berend-Jan Bosch[5], Brenda Westerhuis[6], Bart Haagmans[7], Marion Koopmans[1], Pieter Fraaij[8]
[1]Erasmus MC, Viroscience, Rotterdam, Netherlands, [2]Utrecht University, Department Biomolecular Health Sciences, Utrecht, Netherlands, [3]Erasmus MC, Clinical Chemistry, Rotterdam, Netherlands, [4]Amphia Hospital, Microvida Laboratory For Microbiology, Breda, Netherlands, [5]Utrecht University, Infectious Diseases & Immunology, Faculty Of Veterinary Medicine, Utrecht, Netherlands, [6]GGD Amsterdam, Infectious Diseases, amsterdam, Netherlands, [7]Erasmus MC, Vioscience, Rottrdam, Netherlands, [8]Erasmus MC, Paediatrics/viroscience, Rotterdam, Netherlands

Backgrounds: SARS-CoV-2 prevention and control measures did not only impact SARS-CoV-2 circulation, but also the timing and prevalence of other seasonal respiratory viruses. Especially in children, information on exposure and infections to seasonal coronaviruses as well as SARS-CoV-2 in the first year of the pandemic is largely lacking. Therefore, we set up a one-year serological survey in a large tertiary hospital in the Netherlands.
Methods: Sample Collection: Leftover lithium-heparin plasma samples were collected at the Erasmus medical center. Samples from (suspect) COVID-19 patients were automatically excluded regardless of the result. Only age category information was collected. Protein Microarray: All sera were tested against 13 different antigens from the 4 seasonal coronaviruses and pandemic coronavirus (OC43, 229E, NL63, HKU1, and SARS-CoV-2). Single-spot median fluorescent signals using per-spot background correction were measured using a Powerscanner (Tecan Group Ltd., Mannedorf, Switzerland). Data Analysis: Fluorescence values were determined using Imagene 8.0 software (Biodiscovery, El Segundo (CA), USA). Statistical differences between groups were calculated using the Mann–Whitney test (seasonal coronaviruses-sCoVs) and Fisher's exact test (SARS-CoV-2).
Results: We show that seasonal coronavirus seroprevalence significantly decreased in 2021 in children less than one year, most likely due to COVID-19 control measures (see figure below). The SARS-CoV-2 seroprevalence in children and adolescents increased from 0.4% to 11.3%, the highest in



adolescents. Figure 1. Antibody binding to S1 and nucleocapsid antigens of SARS-CoV-2, OC43, HKU1, 229E, and NL63. For SARS-CoV-2 antigens, the calculated cutoff for positivity is indicated. * represents $p < 0.05$; ** represents $p < 0.01$, *** represents $p < 0.001$, **** represents $p < 0.0001$. .

Conclusions/Learning Points: It is clear that there have been significant changes in the circulation and subsequent immunity against most respiratory pathogens as a result of the mitigation measures.

PD0099 / #2509

CELLULAR AND HUMORAL IMMUNE RESPONSE AFTER VACCINATION AGAINST SARS-COV-2 IN CHILDREN AGED 5 TO 11 YEARS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 09: COVID-19 & MIS-C (STATION 03)

Alfredo Tagarro[1], Angelina Konnova[2], Irati Gastesi[3], Akshita Gupta[2], Santiago Salso[4], Sara Villanueva[3], Raquel Guillén[4], Ángela Manzanares[5], Carlo Giaquinto[6], Sara Domínguez[3], Mª Carmen Plata[4], David Aguilera-Alonso[3], Cinta Moraleda[7], Samir Kumar-Singh[2]
[1]Hospital Universitario 12 de Octubre. Instituto de investigacion imas12. Universidad Complutense de Madrid. RITIP, Paediatric Infectious Diseases, Madrid, Spain, [2]Molecular Pathology Group, Cell Biology And Histology, Faculty Of Medicine And Health Sciences, Antwerp, Belgium, [3]Fundación para la Investigación Hospital 12 de Octubre, Hospital 12 De Octubre, Madrid, Spain, [4]UR Salud, Ur Salud, San Sebastián de los Reyes, Spain, [5]12 de Octubre University Hospital, Pediatric Infectious Diseases, Madrid, Spain, [6]University of Padua, Paediatric Infectious Diseases, Padua, Italy, [7]12 de Octubre University Hospital, Infectious Diseases, Madrid, Spain

Background: We aimed to investigate the relationship between humoral and cellular immunity in healthy children from 5 to 11 years vaccinated with Pfizer/BioNTech BNT162B2.
Methods: Healthy children from 5 to 11 years immunized with 2 doses of Pfizer/BioNTech-BNT162B2 were enrolled in December 2021 and followed up for 1 year. Six months later, we evaluated IFN γ-based Th-cellular immunity (QuantiFERON^{TM}). Humoral immunity was tested at 1 and 6 months after 2nd dose, measuring IgG against nuclecapside (anti-N), spike (anti-S), RBD, and anti-S of B.1.1.7, B.1.351, P.1, B.1.617.2; AY 4Alt Seq 2, BA.2.12.1, BA.2+L452M, BA.2+L452R, BA.3, BA.4, BA.5, % inhibition (neutralization) against all mentioned variants, and neutralizing antibody concentration against all variants except BA.4 and BA.5. We assessed the correlation between CD4 response and antibodies with univariate linear regression.
Results: 18 children were followed for 12 months after vaccination. 5/18 children (27%) had either PCR-confirmed COVID-19 or increased anti-N titers between vaccination and 6-months follow-up. Median IFN-γ after CD4 stimulation was 0.72 (0.24-2.04) IU/mL. CD4 response positively correlated with simultaneous serological IgG responses against various SARS-CoV-2 antigens including anti-RBD (R =0.6, p=0.0071), anti-S (R =0.6, P=0.0059), anti-S D615G (R =0.6, P=0.0064), anti-S B.1.1.7 (R =0.7, P=0.0023), anti-S P.1 (R =0.6, P=0.0047), anti-S BA.3 (R =0.8, P=0.0003), anti-S BA.4 (R =0.6, P=0.0088), as well as % inhibition (neutralization) of BA.4 (R =0.4, P=0.047). 2/12 (16.67%) children reported COVID (PCR+) up to 6 months after testing immunity. In both cases, CD4 response was < 0.2 IU/mL. No children with >0.2 IU/mL reported COVID-19 in the 6 months after testing.
Conclusions/Learning Points: We propose anti-S antibodies as a proxy of cellular immunity. A CD4 response >0.2 IU/mL may confer protection for at least 6 months.

PD0100 / #2611

CMV HYPERIMMUNE GLOBULIN AS SALVAGE THERAPY FOR RECURRENT OR REFRACTORY CMV INFECTION IN CHILDREN UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION.

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Melissa Panesso[1], Luz Uria[1], Berta Renedo Miró[2], Juliana Esperalba[3], Maria Isabel Benitez Carbante[1], Natalia Ana Mendoza-Palomar[4], Laura Alonso[1], Maria Oliveras[2], Cristina Diaz De Heredia[1]
[1]Hospital Universitari Vall d'Hebron, Pediatric Hematology And Oncology Division, Barcelona, Spain, [2]Hospital Universitari Vall d'Hebron, Pharmacy Department, Barcelona, Spain, [3]Hospital Universitari Vall d'Hebron, Microbiology Department, Barcelona, Spain, [4]Hospital Universitari Vall d'Hebron, Pediatric Infectious Diseases And Inmunodeficiencies Unit, Barcelona, Spain

Background: CMV infection remains a major cause of mortality and morbidity in patients undergoing SCT, due to suboptimal prophylaxis strategies and treatment toxicity. Anti-CMV hyperimmune globulins (CMVIG) have high titers of specific antibodies, and have been used as rescue therapy in adults with good efficacy and safety results. We aimed to evaluate the outcome of SCT children suffering from CMV and treated with CMVIG.
Methods: Retrospective description of patients <18 years who received an allo-TPH and CMVIG due to recurrent/refractory CMV infection (2018-2021). All patients received CMVIGs in combination with antiviral drugs. Dosage was 400 U/kg (d1, d4 and d8) and 200 U/kg (d12 and d16). Response was defined as negative CMV DNAemia since the initiation of CMVIG without changing or adding anti-CMV therapy.
Results: Fifteen patients (8 woman, median age 14years [IQR 9-17y]) were included. 10/15 were receiving corticosteroids (≥0.5 mg/kg/day), 8/15 presented moderate-severe acut GVHD, 2 had received a second allo-STC. CMV resistance was negative in 5 tested patients. Indication for CMVIG was recurrent infection (8) and refractory infection (7). 10/15 (66%) patients presented a satisfactory response (mainly in CMV-recurrent patients -7/10-). Median time to response was 27 days (IQR 19-33d). Subsequently, 4 patients reactivated CMV and 3 patients received CMV-specific cytotoxic T lymphocytes. One patient died due to CMV (pneumonitis). Administration of CMVIG was well tolerated, without any adverse events.
Conclusions/Learning Points: In our cohort, CMVIG administration was safe and provide promising efficacy results as an adjuvant treatement, as 10/15 patients achieved CMV clearance after CMVIG infusion. Although CMV recurred in some cases and response was worse in children with refractory viremia, our study provides safety data to encourage larger prospective studies to better characterize the role of CMVIG in those difficult-to-treat patients.

PD0101 / #1890

QUANTIFERON®-CMV ASSAY AS A PROGNOSTIC TOOL IN CHILDREN WITH CONGENITAL CYTOMEGALOVIRUS INFECTION

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Artemis Mavridi[1], Garyfallia Syridou[1], Angeliki Tzaki[1], Sofia Karagiannidou[1], Dimitra Korakaki[2], Fanourios Kontos[2], Nikolaos Siafakas[2], Vassiliki Papaevangelou[1]
[1]National and Kapodistrian University of Athens, Third Department Of Paediatrics, Attikon General Hospital, Athens, Greece, [2]General University Hospital Attikon, Microbiology Department, Athens, Greece

Backgrounds: The assessment of Cytomegalovirus (CMV)-specific T-cell responses has shown great promise in the evaluation of transplant patients at high risk of CMV infection. However, their value as a potential predictive factor in children with congenital CMV (cCMV) infection is yet to be determined.
Methods: In this prospective ongoing study, we used the QuantiFERON®-CMV assay (Qiagen, Hilden, Germany) in blood samples drawn within the first month of life and at the age of six months, in order to assess the anti-CMV cell-mediated immunity in children with cCMV infection. The association with symptomatic disease at birth, and trimester of maternal CMV infection (PMI) was examined using chi-square test.
Results: QuantiFERON-CMV® assay (QFT-CMV) was performed in blood samples from 22 neonates and eighteen 6-month-old infants with cCMV infection. Children with symptomatic neonatal cCMV disease were less likely to have a reactive QFT-CMV when compared to asymptomatic newborns both at birth (1/13 versus 7/9) and at the age of 6 months (3/8 versus 9/10) (p=0.00078 and p=0.019 respectively). Timing of maternal CMV infection had no effect on the QFT-CMV reactivity at birth. Infants born post maternal primary CMV infection during the first trimester of pregnancy were less likely to present with a reactive QFT-CMV at the age of 6 months (2/7) when compared to those born post maternal infection later in pregnancy (9/10, p=0.009).
Conclusions/Learning Points: Based on these preliminary results, it appears that children with asymptomatic neonatal disease and infants born post PMI later in pregnancy are more likely to develop anti-CMV specific cell-mediated immunity. However, further research is required to assess whether the QFT-CMV assay could be used as an additional prognostic biomarker in infants with mild cCMV symptomatic disease.

PD0102 / #2006

INFANT BOTULISM IN SOUTHERN SPAIN: EPIDEMIOLOGY AND OUTCOMES, 1997-2022

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Beatriz Ruiz-Saez[1], Alvaro Villarejo Perez[2], Laura Palomino-Fernandez[1], Cecilia Fernandez-Fuentes[2], Noorelain De Leon[3], María Sánchez Codez[4], Silvia Gallego-Gutierrez[5], Estrella Peromingo Matute[6], Begoña Carazo-Gallego[7], Eduardo Lopez-Laso[3], Dolores Falcon[8]
[1]Hospital Reina Sofía, Pediatric Infectious Diseases Unit, CORDOBA, Spain, [2]Hospital Universitario Virgen del Rocío, Servicio De Infectología, Reumatología E Inmunología Pediátrica, Sevilla, Spain, [3]Hospital Universitario Reina Sofia, Paediatrics, CORDOBA, Spain, [4]Puerta del Mar Hospital, Paediatrics, Cádiz, Spain, [5]Hospital Regional Universitario de Málaga, Department Of Paediatrics, CÓRDOBA, Spain, [6]Puerta del Mar Hospital, Division Of Pediatric Infectious Diseases, Puerta Del Mar, Cadiz, Spain, Cádiz, Spain, [7]Hospital Regional Universitario de Málaga, Department Of Paediatrics, Malaga, Spain, [8]Hospital Virgen del Rocío. RITIP., Paediatric Infectious Diseases, Rheumatology And Immunodeficiency, Seville, Spain

Backgrounds: Infant Botulism (IB) is caused by the intestinal colonization by Clostridium botulinum in the first year of life and its production of neurotoxins. In Europe, IB is a rare disorder. The aim of our study was to analyze epidemiology and management of IB.
Methods: Retrospective multicenter study of IB cases detected in Andalusia (Southern Spain) since 1997. Epidemiological, clinical, diagnostic and outcomes variables were analyzed.
Results: Twenty-one confirmed cases of IB from 6 third-level hospitals in Andalusia, were included. Sixty-six percent of cases were presented during the second period of study (2010-2022). Median age 3 months (IQR 1.5-6), 3 cases were exposed to honey. More than 90% presented with hypotonia, weak cry, constipation, and ptosis. Two thirds experienced somnolence, myotactic reflexes were diminished in 71 %, and 33% needed ventilation support. At diagnosis 76 % presented alterations in neurophysiological studies. Diagnosis was confirmed in all cases by the analysis of stool samples with the mouse-neutralization bioassay and in 5 cases toxin B was detected. Only two patients received specific immunoglobulin, and 43% received empirically intravenous immunoglobulin (IVIG). One patient with myopathy died. Median time to improvement in patients who received IVIG was slightly shorter (16 days) than in patients who did not (21 days), but statistical significance was not achieved. In the second period of study antimicrobial therapy and time to hospitalization was analysed: those cases who received empirically antibiotic treatment, required prolonged hospitalizations: 22 days vs 12 days (p 0.02).
Conclusions/Learning Points: An increase of IB has been detected in our region since 2010. Inespecific immunoglobulin could be an effective treatment, but further longer studies are required. Broad spectrum antibiotics, may cause progression of the patients´s paralysis, increasing the amount of neurotoxin available for absorption.

PD0103 / #544

A PARALLEL THREAT OF EXTENSIVELY DRUG-RESISTANT TYPHOID FEVER IN PEDIATRIC COHORT DURING COVID-19 PANDEMIC

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Maria Khan
Rehman Medical Institute, Microbiology/ Pathology, Peshawar, Pakistan

Backgrounds: The extensively drug-resistant (XDR) Salmonella typhi isolates are on the rise in north western part of Pakistan, with fragile health care systems especially during the challenging period of Coronavirus disease (CoVID-19) pandemic when systems are already over strained. At this point, we report the first large-scale emergence of an XDR S. Typhi outbreak in Khyber Pakhtunkhwa, Pakistan during CoVID-19 pandemic. This strain of S. Typhi is resistant to all i.e. first line and second line recommended antibiotics; including the third generation cephalosporin
Methods: From November till December 2020, significant level of resistance was observed to different groups of antibiotics tested in Salmonella species isolated from blood samples of pediatric age group. Demographic data including age, gender, address and clinical manifestations were documented. A total of 562 blood cultures from symptomatic patients were submitted to Pathology Laboratory at a tertiary care hospital of Rehman Medical Institute, Peshawar. All samples were incubated in BacT/ALERT 3D and processed according to standard recommendations.
Results: Salmonella Typhi was isolated among 71 of 562 blood samples, out of which 66 (92.9%) and 5 (7%) were XDR and multidrug resistant (MDR), respectively. All isolates were completely resistant to chloramphenicol (100%), ampicillin (100%), ciprofloxacin (100%), ceftriaxone (100%) and co-trimaxazole (93%). All MDR and XDR Salmonella Typhi isolates were sensitive to carbapenems and azithromycin. The children under 15 years' age (88%) has a significantly high prevalence as compared to adults (p=0.0016) and males (76%) were affected more than females (24%).
Conclusions/Learning Points: The emergence of XDR S. Typhi with high level of resistance is quite alarming. With inadequate treatments options, the present situation calls for immediate effective preventive measures including food and water safety, improved sanitation, public awareness sessions and typhoid vaccination campaigns.

PD0104 / #353

LONG-TERM CARDIOLOGY OUTCOMES IN CHILDREN AFTER EARLY TREATMENT FOR CHAGAS DISEASE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Nicolás González[1], Guillermo Moscatelli[1], Samanta Moroni[1], Griselda Ballering[1], Laura Jurado[1], Nicolás Falk[1], Andres Bochoeyer[2], Alejandro Goldsman[2], Maria Grippo[2], Hector Freilij[1], Facundo Garcia Bournissen[3], Eric Chatelain[4], Jaime Altcheh[1]
[1]Hospital de Niños Ricardo Gutierrez, Servicio De Parasitologia Y Enfermedad De Chagas, Buenos Aires, Argentina, [2]Hospital de Niños Ricardo Gutierrez, Servicio De Cardiologia, Buenos Aires, Argentina, [3]Schulich School of Medicine and Dentistry Western University, Department Of Paediatrics, Ontario, Canada, [4]Drugs for Neglected Diseases initiative, Drug Discovery, Geneva, Switzerland

Backgrounds: Parasite persistence after acute infection with Trypanosoma cruzi is an important factor in the development of Chagas disease (CD) cardiomyopathy. Few studies have investigated the clinical effectiveness of treatment through the evaluation of cardiological events by long-term follow-up of treated children. Features that would be diagnosed as abnormal in an adult's ECG may be normal in a pediatric ECG trace. The objective was to evaluate cardiac involvement in patients with CD with a minimum follow-up of 6 years post-treatment.
Methods: A descriptive study of a cohort of CD's pediatric patients (N=234) treated with benznidazole or nifurtimox with at least 6 years post-treatment follow-up at the Parasitology and Chagas Service, Buenos Aires Children's Hospital (Argentina) were enrolled. By convenience sampling, children who attended a clinical visit between August 2015 and November 2019 were also invited to participate for additional cardiovascular studies (24-hour Holter monitoring and speckle-tracking 2D echocardiogram).
Results: Benznidazole was prescribed in 171 patients and nifurtimox in 63 patients. Baseline parasitemia data was available for 168/234 patients. During the follow-up period, alterations in routine ECG were observed in 11/234 (4.7%, 95% CI [2–7.4%]) patients. In only four patients, with complete right bundle branch block (cRBBB) and left anterior fascicular block (LAFB), ECG alterations were considered probably related to CD. During follow-up, 129/130 (99%) treated patients achieved persistent negative parasitemia by qPCR. Also decrease in T.cruzi antibodies titers was observed in all patients and negative seroconversion occurred in 123/234 (52%) patients.
Conclusions/Learning Points: A low incidence of cardiological lesions related to CD was observed in patients treated early for pediatric CD. This suggests a protective effect of parasiticidal treatment on the development of cardiological lesions and highlights the importance of early treatment of infected children.

PD0105 / #1109

TRANSMISSION OF EXTENDED-SPECTRUM BETA-LACTAMASE-PRODUCING ESCHERICHIA COLI TO NEONATES: A CROSS-SECTIONAL STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Tomohiro Hirade, Daisuke Koike, Yasuhiro Haneda, Sakiko Kawano, Rie Kanai
Shimane Prefectural Central Hospital, Pediatrics, Izumo, Japan

Backgrounds: The increase in extended-spectrum beta-lactamase (ESBL)-producing Escherichia coli (ESBL-E) has become a global issue. The route of transmission of ESBL-E to infants remain unknown. This study aims to identify whether the transmission of ESBL-E can occur from mother to neonate.
Methods: In this cross-sectional prospective study, we collected rectal samples from neonates who were born with normal gestational age in our hospital from September 2019 to December 2020. Two samples were obtained from each neonate, day 5 and one month after the birth. In Japan, vaginal-rectal samples are routinely obtained from pregnant women at around 34 gestational weeks for screening of Group B streptococcus. We compared the results from the neonatal and maternal cultures. Logistic analyses were performed to identify potential risk factors for the transmission of ESBL-E.
Results: The study included 631 neonates and their 629 mothers. ESBL-E was isolated from 31 (4.9%) neonates. The majority (n=21) of ESBL-E-positive neonates were identified at day 5. ESBL-E was isolated from 25 (4.0%) pregnant women. Of the 25 neonates whose mothers had ESBL-E, 10 (40%) neonates had ESBL-E. Among the 21 neonates who had ESBL-E but whose mothers did not, ESBL-E was isolated from 14 on day 5 and 7 at one month. Vaginal delivery [OR 1.96, 95% CI (0.8–5.4)], breast feeding [OR 1.34, 95% CI (0.3–24.6)], siblings [OR 2.19, 95% CI (0.2–85.4)], and grandparents [OR 2.02, 95% CI (1.0–4.6)] were risk factors for the transmission of ESBL-E.
Conclusions/Learning Points: This study suggests that ESBL-E can be transmitted from mother to neonate. Vaginal delivery, breast feeding, siblings, and grandparents were associated with an increased risk of ESBL-E transmission. Nosocomial or domestic transmission is another potential transmission route of ESBL-E among neonates.

PD0106 / #1834

PEDIATRIC HEPATITIS OF UNKNOWN AETIOLOGY: AN INVESTIGATION INTO SEVENTEEN CONSECUTIVE CASES ADMITTED TO THE BAMBINO GESÙ CHILDREN'S HOSPITAL IN ROME BETWEEN APRIL AND NOVEMBER 2022

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Velia Chiara Di Maio[1], Leonarda Gentile[1], Luna Colagrossi[1], Luana Coltella[1], Stefania Ranno[1], Giulia Linardos[1], Maria Sole Basso[2], Daniela Liccardo[2], Simona Landi[1], Marta Luisa Ciofi Degli Atti[3], Giuseppe Maggiore[2], Massimiliano Raponi[4], Cristina Russo[1], Carlo Federico Perno[1]
[1]Bambino Gesù Children's Hospital, Unit Of Diagnostic Microbiology And Immunology, Rome, Italy, [2]Bambino Gesù Children's Hospital, Hepatology, Gastroenterology, Nutrition, Digestive Endoscopy And Liver Transplantation Unit, Rome, Italy, [3]Bambino Gesù Children's Hospital, Clinical Pathways And Epidemiology Unit, Rome, Italy, [4]Bambino Gesù Children's Hospital, Medical Direction, Rome, Italy

Backgrounds: Since April 2022, an increase in pediatric acute hepatitis of unknown aetiology was reported by different countries. We describe seventeen cases of children admitted to the Bambino Gesù Children's Hospital in Rome, for acute hepatitis of unknown cause between mid-April and November 2022.
Methods: According to the World Health Organization working case definition, 17 children (N=10, male; N=7, female) with a median age of 2.1 years (interquartile range:1.0-7.1) presenting with acute hepatitis non-A-E with serum transaminase >500 IU/L, were considered as probable cases. A pre-specified set of microbiological tests was performed for all of them in different specimen types.
Results: All patients were born in Italy. At hospital admission, presenting features were fever (52.9%), vomiting (35.3%) and diarrhoea (29.4%). All 17 patients resulted negative for the common hepatotropic viruses (A/B/C/D/E). By performing molecular tests, HHV-7 was the most common pathogen detected in blood specimens 9/17 (52.9%). Adenovirus was mostly detected in stool specimens (10/16, 62.5%) than in respiratory (3/15, 20.0%) or blood samples (3/17, 17.6%). Rhinovirus was the most frequently detected pathogen in respiratory samples (6/15, 40.0%). Regarding SARS-CoV-2 infection, only one child had a positive test two days upon hospital admission while antibodies against SARS-CoV-2 spike and nucleoprotein were detected in 14/17 (82.3%) patients. Considering adenovirus-positive patients (N=12), all of them showed at least one co-pathogen detection and 9/12 (75.0%) had a prior SARS-CoV-2 exposure. Overall, 16 children have recovered without clinical complications while one patient required liver transplantation.
Conclusions/Learning Points: In these cases of acute hepatitis of unknown origin, adenovirus was detected mainly in stool samples and a co-pathogen detection was also frequently observed, suggesting that the aetiology of this acute hepatitis is most probably multifactorial.

PD0107 / #395

SEXUALLY TRANSMITTED INFECTIONS IN PAEDIATRIC PATIENTS: A RETROSPECTIVE OBSERVATIONAL STUDY OF A REFERENCE OUTPATIENT CLINIC IN BARCELONA CITY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Cristina Ferrer-Mileo, Marc García-Lorenzo, Maria Espiau-Guarner, Antoni Soriano-Arandes, Natalia Mendoza-Palomar, Pere Soler-Palacín, Claudia Broto-Cortés
Hospital Vall Hebrón, Paediatrics, Barcelona, Spain

Backgrounds: The detection of sexually transmitted infections (STIs) in adolescents is increasing, probably due to a change in relationships and behaviours, as well as to an increase in their screening, since they can be asymptomatic.
Methods: Retrospective observational study including patients less than 18 years attended at a reference STIs clinic in Barcelona city between May 2019 and October 2022. Clinical and sociodemographic variables and risk behaviours were collected in the clinical interview and microbiological results were analysed.
Results: A total of 167 first consultations were registered among 143 patients. Seventy-three (51%) were male, with a median age of 16 years (IQR 15-17). The main reasons for consultation were: symptoms (37%), screening (30%), contact tracing study (19%) and study in the context of sexual violence (14%). Nearly a quarter of them (23%) had previous STIs. Nearly a half (45%) tested positive in microbiological exams, presenting co-infections 38% of them. The most frequent isolated pathogens were Neisseria gonorrhoeae and Chlamydia trachomatis (table). The median age at first sexual relation was 14 years (IQR 13,25-15). Three quarters (72%) were drug users (table). Regarding the number of sexual partners, 65% reported less than 5 in the last 12 months but 17% reported having 10 or more. The regular use of barrier methods varied according to the type of sexual practice decreasing from 35% to 20% and 5% in anal, vaginal and oral sex,
respectively.

Microbiological results	**% (N)**
Neisseria gonorrhoea	19.7% (33/167)
Chlamydia trachomatis	16.7% (28/167)
Ureaplasma urealyticum	14.4% (24/167)
Mycoplasma genitalium	4.2% (7/167)
Scabies	3.6% (6/167)
Molluscum contagiosum	2.4% (4/167)
HSV-1	1.8% (3/167)
HSV-2	1.2% (2/167)
HPV	1.2% (2/167)
Treponema pallidum	0.6% (1/167)
HBV	0.6% (1/167)
Trichomonas vaginalis	0.6% (1/167)
HIV	0% (0/167)
HCV	0% (0/167)

Use of drugs	**% (N)**
Alcohol	56.4% (53/94)
Tobacco	50% (47/94)
Cannabis	26.6% (25/94)
Other drugs	8.5% (8/94)

Conclusions/Learning Points: This study focused exclusively on paediatric patients presents similar results to previous studies in adolescents up to 19 years old, which shows that STIs are also a public health problem in minors. In addition to prevention programs, targeted and accessible screening strategies are required to address STIs at an earlier age.

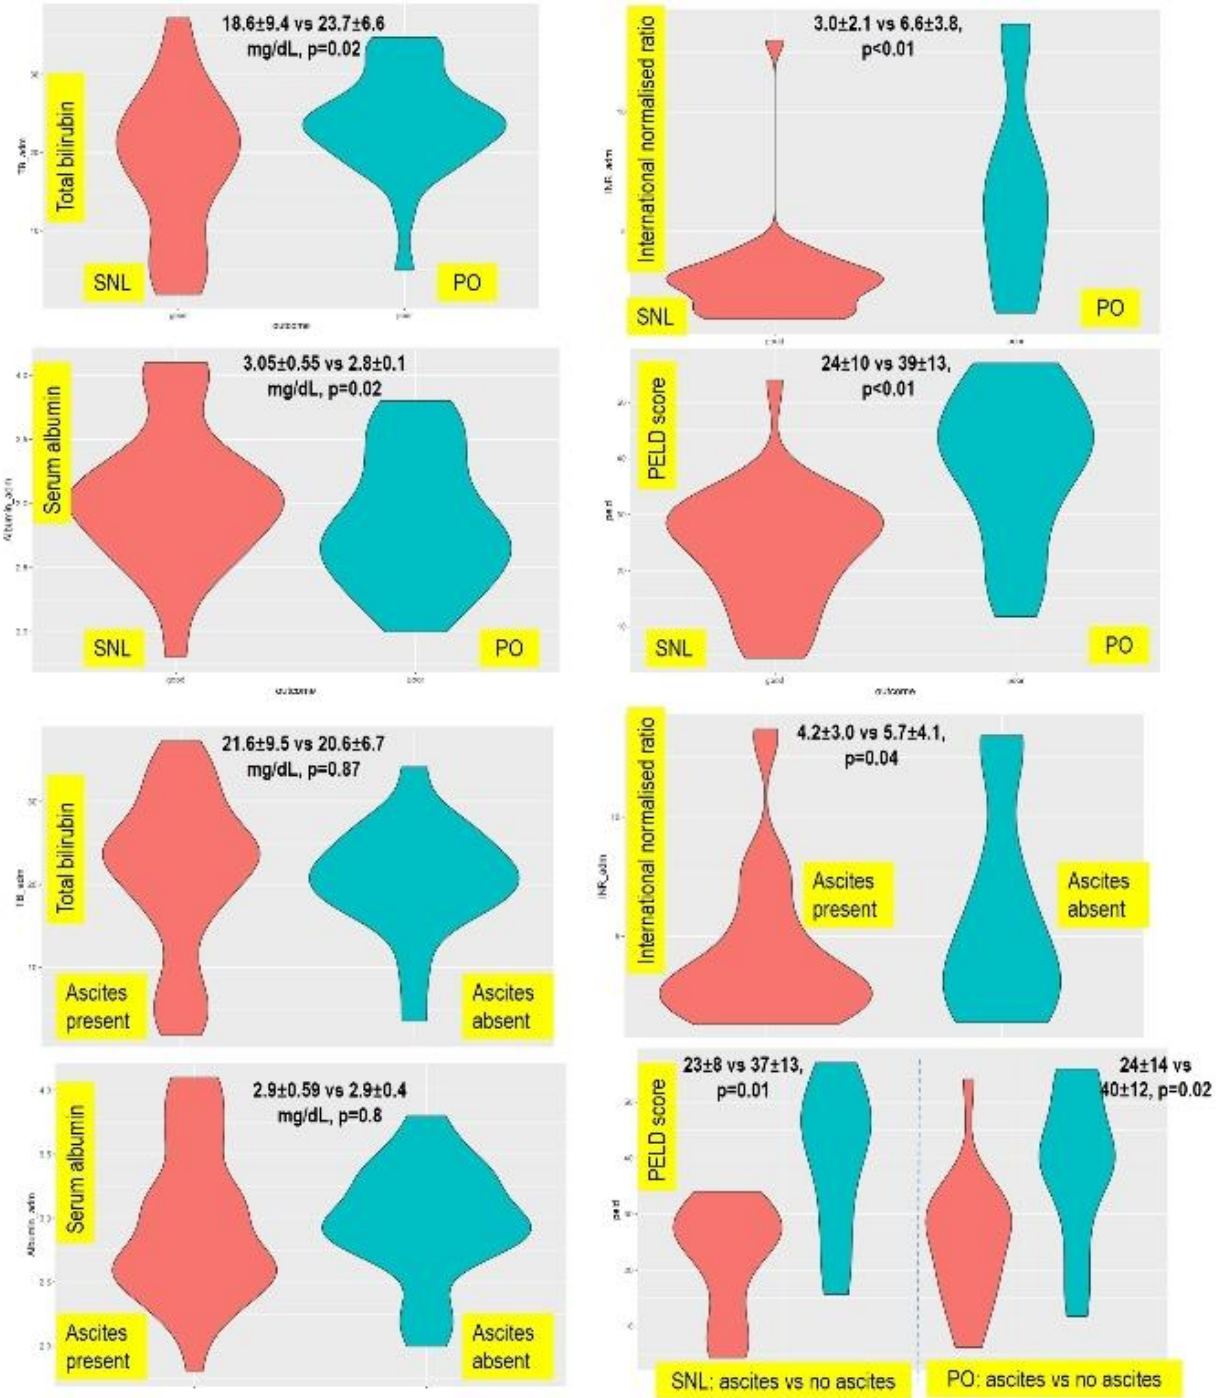
PD0108 / #1569

HEPATITIS A-INDUCED ACUTE LIVER FAILURE: ARE THERE NEW RISK FACTORS OF OUTCOME?

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Moinak Sen Sarma, Ujjal Poddar, Anshu Srivastava, Surender Yachha
Sanjay Gandhi Postgraduate Institute of Medical Sciences, Pediatric Gastroenterology, Lucknow, India

Backgrounds: Hepatitis A virus (HAV) in developing nations is one of the leading causes of acute liver failure (ALF) in children. Survival with native liver (SNL) is guarded. We aimed to study the factors that are associated with outcomes in this condition.
Methods: We analysed the clinical-laboratory data of patients admitted with ALF (IgM-anti-HAV and other causes) between 2017-2022. Poor outcome(PO) was defined as death or requirement of liver transplantation. Underlying chronic liver disease was excluded.
Results: Comparison of HAV-ALF (n=55) vs non-HAV-ALF (n=44) [hepatitis B (n=12), hepatitis E (n=2), Epstein-Barr (n=7), parvovirus (n=6) and indeterminate (n=19)] showed age (7.1±4.0y vs.9.9 ±4.6y, p=0.002), duration of illness (33.9±23.8 vs 21±6.8 days, p=0.04), PELD (pediatric-end-stage-liver-disease) score (31.4±14.1 vs 27.4±20.1, p=0.07) and SNL (51% vs 38%, p=0.1). Among HAV-ALF, 61% had ascites (35% at presentation, 26% during admission; jaundice to ascites duration 17±22 days) and 65% had encephalopathy (55% at presentation, 10% during admission; jaundice to encephalopathy duration 15.5±19 days). PO was seen in 90% of those who developed ascites prior to encephalopathy (41%) and required large-volume paracentesis (33%). Violin plots (Figure 1) show comparison of liver function with final outcome.



Complications of HAV-ALF were infections (66%), cerebral edema (54%), acute kidney injury (34%), bleeding (30%), and hepatic hydrothorax (10%). On multiple step-wise logistic regression, ascites preceding encephalopathy [OR 2.1(1.6-3.3), p=0.002], spontaneous bacterial peritonitis [OR 1.8(1.2-2.3), p=0.02] and PELD score [OR 4.3(2.3-4.8),p=0.001] were independent predictors of PO. At presentation, PELD score cutoff <23.5 (AUROC 0.86, sensitivity:83%, specificity:50%) and serum albumin >3.1 g/dL (AUROC 0.77, sensitivity:85%, specificity:56%) were associated with SNL.

Conclusions/Learning Points: Ascites preceding encephalopathy and spontaneous bacterial peritonitis is associated with poor outcomes in acute liver failure. Universal vaccination policies need to be reinforced in developing nations.

PD0109 / #1603

INTERVERTEBRAL DISCITIS TREATMENT IN CHILDREN - CHANGING PRACTICE

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Doron Mulla[1], Yoel Levinsky[1], Nufar Marcus[1], Shelly Kagan[1], Lotem Goldberg[1], Yoav Vardi[1], Yael Brody[2], Eran Rom[3], Zvi Bar Sever[4], Oded Scheuerman[1]
[1]Schneider's Childrens Hospital, B, Petah Tikva, Israel, [2]Schneider's Childrens Hospital, A, Petah Tikva, Israel, [3]Schneider's Childrens Hospital, C, Petah Tikva, Israel, [4]Schneider's Childrens Hospital, Institute Of Nuclear Medicine, Petah Tikva, Israel

Backgrounds: Discitis is an inflammatory process of the intervertebral disc. To date, no guidelines are available for treatment and there seems to be a practical shift towards shorter intravenous (IV) antibiotic regimen. We aimed to describe the clinical characteristics, treatment approach throughout the years, and the clinical implications of the change in treatment approach.
Methods: The study included all patients diagnosed with imaging confirmed discitis from 2000 - 2022. Data extracted from patient's files included patient demographics, clinical presentation and findings during hospitalization, treatment regimens, and follow-up.
Results: Included were 131 cases. Median patient age was 14.7 months (IQR 6.9). Irritability, refusal to stand / walk, and pain while changing diaper were common symptoms (52.7%, 68.7%, and 48.1%, respectively). Elevated CRP was the most common laboratory finding (76.3%, median value of 1.9 (IQR 2.5) mg/dl). Mean duration of antibiotic treatment was 15.4 (SD±10) days IV and 30 (±9.7) days in total. Over the years there was a trend towards shorter IV treatment; Only 3 cases were treated intravenously for ≤ 7 days before 2010 (5%) compared with 31 (44.3%) from 2010 forward. Only one child in the short duration group needed re-hospitalization due to treatment failure (2.9%) and none suffered long-term complications. On the other hand, nine children suffered from IV treatment related complications, all treated IV for longer than 7 days (9.4%).
Conclusions/Learning Points: Early switching to oral treatment in pediatric discitis patients is clinically appropriate, possibly preventing treatment related complications and saving costs with no major negative clinical impact.

PD0110 / #2666

ANALYSIS OF GENOMIC DIVERSITY, BACTERIAL POPULATION STRUCTURE, VIRULENCE, AND ANTIMICROBIAL RESISTANCE IN ENTEROBACTERALES FROM NEONATES AND INFANTS AGED 0-90 DAYS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Lucia Barcellini[1], Francesco Comandatore[2], Aurora Piazza[3], Francesca Casini[1], Anna Banfi[1], Gian Vincenzo Zuccotti[1], Mike Sharland[4], Laura Folgori[1]
[1]Vittore Buzzi Children's Hospital, Department Of Paediatrics, Milan, Italy, [2]Romeo and Enrica Invernizzi Pediatric Clinical Research Center, University of Milan, Department Of Biomedical And Clinical Sciences, Milan, Italy, [3]University of Pavia, Unit Of Microbiology And Clinical Microbiology, Department Of Clinical-surgical, Diagnostic And Pediatric Sciences, Pavia, Italy, [4]St George's, University of London, Centre For Neonatal And Paediatric Infection, London, United Kingdom

Background: Babies are particularly at risk for invasive infections caused by Enterobacterales with high rate of mortality. Little is known about the population structure of Enterobacterales, so it is difficult to recognise the emergence of clinically important clones within this highly genetically diverse species. We compared the gene profile in terms of virulence (VG) and resistance genes (RG) among invasive and non-invasive isolates.
Methods: Enterobacterales from blood (invasive) and gut (non-invasive) were collected from European infants <90-day and characterised by Whole-Genome-Sequencing (WGS, Illumina MiSeq platform). The Wilcoxon test was used to compare the median number of VG and RG per class. The Spearman's rank correlation was used to evaluate the relationship between the number of RG and VG carried by each isolate.
Results: Overall, 81 invasive and 33 non-invasive isolates were characterised. Invasive isolates harboured a significantly higher median number of VG (p=0.003) and RG (p=0.02) compared to colonizing ones. Genes involved in adherence (p=0.001), bacterial metabolism (p=0.005), cell invasion (p=0.001), iron metabolism (p=0.02), motility/chemotaxis (p=0.04), and toxins (p=0.001) were disproportionately represented among invasive isolates as well as those involved in antibiotic efflux, antibiotic target alteration, and reduction of permeability to antibiotics (p<0.01). Among invasive isolates, there was a strong positive correlation between the number of carried RG and VG (Rho=0.79; p=0.001) whereas this was not significant among non-invasive ones (Rho=0.16; p=0.35).
Conclusions/Learning Points: Invasive pathogens carried significantly more RG and VG than faecal ones. The convergence of virulence and resistance potentially could lead to the emergence of untreatable infections. Our data provide an example of a whole-genome framework against which to track the emergence of such threats. WGS on RG and VG needs to be repeated in global larger prospective cohort studies and trials.

PD0111 / #2473

RISK FACTORS FOR OSTEOARTICULAR INFECTIONS IN CHILDREN IN A EUROPEAN COHORT

E-Poster Discussion
E-POSTER DISCUSSION SESSION 10: NON-RESPIRATORY INFECTIONS (STATION 04)

Catarina Gouveia[1], Ana Subtil[2], Pedro Aguiar[2], Helena Canhão[3], Susana Norte[3], Joana Arcângelo[4], Luís Varandas[5], Delfin Tavares[3]
[1]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatric Infectious Diseases Unit, Lisbon, Portugal, [2]NOVA National School of Public Health, Public Health Research Centre, Comprehensive Health Research Center, Chrc, Nova University Lisbon, Lisbon, Portugal, Lisboa, Portugal, [3]NOVA Medical School, Comprehensive Health Research Center, Chrc, Nova University Lisbon, Lisbon, Portugal, Lisboa, Portugal, [4]Hospital Dona Estefania, Centro Hospitalar Lisboa Central, Pediatric Orthopedic Unit, Lisboa, Portugal, [5]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatrics, Lisboa, Portugal

Background: Osteoarticular infections (OAI) are associated with long term morbidity in children. Timeless diagnosis and prediction of complications and sequelae is of utmost importance to improve outcomes. We aimed to build risk prediction models to early recognize complications and sequelae in OAI in children.
Methods: Longitudinal observational study of children (>3months-17 years-old) with acute OAI admitted to a tertiary care pediatric hospital, from 2008 to 2018. Clinical, treatment, complications and sequelae were obtained. We developed a multivariable logistic predictive model for acute complicated course (ACC) and another for sequelae
Results: A total of 240 children were identified, 17,5% with an ACC, 5.8% and 3,3% with sequelae at 6 and at 12 months follow-up, respectively. In the multivariable logistic predictive model for ACC, fever at admission (adjusted odds ratio [aOR] 2.98; 95% CI 1.10 to 8.12), CRP ≥100mg/L (aOR 2.37; 95% CI 1.05 to 5.35), osteomyelitis (aOR 4.39; 95% CI 2.04 to 9.46) and S. aureus infection (aOR 3.50; 95% CI 1.39 to 8.77) predicted ACC, with an area under the ROC curve (AUC) of 0.831 (95% CI 0.767-0.895). For sequelae at 6 month predictors were age ≥ 4 years (aOR 4.08; 95%CI 1.00 to 16.53), CRP ≥110mg/L (aOR 4.59; 95%CI 1.25 to 16.90), disseminated disease (aOR 9.21; 95% CI 1.82 to 46.73) and bone abscess (OR 5.46; 95% CI 1.23-24.21), with an AUC of 0.887 (95% CI 0.815-0.959)
Conclusions/Learning Points: OAI in younger children with low inflammatory patterns, after exclusion of S. aureus infection, bone involvement or disseminated disease, have a better prognosis and should be treated less aggressively.

PD0112 / #1423

METABOLOMIC STUDY OF THE INTESTINAL MICROBIOTA FOR ALLERGIC INFANTS' DIAGNOSIS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Ricardo Gurgel[1], Katia Suzane Silva[2], Alberto Wisnieswsky_Jr[3], Antonia Gois[3], Wenes Ramos[4], Ricardo Silva[5], Tassia Brena Costa[5], Sarah Cristina Vieira[1], Jackeline Motta-Franco[6]
[1]Federal University of Sergipe, Graduate Program In Health Sciences, Aracaju, Brazil, [2]Federal University of Sergipe, Graduate Program In Parasitic Biology, Aracaju, Brazil, [3]Federal University of Sergipe, Department Of Quimistry, São Cristóvão, Brazil, [4]Federal University of Sergipe, Quiistry, Aracaju, Brazil, [5]Federal University of Pernambuco, Department Of Fundamental Quimistry, Recife, Brazil, [6]Federal Univesity of Sergipe, University Hospital, Aracaju, Brazil

Backgrounds: The intestinal microbiota establishes a relationship of mutual benefit in the human intestine, playing several roles since it's conception, increasing it in its first months of life. The symbiotic bacteria's action, which is responsible for the homeostatic regulation, contributes to the organism's physiological stability, and they also expel metabolites associated with normal processes, and in response to dysfunctions. Food allergy is an important cause of variation in the intestinal microbiota, resulting in difficult diagnoses.
Methods: In this study, the fecal samples' intestinal metabolite profiles from infants symptomatic and suggestive of Cow's Milk Protein Allergy (CMPA), assessed by oral provocation test (OPT), were treated in a metabolomic study approach to propose a diagnostic model in children with cow's milk intolerance with or without CMPA. 24 samples were obtained from the Alimentary Food Allergy of Sergipe (Brazil) were submitted to an extraction protocol, with the extracts being analyzed by ultra-high resolution mass spectrometry (HESI-FT-Orbitrap MS).
Results: The principal component analysis (PCA) was applied separately to both positive and negative mode data and there were no different substances between groups. Spectral data was processed using partial least squares discriminant analysis (PLS-DA) to separate TPO+ and TPO− groups. The values for the assessment of the model obtained from the negative mode data, using three latent variables, could differentiate the two groups, with R^2=0.844 (model fit), 88.3% accuracy and Q^2=0.507 (predictive capacity). The metabolomic profiles obtained in the positive mode of analysis were not statistically significant.
Conclusions/Learning Points: As a preliminary study, the predictive model using the metabolic profile, obtained in the negative mode, showed significant values in the validation, and may become a possible tool for the diagnosis of patients with CMPA.

PD0113 / #1528

GUT, ORAL AND NASOPHARYNGEAL MICROBIOTA TRAJECTORY IN HOSPITALIZED INFANTS WITH RSV-BRONCHIOLITIS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Sara Roggiani[1], Federica D'Amico[1], Daniele Zama[1], Alessandro Rocca[1], Camilla Totaro[1], Silvia Turroni[2], Marcello Lanari[1], Patrizia Brigidi[1]
[1]University of Bologna, Medical And Surgical Sciences, Bologna, Italy, [2]University of Bologna, Pharmacy And Biotechnology, Bologna, Italy

Backgrounds: Respiratory syncytial virus (RSV) is the leading cause of lower respiratory tract infections and hospitalizations in infants worldwide. Some studies have evaluated the gut and respiratory microbiota in these patients, but mainly focusing on a single timepoint. Here, we reconstructed the gut, oral and nasopharyngeal microbiota trajectory in infants with RSV-bronchiolitis in relation to disease severity.
Methods: Twenty infants under one year of age hospitalized in the last epidemic season for RSV-bronchiolitis were enrolled. For all patients, fecal samples, oral swabs and nasopharyngeal aspirates were collected at three timepoints: emergency room admission, discharge and 6-months follow up. The microbiota of the three ecosystems was profiled by 16S rRNA amplicon sequencing. Patients were stratified by length of hospitalization (more or less than 5 days).
Results: A general increase in alpha diversity was observed over time for all ecosystems in less severe patients (i.e., hospitalized less than 5 days). Furthermore, the gut microbiota of less severe patients was enriched over time in typically health-associated taxa (e.g., Blautia, Faecalibacterium), while patients hospitalized for longer were featured by increased proportions of potential pathobionts belonging to Enterobacteriaceae. As for oral microbiota, increasing trends of commensal bacteria (such as Haemophilus and Fusobacterium) characterized the less severe patients. Finally, overabundances of Neisseria and Prevotella (commonly residing in the nasopharynx) characterized the dynamics of the nasopharyngeal microbiota in less severe patients, while Janthinobacterium appeared to be associated with higher disease severity (Figure
1).

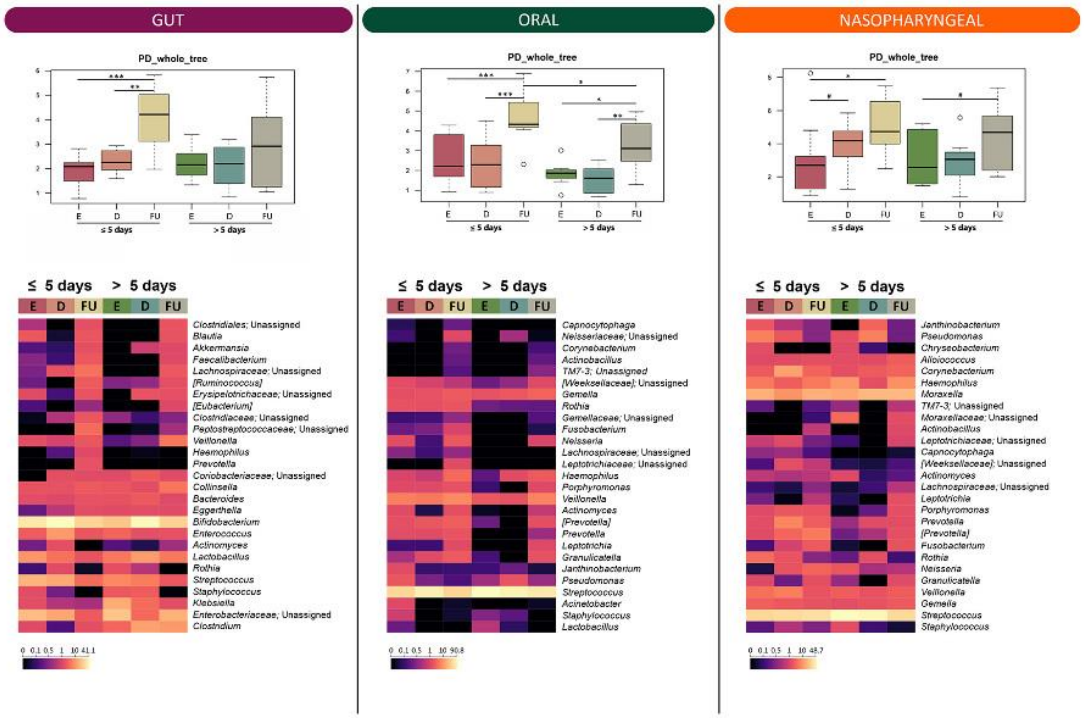


Figure 1: Gut, oral and nasopharyngeal microbiota trajectory in infants under 1 year of age with RSV-bronchiolitis with different length of hospitalization. Top, boxplots showing the distribution of alpha diversity, computed with Faith's Phylogenetic Diversity (PD_whole_tree), for samples collected at emergency room admission (E), discharge (D) and 6-months follow up (FU), in patients hospitalized for more or less than 5 days. Wilcoxon test, * for $p < 0.05$; ** for $p < 0.01$; *** for $p < 0.001$; # for $p > 0.05$. Bottom, heatmaps showing mean relative abundance of the top 27 most abundant genera for each ecosystem in relation to sampling timepoint and length of hospitalization.

Conclusions/Learning Points: Infant microbiomes (fecal, nasopharyngeal and oral) were affected by RSV-bronchiolitis. Notably, the most severe patients exhibited potentially harmful microbial signatures up to 6 months post discharge. Monitoring the microbiome during RSV-bronchiolitis could be important for infants' prognosis and future health.

PD0114 / #2114

STAYING ALIVE: SURVIVAL CHARACTERISTICS OF GROUP A STREPTOCOCCUS IN AEROSOL

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Henry Oswin[1], Evie Blake[2], Allen Haddrell[1], Adam Finn[2,3], Jonathon Reid[1], Alice Halliday[2], Anu Goenka[2,3]
[1]University of Bristol, Bristol Aerosol Research Centre, Bristol, United Kingdom, [2]University of Bristol, Cellular And Molecular Medicine, BS TD, United Kingdom, [3]Bristol Royal Hospital for Children, Department Of Paediatric Immunology & Infectious Diseases, Bristol, United Kingdom

Backgrounds: Future vaccines against Group A Streptococcus (GAS) need to reduce transmission. Although transmission occurs via the respiratory droplet route, there are no published data characterising GAS survival in droplets to inform candidate vaccine antigen selection.
Methods: The airborne survival of GAS serotypes M1 and M89, and Escherichia coli, was compared using an Electrodynamic Trap. This unique methodology allows levitation of droplets and precise control of environmental conditions such as relative humidity (RH) before deposition on agar plates for colony counting.
Results: GAS serotypes M1 and M89 exhibited a similar median survival of 75-80% after 20min levitation in typical indoor conditions (18^{o}C, 50% RH), but significantly higher than 45% survival of E.coli. Although there was no significant difference in survival when GAS was levitated in Todd-Hewitt broth, Luria-Bertani broth or Minimum Essential Media, survival was significantly lower in artificial saliva. Higher RH supported GAS survival, with M1 GAS exhibiting 50% survival at 30% RH and >80% survival at 75% RH. This RH-related difference in GAS survival was further accentuated by the addition of sodium chloride 10g/L, suggesting that airborne loss of GAS is dependent on efflorescence (dried salt crystals). Low RH-driven loss of survival could be reversed by the addition of 2% foetal calf serum, suggesting an ability of the bacteria to survive in the droplet's organic fraction.
Conclusions/Learning Points: GAS is strikingly aerostable compared with E. coli. The organic fraction of the droplet may protect GAS from efflorescence-driven loss. Collectively, our observations suggest that GAS has evolved specific mechanisms to survive in aerosol, and thus future studies of bacterial gene expression in aerosol compared with liquid phase may identify novel and clinically-relevant vaccine antigens.

PD0115 / #1143

CENTRAL-LINE ASSOCIATED BLOODSTREAM INFECTIONS IN PEDIATRIC ONCOLOGY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Diana Gonçalves[1], Beatriz Vala[2,3], Catarina Chaves[4], Sónia Silva[2], Ana Simões[1,2]
[1]Universidade de Coimbra, Faculdade De Medicina, Coimbra, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Serviço De Oncologia Pediátrica, Coimbra, Portugal, [3]Centro Hospitalar de Leiria, Serviço De Pediatria, Leiria, Portugal, [4]Centro Hospitalar e Universitário de Coimbra, Serviço De Patologia Clínica, Coimbra, Portugal

Backgrounds: Central venous lines (CVLs) are the most common vascular access used for children with cancer. Central line-associated bloodstream infections (CLABSIs) are still an important cause of morbimortality in these patients. The aims of this study were to describe the epidemiology, microbiology, and risk factors for CLABSIs and determine the incidence rate of CLABSIs among pediatric oncology patients.
Methods: We conducted a retrospective study of CLABSI in pediatric oncology patients from January 2018 to December 2022. A p value of <0.05 was considered statistically significant.
Results: Over a five-year period, 126 CLABSIs (80 patients: 66% males) were included, with a median age at diagnosis of 3 years. Acute lymphoblastic leukemia was the most common underlying disease (28.7%). Long-term CVLs were the most commonly placed device (64.3%) and jugular internal vein was the most common insertion site (43.7%). Overall CLABSI rate was 2.52 infections per 1000 line-days (126 episodes in 499935 line-days). The median time from insertion to first CLABSI episode was 54 days. S. epidermidis was the most common pathogen (33.8%). The lethality rate was 3.2%. The use of short-term CVL was a significant risk factor for CLABSI (table 1).

	Incidence rate	95% Confidence interval	p value
Age at insertion (years)			
≤2	2.4	1.8-3.1	0.7
>2	2.6	2-3.3	
Diagnosis			
Hematologic malignancy	2.7	2.1-3.4	0.41
Solid tumor	2.3	1.8-3	
Neutropenia at insertion			
ANC ≤0.5 × 10^9/L	3.7	2-6.1	0.135
ANC >0.5 × 10^9/L	2.3	1.9-2.8	
Neutropenia duration			
>7 days	2.6	1.9-3.6	0.13
≤7 days	1.7	0.8-2.8	
Type of CVL			
Short-term	5.2	3.8-6.9	p<0.0001
Mild and long-term	1.9	1.5-2.4	

Conclusions/Learning Points: A low CLABSI rate was reported compared to others publish reports. It is very important to follow CLABSI rates closely and take precautions to prevent infections.

PD0116 / #1636

THE EFFICACY OF ANTIBIOTIC PROPHYLAXIS PRIOR TO VOIDING CYSTOURETHROGRAM IN PREVENTING URINARY TRACT AND BLOOD STREAM INFECTIONS IN CHILDREN

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Ranaa Damouni Shalabi[1], Gharam Salameh[2], Akram Assadi[3], Omri Nativ[3], Ehud Berger[2], Imad Kassis[1], Anat Ilivitzki[4], Haleema Dabaja-Younis[1]
[1]Rambam Health Care Campus, Pediatric Infectious Disease Unit, Haifa, Israel, [2]Technion, Faculty Of Medicine, Haifa, Israel, [3]Rambam Health Care Campus, Urology, Haifa, Israel, [4]Rambam Health Care Campus, Radiology, Haifa, Israel

Backgrounds: Voiding cystourethrogram (VCUG) is an invasive procedure with potential complications such as urinary tract infections (UTI) and subsequent bloodstream infections (BSI). Therefore, physicians tend to administer antibiotic treatment before the procedure, although the efficacy of such treatment has not been proven. Our aim is to evaluate the role of prophylactic antibiotic treatment in preventing such complications and to identify higher-risk patients who might benefit most from antibiotic prophylaxis.
Methods: A retrospective cohort study conducted at a tertiary center in northern Israel. Data were collected from electronic records of children < 18 years of age admitted to VCUG between 2016 and 2020. Rates of UTI or BSI as well as demographic and clinical variables were compared between children with and without antibiotic treatment prior the procedure.
Results: A total of 463 procedures were included in the final analysis, of which 375 (~81%) received antibiotic prophylaxis. Overall, 34/460 (~7%) patients were hospitalized in the first 30 days after the procedure, and 17/460 (3.6%) developed UTI. One patient developed urosepsis. No difference in the incidence of UTI was observed between patients without antibiotic treatment (5.9%), patients treated with prophylactic dosage (5.3%) and patients with therapeutic dosage (3.3%) (p=0.576). However, increased risk of UTI was noted in females (5.3% vs. 1.8%, p=0.022, OR =3.84, 95%CI: 1.21-12.19) and in patients with known urinary tract anomaly at the time of the procedure (6.6% vs. 0.5%, p=0.042, OR =4.77, 95%CI: 1.06-21.51).
Conclusions/Learning Points: Prophylactic antibiotics used in VCUG procedures do not significantly affect the incidence of UTI and BSI, which have a low incidence with or without prior antibiotic administration. Future prospective studies are needed to support the findings of the current study.

PD0117 / #111

EARLY LIFE MICROBIOME OF GHANAIAN INFANTS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Adwoa Asante-Poku[1,2], Taiba Afaa[2], Christain Bonsu[1], Elizaberth Antwi[1], Pierre Schneeberger[3]
[1]University of Ghana, Bacteriology, Accra, Ghana, [2]Korle Bu Teaching Hospital, Child Health, Accra, Ghana, [3]Swiss Tropical and Public Health Institute, Medical Parasitology And Infection Biology, Allschwil, Switzerland

Backgrounds: Early development of the microbiome has long been associated with general health and physical development of the infant. The use of antibiotic for pre-term infants, coupled with their underdeveloped immune systems, promotes intestinal bacterial communities that are less diverse and enriched with potential pathogens
Methods: We examined fecal samples from pre-term infants (cases) and full-term infants (controls) for presence of bacteria. Samples were cultured and isolates confirmed by the matrix- assisted laser desorption ionization–time of flight mass spectrometry (MALDI-TOF MS). Antimicrobial susceptibility testing of isolates was done using disk diffusion and interpreted according to a standard guideline (CLSI or EUCAST)
Results: Six hundred and seventy samples (262 meconium and 414 fecal samples) have been analyzed so far. Findings revealed that the most abundant genera in all the tested samples were Escherichia coli, Staphylococcus and Klebsiella pneumoniae. E coli predominated in meconium and 1st week's fecal samples. Whilst the second week samples were dominated by other Gram-positive (belonging to the genera Corynebacterium and Rothia), and Gram-negative bacteria belonging to the genera Enterobacter, Pseudomonas, as well as some yeasts. Distinct differences were observed among the two groups, whilst preterm babies dominated by Gram positive bacteria , full term babies were dominated with Gram negative bacteria.
Conclusions/Learning Points: Our study revealed diverse bacteria communities with the potential to impact physical and neurocognitive development and life course disease risk. Understanding these influences on life development will inform newborn care and parental education with the aim of identifying microbial intervention strategies to promote the health of infants.

PD0118 / #1512

PERTUSSIS-SPECIFIC IGG SUBCLASS DETECTION AT DELIVERY AFTER TDAP VACCINATION IN SUCCESSIVE PREGNANCIES

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Louise De Weerdt[1], Anaïs Thiriard[2], Elke Leuridan[1], Arnaud Marchant[2], Kirsten Maertens[1]
[1]University of Antwerp, Vaccine & Infectious Disease Institute, Antwerp, Belgium, [2]Université Libre de Bruxelles, Institute Of Medical Immunology, Brussels, Belgium

Backgrounds: Tetanus, diphtheria, acellular pertussis (Tdap) vaccination is recommended during every pregnancy in many countries. Although the safety of this strategy has been confirmed, the immunogenicity of Tdap vaccination in two successive pregnancies has not yet been described. Here we report our IgG subclass analysis at delivery in mothers and newborns.
Methods: Women enrolled in prior studies of Tdap vaccination during pregnancy were invited to participate in a follow-up study if they became pregnant again. Women who received a Tdap vaccine in both pregnancies were considered for analysis. Maternal and cord serum samples were collected at each delivery and the Tdap-specific IgG antibody subclass levels were measured with an in-house bead-based multiplex immunoassay. The mean fluorescence intensity of the first versus second delivery was plotted for all IgG subclasses in maternal and cord blood.
Results: Maternal and cord blood samples from both deliveries were available from 27 participants. For these participants, the mean interval between the deliveries was 2.4 (1.4-3.9) years. In maternal blood, the levels of IgG subclasses against all tested antigens were comparable in the first and second pregnancies, except for anti-PRN IgG1 antibodies that were lower in the second pregnancy. In cord blood, the levels of FHA, DT and TT-specific IgG1 were lower in the second compared to the first pregnancy. In contrast, serum levels of PRN, DT and TT-specific IgG4 were higher in the second pregnancy. The levels of IgG2 and IgG3 against all tested antigens remained stable across pregnancies.
Conclusions/Learning Points: Tdap-specific IgG subclasses appear to remain stable in maternal blood following vaccination in successive pregnancies whereas in cord blood IgG subclass distribution seems to be modified, pointing towards a possible impact on the transplacental transport to the newborn.

PD0119 / #1853

DECIPHERING IMMUNE RESPONSES TO IMMUNIZATION VIA TRANSCRIPTOMIC ANALYSIS: A NARRATIVE REVIEW OF THE CURRENT EVIDENCE TOWARDS PERSONALIZED VACCINATION STRATEGIES

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Maria Geropeppa, Ioanna Papadatou, Vana Spoulou
National and Kapodistrian University of Athens, Immunobiology And Vaccinology Research Laboratory, First Department Of Paediatrics, Athens, Greece

Backgrounds: The immunological mechanisms dictating the development of vaccine-induced protective immunity remain unclear. Conventional immunological methods provide significant, yet limited insights into vaccine-induced immune responses. Integrating multiple layers of information from 'Omics' analyses may facilitate a better understanding of vaccine-induced immunity. We review data on transcriptional profiling of immune responses to vaccination.
Methods: A search via PUBMED using the terms "systems vaccinology","transcriptomics","vaccines","molecular signatures" was conducted.
Results: We identified 47 studies on the transcriptional profiling of the immune response to currently licensed vaccines: 37 studies focused on vaccines against viruses and 10 studies on vaccines against bacterial/parasitic infections; 11 and 13 out of 47 studies involved pediatric and elderly populations,respectively. Vaccines against viral infections,including yellow fever,influenza,hepatitis B,SARS-CoV-2 and Ebola stimulated interferon-,complement pathway- and antiviral-related gene signatures. Polysaccharide pneumococcal and meningococcal immunization induced enrichment of inflammation- and plasmablast-related modules and downregulation of switched memory B cell-associated genes,respectively. In children,innate and plasma cell transcriptional signatures were detected on days 1 and 7 after influenza vaccination,respectively; a gene signature predicting febrile response to infantile meningococcal 4CMenB vaccination was identified,while malaria vaccination induced enrichment of T-cell-related modules and downregulation of B-cell- and monocyte-related modules. Age-related transcriptional analysis of hepatitis B vaccination revealed enriched B-cell and T-cell signalling,antiviral and metabolic pathways expression in younger individuals compared to predominance of pro-inflammatory pathways in elderly individuals,which was also reported for elderly individuals vaccinated against influenza and SARS-CoV-2. Baseline vaccine-specific transcriptional signatures and a time-adjusted,plasma cell-related gene signature predicted subsequent humoral response to several vaccines.
Conclusions/Learning Points: This review provides an evaluation of transcriptional profiling as a tool for the characterization of immune responses to immunization and the identification of predictive biomarkers for the vaccine-induced immunity, thus contributing to the optimization of tailored vaccination schedules.

PD0120 / #2616

INFANTS NOT EXPOSED TO BRONCHIOLITIS DURING THE 2020 LOCKDOWN PRESENT A REDUCTION OF SUBSEQUENT WHEEZING ILLNESSES: A POPULATION DATABASE ANALYSIS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Elisa Barbieri[1], Anna Cantarutti[2], Riccardo Boracchini[3], Luca Bonadies[4], Daniele Donà[5], Antonio Scamarcia[6], Luigi Cantarutti[6], Carlo Giaquinto[7], Eugenio Baraldi[4]
[1]University of Padova, Division Of Paediatric Infectious Diseases, Department For Women And Children's Health, Padova, Italy, [2]University of Milano Bicocca, Department Of Statistics And Quantitative Methods, Division Of Biostatistics, Epidemiology And Public Health, Laboratory Of Healthcare Research And Pharmacoepidemiology, Milano, Italy, [3]University of Milano Bicocca, Laboratory Of Healthcare Research & Pharmacoepidemiology, Unit Of Biostatistics, Epidemiology And Public Health, Department Of Statistics And Quantitative Methods, Milan, Italy, [4]University of Padua, Neonatal Intensive Care Unit, Department Of Women's And Children's Health, Padova, Italy, [5]University of Padova, Division Of Pediatric Infectious Diseases, Department For Women's And Children's Health, Padova, Italy, [6]Societa' Servizi Telematici, Pedianet, Padova, Italy, [7]Division of Pediatric Infectious Diseases, Department For Women's And Children's Health,, Padova, Italy

Background: Up to 40% of children experiencing bronchiolitis subsequently develop wheezing illnesses, but the causality is yet to be determined. We aimed to assess if there was a change in the rate of wheezing episodes in children born during the 2020 lockdown, a period in which bronchiolitis almost disappeared, compared to a historical cohort born in a previous typical winter season.
Methods: This retrospective analysis uses data from Pedianet, a comprehensive paediatric primary-care database of 154 family paediatricians in Italy caring for around 1400 children <15 years of age each from birth. We retrieved all bronchiolitis episodes during the first year of life, the exposure of interest, and all wheezing episodes, the outcome of interest, in children born between February and April 2020 (lockdown cohort) and in children born between November 2016 and January 2017 (historical cohort). Children were followed up until 30 months of age, or lost to follow-up, or the first visit for wheezing, whichever came first. Characteristics were described and compared using $\chi 2$ and the Wilcoxon rank-sum test, and a Cox regression model was applied.
Results: During the 30 months of follow-up 210 of the 2225 children of the lockdown cohort experienced wheezing (9.4%), compared to 414 (16.9%) of the 2446 children of the historical cohort (p-value<0.0001) (Table 1); the risk of experiencing wheezing was reduced by 42% (HR 0.58[95%CI:0.49-0.69]). Still, children with bronchiolitis had a three times higher risk of experiencing wheezing compared to children without bronchiolitis (HR 3.24[95%CI: 2.54-
4.15]).

		Lockdown cohort N = 2225	Historical cohort N = 2446	P - value
Sex				0.5685
	Male	1162 (52.2)	1257 (51.4)	
	Female	1063 (47.8)	1189 (48.6)	
Bronchiolitis in the first year of life		18 (0.8)	189 (7.7)	**< 0.0001**
Wheezing*		210 (9.4)	414 (16.9)	**< 0.0001**
	Age in months at first episode - median (IQR)	19 (14.7-21.0)	12.4 (5.3-19.6)	**<0.0001**
At least one parent with atopic disease				**0.0053**
	None	2122 (95.4)	2371 (96.9)	
	Yes	103 (4.6)	75 (3.1)	

*Children with at least one episode of wheezing from one month to 30 months of life

Conclusions/Learning Points: Our results demonstrate that children born during 2020 lockdown present a significant reduction in subsequent wheezing episodes supporting the role of RSV in wheezing illnesses inception and laying the rationale for RSV prophylaxis extended to the whole paediatric population.

PD0121 / #2597

NATURAL SUBSTRATES OF MULTIDRUG EFFLUX PUMPS IN PSEUDOMONAS AERUGINOSA AS A POSSIBLE SOURCE FOR EFFLUX PUMP INHIBITORS : THE EXEMPLE OF ALKYL-QUINOLINES

E-Poster Discussion
E-POSTER DISCUSSION SESSION 11: MISCELLANEOUS (STATION 05)

Léna Mazza
University of Geneva, Microbiology And Molecular Biology, Geneva, Switzerland

Background: Multidrug resistant (MDR) bacteria are a major threat to human health. Amongst the proposed new strategies to tackle this problem is drug potentiation such as efflux pump inhibition. Efflux pumps (EPs) are major determinants of the multidrug resistance phenotype of clinically relevant gram-negative bacteria such as Resistance Nodulation-Division (RND) pumps. These form a tripartite transmembrane spanning complex composed of three proteins. Besides defence against antimicrobials, we hypothesize that these pumps have several functions, namely secretion of signalling molecules, disposal of self-produced toxic waste and secretion of secondary metabolites. My project focuses on P. aeruginosa, an opportunistic Gram-negative pathogen responsible for acute nosocomial infections, as well as chronic infections in cystic fibrosis patients. P. aeruginosa encodes up to 12 different RND efflux systems on its chromosome. Four of these have been shown to confer multidrug resistance to clinical isolates. EP inhibition is a promising strategy to increase the efficacy of classical antibiotics.
Methods: My project aims at identifying natural substrates of these efflux pumps in P. aeruginosa through genetic screening as well as metabolomics and evaluate their potential use as efflux pump inhibitors via competitive inhibition.
Results: Using both strategies we were able to identify a wide range of metabolites as potential specific efflux pumps substrates that could be used as antibiotic potentiator. Amongst these metabolites were numerous signalling molecules such as Pseudomonas Quinolone Signal (PQS), pyocyanin, and many fatty acid signal molecules. The metabolites of the quinolins family, to which PQS belongs, showed a promising efficacy increase of several antibiotics, as the indeed increased the minimal inhibitory concentration (MIC) of sulfamthexazole on P. aeruginosa by four folds.
Conclusions/Learning Points: Efflux pumps natural substrates use as competitive inhibitors is promising for antimicrobial development against multidrug resistant bacteria.

PD0122 / #2651

COMPREHENSIVE SUMMARY OF ALL SAFETY DATA OF NIRSEVIMAB IN HEALTHY INFANTS: EXPERIENCE TO DATE FROM PIVOTAL TRIALS

E-Poster Discussion
E-POSTER DISCUSSION SESSION 12: LATE BREAKING (STATION 06)

Vaishali Mankad[1], Amanda Leach[2], Yue Chang[2], Alexandre Kiazand[2], Therese Takas[2], Tonya Villafana[2], Manish Shroff[3]
[1]AstraZeneca, Vaccines & Immune Therapies, Biopharmaceuticals R&d, Durham, United States of America, [2]Astrazeneca, Vaccines & Immune Therapies, Biopharmaceuticals R&d, Gaithersburg, United States of America, [3]AstraZeneca, Patient Safety, Chief Medical Office, R&d, Waltham, United States of America

Background: Nirsevimab, a monoclonal antibody with extended half-life, is authorised in the European Union and Great Britain for the prevention of respiratory syncytial virus (RSV) lower respiratory tract disease in neonates and infants during their first RSV season, with intent for broad implementation. We present a pooled analysis of safety in healthy term and preterm infants ≥29 weeks gestational age (wGA) who received the authorised dose of nirsevimab.
Methods: Data were pooled from two double-blind, randomised trials: Phase 2b (infants ≥29 to <35 wGA; NCT02878330) and Phase 3 MELODY (infants ≥35 wGA; NCT03979313) and analysed for all participants who received the authorised dose of nirsevimab (infants <5 kg, 50 mg; ≥5 kg, 100 mg) or placebo before their first RSV season. All treatment-emergent adverse events (AEs) were captured through 360 days post-dose (5 nirsevimab half-lives). Specific theoretical risks of monoclonal antibody treatment, (immediate hypersensitivity, immune complex disease, and thrombocytopenia [previously associated with palivizumab]) were defined as AEs of special interest.
Results: Overall, 3854 participants received the authorised dose of nirsevimab (n=2570) or placebo (n=1284). Incidence of AEs was similar between treatments (Table); most were mild or moderate in severity, with few considered to be treatment related. There was a low incidence of AEs of special interest, reported in 6 nirsevimab recipients (0.2%); all were characterised as hypersensitivity events limited to cutaneous findings. Incidence of AEs with outcome death was the same for each treatment (0.2%; 3 placebo, 6 nirsevimab recipients); none were considered treatment related.
Conclusions/Learning Points: In a large, pooled analysis of healthy infants ≥29 wGA who received the authorised dose of nirsevimab prior to their first RSV season, the safety profile of nirsevimab was acceptable through 360 days post-

dose.

Table 1. Summary of treatment-emergent adverse events through 360 days post- dose from two pivotal clinical trials

	Placebo (N=1284)	Nirsevimab[a] (N=2570)	Total (N=3854)
Any adverse event	1088 (84.7)	2207 (85.9)	3295 (85.5)
Treatment-related adverse event	18 (1.4)	33 (1.3)	51 (1.3)
Adverse event ≥Grade 3 severity[b]	84 (6.5)	120 (4.7)	204 (5.3)
Treatment-related ≥Grade 3 severity[b]	1 (<0.1)	1 (<0.1)	2 (<0.1)
Serious adverse event[c]	144 (11.2)	219 (8.5)	363 (9.4)
Treatment-related serious adverse event[c]	1 (<0.1)	0	1 (<0.1)
Serious adverse event[d] and/or ≥Grade 3 severity[b]	152 (11.8)	237 (9.2)	389 (10.1)
Adverse event of special interest[d]	0	6 (0.2)[e]	6 (0.2)
Any adverse event with outcome death[f]	3 (0.2)[g]	6 (0.2)[h]	9 (0.2)

All data reported as n (%). Participants with multiple events in the same category were counted once in that category; participants with events in >1 category were counted once in each category.

[a]Authorised dose: infants <5 kg received 50 mg (n=1377, 53.6%); infants ≥5 kg received 100 mg (n=1193 (46.4%) received 100 mg.

[b]Grade 1: mild, Grade 2: moderate, Grade 3: severe, Grade 4: life-threatening, Grade 5: fatal

[c]Death, life-threatening, required inpatient hospitalisation, prolongation of existing hospitalisation, persistent or significant disability/incapacity, important medical event, congenital anomaly/birth defect.

[d]Comprised immediate hypersensitivity (including anaphylaxis), immune complex disease, or thrombocytopenia.

[e]Observed events were reported as hypersensitivity: rash (2 participants), maculo-papular rash (2 participants), petechiac (1 participant), and papular rash (1 participant); post-baseline anti-drug antibody levels to nirsevimab were undetectable through 360 days post-dose in these participants. No anaphylaxis or serious thrombocytopenia was attributed to study drug and no immune complex disease was reported in any participant.

[f]None of the deaths in either treatment group were considered treatment related by the investigator.

[g]One death (342 days post-dose) was caused by pericardial effusion, and two deaths (25 and 108 days post-dose) were caused by pneumonia.

[h]One death (96 days post-dose) was caused by previously undiagnosed pulmonary vein stenosis; two deaths of unknown cause occurred 122 days post-dose (infant was well when put to bed) and 139 days post-dose (based on reported adverse events of failure to thrive, recurrent vomiting, hypoglycaemia, and anaemia, investigator suspected an underlying chronic illness that was undiagnosed before death); two deaths (142 and 337 days post-dose) were caused by gastroenteritis; and one death (285 days post-dose) was caused by a skull base fracture resulting from an automobile accident.

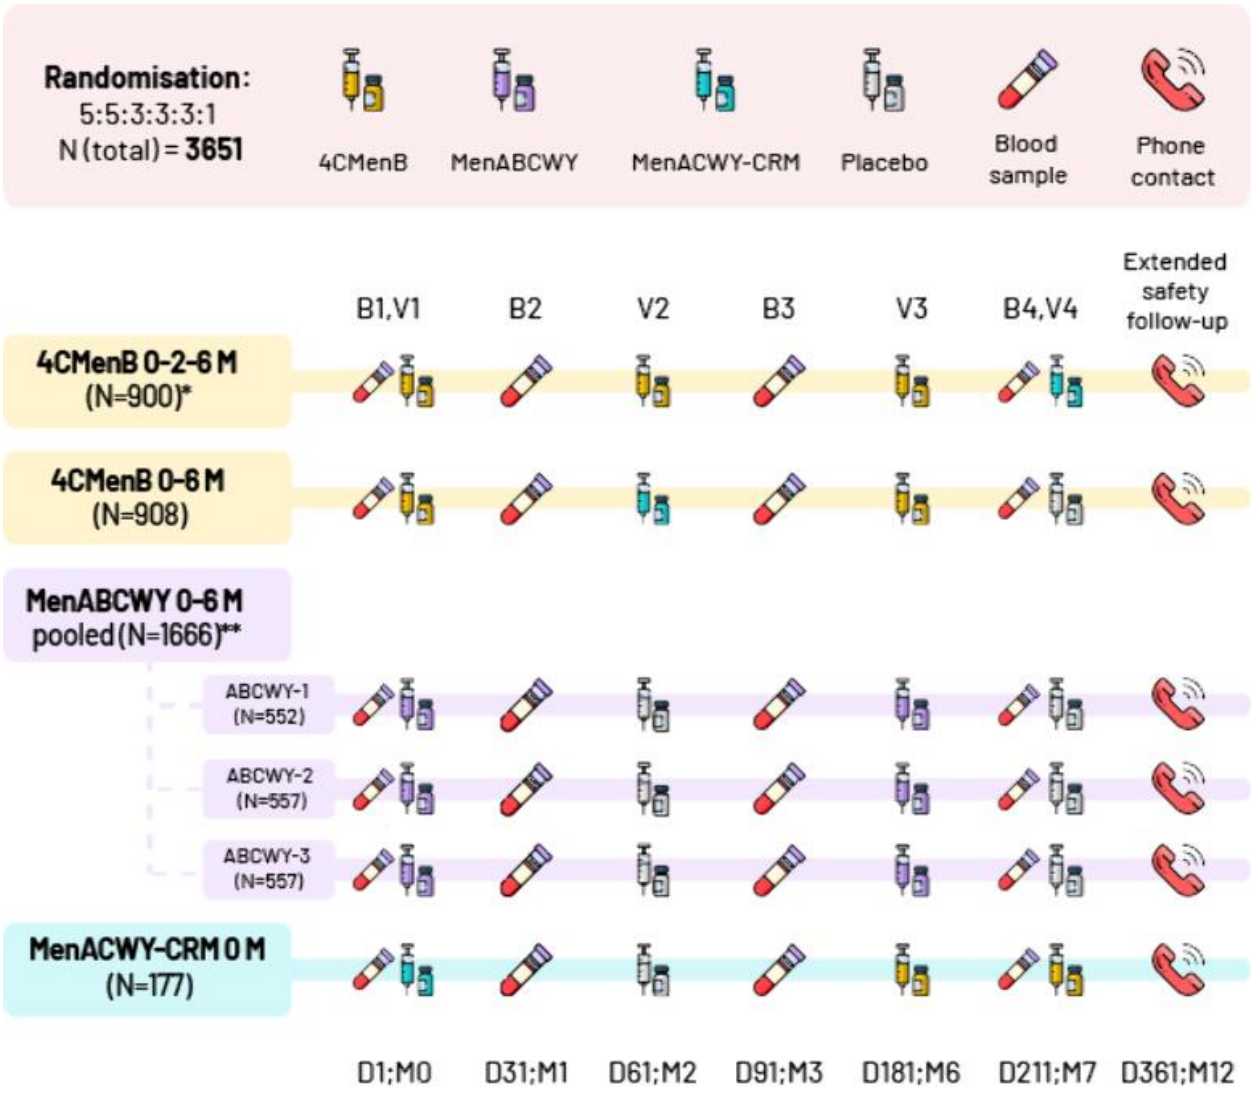
PD0123 / #2639

4CMENB VACCINE EFFECTIVENESS, IMMUNOGENICITY AND SAFETY IN ADOLESCENTS AND YOUNG ADULTS WHEN GIVEN IN 3-DOSE OR 2-DOSE SCHEDULE: RESULTS FROM PHASE 3 RANDOMIZED CONTROLLED STUDY

E-Poster Discussion
E-POSTER DISCUSSION SESSION 12: LATE BREAKING (STATION 06)

Terry Nolan[1,2], Peter Silas[3], Arnold Willemsen[4], Chiranjiwi Bhusal[4], Daniella Toneatto[5], . The Quintet Study Group[6]
[1]Murdoch Children's Research Institute, Virgo, Parkville, Australia, [2]Peter Doherty Institute for Infection & Immunity, Infectious Diseases, Melbourne, Australia, [3]Wee Care Pediatrics, Pediatrics, Syracuse, United States of America, [4]GSK, Statistics, Amsterdam, Netherlands, [5]GSK, Neisseria, Siena, Italy, [6]., ., Multiple Cities, Australia

Background: A phase 3 study assessed the safety and vaccine effectiveness (VE) of 4CMenB 3-dose (0-2-6 months) or 2-dose (0-6; 0-2 months) schedules against a genetically-diverse meningococcal serogroup B (MenB) strain panel.
Methods: In this observer-blind trial (NCT04502693), 3651 healthy individuals aged 10–25 years were randomized 5:5:9:1 to receive 4CMenB (0-2-6 months), 4CMenB (0-6 months), investigational MenABCWY vaccine, or MenACWY-CRM (control). The 4CMenB primary objectives were to evaluate safety and demonstrate VE using enc-hSBA, a human serum bactericidal antibody assay (hSBA) using endogenous complement in each vaccinee’s serum, against a 110-strain MenB panel. VE was demonstrated via 2 approaches: test-based (percentages of samples without bactericidal activity against 110-strain panel post-second/third 4CMenB dose versus post-MenACWY dose) and responder-based (percentage of participants whose sera kill ≥70% strains at 1 month post-second/third dose). Success was demonstrated with a lower limit (LL) of two-sided 97.5% confidence interval >65%. Immune responses against MenB indicator strains were also assessed.
Results:



* 4CMenB 0-2-6 M and 0-2 M schedules evaluated

** Each MenABCWY group received 1 of 3 lots of MenACWY component of MenABCWY vaccine; results pooled

B blood sample, **D** day, **M** study month, **N** number of participants, **V** visit

Test-based VE was 83.2% (LL 81.9%, upper limit [UL] 84.4%), 81.8% (80.4%, 83.1%), 78.7% (77.2%, 80.1%) for the 0-2-6, 0-6, 0-2 schedules, respectively. Responder-based VE was 93.4% (LL 91.2%, UL 95.2%), 89.8% (87.2%, 92.0%), 84.8% (81.8%, 87.5%), respectively. No clinically-meaningful differences in VE or hSBA immunogenicity were observed across schedules. Safety results were in line with the established 4CMenB safety profile.

Conclusions/Learning Points: The 2-dose (0-6, 0-2 months) and 3-dose (0-2-6 months) 4CMenB schedules met the pre-defined criteria for success for both VE endpoints, demonstrating VE against a panel of 110 epidemiologically-relevant MenB strains at a population and individual level in adolescents and young adults. No clinically-meaningful differences in VE or immunogenicity were observed between the 3-dose and 2-dose schedules. Safety results were consistent across schedules.

PD0124 / #2474

IDENTIFICATION OF BACTERIAL INFECTION IN A LARGE PAEDIATRIC FEBRILE COHORT (PERFORM) BY BLOOD GENE EXPRESSION QUANTIFICATION ON THE FILMARRAY® PLATFORM

E-Poster Discussion
E-POSTER DISCUSSION SESSION 12: LATE BREAKING (STATION 06)

Rebecca Womersley[1], Marine Mommert[2], Audrey Guichard[2], Dominic Habgood-Coote[1], Giselle D'Souza[1], Samuel Nichols[3], Tisham De[4], Aubrey Cunnington[5], Victoria Wright[3], Jethro Herberg[1], François Mallet[6], Myrsini Kaforou[1], Karen Brengel-Pesce[2], Michael Levin[1], Perform Consortium[7]
[1]Imperial College London, Department Of Infectious Diseases, London, United Kingdom, [2]BioMerieux, Open Innovation And Partnerships, Cedex, France, [3]Imperial College London, Department Of Infectious Disease, London, United Kingdom, [4]Paediatric Infectious Diseases, Imperial College, London, United Kingdom, [5]Imperial College London, Infectious Disease, London, United Kingdom, [6]Centre Hospitalier Lyon Sud, Joint Research Unit Hospice Civils De Lyon - Biomérieux, Lyon, France, [7]PERFORM Consortium, Europe, London, United Kingdom

Background: Distinguishing between bacterial and non-bacterial disease aetiologies of febrile illness is a critical challenge in the field of paediatric infectious disease. Recent research developments have shown that sparse gene expression signatures measured in patients' blood can identify bacterial infection. Translation of biomarker signatures to platforms enabling rapid, affordable and accurate quantification of gene expression is the first vital step for introducing gene expression markers to patient management.
Methods: Paediatric cases with confirmed bacterial and viral infection, alongside indeterminate groups were recruited in the multi-centre EU funded PERFORM study. PAXgene™ blood samples were run on the BIOFIRE® FILMARRAY® TORCH (BioFire Diagnostics®, USA) using the prototype 12 biomarker PERFORM gene set(1). Results were delivered in less than an hour and normalized expression of markers computed for analyses. A linear classifier model was built and assessed on patients with definite and intermediate diagnosis.
Results: Patients were divided into training (n=238) and testing sets (n=340) based on recruitment date. A 12-transcript model was defined by the training set, distinguishing bacterial from viral infections with an AUC of 92.8% (90.1 – 95.6%) in the test set. The model was able to classify previously unclassified patients in the indeterminate groups to those with a bacterial-like and those with viral-like profile.
Conclusions/Learning Points: The 12-gene signature distinguishes confirmed bacterial and viral infection in febrile children, encouraging both the use of this host-transcriptomic signature for diagnostics and the FILMARRAY® device as a platform to translate gene biomarker signatures. The translation of this model has wide-reaching potential to improve diagnosis of children with febrile illness, helping to reduce unnecessary antibiotic prescriptions in this difficult-to-diagnose group. (1)This prototype has not been validated nor submitted to any regulatory agency for review at time of writing

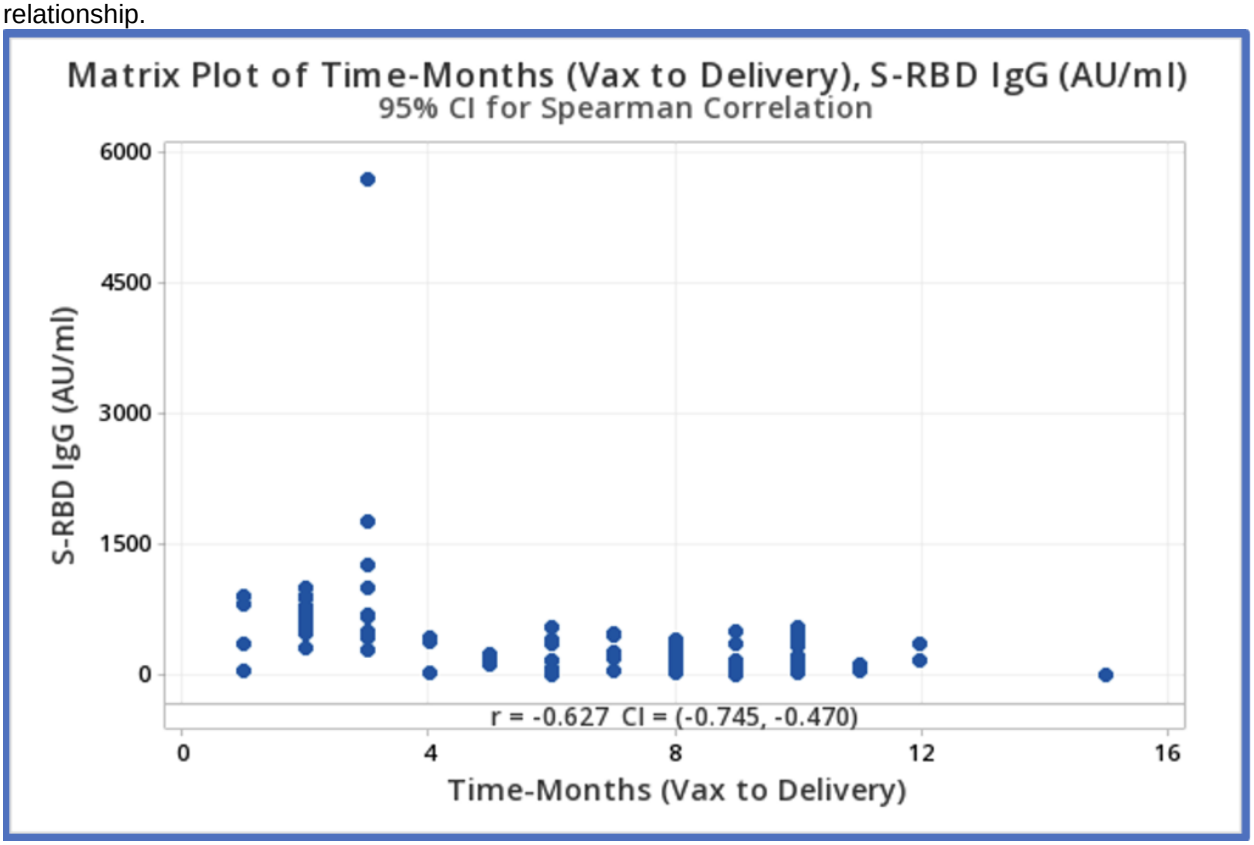
PD0125 / #2498

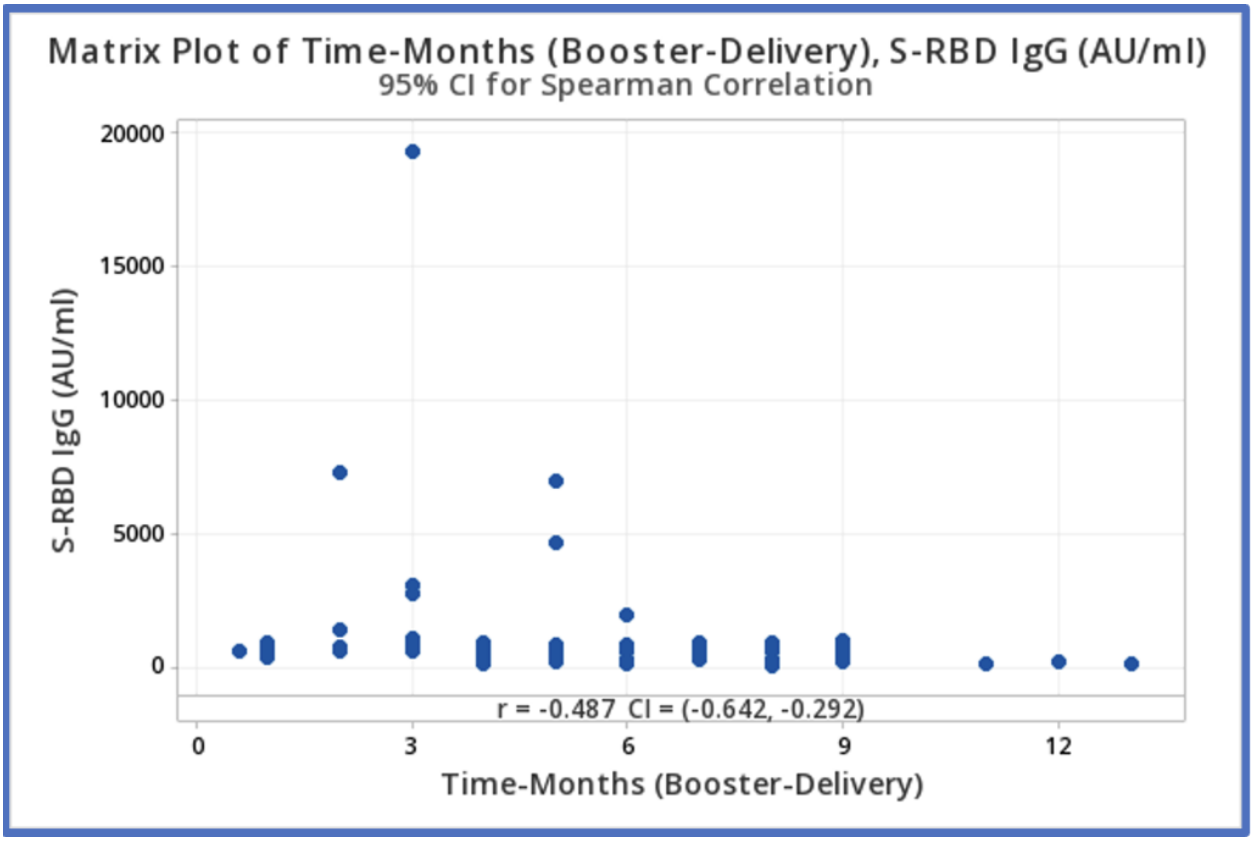
COVID-19 IGG LEVELS USING CLIA ANTI-S-RBD IN TERM NEWBORNS OF VACCINATED MOTHERS WHO DELIVERED IN A TERTIARY HOSPITAL IN CEBU FROM JULY TO SEPTEMBER 2022

E-Poster Discussion
E-POSTER DISCUSSION SESSION 12: LATE BREAKING (STATION 06)

Ray Mendoza
Cebu Doctors' University Hospital, Pediatrics, Mandaue City, Cebu, Philippines

Background: Transplacental transfer of antibodies to SARS-CoV2 after maternal vaccination was evidenced after cord blood samples showed reactive titers via immunoassay. Titer levels also varied from time of dose completion to delivery, vaccine type, and those with booster shots. This study aims to correlate IgG titers of term (>37 weeks AOG) newborns delivered to fully vaccinated/boosted mothers with the time of dose completion and type of vaccine given.
Methods: This was a single center prospective cohort study and utilized CLIA Anti-Spike Receptor Binding Domain (RBD) IgG in sampling cord blood samples. Kruskal-Wallis and Mann-Whitney U Test were used to determine the significant differences of the IgG titers between each type of vaccine and groups, respectively. Spearman's rank correlation was used to determine the correlation between IgG levels and time of dose completion.
Results: A total of 177 newborns were enrolled in the study. All samples were reactive (> 1 AU/ml) irrespective of vaccine type and regardless of which trimester it was given. The highest titer recorded was 19,340 from the booster group and the lowest at 5.4 from a mother without booster. Higher titers were recorded in more recent dose completion from delivery for both groups (p-value <0.001) indicating a significant
relationship.





Conclusions/Learning Points: There was a significant difference between IgG levels with higher titers in the booster group regardless of which trimester the dose was completed. The mRNA type of vaccine also exhibited higher titers compared to the other types. Lastly, there was a significant correlation between titer levels and time of vaccine/booster completion to delivery with higher titers associated in more recent dose completion.

PD0126 / #2463

ANTIBIOTIC RESISTANCE IN BLOODSTREAM ISOLATES FROM HIGH-COMPLEXITY PAEDIATRIC UNITS IN MADRID, SPAIN: 2013-2021

E-Poster Discussion
E-POSTER DISCUSSION SESSION 12: LATE BREAKING (STATION 06)

Blanca Bravo Queipo De Llano[1], Filip Camil Olteanu Olteanu[2], Luis Escosa[1], Jesus Saavedra-Lozano[3], Cristina Epalza[4], Emilio Cendejas Bueno[5], Emilia Cercenado[6], María Ángeles Orellana[7], David Aguilera-Alonso[8]
[1]Hospital Universitario La Paz, Paediatric Infectious And Tropical Diseases Department, Madrid, Spain, [2]Hospital Universitario 12 de Octubre, Paediatric Infectious Diseases Department, Madrid, Spain, [3]Hospital Universitario Gregorio Marañón, Infectious Diseases Unit, Madrid, Spain, [4]Hospital Universitario 12 de Octubre, Paediatric Infectious Diseases Unit, Madrid, Spain, [5]Hospital Universitario La Paz, Microbiology, Madrid, Spain, [6]Hospital Universitario Gregorio Marañon, Microbiology, Madrid, Spain, [7]Hospital Universitario 12 de Octubre, Microbiology, Madrid, Spain, [8]Hospital Universitario Gregorio Marañón, Pediatric Infectious Diseases Unit, Madrid, Spain

Background: Antimicrobial resistance (AMR) to common first-line antimicrobials has significantly increased in recent decades and has become particularly important in high-complexity healthcare settings. We aimed to describe AMR prevalence in bloodstream isolates from high-complexity Paediatric Units in Madrid (Spain) over a 9-year period.
Methods: Retrospective observational multicenter study performed in three tertiary hospitals. Bloodstream isolates (Enterobacterales, Pseudomonas aeruginosa, Staphylococcus aureus and Enterococcus spp.) from patients <18 years admitted to PICU, Neonatology and Oncology-Haematology Units between 2013-2021 were reviewed. Demographics, antimicrobial susceptibility and resistance mechanisms were determined. Microorganisms were classified as multidrug-resistant (MDR) and difficult-to-treat-resistant (DTR) based on standardized criteria.
Results: 1,255 isolates, corresponding to 988 patients, were included. The most frequent organism was Klebsiella spp. (33.4%), followed by E. coli (30.7%). Figure 1 displays the prevalence of AMR and its change over the study period. Extended-spectrum β-lactamases were identified in 9.3% of Enterobacterales, and carbapenemase production in 3.5% of gram-negative bacilli (GNB). The most common carbapenemase was VIM (67.9%), followed by OXA-48 (20.7%). 9.9% of GNB were classified as MDR and 2.3% as DTR. Methicillin resistance was observed in 11.0% of S. aureus isolates and vancomycin resistance among 1.4% Enterococcus spp. isolates. Oncology-Haematology patients had the highest prevalence of AMR among Enterobacterales isolates. Among Pseudomonas, there was a trend towards higher resistance in those isolated in PICU. Older children had higher odds of resistant isolates. Throughout the study period, the prevalence of Enterobacterales resistant to extended-spectrum cephalosporins, carbapenems or fluoroquinolones increased, while MRSA and vancomycin-resistant Enterococcus spp. remained
stable.

	Total	2013-2017	2017-2021	p-value	OR (95% CI)
Enterobacterales	N=736 (58.7%*)	N=369	N=367

Background: Research on vaccine effectiveness (VE) against COVID-19 using real-world data is ongoing. We aimed to estimate VE against COVID-19-related hospitalization in the pediatric population in Galicia, Northwest Spain.
Methods: We undertook a retrospective longitudinal study encompassing all individuals <18 years who were eligible for vaccination in Galicia between July 13th, 2021, and October 1st, 2022. The hazard ratio (HR) of hospitalization for COVID-19 and its 95% CI adjusted for sex and age were estimated using Cox regression models. Unvaccinated hospitalized children for COVID-19 were used as a reference category. Individuals who received the two doses of the COVID-19 vaccine were considered fully vaccinated one week after the second dose. VE was estimated as 1-HR.

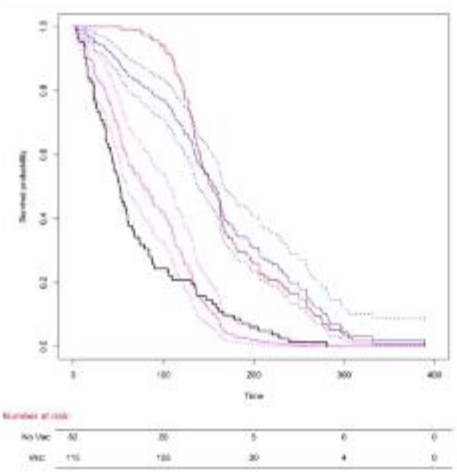

Figure 1. Survival analysis of hospitalization for COVID-19. Red line: survival probability in the vaccinated group. Black line: survival probability in the non-vaccinated group. Blue line: cox regression results including 95% CI in the vaccinated group. Magenta: cox regression results including 95% CI in the non-vaccinated group.

Results:

762,823 individuals were eligible for the study. COVID-19 vaccine coverage was 28.6% for subjects aged 5-17.9 years, 22.7% for 5-12 years, and 33.5% for 12.1-17.9 years. 197 children were hospitalized for COVID-19 and entered into the analysis. Hospitalized individuals aged between 5 and 17.9 years with a mean age of 12.3 years (SD=3.94). Of the hospitalized individuals, 115 (58%) were vaccinated. More females (N=106; 53.8%) were hospitalized than males (N=91; 46.2%). Comorbidities were not frequent in our study population. The survival curve is shown in Figure 1. Vaccinated children are at 73% (95%CI:

61% - 80%) lower risk of getting hospitalized for COVID-19 than non-vaccinated children [HR=0.27 (95%CI: 0.2 – 0.39)]. VE was maintained upon stratifying the analysis by age group (5-12 years) versus (12.1-17.9 years).
Conclusions/Learning Points: Vaccines against COVID-19 are highly effective in the Galician pediatric population and substantially reduce the risk of hospitalization for this disease.

Background: Isavuconazole (ISA) is approved for the treatment of invasive aspergillosis and mucormycosis in adults. Its use in children remains off-label. The aim of the study was to describe the efficacy and safety of ISA and the usefulness of therapeutic drug monitoring (TDM) in pediatric patients in a tertiary care pediatric hospital.
Methods: single-centre, retrospective study, including patients <18 years receiving ISA treatment between 2018-2021. TDM was performed with targeted ISA plasma trough levels (C_{trough}) 2.5-5 mcg/ml, based on adults' data. Treatment response was evaluated at 6, 12 weeks and end of treatment. Adverse events related to ISA were monitored by treating physician.
Results: Sixteen patients received ISA for invasive fungal infections (IFI) median age 12 years (IQR 8-14y). Eight patients underwent stem cell trasplantation; three patients were under ECMO support at some point during ISA treatment. Median ISA plasma trough levels (C_{trough}) were 3.1mcg/mL (IQR 2.4-4.5 mcg/mL), being 51/111 (45.9%) out of range. ECMO patients had lower C_{trough} (median C_{trough} ECMO 2.8mcg/mL vs. 3.3 mcg/mL non-ECMO) and required higher ISA doses to maintain C_{trough} in range. ISA response to treatment was favourable in 4/8 patients with proven or probable IFI at the end of treatment. Only one patient presented a mild adverse event attributed to ISA.
Conclusions/Learning Points: Our data supports the use of ISA as a safe therapeutic alternative for IFI in children. Pediatric patients, especially those under ECMO support, may benefit from systematic TDM as initial dosage is not well defined and high proportion of patients did not achieve plasma levels within range.

PD0129 / #2573

THE CLINICAL PHENOTYPE OF THE SARS-COV-2 OMICRON VARIANT IS DISTINCT FROM OTHER SARS-COV-2 VARIANTS IN CHILDREN

E-Poster Discussion
E-POSTER DISCUSSION SESSION 12: LATE BREAKING (STATION 06)

Will De Vivo, Nazima Pathan, Iain Kean, John Clark, Zhenguang Zhang, Esther Daubney, Deborah White
University of Cambridge, Picu, Addenbrooke's Hospital, Cambridge, United Kingdom

Background: Throughout the SARS-CoV-2 (COVID-19) pandemic, different variants of the virus have circulated on a national scale. However, the clinical presentation of these variants in children is not clearly established. Here, we established how the symptomatic presentation of COVID-19 infection in children changed throughout the pandemic.
Methods: We conducted a retrospective case note review of paediatric COVID-19 infections in a large tertiary paediatric centre, focussing on presenting symptoms. We screened the records of hospitalised children with PCR-positive COVID-19 from March 2020 to May 2022 (n=202). Within this dataset, we identified those whose primary indication for admission was COVID-19 infection (n=121).
Results: The prevalence of symptoms resulting in hospitalisation changed over the pandemic with the emergence of different variants. Interestingly, the omicron variant resulted in a greater proportion of patients presenting with upper respiratory symptoms, whilst previous variants more commonly produced lower respiratory tract symptoms. The prevalence of multi-system inflammatory syndrome in children (MIS-C) was also lower with the omicron variant compared to previous variants that circulated during the pandemic.

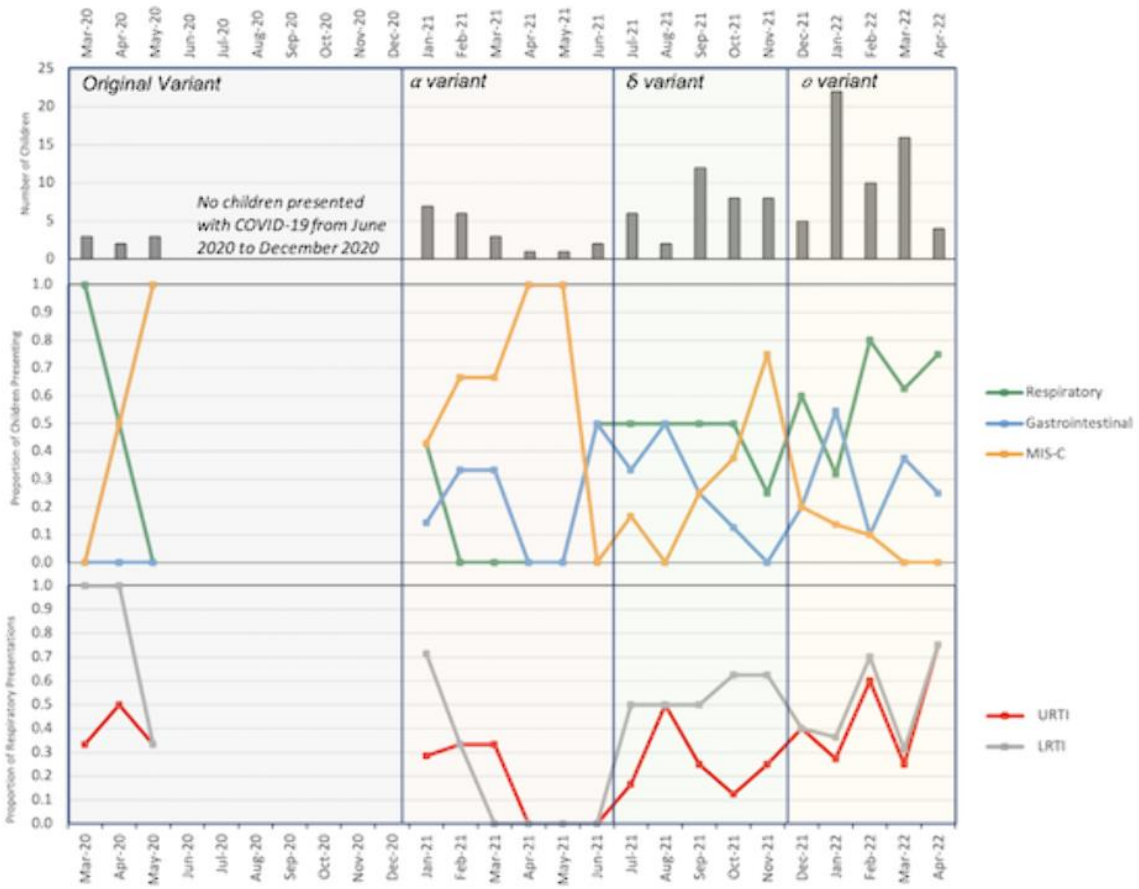

Figure 1: Clinical presentations of SARS-CoV-2 in children in a tertiary paediatric centre

Top panel: total number of children admitted to hospital with an active COVID-19 infection (incidental infections have been excluded). Middle panel: proportion of children by presenting phenotype of COVID-19 infection when admitted to hospital. Bottom panel: proportion of respiratory presentations of COVID-19 infections in children admitted to hospital. LRTI: lower respiratory tract infection; MIS-C: multi-system inflammatory syndrome in children; URTI: upper respiratory tract infection

Conclusions/Learning Points: Changes in the viral genotype can affect clinical presentation, even during an active pandemic. This illustrates the need to keep clinician knowledge up to date, to facilitate adequate diagnoses.

PD0130 / #2649

EXPERIENCE OF ESTABLISHING AND COORDINATING SENTINEL VACCINE SAFETY SURVEILLANCE NETWORK IN INDIA: LESSONS FROM TWO MULTISITE RESEARCH STUDIES

E-Poster Discussion
E-POSTER DISCUSSION SESSION 12: LATE BREAKING (STATION 06)

Manoja Das[1], Apoorva Sharan[2], Ramesh Poluru[2], Neeraj Kashyap[2], Narendra Arora[2]
[1]The INCLEN Trust International, Child Health, New Delhi, India, [2]The INCLEN Trust International, Public Health, New Delhi, India

Background: Introduction: Multisite sentinel surveillance has high relevance in vaccine safety research. The multisite studies experience challenges involving recruitment, protocol adherence, data quality and coordination. Lessons from developing countries are important to inform the organization and conduct of multisite sentinel surveillance. This paper presents the process and experience of the establishment and conduct of two sentinel surveillance studies in India.
Methods: The studies included intussusception surveillance linked to rotavirus vaccine introduction (Study-1, 2015-2017) and surveillance for multiple AEFIs related to routine immunization (Study-2, 2017-2020) in children aged 1-24 months. The study sites were selected through a systematic and objective four-step selection process. The multilayer quality assurance measures were adopted to document protocol adherence and data collection quality.
Results: The study site selection involved four steps: shortlisting of potential institutions, invitation for expression of interest and interactions, site visits and site selection using objective criteria. The process and data collected from the two surveillance studies are presented in Table-1.

Table 1: The site selection processes and performance of two sentinel surveillance in India

Parameter	Study-1 (Intussusception surveillance)	Study-2 (Multiple AEFI surveillance)
Selection process		
Institutions screened	438	484
Expression of interest invited	40	68
Institutions visited for assessment	25	31
Institutions included in network	19	24
Surveillance performance		
Screened participants	42866	90147
Eligible participants	2092	8756
Recruited participants	1588	8458

The key challenges included time taken for regulatory/ethical approvals, variation in clinical practices, data quality (completeness, timelines), medical record-keeping, vaccine information retrieval and investigator commitment and transition.

Conclusions/Learning Points: The experience of multisite sentinel vaccine safety surveillance with systematic multi-step site selection and data quality assurance methods are feasible, and practical and can inform similar studies in developing countries.

PD0131 / #2518

CLINICAL FEATURES AND SEVERITY OF COVID-19 WITH RESPIRATORY VIRAL COINFECTIONS VERSUS SARS-COV-2 MONOINFECTION IN HOSPITALIZED CHILDREN: A CANADIAN NATIONAL SURVEILLANCE STUDY

E-Poster Discussion

Background: The circulation of SARS-CoV-2 with other respiratory viruses led to an increased risk of coinfections, and potentially increased severity, especially in children. This study aims to examine the epidemiology, clinical features, and outcomes of SARS-CoV-2 respiratory viral coinfections compared to SARS-CoV-2 monoinfections in hospitalized children.
Methods: We conducted a national surveillance study evaluating pediatric COVID-19-related hospitalizations across Canada from April/2020-May/2022. Data were captured through two datasets covering ~90% of all Canadian tertiary-care pediatric beds: The Canadian Pediatric Surveillance Program and the Canadian Immunization Monitoring Program, ACTive. Coinfections were defined as the simultaneous detection of SARS-CoV-2 and >=1 other respiratory virus. Severe infection was defined as intensive care, ventilatory, or hemodynamic support requirements, organ system complications, or death. Variables/outcomes were summarized/compared using the appropriate statistical tests.
Results: Overall, 1357 COVID-19-related hospitalizations were included in this study, of which, 104 (7.7%) had documented coinfections (11/104 [10.6%] with SARS-COV-2 plus ≥2 other respiratory

viruses). Enterovirus/rhinovirus (N=48/104, 46%) and RSV (N=36/104, 35%) coinfections were the most common. Children with coinfections were significantly younger than SARS-COV-2 monoinfections cases (median age 1.1 [IQR:0.3-2.6] vs 1.6 [IQR:0.2-8.3] years, p=0.009). Overall, severe outcomes (p=0.008), as well as the need for any respiratory support (p<0.001) were more frequent among coinfection cases. In particular, we observed that severe outcomes were significantly higher in SARS-CoV-2 coinfections compared to mono-infection cases during the Omicron period (table). Severe infection was most common in children with both enterovirus/rhinovirus (19/48, 39.6%) and RSV (14/36, 38.9%) coinfections.

Table. Characteristics of hospitalized children with SARS-CoV-2 mono-infection vs. with respiratory virus coinfections from April 2020–May 2022.

Characteristic	SARS-CoV-2 mono-infection	SARS-CoV-2 viral coinfection	*P* value
	N = 1253	N = 104	
Age (years), median (IQR)	1.6 (0.2–8.3)	1.1 (0.3–2.6)	0.009
Age, n (%)			<0.001
<1 year	522 (41.7)	48 (46.2)	
1–4 years	318 (25.4)	42 (40.4)	
5–<17 years	413 (33.0)	14 (13.5)	
Sex, n (%)			0.03
Female	525 (41.9)	32 (30.8)	
Male	728 (58.1)	72 (69.2)	
Comorbid conditions, n (%)			0.18
None/Unknown	652 (52.0)	64 (61.5)	
One	328 (26.2)	22 (21.2)	
≥Two	273 (21.8)	18 (17.3)	
Any immunodeficiency, n (%)	106 (8.5)	<5 (<4.8)	0.10
Received any COVID-19 vaccine, n (%)	103 (8.2)	<5 (<4.8)	0.05
Outcomes, n (%)			
Any respiratory support	272 (21.7)	46 (44.2)	<0.001
Any ventilation	101 (8.1)	26 (25.0)	<0.001
Any vasopressors	43 (3.4)	7 (6.7)	0.10
Admitted to ICU	191 (15.2)	30 (28.9)	<0.001
Severe infection[2]	310 (24.7)	38 (36.5)	0.008
Child died	14 (1.1)	<5 (<4.8)	0.35
Outcomes according to pandemic waves[1]			<0.001
Delta period, N	150	25	
Any respiratory support, n/N (%)	46/150 (30.7)	10/25 (40.0)	0.35
Ventilation, n/N (%)	15/150 (10.0)	10/25 (40.0)	<0.001
ICU admission, n/N (%)	35/150 (23.3)	9/25 (36.0)	0.18
Severe infection, n/N (%)	46/150 (30.7)	12/25 (48.0)	0.09
Omicron period, N	755	68	
Any respiratory support, n/N (%)	136/755 (18.0)	32/68 (47.1)	<0.001
Ventilation, n/N (%)	52/755 (6.9)	15/68 (22.1)	<0.001
ICU admission, n/N (%)	98/755 (13.0)	19/68 (27.9)	0.001
Severe infection, n/N (%)	182/755 (24.1)	24/68 (35.3)	0.04

[1]The ancestral period is defined as March 1, 2020–April 17, 2021, the pre-Delta period is defined as April 18–June 28, 2021, the Delta period is defined as June 29–December 15, 2021, and the Omicron period is defined as December 16, 2021–current. Time periods were defined as the week when a SARS-CoV-2 lineage first comprised >50% of all Canadian cases until the week another lineage comprised >50% of all Canadian cases.
[2]Severe infection was defined as intensive care, ventilatory, or hemodynamic support requirements, organ system complications, or death.

Conclusions/Learning Points: Children with documented viral coinfections had more severe respiratory disease compared to SARS-COV-2 monoinfections. Further work needs are needed to assess how different virus coinfections may together affect children and which, if any, may be a predominant driver of disease severity.

ME0001 / #1471

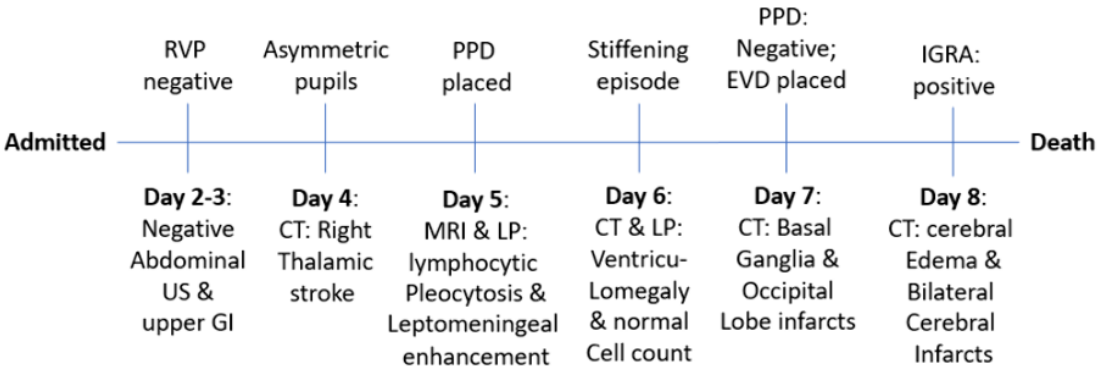
A FATAL CASE OF PEDIATRIC TUBERCULOSIS MENINGITIS AND CEREBRAL INFARCTION

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Melissa Shenep[1,2], Timothy Minniear[2]
[1]St Jude Children's Research Hospital, Infectious Diseases, Memphis, United States of America, [2]University of Tennessee Health Science Center, Pediatrics, Memphis, United States of America

Title of Case: A Fatal Case of Pediatric Tuberculosis Meningitis and Cerebral Infarction
Background: Tuberculosis (TB) meningitis is a rare disease with a high mortality rate. Children often present in the later stages, making it critical to quickly identify and start anti-tuberculosis treatment when tuberculosis meningitis is suspected.
Case Presentation Summary: This is a case report of tuberculosis meningitis in a previously healthy 11-month-old female who presented with ten days of fever and six days of non-bloody, non-bilious emesis. She had no night sweats, weight loss, or nuchal rigidity. Initial studies showed chest radiograph demonstrating central bronchial wall thickening with mild hazy airspace disease in the right base. On the fourth day of admission, patient was noted to have asymmetric pupils and a CT scan demonstrated right thalamic lacunar stroke of unknown age. A lumbar puncture (LP) was performed which demonstrated mild lymphocytic pleocytosis, hypoglycorrhachia, and elevated protein. She was started on broad-spectrum antimicrobials; however, the following day, magnetic resonance imaging of the brain demonstrated multiple scattered foci of restricted diffusion involving multiple arterial territory distributions and diffuse leptomeningeal enhancement of the skull base, bilateral sylvian fissure regions, and meninges surrounding the brainstem and cerebellum. Patient's tuberculin skin test (TST) was negative. She developed hydrocephalus, requiring an external ventricular drain (EVD) placement on day 7 of admission. Her Interferon-Gamma Release Assay (IGRA) eventually returned positive. Cerebral infarction rapidly progressed and following compassionate extubation, she passed away.

Figure 1: Hospital Course of Patient with Tuberculosis Meningitis



Learning Points/Discussion: TB meningitis should be considered in a patient with prolonged fever and cerebral infarctions. A negative TST does not preclude TB meningitis. Due to the high mortality and morbidity of tuberculosis meningitis, it is crucial to initiate anti-tuberculosis therapy early.

RECURRENT PNEUMOTHORAX IN A 4-YEAR-OLD IMMUNOCOMPETENT GIRL WITH CAVITATING PULMONARY TUBERCULOSIS

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Irene Tzovara, Ioanna Farakla, Theoni Petropoulou, Evanthia Botsa, Vana Spoulou
Aghia Sophia Children's Hospital, First Department Of Pediatrics - University Of Athens, Athens, Greece

Title of Case: RECURRENT PNEUMOTHORAX IN A 4-YEAR-OLD IMMUNOCOMPETENT GIRL WITH CAVITATING PULMONARY TUBERCULOSIS
Background: Pulmonary tuberculosis (TB) can be complicated by spontaneous pneumothorax, especially when cavities are present. In children, however, cavity formation is uncommon.
Case Presentation Summary: We present a rare case of pulmonary (non-MDR) TB in an immunocompetent 4-year-old Roma girl with extensive parenchymal damage, multiple cavities and emphysematous lesions which presented with recurrent pneumothorax. The girl had been diagnosed with latent TB 2 years earlier, after her father was diagnosed with active pulmonary TB. Both had poor compliance to treatment. The recurrence of pneumothorax, possibly indicating the presence of a bronchopleural fistula, eventually required surgical management 6months after the onset of the pneumothorax. Right lower lobectomy and sub-lobar resection of the right middle lobe were performed. The patient had an uneventful postoperative course with satisfactory re-expansion of the residual lung, and received anti-TB treatment (rifampicin, isoniazide, pyrazinamide) for 12 months after surgery (17 months in total). She is regularly assessed at our infectious disease clinic and has had no sign of pneumothorax or respiratory deterioration 15 months after lobectomy, even though she had an uneventful SARS-CoV-2 infection.
Learning Points/Discussion: Chemotherapy successfully replaced surgical treatment of TB several decades ago. However, it may be still indicated in drug-resistant TB cases with poor response to anti-TB agents and/or in cases with complications such as recurrent pneumothorax. This case highlights the importance of contact tracing for TB, especially when children are involved, and BCG vaccination at birth for children from high-risk populations. Moreover, it emphasizes the need to ensure that both patients and their infected contacts receive appropriate treatment through Directly Observed Therapy (DOT) when necessary, as poor treatment compliance can lead to life-threatening complications even in immunocompetent individuals.

Title of Case: Herpes Simplex Meningitis presenting with stroke-like onset in an infant
Background: Herpes simplex virus meningoencephalitis (HSVM) is an acute or subacute illness caused by herpes simplex viruses belonging to either type 1 (HSV-1) or type 2 (HSV-2), with high risk of mortality and comorbidities. Ischemic stroke is a rare complication of herpes simplex type-1 (HSV-1) encephalitis in childhood.
Case Presentation Summary: A 11-months-old male presented to the Emergency Room with subfebrile temperature, hypomobility and clonuses of the upper left limb. Cranial CT scan and CT angiography pointed out a right frontal hypodense area. EEG showed slow abnormalities and the appearance of PLEDs. Admitted to the Neurology Unit, he received a brain MRI that showed a right middle cerebral artery stroke. Considering the persistence of fever and the altered neurological status characterized by sopor and irritability, LP, blood chemistry and blood cultures were performed and empirical antibiotic intravenous treatment with Acyclovir and Ceftriaxone initiated. The CFS analysis and blood cultures revealed a positivity for HSV-1; therefore, antibiotic treatment was interrupted. Despite treatment neurological status worsened with increasing of clonuses and hypomobility of the upper right limb and lower left limb, respectively, and enlargement of ischemic areas was revealed by neuroimaging, thus methylprednisolone was started and received IVIG infusion (2g/kg). On day 9 of antiviral therapy HSV DNA in the blood was not found. Afterwards clinical improvement was seen and patient was discharged on day 20 with close follow-up and continuation of treatment at the pediatric neurorehabilitation.
Learning Points/Discussion: Ischemic stroke, although infrequent, can be either complication and presentation of HSV-1 central nervous system infection. HSV-1 research on CFS should be included in children with ischemic stroke in order to start the antiviral treatment promptly.

THE NIGHTMARE OF RECURRENT PNEUMOCOCCAL MENINGITIS

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Rosa Francavilla, Orsola Imbornone, Felicia Stella, Valentina Alberghini, Anna Martoni, Di Florio Francesca, Paola Salvago, Claudia Balsamo, Francesca Lombardi, Cristiana Retetangos, Emanuele Filice, Matteo Meli, Chiara Ghizzi
Unit Paediatrics - Ausl Bologna, Bologna, Italy, Department Of Pediatrics, Maggiore Hospital, Bologna, Italy, Bologna, Italy

Title of Case: The nightmare of recurrent pneumococcal meningitis
Background: Pneumococcal meningitis (PM) is a medical emergency, associated with high mortality (10.4%-11.4%) and morbidity (30%-50. In rare cases, PM can be recurrent (PMR). In the child, the recurrences are linked to immunodeficiency or CSF leak.
Case Presentation Summary: 11-year-old boy with fever (TC 40°C) started 6 hours ago, headache and onset of aimless movements during sleep, with difficulty waking up are admitted in pediatric emergency departement. The child was vaccinated with pneumococcal conjugate vaccine 13 valent. He had a trauma from a fall from a height of 2 meters 6 months before. Upon arrival in ED: GCS 5, meningitis is diagnosed. Brain CT showed initial signs of cerebral edema, lumbar puncture: turbid CSF, with increased pressure, with chemical-physical characteristics of bacterial meningitis. CSF PCR was positive for Str. pneumoniae, but blood and CSF cultures were negative. He developed severe right sensorineural hearing loss. After 3 months the child had a second episode of meningitis. CSF PCR was positive for Str. pneumoniae. Serotype 11A Str. pneumoniae was identified from blood culture Intermittent rhinorrhoea from the right nostril was found, for which the liquid was collected and tested positive for beta-trace protein assay. Subsequent brain CT and MRI investigations failed to identify CSF leak, therefore intrathecal fluorescein tests and closure of the left ethmoid fistula will be performed. Nevertheless six months after surgery, the patient presented a third episode of pneumococcal meningitis serotype 33C.
Learning Points/Discussion: In the case of PM, immunodeficiency must be excluded and favorable anatomical conditions such as CSF fistulas must be sought, and in the case of PMR, all the diagnostic procedures necessary to search for a CSF fistula must be used.

PEDIATRIC TUBULAR LYMPHANGITIS CAUSED BY RICKETTSIA SIBIRICA MONGOLITIMONAE

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Álvaro Vázquez-Pérez[1], Javier Rodríguez-Granger[2], Elizabeth Calatrava-Hernández[2], Juan Luis Santos-Pérez[1]
[1]Hospital Universitario Materno-Infantil Virgen de las Nieves, Pediatrics- Pediatric Infectious Diseases/Granada, Spain, [2]Hospital Universitario Virgen de las Nieves, Microbiology, Granada, Spain

Title of Case: PEDIATRIC TUBULAR LYMPHANGITIS CAUSED BY RICKETTSIA SIBIRICA MONGOLITIMONAE
Background: Rickettsioses are challenging infections in children that should be suspected in the presence of typical guide symptoms, such as the history or suspicion of tick bite, and associated lymphangitis. Rickettsia sibirica mongolotimonae was first isolated in 1991 in Mongolia. Just 5 cases of the infection in children have been reported worldwide. Different clinical manifestations of the infection have been described, such as tick-borne lymphadenopathy (TIBOLA) and mainly, lymphangitis-associated rickettsiosis (LAR). Its main vector is considered to be species of the genus Hyalomma.
Case Presentation Summary: We report the case of a 4-year-old boy with fever of up to 39.7 ◦C for 5 days. He presented a bite lesion on the inner side of the right thigh. Physical examination revealed a circular lesion (5 mm) with a necrotic eschar. He associated rope-like lymphangitis running from the eschar up to the inguinal region, where a painful adenopathy was found. A shave biopsy was performed to determine a PCR for Rickettsia. Laboratory tests were normal. He began treatment with oral azithromycin and intravenous amoxicillin-clavulanate, with a favorable evolution. The diagnosis was confirmed with the results of PCR in the eschar sample: positive for Rickettsia sibirica mongolotimonae.
Learning Points/Discussion: When LAR is suspected, empirical treatment with doxycycline should be started. In Spain, a progressive increase in the population of Hyalomma species has been reported. The change in climatic conditions seems to play an important role in this increasement. In Spain, the human transmission of other life-threatening zoonotic agents by Hyalomma ticks, such as Crimean-Congo virus has already been reported. These potential risks emphasize the importance of the development of new prevention strategies and the evaluation of this threat to public health.

Title of Case: SENLAT (SCALP ESCHAR AND NECK LYMPHADENOPATHY AFTER TICK BITE) CAUSED BY RICKETTSIA SLOVACA AND RICKETTSIA RAOULTII AFTER A TICK BITE: PAEDIATRIC CASE REPORTS, PORTUGAL
Background: Tick-Borne Lymphadenopathy (TIBOLA) or Scalp Eschar and Neck Lymphadenopathy After Tick Bite (SENLAT) are designations for rickettsioses characterized by enlarged neck lymph nodes and scalp eschar after a tick bite.TIBOLA/SENLAT is the second most common tick-borne rickettsiosis in Portugal,after Mediterranean Spotted Fever.Dermacentor ticks species are the most frequently associated with Rickettsia slovaca and R. raoultii transmission. Methods:Paediatric patients (0-17 years old) who presented to a tertiary-level children's hospital in Portugal,to remove a tick after its bite,with or without symptoms over 2020-2021.Ticks removed were identified and screened by PCR for Rickettsia.
Case Presentation Summary: We identified 6 children,aged 4-10 years old,admitted through the emergency department mostly during spring (4) and coming from an urban area (5).1 patient reported outdoor activities and another contact with a dog.No children had travelled recently.On admission,3 patients had history of removed tick from the scalp,latter developing symptoms compatible with TIBOLA/SENLAT.Analysed ticks from these patients showed that all were Dermacentor marginatus,1 infected with R. slovaca and 2 with R. raoultii.R. slovaca patient had eschar,fever,rash and adenopathies,while R. raoultii patients had fewer symptoms,1 only presenting scalp eschar with erythema.2/3 symptomatic patients underwent laboratory evaluation,unremarkable, and were treated with doxycycline with resolution of symptoms and without sequelae.In the 3 asymptomatic patients,2 ticks were infected with R. massiliae and 1 with R. monacensis.
Learning Points/Discussion: Early recognition and diagnosis of rickettsioses based on clinical presentation remains a big challenge as it can present from asymptomatic to severe disease. Molecular characterization of Rickettsia spp. and associated ticks removed from asymptomatic or symptomatic patients can contribute to a better understanding of rickettsial diseases.

Title of Case: Safety of Molnupinavir in SARS COV 2 infected children
Background: After 3 years of pandemia of Sars Cov 2 we have understood that an higher risk for progression to sever clinical manifestations is related to infants and children with underlying medical conditions like immunodeficiency or heart and lung disorders. Early antiviral treatment allows to change not only the course of the infection but also to avoid the serious effects due to the delay of necessary other treatments. Even today, the antivirals used in adults with SARS COV 2 infection are not licensed for children.
Case Presentation Summary: We describe 4 cases of children followed up at the Bambino Gesù Children's hospital with SARS COV 2 infection (Omicron B variant) median age 8 years affected by oncological pathology under treatment and complex heart disease. None of them had been able to carry out the anti SARS COV 2 vaccination, one of them had previously contracted SARS COV 2 infection and had been treated with oral antivirals. All were on severe immunosuppressive or cardiological therapy. Only one had fever. In one patient Remdesivir treatment was stopped after the first dose due to side effects. After collection of Informed consent, therapy with Molnupinavir was prescribed for five days. No patient showed any adverse events to taking the drug and the mean time to virus negative was 5.5 days. When the virus was negative, everyone resumed the necessary therapies for the underlying disease
Learning Points/Discussion: After three years of Pandemic it is increasingly priority and urgent to integrate the pharmacokinetic studies of the new antiviral drugs also for the paediatric age. The feasibility of early treatments should be an integral part of the processes of preparedness in the future of infectious diseases

[1]università degli studi di milano, Pediatric Infectious Disease, Luigi Sacco Hospital, Milan, Italy, [2]Università degli Studi di Milano, Department Of Biomedical And Clinical Sciences, milano, Italy, [3]Università degli Studi di Milano, Department Of Pediatrics, V. Buzzi Children's Hospital, Milan, Italy

Title of Case: ROLE OF BOOSTER DOSE IN A X-LINKED AGAMMAGLOBULINEMIA ADOLESCENT SARS-COV-2 INFECTED
Background: A very limited amount of data is present in literature on SARS-CoV-2 infection in X-Linked Agammaglobulinemia (XLA) patients. Moreover, it remains unclear the role of vaccination against SARS-CoV-2 in these subjects. We investigated immune response of a mild symptomatic SARS-CoV-2 strain BA.2 (B.1.1.529.2) infected XLA 12 years old male, vaccinated with booster dose during acute infection (AI) and after one month post COVID-19 diagnosis (PI).
Case Presentation Summary: B cell compartment was compromised (CD19+ 0,004*103/mL, 0,2%). No NTA was found against Omicron. No significant differences in CD4+ and CD8+ T effector memory (CD4+/CCR7-/CD45RA-, CD8+/CCR7-/CD45RA-) and central memory (CD4+/CCR7+/CD45RA-, CD8+/CCR7+/CD45RA-) lymphocytes were observed in unstimulated compared to SARS-CoV-2-specific cells at AI. In contrast with these data, SARS-CoV-2-specific IFNg-producing CD8+ T lymphocyte were increased compared to the unstimulated condition. We treated our patient with Xevudy (Sotrovimab) monoclonal antibodies. According to the monoclonal antibodies infusion, at PI high level of NTA was found against Omicron (1:60) variants. A moderate increment of SARS-CoV-2-specific IFNg-producing CD8+ T lymphocyte and degranulating CTL were detected when compared to the unstimulated condition. Notably, a robust increment in CD4+ and CD8+ central memory T lymphocytes was detected at PI compared to AI.
Learning Points/Discussion: Due to the lack of the NTA in AI and the observation that virus-specific memory T cell was only seen at PI, we conclude that the booster dose of COVID-19 vaccine was unable to trigger a relevant immunological protection in this patient. The absence of BTK have a role in mitigate symptoms by impairing IL-6 production.

STREPTOCOCCUS PYOGENES: AN EMERGING CAUSE OF INVASIVE DISEASE AND SEVERE PNEUMONIA

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Daniel Jarovsky, Emmanuella De Jesus D'Elia, Camila Ohomoto De Morais, Giovanna Guerra, Samantha Matos, Flavia Almeida, Marco Aurelio Safadi, Eitan Naaman Berezin
Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil

Title of Case: Streptococcus pyogenes: an emerging cause of invasive disease and severe pneumonia
Background: Streptococcus pyogenes (group A streptococcus - GAS) is generally an uncommon cause of community-acquired pleuropneumonia/empyema in children but has been described as a leading pathogen after pneumococcal conjugate vaccine implementation. The relative incidence of this potentially severe disease has been rising in the last decade and peaked in late 2022 worldwide. We describe a rare case of severe and complicated GAS pneumonia in a fully vaccinated infant in mid-2022.
Case Presentation Summary: A previously healthy 14-month-old boy presented to the ER with cough, runny nose, and high recurrent fever (up to 38.8°C) for 7 days, but with significant worsening of the general condition and respiratory pattern during the last 12h. In the initial evaluation, the infant was groaning, tachydyspneic, and with subcostal and intercostal retractions on room air. Pulmonary auscultation was reduced at the right base, and chest X-ray revealed consolidation in the same topography. A high-flow nasal cannula and empiric treatment with high-dose ceftriaxone plus oxacillin were initiated. Still, the latter was changed to vancomycin after 24h due to clinical instability and the need for mechanical ventilation. Complicated pneumonia with pleural effusion was identified at the control X-ray – diagnostic thoracentesis was promptly performed. Streptococcus pyogenes was identified in the pleural fluid in less than 48h by multiplex RT-PCR and clindamycin was then added due to clinical severity and risk of STSS. S. pyogenes was also recovered from blood at admission. He recovered completely after 21 days of hospitalization (13 were at the PICU).
Learning Points/Discussion: Children with GAS pneumonia are more likely to have more extensive pleural effusion requiring drainage, longer hospitalization, and prolonged antibiotic use.

MEET THE EXPERT POSTERS

Sophie Cahen[1], Sarah Jourdain[1], Gabrielle De Crombrugghe De Looringhe[2], Anne Botteaux[2], Pierre Smeesters[1]
[1]HUDERF, Infectious Diseases, Brussels, Belgium, [2]ULB, Molecular Bacteriology, Brussels, Belgium

Title of Case: Group A Sreptococcal meningitis
Background: On December 12, 2022, WHO has released a statement alerting about an increase of Invasive Group A streptococcal (iGAS) infections in Europe. We report the case of a 9-years-old boy presenting with GAS meningitis and Toxic Shock syndrome (TSS).
Case Presentation Summary: A previously healthy patient presented at the Emergency Room with fever (39°C), diarrhea and vomiting for 2 days. He presented an episode of generalized tonic clonic seizures which stopped after 2 doses of lorazepam (0.1 mg/kg). The patient remained comatose (GCS 2/15). Blood cultures and lumbar punction were taken, chest tube placed, and IV ceftriaxone (100 mg/kg q24h) treatment was started. The patient was transferred to PICU 5 hours after admission for hypotension (70/52 mmHg) and developed a generalized skin rash with a renal impairment (creatinine 1.3 mg/dL). The patient therefore met the CDC criteria for TSS. Adjunctive therapy with IV clindamycine (20 mg/kg/day q8h) and IVIG (2g/kg) was immediately started. Blood and CSF were GAS positive at day 2. Close relatives living under the same roof were prescribed Cefadroxyl as secondary iGAS prophylaxis.
Learning Points/Discussion: The microbiological characterization (emm-typing and virulence typing) of our strain in under progress using nanopore genome sequencing. No specific virulence factor has yet been associated with GAS meningitis which is associated with a 43% case fatality rate. GAS meningitis remains however uncommon among iGAS (2% in Europe) and represents a rare aetiologia of all-age bacterial meningitis. GAS meningitis usually occurs in association with an extra-meningeal primary focus of infection, most commonly otitis media. This case reminds us of the possibility of GAS meningitis without other foci of infection. This might be especially relevant in a context of raising concerns about iGAS in Europe.

[1]Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Marmara University School of Medicine, Neurosurgery, İstanbul, Turkey, [3]Marmara University School of Medicine, Radiology, İstanbul, Turkey

Title of Case: Treatment of Intraventricular Liposomal Amphotericin B in a Child with Central Nervous System Aspergillosis
Background: Central nervous system (CNS) aspergillosis is a rare and fatal opportunistic infection. Here, we present a child with CNS aspergillosis who was treated with intraventricular liposomal amphotericin B (L-AmB), voriconazole, and intravenous (IV) L-AmB.
Case Presentation Summary: A 10-year-old male with nephrotic syndrome presented with limping and weakness. He was on steroid therapy for a month. The cranial magnetic resonance imaging (MRI) showed multiple intraparenchymal scattered abscesses (Figure 1-A). The largest one located to the right parasagittal region was drained. Vancomycin, ceftriaxone, and metronidazole treatments were started. Abscess culture revealed Aspergillus fumigatus and IV voriconazole was added. The histopathological examination revealed septate hyphae compatible with Aspergillus
spp.

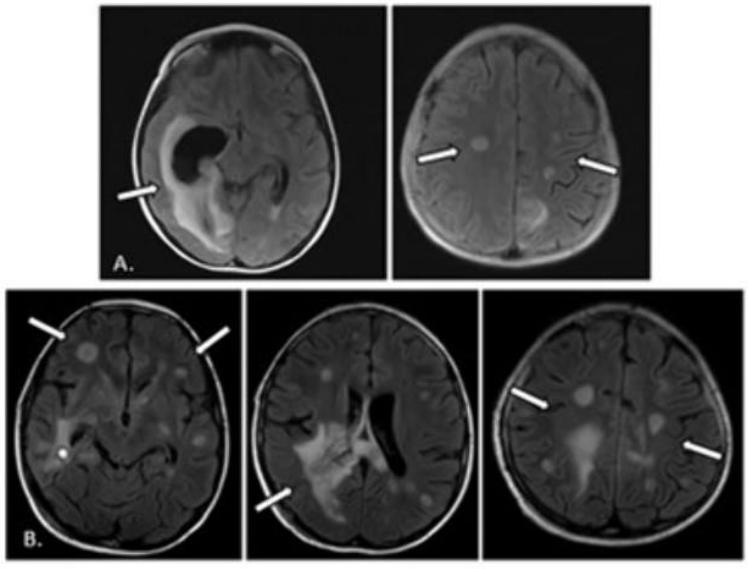

Figure 1. A. Scattered abscesses in initial cranial MRI B. An increase in the number and size of the lesions in his control cranial MRI On the 7th day of voriconazole therapy, his consciousness deteriorated and an increase in the size and number of lesions was detected by cranial MRI (Figure 1-B.). Hence, IV L-AmB was added. The size of lesions and perilesional edema continued to increase under IV L-AmB and voriconazole therapy. Then intraventricular L-AmB (1 mg/day, dissolved in 3 mL of 5% dextrose) was added to combined antifungal therapy. On the 10th day of the intraventricular treatment, regression of the lesions was observed. His follow-up continues with steroid dose reduction and combined systemic and intraventricular antifungal therapy.
Learning Points/Discussion: Management of CNS aspergillosis is challenging. Combined systemic and

intraventricular antifungal therapy may increase the success rate. More experience is needed for the efficacy and safety of intraventricular therapy.

DISSEMINATED ADENOVIRUS INFECTION TREATED WITH CIDOFOVIR IN A CHILD WITH A SOLID TUMOR

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Pınar Canizci Erdemli[1], Zeynep Ergenç[1], Sevgi Aslan Tuncay[1], Seyhan Yılmaz[1], Burcu Parlak[1], Aylin Dizi Işık[1], Birsen Baysal[2], Nurşah Eker[2], Eda Kepenekli[1]
[1]Marmara University School of Medicine, Pediatric Infectious Diseases, Istanbul, Turkey, [2]Marmara University School of Medicine, Pediatric Hematology And Oncology, Istanbul, Turkey

Title of Case: DISSEMINATED ADENOVIRUS INFECTION TREATED WITH CIDOFOVIR IN A CHILD WITH A SOLID TUMOR
Background: Human Adenovirus infection may be severe in immunocompromised patients, with multiorgan involvement and mortality around 50%. Disseminated adenovirus infection with acute hepatitis is uncommon in children undergoing standard chemotherapy. Most studies demonstrated that cidofovir is effective and safe in children. Here, we report a disseminated adenovirus infection associated with acute hepatitis, treated with cidofovir in a one-year-old immunocompromised child with relapsed neuroblastoma.
Case Presentation Summary: The patient has been admitted with diarrhea, coryza, and febrile neutropenia. Adenovirus PCR was positive in the nasopharyngeal aspirate. Nevertheless, supportive treatments and standard febrile neutropenia treatments were applied to the patient per the guidelines. After ten days of supportive, antibacterial, and antifungal therapy, the patient had pancytopenia, acute hepatitis, bloody diarrhea, macroscopic hematuria, and conjunctivitis and continued to have a recurring fever. There was no adequate response to oral intravenous immunoglobulin treatment. Her medical condition worsened. Then, cidofovir plus probenecid treatment was initiated. The fever subsided dramatically after the first dose of cidofovir. The transaminase levels decreased, the urine color cleared, diarrhea continued without blood, and the macroscopic hematuria did not recur after the second dose. After the third dose, all clinical findings regressed, the complete blood count returned to normal. The cidofovir treatment was continued on outpatient basis until the nasopharyngeal aspirate and stool Adenovirus PCR became negative. Nephrotoxicity was not observed during the treatment. Her clinical condition improved, hepatitis recovered, and chemotherapy for neuroblastoma was resumed.
Learning Points/Discussion: This case reveals the successful use of cidofovir to manage severe disseminated adenovirus infection in an immunocompromised child with a solid tumor.

MEET THE EXPERT POSTERS

Laia Baleta Riera[1], Katherine Quinan[2], Laura Ferreras Antolín[3], Borbala Zsigmond[3], Christopher Ward[4], Aodhan Breathnach[4], Amaya Bustinduy[3]
[1]Hospital Sant Joan de Déu Children's Hospital, Paediatrics, Esplugues de Llobregat, Spain, [2]St. George's NHS trust. London, Paediatrics, London, United Kingdom, [3]St. George's Hospital, Paediatric Infectious Disease, London, United Kingdom, [4]St. George's NHS trust. London, Miccrobiology, London, United Kingdom

Title of Case: Cutaneous Diphtheria in a family from Sri Lanka
Background: Cutaneous Diphtheria has been recently recognised as an emerging disease in Europe. The typical clinical features are well circumscribed round ulcers predominantly on the lower limbs. The diagnosis is made through swab culture and toxin gene testing of C.diphtheriae.
Case Presentation Summary: Two male siblings, aged 10- and 13-years, who had recently returned from Sri Lanka, attended an Accident and Emergency Department complaining of multiple ulcerated skin lesions of two weeks duration and no systemic symptoms reported. Well appearing children with multiple ulcerated lesions over all four limbs were found on examination. Wound swabs were sent for culture as well as routine laboratory investigations. They were both admitted to the Paediatric Infectious Disease ward with intravenous flucloxacillin and clindamycin. Results of both cutaneous cultures were positive for Corynebacterium diphtheriae, toxin positive, and therefore they were both diagnosed with Cutaneous Diphtheria. All close contacts were screened for the presence of C. diphteriae with a nasopharyngeal and throat swabs with no positive results. After receiving 72 hours of intravenous antibiotics both siblings were switched to oral with amoxicillin-clavulanate and clindamycin for a total of 10 days. Two follow up swab cultures were performed after finishing the treatment and remained negative. They received a booster dose of a diphtheria-toxoid containing vaccine.
Learning Points/Discussion: Cutaneous Diphtheri should be included in the differential diagnosis of skin lesions of returning travellers' as the disease remains endemic in many countries. When the diagnosis is suspected, a swab culture should be performed and start treatment with an oral macrolide for 14 days. All patients should be isolated until two cultures remain negative. Close contact tracing should be performed and they should receive both vaccination and chemoprophylaxis.

AMOEBIC LIVER ABSCESS IN A 6-YEARS-OLD GIRL: A CASE REPORT

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Nina Berdianu[1], Ana Margarida Garcia[2], Cristina Gonçalves[3], Catarina Gouveia[2]
[1]Hospital de Dona Estefânia - Central Lisbon Universitary Hospital Center, Paediatrics, Lisbon, Portugal, [2]Hospital Dona Estefânia - Central Lisbon Universitary Hospital Center, Paediatrics Infectious Diseases Unit, Lisbon, Portugal, [3]Hospital Dona Estefânia - Central Lisbon Universitary Hospital Center, Paediatrics Gastroenterology Unit, Lisbon, Portugal

Title of Case: AMOEBIC LIVER ABSCESS IN A 6-YEARS-OLD GIRL: A CASE REPORT
Background: Amebiasis is a parasitic disease caused by Entamoeba histolytica, which mainly affects people from developing countries. The majority of individuals have intestinal tract infections. Occasionally, they can present with extraintestinal infection, most commonly liver abscess.
Case Presentation Summary: We describe a 6-years-old girl, born and resident in São Tomé and Principe evacuated to Portugal due to a hepatic abscess. She presented recurrent episodes of abdominal pain and fever for 4 years. No other significant medical or surgical history was present. On physical examination she presented deep abdominal left flank tenderness, without hepatomegaly. Abdominal computed tomography revealed a heterogeneous liver hypoechoic mass, 40 x 33 x 24 mm, with peripheral calcifications and two central necrotic regions, in segment 7 of the liver, suggestive of abscesses. Blood tests showed white cell count 9.8 × 10^9/L, C-reactive protein 9 mg/L, alkaline phosphatase 277 U/L, AST 25 U/L, ALT 14 U/L, bilirubin 0,14 mg/dl. Tumor markers, blood cultures, IGRA, HIV, Bartonella, Brucella and Echinococcus serology and stool parasitological examination were negative. Serology for Entamoeba histolytica (IgG) was positive and stool PCR was negative. Management included oral metronidazole. Abdominal ultrasound scan taken 1 year later showed calcification of the abscess and decreased size.
Learning Points/Discussion: Amoebic liver abscess can cause significant morbidity and mortality. Although there is a broad differential diagnosis, epidemiologic history and serology are important clues to the diagnosis. In this case, there was no need of surgical approach because of a good medical therapy response.

NEONATAL COLLAPSE: FORGET NOT THE VIRUS

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Khuen Foong Ng[1], Jolanta Bernatoniene[1], Stefania Vergnano[1], Anu Goenka[1], Marion Roderick[1], Siske Struik[2]
[1]Bristol Royal Hospital for Children, Paediatric Infectious Diseases And Immunology, Bristol, United Kingdom, [2]Children's Hospital for Wales, Paediatric Infectious Diseases And Immunology, Cardiff, United Kingdom

Title of Case: Neonatal collapse: Forget not THE virus
Background: The presentation of a neonate with poor feeding and respiratory distress is a common paediatric scenario. Whilst acute myocarditis is an uncommon cause of this presentation, rapid recognition and intensive care support gives these infants the best possible chance of survival. Therefore, it is important to consider cardiac causes, especially in the presence of inappropriate persistent tachycardia.
Case Presentation Summary: During September to December 2022, nine infants were admitted to PICUs in the Southwest of England and South Wales with neonatal enterovirus myocarditis (NEM) (incidence rate 65/100,000 person-years). All cases presented in extremis with reduced feeding, tachypnoea and cardiogenic shock with severe left ventricular dysfunction on echocardiography and NT-ProBNP over 35000pg/ml. They had laboratory features overlapping with haemophagocytic lymphohistiocytosis. Coxsackievirus B3 were documented in three patients and Coxsackievirus B4 in another three. SARS-CoV-2 antibody was positive in six infants but they were most likely maternally derived. Due to the severity of their condition, clinical trajectory and hyperinflammation, immunomodulation and antiviral therapy (where possible) were commenced. ECMO was considered in all patients but not initiated. No mortality was recorded up until 31-Dec-

Table 1: Demographics, laboratory and cardiac investigations, treatment and outcomes of the nine patients with neonatal myocarditis

† Enteral pocapavir 40mg/kg/day; obtained via the compassionate use scheme from Virodefense Ltd.

2022.

Learning Points/Discussion: Enterovirus is a common cause of neonatal infection but rarely leads to myocarditis. In NEM, the most frequently identified serotypes are coxsackievirus B, with a mortality rate of 40%. These infants are at high risk of arrhythmias. Our observation is significantly higher than the estimated background NEM incidence rate (3.1/100,000 person-years) with an incidence rate ratio of 20.8 (95% confidence interval 7.59-58.91). Whilst there is no agreed treatment, evidence from cardiac biopsies

suggests direct damage to myocytes with enterovirus replication and inflammatory infiltration. Intravenous immunoglobulin is frequently given although reports of benefit are anecdotal.

Title of Case: ENTEROVIRUS A71 AND NEUROLOGIC DISEASE: CASE SERIES OF A SINGLE PAEDIATRIC HOSPITAL
Background: Enterovirus A71 (EV-71) is a common cause of hand-foot-mouth disease but has emerged as a neurotropic agent. Our aim was to characterize clinical features and evolution of children with EV-71 neurologic disease. Retrospective observational study of paediatric patients (<18 years) with neurologic disease and detection of EV-71 from any biologic specimen in a tertiary-level paediatric hospital in Portugal, over a 5-year period (2018-2022).
Case Presentation Summary: Five children were identified, with a median age of 26 months (min 16 days, max 4 years old), 3 males and 4 became ill during September-October.The diagnosis were rhombencephalitis (2/5),rhombencephalomyelitis (n=1) and aseptic meningitis (n=1). Other diagnosis was viral sepsis with positive CSF EV71 PCR. Neurological symptoms identified were drowsiness (4/5), ataxia (2/5), non epileptic myoclonic jerks (1/5), hypotonia (1/5), diplopia (1/5) and dysautonomia (1/5). Other non-neurological symptoms were fever (4/5), vomiting (4/5), exanthema (2/5) and herpangina (2/5). CSF showed pleocytosis in 4/5 patients, 2/4 polymorphonuclear. MRI (n=3) showed increased T2-weighted signal in the dorsal part of the hindbrain, 2/3 involving the cerebellum and 1/3 including cervical and dorsal myelitis. PCR detected enterovirus in nasopharyngeal (5/5), stool (5/5), CSF (2/5) and blood (1/1).Three patients were treated: intravenous immunoglobulin (incipient bulbar symptoms-diplopia) (1/3), methylprednisolone (severe lethargy) (1/3) and both (flaccid paresis with autonomic dysregulation) (1/3). One patient required PICU admission. Median length of stay was 7 days [4;15]. At one month follow-up, no neurologic sequelae were found.
Learning Points/Discussion: EV-71 can cause serious neurologic disease. Early recognition and timely intervention are the key to reducing morbidity and mortality in moderate to severe neurologic disease. Randomized controlled trials are crucial to define best therapeutic management of these patients.

