Title of Case: CONGENITAL SYPHILIS PRESENTING AS FEVER WITHOUT LOCALIZING SIGNS AFTER THE NEWBORN PERIOD
Background: Congenital syphilis (CS) remains a worldwide public health problem and has been increasing at higher rates in the last 20 years. As the diagnosis (pre and postnatal) is crucial for adequate treatment and prevention of severe consequences, acknowledgement of clinical and analytical signs is mandatory. Portuguese antenatal care programs advocate universal VDRL screening in all pregnant women. Failure to detect maternal disease results in CS. We describe an early CS in an infant with fever without localizing signs.
Case Presentation Summary: A 2-month-old, previously healthy male infant, was brought to the ER with a 24-hour history of fever and diffuse rash. His mother's third trimester serologies were negative. At 38 weeks she presented vulvar ulcers and only herpes PCR was performed, with a negative result. The infant's ER blood tests revealed anemia (Hb 7,6x10g/L), leukocytosis (22000/uL) with monocytosis (5500/uL), thrombocytopenia (minimum 55000/uL) and CRP 263 mg/L. He started cefotaxime and gentamicin due to sepsis. On day 2, palms and soles rash appeared and VDRL (1/4) and TPHA were positive. Other TORCH, enteroviral and rickettsia infections were excluded. After full organ involvement studies (lumbar puncture, transfontanellar ultrasound, hearing test, eye examination and long bone radiographs), the infant was treated with penicillin G for 10 days with good serologic response after 12-months follow-up. Anemia, thrombocytopenia and elevated transaminases values normalised after treatment.
Learning Points/Discussion: CS is a preventable and treatable disease. We pretend to highlight how important high suspicion for CS is and how detailed maternal history provides important clues for the diagnosis. Palms and soles rash raised a high suspicion of the diagnosis and, monocytosis is very common in these cases. We must keep in mind that third trimester negative serologies do not exclude this diagnosis.

Backgrounds: Development of chronic lung disease (CLD) in premature infants is associated with inflammation and infection with pathogens such as Ureaplasma. However, it is unknown whether the inflammatory response elicited in alveolar epithelial cells differs between the Ureaplasma biovars: U. urealyticum (UU) and U. parvum (UP). Here, we compared the inflammation induced by UU and UP in respiratory epithelial cells upon infection.
Methods: Human alveolar epithelial cells were co-cultured with different Ureaplasma strains of UU and UP, at different ratio's. Inflammatory responses of alveolar epithelial cells were assessed by detecting the cytokines interleukin-6 (IL-6), IL-8 and C-C Motif Chemokine Ligand 2 (CCL-2) in co-culture supernatants by ELISA. The effect of Ureaplasma exposure on alveolar epithelial cell apoptosis and cell death was evaluated by flow cytometry using anti-cleaved-caspase-3 specific antibodies and a viability dye, respectively. Uninfected alveolar epithelial cells, treated with TLR2/TLR6 agonist or DMSO respectively, served as a control.
Results: Infection of alveolar epithelial cells with UP led to a greater production of the pro-inflammatory mediators IL-6 and IL-8 and a higher expression of CCL2 mRNA than UU, and was most distinct at higher ratios. We did not detect apoptosis of alveolar epithelial cells upon co-cultures with either Ureaplasma species. However, UU induced more cell death than UP. Remarkably, Ureaplasma-induced responses appear dependent on secreted factors as responses induced by heat-inactivated bacteria were lower than those by alive bacteria.
Conclusions/Learning Points: By directly comparing Ureaplasma biovars in a controlled in-vitro infection model we demonstrate that both UU and UP may contribute to inflammation and cell damage seen in CLD, but differ in their mechanism of action. Our data shed light on the role of Ureaplasma in development of CLD in premature infants.

SPORADIC EARLY ONSET SEPSIS IN EXTREME PRETERM CAUSED BY PANTOEA AGGLOMERANS IN LEVEL THREE NEONATAL UNIT IN THE UK

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Leina Ahmed, Fazalur Rehman
Northen Care Alliance NHS group, Royal Oldham hospital, Neonatal Intensive Care Unit, Manchester, United Kingdom

Title of Case: Sporadic early onset sepsis in extreme preterm caused by Pantoea agglomerans in level 3 neonatal unit in the UK
Background: Pantoea agglomerans is a gram-negative plant pathogen. It can infrequently cause opportunistic infections in humans. Neonatal bloodstream infections in neonatal intensive care units had been reported with high mortality rates. Here we report neonatal sepsis caused by Pantoea agglomerans in a level three NICU in the UK.
Case Presentation Summary: Extreme preterm male born at 26+5 via emergency C/S for prolonged rupture of membranes and abnormal CTG. His birth weight was 1 Kg. He received surfactant at delivery and was extubated to CPAP after a few hours. On admission to NICU, umbilical lines were inserted and TPN was commenced. Benzylpenicillin and Gentamicin were received and stopped at 36 hours following negative sepsis screening. At 48 hours he was intubated for profound apnoea, had a repeat of the sepsis screen, and was commenced on Cefotaxime and Vancomycin. His blood culture grew Pantoea Agglomerans which remained positive on the repeated sample five days later. His CRP peaked at 108, his WBC count peaked at 36.3. He received platelet transfusion twice; the lowest platelet count was 9. The lumbar puncture was not done as he was very sick, but he had a normal cranial ultrasound scan. He was switched to the maximum dose of Meropenem for 3 weeks. The fourth and fifth blood cultures were negative, and he recovered. Written informed consent was obtained from the patient's legal guardians for the publication of this case report.
Learning Points/Discussion: From the literature, Pantoea Agglomerans has been associated with high mortality in newborn infants, especially preterm. Early identification with proper management is paramount for a better outcome.

MEDICSI Islamabad, Neonatal Intensive Care Unit, Islamabad, Pakistan

Title of Case: SALMONELLA SEPSIS IN A PRETERM AND SEVERE THROMBOCYTOPENIA
Background: Salmonella, although a rare cause of neonatal sepsis has been documented to have serious complications in affected neonates.
Case Presentation Summary: We present a case of a Preterm who developed Salmonella sepsis associated with severe thrombocytopenia. Born at 31 weeks with a weight of 800 grams to a primigravida mother. He was growth restricted secondary to absent end diastolic flow and anhydramnios. On admission, he was started on first line antibiotics, Cefotaxime and Amikacin due to respiratory distress requiring ventilation. First CRP was 0.5. Antibiotics were stopped with the first negative culture. On day 9^{th} of life there was clinical deterioration and CRP increased to a maximum of 74. Blood cultures were sent and Meropenem and Vancomycin were started. The blood culture was positive for Salmonella and sensitive to Meropenem. Despite being on Meropenem for 10 days, the baby continued to develop severe refractory thrombocytopenia and no clinical improvement. Platelet count was persistently less than 10×10^3. His antibiotics were changed to Piperacillin / Tazobactam as per culture sensitivity because of suspicion of Meropenem induced Pancytopenia. Due to no clinical improvement for the next 7 days and further reduction of platelet count to a minimum of 4×10^3, Antibiotics were changed to a combination of beta- lactam 3^{rd} generation cephalosporin, Cefoperazone Sodium and beta-lactamase inhibitor Sulbactam Sodium as per culture sensitivity. Clinical improvement was noticed in the first week of this combination treatment along with a recovery in the platelet counts. He was given 21 days of this combination treatment.
Learning Points/Discussion: Salmonella sepsis can be challenging to treat. Change of antibiotic as per sensitivities should be considered in cases where there is no clinical improvement.

Backgrounds: Neonatal sepsis triggers inflammation that contributes to increased mortality and acute kidney injury (AKI). Male sex is a risk factor for AKI in rodents and critically-ill human newborns. The phosphodiesterase inhibitor pentoxifylline (PTX) may protect immature kidneys from sepsis-induced injury. We aimed to determine if sex influenced inflammatory and kidney injury biomarkers (as surrogate for AKI) in response to pentoxifylline among Escherichia coli-septic neonatal mice.
Methods: Newborn (<24 hours old) C57BL/6J mice (Jackson Laboratory; n=98, 60.2% male) were intravenously injected with live E. coli K1 (10^5 colony forming units/gram weight). After 1.5 hours, pups randomly received saline, gentamicin, PTX, or gentamicin with PTX (GENT+PTX), and were euthanized 4 hours later. Cytokine and kidney injury marker concentrations were measured in homogenized renal tissue, and sex determined through y chormosome genotyping. Analysis employed linear mixed effects models with litter as random, and sex and treatment as fixed effects, adjusted for sex and treatment interaction.
Results: Gentamicin alone significantly ($p<0.05$) diminished renal tissue interleukin (IL)-1β and granulocytes colony stimulating factor (G-CSF); gentamicin or GENT+PTX suppressed IL-17, IL-12(p40), chemokine (C-X-C motif) ligand 1 (CXCL1), chemokine ligand 2 (CCL2), CCL3, and CCL4; while GENT+PTX decreased neutrophil gelatinase-associated lipocalin, CXCL10, and vascular endothelial growth factor. Sex significantly ($p<0.05$) interacted with treatment for IL-1α, IL-1β, IL-12(p40), G-CSF, CXCL1, and tumor necrosis factor (TNF): GENT+PTX decreased IL-1α, IL-12(p40), and G-CSF compared to untreated, and IL-1α and IL-12(p40) compared to gentamicin-treated female pups, but increased IL-1β, G-CSF, CXCL1, and TNF compared to gentamicin alone in male mice.
Conclusions/Learning Points: Addition of PTX to gentamicin preferentially suppressed pro-inflammatory cytokines in female septic pups, which may have therapeutic implications.

GROUP B STREPTOCOCCAL INFECTION IN NEONATES – A CASE SERIES

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Rita Calejo[1], Inês Aires Martins[2], Inês Paiva Ferreira[1], Joana Carvalho Queirós[2], Andreia Meireles[1], Abílio Oliveira[1]
[1]Centro Hospitalar Tâmega e Sousa, Department Of Pediatrics And Neonatology, Penafiel, Portugal, [2]Centro Materno Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatrics, Porto, Portugal

Title of Case: GROUP B STREPTOCOCCAL INFECTION IN NEONATES – A CASE SERIES
Background: Group B Streptococcus (GBS) remains the most important cause of neonatal bacterial infection, with significant morbidity and mortality. Some important risk factors are maternal vaginal or rectal GBS colonization, maternal fever, prolonged rupture of membranes and prematurity. A retrospective observational study of the neonates diagnosed with GBS infection was performed, between January 2018 and December 2022.
Case Presentation Summary: 6 neonates presented with GBS infection in 10 923 births. All pregnancies were uneventful and the majority were full term neonates. 3 were caesarian deliveries, 2 were vacuum deliveries and 1 was an eutocic delivery. 4 had infectious risk, being the common factor maternal fever. GBS screening was performed in all full term neonates, with negative result. When not performed, adequate prophylaxis was administered. They all had weight adequate to gestational age. The minimum Apgar score was 6 at the 1st minute and at the 10th minute all had 9 or 10. 5 cases had manifestations in the first 12 hours of life and the other case presented at the 10th day of life. The major symptoms were moan (4), fever (3) and 1 presented with septic shock, needing admission to an Intensive Care Unit. 1 of them had meningitis. All had favorable evolution at the end of the treatment and at posterior ambulatory follow-up.
Learning Points/Discussion: The incidence and unspecific manifestations of the infection in our population are similar to that described in the literature. The fact that all mothers had GBS negative screening should alert us to the possibility of intermittent infection. Adequate prophylaxis still requires close vigilance and other contributing factors can influence the possibility of neonatal infection.

MICROBIOLOGICAL PROFILE OF NEONATAL SEPSIS IN AN INTENSIVE CARE UNIT OF A HOSPITAL IN SOUTHERN BRAZIL

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Diana Duessmann[1], João Pedro Câmera[2], Ana Paula Brandalize[3]
[1]Federal University of Santa Maria, Medicine, Santa Maria, Brazil, [2]Bom Jesus Hospital, Neonatal Intensive Care Unit, Toledo, Brazil, [3]Federal University of Paraná, Medicine, Toledo, Brazil

Background: In Brazil, it is estimated that 60% of infant mortality occurs in the neonatal period, with a significant proportion attributable to sepsis. Blood culture is a gold standard test for diagnosis but due to the time of identification, an empirical therapy is established. In this case ampicillin and gentamicin in early neonatal sepsis, and in late oxacillin and an aminoglycoside, according to Brazilian guidelines.
Methods: A prospective observational cohort study was conducted, composed of 118 newborns admitted to a Neonatal Intensive Care Unit in southern Brazil. The medical records of patients were evaluated from January 2021 to September 2021.
Results: In this period, 45.8% of neonates were moderate/late preterm, 41.5% with low birth weight. Sepsis was the third leading cause of hospitalization (29.7%), associated with a higher median length of hospitalization (25 ± 33.5 days). Blood cultures were collected from 55.1% of patients. Only 15.3% of them had positive results, with Staphylococcus epidermidis (4.2%) being the most prevalent, followed by Klebsiella pneumoniae (3.4%). After empirical therapy, 57.1% of the agents were sensitive to the therapy. Approximately 3.4% of those hospitalized patients died, which were mainly caused by septic shock.
Conclusions/Learning Points: Our study indicated the microbiological profile of sepsis and the characteristics of our population are very similar to those reported in the literature for developing countries. Knowledge of the characteristics related to microbial sensitivity and resistance to drugs used remains fundamental for a better approach. Although the COVID-19 pandemic is active in this period, no change in expected patterns was observed. Further research is required to identify other clinical parameters important for an ideal infection surveillance program in Brazil.

PLESIOMONAS SHIGELLOIDES NEONATAL SEPSIS: CASE REPORT AND LITERATURE REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Sandra Catarina Ferraz, Beatriz Sousa, Isabel Soro, Carla João Dias, Dalila Rocha, José Rei Amorim, Armando Laranjeira, Arnaldo Rego
Unidade Local de Saúde do Alto Minho, Paediatrics, Viana do Castelo, Portugal

Title of Case: Plesiomonas shigelloides neonatal sepsis: case report and literature review
Background: Plesiomonas shigelloides is a Gram-negative rod, belonging to Enterobactereacea family, that is generally found in fresh water. The most frequent presentation of P. Shigelloides infection is gastroenteritis, although it can also be an agent of bacteriemia, meningoencephalitis, and others. Extraintestinal manifestations are more common in newborns and immunocompromised individuals.
Case Presentation Summary: A male term newborn, from an uncomplicated pregnancy and delivery was admitted in a neonatal care unit at 11 hours of life for continuous grunting and subfebrile temperature. Faced with the clinical suspicion of early neonatal sepsis, an analytical study and septic screening were performed and empirical antibiotic therapy was started with ampicillin and gentamicin. In the analytical study on admission, he had leukopenia and negative CRP. The cytochemical examination of the cerebrospinal fluid (CSF) showed no suggestions of central nervous system (CNS) infection. After 24 hours of therapy, due to clinical deterioration, cefotaxime was started, and the newborn improved. The blood culture came back positive for Plesiomonas shigelloides, resistant to ampicillin and gentamicin and sensitive to cefotaxime. The urine and CSF cultures were negative, and the control blood culture was negative. This microorganism was not isolated from the mother's feces, and it was not possible to confirm its origin. The child is currently without sequelae.
Learning Points/Discussion: Plesiomonas shigelloides is a very rare agent of neonatal sepsis, there are only 15 previous reported cases of neonatal sepsis and all the previous described cases had simultaneous CNS infection symptoms, while in this case there was no CNS involvement. The mortality rate associated with neonatal infection by this agent is 60% and morbidity and mortality depend on the timely institution of antibiotics with an adequate spectrum.

ROLE OF POSTNATAL MATURATION AND CELLULAR INNATE IMMUNITY IN INTESTINAL COLONISATION WITH GROUP B STREPTOCOCCUS

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Mirjam Freudenhammer[1], Zohreh Mansoori Moghadam[2], Philipp Henneke[2]
[1]Medical Center - University of Freiburg, Faculty of Medicine, 2institute For Immunodeficiency, Center For Chronic Immunodeficiency (cci), Freiburg, Germany, [2]Medical Center - University of Freiburg, Faculty of Medicine, Institute For Immunodeficiency, Center For Chronic Immunodeficiency (cci), Freiburg, Germany

Backgrounds: GBS remains a leading pathogens causing neonatal sepsis and meningitis worldwide. The neonatal gut constitutes a reservoir for GBS as a pathogen in late-onset GBS sepsis, whereas the adult gut may serve as a safe haven for GBS as a harmless commensal. However, host factors that control intestinal colonisation with GBS and prevent translocation are largely unknown.
Methods: We developed a GBS colonisation model where mice (14 days – 6 weeks) were colonized with GBS via gastral gavage. Selective agar was used to determine colonization density and organ dissemination. Lamina propria macrophages were extracted and analysed with flow cytometry or sorted by FACS for subsequent PCR or RNA sequencing. Different transgenic mouse strains and depletion methods as well as bone marrow transfer were used for detailed analysis of host factors.
Results: While stable colonisation is frequently achieved in 14 days old neonatal mice, it is uncommon or occurs only at low density in adult mice. Yet, a deficiency in MyD88, the common adapter of Toll-like receptors, results in lethal GBS dissemination in neonatal mice and causes substantially increased colonisation densities and sepsis rates in adult mice. In contrast, other innate signalling pathways were redundant in controlling GBS in the gut, as demonstrated in ACS-, CCR2-, UNC93B-deficient mice. Analysis of intestinal macrophages from colonised neonatal mice revealed a distinct cytokine expression pattern, e.g. downregulated IL-6 and IL-10, as well as metabolic differences with reduced mitochondrial mass and membrane potential.
Conclusions/Learning Points: Non-epithelial MyD88 plays a central role in control of intestinal GBS colonisation and protection from sepsis originating from the gut. Colonisation with GBS changes inflammatory and metabolic states of intestinal macrophages, highlighting their role as critical mediators of innate immune response.

PASTEURELLA MULTOCIDA: SEPSIS IN A YOUNG INFANT

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Ariana Gonçalves Marques, Elsa Machado Guimarães, Margarida Pereira, João Agro
Centro Hospitalar de Leiria, Pediatrics, Leiria, Portugal

Title of Case: PASTEURELLA MULTOCIDA: SEPSIS IN A YOUNG INFANT
Background: Pasteurella multocida is a rare cause of infection in pediatric age. This bacterium is a gram negative coccobacillus that is part of many domestic animals' nasopharyngeal flora, such as cats and dogs. This infection can be acquired through contact with domestic animals' oropharyngeal secretions (bite, scratching and licking) and, less frequently, through vertical transmission.
Case Presentation Summary: A 30 days old infant presenting intermittent whining was examined at the neonatology appointment. No history of fever. Ill-looking, decreased vitality and decreased peripheral perfusion, with no other positive findings. Blood tests with blood gas analysis were performed, revealing hyperglycemia (256 mg/dl), hyponatremia (128 mmol/L) and respiratory acidosis (pH 7.3, pCO_2 58 mmHg, HCO_3 27.6 mmol/L), with a slight increase of C- reactive protein (18,3 mg/L). He was admitted to the hospital. Six hours after admission, fever, whining and marbled skin were objectivated and new blood tests were performed, this time with increased C- reactive protein (75,5 mg/L) and lactate (3,5 mmol/l). He started antibiotic therapy with ceftriaxone and ampicillin. Hemoculture was positive for Pasteurella multocida therefore ceftriaxone was suspended, continuing ampicillin for 14 days. CSF and urine culture were negative. Following the first day of admission, he had a favorable clinical evolution with sustained apyrexia and no other episodes of hyperglycemia. He had a prior contact with a dog at home.
Learning Points/Discussion: Pasteurella multocida infection is associated with life-threatening complications. Domestic animals are frequent members of today's families, which increases the risk of being in contact with this agent. Parents should be reminded to avoid direct interactions between these animals and infants, reinforcing how important handwashing is after any contact with the formers.

EARLY ONSET NEONATAL SEPSIS CAUSED BY PASTEURELLA MULTOCIDA

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Aleksandra Hristova
General Hospital, Neonatology, Kumanovo, North Macedonia

Title of Case: Early-Onset Neonatal Sepsis caused by Pasteurella multocida
Background: Neonatal sepsis is a major contributing cause of neonatal morbidity and mortality. EOS is most often caused by intrapartum maternal- vertical transmission, by group streptococcus, Escherichia colli and other less common bacteria. Less common bacteria are also responsible for neonatal EOS and we must considered to ensure appropriate management.
Case Presentation Summary: The mother was 29-year old who received routine prenatal care, all vaginal swabs and serologies were all negative. She went into spontaneous labor and spontaneous rupture of membranes occurred 5 hours prior to delivery. She delivered at 40 weeks of GA a male newborn with birth weight 3100 grams and 50sm birth length, APGAR score 8/9 with no resuscitation required. The infant developed respiratory distress with grunting 4 hours after birth. The infant was lethargic and hypoglycemic. We initiated oxygen via nasal cannula and I.V. access was obtained for empiric administration of ampicillin +sulbactam and gentamicin. After 16 ours after birth the newborn got a high temperature 38,6C. After that we transport the neonate to higher level of health care. After 48 hours blood culture revealed pasteurella multocida. The neonate was treated with antibiotics, supportive care within 3 weeks and recovered without complications.
Learning Points/Discussion: Neonatal care providers should often take a consideration non-common bacterial species of early onset sepsis in neonate.

PV0404 / #2505

PROCALCITONIN AND OTHER BIOMARKERS OF SEPSIS IN NEWBORN IN DEPARTMENT OF NEONATOLOGY IN GENERAL HOSPITAL KUMANOVO

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Aleksandra Hristova
General Hospital, Neonatology, Kumanovo, North Macedonia

Background: Objective: Neonatal Sepsis is one of the most significant causes of mortality and morbidity in infants. There are numerous parameters available to confirm presence of early sepsis in newborn. This study is undertaken to determine the importance of early laboratory signs to confirm early neonatal sepsis in our department.
Methods: Material and Methods: We chose procalcitonin, WBC and CRP in blood sample obtained by puncture of peripheral vain within first 12 hours after birth. We included 228 newborn infants suspected for bacterial infection in period from 01 January 2022 until 31 December 2022.
Results: In every newborn suspected for neonatal infection, we noticed elevated levels of procalcitonin (above 0,5ng/ml). Level of 33,4 ng/ml was found in patient with streptococcus type B sepsis, 27ng/ml in patient with staphylococcus aureus methicillin resistant sepsis and 9ng/ml in newborn with pyelonephritis ac lat dex. In 110 newborns we noticed elevated levels of CRP (above 10 mg/L) and in every newborn we noticed elevated or depleted values of WBC.
Conclusions/Learning Points: Conclusion: Although diagnosis of neonatal sepsis is based of isolation of bacteria in blood sample and measurement of endotoxins, elevated levels of PCT, CRP and elevated or depleted values of WBC are very important biomarkers for early diagnose of early onset of neonatal sepsis.

PV0405 / #1651

THE PRO-INFLAMMATORY CYTOKINE RESPONSE BY PRETERM NEWBORNS IS HIGHLY VARIABLE AT BIRTH BUT COMPARABLE WITH TERM NEWBORNS AND ADULTS

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Jop Jans[1], Tess Voskamp[1], Renske Gorissen[1], Annemarie Van Rossum[2], W.W.J. Unger[1]
[1]Erasmus MC University Medical Centre Rotterdam - Sophia Children's Hospital, Department Of Pediatrics, Laboratory Of Pediatrics, Rotterdam, Netherlands, [2]Erasmus MC University Medical Centre Rotterdam-Sophia Children's Hospital, Department Of Pediatrics, Division Of Paediatric Infectious Diseases And Immunology, Rotterdam, Netherlands

Backgrounds: Bacterial infections can lead to a harmful inflammatory response in newborns, called neonatal sepsis. The high incidence of sepsis in preterm newborns highlights the need to better understand the neonatal inflammatory response. A high degree of variation in serum cytokine responses is observed during neonatal sepsis and high levels of TNF and IL-6 are correlated with increased disease severity. However, it is unclear whether preterm newborns with a hyperinflammatory response can already be identified at birth. This study determined (I) the variation in cytokine production between preterm newborns at birth and (II) the production of TNF and IL-6 by preterm newborns compared to term newborns and adults. This knowledge could provide clinicians with tools at birth to identify preterm newborns with a hyperinflammatory cytokine response.
Methods: Whole blood was collected from the umbilical cord or healthy adults. Prematurity was defined as gestational age < 37 weeks. Whole blood was stimulated with TLR ligands (LPS, Pam3Cys4K, R848) or bacteria (E. coli, S. epidermidis, S. agalactiae). After 5 hours, the production of TNF and IL-6 was measured with ELISA and the interindividual variation was calculated.
Results: No differences were observed for the production of TNF and IL-6 by preterm newborns (N=10), term newborns (N=15) or adults (N=16) for all stimuli (Fig. 1A-D). A high degree of variation in the production of TNF and IL-6 by preterm newborn was already present at birth for all stimuli (Fig 1E).

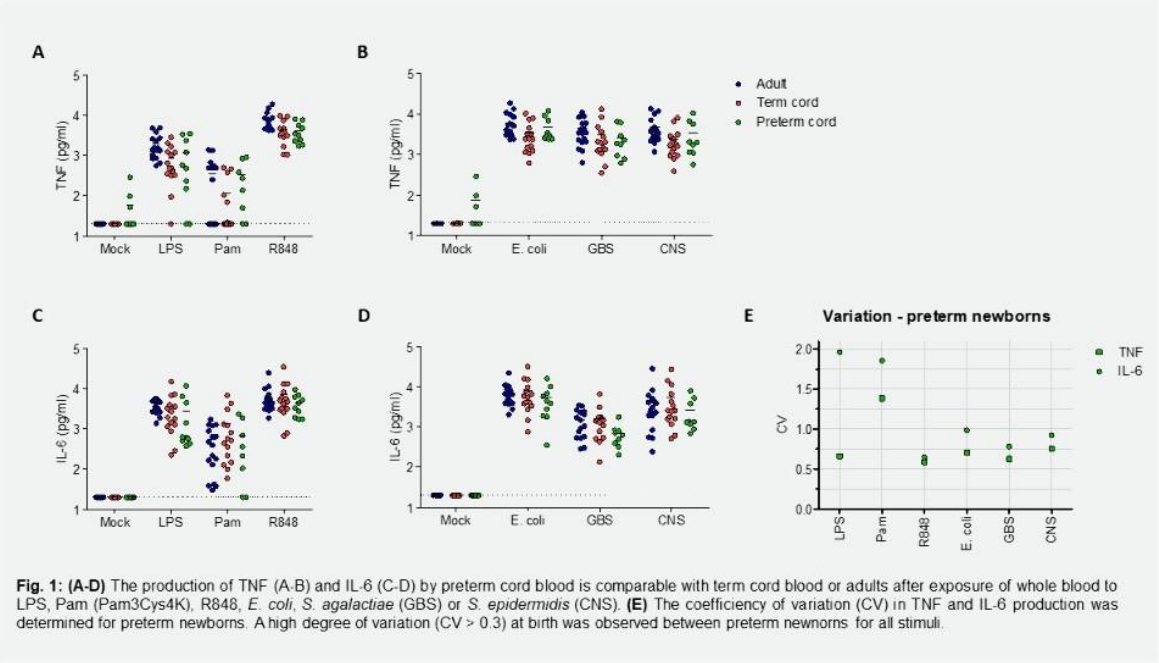

Fig. 1: (A-D) The production of TNF (A-B) and IL-6 (C-D) by preterm cord blood is comparable with term cord blood or adults after exposure of whole blood to LPS, Pam (Pam3Cys4K), R848, *E. coli*, *S. agalactiae* (GBS) or *S. epidermidis* (CNS). **(E)** The coefficiency of variation (CV) in TNF and IL-6 production was determined for preterm newborns. A high degree of variation (CV > 0.3) at birth was observed between preterm newnorns for all stimuli.

Conclusions/Learning Points: Preterm newborns mount an adult-like production of TNF and IL-6 at

birth. More importantly, the production of TNF and IL-6 is highly variable between individuals. This knowledge is clinically relevant, because it could provide clinicians with tools at birth to identify preterm newborns with a hyperinflammatory response.

GROUP B STREPTOCOCCUS AMONG PREGNANT WOMEN AND INFANTS IN KOREA: COLONIZATION DYNAMICS, VERTICAL TRANSMISSION RATE, AND SEROTYPE DISTRIBUTION

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Dong Hyun Kim[1], Byung Ok Kwak[2]
[1]Inha University College of Medicine, Pediatrics, Incheon, Korea, Republic of, [2]Hallym University Kangnam Sacred Heart Hospital, Paediatrics, Seoul, Korea, Republic of

Backgrounds: Group B Streptococcus (GBS) remains a leading cause of invasive infections in infants in the first 90 days of life. This study aimed to analyze the colonization dynamics, vertical transmission rate, and serotype distribution in pregnant women and their infants.
Methods: The prospective cohort study of mother-infant pairs was conducted between January 2020 and August 2021 at Hallym University Sacred Heart Hospital in Korea. In pregnant women, swab samples were obtained from the vagina and rectum, and in their newborns, gastric juice and nasopharyngeal aspirate were collected within one hour of birth. Nasopharyngeal and rectal swab samples were obtained at one month and two months of age. These were assessed for GBS presence using culture, and serotyping was conducted using multiplex PCR.
Results: The authors confirmed that 40 among 213 pregnant women were positive for GBS culture in rectovaginal swab samples, establishing a colonization rate of 18.8%. Dominant serotypes were VII (20%), III (17.5%), V (15%), and Ib (15%). Vertical transmission of GBS infection was not identified. Colonization of GBS was observed in 4 and 3 cases at one month and two months of age, respectively, and common serotypes were Ia and VIII for 1-month-old infants and Ia and III types for 2-month-old infants.
Conclusions/Learning Points: The colonization rate of GBS in pregnant women was higher than in previous Asian studies, and vertical transmission was not observed. However, GBS colonization was observed in infants at 1 and 2 months of age. This is the first cohort study to assess GBS dynamics in Korean mother-infant pairs and will be beneficial for developing clinical guidelines and therapeutic approaches.

USE OF THE SCALE SNAP-II TO ASSESS THE SEVERITY OF ECO-DEPENDENT NEONATAL SEPSIS

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Olena Vlasova, Daryna Klymovych, Alona Yakob, Anastasiia Zapotichna
Bukovynian State Medical University of Ukraine,, Department Of Pediatrics And Children's Infectious Diseases, Chernivtsi, Ukraine

Background: Immaturity of immune protection factors, genetically determined expression of immune factors determine the susceptibility of newborns to infection. Environmental factors of varying intensity due to the bioaccumulation of xenobiotics in the mother's tissues and their release into the bloodstream during pregnancy can have a pathogenic effect on the fetus.
Methods: Newborns were divided into two groups. Group I(30 children) - parents who lived in places affected by adverse environmental factors, and Group II(26) - parents who lived in favorable conditions. A diagnostic scale SNAPII was used to assess the condition.
Results: When using the diagnostic system to assess the severity of the disease, a more severe condition was found in the patients of the main group, which is also confirmed by the fact that when choosing the distribution points for SNAP II-10 or more points. Thus, the number of points for assessing the severity of general condition disorders according to the SNAPII scale is given in 70.0% and 46.1%($P<0.05$) of patients of observations. The more severe clinical course of sepsis in the newborns of the main group compared to the children of the II group was also evidenced by a higher reliable degree of correlation when assessing their general condition using the indicated indicative prognostic system ($r=0.95$,($P<0.05$)). In the 1st clinical group, the average duration of treatment in the intensive care unit was 9.0 ± 0.5 days, and in the hospital - 44.1 ± 1.6 days. In the comparison group, these indicators reached 7.0 ± 0.3 days ($P<0.05$) and 37.5 ± 1.7 days ($P<0.05$), respectively.
Conclusions/Learning Points: Therefore, the residence of parents of children with neonatal sepsis in places with worse environmental conditions affects the severity of the disease.

CHARACTERIZATION OF GRAM-NEGATIVE BACILLI BACTERAEMIAS IN THE NEONATAL INTENSIVE CARE UNIT OF A TERTIARY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Gerard Martínez Segura[1], María Ríos-Barnes[2], Maria Goretti López-Ramos[3], Amadeu Gené Giralt[4], Antoni Noguera[5], Claudia Fortuny[6]
[1]Hospital Sant Joan de Déu, Paediatrics, Barcelona, Spain, [2]Hospital Sant Joan de Deu, Infectious And Imported Diseases, Pediatric Unit, Esplugues de Llobregat, Spain, [3]Hospital Sant Joan de Déu, Barcelona, Spain., Pharmacy Department, Esplugues de Llobregat, Spain, [4]Hospital Sant Joan de Déu, Microbiology, Esplugues de Llobregat, Spain, [5]4. Hospital Sant Joan de Déu, Pediatrics, Barcelona, Spain, [6]Hospital Sant Joan de Déu, Universitat de Barcelona. RITIP., Paediatric Infectious Diseases, Barcelona, Spain

Backgrounds: Despite the effort put in preventive measures, neonatal sepsis is still a major cause of morbidity and mortality. An increase in hospital and community-based multidrug-resistant enterobacterial infections has been reported in the last years. We aim to describe the clinical and microbiological characteristics of Gram-negative bacilli bacteraemias in neonates in our hospital.
Methods: Single-centre retrospective observational study in the neonatal intensive care unit of a paediatric tertiary hospital. We included all episodes of neonatal bacteraemia during 2019-2020, outside of any outbreak period.
Results: One hundred forty-four positive blood cultures were documented in the study period, resulting in 104 episodes of clinically significant bacteraemia (72.2%); 22/104 (21.1%) were caused by Gram-negative bacilli and were included in this analysis (Table 1). Two multidrug-resistant microorganisms were identified (2/22, 9.1%), both producers of extended-spectrum beta-lactamase (ESBL), one of them AmpC type. A previously known colonizing microorganism caused 4/7 (57.1%) episodes. Median treatment duration was 16.3 days (p25-75; 11.0 – 16.0). Complications were observed in 7 patients: disseminated disease (n=1, 4.5%), persistent bacteraemia (n=4, 18.2%), and death (n=2, 9.1%).

Table 1.	
Epidemiology	
Woman	6/22 (27.3%)
Age at bacteraemia diagnose, days *(Mean, range)*	23.8 (1-66)
Ethnicity	
Arab	7/22 (31.8%)
Hispanic-American	4/22 (18.2%)
White	11/22 (50.0%)
Delivery	
Non-instrumented vaginal	9/22 (40.9%)
Instrumented vaginal	4/22 (18.1%)
Caesarean	9/22 (40.9%)
Risk factors	
Antenatal infectious risk factors	13/22 (59.1%)
Group B *Streptococcus* maternal colonization	1/22 (4.5%)
Chorioamnionitis	5/22 (22.7%)
Prolonged membrane rupture (>18h)	3/22 (13.6%)
Other	4/22 (18.1%)
Prophylactic intrapartum antibiotic use	12/22 (54.5%)
Low birthweight	8/22 (36.4%)
Very low birthweight	9/22 (40.8%)
Prematurity	19/22 (86.4%)
Catheter Use, number *(Mean, range)*	1,52 (0-3)
Central catheter	9/22 (40.9%)
Peripherally inserted central catheter	5/22 (22.7%)
Days of catheter *(Mean, p25-75)*	11.12 (4.0-15.0)
Invasive mechanical ventilation	15/22 (68.2%)
Severe illness	
Surgery	12/22 (54.5%)
Parenteral feeding	9/22 (40.9%)
Necrotizing enterocolitis	7/22 (31.8%)
Major congenital anomaly	9/22 (40.9%)
Extracorporeal membrane oxygenation	1/22 (4.5%)
Prior antibiotic therapy	11/22 (50.0%)
Prolonged stay in neonatal unit, days *(Mean, range)*	23.6 (1-66)
Colonization, any species	7/22 (31.8%)
Klebsiella spp.	4/7 (57.1%)
Serratia spp.	3/7 (42.9%)
Colonization, same microorganism as bacteraemia	4/7 (57.1%)
No breastmilk feeding	1/22 (4.5%)
Clinical and microbiological features	
Clinical presentation	
Only Fever	2/22 (9.1%)
Only Apnoea	3/22 (13.6%)
Abdominal abnormalities	3/22 (13.6%)
Late-onset sepsis	11/22 (50.0%)
Early-onset sepsis	1/22 (4.5%)
Asymptomatic bacteraemia	2/22 (9.1%)
Infection source	
Catheter-associated	7/22 (31.8%)
Respiratory	1/22 (4.5%)
Urinary	1/22 (4.5%)
Gastrointestinal	6/22 (27.3%)
Unknown	7/22 (31.8%)
Microbiological isolate

Klebsiella (K. oxytoca, K. pneumoniae)	9/22 (40.9%)
Serratia marcescens	4/22 (18.2%)
Other microorganisms	5/22 (22.7%)
Multidrug-resistant Gram-negative bacilli	2/22 (9.1%)
Lumbar puncture performed	16/22 (72.7%)
Days until lumbar puncture *(Mean, p25-75)*	2.14 (0-3)
Abnormal CSF result	3/16 (18.8%)
Positive CSF culture or molecular analysis	0/16 (0%)
Empirical antibiotic regimen	
Vancomycin + Amikacin	4/22 (18.2%)
Vancomycin + Ceftazidime	7/22 (31.2%)
Vancomycin + Meropenem	8/22 (36.4%)
Ampicillin + Gentamycin	1/22 (4.5%)
Ampicillin + Cefotaxime	1/22 (4.5%)
Ampicillin + Metronidazole	1/22 (4.5%)
Days of antibiotic treatment *(Mean, p25-75)*	16.34 (11.0-16.0)
Survival without complications	15/22 (68.2%)
Complications	
Persistent bacteraemia	4/22 (18.2%)
Dissemination (to central nervous system)	1/22 (4.5%)
Deaths	2/22 (9.1%)

Conclusions/Learning Points: The present study revealed the characteristics of Gram-negative bacilli bacteraemias in the neonatal intensive care unit in our hospital. Multidrug-resistant microorganisms caused 9.1% of the episodes, all of them related with ESBL producers, as previously reported in a similar study from Spain (Aguilera-Alonso D., An Pediatr, 2019). Colonization screening can be useful to guide empirical treatments. Meadin antibiotic duration exceeded the current recommendations for sepsis-bacteraemia. Meropenem and ceftazidime were used as empirical Gram-negative active drugs in most cases. Monitoring of antimicrobial susceptibilities of the isolates and treatment regimens is necessary for appropriate selection of empirical therapies while promoting a rational antibiotic use.

LEVOFLOXACIN AS TREATMENT OF STERNOTROPHOMONAS MALTOPHILIA BACTERAEMIA IN A NEONATE

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Aliyyah Mohammad Khuzaini[1,2]
[1]Universiti Sains Islam Malaysia, Paediatric Department, Nilai, Malaysia, [2]Hospital Ampang, Paediatrics, Ampang, Malaysia

Title of Case: LEVOFLOXACIN AS TREATMENT OF STENOTROPHOMONAS MALTOPHILIA BACTERAEMIA IN A NEONATE
Background: Stenotrophomonas maltophilia is a multi-drug resistant non-fermenting gram negative bacillus. It is an emerging cause of nosocomial sepsis in neonatal intensive care units and is challenging to treat due to its multidrug resistance.
Case Presentation Summary: We report a case of Stenotrophomonas maltophilia bacteraemia in a premature neonate treated with Levofloxacin. A newborn weighing 1110g was born by caesarian section at 32 weeks gestation. The mother was 35 years old primigravida with a dichorionic diamniotic twin pregnancy. She developed a Covid-19 infection and developed premature contractions at 32 weeks gestation. At birth, the neonate was treated for mild respiratory distress syndrome and presumed sepsis, and completed a week of intravenous C-penicillin and cefotaxime. Cultures during this period were negative. At day 20 of life, she developed severe Klebsiella pneumoniae sepsis with septic shock, hepatitis, and septic ileus. She was on day 21 of intravenous meropenem when blood cultures taken due to persistent thrombocytopenia despite clinical recovery reported Stenotrophomonas maltophilia. Two subsequent blood cultures isolated the same organism. Concurrently, she had liver impairment with direct hyperbilirubinaemia attributed to bile plug syndrome and total parenteral nutrition. Hence, sulfamethoxazole-trimethoprim were contraindicated. She completed a three-week course of intravenous levofloxacin with clearance of bacteraemia after 10 days.
Learning Points/Discussion: Due to uncertain neonatal dose, we used the paediatric dose of 10 mg/kg per dose every 12 hours. Clinical resolution with clearance of bacteraemia was obtained with no observed side effects or blood parameter impairments. No increase in direct hyperbilirubinaemia was observed despite published reports in the literature noting its association. The use of levofloxacin as an alternative antibiotic in neonates should be explored further to establish its safety and therapeutic profile.

PROBABLE PHREATOBACTER OLIGOTROPHUS SEPSIS IN A PRETERM NEONATE

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Aliyyah Mohammad Khuzaini[1,2], Saarah Huurieyah Binti Wan Rosli[3]
[1]Universiti Sains Islam Malaysia, Paediatric Department, Nilai, Malaysia, [2]Hospital Ampang, Paediatrics, Ampang, Malaysia, [3]Universiti Sains Islam Malaysia, Microbiology, Nilai, Malaysia

Title of Case: PROBABLE PHREATOBACTER OLIGOTROPHUS SEPSIS IN A PRETERM NEONATE
Background: Phreatobacter oligotrophus is a recently described genus which was first isolated from ultrapure water in a Hungarian power plant (Toth et al. in 2014). This is a very rare organism of environmental origin and has not been reported to be associated with any human infections.
Case Presentation Summary: We report a case of probable Phreatobacter oligotrophus sepsis in a 5-day old premature neonate. Mother was 36 years old primigravida who had primary infertility of unknown cause for 11 years. Antenatally, she had gestational diabetes mellitus on diet control with positive Group B streptococcus vaginal colonisation. She developed spontaneous premature labour at 29 weeks. The baby had moderate respiratory distress syndrome and clinical sepsis at birth, complicated with metabolic acidosis, acute kidney injury, coagulopathy, and hyperglycaemia. Initial blood culture was negative, and she was initially on intravenous C-penicillin and gentamicin. However, on day 5 of life, the patient became less active with increased respiratory distress. Inflammatory markers were normal, however there was presence of new thrombocytopenia and leukopenia. Two separate blood cultures taken on the day of deterioration and 3 days later grew Phreatobacter oligotrophus. She completed a course of Vancomycin and clinically improved with three negative blood cultures subsequently.
Learning Points/Discussion: Phreatobacter oligotrophus is a strictly aerobic motile gram-negative rods which grew after 48 hours of incubation. We identified the organism using MALDI-TOF with the score of 2.56. Clearance in blood culture was achieved with clinical improvement, despite the unknown antibiotic sensitivity. The origin of the organism in this patient is uncertain. This case proposes the potential for neonatal sepsis by an environmental bacterium not known to invade human hosts.

Title of Case: Being on the ball: case report of C. tropicalis' urosepsis treated with a conservative approach
Background: Renal fungal balls are concretions in the renal pelvis formed by cellular debris and fungal mycelia. They may represent a rare but severe complication of ascending urinary tract infections.
Case Presentation Summary: Herein we describe a case of urosepsis from C. tropicalis in a term newborn with severe hydronephrosis secondary to PUV, presenting with fever, poor feeding, weight loss and initial circulatory failure. Initial work-up showed mild kidney failure, significant elevation of inflammation markers and leukocyturia, with no improvement after IV broad-spectrum antibiotics administration. A kidney ultrasound performed on admission revealed severe dilation in the left kidney, with calyces occupied by hyperechogenic formations compatible with fungal masses, therefore a combination of fluconazole and micafungin was started. The day after, urine cultures returned positive for Candida tropicalis fluconazole-resistant, thus antimycotic treatment was shifted to IV amphotericin B with concomitant de-escalation of antibacterials. Further work-up with echocardiography displayed mitral insufficiency from anterior leaflet perforation secondary to mycotic embolization, requiring no invasive maneuvers. After multidisciplinary discussion, according to the good response to antimycotics, the clinical picture and the cardiac involvement, the conservative approach was continued. Forty-eight hours after treatment initiation, the patient was apyretic and started to feed well again. The fungal balls in the left kidney were monitored over time, with the progressive shrinking of the masses and disappearance after six weeks from the start of the antimycotic regimen, which was stopped after two months when the patient was finally discharged home. Follow-up controls documented good thriving and growth and no residual lesions, with good renal function and severe dilation of bilateral pelvis.
Learning Points/Discussion:

Conservative treatment vs invasive for neonatal urosepsis

EARLY-ONSET NEONATAL SEPSIS IN A TERCIARY NEONATAL INTENSIVE CARE UNIT AFTER THE IMPLEMENTATION OF MATERNAL GROUP B STREPTOCOCCUS SCREENING AND INTRAPARTUM PROPHYLAXIS

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Ana Moura Figueiredo[1,2], Teresa Almeida Lopes[1], Muriel Ferreira[1], Adelaide Taborda[1], Dolores Faria[1]
[1]Centro Hospitalar Universitário de Coimbra, Neonatology B - Maternidade Bissaya Barreto, Coimbra, Portugal, [2]Centro Hospitalar do Médio Tejo, Pediatrics Department, Torres Novas, Portugal

Backgrounds: Early-onset sepsis (EOS) is the major cause of neonatal morbidity and mortality. The currently recommended Group B Streptococcus (GBS) screening and intrapartum antibiotic prophylaxis (IAP) has led to growing concerns about modification of EOS-causing pathogens. Our aim is to evaluate the changes of pathogens and their antibiotic susceptibility after implementation of maternal GBS screening and IAP in our hospital.
Methods: Data from medical charts of mothers and newborns with EOS 10 years prior and 10 years after this implementation (P1: 2003-2012; P2: 2013-2022) was retrospectively collected and analyzed using SPSS®v26.
Results: Between 2003 and 2022 we registered 55412 live births (P1: 30998; P2: 24414) and 47 EOS confirmed by positive blood culture (P1: 32; P2: 15). SGB EOS rate decreased from 0.44‰ in P1 to 0.12‰ in P2 (p=0.047). E.coli EOS rate was 0.19‰ in P1 and 0.25‰ in P2 (p=0.620). S.aureus EOS rate had a reduction from 0.16‰ in P1 to 0.00‰ in P2 (p=0.031), with only 1 MRSA in P1. Remaining pathogens didn't show significant differences between P1 and P2. Regarding SGB, 0.0% of the strains tested were resistant to ampicillin in both periods. As for E.coli tested strains, resistance to ampicillin was 80% in P1 and 66.7% in P2 (p=1.000) and to gentamicin 0.0% in P1 and 16.7% in P2 (p=1.000).
Conclusions/Learning Points: After the introduction of maternal GBS screening and IAP, there was a statistically significant reduction in GBS EOS rate without an increase in E.coli EOS rate. There was no statistically significant increase in resistance to the antibiotics empirically used in EOS, so it seems appropriate to maintain their use. Continuous monitoring of microorganisms causing EOS and their antibiotic sensitivity is essential for EOS effective treatment.

[1]Central Research Laboratory, Molecular Biology, Bangalore, India, [2]Central Research Laboratory, Microbial Informatics And Genomics, Bangalore, India, [3]Central Research Laboratory, Microbiology, Bangalore, India

Backgrounds: The emergence of multi-drug-resistant Pseudomonas aeruginosa poses a global threat worldwide. There is a paucity of studies addressing the prevalence and epidemiology of P. aeruginosa in Paediatric India population. The goal of the current study is to bridge the knowledge gap
Methods: Thirty-one paediatric P.aeruginosa clinical isolates were obtained from 11 medical centers across 11 states between 2017-2022. Whole-genome sequencing (WGS) was performed on Illumina MiSeq Platform and inhouse bioinformatic pipelines were used for genomic characterization, sequence typing, and phylogenetic analysis
Results: Results showed that local high risk novel lineages outnumbered (n=10) the globally distributed high-risk clones (ST235 and ST357, n=4 each). These isolates were obtained from blood (80%) and CSF (20%). There were sensitive to Aminoglycosides, Carbapenem, Cephalosporins, Macrolides, Tetracyclines and Trimethoprim and resistant to Pheicols(catB7 gene). Fluroquinolone(crpP) and Quinolone(parC_S87L,gyrA_T83I mutation) resistance was observed in 2 isolates. Interestingly, these novel lineages contained pleothera of virulence genes, of particular importance is presence of exoS, exot, exou, exoy, toxA genes in all isolates apart from genes encoding TTSS secretion system, Flagella, Pili, Aliginate biosynthesis, Quorum sensing and iron uptake. Isolates from neonates (Age <=1 yr, n=10) constituted major chunk of the dataset. These were isolated from blood stream infection. Two isolates had novel STs. ST235, 308, 357, 381, 654, 664, 1197 and 1978 were the other STs found. Displayed varying resistance to different antibiotic classes but in contrast showed to contain an array of virulence responsible of emergence of virulent strains in hospital settings
Conclusions/Learning Points: It is of utmost importance to address the dearth of studies examining the prevalence and epidemiology of P. aeruginosa in the paediatric population of India and take proper measures to avoid transmission of the high-risk clone

SEPSIS ASSOCIATED WITH HIGH INCIDENCE OF PULMONARY HEMORRHAGE IN A NEONATAL POPULATION IN BOTSWANA

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Alemayehu Gezmu[1], Endale Tefera[1], Britt Nakstad[1,2]
[1]University of Botswana, Department Of Paediatrics And Adolescent Health, Gaborone, Botswana, [2]University of Oslo, Division Of Paediatric And Adolescent Medicine, Oslo, Norway

Backgrounds: Neonatal sepsis is a life-threatening complication with high morbidity and mortality. Sub-Saharan African countries experience shortages of antibiotics, materials and equipment for work-up. Overuse of available antibiotics and recurrent outbreaks of multidrug resistant bacteria contribute to morbidity and mortality in our neonatal unit. We explored incidence, risk factors and survival of newborns with sepsis and pulmonary hemorrhage in Botswana.
Methods: A cohort study with prospective data collection was conducted in a tertiary level hospital in Botswana. All newborns admitted in the neonatal unit from 1st January 2020 to 31st December 2021 were included in the study. Data were collected using check lists developed on RedCap database (https//: ehealth.ub.ac.bw/redcap). Incidence rate of neonatal sepsis and pulmonary hemorrhage was calculated. Group comparisons were made using X^2 and student t-test. Multivariate logistic regression was used to identify risk factors independently associated with pulmonary hemorrhage.
Results: 1350 newborns were enrolled during study period, males 729(54%). The mean (SD) birthweight was 2154(+997.5) gram, and gestational age 34.3(+4.7) weeks. Eighty percent of the newborns were delivered in the same facility. The incidence of sepsis was 101/1350(75 per 1000 live births) and pulmonary hemorrhage was 54/1350 (40 per 1000 live births) among the newborns admitted in the unit. Mortality rate in those diagnosed with pulmonary hemorrhage was 29/54 (53.7%). Multivariate logistic regression identified neonatal sepsis and disseminated intravascular coagulopathy (DIC), and birthweight, anemia, apnea of prematurity, neonatal encephalopathy, intraventricular hemorrhage, mechanical ventilation and blood transfusion as risk factors independently associated with pulmonary hemorrhage.
Conclusions/Learning Points: Pulmonary hemorrhage associated with sepsis is a recurrent experience in critically ill newborns in Botswana. Exploring risk factors and guidelines for appropriate treatment will likely improve neonatal morbidity and mortality rates

RELIABILITY AND VALIDITY OF AXILLARY AND TYMPANIC THERMOMETRY COMPARED WITH RECTAL THERMOMETRY AMONG YOUNG UGANDAN INFANTS

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Olive Namugga[1], Halvor Sommerfelt1[2], Hans Steinsland[2], Jacinta Waila[1], Victoria Nankabirwa[1]
[1]Makerere University, Kampala, Uganda, Department Of Epidemiology And Biostatistics, School Of Public Health, College Of Health Sciences., Mulago hill road, Kampala, Uganda, [2]University of Bergen, Bergen, Norway, Centre For Intervention Science In Maternal And Child Health (cismac), Centre For International Health, Bergen, Norway

Background: Fever and hypothermia are critical indicators of severe bacterial infection in sick infants aged up to two months. Although rectal thermometry is the gold standard method, it poses a risk of rectal perforation. This study evaluated the accuracy and validity of less-invasive axillary and tympanic thermometry methods and explore the need for new temperature cutoffs.
Methods: The study was conducted on 713 infants at Mulago National Referral Hospital in Kampala, Uganda, using digital thermometers to measure rectal, tympanic, and axillary temperatures. The reliability of measurements was assessed by calculating Pearson correlation coefficients, technical errors, and coefficients of variation. The agreement between the three thermometry methods was evaluated using Bland-Altman analyses, and the validity of axillary and tympanic temperature measurements were compared to rectal temperature measurements.
Results: Axillary and tympanic measurements showed small mean differences from rectal measurements (-0.24°C and 0.43°C, respectively), but had relatively wide limits of agreement (approximately 1.6°C). Axillary and tympanic measurements had high sensitivity for detecting fever (98.4% and 100%, respectively). Axillary measurements had higher sensitivity (70.8%) and specificity (100%) for detecting hypothermia compared to tympanic measurements (58.5% and 98.7%, respectively). Increasing the hypothermia cutoff point for axillary and tympanic measurements improved sensitivity to 99.4% and 96.8%, respectively, with only a slight reduction in specificity.
Conclusions/Learning Points: Axillary thermometry has both a high sensitivity and a high specificity for detecting fever in young infants, while tympanic measurements tended to overestimate temperature and its specificity for fever was accordingly suboptimal. Increasing the temperature threshold for hypothermia detection improves the sensitivity of both methods without significantly reducing specificity. These findings suggest that axillary thermometry can be a reliable alternative to rectal thermometry for detecting fever and hypothermia in young infants.

[1]Queen's University Belfast, School Of Pharmacy, Belfast, United Kingdom, [2]Beijing Children's Hospital, Capital Medical University, Department Of Neonatology, Beijing, China, [3]Children's Hospital, Capital Institute of Pediatrics, Department Of Neonatology, Beijing, China, [4]University of Medicine and Pharmacy at Ho Chi Minh city, Faculty Of Pharmacy, Ho Chi Minh City, Viet Nam, [5]Queens' University Belfast, School Of Electronics, Electrical Engineering And Computer Science, Belfast, United Kingdom, [6]St George's, University of London, Centre For Neonatal And Paediatric Infection, London, United Kingdom

Backgrounds: Neonatal bloodstream infections (BSI) are a significant cause of health loss worldwide. Escherichia coli is a leading cause of neonatal bloodstream infections. There is limited comprehensive epidemiological evidence on E. coli BSIs in infants at a global level. We undertook a systematic review and meta-analysis to characterise E. coli in this population.
Methods: We searched MEDLINE, EMBASE, Scopus, LILACS and Cochrane Library for studies published in English language and Wanfang, the China National Knowledge Infrastructure and Chinese Scientific Journal Database for studies published in Chinese language between January 2000 and February 2021. E. coli infections were defined as positive cultures from blood/cerebrospinal fluid. The primary outcomes were to estimate incidence per 1000 live births and case fatality rate (CFR) of E. coli in infants aged under 6 months. The sub-group estimates were performed by WHO regions. Sensitivity analysis was performed to observe the effects of early-onset sepsis (EOS: <72 hours of age), late-onset sepsis (LOS: 72h-90 days) and meningitis.
Results: The overall estimated incidence of E. coli BSIs was 0.45/1000 live births (95% CI 0.32-0.60). Incidence was lowest in Western Pacific Region (0.31; 95% CI 0.04-0.79) and European Region (0.31; 95% CI 0.16-0.50) and highest in South-East Asia Region (1.47; 95% CI 1.12-1.86). CFR was 18.46% (95% CI 15.26-21.65%), being lowest in Western Pacific Region (14.37%; 95% CI 10.42-18.32%) and highest in Eastern Mediterranean Region (32.96%; 95% CI 25.55-40.37%). No studies reported CFR from African Region and only one study reported live birth data. A high heterogeneity between studies was observed.

WHO Region	Incidence (95% CI)	CFR (95% CI)
African Region	NA	NA
Eastern Mediterranean Region	0.49 (0.13 – 1.06)	32.96 (25.55 – 40.37)
European Region	0.31 (0.16 – 0.50)	15.72 (11.96 – 19.49)
Region of the Americas	0.56 (0.24 – 1.00)	22.58 (15.96 – 29.20)
South-East Asia Region	1.47 (1.12 – 1.86)	30.19 (0.00 – 71.72)
Western Pacific Region	0.31 (0.04 – 0.79)	14.37 (10.42 – 18.32)
All studies	0.45 (0.32 – 0.60)	18.46 (15.26 – 21.65)

Conclusions/Learning Points: The estimated disease burden rate of E. coli in infants varied significantly across WHO regions. We plan to investigate the AMR patterns of E. coli BSIs in this population.

[1]University of Crete, Department Of Mother And Child, School Of Medicine, Heraklion, Greece, [2]Institute of Molecular Biology and Biotechnology, Clinical Chemistry, Heraklion, Greece, [3]University of Crete, Laboratory Of Clinical Chemistry, School Of Medicine, Heraklion, Greece, [4]Heraklion University Hospital, Department Of Paediatrics, Heraklion of Crete, Greece

Backgrounds: Group B Streptococcus (GBS) is a gram-positive bacterium that is harmless for healthy individuals but may provoke invasive disease in young infants, causing pneumonia, sepsis, and meningitis. As GBS invades epithelial barriers to enter the bloodstream, strategies that enhance epithelial cell responses may hamper GBS invasion. In the present study, we investigated whether inhibition of Akt, a kinase that regulates host inflammatory responses and autophagy via suppression of mTOR, can enhance the response of non-phagocytic alveolar epithelial cells against GBS.
Methods: A549 cell line served as a model of type II pulmonary epithelial cells. Akt inhibition was performed using the selective Akt 1/2 inhibitor MK-2206. A549 cells were infected ex vivo with GBS (MOI 1:10). MK2206 was administered via oral gavage in C57BL/6 subjected to GBS pneumonia, for in vivo experiments.
Results: Treatment of the GBS-infected alveolar epithelial cell line A549 with the Akt inhibitor MK-2206, resulted in enhanced production of reactive oxygen species and inflammatory mediators. Akt inhibition via MK-2206 led to reduced phosphorylation of the mTOR targets S6 and 4E-BP1, LC3 lipidation and increased autophagic flux. Importantly, inhibition of Akt promoted GBS clearance both in alveolar epithelial cells in vitro and in lung tissue in vivo, in a murine model of GBS pneumonia. Induction of autophagy was essential for GBS clearance in MK-2206 treated cells as knockdown of ATG5, a critical component of autophagy, abrogated the effect of Akt inhibition on GBS clearance.
Conclusions/Learning Points: Our findings highlight the role of Akt kinase inhibition in promoting autophagy and GBS clearance in the alveolar epithelium. Inhibition of Akt may serve as a promising measure to strengthen epithelial barriers and prevent GBS invasion in susceptible hosts.

INCIDENCE OF NEONATAL SEPSIS FOLLOWING PROLONGED RUPTURE OF MEMBRANES AMONG PATIENTS ADMITTED AT THE NICU OF JOSE R. REYES MEMORIAL MEDICAL CENTER

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Niko Miguel Pasatiempo
JOSE R. REYES MEMORIAL MEDICAL CENTER, Pediatrics, CITY OF MANILA, Philippines

Backgrounds: Neonatal mortality is a global burden and a significant number of neonatal deaths are attributed to early onset sepsis. Prolonged rupture of membranes is an important risk factor for the development of early onset neonatal sepsis (EONS). This study aims determine the incidence of early onset neonatal sepsis in relation to mothers with prolonged rupture of membranes (PROM) of more than 18 hours.
Methods: This is a prospective cohort study which aimed to identify the incidence of early onset neonatal sepsis following prolonged rupture of membranes among patients admitted at the NICU of Jose R. Reyes Memorial Medical Center. Patients included in the study were admitted at the NICU and followed up whether they will develop neonatal sepsis or not.
Results: Out of 105 neonates with maternal history of prolonged rupture of membranes of > 18hours in this study, incidence of neonatal sepsis was reported at 39% with a total of 41 neonates; 3 of them or 7.31% had culture proven sepsis. 64 neonates did not develop clinical signs consistent with sepsis. The birth weight of neonates is more than 2500g at 59% With regards to WBC count, 77.14% belongs to the bracket of 9,000 – 20,000 WBC count. In Neutrophil Count, 61.90% had less than 60,000. Bacterial isolates found in one patient, Staphylococcus epidermidis and two patients with growth of Enterobacter cloace.
Conclusions/Learning Points: Prolonged rupture of membranes was found out to be significantly associated among mothers with history of maternal fever. Also, low birth weight (< 2500g) neonates was found out to be significantly associated with development of sepsis among newborns with prolonged rupture of membranes. Elevated WBC and elevated neutrophil counts were found out to be significant characteristics of neonates with sepsis.

Title of Case: Fulminant neonatal sepsis by an uncommon bacteria.
Background: The incidence of early-onset neonatal sepsis has decreased thanks to the screening protocols. However, its impact on atypical microorganisms remains unclear. We present a neonatal fulminant sepsis due to a uncommon bacteria.
Case Presentation Summary: On-term pregnant woman, admitted to our center for premature rupture of membranes. The pregnancy had elapsed without complications. GBS swab negative. At the 24th hour, she spiked a fever (38.6ºC), associating a pathological fetal register, whereby an emergent C-section was performed. A hypotonic female was born, without respiratory effort and heart rate around 80 bpm. Despite stabilization measures, at the 4th minute she suffered a cardiorespiratory arrest. CPR was performed, recovering pulse after 25 minutes. pH-UV: 6.3. During resuscitation, severe difficulties on ventilation were detected. Before referring the patient to NICU, intravenous antibiotics (Ampicillin-Cefotaxime) and vasoactive drugs were started. At the reference center, therapeutic hypothermia and high frequence ventilation (FiO2 100%) were started. Notwithsanding, the patient died at 12th hour of life. The family allowed pulmonary biopsy.
Both cultures (patient's blood and placenta) were positive for Streptococcus Gallolyticus ssp gallolyticus (R to Eritromicine and Clindamicine), and the pulmonary sample showed signs of intrauterine pneumonia. Finally, the case was diagnosed as a S.Gallolyticus sepsis.
Learning Points/Discussion: Streptococcus Gallolyticus are described in several reviews as an unusual but possible cause of neonatal sepsis, specially Ssp Pasteurianus. Mots of described cases had a severe course with a long-term good outcome, except for one case of fulminant sepsis, as the exposed one. We consider that further epidemiological surveillance is necessary in order to detect its emergency as a potentially pathogen microorganism. Finally, we want to emphasize the importance of coordinated interhospitallary network on the assistance of critical cases.

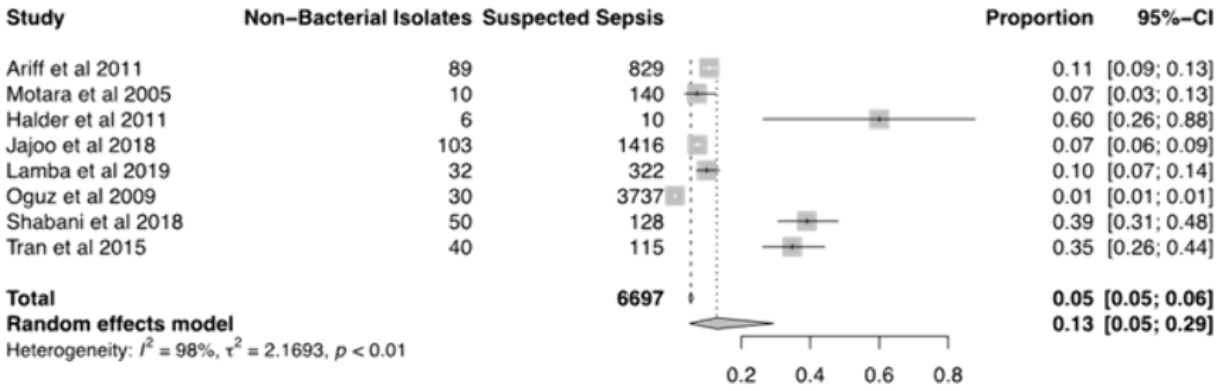
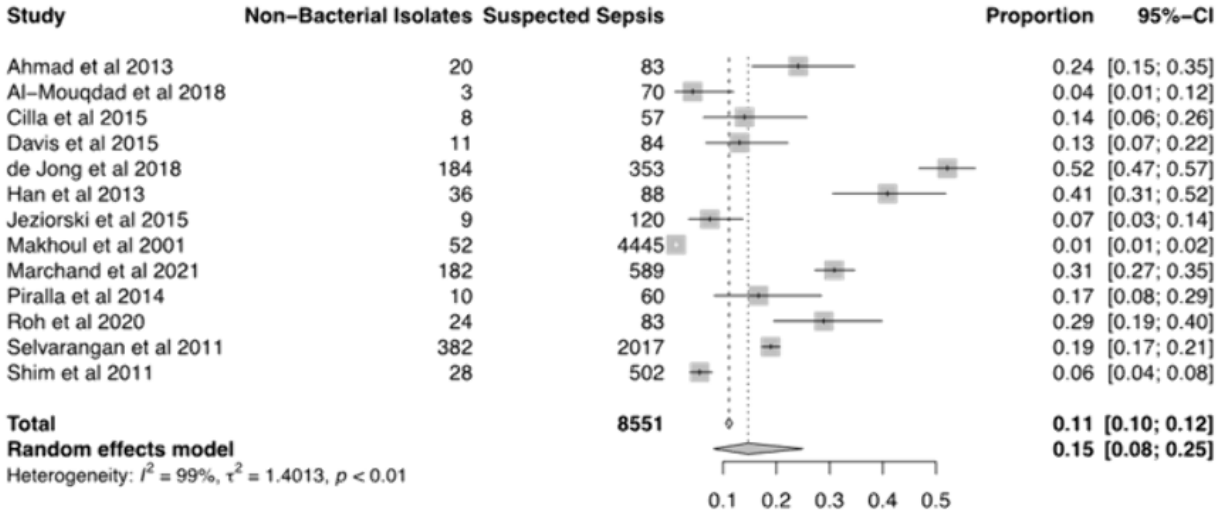
[1]St. George's, University of London, Antimicrobial Resistance Research, Centre For Neonatal And Paediatric Infection, London, United Kingdom, [2]University of Basel Children's Hospital (UKBB), Department For Infectious Diseases And Vaccinology, Basel, Switzerland

Backgrounds: Sepsis is one of the greatest threats to global health with an estimated incidence of 3 million cases every year. In approximately 2/3 of cases with blood cultures taken, no bacterial pathogen is identified. The aim of this review was to aggregate the existing evidence on detection of non-bacterial pathogens in neonates presenting with signs of sepsis.
Methods: EMBASE, MEDLINE and Ovid Global Health were searched for studies published since 1996 reporting on detection of non-bacterial pathogens in sepsis and sepsis-like syndrome in infants ≤ 6 months of age. Pathogen detection data was extracted from eligible articles with low risk of bias (JBI Critical Appraisal Checklist for Analytical Cross-Sectional Studies) and combined prevalence estimates for high- (HIC) and lower- or middle-income settings (LMIC) were constructed using a random effects model.
Results:

A – studies from lower and middle income settings



B – studies from high income settings



After duplicate removal, our database search yielded 267 articles. 8 more articles were identified through reference lists. 21 articles fulfilled eligibility criteria and passed bias assessment. Figure 1 shows forest plots for proportions of non-bacterial pathogens detected. Non-bacterial isolates most often detected in LMIC were fungi (86.49% of reported isolates), most commonly C. albicans. In HIC, 89.88% of reported isolates were viruses, with enteroviruses alone accounting for 67.7% of isolates.

Conclusions/Learning Points: Studies aiming for the detection of non-bacterial pathogens found these in ca. 15% of neonatal and young infant sepsis cases, with high heterogeneity between studies. Detection of viral pathogens in LMIC is commonly limited by testing capacities and lack of detection most likely reflects lack of testing. Fungal sepsis, while rare in HIC, may account for around 10% of neonatal and young infant sepsis cases in LMIC.

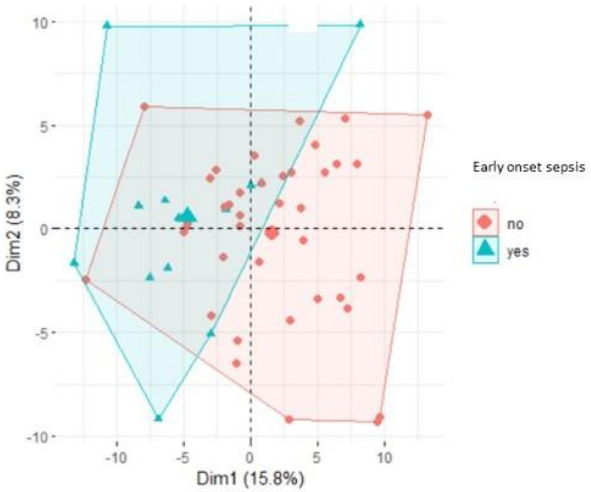
PROTEOMICS IN EARLY ONSET SEPSIS: A COHORT STUDY OF 53 NEONATES BORN BEFORE 28 GESTATIONAL WEEKS

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Anna Sellmer[1], Tue Bennike[2], Johan Palmfeldt[3], Tine Henriksen[4]
[1]Aarhus University Hospital, Department Of Pediatrics And Adolescent Medicine, Aarhus N, Denmark, [2]Aalborg University, Department Of Health Science And Technology, Aalborg, Denmark, [3]Aarhus University Hospital, Department Of Clinical Medicine, Research Unit For Molecular Medicine, Aarhus, Denmark, [4]Aarhus University Hospital, Department Of Pediatrics And Adolescent Medicine, Aarhus, Denmark

Backgrounds: Early onset sepsis (EOS) in extremely preterm neonates is a significant cause of morbidity and mortality. We have only just started to understand the pathophysiology of sepsis in the extremely preterm neonates. Neonatal sepsis pathophysiology involves multiple organ systems; highlighting the need for a systems biology approach to capture the complex interactions between biological systems during EOS. Elucidating this may in time enable us to promptly and accurately diagnose EOS and point towards potential therapeutic targets. The aim of our study was to identify proteins and biological systems involved in EOS in extremely preterm neonates.
Methods: In blood samples from 53 consecutively born neonates born before 28 gestational weeks the proteome was analyzed by mass spectrometry (nanoLC-MS/MS). EOS was defined pragmatically as 7 days or more of antibiotics treatment initiated within 72 hours after birth.
Results: We identified 27 proteins with different abundance in neonates with EOS compared to neonates without EOS. Among others we found decreased levels of Neural cell adhesion molecule 1 (CD56) (NCAM1), Alpha-2-antiplasmin (SERPINF2), Attractin (ATRN), Hepatocyte growth factor activator (HGFAC), and Apolipoprotein A-I (APOA1). Whereas C4b-binding protein alpha chain (C4BPA), Alpha-1-antichymotrypsin (SERPINA3), and Apolipoprotein B-100 (APOB) was found in increased levels in neonates with
EOS.



Unsupervised principal component analysis (PCA). Every dot represents a sample.

Conclusions/Learning Points: With this study we provide further insight into EOS in extremely preterm neonates. We identified proteins that are part of core biological systems including coagulation, endothelial function, lipid metabolism and immunity, in particular NK-cell function and complement system. These systems are all believed to be related to sepsis in adults; however, they are scarcely described in relation to EOS in extremely preterm neonates who often lack the symptomatology seen in adults.

[1]Tokyo Metropolitan Children's Medical Center, Infectious Diseases, Tokyo, Japan, [2]Nishi-Kobe Medical Center, Pediatrics, Kobe, Japan, [3]St George's University of London, Infection And Immunity, London, United Kingdom

Backgrounds: Group B streptococcus (GBS) can cause invasive disease in neonates and young infants. Understanding the burden and serotype distribution among infants with GBS disease is crucial in assessing the success of current guidelines as well as the potential impact of a GBS vaccination program in pregnancy. The epidemiology of GBS diseases varies considerably geographically and over time. The aim of this study to define the burden and clinical features of invasive GBS disease in infants younger than 1 year in Japan.
Methods: We conducted a retrospective, questionnaire-based nationwide surveillance study between 2016 and 2020.
Results: A total of 875 GBS cases were identified, including 186 early-onset disease, 628 late-onset disease (LOD), and 61 ultra-late-onset disease. Case fatality rate in each age category was 6.5%, 3.0%, and 3.3%, respectively. Patients with meningitis had sequelae in 21.5% (64/297). Annual incidence in infants younger than 1 year and in LOD significantly increased from 0.28 to 0.44/1000 livebirths (p=0.021) and from 0.19 to 0.29/1000 livebirths (p=0.046), respectively. Maternal colonization status at the LOD diagnosis was available for 148 mothers, of whom 21/58 (36.2%) had positive rectovaginal swabs and 42/117 (36.2%) had GBS in breastmilk culture. The four leading disease-causing serotypes were III, Ia, Ib, and V. Thirty-one recurrent cases were identified, and prematurity and antepartum maternal GBS colonization were risk factors for recurrence. Three pairs of twins were affected with invasive GBS diseases. All episodes presented with LOD.
Conclusions/Learning Points: A significantly increased trend was observed in infant GBS disease in the first year of life, mainly driven by LOD. GBS disease burden still remains with considerable mortality and morbidity in Japan, and thus effective vaccine is anticipated.