AN UNEXPECTED CAUSE OF RIGHT UPPER QUADRANT ABDOMINAL PAIN IN A TEENAGER

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Marta Pelicano, Mariana Eiras Dias, Rita Morais
Centro Hospitalar Lisboa Ocidental- Hospital São Francisco Xavier, Paediatrics, - Lisboa, Portugal

Title of Case: AN UNEXPECTED CAUSE OF RIGHT UPPER QUADRANT ABDOMINAL PAIN IN A TEENAGER
Background: Fitz-Hugh-Curtis syndrome is an association between pelvic inflammatory disease and perihepatitis, primarily attributable to Neisseria Gonorrhoeae and Chlamydia Trachomatis. Classically it manifests as pain in the right hypochondrium.
Case Presentation Summary: A previously healthy and sexually active 17-year-old female, was admitted with a 4-day history of right upper quadrant abdominal pain, associated with high fever and vaginal bleeding. On examination she had tenderness on palpation of the right hypochondrium. Gynecological observation showed sparse vaginal bleeding and pain on deep palpation and mobilization of the cervix and adnexa. Blood analysis revealed 16900/uL leukocytes and C-reative protein level of 259 mg/L. Abdominal ultrasound was inconclusive and abdominal CT showed signs of inflammation of the pelvic fat. The urine sample was PCR positive for Neisseria Gonorrhoeae, so pelvic inflammatory disease was assumed. She was started on oral doxycycline, intravenous ceftriaxone and metronidazole. During hospitalization, abdominal ultrasound revealed mild hepatomegaly and perihepatic free fluid. Fitz-Hugh-Curtis syndrome was diagnosed. The patient had clinical improvement and was discharged after 5 days, completing a 14-days course of treatment with oral doxycycline and metronidazole. On follow-up she had no abdominal signs or symptoms and had a negative vaginal swab PCR for Neisseria Gonorrhoeae and Chlamydia Trachomatis.
Learning Points/Discussion: Early detection and treatment of pelvic inflammatory disease is essential to prevent complications such as infertility. The nonspecific presentation of Fitz-Hugh-Curtis syndrome as a complication of pelvic inflammatory disease makes it a challenging diagnosis, however it should be considered in the differential diagnosis of right upper quadrant pain in the sexually active adolescent.

CASE REPORT: SEXUALLY TRANSMITTED INFECTIONS IN PEDIATRICS – ACQUIRED OR CONGENITAL?

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Vykinta Zeleckytė, Milda Šeškutė
Lithuanian University of Health Sciences, Paediatrics, Kaunas, Lithuania

Title of Case: CASE REPORT: SEXUALLY TRANSMITTED INFECTIONS IN PEDIATRICS – ACQUIRED OR CONGENITAL?
Background: A resurgence of syphilis is seen worldwide that results in increased number of infected children. Although most of the cases in young children are congenital, the possibility of acquired infection should not be forgotten. This case illustratesthe difficulties differentiating congenital and acquired syphilis in a young child.
Case Presentation Summary: A 5-year-old firstborn boy was referred for investigation for syphilis due to positive maternal tests during mother's second pregnancy who was found to have latent infection (RPR 1:4, TPHA 4+, anti-T.pallidum IgM/G 270 U/l). Detailed examination of the boy revealed active syphilis (RPR 1:16, TPHA 4+, anti-T.pallidum IgM/G 296 U/l) but no clinical signs of the disease. At first congenital infection was suspected as the results of syphilis screening tests of the first pregnancy were missing and the mother was treated with penicillin postpartum due to sepsis. However, the boy was found to have perianal dermatitis with suspected previous anal lacerations. The mother denied sexual abuse but the father who was also found to be positive was incarcerated, the boy spent most of his time with untested grandparents. As proofs of sexual abuse were lacking and congenital syphilis could not be ruled out, the patient received a 10-day course of penicillinG IV and was discharged home under the care of child protection services.
Learning Points/Discussion: 1. Sexual abuse should be ruled out in a young child with syphilis but may be difficult to prove. 2. Differentiation of congenital and acquired sexually transmitted infections in children might be challenging.

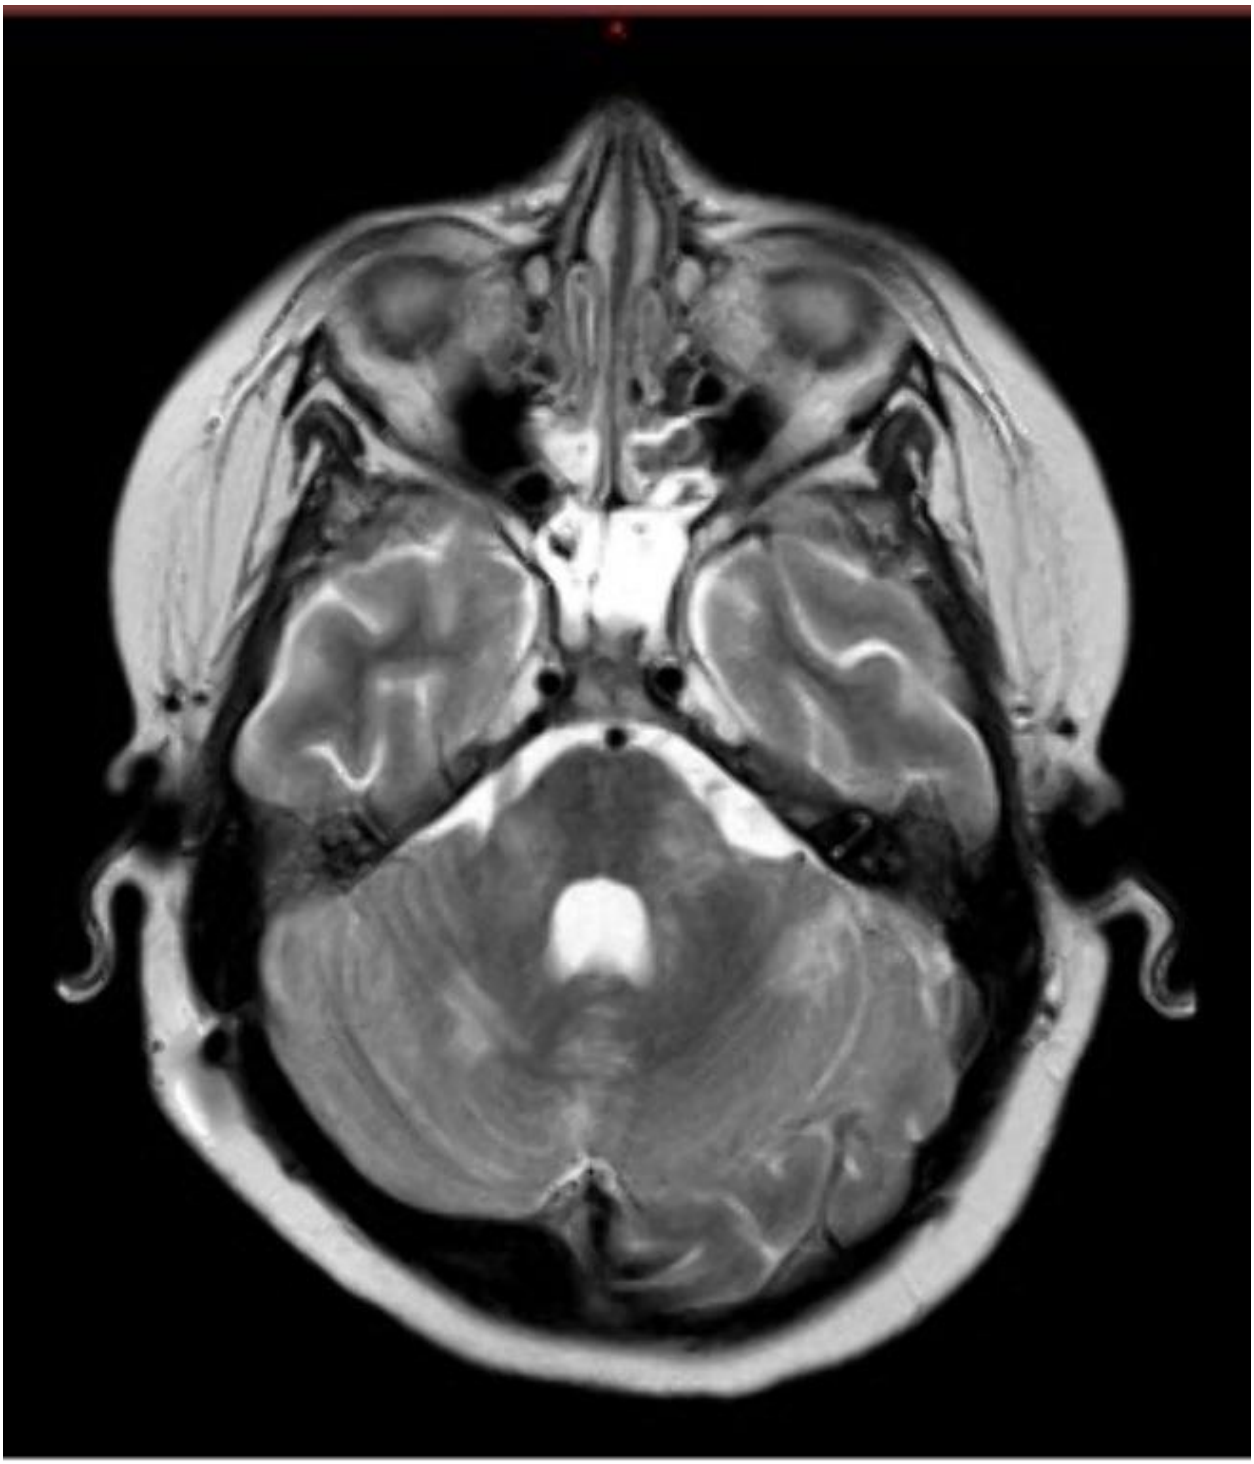
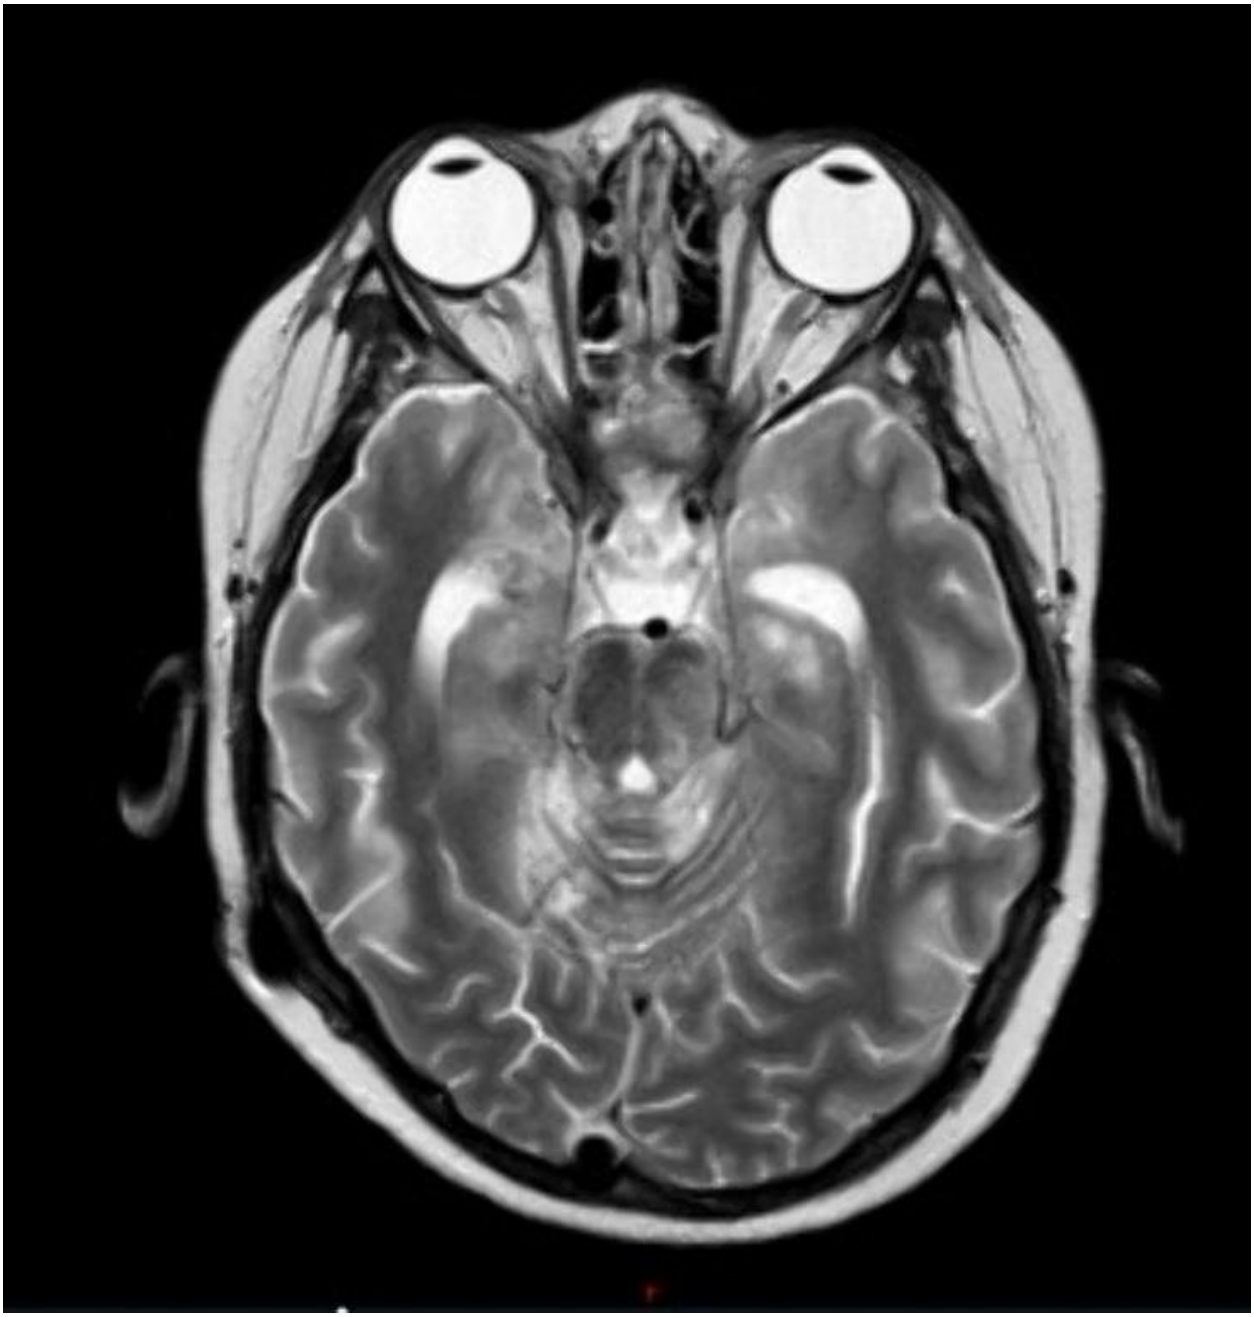
Title of Case: CHRONIC LYMPHOMONOCYTIC MENINGITIS IN A HEALTHY ADOLESCENT
Background: Histoplamosis is one of the most endemic mycoses in the Americas,although it is often underdiagnosed.Clinical presentation can be variable and some forms can progress to life-threatening illnesses.
Case Presentation Summary:





A 13 year old male,previously healthy,developed an insidious headache which progressed over the last 2 years.Investigation was started and included a number of analysis of Cerebrospinal Fluid(CSF)which showed low cell count(5-119 cels,mostly lymphocytes),low glucose(5 –27) and elevated protein(171-1500).Film array was negative in all samples.Brain MRI showed multiple heterogeneous lesions in the midbrain region and posterior fossa structures, with a predominance of hyperintensity on T2.Spine MRI showed multiple lesions with hyperintensity on T2 that affect the spinal cord at the cervical and thoracic levels, in addition to exuberant thickening and diffuse leptomeningeal enhancement in the vertebral canal.Due to the involvement of the brain, meninges and spinal cord, meningo-tuberculosis was hypothesized and treatment was initiated. However,there was no epidemiology,the PPD was non-reactive and the CSF PCR for M.tuberculosis was negative.The patient evolved with neurological worsening, lowered level of consciousness, recurrent seizures and left hemiparesis,requiring tracheal intubation.The investigation was expanded for Histoplamosis and the patient had a positive serology, positive antibody and positive antigen research in the CSF.Immunodeficiency and HIV were excluded.Amphotericin

B(5mg/kg/day)was started on 08/19/22,however there was no neurological improvement.Patient remains on MV(already with tracheostomy),with little contact with the environment.MRI already shows sequelae lesions.After 4 months of treatment,the patient maintains neurological lowering with the need for MV.The CSF antigen test remains positive,but decreasing titles.Amphotericin was suspended and oral posaconazole was started with a schedule of completing one year of treatment
Learning Points/Discussion: This case report brings an important alert for the suspicion of CNS histoplasmosis in chronic lymphomonocytic meningitis.

SEVERE PULMONARY ASPERGILLOSIS POST LIVER AND HAEMATOPOIETIC TRANSPLANT

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Ashwin Pandey, Khushnuma Mullanfiroze, Adilia Warris
Great Ormond Street Hospital, Infectious Diseases, London, United Kingdom

Title of Case: Challenges in treating Severe Pulmonary Aspergillosis Post Hepatic and Haematopoietic transplant
Background: Invasive pulmonary aspergillosis can pose high mortality risk in immunocompromised patients. There is need for innovative approach for treating such opportunistic infections.
Case Presentation Summary: 10 year old boy underwent Auxillary Liver tranplant for Non Hep A-E Hepatitis induced liver failure in September2020. Soon developed fever, his CT showed bilateral conslidations and pleural effusion. Soon grew Candida Guilliermodi from blood and Candida Fermentati from pleural fluid, treated with Ambisom+Caspofungin and later Isovucoazole was added due to worsening radiological findings. Had HSCT in November 2020 while on tripe antifungals, since lesions continued to progress and cavitate leading to haemoptysis, he underwent wedge excision of right upper lobe on 2/3/21 and then of Right lower lobe on October 2021. Aspergillus Falvus pcr were positive on both biopsy samples, but sensitivity failed. Hence were treated with multipe antifungals Ambisome+Caspofungin+Isavuconazole. Haemoptyis persisted with worsening cavitatory lesions, cardiothoracic team felt there was major risk of bleading as cavitations were very close to major arteries. Hence after expert advice from senior Mycologist and Interventional Radiologit he received Interventional Radiology guided percutaneous intralesional i.v Voriconazole in November 2021. Serial CT scans since then show stable bilateral multifocal areas of bronchiectatic change with cavitation and endoluminal soft tissue nodularity and no new areas of nodularity. No further Haemoptysis episodes sinece April 2022 and contiues to be on IV Caspofungin + oral isavuconazole with aim to complete minium 2 years of antifungal treatment. He is 14 months post HSCT with good immune reconstitution.
Learning Points/Discussion: High index of suspicion/early treatment remains mainstay for treating invasive fungal infections. Intralesional Antifungal therapy should be considered Availability of expert Mycologist is essential in transplant units.

Title of Case: A RARE CASE OF EMPYEMA NECESSITANS CAUSED BY STREPTOCOCCUS PNEUMONIAE IN A 6-YEAR-OLD GIRL
Background: Empyema necessitans is a complication of empyema, characterized by the spontaneous extension of purulent material outside the pleural space, into the soft tissues of the chest wall. Herein we report a rare case of a 6-year-old girl with Pneumococcal empyema necessitans.
Case Presentation Summary: A 6-year-old girl, with no significant past medical history and a full immunization schedule, including the 13-valent conjugate pneumococcal vaccine, presented with respiratory distress, following a 1-week history of cough and fever. Upon physical examination, the patient was found ill-appearing, febrile, tachycardic, tachypneic with abolished breath sounds in the lower left lung. Imaging findings indicated a large left-sided pleural effusion. The patient was started on empiric broad-spectrum antibiotics and underwent a left pleurotomy. Gram stain of the fluid demonstrated many leukocytes and Gram-positive cocci in diplo, while cultures were positive for Streptococcus Pneumoniae. However, the fever did not resolve and 4 days after admission, an enlarging, painful, erythematous mass on the left abdominal flank was noticed. A contrast CT scan was ordered, which revealed that the purulent material had spread to the left anterior abdominal wall and to the left lumbar region (Figure 1). The patient was diagnosed with empyema necessitans. The invasive nature of the empyema led to 2 more surgical interventions and 4 drain tubes inserted. 33 days after admission, the drain tubes were removed, as both the clinical and radiological picture
improved.

Figure 1. Coronal contrast CT scan demonstrating the extension of the empyema

Learning Points/Discussion: Pneumococcal empyema necessitans is a rare finding in the present-day, especially in the pediatric population. The most common etiology is tuberculosis, followed by actinomycosis, pneumococcal and staphylococcal infection.

STAPHYLOCOCCUS NECROTIZING PNEUMONIA IN A CHILD WITH COVID-19

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Dwiyanti Puspitasari[1], Dominicus Husada[2], Ismoedijanto Moedjito[1], Leny Kartina[2], Parwati Basuki[2]
[1]Faculty of Medicine Airlangga University, Pediatrics, Surabaya, Indonesia, [2]Soetomo General Hospital, Pediatrics, Surabaya, Indonesia

Title of Case: STAPHYLOCOCCUS NECROTIZING PNEUMONIA IN A CHILD WITH COVID-19
Background: Clinical manifestations of COVID-19 is usually milder in children, but some children do require hospitalization and intensive care. Twenty-five percent of older children with SARS-CoV-2 may had secondary bacterial infections. Staphylococcus aureus is a major human pathogen causing a wide range of clinical infection, including bacteremia, skin and soft tissue infection and pleuropneumonia. This report aim to present a case with Staphylococcus necrotizing pneumonias as COVID-19 co-infection in a child.
Case Presentation Summary: An eleven-year-old boy was referred from previous hospital due to pneumonia and fever which not improved after 10 days of intravenous Levofloxacin and Gentamycin. Blood culture taken on first admission revealed MRSA sensitive to both antibiotics given, positive COVID-19 PCR. Chest x-ray evaluation showed worsen pneumonia, bilateral pleural empyema, and necrotizing pneumonia was shown from the Chest CT-scan. WBC was 38,510/mm3, neutrophil 90%, thrombocytosis, increased CRP, anemia, hypoalbuminemia and D-dimer 3060. Chest tube drainage was inserted and pleural fluid culture revealed MRSA, and repeated COVID-19 PCR already negative. Treatment given were Vancomycin for 20 days, enoxaparine, anemia and hypoalbuminemia correction. Fever was resolved on days-4 of Vancomycin, and the patient was discharged in good condition.
Learning Points/Discussion: COVID-19 in children may present with severe manifestation in patients with co-morbid diseases or bacterial co-infection. Staphylococcus aureus was one common cause of bacterial co-infection especially with necrotizing pneumonia characteristics. Other common causes was Streptococcus pneumonia. Vancomycin should be considered as the treatment of choice in MRSA infections, especially if clinical improvements were not observed after adequate treatment with sensitive antibiotics.

Title of Case: Severe infection in an infant
Background: Staphylococcus aureus is a major human pathogen.Panton-Valentine leukocidin (PVL) is a virulence factor produced by some strains that causes leukocyte lysis and tissue necrosis.PVL-associated S.aureus (PVL-SA) predominantly causes skin and soft-tissue infections (SSTIs)but can also cause invasive infections such as necrotizing pneumonia.
Case Presentation Summary: A 35-week gestation preterm male on day 24 of life previously healthy was referred to our hospital for poor feeding and fever.He deteriorated within hours,intubated due to respiratory distress,and referred to the Neonatal Intensive Care Unit (NICU).He was initially managed with ampicillin and amikacin and then changed to meropenem and vancomycin.He was extubated the next day and commenced on humidified high-flow nasal cannula oxygen.Blood culture taken upon admission was positive for Methicillin-Resistant SA (MRSA).A day later, he exhibited reduced mobility of the right leg with oedema along with a respiratory deterioration requiring intubation.Chest contrast-enhanced CT scan revealed necrotizing pneumonia and MR imaging demonstrated osteomyelitis of the right sciatic bone. Blood culture and bronchoalveolar lavage grew MRSA.Second blood and bronchoalveolar lavage sample cultures also grew MRSA. Suspected PVL-SA-related infection was confirmed by endpoint PCR amplification of MRSA-PVL and MecA genes and validated with SangerdideoxyDNA sequencing.Treatment was changed to gentamicin, ceftarolin and linezolid.A gradual improvement of symptoms and general condition occurred.Ceftarolin was discontinued after 3wks and linezolid after 5wks.He was discharged with oral co-trimoxazole for a total treatment of 8wks.Due to nasal carriage of his mother for PVL- MRSA, both parents received intranasal mupirocin.There was no respiratory compromise or other residual SA complication noticed in follow-up.
Learning Points/Discussion: Our report highlights the importance of improving awareness of this severe infection.High suspicion and vigilance for a life-threatening PLV-SA infection is essential for a prompt diagnosis and adequate treatment.

OFF-LABEL USE OF CEFTAZIDIME AVIBACTAM IN INFANT WITH HOSPITAL-ACQUIRED PNEUMONIA CAUSED BY PANDRUG-RESISTANT KLEBSIELLA PNEUMONIA INFECTION: A CASE REPORT

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Sirma I Mada, Nina Dwi Putri, Rinawati Rohsiswatmo
Cipto Mangunkusumo National Hospital, Faculty of Medicine University of Indonesia, Child Health Department, Jakarta, Indonesia

Title of Case: OFF-LABEL USE OF CEFTAZIDIME AVIBACTAM IN INFANT WITH HOSPITAL ACQUIRED PNEUMONIA CAUSED BY PANDRUG-RESISTANT KLEBSIELLA PNEUMONIA INFECTION: A CASE REPORT
Background: The prevalence of pan drug-resistant (PDR) Klebsiella pneumonia infection has increased immensely in pediatric unit. This has been a crucial health issue because of the limited choices of antimicrobial agents in pediatric population.
Case Presentation Summary: We reported a case of a full term small for gestational age infant with gastroschisis who was referred to our hospital since 2 days old. Multiple surgical interventions were conducted to repair gastroschisis. Following the surgeries, her condition was improved gradually. However, within one week, she displayed signs of pneumonia and sepsis with significant increase of C-reactive protein and procalcitonin. She required high frequency oscillatory (HFO) ventilation, inotropic agents, and empiric antibiotics. Subsequent endotracheal tube (ETT) aspirate culture and two-site blood cultures results were PDR K. pneumonia infection. Intravenous antibiotic regimens were given, including cefepime, fosfomycin, cefoperazon sulbactam, amikacin, tigecyline, polymyxin B, imipenem, and ceftazidime. The blood culture result was sterile after administration of polymyxin B for the second times. Hemodynamic was stable, yet the patient could not wean HFO ventilation for 4 weeks and the ETT aspirate cultures were persistent for PDR K. pneumonia. Therefore, intravenous ceftazidim avibactam was administered for 10 days with dose of 50 mg/kgBB/dose q8h. Pneumonia was resolved, HFO was changed to conventional ventilator on day 8^{th} of ceftazidime avibactam treatment, and extubation was performed on day 10^{th}. After completion of ceftazidime avibactam treatment, low dose dexamethasone therapy was given for bronchopulmonary dysplasia. The patient recovered fully and was discharged after 100 days of hospitalization.
Learning Points/Discussion: Administration of ceftazidime avibactam appears to be well tolerated and effective in pediatric with PDR K. pneumonia infection.

ACINETOBACTER BAUMANNII EARLY ONSET SEPSIS - NOSOCOMIAL OR COMMUNITY ACQUIRED?

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Patrícia Sousa[1], Beatriz Sousa[1], Joana Neves[2], Francisca Calheiros Trigo[2], Mariana Martins[2], Clara Paz Dias[2]
[1]Hospital Senhora da Oliveira - Guimarães, Pediatrics, Portugal, Portugal, [2]Hospital Senhora da Oliveira - Guimarães, Neonatology, Portugal, Portugal

Title of Case: Acinetobacter baumannii Early Onset Sepsis - Nosocomial or Community Acquired?
Background: Early onset sepsis (EOS) is most frequently caused by organisms acquired intrapartum. It affects term neonates lessfrequently than preterms, but is an important cause of morbidity and mortality
Case Presentation Summary: We present the case of a term neonate with an unsupervised pregnancy born by eutocic home delivery in the toilet. At hospital admission he presented with polycythemia due to late cord clamping, hypothermia, and hypoglycemia. Forty-eight hours after birth he became pale and presented with prolonged capillary refill time, temperature instability, thrombocytopenia, and an elevated C reactive protein (110.7 mg/L). Following the suspicion of EOS, antibiotic therapy with ampicillin and cefotaxime was started and then switched to meropenem after Acinetobacter baumannii complex was isolated from blood culture, with no documented drug resistances. Cerebrospinal fluid culture was negative. Meropenem was continued for 21 days. Despite the overall improvement, severe thrombocytopenia persisted (minimum 4000/uL), requiring seven platelet transfusions and one dose of intravenous immunoglobulin, and resolving on the 14th day of life, along with the polycythemia. There was no maternal thrombocytopenia and maternal platelet antibodies were negative. Because the father's identity was not confirmed, further studies were non-viable. On the 17th day of life, the patient developed neutropenia (minimum 500/uL), which resolved by the 27th day of life.
Learning Points/Discussion: Neonatal sepsis by Acinetobacter baumannii incidence is increasingh worldwide, but it is usually associated with late onset sepsis. This is the first case in our unit. Despite being more frequently associated with nosocomial infection, the birth circumstances may have been the origin in this case. Severe and prolonged thrombocytopenia could be sepsis-related or immune in etiology. Neutropenia was most likely caused by treatment with meropenem.

NEONATE WITH COVID-19 RELATED ENCEPHALOPATHY

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

Eleni Salonidi, Christos Mpiliris, Polyxeni Pelekouda, Anastasia Varvarigou, Gabriel Dimitriou, Despoina Gkentzi
Patras Medical School, Paediatrics, Patras, Greece

Title of Case: NEONATE WITH COVID-19 RELATED ENCEPHALOPATHY
Background: Neurological manifestations of COVID-19, although rare, have been described in children. Non specific neurological symptoms, such as headache are common in older children yet specific neurological deficits such as seizures or encephalopathy are less prevalent
Case Presentation Summary: We present a a twin girl born at 35 weeks through c-section, who tested positive for COVID-19 on day 10 of life, and hospitalization was required due to a suspected episode of apnea. On day two she had further episodes of apneas as well as clonic, myoclonic and migratory seizures. She subsequently developed signs of encephalopathy with thermoregulation disturbance, hypotension, and lethargy. She was hypotonic with weak primitive reflexes. Blood tests demonstrated hypoglycaemia and elevated D-dimers with normal fibrinogen. Empirical antibiotics, remdesivir, acyclovir and anticonvulsants were started. Cerebrospinal fluid (CSF) analysis was normal for her age and all virological PCR samples (including SARS-CoV2, HSV type 1, 2) and cultures were negative. Screening for inborn errors of metabolism, neurotransmitters, congenital infections, ECG and chest radiogram did not reveal any abnormalities. Brain MRI showed multiple bilateral white matter signal abnormalities and restricted diffusion, particularly in the frontal lobes and corpus callosum. Given the severe clinical presentation and neuroimaging findings, previously described as being associated with COVID-19, the most likely diagnosis was COVID-19 related encephalopathy. Hence, she was given steroids (prednisolone 1mg/kg for 5 days and intravenous IVG (400mg/kg). The neonate had an uneventful further course on the ward and and discharged on day 24 of life. Of note, four months later her follow up MRI was normal and neurodevelopmental assessment age appropriate.
Learning Points/Discussion: Although extremely rare, clinicians should be aware of the possibility of COVID-19 associated severe central nervous system involvement in neonates.

WHEN VARICELLA-ZOSTER VIRUS “OPENS THE DOOR” – A CASE REPORT OF STREPTOCOCCUS PYOGENES SOFT TISSUE INFECTION TREATED WITHOUT SURGICAL INTERVENTION

E-Poster Meet the Expert
MEET THE EXPERT POSTERS

David Rabiço-Costa[1], Laura Leite De Almeida[1], Débora Valente Silva[1], Ana Melo[1,2], Artur Vítor[1,2]
[1]Department of Paediatrics, São João University Hospital Centre, Porto, Portugal, [2]Pediatric Infectious Diseases and Primary Immunodeficiencies Unit, Department Of Paediatrics, São João University Hospital Centre, Porto, Portugal

Title of Case: WHEN VARICELLA-ZOSTER VIRUS “OPENS THE DOOR” – A CASE REPORT OF STREPTOCOCCUS PYOGENES SOFT TISSUE INFECTION TREATED WITHOUT SURGICAL INTERVENTION
Background: Primary varicella infection in children has been associated with an increased incidence of invasive group A streptococcal soft tissue infection including cellulitis, myositis, necrotizing fasciitis, and toxic shock syndrome.
Case Presentation Summary:

A 12 months-old male, all vaccines up-to-date, was taken to the Paediatric Emergency Department for presenting fever every 6h, Tmáx:40.5ºC, with 2 days of evolution and pain in the right shoulder region with limitation to mobilisation, a discrete irritative cough and partial refusal to eat since the day before. Chickenpox was established the day before the onset of fever. At admission, reasonable general condition with vesiculo-papular exanthema with scattered crusts. Noteworthy, a redness, heat and swelling right shoulder. Remaining examination was unremarkable. Patient underwent blood tests, blood culture and shoulder radiography and ultrasound, of which highlight: Erythrocytes:9.4g/dL, Leukocytes:23.4x10^9/uL (Neutrophils:67%, Lymphocytes:21%), C-Reactive Protein:303mg/L, Lactate Dehydrogenase:475U/L, Alanine aminotransferase:39U/L. Shoulder radiography was normal. Ultrasound revealed thickening and densification of subcutaneous cellular tissue, without joint effusion or collections. Patient started on IV acyclovir, clindamycin and flucloxacillin. Blood culture was positive for Streptococcus pyogenes which prompt change to penicillin G. Magnetic resonance imaging revealed an elongated liquid collection in muscles of posterior face of shoulder and diffuse oedema of the muscular planes. During hospitalisation there was an improvement in clinical and laboratory tests. Last shoulder ultrasound revealed resolution of the previous soft tissue alterations. He was discharged home with shoulder mobility

restored and completed 4 weeks of antibiotic.
Learning Points/Discussion: The early start of antibiotics shaped the outcome of this case and allowed the excellent evolution with only medical treatment and close monitoring.

Title of Case: Purpura fulminans Secondary to Varicella-zoster Infection
Background: Purpura fulminans is a rare, life-threatening syndrome with disseminated intravascular coagulation and intravascular thrombosis, causing purpura and necrosis in the skin and soft tissue. The most common type is acute infectious purpura fulminans, and the most common viral agent is varicella zoster. Here we present 4 years old Tajiki girl with purpura fulminans secondary to varicella-zoster infection.
Case Presentation Summary: A 4-year-old Tajiki girl presented with red-purple, diffuse, painful lesions localized to the whole right leg. Her vaccination status was unknown in her history, and there was not a concomitant chronic illness. 10 days before admission, she was admitted to another hospital in Tajikistan with a diagnosis of chickenpox and purpura fulminans. Then she was transferred to our hospital due to enlargement of her lesions to the gluteal region, a change in color of her lesions from red to black, and detection of arterial thrombosis in the Doppler ultrasound.

Figure 1. Her necrotic right leg In our hospital, fresh frozen plasma, thrombolytic, and anticoagulant treatments were started. Multiple surgical debridements were performed for necrotic tissues. In surgical debridement specimens, Candida spp., Acinetobacter baumannii, Enterococcus faecium, Escherichia

Coli, Stenotrophomonas maltophilia, and Bacteroides fragilis were yielded. Her right leg amputation is planned.

Learning Points/Discussion: Vaccination can prevent Varicella zoster and its life-threatening complications such as purpura fulminans. As pediatricians, we need to support every child getting their vaccines.

CEFTZIDIME-AVIBACTAM USE IN CHILDREN ADMITTED IN PEDIATRIC INTENSIVE CARE UNITS

E-Posters Viewing
E-POSTER VIEWING: AS01.A. NOVEL ANTIMICROBIAL TREATMENTS

André Ricardo Araujo Da Silva[1], Rafael Quijada[1], Cristina Souza[2], Cristiane Teixeira[2]
[1]Universidade Federal Fluminense, Materno Infantil, Niterói, Brazil, [2]Prontobaby, Infection Control Comittee, Niterói, Brazil

Backgrounds: Ceftazidime-Avibactam (CAZ-AVI) is one of the new antibiotics available to treat infections due to carbapenem-resistant Gram-negative bacteria. The aim of the manuscript is to describe CAZ-AVI treatments in chidren admitted in pediatric intensive care units (PICUs).
Methods: We conducted a retrospective desciptive study in two PICUS of Rio de Janeiro city, Brazil, between January 2020 and December 2022. We included children between 0 and 18 years that used CAZ-AVI por more than 24 hours. Duration of CAZ-AVI use, previous healthcare-associated infections and carbapenem use, length of stay and outcome in 30 days. All treatments were previouly discussed with a infectious disease specialist.
Results: CAZ-AVI was used in 29 patients. Median of age was 23 months, 13 (44.8%) were male. Median time of admission until the initial day of CAZ-AVI prescription was 36.6 days (variation between 1-138 days). Twenty-five (86.2%) children had at least one comorbity, 27/29 (93.1%) used at least one invasive device previously CAZ-AVI presciption, 26/29 (89.7%) used carbapenem before and 9 (31%) had a HAI before CAZ-AVI use. The mean time of use was 10.9 days (variation 1 to 22 days). Eleven (37.9%) patients presented positive cultures to Gram-negative bacteria in the 24h before presciption or in the day of presciption. Mortality in 30 days was 11/29 (37.9%).
Conclusions/Learning Points: Almost all patients that used CAZ-AVI were critical children, with multiple comorbidities, previouly use of carbapenem and high rate of mortality.

IN VITRO ACTIVITY OF CEFTAROLINE AND CEFTRIAXONE AGAINST CLINICAL ISOLATES OF STREPTOCOCCUS PNEUMONIAE WITH DIFFERENT SUSCEPTIBILITY TO PENICILLIN FROM CHILDREN WITH INVASIVE AND NON-INVASIVE DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS01.A. NOVEL ANTIMICROBIAL TREATMENTS

Charilaos Dellis, Elizabeth-Barbara Tatsi, Dimitra-Maria Koukou, Athanasios Michos, Vasiliki Syriopoulou
National and Kapodistrian University of Athens, First Department Of Pediatrics, Infectious Diseases And Chemotherapy Research Laboratory, Medical School, Athens, Greece

Backgrounds: This study assessed the susceptibility to ceftaroline and ceftriaxone of Streptococcus pneumoniae isolates with different susceptibility to penicillin from children with invasive pneumococcal disease (IPD) and non-IPD.
Methods: Pneumococcal isolates equally divided according to their susceptibility to penicillin (one-third penicillin-sensitive, one-third with intermediate susceptibility and one-third penicillin-resistant) were randomly selected among isolates collected over the years 2010-2020 at our laboratory from children with IPD and non-IPD. Antimicrobial susceptibility testing to penicillin, ceftriaxone and ceftaroline was performed by E-test. The CLSI susceptibility breakpoints were used. Pneumococci were serotyped by latex agglutination and the Neufeld-Quellung reaction using anti-sera (Statens Serum Institute, Copenhagen, Denmark). Alterations in the structure of penicillin-binding protein (PBP) genes were identified by PCR.
Results: A total of 360 pneumococcal isolates from children (median age: 24 months) were included. Regarding ceftriaxone, 69.4% of the isolates were sensitive, 18.1% had intermediate susceptibility and 12.5% were resistant. Although all 360 isolates were sensitive to ceftaroline, the MICs ranged, with the majority (93.9%) having MIC ≤0.125 μg/ml. Non-IPD isolates exhibited higher MICs than IPD isolates (p-value < 0.001). The majority of penicillin-resistant (88/120, 73.3%) and ceftriaxone-resistant isolates (32/45, 71.1%) had MIC to ceftaroline >0.06 and ≤0.125 μg/ml. There were 22 isolates with MIC to ceftaroline >0.125 μg/ml, mainly identified as serotype 19A (77.3%). 99.2% of the penicillin-intermediate isolates had at least 1 PBP-gene mutation, the most frequent profiles being pbp1a only, pbp2x only. All penicillin-resistant and all ceftriaxone-intermediate and resistant isolates had at least 1 PBP-gene mutation, the most frequent profiles being pbp2x + pbp1a, pbp2b + pbp2x + pbp1a.
Conclusions/Learning Points: Ceftaroline exhibited potent in vitro activity against a collection of pneumococcal isolates from Greece, highlighting its value as a treatment option.

Background: Atrocious antibiotic usage has led to the development of multi-drug resistance (MDR) in uropathogenic Escherichia coli (UPEC) leading to mortality in urinary tract infections (UTIs). Hence, we are exploring phage encoded-lysins as alternatives to treat UTIs. Our study involved an in silico strategy for the discovery and characterization of lysin sequences (seq) targeting E. coli cell wall and evaluating the bactericidal activity of these recombinant lysins using in vitro assays.
Methods: Novel lysin sequences were searched by BLAST homology and by screening E. coli prophages in the database (using PHASTER). Lysozyme-like domain was observed in 9/16 lysins. Their characterization depicted modular or globular structure. Based on physicochemical properties, 7/16 were selected for cloning, expression, and purification as recombinant proteins for evaluating bactericidal activity.
Results: Among the several endolysins identified, lysin seq 5 demonstrated highest activity using in vitro assays. Using static biofilm assay, seq 5 showed efficient reduction (>50%) in the biofilm formation by resistant ATCC UPEC 700928 strain. Using spot on lawn assay, seq 5 also showed inherent bactericidal activity on ATCC UPEC 700928 strain at higher concentration. At lower concentration, seq 5 exhibited lytic activity using outer membrane permeabilizers such as EDTA on ATCC 25922 as well as ATCC 700928 strain. Furthermore, turbidity reduction method showed a drop of 74.94% in OD_{600nm} on BL21 DE3 cells treated with seq 5 after 3 hrs of incubation at 37°C. Log killing assay displayed 4 $\log_{10}$ reduction on BL21 DE3 lysin treated cells. Lysozyme assay also corroborated in silico analysis and showed comparable lysozyme activity with the positive control.
Conclusions/Learning Points: Seq 5 exhibited highest activity against E. coli strains especially the UPEC strain. Screening E. coli clinical isolates from UTI patients is underway.

ISAVUCONAZOLE USE IN CHILDREN WITH INVASIVE FUNGAL DISEASE: TERTIARY PAEDIATRIC CENTRE EXPERIENCE

E-Posters Viewing
E-POSTER VIEWING: AS01.A. NOVEL ANTIMICROBIAL TREATMENTS

Clara Izquierdo Antó[1], Sílvia Simó Nebot[1], Mónica Sánchez Celma[2]
[1]Hospital Sant Joan de Déu, Infectious Diseases, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Déu, Pharmacy, Esplugues de Llobregat, Spain

Backgrounds: Isavuconazole (ISA) is a promising antifungal agent for the treatment of invasive fungal diseases (IFD) due to its broad spectrum of action, favorable interaction and safety profile. However, there is still limited experience of its use in children. Objective: To describe ISA use in our current clinical practice in terms of indication, dosage, therapeutic drug monitoring (TDM), clinical outcomes and toxicity.
Methods: Retrospective observational study, describing all pediatric patients who received ISA as treatment for IFD in our center from January 2016 until December 2022.
Results: Eleven patients were included, 7 males and 4 females, with a median age of 14 years (5-17) and weight of 48 kg (17-63) (Table 1). Most of them had relapsed or refractory malignant diseases and/or have received an alloSCT. ISA was administered at 10 mg/kg/8h for the first 48h, followed by 10 mg/kg/24h (200 mg/dose max), for a median duration of 31 days (2-214). Therapeutic levels were reached at 5th day of treatment in most cases, but dose had to be increased in 4 of them. Adverse events (increased transaminase and/or creatinine levels) were observed in 8 patients, all of them non clearly associated with ISA or with multifactorial cause. The overall response rate was 45% and nearly half of the patients (5/11) died, either because of IFD (60%) or disease progression (40%).

Case no.	Sex	Age (y)	Weight (kg)	Disease	Type of IFD	Site of IFD	Pathogen	Previous treatment	Reason to use ISA	Co-antifungal	ISA dose	Duration (days)	Time to first levels (days)	Time to reach levels (days)	IFD outcome	Mortality (Cause of death)	Adverse events (grade)
1	M	15	60	L	Possible	Lung		L-AMB + VCZ	Toxicity		Standard (iv)	2			P	D (Disease)	↑AST/ALT (g3), ↑Cr (g1)

7	F	17	37	PID	Probable	Lung		L-AMB	Toxicity/IFD progression	L-AMB	Increased (iv → po)	122	10	19	CR	A	↑AST/ALT (g2), ↑Cr (g1)
8	F	16	48	PID	Possible	Oral mucosa			Toxicity	L-AMB	Increased (iv)	38	12	33	CR	A	↑AST/ALT (g1), ↑Cr (g1)
9	M	5	21	BMF	Possible	Lung			Toxicity		Standard (iv)	14	4	4	P	D (Disease)	↑Cr (g2)
10	M	16	63	ALL	Possible	Lung		L-AMB + PCZ	Toxicity		Increased (iv)	35	4	16	CR	A	None
11	M	14	48	BMF	Possible	Lung		L-AMB + VCZ	Toxicity		Standard (iv)	35	5	5	P	D (IFD)	↑AST/ALT (g3), ↑Cr (g3)

Table 1. Overview of patient characteristics.

Abbreviations: M: male, F: female. L: lymphoma, AML: acute myeloid leukemia, AUL: acute undifferentiated leukemia, ALL: acute lymphoblastic leukemia, MDS: myelodysplastic syndrome, BMF: bone marrow failure, PID: primary immunodeficiency, SID: secondary immunodeficiency. CNS: central nervous system. L-AMB: liposomal amphotericin B, VCZ: voriconazole, PCZ: posaconazole, AFG: anidulafungin. iv: intravenous, po: oral. CR: complete response, SD: stable disease, P: progression. D: death, A: alive. AST: aspartate aminotransferase, ALT: alanine aminotransferase, Cr: creatinine.

Conclusions/Learning Points: ISA seems to have a favorable interaction and safety profile in children. However, as there is variability in the time to reach therapeutic levels, we recommend TDM in this population. We need further studies with a larger sample size to better evaluate ISA efficacy, as it was used as a salvage drug in the majority of cases.

Background: Production of filamentous bacteriophages such as Pf1 or Pf4 by Pseudomonas aeruginosa has been shown to be associated with increased bacterial resistance to phagocytosis and decreased inflammatory response of the host, which accounts for chronic lung infections in CF subjects. Moreover, the inactivation of endogenous antimicrobial molecules and positively-charged antibiotics as a result of their electrostatic interaction with bacteriophage was previously described. Additional studies are necessary to understand the role of Pf-like bacteriophages in infections caused by P. aeruginosa from the perspective of their pathophysiology and treatment.
Methods: This study aimed to evaluate the antibacterial activity of ceragenins against clinical isolates of P. aeruginosa using strains that differ based on their ability to express Pf-like bacteriophages. Minimal inhibitory concentrations (MICs) of ceragenins CSA-13, CSA-44, and CSA-131 were estimated using the broth dilution method, while the P. aeruginosa biofilm mass developed in the presence of ceragenins [administrated alone or combined with DNase I or poly-aspartic acid (pASP)], was assessed using crystal violet staining.
Results: The results obtained indicate that ceragenins retain strong antimicrobial activity, both against strains with bacteriophage expression and isolates that do not produce bacteriophages. Moreover, ceragenins are able to significantly prevent the formation of biofilm by P. aeruginosa. When administrated together, ceragenin CSA-13 displays an increasing effect in combined therapy with pASP and DNase, although higher sensitivity characterized strains lacking production of bacteriophages.
Conclusions/Learning Points: Our data strongly suggest the potential of ceragenins to develop a new treatment against P. aeruginosa-caused chronic lung infections in CF subjects. Funding: This work was financially supported by grants from the National Science Centre, Poland: UMO-2018/30/M/NZ6/00502 (RB)

PERIORBITAL AND ORBITAL CELLULITIS IN CHILDREN IN ARMENIAN HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS01.A. NOVEL ANTIMICROBIAL TREATMENTS

Tehmine Ghalechyan, Magda Sarukhanyan, Tamara Simonyan
Wigmore hospital for children, Pediatric, Yerevan, Armenia

Background: Periorbital cellulitis is a skin and soft tissue infection anterior to the orbital septum, and orbital cellulitis is an infection posterior to the orbital septum. Our aim is to describe the importance of prompt initiation of antibiotic therapy in both conditions.
Methods: We included patients hospitalized at “Wigmore hospital for children” in Armenia, from May 1, 2021, to February 1, 2023, with PC and OC diagnoses based on clinical characteristics and CT scans. Data were extracted from patients’ medical records retrospectively.
Results: The study included 27 patients (females 17 (63%), males 10 (37%), mean age of 4.7 years). 21 cases were with PC (77.8%) and 6(22.2%) with OC, and complications (periosteal or orbital abscess) were seen in 5 cases (18.5%). CT scan was done in 11 cases (40.7%) and 17.8% of patients with PC and OC had evidence of sinusitis on CT scan. Haemophilus spp ., Corynebacterium spp., Peptostreptococcus spp., Staphylococcus aureus, and Moraxella catarrhalis were identified with eye swab culture. Blood culture was taken only in severe cases and was negative. All patients were treated initially with intravenous antibiotics, 66.7% of patients were treated with amoxicillin/clavulanic acid, 25.9% only with Ceftriaxone, and 7.4% with combination of Ceftriaxone, Metronidazole and Vancomycin. The duration of antibacterial treatment was 7-42 days. Surgical drainage was performed in 2 (7.4%) cases and both cases were diagnosed late with inappropriate antibiotic therapy for about two weeks. All patients were discharged with improvement. Follow-up was unremarkable for more than one month.
Conclusions/Learning Points: Prompt initiation of intravenous antibiotics is mandatory and can prevent surgical procedures even in cases with incipient abscesses. Severe complications and surgical interventions are more common for late-diagnosed cases with inappropriate antibiotic therapy.

EFFECTIVE TREATMENT OF XDR PSEUDOMONAS AERUGINOSA ENDOCARDITIS IN A CHILD WITH CEFTOLOZANE-TAZOBACTAM: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS01.A. NOVEL ANTIMICROBIAL TREATMENTS

Giulia Sturniolo, Cecilia Liberati, Daniele Donà, Giovanni Di Salvo, Marica De Pieri
University of Padova, Division Of Pediatric Infectious Diseases, Department Of Women's And Children's Health, Padova, Italy

Title of Case: Effective treatment of XDR Pseudomonas aeruginosa endocarditis in a child with Ceftolozane-tazobactam: a case report
Background: Extensive drug-resistant P. aeruginosa (XDR-PA) infections represent a therapeutic challenge in pediatrics, for the limited antimicrobial possibilities. Furthermore, PA is a rare cause of infective endocarditis. Ceftolozane-tazobactam is a novel beta-lactam/beta-lactamase inhibitor combination with a potent anti-pseudomonal activity, currently approved by the European Medicines Agency for the treatment of complicated intra-abdominal infections and complicated urinary tract infections in children.
Case Presentation Summary: A 7 year-old boy with a history of surgically repaired complete atrioventricular canal was admitted for high fever in the previous week. Physical examination revealed a new systolic heart murmur, and echocardiography showed a macrovegetation on the left atrio-ventricular valve, suggestive of infective endocarditis. He was known to be colonized with MDR P.aeruginosa from previous hospitalizations. The work-up for disseminated foci was negative, and antibiotic treatment was initiated with ampicillin, cefazolin and gentamicin. After 48 hours the patient had persisting high fever with increased inflammatory markers, and therapy was shifted to meropenem and gentamicin. After multidisciplinary discussion, a surgical approach was excluded. On day 4 of antibiotic treatment, XDR P. aeruginosa was isolated in blood and antibiotic therapy was shifted to off-label ceftolozane-tazobactam plus amikacin in accordance with antimicrobial susceptibility testing. After 48 hours the patient showed clinical improvement and became afebrile. Weekly monitoring with echocardiography showed reduction of the vegetation and disappearance by week 6. Therapy was continued for 6 weeks, without recurrences or complications in the following 6 months.
Learning Points/Discussion: Albeit very rare, PA can cause endocarditis in colonized patients with predisposing conditions. Ceftolozane-tazobactam, although not approved to treat bloodstream infections, proved to be safe and showed an effective bactericidal activity against XDR-PA infective endocarditis.

[1]Bambino Gesù Children's Hospital, Infectious Disease Unit, Roma, Italy, [2]Bambino Gesù Children's Hospital IRCCS,, Cardiology And Cardiac Surgery, Pediatric Cardiac Intensive Care Unit, Rome, Italy, [3]Bambino Gesù Children's Hospital IRCCS,, Unit Of Microbiology And Diagnostic Immunology, Rome, Italy, [4]Bambino Gesù Children's Hospital IRCCS,, Hospital Pharmacy Unit, Rome, Italy

Backgrounds: The global spread of carbapenem resistant organisms (CROs) is an important threat to vulnerable populations worldwide. Currently, the antibiotic options for CROs are very limited. Recently, potentially promising new antibiotics have become available such as novel cephalosporins. However, strong comparative data towards older drugs are lacking, especially in the pediatric setting. Here we describe a cohort of pediatric patients affected by CROs infections admitted in a cardiac ICU treated with novel cephalosporins (N-CEF) compared to Colistin-based regimens (COLI).
Methods: All patients admitted to the Cardiac-ICU of the Bambino Gesù Children's Hospital in Rome during the 2016-2022 period and treated with novel cephalosporins or Colistin for an infection caused by a CRO were enrolled.
Results: Data were collected from 29 patients, 12 treated with N-CEF (ceftazidime/avibactam, ceftolozane/tazobactam, cefiderocol) and 17 treated with COLI. Age, baseline comorbidities and the reason of CICU admission were similar between the two groups. The most common type of CRE infections in both sets was hospital acquired pneumonia. P.aeruginosa was the predominant pathogen in both groups. A carbapenemase production was detected in 38% of cases and the VIM gene was the predominant gene in both groups. Eight of twelve patients (67%) in the N-CEF group and five (29%) of seventeen in the comparative group achieved clinical remission ($p = 0.04$). Moreover, after thirty days, all-cause mortality was observed in 1 patients in the N-CEF group and in 3 patients in the comparative group. One patient died for CRO infections in the COLI group, while no deaths were recorded in the other group.
Conclusions/Learning Points: In pediatric patients with severe CRO infection, N-CEF is a reasonable alternative to standard therapy. These findings need to be confirmed in larger prospective studies.

ESCHERICHIA COLI ANTIMICROBIAL RESISTANCE IN THE LAST 6 YEARS IN A PEDIATRIC POPULATION FROM NORTHERN SPAIN. A RETROSPECTIVE ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Méndez-Sánchez A[1], Pérez-Méndez C[1], Calle-Miguel L[2], Rodríguez-Lorenzo P[1], De La Iglesia-Rivaya A[1], De La Iglesia-Martínez P.A.[3]
[1]Hospital Universitario de Cabueñes, Pediatrics, Gijón, Spain, [2]Hospital Universitario Central de Asturias, Pediatrics, Oviedo, Spain, [3]Hospital Universitario de Cabueñes, Microbiology, Gijón, Spain

Backgrounds: The aim of this analysis is to evaluate the antimicrobial resistance pattern of Escherichia coli in urinary tract infections (UTI) in a pediatric population from a single center in Asturias (northern Spain).
Methods: Retrospective study included patients up to 14 years old with isolation of E. coli in urine samples from January 2016 to December 2021. The minimum inhibitory concentrations and their interpretation according to the EUCAST criteria (version from 2022) for different antibiotics were analyzed (Table). A comparative analysis between two periods (2016-2018 vs 2019-2021) was done.
Results: A total of 923 samples (clean catch: 735; urinary catheterization: 178; urine bag: 10) from 751 patients were included [79.0% females; median age: 4.67 years (0.00-13.97 years)]. Twenty of the 923 samples (2.16%) were extended-spectrum beta-lactamase (ESBL) producers. In the analysis by periods (table) a decrease in the rate of resistance to ampicillin and gentamicin was detected. No significant differences in the rate of ESBL between the two periods were observed.

Table: Comparison between two periods in the rate of antibiotic resistance and ESBL in E. coli from urine samples.

	2016-2018	2019-2021	p
Ampicillin	54.5	47.3	0.029
Amoxicillin-clavulanic acid	18.4	15.0	0.164
Cefuroxime	4.3	3.2	0.354
Cefotaxime	2.5	2.7	0.817
Cefixime	No data	3.3	-
Imipenem	0.2	0	0.340
Gentamicin	9.7	5.9	0.032
Amikacin	2.0	1.6	0.614
Fosfomycin	1.4	0.5	0.125
Trimethoprim-sulfamethoxazole	20.9	20.0	0.548
Nitrofurantoin	0.6	0.5	0.565
ESBL	1.7	2.7	0.264

Conclusions/Learning Points: The rate of resistance to ampicillin, amoxicillin-clavulanic acid, and trimethoprim-sulfamethoxazole render them unsuitable for the empiric treatment of E. coli UTI in our area. An increase in E. coli susceptibility to ampicillin and gentamicin was observed along the study period. No rise in the prevalence of ESBL-producing E. coli was observed.

PV0010 / #1957

AMIKACIN, AN ALTERNATIVE TO MAJOR ANTIMICROBIAL CLASSES AS EMPIRIC TREATMENT FOR URINARY TRACT INFECTIONS IN INFANTS

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Elena Andone[1], Anca Ilea[1], Laura Bleotu[1], Oana Falup-Pecurariu[1,2]
[1]Children's Emergency Clinic Hospital, Brașov, Romania, Pediatrics, Brasov, Romania, [2]Transylvania University, Faculty Of Medicine, Brasov, Romania

Backgrounds: Urinary tract infection (UTI) represents a significant cause of morbidity in children and one of the main reasons for antibiotic treatment. The purpose of this study was to evaluate the distribution of uropathogens, antimicrobial resistance rates and the outcome of Amikacin as an empiric treatment.
Methods: Monocentric retrospective study performed at Children's Emergency Clinical Hospital, during 2016-2022 among children under 12 months of age with UTI treated with Amikacin. The enrolled infants were divided into 2 groups: one who received empiric treatment with Amikacin and another who received other antibiotics as empiric treatment, followed by Amikacin after the DST.
Results: The most common pathogen was E. coli (53,5% of which 43,3% ESBL), followed by Klebsiella pneumoniae (31,3% of which 50% ESBL and 6,25% CRE), Klebsiella oxytoca, Citrobacter spp, Enterococcus spp, MRSA (3,92% each) and Pseudomonas aeruginosa (1,96%). The antimicrobial resistance rates of E. coli were 80%, 76,6%, 50%, 53,3% and 6,6% for Ampicilin, Amoxicilin, Ceftriaxone, Gentamicin and Amikacin. Regarding Klebsiella pneumoniae, the antimicrobial resistance rates were 100%, 100%, 81,2%, 75% and 12,5% for the formentioned antibiotics. Klebsiella oxytoca, Citrobacter spp, Enterococcus spp, Pseudomonas aeruginosa and MRSA hadn't proved any resistance to Amikacin. 43% of infants were included in the Amikacin empiric treatment group and 47% in the group with other antibiotics empiric treatment. The two groups had similar results, although the first group tended to have a lower fever resolution time after beginning Amikacin therapy (1,20 versus 1,51 days on average) and decreased treatment duration (5,6 versus 6,1 days on average).
Conclusions/Learning Points: Amikacin remains an alternative to empiric treatment, due to increasing resistance rates for major antimicrobial classes, saving carbapenems for more severe infections.

PV0011 / #437

CHANGES IN ANTIBACTERIAL RESISTANCE AFTER CORRECTION OF FEBRILE NEUTROPENIA GUIDELINES IN PEDIATRIC PATIENTS TREATED FOR ONCOLOGICAL AND HEMATOLOGICAL DISEASES

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Barbara Avizenis[1,2], Goda Vaitkeviciene[2,3], Inga Ivaskeviciene[1,2], Lauryna Aukstikalne[4]
[1]Vilnius University Hospital Santaros Klinikos, Paediatrics Centre, Vilnius, Lithuania, [2]Faculty of Medicine, Vilnius University, Clinic Of Children Diseases, Institute Of Clinical Medicine, Vilnius, Lithuania, [3]Vilnius University Hospital Santaros Klinikos, Center For Pediatric Oncology And Hematology, Vilnius, Lithuania, [4]Vilnius University Hospital Santaros Klinikos, Department Of Biomedical Research, Vilnius, Lithuania

Backgrounds: Bloodstream infections are the major cause of morbidity and mortality in children with cancer and non-malignant hematological diseases. Local epidemiological data are necessary to tailor empirical treatment. The aim of the study was to evaluate microbiological profile and antimicrobial resistance data and compare with the data from previous period when antimicrobial treatment was changed due to high resistance: ciprofloxacin was stopped as prophylactic agent; meropenem was introduced instead of piperacillin/tazobactam for empirical febrile neutropenia treatment.
Methods: An audit of positive blood cultures was performed at a tertiary care hematology center from 2018-2022. Etiology and antibiotic resistance data of BSI were compared with the results from 2010-2016 period.
Results: A total of 205 positive bacterial culture episodes were identified in 84 consecutive patients. Boys and patients <5 years predominated (N=140/205 (68.3%) and N=110/205 (53.7%), respectively). The majority of BSI were documented in patients with hematological malignancies (N=161/205, 78.5%). Most episodes (N=159) developed in patients with neutropenia <0.5x10*9/L (77.6%), including 115/159 cases with neutrophils <0.1x10*9/L. E. coli and coagulase-negative Staphylococcus (CoNS) predominated among gram-negative (GNB) and gram-positive (GPB) bacteria (N=21/64 (31.2%) and N=70/139 (50.4 %), respectively). GNBs were resistant to ciprofloxacin (11/43 GNB tested (25.5%)) and piperacillin/tazobactam (7/40 (17.5%)), particularly Klebsiella spp. In GNB, the lowest resistance rate of N=1/41 (2.4%) and N=3/43 (6.9%) revealed for amikacin and meropenem. No resistance to vancomycin or linezolid in GP was documented. As compared to 2010-2016, resistance to meropenem increased from 2.2% to 6.9% and decreased to piperacillin/tazobactam from 34.5% to 17.5%.
Conclusions/Learning Points: GNB sensivity to piperacillin/tazobactam improved over time after discontinuation of this drug as a first-line agent for febrile neutropenia. Regular evaluation of antibacterial resistance and subsequent corrections of the empiric antimicrobial treatment guidelines is necessary.

DETERMINATION OF ANTIBIOTIC RESISTANCE PATTERN OF BACTERIA ISOLATED FROM INVASIVE SAMPLES IN NEONATAL INTENSIVE CARE UNIT OF UNIVERSITY CLINICAL CENTRE OF KOSOVO

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Rrezarta Bajrami[1], Greta Lila[2], Arsim Kurti[1]
[1]National Institute of Public Health of Kosovo, Microbiology, Pristina, Kosovo, [2]University Clinical Center of Kosovo, Clinical Microbiology Laboratory, Pristina, Kosovo

Backgrounds: Background: Bacterial infections account for a huge proportion of neonatal deaths wordwide, especially in developing countries. Inappropriate use and administration of antibiotics can contribute to the resistance and spread of infection. In this study, we determined the antibiotic resistance pattern of the bacteria isolated from invasive clinical samples in the neonatal intensive care unit (NICU) of University Clinical Centre of Kosovo during 2019.
Methods: For the purposes of the study, clinical samples of blood and CSF were collected from the NICU of University Clinical Centre during 2019. The type of bacterial strain and antibiotic susceptibility pattern was determined by routine microbiological tests. The collected data were analysed in SPSS software (version 19), using $\chi 2$, Student's t-test, and ANOVA test for comparison.
Results: In total,188 positive culture samples were collected for this research. Resistance levels for E.coli and K.pneumoniae among blood and CSF isolates to third-generation cephalosporins (cefotaxime/ ceftriaxone) in E.coli 17 isolates (41%) and K.pneumoniae 55 isolates (85 %), resistance level to aminoglycosides (gentamicin/tobramycin) were high in E.coli 17 isolates (although based on a small number of isolates) (29%) and very high in K. pneumoniae isolates 55(82%). Resistance levels for P.aeruginosa and Acinetobacter spp. among blood and CSF isolates to Imipenem /Meropenem it's high , P.aeruginosa isolates 13(77%) and Acinetobacter spp isolates 70(89%) also resistance level to aminoglycosides (gentamicin/tobramycin) were high in P.aeruginosa isolates 13(69%) and Acinetobacter spp isolates 70(90%).
Conclusions/Learning Points: Conclusion: Continuous surveillance for antibiotic susceptibility, rational use of antibiotics, and the strategy of antibiotic cycling can provide some answers to the emerging problem of antibiotic resistance.

IN VITRO ACTIVITY OF LEVONADIFLOXACIN AGAINST GRAM POSITIVE PATHOGENS ISOLATED IN PEDIATRIC CANCER PATIENTS

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Sanjay Biswas
TATA MEMORIAL HOSPITAL, Microbiology, MUMBAI, India

Backgrounds: The growing incidence and severity of infections due to Gram-positive pathogens throughout the world have presented clinicians with therapeutic dilemmas. Infections caused by Staphylococcus aureus account for a significant percentage of nosocomial infections, such as bacteremia, pneumonia, and skin and skin structure infection. Vancomycin, teicoplanin, linezolid and daptomycin are the common antibiotics used for Staphylococcus aureus infections. Levonadifloxacin is a novel broad-spectrum agents against Staphylococcus aureus including methicillin resistant S. aureus (MRSA).
Methods: A total of 35130 samples were received in the Dept of Microbiology, Tata Memorial Hospital, Mumbai, from January - December 2022. All samples were processed as per routine microbiological methods and identification and antimicrobial susceptibility testing was performed on VITEK-2. Antimicrobial susceptibility testing for levonadifloxacin was performed by disc diffusion method.
Results: Of the 35130 samples received in the laboratory, urine was the most common specimen followed by wound swabs, blood, bile, drain fluids, sputum, BAL and pus. Of the 35130 samples, 9380 showed growth of pathogens. 73 % of the pathogens were Gram Negative Bacilli and 27% were Gram Positive Cocci growth. Staphylococcus aureus (was the predominant organism amongst Gram Positive Cocci growth followed by Enterococcus spp , Group A Streptococcus and Group D Streptococcus and other Streptococcus spp. Of the 475 isolates of Staphylococcus aureus, 51.6% were MRSA. Vancomycin, teicoplanin, linezolid, daptomycin and levonadifloxacin showed susceptibility of 100% whereas gentamicin showed 76% and clindamycin showed 60% susceptibility.
Conclusions/Learning Points: Levonadifloxacin and its ester oral prodrug, alalevonadifloxacin, are the broad-spectrum benzoquinolizine subclass of quinolones having activity against multi-drug-resistant Gram-positive pathogens including MRSA. The 100% susceptibility of isolates to levonadifloxacin observed in this study supports its potential clinical use in the treatment of infections caused by MRSA and other Gram-positive organisms.

STAPHYLOCOCCUS AUREUS RESISTANCE TO EMPIRICALLY USED ANTIBIOTICS IN PEDIATRIC EMERGENCIES: IS CLINDAMYCIN STILL A GOOD ALTERNATIVE?

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Natalia Mateos Sanchez, Lluis Galmés Rosselló, Jaime Carrasco-Colom, Lidia Ciudad Aguilar, Isabel Viñuela Díaz-Moro, Xavier Mulet Aguiló, Nuria Gilabert Iriondo, Maria José Pérez García, Joaquín Dueñas Morales
Hospital Universitario Son Espases, Paediatric Infectious Diseases, Palma de Mallorca, Spain

Backgrounds: Staphylococcus aureus infections are frequent in Pediatric Emergency Departments (PED). Attention is usually paid to methicillin-resistant strains (MRSA). The objective is to determine the evolution of resistance of S.aureus against antibiotics used empirically and to analyze its clinical implications.
Methods: Retrospective observational study. S.aureus positive cultures from patients attended in the PED of a tertiary hospital (01/01/2018-12/31/2021) were included. Those considered contaminants were excluded. Past history (devices, surgery or admission in the previous 6 months, antibiotics in the previous 2 months, previous infections by S.aureus), clinical and microbiological data were collected. Community origin was considered if they didn't present any of the first 3 items. Data were compared regarding susceptibility status to the analyzed antibiotics.
Results: There were 335 positive cultures (328 patients, 59.7% women, mean age 5.4 years (SD 4.7). The most frequent diagnoses were cellulitis/abscesses (34.4%), scalded skin syndrome (12.9%) and osteomyelitis (8.6%). The most frequent empirical treatments were amoxicillin-clavulanate (67%) and cefadroxil (8%). 22.4% required change of antibiotic, half of them presented resistance to empirical treatment. 27.8% were admitted [average stay 4.7 days (1.2-9.6)]. MRSA rate was 14.6%, with a stable evolution in recent years. 85.7% were community-acquired. Compared with sensitive ones, patients with MRSA had more frequently previous S. aureus infections [OR 2.6 (1.12-6),$p<0.05$]. Clindamycin-resistant S. aureus (CRSA) rate was 16.4%, with an upward trend (2018: 9%, 2021: 22.9%). 60% were community-acquired. Compared with sensitive ones, patients with CRSA had more frequently previous admissions [OR 2.85 (1.54-53), $p<0.05$]. 98% of cultures were cotrimoxazole-sensitive.
Conclusions/Learning Points: MRSA rate remains stable, while CRSA rate reaches worrying levels. It is necessary to consider empirical treatment alternatives such as cotrimoxazole in cases with a higher risk of resistance.

SURVEILLANCE OF ANTIMICROBIAL RESISTANCE IN CHINESE CHILDREN FROM 2017 TO 2021

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Yingying Wang, Na Wang, Qingwu Jiang, Chaowei Fu
Fudan University, Department Of Epidemiology, Shanghai, China

Backgrounds: The epidemic of antimicrobial resistance have become a serous challenge worldwide. This study aimed to analyze the antimicrobial resistance in Chinese children from 2017 to 2021, in order to provide a basis for rational use of antibiotics in clinical practice.
Methods: The data of antimicrobial resistance were collected from children aged less than 14 years in 13 tertiary children hospitals in China from 2014 to 2021. Antimicrobial susceptibility was tested using Kirby-Bauer method, penicillin susceptibility of streptococcus pneumonia was detected by E-test. The annual percentage change (APC) was used to analyze the time trend of antimicrobial resistance.
Results: A total of 312567 isolates were collected from 2017 to 2021, of which 40.9% (127778) was gram-positive organisms and 59.1% (184789) was gram-negative organisms. The strains isolated from newborns (≤28d), children aged less than 1 year, 1-3 years, 3-5 years and 5-14 years accounted for 12.0%, 37.3%, 18.3%, 12.2% and 20.2%, respectively. The top five isolates were Escherichia coli (13.2%), Streptococcus pneumonia (11.9%), Straphylococcus aureus (11.1%), Haemophilus influenza (10.3%), Klebsiella pneumonia (6.6%). The prevalence of cefuroxime-resistant E. coli and K. pneumonia gradually decreased from 58.1% to 47.5% (APC= -5.14%, P<0.001), and 68.8% to 49.0% (APC= -9.25%, P=0.021), respectively. The prevalence of ciprofloxacin-resistant E. coli and levofloxacin-resistant S. aureus gradually increased from 32.3% to 40.3% (APC= 7.65%, P=0.044), and from 4.4% to 5.8% (APC= 9.30%, P=0.041), respectively. The resistance rates of carbapenem-resistant E. coli (CRE) to class I-IV cephalosporins ranged from 71.8% to 99.5%.
Conclusions/Learning Points: The prevalence of ciprofloxacin-resistant E. coli, levofloxacin-resistant S. aureus, gentamycin-resistant CR-ABA and levofloxacin-resistant CR-PAE gradually increased in Chinese children from 2017 to 2021. The detection rates of CRE in Chinese children kept at high levels.

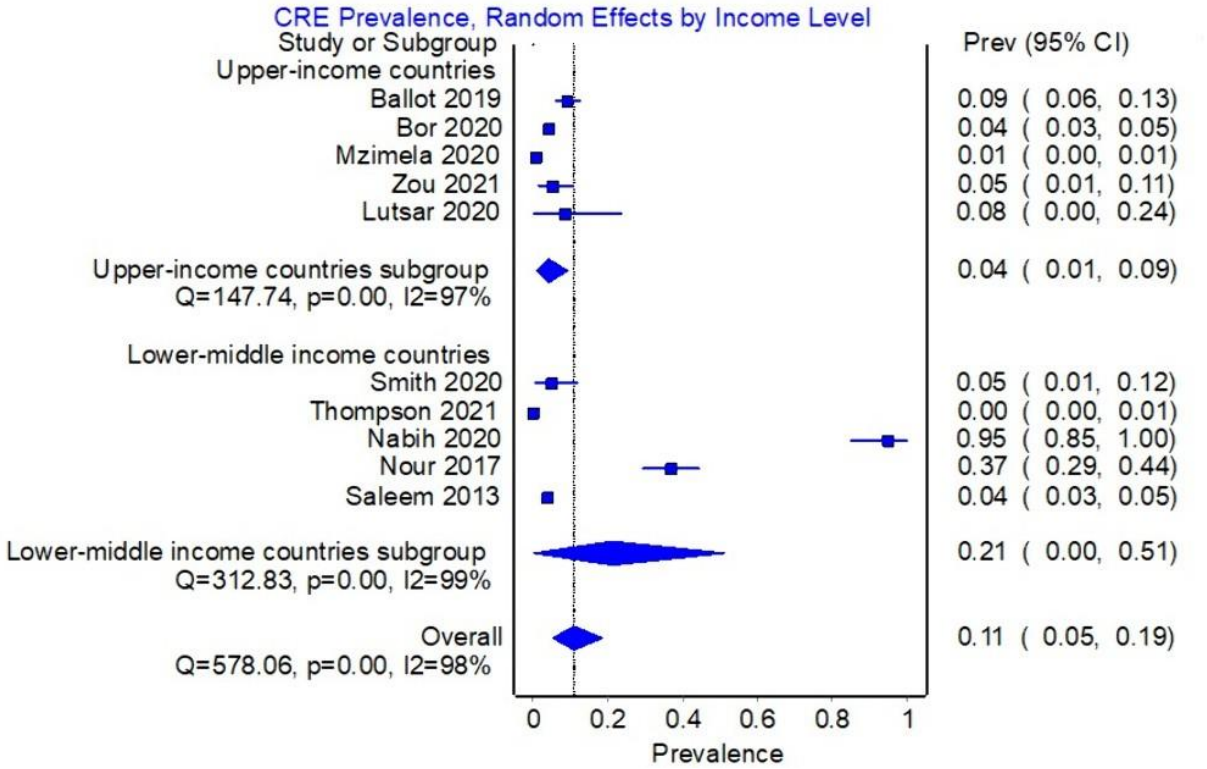
CARBAPENEM RESISTANCE ENTEROBACTERIACEAE IN LATE-ONSET NEONATAL SEPSIS AS EMERGING THREAT: SYSTEMATIC REVIEW AND META-ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Nida Ghitha[1], Lowilius Wiyono[1], Dina Clarisa Rumora Abigail[1], Nabila Vathania[1], Nina Dwi Putri[2]
[1]Universitas Indonesia, Faculty Of Medicine, Jakarta, Indonesia, [2]Cipto Mangunkusumo Hospital, Department Of Child Health, Faculty Of Medicine, Universitas Indonesia, Jakarta, Indonesia

Backgrounds: Carbapenem-resistant enterobacteriaceae (CRE) is a great concern in neonatal sepsis. With an increasing incidence and very limited therapeutic options in neonatal sepsis, these organisms worsen clinical outcomes, increase morbidity, and mortality. Therefore, this systematic review and meta-analysis aims to quantitatively estimate the prevalence, mortality rate, and risk factors of CRE in neonatal late-onset sepsis (LOS).
Methods: We conduct systematic search and screening process through several databases (PubMed, ScienceDirect, EMBASE, and Global Health EBSCO) based on predetermined PICO criteria on studies regarding CRE in neonatal LOS. Included studies were assessed for quality assessment with Newcastle-Ottawa Scale. Data extraction on prevalence, mortality rate, risk factors, and bacteria species were retrieved. Random-effect meta analysis was conducted using MetaXL software.
Results: 1395 studies were obtained at first hit. 133 duplicates were removed and 10 studies (4 cross-sectional, 2 case control, and 3 cohorts) were included. The meta-analysis showed a cumulative effect on a prevalence of CRE in neonatal LOS of 0.11 (95%CI: 0.05; 0.19); 0.04 (95%CI: 0.01; 0.09) from upper-middle income countries and 0.21 (95%CI: 0.00; 0.51) from lower-middle income countries. The prevalence of CRE mortality was 0.21 (95%CI: 0.09; 0.36). Risk factor include mechanical ventilation (OR 8.57 (95%CI:2.55; 27.73)), total parenteral nutrition (OR 1.15 (95%CI: 1.09; 1.29)), central vein device (OR 1.89 (95%CI: 0.22; 16.09)), carbapenem exposure (OR 0.27 (95%CI: 0.10; 0.72)), thrombocytopenia (OR 7.90 (95%CI: 4.69; 13.29)) from three studies, high CRP value (OR 0.27 (95%CI: 0.06;0.92)), and congenital anomalies (OR 4.25 (95%CI: 0.74;
24.37)).



Conclusions/Learning Points: Enterobacteriaceae found in neonates late-onset sepsis were more likely to be carbapenem-resistant. Strict infection prevention and control during first weeks of life is important to decrease mortality and morbidity caused by CRE.

REGIMENS IN PEDIATRIC INTENSIVE CARE UNIT PATIENTS WITH ENTEROBACTERIACEAE MULTIDRUG-RESISTANT INFECTIONS: A TEN-YEAR RETROSPECTIVE STUDY

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Joana Faustino[1], Lorena Stella[2], Anaxore Casimiro[3], Inês Salva[3], Joana Branco[3], Olinda Pereira[4], João Estrada[3], Catarina Gouveia[5]
[1]Hospital Dona Estefânia, Pediatrics Department, Lisbon, Portugal, [2]Hospital Dona Estefânia, Infectious Disease Unit, Lisbon, Portugal, [3]Hospital Dona Estefânia, Intensive Care Unit, Lisbon, Portugal, [4]Hospital Dona Estefânia, Local Coordination Group Of The Infection Prevention And Control Program And Antimicrobial Resistance, Lisbon, Portugal, [5]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatric Infectious Diseases Unit, Lisbon, Portugal

Backgrounds: Susceptibility to infection with gram negative microrganisms in PICU is increased, mainly due to the frequent use of invasive devices, , implying a growing number of manipulations, bacterial contamination, and colonization. This study aimed to identify the risk factors for 30-day mortality in PICU patients with Enterobacteriaceae multidrug-resistant (MDR) infections and compare the clinical outcomes and various antimicrobial regimens.
Methods: A retrospective, observational study was performed on patients admitted to the PICU with MDR Enterobacteriaceae infection, in accordance with the Magiorakos definition between January 2013 and December 2022. Data were obtained from patient records and analyzed using SPSS 22®.
Results: Forty-five patients were admitted to the PICU with MDR enterobacterial infections, 53% female, median age was 45 months (min 1, max 216 mo) and 91% (n=41) had history of underlying pathology. Sixty-four percent required mechanical ventilation and 28% had septic shock. The majority (96%) had at least one invasive device, central lines present in all cases. The correct choice of antibiotics was confirmed in 32 patients (71%), but adjustment to recent guidelines was 46%. The most frequently used antibiotic was meropenem (n=17). The most isolated Enterobacteriaceae was Klebsiella pneumonia on 23% (24 of the series). Thirty-day adjusted mortality risk factors were septic shock (OR 5,062;95% CI:1,140-22,485), neutropenia (OR 5,176; 95% CI:1,004-26,597) and immunodeficiencies (OR 7,111;95% CI:1,258-40,207). Overall mortality was 24% (n=11), but if adjusted to 30 days, 22% (n=10).
Conclusions/Learning Points: Our study suggests that MDR Enterobacteriaceae infections primarily affected children with immunosuppression and presentation is severe, with higher overall mortality despite antibiotic sensitivity testing oriented therapy.

EPIDEMIOLOGY AND ANTIBIOTIC SUSCEPTIBILITY PATTERNS OF PATHOGENS IN COMPLICATED APPENDICITIS IN CHILDREN. A 10-YEAR-STUDY IN A TERTIARY CARE HOSPITAL OF NORTHERN GREECE.

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Christos Kaselas[1], Elias Iosifidis[2], Maria Sekeroglou[1], Christina Trakateli[1], Ioannis Spyridakis[1]
[1]Aristotle University of Thessaloniki, 2nd Pediatric Surgical Department, Greece, Greece, [2]Aristotle University of Thessaloniki, 3rd Pediatric Department, THESSALONIKI, Greece

Backgrounds: The aim of this study was to identify the most common bacteria responsible for complicated appendicitis in children and their antimicrobial susceptibility in order to customize empirical antimicrobial treatment.
Methods: We reviewed all medical files of children 0-16 years-old with complicated appendicitis that were treated between 2012 and 2021 in a Pediatric Surgical Department. Inclusion criteria consisted of a) histopathological confirmation of complicated appendicitis and b) intraoperative culture sampling. Bacterial identification and antimicrobial susceptibility testing was performed using the VITEK 2 (Biomereux ®) automated system.
Results: A total of 107 children (57 males, 52.9%) with a mean age of 8.32±3.64 years were included. Mean preoperative abdominal pain duration was 60.50 ± 28.45h, mean WBC and neutrophil count was 17.02±6.23x10^3/mm^3 and 14.31±5.67x10^3/mm^3, respectively, and mean CRP value was 16.8±13.59 mg/dl. There were 21(19.6%) complications including 9 cases (8.4%) of surgical wound dehiscence. Among patients with a positive peritoneal fluid culture, Gram-negative bacteria were isolated in 75% cases and Gram-positive in 25%. Escherichia coli was the most commonly detected bacterium (51%) followed by Streptococcus species (19.4%) and Pseudomonas aeruginosa (17.6%). Gram-negative bacteria were highly susceptible to piperacillin/tazobactam (>99%), carbapenems (meropenem 100%), aminoglycosides (amikacin 100%), fluoroquinolones (ciprofloxacin 100%) and cephalosporins (>94% for cefepime and ceftazidime). Amoxicillin/clavulonate was active against 88.3% of Enterobacteriales and 90.4% of E. coli. Gram-positive bacteria were fully susceptible to vancomycin, linezolid and >78% of Streptococcus spp were susceptible to penicillin and ampicillin. None of the complications were correlated to any particular bacteria.
Conclusions/Learning Points: Low prevalence of antimicrobial resistance was found in this study. Piperacillin/tazobactam was highly active against most of the anticipating bacterial pathogens. Continuous evaluation of bacterial epidemiology and susceptibility testing of intraabdominal infections in children is needed for customizing empirical treatment.

EPIDEMIOLOGICAL DATA, CAUSATIVE AGENTS AND ANTIMICROBIAL RESISTANCE AMONG CHILDREN WITH URINARY TRACT INFECTIONS (UTIS) IN A GREEK TERTIARY HOSPITAL, ATHENS, GREECE

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Chrysi Aikaterini Georgokosta, Theano Lagousi, Ioanna Papadatou, Maria Noni, Niki Petropoulou, Athanasios Michos, Vana Spoulou, Christina Kanaka Gantenbein, Evanthia Botsa
National and Kapodistrian University of Athens, Athens, Greece, Infectious Diseases Department, Athens, Greece

Backgrounds: UTIs remain a major bacterial infection among children. Herein, we describe epidemiological data on the pathogenesis and antimicrobial resistance, focusing on pathogens resistant to common antimicrobials, associated with UTIS in children.
Methods: A retrospective study was performed among children aged 0-16 years. Epidemiological data, pathogenesis and antimicrobial resistance profile for children with UTIS were captured, covering a 3-month period (Oct 2022-Dec 2022). Antimicrobial susceptibility was determined by Kirby-Bauer disk diffusion method and VITEK.
Results: Overall, 160 microbiologically confirmed UTIS were collected; 73 (45,6%) were infants, 53,4% male. The commonest pathogen was E.coli (55%), incidence in infants was 72,6%, followed by Klebsiella spp (13,8%), Proteus mirabillis 10,6%, Pseudomonas aeruginosa (8,1%), Enterococcus spp 5%. A total of 33/160 samples were MDR (20,6%). No significant difference was recorded between genders. Among E. coli isolates, 11,4% were ESBL (Extended spectrum b-Lactamase); 27,3% of Klebsiella spp isolates were Klebsiella pneumoniae ESBL; 61,5 % of Pseudomonas aeruginosa isolates were MDR (multidrug resistance was defined as resistance to at least three drugs from a variety of antibiotic classes, mainly aminoglycosides, antipseudomonal penicillins, cephalosporins, carbapenems and fluoroquinolones).None of Proteus mirabillis species was MDR (Multidrug resistance was defined as nonsusceptibility to at least 1 agent in 3 or more of the following antimicrobial classes: oxyimino-cephalosporins, β-lactam–β-lactam inhibitor combinations, fluoroquinolones, trimethoprim-sulfamethoxazole, or aminoglycosides).Rare isolates resistant to common antimicrobials included Morganella morganii ESBL, Enterobacter cloacae AMP-C, Pseudomonas Putida (~3% each of MDR pathogens).
Conclusions/Learning Points: E. coli remains the main pathogen associated with UTIS in children, albeit high resistance rates have been recorded. Pathogens resistant to common antimicrobials comprised a significant percentage of all isolates associated with UTIS. To limit the emergence of resistance, every effort to minimize inappropriate antibiotic consumption is of paramount importance.

PAEDIATRIC CYSTIC FIBROSIS WITH PNEUMONIA DUE TO RESISTANT BACTERIAL ORGANISMS REQUIRING DESENSITISATION TO ANTIMICROBIAL THERAPIES

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Sophie Hon Yu Lai
Queen Mary Hospital, Hong Kong, Department Of Paediatrics, Hong Kong, Hong Kong PRC

Title of Case: PAEDIATRIC CYSTIC FIBROSIS WITH PNEUMONIA DUE TO RESISTANT BACTERIAL ORGANISMS REQUIRING DESENSITISATION TO ANTIMICROBIAL THERAPIES
Background: Multidrug resistant Pseudomonas Aeruginosa represents a frequently challenging nosocomial pathogen with resistance ranging from 11.5-24.7%. Among children with cystic fibrosis, it is a common of respiratory infections and leading cause of mortality. To further complicate the situation, antibiotic allergies are more frequent in this group of patients given the repeated exposure during their lifetime to numerous classes of antibiotics. Therefore, the combination of the above mentioned factors creates a therapeutic challenge for clinicians.
Case Presentation Summary: A 8 year old girl born to non-consanguineous Palestinian parents with cystic fibrosis complicated by worsening bronchiectasis. She has Piperacillin/tazobactam allergy with drug challenge proven anaphylaxis. She had a pulmonary exacerbation in which sputum culture grew Pseudomonas resistant to Ceftazidime, Imipenem, Piperacillin/tazobactam, Ciprofloxacin, Cefoperazone/sulbactam and moderate resistance to Ceftozolone/tazobactam. In view of the need for combination of intravenous antibiotics, she underwent drug desensitization to Ceftozolone/tazobactam in intensive care and completed 14 days combination regimen together with intravenous tobramycin to which her respiratory condition gradually improved. A 15 year old Chinese boy with cystic fibrosis with known Meropenem and Piperacillin/tazobactam allergy admitted for pulmonary exacerbation with gradual deterioration eventually requiring venovenous extracorporeal membrane oxygenation. His sputum grew Pseudomonas aeruginosa which was resistant to Piperacillin/tazobactam, Ceftazidime, Cefoperazone/sulbactam, Imipenem, Levofloxacin. He was given a combination of Ceftazidime/avibactam and tobramycin for which he had clinical response.
Learning Points/Discussion: Multidrug resistant Pseudomonas is a growing challenge for patients with cystic fibrosis prone to recurrent pulmonary exacerbations. Antibiotic allergies among this group of patients are also greater than the general population. Drug desensitization in the setting of intensive care may provide a promising option given the challenging circumstances.

LABORATORY SURVEILLANCE OF PAEDIATRIC BLOODSTREAM INFECTIONS AND ANTIMICROBIAL RESISTANCE IN ENGLAND: 2017 TO 2021

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Sarah Leaver[1], Rebecca Guy[1], Katherine Henderson[1], Berit Muller-Pebody[1], Alicia Demirjian[1,2,3]
[1]UK Health Security Agency, Hcai, Fungal, Amr, Amu, & Sepsis Division, London, United Kingdom, [2]King's College London, Faculty Of Life Sciences & Medicine, London, United Kingdom, [3]Evelina London Children's Hospital, Paediatric Infectious Diseases, London, United Kingdom

Background: To highlight trends in bacterial bloodstream infections (BSI) and antimicrobial resistance (AMR) in the paediatric population (0-17 years) in England between 2017 and 2021. This analysis complements the total population focus of the English Surveillance Programme for Antimicrobial Utilisation and Resistance (ESPAUR) report (2020-2021).
Methods: Reports of BSI and associated AMR from National Health Service laboratories in England between 01/01/2017- 31/12/2021 were extracted from UK Health Security Agency's (UKHSA) voluntary national laboratory database (SGSS). Statistical analysis was performed in STATAv17.
Results: A total of 15,928 BSI reports were identified from 2017-2021. Between 2020-21, Streptococcus pneumoniae and Enterococcus spp. BSI increased in children whilst Staphylococcus aureus BSI decreased. Gram-negative BSI increased in all key organisms (Escherichia coli, Klebsiella pneumoniae, Pseudomonas spp. and Acinetobacter spp.). Between 2020-21, K. pneumoniae resistance to all antibiotics tested increased (except carbapenems), although only significantly for third-generation cephalosporins (22.1% to 33.1%;$p<0.05$). Since 2017, increasing trends of K. pneumoniae resistance to ciprofloxacin were observed in all age-groups, particularly in <4 years (neonates: 2.4% to 26.1%;$p<0.05$, 1-11 months: 6.6% to 22.4%;$p<0.05$, 1-4 years: 12.8% to 38.6%;$p<0.05$). E. coli resistance to all antibiotics tested increased (except carbapenems and co-amoxiclav) in children between 2020-21. Between 2017-2021, this increase was significant for ciprofloxacin and third-generation cephalosporins (10.6% to 15.4%;$p<0.05$ and 9.9% to 14.9%;$p<0.05$). S. aureus resistance to meticillin decreased slightly between 2020-21 (6.1% to 4.5%;$p=0.208$).
Conclusions/Learning Points: With the exception of S. aureus, rates of BSI and associated AMR to a number of agents in children increased between 2020-21, especially in K. pneumoniae. Caution is required when interpreting resistance rates due to smaller sample sizes but can help to inform national guidance on paediatric treatment choices by age group.

[1]Centro Hospitalar Entre Douro e Vouga, Serviço De Pediatria/neonatologia, Santa Maria da Feira, Portugal, [2]Centro Hospitalar Vila Nova de Gaia/Espinho, Serviço De Pediatria/neonatologia, Vila Nova de Gaia, Portugal, [3]Centro Hospitalar Entre Douro e Vouga, Serviço De Patologia Clínica, Santa Maria da Feira, Portugal

Backgrounds: Urinary Tract Infections (UTI) are a common cause of admission in the pediatric emergency department (PED) and antibiotic prescription. As multidrug-resistant (MDR) bacteria are rising, it is necessary to analyze their profile within our population
Methods: Our aim is to identify most common agents of UTI and their resistance profile in a secondary hospital pediatric population.

Retrospective observational study analyzing the positive urine cultures in a PED between July-2020 and June-2022. Sex, age, personal history of UTI and anomalies of urinary tract were assessed. Urine collection method, cultural exam, isolated bacteria and antibiotic sensitivity test were analyzed. In cases where information was not available, sphincter continence was assumed from 48 months of age.
Results: 3206 urine cultures were performed, with 803 positive results (median age 4.8 years-old), mostly in girls (68%). 41% of samples were collected by clean-catch, 18% by urethral catheterization and 20% by urine collection bag. Only one suprapubic aspiration was performed, and in 158 of cases there was no information available on the collecting method. The most identified agents were Escherichia coli, (68%), Proteus mirabillis (14%) and Klebsiella pneumoniae (4%). In 22.6% there was a history of UTI and 9% of UT anomalies. In 50 cultures (6%), a MDR bacteria was isolated, with E. coli present in 34 and K. pneumoniae in 10. History of UTI and UT anomalies were more common in this group. (36 and 16%, respectively).
Conclusions/Learning Points: Infections caused my MDR bacteria is a growing reality in pediatric age. Knowing their prevalence in our population can help implement preventive measures, as well as a more cautious and self-aware antibiotics prescription.

EVALUATING THE ANTIMICROBIAL RESISTANCE PATTERNS AMONG MAJOR BACTERIAL PATHOGENS ISOLATED FROM CLINICAL SPECIMENS TAKEN FROM PEDIATRIC PATIENTS IN TERTIARY HEALTH CARE IN KOSOVO

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Greta Lila[1], Rrezarta Bajrami[2], Fikrije Misimi[1], Yllka Begolli[1], Aferdita Alaj[1], Rukije Kastrati[1]
[1]University Clinical Center of Kosovo, Clinical Microbiology Laboratory, Pristina, Kosovo, [2]National Institute of Public Health of Kosovo, Microbiology, Pristina, Kosovo

Backgrounds: This study evaluates the epidemiology and antimicrobial resistance profile of Gram-negative bacteria (GNB), Gram-positive bacteria (GPB), and Candida spp. isolated from various clinical specimens in children.
Methods: Study included patient's clinical specimens collected during year 2022, for routine culture and their susceptibility testing. Isolation, identification and susceptibility were performed using conventional methods, Vitek 2. and broth microdilution methods.
Results: 1450 clinical specimens were tested, and the overall detection rate was 21.3%. 57.1% were GNB and 22.8% were GPB, while Candida spp. was 20%. The most isolated pathogens were Escherichia coli, Pseudomonas aeruginosa, Klebsiella spp., Acinetobacter baumannii, Burkholderia cepacia, Enterobacter spp. and Enterococcus spp. Highest resistance rate was observed for Klebsiella spp., ampicillin 100%, cefotaxime 88%, amoxicillin–clavulanic acid 76%, ceftazidime 60%. Salmonella enteritidis was found in 16 samples and resistance to levofloxacin was 25%. A. baumannii was sensitive only to colistin, and P. aeruginosa had low levels of resistance to amikacin, tobramycin and meropenem. Among GPB, CoNS was the most frequent, and Enterococcus spp. was found to have low levels of resistance to vancomycin and linezolid. Two isolates of VRE were detected with presence of Van A gene (Univero multiplex diagnostic). In GNB, A. baumannii was sensitive only to colistin, and P. aeruginosa had low levels of resistance to amikacin, tobramycin and meropenem.
Conclusions/Learning Points: This study entails the first descriptive report of resistant patterns, expressed by bacterial pathogens, affecting pediatric patients. Our findings revealed that the resistance rate among GNB and GPB associated with different infections in children is very high. These results suggest a constant screening and follow-up programs for the detection of antibiotic resistance, it also suggests development of antimicrobial stewardship programs in our country.

THE HORMETIC EFFECT OF DISINFECTANTS: MAKING PATHOGENS STRONGER

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Samantha Mccarlie, Robert Bragg
University of the Free State, Microbiology & Biochemistry, Bloemfontein, South Africa

Backgrounds: Hormesis or the hormetic effect, is a phenomenon that occurs when an antimicrobial used at a low concentration or dose has a stimulatory effect on microbial growth instead of the intended inhibitory or microbicidal effect. This has been observed for several antibiotics such as tobramycin, tetracycline, and norfloxacin in ESKAPE bacterial pathogens such as Pseudomonas auruginosa. Recently research has shifted on to whether this phenomenon can be elicited by bacteria challenged by antiseptics, sanitisers and disinfectants. An increasing number of hospital acquired infections have been attributable to Serratia sp.
Methods: Therefore, the effect of sub-lethal levels of disinfectants on the growth Serratia sp. HRI (resistant isolate) and Serratia marcescens ATCC 13880 (type strain) were evaluated. The bacteria were cultivated in sub-lethal levels of the following antimicrobial compounds: benzalkonium chloride (BAC), Didecyldimethylammonium chloride (DDAC) and Virukill™. The maximum specific growth rate, doubling time and cell counts were compared between the two bacteria for all three QAC-based disinfectants.
Results: The results revealed significant increases in maximum specific growth rate and shorter doubling times for the resistant isolate, Serratia sp. HRI, when cultivated in sub-lethal levels of BAC and DDAC antimicrobials. These results confirm that the hormetic effect is not unique to antibiotics but can be conferred by antiseptic, disinfectant and sanitiser products as well.
Conclusions/Learning Points: This is deeply troubling as these compounds are vitally important in wound care, and instrument and equipment cleaning in healthcare. Incorrect dosage or inaccurate dilution of these products can cause an inadvertent stimulation of microbial growth instead of inhibition. The significant stimulatory effect for Serratia sp. HRI presented here represents the first time that hormesis has been observed in a Gram-negative bacteria for any disinfectant.

MOLECULAR INSIGHTS INTO ANTIMICROBIAL RESISTANCE OF SERRATIA SP. HRI

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Samantha Mccarlie, Robert Bragg
University of the Free State, Microbiology & Biochemistry, Bloemfontein, South Africa

Backgrounds: The increasing prevalence of antibiotic resistance has highlighted the importance of biosecurity as the only viable alternative to control microbial growth currently. Biosecurity relies heavily on effective disinfection which makes it troubling that disinfectant resistance is emerging at an alarming rate. Relatively little is known about disinfectant resistance, however, a few mechanisms have been elucidated with the help of bioinformatics.
Methods: Serratia sp. HRI is a multidrug resistant bacterium with high resistance capabilities across a broad range of disinfectants. Bioinformatics programs were run to combine data on whole genome sequencing, plasmid analysis and genomic island prediction tools to generate an antimicrobial resistance genes profile.
Results: Serratia sp. HRI harbours multiple low copy number plasmids containing 3 confirmed resistance genes encoding a SMR transporter (QacE), DMT/EmrE multidrug transporter and an EmrE family multidrug efflux pump. These antimicrobial resistance genes are located on plasmids with multiple toxin/antitoxin systems are so were conserved within the population after 90+ days of passaging. This shows that these resistance genes are highly conserved and have the potential to be highly mobile. In addition, whole genome sequencing and bioinformatic software were used to identify resistance islands within the genome of Serratia sp. HRI and a total of 90 antimicrobial resistance genes. Of the 90 genomic resistance genes, 21 were antibiotic resistance genes, 6 were disinfectant resistance genes and 52 multidrug resistance genes were identified.
Conclusions/Learning Points: The study of multidrug resistant bacteria such as Serratia sp. HRI provide a unique opportunity to find new resistance genes and elucidate new resistance mechanisms with the help of sequencing technology.

ANTIMICROBIAL RESISTANCE OF UROPATHOGENS IN PEDIATRIC URINARY INFECTIONS IN CENTRAL GREECE DURING 2012-2022

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Aspasia Michoula, Eleni Papadimitriou, Stavroula Kontogianni, Eftychia Svarna, Ioulia Sirina, Georgia Gazeti, Dimitrios Pipilas, George Syrogiannopoulos, Ioanna Grivea
Faculty of Medicine, School of Health Sciences, University of Thessaly, Department Of Pediatrics, Larissa, Greece

Backgrounds: Urinary tract infection (UTI) is a common cause of antibiotic use and/or hospitalization in childhood. Recently, there is a growing interest on emergence of resistant uropathogens. The aim of this study was to identify the most common UTI pathogens and their antimicrobial resistance patterns in Central Greece.
Methods: This is an 11-year study of UTI cases admitted to the Department of Pediatrics of the University General Hospital of Thessaly from January 1st 2012 to December 31st 2022.
Results: Based on the guidelines developed by the European Association of Urology and European Society for Paediatric Urology, we included children in whom a uropathogen was identified in a urine sample obtained by either clean-catch collection/midstream void or bladder catheterization, or suprapubic bladder aspiration. 543 UTI cases (53.4% female) aged 5 days to 17.2 years (median: 6.9 months, interquartile range: 1.9-30.3 months) were included. 137 (25.2%) of the 543 patients had at least one previous episode of UTI. In eight patients 2 pathogens were recovered in the same urine sample. In total, among 551 isolates, the five most frequently recovered pathogens were: Escherichia coli (396;71.9%), Klebsiella spp. (49;8.9%), Pseudomonas spp. (31;5.6%), Proteus spp. (27;4.9%), and Enterococcus spp. (20;3.6%). Klebsiella spp. isolates were more resistant to amoxicillin-clavulanic acid/cefotaxime/ceftriaxone/meropenem than E. coli isolates ($p<0.001$). Based on the availability of antimicrobial agent's susceptibility tests, when comparing the period 2018-2022 to the period 2012-2017, we noted an increase of both E. coli and Klebsiella spp. non-susceptibility to cefuroxime, cefotaxime/ceftriaxone and trimethoprim/sulfamethoxazole
(Table).

		Study period Number of patients with UTI		p
		2012-2017 N=332 UTI episodes	2018-2022 N=211 UTI episodes	
	Escherichia coli	n=242	n=154	
	Amoxicillin-clavulanic acid	35[a]/206 (17.0)[¶]	23[j]/143 (16.1)	0.82
	Cefuroxime	17[b]/201 (8.5)	58[j]/139 (41.7)	**<0.001**
Antibiotic resistance	Cefotaxime/ceftriaxone	8[c,j]/229 (3.5)	13/149 (8.7)	**0.03**
Antibiotic resistance	Meropenem	1[d]/163 (0.6)	1/122 (0.8)	0.84
Antibiotic resistance	Amikacin	1[e]/195 (0.5)	3/142 (2.1)	0.18
Antibiotic resistance	Trimethoprim-sulfamethoxazole	36/188 (19.1)	42[k]/142 (29.6)	**0.03**
	Klebsiella spp.	n=27	n=22	
	Amoxicillin-clavulanic acid	8[f]/23 (34.8)	9/20 (45.0)	0.49
	Cefuroxime	4[g]/20 (20.0)	12[l]/15 (80.0)	**<0.001**
Antibiotic resistance	Cefotaxime/ceftriaxone	3/22 (13.6)	8/21 (38.1)	0.07
Antibiotic resistance	Meropenem	0/21 (0)	3/17 (17.6)	N/A
Antibiotic resistance	Amikacin	2[h]/23 (8.7)	0/20 (0)	N/A
Antibiotic resistance	Trimethoprim-sulfamethoxazole	1/20 (5.0)	5/20 (25.0)	0.08

Intermediate: [a]21; [b]7; [c]1; [d]1; [e]1; [f]4; [g]2; [h]2; [i]1; [j]44; [k]2; [l]6

[¶]non-susceptible isolates/isolates tested (percent in parenthesis)

Conclusions/Learning Points: The emergence of non-susceptibility to several antimicrobial agents of E. coli or Klebsiella spp. strains has been noted recently. Pediatricians should be aware of the uropathogens antibiotic resistance.

Title of Case: A PILOT STUDY TO DETERMINE RESISTANCE TO CLARITHROMYCIN BY RT-PCR IN PEDIATRIC PACIENTS WITH HELICOBACTER PYLORI INFECTION
Background: H.pylori remains the most common cause of gastro-duodenal diseases. The increase in antibiotic resistance worldwide is worsening its eradication rates. The aim of study is to describe the population of patients infected by H.pylori finding out the resistance rates in our area.
.
Case Presentation Summary: Methods A descriptive study has been realized in the Hospital of Germans Trias i Pujol in Barcelona. We enrolled patients with H.pylori symptoms and positive stool antigen test (SAT). We performed an upper endoscopy and obtained gastric biopsies for rapid urease test (RUT) , Real-Time-Protein Chain Reaction (RT-PCR),and histological studies (hematoxilyn-eosin stain or immunohistochemistry). Results We enrolled 64 patients (4-17y). 90,6% of patients had dyspepsia, 3% anaemia, 4,7% both and only 1,6% gastrointestinal bleeding. In upper endoscopy we observed nodular antritis or gastritis in 46/64 (72%). RUT was positive in 89%. Histological analysis of biopsies documented gastritis low-moderate in antral mucosae (93,8%), finding H.pylori structure in the 90,6% of specimens. We perform 60 RT-PCR H.pylori in gastric sample: 6 were RT-PCR negative and 5/6 were also negative for RUT and histological studies. From the positive RT-PCR-biopsies, 40.7% showed mutation in the 23S rRNA gene (A2143G) associated with clarithromycin-resistance. Regarding treatment, 19/60 of patients (29.7%) received clarithromycin-based treatment and 41/60 (64.1%) metronidazole-based therapy. At the post-eradication control 43/60 had negative SAT (71,6%)
Learning Points/Discussion: Conclusions Our study demonstrates a high correlation between PCR-data and RUT / histological test and the high sensitivity of RT-PCR. In our area we find a resistance clarithromycin rate above 40%. Therefore we advise avoiding its use as a first- line treatment to improve the current eradication rates

PREVALENCE OF MALARIA AND EARLY CLINICAL AND PARASITOLOGICAL RESPONSES TO TREATMENT OF ARTEMISININ-BASED COMBINATIONS IN ANGOLA.

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Mbueno Nzila
Instituto de Higiene e Medicina Tropical, Doutoramento Em Doenças Tropicais E Saúde Global, Lisbon, Portugal

Backgrounds: In Angola, MINSA data show that 9,169,267 cases of malaria were registered in 2021: 90.8% (8,325,921) were confirmed cases whose 13,676 deaths. The dominant age group is children under 5 years with 35% of the total number of cases, representing 51% of deaths. We aimed to assess the prevalence of malaria and the early clinical and parasitological responses to treatment of Artemisinin-based combinations.
Methods: The research is observational and prospective based on early clinical and parasitological responses to treatment of Artemisinin-based combinations (Artemether+Lumefantrine and Artesunate+Amodiaquine). Monitoring was done on days 0, 1, 2, 3 and 7 (Figure 1). Children were selected by a systematic sampling method. The study was conducted between November and December 2022.

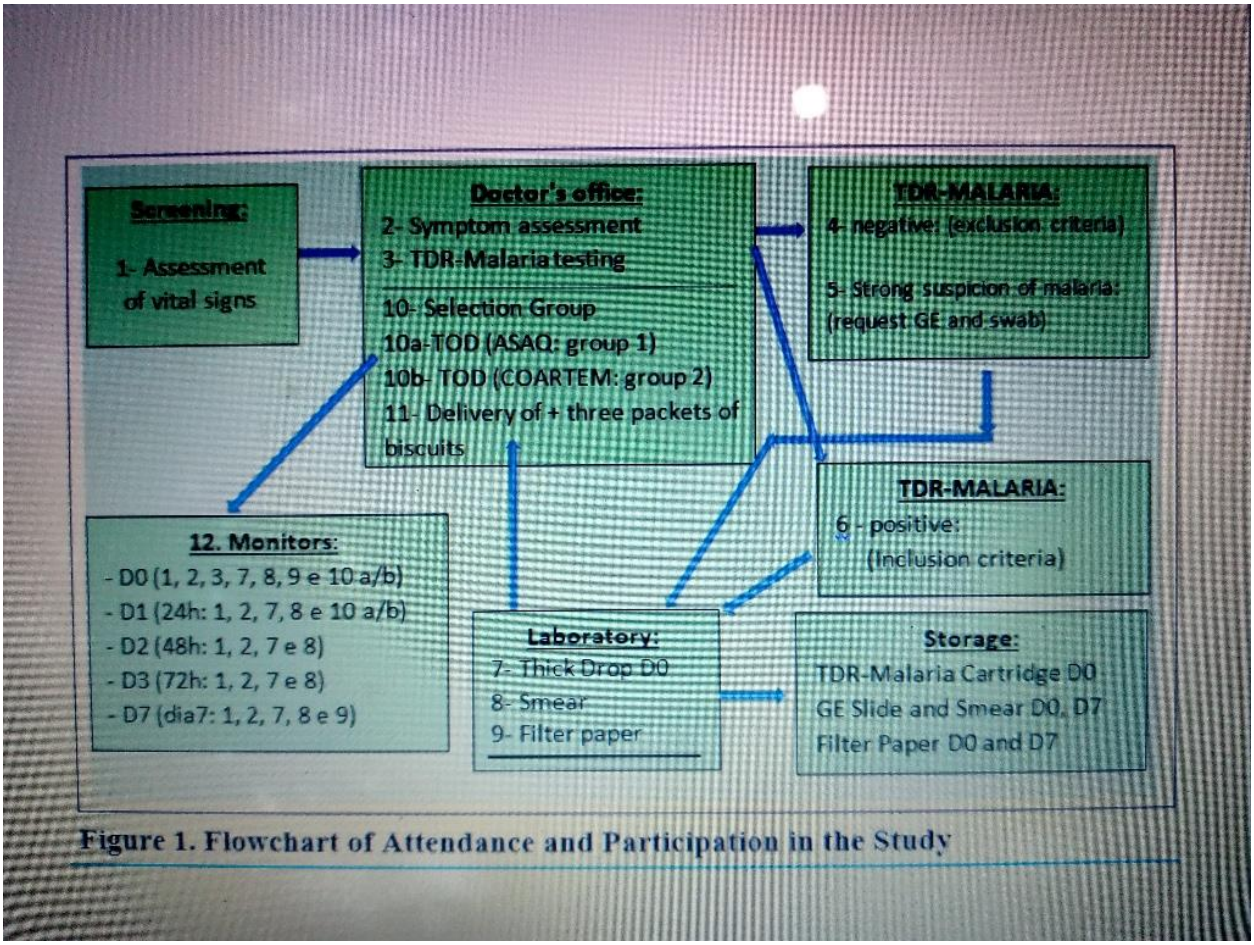

Figure 1. Flowchart of Attendance and Participation in the Study

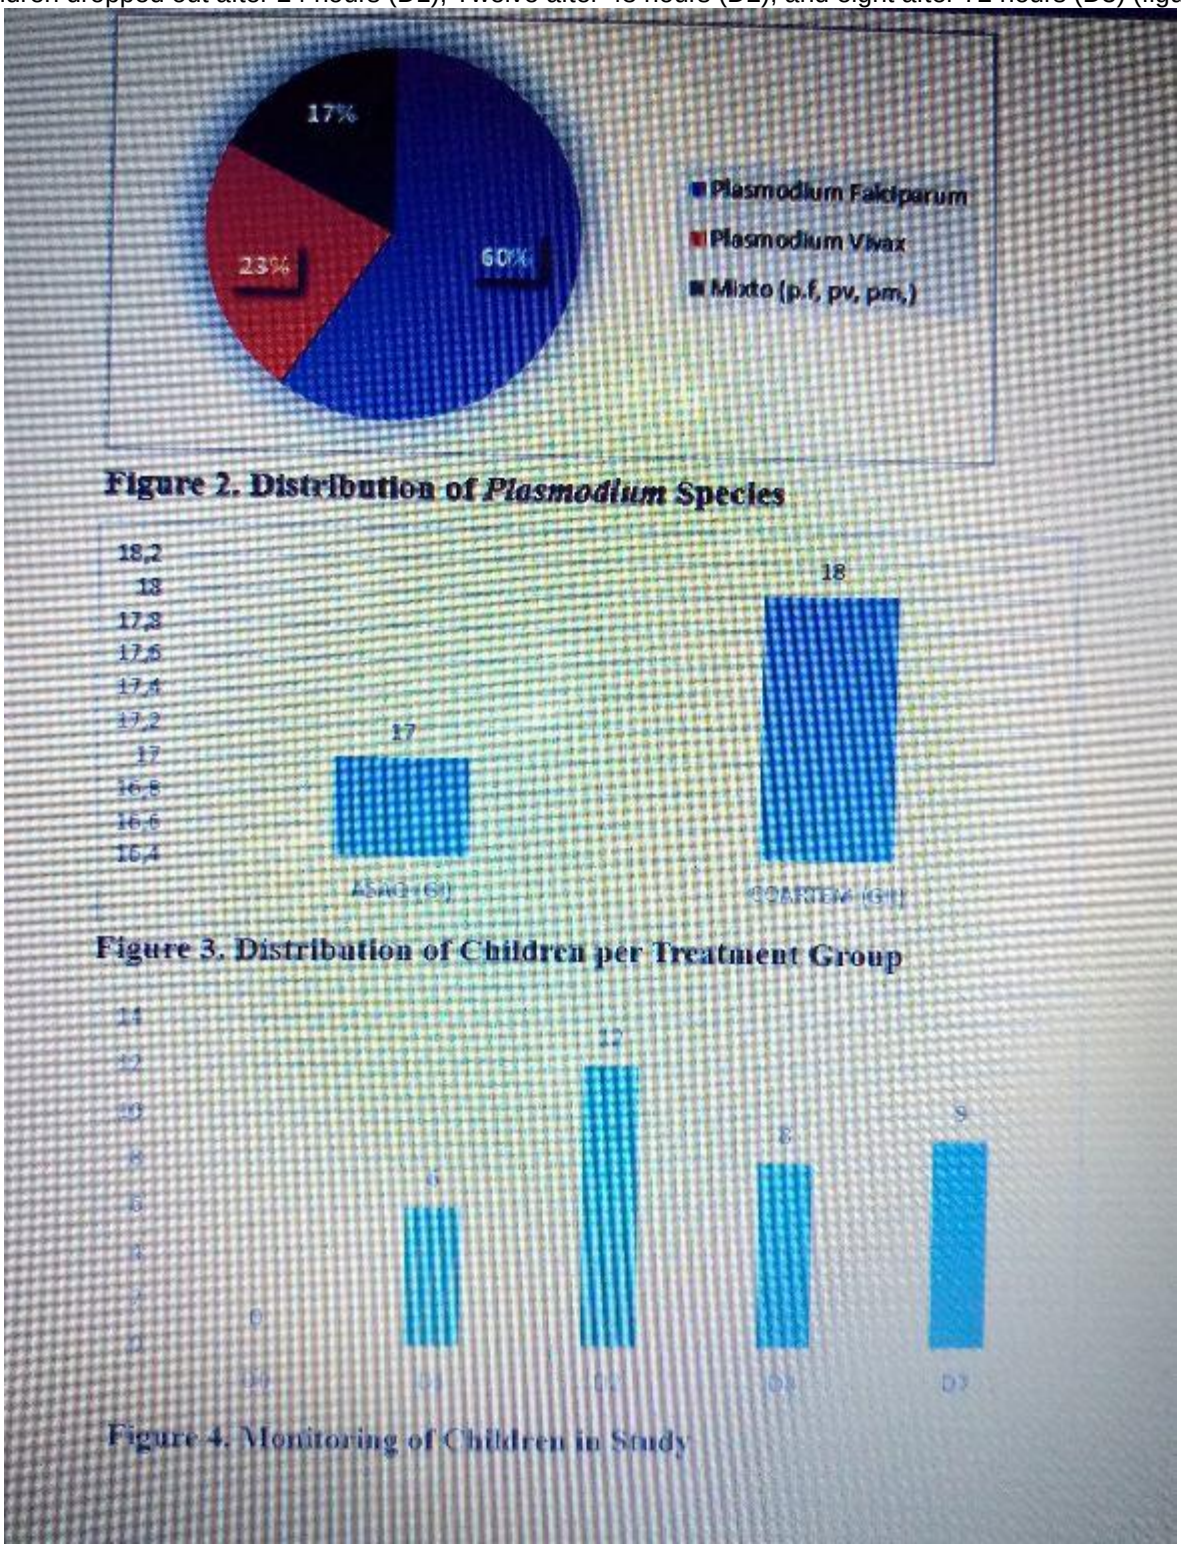
Results: Eighty-two children were enrolled in the study. All were submitted to Rapid Diagnostic Test for malaria: 57% were female. Only 35 with Plasmodium spp. and thin and thick blood smears. Of these, 21

had Plasmodium falciparum, 8 with plasmodium vivax and 6 mixed (p.f, p.v and p.m.) (figure 2). Figure 3 shows that 51% received Coartem. All treated, only 9 completed the treatment with monitoring; Six children dropped out after 24 hours (D1); Twelve after 48 hours (D2), and eight after 72 hours (D3) (figure 4).



Conclusions/Learning Points: Although the number of children enrolled was low (82), the estimated prevalence of falciparum malaria (42.68%) follows the national average (35%). One of the reasons for the

high drop-out rate observed (74.29%), could be the strong appreciation of farming activities in this rainy season. These may have a negative impact on the success of malaria treatment.

ETIOLOGY AND ANTIMICROBIAL RESISTANCE PATTERNS OF ACUTE PYELONEPHRITIS CASES IN THE PAEDIATRIC CLINIC IN WARSAW.

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Marcin Rozwadowski[1,2], August Wrotek[1,2], Teresa Jackowska[1,2]
[1]Bielanski Hospital, Department Of Pediatrics, Warsaw, Poland, [2]Centre of Postgraduate Medical Education, Department Of Pediatrics, Warsaw, Poland

Backgrounds: Urinary tract infections (UTIs) are one of the most common infections in children. Involvement of the upper urinary tract as in acute pyelonephritis (AP) is particularly dangerous. AP can lead to permanent renal damage and often requires prolonged hospitalization. The rapid emergence of multidrug-resistant (MDR) bacteria constitutes a major health problem as it may affect the effectiveness of UTI empiric treatment. Therefore continuous regional surveillance of antibiotic resistance (AR) is pivotal in proper selection of antimicrobials.
Methods: We performed quantitative retrospective analyses of urine cultures collected form children diagnosed with AP, admitted to the Paediatric Clinic at Bielański Hospital in Warsaw, from January 2020 to December 2022. We analysed 152 urine sample and positive monocultures were identified in 144 (94,7%) cases. Sensitivity tests to 19 antimicrobial drugs, belonging to 5 different classes (β-lactams, quinolones, phosphonates, aminoglycosides, antifolates), were performed.
Results: Escherichia coli was the most frequently isolated pathogen and was responsible for the 124 (86,1%) urine positive cultures of AP cases, followed by Klebsiella pneumoniae 6 (4,2%) and Enterococcus faecalis 5 (3,5%). In positive monocultures, 72 (50%) pathogens were sensitive to all tested antimicrobials, 10 (6.9%) expressed MDR. 72 (50%) pathogens were resistant to at least one antimicrobial: 68 (47,2%) ampicillin, 66 (45,8%) piperacillin, 37 (25.7%) trimethoprim, 19 (13,2%) amoxicillin/clavulanic acid. Empiric therapy, which usually consisted of II/III generation of cephalosporins, was effective in 128 (88,9%) patients, as AR to cefuroxime and cefotaxime were detected in 10 (6,9%) and 8 (5,6%) cases, respectively.
Conclusions/Learning Points: E. coli remains the leading cause of AP in our clinic. Empiric therapy with II/III generation cephalosporins was found effective in most cases. However, as MDR emerges AR surveillance should be continued. Acknowledgements: CMKP grant 501-1-020-19-22.

Instituto de investigacion imas12. Universidad Complutense de Madrid. RITIP, Paediatric Infectious Diseases, Madrid, Spain, [15]Hospital Universitario Gregorio Marañón, Infectious Diseases Unit, Madrid, Spain

Backgrounds: Multidrug resistant bacteria (MDRB) infections are a rising concern, especially in healthcare environment. The aims of this study were to describe the characteristics and risk factors for a new MDRB colonization and infection in paediatric patients admitted to a Haemato-Oncology ward.
Methods: Multicentre prospective study from May 2021-March 2022 in Spain. Patients < 18 years with diagnosed with cancer or stem cell transplantation (SCT) admitted to Hemato-Oncology wards were included. Rectal/nasal swabs for MDRB detection were performed at inclusion and periodically during a 90-day period. Active infection surveillance was performed during follow-up. Data of new colonisations and infections during the follow-up are presented.
Results: 142 patients were included; 136 (95.8%) completed the follow-up. 28 (20.6%) had undergone a SCT. Diagnoses were leukaemia (58;42.6%), solid organ tumour (67;41.9%), lymphoma (7;5.1%), sickle cell disease (SCD) (6;4.4%) and other diagnosis (7;5.1%). 11 (8%) patients had 13 new colonisations within the study period (one patient had 3). Six (46.2%) were carbapenemase-producing (100% VIM), and 5 (38.4%) ESBL-producing Enterobacteriaceae, 1 (7.7%) multi-drug resistant Pseudomonas and 1 (7.7%) SARM. Patients with SCT (OR:5.6[95%CI:1.6-19.9];p=0.004), SCD (OR:6.7[95%CI:1.1-41.5];p=0.021), more days of total hospital admission (OR:1.1[95%CI:1.0-1.1];p=0.004), having received more days of antibiotics (OR:1.0[95%CI:1.0-1.1]; p=0.044), and born abroad (OR:6.3[95%CI:1.4-19.0];p=0.036) had a higher risk (table). 41 (30.1%) patients had a bacterial infection, 3(2.2%) due to a MDRB; patients previously colonised did not have a higher
risk.

	New colonization		Total N=136	P value (OR [95%CI])

URINARY TRACT INFECTION CAUSED BY EXTENDED-SPECTRUM B-LACTAMASE PRODUCING ENTEROBACTERALES: A RETROSPECTIVE STUDY IN A PEDIATRIC DEPARTMENT OF A PORTUGUESE HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Paula Santos[1], Rosa Soares[2], Jóni Mota[2], Catarina Ribeiro[1], Julieta Morais[1], Carlos Cortes[2]
[1]Centro Hospitalar Médio Tejo, Paediatric, Torres Novas, Portugal, [2]Centro Hospitalar Médio Tejo, Clinical Pathology, Tomar, Portugal

Backgrounds: Enterobacterales are the most common cause of urinary tract infections (UTI). The production of extended-spectrum ß-lactamase (ESBL) by these bacteria and resistance to several antibiotics has become increasingly more common, limiting treatment options among children presenting with febrile UTI. The aim of this study was to analyze clinical, laboratory and therapeutic data of children with UTI caused by ESBL-producing bacilli.
Methods: Retrospective study, conducted in a pediatric department of a level II portuguese hospital, from January 2017 to December 2022. Children were identified from the microbiology database and data were collected from patient medical record.
Results: Over the 6-year study period, 1484 urine culture were positive for Enterobacterales; of these, 28 (1,9%) were found to be ESBL-producing bacteria: 20 Escherichia coli (71,5%), 7 Klebsiella pneumoniae (25%), 1 Enterobacter cloacae complex (3,5%). The ESBL-producing phenotype was detected in 1,8% E. coli and 11% K. pneumoniae. In 16 children (55%) it was the first UTI and in 27 (93%) it was community-acquired. In 15 cases (52%) were identified chronic conditions (mainly urological disorders). In the 30 days prior to UTI, 13 children (44,8%) received antibiotic treatment. Hospital admission was required in 7 cases (24,2%). In 13 cases (48,3%), antibiotic treatment was changed after identification of microorganism and its antimicrobial susceptibility. The prevalence of ESBL-producing bacilli UTI increased meaningly during the study (1,6% in 2017 versus 2,7% in 2022).
Conclusions/Learning Points: While the presence of ESBL-producing Enterobacterales has been predominantly associated to healthcare related infection, in our study, most cases were identified in the first episode of community-acquired UTI and in children with chronic conditions. Recognition of the emergence of ITU caused by community-acquired ESBL-producing bacilli is important to improve management of this cases in pediatric age.

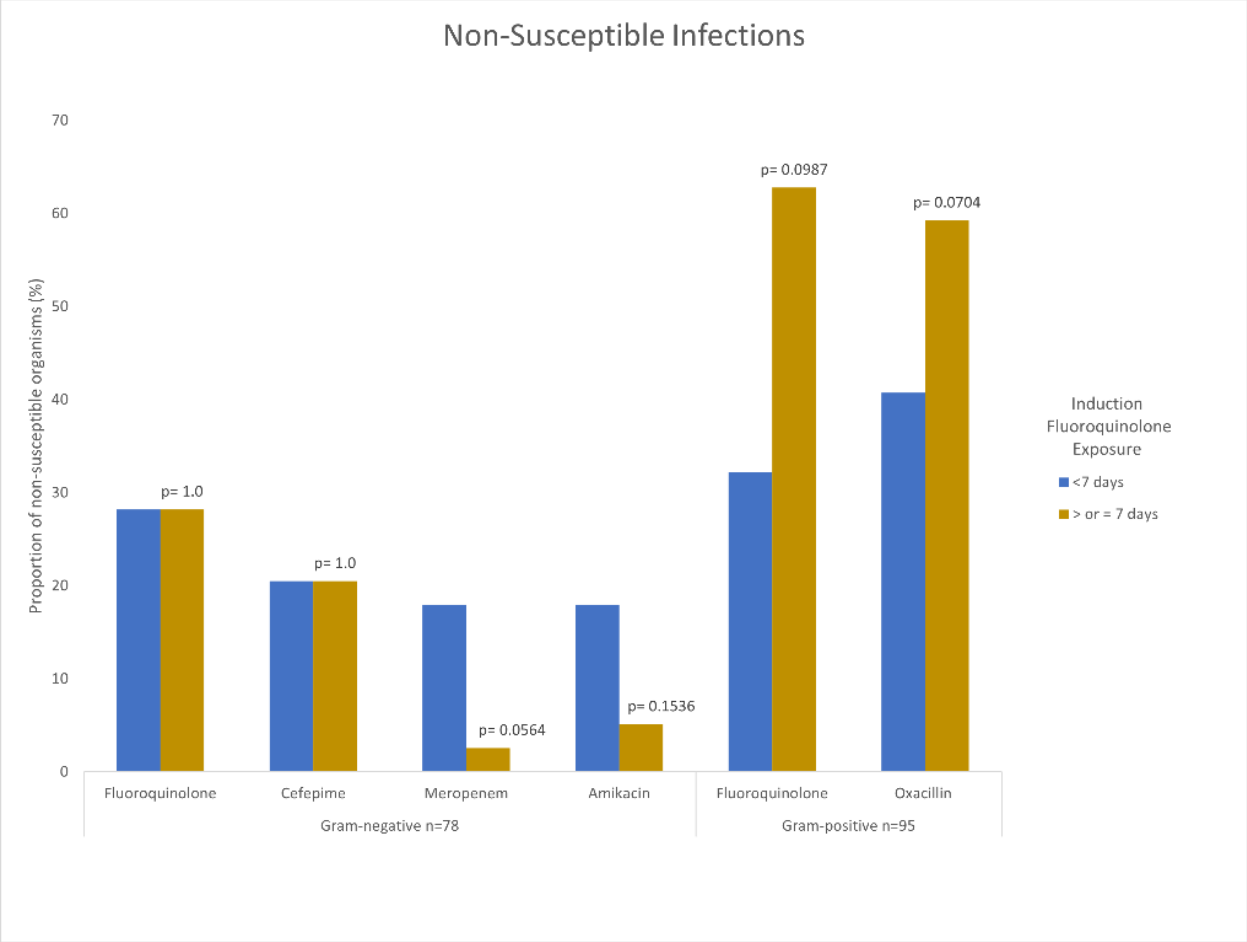
ANTIMICROBIAL RESISTANCE FOLLOWING LEVOFLOXACIN PROPHYLAXIS DURING INDUCTION THERAPY FOR PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Melissa Shenep[1], Li Tang[2], Jose Ferrolino[1], Randall Hayden[3], Kim Allison[1], Ronald Dallas[1], Ellie Margolis[1], Ching-Hon Pui[4], Sima Jeha[4], Joshua Wolf[1]
[1]St. Jude Children's Research Hospital, Infectious Diseases, Memphis, United States of America, [2]St. Jude Children's Research Hospital, Biostatistics, Memphis, United States of America, [3]St. Jude Children's Research Hospital, Pathology, Memphis, United States of America, [4]St Jude Children's Research Hospital, Oncology, Memphis, United States of America

Backgrounds: Levofloxacin prophylaxis during induction therapy for pediatric acute lymphoblastic leukemia (ALL) can prevent life-threatening infections, but increases cumulative antimicrobial exposure while reducing cephalosporin, aminoglycoside and carbapenem exposure. Because of this mixed effect on antibiotic exposure, the effect of prolonged exposure to fluoroquinolones on subsequent risk of antimicrobial resistant infections is unknown.
Methods: This IRB-approved, single-center, retrospective cohort study of pediatric patients with newly diagnosed acute lymphoblastic leukemia (ALL) compared rates of antimicrobial resistance in microbiologically-documented infections occurring after completion of induction therapy in patients who had received <7 days vs ≥ 7 days of fluoroquinolone during induction on the Total XVI protocol from September 2008 to March 2020. Of participants who had ≥1 microbiologically documented bacterial infection, we calculated the proportion who had known bacteria non-susceptible to fluoroquinolones, cefepime, meropenem, amikacin, or oxacillin. Two-tailed p-values were estimated with Fisher's exact test. Multivariable logistic regression was used to test the possible effect of institutional secular resistance trends.
Results: Of the 598 evaluable participants with ALL, 138 had ≥1 culture-positive infection during post-induction therapy with known levofloxacin susceptibility (78 Gram-negative and 95 Gram-positive). In participants with ≥7 days induction fluoroquinolone exposure, there was a trend towards decreased meropenem and amikacin resistance in Gram-negatives and increased fluoroquinolone and oxacillin resistance in Gram-positives, mostly coagulase negative staphylococci (79%), but none were statistically significant. This finding was not better explained by institutional secular
trends.



Conclusions/Learning Points: Antimicrobial exposure is an important catalyst of antimicrobial resistance; in this study, there was a trend towards increasing resistance in low-pathogenicity Gram-positive, but not in Gram-negative organisms. Additional studies are needed to monitor the long-term effect of continued prophylaxis at the patient- and institutional-level.

CEFTAZIDIME-AVIBACTAM AZTREONAM VERSUS MEROPENEM COLISTIN FOR THE TREATMENT OF INFECTIONS DUE TO CARBAPENEM-RESISTANT ENTEROBACTER ALES IN CHILDREN: SINGLE CENTRE RETROSPECTIVE COHORT STUDY

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Bhaskar Shenoy, Pooja Doddikoppad, Archana Mahalingam, Ranjeeta Adhikary, Bhavana M V
Manipal Hospital, Pediatrics, Bangalore, India

Backgrounds: There has been a worldwide increase and emergence of Carbapenem-resistant Enterobacteriaceae (CRE) which are leading cause of morbidity and mortality in intensive care units. Therapeutic regimen for CRE have evolved significantly in recent years with availability of novel β-lactam-β-lactamase inhibitor (βL-βLI) agents (e.g., ceftazidime-avibactam, meropenem-vaborbactam).
Methods: Retrospective, single, observational cohort study of inpatients who received CAZ-AVI or IV colistin with Meropenem for treatment of CRE infections between January 2019 and June 2022 .Data collected:- demographic characteristics , study drug, duration of therapy, etiologic pathogen, surgical intervention, comorbid conditions, risk factors, indwelling device and the clinical outcome .
Results: Total 33 patients with CRE were included in our study. Klebsiella pneumoniae was most common pathogen (87.3%) followed by E coli (12.7%). Most common carbapenemase isolated was NDM/OXA -48 from Carba R assay/BCID done in 9 patients out of 33. All episodes of infection were associated with healthcare interventions.- indwelling devices and central lines (96%). Polymicrobial infection was in 30% and 45% had surgical intervention in last 90 days. In hospital mortality was seen in 30.3%(n=10) of children . 17 (51.2%) children received meropenem- colistin therapy, out of which 8 (25.2%) had in hospital mortality ,12 received ceftazidime avibactam aztreonam of which 3.03% (n=1) had in hospital mortality. 3 children received high dose extended infusion of meropenem , 1 child received IV Fosfomycin. Clinical recovery from the CRE infection was significantly more common in patients who received Ceftazidime avibactam aztreonam [p-value=0.028, OR= 8.25, CI= (-0.1, 4.32)] than in patients who received colistin-meropenem regimen.
Conclusions/Learning Points: Ceftazidime avibactam aztreonam is associated with higher rate of clinical cure ,lower rate of mortality when compared with colistin meropenem -based regimen for treatment of CRE infections in children.

Backgrounds: Antimicrobial resistance (AMR) is a growing global problem and the ongoing COVID-19 pandemic brought an alert about the increase in Multidrug Resistance (MDR) bacteria, due to the greater use of antibiotics. However, data obtained so far are conflicting, some, mainly in developing countries, showing an increase in MDR bacteria and in other regions revealing a decrease. We analyzed the differences in the epidemiology of MDR bacteria during the COVID-19 pandemic.
Methods: We conducted a descriptive study with positive blood cultures from pediatric cancer patients (up to 18 years old) treated at our service during the COVID-19 pandemic (2020 to 2022) compared to in the pre-pandemic period (2017 to 2019).
Results: In pre-pandemic period, 222 positive blood cultures were obtained, with 81 MDR bacteria (36.5%), 76.5% (62/81) ESBL, 13.6% (11/81) Carbapenem-resistant (CR), 6.2% (5/81) Carbapenem and Polymyxin resistance and 3.7% (3/81) VRE. Among the ESBL, E. coli, 32.3%, and K. pneumoniae, 29% ($p<0.001$) stand out mainly. Of the CR bacteria, 36.4% were Pseudomonas aeruginosa and 27.3% K. pneumoniae and Acinetobacter baumannii. All Carbapenem and Polymyxin resistance were K. pneumoniae and of VRE, Enterococcus faecium. During pandemic, 178 positive blood cultures were obtained, with 64 MDR bacteria (36%). There was a reduction in ESBL (68.75%), an increase in CR (18.75%) and a significant increase in VRE (12.5%, $p=0.047$). The main ESBL (44), again, E. coli, 38.6%, and K. pneumoniae, 29.5% ($p<0.001$). K. pneumoniae was also the most isolated within the CR, with 41.7% (5/12). Enterococcus faecium was isolated from 50% of VRE.
Conclusions/Learning Points: Cause of the increase in MDR is multifactorial and is associated with use of antibiotics, but also with other factors such as the environment, cross-transmission and difficulty in isolation due viruses.

SINGLE NUCLEOTIDE POLYMORPHISM IN QUINOLONE RESISTANCE-DETERMINING REGION IN DIARRHOEAGENIC E. COLI ISOLATES IN INDIAN PEDIATRIC POPULATION

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Taru Singh, Shukla Das
University of Delhi, Microbiology, Delhi, India

Backgrounds: Antimicrobial resistance happens when microorganisms mutates in manners that render the drugs like antibacterial, antiviral, antiparasitic and antifungal, ineffective. The normal mutation process is encouraged by the improper use of antibiotics. Mutations leading to quinolone resistance occur in a highly conserved region of the quinolone resistance-determining region (QRDR) of DNA gyrAse and topoisomerase IV gene. In the current study, Single Nucleotide Polymorphism (SNP) in gyrA and parC genes in QRDR were analysed.
Methods: A total of 120 E. coli isolates (Diarrheagenic and nonpathogenic, both) recovered from fresh stool samples collected from children aged less than five years from Delhi, India.Antibiotic susceptibility testing was performed according to standard Clinical and laboratory standards Institute (CLSI) guidelines. Multiplex PCR was performed for SNP detection and confirmed by sequencing.
Results: SNPs in gyrA (A660-T660) and parC (C330-T330) were detected in 11.66 % and 2.5 % isolates, respectively. Among all Nalidixic acid and Ciprofloxacin resistant isolates, 29.78% isolates showed point mutation for gyrA gene, while 27.27 % isolates showed point mutation for parC and 5.17% isolates showed mutation for both gyrA and parC.
Conclusions/Learning Points: Current findings show that the QRDR have mutations in gyrA, parC genes. Our results suggest SNP in children may contribute to the development of multi drug resistance (MDR) in E. coli. These findings may be useful to understand the genetic factors involved in development of antibiotic resistance in pediatric population. DEC group are relevant in advancing our understanding of the disease for the synthesis of new diagnostic biomarkers.

INCORRECTLY USED DISINFECTANTS MAY DRIVE RESISTANCE DEVELOPMENT IN CLINICAL SETTINGS

E-Posters Viewing
E-POSTER VIEWING: AS01.B. RESISTANCE

Wanja Swart, Robert Bragg, Samantha Mccarlie
University of the Free State, Microbiology & Biochemistry, Bloemfontein, South Africa

Backgrounds: Since 2020 the public has been required to drastically increase the use of certain disinfectants but due to the use of inefficient or poorly diluted disinfectants, bacteria are exposed to sub minimum inhibitory concentrations (MIC) of disinfectant, which may cause resistance to develop within the community. This is especially concerning in the clinical setting, where disinfectants are regularly used. With the last of our available antibiotics now showing decreased effectiveness against MDR gram negative bacillicocci ESKAP, it is important to establish wether or not incorrectly used disinfectants drives resistance development in the clinical setting.
Methods: Samples were collected from three hospitals and isolates with reduced susceptibility to quaternary ammonium compounds (QACs) were isolated. Abovementioned cultures were exposed to four dilutions of DDAC based disinfectant for a contact time. Surviving isolates were identified to be gram negative bacillicocci. ATCC wild type strains were subject to the same protocol and compared to that of the resistant isolates in order to determine degree of resistance.Gram negative ATCC Escherichia coli was exposed to sub MIC levels of DDAC based disinfectant with routine reasessment, to determine if exposure to sub MIC levels of disinfectant causes resistance to develop in gram negative bacillicocci.
Results: 99 samples were collected which yielded 260 CFUs with an average resistant population of 17%. Five resistant strains were identified and showed between 200%-400% reduced susceptibility to QACs compared to the ATCC strains. ATCC Echerichia coli exhibited a 100% decrease in susceptibility to QACs following sub MIC exposure for 20 days.
Conclusions/Learning Points: The clinical setting has an established resistant population of gram negative bacillicocci that likely have developed resistance due to exposure to sub MIC levels of disinfectant within the hospital setting.

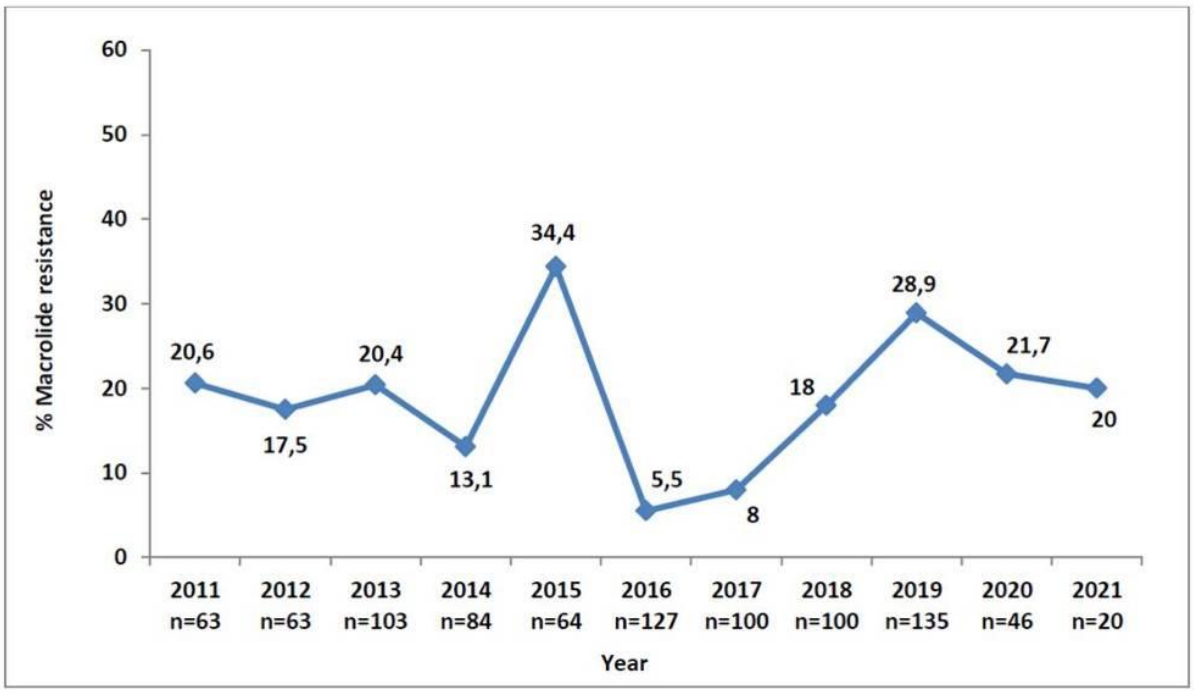
Backgrounds: Group A Streptococcus pyogenes (GAS) is the etiological agent of a wide range of infections. A greatly variable incidence in macrolide resistance has been reported world-wide for GAS. The aim of this study was το highlight macrolide resistance and determinants of GAS pediatric clinical isolates in Central Greece.
Methods: During the period 2011-2021, GAS isolates were collected from children with invasive and non-invasive infections, mostly pharyngeal, who were either examined in the outpatient clinics or admitted to the pediatric wards of the University General Hospital of Larissa.
Results: GAS was recovered from 905 children aged 0.8-15.6 years; Thirteen were recovered from patients with invasive disease cases, whereas 892 from non-invasive cases, mostly pharyngeal. We noted continuing fluctuation of macrolide-resistant isolates, while macrolide resistance was ≥20% in 6 out of the 11 study-years (Figure). No difference was observed in macrolide-resistance rates between invasive and non-invasive isolates (p=0.32). Among 164 macrolide-resistant isolates, 156 were emm-typed and belonged to 12 types, the five most common of which, in descending order, were emm28, emm77, emm12, emm9 and emm89. Each of the three most frequent emm types were revealed in 6 of the 11 study years, whereas emm9 predominated during 2019-2021. One hundred and nine of 156 genotyped resistant isolates possessed the erm(B) gene, either alone or in combination with the mef(A) gene.



Conclusions/Learning Points: Macrolide GAS resistance fluctuates considerably over time. Therefore, ongoing monitoring of sporadic clones of macrolide-resistant streptococcal isolates broadens the perspective of pediatric care physicians and may assist in the guidance of antibiotic usage.

Title of Case: SUCCESSFUL TREATMENT OF PERSISTENT MULTIDRUG-RESISTANT KLEBSIELLA PNEUMONIAE BACTEREMIA WITH CEFTAZIDIME-AVIBACTAM IN CHILDREN
Background: Multidrug-resistant Klebsiella pneumonia (MDRKP) infection has been associated with high mortality. Ceftazidime-avibactam has been shown to be safety and efficacious in children and infants with multidrug-resistant gram-negative bacteria infections. We present two pediatric cases of persistent MDRKP successfully treated with ceftazidime-avibactam at Cipto Mangunkusumo hospital, Indonesia.
Case Presentation Summary: Case 1: A 9-month-old boy with a history of Kasai procedure for biliary atresia, presented with fever and was diagnosed with cholangitis. The infection was successfully managed with meropenem for 14 days based on a blood culture data of recent hospitalization that showed MDRKP (sensitive to carbapenem). Another infection occurred after meropenem was stopped, piperacillin-tazobactam and amikacin were given empirically. A blood culture again revealed MDRKP (pandrug resistant). Ceftazidime-avibactam was given for 10 days. Clinical improvement and bacterial clearance were seen on day 2 of the therapy without any renal or liver function disturbance. Case 2: A term baby girl, presented with gastrointestinal bleeding with a suspicion of neonatal sepsis, was treated with ampicillin-sulbactam. On day 5, she had pneumonia and the antibiotic was changed to cefoperazone-sulbactam and amikacin. On day 9, as infection worsened, meropenem and metronidazole replaced the antibiotics. Her clinical conditions continued to deteriorate that she needed mechanical ventilator and vasopressors. A blood culture revealed MDRKP (sensitive to levofloxacin and tetracycline). Clinical instability continued after levofloxacin and amikacin was given. Blood cultures on day 13 and day 17 again both revealed MDRKP. Levofloxacin was replaced by ceftazidime-avibactam for 10 days. She was discharged on day 54. Liver enzymes was slightly elevated, but normalized within 2 weeks.
Learning Points/Discussion: Ceftazidime-avibactam use in children and neonates was both safe and efficacious against MDRKP bacteremia.

Backgrounds: Antifungal agents are often prescribed in pediatric patients but data on antifungal prescribing in specific pediatric settings are limited. The aim of this study was to record antifungal consumption in pediatric units of a single tertiary level hospital during and after Covid-19 pandemic.
Methods: A modified point-prevalence study (mPPS) was conducted in 2020 and 2022. All patients hospitalized in 6 pediatric departments [1 pediatric intensive care unit (PICU), 1 neonatal intensive care unit (NICU), 1 pediatric hematology/oncology department (PONC), 1 pediatric surgery and two general pediatric departments] of a general hospital, who were on systemic antifungals were recorded. Weekly data of antifungal consumption and individual patient data were collected prospectively during a 12-wk study period and compared between 2020 and 2022.
Results: The median percentage of pediatric patients receiving antifungal agents per mPPS week across all units on 2022 was 7.6% (range 5.1-9.1) in comparison to 10.7% (range 8.2-21.3) on 2020. The highest antifungal use in 2022 was found in PICU (md consumption= 37% per mPPS week), followed by PONC (md consumption 35% per mPPS week), whereas PONC had the highest consumption (md 57%), followed by PICU (md 17%) in 2020. Median consumption slightly increased from 3.4 to 5% in NICU. Micafungin was the most frequently prescribed agent followed by liposomal amphotericin B both in 2022 (39%, 29%, N=56), and 2020 (33%, 31%, N=52), accordingly. The third most common antifungal agent used on 2022 was fluconazole (13%, N=56) whereas on 2020 was voriconazole (17%, N=52).
Conclusions/Learning Points: A decrease in antifungal consumption among neonatal and pediatric departments was found during this study, with the majority of antifungal use found in PICU and PONC.

IDENTIFYING VARIABLES BEHIND SUB-THERAPEUTIC LEVELS SERUM VANCOMYCIN TROUGH LEVELS IN PAEDIATRIC PATIENTS

E-Posters Viewing
E-POSTER VIEWING: AS01.C. PHARMACOLOGY

Neil Dawson
Royal Victoria Hospital, Pharmacy Department, BT BA, United Kingdom

Backgrounds: Vancomycin is used for the treatment of gram positive bacteria. The concentration of vancomycin trough levels must be maintained between 10-20mg/L. In our hospital 49% of serum vancomycin levels are therapeutic whilst 34% of first levels are sub-therapeutic. Variables that affect the pharmacokinetics of vancomycin in children are age, gender, dose, frequency, renal function, weight, albumin, co-morbidities, medication and human error. The aim is to identify why 34% of first vancomycin trough levels are under 10mg/L in children in our hospital.
Methods: This project was developed as a retrospective cross sectional study between 2019 and 2021. Quantitative multi-stage sampling was used to collect the data. Variables were collected through the electronic/medical records. Analysis fell into two categories: Combined analysis with all age ranges and within infants, children and adolescents. Significance set at $p<0.05$ with 95% confidence intervals.
Results: The number of patients identified was 227 with 69 patients excluded from the dataset. 48% of patients achieved a therapeutic level, 38% of levels were sub-therapeutic and 14% were supra-therapeutic. Patients achieved a similar percentage total of therapeutic levels throughout each age group. Statistically significant variables were, gender, renal function, ward, co-morbidities (cancer or not) and medication.
Conclusions/Learning Points: Glomerular filtration rate was a significant variable in this service evaluation. Patients on a known interactive medication are more likely to attain a therapeutic vancomycin level, potentially due to the affect that two nephrotoxic drugs can have on renal function. Patients with a malignancy or solid tumour are more likely to attain a sub-therapeutic level than those patients who do not have a form of cancer. This may be due to augmented renal clearance that enhances the clearance of vancomycin resulting in lower serum trough levels.

Backgrounds: The rational use of antibiotics is crucial to prevent the emergence of multi-resistant bacteria that can lead to therapeutic impasse, especially in intensive care units. The de-escalation strategy is therefore naturally advocated as part of a better use of antibiotics. We aimed to evaluate the applicability and impact of this strategy in the pediatric intensive care unit
Methods: We conducted a prospective study spread over 4 months in the pediatric intensivr care unit of the CHU ibn rochd, including all patients under 15 years of age who had received probabilistic antibiotic therapy for more than 48 hours. Data analysis was performed usung SPSS software
Results: Out of 130 patients included in our study, 15,38% were de-escalated and 84,62% were not de-escalated. The yield of cultures was 39,9%. The clinical and biological deterioration rate after de-escalation was 10% vs 31,8% in the non-de-escalation group. Hospital mortality after de-escalation was 10%.
Conclusions/Learning Points: Antibiotic de-escalation appears to be a safe strategy to apply in critically ill children

[1]IRCCS Istituto Giannina Gaslini, Pediatrics And Infectious Disease Unit, Genova, Italy, [2]IRCCS Istituto Giannina Gaslini, Intensive Care Unit, Genova, Italy, [3]IRCCS Istituto Giannina Gaslini, Neonatal Intensive Care Unit, Genova, Italy, [4]IRCCS Istituto Giannina Gaslini, Microbiology Laboratory, Genova, Italy

Backgrounds: Bloodstream infections caused by CoNS are among the most frequent ICU-acquired-HAIs globally. First-line treatment for these infections is represented by vancomycin, an antibiotic with variable protein binding, eliminated via glomerular filtration, with time-dependent killing and prolonged post-antibiotic effect, whose optimal PK/PD target for efficacy and safety, although referred to severe MRSA infections, is an AUC/MIC ratio ≥400 with AUC<600. In case of MIC for vancomycin >1, the possibility of reaching this target with conventional non-toxic dosages is very poor, so alternative molecules should be considered.
Methods: A retrospective, single-center study was conducted regarding CoNS BSI events in critically-ill patients that occurred at Gaslini Hospital over five years, with the aim of evaluating the efficacy of vancomycin therapy in terms of achieving the desired PK/PD target and to determine whether there are any variables that interfere with the achievement of this target.
Results: The target of AUC/MIC≥400 with AUC<600, at 48 and 72 hours after initiation of therapy, was achieved in only 21% of neonates and 25% of pediatric patients, with an otherwise favourable outcome in terms of mortality and reinfection. In neonates population, mean albumin levels were higher in events in which, at 48 hours after initiation of therapy, AUC was ≥400 than in those in which <400 ($p<0.04$). In patients older than 30 days an inverse correlation was observed between eGFR and achieved AUC levels. Median eGFR at 72 hours was statistically higher (expression of hyperfiltration) in events with AUC<400, compared with those with AUC≥400 ($p<0.001$).
Conclusions/Learning Points: A cut-off of eGFR value in the first 72 hours of antibiotic treatment (145 ml/min/1.73m2) was identified, beyond which it is extremely unlikely to achieve an AUC≥400 for vancomycin in patients older than 30 days. A different antistaphylococcal empirical treatment is thus indicated in these patients.

[1]University of São Paulo, School Of Pharmaceutical Sciences, São Paulo, Brazil, [2]University of Sao Paulo, Surgery Plastic And Burns Division, São Paulo, Brazil

Backgrounds: Optimizing antimicrobial prescriptions for severe infections is a challenge in critically ill children to improve clinical outcomes. The aim of this study was to evaluate drug effectiveness in septic pediatric burn patients undergoing vancomycin-meropenem combined therapy.
Methods: Pediatric septic patients with major burns (>30%) and preserved renal function receiving vancomycin (10-15 mg/kg q6h, 1-hour infusion) and meropenem (40 mg/kg q8h, 30-minutes infusion) were included. Individualized dose adjustments were made from therapeutic drug monitoring using two steady-state blood levels. Pharmacokinetic-pharmacodynamics (PK/PD) target recommended for vancomycin was $AUC^{ss}_{0\text{-}24}$/MIC>400; while the meropenem target considered was 100%fT>MIC. The main outcomes were therapeutic target attainment, clinical and microbiological cure.
Results: We included 17 patients, medians: 5 years, 18 kg. Vancomycin therapeutic target was attained in only 47% of patients against Gram-positive strains up to MIC 1 mg/L, and then individual dosing adjustments were performed to ensure antimicrobial coverage. Meropenem therapeutic target was initially attained against Gram-negative susceptible strains up to MIC 2 mg/L, and subsequently increased to MIC 4 mg/L using a 3-hour extended infusion. All patients presented clinical cure or negative cultures.
Conclusions/Learning Points: The combined vancomycin-meropenem with real-time therapeutic drug monitoring improves the effectiveness against infections in pediatric burn patients. The PK/PD approach allows individual dosing adjustments.