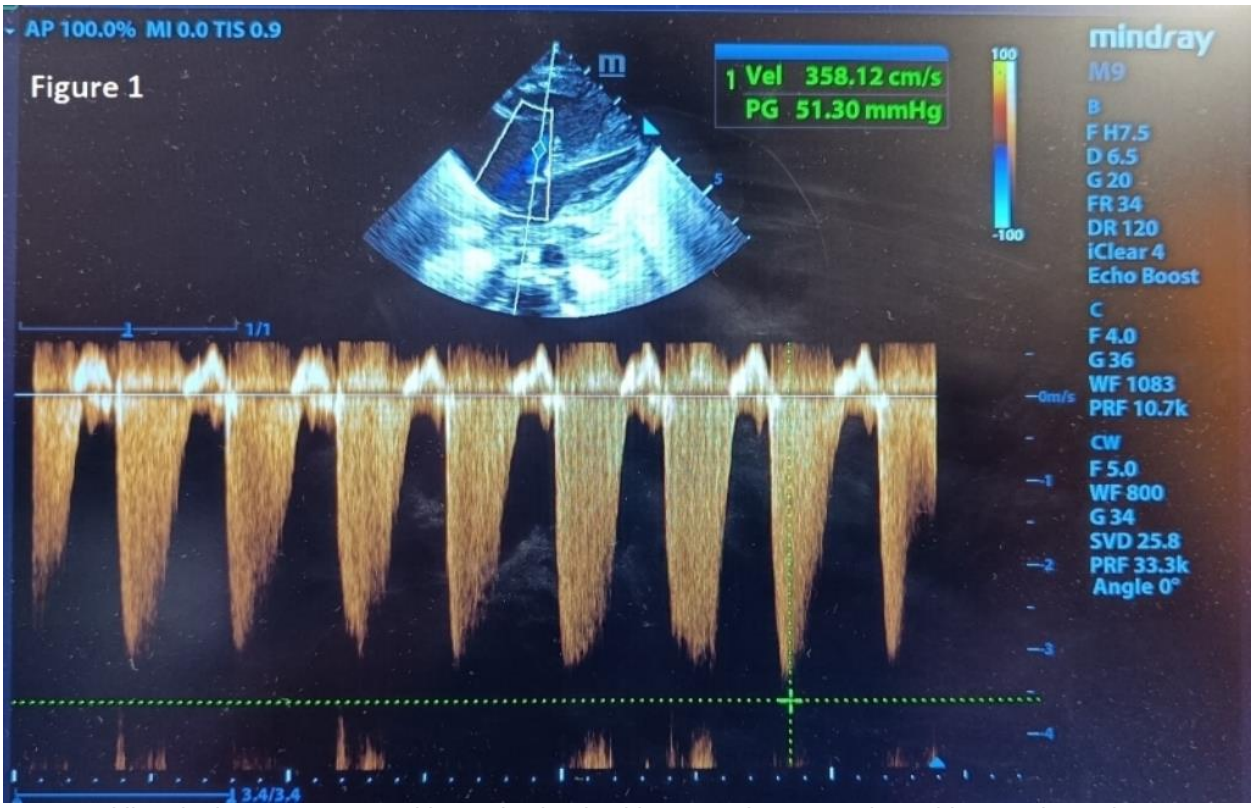
Title of Case: SEVERE PERSISTENT PULMONARY HYPERTENSION IN INFANT WITH SEPSIS BY LISTERIA MONOCYTOGENES: WHEN ECMO CAN CHANGE THE OUTCOME
Background: Listeria is a foodborne Gram-positive pathogen that can cause neonatal sepsis/meningitis due to transplacental acquisition via maternal bacteremia. Early onset neonatal listeriosis is rare but can result in significant mortality, morbidity and severe neurological sequelae.
Case Presentation Summary: Here a case of early onset listeriosis in a full-term newborn (37+2/7 weeks), female, appropriate for gestational age (AGA), born with cesarean section. Maternal swabs were negative for Group B Streptococcus (GBS). Amniotic fluid was meconium-stained. Apgar scores were 8 at 1 minutes and 9 at 5. At 12 hours of life, the patient showed severe desaturation, polypnea and chest retractions, so she was admitted to Neonatal Intensive Care Unit. Blood tests showed acidosis with high lactates, severe hypoxemia and elevated C-reactive protein levels. For this reasons, oxygen therapy and empirical intravenous antibiotic therapy with ampicillin and gentamicin were started. Continuous Positive Airway Pressure (CPAP) and High Frequency Oscillatory Ventilation (HFOV) were required due to worsening of respiratory distress. Due to hemodynamic instability and refractary persistent hypoxiaemia, echocardiogram was performed and showed severe pulmonary hypertension (Figure 1), so noradrenaline, dobutamine and then milrinone and also inalatory nitric oxide were started. Mother and children’s blood cultures resulted positive for Listeria monocytogenes. Because of persistent refractoriness to medical therapies, Extracorporeal Membrane Oxygenation (ECMO) program was started. After that, there was a gradual and significative improvement of clinical conditions and need for oxygen.The baby was dismitted after about one month in good clinical conditions.
Learning Points/Discussion:



Neonatal listeriosis may present with septic shock with severe hypoxaemia and haemodynamic decompensation. ECMO should be considered as therapeutic option in severe cases non-responsive to medical therapy.

E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Carolina Simão, Inês Carvalho, Joana Fortuna, Beatriz Fraga, Lucinda Pacheco
Hospital do Divino Espírito Santo de Ponta Delgada, Pediatrics Department, Ponta delgada, Portugal

Title of Case: NEONATAL MENINGITIS DUE TO STAPHYLOCOCCUS AUREUS: A CASE REPORT
Background: Bacterial meningitis is more common in the first month of life and occurs in as many as 15 percent of neonates with bacteremia. Staphylococcus aureus is an uncommon cause of meningitis associated with high mortality.
Case Presentation Summary: This is the case of a 16-days-old, healthy girl, who was admitted to the emergency department with fever, irritability, inconsolable crying and three episodes of loose stools since that day. Physical examination showed no other alterations. Urinalysis presented leukocyturia with 36 leukocytes/field. The newborn was admitted for intravenous treatment with cefotaxime and ampicillin. After 24 hours of antibiotic therapy, due to worsening irritability, a lumbar puncture (LP) was performed. Cerebrospinal fluid (CSF) was cloudy and revealed 24.673 cells/mm3, polymorphonuclear cells, pH >8.000, glucose <4.0mg/dL and proteins 2.46g/L. Blood culture was positive for Staphylococcus aureus and vancomycin was added to antibiotic therapy. The CSF culture was negative and echocardiography excluded endocarditis. On the fourth day she had a generalized tonic-clonic seizure. Electroencephalogram showed paroxysmal frontal activity and phenobarbital was initiated. Cranial computed tomography scan was normal. She had a favorable evolution and was discharged after completing 14 days of antibiotic therapy.
Learning Points/Discussion: With this case we want to draw attention to Staphylococcus aureus as a rare etiology of neonatal meningitis, whose prognosis can be potentially serious. As we know, the non-specificity of symptoms makes diagnosis difficult and early suspicion is important. The diagnosis of bacterial meningitis may be made if the initial blood culture grows a pathogen and the CSF obtained 24 to 36 hours after initiation of antibiotic therapy is abnormal.

LATE ONSET SEPSIS IN A PORTUGUESE NEONATAL INTENSIVE CARE UNIT - A 5-YEAR REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Patrícia Sousa[1], Beatriz Sousa[1], Francisca Calheiros Trigo[2], Mariana Martins[2], Clara Paz Dias[2]
[1]Hospital Senhora da Oliveira - Guimarães, Pediatrics, Portugal, Portugal, [2]Hospital Senhora da Oliveira - Guimarães, Neonatology, Portugal, Portugal

Backgrounds: Late Onset Sepsis (LOS) is an important cause of morbidity and mortality in neonates, particularly preterms. Understanding local epidemiology is key to adequate treatment strategies. We aimed to review the cases of LOS in our neonatal intensive care unit (NICU) over the last five years.
Methods: An observational cross-sectional study including neonates admitted to our NICU between January 1st 2018 and December 31st 2022, diagnosed with late onset sepsis. Statistically significance was established at $p<0.05$.
Results: We found 50 cases, 64,0% in males, at a median gestational age of 20,0 (26,3-35,3) weeks, median birth weight of 994,0 (807,5-1771,3) grams and median age of presentation of 13,0 (8,8-20,5) days. Blood culture was obtained in 100,0% and cerebrospinal fluid culture in 40,0%. In 70,0% of cases the pathogen was identified, the most common of which was Staphylococcus epidermidis (36,0%), followed by Klebsiella pneumoniae (10,0%). The most common option for empiric antibiotics was vancomycin and amikacin (38,0%). There were no resistances to amikacin or meropenem. Only one Staphylococcus epidermidis was resistant to vancomycin. Gram negative pathogens had higher resistance rates and 40,0% were resistant to gentamicin. Median antibiotic duration was 10,0 (7,0-13,25) days. Mortality was 10,0% in our sample; those neonates had a lower age at presentation, but there were no statistical significant differences in CRP or procalcitonin elevation.
Conclusions/Learning Points: Staphylococcus epidermidis was the most common cause of LOS. Vancomycin, amikacin and meropenem resistance is low but gentamicin resistance is of increasing concern. This should influence antibiotic selection for empirical treatment of LOS.

NEONATAL SEPSIS IN A RESOURCE-CONSTRAINED COUNTRY WITHOUT BLOOD CULTURES

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Joana Vasconcelos[1], Ana Beatriz Luzio Vaz[1], Swasilanne Sousa[2], Marta Alves[3], Ana Papoila[3], Alexandra Vasconcelos[4]
[1]Hospital Dona Estefânia - Centro Hospitalar Universitário Lisboa Central, Paediatrics Department, Lisbon, Portugal, [2]Hospital Dr. Ayres de Menezes, Paediatrics Department, Sao Tome, Sao Tome and Principe, [3]CEAUL, Nova Medical School/Faculdade de Ciências Médicas, Epidemiologic And Statistics Department, Lisbon, Portugal, [4]Global Health and Tropical Medicine, Instituto de Higiene e Medicina Tropical (IHMT), Universidade Nova de Lisboa, Unidade De Clinica Tropical, Lisbon, Portugal

Backgrounds: Sepsis is one of the foremost reasons for neonatal death in Sub-Saharan Africa (SSA). Sao Tome and Principe (STP) is a resource-constrained SSA country. Probable early-onset neonatal sepsis (EOS) in STP is defined as having an intrapartum infectious risk and clinical suspicion, without gold-standard culture diagnosis. In this study we aimed to describe probable EOS and infectious risk among newborns admitted at the only neonatal care unit (NCU) in STP.This is the first study ever conducted at this NCU.
Methods: Retrospective chart review of neonatal admissions at NCU in Hospital Dr. Ayres de Menezes in STP, between October 2021-October 2022.
Results: Of 948 neonatal admissions, 53.2% were male, 5.8% twins, 73% birthweight ≥2500g-<4000g, 16.2% premature (1.7% EPT, 3.8% VPT, 10.7% LPT). Most common reasons for admission were: 1) infectious risk with meconium-stained amniotic fluid (25.2%), 2) probable EOS (17.1%), 3) prematurity-complications (9.8%), asphyxia (6.1%), congenital anomalies (3.5%), HIV-MTCT treatment (3.1%). The average length of stay was 5.5 days (SD 7.8). The overall mortality rate was 6% (57), with 20% (200) missing discharge information. Infectious risk neonates (239) characteristics: 50.6% female, mean birthweight 3146g and GA 39.53 weeks, mean maternal age was 26, 23.4% caesarean, 12.6% foetal distress (1-min Apgar<7), 5.4% clinical asphyxia (5-min Apgar<7), 98.7% completed 48h-antibiotic, 2 neonatal deaths (2.1%). Probable EOS neonates (162) characteristics: 55.6% male, mean maternal age 25.6, mean birthweight 3135g and GA 39.43, 99.4% completed 7/14 days empiric antibiotics, 4 neonatal deaths (2.5%).
Conclusions/Learning Points: The positive outcomes among EOS and infectious risk newborns of this study highlights that having a well-defined risk-based diagnosis strategy through identification of risk factors and timely initiation of antibiotics, can save many newborn's lives in limited resource-settings.

Backgrounds: Group B Streptococcus (GBS) persists inside neonatal phagocytes and resists killing, facilitating its dissemination in neonatal hosts. Classical activation of macrophages results in enhanced bactericidal capacity, and ablation of Akt1 kinase is known to induce classical macrophage activation. By utilizing Akt1-deficient macrophages, this study aimed to delineate the role of classical phagocyte activation in GBS elimination and elucidate the molecular pathways that confer protection from GBS infection in neonates.
Methods: Macrophages from murine WT and Akt1-/- newborn mice were infected with GBS ex vivo. High-throughput RNA sequencing, microscopy, real-time PCR, flow cytometry and gene silencing experiments were further performed.
Results: Akt1-deficient neonatal macrophages had a significantly enhanced ability to eliminate intracellular GBS ex vivo. Neonatal macrophages had more proliferating GBS bacteria in their cytoplasm compared to Akt1-/- cells, in which GBS was primarily localized inside single membrane vacuoles. Phagosome examination by electron microscopy revealed that a significantly higher number of GBS–containing phagosomes was damaged in WT neonatal macrophages compared to Akt1-/- ones. In Akt1-/- neonatal macrophages, GBS colocalized with LAMP-1 protein, a marker of endosomal to lysosomal fusion, while this phenomenon was less commonly observed in WT macrophages. RNA sequencing analysis showed that the signaling lymphocytic activation molecule family receptor 8 (SLAM8), a protein that can induce receptor-mediated phagocytosis, was significantly elevated in GBS-infected Akt1-/- macrophages. Subsequently, mRNA silencing of SLAMF8 abrogated GBS clearance and phagosomal maturation in Akt1-/- neonatal macrophages.
Conclusions/Learning Points: Classical activation of neonatal macrophages, via suppression of Akt1 kinase, induces SLAMF8-receptor dependent activation of phagosomal maturation and leads to rapid GBS elimination and better survival rates from GBS sepsis.

E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Olena Vlasova[1], Kateryna Vlasova[2]
[1]Bukovynian State Medical University of Ukraine,, Department Of Pediatrics And Children's Infectious Diseases, Chernivtsi, Ukraine, [2]Bukovynian State Medical University of Ukraine,, Department Of Medical Biology And Genetics, Chernivtsi, Ukraine

Backgrounds: Due to the effect of bioaccumulation of environmental pollutants in the woman's tissues and their release from the depot during pregnancy, their content in the umbilical cord blood of the fetus can exceed the safety threshold for it and lead to a pathogenic effect on the body.
Methods: The main clinical group was formed by 141 newborns, whose parents permanently resided in areas with the different ecological risk coefficient
Results: The average systolic pressure on days 1-3 of treatment of neonatal sepsis of the main group was significantly lower than that of patients in the comparison group. Thus, on the 1st day of treatment, patients in the main group have a systolic blood pressure of less than 50 mm Hg. Art. was determined in 18.8±3.2% of cases, and in the comparison group only in 8.3±2.5% of newborns ($P<0.05$). Slowed filling of the vascular bed after pressure was observed significantly more often in patients of the I group on these days of observation. On the 1st day of treatment of sepsis in these children, the symptom of a white spot for more than 3 seconds occurred in 26.4±3.7% of cases, and in the comparison group - in 14.4±3.2% of observations ($P<0.05$). On the 3rd day of treatment, a positive white spot symptom was determined in 13.7±2.8% of children (P1:3<0.05) and 6.8±2.3% (P1:3>0.05) of observations, respectively .
Conclusions/Learning Points: Thus, the given data of the clinical examination of patients with neonatal sepsis allow us to believe that in children whose parents lived for a long time in places of high environmental risk, the cardiological changes were more significant, which indicated the severity of the disease

PARACLINICAL FEATURES OF THE COURSE OF NEONATAL SEPSIS TAKING INTO ACCOUNT THE FEATURES OF THE INFLAMMATORY RESPONSE

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Olena Vlasova[1], Kateryna Vlasova[2]
[1]Bukovynian State Medical University of Ukraine,, Department Of Pediatrics And Children's Infectious Diseases, Chernivtsi, Ukraine, [2]Bukovynian State Medical University of Ukraine,, Department Of Medical Biology And Genetics, Chernivtsi, Ukraine

Background: Limited opportunities for bacteriological confirmation of sepsis in newborns and low specificity and/or sensitivity of clinical manifestations of the disease prompt clinicians to look for surrogate markers of neonatal sepsis to justify initial therapy.
Methods: 60 newborns with a diagnosis of "neonatal sepsis" were taken for the study. The group-forming feature was the level of C-reactive protein in blood serum and the level of presepsin > 300 pg/ml. Thus, the first clinical group (main) included 25 patients with neonatal sepsis with a serum level of C-reactive protein < 20 mg/l and a presepsin level >300 pg/ml. The second group (comparison) was formed by 31 newborns with sepsis in serum C-reactive protein > 20 mg/l and presepsin level >300 pg/ml.
Results: Biochemical indicators of organ dysfunction and hemostasis disorders were significantly more common in newborns of the second group (P<0.05). In these patients, signs of decompensated metabolic acidosis and acute lung damage were determined significantly more often (P<0.05). The results of the immunological examination on the first day of the disease were characterized by signs of a systemic inflammatory reaction (Interleukin-8 content greater than 24.0 pg/ml was detected in 20.0±8.0% of cases in the main group and in 54.2±8.8%(P<0.05) in the comparison group), indicating about the severity of the course in newborn patients with neonatal sepsis. It should be noted that the ratio of interleukin-6 to interleukin-10, which is a specific indicator of neonatal sepsis in children of the comparison groups, was 1.3 in the first group and 1.5 in the comparison group.
Conclusions/Learning Points: The conducted correlation analysis showed that the condition of children according to the assessment of organ dysfunction on the SOFA scale in the second group is more severe r=0.08 (P<0.05)/

Backgrounds: National Neonatal Audit Programme (NNAP) highlighted that our unit had high rate of late onset (>72 hrs) blood stream infections with clearly defined pathogenic organisms (pBSI) in preterm babies <32 weeks gestation in 2021[(1)]. With our unit's ethos of less invasive approach with ventilation, central line insertions and early enteral feeding, we aimed to review the characteristics of the neonates who had pBSI to check compliance with guidelines.
Methods: NNAP electronic source document was used to conduct retrospective analysis all preterm babies <32 weeks with pBSI discharged from our NICU over 10 years between January 2013 and December 2022.
Results: Of 1305 admissions in 1187 babies over 10 years, 61 babies had 63 episodes of pBSI giving a total of 5.3%. The most common organisms were Staph Aureus (28%), E-coli (20%), Enterococcus Fecalis (12%). The characteristics of these babies are presented in table below. However, for 2021 and 2022, our pBSI rate was 14.8 and 10.5 respectively. While the 10 year review showed a lower rate and consistent practice in line with our guidelines, the rate of PBSI had risen significantly in the last 2 years.

Table: Baseline demographics and Clinical characteristics of the babies with late onset pBSI over last 10 years.

Sex (Male, Female)	54%, 46%
Gestation age (IQ1, Mean, IQ3), weeks	24+1, 25+2, 27+5
Birth weight (IQ1, Mean, IQ3), grams	605, 806, 880
Ethnicity: British/Other White/Asian/Black/ mixed /missing info	 56%,11%, 11%,10%, 7%, 4%
Inborn, Outborn	77%, 23%
Singleton, Multiple	72%, 28%
Vaginal birth, C section	54%, 46%
Antenatal/intrapartum Risk factors: Maternal chorioamnionitis Reversed end diastolic flow Preterm rupture of membranes	 18% 8% 23%
Mean APGAR score at 1,5 and 10 mins	5,7,8
Day of life at the time of pBSI mean	15 days
Invasive ventilation /Nasal high flow at the time of pBSI	54%, 44%
Days of invasive ventilation at the time of pBSI, mean	7 days
Total days of ventilation till discharge from unit, mean	16 days
Inhaled budesonide, %	53%
Presence of central lines: Umbilical/PICC/None	 35%, 28.5%, 36.5%
Feeds initiated with 24 hrs of life	79%
Fully fed at the time of infection	28%
Average length of stay	53 days
Blood transfusion prior to infection	56%
Co-morbidities: PDA/ IVH / NEC	31%, 18%, 5%
Transfer /Discharge /Death	57%, 31%, 12%

Conclusions/Learning Points: Despite effectively following the non-invasive strategy, we have seen a high rate of pBSI in our unit in recent years. This is likely due to better data entry since the implementation of paperless records. Other factors including effective infection control measures and environmental risks need to be explored further. Reference: 1. 2022_nnap_audit_measures_guide_v1.2.pdf (rcpch.ac.uk)

CAN THE MODIFIED SOFA SCALE BE USED TO ASSESS THE SEVERITY OF THE CONDITION OF NEWBORNS WITH SEPSIS?

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Olena Vlasova, Alona Yakob, Daryna Klymovych, Anastasiia Zapotichna
Bukovynian State Medical University of Ukraine,, Department Of Pediatrics And Children's Infectious Diseases, Chernivtsi, Ukraine

Background: The Sofa scale is used to assess multiple organ failure in adults with sepsis. The score ranges from 0-24 points. A score of > 2 points on the scale indicates the presence of multiple organ failure. Our team decided to modify this scale and evaluate the results. We replaced the Glasgow Coma Scale with the modified Glasgow Coma Scale for Infants.
Methods: The assessment of the ecological situation in the places of permanent residence of the parents of newborns, which was determined by the value of the ecological risk coefficient (ERC), served as a group-forming feature. The value of ERC <2.0 was regarded as an indicator of favorable environmental conditions-group I(30 children), and ERC ≥ 2.0 indicated the risk of adverse effects of environmental factors on the body-group II (26children)
Results: The assessment of the severity of the condition of the newborn according to the Sofa scale >5 points showed that in the first group of newborns with eco-dependent sepsis, 80.0% of patients were observed and in the comparison group - 7.7% (P<0.05). The more severe clinical course of sepsis in newborns of the main group compared to children of the II group was also evidenced by a higher reliable degree of correlation when assessing their general condition according to the specified prognostic scale (r=0.80, (P <0.05)).
Conclusions/Learning Points: Therefore, the Sofa scale can be used to assess the severity of the condition of newborns with sepsis, with a starting score > 5 points. It was also established that the risk of indicators of the severity of the condition increases by 5.1 (CI 95% 2.2-12.0) in newborns with sepsis whose parents lived in places with worse environmental conditions.

MOLECULAR CHARACTERISTICS AND CLINICAL FEATURES OF STAPHYLOCOCCUS CAPITIS LATE-ONSET BACTEREMIA AMONG INFANTS HOSPITALIZED IN NEONATAL INTENSIVE CARE UNITS

E-Posters Viewing
E-POSTER VIEWING: AS06.B. NEONATAL SEPSIS

Yu-Rou Yeh[1], Yi-Hsuan Huang[1], Yhu-Chering Huang[2]
[1]Linkou Chang Gung Memorial Hospital, Department Of Medical Education, Taoyuan, Taiwan, [2]Chang Gung Memorial Hospital, Division Of Pediatric Infectious Diseases, Departments Of Pediatrics, Taoyuan, Taiwan

Backgrounds: Coagulase-negative Staphylococcus (CoNS) were the most common pathogen of late-onset sepsis (LOS) in neonatal units in Taiwan; however, scant studies evaluated the role of Staphylococcus capitis. Recently, a specific clone of S. capitis, named NRCS-A, spread in NICU worldwide.
Methods: We collected and molecularly characterized all S. capitis bloodstream isolates from infants hospitalized in neonatal units of a medical center in Taiwan between 2014 and 2021. Medical records of these infants were retrospectively reviewed.
Results: A total of 48 isolates identified from 48 episodes of bacteremia in 47 infants were included for analysis. 27 (56%) case patients were male. Mean age at onset was 34.3 days (+ 21.6). Common presentations at onset included desaturation (50%), apnea (23%), bradycardia (40%), cyanosis (23%), and fever (17%). Mean serum C-reactive protein level at onset was 19 mg/L (+ 30). Of the 48 isolates (episodes), only 2 pulsotypes and 2 types of staphylococcal chromosomal cassette (types III & V) were identified. One pulsotype accounted for 85.4% of the isolates. No statistically significant differences were found between patients infected with both pulsotypes in terms of clinical and laboratory characteristics. All the isolates were susceptible to teicoplanin, vancomycin and rifampin, but resistant to oxacillin and penicillin. All the isolates with major pulsotype were resistant to erythromycin, and clindamycin.
Conclusions/Learning Points: All S. capitis bloodstream isolates from infants in neonatal units in Northern Taiwan were resistant to oxacillin, and shared two pulsotypes. One pulsotype, the minor clone, was similar to that of the NRCS-A strain.

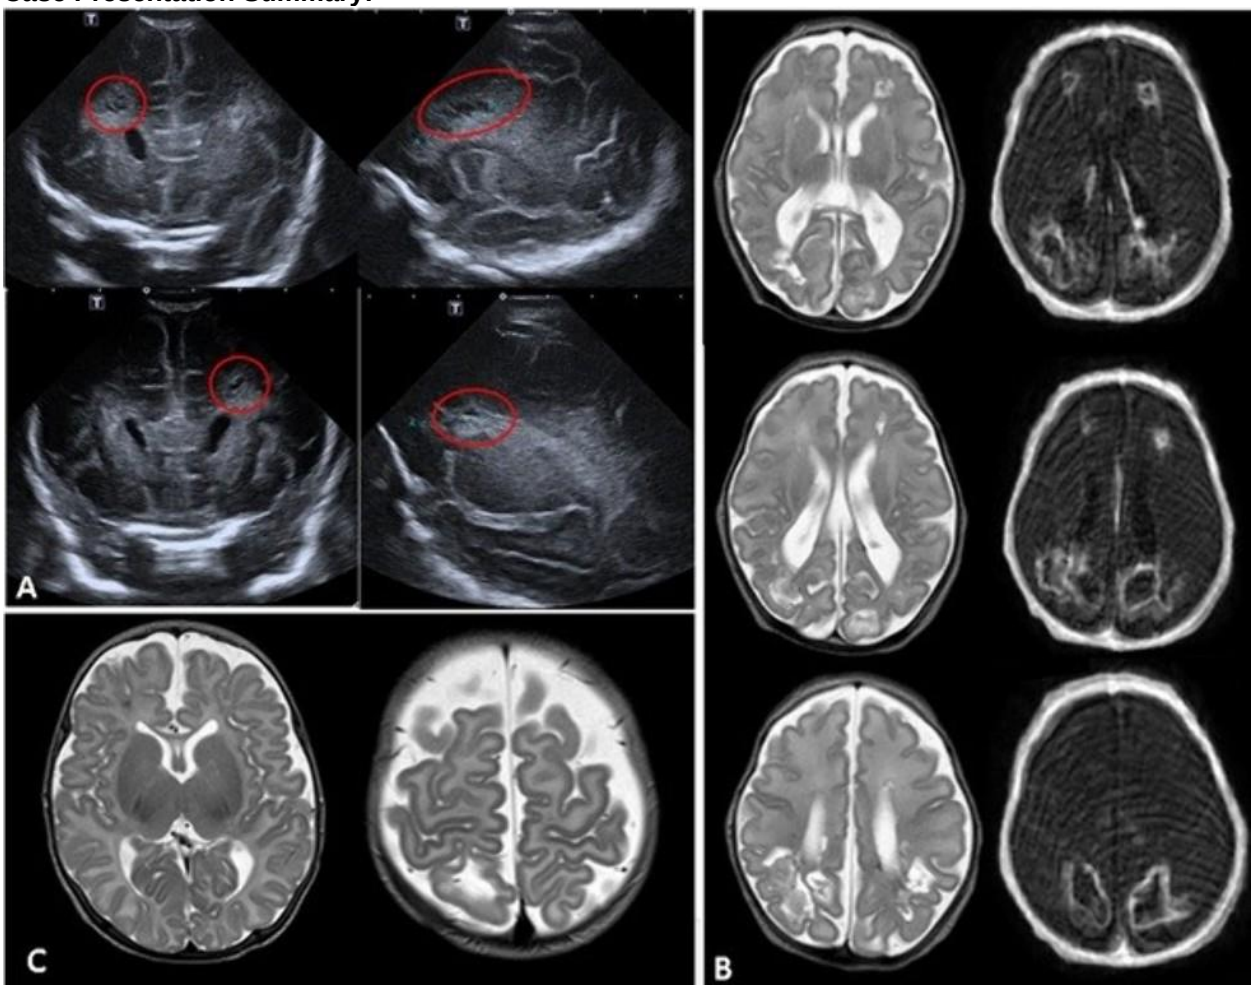
[1]Helios Klinikum Krefeld, Pediatrics, Krefeld, Germany, [2]Lukaskrankenhaus Neuss, Pediatrics, Neuss, Germany, [3]Helios Klinikum Krefeld, Neurosurgery, Krefeld, Germany

Title of Case: We report the case of a preterm infant that developed cerebral abscesses within a E.cloacae late-onset sepsis that needed surgical and antibiotic treatment employing prolonged Meropenem infusions plus Fosfomycin and maintenance with Trimethoprim/Sulfamethoxazole.
Background: E.cloacae is a gram-negative rod-shaped bacterium that can lead to nosocomial infections in neonates but is rarely reported as the cause of cerebral abscesses.
Case Presentation Summary:



A female preterm infant born at a gestational age of 26 weeks and 4 days developed a late-onset sepsis with E.cloacae at a corrected gestational age of 32 weeks and 2 days. The initial regimen with Meropenem and Vancomycin was changed to Cefotaxime due to a Cefotaxim-susceptible strain in the blood culture. After ending of antibiotic treatment, a multi-resistant strain of E. cloacae (resistant to Cefotaxime, Piperacillin/Tazobactam and Ertapenem) was detected in the routine throat and anal swabs.

Furthermore, sonographic controls of the brain revealed bihemipsheric periventricular cystic changes(A). An MRI showed them to be abscesses(B). The biggest abscess was drained surgically for decompensation and also for identifiying the causing pathogen which occured to be a Meropenem-susceptible E. cloacae strain. The patient was treated with high-dose Meropenem over a prolonged infusion time. Fosfomycin was later added to the regimen. The patient received 4 weeks intravenous antibiotics and was discharged with Trimethoprim/ Sulfamethoxazole orally for another 6 weeks. Control-MRI showed significant improvement of findings(C).

Learning Points/Discussion: Diagnosis of brain abscesses in neonates is difficult, early imaging with MRI is a key diagnosis tool. The choice and duration of antibiotic regimens should be considered carefully with unusual pathogens or infection sites. Single cephalosporine therapy in known E. cloacae sepsis may lead to colonization with resistant E. cloacae. If larger cerebral abscesses are present, neurosurgical drainage is to be considered.

HEPATITIS C POST-TRASNFUSION IN 2 VENEZEUELAN CHILDREN: CASE SERIES

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Leslie Cruz[1], Andres Arias[2], Lorena Mahuad[1], Juan Ramirez[3], Camilo Acosta[2], Andrea Restrepo[4], Omar Escobar[1]
[1]Universidad CES, Antioquia, Medellín, Colombia, [2]Erasmo Meoz University Hospital, Norte De Santander, Cucuta, Colombia, [3]Sanitas Foundation Univestiy, Bogota Dc, Bogota BC, Colombia, [4]Pablo Tobon Uribe Hospital, Antioquia, Medellín, Colombia

Title of Case: HEPATITIS C POST-TRASNFUSION IN 2 VENEZEUELAN CHILDREN: CASE SERIES
Background: 2 cases of post-transfusion hepatitis C in an 8 and 12-year old males, both from Venezuelawho received blood transfusion in their former country are presented.
Case Presentation Summary: The first 8-year-old male received blood transfusions since 2021 due to immune thrombocytopenic purpura reported in positive hepatitis C antibodies with a confirming viral load in 15720781 copies in follow-up laboratories. Chronic hepatitis C was diagnosed and sofosbuvir + velpatasvir every day for 12 weeks was prescribed. The second case is a 12-year-old male with the antecedent of acute lymphoid leukemia B diagnosed in 2015 who presented with a clinical picture compatible with leukemia relapse. Before our evaluation in Colombia, he received several blood products transfusion with positive Hepatitis C antibodies in 2016. No previous treatment was indicated with persistent positive viral loads since 2016. The last viral load with 117,977 copies/ml, sofosbuvir + velpatasvir every day for 12 weeks was ordered.
Learning Points/Discussion: With technology advances in Hepatitis C detection by PCR, this entity is exceptionally related to blood products transfusion. However, in low and middle-income countries, routine screening in blood banks is deficient and is based on antibodies, so, blood products still represent a risk for viral blood-borne diseases such as Hepatitis C. With the advance of pan-genotypic treatment plans that involves also pediatric patients the cure rates of the disease exceed 95%, having an important impact on the development of liver cirrhosis and hepatocellular carcinoma.

DIFFERENCES IN CLOSTRIDIOIDES DIFFICILE INFECTION BETWEEN CHILDREN AND ADULTS IN MEDELLÍN, COLOMBIA.

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Andres Arias[1], Stephanie Casadiego[2], Andrea Restrepo[3], Omar Escobar[2]
[1]Erasmo Meoz University Hospital, Norte De Santander, Cucuta, Colombia, [2]Universidad CES, Antioquia, Medellín, Colombia, [3]Pablo Tobon Uribe Hospital, Antioquia, Medellín, Colombia

Title of Case: DIFFERENCES IN CLOSTRIDIOIDES DIFFICILE INFECTION BETWEEN CHILDREN AND ADULTS IN MEDELLÍN, COLOMBIA.
Background: C.difficile infection (CDI) is the most frequent healthcare Infection (HAI), is associated with antibiotic´s use, prolonged hospital stay, morbidity and increased costs. We report one of the most numerous outbreaks in children and describe differences with adults. A Retrospective report (September 2017-March 2018) of an outbreak of healthcare facility-onset (HO)-CDI with detection of toxin A/B and 3-month follow-up, prior approval of ethics committee of Hospital Pablo Tobon Uribe, Medellín- Colombia.
Case Presentation Summary: 25 cases, 15 pediatric (60%); the index case was a 79-year-old woman. 68% were immunocompromised. Children had more symptoms and abnormal physical examination findings; 68% received more than 1 previous course of antibiotics, mostly children (80% vs 50%, p 0.11); cephalosporins were the most prescribed in children (73.3% vs 50%) and 92% were diagnosed in the first 3 months. PPIs and abdominal surgery predominate in adults [(33.3% vs 90%, p 0.005) and (60% vs 20%, p 0.04)]. There were 2 severe cases, one adult and one child with BI-NAP1-027. All received oral treatment (vancomycin 56%). Children were treated for 10 days, showing a statistically significant difference with adults (10 days: 86.6% vs 40%, p 0.01; 14 days: 13.3% vs 60%, p 0.01). There was 1 recurrence and no mortality attributable to infection.
Learning Points/Discussion: In our study, clinical risk factors for CDI are similar to the reported in the literature, more common in immunocompromised patients. Children are more symptomatic, but as reported, can be treated with shorter regimens with good clinical results and low probability of recurrence. The use of PPIs and abdominal surgery were more important in adults than in pediatrics.