E-POSTER VIEWING: AS01.C. PHARMACOLOGY

Ronaldo Morales Junior[1], Thais De Camargo[1], Leonard Kupa[1], Edvaldo De Campos[2], David Gomez[2], Silvia Santos[1]
[1]University of São Paulo, School Of Pharmaceutical Sciences, São Paulo, Brazil, [2]University of Sao Paulo, Surgery Plastic And Burns Division, São Paulo, Brazil

Backgrounds: Meropenem is largely prescribed to septic patients with infections caused by Gram-negative nosocomial pathogens. Pathophysiological changes during the systemic inflammatory response syndrome may impact the pharmacokinetics of meropenem and the desired outcome. The objective of this study was to investigate meropenem effectiveness and drug disposition in pediatric major burns through real-time therapeutic drug monitoring and pharmacokinetic-pharmacodynamic (PK/PD) approach.
Methods: Pediatric burn patients with preserved renal function receiving meropenem and vasopressors were investigated after the recommended dose of 40 mg/kg every 8 hours administered by 3-hour extended infusion. Two blood samples were collected at the 3rd and 7th hours of starting the infusion and meropenem serum measurements were done by liquid chromatography. The therapeutic target considered was 100%fT>MIC. The one-compartment open model was chosen to investigate meropenem pharmacokinetics.
Results: The 42 included patients were distributed by age: 2-7 years (Group 1, n=11); 8-13 years (Group 2, n=11); 14-18 years. (Group 3, n=20). Significant changes between groups occurred in meropenem clearance, biological half-life, and volume of distribution. With the 3-hour extended infusion, therapeutic target attainment was attained against Gram-negative strains with intermediate susceptibility (MIC 4 mg/L).
Conclusions/Learning Points: The meropenem therapeutic target of 100%fT>MIC was attained for all patients despite significant pharmacokinetic changes resulting from burn injuries, septic shock, and body composition variation. The PK/PD approach based on real-time serum monitoring is an important tool to assess meropenem effectiveness and, consequently, to avoid antimicrobial resistance.

DO SEPTIC PEDIATRIC BURN PATIENTS UNDERGOING VANCOMYCIN THERAPY REQUIRE DOSE ADJUSTMENT BY PHARMACOKINETIC-PHARMACODYNAMICS APPROACH IN A REAL TIME FOR DRUG EFFECTIVENESS?

E-Posters Viewing
E-POSTER VIEWING: AS01.C. PHARMACOLOGY

Ronaldo Morales Junior[1], Thais De Camargo[1], Leonard Kupa[1], Edvaldo De Campos[2], David Gomez[2], Vera Lanchote[1], Silvia Santos[1]
[1]University of São Paulo, School Of Pharmaceutical Sciences, São Paulo, Brazil, [2]University of Sao Paulo, Surgery Plastic And Burns Division, São Paulo, Brazil

Backgrounds: Vancomycin serum monitoring is recommended for critically ill pediatric patients with infections caused by Gram-positive strains. It was investigated if dose adjustments must be done at the earlier period of septic shock based on the pharmacokinetics-pharmacodynamics (PK/PD) approach in pediatric burn patients.
Methods: Patients receiving vancomycin were investigated after the empiric daily dose and after dose adjustment. Therapy started with 40-60 mg/kg daily, one-hour infusion, and, if required, the dose was adjusted to attain the vancomycin therapeutic target: area under the curve/minimum inhibitory concentration ($AUC^{ss}_{0\text{-}24}$/MIC) > 400. Blood was sampled at the 3rd and 5th hour and the one-compartment open model was applied to investigate the pharmacokinetics. The outcomes considered were therapeutic target attainment, clinical and microbiological cure.
Results: We included 42 septic burn patients. The vancomycin therapeutic target was attained against Gram-positive pathogens up to MIC 1mg/L in only 43% of patients. With individualized dosing adjustments, the target was attained for all patients considering MIC of 1 mg/L and for 57% of patients against strains with MIC 2 mg/L. Clinical cure occurred in all patients.
Conclusions/Learning Points: Initial dose of vancomycin was subtherapeutic in most septic pediatric burn patients. Vancomycin therapy guided by cultures and serum levels for dose adjustment in real-time using the PK/PD approach permits an earlier intervention to reach the desired clinical outcome.

PV0046 / #379

LIVER ENZYMES DURING AND AFTER ANTIMALARIAL THERAPY IN NIGERIAN CHILDREN WITH UNCOMPLICATED PLASMODIUM FALCIPARUM INFECTION.

E-Posters Viewing
E-POSTER VIEWING: AS01.C. PHARMACOLOGY

Zacchaeus Olofin[1,2], Adebola Orimadegun[3], Catherine Falade[1,4]
[1]University of Ibadan, Pharmacology And Therapeutics, Ibadan, Nigeria, [2]Bowen University, Pharmacology And Therapeutics, Iwo, Nigeria, [3]University of Ibadan, Institute Of Child Health, Ibadan, Nigeria, [4]University of Ibadan, Institute For Advanced Medical Research And Training, Ibadan, Nigeria

Backgrounds: Derangement of liver enzymes could occur during antimalarial treatment according to literature and this has been attributed to drug-induced liver toxicity.However, it remains unclear whether these changes in liver enzyme levels persist following the completion of antimalarial therapy. This study determines the effect of artemether-lumefantrine on plasma levels of four liver enzymes, namely;alanine aminotransferase [ALT],aspartate aminotransferase [AST],alkaline phosphatase [ALP] and gamma glutamyl transpeptidase [GGT] in children with uncomplicated Plasmodium falciparum infection.
Methods: We reviewed the records of all children who participated in a clinical trial of antimalarial drug in Ibadan, Nigeria and a sample of 102 children who met eligible criteria and with microscopically-proven Plasmodium falciparum infection treated with artemether-lumefantrine at recommended age-specific doses for 3 days.Study participants were followed up on days 3,7,14,21,and28 according to the WHO recommendation for treatment of malaria research participants.Inclusion criteria included symptoms attuned with acute uncomplicated malaria, including parasite density of at least 1000/µL and absence of chronic illness or danger signs of severe malaria.The results of ALT (U/L),AST (U/L),ALP (U/L)andGGT (U/L) at baseline (day 0),on day 3,and day 28 post-treatments were extracted and compared using Friedman tests.
Results: The median age of participants was 25 months(range =3 to119),and 49% were male.The mean values of ALTandAST did not change significantly over the course of the 28-day follow-up from baseline(25.8–19.1U/L p= 0.0984and50.4–52.2U/L p=0.1943 respectively). GGT decreased substantially between baseline 17.0 U/L(11.0-22.5) andday 28 15.0U/L(10.5-21.5) p=0.0010 while ALP increased over time(baseline:305.0U/L(216.0–403.5);day 28: 345.0 U/L(241.0–492.5)p=0.0303. Elevated ALT,AST,ALPandGGT were observed in 8.5%,20.0%,20.9%,and14.8% of participants,respectively.
Conclusions/Learning Points: Considerable rise in plasma levels occurred in ALP which could be indicative of liver injury occurring during antimalarial treatment among Nigerian children.Further research is needed to identify the underlying mechanism responsible for this drug-induced liver toxicity.

RIFAMPICIN AND NEUROPROTECTION - A SYSTEMATIC REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS01.C. PHARMACOLOGY

Nina Vaezipour[1,2], Sandra Bigi[3], Rinn Song[1,4], Nicole Ritz[5,6,7]
[1]University of Oxford, Paediatrics, Oxford, United Kingdom, [2]University Childrens Hospital Basel, Paediatrics, Basel, Switzerland, [3]Lucerne Childrens Hospital, Paediatrics, Lucerne, Switzerland, [4]University of Oxford, Oxford Vaccine Group, Department Of Paediatrics, And The Nihr Oxford Biomedical Research Centre, Oxford, United Kingdom, [5]Children's Hospital Lucerne, Paediatric Infectious Diseases, Luzern, Switzerland, [6]University Children Hospital Basel and University Basel, Department Of Clinical Reserach, Basel, Switzerland, [7]The Royal Children's Hospital Melbourne, Paediatric Infectious Diseases Unit, Melbourne, Australia

Backgrounds: Patients with tuberculous meningitis (TBM) are at considerable risk for neurological sequelae. The aim of this study was to systematically review the evidence for neuroprotective effects of rifampicin in infectious and non-infectious diseases.
Methods: A systematic literature search was done in MEDLINE and Embase using the OVID interface with a time window of reported studies from 1 Jan 1946/47 to 8 Aug 2022, in accordance PRISMA. (PROSPERO ID: CRD42022349852). Articles were identified using the following search terms: tuberculosis, rifampicin, CNS, brain, neurodegenerative, stroke, dementia, Alzheimer, Parkinson, multiple sclerosis, demyelination, meningitis, encephalitis, neuropsychiatric, encephalopathy, and inflammation. Original articles investigating the effect of rifampicin in neurologically affected patients, either by infections of the central nervous system (CNS) or by neurodegeneration, were included.
Results: 1428 articles were identified, 62 were selected for assessment. 6 randomized, controlled trials were included in the analysis. Four of the studies showed a beneficial effect of rifampicin with reduced inflammatory parameters in the cerebrospinal fluid (CSF), less cognitive decline or brain atrophy. One study showed worsening of cognitive assessment scales in neurodegenerative patients treated with rifampicin compared to placebo.
Conclusions/Learning Points: Rifampicin might reduce neuronal inflammation in both infectious and non-infectious neurodegenerative diseases. High doses of rifampicin seem to be necessary for improved CNS effects in patients with TBM and the risk of increasing adverse effects with higher dosages seems low. Comparison between studies was, however, limited by different study designs including dose and duration of rifampicin as well as variable outcomes measured. To assess the potential neuroprotective effect of rifampicin in patients with neurodegenerative or infectious diseases, further trials using standardized evaluation of clinical, radiological and neuropsychological follow-up and a consensus definition of clinical neuroprotection are required.

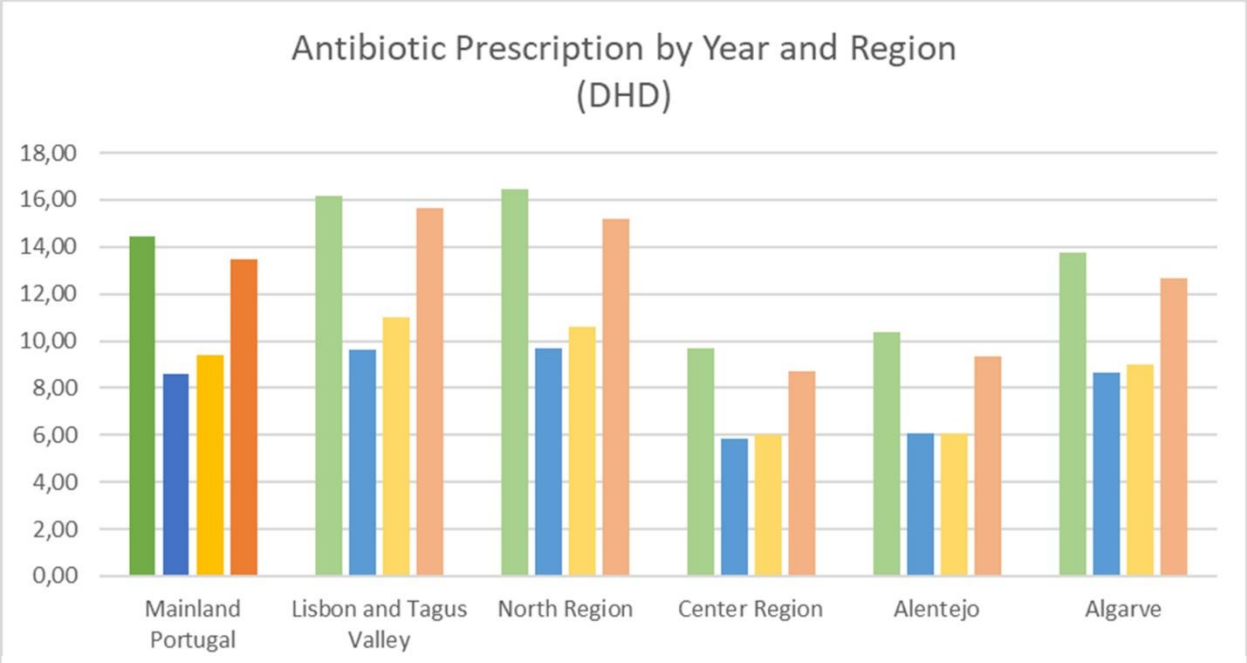
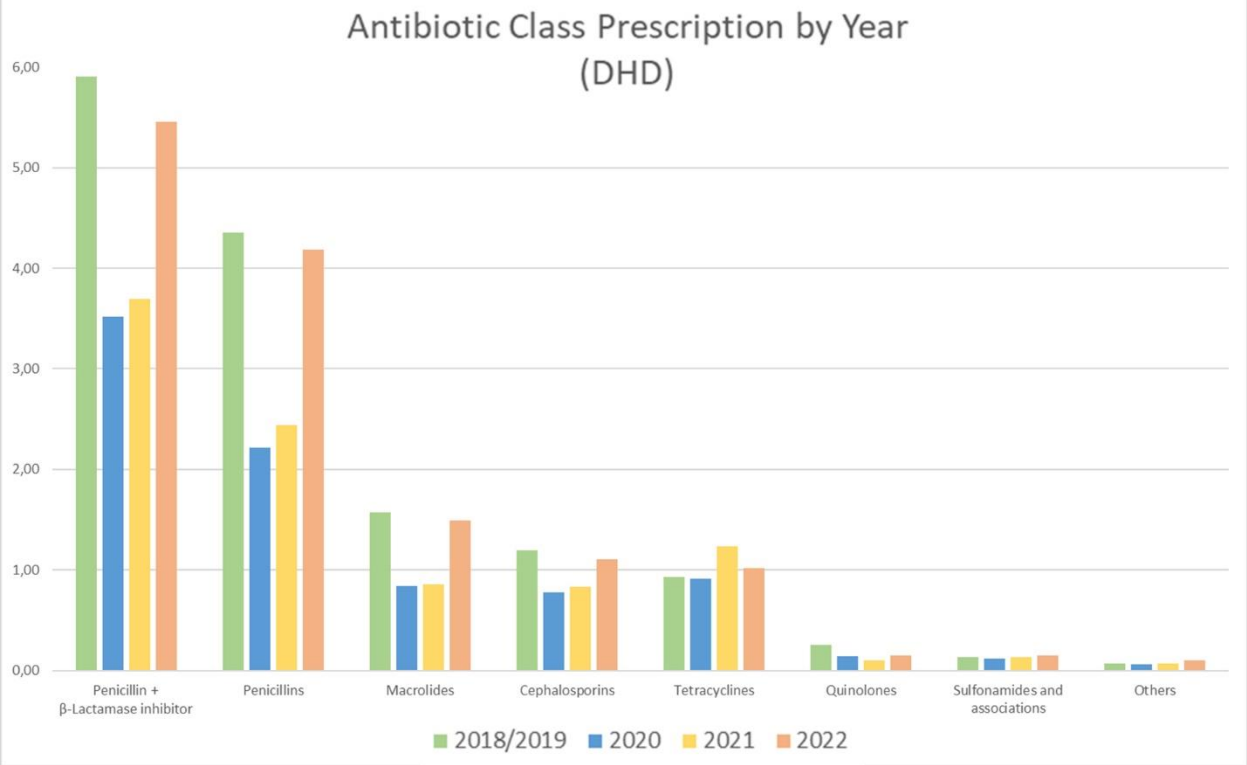
INCREASE IN PAEDIATRIC OUTPATIENT ANTIBIOTIC PRESCRIBING FOLLOWING MARKED REDUCTIONS DURING THE PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

José Alarcão[1], Ana Teresa Gil[1], Fernanda Rodrigues[2]
[1]Hospital Pediátrico de Coimbra, Serviço De Urgência, Coimbra, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Hospital Pediátrico, Coimbra, Portugal

Backgrounds: The COVID-19 pandemic brought unexpected and unprecedented epidemiological changes in several common infectious diseases, with profound reductions in antibiotic use in ambulatory care in children in Portugal, a country that is in the “middle band’ for usage of antibiotics, to rates comparable to those normally seen in “low-use” countries. The aim of this study is to ascertain whether this reduction in prescription persisted when the non-pharmaceutical interventions were reduced and infections returned.
Methods: This is a retrospective, observational cohort study. Paediatric (<18 years) antibiotic prescription data, in Defined Daily Dose (DDD), was obtained from the Ministry of Health Primary Health Care Identity Card “BI-CSP” (https://bicsp.min-saude.pt), a public-access platform, that includes information about ambulatory prescribing from all primary care centers and public and private hospitals in mainland Portugal. Results are expressed in DHD, or DDD per 1000 inhabitants (<18 years) per day.
Results:





The marked reduction in antimicrobial prescribing, particularly in younger children and during the lockdown periods, especially for those antimicrobials most commonly used to treat respiratory-tract infections was quickly reversed in the first year after non-pharmaceutical interventions were lifted. There are marked asymmetries in prescribing amongst regions and high prescribing rates of Penicillin/beta lactamase inhibitors combinations (figure 1).

Conclusions/Learning Points: Our findings indicate that the profound changes in antibiotic use in ambulatory care in children in Portugal driven by the COVID-19 pandemic have very quickly reverted to prepandemic patterns.

PV0049 / #1960

THE EFFECT OF MULTIPLEX POLYMERASE CHAIN REACTION PANEL UTILIZIATION IN PEDIATRICS MENINGITIS MANAGEMENT/ANTIMICROBIAL STEWARDSHIP

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Mohamed Alhosani, Huda Aldhanhani
Sheikh Khalifa Medical City, Pediatrics, Abu Dhabi, United Arab Emirates

Backgrounds: Empiric antibiotics use in children with suspected meningitis while awaiting CSF culture results may lead to inappropriate use of antimicrobial agents and exposure to their side effects unnecessarily. Multiplex Polymerase Chain Reaction (mPCR) is a diagnostic tool that can potentially aid in rapid identification of causative microorganism and providing targeted antimicrobial therapy particularly in patients who were pre-treated with antimicrobials prior to CSF culture which can reduce the sensitivity of the gram staining and culture.
Methods: A retrospective chart review of electronic medical records in the setting of inpatient encounters. It will be looking at children and adolescents (age 0 -16 years), admitted to Sheikh Khalifa Medical City (SKMC) with bacterial meningitis during the period from January 2018 to January 2022. mPRC was implemented at SKMC starting January 2020
Results: 98 patients were eligible to study criteria. 70 patients in the pre implemention of mPCR group and 28 after implementation. Most presenting symptoms were fever and lethargy that were present for 1 day. Duration of antibiotics were averaged to 2.5 days while awaiting initial CSF culture result. On the other hand, mPCR results were available on average by 2 hours from processing. Time to targeted therapy was on average 2 days. No early de-escalation of antimicrobials was seen in either group.
Conclusions/Learning Points: Despite much earlier access to negative mPCR CSF results, empiric antibiotics use continued until initial CSF culture results were present by 48 hours from processing them. On top of that, even if viral etiology detected on mPCR, antibiotics would still be continued. As a result, duration of hospital stay was increased by 2-3 days and more exposure to unnecessary antibiotics.

RULE OF ANTIBIOTIC PRESCRIBING FOR VIRAL RESPIRATORY INFECTIONS IN THE PEDIATRIC CLINIC AND URGENT CARE IN ALHASA REGION

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Mansoor Alnaim
King Abdulaziz National Guard Hospital, Family Medicine, Hofuf, Saudi Arabia

Backgrounds: Viral acute respiratory tract infections are a frequent source of inappropriate antibiotic prescribing. We describe the prevalence of antibiotic prescribing for viral acute respiratory tract infections in the pediatric clinic and urgent care within a health system, and identify factors associated with overall and broad-spectrum antibiotic prescribing.
Methods: Retrospective chart review within a single pediatric referral health system. Visits of patients, 6 months- 15 years old, with a discharge diagnosis of a Viral acute respiratory tract infections from January 2022 to November 2022 . Data collected included specific Viral acute respiratory tract infections diagnosis, site type (Pedaitric Clinic or Urgent Care), provider type [pediatric medicine subspecialist or physicians, nurse practitioners, physician assistants and discharge antibiotics. Odds ratios and 95% confidence intervals were calculated where appropriate.
Results: There were 74,675 eligible visits, mean age 4.2 ± 4.4 years. Fifty-three percent were treated in Pediatric Clinic. Advanced practice providers, a term encompassing nurse practitioners and physician assistants, were the most common provider type (47.7%); 16.5% of patients were treated by a pediatric medicine subspecialist. Antibiotics were prescribed for 3.6% (95% CI: 3.72-3.92) of children with Viral acute respiratory tract infections; 23.4% (95% CI: 24.2-26.6) of these were broad-spectrum, most commonly first-generation cephalosporins (11%; 95% CI 10.2-11.9). Patients treated in an Pediatric Clinic or by a nurse practitioners, physician assistants and those receiving chest radiograph received antibiotics most frequently. Prescribing rates varied by specific Viral acute respiratory tract infections diagnosis.
Conclusions/Learning Points: Patients discharged from the pediatric clinic or Urgent care with Viral acute respiratory tract infections receive inappropriate antibiotics at a lower rate than reported in other community settings; however, they frequently receive broad-spectrum agents.

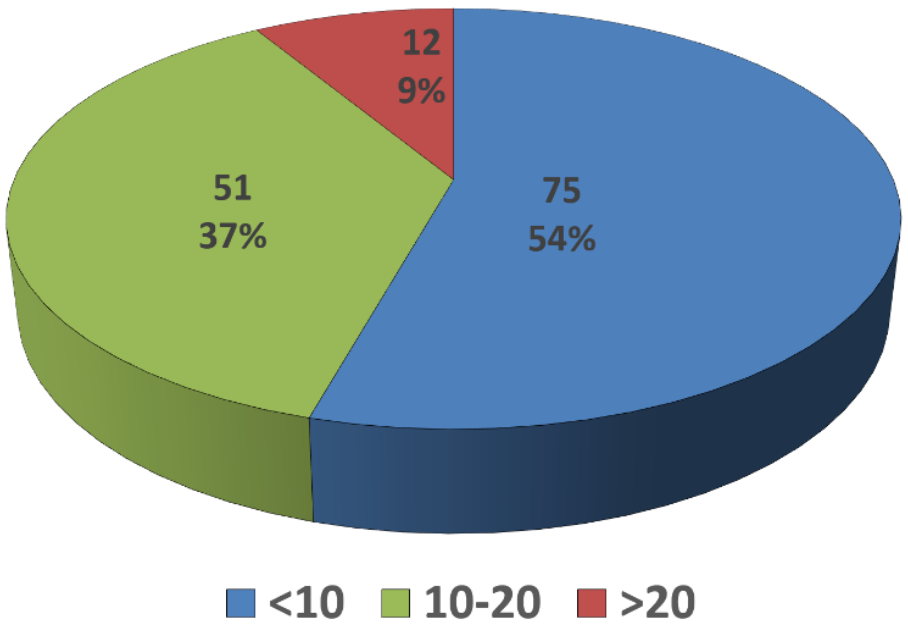
PV0051 / #801

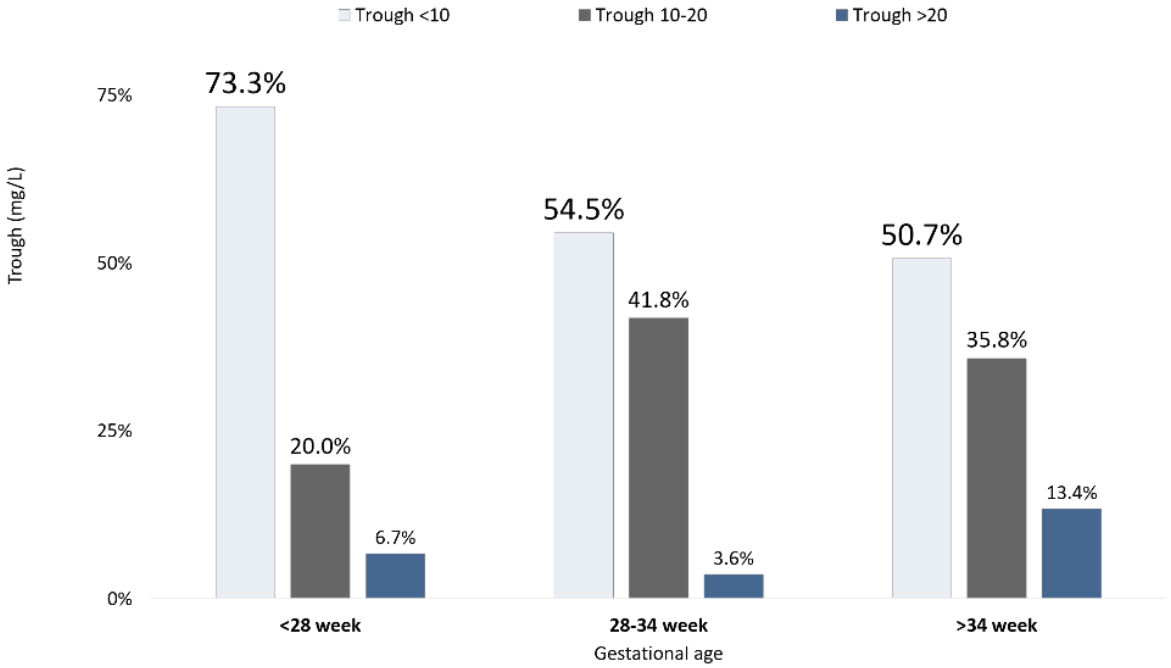
CHALLENGES IN REACHING VANCOMYCIN TARGET TROUGH LEVEL IN NEONATES WITH THE CURRENT DOSING REGIMEN

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Asmaa Alzubaidi, Mohammad Alharbi
King Abdulaziz medical city, Pharmacy, Jeddah, Saudi Arabia

Backgrounds: Vancomycin is frequently recommended in neonates for infections caused by gram-positive bacteria resistant to ß-lactams.There are several different vancomycin dosing regimens for neonates, although attaining therapeutic trough level remains a challenge. Moreover, all of the dosing regimens are presented in a table format, with a restricted number of "dose categories" to account for population variation. The aim of this study is to evaluate the efficacy of vancomycin dosing based on NeoFax to achieve the target trough level and the proportion of neonates achieving an optimal therapeutic vancomycin level at the first vancomycin concentration assay.
Methods: A retrospective cohort study conducted in a tertiary care hospital from2019-2021.The study included138 neonates.In NICU up to44weeks of gestational age who received a minimum of three doses of vancomycin and had at least one concentration correctly drawn through. The primary outcome is the percentage of neonates that attained serum trough levels(10-20mg/L).In addition,The secondary outcomes are to evaluate the association between urine output and vancomycin trough and the incidence of nephrotoxicity of vancomycin alone or when combined with other nephrotoxic medicine.
Results: 37.0% achieved goal trough of(10–20mcg/mL), 54.3% had trough(<10mcg/mL)(p0.003), and 8.7% had trough(>20mcg/mL). In neonates<28weeks; 20% had trough(10–20mcg/mL) with q12hours dosing and wasn't associated with nephrotoxicity while NeoFax frequency was q18hours. For secondary outcomes only 2.2% of patients had post-vancomycin acute kidney injury and there was no significant association between gestational age(weeks) and urine output (ml/kg/hr).





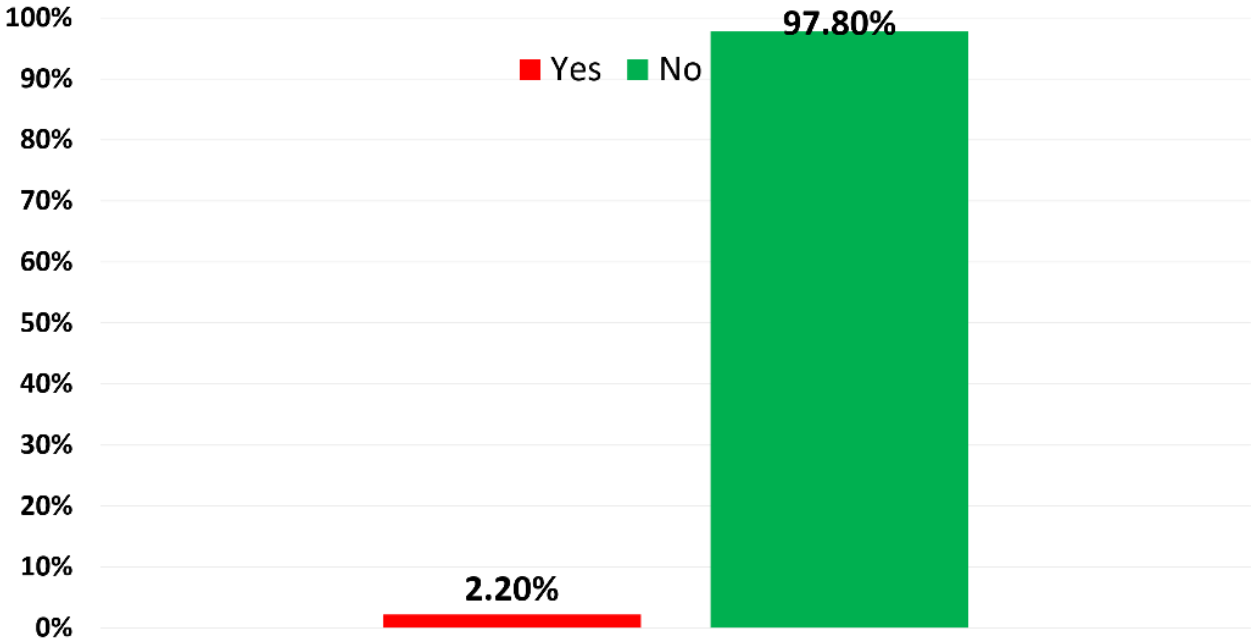


Figure 3: Vancomycin Acute Kidney injury

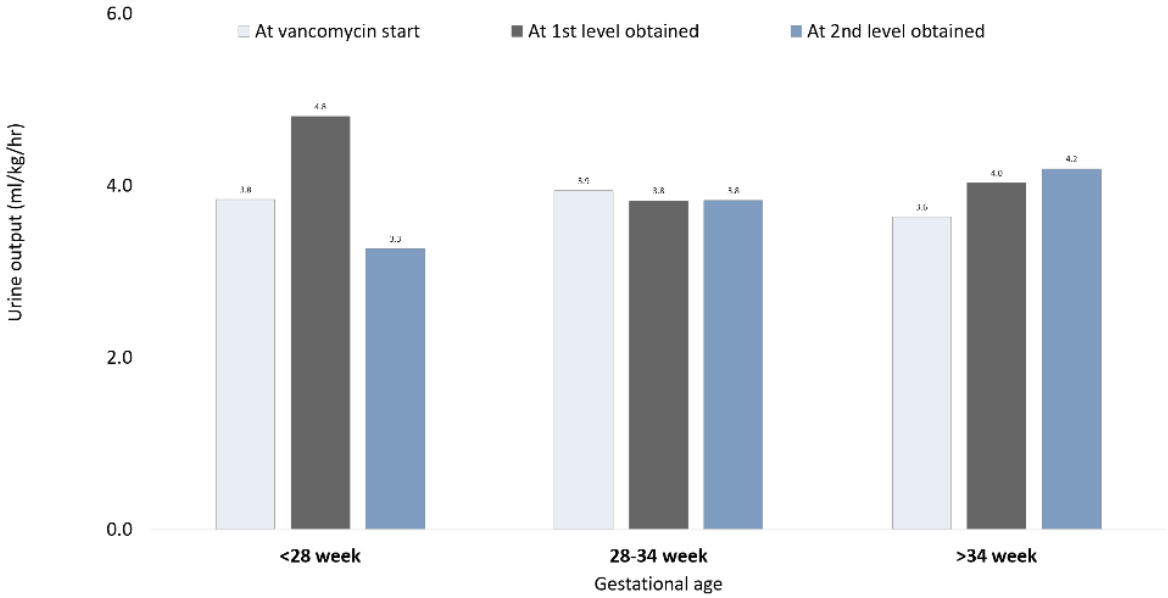

Conclusions/Learning Points: The current vancomycin dosing regimen based on Neofax®in NICU patients is insufficient in yielding serum trough concentrations of 10 to 20mg/L.

PV0052 / #2259

MANAGEMENT OF ANTIMICROBIALS IN PEDIATRIC HOME CARE IN RIO DE JANEIRO

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

André Ricardo Araujo Da Silva[1], Izabel Leal[2], Cristiane Teixeira[3], Cristina Souza[4], Mirian Cardoso[2]
[1]Universidade Federal Fluminense, Materno Infantil, Nterói, Brazil, [2]Prontobaby, Infection Control Comittee, Rio de Janeiro, Brazil, [3]Prontobaby Group, Infection Control Committee, Rio de Janeiro, Brazil, [4]Prontobaby, Infection Control Comittee, Niterói, Brazil

Backgrounds: Management of antimicrobials is necessary in pediatric home care population. The aim is to identify the most used antibiotics in the treatment of tracheitis and pneumonia in pediatric home care patients.
Methods: We conducted a retrospective analysis of antimicrobials prescriptions during 2022. Need to change antibiotics within 15 days for the same infection due to lack of clinical response was considered TF. Patients hospitalized for the initial infectious reason were considered for HA.
Results: Two-hundred two patients were analyzed and the most used antibiotic in TRACHEITIS was ciprofloxacin. Treatment failure: We identified 14 FT among all 69 treatments for tracheitis (14/69=20%). Of these, 8 were using ciprofloxacin: 8/69 total = 12% FT among all treatments, and (8/28=28%) among ciprofloxacin treatments for this site. Hospital admission: despite starting treatment, 9 cases required HA (9/69 = 13%) and 5 of the patients who used ciprofloxacin for this site required HA (5/28= 18%). The most used antibiotic in PNEUMONIAS was amoxicillin/clavulanate. Treatment failure: We identified 13 FT among all 52 pneumonia treatments (13/52=25%). Of these, 9/52(17%) used amox/clav. FT among all treatments, and 9/18=50% among amox/clav treatments for this site. Hospital admission: despite starting treatment, 17 cases needed HA (17/52=33%) and 7 cases of patients who used amox/clav for this site required HA (7/18=39%).
Conclusions/Learning Points: the most commonly used antibiotics for tracheitis and pneumonia were ciprofloxacin and amoxicillin/clavulanate, respectively. We identified a high rate of TF and HA among pneumonia treatments with amoxicillin/clavulanate (39% and 50% respectively), suggesting that this should not be a first-line option for this indication in this population. Among tracheitis treatments with ciprofloxacin, the rate of HA was lower than that of TF (28% and 18% respectively).

ANTIMICROBIAL USE AND UNDERSTANDING IN THE GAMBIA: A FRAMEWORK ANALYSIS OF PATIENT AND CAREGIVER PERSPECTIVES

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Giselle Ayoub[1], Katie Parker[1], Stephen Owens[2], Matthew Breckons[2], Karen Forrest[3], Behzad Nadjm[3]
[1]Newcastle University, Faculty Of Medical Sciences, Newcastle Upon Tyne, United Kingdom, [2]Newcastle University, Population Health Sciences Institute, Newcastle Upon Tyne, United Kingdom, [3]MRC Unit The Gambia at LSHTM, Clinical Services Department, Banjul, Gambia

Backgrounds: Antimicrobial resistance (AMR) is a global issue exacerbated by systemic antibiotic overuse and misuse. In Sub-Saharan Africa (SSA), quality AMR data is lacking, antibiotic regulation is poor, and infectious disease rates are high. To ensure the sustainability of an effective global response to infectious disease, coordinated action is required to limit further AMR whilst maintaining access to appropriate antibiotics. Assessing antibiotic use and understanding in areas where AMR is particularly problematic is essential. This includes exploring knowledge, attitudes, and practices underpinning antibiotic consumption. Our study addressed these themes in The Gambia, where such research is scarce.
Methods: Semi-structured interviews were conducted with clinic patients and caregivers. Topics included knowledge of antibiotics and AMR, experience of antibiotic use, and clinical scenarios where antibiotics should be sought or supplied. Contemporary fieldnotes were analysed according to Ritchie and Spencer's Framework Method, comprising familiarisation, coding, analytical framework development, and framework matrix data charting.
Results: The sample included 3 patients aged 12-20 and 7 caregivers of patients aged 4 months-12 years. Recurring concepts centred around antibiotic knowledge and use, health and disease understanding, and antibiotic supplier duties. Most participants demonstrated little antibiotic knowledge or AMR awareness. Despite some not knowing what antibiotics are, they reported having previously taken named examples for symptoms including pain and cough. When seeking antibiotics, participants described deferring to professional expertise over adopting a consumeristic approach. However, nobody had ever been advised against antibiotics.
Conclusions/Learning Points: Improved regulatory policies, supplier training and population education are required to ensure appropriate antibiotic use. These findings could inform interventions and future research evaluating their efficacy. Greater knowledge and rationalised antibiotic use have the potential to abate the current trajectory of rising AMR in SSA.

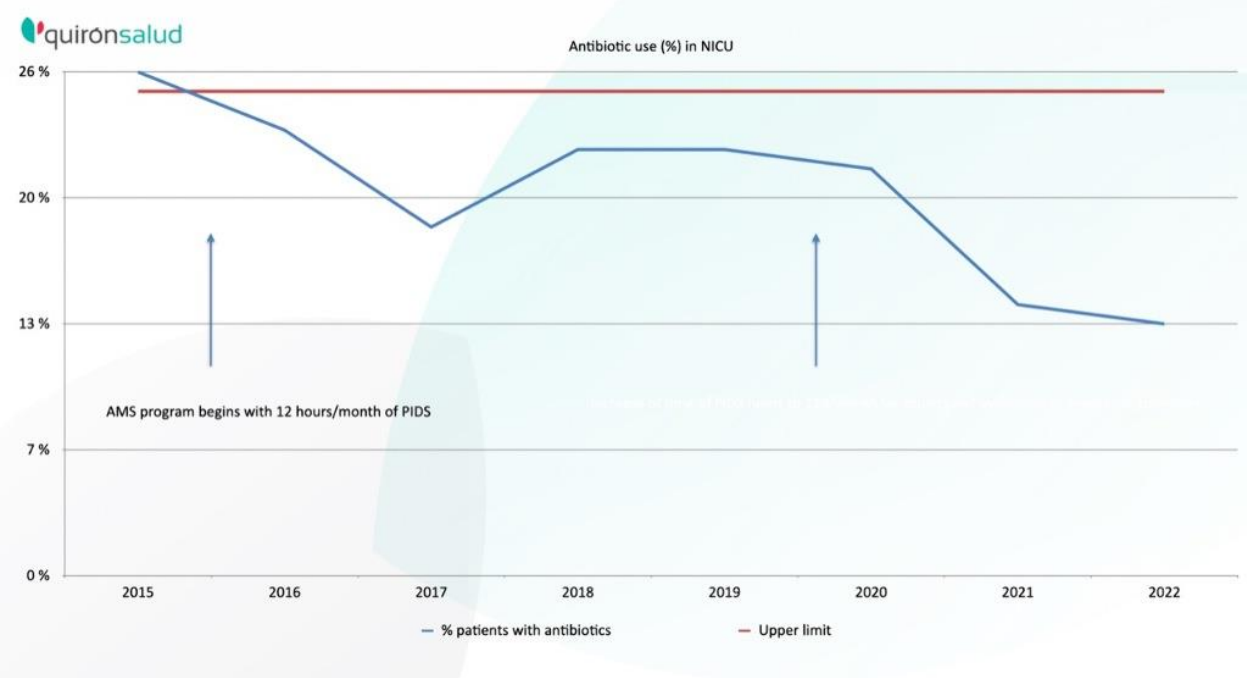
IMPACT OF ANTIMICROBIAL STEWARDSHIP PROGRAM IN THE USE OF ANTIBIOTIC IN THE NICU

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Claudia Patricia Beltrán Arroyave[1], Monica Castaño Galvis[2], Carmen Rios[2], Alejandro Diaz[3]
[1]Universidad de Antioquia. Clínica del Prado. Clinica El rosario, Antioquia, Antioquia, Colombia, [2]Clínica Del Prado QuironSalud, Antioquia, Medellin, Colombia, [3]Hospital general. Hospital Pablo Tobon, Infectious Diseases, Medellín, Colombia

Backgrounds: Newborn are at high risk for infections, and sepsis is frequent in neonatal intensive care units (NICU) with high mortality and non-specific clinical manifestations has led to an overuse of antibiotics with prolonged duration and impact on the neonatal microbiome with sequelae in the medium and long term, and a dangerous effect on antimicrobial resistance. The objective of this study is to demonstrate the impact of of an antimicrobial stewardship program (AMS) on the reduction of the general use of antibiotics in a neonatal unit.
Methods: The trend in percentage of antibiotic use was calculated and analyzed (number of patients with antibiotics / number of patients hospitalized) for seven years (2015 to 2022) when the AMS program began. The program includes monitoring the consumption of restricted antibiotics, updating management guidelines, conducting rounds for the evaluation of the relevance of the antibiotics.
Results:



During the period analyzed, a downward trend in the use of antibiotics was observed, initially 27% in 2015 and 13% in 2022. This decrease was more noticeable after the intensification of the strategy with the hiring of pediatric infectology (2016) and the update of treatment guidelines (2019). No increase in mortality was observed. The percentage of resistant microorganisms stay very low in the last year (4,5% for ESBL in 2022 and witn no one carbapenemases).
Conclusions/Learning Points: AMS strategy has a positive impact in reducing the consumption of antibiotics in the neonatal unit.

PV0055 / #106

DRUG UTILIZATION EVALUATION OF VANCOMYCIN USE IN PEDIATRIC PATIENTS

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Sophida Boonsathorn[1], Chanya Pongpatipat[2], Chonnamet Techaseansiri[2], Sujittra Chaisavaneeyakorn[2], Nopporn Apiwattanakul[2]
[1]Faculty of Medicine Ramathibohi Hospital, Department Of Pediatrics, Bangkok, Thailand, [2]Ramathibodi Hospital Mahidol University, Pediatrics, Bangkok, Thailand

Backgrounds: The judicious administration of vancomycin is necessary to prevent the further emergence of resistant organisms. The objective of this study was to evaluate the appropriateness of vancomycin prescriptions and the performance of drug utilization evaluation (DUE) on vancomycin prescriptions in an institutional setting with a low prevalence of MRSA infection.
Methods: Between April 2020 and March 2022, a historical-control study was conducted at the Department of Pediatrics, Ramathibodi Hospital in Bangkok, Thailand. All hospitalized children aged 0 to 18 years who received at least one dose of vancomycin were included. Before implementing DUE, the appropriateness of vancomycin prescriptions was retrospectively evaluated using DUE criteria. From April 2021 to March 2022, DUE was introduced on a voluntary basis. Demographic data, vancomycin usage, and clinical data were recorded. The outcome measures were the appropriateness of vancomycin prescriptions according to the indications based on the institutional guideline.
Results: A total of 423 vancomycin prescriptions were collected. There were 232 and 191 prescriptions in the non-DUE and DUE groups, respectively. The appropriateness of prescription was higher in the DUE group than in the non-DUE group (87.9% vs. 72.0%; p-value < 0.001). The DUE form was significantly associated with appropriate vancomycin prescriptions (adjusted OR 2.96: 95%CI 1.44-6.10; p-value = 0.003). In addition, ID consultation corresponded with more appropriate prescriptions (adjusted OR 3.87: 95%CI 1.95-7.67; p-value < 0.001).
Conclusions/Learning Points: DUE and ID consultation improved the appropriateness of vancomycin prescriptions in pediatric patients. Immunocompromised patients, such as cancer patients or transplant recipients, appeared to be associated with inappropriate vancomycin prescriptions.

[1]Padua University, Department Of Women's And Children's Health, Padua, Italy, [2]Padua University, Pediatric Emergency Department, Department Of Women's And Children's Health, University Of Padua, Padua, Italy, Padua, Italy, [3]University of Padova, Division Of Paediatric Infectious Diseases, Department For Women And Children's Health, Padova, Italy, [4]University of Milano Bicocca, Laboratory Of Healthcare Research & Pharmacoepidemiology, Unit Of Biostatistics, Epidemiology And Public Health, Department Of Statistics And Quantitative Methods, Milan, Italy, [5]University of Padua, Paediatric Infectious Diseases, Padua, Italy, [6]University of Padua, Pediatric Emergency Department, Padua, Italy, [7]University of Padova, Division Of Pediatric Infectious Diseases, Department For Women's And Children's Health, Padova, Italy

Background: To evaluate the change in antimicrobial prescriptions after the implementation of a stewrdship program, Point Prevalence Surveys (PPSs) have been used worldwide. However, the optimal frequency for PPS is still not known. The objective of this study was to assess the most feasible and sustainable timing for PPSs using AWARE classification that best defines patterns of hospital antibiotic use.
Methods: This is a secondary analysis of a dataset with daily antibiotic prescriptions in children admitted to the Pediatric Acute Care Unit of Padua University from October 2014 to August 2022. All prescriptions were collected and analyzed using the AWaRe classification. Different PPS timing were tested to evaluate which one could best reflect the prevalence of total annual prescriptions. The rate of antibiotic prescriptions in the specific time intervals was compared to the annual rate, and the difference was calculated.
Results: 4849 prescriptions were collected. The percentage of prescriptions collected with 1- or 2-times per year PPS was less than 5% of the total prescriptions, while with 1- or 2-times per month PPSs it was greater than 20%. Due to the substantial differences between rates, PPSs once and twice per year did not seem appropriate. Instead, once per month PPS seems to reflect, at best, the annual prescriptions, following the seasonal trend of antibiotic prescriptions. However, 3-,4- and 6-times per year PPSs could be acceptable, best combining the least number of surveys with adequate precision.
Conclusions/Learning Points: Collection of antibiotic prescriptions using PPSs 3-,4- or 6-times per year seems a feasible and sustainable method to monitor antibiotic consumption instead of daily data collection. This could be particularly relevant in low-resource settings, in which continuous data collection is not feasible due to high workload and lack of resources.

SINGLE-CENTRE EXPERIENCE: EARLY DISCONTINUATION OF ANTIBIOTICS (BEFORE ABSOLUTE NEUTROPHIL COUNT >500/MM3) IN PAEDIATRIC PATIENTS WITH CANCER AND/OR HSCT AND FEBRILE NEUTROPENIA

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Cristina Camara Costa[1], Anna Faura[2], Sílvia Simó Nebot[3]
[1]Sant Joan de Déu Hospital, Pediatric Department, Esplugues de Llobregat, Barcelona, Spain, [2]Sant Joan de Déu Hospital, Oncology Department, Esplugues de Llobregat, Spain, [3]Hospital Sant Joan de Déu, Infectious Diseases Unit, Esplugues de Llobregat, Spain

Backgrounds: Maintaining broad-spectrum antibiotics until resolution of fever and absolute neutrophil count (ANC) recovery is the standard of care for paediatric patients with cancer or haematopoietic stem cell transplantation (HSCT) and febrile neutropenia (FN). Despite this, there is growing evidence showing that stopping antibiotics before ANC recovery in low risk patients is safe. Data in the paediatric population is scarce. Objective: to describe characteristics and outcomes paediatric cancer patients with FN and discontinuation of antibiotics before ANC recovery.
Methods: Observational and retrospective study, including patients <18 years of age with cancer/HSCT admitted in a referral paediatric cancer centre for FN (June-November 2022) and in whom antibiotic treatment was discontinued before ANC >500/mm3. Patients with an identifiable source of infection, sepsis, PICU admission or antibiotic therapy prior to admission were excluded. We analysed epidemiological, clinical and laboratory data. Patients' outcome regarding readmission, new infection or death in the following 7-day period was recorded
Results: 43 episodes corresponding to 34 different patients were included. Generally, patients included and considered for early antibiotic discontinuation presented with low-grade fever and low procalcitonin levels. Table 1 shows main clinical, epidemiological and laboratory data. During the 7-day follow-up period, fever reappeared in 5 patients (11%), of whom only 2 required readmission (no PICU). No evidence of new bacterial infections and no deaths were
reported

Table 1

Qualitative variables	Frequency	Percentage
Gender (%) n= 34		
• Male	23	67.7%
• Female	11	32.3%
Diagnosis (%) n=34		
• Leukaemia or lymphoma	12	35.2%
• Solid tumours	18	52.9%
• Non-malignant haematological disease	4	11.7%
Fever duration (%) n=34		
• ≤ 24 hours	27	79.4%
• > 24 hours	7	20.5%
Antibiotic therapy (%) n=34		
• Piperacillin-tazobactam +/- amikacin	31	91.1%
• Meropenem	1	2.9%
• Teicoplanin	1	2.9%
• Vancomycin	1	2.9%
Quantitative variables	**Median (IQR)**	**Interquartile range (IQR)**
Age (years) n=34	7	2 - 12.2
Axillary temperature (ºC) n=34	38.1	37.8 - 38.6
Maximum C reactive protein (mg/L) n= 34	54	28.5 - 102.5
Maximum Procalcitonine (ng/mL) n= 32	0.11	0 - 0.29
Duration of antibiotic therapy (days) n= 34	3	3 - 4
ANC at the time of discontinuing antibiotics (mm3) n= 34	100	0 - 300

Conclusions/Learning Points: Our results suggest that antibiotic discontinuation before ANC recovery in selected paediatric patients with FN is safe and could allow early hospital discharge and reduce costs, drug toxicity and antimicrobial resistance. Our results are limited because of the retrospective and single-centre study design. Further prospective, controlled and multicentric studies are required to prove the safety of this strategy.

[1]HOSPITAL UNIVERSITARIO DE CANARIAS, Pediatric Service, la laguna, Spain, [2]HUC, Pediatric Surgery, LA LAGUNA, Spain, [3]HOSPITAL UNIVERSITARIO DE CANARIAS, Internal Medicine, la laguna, Spain

Backgrounds: The effectiveness of antimicrobial stewardship programs (ASP) has shown a relevant impact in global health in the last decades, even though the data is still limited in the pediatric population. We performed a study to demonstrate the benefit of the implementation of an ASP in the pediatric ward.
Methods: Data from January-2021 to December-2022 was collected from a regional appendicitis database. We evaluated the use of broad-spectrum antibiotics, Days of Therapy (DOT), Length of Stay (LOS) and complications rate, before (group-A, n=43) and after (group-B n=34) the implementation of an ASP in complicated appendicitis (CA).
Results: A total of 153 children were diagnosed with appendicitis, 50.2% (n=77) were complicated. The average age in CA was 8.8 years-old (3-14 years) and 49 patients were male. Comparing age, sex, LOS and complications rate, no statistical differences were found in both groups (p>0.05). DOT in group-B was 1.8 days less compared to group A (p0.06), excluding the appendix mass, the reduction was higher, with 2.8 days. An important reduction in the use of broad-spectrum antibiotics was observed in group-B: 38% for piperacillin-tazobactam, 21.1% for amoxicillin-clavulanate and 100% for others such carbapenems, clindamycin or quinolones, with an increase of 91,8% for ceftriaxone/metronidazole. No statistically significant differences were found in LOS, with an average of 6.17 days and neither in complication rates. Yet, one moderate Clostridium difficile infection was observed in group A.
Conclusions/Learning Points: The implementation of ASP has improved the use of broad-spectrum antibiotics and DOT, without increased complications in complicated appendicitis. Although our data is limited, differences could be found in a long period of time. More studies are needed to define a best strategy in the treatment in CA in the pediatric population.

STAPHYLOCOCCUS AUREUS BACTEREMIA IN CHILDREN : THE NEED FOR AN ANTIBIOTIC STEWARDSHIP PROGRAM

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Alexandra Falke[1], Luc Panetta[2], Dominique Ploin[3], Yves Gillet[3]
[1]HFME, Pediatric Emergency Department, Infectious Disease Department, Bron, France, [2]Hôpital Femme Mère Enfant - Hospices Civils de Lyon, Emergency - Pediatric Infectious Disease, Bron, France, [3]Hôpital Femme Mère Enfant - Hospices Civils de Lyon, Emergency - Infectious Disease, Bron, France

Backgrounds: Staphylococcus aureus bacteremia is a frequent and severe infection with well-established management guidelines. The aim of this study was to assess the adherence to current management guidelines of Staphylococcus aureus bacteremia in pediatrics.
Methods: This was a single-center retrospective observational study from January 2020 to May 2022. We included all children (<18 years) with a blood culture positive for Staphylococcus aureus. The primary outcome was a composite criteria of blood culture monitoring (until a negative culture was obtain), antibiotic adaptation in the case of methicillin-sensitive Staphylococcus aureus, duration of antibiotic therapy, and removal of central venous catheter if present. We looked at this primary outcome in our whole population, in each department, and finally depending on the use of a pediatric infection disease consultation.
Results: Out of 114 children with a Staphylococcus aureus bacteremia, the management was in complete accordance with the guidelines for 29.8% of patients, in partial accordance for 62.3% of patients, mainly due to delayed therapeutic adaptations and short duration of antibiotic therapy, and in non-accordance for 7.9% of patients. The departments with the lowest adherence were the surgical departments (91.3% of partial or non-accordance). A significant association between the adherence to guidelines and the use of pediatric infectious disease consultation was found ($p = 0.024$).
Conclusions/Learning Points: This study showed that the management of Staphylococcus aureus bacteremia in our center is mostly not or partially in accordance with the current guidelines. We found a strong association between the use of pediatric infectious disease consultation and a better accordance to the management guidelines. This tends to justify the implementation of an antibiotic stewardship program with a systematic pediatric infectious disease consultation.

[1]Hospital Sant Joan de Déu, Paediatrics Department, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Déu, Paediatric Intensive Care Unit, Esplugues de Llobregat, Spain, [3]Hospital Gregorio Marañón, Paediatric Intensive Care Unit, Madrid, Spain, [4]Hospital Son Espases, Paediatric Intensive Care Unit, Palma de Mallorca, Spain, [5]Hospital Sant Joan de Deu, Pediatric Intensive Care Unit, Esplugues de Llobregat (Barcelona), Spain, [6]Hospital Vall d'Hebron, Epidemiology, Barcelona, Spain

Backgrounds: Healthcare-associated infections (HAI) are a major public-health problem. The aim of this study is to compare the evolution of the antibiotics (ATB) used for HAI treated in Paediatric Intensive Care Units (PICU) from the Spanish registry Paediatric-ENVIN-HELICS.
Methods: Multicentre, prospective and observational study of HAI diagnosed in 25 Spanish PICU, during a three-month period from 2014–2021. The ENVIN diagnostic criteria adapted to paediatrics were used, based on ECDC recommendations.
Results: Total number of patients was 12958. In 2021 the rate of antibiotics use was 67%. Comparing 2021 with 2014, this rate decreased 12% ($p<0.001$). The number of ATB was 1.3/patient and 1.9/patient treated with ATB. An increase was observed in the prescription of meropenem for HAI diagnosed previous PICU admission of 1.6% and a decrease of 0.8% for HAI diagnosed in PICU ($p>0.05$). The empirical ATB treatment was inadequate in 10% of the cases (n=118). Comparing the last and the first year of the registry, in 2021 the early suspension antibiotic rate increases 8% ($p<0.001$) and the antibiotic stewardship is 12% higher ($p=0.016$). Antibiotic modifications happened in 14% of cases (n=199). Modifications due to poor clinical course decreased by 9.5% ($p=0.036$), and due to adverse effects/toxicity or the appearance of resistances remained stable since the beginning of the registry.
Conclusions/Learning Points: ATB use rate remains high (67%) in our patients, but trends downwards for the first time in 2021. Each patient receives almost 2 ATB. Carbapenems' use remains high for the treatment of HAI. Improvement of antibiotic policy has been effective through an increase in the rate of antibiotic stewardship and early suspension antibiotic rate. Modifications due to poor clinical course has decreased, while those due to adverse effects or new resistances remained stable.

Ciber De Enfermedades Infecciosas (ciberinfec), Instituto De Salud Carlos Iii. Fundación Idipaz. Translational Reserch Network In Pediatric Infectious Disease (ritip), Madrid, Spain

Backgrounds: Pseudomonas aeruginosa bacteremia (PAB) is a serious infection and a therapeutic challenge due to increased resistance to carbapenems although risk factors in pediatrics are limited. Our objectives were to describe the prevalence and risk factors associated with carbapenem resistance (CR) and mortality in PAB.
Methods: Multicentric and retrospective study including patients <20 years old with PAB in four tertiary hospitals in Madrid between 2010-2020. Risk factors for CR-PAB and 30 day-mortality were analyzed with a multivariate analysis with stepwise regression.
Results: We included 151 PAB episodes (median age 29 months, IQR 3.5-87.1, 55% male) and 45 episodes (29.8%) were CR-PAB (8.0% VIM-type carbapenemase producers, 9.9% multidrug-resistant and 6.6% extensively drug-resistant, 5.3 % undetermined). CR was associated in the univariate analysis with carbapenem treatment in the previous month (OR: 8.82) and in the previous 6 months (OR: 6.11) and in the multivariate analysis with antibiotic treatment in the previous month (aOR: 11.15, 95%CI 4.40-28.19) and solid organ transplantation (aOR: 7.64, 95%CI 1.91-30.58). Thirty-day mortality was 23.5%; risk factors associated with PAB mortality are shown in Table 1. Source control was a protective factor (aOR: 0.11, 95%CI 0.03-0.34). Risk factors for mortality in CR-PAB were neutropenia (OR: 7.95 95%CI 1.19-85.98) and isolation of VIM-producing P. aeruginosa (OR: 5.23, 95%CI 1.50-18.17), being again the source control was a protective factor (OR: 0.06, 95%CI 0.01-0.38).

Table 1. Risk factors associated with mortality in *Pseudomonas aeruginosa* bacteremia (n=151). *Adjusted OR of variables included in the final multivariate logistic regression model selected through stepwise regression.

Risk factors	OR (95% CI)	Adjusted OR (95% CI) *
Carbapenem resistance	3.49 (1.46-8.28)	
Mechanical ventilation	2.99 (1.27-7.00)	
Parenteral nutrition	5.17 (1.22-6.72)	
ICU admission	2.92 (1.24 -7.06)	
Carbapenems in the previous 6 months	2.96 (1.22-7.22)	
Neutropenia	2.84 (1.11-7.05)	
Appropriate treatment delay	5.19 (1.75- 14.99)	
Renal insufficiency	3.34 (1.20-9.01)	
Inadequate empirical treatment	4.17 (1.60-10.65)	4.69 (1.65-13.32)
Sepsis at diagnosis	8.08 (2.30- 43.09)	7.17 (1.86-27.52)

Conclusions/Learning Points: PAB in children and adolescents has a high mortality. Nearly one-third are CR, being associated with the recent administration of carbapenems and solid organ transplantation. Inadequate empirical treatment, carbapenem resistance and sepsis at diagnosis were associated with mortality.

PV0062 / #2563

A DESCRIPTIVE STUDY OF VANCOMYCIN USE AT RED CROSS WAR MEMORIAL CHILDREN'S HOSPITAL, CAPE TOWN

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Leonore Greybe[1], Brian Eley[2], Hafsah Tootla[3], Wisdom Basera[4], Anna Botha[5], James Nuttall[1]
[1]University of Cape Town, Department Of Paediatrics And Child Health, Cape Town, South Africa, [2]University of Cape Town, Department Of Paediatrics And Child Health, Red Cross War Memorial Children's Hospital, Cape Town, South Africa, [3]National Health Laboratory Service, Red Cross War Memorial Children's Hospital, Medical Microbiology, Cape Town, South Africa, [4]University of Cape Town. Burden of Disease Research Unit, South African Medical Research Council, School Of Public Health And Family Medicine, Cape Town, South Africa, [5]Red Cross War memorial Children's Hospital, Department Of Health, Cape Town, South Africa

Background: Antimicrobial stewardship principles guide the clinical use of vancomycin, but paediatric vancomycin prescribing practices have not been evaluated in South Africa.
Methods: A retrospective audit of the use, prescribing practices, and monitoring of intravenous vancomycin and the spectrum of bacteria isolated on microbiological culture in children treated with intravenous vancomycin during a 12-month period at Red Cross War Memorial Children's Hospital (RCWMCH).
Results: 158 vancomycin prescription episodes for 143 children were included. Overall usage of intravenous vancomycin was 63 days of therapy/1000 patient days (IQR 38–72). The median starting dose was 15 mg/kg/dose (IQR 14–15) and the median daily dose was 45 mg/kg/day (IQR 43–60). Vancomycin was prescribed as empiric (127/158, 80%) and directed (31/158, 20%) treatment. The median duration of treatment for the definitive group was longer than the empiric group (p=0.001). Only 65/98 (66%) episodes where vancomycin treatment exceeded three days had vancomycin serum trough concentrations performed, and only 16/65 (25%) of these samples were obtained before the fourth dose. Prolonged antibiotic treatment of 14 days or more was not associated with gram-positive bacteria on culture (OR 1.02, 95% CI 0.17–4.2).
Conclusions/Learning Points: Dosing errors, prolonged empiric treatment and inappropriate vancomycin monitoring were problems associated with vancomycin prescriptions.

IMPACT ON COST AND TIME REDUCTION WITH SYSTEMATIZATION OF AN ANTIMICROBIAL STEWARDSHIP PROGRAM (ASP) IN A CLINIC IN BOGOTÁ, COLOMBIA

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Ivan Gutierrez Tobar, Juan Bravo
Clínica Santa María del lago, Bogota, Bogota, Colombia

Backgrounds: Antimicrobial stewardship programs (ASP) are a necessity to combat bacterial resistance. Limited resources make it difficult to analyze the information. The development of technological tools to systematize the ASP and optimize their management are needed
Methods: Quantitative, descriptive, retrospective study. Describes the process of developing and implementing a systematic tool for prescribing and analyzing antibiotic use. Comparing completion time, costs and frequency of errors using the manual method of prescription vs. The systematized tool. Describes indicators that can be analyzed with the 2 strategies and makes projections of costs, times and errors to date, in case of having continued with the antibiotic sheet (manual)
Results: Since its implementation, the strategy has saved clinicians 588 hours in prescribing antibiotics, and $56,000,000 COP. To the ASP group, 616 hours, and $76,407,853 COP. Added to $2,237,582 COP direct cost from the paper. Given that 14% of the sheets were filled out improperly, as of today it would not have been possible to analyze 5,401 prescriptions. Due to the automation and visualization on dashboards, the ASP will be able to carry out interventions in real-time, and analyze adherence to guidelines, doses, antibiotics, and cultures in real-time.
Conclusions/Learning Points: The systematization of the prescription and analysis of antibiotics optimized the management of the ASP. It reduced time, costs and facilitated its analysis, allowing resources to be directed to other needs. The analysis in real-time will allow targeted interventions to improve the use of antibiotics in the institution.

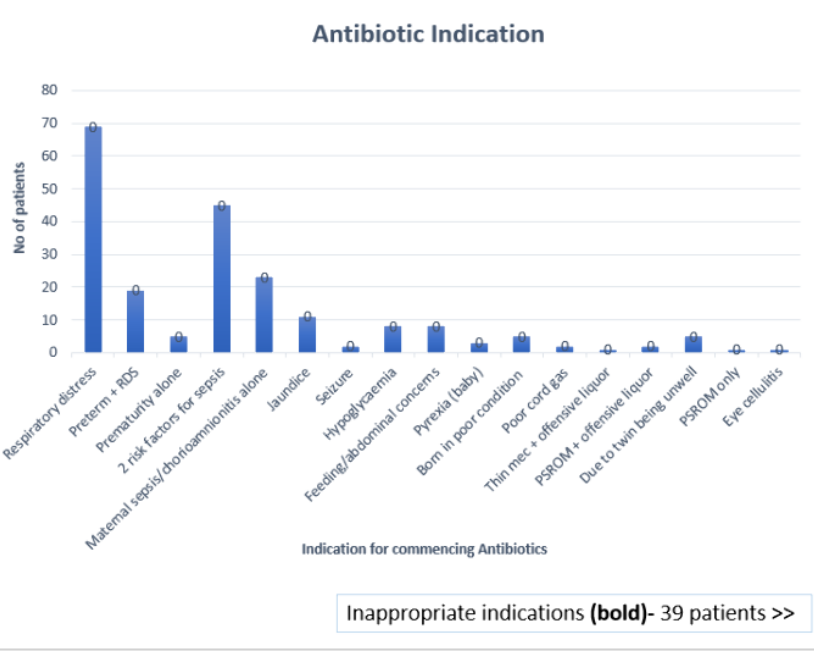
ANTIBIOTICS STEWARDSHIP AND GUIDELINE ADHERENCE IN A SECONDARY LEVEL NEONATAL UNIT, ENGLAND.

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Eiman Hamid, Alexandra Large, Lina Salih, Abigail Soul, Laura Summmerfield, James Houston
Calderdale Royal Hospital-NHS, Paediatrics, Halifax, United Kingdom

Backgrounds: Antibiotics are the most commonly prescribed medications in the neonatal unit. Higher levels of antimicrobial resistance among UK neonatal pathogens have been reported. We aimed to assess our antibiotics practice adherence to a) NICE guidelines (NG195) on antibiotics for the prevention and treatment of neonatal infection and b) The public health England toolkit for antimicrobial stewardship.
Methods: A retrospective observational study of all patients started on first-line antibiotics after birth, born from July 2021 to December 2021 in a level 2 neonatal unit in England. We examined clinical records, microbiology charts and drug charts. We reviewed the indication, time to first dose antibiotics given, time to blood culture result, duration, and justification If antibiotics were given more than 36 hours.
Results: 109 patients were included;130 (62%) from NICU and 79 (38%) from the postnatal ward. 75% were given antibiotics within 1hr of decision, delay beyond 1 hr was due to multiple cannulation attempts. Isolated maternal sepsis/chorioamnionitis was the major improper indication of starting antibiotics (Figure 1). Antibiotics were properly stopped at 36 hrs in 10% of patients and at 48hrs in 50% .88% of well babies, with negative CRP and blood culture received 2 doses of gentamicin while awaiting blood culture results. It takes an average of 42 hours to report a negative blood culture (an average of 38 if taken in-hours vs 43 if taken out-of-hours). and an average of 26hrs to report a positive Blood culture.



Indication	Number
Respiratory distress	69
Preterm+RDS	19
Prematurity alone	5
2 risk factors for sepsis	47
Maternal sepsis/chorioamnionitis alone	21
Jaundice	11
Seizure	2
Hypoglycaemia	8
Feeding/abdominal concerns	8
Pyrexia (baby)	3
Born in poor condition	5
Poor cord gas	2
Thin mec + offensive liquor	1
PSROM + offensive liquor	2
Due to twin being unwell	5
PSROM only	1
Eye cellulitis	1

Conclusions/Learning Points: The majority of antibiotics were started appropriately. The latest NICE guideline omitted isolated suspected maternal sepsis/chorioamnionitis as a red flag. We recommend refreshing juniors' knowledge of the guidelines, limiting cannulation attempts to 2 trials before escalation, and working with the microbiology lab to enhance the BC reporting time at 36 hrs.

PV0065 / #662

VANCOMYCIN PRESCRIBING PRACTICES ACROSS NEONATAL UNITS (NNUS) IN THE UNITED KINGDOM AND IRELAND

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Louise Hill[1], Jabina Randev[2], Mike Sharland[1], Jodi Lindsay[3], Michelle Clements[4], Mark Turner[5], Paul Heath[1]
[1]St George's, University of London, Centre For Neonatal And Paediatric Infection, London, United Kingdom, [2]Guy's and St Thomas' NHS Foundation Trust, Evelina London Children's Hospital, London, United Kingdom, [3]St George's, University of London, Institute For Infection And Immunity, London, United Kingdom, [4]University College London, Mrc Clinical Trials Unit, London, United Kingdom, [5]University of Liverpool, Institute Of Translational Medicine, Liverpool, United Kingdom

Backgrounds: Vancomycin is one of the most widely prescribed antibiotics on NNUs for Gram-positive sepsis. Neonatal randomised controlled trial (RCT) data are lacking, which impacts standardisation of antibiotic prescribing guidelines. Improper dosing of antibiotics can affect antimicrobial resistance development, and also clinical and safety outcomes. A comprehensive survey of vancomycin prescribing on NNUs in the United Kingdom and Ireland has not previously been conducted.
Methods: Local neonatal units (LNUs) and neonatal intensive care units (NICUs) were contacted between October 2019 and November 2022. Data were entered into a proforma then summarised. Data are presented for babies 23–44 weeks postmenstrual age (PMA) and 0–28 days postnatal age.
Results: 161 NNUs were identified and approached with a response rate of 96% (154/161; 71 NICUs and 83 LNUs). Vancomycin was prescribed by 110/154 (71%) NNUs. A large majority of NNUs (77/110; 70%) prescribed intermittent infusion regimens only; 9/110 (8.2%) prescribed continuous infusion only and 24/110 (21.8%) prescribed both. Twenty-three distinct intermittent infusion regimens and 13 distinct continuous infusion regimens were identified. PMA was the most commonly considered covariate in intermittent and continuous infusion regimens (21/23 (91%) and 10/13 (77%) respectively). Figure 1 shows the broad range of total daily doses by PMA, prescribed in intermittent infusion regimens. A 3-fold difference for PMAs 23–29 weeks was
seen.

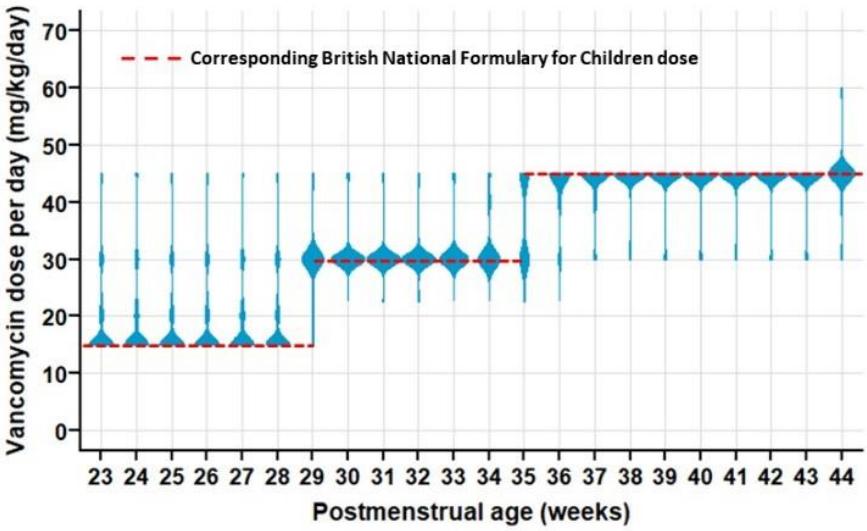


Figure 1: Range of vancomycin total daily doses seen in intermittent infusion regimens prescribed on British and Irish neonatal units

Dosing ranges are shown by postmenstrual age and for babies with postnatal ages between 0 and 28 days. Thicker lines represent a greater number of neonatal units prescribing that particular dose.

Conclusions/Learning Points: 57% of NNUs prescribing intermittent dosing regimens followed the British National Formulary for Children guidelines, however, a wide range of total daily doses were observed. This is concerning given the unknown consequences to treatment outcomes, potential toxicity and vancomycin (hetero)resistance emergence. 30% of NNUs prescribed continuous infusion regimens, despite no previous neonatal RCT comparing intermittent and continuous infusion regimens with an efficacy primary endpoint. Standardisation of vancomycin dosing practices are necessary.

PV0066 / #46

TEMPORAL PROFILE OF EMPIRICAL ANTIBIOTIC TREATMENT (EAT) USE IN CHILDREN 0-2 YEARS HOSPITALIZED FOR COVID 19 IN BUCHAREST, ROMANIA

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Niculae Ion Nedelcu, Simin-Aysel Florescu
Bd Mihai Bravu 281 Sector 3 Bucharest, Infectious Diseases, Bucharest, Romania

Backgrounds: Ever since the beginning of the Covid 19 pandemic EAT has been frequently prescribed in patients with this condition - over time due to recommendations made by WHO the rate of use of EAT has decreased consistently ; however there are scarce published information regarding this decreasing in pediatric patients. Objective: assesment of the evolution over time of the rate of use of EAT in children 0-2 years hospitalized in our clinic with a positive PCR test for SARS-CoV-2 (Covid 19).
Methods: The study population - included children with Covid 19 discharged from our hospital in the 2nd semester of 2021 (lot A; = n: 96) and respectively the ones discharged in the 1st semester of 2022 (lot B; n= 84). In both lots was calculated the prevalences of children who received EAT. The prevalences were comparated and a $p<0.05$ was selected to denote statisticaly sigificances.
Results: The prevalence of children receiving EAT was (62.5 %) in lot A compared with (39.1 %) in lot B; the difference (24.30 %) being statisticaly significant (RR:0.62; 95% CI (0.46 – 0.84); p= 0.00087
Conclusions/Learning Points: We postulate that prospective audit and feedback, the main antibiotic stewardship intervention conducted in our hospital improved consistenly the manner of EAT prescribing, a way to mitigate the antimicrobial resistance.

PV0067 / #369

IMPACT OF A MULTI-FACETED ASP ON ANTIBIOTIC UTILIZATION AND GUIDELINE COMPLIANCE IN A TERTIARY PEDIATRICS HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Xue Fen Valerie Seah[1], Yue Ling Rina Ong[1], Kai Qian Kam[2], Koh Cheng Thoon[2]
[1]KK Women's and Children's Hospital, Pharmacy, Singapore, Singapore, [2]KK Women's and Children's Hospital, Singapore, Paediatrics, Infectious Disease Service, Singapore, Singapore

Backgrounds: Antimicrobial stewardship programs (ASPs) promote the judicious use of antimicrobials. We evaluate the impact of a multi-faceted ASP on the utilization of antibiotics in a tertiary pediatrics hospital in Singapore (KKH) after formal ASP establishment in July 2011.
Methods: ASP strategies included a prospective daily active review-and-feedback of broad-spectrum antibiotics (carbapenems, cefepime, vancomycin in year 1, and piperacillin-tazobactam in year 6) and a collaborative inter-departmental consolidation and implementation of evidence-based, hospital-wide guidelines from years 2 to 4, with yearly review and updates. This was a retrospective, pre-post single-center study on the impact of ASP (post-ASP: July 2011 to December 2021). Utilization of selected antibiotics was evaluated from January 2010 by days of therapy (DOTs) if available, and daily defined doses (DDDs) otherwise. Point-prevalence surveys in 2017 and 2021 was conducted to review the percentage of guidelines compliance.
Results: Appropriateness of carbapenem prescriptions improved from 56% to 80% post-ASP, p=0004; and piperacillin-tazobactam from 62% to 90% post-audit (years 6-11), p<0.001. Overall appropriateness of audited antibiotics ranged from 80 to 89%. Intervention acceptance improved from 57% in year 1 of ASP to 83% in year 11 post-ASP. There was a significant reduction in average carbapenem and vancomycin DOT per 1000 patient-days (13.5 to 6.2, p=0.002, and 9.5 to 3.8, p=0.04, respectively). Cefepime, piperacillin-tazobactam, ceftriaxone, augmentin, ceftazidime DDDs remained stable, though an increase in cefepime and decrease in piperacillin-tazobactam and ceftazidime utilization was observed (non-significant). Guideline compliance was 74% in year 5, compared to 84% in year 11.
Conclusions/Learning Points: A multi-faceted pediatric ASP improved the appropriateness of and reduced the utilization of certain broad-spectrum antibiotics prescribing.

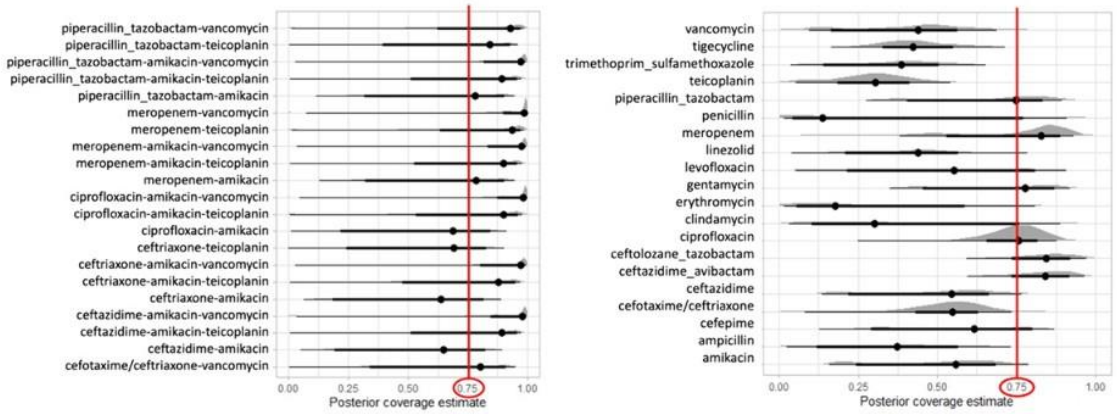
APPLICATION OF WISCA (WEIGHTED-INCIDENCE SYNDROMIC COMBINATION ANTIBIOGRAM) TO GUIDE THE CHOICE OF EMPIRIC ANTIBIOTIC TREATMENT IN ONCOLOGICAL PAEDIATRIC PATIENTS WITH FEBRILE NEUTROPENIA: AN ITALIAN MULTICENTER STUDY

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Linda Maestri[1], Cecilia Liberati[1], Elisa Barbieri[1], Elisa Gallo[2], Jacopo Gallocchio[2], Lorenzo Chiusaroli[1], Elisabetta Calore[3], Marta Pierobon[3], Maria Grazia Petris[3], Marcello Mariani[4], Alessio Mesini[4], Carolina Saffioti[4], Elisabetta Ugolotti[5], Dario Gregori[2], Elio Castagnola[4], Alessandra Biffi[3], Daniele Donà[1]
[1]University of Padua, Paediatric Infectious Diseases, Padua, Italy, [2]University of Padua, Department Of Cardiac, Thoracic And Vascular Sciences, Unit Of Biostatistics, Epidemiology And Public Health, Padova, Italy, [3]University of Padua, Department For Woman And Child Health, Hematology And Oncology Unit, Padova, Italy, [4]Giannina Gaslini Children's Hospital, Infectious Disease Unit, Genova, Italy, [5]Giannina Gaslini Children's Hospital, Molecular Medicine, Genova, Italy

Backgrounds: Guidelines about febrile neutropenia (FN) in paediatric patients are not homogeneous; with the increasing number of multidrug-resistant organisms, the best empiric therapy should be driven by local epidemiology. The Weighted-Incidence Syndromic Combination Antibiogram (WISCA) attempts to satisfy the unmet need to obtain syndrome-specific local susceptibility data to guide empiric prescribing, providing estimates for several treatment regimens as a weighted average of pathogens susceptibilities. This study aimed to develop a WISCA model to inform empirical antibiotic regimens selection for FN in children in two Italian pediatric tertiary centers.
Methods: We included blood cultures from patients with a bloodstream infection and neutropenia admitted to the Paediatric Oncology/Haematology wards in Padua and Genoa from 2016 to 2021. Contaminants were excluded from the pool. WISCAs were developed by estimating the coverage of 20 antibiotics as monotherapy and of 21 combined regimens with a Bayesian probabilities distribution.
Results: We collected 350 blood cultures, including 196 gram-negative and 154 gram-positive bacteria. Considering most used antibiotic combinations, such as piperacillin-tazobactam (PI-TZ) plus amikacin, the median coverage was 78%. When adding a glycopeptide, the median coverage increased to 89%, while the replacement of PI-TZ with meropenem did not provide benefits (Figure). The developed WISCAs showed that no monotherapy offered an adequate coverage rate for the identified pathogens and confirmed the validity of the empiric regimens used in both centers (PI-TZ, amikacin and teicoplanin for Padua and PI-TZ plus amikacin for Genoa). The statistical significance, however, was not reached because of the limited sample
size.



Conclusions/Learning Points: The application of WISCA offers the possibility of maximizing the clinical utility of microbiological surveillance data derived from larger hospitals to inform the selection of the best empiric therapy while contributing to spare broad-spectrum antibiotics.

PV0069 / #603

IMPACT OF ANTIBIOTIC EXPOSURES ON ADVERSE INPATIENT OUTCOMES AMONG PRETERM, VERY LOW BIRTH WEIGHT (VLBW) INFANTS

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Marcus Wing Choy Loe[1], Rehena Sultana[2], Selina Wan Xuan Lim[3], Guan Lin Goh[4], Kee Thai Yeo[4]
[1]Duke-NUS Medical School, ., Singapore, Singapore, [2]Duke-NUS Medical School, Center For Quantitative Medicine, Singapore, Singapore, [3]KK Women's and Children's Hospital, Department Of Pharmacy, Singapore, Singapore, [4]KK Women's and Children's Hospital, Department Of Neonatology, Singapore, Singapore

Backgrounds: Recent data suggests that excessive antibiotic usage among preterm infants have been independently associated with increased risk of adverse outcomes. As such, we aim to evaluate the association between antibiotic duration and inpatient outcomes of pre-term infants in our setting.
Methods: We conducted a cohort study involving infants born <32 weeks gestation, admitted to our tertiary-level NICU (1 January 2016-31 December 2021). Clinical characteristics, outcomes and antibiotic exposure was extracted from the department data collection and hospital electronic database.
Results: A total of 740 infants were included - median 28 weeks (IQR 26, 30) gestation, median birthweight 1057g (IQR 840, 1298), 379 (51.2%) male and 685 (92.6%) received antenatal steroids (Table1). Of these, 32 died (4.3%) and 321 (43.1%) had at least one severe morbidity. Overall, 130 (17.6%) did not receive antibiotics during admission, 274 (37.0%) received <4 days, 222 (30.0%) received 4-7 days and 244 (33.0%) received >7 days. After adjusting for gestational age, sex and antenatal steroids, compared to infants with <4 days of antibiotics, the adjusted odds ratio (AOR) of death among infants with 4-7 days of antibiotics was 1.1 (95%CI 0.15-7.4)(p=0.9) and 2.6 (95% CI 0.4-15.3)(p=0.2) for > 7 days. The AOR for deaths and/or severe morbidity were 1.5 (95%CI 0.9-2.3)(p=0.08) for infants with 4-7 days and 4.5 (95%CI 2.7-7.3)(p<0.0001) for >7 days exposure, compared to those with <4 days.

	Total Antibiotic Exposure (days)			
Infant baseline characteristics	**0-3**	**4-7**	**>7**	**Overall**
Gestational age, median (maximum, minimum) (weeks)	29 (24,31)	28 (23,31)*	26 (22,31)*	28 (22,31)
Gender (male), no. (%)	120 (44.4%)	121 (54.3%)*	138 (56.8%)*	379 (51.2%)
Birth weight, mean (SD) (g)	1183 ± 220	1086 ± 241*	887 ± 269*	1057 ± 274
Mode of delivery (Caesarean section), no. (%)	197 (71.9%)	151 (67.7%)	150 (57.7%)*	498 (67.3%)
Antenatal Steroids, no. (%)	256 (93.4%)	204 (91.5%)	225 (92.6%)*	685 (92.6%)
Death	1 (0.4%)	3 (1.3%)	28 (11.5%)*	32 (4.3%)
NEC, no. (%)	1 (0.4%)	0 (0.0%)	11 (4.5%)*	12 (1.6%)
BPD, no. (%)	49 (17.9%)	80 (35.9%)*	152 (62.6%)*	281 (38.0%)
Severe ROP, no. (%)	7 (2.6%)	6 (2.7%)	60 (24.7%)*	73 (9.9%)
Severe IVH, no. (%)	0 (0.0%)	2 (0.9%)	20 (8.2%)*	22 (3.0%)
Composite outcome, no. (%)	52 (19.0%)	83 (37.2%)*	186 (76.5%)*	321 (43.1%)

Necrotising enterocolitis (NEC) – Stage II and above using the modified Bell criteria; severe retinopathy of prematurity (ROP) – > stage 3; severe intraventricular haemorrhage – grade 3 or 4; bronchopulmonary dysplasia – defined as the receipt of oxygen or respiratory support at 36 weeks' postmenstrual age; * indicates that comparisons with infants who received 0-3 days of antibiotic exposure were statistically significant (p<0.05)

Conclusions/Learning Points: In our cohort of preterm VLBW infants <32 weeks gestation, infants with antibiotics exposure >7 days had 4.5 times the odds of death and/or severe morbidity compared to those

with <4 days, Given the high proportion of infants receiving prolonged antibiotics in the NICU, efforts to limit unnecessary antibiotic exposure are critical.

CLINICAL ASSESSMENT OF GROUP A STREPTOCOCCAL PHARYNGITIS IN AN EMERGENCY DEPARTMENT SETTING AT A TIME OF HEIGHTENED PUBLIC AWARENESS

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Leah Loughlin[1], Muhammad Azam[2]
[1]Wexford General Hospital, Department Of Paediatrics, Wexford, Ireland, [2]RCSI, Department Of Paediatrics, Dublin, Ireland

Backgrounds: Public awareness of invasive Group A Streptococcal (iGAS) disease in children increased following media reporting of infections and deaths in the latter half of 2022 in Ireland, the UK, France and elsewhere. Rapid GAS testing has been validated for use in Emergency Department (ED) settings however is not routinely available in Irish EDs. The main objective of this study was to determine if formal culture and sensitivity (C&S) testing for GAS was performed in line with clinical decision rules (CDRs), where rapid testing remains unavailable, particularly in light of increased public awareness and parental concern.
Methods: Observational and retrospective study carried out by reviewing medical records and a register of throat swab specimens in the ED of a level 4 hospital. Data for patients <16 years old with a diagnosis of suspected bacterial tonsillitis between 6th December 2022 and 6th January 2023 were included. Data analysed included: age at presentation; presenting clinical symptoms; comorbid conditions and microbiological results.
Results: 34 patients were identified from the register of throat swabs sent for C&S. The mean age was 5.2 years. N=26 (76.5%) had no growth on throat swabs sent for culture, n=7 (20.6%) were positive for GAS and n=1 (2.9%) were positive for Streptococcus groups C and G. Logistic regression was performed; only the absence of cough was a significant predictor of GAS [OR 0.16 95% C.I. 0.02 – 0.09].
Conclusions/Learning Points: Allowing for a small sample, this group presented with heterogenous symptoms; CDRs may have had limited value. POC Rapid GAS testing may be a helpful adjunct to clinical evaluation in deciding when to treat with antibiotics. Assuaging parental concerns must be balanced with the principles guiding antimicrobial stewardship.

SKIN ERUPTIONS AND ANTIBIOTIC THERAPY- EFFECTIVENESS OF THE ORAL CHALLENGE TEST

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Teresa Magalhães, Mariana Viegas, Catarina Mendonça, Gonçalo Croca, Sara Santos, Daniel Soares
Centro Hospitalar do Oeste, Caldas da Rainha, Pediatrics, Caldas da Rainha, Portugal

Backgrounds: Skin eruptions can occur over the course of antibiotic therapy and concomitant viral infection. Differential diagnosis is often challenging. Thus, it is important to confirm or rule out drug hypersensitivity, allowing the safe prescription of these drugs.
Methods: The aim of this study was to evaluate the prevalence of positive oral challenge test (OCT) in children and to verify its application in detecting allergic antibiotic reactions. Retrospective analysis of the pediatric patients' clinical files in a Portuguese level II hospital. The patients were referred for suspected allergy to Amoxicillin and underwent OCT from January 2019 to December 2022. In the case of the patient had a compatible clinical manifestation, the OCT was interrupted and considered positive.
Results: A total of 75 patients were enrolled with an average age of 9.5 years (28 male (37,3%)). Of those, 74 reported cutaneous signs and symptoms. The most frequent symptoms were maculopapular rash (91%) and pruritus (55%), followed by urticarial lesions (14%), edema (7%) and gastrointestinal symptoms (5.4%). In 65% of cases Amoxicillin was the studied drug while in 35% was Amoxicillin-Clavulanic Acid (ACA). Both antibiotic therapies were prescribed for the treatment of acute otitis media (43%), acute tonsillitis (32%), urinary (12%) and respiratory (5%) tract infections and dental abscess (4%). OPP was positive in 4% (n=3): all of them manifested non-immediate rash, one presented edema and other one gastrointestinal symptoms.
Conclusions/Learning Points: This study demonstrated that the incidence of allergy to Amoxicilin or ACA is very low in children. This reinforces the importance of performing OCT, to rule out rather than to confirm drug allergy. The presence of allergy was excluded in a significant number of children, allowing the safe prescription of these first-line drugs.

PV0072 / #384

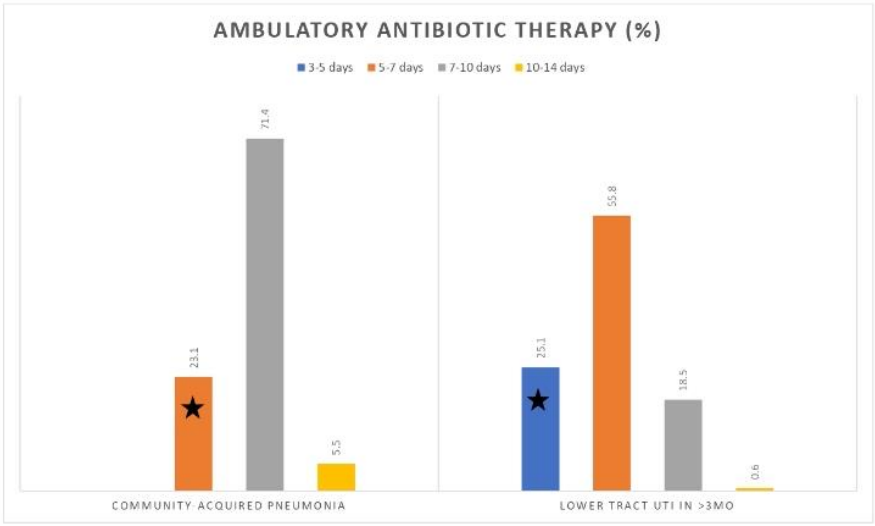
CURRENT CLINICAL PRACTICE IN SPAIN REGARDING DURATION OF ANTIBIOTIC THERAPY. NATIONAL SURVEY.

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Isabel Mellado Sola[1], Paula Rodriguez Molino[1], Mariana Diaz[1], David Moreno[2], Fernando Baquero[1], Jaime Gutierrez Del Alamo[2], Cristina Calvo[1], Luis Escosa[1]
[1]Hospital Universitario La Paz, Pediatrics, Madrid, Spain, [2]Hospital Materno Infantil de Malaga, Pediatrics, Madrid, Spain

Backgrounds: Appropriate duration of antibiotic treatment is a key principle. Our aim is to document the current clinical practice among Spanish pediatricians in terms of the duration of antibiotic therapy in both inpatient and outpatient settings, mapping the difference between practice and guidelines, and thus detect opportunities to improve practice.
Methods: A national survey distributed in 2020 as a questionnaire about 7 main infectious syndromes in children: genitourinary, skin and soft tissue, osteoarticular, ear, nose and throat, pneumonia, central nervous system infections and bacteremia. Answers were contrasted with current recommendations regarding the duration of antibiotic therapy. Demographic analysis was also performed.
Results: Survey completed by 992 pediatricians in Spain (15590 total responses; 6662 by those used to prescribing intravenous antibiotics); 9.5% of pediatricians attending in the Spanish National Health System. Overall antibiotic duration was longer than recommended in 40.8% (6359/15590) and shorter in 16% (1705/10654). Among community-acquired infections: ⩽25% would opt for the recommended duration of lower urinary tract infection (UTI) (249/992) and pneumonia (229/992) respectively (figure 1). Among severe hospital-managed infections: longer courses were evidenced for non-complicated meningococcal infections (meningitis: 87.5% - 343/392; bacteremia: 91.3% - 358/392) and non-complicated pneumococcal (52.3%; 205/392), Gram-negative (86%; 337/392) and S. aureus bacteremia (55.8%; 219/392). Interventions may focus especially on more experienced clinicians for ambulatory infections and less experienced clinicians for invasive meningococcal infections and pneumococcal bacteremia. Also training of residents is needed for pyelonephritis, otomastoiditis, meningococcal meningitis and bacteremia.

Figure 1. Antibiotic duration practices for pneumonia and UTI. The black star shows the considered correct answer.



Conclusions/Learning Points: A noteworthy tendency towards prescribing longer than recommended antibiotic regimes among pediatricians was evidenced in this nationwide study, pointing out a wide range for potential improvement.

ANALYSIS OF ANTIBIOTIC CONSUMPTION ACCORDING TO THE AWARE CLASSIFICATION (ACCES, WATCH AND RESERVE) IN A TERTIARY PEDIATRIC HOSPITAL.

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Fernández-Polo Aurora[1], Natalia Ana Mendoza-Palomar[2], Adrian Puertas-San Juan[1], Susana Melendo[2], María Nieves Larrosa[3], Maria Queralt Gorgas[1], Pere Soler-Palacín[2]
[1]Hospital Universitari Vall d'Hebron, Pharmacy Department, Barcelona, Spain, [2]Hospital Universitari Vall d'Hebron, Pediatric Infectious Diseases And Inmunodeficiencies Unit, Barcelona, Spain, [3]Hospital Universitari Vall d'Hebron, Microbiology Department, Barcelona, Spain

Backgrounds: In 2017, the World Health Organization developed the AWaRe classification in which antibiotics are ordered in three categories: Access (free access), Watch (controlled use) and Reserve (reserved use). Our aim was to evaluate antibiotic consumption in a third level pediatric hospital according to the AWaRe classification, as a qualitative indicator of antibiotic use within a pediatric Antibiotic Stewardship Program.
Methods: Single-center retrospective study including the consumption of all parenteral antibacterial drugs in pediatric (≤18y) patients, from January 2015 to December 2019. Evaluation comprised medical, surgical and pediatric intensive care (P-ICU) and neonatal intensive care (N-ICU). Trend analysis of consumption was calculated based on days on treatment (DOT) weighted by care activity expressed in stays calculated as patient-days (PD). Antibiotics were classified according to the definitions of the AWaRe classification and described as the proportion (%) of each category.
Results: During the study period, the distribution of different antibiotics according to the AWaRe classification remained stable: Access antibiotics accounted for 43.1% of total consumption while Watch antibiotics represented 54.5%. Use of Reserve antibiotics was around 2.4% from 2015 to 2018, with a slight increase (4%) in 2019. The proportion of Access antibiotics was higher in surgical units (63.4%) and N-ICU (58.9%), and lower in medical units (36.2%) and P-ICU (30.1%). Reserve antibiotics were mainly used in medical specialties units, mostly colistin in cystic fibrosis patients with respiratory exacerbations.
Conclusions/Learning Points: Watch group use was higher than recommended, thus specific actions are needed to increase use of Access antibiotics. Nonetheless, Reserve antibiotics use was minimum and focused on cystic fibrosis. However, it's necessary to define the desirable percentages according to the hospitals' complexity, in order to correctly interpret our data and compare them with similar centers.

IMPACT OF GUIDELINES IMPLEMENTATION ON EMPIRIC ANTIBIOTIC TREATMENT FOR PEDIATRIC UNCOMPLICATED OSTEOMYELITIS AND SEPTIC ARTHRITIS OVER A TEN-YEAR PERIOD: RESULTS OF THE ELECTRIC STUDY (OSTEOMYELITIS AND SEPTIC ARTHRITIS TREATMENT IN CHILDREN).

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Chiara Minotti[1], Francesca Tirelli[2], Chiara Guariento[1], Giulia Sturniolo[1], Carlo Giaquinto[1], Liviana Da Dalt[3], Francesco Zulian[2], Alessandra Meneghel[2], Giorgia Martini[2], Daniele Donà[1]
[1]University of Padua, Paediatric Infectious Diseases, Padua, Italy, [2]University Hospital of Padua, Pediatric Rheumatology, Padua, Italy, [3]University of Padua, Pediatric Emergency Department, Padua, Italy

Backgrounds: Due to the growing evidence of the efficacy of intravenous cefazolin with an early switch to oral cefalexin in uncomplicated pediatric osteomyelitis (OM) and septic arthritis (SA) in children, we changed our guidelines for empiric antibiotic therapy in these conditions. This study aims at evaluating the impact of the guidelines' implementation in reducing broad-spectrum antibiotic prescriptions, duration of IV antibiotics and hospital stay, treatment failure, and recurrence.
Methods: This is a retrospective, observational, quasi-experimental study. The four years pre-intervention were compared to the nearly eleven years post-intervention (January 2012 - December 2015; January 2016 - October 2022). All patients aged 3 months to 18 years with OM/SA were evaluated for inclusion. Each population was divided into three groups: pre-intervention, post-intervention not following the guidelines, and post-intervention following the guidelines. Days of Therapy (DOT), Length of Therapy (LOT), length of hospital stay (LOS), broad-spectrum antibiotics duration (bsDOT), treatment failure, and relapse at six months were evaluated as outcomes.
Results: Of 87 included patients, 48 had OM and 39 SA. In OM patients, IV DOT, DOT/LOT ratio, and bsDOT were significantly lower in the guidelines group, with also the lowest proportion of patients discharged on IV treatment. Notably, significantly fewer cases required surgery in the post-intervention groups. Considering SA, LOS, IV DOT, DOT/LOT ratio, and bsDOT were significantly lower in the guidelines group. The treatment failure rate was comparable among all groups. There were no relapse cases. The overall adherence was over 70%.
Conclusions/Learning Points: The implementation of guidelines was effective in decreasing the use of combination, broad-spectrum antibiotics for both OM and SA. Our results show the applicability, safety, and efficacy of a narrow-spectrum IV empirical antibiotic regimen, which was non-inferior to broad-spectrum regimens.

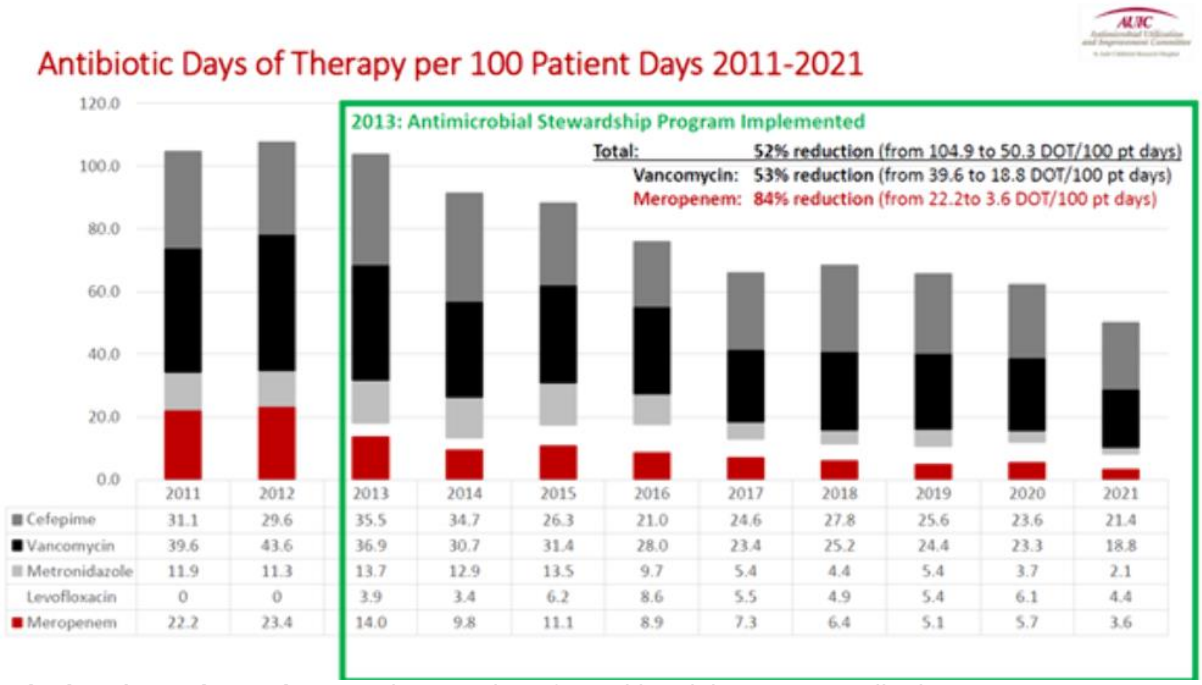
[1]St. Jude Children's Research Hospital, Infectious Diseases; Pharmacy And Pharmaceutical Sciences, Memphis, United States of America, [2]St. Jude Children's Research Hospital, Pharmacy And Pharmaceutical Sciences, Memphis, United States of America, [3]St. Jude Children's Research Hospital, Infectious Diseases, Memphis, United States of America, [4]St. Jude Children's Research Hospital, Information Services, Memphis, United States of America, [5]St. Jude Children's Research Hospital, Pathology, Memphis, United States of America, [6]St. Jude Children's Research Hospital, Oncology, Memphis, United States of America

Backgrounds: Successful implementation of antimicrobial stewardship programs (ASP) in pediatric cancer hospitals is complex and challenging, and little is known of such programs' impact.
Methods: From 2011-2021 a multimodal antimicrobial stewardship program was incrementally implemented at a 76-bed pediatric cancer center. A multidisciplinary Antimicrobial Use and Improvement Committee (AUIC) led by physician and pharmacist directors of ASP was founded. After 5 years a second ASP pharmacist was hired. Processes for Prospective Audit with Feedback (PAWF) and Antimicrobial Time Outs (ATO) were developed and implemented. Institution-specific guidelines for common disease states were created, updated, and standardized through multidisciplinary consensus. Standardized measurement of antimicrobial use was validated and used for tracking outcomes.
Results: Prospective Audit With Feedback (PAWF) for meropenem and linezolid was implemented in 2013, and in 2021 there were 160 PAWF completed for meropenem with a 99% rate of recommendation acceptance. Beginning 2019, Antibiotic Time Outs (ATO) after 48 hours of therapy were performed for all (100%) inpatient antibiotic treatment courses, with an average of 2,000 courses per year. In 2021 the majority (75%) of ATO were performed by the primary medical services before 48 hours of therapy, and only 16% of courses were escalated or continued unchanged. From 2013-2021, institutional consensus guidelines were published on the hospital's intranet site for the clinical care of 28 infectious syndromes. During the 11-year study period, use of the 5 most common antibiotics decreased 52% from 104.9 days of therapy (DOT) per 100 days to 50.3 DOT/100 patient days. This reduction was led by an 84% reduction in meropenem use from 22.2 to 3.6 DOT/100 patient
days.



Conclusions/Learning Points: Implementation of a multimodal ASP at a pediatric cancer center was associated with reduction and modification of antimicrobial usage.

PV0076 / #2676

THE IMPACT OF THE IMPLEMENTATION OF A NEW CELLULITIS MANAGEMENT PROTOCOL IN A PAEDIATRIC EMERGENCY DEPARTMENT (ED)

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Eider Oñate[1], Maddi Beloki[2], Paula Mercado[2], Amaia Camara[2]
[1]Donostia University Hospital, Paediatric Intensive Care Unit, Donostia/San Sebastián, Spain, [2]Donostia University Hospital, Emergency Care, San Sebastián, Spain

Background: Frequently patients with cellulitis requiring intravenous antibiotic therapy(IAT), were hospitalized. However, some cellulitis practice guidelines recommend short-course IAT as the first choice treatment. With the aim of reducing hospital-admissions, in December 2021 we implemented a new cellulitis management protocol, which establishes treatment using short-duration IAT in the emergency department short-stay area (ESA).
Methods: Observationl and retrospective study carried out by reviewing the medical records of patients<14 years-old with a diagnosis of cellulitis in the emergency-room of a tertiary hospital of a Spanish province between January-2021, to December-2022. Patients<6 months-old, immunocompromised patients, those with foreign-body cellulitis and orbital cellulitis were excluded. Data from 2022(n=186), after the application of the new protocol, were compared to data from 2021(n=147) using a statistical software (SPSS).
Results: Of 186 patients with cellulitis treated in 2022, 53(28%) required IAT. 9 were directly hospitalized and 44(83%) received IAT in the ESA: 6(13.63%) of them were hospitalized due to unfavorable evolution and the rest were discharged. In 9(4.83%) cases the new protocol was not followed. As shown in the table, in 2022 the number of hospitalizations was significantly lower than in 2021 (8%vs18.3%), moreover 56% of hospitalizations could have been avoided with the new protocol (attributable risk fraction = 0.56). Likewise, there was a reduction in the length of hospital stay, 2.13±2.5 days in 2022 vs 2.95±2.43 in 2021.

	2021	2022 After the n
Number of cellulites	147	186
Number of hospitalizations	27 (18,3%)	15 (8%)
Length of hospital stay	2,95 ± 2,43	2,13 ±2,5
Reconsults	0	1

Conclusions/Learning Points: After the implementation of the new protocol, the number of admissions and length stay have significantly decreased without complications or more visits to the ED.

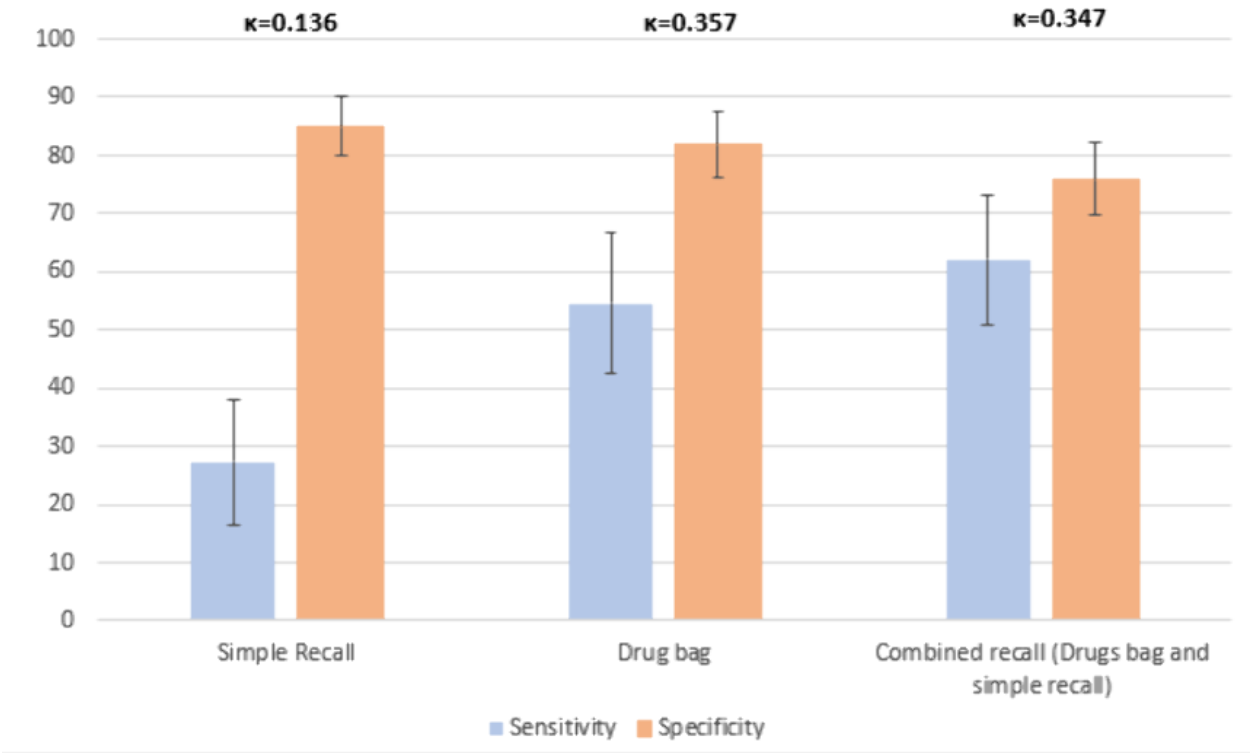
METHODS OF DETERMINING PRIOR ANTIBIOTIC USE IN PATIENTS PRESENTING TO AN OUTPATIENT DEPARTMENT IN THE GAMBIA

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Katie Parker[1], Giselle Ayoub[1], Stephen Owens[2], Karen Forrest[3], Behzad Nadjm[3], Matthew Breckons[2]
[1]Newcastle University, Faculty Of Medical Sciences, Newcastle Upon Tyne, United Kingdom, [2]Newcastle University, Population Health Sciences Institute, Newcastle Upon Tyne, United Kingdom, [3]MRC Unit The Gambia at LSHTM, Clinical Services Department, Banjul, Gambia

Backgrounds: Accurate data describing community antibiotic consumption are essential to inform policies which optimise antibiotic use and limit antimicrobial resistance. Data from Sub-Saharan Africa are especially sparse and prone to bias, being frequently derived from patient Simple Recall. The 'Drugs Bag Method' was designed to augment recall but has not been well-validated. Urinary antimicrobial activity (UAA) assays can be used to identify recent antibiotic consumption, but the impact of storage on their accuracy is unknown. We sought to assess the validity of Simple Recall and the Drugs Bag Method, and to investigate the effect of sample storage on UAA.
Methods: A ‘drugs bag’ was compiled containing antibiotics from dispensaries around the Medical Research Council Outpatient Clinic, Fajara, The Gambia. 600 patients were recruited from the clinic including 146 aged 3-19 years. Patients or their carers were asked about antibiotic consumption over the previous two days (Simple Recall), then if they remembered taking any medications from the drugs bag. Recall data were compared to a UAA assay. Positive urine samples were stored for seven days (at room temperature, 4°C and on dried filter paper) and re-tested.
Results: Drugs Bag aided recall had a greater sensitivity and agreement in comparison with UAA, than simple recall, as illustrated by Figure 1. UAA remained stable after sample storage on dried filter paper or at
4°C.

Figure 1 - A summary of comparisons between different recall methods.



Sensitivity and specificity are shown with error bars showing the 95% confidence intervals

Measure of agreement (Cohen's Kappa) is shown above the bars.

Conclusions/Learning Points: Simple Recall is frequently cited in studies investigating community antibiotic consumption in resource limited settings but is largely inaccurate. This study demonstrates that the 'Drugs Bag Method' can improve recall accuracy. Sample storage on dried filter paper could expand the use of UAA assays. These methods could improve accuracy of antibiotic consumption data in resource limited settings.

TREATMENT WITH FOSFOMYCIN FOR MULTI-DRUG RESISTANT KLEBSIELLA PNEUMONIAE IN INFANT WITH SEVERE SEPSIS: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Enrico Sierchio[1], Vincenzina Roma[1], Alessandro Piccirillo[1], Lorenzo Bufalo[2], Antonio Paride Passaro[3], Gaia De Toro[4], Lucio Giordano[1]
[1]Pineta Grande Hospital, Neonatology And Nicu, Castelvolturno, Italy, [2]Federico II University, Naples, Italy, Department Of Translational Medical Sciences - Division Of Neonatology, Naples, Italy, [3]University of Campania "Luigi Vanvitelli", 80138 Naples, Italy, Department Of Woman, Child And Of General And Specialized Surgery, Naples, Italy, [4]Federico II University, Naples, Italy, Department Of Translational Medical Sciences, Naples, Italy

Title of Case: TREATMENT WITH FOSFOMYCIN FOR MULTI-DRUG RESISTANT KLEBSIELLA PNEUMONIAE IN INFANT WITH SEVERE SEPSIS: A CASE REPORT
Background: Management of multi-drug-resistant Klebsiella pneumoniae (MDR-KP) is still a major challenge for clinicians in NICU, with severe mortality and morbility. The optimal therapy for MDR-KP infections is still not well established and may includemeropenem, colistin, fosfomycin, tigecycline, and aminoglycosides, with suboptimal results.
Case Presentation Summary: Here is a case of severe late-onset neonatal sepsis in a preterm infant (28+2/7 weeks), male, appropriate for gestational age (AGA), born with cesarean section. Apgar score was 6 at 1' and 8 at 5'. At birth he was assisted in Continous Positive Airway Pressuse (CPAP) and transferred to Neonatal Intensive Care Unit (NICU), where he continued CPAP assistance. On day 6th elevated levels of C-Reactive Protein (CRP) were found, so empiric therapy with ampicillin and gentamicin was started. The impaired contractility shown at echocardiography led to start treatment with dobutamine. Due to worsening of respiratory distress, on day 10 the baby was intubated and needed invasive respiratory support. Emocolture showed positivity for MDR-KP. Due to persistent positivity of CRP and worsening of clinical conditions, gentamicin was replaced by cefotaxime on day 15. Blood cultures taken on days 15 and 18 were still positive for MDR-KP, so therapy with intravenous fosfomycin and meropenem in continous infusion was started. Hence, there was a progressive improvement of clinical conditions and the baby was extubated on day 22 and assisted with CPAP. CRP levels and emocolture were found negative and CPAP was suspended on day 25 .
Learning Points/Discussion: The results of this case suggest that the combination of fosfomycin and meropenem in continuous infusion effectively provided rapid therapeutic effect against MDR-K in a preterm infant with severe sepsis

SELECTIVE ALLERGIC REACTIONS TO CLAVULANIC ACID IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Joana Pinto Oliveira, Joana Azevedo Silva, Raquel Santos, Tânia Monteiro
Centro Hospitalar de Trás-os-Montes e Alto Douro, Serviço De Pediatria E Neonatologia, - Vila Real, Portugal

Title of Case: Selective allergic reactions to clavulanic acid in children
Background: Beta-lactam antibiotics are commonly prescribed drugs and allergic reactions to them have been frequently reported, and although most allergic reactions are due to amoxicillin, some reports indicate a selective drug allergy to clavulanic acid. The aim of the study was to characterize the population referred to the Pediatric Allergology consultation that underwent an oral challenge test due to suspected allergy to amoxicillin-clavulanic acid and whose diagnosis of exclusive allergy was later confirmed.
Case Presentation Summary: In the pediatric allergology consultation, 133 patients had oral provocation tests due to suspected allergy to amoxicillin–clavulanic acid. Most cases (69.5%) referred from the emergency department. The oral provocation test with amoxicillin–clavulanic acid was positive in 14 cases, of which 42,9% (n=6) had previously received amoxicillin–clavulanic acid without adverse events. Of the 10 patients who attended for oral provocation tests to amoxicillin, only 2 tested positive with a delayed skin rash reaction. It was found that 8 (57,1%) children had selective allergic reactions to clavulanic acid and 2 children had selective allergic reactions to beta-lactam.
Learning Points/Discussion: Our study demonstrates that, in the event of a positive oral provocation test to amoxicillin-clavulanic acid, investigation must continue with and oral provocation test to amoxicillin in order to determine if the clavulanic acid is the culprit drug. Selective allergic reactions to clavulanic acid allows the use of amoxicillin and other beta-lactams, which is important in daily clinical practice when offering alternative drugs to patients.

IMPACT OF A URINE CULTURE FOLLOW-UP PROGRAM ON THE REDUCTION OF INAPPROPRIATE ANTIBIOTIC USE IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Mariana Poppe[1], Francisco Branco Caetano[2], Rodrigo Sousa[1], Paulo Oom[1]
[1]Hospital Beatriz Ângelo, Paediatrics, Lisbon, Portugal, [2]Hospital Dona Estefânia, Paediatrics, Lisbon, Portugal

Backgrounds: Antibiotics are among the most prescribed drugs in the pediatric population and its' prescription is often inappropriate. Antimicrobial stewardship strategies are essential to reduce the emergence of antibiotic resistance. Ensuring a follow-up of results of urine cultures contributes to improve patient care as well as avoid unnecessary therapy. We aim to characterise the follow-up management of urine culture results of a paediatric emergency department (ED) and quantify the days of inappropriate antibiotic therapy avoided due to this approach.
Methods: We conducted a retrospective study in a hospital in the metropolitan area of Lisbon. Data was collected through a dataset referring to pediatric patients who visited the ED and had a urine culture performed in 2021. Urine culture results were reviewed and patients were contacted in ordered to iniciate, suspend or switch antibiotic treatment.
Results: 858 children and adolescents were included in the study. Approximately half of the patients (48.4%) who performed a urine culture in the ED were prescribed an antibiotic. 71.5% of patients who were prescribed an antibiotic and had a negative urine culture were contacted to discontinue the antibiotic. 494 days of inappropriate antibiotic treatment were avoided, corresponding to a 44.5% reduction in the number of antibiotic treatment days for these patients.
Conclusions/Learning Points: Our follow-up management led to a reduction of unnecessary antibiotic therapy days, thus leading to better patient care and potentially contributing towards a decreased spread of antibiotic resistance. Similar follow-up methods could be implemented in other hospitals with minimal added resources and with clear benefits for patients. Further efforts in implementing antimicrobial stewardship strategies in pediatric settings are needed.

PV0081 / #149

RETROSPECTIVE COHORT ANALYSIS OF OUTPATIENT ANTIBIOTIC USE FOR CLOSTRIDIOIDES DIFFICILE-INDICATED AGENTS IN BRITISH COLUMBIA, FROM 2000 TO 2018

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Ariana Saatchi, Sungeun Kim, Fawziah Marra
University of British Columbia, Faculty Of Pharmaceutical Sciences, Vancouver, Canada

Backgrounds: Clostridioides difficile (CDI) is the most common cause of nosocomial diarrheal infections. Historically, first-line treatment was metronidazole, but recent guidelines indicate oral vancomycin and fidaxomicin as primary for initial episodes. A provincial stewardship program has operated since 2005. Since program inception, surveillance of antibiotic use has been ongoing. However, this is the first study to review community-acquired CDI-indicated antibiotic use. Moreover, this study offers the first interpretation of fidaxomicin use since its addition to provincial formulary.
Methods: A retrospective cohort analysis included all outpatient dispensations for CDI-related antibiotics from January 1, 2000 to December 31, 2018. Antibiotic dispensations were extracted for: metronidazole (J01XD01), vancomycin (J01XA01), and fidaxomicin (A07AA12). Consumption rates were calculated as prescriptions per 1000 population. Rates were examined overall and then stratified by medication, age, and sex. Secondary outcomes of interest included adherence to provincial special authority criteria; and proportions of antibiotic use attributable to administrative health records for CDI.
Results: The average annual rate of prescribing was 18.5 per 1000 population for all CDI-indicated antibiotics. The rate of prescribing increased (15%) over the 19-year study period, from 17.2 to 19.8 dispensations per 1000 population. Metronidazole accounted for the most antibiotics dispensed year-on-year, however by 2018 it demonstrated only modest increase in use (15%). In comparison, fidaxomicin increased by 226% by 2018. Vancomycin had the highest percentage increase (621%), with greatest change occurring from 2014-2015, correlating to the dissemination of new clinical practice guidelines.

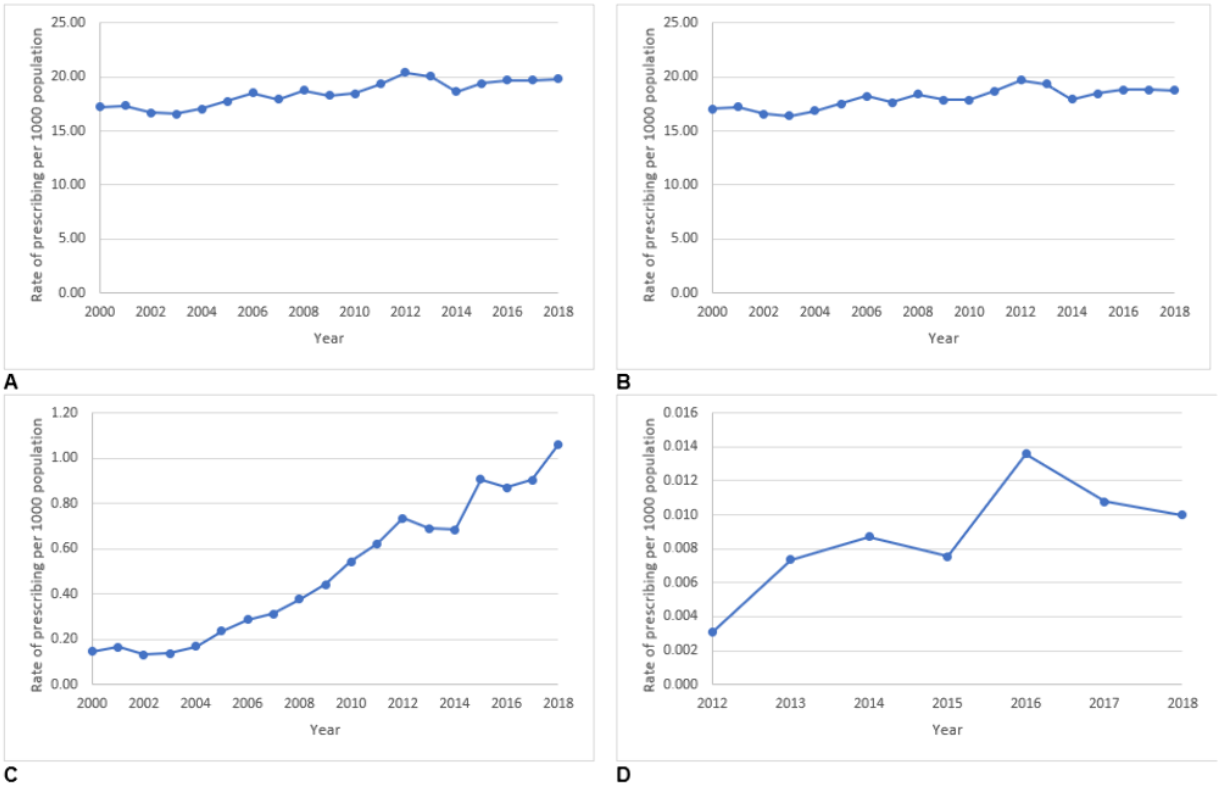

Figure 1. Overall rate of total oral CDI-indicated antibiotic prescribing and by individual antibiotic in British Columbia, 2000-18. (A) shows the rate of total antibiotic prescribing, combining all three antibiotics of interest. (B), (C), and (D) show the rate of prescribing for metronidazole, vancomycin, and fidaxomicin, respectively, throughout the study period.

Conclusions/Learning Points: This is the first study to evaluate outpatient prescribing for CDI-indicated antibiotics, and one of few studies to examine fidaxomicin since its introduction to Canadian formularies. Although causation cannot be inferred from study results, oral vancomycin and fidaxomicin use have increased with, or in advance-of, guidelines.

PV0082 / #389

OROFACIAL CLEFTS: IMPACT OF THE IMPLEMENTATION OF THE ANTIMICROBIAL PROGRAM IN OROFACIAL CLEFTS - CAN WE DO BETTER?

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Sandra Ruiz Ramos, Estrella Peromingo Matute, María Sánchez Codez
Puerta del Mar Hospital, Paediatrics, Cádiz, Spain

Backgrounds: Orofacial clefts (OC) constitute the most frequent facial malformation concerning 1/700 neonates in Europe. Treatment is multidisciplinary between maxillofacial surgeons and Pediatric Antimicrobial Stewardship Program (ASP), with a key role in the surgical prophylaxis and antibiotic treatment decision. We describe our ASP experience in OC surgery.
Methods: Retrospective cross-sectional study of patients ≤ 14 years old with OC intervened from 01/2020 to 06/2022 in Puerta del Mar University Hospital (Cadiz, Spain). ASP recommendations included: 1) Discontinuation of surgical prophylaxis within 24 hours after the procedure; 2) Antimicrobials of choice were cefazolin (25 mg/Kg/dose every 8 hours) plus metronidazole (30 mg/Kg/dose every 8 hours) OR amoxicillin-clavulanic (25 mg/Kg/dose every 6 hours); 3) Do not administer antimicrobial treatment. Surgical wound infections were also analyzed as complications.
Results: 41 children were operated: 58.5% (n=24) males and 41.5% (n=17) females. Of those, 48.8% (n=20) had cleft lip and palate, 39% (n=16) had isolated cleft palate, and 12.2% (n=5) had isolated cleft lip. A total of 24.3% (n=9) presented a genetic syndrome, being Pierre Robin sequence the most frequent. Antibiotic prophylaxis was used in 83% (n=34) of the patients, most commonly with amoxicillin-clavulanic (97%; n=33/34). Of those, 59% (n=20/34) received the right dose. The duration of antimicrobial prophylaxis was 1.9 days (1-7). In addition, 46% (n=19) children were treated at discharge, with amoxicillin-clavulanic (89%; n=17/19), during 5.9 days (3-7) and 79% (n=15/19) with correct dose. Interestingly, 68% (n=28) followed ASP recommendations. Surgical wound infections were reported in 4.9% (n=2): none of which followed ASP interventions.
Conclusions/Learning Points: Most of patients received prophylaxis with appropriate antimicrobial. High percentage of incorrect doses and long-lasting antimicrobial treatments were implemented. It is still important to conduct educational sessions and improve audits between specialist.

PV0083 / #912

PORT - A - CATH - RELATED INFECTIONS IN CHILDREN. HOW CAN WE IMPROVE THE MANAGEMENT OF THIS COMPLICATION?

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Teresa Silva García, María Sánchez Codez, Estrella Peromingo Matute
Puerta del Mar University Hospital, Paediatrics, Cadiz, Spain

Backgrounds: Placement of long-term central venous catheters (CVC) in children is increasing in recent years, and consequently the prevalence of related blood stream infections (BSI) . The use of CVC is indicated especially in case of difficult venous access, administration of medication (as chemotherapy) and parenteral nutrition. The serious consequences of CVC-BSI explain the need to implement local protocols and administer the most adequate antibiotic therapy. We analyse Port-A-Cath (PAC) related infections in our centre.
Methods: Retrospective observational study of patients ≤ 14 years old with PAC hospitalised between October 2017 to October 2022 in Puerta del Mar University Hospital (Cadiz, Spain). Information retrieved included demographic data, reason for placement and removal, duration of use, infectious event, microbiological data, and antimicrobial treatment. Differential time of positivity and differential quantitative blood cultures were the methods used to diagnose BSI.
Results: Of the 42 children with PAC included most of them had leukaemia 59% (25/42). In 95.2% (40/42) PAC was placed for treatment requirement. In 61.5 (16/26) patients, PAC was removed due to the end of therapy. 18/42 (43%) presented suspected PAC - BSI related infection. Peripheral blood cultures were not taken in 22 % (4/18) patients. The most frequent species detected were S. epidermidis 39% (7/18) and Gram - negative microorganisms 22% (4/18). There was great variability in the empirical antibiotic therapy used and 39% (7/18) of patients received targeted antibiotic. PAC sealing was performed in 50% (9/18) of children and vancomycin was used in 67% (6/9).
Conclusions/Learning Points: It is necessary to rule out PAC-BSI especially in hematologic patients with fever. It is still important to set local guidelines of management of CVC-BSI with appropriate microbiological diagnosis and therapy according to antimicrobial stewardship programs.

PREDICTORS OF ANTIBIOTIC ADMINISTRATION IN CHILDREN WITH RESPIRATORY INFECTION DIAGNOSED WITH SYNDROMIC PANELS

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Angeliki-Eleni Sfetsiori[1], Christianna Rapti[1], Christina Louka[2], Constantinos Patelakis[1], Vasiliki-Tsieko Melikoki[1], Evangelia Xenou[1], Olympia Zarkotou[2], Georgios Triantafyllidis[1]
[1]Tzaneio, General Hospital of Piraeus, Pediatric Department, Greece, Greece, [2]Tzaneio, General Hospital of Piraeus, Department Of Microbiology, Piraeus, Greece

Backgrounds: Respiratory infections are the major cause of antibiotic overuse or abuse. The use of syndromic panels can reduce unnecessary antibiotic use and it may contribute to antimicrobial stewardship efforts. The aim of this study was to define predictors of antibiotic administration in children with respiratory infections.
Methods: Microbiological, clinical and laboratory data of children with respiratory infections were recorded retrospectively and were correlated with antibiotic use. In all children included in the study, a syndromic panel was applied (BIOFIRE® FILMARRAY® Respiratory panel, bioMerieux, USA).
Results: FilmArray was performed in 45 children with respiratory infection yielding positive results in 33/45. Viral pathogens were detected in all 33 cases. Antibiotic administration was documented in 15/45 cases (33.3%). No difference in antibiotic use was observed comparing treatment approaches before and during COVID-19 pandemic (41.2% versus 28.6%, p=0.384). Antibiotic use was not significantly correlated with negative results in FilmArray (26.7% in positive versus 46.7% in negative, p=0.180) or detection of coinfection (25% versus 26,9%, p=0.935). Absence of rhinitis (p=0.049) or sore throat (p=0.05) was associated with more frequent antibiotic administration, whereas symptoms indicative of acute bronchiolitis (18.8% versus 4.,8% in non-bronchiolitis group, p=0.05) were found to be correlated with less frequent antibiotic use. Higher CRP levels (p=0.013) and especially a cut-off of 40mg/dl (p=0.013) increased the risk for antibiotic prescriptions.
Conclusions/Learning Points: This study revealed that absence of symptoms indicative of viral infection, as well as higher CRP levels, are strongly associated with more frequent antibiotic administration. Study findings highlighted the impact of both clinical and laboratory parameters on treatment approach. Clinical diagnosis of acute bronchiolitis leads to decreased use of antibiotics in children treated for respiratory infections in accordance to guidelines.

A NATIONAL REVIEW OF UK PAEDIATRIC ANTIMICROBIAL GUIDELINES

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Annalie Shears[1], Simon Drysdale[2], Stefania Vergnano[3], Marieke Emonts[4], Sanjay Patel[5], Laura Ferreras-Antolin[6], Katja Doerholt[2], Lucy Hoskyns[7], Ashifa Trivedi[8], Alicia Demirjian[9], Aisling Rafferty[10], Paddy Mcmaster[7]
[1]Stepping Hill Hospital, Paediatrics, Manchester, United Kingdom, [2]Institute for Infection and Immunity, Saint George's, Centre For Neonatal And Paediatric Infection, London, United Kingdom, [3]Bristol Royal Hospital for Children, Paediatric Infectious Diseases And Immunology, Bristol, United Kingdom, [4]Great North Children's Hospital, Paediatric Immunology, Infectious Diseases & Allergy, Newcastle upon Tyne, United Kingdom, [5]Southampton Childrens Hospital, Paediatrics, Southampton, United Kingdom, [6]University of Exeter, Mrc Centre For Medical Mycology, Exeter, United Kingdom, [7]Manchester Foundation Trust, Paediatric Infectious Diseases, Manchester, United Kingdom, [8]Hillingdon Hospitals NHS Foundation Trust, Pharmacy, London, United Kingdom, [9]Evelina London Children's Hospital, Paediatric Infectious Diseases, London, United Kingdom, [10]Children's Health Ireland, Pharmacy, Dublin, Ireland

Backgrounds: Clinical antimicrobial guidelines are a core component of antimicrobial stewardship (AMS) and the battle against antimicrobial resistance. This study therefore aimed to evaluate local paediatric antimicrobial guidelines across the UK.
Methods: All NHS trusts that care for paediatric inpatients across the United Kingdom were contacted and their inpatient paediatric antimicrobial guideline was requested. Four paediatric trainees reviewed and extracted data from collected guidelines December 2021- June 2022.
Results: A total of 121/154 (79%) of NHS trusts responded with a copy of their antimicrobial guideline, five trusts had no guideline. 116 guidelines were evaluated from England (98), Scotland (11), Wales (4) and Northern Ireland (3). Fifteen responses (13%) were from tertiary children hospitals with PID services. The majority of trusts (89%) followed local guidelines . Almost half of guidelines (49%) were delivered using smart phone applications. There was wide variation in the number of conditions covered in guidelines (range 8-57) and for each condition evaluated 10-77% of trusts did not provide a recommended duration for antibiotics. 29% (34/116) of guidelines did not include antimicrobial stewardship advice, however 100% (15/15) of trusts with local PID services provided AMS guidance. PID trusts covered a higher mean number of conditions (41 vs 34). Surgical and genitourinary conditions such as appendicitis (49%) and epididymitis (9%) were often absent from guidelines. Only 49% of guidelines provided an antibiotic recommendation for patients with penicillin allergy and sepsis. Antibiotics on the WHO 'Reserve' list were recommended in over a third of guidelines
Conclusions/Learning Points: UK local paediatric antimicrobial guidelines were variable in nature, often neglecting to include antimicrobial duration and stewardship. Future steps will involve disseminating individualised guideline feedback to local trusts, with the aim to improve antimicrobial stewardship across the UK.

ANTIMICROBIAL USE IN PATIENTS WITH CANCER AND HSCT IN A REFERRAL PEDIATRIC CENTER AFTER THE IMPLEMENTATION OF A NON-RESTRICTIVE ANTIMICROBIAL STEWARDSHIP PROGRAM

E-Posters Viewing
E-POSTER VIEWING: AS01.D. ANTIBIOTIC STEWARDSHIP

Marina Toral Fernandez[1], Sílvia Simó Nebot[2], Judit Alsina Rossell[1]
[1]Hospital Sant Joan de Déu de Barcelona, Pediatria, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Déu, Infectious Diseases, Esplugues de Llobregat, Spain

Backgrounds: Antimicrobial stewardship programs (ASP) are important tools to improve antimicrobial use in the context of global growing resistance rates, especially in immunosuppressed patients. Objective: to describe antimicrobial use in admitted cancer/HSCT paediatric patients after the implementation of a post prescription review and feedback (PPRF)-based ASP, including the incorporation of a specifically dedicated infectious diseases (ID) paediatrician.
Methods: Observational retrospective study describing antimicrobial use in cancer/HSCT admitted patients in a referral paediatric centre in Barcelona (Spain), after the progressive implementation of an ASP (January 2019-December 2021). Prescriptions were evaluated regarding indication, spectrum, dosage, duration, and route of administration, and classified as optimal or non-optimal. Quantitative data, expressed in days-of-therapy/100 days present (DOT/100DP), was also recorded.
Results: 154 cross-sectional quality surveys were conducted (1410 prescriptions). The indication was therapeutic in 62.1% and prophylactic in 34.5%. The main indication for prescription was febrile neutropenia (37.9%). The overall percentage of optimal prescriptions was 82.7% (82% in 2019, 84% in 2020 and 82% in 2021). The main reasons for non-optimal prescription were excessive antibiotic spectrum (44%) and lack of indication (42%) (Figure 1a).There was an initial decrease and posterior stability in the use of antibacterials, specially in meropenem prescriptions (Figure 1b).

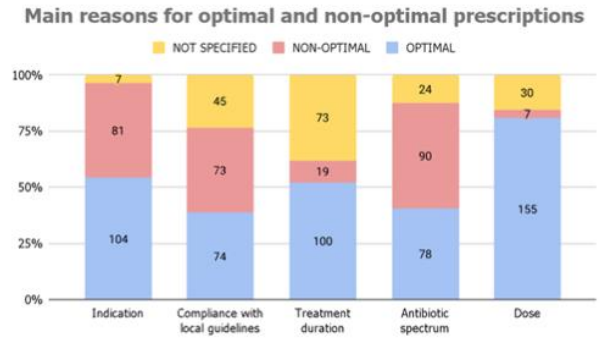

Figure 1a. Main reasons for optimal and non-optimal prescriptions during the studied period.

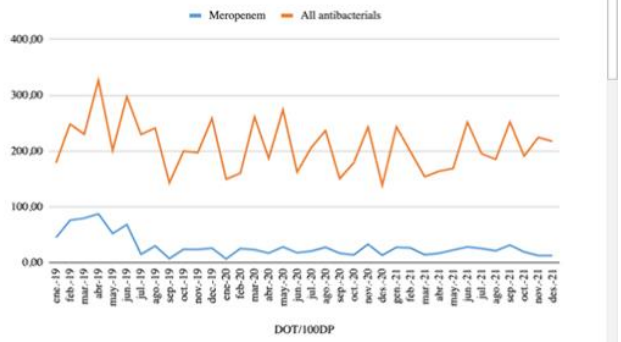

Figure 1b. Evolution of meropenem and antibacterial prescriptions, expressed in days-of-therapy/100 days present (DOT/100DP).

Conclusions/Learning Points: The implementation of an ASP contributed to achieve a relatively high quality of antimicrobial use and a trend to decrease in antibacterial prescription in cancer and HSCT paediatric patients. Longer follow-up could show further improvement. ASP evaluations identify areas of needed improvement, such as compliance to local guidelines and choosing an adequate antimicrobial spectrum. Allowing an improvement in clinical practice and a safer use of antimicrobials.

[1]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatric Infectious Diseases Unit, Lisbon, Portugal, [2]Hospital Dona Estefania – Central Lisbon University Hospital Center, Surgical Department, Lisbon, Portugal, [3]Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal, Neuroradiology, Lisbon, Portugal

Background: Mycetoma is a chronic suppurative granulomatous, localized, and destructive infection involving skin, subcutaneous tissue, fascia, muscle and sometimes invade the underlying bone. The infection is prevalent in tropical countries, generally follows traumatic inoculation.
Methods: Case report
Results: A 15-year-old, HIV negative male from S. Tomé e Principe presented with an ulcerated scalp lesion following face and head trauma three years earlier. There was progressively worsening with multiple painful inflammatory ulcerated scalp lesions, some with tender fluctuant swelling and superficial purulent discharge. Underlying bone with sclerotic lesions. Additionally, he had an ulcerated lesion on the left superior eyelid with episcleritis. MRI showed extensive sub-cutaneous, bone, orbit and pachymeningeal involvement. Biopsy of the lesions revealed granulation tissue with edema and hemorrhage areas, occasional giant multinucleated cells, and abscessed pseudocysts with white/greyish granules. Staining of granules revealed filamentous structures in their interior, Gram, PAS and Ziehl-Neelsen negative, and Grocott positive (negative on the first biopsy). These aspects were possible compatible with soft tissue mycetoma, particularly eumycetoma. Culture, pan fungic PCR, 16SRNA PCR and bacterial DNA sequencing were repetitively negative. Due to clinical severity, doubts in histopathology (initially suggestion of actinomycetes) and improvement with treatment regimen we maintained fungal and bacterial coverage during 18th months, with progressive clinical improvement after 2 months, complete resolution of cutaneous lesion after 6-12 months and MRI improvement after 18 months.
Conclusions/Learning Points: Mycetoma though rare can present in child with significant morbidity requiring early intervention to prevent further deeper extension and subsequent complications. Treatment of mycetoma usually was suboptimal, based on expert opinions, with a low cure rate despite a long treatment duration. In our case, despite the extension of the lesions and the therapeutic duration, there was a significant clinical improvement

[1]MENA Center for Research and Development and Internship, Medical Department, Amman, Jordan, [2]Yarmouk University, Department Of Basic Medical Sciences, College Of Medicine,, Irbid, Jordan, [3]Yarmouk University, Radiology, Irbid, Jordan, [4]Ministry of health, Princess Rahma Pediatrics Hospital, Irbid, Jordan, [5]Mutah University, Pediatrics, Faculty Of Medicine, Karak, Jordan, [6]Royal Medical Services, Pediatrics, Irbid, Jordan, [7]Jordan university, Pediatrics, Faculty Of Medicine, Amman, Jordan, [8]Ministry of health, Zarqa Governmental Hospital, Zarqa, Jordan, [9]Royal Medical Services, Medical Microbiology, Amman, Jordan, [10]Royal Medical Services, Pediatrics, Amman, Jordan, [11]Private Sector, Private Sector, Amman, Jordan

Backgrounds: Streptococcus pneumoniae is the most common cause of community acquired pneumonia requiring hospitalization. Most of the countries in the Middle East have introduced PCV vaccine for the prevention of strep. pneumonia infections. Jordan is one of the few countries in the region who has not introduced the vaccine due to limited local evidence. Depending only on the culture results has underestimated the magnitude of the problem locally. This is in addition to lack of data on specific serotypes of strep. pneumonia leading to invasive infections locally.
Methods: a cross-sectional study to identify serotypes of pneumococcal bacteria for children hospitalized with invasive infections for children younger than age of 5 in representative national sites for the period between 1 October 2021 and 31 December 2022. The capsular reaction test, Quellung reaction, was conducted for culture positive cases. For children with radiological evidence suggestive of lobar pneumonia, blood samples were collected for the detection of Streptococcus pneumoniae nucleic acid using a qPCR assay
Results: 1007 cases with pneumonia, septicemia, meningitis were included. 990 cases with lobar pneumonia had postive PCR for blood samples. 12 septicemia cases were identified through blood culture and 7 cases of menigitis through CSF culture. Strep. Pneunomia contributed to 50% of all community pneumonia cases hospitalized. Serotypes 6B (17%) and 6A (14%) were the most common identified serotypes.
Conclusions/Learning Points: Strep. Pneumonia has a high underestimated burden in Jordan, revealved through the qPCR molecular assay. PCV-13 covers significantly more strep. Pneumonia serotypes in Jordan when compared with PCV-10, and ,therefore, is recommended as the first choice for the national immunization program in Jordan.

E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Mirta Acuna, Dona Benadoff, Yennybeth Leiva, Faustino Alonso, Karla Yohannessen
Universidad de Chile, Pediatric And Pediatric Surgery, Santiago, Chile

Backgrounds: S. aureus (SA) infections have multiple clinical presentations. The incidence of these infections in children is poorly documented and information on risk factors associated with severe evolution is also scarce. Objective of this study was to determine the incidence of severe SA infections in the pediatric population treated at the Roberto del Río Children's Hospital (HRR) and to evaluate its association with possible microbiological, clinical, or social determinant risk factors.
Methods: Retrospective cohort, carried out at the HRR, in those patients with SA infection between 2016 and 2019. Outcome was severe SA infection. Data collection was obtained from electronical medical records. Ethics committee approved study. Descriptive statistics was use for description group. For analytic analysis was used Relative Risk with CI 95%. Statistical analysis with Stata16.
Results: 894 patients with SA infection were analyzed. 73% were managed hospitalized, 18% of them required to be managed in the Intensive Care Unit. 19.1% presented severe evolution. 0.8% lethality. 89.6% were MSSA. The cumulative incidence of SA infections in Northern Metropolitan Health Service population was 284/100,000 inhabitants <18 years of age. Risk factors associated with severe infection were age <2 years, comorbidity, previous hospitalization, and bacteremia.
Conclusions/Learning Points: Pediatric SA infections incidence is high, in our population, almost 90% SA are methicillin susceptible. Severe course of SA infection is associated with age <2 years, presence of comorbidities, previous hospitalization, and bacteremia like primary focus. No association with MRSA was found

[1]Faculty of Medicine, Vilnius University, Clinic Of Children Diseases, Institute Of Clinical Medicine, Vilnius, Lithuania, [2]Vilnius University Hospital Santaros Klinikos, Paediatrics Centre, Vilnius, Lithuania, [3]Vilnius University, Institute Of Biotechnology, Life Sciences Center, Vilnius, Lithuania, [4]Vilnius University, Department Of Physiology, Biochemistry, Microbiology And Laboratory Medicine Institute Of Biomedical Sciences Faculty Of Medicine, Vilnius, Lithuania, [5]Vilnius University Hospital Santaros Klinikos, Centre Of Laboratory Medicine, Vilnius, Lithuania

Backgrounds: Lithuania is one of the most affected countries by invasive meningococcal disease in Europe, accounting for 2.9 cases per 100,000 population in 2017. Oropharyngeal carriage of N. meningitidis is thought to be a prerequisite for the development of invasive disease. In the industrialized countries, the highest prevalence of meningococcal carriage is in young adults reaches from 1 to 40%. The aim of this study was to determine risk factors that could influence meningococcal carriage, prevalence of carriage among Vilnius University students, and to perform genogrouping of carrier isolates.
Methods: Questionnaires and oropharyngeal swabs were collected from 18-25 year-olds students (n=300) in 2021-2022. Specimens were evaluated using culture and real-time polymerase chain reaction (rt-PCR) targeting the ctrA and porA genes. Cultured meningococcal isolates were genogrouped by the end-point PCR.
Results: Carriage prevalence detected by rt-PCR was 5.7% (17/300) for the total cohort. Out of 17 carrier isolates four isolates were encapsulated: three belong to genogroup B and one to Y. Four isolates were classified as capsule operon-null locus (cnl) and two ctrA-positive isolates were nongroupable. Meningococcal carriage was more common in males (6/71 (8.4%), p=0.2), students living in dormitories (5/59 (8.5%), p=0.7), smokers (7/80 (8.75%), p=0.3) and those who were not treated with antibiotics within the last year (14/231 (6,06%), p=0.58). Pubs or nightclubs attendance ≥5 times per 2 weeks, statistically significantly increased N. meningitidis carriage risk (3/9 (33.3%), p = 0.0).
Conclusions/Learning Points: The prevalence of N. meningitidis carriage was low among Vilnius university students. Most of the carriage isolates were unencapsulated. Encapsulated isolates belong to genogroups B and Y. Nightclubbing was associated with higher carriage rate. Further evaluation is needed to understand the dynamics of carriage among university students.

[1]Children´s Hospital Iceland, Infectious Diseases, Reykjavik, Iceland, [2]Children´s Hospital Iceland, Immunology, Reykjavik, Iceland, [3]Landspitali University Hospital, Children's Hospital, Reykjavik, Iceland, [4]Landspitali University Hospital, Children's Hospital, Reykjavik, Iceland

Backgrounds: Antimicrobials revolutionized modern day medicine and their use has saved millions of lives. However, through disruption of the immature gut microbiome, antibiotics, may have adverse effects on later health.
Methods: This population based birth cohort study included full term children born in Iceland from 2010 to 2019. The cohort of infants was divided into four groups according to early antibiotic exposure; I: Elective caesarean section. II: Vaginal birth and mothers received intrapartum antibiotics. III: Vaginal birth and infants received antibiotics during the first week of life for at least 48 hours. IV: Vaginal birth and no perinatal antibiotic exposure.
Results: In total, 43.547 children were born in Iceland from 2010 to 2019. Included in the study cohort were 22.393 children. Incidence rate ratio (IRR) of various infections and odds ratio (OR) of asthma later in childhood was calculated for each group. For all antibiotic exposure types, risk of infections and filled prescriptions was significantly increased with the largest risk observed for infants treated with antibiotics (20-100% increased risk, Table 1). In addition, the risk of diagnosis of asthma was significantly increased for exposed infants when compared with controls (OR: 1.28 – 1.89, p<0.05).

	I: Elective c-section (N = 1496)	II: Intrapartum antibiotics (N = 3413)	III: Antibiotics during first week (N = 356)	IV: No antibiotic exposure (N = 17128)	P-value
Incidence rate ratio (IRR)					
Respiratory infections	1.13	1.08	1.20	1.00	<0.05
Gastrointestinal infections	1.22	1.09	1.28	1.00	<0.05
Urinary tract infections	1.52	1.32	2.04	1.00	<0.05
Antibiotic prescriptions	1.20	1.19	1.25	1.00	<0.05

Table 1: Incidence rate ratio (IRR) for various infections and antibiotic prescriptions in four groups of children born in Iceland from 2010-2019 with different antibiotic exposure in early life.

Conclusions/Learning Points: In this cohort study, children with early antibiotic exposure had higher rates of infections and needed antibiotics more often later in childhood than children with no antibiotic exposure. Asthma was also significantly more common in children with early exposure to antibiotics. The potential late side-effect of antibiotic use seems to be of clinical importance and the data should encourage health care professionals to avoid unnecessary treatment of young infants.

PV0092 / #1844

A RETROSPECTIVE DATABASE ANALYSIS TO DESCRIBE SEQUELAE OF MENINGOCOCCAL DISEASE IN CHILDREN 0-14 YEARS IN ITALY

E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Elisa Barbieri[1], Daniele Donà[1], Costanza Di Chiara[2], Antonio Scamarcia[3], Lorenzo Bertizzolo[4], Marta Borchiellini[5], Luigi Cantarutti[3], Anna Cantarutti[6], Carlo Giaquinto[1]
[1]University of Padova, Division Of Paediatric Infectious Diseases, Department For Women And Children's Health, Padova, Italy, [2]University of Padova, Division Of Pediatric Infectious Diseases, Department For Women's And Children's Health, Padova, Italy, [3]Societa' Servizi Telematici, Pedianet, Padova, Italy, [4]Sanofi, 14 Espa. Henry Vallée, Lyon, France, [5]Sanofi, Vaccines, Milan, Italy, [6]University of Milano Bicocca, Department Of Statistics And Quantitative Methods, Division Of Biostatistics, Epidemiology And Public Health, Laboratory Of Healthcare Research And Pharmacoepidemiology, Milano, Italy

Backgrounds: Although there are several studies on the incidence of meningitis, these are mainly based on surveillance or hospital data, and evidence regarding the long-term sequelae of invasive meningococcal disease (IMD) is lacking in Italy. Our study aimed to gather evidence on the burden of IMD, including long-term sequelae in children in Italy.
Methods: We used Pedianet, a nationwide database that contains anonymous patient-level data of more than 500.000 children enrolled by one of the family paediatricians part of the network since 2004, corresponding to about 4% of the annual paediatric population in Italy. Cases and sequelae were identified by searching the outpatient and inpatient diagnosis, clinical notes and hospital discharge letters for a diagnosis of IMD or a predefined sequela.
Results: From 2004 to 2021, we found 30 cases of IMD where the aetiology was confirmed to be Neisseria meningitidis. In 18 of the 30 cases, patients were boys, and the median age at the infection was 2.94 years. Sequelae related to the IMD episode were found in five boys (17% of IMD cases). The age at the IMD varied from 4 months to 6 years, and all the children were born between the years 2001 and 2008 (Table1).

Id	Sex	IMD date	Age at IMD	Sequela 1 date	Sequela 1	Delta in years	Sequela 2 date	Sequela 2	Delta in years
1	M	12/02/06	4.24	26/10/07	Emotional and behavioral disorders - Learning disabilities	1.70			
2	M	28/05/07	5.12	05/11/10	Musculoskeletal deficiencies - Strabismus and other disturbances of binocular movement, Other - Headache	3.44	23/09/13	Emotional and behavioral disorders - Emotional disorders specific to childhood and adolescence, Emotional and behavioral disorders - nausea, Emotional and behavioral disorders - vomiting	6.32
3	M	01/03/04	0.46	28/10/11	Emotional and behavioral disorders - Dyslexia and dysorthography	7.66	08/03/12	Other - Maculopathy on the retina	8.02
4	M	29/04/08	6.45	22/03/13	Emotional and behavioral disorders - Learning disabilities	4.90	21/01/15	Other - Headache, dizziness	6.73
5	M	23/09/10	2.02	02/10/14	Other - Sensorineural deafness	4.02	05/06/15	Neuromuscular diseases - Spastic hemiplegia and hemiparesis of the dominant hemisphere	4.70

Conclusions/Learning Points: Most of the sequelae included functional, emotional and behavioral

disorders, that are consistent with results observed in other European studies. Further real-world studies are needed to draw more comprehensive conclusions about IMD and sequelae in the Italian pediatric population.

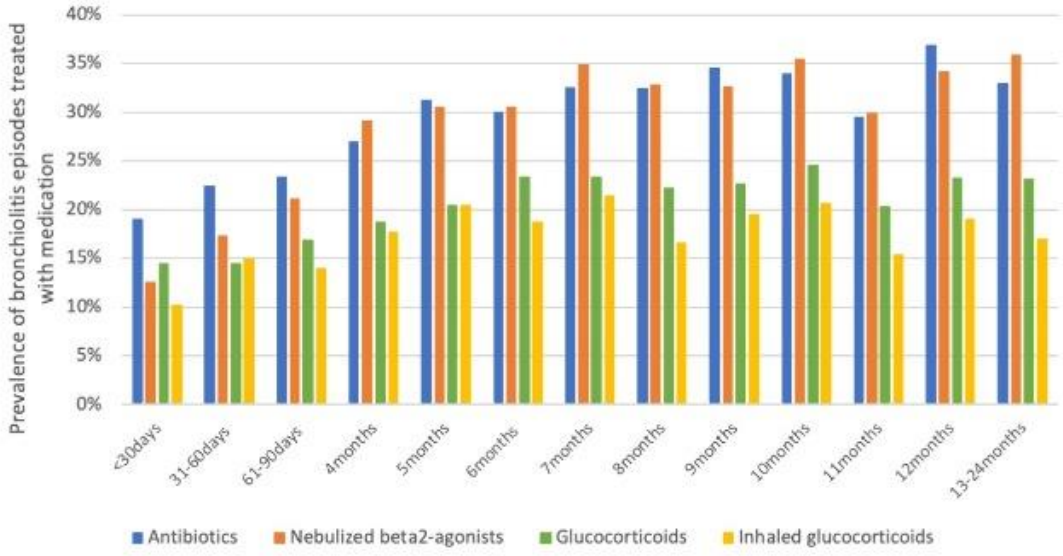
PV0093 / #2612

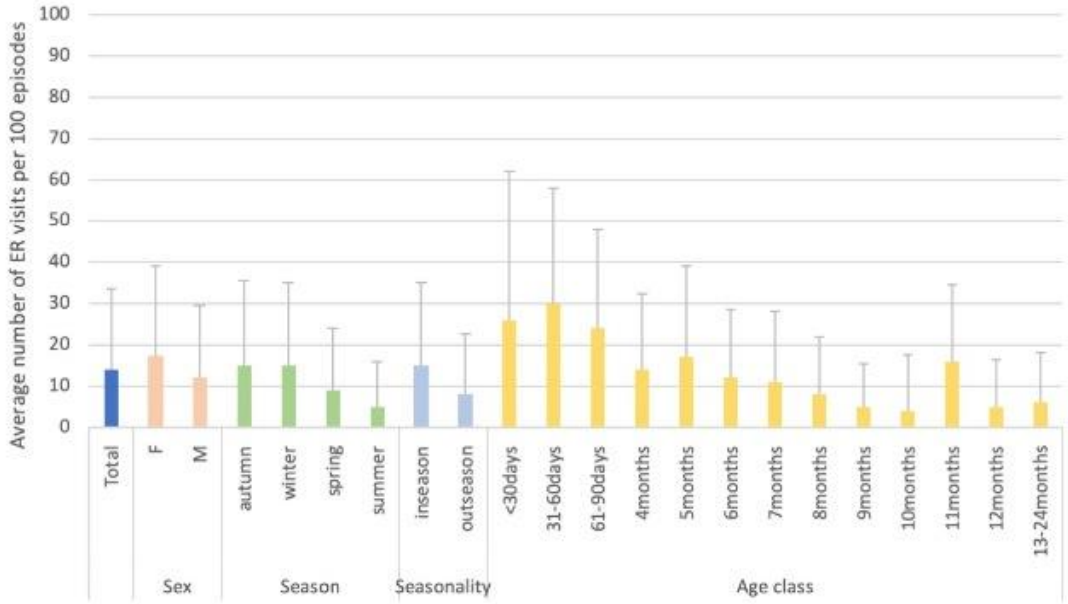
A RETROSPECTIVE STUDY USING PEDIANET DATABASE TO EXPLORE HEALTHCARE RESOURCES UTILIZATION IN CHILDREN AGED ≤24 MONTHS WITH BRONCHIOLITIS IN ITALY

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Elisa Barbieri[1], Sara Cavagnis[2], Antonio Scamarcia[3], Luigi Cantarutti[3], Salvatore Parisi[4], Lorenzo Bertizzolo[5], Mathieu Bangert[6], Anna Cantarutti[7], Eugenio Baraldi[8], Carlo Giaquinto[9]
[1]University of Padova, Division Of Paediatric Infectious Diseases, Department For Women And Children's Health, Padova, Italy, [2]Società Servizi Telematici, Pedianet, Padova, Italy, [3]Societa' Servizi Telematici, Pedianet, Padova, Italy, [4]Sanofi Vaccines, Viale L. Bodio, 37/b, Milan, Italy, [5]Sanofi, 14 Espa. Henry Vallée, Lyon, France, [6]Sanofi Vaccines, Vaccines, Lyon, France, [7]University of Milano Bicocca, Department Of Statistics And Quantitative Methods, Division Of Biostatistics, Epidemiology And Public Health, Laboratory Of Healthcare Research And Pharmacoepidemiology, Milano, Italy, [8]University of Padua, Neonatal Intensive Care Unit, Department Of Women's And Children's Health, Padova, Italy, [9]Division of Pediatric Infectious Diseases, Department For Women's And Children's Health,, Padova, Italy

Background: Respiratory Syncytial Virus (RSV) is the leading cause of bronchiolitis, a common lower respiratory tract infection in children. >20% of children aged ≤24 months require medical assistance at the outpatient level because of RSV respiratory infection. However, the true burden of RSV-bronchiolitis is not well understood in Italy. This study aims to explore the burden of bronchiolitis and the one related to RSV.
Methods: The retrospective analysis retrieved data from Pedianet, a database of 161 family paediatricians in Italy, each one caring for around 1,400 children aged ≤14 years. We explored the healthcare resources utilization for all-cause bronchiolitis in subjects aged ≤24 months, from January 2012 to December 2019. Ambulatory visits, medications and examinations were collected for the cohort of Italy, while ER accesses were collected for the cohort of the Veneto Region.
Results: Among 108,960 children, we identified 7,956 episodes of bronchiolitis. Family paediatrician visits were more frequent in younger and previously healthy children. Each bronchiolitis episode required 2.2 visits on average. ER accesses were more frequent in children aged 0-7 months (Figure 1). X-ray chest, PCR and pulse oximetry were performed in 17%, 64% and 72% of ER cases, respectively. Finally, the prevalence of bronchiolitis at the outpatient level treated with Beta2-agonists and antibiotics was >30% (Figure
1).