ACUTE HEPATITIS OF UNKHONW AETIOLOGY IN CHILDREN. EXPERIENCE OF A TERTIARY HOSPITAL IN GREECE

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Danai Sofianou-Petraki, Evanthia Botsa, Aikaterini Vlachodimitropoulou, Georgia Fiste, Daphni Margoni, Ioanna Farakla, Evangelia Lykopoulou, Vana Spoulou, Christina Kanaka Gantenbein
"Agia Sophia" Children's Hospital, Athens, Greece, First Department Of Pediatrics, University Of Athens, Athens, Greece

Backgrounds: Since April 2022, an increasing number of acute hepatitis cases of unknown aetiology in previously healthy children have been reported worldwide. Concerning Greece, the first probable cases were recorded during May 2022, with the National Public Health Organisation defining the probable case as a person under 16 years old, presenting with acute hepatitis (non-hepatitis A-E) with serum transaminase>500IU/L (AST or ALT) since the 1st of January 2022.
Methods: Retrospective study of 20 probable cases of acute hepatitis of unknown origin, detected in a tertiary hospital in Athens, Greece, until May 2022.
Results: Patient's age ranged between 2 months and 15,5 years. All had abnormal laboratory findings of liver function. The FILMARRAY® of the respiratory panel detected Adenovirus and Human Rhinovirus/Enterovirus in three and six patients, respectively and SARS-CoV-2 in one patient. From the FILMARRAY® of the gastrointestinal panel, four children appeared to have different pathotypes of pathogenic E.Coli; 2 of whom had Enteropathogenic E.Coli. Polymerase chain reaction of blood samples was positive for Human Herpesvirus7 in four children, two of whom were also positive for Epstein-Barr virus. Among all cases, only one was Adenovirus positive, and genetic sequencing identified Mastadenovirus type C. Same pathogen was also isolated in the child's stool. Past SARS-CoV-2 infection was detected in eight cases. Epstein-Barr IgM antibodies were detected in four patients and Cytomegalovirus IgM antibodies in equal number. One child was HIV positive, although the titre of antibodies was low.
Conclusions/Learning Points: Despite international concern, Adenovirus was detected only in four out of twenty cases, none with adenovirus 40/41. Hepatitis of unknown aetiology is a previously existing phenomenon among children, although the 2022 outbreak remains unsolved.

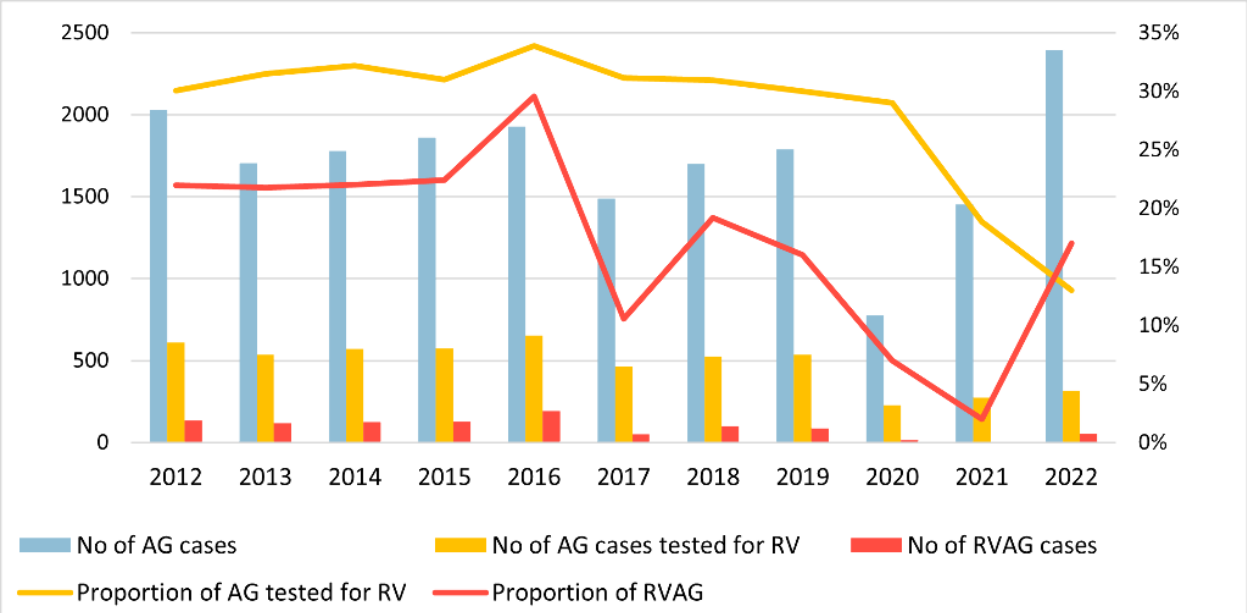
ROTAVIRUS ACUTE GASTROENTERITIS (RVAG) BEYOND THE COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Margarida Camacho Sampaio[1], Catarina Leuzinger-Dias[1], Cátia Martins[1], Ana Brett[1,2], Alexandra Canha[3], Dina Domingues[3], Lurdes Correia[3], Fernanda Rodrigues[1,2]
[1]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Universidade de Coimbra, Faculty Of Medicine, Coimbra, Portugal, [3]Clinical Pathology Service, Centro Hospitalar E Universitário De Coimbra, Portugal, Coimbra, Portugal

Backgrounds: In Portugal, rotavirus (RV) remains an important cause of acute gastroenteritis (AG). RV vaccine has been available in the private market since 2006 (with an estimated coverage ~60%) and in December 2019, was introduced in the National Immunization Program for risk groups. Non-pharmacological interventions during the COVID-19 pandemic had a dramatic impact on several infections, with important reduction or disappearance, followed by resurgence, in some cases with big epidemics outside the usual seasonality. The aim of this study is to describe the impact of the COVID-19 pandemic on annual RV epidemics.
Methods: Retrospective analysis of all AG episodes (≥3 stools/24h) in children aged <=36 months, observed in an Emergency Service (ES) of a tertiary paediatric hospital, between Jan 2012-Dec 2022 (n=18901). Stool samples were tested for RV using a rapid immunochromatographic test.Around 30% of children with AG were tested for RV each year, with a decrease in the past 2 years (16 and 13%, respectively).
Results: The number and proportion of cases of AG observed and tested for RV over the last decade is shown in the figure. An important reduction of AG cases in 2020, was followed by a significant increase, that reached the highest level in the last decade. The proportion of RVAG returned to the prepandemic values, peaking in the Spring-Summer, unusually late but already observed in previous epidemics in this community. The average age of RVAG was slightly lower (13.5 vs 16 months).



Conclusions/Learning Points: The downward trend in RVAG observed in the ES since 2016 and accelerated during the COVID-19 pandemic, was followed by an increase in AG cases and in the RV positivity rate that went back to prepandemic levels.

BENIGN TRANSIENT HYPERPHOSPHATASEMIA AND ACUTE CAMPYLOBACTER SPP GASTROENTERITIS

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Inês Candeias, Cláudia Magalhães, Francisca Gomes, Manuela Costa Alves, Ivo Miguel Neves
Hospital de Braga, Paediatrics, Braga, Portugal

Title of Case: BENIGN TRANSIENT HYPERPHOSPHATASEMIA AND ACUTE CAMPYLOBACTER SPP GASTROENTERITIS
Background: Benign Transient Hyperphosphatasemia (BTH) is associated with several pathologies, including infections. It is characterized by a transient elevation of serum alkaline phosphatase (ALP) in the absence of liver or bone disease.
Case Presentation Summary: A three-year-old male child with no prior medical history and good weight-height evolution, was referred to the Pediatrics clinic for recurrent episodes of abdominal pain accompanied by loose stools with mucus, but no blood. Due to the recurring nature of these symptoms, a microbiological stool analysis was conducted and the diagnosis of acute Campylobacter spp. gastroenteritis was confirmed. Blood tests also revealed an elevation of ALP (722U/L), with normal kidney function. An abdominal ultrasound revealed no significant changes, particularly in the liver parenchyma or bile ducts. The patient did not consume contaminated water, expired foods or medications, including phenobarbital and sodium valproate. During the appointment, any relevant family history, such as benign familial hyperphosphatasemia or inflammatory bowel disease, was excluded and no clinical signs of bone or liver disease were observed during physical examination. The patient was re-evaluated 6 months later with resolution of complaints.
Learning Points/Discussion: The authors believe it is crucial to emphasize that a simultaneous diagnosis of acute gastroenteritis caused by Campylobacter jejuni was made in this case, which is also reported in other BTH cases. However, it is not currently possible to establish a causal link between infection by Campylobacter jejuni and BTH. The child's follow-up, confirmation of normalization of the ALP values, age of presentation, and lack of underlying disease are essential to confirm the diagnosis of BTH. Recognizing BTH prevents the unnecessary conduct of additional investigation.

ROTAVIRUS GASTROENTERITIS - DESCRIPTIVE STATISTICS OF 10 YEARS IN A LEVEL II HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Madalena Carvalho[1], Maria Ravara[1], Rita Martins[1], Joana Lage[1], Maria Guerra[2], Elzara Aliyeva[2], Francisca Costa[1], Paula Correia[1]
[1]Hospital Professor Doutor Fernando Fonseca, Serviço De Pediatria, Departamento Da Criança E Jovem, Lisboa, Portugal, [2]Hospital Professor Doutor Fernando Fonseca, Serviço De Patologia Clínica, Lisboa, Portugal

Backgrounds: Rotavirus infection is the leading cause of acute gastroenteritis in children under 5 years of age. In Portugal, the vaccine is indicated for risk groups since october 2021. In other European countries there was a significant reduction in hospitalizations (69-89%) after the introduction of this vaccine in the vaccination program.
Methods: Descriptive retrospective study of pediatric patients with acute gastroenteritis and identification of rotavirus in stool (antigen) over a 10-year period (january 2012 - january 2022) in a level II hospital. Statistical analysis: Microsoft Excel.
Results: 609 patients were included, representing 4% of total admissions. 58% male, median age 1 year (mín. 6 days, máx. 15 years). 10.3% belonged to risk groups. The month with the highest number of hospitalizations was march. Clinically: 97% presented diarrhea, 90% vomit, 58% fever, 3.3% bloody diarrhea and 1.3% seizures. The most common reasons for hospitalization were dehydration (51.6%) and persistent vomiting (23.6%). The most frequent complications were metabolic acidosis (41.2%), hypoglycemia (14.6%) and acute kidney injury (10.3%). 2.8% had gastrointestinal coinfection, the most prevalent agent was adenovirus. There were 5.3% readmissions and 11.5% nosocomial infections. The median length of hospitalization for community infections was 2 days (mín. 1, máx. 28). Nosocomial infections occurred mainly in patients with prolonged hospital stay, some with severe illness. Only 2.5% had complete vaccination against rotavirus infection.
Conclusions/Learning Points: In most cases, children do not have serious complications. However, it may cause a significative burden in children and their families, being a frequent cause for school and work absence. In this study, we emphasize the low vaccination rate and high number of nosocomial infections. In the future, we hope to reduce the number of hospitalizations by vaccinating risk groups.

[1]Regional Hospital of Infectious Diseases in Warsaw, Department Of Pediatric Infectious Diseases, Warsaw, Poland, [2]Medical University of Warsaw, Department Of Children's Infectious Diseases, Warsaw, Poland

Title of Case: SEVERE COURSE OF HEPATITIS A IN CHILDREN DURING AN OUTBREAK IN PRESCHOOL.
Background: Hepatitis A is a liver disease caused by hepatitis A virus(HAV). In children,HAV infection is usually subclinical. The aim of this report was to present two patients,who were hospitalized with severe course of hepatitis A.
Case Presentation Summary: Two children aged 6.5 years were admitted with suspicion of acute hepatitis. Both patients had attended the same preschool, where between November 2021 and January 2022, hepatitis A outbreak occurred. On admission,patient 1, female, presented with two days history of nausea, fatigue, hepatomegaly and jaundice. During four days of hospitalization progression of liver disease and deterioration in general condition was observed. Liver tests showed alanine aminotransferase (ALT) maximum level up to 5148 U/L, aspartate aminotransferase (AST) of 7805 U/L(N.10-36), gamma-glutamylotranspeptidase(GGTP) 268 U/L(N.12-43), total bilirubin(TBil) 120.6 µmol/l(N.3.0-22.0), direct bilirubin(DBil)106.0 µmol/l(N.0.0-5.0), prothrombin time(PT) 60.30s(N.9-16.7), international normalized ratio (INR)1.63 (N.0.86-1.20).Anti-HAV IgM antibodies and anti-Epstein-Barr Virus IgM VCA(EBV) antibodies were detected. Patient 2,male,presented with three days history of malaise, stomachache, choluria, slightly enlarged liver, and jaundice. Laboratory tests showed ALT 2224 U/L, AST 542 U/L, GGTP 105 U/L, TBil 87.3 µmol/l, DBil 69.7 µmol/l, PT 22.9 s, INR 2.07.Anti-HAV IgM were positive. Both children were diagnosed with hepatitis A,patient 1 had HAV/EBV coinfection. We excluded other hepatotropic viruses. Both patients required vitamin K supplementation and supportive therapy. Patient was treated with rifaximin and consulted with Children's Transplant Center. We observed gradual normalization of liver function tests. In patient 2,coagulopathy persisted for 3 months after discharge.
Learning Points/Discussion: Hepatitis A may have a severe course in children. Postexposure prophylaxis of the HAV infection with effective immunization should be implemented in case of an outbreak for all children attending the setting.

CHALLENGES AND EFFECTS OF OUTCOMES TREATMENT OF CHRONIC HEPATITIS C IN 5-YEAR OLD CHILDREN WITH COMORBIDITIES.

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Anna Dobrzeniecka[1], Maria Pokorska-Śpiewak[1,2], Magdalena Marczyńska[1,2]
[1]Regional Hospital of Infectious Diseases in Warsaw, Department Of Pediatric Infectious Diseases, Warsaw, Poland, [2]Medical University of Warsaw, Department Of Children's Infectious Diseases, Warsaw, Poland

Title of Case: CHALLENGES AND EFFECTS OF OUTCOMES TREATMENT OF CHRONIC HEPATITIS C IN 5-YEAR OLD CHILDREN WITH COMORBIDITIES.
Background: Real-life data on effects and course of treatment with fixed-dose combination of sofosbuvir/ledipasvir (SOF/LDV) in pediatric patients with chronic hepatitis C are limited. The efficacy and safety of 12 weeks of therapy with SOF/LDV in 5-year old tweens suffering from comorbidities are presented.
Case Presentation Summary: 5-year-old twins (a boy and a girl) were infected vertically with genotype 1 HCV, and they were negative for HBs antigen, anti-HBc antibodies, and anti-HIV antibodies. They presented with a history of prematurity, delayed psychomotor development, chronic kidney disease, renal hypodysplasia, and growth deficiency. In addition, the boy had hypertension, he was treated with ramipril and received trimethoprim/sulfamethoxazole to prevent urinary tract infections. No fibrosis (Metavir F0-1) was found in either child. They were qualified for 12 weeks of therapy with SOF/LDV and started the treatment in November 2021. As they weighted below 17 kg at baseline, both received pellets containing 150/33.75 mg of SOF/LDV. After 4 weeks of treatment, due to the weight gain, the dose was increased to 200/45 mg. Both patients achieved a sustained virologic response (SVR12) 12 weeks after the end of treatment. No adverse effects during and after treatment were reported and compliance was good.
Learning Points/Discussion: Decision on starting the treatment in special groups of patients like children under 6 years of age or with comorbidities should be made individually. The adjustment of formulation and dosing of medication during treatment is necessary.

PV0442 / #2220

GASTROINTESTINAL BLEEDING FROM CADE OIL POISONING

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Anas Erragh[1,2], Marouane Elharit[3], Amine Afif[1], Kaoutar Elfakhr[1], Samira Kalouch[1], Abdelaziz Chlilek[1]
[1]CHU Ibn Rochd, Anesthesiology-intensive Care Medicine Department, Casablanca, Morocco, [2]CHU IBN ROCHD, Anesthesia Resuscitation, CASABLANCA, Morocco, [3]CHU IN ROCHD, Anesthesia Resuscitation, casablanca, Morocco

Title of Case: GASTROINTESTINAL BLEEDING FROM CADE OIL INTOXICATION
Background: Intoxication by cade oil is often of iatrogenic origin resulting mainly from the ingestion of a large quantity or, in infants and newborns, from prolonged and extensive cutaneous application. Used for therapeutic purposes, this oil can be responsible of poisonings that can even be fatal.
Case Presentation Summary: An 11-month-old infant with no pathological history. Brought by his mother to the pediatric emergency room for respiratory distress with generalized cyanosis and loss of consciousness, which appeared two days after an extensive application of an imprecise quantity of cade oil to the scalp and nostrils to treat an influenza-like syndrome complicated by two episodes of hematemesis. The infant was comatose, hypotonic with bradycardia at 61/min and blood pressure at 65/35 mm Hg. He was polypneic and showed signs of respiratory struggle. Its saturation at 78%. Capillary blood glucose was correct. The initial biological report showed anemia at 9 g/dl, thrombocytopenia at 50,000 platelets/mm3, renal function preserved with hepatic cytolysis and CPK level at 3458 IU/L. Initial arterial blood gas analysis revealed severe metabolic acidosis The initial management included intubation for mechanical ventilation, a filling test completed by the administration of norepinephrine 0.1ug/kg/min and decontamination with soapy water to eliminate cade oil. After receiving the report, it was completed by the administration of 1.4% bicarbonates 10 mL/kg and a transfusion of red blood cells (80 mL). The immediate evolution was marked by an alteration of the hemodynamic state, oliguria, persistence of metabolic acidosis, leading to death in multiorgan failure chart 3 days after admission.
Learning Points/Discussion: Reducing the incidence of this type of poisoning requires preventive measures based on public awareness and the implementation of a strategy to combat these intoxications

ETIOLOGICAL STRUCTURE OF ACUTE VIRAL HEPATITIS IN THE POST-PANDEMIC PERIOD

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Malvina Javakhadze[1], Manana Kachlishvili[2], Irma Korinteli[1], Tamar Didbaridze[3]
[1]Tbilisi State Medical University, Infectious Diseases Departament, T'bilisi, Georgia, [2]Acad.V.Bochorishvili clinic, Pediatric, T'bilisi, Georgia, [3]Tbilisi State Medical University, Microbiology, T'bilisi, Georgia

Title of Case: Etiological structure of acute viral hepatitis in the post-pandemic period
Background: Backgrounds: Hepatitis in children has significantly increased recently. This problem has become even more important during in the post-covid period. Nowadays, according to the data reported from many countries, there is information about the increasing numbers of non A-E hepatitis, which mostly have an unknown etiology.
Case Presentation Summary: Methods:The research is prospective. From January 2021 to December 2022,27 patients diagnosed with acute viral hepatitis were treated in the hospital of Acad. V. Bochorishvili Clinic. According to the WHO definition, the diagnosis of hepatitis of unknown etiology was initally made.11 Of them were hepatitis A-E.In order to determine the etiology in 16 patients, research of 4 different samples was performed-blood,urine,feces,and mouth-throat smear, Research method–was RT-PCR. The exclusion criteria from the study were hepatitis A-E. Results: By WHO working case definition-Probable case: A person presenting with acute hepatitis (hepatitis non A-E) with serum transaminase >500 IU/L (ALT, AST), who is <16 years. 16 patients who were treated with the diagnosis of hepatitis were identified by this criterion. The research was conducted on the following pathogens:Paraechovirus,Enterovirus,HH6,HH7,Parvovirus B19,HSV1,HSV2,VZV,Adenovirus, EBV, CMV. Studies with autoimmune panel-ANA, AMA, AAB to liver-Kidney Microsomes, SLA/LP AB,Smooth muscle Ab. Biochemical studies: ALT, AST, GGT, ALP, Total bilirubin (Direct/ indirect), CBC, CRP,Ferritin,Procalcitonin,Ammonia,Creatinine. Adenovirus was confirmed in 3 cases;in 2 cases-SARS CoV-2;in 2 cases VZV;in 3 cases CMV;in 2- EBV;in 3-HH7,and in 1 case remained of unknown etiology.The severity was relatively more prominent in the case of adenoviral and covid infection.During the infection caused by herpes zoster,hepatitis was less acute and progressed more slowly.
Learning Points/Discussion: Conclusion, hepatitis at this stage is polyetiological.For more accurate conclusions, studies should be continued and meta-analysis should be performed.

CRYPTOCOCCAL HEPATITIS IN AN IMMUNOCOMPETENT CHILD

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Pramod Kulkarni
KEM Hospital Research Centre Pune, Pediatrics, PUNE, India

Title of Case: Cryptococcal Hepatitis in an immunocompetent child
Background: Cryptococcosis is a systemic mycosis, frequently occurring in immunologically compromised human host. It usually involves central nervous system, lungs and skin. Cryptococcal involvement of the hepatobiliary system is very rare. A rare case of localised hepatic cryptococcosis in an immunocompetent child responding well to standard treatment is reported here.
Case Presentation Summary: A 2.5 year old girl child, was referred for intermittent, high grade fever for 3 months, periumbilical abdominal pain, jaundice & poor appetite; after treatment at 2 hospitals without relief. On examination, she had fever, pallor, jaundice and moderate hepatomegaly and normal other systems. Investigations- Hb-7gm/dl, TWBC 25550/cmm P76,L20,E2,M2, platelets11.4 lakh. LFT- total bilirubin 8.4 mg/dl, direct 6.15mg/ dl), SGPT 198 IU/L, SGOT 219 IU/L , GGT 516IU/L, alkaline phosphatase 1658 IU/L, serum albumin 3.14 g/dL & INR 2.2 (normalized after 1 dose of vitamin K). Normal Immunoglobulin levels, Negative HIV, brucella, leptospira, typhoid and tuberculosis serology. Abdominal ultrasound showed bright liver parenchyma with heterogenous echotexture, mild splenomegaly, few enlarged lymph nodes at porta. chest x-ray was normal. Liver biopsy histopathology showed hepatocellular and canalicular cholestasis, portal based granulomatous inflammation with eosinophils. Occasional yeast forms were seen extracellularly and within multinucleate giant cells. Mucicarmine stain highlighted and confirmed the diagnosis of Cryptococcosis . Serology for cryptococcal antigen was positive with titre 1:4. Standard treatment - IV Amphotericin-B and flucytosine for 3 weeks, followed by oral fluconazole and flucytosin for 6 weeks and oral fluconazole continued for 6 months. Child improved clinically by 1st week, and was totally asymptomatic after 6 weeks of treatment,
Learning Points/Discussion: Cryptococcosis is a rare consideration in immunocompetent children as is hepatic involvement There is a need to identify liver dysfunction as a possible initial manifestation of fungal infection, a treatable cause with good outcome.

ACUTE PANCREATITIS AND HEPATITIS AS A COMPLICATION OF SALMONELLA GASTROENTERITIS

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Carlota Lopes, Francisca Manoel, Isabel Coelho, David Gomes, António Guerra, Carla Cruz
Hospital Espírito Santo de Évora, Departamento Da Mulher E Da Criança, Évora, Portugal

Title of Case: ACUTE PANCREATITIS AND HEPATITIS AS A COMPLICATION OF SALMONELLA GASTROENTERITIS
Background: Salmonella gastroenteritis ranges from self-limited to fulminant illness, seldom associated with transient bacteriemia (1-5%) and extraintestinal organ involvement. Liver and pancreatic damage are rare complications of salmonellosis and may alter its course resulting in poorer outcomes. We report a paediatric case of acute pancreatitis and hepatitis complicating Salmonella infection.
Case Presentation Summary: A healthy nine-year-old girl, without epidemiological context, presented with a 4-day history of febrile non-bloody-diarrhoea associated with anorexia, vomiting and abdominal colic that aggravated with food intake. The pain was initially periumbilical and within 24 hours it intensified and irradiated to the back. On examination the child was lethargic, pale, anicteric and hemodynamically stable with an overall abdominal tenderness on palpation without organomegalies or peritoneal irritation. Laboratory workup reported lipase (688U/L), amylase (75U/L), ALT (108U/L), and AST (154U/L). Abdominal ultrasound showed no signs of acute pancreatitis, lithiasis or extrahepatic biliary tract obstruction. Mild-to-moderate acute pancreatitis was admitted, and the patient was treated with IV fluids, analgesia, and oral intake was suspended for 24h hours. On the 4th day of hospitalization, stool culture was positive for Salmonella enterica subsp. enterica and the diagnosis of salmonellosis complicated with acute pancreatitis and noncholestatic hepatitis was confirmed. Assuming extraintestinal involvement ampicillin was started, according to antibiogram, with clinical improvement.
Learning Points/Discussion: The coexistence of pancreatitis and hepatitis is a rare complication of Salmonella infections, with few paediatric cases described in literature. This disease may be underdiagnosed since its symptoms may overlap with those of enteritis. The characteristics and intensity of abdominal pain should draw clinicians' attention to the possibility of a pancreatic complication. Early recognition and timely treatment halt further progression and are associated with better outcomes.

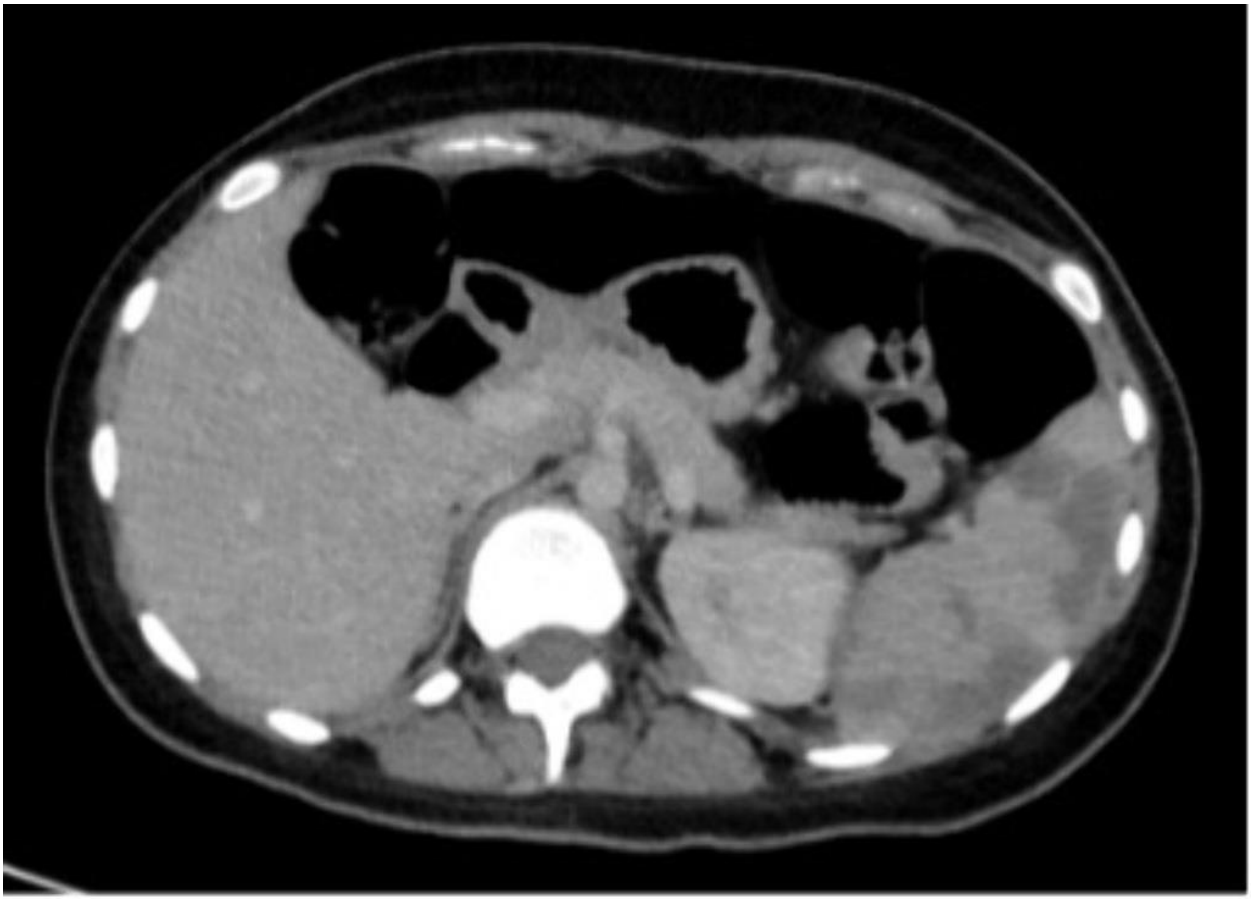
MASSIVE SPLENIC INFARCTATION, A RARE ENTITY IN A FEMALE TEENAGER

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Margarida Moreno Fernandes, Mariana Rodrigues Neto, Ana Garrido, Otília Cunha, Joana Rodrigues, Joana Reis, Teresa Pena, Joana Silva, Maria Adriana Rangel
Centro Hospitalar de Vila Nova de Gaia/Espinho, Pediatrics, Esmoriz, Portugal

Title of Case: MASSIVE SPLENIC INFARCTATION, A RARE ENTITY IN A FEMALE TEENAGER
Background: Splenic infarction is a rare entity in the pediatric age that most commonly is associated with predisposing factors such as oncological, hematological or infectious diseases. Abdominal pain is the most common complaint, and a high degree of clinical suspicion is necessary, as it can mimic other causes of abdominal pain. There is no consensus about the best treatment option.
Case Presentation Summary: A 15-year-old female with Steinert myotonic dystrophy presented to our pediatric emergency department with a 1-week history of intense abdominal pain, worsened in the last two days, and recent onset fever. Initial labs revealed leukocytosis, lymphocytosis, hypoalbuminemia, thrombocytosis, elevated serum liver enzymes, lactate dehydrogenase, C-reactive protein, and Erythrocyte sedimentation rate. Blood smear showed atypical lymphocytes. History of trauma was denied. Abdominal ultrasound, limited by abundant intestinal air, revealed homogeneous splenomegaly. Abdominal X-ray was suspicious for bowel obstruction, and an abdominal CT was performed, revealing extensive splenic infarctions. EBV VCA IgM antibody test was positive, and remaining microbiological investigation was negative. Tests for thrombophilia and malignancy were also negative. Transthoracic echocardiogram was normal. Treatment with enoxaparin was started, with progressive clinical improvement and no complications. She repeated abdominal ultrasound 1 week later with overlapping and stable splenic subcapsular infarctions involving more than 50% of the parenchyma.



Learning Points/Discussion: We report a case report of massive splenic infarction as a rare complication of infectious mononucleosis due do primary EBV infection. Signs and symptoms are nonspecific, so a high index of suspicion is important. Due to its massive extension and severe abdominal pain, enoxaparin was started in this girl, however, most cases are managed conservatively. Close monitoring is necessary as there is risk of splenic rupture.

Title of Case: AN UNUSUAL EBV PRESENTATION IN A 11-YEAR-OLD CHILD
Background: Epstein-Barr virus (EBV) is a member of the gamma herpesvirus family (human herpes virus 4). The majority of EBV infections that occur in childhood are mild and hepatic involvement is not uncommon.
Case Presentation Summary: We present a case of a 11-year-old girl, admitted to our Tertiary hospital due to fever and abdominal pain. Clinical examination revealed an unwell child with jaundice, hepatomegaly, splenomegaly, mild ascites, lymphadenopathy and sore throat. Empirical antibiotics were started. Laboratory investigations revealed elevated aminotransferases , triglycerides, bilirubin and ferritin. Serological tests for Epstein-Barr virus (EBV IgM/IgG) were positive. Criteria for Hemophagocytic lymphohistiocytosis (HLH) were not met. Blood cultures were negative. Nasopharyngeal RT-PCR multiplex tests (Influenza A/B, RSV A/B, Paraninfluenza 1/2/3/4, Coronavirus OC43/229E/ HKU1/NL63, Rhinovirus/Enterovirus, Aderovirus, Human Metapneumovirus, Bocavirus 1, Mycoplasma pneumonia, Chlamydophila pneumonia, Legionella pneumonophila, Bordetella pertussis, Mers, Sars-CoV-2) came back negative. Due to her ongoing fever, ascites and worsening abdominal pain, that could be due to an excessive immunological response to EBV, we administered methylprednisolone for 7 days (dose of 1.5 mg/kg) and a single intravenous immunoglobulin infusion (dose of 1g/kg). Fever settled 4 days later and the child improved clinically. She was discharged on day 10 of hospitalization and remained well in her follow- up visit a month later.
Learning Points/Discussion: The development of ascites has rarely being reported in the literature during EBV infection and appropriate management of severe cases remains unclear.

[1]Instituto da Criança e do Adolescente - FMUSP, Paediatric Infectious Disease, São Paulo, Brazil, [2]Universidade de São Paulo, Pediatric Infectious Disease, São Paulo - SP, Brazil, [3]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, Instituto da Criança e do Adolescente, Departamento De Pediatria, Unidade De Infectologia Pediátrica, São Paulo, Brazil, [4]Universidade de São Paulo, Pediatric Infectious Disease, São Paulo, Brazil, [5]Instituto da Criança e do Adolescente - FMUSP, Paediatric Hepatology, São Paulo, Brazil, [6]Laboratório Central - FMUSP, Infectious Disease, São Paulo, Brazil

Backgrounds: WHO global strategy aims to reduce new hepatitis infections by 90% in up to 2030. Identifying children and adolescents with chronic hepatitis C and treating contribute to hepatitis decrease. Direct acting antivirals (DAAs) have more than 90% efficacy. Poor adherence is the main reason for treatment failure. The goal of this study was to describe features and outcomes of chronic hepatitis C pediatric patients treated with DAA and to compare adherence in person up versus by telemedicine.
Methods: We conducted an observational prospective cohort at outpatient in a Brazilian center since May 2019. HCV chronically infected pediatric patients treated with DAA were included. Brazil's Ministry of Health approved DAAs for children older than 12 years or weighing more than 35Kg: ledipasvir90mg +sofosbuvir400mg(SOF-LDV) once daily for 12 weeks for genotype 1 and sofosbuvir(SOF)400mg+ribavirin(RBV)1g daily for 24 weeks for genotype 3. From November 2022 there was a change to the pangenotypic regimen: sofosbuvir400mg+velpatasvir100mg. We analyzed clinical profile, side-effects, and treatment response. Adherence was evaluated in person up to January 2020 (n=10) and by telemedicine from February 2020 (n=13).
Results: Twenty-three pediatric chronic HCV infected received DAA: mean age 13y(9-17), 56.5% females, 8.6% HIV co-infected, 91.3% vertical transmission, genotype: 1(91.3%), 2(4.3%), 3(4.3%). No known cirrhosis. Side-effects were transient and non-severe: 60%headache, 30%nausea, 20%fatigue and 10%diarrhea. All patients had good adherence. Quantitative detection HCV-RNA was <12 UI/ml in week-12 of treatment for all patients. Sustained virologic response (SVR) in posttreatment week-12 was achieved in all 21patients that already performed the test.
Conclusions/Learning Points: In our study, we observed high tolerability and excellent response to DAAs. Telemedicine attendance was good for assessing adherence. We reinforced pediatric hepatitis C treatment as part of the global strategies for reduction Hepatitis C.

Backgrounds: A new outbreak of acute hepatitis of unknown etiology (AHUO) has raised awareness in April 2022. The study's aim was to describe AHUO pediatric cases.
Methods: Retrospective study of pediatric patients with acute non-A-E hepatitis, as described by the The World Health Organization(WHO) criteria(Acute non-A-E hepatitis with serum transaminase (ALT or AST) > 500 IU/L, with 16 years of age or younger) admitted to the Pediatric Intensive Care Unit of Instituto da Criança e Adolescente-HCFMUSP, from January to April 2022, was performed. Prospective study started on May 2022. Local ethics committee approval the study. Demographic, clinical, and laboratorial data were collected. Etiological research included: viral and auto-antibody serologic tests [anti-LKM1, anti-smooth-muscle, Cytomegalovirus(CMV), EBV, Hepatitis A-E, HIV, HTLV, Toxoplasmosis, Herpes simplex 1+2, Mumps, Rubella, Chagas disease, SARS-CoV-2]; polymerase chain reaction PCR) for Hepatitis E, Yellow Fever, Dengue, Chikungunya, and adeno-associated virus type 2(AAV-2) in plasma; molecular panel for 22 respiratory pathogens (containing SARS-CoV-2) in nasopharynx and molecular virus panel in hole blood [Adenovirus, CMV, EBV, Enterovirus, Parvovirus B19, Herpes simplex 1/2, HHV-6, HHV-7, Paraechovirus, Varicella Zoster Virus].
Results: Ten pediatric patients with Acute non-A-E hepatitis were included from January to June 2022. Main symptoms were jaundice, loss of appetite and abdominal pain. Seven of 10 patients had viral isolates: AAV-2(n=3), respiratory syncytial virus(n=2), CMV(n=2), adenovirus(n=2), metapneumovirus(n=1), rhinovirus(n=1). Co-infection was observed in 3 patients: AAV2+RSV(n=1), adenovirus+rhinovirus+CMV(n=1), CMV+ metapneumovirus(n=1). Immunohistochemical for CMV and adenovirus was positive in the liver explant in one case each. Five patients received corticosteroid pulsetherapy, 3 of them improved. Five patients underwent liver transplantation. One patient dying on day 1 after transplantation.
Conclusions/Learning Points: Different from United Kingdom, we did not found adenovirus predominance, nor observed a similar pattern in AHUO cases.