Conclusions/Learning Points: This analysis shows how relevant is the burden of bronchiolitis at the primary-care level in Italy, especially for all infants in their first year of life. Because pathogen identification with PCR testing in outpatients is not frequent, especially at family paediatricians' offices, the true burden of RSV is unseen. Therefore, strengthening RSV surveillance at the outpatient level, both at family paediatricians' offices and ER, is a priority.

WHAT DO MEDICAL STUDENTS KNOW ABOUT CONGENITAL CMV INFECTION IN GREECE? – A NATIONAL STUDY

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Sofia Benou[1], Eleftheria Hatzidaki[2], Sofia Tsihla[1], Anna Kalaitzi[3], Ioanna Grivea[3], Maria Baltogianni[4], Vasileios Giapros[4], Gabriel Dimitriou[1], Vassiliki Papaevangelou[5], Despoina Gkentzi[1]
[1]Medical School, University of Patras, Department Of Paediatrics, Rion, Greece, [2]Heraklion University Hospital, School of Medicine, University of Crete, Department Of Neonatology, Heraklion of Crete, Greece, [3]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department Of Paediatrics, Larissa, Greece, [4]Faculty of Medicine, School of Health Sciences, University of Ioannina, Neonatal Intensive Care Unit, Ioannina, Greece, [5]National and Kapodistrian University of Athens, Third Department Of Pediatrics, Athens, Greece

Backgrounds: Cytomegalovirus is the most frequent cause of congenital infection worldwide causing serious morbidity in newborns, infants, and children. Despite the clinical importance of congenital CMV(cCMV) infection, studies conducted so far conclude that there is limited awareness in medical community in the field. The aim of this national cross-sectional study was to assess the knowledge of cCMV infection among medical students in Greece.
Methods: We performed a questionnaire-based study on a convenient sample of medical students of seven medical schools assessing their knowledge in cCMV. The survey was conducted between September 2022 to December 2022
Results: A total of 515 questionnaires were returned and analyzed. The majority of participants(72%) were final year medical students and 57% were women. 51% of them admitted being aware of the disease burden. As for the ways of transmission, 60% could recognize kiss and blood as common ways of transmission, but only 18% mentioned infant`s urine. Most students (50-80%) were able to identify the clinical manifestations of cCMV infection, while the knowledge about diagnostic methods was low to moderate. Nearly one third of them (35%) did not know whether a licensed vaccine exists to prevent cCMV infection. Nearly all of them (94%) reported that the main source of information about cCMV was medical school training and internet. Finally, a great proportion(67%) admitted feeling overall inadequate as far as knowledge of cCMV infection is concerned.
Conclusions/Learning Points: Overall, our study indicates that further educational opportunities about cCMV should be offered medical students, particularly in subjects of the curriculum involving the care of women and children. Establishing medical students' solid knowledge background of the disease burden and educating them about preventative strategies for at-risk populations, should be the main pillars of such efforts.

BACTEREMIA DUE TO ELIZABETHKINGIA SPECIES

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Burcu Parlak, Aylin Dizi Işık, Seyhan Yılmaz, Pınar Canizci Erdemli, Sevgi Aslan Tuncay, Zeynep Ergenç, Yasemin Gökdemir, Ela Eralp, Feyza Girgin, Eda Kepenekli
Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey

Title of Case: Bacteremia due to Elizabethkingia species
Background: The ubiquitous bacterium Elizabethkingia spp., which has been linked to a number of illnesses including bloodstream and respiratory infections or meningitis or skin and soft tissue infections is typically seen in newborns and immunocompromised, and has substantial mortality rates. There have been a few small, localized outbreaks, mostly in healthcare facilities. Elizabethkingia are Gram-negative bacteria that tend to be intrinsically resistant to β-lactam/lactamase inhibitors, and carbapenems.
Case Presentation Summary: The first case was a 3-year-2-month-old boy, who was on the sixth day of ceftazidime treatment, with pneumoniae. Elizabethkingiae meningoseptica grew in endotracheal aspirate (ETA) culture. Levofloxacin was added to his treatment. The second case, a two-year-old boy with intracranial hemorrhage, pulmonary embolism, and pulmonary hypertension after an traffic accident was treated with extracorporeal membrane oxygenation. E.meningoseptica grew in ETA culture. Ceftazidime-avibactam was used. ETA culture cleared. Brain death occurred on 3 months later. The third case, a 2.5-year-old boy with aspiration pneumonia and pneumothorax due to feed a nasogastric tube, was brought to the pediatric critical care unit and had a thorax tube placed. Elizabethkingia anophelis was grown in blood culture. Meropenem, vancomycin, and gentamicin treatments were given because there was also K. pneumoniae growth in the concurrent catheter cultures. Vancomycin and gentamycin was stopped on 10th day, the growth ceased.
Learning Points/Discussion: There is still much to learn about the pathogen Elizabethkingia spp. with an intrinsic multidrug resistance phenotype, which causes opportunistic infections with significant fatality rates. Source control and strict compliance to isolation precautions is important.

PV0096 / #1531

ROTAVIRUS STRAIN CIRCULATION IN EUROPE AND THE MIDDLE EAST: SYSTEMATIC LITERATURE REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Tim Jesudason[1], Sharomi Oluwaseun[2], Alex Lapting Cheuk[1], Christian Hauck[1], David Tordrup[1], Stasha Mamotra[1], Anastasia Döldös[1], Cristina Carias[3]
[1]Triangulate Health, Health Economics, Doncaster, United Kingdom, [2]Merck & Co., Inc, Rahway, NJ, USA, Mrl, North Wales, United States of America, [3]Merck & Co., Inc, Rahway, NJ, USA, Core, North Wales, United States of America

Backgrounds: Rotavirus strain circulation varies unpredictably. While different countries have implemented rotavirus strain circulation surveillance, regional studies aggregating information for Europe and the Middle East are needed. We performed a systematic literature review on rotavirus strain prevalence in Europe and the Middle East.
Methods: We included longitudinal and cross-sectional studies from multiple time points in the same setting, from Europe and the Middle East from January 2006 to August 2021, across all languages. We excluded studies of less than 6 months duration; we also excluded studies with a sample size of less than 30 individuals. One reviewer screened the titles and abstracts to remove all studies unrelated to rotavirus epidemiology. Two reviewers then screened all remaining studies. Data extraction on strain prevalence was subsequently performed by one reviewer and independently verified by a second reviewer, with disputes resolved through discussion.
Results: The search retrieved 7601 non-duplicate papers, of which 87 studies met inclusion criteria. Study locations included 22 countries spread over the Middle East and Western, Eastern, Northern, and Southern Europe. Countries in Europe and the Middle East displayed similar strain-specific distribution patterns. Since 2006 the prevalence of common rotavirus strains (such as G1 in the Middle East and Western, Southern and Northern Europe, and G2 and G4 in Eastern Europe) shifted towards greater strain diversity and less strain dominance by a particular strain. Further investigations are required to understand the mechanisms of changes.
Conclusions/Learning Points: This study provides an update on the rotavirus strain prevalence in Europe and the Middle East in the post-vaccination period. Continuous surveillance is important to monitor strain dynamics.

INFLUENCE OF THE PANDEMIC RESPIRATORY DISEASES ON COMMON INFECTIOUS DISEASE IN TAIWAN, 2008~2023

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Po-Yen Chen
Taichung Veterans General Hospital, Infection Control, Taichung, Taiwan

Backgrounds: There were 2 pandemic respiratory diseases since 21th century: One was pH1N1 and the other was SARS-CoV-2. Both of them had cause major limitation on human transportation and social activity. We aimed to evaluate the influence of these two pandemics on some common infectious diseases in Taiwan.
Methods: The data of RODS (Real-time Outbreak and Disease Surveillance System, is a modular system that adheres to CDC's National Electronic Disease Surveillance System-NEDSS, which included Influenza like illness, acute diarrhea, hand-foot-mouth disease/herpangina, acute conjunctivitis and dengue fever) and notifiable diseases of Taiwan, were used to evaluate the influence of pH1N1 in 2009 and COVID-19 during 2020 to 2022.
Results: The influence of pandemic pH1N1 in 2009 did only little influence on the common infectious diseases in Taiwan. The activity of Influenza, enteroviral hand-foot-mouth disease/herpangina and red-eye disease (acute conjunctivitis) were dramatically decreased during the pandemic COVID-19 period, while was not the acute diarrhea in winter (mainly Norovirus). There were two autumn outbreaks of RSV in 2020 and 2022, and a summer endemic diarrhea in 2020 due to the lift of lockdown.
Conclusions/Learning Points: Pandemic respiratory disease (e.g. influenza and new Coronavirus) can cause transient change of common viral respiratory and enteroviral activity, while was not for acute diarrhea and zoonotic disease due to the limitation of movement and social contact. However, we should alert the immune debt after the pandemic COVID-19.

DIAGNOSIS AND TREATMENT OF GESTATIONAL AND CONGENITAL TOXOPLASMOSIS IN TWO HOSPITALS IN MEDELLÍN-COLOMBIA FROM 2016 TO 2020

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Sara Correa Perez[1], Mauricio Carrascal Petro[1], Catalina Arango Ferreira[1,2], Claudia Beltrán[1,3], Javier Sierra Abaunza[1]
[1]Universidad de Antioquia, Antioquia, Medellin, Colombia, [2]Hospital Universitario San Vicente Fundación, Antioquia, Medellín, Colombia, [3]Clínica el Rosario, Infectious Diseases, Medellín, Colombia

Backgrounds: Congenital toxoplasmosis is the second cause of preventable congenital blindness worldwide and an important cause of neurological sequelae. The prevalence of toxoplasmosis in the Colombian general population is high (up to 47.1%). Less than 40% of pregnant women are properly screened or receive adequate and timely therapeutic management for gestational toxoplasmosis. Consequently, between 2-10 per 1,000 newborns are diagnosed with congenital toxoplasmosis. This study describes the characteristics of diagnosis, follow-up, and treatment of gestational and congenital toxoplasmosis in a population based on adherence to the recommendations of the Clinical Practice Guidelines in force in Colombia.
Methods: A retrospective descriptive study of a cohort of children under follow-up for pediatric infectious diseases due to exposure to gestational toxoplasmosis, with diagnosis or suspicion of congenital toxoplasmosis; evaluated in two high-complexity hospitals in Colombia between 2016 and 2020.
Results: Congenital toxoplasmosis was confirmed in 17.4% of the 247 infants included. In 98.3% of the pregnant women, the median number of prenatal check-ups was 7, and in 23.4% some risk factor for Toxoplasma gondii transmission was identified. IgM and IgG serologies were sent to 90% of the patients upon admission. 62.7% had positive IgM and IgG on admission, and positive IgM was documented in 22.2% during follow-up. 43 IgG avidity tests were performed, of which 26 were high; and there was positivity in 63.4% of the IgA performed on pregnant women. 89% of the pregnant women underwent fetal ultrasound, of which 19% had imaging alterations, such as cerebral calcifications. Primary prophylaxis with spiramycin was received by 65.5% of the mothers.
Conclusions/Learning Points: A high rate of gestational toxoplasmosis and variability in behaviors regarding the different guideline recommendations were detected, mainly in the diagnosis of gestational and congenital toxoplasmosis.

A PROPOSAL FOR STUDYING GPS' COMMUNICATION STYLES ABOUT MANDATORY CHILDREN VACCINATIONS

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Veronika Dimitrova[1], Vanya Rangelova[2], Lubomira Nikolaeva-Glomb[3]
[1]Sofia University, Sociology, bl. , Bulgaria, [2]Medical University of Plovdiv, Department Of Epidemiology And Disaster Medicine, Plovdiv, Bulgaria, [3]National Center for Infectious and Parasitic Diseases, Department Of Virology, Sofia, Bulgaria

Background: While hesitancy among physicians has been studied in depth, their communication practices about vaccines have not been a topic of wide scientific interest.
Methods: Sample: Simple random sample was used to ensure representativeness. The sample consists of 358 interviews with GPs in Bulgaria. Statistical analysis: We conducted an exploratory factor analysis using the questions about the role of the GPs which measures the model of communication. We forced the creating of four factors. Factor scores for each individual were computed as averages of the corresponding variables. ANOVA analysis and T-test were performed for studying relationships between variables.
Results: Our analysis reveal four factors and models of communication. The first is physician-centered model in which, refusal to vaccinate is equated with refusal to enrolment in the practice. The second is the patient-centered model in which the role of the practitioner is of an active communicator. The third model is of the informing physician – it is a model that is an exaggerated form of the patient-centered model in a context of mandates and personalized care. The fourth designates the tension felt by the GPs related to administration of vaccines. The analysis reveal complex relationships with other variables such as type of settlement, specialty, having hesitant parents in the practice, having experience with vaccine communicable diseases, etc.
Conclusions/Learning Points: We found paradoxical conclusion that in Bulgaria the hesitant parents are not sufficiently involved in active communication about vaccines by GPs. This means that most of the models of communications are formed on the basis of avoiding demanding patient-provider relationship (Reno et al. 2018), that possibly can lengthen the communication (Perkins and Clark, 2013) and impact the feelings of administrative burden and tension.

Backgrounds: Pertussis is a contagious respiratory disease that can infect people of all ages, especially newborns and infants whose vaccination has not been completed. Despite the increase in vaccination rates, epidemics continue to occur every 3-4 years. Adolescents and adults are a source of infection for infants and young children.
Methods: Our study, it was aimed to determine the pertussis antibody level in children aged 10-18 in Eskişehir province, where we think that vaccine protection has decreased. The research was carried out in Eskişehir Osmangazi University Faculty of Medicine, Department of Child Health and Diseases. Between April 2021 and June 2021, they applied to Eskişehir Osmangazi University Faculty of Medicine, Department of Pediatrics 438 children with consent were included. Anti-pertussis toxin IgG and anti-filamentous hemagglutinin IgG from serum samples were studied using a commercial ELISA kit (EUROIMMUN, Lübeck, Germany). The analysis of the data was done with the chi-square test, and the results were considered significant at the $p<0.05$ level.
Results: Of the children, 45.7% (n=200) were boys and 54.3% (n=238) were girls, with a mean age of13.78±2.46 years. 99.8% (n=437) of the participants were vaccinated in accordance with the Vaccination Schedule of the Ministry of Health. Seropositivity was found to be 61.9%. The highest seropositivity was observed at the age of 11 at 68.5%, and the lowest seropositivity was observed at the age of 17 at 54.2%.
Conclusions/Learning Points: It was observed that seropositivity continued to decrease after the age of 14, but there was no significant difference between the ages.

ESCHERICHIA COLI PSEUDO-OUTBREAK AS A RESULT OF CONTAMINATION OF SALINE SOLUTIONS USED FOR PASSAGE IN THE LABORATORY

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Burcu Parlak, Nazlı Pazar, Işıl Küçüker, Pınar Canizci Erdemli, Aylin Dizi Işık, Seyhan Yılmaz, Sevgi Aslan Tuncay, Zeynep Ergenç, Feyza Girgin, Eda Kepenekli
Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey

Title of Case: Escherichia coli Pseudo-outbreak as a Result of Contamination of Saline Solutions Used for Passage in the Laboratory
Background: The term ‘pseudo-outbreak’ refers to a condition in which a microorganism is found in culture at a greater rate than expected and that cannot be correlated, from a clinical perspective, with the supposed infection implied by results of cultures due to contamination of materials that would normally be sterile. Escherichia coli growths were observed in endotracheal aspirate (ETA) cultures of 18 adults in intensive care units (ICUs) and 6 children in the pediatric ICU in one-month.
Case Presentation Summary: A 3.5-year-old boy with pneumonia, a 6-month-old boy with the ARDS, a 6.5-year-old girl with a craniocervical mass, wound infection, an 8-month-old girl with bronchopulmonary dysplasia and respiratory failure, a 2.5-month-old girl with diarrhea and a 2.5-year-old boy with aspiration pneumonia and pneumothorax was admitted to PICU. There were changes in blood gase, respiratory parameters, respiratory sounds, or respiratory rate per minute. E. coli grew in all ETA cultures. Sensitivity remained the same. When it was noticed that the same microorganism was isolated more frequently than usual in different intensive care units of the hospital, an epidemic investigation was launched and it was determined that the saline solutions in the laboratory were contaminated.
Learning Points/Discussion: An outbreak is a sudden rise in the number of cases of a disease. Even if it is a gold standard diagnostic method such as culture, laboratory results should not preclude clinical evaluation, and physical examination findings should be considered distinguishing an outbreak from a pseudo-outbreak.

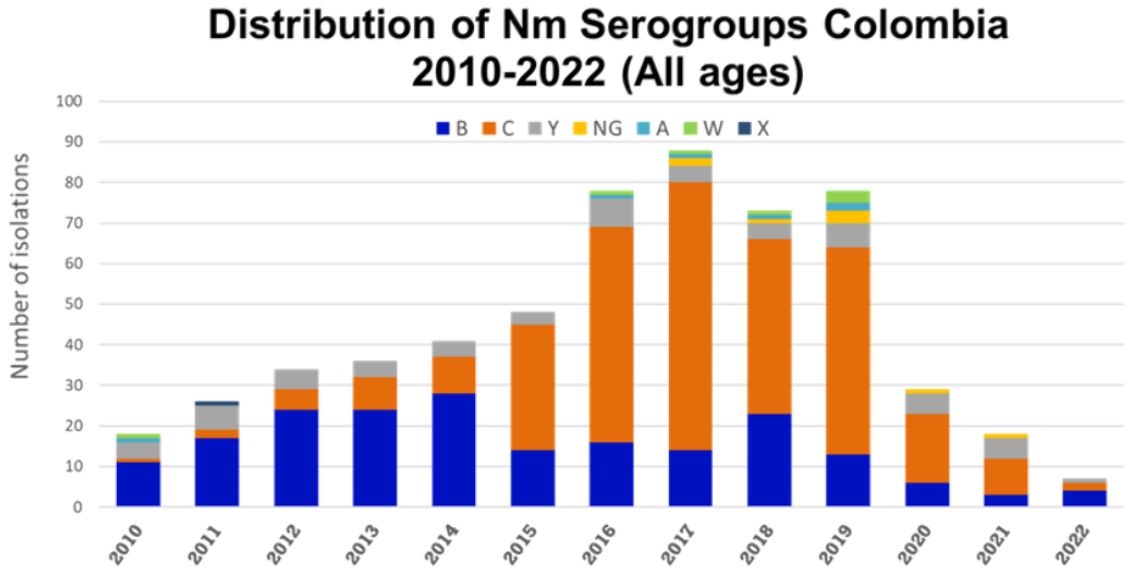
PV0102 / #1451

MENINGOCOCCAL EPIDEMIOLOGY IN COLOMBIA POST-PANDEMIC SEROTYPES SHUFFLING AGAIN

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Omar Escobar[1,2], Jorge La Rotta[1]
[1]Pfizer, Cundinamarca, Bogotá, Colombia, [2]Universidad CES, Antioquia, Medellín, Colombia

Backgrounds: In Colombia, by the 1990s the prevalent serogroup was MenB and since 2015 it has been MenC, with some isolates of MenY . As of 2019, the incidence per Nm was 0.22 with lethality in the general population of 23%. During the period from 2010 to 2020, different Nm outbreaks occurred in the country, and of all isolates, most were distributed in the age group 15-29 years, followed by <12 years and adults 30-49 years.
Methods: A retrospective descriptive study with information collected through the National Public Health Surveillance System
Results: During the period of the COVID-19 pandemic, the introduction of sanitary measures for the prevention and containment of SARS-CoV-2, as well as public information campaigns about the disease, generated an indirect reduction in the transmission of S. pneumoniae, H. influenzae and N. meningitidis, which in turn led to a significant reduction in life-threatening invasive diseases in many countries of the world caused by these pathogens, in the case of Colombia, these data were consistent with the decreases in cases reported for 2020 and part of 2021, until the beginning of 2022 when there was a rebound in suspected cases; however, the isolates obtained show a change in the predominant serogroup, now MenB is 50%, MenC is 40% and MenY
10%.



Conclusions/Learning Points: Due to the epidemic potential of IMD, it is important to establish a systematic surveillance system in each country that allows for rapid identification of the outbreak; implement effective control measures, such as access to vaccine supplies; and develop preventive policies against outbreaks and control of endemics.

PV0103 / #1535

THE FIRST CASE OF A DIPHTHERIA-LIKE ILLNESS CAUSED BY CORYNEBACTERIUM ULCERANS IN CZECHIA

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Kateřina Fabiánová[1], Jana Zavadilova[2], Jan Kyncl[3], Hana Pavlasova[4]
[1]National Institute of Public Health, Dpt. Of Infectious Diseases Epidemiology, Praha, Czech Republic, [2]National Institute of Public Health, National Reference Laboratory For Pertussis And Diphtheria, Prague, Czech Republic, [3]National Institute of Public Health, Dpt. Of Infectious Diseases Epidemiology, Prague, Czech Republic, [4]Regional Hygiene Station Vysocina, Anti-epidemic Department, Jihlava, Czech Republic

Backgrounds: Corynebacterium ulcerans (C. ulcerans) may cause zoonotic infections in humans, such as diphtheria and extrapharyngeal infections. We report the first case of a diphtheria-like illness caused by C. ulcerans in Czechia and transmitted likely by a family dog to 87 years old immunocompromised woman. She was hospitalized with shortness of breath, hoarseness and aphonia and primarily diagnosed as nasopharyngitis mucopurulenta.
Methods: Swabs were taken from a sick woman with clinical signs of respiratory diphtheria and from the mouth and muzzle of a 9-month-old mastiff puppy. Confirmation of presence of the tox gene and toxin expression were carried out by the National Reference Laboratory at National Institute of Public Health in accordance with national surveillance requirements.
Results: Subsequently, MLST was used and confirmed the match between the strain C. ulcerans from a sick woman and strain C. ulcerans from her dog.
Conclusions/Learning Points: Mandatory vaccination against diphtheria was started in 1946. The last case of diphtheria in Czechia was reported in 1995 but a total of 5 cases of diphtheria, of which 3 cases of cutaneous form caused by C. diphtheria were diagnosed in family cluster (two siblings 5 and 9 years old and their father) and two cases caused by C. ulcerans were reported in 2022. Revaccination of the adult population is not yet recommended. In connection with the recommendations of the WHO and ECDC, we propose to sustain high vaccine coverage among children, the introduction of vaccination booster doses for the adult population and recommendations for experts to increase awareness of this disease.

[1]Children Emergency Clinical Hospital of Brasov, Pediatrics, Brasov, Romania, [2]Transylvania University, Faculty Of Medicine, Brasov, Romania, [3]Faculty of Mathematics and Computer Sciences, Computer Sciences, Brasov, Romania

Backgrounds: Gastroenteritis is one of the most common cause of hospitalization worldwide.
Methods: The study is an observational, descriptive, retrospective/prospective study enrolling 2065 children aged 0-60 months hospitalized at Children's Clinical Hospital of Brasov between 2011 and 2021. All children had a positive rotavirus result in stool specimen detected by immunochromatography. We aimed to evaluate and compare socio-demographic, clinical and treatment aspects between community acquired rotavirus gastroenteritis (CARG) and hospital acquired rotavirus gastroenteritis (HARG) at children hospitalized at the Children's Clinical Hospital of Brasov, Central Romania.
Results: Total number of rotavirus gastroenteritis cases between January 2011- December 2021 was 2065 cases. Community acquired rotavirus gastroenteritis (CARG) were 1739 cases (84,2%) and 326 cases (15,7%) hospital acquired rotavirus gastroenteritis (HARG). Urban and rural areas had equal percentage - 961 cases (55,2%) for CARG, 181 cases (55,5%) for HARG. Rroma children were 957 cases (56%) in CARG group and 194 cases (59,5%) in HARG. Girls - 933 (53,6%) in the CARG vs in HARG boys - 171 (52,4%). Average age for CARG was 14,64 months vs 12,24 months for HARG. Average hospitalization days for CARG - 5,09 days vs 7,51 days for HARG. Diarrhea was main admittance symptom - 1609 cases (92,5%) for CARG and 308 cases (94,4%) for HARG. HARG group received antibiotics more often - 204 (62,6%) vs 602 (34,6%) children in CARG.
Conclusions/Learning Points: Urban areas and rroma population were predominant for both studied groups. Girls were prevalent in CARG and boys in HARG. Different age group were affected 12-24 months for CARG and 1-6 months for HARG. Longer hospitalization days for HARG 7,51 days vs 5,09 days.

EPIDEMIOLOGICAL, LABORATORY AND CLINICAL CHARACTERISTICS OF CHILDREN WITH MEASLES AT ZIV MEDICAL CENTER DURING THE MEASLES OUTBREAK IN ISRAEL IN THE YEARS 2018-2019

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Hanna Farah
Ziv Medical Center, Pediatrics, Safed, Israel

Background: We aimed to study the epidemiological, laboratory and clinical characteristics of children admitted with measles to a Northern Israeli hospital during the measles outbreak in the years 2018-2019
Methods: Children diagnosed with measles by PCR and/or serology, were included. Demographic, clinical and laboratory data were collected and analyzed into 3 age subgroups : 0-1y, 1-6y and 6-18y.
Results: Most of the 56 diagnosed children were 0-6 years old with median age of 51 months. The percentage of unvaccinated children 92.9% compared to 5.4% of patients who received only one dose of vaccine. One patient (1.8%) received two doses of vaccine. Overall, 53.6% of the diagnosed children were hospitalized with average length of hospitalization of 2.1 days. Clinically, all had a high fever and the most common symptoms were coryza, rash and conjunctivitis. Koplik spots were observed in 46.4% of children. The most common complications were pneumonia and oititis media. Lymphopenia and hyponatremia were observed in 42% and 90% of children respectively and both were mainly observed in the age group 7-18 years (p value <0.001 and 0.013 respectively)
Conclusions/Learning Points: The outbreak of measles in Israel in 2018-2019 proves that measles is still a viral disease with considerable hospitalization and morbidity rates. Since a significant number of patients are under the age of one year, the question arises regarding predating the first dose of the measles vaccine before the age of one year and likewise predating the second dose before the age of 6 years in order to ensure a higher immunity rate in young children.

MATERNAL VACCINATION FOR BORDETELLA PERTUSSIS IN LATIN AMERICA: REGIONAL SITUATION AND IMPACT OF IMPLEMENTATION ON NATIONAL VACCINATION SCHEDULES IN SELECTED COUNTRIES.

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Angela Gentile[1], Maria Avila-Aguero[2], Lourdes Dueñas[3], Rolando Ulloa-Gutierrez[2], Juan Pablo Torres[4], Giannina Izquierdo[4], Cristina Mariño[5], Vanesa Castellano[1]
[1]Ricardo Gutiérrez Children´s Hospital, Epidemiology, Buenos Aires, Argentina, [2]Dr. Carlos Sáenz Herrera Children´s Hospital, Pediatric Infectious Disease Department, San Jose, Costa Rica, [3]Benjamin Bloom's Children Hospital, Infectious Disease Department, San Salvador, El Salvador, [4]Faculty of Medicine, Universidad de Chile, Department Of Pediatrics, Santiago, Chile, [5]Central Military Hospital of Bogotá, Infectious Disease Department, Bogotá, Colombia

Background: Infants are at high risk of serious morbidity and mortality attributed to Bordetella pertussis (Bp) in early childhood. Vaccination in pregnancy has become a key strategy to protect babies during these first months of life. The objectives of this study were to review of the situation of maternal vaccination for Bp in selected LATAM countries and to analyze the impact of the maternal vaccination strategy.
Methods: Working group from LATAM countries, where maternal pertussis vaccination was implemented, were invited to participate, with at least 5 years since the introduction of the maternal tetanus, diphtheria, and acelular pertussis (Tdap) vaccines in the National Calendar. For each country, the following information was requested: a- Incidence of total pertussis in < 1 year; b-Introduction of pertussis vaccine in pregnant women: year of onset and week of recommended pregnancy; c- Tdap vaccination coverage during pregnancy since implementation.
Results: Argentina, Chile, Costa Rica, Colombia and El Salvador participated. The data analyzed showed that the countries presented epidemic cycles with a decrease in incidence after the incorporation of the Tdap maternal vaccine and a greatest decline from the pandemic year (2020). The year of initiation and gestational week of recommendation are shown in Table 1. Years of introduction and vaccination coverage showed variability between countries. Table 1

Country	Year of introduction
Costa Rica	2011
Argentina	2012
Colombia	2013
El Salvador	2014
Chile	2017

Conclusions/Learning Points: The introduction of Tdap vaccine in pregnancy showed variations in the years of introduction of countries, as well as the recommended gestational age. Coverage differs across countries and over the years of introduction. Bp incidence decrease after maternal vaccination.

E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Angela Gentile[1], Julia Bakir[1], Mara Maydana[2], Juan Morales[2], Gabriela Ensinck[3], Adriana Ernst[3], Pablo Melonari[4], Lucía Romero Bollon[1], Ana Cardozo[5], Andrea Gajo Gane[5], Santiago Alejandro Santillan Iturres[6], Mauricio Santos[7], Adriana Efron[7]
[1]Ricardo Gutierrez Children's Hospital, Epidemiology, Buenos Aires, Argentina, [2]Sor María Ludovica Children's Hospital, Infectious Disease, La Plata, Argentina, [3]Vilela Children's Hospital, Infectious Disease, Rosario, Argentina, [4]Notti Pediatric Hospital, Infectious Disease, Mendoza, Argentina, [5]J. Pablo II Pediatric Hospital, Infectious Disease, Corrientes, Argentina, [6]Eva Peron Children Hospital, Infectious Disease, Catamarca, Argentina, [7]INEI-ANLIS “Dr. Carlos G. Malbrán”, Clinical Bacteriology, Buenos Aires, Argentina

Backgrounds: In 2017, MenACWY-CRM197vaccine was introduced in the immunization schedule in Argentina (2+1,+1 at 11ys). In the pre-vaccination period (preVp,2012-2015), the burden of meningococcal disease (MD) had been assessed. To assess the impact of the intervention on MD incidence in ≤15ys during the post-vaccination period (postVp, Nov/2019-Oct/2022) and describe the clinical-epidemiological-bacteriological pattern of all confirmed MD cases of postVp vs preVp.
Methods: Active hospital surveillance in 6 pediatric sentinel units (PSUs) in Argentina. MD incidence per 10,000 hospital discharges between preVp and postVp was compared.
Results: In postVp, out of a total of 135,588 patients admitted to the 6 PSUs, 751 met the inclusion criteria as a suspected case of meningitis or MD (0.6%), of which 9.3%(70/751) had acute bacterial meningitis (ABM) and 1.1%(8/751) meningococcemia; 80.0%(56/70) of ABM cases and 12.5%(1/8) of meningococcemia cases were culture-positive, corresponding to Neisseria meningitidis 12.3%(7/57). 33.3%(7/21) of MD culture-negative cases were confirmed by PCR. Thus, there were a total of 14 MD cases, MD incidence rate 1.0(0.5-1.7) and reduction of 79.7%(64.5-88.4) in compared to the preVp. Of the 14 MD patients in the postVp, 7 were male, median age 44 months(IQR19-72), 7 had MenACWY-CRM_{197}, 3 underlying disease. Clinical presentations(n;%): meningitis with meningococcemia (6;42.9%), meningitis (5;35.7%) and meningococcemia (3;21.4%), without significant differences with preVp. There were no patients with neurological complications, sequelae, or deaths. Microbiological/molecular diagnosis was made in blood/serum (7;46.7%) and CSF (8;53.3%). Capsular group was identified in 9 samples (B:8; C:1).
Conclusions/Learning Points: The burden of MD caused by any capsular group in ≤15 years was reduced by 79.7%. The predominant capsular group was B. There were no fatalities. These data must be interpreted in the context of the pandemic and its impact.

COVID PANDEMIC INFLUENCE ON THE HOSPITALIZATIONS RELATED TO RESPIRATORY SYNCYTIAL VIRUS (RSV) AMONG SPANISH INFANTS

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Enrique Gea-Izquierdo, Ruth Gil Prieto, Valentín Hernández-Barrera, Angel Gil De Miguel
Rey Juan Carlos University, Medical Specialities And Public Health, Móstoles, Spain

Backgrounds: This epidemiological survey estimates the burden of bronchiolitis in children up to 2 year old in Spain during a three-year period (2019-2021)
Methods: Retrospective survey by reviewing data of the National Surveillance System for Hospital Data, including more than 98% of Spanish hospitals. All hospitalizations related to bronchiolitis for children up to 2 year old, reported during 2019-2021 period, were analysed. Codes were selected by using the 10th International Classification of Diseases: ICD-10-CM J21.0, J21.1, J21.8, J21.9. The monthly hospitalization rate, average length of hospitalization and case-fatality rate were calculated by using municipal register data.
Results: A total of 40,401 hospital discharges in children up to 2 year old were reported during the study period. The hospitalization rate was 2,305.48, 1,214.51 and 2,035.3 hospitalizations per 100,000 in 2019, 2020 and 2021, respectively. The average length of stay was 5.22 (5.15-5.30) days. 24 deaths were reported. The case-fatality rate was 0.06% (CI 95%: 0.04-0.09). Hospitalization rates were significantly higher in males (2,068.5 vs. 1,631.89 hospitalizations per 100,000, respectively). The typical seasonal epidemic pattern of bronchiolitis disappeared in 2020, after the COVID pandemics started and the epidemic peak was delayed from winter 2020 to spring 2021. Annual average cost for National Health Care System was 49 M€ with a mean hospitalization cost of 3,643 €.
Conclusions/Learning Points: Bronchiolitis in children up to 2 year of age still pose a significant health threat in Spain. The epidemiology of RSV has changed due to the impact of COVID-19 pandemics. Measures as the use of new monoclonal antibodies in newborns may help to decrease the burden of bronchiolitis.

PV0109 / #817

HOSPITALIZATIONS RELATED TO PNEUMOCOCCAL INFECTION IN CHILDREN IN SPAIN. INFLUENCE OF THE COVID-19 PANDEMICS (2019-2021)

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Ruth Gil Prieto, Enrique Gea-Izquierdo, Valentín Hernández-Barrera, Angel Gil De Miguel
Rey Juan Carlos University, Medical Specialities And Public Health, Móstoles, Spain

Backgrounds: This epidemiological survey estimates the hospital burden of pneumococcal disease in children in Spain during a three-year period (2019-2021)
Methods: Retrospective survey by reviewing data of the National Surveillance System for Hospital Data, including more than 98% of Spanish hospitals. All hospitalizations related to pneumococcal infection in children up to 14 years old, reported during 2019-2021 period, were analysed. Codes were selected by using the 10th International Classification of Diseases. The hospitalization rate, average length of hospitalization and case-fatality rate were calculated
Results: A total of 5,428 hospital discharges were reported during the study period. The hospitalization rate was 15.58(CI 95% 14.83-16.34) hospitalizations per 10,000 children up to 1 year old, 4.35(CI 95% 4.17-4.54) hospitalizations per 10,000 children from 1 to 4 years old and 1.17 (CI 95% 1.11-1.23) hospitalizations per 10,000 children from 5 to 14 years old. A total of 85 deaths were reported during the study period. The case-fatality rate was 1.6% (CI 95% (1.07-2.3 %), 1.38% (CI 95% (0.94-1.95 %) and 1.77% (CI 95% (1.22-2.48 %), in <1, 1-4 and 5-14 year old age groups, respectively. The hospitalization rate during the study period peaked for children aged 1-4 years old for pneumococcal pneumonia with 0.83 (CI 95% 0.75-0.91) hospitalizations per 10,000. For both pneumococcal sepsis and meningitis the highest hospitalization rate was found in infants up to 1 year old with 0.37 (CI 95% 0.25-0.49) and 0.27 (CI 95% 0.27-0.37) hospitalizations per 10,000 children, respectively.
Conclusions/Learning Points: Despite the impact of COVID-19 pandemics in most of the respiratory low tract diseases, pneumococcal disease has caused a high hospital burden and a significant health threat in children in Spain.

PRESCHOOL-LOCATED INFLUENZA VACCINATION COUPLED WITH INFLUENZA-LIKE ILLNESSES SURVEILLANCE: AN ITALIAN PILOT COMMUNITY STUDY

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Maria Gori[1], Clara Fappani[1], Silvia Bianchi[1], Lucia Barcellini[2], Chiara Gasparini[2], Elisa Borghi[1], Nicolò Garancini[2], Chiara Nava[2], Alessandra Mari[2], Anna Sala[2], Federica Forlanini[2], Emerenziana Ottaviano[1], Daniela Colzani[1], Elisabetta Tanzi[1], Gianvincenzo Zuccotti[2], Antonella Amendola[1]
[1]Università degli Studi di Milano, Department Of Health Sciences, Milan, Italy, [2]Università degli Studi di Milano, Department Of Pediatrics, V. Buzzi Children's Hospital, Milan, Italy

Backgrounds: Following the WHO recommendation to improve the Influenza vaccination coverage in children, we have launched the first school-located influenza vaccination (SLIV) campaign with intranasal quadrivalent live-attenuated influenza vaccine (LAIV) among pre-school children in Italy. School-based immunization program was coupled with influenza-like illnesses (ILIs) surveillance using a self-sampling non-invasive saliva collection method. We describe the results of the pilot study conducted during the 2021/2022 influenza season.
Methods: The study involved five pre-schools in the Milan municipality (432 children). Immunization was carried out directly in school settings to all healthy children with Fluenz™ Tetra (AstraZeneca). Children - both vaccinated and unvaccinated - showing symptoms to be considered for ILI suspicion (onset of fever or feverishness, one or more respiratory and systemic symptoms), were asked to self-sample saliva under the parent/legal guardian's supervision. Saliva was tested for ILI differential diagnosis (Influenza A/B and SARS-CoV-2) by real-time RT-PCR.
Results: One hundred thirty-five children (mean age 5.2 years, range 3-6 years) participated in the study, adhering to both surveillance and vaccination. The percentage of adherence was 11-49%, with the lowest participation recorded in the last enrolled school. No children experienced adverse reactions after vaccination. During surveillance activity, 19 saliva samples were collected from 16 children; 31.6% tested positive for SARS-CoV-2, and none was positive for influenza.
Conclusions/Learning Points: For very young children and consequently for their parents, the school represents a familiar and trusted community environment. The participation in the school immunization campaign was good, considering possible absences due to the ongoing COVID-19 pandemic, and the intranasal administration was well-tolerated and could help to overcome parental hesitancy. Moreover, saliva sampling was a useful tool to reduce children's stress and increase parents' compliance.

TRENDS IN INVASIVE HAEMOPHILUS INFLUENZAE SEROTYPE B (HIB) DISEASE IN ENGLAND; 2008/09 TO 2021/22

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Erjola Hani[1], Marta Bertran[2], Seyi Eletu[1], Joshua D'Aeth[1], David Litt[3], Norman Fry[3], Shamez Ladhani[3]
[1]UK Health Security Agency, Immunisations And Vaccine Preventable Diseases, London, United Kingdom, [2]UK Health Security Agency, Immunisations And Vaccine Preventable Diseases Division, London, United Kingdom, [3]UK Health Security Agency, Respiratory And Vaccine Preventable Bacteria Reference Unit, London, United Kingdom

Backgrounds: The Haemophilus influenzae serotype b (Hib) conjugate vaccine has been highly successful in reducing the incidence of invasive Hib disease through a combination of direct and indirect protection. Recently, a number of European countries have reported an increase in invasive Hib disease. We aimed to describe the epidemiology, clinical characteristics and outcomes of children aged <15 years with invasive Hib disease over the past 14 years in England.
Methods: UKHSA conducts national surveillance of invasive Hib disease and provides a national reference laboratory for confirmation and serotyping. General practitioners are contacted to complete a clinical questionnaire for all confirmed Hib cases.
Results: During 2008/09-2021/22, there were 8,412 invasive H. influenzae infections overall, including 1,316 in children, of which 1,139 (86.6%) were serotyped. Most (937, 82.3%) were due to non-encapsulated H. influenzae, followed by Hif (106, 9.3%), Hie (24, 2.1%), Hib (50, 4.4%) and Hia (20, 1.8%). Invasive Hib disease in children declined from 18 cases in 2008/09 to 3 in 2018/19[MB1] , and only two cases since 2020/21, when COVID-19 pandemic restrictions were implemented. Hib incidence was highest in <1-year-olds (4.9/100,000[MB2] ; n=32). Most children presented with meningitis (23/49, 46.9%) and 80% (40/50) had an underlying comorbidity. Deaths due to Hib were rare (case fatality rate, 4%), with only two deaths, during 2010/2011.
Conclusions/Learning Points: In England, invasive Hib disease remains rare in children, with no fatalities reported for more than a decade.

MEASLES OUTBREAK IN EAST JAVA, INDONESIA, IN 2022

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Dominicus Husada[1], Leny Kartina[1], Dwiyanti Puspitasari[1], Parwati Basuki[1], Ismoedijanto Moedjito[1], Zumaroh Zumaroh[2], Gito Hartono[2], Mvs Mahanani[2], Erwin Triyono[2]
[1]Faculty of Medicine Universitas Airlangga/Dr. Soetomo General Hospital, Pediatrics, Surabaya, Indonesia, [2]East Java Provincial Health Office, Surveillance, Surabaya, Indonesia

Backgrounds: The impact of the Covid-19 pandemic affected the high incidences of many vaccines preventable diseases, especially measles. In 2022 the Indonesian Government made Child Immunization Month Program all over the country with variable results; however, the outbreak of these diseases continues. This study aimed to analyze the measles outbreak in East Java Province, Indonesia in 2022.
Methods: This surveillance study was based on daily, weekly, and monthly reports from 38 District Health Offices. The information mentioned many items, including name, sex, age, address, the immunization status of the children, day of diagnosis, place of health services, and the data of the specimen (blood and urine). The confirmed diagnosis was made based on serology results from the referral laboratory in Surabaya.
Results: During 2022 there were 1689 clinically compatible cases of measles. Positive serology results were found in 436 cases. More than half cases were from September – December 2022. Madura Island, with 4 districts, has 45% of cases; meanwhile, Surabaya, as the capital city of the province, had 22% of cases. The biggest age group were 1-4 and 5-9 years old (range 4 months – 64 years). Girls (51%) slightly outnumbered boys. Fourteen percent of patients received measles vaccines at least twice. All patients survived. The total cases in Indonesia in 2022 were 3341 confirmed cases. In East Java itself, in 2021, all confirmed cases were only 13.
Conclusions/Learning Points: There were significantly increased measles cases in East Java in 2022. The additional immunization program had given little impact. Some questions, such as the quality of the routine immunization program and methods of recording and reporting, also arise from the outbreak data

PERINATAL AND OTHER RISK FACTORS FOR COMMON INFECTIONS IN INFANCY: A PROSPECTIVE COHORT STUDY

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Sanni Hyvönen[1,2], Terhi Tapiainen[3,4], Tytti Pokka[5,6], Terhi Solasaari[2,7], Katri Korpela[8], Willem De Vos[8,9], Anne Salonen[8], Kaija-Leena Kolho[1,2,8,10,11]
[1]Tampere University Hospital, Department Of Pediatrics, Tampere, Finland, [2]University of Helsinki, Faculty Of Medicine, Helsinki, Finland, [3]Oulu University Hospital, Department Of Pediatrics And Adolescent Medicine, Oulu, Finland, [4]University of Oulu, Biocenter Oulu, Oulu, Finland, [5]Oulu University Hospital, Research Service Unit, Oulu, Finland, [6]University of Oulu, Research Unit Of Clinical Medicine And Medical Research Centre Oulu, Oulu, Finland, [7]City of Helsinki, Pediatric Clinic, Social Services And Health Care Division, Helsinki, Finland, [8]University of Helsinki, Human Microbiome Research Program, Helsinki, Finland, [9]Wageningen University, Laboratory Of Microbiology, Wageningen, Netherlands, [10]Helsinki University, Children's Hospital, Helsinki, Finland, [11]University of Tampere, Faculty Of Medicine And Health Technology, Tampere, Finland

Backgrounds: Limited data from prospective cohort studies in high income countries are available on the perinatal risk factors for common infections in children. Our hypothesis was that perinatal factors may be risk factors for the number of and duration of infectious episodes during the first year of life.
Methods: In this prospective HELMi (Health and Early Life Microbiota) birth cohort study of full-term infants (n=1052) born in 2016-2018, the number and duration of infection episodes were collected online at weekly to monthly intervals. In a multivariate regression model, the main exposures were perinatal factors such as mode of delivery and intrapartum antibiotics. Environmental factors were additional exposures. The outcomes were the number and duration of infectious episodes in the first year of life.
Results: The mean number of infection episodes was 4.2 (2.9SD) and the mean duration of infection symptoms was 44 days (40SD). Upper respiratory infections accounted for 83% of the episodes (3674/4455). Perinatal factors were not associated with the number nor the duration of infection episodes, but Caesarean section was associated with an increased occurrence of urinary tract infections in infancy (adjusted odds ratio (aOR) 3.6, 95%CI 1.13-11.1). Of the additional exposures male sex (aOR 1.1, 95%CI 1.0-1.2) and the presence of siblings (aOR 1.3, 95%CI 1.2-1.4) were associated with the number of infection episodes.

TABLE 1. Mode of delivery and intrapartum antibiotics as a risk factor for the occurrence of infections in full-term infants during their first year of life

	Caesarean delivery n=176 No. of episodes Mean (SD), crude	Vaginal delivery n=876 No. of episodes Mean (SD), crude	Caesarean delivery versus Vaginal delivery aOR[a] (95% CI)	Vaginal delivery, antibiotics yes n = 208 No. of episodes Mean (SD), crude	Vaginal delivery, antibiotics no n = 668 No. of episodes Mean (SD), crude	Exposure to antibiotics in vaginal delivery yes versus no aOR[a] (95% CI)
All infections	3.8 (2.5)	4.3 (3.0)	0.93 (0.86–1.01)	4.1 (3.0)	4.4 (3.0)	0.95 (0.88–1.03)
Respiratory tract infections	3.2 (2.4)	3.6 (2.7)	0.93 (0.85–1.02)	3.3 (2.6)	3.7 (2.7)	0.92 (0.83–1.00, p=0.051)
Upper respiratory tract infections	3.2 (2.4)	3.6 (2.7)	0.94 (0.86–1.03)	3.3 (2.6)	3.7 (2.7)	0.92 (0.84–1.00, p=0.050)
Urinary tract infections	0.03 (0.3)	0.01 (0.1)	3.6 (1.1–11.1)	0.01 (0.1)	0.01 (0.1)	1.2 (0.20–5.8)
Gastrointestinal infections	0.2 (0.4)	0.2 (0.5)	0.83 (0.58–1.2)	0.2 (0.5)	0.2 (0.5)	1.0 (0.75–1.4)
Other infections	0.4 (0.7)	0.5 (0.8)	0.90 (0.71–1.2)	0.6 (0.8)	0.5 (0.8)	1.1 (0.92–1.4)

aOR, adjusted odds ratio; CI, confidence interval

Values are aORs and 95% CIs obtained by using a Poisson regression model.

[a]All the aORs were adjusted for sex, year of birth, mode of delivery, intrapartum antibiotics, number of siblings, parental asthma, maternal education, use of probiotics during pregnancy and a furry pet in the household.

Conclusions/Learning Points: This prospective cohort study showed that perinatal factors, mode of delivery and intrapartum antibiotics were not associated with the risk of common infections in infancy, but Caesarean delivery was associated with a risk of urinary tract infections.

RESPIRATORY SYNCYTIAL VIRUS (RSV) HOSPITALIZATION IN

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Raffaella Iantomasi[1], Daniela D'Angela[2], Ciro Carrieri[2], Vittucci Anna Chiara[3], Eva Agostina Montuori[1], Luigi Orfeo[4], Renato Cutrera[5]
[1]Pfizer srl, Medical Vaccine, Rome, Italy, [2]C.R.E.A. Sanità, Health Economic Research, Rome, Italy, [3]Bambino Gesù Children's Hospital, IRCCS, General Pediatrics Unit,, Rome, Italy, [4]Fatebenefratelli Hospital Gemelli isola, Fatebenefratelli Hospital Gemelli Isola, Rome, Italy, [5]Bambino Gesù Children's Hospital, IRCCS, Pneumology And Cystic Fibrosis Unit, Rome, Italy

Backgrounds: This study analyzed hospital admissions in Italy for RSV for infants below one year of age, and their variation between seasons June 2015-May 2016, and June 2018-May 2019.
Methods: The volume of acute admissions for RSV diagnosis was analyzed in two periods, June 2015-May 2016 and June 2018-May 2019, through Italian Hospital Admission database. Several respiratory illness admissions were identified by ICD-9-CM diagnoses (main and secondaries) and divided in three groups: RSV coded (ICD-9-CM 079.6, 466.11 and 480.1, group 1), bronchiolitis (ICD-9-CM 466.19; group 2) and others respiratory associated illness codes group 3); the share of each group and its dynamic all over the time have been calculated as well as the length of stay
Results: In June 2018-May 2019, a total of 20,937 admissions were recorded in Italy. The 36.9% of them were specifically due to RSV, cases in group 1, the 48.5% were bronchiolitis of unknown infection agents (group 2) and the 14.7% belonged to group 3. The highest hospitalization rate for RSV (group 1) was found in January (575.6 for 100,000 inhabitants), followed by February (511.1) and December (273.1). The mean length of hospital stay varied from 9 days in October to 4.0 days in August. Respect to the first period considered (June 2015-May 2016) overall trends in incidence of respiratory illness showed an increase of 5.4%, while the incidence of RSV coded cases increase of 28.8%. The share of RSV coded cases (group 1) increased of 6.7 percentage points between the two periods considered.
Conclusions/Learning Points: In the last three years, hospitalizations for bronchiolitis in infants below 1 year appear to be increased in Italy, especially the RSV-codes bronchiolitis, which may be attributable to increased use of appropriate diagnostic tests.

PV0115 / #352

EPIDEMIOLOGICAL ANALYSIS ON INVASIVE MENINGOCOCCAL DISEASE (IMD) IN ITALY: FOCUS ON HOSPITALIZATION FROM 2015 TO 2019

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Raffaella Iantomasi[1], Carlo Tascini[2], Francesco Sbrana[3], Ciro Carrieri[4], Daniela D'Angela[4], Marco Cotrufo[2], Silvia Cocchio[5], Barbara Polistena[4], Spandonaro Federico[4], Eva Agostina Montuori[1], Vincenzo Baldo[5]
[1]Pfizer srl, Medical Vaccine, Rome, Italy, [2]U.O. Malattie Infettive, Azienda Sanitaria Universitaria Integrata Di Udine, Udine, Italy, [3]Fondazione Toscana Gabriele Monasterio, 3. u.o. Lipoapheresis And Center For Inherited Dyslipidemias, Pisa, Italy, [4]C.R.E.A. Sanità, Health Economic Research, Rome, Italy, [5]University of Padua, Department Of Public Health, Padua, Italy

Backgrounds: Invasive meningococcal disease (IMD) is a life-threatening illness caused by the pathogen Neisseria meningitidis. IMD affects all ages, can progress rapidly, have several manifestations and can cause serious lifelong sequelae. This study analyzed hospital admissions for IMD in epidemiological and economic terms in Italy from 2015–2019 with focus on 0-19 years old population.
Methods: The volume of acute admissions for meningococcal diagnosis was analyzed in the period from 2015–2019. IMD admissions were identified by ICD-9-CM diagnoses. Costs were assessed using current DRG tariffs
Results: In 2019, a total of 237 admissions for meningococcal disease were recorded in Italy. The highest IMD rate was found in infants below one year of age (3.48/100,000), followed by 1-4 years (1.05/100,000) and 15-19 years (0.84/100,000). The mean length of hospital stay varied from 8.6 days in 1-4 years to 11.9 days in age group 15-19. For the year 2019, the total costs for acute inpatient admissions were €2,001,093 (all ages included), while the mean cost of hospitalization was €9,307.4 (+1.3% vs. 2015). When the costs were stratified, the highest mean acute inpatient admission costs were seen in those 15-19 years (€9,099.60) and the lowest in the 0-1 year range (€5,997). Trends in incidence by age group from 2015-2019 showed a statistically significant decrease in the age group 0-1 year. For all years, mortality associated with meningeal syndrome was lower compared to septic shock with or without meningitis and for the period considered mortality rates ranged from 6.7% to 7.3%.
Conclusions/Learning Points: From 2015-2019, hospitalizations for IMD appear to be decreasing slightly in Italy, even if mortality remains high. Favorable trends in hospitalizations for IMD were seen in the 0-1 year age group, which may be attributable to increased vaccination.

[1]Ricardo Gutierrez Children's Hospital, Epidemiology, Buenos Aires, Argentina, [2]Ricardo Gutierrez Children's Hospital, Virology, Buenos Aires, Argentina, [3]Ricardo Gutierrez Children's Hospital, Emergency, Buenos Aires, Argentina, [4]Comisión de Investigaciones Científicas de la Provincia de Buenos Aires (CIC), Virology, La Plata, Argentina

Backgrounds: Respiratory viruses are the main cause of respiratory infection in the pediatric population. Before the COVID-19 pandemic, Influenza had a typical epidemiological pattern in winter season. During 2020 and 2021, no influenza cases were detected while in 2022 it had an atypical behavior with outbreaks in summer and spring months. Objective: To compare the viral circulation pattern in ARI cases under 18 years of age with and without hospitalization criteria in a pediatric hospital in Buenos Aires between EW 1-52 of 2022.
Methods: Observational, cross-sectional, descriptive study of patients with respiratory symptoms with and without requiring hospitalization in 2022. Virological diagnosis was made by RT-PCR of nasopharyngeal aspirates.
Results: During 2022, from a total of 4,097 outpatient visits for respiratory infection, 2,399 were tested (58.5 %) and 1,224 (51 %) were positive for viruses: influenza (22.9 %) was predominant followed by rhinovirus (11.6 %). Meanwhile 492 hospitalized ARI cases were reported with a positivity rate of 66.3% being RSV (24.6%) predominant followed by influenza with a prevalence of 7.9%. Influenza A showed a bimodal pattern (EW 10-12 late summer; EW 38-42 spring), coinciding both peaks in outpatient and hospitalized cases. Influenza B showed a single peak in late winter first in outpatient cases with an impact on hospitalized cases 3 weeks later. Outpatient cases were older, with lowest frequency of comorbidities and history of previous hospitalizations for respiratory causes compared to hospitalized patients.
Conclusions/Learning Points: During and after COVID-19 pandemic influenza showed changes in epidemiological pattern and seasonality.

[1]Federal University of Pará, Child Health, Belém, Pará, Brazil, [2]Instituto EVANDRO CHAGAS, Virology Section, Belém, Pará, Brazil, [3]Department of Health of the state of Pará, Center For Strategic Information On Health Surveillance, Belém, Pará, Brazil, [4]Centro Universitário Metropolitano da Amazônia, Faculty Of Medicine, Belém, Pará, Brazil

Backgrounds: Hand-foot-mouth disease (HFMD) caused by Enterovirus A71, Coxsackievirus and Echovirus, characterized by fever and erythematous papular eruption located mainly on hands, feet and mouth. In Asia and the USA, the disease is notifiable allowing the monitoring of clinical manifestations and circulating viral genotypes. In Brazil it is not possible estimate the impact and profile of the disease.
Methods: An observational, prospective and longitudinal study was carried out from January 2019 to February 2020, in Pará state, north of Brazil, Amazon region. Outpatients with symptoms of HFMD were followed until resolution of symptoms. Stool samples, oropharyngeal swab, skin swab and blood samples were obtained for detection of enteroviruses by viral isolation, RT-PCR and genotyping.
Results: A total of 92 participants were included, of which 81% (75/92) had laboratory confirmation of the disease. Enterovirus were detected in 73% (55/75) of stool samples; 65% (49/75) of oral swab: 57% (43/75) of skin lesion swab and 28% (21/75) on blood samples. The time elapsed between onset of symptoms and the collection of stool samples averaged 7.7 days. Most outpatients were male (53%), younger than five years (82,6%). Vesiculobullous lesions were predominant (83%) and peeling of skin was observed in 91% of participants, about 11 days after the onset of disease (mean duration 17 days); onychomadesis occurred in 37% of cases, about 20 days after onset of symptoms (mean duration 22 days). Fever occurred in 91% of subjects. The genotyping was possible in 47 fecal samples, showing Coxsackievirus type A6 in 85% (40/47).
Conclusions/Learning Points: This study revealed predominance of bullous lesions in children with HFMD caused by Coxsackievirus A6 in amazon region. Such findings reveal the importance of continuous surveillance of HFMD in tropical countries.

UNSATISFACTORY LEVEL OF TICK-BORNE ENCEPHALITIS MORBIDITY IN CZECHIA CONTINUES

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Jan Kyncl[1], Hana Orlikova[1], Iva Vlckova[2], Kateřina Fabiánová[1]
[1]National Institute of Public Health, Department Of Infectious Diseases Epidemiology, Prague, Czech Republic, [2]National Institute of Public Health, Department Of Biostatistics, Prague, Czech Republic

Backgrounds: Tick-borne encephalitis (TBE) is a severe acute neuroinfection transmitted predominantly by tick bite or consumption of raw milk. The incidence of TBE is particularly high in Central Europe but foci of infection are still spreading to other countries as well as to higher altitudes. The disease affects all age groups including children. With increasing age, both the clinical severity of the disease and the risk of complications and sequelae increase.
Methods: Retrospective descriptive analysis of case-based TBE data from the Czech nationwide infectious disease reporting system.
Results: In 2021, 589 TBE cases were reported in Czechia (incidence 5.5 per 100,000 inhabitants). The continuous increase in incidence for six years between 2015-2020 was thus interrupted and the 2021 season was milder. According to preliminary data for 2022, the number of cases increased again, reaching 697 cases with an incidence of 6.6 per 100,000 inhabitants. The incidence of tick-borne encephalitis is highest in adults between 50 - 75 years, however in children and adolescents is increasing; on average it represents 15.2% of all reported cases in 2015-2019 but in 2021 and 2022 it was more than 17%.
Conclusions/Learning Points: Czechia is one of the countries with the highest TBE incidence in Europe and the number of TBE cases accounts for almost a quarter of all cases reported in the EU. The proportion of TBE in children and adolescents is increasing. Vaccine prevention is desirable in all age groups

EARLY-LIFE PNEUMONIA IDENTIFIES CHILDREN AT ELEVATED RISK OF CHRONIC RESPIRATORY DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Ahuva Averin[1], Stephen Pelton[2,3], Derek Weycker[1], Liping Huang[4], Jeffrey Vietri[4], Maria Tort[5], Adriano Arguedas[5], Alejandro Cane[5], Rotem Lapidot[2,3,6]
[1]Policy Analysis Inc., N/a, Chestnut Hill, United States of America, [2]BMC, Pediatrics, Boston, United States of America, [3]Boston University, Pediatrics, Boston, United States of America, [4]Pfizer Inc., Patient Health And Impact, Collegeville, United States of America, [5]Pfizer Inc., Medical Affairs, Collegeville, United States of America, [6]Rambam, Pediatric Infectious Diseases, Haifa, Israel

Backgrounds: Chronic respiratory disease (CRD) is frequent in children. We hypothesized hospitalized community-acquired pneumonia (CAP) before age 2 years may identify infants at higher risk of subsequent CRD as well as other respiratory outcomes, especially among infants with comorbidities.
Methods: A retrospective matched-cohort design and data from two sources—Optum Electronic Health Record Database (2012-2019, commercial) and Merative Medicaid Multi-State Database (2013-2019)—were employed. Each study population comprised infants hospitalized for CAP before age 2 years ("CAP patients") as well as comparators without CAP before age 2 years ("comparison patients") who were matched on comorbidity profile and propensity scores. Risks of study outcomes—CRD, reactive airway disease (RAD), CAP hospitalization, outpatient CAP, all-cause hospitalization—from age 2-5 years were estimated for CAP and comparison patients in each study population, overall and by comorbidity profile.
Results: Risks of study outcomes from age 2-5 years were markedly higher among CAP patients versus comparison patients in both commercial and Medicaid populations, by: 1.9 and 1.5 for CRD; 2.5 and 2.0 for RAD; 6.4 and 7.3 for CAP hospitalization (Table). CAP patients with comorbidities had higher risks of outcomes than CAP patients without comorbidities, but relative risks of outcomes for CAP patients versus comparison patients were comparable irrespective of comorbidity profile. Risk of CRD after age 2 years was highest among infants with hospitalized CAP closer to age 2 years (not presented herein).

Table. Rates and relative risks of study outcomes from age 2 to 5 years among commercially and Medicaid-insured CAP patients and comparison patients, overall and within subgroups defined on comorbidity profile

		Chronic Respiratory Disease*		Reactive Airway Disease*		CAP Hospitalization		Outpatient CAP		All-Cause Hospitalization

Comparison	5,610	9.6	--	3.3	--	0.1	--	1.4	--	1.2	--

CAP: community-acquired pneumonia; PY: patient-years; RR: relative risk

*Chronic respiratory disease (CRD) was defined as asthma, hyperactive airway disease, recurrent wheezing, recurrent bronchitis, recurrent OM, recurrent pneumonia, recurrent sinusitis; reactive airway disease (RAD) was defined as asthma, hyperactive airway disease, recurrent wheezing.

Conclusions/Learning Points: Pneumonia before age 2 years is associated with increased risk of CRD between ages 2 and 5 years. The proportion of infants with subsequent CRD is highest among infants with comorbidities and highest when pneumonia occurs closest to age 2 years. These observations suggest a potential causative role for early pneumonia in subsequent CRD.

PV0120 / #1820

CLOSTRIDIOIDES DIFFICILE AMONG CHILDREN WITH ACUTE GASTROENTERITIS IN THE COMMUNITY

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Jian-Te Lee[1], Yu-Chen Huang[2], Chieh-Chang Chen[3], Jia-Feng Wu[4], Luan-Yin Chang[4]
[1]National Taiwan University Hospital, Yunlin Branch, Paediatrics, Yunlin, Taiwan, [2]National Taiwan University Hospital, Yunlin Branch, Laboratory Medicine, Yunlin, Taiwan, [3]National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan, [4]National Taiwan University Hospital, Paediatrics, Taipei, Taiwan

Backgrounds: Clostridioides difficile infections (CDI) in children are usually milder as compared to adults. The reports of CDIs in children have been increasing but were mainly hospital based. We explored CDIs among children with acute gastroenteritis in the community.
Methods: We conducted a prospective cohort study recruiting children >3 years from kindergartens. The prescriptions of children were submitted by their parents to the investigators to determine consumption of antibiotics. When acute diarrhea developed, children's fecal specimens were subjected to an enzyme immunoassay (EIA) of glutamate dehydrogenase (GDH) plus toxins. The specimens testing positive for GDH were further analyzed by Xpert® CD assay. Confirmed C. difficile cases refer to positive EIA test and/or Xpert® CD assay. All specimens were tested by FilmArray® GI panels for pathogen detection.
Results: Of the 318 enrolled children in 2021–2022, 387 prescriptions were received. Antibiotics prescription rates varied in hospitals (9/44, 20.5%), pediatric clinics (31/226, 13.7%) and non-pediatric clinics (65/117, 55.6%). A total of 15 episodes of acute gastroenteritis, 3.7 episodes per 1000 children-month follow up, were reported. Among 8 episodes during September and December 2022, 11.4 per 1000 children-month follow up, 2 episodes (2/15, 13.3%) were associated with C. difficile. Both cases received a cephalosporin before CDIs and recovered smoothly. The rate of antibiotics-associated diarrhea was 1.9% (2/105). At least one pathogen could be found in 73.3% (11/15) of fecal specimens, including norovirus (4), campylobacter (2), enteropathogenic Escherichia coli (EPEC) (2), sapovirus (2) and salmonella (1).
Conclusions/Learning Points: CDIs should be considered among children with acute gastroenteritis in the community, especially those with prior antibiotics consumption.

INTERCHANGES OF HEXAVALENT VACCINES, DATA FROM THE FRENCH PEDIATRIC AMBULATORY RESEARCH IN INFECTIOUS DISEASES (PARI)

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Corinne Levy[1], Alexis Rybak[1], Stéphane Béchet[1], Nathalie Gelbert[2], Bruno Frandji[3], Georges Thiebault[2], Andreas Werner[2], Naim Ouldali[1,4], Robert Cohen[5]
[1]ACTIV, Infectious Disease, Créteil, France, [2]AFPA, Pediatrics, Créteil, France, [3]CGM, Public Health, Paris, France, [4]Robert Debré Hospital, Pediatrics, Paris, France, [5]ACTIV, Pediatric, Créteil, France

Backgrounds: Vaccine interchanges occur when two or more vaccines covering the same diseases are used to complete a multi-dose immunization series. In France, two hexavalent vaccines have been marketed for many years, Infanrix Hexa® (IH) and Hexyon® (H), whereas Vaxelis® (V) has been available since April 2018. Data on interchangeability of hexavalent are scarce, while this may occur in practice with parents bringing to the pediatrician the vaccine delivered by pharmacy or during shortage.
Methods: For children born between January 2020 and December 2022, we prospectively collected anonymized vaccination data using the PARI (pediatric ambulatory research in infectious disease) network based on automated data extraction from the software (Axi5-Infansoft®, CompuGroup Medical) of 125 pediatricians of the French primary care association (AFPA).
Results: Among the 41,750 hexavalent doses administered (including 7% preterm infants [<37 weeks]), H represented the majority (63.1%), followed by V (21.5%) and IH (15.5%). For preterms ≤ 32 weeks, the distribution was about 50% each for IH and H. Among the 5,843 children who received 2 doses of hexavalent, H+H represented 62%, V+V, 20% and I+I, 14% of the schedules while interchangeability accounted for 4% with 6 different combinations observed. Among the 8,675 children who received 3 doses of hexavalent, H+H+H represented 61% of the schedules, V+V+V, 21%, I+I+I,13% and interchangeability accounted for 5% with 18 different combinations observed.

	<28 weeks (n=107)	28-32 weeks (n=566)	33-36 weeks (n=1,922)	≥37 weeks (n=32,711)	Total (n=41,733)
Infanrix Hexa®	50 (46.7%) [37;57]	282 (49.8%) [46;54]	394 (20.5%) [19;22]	4,982 (15.2%) [15;16]	6,453 (15.5%) [15;16]
Hexyon®	56 (52.3%) [42;62]	271 (47.9%) [44;52]	1,212 (63.1%) [61;65]	21,215 (64.9%) [64;65]	26,315 (63.1%) [63;64]
Vaxelis®	1 (0.9%) [0;5]	13 (2.3%) [1;4]	316 (16.4%) [15;18]	6,514 (19.9%) [19;20]	8,965 (21.5%) [21;22]

Conclusions/Learning Points: This large study evaluating real practice of hexavalent vaccines in France showed rare occurrence of interchanges and a different distribution of the 3 available vaccines according to gestational age at-birth.

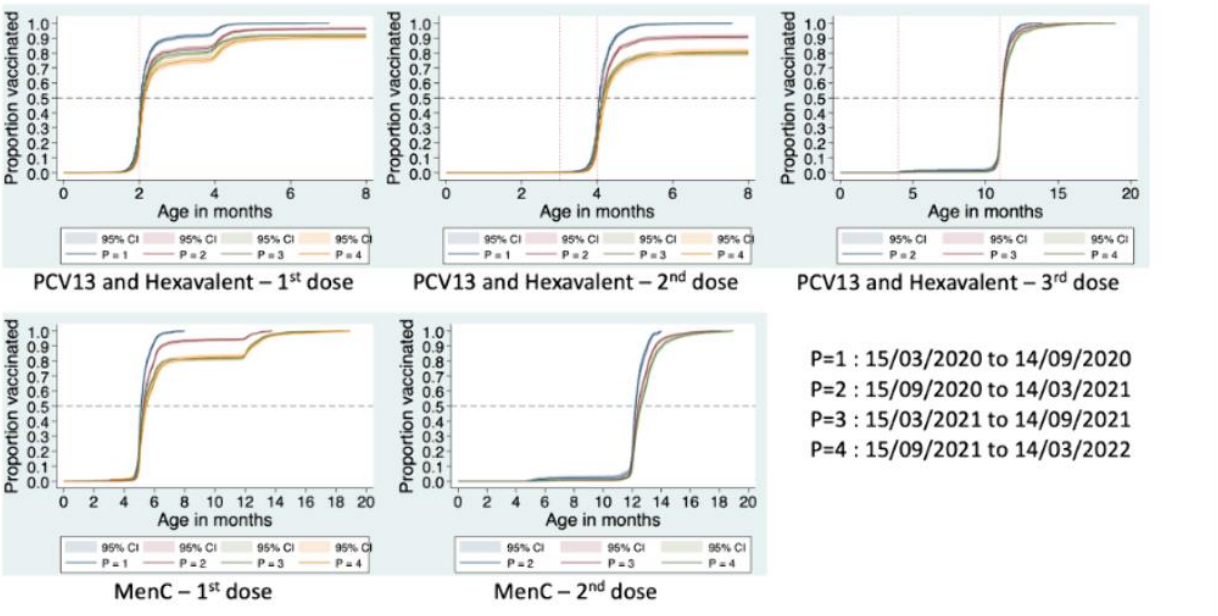
PV0122 / #804

WORRYING INCREASE IN VACCINATION DELAYS AFTER COVID PANDEMIC, DATA FROM THE FRENCH PEDIATRIC AMBULATORY RESEARCH IN INFECTIOUS DISEASES (PARI)

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Corinne Levy[1], Alexis Rybak[2], Stéphane Béchet[2], François Vie Le Sage[3], Bruno Frandji[4], Christophe Batard[1], Elisa Seror[1], Naim Ouldali[5], Robert Cohen[2]
[1]ACTIV, Infectious Disease, Créteil, France, [2]ACTIV, Pediatric, Créteil, France, [3]AFPA, Pediatrics, Créteil, France, [4]CGM, Public Health, Paris, France, [5]Robert Debré Hospital, Pediatrics, Paris, France

Backgrounds: In France, infant vaccination against 11 diseases is mandatory since January 2018. In the context of COVID pandemic, we aimed to describe compliance with the immunization program according to the age recommended for each dose for non-preterm children <18 months old.
Methods: We used the PARI network, based on automated data extraction from the software (Axi5-Infansoft®, CompuGroup Medical) of 125 pediatricians of AFPA to provide real-time vaccination data. Children vaccination data were analysed in 6-month intervals, starting with the first French lockdown from March 15th 2020 to September 14th 2020 (Period 1), September 15th 2020 to March 14th 2021 (Period 2), March 15th 2021 to September 14th 2021 (Period 3), September 15th 2021 to March 14th 2022 (Period 4). Delayed immunization was defined as >15 days after the recommended age for vaccines administered before 6 months of age, and >2 months for vaccines administered after 10 months of age. Delays in vaccination were described with survival curves.
Results: Data for 19,207 children in France with 159,341 vaccinations showed that the delays in vaccination significantly increased after the lockdown. From periods 1 to 4, for PCV13 and hexavalent, the percentage of delay >15 days increased from 13 to 30% and from 10 to 33%, for the first dose and the second dose, respectively. For first dose of MenC, the percentage of delay >15 days increased from 21 to 48% from periods 1 to
4.



Conclusions/Learning Points: This large study based on automated data extraction of vaccines data evaluated real practices of mandatory vaccinations in France. Our results raise concerns about the

increasing delays in mandatory vaccination after the COVID lockdown. High coverage and timely vaccination are necessary to maintain disease protection.

PV0123 / #2720

MEASLES VIRUS INFECTION AMONG VACCINATED AND UNVACCINATED CHILDREN AND ADOLESCENTS IN POLAND (2019-2022)

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Katarzyna Lewtak[1], Joanna Bogusz[2], Ewa Urban[1], Maria Piotrowicz[1], Małgorzata Gajewska[1]
[1]National Institute of Public Health NIH - NRI, Department Of Health Promotion And Prevention Of Chronic Diseases, Warsaw, Poland, [2]National Institute of Public Health NIH - NRI, Department Of Epidemiology, Warsaw, Poland

Background: Despite the availability of a safe and effective vaccine, measles is re-emerging in Poland due to sub-optimal measles vaccine coverage. The study aim was to document trends and characteristics of reported cases of measles in Poland in the recent years (2019-2022).
Methods: The epidemiological situation of measles among children and adolescents (aged 0-19 years) in Poland was analyzed on the basis of the case-based questionnaires of cases suspected of measles sent to National Institute of Public Health by the Sanitary and Epidemiological Stations.
Results: Between 2019 and 2022, there were 441 measles cases among children and adolescents, out of which 399 (90.5%) occurred in 2019. Most patients in 2019 were adolescents aged 10-19 years (63.3%) and unvaccinated individuals (67.9%). In the last three years, the most commonly affected age groups were 1 to 4 years (47.6%), and 5 to 9 years (33.3%). Among 40 measles cases with known vaccination status, 62.5% had been vaccinated and 72% of those had only received one dose of vaccine. No deaths due to measles have been reported during the period 2019-2022.
Conclusions/Learning Points: Public health strategies to increase vaccine coverage with routine and supplementary vaccination campaigns must be supported, especially now, facing humanitarian crises, global mobility and sub-optimal measles vaccine coverage.

RAPID STAND-UP OF A NATIONAL SEMI-HARMONISED APPROACH TO HUMAN JAPANESE ENCEPHALITIS VIRUS SEROSURVEILLANCE FOLLOWING NOVEL EPIDEMIC SPREAD IN AUSTRALIA

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Noni Winkler[1], Archana Koirala[1], Rena Hirani[2], Linda Hueston[3], Matthew O'Sullivan[3], Guddu Kaur[1], Shayal Prasad[1], Jen Kok[3], Dominic Dwyer[3], Veronica Hoad[2], Iain Gosbell[2], David Irving[2], Stephen Lambert[1], Kristine Macartney[1]
[1]Sydney Children's Hospital Network, National Centre For Immunisation Research And Surveillance, Sydney, Australia, [2]Australian Red Cross Lifeblood, Research And Development, West Melbourne, Australia, [3]NSW Health Pathology-ICPMR, Microbiology, Westmead, Australia

Backgrounds: Japanese encephalitis (JE), is caused by the mosquito-borne JE virus (JEV), is endemic to Asia. Approximately 68,000 cases occur annually, most of which are in children. In 2021 human/swine/vector infections were detected across large geographic areas of eastern and southern Australia; only rare sporadic JEV infections in remote Northern Australia had been detected previously.
Methods: Multiple human/animal/vector surveillance activities were designed to assess JEV transmission risk. A national human serosurveillance program tested sera from blood donors and targeted high-risk human populations (people of all ages living in areas with detection of infected animals or vectors). Consent-based sampling included a detailed participant questionnaire on demographic, vaccination, exposure and other data. Blood samples were tested for JEV-specific total antibody using a defined epitope blocking assay, and examined for cross-reactivity to other local endemic flaviviruses, MVE and Kunjin.
Results: A total of 5,254 serum samples from blood donors attending nine blood collection centres in high-risk areas and three lower-risk centres in six of eight Australian states and territories were analysed. Preliminary results indicated 2.1% (95% CI 1.6–2.6) seropositivity in high-risk areas, compared to 1.1% (95% CI 0.7–1.7) in low-risk areas. Higher JEV seroprevalance rates (4-8%) were seen in targeted high-risk populations. Additional results will be presented and data mapped to information from animal and vector studies.
Conclusions/Learning Points: In response to the unexpected emergence of JEV across the vast Australian continent, a nationally consistent multimodal human serosurveillance program has provided evidence of infection in asymptomatic populations and informed targeted allocation of limited JEV vaccines to risk areas.

[1]MSD Colombia, Gmvc, Bogota, Colombia, [2]Estudios Avanzados en Salud S.A, Medical Director, Guatemala City, Guatemala, [3]Hospital General San Juan de Dios, Pediatricts, Guatemala City, Guatemala, [4]Hospital Roosevelt, Comprehensive Care Unit For Hiv And Chronic Infections, Guatemala City, Guatemala, [5]Estudios Avanzados en Salud S.A, Department Of Coordination, Guatemala City, Guatemala, [6]Hospital Roosevelt, Pediatricts, Guatemala City, Guatemala, [7]Hostpital Infantil de Infectologia y Rehabilitacion, Pediatricts, Guatemala City, Guatemala, [8]Estudios Avanzados en Salud S.A, Department Of Investigators, Guatemala City, Guatemala, [9]MSD Costa Rica, Gmsa, Guatemala City, Costa Rica

Backgrounds: There is a lack of information in Guatemala regarding health resource utilization (HCRU) and associated costs among the hospitalized pediatric population diagnosed with varicella.
Methods: A retrospective, observational, multicenter study was conducted in four hospitals in Guatemala City. Medical records of patients aged 0-14 years diagnosed with varicella from 2015 to 2019 were reviewed. HCRU was estimated from medical records. The direct costs were calculated using data from national formularies, insurance, and official national sources. All costs were obtained in local currency (Quetzal) and an exchange rate of $7.579926 was used
Results: Records of 124 hospitalized patients were analyzed, 40.3 % were female and 58.9% male. 98.4% patients had one hospitalization and 1.6% two. An average of 10.6 lab and 1 imaging test per patient were performed. Over-the-counter drugs were prescribed by 55.6%, antibiotics in 66.1% and antivirals in 69.4%. The median hospital stay in bed service was 7.7 days (IQR:4,9) and ICU stay were 7.5 days (IQR:2,9). 21.8% of the patients required intensive care. The median healthcare cost per patient was $1,397 (IQR:906, 3335). Among them, most costly were: hospitalization $892 (IQR:595,1338), lab tests $51 (IQR:28,84.), antibiotics $45 (IQR:0.00,141) and prescription medications $18 (IQR:6, 37). Complications related to varicella were present in 66 % of patients, most frequent were the infectious ones, mainly soft tissue infection (35.5%) and pneumonia (13.7%). The most frequent non-infectious complication was haematological alterations (10.5%). The median difference in direct costs between patients with and without complications was $908, which represented an increase of 52%.
Conclusions/Learning Points: Hospitalizations due to varicella are associated with a considerable economic and clinical burden. Complications related to this disease are frequent and have an important impact in the costs associated to health care.

PV0126 / #1761

RESPIRATORY SYNCYTIAL VIRUS (RSV) INFECTION IN CHILDREN IN SOUTHERN MOZAMBIQUE: INCIDENCE OF DISEASE, ASSOCIATED MORTALITY, AND RISK FACTORS

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Sergio Massora[1], Leocadia Vilanculos[1], Helio Mucavele[1], Percy Efrain Pantoja[2], Elena - Castro[2], Anelsio Cossa[1], Avertino Benedito[1], Nelson Tembe[1,3], Inacio Munduapege Mandomando[1], Clara Menendez[1,2,4], Azucena Bardajii[1,2,4]
[1]Centro de investigação em saúde de Manhiça, Research, Maputo, Mozambique, [2]ISGlobal - Barcelona Institute for Global Health, Maternal, Child And Reproductive Health, Barcelona, Spain, [3]Instituto nacional de saude, Reseacher, Maputo, Mozambique, [4]Consorcio de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBERESP), Reseacher, Madrid, Spain

Backgrounds: Respiratory syncytial virus (RSV) is a leading cause of under-5 morbidity and mortality. Low and middle-income countries concentrate most (90%) of the RSV burden. We aimed to determine the incidence of RSV acute lower respiratory infections (ALRI), and associated mortality and risk factors, among African children.
Methods: A health facility-based prospective observational study was carried out in children aged 0-60 months hospitalized with WHO-defined clinical criteria for pneumonia at the Manhiça District Hospital (MDH), in Southern Mozambique. Clinical and demographic data was collected through standardized questionnaires. A nasopharyngeal aspirate (NPA)/swab (NP) was collected from all study children at enrolment. Respiratory samples were analyzed for RSV detection by molecular methods (TaqMan Array). In this area, HIV prevalence in pregnant women attending ANC is high (21%), and 30% of admitted children at MDH are HIV positive.
Results: A total of 330 children admitted with WHO-defined criteria for severe pneumonia were recruited between October 2019 and September 2022. Among 90 NP tested RSV prevalence was 22.2% (20/90). NP and NPA are being tested at Centro de Investigação em Saúde de Manhiça (CISM) using TaqMan Array Card technology, and primers and probes specific for RSV-A and RSV-B using RT nested PCR. Final analyses of clinical and microbiological data are currently ongoing, and will be presented in May at ESPID 2023.
Conclusions/Learning Points: An RSV maternal immunization strategy is being considered for the prevention of severe disease in infants less than six months of age. In this context, generating data of the burden and RSV infection in African young infants is essential.

RECENT MICROBIOLOGICAL TRENDS OF STREPTOCOCCUS PNEUMONIAE FROM CHILDREN IN JAPAN

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Masaaki Minami[1], Syunsuke Akahori[2], Ryoko Sakakibara[3]
[1]Nagoya City University Graduate School of Medical Sciences, Bacteriology, Nagoya, Japan, [2]Nagoya City University, Medicine, nagoya, Japan, [3]Daido Hospital, Clinical Investigation, nagoya, Japan

Backgrounds: With the worldwide focus on COVID-19 infections, interest in multidrug-resistant bacterial infections, including Streptococcus pneumoniae, is declining. However, pneumococcal infections are an important cause of morbidity and mortality in pediatric infectious diseases. In this study, we aimed to determine the prevalence and antimicrobial susceptibility patterns of Streptococcus pneumoniae isolated from pediatric patients in general hospitals in central Japan from 2021 to 2022.
Methods: A cross-sectional study was conducted on 40 patients diagnosed with pediatric sepsis at a Japanese general hospital for 2 years.Medical records added to the clinical species were used for clinical characteristics. Microorganism identification and antimicrobial susceptibility testing were performed with the VITEK2 system.
Results: Forty Streptococcus pneumoniae were isolated among which 26 (65%) were males and 14 (35%) were females. Thirty (75%) bacteria were isolated from nasal discharge and 4 (10%) isolates were isolated from blood. The age incidence of 0 - 1 years, 1 years, 2 years, and over 3 years age groups were 6 (15%), 16 (40%), 5 (12.5%), and 13(32.5%), respectively. In this study, 14 (30.5%) Streptococcus pneumoniae strains were found to be multidrug resistant to three or more drugs. These 11 cases contained all penicillin-resistant Streptococcus pneumoniae. Twenty-eight (70%) Streptococcus pneumoniae cases were resistant to both erythromycin and tetracycline.
Conclusions/Learning Points: Despite infection control measures with COVID-19, pneumococcal infections spread easily in the community, suggesting progressive multidrug resistance of Streptococcus pneumoniae. Continuous drug susceptibility surveillance, not only in Japan but also at the global level, is essential to reduce morbidity and mortality of pneumococcal infections in the future.

VACCINATION DELAY AND COMPLETE VACCINE COVERAGE IN BRAZILIAN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Jose Cassio Moraes, Ana França, Ione Guibu, Rita Barata
Faculdade de Ciências Médicas da Santa Casa de São Paulo, Saúde Coletiva, São Paulo, Brazil

Background: Vaccine coverage has been dropping in Brazil since 2016.
Methods: In order to learn its true proportion and some of the associated factors, we carried out a vaccine coverage survey in all Brazilian capital cities (27) of children born in 2017 and 2018 living in urban areas. The sample size was 31028. The dates that the vaccines recommended by the National Immunization Program (PNI) were administered were obtained by photographing vaccination cards or searching the PNI registry. We classified as delayed doses those given 30 days or more of the date scheduled by the PNI. We defined complete administered vaccine coverage (CVA) when a child had been given all the vaccines recommended by the PNI up to 24 months of age. Up to the age of 6 months, the PNI recommends the administration of one dose of intradermal BCG and hepatitis B, two doses of rotavirus, pneumococcus, and meningococcus, three doses of inactivated poliomyelitis vaccine, and the pentavalent vaccine (diphtheria, tetanus, whole cell pertussis, hepatitis B and Haemophilus influenzae B).
Results: CVA for children who had received all doses scheduled for the first 6 months of life without any delay was 80% (IC95% 78-82), and 55% with any delayed dose (53-58). Delay was higher in the North region; for younger mothers with less schooling, who were single and had more children; lower income families; children vaccinated at public services, with more difficult access to vaccination centers or facing difficulties to be vaccinated at a center.
Conclusions/Learning Points: Delay reduces CVA significantly and is associated with characteristics of mothers, socioeconomic status of families, and access to vaccination centers and how they operate.

SPORTS PRACTICE AND INFECTIONS IN THE PEDIATRIC AGE: PROTECTION OR RISK FACTOR?

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Alberto Muñoz Ramos[1], Belén Hernández Fuentes[2], Gema Cuesta Sánchez[2], María Cristina Iglesias Robles[2], Beatriz Bautista Mezquita[1], Pilar Díaz Pernas[1], María Rosario Benítez Rubio[1], Ana Isabel Madrigal Terrazas[1], Alicia Borreguero Hinarejos[1], María Teresa Guisado Garrido[2], Noelia Rodríguez Agudo[2], Ana Isabel Díaz Cirujano[1]
[1]Rosa de Luxemburgo Primary Care Center (Madrid Health Service), Pediatrics, San Sebastián de los Reyes (Madrid), Spain, [2]Rosa de Luxemburgo Primary Care Center (Madrid Health Service), Pediatric Nursing Staff, San Sebastián de los Reyes (Madrid), Spain

Backgrounds: Infections are often non-severe in the pediatric population, but if they occur frequently, they can be life-altering. Regular sport practice has been associated with protection against respiratory tract infections (RTI) but also with a predisposition to suffer from some entities such as skin infections. Our objective is to evaluate the relationship between sports activity and infections in children.
Methods: An analytical retrospective study including all the patients attending to the Child Health Program visits at 6 and 12-14 years old between April 2022 and July 2022 was performed. Demography, extracurricular sports activity (frequency, type of sport) and the number of infections in the last year were analyzed. Patients who practice sports regularly and those who do not were compared to assess the infection rate in each group.
Results: Three hundred and tree children were included, 112 were 6 years old and 191 were teenagers (12-14 years old). 248 (81.8%) practiced sport regularly, 69 (36.1%) with a frequency of more than 6 hours per week in the teenagers group. The most common infection was upper RTI (34.6% of patients). Only three patients (1%) required hospitalization for infectious causes. No influence was observed between sport practice and the frequency of infections in general (p=0.385). A decrease in upper RTI was observed in children who practiced team sports (p=0.003). Sport practice, contact sports and team sports practice did not show an increase in skin infections. The complete results are summarized in Table 1.

TABLE 1. STATISTIC ANALYSISIS BETWEEN SPORTS ACTIVITY AND THE INCIDENCE OF INFECTIONS IN THE LAST YEAR, BOTH IN THE OVERALL SAMPLE AND BY AGE GROUP.

	OVERALL (n=303)		
	Yes	No	p
Sport activity	248 (81.8%)	55 (18.2%)	
Two or more infections/Y			0.385
Yes	71 (28.6%)	19 (34.5%)	
No	177 (71.4%)	36 (65.5%)	
Upper RTI			0.357
Yes	83 (33.5%)	22 (40.0%)	
No	165 (66.5%)	33 (60.0%)	
Skin infections			0.465
Yes	12 (4.8%)	4 (7.2%)	
No	236 (95.2%)	51 (97.8%)	
Contact sports	25 (8.2%)	278 (91.8%)	
Two or more infections/Y			0.515
Yes	6 (24%)	84 (30.2%)	
No	19 (76%)	194 (69.8%)

No	15 (60.0%)	183 (65.8%)	
Skin infections			0.765
Yes	1 (4.0%)	15 (5.3%)	
No	24 (96.0%)	263 (94.7%)	
Team sport	118 (38.9%)	185 (61.1%)	
Two or more infections/Y			0.119
Yes	29 (24.5%)	61 (32.9%)	
No	89 (75.4%)	124 (67.1%)	
Upper RTI			**0.003**
Yes	**29 (24.5%)**	**76 (41.1%)**	
No	**89 (75.4%)**	**109 (58.9%)**	
Skin infections			0.240
Yes	4 (3.3%)	12 (6.4%)	
No	114 (96.7%)	173 (93.6%)	

	AGE GROUP					
	6 years (n=112)			12- 14 years (n=191)		
Sport activity	Yes	No	p	More than 6 H/W	Less than 6 H/W	p
	92 (82.1%)	20 (17.9%)		69 (36.1%)	122 (63.9%)	
Two or more infections/Y			0.097			0.442
Yes	41 (44.5%)	13 (65.0%)		54 (78.2%)	101 (82.8%)	
No	51 (55.5%)	7 (35.0%)		15 (21.8%)	21 (17.2%)	
Upper RTI			0.074			0.546
Yes	40 (43.5%)	14 (70.0%)		17 (24.6%)	35 (28.6%)	
No	52 (56.5%)	6 (30.0%)		52 (75.4%)	87 (71.4%)	
Skin infections			0.074			0.214
Yes	4 (4.3%)	3 (15.0%)		5 (7.2%)	4 (3.2%)	
No	88 (95.7%)	17 (85.0%)		64 (92.8%)	118 (96.8%)	

ABBREVIATIONS. Y: Year. RTI: Respiratory tract infections. H/W: Hours per week.

Conclusions/Learning Points: We did not find an increase of infections, including skin infections, in patients who practice sports. Sports activity could be a protective factor for the development of upper RTI in children. However, larger-scale researches are needed to clarify this fact.

PV0130 / #1899

BLOOD CELLS DISORDERS IN HIV INFECTED CHILDREN IN DOUALA CITY ,CAMEROON

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Charlie Ngo Bayoï[1,2], Calvin Tonga[2], Léopold Lehman[2]
[1]Faculty of Sciences, University of Douala, Animal Biology, BP, Cameroon, [2]Faculty of Sciences, University of Douala, Animal Biology, Douala, Cameroon

Backgrounds: HIV infection is a priority health issue for sub-saharan Africa. Litterature suggests that this disease impairs the human body through its effects on blood cells, preferentially immune cells and hematological parameters. This study aimed at determining the effects of HIV infection on blood cells in children
Methods: The survey was conducted from April 2016 to April 2017. Children up to 19 years, 139 HIV negative and 286 HIV positive were enrolled. A flow cytometer and an automated analyzer were used to assess immunological and hematological parameters respectively. Chi-2 or Fischer's exact tests were used to compare proportions; Mann-Whitney and Anova tests for means. Statistical significance was set at $p<0.05$.
Results: Anemia prevalence was 42.82 % with two cases of severe anemia. Anemia was associated with HIV statut. Children with HIV presented higher anemia prevalence 47.2 versus 31.7% (p=0.003). Anemia was also associated with immunodeficiency. Children with moderate and severe CD4 T cells suppression presented the highest burden in both under 6 years (P= 0.004) and children aged 6 years and above (P=0.01). Anemia was normocytic both in HIV and HIV free groups and mostly hypochromic than normochromic. Thrombopenia was not associated with HIV status (P=0.7)
Conclusions/Learning Points: Anemia was high in HIV infected. A better management of anemia in those groups is thus very important for a healthy community

INVASIVE PNEUMOCOCCAL DISEASE IN THE CZECH REPUBLIC AND WHOLE GENOME SEQUENCING ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Zuzana Okonji[1], Jana Kozakova[2]
[1]The National Institute of Public Health (NIPH), Centre For Epidemiology And Microbiology, Prague , Czech Republic, [2]The National Institute of Public Health (NIPH), Centre For Epidemiology And Microbiology, Prague, Czech Republic

Backgrounds: In 2021, altogether 264 cases of invasive pneumococcal disease (IPD) were entered in the surveillance database of the Czech Republic (CR). The age-specific incidence rates reached 0.9/100 000 in children under 1 year of age, i.e. 1 IPD case, com- pared to 4.5 /100 000 in 2020, i.e. five cases of IPD, and 2.6/100 000 in children aged 1 to 4 years, i.e. 12 cases, compared to 1.8/100 000 in 2020, i.e. eight cases of IPD. The most afflicted age group was 65 years and over, with an absolute number of 140 cases, i.e. 6.6/100 000, in comparison to 119 cases, i.e. 5.6/100 000, in 2020. Fourteen cases of IPD occurred in persons previously vaccinated with pneumococcal vaccines, six of whom were children aged 0–4 years, one was from the age group 5–39 years, and seven were 65 years and over. Forty-eight reported deaths were associated with the detection of pneumococci in clinical specimens from normally sterile body sites. Streptococcal Infections for typing. The most commonly identified serotypes in 2021 were 3, 8, 19A, and 6C.
Methods: The diagnosis was based not only on the conventional but also on the molecular methods.
Results: Whole genome sequencing (WGS) is currently the most sensitive and the most effective method to study populations of infectious agents. WGS data analysis will provide a detailed insight into the genetic relationships among the Czech populations of S. pneumoniae of all serotypes studied. This WGS data will be presented until 2022.
Conclusions/Learning Points: Supported by Ministry of Health of the Czech Republic, grant nr. NU22-09-00433 from the.

HUMAN PAPILLOMAVIRUS-ASSOCIATED CANCERS IN MEN IN COLOMBIA

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Cintia Parellada[1], Juan Orengo[2], Melissa Diaz[3], Diana Buitrago[3], Claudia Beltran[4], Fabian Hernandez[3], Sebastian Medina[4], Fernando De La Hoz[5]
[1]MSD Brazil, Core, Sao Paulo, Brazil, [2]MSD (IA) LLC, Guaynabo, Puerto Rico, Core, Guaynabo, Puerto Rico, [3]IQVIA, Iqvia, Bogota, Colombia, [4]MSD Colombia, Gmac, Bogota, Colombia, [5]Universidad Nacional de Colombia, Public Health, Bogota, Colombia

Backgrounds: HPV-associated cancers affect both genders. Since 2012, HPV vaccination has been included in the Colombian Immunization Program targeting 9-17-year-old girls. Data on burden of disease in men is crucial to support policy recommendations to expand vaccination to boys.
Methods: To estimate the burden characterize hospitalization and mortality rate of HPV-associated cancers in adult men in Colombia. This was a retrospective cohort study evaluating adult men with HPV-associated cancers (anus, penis, and selected head and neck sites). All new cases hospitalized in 2015 (index data), were extracted from the national administrative database under the International Classification of Diseases-10 for HPV-associated cancers (SISPRO; hospitalization, length-of-stay [LOS] and age). This cohort was followed for 3 years. From a disaggregated national base (MIPRES-SISPRO), incident cases and deaths were obtained to estimate mortality rate and mortality-to-incidence ratio (MIR) from 2015-2019.
Results:

Table 1. Summary of main findings of HPV-associated cancers among men in Colombia

Anatomical Site	Hospitalization (2015-2018 data from 2015 cohort population)				Mortality (2015-2019 national data)			
	Age, mean (SD)	Frequency	Hospitalization rate /100,000	LOS (days), (SD)	New cases	Deaths Frequency	Mortality-to-incidence ratio	Mortality Rate /100,000
Anus	51.5 (±17.3)	405	0.1	6.2 (±10.2)	4,268	4,268	1.1(1.05 -1.12)*	5.3
Penis	55 (±18.2)	764	0.07	7.5 (±10.2)	554	554	0.2(0.19 -0.22)	0.7
H&N	60.1. (±15.7)	2,153	0.18	10.3 (±14.8)	4,492	4,492	0.9(0.88 -0.94)	5.6
Larynx	64.9 (±13)	900	0.32	11.4 (±13.5)	2,033	2,033	1.3(1.26 -1.37)*	2.5
Oral cavity	57.8 (±16.9)	631	0.11	11.8 (±17.9)	1,332	1,332	0.8(0.74 -0.82)	1.7
Oropharynx	56.8 (±15.9)	622	0.15	7.3 (±12.3)	1,125	1,125	0.6(0.6 -0.67)	1.4

*Ratio above 1 are considered unreliable

We identified a total of 3,322 new hospitalizations by HPV-associated cancer in men. The mean age at index data ranged from 51.5 years in anal cancer from 64.9 in larynx. The highest hospitalization rate and LOS were seen in head and neck cancer (H&N)(Table 1). The percentage of re-hospitalization in the year 2 and 3 was 10.5% and 3.1%, 31.5% and 6.7, and 30.9% and 8.5% for anal, penile, and H&N cancers, respectively. Among the H&N sites, laryngeal cancer has the highest re-hospitalization rate (45.4%). Between 2015-2019, 13,004 men died of HPV-associated cancers; larynx had the higher cancer death rate. High MIR were seen in all HPV-associated cancers.
Conclusions/Learning Points: This study provides real-world evidence on the substantial burden of HPV-associated cancers among men in Colombia. These findings can be used to evidence-inform policymaking regarding HPV prevention in men.

PV0133 / #1675

BURDEN OF HPV-ASSOCIATED CANCERS AMONG MEN IN MEXICO

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Carlos Aranda[1], Juan Orengo[2], Carlos Lara[1], Arturo Del Valle[1], Melissa Diaz[3], Fabian Hernandez[3], Diana Buitrago[3], Cintia Parellada[4]
[1]Hospital General de México Dr. Eduardo Liceaga, Medicine, Mexico, Mexico, [2]MSD (IA) LLC, Guaynabo, Puerto Rico, Core, Guaynabo, Puerto Rico, [3]IQVIA, Iqvia, Bogota, Colombia, [4]MSD Brazil, Core, Sao Paulo, Brazil

Backgrounds: In addition to anogenital warts, the prevention of penile, anal, and head and neck cancers represents potential benefits of the HPV vaccine. Currently, vaccination of boys is not included in the National Immunization Program in Mexico. Since there is a lack of data on HPV burden of disease in men, the use of real-world evidence using national databases can offer a magnitude of the problem.
Methods: To describe hospitalization characteristics and mortality rate of HPV-associated cancers among men in Mexico from 2012-2017. This was a retrospective observational study using national databases in Mexico to identify penis, anus, and selected sites of head and neck (H&N [oropharynx, oral cavity, and larynx]) cancers in men ≥ 18 years, according to the International Classification of Diseases, from 2012-2017. Hospitalization rate, length of stay (LOS) and age at discharge were obtained from two structured hospital discharge databases (SAEH and Sectorial). Mortality data was extracted from the National Mortality Epidemiological and Statistical System (SEED).
Results: From 2012 to 2017, a total of 9,004 hospitalizations occurred among men with anal, penile, and selected H&N cancers. The mean age at hospitalization ranged from 53.5 years for anal cancer to 63.8 years in larynx. H&N cancer was the most common HPV-associated cancer and had the highest hospitalization and mortality rates, driven by laryngeal cancer. The LOS was 2.5, 4.0, and 4.1 for anal, penile, and H&N cancers, respectively (Table
1).

Table 1. Mean age at discharge, hospitalization rate, LOS, and mortality rate by anatomical site, 2012-2017

Anatomical Site	Age (years), mean (SD)	Hospitalization			Mortality
		Frequency	Rate 100,000 (CI)	LOS (days) mean (CI)	Rate 100,000 (CI)
Anus	53.5(±38)	352	0.9 (0.78-0.96)	4.1 (3.58-4.56)	0.1 (0.06-0.08)
Penis	55.6(±15.3)	1,256	3.1 (2.94-3.28)	4 (3.81-4.28)	0.5 (0.45-0.51)
Head and neck	60.8(±14.6)	3,698	9.2 (8.86-9.45)	2.5 (2.37-2.6)	3.1 (3.05-3.2)
Larynx	63.6(±11.7)	2,182	5.4 (5.17-5.63)	2.6 (2.46-2.81)	1.8 (1.75-1.86)
Oral cavity	57.3(±17.5)	1,009	2.5 (2.34-2.65)	2.2 (2.05-2.36)	0.7 (0.66-0.73)
Oropharynx	57.1(±15.7)	507	1.3 (1.15-1.36)	2.5 (2.2-2.75)	0.6 (0.59-0.66)

Conclusions/Learning Points: In Mexico, real-world evidence of hospitalizations, LOS, and mortality showed a substantial disease burden of HPV cancers among men in Mexico. These findings may inform policy decisions focused on the need for HPV disease prevention strategies in men.

PV0134 / #1192

PASSIVE SURVEILLANCE FOLLOWING VACCINATION WITH TYPHOID CONJUGATE VACCINE IN NEPALESE CHILDREN.

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Dikshya Pant[1], Mila Shakya[2], Suchita Shrestha[2], Shrijana Shrestha[1], Buddha Basnyat[2], Andrew Pollard[3], Merryn Voysey[3]
[1]Patan Academy of Health Sciences, Paediatrics, Kathmandu, Nepal, [2]Patan Academy of Health Sciences, Oxford University Research Unit (oucru), Kathmandu, Nepal, [3]University of Oxford, Oxford Vaccine Group, Oxford, United Kingdom

Backgrounds: Typhoid fever is endemic in low-income countries. The WHO recommends the use of typhoid conjugate vaccines (TCV) to control typhoid in high burden settings. In 2017, short term efficacy of TCV was evaluated in a field study in Nepal.In this participant and observer blinded randomized controlled trial, 20,019 children 9 months to less than 16 years, were vaccinated either with TCV or meningococcal conjugate vaccine (MenA).After 2 years of follow up, participants were unblinded and those in the control arm were offered Vi-TCV vaccine and vice-versa. The objective of this study is to assess the incidence of typhoid and paratyphoid fever in the vaccinees as well the background incidence in the non vaccinated individuals of the catchment area.
Methods: This is an ongoing prospective cohort study conducted in 18 community clinics along with a hospital based fever clinic. Any clinic attendee from the catchment area, who had fever for 2 or more days and/or temperature>_38C had their blood cultures drawn. Blood culture data were recorded in the redcap.
Results: A total of 8054 participants attended the fever clinics from Oct 2021-Dec 2022. There were 2090 febrile participants and 1995 had their blood cultures drawn. Out of 105(5.2%) positive blood cultures 33.3%(35/105) were contaminated, 27.6 %(29/ 105) grew S.Typhi and 36.1 %(38/ 105) grew S.Paratyphi . Similarly, 2 cultures were positive for Streptococcus pneumonia and 1 positive for E.Coli.
Conclusions/Learning Points: In this ongoing study of relative vaccine effectiveness (VE measured between groups vaccinated at different time points), passive surveillance for enteric fever provides data on burden in children presenting with fever and will be used to establish whether there is waning in vaccine efficacy over time.

PV0135 / #1633

THE BURDEN OF ROTAVIRUS GASTROENTERITIS IN THE CZECH REPUBLIC, DATA ABOUT THE COVERAGE OF VACCINATION

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Petr Pazdiora[1], Iva Vlckova[2]
[1]Medical Faculty of Charles University, Epidemiology, Pilsen, Czech Republic, [2]National Institute of Public Health, Institute Of Biostatistics And Informatics, Prague, Czech Republic

Backgrounds: Rotaviruses are the most frequent aetiological agent among patients with diarrhoeal disease worldwide. Epidemiological data could be the basis for the recommendation of vaccination.
Methods: The importance of rotavirus gastroenteritis was analysed retrospectively using official reports, and laboratory data from Czech laboratories from the years 2002-2022. Data on the vaccination against rotavirus infections was estimated on the basis of the numbers of vaccines distributed.
Results: There were 95,816 reported cases of rotavirus gastroenteritis in total. Among them 63,3% were children under the age of 5 (the incidence 534.2/100,000 inhabitants per year). Hospitalisations were also reported as a 76.6% of all reported cases. Among children under 5 years of age 3,219 hospitalizations were reported in 2022. Based on this data and with the use of the Soriano-Gabarroś method, it is estimated that, annually in this agegroup, another 25,752 were out-patients with more benign rotavirus gastroenteritis . There were 48 deaths reported from rotavirus gastroenteritis (among these 10 children under 1 year). The highest case fatality rate is among people over 65 years of age (0.34%). The highest incidence rate was between March and May in the analysed period. On the basis of the more frequent and more sensitive laboratory confirmation of diarrhoeal disease in recent years, as well as better reporting, rotavirus gastroenteritis is seen to be increasing. At the same time, the numbers of vaccinated children are very low. Vaccination started in 2007, and the estimated coverage of vaccinated of children in the first year of life was 21.7% by the end of 2021.
Conclusions/Learning Points: The results indicate the need for universal vaccination against rotavirus infections in the Czech Republic.

PV0136 / #1918

EPIDEMIOLOGICAL-MOLECULAR STUDY OF RESPIRATORY VIRUSES INVOLVED IN PAEDIATRIC INFLUENZA-LIKE ILLNESS (ILI) CASES IN LOMBARDY (NORTHERN ITALY) FROM AUGUST 2021 TO NOVEMBER 2022

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

[1]UNIVERSITY OF MILAN, Department Of Biomedical Sciences For Health, MILAN, Italy, [2]DG Welfare, Uo Prevenzione, Milan, Italy

Backgrounds: As a regional reference laboratory of the Italian influenza-like illness (ILI) surveillance network (InfluNet&RespiVirNet), we conducted an epidemiological-molecular study to track the respiratory virus circulation in paediatric ILIs in Lombardy (Northern Italy) in 16 consecutive months.
Methods: In the framework of the InfluNet&RespiVirNet activities, 1274 nasal-pharyngeal swabs (NPSs) were collected from as many outpatients aged ≤14 years in Lombardy from August 1st, 2021 to November 30th, 2022. Specific real-time PCR assays were performed to detect influenza viruses (IVs), SARS-CoV-2, respiratory syncytial virus (RSV), metapneumovirus (MPV), parainfluenza viruses (PIV), rhinovirus (RV), enterovirus (EV) and adenovirus (AdV).
Results: Overall, in 84.5% of NPS at least one virus was identified; a single virus was in 67.6% and more than one virus was co-detected in 32.4%. IVs were detected in 19.4% of NPSs, almost all (98%) were A(H3N2), with an epidemic peak in March/April 2022 and then in September/November 2022. SARS-CoV-2 was identified in 6.1% of ILIs with the highest detection frequencies in January, March/April, June and November/December 2022. RSV was detected in 17% of ILIs with an epidemic in November 2021 and November 2022. 13,8% of ILIs were PIV-positive and three epidemic curves were observed: November/December 2021, April/July and September/November 2022. RV, EV, AdV and MPV were detected in 27.3%, 11.1%, 9.7% and 9.4% of ILIs, respectively. These viruses circulated throughout the study period with no specific pattern. A higher risk of infection for RV was estimated in 0-2 years (37%) and 3-5 years (23.1%) age groups, and for IVs in children 6-10 years (43.6%) and 11-14 years (46.6%).
Conclusions/Learning Points: ILIs integrated surveillance allows the monitoring of the community transmission of viral respiratory infections by uncovering any change in their epidemiological features.

A RISK PANEL FOR THE EVOLUTION OF SEASONAL EPIDEMICS OF BRONCHIOLITIS AND FLU IN CATALONIA, SPAIN

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Aida Perramon-Malavez[1], Víctor López De Rioja[1], Martí Català[2], Sergio Alonso[1], Enric Alvarez[1], Daniel López[1], Antoni Soriano-Arandes[3,4], Clara Prats[1]
[1]Universitat Politècnica de Catalunya, Department Of Physics, Barcelona, Spain, [2]University of Oxford, Nuffield Department Of Orthopaedics, Rheumatology And Musculoskeletal Sciences (ndorms), Oxford, United Kingdom, [3]Hospital Vall Hebrón, Paediatrics, Barcelona, Spain, [4]Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Paediatric Infectious Diseases And Immunodeficiencies Unit, Department Of Paediatrics, Barcelona, Spain

Backgrounds: Bronchiolitis, mostly caused by respiratory syncytial virus (RSV), and flu among other respiratory viruses, are behind seasonal saturation at healthcare centres in Catalonia (Spain). We aimed to define a set of indicators to assess the risk level of these epidemics, based on both incidence and their dynamics, and considering epidemical thresholds.
Methods: We performed a risk evaluation system that we previously developed for monitoring COVID-19. We used publicly available data on daily cases of influenza and bronchiolitis in children from the Information System for Infection Surveillance in Catalonia (SIVIC) of the Health Department of Catalonia, including the Moving Epidemic Method (MEM) to define epidemic thresholds. We pre-processed the data with a 7-day average and consider the data's weekly report pattern. We named our indicator effective potential growth (EPG) and defined it as the product of the 7-day cumulated incidence of infections (A_7) by the empirical reproduction number (ρ_5) which is computed as the ratio of new cases with respect to cases 5 days ago ($EPG=A_7 \cdot \rho_5$). Finally, we performed a retrospective analysis to determine the suitability of the indicator.
Results:

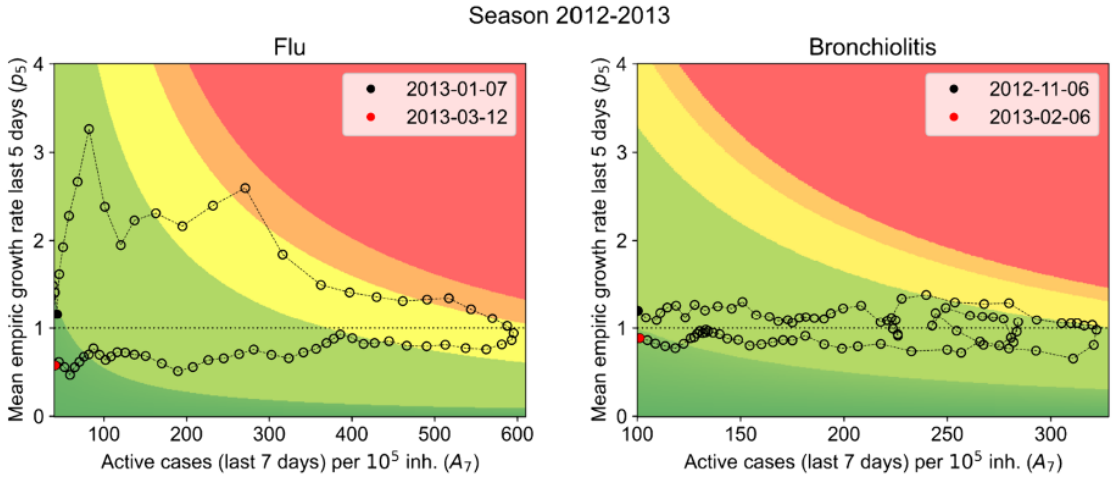

Figure 1. Risk diagrams for season 2012-2013 for flu (left) and bronchiolitis (right). They show ρ_5 with respect to A_7 starting from the black point and finishing at the red point. The background colours correspond to EPG values classified by the epidemic levels.

The MEM method allowed us to define epidemic weekly incidence levels (infections per 10^5 inhabitants)

for influenza (<15 yo) and bronchiolitis (<4 yo) as 55 and 100 baseline, 370 and 330 medium, 640 and 430 high and 810 and 480 very high, respectively. We observed that EPG forecasts properly when the epidemic exceeds these thresholds in 1 week. Figure 1 shows an example of risk diagram.
Conclusions/Learning Points: We created a new EPG that successfully anticipates overcoming bronchiolitis and influenza epidemic thresholds. Together with the weekly growth tax, this can be a powerful surveillance tool to be generalised to other infectious diseases with seasonal epidemics.

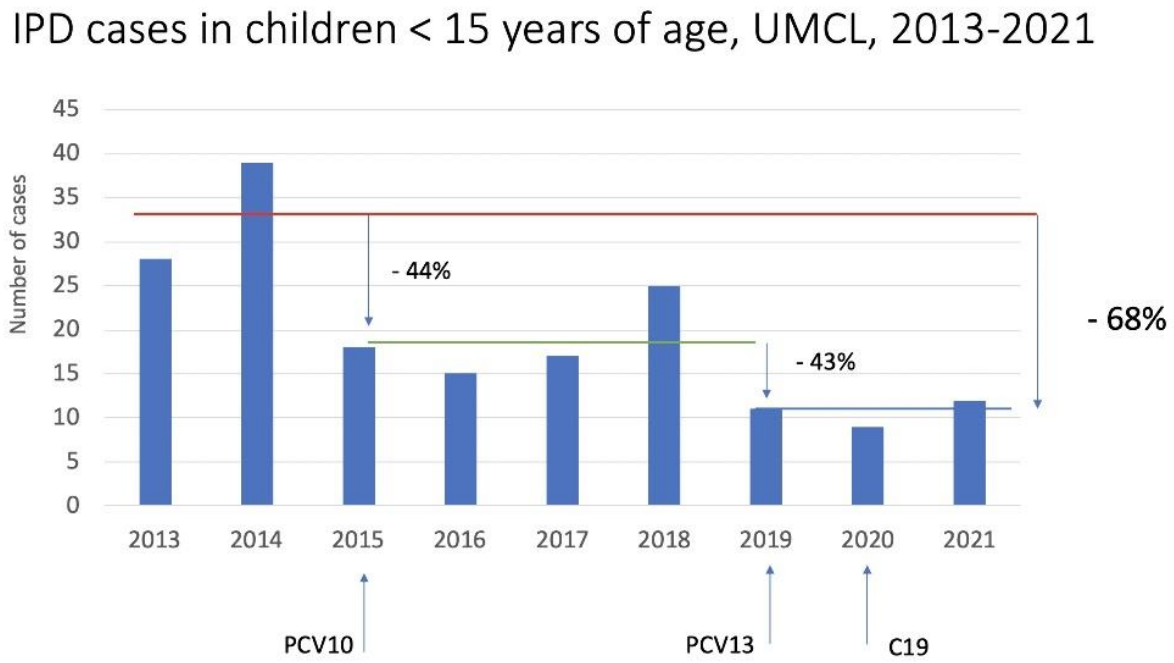
INVASIVE PNEUMOCOCCAL DISEASE IN CHILDREN AT THE UNIVERSITY MEDICAL CENTRE LJUBLJANA, SLOVENIA, 2013-2021: THE SURPRISING IMPACT OF SUBOPTIMAL VACCINE UPTAKE

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Marko Pokorn[1], Katarina Vincek[2], Mojca Kolnik[1], Rok Kučan[1], Tamara Kastrin[3]
[1]University Medical Centre Ljubljana, Division Of Pediatrics, Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Department Of Infectious Diseases, Ljubljana, Slovenia, [3]National Laboratory of Health, Environment and Food, Department For Public Health Microbiology, Ljubljana, Slovenia

Backgrounds: In Slovenia, PCV10 was introduced in the NIP in 2015 on a 2+1 schedule and in 2019 a switch to PCV13 was made. Unlike other vaccines PCV is non-mandatory with lower vaccine uptake (58.2% of children being completely vaccinated in 2021). We aimed to investigate the number of invasive pneumococcal disease (IPD) cases and serotypes in children < 15 years of age from 2013 to 2021 at the University Medical Centre Ljubljana (UMCL), the largest academic tertiary care hospital in Slovenia.
Methods: Clinical features and demographic data of all IPD cases were analyzed with serotyping being performed at the National Laboratory of Health, Environment and Food.
Results: There were 174 cases of IPD in the study period with bacteremia and bacteremic pneumonia being the predominant clinical syndromes. From the prevaccine period 2013- 2014 to PCV10 period 2015-2018 there was a 44% decrease in the average number of IPD cases with a further 43% decrease in the PCV13 period from 2019 to 2021 with covid prevention measures having additional impact on IPD incidence. There was a gradual switch to non-vaccine serotypes from 2013 to 2021 with serotypes 14, 1, 18C, 19A and 6A being the most prevalent in prevaccine era, serotypes 1, 14 and 19A prevailing during PCV10 era and nonPCV13 vaccine serotypes representing more than 50% of isolates in the PCV13 era with 24F becoming the most prevalent
serotype.



Conclusions/Learning Points: In spite of suboptimal PCV uptake a 68% decrease in IPD number in children was observed at the UMCL 4-6 years after PCV introduction accompanied by serotype replacement.

PV0139 / #2051

SEASONALITY OF RESPIRATORY SYNCYTIAL VIRUS IN CHILDREN IN BELGIUM AND THE IMPACT OF THE SARS-COV-2 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Marc Raes[1], Nathalie Bossuyt[2], Daan Van Brusselen[3]
[1]Jessa Hospital, Pediatrics, Hasselt, Belgium, [2]sciensano, Epidemiology, Brussels, Belgium, [3]GZA, Pediatrics, Wilrijk, Belgium

Backgrounds: The Covid-19 pandemic has disrupted the typical seasonality of respiratory infections worldwide. To secure proper preventive actions against RSV in children, many countries were alerted to improve their surveillance systems to ensure timely detection of the virus.
Methods: Local data from the Jessa Hospital was compared to data collected by the national institute of Health (Sciensano).
Results: Before the Covid-19 pandemic, the start of the RSV season was found to be relatively consistent, most often around week 41/42, (beginning of October), with a median peak at week 49 (December). The end of the season was more difficult to define with season duration ranging from 13 to 28 weeks. The emergence of SARS-CoV-2influenced the dynamics of RSV. In Belgium, there was no 2020 winter peak. Local and national data show a delayed RSV wave in the 2021 spring season. Peak values did not exceed the regular winter peaks, but an 'ongoing plateau' from early spring to mid-summer. Also 2021 showed atypical seasonality, lacking a high winter peak but continued reporting of RSV infections beyond the normal end of season in March (week 13). The 2022 winter season is ongoing, with clear increase of RSV-positive cases since October 2022. The epidemic threshold was exceeded mid-November.
Conclusions/Learning Points: The COVID-19 pandemic situation showed the importance of surveillance and the need for real-time registration of in- and out-of-season RSV outbreaks. In Belgium, current RSV surveillance could be optimized to allow efficient RSV prophylaxis guidelines.

[1]Genetics, Vaccines and Pediatric Infectious Diseases Research Group (GENVIP),, Instituto De Investigación Sanitaria De Santiago And Universidad De Santiago De Compostela (usc), Galicia, Spain., Santiago de Compostela, Spain, [2]Instituto de Investigación Sanitaria de Santiago and Universidad de Santiago de Compostela (USC),, Genetics, Vaccines And Pediatric Infectious Diseases Research Group (genvip), Santiago de Compostela, Spain, [3]Consellería de Sanidade, Xunta de Galicia, Galicia, Spain., Dirección Xeral De Saude Pública,, Santiago de Compostelo, Spain, [4]Hospital Clínico Universitario de Santiago, Translational Pediatrics And Infectious Diseases, Santiago de Compostela, Spain

Backgrounds: An influenza vaccination campaign for children aged 6-59 months was launched in Galicia (Spain) on October 17th, 2022. Vaccines were delivered through the regular vaccination points in primary care, targeting a total of 69,142 children and aiming for 60% vaccination coverage (VC).
Methods: A pilot plan to boost vaccine uptake was launched, consisting of an information campaign, mass vaccination sites opening during a weekend, and flexible electronic citation. Pilot 1 targeted 3,293 families with unvaccinated children within a 20-minute isochrone of the Santiago de Compostela hospital. Providing easy parking and access to the outpatient facilities of the hospital, where a multidisciplinary clinic with 6 simultaneous vaccination points was set. Pilot 1 SMS was sent on November 17th.Following Pilot 1, the health authorities decided to implement a second pilot study (Pilot 2) that was extended to the seven Galician healthcare districts, 43,900 families with unvaccinated children received the invitation to bring their child for flu vaccination to the nearest hospital among any of the 14 hospitals in the region, in addition to the usual vaccination points, during the weekend of November 26th and 27th.
Results: Pilot 1 intervention had the immediate effect of increasing VC by 2.5%. During the vaccination weekend at the hospital, a further 3.5% VC was achieved, resulting in an overall increase of 6%. A multivariate linear model adjusted for days and health districs showed a significant 5.84% increase (95% CI: 2.75, 8.92) of vaccination coverage in Pilot 1 and VC increase of 4.48% (95% CI: 3.17,5.78) in Pilot2.
Conclusions/Learning Points: Boosting flu vaccine uptake in children leveraging on past lessons learnt during COVID-19 vaccine campaigns may be useful for other countries as part of their measures promoting influenza vaccination in children.

AGE-DEPENDANT INCREASE IN IPD INCIDENCE IN 2022 CORRELATES WITH RESPIRATORY VIRUSES DYNAMICS.

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Alexis Rybak[1,2,3], Corinne Levy[1], Zein Assad[4], Emmanuelle Varon[5], François Angoulvant[6], Robert Cohen[1,7], Naim Ouldali[1,4]
[1]ACTIV, Infectious Disease, Créteil, France, [2]ECEVE, Umr S-1123, Paris, France, [3]Trousseau Hospital - APHP, Pediatric Emergency Department, Paris, France, [4]Robert Debre University Hospital, General Pediatrics And Infectious Diseases, PARIS, France, [5]Centre Hospitalier intercommunal de Créteil (CHIC), National Reference Center For Pneumococci, Créteil, France, [6]CHUV, Pediatrics, Lausanne, Switzerland, [7]CHI Créteil, Unité Court Séjour Petits Nourrissons, Créteil, France

Backgrounds: Non pharmaceutical interventions (NPIs) implemented against the spread of COVID-19 have led to an unprecedented decrease of both viral and invasive pneumococcal diseases (IPD). An IPD rebound in some age groups has been reported after NPI partial relaxation. Viral infections, mainly respiratory syncytial virus (RSV), influenza, and human metapneumovirus (hMPV), are potential triggers of IPD.
Methods: We analyzed the incidences of IPD and hospitalizations for RSV, influenza, hMPV, and adenovirus in France between 2015 and May 2022 using the National medico-administrative database. Quasi-Poisson regression was used to estimate standardized incidence ratios (SIRs) by dividing the observed incidence by the “expected” incidence if NPIs would not have been implemented. SIRs were calculated for the early COVID-19 period (from March 2020 to March 2021), and the late COVID-19 period (from April 2021 to May 2022), for the following age groups (<2 years, 2-4 years, 5-14 years, 15-44 years, 45-64 years, and ≥65 years). Correlation between IPD SIRs, and of viral infections was assessed with the Spearman correlation method.
Results: We analyzed 25,890 IPD, and 402,523 hospitalizations for the viruses of interest. Compared to the early COVID-19 period, a significant difference was only observed for children aged 5-14 years during the late COVID-19 period (SIRs from 25.3%, 95%CI 19.3-37.0 to 53.2%, 95%CI 38.7-85.1). Observed IPD incidence remained lower than expected for all age groups and during both COVID-19 periods. We observed a significant correlation between IPD SIRs and those for influenza (Spearman correlation coefficient r=0.65, p=0.03), RSV (r=0.82, p=0.002), and hMPV (r=0.78, p=0.004) by contrast to adenovirus (r=0.36, p=0.26).
Conclusions/Learning Points: Differences in viral infection may partially explain the different age-specific patterns of IPD, reinforcing the link between IPD and viral infections.

Backgrounds: S. aureus, especially MRSA, can cause severe osteoarticular infections (OAI). The aim of this study was to compare the clinical presentation and outcome between OAI caused by clindamycin-resistant (CRSA) and clindamycin-susceptible (CSSA) S. aureus and to evaluate the prevalence of antibiotic resistance of S. aureus within the study period.
Methods: Children with S. aureus OAI prospectively enrolled in the RioPed National-network (2015-2022) were retrospectively evaluated. Epidemiological, clinical, microbiological and outcome data collected in a RedCap platform were used. We analysed possible factors linked to clindamycin resistance and susceptibility. The study was divided in two periods (P1:2015-2018 and P2:2019-2022).
Results: S. aureus was identified in 320 (21.4%) of the 1,494 children with OAI enrolled. The susceptibility to clindamycin was available in 128 isolates(MRSA 9.4%) which were evaluated. No differences were observed in prevalence of CRSA between MSSA and MRSA (12.9 vs 8.3% p 0.640). No increase in the resistant rates to methicillin and clindamycin was observed during the study period: MRSA: 12% P1 vs 7.8% P2 and CRSA 12% P1 vs 13% P2. All isolates evaluated were susceptible to vancomycin, rifampin, TMP-SMX and linezolid. Levofloxacin resistance was 1.8%. The rate of penicillin-resistant S.aureus (PRSA) decreased from P1 to P2 (95.8 vs 82.5%; p=0.036). MRSA OAI required more surgery (83.3 vs 48.7%;OR 95% CI:5.27[1.10-25.11]), more PICU admissions (28.6 vs 3.7%;OR 95% CI:10.40[1.40-77.21]) and had non-significant higher rate of complications (66.7 vs 38.3%;OR 95% CI:3.23[0.92-11.35]). No differences were observed according to clindamycin susceptibility.
Conclusions/Learning Points: In our study, the prevalence of MRSA and CRSA OAI in children remained stable in recent years, whereas PRSA significantly decreased. Resistance to clindamycin was not associated to MRSA. Unlike MRSA OAI, those produced by CRSA were not associated to worse clinical outcome.

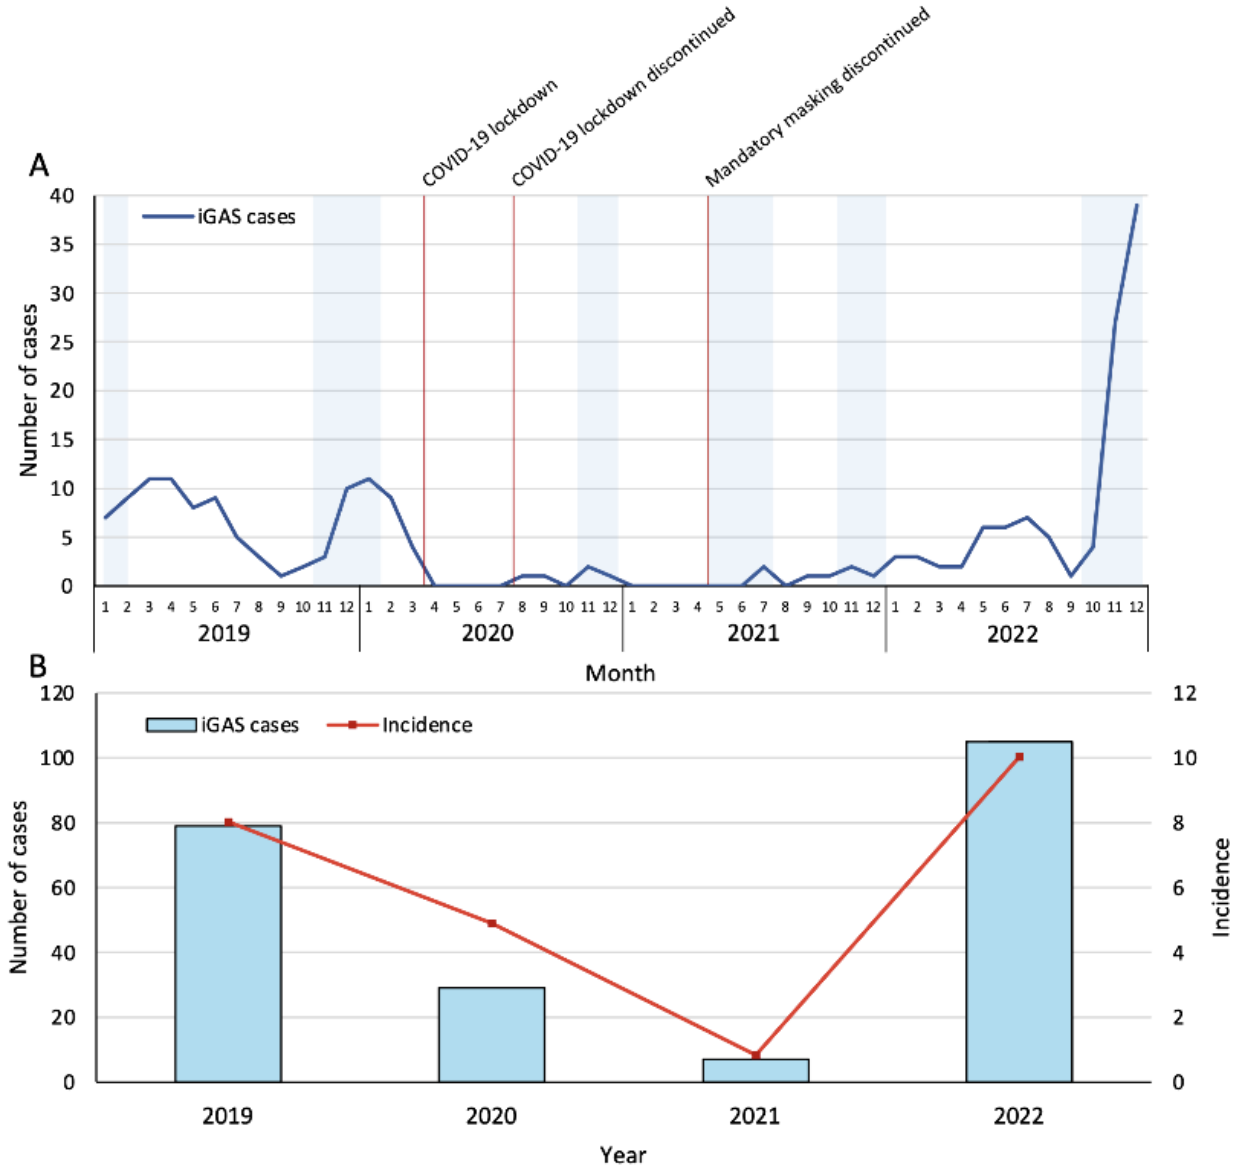
Backgrounds: In December 2022, the United Kingdom and other countries alerted of a significant increase in severe invasive group A streptococcal infection (iGASi) in children. An increase in mortality was also observed. This study aimed to describe iGASi cases in Spain over four years, analyzing

changes in incidence or severity.
Methods: PedGAS-net is a multicenter ambispective cohort study conducted in 29 Spanish hospitals to evaluate patients ≤16 years diagnosed with microbiologically confirmed iGASi. The epidemiology, clinical syndromes, and outcomes of these children between January 1, 2019-December 31, 2022, were analyzed.
Results: Two hundred and twenty children with iGASi were evaluated;125 (56.8%) male. Median age was 41.2 months (IQR:19.3–81.0). Eighty-nine (40.5%) children required PICU. Most common clinical syndromes were pneumonia (n=66, 29.6%;42/66 with pleural effusion), skin and soft tissue infection (n=50, 22.7%), osteoarticular infection (n=27, 12.3%) and primary bloodstream infection (n=23, 10.5%). Furthermore, twenty-five (11.4%) and ten (4.5%) children developed streptococcal toxic shock syndrome and necrotizing fasciitis, respectively. The average annual incidence rate of iGAS was 5.96 episodes/100,000 children attended at the emergency department/year. Incidence and its distribution are depicted in Figure1. Comparing iGASi in 2019 versus 2022, we found higher incidence in 2022 (8.0/100,000 vs. 10.0/100,000; p=0.134), mainly November-December 2022. Additionally, PICU admission and pneumonia were also more frequent in 2022 (48.6%vs.30.4%, p=0.013, and 36.2%vs.22.8%, p=0.050, respectively). Four patients (1.8%) died, three in December/2022. Figure: 1A:iGAS infections by moths/year. RSV season (blueshading). COVID-19 measures (red lines) in Spain. 1B:Incidence of
iGASi/year.



Conclusions/Learning Points: Compared to the pre-pandemic COVID-19 period, observed a significant increase in severity and number of iGASi in 2022, remarkably clustered in last weeks. We have also seen an increase in pneumonia cases, possibly related to temporal coincidence with RSV and influenza seasons in Spain.

ACUTE GASTROENTERITIS IN ALBANIAN CHILDREN DURING THE YEAR 2021

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Laureta Sadedini[1], Ergena Neziri[1], Geogina Kuli-Lito[2], Numila Kuneshka[1], Bashkim Nezaj[2], Diana Shtembari[2], Floreta Kurumi[1], Elda Skenderi[3], Mirzana Kapllani[4]
[1]University Hospital Center: 'Mother Theresa', Tirana, Albania, Pediatric Emergency, Tirana, Albania, [2]University Hospital Center: 'Mother Theresa', Tirana, Albania, Infectious Diseases, Tirana, Albania, [3]University Hospital Center: 'Mother Theresa', Tirana, Albania, General Pediatric, Tirana, Albania, [4]University Hospital Center: 'Mother Theresa', Tirana, Albania, Pediatric Onco-hematology, Tirana, Albania

Backgrounds: Acute gastroenteritis (AGE) is a common infectious disease in the pediatric age and the major presenting situation in our hospital's Emergency department (ED). 2021 was the second year of the Covid-19 pandemic, and measures to prevent its spread have influenced reducing the AGE cases but not so much because these have not been strictly respected as in the previous year.
Methods: The aim of this study was to show the epidemiological data, risk factors, clinical characteristics, complications, and the tendency of this disease. The study included all children with signs of AGE aged from 1mounth to 14 years old, presented in the Pediatric Emergency room of University Hospital: 'Mother Teresa,' Tirana, Albania, during the period 1 January to 31 December 2021.
Results: During this period 5613 children presented with signs of acute gastroenteritis, among them 351(6.2%) were severe cases that have been admitted to the hospital. The most affected age groups were 13m-4 years and 4-14 years which also, had an equal number of 1926(34%) cases, almost, the same as we noted for severe forms too, of 127(2.2%). The peak of incidence was in august with 1704(30%), meanwhile, the majority of admissions were in July with 75 (1.3%). About the causative agents, we found mostly rotavirus and cases with the SARS-Cov2 virus.
Conclusions/Learning Points: AGE continues to cause a large number of hospital visits. It's been three years since the rotavirus vaccine was introduced in Albanian's main national vaccination scheme. As a developing country, we have few possibilities for performing tests to discover the etiology of all the AGE cases even those of severe forms. We hope to achieve this in the following periods in order to complete our study.

COMPARISON OF CLINICAL COURSE AND OUTCOME OF CONFIRMED DENGUE PATIENTS WITH AND WITHOUT DENGUE VACCINE IN A TERTIARY HOSPITAL IN THE PHILIPPINES

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Christine Marie San Pedro, Maria Bettina Ines Santos, Lorraine Marie Item
Bataan General Hospital and Medical Center, Department Of Pediatrics, Balanga City, Philippines

Backgrounds: Dengue is the leading cause of childhood morbidity and mortality globally more than any other vector-borne viral disease. In 2016, Dengue vaccine was introduced in a school based immunization program in the Philippines however was discontinued after nearly 3 years. Local data regarding Dengue vaccine that would supplement vaccine research and development are limited.
Methods: This is a retrospective, cohort study of clinical course and outcome in confirmed pediatric Dengue patients with and without Dengue vaccine between January of 2018 and December 2019 in a Tertiary Hospital from Bataan, Philippines. Clinical records were analyzed using statistical tools.
Results: A total of 239 subjects were included in the study – 177 non-vaccine recipients and 62 vaccine recipients. The mean age group among the 239 subjects was 12.5 years old with male predominance. Three doses were administered among the vaccinated. Previously infected were only 18.8%. No significant difference was seen among 197 admitted as Dengue with warning signs, while 42 were with Severe Dengue. There is a statistical significance among the non-vaccinated who experienced anorexia and abdominal pain. Joint pains and narrow pulse pressure were more on those vaccinated. Significantly, non-vaccinated patients were NS1 positive and were more leukopenic and thrombocytopenic upon admission. Patients found positive to IgM and IgG were however significant among the vaccinated group. Mortality was at 1.3% on the non-vaccinated patients, while 0% on those vaccinated patients. The non-vaccinated patients stayed longer, which was statistically significant. No significant difference in the management and outcome was
seen.

Summary Statistics the Significant Values of each Variables

	All (n=239)	Without Vaccine (n=177)	With Vaccine (n=62)	P value

INCIDENCE OF PUBLIC HEALTH SURVEILLANCE REPORTED LYME BORRELIOSIS CASES AMONG CHILDREN IN 19 COUNTRIES, 2005-2020

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Madiha Shafquat[1], Frederick Angulo[1], Sarah Pugh[1], Andreas Pilz[2], Jennifer Moïsi[3], James Stark[1]
[1]Scientific and Clinical Affairs, Pfizer Vaccines Medical Development, Collegeville, United States of America, [2]Vaccines, Pfizer Global Medical Affairs, Vienna, Austria, [3]Vaccines, Pfizer Medical Development, Scientific And Clinical Affairs, Paris, France

Backgrounds: Lyme borreliosis (LB), the most common tick-borne illness in Europe and North America, occurs among both adults and children. The global burden of LB in children has not been well described.
Methods: We reviewed national public health agency websites to identify LB surveillance systems that report age-specific data. Census data were used to derive incidence estimates. Incidence in children were estimated for the years of available surveillance data in each country.
Results: We identified age-specific data in 19 (68%) of 28 countries with public health surveillance for LB: 2 countries in Asia (Japan and South Korea), 15 countries in Europe, and 2 countries in North America (USA and Canada). The following age strata were used to report pediatric data: <19 years of age (14 (74%) countries); <14 years (3 (16%) countries), <17 years and <24 years (1 (5%) country each). Across all 19 countries, the 5–9 year age stratum had the highest proportion of LB cases in children. Pediatric LB incidence was low in the two countries in Asia (<1/100,000 children per year [PCY]), high in the USA (5-15/100,000 PCY) and varied widely across countries in Europe (<1-240/100,000 PCY). The highest LB incidence in children worldwide was in Slovenia (150-240/100,000 PCY). In Denmark, Norway, and the USA, pediatric LB cases represented >20% of total reported cases.
Conclusions/Learning Points: Pediatric LB cases represent an important proportion of the LB cases reported in public health surveillance systems worldwide, highlighting the need for prevention efforts targeting pediatric populations.

GENDERNEUTRAL HPV-VACCINATION IN THE VACCINATION PROGRAMME IN FLANDERS 2019-2022 – ESTIMATE OF GENDER DIFFERENCE IN PARTICIPATION AND COVERAGE

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Geert Top, Annick Paeps, Heidi Theeten, Dirk Wildemeersch, Iris De Schutter
Agency for Care and Health, Prevention, Brussels, Belgium

Backgrounds: The HPV-vaccination programme was introduced in Flanders in September 2010 for girls (first year of secondary school). Since September 2019 the programme is gender neutral. A vaccination coverage survey in 2020 for adolescents born in 2007 showed an HPV vaccination coverage for the first dose of 92,3 % in girls and 86,7% in boys and for the 2nd dose 84,3% in girls and 77,3% in boys. All vaccinations with free-of-charge vaccines should be registered in the vaccination registry (Vaccinnet).
Methods: We analysed HPV-vaccination data for adolescents born from 2006 to 2010, registered in Vaccinnet during the school years 2019-2020, 2020-2021 and 2021-2022 in order to evaluate to what extent the difference in coverage between girls and boys persisted after the starting schoolyear 2019-2020. We also aimed to evaluate whether the 2nd dose coverage has increased.
Results: The number of registered vaccinations from September 2019 to August 2022 was similar for girls and boys born in 2007, 2008 and 2009. From all adolescents who received a first HPV-vaccination during this period about 95% completed their vaccination with a 2nd dose.
Conclusions/Learning Points: Data analysis of registered HPV-vaccinations showed that the vaccination uptake in the vaccination programme is similar for boys as for girls born in 2007, 2008 and 2009. Over 95% of participants at the programme completed the vaccination with a second dose. This suggests that the difference in coverage for the first year of the programme was mainly because of boys who hadn't been offered the vaccination yet at the time of the coverage study.

INTUSSUSCEPTION: AN ASSESSMENT OF THE IMPACTS OF THE COVID-19 LOCKDOWNS AND LINKS TO VIRAL AETIOLOGY

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Benjamin Townley[1,2], Deniz Akin[1], Gerardo Dimaguila[3], Rana Sawires[1], Gonzalo Sepulveda Kattan[1], Julie Bines[4], Sebastian King[4], Tim Harrold[5], Nicholas Wood[6], Stephen Lambert[6], Jim Buttery[3]
[1]Murdoch Children's Research Institute, Paediatric Infectious Diseases Research Group, Parkville, Australia, [2]Monash University, School Of Medicine, Clayton, Australia, [3]Murdoch Children's Research Institute, Health Informatics, Melbourne, Australia, [4]Murdoch Children's Research Institiue, Paediatrics, Parkville, Australia, [5]NSW Ministry of Health, Centre For Epidemiology And Evidence, St Leonards, Australia, [6]Sydney Children's Hospital Network, National Centre For Immunisation Research And Surveillance, Sydney, Australia

Backgrounds: Intussusception is the primary cause of acute bowel obstruction in infants. The majority of cases are classed as idiopathic and of these cases viral infection has been implicated as a cause. In recent years, the implementation of COVID-19 public health measures led to significant decreases in the prevalence of communicable diseases. During these times, reductions in intussusception frequency were anecdotally reported - reductions greater than would be expected with our current understanding of its infectious aetiology.
Methods: We conducted a retrospective, multi-state, ecological study that covered a twelve year period. Monthly case numbers of ICD-10-AM K56.1 'Intussusception' coded admissions were acquired from state-wide admissions datasets from New South Wales (NSW), Victoria and Queensland, representing 77.62% of the eligible Australian population. These counts were compared against publicly available information regarding the differing jurisdictional lockdowns in order to investigate a correlation between intussusception frequency and lockdown periods.
Results: We found a negative association between intussusception frequency and lockdown periods in both eligible states. The largest reductions were seen in the under 2 year age groups with Victoria experiencing a 62.7% reduction (Rate ratio (RR) = 0.37, $p < 0.0001$) and NSW a 40.1% reduction (RR = 0.599, $p = 0.006$) during lockdown times. Geographical variations in lockdown restrictions were controlled for in both states and in Victoria both Metropolitan Melbourne and Regional Victoria experienced decreases of 51%.
Conclusions/Learning Points: Our ecological study demonstrates significant decreases in the frequency of paediatric intussusception admissions during the COVID-19 lockdown periods. We hypothesise that this decrease is due to a reduction in circulating viruses during these times. The unexpected magnitude of the reductions suggests that the true proportion of infectious disease-caused idiopathic intussusception may be greatly underestimated.

TRENDS OF CARBAPENEM RESISTANCE IN PEDIATRIC CARDIAC ICU: A 7-YEAR EXPERIENCE IN AN ITALIAN HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Costanza Tripiciano[1], Stefania Mercadante[1], Lorenza Romani[1], Laura Cursi[1], Martina Di Giuseppe[1], Francesca Ippolita Calò Carducci[1], Tiziana Fragasso[2], Cristiana Garisto[2], Roberta Haiberger[2], Annamaria Sisto[3], Leonardo Vallesi[4], Valentino Costabile[3], Laura Lancella[1], Paola Bernaschi[3], Maia De Luca[1]
[1]Bambino Gesù Children's Hospital, Infectious Disease Unit, Roma, Italy, [2]Bambino Gesù Children's Hospital IRCCS,, Cardiology And Cardiac Surgery, Pediatric Cardiac Intensive Care Unit, Rome, Italy, [3]Bambino Gesù Children's Hospital IRCCS,, Unit Of Microbiology And Diagnostic Immunology, Rome, Italy, [4]Bambino Gesù Children's Hospital IRCCS,, Hospital Pharmacy Unit, Rome, Italy

Backgrounds: The impact of Gram- resistance is considerably greater in intensive care unit (ICU), where prevalence is high and clinical outcomes are especially poor. In Italy, the national surveillance performed from 2014 to 2017 on sepsis reported 7,632 carbapenem-resistant organism (CRO) infections, almost all due to K.pneumoniae carbapenemase (KPC) enzyme (95.2%). Here we describe a cohort of pediatric patients with CRO infections admitted in a cardiac ICU, highlighting the important changes in carbapenemase production occurred in the last years in our hospital.
Methods: All patients admitted to the cardiac-ICU of the Bambino Gesù Children's Hospital in Rome during the 2016-2022 period with an infection caused by a CRO were enrolled in the study.
Results: Data were collected from 42 patients. The reason of CICU admission was cardiac surgery in 50% of cases and heart failure in 38%. 40% of patients needed ventricular assistance or ECMO. 52% of patients were already colonized by a CRO. Pseudomonas was the main isolated CRO, followed by Klebsiella and Enterobacter. Carbapenemase production was present in 31% of cases, with VIMs being highly predominant. The main type of CRO infection was pneumonia (64%), followed by sepsis (34%) and urinary tract infections (7%). Attribuable mortality to CROs was 5%; 30-day relapse rate by the same isolate was 5%. During the 7-year period, we observed important changes in carbapenemase production by CROs; since 2018, VIMs progressively increased becoming the most identified carbapenemases in 2021.
Conclusions/Learning Points: The progressive increase of MBL-producing pathogens in our hospital is challenging in terms of therapeutic options. Updated national and international estimates on trends and molecular characteristics of carbapenemase production by CROs are needed to guide studies on new antibiotic agents that could target these MDR bacteria.

PROSPECTIVE STUDY OF ANNUALLY RECORDED INFLUENZA CASES IN A PEDIATRIC POPULATION: THE PANDEMIC EFFECT

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Effrosssine Tsekoura, Aikaterini Marathoniti, Aggeliki Lyndiakou, Chrysa Athousaki
Asklepieion General Hospital, Pediatric Department, Athens, Greece

Backgrounds: Following discontinuation of COVID-19 quarantine isolation measures an increase of various viral and becterial infections has been observed amongst pediatric populations. The aim of our study was to investigate the distribution of hospitlized type A and B influenza pediatric cases during 2022 compared to before Covid-19 pandemic.
Methods: Data from hospitalized cases were consecutively collected in a district Pediatric Department for the period 1st January 2022 up to 31st December 2022 and were compared with similar data from 2019, before Covid-19 pandemic. Cases were analyzed in relation to their sociodemographic characteristics, influenza and coronavirus vaccination status, clinical and laboratory findings and complications.
Results: Prevalence of pediatric hospitalized influenza cases was quadrupled in the year 2022 (29/262, 11%) compared to 2019 (before the Covid-19 pandemic) (9/288, 3%). In 2022 a second influenza wave has been observed started in September. Peak month of the year came earlier in December 2022 (51.7%) compared to February 2019 (66%). Influenza type A was 93% of the cases with mean duration of hospitalization 3,3 days. Boys were 55%, mean age was 6 years, and of Greek nationality were 79%. Amongst cases influenza vaccination rate was 11% and of those eligible for Covid-19 vaccination 85% were unvaccinated. Complications had 41% of cases; 8% bacteremia, 25% pneumonia, 25% otitis media, 16.6% myositis and 8% eyelid oedema.
Conclusions/Learning Points: Prevalence of influenza pediatric hospitalized cases has been increased in the years following Covid-19 pandemic compared to before with low timely vaccination rate observed. Our data corresponds with data from the National Public Health Organization. They can be used to make necessary accommodations in the national pediatric vaccination schedule regarding influenza, in order to prevent future outbursts.

REGIONAL ASSESSMENT OF TETANUS AND DIPHTHERIA PREVALENCE IN ADULT POPULATION.

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Ioanna Tsiaousi[1], Eleftherios Thireos[2], Anargyros Mariolis[3], Alexandros Vlachos[4], Dimitrios Papagiannis[5]
[1]Private Primary Health Sector, Primary Health Gyn Center, ATHENS, Greece, [2]National Health System of Greece, Primary Health Center Of Vari, ATHENS, Greece, [3]National Health System of Greece, Primary Health Center Of Areopolis, AEROPOLIS, Greece, [4]MEDICAL SCHOOL OF SHEFFIELD, Medical School, Sheffield, United Kingdom, [5]Public Health & adults immunization Laboratory, Faculty Of Nursing, School Of Health Sciences, LARISSA, Greece

Background: Immunizations against influenza and other antigens such a Streptococcus pneumoniae herpes zoster, covid-19 are recommended for elderly people furthermore regular booster vaccinations against tetanus, diphtheria and in some cases, pertussis are recommended in many European countries for adults, including elderly people. Vaccination recommendations for adults differ between individual countries and vaccination coverage data is sparse. Tetanus-specific antibody concentrations are generally higher than diphtheria-specific antibodies, and a substantial proportion of adults, and particularly of elderly people, do not have protective antibody concentrations against diphtheria.
Methods: We aimed to record the Tetanus and Diphtheria prevalence in prefecture of Attica in Greece by measuring serum IgG specific antibody levels to Tetanus and Diphtheria. A stratified sampling plan based on region of Attica was applied in order to produce a representative sample, taking into consideration age group (30 to 80+) and sex. During September 2022 to March 2023 In total 466 subjects participated in the study. Exclusion criteria were age under 30 years old, residence, and symptoms for illness. We excluded participants under 30 years old from the study because the vaccination coverage in the infants and young teenagers in Greece is in a high proportion
Results: The proportion of antibody prevalence for diphtheria of sera with diphtheria antibody levels varied between 0.01 το 0.69 IU/mL. The majority of the participants 64% has been protective antibody levels. The proportion antibody prevalence for tetanus of sera with tetanus antibody levels varied between 0.01 to 0.72 IU/mL. We record proportion of protective levels for tetanus 81%.
Conclusions/Learning Points: A considerable proportion of adults in the prefecture of Attica do not have antibody levels that are protective against diphtheria and tetanus.

COHORT EVENT MONITORING ON ADVERSE EVENTS FOLLOWING IMMUNIZATION DURING THE FIRST FOUR YEARS OF CHILDHOOD VACCINATIONS IN THE DUTCH NATIONAL IMMUNIZATION PROGRAMME

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Jasper Schmitz, Marga Eikelboom, Damla Bulut, Agnes Kant, Leàn Rolfes, Leontine Van Balveren
The Netherlands Pharmacovigilance Centre Lareb, Vaccins, 's-Hertogenbosch, Netherlands

Backgrounds: Although a lot is known about the adverse event following immunization (AEFIs) profile of childhood vaccinations, there is a gap in knowledge concerning the (risk factors of) recurrence, time course and burden of AEFIs after multi-dose vaccines. To gain more insight into these aspects, the Netherlands Pharmacovigilance Centre Lareb set up a cohort event monitoring (CEM) study for vaccines being administered according to the Dutch National Immunisation Program (DNIP) within the first four years of a child's life.
Methods: The inclusion period for this prospective cohort study ran for a year and will follow children vaccinated in the DNIP from birth until the age of four. During this period, there are 4 to 5 vaccination moments. Parents of children were invited to participate during regular DNIP vaccination invitation letters. After registration, parents will receive two online questionnaires per vaccination moment to gain insight into experienced AEFIs by their children. In addition to this, two medical background baseline questionnaires will be sent. There will be two interim analysis and one final analysis. Due to the long-running period in which data is collected, we are able to perform both cross-sectional (i.e. per vaccination moment) and longitudinal (i.e. transcending multiple vaccination moments) analysis. Allowing for the calculation of recurrence risks of certain adverse events over a child's vaccination period.