LIVER ELASTOGRAPHY IN HEPATITIS C INFECTED CHILDREN: WHAT ROLE?

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Cecilia Porro[1], Alessandro Cibarelli[1], Elisa Crivellaro[1], Elena Ghidoni[1], Valeria Rubinacci[1], Marta Stracuzzi[1], Gian Vincenzo Zuccotti[2], Vania Gaicomet[1]
[1]Università degli Studi di Milano, Pediatric Infectious Diseases Unit, Milano, Italy, [2]Università degli Studi di Milano, Ospedale Dei Bambini Vittore Buzzi, Milano, Italy

Backgrounds: To date, there are few studies investigating the role of elastography in the management of children and adolescent HCV infected. We performed a retrospective analysis of our HCV infected pediatric cohort, in order to evaluate elastography modification before (EPre) and after therapy (EPost).
Methods: We retrospectively evaluated the clinical records of 57 children referred to the Pediatric Infectious Disease Unit of Luigi Sacco Hospital (Milan, Italy) for vertically and horizontally acquired hepatitis C virus (HCV) infection, from January 1997 to January 2022.
Results: In this study h 57 patients were enrolled: 28 treated (49,1%),13 non treated (22,8%), 6 of which haven't been treated for spontaneous viral clereance (10,5%). All patient treated underwent elastography one month before therapy began and then the exam was repeated after one year after therapy according to our clinical management protocol. HCV RNA was undetectable in all treated patients after treatment. Comparing EPre to EPost of treated children we did not find any statistically difference between the two groups. As expected, however, alanine (ALT) and aspartate (AST) aminotransferase and HCV RNA decreased significantly from EPre to EPost. We found a positive correlation between EPre and EPost, and a positive correlation between EPre and pre-therapy aspartate transaminase values. Furthermore, a statistically significant linear regression between EPre and Epost were reported, as same result emerged between EPre and AST values pre-therapy.
Conclusions/Learning Points: Liver Elastography is not well recognize as a valid instrument to check therapy effectiveness in HCV patients, but according to our data it can be highly informative about the patient's status as the transaminases. More data are needed to evaluate a diagnostic accuracy and its appropriateness as a follow-up tool.

PV0451 / #167

HISTOPATHOLOGICAL PARAMETERS IN H. PYLORI INFECTION WITH ENDOSCOPIC NODULAR GASTRITIS

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Kaushal Kishor Prasad, Sadhna Lal, Uma Debi, Arun Sharma
PGIMER, Gastroenterology, Chandigarh, India

Backgrounds: To assess the severity of histopathological variables of gastritis in children with Helicobacter pylori infection associated with endoscopic nodular gastritis.
Methods: This prospective study carried out over two years period and included 468 children and adolescent in whom upper digestive endoscopy was performed for gastrointestinal symptoms and gastric antral mucosal biopsy was taken. Sixty-seven children and adolescent were diagnosed as having nodular gastritis and were included in the study. Demographics, clinical characteristics, endoscopic and pathologic findings were recorded. H pylori were recognized in gastric biopsy on H&E sections; a modified Giemsa stain was performed in biopsy suspicious for H pylori.
Results: The prevalence of nodular gastritis in children and adolescent was 14.3% (67/468) and consisted of 46.3% male and 53.7% female. The age ranged from 3 - 18 years (mean age, 9.2 + 0.4 years). The prevalence of nodular gastritis increased gradually with age. H pylori infection was identified in 68/468 (14.5%) children and adolescent. Nodular gastritis had a poor accuracy rate to determine H. pylori infection (sensitivity, 40.3%; positive predictive value, 39.7%) and was observed in 27/68 (39.7%) H pylori positive patients and in 40/400 (10%) H pylori negative patients. There was a significant increase in grade of inflammation, activity, atrophy, number of lymphoid follicles and H. pylori density on histological evaluation in H pylori positive patients with nodular gastritis than other groups.
Conclusions/Learning Points: H. pylori infection in children and adolescent with nodular gastritis identifies cases with severe gastritis and marked bacterial colonization. Nodular gastritis has a poor prediction for H. pylori infection. Gastric biopsies should always be obtained during endoscopy to establish the H pylori infection.

NEUROLOGICAL COMPLICATIONS OF ROTAVIRUS INFECTIONS IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

David Slotboom, Daphne Peeters, Stefan Groeneweg, Anneloes Van Rijn, Elke Jacobs, Michiel Schoenaker, Mirjam Van Veen
Juliana Children's Hospital, Pediatrics, Den Haag, Netherlands

Backgrounds: Rotavirus is the leading cause for complicated gastroenteritis in children younger than 5 years in countries where vaccination is not implemented. Besides the intestinal symptoms that are associated with ordinary gastroenteritis, rotavirus can cause neurological complications. The aim of this study is to describe the clinical characteristics of complicated rotavirus infections.
Methods: From 1 January 2016 to 31 January 2022, all children (below the age of 18) with a positive rotavirus test in feces that were either hospitalized or presented at the outpatient clinic or emergency department of a large pediatric hospital in the Netherlands were included. Rotavirus was only tested in case of a severe or abnormal disease course. We described the clinical characteristics and outcome with a particular focus on neurological manifestations.
Results: In total, 59 patients with rotavirus were included of whom 50 (84.7%) were hospitalized and 18 (30.5%) needed intravenous rehydration. 10 patients (16.9%) had neurological complications, of whom six patients (60.0%) presented encephalopathy. Two patients (20.0%) with neurological symptoms showed abnormalities on diagnostic imaging.
Conclusions/Learning Points: Rotavirus can cause gastroenteritis with severe, but apparently self-limiting, neurological manifestations. Considering rotavirus in pediatric patients with neurological symptoms such as encephalopathy and encephalitis is therefore important. Early detection of rotavirus infection may predict a favorable course of disease and may thereby prevent unnecessary treatment and should be further investigated.

GENE EXPRESSION ANALYSIS OF LIVER TISSUE TO EXPLORE PATHOGENIC PATHWAYS IN INFLAMMATION

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Michael Stephanou
University of Oxford, Peter Medawar Building For Pathogen Research, Oxford, United Kingdom

Backgrounds: Liver diseases such as Non-alcoholic fatty liver disease (NAFLD) and Non-Alcoholic Steatohepatitis (NASH) are extremely prevalent worldwide and carry a poor prognosis. Gaining insight into the transcriptional profiles of these conditions is therefore crucial for understanding their pathogenesis. We therefore aimed to compare hepatocyte transcriptomic data in control and diseased states using differential expression analysis. We hypothesised that different drivers of inflammation are present in distinct liver diseases, and that gender impacts expression.
Methods: We made use of data from two large studies which had retrieved liver biopsies. The first study looked at 195 Hepatitis C (HCV) infected individuals, while the second took samples from obese (12), control, (14), NAFLD (15) and NASH-affected (16) individuals. We analysed the second study independently, comparing gene expressions for all states against the controls and then merged the datasets to compare HCV-infected gene expression to controls. The impact of gender on gene expression was also compared. Multiple R software packages and Gene-set enrichment analysis (GSEA) were used to analyse the data.
Results: All studied liver diseases (NAFLD, NASH, HCV-infection) resulted in upregulation of inflammatory markers compared to control, with the biggest difference noted in HCV-infection. Meanwhile, obesity did not alter gene expression significantly. GSEA confirmed these findings, further revealing that complement dysregulation is present in all these conditions. We also demonstrated that gender drives differences in gene expression in HCV infection specifically.
Conclusions/Learning Points: Differential expression analysis of diseased and control liver tissue reveals a host of inflammatory markers that are upregulated. Gaining a better understanding of these inflammatory drivers could help in the development of therapeutic targets, for example in the form of complement or IL-2 blockade, which could potentially assist in the halting of hepatocyte inflammation.

HEPATIC ABSCESS: DON'T FORGET BRUCELLA IN SUSCEPTIBLE HOST

E-Posters Viewing
E-POSTER VIEWING: AS07.A. GASTROINTESTINAL INFECTIONS - HEPATITIS

Gajanand Singh Tanwar[1], Naveen Kumar[1], Divya Mohta[1], Akshay Sharma[1], Priya Tanwar[2]
[1]S. P. Medical College,, Pediatrics, BIKANER, India, [2]SP Medical College, Pediatrics, BIKANER, India

Title of Case: HEPATIC ABSCESS: DON'T FORGET BRUCELLA IN SUSCEPTIBLE HOST
Background: Brucellosis is the most common zoonosis worldwide that may affect any organ or system of the human body. Diffuse hepatic involvement is common during the course of human brucellosis, however, hepatic abscess formation is very rare presentation, specifically in pediatric age group.
Case Presentation Summary: A 7.5 years male child was admitted with the complaints of high grade fever, vomiting, and weakness for 8 days. He had history of ingestion of raw goat milk and also complaints of arthritis in goat. On clinical examination, there was right upper quadrant tenderness. The significant laboratory investigations were normocytic normochromic anemia (hemoglobin 9.6 g/dL), a moderate hyper-leucocytosis (11,600/mm3) with a slightly neutrophilic differential count (64%) and increased ESR (65 mm/h). Liver function tests were slightly abnormal as serum alanine transferase (ALT), 422 U/L; serum aspartate transferase (AST), 192 U/L; serum gamma-glutamyl transpeptidase, 110 U/L; and alkaline phosphatase, 135 IU/mL. Viral hepatitis markers (HBsAg, anti-HBc IgM, anti-HAV IgM, and anti-HCV tests) and serology tests for hydatidosis, amebiasis, syphilis, and cytomegalovirus were negative. The Brucella standard tube agglutination test was positive at a titer of 1:1280 and immunoglobulin M and G were significantly raised for B.melitensis. Abdominal ultrasonography showed 8cmx10cmx8 cm echogenic foci in the right lobe of the liver. MRI confirmed the US findings, and also revealed further inner features of the mass-like liver lesion and changes in the surrounding liver parenchyma. The child was diagnosed as having hepatic abscess due to brucellosis. Doxycycline and rifampicin were started in standard doses. The child recovered well with normal hepatic function in 3 months.
Learning Points/Discussion: Clinicians should consider brucella in the differential diagnosis of liver abscess with history of livestock.

[1]Aghia Sophia Children's Hospital, Athens, Greece, 1 First Department Of Pediatrics, Medical School, Aghia Sophia Children's Hospital, National And Kapodistrian University Of Athens, Athens, Greece, Athens, Greece, [2]Aghia Sophia Children's Hospital, National and Kapodistrian University of Athens, Athens, Greece, Laboratory Of Microbiology, Athens, Greece

Backgrounds: Foodborne diseases remain a burden to public health systems worldwide. Their epidemiological surveillance is crucial to strengthen their prevention and optimal management. Objectives of our study were to report the incidence of pathogens, examine their seasonal distribution and prevalence among gender and age and log their treatment.
Methods: We performed a single-tertiary center retrospective cohort study on a sample of 1155 children hospitalized in our Department from May 2022 to September 2022, who presented with gastrointestinal symptoms. Stool and blood cultures, antigen testing, multiple polymerase chain reaction were used to specify the virulent factors. Demographic profiles were, also, recorded.
Results: Out of 105 foodborne infections in children aged 2 months to 16 years old, 37 (35.2%) were reported as Rotavirus infection, 29 (27.6%) Salmonella spp infection, (comprising the most common bacterial pathogen), 19 (18%) Campylobacter infection, 7 (6.6%) E.coli infection (50% of which EPEC), 6 (5.7%) Shigella sppinfection, 4 (3.8%) Norovirus infection, 2 (1.9%) G. lamblia and 1 (0.9%) Yersinia spp. Blood cultures were positive in 3 cases (10%) of Salmonellosis. Regarding antibiotic resistance, 82% of Salmonella strains were pansusceptible and 4% were multiresistant. For Campylobacter over 64% of strains were reported multiresistant. Antibiotics were given to 37.9% of patients with Salmonella, 50% of patients with Shigella and 21% of patients with Campylobacter. Overall, children under the age of four were mostly affected with no statistically significant difference among genders. The majority of bacterial infections 19/64 were reported in September.
Conclusions/Learning Points: In our study, the most common bacterial factor isolated was Salmonella spp and not Campylobacter, as shown in other published European data. In addition, we noticed a change in the seasonal pattern, possibly due to climate change, with the peak of bacterial infection in September.

[1]Medical University of Silesia, Department Of Paediatrics, Katowice, Poland, [2]Medical University of Silesia, Students' Scientific Society, Department Of Paediatrics, Katowice, Poland

Backgrounds: Rotavirus is the leading cause of acute diarrhea in children in the first years of life. In the last 3 years, two factors emerged that may affect the morbidity and severity of RV infections. The first one is mandatory rotavirus vaccination and the second one is pandemic restrictions in 2020 and 2021.
Methods: 323 children diagnosed with acute gastroenteritis caused by rotavirus between June 2019 and August 2022 were examined. The information about clinical picture, month of illness, as well as laboratory tests results were obtained from medical documents. Vaccine impact on rotavirus course of infection was also assessed. An important question in our study is also whether pandemic restrictions such as lockdown, social distancing and compulsory hand sanitisation have an impact on the number of cases.
Results: Analyzes of the collected medical data of patients showed that the age on the day of admission to the ward was significantly higher after the introduction of compulsory vaccinations compared to the period before introduction (3 years 7 months vs 1 year 7 months). Similar significant differences were noted for the length of hospitalization. After the introduction of compulsory vaccinations (mean= 4.97), the length of required hospitalization decreased significantly compared to the period before vaccination (mean= 6.42).In the months in which pandemic restrictions such as social distancing, the order to wear masks, lockdown, and widespread hand sanitizing were mandatory, the number of infections was lower than before the pandemic, and after the 'return to normality.
Conclusions/Learning Points: We can conclude that compulsory vaccinations have a positive effect on the morbidity in the affected group and the overall length of hospitalization. An additional conclusion is the positive effect of pandemic restrictions on the number of RV infections.

URINARY TRACT INFECTIONS CLINICAL EVOLUTION – A COMPARISON WITH THE ANTIBIOGRAM

E-Posters Viewing
E-POSTER VIEWING: AS07.B. UROGENITAL INFECTIONS

Joana Carvalho Queirós[1], Rita Calejo[2], Inês Aires Martins[1], Inês Paiva Ferreira[2], Marvin Oliveira[3], Fábio Barroso[2], Joaquim Cunha[2], Edite Tomás[2]
[1]CMIN-CHUPorto, Paediatrics, Porto, Portugal, [2]Centro Hospitalar Tâmega e Sousa, Paediatrics And Neonatology, Penafiel, Portugal, [3]Centro Hospitalar Tâmega e Sousa, Clinical Pathology, Penafiel, Portugal

Backgrounds: Urinary tract infection (UTI) is one of the most common infections in childhood and the most frequent pathogen is Escherichia coli (E. coli). Age, clinical presentation, and local patterns of antibiotic susceptibility are essential to choose the empirical antibiotherapy. Our main aim was to describe the pathogens causing UTI and its antibiotic susceptibility patterns. Posteriorly analyse the clinical evolution with the prescribed antibiotic and comparing it with the susceptibilities found.
Methods: Retrospective cohort study including all 2021's positive urine cultures in children between 3 months and 10 years.
Results: A total of 348 urine cultures were included, 284 (81.6%) were from females. The median age was 21 months (Interquartile Range (IQR): 41), 185 (53.2%) under 24 months and 163 (46.8%) above. Pre or postnatal nephrological alterations were present in 26 (7.5%). 95 (27.3%) had previous UTI episodes, of which 18 (5.2%) were under antibiotic prophylaxis. In the group under 24-months-old, fever was present in 162 (83.3%) and vomiting in 39 (19.1%). In patients above 24-months-old, 105 (64.4%) had afebrile UTI and 108 (66.3%) had dysuria. The most common bacteria was E. coli (88.8%), followed by Proteus mirabilis (10.1%) and Klebsiella pneumoniae (3.5%). E. coli was mostly resistant to Ampicillin (40.8%) and Amoxicillin/clavulanic acid (33.0%), and 23 (7.4%) were multidrug resistant. Klebsiella pneumoniae was resistant to at least 1 class of antibiotic in 100%. From the 159 cases of pathogens resistant to the prescribed antibiotic, 42 (89.3%) had favorable clinical evolution.
Conclusions/Learning Points: In vitro susceptibility is not always verified clinically. In most cases in our sample (89.3%) there was a positive clinical evolution despite treatment with an antibiotic classified as resistant in the antibiogram.

[1]Albert Royer children hospital, Paediatric Surgery, dakar, Senegal, [2]Aristide Ledantec university hospital, Paediatric Surgery, dakar, Senegal

Backgrounds: Urinary tract infection is one of the most common bacterial infections in pediatrics. The objective of our work is to determine the epidemiology and the profile of patients likely to develop a urinary infection in pediatric surgery.
Methods: This is a prospective, descriptive study conducted in the pediatric surgery department of the Albert Royer Children's Hospital in Dakar over a period of 14 months, from April 1, 2020 to May 31, 2021.
Results: We collected 36 patients, representing 3.08% of the patients hospitalized and followed during the study period. The average age was 3 years and infants represented 41.6%. The sex ratio was 3. Thirty-three patients had abnormalities of the urinary tract defect, including 21 posterior urethral valves (58.7%). Fourteen patients (38.9%) had a history of urinary catheterization. Probabilistic antibiotic therapy combining a 3rd generation cephalosporin and an aminoglycoside was used as first-line treatment in 22 cases (61%). Adaptation of antibiotic therapy was necessary in 4 patients with multi-resistant bacteria secreting extended-spectrum β-lactamase. Ten patients presented a recurrence requiring circumcision in 5 children with urinary tract abnormalities.
Conclusions/Learning Points: Urinary tract infections are frequent in pediatric surgery. They mainly affect male infants with urinary tract abnormalities or who have had an urinary catheterization.

CLINICAL CHARACTERISTICS AND ANTIMICROBIAL RESISTANCE PATTERNS OF COMMUNITY-ACQUIRED URINARY TRACT INFECTIONS IN INFANTS UNDER THREE MONTHS OF AGE IN THE SOUTH OF SPAIN

E-Posters Viewing
E-POSTER VIEWING: AS07.B. UROGENITAL INFECTIONS

Fuensanta Guerrero Del Cueto, Alfonso Lendínez-Jurado, Alba Montero-Reina, Antonio Medina-Claros, Begoña Carazo-Gallego
Hospital Regional Universitario de Málaga, Department Of Paediatrics, Malaga, Spain

Backgrounds: Urinary tract infections (UTI) are a common and potentially severe illness that must be considered when evaluating febrile infants <3 months, at higher risk of invasive bacterial infection. Studying antimicrobial resistance patterns of community-acquired pathogens is necessary to guide empirical treatment.
Methods: Descriptive observational study including patients <90 days old in the Emergency Department of a tertiary paediatric hospital diagnosed with a UTI between 2017-2022.
Results: 302 patients were assessed for suspected UTI, 99% as part of the evaluation of fever without a source. 61.6% were male. The age at presentation in 26.6% was <1 month, 33.3% 1-2 months and 40.1% 2-3 months. 74.8% of the patients were hospitalized, with a mean length of stay 5.02 days (SD 2.8), mean antibiotic treatment duration 9.6 days (SD 4.9). Catheter-obtained urine cultures were positive in 221 (73.2%) patients. The most frequent pathogens isolated were E. coli (80.1%), followed by Klebsiella spp. (9.5%), Citrobacter spp. (2.7%) and E. faecalis (2.7%). Twelve patients (5.4%) had bacteremia, nine (75%) E. coli, one E. faecalis (8.3%), one Acinetobacter ursingii (8.3%) and one MRSA (8.3%), which was isolated in a neonate who also had the only positive cerebrospinal fluid culture (0.5%) in our sample. 86.5% of all the urine isolates tested were susceptible to second-generation cephalosporins, 95.9% to third-generation cephalosporins, and 95.1% to aminoglycosides. E. coli were resistant in 49.4% to amoxicillin, 36.4% to amoxicillin-clavulanate, 23.1% to trimethoprim-sulfamethoxazole and 7.6% to quinolones.
Conclusions/Learning Points: -Urinary pathogen resistance to aminoglycosides and cephalosporins is low and remains the current recommended treatment in this age group. -Amoxicillin-clavulanate and trimethoprim-sulfamethoxazole should not be used as empirical UTI treatment due to high resistance of the most frequent pathogen in our context.

AN ADOLESCENT CASE PRESENTING WITH EPIDIDYMO-ORCHITIS BRUCELLOSIS

E-Posters Viewing
E-POSTER VIEWING: AS07.B. UROGENITAL INFECTIONS

Tuğba Erem[1], Yalçın Kara[2], Mahmut Kızıl[3], Ömer Kiliç[2], Ener Çağrı Dinleyici[4]
[1]Eskişehir Osmangazi University, Pediatric, Eskişehir, Turkey, [2]Eskişehir Osmangazi University, Pediatric Infectious Disease, ESKİŞEHİR, Turkey, [3]Eskişehir Osmangazi University, Pediatric Infectious Disease, Eskiehir, Turkey, [4]Eskişehir Osmangazi University, Pediatric Intensive Care, Eskişehir, Turkey

Title of Case: An Adolescent Case Presenting With Epididymo-Orchitis Brucellosis
Background: Brucellosis is a zoonotic disease that can be transmitted from animal to human and affects many systems in the body . Fever , sweating, weakness, lethargy, anorexia and joint pain are the most common complaints in childhood . Genitourinary system involvement and renal complications are rare in children . We would like to present a brucellosis case who applied to our clinic with epididymo-orchitis.
Case Presentation Summary: A 13-year-old male patient was admitted to our pediatric infection clinic with fever for 2 days, pain and redness in the testicle and testicular pain. It was learned that the patient, whose family was engaged in animal husbandry, was diagnosed with brucellosis 6 months ago with other family members, but stopped the treatment at the 3rd week. On physical examination, swelling in the left testis, hyperemia and tenderness on palpation. Brucella coombs test were positive with 1/640 titer, leukocytes, CRP and sedimentation were high. Treponema pallidum IgM and HIV antibody were negative. Scrotal usg was made and it was found to be compatible with epididymo-orchitis. Pediatric surgery department was consulted, cefixime antibiotic therapy was started. Due to brucellosis , 6-week rifampicin , doxycycline and gentamicin treatment was started. It was planned that the patient, who had regression in the complaints of pain and redness in the polyclinic control, to continue the rifampicin, doxycycline and gentamicin treatment and to have a control USG at the end of the treatment.
Learning Points/Discussion: As a result, brucellosis may rarely present with epididymo-orchitis in childhood . It is important to keep in mind epididymo-orchitis due to brucellosis in the differential diagnosis of scrotal diseases, especially in regions where the disease is endemic.

EVALUATION OF CLINICAL SPECTRUM, ANTIBIOTIC SENSITIVITY AND CLINICAL OUTCOME IN PEDIATRIC AGE GROUP (0 TO 18 YEARS) WITH EXTENDED-SPECTRUM BETA-LACTAMASE (ESBL) PRODUCING ESCHERICHIA COLI ASSOCIATED URINARY TRACT INFECTION IN TERTIARY CARE HOSPITAL IN INDIA

E-Posters Viewing
E-POSTER VIEWING: AS07.B. UROGENITAL INFECTIONS

Keyur Mahajan, Rajan Joshi
Deenanath Mangeshkar Hospital and Research Centre, Paediatrics, Pune, Maharashtra, India

Backgrounds: There is increasing prevalence of ESBL E.coli associated UTIs in paediatric population. These multidrug infections are challenging to treat. Our aim is to study the clinical profile, antibiotic sensitivity pattern and clinical outcomes in ESBL E.coli UTIs.
Methods: We collected reports of all urine cultures for age group 0 to 18 years with colony counts >10^5 CFU/mL and single organism isolated, from January 2017 to December 2021. All positive reports were separated according to causative organism. Prevalence of ESBL E. coli was calculated and were further analysed for clinical spectrum, antibiotic sensitivity pattern and clinical outcome.
Results: E.coli was commonest organism with 259(57%) cases, 158(35%) were ESBL E. coli. Maximum incidence was between ages 0 to 5 years (56%). Prevalence of infection in females(59%) was higher than in males(41%). ESBL E. coli were highly sensitive to carbapenems, amikacin, fosfomycin. Resistance was high for trimethoprim/sulfamethoxazole and fluoroquinolones and 100% for beta-lactams. 25% had h/o previous UTIs, 43% had significant underlying medical problem. 51% of IPD patients had normal USG. Each patient was averagely treated with antibiotics (IV plus oral) for 11 days. 26 patients were started with beta-lactam antibiotics as an empirical treatment and by the time the culture report came, 16 patients had improved clinically hence they were continued on the same antibiotic and discharged. Mortality among IPD patients was 4%.
Conclusions/Learning Points: E. coli is most common causative organism. Prevalence of ESBL E. coli is increasing. Based on sensitivity patterns carbapenems, amikacin, and fosfomycin were good options for ESBL E. coli. Antibiotic sensitivity for cephalosporins derived by currently available methods do not always match clinical experience and third generation cephalosporin still can be used as an empirical antibiotic on admission with suspected UTI.

PV0462 / #1861

URINARY TRACT INFECTIONS UNDER 3 MONTHS OF AGE: WHICH IMPLICATIONS?

E-Posters Viewing
E-POSTER VIEWING: AS07.B. UROGENITAL INFECTIONS

Inês Paiva Ferreira[1], Inês Aires Martins[2], Joana Carvalho Queirós[2], Rita Calejo[1], Marvin Oliveira[3], Fábio Barroso[1], Joaquim Cunha[4], Edite Tomás[1]
[1]Centro Hospitalar Tâmega e Sousa, Paediatrics And Neonatology, Penafiel, Portugal, [2]CMIN-CHUPorto, Paediatrics, Porto, Portugal, [3]Centro Hospitalar Tâmega e Sousa, Clinical Pathology, Penafiel, Portugal, [4]Centro Hospitalar do Tâmega e Sousa, Paediatrics And Neonatology Department, Penafiel, Portugal

Backgrounds: Although a very common disease in infants, urinary tract infections (UTIs) shouldn't be overlooked as they can lead to permanent renal damage. The aim of this study was to characterize UTIs under the age of 3 months and to identify predictive factors for UTI-related renal damage (UTI-RRD).
Methods: A retrospective cohort study was performed focusing on UTIs under the age of 3 months occurred between January 2018 and December 2021 in a Portuguese hospital.
Results: A total of 109 UTIs were identified. 61.5% of the affected patients were male. The median age was 53 days (IQR 48). The most frequent manifestations were fever (83.5%) and poor feeding (35.8%). Only two patients met criteria for severe infection. Escherichia coli was isolated in 92.7% of cases and showed a high rate of resistance to ampicilin (48.5%), amoxicillin-clavulanic acid (35.6%) and trimethoprim-sulfamethoxazole (22.8%). Approximately 3% of E. coli were multidrug resistant. In the followed period, of the 91 patients submitted to ^{99m}technetium dimercapto-succinic acid renal scintigraphy (TC99mDMSA), 16.5% showed renal damage. The binary logistic regression analysis confirmed a statistically significant association between history of urinary tract pathology in first degree relatives and altered TC99mDMSA (p=0.013, OR=27.47). No other variables were assumed as predictors for UTI-RRD after controlling for confounding factors.
Conclusions/Learning Points: This study documented a high rate of antimicrobial resistance in UTIs among very young patients. This represents an alarming finding considering the age of the patients and the null or low previous antibiotic exposure. Moreover, these high rates of resistance were recorded for some of the most commonly used antibiotics for the treatment and prophylaxis of UTIs. More studies are needed to identify predictors of ITU-RRD so a more evident-based follow-up can be mounted.

PNEUMOCOCCAL PNEUMONIA AND POST-INFECTIOUS GLOMERULONEPHRITIS - AN UNUSUAL ASSOCIATION

E-Posters Viewing
E-POSTER VIEWING: AS07.B. UROGENITAL INFECTIONS

Ana Pereira, Madalena Afonso, Marta Pelicano, Liliana Franco, Paula Nunes
Centro Hospitalar Lisboa Ocidental - Hospital de São Francisco Xavier, Serviço De Pediatria, Lisboa, Portugal

Title of Case: Pneumococcal pneumonia and post-infectious glomerulonephritis - an unusual association
Background: Streptococcus pyogenes is the most common cause of post-infectious glomerulonephritis in children. However, a few cases have been associated with Streptococcus pneumoniae. Typically, post-infectious glomerulonephritis occurs 1-3 weeks after the infection, but when S. pneumoniae is associated it can develop simultaneously.
Case Presentation Summary: A previous healthy 7-year-old boy presented to the emergency department with cough and fever for 3 days, associated with haematuria and abdominal pain for 2 days. Physical examination showed only crusty skin sores on the left leg, blood pressure was normal and absence of edema. Urinalysis revealed non-nephrotic proteinuria (protein/creatinine ratio 0,85 mg/mg), haematuria, leukocyturia, some granular cylinders, and rare acanthocytes. Blood tests revealed leucocytosis (32.700/uL, with 92.2% neutrophils), elevated C-reactive protein (28,2 g/dL), acute kidney injury with creatinine 2,11 mg/dL (GFR 27 mL/min/m^2, K:0.413), urea 133 mg/dL and hyperuricemia (10.8mg/dL). ASOT was increased (717 U/ml), C3 was diminished (32.3 mg/dL) and C4 was within normal ranges. X-ray revealed an hypotransparency on the superior right lobe. Renal ultrasound was normal. The patient was admitted in the hospital with lobar pneumonia and acute glomerulonephritis and started ceftriaxone IV 100mg/kg/day. On the fifth day after admission amlodipine was initiated due to hypertension and proteinuria reached nephrotic levels (protein/creatinine ratio 3,4 mg/mg). Haemoculture was positive for Streptococcus pneumoniae serotype 18A. Cultures of urine and pharyngeal swabs were negative.
Learning Points/Discussion: Although pneumonia associated with acute glomerulonephritis is a rare condition, S. pneumoniae should be considered in the differential diagnosis of children presenting with fever and respiratory symptoms. The prognostic is usually excellent, with complete recovery in most cases and recurrency is rare.

PV0464 / #2462

CHOOSE THE RIGHT ANTIBIOTIC

E-Posters Viewing
E-POSTER VIEWING: AS07.B. UROGENITAL INFECTIONS

Milica Šofranac
Pedijatrijska poliklinika MojLab, Pedijatrija, Montenegro, Montenegro

Background: Introduction : Urinary tract infection occurs at all ages,occurring in the form of asymptomatic bacteriuria up to pyelonephritis. The cause is scarring kidney disease, which is one of the reasons for kidney failure in children.
Methods: Methods : Analyzed the results of the urine culture of patients aged 0-16 years . Objective: To determine the most common cause of urinary tract infections and their sensitivity to antibiotics.
Results: Results : Positive results of urine culture was 135.The leading cause E.coli 96 (71.1 %).Next Proteus spp.23 (9.62 %),Klebsiella 9(6.66 %)and 5 Enterococus (3 , 7 %).Other causes are Staphylococcus aureus and Pseudomonas to 1 positive result.Test the sensitivity of E. coli in the most used anti microbial therapy : the highest level of resistance to Ampicillin 86 (63.7 %) , the Bactrim 53 (39.2 %) .Cephalexin was 16 resistant (11.8%) and the same moderate sensitivs.On Cefotaxime was 9 (6.66 %) resistant , Amikacin were resistant only 2causal(1.48 %) , as well as pipemidic acid.On Gentamicin only 1 (0.74 %) . Ceftriaxon data are not valid, because the sample was not representative .
Conclusions/Learning Points: Conclusion: The main reason for the high resistance to Ampicillin and Bactrim , and a relatively high resistance to Cephalexin , probably a consequence of the widespread and irrational use of antibiotics . Low resistance to gentamicin confirms that this is the drug of choice for initial therapy of acute pyelonephritis . Cooperation between clinicians and microbiologists , as well as continuous monitoring of bacterial resistance,is the right time ,to the rational and proper antimicrobial therapy .

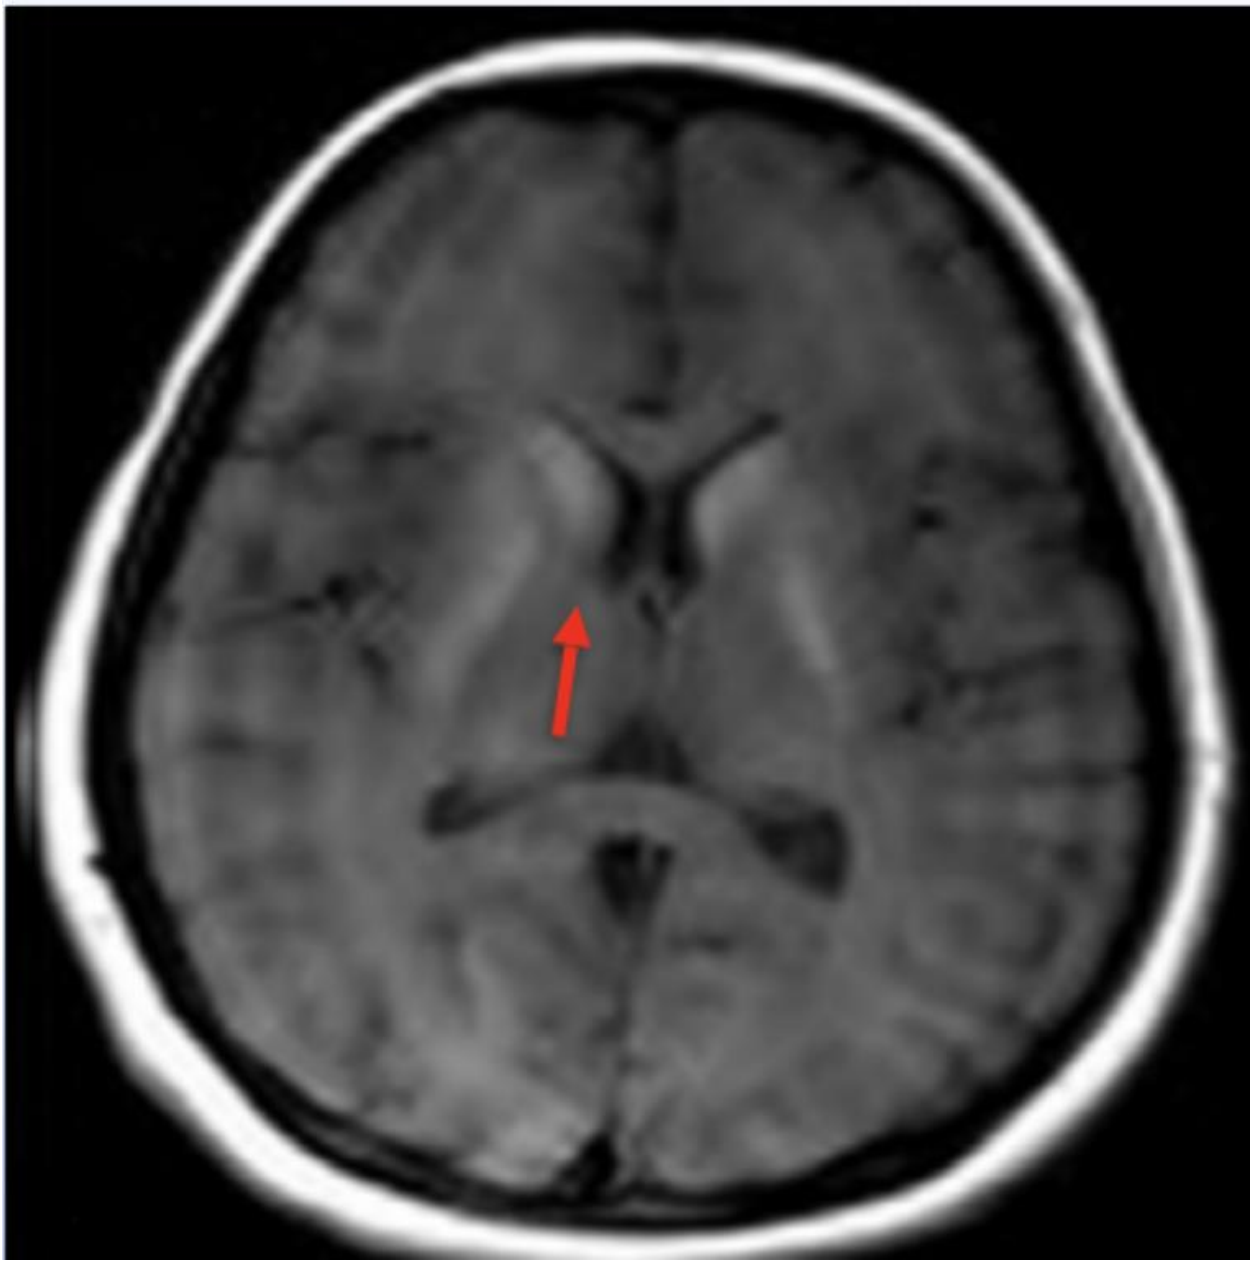
A CASE OF ACUTE DEMYELINATING ENCEPHALOMYELITIS (ADEM) ASSOCIATED WITH HUMAN BOCAVIRUS INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Sevgi Aslan Tuncay[1], Zeynep Ergenç[1], Seyhan Yılmaz[1], Burcu Parlak[1], Pınar Canizci Erdemli[1], Aylin Dizi Işık[1], Gülten Öztürk[2], Özge Yapıcı[3], Eda Kepenekli[1]
[1]Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Marmara University School of Medicine, Pediatric Neurology, İstanbul, Turkey, [3]Marmara University School of Medicine, Radiology, İstanbul, Turkey

Title of Case: A Case of Acute Demyelinating Encephalomyelitis (ADEM) Associated with Human Bocavirus Infection
Background: Acute demyelinating encephalomyelitis (ADEM) is an immune-mediated central nervous system disease that is seen after a viral infection or vaccination and manifests as sudden neurological symptoms. A wide varity of viral infections are associated with ADEM, can also cause acute encephalitis. Here, a four-year-old patient diagnosed with ADEM secondary to Human Bocavirus (HboV) is presented.
Case Presentation Summary: A four-year-old girl was admitted to emergency room with fever and drowsiness. She had severe headache and vomiting for one month. On physical examination, she was lethargic with glasgow coma scale of 11. There was no signs of meningeal irritation. Lumbar puncture was perfomed. Cerebrospinal fluid (CSF) protein level was 37 mg/dL and glucose level was 52 mg/dL. Microscopic examination showed 60 leukocytes/mm3. Ceftriaxone and acyclovir therapies were started. CSF syndromic PCR panel was negative. HboV was positive in the respiratory tract PCR panel and CSF PCR. EEG showed bioelectrical disruption in both posterior regions. Cranial magnetic resonance image study showed changes in basal ganglia and corpus callosum, compatible with viral encephalitis (Figure 1).