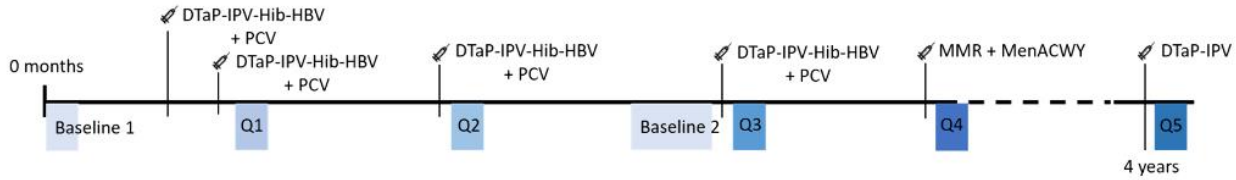

Figure 1: Timeline of the DNIP and questionnaire (Q) scheduling. Each questionnaire is sent 7 days after the expected vaccination date.

Results: Currently, 6300 participants have been included that together have reported a total of 7992 AEFIs.
Conclusions/Learning Points: This unique study hopes to provide insight into (risk factors of) recurrence of AEFI, course of experienced AEFIs and its burden on the child's daily life. In addition, collected data will also be used as a baseline dataset to which later modifications of the DNIP can be compared to.

PV0153 / #2737

A NATIONWIDE DATABASE ANALYSIS OF THE BURDEN OF HOSPITALIZED PEDIATRIC PERTUSSIS IN FRANCE, 2008-2020

Background: Introduction
In the absence of mandatory notification, estimating the burden of pertussis in France has mostly relied on sentinel surveillance. In 2013, the pertussis vaccination schedule shifted the infant series from a 3+1 to a 2+1 series with the inclusion of a booster at 6 years while keeping the 11-13 years booster.
Objective
To estimate the cumulative incidence of hospitalized pertussis in <18 years-old from 2008 to 2020 in France, overall and stratified by age group, and vaccination schedule.
Methods: This retrospective cohort study among <18 years-olds over 2008-2020 used the French healthcare claims database (SNDS). Cases were identified by ICD-10 codes A37. Cumulative incidences were estimated against age- and sex-representative SNDS sample and census data. Negative binomial regression was used to generate cumulative incidence ratios (CIR) adjusted for the cyclical pattern of pertussis.
Results: In total, 7,212 hospitalized pertussis cases <18 years-old were identified, with outbreaks in 2009, 2012/13 and 2017/18. CIR in 2008-2012 vs. 2013-2020 periods were not statistically significant except in the 12-17 years group.
Conclusions/Learning Points: Like other countries, cyclical endemicity of pertussis was observed in France, with the highest burden in infants <6 months. The change in vaccination schedule did not affect the incidence of hospitalized pertussis in most age groups.

Age-group	Cases (n)	Cumulative Incidence 2008-2012*	Cumulative Incidence 2013-2020*	Adjusted CIR 2008-2012 vs. 2013-2020 schedule [95% CI]*¥
0-1 months	1,962	125.8	109.5	0.86 [0.66;1.12]

NEED FOR VARICELLA VACCINATION IN INDIA

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Sanjay Verma[1], Mirza Baig[1], Amit Rawat[1], Vikas Suri[2], Vanita Suri[3]
[1]PGIMER, Pediatrics, Chandigarh, India, [2]PGIMER, Internal Medicine, Chandigarh, India, [3]PGIMER, Obstetrics And Gynecology, Chandigarh, India

Backgrounds: Varicella vaccination is not yet a part of the national immunization program in India. In absence of this, varicella outbreaks keep on occurring in various parts of the country. In view of the nonavailability of recent seroprevalence data from India, this study was planned.
Methods: This study aimed to find out the proportion of protected individuals against varicella by measuring the specific IgG antibody titer among children (9-12 years), adolescents (15-18 years), and adults (25-30 years). In this cross-sectional, observational study, apparently healthy subjets from Outpatient departments (OPDs) of a tertiary care hospital in Northern India, over one year period (July 17-June 18), were enrolled after taking informed written consent; and their blood sample was collected. Institute ethics committee clearance was obtained before enrollment. IMMUNOLAB GmbH, Kassel (Germany) Varicella Zoster IgG ELISA kit was used.
Results: A total of 80 healthy subjects (M:F=47:33) were enrolled from three age groups having mean ages of 10.7, 17.0, and 26.9 years. Subjects with a history of varicella vaccination in past were excluded from enrollment. In our study, antibodies (IgG) against varicella were >12 U/ml (seroprotective) in 40% (10/25), 96% (24/25), 76.7% (23/30) in age groups 9-12 years, 15-18 years and 25-30 years respectively. A total of 46.3%(37/80) of subjects were sure about the history of having varicella in past, and 86.5%(32/37) of them had protective antibodies having a positive predictive value of 86.5%.
Conclusions/Learning Points: A large proportion (about 1/4th) of young adults remains susceptible to varicella infection in India, which could have a potential to cause outbreaks. For countries having higher proportion of susceptible population after age of 18 years, most cost-effective strategy could be selective immunization of adolescents, who didn't have history of varicella in past.

SEROEPIDEMIOLOGY OF DENGUE IN INDIA

E-Posters Viewing
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Sanjay Verma[1], Rajesh Kapoor[1], Amit Rawat[1], Vikas Suri[2], Vanita Suri[3]
[1]PGIMER, Pediatrics, Chandigarh, India, [2]PGIMER, Internal Medicine, Chandigarh, India, [3]PGIMER, Obstetrics And Gynecology, Chandigarh, India

Backgrounds: Vaccination against dengue remains an important prevention strategy today. Dengvaxia, the first dengue vaccine that has been approved for use in 9-45 years, was found safe only in seropositive (dengue IgG+ve) individuals. WHO recommends its use only in seropositive individuals after the prevaccination screening. In public health, it can be used without a prevaccination strategy, only for populations having very high seroprevalence (>80%). In view of the nonavailability of such regional seroprevalence data, this study was planned.
Methods: This study aimed to find out the proportion of seropositive individuals against dengue infection by measuring the specific (IgG) antibody titer among children (9-12 years), adolescents (15-18 years), and adults (25-30 years). In this cross-sectional, observational study, apparently healthy subjects from OPDs of a tertiary care hospital in Northern India, over a one-year period (Jan19-Dec19), were enrolled after taking informed consent; and their blood sample was collected. Institute ethics committee clearance was obtained before enrolment. Penbio dengue virus (Standard Diagnostics, Yongin-si, South Korea) IgG indirect ELISA quantitative kits were used. A Panbio units >11 was labelled as seropositive for IgG against Dengue infection, indicating evidence of past dengue infection.
Results: A total of 80 subjects(M:F=39:41) were enrolled from three age groups(25 in 9-12 yrs, 25 in 15-18 yrs, and 30 in 25-30 years). In our study dengue antibodies(IgG) were >11 Penbio Units(seroprotective) in 44%(11/25), 72%(18/25), 73%(22/30) in age groups 9-12 years, 15-18 years and 25-30 years,respectively.
Conclusions/Learning Points: Although the seroprevalence against dengue(IgG) antibodies in our study was on the higher side, in studied age groups; but this was below WHO predefined cut-off of >80%. Based on the above study, if Dengvaxia has to be used in India, it should only be done only after individual prevaccination screening.

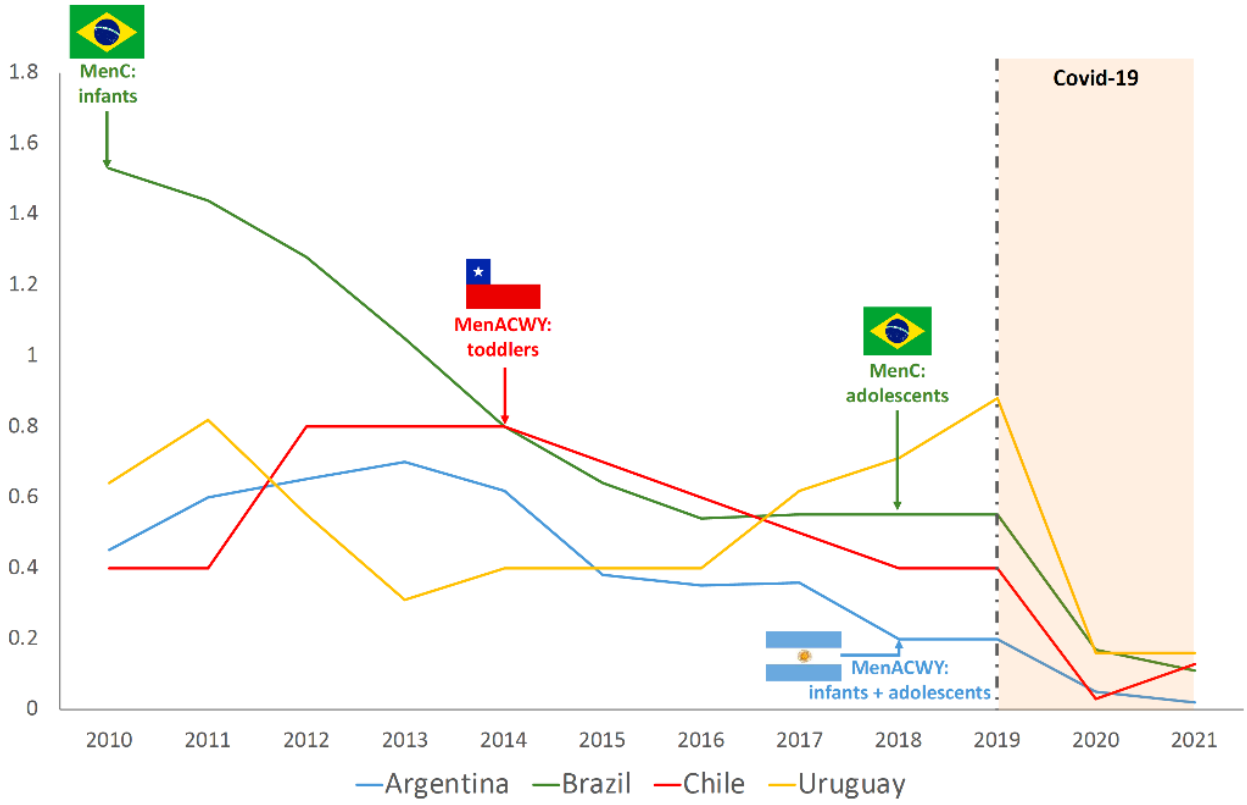
E-POSTER VIEWING: AS02.A. POPULATION STUDIES AND SURVEILLANCE

Rodolfo Villena[1], Marco Aurelio Safadi[2], Angela Gentile[3], Monica Pujadas[4], Veronica De La Maza[1], Sergio George[1], Juan Pablo Torres[1]
[1]Universidad de Chile, Infectious Diseases, Santiago, Chile, [2]Hospital Santa Casa de Misericordia, Infectious Diseases, Sao Paulo, Brazil, [3]Ricardo Gutiérrez Children´s Hospital, Epidemiology, Buenos Aires, Argentina, [4]Hospital Pereira Rossell, Infectious Diseases, Montevideo, Uruguay

Backgrounds: Surveillance of meningococcal disease (MD) is crucial after the implementation of vaccination strategies to monitor its impact on disease burden. Argentina, Brazil and Chile have introduced meningococcal conjugate vaccines (MCV) into their National Immunization Programs (NIP), while Uruguay has not. The aim of this study is to describe epidemiological trends in these countries
Methods: Descriptive study of MD incidence rates, serogroup distribution, case fatality rates (CFR) and MCV uptakes, during the period 2010-2021 in Argentina, Brazil, Chile and Uruguay. Data were extracted from national surveillance programs, references laboratories and NIPs.
Results: A decreasing incidence trend was observed in Argentina, Brazil and Chile from 2010 to 2019, while a significant increase was seen in Uruguay from 2017 to 2019. During Covid-19 pandemic a sharp decrease in incidence rates was demonstrated in all countries. The following median incidence rates were found during the study period: Argentina: 0.37 (IQR= 0.2-0.61), Brazil: 0.59 (IQR= 0.54-1.22), Chile: 0.45 (IQR= 0.4-0.77), and Uruguay: 0.44 (IQR 0.18-0.78). Infants had the highest incidence rates, followed by children 1-4 years, without a peak in adolescents. A reduction of serogroups C, W and Y cases occurred in Argentina, Brazil and Chile, after introduction of MCV, while the proportion of cases due to serogroup B increased in all-four countries. Overall median CFR was 21%. Median uptake of MCV for Argentina and Brazil were respectively, 71.5% and 94.5% for infants, 62.5% and 85% for toddlers and 47.5% and 61% for adolescents; while for Chile was 96% for
toddlers.

Figure. Incidence of meningococcal disease, Argentina, Brazil, Chile and Uruguay, 2010-2021



Conclusions/Learning Points: Experience after the implementation of MCV programs in South America was successful, reducing the burden of MD due to the vaccine serogroups. High vaccine coverage will be crucial in the post-pandemic period to maintain population protected.

COST-EFFECTIVENESS ANALYSIS OF CELL-BASED VERSUS EGG-BASED SEASONAL INFLUENZA VACCINATION IN PEDIATRIC POPULATION IN TAIWAN

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

Chia-Yu Chi[1], Ming-Fang Cheng[2], Karam Ko[3], Joaquin Mould[4], Chih-Jung Chen[5], Yhu-Chering Huang[5], Ping-Ing Lee[6]
[1]National Health Research Institutes, National Institute Of Infectious Diseases And Vaccinology, Miaoli, Taiwan, [2]Kaohsiung Veterans General Hospital, Department Of Paediatrics, Kaohsiung, Taiwan, [3]Seqirus Korea, Medical Affairs, Seoul, Korea, Republic of, [4]Seqirus USA Inc, Medical Affairs, Summit, United States of America, [5]Chang Gung Memorial Hospital, Division Of Pediatric Infectious Diseases, Departments Of Pediatrics, Taoyuan, Taiwan, [6]National Taiwan University Hospital and National Taiwan University College of Medicine, Department Of Pediatrics, Taipei City, Taiwan

Backgrounds: Virus mutations can be introduced during egg-based influenza vaccine production, potentially reducing vaccine effectiveness (VE). Cell-based influenza vaccines avoid egg-adaptive mutations, potentially improving VE. We assessed the cost-effectiveness of cell-based quadrivalent influenza vaccine (QIVc) versus egg-derived quadrivalent influenza vaccine (QIVe) in children (6mons-17yrs) from the payer's and societal perspective in Taiwan.
Methods: We developed an age-stratified static model comparing estimated costs and health benefits of vaccination using a one-year time horizon. Taiwanese influenza disease burden data, vaccination coverage rates and healthcare resource use, utility and unit costs inputs were sourced from reports from Taiwan. The relative VE (rVE) of QIVc vs QIVe was assumed to be 8.1% for this pediatric population based on a published meta-analysis. A high egg-adaptation scenario was also assessed. Costs were expressed in 2022 U.S. dollars and cost-effectiveness threshold was three times Taiwan's Gross Domestic Product per capita (US$99,177). Deterministic and probabilistic sensitivity analyses were performed.
Results: Compared to QIVe, QIVc would prevent additional 18,141 influenza cases, 2,598 complications, and 301 hospitalizations per year. The incremental cost-effectiveness ratio (ICER) per QALY from the payer's and the societal perspective, respectively, was US$65,176.40 and US$36,292.01 in the base case and US$43,223.71 and US$14,339.33 in the high egg-adaptation scenario. Deterministic sensitivity analyses showed that infection incidence rate, vaccine coverage and prevalence of A/H3N2 strain were the main drivers of the ICER. Deterministic sensitivity analyses showed that infection incidence rate, vaccine coverage and prevalence of A/H3N2 strain were the main drivers of the ICER.
Conclusions/Learning Points: Switching vaccination strategy from QIVe to QIVc is predicted to have significant impact in reducing influenza-associated disease burden for the pediatric population in Taiwan. The potential benefits with QIVc would be even higher within high egg-adaptation influenza seasons.

ASSOCIATION BETWEEN AIR POLLUTANTS, SEASONAL INFLUENZA, AND ACUTE OTITIS MEDIA IN CHILDREN: RETROSPECTIVE ANALYSIS USING INPATIENT DATA ACROSS 22 YEARS

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

Conglu Li[1], Xiaoting Jiang[1], Yuchen Wei[1], Yawen Wang[1], Ka Chun Chong[1,2], Qianying Yue[1]
[1]The Chinese University of Hong Kong, School Of Public Health And Primary Care, Hong Kong, Hong Kong PRC, [2]The Chinese University of Hong Kong, Centre For Health Systems And Policy Research, Hong Kong, Hong Kong PRC

Backgrounds: Acute otitis media (AOM) is the most common diagnosis for childhood acute illness, accounting for 13.6 million pediatric office visits annually. It is currently acknowledged as a bacterial complication of viral upper respiratory tract infection (URI). Other potential risk factors of AOM aside from URI, involve exposure to environmental air pollution and cold seasons. In this study, we examined the relationship between meteorological factors, air pollutants, influenza infection, and AOM in children.
Methods: We collected territory-wide hospitalization data from 1998 to 2019 in Hong Kong to investigate the relationship in children aged below 16 years. Quasi-Poisson generalized additive model in conjunction with distributed-lag non-linear model was used to elucidate the association of interest, with weekly AOM admissions for children as the response variable and weekly influenza-like illness-positive (ILI+) rates and air pollutants (i.e., oxidant gases, sulfur dioxide, and fine particulate matter) as predictors, while controlling for meteorological variations.
Results: There were 21,224 hospital admissions due to AOM for children throughout a 22-year period. The cumulative adjusted relative risks (ARR) of AOM were 1.15 (95% CI, 1.04-1.28) and 1.07 (95% CI, 0.97-1.18) at the 95th percentile concentration of oxidant gases (65.9 ppm) and fine particulate matter (62.2 μg/m³) respectively, with reference set to their medians of concentration. The ARRs exhibited a monotone increasing trend for all-type and type-specific ILI+ rates, indicating ILI+ Total, A/H1N1, A/H3N2, and B were all statistically significantly associated with an increased risk of AOM.
Conclusions/Learning Points: Our findings suggested that policy on air pollution control and influenza vaccination for children need to be implemented, which might have significant implications for averting AOM in children.

COST-EFFECTIVENESS OF THE 20-VALENT PNEUMOCOCCAL VACCINE COMPARED TO THE 15-VALENT PNEUMOCOCCAL VACCINE IN SWEDISH CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

Ann-Charlotte Dorange[1], Andreas Palmborg[2], Michele Wilson[3], Sophie Warren[4], Johnna Perdrizet[4]
[1]Pfizer AB, Health Economics And Outcomes Research, Sollentuna, Sweden, [2]Pfizer AB, Vaccines, Medical Development, Scientific And Clinical Affairs, Sollentuna, Sweden, [3]RTI Health Solutions, Health Economics, Research Triangle Park, United States of America, [4]Pfizer Inc, Global Value & Evidence, New York, United States of America

Backgrounds: Since September 2019, only the 10-valent pneumococcal conjugate vaccine (PCV10) has been used across all counties in the Swedish pediatric national immunization program (NIP). The 15-valent vaccine (PCV15) is to be used in the pediatric NIP from September 2023, but much of the current disease burden is attributed to serotypes contained in higher-valent vaccines (PCV20). The objective of this study is to determine the cost-effectiveness of switching from PCV15 to PCV20 in Sweden's paediatric NIP.
Methods: A decision-analytic model was used to compare the cost-effectiveness of switching from PCV15 to PCV20 in 2024 over a 10-year time horizon from a payer perspective. The model uses historical age and serotype-specific invasive pneumococcal disease (IPD) epidemiological data from Sweden between 2011 and 2018 to project future incidence across all ages. Projections of non-invasive disease incidence rates are assumed to vary proportionally with IPD. Vaccine and direct medical costs were publicly available and obtained from Apotek Hjärtat and the Västra Götalandsregionen (VGR) price list, respectively. Costs and outcomes are both discounted at a rate of 3%.
Results: PCV20 is estimated to avert an additional 111 IPD cases, 4,933 otitis media cases, 1,377 pneumonia cases, and 32 deaths over 10 years across all ages. Despite higher vaccine acquisition costs, PCV20 is cost-saving compared to PCV15 and would reduce healthcare spending by over 270 million SEK (Table

Table 1. Results on cost-effectiveness of PCV20 vs PCV15 in Sweden's paediatric NIP			
Outcomes	**PCV15**	**PCV20**	**Incremental**
Disease cases			
Bacteremia	3,275	3,164	-111

ICER			**PCV20 dominant (cost-saving)**
Abbreviations: IPD = invasive pneumococcal disease; OM = otitis media; NIP = national immunization program; PCV = pneumococcal conjugate vaccines; QALY = quality-adjusted life year.			
Notes: The cost-effectiveness analysis was run over 10-year time horizon from a payer perspective.			

1).

Conclusions/Learning Points: In Sweden, replacing PCV15 with PCV20 on the pediatric NIP is not only estimated to provide greater public health impact, but also save substantial future healthcare costs and individual suffering. The inclusion of PCV20 in Sweden's adult NIP as of 1 December 2022 may also further reduce remaining pneumococcal disease burden in older populations.

PUBLIC HEALTH IMPACT AND COST-EFFECTIVENESS OF POTENTIAL ADOLESCENT MENACWY VACCINATION STRATEGIES IN GERMANY

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

Sabrina Janßen[1], Katharina Schley[1], Shannon Sullivan[2], Eszter Tichy[3], Jamie Findlow[4]
[1]Pfizer Pharma GmbH, Vaccines, Berlin, Germany, [2]EVIDERA/PPD, Evidence Synthesis, Modeling & Communication, Ivry-sur-Sein, France, [3]EVIDERA/PPD, Evidence, Value & Access, Budapest, Hungary, [4]Pfizer Limited, Clinresclinnmd, Meningococcal Vaccines, Surrey, United Kingdom

Backgrounds: In Germany, invasive meningococcal disease (IMD) caused by serogroups C, W and Y is accountable for almost half of all reported cases. IMD incidence peaks in the infant/toddler and adolescent/young adult populations. Nevertheless, the German Standing Committee on Vaccination (STIKO) so far only recommends meningococcal C conjugate vaccination at 12 months of age as well as a catch-up for unvaccinated individuals up to 17 years. Currently there is no routine MenACWY vaccination recommended. The aim of this study was to analyze the impact of implementing various hypothetical infant and/or adolescent vaccination strategies on the protection against IMD caused by serogroup A, C, W and Y in Germany. Our results can serve as evidence to consider a recommendation switch from monovalent to a quadrivalent vaccine, as implemented in other European countries such as the UK and Netherlands.
Methods: Analysis was performed using a static population-cohort model, that evaluates the burden of IMD and associated costs and outcomes. We compared the cost-effectiveness of various meningococcal vaccination strategies. The model considers the effects of both acute IMD and its long-term complications as well as direct and indirect costs of IMD.
Results: Our modelling demonstrated that all strategies including MenACWY vaccine are extremely effective in decreasing the number of cases and preventing death and offer good value for money, with the greatest benefit observed when individuals are vaccinated with MenACWY at both 12 months and 16 years of age.
Conclusions/Learning Points: These results indicate the advantage of implementing a broader meningococcal vaccine recommendation in Germany that can provide toddler and adolescents with direct protection against IMD caused by serogroup A, C, W and Y as well as protecting other population groups via an adolescent herd effect.

PUBLIC HEALTH IMPACT OF THE 20-VALENT PNEUMOCOCCAL CONJUGATE VACCINE COMPARED WITH THE 15-VALENT PNEUMOCOCCAL VACCINE IN CHILDREN ACROSS THREE SPANISH REGIONS

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

Alejandra López-Ibáñez De Aldecoa[1], Maria Del Amo[2], Xiuyan Li[3], Cheryl Mcdade[4], Michele Wilson[4], Johnna Perdrizet[3]
[1]Pfizer SLU, Health Economics And Outcome Research, Madrid, Spain, [2]Pfizer SLU, Medical Department, Madrid, Spain, [3]Pfizer Inc, Global Value & Evidence, New York, United States of America, [4]RTI Health Solutions, Health Economics, Research Triangle Park, United States of America

Backgrounds: In Spain, the 13-valent pneumococcal conjugate vaccine (PCV13) is part of regional infant national immunization programs (NIPs). Higher-valent PCVs, 15-valent (PCV15) and 20-valent (PCV20), might be implemented in the future as they cover a larger portion of the remaining pneumococcal disease burden. Therefore, we aim to estimate the public health impact of switching from PCV13 to PCV15 or PCV20 in the three most populated regions of Spain: Madrid, Andalusia, and Catalonia.
Methods: A decision-analytic model was adapted to estimate the future public health impact of switching from PCV13 to PCV15 in 2023, or PCV20 in 2024, considering the potential availability of the pediatric indication. The model used historical age- and serotype-specific epidemiological data of invasive pneumococcal disease (IPD) and non-invasive pneumococcal diseases from three Spanish regions between 2013 and 2019 to estimate future disease burden. The public health impact for each program was compared over 5-years and reported in ages <5 years and 5-14 years.
Results: Compared to PCV15, switching to PCV20 is estimated to avert more pneumococcal disease cases and deaths in Spain regions (Table 1). As in Madrid, PCV20 is estimated to prevent an additional 77 IPD cases, 6,726 otitis media (OM) cases, 595 inpatient and outpatient pneumonia cases. In Andalusia, the incremental impact of PCV20 amounts to 46 IPD cases, 15,322 OM cases, 507 inpatient pneumonia cases. Meanwhile, an additional 93 IPD cases, 6,500 OM cases, 354 inpatient and outpatient pneumonia cases are estimated to be averted by PCV20 in
Catalonia.

Table 1. Results on public health impact associated with higher-valent PCV implementation in Spain's pediatric population across three Spanish regions over five years.

Regions	**Madrid**		**Andalusia**		**Catalonia**	
Population Size	**1,026,826**		**1,336,821**		**1,178,946**	
Ages < 5 years	328,971		394,429		356,465	
Ages 5-14 years	697,855		942,392		822,481	
Vaccination Strategies	**PCV15**	**PCV20**	**PCV15**	**PCV20**	**PCV15**	**PCV20**
Disease Cases						
Bacteraemia	**535**	**468**	**329**	**289**	**650**	**570**
Bacteraemia cases < 5 years	346	316	296	269	499	452
Bacteraemia cases 5-14 years	189	152	33	20	151	118
Meningitis	**88**	**78**	**54**	**48**	**108**	**95**
Meningitis cases < 5 years	57	53	49	45	83	75
Meningitis cases ≥ 5-14 years	31	25	5	3	25	20
Inpatient pneumonia	**3,067**	**2,723**	**3,142**	**2,635**	**1,482**	**1,260**
Inpatient pneumonia cases < 5 years	2,321	2,123	2,594	2,306	848	767
Inpatient pneumonia cases 5-14 years	746	600	548	329	634	493
Outpatient pneumonia	**12,953**	**12,702**	**N/A***	**N/A***	**2,882**	**2,750**
Outpatient pneumonia cases < 5 years	2,951	2,700	-	-	1,382	1,250
Outpatient pneumonia cases 5-14 years	10,002	10,002	-	-	1,500	1,500
Simple Otitis Media	**320,050**	**313,324**	**247,761**	**232,439**	**112,489**	**105,989**
Total	336,693	329,295	251,286	235,411	117,611	110,664
Deaths						
IPD	**20**	**18**	**15**	**13**	**28**	**24**
IPD deaths < 5 years	17	15	14	13	25	22
IPD deaths 5-14 years	3	3	1	0	3	2
Inpatient pneumonia	**15**	**12**	**13**	**9**	**10**	**8**
Inpatient pneumonia deaths < 5 years	6	5	6	5	2	2
Inpatient pneumonia deaths 5-14 years	9	7	7	4	8	6
Total	35	30	28	22	38	32

Abbreviations: PCV = pneumococcal conjugate vaccine; IPD = Invasive pneumococcal disease.
*N/A = Due to the lack of local incidence data, outpatient pneumonia cases for Andalusia were not estimated in this analysis.
Notes: In the 5-year impact analysis, PCV15 is assumed to be available in 2023, one year before the PCV20, which is assumed to be available in 2024.

Conclusions/Learning Points: Compared to implementing PCV15 in 2023, implementing PCV20 in 2024 is estimated to provide greater public health impact on pneumococcal disease for children in three Spanish regions over a 5-year time horizon, despite a one-year delay in implementation.

PV0162 / #749

ESTIMATING THE COST EFFECTIVENESS OF SWITCHING TO HIGHER-VALENT PEDIATRIC PNEUMOCOCCAL CONJUGATE VACCINES IN THE UNITED KINGDOM

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

Michele Wilson[1], Aaron Lucas[1], Diana Mendes[2], Andrew Vyse[3], Boglarka Mikudina[2], Carole Czudek[3], Gillian Ellsbury[3], Johnna Perdrizet[4]
[1]RTI Health Solutions, Health Economics, Research Triangle Park, United States of America, [2]Pfizer Ltd, Health & Value, Tadworth, United Kingdom, [3]Pfizer Ltd, Medical Affairs, Tadworth, United Kingdom, [4]Pfizer Inc, Global Value & Evidence, New York, United States of America

Backgrounds: Currently, the 13-valent pneumococcal conjugate vaccine (PCV13) is administered under a 1+1 schedule for children in the United Kingdom (UK). Higher-valency PCVs, 15-valent (PCV15) and 20-valent (PCV20), might be considered in the future for expanding coverage and improving protection. We evaluate the cost-effectiveness of PCV20 or PCV15 using either a 2+1 or 1+1 schedule for pediatric vaccination in the UK.
Methods: Using a dynamic transmission model, we simulated future disease incidence and costs under PCV13 1+1, versus PCV20 2+1, PCV20 1+1, PCV15 2+1, and PCV15 1+1, from the UK National Health Service perspective. The model was parameterized using UK serotype specific invasive pneumococcal disease (IPD) surveillance data and published literature for other epidemiological and economic parameters. Unknown epidemiological inputs were fitted using a calibration procedure. For each vaccination program, we prospectively estimated disease cases, direct costs, quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratio (ICER). Scenario analyses were undertaken to examine impact of model assumptions and parameter uncertainty.
Results: Over a 5-year period, PCV20 2+1 was estimated to avert the most disease cases and gain the most additional QALYs versus other vaccination programs (Table 1). PCV20 2+1 was the optimal strategy with an ICER of £12,374/QALY versus PCV20 1+1, and was dominant (cost saving and more effective) versus PCV15 (2+1 or 1+1) and PCV13 1+1. PCV15 1+1 was dominant versus PCV13 1+1, but PCV15 2+1 was not cost-effective compared with PCV13
1+1.

Table 1. Cost-effectiveness results for PCV20 2+1 versus other vaccination program strategies (5-year time horizon)

Parameter	PCV13 1+1	PCV15 1+1	PCV15 2+1	PCV20 1+1	PCV20 2+1
Disease Cases					
Bacteremia	28,577	28,525	28,484	24,799	24,027

IPD	£196,431,422	£196,141,864	£195,895,456	£170,816,678	£165,490,643
Inpatient Pneumonia	£5,868,877,199	£5,863,316,038	£5,858,145,157	£5,197,011,899	£5,058,336,082
Otitis media	£36,680,558	£36,249,317	£36,017,319	£33,234,765	£32,373,327
Total	£6,491,261,225	£6,488,411,620	£6,688,631,362	£5,818,556,974	£5,888,548,962
ICER					
Vs PCV13 1+1		Dominant	£428,644/QALY	Dominant	Dominant
Vs PCV15 1+1			£921,330/QALY	Dominant	Dominant
Vs PCV15 2+1				Dominant	Dominant
Vs PCV20 1+1					£12,374/QALY

ICER = incremental cost-effectiveness ratio; IP = inpatient; IPD = invasive pneumococcal disease; OP = outpatient; PCV20 = 20-valent pneumococcal conjugate vaccine; PCV15 = 15-valent pneumococcal conjugate vaccine; PCV13 = 13-valent pneumococcal conjugate vaccine; QALY = quality adjusted life year.

Keywords: pneumococcal disease; vaccine; cost-effectiveness

Conclusions/Learning Points: Results demonstrate PCV20 is more effective and cost-saving compared with PCV13 or PCV15. PCV20 administered under a 2+1 schedule compared with a 1+1 schedule was estimated to be cost-effective. Policymakers should consider the substantial reduction in disease cases with PCV20, which may more than offset vaccination costs.

PV0163 / #528

QUANTIFYING THE HISTORIC IMPACT OF PCV13 AND CURRENT BURDEN OF PNEUMOCOCCAL VACCINE SEROTYPES IN ROMANIAN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

Alin Preda[1], Veronica Purdel[1], Sophie Warren[2], Johnna Perdrizet[2]
[1]Pfizer Romania, Vaccines, Bucharest, Romania, [2]Pfizer Inc, Global Value & Evidence, New York, United States of America

Backgrounds: Romania introduced the 13-valent PCV (PCV13) into the pediatric national immunization program (NIP) in 2017, yet there remains residual pneumococcal disease burden associated with non-PCV13 serotype disease. Higher-valent PCVs (PCV15 and PCV20) share the same serotypes covered by PCV13, while PCV15 covers 2 additional serotypes, whereas PCV20 covers 7 additional serotypes. We estimated the retrospective impact of PCV13 as well as the remaining clinical and economic burden attributed to PCV serotypes in Romanians <5 years.
Methods: Two Excel-based models were used to estimate (1) the historic number of pneumococcal disease cases and deaths averted since PCV13 implementation; and (2) the current annual clinical and economic burden of invasive pneumococcal disease (IPD), pneumonia, and acute otitis media (AOM) based on IPD serotype distribution in Romanians <5 years for PCV13 (63%), PCV15 (63%) and PCV20 (81%). For both analyses, the clinical, epidemiologic, and cost data were sourced or estimated from published studies. A human capital approach was taken to estimate hours of caregiver lost productivity per episode of pediatric pneumococcal disease and consequent indirect non-medical burden.
Results: Since 2017, PCV13 was estimated to avert over 188,000 pneumococcal disease cases and 950 deaths in 3 years. Based on current epidemiology in Romania, PCV20-unique serotypes are estimated to account for 38,811 cases, 94 deaths, and 21,399,589 lei in direct medical and indirect non-medical costs compared to PCV13 and PCV15 serotypes annually (Table

Table 1. Estimated burden of current PCV serotypes in Romanian children.

Total costs (direct + indirect)	74,898,309 lei	74,898,309 lei	96,297,898 lei
Abbreviations: PCV = pneumococcal conjugate vaccine; IPD = invasive pneumococcal disease; CAP – community acquired pneumonia; AOM – acute otitis media. [a]Serotype distributions sourced from Falup-Pecurariu et al., 2022			

1).

Conclusions/Learning Points: PCV13 has had substantial impact since its introduction in the pediatric population. However, PCV20 serotypes encompass a considerable amount of the current pneumococcal disease burden in Romanian children <5 years. When available, PCV20 may substantially reduce disease, healthcare expenditure, and productivity loss.

IMPACT OF THE COVID-19 PANDEMIC ON SOME PEDIATRIC INFECTIOUS DISEASES IN ALBANIA

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

Diana Shtembari[1], Georgina Kuli-Lito[2], Raida Petrela[2], Bashkim Nezaj[2], Blerina Gjoni[2], Laureta Sadedini[3], Ervisa Gogo[3]
[1]University Hospital Center"Mother Thereza", Pediatric Infectious Disease, TIRANA, Albania, [2]University Hospital Center "Mother Thereza", Pediatric Infectious Disease, Tirana, Albania, [3]University Hospital Center "Mother Thereza", Pediatric Emergency, Tirana, Albania

Backgrounds: The first case of the 2019 Coronavirus Disease (COVID-19) in Albania was identified on March 8, 2020.The aim of this study is to evaluate impact of the COVID-19 pandemic on pediatric infectious diseases such as Infectious Mononucleosis,Visceral Leishmaniasis,Varicella,Sepsis et Skin and Soft tissue infections by comparing them before (January 2105-February 2020) and after the start of the COVID-19 pandemic (March 2020-September 2022).
Methods: Our study presents a retrospective analysis based on the collection of epidemiological data such as age, gender, days of hospital stay on 1482 patients admitted to the University Hospital Center"Mother Thereza",Pediatric Infection Diseases Department for the period January 2015-September 2022 with the diseases taken in the study.
Results: 1482 hospitalized children included in the study make up 9.35% of the total number of admissions in the department of pediatrics ID.1164(9.64%) were before the COVID19 pandemic and 334(8.5%) after its onset. In the first year of the pandemic, the diseases studied were 6.36% of the total number of admissions, in the second year 9.74% and in the current year up to September11%.For diseases such as Visceral Leishmaniasis,Sepsis,Skin and Soft tissue infections, a significant difference was observed after the pandemic.The average age of the children to the study was 3.81 ± 3.20 before and 3.57 ± 2.97 after its start (p 0.242).No significant effect on gender
Conclusions/Learning Points: The strategies taken to reduce COVID-19 have effectively affected not only the maintenance of control of COVID-19, but also the prevalence of hospitalizations for infectious diseases.COVID 19 pandemic has also affected and the duration of hospitalization for infectious diseases.A continuous increase of these infectious diseases is observed during the second year of the pandemic and currently.

RANKING OF IMMUNIZATION PROGRAMS IN LATIN AMERICA, YEAR 2020

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

María Rombini, Romina Mauas, Analia Urueña
Universidad Isalud, Centro De Estudios Para La Prevención Y Control De Enfermedades Transmisibles, Ciudad Autónoma de Buenos Aires, Argentina

Backgrounds: The Expanded Program on Immunization (EPI) of the Americas is one of WHO's most successful. However, the implementation and achievements of goals show inequalities between countries. We aimed to build a Ranking of Latin-American national immunization programs (NIPs) that compares different realities, identifies challenges, and encourages countries to improve.
Methods: Eighteen countries were selected. Information published on official websites of ministries of health, WHO, PAHO and UNICEF, and from interviews with experts from each country were collected. A ranking was constructed for the year 2020, with a maximum score of 417 points, based on domains and indicators linked to vaccinations given at different stages of life, influenza vaccination, vaccination in special populations; programmatic aspects; and vaccine coverage rates (VCRs).
Results: Access to public information was heterogeneous between countries. Calendars differed mainly in the use of novel, acellular, inactivated, or combined vaccines, and the extent to non-pediatric vaccination. VCRs were low for the region and only 4 countries reported VCRs >95% for DPT1, DPT3, POL3 and SRP1 in 2019. The general ranking was led by Chile, reaching 66.4% of the maximum score. Other countries' scores varied between 51.3% (Uruguay) and 23.9% (Bolivia), showing, the lowest ranked, most restricted calendars, limited scope of flu vaccination and/or to special populations, low VCRs, and programmatic gaps. However, when domains were analyzed individually, the order of the ranking changed highlighting strengths and weaknesses in each country.
Conclusions/Learning Points: Achieving adequate VCRs, transparency in public information, and progression in vaccination schedules are common challenges in most Latin-American countries. This Ranking aims to stimulate PNI leaders to improve and reach unmet goals. The periodicity of this exercise will show the evolution and positioning of these programs over time.

[1]Nanjing Medical University, School Of Public Health, Nanjing, China, [2]Wilhelmina Children's Hospital/UMC Utrecht, Department Of Paediatric Immunology And Infectious Diseases, Wilhelmina Children's Hospital/university Medical Center Utrecht, Utrecht, Netherlands, [3]University of Washington, Seattle, Washington, USA, Department Of Medicine, Seattle, Washington, United States of America, [4]University of Colorado, Department Of Pediatrics, Section Of Infectious Diseases, Colorado, United States of America, [5]University of Cape Town, Department Of Paediatrics And Child Health, Cape Town, South Africa, [6]University of Cape Town, Paediatrics, Red Cross War Memorial Children's Hospital, Cape Town, South Africa, [7]University of Edinburgh, Centre For Global Health, Usher Institute, Edinburgh, United Kingdom, [8]University of Edinburgh, Edinburgh Medical School, Edinburgh, United Kingdom, [9]Imperial College London, Department Of Mathematics, London, United Kingdom, [10]University of Edinburgh, Centre For Global Health, Edinburgh, United Kingdom

Backgrounds: Preterm children form a high-risk group for respiratory syncytial virus (RSV) infection and severity outcomes. We assessed the global disease burden and risk factors for RSV-associated acute lower respiratory infection (ALRI) in preterm children.
Methods: Using aggregated data from published studies and individual participant data shared by the investigator group on respiratory infectious diseases, we estimated RSV-associated ALRI community incidence and hospital admission among preterm children, <37 weeks of gestational age (wGA), aged under two years in 2019, through two-stage random-effects meta-regression analyses that accounted for age, gestational age and time trend. Using individual participant data, we assessed individual-level prenatal, sociodemographic and household factors, and underlying medical conditions for RSV-associated ALRI incidence, hospital admission, and severe outcomes.
Results: We included 47 studies from published studies and 17 studies with individual participant data. We estimated globally in 2019, there were 1.64 million (95% uncertainty range: 1.36–1.99) RSV-associated ALRI episodes and 533,000 (385,000–730,000) hospital admissions in preterm infants under one year. Compared with all infants, preterm infants had comparable RSV-associated ALRI incidence rate but higher hospitalisation rate (rate ratio= 2.30, 95% CI: 1.48-3.51); for the second year of life, RSV-associated hospital admission rate remained higher in early preterm children (<32 wGA; rate ratio=2.26, 1.27–3.98). (Table) Analyses of risk factors showed that while most factors associated with RSV-associated ALRI were perinatal and sociodemographic characteristics, factors associated with severe outcomes were mainly underlying medical conditions such as congenital heart disease and chronic lung disease.
Conclusions/Learning Points: Preterm infants carry a disproportionately high RSV disease burden in the first year of life. Early preterm children have lower but noteworthy RSV hospital burden in the second year of life.

MODELLING THE PUBLIC HEALTH IMPACT OF MENACWY AND MENC ADOLESCENT BOOSTER VACCINATION STRATEGIES IN GERMANY.

E-Posters Viewing
E-POSTER VIEWING: AS02.B. MODELLING STUDIES

Sebastian Gruhn[1], Manuel Batram[2], Moritz Wick[3], Edith Langevin[4], Oliver Damm[3]
[1]Bielefeld University, Health Economics And Health Care Management, Bielefeld, Germany, [2]Vandage GmbH, Health Economics, Bielefeld, Germany, [3]Sanofi-Aventis Deutschland GmbH, Evidence-based Medicine/heor Vaccines Market Access, Berlin, Germany, [4]Sanofi Vaccines, Global Health Economics & Value Assessment, Lyon, France

Backgrounds: Invasive meningococcal disease (IMD) is a severe infection caused by Neisseria meningitidis, which can be life threatening or lead to lifelong impairments. Adolescent vaccination has largely contributed to decreased IMD burden in several countries. In Germany, routine vaccination against meningococcal disease is only recommended for MenC in toddlers, and protective effects wane over time. Our objective was to assess the public health impact of adolescent booster strategies with conjugate meningococcal vaccines in Germany.
Methods: We developed a dynamic transmission model to estimate meningococcal carriage of five serogroup-compartments (AY/B/C/W/Others) across all age groups until 2060 and derived cases of IMD via case:carrier-ratios. In evaluated scenarios, the status quo of MenC toddler vaccination was compared to the addition of either a MenC or MenACWY booster at ages 12-14 or 15-17 years. In all scenarios, we considered vaccine effectiveness against IMD and carriage acquisition.
Results: The model estimated the introduction of a MenACWY booster to significantly decrease IMD incidence, preventing up to 34 IMD cases per year and up to 762 cases overall until 2060. The majority of prevented cases was due to herd effects, decreasing IMD cases across all age groups. The protective effect was independent of booster vaccination age. In contrast, introducing a MenC booster led to a small decrease in IMD incidence of up to 3 IMD cases per year and 49 cases prevented over the total extrapolation period.
Conclusions/Learning Points: The results suggest that MenACWY booster vaccination in adolescents in Germany could have a significant impact in reducing IMD cases in all age groups, whereas adding MenC booster vaccination has a minor impact. Our analysis can inform public health policy decisions to maximize the population-level benefits of meningococcal vaccination.

NURSING BEST PRACTICES AND CHALLENGES IN THE FIRST RSV CONTROLLED HUMAN INFECTION MODEL IN THE NETHERLANDS

E-Posters Viewing
E-POSTER VIEWING: AS03.A. VACCINE DEVELOPMENT (PHASE 1-2) – VIRAL

Elisabeth Nibbelke[1], Brigitte Buiteman[1], Stephanie Ascough[2], Emma Bergstrom[2], Klasina Chappin[1], Pete Dayananda[2], Eveline Delemarre[1], Lobke Hensen[1], Julie Schoevers[1], Lisa Siegal[1], Lydia Taylor[2], Jonne Terstappen[1], Michelle Van Wijk[1], Hanneke Van Zoggel[1], Christopher Chiu[2], Louis Bont[1], Natalie Mazur[1]
[1]Wilhelmina Children's Hospital, Pediatric Infectious Diseases, Utrecht, Netherlands, [2]Imperial College London, Infectious Diseases, London, United Kingdom

Backgrounds: Respiratory syncytial virus (RSV) is the second cause of death in infants worldwide. Controlled Human Infection Model (CHIM) studies are an important tool to limit costs and accelerate the development of new vaccines. Conducting a CHIM is challenging and requires best practices for nursing. Participant satisfaction and compliance are essential to conduct a successful CHIM.
Methods: We aim to distill best nursing practices from an inpatient RSV CHIM for use in a future outpatient CHIM. We describe nursing practices and challenges in an inpatient quarantine setting, where six healthy adults were inoculated with 0.5 mL of 104PFUs RSV-A Memphis 37. Nasal sampling, blood draws and oral swabs were performed daily. Upper respiratory tract symptoms and temperature were self-reported. Data on nursing challenges and best practices was obtained by surveying potential study participants before recruitment and final study participants after trial termination.
Results: Privacy as well as a common space to meet fellow-participants, facilities to study and exercise, a global day structure and possibility to go outside during quarantine were the most important conditions to participate. Our nursing best practices, including hygiene measures like droplet isolation, made it possible to safely meet these conditions. Research personnel in close and frequent contact with infected participants remained RSV negative during the study period. The most important recommendation after trial termination from study participants was a personal investment in the relationship between study participants and study personnel.
Conclusions/Learning Points: In a future outpatient RSV CHIM participants can safely make use of outdoor space and a shared living room. Adopting hygiene measures around these key conditions for study participation will be important in the conduction of a successful outpatient RSV CHIM with high participant compliance.

RESPIRATORY SYNCYTIAL VIRUS CONTROLLED HUMAN INFECTION MODELS (CHIM) AS A TOOL FOR ACCELERATED VACCINE DEVELOPMENT

E-Posters Viewing
E-POSTER VIEWING: AS03.A. VACCINE DEVELOPMENT (PHASE 1-2) – VIRAL

Jonne Terstappen[1], Eveline Delemarre[1], Lisa Siegal[1], Stephanie Ascough[2], Emma Bergstrom[2], Brigitte Buiteman[1], Klasina Chappin[1], Pete Dayananda[2], Lobke Hensen[1], Elisabeth Nibbelke[1], Julie Schoevers[1], Lydia Taylor[2], Michelle Van Wijk[1], Hanneke Van Zoggel[1], Christopher Chiu[2], Louis Bont[1], Natalie Mazur[1]
[1]Wilhelmina Children's Hospital, University Medical Center Utrecht, Paediatric Infectious Disease And Immunology, Utrecht, Netherlands, [2]Imperial College London, Infectious Diseases, London, United Kingdom

Backgrounds: Globally respiratory syncytial virus (RSV) is the second cause of death in infants. Thirty-three RSV prevention candidates are in development with an extended half-life monoclonal antibody within reach for high-income countries. Urgent next steps include ensuring access and affordability to RSV interventions of an RSV vaccine globally. RSV Controlled Human Infection Models (CHIM) limit costs and time of vaccine development and potentially prevent large and costly late-stage failures in clinical trials.
Methods: The aim was to set up an RSV CHIM in the Netherlands. The primary outcome was at least one productive infection. Secondary outcomes included viral load and self-reported upper respiratory tract (URT) symptom scores over time. Six healthy adults were inoculated with 0.5mL of 10^4PFU RSV-A Memphis 37. Nasal lavages were performed daily. URT symptoms (maximum score 24) and temperature were self-reported from baseline (day 0) through 10 days post-inoculation (DPI). We measured RSV viral load by RT-qPCR and viral titration by TCID50 on nasal washes. A productive infection was defined as two positive PCR tests on two consecutive days after 2 DPI.
Results: 83.3% (5/6) participants were infected with RSV. One RSV+ participant was asymptomatic. Symptoms started at median 2 DPI (range 0-3) with main complaints of sneezing and a runny nose. No participants developed a fever. The total URT symptom scores of infected participants peaked on 5 DPI (median score 4, range 1-4), which coincided with the peak in viral load on 4 DPI (median 5.32×10^9 RSV copies/mL, range 4.86×10^6-1.52×10^{10}).
Conclusions/Learning Points: We performed a successful proof-of-concept of RSV CHIM in the Netherlands with an infection rate of 83.3%. Next steps include use of RSV CHIM in the Netherlands as a tool for rapid vaccine development.

ANTIBODY LEVELS TO SIX STAPHYLOCOCCUS AUREUS VACCINE CANDIDATES IN HEALTHY ADULTS

E-Posters Viewing
E-POSTER VIEWING: AS03.B. VACCINE DEVELOPMENT (PHASE 1-2) – BACTERIAL AND ALL NON-VIRAL

Kyung-Hyo Kim[1], Hye Kyung Cho[1], Hyun Jung Ji[2], Hyunju Lee[3], Han Wool Kim[4], Ji Hyen Lee[5], Ho Seong Seo[2]
[1]Ewha Womans University Mokdong Hospital, Pediatrics, Seoul, Korea, Republic of, [2]Korea Atomic Energy Research Institute, Biotechnology, Jeongeup, Korea, Republic of, [3]Seoul National University College of Medicine, Pediatrics, Seoul, Korea, Republic of, [4]Hallym University Sacred Heart Hospital, Pediatrics, Anyang, Korea, Republic of, [5]Ewha Womans University Seoul Hospital, Pediatrics, Seoul, Korea, Republic of

Backgrounds: Staphylococcus aureus (SA) is important pathogen responsible for significant morbidity and mortality worldwide. Its high antibiotic resistance profile reinforces the need for efficacious vaccines. Although several promising animal studies of SA vaccine candidates have been reported, most of human SA vaccine trials have fallen short of expectation. Since SA is a commensal opportunistic bacterium and humans encounter SA frequently throughout their lifetime, we hypothesized that the antibody level of the SA vaccine candidate antigens would be high even in the serum of healthy adults who had not been infected with invasive SA, and that these antibodies would interact with functional antibodies induced with vaccines.
Methods: We purified six protein vaccine candidates, ClfA (clumping factor A), IsdB (iron-regulated surface determinant B), SpA (staphylococcal protein A), MntC (manganese transport protein C), Hla (alpha-hemolysin toxin) and TBA . We performed ELISA to measure specific antibody titers in healthy adult sera (n=85) and immunoglobulin products (n=25).
Results: All tested adult sera showed extremely high levels of Hla-specific antibody (18,504±10,700), whereas the mutated toxoid (Hla toxoid) showed only 7,216±4,885 indicating that the structural changes in Hla toxoid do not interact with some Hla-specific antibody. Other vaccine candidate antigens also showed very high antigen-specific IgG levels in sera [TBA (8,590±7,070), ClfA (3,922±2,490), IsdB (8,072±5,665), Spa (4,385±2,694)]. Surprisingly, MntC antigen showed relatively low antibody levels (1,602±1,319). Specific IgG levels to all six antigens in immunoglobulin products were higher than those in human sera..
Conclusions/Learning Points: We speculated that the presence of a natural antibody induced by commensal SA may interact with the binding of functional antibodies induced by the vaccine, thereby influencing the efficacy of the vaccine. Natural SA specific Ab should be considered in the development of efficacious SA vaccines.

IMPACT OF A NEW ADJUVANT, VSA-1 ON THE IGG SUBCLASS COMPOSITION OF PNEUMOCOCCAL ANTIBODIES

E-Posters Viewing
E-POSTER VIEWING: AS03.B. VACCINE DEVELOPMENT (PHASE 1-2) – BACTERIAL AND ALL NON-VIRAL

Moon Nahm[1], Pengfei Wang[2], Hyunjung Kim[2], Jigui Yu[1], Di Bai[2]
[1]UAB, Medicine, Birmingham, United States of America, [2]UAB, Chemistry, Birmingham, United States of America

Backgrounds: Streptococcus pneumoniae is an important human pathogen and pneumococcal conjugate vaccines (PCVs) have been highly effective against the serotypes included in the vaccine. However, infections by the non-vaccine serotypes have become more common and PCVs with twenty or more serotypes are being developed. Since inclusion of more serotypes has greatly reduced the immunogenicity of PCVs, a novel adjuvant is desirable. We have therefore examined a new adjuvant (VSA-1) for enhancing immunogenicity of PCV13 and IgG2a antibody response. VSA-1 is a semisynthetic saponin adjuvant prepared from naturally occurring and abundantly available Momordica saponin (Wang et al. J Med Chem. 2019; 62:9976).
Methods: Four groups of female BALB/c mice (6 per group) were immunized with normal saline, one tenth human dose of PCV13, PCV13+VSA-1, and PCV13-QS21 on days 0, 14 and 14. QS21 is another saponin adjuvant. Blood samples were obtained on day 42. IgG subclass of pneumococcal antibodies in the pooled serum samples of each group were determined with pneumococcal antibody ELISA for seven serotypes (3, 4, 6B, 9V, 14, 19A and 19F) using enzyme-conjugated antibodies against mouse IgG1, IgG2a or IgG3.
Results: Both VSA-1 and QS-21 boosted IgG1, IgG2a and IgG3 antibodies titers against seven selected serotypes (Table
1).

Table: Fold increase in ELISA titer of each IgG subclass over the saline group

		Serotype							Average
	Group	3	4	6B	9V	14	19A	19F	(n=7)
IgG1	A (Saline)	1	1	1	1	1	1	1	1
	B (PCV only)	27	737	39	1056	42	102	119	303
	C (PCV+QS21)	119	1370	300	2187	793	173	175	731
	D (PCV+VSA1)	112	2187	222	2187	1741	219	236	986
IgG2a	A (Saline)	1	1	1	1	1	1	1	1
	B (PCV only)	2	3	1	17	1	2	1	4
	C (PCV+QS21)	10	71	8	678	17	14	15	116
	D (PCV+VSA1)	5	96	1	618	216	23	49	144
IgG3	A (Saline)	1	1	1	1	1	1	1	1
	B (PCV only)	7	30	2	29	22	1	14	15
	C (PCV+QS21)	18	165	8	402	360	49	246	178
	D (PCV+VSA1)	19	182	6	301	2187	44	15	393

The titer is defined as the serum dilution that produced 6X above the background signal.

Conclusions/Learning Points: VSA-1 is as effective as QS21 in enhancing antibody response to PCV13

and significantly increasing IgG2a antibody response. While additional studies are required, VSA-1, which is much more accessible and of lower toxicity than QS-21, appears to stimulate Th1 as QS-21 does.

MEASLES AND RUBELLA SEROEPIDEMIOLOGY IN PREVIOUSLY VACCINATED YOUNG ADULTS AGED 18-30 IN A NON-ENDEMIC REGION

E-Posters Viewing
E-POSTER VIEWING: AS03.C. VACCINE EFFICACY (PHASE 3) AND EFFECTIVENESS – VIRAL

Daniel Leung, Jaime Rosa Duque, Yu Lung Lau
The University of Hong Kong, Department Of Paediatrics And Adolescent Medicine, Hong Kong, Hong Kong PRC

Backgrounds: The WHO Western Pacific Region has set the goals to eliminate measles and rubella. Yet, 95% measles seroprevalence is needed to achieve herd immunity as measles virus is very transmissible with an R0 of 12-18. In 2019, a measles outbreak occurred in the Hong Kong International Airport with 29 airport staff infected within a month, and further led to transmission to 2 healthcare workers aged between 20-25 known to have received 2 doses of MMR vaccine. Secondary vaccine failure due to antibody waning and lack of boosting by circulating virus, as well as interrupted vaccination efforts during COVID-19 pandemic, slows measles and rubella eradication worldwide. Resumption of international travel after COVID restrictions are lifted may lead to imported measles outbreak in non-endemic regions.
Methods: We conduct a cross-sectional study for healthcare students and workers aged between 18-30 innoculated by 2 doses of MMR vaccine, with a follow-up prospective cohort study for those screened to be without adequate antibody protection. Luminex assay is used to screen for measles and rubella seronegativity, and those negative are confirmed by enzyme linked fluorescent assay (VIDAS).
Results: 792 participants were recruited in the study. 427 participants (53.9% of total) tested seronegative for measles by Luminex, and 240 participants (30.3%) were confirmed seronegative or indeterminate for measles on VIDAS. 93 participants (11.7%) tested seronegative for rubella on Luminex, and 20 participants (2.5%) were confirmed seronegative for rubella on VIDAS.
Conclusions/Learning Points: There is a high rate of measles seronegativity among previously twice-vaccinated healthy adults aged 18-30 living in regions with no local transmission. We will study the immunogenicity of a booster dose of measles-mumps-rubella in seronegative young adults.

PV0173 / #1732

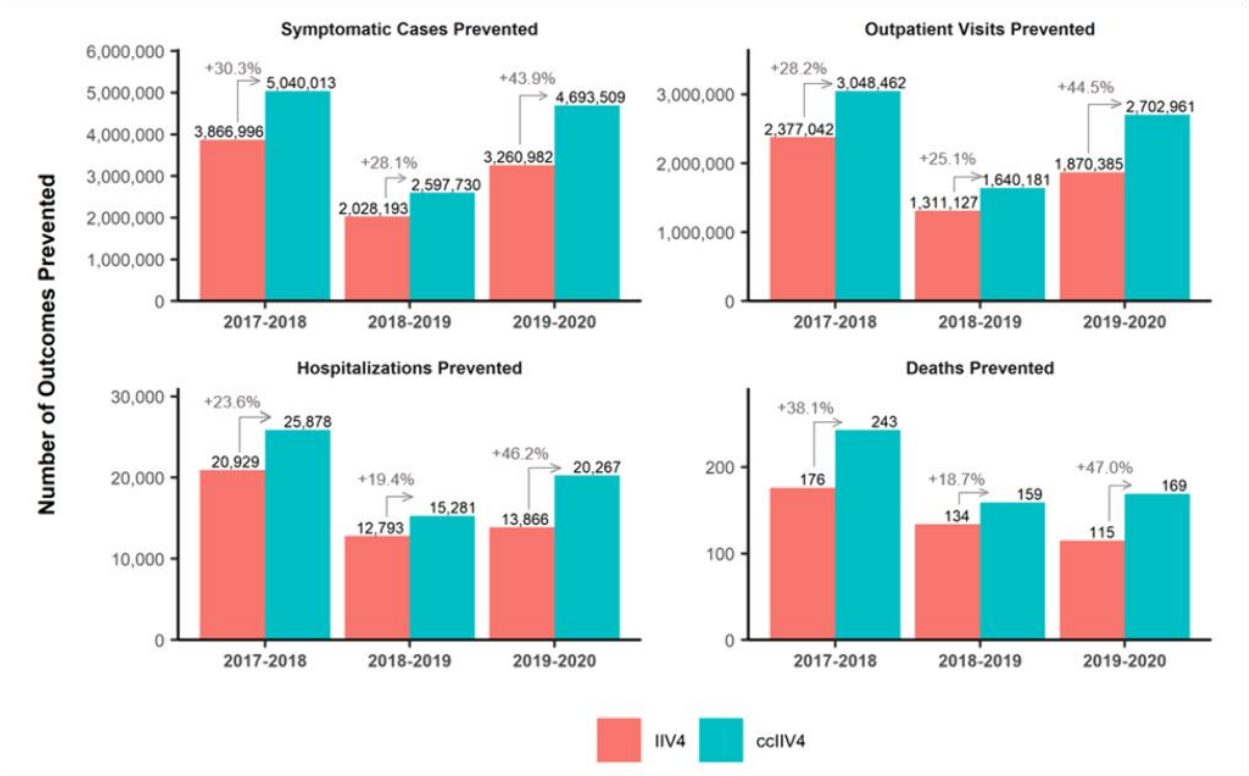
ESTIMATED ADDITIONAL BURDEN AVERTED FROM USE OF CELL-BASED INFLUENZA VACCINES COMPARED TO EGG-BASED INFLUENZA VACCINES AMONG CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS03.C. VACCINE EFFICACY (PHASE 3) AND EFFECTIVENESS – VIRAL

Ian Mcgovern[1], Alexandra Taylor[2], Aditya Sardesai[2], Hector Toro-Diaz[3], Mendel Haag[4]
[1]CSL Seqirus, Center For Outcomes Research And Epidemiology, Waltham, United States of America, [2]Evidera, Evidence Synthesis, Modeling & Communication, San Francisco, United States of America, [3]Evidera, Evidence Synthesis, Modeling & Communication, Bethesda, United States of America, [4]CSL Seqirus, Center For Outcomes Research And Epidemiology, Amsterdam, Netherlands

Backgrounds: Influenza vaccines have traditionally been produced in eggs, which can introduce egg-adaptive mutations. Cell-based influenza vaccines avoid egg-adaptive mutations, potentially improving match to circulating influenza viruses and therefore vaccine effectiveness. This study modeled the public health impact if all vaccinated children (<18 years of age) in the United States received cell-propagated inactivated quadrivalent influenza vaccine (ccIIV4) compared to egg-propagated inactivated quadrivalent influenza vaccine (IIV4) across the 2017-2018 through 2019-2020 Influenza Seasons.
Methods: The modeling method used by the US Centers for Disease Control and Prevention (CDC) for estimating overall burden averted due to influenza vaccination was extended to a relative vaccine effectiveness (rVE) context. The model utilized CDC data on influenza vaccine uptake, influenza incidence, influenza-related healthcare resource use and deaths. CDC estimates of absolute vaccine effectiveness (aVE) (any vaccine) were used as the aVE ofIIV4. Based on previously published rVE estimates generated from the same real-world database, the rVE of ccIIV4 vs IIV4 was assumed to be 19.3% in 2017-2018, 7.6% in 2018-2019, and 17.2% in 2019-2020.
Results: The CDC estimated that influenza vaccine coverage ranged from 58-75% among the 73.8 million children <18 years of age in the US during the 2017-2020 influenza seasons. Figure 1 shows the anticipated number influenza-related cases and complications that would be averted if all vaccinated children received ccIIV4 or IIV4. Across the 3 influenza seasons, use of ccIIV4 would result in prevention of an additional 3,175,081 symptomatic illnesses, 1,833,049 outpatient visits, 13,837 hospitalizations, and 147
deaths.

Figure 1: Number of Outcomes Prevented from Use of ccIIV4 Compared to IIV4 Among Children <18 Years of Age: 2017-2018 Through 2019-2020 Seasons



Conclusions/Learning Points: Use of ccIIV4 instead of IIV4 during the 2017-2020 influenza seasons in the US would have had a substantial public health impact due to a 28.1% to 43.9% increase in influenza cases prevented.

[1]Murcian health service, Preventive Medicina And Public Health Teaching Unit, Murcia, Spain, [2]Virgen de la Arrixaca University Hospital, Pediatric Teaching Unit, Murcia, Spain, [3]Health Counseling, Addiction Protection And Prevention Service, Murcia, Spain

Backgrounds: Although HPV vaccination is important in preadolescent males, in neighbouring countries coverage is lower than in females. Vaccination of males has been included for the first time in Spain during 2022. Our objective is to evaluate coverage in 12-year-old males and females, comparing them with each other and with last year.
Methods: A descriptive study was carried out to evaluate HPV coverage up to January 9, 2022 in those born in 2010 and up to January 9, 2023 in those born in 2011. They were compared by sex in both years (provisional data) and estimated the variation based on the consolidated data of the previous year. Vaccination was carried out through a school program with time to receive both cohorts only the first dose.
Results: Until January 9, 2022, where vaccination programs only included females, provisional data for 2010 cohort show coverage in females (71.4%) higher than in males (1.1%) ($p<0.05$). The consolidated data show a percentage increase of 19.7% in the female sex, reaching a coverage of 85.5%. For the 2011 cohort, the provisional data until January 9, 2023 again show greater coverage in the female sex (67.3%) compared to the male sex (61.3%) ($p<0.05$). If this variation remained constant, the consolidated data for the 2011 cohort would show coverage of 73.4% in men and 80.6% in women.
Conclusions/Learning Points: HPV coverage in preadolescent males is lower compared to other unfunded vaccines in Spain, where acceptance of unfunded vaccines can reach 70%. Universal vaccination against HPV increases coverage in males and approaches it to that observed in females. In our work, the difference between the sexes is smaller than in neighbouring countries and the consolidated data may reduce it further.

DIVERSITY, QUALITY, MAGNITUDE, AND FUNCTIONALITY OF THE HUMORAL RESPONSE TO A LIVE-ATTENUATED TETRAVALENT DENGUE VACCINE IN PEDIATRIC PARTICIPANTS FROM A PHASE 3 EFFICACY TRIAL

E-Posters Viewing
E-POSTER VIEWING: AS03.C. VACCINE EFFICACY (PHASE 3) AND EFFECTIVENESS – VIRAL

Mayuri Sharma, Eduardo Nascimento, Christina Demaso, Heather Watkins, Isamu Tsuji, Allan Parker, David Dominguez, Lovkesh Karwal, Melissa Zahralban-Steele, Shibadas Biswal
Takeda, Vaccines Business Unit, Cambridge, United States of America

Backgrounds: Most dengue cases occur in children, and severe dengue drives the global economic burden of the disease. Immune responses targeting viral structural and nonstructural (NS) proteins have a role in protection against severe dengue. Takeda's live-attenuated tetravalent dengue vaccine, TAK-003, is comprised of structural proteins from each serotype in an attenuated dengue virus (DENV) serotype 2 (DENV-2) genomic backbone. TAK-003 was designed to elicit a dengue-specific immune response against the entire DENV backbone.
Methods: Samples from children and adolescents aged 4–16 years participating in a phase 3 efficacy trial (DEN-301, NCT02747927) of 2 doses of TAK-003 were assessed for magnitude and functionality of antibody (Ab) responses to structural and NS DENV proteins. Measurements included concentration and affinity maturation of vaccine-elicited binding Abs; breadth and specificity of neutralizing Abs; magnitude of complement-fixing Abs (CFAs); and Abs against the viral toxin NS1.
Results: TAK-003 elicited robust, tetravalent humoral responses against DENV in both baseline seronegative and seropositive vaccine recipients, including affinity-matured anti-DENV binding Abs, cross-reactive and serotype-specific nAbs with coverage across genetically diverse DENVs, CFAs, and anti-NS1 Abs. These Ab responses peaked at 30 days post-second vaccination and remained above baseline levels through the end of 1 year post-second dose. The data also showed high correlation and concordance with the neutralizing Ab responses observed in DEN-301 against all 4 DENV serotypes.
Conclusions/Learning Points: This is the first comprehensive characterization of the magnitude, quality, and functionality of the humoral immune response to a dengue vaccine in a pediatric population. The diversity of TAK-003-driven Ab responses observed in this analysis may contribute to the robust efficacy against hospitalized dengue cases reported in children and adolescents during the pivotal efficacy trial.
Acknowledgements: Study sponsored by Takeda.

EFFECT OF THE INTERVAL BETWEEN BIRTH- AND SECOND-DOSE OF HEPATITIS B VACCINE ON PERINATAL TRANSMISSION OF HEPATITIS B VIRUS

E-Posters Viewing
E-POSTER VIEWING: AS03.C. VACCINE EFFICACY (PHASE 3) AND EFFECTIVENESS – VIRAL

Tae Un Yang[1], Juan Vargas-Zambrano[2], Hang Park[3], Chae Jung[4], Dongwook Kim[5]
[1]University of Helsinki, Faculty Of Medicine, Helsinki, Finland, [2]Sanofi, Medical, Lyon, France, [3]Seoul National University, Department Of Public Health, Seoul, Korea, Republic of, [4]Ministry of Health and Welfare, National Institute Of Organ, Seoul, Korea, Republic of, [5]Division of Immunization, Korea Disease Control And Prevention Agency, Seoul, Korea, Republic of

Backgrounds: Mother-to-child-transmission is one of the most common ways of hepatitis B infection. Different interventions are in place to reduce perinatal transmission but there is scarce data on the impact if any, of the interval between the birth dose (HepB-BD) and the second dose (HepB-SD) of Hepatitis B vaccine. To compare perinatal transmission of HBV according to the time interval between HepB-BD and HepB-SD in South Korea between 2002 and 2013.
Methods: This was a retrospective cohort study using an administrative de-identified dataset containing relevant information of mothers and their offspring regarding Hepatitis B. Descriptive analyses as well as univariate (chi-square) and multivariate analyses (logistic regression) were conducted to assess association between the outcome and the exposure.
Results: In the dataset 39,313 infants were born to HBsAg-positive mothers, and 1027 (2.6%) were HBsAg-positive at ≥9 months. Results of the multivariate analysis are shown in table 1. Table 1. Multivariable analyses for factors associated with risk of perinatal HBV infection among infants born to HBV-infected mothers

	Adjusted OR
Second dose schedule <8 weeks (vs. ≥8 weeks)	0.79
Maternal age (vs. ≥35 years)	
<25 years	1.52
25–29 years	1.06
30–34 years	0.91
Non-Korean mother (vs. Korean mother)	1.56
Maternal HBeAg-positive (vs. maternal HBeAg-negative)	7.66
Short gestational length (24–36 weeks) (vs. 37–42 weeks)	0.68
Vaginal delivery (vs. Caesarean section)	0.94

Conclusions/Learning Points: In South Korea maternal factors (i.e., HepB e antigen status, age or nationality) increased the risk of infection whereas short gestational length decreased this risk. The HepB-BD–HepB-SD interval (<8 vs. ≥8 weeks) did not alter the risk.

[1]Herlev Hospital, Dept. For Children And Adolescents, Herlev, Denmark, [2]Rigshospitalet, Dept. For Children And Adolescents, Copenhagen E, Denmark

Backgrounds: Measles is an extremely contagious disease with the highest risk of complications in infants under twelve months of age. Vaccination rates are below levels eliciting herd immunity. Thus, efforts must be made to protect infants. Early MMR vaccination could be a solution to this challenge, but maternal antibodies may blunt responses. Studies regarding MMR immunogenicity in six months old infants are sparse.
Methods: In this double-blind placebo-controlled RCT, 6540 healthy infants were randomized 1:1 to receive either M-M-R VaxPro or placebo (solvent only) at age five to seven months. A sub-population (N=647) had serum samples collected prior to intervention, and four weeks after both intervention and routine vaccination at 15 months of age. Data were analyzed using Tobit regression adjusted by sex and prematurity as randomization was stratified by these factors. Geometric mean concentrations (GMC) and GMC ratios (GMR) are reported. Seroprotection rates (SPRs) were calculated using the WHO-convention cut-off concentrations of 120 mIU/mL for measles neutralizing antibodies and 10 IU/mL for mumps and rubella IgG. Influence of maternal measles antibodies was examined graphically.
Results: Mean age at intervention was 6.4 months. Samples were collected 26.9 days after intervention. Post-intervention PRNT GMC was 119.6 mIU/mL for MMR group (placebo 25.0 mIU/mL), GMR 4.8 (95%CI 3.8-5.9). SPRs were; PRNT 44.0% MMR group (placebo, 12.5%), and in the ELISA IgG analysis mumps 33.0% (placebo 2.1%), rubella 60.8% (placebo 10.0%). Responses were inhibited by presence of even low levels of maternal antibodies. Early MMR did not affect the response to routine MMR at 15 months.
Conclusions/Learning Points: MMR at five to seven months of age is immunogenic in 30 % of vaccinated infants against measles and mumps and in 50% against rubella measured four weeks after intervention.

Backgrounds: Tick-borne Encephalitis (TBE) is an infection by the Tick-borne Encephalitis virus (TBEV) with central nervous system signs and/or symptoms. TBE is endemic in Latvia and elsewhere in Europe and Asia. In Latvia, pediatric TBE vaccines, including FSME-IMMUN Junior (FSME-Jr), are recommended, and partially government-reimbursed, for children 1-15 years-of-age but TBE vaccine effectiveness (VE) in children has not been reported.
Methods: Rīga Stradinš University conducted nationwide population-based surveillance for TBE cases in collaboration with the Centre for Disease Prevention and Control, the National Reference Laboratory, and 15 hospitals. Serum and cerebrospinal fluid were tested by ELISA for TBEV-specific IgG and IgM antibodies. After informed consent, patient interviews and medical record review were used to determine the proportion of TBE cases FSME-Jr fully-vaccinated (on-schedule receipt of the three-dose primary series) (PCV). General population surveys conducted by IPSOS in 2019 and 2020 were used to determine the proportion of the population FSME-Jr fully-vaccinated (PPV). FSME-Jr VE (with 95% confidence interval) was estimated using the screening method (VE=1−((PCV/(1−PCV)/(PPV/(1−PPV)).
Results: From 2018-2020, surveillance identified 36 TBE cases in children 1-15 years-of-age; all cases were hospitalized, 5 (14%) for >12 days. TBE incidence in children 1-15 years-of-age was 4.0/100,000 population per year. Of the TBE cases, 34 (94%) were unvaccinated, 1 (3%) was FSME-Jr fully-vaccinated, and 1 (3%%) was partially-vaccinated. Among children 1-15 years-of-age with a reported vaccination status in the general population, 44% were unvaccinated, 13% were FSME-Jr fully-vaccinated, and 43% were partially-vaccinated or received another TBE vaccine. VE of FSME-Jr was 90.1% (27.3-98.6) against TBE.
Conclusions/Learning Points: FSME-Jr was highly effective in preventing TBE in children 1-15 years-of-age in Latvia. Increasing FSME-Jr uptake and adherence to the recommended three-dose schedule is essential to maximize FSME-Jr public health impact.

ANALYSIS OF INFLUENZA VACCINATION COVERAGE IN THE ARAB POPULATION AGED 6 TO 59 MONTHS IN A SOUTHEAST SPANISH REGION

E-Posters Viewing
E-POSTER VIEWING: AS03.C. VACCINE EFFICACY (PHASE 3) AND EFFECTIVENESS – VIRAL

Senay Rueda-Nieto[1], Matilde Zornoza-Moreno[2], María Teresa Navarro-Esteban[3], Francisca Tornel-Miñarro[2], Francisco Hernández-Fuentes[3], Jaime Jesús Pérez-Martín[2]
[1]Murcian Health Service, Preventive Medicina And Public Health Teaching Unit, Murcia, Spain, [2]Health Counseling, Addiction Protection And Prevention Service, Murcia, Spain, [3]Virgen de la Arrixaca University Hospital, Pediatric Teaching Unit, Murcia, Spain

Backgrounds: The 2022/2023 influenza vaccination campaign is the first in which children aged 6 to 59 months are vaccinated in Murcia (Spain), observing halfway through the campaign a notably lower coverage in Arabs (6.5%) compared to general population (29.1%). We believe that the language barrier may be one of the reasons, so the objective is to evaluate such coverage in Arabs under 5 years of age, before and after implementing a communication strategy.
Methods: A quasi-experimental study was conducted from December 2022 to January 2023, evaluating influenza vaccination coverage in under 5 years of age after 2 and 4 weeks of sending SMS messages to parents with infographics in Arabic about the suitability of the vaccine and a link to request an appointment for its administration. The children were divided into group A (health areas 1-4) and group B (health areas 5-9) which served as a control by sending them the SMS one week later.
Results: Before the implementation of the strategy, coverage was 4.7% in group A and 8.8% in group B. In the 2-week evaluation in group A, coverage increased to 7.7% and in group B up to 11.4% ($p<0.01$). At 4 weeks, group A reached 9.0% coverage and group B 12.9%, with no significant differences from the previous intervention in any of the groups ($p=0.23$ and $P=0.53$ respectively), but finding significant differences with respect to the previous intervention ($p=0.05$). Global coverage was 10.74% at the end of the evaluation.
Conclusions/Learning Points: The language barrier may explain part of the low coverage in this population, but these figures are not explained solely by language problems, since the effect of the strategy dissipates. More studies are needed to assess the causes of this problem.

TYPHOID ANTI-VI ANTIBODIES SEROPREVALENCE AMONG PREVIOUSLY TYPHOID CONJUGATE VACCINE (TCV) UNVACCINATED AND VACCINATED INDIAN CHILDREN AND ADULTS

E-Posters Viewing
E-POSTER VIEWING: AS03.D. VACCINE EFFICACY (PHASE 3) AND EFFECTIVENESS – BACTERIAL AND ALL NON-VIRAL

Appala Karthik Adari
PGIMER, Pediatrics, sector D, Chandigarh, India

Backgrounds: Prevalence of high typhoid anti-Vi-IgG antibodies could infer protection and serve as a marker for typhoid exposure. Therefore, this study was planned which aimed to define age-wise trend of seropositivity among previously TCV unvaccinated and vaccinated subjects.
Methods: In this observational cross-sectional study, apparently healthy subjects of identified age groups attending OPDs of a tertiary care hospital in Northern India over last one year were enrolled. Prior ethical clearance was obtained. Serum was tested for typhoid anti-Vi-IgG antibodies using specific ELISA VaccZyme kit. Those with GMTs >10 IU/ml(~2 ug/ml) were considered seropositive.
Results: Out of a total 80 subjects enrolled, 31,16,10,15, and 8 were in 5-8,9-12, 13-16,17-20 and 21-24 years age-groups. Out of these 80 subjects, 29(36.3%) received 1-dose TCV in past. Baseline seropositivity rates for seropositivity among previously unvaccinated subjects in these defined five age groups were 33.3%,25%,25%,27.3%, and 16.7%, respectively, even without receiving any TCV in past. GMTs in these age groups were 4.52,19.84,5.74,3.44, and 4.4 IU/ml, respectively. While the proportion of seropositive subjects in those who received one dose of TCV in past was 92.3%,50%,100%,75%, and 50% in same age groups. Out of these 29 subjects, 24(82.8%) had titers in seroprotective range. GMT in these vaccinated groups was 69.98,59.11,73.23,19.84 and 31.36 IU/ml. Median duration since vaccination(one dose TCV) and testing was 50.0 months, showing average persistence of antibodies at least for 4-5 years, although it could be longer if followed further.
Conclusions/Learning Points: Persistence of protective antibodies against typhoid in the majority(82.8%) of subjects in follow-up(after receiving 1-dose TCV in past) and significantly higher titers among vaccinated compared to previously unvaccinated subjects, given the high disease burden and emerging drug resistance justifies the introduction of TCV in our national immunization program.

UNDERSTANDING RESPIRATORY TISSUE RESIDENT MEMORY T-CELL RESPONSES FOLLOWING BORDETELLA PERTUSSIS VACCINATION – PROGRESS TOWARD MORE EFFECTIVE NEXT GENERATION VACCINES

E-Posters Viewing

E-POSTER VIEWING: AS03.D. VACCINE EFFICACY (PHASE 3) AND EFFECTIVENESS – BACTERIAL AND ALL NON-VIRAL

Karen Mccarthy, Kingston Mills, Rachel Mcloughlin
Trinity Biomedical Sciences Institute, School Of Biochemistry And Immunology, Dublin, Ireland

Backgrounds: Bordetella pertussis is the third leading cause of vaccine-preventable deaths in under-5's, despite high global vaccination coverage. This is proposed to be due to rapidly waning immunity following the switch from whole cell (wP) to acellular (aP) vaccination. Evidence from animal models suggests aP vaccines, in contrast to wP vaccines or natural infection, fail to prime tissue resident memory t-cell (TRM) responses in the nasal mucosa and lung that prevent colonisation with B.pertussis. The objective of the study was to investigate the impact of aP or wP vaccines on TRM frequency and function.
Methods: We recruited patients undergoing elective tonsillectomy (n=20), bronchoscopy (n=10) or healthy volunteers (n=20) and sub-divided by priming childhood immunisation with aP or wP. Tonsil, bronchoalveolar lavage fluid (BALF), nasal mucosa and blood samples were collected. Immune cells were isolated and cultured with B.pertussis antigens. Antigen-specific cytokine-producing TRM cells were quantified by flow cytometry.
Results: We identified IFN-γ and IL-17-producing $CD4^+$ TRM in human adeno-tonsillar, nasal and BALF. These TRM were expanded by culture with sonicated B. pertussis. Adults immunised with wP as infants have significantly more B. pertussis-specific IL-17-producing CD4 TRM in nasal mucosa and IFN-γ-producing CD4 TRM in tonsil than adults who received aP ($p=0.005$, $p=0.007$). We have also demonstrated IFN-γ-producing B.pertussis-specific TRM in the airway epithelium of wP vaccine recipients.
Conclusions/Learning Points: Immunisation with wP but not aP vaccines induces antigen-specific cytokine-producing TRM throughout respiratory tissues that persist up to 30-years following initial vaccination. In mice, these cells in the nose and lung have been associated with protection against colonisation following B. pertussis aerosol challenge. Our findings support a novel vaccine that induces IL-17 and IFN-γ-producing TRM is likely to be more effective than current aP vaccines.

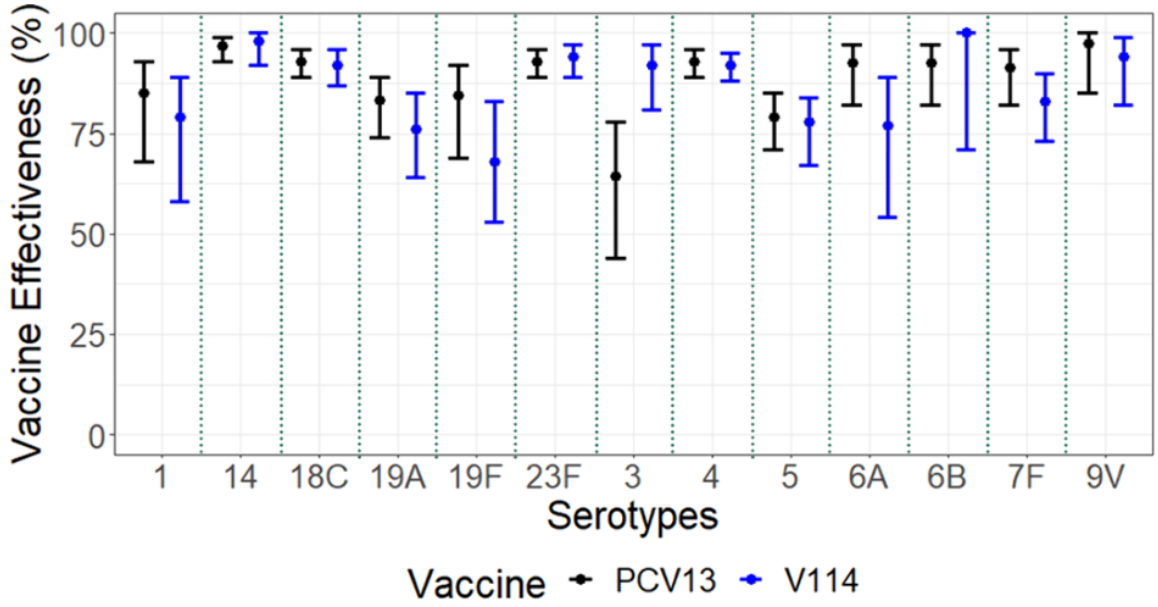
PREDICTING EFFECTIVENESS OF THE V114 VACCINE 2+1 REGIMEN AGAINST INVASIVE PNEUMOCOCCAL DISEASE IN A PEDIATRIC POPULATION

E-Posters Viewing
E-POSTER VIEWING: AS03.D. VACCINE EFFICACY (PHASE 3) AND EFFECTIVENESS – BACTERIAL AND ALL NON-VIRAL

Josiah Ryman[1], Jessica Weaver[2], Ka Lai Yee[1], Jeffrey Sachs[1]
[1]MSD, Quantitative Pharmacology And Pharmacometrics, Rahway, United States of America, [2]MSD, Center For Observational And Real-world Evidence, Rahway, United States of America

Backgrounds: Pneumococcal conjugate vaccines' (PCVs) strength of immune response across each serotype, as measured by antibody concentrations, varies by vaccine and may be reduced by increasing valency. Therefore, because clinical trials for novel PCVs lack efficacy endpoints, it is important to assess the impact of these vaccines by predicting their effectiveness against invasive pneumococcal disease (IPD). The objective of this work was to predict the serotype-specific effectiveness of V114 against IPD in a European Union (EU) pediatric population given a 2+1 regimen using a previously qualified method[1]. [1]Ryman (2022)
Methods: The first step was to estimate serotype-specific protective antibody concentrations (C_p) for each serotype in PCV13. Using serotype-specific antibody concentrations after primary series vaccination with placebo and PCV13 (in an EU pediatric population administered a 2+1 regimen), reverse cumulative distribution curves (RCDCs) were generated. These were combined with the known serotype-specific vaccine effectiveness values of PCV13[2] to estimate serotype specific C_p values. The second step predicted the vaccine effectiveness for each serotype using these C_p value estimates and the RCDCs of serotype-specific antibody concentrations (after primary series vaccination with placebo and V114). [2]Savulescu (2022)
Results: Observed and predicted vaccine effectiveness against IPD shown in figure below.



*Observed PCV13 effectiveness values are from an indirect cohort analysis[2]. PCV13 effectiveness values for serotypes 4, 18C, and 23F are an aggregate value of PCV7-common serotypes, and the serotype 5 effectiveness value is an aggregate of non-PCV7 serotypes.

Conclusions/Learning Points: V114 serotype-specific effectiveness against IPD in an EU pediatric

population (administered in a 2+1 dosing regimen) was predicted to be similar for most of the shared serotypes with PCV13, greater for serotype 3, and lower against the less common serotypes 6A and 19F.

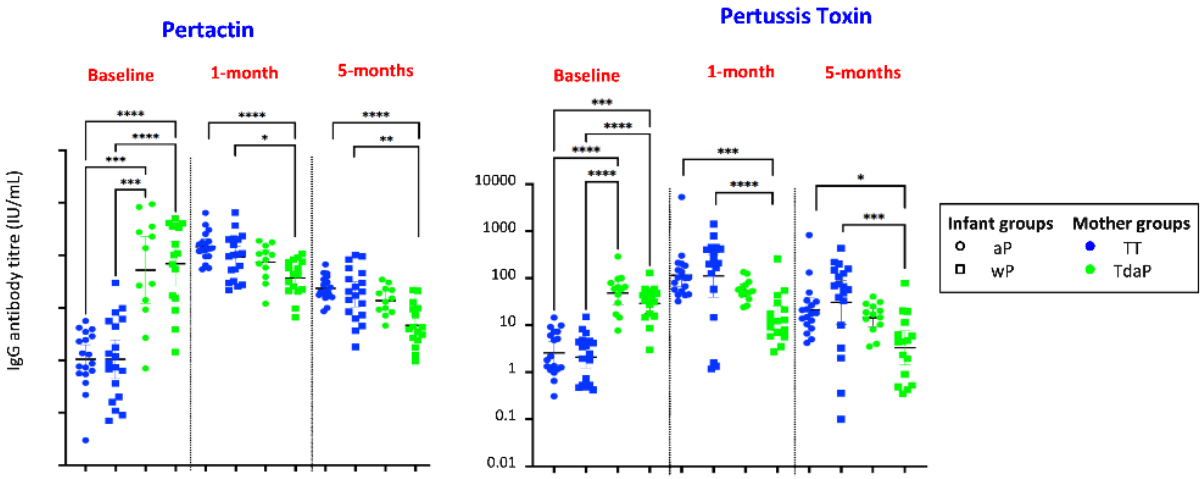
DOES MATERNAL PERTUSSIS IMMUNISATION DURING PREGNANCY IMPACT INFANT ANTIBODY RESPONSES TO SUBSEQUENT ROUTINE PERTUSSIS VACCINES?

E-Posters Viewing
E-POSTER VIEWING: AS03.D. VACCINE EFFICACY (PHASE 3) AND EFFECTIVENESS – BACTERIAL AND ALL NON-VIRAL

Anja Saso[1,2], Sophie Roetynck[2], Beate Kampmann[2,3]
[1]London School of Hygiene & Tropical Medicine, Faculty Of Infectious And Tropical Diseases, London, United Kingdom, [2]MRC Unit The Gambia, Vaccines & Immunity Theme, Banjul, Gambia, [3]London School of Hygiene and Tropical Medicine, Vaccine Centre, London, United Kingdom

Backgrounds: Replacement of whole-cell (wP) by acellular pertussis (aP) vaccines may be a key factor underlying recent resurgence in pertussis, especially in highly vaccinated populations. This has led to the implementation of additional pertussis boosters, including tetanus-diphtheria-aP (TdaP) during pregnancy. A concern, however, is potential blunting of infants' endogenous immune responses to subsequent routine vaccines. We conducted a randomised-control trial, the Gambian Pertussis study (GaPs), as part of PERtussIS COrrelates of Protection Europe (PERISCOPE) consortium, to investigate the immunogenicity of primary infant vaccination with aP versus wP vaccines, and the impact of maternal TdaP immunisation in The Gambia.
Methods: Samples of serology were collected from up to 342 infants until 9-months of age, at up to 5 time points pre-and post-completion of primary immunisation. Systemic vaccine-specific IgG was quantified using a fluorescent bead-based multiplex immunoassay; pertussis-toxin (PT) neutralisation and serum-bactericidal assays assessed antibody function.
Results: Preliminary analysis of an initial cohort demonstrated that infants born to TdaP-vaccinated mothers (versus tetanus-toxoid only) had: a)significantly higher pertussis-specific antibody responses at baseline prior to primary immunisation b)following primary vaccination, less prominent antibody increases from baseline, with the lowest anti-PT and anti-pertactin IgG levels observed at 1-and 5-months post immunisation in those who had received wP c)notably, no significant difference in PT-neutralising antibody
levels



Conclusions/Learning Points: This is the first mother-infant vaccine study of its kind on pertussis in a Sub-Saharan African setting. Our findings point to a blunting effect of maternal immunisation on infant pertussis antibody responses following primary vaccination, although patterns and functional relevance may vary between specific vaccine antigens, with clinical significance yet to be established. Formal in-

depth analysis of the entire cohort and correlation with data on cellular and mucosal antibody responses will be informative.

PV0184 / #852

POST HOC ANALYSIS OF IMMUNOGENICITY OF A 20-VALENT PNEUMOCOCCAL CONJUGATE VACCINE (PCV20) IN A 3-DOSE INFANT IMMUNIZATION SERIES BY AGE OF INFANT DOSE

Backgrounds: PCV20 was developed to expand pneumococcal disease protection. This report describes the immunogenicity of a PCV20 3-dose series in infants starting at 2 or at 3 months of age.
Methods: In this Phase 3 study (NCT04546425) conducted in Europe and Australia, infants were randomized to receive 3 doses of PCV20 or PCV13, with the first dose at ≥42-≤112 days of age. Primary results from this trial will be presented separately. A descriptive post hoc analysis was performed to summarize the immunoglobulin G (IgG) responses to PCV20 in subgroups who received Dose 1 at 42-74 days of age and Dose 2 at 85-134 days of age (2-4-month subgroup) or Dose 1 at 75-115 days of age and Dose 2 at 135-180 days of age (3-5-month subgroup). Both subgroups received Dose 3 (toddler dose) at 11-12 months of age.
Results: 660 infants were in the 2-4-month subgroup (PCV20, n=331; PCV13, n=329), 296 were in the 3-5-month subgroup (PCV20, n=140; PCV13, n=156). After PCV20 Dose 2, IgG geometric mean concentrations (GMCs) ranged from 0.03 µg/mL (serotype 6B) to 2.97 µg/mL (serotype 15B) in the 2-4-month subgroup and 0.05 µg/mL (serotype 6B) to 4.55 µg/mL (serotype 15B) in the 3-5-month subgroup. After PCV20 Dose 3, GMCs were 0.74 µg/mL (serotype 3) to 13.89 µg/mL (serotype 15B) and 0.71 µg/mL (serotype 3) to 11.81 µg/mL (serotype 15B) in the 2-4-month and 3-5-month subgroups respectively.
Conclusions/Learning Points: IgG responses observed after 2 doses of PCV20 were generally higher in the 3-5-month subgroup, but by the 3rd (toddler) dose there was a strong boost and the responses in both subgroups were similar PCV13 subgroups also showed this trend. This study was funded by Pfizer Inc.

Backgrounds: The 20-valent pneumococcal conjugate vaccine (PCV20) was developed to expand pneumococcal disease protection. This phase 3 study evaluated key safety and immunogenicity data of PCV20 with a 4-dose infant immunization series.
Methods: In this phase 3, double-blind study (NCT04382326) conducted in the United States and Puerto Rico, healthy infants were randomized equally to receive 4 doses of PCV20 or PCV13 at 2, 4, 6, and 12–15 months of age. Objectives included noninferiority of immunoglobulin G (IgG) geometric mean concentrations (GMCs;2-fold criterion) at 1 month after Dose 4 (co-primary) and Dose 3 (key secondary), and participants (%) with predefined IgG concentrations 1 month after Dose 3 (co-primary; 10% criterion). The 7 additional PCV20 serotypes were compared with the lowest result among vaccine serotypes in the PCV13 group for noninferiority evaluation. Other objectives included demonstration of opsonophagocytic activity (OPA) and boosting responses. Safety assessments included local reactions, systemic events, and adverse events.
Results: 1991 participants received Dose 1 (PCV20, n=1001; PCV13, n=990); 85% received all doses. For IgG GMCs 1 month after both Dose 4 and Dose 3, all 20 serotypes met noninferiority criteria. For the percentage of participants with predefined IgG concentrations after Dose 3, noninferiority was met for 8/13 matched serotypes and 6/7 additional serotypes; four serotypes narrowly missed the statistical noninferiority criterion. PCV20 elicited OPA responses after Doses 3 and 4, and booster responses after Dose 4. The safety profile of PCV20 was similar to PCV13.
Conclusions/Learning Points: A 4-dose infant series of PVC20 had a safety profile similar to PCV13 and elicited robust serotype-specific immune responses expected to protect against pneumococcal disease due to the 20 vaccine serotypes.

SHOULDER INJURY RELATED TO VACCINE ADMINISTRATION (SIRVA) IN PAEDIATRIC PATIENTS: A CASE SERIES

E-Posters Viewing
E-POSTER VIEWING: AS03.E. VACCINE SAFETY (POST LICENSURE)

Mel Addison[1,2], John Mallard[1,3], Hazel Clothier[1,3,4,5], Nigel Crawford[1,4,6], Jim Buttery[1,3,6]
[1]Murdoch Children's Research Institute, Saefvic, Parkville, Australia, [2]Royal Children's Hospital, Dermatology, Parkville, Australia, [3]Melbourne Children's Campus, Centre For Health Analytics, Parkville, Australia, [4]University of Melbourne, Paediatrics, Parkville, Australia, [5]University of Melbourne, School Of Population And Global Health, Parkville, Australia, [6]Royal Children's Hospital Melbourne, General Medicine, Parkville, Australia

Title of Case: SHOULDER INJURY RELATED TO VACCINE ADMINISTRATION (SIRVA) IN PAEDIATRIC PATIENTS: A CASE SERIES
Background: Shoulder injury related to vaccine administration (SIRVA) is a rare but serious adverse event following immunisation (AEFI) following improper vaccine administration too high in the shoulder. It characteristically presents as sudden onset shoulder pain and restricted movement within 48 hours of vaccination. Symptoms can last for months, impacting physical and mental health, and impacting activities of daily living. SIRVA is well recognised in adults but there is limited information on paediatric populations. We examined reports submitted to SAEFVIC, the vaccine safety surveillance service in Victoria, Australia, from 2007-2022 to identify cases of SIRVA in vaccinees over 12 months old and describe the occurrence and outcomes of SIRVA in paediatric vaccinees.
Case Presentation Summary: Among 66,661 AEFI reports received, 354 SIRVA reports were identified, of which 13 (3.7%) were in <18-year-olds (range 1-16, median 12 years); 8 females and 5 males. Median time to symptom resolution was shorter in <18-year-olds (45.5 days) compared with adults (92.5 days, [p=0.01]).
Learning Points/Discussion: Reports of paediatric SIRVA were low, despite the volume of routine vaccines administered during childhood. Influencing factors may include developing shoulder anatomy, positioning during vaccination, immuniser experience, and, in young children, inability to fully communicate their symptoms. SIRVA should be considered as a differential diagnosis in recently vaccinated children presenting with persisting shoulder pain and restricted movement of the vaccinated limb , with timely diagnosis and treatment important to minimise symptom duration.

INFANT VACCINATION AGAINST PERTUSSIS IN ARGENTINA: PARENT-REPORTED OUTCOMES ON REACTOGENICITY, IMPACT ON DAILY ROUTINE AND SATISFACTION AFTER PENTAVALENT WHOLE-CELL OR HEXAVALENT ACELLULAR PERTUSSIS VACCINES

E-Posters Viewing
E-POSTER VIEWING: AS03.E. VACCINE SAFETY (POST LICENSURE)

Angela Gentile[1], Vanesa Castellano[1], Anabella Pacchiotti[1], Mariela Del Pino[1], Lucía Romero Bollon[2], Micaela Lieste[2], Mercedes Deluca[2], Juan Vargas-Zambrano[3]
[1]Ricardo Gutiérrez Children´s Hospital, Epidemiology, Buenos Aires, Argentina, [2]Stamboulian, Vaccines Services, Buenos Aires, Argentina, [3]Sanofi, Medical, Lyon, France

Backgrounds: In Argentina, a pentavalent whole-cell pertussis vaccine is used in the National Immunization Program, however hexavalent acellular vaccines are available in the private market. The objetive was to describe parent or guardians´ perceptions on reactogenicity, daily routine and satisfaction after a 1st or 3rd dose of a DTwP-Hib-HB plus IPV (wP-group) or DTaP-IPV-HB-Hib vaccine (aP-group; Hexaxim) in infants.
Methods: Prospective observational study. Parents/guardians of infants attending vaccination centers in Buenos Aires city were asked to fill out an online 7-day post vaccination questionnaire. Descriptive analyses of study variables were carried out.
Results: Five-hundred and thirty parents/guardians answered the questionnaire for wP-group (276 1st and 254 3rd dose) and 541 for aP-group (289 1st and 252 3rd dose). The percentage of parents/guardians referring solicited reactions by dose are shown in table 1. Negative impact on daily life in wP-group and aP-group were, respectively: social activities 36%, 20%; routine 48%, 24%; mood 39%, 23%; vitality 47%, 24%; sleep 50%, 30%; and appetite 22%, 7%. Parents satisfaction with the vaccination process (very satisfied or satisfied) was 96% and 98% for wP-group and aP-group respectively. Table 1.

Adverse Event	Vaccine Dose	Percentage of AE (%)	
		wP-group	aP-group
Pain	1st	92.7	32.3
	3rd	72.0	23.8
Redness	1st	53.4	18.4
	3rd	49.6	26.6
Swelling	1st	65.9	11.2
	3rd	59.1	20.6
Fever	1st	55.8	17.1
	3rd	41.4	12.3
Irritability	1st	75.8	60.4
	3rd	69.4	42.0
Vomiting	1st	18.9	15.3
	3rd	11.5	6.4
Loss of appetite	1st	34.2	19.8
	3rd	38.2	17.5
Drowsiness	1st	43.2	34.0
	3rd	32.3	18.7

Conclusions/Learning Points: Reported reactogenicity and impact on family daily routine

was higher in infants receiving wP-pentavalent than aP-hexavalent vaccines. Both groups showed a high level of satisfaction with the vaccination process.

SAFETY AND EFFICACY OF ONE VERSUS TWO DOSES OF THE LIVE ATTENUATED VARICELLA VACCINE IN CHILDREN THAT HAVE UNDERGONE HEMATOPOIETIC STEM CELL TRANSPLANTATION

E-Posters Viewing
E-POSTER VIEWING: AS03.E. VACCINE SAFETY (POST LICENSURE)

Yoon Kyung Cho[1], Kyu Ri Kang[2], Gwanglok Kim[3], Ye Ji Kim[1,2], Hyun Mi Kang[1,2], Jin Han Kang[2]
[1]Seoul St. Mary's Hospital, The Catholic University of Korea, Department Of Pediatrics, Seoul, Korea, Democratic People's Republic of, [2]Vaccine Bio Research Institute, Research And Development, Seoul, Korea, Republic of, [3]GC Biopharma, Department Of Research And Development, Yongin, Korea, Republic of

Backgrounds: Life threatening varicella zoster virus (VZV) infections can occur after hematopoietic stem cell transplantation (HSCT); therefore, prevention is important in these patients. However, fatal cases of vaccine-induced disseminated VZV infections have been occasionally reported with LAVV after HSCT, and low response rates at around 65% have been observed, without a clear benefit of a second dose. Due to the lack of data in children, we aimed to investigate safety and immunogenicity of the live attenuated varicella vaccine (LAVV) in children that underwent HSCT after administration of the MAV/06 strain LAVV.
Methods: This was a prospective study of children <19 years old that were seronegative for VZV IgG post-HSCT. Varicella-like rash within 3-weeks of immunization, and herpes-zoster-like blisters were monitored at each monthly visit after immunization. ELISA and FAMA assays were carried out 4-12 weeks after dose-1 and after dose-2 in children that were seronegative after dose-1.
Results: A total of 45 children were included in this study. No varicella-like rash of herpes zoster-like blisters were observed in any of the patients. A total 71.1% (n=32/45) achieved seroconversion after 1-dose. A second dose was administered in children that were seronegative after the 1st dose. Overall, a total 96.3% (n=43/45) achieved seroconversion after 1-dose or 2-doses of the MAV/06 LAVV. Two patients that did not achieve seroconversion after the 2nd dose received a 3rd dose of the MAV/06 LAVV, however, remained seronegative.
Conclusions/Learning Points: The MAV/06 LAVV post-HSCT is safe and effective in inducing immunity against VZV in children.

ESTIMATING HOSPITAL RATES OF SERIOUS ADVERSE EVENTS IN CHILDREN IN INDIA- ARE WE MISSING THESE IN THE AEFI SURVEILLANCE REPORTING?

E-Posters Viewing
E-POSTER VIEWING: AS03.E. VACCINE SAFETY (POST LICENSURE)

Manoja Das[1], Apoorva Sharan[2], Ramesh Poluru[2], Neeraj Kashyap[2], Narendra Arora[2]
[1]The INCLEN Trust International, Child Health, New Delhi, India, [2]The INCLEN Trust International, Public Health, New Delhi, India

Background: The adverse events following immunization (AEFI) surveillance in India suffers from underreporting, bias and quality challenges. The lack of background rates for key AEFI events further challenges the interpretation. This multisite network study targeted to estimate the baseline hospital outcome rates for the selected AEFI and control conditions/outcomes, document the vaccine exposure status and investigate the association between select vaccine-event pairs. The current abstract presents the hospital event rates and vaccine exposure status.
Methods: The MAASS network undertook a prospective observational surveillance study and collected data over a 29-month period (November 2017- March 2020) at 22 (15 public and 7 private) hospitals in India. All hospitalized children aged 1-24 months were screened to identify the conditions of interest and for the eligible ones, detailed data were collected using standardized tools. Seven AEFIs conditions including acute demyelinating encephalomyelitis (ADEM), aseptic meningitis, Guillain-Barré syndrome (GBS), Kawasaki disease, intussusception, seizures, and thrombocytopenia; and four control conditions including dengue, malaria, sepsis and urinary tract infections (UTI) were targeted.
Results: A total of 90,147 age-eligible children were screened and 8,362 definite cases were documented. The event rates for AEFIs were: ADEM- 5.5, aseptic meningitis- 424.9, GBS-8.9, Kawasaki disease-43.4, intussusception-725.5, seizure-4946.6, and thrombocytopenia-262.9; and for the non-AEFI control conditions were: dengue-443.7, malaria-140.9, sepsis-1458.7, and, & UTI-815.3 cases per 100,000 hospitalized children aged 1-24 months. Standardized case definitions were met for > 90% of dengue, thrombocytopenia, intussusception, and malaria cases, while <50% of aseptic meningitis and UTI cases met the criteria. Vaccine exposure information was obtained for 89% of the cases and 42% had exposure within four weeks.
Conclusions/Learning Points: These findings address a critical evidence gap and provide pre-pandemic background rates for potential AEFIs for vaccine safety surveillance purpose.

USE OF MOBILE TECHNOLOGY FOR THE REPORT ON PHARMACOVIGILANCE OF VACCINES IN PANAMA

E-Posters Viewing
E-POSTER VIEWING: AS03.E. VACCINE SAFETY (POST LICENSURE)

Rodrigo Deantonio[1], Tirza De Leon[1,2], Yostin Añino Ramos[3], Natalia Vega[1], Laura Prada[1], Gabriel Rebollon[1], Xavier Saez-Llorens[1,4]
[1]CEVAXIN, Centro De Vacunación E Investigación, Panama, Panama, [2]Hospital Materno Infantil José Domingo De Obaldía, Infectious Diseases, David, Panama, [3]Universidad de Panama, Biostatistics, Panama, Panama, [4]Hospital del Niño Dr. José Renán Esquivel, Sistema Nacional De Investigación At Secretaria Nacional De Ciencia Y Tecnologia, Panama, Panama

Backgrounds: Opportune reporting of adverse reactions following immunization is a priority in the context of the Expanded Program on Immunizations (EPI) worldwide. We aimed to validate the use of a mobile app to record and monitor the adverse events and reactions after immunization and compare its performance against paper-diary.
Methods: We conducted a translational, observational cohort study of children/parents, pregnant women, or older adults to evaluate the use of an electronic-diary mobile-app TrialPal® by IntegraIT (e-diary) compared to a paper-diary as reporting instrument for adverse events and reactions after immunization. A pilot phase with focus groups was followed by an implementation/ vaccination phase. The participants were subjects eligible to receive vaccination from the Expanded Program on Immunizations (EPI) of Panama. The following outcomes were assessed within the next 7 days following immunization: timeliness, completeness, compliance, and user preference. User preference was evaluated by the participants through a confidential survey. Descriptive statistics and t-test and Chi-square tests were used to analyze the difference between the groups.
Results: A total of 362 participants were screened, and a total of 180 participants were included, as follows: 79 children/parents, 21 pregnant women, and 80 older adults. Overall, an opportune real-time reporting was observed through the e-diary, without differences among study groups. Children/parents were more compliant than adults, and compliance was better with the e-diary. A significant number of symptoms were reported in the e-diary than in the paper diary. The experience using both diaries was similar according to the satisfaction survey, but e-diary was a preferred option to report.
Conclusions/Learning Points: Adverse reactions to immunization through mobile applications might be a suitable alternative for pharmacovigilance in clinical trials or in real world settings.

ATTENUATION FAILURE LEADING TO MORBIDITY AND MORTALITY CASES IN IMMUNOCOMPETENT CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS03.E. VACCINE SAFETY (POST LICENSURE)

Hyun Mi Kang[1,2], Kyu Ri Kang[2], Ye Ji Kim[1,2], Jin Han Kang[2], Soo-Young Lee[1,2]
[1]Seoul St. Mary's Hospital, The Catholic University of Korea, Department Of Pediatrics, Seoul, Korea, Democratic People's Republic of, [2]Vaccine Bio Research Institute, Research And Development, Seoul, Korea, Republic of

Backgrounds: Problems with viral attenuation have led to pathogenic varicella zoster virus (VZV) vaccine strains causing varicella-like rash and herpes zoster in immunocompetent children post-immunization. Therefore, discrete monitoring post-licensure is extremely important. This study aimed to differentiate between wild versus vaccine strain in children suspicious of vaccine-related VZV infections and investigate causes for attenuation failure.
Methods: Vesicle fluid, blood, or cerebrospinal fluid (CSF) samples from cases suspicious of vaccine-related VZV infections were collected prospectively. VZV DNA was isolated and ORF 22, ORF 62, and six SNPs exclusively only identified in vaccine S were sequenced in the patient's samples, and in vaccines A, B, C, and S.
Results: During the study period, 14 patients were diagnosed with vaccine-related VZV infections. Of these, 71.4% (n=10/14) presented as herpes zoster, all involving the ipsilateral C5-7 dermatome of the injection site, and 50% (n=7/14) had samples available for DNA isolation and sequencing. A total 85.7% (n=6/7) were 100% genotypically identical to vaccine S's pOKA strain which the patients were all found to have received, whereas one identified as wild type pOKA strain. Disseminated VZV infection occured in one case, which progressed to hemophagocytic lymphohistiocytosis and died of pulmonary hemorrhage within two months of immunisation. VZV DNA was isolated from his vesicle fluid, blood, and CSF, and was identical to vaccine S's pOKA VZV strain. Compared to wild type pOKA, in vaccines A, B, and C, two SNPs in ORF62 caused synonymous mutations in the amino acid sequence of VZV's Immediate-Early Protein 62 (IE62), however, vaccine S did not have acquire these two mutations during attenuation.
Conclusions/Learning Points: Attenuation failure may result in not only VZV related rash or herpes zoster but disseminated VZV infections leading to mortality.

PHARMACOVIGILANCE: A REVIEW OF SERIOUS ADVERSE EVENTS IN PAEDIATRIC VACCINE TRIALS IN AFRICA FROM 2000 TO 2015

E-Posters Viewing
E-POSTER VIEWING: AS03.E. VACCINE SAFETY (POST LICENSURE)

Joy Githua[1,2], Joseph Mbuthia[2], Edwina Oboke[3], Jay Berkley[4]
[1]Kenya Medical Research Institute, Clinical Research, Nairobi, Kenya, [2]Gertrude's Children's Hospital, Infectious Disease(paediatrics), Nairobi, Kenya, [3]Gertrude's Children's Hospital, Research, Nairobi, Kenya, [4]KEMRI-Wellcome Trust, Infectious Disease(paediatrics), Kilifi, Kenya

Backgrounds: The World Health Organization (WHO)'s defines severe adverse events (SAEs) as "any untoward medical occurrence that at any dose may result in death or requires inpatient hospitalization or prolongation of existing hospitalization, results in persistent or significant disability/incapacity or is life-threatening". SAEs are an important component of adverse events following immunization (AEFIs) usually monitored for ensuring the safety of vaccines. Scarce data exist on the occurrence of severe adverse events (SAEs) in paediatric vaccine trials.
Methods: A systematic review was performed. Severe Adverse events were tabulated and the Rates per thousand child days were calculated in each arm of the trial. SAE rate ratios were calculated and a meta-analysis was performed
Results: Out of a total of 6459 trials listed from the search, 30 were found suitable for analysis. There were 34560 children enrolled in the 30 studies, 21462 (62%) of them in the trial arm. A wide range in SAE rates was noted and thought largely to be due to the heterogeneity of the trials and the diverse geographical region. The classification and reporting of SAEs were not standardised. Larger studies were noted to have lower SAE rates. The pooled SAE rate in the control arm participants in the 30 studies was 0.11/1000 child days (95% CI 0.06-0.18).
Conclusions/Learning Points: Harmonized standard definitions and grading systems are key in the reporting of SAEs to allow monitoring of the safety of participants in clinical trials. The pooled rate from this review may serve as a reference for future paediatric vaccine trials in Africa.

PV0193 / #1226

POST-MARKETING ACTIVE SURVEILLANCE OF ADVERSE EVENTS FOLLOWING MEN B PEDIATRIC IMMUNIZATION (AEFIS) AND PROPHYLACTIC PARACETAMOL ADMINISTRATION: DATA FROM APULIA REGION (ITALY), 2019-2022

Pasquale Stefanizzi[1], Lorenza Moscara[1], Domenica Ancona[2], Paolo Stella[2], Andrea Martinelli[2], Sabrina Lattanzio[1], Giacomo Riformato[1], Federica Toro[1], Silvio Tafuri[1]
[1]University of Bari Aldo Moro, Interdisciplinary Department Of Medicine, Bari, Italy, [2]Apulia Region, Health Department, Bari, Italy

Backgrounds: The perceived risk of adverse events is the most important threat for implementing successful vaccination programs, because it may cause hesitancy, delays or refusal of vaccination. Apulia is a large region in the South of Italy (4,000,000 inhabitants) where meningococcal B vaccine (Bexsero is offered free-of-charge to all newborns since 2014.
Methods: In order to better monitor the safety of vaccine the Apulian Regional Health Authority implemented an active surveillance program of adverse events following the first dose of meningococcal b immunization. The project was carried out in 12 vaccination clinics of the 6 Regional Districts since 2019 to 2022. With prior consent, children in the first year of life admitted to the vaccination centers adhering to the program for the first dose of the anti-MenB vaccine were enrolled. The parents of the children were given the "Post-vaccination diary" for reporting the adverse events that arose in the following 7 days and were phoned after this time. All reported AEFIs detected were included in the National Pharmacovigilance Network (RNF); the causality assessment algorithm was applied to the serious ones
Results: All reported AEFIs detected were included in the National Pharmacovigilance Network (RNF); the causality assessment algorithm was applied to the serious ones. 4362 children were enrolled; 4274/4362(98.0%) completed post-vaccination follow-up. 3283 AEFIs are registered with a reporting rate of 76.8x100 follow up. Only 23 AEFIs(reporting rate 0.5x100 follow up) were serious: 19 cases of hyperpyrexia, 3 cases of hypotonic-hyporesponsive episode and 1 case of seizure. All adverse events were resolved. The prophylactic paracetamol administration is associated with a significant reduction in these events ((OddsRatio 0.79; IC95:0.68–0.93; p<0.01)
Conclusions/Learning Points: The post-marketing safety profile in our study reinforces pre-licensure data and no emerging signals were detected

PV0194 / #721

IMPACT OF VACCINES ON STAPHYLOCOCCUS AUREUS COLONIZATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS03.E. VACCINE SAFETY (POST LICENSURE)

Maria Tsirigotaki, Emmanouil Galanakis
MEDICAL SCHOOL, University Of Crete, HERAKLION, Greece

Backgrounds: Concerns regarding vaccine effects on microbial ecology have led to interest in the non-targeted effects of vaccinations.Our aim was to systematically review the literature related to the impact of vaccines on S.aureus carriage.
Methods: We conducted a systematic search of MEDLINE, Scopus and clinical trials.gov for studies that assessed vaccine effects on S. aureus carriage in children and adults using predefined inclusion and exclusion criteria. Generic inverse variance meta-analysis was done using random-effects models.
Results: Of 1,686 studies screened, 34 were eligible for inclusion, 22 were observational and 12 randomized controlled studies (RCTs). 88.2% (30/34) provided data on pneumococcal conjugate vaccines (PCV), 23.5% on influenza vaccines (8/34) and 6% on other vaccines (2/34). Most studies tested nasopharyngeal specimens (82.3%, 28/34). Among children aged more than 18-24 months, evidence suggested no effect of PCV on S. aureus colonization [2 RCTs, pooled OR 1.09 (95% CI 0.94-1.25), p 0.25; 7 observational studies, pooled OR: 1.02 (95% CI 0.83-1.25), p 0.86]. A transient increase in S. aureus carriage in PCV-vaccinated infants 9-15 months was shown [2 RCTs, pooled OR 1.11 (95% CI 1.00-1.23), p 0.06; 4 observational studies, pooled OR 1.64 (95% CI 1.00-2.68), p 0.05]. A reduction in S. aureus carriage was observed after influenza vaccination [4 observational studies; OR 0.85 (95% CI 0.78-0.94), p 0.0001]. Based on the GRADE criteria, the quality of evidence was considered low and very low.
Conclusions/Learning Points: Evidence did not suggest long-term effects of pneumococcal vaccinations on S. aureus nasopharyngeal carriage in children, however transient niche changes may occur in infants. Influenza vaccination was related to decreased rates of S. aureus carriage. Data regarding other vaccines is scarce. Further research and ongoing surveillance are needed to monitor colonization changes.

DETERMINING PRIOR DENGUE SEROSTATUS AMONG CHILDREN RECEIVING DENGVAXIA IN PHILIPPINES BY A NONSTRUCTURAL PROTEIN 1-BASED ENZYME-LINKED IMMUNOSORBENT ASSAY

E-Posters Viewing
E-POSTER VIEWING: AS03.E. VACCINE SAFETY (POST LICENSURE)

Yu-Ching Dai[1], Ava Sy[2], Mario Jiz[3], Jih-Jin Tsai[4], Joan Bato[2], Mary Quinoñes[2], Mary Reyes[2], Wei-Kung Wang[1]
[1]John A. Burns School of Medicine, University of Hawaii at Manoa, Tropical Medicine, Medical Microbiology And Pharmacology, Honolulu, United States of America, [2]Research Institute for Tropical Medicine, National Reference Laboratory For Dengue And Other Arbovirus, Virology Department, Muntinlupa City, Philippines, [3]Research Institute for Tropical Medicine, Immunology Department, Muntinlupa City, Philippines, [4]KaohsiunMedical University Hospital, Department Of Internal Medicine,, Kaohsiung, Taiwan

Backgrounds: The four serotypes of dengue virus (DENV) cause the most important arboviral disease in humans. Dengvaxia, a chimeric yellow fever tetravalent dengue vaccine and the first licensed dengue vaccine, was recommended for DENV-seropositive individuals aged 9-45 years due to increased risk of hospitalization and severe dengue among DENV-seronegative recipients. While considerable efforts have been made to develop serological test to determine DENV serostatus for pre-vaccination screening, few studies focused on determining prior DENV serostatus among Dengvaxia recipients, including >830,000 children in Philippines, to facilitate assessing the safety and effectiveness of Dengvaxia in the post-licensure period.
Methods: We evaluated the performance of a DENV1-4 nonstructural protein 1 (NS1) IgG enzyme-linked immunosorbent assay (ELISA) using well documented control samples (n=371) of different flavivirus infections including those >20 years after DENV infection, and a yellow fever virus (YFV) NS1 IgG ELISA in 199 samples from the fever surveillance program in Philippines. RT-PCR and Panbio IgM were used to determine acute dengue.
Results: The DENV1-4 IgG ELISA had a sensitivity/specificity of 97.0/99.4% and can be used to determine prior DENV serostatus among Dengvaxia recipients (n=100) with or without acute dengue, up to 30 months after vaccination. The overall detection rate of anti-YFV NS1 IgG among Dengvaxia recipients was 40%, suggesting the difficulty of using it as a biomarker of Dengvaxia. Previous DENV-naïve children of Dengvaxia recipients (10/23) had a significantly higher rate of symptomatic DENV breakthrough infection than previous DENV-immune children (7/53) (p=0.004, Fisher's exact test).
Conclusions/Learning Points: Our DENV1-4 NS1 IgG ELISA and the algorithms developed can determine prior DENV serostatus among Dengvaxia recipients during both DENV breakthrough infection and non-dengue period to assess the long-term safety and effectiveness of Dengvaxia in the real world.

IMPACT OF COVID 19 PANDEMIC ON PARENTS′ ADHERENCE, KNOWLEDGE AND ATTITUDES TOWARDS CHILDHOOD VACCINATION PROGRAM, RIYADH, SAUDI ARABIA

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Khalaf Aljumah
MOH, Pharmacy, Riyadh, Saudi Arabia

Backgrounds: Parents' knowledge, adherence and attitudes towards immunization can be affected by covid 19 pandemic. previous studies revealed good adherence, knowledge, and positive attitudes towards childhood immunization in Saudi Arabia before covid 19 pandemic.
Methods: A cross-sectional study was conducted during November 2022 in Riyadh, Saudi Arabia. convenient method of sampling was adopted. carents with children of 0-2 years old were invited to participate. Data was collected through face- to -face interview method using Arabic validated questionnaire to collect demographic data, education level, time of vaccination, adherence, knowledge about childhood vaccination program and attitudes of the parents. Informed consent was obtained from parents or companions to conduct adherence evaluation following immunization visit. A patient's information sheet was handed to the companion for introduction of the study. Descriptive statistics were used to describe all variables
Results: A total of 260 parents were participated. The mother was interviewed in 99 % of cases, Infant's ages ranged between 2-24 months (mean 10.2 months, standard deviation (SD) 8.1). 33 years and 41 years was the mean age of mothers and fathers respectively. Parents had good adherence to vaccination program reached up to (89%) on time without delay. Main reason for not-adhere to vaccination program was lack of education. poor knowledge was documented about the importance of administration of multiple doses of the same vaccine to child immunity (44.3 %), administration of multiple vaccines at the same time has no negative impacts on child immunity (50%).
Conclusions/Learning Points: No significant impact of covid 19 pandemic on parents' adherence, knowledge, and attitudes towards childhood vaccination program in Saudi Arabia, either positive or negative change in adherence were not reported after covid 19 pandemic.

Backgrounds: Maternal immunization is an excellent approach for preventing severe disease and mortality in young infants. However, despite proven benefits, coverage of maternal vaccines remain suboptimal. We aimed to understand the drivers that influence Tdap and Influenza maternal vaccines acceptance in pregnant women.
Methods: A web-based cross-sectional quantitative study was conducted in pregnant women attending ANC services at a referral hospital and primary care centres in Barcelona, Spain. Pregnant women of any maternal age and gestational age were invited to participate. The online survey instrument covered three key domains of vaccine hesitancy and acceptance: contextual, individual and group influences, and vaccine-specific issues.
Results: A total of 302 pregnant women were enrolled between June 2021 and March 2022. Most women (>80%) were aware of recommendation of maternal vaccines in pregnancy, and of the protection conferred to infants in early life. On perceptions towards vaccination in pregnancy, 84% of women considered maternal vaccines as safe and important for the baby, while 60% reported so for themselves. On factors influencing decisions on maternal vaccination, evidence on vaccine safety and a recommendation from a health care professional, particularly midwives and obstetricians, were recognized as the greatest facilitators for maternal vaccine uptake, while the fear of harming the foetus and not having been offered maternal vaccination by a health professional were the most significant barriers reported for rejecting vaccination.
Conclusions/Learning Points: Despite recognition among pregnant women of the benefits associated with maternal immunization, perceived risks for the infants and inadequate information about vaccines safety may hinder vaccine decisions. Health professionals are key drivers for maternal vaccination acceptance.

INCREASED INFLUENZA VACCINATION COVERAGE IN IMMIGRANT CHILDREN AND AGE EFFECT MODIFICATION IN CANADA

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Yue Chen
University of Ottawa, School Of Epidemiology And Public Health, Ottawa, Canada

Backgrounds: Influenza (flu) vaccination can prevent flu and reduce the risk of its complications and is recommended for almost all Canadians aged 6 months or older. The aim of the study was to determine the rate of flu vaccination in adolescents and age-related difference between immigrants and non-immigrants.
Methods: The analysis was based on data from 10,542 Canadian adolescents 12-19 years of age who participated in a national survey conducted in 2017-18. Each participant was asked if he/she had a flu shot during the past 12 months and was an immigrant or not. The rate of flu vaccination was calculated according to immigration status and covariates. All the point and variance estimates accounted for complex survey design including multiple stratification, clustering, and unequal selection probability.
Results: The overall rate of flu vaccination was 21.5% and the proportion of immigration was 15.4%. The rate of flu shot was higher in immigrants than in non-immigrants (25.5%% vs. 20.7%, $p<0.01$) and decreased with age (12-14 years: 24.7%; 15-17 years: 21.5%; 18-19 years:17.1%; $p<0.01$). The odds ratio for flu shot in association with immigration status was 1.37 (95% confidence interval: 1.17-1.61) after adjustment for age and sex. The difference in the flu shot rate between immigrants and non-immigrants was greater in the younger than older age groups and disappeared in the 18-19-year age group (12-14 years: 34.4% vs. 23.4%; 15-17 years: 28.1% vs. 20.3%; 18-19 years: 16.2% vs. 17.4%), and the age effect modification was statistically significant (Breslow-Day test for homogeneity of odds ratio: $p<0.01$).
Conclusions/Learning Points: The rate of flu vaccination was low in adolescents, especially for native Canadians, and the effect of immigration status on flu vaccination was only observed in children but not in young adults.

COVID-19 VACCINE ACCEPTANCE AMONG NORTH INDIAN PREGNANT WOMEN

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Manoja Das[1], Sabiya Mirza[2], Lalan Bharti[3], Neeta Sagar[4], Nilanjan Saha[2]
[1]The INCLEN Trust International, Child Health, New Delhi, India, [2]Jamia Hamdard University, Centre For Translational & Clinical Research Pharmacology And Clinical Research, New Delhi, India, [3]Jag Pravesh Chandra Hospital, Department Of Pediatrics, New Delhi, India, [4]Jag Pravesh Chandra Hospital, Department Of Obstetrics & Gynaecology, New Delhi, India

Background: The COVID-19 vaccination coverage for pregnant women has been lower than the general population in India and other developed countries. This study documented the vaccine acceptance, hesitance and knowledge, attitude and practices of pregnant women on COVID-19 vaccine and vaccination.
Methods: This cross-sectional study included 540 pregnant women attending an antenatal clinic.
Results: Majority (62.4%) of the participants were aged 18-25 years. 82.6% of the participants received two doses, 13% received one dose, 1.6% received one booster dose and 2.7% didn't receive any COVID-19 vaccine dose. Table-1 summarizes the profile, period and hesitancy-related information for the participants.

Table 1: Profile of vaccinated pregnant women and vaccine hesitancy status

Parameter	One dose (n=70)		Two doses (n=446)		2 primary + 1 booster dose (n=9)		Pooled (n=525)	
Vaccination before/during pregnancy	Before	During	Before	During	Before	During	Before	During
Vaccinated pregnant women, n (%)	22 (31.4)	48 (68.6)	168 (37.7)	278 (62.3)	4 (44.4)	5 (55.6)	194 (37)	331 (63)
Hesitancy for vaccination, n (%)	22 (31.4)	38 (54.3)	107 (24)	192 (43)	3 (33.3)	5 (55.6)	132 (25.1)	235 (44.8)
Concern about serious side effects, n (%)	21 (30)	48 (68.6)	157 (35.2)	262 (58.7)	3 (33.3)	5 (55.6)	181 (34.5)	315 (60)

The 15 unvaccinated participants cited safety concerns as the primary reason. Several factors influenced vaccine acceptance negatively (new vaccine, safety concerns, pregnancy complications and infection burden) and positively (counseling by healthcare provider). Among the unvaccinated and partially vaccinated participants, the concerns were: efficacy, safety and lack of information.

Conclusions/Learning Points: Although the COVID-19 vaccination status was high among these pregnant women, there was sizable vaccine hesitancy and concerns about vaccine safety. Counseling by the healthcare providers was the key factor for getting the vaccination by them.

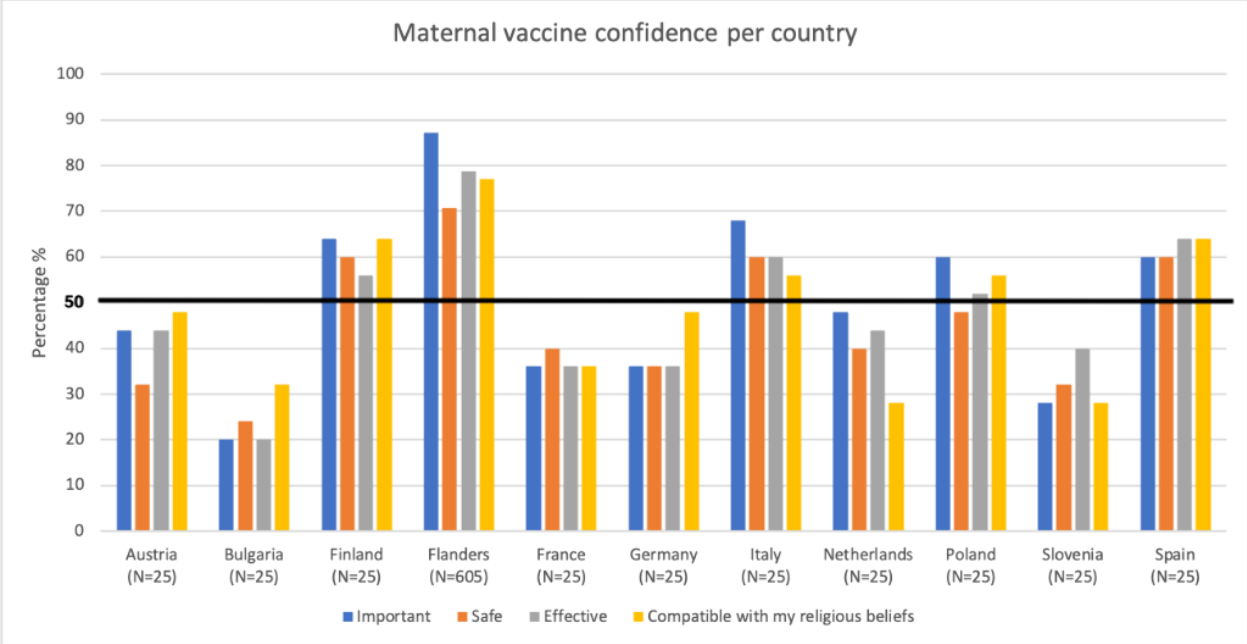
PV0200 / #1589

CONFIDENCE TOWARDS VACCINATION DURING PREGNANCY VARIES WIDELY ACROSS THE EUROPEAN REGION

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Larissa De Brabandere, Greet Hendrickx, Pierre Van Damme, Kirsten Maertens
University of Antwerp, Vaccine & Infectious Disease Institute, Wilrijk, Belgium

Backgrounds: Pregnant women and their offspring are at risk for infectious disease-related complications. To better protect this target group, the maternal vaccination strategy has been developed. Despite the proven benefit and the broad implementation of this vaccination strategy, there still exists a significant amount of hesitancy towards maternal vaccination policies. Our study compared maternal vaccine confidence in 11 European countries, including Flanders (Belgium).
Methods: A validated survey including questions on confidence towards maternal vaccination was spread via ORB International in 10 European countries (N=25/country) between March 29th and April 6th, 2022. Afterwards, surveys were distributed via well-baby clinics in Flanders (Belgium) between October 14th and 26th, 2022 (N=605). All the participants were either pregnant or gave birth in the last two years.
Results: In European countries like Austria, Bulgaria, France, Germany, the Netherlands and Slovenia, confidence in maternal vaccination is low (<50%), with the lowest confidence registered in Bulgaria, the only country included in the survey without a maternal vaccination program in place. Additionally, in Austria, France, Slovenia and the Netherlands, a WHO survey showed that the likelihood of health care practitioners (HCPs) recommending maternal influenza and/or COVID-19 vaccination is equal to or lower than 85%, which is lower than in other countries included in the survey (>85%) (https://health.ec.europa.eu/system/files/2022-11/2022_confidence_rep_en.pdf). In other regions like Flanders (Belgium), Finland, Italy and Spain, the belief that maternal vaccination is important, safe and effective is higher (respectively 64.0-87.1%; 60.0-70.7%; 56.0-78.7%). For Flanders (Belgium) is this in line with maternal vaccination coverage measured in 2020 (https://www.laatjevaccineren.be/vaccinatiegraadstudie).



Conclusions/Learning Points: Confidence in maternal vaccination varies widely across Europe. The implementation of clear-cut, scientifically-based maternal vaccination programs and vaccine training of HCPs could further increase the willingness of pregnant women to get vaccinated.

DETERMINANTS OF HUMAN PAPILLOMAVIRUS VACCINE HESITANCY IN PEDIATRICS

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Nicole Dinescu-Munoz[1], Andrea Lafnitzegger[1], Alyssa Clare[2], Jennifer Takagishi[1], Sara Garcia[1], Farina Klocksieben[3], Claudia Gaviria-Agudelo[4]
[1]University of South Florida Morsani College of Medicine, Pediatrics, Tampa, United States of America, [2]University of South Florida, Pediatrics, Tampa, United States of America, [3]University of South Florida College of Medicine, Department Of Research, Tampa, United States of America, [4]University of South Florida Morsani College of Medicine, Pediatric Infectious Diseases, Tampa, United States of America

Backgrounds: The human papillomavirus (HPV) vaccine has the potential to protect against HPV-related cancers. Despite this, about 23% of parents across the United States are hesitant to vaccinate their child against HPV. Parental vaccine hesitancy (VH) is strongly associated with adolescents not receiving HPV vaccination. Validated measurements of vaccine-specific hesitancy are sparse in current literature. We aim to assess the impact of an educational video on parents' attitudes towards the HPV vaccine using a validated HPV vaccine hesitancy scale (VHS) at two university-associated pediatric clinics.
Methods: Inclusion criteria included parents of patients aged 9 to 17 who had not received their HPV vaccine. Participants completed an identical VHS prior to and directly after observing an educational video on the HPV vaccine. Mean VH scores were compared pre- and post-educational video. Responses were based on a 4-point Likert scale, with higher scores indicating greater hesitancy.
Results: 26 participants completed the VHS. Likelihood to vaccinate pre-intervention was 73.1% and post-intervention was 76.9%. The VH scores were compared by calculating the overall mean pre- and post-intervention score for the 9 questions and across each item. Out of a maximum of 45 points, the pre-intervention VH score was 20.2 and the post-intervention score was 19.3 (a difference of 0.9, p-value 0.233). VH scores across each item surveyed decreased post-intervention except for the statements regarding "how long the vaccine has been around to be sure it is safe" and "concerns for serious side effects."
Conclusions/Learning Points: Overall, our educational intervention increased likelihood to vaccinate with partial effectiveness in decreasing VH against HPV vaccine. The timing of post-intervention assessment may have impacted the study findings. Addressing HPV vaccine safety concerns among parents could help improve suboptimal HPV vaccination coverage.

VACCINATION AT A PORTUGUESE PRIMARY CARE FACILITY DURING 2022: INTERVENTIONS TO IMPROVE VACCINE COVERAGE

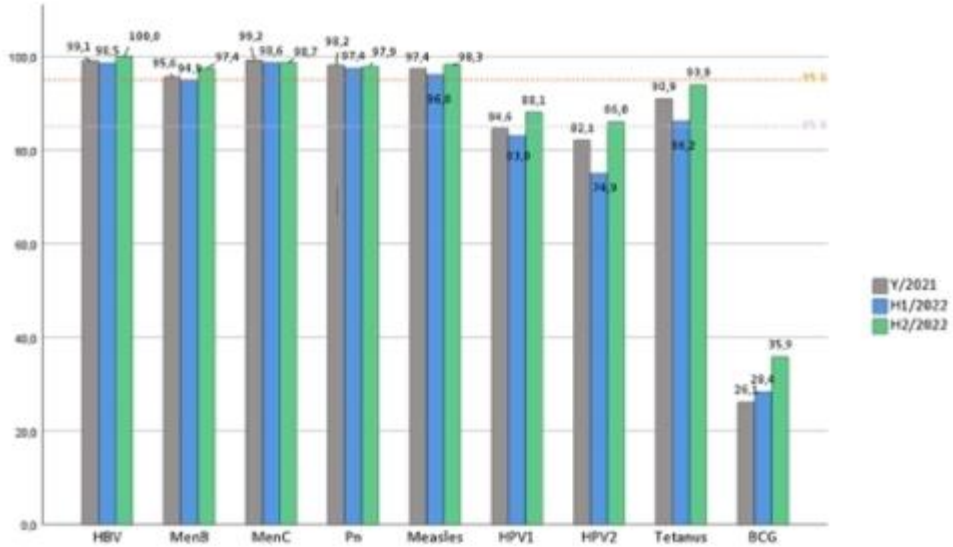
E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Tomás Ferrão[1], Fábio Bastos[2], Mariana Santiago[2], Diana Gavião[2], Maria Miguel Almiro[1], José Pedro Antunes[2], Maria Manuel Flores[1]
[1]Centro Hospitalar do Baixo Vouga, Pediatrics, Aveiro, Portugal, [2]ACeS Baixo Vouga, Usf Arte Nova, Oliveirinha, Portugal

Background: Vaccination is a crucial measure for preventing disease at both populational and individual scope level, especially in paediatric patients. Primary care providers often play a vital role in improving and maintaining vaccine coverage (VC), which can be enhanced through specific organisational interventions.
Methods: We describe the National Vaccination Program's (PNV) coverage in a Primary Care Facility (PCF) in a Portuguese city. This PCF developed a vaccination task force which held periodical meetings and VC monitoring. Diverse strategies were established to optimise VC, including internal audits, professional training, telephonic invitations, opportunistic vaccination, and immediate rescheduling after missed appointments. We evaluated VC at the end of 2021 and each semester in 2022 (Y/2021, H1/2022 and H2/2022, respectively) using statistical analysis with SPSS v.29 and a $p<0,05$ was considered significant. PNV recommended levels of VC are 85% for HPV and 95% for remaining diseases. Except for tetanus, every vaccine's target population included only paediatric patients.
Results: Median VC in Y/2021, H1/2022 and H2/2022 was 96,50%, 95,47% and 97,65% respectively (excluding BCG, since target population includes eligible plus non-eligible individuals following national vaccination guidelines). Coverage for preventable diseases decreased from 2021 to H1/2022, followed by an increase during H2/2022. Median VC increased from 95,64% to 97,44% ($p=0,021$). Detailed results for each disease are presented on Table 1 and Graph

Disease	Measurement	Y/2021	H1/2022	H2/2022	VC change Y/2022 to H2/2022 (pp%)
HBV	Vaccinated individuals (n)	110	66	145	+0,90
	Target population (n)	111	67	145	
	VC (%)	**99,10**	**98,51**	**100**	
MenB	Vaccinated individuals (n)	263	260	418	+1,80
	Target population (n)	275	274	429	
	VC (%)	**95,64**	**94,89**	**97,44**	
MenC	Vaccinated individuals (n)	130	146	149	-0,56
	Target population (n)	131	148	151	
	VC (%)	**99,24**	**98,65**	**98,68**	
Pn	Vaccinated individuals (n)	270	267	274	-0,32
	Target population (n)	275	274	280	
	VC (%)	**98,18**	**97,45**	**97,86**	
Measles	Vaccinated individuals (n)	445	510	394	+0,88
	Target population (n)	457	531	401	
	VC (%)	**97,37**	**96,05**	**98,25**	
HPV1	Vaccinated individuals (n)	191	203	182	+3,55
	Target population (n)	225	243	204	
	VC (%)	**84,59**	**83,03**	**88,14**	
HPV2	Vaccinated individuals (n)	134	136	160	+3,93
	Target population (n)	161	181	186	
	VC (%)	**82,11**	**74,93**	**86,04**	
Tetanus	Vaccinated individuals (n)	1271	1030	1657	+3,01
	Target population (n)	1398	1195	1764	
	VC (%)	**90,92**	**86,19**	**93,93**	
BCG	Vaccinated individuals (n)	29	19	52	+9,73
	Target population (n)	111	67	145	
	VC (%)	**26,13**	**28,36**	**35,86**	
Median VC (excluding BCG)		**96,50%**	**95,47%**	**97,65%**	**+1,15 (p=0,036)**

Table 1: Vaccinated (n) and number of target individuals (n), and VC (%) for each target disease and respective change from previous time period (in pp%). HPV1 and HPV2 correspond to first and second dose, respectively. BCG target population includes eligible and non-eligible patients.



Graph 1: VC (%) for each time period and disease. Minimum recommended levels of VC in Portugal's PNV are 85% for HPV and 95% for every remaining disease.

1.

Conclusions/Learning Points: Overall, efforts implemented at the PCF resulted in favourable outcomes. However, it is challenging to determine the impact of each intervention, which limits our ability to assess their significance. Other factors, such as vaccine hesitancy and access to healthcare, may also contribute to challenges in achieving optimal VC.

PV0203 / #963

THE HPV VACCINATION DEFICIT IN GREECE IS INCREASING. IS THE EFFECTIVENESS OF THE ANNOUNCED CATCH-UP INITIATIVE CAPABLE TO ELIMINATE THE HPV VACCINATION DEFICIT IN GREECE?

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Ilias Gountas[1], Anastasios Skroumpelos[1], Georgios Trimis[1], Nikos Markoulatos[1], Ugne Sabale[2], Stina Salomonsson[2], Kunal Saxena[3], Lazaros Poughias[1], Antonis Karokis[1]
[1]MSD Greece, External Affairs, Athens, Greece, [2]MSD Sweden, Center For Observational And Real World Evidence (core), Stockholm, Sweden, [3]Merck & Co., Inc., Center For Observational Research And Real World Evidence, North Wales, United States of America

Backgrounds: During the COVID-19 pandemic, a significant reduction in the number of administered HPV doses was observed in Greece. To prevent future HPV burden increases, the National Immunization Committee (NIC) announced in 04/2022 a catch-up initiative to run until 12/2023. The study aims to assess the effectiveness of the running catch-up intervention.
Methods: A published calculator (Saxena CMRO 2022) seeded with local HPV vaccine sales data was utilized. During the pandemic and until April 2022, only girls were eligible for HPV vaccination, thus the dose deficit was only attributed to them. To exclude boys' post-April contribution, two scenarios were examined: 35% (conservative) and 50% (optimistic) of the observed HPV sales data were attributed to girls. Those scenarios were based on IQVIA estimations. The accumulated deficit was expressed as a function of the number of months of the last pre-pandemic year (e.g., 2019).
Results: The expected number of doses administered to girls in 2022 would be 14-34% lower than in 2021. The accumulated deficit at the end of 2022 is estimated at 5-7 months of vaccination of 2019. To clear the HPV deficit at the end of 2023, the administered doses should be increased by 69% and 154% compared to that of 2022, under the optimistic and conservative scenario, respectively. Expanding catch-up program duration by 1 or 2 years would reduce the annual required doses by 27% and 42%, respectively, compared to the announced catch-up duration.
Conclusions/Learning Points: Although a catch-up initiative is running, the HPV vaccination deficit is increasing. Under the observed effectiveness of the catch-up, the HPV deficit elimination is unlikely. Expanding catch-up duration and accompanying it with interventions to increase catch-up effectiveness is required to make HPV deficit elimination a realistic target.

PARENTAL CONCERNS ABOUT CHILDHOOD VACCINATION IN RELATION TO AEFI

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Muhammad Javed, Jim Buttery, Sedigh Habibabadi, Christopher Palmer, Gerardo Dimaguila
Murdoch Children's Research Institute, Health Informatics, Melbourne, Australia

Backgrounds: In the last decade, parental concerns about childhood vaccination have increased, and these concerns are often associated with vaccine hesitancy, a serious threat to public health. Hesitancy leads to vaccine rejection or delayed vaccine coverage. Concerns regarding adverse events following immunisation (AEFI) are the key driver of vaccine hesitancy. It is very important to understand parents' specific concerns to design bespoke strategies to address them. We used social media to identify these concerns; a recognised social listening method for tracking public concerns.
Methods: 108,482 Reddit comments about childhood immunisation and related AEFI were retrieved (January 2015-June 2020). We fine-tuned a COVID-Twitter-BERT V2 model for sentiment analysis. Topics of discussion were identified using BERtopic, which helps to organize a large collection of documents by thematically grouping them.
Results: Sentiment analysis identified neutral (n=71,672), negative (n=10,233), and positive (n=26,577) comments from the dataset. People expressed hesitancies either by asking questions or sharing personal and others' experiences in comments with neutral sentiments or rejecting with negative sentiments. Therefore, we selected comments with neutral or negative sentiments to extract the topics of discussion.

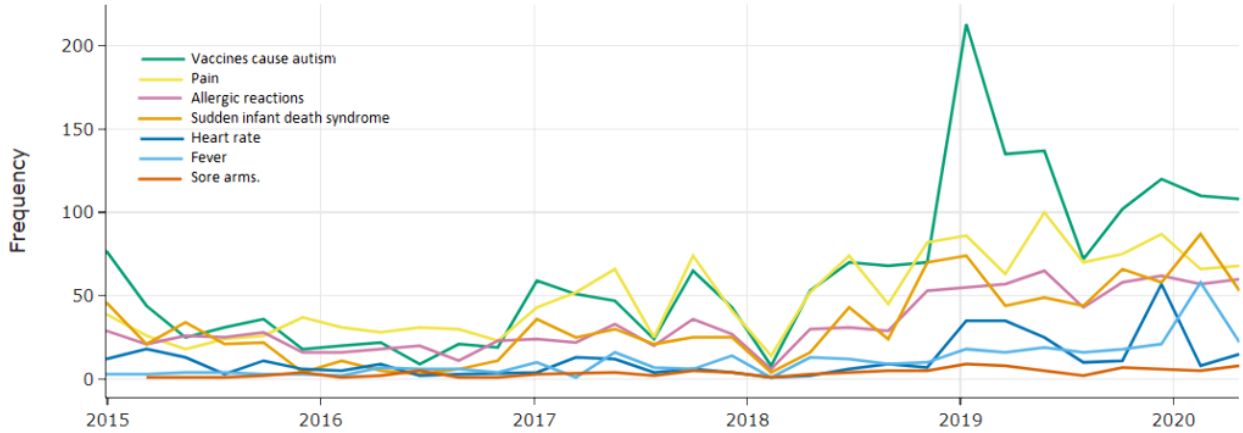

Figure 1. Parents' concerns about childhood vaccination The top concern identified was 'vaccines cause autism' with a higher frequency in 2015 2019, and 2020. Parents also frequently expressed hesitancies about vaccination in relation to 'sudden infant death syndrome'. Heart rate is another serious AEFI discussed in relation to childhood vaccination. Some common AEFIs (i.e., pain, allergic reactions, fever, and sore arms) were also identified.

Conclusions/Learning Points: Our findings highlight the top concerns that parents have about childhood vaccination and indicate which AEFI topics are more vulnerable to mis-/dis-information. Social media surveillance is a cost-effective and timely method to help inform targeted vaccine uptake strategies.

LOW VACINNATION COVERAGE OF PEDIATRIC PATIENTS WITH CHRONIC HEALTH CONDITIONS AGAINST SEASONAL INFLUENZA AND COVID-19 FOR THE WINTER PERIOD 2022-2023: AWARENESS IS NEEDED

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Sofia Karagiannidou[1], Garyfallia Syridou[1], Angeliki Tzaki[1], Olympia Sardeli[1], Dafni Moriki[1], Katerina Kourtesi[1], Artemis Stefanidi[1], Melpomeni Giorgi[1], Afroditi Kourti[1], Vassiliki Papaevangelou[2]
[1]"ATTIKON" UNIVERSITY HOSPITAL, Third Department Of Pediatrics, ATHENS, Greece, [2]National and Kapodistrian University of Athens, Third Department Of Pediatrics, Athens, Greece

Backgrounds: Our aim was to record the vaccination rates of pediatric patients with chronic health conditions (CHC) against seasonal influenza and COVID-19, as well as to determine factors associated with vaccination hesitancy.
Methods: A cross-sectional study was performed (and is ongoing). Children (6 months - 18 years) that visited either the Pediatric ER or the Pediatric Outpatient Clinic in Attikon Hospital (Athens, Greece) during 01/11/22 – 10/01/23 were eligible. Demographic and clinical characteristics (age, sex, underlying diseases, history of allergies), medication, and personal/family vaccination history were recorded.
Results: 270 children were enrolled: 142 (52.6%) girls, with a mean (SD) age of 8.94 years (5.0), and 203 (75.2%) with CHC (asthma, Inflammatory Bowel Disease-IBD, neurologic, rheumatologic). 54/203 (26.6%) CHC children were influenza vaccinated; influenza vaccination rate did not differ significantly between any of the chronic illness sub-categories (asthma 25%, IBD 58.8%, neurologic 21.2%, rheumatologic 25.4%) versus healthy controls (34.3%). 76/203 (37.4%) CHC children were COVID-19 vaccinated (asthma 41.7%, rheumatologic 38.6%); more children with IBD (64.7%, p=0.011) and less children with neurologic conditions (9.1%, p=0.014) were COVID-19 vaccinated versus healthy controls (35.9%). Influenza non-vaccination in CHC children was correlated with non-COVID-19 vaccination (p=0.002), non-influenza/COVID-19 vaccination of the father (p<0.001/p=0.029) and of the mother (p<0.001 for both), non-sibling influenza vaccination (p<0.001), and no past influenza vaccination (p<0.001). COVID-19 vaccination hesitancy in CHC children was correlated with younger age (p<0.001), absence of biologic agent medication (p=0.011), no influenza vaccination (p=0.002), non-COVID-19 vaccination of the father/mother/siblings (all p<0.001), and no past influenza vaccination (p<0.001). Younger age (p<0.001) and no past influenza vaccination (p=0.002) remained significant by multivariate analysis.
Conclusions/Learning Points: Influenza and COVID-19 vaccination seems to still rely on family perceptions, also for CHC children, underlying the need for intervention.

AWARENESS AND ACCEPTABILITY OF PARENTS TOWARDS THE TYPHOID CONJUGATE VACCINE: A CROSS-SECTIONAL STUDY FROM PAKISTAN

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Rutaab Kareem[1], Noor Us Sehar[1], Zuha Majid[2], Tehniat Fatima[1], Aimen Nadeem[1], Samia Aslam[3], Muhammad Haroon Hamid[4]
[1]King Edward Medical University, Mbbs, Lahore, Pakistan, [2]King Edward Medical University., Mbbs, Lahore, Pakistan, [3]KEMU/MHL, Pediatrics Medicine Unit 1, Lahore, Pakistan, [4]King Edward Medical University, Pediatrics, Lahore, Pakistan

Backgrounds: Extensively drug-resistant (XDR) Salmonella typhi was first reported in Pakistan in 2016 and cases have been rising at an exponential rate. Vaccination is one of the important public health measures to curb this problem. The typhoid conjugate vaccine (TCV) was introduced in Pakistan in 2019 to bolster the prevention of this disease. We aimed to evaluate the knowledge and level of acceptability regarding the vaccine among parents.
Methods: We conducted a monocentric cross-sectional retrospective study that included 290 parents of children admitted to the Pediatric Department of Mayo hospital (KEMU) Lahore, Pakistan, having at least one child aged between 9 months to 15 years, using consecutive sampling. We collected the data through interviews using a pre-designed questionnaire and a modified, validated tool–Parental Attitude to Childhood Vaccinations (PACV) and analyzed it using SPSS (v 26.0).
Results: Out of 290 participants, 204 (70.3%) were aware that a new typhoid vaccine (TCV) was recently introduced by the government. Eighty-two (40.2%) of these participants had received this information via mass media. Regarding the acceptability score, only 49 (16.9%) were hesitant toward TCV. One hundred and sixty-one (55.5%) participants had gotten their children vaccinated against typhoid. Out of the 129 (44.5%) participants with unvaccinated children, 92 (71.3%) were willing to get their children vaccinated, 18 (14%) were unsure regarding this decision and 19 (14.7%) were against getting their child vaccinated. 87 (54%) children had gotten their shot as part of government-sponsored door-to-door community campaigns.
Conclusions/Learning Points: Although the majority of our participants were aware and accepting of the TCV, 45.5% had not gotten their children vaccinated. Further high-powered & community-based studies are needed to identify the cause of this disparity.

MISSED OPPORTUNITIES FOR VACCINE EQUITY (MOVE): INCREASING CHILDHOOD VACCINATION THROUGH HOSPITAL-BASED CATCH-UP VACCINATIONS AND COMMUNITY OUTREACH IN INDIA: A PRE- AND POST-INTERVENTION ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Kescha Kazmi[1,2], Joseph Mathew[3], Baldeep Dhaliwal[4,5], Chizoba Wonodi[4,5], Anita Shet[4,5]
[1]The Hospital for Sick Children, University of Toronto, Pediatric Infectious Diseases, Toronto, Canada, [2]Johns Hopkins University, Bloomberg School Of Public Health, Baltimore, United States of America, [3]Post Graduate Institute of Medical Education and Research, Pediatrics, Chandigarh, India, [4]Johns Hopkins University, International Health, Baltimore, United States of America, [5]Johns Hopkins University, International Vaccine Access Center, Baltimore, United States of America

Backgrounds: A missed opportunity for vaccination (MOV) occurs when a person eligible for vaccination attends a health facility and does not receive due vaccinations. Hospitalized children represent a vulnerable group who likely have risk factors for vaccine-preventable disease morbidity and mortality.
Methods: We conducted a prospective, pre-post intervention pilot study on MOV in hospitalized children aged 0-23 months in Chandigarh, India. Using a human-centered design (HCD) approach, an intervention was designed and implemented by key stakeholders. The intervention consisted of 4 components: disseminating vaccine information to healthcare staff, documenting children's vaccination status prominently on medical charts, strengthening linkages between outpatient immunization services and pediatric inpatients, and ensuring caregivers receive advice and referrals on due vaccinations at discharge. The proportion of MOV was measured and compared pre- and post-intervention.
Results: 640 children (256 pre-intervention 384 post-intervention) were enrolled in the study. On admission to hospital, 61.7% (158/256) and 64.1% (246/384) of children were under-vaccinated according to the Indian national schedule, pre- and post-intervention, respectively. During hospitalization, a significantly higher proportion of caregivers reported receiving vaccination advice ($p<.0001$) post-intervention (63.8%; 224/351) compared pre-intervention (14.4%; 34/237). Among under-vaccinated children followed through to discharge, the prevalence of MOV was significantly lower ($p<0.0001$) post-intervention (52.9%; 117/221) compared to pre-intervention (89%; 129/145).
Conclusions/Learning Points: We found a high proportion of MOV among hospitalized under-vaccinated children pre-intervention. Using a HCD approach in the design and implementation of an intervention that utilized existing healthcare resources and repurposing of hospital staff, we found that MOV can be significantly decreased post-intervention. Our findings suggest that simple, stakeholder-led approaches, if scaled up, can play a role in improving vaccine uptake.