In follow-up, her axial hypotonicity persisted, and the cranial imaging showed progression. Intravenous immunoglobulin and pulse steroid was started. Plasmapheresis was performed for the presumed diagnosis of ADEM. Following plasmapheresis, clinical condition improved rapidly. Her axial hypotonicity was completely resolved and cognitive functions became compatible with her age. The patient is still on outpatient without any sequelae

Learning Points/Discussion: Although HboV mainly cause respiratory tract infections and gastroenteritis, they may rarely present with other end-organ involvements. Since it is a virus that was only identified in 2005, the experience on end organ involvement and management is very limited.

E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Teresa Cachada Baptista, Isabel Pinheiro, Inês Paiva Ferreira, Joaquim Cunha
Centro Hospitalar do Tâmega e Sousa, Pediatrics/neonatology, Penafiel, Portugal

Title of Case: AN UNCOMMON CAUSE OF BACTERIAL MENINGITIS IN A 3-MONTH-OLD INFANT
Background: Bacterial meningitis represents an important cause of pediatric morbimortality, manifesting in a nonspecific way in infants. It's crucial that the diagnosis and antibiotherapy be carried out at an early stage.
Case Presentation Summary: Infant aged 3 months and 23 days, female. Perinatal history of maternal colonization by group B Streptococcus (GBS) with complete antibiotic prophylaxis and late prematurity. Brought to the emergency department due to moaning cry and irritability with 4 hours of evolution. The physical examination highlighted moaning cry and fever. In blood tests (BT) leucocytes (L) 11080/uL, neutrophils (N) 8400/uL, C-reactive protein (CRP) <5 mg/L, procalcitonin (PCT) 4,97 ng/mL, normal urine sediment and chest radiography. Cerebrospinal fluid with 3020 cells/uL, 98% of N, glucose <10 mg/dL, proteins 517 mg/dL. Started ceftriaxone and vancomycin. On D2 of admission, BT with L 12580/uL, N 7490/uL, CRP 126,2 mg/L and PCT 35,46 ng/mL. Urine culture was sterile and multisensitive Streptococcus agalactiae was isolated from CSF and blood culture, so vancomycin was suspended. She maintained fever until D5, with subsequent maintenance of apyrexia and improvement in general condition. Laboratory reassessment on D5 and D12 with normalization of inflammatory parameters. Normal transfontanellar ultrasound and bilateral pass in otoacoustic emissions. Discharge oriented to Pediatric consultation. An immunological study was performed, which was normal and maintained age-appropriate psychomotor development.
Learning Points/Discussion: We highlight a rare clinical entity which is very late onsept sepsis due to Streptococcus agalactiae complicated with bacterial meningitis. It should be noted that carrying out intrapartum prophylactic antibiotic therapy in maternal colonization by GBS only influences the reduction of early infection. Risk factors for late infection are still poorly understood, but prematurity is a well-established factor.

INVASIVE MENINGOCOCCAL DISEASE IN BRAZIL IN THE ERA OF MENINGOCOCCAL C VACCINE.

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Eitan Berezin, Ana Marcos
santa casa sp, Pediatric, sao paulo, Brazil

Title of Case: Invasive meningococcal disease in Brazil in the era of Meningococcal C vaccine
Background: Background- In 2010 was included in the l Brazilian schedule a Meningococcal C conjugate vaccine for children We aim to report an experience with meningococcal disease
Case Presentation Summary: We have performed a retrospective study, through analysis of medical records and a database of exams, in patients under 18 years of ageadmitted with Meningococcal Diseases (MD) in the period from 2012 to 2018 in the Emilio Ribas Hospital We included 60 patients with confirmed meningococcal disease, 46/60 presented confirmation by specific laboratory criterion (RT-PCR, latex,or culture), 5/60 presented confirmation by nonspecific laboratory criterion (bacterioscopy), 8/60 by clinical criterion and 1/60 by epidemiological link. Seventy-four percent were serogroup C and 7.8% serogroup B. Six percent had the ACWY group identified in latex, without differentiation. Seventy-five percent of patients were admitted to the intensive care unit and the median stay was 3 days (1-48 days). Eighty-three percent had associated sepsis, 27% had a shock, 17% required orotracheal intubation, and 10% vasoactive drugs. Two patients died (lethality of 3.3%).21% (12/58) of patients were discharged with at least one sequela and 79% (46/58) of patients had a complete recovery. Five patients presented hearing loss (8.6%), four of them with altered audiometry. Three (5%) patients were discharged with arthralgia: t. One patient presented difficulty in walking referred after discharge, with an enlarged gait. One patient evolved with chronic non-evolutionary encephalopathy and another one with corneal opacity.
Learning Points/Discussion: In Brazil, most of the cases are due to N. meningitidis serogroup C even after the inclusion of the Meningococcal C vaccine in the public health system in Brazil. Follow-up of post-MD patients is essential to assess sequelae in these group

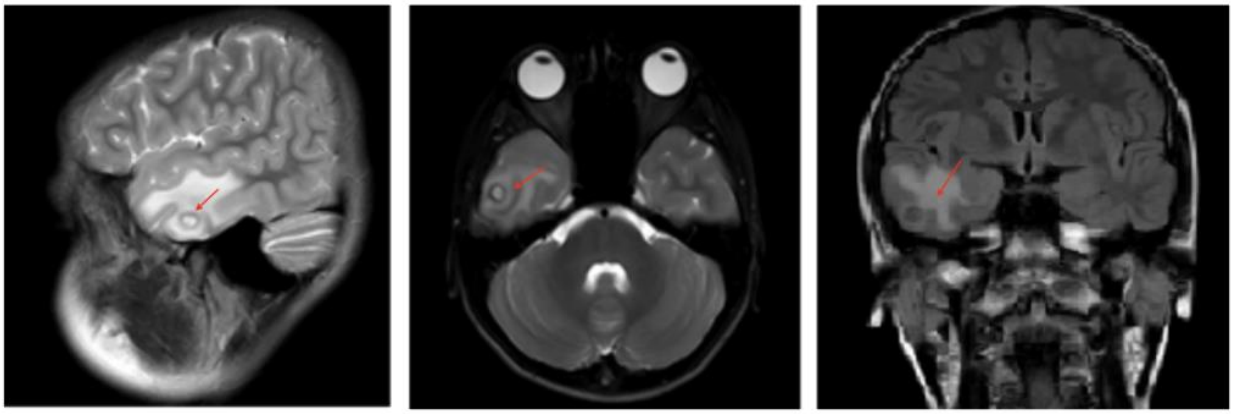
CASE OF INTRACRANIAL NEUROCYSTICERCOSIS

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Sevgi Aslan Tuncay[1], Zeynep Ergenç[1], Seyhan Yılmaz[1], Burcu Parlak[1], Pınar Canizci Erdemli[1], Aylin Dizi Işık[1], Adnan Dağçınar[2], Eda Kepenekli[1]
[1]Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Marmara University School of Medicine, Neurosurgery, İstanbul, Turkey

Title of Case: CASE OF INTRACRANIAL NEUROCYSTICERCOSIS
Background: Neurocysticercosis (NCC) is a central nervous system infection caused by the pig tapeworm, Taenia solium. It is one of the major causes of the seizures and neurologic abnormalities in children, especially in pork consuming countries. Here we present a case with NCC who operated with the presumed diagnosis of brain tumor.
Case Presentation Summary: An 11-year-old male patient admitted to another hospital with headache and dizziness. He was referred to our center with the suspicion of an intracranial mass that was detected in cranial MRI. The imaging studies showed a 6x8 mm lesion with peripheral contrast enhancement located in the right temporal region (Figure
1).



In the histopathological examination, there was an encapsulated tissue specimen. Absorbent disc-like structures were seen with PAS staining. These structures were consistent with Tenia solium larvae.In history, unknown parasites had been detected in his siblings with stool examination. Albendazole treatment was given to patient and his house-hold contacts. Entomeaboe histolytica and Giardia lamblia antigens were negative in stool examination. Serological tests were negative for human immunodeficiency virus (HIV), toxoplasmosis, echinococcosis, and brucellosis. MRI findings regressed in control imaging studies and albendazole was discontinued after completing ten days. He is still on follw-up without neurological problem and complaint.
Learning Points/Discussion: Although pork is consumed less in our country due to the Muslim population in the majority, neurocysticercosis should still be considered in patients with intracranial mass.

HEALTHCARE-ASSOCIATED VENTRICULITIS AND MENINGITIS (HAVM) IN CHILDREN, DO WE ALWAYS DO THE SAME?

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Javier Cantero Garcia[1], Natalia Ana Mendoza-Palomar[1], Susana Melendo-Perez[1], Berta Fernandez Ledesma[1], Marie Antoinette Frick[1], Mayli Lung-Suárez[2], Katiuska Carolina Rosas Soto[3], Victoria Rello-Saltor[4], Pere Soler-Palacín[1]
[1]Hospital Universitari Vall d'Hebron, Pediatric Infectious Diseases And Inmunodeficiencies Unit, Barcelona, Spain, [2]Hospital Universitari Vall d'Hebron, Microbiology, Barcelona, Spain, [3]Hospital Universitari Vall d'Hebron, Neurosurgery, Barcelona, Spain, [4]Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Paediatric Hospitalisation Unit, Department Of Paediatrics, Barcelona, Spain

Backgrounds: Healthcare-associated ventriculitis and meningitis (HAVM) represent a major complication in neurosurgical patients. Due to the lack of randomized studies addressing its management, usually clinicians follow recommendations base on expert opinions. Our aim was to describe a cohort of pediatric patients with HAVM in order to identify points for improvement, within a pediatric Antibiotic Stewardship Program.
Methods: Retrospective, descriptive and single-center study, including all pediatric (0-17 years) cases of HAVM defined by positive CSF culture, from January 2019 to September 2021. Epidemiological, clinical and laboratory data were collected from electronic medical history.
Results: 31 episodes were reported in 28 patients (17 male, median age 3 [IQR 0,7-11]y), most (28/31, 90%) occurred within 60 days after surgery. Common symptoms were fever (80.6%) and neurological dysfunction (45.2%). Blood tests showed leukocytosis (48.4%) and increased CRP (32.3%). CSF culture results: 22 Gram-positive cocci (15 coagulase-negative staphylococci), 9 Gram-negative rods (4 Klebsiella spp., 2 Pseudomonas spp.). Most empirical scheme included a third-generation cephalosporin (with or without antipseudomonal action) plus vancomycin. Twelve patients received intraventricular therapy (7 vancomycin, 5 amikacin). Device was removed in 28/31 episodes (24 at diagnosis).

Table 1. Age, device and underlying disease at presentation

Group of age (n=31 cases)	< 1 year: 9 cases (29%) 1-6 years: 10 cases (32.3%) 7-11 years: 7 cases (22.6%) 12-17 years: 5 cases (16.1%)
Device (n= 31 cases)	External ventricular drainage: 17 cases (54.9%) Ventriculoperitoneal shunt: 10 cases (32.3%) External ventricular drainage and ventriculoperitoneal shunt: 1 case (3.2%) External lumbar drainage: 1 case (3.2%) External subdural drainage: 1 case (3.2%) Permanent lumbar catheter: 1 case (3.2%)
Underlying disease (n= 28 patients)	Intraventricular hemorrhage due to prematurity (n=8) Pilocytic astrocytoma (n=4) Medulloblastoma (n=4) Other CNS tumors (n=4) Intracerebral hemorrhage (n=3) Arnold-Chiari malformation (n=2) Metabolic disease with hydrocephalus (n=1) Metabolic disease with lumbar catheter for drugs administration (n=1) Arachnoid cyst (n=1)

Conclusions/Learning Points: Remarkably, most episodes occurred early after the surgery, and device removal frequent as recommended. However, we observed some heterogeneity in the choice of empirical treatment, specially regarding to the antipseudomonal coverage and the addition of intraventricular therapy. More studies are needed to standardize the management of HAVM taking into account the particularities of the cases.

CEREBROSPINAL FLUID SHUNT MALFUNCTIONS DUE TO INFECTION IN A TERTIARY LEVEL PAEDIATRIC HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Maria Ciutad Celdran[1], Laura Pellicer Casanova[1], Georgina Armero Campos[1], Maria Hernandez-Garcia[1], Cristian Launes Montaña[1], Eneritz Velasco Arnaiz[2], Maria Becerra Castro[3], José Hinojosa Mena Bernal[3], Mariona Fernández De Sevilla Estrach[1], Juan Jose Garcia-Garcia[1]
[1]Hospital Sant Joan de Deu, Paediatrics Hospitalization, Esplugues de Llobregat, Barcelona, Spain, [2]Hospital Sant Joan de Deu, Infectious Diseases, Esplugues de Llobregat, Barcelona, Spain, [3]Hospital Sant Joan de Déu, Neurosurgery, Esplugues de Llobregat, Spain

Backgrounds: Cerebrospinal fluid (CSF) shunts are the main treatment for hydrocephalus. Infection is reported as the etiology of 5-20% of shunt malfunctions, requiring antibiotic treatment and the removal of the device. The aim of this study was to describe demographic, analytical and microbiological characteristics of CSF shunt malfunctions caused by infection and compare them with mechanical malfunctions.
Methods: Observational retrospective study was conducted in paediatric patients (0-18 years) with CSF shunt malfunction admitted to a tertiary hospital in Barcelona (Spain) from January 2020 to December 2021. Infection was defined following Hydrocephalus Clinical Research Network criteria.
Results: Eighty-nine malfunction episodes were identified in 46 patients (63% male, median age 7.4 years [IQR 3.6-14]). Main causes of hydrocephalus were brain tumour (45%), intraventricular haemorrhage (IVH) in premature infants (22%) and meningitis (12%). Infection was present in 11 (12%) episodes and was more frequent in patients with hydrocephalus due to IVH (p=0.015). CSF culture was positive in all cases and S. epidermidis was the most frequent microorganism (60%). FilmArray® sepsis Panel (Biomerieux), conducted in 6 CSF samples, resulted negative in all. The median duration of antibiotic treatment was 13 days [IQR: 10-23]. Table 1 describes comparative variables between infectious malfunctions and mechanical malfunctions (results shown as n, % or median with interquartile range). Table 1.

	Infectious malfunction (n=11)	Mechanical malfunction (n=78)	p-value
Gender (males)	9 (82%)	46 (59%)	0.198
Background:			
• Prematurity	6 (55%)	14 (18%)	**0.015**
• Other causes	5 (45%)	64 (82%)	
PICU admission	9 (82%)	40 (51%)	0.103
Median PICU stay (days)	7 (1.2-150)	1 (0-2)	**0.003**
Median Hospital stay (days)	31 (22-180)	5 (2.5-12)	**<0.001**
Blood:			
• Leukocytes (/mm3)	8950 (6900-17600)	8250 (5900-10300)	0.314
• CRP (mg/l) (n=43)	57 (3-119)	2 (0-7)	**0.001**
• PCT (ng/ml) (n=17)	0.55 (0.03-2.03)	0.03 (0.02-0.07)	**0.014**
CSF:			
• Leukocytes (/mm3)	40 (6-280)	8 (3-30)	**0.022**
• Proteins (mg/dl)	112 (22-556)	29 (11-60)	**0.017**
• Glucose (mg/dl)	45 (14-61)	61 (56-67)	**0.031**

(PICU: Paediatric Intensive Care Unit; CRP: C-Reactive Protein; PCT: Procalcitonin; CSF: Cerebrospinal Fluid)

Conclusions/Learning Points: In our series, infection was identified in 12% of CSF shunt malfunctions and was more frequent in patients with history of prematurity. Statistically significant differences between the characteristics of the CSF and blood inflammatory biomarkers of the infectious and mechanical malfunctions were observed. Studies with larger samples are necessary to validate these results and to determine cut-off points suggestive of infectious shunt malfunctions.

PV0471 / #2159

ACUTE RHINOSINUSITIS COMPLICATIONS: STREPTOCOCCUS INTERMEDIUS AS PROTAGONIST

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Marina Moreno Díez, Laura Centeno Burgos, Sara Diaz Martin, Alba Gutiérrez Nieto, Beatriz Palenzuela Afonso, Deborah Becerra Alonso
Hospital Universitario de Canarias, Pediatría, San Cristobal de La Laguna, Spain

Backgrounds: Acute rhinosinusitis is a frequent complication of upper respiratory airway infections. Adequate clinical diagnosis and antibiotic treatment prevent further adverse outcomes, including orbital/intracranial complications and craniofacial osteomyelitis. We present a 17-patient trial describing complicated sinusitis, being majority orbital cellulitis followed by brain abscess, where principal responsible was Streptococcus intermedius, commensal in oral cavity and nasopharynx, related to higher mortality and longer hospital stay. Furthermore, it is being studied an increase in brain abscesses after SARS-CoV2 pandemic.
Methods: A descriptive observational trial, n=17 aged under 14. Data is gathered between 2017-2022 from medical records in Excel database. We studied demographic variables, symptoms, diagnosis, microbiology and antibiotic and surgical treatment.
Results: Peak age for onset was 9-12 years; 59% were male. Generally, the children were febrile (71%) and almost half added other nonspecific symptoms such as rhinorrhea, cough, headache or eyelid edema. Most common complication was orbital cellulitis, followed by brain abscess. Culture samples were obtained in all patients where surgical drainage was carried (41%), mostly isolating Streptococcus intermedius, followed by polymicrobial infection; 5.8% cultures were negative. In addition, 17,8% associated bacteremia, being once again Streptococcus Intermedius the main responsible. Over 80% had previously received oral antibiotics for bacterial sinusitis, usually amoxicillin clavulanate. Antimicrobial treatment after identifying complications varied between 2 to >4 weeks, depending on diagnosis and surgical drainage. Mono or multitherapy depended on cultures, and elected antibiotics had good penetration in central nervous system.
Conclusions/Learning Points: - Symptoms in complicated sinusitis can be unspecific, needing high level of suspicion. - We mostly isolated Streptococcus intermedius, as a cause of complications such as bacteremia and brain abscess. - Most patients required antibiotic multitherapy for a prolonged period of time, from two to four weeks.

Vivantes Clinic Friedrichshain, Children's Hospital, Berlin, Germany

Title of Case: DELAYED DIAGNOSIS OF HERPES SIMPLEX ENCEPHALITIS IN A 10-YEAR-OLD PATIENT WITH INTERMITTENTLY ASYMPTOMATIC APPEARANCE
Background: Infection with herpes simplex virus (HSV) can cause severe encephalitis including impaired consciousness, focal neurologic deficits and seizures. Immediate start of antiviral treatment is crucial for prognosis and neurological outcome.
Case Presentation Summary: We report a 10-year-old boy who presented to the emergency room after showing a bilateral tonic-clonic seizure along with elevated temperature, reported cough and frontal headache for 2 days. The seizure was followed by residual focal movements after the nasal administration of midazolam. Evidence of a primary focal seizure condition was found in the patient's history. Still, comprehensive diagnostic work-up including lumbar puncture and imaging was postponed given the patient's "stable" general condition with predominantly asymptomatic appearance, adequate reaction and lack of cognitive impairment. However, during the course of the hospital stay, the patient reported visual hallucinations and showed signs of disorientation and recurrence of focal motor seizures at day 3 of admission. Consequently, lumbar puncture and magnetic resonance imaging (MRI) was performed, revealing an elevated cell count and radiological signs of frontotemporal inflammation. Thus, intravenous antiviral treatment with aciclovir, antibiotic treatment with cefotaxime and clarithromycin and anti-inflammatory therapy using methylprednisolone was initiated. At discharge at day 27, the patient's clinical state had improved without signs of cognitive or motor impairment in line with decreasing cerebral edema in MRI. The diagnosis of encephalitis caused by HSV-1 was confirmed by polymerase chain reaction (PCR) in cerebrospinal fluid.
Learning Points/Discussion: Precise recording of patient's history is indispensable for correct differential diagnosis and consequent treatment. Additionally, thorough re-analysis in the first days of admission is essential. Herpes simplex encephalitis must be considered in events of focal seizures or focal neurologic deficits.

NEUROCYSTICEROSIS IN CHILDREN: A 13-YEAR RETROSPECTIVE REVIEW IN A PORTUGUESE TERTIARY-LEVEL HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Ana Rita Gonçalves[1], Ana Margarida Garcia[2], Ana Lemos[2], José Pedro Vieira[3], Carla Ribeiro Da Conceição[4], Catarina Gouveia[2]
[1]Hospital Dona Estefania, Pediatrics, Lisboa, Portugal, [2]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatrics Infectious Diseases Unit, Lisbon, Portugal, [3]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal, Paediatric Neurology Unit, Lisbon, Portugal, [4]Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal, Neuroradiology, Lisbon, Portugal

Title of Case: NEUROCYSTICEROSIS IN CHILDREN: A 13-YEAR RETROSPECTIVE REVIEW IN A PORTUGUESE TERTIARY-LEVEL HOSPITAL
Background: Neurocysticercosis (NCC) is a neglected tropical disease, representing one of the leading treatable causes of seizures in endemic areas. In Portugal is not a statutory notifiable disease. The aim of this study is to retrospectively review clinical features of paediatric patients (0-17 years old) with NCC,admitted to a tertiary-level hospital in Portugal over thirteen-year period (2010-2022).
Case Presentation Summary: Fifteen children were identified (median age 8 [4-14], 10/15 males). According to Del Brutto criteria,7/15 were considered definitive and 4/15 probable diagnosis.12/15 had a recent history of travel to an endemic area (Cape Verde and Guinea-Bissau). All patients presented with neurological symptoms, mostly seizures (13/15) and headache (5/15). Diagnosis was made by neuroimaging: 2/15 had viable lesion,11/15 single enhancing lesion (SEL) and 5/15 calcification. No serological serum studies or parasitological examination of feces was positive. Patients with more than a lesion (n=3) were treated with anthelmintics and corticosteroid therapy. 9/15 patients with viable lesion or SEL did not receive treatment. Patients with seizures were treated with antiepileptic drug. On clinical follow-up at six months,only one patient had symptoms (seizures).The median time for repeating image was six months and all showed improved lesions,7/10 being calcified.
Learning Points/Discussion: NCC can cause preventable severe neurologic disease. Treatment with anthelmintic and corticosteroid therapy is crucial to improve prognosis. OMS (2021) suggests new guidelines for treatment of patients with viable lesion or SEL that we should apply in the future. Our cases were mainly imported from endemic regions,but local transmission also occurred,probably in the setting of a tapeworm carrier in the household. Indeed,NCC is an important public health problem that should not be neglected also in developed countries.

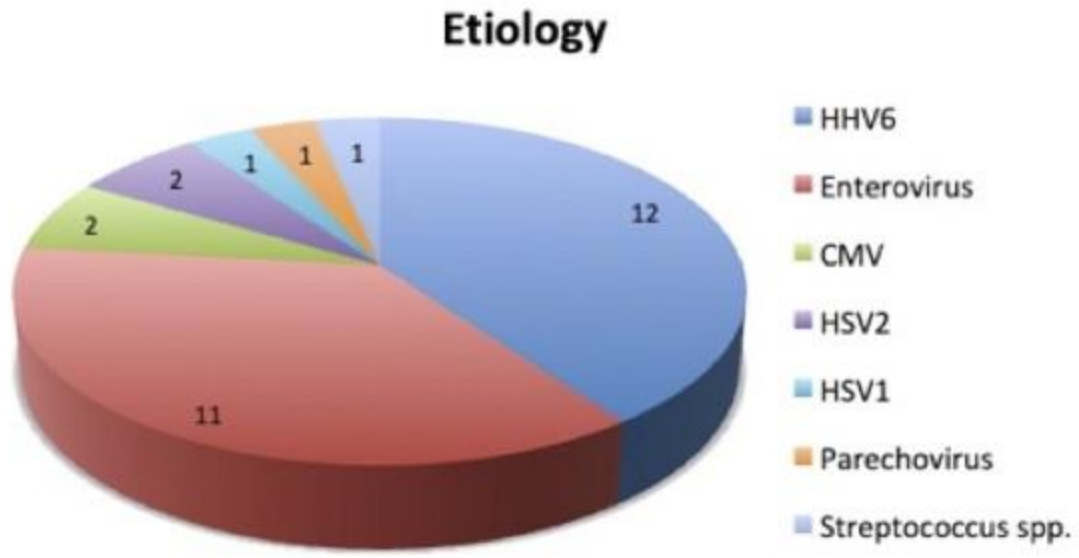
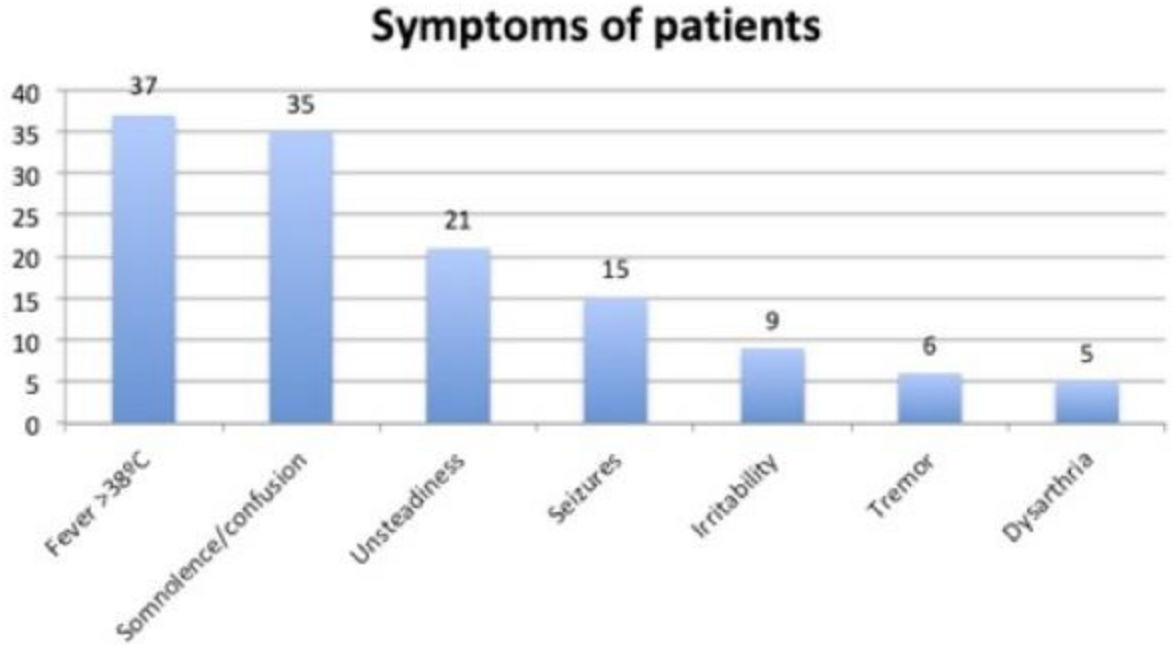
Universidad Autonoma de Madrid, Paediatric Infectious Diseases, Madrid, Spain, [7]Hospital Universitario la Paz, Pediatric Neurology, Madrid, Spain

Backgrounds: Encephalitis is an infrequent pathology. Infectious and non-infectious origin should be considered, with viruses standing out among the infectious agents. Our objective is to describe the prevalence and characteristics of encephalitis and meningoencephalitis in children in a tertiary pediatric hospital.
Methods: Retrospective descriptive observational study, including only immunocompetent patients <15 years of age, with microbiological confirmed (meningo)encephalitis, admitted to a tertiary hospital, between 2012-2022. To define (meningo)encephalitis we used Granerod J. (2010) criteria.
Results: Thirty-nine patients were included, 18 diagnosed with meningoencephalitis and 21 with encephalitis. The median age was 3.2 years (IQR 19 months-4.5 years), 59% male. Regarding etiology, all cases were sporadic except 5: 3 associated with an outbreak of enterovirus A71 occurring in 2016 and 2 with an outbreak of HHV6 in 2019 (Figure 1A). Symptoms are shown in Figure 1B. Admission to PICU was required in 56.4%, with a median stay of 3 days (IQR 1-6 days). Electroencephalogram (EEG) abnormalities were observed in 25/37 (67.5%) and abnormal magnetic resonance imaging (MRI) in 17/25 (68%). Computed tomography detected findings in only 9/31 (29%) patients. Acyclovir was started in 94.8% of cases, associated with antibiotics (70%), and changed to ganciclovir in 12.8%. Steroids were co-administered in 13 (33.3%) and gammaglobulin in 8 (20.5%). No patient died. Long-term sequelae, such as hemiparesis, dysphagia, aphasia or spastic paresis were present in 10% of cases.



A. Etiology of cases of encephalitis



B. Symptoms of cases of encephalitis

Conclusions/Learning Points: Encephalitis affects mainly preschool infants, with nonspecific clinical manifestations and high morbidity. Therefore, a high index of suspicion is capital. As described in the literature, viral etiology is the most frequent (mainly HHV6 and enterovirus) and EEG and brain MRI are the tests with the highest diagnostic yield.

PAEDIATRIC INTRACRANIAL ABSCESSES: 13 YEARS OF EXPERIENCE ON AN INFREQUENT BUT SERIOUS DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Fuensanta Guerrero Del Cueto, Diego Lozano-Durán, María Mora-Loro, Laura Martín-Pedraz, Antonio Medina-Claros, Begoña Carazo-Gallego
Hospital Regional Universitario de Málaga, Department Of Paediatrics, Malaga, Spain

Backgrounds: Intracranial abscesses (IA) are an uncommon infection that may cause sequelae or death if not recognised and treated promptly, frequently requiring neurosurgery and long antibiotic courses.
Methods: Retrospective study in children <14 years-old diagnosed with IA in a tertiary paediatric hospital between 2010-2022. Descriptive analysis of clinical, microbiological and treatment variables, and logistic regression of risk factors for adverse outcomes were performed.
Results: 31 patients, 61.3% male, median age 59 months (IQR=124). Main presenting symptoms were fever (87.1%), headache (45.16%) and focal neurologic deficit (41.94%). Mean days of symptoms before diagnosis was 8 (SD= 5); only 19.35% had the classical triad. 9.68% were premature; 6.45% immunosuppressed; 6.45% had congenital heart disease; 6.45% ventriculoperitoneal shunt; 3.23% neural tube defect. 32.26% had sinusitis, 22.58% mastoiditis and 22.58% meningitis. The most frequent location was frontal (64.52%) and 48.39% had multiple abscesses. 23/31 (74.19%) had microbiological isolates. Main single isolates were Streptococcus spp. (11/23, 47.83%) including 7/11 (63.63%) viridans-group-streptococci. 6/23 (26.09%) had Gram-negative-bacilli, 4/23 (17.39%) anaerobes, 2/23 (8.69%) C. albicans and 1/23 (4.35%) P. anaerobius. 3/23 (13.04%) were polymicrobial, 3/3 (100%) anaerobes and 2/3 (66.66%) viridans-group-streptococci. 77.4% required neurosurgery. 16 different empirical antimicrobial therapies were used, mainly (45.16%) cefotaxime+vancomycin+metronidazole. Antibiotics were changed in 58.06%. The median duration of treatment was 30 days (IQR=23). 51.61% of patients had sequelae, mainly cerebral palsy, epilepsy, and hydrocephalus; one patient (3.23%) died. Risk factors for adverse outcomes were meningitis (p=0.023), multiple abscesses (p=0.008) and focal deficit (p=0.008), the latter being the only significant factor after logistic regression (OR 42.81; 95%CI 2.58-708.53; p=0.009).
Conclusions/Learning Points: -Empirical treatments were diverse; coverage for Gram-positives, Gram-negatives and anaerobes is necessary. -Most patients had adverse outcomes; multiple abscesses, meningitis, and focal deficit were the main risk factors.

[1]Great Ormond Street Hospital for Children NHS Foundation Trust, Neurosurgery, JNH, United Kingdom, [2]Great Ormond Street Hospital for Children NHS Foundation Trust, Department Of Microbiology, Laboratory Medicine, London, United Kingdom, [3]Great Ormond Street Hospital, Paediatric Infectious Diseases, London, United Kingdom, [4]UCL Great Ormond Street Institute of Child Health, Paediatric Infectious Diseases, London, United Kingdom, [5]Great Ormond Street Hospital for Children NHS Foundation Trust, Paediatric Infectious Diseases, London, United Kingdom

Backgrounds: Invasive Group A Streptococcal (iGAS) disease is associated with a high rate of morbidity and mortality. High income countries have reported incidences of 2-4 cases per 100,000 population per year; and case fatality rates of ~15-20%. Central nervous system (CNS) involvement is rare, accounting for only 0.2-1% of all childhood bacterial meningitis. In 2022 a significant rise in scarlet fever and iGAS was noted globally with a displacement of serotype causing a predominance of emm type 1.0
Methods: Retrospective review of a prospectively collected electronic departmental database identified patients in 2022. Further demographic and microbiological information obtained from electronic patient records and laboratory management systems.
Results: We identified 5 patients over a 2-month period between November and December 2022 with intracranial Group A Streptococcus infection. Prior to this cluster, we reported only two cases in the prior two years. All patients had preceding illnesses including chicken pox, and upper respiratory tract infections. Intracranial pathology varied; three patients had subdural empyema secondary to sinusitis; 1 patient had primary meningitis; 1 patient had an extradural empyema secondary to mastoiditis. Four patients (80%) cultured Streptococcus pyogenes of which 2 (50%) were emm 1.0 subtype. One patient was positive only on specific Group A Streptococcus PCR. Antimicrobial therapy in all patients included a third-generation cephalosporin, often including a toxin synthesis inhibitor antibiotic such as clindamycin. Neurological outcomes varied; 3 patients returned to near neurological baseline; 1 patient had significant residual neurological deficits; 1 patient died.
Conclusions/Learning Points: Despite the worldwide increased incidence, intracranial complications remain rarely reported resulting in a lack of awareness of iGAS-related intracranial disease. Awareness and prompt referral to a paediatric neurology/neurosurgical/infection team is crucial to optimise neurological outcomes.