PARENTAL ATTITUDES, INTENTION AND BELIEFS TOWARDS CHILDHOOD VACCINATION IN THE NETHERLANDS AND A COMPARISON BETWEEN TWO POINTS IN TIME

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Marthe Knijff, Alies Van Lier, Hester De Melker
National Institute for Public Health and the Environment (RIVM), Centre For Infectious Disease Control, Bilthoven, Netherlands

Backgrounds: Vaccine uptake of the Dutch National Immunization Program (NIP) has slightly declined. The COVID-19 pandemic may have played a role. We assessed current parental attitudes, intention and beliefs towards vaccination and investigated how these may have changed.
Methods: In 2013 and 2022, parents with at least one child aged <3.5 years were invited to participate in online surveys on vaccination. Chi-square tests were used to compare parental attitudes (i.e. whether they think vaccinating their child(ren) according to the NIP is bad/good, (un)important and/or (un)necessary), participation within the NIP, intention and other psychosocial factors between 2013 and 2022.
Results: The 2022 survey was completed by 998 parents (response: 12.2%) and the 2013 survey by 797 parents (response: 37.1%). Preliminary results showed that in 2022 significantly larger proportions of parents felt that vaccinating their child(ren) according to the NIP is (very) bad (2013: 1.4%; 2022: 4.5%; p-value=0.0002), (very) unimportant (2013: 2.2%; 2022: 4.9%; p-value=0.003) and (very) unnecessary (2013: 3.3%; 2015: 5.9%; p-value=0.009) and did not participate in the NIP (2013: 2.6%; 2022: 5.4%; p-value=0.003). Similarly, in 2022 a significantly smaller proportion of parents intended to vaccinate their (youngest) child according to the NIP in the future (2013: 87.0%; 2022: 83.1%; p-value=0.03). Other factors, such as beliefs about vaccination and infectious diseases, trust and consideration, displayed similar
trends.

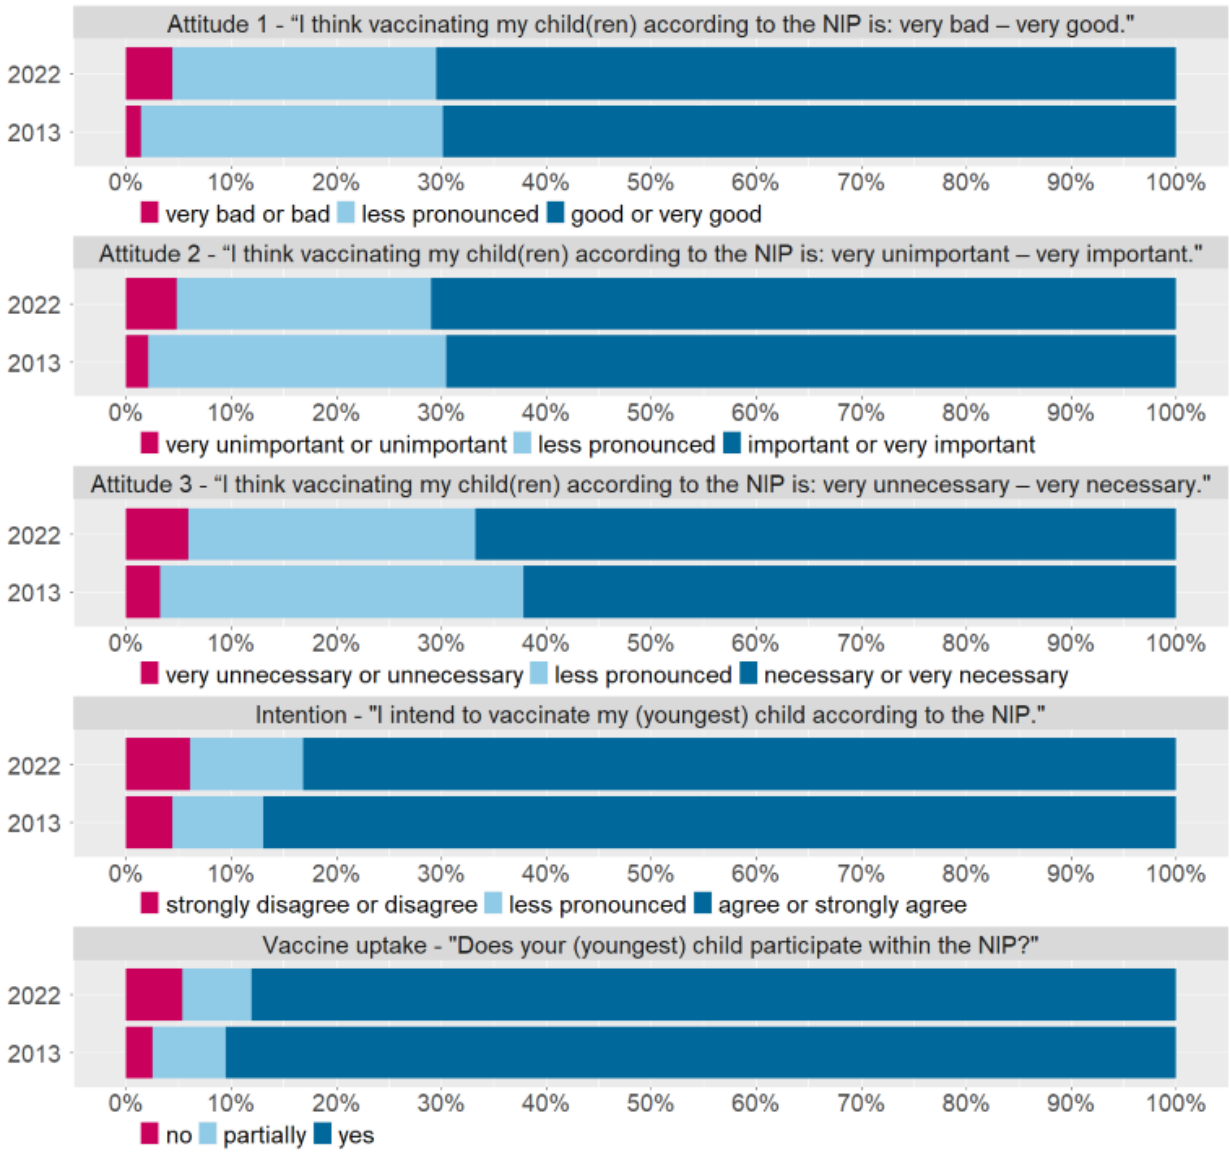

Figure 1. Attitudes, intention and vaccine uptake of parents with at least one child aged <3.5 years in 2013 and 2022. All psychosocial items, except vaccine uptake, were measured on a 7-point Likert scale with responses grouped as: 1-2 negative (rubine red), 3-5 less pronounced (light blue), 6-7 positive (dark blue).

Conclusions/Learning Points: This study showed that, although parental attitudes, intention and beliefs towards vaccination are still largely positive in 2022, there are indications that they have become slightly more negative. As attitudes, beliefs and intention are important prerequisites of vaccine uptake and the COVID-19 pandemic may have played a role, monitoring these factors is important. Researching possible causes could contribute to developing appropriate interventions to sustain high vaccine uptake.

Background: Low COVID-19 vaccine uptake amongst children can be attributed to vaccine hesitancy (VH) and is a major obstacle in resumption to normalcy. With the overabundance of online and offline vaccine-related misinformation, digital interventions such as chatbot is a promising tool for providing accurate and timely information at scale. We evaluate the effectiveness of chatbot intervention in addressing VH amongst parents making vaccination decisions for their children, through increasing COVID-19 vaccine confidence and acceptance.
Methods: We conducted a multisite, parallel, randomised controlled trial (RCT) from February to June 2022 in Thailand (TH), Hong Kong (HK), and Singapore (SG). We randomly recruited parents of children who were unvaccinated or have delayed vaccination until governmental vaccine mandates. Participants were assigned to the control or intervention group with a 1:1 allocation ratio. The week-long intervention involved using vaccine chatbots covering topics like vaccine importance, safety, effectiveness, how to get vaccinated, tips before vaccination, and misinformation; chatbots were in English and the local languages and were hosted on Facebook Messenger (TH) and WhatsApp (HK, SG). Participants answered pre- and post-intervention surveys on COVID-19 vaccine confidence, acceptance, and vaccine-related misinformation.
Results: Out of 428 participants, 204 (TH: 69, HK: 90, SG:45) were assigned to the intervention. Regression models show mixed effects of the intervention. Compared to control, Thailand intervention group was more likely to have increase confidence in vaccines' importance [OR = 2.40 (95% CI: 1.34 to 4.32)], but Hong Kong intervention group was less likely to have increased vaccine acceptance [0.24 (0.17-0.34)].
Conclusions/Learning Points: Results of chatbot intervention effectiveness amongst parents are inconclusive and further studies are needed to better understand how digital interventions can address VH through increasing vaccine confidence and acceptance.

VACCINATION IN PHARMACY: RESULTS OF PILOT PROJECT IN UKRAINE

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Iryna Voloshyna[1], Fedir Lapii[2]
[1]NGO Academy Family Medicine of Ukraine, None, Kyiv, Ukraine, [2]European International University, Department Of Pediatrics, Immunology Of Infectious And Rare Diseases, Kyiv, Ukraine

Backgrounds: COVID-19 pandemic was associated with decreasing of routine vaccination rates in Ukraine. In coordination with Ministry of Health, NITAG, NGO "Academy of Family Medicine of Ukraine" provided the pilot project "Vaccination in pharmacy" from Nov 2021-Jan 2022 in Kyiv as the first experience of engaging pharmacies in immunisation.The aim of the project was to clarify the patient's attitude and adherence to vaccination in pharmacies for further implementation.
Methods: The results of the project were analyzed retrospectively, using medical records and interviews of participants in 6 pharmacies of Kyiv city. The announcement of pilot project was launched on MoH official site and several mass media sources. The vaccination procedure has been provided due to Ukrainian regulations: signing informed consent, short clinical examination to exclude possible contraindications, vaccination and 15 min follow-up. Simultaneous vaccination was provided in one pharmacy where children were also eligible for immunization.
Results: Overall 1862 participants (59% female, 41% man) were engaged in the pilot project. Most of the patients (94%) got flu vaccine. In one pharmacy where all-aged patients had possibility to get shots a total number of 98 patients including 36 kids aged 1-18 yrs were vaccinated, 47 persons (48%) received more than 1 vaccine.The rate of return visits was 19% for 3 months, some of the patients invited their family members on the next visit to get shot. All doctors and pharmacists were satisfied with the project and wished to continue such practice. Among the patient there was any complaints on the vaccination and over 27% actively wished to get vaccination in pharmacy next year. No serious events have been observed during the project.
Conclusions/Learning Points: Vaccination in pharmacies will have development in Ukraine with consistently legislation changing.

COMPARING PARENTAL VACCINE HESITANCY IN TWO NEIGHBOURING ASIAN COUNTRIES

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Le Ye Lee[1], Jia Ming Low[1], Chloe Soo[1], Anh Puong Tran[1], Edwin Khoo[2], Mk Thong[3], Fc Cheah[4]
[1]National university Hospital, Neonatology, Singapore, Singapore, [2]International Medical University, Paediatrics, Kuala Lumpur, Malaysia, [3]University of Malaya, Paediatrics, Kuala Lumpur, Malaysia, [4]Universiti Kebangsaan Malaysia, Paediatrics, Kuala Lumpur, Malaysia

Backgrounds: Vaccine hesitancy is one of the major concerns for WHO in addressing transmissible and vaccine preventable diseases. Worldwide, high vaccine hesitancy rates have impeded the rollout of successful vaccination programs in the COVID-19 pandemic. Mistrust of the child's doctors had been identified as one of the major factors contributing to vaccine hesitancy. We aimed to compare the vaccine hesitancy rates in two Asian countries, Malaysia and Singapore and study the health beliefs of parents.
Methods: An online voluntary survey was carried out in both countries from November, 2021 until August, 2022.
Results: A total of 226 Malaysian parents (MPs) and 635 Singaporean parents (SPs) were surveyed. MPs were on average younger (38.0±8.8 vs 39.1±6.7) and had more children compared to SPs (2.4±1.8 vs 2.0±0.8). MPs were also less likely to have received the COVID-19 vaccine themselves (96% vs 99%) and were more vaccine hesitant (16.4% vs 5.8%). More MPs delayed vaccination for their children (26.5% vs 19.4%) and did not perceive vaccine preventable diseases as 'severe' compared to SPs (10.6% vs 4.9%). Twice as many MPs believed that it is better for children to acquire immunity through natural infections than vaccination. More MPs were concerned that vaccines may not actually prevent the disease (36.3% vs 27.2%). Overall, more MPs mistrust the information on vaccines (14.6% vs 6.6%), their children's doctors (4% vs 0.6%) and healthcare authorities (76.5% vs 23.5%) compared to SPs. All comparisons are statistically significant ($p < 0.01$)
Conclusions/Learning Points: Despite the proximity of these two countries and sharing many ethnographic similarities, parental vaccine hesitancy is more common in Malaysia than Singapore because of different healthcare beliefs. More public health campaigns can be done to increase parental trust

INFLUENZA VACCINATION IN CHILDREN WITH PULMONARY DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Nofar Amitai[1], Gilat Livni[2], Dario Prais[1], Reut Wertheimer[2], Keren-Or Wertheimer[2]
[1]Schneider Childrens Medical Center, Pulmonary Institute, Petcah Tikva, Israel, [2]Schneider Childrens Medical Center, Pediatrics A, Petcah Tikva, Israel

Backgrounds: Influenza is associated with considerable respiratory morbidity and mortality. Healthcare authorities recommend immunization of all children. The vaccination showed protection against Influenza triggered asthma attacks. Medical professionals caring for children with chronic lung disease should counsel parents on the importance of annual Influenza vaccination as part of supportive care.
We aimed to describe adherence to Influenza vaccination in respiratory patients and identify potential reasons for non-vaccination in this patient population.
Methods: The study included questionnaires reviewing personal experience and beliefs regarding Influenza vaccination, provided by parents of patients who visited the Pediatric Pulmonary Institute in Schneider Children's Medical Center with their children, between March- August 2021.

Results: Of 199 parents who completed our questionnaire, 117 (57.3%) vaccinated their children against Influenza during the recent year. Mean age was 6.9±4.5 years, demographic data were similar between the vaccinated and unvaccinated groups. Vaccination rates differed significantly comparing parents who received an explanation from their primary physician regarding the Influenza vaccine and those who didn't, 43.8% and 64.6% (p=0.004), and parents who received explanation from a pulmonary specialist and those who didn't, 77.3% vs. 51% (p=0.003). The primary physician's and the pulmonologist's recommendation to vaccinate both showed to be significantly effective (OR 0.2). Parents who believed in vaccine efficacy and safety were more likely to vaccinate their children (p<0.001). Factors significantly affecting the decision of the parents to have their child vaccinated were their knowledge, beliefs and conceptions about the vaccine.

Conclusions/Learning Points: Pediatric respiratory patients' Influenza vaccination rate was 57%. Major factors encouraging vaccination were proper parental knowledge and the recommendation of the primary physician\pulmonologist. This emphasizes the need for providing patients with information, by first explaining the vaccine's importance to doctors.

ROTAVIRUS IMMUNIZATION COVERAGE AND TIMING OF ADMINISTRATION: A REGIONAL PROSPECTIVE COHORT STUDY IN SOUTHERN ITALY

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Sara Maria Scarano[1], Pietro Buono[2], Alessandro Scoppa[2], Alfonso Maria Farina[1], Rita Nunziata[1], Alfredo Guarino[1], Andrea Lo Vecchio[1]
[1]University of Naples, Federico II, Department Of Translational Medical Sciences - Section Of Pediatrics, Naples, Italy, [2]General Directorate for Health, Department Of Maternal And Child Health, Naples, Italy

Backgrounds: Since fifteen years, two oral live attenuated Rotavirus vaccines (RVV) are available in Europe: a human monovalent vaccine (mRVV 2-doses) and a re-assortant human bovine pentavalent vaccine (pRVV 3-doses). In Italy, RVV is recommended and provided free of charge from 2018, however, the coverage is scattered and suboptimal.
Methods: The Vaccination Registry of Campania Region (Southern Italy) was used to retrospectively study the RVV coverage and its timing of administration in the entire pediatric cohort receiving vaccines scheduled in the first year of life between January 1, 2016 and December 31, 2020.
Results: Overall, 224.110 children were enrolled during the study period, 60.614 (27.0%) received a complete RVV schedule,15.271 (6.8%) an incomplete schedule and 148.225 (66.1%) were not vaccinated against RV. Immunization rate increased overtime, either for fully (1.15% in 2016 to 56.92% in 2020) or partially vaccinated children (0.14% in 2016 to 11.0% in 2020). pRVV was administered in 89.8% and mRVV schedule in 7.5%, data were missing for 2.7% of children. A higher proportion of children receiving mRVV completed the schedule compared to those receiving pRVV (91% vs 81%, $p<0.0001$). 76.6% received first RVV dose by 12 weeks of age and 18% between 12-15 weeks. mRVV schedule was completed within the recommended timing (24 weeks) according to product labels in 86.8% of children, compared to pRVV (32 weeks) in 93.7% ($p<0.00001$). 11.9% of children completed mRVV schedule between 24-32 weeks, a time interval indicated as possible by some Health Authorities.
Conclusions/Learning Points: Different RVV schedules are associated with a variable probability to complete the schedule and timely administering the doses. Although still far from the target, RVV coverage progressively increased in Campania, further efforts are needed to achieve this goal.

VACCINE HESITANCY IN BRAZILIAN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Jose Cassio Moraes[1,2], Ione Guibu[2], Ana França[2], Carla Domingues[2]
[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, Saúde Coletiva, -, Brazil, [2]Faculdade de Ciências Médicas da Santa Casa de São Paulo, Saúde Coletiva, São Paulo, Brazil

Background: Vaccine coverage has been dropping in Brazil since 2016. Vaccine hesitancy is the delay or refusal in completing the vaccination schedule, despite the availability of vaccines in health care services.
Methods: To identify vaccine hesitancy and reasons for non-vaccination in children born in 2017 and 2018, residing in urban areas of Brazilian capitals and the Federal District, we carried out a vaccine coverage survey in all Brazilian capital cities (27) of children born in 2017 and 2018 living in urban areas. The sample size was 31028. Data from the household interviews were recorded on a digital form that included questions about the decision not to vaccinate and the reasons for it, the importance of vaccines for the health of the child, fear of adverse reactions, the need for vaccines against “eliminated diseases”, and difficulty reaching a vaccination site.
Results: Vaccination coverage under 1 year old was lower in children of parents who said they were afraid of serious reactions (PR=0,95;CI:0,93-0,97), who decided not to give one or more vaccines (PR=0,71;CI:0,66-0,75), and who had difficulty taking their child to a vaccination site (PR=0,90;CI:0,87-0,92). Fear of serious vaccine reactions was higher in mothers younger than 35 years (PR=1,30;CI:1,24-1,37), with lower educational level (PR=1,45;CI:1,38-1,53), and when the child was the third or more (PR=0,86;CI:0,82-0,91). Fathers or caretakers in families with higher household consumption level reported greater need to maintain vaccination against controlled diseases (PR=1,07;CI:1,06-1,08), and those in lower household consumption level had the highest proportion of children brought to the vaccination site who were not vaccinated due operational issues (PR=0,82;CI:0,79-0,85).
Conclusions/Learning Points: Vaccine hesitancy is associated with decreased vaccine coverage in children.

MODELING THE DEFICIT OF HPV VACCINATION IN ADOLESCENT GIRLS DURING THE COVID-19 PANDEMIC IN GERMANY

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Kunal Saxena[1], Edith Morais[1], Cornelia Waehner[2], Thorsten Reuter[2], Agnes Luzak[2], Ya-Ting Chen[1]
[1]Merck & Co., Inc., Center For Observational Research And Real World Evidence, North Wales, United States of America, [2]MSD Sharp & Dohme GmbH, Medical Affairs, Munich, Germany

Backgrounds: The COVID-19 pandemic led to significant disruption in health care services in Germany including reduced administration of routinely recommended HPV vaccines among adolescents. The time and effort required to catch up these missed doses is unclear. We modeled the estimated cumulative dose deficit and time to recover from this deficit in Germany.
Methods: HPV doses administered to adolescent girls in Germany prior to and during the COVID-19 pandemic, were estimated from a retrospective analysis between January 2018 and September 2022 using electronic medical records. A previously published model was then utilized to estimate the accumulated deficits (based on prior vaccine uptake) and time-to-recover from that deficit at different catch-up rates.
Results: Real-world data showed that the first dose uptake of HPV vaccines dropped annually by 25% on an average by the end of September 2022, compared to 2019 (pre pandemic uptake). The accumulated deficit as a % of total annual doses administered during the reference period (2019) was estimated to be around 63%. This deficit is projected to clear between September 2029 and January 2036, assuming annual catch-up rates of 10% and 5% respectively, in addition to 2019 uptake rates. Similarly, all dose uptake dropped by 20% annually by the end of September 2022 (relative to 2019), and the accumulated deficit was estimated to be around 53%. This deficit is projected to clear between September 2028 and January 2034, assuming annual catch-up rates of 10% and 5% respectively.
Conclusions/Learning Points: Administration rates of routine HPV vaccines decreased significantly among German adolescent girls during COVID-19 pandemic and continue to remain at a low level. To reduce vaccine preventable HPV related diseases, sustained efforts to vaccinate the missed cohorts will be needed over the next multiple years.

PREVENTING THE NEXT PANDEMIC IN LEBANON

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

George Porter[1], Diana Maddah[2], Ram Vadi[2], Stephen Owens[1]
[1]Newcastle University, Population Health Sciences Institute, Newcastle Upon Tyne, United Kingdom, [2]UK-Med, Health Department, Manchester, United Kingdom

Backgrounds: Lebanese non-government organisations (NGOs) and Primary Healthcare Centres (PHCs) have reported a fall in routine vaccination rates, some by over 50%. We investigated the reasons behind this decline.
Methods: 32 parents from the Old Saida UN Habitat Neighbourhood were selected via purposive sampling from a list of those whose children had fallen behind their routine vaccination schedule. These parents underwent semi-structured interviews with one of two interviewers while a focus group of 8 healthcare workers (HCWs) was also convened. The resultant transcripts underwent thematic analysis: they were coded into concepts, which were consolidated into themes, which are presented. The study was approved by the Ministry of Public Health.
Results: The most commonly identified barrier was cost. Vaccines themselves are free at PHCs but increasing numbers are charging ancillary fees such as a physician consultation fee due to the current economic crisis. These, as well as transport costs, are unaffordable to many. Additionally, PHCs often cannot stock all routine vaccinations simultaneously, necessitating parents to pay for multiple visits. Additionally, around half of the parents and some HCWs had a misconception that vaccines in private clinics were safer. The vast majority of participants described vaccines as safe and important, while two participants expressed doubts about their effectiveness. However, no parents listed vaccine-preventable diseases as an important health problem in their community, and half had spoken to people who believed vaccines to be ineffective and/or unimportant.
Conclusions/Learning Points: In summary, while economic barriers significantly contribute to vaccine hesitancy, they are exacerbated by misinformation, logistics barriers and an underestimation of the importance of vaccines. We argue that an integrated approach of risk communication and community engagement alongside targeted ‘Vaccine Drives’ is urgently needed to avert future outbreaks.

VACCINATION OF UKRAINIAN REFUGEE CHILDREN AS AN INTERNATIONAL ISSUE

E-Posters Viewing
E-POSTER VIEWING: AS03.F. VACCINE HESITANCY

Olha Shvaratska[1], Victor Mavrutenkov[2], Tatiana Mavrutenkova[3]
[1]Dnipro State Medical University, Pediatrics 3 And Neonatology, Dnipro, Ukraine, [2]Dnipro State Medical University, Department Of Infectious Diseases, Dnipro, Ukraine, [3]Diagnostic Center of Medical Academy, Department Of Pcr Diagnostics, Dnipro, Ukraine

Backgrounds: The Russia-Ukraine war has caused significant humanitarian crisis on the Ukraine territory and put Ukrainian citizens in search of safety across borders. According to the United Nation data, almost eight million Ukrainian refugees have been registered in European Union by January 3, 2023, and children constitute half of this number. According to the national open registry data, population immunization rates in Ukraine are insufficient, both for subjective (anti-vaccination beliefs) and objective (insufficient vaccine supply) reasons.
Methods: We performed an assessment of immunization status of children and parental attitudes towards vaccination in refugee families by running a dedicated electronic survey. A total of 92 Ukrainian families who fled to the European Union, United Kingdom, Israel, United States and Canada in 2022 responded to the questionnaire.
Results: Before emigration, only 81.5 % of children were fully vaccinated according to the Ukrainian immunization schedule, and less than half of children received some of the recommended vaccines not included into the regular national schedule (against rotavirus, varicella, pneumococcal infection, etc.). After emigration all children who remained in the countries of asylum completed all the vaccinations that were offered in those countries, including children from the families with negative parental attitude towards vaccines. Parental concerns of vaccine safety and efficacy did not change significantly. However, the fact that unvaccinated children have limited options to attend educational/daycare settings in a host country became the main reason to catch-up the necessary vaccinations. Simultaneously, up to 30 % of families who returned to Ukraine had refused vaccination for their children in the countries of refuge.
Conclusions/Learning Points: Anti-vaccination attitudes in Ukrainian families are a threat to the public health of asylum countries. A special vaccination program for refugee children should be developed.

SAFETY AND IMMUNOGENICITY AFTER TWO-DOSE BNT162B2 MRNA VACCINE IN CHILDREN AND ADOLESCENT LIVER TRANSPLANT RECIPIENTS

E-Posters Viewing
E-POSTER VIEWING: AS04.A. HOST-PATHOGEN INTERACTION

Sophida Boonsathorn[1], Chonnamet Techaseansiri[2], Pornthep Tanpowpong[1], Chatmanee Lertudomphonwanit[1], Suporn Treepongkaruna[1], Nopporn Apiwattanakul[2]
[1]Faculty of Medicine Ramathibohi Hospital, Department Of Pediatrics, Bangkok, Thailand, [2]Ramathibodi Hospital Mahidol University, Pediatrics, Bangkok, Thailand

Backgrounds: Solid organ transplant recipients may have suboptimal immune responses to COVID-19 vaccines. This study aimed to evaluate the safety and immunogenicity after 2 doses of the BNT162b2 mRNA vaccine in adolescent liver transplantation (LT) recipients.
Methods: Eighteen LT recipients who received two doses, at 3-week intervals, of the BNT162b2 vaccine were enrolled. Anti-RBD IgG was measured before, 3 weeks post-first dose, and 4 and 12 weeks after the second dose. The surrogate virus neutralization test (sVNT) and anti-nucleocapsid immunoglobulin (anti-N Ab) were evaluated at 4 and 12 weeks post-second dose. After each vaccination, adverse events (AEs) were recorded from days 0-7, and acute cellular rejection (ACR) was monitored for up to 3 months.
Results: The mean (SD) age of LT recipients was 14.9 (2.1) years, and 67% received calcineurin inhibitors/mycophenolate/corticosteroid regimens. The mean time since the transplant was 10.3 (4.8) years. At 3 weeks post-first dose, anti-RBD IgG was positive in 13 of 18 (72.2%) LT recipients with a median level of 244.7 AU/mL (IQR 13.9, 632.6). At 4 and 12 weeks after completion, 14/18 (77.8%) were positive for anti-RBD IgG, with median levels of 9,180 AU/mL (IQR 307.5, 19545.3) and 2,949.6 (IQR 415.4, 5992.9), respectively. All patients tested negative for anti-N Ab, indicating no COVID-19 infection after vaccination. At 4 weeks after the second dose, the median percentage of inhibition by neutralizing antibodies, as measured by the %sVNT, was 97.4% (IQR 16.3, 98.9), and slightly declined to 93.4% (IQR 19.9, 96.9) at 12 weeks after completion of vaccination. There were no serious AEs or ACR following each vaccination.
Conclusions/Learning Points: Although suboptimal immune responses were observed, the administration of two doses of BNT162b2 mRNA vaccine to pediatric LT recipients was found to be safe and immunogenic.

GUILLAIN BARRE

E-Posters Viewing
E-POSTER VIEWING: AS04.A. HOST-PATHOGEN INTERACTION

Anas Erragh[1,2], Amine Afif[1], Kaoutar Elfakhr[1], Samira Kalouch[1], Abdelaziz Chlilek[1]
[1]CHU Ibn Rochd, Anesthesiology-intensive Care Medicine Department, Casablanca, Morocco, [2]CHU IBN ROCHD, Anesthesia Resuscitation, CASABLANCA, Morocco

Backgrounds: Guillain-Barré syndrome (GBS) is the most common form of acute polyradiculoneuritis (PRNA). It is a medical emergency in pediatrics that requires rapid diagnosis and immediate assessment of the severity criteria for the implementation of appropriate treatment.
Methods: Retrospective, descriptive study in 24 patients under the age of 18, who presented with GBS between September 2017 and July 2021 and hospitalized in the multipurpose pediatric intensive care unit of the Abderrahim EL Harouchi children's hospital in Casablanca.
Results: The average age was 7.91 years with extremes ranging from 18 months and 14 years, and a male predominance of 75%. After a prodromal event, most often infectious (80%) and a free interval of 12 days on average, 2 types of motor disorders begin: either hypo or arereflectic flaccid paralysis of the lower limbs (45.8%) or flaccid quadriplegia hypo or arereflectic (54.2%) During GBS, the most formidable complication is respiratory distress, it can occur at any time. In our study, respiratory impairment was observed in 70.8% of cases, in addition other signs of severity such as swallowing disorders (75%) and dysautonomic disorders (8.33%) were also observed. which justified care in the intensive care unit for all of our patients. The use of invasive ventilation was necessary in 76.5% of cases, and specific treatments based on immunoglobulins were administered in all our patients. Despite everything, the death rate remains high (25%) and is mainly due to complications related to hospitalization.
Conclusions/Learning Points: Guillain Barré syndrome is therefore a pediatric emergency that requires rapid diagnosis and immediate assessment of severity criteria for the implementation of appropriate treatment

HIV INFECTION WITH RAPID PROGRESSION TO AIDS IN AN ADOLESCENT 16-YEAR-OLD MALE

E-Posters Viewing
E-POSTER VIEWING: AS04.A. HOST-PATHOGEN INTERACTION

Giulietta Keiser[1], Anna Conen[2], Henrik Köhler[1], Florence Barbey[1,3]
[1]Kantonsspital Aarau, Children's Hospital, Aarau, Switzerland, [2]Kantonsspital Aarau, Department Of Infectious Diseases And Infection Control, Aarau, Switzerland, [3]Kantonsspital Aarau, Division Of Pediatric Infectious Diseases, Aarau, Switzerland

Title of Case: HIV infection with rapid progression to AIDS in an adolescent 16-year-old male
Background: Rapid progression from HIV primary infection to AIDS within 12 months to two years is reported in <1% of all patients. Younger age at seroconversion has been shown to be a protective factor of disease progression, whereas genetic predisposition, co-infection with other pathogens and different HIV-1 subtypes have been associated with rapid progression. Research is mainly focused on naturally HIV-resistant people to understand the mechanisms for disease control. Patients with rapid progression to AIDS within a few months have been published in adults, but not in adolescents to the best of our knowledge. We present a case of a 16-year-old male with progression from HIV primary infection to AIDS within a documented time interval of 16 weeks, considering the diagnostic gap of six weeks related to the fourth generation HIV tests.
Case Presentation Summary: A previously healthy 16-year-old male presented to emergency departement with fever, extensive apthous stomatits, dysphagia, and retrosternal pain during swallowing. Personal history yielded an episode of fever, pharyngitis and rash six weeks before. The patient reported regular unprotected sex with men. A negative fourth generation HIV test was documented 76 days before admission. Screening for sexually transmitted diseases yielded a positive fourth generation HIV test with a viral load of 41'900 copies/ml and a CD4+ count of 193/ul (16%). An oral swab yielded a positive PCR for herpes simplex virus 1 and Neisseria gonorrhea, and a positive culture for Candida albicans. Monkeypox was excluded resulting in a presumed AIDS defining diagnosis.
Learning Points/Discussion: This young patient did not show relevant risk for rapid HIV progression to AIDS as described in the current literature, making widely unknown factors for rapid progression likely.

PV0221 / #1076

DERMAL MACROPHAGES DIVIDE LABOR IN MYCOBACTERIAL INFECTIONS

E-Posters Viewing
E-POSTER VIEWING: AS04.A. HOST-PATHOGEN INTERACTION

Florens Lohrmann, Philipp Henneke
University hospital Freiburg, Center For Pediatrics And Adolescent Medidicine, Freiburg, Germany

Backgrounds: Dermal macrophages, which protect the host from colonizing and invading bacteria, originate from either primitive or definitive hematopoiesis, and are largely renewed by monocyte-derived macrophages. IRF8-deficiency is associated with developmental defects in myelogenesis and profound paucity of monocytes, leading to a specific susceptibility to mycobacteria, which exhibit an intracellular lifestyle in macrophages.
Methods: For this study we used murine models of IRF8 deficiency and a combination of fate-mapping, single-cell RNA sequencing and tissue microscopy.
Results: We demonstrate that homeostatic dermal macrophage density and subset distribution is not affected by the lack of monocytes, demonstrating profound plasticity in macrophage differentiation and maintenance. Furthermore, it uncovers distinct differentiation pathways that converge at a subset of immunologically non-reactive tissue resident macrophages. In contrast to the homeostatic situation, IRF8 deficiency leads to a severe defect in dermal macrophage density at the site of the mycobacterial infection, resulting from lacking recruitment of monocyte-derived macrophages. Further dissecting the role of macrophage density and renewal regulation in general, we discovered that recently immigrated macrophages are primed towards antibacterial immunity, while persistence in the dermal environment imprints a less inflammatory transcriptional profile upon macrophages. Turnover kinetics of different clusters reveal a time dependent priming of dermal macrophages, i.e. tissue persistence defines function, rather then origin. This situation uncovered a striking distribution of labor between long-term resident and recently recruited, monocyte-derived macrophages. Whereas recruited macrophages take up bacteria and produce anti-mycobacterial iNos, resident macrophages do no substantially contribute to these processes but initiate a tissue-remodeling program early in infection.
Conclusions/Learning Points: Tissue persistence defines dermal macrophage functions. Macrophage plasticity compensates for the lack of renewal in homeostasis, by a convergent differentiation towards resident macrophages, but clearance of mycobacterial infections relies on monocyte recruitment.

THE IMPORTANCE OF THE MICROBIAL FLORA OF THE NASOPHARYNGEAL MUCOSA IN THE FORMATION OF IMMUNE RESPONSE OF INFECTIOUS MONONUCLEOSIS IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS04.A. HOST-PATHOGEN INTERACTION

Olena Prus
Kharkiv National Medical University, Department Of Children's Infectious Diseases, Kharkiv, Ukraine

Title of Case: The children with mononucleosis
Background: Infectious mononucleosis is one of the most common childhood diseases.
Case Presentation Summary: Objective: to determine the significance of the microbial flora of the nasal and oropharyngeal mucosa in the formation of immune response of children with infectious mononucleosis. Under the supervision were 184 children aged 3-9 years, patients with mononucleosis. First group (31 children) - Staphylococcus aureus was detected; second (33) - Streptococcus pyogenes in combination with Staphylococcus aureus; third group (60) - Streptococcus pyogenes; fourth (29) - E. Coli; fifth group (31) - Streptococcus pyogenes with E. Coli. The immune status was assessed by indicators of levels of lymphocytes $CD3^+$,$CD4^+$,$CD8^+$,$CD22^+$ and the content of interleukins 1β,4,TNFα.
Learning Points/Discussion: The acute period of the mononucleosis in children of 2,3,4 groups was characterized decrease in the relative amount of $CD3^+$,$CD4^+$,$CD8^+$. And more significant increase in blood $CD22^+$ content. The content of IL-1β and TNFα in all patients was higher than in healthy children. The IL-4 increased in children of the 1 and 5 groups. In the period of early convalescence in children of the 1 and 5 groups, the relative content of $CD3^+$,$CD4^+$,$CD8^+$cells approached the corresponding indices of the control group. This was not observed in children of the 2,3,4 groups. $CD22^+$ levels in all observation groups decreased by the convalescence period. The more significant decrease in the levels of IL-1β,TNFα are observed in 1 and 5 groups. In the 2,3,4 groups, proinflammatory interleukins remained high. The presence of streptococcus to the formation of cellular immunosuppression and a pronounced reaction of pro-inflammatory interleukins at the initial stage of the disease, which, leads to aggravation of clinical manifestations of the disease and contributes to the unfavorable course of the disease.

MICROBIOLOGICAL ETIOLOGY AND PULMONARY TOMOGRAPHIC FINDINGS IN CHILDREN WITH CANCER AND EPISODES OF PERSISTENT FEBRILE HIGH RISK NEUTROPENIA

E-Posters Viewing
E-POSTER VIEWING: AS04.B. HOST RESPONSE DIAGNOSTICS AND IMAGING

Carolina Ibanez[1], Veronica De La Maza[1], Daniza Jaldin[2], Romina Valenzuea[1], Lisbet Perez[3], Isabel Fuentealba[3], Juan Pablo Torres[1], Maria Elena Santolaya[1]
[1]Universidad de Chile, Departamento De Pediatría Y Cirugía Oriente, Hospital Dr. Luis Calvo Mackenna, Santiago, Chile, [2]Universidad de Chile, Residente Infectología, Departamento De Pediatría Y Cirugía Oriente, Hospital Dr. Luis Calvo Mackenna, Santiago, Chile, [3]Hospital Dr. Luis Calvo Mackenna, Radiología, Santiago, Chile

Backgrounds: Febrile neutropenia(FN) a frequent complications of anti-neoplastic treatment. 1/3 of high risk(HR) episodes have persistence of fever after 96 hours of proper treatment. Chest-CT patterns of different microorganisms overlap. Multiple organisms cause pulmonary infections in immunocompromised hosts. The aim of this study was to compare chest-CT findings with the microbiological aetiologic causes in persistent high risk febrile neutropenia episodes.
Methods: 2016-2020, we enrroled children with cancer and FN. Physical examination, blood cultures, CRP, CBC, and risk stratification at admission. Daily monitoring. If remained febrile after 96 hours were included in the analysis. Chest-CT were performed. Subjects with persistent HRFN and abnormal chest CT were compared to controls. A blind investigator determined the cause of infection. Chest CT images were analyzed by two blind pediatric radiologists, and a third pediatric radiologist if necessary.
Results: 401episodes of HRFN, 176 of persistent HRFN, 50 with a chest CT, 36 withabnormal chest CT. In 31 of 36 episodes, the etiology could be determined (13 bacterial, 10 fungal and 8 viral), with 5 unknown origin. Subjects with persistent HRFN and an abnormal chest CT had longer hospital stays, longer days of fever, higher PICU admission and more use of oxygen, the length of antibiotics courses and antifungals was higher all statistically significant differences. Mechanical ventilation as well as deaths, showed no difference between both groups. Chest CT showed no statistically significant differences when findings were compared by etiology of episodes.
Conclusions/Learning Points: Abnormal chest CT result in patients with persistent HRFN determines worse clinical outcomes. Single center setting could determine biases, however, the period of observation is long. Previous studies have described the usefulness of CT scans in children with fever during episodes of FN, however, specific CT findings are scarce.

QUANTIFERON-CMV IN A PEDIATRIC TERTIARY CARE CENTRE: A USEFUL TOOL FOR TRICKY SITUATIONS

E-Posters Viewing
E-POSTER VIEWING: AS04.B. HOST RESPONSE DIAGNOSTICS AND IMAGING

Natalia Ana Mendoza-Palomar[1], Susana Melendo[1], Juliana Esperalba[2], Marie Antoinette Frick[1], Laura Alonso[3], Gema Ariceta[4], Paola Dolader[5], Cinzia Tripodi[6], Pere Soler-Palacín[1]
[1]Hospital Universitari Vall d'Hebron, Pediatric Infectious Diseases And Inmunodeficiencies Unit, Barcelona, Spain, [2]Hospital Universitari Vall d'Hebron, Microbiology Department, Barcelona, Spain, [3]Hospital Universitari Vall d'Hebron, Pediatric Hemato-oncology Department, Barcelona, Spain, [4]Hospital Universitari Vall d'Hebron, Nephrology Department, Barcelona, Spain, [5]Hospital Universitari Vall d'Hebron, Cardiology Department, Barcelona, Spain, [6]Hospital Universitari Vall d'Hebron, Neonatology Department, Barcelona, Spain

Backgrounds: Cell-mediated immunity (CD4+ and CD8+) is a key point to control cytomegalovirus (CMV) replication. Its evaluation by interferon gamma-release assay (IGRA) methods is a promising tool, but it has not been included yet in clinical practice algorithms due to lack of consistent data, especially in children. Our aim was to describe the use of QuantiFERON®-CMV in a tertiary pediatric hospital.
Methods: Retrospective, descriptive study of pediatric patients (≤18a) who underwent QuantiFERON®-CMV (QIAGEN®, Hilden, Germany) according to clinical criteria during 2022. QuantiFERON®-CMV uses specialized blood collection tube that are coated with peptides simulating CD8+-specific epitopes of CMV proteins, along with negative and positive control tubes. After incubation, INFg is measured in plasma. A result equal or greater than 0.2 IU/ml is considered reactive. Demographic and clinical data were collected from medical electronic history.
Results: Ten QuantiFERON®-CMV tests were performed in 9 patients (8 males, median age 11[IQR 5-13]y). Main underlying diseases were stem cell (5) and solid organ transplant (2 kidney, 1 heart). Two had previous CMV disease (1 retinitis, 1 pneumonitis). Main reasons for QuantiFERON®-CMV request were maintenance/withholding of treatment (6) and maintenace/withdrawal of prophylaxis (4). The result was reactive (7, median value 1.9 [IQR 0.415-3.395] IU/ml), non-reactive (2), indeterminate (1). QuantiFERON®-CMV results led to prophylaxis/treatment decisions in 9/10 (discontinuing or withholding if positive, maintaining if negative). No ulterior CMV-disease was observed.

Table 1. Patients' demographic and clinical characteristics, QuantiFERON-CMV request and influence in clinical decisions.

Patient	Age	Sex	Underlying disease	CMV history	QTF-CMV date	IFNg value (UI/mL)	QTF-CMV result	Reason for QTF-CMV request	QTF-CMV-guided decision	Ulterior CMV disease
1	18y	M	IEI	No	25/02/2022	0,11	Not reactive	Treatment initiation	No	No
2	13y	M	SCT (ALL-B)	Viremia	23/03/2022	0,45	Reactive	Prophylaxis withdraw	Yes (treatment withdraw)	No
3	8y	M	SCT (congenital dyskeratosis)	Viremia	06/04/2022	3,18	Reactive	Treatment initiation	Yes (treatment withhold)	No
4	13y	M	Kidney transplant	Viremia	13/06/2022	2,41	Reactive	Treatment withdraw (adverse effects)	Yes (treatment withdraw)	No
5	4y	M	SCT (talasemia major)	Viremia	06/07/2022	0,31	Reactive	Considering other therapies in refractory viremia	Yes (maintaining therapy)	No
6	17y	M	Kidney transplant	No	28/09/2022	4,04	Reactive	Prophylaxis withdraw (adverse effects)	Yes (prophylaxis withdraw)	No
4	13y	M	Kidney transplant	Viremia	11/10/2022	1,39	Reactive	Treatment withhold (adverse effects)	Yes (treatment withhold)	No
7	12y	F	SCT (STAT-1-GOF)	Disease (retinitis)	14/10/2022	33,9	Reactive	Prophylaxis initiation	No	No
8	2y	M	Heart trasplant	Viremia	28/10/2022	-0,01	Not reactive	Prophylaxis withdraw (adverse effects)	Yes (prophylaxis withdraw)	No
9	4mo	M	Childhood pneumonitis	Disease (pneumonitis)	02/12/2022	0,31	Reactive	Prophylaxis initiation	Yes (prophylaxis withhold)	No
10	10y	M	SCT (SAA)	Viremia	30/12/2022	0,01	Indeterminate	Treatment withdraw	Yes (maintaning therapy)	No

AAL, acute lymphoblastic leukemia; CMV, cytomegalovirus; F, female; IEI, inborn error of immunity; IFNg, interferon gamma; M, male; mo, months; QTF-CMV, QuantiFERON CMV; SAA; severe aplastic anemia; SCT, stem cell transplant, y, years.

Conclusions/Learning Points: QuantiFERON®-CMV was useful to make clinical decisions, in addition to other microbiological and clinical data, in controversial settings like low-grade persistent viremia or antiviral drug adverse effects in a selected cohort of immunosuppressed pediatric patients (mainly stem cell transplant patients). More studies are needed to define the predictive value of QuantiFERON®-CMV and to validate its use into clinical decision rules.

USEFULNESS OF PERIPHERAL BLOOD CULTURES IN CHILDREN WITH CANCER AND EPISODES OF FEVER AND NEUTROPENIA

E-Posters Viewing
E-POSTER VIEWING: AS04.B. HOST RESPONSE DIAGNOSTICS AND IMAGING

Teresita Sarquis, Carolina Ibanez, Veronica De La Maza, Romina Valenzuea, Maria Elena Santolaya
Universidad de Chile, Departamento De Pediatría Y Cirugía Oriente, Hospital Dr. Luis Calvo Mackenna, Santiago, Chile

Backgrounds: The initial collection of blood cultures (BC) is key for guiding antimicrobial therapy in children with febrile neutropenia (FN), of which more than 90% have central venous catheters (CVC). There is no consensus on the need for peripheral BC over central BCs in this population. The aim of this study was to determine the contribution of peripheral BC over central BC in the diagnosis of blood stream infections (BSI) in children withFN.
Methods: Descriptive study, including all episodes of FN enrolled prospectively in 6 hospitals in Santiago, Chile, between 2016 and 2020. Central and peripheral BC were drawn at admission. All episodes with at least one (+) BC were allocated to one of the following groups: 1) Congruent (+) BC, 2) Incongruent (+) BC, 3) Only CVC (+) BC, 4) Only peripheral (+) BC. The volume of the samples was recorded as a variable that could influence the % of positivity.
Results: The analysis included 241 episodes of FN with at least one(+) BC. The median age was 7.2 years, 49% were male, 84% had hematological cancer and 98% had episodes of high-risk FN. Of the total of 241 episodes, 135 (56%) had congruent (+) BC, 13 (5%) had incongruent (+) BC, 35 (15%) had only CVC (+) BC and 54 (24%) had only peripheral (+) BC. There were no significant differences in the volume of the samples between central and peripheral BCs.
Conclusions/Learning Points: The proportion of BSI detected only through peripheralBC was 24%, higher than previously reported. This difference was not due to sample volume. According to our results, we recommend to obtain peripheral as well CVC BC in children with FN.

[1]OMSB, Child Health, Muscat, Oman, [2]Nizwa University, Natural & Medical Sciences Research Centre, University Of Nizwa, Nizwa, Oman, Muscat, Oman, [3]Nizwa University, 4natural & Medical Sciences Research Centre, University Of Nizwa, Nizwa, Oman, Muscat, Oman, [4]Royal Hospital, Child Health, Muscat, Oman, [5]Nizwa Univercity, 5center Of Expertise In Mycology, Radboud University Medical Center/canisius Wilhelmina Hospital, Nijmegen, The Netherlands, Muscat, Oman

Backgrounds: Invasive fungal disease (IFD) is a common and serious consequence of leukaemia in children and the incidence of these infections increased due to chemotherapy. We present the epidemiology of IFD in a cohort of leukaemia patients from a tertiary reference institution in Oman.
Methods: A retrospective study was conducted of IFDs in pediatric patients with newly diagnosed or relapsed leukaemia, at Royal Hospital, Muscat, Oman. From 2010 to 2017, Patients data was evaluated retrospectively including the Epidemiology, clinical spectrum, risk factors,treatment and outcome were analysed.
Results: 198 children with leukemia were admitted and treated at Royal Hospital. In retrospect, IFI were defined as probable and proven in 53 % (17 patients) and 47% (15 patients) of the attacks. At 1.1:1, the male-to-female ratio was roughly equal. All of the children developed neutropenia, and majority developed thrombocytopenia. 65.6% of patients had radiological features of fungal infections. Positive fungal cultures were found in three patients' bronchoalveolar lavage (BAL), 37.5% of whom had positive blood cultures, and 3% of whom had positive urine cultures. In 3 patients, invasive aspergillosis caused pulmonary IFD, accounting for 9.3% of all infection sites. Candidaemia was found in 28% of IFD patients. The most common organism was Candida tropicalis (15.6%), followed by Candida prapsilosis (6.25%). Two patients were infected with two different fungi, while others were only infected with one. Majority of the patients (84%) had a central line and were receiving one or more antifungals during the infection episodes.
Conclusions/Learning Points: In children with leukemia, invasive fungal infection is common and serious, with high mortality and morbidity. This study emphasizes the difficulties of treating IFIs in leukemic patients, as well as the need for a therapeutic procedure for managing IFIs

[1]Hospital Reina Sofía, Pediatric Infectious Diseases Unit, CORDOBA, Spain, [2]Hospital Regional Universitario de Málaga, Department Of Paediatrics, Malaga, Spain, [3]Hospital Materno-Infantil Torrecardenas, Servicio De Pediatria, ALMERIA, Spain, [4]Hospital Universitario Virgen de las Nieves., Servicio De Pediatria, Granada, Spain, [5]Puerta del Mar Hospital, Division Of Pediatric Infectious Diseases, Puerta Del Mar, Cadiz, Spain, Cádiz, Spain, [6]Hospital Universitario Virgen del Rocío, Servicio De Infectología, Reumatología E Inmunología Pediátrica, Sevilla, Spain

Backgrounds: Candida bloodstream infections are the most frequent fungal invasive infections in children, with a high mortality, especially if antifungal treatment is delayed. The aim of our study was to analyze the main risk factors (RF) for mortality in children and neonates with diagnosis of candidemia.
Methods: Retrospective multicenter cross sectional study of children under ≤ 14 years-old and neonates with candidemia. Epidemiological, clinical, laboratory and outcomes variables were analyzed using the appropriate statistical tests.
Results: Five tertiary pediatric hospitals participated in the study and 204 patients were analyzed. Sixty-six percent were admitted in Pediatric and Neonatal Critical Care Units (PICU and NICU) and 17.6% in haemato-oncology departments. 30.9% were premature. C.parapsilosis was the most frequent specie isolated (46.6%), followed by C.albicans (35.3%). C.glabrata and C.krusei were isolated in 3% respectively. Liposomal amphotericin B was the most widely used initial antifungal (55.9%) followed by fluconazole (27.4%) and in 14.2% combined therapy was prescribed. Forty patients deceased in the study period (19.6%), 60% male and 35% premature. Mostly (87.5%) were admitted in Intensive Care Units. C.parapsilosis was also the most frequent isolated specie in this subgroup (52.5%). A logistic regression analysis was made to determine the RF for mortality. Recurrent candidemia in the following 30 days after diagnosis (OR 4.8, CI 95%: 1.55-14.79) and admission in PICU (OR: 4.829, CI: 1.82-12.79) were the only RF statistically associated with mortality.
Conclusions/Learning Points: - Candidemia continues having a high mortality in children with a 19% in our sample. - C.parapsilosis was globally the most frequent specie isolated in our study, as seen in other recent published studies. - Recurrent candidemia and admission in PICU were RF associated with mortality.

[1]Marmara University School of Medicine, Pediatric Infectious Diseases, Istanbul, Turkey, [2]Cerrahpaşa School of Medicine, Pediatric Immunology, Istanbul, Turkey, [3]Çukurova University School of Medicine, Pediatric Immunology, Adana, Turkey, [4]Marmara University School of Medicine, Pediatric Immunology, Istanbul, Turkey

Backgrounds: Patients with chronic granulomatous disease (CGD) tend to face invasive fungal infections, which significantly cause mortality. In this multicenter study, we aimed to determine the characteristics of invasive mould infections in CGD cases.
Methods: All CGD patients followed up in Divisions of Pediatric Immunology of Marmara, Cerrahpaşa, and Çukurova University School of Medicine, Turkey between 1991 and 2022 were included. Demographic and clinical characteristics, primary antifungal prophylaxis regimen, and if seen, type, treatment, prognosis, and secondary prophylaxis regimen used for mould-associated invasive fungal infection (mIFI) were reviewed retrospectively.
Results: Between 1991 and 2022, 74 CGD patients diagnosed with the DihydroRhodamine (DHR) test were followed-up. Fifty-nine patients (79.7%) were male. Thirty-eight (51.3%) patients had autosomal recessive CGD. The median age at diagnosis was 45 (IQR25: 10.75- IQR75: 148.25) months. Allogeneic hematopoietic stem cell transplantation was performed in 10 patients. Forty mIFI episodes were detected in 38 of 74 patients. The first mIFI episode median age was 42 (IQR25: 26.25, IQR75: 166.50) months. The type of mIFI was proven in 14 (17 episodes), probable in 10, and possible in 13 patients. There was a significant difference in the development of mIFI between CGD patients who received (36.7%) and did not receive (85.7%) itraconazole prophylaxis (p=0.000). A total of 13 patients died, and 11 of them were due to mIFI. The median age of the 61 patients who are still living today is 180 months (IQR25: 105, IQR75: 245). The oldest living patient is now 45 years old.
Conclusions/Learning Points: Itraconazole prophylaxis is effective in preventing mIFI in cases of CGD. However, the development of mIFI in 1 out of every 3 CGD patients receiving itraconazole suggests that an antifungal agent with better mould activity should be considered.

Title of Case: LIFEBUOYS FOR NEAR-DROWNING VICTIMS: LESSONS TO LEARN FROM TREATING SYSTEMIC SCEDOSPORIOSIS IN AN IMMUNOCOMPETENT PEDIATRIC PATIENT
Background: Scedosporium apiospermum is an ubiquitous saprophytic fungus and relevant human pathogen with low susceptibility to antifungals causing pneumonia, sinusitis and invasive disease in near-drowning victims following contaminated water aspiration. Delayed and predominantly lethal central nervous system manifestations and septicemias also occur.
Case Presentation Summary: This report illustrates important lessons to learn in diagnosing and treating systemic Scedosporiosis in an allegedly fully recovered pediatric, immunocompetent near-drowning victim. Two months following the drowning emergency and resuscitation event, the critically ill and septic girl was transferred to our hospital with persistent pulmonary and sinus lesions, meningoencephalitis, intracerebral vasculitis including associated watershed strokes and abscesses, as well as septic osteomyelitis. Voriconazole for presumed Scedoporiosis was added immediately to the current broad antibiotic regimen. Biopsies of osteomyelitic lesions eventually led to culture identification of Scedosporium apiospermum. In due course Micafungin and Terbinafine were added to ensure broad antifungal coverage based on in vitro susceptibility testing. The patient’s state improved gradually. Voriconazole was chosen as the long-term single therapeutic agent. Maintenance therapy has been complicated by voriconazole autoinduction, toxic plasma levels and lack of validated tests to assess disease activity.
Learning Points/Discussion: We propose that early preventive treatment with the addition of voriconazole to the empiric antimicrobial regimen of near- drowning victims may help to prevent haematogenous or sinus spread of Scedosporium apiospermum and thus delayed manifestations of invasive disease. Clinicians should be aware of both the pathogen and the fatal consequences of systemic spread. Prompt isolation and susceptibility testing are key to establishing an effective antifungal treatment regimen. Better measures to guide effective long-term voriconazole treatment, as well as new antifungal medications are needed.

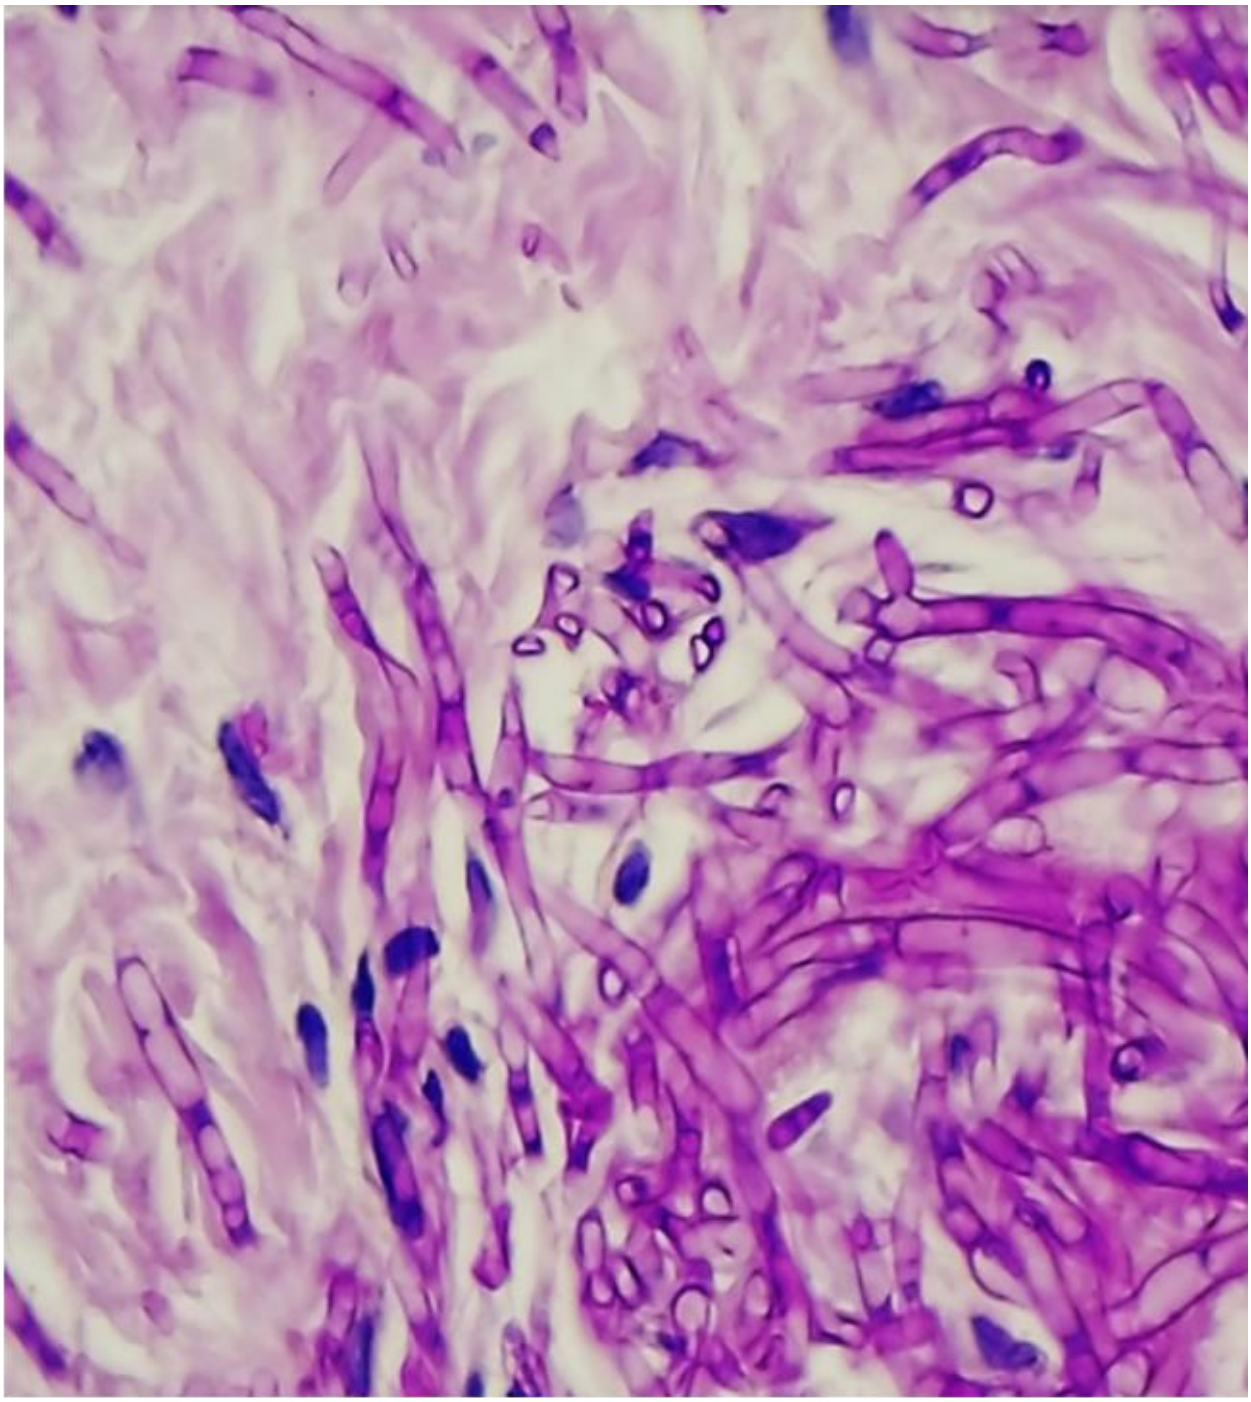
RARE OPPORTUNISTIC INFECTIONS IN PATIENT WITH HEMATOPOIETIC STEM CELL TRANSPLANT

E-Posters Viewing
E-POSTER VIEWING: AS04.C. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Juan López-Cubillos[1], Lauren Ramirez-Celis[2,3], Mariana Medina-Soler[2,3], Fabian Barrero-Florez[4], Mauricio Chaparro[5], Natalia Olaya[6], David Aristizabal[3]
[1]Fundacion HOMI, Infectious Diseases, Bogotá, Colombia, [2]Universidad Nacional de Colombia, Medicine, Bogotá, Colombia, [3]Fundacion HOMI, Pediatrics, Bogotá, Colombia, [4]Universidad Nacional de Colombia, Pathology, Bogotá, Colombia, [5]Fundacion HOMI, Bone Marrow Transplantation, Bogotá, Colombia, [6]Fundacion HOMI, Pathology, Bogotá, Colombia

Title of Case: Rare opportunistic infections in patient with HSCT
Background: A 14-year-old boy who received allogenic HSCT, for acquired aplastic anemia after SARS-CoV-2 infection. Twoweeks before transplant, the patient was taken to a bronchoalveolar lavage due to the presence of pulmonarynodules in tomography with diagnosis of tuberculosis (positive PCR) and probable aspergillosis by positivegalactomannan, for which tetraconjugate and voriconazole treatment was started.
Case Presentation Summary: At day +10, patient presents fever, generalized indurated skin papules with a necrotic center, and increasednodules in chest tomography, therapy was changed to liposomal amphotericin B, blood culture isolates Fusariumspp. MRI shows compromised soft and skeletal tissue; furthermore, cutaneous biopsy confirms Fusarium byhistopathology. There was a decrease in acute phase reactants and neutrophil recovery from the day +18, butfever persisted. CMV reactivation positive viral load on day +27 treated with ganciclovir with subsequentimprovement. Later in day +47, the central nervous system was compromised, with subarachnoid hemorrhage anddissecting aneurysm of the middle cerebral artery, which required embolization.
Patient had persistent fever since diagnosis of fusariosis, susceptibility study with apparent low MIC´s tovoriconazole and amphotericin B based on other reports. Despite of it, it evolves towards disseminatedintravascular coagulation. On day + 60 presents severe abdominal pain, laparotomy shows intestinal perforation,and severe peritoneal bleeding. Shock refractory to treatment; the patient died on day +64 post-transplant.



Fusarium in skin biopsy. PAS X40

Learning Points/Discussion: HSCT patients may have rare opportunistic infections concomitantly as Fusarium and tuberculosis. Theinterpretation of antifungal susceptibility is difficult in these cases and clinical breakpoints are not clear. Despiteimprovements in reactants, neutrophil counts and decrease in skin lesions, the persistence of fever and the laterCNS compromise suggests that the fungal infection could not be controlled.

[1]Bambino Gesù Children's Hospital, Unit Of Clinical Immunology And Vaccinology, Rome, Italy, [2]University of Rome Tor Vergata, Chair of Pediatrics, Department Of Systems Medicine, Rome, Italy, [3]University of Rome La Sapienza, Maternal, Infantile And Urological Sciences Department, Rome, Italy

Title of Case: Pneumocystis Pneumonia in infants-A red flag not only for the immunodeficiencies
Background: Pneumocystis jirovecii (Pj) is an opportunistic pathogen causing pneumocystis pneumonia (PCP), a life-threatening infection, mainly described in HIV infected patients and primary immunedeficiencies.Here we describe PCP in apparently immunocompetent infants affected by chronic diseases.
Case Presentation Summary: Between November 2021 and December 2022 we observed 5 infants with acute respiratory failure and positive Pj on naso-pharyngeal aspirates (NPA).For the detection of Pj was used Quantitative Real-Time Polymerase Chain Reaction (qRT-PCR).No seasonality was observed.The average age was 4 months, and the sex ratio (M/F) was 0.66. All patients presented respiratory virus coinfection.The most common viruses involved were Parainfluenza and Rhinovirus, detected in 60% of cases.The chest computed tomography (TC) imaging resulted consistent with PCP in all patients.The infants were studied for immunodeficiencies and HIV infection was excluded.The median of CD4/CD8 ratio was 1,8 and the total lymphocyte numbers was normal by age as well as the IgG levels (Table 1).All children received corticosteroid and curative treatment with trimethoprim/sulfamethoxazole.In consideration of the poor clinical condition and the little clinal improvement with the standard therapy, two patients were treated with Caspofungin.All patients needed oxygen (O2) supplementation and 3 children were admitted to pediatric intensive care unit (PICU). Four patients were diagnosed for chronic condition after PCP episode. One patient had already diagnosed with congenital cardiopathy at the time of PCP. After the discontinuation of therapy, the patients continued trimethoprim/sulfamethoxazole at prophylactic dosage.
Learning Points/Discussion: PCP is not only the prerogative of HIV infected or primary immunedeficient children.This infection should be also considered in other chronic conditions, such as, congenital heart and lung disorders.In these patients, criteria for evaluating prophylactic treatment of trimethoprim/sulfamethoxazole to prevent PCP are needed.

[1]Hospital Sant Joan de Déu, Paediatrics Hospitalization, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Déu, Universitat de Barcelona. RITIP., Paediatric Infectious Diseases, Barcelona, Spain, [3]Hospital Sant Joan de Déu, Infectious Diseases, Esplugues de Llobregat, Spain

Backgrounds: Invasive fungal disease (IFD) leads to high morbidity and mortality among immunosuppressed patients. Objective: describe the risk factors, causative pathogens, management, and impact on the survival of IFD in our center.
Methods: Observational retrospective study including patients ≤18y admitted at a tertiary paediatric center with an average of 400 cancer and HSCT patients/year from Jan-2021 to Dec-2022. IFD were defined according to EORTC criteria. Demographic, clinical, laboratory, pharmacological and radiological data were recorded.
Results: 13 patients were included (median age of 9.5, IQR 5.3-15.2). 38.5% (5) had a proven, 15.4% (2) probable and 46.2% (6) possible IFD. Table 1 summarizes the main characteristics of the included episodes. Acute leukemia was the most frequent underlying disease (8, 61.5%). 92.3% (12) of patients were receiving antifungal prophylaxis. Invasive pulmonary aspergillosis (5, 38.5%) was the most frequent infection and voriconazole was the most common treatment (6, 46.2%). Isavuconazole was used in four patients. In 100% of patients, TDM was performed. The overall curation rate was 69.2% (9). Three deaths occurred due to
IFD.

Table 1. *Characteristics of the included episodes*

Patient	Underlying disease	Prophylaxis	Max. C-reactive protein (mg/L)	Max. procalcitonin (ng/mL)	ANC	Final diagnosis	IFD treatment	Surgical treatment/biopsy	Radiological findings	Positive galactomannan	Outcome
1	Primary immunodeficiency (HSCT)	Posaconazole	59,4	N/A	<500/mcL	PROVEN IFD -> positive PCR and culture in CSF: ***Rasamsonia piperina***	Voriconazole	No	Brain CT, MRI: affection of CNS	No	Death due to IFD
2	Acute leukemia	Posaconazole	160,3	N/A	<500/mcL	PROBABLE IFD	Posaconazole	No	Lung CT: nodules with ground glass opacities	Yes (blood)	IFD complete remission
3	Acute leukemia	B-amphotericin	514.4	1,09	<500/mcL	PROVEN IFD -> positive culture in lung biopsy: ***Aspergillus flavus***	B-amphotericin + isavuconazole	Yes	Lung CT: nodules with ground glass opacities	Yes (blood)	Death due to IFD
4	Acute leukemia	B-amphotericin	58,6	0,35	<500/mcL	PROVEN IFD -> non-septate hyphae branching at right angles seen in lung biopsy (high suspicion of ***Mucor spp***)	Voriconazole	Yes	Lung CT: pulmonary nodule	No	IFD complete remission
5	Burkitt lymphoma	B-amphotericin	66,4	O,19	<500/mcL	PROVEN IFD -> septate hyphae branching at acute angles seen in lung biopsy (***Aspergillus spp.***)	Voriconazole	Yes	Lung CT: nodular ground glass opacities	No	IFD complete remission
6	Primary immunodeficiency (HSCT)	No	268,6	8,16	2200/mcL	PROBABLE IFD	B-amphotericin + isavuconazole	No	Lung CT: alveolar consolidation + pleural effusion	Yes (BAL)	IFD complete remission
7	Fanconi anemia (HSCT)	Isavuconazole + B-amphotericin	143,7	2,03	8800/mcL	PROVEN IFD -> positive culture and PCR in BAL: ***Aspergillus spp.***	Isavuconazole	No	Lung CT: nodules with ground glass opacities	Yes (blood)	Death due to IFD
8	Acute leukemia	Posaconazole	83,7	0,69	<500/mcL	POSSIBLE IFD	B amphotericin + Voriconazole	No	Lung CT: unspecific	No	IFD complete remission
9	Acute leukemia	Posaconazole	184,4	0,27	5300/mcL	POSSIBLE IFD	Posaconazole	Yes	Lung CT: unspecific	No	IFD complete remission
10	Acute leukemia	B-amphotericin	187	0,11	<500/mCL	POSSIBLE IFD	Voriconazole	No	Lung CT: nodules with ground glass opacities	No	Death non- IFD related
11	Acute leukemia	Posaconazole	0,8	N/A	1500/mcL	POSSIBLE IFD	B-amphotericin + isavuconazole	No	Lung CT: nodules with ground glass opacities	No	IFD complete remission
12	Bone marrow aplasia (HSCT)	Micafungine	138,6	9,24	4600/mcL	POSSIBLE IFD	Isavuconazole	Yes	Lung CT: nodules with ground glass opacities	No	Death non- IFD related
13	Acute leukemia	Voriconazole	101,2	N/A	<500/mcL	POSSIBLE IFD	Voriconazole	No	Lung CT: nodules with ground glass opacities	No	IFD in treatment

Conclusions/Learning Points: Acute leukemia remained as the main risk factor for IFD in our cohort. Although the number of admitted cancer/HSCT patients is increasing in our center, the incidence of IFD was low. Nevertheless, the majority occurred as breakthrough infections despite antifungal prophylaxis. Continuous reevaluation of patient risk factors, the use of new diagnostic tools together with the use of TDM and new antifungal agents may help to improve the outcomes of these patients.

RETROSPECTIVE STUDY OF CANDIDA INFECTIONS IN A TERTIARY CARE CENTER FROM INDIA

E-Posters Viewing
E-POSTER VIEWING: AS04.C. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Bhaskar Shenoy, Devesh Joshi, Pooja Doddikoppad, Ranjeeta Adhikary, Bhavana M V
Manipal Hospital, Pediatrics, Bangalore, India

Backgrounds: Advanced healthcare facilities have improved the survival of preterm babies, critically ill and immune-compromised children. However, it has simultaneously increased the incidence of opportunistic infections like candidiasis.
Methods: This is a 3-year(January 2019 to December 2021) retrospective study from PICU and NICU of a tertiary care hospital. Data of culture proven candidiasis were analised Candida was identified by the BacT/ALERT 3D automated blood culture system, species identification was done with Vitek 2 YST identification card . Aims- 1)To identify most common candida species and its susceptibility pattern. 2)to study epidemiology, predisposing risk factors and final outcome
Results: Of 22 culture positive candida infections , 77.2 % were from PICU and 22.7% from NICU. 40% were isolated from blood, 40% from urine and 20% from other fluids. C.albicans and C.tropicalis were the most common isolates in NICU (40%) and PICU respectively and they were sensitive to fluconazole and other azoles, echinocandins. Predisposing factors were invasive lines (77.3%), prior antibiotic exposure (95%), surgical intervention (10%). 54.5% had bacterial co-infection with K.neumoniae . Overall mortality was 22.7 %. (20% of NICU ,23.5% PICU) . 80% of the mortality was observed in blood culture positive children.
Conclusions/Learning Points: Candida albicans and tropicalis are most common species isolated among candidemia cases in ICU ,All isolates were sensitive to fluconazole. Early diagnosis and treatment are crucial for survival outcomes . Regular antibiotic stewardship, restricted and judicious usage of invasive lines with prompt removal when not necessary can prevent these infections. Empirical therapy with fluconazole can be initiated when fungal infections are suspected.

Backgrounds: Allogeneic hematopoietic stem cell transplant (HSCT) recipients experience an acquired cell-mediated immunodeficiency that leads to infectious complications which impact on procedure-related morbidity and mortality. Recent studies show a rising incidence of non-tuberculous mycobacterial (NTM) infections in these patients. However, limited paediatric data are available.
Methods: Retrospective study including all paediatric HSCT recipients (aged 0-18 years) with microbiologically confirmed NTM disease, between 2013 and 2022 in a tertiary paediatric hospital.
Results: A total of 331 HSCT were performed, identifying 5 patients (1.5%) with NTM infection. One patient had two different infections (Table). The median age at HSCT was 12 years (IQR 7.5-16.5 years). The median time to infection after HSCT was 7.3 months (IQR 3.5-11 months). There were two episodes of disseminated infection and four of pulmonary disease. All patients had active pulmonary graft-versus-host disease (GvHD) and carried a subcutaneous reservoir at the time of infection, but none developed central line-associated infections. Three patients had CD4+ counts <200/mm3, and one also neutropenia <500/mm3. Five infections were caused by Mycobacterium avium complex (MAC): 3 M. avium and 2 M. intracellulare; and one by M. abscessus. The latter occurred in a patient undergoing treatment for MAC infection. All MAC isolates were sensitive to clarithromycin. All patients received combined antimicrobial therapy. Four patients died at a median of 2 months after initial diagnosis (range, 2-9 months). NTM contributed to the death of two patients. The only patient still alive completed 14 months of antibiotic treatment without posterior
relapses.

Episode	Sex	Diagnosis	Type of HSCT	Age at HSCT (years)	NTM diagnosis					Initial treatment	Treatment duration (months)	Status
					Post-HSCT day	GvHD	CD4+ /µL	NTM species	NTM culture site			
1	M	AML	Haplo.	16	+105	aGvHD (gi) cGvHD (lung)	**114**	*M. avium*	BAL	Azi + Cipro	2	Died due to intestinal GvHD
2	F	IEI[1]	MUD	12	+330	cGvHD (lung)	210	*M. intracellulare*	BAL	Am + Clm + E + R	14	Recovered
3	F	IEI[2]	MUD	5	+195	aGvHD (skin, gi) cGvHD (lung)	410	*M. intracellulare*	BAL, skin	Am + Azi + E + R	2	Died due to bacterial pneumonia (*P. aeruginosa*)
4	F	MDS	MMUD	10	+240	cGvHD (lung)	**50**	*M. avium*	BAL, urine	Azi + Cipro + E	9	*Died due to multiple active pulmonary* infections *(Nocardia, adenovirus, Aspergillus fumigatus, M. abscessus, CMV*)
5					+480		NA[3]	*M.abscessus*	BAL	Lfx + Am + Azi	2	
6	M	T-ALL	MUD	17	+9	cGvHD (lung)	**30**	*M. avium*	BAL	Am + Azi + E + Lzd	2	Died due to multifactorial respiratory failure (GvHD, M. avium, probable invasive aspergillosis, pneumothorax)

[1] CTLA-4 haploinsufficiency

[2] MHC class II deficiency

[3] Not Available

aGvHD: acute graft vs host disease; Am: amikacin; AML: acute myeloid leukemia; Azi: azithromycin; BAL: bronchoalveolar lavage; cGvHD: chronic graft vs host disease; Cipro: ciprofloxacin; Clm: clarithromycin; E: ethambutol; gi: gastro-intestinal; haplo: haploidentical; HSCT: hematopoietic stem cell transplant; IEI: inborn error of immunity; Lfx: levofloxacin; Lzd: linezolid; MDS: myelodysplastic syndrome; MMUD: mismatched unrelated donor; MUD: matched unrelated donor; R: rifampin; T-ALL: T-cell acute lymphoblastic Leukaemia.

Conclusions/Learning Points: NTM infections are an infrequent but severe cause of morbidity and mortality after allogeneic HSCT, affecting mainly patients with compromised cell-mediated immunity and active pulmonary GvHD. The most common pathogens in our setting are members of the MAC.

INFANT WITH POST-INFECTIOUS BRONCHIOLITIS OBLITERANS AND INBORN ERROR OF IMMUNITY

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Sofia Benou[1], Christos Mpiliris[1], Manolis Liatsis[2], Sotirios Fouzas[1], Gabriel Dimitriou[1], Anastasia Varvarigou[1], Despoina Gkentzi[1]
[1]General University Hospital of Patras, University of Patras, Department Of Paediatrics, Rion, Greece, [2]Specialized Center & Referral Center for Primary Immunodeficiencies - Paediatric Immunology, "Aghia Sophia" Children's Hospital, Department Of Immunology-histocompatibility, Athens, Greece

Title of Case: INFANT WITH POST-INFECTIOUS BRONCHIOLITIS OBLITERANS AND INBORN ERROR OF IMMUNITY
Background: Infants with inborn errors of immunity may present with infections with severe outcomes early in their lives. We describe a case of an infant who developed postinfectious bronchiolitis obliterans secondary to adenovirus infection and was diagnosed with agammaglobulinemia and B-lymphocytes deficiency.
Case Presentation Summary: A 3-months old full-term male infant, with personal history of failure to thrive was referred to our Paediatric Department because of a 4-day history of fever and tachypnoea. Physical examination revealed hypoxia,tachypnoea but normal breathing sounds on auscultation. Chest X-ray showed bilateral diffuse infiltrations and respiratory PCR-panel-assay on nasopharyngeal swab revealed adenovirus and parainfluenza virus. He received oxygen,IV ceftriaxone,IV methylprednisolone but because of his clinical deterioration, he underwent invasive-mechanical ventilation for 14-days in the ICU. Chest CT-scan revealed diffuse bilateral ground-glass infiltrates,interstitial lung involvement and air-trapping, while multiple-breath washout test after 4 weeks course of bronchodilators and corticosteroids was indicative of persistent airway obstruction. Consequently,after 60 days of hospitalization,the patient was discharged with the diagnosis of post-infectious bronchiolitis obliterans. However, he was readmitted after 3 days with severe respiratory distress because of lower respiratory tract infection. Immunologic evaluation revealed extremely low-for-age values of IgG, IgM and IgA immunoglobins and almost absent number of B-lymphocytes with normal number of T-lymphocytes. However, genetic testing(whole-exome sequencing) for already known immunodeficiencies was negative. Following immunology review,he empirically started receiving intravenous IgG replacement therapy monthly and trimethoprim/sulfamethoxazole prophylaxis and he has shown improvement in growth and no other severe infections.
Learning Points/Discussion: This case highlights the importance of early identification of underlying immunological problems following a severe infection early in life. Immunological follow-up is required and further work up for possible yet not known immunological deficiencies.

DECREASED NEUTROPHIL SURVIVAL AND SEVERE STAPHYLOCOCCUS AUREUS INFECTION IN A PATIENT WITH X-LINKED INHIBITOR OF APOPTOSIS PROTEIN (XIAP) DEFICIENCY

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Coco Beudeker[1], Leire Aguinagalde[2], Anton Tool[3], Joris Van Montfrans[1], Suzan Rooijakkers[2], Taco Kuijpers[4], Michiel Van Der Flier[1]
[1]University Medical Center Utrecht, Pediatric Infectious Diseases, Immunology And Rheumatology, Utrecht, Netherlands, [2]UMC Utrecht, Medical Microbiology, Utrecht, Netherlands, [3]Amsterdam University Medical Center, Department Of Molecular Hematology, Sanquin Research And Laboratory Services And Landsteiner Laboratory, Amsterdam, Netherlands, [4]Amsterdam University Medical Center, Pediatric Immunology, Rheumatology And Infectious Diseases, Amsterdam, Netherlands

Title of Case: DECREASED NEUTROPHIL SURVIVAL AND SEVERE STAPHYLOCOCCUS AUREUS INFECTION IN A PATIENT WITH X-LINKED INHIBITOR OF APOPTOSIS PROTEIN (XIAP) DEFICIENCY
Background: XIAP is an inhibitor of apoptosis in immune cells that blocks caspase-9, 3 and 7. XIAP deficiency is classified as a primary immunodeficiency, may cause hemophagocytic lymphohistiocytosis (HLH) and can be associated with S. aureus infections. In mice, XIAP deficiency results in increased TNF-α induced apoptosis in neutrophils, especially when primed with granulocyte macrophage colony-stimulating factor (GM-CSF), which normally improves neutrophil survival. XIAP deficient mice also show a higher bacterial burden after experimental infection.
Case Presentation Summary: A 15-year-old male presented with HLH and was diagnosed with XIAP deficiency. His HLH was treated with rituximab, dexamethasone and cyclosporine, which improved his clinical condition. He then developed bilateral arthritis of the knees diagnosed as XIAP deficiency associated inflammatory arthritis, for which he received intra-articular steroid injections. The bilateral arthritis deteriorated and septic arthritis was diagnosed due to S. aureus infection. The patient then developed severe sepsis and extensive soft tissue abscesses in both legs. After prolonged antibiotic therapy and surgical drainage the patient recovered. Comparing isolated neutrophils from our reconvalescent XIAP deficient patient and healthy controls, we performed apoptosis assays in the presence of TNF-α and/or GM-CSF. Both in unstimulated neutrophils and in neutrophils stimulated with TNF-α and/or GM-CSF, XIAP deficient neutrophils demonstrated enhanced apoptosis, compared to control neutrophils. Addition of apoptosis-inhibitor zVAD made XIAP deficient and control neutrophil survival identical.
Learning Points/Discussion: Concluding, we present a case of severe S. aureus infection in a patient with XIAP deficiency and show that XIAP deficiency results in decreased neutrophil survival compared to healthy controls. Increased neutrophil apoptosis during inflammation may contribute to decreased bacterial clearance.

THE HIGH BURDEN OF FUNGAL INFECTION WITHIN 3 MONTHS FOLLOWING PEDIATRIC LIVER TRANSPLANTATION: A 10-YEAR EXPERIENCE

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Sophida Boonsathorn[1], Chanita Phichaphop[1], Nopporn Apiwattanakul[2], Pornthep Tanpowpong[1], Suporn Treepongkaruna[1]
[1]Faculty of Medicine Ramathibohi Hospital, Department Of Pediatrics, Bangkok, Thailand, [2]Ramathibodi Hospital Mahidol University, Pediatrics, Bangkok, Thailand

Backgrounds: Fungal infections (FI) remain problematic following liver transplantation (LT). However, data regarding the incidence and risk factors for FI in the pediatric population are scarce. This study aimed to evaluate the incidence of FI, clinical outcomes, and associated risk factors in pediatric LT recipients during the early post-transplantation period.
Methods: We conducted a single-center retrospective study of 136 children who underwent LT between January 2010 and December 2019. Within 3 months following LT, data on clinical characteristics, incidence, types, and sites of FI, treatment, and outcomes (e.g., hospital stays, death) were systematically collected from medical records. Potential risk factors for developing FI and FI-related deaths were analyzed.
Results: Forty-two (31%) patients developed 43 episodes of FI. The median time to the occurrence of FI was 7.5 days (interquartile range [IQR] 4, 16). Among the 41 fungal isolates, Candida albicans was the most common isolate (56%), followed by C. tropicalis (39%). The most common site was intra-abdomen (78%). Significant predictors of FI were re-exploratory laparotomy (odds ratio [OR] 4.9, 95%confidence interval [CI] 1.8–13.3, p = 0.002) and postoperative bacterial infection (OR 3.0, 95%CI 1.1–7.9, p = 0.03). Two patients died with ongoing active FI, representing a case fatality rate of 5% attributable to FI. We found no significant correlation between the history of FI and mortality (OR 1.9, 95%CI 0.5–7.4, p = 0.4).
Conclusions/Learning Points: Almost one-third of pediatric LT recipients experienced FI in the early post-transplant period. C. albicans was the most prevalent causal organism, while the intra-abdomen was the most common FI site. This study highlighted the high burden of FI following pediatric LT and demonstrated that the technical complexity of the surgery and postoperative bacterial infection had a significant impact on FI.

E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Blanca Bravo Queipo De Llano[1], Carmen Morales[2], Jose Manuel Lucena-Soto[2], Peter Olbrich[3], Olaf Neth[3]
[1]Hospital Universitario La Paz, Paediatric Infectious And Tropical Diseases Department, Madrid, Spain, [2]Hospital Universitario Virgen del Rocío, Immunology Department, Sevilla, Spain, [3]Hospital Universitario Virgen del Rocío, Pediatric Infectious Diseases, Rheumatology And Immunology Department, Sevilla, Spain

Backgrounds: Ataxia-telangiectasia (A-T) is an autosomal recessive inborn error of immunity characterized by chromosomal instability resulting a syndromic immunodeficiency often including recurrent infections. The aim of this study was to evaluate potential associations between immunologic parameters and infectious disease susceptibility in children with A-T.
Methods: Retrospective study performed in a tertiary hospital in Spain. Medical records of A-T patients diagnosed with <18 years were reviewed focusing on infectious manifestations and immunologic evaluations.
Results: Twelve A-T patients were identified. First disease characteristic symptoms were present at a median age of 1.5 years (RIC 1.3-2) and a genetic diagnosis was established at a median age of 6.5 years (IQR 2-11). One patient was diagnosed by neonatal screening. Recurrent respiratory tract infections were observed in 5/12 patients. The immunological evaluation revealed defective lymphocyte production as 8/11 patients presented lymphopenia for their age, with median lymphocyte count 1329/µL (IQR 1077-1525). T lymphocytes were predominantly altered as 6/10 patients had low CD3+ counts (both CD4+ and CD8+) and low percentage of recent thymic emigrants (6/7). Also 5/10 patients presented with decreased B cell count, with median 234/µL (IQR 112-272). We found hypogammaglobulinemia, especially IgA with <15 mg/dL in 7/11 patients. All of them received antibiotic prophylaxis with cotrimoxazole and 8/12 intravenous immunoglobulin substitution. Severe complications include tumours (3/12), liver failure (2/12) and infections: bronchitis (4/12), pneumonia (3/12), otitis (2/12), gastroenteritis (1/12). We registered two deaths, one due to severe lung infections secondary to Mycobacterium abscessus and Fusarium spp. aged 20 and one due to hepatocellular-ca aged 22 years.
Conclusions/Learning Points: In our setting A-T often presents with T cell lymphopenia and decreased IgA production favouring potentially fatal respiratory infections. A close multidisciplinary follow-up remains essential as currently no curative treatment exist.

RETROSPECTIVE STUDY ON THE EFFICACY AND SAFETY OF OFF-LABEL ISAVUCONAZOLE AND POSACONAZOLE TREATMENTS, INCLUDING PROPHYLAXIS, IN A PEDIATRIC ONCO-HEMATOLOGICAL COHORT

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Lorenzo Chiusaroli[1], Lucia Dell'Anna[1], Elisa Barbieri[1], Marica De Pieri[1], Cecilia Liberati[1], Maria Grazia Petris[2], Elisabetta Calore[2], Marta Pierobon[2], Carlo Giaquinto[1], Alessandra Biffi[2], Daniele Donà[1]
[1]University of Padova, Division Of Pediatric Infectious Diseases, Department For Woman's And Child's Health, Padova, Italy, [2]University of Padua, Department For Woman's And Child's Health, Hematology And Oncology Unit, Padova, Italy

Backgrounds: Invasive fungal infections (IFDs) are a significant problem in pediatric oncohematological patients. Prevention of IFDs through prophylactics and early treatment are crucial to reduce the severity of this event. Posaconazole and isavuconazole are important prophylactic and therapeutic options in managing IFDs.
Methods: This is a retrospective, monocentric study, including patients between 3 months and 21 years of age with oncohematological disease who received posaconazole and/or isavuconazole as prophylactic and/or therapeutic regimes between January 2017 and November 2021. The efficacy and safety of posaconazole in primary prophylaxis were evaluated by comparing the rate of IFD breakthrough and side effects between patients who underwent primary prophylaxis with posaconazole versus a control group prophylaxis with amphotericin B (Lamb). Clinical efficacy and side effects attributable to posaconazole and isavuconazole as therapeutic regimens were analyzed.
Results: Comparing the prophylactic use of posaconazole and Lamb, 40 and 37 patients were analyzed, respectively. IFI breakthrough rate was similar in the two populations (7.5 % posaconazole vs 10.8 % Lamb). Posaconazole was associated with a lower frequency of side effects than Lamb (10% posaconazole vs 62.2% Lamb). At therapeutic dosage, posaconazole was predominantly administered in combination with other antifungals (71.4%). By the 12th week of treatment, 71.4% of patients had a full clinical response, while the remaining 28.6% had a partial response. Side effects from using posaconazole were detected in 10% of the patients in prophylaxis and 28.6% receiving therapeutic dosage. Isavuconazole was used at therapeutic regimen, mainly in monotherapy (60%). A complete therapeutic response was observed in 70% of cases; 30% of cases experienced therapeutic failure. Side effects occurred in 20% of patients.
Conclusions/Learning Points: Both posaconazole and isavuconazole are well tolerated in the pediatric population and have shown promising prophylactic and therapeutic properties.

Backgrounds: This study aimed to evaluate the prevalence of EBV-infection in paediatric patients (pts) with Acute Leukemia after Hematopoietic Stem Cell Transplant (HSCT).
Methods: From October 2021 to October 2022, 667 patients referred to the Department of Hematology/Oncology at Bambino Gesù Children's Hospital-IRCCS with clinical information available and tested for EBV-DNAemia both as diagnosis of (re)-activation of EBV infection or active surveillance after HSCT, were selected.
Results: A total of 235/667(35.2%) pediatric onco-hematologic pts had at least one EBV positive blood sample. The prevalence of EBV infection was higher in those with Acute Lymphoblastic or Myeloid Leukemia (ALL or AML) (110/235, 46.8%) than in the other subtypes of malignancy (non-malignant haematology disorder [95/235, 40.4%], solid organ transplant [17/235, 7.2%] and lymphoma [13/235, 5.6%]). By focusing on pts with Acute Leukemia, 61/110 were males (55.5%) and 49/110 females (44.5%), with a median (IQR) EBV-DNAemia of 1219(321-4613) cp/mL at onset. Among those, 71/110 (64.5%) underwent a haploidentical-HSCT in 37/71(52.1%) pts, while 34/71(47.9%) pts received a matched unrelated donor HSCT. Graft versus Host Disease was reported in 9/71(12.7%) pts. The prevalence of EBV-infection was higher in pts with ALL-T or ALL-B (76/110, 69.1%), followed by pts with AML (33/110, 30%) and Acute Promyelocytic Leukemia (1/110, 0.1%). The median(IQR) ages at EBV onset and transplantation were 8.6(5.9-14.7) years and 9.0(5.7-13.9) years, respectively. The median(IQR) of duration of infection was 25(0-82.6) days. The median time from transplantation to onset of EBV infection was 115(50-476) days.
Conclusions/Learning Points: This study shows a high prevalence of EBV-infection in pts with Leukemia in our cohort. Monitoring EBV by viral load and defining time-window for screening and early diagnosis of EBV may play an important role for proper strategy of management of onco-hematologic patients.

E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Purva Jain[1], Sandeep Basnet[2], Sahar Syed[1], Brent Arakaki[1], Katherine Mues[1], Zachary Marcum[1], John Diaz-Decaro[2]
[1]Aetion, Inc., Science Delivery, New York City, United States of America, [2]Moderna Therapeutics, Epidemiology, Cmv Vaccine, Cambridge, United States of America

Backgrounds: Cytomegalovirus (CMV) is a latent virus that may result in severe complications and worsening prognosis among immunocompromised individuals. No studies have examined how the COVID-19 pandemic may have impacted CMV testing and diagnosis among immunocompromised children in the United States (US). This study aimed to evaluate changes in CMV testing and diagnosis rates among immunocompromised children (aged <1-11 years) during the COVID-19 pandemic in the US.
Methods: This was an observational retrospective cohort study utilizing HealthVerity claims data from December 2017-May 2022. A quasi-Poisson interrupted time series model accounting for seasonality was used to determine whether the underlying CMV testing and diagnosis trends were associated with COVID-19-related interruption time points. Three distinct time periods were defined: pre-COVID-19 pandemic, 06/01/2018-03/31/2020; pre-COVID-19 vaccine, 04/01/2020-12/31/2020; and post-COVID-19 vaccine, 01/01/2021-05/2022.
Results: Comparing the observed rates of CMV testing in the pre-COVID-19 vaccine and post-COVID-19 vaccine periods to the rate that would have been observed based on the trends observed in the pre-COVID-19 pandemic period (i.e., the counterfactual), the rate of CMV testing slightly decreased in the pre-COVID-19 vaccine (event rate ratio [ERR], 0.98; 95% confidence interval [CI], 0.964-0.995) and post-COVID-19 vaccine periods (ERR, 0.99, 95% CI, 0.979-0.992). The results were consistent for CMV diagnosis (Figure).
Conclusions/Learning Points: Declaration of COVID-19 as a pandemic and the initial EUA for a COVID-19 vaccine were both associated with a slight decrease in CMV testing and diagnosis rates among immunocompromised children.

PRIMARY IMUNNODEFICIENCIES AS A PREDISPOSING OR PROTECTIVE FACTOR FOR SEVERE COVID-19

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Mykola Haras
Bukovinian State Medical University, Pediatrics And Pediatric Infectious Diseases/Chernivtsi, Ukraine

Title of Case: PRIMARY IMUNNODEFICIENCIES AS A PREDISPOSING OR PROTECTIVE FACTOR FOR SEVERE COVID-19
Background: Risk factors associated with severe disease and mortality from COVID-19 includes advancing age and comorbidities associated with direct or indirect suppression of the immune system. The consequences of SARS-CoV-2 infection in individuals with primary immunodeficiency remain uncertain (Adrian M., 2021). In the absence of larg and/or thorough data, it remains unclear whether PID is a predisposing or a protective factor for SARS-CoV-2 infection (Babaha, F., 2020). SARS-CoV-2 infection in children with PID and its complications have not yet been well described, the course of COVID-19 can range from mild illness to death (Meyts I, 2021).
Case Presentation Summary: Boy, 7 years old, was hospitalized on the 14th day of disease in severe condition. Chronic granulomatous disease was diagnosed at 4 years old. Final diagnosis verified as COVID-19, right-sided lower lobe pneumonia. He received oxygen, ceftriaxone, dexamethasone, sulfamethoxazole/trimethoprim, intraconazole. A 15-year-old girl was hospitalized on the 2nd day of disease in moderate condition. WHIM-syndrome was verified at 12 years old. Laboratory findings indicated leukopenia, neutropenia, increased levels of procalcitonin, CRP, D-dimer in serum. Final diagnosis verified as COVID-19, bronchitis. Treatment included oxygen, systemic steroids and topical steroid inhalation, cephalosporins of IV generation, intravenous administration of granulocyte colony-stimulating factor, and symptomatic therapy.
Learning Points/Discussion: The clinical case demonstrated the routine moderate and severe coronavirus disease COVID-19 with bronchitis or pneumonia in the children suffered from different primary imunnodeficiencies. The main treatment of both cases consists of support oxygen, cephalosporin antibacterial and short course systemic steroid therapy and treatment of PID. Clarification of the predisposing/protective role of primary immunodeficiencies on the severity COVID-19 is currently limited to a small number of observations and requires further accumulation of data.

FEVER OF UNKNOWN ORIGIN AFTER HSCT: SYSTEMIC MYCOBACTERIOSIS IN A PEDIATRIC PATIENT WITH MALIGNANT OSTEOPETROSIS

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Verena Herbener[1], Felix Maier[1], Manfred Hönig[1], Katharina Wustrau[1], Ingrid Furlan[1], Matthias Schaal[2], Ansgar Schulz[1], Steffen Stenger[3]
[1]University Ulm, Department For Pediatrics And Adolescent Medicine, Ulm, Germany, [2]University Ulm, Department For Radiology, Ulm, Germany, [3]University Ulm, Department Of Medical Microbiology And Hygiene, Ulm, Germany

Title of Case: Fever of unknown origin after HSCT: systemic mycobacteriosis in a pediatric patient with malignant osteopetrosis
Background: Fever of unknown origin (FUO) is a frequent complication after Hematopoietic Stem Cell Transplantation (HSCT). Identifying the pathogen is essential for optimal treatment.
Case Presentation Summary: A girl three years of age with malignant osteopetrosis received HSCT from a matched unrelated donor. The patient suffered from acute GvHD grade III (skin/liver) and extensive chronic GvHD (gut/skin), treated with steroids, sirolimus and ruxolitinib.
Since d+359 after HSCT the patient experienced multiple episodes of FUO with elevated inflammatory markers, which intermittently responded to antibiotic treatment. Infectious work up remained non-informative. A central venous line was removed. Differentials as adrenal insufficiency and ongoing GvHD were treated accordingly but febrile episodes recurred after four to six weeks.
On d+420 multiple hypointense splenic lesions, suggestive of septic infiltrates, were detected by ultrasound. A PET-MRI showed active lesions in mediastinal lymph nodes and the spleen. As both sites were considered surgically inaccessible for biopsy, the patient received empirical antibiotic treatment (meropenem/ vancomycin) for four weeks. The patient thereafter remained afebrile, the splenic lesions showed signs of organization in ultrasound controls.
On d+554 new rapidly progressive splenic lesions became detectable. Infectious work-up was extended to mycobacteria. Acid-fast rods were detected microscopically in a direct blood smear, in the culture mycobacterium avium was isolated. The interferon-γ-test and the Mantoux test were both negative.
A tuberculostatic therapy according to antibiotic susceptibility pattern (ethambutol/ rifabutin/ clarithromycin) resulted in rapid regression of splenic lesions and solution of febrile episodes.
Learning Points/Discussion: We suggest to rule out mycobacterial infection in patients with intensive immunosuppression after HSCT in case of recurrent episodes of FUO, which do not respond to standard procedures.

SYSTEMATIC LITERATURE REVIEW OF THE EFFICACY, EFFECTIVENESS, AND IMPACT OF PCV13 VERSUS VACCINE TYPE INVASIVE PNEUMOCOCCAL DISEASE IN CHILDREN WITH RISK CONDITIONS

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Heather Sings[1], Iwona Pustulka[2], Carol Forbes[3], Kyla Hayford[4], Adriano Arguedas[1], Alejandro Cane[1], Maria Tort[5], Liping Huang[6]
[1]Pfizer, Medical And Scientific Affairs, Collegeville, United States of America, [2]Evidera, Evidence Synthesis, Warsaw, Poland, [3]Evidera, Evidence Synthesis, London, United Kingdom, [4]Pfizer, Global Medical Affairs, Toronto, Canada, [5]Pfizer, Us Medical Affairs, Collegeville, United States of America, [6]Pfizer, Global Value & Evidence, New York, United States of America

Backgrounds: Routine vaccination with 13-valent pneumococcal conjugate vaccine (PCV) provided additional reduction of invasive pneumococcal disease (IPD) compared with 7-valent PCV. Previous systematic literature reviews (SLRs) have investigated PCV13 efficacy/effectiveness against IPD in healthy children and certain risk conditions (e.g., HIV). Here we summarize PCV13 efficacy/effectiveness/impact in paediatric patients with risk conditions.
Methods: A SLR based on Cochrane methods was conducted to determine the efficacy, effectiveness, and impact of PCV13 against vaccine type (VT) IPD/carriage in children <18 years with risk conditions. The searches were conducted in MEDLINE, Embase, the Cochrane Library (CENTRAL and CDSR) and conference abstracts from January 2000 to September 2022. Only English-language articles were included for extraction.
Results: Two studies reported PCV13 effectiveness on VT-IPD, one study reported PCV13 efficacy on reducing VT serotype acquisition, and three studies reported PCV13 impact on VT-IPD (Table). In transplant recipients ≤18 years who received 2-4 doses of PCV13 or PCV7 (3+1), the effectiveness against VT-IPD was 29.6%–83.8% (non-significant) compared with unvaccinated children. In a study in children with HIV aged 1-14 years, efficacy of PCV13 at preventing new acquisition of VT serotypes versus Hib controls was 30.5%. VT-IPD effectiveness was 91.0% (non-significant) in HIV-infected children ≥16 weeks who received PCV13 (2+1). The impact studies showed that PCV13 (2+1) significantly reduced the number of VT-IPD events in HIV children <2 years by 72% versus the pre-vaccine era (2005 to 2008). Relative risk of VT-IPD decreased in children with sickle cell disease after PCV13 (3+1) versus pre-vaccine era (Table). However, due to low event rates, most results were non-significant.
Conclusions/Learning Points: PCV13 reduced VT-IPD in children with underlying medical conditions that increased their risk to pneumococcal disease, but additional adequately powered studies are

needed.

Table. Efficacy, effectiveness, and impact of PCV13 against VT-IPD/carriage in children with underlying medical conditions

Author year, country (sample size)	Risk condition -	Vaccine, schedule (comparator)	Population	Result*
Vaccine efficacy against VT carriage– vaccine efficacy (95% CI)				
Makenga 2021, Tanzania (N=225)	HIV	PCV13, 3+0 (Hib)	Children infected with HIV aged 1-14 years	Reducing acquisition of all VT serotypes, 2 doses: 30.5% (-6.4 – 54.6%) Preventing new acquisition and clearing existing VT carriage: 31.5% (1.5 – 52.4%)
Vaccine effectiveness against VT IPD – vaccine effectiveness (95% CI)				
Olarte 2017, USA (N=629)	HSCT and solid organ transplant	PCV13 or PCV7, 3+1 (unvaccinated children)	Transplant recipients ≤18 yrs with IPD	2 doses: 47.0% (-442.7 – 94.9%) 3 doses: 29.6% (-674.2 – 93.6%) 4 doses: 83.8% (-44.1 – 98.2%)
Cohen 2017, South Africa (N=358)	HIV	PCV13, 2+1 (unvaccinated children)	Children with HIV aged ≥16 wks	91.0% (-35.5 to 100%)
Vaccine impact against VT IPD –% reduction in IPD events/visits (95% CI)				
Von Gottberg 2014, South Africa (N=24,552)	HIV	PCV13, 2+1 (pre-vaccine era; 2005-2008)	Children with HIV hospitalized for IPD	Aged <2 yrs in 2011: 35% (-3 – 60%) Aged <2 yrs in 2012: 72% (44 – 88%)
Nzenze 2017, South Africa (N=NR)	HIV	PCV13, 2+1 (PCV7 era; 2010)	Children ≤5 yrs with HIV	3 mths-2 yrs: 59.1% (-70.4 – 93%) 2-5 yrs: 49.9% (-97.1 – 89.2%)
Vaccine impact against VT IPD – relative risk (95% CI)				
Adamkiewicz 2021, USA (N=NR)	SCD	PCV13, 3+1 vs PCV7 period (2000-2009)	Aged 0-4 years with Hb SS	0.34 (0.15 to 0.72); p=0.004

IMMUNOGENICITY OF BNT162B2 AND CORONAVAC IN IMMUNOCOMPROMISED CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Daniel Leung, Jaime Rosa Duque, Yu Lung Lau
The University of Hong Kong, Department Of Paediatrics And Adolescent Medicine, Hong Kong, Hong Kong PRC

Backgrounds: Patients with immune compromise are at a higher risk of developing a severe or prolonged disease course after SARS-CoV-2 infection. Immunogenicity data on immunocompromised children are scarce for BNT162b2, and not available for CoronaVac.
Methods: We studied the immunogenicity of BNT162b2 and CoronaVac among 64 pediatric chronic kidney disease patients and 39 patients with inborn errors of immunity (IEI, or primary immunodeficiencies, PID). Patients who received 1, 2, 3 or 4 doses were included. 0.5ml CoronaVac was given to patients of any age, 0.1ml BNT162b2 to those aged 5-11 years, and 0.3ml BNT162b2 to those aged 11+ years.
Results: Weaker binding and surrogate neutralization responses were found after 2 doses in IEI patients with humoral immunodeficiencies and kidney patients on immunosuppressives. BNT162b2 induced T cell responses against S protein, and CoronaVac against S, N and M proteins. Surrogate neutralization was further reduced against Omicron BA.1. T cell responses against Omicron BA.1 were maintained. A third dose increased antibody response. Infected patients who received vaccination had a hybrid antibody response, with higher Omicron BA.1 neutralization than those uninfected. A booster dose (dose 4) increased neutralization against wild-type and Omicron BA.1, BA.2, and BA.5.
Conclusions/Learning Points: Our results show CoronaVac and BNT162b2 are immunogenic in children and adolescents with immunocompromising conditions. Neutralization responses are poorer against Omicron subvariants, which are improved by dose 4.

PV0246 / #2516

HIGH-DOSE INTRAVENOUS IMMUNOGLOBULIN (IVIG) PROVOKED BARTONELLA HENSELAE INFECTION AFTER ONSET OF KAWASAKI DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Daniel Lewandowski, Daiva Gorczyca
Wroclaw Medical University, Immunology And Rheumatology Of Developmental Age, Wroclaw, Poland

Title of Case: High-dose intravenous Immunoglobulin (IVIG) provoked Bartonella henselae infection after onset of Kawasaki Disease
Background: Cat Scratch Disease (CSD), most commonly affecting children and teenagers, is a self-limiting infectious disease characterized by lymphadenopathy caused by Bartonella henselae. A disseminated form of CSD occurs in immunosuppressed patients after solid organ transplantation and patients infected with human immunodeficiency virus. We present a case of disseminated CSD manifestation in a child with Kawasaki Disease after treatment of high-dose intravenous immunoglobulin.
Case Presentation Summary: A 6-year-old girl with a medical history of fever for 8 days, nonpurulent bilateral conjunctivitis, erythema of the abdomen, cervical lymphadenopathy, and diffuse erythema of oral mucosa was diagnosed with Kawasaki disease. Echocardiography revealed dilated left and right coronary arteries, 3 mm and 6 mm respectively. The patient received IVIG therapy (2g/kg), coupled with aspirin. Eighteen hours post IVIG therapy, general patient condition worsened, with reoccurrence of fever, diffuse myalgia, and severe abdominal pain. Abdomen ultrasonography showed an enlarged liver, and hypoechoic areas on the spleen. Further history revealed that the patient had been scratched on the left thumb by a cat prior to admission. Upon examination, a 2 mm erythematous nodule on the thumb was noted. Test for Bartonella henselae antibodies revealed elevated immunoglobulin G (IgG) 1024 (<64 negative) and immunoglobulin M (IgM) 160 (<20) level. The patient was treated with erythromycin.
Learning Points/Discussion: In this case, we see how high doses of IVIG during the treatment of

Kawasaki disease can induce disseminated CSD manifestation. Through antimicrobial therapy a

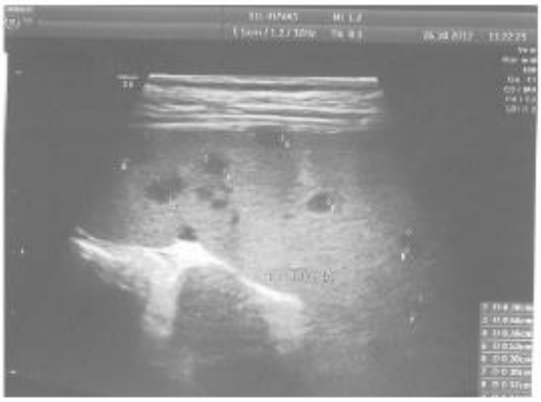

Figure 1. Multiple hypoechogenic areas within the spleen at diagnosis of CSD

Figure 2. Spleen after 2 weeks treatment with erythomycin

Figure 3 .Erlaged axillary lymph nodes at diagnosis of CSD

complete recovery was made.

E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Fabrizio Leone[1], Emma Manno[2], Nicola Cotugno[2,3], Beatrice Rivalta[2,3], Carmela Giancotta[2], Lucia Pacillo[2,3], Martina Di Giuseppe[4], Maia De Luca[4], Cristina Russo[5], Laura Lancella[4], Caterina Cancrini[2,3], Paolo Palma[2,3]
[1]Università di Roma,, Materno-infantile E Scienze Urologiche, Rome, Italy, [2]Bambino Gesù Children's Hospital, Unit Of Clinical Immunology And Vaccinology, Rome, Italy, [3]University of Rome Tor Vergata, Chair of Pediatrics, Department Of Systems Medicine, Rome, Italy, [4]Bambino Gesù Children's Hospital, Infectious Disease Unit, Roma, Italy, [5]Bambino Gesù Children's Hospital, Unit Of Microbiology And Diagnostic Immunology, Roma, Italy

Title of Case: Nontuberculous Mycobacteria (NTM) in adolescents with Common Variable Immune Deficiency (CVID): a case-series
Background: Nontuberculous mycobacterium (NTM) cause various diseases such as skin infection, lymphadenitis, pulmonary infection and disseminated infection most commonly in young children and immunocompromised individuals. Here we describe NTM Lung Disease (NTM-LD) in male adolescents with Common Variable Immunodeficiency (CVID).
Case Presentation Summary: The average age was 14.5 years (range 12-17 years). The patients were receiving subcutaneous immunoglobulin replacement therapy. These patients were also already suffering from granulomatous-lymphocytic interstitial lung disease (GLILD). For this reason they received previously treatment with Rituximab. NTM infection was detected during investigations for respiratory symptoms and fever unresponsive to broad-spectrum antibiotic therapy. NTM were detected with Polymerase Chain Reaction (qRT-PCR) and culture test on bronchoalveolar lavage (BAL). In one patient was isolated Mycobacterium Chimaera and in the other Mycobacterium Kansasii. The other most common bacterial and viral infections typical in patients with CVID were excluded. The chest computed tomography (CT) imaging showed worsening of previous micronodular lesions. The patient received combined antibiotic therapy with Macrolides, Ethambutol and Rifampicin. The treatment lasted 1 year. The patients were under close clinical follow-up to monitoring adverse events and the treatment was discontinued after 1 year when we obtained three negative culture on sputum and improvement of chest CT.

	Pt1	Pt2
Sex	Male	Male
IEI	CVID	CVID
Hypogammaglobulinemia	Yes	Yes
IgEV Therapy	Yes	Yes
Splenomegaly	Yes	N
ITP	N	N
GLILD	Y	Y
NTM infection (years)	12	17
Atypical Mycobacteria	Kansasii	Chimaera
Therapy	Azithromycin Ethambutol Rifampicin	Clarithromycin Ethambutol Rifampicin
Duration of Therapy (months)	12	12
Chest CT Tubercolosis	Y	Y
Negative TB test (months)	12	12

Learning Points/Discussion: NTM infections are frequently difficult to be identified. Molecular techniques may support the diagnosis. Treatment requires extended course of combination antibiotic therapy supported by molecular, culture and antimycobacteriogram tests in order to assess the resistance profile. In patients with GLILD it is important to investigate this infection which may be subtle. In this kind of patients diagnosis of NTM-LD could be more complicated due to overlapping of chest CT images.

Title of Case: Two cases of severe influenza infection in immunocompromised children: the importance of timely vaccination
Background: Immunocompromised children are at high risk of severe illness and complications from influenza infection.Timely flu immunization is recommended for all patients affected by primary or secondary immunodeficiencies.Often the vaccination is postponed on the basis of false contraindications.Here we describe two cases of immunocompromised children with complicated influenza A infection.
Case Presentation Summary: The Case 1 was a 9-year old boy affected by RAG1 deficiency who underwent a hematopoietic stem cell transplantation (HSCT) resulted in an incomplete donor chimerism with mild immunocompromission and autoimmunity.The Case 2 was a 11-year old boy with Chronic Granulomatous Disease (CGD).Both patients were unvaccited for medical reason (rhinitis the day of scheduled appointment).They presented at emergency department with fever and dry cough.The chest X-ray and the computed tomography (CT) of the first patient revealed bilateral basal pleural effusion and diffuse ground-glass opacities in both lungs.The CT-scan of the second patients showed an extensive area of consolidation on the left lobes.The nasopharyngeal swabs turned out positive for Influenza A, H1N1 in the first case and H3N2 in the latter case. Both were treated with intravenous wide spectrum antibiotics and with a 10-day course of oseltamivir. They also received a 5-day course of IVIG. The first patient was discharged after 7 days with chest X-ray negative for pleural effusion. The second child developed macrophage activation syndrome that required treatment with corticosteroid and anti-interleukin-1. The patient was discharged in well clinical condition after 30 days with improvement of consolidation at CT-scan.
Learning Points/Discussion: Poor timing of influenza vaccination could lead to severe complications in immunocompromised children. Early and effective vaccination campaigns outlining the real contraindications to flu vaccine are needed.

EBV INFECTION IN KIDNEY TRANSPLANT PATIENTS: ANALYSIS OF AN ITALIAN PEDIATRIC COHORT OVER A 10- YEAR PERIOD

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Stefania Mercadante[1], Costanza Tripiciano[1], Sara Chiurchiù[1], Laura Lancella[1], Isabella Guzzo[2], Raffaella Labbadia[2], Andrea Cappoli[2], Donato Amodio[3], Lorenza Romani[1], Maia De Luca[1]
[1]Bambino Gesù Children's Hospital, IRCCS, Infectious Disease Unit, Rome, Italy, [2]Bambino Gesù Children's Hospital, IRCCS, Division Of Nephrology And Dialysis, Rome, Italy, [3]Bambino Gesù Children's Hospital, Unit Of Clinical Immunology And Vaccinology, Rome, Italy

Backgrounds: Pediatric solid organ transplant (SOT) recipients commonly have Epstein-Barr virus (EBV) DNAemia. EBV is related to post-transplant
lymphoproliferative disease (PTLD), a potentially fatal complication occurring in 1-20% of SOT.
Methods: All patients who underwent a renal transplant between 2011-2022 at Bambino Gesù Children's Hospital in Rome were enrolled in this study. A "persistent" EBV infection was defined as a blood viral load ≥ 5.000 cp/µl detected for ≥ 6 consecutive months. An "high" EBV viral load was defined as ≥100.000 cp/µl on blood.
Results: Of the 240 patients included, 97 (40.4%) developed a persistent EBV infection during follow-up. Among these 49 (20.4%) developed a high viral load. Primary infections evolved more frequently into persistent infections (p 0.002) and high EBV viraemia (p <0.000) than reactivations. Seropositive CMV recipients less frequently developed a high EBV viral load (p 0.043), probably because they did not experienced the predisposing effect of primary CMV infection on reactivation of other herpesviruses. Patients with high EBV viral load developed more frequently coinfections from BK virus (0.025). Rituximab has been used in 14 patients, resulting in a reduction of EBV viral load <5000 cp/µl in almost 80% of cases with an average time of 28,7 days. The cases of PTLD in the cohort were 9, of which 6 non-destructive PTLD and 3 malignant lymphomas. The incidence of malignant lymphomas significantly reduced compared to the previous decade in our hospital, suggesting the efficacy of pre-emptive strategies.
Conclusions/Learning Points: Prevention of PTLD remains a clinical challenge. Our study identified risk factors for persistent EBV infection and high EBV viral load. Further studies are needed to identify predictive markers of PTLD and to define the real effecacy of pre-emptive strategies.

INFECTIOUS EVENTS IN CHILDREN WITH SICKLE CELL DISEASE HOSPITALIZED IN A SECONDARY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Filip Camil Olteanu Olteanu, Maria Jesús García Mazario, Ana Loscos Camarón, Ana María De La Torre Sanz, Ana Moreno Molinero, Beatriz Blázquez Arrabal, Alfonso Ortigado Matamala
Guadalajara University Hospital, Department Of Pediatrics, Guadalajara, Spain

Backgrounds: Patients with sickle cell disease (SCD) have an increased risk of complications that require hospitalization.
Methods: Descriptive study of the children with SCD admitted in a secondary hospital between 2016 and 2022 focusing on their infectious susceptibility.
Results: 28 events of hospitalization were included. The median age at admission was 2,5 years. 22/28 (78,5%) were younger than 5 years old. The length of hospital stay was 5,9 ± 4,7 days. Acute vaso-occlusive crisis was the most common cause of hospitalization (50%) followed by viral infection, documented in 8/28 cases (28,6%). SARS-CoV-2 and adenovirus were the main virus detected. Next in frequency, 6/28 (21,4%) had fever of unknown origin. Osteomyelitis was seen in 5/28 (17,9%): two affecting the spinal bones, in one case also with sternal involvement; two the lower limb (foot and femur) and one the humerus. 4/28 (14,3%) had pneumonia or acute chest syndrome. Other infections seen were S.aureus bacteriemia, preseptal celullitis or streptococcal pharyngotonsillitis. 3 cases were transferred to a tertiary reference center due to lack of improvment with standard treatment. 22/28 (78,6%) received empiric antibiotic treatment, most of them with a third generation cephalosporin (cefotaxime) and one with amoxicillin/clavulanic acid. In suspected osteomyelitis, treatment was switched to a combination of cefotaxime and cloxacillin. The median duration of intravenous therapy was 4 days (range 1-14), and the total was 10 days, more prolonged when bone infection was documented (3 or 6 weeks). When discharged, treatment was continued with amoxicillin/clavulanic acid in 12/28 (42,9%) or cefuroxime.
Conclusions/Learning Points: Infections were reported in a significant proportion of the patients with SCD hospitalized in our setting. It is important to have a high index of suspicion for early identification and treatment.

[1]Aglaia Kiriakou Hospital, 2nd Department Of Pediatrics Of The National And Kapodistrian University Of Athens, ATHENS, Greece, [2]Aghia Sophia Children's Hospital, Department Of Immunology-histocompatibility, Specialized Center & Referral Center For Primary Immunodeficiencies,, ATHENS, Greece

Backgrounds: Patients with primary antibody deficiencies are at risk in the current COVID-19 pandemic due to their impaired response to infection and vaccination. Given the lack of information on effectiveness of anti-SARS-CoV-2 vaccines in common variable immunodeficiency (CVID) patients, we seek to describe the immunogenicity of the COVID-19 vaccines in CVID patients.
Methods: Ten patients (15-60 years) with CVID were enrolled in this study according to ESID criteria. Seven patients were naïve to SARS-CoV-2 infections and received mRNA COVID-19 vaccine, with a schedule of two doses with 21 days apart. Blood samples were collected at least 7 days after the second dose. Three CVID patients, unvaccinated and non-infected with SARS-CoV-2 were also tested. Ten healthy donors similarly vaccinated and non-infected with SARS-CoV-2 were used as controls(HC). The EliA SARS-CoV-2-Sp1 IgG (Thermo Fisher S1 IgG) assay was used for the measurement of SARS-CoV-2 (Covid-19) IgG antibodies.
Results: Overall, both HC and CVID patients showed a detectable SARS-CoV-2 specific humoral after COVID-19 vaccination, with only the three unvaccinated CVID patients lacking anti- SARS-CoV-2 Abs. Of note, CVID patients showed a lower anti- SARS-CoV-2 titers compared to HC.
Conclusions/Learning Points: These results suggest that CVID patients can still benefit from vaccination. Thus, they should be encouraged to get vaccinated. Additional studies will be needed to further define the variability of humoral and cellular protective immune response after COVID-19 vaccination in immunocompromised patients.

Backgrounds: Japanese encephalitis virus (JEV) is the most common cause of encephalitis in the Asia-Pacific region, and vaccination against JEV in human is the best preventive strategy. Currently, booster vaccination is not recommended for pediatric solid organ transplant recipients (SOTRs) in JEV epidemic areas, but evidence of this recommendation is still lacking.
Methods: This study was conducted on children who underwent SOT at Severance Hospital in Seoul, from 2010 to 2021. The standard plaque reduction neutralization test (PRNT) method was used for the seroprotectivity (PRNT50 cut-off, 1:10). For comparison, serum samples from healthcare workers were used as a control.
Results: A total 22 pediatric SOTRs were enrolled. Liver transplantation was the most common (64%), followed by kidney transplantation (27%), and heart transplantation (9%). The median age at sample collection was 14.1 years (interquartile range [IQR], 12.7 to 15.7 years), and 10 children (45%) were male. 14 children (63%) received at least one dose of JEV vaccine after SOT. The median time from SOT to the last vaccination was 3.6 years (IQR, 1.8 to 9.0), and the median time from the last vaccination to sampling was 16.1 months (IQR, 3.5 to 27.3). The seropositive rate of pediatric SOTR group was 82%, which was lower than 90% of the control group, but there was no statistical significance (P=0.33). In the logistic regression analysis, there was no significant risk factor for poor seroprotectivity.
Conclusions/Learning Points: Seropositive rate of JEV in pediatric SOTRs is not lower than that in the healthy adults. There is a concern about the waning effect after vaccination in adults, so caution is needed in interpretation.

Niamh Donaldson[1], Helen Payne[1], Tan.B Huat[1], Rachel Savage[1], Weixun Peng[1], Hana Jadayel[2], Elizabeth Whittaker[1], Sarah Fidler[3], Caroline Foster[2]
[1]Paediatric Infectious Diseases, Imperial College, London, United Kingdom, [2]Imperial College Healthcare NHS Trust, Paediatric Infectious Diseases, London, United Kingdom, [3]Infectious Diseases, Imperial College, London, United Kingdom

Backgrounds: There is an increasing burden of chronic non-AIDS co-morbidities in youth living with paHIV (YLWPaHIV), despite long-term suppression of HIV. Chronic lung disease (CLD), defined as persistent respiratory symptoms and airflow obstruction attributable to long-term inflammation, is observed in one third of children with paHIV. Rates of cytomegalovirus (CMV) seropositivity are high among children with paHIV, and this may be associated with increased immune activation and systemic inflammation, and potentially contribute to the pathogenesis of HIV-associated CLD.
Methods: Attendees of a tertiary service for YLWPaHIV with HIV viral suppression for >6 months were enrolled in The CHECKPOINT study. Participants completed a respiratory questionnaire, measured lung function by spirometry, CMV DNA in saliva by polymerase chain reaction and CMV-specific IgG was quantified by enzyme-linked immunosorbent assay.
Results: 73 individuals, median age 27 (IQR 25-30) years, 56% female, 73% black ethnicity with median age ART of initiation 7 (IQR 2-12) years and CD4 638 (IQR 497-795) count participated. 19/73 (26%) had an underlying respiratory condition such as bronchiectasis, asthma, history of lymphocytic interstitial pneumonia or tuberculosis. 40/73 (55%) demonstrated low forced vital capacity (<80% predicted) with a normal FEV1/FVC ratio in 67/73 (72%). 2/73 (3%) had detectable saliva CMV DNA and 66/73 (90%) were CMV seropositive. There were no statistically significant correlations between lung function, respiratory diagnosis and quantitative CMV-specific IgG.
Conclusions/Learning Points: Our findings suggest a pattern of restrictive lung disease in this population of YLWPaHIV, however unlike studies in low-income settings, this was not associated with levels of CMV-specific IgG despite high seroprevalence. Measurement of cellular immune activation and inflammation in this population alongside an ethnically-matched HIV-seronegative control group may help to elucidate the potential role of CMV in the pathogenesis of HIV-associated CLD.

E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Tan.B Huat[1], Helen Payne[1], Rachel Savage[1], Niamh Donaldson[1], Weixun Peng[1], Hana Jadayel[2], Elizabeth Whittaker[1], Sarah Fidler[3], Caroline Foster[2]
[1]Paediatric Infectious Diseases, Imperial College, London, United Kingdom, [2]Imperial College Healthcare NHS Trust, Paediatric Infectious Diseases, London, United Kingdom, [3]Infectious Diseases, Imperial College, London, United Kingdom

Backgrounds: There are increased risk factors for cardiovascular and chronic lung disease in youth living with perinatally-acquired HIV (YLWpaHIV) compared to their HIV-seronegative peers. This study aimed to explore the association between cytomegalovirus (CMV) seroprevalence with correlates of immune-activation and inflammation that may contribute to the increased risk factors for non-AIDS co-morbidities.
Methods: Asymptomatic YLWpaHIV on suppressive antiretroviral therapy for >6 months were recruited to the CHECKPOINT study. Spirometry, anthropometrics and blood pressure were recorded. Salivary CMV DNA was measured by PCR, with cell-associated CMV DNA by digital droplet PCR in total PBMCs. Biomarkers associated with cardiovascular and chronic lung disease were quantified from plasma using ELISA and Luminex.
Results: 48 YLWpaHIV, median age 23 (IQR 16-34) years, 42% female, 79% black African were recruited, 45 (94%) of whom were CMV seropositive. No CMV DNA was detected in saliva and only 1 individual had cell-associated CMV DNA (176.6 copies per million PBMCs). Blood pressure measurements did not differ between CMV-seropositive and seronegative participants, but BMI was higher (25.2, IQR 22.7-28.5 vs 23, IQR 19.1-26.9). CMV-seropositive individuals had non-significantly lower FEV_1 and FVC (<80%), and normal FEV_1/FVC ratio (>80%). There was a trend towards higher $CD4^+$ activation and immune-exhaustion markers (Ki67 and PD-1) in CMV-seropositive participants, and .higher inflammatory markers: CRP, VCAM-1, D-dimer, IL-6, and MPO; however IFN-g, and IL-6 were significantly higher ($p<0.05$).
Conclusions/Learning Points: There is a very high seroprevalence of CMV in this population of YLWpaHIV. It is difficult to determine an association between CMV co-infection driving immune-activation and inflammation, and subsequent increased risk factors for cardiovascular and chronic lung disease, without an ethnically-matched HIV-seronegative control group. Further work will include appropriate comparison populations and longitudinal observation to better understand this association.

POST-NATAL CMV INFECTION LEADING TO HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN A 1-MONTH-OLD BOY

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Daniela Pestana, Marta Marques, Marta Cabral, João Neves
Hospital Luz Lisboa, Departamento De Pediatria, Hospital Da Criança E Do Adolescente, Lisboa, Portugal

Title of Case: POST-NATAL CMV INFECTION LEADING TO HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN A 1-MONTH-OLD BOY
Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, life-threatening hyperinflammatory syndrome. Frequently HLH is triggered by intracellular infections, but it can be associated to malignancies and autoinflammatory syndromes. Familial HLH (fHLH) is mostly caused by genetic defects of the lymphocyte cytotoxicity, but it can also be related to inborn errors of immunity, inflammation or even metabolism. HLH occurring in the first months of age is a clue to an underlying genetic defect.
Case Presentation Summary: 41-day old healthy male new-born, admitted with fever, rhinorrhoea, and irritability. Birth and past medical records were unremarkable. He was febrile and a micropapular rash was present over his trunk. He had bicytopenia (HGB 8.4g/dL; platelets 84 000/uL) and hepatosplenomegaly (AST and ALT, were 173UI/L and 200UI/L respectively). Ferritin levels 1340ug/L, fasting triglycerides 206 mg/dL and elevated serum soluble CD25 (25000 UI/mL), fulfilling 6/9 HLH criteria. CMV serologies showed positive IgG antibodies, negative CMV IgM and an elevated viral load. CNS imaging and ophthalmology observation were unremarkable. Postnatal infection was confirmed and he was started on ganciclovir, completing a 7-day total of IV treatment, with complete resolution, being discharged on valganciclovir (completing 10-week treatment and 2 negative serum viral loads, two weeks apart). NK citotoxicity and degranulation were normal and no variants were identified in the HLH-related genes.
Learning Points/Discussion: Most cases of HLH are triggered by viral infections, including CMV or EBV. In mild cases, a stepwise approach can help avoiding unnecessary harmful interventions. Functional and Genetic studies are crucial in identifying fHLH. This case highlights the importance of prompt recognition and treatment, leading to a better prognosis in the long run after identifying and treating the eventual trigger.

[1]Centro Hospitalar do Porto, Paediatrics, Porto, Portugal, [2]Centro Materno Infantil do Norte, Centro Hospitalar Universitário do Porto, Serviço De Pediatria, Porto, Portugal, [3]Centro Materno-Infantil do Norte, Centro Hospitalar e Universitário do Porto, Infectious Diseases And Immunodeficiencies Unit, Paediatric Department, Porto, Portugal, [4]Centro Materno-Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatrics, Porto, Portugal

Title of Case: Refractory mucosal infections in a XLA patient
Background: X-linked agammaglobulinemia is a rare pediatric primary immunodeficiency. There is a defect in Btk gene blocking maturation of precursor B cells in the bone marrow to mature circulating B-lymphocytes, leading to absent immunoglobulin isotypes in the serum. XLA patients are more vulnerable to invasive infections from encapsulated bacteria, enterovirus and Giardia.
Case Presentation Summary: Male child aged 4 years admitted with complicated pneumonia. He had recurrent otitis media since the age of 4 months and three episodes of otomastoiditis. Absent immunoglobulins and 0,1% of CD19 lymphocytes. XLA was diagnosed and confirmed by genetic study: mutation R64117 in exon 19 of the BTK gene. Treated with subcutaneous IgG, achieving stable serum levels over 800 mg/dl. He had recurrent conjunctivitis without serious infections. At the age of 11, presented persistent dyspeptic symptoms. Esophagogastroduodenoscopy revealed erosive pangastritis and histopathology chronic superficial gastritis with focal intestinal metaplasia associated with Helicobacter pylori (positive culture and RT-PCR) and presence of a mutation in the 23S rDNA gene associated with clarithromycin resistance. He started 14 days treatment with amoxicillin + metronidazole + PPI. 6 months later, EGD revealed persistence of H. pylori erosive gastritis. He underwent treatment with amoxicillin + levofloxacin + PPI. 3 months later, a positive breath test led to a new eradication with PPI + amoxicillin + metronidazol + rifabutin and concomitantly IgG 1 g/kg for 5 days. He maintained symptoms and persistence of H. pylori erosive gastritis in EGD and underwent rescue therapy with PPI + bismuth + metronidazole + tetracycline with success.
Learning Points/Discussion: Mucosal infections are very difficult to resolve in XLA patients even with adequate IgG replacement therapy. These patients lack mucosal antibodies, very important to control infection.

[1]COMPLEJO ASISTENCIAL UNIVERSITARIO DE LEON, Paediatrics, LEON, Spain, [2]COMPLEJO ASISTENCIAL UNIVERSITARIO DE LEON, Immunology Laboratory, LEON, Spain, [3]COMPLEJO ASISTENCIAL UNIVERSITARIO DE LEON, Paediatric Surgery, LEON, Spain

Title of Case: GATA2 DEFICIENCY, A RARE TYPE OF PRIMARY IMMUNODEFICIENCY DISORDER IDENTIFIED IN AN INFANT WITH ABDOMINAL MYCOBACTERIUM INFECTION.
Background: We present the case of an infant with GATA2 deficiency, an immune system condition which increases susceptibility to infections. The patient presented repeated acute febrile episodes, being diagnosed of Multisystem Inflammatory Syndrome associated with Covid-19 (MIS-C) and mesenteric adenitis by Mycobacterium avium.
Case Presentation Summary: A four-month-old female infant was admitted with a five-day episode of high fever and raised sepsis biomarkers. She was diagnosed of upper respiratory tract infection and Enterococcus faecalis sepsis. She was readmitted one month later due to a gastrointestinal condition and fever. Serological tests, IGRA and multiple microbiological investigations were undertaken, resulting all negative. She was diagnosed of MIS-C and started specific treatment successfully. At 6 months of age, she was admitted for third time due to recurrent fever. Abdominal ultrasound revealed large mesenteric adenopathies. Further studies were performed with mesenteric adenopathies fluorodeoxyglucose uptake in PET-CT as the only finding. Biopsy showed necrotizing granulomas and acid-fast bacilli. PCR for Mycobacterium Tuberculosis Complex was negative in the gastric juice aspiration sample. Mycobacterium avium was isolated in cultures, showing susceptibility to clarithromycin and ciprofloxacin, so treatment with this therapy was continued. Initial evaluation for immunodeficiency showed no pathological findings. Next generation sequencing testing was used to identify heterozygous GATA2 deficiency and interferon regulatory factor 7 pathogenic mutations (both inherited from mother).
Learning Points/Discussion: Recurrent fever in young infants is a warning sign for underlying disorders such as unusual infections, tumors, immunodeficiency or autoimmune and autoinflammatory diseases. GATA2 deficiency is a rare disorder of the immune system characterized by the susceptibility to develop major viral and bacterial infections (typically Mycobacterium avium complex), cytopenias, leukemia and myelodysplasia.

ECTHYMA GANGRENOSUM: A KEY TO IMMUNITY

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Inês R.S. Monteiro, Maria Inês Marques, Joana Martins, Margarida Pinto, Paulo Calhau
Hospital Garcia de Orta, Serviço De Pediatria, Almada, Portugal

Title of Case: ECTHYMA GANGRENOSUM: A KEY TO IMMUNITY
Background: Ecthyma gangrenosum (EG) is a rare skin infection. Although not pathognomonic, it is classically associated with Pseudomonas aeruginosa. Despite some cases of EG being reported in healthy patients, it is most frequently described in the setting of bacteremia in immunocompromised patients. EG lesions can be single or multiple and usually begin as erythematous macules that rapidly progress to areas of induration, followed by pustules, and ultimately gangrenous ulcers surrounded by erythema. The disease has a high mortality rate.
Case Presentation Summary: A previously healthy 32-month-old girl presented to the emergency department with a 3-day history of fever associated with a non-traumatic lesion on her left thigh, despite antibiotic therapy with oral amoxicillin and clavulanic acid (AAC). The patient was well-appearing and hemodynamically stable. Examination revealed a necrotic lesion surrounded by erythema in her left thigh, small bruises in her legs and a right periorbital hematoma. Initial laboratory tests revealed anemia, thrombocytopenia, neutropenia and increased C-reactive protein. She was admitted for treatment with iv AAC. Due to persistence of fever and lack of wound improvement gentamicin was added. Upon dermatology consultation EG was diagnosed. Wound cultures isolated Pseudomonas aeruginosa. Blood cultures were negative. Abdominal ultrasound revealed slight hepatomegaly and spleen dimensions at the upper limit of normality. Quantitative immunoglobulin levels were normal. The blood smear later revealed the presence of blasts. The child was transferred to an oncology center, where a myelogram confirmed the diagnosis of B cell acute lymphoblastic leukemia and treatment was initiated.

Learning Points/Discussion: This case shows the critical importance of the identification of EG to start an early and directed antipseudomonal therapy and to prompt thorough investigation of possible underlying causes of immunosuppression.

Buzzi Children's Hospital, Milan, Italy

Title of Case: AN ATYPICAL PRESENTATION OF VZV DISSEMINATED INFECTION ASSOCIATED WITH POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME (PRES) AND MULTISYSTEMIC INFLAMMATION IN A 17-YEAR-OLD IMMUNOCOMPROMISED PATIENT
Background: VZV disseminated infection in immunocompromised patients can have insidious onset and severe visceral involvement.
Case Presentation Summary: 17 year-old girl, with allogenic HSCT for LH 15 months before and hypertension. Acyclovir suspended 12 months after HSCT. She presented to ER with upper abdominal pain. Afebrile, SARS-CoV2 infection 2 months prior. Normal blood tests except for known leukopenia (WBC 3900/mmc) and thrombocytopenia (PTL <42000/mmc). Antihypertensive therapy not taken for vomit. Abdomen ultrasound and CT scan were negative. EGDS revealed mucosal lesion in distal oesophagus (biopsy collected). 48 hours later, seizures started. Brain CT scan and LP were normal;slowing of the EEG was detected. Angio-MRI revealed non-haemorrhagic PRES. At 96 hours hypertension worsened, fever and vesicular diffuse rash appeared, with vesicular liquid testing positive for VZV DNA; VZV-IgM positive, IgG negative. Subsequently she developed pancreatitis, with hyperlipasemia and radiological findings, hepatitis ,with severe hypertransaminasemia, cholestasis and elevated LDH. Blood tests revealed pancytopenia (PLT 15000 /mmc, Hb 7.9 g/dL andWBC 4000/mmc), CRP elevation (98 mg/dL), hyperferritinemia (4625 mcg/L), hypertriglyceridemia (211 mg/dL), elevated d-dimer (14665 mcg/L). Herpes virus lesions in oesophageal biopsy. EEG was compatible with encephalitis. Intravenous Acyclovir and Ig were administered for 10 and 5 days respectively, with gradual improvement until resolution.
Learning Points/Discussion: Our case is noteworthy due to a conjunction of factors not previously described in the literature: atypical young age, insidious paucisymptomatic presentation more than a year after HSCT and the association to PRES syndrome and multi-systemic inflammation. The overlapping of clinical manifestations with multifactorial aetiopathogenesis in immunocompromised hosts can make both diagnosis and management very challenging.

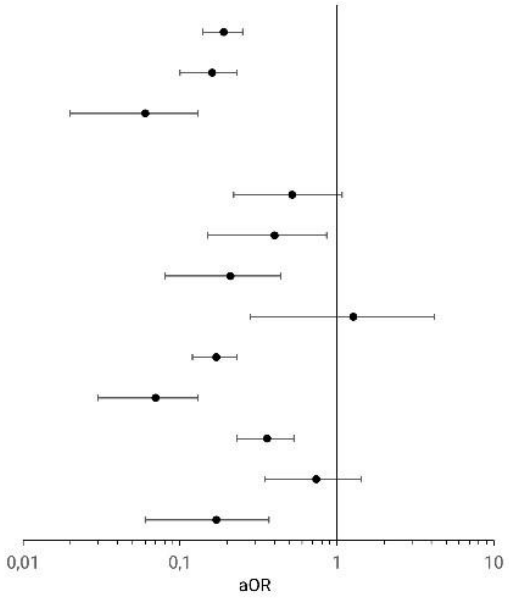
Backgrounds: This study aimed to evaluate immunocompromising conditions and specific subgroups of immunocompromise as risk factors for severe outcomes among children admitted for influenza.
Methods: We performed active surveillance for laboratory-confirmed influenza hospitalizations among children ≤16 years old at the 12 Canadian Immunization Monitoring Program Active hospitals, from 2010-11 to 2020-21. Logistic regression analyses were used to compare outcomes between immunocompromised and non-immunocompromised children, and for different subgroups of immunocompromise. The primary outcome was intensive care unit (ICU) admission; secondary outcomes were mechanical ventilation and death.
Results: Among 8982 children, 892 (9.9%) were immunocompromised; these patients were older (median 5.6 [IQR 3.1 - 10.0] vs 2.4 [1 -6] years, p<0.001) than non-immunocompromised children, had similar frequency of comorbidities excluding immunocompromise and/or malignancy (38% vs 40%, p=0.2), but fewer respiratory symptoms, such as respiratory distress (20% vs 42%, p<0.001).
In multivariable analyses, immunocompromise (adjusted odds ratio [aOR] 0.19, 95% CI 0.14–0.25) and its subcategories immunodeficiency (aOR 0.16, 95% CI 0.10–0.23), immunosuppression (aOR 0.17, 95% CI 0.12–0.23), chemotherapy (aOR 0.07, 95% CI 0.03–0.13) and solid organ transplantation (aOR 0.17, 95% CI 0.06–0.37) were associated with decreased probability of ICU admission in children admitted for influenza. Immunocompromise was also associated with decreased probability for mechanical ventilation (aOR 0.26, 95% CI 0.16–0.38) or death (aOR 0.22, 95% CI 0.03–0.72).

Multivariable logistic regression models for the association between ICU admission and immunocompromise or its subgroups

Characteristic	aOR*	95% CI*
Immunocompromised	0.19	0.14, 0.25
Immunodeficiency	0.16	0.10, 0.23
Haematological malignancies (active)	0.06	0.02, 0.13
Stem cell transplant	0.00	0.00, 0.00
Defects primarily in lymphocytes	0.52	0.22, 1.08
Defects primarily in neutrophiles	0.41	0.16, 0.89
Asplenia and complement deficiency	0.21	0.08, 0.44
Other immunodeficiency	1.27	0.28, 4.19
Immunosuppression	0.17	0.12, 0.23
Chemotherapy	0.07	0.03, 0.13
Immunosuppression other than chemotherapy	0.36	0.23, 0.53
Steroids, no other immunosuppression	0.74	0.35, 1.43
Solid organ transplant	0.17	0.06, 0.37

*adjusted for age (continuous), sex, influenza season, IMPACT center, presence of underlying chronic health conditions other than immunocompromise, influenza virus type



Conclusions/Learning Points: Immunocompromised children are overrepresented among hospitalizations for influenza, but have decreased probability of ICU admission, mechanical ventilation, and mortality following admission.

PV0261 / #1432

INCIDENCE OF INFECTIONS IN PEDIATRIC PATIENTS WHO RECEIVED BIOLOGICAL AND TARGETED SYNTHETIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS (BDMARDS), AT A REFERRAL CENTER IN CHILE.

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Consuelo Schweinitz, Cecilia Vizcaya
Pontificia Universidad Católica de Chile, Pediatrics, Santiago, Chile

Backgrounds: bDMARDs have changed the physical and functional prognosis of patients with inflammatory diseases. Nevertheless, there is an increased risk of infections reported in the literature. This study aims to describe the incidence of mild infections (MI) and severe infections (SI) in pediatric patients using bDMARDs.
Methods: We conducted a retrospective cohort study of 128 pediatric patients with rheumatic diseases and inflammatory bowel disease (IBD), with 173 bDMARD treatment episodes; attended at a referral center in Chile between 2007-2019.
Results: 128 patients met the inclusion criteria, with 173 treatment episodes of bDMARDs. 76% were female. The primary underlying pathology was Juvenile Rheumatoid Arthritis (JIA) at 89.8% (115), followed by Vasculitis at 3.91% (5) and at IBD 3.12% (4). The most common bDMARDs were Adalimumab 43.9% (76) and Etanercept 22.5% (39). Upper respiratory tract infection (URTI) was the most common MI (66.6%, N=272), followed by lower respiratory tract infections (LRTI) (11.5%, N=47). The most common SI were gastrointestinal infections (36.1%, N=13), LRTI (22.2%, N=8) and skin infections (16.6%, N=6). The incidence rate of MI was 119.7 (CI 106-128) per 100 person-years, and the incidence rate of SI was 10.3 (CI 73.7-142.1) per 100 person-years. No cases of tuberculosis or hepatitis-B virus were observed. The median time of hospitalization was 2.92 (SD 19.8) days. There were no hospitalizations in intensive care units, deaths or need to suspend bDMARDs due to infections.
Conclusions/Learning Points: bDMARDs seem to have a good safety profile. The study provides valuable information to parents and caregivers regarding the risk of infections of patients starting bDMARDs.

Backgrounds: Neutropenic enterocolitis (NE) is a life-threatening form of inflammatory enterocolitis seen in neutropenic patients, mainly in the setting of exposure to cytotoxic chemotherapy. We aimed to describe NE episodes, with regard to NE presentation and evolution.
Methods: We designed a descriptive study, including all episodes of NE (abdominal symptoms, neutropenia (<500 neutrophils/mm^3) and tomography of the abdomen with bowel wall thickness) in pediatric cancer patients (up to 18 years old) treated at our service from 2017 to 2022.
Results: During the studied period, 195 episodes of NE were obtained, with a mean age of patients of 7.6 years. The majority had solid tumors, with 41.5%, and acute lymphocytic leukemia (ALL), 30.8% ($p<0.001$). Patients had abdominal pain as the main symptom, present in 90.8% of the episodes, followed by fever in 65.6%, diarrhea in 60.5%, abdominal distention in 42% and vomiting in 33.8%. In 64 episodes (32.8%) a microbial agent was isolated, with gram negative bacteria being the most common, in 62.5% (40/64) of cultures ($p<0.001$), with emphasis on E. coli, with 47.5% (19/40) ($p<0.001$). Klebsiella pneumoniae and Pseudomonas aeruginosa were isolated in 17.5%. Gram positive bacteria were isolated in 28.1% (18/64) episodes, S. viridans and Clostridioides difficile were more frequent with 33.3%. Six fungi (9.4%) were isolated, 5 (83.3%) Candida spp (2 C. krusei, 2 C. albicans and 1 C. tropicalis) and 1 Trichosporon asahii (16.7%). The mean fasting due to NEC was 10.4 days and hospital stay 24.8 days. The associated death rate was 9.7%.
Conclusions/Learning Points: NE should always be considered as a possible diagnosis in a cancer patient presenting with abdominal symptoms, neutropenia and exposure to cytotoxic chemotherapy. Early diagnosis is crucial to improve outcomes.

THE INCIDENCE AND RISK FACTORS FOR CMV REACTIVATION IN PEDIATRIC ALLOGENIC STEM CELL TRANSPLANT RECIPIENTS IN MUMBAI, INDIA

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Tanu Singhal, Keval Sheth, Juhi Mehrotra, Namita Davar, Santanu Sen
Kokilaben Dhirubhai Ambani Hospital and Medical Research Institute, Paediatrics, Mumbai, India

Title of Case: The incidence and risk factors for CMV reactivation in pediatric allogenic stem cell transplant recipients in Mumbai, India
Background: There is paucity of data on CMV reactivation in India where nearly all donors and recipients are CMV IgG positive.
Case Presentation Summary: This retrospective study recruited all children who underwent allogenic HSCT between September 2020 and Sep 2022 to ascertain CMV reactivation in the first 100 days of transplant. CMV reactivation was defined as plasma viral load of >1000 copies per ml or that between 300-1000 copies/ ml if antiviral therapy was initiated. Details related to donor/ recipient CMV serostatus, indication and type of HSCT, conditioning regime, median time to CMV reactivation and outcome of graft were recorded. Thirty five children (18 males and 17 females) with ages ranging from 2-13 years (mean age 7 years) underwent allogenic HSCT in the study period. The indications for transplant were thalassemia major (22), cancer (8), aplastic anemia (3) and others (2). Seventeen patients underwent matched sibling donor (MSD), 16 underwent haplo identical transplants while 2 underwent matched unrelated donor transplants. All the donors and recipients were CMV IgG positive. CMV reactivation was seen in 23/35 patients (66%) at a mean of 26 days post-transplant. Three patients developed graft failure possibly due to CMV. The rates of CMV reactivation in Haplo identical transplants (75%) was higher than MSD (52%) albeit not statistically significant. Addition of cyclophosphamide in the conditioning regime for MSD transplants was associated with higher risk of CMV reactivation than without it (87% vs 33%; $p<0.05$)
Learning Points/Discussion: The high rates of CMV reactivation in our setting may warrant a change in conditioning regime and/or switch to preventive from pre emptive strategy.

SINGLE CENTER STUDY ON RISK FACTORS FOR POSITIVE BLOOD CULTURES IN PEDIATRIC ONCOLOGY PATIENTS IN BRASOV, CENTRAL ROMANIA

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Bianca Stoia[1], Oana Falup-Pecurariu[1,2], Ioana Arbanas[1,2], Mirela Comsa[1], Anca Ilea[1,2], Laura Bleotu[1], Daniela Voda[1,2]
[1]Children's Emergency Clinical Hospital, Pediatrics, Brasov, Romania, [2]Transylvania University, Faculty Of Medicine, Brasov, Romania

Backgrounds: Bloodstream infections in pediatric oncology patients are an important cause of morbidity, mortality, extended hospital stays and increased healthcare costs.
Methods: Retrospective observational study of 33 patients, under 18 years with a diagnosed malignancy, that were hospitalized between January 2019-December 2022 at the Children's Emergency Clinical Hospital Brasov, Romania. All patients had a subcutaneous port inserted before starting chemotherapy. Data were collected by evaluating patient electronic medical records. Aim of the study: to determine whether demographic data, parents' education, type of malignancy, a low absolute neutrophil count (ANC), lymphopenia and chemotherapy course are risk factors for positive blood cultures.
Results: 57.6% of the patients had at least one positive blood culture. The most frequent encountered organisms were: Coagulase-negative Staphylococci (33%), Candida spp. (30.9%), Pseudomonas aeruginosa (8.45%), Enterococcus spp. (5.63%) and Enterobacter cloacae (5.63%). 54,5% of the patients were male. The median age was 6.38 years. 60.6% come from rural areas. 45.5% of the parents of the studied patients did not finish high school. The most frequent diagnosed malignancies were acute lymphoblastic leukemia (60.6%), solid tumors (15.2%) and Hodgkin's lymphoma (12.1%). 46.9% of the patients had ANC<500/µl (NV:1800-8000/µl) and 40.6% had severe lymphopenia<500/µl (NV:1500-6500/µl) at time when blood cultures were collected. Statistical analyses showed that rural environment (p=0.01) and lower education levels of the parents (p<0, 01) were associated with a higher risk of positive blood cultures. All other studied variables didn't prove to be risk factors.
Conclusions/Learning Points: Risk factors for positive blood cultures in the studied pediatric patients are parents' education and rural environment. This data will increase our precautionary measures at these group of patients.

[1]Children Emergency Clinical Hospital of Brasov, Pediatrics, Brasov, Romania, [2]Transylvania University, Faculty Of Medicine, Brasov, Romania

Backgrounds: Malignancies and chemotherapy modify blood parameters.
Methods: The study is an observational, descriptive, retrospective study enrolling - 314 hemoculture results of 33 children with cancer hospitalized at Children's Clinical Hospital of Brasov during 2019-2022. All children had a subcutaneous port and at least one hemoculture taken during the study time. The analysed data was collected evaluating the patients' electronic recorded files. The study evaluates the value of acute phase reactants (C-reactive protein-CRP, erythrocyte sedimentation rate-ESR, procalcitonin-PCT and fibrinogen), value of neutrophils(N) and value of fever in children with malignancies that have had positive hemoculture results compared to those with negative hemoculture results.
Results: Children included in the study had an average of 9 hemoculture (range=1-23 hemocultures). 245 hemocultures (78%) were negative and 69 positive (21.9%). Acute phase reactants studied: CRP was>1mg/dL in 65.2% (average 6.02mg/dL, median=2.27) children with positive hemocultures vs 48.1% (average 3.5 mg/dL, median=0.83) in children with negative hemocultures. ESR >10 mm/hr was 75.9% (average 47.5 mm/hr) in children with positive hemocultures and 72.4% (average=42.9 mm/hr) in children with negative hemoculture results. 54.6% (average 415 mg/dL) and 60.8% (average 399.7 mg/dL) presented normal value of fibrinogen in children with negative hemocultures vs negative hemocultures. Procalcitonin >2 ng/mL in 11.5% in positive hemocultures and 2.04% in negative hemocultures. 52.2% (average 2.230/uL) children had neutropenia while negative hemocultures and 49.2% normal value of neutrophils while positive hemocultures. Fever (>38degreesCelsius) was present in 69.5% children with positive hemocultures and 25.7% in children with negative hemocultures.
Conclusions/Learning Points: CRP and fever were modified in children with malignancies and positive blood cultures.

Backgrounds: Data on direct-acting antivirals (DAAs) against HCV in adolescents or youths with perinatally acquired HIV are limited and with a relatively short observation period. This study aimed to analyse the long-term effect of DAAs in that population.
Methods: We performed a multicentre, longitudinal and observational study within the Spanish Cohort of HIV-infected children/adolescents (CoRISpe) and Cohort of perinatally HIV-infected patients transferred to Adult Units (CoRISpe-FARO). HIV/HCV-coinfected youths that received DAAs between 2015 and 2017 with successful sustained viral response (SVR) and with a subsequent follow-up of at least three years were included (n=24) and compared with perinatally HIV-monoinfected youths (n=19) never infected by HCV. Long-term evolution in liver disease severity and haematologic markers, lipid and immune profiles after SVR were assessed. Study times were the start date of DAAs treatment (baseline, T0) and one time-point each year after SVR (T1, T2, T3, T4 and T5 respectively).
Results: We observed global improvements in liver function data that persist over time (ALT, AST, γ-glutamyl transferase and Alkaline Phosphatase) and a favourable haematologic and immune outcome at the long-term including a constant augment in leukocytes, neutrophils, neutrophils to lymphocytes ratio and CD4/CD8 ratio over-time. Regarding the lipid profile, we found a significant increase in total cholesterol at 2-year follow-up (T2), total cholesterol/high-density lipoprotein (cholesterol/HDL) ratio at T4, triglycerides at T5 and a decrease in HDL and in low-density lipoprotein (LDL) over time in all patients but with marked higher levels in the subgroup receiving anti-HIV Protease Inhibitor-based regimens.
Conclusions/Learning Points: Comparisons of perinatally HIV/HCV-coinfected youths at 3-year follow-up after SVR and a control group of perinatally HIV-monoinfected youths showed no significant differences in most parameters analysed, suggesting a possible normalization in all parameters (Table

1).