COMPARISON OF ENDOSCOPIC SINUS SAMPLING VERSUS INTRACRANIAL SAMPLING FOR MICROBIOLOGICAL DIAGNOSIS OF SUBDURAL EMPYEMAS IN CHILDREN: A CASE SERIES AND LITERATURE REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Michelle Kameda-Smith[1], Li-An Brown[2], John Hartley[2], Owase Jeelani[3], Martin Tisdall[1], Dominic Thompson[1], Alaisdair Bamford[4], Dulanka Silva[1], Kristian Aquilina[1], Gregory James[1], Zubair Tahir[1], James Hatcher[2]
[1]Great Ormond Street Hospital for Children NHS Foundation Trust, Neurosurgery, JNH, United Kingdom, [2]Great Ormond Street Hospital for Children NHS Foundation Trust, Department Of Microbiology, Laboratory Medicine, London, United Kingdom, [3]Great Ormond Street Hospital for Children NHS Foundation Trust, Neurosurgery, London, United Kingdom, [4]Great Ormond Street Hospital, Paediatric Infectious Diseases, London, United Kingdom

Backgrounds: Subdural empyemas are often associated with contiguous sinus infection, with Streptococcus intermedius being the most common pathogen. Microbiological diagnosis is possible either via sinus or transcranial sampling. A sinus approach is minimally invasive, however the sensitivity and specificity for identifying the organism causing intracranial infection are unclear. This information is key to assessing its utility in optimising antimicrobial therapy and avoidance of intracranial surgery
Methods: Retrospective review of a prospectively collected electronic departmental database identified patients between 2019-2022. Further demographic and microbiological information obtained from electronic patient records and laboratory management systems.
Results: Twenty-eight patients were identified with intracranial empyema and sinus involvement during the 3-year period. Median age of onset was 10 years with a slight male predominance (57%). All patients had intracranial sampling;14 patients undergoing additional sinus sampling. Only 1 patient (7%) had the same organism(s) grown from both samples. Streptococcus intermedius was the most common pathogen. Eight patients (29%) had mixed growth and 65% of samples undergoing bacterial PCR identified additional organisms. Sinus samples had a significant addition of nasal flora and Staphylococcus aureus. Of concern, 9/14 (64%) of sinus samples missed the main pathogen compared to intracranial culture with additional PCR. Literature review identified 21 papers where sinus drainage was used to treat subdural empyema, with only 6 papers reporting concurrent microbiology results. It confirmed ours to be the largest comparative study and no paper reported greater than 50% concordance in microbiological diagnoses.
Conclusions/Learning Points: Endoscopic sinus surgery may have therapeutic benefit, but it is not an appropriate approach for microbiological diagnosis in paediatric subdural empyemas. High rates of contaminating nasal flora can lead to misdiagnosis and inappropriate treatment. Routine addition of 16S rRNA PCR to intracranial samples is recommended.

E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Chong-Wei Huang[1], Jainn-Jim Lin[1], Cheng-Hsun Chiu[1], Yhu-Chering Huang[1,2], Chih-Jung Chen[1], Chen Yen Kuo[1], Yu-Chia Hsieh[1]
[1]Chang Gung Memorial Hospital, Division Of Pediatric Infectious Diseases, Department Of Pediatrics/Taoyuan, Taiwan, [2]Chang Gung Memorial Hospital, Division Of Pediatric Infectious Diseases, Departments Of Pediatrics, Taoyuan, Taiwan

Backgrounds: The outbreak of COVID-19, Omicron BA.2 variant, pandemic in Taiwan is ongoing since April, 2022. Rapid increase in COVID-19 pediatric cases and associated hospitalization were noticed. Encephalitis/acute encephalopathy, an uncommon but serious neurological complication in children, has been reported in several countries. The disease course of acute encephalitis could be benign with spontaneous resolution or rapidly progressed and even fatal. The mechanism of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)induced encephalitis was possibly due to direct virus invasion, indirect immune-mediated inflammatory effect or both. We would like to describe the COVID-19 neurological presentation in children and explore the clinical factors to predict severe neurological complications and associated ICU admission.
Methods: Pediatric inpatients (age ≤ 18 years) with confirmed SARS-CoV-2 infection within one week before admission at Chang Gung Memorial Hospital, Linkou or Kaohsiung branch from April to August 2022, were prospectively enrolled. Demographic description, clinical manifestations and laboratory data were collected. The definition of encephalitis and acute encephalopathy was based on International Encephalitis Consortium definition, Brighton criteria and current consensus.
Results: Of 328 patients (188 [57.3%] male; median [IQR] age 21 [6.2-54.8] months), 98 (29.9%) had neurological symptoms including 38 (38.8%) febrile convulsion, 38 (38.8%) encephalitis/acute encephalopathy, 30 (30.6%) headache/dizziness. The common symptoms of encephalitis/acute encephalopathy were fever (97.3%), seizure (52.6%), and impaired consciousness (36.8%); 12 (31.6%) developed life-threatening conditions, required ICU care. The independent predicted risk factors for encephalitis/acute encephalopathy associated ICU admission were absolute neutrophil count (ANC) ≥ 3500mm^3/L and procalcitonin (PCT) ≥ 0.7ng/mL.
Conclusions/Learning Points: The combination of demographic data and biomarkers could assist physicians to identify children with COVID-19 infection at high risk for encephalitis/acute encephalopathy associated ICU admission.

Title of Case: ATYPICAL ACUTE MASTOIDITIS AND INTRACRANIAL ABSCESSES COMPLICATING ACUTE OTITIS MEDIA
Background: Antibiotics have produced an overall decline in the frequency of complications of acute otitis media (AOM) relative to the pre-antibiotic era. However, severe intracranial complications (ICCs) still occur and their clinical picture has changed with the advent of antibiotics. A delay in their recognition may result in morbidity and mortality.
Case Presentation Summary: We admitted a 5-year-old girl with fever, severe pain of the right ear, treated with two-day course of intamuscular ceftriaxone. Due to worsening general condition and elevated C-reactive protein (80 mg/L), she was admitted to our hospital. On admission the girl was dehydrated ,with clinical findings of right AOM. There were no clinical signs of acute mastoiditis and her neurological examination was unremarkable. Cefotaxime was administered for AOM. On the third day of treatment, the fever continued and C-reactive protein remained elevated (175 mg/L). Vancomycin was added to her treatment. On the fifth day of her therapy, the girl complained for headache localized on the right frontotemporal area. Brain CT scan showed right mastoiditis, right temporofrontal epidural abscess and a small subdural collection in the right frontal region. Cefotaxime was switched to meropenem and the girl was referred to the Neurosurgeons and Ear Nose Throat(ENT) specialists. A second CT scan was performed a week after switching to meropenem and it showed a brain abscess formation on the right temporal lobe. Craniotomy and abscess drainage along with mastoidectomy with ventilation drainage of the right ear was then performed. She continued with meropenem and linezolid and she fully recovered.Her immunology profile was normal.
Learning Points/Discussion: Intracranial complications of AOM, although uncommon, still occur despite appropriate antibacterial treatment and require expensive and long-term inpatient treatment.

MANAGEMENT OF INFANT BOTULISM IN SINGAPORE

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Kai Qian Kam, Karen Nadua, Chee Fu Yung, Chia Yin Chong, Koh Cheng Thoon, Natalie Woon Hui Tan, Jiahui Li
KK Women's and Children's Hospital, Singapore, Paediatrics, Infectious Disease Service, Singapore, Singapore

Title of Case: MANAGEMENT OF INFANT BOTULISM IN SINGAPORE
Background: Infant botulism caused by Clostridium botulinum is a rare and potentially lethal condition affecting children < 1-year-old. Treatment with Human Botulism Immune Globulin Intravenous (BIG-IV) had been shown to accelerate the neurological recovery but this is expensive and difficult to obtain outside USA. We present our clinical experience in managing infant botulism from 2000-2022, including the use of Heptavalent Botulinum Antitoxin (HBAT).
Case Presentation Summary: Four infants (median age: 5.5 month, IQR: 3.5-8.3) were diagnosed with infant botulism. Only 2 infants had a history of honey ingestion. All infants presented with lethargy, poor feeding and symmetrical acute flaccid paralysis (AFP). Stool Clostridium botulinum were positive in all cases (2 with toxin A&B, 2 with toxin B&F). Invasive mechanical ventilation was required in 3 infants. Two infants were treated with BIG-IV; other 2 infants were treated with HBAT. BIG-IV and HBAT were started at a mean of 17 (SD: 8.5) and 6 days (SD: 1.4) from symptom onset, respectively. The mean duration of intensive care admission for those treated with BIG-IV and HBAT were 11.5 (SD: 4.9) and 9.5 (SD: 2.1) days, respectively. The mean duration of hospital admission for those treated with BIG-IV and HBAT were 26.0 (SD: 8.5) and 20.0 (SD: 2.8) days, respectively. Infants who received HBAT reported no side effects, similar to those who received BIG-IV. All patients recovered well without long term sequelae.
Learning Points/Discussion: Diagnosis of infant botulism should be considered in infants presenting with non-specific symptoms and AFP, even in the absence of honey ingestion. Our experience suggests that HBAT is safe and can be considered as an alternative treatment option, although it is not currently licensed for use in infant botulism.

ETIOLOGY AND CLINICAL FEATURES OF ENCEPHALITIS IN KOREAN CHILDREN – A RETROSPECTIVE SINGLE CENTER STUDY, 2005-2020

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Ahra Kim[1], Minyoung Kim[1,2], Ji Yeon Baek[1,2], Ji Young Lee[2], Jong Gyun Ahn[1,2], Se-Hee Kim[1], Hoon-Chul Kang[1], Jiman Kang[1,2]
[1]Yonsei University College of Medicine, Department Of Pediatrics, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Pediatrics, Institute For Immunology And Immunological Disease, Seoul, Korea, Republic of

Backgrounds: Encephalitis usually develops in childhood, and early diagnosis and targeted treatment can affect better prognosis. However, in most cases the cause is still unknown. We investigated the etiology of encephalitis in Korean children. We also explored the clinical features and prognosis according to the etiology.
Methods: This retrospective study was conducted between 2005 and 2020 at Severance Children's Hospital. For the diagnosis of encephalitis, we used the 2013 International Encephalitis Consortium (ICS) criteria. In the evaluation of causality between encephalitis and the causative pathogen, a proven/probable case was defined as a case when a cause was confirmed in a CNS specimen or a well-known antibody for autoimmune encephalitis (AIE) was detected. Neurological sequelae were categorized by modified Rankin Scale (mRS) score.
Results: A total of 555 children were included. The median age was 6.3 years (range, 0-14 years). By diagnostic grade of encephalitis, 7% were possible, 77% probable, and 15% proven. At least one pathogen was identified in 42% (n=222). Viruses were the most common at 42%, bacteria at 38%, and AIE at 12%. When restricted to proven/probable pathogens (n=65), bacteria accounted for 52%, viruses 25% and AIE 22%. In order of single pathogen, NDMA (N-methyl-D-aspartate) receptor autoantibody (n=14), GBS (n=13), HSV (n=11), and Enterovirus (n=4) were commonly identified. About 37% of patients at discharge had sequelae of mRS ≥2, but there was no difference in prognosis according to the etiology.
Conclusions/Learning Points: This is the largest epidemiology study on pediatric encephalitis in Korea. As the cause of pediatric encephalitis, not only infection but also AIE account for a significant portion, so efforts are needed for early diagnosis and targeted treatment.

PV0482 / #2208

BETTER DIAGNOSTIC TESTS ARE NEEDED TO GUIDE EMPIRICAL ANTIBIOTIC TREATMENT IN CHILDREN WITH CNS INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Mojca Kolnik[1], Karmen Krejan[1], Katarina Vincek[2], Perform Consortium[3], Marko Pokorn[1]
[1]University Medical Centre Ljubljana, University Children's Hospital, Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Department Of Infectious Diseases, Ljubljana, Slovenia, [3]Paediatric Infectious Diseases, Imperial College, London, United Kingdom

Backgrounds: Central nervous system infections in children present a diagnostic challenge. The rapid evolution of the disease and potential sequelae call for prompt broad-spectrum antimicrobial treatment even before the aetiology is confirmed.
Methods: Review of 6313 entries of children <18 years enrolled in PERFORM BIVA-ED study between 2016-2021 identifying those with a diagnosis “meningitis”, “encephalitis” or “brain abscess”.
Results: There were 202 cases, 87 female, 115 male with median age: 4.04 (range: 0-17.5) years. 58.9% appeared ill at the time of presentation and 22,8% required lifesaving interventions. One hundred and thirty-five (66.8%) were admitted to ward, 75 (37.1%) to PICU - 44 from ED and 31 later. Six children (3%) died. Bacterial pathogens were identified from any microbiological sample in 74 (36.6%) cases and viral in 116 (57.4%). Thirty (14.9%) children had a bacterial-viral coinfection. The commonly identified bacteria were Neisseria meningitidis (N=15), Streptococcus pneumoniae (N=14), Escherichia coli (N=8), Borrelia burgdorferi (6). The main viruses were enterovirus (N=67), adenovirus (N=16), and tick-borne encephalitis virus (N=8). A phenotype was assigned according to the likelihood for bacterial/viral/inflammatory condition: 63 (31.2%) had phenotypes related to bacterial infection, 105 (52%) phenotypes related to viral infection, 23 (11.4%) unknown bacterial or viral, 7 (3.5%) uncertain infection or inflammation, 2 (1%) inflammatory syndrome, 1 (0.5%) other infection. Thirty-two (15.8%) patients had received antibiotic treatment in the last 7 days before presentation and 159 (78.7%) were given new antimicrobial treatment during admission.
Conclusions/Learning Points: The majority of children presenting with CNS infections are prescribed antibiotics, despite only about a third having a bacteria-related phenotype. Better diagnostic tests are needed to optimise the use of antibiotics in this group of patients. Funding: EU H2020, GA No 66830.

ACUTE SEVERE HEADACHE IN A 6-YEAR OLD BOY

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Liza Lah
General Hospital Celje, Children's Department, Celje, Slovenia

Title of Case: Acute severe headache in a 6-year old boy
Background: A 6-yr old presented to our ED in late summer due to a severe headache of 24-hrs duration. Multiple doses of paracetamol orally offered no relief. No vomiting or fever. The boy had complained of chronic rhinitis and recently had two small abscesses in his ear canal.
Case Presentation Summary: When admitted, he complained of a headache 8/10 VAS, had slight photophobia and bilateral conjunctivitis. His nasal pasages were congested and signs of inflammation were seen in the right ear canal. Meningeal signs were negative and no abnormal signs on the neurologic exam were noted.He became febrile (38,7°C) with a CRP of 38 - mg/L and slightly elevated leukocyte count. A head CT showed bilateral sphenoid sinusitis. Treatment was started with amoxicilin and clavulanic acid. No clinical improvement was apparent after 24 hours. A further elevation in CRP was noted (max 136 mg/L). Oedema of the eyelids and nose developed. The headache did not improve. Analgesics were needed regularly and in high doses (ibuprofen, metamisole). MRI showed significant eyelid and facial edema and bilateral sphenoid sinusitis with progression to the right ethmoid sinus. No venous thrombosis or orbital cellulitis was seen.
Learning Points/Discussion: Staphylococcus aureus was isolated from BC. Treatment with flucloxacillin, cefotaxime, and metronidazole was started. One dose of prednisone was given to reduce inflammation. Treatment with nasal corticosteroids was also prescribed. He became afebrile and his condition improved after 24h. ENT specialists were consulted and suction of the sphenoid sinus was performed. A sample grew Staphylococcus aureus, resistant to penicillin, sensitive to oxacilin, vacomycin, erithromycin, clindamycin, gentamicin, rifamycin and trimethoprin and sulphametoxazole.Three tier antibiotic treatment was continued for 14 days. Treatment with flucloxacilin was continued until day 21.

INHERITED CHROMOSOMALLY INTEGRATED HUMAN HERPESVIRUS 6 – A CLINICAL CASE DEPICTING THE DIAGNOSTIC APPROACH

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Coralie Morelle, Laurie Lecomte, Catherine Heijmans
Centres Hospitaliers Jolimont, Pédiatrics, La Louvière, Belgium

Title of Case: Inherited chromosomally integrated human herpesvirus 6 – a clinical case depicting the diagnostic approach
Background: Human herpesvirus 6 (HHV-6) has the unique ability to integrate its entire genome into human telomeres, including in the gametes. This enables him to be vertically transmitted in the form of inherited chromosomally integrated HHV-6 (iciHHV-6). We present the process which allowed us to diagnose iciHHV-6B in a neonate.
Case Presentation Summary: A neonate was admitted in neonatalogy on 1st day of life (DOL) for pyrexia, tremulations, and irritability, without neonatal infectious risk factors. The biology showed an elevated CRP without hyperleukocytosis and the lumbar puncture revealed a pleiocytosis with atypical formula (mostly monocytic and lymphocytic). Initial treatment with aciclovir and broad-spectrum antibiotics was administered, with a favorable evolution. On DOL5, the multiplex PCR assay for meningoencephalitis (ME) performed on the CSF was positive for HHV-6B, and was confirmed by a quantitative PCR. A shift from aciclovir to ganciclovir was performed. EEG and transfontanellar ultrasound showed no abnormality. Later, the child's blood qPCR revealed >10^6 copies/ml of HHV-6B DNA. This was strongly suggestive of iciHHV-6B and motivated the interruption of ganciclovir administration. Finally, qPCR >10^6copies/ml in the father's and the child's blood at 1 month of life confirmed this diagnosis.
Learning Points/Discussion: The detection of HHV-6 can be explained by congenital transmission (iciHHV-6 or transplacental infection in neonatal period) or acquired infection. Chromosomal integration in the form of iciHHV-6 is very common (~1% of the general population), however it is widely unknown by clinicians. Incidental detections of HHV-6 are becoming more frequent due to increased use of multiplex PCR assay ME.
Our case illustrates the difficulty to distinguish between iciHHV-6 and active infection, which can result in misdiagnosis and inappropriate treatments.

LONG-TERM CONSEQUENCES OF PARECHOVIRUS ENCEPHALITIS IN A NEONATE

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Dawid Lewandowski, Kacper Toczylowski, Artur Sulik
Medical University of Bialystok, Department Of Pediatric Infectious Diseases, Bialystok, Poland

Title of Case: LONG-TERM CONSEQUENCES OF PARECHOVIRUS ENCEPHALITIS IN A NEONATE
Background: Parechovirus is a rare cause of neuroinfections in children, but complications of this infection may be devastating. We report a case of a neonate with encephalitis caused by parechovirus who developed serious long-term sequelae.
Case Presentation Summary: A previously healthy, term, 19-day-old newborn was admitted because of poor feeding, diarrhea and fever. He was restless and crying on admission. On examination nystagmus and yellowish pale skin were noticed. His fontanelles were normal. Initial lab tests showed low CRP and low procalcitonin levels. The next day he developed seizures and apnea. Blood and stool samples were collected for cultures and metabolic panels. He received treatment with ampicillin, gentamicin, aciclovir and phenobarbital. The first CSF examination revealed pleocytosis of 3 cells/µL. Due to recurrent episodes of seizures and apnea, the boy was transmitted to intensive care, intubated and ventilated. Repeated CSF examination revealed pleocytosis of 12 cells/µL and the presence of parechovirus RNA in the CSF sample. Metabolic disorders were excluded. Dexamethasone and mannitol were added to the therapy. Initial head MRI and ultrasound were normal. After eight days of ICU treatment the boy was transferred to the PID department, fully recovered showing no symptoms, and eventually was discharged home after 15 days of hospital stay. On follow-up he revealed signs of significant developmental delay. His head and brain MRI scans done two and six months after the infection showed progressive brain atrophy.
Learning Points/Discussion: Although parechovirus is a rare cause of CNS infections, the disease might be devastating and should be considered in differential diagnosis. Normal CSF cytosis does not rule out encephalitis. Patients with neuroinfections may develop long-term complications that cannot be overlooked.

NEURODEVELOPMENTAL DISABILITY AFTER MENINGITIS – A CASE SERIES

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Ana Rita Matos[1], Ana Rita Albuquerque Costa[1], Joana Monteiro[1], Jorge Rodrigues[2], Francisco Ruas[2], Cristina Faria[2]
[1]Centro Hospitalat Tondela-Viseu, Pediatria, Viseu, Portugal, [2]CH Tondela-Viseu EPE, Pediatric Department, Viseu, Portugal

Backgrounds: Meningitis, although mild and self-limited in most cases, can lead to significant morbidity in up to 20% of cases, especially if bacterial. As of today, there are no consensus in published literature regarding a routine follow-up appointment aimed at detecting neuropsychiatric or developmental disabilities. The aim of this study was to assess clinical outcome following an episode of meningitis and evaluate the need for such a formal evaluation.
Methods: Single center, 8-year, retrospective cohort study of children admitted for meningitis.
Results: During this period, there was a total of 64 patients, median age of 6 years old (IQR 4,3-9). Aseptic meningitis accounted for 39.1% of cases. The remainder were 14% bacterial and 46.9% viral. The most frequent viral and bacterial pathogens isolated were Enterovirus (96.6%) and Neisseria meningitidis (55.5%), respectively. 34.4% of patients underwent antibiotic therapy. No deaths were reported. 7.8% of children had neurodevelopmental delay prior to the episode. Among those with isolated pathogens, there were 25.6% of children that developed neurological, developmental or psychiatric impartment: behavioral disorder (3), attention deficit-hyperactivity disorder (3), reading and writing disorder (2), chronic headache (2), speech delay (1) and intellectual disability (1).
Conclusions/Learning Points: In our study, there were no severe neurological complications nor sequelae. However, 25.6% developed disabilities that can affect daily life after contracting meningitis. As such, monitoring of neurological and psychiatric development of these patients should be recommended, even in mild cases, for early assessment and intervention.

A RARE CASE OF PAEDIATRIC INVASIVE DISEASE DUE TO HAEMOPHILUS INFLUENZAE SEROGROUP A

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Inês Mazeda[1], Joana Ventura Lourenço[2], David Nascimento Moreira[3], Gracinda Oliveira[1], Sílvia Saraiva[1], Isabel Mendes[1]
[1]Centro Hospitalar Póvoa de Varzim - Vila do Conde, Department Of Paediatrics, Porto, Portugal, [2]Centro Hospitalar e Universitário de São João, Department Of Paediatrics, Porto, Portugal, [3]Agrupamento de Centros de Saúde Cávado III - Barcelos/Esposende, Public Health Unit, Braga, Portugal

Title of Case: A RARE CASE OF PAEDIATRIC INVASIVE DISEASE DUE TO HAEMOPHILUS INFLUENZAE SEROGROUP A
Background: Invasive disease is a serious condition that can cause severe morbidity and mortality in infants. Haemophilus influenzae (Hi) is among the causative pathogens, typically serogroup b (Hib), but the serogroup a (Hia) currently emerging is being recognized as a cause in the post-vaccinal era, especially in young children.
Case Presentation Summary: We report a 6-month-old boy who presented to the emergency room (ER) with a 3-day history of fever, nasal drip and cough. During his ER stay, he developed lethargy and a bulging fontanel. Initial blood work showed leukopenia and an elevated C reactive protein (127 mg/L). The liquor revealed pleocytosis (3 509 cells/uL), low glucose and high protein count, consistent with bacterial meningitis. Further investigations, including blood and liquor cultures, were performed. Both cultures were positive for Hia. Additional testing of both liquor and nasal secretions were positive for adenovirus coinfection. The patient was initiated on a 10-day course of ceftriaxone (100 mg/kg/day), which led to significant clinical improvement.
Learning Points/Discussion: This case highlights the importance of considering Hi as a potential pathogen in invasive disease, and the need to also consider viral coinfections. In this case, the adenovirus coinfection may have contributed to the patient's disease severity. Clinicians should be aware of the emerging Hi non-b serogroups that can cause invasive disease and are not covered by the current immunisation programs. This can have implications in future vaccine development.

INVASIVE MENINGOCOCCAL DISEASE (IMD): THERAPEUTIC APPROACHES AND OUTCOMES DURING 2010-2020 IN GREECE

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Panagiotis Poulikakos[1,2], Athanasia Xirogianni[2], Stelmos Simantirakis[2], Athanasios Michos[3], Elpidoforos Mantadakis[4], Vassiliki Papaevangelou[5], Maria Tsolia[6], Georgina Tzanakaki[2]
[1]Anticancer Hospital "Metaxa", Pireaus, Greece, Intensive Care Unit, Pireaus, Greece, [2]University of West Attica, National Meningitis Reference Laboratory, Department Of Public Health Policy, School Of Public Health, Athens, Greece, [3]National and Kapodistrian University of Athens, First Department Of Pediatrics, Infectious Diseases And Chemotherapy Research Laboratory , 'aghia Sophia' Children's Hospital, ATHENS, Greece, [4]Democritus University of Thrace Faculty of Medicine, Pediatrics-pediatric Hematology/oncology, Alexandroupolis, Greece, [5]National and Kapodistrian University of Athens, Third Department Of Pediatrics, University General Hospital "attikon", ATHENS, Greece, [6]National and Kapodistrian University of Athens, Second Department Of Paediatrics, "p & A Kyriakou" Children's Hospital, Athens, Greece

Backgrounds: Despite progress in the management of IMD, it remains a severe disease with a case fatality rate of 3%-7% and a high risk of neurological sequelae (16%-50%). Although the use of dexamethasone has shown to reduce complications in IMD, this remains controversial. The aim is to analyze data on therapeutic approaches and outcomes in children with IMD in Greece (2010-2020).
Methods: Medical records from IMD cases aged 0-15 years were retrospectively analyzed.
Results: Among the 123 IMD confirmed cases, medical files of 63 cases (51.2%) were available. Age ranged between 22 days - 15 years old (median=36 months). Discharge diagnosis included meningitis (46%), meningitis and septicemia (38%) and septicemia (16%). Most patients (96.8%) received treatment with 3rd generation cephalosporin, while 33.32% received combination treatment (glycopeptides, aminoglycoside and ampicillin). Treatment duration was 1-15days (median=8d), hospitalization length was 1-44 days (median=9 d), while, 37.1% were admitted to ICU. Upon discharge, 14.5% (9/62) suffered complications including: (a) neurological complications (4/9) ; (mild walking imbalance (1/4), strabismus, dorsal imbalance, head, speech and movement difficulties (1/4)), walking imbalance and abducens nerve palsy (1/4), speech impairment (1/4)) (b) skin and soft tissue impairment 4/9 (c) Hearing impairment (1/9). Overall, 31 (49.2%) received corticosteroids: dexamethasone (26), methylprednisolone (1) and hydrocortisone (4). Case fatality rate was 4.8%. Analysis showed that there is a trend on reduction on the neurological complications risk by the use of corticosteroids in patients >2 months old (3.2% vs 12%, P=0.3).
Conclusions/Learning Points: Overall, 14.5% (9/62) IMD patients suffered complications, case fatality rate was 4,8%. Dexamethasone patients presented a trend towards less neurologic complications, however more studies are necessary towards robust conclusions.

PRESENTATION OF BACTERIAL MENINGITIS IN CHILDREN BY AGE GROUPS

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Sadie Namani, Albina Ponosheci Bicaku, Luljeta Hasani, Gramoz Bunjaku
University Clinical Center of Kosovo, Infectious Diseases, Prishtina, Kosovo

Backgrounds: Children are at greater risk from getting bacterial meningitis especially young ages.
Methods: This prospective study included children diagnosed with bacterial meningitis and treated at the Clinic for Infectious diseases in Prishtina during years 2018-2019. There were 21 infants (group 1), 16 older >1 – 6 years (group 2) and 17 older >6-16 years of age (group 3).
Results: Of the 91 patients treated for bacterial meningitis, 54 were children from 1 month to 16 years old. Distribution among age groups was almost equally presented without statistical differences. Male gender dominated mostly in infants and in third age group (81%; 82%). Infants were more often infected in villages (57%), older children in cities (59%). 40% were previously hospitalized in other hospital centers mostly infants (52%). Majority of children were admitted with duration of symptoms >48 hours (59%) mostly infants (67%). The etiology was confirmed in 22 cases (41); pneumococcus predominated in infants and in third age group, while in second age group dominated meningococcus. For the initial therapy was given most often combination of Ceftriaxone with Vancomycin in 25 cases (46%) and Ceftriaxone alone in 22 cases (41%). Neurologic complications were observed in 9 patients (17%) mostly in infants 7 cases (33%) [RR=4.3 (CI 95%)] with subdural effusion being the most common. There was one fatal case of a 5 years old boy.
Conclusions/Learning Points: Bacterial meningitis cases were almost equally distributed among pediatric age groups with pneumococcus being the most common pathogen. Infants age, late admission, male gender, infection with pneumococcus, rural location were factors associated with higher incidence of neurologic complications.

E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Natsune Nishimura[1], Kotaro Araki[2], Kouki Tomari[2], Yoshiaki Cho[3], Tsuyoshi Matsuoka[4], Takashi Matsuoka[2]
[1]Okinawa prefectural Medical Center & Children's Medical center, Depertment Of Pedeatrics, - Arakawa Haebaru Okinawa, Japan, [2]Okinawa Prefectural Nanbu Medical Center & Children's Medical Center, Division Of General Pediatrics, Department Of Pediatrics, Okinawa, Japan, [3]Okinawa Prefectural Nanbu Medical Center & Children's Medical Center, Division Of Pediatrics Infectious Diseases, Department Of Pediatrics, Japan, Japan, [4]Okinawa Prefectural Nanbu Medical Center & Children's Medical Center, Division Of Pediatrics Neurology, Department Of Pediatrics, Okinawa, Japan

Title of Case: AN UNUSUAL CASE OF ASEPTIC MENINGITIS COMPLICATED BY URINARY RETENTION
Background: Aseptic meningitis complicated by urinary retention is called meningitis-retention syndrome (MRS). Herpes simplex virus (HSV)-2 is the most common cause of MRS. We encountered a rare case of HSV-1 meningitis complicated by urinary retention.
Case Presentation Summary: A previously healthy 8-year-old boy presented with fever, headache, and neck pain for five days, followed by difficulty walking and acute urinary retention. Although bladder-filling sensation was preserved, he could not urinate. He also complained of constipation; however, his anal sphincter reflex was not depressed. On neurological examination, he was alert and had nuchal rigidity. Cerebrospinal fluid analysis showed elevated white blood cell count (53/mm^3), and HSV-1 was detected by FilmArray® meningitis/encephalitis panel. These findings suggested that HSV-1 infection had caused the meningitis. Treatment with acyclovir 45mg/kg/day was initiated, and the symptoms of meningitis and urinary retention gradually improved. Although brain Magnetic Resonance Imaging (MRI) showed no evidence of encephalitis, MRI of the spinal cord indicated possibility of myelitis; therefore, methylprednisolone was also administered. Urinary retention improved approximately 13 days after the onset of meningitis.
Learning Points/Discussion: MRS is a rare presentation of aseptic meningitis, and the diagnosis was delayed in our case. It is important to recognize that aseptic meningitis may be complicated with urinary retention and dysuria with fever.

SURGICAL SITE INFECTIONS FOLLOWING PAEDIATRIC NEUROSURGICAL PROCEDURES - A SINGLE-CENTER RETROSPECTIVE STUDY FROM A UNIVERSITY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Veronika Osterman[1,2], Peter Spazzapan[3]
[1]University Medical Centre Ljubljana, Department Of Paediatric Surgery, Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Hospital Infection Control And Prevention Services, Ljubljana, Slovenia, [3]University Medical Centre Ljubljana, Department Of Neurosurgery, Ljubljana, Slovenia

Backgrounds: Children after neurosurgical procedures are at high risk of surgical site infections (SSI), a complication associated with increased morbidity, mortality, and cost.
Methods: The objective of this retrospective cohort study was to perform a review of demographic, laboratory, and surgical characteristics of children following neurosurgical procedures, hospitalized at the Department of Paediatric Surgery, University Medical Centre Ljubljana (UMCL) from January 2019 to December 2021, and to determine the SSI rates and risk factors for SSI development. SSIs occurring within 30 days of a procedure without an implant and up to 90 days with an implant, were identified. Univariate analyses of SSI association with demographic, clinical, laboratory, and surgical variables were performed, with subsequent bivariate logistic regression analysis to determine independent risk factors.
Results: A total of 332 procedures were performed on 297 children. The overall 30-day SSI rate was 5.7% and the 90-day SSI rate was 6.9%. SSI occurred 16.5 ± 12.4 days postoperatively, with the highest SSI rates following implantation of subgaleal reservoir (33%), transsphenoidal procedures (16.6%), and insertion of ICR electrodes (16%). The organ/deep SSI vs. superficial SSI ratio was 3:1. The most common isolates were Staphylococcus epidermidis (40%) and methicillin-susceptible Staphylococcus aureus (20%). Degree of wound contamination ≥W2, emergency surgery, history of previous neurosurgical procedures, presence of surgical drainage, need for vasoactive support, need for re-intubation, and presence of fever ≥ 39.5ºC were all found to be independently and significantly associated with SSI.
Conclusions/Learning Points: Due to their serious and potentially life-threatening complications, neuro-SSIs remain one of the most feared infections. As an important measure of the quality of care, reducing SSI numbers is paramount. Additional multi-center clinical studies are warranted to identify risk factors for SSIs across different neurosurgical procedures.

Title of Case: A rare case of HHV6 encephalitis in a 3year old immunocompetent girl; an unusual case - an out of the box treatment
Background: Human herpesvirus 6 commonly affects children younger than 3 years old and manifests with exanthema subitum associated with neurological symptoms such as febrile seizures and encephalitis. HHV-6 presents lifelong latency with possible reactivation when immunosuppression occurs. We report a rare severe case of of HHV-6 encephalitis in a 2,5years old immunocompetent girl.
Case Presentation Summary: Our patient, with a follow up for retarded speech development, was admitted at the ER for febrile convulsion and mild diarrhea for ten days. On admission, her clinical examination and laboratory work up were strictly normal. During the first day of hospitalization, she presented multiple episodes of generalized convulsions, refractory to triple antiepilectic treatment and progressively became encephalopathic with reaction only to extreme pain stimulus. The brain MRI and initial EEG were normal whereas the control EEG was compatible with encephalopathy. Blood and CSF PCR were highly positive for HHV-6. She received a five day course of immunoglobulins and a ten day course of ganciclovir. Due to persistant encephalopatic clinical state, after multidisciplinary discussion, our patient received high doses of prednisolone for three days with progressive amelioration till complete resolution of the symptoms and negative blood HHV-6 PCR on the tenth day of hospitalization. Her complete work up for autoimmune encephalopathies and immunodeficiencies was normal.
Learning Points/Discussion: The diagnosis and the treatment of severe HHV-6 encephalitis in immunocompetent children is challenging. Some studies imply that HHV-6-related neurological symptoms occur because of cytokine release rather than direct CNS infection. Nevertheless, no evidence based guidelines exist for immunocompetent pediatric patients and further studies need to be organized in this direction.

Title of Case: Varicella Zoster Virus Meningitis in the course of herpes zoster ophthalmicus
Background: Herpes zoster is a reactivation of a latent varicella zoster virus (VZV) infection, most often occurring in older or immunocompromised patients. We present a case of VZV meningitis in the course of herpes zoster ophthalmicus in a 12-year old immunocompetent boy.
Case Presentation Summary: 12-year-old boy presented to the ER with a suspicion of herpes zoster ophthalmicus. 6 days before admission patient developed fever >39^0C, left-sided headache, followed by 2 episodes of vomiting. 3 days before the admission, patient's mother noticed vesicular lesions on the left upper eyelid and eyebrow. The boy had a history of varicella at the age of 2 weeks. Patient reported no chronic diseases, no recurrent infections, or loss of weight. On admission, the patient was in a fair general condition, GCS 15, with normal vital signs. Vesicular lesions were found on the left upper eyelid, the left eyebrow and the left frontotemporal region. His head was tender on palpation in the regions of C2-C3 dermatomes. Meningeal and cerebellar signs were negative. No nuchal rigidity was observed. Blood analysis showed no abnormalities except for slight domination of lymphocytes in the peripheral blood smear. Cerebrospinal fluid (CSF) analysis revealed pleocytosis of 223 (94% lymphocytes), with normal protein and glucose levels. Multiplex PCR test of CSF detected DNA of VZV. Intravenous acyclovir in the dosage of 500mg/m^2 every 8 hours was implemented for 10 days. The patient was discharged in good general condition with no neurological complications.
Learning Points/Discussion: Meningitis in the course of VZV reactivation in immunocompetent children is rare and online medical databases describe scarce amount of such cases. However, it should be considered in patients presenting with headache and fever.