Subject characteristics	Perinatally HIV/HCV-youths after SVR 3-year follow-up (n=24)	Perinatally HIV-monoinfected youths (n=19)	*p*

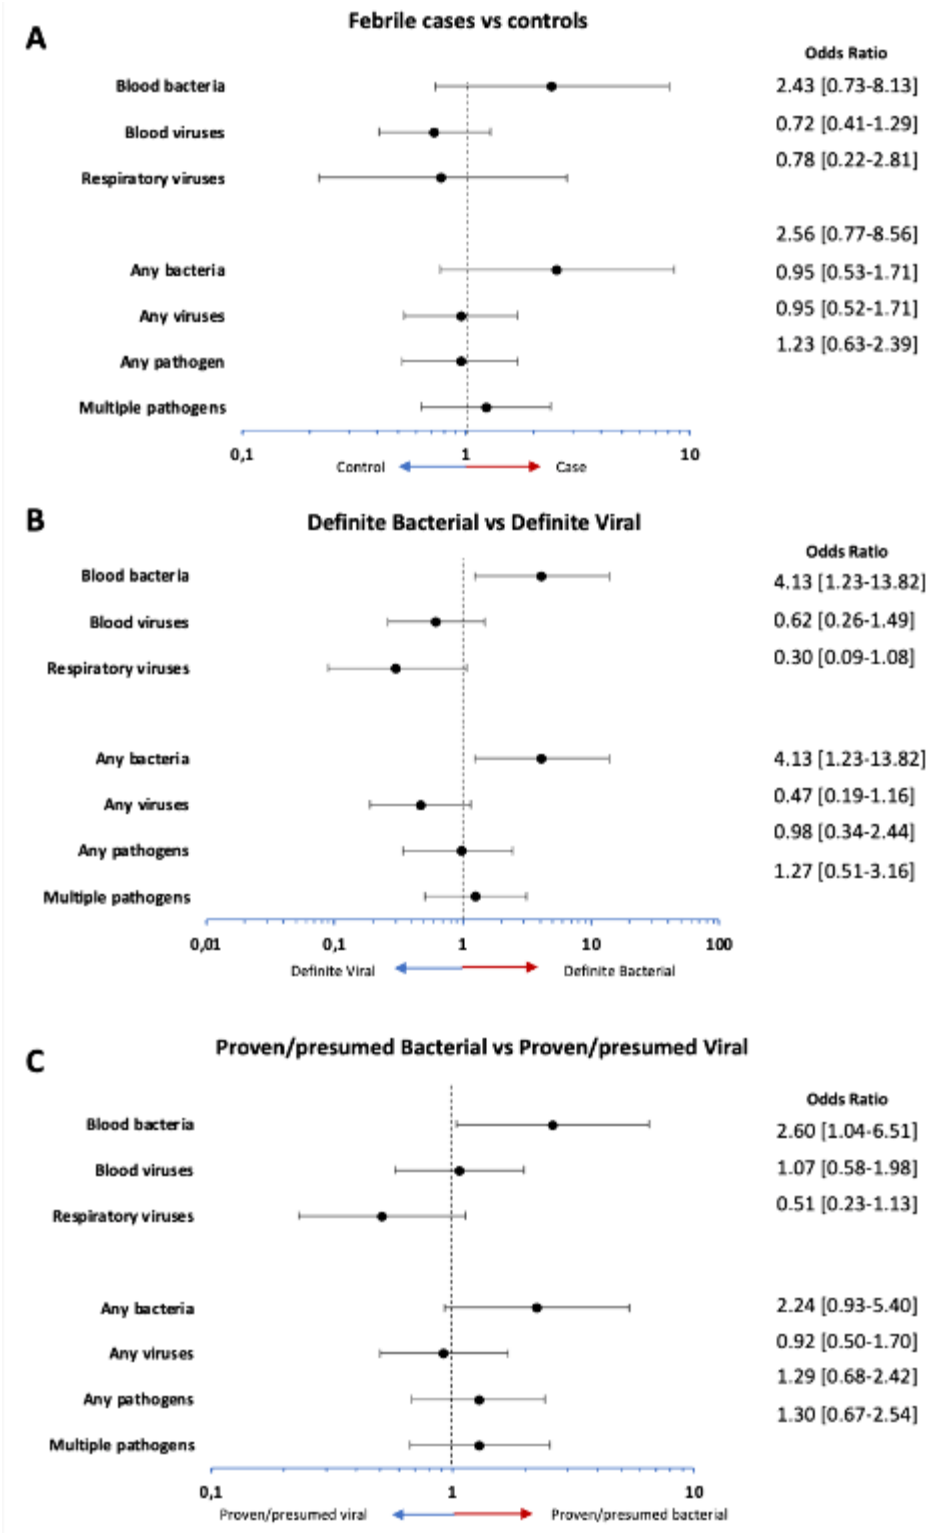
Backgrounds: Diagnosing febrile illness in immunocompromised children remains challenging. Infections can cause significant morbidity, but conventional diagnostics are often negative. Molecular pathogen testing might increase the yield of pathogen detection in this population, potentially improving management and outcome.
Methods: Immunocompromised febrile children recruited to the Personalised Risk assessment in Febrile illness to Optimised Real-life Management study (PERFORM) were evaluated using best practice local diagnostic approaches. Retrospectively, their diagnostics were complemented by additional centralized molecular tests (CMT) for 22 respiratory and 34 blood pathogens.
Results: 336 febrile episodes, of which 45 were definite bacterial (13.4%), 37 definite viral (11.0%) using conventional diagnostic approaches, 254 with uncertain or inflammatory aetiologies (75.6%), and 54 non-febrile controls. CMT subsequently detected pathogens in 201/336 febrile cases (59.8%) and 33/54 non-

febrile controls (61.1%). CMT detected E.cloacae, Enterobacterales16S, and K.pneumoniae more commonly in definite bacterial infections compared to definite viral. No pathogens were significantly more often detected in febrile cases versus controls, nor viruses more often detected in definite viral cases. Bacterial pathogens were more often detected in definite bacterial cases by CMT (OR 20.71 (95%CI 2.11-203.77)) (Figure 1). Viruses were detected in 46.7% of definite bacterial cases (N=21), and 57.4% of controls (N=31). Bacteria were detected in 10.8% of definite viral cases (N= 4), and 5.6% of controls (N=3). HHV7 was the most commonly detected pathogen across all phenotypes (33.6%,



N=113).

Conclusions/Learning Points: CMT frequently detected pathogens in febrile children and non-febrile controls. Except for certain gram-negative bacteria, no pathogens were more commonly detected in definite bacterial or viral cases. Viruses are detected in a significant proportion of patients with bacterial infection. Our data do not suggest CMT will ease the current diagnostic challenges regarding their clinical relevance in this population.

Backgrounds: Epstein-Barr virus (EBV) is a common virus that infects over 95% of the global population. However, a small number of children develop chronic active EBV (CAEBV) disease, which is a rare and potentially fatal condition characterized by persistent high levels of EBV replication. CAEBV can develop into a lymphoproliferative disease involving T, NK, or less frequently B cells. A small number of defective EBV genomes have been found in East Asian and European patients with CAEBV and other EBV-related malignancies; these defective clones are lost following successful treatment.
Methods: To better understand when and where these deletions occur, we sequenced 27 EBV whole blood, B, T and NK cells fractions and tumours samples from 7 patients with CAEBV disease or EBV-related malignancies.
Results: We found EBV deletions in the genomes of 4/7 patients (patient A-D). The deletions were different in every patient but tend to cluster near late lytic genes (e.g. BLXF2 and LF3), Ori Lyt and the BART region of the viral genome, likely leading to a defective lytic cycle. The deletions were also different in different lymphocyte subsets within the same patient (Patient B, C and D). In patient A the initial defective EBV clone disappeared after chemotherapy. However, following treatment failure, another EBV clone emerged and became dominant just before the patient died.
Conclusions/Learning Points: These findings may be explained by the fact that the deletions are present in premalignant clones which occur when a particular subset of the patient's blood cells are infected with EBV. Progenitor lymphoid cells have been suggested to be the target cells, however our results showed that deletions might also occur later when progenitor lymphoid cells differentiate into B, T or NK cells.

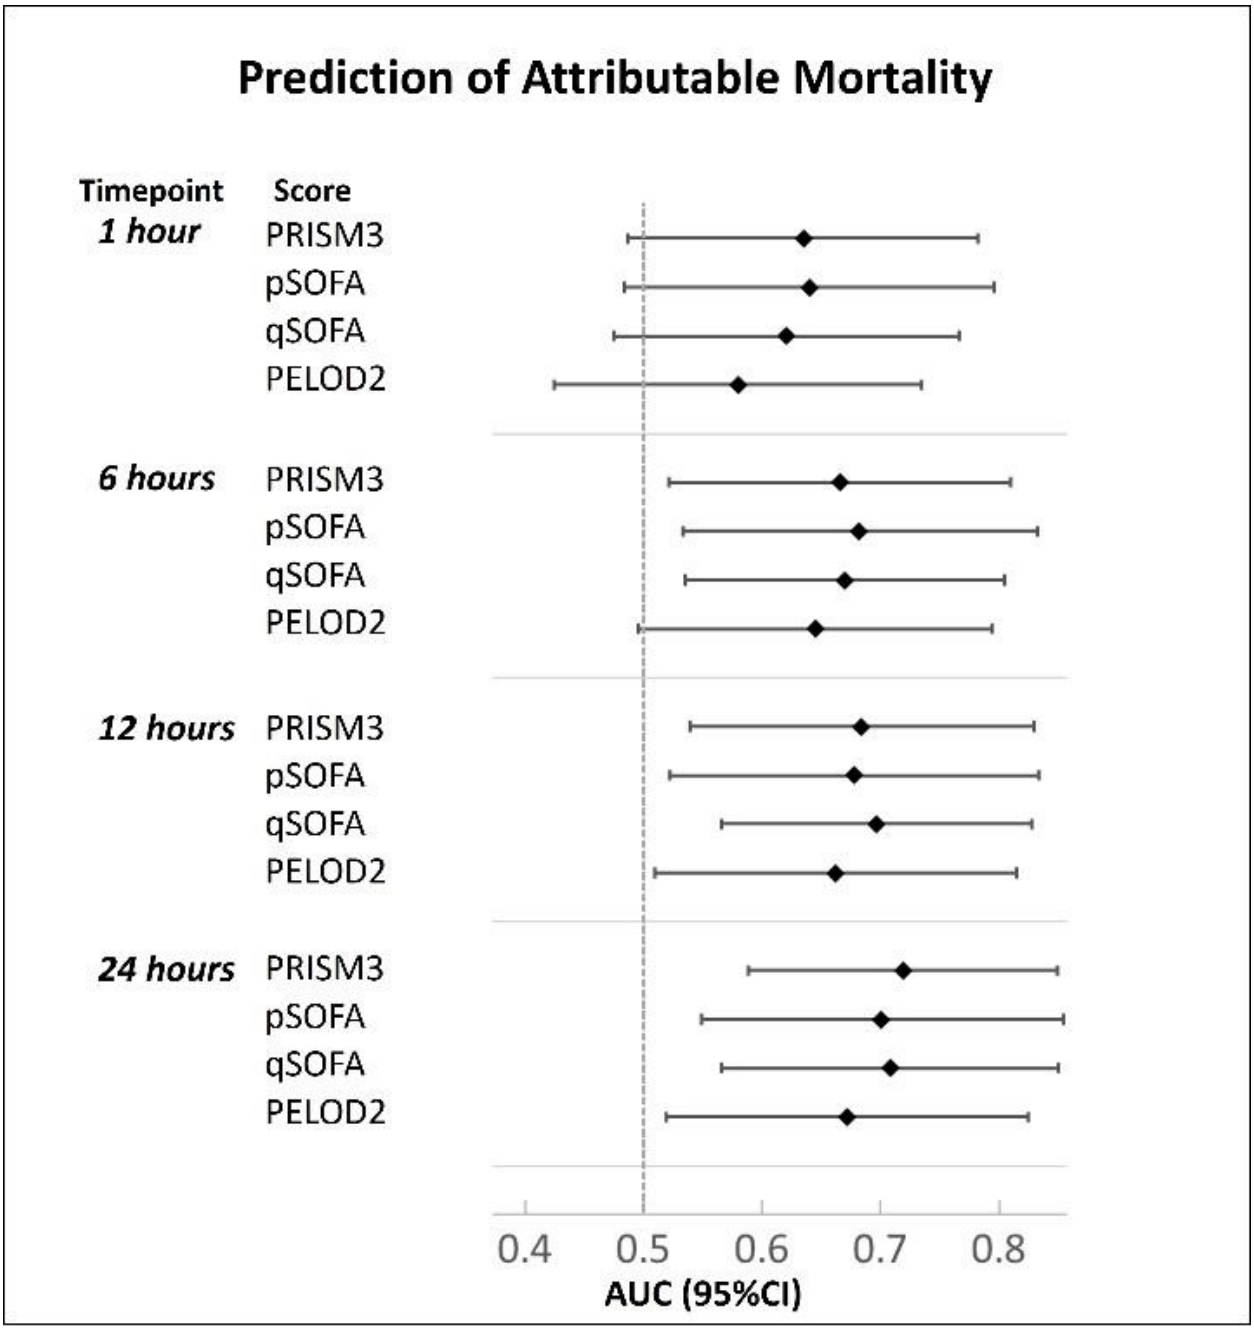
PREDICTION OF ATTRIBUTABLE MORTALITY IN PEDIATRIC PATIENTS WITH CANCER ADMITTED TO THE INTENSIVE CARE UNIT FOR SUSPECTED INFECTION: A COMPREHENSIVE EVALUATION OF RISK SCORES

E-Posters Viewing
E-POSTER VIEWING: AS04.D. SEVERE/SYSTEMIC FUNGAL INFECTIONS

Zachary Rubnitz[1], Yilun Sun[2], Asya Agulnik[3], Pamela Merritt[1], Kim Allison[1], Jose Ferrolino[1], Ronald Dallas[1], Li Tang[2], Joshua Wolf[1]
[1]St. Jude Children's Research Hospital, Infectious Diseases, Memphis, United States of America, [2]St. Jude Children's Research Hospital, Biostatistics, Memphis, United States of America, [3]St. Jude Children's Research Hospital, Global Pediatric Medicine, Memphis, United States of America

Backgrounds: Infection and associated sepsis are important causes of morbidity and death in children with cancer. Although pediatric sepsis risk prediction scores can identify children at high risk of pediatric intensive care unit (PICU) death, performance in immunocompromised children is unknown.
Methods: In this IRB-approved retrospective study, we evaluated 4 pediatric risk scores to predict attributable mortality in children (≤24 years) with cancer admitted to PICU at St. Jude Children's Research Hospital with suspected infection between 2013-2019. Attributable mortality comprised death with sepsis-associated organ dysfunction by ≤60 days or before ICU discharge. HSCT-recipients were excluded. Pediatric Risk of Mortality 3 (PRISM-3), Pediatric Sequential Organ Failure Assessment (pSOFA), Paediatric Logistic Organ Dysfunction 2 (PELOD-2), and Quick Pediatric Sequential Organ Failure Assessment (qSOFA) were calculated using worst values to date at 1, 6, 12 and 24 hours, and we compared area under the receiver operating characteristic curves. We also compared performance of each scores calculated excluding hematologic parameters.
Results: There were 207 episodes of ICU admission for suspected infection in 166 patients; 96 with hematological malignancy and 70 with solid tumors, median age 11.5 years (IQR 4.8-16.2). Attributable mortality was observed in 16 (7.7%) episodes. There was poor to moderate discrimination for all scores, especially early after ICU admission (Fig.1). Scores calculated excluding hematologic parameters did not improve
discrimination.



Conclusions/Learning Points: Attributable mortality was uncommon in children with cancer presenting to ICU with suspected infection at a pediatric comprehensive cancer center. Pediatric sepsis scores showed poor discrimination (all AUC<0.75), even at 24 hours after admission. More research is needed to identify factors that best predict outcomes in this uniquely vulnerable population.

E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Claudia Patricia Beltrán Arroyave[1], Jasmin Abad[1], Ana Maria Realpe[2], Martha Reyes[3]
[1]Universidad de Antioquia. Clínica del Prado. Clinica El rosario, Antioquia, Antioquia, Colombia, [2]Clínica Del Prado. QuironSalud, Antioquia, Medellin, Colombia, [3]Universidad CES. Clinica El Rosario, Antioquia, Medellin, Colombia

Title of Case: Neonatal Tetanus: an old immunopreventable disease
Background: Neonatal tetanus is a rare disease in developed countries but remains common in developing countries. It is an infection by Clostridium tetani which enters the body through a skin wound. The clinical manifestations can be variable, however if there is no detection and timely treatment, its course is lethal
Case Presentation Summary: Male patient, son of a a 20-year-old mother, pregnant without prenatal check-ups admitted on his first day of life, referred from rural area of Antioquia. 36 weeks late preterm. He was born by vaginal delivery attended by her grandmother on the bathroom floor of her home, the umbilical cord was cut with scissors after 10 minutes of delivery. At third day of life, the newborn had clinical deterioration, due to paleness, extreme rigidity, global increase in tone, block movement, apneas and bradycardia that required positive pressure ventilation as well as orotracheal intubation. It was considered a neonatal tetanus case confirmed by clinical endorsed by the technical committee of the national institute of health of Colombia, blood cultures for anaerobes were negative and hypocalcemia was ruled out. Metronidazole was started at 7.5mg/kg every 8 hours in addition to the cristaline penicillin and tetanus immunoglobulin 3000 intramuscular units as a single dose was indicated. HIV was ruled out by ELISA, Hepatitis B by negative surface antigen, and other infectious diseases like toxoplasma. Regarding central nervous system tests, he had a cerebrospinal fluid: D 1020 PH 8. 0 Leukocytes: protein 331 glucose 48, normal brain ultrasound and neonatal polygraphy abnormal for age, external dyssynchronism, excessive left rolandics and central epileptiform activity left parietal artery suggestive of regional cortical dysfunction.
Learning Points/Discussion: This is a case of clinical neonatal tetanus with an early detection and a favorable outcome.

Title of Case: Two locally acquired pediatric malaria cases; First indigenous cases reported in Türkiye since 2010
Background: Malaria is still a global public health problem considering the number of cases and mortality rates worldwide. In our country, the annual number of cases varies between 200-250 and all of these cases consist of patients with a history of travel to the endemic region. The last reported locally transmission in Türkiye was in 2010. Here, we report two indigenous cases of malaria with mixed infection of P. vivax and P. falciparum, who were infected with the same parasites documented with genetic analyzes.
Case Presentation Summary: CASE 1: A 9-year-old girl. She was admitted to the hospital in August 2022 for investigation due to intermittent high fever for about one month. P. falciparum and P. vivax mixed infection was detected by PCR and she developed hemophagocytic lymphohistiocytosis and multiorgan failure during follow-up. Artesunate and immunosuppressive treatment was started together but the patient died in the intensive care unit secondary to nosocomial Acinetobacter baumannii infection.
CASE 2: 4-year-old male patient. The patient, who resided in the Netherlands, was hospitalized in August 2022 for examination due to recurrent high fever and febrile convulsion that started one month after his arrival in Turkey for visiting relatives. The peripheral smear was compatible with malaria. PCR showed P. falciparum and P. vivax mixed infection and the patient was successfully treated with artemether, lumefantrine and primaquine.
As a result of detailed comparison of the DNA sequence analysis, it was determined that two patient were infected with same same isolates.
Learning Points/Discussion: In patients with compatible history and physical examination findings, malaria should be considered in the differential diagnosis even if there is no history of travel.

BRUCELLOSIS WITH PERICARDIAL EFFUSION AND SPLENIC ABSCESS: AN UNUSUAL PRESENTATION.

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Lindsay Concha Mora, Isabel Robles-Lomellin, Oscar Tamez-Rivera
Instituto Tecnológico y Estudios Superiores de Monterrey, Pediatric Residency Program, Programa Multicéntrico De Especialidades Médicas Itesm- Ssnl, Tecnológico De Monterrey, Escuela De Medicina Y Ciencias De La Salud., Monterrey, Mexico

Title of Case: Brucellosis with pericardial effusion and splenic abscess: an unusual presentation
Background: Brucellosis is one of the most common zoonoses worldwide, remaining as a major public health problem in Mexico and worldwide. Due to Covid-19 pandemic, initial symptoms could imitate a SARS-CoV-2 infection, which represented a real challenge in reaching our final diagnosis.
Case Presentation Summary: A previously healthy, fully immunized 7-year-old boy from Mexico presented with a twenty-day of persistent fever, abdominal pain, and nocturnal diaphoresis; generalized pallor, non-purulent conjunctival injection, hepatosplenomegaly, and pain in the upper left quadrant, were founded, the remaining were unremarkable. Laboratory revealed anemia, thrombocytopenia, D-dimer, and ferritin levels elevated, CRP negative. Echocardiography revealed pericardial effusion. The initial diagnostic suspicion was MIS-C, treated with intravenous immunoglobulin and corticosteroids, with no favorable response, on re-examination, the mother reported occasional consumption of unpasteurized dairy products, a positive Rose Bengal (>1:1280) and 2ME (1:120) tests were found, and abdominal ultrasound and CT scan revealed multiple splenic abscesses of 8mm in diameter each. Doxycycline and gentamicin were initiated, with favorable response. After ten days of incubation, Brucella melitensis was identified using the MALDI-TOF and VITEK® 2 systems. Discharged after ten days of intravenous antibiotics with of doxycycline and rifampin for six weeks. During the six-month follow-up, the patient has remained asymptomatic and CT scan revealed complete resolution of the splenic abscesses and the pericardial effusion on echocardiography
Learning Points/Discussion: We present an unusual Brucellosis presentation, due to the SARS-CoV-2 pandemic, we must enhance the relevance of excluding other infectious causes, the screening of endemic pathogens, and the manifestations with low incidence, to give treatments on an individualized basis and close monitoring of patients, to prevent MIS-C overdiagnosis in patients with febrile syndrome and systemic inflammation.

PV0273 / #1448

TEN YEARS SURVEILLANCE MOTHER TO CHILD TRANSMISSION OF CHAGAS DISEASE IN ACONCAGUA VALLEY, CHILE

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Daniel Cortes[1], Catalina Monsalvez[2], Nicol Quiroga[1]
[1]San Camilo Hospital, Department Of Pediatrics, San Felipe, Chile, [2]University of Valparaiso, Medicine School, San Felipe, Chile

Backgrounds: Chagas disease is caused by the protozoan Trypanosoma cruzi. Endemic to Latin America with various transmission mechanisms. In Chile, vector transmission is under control, but congenital transmission is still relevant. Our objective is to describe the results of the monitoring program for children exposed to Chagas disease in the Aconcagua Health Service, years 2013-2022, according to national guidelines.
Methods: Retrospective descriptive study using databases belonging to the congenital Chagas monitoring program of the Aconcagua Health Service, Chile
Results: A total of 82 children of women living with Chagas disease were found, 42 of them female (51%). Of these, 9 cases have not completed the study protocol because they are under 9 months of age; 11 cases were lost during follow-up (13.4%). The main maternal diagnostic category is indeterminate form, with 73 (89%) and only 1 case of dilated colon; 17 (20%) mothers had therapy before pregnancy. The grandmother had a history of Chagas disease in 17 (20%), but the status was unknown in the majority (n=52). 21 (25%) of the mothers are from the Aconcagua Valley, highlighting that 22 (27%) come from Bolivia. There is low adherence to the total number of samples scheduled according to guidelines (48%). Of the 62 patients who have completed follow-up, there were 6 cases of congenital transmission. None of the mothers received therapy before pregnancy; 1 of the cases presented involvement of the central nervous system, and 3 became negative after therapy (50%).
Conclusions/Learning Points: Congenital transmission of Chagas disease is a relevant problem in our region. There are difficulties in monitoring this group, consistent with the status of a neglected disease. Optimising follow-up is key to achieving disease control.

Title of Case: GEOGRAPHICALLY LOCATED AND TROPICAL INFECTION IN EUROPE DURING THE PANDEMIC. A PROSPECTIVELY RECRUITED COHORT THROUGH “DIAMONDS” CONSORTIUM

Background: Characterizing geographically located and tropical infections (GLTI) represents a challenge for researchers, they might gather few patients from their hospital and recruitment might be feasible a few months each year (for example, on summer holidays for tropical diseases in Europe). For that reason, this multicentric prospective cohort study aims to overcome these challenges with broad inclusion criteria, multicentric recruitment. Multicentric prospective cohort study in 11 European countries, plus Taiwan, Nepal, and Gambia. Children <18 years with fever or suspected infection attending EDs of DIAMONDS EU Project (https://www.diamonds2020.eu/) clinical network, between April 2020-December 2022 with geographically located and tropical infections were retrieved. Demographic, clinical and laboratory data were collected and analyzed.

Case Presentation Summary: 129 GLTI were included. The number of patients of each infection are detailed in (Figure 1). Most tuberculosis patients had lung disease and had a homogeneous distribution across the clinical sites. Zoonotic and vectorial diseases such as Hantavirus, Tick-borne encephalitis, or Lyme disease were more difficult to recruit as they appear in outbreaks and are more common in holiday periods due to travel, furthermore, they were unique to the following sites: Slovenia, Austria, Switzerland, Latvia, Germany, Spain and UK with most cases recruited in central Europe.

Figure 1

Infection	Number of patients (1,59% of the cohort)
Tuberculosis	28 (21,7%)
Hantavirus	29 (22,5%%)
Lyme Disease	29 (22,5%%)
Tick-Borne Encephalitis	29 (22,5%)
Malaria	6 (4,65%)
Hepatitis A	8 (6,20%)

Learning Points/Discussion: Conclusions: During the pandemic, Lyme disease, Tick-borne encephalitis and hantavirus were the most frequently detected GLTI .Recruiting a significant number of patients with GLTI is a challenge that can be overcome with multicentric and international studies.

RISK FACTORS FOR DETERIORATION TO SEVERE STATE AFTER HOSPITALIZATION IN CHILDREN WITH DENGUE FEVER

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Gurdeep Singh Dhooria, Deepak Bhat
DAYANAND MEDICAL COLLEGE, LUDHIANA, PUNJAB, INDIA, Pediatrics, Ludhiana, Punjab, India

Backgrounds: Dengue infection is currently one of the most important mosquito-borne viral diseases in the tropical parts of the world. The study was done to identify risk factors in children associated with worsening to severe dengue after hospitalization and thus will require close monitoring and critical inpatient care.
Methods: A total of 200 dengue patients got admitted over 3 year period in the age group of 1 – 18 years in the Department of Pediatrics, Dayanand Medical College and Hospital, Ludhiana, India. Fifty five patients had features of Severe Dengue at admission were not included for analysis. Of the 145 patients with features of Dengue fever with warning signs at admission were included in the study. Of these 145 patients, 60 patients (41.3%) went on to develop features of Severe Dengue during hospital stay. Other 85 patients remained in the Dengue fever with warning signs group. Appropriate statistical methods were used to compare clinical and laboratory profile at admission of patients in the two group and identify risk factors for deterioration.
Results: Of the cases, 60% were > 10 years old, with 73% male. Typical manifestations of dengue like fever (98%), abdominal pain(62%) and vomiting(51%) were the most common presenting symptoms. Fever high grade, fast breathing, Ascites, Pleural effusion on X-ray and on ultrasound were risk factors significantly associated with deterioration to severe dengue after hospitalization. Higher mean haematocrit and SGPT levels, lower platelet counts were significantly more in patients who developed Severe Dengue fever. Overall mortality was 8 % in our study.
Conclusions/Learning Points: Identify individuals with risk factors of deterioration to severe dengue after hospitalization would alert clinicians for early interventions to reducing dengue related morbidity and mortality.

PEDIATRIC NURSES VIEWS AND PERCEPTION IN PROVIDING NURSING CARE FOR CHILDREN IN ISOLATION ROOMS: A QUALITATIVE APPROACH

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Shaher Hamaideh[1], Murad Sawalha[2]
[1]The Hashemite University, Community And Mental Health, Zarqa, Jordan, [2]THE HASHEMITE UNIVERSITY, Maternal, Child And Family Health Nursing, Zarqa, Jordan

Background: Pediatric nurses have faced many challenges in providing high-quality nursing care for children in isolation rooms. Especially with emerging newly infectious diseases such as COVID-19 that sheds the light of the importance of exploring and describing this nurses experience. This phenomenon is under investigated in literature, and there is a dearth of studies that conducted in pediatric clinical area to investigate pediatric nurses experience in providing isolation nursing. The aim of this study was to understand pediatric nurses experience in providing nursing care for children in isolation rooms.
Methods: The study used a generic qualitative approach. This study employed purposive sampling to select 15 pediatric nurses in three different hospitals who were taking care of pediatric patients in isolation rooms. Data were collected through semi-structured interviews and were analyzed using the constant comparative procedure proposed by Strauss and Corbin.
Results: The analysis of the data revealed three major themes: (a) Communication with children was limited and distanced, (b) negative emotions and distress, and (c) concerns of safety.
Conclusions/Learning Points: Pediatric nurses encounter many challenges in caring for children in isolation rooms. Using isolation precautions and PPE seize the communication practices and impacts nursing care. The nurses found themselves socially distanced from children which increase their negative emotions that raised from their working in isolation rooms. However, nurses considering the issue of safety and the importance of balancing the care provided to children while avoiding the spread of infection by using isolation precautions. Therefore, health officials and specialists need to pay special attention to these pediatric nurses' challenges and needs to provide a competent and safe nursing care.

EXTENSIVELY DRUG RESISTANT SALMONELLA IN A RETURNING TRAVELLER FROM PAKISTAN TO IRELAND

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Suzanne Kerswill
Wexford General Hospital, Paediatrics, Wexford, Ireland

Title of Case: EXTENSIVELY DRUG RESISTANT SALMONELLA IN A RETURNING TRAVELLER FROM PAKISTAN TO IRELAND
Background: Extensively drug resistant (XDR) Salmonella enterica first emerged in Pakistan in 2016, and constitutes a serious international public health threat. These isolates are resistant to third generation cephalosporins as well as fluoroquinolones, necessitating the use of potent and expensive antibiotics such as meropenem.
Case Presentation Summary: We present the case of a previously well 9-year-old girl who was admitted to a hospital in Ireland with XDR Salmonella typhi bacteraemia. Our patient initially presented with a 4 week history of intermittent bloody diarrhoea and fever after returning from Pakistan. She was assessed as having uncomplicated dysentery and was discharged home with supportive treatment only as per local guidelines. However, she was recalled to hospital 4 days later after her stool specimen came back PCR positive for Salmonella, Shigella and Campylobacter species. Upon representation, the patient was pyrexial with a temperature of 38.2 degrees, heart rate of 120bpm, blood pressure of 105/72 and sats of 100%. She was well-perfused with no neurological fallout, and her abdomen was soft. In consultation with microbiology and infectious diseases, she was admitted to hospital on meropenem 20mg/kg 8 hourly. Gentamicin was added after she remained pyrexial at 48 hours. Subsequently, her blood culture was positive for Salmonella species which was resistant to amoxicillin, trimethoprim, ciprofloxacin and ceftriaxone, and sensitive to meropenem. Repeat blood culture after 48 hours of treatment was negative and she made a gradual clinical recovery.
Learning Points/Discussion: In conclusion, XDR Salmonella enterica is a major therapeutic and public health challenge, and clinicians should be aware of this entity in returning travellers. Empiric treatment of high-risk individuals with carbapenems should be guided by microbiology and infectious diseases experts.

POTENTIAL ANTIVIRAL EFFECT OF EXOPOLYSACCHARIDES PRODUCED BY LACTIC ACID BACTERIA AGAINST BROAD-SPECTRUM ROTAVIRUS INFECTIONS

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Jong-Hwa Kim[1,2], Wonyong Kim[1,2]
[1]Chung-Ang University College of Medicine, Microbiology, Seoul, Korea, Republic of, [2]LuxBiome Co., Ltd., Seoul, Korea, Republic of

Backgrounds: Rotavirus is recognized as the major causative agent for severe gastroenteritis in children under 5 years of age worldwide. However, the treatment is generally not focused directly on the virus, and there is no effective antiviral treatment available against rotavirus infection. Recently, there is a rising interest on probiotic exopolysaccharide (EPS) that have potential beneficial functions, such as antioxidant, anticancer, and anti-inflammatory effect. Here, the purpose of this study is to investigate the antiviral effect against rotavirus using EPS from Lactiplantibacillus plantarum LB 1020 strain (1020 EPS).
Methods: The antiviral effect of 1020 EPS was evaluated by virucidal activity tests against 10 rotavirus strains at in vitro level. In addition, in order to verify the preventive and therapeutic effects of 1020 EPS on rotavirus infection, rotavirus symptoms, viral shedding and histological changes of small intestine before and after viral infection were evaluated using a neonatal mouse model.
Results: Antiviral activity of 1020 EPS at in vitro level has been confirmed against broad-spectrum of human rotaviruses (G1P[8], G2P[4], G3P[8], G4P[6], G8P[8], G9P[8], G11P[25], G12P[6]), porcine rotavirus (G5P[7]), and bovine rotavirus (G6P[6]). In addition, 1020 EPS was found to have antiviral effect before and after rotavirus infection through alleviation of symptoms including diarrhea frequency and changes in the consistency of fecal, reduction of viral shedding and histological changes in the ileum similar to those of normal neonatal mice.
Conclusions/Learning Points: These results suggest that 1020 EPS can be applied as a potential agent for the prevention and treatment of broad-spectrum of rotavirus infections in both humans and human-animal reassortment.

MONKEYPOX MIMICKING CUTANEUS LEISHMANIA CASE

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Mahmut Kızıl[1], Yalçın Kara[1], Nihal Doğan[2], Ömer Kiliç[1], Ener Çağrı Dinleyici[3]
[1]Eskişehir Osmangazi University, Pediatric Infectious Disease, ESKİŞEHİR, Turkey, [2]Eskisehir osmangazi university, Microbiology, Eskisehir, Turkey, [3]Eskişehir Osmangazi University, Pediatric Infectious Disease, Eskişehir, Turkey

Title of Case: MONKEYPOX MIMICKING CUTANEUS LEISHMANIA CASE
Background: In May 2022, cases have been reported from 107 different countries around the world, and 89 of these countries are countries where no cases have been seen before. The Turkish Ministry of Health also published a guideline for clinicians regarding this increase in cases in October 2022. We will talk about a case who presented with vesicular and crusted lesions from the endemic region and was diagnosed with leishmania in the follow-up with the suspicion of monkeypox.
Case Presentation Summary: 6-year-old male presented with bullous painful lesions on his toes and soles for 2 weeks and a new onset of fever. There were vesicular pus-filled lesions on the soles and backs of both lower extremities and crusted crusty lesions on the anterior surface of the tibia. Laboratory examinations revealed that there was no leukocytosis and no cytopenia, C-reactive protein was 27.9 mg/L, and erythrocyte sedimentation rate was 55 mm/hour. Monkeypox PCR, which was studied from the lesion fluid, was negative, and leachian amastigotes were seen in the microscopy made from the lesion fluid. Because the lesions were more than 4, systemic meglumine antimonate treatment was given for 15 days.
Learning Points/Discussion: A multicountry outbreak of the monkeypox virus has gained global attention. As clinicians, it has emerged with this case that there is not always a clear diagnosis in patients who apply with skin lesions and that we should keep in mind different diagnoses with common features. It is possible that we will encounter leishmania cases in all geographical regions in our country in parallel with the ease of transportation between cities, the increase in travel, and the increase in migration to cities for various reasons.

PV0280 / #2034

PAEDIATRIC LEISHMANIASIS AMONG SYRIAN REFUGEES IN THE REPUBLIC OF CYPRUS, 2016-2020

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Maria Koliou-Mazeri[1], Vasiliki Christodoulou[2], Maria Antoniou[3], Stavroula Gouzelou[4]
[1]University of Cyprus, Medical School, Nicosia, Cyprus, [2]Ministry of Agriculture, Rural Development and Environment, Cyprus Cyprus, Veterinary Services, Nicosia, Cyprus, [3]University of Crete, Faculty Of Medicine, Heraklion, Crete, Greece, [4]University of Cyprus, Laboratory Of Infectious Diseases And Public Health, School Of Medicine, Nicosia, Cyprus

Title of Case: PAEDIATRIC LEISHMANIASIS AMONG SYRIAN REFUGEES IN THE REPUBLIC OF CYPRUS, 2016-2020
Background: In Cyprus human cutaneous and visceral leishmaniasis(HCL, HVL) are caused by Leishmania donovani s.l. variants. Until now, no other Leishmania spp. is identified responsible for human disease, although HCL by Leishmania tropica is highly endemic in Turkey, Syria and other neighboring countries. Since the Syrian war massive flows of Syrian refugees are documented and an increase in HCL cases is reported from resettlement countries. Herein, we describe the first paediatric CL cases identified among Syrian refugees in the Republic of Cyprus (RoC).
Case Presentation Summary: Cases of Syrian children with HCL referred for evaluation at Archbishop Makarios Hospital, Nicosia were reviewed. Clinico-epidemiological data were collected and analysed. Skin lesion biopsies were obtained and processed for histopathological and molecular analysis to confirm clinical diagnosis. DNA from skin lesions or positive parasite cultures was extracted and used for PCR-based diagnosis (T2/B4) and Leishmania spp. identification (ITS, miniexon, k26). 19 HCL cases involving Syrian children were recorded. The majority of patients were boys. Median age of patients was 7 years(11 months to 16 years). Skin lesions were located mainly on uncovered skin areas (face, extremities). Most families followed the pathway from Syria to Turkey before entering the RoC. A 6-month median interval between onset of lesions and HCL diagnosis/treatment was reported. Leishmania isolation was successful in 11 cases and L.tropica was revealed as the causative agent.
Learning Points/Discussion: L.tropica, currently a non-endemic species, has emerged in the RoC. The presence of competent L.tropica vectors and suitable eco-environmental niche, generate concerns of autochthonous transmission to the local population. Increased awareness for early diagnosis and treatment may prove very effective in preventing disease spread.

A CASE OF COMPLICATED MALARIA IN AN ENDEMIC REGION

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Laura Leite De Almeida[1], Silvia Chauque[2]
[1]Centro Hospitalar Universitário de São João, Pediatrics, Porto, Portugal, [2]Hospital Geral José Macamo, Pediatrics, Maputo, Mozambique

Title of Case: A CASE OF COMPLICATED MALARIA IN AN ENDEMIC REGION
Background: Malaria is a common disease in tropical countries and young children are at high risk for severe presentations. The clinical manifestations of malaria are variable and nonspecific. A high index of suspicion is necessary for this disease in endemic areas.
Case Presentation Summary: We present the case of a 5-year-old female child with no significant past medical history, who was evaluated in the emergency department of a tertiary Mozambican hospital due to fever, vomiting, and bloody diarrhea for 4 days. She had previously received oral ciprofloxacin treatment at a primary care facility with only partial improvement. On physical examination, the patient was ill-appearing, with sunken eyes and dry mucous membranes, pallor in the palms and soles, and abdominal distention. A rapid malaria test was positive. Laboratory results revealed severe anemia and thrombocytopenia (Hb 3.6g/dL, 42,000 platelets/uL), without leukocytosis or neutrophilia. The diagnosis of severe malaria, with severe anemia and thrombocytopenia, as well as acute gastroenteritis with moderate dehydration, was established. The patient received two blood transfusions, nine doses of intravenous artesunate, and eight days of intravenous ceftriaxone. The child had a good clinical and laboratory improvement and was discharged after 8 days of hospitalization.
Learning Points/Discussion: It is crucial to screen for malaria all febrile children in endemic regions, regardless of the accompanying symptoms. Early diagnosis is critical for prompt initiation of treatment and reduction of complications. Severe malaria is associated with higher morbimortality, and parenteral artesunate is the recommended treatment.

A CASE OF LEPTOSPIROSIS IN A CHILD WITH UNUSUAL CLINICAL MANIFESTATION

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Ana Beatriz Luzio Vaz[1], Rita Valsassina[2], Cristina Gonçalves[3], Maria Luísa Vieira[4], Catarina Gouveia[5]
[1]Hospital Dona Estefânia, Department Of Paediatric Infectious Diseases, Lisbon, Portugal, [2]Hospital Dona Estefania – Central Lisbon University Hospital Center, Pediatrics Infectious Diseases Unit, Lisbon, Portugal, [3]Hospital Dona Estefânia - Central Lisbon Universitary Hospital Center, Paediatrics Gastroenterology Unit, Lisbon, Portugal, [4]Institute of Hygiene and Tropical Medicine, Lisbon, Lisbon, Portugal, [5]Hospital Dona Estefânia - Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal, Paediatric Infectious Diseases Department, Lisbon, Portugal

Title of Case: A CASE OF LEPTOSPIROSIS IN A CHILD WITH UNUSUAL CLINICAL MANIFESTATION
Background: Leptospirosis is a re-emerging zoonotic disease with a worldwide distribution, more prevalent in tropical areas. Transmittable from exposure to urine-contaminated soil or water from mostly rats. Acute leptospirosis is heterogeneous, ranging from a mild nonspecific febrile illness to a severe disease with organ dysfunction. Laboratory tests are non-specific, challenging the diagnosis.
Case Presentation Summary: We report a 2-year-old girl case, previously healthy, admitted with a 5-day fever, abdominal pain, asthenia and hepatomegaly without jaundice. She had a recent trip to Cuba. Laboratory findings revealed anemia (Hb 8.6 g/dL), leukocytosis (22,180/mm3), high C-reactive protein level (284.9 mg/L), ferritin 369.4 ng/mL, fibrinogen 6.7g/L and cito-cholestatic hepatitis (AST 80 U/L, ALT 297 U/L, total bilirubin 1.86 mg/dL, GGT 646 U/L, FA 542 U/L, INR 1.13, albumin 35.6g/L). The abdominal ultrasound showed biliary intrahepatic duct dilation. Empiric antibiotic with cefotaxime, gentamicin and metronidazole was initiated. She had serological evidence of recent Epstein Barr's infection (VCA IgG, IgM, EBNA, but negative viral load). Other viral infections and cultures were negative. The patient improved, with apyrexy at D1 and was discharged after 8 days. She completed 14 days of antibiotic. The diagnosis of leptospirosis was confirmed by detection of urine Leptospira DNA. The micro agglutination testing (MAT) was negative and was not repeated.
Learning Points/Discussion: Leptospirosis should be considered in all febrile patients particularly if history of exposure to freshwater, resident or travel to endemic areas. Our child developed symptomatic hepatitis, with evidence of simultaneous EBV and Leptospira infections. The role of each infection cannot be assured. Leptospirosis suspicion was based on the epidemiological context, along with the febrile illness, high inflammatory parameters and hepatitis, confirmed by urine Leptospira PCR.

[1]Universitas Indonesia Hospital, Department of Child Health, Faculty of Medicine Universitas Indonesia, Department Of Child Health, Depok, Indonesia, [2]Universitas indonesia, Universitas Indonesia Hospital, Child And Health Department, Depok, Indonesia

Title of Case: SERIAL CASE OF PERTUSSIS IN AN INCOMPLETELY VACCINATED INFANT: AN IMPACT OF COVID-19 PANDEMIC IN DEVELOPING COUNTRY
Background: The COVID-19 pandemic has affected healthcare services and access globally, including vaccination coverage in children, contributing to the rising incidence of vaccine-preventable diseases (VPDs). Pertussis is an acute respiratory illness caused by Bordetella pertussis, one of the VPDs, showing a re-emergence in developing countries.
Case Presentation Summary: We reported a serial case of pertussis in an incompletely vaccinated infant. The first case was 12 months old boy referred to our hospital due to hyperleukocytosis. We found a history of recurrent cough since the age of 2,5 months old. Several kinds of antibiotics were given including beta-lactam antibiweret no macrolides had been prescribed. The second case was a COVID-19-positive 2 months old boy with difficulty breathing and a cough that was numerous and rapid. The suspicion towards pertussis was higher as there was no history of pertussis vaccination in the patient. Polymerase chain reaction (PCR) from the nasopharynx swab was positive for both cases of Bordetella pertussis. They were both given azithromycin and recovered completely after 7 days of administration. The last case was a 4-month-old boy who was hospitalized due to pneumonia. The third generation of cephalosporin for 5 days shows no significant clinical improvement with the cough being paroxysmal and rapid. He hasn’t received the last primer dose of pertussis vaccination. The patient's cough characteristics and age reinforced us to treat it as pertussis. Azithromycin was given and he entirely recovered after 7 days of administration.
Learning Points/Discussion: Unvaccinated or incompletely vaccinated infants younger than 12 months of age have the highest risk to be infected by pertussis. Herd immunity is needed to protect this group.

TICK-BORNE LYMPHOADENOPATHY IN CHILDREN ADMITTED IN A TERTIARY HOSPITAL, PORTUGAL

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Inês Pereira Soares[1], Maria Soto-Maior Costa[2], Madalena Torrado Malato[1], Rita De Sousa[3], Florbela Cunha[1]
[1]Hospital de Vila Franca de Xira, Pediatrics, Vila Franca de Xira, Portugal, [2]Hospital Dona Estefânia, CHULC, Paediatrics, Lisboa, Portugal, [3]National Institute of Health Dr. Ricardo Jorge, Centre Of Study Of Vectors And Infectious Diseases, Lisbon, Portugal

Title of Case: Tick-Borne Lymphoadenopathy
Background: TIck-Borne Lymphadenopathy (TIBOLA) is a tick-borne rickettsial disease oftenly caused by Rickettsia slovaca, which is transmitted by Dermacentor tick species. TIBOLA is characterized by an inoculation eschar at the tick bite site associated with a painful regional lymphadenopathy. We describe paediatric cases in which removed ticks were identified and screened by polymerase chain reaction for rickettsiae.
Case Presentation Summary: During spring/summer of 2022 three children, two boys and one girl, 8 and 7 years old, respectively, were admitted at the emergency department with an attached tick. The ticks were removed and sent to the National Reference Center for vector-borne diseases (INSA) to be identified and analysed. Two of the ticks removed were Rhipicephalus sanguineus and one was Dermacentor marginatus. All of the children were asymptomatic on admission. Physical examinations revealed an occipital eschar in the two boys. One of the boys, in which the tick was infected with R.slovaca, developed a cervical lymphadenopathy (boy 1). Later, the same boy developed an alopecia that remained after cure. The Rhipicephalus tick removed from the girl was not infected. Only boy 1 was treated with doxycycline. The serologic tests were positive in the boys.
Learning Points/Discussion: In the past years several rickettsiae species have been identified in Portugal. Important differences in clinical features and severity of the disease exist according to the rickettsiae. Since the serologic diagnostic does not detect antibodies until 10/14 days after the onset of illness and cannot identify the species of the rickettsiae, it becomes useful to remove the tick. This allows the identification of new rickettsiae species and register their epidemiology and geographical distribution.

[1]University of Turin, Science Of Public Health And Pediatrics, Turin, Italy, [2]Regina Margherita Children's Hospital, Paediatric Infectious Disease, Turin, Italy, [3]Regina Margherita Children's Hospital, Pediatric Emergency, turin, Italy, [4]Regina Margherita Children's Hospital, Pediatric Immunorheumatology, Turin, Italy, [5]Regina Margherita Children's Hospital, University of Turin, Turin, Italy, Paediatric Infectious Diseases Unit, Turin, Italy

Title of Case: Infantile visceral leishmaniosis: do we expect an increasing trend over time?
Background: Infantile visceral leishmaniosis (IVL) is a potentially fatal disease caused by Leishmania spp. parasites. It is moderately-to-highly endemic in Italy and southern Europe and still represents a diagnostic challenge for pediatricians.
Case Presentation Summary: We retrospectively collected IVL cases admitted to Regina Margherita Children's Hospital of Turin (referral centre of Piedmont and Aosta Valley regions) between 2018-2022; the aim of our research was to describe clinical and laboratory features at presentation, timing of treatment and outcomes. A total of 8 IVL cases (75% males) were collected, of which 5 diagnosed in the last year 2022 (62.5%); no IVL was diagnosed between 2020 and 2021. The mean age was 2.5 years. Persistent fever was the main symptom at hospital admission (6/8), followed by non-tender hepatosplenomegaly (8/8), trilinear cytopenia (7/8) and hypergammaglobulinemia (5/8); 3 patients developed hemophagocytic lymphohistiocytosis (HLH). Average time-to-diagnosis was 15 days and diagnosis was performed by microscopic detection (5/8) and PCR-DNA amplification (6/8) on bone marrow blood samples and/or by serologic tests (8/8). Liposomal amphotericin B treatment was administered after an average of 4.1 days from admission and 2 patients received immunosuppressive treatment for HLH. The average length of stay was 13.9 days. No death was recorded and all patients fully recovered.
Learning Points/Discussion: The unexpected increase in IVL cases during the last year raises concern about a possible role of climate change and suggests the enhancement of epidemiological surveillance in the future. High level of suspicion in case of persistent fever of unknown origin and signs/symptoms suggestive for IVL is essential, particularly in pediatric population. Having a better awareness of this disease, especially secondary life-threatening HLH, allows a prompt diagnosis and focused treatment.

TROPICAL FEVER WITH UNEXPECTED TWIST AND TURN

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Bhaskar Shenoy, Pooja Doddikoppad, Devesh Joshi
Manipal Hospital, Pediatrics, Bangalore, India

Title of Case: Tropical Fever with Unexpected Twist and Turn
Background: Tropical fevers present with overlapping clinical features.A significant number of these patients also have one or more organ failures . The challenge lies in clinically diagnosing them at the time of presentation as they often present as undifferentiated fever and with overlapping signs and symptoms It is important to treat them early as delay in institution of specific therapy may lead to increased morbidity and mortality.
Case Presentation Summary: 16year female presented with 4 days high grade fever , maculopapular rashes , diagnosed as dengue fever Day 6 of illness ,developed hypotension , progressive pallor , icterus , managed as severe dengue . ..From day 7 to 12, continued to have high grade fever with worsening liver enzymes. Treated with multiple antibiotics . Referred to our hospital on day 15, with high grade fever. On admission child was pale , icteric . Liver palpable 5cm below RCM, . Child continued to have high grade fever , at admission Hb-8.6, TC-4100 .USG ABDOMEN - coarsened liver echotexture -, Gall bladder wall oedema, . 2D ECHO- normal. Investigated for infectious cause of fever- was negative (Blood , urine culture – no growth, , Leptospira IgM , Scrub typhus , Brucella IgM – negative) Continued to have high grade fever . Investigated further ,had hyperferritinemia (Serum FERRITIN 28349.0 ng/mL) hypertriglyceridemia(TRIGLYCERIDES - 537 mg/dl), hypofibrinogenemia (Fibrinogen -80.6 mg/dl),anaemia and cytopenia .Suspected to have HLH . BONE MARROW EXAMINATION:- Hemophagocytic lymphohistiocytsis .Started on IV Dexamethasone ,Improved clinically and gradual improvement in total counts and liver enzymes .
Learning Points/Discussion: HLH is rare but fatal complication of dengue leading to multiorgan dysfunction thereby increasing morbidity and mortality. Early suspicion and timely treatment are crucial for uneventful recovery

TICK-BORNE DISEASES IN CHILDREN: A RETROSPECTIVE ANALYSIS OF CASES FOLLOWED IN A TERTIARY CHILDREN'S HOSPITAL IN NORTHERN ITALY BETWEEN 2009 AND 2022

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Erika Silvestro[1], Federica Mignone[1], Elisa Funiciello[1], Giuseppe Adimari[2], Giulia Pruccoli[1], Carlo Scolfaro[1], Elisa Barisone[2], Francesca Robasto[1], Silvia Garazzino[1]
[1]Regina Margherita Children's Hospital, Paediatric Infectious Disease, Turin, Italy, [2]University of Turin, Pediatric Infectious Diseases Unit, Turin, Italy

Title of Case: Tick-borne Diseases in a tertiary children's hospital in Northern Italy.
Background: Considering the recent increase in tick-borne diseases in Europe, there is a clear need for studies to help highlight their prevalence in children. We know that the heterogeneity of surveillance across European countries remains challenging to accurately assess disease distribution, incidence, and trend over time.
Case Presentation Summary: AIMS: This study aimed to describe pediatric cases of tick-borne diseases retrospectively admitted to a tertiary children's hospital in Northern Italy between 2009 and 2022, with emphasis on exposure to tick bites, risk factors, epidemiological, clinical and laboratory data, and treatment of Lyme disease (LD) cases. MATERIALS AND METHODS: At the Infectious Diseases Clinic of Regina Margherita Children's Hospital in Turin, 64 patients were evaluated for a history of tick bite or suspected/diagnosed LD between January 2009 and December 2022. RESULTS: Patients with a history of tick bite or suspected/diagnosed LD increased in number over time (44,9% in 2021-2022). 78.1% reported previous tick bites, which occurred in 78% of cases between May and August. 68,8% presented risk factors for contact with ticks. Among the 44 diagnoses of LD, there was an increasing number of cases over time (52,3% in 2021-2022). Erythema migrans (EM) was the most common manifestation of LD (34/44; median incubation time: 13 days); we found 3 cases of neuroborreliosis and 5 cases of arthritis. According to guidelines, treatment resulted fully or partially adequate in 92.8% of EM cases and 100% of disseminated diseases.
Learning Points/Discussion: Our results are in line with the latest scientific evidence. It is essential to raise awareness of tick-borne diseases to promote early diagnosis and treatment and implement appropriate individual and environmental prevention measures in the general and pediatric population.

DENGUE BURDEN OF DISEASE IN ARGENTINA: 10 YEARS EPIDEMIOLOGIC REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS05.A. ZOONOSIS, VECTOR-BORNE AND EMERGING INFECTIONS

Solana Rapaport[1], Mariana Mouriño[2], María Morales[3], Cintia Fabbri[3], Victoria Luppo[3], María Buyayisqui[2], Carlos Giovacchini[2], Analia Urueña[1]
[1]Universidad Isalud, Centro De Estudios Para La Prevención Y Control De Enfermedades Transmisibles, Ciudad Autónoma de Buenos Aires, Argentina, [2]Ministerio de Salud de la Nación, Area De Vigilancia, Dirección De Epidemiología, Ciudad Autónoma de Buenos Aires, Argentina, [3]Ministerio de Salud de la Nación, Inevh - Instituto Nacional De Enfermedades Virales Humanas "dr. Julio I. Maiztegui", Pergamino, Argentina

Backgrounds: Dengue is an important public health problem in Argentina as in other parts of the world. We aimed to review and update information on dengue disease burden in Argentina over a 10-year period that contributes to assessing future prevention strategies.
Methods: Retrospective 2011-2020 descriptive study, based on Argentina Ministry of Health secondary data. Main outcomes included dengue cases, incidence rates, hospitalizations, deaths and serotypes distribution, by season, age groups, and regions.
Results: 109,998 confirmed cases of dengue were reported between epidemiological weeks (EW) 31/2010 and 30/2020 (2010/11 and 2019/20 seasons). Seasonality stands out, prevailing during the summer and autumn. During the entire period, three main outbreaks (seasons 2012/13, 2015/16 and 2019/20), with increasing magnitude, were observed. The 2019/20 season showed the highest number of cases (58,731) and incidence rate (135 cases per 100,000 inhabitants). During these 10 years, the Northeast region had the highest number of cases and the highest incidence rate. The Centro region followed in number of cases, but the Northwest region had a higher incidence rate. In the 2019/20 season, for the first time, autochthonous cases were registered in the Cuyo region. The only region that did not register autochthonous cases was the South. Adolescents and young adults were the most affected. Hospitalizations and deaths were infrequent. Although all 4 serotypes circulated during the evaluated period, the predominant serotype in all regions and seasons was DEN-1 (78%).
Conclusions/Learning Points: Dengue has been expanding temporally and spatially throughout our national territory. While circulation of DEN-1 serotype widely predominated, the increasing co-circulation of other serotypes raises concerns regarding re-exposure and severity of future cases. Understanding epidemiological trends is key to defining public prevention and control policies.

AN OBSERVATIONAL STUDY OF PATIENTS INVESTIGATED FOR MALARIA IN A PAEDIATRIC A&E

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Emma Alexander[1,2], Joanna Boxall[2], Rosanne Verow[2], Bhanu Williams[2]
[1]Queen Mary University of London, Charterhouse Square, London, United Kingdom, [2]Northwick Park Hospital, Department Of Paediatrics, London, United Kingdom

Backgrounds: Fever in the returned traveller is a diagnostic challenge, especially with changing epidemiology for diseases such as malaria. 1700 cases of imported malaria occur in the UK every year, 200 in children. Consequently, we audited the management of children investigated for malaria at our hospital.
Methods: Audit of medical notes for children <16 years who had malaria blood films processed at our District General Hospital, May 2018-December 2019. Audit standard was local 'fever in the returned traveller' guidelines. Reference W&C.NP.20.011.
Results: 188 patients were analysed, 113 boys and 75 girls, median age 4 years (interquartile range 1.75-8 years). Median stay abroad was 28 days (range 7-lifelong), and median time between return and presentation was 8 days (range 0-730 days). Three of 188 malarial blood films were positive. Children travelled to 35 countries, most commonly India (n=71, variable risk of malaria), Pakistan (n=24, low risk), and Sri Lanka (n=14, no risk). Overall, 52.9% received pre-travel vaccines, 36.2% antimalarials. Median WCC was 9.9, median CRP 20.3, median lactate 1.3. 10.1% of blood cultures were positive. 22.3% were admitted to the ward, 26.6% to the Paediatric Assessment Unit, the rest discharged home from the Emergency Department, and all survived. The most common final diagnoses were viral infection (n=30, 16.0%), gastroenteritis (n=29, 15.4%), URTI (n=29, 15.4%), tonsillitis (n=18, 9.6%), LRTI/pneumonia (n=15, 8.0%), UTI (n=10, 5.3%), salmonella/typhoid (n=7, 3.7%) and other diagnoses (including dengue, measles, TB) made in <6 patients (n=57, 30.3%).
Conclusions/Learning Points: In this study malaria was a very rare diagnosis. Many films were requested unnecessarily for patients returning from low- or no-risk areas. Interventions are underway for staff education and use of up-to-date epidemiological data for decision-making. Education around pre-travel vaccines and mosquito bite prevention continue to be needed for travellers.

INTEGRATING THE VAR TRANSCRIPTOME WITH THE HOST AND CLINICAL MARKERS IN SEVERE PLASMODIUM FALCIPARUM MALARIA

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Clare Andradi-Brown[1], Rachel Thompson[1], Hyun Jae Lee[2], Athina Georgiadou[1], Anna Bachmann[3], Thomas Otto[4], Aubrey Cunnington[1,5]
[1]Imperial College London, Section Of Paediatric Infectious Disease, London, United Kingdom, [2]University of Melbourne, Microbiology And Immunology, Victoria, Australia, [3]Bernhard Nocht Institute for Tropical Medicine, Centre For Structural Systems Biology, Hamburg, Germany, [4]University of Glasgow, School Of Infection & Immunity, Glasgow, Germany, [5]Imperial College London, Centre For Paediatrics And Child Health, London, United Kingdom

Backgrounds: Severe and fatal malaria is believed to occur due to a combination of host and parasite factors. Var genes encode major parasite virulence factors which are exported to the surface of infected red cells, bind to host vascular endothelium and cause microvascular dysfunction. However, var genes are extremely polymorphic, making it challenging to determine precise relationships between their expression, pathophysiology, and clinical outcomes.
Methods: We developed a new method for accurate de novo assembly and quantification of var transcripts from RNA-Seq. We applied this to whole blood RNA-Seq from Gambian children with different clinical manifestations of malaria (cerebral malaria, n=4; hyperlactatemia, n=6; cerebral malaria plus hyperlactatemia, n=11; uncomplicated malaria, n =19). Differential gene expression analysis was performed to identify variation in parasite var gene expression between different clinical phenotypes. Regression models were used to relate var gene expression to clinical variables and to host gene expression.
Results: We observed minimal overlap in the var transcripts upregulated in the different severe phenotypes. We found cerebral malaria plus hyperlactatemia patients had significantly higher levels of global var gene expression relative to uncomplicated malaria patients, regardless of the binding phenotype encoded by the var transcript. Higher proportions of group A var gene expression was observed in severe malaria relative to uncomplicated malaria. Work is ongoing to identify relationships between var binding phenotypes and host gene expression and clinical variables.
Conclusions/Learning Points: The data indicates that differences in var gene expression are associated with differences in clinical phenotypes of malaria. Further analysis will provide new insights into the pathogenesis of severe malaria and how the var transcriptome influences the host response. These insights may guide future interventions to disrupt pathological interactions between malaria parasites and the host vascular endothelium.

PAEDIATRIC LEPTOSPIROSIS IN THE SOUTHERNMOST AREAS OF JAPAN

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Kotaro Araki[1], Takuma Kumasaka[2], Miyuki Magota[2], Kenya Matsuda[3]
[1]Okinawa Prefectural Nanbu Medical Center & Children's Medical Center, Division Of General Pediatrics, Department Of Pediatrics, Okinawa, Japan, [2]Okinawa Prefectural Yaeyama Hospital, Department Of Pediatrics, Ishigaki-city, Japan, [3]Okinawa Prefectural Yaeyama Hospital, Department Of Clinical Laboratory, Ishigaki-city, Japan

Backgrounds: Leptospirosis is reported sporadically in Japan. However, it is endemic in the subtropical region of Okinawa and is especially common in Japan's southernmost area. We evaluated the characteristics of children diagnosed with leptospirosis in the Yaeyama Islands.
Methods: Medical records of patients aged <18 years, who were diagnosed with leptospirosis at Okinawa Prefectural Yaeyama Hospital between April 2014 and March 2020 were retrospectively reviewed. Data including symptoms, physical examination findings, blood test results, serogroups and serotypes of Leptospira, presence of Jarisch–Herxheimer reaction, history of freshwater exposure, and exposure area were extracted from the electronic medical records. Data on precipitation before exposure were obtained from the Japan Meteorological Agency.
Results: This study included 7 children, with a median age of 12 years (interquartile range [IQR], 11–17 years). Of these, 4 patients were exposed in the same river. Blood culture and polymerase chain reaction tests on blood or urine samples were used to diagnose 5 and 2 cases, respectively. Leptospira interrogans serovar Hebdomadis, L. interrogans serovar Australis, and L. kirschneri serovar Grippotyphosa were detected in 3, 2, and 1 patients, respectively, and 1 patient was not tested. Conjunctival congestion and generalized myalgia were observed in 7 and 5 patients, respectively. The median precipitation in the 2 weeks before exposure to freshwater and the median precipitation over the past 30 years were 46 mm (IQR, 26.5–63 mm) and 135.7 mm (IQR, 93.9–142.3 mm), respectively.
Conclusions/Learning Points: More than half of the cases of paediatric leptospirosis in the Yaeyama area were exposed in the same river. The amount of precipitation in the 14 days prior to exposure to freshwater was less than the average precipitation in the previous years.

ELIZABETHKINGIA MENINGOSEPTICA BRONCHOPNEUMONIA IN A CHILD WITH TYPHUS FEVER

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Deepak Bhat, Gurdeep Singh Dhooria, Shruti Kakkar
DAYANAND MEDICAL COLLEGE LUDHIANA, Pediatrics, LUDHIANA, India

Title of Case: ELIZABETHKINGIA MENINGOSEPTICA BRONCHOPNEUMONIA IN A CHILD WITH TYPHUS FEVER

Background: Elizabethkingia meningoseptica is an unusual, highly resistant, gram- negative bacillus. While E. meningoseptica-associated meningitis outbreaks have been well-documented in hospital neonatal wards and among immunocompromised adults, reports describing this microorganism in critically ill children are scarce. Hence we report this case in an apparently immunocompetent child having typhus fever

Case Presentation Summary: A 6 year old child was admitted with chief complaints of fever and cough for 15 days,vomiting for 3 days ,generalized weakness from 2 days and difficulty in breathing for 1 day.On examination child's general condition was sick.Her vitals were a pulse rate of 124/mt,peripheral pulses were weak but central pulses were well palpable,CFT of 3 seconds and BP-100/60,respiratory rate of 36/mt with subcostal retractions.On auscultation chest had bilateral crepitations.Child was provisionally managed as a case of tropical fever syndrome with compensated shock and respiratory distress.Child was started on inotropes and NIV support.Initial labs showed a Hb-9.2 gm/dl/,platelet count of 28000/dl,WBC-11400/dl,ESR-2. Inj Ceftrioxone and Azithromycin were started empirically.Tropical fever workup showed positive scrub serology.Gradually child started improving and was weaned off from NIV and ionotropes.But fever continued to trouble the child.On day 6 of hospitalization,blood cuture showed growth of Elizabethkingia meningoseptica.It was resistant to ceftrioxone and sensitive to ciprofloxacin with a MIC of 0.12.So injection ciprofloxacin was started.Child became afebrile over next 3 days and aws discharged on oral ciprofloxacin.

Learning Points/Discussion: Recognition of E. meningoseptica is of critical importance since conventional empirical treatment against gram-negative bacteria may result in unfavorable outcome given its unique antimicrobial susceptible pattern.

SCRUB TYPHUS COINFECTION WITH ACUTE HEPATITIS A & E IN A CHILD WITH HEMOLYTIC ANEMIA

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Deepak Bhat
DAYANAND MEDICAL COLLEGE LUDHIANA, Pediatrics, LUDHIANA, India

Title of Case: Scrub Typhus Coinfection With Acute Viral Hepatitis A & E In A Child With Hemolytic Anemia

Background: Acute viral hepatitis is a major public health problem worldwide. Hepatitis A virus (HAV) and Hepatitis E virus (HEV) are the most common cause of acute viral hepatitis that mainly affects the pediatric age group. Coinfections presents with overlapping clinical features of the causative diseases posing a huge diagnostic dilemma.We report a patient who presented to us with acute viral hepatitis and hemolysis and investigation revealed hepatitis A, E and scrub typhus coinfection.

Case Presentation Summary: A 7 year old girl was admitted for fever for 5 days ,15 days back,yellowish discoloration of eyes for 10 days,vomiting and pain abdomen for 10days,reduced urine output and swelling over body for 4 days prior to the admission.Fever was acute in onset and mod to high grade,got relieved with medication after 5 days.Once fever subsided child developed pain abdomen,vomiting and yellowish discoloration of eyes.Child weight was 28 kg(90th percentile) and height 116 cm(25-50th percentile).On examination child was fully conscious but not alert. with icterus and pallor present.Edema over eyes ,face and legs was present.Liver palpable 5 cm below rt costal margin.Work breathing was increased(48/mt).Initial labs showed a raised CRP-93.9,urea-28,creatinine-0.3,Na -130,TB-6.9,DB-6.1,OT-939,PT-370,TP-5.5,Alb-1.96,ceruloplasmin-17.9,ammonia-72,Hb-7.7,Hct-24.6,MCV-97.3,RDW-21.2,Plt-160 with giant platelets,INR-1.5,Ratio-1.4,anti HAV-13.5,Anti HEV-7.68,Lepto-0.73,Scrub-1.046,ANA titre-0.303(neg),G6PD-normal,B12-1236,LDH-485,Cal-7.5,Vit D=3.66,Dengue NS1-2.67,Dengue IgM-6.65,PCT-9.04,Heptoglobin- 4.1mg/dl(30-200),spot urine to creatinine ratio-0.5.Xray chest-rt pl effusion,usg abd-hepatosplenomegaly with ascites.

Learning Points/Discussion: Varied presentation and low index of suspicion and lack of widespread availability of economical diagnostic test for scrub typhus contributes to increased mortality in spite of availability of effective treatment.We emphasize to keep it as close differential in any sick child presenting with acute undifferentiated fever

PV0294 / #2101

CARDIAC ALTERATIONS IN CHILDREN WITH DENGUE INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Solano Cristina, Stephanie Casadiego
Universidad de Cartagena, Bolivar, aguachica, Colombia

Backgrounds: Objective: describe the cardiac alterations in pediatric patients with dengue with warning signs and severe dengue at the Napoleón Franco Pareja Children's Hospital between June and September 2021.
Methods: retrospective descriptive observational study with children with a clinical diagnosis of dengue (WHO 2009). Random sampling was carried out, considering the prevalence of the event in the previous year. The results of clinical and paraclinical variables (cardiac biomarkers, electrocardiography and echocardiography) are shown in general and with comparisons between the groups of dengue with alarm signs (DSSA) and severe dengue (SD) and according to the state of co-infection with the CHIK virus.
Results: 93 individuals were included, 67.7% with DSSA, 32.3% with SD, 60% male, with a median age of 11 years. 16 had comorbidities, with no statistical differences between groups. The duration of symptoms on admission was 4 days. CHIK coinfection was detected in 20-25%, with 14-36% IgM/IgG/NS1 positivity vs 55-77% of dengue patients without coinfection. Most presented fever, abdominal pain, vomiting and headache. The clinical differences were given by the hemorrhagic manifestations, alteration of consciousness and signs of shock, more frequent in SD. The prevalence of electrocardiographic alterations was 10% and echocardiographic 26.8%. There were no differences in cardiac biomarkers (Troponin I, myoglobin, CK-BM and pro-BNP). Only one case of mortality attributed to severe dengue was presented.
Conclusions/Learning Points: the frequency of severe dengue is high, mortality is more likely in comorbidities. The myocardial compromise is low frequency but the sub diagnosis is high, which limits its study. Prospective studies are lacking in order to define the usefulness of cardiac markers and include interventions such as electrocardiography and echocardiography, which would make it possible to identify patients with a severe course.

EPIDEMIOLOGICAL CHARACTERISTICS CONGENITAL CHAGAS DISEASE IN A NON-ENDEMIC AREA

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Maria Cusso[1], Manuel Monsonis[1], Victoria Fumado[2]
[1]Sant Joan de De Universitary Hospital, Paediatrics, Esplugues de Llobregat, Spain, [2]Saint John of God Hospital, Pediatrics Infectious Diseases, Esplugues de Llobregat, Spain

Backgrounds: Chagas disease (CD) is endemic in Latin America. With the increase of migratory flows, an increase of imported and congenital cases has been seen in Spain. In Catalonia, a systematic screening program was introduced in 2010 to detect the cases of Congenital Chagas Disease (CCD). We evaluated its results over the last five years (2016-2020).
Methods: Descriptive study including T.cruzi seropositive women and their children attended at the HSJD (January 2016 – December 2020). Diagnosis was confirmed by PCR at any age or when serology remained positive at nine months old. All families were interviewed to assess their degree of knowledge about CD, the impact of its diagnosis on health attitudes and pre-pregnancy treatment.
Results: We included 96 infected women (92,7% were from Bolivia; 36,5% had been treated before pregnancy). More than 3/4 of them know about CD transmission and treatment. None of treated mothers transmitted the infectiont while the transmission was of 14,1% among untreated. The congenital transmission rate (CTR) from 2016 to 2020 was 1,4%. Infected infants were all treated with benznidazole (PCR and serologies became negative in a 92,3% and 38,5% respectively). Non-infected children presented a negative PCR at first screening in a 98,2% and negative serology at a mean age of 8,2 months. Of 96 siblings, 80 (83,3%) were tested and 11 (13,8%) were positive. Having other children with Chagas was found to be a risk factor for CCD ($p < 0,05$).
Conclusions/Learning Points: Systematic screening of CCD is necessary in a non-endemic area. Prevalence and CTR in our sample are in accordance with other studies in non-endemic countries. The increase of treatment previous to pregnancy with a rising knowledge about CD could explain the reduction of CTR in our cohort.

A 4-YEAR-OLD CHILD WITH A 13 CM IN DIAMETER CEREBRAL HYDATID CYST

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Aylin Dizi Işık[1], Özcan Sönmez[2], Zeynep Ergenç[1], Seyhan Yılmaz[1], Sevgi Aslan Tuncay[1], Burcu Parlak[1], Pınar Canizci Erdemli[1], Adnan Dağçınar[2], Eda Kepenekli[1]
[1]Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Marmara University School of Medicine, Neurosurgery, İstanbul, Turkey

Title of Case: A 4-year-old Child with a 13 cm in diameter Cerebral Hydatid Cyst
Background: Echinococcosis is the most common cestad infection in the world, caused by Echinococcus granulosus and Echinococcus multilocularis. The infection is mostly localized to the lungs and liver. Here, we present a case with a giant cerebral hydatid cyst.
Case Presentation Summary: A 4-year-old previously healthy boy presented with abnormal gait and walking. Cranial magnetic resonance imaging (MRI) showed a cyst of 13 cm in diameter (Figure 1).

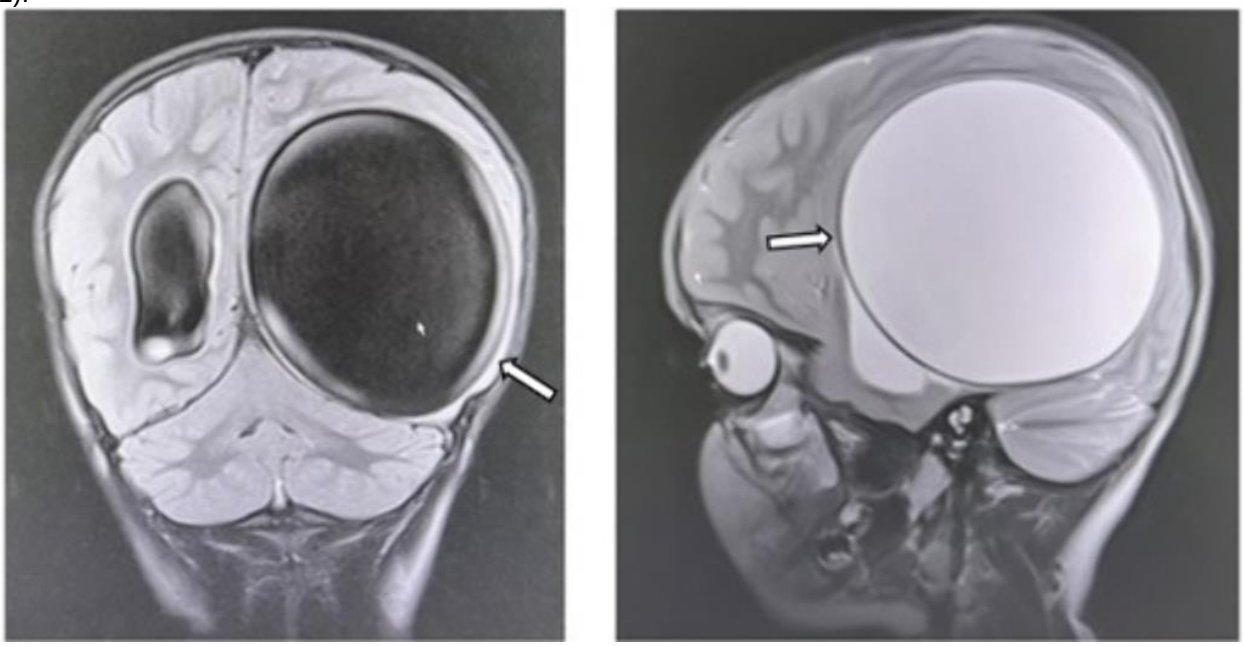

Figure 1. MRI sections showed a cyst 13 cm in diameter localized under the cortex in the left parietooccipital region A 13-cm cyst was enucleated successfully with no rupture. In his story, he had contact with cattle and dogs in the village. Oral albendazole treatment was started. The echinococcal indirect hemagglutination test was negative. An anechoic cystic lesion (10 mm) was detected in the liver by ultrasonography. He was evaluated for deep-organ involvement, however, no cysts were detected in other organs. The histopathological examination was compatible with a hydatic cyst.
Learning Points/Discussion: Although intracranial hydatid disease in children is rare, it should be considered among the differential diagnoses in patients with altered levels of consciousness, especially in highly endemic regions.

QUANTIFYING BETWEEN-PATIENT DIFFERENCES IN RATE OF RECOVERY FROM MALARIA

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Stefan Ebmeier, Nashma Aden, The Script Study Team, Aubrey Cunnington
Imperial College London, Section Of Paediatric Infectious Diseases, London, United Kingdom

Backgrounds: Malaria causes >600,000 deaths annually (mainly in young children) and remains one of the most important infectious diseases affecting humanity. New adjunctive therapies (targeting the human host to promote recovery) may help reduce mortality and morbidity. The SCRIPT (Search for Correlates of Recovery in the Patient Transcriptome) Malaria Study (NCT05149157) is a prospective observational cohort study recruiting returning travellers with malaria in London NHS hospitals. The study's aim is to identify human genes whose expression correlates with rate of recovery. This approach may identify host mechanisms playing an important role in recovery and reveal novel targets for future adjunctive therapies.
Methods: Patients of all ages were recruited to the SCRIPT study at the earliest opportunity after malaria diagnosis. Markers of tissue, organ, or organ system dysfunction (bedside and laboratory test results and organ support requirements) were extracted from the clinical notes from presentation up to day 14 after diagnosis. Patient-specific trends in recovery (or deterioration) for these markers were modelled using all available data and methods adapted from population pharmacokinetics. Estimated trends for selected markers were integrated by Principal Component Analysis to calculate a patient-specific 'composite recovery score' (intended to reflect the 'overall recovery rate').
Results: The first forty patients recruited to the SCRIPT study were included in this preliminary analysis. There was extensive variation in estimated patient-specific recovery rates, both for the novel 'composite recovery score' and for individual markers of tissue, organ, and organ system dysfunction.
Conclusions/Learning Points: Quantifying between-patient differences in recovery rate is an important first step in identifying aspects of host biology playing an important role in recovery. The extensive variation between individuals may be leveraged to identify mechanistic correlates of faster or slower recovery.

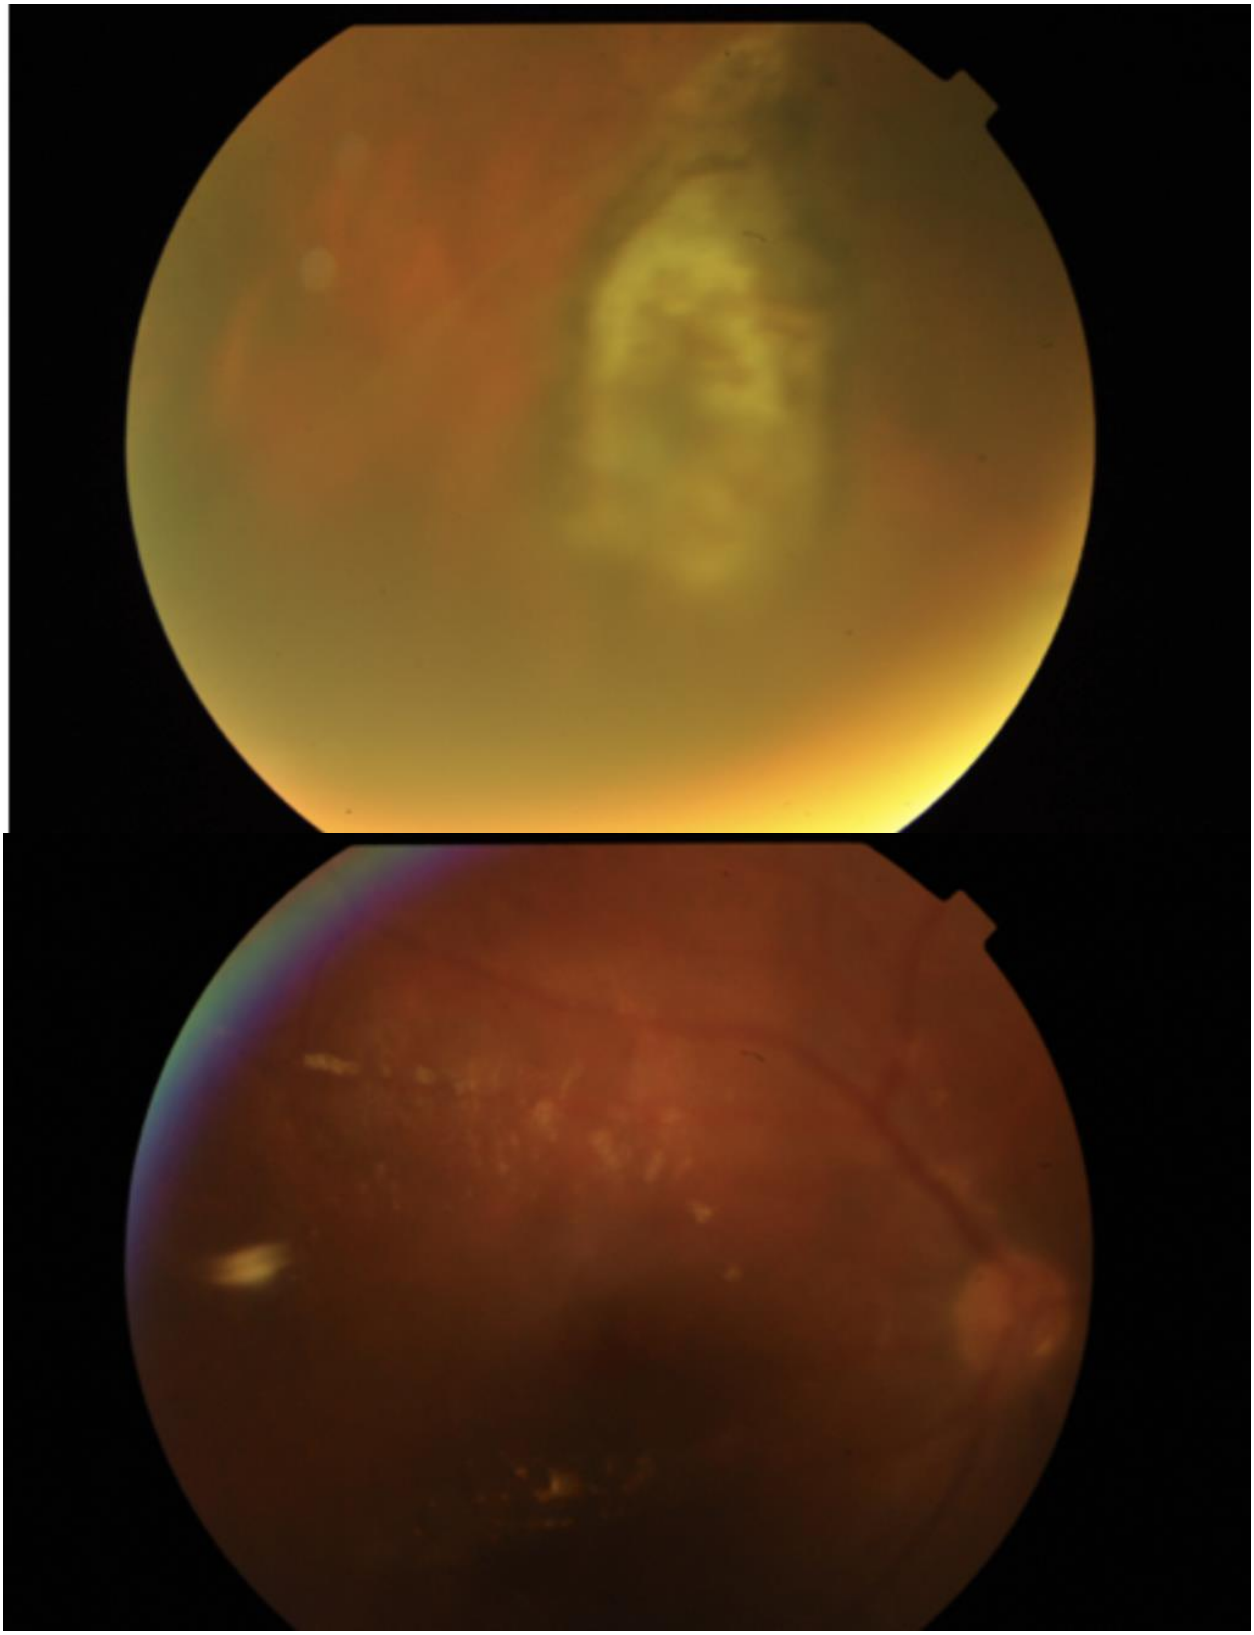
OCULAR TOXOCARIASIS IN A PATIENT WITH RECURRENT TOXOPLASMA RETINITIS: CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Sevgi Aslan Tuncay[1], Zeynep Ergenç[1], Gizem Gök[2], Seyhan Yılmaz[1], Burcu Parlak[1], Hande Çeliker Ataberk[3], Eda Kepenekli[2]
[1]Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Marmara University School of Medicine, Pediatric Infectious Diseases, Istanbul, Turkey, [3]Marmara University School of Medicine, Ophthalmology, İstanbul, Turkey

Title of Case: Ocular Toxocariasis in A Patient with Recurrent Toxoplasma Retinitis: Case Report
Background: Ocular toxocariasis is a parasitic disease caused by Toxocara canis and cati. The most common clinical forms are granuloma, endophthalmitis or uveitis-like appearance. Here we present a case with ocular toxocariasis which responsive to albendazole therapy.
Case Presentation Summary: A 17-year-old male patient admitted with pain and redness in his right eye for one week and he was diagnosed with acute posterior uveitis. It was learned that a granuloma was detected in the right retina after acute posterior uveitis when he was nine years-old. His vision was 5% in the right eye, but he did not continue to follow-up. The laboratory studies showed Anti-Toxoplasma IgM and IgG as positive, and Toxoplasma IgG avidity was high.The right bulbus oculi was smaller than the left in magnetic resonance imaging studies. Posterior uveitis due to toxoplasma was considered in the patient. Since sulfadiazine and pyrimethamine could not be obtained, trimethoprim/sulfamethoxazole and clindamycin combination was started. The serologic tests showed Toxocara canis IgG as positive, than albendazole treatment was started. Oral steroid was added to the treatment because uveitis findings progressed. Toxocara canis IgG from the vitreous fluid could not be performed, but Toxoplasma PCR was negative. No parasites were found in the histopathological examination of anterior capsule fluid and vitreous fluid. The patient's albendazole treatment was completed in 14 days. The patient is still on follow-up without any
complaint.



Learning Points/Discussion: Ocular toxocariasis is common in regions with poor hygiene conditions. Facilitating the access to serological diagnostic methods and appropriate tissue dyes will increase the probability of diagnosis.

[1]Zvitambo Institute for Maternal and Child Health Research, Na, Harare, Zimbabwe, [2]University of Liverpool, Paediatrics, Liverpool, United Kingdom, [3]London School of Hygiene and Tropical Medicine, March Centre, London, United Kingdom, [4]Zvitambo Institute for Maternal and Child Health Research, N/a., Harare, Zimbabwe, [5]University of Liverpool, Global Health, Liverpool, United Kingdom, [6]Queen Mary University of London, Blizard Institute, AT, United Kingdom

Backgrounds: Exposure to maternal CMV in utero may affect early child development (ECD), particularly in communities with a high HIV prevalence. We evaluated ECD among children born to mothers with compared to without CMV viraemia in the third trimester of pregnancy recruited to the SHINE trial in rural Zimbabwe.
Methods: We assessed ECD in a sub-study of children aged 24-months using the Malawi Developmental Assessment Tool (MDAT), assessing fine motor and cognition, gross motor, language and social development. Children were included in this sub-study if their mother had plasma tested for CMV by real-time quantitative PCR in the third trimester of pregnancy. Children living with HIV were excluded. We used generalised estimating equations to compare ECD scores, adjusted for maternal HIV, trial-related factors, and sociodemographics.
Results: 209 children were evaluated. 169 (81%) were born to mothers living with HIV. 49 (23%) of children had exposure to CMV viraemia at a median (IQR) 32 (31, 33) gestational weeks. Women with CMV viraemia in the third trimester were more likely to be living with HIV (88% vs. 79%; P=0.07). Mean total MDAT score was 91.0 (SD 9.4) in children with CMV exposure compared to 94.1 (8.8) in children without CMV exposure (adjusted mean difference -4.02, 95% CI -6.79, -1.25; P=0.004), driven mostly by differences in fine motor (-1.55, 95% CI -2.70, -0.40; P=0.009) and language scores (-1.69, 95% CI 2.86, -0.53; P=0.004). There was some evidence that social scores were lower (adjusted mean difference -0.60, 95%CI -1.29, 0.09; P=0.09) but no evidence for a difference in gross motor scores (-0.45, 95%CI -1.40, 0.50; P=0.35).
Conclusions/Learning Points: In the context of a high HIV prevalence community, exposure to CMV viraemia in utero may be one explanation for neurodevelopmental delay.

PV0300 / #1906

REPORT OF A NEONATAL TETANUS CASE IN SIERRA LEONE. THE IMPACT OF COVID-19 PANDEMIC ON MATERNAL AND NEONATAL TETANUS ELIMINATION.

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Raquel García Romero[1], Gerard Martínez Segura[2], Victoria Fumadó Pérez[3]
[1]Hospital Sant Joan de Déu, Paediatrics, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Déu, Paediatrics, Barcelona, Spain, [3]Hospital maternoinfantil Sant Joan de Déu, Paediatrics, Barcelona, Spain

Title of Case: Neonatal tetanus case in Sierra Leone.
Background: Neonatal tetanus remains a major cause of neonatal mortality in settings with high prevalence of non-vaccinated mothers, associating 80-100% of fatal outcomes without treatment. During major health emergencies, such as the 2014-2016 Ebola and the COVID-19 pandemics, some national immunization programs have been disrupted, causing an arise in preventable infectious diseases
Case Presentation Summary: A 16-day-old neonate born in a healthcare centre of a rural area in Sierra Leone was admitted at the hospital for stiffness. It was an uncontrolled, full term, first pregnancy; neither the mother nor the newborn had received immunizations. The newborn showed irritability, superficial breathing, inability to suck, trismus and opisthotonos, with proper eye movements and no seizures. Umbilical cord showed poor aspect. Patient was afebrile and anicteric. Brain ultrasound, complete blood count and urine analysis were normal. Due to clinical suspicion and absence of anti-tetanic serum, toxoid vaccination was administered both to the mother and to neonate. Patient also received empirical intravenous cefotaxime and metronidazole for 7 days, non-invasive respiratory support for 2 days and symptomatic treatment with paracetamol and diazepam for 3 weeks. Since the newborn was not able to breastfeed until the 7th day, feeding was initially through nasogastric tube. The patient experienced progressive improvement and was discharged after 25 days of admission. At 2-month follow-up visit, patient was completely recovered.
Learning Points/Discussion: Although there has been progress in maternal and neonatal tetanus elimination, in many sub-Saharan countries there is a low maternal and neonatal vaccination coverage and a high prevalence of unsafe deliveries. Once it has started, the most effective treatment for tetanus, anti-tetanic serum, is frequently unavailable in low-resource settings. In emergency contexts, it is critical to safeguard immunization programs.

PRIMARY BRAIN ECHINOCOCCAL CYST IN A 10-YEAR-OLD BOY: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Theano Lagousi[1], Chrysi Aikaterini Georgokosta[1], Kalliopi Stefanaki[2], Elias Antoniadis[3], Dimitrios Panagopoulos[3], Vana Spoulou[1], Athanasios Michos[1]
[1]National and Kapodistrian University of Athens, First Department Of Pediatrics, Division Of Infectious Diseases, Athens, Greece, [2]National and Kapodistrian University of Athens, Athens, Greece, Department Of Pathology, Athens, Greece, [3]National and Kapodistrian University of Athens, Athens, Greece, Department Of Neurosurgery, Athens, Greece

Title of Case: Primary brain echinococcal cyst in a 10-year-old boy: A case report
Background: Primary intracranial hydatid cyst is a rare entity, comprising about 1-2% of all hydatid cysts, mainly among children.
Case Presentation Summary: A case of a 10-year-old boy, livining in rural Greece, with primary intracranial hydatid cyst is presented. The patient was admitted complaining of nausea, vomiting and generalized fatigue. Neurological examination showed left hemianopsia and hemiparesis, while fundoscopy revealed bilateral papilledema. Blood tests were normal. Brain CT scan and MRI showed a well-defined unilocular cystic lesion in the right cerebellar hemisphere, with midline shift. A diagnosis of hydatid cyst was then presumed based on neuroradiological findings. Empiric chemotherapy with albendazole was initiated and surgical en bloc removal of the cyst was performed four days later, allowing the patient to recover without any complications. Histopathologic evaluation confirmed the diagnosis of hydatid cyst. Abdomen and chest CT scan excluded the presence of a primary hydatid cyst in more common sites. Antibodies against echinococcus were negative. The patient received an one-month course albendazole in total. Brain MRI performed 2 months later revealed no relapse. Antibodies against echinococcus remained negative 2 months later.
Learning Points/Discussion: Hydatid cyst is still an endemic manifestation in some rural areas worldwide, and it should be included in the differential diagnosis of children living in or coming from an endemic country who present with generally nonspecific clinical symptoms or symptoms of increased intracranial pressure. Complete blood count may be normal, while up to 50% of serological assays may be false negative. Early diagnosis mainly based on neuroradiological findings and clinical symptoms, and complete surgical removal of the intact cyst, combined with targeted antiparasitic chemotherapy are the main factors that determine a favourable outcome.

CHANGING TRENDS IN ANTIBIOGRAMS OF SALMONELLA ENTERICA IN PEDIATRIC POPULATION FROM A TERTIARY CARE CENTRE IN INDIA

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Bhaskar Shenoy, Devesh Joshi, Pooja Doddikoppad, Ranjeeta Adhikary, Bhavana M V
Manipal Hospital, Pediatrics, Bangalore, India

Backgrounds: Enteric fever is a major public health problem in tropical countries. Antimicrobial resistance is a major issue in enteric fever management. This study evaluated microbial susceptibility patterns of Salmonella enterica serovar Typhi (S. Typhi) and S. Paratyphi obtained from blood culture in a tertiary care hospital in south India.
Methods: Retrospective study of children with positive blood culture for S. enterica serovar Typhi and serovar Paratyphi A strains isolated between November 2008 to December 2021. Antimicrobial susceptibility was as per corresponding CLSI guidelines for each year, Antimicrobial susceptibility by Kirby-Bauer disc diffusion method. MIC of ciprofloxacin was obtained by E-test, and azithromycin MIC was confirmed by agar dilution method
Results: A total of 933 cases of culture positive enteric fever were studied. Out of this, 721 were S. enterica serovar Typhi (77.3%) and 212 serovar Para typhi A strains (22.7%). All strains were susceptible to third-generation cephalosporins. The sensitivity of the salmonella isolates to first-line antityphoid drugs were 95.8%, 97.4%, and 97.9% to ampicillin, cotrimoxazole and chloramphenicol respectively. 4.7 % of salmonella were sensitive to ciprofloxacin. For s. paratyphi chloramphenicol, co-trimoxazole was sensitive 100% and 98.9% respectively. Two cases of azithromycin resistance were documented.
Conclusions/Learning Points: Resistance to nalidixic acid has been increasing. Third generation cephalosporins continue to remain susceptible. Thus, local antibiograms improve patient care. MICs for third-generation cephalosporins and susceptibility patterns must be monitored in view of its emerging resistance . .Isolates showed a high degree of susceptibility to ampicillin, co-trimoxazole and chloramphenicol. These antibiotics may once again be useful for the management of enteric fever .In view of a high prevalence, it is advisable to implement vaccination at an early age and also develop a bivalent vaccine.

A BOY WITH FEVER, ABDOMINAL PAIN AND LOSS OF WEIGHT - A CASE OF AMOEBIC LIVER ABSCESS

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Shanti Shetty[1], Darolyn Tan[1], Natalie Woon Hui Tan[2], Koh Cheng Thoon[2], Chia Yin Chong[2], Chee Fu Yung[2], Jiahui Li[2], Karen Nadua[2], Kai Qian Kam[2]
[1]Kandang Kerbau Women's and Children's Hospital, Paediatrics, Singapore, Singapore, [2]KK Women's and Children's Hospital, Singapore, Paediatrics, Infectious Disease Service, Singapore, Singapore

Title of Case: A BOY WITH FEVER, ABDOMINAL PAIN AND LOSS OF WEIGHT
Background: Amoebic liver abscesses (ALA) are the most common extra-intestinal manifestation of amoebic infections. High index of suspicion should exist in any child with fever, gastrointestinal symptoms, weight loss and travel to endemic countries in the past 6 months.
Case Presentation Summary: A previously well 4 year old boy presented to a Singaporean tertiary paediatric hospital with fever for 10 days, abdominal pain, loss of appetite and weight. He had visited suburban Eastern India 5 months prior, during which he played near a muddy river. Initial blood investigations showed leucocytosis, elevated C-reactive protein (156.6mg/L) and erythrocyte sedimentation rate (70mm/hr). He was commenced on intravenous ceftriaxone and metronidazole. Ultrasound abdomen showed a solitary hepatic abscess in the right hepatic lobe, measuring 2.7 by 2.3 by 2.5 centimetres, which was initially not amenable to drainage. However, despite one week of antibiotics, the abscess continued to enlarge and he underwent percutaneous drainage, yielding thick, fluid appearing like ‘anchovy paste’. Investigations supported ALA, with polymerase chain reaction (PCR) from both fluid aspirate and stool positive for Entamoeba histolytica, serum amoebic antibody titre elevated at 1:2560. Stool culture and microscopy was negative. Following 2 weeks of metronidazole, he received 1 week of paromomycin with resolution of liver abscess.
Learning Points/Discussion: Duration from exposure to onset of symptoms has been described to range from 8 to 20 weeks. Therefore, travel history should be explored extensively up to 20 weeks prior. PCR remains the gold standard to confirm amoebic infection. In scenarios where there is no abscess fluid sample available for testing, a single highly positive serology (≥1:320) can also be used to diagnose ALA in individuals staying in non-endemic country with travel to endemic areas.

IMPORTED TOXIGENIC C. DIPHTHERIAE IN POLYMICROBIAL SKIN INFECTIONS OF REFUGEES

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Benedikt Spielberger[1], Anna Hansel[2], Alea Nazary[2], Eva-Maria Kleißle[2], Claus-Georg Lehr[2], Marcel Utz[3], Juliana Hofer[3], Siegbert Rieg[2], Winfried Kern[2]
[1]Medical Centre, Faculty of Medicine, University of Freiburg, Division Of Pediatric Infectious Diseases And Rheumatology, Department Of Pediatrics, Freiburg, Germany, [2]Medical Centre, Faculty of Medicine, University of Freiburg, Division Of Infectious Diseases, Department Of Medicine Ii, Freiburg, Germany, [3]Medical Centre, Faculty of Medicine, University of Freiburg, Institute For Medical Microbiology And Hygiene, Freiburg, Germany

Background: Diphtheria is a potentially lethal upper respiratory tract infection with systemic illness through toxinaemia, mostly caused by toxigenic Corynebacterium diphtheriae (C. diphtheriae). Transmission and outbreaks in Europe are t mostly related to travel. From July 2022 an increase of imported toxigenic C. diphtheriae has been reported throughout Europe adding up to over 100 cases.
Methods: Between August – December 2023 we identified 25 individuals with skin infections by toxigenic C. diphtheriae. Additionally 2 individuals with non-toxigenic C. diphtheriae throat colonization were identified through screening of 154 contacts.
Results: All individuals were male. The majority was of younger age (mean, 24 years, range, 18-49 years). The majority were born in Afghanistan (15 persons) or Syria (11); one refugee was born in Morocco. Eighteen subjects (67%) were asked about their escape route – all of them had fled via Balkan states. Visually, the skin wounds appeared as partly punched-out, partly erosive lesions with erythematous margins. Clinical differentiation between Ecthyma simplex or wounds with evidence of C. diphtheriae was not possible In addition to C. diphtheria isolation, S. aureus and S. pyogenes were detected in 21 (84%), S. pyogenes in 3 (12%), and in one individual solely C. diphtheriae was detected. All 25 skin infections were colonized with diphtheria toxin-producing C. diphtheriae. Toxigenic C. diphtheriae from throat swabs was detected in 5 of the 25 individuals with cutaneous lesions. No systemic illnesses trough toxinaemia were observed in our cohort.
Conclusions/Learning Points: Particular attention should be paid to chronic erosive/ulcerative wounds in refugees and refugee reception centers. Proper microbiological investigations should be done to rule out cutaneous diphtheria, even if S. aureus or S. pyogenes have already been identified. Vaccinations against DTP should be given generously.

PLASMODIUM FALCIPARUM GENETIC DIVERSITY IN PRE- AND POST-TREATMENT ISOLATES FROM CHILDREN WITH ACUTE UNCOMPLICATED MALARIA IN SOUTH WEST, CAMEROON

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Metoh Theresia Njuabe, Jun Hu Chen
The University of Bamenda, Faculty Of Science, Department Of Biochemistry, Bamenda, Cameroon

Backgrounds: The study of the genetic diversity within parasite population is essential for understanding the mechanism underlying malaria pathology and to determine parasite clones profile in an infection, for proper malaria control strategies. The objective of this study was to perform a molecular characterization of highly polymorphic genetic markers of P. falciparum, and to determine allelic distribution with their influencing factors valuable to investigate malaria transmission dynamics in Cameroon.
Methods: A total of 350 P. falciparum clinical isolates were characterized by genotyping block 2 of msp-1, block 3 of msp-2, and region II of glurp gene using nested PCR and DNA sequencing
Results: A total of 16 different MSP-1 were identified, including K1, MAD20 and RO33 allelic families . A peculiarity of this study is that RO33 revealed a monomorphic pattern among the Pfmsp-1 allelic type. A total of 27 different Pfmsp-2 genotypes,were recorded of which 15 belonged to the 3D7-type and 12 to the FC27 allelic families. The analysis of the MSP-1 and MSP-2 peptides reveals that the region of the alignment corresponding K1 polymorphism had the highest similarity in the MSP1and MSP2 clade followed by MAD20 with 93% to 100% homology. Therefore, population structure of P. falciparum isolates is identical to that of other areas in Africa, suggesting that vaccine developed with k1 and MAD20 of Pfmsp1 allelic variant could be protective for Africa children. The MOI was significantly higher ($P<0.05$) for Pfmsp-2 loci (3.82), as compare with Pfmsp-1 (2.51) and heterozygotes ranged from 0.55 for Pfmsp-1 to 0.96 for Pfmsp-2
Conclusions/Learning Points: High genetic diversity and allelic frequencies in Plasmodium falciparum isolates indicate a persisting high level of transmission. This study advocate for an intensification of the malaria control strategies in Cameroon.

Backgrounds: Fever is one of the most common symptoms leading to health care seeking. With the decline of malaria incidence and the introduction of routine rapid malaria diagnostic testing, non-malarial febrile illness (NMFI) calls for a better understanding of its epidemiology in order to improve its management. We aim to describe the historical changes of NMFI in Manhiça.
Methods: We performed a retrospective descriptive study of the paediatric visits in Manhiça District Hospital (MDH) and seven outpatient clinics during a 17 year-long period (2004 to 2020). Fever was defined as temperature ≥37.5ºC or reported fever in the previous 24 hours. Demographic, clinical and outcome data were routinely collected. Blood films were performed if a patient presented with fever, and blood cultures if severe criteria were fulfilled.
Results: During the study period, 1,164,688 children were seen as outpatients, 858,241/1,164,688 (73.69%) with fever. In MDH 41,485 children were admitted, and 38,353/41,485 (92.4%) had fever. Among admitted febrile patients, 17,199 (51.6%) were malarial febrile patients (MFP) and 15,551 (46.6%) were non-malarial febrile patients (NMFP). There was a higher frequency of HIV in NMFP (12.39%) versus MFP (2.88%), and a high frequency of moderate anaemia (14.54%) among NMFP. The antibiotic use was higher in NMFP than in MFP (94.7% vs 32.1%), and hospitalization longer than 5 days and mortality were also higher among NMFP compared with MFP (46.2% vs 18.6%, and 4.4% vs 1.7%, respectively). The distribution of diagnosis among NMFP was very imbalanced, with zoonosis, viral infections and urinary tract infections being unfrequently diagnosed, with less than 200 cases each (<0.5%).
Conclusions/Learning Points: NMFI remains a clinical challenge, with underdiagnosed diseases, over use of antimicrobials and poor outcome. Efforts are needed to improve its diagnosis, management and prognosis.

HAEMOPHAGOCYTIC SYNDROME ASSOCIATED WITH TYPHOID FEVER

E-Posters Viewing
E-POSTER VIEWING: AS05.B. TROPICAL/PARASITE INFECTIONS & TRAVEL MEDICINE

Isabel Viñuela Díaz-Moro, Lluis Galmés Rosselló, Lidia Ciudad Aguilar, Jaime Carrasco-Colom, Joaquín Dueñas Morales
Hospital Universitario Son Espases, Paediatric Infectious Diseases, Palma de Mallorca, Spain

Title of Case: HAEMOPHAGOCYTIC SYNDROME ASSOCIATED WITH TYPHOID FEVER
Background: Haemophagocytic lymphohistiocytosis (HLH) is based on an inappropriate immune system response. It has been associated with multiple triggers, including numerous infectious causes. Salmonella enterica is a rare cause, especially in our environment.
Case Presentation Summary: A 13-year-old patient from Pakistan presented with vomiting and diarrhoea one month after moving to Spain. On the 5th day of evolution, he developed fever, headache and dizziness. On arrival to the emergency room, blood work revealed microcytic and hypochromic anaemia with elevated acute phase reactants (APR). Given fever of unknown origin in an immigrant, Mantoux, serology and chest X-ray were performed, with no notable findings. He remained febrile despite intravenous cefotaxime, and pancytopenia, increased APR and hypertriglyceridaemia were observed. In addition, Salmonella enterica serotype Typhi was isolated in blood and stool cultures. HLH secondary to typhoid fever (TF) was suspected and the patient was referred to our centre. During the first few days the patient remained febrile and weak, thus intravenous dexamethasone was added with a good clinical response. The patient met 6/8 diagnostic criteria for HLH, and a genetic study was requested which ruled out primary HLH. He was discharged after 14 days of intravenous antibiotic therapy, with a corticosteroid tapering regimen.
Learning Points/Discussion: The association between HLH and TF, although rare, has been previously described. The difficulty lies in the similarity between advanced phase TF and HLH, both of which may present with persistent fever, hepatosplenomegaly, neurological symptoms or cytopenia. Differential diagnosis is important, especially in severe cases of HLH, which may require immunomodulatory drugs to reverse excessive activation of lymphocytes and macrophages.

EXPLORING THE INITIAL HEALTH ASSESSMENT PROCESS FOR ASYLUM-SEEKING/REFUGEE CHILDREN ACROSS EUROPE - A QUALITATIVE STUDY

E-Posters Viewing
E-POSTER VIEWING: AS05.C. REFUGEES AND MIGRANTS

Marta Alustiza[1], Shunmay Yeung[1], Nicky Longley[1], Sarah Eisen[2]
[1]London School of Hygiene and Tropical Medicine, Faculty Of Tropical And Infectious Disease, London, United Kingdom, [2]University College London Hospital, Paediatric Infectious Diseases, London, United Kingdom

Backgrounds: In 2022, the number of migrants worldwide reached a record high, with 14.6% being children. Despite the availability of expert guidelines for the health assessment (HA) of migrant children in Europe, such as the consensus-based recommendations of the European Academy of Paediatrics, there remains, anecdotally, considerable variation in practice. This study aims to explore the current provision of services by European centres providing HA to migrant children and examine barriers and facilitators that affect the delivery of these services.
Methods: A purposive sampling method was utilized to identify potential participants from national and international expert networks. Clinicians working in services delivering HA to migrant minors across Europe were approached by email and invited to participate. Qualitative research was conducted using questionnaires and semi-structured interviews between July and August 2022. A content thematic analysis was held using the NVivo 12 software.
Results: Seventeen clinicians from eight European countries participated. The key themes approached were: service structure, features of the HA, and available resources. We identified a lack of standardization in the content and process of the HA, with significant variation in screening processes and approaches for both communicable and non-communicable diseases and mental health issues. There were common experiences regarding challenges to service delivery; in particular access to immunization, Psychiatry and Psychology services. Other common challenges were a lack of documentation, limited access to adequate funding and staff, and high patient mobility.
Conclusions/Learning Points: We need to optimise the standardisation of HA for this vulnerable population to support both best clinical practice and the development of the evidence base which underpins guidance to support this.

"EVERYBODY'S SINGING FROM THE SAME SONGBOOK": STRATEGIES TO IMPROVE ACCESS TO CATCH-UP IMMUNISATIONS FOR HUMANITARIAN ARRIVALS ON THE GOLD COAST.

E-Posters Viewing
E-POSTER VIEWING: AS05.C. REFUGEES AND MIGRANTS

Shamila Ginige[1], Kate Alexander[1], Holly Seale[2]
[1]Gold Coast Public Health Unit, Public Health, Carrara, Australia, [2]UNSW Medicine and Health, School Of Population Health, Sydney, Australia

Backgrounds: No one arriving as a refugee or asylum seeker to Australia will be up-to-date with vaccinations aligning with the Australian National Immunisation Program (NIP) Schedule. One-third of permanent humanitarian visa holders settled in Queensland live outside of the main local government areas. With international borders open again, it is important to understand the barriers faced by this vulnerable population in accessing their funded catch-up immunisations. The aim of this qualitative study was to understand the local issues faced by those community members who settle on the Gold Coast, as well as those faced by the refugee health service providers.
Methods: Semi-structured interviews with ten Gold Coast community members with a humanitarian arrival background, and ten Gold Coast refugee health service providers were organised to address vaccine acceptance, access, and uptake. Key themes were identified and coded using inductive thematic analysis.
Results: The key themes identified were a general sense of vaccine acceptance by community members, but ineffective use of interpreters and a deficiency in cultural competence by primary care. Vaccine providers were seeking more time, training and resources and there was a distinct gap in, and lack of financial incentive for, adult immunisations. Solutions were put forward with a focus on a consistent message with a centralised system, or a middle conduit between case managers and primary care (e.g., refugee health nurses).
Conclusions/Learning Points: Ensuring childhood immunisation rates reach their targets is vitally important in preventing outbreaks of vaccine-preventable diseases but there also needs to be geographically targeted strategies towards susceptible minority groups, including refugees and humanitarian arrivals. Ideally, these strategies would be consistent nation-wide and utilise a whole-of-practice approach with input from community members, practice nurses, medical practitioners, and multicultural organisation staff.

"SAY YES TO VACCINATIONS" – PRELIMINARY RESULTS OF UNICEF EDUCATIONAL PROJECT ON INCREASING AWARENESS OF UKRAINIAN MOTHERS RESIDING IN POLAND

E-Posters Viewing
E-POSTER VIEWING: AS05.C. REFUGEES AND MIGRANTS

Dorota Kleszczewska[1], Anna Dzielska[2], Katarzyna Lewtak[3,4], Joanna Bogusz[5]
[1]Institute of Mother and Child Foundation, Institute Of Mother And Child Foundation, Warsaw, Poland, [2]Institute of Mother and Child, Department Of Child And Adolescent Health, Warsaw, Poland, [3]Medical University of Warsaw, Department Of Social Medicine And Public Health, Warsaw, Poland, [4]National Institute of Public Health NIH - NRI, Department Of Health Promotion And Prevention Of Chronic Diseases, Warsaw, Poland, [5]National Institute of Public Health NIH - NRI, Department Of Epidemiology, Warsaw, Poland

Background: According to the UNICEF data there are over 1.5 million registered refugees from Ukraine in Poland, 90% of them are women and children. The WHO data shows that in 2021 80% of children in Ukraine were fully vaccinated against polio and 87% - against measles. The main objective of the project is to increase the vaccination rate among Ukrainian children (6-60 months) residing in Poland. The first part was the online pilot study aimed at understanding barriers of Ukrainian mothers to vaccinating their children against polio and measles.
Methods: 187 refugees from Ukraine took part in the pilot survey (96.3% were women, at average age of 39.5 years, with one (51.1%) or two (34.4%) or more children (13.5%), 94.1% arrived in Poland after 24.02.2022). Participants indicated main barriers to the vaccination of children. Planned educational activities targeted at Ukrainian mothers will address obtained data. The project has funding from UNICEF (SBC office).
Results: Preliminary results show that the main source of vaccination information for Ukrainian mothers are doctors (16.1%) and media (13.9%). As the most important barriers, 64.3% to 75.3% mothers considered those related to approachability: long waiting time for appointments, lack of knowledge about where, when and against what to vaccinate a child. Followed by a language barrier (53.7%), awaiting return to Ukraine (53.6%), a lack of knowledge about the effects of vaccines (50.7%), on side effects (48.4%), high costs (47.7%), lack of health insurance (43.1%) and a concern about vaccines quality (41.9%). Almost one third indicated religious beliefs (27.1%).
Conclusions/Learning Points: The need for further research has been confirmed. Media, health care workers, NGOs and Orthodox church should be involved in educational campaign to encourage Ukrainian mothers to get their children vaccinated.

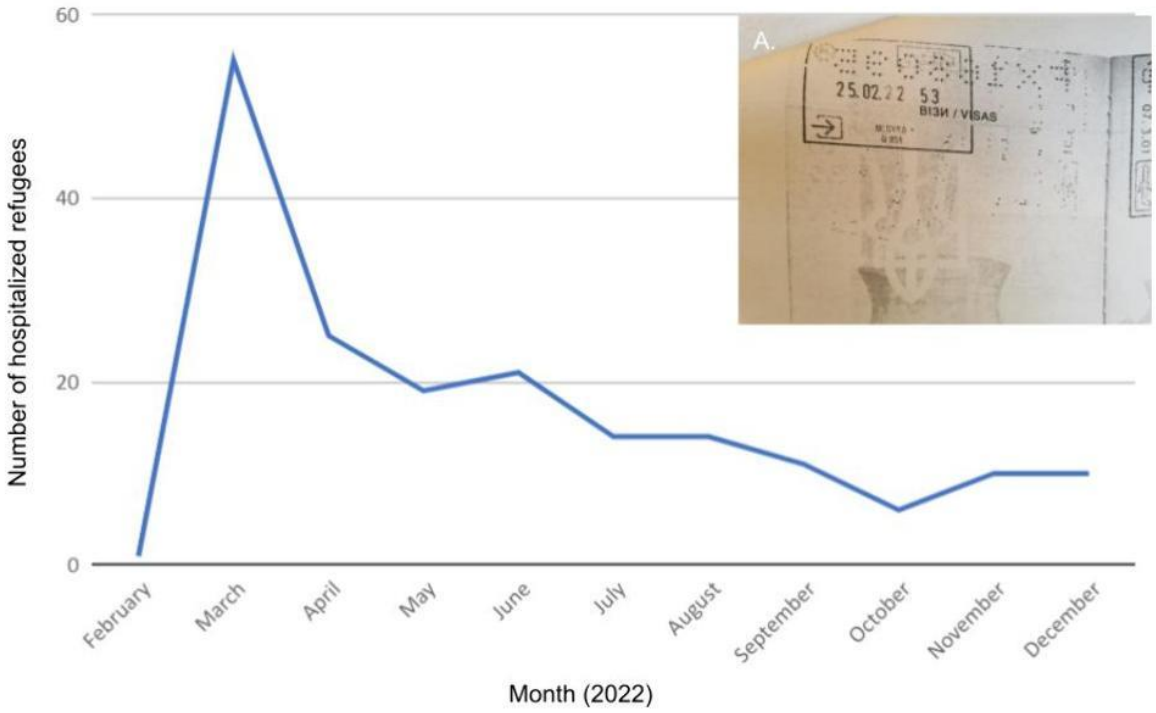
HUMAN FACE OF MEDICINE DURING THE HUMANITARIAN CRISIS

E-Posters Viewing
E-POSTER VIEWING: AS05.C. REFUGEES AND MIGRANTS

Kamila Ludwikowska[1], Leszek Szenborn[2]
[1]Wroclaw Medical University, Department Of Pediatric Infectious Diseases, Wroclaw, Poland, [2]Wroclaw Medical University, Department Of Pediatric Infectious Diseases, Wrocław, Poland

Backgrounds: With the Russian invasion of Ukraine, on February 24th 2022, the greatest humanitarian crisis in Europe since World War II began. Over 9 million people crossed the border from Ukraine to Poland. Around 3 million people were seeking asylum, and ~1.5 million stayed in Poland. Wroclaw, having already had numerous Ukrainian citizens, was one of the most picked destinations. It is estimated that 20-30% of the Wroclaw population is Ukrainian now. The aim of this study is to present the experience of our clinic connected with a huge migration wave from Ukraine to Wroclaw, Poland. Considering unsatisfying vaccine coverage in Ukraine, in our pediatric infectious disease clinic, we were preparing for the new infectious diseases' outbreaks, including these vaccine-preventable diseases. However, as there were no big refugee camps, no cases of measles or pertussis occurred. We took refugees to our homes, provided them with healthcare and vaccinations, and avoided new great epidemics that were the next real threat for all.
Methods: This is an epidemiological study.
Results: From 191 hospitalizations of Ukrainian refugees in our clinic in 2022 (Figure 1), the most common cause in the first weeks was COVID-19 with severe dehydration. In March (55 admissions), patients often came to our clinic directly from the train, after a few days of travel. Second often cause was HIV infection requiring continuation of ARV treatment or the prophylaxis for newborns.



Number of Ukrainian refugees hospitalized in the Department of Pediatric Infectious Diseases, Wroclaw Medical University, Wroclaw Poland in 2022.

A. A stamp in the passport of a Ukrainian refugee with the date of Polish border crossing.

Conclusions/Learning Points: We faced many challenges. Aside from health care provided, we had to engage in more forms of humanitarian aid, such as gathering basic needs products for refugees. Our experience is that dispersion and catch-up vaccination are necessary to avoid diseases outbreaks, while the human face of medicine helps people survive the trauma.

INFECTIOUS DISEASES IN INTERNATIONALLY ADOPTED CHILDREN IN CROATIA (2012-2022)

E-Posters Viewing
E-POSTER VIEWING: AS05.C. REFUGEES AND MIGRANTS

Vedran Stevanovic, Srđan Roglić, Goran Tešović
University Hospital for Infectious Diseases "Dr Fran Mihaljević", Pediatric Infectious Diseases Department, Zagreb, Croatia

Backgrounds: Internationally adopted children (IAC) are at higher risk for infectious diseases. In the last five years, a higher number of IAC has been arriving to Croatia, exclusively from Democratic Republic of Congo. The aim of this study was to evaluate the prevalence of ID in IAC arriving to Croatia as well as compliance of attending phyisicians with the 2018 ECDC public health guidance on screening and vaccination for infectious diseases in newly arrived migrants within EU/EEA, including IAC.
Methods: We retrospectively examined hospital records including demographic data, clinical presentations, diagnostic tools, management and outcomes of all IAC who were admitted to University Hospital for Infectious Diseases “Dr Fran Mihaljević” from 2012 to 2022.
Results: We identified 49 IAC who arrived to Croatia from Democratic Republic of Congo from 2012 to 2022. Out of 49 examined IAC, 9/49 presented with fever due to uncomplicated malaria and 5/49 due to other diagnoses. There were no poor outcomes in children treated for malaria. Out of 35 IAC without fever, 21/35 had negative screening for infectious diseases. Out of other 14/35 the most prevelant ID were malaria and giardiasis whilst in 8/35 other diagnoses were made. Compliance with 2018 ECDC guidance was not recorded in 13/49 IAC, mostly missing chest X-ray and/or TST/IGRA.
Conclusions/Learning Points: Infectious diseases are common in Croatian IAC, diagnosed in 57% of examined Croatian children. The most prevalent infectious diseases in Croatian IAC are malaria and giardiasis. Compliance of attending physicians with the 2018 ECDC guidance is satisfactory, however, more focus should be placed on excluding active or latent tuberculosis infection.

EPIDEMIOLOGIC CHALLENGES AFTER INFLUX OF UKRAINIAN REFUGEE CHILDREN TO POLAND IN 2022.

E-Posters Viewing
E-POSTER VIEWING: AS05.C. REFUGEES AND MIGRANTS

Lidia Stopyra[1], Karolina Banach[1], Katarzyna Turek-Fornelska[1], Mariusz Skórski[2], Justyna Szebla[1], Magdalena Wood[1]
[1]Zeromski Specialist Hospital, Infectious Diseases And Pediatrics, Kraków, Poland, [2]Zeromski Specialist Hospital, Specialistic Outpatient Clinics, Kraków, Poland

Backgrounds: Russia's invasion of Ukraine has caused a high influx of refugees to Poland. Since Feb 24, 2022, the number of Ukrainian refugees living in Krakow was 178000, resulting in the population of the city increasing to 957000. Most refugees are women and children. According to WHO data, in 2020 the rate of realization of the vaccination schedule in Ukraine was about 80%, and in some regions only 30-40%. In Poland, in the last few years, the rate of vaccination among children has decreased. This resulted in the risk of outbreaks of diseases which were previously controlled by vaccination.
Methods: A campaign of free diagnostic screening tests for Ukrainian refugees aged 0-18 years was conducted at Zeromski Specialist Hospital in Krakow. 826 children, comprising 420 boys and 406 girls, were examined. The medium age was 9 years 11 months.
Results: In total, there were 271 (32,8%) children with no anti-Hbs antibodies detected in their blood serum, although HBV vaccination is obligatory in Ukraine. Although vaccination certificates were not available, according to data provided by caregivers 719 (87%) children were vaccinated according to the Ukrainian vaccination schedule. Among the 719 children reported as fully vaccinated, 228 (31,7%) had no anti-Hbs antibodies although the standard hepatitis B vaccination provides protection in over 96%. Only one of all tested children had a positive Hbs antigen. HCV infection was also confirmed in one patient. None of the children were diagnosed with HIV infection.
Conclusions/Learning Points: In the new epidemiological situation, testing refugee children for HBV infection should be considered. Organizing vaccinations among refugees is a priority. It should also be necessary to organize the treatment of chronic hepatitis B in children.

LOW ENGLISH/FRENCH LANGUAGE SKILLS IS ASSOCIATED WITH FEAR OF COVID-19 AMONG SYRIAN REFUGEE PARENTS IN CANADA

E-Posters Viewing
E-POSTER VIEWING: AS05.C. REFUGEES AND MIGRANTS

Hala Tamim[1], Aseel Alzaghoul[2], Rama Eloulabi[3], Paniz Fotoohi[1]
[1]York University, Kinesiology And Health Science, Toronto, Canada, [2]McGill University, Psychiatry, Montreal, Canada, [3]Western University, Psychology, London, Canada

Background: The aim was to assess the association between English/French language skills and fear of COVID-19 among Syrian refugee parents in Ontario, Canada.
Methods: A total of 540 Syrian refugee parents who resettled in Canada were interviewed between March 2021, and March 2022. Fear of Covid-19 was measured using the Fear of COVID-19 scale (FCV-19S). Self-ratings of participants' official Canadian language (English or French) skills and the need for and availability of a language interpreter were collected. Multiple Linear regression analysis was performed to assess the relationships between language ability and need and availability of an interpreter and fear of COVID-19 after adjusting for several socio-demographic, immigration and health related factors.
Results: The mean (SD) score for the FCV-19S was 15.6 (6.02) and 15.4% of the participants were categorized as having high levels of FCV-19S. Results of the multiple linear regression analysis showed that low self-rated English/French language skills was significantly associated with increased FCV-19S scores (Adjβ=0.65, p= 0.047). When compared to participants who do not need an interpreter, those who needed an interpreter and were always provided with one were at reduced FCV-19S scores (Adjβ=-1.56, p= 0.061). In addition, findings indicated that low self-perceived socioeconomic status, longer years spent in Canada, living in a refugee camp and poor self-rated mental health contributed significantly to elevated levels of FCV-19S.
Conclusions/Learning Points: Targeted intervention and prevention strategies such as providing information in different languages for reducing the fear of COVID-19 should be considered for the Syrian refugee population in Canada.

HAVING A FAMILY DOCTOR IS ASSOCIATED WITH REDUCED COVID-19 VACCINE HESITANCY AMONG SYRIAN REFUGEE PARENTS IN CANADA

E-Posters Viewing
E-POSTER VIEWING: AS05.C. REFUGEES AND MIGRANTS

Hala Tamim[1], Yasma Ali-Hassan[2], Rama Eloulabi[3], Aseel Alzaghoul[4]
[1]York University, Kinesiology And Health Science, MJ P, Canada, [2]University of Toronto, Physiotherapy, Toronto, Canada, [3]Western University, Psychology, London, Canada, [4]McGill University, Psychiatry, Montreal, Canada

Background: At the time of data collection for this survey, COVID-19 vaccines for children were not yet authorized. The aim of the study was to assess the hesitancy in Covid-19 vaccine among Syrian refugee mothers and fathers who resettled in Canada.
Methods: A total of 540 Syrian refugee parents (329 mothers and 211 fathers), who resettled in Ontario, Canada, were recruited between March 2021, and March 2022. Vaccine hesitancy was measured by the question “Are you going to take the vaccine for the Coronavirus-19 when it becomes available to you?”. Those who answered “No” or “don’t know” were classified as being hesitant, whereas those who answered “yes” or “Already took the vaccine” were classified as being non-hesitant. Multivariable logistic regression analysis was conducted to assess the association between having a family doctor and Covid-19 vaccine hesitancy after adjusting for several socio-demographic, immigration, and health related factors.
Results: 67% of the participants had more than 3 children and 15% were hesitant about taking the Covid-19 vaccine (17% and 13% among mothers and fathers respectively). Participants who reported not having a family doctor were 3.3 times at increased odds of being hesitant to have the Covid-19 vaccine compared to those without a family doctor (Odds Ratio=3.3, 95% Confidence Interval: 1.4-8.1). Lower education, arriving in Canada before 2016, poor mental health and having lived in a refugee camp were associated with increased Covid-19 vaccine hesitancy, whereas higher number of children and having a job were associated with reduced vaccine hesitancy.
Conclusions/Learning Points: Having a family doctor plays a major role in dispelling misinformation of COVID-19 vaccines and in promoting trust for vaccine acceptance among the refugee population in Canada.

INFECTION SCREENING OUTCOMES FOR UNACCOMPANIED ASYLUM-SEEKING CHILDREN (UASC) IN A UK TERTIARY PAEDIATRIC CENTRE

E-Posters Viewing
E-POSTER VIEWING: AS05.C. REFUGEES AND MIGRANTS

Waison Wong, Ahmed Ali, Cathryn Benson
Alder Hey Children's NHS Foundation Trust, Paediatric Infectious Diseases And Immunology, Liverpool, United Kingdom

Backgrounds: There is an increasing number of unaccompanied asylum-seeking children (UASC) entering the UK. This vulnerable group has complex health needs including management of infections. The Royal College of Paediatrics and Child Health recommend screening UASC at risk of communicable infections. Common practice is to not screen individuals for tuberculosis (TB) if entering from a country of low prevalence (<40/100,000).
Methods: We retrospectively reviewed all UASC referred to our tertiary paediatric infectious diseases clinic between January 1st 2021 to December 31st 2022. Data was extracted from electronic medical records.
Results: A total of 65 USAC were referred to the clinic; 97% were male with a median age of 17.8 years (range 16-19 years). Median time from UK entry to infection screening was 11.5 months. One UASC was lost to follow up before screening. The commonest countries of origin include Sudan (18%), Iraq (15%), Iran (15%) and Afghanistan (11%). Twenty-five (39%) were diagnosed with latent TB, six of whom originated from, and travelled through countries with reportedly low TB prevalence. Four (6%) were diagnosed with hepatitis B infection, 4 (6%) with syphilis and no UASC were infected with hepatitis C or human-immunodeficiency-virus. One UASC from Sudan had targeted testing for symptomatic urinary Schistosomiasis, which was positive. Our clinic did not routinely test for parasites or sexually-transmitted infections other than syphilis.
Conclusions/Learning Points: Our clinic identify higher rates of tuberculosis compared with other UK tertiary paediatric centres such as London (39% vs 21%). Furthermore, we identified 6 individuals infected with TB who were classified as low risk. This highlights the high risk of contracting TB during the migration journey and the importance of screening all UASC for TB regardless of country of origin to ensure appropriate treatment is delivered.

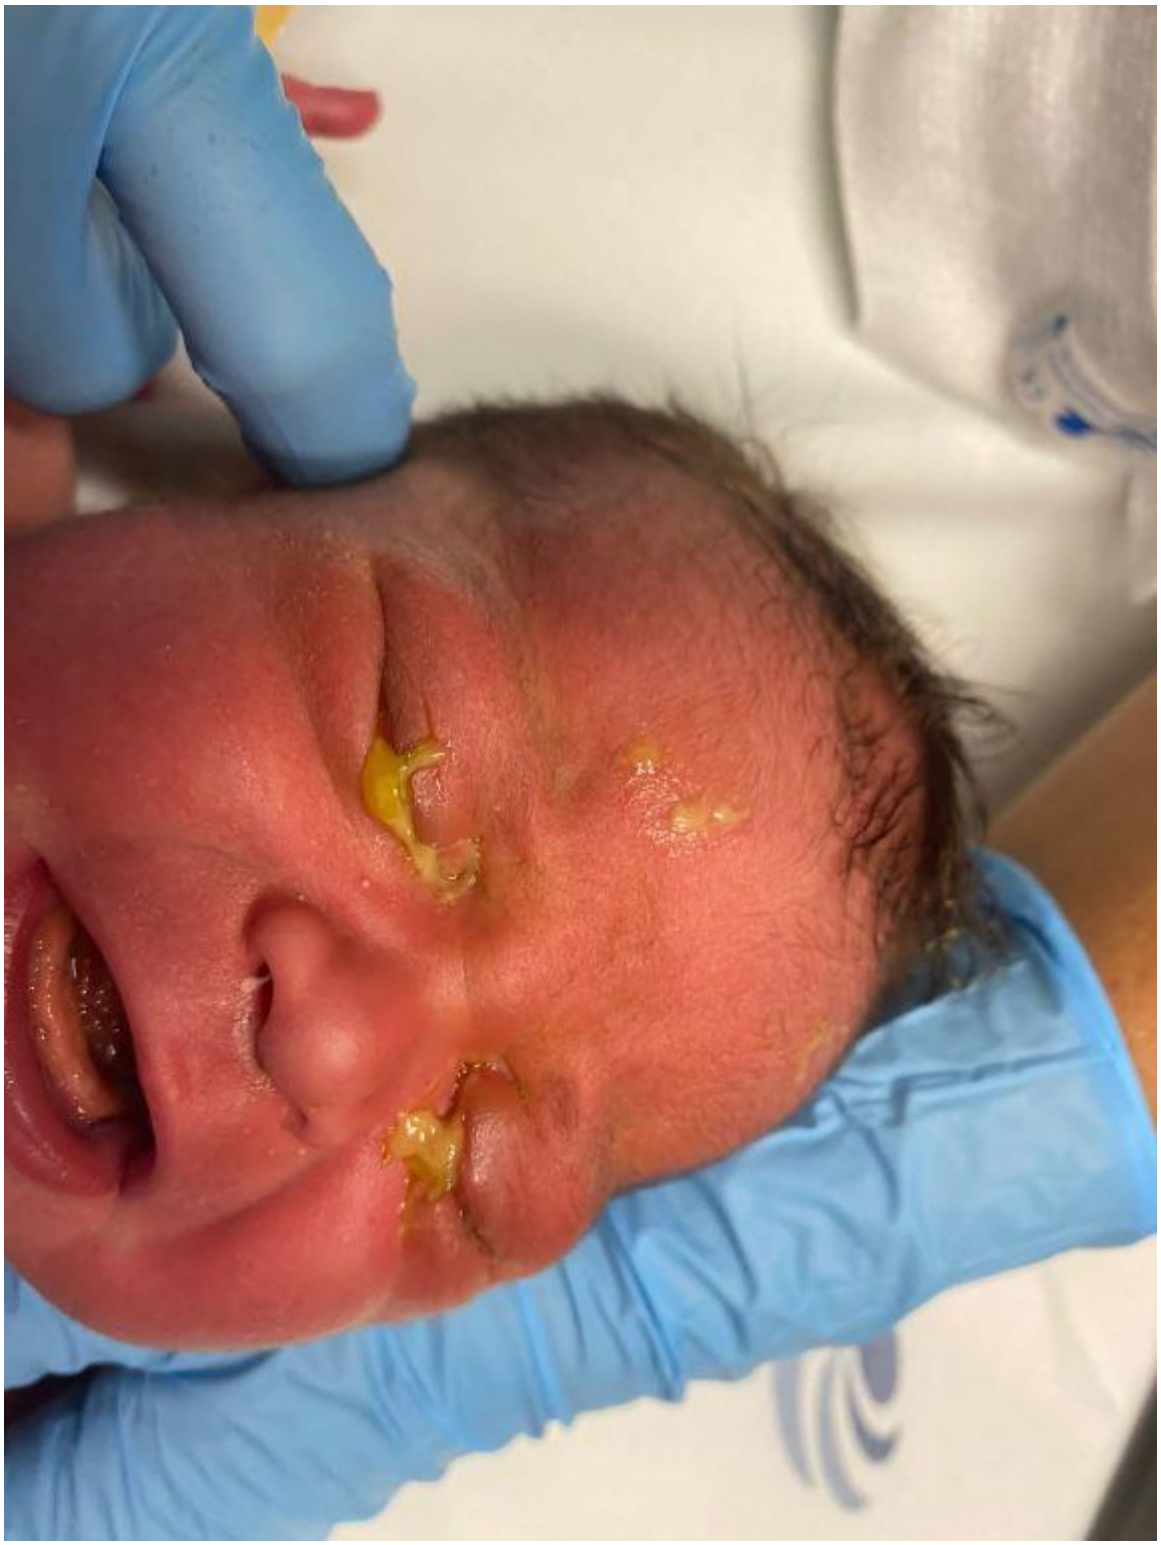
PV0317 / #357

OPHTHALMIA NEONATORUM DUE TO N. GONORRHOEAE AND E. COLI – A NEW CHALLENGE IN A DEVELOPED COUNTRY

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Luciana Abelha[1], Ana Isabel Sequeira[1], Inês Eiras[1], Licínia Lima[1], Joana Teixeira[2], Carla João Dias[1], Isabel Soro[1], Arnaldo Rego[1]
[1]Unidade Local de Saúde do Alto Minho, Paediatrics, Viana do Castelo, Portugal, [2]Hospital de Braga, Paediatrics, Braga, Portugal

Backgrounds: Ophthalmia neonatorum is a conjunctivitis that occurs in the first 28 days of life, affecting 1-12% of neonates. Neisseria gonorrhoeae and Chlamydia trachomatis were the main causes; with the implementation of ocular antibiotic prophylaxis at birth, the incidence decreased, and bacteria such as Escherichia coli became common.
Methods: Newborn, with bilateral ocular mucopurulent exudate on second day of life, associated with conjunctival hyperemia and periorbital edema. Maternal history with no pathological antecedents; maternal serologies: negative; group B streptococcus negative at 36W+5d; prenatal ultrasounds: normal. Vacum delivery at 40weeks + 2days; artificial rupture of membranes lasting 5 hours; Apgar score: 10/10/10; no record of administration of ocular prophylaxis; Biometrics: weight 3985g, height: 49.1 cm, head circumference: 34.20
cm.



Results: Laboratory findings (day 2): C-reactive protein 1.26 mg/dl; total bilirubin: 16.5 mg/dl; remaining analytical study unchanged. On suspicion of N. gonorrhoeae, the treatment was started: a single IM dose of cefotaxime; eyes wash with saline solution, and topical Azithromycin + Oxytetracycline. Ocular swab was positive for N. gonorrhoeae and E. coli; On day 3 evaluation by Ophthalmology, showed no corneal lesions. For E.Coli proven early sepsis (CRP max 4.89 mg/dL), Ampicillin and Gentamicin were given for 7 days; The blood culture result became positive 5 days later, and cultural examination of the catheter tip

was positive for E.coli The newborn showed clinical and laboratory improvement; and after being discharged from the hospital, missed all the appointments.
Conclusions/Learning Points: Gonococcal infection is a rare cause of neonatal ophthalmia in developed countries due to the use of routine prophylaxis. Although there is no screening for Chlamydia or N. gonorrhea infection during pregnancy, prompt treatment of these and neonatal ocular antibiotic prophylaxis are important measures to avoid neonatal conjunctivitis.

PV0318 / #1016

CYTOMEGALOVIRUS ULCERATIVE ESOPHAGITIS ASSOCIATED WITH EOSINOPHILIC ESOPHAGITIS IN AN IMMUNOCOMPETENT INFANT

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Tanya Abraham[1], Stephanie Fabry[1], Denise Young[1], Shahrazad Saab[2], Peter Paul Lim[3]
[1]Rainbow Babies and Children's Hospital/University Hospitals-Cleveland Medical Center, Pediatrics, Cleveland, United States of America, [2]Rainbow Babies and Children's Hospital/University Hospitals-Cleveland Medical Center, Pathology, Cleveland, United States of America, [3]Avera McKennan University Hospital/University of South Dakota School of Medicine, Pediatric Infectious Diseases, Sioux Falls, United States of America

Title of Case: CYTOMEGALOVIRUS ULCERATIVE ESOPHAGITIS ASSOCIATED WITH EOSINOPHILIC ESOPHAGITIS IN AN IMMUNOCOMPETENT INFANT
Background: The mechanism for eosinophilic esophagitis (EoE) after acute infectious esophagitis is not known; however, the association between EoE and herpes simplex virus esophagitis has been reported. To our knowledge, EoE associated with CMV in an immunocompetent neonate has never been reported in relevant literature.
Case Presentation Summary: A 25 day-old female born term with poor weight gain and frequent postprandial spit-ups presented to the emergency department with a choking episode associated with cyanotic apnea. Physical exam, laboratory evaluation, and abdominal ultrasound showed no significant abnormalities. Her weight was 2.4% below birth weight. Upper gastrointestinal series demonstrated a dilated esophagus with decreased peristalsis concerning for early achalasia. Upper endoscopy showed esophageal erosions and mild bleeding in the distal esophagus (Fig 1a). The biopsy showed CMV esophagitis, confirmed by immunohistochemical staining. Head ultrasound and ophthalmic exam were negative for typical findings of CMV. Immunodeficiency work-up was negative. She was started on Valganciclovir and a proton pump inhibitor with clinical improvement. Two months later, the patient had worsening emesis after stopping Valganciclovir. Repeat upper endoscopy demonstrated furrows, edema, and friability with aphthous ulcers (Fig 1b). Her biopsy showed 75/42 eosinophils/hpf in the distal esophagus with negative CMV stain. The patient’s formula was switched to an amino acid formula with improvement of
symptoms.

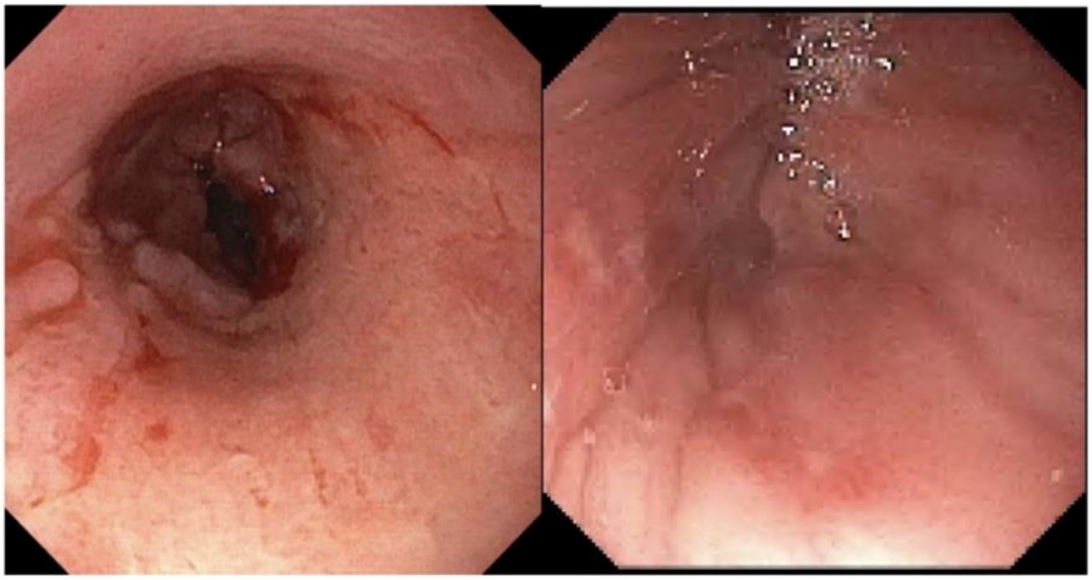


Fig. 1A: Esophagitis in distal esophagus

Fig 1B: Edema and linear furrows in distal esophagus

Learning Points/Discussion: Cytomegalovirus esophagitis is an unusual presentation of CMV infection among immunocompetent neonates that can potentially lead to development of eosinophilic esophagitis. Since upper endoscopy and biopsy are warranted to establish this diagnosis, a heightened index of suspicion especially among neonates who are failing to thrive and who do not respond to routine management of emesis is imperative for timely intervention to be initiated.

PV0319 / #1028

DOSING REGIME, SAFETY PROFILE AND DRUG LEVELS FOR INTRAVENOUS GANCICLOVIR AND ORAL VALGANCICLOVIR IN PRE-TERM INFANTS TREATED FOR CMV DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Asrar Abu Bakar[1], Hermione Lyall[2], Helen Payne[2], Neil Tickner[2]
[1]International Islamic University of Malaysia, Paediatrics, Kuantan, Malaysia, [2]Imperial College Healthcare NHS Trust, Imperial College Healthcare Nhs Trust, London, United Kingdom

Backgrounds: To date, there is no data on the appropriate dosing regime and safety profile of Ganciclovir (GCV) or Valganciclovir (VALGCV) in the treatment of pre-term infants with cytomegalovirus (CMV) disease.
Methods: Pre-term infants with corrected gestational age <32 weeks and/or weight <1.8kg treated for CMV disease between 2016 and 2022 were included. Clinical data was collected including GCV or VALGCV dosage, safety profile and therapeutic drug monitoring.
Results: Twenty-three infants (57% male and 48% Asian ethnicity) with median corrected gestation of 31 weeks (IQR 26.6 - 36.1) and median weight of 922g (IQR 470 - 1692) at treatment initiation were included. Postnatally acquired CMV (pCMV) (74%) with symptomatic thrombocytopenia (71%) was the main reason for treatment; 6 infants were treated for congenital CMV. 92% of infants received intravenous (IV) GCV at 6mg/kg twice daily (BD), whilst 90% of infants with oral (PO) VALGCV received 16mg/kg BD. 48% infants had GCV levels during their course of treatment. The mean pre-dose GCV level was 2.3 and 2.7 in the 6mg/kg BD IV GCV and 16mg/kg BD PO VALGCV respectively (accepted range 0.5 - 1.0 mg/L). The 1 hour post-dose GCV level with 6mg/kg BD IV GCV had a mean of 7.7 (accepted range 7 - 9 mg/L). Six infants (26%) had no documented side effects within 28 days of treatment. 59% had 2 or more side effects with neutropenia (ANC <1.0 x 10^9/L) the most common (43%). However only two infants had their treatment interrupted (ANC <0.5 x

Characteristics	n, (%)
Male	13 (57)
Female	10 (43)
Asian	11 (48)
White	5 (22)
Other	2 (8)
Type of infection	
cCMV	6 (26)
pCMV	17 (74)
Gestation at point of treatment (wks)	
<32 weeks	15 (65)
Weight at point of treatment	
<1.8kg	23 (100)
Dosing	
IV GCV 6mg/kg BD	11 (92)
IV GCV 5mg/kg BD	1 (8)
PO VALGCV 16mg/kg BD	18 (90)
PO VALGCV 15mg/kg BD	1 (5)
PO VALGCV 14mg/kg BD	1 (5)
GCV drug levels	
Levels performed	11 (48)
Acceptable pre-dose levels	1 (14)
Acceptable 1 hour post-dose levels	2 (33)
Acceptable 2 hour post-dose levels	2 (66)
Dose change following level	2 (18)
Treatment side effects	
None	6 (23)
2 or more side effects	9 (39)
Neutropenia	10 (43)
Anaemia	9 (39)
Transaminitis	3 (13)

10^9/L).

Conclusions/Learning Points: Ganciclovir was generally well tolerated among pre-term and extremely low weight infants albeit with higher than accepted pre-dose levels. However more data is required for appropriate dosing and GCV drug levels in this unique patient population.

NEONATAL OMPHALITIS – TEN-YEAR EXPERIENCE AT A TERTIARY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Catarina Albuquerque, Marta Figueiredo, Mariana Eiras Dias, Rita Morais, Mónica Marçal
Hospital São Francisco Xavier - Centro Hospitalar Lisboa Ocidental, Pediatrics, Lisboa, Portugal

Backgrounds: Omphalitis is a soft tissue infection involving the umbilicus and surrounding tissues. Although rare in developed countries, omphalitis significantly affects neonates with increased risk of systemic disease and mortality.
Methods: Retrospective study of neonates admitted at a tertiary hospital diagnosed with omphalitis between 2013-2022. demographics, clinical presentation, laboratory and microbiologic findings, treatment and outcomes are described.
Results: Thirty neonates were admitted, median age 9.5 days (interquartile range (IQR) 6-13.5). Two had risk factors for omphalitis (maternal infection). Purulent discharge from the umbilical stump was the most common finding (n=24), followed by erythema (n=20). One infant had fever. Median leucocyte count was 13.250 x 10^9/L (IQR 10.475-15.275), and C-reactive protein was 0.37 mg/dL (IQR 0.1-0-38). Cultures were collected in all neonates: site cultures in 90% (n=27), all positive, most commonly with methicillin-sensitive Staphylococcus aureus alone (40%, n=12) or in combination with other bacteria (16.7%, n=5) and Escherichia coli (16.7%, n=5); blood cultures in 97% (n=29) with positive results for Staphylococcus epidermidis (n=2) and Staphylococcus warneri (n=1); urine and cerebrospinal fluid cultures in 5 and 2 children, respectively. Flucloxacillin ± gentamicin was the most frequent therapeutic option. All neonates completed at least 7 days of antibiotics, for a median time of 5 days of intravenous therapy followed by oral therapy. Median time of hospitalization was 7 days, without complications or readmissions.
Conclusions/Learning Points: Neonates with omphalitis had mild disease, with 10% of bacteriemia and no further complications. Blood or site of infection cultures were collected in all children. Urine and cerebrospinal fluid cultures were collected in selected cases. They all had good outcomes, including those who started intravenous antibiotics and completed with oral therapy.

CONGENITAL SYPHILIS: PREVENTABLE, YET INCREASING?

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Filipa Alveirinho, Maria Sousa, Inês Noites, João Vasco, Beatriz Fraga, Isabel Monteiro
Hospital do Divino Espirito Santo de Ponta Delgada, Paediatrics, Ponta Delgada, Portugal

Title of Case: CONGENITAL SYPHILIS: PREVENTABLE, YET INCREASING?
Background: Congenital Syphilis (CS), caused by the bacterium Treponema pallidum, is a vertically transmitted infection responsible for a wide range of clinical manifestations in infants. Early detection and treatment of maternal syphilis through prenatal care are pivotal in primary care efforts to control and prevent CS. In our Neonatal Intensive Care Unit (NICU), we have observed an increase in the number of cases of CS.
Case Presentation Summary: To investigate the trend, we analyzed the discharge papers of all newborns over the past 10 years with a diagnosis of CS. Our study group included 20 newborns, more than half (11) of them were born after 2020. 4 presented with severe forms of CS at birth, including very premature birth, sepsis with coagulopathy and meningitis. 1 of these newborns died. None of the mothers of these symptomatic newborns had been treated. 3 of these severe cases occurred after 2020. Other clinical findings were jaundice (11), followed by cholestatic hepatitis with hepatomegaly (3), mucocutaneous lesions (including 2 cases of pemphigus syphiliticus), splenomegaly (2) and ascites (1). Infants were treated with IV benzylpenicillin (according to guidelines), combined with gentamicin in severe cases. 14 of the 20 mothers were not adequately treated during the pregnancy, even though the diagnosis had been made in a timely manner.
Learning Points/Discussion: The emergence of more and more severe cases of CS in recent years may be related to failures in the follow-up of pregnant women, possibly resulting from the Covid-19 pandemic. Our findings highlight the importance of raising awareness among clinicians about the risks and consequences of CS. Early detection, treatment and notification to public health authorities are essential for preventing and managing this disease in newborns.

NEONATAL HERPETIC INFECTION – A RARE BUT CHALLENGING CONDITION

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Sara Alves Araújo, Ana Rebelo, Benedita Aguiar, Joana Monteiro
Centro Hospitalar de Entre o Douro e Vouga, Pediatrics, Santa Maria da Feira, Portugal

Title of Case: Neonatal Herpetic Infection - a rare but challenging condition
Background: Herpetic infection during the neonatal period may have intrauterine, perinatal, or postnatal transmission. Despite its low incidence, morbidity and mortality are significant in newborns, with a high potential for long-term sequelae.
Case Presentation Summary: 11-day-old, full-term female newborn, with unremarkable prenatal history. Born by cesarean section, with adequate weight for her gestational age. Admitted to the emergency department due to cutaneous lesions scattered over her face, trunk and back with a two-day evolution, without fever, discomfort or itching. Objectively she presented five bullous meliceric lesions on the face, trunk, left armpit and back, with an erythematous halo and drainage of purulent content. The remaining exam was unremarkable. An initial analytical study, including blood and urine cultures, was negative. Due to the suspicion of impetigo, she was hospitalized with intravenous Flucloxacillin 100mg/kg/day. On the second day of hospitalization, the skin lesions worsened, presenting several confluent and ulcerated lesions on the face and trunk, with small satellite vesicles, highly suspicious of herpetic infection. A swab collection of exudates from the cutaneous lesions was performed. Lumbar puncture and serologic testing for herpes simplex virus (HSV) antibodies were negative. Empirical therapy with intravenous Acyclovir 60mg/kg/day was started, with posterior confirmation of skin infection by HSV-1. Gradual improvement was verified, with complete resolution after 14 days of Acyclovir. She was discharged with oral suppressive therapy with acyclovir and currently remains asymptomatic.
Learning Points/Discussion: Mucocutaneous disease accounts for 45% of neonatal HSV infection, and HSV-1 is the main responsible for isolated cutaneous involvement. Despite the absence of symptoms of systemic disease, it is mandatory to exclude multisystemic involvement, namely of the central nervous system. Timely treatment is essential for a favorable prognosis.

CONGENITAL RUBELLA SYNDROME PRESENTING WITH BLUEBERRY MUFFIN BABY: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Mulki Angela[1], Muhammad Azharry Rully Sjahrulla[2], Distyayu Sukarja[2], Nina Dwi Putri[2]
[1]Paediatric Resident, Department Of Child Health, Faculty Of Medicine University Of Indonesia, Cipto Mangunkusumo Hospital, Jakarta, Indonesia, [2]Paediatrician, Department Of Child Health, Faculty Of Medicine University Of Indonesia, Cipto Mangunkusumo Hospital, Jakarta, Indonesia

Title of Case: CONGENITAL RUBELLA SYNDROME PRESENTING WITH BLUEBERRY MUFFIN BABY: A CASE REPORT

Background: Blueberry muffin baby is a rare clinical presentation in newborn. It is characterized by the presence of widespread, maculopapular lesions of purple colour. The presence of skin lesions could be resulted from intrauterine viral infections.

Case Presentation Summary: A male infant with a birth weight of 2075 g, Apgar score 3/5/7, who was born in gestation week 36 by caesarean section from mother with G3P0A2. The first pregnancy was hydrocephalus baby and intrauterine fetal death around gestation week 22. The second pregnancy was spontaneous abortion around gestation week 17. Mother came to emergency room with premature rupture of membrane. Laboratory results of mother showed that HIV, HBsAg, RPR and TPHA were non-reactive. Immunoglobulin G (IgG) rubella, cytomegalovirus, and toxoplasma were reactive, and only IgM of toxoplasma was reactive. The baby had a “blueberry muffin appearance” with widespread purple papules (Figure 1) and macrocephaly. Laboratory results showed pancytopenia and increased procalcitonin. Blood culture result was negative. Serology testing showed congenital infection with rubella. The results of RPR and TPHA were negative. Brain CT scan examination showed non-obstructive hydrocephalus, colpocephaly, lateral periventricular oedema, multiple calcification, and suspected retinochoroiditis. Ophthalmic examination showed vitreous haziness, suspected chorioretinitis. The skin lesions gradually progressed over
time.

Figure 1. skin lesions

Learning Points/Discussion: Early detection and prompt treatment for newborn presenting with

blueberry muffin rashes and next antenatal counselling for mother, especially related to toxoplasmosis, rubella, cytomegalovirus, and herpes simplex (TORCH) infections should be emphasized.

[1]university of Algiers, Medecine, Ouled fayet, Algeria, [2]university of Algiers, Medecine, Algiers, Algeria, [3]university of Kolea, Statistics, Kolea, Algeria, [4]university of Algiers, Biostatistics, Algiers, Algeria

Title of Case: ASSOCIATION OF PERINATAL INFECTIONS AND LENTICULOSTRIATE VASCULOPATHY
Background: Introduction Lenticulostriate vasculopathy (LSV) refers to the sonographic finding of increased echogenicity of the lenticulostriate vessels. The etiologies are various and sometimes there is no évident etiology identified. we report 04 cases of LSV lesions discovered at birth by CUS, performed systematically in view of the notion of maternal infection during pregnancy.
Case Presentation Summary: Cases report Maternal pathologies proven by specific serological tests performed during pregnancy: toxoplasmosis, CMV and Covid-19. The serological tests for the three patients born in the context of CMV and Covid-19 were posistives and the children presented a severe multi-visceral involvement. whereas in the context of toxoplasmosis, the newborn's serology was twice negative and the child presented with only moderate axial hypotonia and has not received specific treatment but he is still being followed in consultation. The two children with covid-19 died at 25 days of life in an array of multiorgan failure.
Learning Points/Discussion: LSV is currently described in newborns with congenital infection or with others etiologies. In our series, we find two cases of Covid -19 in its severe form like some authors. The association between LSV and Covid-19 is recently described but not well established. In our cases, the LSV appear to be associated with the severe forms of perinatal covid-19.

MATERNAL URINARY TRACT INFECTION AND EARLY BRAIN LESIONS OF THE PREMATURE INFANT.

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Hanifa Arfi[1], Samira Abrouk[2], Ayoub Asri[3], Djamil Lebane[4]
[1]university of Algiers, Medecine, Ouled fayet, Algeria, [2]university of Algiers, Medecine, Algiers, Algeria, [3]university of Blida, Biostatistics, Blida, Algeria, [4]university of Algiers, Medecine, Cheraga, Algeria

Backgrounds: Maternal urinary tract infection (MUTI) is considered as a potential risk factor of fetal infection. If the fetus is affected (via SRIF), brain damage can occur and leave long-term sequelae in the child born prematurely. Aim: Estimate the association between MUTI and early brain damage in premature babies.
Methods: -Case control study at the neonatal service of CHU Mustapha of Algiers from 01/12/2007 to 31/12/2012. -Population: 801 in born babies aged between 24 to 36 weeks +6 days. -Exam: 1-Histological study of the placenta 2-Cranial ultrasonography within the 72 hours of birth followed by weekly controls until the patients reached the term. 3-MRI after 40 weeks if the lesions persisted after the acquired term and, and if GA<32 weeks. 4-EEG :realized during the first week of life. -24 Risk factors studied, among them, MUTI. -The statistical method : bi-varied analysis, logistic regression. P < to 0.05 was significant.
Results: -In bi-varied analysis: OR=4,79 IC95 (1,71-13,78) $p<10^{-3}$ (S) -After logistic regression : OR^{a} =1,082 IC95 (0,306-3,832) p=0,902 (NS) MUTI is not an independent factor.
Conclusions/Learning Points: Several authors have found a deleterious correlation between maternal urinary tract infection and WMD in the premature infant. In our study, this link was not found. However, a more rigorous study with little bias is needed before ruling out this possible link.

CONGENITAL CMV INFECTION OR SOMETHING MORE…

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Aida Azevedo, Ana Rodrigues, Felisbela Rocha, Clara Vieira
Centro Hospitalar do Médio Ave, Paediatrics, Vila Nova de Famalicão, Portugal

Title of Case: CONGENITAL CMV INFECTION OR SOMETHING MORE…
Background: Congenital Cytomegalovirus (CMV) infection is relatively common worldwide and is the leading cause of nonhereditary sensorineural hearing loss. It can also cause a variety of other symptoms such as neurodevelopmental delay or vision impairment, common to many other conditions.
Case Presentation Summary: A 4-year-old girl, with prenatal history of confirmed maternal CMV infection at 32 weeks of gestational age, with the remaining serologic tests normal. After birth, the newborn's CMV infection was confirmed by the detection of CMV in urine by PCR test. She was asymptomatic, her hearing screening was normal as well as transcranial ultrasound and blood work. She maintained regular follow-up since birth and with her growth some dysmorphic characteristics became more evident: hypertelorism, thin upper lip, shoulder asymmetry with the left nipple in a higher position and several coccygeal pits. She also presented a neurodevelopmental delay. A brain MRI scan showed areas of pachygyria with frontotemporoparietal and left insular polymicrogyria and bilateral subcortical T2-hypersignal, concordant with CMV infection sequelae. A lumbosacral MRI was normal. Genetic testing (array-CGH) revealed an interstitial deletion of 2.55 Mb in the 22q11.21 region, an alteration that is associated with DiGeorge syndrome. Currently, the girl maintains multidisciplinary follow-up and multiple therapies, including physical, occupational and speech therapies and hippotherapy and is showing satisfactory improvement.
Learning Points/Discussion: DiGeorge syndrome is a genetic disorder that results from 22q11.2 deletion. It has a wide spectrum of clinical manifestations, with neurodevelopmental delay, speech and hearing impairment being the most frequent. This case brings attention to the fact that many of the symptoms could be explained either by the genetic syndrome or the congenital CMV infection, which could have delayed the diagnosis and therefore genetic counseling.

A SINGLE-CENTER RETROSPECTIVE OBSERVATIONAL STUDY OF CONGENITAL SYPHILIS IN A TERTIARY NICU IN CAMBODIA DURING 48 MONTHS

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Sakviseth Bin, Sethikar Im
Calmette Hospital, Neonatal Icu, Phnom Penh, Cambodia

Backgrounds: During COVID-19 pandemic, there was a resurgence of congenital syphilis in Cambodia. In our center, the first case was reported in January 2021 in spite of its absence since 2005.
Methods: This retrospective study was conducted in Neonatal ICU in Calmette Hospital to determine the incidence of congenital syphilis (confirmed and possible case), the maternal treatment status, the newborn' clinical and laboratory findings and the compliance of follow-up. Paired serology (RPR and TPHA) were done in all cases. Case definition was based on CDC's recommendation. The data was collected for 2 years (Jan 2021 to December 2022). The study did not include stillbirths.
Results: A total of 53 neonates (31 males) with the diagnosis of congenital syphilis were included in the study. Preterm birth was reported in 58.5%, with mean duration of gestation of 36 weeks. Low birth weight was reported in 43.4% (means 2490g; range 1150-3800g). Only 12 mothers (22.6%) were treated during pregnancy: penicillin-regimen was used only in 58% of cases and none were completed by the time of birth. 18 infants were symptomatic (34%) and the most common features included pemphigus (44%), hepatomegaly (39%) and splenomegaly (22%). Anemia was observed in 6 neonates (33%) and thrombocytopenia 28%. 19/45 cases (35%) got elevated CRP at admission (means: 79mg/L; range 17-175). CSF was abnormal in one case. All neonates were treated immediately at birth, with Benzyl-penicillin for 10 days. Mortality rate was 2% (A preterm of 30WGA with birth asphyxia). Follow-up rate was 57% (at least 1 follow-up).
Conclusions/Learning Points: Congenital syphilis is a global burden. However, it is preventable. The mother-to-child transmission should be and can be prevented by early diagnosis and on-time, accurate treatment of the mother by proper regimen.

REGIONAL NEWBORN SCREENING FOR CONGENITAL CYTOMEGALOVIRUS INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Margarida Borges[1], Jenny Gonçalves[2], Beatriz Pedreira[3], Tânia Teixeira[1]
[1]SESARAM, EPERAM, Machico Health Care Center, Machico, Portugal, [2]Hospital Nélio Mendonça, SESARAM, EPERAM, Neonatology, Funchal, Portugal, [3]Hospital Nélio Mendonça, SESARAM, EPERAM, Pediatrics, Funchal, Portugal

Background: Cytomegalovirus is the most common congenital infection, affecting 0.5-1% of all live births, and is the leading non-genetic cause of congenital sensorineural hearing loss and neurological damage. In Portugal, the estimated prevalence is approximately 1.05%. There is an emerging evidence-based consensus that a systematic approach based on universal newborn screening and timely treatment and appropriate follow-up services is feasible and can yield substantial net benefits for many affected children and families.
Methods: A narrative review based on relevant literature from the PubMed data search outlines current evidence on key aspects of a screening program for congenital cytomegalovirus (cCMV).
Results: A cCMV screening program is proposed to all newborns in the Autonomous Region of Madeira, in the first three weeks of life, using CMV DNA polymerase chain reaction on urine or saliva samples, allowing timely audiologic, neurologic and ophthalmologic assessment and intervention, as well as sensory and neurodevelopmental follow-up. The use of hearing devices, speech and language programs, and educational accommodations can ultimately improve developmental outcomes, increasing productivity and minimizing the health-care burden.
Conclusions/Learning Points: Current evidence regarding cCMV infection supports the need of an organized neonatal screening program, which may provide the opportunity to implement best practices regionally.

MATERNAL TOXOPLASMA SEROPREVALENCE RATES IN NORTHERN GREECE

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Nourchan Bourmpoun[1], Olga Tsiatsiou[1], Elias Iosifidis[2], Grigoris Grimbizis[3], Konstantinos Dinas[4], Apostolos Athanasiadis[5], Emmanuel Roilides[6]
[1]Hippokration General Hospital of Thessaloniki, 3rdpediatric Department, Thessaloniki, Greece, [2]Aristotle University of Thessaliniki, Third Department Of Pediatrics, Infectious Diseases Unit, Thessaloniki, Greece, [3]General hospital Papageorgiou of Thessaloniki, First Department Of Obstetrics & Gynecology, Thessaloniki, Greece, [4]Hippokration General Hospital of Thessaloniki, First Department Of Obstetrics & Gynecology, Thessaloniki, Greece, [5]Hippokration General Hospital of Thessaloniki, Third Department Of Obstetrics & Gynecology, Thessaloniki, Greece, [6]Aristotle University, 3rd Department Of Paediatrics, Thessaloniki, Greece

Backgrounds: Toxoplasma gondii's importance for humans refers mainly to primary infection during pregnancy, resulting in abortion/stillbirth or congenital toxoplasmosis. This study aims to evaluate maternal Toxoplasma seroprevalence during pregnancy and correlate to congenital toxoplasmosis in Northern Greece.
Methods: This is a retrospective study conducted in two major tertiary-level public hospitals with maternity services from January 2019 to December 2020. Prenatal Toxoplasma serology (IgM and IgG antibodies) was evaluated in all pregnant women who gave birth to live neonates. Medical records of all these neonates were assessed for congenital toxoplasmosis.
Results: During the study period there were 6472 pregnant women with live births. Medical records were accessible for 4417 of them and 1803 had a documented prenatal screening for toxoplasma serology. Among those 1803 women, only 987 (55%) had performed toxoplasma serology during the first 10 weeks of pregnancy, and 151/987 (15%) were found seropositive. At the time of delivery, independently of the number of toxoplasma serology testing, 1465 (81%) women were found seronegative, 315 seropositive and 23 with toxoplasma infection based on serology (positive IgM and IgG). Among seronegative women, only 226 (15.4%) had repeated serology testing during pregnancy and none were found seropositive. Among 23 pregnant women with possible toxoplasma infection, further neonatal evaluation for congenital infection was recorded only in 13 (56.5%) neonates from whom 12 were found negative, and only 1 was diagnosed with congenital toxoplasmosis.
Conclusions/Learning Points: A significant number of seronegative women who are susceptible to toxoplasma infection do not repeat toxoplasma serology during their pregnancy. Moreover, further evaluation of the neonates of women with possible infection during pregnancy seems to be poor. All these can lead to undiagnosed asymptomatic neonates with congenital toxoplasmosis.

TWO YEAR BURDEN OF CONGENITAL CYTOMEGALOVIRUS INFECTION IN COMMERCIALLY- AND MEDICAID-INSURED PATIENTS IN THE UNITED STATES

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

John Diaz-Decaro[1], Gail Demmler-Harrison[2], Jessica Marden[3], Annika Anderson[4], Sandeep Basnet[1], Katherine Gaburo[3], Danielle Peterson[3], Noam Kirson[3], Urvi Desai[3], Philip Buck[5]
[1]Moderna, Inc., Epidemiology, Cmv Vaccine, Cambridge, United States of America, [2]Baylor College of Medicine, Pediatric Infectious Disease, Texas Children's Hospital, Houston, United States of America, [3]Analysis Group, Inc., Health Economics And Outcomes Research, Boston, United States of America, [4]Analysis Group, Inc., Health Economics And Outcomes Research, New York, United States of America, [5]Moderna, Inc., Health Economics And Outcomes Research, Cambridge, United States of America

Backgrounds: Congenital cytomegalovirus (cCMV) infection is the leading infectious cause of congenital birth defects. Approximately 20-25% of infants born with cCMV develop long-term health complications including hearing loss. Despite this, studies on the burden of cCMV are limited. We assessed the healthcare resource utilization (HRU) and cost burden among cCMV patients in the US using insurance claims data.
Methods: This retrospective study utilized IBM Watson Health MarketScan® Commercial Claims and Encounters and Multi-State Medicaid data from January 1, 2010 to December 31, 2019. Patients with a first diagnosis (index date) of cCMV (ICD-9: 771.1; ICD-10: P35.1) or CMV (ICD-9: 78.5; ICD-10: B25.x) within 1 month of birth were included in the cCMV cohort. Index date for non-cCMV controls was randomly selected from all medical claims within 1 month of birth. cCMV patients were matched 1:1 to controls. All patients were required to have ≥2 years of continuous health plan enrollment post-index; HRU and costs (US$2021) were summarized over the 2-year study period.
Results: 118 Commercial and 351 Medicaid matched pairs were included in the analyses. Mean ±SD (median) birth length of stay was 27.3 ±58.2 (7.0) days for Commercial cases (vs. 6.4 ±11.5 [6.4] days for controls; p<.001) and 26.6 ±39.9 (11.0) days for Medicaid cases (vs. 5.7 ±9.0 [3.0] days for controls; p<.0001), with mean birth admission costs of $195,630 ±760,256 (vs. $24,195 ±101,786; p=.025) and $57,182 ±160,996 (vs. $5,732 ±29,906; p<.0001), respectively. On average, cCMV patients had significantly higher study period HRU and costs compared to controls over 2 years (Table 1).
Conclusions/Learning Points: cCMV patients have substantial HRU and costs during the 2 years post-diagnosis. While the majority of patients did not require hospitalization, inpatient care contributed greatly to overall cost

burden.

Table 1. All-cause HRU and costs of cCMV in Commercially- and Medicaid-insured patients during the first- and second-year following index diagnosis

STREPTOCOCCUS AGALACTIAE ARTHRITIS PRESENTING AS PSEUDO PARALYSIS IN AN INFANT

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Christian Capirig[1], Connie Taylor[2], Casey Swenson[3], Peter Paul Lim[4]
[1]Davao Medical School Foundation, Pharmacology, Davao, Philippines, [2]Avera McKennan University Hospital/University of South Dakota School of Medicine, Pediatric Neurology, Sioux Falls, United States of America, [3]Avera McKennan University Hospital/University of South Dakota School of Medicine, Radiology, Sioux Falls, United States of America, [4]Avera McKennan University Hospital/University of South Dakota School of Medicine, Pediatric Infectious Diseases, Sioux Falls, United States of America

Title of Case: STREPTOCOCCUS AGALACTIAE ARTHRITIS PRESENTING AS PSEUDO PARALYSIS IN AN INFANT
Background: Streptococcus agalactiae (GBS) is a common pathogen of neonatal sepsis. However, it is rarely implicated in infantile septic arthritis presenting as pseudoparalysis in the absence of fever.
Case Presentation Summary: A 6-week-old term male with unremarkable prenatal history presented with an apparent late-onset Erb's palsy (weakness of deltoid and infraspinatus muscles). The paralysis was noted shortly after lip frenulectomy for ankyloglossia. Six days later, decreased movement was also noted in the left arm. The mother denied any fevers but the baby was noted to be fussier than baseline. On physical examination, the right arm was preferentially abducted and internally rotated with normal muscle bulk, tone, and deep tendon reflexes. Movement was maintained distally in the hand. Right Moro reflex was absent. Shoulder radiograph did not show any abnormality. MRI showed abnormal enhancement compatible with bilateral shoulder joint effusion (Figure). Laboratory showed leukocytosis of 14k (neutrophil 53%), thrombocytosis of 724,000, ESR 66 mm/hr, and CRP of 6.7 mg/dL. Blood culture was positive for GBS prompting antibiotics. He underwent bilateral shoulder debridement. Intraoperative findings showed pustular debris in bilateral shoulders worse on the left. The right shoulder culture demonstrated GBS susceptible to ampicillin. Recurring right shoulder effusion necessitated repeat debridement. Subsequent radiologic studies demonstrated secondary right proximal humerus pathologic fracture. He was sent home on intravenous ceftriaxone. He completed 6 weeks of intravenous antibiotic with excellent recovery. The range of motion of bilateral shoulders was restored back to baseline. There were some residual lucencies on the right proximal humerus which would need long-term surveillance.

Learning Points/Discussion: Infantile septic arthritis can present as afebrile pseudoparalysis. GBS is an important pathogen in infantile septic arthritis presenting with pseudoparalysis.

HIDDEN BEHIND A (PALE) MASK

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Carolina Baltazar[1], Madalena Ferreira[1], Joana Jonet[1], Carolina Guimarães[1], Carina Cardoso[2]
[1]Av. Brigadeiro Victor Novais Gonçalves, Unidade Funcional De Pediatria, Departamento Da Criança, Cascais, Portugal, [2]Av. Brigadeiro Victor Novais Gonçalves, Unidade Funcional De Pediatria, Departamento Da Criança, Portugal, Portugal

Title of Case: Hidden behind a (pale) mask
Background: Early detection and treatment of STDs in pregnant women prevents complications to both mother and baby. Improving awareness on sexual and reproductive health requires healthcare to provide universal counseling and implement strategic initiatives targeting all groups of women.
Case Presentation Summary: A 29-year-old pregnant woman, G3P3, despite social precarity completed prenatal care without abnormal findings. At 39-weeks', she gave birth to a female baby, who at 2-month-old was referred to our pediatric emergency for severe anemia. Upon admission, she was extremely pale, had a grade 3 systolic heart murmur and an enlarged liver expanded towards the right iliac fossa. Laboratory work-up revealed Hb 4.2g/dL, platelet count of 96.000cells/mL, high alkaline phosphatase and hypoalbuminemia. Abdominal ultrasound, describing a multinodular enlarged liver and splenomegaly, prompted a suspicion of hepatoblastoma. There was a multidisciplinary decision to initiate treatment with a transfusion of packed red blood cells. As the investigation went through, serological work-up revealed a RPR titre of 1:1024, positive TPHA and IgM anti-treponemal antibody. Tests performed on cerebrospinal fluid were negative, but the x-rays showed syphilitic periosteitis. Positive anti-EBNA IgG and anti-VCA IgM were found and cardiac evaluation diagnosed a dilated right ventricle due to patent foramen ovale with left-right shunt. Treatment consisted on a 10-day course of benzylpenicillin and the mother was also diagnosed and treated. Now, at 8-months-old, the infant has a good psychomotor development and no sequelae, however her social conditions remain unaltered.
Learning Points/Discussion: Congenital syphilis, a preventable infection, has recently increased in medium to high income countries. Clinicians must provide counseling and be aware of risk factors. In this case of late presentation, maternal infection occured after a complete prenatal screening, nevertheless clinical cognizant and timely approachment permitted a favourable prognosis.

IF IT LOOKS LIKE A DUCK, THAN IT PROBABLY IS A DUCK

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Madalena Ferreira, Carolina Baltazar, Joana Jonet, Ana Tavares, Carina Cardoso
Av. Brigadeiro Victor Novais Gonçalves, Unidade Funcional De Pediatria, Departamento Da Criança, Cascais, Portugal

Title of Case: If it looks like a duck, than it probably is a duck
Background: HIV infection renders lesser reliability of serological markers in pregnant women, depending on the degree of immunosuppression. Greater attention should be given to pregnant migrants, especially when coming from regions with high prevalence of SCORTCH diseases, for the impact on mother-to-child transmission can be mitigated.
Case Presentation Summary: A 30-year-old woman, G1P1, from Guinea-Bissau, was diagnosed with HIV-1 during the first trimester of pregnancy, initiating ART at 21-weeks'. CD4 count was 1531 cells/mm3 (80.2%) and viral load was 337861 copies/mL. During prenatal care, there was a suspicion of toxoplasmosis, however serological markers did not seem accurate, so this patient started spyromicin after 21-weeks' until delivery. At 39-weeks, with less than 30 copies/mL viral load, she gave birth to a female baby, whose laboratory work-up revealed positive anti-Toxoplasma IgM and IgG (avidity 82.3%) and positive DNA in the peripheral blood. Placental tissue was considered not viable and the spinal fluid was negative for Toxoplasma gondii. The infant was treated with sulfadiazine, pyrimethamine and folic acid. Throughout multidisciplinary follow-up, she was also diagnosed with chorioretinitis of the right eye and started oral prednisolone. Nowadays, she completed a full-year treatment and already has a negative Toxoplasma gondii's work-up; yet, the ophthalmologist suspects of a vision acuity 20/200 in the right eye.
Learning Points/Discussion: Although evidence is limited, the risk of vertical transmission of Toxoplasma gondii among HIV-1 infected women is low and has been associated with maternal immunosuppression and elevated viral load. In this case, it is uncertain whether reinfection or reactivation occurred; nonetheless, a high clinical concern is needed for timely diagnosis and proper approachment, especially before patients with acquired immunodeficiency and social precarity.

A SHOULDER TO CRY ON: CLINICAL CASE REPORT ABOUT A NEONATAL OSTEOMYELITIS WITH REVIEW OF LITERATURE

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Giulia Cassol[1], Federica Minniti[2], Pierantonio Santuz[2]
[1]Azienda Ospedaliera Universitaria Integrata, Ospedale Della Donna E Del Bambino - Pediatria, Verona, Italy, [2]AOUI Verona, Pediatric Emergency Department, Verona, Italy

Title of Case: A SHOULDER TO CRY ON: CLINICAL CASE REPORT ABOUT A NEONATAL OSTEOMYELITIS WITH REVIEW OF LITERATURE
Background: Osteomyelitis and surrounding tissues infections are rare in neonatal population, but we must think about them in case of impaired mobility. A prompt recourse to ultrasound or MRI can help.
Case Presentation Summary: A 8-days newborn presents impaired arm mobility, focal tenderness and pain, any other sign of infection. Diagnosis is made by clinical features, elevation in inflammatory markers (RCP, ESR, WBC) and charateristic imaging abnormalities. The ultrasound imaging helps in diagnosis and treatment, i.e. infiltrations.The most common pathogens are bacteria. The mother was a carrier of S. aureus. The iv antibiotical therapy is based on the age of the child and the epidemiology of the surrounding community. It lasts from 4 to 6 weeks, released by positioning central venous catheters.

Years	Agent	Treatment
< 1 mo	SGB Gram-negatives (Salmonella spp) MSSA (significant systemic manifestations)	Third/fourth-generation cephalosporine (Cefotaxime) combined with Vancomycin (augmented risk of MR if newborns are ammitted >7 days in neonatal ICU or newborn from a woman carrier of SA); Tobramicin alternatively.
1 mo- 2 yrs	SA Streptococcus pneumoniae Kingella kingae (mild symptoms, less complications) Haemophlius influenzae B	Ceftriaxone/cefotaxime, Oxacillin/Nafcillin and Vancomycin. Life-threatening infection: Vancomycin and Oxacillin/Nafcillin. Non life-threatening infection and <10% of the community SA isolates are MR: Oxacillin/Nafcillin or Cefazolin. If >10% of the community SA isolates are MR: Vancomycin.
> 2 yrs	SA K. kingae	Vancomycin or Clindamycin. Additional coverage with Cefazolin for K. kingae or if the antimicrobial response is insufficient.

Learning Points/Discussion: If undiagnosed, long-term sequelae can occur and should be avoided: abnormal bone growth, pathological fractures or avascular necrosis. It is essential a 1 year-long, or more, clinical and radiological follow-up.

Title of Case: CONGENITAL SYPHILIS ON THE RISE - REVIEW OF THE LAST FIVE YEARS OF A REFERRAL HOSPITAL IN PORTUGAL
Background: The resurgence of syphilis and subsequent risk for newborns has been described worldwide. The last annual European epidemiological-report on congenital syphilis (CS) showed an increasing number of notified cases, being the highest 2019 rate increase in Portugal (three-fold). We conducted a retrospective study including children exposed to Treponema pallidum in utero and/or congenitally infected, between 2018-2022, followed-up in our hospital. We collected sociodemographic data, maternal VDRL and newborn/child titers, co-infections, birth records, treatment during pregnancy, clinical features, treatment, and follow-up.
Case Presentation Summary: We present 9 cases of suspected CS; 9 mothers and 7 newborns had positive VDRL titers. Maternal characteristics were: 37.5%(3) young mothers (≤25y), 71.4%(5) basic educational levels, 57.1%(4) unemployed, 22.2%(2) foreign origin (1-Guinean, 1-Brazilian), 11.1%(1) co-infected with human immunodeficiency virus, 22.2%(2) drug abuse. Prenatal care coverage was provided in 77.8%(7) of the mothers, with only 33.3%(3) adequately treated. Maternal syphilis was classified: 55.6%(5) early, 33.3%(3) late, 11.1%(1) undetermined. The newborns were classified: 22.2%(2) highly probable and 77.8%(7) possible. There were two cases of symptomatic CS and one of them being neurosyphilis. All patients were treated with penicillin, and are healthy post-treatment; 22.2%(2) were lost to follow-
up.

Outcome	Unknown	Healthy	Healthy	Healthy	Unknown	Healthy	Healthy	Healthy	Healthy

Table 1. Clinical details of the cases

Learning Points/Discussion: Although CS is a preventable disease, it remains a major health problem worldwide, and its increment reflects a prenatal care deficiency. CS still compounds a significant impact and prevention should target specific maternal risk profiles. Changes in global population demographics and distribution, reflected on the increasing birth rates among foreign mothers in Portugal, disrupts the close prenatal surveillance, possibly amounting to greater congenital infections. Additional data are needed to ascertain factors associated with CS prevention failure.

THE CHALLENGES OF MANAGEMENT IN NEONATAL VARICELLA IN CAMBODIA WITH A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Chariya Chap
National Paediatric Hospital, Neonatology, Phnom Penh, Cambodia

Title of Case: Challenges in management of neonatal varicella in Cambodia with a case report
Background: Neonatal varicella is uncommon and associated with high mortality rate up to 30%. The diagnosis is based on the characteristic appearance of skin lesions in an infant born to a mother exposed to VZV and confirmed by detection of PCR. We are reporting one case of neonatal varicella treated by oral acyclovir with good evolution.
Case Presentation Summary: A 15-day old boy, born at term, weighed 2600g, good apgar score, to mother with symptoms of varicella 3 days prior to delivery, was admitted for fever and skin lesion appeared 7 days prior. Because of unavailable prophylactic immunoglobulin, he was isolated from his mother. On arrival, he had fever to 38,5 ^{o}c, weight 2500g, SpO_2 95% in room air, generalized vesicular skin lesion with some crusting and irritability. The blood result showed the white blood cells 22 G/L, PNN 12 G/L, hemoglobin 13,5g/dl, platelet 331G/L, C-RP: 1,3mg/L and ASAT 102 UI/L. The blood culture and CSF were not negative. Oral acyclovir 25mg/kg/8h was immediately commenced (the intravenous acyclovir is unavailable in our country) and associated with broad intravenous antibiotics (Cloxacillin and C3G). After 10 days of treatment, he was discharged with good improvement.
Learning Points/Discussion: According to CDC, the varicella immunoglobulin should be recommended in neonatal varicella. The key treatement is intravenous acyclovir (20mg/kg/8h) that must be started as soon as possible after the onset of symptoms. In case of fever, the broad intravenous antibiotics must be added. For M.TOD et al. the biodisponibility of oral acyclovir is good with dose 28mg/kg/8h. However, the management of neonatal varicella is still a challenge for cliniciens especially in low-resource settings.

MELANOMA MIMIC ACUTE MASTOIDITIS IN A 10-MONTH-OLD FEMALE CHILD

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Konstantina Chrysouli
PENTELI CHILDREN HOSPITAL, Ent, ATHENS, Greece

Title of Case: Melanoma mimic Acute Mastoiditis in a 10-Month-Old Female Child
Background: Foetal metastases are rare. Melanoma is the most common neoplasm with transplacental transmission to the foetus with very poor prognosis
Case Presentation Summary: We present a rare case of transplacental-transmitted maternal melanoma to the placenta and foetus during the pregnancy of a 34-year-old woman. She was diagnosed with a melanoma at the age of 25, for which she was treated with chemotherapy. During her pregnancy, she presented with a recurrence of the disease and died 3 months after delivery. The 10-month-old female child presented with a recurrent retroauricular oedema on the left side, as in acute mastoiditis. A trephination of mastoid apophysis followed. Multiple fragments of dark-coloured tissue were sent for histological examination, and the immunophenotype showed a melanocytic tumour in the mastoid. A full radiological assessment showed no sign of metastasis. The child remained without treatment. Complete remission of bone metastatic lesion has been confirmed by follow-up; now, the child is 4 years old, alive, and without evidence of disease.
Learning Points/Discussion: Melanoma most frequently involves the placenta or the foetus.Our report represents the tenth case of maternal transplacental-transmitted melanoma to the foetus and the second case of metastatic lesion on the mastoid reported in the literature till date. In this paper, we have reported the fourth case of spontaneous regression of metastatic melanoma transferred from the mother to the foetus.The mechanism of spontaneous regression of cancer is still under investigation: operative trauma, infection, and immunologic factors have been reported.The pathophysiology of transplacental spread of melanoma is unknown. Factors involved can be the high vascularity of the placenta, placental production of angiogenic and vascular endothelial growth factors, and impaired fetal immune response

Backgrounds: Herpes simplex virus (HSV) disease in infancy is not a mandatory notifiable condition in Australia despite severe morbidity and mortality. Australian surveillance relies on voluntary prospective reporting of cases to the Australian Paediatric Surveillance Unit (APSU)by clinicans. We sought to evaluate the epidemiology, disease characteristics and outcomes of HSV disease in infancy in the Australian states of Queensland (QLD) and Western Australia (WA) using statewide laboratory and clinical data and complementary national surveillance data collected via the APSU.
Methods: Positive HSV 1 and 2 PCR results were obtained from state-wide public pathology providers in QLD and WA for infants aged 0-3 months from 2007-2017. Clinical data were obtained from patient records. These cases were then compared to cases collected via APSU surveillance for these states.
Results: Ninety-four cases of neonatal HSV disease (70 QLD; 24 WA) were identified from laboratory datasets, compared to 36 cases (26 QLD; 10 WA) reported to the APSU during the study period. Twenty-eight cases were common to both datasets, (7/28 skin eye mouth (SEM) disease, 13/28 central nervous system (CNS) disease and 8/28 disseminated disease).Of the 66 laboratory cases not reported to the APSU, the majority (57/66) had SEM disease, with 5/66 CNS disease and 4/66 disseminated disease. Eight cases reported to the APSU were not captured by laboratory datasets (5 SEM disease, 1 CNS disease, 2 disseminated disease).Surveillance cases had a higher case-fatality rate (13.9%) compared to laboratory cases (7.4%) Neurological sequelae at discharge were comparable between the groups (8.3% APSU vs 7.4% laboratory).
Conclusions/Learning Points: Active surveillance captured approximately one third of the cases of hospitalised HSV disease, mostly severe disease. Increased case ascertainment would be achieved with a combination of laboratory identified cases to existing clinician reports.

[1]Centro Hospitalar Universitário do Algarve, Pediatrics, Faro, Portugal, [2]Centro Hospitalar Universitário do Algarve, Pediatric And Neonatal Intensive Care Unit, Faro, Portugal, [3]Hospital Santa Maria, Medical Genetics, Lisbon, Portugal, [4]Hospital Santa Maria, Pediatric Infectious Diseases Unit, Lisbon, Portugal

Title of Case: Recurrent nail infections, anonychia and development delay: a new syndrome?
Background: Nail disorders in children can have multiple causes. Congenital nail diseases are a heterogeneous group, which can occur isolated or included in genetic syndromes. Anonychia/hyponychia is characterized by complete absence of nails or presence of rudimentary nails.
Case Presentation Summary: Two siblings, a 22 months-old girl and an 11-year-old boy, presented since the first year of life with nail dystrophy and recurrent nail infections, leading to spontaneous nail expulsion. No other alterations were reported in skin or other ectodermal derivatives, such as hair, teeth and sweat glands. No significant dysmorphisms were identified. Both had multiple recurrent nail infections along the years, with isolation of Candida and S. aureus and response to antibiotics and antifungals. No history of other recurrent infections.The mother had sparse eyebrows and mild learning difficulties, without nail dystrophy.No other known similar cases in family, since mother was adopted. Both sibling evolved with psychomotor development delay, which led to further genetic workup, with the diagnosis of 15q13.3 microdeletion syndrome, an autosomal dominant disease, associated with intellectual disability, speech delay, seizures, autism and behavior alterations. This deletion was inherited from the mother. No signs of autism or seizures were found. Immune study showed no immunodeficiency, with normal CH50 and TH17 cells.
Learning Points/Discussion: Although differential diagnosis of nail dystrophy is wide, congenital isolated anonychia is a rare condition.Despite 15q13.3 microdeletion syndrome justifies development delay, it can not explain the nail dystrophy in the siblings.Until now there is no known association between these two entities.Is nail disease an atypical manifestation of 15q13.3 microdeletion syndrome or is there a second genetic alteration that explains the nail dystrophy? Further investigation is needed. We bring this case to discussion.

CONGENITAL CYTOMEGALOVIRUS INFECTION: AN OLD PROBLEM STILL UNSOLVED – TWO CASE REPORTS

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Carolina Curto, Adriana Martins Ferreira, Catarina Valpaços, Carmen Carvalho, Miguel Fonte
Centro Materno Infantil do Norte, Pediatrics, Porto, Portugal

Title of Case: Congenital cytomegalovirus infection: an old problem still unsolved – two case reports
Background: Cytomegalovirus(CMV) is a leading agent of congenital infection. Yet, universal screening in pregnancy is not recommended due to constraints in serologic interpretation and a lack of evidence for any therapeutic approach. A wide range of clinical manifestations can lead to severe outcomes, regardless of antiviral treatment, as illustrated by the two following cases.
Case Presentation Summary: Case 1:Prenatal diagnosis of hydrops fetalis with ventriculomegaly, leading to termination of pregnancy at 27 weeks and 6 days. At preconception and 2nd trimester, maternal CMV serostatus was IgG positive/IgM negative. The newborn had positive urine CMV DNA, with a blood viral load of 348.319 copies/mL. Aggressive measures were undertaken in the context of anasarca and multiple-organ dysfunction. Ganciclovir was initiated on day 4, but a fatal outcome occurred on day 6. The autopsy revealed cytomegalic inclusions in multiple organs. Case 2:Late-onset fetal growth restriction, with elective cesarean section at 38 weeks and 4 days. Maternal CMV serostatus was unknown. The newborn was small for gestational age, presented with petechial rash immediately after birth and had severe thrombocytopenia. Urine CMV DNA was positive, with a blood viral load of 330 copies/mL. Brain imaging revealed extensive cerebral bilateral hemorrhagic and ischemic lesions. Ganciclovir was initiated on day 2, followed by valganciclovir. Discharge on day 25. Currently, at 5 months old, he shows motor development delay, microcephaly and severe neutropenia, demanding temporary interruption of valganciclovir.
Learning Points/Discussion: These two cases exemplify the potential severity of a congenital infection in which postnatal diagnosis and treatment are often insufficient to improve outcomes. More awareness of congenital CMV is needed, as primary prevention is essential for reducing the disease burden of this condition.

SIMULTANEOUS PERIPARTUM ENTEROVIRUS INFECTION IN TWIN PAIRS, COMMON CAUSATIVE AGENT OF A RARE COINCIDENCE

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Ranaa Damouni Shalabi, Haleema Dabaja-Younis
Rambam Health Care Campus, Pediatric Infectious Disease Unit, Haifa, Israel

Title of Case: Simultaneous peripartum enterovirus infection in twin pairs, common causative agent of a rare coincidence
Background: Enterovirus infection manifesting as aseptic meningitis is a common cause of fever in the neonatal period. Several mechanisms for transmission of enteroviruses from caregivers to neonates have been described in the literature. One of the proposed mechanisms is vertical or horizontal transmission through the mother. Concurrent infections in twin pairs may point to the mother as the source of enterovirus. Simultaneous infections of twins during the neonatal period is rare and usually known only as case reports.
Case Presentation Summary: We described the clinical presentation and outcome of enterovirus peripartum infection detected by positive polymerase chain in cerebrospinal fluid in four pairs of dichorionic diamniotic twins, three of whom were delivered by cesarean section and all as late preterm or early term deliveries. Infection occurred between 8 and 33 days of age. All neonates had mild course of illness and recovered with no sequela.
Learning Points/Discussion: The delayed onset of symptom development after birth rules out intrapartum infection, and the mild course of the disease may be explained by late prenatal maternal infection when neonates have acquired sufficient amounts of protective maternal specific antibodies via the placenta. It is assumed that the neonates were colonized with enterovirus either by the vertical route from the mother during passage through the birth canal or by the horizontal route during maternal care and that breakthrough infection occurred later in these colonized neonates. Conclusion: Enteroviruses may be an important colonizer of the maternal genital tract and may cause neonatal infection that can mimic other maternally transmitted infections. Future

NATURAL HISTORY OF POSTNATAL HUMAN CYTOMEGALOVIRUS INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Piera D'Angelo[1], Paola Zelini[1], Federica Zavaglio[1], Stefania Piccini[2], Daniela Cirasola[3], Alessia Arossa[2], Arsenio Spinillo[2], Daniele Lilleri[1], Fausto Baldanti[1]
[1]Fondazione IRCCS Policlinico San Matteo, Microbiology And Virology Department, Pavia, Italy, [2]Fondazione IRCCS Policlinico San Matteo, Obstetric And Gynecology, Pavia, Italy, [3]Humanitas research Hospital, Microbiology And Virology Analysis Laboratory, Milano, Italy

Background: Postnatal cytomegalovirus (HCMV) infection is well characterized in preterm infants, where it can lead to severe symptomatic infection. We analyzed the rate and route of transmission of postnatal HCMV infections in full-term babies during the first year of life.
Methods: A cohort of 120 HCMV seropositive mothers and their 122 newborns were tested after delivery for HCMV DNA shedding in different bodily fluids. Postnatal HCMV infection was defined as the detection of $>2.5\times10^2$ HCMV-DNA copies/mL in infants' saliva swabs. Maternal neutralizing antibody serum titer, HCMV specific T-cell response, and HCMV glycoprotein B (gB) IgG on breastmilk were analyzed.
Results: HCMV shedding was detected in 67 of 120 mothers (55.8%), and 20 of 122 infants (16.4%) developed HCMV infection within the first three months of life. Six additional infants were infected during the first year, for a postnatal infection rate of 21.3%. Viral shedding was more frequent in breastmilk than saliva, urine and vaginal secretions, and the mothers of infected infants showed higher levels of HCMV-DNA in milk. No association was found between the antibody levels in serum or milk and maternal viral shedding, whereas a slightly lower frequency of HCMV-specific $CD4^+$ T-cells with long-term memory phenotype was observed in women with HCM-DNA-positive milk.
Conclusions/Learning Points: About one out of five infants develop HCMV infection within the first year of life. Breastmilk appears the major route of transmission of the infection, maternal saliva have a minor role whereas the role of vaginal secretions is negligible.

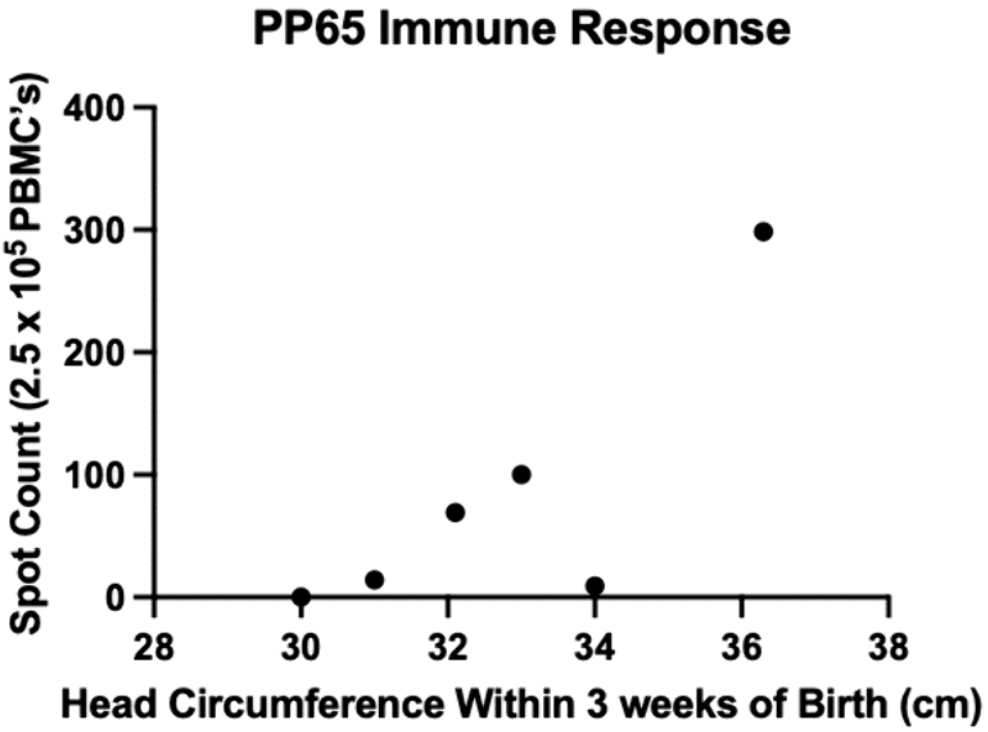
EXPLORING THE USE OF THE CYTOMEGALOVIRUS INTERFERON GAMMA RELEASE ASSAY IN CONGENITAL CYTOMEGALOVIRUS INFECTION.

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Kailas Dhond[1], Helen Payne[1], Harsita Patel[1], Hermione Lyall[2], Elizabeth Whittaker[1]
[1]Paediatric Infectious Diseases, Imperial College, London, United Kingdom, [2]Imperial College Healthcare NHS Trust, Paediatric Infectious Diseases, London, United Kingdom

Backgrounds: Cytomegalovirus (CMV)-specific interferon gamma release assays may be a useful tool to monitor the development of CMV-specific immune responses to control CMV in infants with congenital infection, and could potentially help determine appropriate duration of antiviral treatment.
Methods: Infants with confirmed congenital CMV (cCMV) infection and at least one valid T-spot CMV ELISPOT assay during the first 9 months of life were included. The cellular responses to CMV antigens Immediate Early 1 (IE-1) and phosphoprotein 65 (pp65) were quantified and analysed alongside clinical data.
Results: 13 infants (69% male) with median gestational age 37 (37-39) weeks were included. The median birth weight and head circumference were 2575g (2160-3100) and 33cm (30.5-35). 8/13 (61.5%) had intrauterine growth restriction (IUGR), 7/13 (53.8%) had sensorineural hearing loss (SNHL), and 11/13 (84.6%) had an abnormal brain MRI. The average ELISPOT spot counts between 0-3 months and 4-6 months of life were 52.2 and 112.1 (IE-1) and 82.9 and 271.7 (pp65) standardized units/25x10^4 PBMCs. IE-1 ELISPOT results for infants with assays performed during the first 2 months of life showed a positive correlation between lymphocyte, neutrophil, and platelet counts at diagnosis (P=0.0480, 0.0427, 0.0411, R^2=0.4048, 0.4201, 0.4249). PP65 ELISPOT results taken between 0-1 months of life had a positive correlation to infants' head circumference (P=0.049, R^2=0.6615, n=6) (Figure 1).



Conclusions/Learning Points: Our small study demonstrates the potential use of CMV ELISPOT in this population. There is a suggestion that CMV-specific immune responses increase with age over the first 6 months of life, however further longitudinal analysis of this cohort and CMV-uninfected control infants is required. Our results infer that the infants with the most severe microcephaly had the lowest CMV-specific responses.

RAOULTELLA PLANTICOLA UTI PRESENTING AS HYPERBILIRUBINEMIA IN A 3-DAY-OLD INFANT

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

David Jensen[1], Anthony Drazick[1], Rochelle Boote[2], Peter Paul Lim[3]
[1]University of South Dakota Sanford School of Medicine, Medical School, Vermillion, United States of America, [2]Avera McKennan University Hospitals, Pediatrics, Sioux Falls, United States of America, [3]Avera McKennan University Hospital/University of South Dakota School of Medicine, Pediatric Infectious Diseases, Sioux Falls, United States of America

Title of Case: Raoultella planticola UTI presenting as hyperbilirubinemia in a 3-day-old infant
Background: Raoultella planticola is a Gram-negative, aerobic, nonmotile bacterium that is ubiquitous in the environment usually implicated in opportunistic infection. There have been very few reported cases of Raoultella planticola infection in the pediatric population. Most of these reports have been in cases of neonatal septicemia.
Case Presentation Summary: A 3-day-old term, non-circumcised, male infant presented with jaundice and scleral icterus. Maternal prenatal course was unremarkable. Initial total bilirubin was 16.2 mg/dL on presentation. Transcutaneous phototherapy was initiated the day following presentation. Despite maximal outpatient phototherapy, the baby's bilirubin peaked to 25 mg/dL at 6 days of life that prompted admission. Sepsis work up was initiated despite absence of fever and other symptoms because of the baby's age. His laboratory work up were all reassuring except for bagged urine analysis that showed 3+ leukocyte esterase and significant leukocyturia which eventually grew Gram-negative rods. This warranted repeat catheterized urine collection. He was empirically started on ampicillin and gentamicin. His blood culture was negative. Both bagged and catheterized urine samples grew >100,000 CFU/mL of Raoultella planticola resistant to ampicillin. He was switched to cefazolin per susceptibility profile and his hyperbilirubinemia started to trend down. Repeat urine culture was negative after 5 days of cefazolin. The patient completed 14 days total therapy with oral cephalexin. Renal ultrasound and VCUG were normal.

Learning Points/Discussion: Neonatal UTI can present as recalcitrant hyperbilirubinemia. Raoultella planticola is a rare organism that is normally found in the environment but may be a bona fide etiologic agent in neonatal UTI.

E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Lesly Guerrero[1], Dolores Freire[1,2], Carmen Arreaga[3]
[1]Universidad de Guayaquil, Pediatria, Guayaquil, Ecuador, [2]University of Alberta, Pediatrics, Edmonton, Canada, [3]Hospital Alcivar, Pediatria, Guayaquil, Ecuador

Background: Timely identification and follow-up of perinatally exposed infants to HIV is essential to prevent vertical transmission. As of 2020 in Ecuador, the prevalence of HIV in pregnant women was 0.25% and the vertical transmission rate was 2.8%. We aim to describe the process of recruitment, management and follow-up of perinatal HIV-exposed patients at a community hospital at the second largest health zone with reported infections.
Methods: Retrospective chart review of mother/child pairs under follow-up from first prenatal consult up to 18 month visit at a community hospital in Quevedo from January 2018 to December 2022.
Results: Of 130 mother/child pairs, the median for gestational week of recruitment was 13.5 weeks [IQR 10-18]. The median age of mothers was 24 years [IQR 21-30]. Of them, 54 (41%) were unaware of their infection, 46 (34.4%) had a viral load >1000 copies/ml at diagnosis, 126 (96.9%) completed > 5 prenatal consultations, 1 (0.5%) declined antiretroviral treatment. At delivery, 18 (13.9%) mothers maintained a viral load > 1000 copies/ml, 128 (98.5%) underwent caesarean section, all received intravenous zidovudine. In neonates, 21 (16.2%) received triple therapy with AZT + 3TC + NVP for 6 weeks, 8 (6.2%) AZT for 6 weeks, and 101 (77.7%) AZT for 4 weeks. All babies completed their medication, 2(1.5%) had detectable viral load at 1 month. Up to 18 months, none received breastfeeding, 127 (97.7%) completed at least 14 consultations, 3 (2.3%) changed address. Overall, 4/127(3.1%) infants were identified as infected by serology.
Conclusions/Learning Points: Despite antiretroviral treatment in the mother, 34% had > 1000 copies/ml at the time of delivery. Universal HIV testing, earlier recruitment during pregnancy, adherence to ARV treatment in mothers and avoiding loss of follow-up in infants represent opportunities for intervention.

Backgrounds: Neonatal herpes simplex virus (NHSV) infection, although rare, is related to high rates of morbidity and mortality. The reported incidence of NHSV from several countries around the world varies widely between 1.6 and 60/100,000 live births. Previous data regarding NHSV Israeli epidemiology is limited, and reported an incidence rate of 8.4/100,000 live births. In the current study we aimed to expand our database to a nationwide level.
Methods: We included all Israeli neonates, born between 2015-2022, diagnosed with NHSV infection, causing any form of morbidity (localized to skin, eye and mouth (SEM)/ central nervous system (CNS) disease/ disseminated disease) and documented the clinical presentation, laboratory and imaging findings, treatment and long-term complications.
Results: To date we have received data from 15 out of the 22 Israeli paediatric wards medical centres, and 68 neonates have been included in the study. The mean incidence of NHSV was 7.5/100,000 live births. 50/68 (73.5%) were male, 65/68 (95.6%) were term newborns, with the majority born by vaginal delivery (88.2%). Mean age at diagnosis was 14±6.7 days, 34/50 (68%) of males went through ritual circumcision 7.65±4.5 days, on average, before clinical presentation. Intrapartum maternal fever was reported in 3 mothers and 1 mother had active genital herpetic lesions during labor. HSV1 was much more common than HSV2 as the detectable infectious agent (64/68, 94.1%); 52/68 (76.5%) presented with SEM disease, 19/68 (27.9%) were admitted to intensive care units, 5/68 (7.4%) experienced neurological deficits and 4/68 (5.9%) died.
Conclusions/Learning Points: SEM disease is the most common morbidity of postnatal NHSV infection, the incidence of HSV1 infection is higher than that of HSV2, and the majority of treated neonates did not suffer from long term complications.

PV0347 / #1395

CONGENITAL CYTOMEGALOVIRUS PRESENTS DIFFERENTLY IN PRETERM INFANTS

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Ekaterina Gritsay[1], Yury Petrunin[2], Helen Payne[3], Sunit Godambe[4], Hermione Lyall[5]
[1]Queen Elizabeth Hospital, Paediatrics, London, United Kingdom, [2]The Royal London Hospital, Neonatal Intensive Care, London, United Kingdom, [3]Imperial College Healthcare NHS Trust, Imperial College Healthcare Nhs Trust, London, United Kingdom, [4]Imperial College Healthcare NHS Trust, Neonatal Intensive Care, London, United Kingdom, [5]Imperial College Healthcare NHS Trust, Paediatric Infectious Diseases, London, United Kingdom

Backgrounds: Congenital cytomegalovirus (cCMV) is the most common congenital viral infection in the world. It is symptomatic in 10-15% of infected infants and is associated with sensorineural hearing loss and neurodevelopmental abnormalities. In the UK, the incidence of cCMV is higher in preterm infants, who have been shown to frequently have poor outcomes. However, clinical manifestations of cCMV in neonates born before 32 weeks gestation have not been explored.
Methods: Infants with cCMV born before 32 weeks gestation were identified through targeted screening on admission to neonatal intensive care units or referred to tertiary paediatric infectious diseases services between February 2015 and October 2022. We performed a retrospective analysis of their electronic patient records to describe clinical, laboratory and imaging manifestations of cCMV.
Results: We identified 14 infants (median gestation 27+5, median birth weight 952.5g). All were symptomatic and received treatment. Head circumference below the third centile was documented in 73% (8/11). 79% (11/14) required red cell transfusion at a median age of three days. All infants with documented platelet counts (13/13) had thrombocytopenia (<150,000/microL) with a median onset of 10 days of age. 62% (8/13) required platelet transfusion. Serum viral loads were recorded in nine patients and peaked at the median age of nine days. 78% (8/9) had germinal matrix or grade 2 intraventricular haemorrhages on cranial ultrasound. 21% (3/14) had periventricular calcifications. MRI brain was abnormal for gestation in 80% (8/10) of infants.
Conclusions/Learning Points: In contrast to term infants, cCMV in preterms mainly presents with symptomatic disease, difficult to distinguish from other manifestations of prematurity (emphasizing the importance of targeted screening). These include microcephaly, severe thrombocytopenia, anaemia, intraventricular haemorrhages on cranial ultrasound and abnormal brain MRI findings.

CONGENITAL SYPHILIS IN BRAZIL – THE CLINICAL MANIFESTATIONS AND SEQUELAE

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Marcia Sampaio[1], Barbara Amaral[1], Cristina Hofer[2]
[1]HGNI, Pediatrics, Rio de Janeiro, Brazil, [2]IPPMG - UFRJ, Infectious Diseases, Rio de Janeiro, Brazil

Title of Case: Congenital syphilis in Brazil – The clinical manifestations and sequelae
Background: In Brazil, the congenital syphilis (CS) is an important public health problem, with high prevalence and morbidity, mainly in socioeconomical vulnerable population. Children with CS must be followed for two years.
Case Presentation Summary: Objective: Describe the follow up and findings in a cohort study of CS in Rio de Janeiro. Methods: Prospective cohort study of infants born with CS, we excluded infants with metabolic diseases or congenital malformations (not related to CS) and infants treated after one year of age. The follow up was:monthly in the first 6 months of age, bimonthly in the subsequent 6 months, and every 3 months in their second year of life. They must have two non-reactive non-venereal test and one venereal test performed after 18 months of life. They also must have at least evaluations with a neurologist, ophtalmologist and audiologist. Results: 70 infants were followed up. Their median age at enrollment was 2 months, 51% were girls, 79% were asymptomatic at birth, 97% were treated in the maternity. During their antenatal care, 96% had antenatal care, 42% initiated the antenatal care after the first trimester of pregnancy, and 97% of their mothers performed at least one syphilis serology test during the antenatal care. Among the 70 children, 8 (11%) presented at least one abnormality in the follow up: neurology – 3 had delayed neurodevelopment exam, 4 had abnormalities in the ophthalmology evaluation (strabismus, retina and iris coloboma, increased pigmentation around maculae, and increased vascularization), one child presented with abnormal PEATE.
Learning Points/Discussion: Although most of the children with CS were born asymptomatic, they still presented several abnormalities during their follow up.

[1]IPPMG - UFRJ, Infectious Diseases, Rio de Janeiro, Brazil, [2]Universidade Federal do Rio de Janeiro, Ippmg, rio de janeiro, Brazil

Backgrounds: In Rio de Janeiro, the second largest city in Brazil, there was no reference center for congenital infections (CI). We intend to describe the implementation of such a center at Instituto de Puericultura e Pediatria Martagão Gesteira – Universidade Federal do Rio de Janeiro (IPPMG-UFRJ).
Methods: At IPPMG-UFRJ, In the CI Unit, infectious diseases specialists for pregnant women and children work together, patients were referenced from primary health units. This service plays a leading role in this Unit, receiving children to be screened and treated. The other services that are included in this Unit are: audiology, ophthalmology, neurology, neurodevelopment, and radiology. A specific electronic medical record was created for both women and children putting together all respective data providing a dataset for research initiatives.
Results: Since April, 2022 we followed 140 women living with HIV: their average age was 26 years; 41 were antiretroviral naïve, and 11 were infected through vertical transmission. 85/121 had viral load undetectable at 34 weeks of gestation. We also followed up 46 HIV exposed but uninfected infants, and 4 were HIV infected. Ninety-one pregnant women were followed with Toxoplasma gondii infection: in 10 amniocentesis was performed; in one PCR was positive for T. gondii. We followed 28 children in utero exposed to T. gondii, six of them were infected (4 chorioretinitis, 4 CNS abnormalities, and two with IgM/PCR reactive). We also followed 4 pregnant women and three neonates with cytomegalovirus infection, and two pregnant women living with HTLV-1 virus.
Conclusions/Learning Points: We believe that is important to build reference centers projected to deal with complex and multidisciplinary care required diseases as CI. It may be an excellent platform to support research, including clinical trials.

EARLY – ONSET NEONATAL INFECTION IN PREGNANCIES WITH PRELABOR RUPTURE OF MEMBRANES IN GENERAL HOSPITAL, KUMANOVO

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Aleksandra Hristova
General Hospital, Neonatology, Kumanovo, North Macedonia

Background: Perinatal infections are one of the main causes of early neonatal morbidity and mortality. PROM is condition linked to early–onset of neonatal infection. PROM refers to the rupture of the chorioamniotic membranes prior to onset of labor and prior to onset of clinically-apparent labor contractions. PROM can occur at any gestational age, before or after 37 weeks of gestation.
Methods: We performed a descriptive analysis of 72 pregnant women presenting to Department of Obstetrics in General Hospital Kumanovo from 01 January 2022 till 31 December 2022 with PROM who gave birth to single newborns within 72 hours after PROM. The data we used was collected from the newborn medical history. Data included gestational age at birth, gestational weight at birth, 1 and 5 minute APGAR score, interval from PROM to delivery and early neonatal infections morbidity.
Results: The analysis included 72 pregnant women with PROM and their newborns. The majority were aged between 20 and 30 years old (63,8%), primiparous (50,4%), unemployed (90,2%), completed secondary level of education (93,05%), newborns with EONI (15,2%), preterm newborns (5,5%), SGA (11,1%).
Conclusions/Learning Points: The rate of EONI in pregnancies complications attributed to PROM is still a major challenge in our department and city. Risk factors for developing EONI in pregnancies associated with PROM are: PROM–delivery interval, SGA, preterm newborn, maternal colonization and low APGAR score. Further steps to be undertaken include revision and improvement of antenatal care and prophylactic use of AB in PROM.

[1]Okinawa Prefectural Nanbu Medical Center and Children's Medical Center, Pediatrics, Okinawa, Japan, [2]Okinawa Prefectural Nanbu Medical Center & Children's Medical Center, Division Of General Pediatrics, Department Of Pediatrics, Okinawa, Japan, [3]Okinawa Prefectural Nanbu Medical Center & Children's Medical Center, Division Of Pediatrics Infectious Diseases, Department Of Pediatrics, Japan, Japan

Title of Case: A NEONATAL CASE OF DEEP NECK AND MEDIASTINAL ABSCESSES CAUSED BY ROTHIA MUCILAGINOSA
Background: Rothia mucilaginosa, which commonly found in the oral cavity, is a coagulase-negative gram-positive coccus and rarely causes bacteraemia and endocarditis in immunocompromised patients. Usually, vancomycin is recommended as empiric therapy. In neonates, cases of non-postoperative mediastinal abscesses are rarely seen, with only four cases were previously reported.
Case Presentation Summary: An eight-day-old infant presented to our emergency department with breathlessness, decrease in suckling activity, and fever. Physical examination revealed he had stridor, and the computed tomography scan showed airway compression because of right deep neck and mediastinal abscesses. The patient was intubated, and abscess drainage was performed. Gram stain of abscess aspirates showed clustered gram-positive cocci, thus intravenous vancomycin was initiated. Subsequently, Rothia mucilaginosa and Streptococcus mitis/oralis were detected. The antibiotic was changed to oral clindamycin on day 32 of hospitalization, and he was discharged. When the patient was 54 days old, the discharge of pus ceased, and clindamycin was discontinued. However, when the patient was 9 months old, the right cervical abscess recurred. Blood tests showed a normal immune response, and fistulography revealed the presence of a right pyriform sinus fistula. It was removed by surgery when the patient was 11 months. After the surgery, recurrence of the abscess was not observed.
Learning Points/Discussion: The bacteria originating in a neonate's oral cavity are generally gram-positive; infections caused by some species such as R. mucilaginosa necessitate vancomycin therapy. Paediatricians should consider mediastinal abscesses when treating neonates with fever and stridor. Additionally, confronting to rare infectious diseases in neonates, it is crucial to investigate the cause of infection; not only immunity but also congenital structures.

Title of Case: CONGENITAL STAPHYLOCOCCAL SCALDED SKIN SYNDROME (SSSS) IN A PRETERM INFANT: WHAT DO YOU NEED TO KNOWN
Background: SSSS is a condition of the skin characterized by blistering and epidermal peeling. It could be life-threatening in extremely preterm.The aim is to describe a case of congenital-SSSS in a preterm infant within the first 24 hrs.of life.
Case Presentation Summary: Preterm neonate, 29-weeks of gestation, whose mother presents 24 hrs. of rupture of membranes and chorioamnionitis. A 1,227g infant was delivered vaginally. Intubated for surfactant administration, admitted to NICU, and started on ampicillin-gentamicin. Laboratory examinations at 12 hrs. showed leukopenia (4580/µl) and C-reactive protein elevation (58 mg/L). At 17 hrs. of life diffuse erythroderma and perioral blisters develop, followed by bullous lesions on palms and soles, upper chest and lower neck. The bullae subsequently ruptured leaving erythematous and denuded areas of the skin (positive Nicolsky sign). Clinical diagnosis of SSSS was made, and IV oxacilin-vancomicyn was added. Blood and wound culture were positive to methicillin-sensitive S.aureus. HSV1-2 PCR on blood and skin, Varicella-Zoster PCR of skin and Treponemal test were all negative. No new lesions appeared after starting antibiotics. On day 3 of life, epithelialization began and was complete on the seventh day. The infant died 9 days after birth because of S.aureus pneumonia and respiratory failure.

Learning Points/Discussion: Congenital SSSS has been reported in few cases in preterm infants. Diagnosis is based on clinical findings, histology and isolation of S.aureus. Differential diagnosis includes: toxic epidermal necrolysis, epidermolysis bullosa, neonatal pemphigus, bullous mastocytosis, and infectious diseases like bullous impetigo, congenital syphilis or herpes. It is important an early clinical suspicion and antibiotic therapy because it´s a serious and occasionally fatal disease in neonates, with risk of nosocomial spread.

OPTIMIZING CONGENITAL CMV (CCMV) DETECTION BY POOL TESTING IN SALIVA SAMPLES: LABORATORY VALIDATION OF A RAPID DIAGNOSTIC MOLECULAR TEST.

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Giannina Izquierdo[1,2], Leonel Villavicencio[3], Mauricio Farfan[1], Felipe Tarque[3], Luisa Montecinos[3], Jocelyn Mendez[4], Carolina Guerra[2], Leslie Araya[1,2], Roberto Reyes[2], Belen Sepulveda[5], Pamela Medina[2], Juan Pablo Torres[1,6]
[1]Faculty of Medicine, Universidad de Chile, Department Of Pediatrics, Santiago, Chile, [2]Hospital Barros Luco Trudeau, Neonatal Intensive Care Unit, Santiago, Chile, [3]Hospital Lucio Cordova, Molecular Biology Laboratory, Santiago, Chile, [4]Hospital Luis Calvo Mackenna, Molecular Biology Laboratory, Santiago, Chile, [5]Hospital Exequiel González Cortés, Infectious Diseases Unit, Santiago, Chile, [6]Hospital Luis Calvo Mackenna, Infectious Diseases Unit, Santiago, Chile

Backgrounds: Universal cCMV screening is increasingly recommended. Saliva is an easy-to-get sample for CMV testing and some rapid molecular diagnostic techniques have shown high sensitivity-specificity in newborns. Our aim was to correlate the performance of a rapid molecular CMV test with CMV-PCR detection in saliva pools from newborns under a cCMV universal screening strategy.
Methods: From September 2022, saliva swabs were prospectively collected from newborns <21 days old at Hospital Barros-Luco, Santiago, Chile and tested by Alethia-LAMP-CMV assay in pools of 5 samples. In positive pools, the samples were tested individually with both, Alethia-LAMP-CMV assay and saliva CMV-PCR. A subset of negative pools and their individual samples were also studied with both techniques. Positive cases were confirmed by urine CMV-PCR.
Results: Eight-hundred ninety eight out of 1231 (73%) newborns were included in the study; 180 pools were screened. All but one pool were negative. The positive pool was verified by saliva PCR, and the positive individual sample was identified by both techniques and confirmed by positive urine CMV-PCR (Cycle threshold in saliva PCR was 31.3). A subset of 17 negative pools (85 samples) were studied by saliva PCR, obtaining a 100% of concordance. No false-positive results were observed. In an additional subset of 42 newborns with cCMV risk factors, the pool testing, individual Alethia-LAMP-CMV assay, and urine PCR were negative. The prevalence of cCMV was 0.1%.
Conclusions/Learning Points: CMV pool-testing by a rapid molecular test in saliva was feasible to perform in newborns under a universal screening . A high concordance was observed in negative samples and also in the positive cCMV-case. This strategy could be a new and more cost-effective alternative for cCMV neonatal screening specially in low-prevalence settings.

[1]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [2]Santa Casa de São Paulo, Department Of Pediatrics, Sao Paulo, Brazil

Title of Case: Systemic bevacizumab as adjuvant therapy for recurrent respiratory papillomatosis in children: a series of four cases
Background: Recurrent respiratory papillomatosis (RRP) is a rare disease form caused by human papillomavirus (HPV) characterized by recurrent papilloma growth at the epithelial mucosa in the respiratory tract. It represents the most common benign neoplasm of the larynx and central airways, but it significantly impacts the quality of life and is potentially fatal. We describe our experience with systemic bevacizumab (Avastin®), a humanized anti-VEGF monoclonal antibody, as adjuvant management of RRP.
Case Presentation Summary: Four patients with RPP that used bevacizumab as therapy in 2021-2022 were included. The majority were boys (75%), and the age range varied from 2-5 years old. All presented with laryngeal stridor, dysphonia, and dyspnea at diagnosis. In three patients, at least five surgical removals were necessary before adjuvant therapy – a single child required just one surgery, but the lesions were extended to the esophagus. Papillomas were identified in the trachea in 75% of the cases, all requiring tracheostomy. Children received a 5 mg/kg starting dose that increased to 10 mg/kg cycles every 4 weeks, with good tolerance and no adverse events. Half of the patients had no lesions at bronchoscopies after the third dose, and the remaining improved after the fourth cycle. The esophageal papilloma disappeared after five doses. Tracheostomy decannulation was achieved in 50% of the cases. Two patients finished ten cycles in one year, and the other two were treated for six months. No recurrences were detected until January 2023.
Learning Points/Discussion: Bevacizumab is a promising treatment for RRP, as it might reduce surgical procedures and lead to prolonged remission. Further studies are necessary to define efficacy and safety of this drug.

TRANSAMINASEMIA DUE TO CONGENITAL CYTOMEGALOVIRUS INFECTION (CCMV): EXPERIENCE FROM A TERTIARY REFERRAL CENTER FOR CONGENITAL INFECTIONS

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Sofia Karagiannidou, Garyfallia Syridou, Ino Kanavaki, Angeliki Tzaki, Artemis Mavridi, Afroditi Kourti, Smaragdi Fessatou, Vassiliki Papaevangelou
"ATTIKON" UNIVERSITY HOSPITAL, Third Department Of Pediatrics, ATHENS, Greece

Backgrounds: Congenital Cytomegalovirus infection (cCMV), the most common congenital infection in the developed world, presents with various clinical features. Transaminasemia due to cCMV, although self-limiting, defines one as symptomatic, thus guiding the therapeutic decision. We aimed to estimate the prevalence of transaminasemia affecting the cCMV infants followed-up by our center, as well as to reveal possible related risk factors.
Methods: A retrospective observational study was performed. Neonates/infants with confirmed cCMV that were followed-up at the Pediatric Infectious Disease Unit of “Attikon” University Hospital (Athens, Greece) during the last decade (06/2012 – 01/2023), and for which hepatic enzyme values were available at diagnosis (before treatment initiation), were eligible. Transaminasemia was defined as AST>80 IU/ml +/- conjugated hyperbilirubinemia (>2mg/dl). Demographic, somatometric, and clinical characteristics [sex, gestational age, birth weight, head circumference, trimester of cCMV diagnosis, maternal therapy, presence of sensorineural hearing loss (SNHL), thrombocytopenia, neutropenia, abnormal brain ultrasound/MRI findings] were recorded.
Results: 66 cCMV babies were included, 28/66 (42.4%) male. Transaminasemia occurred in 8/66 babies (12.1%), and was the only clinical sign that led to cCMV diagnosis for one baby. Median (range) age at transaminasemia diagnosis was 5 days (0-108), median (range) AST was 109.5 IU/ml (84-315), and median (range) direct bilirubin was 0.6 mg/dl (0.13-5.02). Transaminasemia affected 8/52 (15.4%) of the symptomatic and 2/7 (28.6%) of the severe symptomatic babies. By univariate analysis, transaminasemia was correlated with the presence of SNHL at birth (p=0.04), and thrombocytopenia (p=0.012). All of our transaminasemia cases were self-limiting.
Conclusions/Learning Points: According to our results, cCMV transaminasemia is relatively frequent, affecting >1/10 babies, and also related to factors stating illness severity (SNHL, thrombocytopenia). Future multicenter studies are required, in order to confirm/extend those results.

ESCHERICIA COLI MENINGITIS AND PACHYMENINGITIS IN A NEWBORN :TREATMENT CHALLANGES

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Evelina Kreko, Guriel Nasto, Alketa Hoxha
University Hospital of Obstetrics and Gynecology Koco Gliozheni t, Pediatric, Tirana, Albania

Title of Case: ESCHERICIA COLI MENINGITIS AND PACHYMENINGITIS IN A NEWBORN :TREATMENT CHALLANGES

Background: Escherichia coli is a frequent cause of early onset sepsis among infants . Over the past decades, ampicillin and gentamicin/ESC are the empirical antibiotics for early-onset infection in neonates the majority of the neonatal intensive care units in Albania. However, most of the E. coli isolates remained susceptible to aminoglycosides and extended spectrum cephalosporins (ESC).Currently, extended-spectrum β-lactamases (ESBLs) are becoming an increasingly important cause of resistance to aminoglycosides and ESC in E. coli.

Case Presentation Summary: In this case report, we describe the history of a moderately preterm boy born after preterm prolonged rupture of membranes. The mother had urinary tract infections during pregnancy.Imediately after birth he was given first-line therapy for prevention of early onset sepsis. The 5^{th} day of life the clinical situation deteriorated , he developed seizures, high grade fever . The treatment was changed to cover suspected meningitis. Culture showed growth of E. coli in cerebrospinal fluide,but unable to detect the strain and the sequence type. Antibiotics were adapted.The MRI resulted left temporal subdural Pachymeningitis(Fig.1,2) .His clinical condition improved the first 3 days ,but the laboratory tests delayed and were back to normal rates only after a 6 week course of different antibiotics adopted according to antibiogram. The boy left the hospital in good condition, but in need of close follow up of his neurological and physical development .

Learning Points/Discussion: Our case confirms the emergence of E. coli as a problem not only in adults but also in neonates. Establishing an early diagnosis by care providers along with prompt deliverance of effective treatment would result in a better outcome.

PSEUDOPARALYSIS OF PARROT- FORGOTTEN PAST? FOXING PRESENT?

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Pramod Kulkarni
KEM Hospital Research Centre Pune, Pediatrics, PUNE, India

Title of Case: Pseudoparalysis of Parrot, known yet missed presentation of congenital syphilis.
Background: Vertical transmission of Treponema Pallidum can result in congenital syphilis- a multisystem disease with protean manifestations. Universal antenatal screening, effective penicillin therapy & lack of clinical awareness ,experience of new generation pediatricians have made congenital syphilis a rarely considered differential diagnosis in recent era. Last decade has seen global re-emergence of congenital syphilis for various reasons. The presentation of congenital syphilis can be masquerading many infective & non infective conditions posing diagnostic challenge.
Case Presentation Summary: Master "A", 3 month old male infant was referred for inability to move & pain on handling of both upper limbs since 4days Pediatric Hematology ,neurology & orthopedic expert consult & investigations were inconclusive. This 38weeker 3,6kg BW boy was growing well without any concerns. Mother had negative VDRL at 12 weeks of gestation. Physical examination- afebrile, responsive, alert infant with stable vitals and normal growth & development. Pallor, enlarged axillary & right trochlear lymph node, hepatosplenomegaly notable. Hypotonic severe weakness of both upper limbs, hyporeflexia and non localized tenderness was only neuro deficit. Hb- 9, normocytic-chromic anemia, TWBC-15620/cmm, P-23, L71. E 1, M5, platelets-3,93L/cmm, MRI neck & spine - cervical, axillary lymph nodes, bilateral mastoid fluid. normal CSF & Bone marrow reports. Serum & CSF VDRL & TPHA were positive as were both parents. Child recovered with IV Penicillin therapy over 10days.
Learning Points/Discussion: Pseudoparalysis of Parrot is a well knownyet uncommon presentation of early onset congenital syphilis. Syphilis is now a less seen & clinically considered infection in infants, particularly with effective universal Antenatal screening & easy penicillin therapy. Syphilis acquired in late pregnancy can be missed and carries high vertical transmission risk to affect young infants & a diagnostic c dilemma for pediatricians.

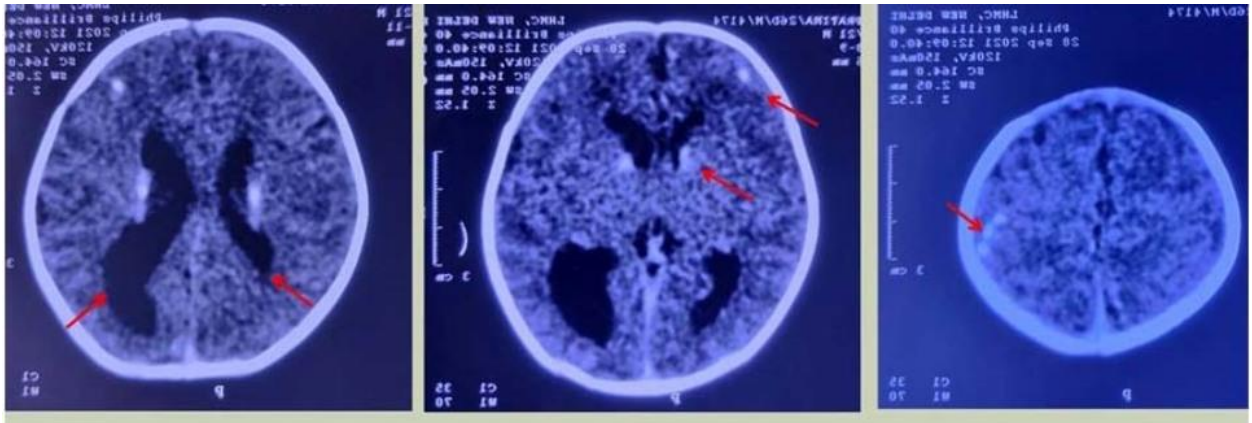
CONGENITAL TOXOPLMOSIS: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

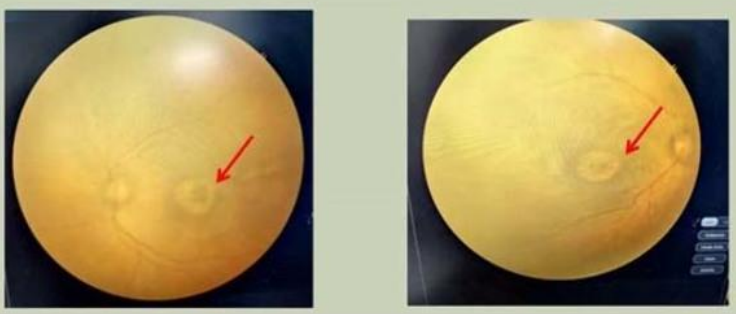
Ajay Kumar, Shikha Khandelwal, Sushma Nangia
Lady Hardinge Medical College and Assoc. Kalawati Saran Children Hospital, Neonatology, Delhi, India

Title of Case: CONGENITAL TOXOPLMOSIS: A CASE REPORT
Background: Severity of Congenital Toxoplasmosis may vary from fetal demise to post-natal asymptomatic course to severe eye and CNS involvement. We present a case of congenital toxoplasmosis in one of the surviving twin.
Case Presentation Summary: A 34+2 week, 1600 gm, SGA, male, IVF conceived, Twin A of DADC twins was delivered by Cesarean Section (Indication: abnormal Doppler). Mother was 25 years Primi with uneventful pregnancy (Toxoplasma screen during infertility work up was negative). At 30 weeks of pregnancy demise of one of the twin was detected. Baby was admitted for prematurity, low birth weight and respiratory distress. Liver was palpable 3cm and spleen 1 cm below costal margin. On D11 of life there was clinical worsening with increase in hepatosplenomegaly. CSF: 51 cell/cubic mm (95% lymphocytes), normal biochemistry. Blood and CSF culture were sterile. Liver function and kidney function tests were normal. Toxoplasma serology was IgM positive. CSF PCR was also positive. Mothers Toxoplasma IgG and IgM was positive. Eye examination revealed focal chorioretinitis. CT head showed enlarged lateral ventricles and multiple calcifications (Fig). Baby was started on Sulfadiazine, Pyrimethamine and Folinic acid. One weak latter baby developed neutropenia which did not respond to increase in dose of Folinic Acid and required cessation of treatment for 2 weeks. Baby has now completed one year of anti-Toxoplasma treatment and is well.



CECT brain: B/l lateral ventricles enlarged (left> right) with grossly normal 4th ventricle, multiple chunky calcifications in cortical , subcortical and periventricular region in bilateral cerebral hemisphere with ventriculomegaly. Findings are consistent with congenital toxoplasmosis.

- Ophthalmology evaluation after 2weeks of treatment- no active lesion, b/l macular scarring present.



Learning Points/Discussion: Toxoplasma surveillance should be performed in all trimesters of pregnancy to reduce mother to child transmission. Close monitoring for medication toxicity, therapeutic response and disease recurrence is critical. Neutropenia is known side effect and mostly due to Pyrimethamine. It is preferable to use first line treatment as it is the only treatment that has been shown to be effective.

ONLINE CME EFFECTIVELY IMPROVES PEDIATRICIANS CLINICAL KNOWLEDGE AND CONFIDENCE RELATED TO CYTOMEGALOVIRUS

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Amy Larkin, Iwona Misiuta
Medscape Education, Medical Education Director, Newark, United States of America

Backgrounds: We sought to determine if an online continuing medical education (CME) series could improve the clinical knowledge and confidence of pediatricians related to cytomegalovirus (CMV).
Methods: 2 online, 30-minute panel discussions, with educational effects assessed for matched learners completing all pre/post questions. The McNemar's test assessed differences from pre to post ($P < .05$ are statistically significant). The activities launched in March and April, 2022, and data were collected for 3 months for each activity.
Results: Overall, 40%-46% ($P < .01$) of pediatricians demonstrated improvements Activity 1 (N=84) 27% improved at recognizing the burden of CMV ($P < .01$; 57% need additional education) 23% improved at selecting CMV acquisition risk reduction strategies ($P < .01$; 40% need additional education) 15% improved at identifying complications of congenital CMV ($P < .01$; 38% need additional education) 48% increased confidence at educating pregnant women about CMV risk reduction ($P < .01$), with an average confidence shift of +87% among those who improved Activity 2 (N=107) 21% improved at recognizing the lifecycle of CMV ($P < .05$; 38% need additional education) 16% improved at selecting factors associated with CMV seropositivity ($P < .05$; 36% need additional education) 14% improved at identifying common complications of CMV at birth ($P < .01$; 36% need additional education) 45% increased confidence at understanding of the role of CMV serostatus in pregnant patients ($P < .01$), with an average confidence shift of +69% among those who improved
Conclusions/Learning Points: This study demonstrates the success of an online, serial learning initiative at improving clinical knowledge and confidence of pediatricians related to CMV. Continued gaps were identified for future education.

MATERNAL CYTOMEGALOVIRUS REINFECTION AND VIRAEMIA DURING PREGNANCY AMONG WOMEN LIVING WITH HIV

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Ariane Larouche[1], Elisabeth Mcclymont[2], Hélène Côté[3], Fatima Kakkar[4], Deborah Money[5], Hugo Soudeyns[1], Soren Gantt[1], Isabelle Boucoiran[1]
[1]CHU Sainte-Justine, Women And Children Infectious Disease Center, Montreal, Canada, [2]University of British Columbia, Department Of Obstetrics And Gynecology, Vancouver, Canada, [3]University of British Columbia, Pathology And Laboratory Medicine, Vancouver, Canada, [4]Centre hospitalier universitaire Sainte-Justine, Division Of Infectious Diseases, Montreal, Canada, [5]Woman's Health Research Institute, Reproductive Infectious Diseases, Vancouver, Canada

Backgrounds: Congenital CMV (cCMV) is a leading cause of childhood neurodevelopmental complications and is more common in children born to women living with HIV (WLWH), even with effective antiretroviral therapy. Most cCMV occurs in children of women who were already CMV-seropositive before pregnancy. Reinfection with different CMV strains during pregnancy is associated with cCMV in HIV-negative women, but has not been characterized among WLWH.
Methods: To investigate CMV reinfection in CMV-seropositive pregnant WLWH from a prospective Canadian cohort, we used a strain-specific ELISA able to detect antibodies targeting glycoproteins gH and gB from 2 CMV strains (4 epitopes), comparing plasma from the first and third trimester of pregnancy. An antibody response targeting a new epitope in the third trimester not found in the first trimester was defined as reinfection. Maternal CMV viremia was quantified by plasma qPCR in each trimester, and cCMV was defined by positive saliva or blood qPCR within 3 weeks of life.
Results: Among 6 children with cCMV, at least 2(33%) of their mothers had reinfection during pregnancy. In contrast, none of the 24 mothers of children without cCMV tested so far had reinfection during pregnancy, even though 14 had CMV viremia. Notably, in the first trimester, 6/15(40%) WLWH with detectable viremia had antibodies to >2 epitopes versus 0% in non-viremic WLWH. Also, the strain-specific responses in non-viremic WLWH were solely restricted to gB epitopes.
Conclusions/Learning Points: CMV reinfection during pregnancy appears common among WLWH with cCMV-affected infants. Although reinfection was not found to be associated with CMV viremia, frequent responses to multiple CMV epitopes at baseline limit the ability to detect reinfection by strain-specific ELISA. As such, the development of more sensitive methods to detect CMV reinfection is needed.

Title of Case: ANTENATAL CONGENITAL INFECTIOUS SCREENING, CAN WE ALWAYS TRUST THE RESULT?
Background: Congenital syphilis is an emergent public health problem. Early diagnosis can be difficult due to its varied and unpredictable manifestations.
Case Presentation Summary: A 3-month-old female infant was referred to our institution due to severe hemolytic anemia and hepatitis. Family history and Pregnancy were unremarkable,with a negative third trimester non treponemal test. Apart from pallor, the mother denied fever,jaundice,bleeding,failure to thrive,or prostration. On admission the infant had a clear nasal discharge and hepatosplenomegaly. Blood work revealed nonimmune hemolytic anemia (Hb 4.4g/dL, reticulocytes 11%, total bilirubin 0,67mg/dL, LDH 508U/L, haptoglobin 158 mg/dL, negative coombs test) and thrombocytopenia (103.000/uL), mildly elevated C reactive protein (23mg/L), and schizocytes on morphology. Syphilis screening revealed a positive non-treponemal RPR test of 1:4 (maternal titer 1:8), but due to a high index of suspicion another sample was analyzed with a RPR titre of 1:1024. The infant's anti-treponemal IgM antibody was positive and the infant and maternal's TPHA tests were both reactive, supporting the diagnosis of congenital syphilis. Polymerase chain reaction test for Treponema pallidum was negative on infant's nasal secretions, blood and CSF. Furthermore, at Day 1 of treatment she developed thoracic vesicular lesions with shedding palmoplantar erythema and long simple x-ray showed bilateral periosteal reaction along the tibial diaphysis. Other infections and hemolytic anemia causes were excluded. The patient completed a 10-day-course of intravenous penicillin G, with a decrease in RPR titer and clinical improvement. Parents also received treatment.
Learning Points/Discussion: Negativity of prenatal screening or postnatal low titers should not exclude the diagnosis of congenital syphilis. Pursuing the diagnosis when there is a high index of suspicion by repeat testing is essential to provide treatment and prevent long-term complications.

CONGENITAL TOXOPLASMOSIS – RETROSPECTIVE STUDY OF 15 YEARS IN A TERTIARY CENTER

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Ana Losa[1], Indira Carvalho[1], Bebiana Sousa[1], Joanna Ashworth[1], Ana Guedes[2], Luísa Carreira[2], Liliana Pinho[2], Carmen Carvalho[2], Cristina Godinho[2]
[1]Centro Materno-Infantil do Norte, Centro Hospitalar Universitario do Porto, Pediatrics Department, Porto, Portugal, [2]Centro Materno-infantil do Norte, Centro Hospitalar e Universitário do Porto, Neonatology Unit, Neonatal And Pediatric Intensive Care Department, Porto, Portugal

Backgrounds: Congenital toxoplasmosis (CT) can cause disabling disease in the fetus or long-term sequelae, despite being mostly subclinical at birth, and is an important cause of chorioretinitis. Data on postnatal treatment are controversial and there is a lack of universal guidelines.
Methods: Retrospective study of newborns with suspected CT followed in the Neonatology Unit of a tertiary hospital between January 2007 and December 2021. Data were collected through patients' electronic clinical records.
Results: A total of 71 patients with suspected CT were included. During pregnancy 90.1% of the mothers underwent therapy and amniocentesis was performed in 52.1% and identified one positive PCR for T.Gondii. Most newborns were asymptomatic with normal laboratory work-up, ophthalmological and hearing screening. There was one case of hyperproteinorrachia and none had typical findings on neuroimaging. Fifty-seven patients started treatment: 42 spiramycin (74%) and 15 pyrimethamine, sulfadiazine and folic acid (P+S+FA); adverse effects were found in 11 cases and the most frequent was neutropenia. Three cases of CT were confirmed by serologies, corresponding to 4.2% of suspected cases and a prevalence of 0.4 per 10,000 births. All had normal clinical and laboratory exams and started treatment with P+S+FA fulfilling 12 months of therapy. During follow-up, none developed any long-term sequelae and all had normal psychomotor development.
Conclusions/Learning Points: The low incidence of CT in our study may be related to the decline in the prevalence of toxoplasmosis, as well as the effectiveness of measures to prevent primary infection in pregnancy and a well-established program of neonatal screening. In the future, new studies are needed to determine the effectiveness of postnatal treatment for asymptomatic cases in reducing the development of late sequelae.

CONGENITAL TOXOPLASMOSIS IN AN INFANT OF AN IMMUNE MOTHER

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Vitória Schinneider Muller[1], Júlia Machado[2], Wilson Hoshino[2], Aida De Fátima Gouveia[2], Fabiana Carmo[2], Kelly Cunegundes[2], Daisy Maria Machado[2], Maria Aparecida Ferrarini[2], Annelise Monteiro[3], Ana Isabel Monteiro[2]
[1]universidade federal de são paulo, Infectologia Pediátrica, São paulo, Brazil, [2]universidade federal de são paulo, Departament Of Pediatric Infectology, São paulo, Brazil, [3]Universidade de Santo Amaro, Medical College, são paulo, Brazil

Title of Case: CONGENITAL TOXOPLASMOSIS IN AN INFANT OF AN IMMUNE MOTHER
Background: Congenital toxoplasmosis has high mortality, high morbidity and can be avoided through primary prophylaxis for pregnant women such as hygiene habits and avoiding consumption of raw meat. This report aims to describe a case of congenital toxoplasmosis in a newborn with an immunocompetent mother previously immune to this condition.
Case Presentation Summary: 35 years old woman, 4th pregnancy, with gestational diabetes in need of insulin treatment. Serology of the last pregnancy and collected at first and third quarter of current pregnancy showing IgG + and IgM - for toxoplasmosis. Cesarean section was indicated due to acute fetal distress. Female preterm newborn, 33 weeks, adequate for gestational age, apgar 9/10. Eye screening was performed into the newborn, with an absent red eye reflex bilaterally and heel prick test showing IgM + for toxoplasmosis. After, a new serology test confirming the finding with IgM and IgG +. Treatment was initiated with Sulfadiazine, Pyrimethamine, Folinic acid and Prednisolone. Initially, the eye physical exam showed bilateral chorioretinitis. One month later, both eyes presented a large scar on the posterior pole with vitreous beam and pale optic nerve. Ocular US was performed with diameters below normal limits in both eyes. Left eye Membrane echo was suggestive of retinal detachment. Brain TC in the 3rd month showed bilateral calcifications in the cerebral parenchyma.
Learning Points/Discussion: Despite being a rare event, vertical transmission of toxoplasmosis can occur in immunocompetent pregnant women who are previously immune, probably to maternal disease reactivation or new infection with different strains of T. gondii. This makes it necessary to review the concept of immunity in toxoplasmosis during pregnancy and expand the guidelines for prenatal prevention.

CYTOMEGALOVIRUS INFECTION AND NEWBORNS: DIAGNOSIS OF CONGENITAL INFECTION USING SALIVA

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Elsa Machado Guimarães[1], Gina Marrão[2], João Agro[1]
[1]Centro Hospitalar de Leiria, Pediatrics, Leiria, Portugal, [2]Centro Hospitalar de Leiria, Microbiology, Leiria, Portugal

Backgrounds: Cytomegalovirus (CMV) is the most frequent cause of congenital infection. CMV can be tested in both urine and saliva. Even though saliva testing is more accessible, a higher number of false positives (FP) has been described.
Methods: We conducted a retrospective study of all the saliva and urine polymerase chain reaction (PCR) tests performed in newborns to detect CMV, between July 2016 and November 2022. Our goal was to calculate de positive (PPV) and negative (NPV) predictive values of CMV testing in saliva at a peripheral hospital.
Results: 316 newborns underwent both saliva and urine CMV testing. 9 were positive in at least 1 of the tests, 1 was exclusively positive in urine, 4 were positive in saliva and 4 in both tests. Significant differences were found between the viral load of FP and true positives (TP). (p=0.029) Our PPV was 50% and NPV was 99.7% using urine testing as the gold-standard.
Conclusions/Learning Points: In our study, the NPV of saliva testing excludes, most of the times, CMV infection. FP in urine are associated to contamination of saliva samples with breastmilk and genital tract secretions or non-sterile urine samples. The viral load value could be used to distinguish FP from TP. However, viral-shedding is yet not fully understood and highly variable. This variation could be explained by the timing of infection (maternal primary infection, reinfection and reactivation) or strain variation. Therefore, false negatives can be found in urine and saliva. Congenital CMV infection can be diagnosed using saliva and urine samples, but a confirmatory test is needed. In the future, a deeper understanding of viral-shedding might simplify the process of congenital CMV infection diagnosis.

URINARY TRACT INFECTIONS IN NEONATES IN COMPARISON WITH OLDER CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Emmanouela Maltezaki[1], Maria Bitsori[1], Eleni Vergadi[1], Sofia Maraki[2], Eleftheria Hatzidaki[3], Emmanouil Galanakis[1]
[1]Heraklion University Hospital, Department Of Paediatrics, Heraklion of Crete, Greece, [2]Heraklion University Hospital, Department Of Clinical Microbiology, Heraklion of Crete, Greece, [3]Heraklion University Hospital, Department Of Neonatology, Heraklion of Crete, Greece

Backgrounds: Urinary tract infections (UTIs) in neonates have not been studied extensively and therefore neonates are not included in common guidelines. In this study we investigated the differences of UTIs in neonates as compared to older children.
Methods: Neonates (0-28 days old) hospitalized for UTI over a 13-year period (January 2008 – December 2020) were compared with children older than 29 days hospitalized for UTI at the same period. Comparative univariate analysis among groups and logistic regression models for pathogen prediction in each group were performed.
Results: The study included 98 neonates (median age, 15 days) and 777 children > 29 days (median age, 0.6 years). Neonatal UTIs were all first episodes, 43.8% were nosocomial and 36.7% presented with non-suggestive of UTI symptoms. Compared to older children, neonates had higher male-to-female ratio (81.6% vs 44.4%, p<0.0001), less commonly vesicoureteral reflux (VUR) (13.3% vs 23.9%, p=0.023) and more frequently non-E. coli pathogens (61.2% vs 33.1%, p<0.0001), especially neonates born with Caesarian section compared to those born with vaginal delivery (58.2% vs 41.8%, p=0.01). UTIs due to Klebsiella spp were more prevalent in neonates (42.8% vs 10,4%, p<0.0001). The only predictive variable of non-E. coli pathogens in neonates was the type of delivery whereas in older children non-E. coli pathogens were associated mostly with male gender, urinary tract abnormalities and previous exposure to antibiotics.
Conclusions/Learning Points: Neonatal UTIs differ from UTIs in older children in terms of uropathogens' profile, clinical presentation and risk factors and are mainly associated with perinatal factors. These findings may contribute to formulation of guidelines for the neonatal period and the very early infancy.

[1]University Children's Hospital Zurich, Infectious Diseases And Hospital Epidemiology, Zurich, Switzerland, [2]Triemli Hospital Zurich, Department Of Paediatrics, Zurich, Switzerland, [3]University Hospital Zurich, Department Of Neonatology, Zurich, Switzerland, [4]Cantonal Hospital Winterthur, Paediatric Infectious Diseases, Department Of Paediatrics, Winterthur, Switzerland, [5]University Children's Hospital Zurich, Paediatric Skin Centre, Department Of Dermatology, Zurich, Switzerland, [6]Geneva University Hospitals, Department Of Dermatology And Venereology, Geneva, Switzerland, [7]Federal Office of Public Health, Transmissible Id, Bern, Switzerland, [8]University Hospital Zurich, Department Of Dermatology, Zurich, Switzerland

Background: We previously reported a re-emergence of syphilis from 2006–2009 with detection of congenital syphilis in Switzerland. This study aimed to reassess the incidence of children with exposure to maternal syphilis during pregnancy and congenital syphilis in a following 10-year period in the canton of Zurich, the epidemic hotspot for syphilis in Switzerland.
Methods: Children were identified both by reviewing medical records at the four major neonatal and paediatric hospitals providing acute care in the canton of Zurich and by the serologic database of the syphilis reference laboratory. Inclusion criteria for children were (a) date of birth from 2010–2019, (b) place of birth in canton of Zurich, (c) evaluation for syphilis due to positive syphilis pregnancy screening, and (d) age <1 year. Results were compared with epidemiological data provided by the Federal Office of Public Health (FOPH).
Results: We identified and evaluated 17 children after potential exposure to maternal syphilis. Residual antibodies of a past infection were found in 11 mothers. Six children were identified as having had real exposure to asymptomatic maternal syphilis. The distribution of the cases followed a similar pattern as confirmed syphilis cases in women of childbearing age reported to the FOPH. No case of congenital syphilis was observed.
Conclusions/Learning Points: In contrast to the rise in syphilis infections, this study identified no case of congenital syphilis in the canton of Zurich, Switzerland, from 2010–2019. Syphilis pregnancy screening prevented congenital syphilis by diagnosing and allowing adequate treatment of asymptomatic maternal syphilis.

PREVENTING VERTICAL HEPATITIS B TRANSMISSION: A FIVE-YEAR OVERVIEW OF A UK FAMILY HEPATITIS CLINIC

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Lizzie O'Mahony[1], Caroline Foster[2], Ashley Brown[3], Sophie Raghunanan[3]
[1]Chelsea and Westminster Hospital, Paediatrics, London, United Kingdom, [2]Imperial College, Paediatric Infectious Disease, London, United Kingdom, [3]Imperial College, Paediatrics Infectious Disease, London, United Kingdom

Backgrounds: The WHO estimate 3.5% of the population live with hepatitis B (HBV); migrants to Europe being disproportionately affected. UK infant HBV vaccination begins from 8 weeks, with birth dose limited to infants born to women living with HBV (WLHBV). High risk infants (prematurity, high maternal viral load) also receive HBV immunoglobulin (HBIG). The Family Clinic follows up infants and WLHBV working towards WHO goals of combating viral hepatitis by 2030.
Methods: A single centre electronic note review of outcomes for infants born to WLHBV (2016-2020).
Results: 271 infants, 140 (52%) female, 71% born to first generation migrants (0.3% UK-born mothers, 28% unrecorded) born to WLHBV were referred. 216 (80%) attended follow-up with a vertical transmission rate of 0%. 22 (8%) WLHBV received third trimester tenofovir disoproxil fumerate (TDF); median viral load (VL) at initiation 125,416,376 DNA c/ml- one having birth VL. 31 (11%) infants received HBIG; 10 (32%) were lost to follow-up, compared to 46 (19%) low risk infants. 246 (90%) had birth dose vaccination documented and 210 (77%) received at least 4 doses. 227 (83%) infants had serology by 24 months; 209 (92%) HBsAb >100 and 167 (73%) >1000. 7.3% (20) required repeat serology due to persistent maternal core antibodies at median 16 months.
Conclusions/Learning Points: Prevention of vertical transmission of HBV was universal in those attending although higher risk infants were more likely to be lost to follow up (32% versus 19%). HBV serological protection was comparable with national data from 2021 (77% > 4 doses, 77% HBsAb >100). Service improvements in birth VL for mothers on TDF, enhanced engagement for high risk infants and serology moving to 22 months are subsequently being instituted.

NEONATAL STAPHYLOCOCCAL SCALDED SKIN SYNDROME – A DIAGNOSIS TO KEEP IN MIND

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Inês Paiva Ferreira, Joana Soares, Mariana Ferreira, Juliana Oliveira, Abílio Oliveira
Centro Hospitalar Tâmega e Sousa, Paediatrics And Neonatology, Penafiel, Portugal

Title of Case: Neonatal Staphylococcal Scalded Skin Syndrome – a diagnosis to keep in mind
Background: Staphylococcal-scalded skin syndrome (SSSS) is a rare but potentially life-threatening exfoliative skin infection, primarily seen in young children. A high index of suspicion is essential for an accurate diagnosis and to initiate prompt treatment.
Case Presentation Summary: A full term caesarean-delivered newborn male presented at day 3 of life with exuberant purulent drainage from the umbilical stump associated with periumbilical erythema and minor cutaneous desquamation. Laboratory evaluation was unremarkable. A diagnosis of omphalitis was made and the patient was started on empiric antibiotic treatment with flucloxacillin plus gentamicin and admitted to the neonatology unit. At day 7 of life, the patient presented with new erythematous and desquamative lesions in the perioral, axillary and limbs regions. There was no fever or mucous membranes involvement. Blood pressure remained adequate. A presumptive diagnosis of SSSS was made. Identification of a Staphylococcus aureus was made in the umbilical stump's purulent discharge. Blood cultures were sterile. The patient underwent a 10-day antibiotic course with resolution of the skin lesions at
discharge.

Learning Points/Discussion: This clinical case illustrates a typical SSSS case with omphalitis as the starting point. If promptly recognized and treated, the majority of cases will have a benign clinical evolution. Antibiotic therapy, pain control, adequate hydration and skin care constitute the cornerstone of treatment.

PV0369 / #1997

NEONATAL HERPES SIMPLEX MENINGOENCEPHALITIS IN A 22 DAYS OLD INFANT WITH FEVER

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Andreea Panciu[1], Ana-Maria Caia-Honas[2], Adelina Dobre[2], Irina Apostol[2], Tatiana Ciomartan[3]
[1]National Institute of Infectiouse Disease, 9th Pediatric Department, Romania, Romania, [2]National Institute for the health of mother and child -Alessandrescu Rusescu, Intensive Care Department, Bucharest, Romania, [3]University of Medicine and Pharmacy Carol Davila, Paediatric, Bucharest, Romania

Title of Case: Neonatal herpes simplex meningoencephalitis in a 22 days old infant with fever
Background: Herpes simplex virus (HSV),can cause serious disease in the neonatal period, with high mortality and long term morbidity.Neonatal herpes simplex infection can have three types of clinical manifestations.One form of is the CNS involvement, with or without skin lesions.
Case Presentation Summary: We present the case of a 22 days old, male patient, admitted to the hospital for low grade fever, loss of appetite and inconsolable cry, with onset a few hours prior to admission.The infant was alert, with normotensive anterior fontanelle.Born at term, via spontaneous delivery, breastfed,3rd child of a 25 years old female,with no genital lesions present at birth.Blood tests at admission were in normal ranges,with no inflammatory syndrome,negative rapid tests for Covid-19 and flu.We performed a lombar puncture.CSF was xanthochromic, hypertensive, with pleyocitosis 280 cells/mm3 and positive PCR Panel for HSV2.During hospitalization,the infant developed vesicular rash in multiple skin regions and multiple tonic-clonic generalized seizures.EEG examination showed lesional slow waves in posterior right deviations and cerebal MRI showed multiple bilateral lesions.The patient received treatment with intravenous Acyclovir for 24 days and multiple antiepileptic drugs.Under this treatment seizures ceased,skin lesions gradually improved, and he was discharged from hospital after 24 days with subsequent pediatric and infectious disease follow-up.
Learning Points/Discussion: Fast diagnosis and treatment can influence the outcome in neonatal herpes encephalitis. In 85% of the cases transmission occurs intrapartum and the majority of women do not report a history of lesions suggestive of genital herpes.Workup protocols for febrile neonates include lombar puncture, that was of great importance in our case. Evaluation for HSV infections in febrile neonates should be considered,especially in the presence of suggestive symptoms or risk factors.

A NEONATE WITH VESICULO-BULLOUS LESIONS

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Dikshya Pant
Patan Academy of Health Sciences, Paediatrics, Kathmandu, Nepal

Title of Case: A NEONATE WITH VESICULO BULLOUS LEISON
Background: Congenital syphilis occurs when Treponema pallidum is transmitted from untreated pregnant woman to her fetus. According to the WHO, approximately 661,000 cases of congenital syphilis occur globally, ranking second in leading infectious cause of stillbirths . There has been a global shortage of benzathine penicillin G (BPG), the only recommended treatment for syphilis in pregnant women leading to difficulty in management of effected mothers and neonates.
Case Presentation Summary: A 28 day old boy, was brought with fever and rhinnorrhoea for 3 days and fast breathing for 1 day. Mother complaints of generalized, non-erythematous, vesiculo-bullous lesions since 10^{th} day of life which have now crusted. Antenatal history revealed that he was born to a 20 year old G2A1 mother at 37 weeks gestation who had a single antenatal visit and was screened for HIV and Hepatitis B. Baby was pale, dehydrated and had generalised excoriated papules .His was febrile, tachypneic and tachycardic. Systemic examination revealed coarse crepitations and hepatosplemegaly. Lab parameters revealed severe anemia, thrombocytopenia and leukocytosis. His LFTs were deranged and blood gas showed metabolic acidosis. He was mechanically ventilated and initially treated in line of late onset neonatal sepsis . The mother's VDRLwas reactive .On further evaluation of the baby,VDRL titre was 1:64.His USG cranium was normal ,CSF count was 5 WBCs/microL ,protein was 170 mg/dL and CSF VDRL was reactive.With a diagnosis of congenital syphilis,Inj Crystalline Peniciilin was planned but Inj Cefotaxime was adminitrated for total of 14 days ,improved and discharged after 20 days.
Learning Points/Discussion: Congenital syphilis has a potential to cause substantial morbidity in a neonate. Global shortages of penicillin has created a treatment dilemma especially in pediatric population where studies with alternate antibiotics are scarce.

Backgrounds: Neutropenia is a common adverse event associated with ganciclovir and valganciclovir treatment in infants with congenital cytomegalovirus infection (cCMV). Severe neutropenia, often leads to treatment discontinuation, as it puts the patient at risk of invasive bacterial infection.
Methods: A multicenter retrospective study was performed within the European cCMVnet registry, including patients from Spain, Greece, Italy and Portugal. Severe neutropenia during antiviral treatment was defined as an absolute neutrophil count (ANC) below 500 cells/mm^3. Management with antiviral treatment was according to national and international guidelines. Maternal demographic and clinical data as well as somatometric, clinical and laboratory infant data were extracted from the cCMVnet registry. The prevalence of risk factors (clinical and laboratory) between infants with and without neutropenia was compared and logistic regression analysis was applied with neutropenia as the dependent variable.

Results: 517 infants with cCMV who received antivirals since 2011 were included. Most infants were treated with oral valganciclovir alone (280; 54.2%), while 29 received IV ganciclovir and 208 combination of both. Overall, 95 infants (18.4%) presented with severe neutropenia. Severe neutropenia was associated with gestational age at birth ($p<0.001$), birthweight (BW) ($p<0.001$), birth head circumference ($p<0.001$), BW <1500 grs ($p<0.001$) and ANC at birth ($p=0.001$). Severe neutropenia was not associated with gestational age at maternal CMV infection, abnormalities in cranial ultrasonography, occurrence of SNHL at birth, blood CMV viral load at birth. Ganciclovir treatment for >14 days, prematurity (GA <36 weeks) and lower pre-treatment ANC were strongly associated with the development of neutropenia.
Conclusions/Learning Points: Development of severe neutropenia during antiviral treatment was associated with ganciclovir treatment for more than 14 days, prematurity and low baseline neutrophil count. Identifying risk factors will enable better parental anticipatory guidance.

Title of Case: Congenital enterovirus infection triggering haemophagocytic lymphohistiocytosis and subsequent autoimmune neutropenia
Background: Haemophagocytic lymphohistiocytosis (HLH) is a rare, severe, and potentially fatal systemic inflammatory syndrome. Congential infections should be considered in the differential diagnosis of secondary HLH in the newborn period, such as enterovirus infection, which can trigger an overwhelming systemic inflammatory state in infants. Furthermore, enterovirus is known to cause transient neutropaenia in healthy children whereas other infectious aetiologies have also been implicated in the pathogenesis of autoimmune neutropenia.
Case Presentation Summary: We describe two patients with secondary HLH presenting in the first week of life triggered by congenital enterovirus infection. Both patients were profoundly unwell requiring PICU admission with severe coagulopathy and multiorgan dysfunction. Enterovirus was isolated from multiple bodily fluids in both patients. Investigations for primary inborn errors of immunity predisposing to HLH were negative. Both mums had contact with family members or were themselves unwell with fever, rash, and gastrointestinal symptoms perinatally. After spontaneous clinical and biochemical improvement, both infants were noted to be neutropaenic in follow-up despite normal neutrophil counts in the acute phase of illness. One patient was found to be positive for anti-granulocyte antibodies (HNA1a) hypothesised to have caused autoimmune neutropaenia.
Learning Points/Discussion: It is essential to differentiate between primary (familial/congenital) forms of HLH and secondary forms triggered by infections such as enterovirus. The two patients exemplify the importance of a detailed perinatal history leading to a broad congenital infections screen, as the spectrum of congenital infections causing HLH features are overlapping and often indistinguishable from one another. Once the acute phase of illness has resolved, persistent neutropaenia should prompt consideration of autoimmune neutropaenia as it is often linked to infection in infancy with subsequent aberrant autoantibody formation.

[1]Policlinico Sant'Orsola Malpighi, Pediatrics, Bologna, Italy, [2]Ospedale Maggiore Carlo Alberto Pizzardi, Neonatology, Bologna, Italy, [3]Ospedale Santa Maria delle Croci, Cardiology, Ravenna, Italy

Title of Case: The Human HerpesVirus 6 (HHV-6) infection in neonatal period
Background: HHV-6 causes “roseola infantum” in infants aged between 6 to 24 months. Its most common route for transmission is saliva. Congenital HHV-6 infection occurs in 1% of births, but transplacental transmission accounts only for 14% of them. In fact, HHV-6 genome can integrate into the host germline chromatin and be transmitted in a Mendelian fashion. The 86% of HHV6 congenital infections is associated with inherited chromosomally integrated HHV-6 (iciHHV-6).
Case Presentation Summary: A.F was born full-term without complications. Twelve days after birth, he developed high fever (38.5°), axial hypotonia and diaper rash. A diagnostic work-up and empiric antibiotic therapy was started. Blood, urine and liquor culture did not reveal any bacteria. Afterwards, the patient developed exanthema characterized by small and erythematous papules on the trunk, face and arms. In the meantime, virological examinations detected 335.449 copies/ml of HHV6-DNA on blood sample. After few days the baby was discharged in good clinical conditions. Three months later, the viral load was low (< 500 copies/ml), excluding the presence of iciHHV-6 in patient’s genome.
Learning Points/Discussion: IciHHV-6 subjects can be identified by their persistently high viral load (>1 copy of genomic HHV6 DNA/leukocyte), unlike what occurs in postnatal or transplacental infections. Recognizing iciHHV-6 status would allow to avoid misdiagnosis of active HHV-6 infection and consequently unnecessary antiviral treatment. It also would prevent exposure to drugs involved in virus reactivation in iciHHV-6 carriers, associated with drug-induced hypersensitivity syndrome/drug reaction with eosinophilia and systemic symptoms. In this case we underline the importance to make virologic examinations in all patients with a suspected sepsis, and in case of documented HHV6 infection, to control the viral load trend, in order to exclude iciHHV-6.

Hospital of Magenta (Milan, Italy), ASST Ovest Milanese, Pediatric, Neonatal And Neonatal Pathology Units, Magenta, Italy

Title of Case: FOLLOW-UP OF NEWBORNS FROM HBV POSITIVE MOTHERS IN A SECONDARY LEVEL NEONATAL UNIT FROM 2018 TO 2021
Background: Despite the continue improving of prevention, HBV infection remains an important infectious problem worldwide. Considering pediatric age, the introduction of specific vaccination in first infancy has drastically decreased the prevalence of HBV infection, and most of pediatric HBV positive patients are due to mother to fetal transmission. In a four-year period, from 2018 to 2021, we collected data of newborns from HBV positive mothers followed in the Pediatric Infectious Diseases Outpatient Unit of the Hospital of Magenta.
Case Presentation Summary: From 2018 to 2021, 11 patients were born from HBV positive mothers (0.2% of all newborns in our neonatal unit). All these patients were treated within the first 12 hours of life with a first dose of anti-HBV vaccine and an intramuscular injection of specific immunoglobulin. Vaginal delivery and breast feeding weren't contraindicated in any patient. Follow-up was characterized by two blood tests looking for HBsAg and HBeAg: the first at 6-7 months of life (to early detect possible congenitally infected children) and a last at 12-15 months of life. None of the 11 patients resulted positive (all patients completed the follow-up).
Learning Points/Discussion: During the study period, none of the newborns from HBV positive mothers resulted infected at the end of the follow-up. Early newborn immunization and vaccination, when correctly applied, is able to drastically reduce rate of vertical transmission, even if in the literature is described that approximately 10% of these newborns can acquire HBV infection.

[1]St Mary's Hospital, Department Of Paediatric Infectious Diseases, W NY, United Kingdom, [2]Royal Alexandra Children's Hospital, Paediatrics, Brighton, United Kingdom, [3]UCL Great Ormond Street Institute of Child Health, Paediatric Infectious Diseases, London, United Kingdom, [4]Imperial College Healthcare NHS Trust, Paediatric Infectious Diseases, London, United Kingdom

Title of Case: DISSEMINATED HSV INFECTION IN INFANTS ASSOCIATED WITH POSTNATAL ONSET OF MATERNAL HSV SYMPTOMS
Background: Neonatal Herpes Simplex Virus (HSV) is a dangerous condition with a rising incidence. Management of maternal HSV infection during pregnancy and at birth is incorporated into national guidelines but management of mother-infant pairs presenting postnatally is not. This represents an important population in whom potentially devastating neonatal HSV may be missed.
Case Presentation Summary: We report 5 mother-infant pairs presenting post-delivery with symptoms due to HSV. Data was gathered regarding pregnancy, delivery, maternal and neonatal symptoms and microbiology results. Timelines were created with points of potential intervention, which could have improved outcome had earlier action been taken. Symptomatic mothers presented on day 1-6 after delivery. 3 infants died of disseminated HSV, 1 infant survived with long term ophthalmological complications, and 1 infant remains well. All 3 who died had had opportunities for earlier initiation of acyclovir. All infants were tested after the reported maternal symptoms and after they had developed symptoms. Multiple timepoints were identified when earlier recognition may have resulted in earlier infant HSV
treatment.

Figure 1: Overview of all reported cases included in the series
Abbreviations - HSV (Herpes Simplex Virus), ACV (Aciclovir), CSF (Cerebrospinal Fluid), IV (Intravenous), D* - Day * postpartum

Case	Pregnancy	Delivery	Maternal symptoms	First maternal confirmation of HSV	Neonatal symptoms and outcome	Neonatal confirmation	Relation of neonatal testing prior to maternal testing/neonatal symptoms
1	No history of herpetic lesions P0 Antenatal scans normal 40+0	Emergency C-section Nil herpetic lesions at delivery	D2 - post-op paralytic ileus, caecal dilation and ascites – not considered HSV symptoms D6 - Herpetic genital lesions	D7 HSV PCR positive blood	D1 - Pyrexia and jaundice D5 - Seizures D6 - Disseminated HSV Outcome: D36 - death	D6 - HSV positive saliva swabs	Tested before maternal results came back Tested after neonatal symptoms
2	Nil history of herpetic lesions P0 Antenatal scans normal PET – on atenolol 40+0	Forceps Nil herpetic lesions at delivery	D3 Genital lesions – Not considered HSV symptoms	D10 - HSV DNA positive blood	D4 - "Snuffly" D6 - Poor feeding, lethargic, D10 - Disseminated HSV Outcome: D11 - Death due to PEA arrest	D18 - Blood HSV detected, result only available after death	Tested before maternal results came back Tested after neonatal symptoms
3	Nil history of herpetic lesions P0 Antenatal scans normal 40+5	Emergency C-Section Nil herpetic lesions at delivery	Postpartum fever – Not considered HSV symptoms	D9 - Positive HSV DNA blood	D9 - Pyrexia, poor feeding, O2 requirement Outcome: D10 - Death	D9 - Positive CSF for HSV	Tested before maternal results came back Tested after neonatal symptoms
4	Nil history of herpetic lesions Antenatal scans normal Previous maternal genital herpes 40+0	Forceps Nil herpetic lesions at delivery	D6 - Outbreak of lesions	Mother reported symptoms and volunteered history of genital herpes to clinician	D4 - Spot on scalp D6 - Sought medical attention, clinically well, no fever Outcome: Normal development at 12 month follow-up On ACV as needed	Blood, CSF, skin & eye swabs: all HSV	Tested after neonatal symptoms
5	Nil history of herpetic lesions Antenatal scans normal 40+0	Ventouse Nil herpetic lesions at delivery	Maternal Disseminated HSV disease- unwell few days postpartum and admitted to ITU	D10 - HSV diagnosed	D4 - Respiratory distress, ventilated and IV antibiotics D5 - 1 abnormal movement so IV ACV commenced D8 - CSF neg, ACV stopped, deterioration D10 - ACV restarted, deteriorated and transferred to regional liver unit but survived without liver transplant Outcome: Survived - significant ophthalmic involvement. Normal development Remains on prophylactic oral and topical eye valaciclovir	HSV Blood PCR	Tested initially before maternal results came back as CSF neg no blood por Tested again after neonatal symptoms and maternal result CSF still neg Blood PCR positive

Learning Points/Discussion: Early postnatal presentation of mothers with symptomatic herpetic infection should alert clinicians to the possibility of neonatal HSV infection, as these women were likely to have been viraemic at delivery and therefore at very high risk for transplacental and/or birth canal transmission of HSV. Without waiting for maternal results their infants should be urgently assessed, investigated for HSV and treatment commenced until confirmatory results are available. Ideally this should happen before the infant develops any systemic symptoms as once the infants are unwell the

outcomes from disseminated HSV are very poor. National guidance should include the management of this serious postnatal presentation of HSV.

NEONATAL INVASIVE GROUP B STREPTOCOCCAL DISEASE AND LONG-TERM RISK OF PSYCHIATRIC DISORDERS. A POPULATION-BASED COHORT STUDY IN DENMARK.

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Malene Risager Lykke
Aarhus University Hospital, Aarhus University, Department Of Clinical Epidemioly, Aarhus N, Denmark

Backgrounds: The risk of psychiatric disorders up to adolescents after neonatal invasive group B Streptococcus disease (iGBS), particularly iGBS sepsis, is poorly understood.
Methods: We conducted a population-based cohort study based on health care data from 1997 to 2018 in Denmark. Exposed children had a hospital-diagnosed iGBS (sepsis or meningitis) during the first 89 days of life. A general population comparison cohort was randomly sampled and matched 10:1 by sex, child year of birth, and gestational age to the exposed cohort. Psychiatric disorders were defined by International Classification of Diseases, Tenth Revision codes (ICD-10-codes). The cumulative risk (CR) of psychiatric disorders was calculated by treating death as a competing event. Cox proportional hazards regression was used to compute hazard ratios (HRs) and, as a measure of relative risks, associated 95% confidence intervals (CIs).
Results: 1432 children were identified with iGBS: 1264 with sepsis and 168 with meningitis. The overall CR (0–22 years) of any psychiatric disorder was 22.6% (95%CI 19.4–25.9) in children with iGBS and 19.4% (95% CI 18–20.8) in the comparison cohort. The overall CR of any psychiatric disorder was 24.6% (95%CI 16.1–34) for $iGBS_{meningitis}$ and 22.2% (95%CI 18.8–25.8) for $iGBS_{sepsis}$. The overall adjusted hazard ratio for any psychiatric disorder was 1.42 (95%CI 1.22–1.66). We observed an increased risk of neurotic disorders (HR 1.74 (95%CI 1.34–2.26)), mental developmental disorders (HR 1.32 (95%CI 1.02–1.71)) and emotional disturbances (HR 1.48 (95%CI 1.19–1.83)).
Conclusions/Learning Points: Invasive group B Streptococcus disease, both meningitis and sepsis, was associated with a higher risk of psychiatric disorder in later childhood.

CHORIOAMNIONITIS WITH FUNISITIS AND CHORIONIC VASCULITIS: THE IMPORTANCE OF THE HEMATOLOGICAL PROFILE AT BIRTH IN PRETERM INFANTS

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Inês Rodrigues[1,2], Filipa Flôr-De-Lima[1,3], Cristina Ferreras[1], Rita Moita[1,3], Gustavo Rocha[1]
[1]Centro Hospitalar Universitário de São João, Neonatology, Porto, Portugal, [2]Centro Hospitalar de Trás-os-Montes e Alto Douro, Paediatrics, Vila Real, Portugal, [3]Faculty of Medicine of the University of Porto, Paediatrics, Porto, Portugal

Backgrounds: In the setting of acute intrauterine inflammation or infection, funisitis and chorionic vasculitis are the histological hallmarks of fetal compromise. The aim of this study was to evaluate changes in the hematological profile at birth of preterm infants with funisitis/chorionic vasculitis, that could be used as early markers of inflammation/infection.
Methods: Retrospective analysis of a cohort of preterm infants (gestational age [GA] <30 weeks) admitted to a level III NICU, from 2008 to 2022. The exclusion criteria were: outborn infants, TORCH infections, major congenital anomalies or absent placental histology. Maternal, perinatal, and hematological data were compared, according to the presence or absence of acute funisitis/chorionic vasculitis. Univariate, multivariate, and Receiver Operating Characteristic (ROC) analysis were performed using SPSS® v.28. A p-value <0.05 was considered statistically significant.
Results: A total of 113 neonates were included, 27 (23.9%) of which had funisitis/chorionic vasculitis. The univariate analysis showed that these neonates had a higher GA (28 weeks vs 27.5 weeks, p=0.036), a higher prevalence of prolonged rupture of membranes (40.7% vs 12.7%, p=0.002), and a lower prevalence of pre-eclampsia/eclampsia (0% vs 25.6%, p=0.004). The logistic regression (adjusted for GA, prolonged rupture of membranes and maternal pre-eclampsia/eclampsia), revealed an association between funisitis/chorionic vasculitis and a higher mean absolute leukocyte, neutrophile, eosinophile, lymphocyte and immature granulocyte counts, and a lower platelet-to-lymphocyte ratio (Table 1). The cut-off values of these parameters, for a specificity over 80%, are presented in Table 1.

	*OR**	*95% Confidence Interval*	*p*	*AUC***	*p*	*Cut-off values (specificity = 80%)*
Leucocytes ($x10^9/L$)	1.1	1.1 – 1.2	0.029	0.710	0.001	10.05
Neutrophils ($x10^9/L$)	1.2	1.1 – 1.4	0.011	0.720	0.001	3.46
Lymphocytes ($x10^9/L$)	1.3	1.1 – 1.7	0.02	0.738	<0.0001	5.14
Eosinophils ($x10^9/L$)	42.5	3.4 – 52.9	0.004	0.770	<0.0005	0.18
Immature Granulocytes ($x10^9/L$)	16.5	1.7 – 15.9	0.016	0.739	0.009	0.13
Platelet-to-Lymphocyte ratio	0.96	0.9 – 0.99	0.005	0.732	<0.0001	31.0

Table 1: *Multivariate analysis by logistic regression and **ROC analysis of the hematological profile. AUC – area under the curve, OR – odds ratio

Conclusions/Learning Points: The hematological profile of preterm infants with funisitis/chorionic vasculitis revealed important changes, the most significant being an increased eosinophil and immature granulocyte counts. This study suggests that these parameters can be used as early markers of intrauterine inflammation/infection.

THE ROLE OF IGRA TEST IN THE DIAGNOSIS OF CONGENITAL TOXOPLASMOSIS

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Serena Salomè[1], Valeria Delle Cave[1], Annapaola Amitrano[1], Ambra Vola[2], Valeria Meroni[2], Paola Salvatore[3]
[1]University of Naples “Federico II”, Naples, Italy,, Department Of Translational Medical Sciences, Naples, Italy, [2]IRCCS San Matteo Hospital, 2microbiology And Virology Unit, Pavia, Italy, [3]University of Naples, Department Of Microbiology, Naples, Italy

Title of Case: The role of IGRA test in the diagnosis of congenital toxoplasmosis
Background: Congenital Toxoplasmosis (CT) is asymptomatic at birth in 85% of cases and the diagnosis is based on positive IgM and/or and IgA antibodies, persistence of IgG antibodies up to one year or their increase in the first months and the early detection of synthesized neonatal antibodies through a comparative mother-infant Western blot (WB). In infected infants, Interferon release assay (IGRA) may be used to evidence lymphocytes activation and secretion of interferon gamma, following in vitro stimulation with T. gondii antigens.
Case Presentation Summary: Since 2000 we enrolled 162 patients with CT and 3,000 in utero exposed ones. We performed IGRA test in 16 asymptomatic patients with suspected CT because of not reassuring IgG decay or IgM/IgA doubtful results with not definite results at WB. Moreover, we performed the test in 10 patients diagnosed with asymptomatic CT infection in previous years because of not reassuring IgG decay.
Learning Points/Discussion: One patient in the first group presented positive IGRA test so that he promptly started specific therapy and now is 14 months old and persists asymptomatic. The others had negative IGRA test and resulted with negative IgG at one year of age. In the second group all the patients presented a negative IGRA test so that the diagnosis was definitely excluded and follow-up stopped.
Conclusions: IGRA test is useful in selected cases for early diagnosis of CT in asymptomatic infants. Moreover, it could be useful in previously suspected diagnosis to confirm or not the infection and decide if continue or not the specific follow-up.

THE UNEXPECTED HSV

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Eleni Sarridimitriou, George Eskander, Joanna Maynard
Chelsea and Westminster Hospital, NHS Trust, General Paediatrics, London, United Kingdom

Title of Case: The unexpected HSV
Background: Neonatal Herpes Simplex (HSV) is a rare but severe infection with increased mortality and morbidity. It is subdivided to : 1. Disease of skin, eyes, and mouth. 2. Central nervous system disease. 3. Disseminated infection. The risk of maternal neonatal transmission is highest in primary infection.
Case Presentation Summary: A 2-weeks-old term boy was treated with intravenous (IV) antibiotics for suspected sepsis. While on treatment, he developed a vesicular rash on hands and feet. At that time, it was felt that it was likely HSV rash, so IV acyclovir was started and appropriate investigations were sent. However, due to the lack of maternal clinical history of herpes and clinical improvement,IV acyclovir was stopped. The baby was discharged. Later that day neonatal eye swabs for HSV came back positive. The child was readmitted. It was challenging to convince parents of the need for prolonged acyclovir treatment despite negative maternal history of herpes. From a detailed history, it was noted that mum had developed a new onset genital rash on day 17 postpartum but this had been diagnosed as an allergic reaction. Initial maternal genital swabs showed low HSV levels ” uncertain significance”, so both maternal and neonatal swabs were re-rounded and were positive for HSV-1. Maternal antenatal booking bloods were revisited and showed HSV IgG Positive. Lumbar puncture (LP) was repeated and was negative for HSV-1, along with no neurological concerns. The baby received 14 days of IV acyclovir followed by six months of oral prophylaxis.
Learning Points/Discussion: The diagnosis was difficult since the initial swabs were negative and negative maternal history of herpes infection. High clinical suspicion is essential to prompt detection of nonspecific symptoms of HSV to prevent delay in treatment.

MOTHER-TO-CHILD TRANSMISSION OF CHAGAS DISEASE IN PRETERM TRIPLETS: TREATMENT MONITORING.

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Cintia Cruz[1,2], Margarita Satostegui[2], Carlos Perez Montilla[3], Fernanda Lascano[2], Juan Ramirez[3], Franco Mangone[3], Jaime Altcheh[2,3]
[1]Mahidol Oxford Research Unit, Clinical Therapeutics Unit, Bangkok, Argentina, [2]Hospital de Niños Ricardo Gutierrez, Servicio De Parasitología Y Chagas, Ciudad Autónoma de Buenos Aires, Argentina, [3]Instituto Multidisciplinario de Investigaciones en Patología Pediátrica, Parasitologia Y Chagas, CABA, Argentina

Title of Case: Mother-to-child transmission of Chagas disease in preterm triplets: treatment monitoring.
Background: Chagas disease is a worldwide disease. Mother-to-child transmission of T.Cruzi parasite is the main route of infection in non-endemic areas. Previous studies report lower Benznidazole (BZN) plasma concentrations in children than adults. This has not been studied in preterm infants.
Case Presentation Summary: Preterm triplets (27 weeks) with congenital Chagas disease diagnosed by positive parasitemia by T.Cruzi DNA qPCR. The first newborn showed myocarditis, hyaline membrane disease (HMD) and died at 6 days of life. The second suffered HMD, and the third one showed anasarca, anemia and hepatomegaly at birth. Treatment: BZN 5 mg/kg/day for 30 days was administered by nasogastric tube diluted in milk due to patient's critical condition. BNZ dosages at steady state in blood were performed 5 times by mass spectrometry. Therapeutic response was monitored by qPCR. In the 2nd newborn, clinical condition improved, qPCR was negative at the end of treatment. BZN concentrations were between 0.3-0.7mg/L. At 4th month of follow up, qPCR turned into positive result. A second course of BNZ was prescribed and one concentration was tested resulting 3.6mg/L. qPCR remained negative during 3 months follow-up. Regarding 3rd newborn, first 3 BZN dosages were between 2.1-2.5mg/L and in 2 were 0.1 and 04mg/L. Persistent positive qPCR was observed. A second course of BZN was prescribed. BZN concentrations were taken 4 times and resulted between 0.2-1.8 mg/L. qPCR remained negative during 7 months follow-up. No related adverse events of BNZ were reported.
Learning Points/Discussion: This is the first report of therapeutic evaluation by BNZ dosing in extreme preterm infants. Close therapeutic drug monitoring and qPCR parasitemia allowed early detection treatment failure related to low concentration of BNZ.

[1]Belarussian State Medical University, Children Diseases, Minsk, Belarus, [2]Belarussian State Medical University, Children Infections Diseases, Minsk, Belarus, [3]State Republican scientific and practical center "Mother and child", Clinical Department Of Anesthesiology, Resuscitation And Intensive Care For Newborns, Minsk, Belarus

Backgrounds: Congenital infections are the 3rd leading cause of death in neonatology. The study of methods for confirming infection is an urgent problem of our time.
Methods: 49 children of the early neonatal period were examined. Patients were divided into 3 groups: Gr1 - bacterial sepsis (n=15), Gr2 - congenital infection, unspecified (n=14), Gr3 - RDS (n=20). Analysis of clinical and laboratory data was on the 1st and 3-5rd days of life. The sensitivity (Se) and specificity (Sp) of pro-inflammatory biomarkers (CRP, PCT, IL-6) were determined.
Results: Gestational age and weight did not affect the levels of pro-inflammatory markers. IL -6 (pg/ml) levels in Gr1 – 247 (137–421) (Me (25%–75%)), Gr2 – 139 (102–226), Gr3 – 66 (39–104) (H=17.4, p<0.001, p1-3<0.001, p2-3=0.043). On day 1, the groups showed differences in CRP (H=14.6, p<0.001, p1-3<0.001) and PCT (H=10.7, p=0.005, p1-3=0.003). On days 3–5, IL-6 had no differences (Gr1 - 16 (12–46), Gr2 - 52 (0.8-102), Gr3 - 9 (0.8-19) pg/ml, H=3.33, p=0.189). An increased level of CRP (mg/l) was noted in patients Gr1 compared with children Gr2, Gr3 (8.6 (5.3–9.0), 5.2 (3.6–6.5) and 2.8 (1.6–5 ,1), H=15.9, p<0.001), there were no statistically significant differences among Gr1 and Gr2 (p=0.180). The PCT (ng/ml) was 14.3 (9.4–17.3) in Gr1, 4.0 (2.4–6.3) in Gr2, and Gr3 1.1 (0.8–3.1) (H=33.0, p<0.001, p1-3<0.001, p2-3=0.048, p1-2<0.001). Sensitivity and specificity of markers on 1st day (Se; Sp): IL-6 (81%; 69%), CRP (50%; 83%), PCT (43%; 85%). 3-5rd day: IL-6 (50%; 94%), CRP (86%; 83%), PCT (93%; 85%).
Conclusions/Learning Points: On the 1st day, the most reliable marker is IL-6, on the 3-5rd day – PCT.

PV0382 / #1125

UREAPLASMA IN NEONATES – CAN WE IMPROVE OUR TESTING?

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Jade Sheil[1], Anna Jarchow-Macdonald[2]
[1]University of Dundee, School Of Medicine, Dundee, United Kingdom, [2]Ninewells Hospital, Medical Microbiology, Dundee, United Kingdom

Backgrounds: Ureaplasma detection in neonates is associated with afebrile pneumonia and chronic lung disease but testing recommendations vary and incidence is uncertain. We aimed to analyse current testing practices in the Neonatal Unit in NHS Tayside, Scotland, with regards to Ureaplasma detection to establish if consistency in testing practices can be improved. This was relevant both for the Neonatal Unit as well as the Medical Microbiology Laboratory.
Methods: Our work involved a laboratory search from 2017 - 2022 to establish the overall number of endotracheal aspirate (ETA) specimens tested via culture method in the Neonatal Unit, the number of specimens tested for Ureaplasma, the number of positive Ureaplasma tests and whether any other pathogens were isolated. The data was collected on an Excel spreadsheet, analysed and discussed with experts from both the Laboratory and the Neonatal Unit, in order to improve the management of lung disease in neonates.
Results: Overall, 114 ETA specimens were received by the Laboratory from 48 neonates in the Neonatal Unit, during 2017-2022. Of the forty specimens tested for Ureaplasma on culture, 11 specimens tested positive (4 for Ureaplasma species and 7 for U. urealyticum). Thirty-one of the 48 neonates had at least one specimens tested for Ureaplasma. Of these, 10 specimens were positive (3 Ureaplasma species and 7 Ureaplama urealyticum). In six specimens, Ureaplasma was isolated alongside other pathogens (Pantoea sp; E. coli; S. aureus; H. influenzae; Citrobacter freundii and Acinetobacter baumanii).
Conclusions/Learning Points: Our results indicate that testing of all specimens from the Neonatal Unit might be beneficial, as approximately 1 in 3 neonates tested positive for Ureaplasma.

Title of Case: Incidental Finding of Trichomonas Vaginalis in a Preterm Neonate: A Case Report
Background: Trichomonas vaginalis (TV) is a common risk factor for preterm labor; however, perinatal transmission of TV is a rare phenomenon. We present a case report of incidental TV infection in a preterm infant at 2 months of age.
Case Presentation Summary: A 22-year-old woman, para 2 gravida 3 with gestational hypertension and chronic placental abruption delivered a female infant, estimated gestational age of 25 weeks, at home. The infant was transferred to the neonatal intensive care unit and the mother was admitted to the obstetrics unit. The infant's mother had a normal urine analysis (UA) without any signs of TV on day of delivery and a negative nucleic acid amplification testing for TV three months prior to delivery. During admission, at approximately 2 months of age, the infant developed signs of sepsis. Methicillin-resistant Staphylococcus aureus was isolated from a blood culture. Repeat blood culture grew Enterococcus faecalis. In pursuit of a source of E. faecalis, UA and culture were obtained. The urine microscopy revealed 10 white blood cells, 4 red blood cells and 1+ Trichomonas. Repeat testing confirmed the presence of trichomonas and the infant received a 5-day course of metronidazole to treat perinatal TV urethritis in addition to treatment for gram-positive sepsis.
Learning Points/Discussion: The prevalence of TV in preterm infants is unknown. TV can survive for several weeks in a neonate following delivery and has been associated with severe complications, such as brain abscess. Nucleic acid amplification for TV should be considered as some studies indicate it is more sensitive than UA. Further studies are needed to understand the best diagnostic approach and significance of TV infection in neonates.

EXPERIENCE OF PROLONGED ANTIVIRAL CHEMOTHERAPY FOR PERINATAL HERPES SIMPLEX INFECTION TYPE 2: EFFECTIVENESS, SAFETY, PROBLEMS – A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Olha Shvaratska[1], Victor Mavrutenkov[2], Tatiana Mavrutenkova[3]
[1]Dnipro State Medical University, Department Of Pediatrics 3 And Neonatology, Dnipro, Ukraine, [2]Dnipro State Medical University, Department Of Infectious Diseases, Dnipro, Ukraine, [3]Diagnostic Center of Medical Academy, Department Of Pcr Diagnostics, Dnipro, Ukraine

Title of Case: EXPERIENCE OF LONG-TERM ANTIVIRAL CHEMOTHERAPY FOR PERINATAL HERPES SIMPLEX INFECTION TYPE 2
Background: Herpes simplex virus (HSV) infection type 1+2 has several routes of transmission including a vertical one. In newborns who develop neonatal herpes administration of prolonged suppressive antiviral therapy should be considered to reduce the rate of recurrence, and tolerability of such therapies is an issue of special concern.
Case Presentation Summary: An 8-year-old male has a history of intranatal HSV-2 transmission due to the erroneous obstetric tactics which resulted into neonatal herpes infection. Due to frequent HSV-2 infection relapses, the child received continuous oral treatment with acyclovir until the age of three years, and then valacyclovir until now. Clinical and laboratory monitoring of treatment tolerability was continuously performed, with no abnormalities revealed. The absence of recognized specific laboratory criteria for treatment cessation caused several unauthorized parental attempts to cancel the medications, which resulted into recurrent severe herpetic keratoconjunctivitis, with further resumption of antivirals. Also, persistent parental search for alternative treatments caused unjustified management with immune modulators, human intravenous immunoglobulin and vitamin supplementation in different medical settings. In 2022, the family fled the war in Ukraine to Germany, being at risk of premature discontinuation of antiviral treatment, which risk, however, was avoided. Currently a one year relapse-free period was reached for the first time in eight years.
Learning Points/Discussion: For perinatal HSV type 1-2 infection, establishing of virological/immunological criteria for treatment efficacy and discontinuation is necessary. Physician-patient communication issues along with availability of an array of non-evidence-based information interferes with rational therapy and decrease the effectiveness of patient management. Long-term use of acyclovir/valacyclovir is believed to be generally safe and effective, therefore may be preferred over short-term courses used only for suppressing HSV exacerbations.

EARLY NEURODEVELOPMENTAL MILESTONES AND CONGENITAL ZIKA SYNDROME

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Nathani Silva, Celia Giacheti, Erlane Ribeiro, Luciana Pinato
Paulista State University, Speech, Language, And Hearing Sciences, Marilia, Brazil

Backgrounds: The phenotype of the Congenital Zika Virus Syndrome is still being delineated and among the clinical consequences of CZS are severe language impairment and a high frequency of sleep disorders. The aim of the present study is to answer the question if, after three years of follow-up is possible to make some predictions about what might be expected as they get older regarding to sleep quality and language development.
Methods: This study was approved by the Ethics Committee under protocol 1.743.023. composed by 39 boys and 44 girls, of a well-characterized sample of children with clinical and laboratory diagnosis of CZS, ages ranging from 2 to 36 months. The assessment consisted of children subdivided into groups: 2 to 6 months (N=4), 7 to 12 months (N=18), 12 to 18 months (N=22), 19 to 24 months (N=22), 25 to 30 months (N=19), 31 to 36 months (N=20). The language development was assessed by means of the Early Language Milestone Scale (ELM Scale) and the quality of sleep assessed by the Brief Childhood Sleep Questionnaire (BQSI).
Results: The results showed that independent of age, 100% of the children presented auditory expressive and auditory receptive language skills below the expected and 96% presented scores of visual skills below the expected, showing a severe impairment in all groups without significant difference. When we compared the sleep parameters, we observed that a sleep latency greater than acceptable was found in all groups. The only difference in the sleep parameters was a decrease in both nighttime sleep time and total sleep time between the 13-18 and 25-30 age groups.
Conclusions/Learning Points: Most children should remain with skills that would be expected in children from 2 to 3 months of age.

[1]Sant'Anna Hospital, City of Health and Science, Neonatology Intensive Care Unit Of The University, Turin, Italy, [2]Laboratory of Pathogenesis of Viral Infections, Department Of Publich Health And Paediatrics, Turin, Italy

Title of Case: REPLICATION PROPERTIES AND IMMUNOMODULATORY EFFECTS OF HUMAN CYTOMEGALOVIRUS INFECTION IMPACT THE CLINICAL PRESENTATION IN CONGENITAL PATIENTS
Background: Human cytomegalovirus (HCMV) is the leading cause of congenital infections resulting in severe
morbidity and mortality among newborns worldwide. Although both the host's and the virus' genetic backgrounds contribute to the outcome of infections, significant gaps remain in our understanding of the exact mechanisms that determine disease severity.
Case Presentation Summary: In this study, we sought to identify a correlation between the virological features of different
HCMV strains with the clinical and pathological features of congenitally infected newborns, therefore proposing new possible prognostic factors. We present five newborns with congenital cytomegalovirus infection,
whose clinical phenotype during fetal, neonatal, and follow-up period is correlated with in-vitro growth properties, immunomodulatory abilities and genome variability of HCMV strains isolated from organic samples (urine) of the patients.
Learning Points/Discussion: The five patients described in this case series displayed a heterogeneous clinical
phenotype and different virus replication properties, immunomodulatory abilities, and genetic polymorphisms. Interestingly, we observed that an attenuate viral replication in-vitro influences the immunomodulatory abilities of HCMV, leading to more severe congenital infections and long-term sequelae. Conversely, infection with viruses characterized by aggressive replicative behavior in-vitro resulted in asymptomatic patients' phenotypes.
Overall, this case series suggests the hypothesis that genetic variability and differences in the replicative behavior of HCMV strains result in clinical phenotypes of different severity, most likely due to different immunomodulatory properties of the virus.

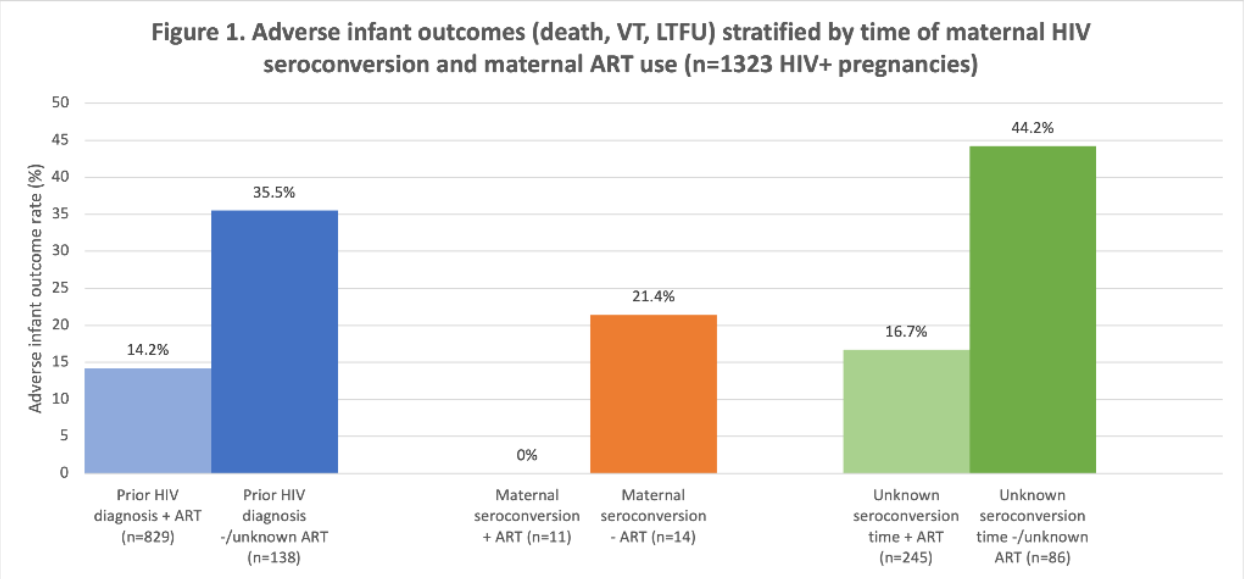
Backgrounds: Southern Brazil has the highest countrywide prevalence of HIV in pregnancy. The contribution of primary HIV infection during pregnancy to adverse infant outcomes [AIO: death, vertical transmission (VT), lost-to-follow-up (LTFU)] is unknown.
Methods: We analyzed data from a retrospective cohort of pregnant women living with HIV (WLH) delivering at an urban tertiary hospital in southern Brazil from 01/2008-12/2018.
Results: 1,323 pregnancies of WLH resulted in 1,348 births including 54 stillbirths/early infant deaths (4.0%). Twenty-five of 1,294 surviving infants (1.9%) were HIV infected; 174 (13.4%) were LTFU before determination of HIV status. Twenty-five women (1.9%) HIV seroconverted during pregnancy (SDP), 967 (73.1%) had pre-pregnancy HIV diagnoses (PPD), 331 (25.0%) had unknown HIV seroconversion time (UST). AIO occurred in 3/25 (12.0%) pregnancies with SDP, 167/967 (17.3%) with PPD and 79/331 (23.9%) with UST (p=0.020). VT rates were 4.0% (1/25) in SDP, 1.1% (11/967) in PPD and 3.9% (13/331) in UST (p=0.007). Antiretrovirals (ART) were used in 1,085 (82.0%) pregnancies; AIO occurred in 14.7% (159/1,085) of pregnancies with ART use versus 37.8% (90/238) without/unknown ART (p<0.001). Among women with PPD, AIO occurred in 14.2% (118/829) of pregnancies with ART use versus 35.5% (49/138) without/unknown ART (p<0.001); in women with UST, AIO occurred in 16.7% (41/245) of pregnancies with ART use versus 44.2% (38/86) without/unknown ART (p<0.001); among SDP, AIO occurred in 0% (0/11) cases of ART use versus 21.4% (3/14) cases without/unknown ART (p=0.102). SDP (aRR:0.45,95%CI:0.16-1.27) and UST (aRR:1.10,95%CI:0.87-1.39) were not associated with increased AIO risk. No/unknown ART use (aRR:1.98,95%CI:1.43-2.73) and detectable maternal viral load >50 copies/ml (aRR:1.52,95%CI:1.14-2.03) increased AIO
risk.



Conclusions/Learning Points: Although seroconversion in pregnancy is traditionally associated with VT, absent ART use is the major risk factor for AIO, not timing of maternal infection.

[1]ATTIKON UNIVERSITY HOSPITAL, Third Department Of Pediatrics, ATHENS, Greece, [2]"ATTIKON" UNIVERSITY HOSPITAL, Third Department Of Pediatrics, ATHENS, Greece, [3]PANAGIOTIS AND AGLAIA KYRIAKOY CHILDREN'S HOSPITAL, Neonatal Intensive Care Unit, ATHENS, Greece, [4]GENERAL HOSPITAL OF NIKAIA, Neonatal Intensive Care Unit, ATHENS, Greece, [5]GENERAL MATERNAL HOSPITAL OF ATHENS ELENA VENIZELOU, Neonatal Intensive Care Unit, ATHENS, Greece, [6]National and Kapodistrian University of, Neonatal Unit Of The First Department Of Pediatrics, School Of Medicine, Athens, Greece, [7]National and Kapodistrian University of Athens, Third Department Of Pediatrics, Athens, Greece, [8]ANDREAS SYGGROS HOSPITAL, Microbiology Department, ATHENS, Greece

Backgrounds: A rise in congenital syphilis (CS) incidence in Europe has been recorded and COVID-19 pandemic seems to contribute in this trend. The study's aim was primarily to evaluate the epidemiological and clinical features of CS in the Greater Athens area in the last decade and secondarily to investigate the impact COVID19 pandemic might had on this trend.
Methods: We retrospectively reviewed all neonatal cases with positive VDRL or Tr Pallidum IgM (EIA) in serum or CSF diagnosed at the reference center for STDs in Athens "A. Syggros" between 01/2012 – 01/2022. Maternal syphilis serology at birth was also recorded. Neonatal/maternal demographic/clinical data derived from the 5 referring hospitals' records were analysed. Serology reactivity and congenital syphilis' rate before and after COVID19 pandemic was compared.
Results: In total, 204 neonates were tested for CS and 36/204 (20.8%) had probable/confirmed CS. Mean GA of probable/confirmed CS cases was 36. 9 wks (SD 4.56). Mean maternal age was 30.14 years (SD 6.02). Among 14/36 neonates with complete medical history 5 were symptomatic (13.9%). All probable/confirmed CS cases were treated (mean penicillin dose number 18.64,SD 9.73). The majority (66.7%) of mothers with syphilis detection during pregnancy were Greek; interestingly only 3/15 (8.3%) receive treatment. Over the period 2017-2022, 53% of the tested high-risk mothers were positive versus 46,5% in the previous 5 years. The increase was similar in neonates; 67,6% were considered probable/confirmed during 2017-2022 versus 32,4% during the previous 5 years(p=0.056).
Conclusions/Learning Points: Although prenatal screening for CS is mandatory in Greece, our first results clearly highlight the problem of undiagnosed and thus untreated maternal infection cases, leading to congenital disease. In this study, COVID-19 does note seem to affect the epidemiology of CS in our area.

NEWBORN EXPOSED TO THE MONKEYPOX VIRUS: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Daniela Teixeira[1], Maria Luíza Soares[2], Walquíria Pinto[2], Izabel Coelho[2], José Matos[2], Roberta Romanelli[1]
[1]Federal University of Minas Gerais, Pediatrics, Belo Horizonte, Brazil, [2]Betim Regional Hospital, Infection Control Service, Belo Horizonte, Brazil

Title of Case: Newborn exposed to the monkeypox virus: a case report
Background: The cases of monkeypox in pregnant women reported in the literature are sparse. For this reason, little is known about the best protocol for monitoring exposed newborns. Here, we report the follow-up of a newborn whose mother developed monkeypox lesions 11 days before delivery.
Case Presentation Summary: A 37-week and 3-day pregnant woman presented with papular lesions on the right upper limb, evolving to a pustule. Eleven days after, she was admitted to the maternity hospital because of spontaneous rupture ofthe amniotic membranes and uterine contractions. The infant was born asymptomatic, without skin or mucosal lesions. After delivery, the binomial was separated and breastfeeding was contraindicated. The newborn was kept hospitalized despite being asymptomatic for clinical follow-up. Oropharyngeal swab samples were collected to perform PCR for themonkeypox virus every 3 days until 21 days of age. All newborn examinations were negative and the newborn showed no symptoms of monkeypox. In the breast milk analysis, the monkeypox virus was undetectablein PCR. Due to the lack of standardization of the examination for samples of breast milk, the negative result could not exclude the presence of the virus in the sample.
Learning Points/Discussion: The World Health Organization recommends close monitoring of newborns exposed to the monkeypox virus to assess the evidence of possible exposure or congenital or perinatal infection. Here, we performed an individualized discussion of the case with state and national agencies that guided the newborn's surveillance for 21 days and serial nasopharyngeal swab examinations every 3 days until postpartum day 21. However, no such recommendation has been documented in literature to date.

CONGENITAL CYTOMEGALOVIRUS: WHAT'S OUR OUTCOME?

E-Posters Viewing
E-POSTER VIEWING: AS06.A. CONGENITAL AND PERINATAL INFECTIONS

Joana Teixeira Carvalho[1], Ana Rodrigues Silva[2], Margarida Fonseca[1], Sofia Morais[1]
[1]Centro Hospitalar e Universitário de Coimbra, Maternidade Bissaya Barreto, Coimbra, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Maternidade Daniel De Matos, Coimbra, Portugal

Backgrounds: Fetal/congenital cytomegalovirus (CMV) infection is the leading infectious cause of central nervous system sequelae. Our aim was to characterize the congenital CMV infection population in our hospital.
Methods: Retrospective descriptive analysis of all confirmed congenital CMV infections, detected by PCR CMV DNA from urine specimen, from 2009 to 2020. Patients were classified at birth as asymptomatic, mild, moderate or severe disease, according to 2017 ESPID consensus. Outcome of congenital CMV infection was assessed by 2-year follow-up of the infected cohort.
Results: The analysis included 18 newborns with confirmed congenital CMV infection. Testing for CMV at birth was prompted in all newborns by documented seroconversion in maternal serology; in 3 of them, there were characteristics findings in prenatal scans that elicited maternal serology. At birth, we reported 12 (66.7%) asymptomatic patients, none with mild and moderate disease and 6 (33.3%) with severe disease – all with central nervous system neuroimaging findings, 2 with hepatitis and 1 with chorioretinitis. The mother had the infection during the first trimester of pregnancy in 5 (83.3%) of the severe cases. Valganciclovir therapy was given in 4 (66.7%) of the severe cases, within the first month of life. In the 2-year follow-up, we have 5 (27.8%) cases with sequelae: 1 cerebral palsy and bilateral sensorineural hearing loss; 1 cerebral palsy with chronic hepatitis; 1 delayed psychomotor development; 2 unilateral sensorineural hearing loss.
Conclusions/Learning Points: CMV infection had severe course in one-third of the identified cases and caused neurologic impairment and hearing loss in about one-fourth. Although there is no universal screening, in our tertiary center we receive all severe cases with positive maternal serology and fetal neuroimaging abnormalities, which can explain the higher proportion of symptomatic infections.

Backgrounds: With the introduction of combination antiretroviral therapy (cART), mortality rates of children with perinatally acquired Human Immunodeficiency Virus (PHIV) have declined. Adolescents are growing up with disease and treatment associated comorbidities, such as dyslipidemia. HIV is identified as independent risk factor for CVD. Hypothesis include vascular inflammation, dyslipidemia and cART toxicity. Lipidomic analysis, comprehensive lipid analysis, measuring concentration and composition of individual lipid species, can be used to evaluate and identify possible lipid risk profiles. To investigate differences in lipid profile and to further understand pathophysiological mechanisms of CVD risk in adolescents with PHIV, we assessed differences in plasma lipidome between PHIV adolescents compared to HIV-negative matched controls.
Methods: We included 21 PHIV-infected adolescents and 23 HIV-negative controls matched for age, sex, ethnic origin and socio-economic status. Lipid composition in plasma was measured using Thermo Scientific Ultimate 3000 binary high-performance liquid chromatography (HPLC)-mass spectrometry. In addition differences in lipid composition were measured between PHIV children and adolescents on different cART regimens known to be associated with lipid alterations. Statistical analysis was performed by in-house developed lipidomics pipeline at the Core Facility Metabolomics of the Amsterdam UMC, location AMC, the Netherlands.
Results: The median age was 17.5 years (15.5–20.7) and 16.5 years (15.7-19.8) for PHIV adolescents and controls, respectively 42 % of PHIV adolescents used an NNRTI-based or PI-based cART regimen. We observed no significant differences between lipidomic profiles or levels of individual lipid species between PHIV adolescents and controls. In PHIV adolescents differences in lipid species between different cART-based regimens were observed.
Conclusions/Learning Points: Plasma lipidomic profiles are comparable in virally suppressed PHIV adolescents and HIV negative controls. Different cART regimens might influence lipid composition and further research could further identify these alterations.

Title of Case: Hemophagocytic lymphohistiocytosis-like syndrome in an infant with parechovirus type 3 infection
Background: Human Parechovirus (HPeV) infection in children usually leads to mild respiratory or gastrointestinal symptoms. However, neonatal infection by type 3 genotype (HPeV-3) has been associated with more severe features namely a hemophagocytic lymphohistiocytosis (HLH)-like clinical presentation, due to a significantly stronger activation of genes involved in immune and inflammatory signalling of the host immune response.
Case Presentation Summary: A 48-day-old, full-term female infant, was brought to the emergency department for fever (38.3ºC). On admission she was febrile (38.1ºC), with normal physical examination. Initial laboratorial workup revealed: haemoglobin 9.5g/L, normal leucocyte and platelet count, C-reactive protein 0.77mg/dL, normal AST; and leukocyturia (75/uL). She was admitted with IV cefuroxime for urinary tract infection. Two days after admission she maintained fever, with irritability, maculopapular exanthem and hepatomegaly. Further lab results revealed: neutropenia 600/uL haemoglobin 11.2g/dL; AST 550U/L, ALT 219U/L, ferritin 8521ug/L, LDH 736U/L and triglycerides 978mg/dL in serum; and normal CSF parameters. She completed 2 days of cefuroxime (until negative urine culture), and was apyretic after 3 days of antibiotic, without other therapeutic intervention. After 5 days, she was discharged against medical advice, but with clinical and laboratory improvement. HPeV-3 was detected in faeces by polymerase chain reaction.
Learning Points/Discussion: This case suggests a self-limited virus-induced secondary HLH-like presentation of HPeV-3 infection in early infancy. Some authors have reported similar cases with different management approaches, including immunomodulatory treatment. Our case highlights the relevance of searching for HPeV-3 in newborns and small infants investigated for HLH, which may reduce the need for more aggressive immunomodulatory treatments, maintaining an appropriate clinical and laboratory follow-up.