HAEMOPHILUS INFLUENZAE TYPE B MENINGITIS AND VACCINE FAILURE – A CASE REPORT TO NEVER FORGET

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Carolina Sá, Ana Oliveira, Tânia Pessoa, Sandra Santos, Susana Castilho
Centro Hospitalar Barreiro Montijo, Paediatrics, Lisbon, Portugal

Title of Case: HAEMOPHILUS INFLUENZAE TYPE B MENINGITIS – CASE REPORT
Background: Invasive Haemophilus influenzae type b (Hib) disease, including meningitis, has decreased dramatically after the introduction of conjugate vaccine in routine immunization schedules. In Portugal, there are still about 2 cases per year of invasive disease, which are usually severe.
Case Presentation Summary: We report a case of a three-year-old boy, previously healthy, with complete immunization schedule, including three doses (at two, four and six months of age) of Hib vaccine. He was admitted in the emergency department with fever, vomiting and somnolence, with progressive deterioration of mental state, since the previous day. At admission, the patient was irritable with nuchal rigidity. The cerebrospinal fluid (CSF) analysis showed increased protein level (322mg/dL) and cell count (4864/mm3), with neutrophil predominance (98%), and low glucose level (<5mg/dL). Empiric intravenous antibiotics (ceftriaxone and vancomycin) were administered for suspected bacterial meningitis. CSF cultures isolated Haemophilus influenzae resistant to ampicillin but sensitive to ceftriaxone. Serotyping of the Haemophilus influenzae strain revealed a serotype b. Vancomicin was stopped, and the patient completed a ten-day course of ceftriaxone, with gradual clinical improvement, and was discharged with no neurologic deficits, referred to a General Pediatrics and Otolaryngology appointment. He did an immunological study which was normal, and vaccine failure was assumed.
Learning Points/Discussion: The present case report alerts to the fact that Hib meningitis is still a diagnosis to be considered, in children with clinical and CFS findings compatible with bacterial meningitis, even if they are previously healthy and vaccinated. Despite vaccination compliance and absence of risk factors, invasive Hib disease can occur due to vaccine failure. Because invasive Hib disease can cause sequelae and complications, early diagnosis and prompt treatment are important to improve prognosis.

PAEDIATRIC INVASIVE MENINGOCOCCAL DISEASE IN SINGAPORE

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Shanti Shetty[1], Lin Jiaying[1], Natalie Woon Hui Tan[2], Koh Cheng Thoon[2], Chia Yin Chong[2], Chee Fu Yung[2], Jiahui Li[2], Karen Nadua[2], Kai Qian Kam[2]
[1]Kandang Kerbau Women's and Children's Hospital, Paediatrics, Singapore, Singapore, [2]KK Women's and Children's Hospital, Singapore, Paediatrics, Infectious Disease Service, Singapore, Singapore

Background: Invasive meningococcal disease (IMD) has known high morbidity and mortality. In Singapore, meningococcal vaccinations are not part of the routine childhood immunization schedule, given the historical low local occurrence of IMD.
Methods: We sought to understand demographics, risk factors and clinical course of children with IMD in our institution. We included all children who were referred to Infectious Disease Service, KK Women's and Children's Hospital in Singapore, for diagnosis of IMD, over 13 years (2009-2021). Diagnosis was made via isolation of Neisseria meningitidis and/or detection of N. meningitidis DNA sequences via nucleic acid testing in a normally sterile site (such as blood, cerebrospinal fluid).
Results: Fourteen children were included. Serotype B (n= 10, 71.4%) was the main serotype isolated. One child had prior vaccination with quadrivalent conjugate vaccine against serotype A, C, W-135, Y. However, he was subsequently infected with serotype B. The only child infected with W-135 serotype had significant travel history to Mecca, Saudi Arabia for Hajj pilgrimage with his family. He had not received any meningococcal vaccination prior to travel. Median age at diagnosis was 5 months (IQR 5.4 – 20.5). Ten children (71.4%) required higher acuity care with admission to high dependency and/or intensive care unit. Median length of stay in HD/ICU was 3.25 (IQR 2.25 – 5.5) days, with median length of overall hospitalization of 12 (IQR 8.0 - 14.8) days. 42.0% (n=6) had neurological complications including that of subdural effusions, empyema, hydrocephalus.
Conclusions/Learning Points: Although IMD in Singapore is sporadic, high morbidity is observed. Meningococcal vaccines should continue to be recommended for children travelling to high risk countries, with consideration given toward advocating for vaccines for young infants given the median age of 5 months seen in our case series.

Walsall Manor Hospital, Paediatrics, Walsall, United Kingdom

Title of Case: H.influenza type F ventriculitis and subdural empyema in an immunocompetent 4-year-old
Background: Ventriculitis is a source of persistent infection following meningitis. We report a case of ventriculitis with subdural empyema in a 4-year-old male.
Case Presentation Summary: A 4-year-old boy presented to ED with a history of 3 days of fever and vomiting. He was reported to be a fit and fully immunized child. The boy was febrile with a GCS of 11/15, neck stiffness, and anisocoria. Blood gas showed metabolic acidosis and blood pressure of 80/60 mmHg was noted. Intravenous ceftriaxone and acyclovir were commenced. A 10ml/kg bolus and dexamethasone were given. The admission CT scan was normal. MRI head showed non-specific right-sided periventricular hyperintensity. He developed bradycardia, hypertension, and focal seizures on the 4th day. Hypertonic saline and levetiracetam were initiated. At this point, blood and CSF cultures were reported H.influenza sensitive to ceftriaxone and serotyping confirmed type-f strain. He was intubated and transferred to PICU. He had a 9-week PICU stay. He was readmitted following discharge from PICU with a new onset fever, headache, right-sided torticollis, and vomiting. He was recommenced on IV ceftriaxone and had CSF sent for analysis. A repeat MRI head showed enhancement of meninges over the right-frontal lobe and a small subdural collection of 2mm noted. Meropenem and Rifampicin were commenced on advice from the microbiologist. He had a prolonged antibiotic course (6 weeks) and his recovery continues to be monitored in the outpatient clinic. His immunological studies to date are negative.
Learning Points/Discussion: The incidence of H.influenza infections in <5s is higher in comparison to children aged >5 years in the recent UKHSA report (2022). This case highlights the severity of this infection and its impact on long-term morbidity.

IDENTIFICATION AND CHARACTERIZATION OF DISTINCT CLINICO-PATHOGENIC SUBGROUPS IN PAEDIATRIC LYME NEUROBORRELIOSIS

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Semjon Sidorov[1], Beat Greiter[1], Annette Hackenberg[2], Roland Martin[3], Rheinhard Zbinden[4], Christoph Berger[1], Patrick M. Meyer Sauteur[5]
[1]University Children's Hospital Zurich, Pediatric Infectious Diseases And Hospital Epidemiology, Zürich, Switzerland, [2]University Children's Hospital of Zurich, Department Of Pediatric Neurology, Zürich, Switzerland, [3]University Hospital Zurich & University of Zurich, Neuroimmunology And Multiple Sclerosis Research Section, Zürich, Switzerland, [4]University of Zurich, Institute Of Medical Microbiology, Zürich, Switzerland, [5]University Children's Hospital Zurich, Infectious Diseases And Hospital Epidemiology, Zürich, Switzerland

Backgrounds: Lyme neuroborreliosis (LNB) is a frequent manifestation of Lyme disease in children. It is caused by the bacteria Borrelia burgdorferi (Bb), and characterized by neurological symptoms, cerebrospinal fluid (CSF) pleocytosis, and intrathecally synthesized Bb-specific antibodies. LNB can affect both the peripheral nervous system (PNS) and the central nervous system (CNS).
Methods: We hypothesized that PNS manifestations (e.g., isolated cranial neuropathy) reflect a localized disease, whereas CNS manifestations (e.g., meningitis) are the result of a more extensive and widespread pathology. To test this hypothesis, we performed a large retrospective cohort study of children (n=191) diagnosed with LNB at the University Children's Hospital Zurich over a 15-year period to characterize clinical and laboratory characteristics, serological responses to Bb and outcome.
Results: We observed two major distinct subgroups of children with LNB: some had isolated peripheral facial palsy (PFP) (34%) which correlated with minimal CSF inflammation, intrathecal antibody production and shorter duration of symptoms, while others presented with meningitis (54%) and meningoradiculitis (8%) together with much more pronounced CSF inflammation, intrathecal antibody production and longer duration of symptoms. Interestingly, patients with meningoradiculitis showed the highest level of CSF inflammation in our patient cohort. We also noted significant differences in magnitude, but not specificity of intrathecal antibody responses to Bb between LNB subgroups.
Conclusions/Learning Points: We propose the terms "focal" and "pervasive" LNB to characterize these two clinico-pathogenic subgroups of LNB observed in our large cohort among children. We will investigate differences in infecting Bb species and underlying immune response between these clinico-pathogenic subgroups in a future prospective LNB study.

STREPTOCOCCUS BOVIS – UNUSUAL ETIOLOGY OF MENINGITIS AND BACTEREMIA: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Maria Inês Soares, Ana Catarina Rosa, Mafalda Cardoso, Sónia Fernandes, Fátima Furtado
Hospital José Joaquim Fernandes, Unidade Local de Saúde do Baixo Alentejo, Serviço De Pediatria, Beja, Portugal

Title of Case: STREPTOCOCCUS BOVIS – UNUSUAL ETIOLOGY OF MENINGITIS AND BACTEREMIA: A CASE REPORT
Background: Bacterial meningitis is a major cause of morbidity and mortality in children. Streptococcus gallolyticus subsp. pasteurianus, previously known as Streptococcus bovis biotype II is a rare cause of meningitis in infants. This etiology is most of the time associated to underlying diseases or previous treatment with pharmacological agents that predisposed the patient to the infection.
Case Presentation Summary: We describe a 5 month old female baby with antecedents of patent foramen ovale and small ostium secundum-type interatrial communication. She arrived at our pediatric emergency room with one day of nasal congestion and anorexia, and 4 hours of fever (axillar temperature 40ºC). She was lethargic and with bulging anterior fontanel. Laboratory confirmation of meningitis and bacteriemia were performed with positive bacteriologic exam for Streptococcus gallolyticus subsp. pasteurianus, in both samples of blood and cerebrospinal fluid. The child was treated with intravenous ceftriaxone and vancomycin. After antimicrobial susceptibility testing it was switched for ampicillin. The infant responded to antibiotic therapy without neurological impairment. Cardiology evaluations with echocardiography were performed, which exclude acute alterations. Abdominal ultrasound, EEG, tympanogram, audiogram and otoacoustic emission were normal. Immunodeficiencies evaluation was normal.
Learning Points/Discussion: Despite being an unusual cause of meningitis in children, the S. bovis biotype II variant seems to be more associated with meningitis or neonatal sepsis, contrary to the S. bovis biotype I, which is more associated with endocarditis and gastrointestinal pathology. Nevertheless, it is important to be alert for these pathologies in every patient with S. bovis meningitis.

LONG FORGOTTEN, BUT WORTH REMEMBERING - ENCEPHALITIS LETHARGICA

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Melissa Szmukala, Joanna Chruszcz, Leszek Szenborn, Kamila Ludwikowska
Wroclaw Medical University, Department Of Pediatric Infectious Diseases, Wrocław, Poland

Title of Case: LONG FORGOTTEN, BUT WORTH REMEMBERING - ENCEPHALITIS LETHARGICA
Background: Encephalitis lethargica is a rare form of encephalitis characterized by fever, lethargy, abnormalities in vision, movement and mental state, and coma. In the 1920 the “sleeping sickness” caused an epidemic that affected millions of people, but cases today occur sporadically.
Case Presentation Summary: We present a case of an 11-year old boy with neuroinfection resembling encephalitis lethargica as a complication of M. pneumoniae infection.
The previously healthy patient presented symptoms of neuroinfection on seventh day of an upper respiratory tract infection and ten days past hand-foot-mouth disease. On admission to the hospital he had muscular hypotony, ataxia and progressively worsening somnolence, muscle weakness and bradykinesia. Encephalitis was diagnosed based on clinical presentation and MRI findings with basal ganglia involvement. Lymphocytic pleocytosis of 10 cells/ml was noted in the cerebrospinal fluid. During first ten days of hospitalization, patient’s condition fluctuated with consciousness impairment (glasgow coma scale of four to ten). He presented episodes of slow or fast speech, temporal mutism, variable muscle rigidity and vegetative involvement with severe bradycardia and rhythm irregularities revealed RBBB. Based on these symptoms, encephalitis lethargica was diagnosed. The most probable cause in this case was the M. pneumoniae infection with a chest X-ray having shown features of interstitial pneumonia and left lung consolidations and seroconversion in IgG. Other causes of encephalitis were excluded. Doxycycline and high dose steroids were used as treatment. Eighteen days after onset the patient started to recover.
Learning Points/Discussion: This is not the first case report, in which upper respiratory tract infections preceded encephalitis lethargica, but one of few with M. pneumoniae etiology. Perhaps the next one brings us closer to solving the mystery of the encephalitis lethargica epidemic.

THE IMPACT OF COVID-19 IN PNEUMOCOCCAL MENINGITIS IN A BRAZILIAN PEDIATRIC HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Daniela Teixeira[1], Lilian Diniz[1], Gabriela Gouvêa[2], Laura Coelho[2], Pedro De Castro[1], Beatriz De Freitas[1], Carolina Carvalho Carvalho[1], Aline Bentes[1], Talitah Candiani[2], Fernanda Lopes[2], Cristiane Dias[1]
[1]Federal University of Minas Gerais, Pediatrics, Belo Horizonte, Brazil, [2]Fundação Hospitalar de Minas Gerais, Hospital Infantil João Paulo Ii, Belo Horizonte, Brazil

Backgrounds: Pneumococcal infection is one of the main causes of meningitis in children. The impact of COVID-19 pandemic on pneumococcal infections has been recently described. The aim of this study was to characterize the epidemiology of pneumococcal meningitis from 2005 to 2022, comparing years before introduction of pneumococcal vaccine (2005-2009), pre-pandemic years after introduction of the vaccine (2010-2019), years of lockdown (2020-2021) and the year after release of lockdown (2022).
Methods: A retrospective cohort study was conducted in children with pneumococcal meningitis, who were admitted to a reference hospital in Brazil.
Results: 67 cases of pneumococcal meningitis were identified. Mean age was 60 months. Since vaccine introduction, more admissions were observed after release of lockdown restrictions (10 cases, 14.9%). 71.6% (48) of patients were treated with cephalosporins, 25.4% (17) with penicillins, and 9% (6) with cephalosporin and vancomycin. No ceftriaxone-resistant pneumococci were identified. Supurative complications occurred in 17 patients (25.4%):16 (24%) empyema and 1 (1,5%) brain abscess. Patients in 2022 had more complications when compared with other periods ($p = 0.032$). Overall mortality was 17.9% (12), with no difference between the periods studied ($p > 0.05$).
Conclusions/Learning Points: Reduced social contact and exposure to respiratory pathogens has led to concerns about immunity debt and risk of higher pneumococcal infection rates as restrictions were lifted. More pneumococcal meningitis and more complications were observed in 2022 in our study. Despite this, no change in Pneumococcal resistance profile has been documented.

A PEDIATRIC CASE OF FATAL AMOEBIC ENCEPHALITIS CAUSED BY BALAMUTHIA MANDRILLARIS

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Nursel Atay Ünal[1], Pelin Kuzucu[2], Tuğba Bedir Demirdağ[1], Mehmet Aykur[3], Yelda Günsoy Kılıç[4], Meltem Polat[1], Funda Doğruman Al[5], Ayşe Kalkancı[5], Alp Özgün Börcek[2], Anıl Tapısız[1], Hasan Tezer[1]
[1]Gazi University Faculty of Medicine, Pediatric Infectious Diseases, Ankara, Turkey, [2]Gazi University Faculty of Medicine, Pediatric Neurosurgery, Ankara, Turkey, [3]Tokat Gaziosmapasa University, Parasitology, Tokat, Turkey, [4]Gazi University Faculty of Medicine, Pathology, Ankara, Turkey, [5]Gazi University Faculty of Medicine, Medical Microbiology, Ankara, Turkey

Title of Case: A pediatric case of fatal amoebic encephalitis caused by Balamuthia mandrillaris
Background: Balamuthia mandrillaris is a free-living amoeba that is common in soil.It causes a rare and mostly fatal infection.It's still full of unknowns in the scientific era because it causes a disease that is rarely considered,its symptoms are nonspecific,the diagnostic process lasts long,the most appropriate approach in treatment is still not known.Therefore,the actual number of cases to date has been underestimated.
Case Presentation Summary: A previously healthy 12-year old male patient presented with headache, vomiting, fever, altered consciousness for one month.In the medical history, it was stated that he was living in a rural area in Kyrgyzstan.On his physical examination,there was right hemiparesis,neck stiffness.Acute phase reactants were negative.Brucella tube agglutination and interferon gamma release test was negative.MRI revealed an invasive-looking,calcified herniating mass and reported as oligodendroglioma.He underwent a diagnostic and therapeutic surgery.Hyphae-like structures were detected in tissue examination of the biopsy specimen with a light microscope.Histopathological examination of brain tissue showed microorganisms compatible with amoebic cystic structures.The diagnosis was confirmed by real-time PCR.
Learning Points/Discussion: This is one of the few cases of Balamuthia mandrillaris ameobic encephalitis reported globally and of the first case in our region.Due to the nonspecific nature of CNS symptoms,it cannot be distinguished from other factors at first glance, except for the subacute clinical course.Our patient could not survive due to undesirable factors such as inaccessible drugs despite early diagnosis,lack of definitive treatment,the lesion being located close to the midline,and the fatal course due to the nature of the agent.As a guide for future cases, amoebic encephalitis should be kept in mind in the case of isolated central nervous system involvement, hemorrhagic CSF, and subacute meningoencephalitis unresponsive to appropriate antibiotic therapy.

STREPTOCOCCUS PYOGENES MENINGITIS IN A PEDIATRIC PATIENT

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Lara Torres, Alexandra Rodrigues, Catarina Francisco, Sónia Santos, Pedro Carvalho
ULS Guarda, Pediatria, Guarda, Portugal

Title of Case: Streptococcus pyogenes meningitis in a pediatric patient
Background: Streptococcus pyogenes (Group A streptococcus, GAS), causes a wide spectrum of diseases in children. GAS Meningitis due to S. pyogenes is highly uncommon, representing one of the most infrequently reported infections due to this pathogen. Although rare, it is associated with a high case fatality and can result in severe neurological sequelae.
Case Presentation Summary: A previously healthy 3 years-old boy was brought to an Emergency Department with a 4-day history of high fever, vomiting and frontal headache. On admission the child was febrile, with a temperature of 39ºC, pale with cold peripheries and had tonsillar exudates. He was haemodynamically stable but appeared unwell and had meningeal signs. A positive rapid antigen detection test (RADT) in pharyngeal swab confirmed GAS tonsillitis. Laboratory tests showed leucocytosis with neutrophilia and high C-reactive protein. A CT scan of the head showed opacification of the right mastoid and all paranasal sinuses. A lumbar puncture was performed and empiric intravenous antibiotic therapy with ceftriaxone and vancomycin was initiated for presumed bacterial meningitis. Examination of the cerebrospinal fluid (CSF) later revealed pleocytosis with 4828/mm^3 leucocytes (69% neutrophils), protein of 234,9 mg/dL and glucose of 25 mg/dL. The CSF Gram stain showed Gram-positive cocci in chains, and subsequently grew beta-haemolytic GAS. Blood cultures were negative. His antibiotics were de-escalated to intravenous ceftriaxone for 10 days. The clinical course was uneventful. He appeared to have a full recovery with no sequelae at discharge.
Learning Points/Discussion: Despite its sporadic occurrence, GAS meningitis should be considered as a cause of meningitis in previously healthy infants because of its frequent association with complications, sequelae and death.

[1]University of West Attica, National Meningitis Reference Laboratory, Department Of Public Health Policy, School Of Public Health, Athens, Greece, [2]Anticancer Hospital "Metaxa", Intensive Care Unit, Pireaus, Greece, [3]National and Kapodistrian University of Athens, First Department Of Pediatrics, Infectious Diseases And Chemotherapy Research Laboratory , 'aghia Sophia' Children's Hospital, ATHENS, Greece, [4]Democritus University of Thrace Faculty of Medicine, Pediatrics-pediatric Hematology/oncology, Alexandroupolis, Greece, [5]National and Kapodistrian University of Athens, Third Department Of Pediatrics, University General Hospital "attikon", ATHENS, Greece, [6]National and Kapodistrian University of Athens, Second Department Of Paediatrics, "p & A Kyriakou" Children's Hospital, Athens, Greece

Backgrounds: CABM is a major cause of morbidity and mortality. Treatment with dexamethasone is controversial and may vary with age (restricted for neonates) and the pathogen. The aim is to investigate data on corticosteroid administration and outcomes, in children with CABM (2010-2020).
Methods: Medical records from children (2m to 15years) were collected and studied retrospectively, from 5 major paediatric hospitals/departments in Greece.
Results: Among the 263 laboratory confirmed cases, medical records were retrieved in 129 (51.5%). Among those, analysis of 76 patients medical records was carried out, age ranging 2 months to 15 years (median=3 years) as 51 were excluded for factors such as septicemia, age (<2 mo), other infections etc. Neisseria meningitidis was the leading cause (60.5%; 46/76) followed by S. pneumoniae (15,8%; 12/76). All cases received effective antibiotic treatment (mainly 3rd generation cephalosporins). One fatal case was recorded, while, complications were presented in 12 patients (15.8%), mainly neurological (66,6%), suffered ulcers (16%), amputated feet (8.3%), hearing impairment-middle ear effusion (8.3%). Half (52.6%) received corticosteroid treatment; dexamethasone (38), methylprednisolone (1) and hydrocortisone (1). Patients receiving corticosteroids were older (43.5 vs 24 months, p=0.039), had higher WBC and serum CRP, and higher WBC and protein levels in CSF. According to the results, there was a trend to less ICU admissions in the corticosteroid group (27,5% vs 33,3%), although not statistically significant.
Conclusions/Learning Points: Complications were recorded in 15.8% of CABM patients while case fatality rate was 1.3%. Corticosteroid administration did not result in statistically significant difference with regards to complications, as they were administered to older children with significantly higher inflammation markers. Use of corticosteroids in childhood CAMB remains still uncertain and controversial.

INFLUENZA A AND PNEUMOCOCCAL SYNERGY IN MENINGITIS – A PAEDIATRIC CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS07.C. CNS INFECTIONS

Inês Vivas[1], João Oliveira[2], Sofia Branco[1], Maria José Dinis[1], Isabel Mendes[1], Inês Falcão[1]
[1]Centro Hospitalar da Póvoa de Varzim e Vila do Conde, Department Of Pediatrics, Póvoa de Varzim, Portugal, [2]Centro Materno Infantil do Norte, Paediatric Department, Porto, Portugal

Title of Case: INFLUENZA A AND PNEUMOCOCCAL SYNERGY IN MENINGITIS – A PAEDIATRIC CASE REPORT
Background: Synergistic influenza–bacterial co-infection represents a serious medical problem. Influenza A virus infection has been associated with pneumococcal transmission and disease. We describe a paediatric case of invasive pneumococcal disease after influenza A infection.
Case Presentation Summary: Previously healthy 6-year-old boy, fully immunized against pneumococcus, meningococcus and Haemophilus Influenzae, was brought to the emergency room with a 2-day fever, myalgias, anorexia, vomiting, and lethargy. The day before, he tested positive for Influenza A and all family members had flu-like symptoms. He was hemodynamically stable, pale and lethargic with signs of acute dehydration. The remaining physical exam was unremarkable with negative meningeal signs. The work-up revealed normal leucocytes with neutrophilia and C-reactive protein of 5.56 mg/dL. The patient was admitted for intravenous fluid therapy and antiviral treatment with oseltamivir. Several hours later, he worsened and developed meningeal signs. A lumbar puncture was performed and intravenous ceftriaxone, vancomycin and acyclovir were started. The cerebrospinal fluid (CSF) revealed bacterial meningitis with positive Streptococcus pneumoniae antigen. Although the brain scan was initially normal, he required to be entubated and subsequently admitted to the Paediatric Intensive Care Unit because of his deteriorating neurological state.The investigation revealed a Streptococcus pneumoniae serotype 11a which was not included in the vaccine. After several days, clinical improvement was observed with good evolution of the neurological deficits.
Learning Points/Discussion: In this case report, influenza A virus infection preceded a bacterial superinfection - pneumococcal meningitis. Although the patient was fully vaccinated with Portuguese schedule, this serotype was not included in the pneumococcal vaccine (PCV13).

PARACOCCIDIOIDOMYCOSIS WITH CLINICAL RECURRENCE IN THE ADOLESCENCE

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Emmanuella D`Elia[1], Flavia Almeida[2], Eitan Berezin[1], Daniel Jarovsky[2], Camila Morais[2], Giovanna Guerra[1], Marco Aurelio Safadi[3], Samantha Matos[2]
[1]santa casa sp, Pediatric, sao paulo, Brazil, [2]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [3]Hospital Santa Casa de Misericordia, Infectious Diseases, Sao Paulo, Brazil

Title of Case: PARACOCCIDIOIDOMYCOSIS WITH CLINICAL RECURRENCE IN THE ADOLESCENCE
Background: Paracoccidioidomycosis is the most prevalent systemic fungal infection in Brazil, being found only in Latin America. Mainly caused by the microorganism Paracoccidioides Brasiliensis.,
Case Presentation Summary: A previously healthy 15-year-old adolescent with a history of 24kg weight loss in 5 months, chills ,night sweats, jaundice, choluria and acholic stools. She presented at the first evalution with painful and bulky cervical lymph node enlargement and intermittent fever which lasted for 2 weeks. Epidemiology: From a rural area, in the municipality of Cajamar- SP. On physical examination she was pale, emaciated, liver was palpable 6cm below the right costal margin and spleen about 4cm below left costal margin. Painful cervical lymph node enlargement, measuring 3 cm in diameter, not adhered to deep planes, and slightly hardened. She also had an inguinal lymph node enlargement in the right inguinal region with 12cm in diameter, not painful, fibroelastic and not adhered.
Laboratory tests: Hb 9.6 g/dL; L=11900/µL (1% metamyelocytes; 7% rods; 66% segmented; 19% lymphocytes); Platelets= 698,000/µL. Biopsy of the inguinal lymph node was performed with a positive result for Paracoccidioidomycosis in the anatomo pathological analysis (figure). The patient was hospitalized and received Lipid Complex Amphotericin 3mg/Kg/day for 21 days, followed by Itraconazole maintained for 12 months. After two months of treatment, she was readmitted due to an enlarged lymph node in the cervical region associated with local pain. Lipid Complex Amphotericin was restarted for 7 days with substantial improvement and oral treatment was
resumed.

Learning Points/Discussion: Paracoccidoimycosis is a systemic fungal infection, related to agricultural activities, with an insidious evolution that can cause severe sequelae. asymptomatic infection to the form of disseminated disease called the acute/subacute phase, with lethal outcome.

PROFILE OF POSITIVE BLOOD CULTURES IN A PEDIATRIC WARD SPECIALIZED IN INFECTIOUS DISEASES DURING A YEAR

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Thessalia Kamilari, Aikaterini Vlachodimitropoulou, Tatiana-Soultana Tziola, Malamati Mika, Chrysi Aikaterini Georgokosta, Maria Eleni Mpompou, Evanthia Botsa
Aghia Sophia Children's Hospital, First Department Of Pediatrics, Athens, Greece

Backgrounds: Although the identification of bacteremia in children is essential it could be challenging to recognise the signs. The aim of the study was to report the spectrum of bacteremia in children, as well as examine clinical characteristics, diagnostic and therapeutic parameters.
Methods: A single-tertiary center retrospective cohort study was performed on a sample of 2200 children admitted as suspected covid-19 cases from November 2021 to October 2022. Children with bacteremia were diagnosed through blood cultures.
Results: Only 2% of hospitalized children were diagnosed with bacteremia. 57% of patients were under the age of 1 year, male:female ratio was 1:3 and monthly distribution of cases was stable. All patients referred fever during their admission. Seventy percent of patients, 32/46 were observed to have bacteremia with gram positive bacteria (50% Staphylococcus species), followed by 13% E.coli. All Staphylococci, except one, as well as Enterococci were resistant to aminopenicillins. Third generation cephalosporins were mostly used as first line treatment, independently of pathogen. Moreover, 20% of patients had normal count of total white blood cells with lymphocyte type, findings predominantly of gram positive bacteremia. Elevation of procalcitonin was found more sensitive compared to c-reactive protein. Furthermore, except from blood cultures, in 33% of patients the pathogen was isolated either from urine, stool or cerebrospinal fluid cultures. Finally, 25% of patients had a co-infection with another confirmed pathogen. Sars-Cov2 was found to be the most common co-infection (7 cases).
Conclusions/Learning Points: This study reveals the limited number of pediatric bacteremia cases. Even though, it highlights that a high level of suspicion should be maintained to achieve early identification.

FEVER WITHOUT A SOURCE UNDER 3 MONTHS OF AGE: ANY PREDICTIVE FACTORS OF SERIOUS BACTERIAL INFECTION?

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Rita Calejo[1], Joana Carvalho Queirós[2], Inês Paiva Ferreira[1], Inês Aires Martins[2], Fábio Barroso[1]
[1]Centro Hospitalar Tâmega e Sousa, Department Of Pediatrics And Neonatology, Penafiel, Portugal, [2]Centro Materno Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatrics, Porto, Portugal

Backgrounds: Fever is one of the main complaints in children admitted to the Emergency Department. It can be a symptom of Serious Bacterial Infection (SBI), being the risk greater in children younger than 3 months. The aim of this study is to evaluate predictive factors of SBI under 3 months.
Methods: We conducted a cohort retrospective study from January 2020 to June 2022 in infants under 3 months who visited the Emergency Department due to fever without a source. Firstly, a bivariate analysis was made to assess the predictive value of clinical and laboratorial parameters. Posteriorly, a backward stepwise model of binary logistic regression was performed, considering the statistical significant variables, with the dependent variable being the presence or absence of SBI.
Results: A total of 292 patients were included, 160 (54.8%) of who were male. The mean age was 57.8 days (SD 22.3). 73 (25%) patients were diagnosed with SBI: 52 (71.2%) urinary tract infections, 13 (17.8%) occult bacteriemias, 8 (11.0%) meningitis, 3 (4.1%) pneumoniae, and 6 (8.2%) bacterial gastroenteritis. We found that classification according to the Rochester criteria, white blood cell count, neutrophil count, C-Reactive Protein (CRP), and procalcitonin values were statistically significantly different between the groups ($p < 0.001$). In the multivariate analysis for evaluating predictive factors to have SBI, CRP values ($p <0.001$; OR 1.045) showed significance (Hosmer-Lemeshow test: $x^2= 12.043$; $p=0.149$).
Conclusions/Learning Points: According to this study the CRP value is the most reliable parameter to predict SBI in this population. This data can be integrated in the evaluation of the patients under 3 months with fever without a source and help in the treatment and follow-up decision.

INFECTIVE ENDOCARDITIS CAUSED BY BARTONELLA QUINTANA ASSOCIATED WITH GLOMERULONEPHRITIS, HYPERGAMMAGLOBULINEMIA AND SPLENOMEGALY

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Daniel Cortes, Isabella Giovine Aracena
San Camilo Hospital, Department Of Pediatrics, San Felipe, Chile

Title of Case: INFECTIVE ENDOCARDITIS CAUSED BY BARTONELLA QUINTANA ASSOCIATED WITH GLOMERULONEPHRITIS, HYPERGAMMAGLOBULINEMIA AND SPLENOMEGALY
Background: Culture-negative endocarditis is a clinical challenge, whose main microorganisms are those of the Bartonella genus. We present the case of a girl with subacute infective endocarditis caused by Bartonella quintana.
Case Presentation Summary: A girl 6 years old with a diagnosis of perimembranous ventricular septal defect, without surgical correction. Consultation due to fever up to 102.2°F of 3 months of evolution and that recur at least 3 times a week. The physical examination highlights a holosystolic systolic murmur and splenomegaly. Normal hematological parameters on admission; CRP: 109 mg/L and ESR 93 mm/hr. Abdominal ultrasound was performed with bilateral renal inflammatory compromise, preserved renal size and splenomegaly up to 13 centimeters. Echocardiogram was done with a refractive image of 12 by 5 millimeters, mobile in the tricuspid valve. Two sets of Blood cultures were requested, both negative. CT angiography did not reveal pulmonary thromboembolism. Complete urine reveals microhematuria, proteinuria with a protein/creatinine ratio of 0.8 and a drop in creatinine clearance up to 35 milliliters/min/1.73 m2. The elevation of total IgG up to 3,182 mg/dL stands out. Starting antimicrobial therapy was ampicillin plus cloxacillin. Serology for Bartonella quintana was 1:8192. PCR whole blood for Bartonella is negative. Treatment was rotated to ceftriaxone associated with amikacin, but ceftriaxone should be discontinued after 3 weeks due to thrombocytopenia. Doxycycline was started with good tolerance, reversing the hematological alteration. There was regression of vegetation and normalization of renal function, which required temporary use of enalapril.
Learning Points/Discussion: Bartonella quintana endocarditis is a clinical challenge, associated with glomerulonephritis and splenomegaly. Require clinical suspicion and the use of doxycycline must to be considered as first line therapy.

PV0509 / #560

KINGELLA KINGAE BACTEREMIA: HARD TO CATCH, RISKY TO MISS

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Marta Figueiredo, Catarina Albuquerque, Rita Morais
Hospital São Francisco Xavier - Centro Hospitalar Lisboa Ocidental, Pediatrics, Lisboa, Portugal

Title of Case: KINGELLA KINGAE BACTEREMIA: HARD TO CATCH, RISKY TO MISS
Background: Kingella kingae is a common colonizer of the oropharynx in children under 5 years. It has increasingly been recognized as a cause of invasive disease. Clinical signs and symptoms of infection are usually mild with slightly increased acute phase reactant levels, causing diagnostic delay. Most cases are benign but may evolve to endocarditis and osteoarticular disease.
Case Presentation Summary: A 2-year-old previously healthy boy was admitted with a 6-day history of fever, odynophagia, sialorrhea and diarrhea. On examination he was well, with a erythematous maculopapular rash and hyperemia of the oropharynx. On previous observations since the beginning of symptoms he had serial analytical evaluations with normal leukocyte and neutrophil counts, maximum C Reactive Protein of 13.3 mg/L, a negative rapid test for group A Streptococcus, normal chest X-ray and a negative blood culture. Analytical evaluation was repeated which revealed 11.000/uL leucocytes, 61% neutrophils and C Reactive Protein 10.6 mg/L. Urine rapid test was normal, and a new blood culture was collected. He was treated symptomatically. Three days later, the blood culture was positive for Kingella kingae, resistant to penicillin-G and susceptible to cefuroxime. He was afebrile and clinically well, so he completed 8 days of oral cefuroxime, with good clinical evolution. On follow-up he remained well, with no signs or symptoms of osteoarticular infection.
Learning Points/Discussion: Kingella kingae may cause bacteremia, with fever and maculopapular rash, though rare and difficult to diagnose. Upper respiratory inflammation and mucosal lesion probably facilitated Kingella kingae access to the blood stream. Although a benign course is to be expected, antibiotic treatment and clinical follow-up are crucial to prevent serious complications.

CLINICAL CHARACTERIZATION OF PEDIATRIC INFECTIVE ENDOCARDITIS IN A TERTIARY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Julià Gotzens Bersch[1], María Ríos-Barnes[2]
[1]Hospital Sant Joan de Deu, Pediatric Unit, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Deu, Infectious And Imported Diseases, Pediatric Unit, Esplugues de Llobregat, Spain

Backgrounds: Pediatric infective endocarditis (IE) is a diagnostic-therapeutic challenge, due to its low incidence and high morbimortality. We aimed to describe the epidemiological and clinical characteristics of patients with pediatric IE.
Methods: Single-center retrospective observational study. Patients <18 years old diagnosed with IE (modified Duke criteria) during the period 2012-2021 in an urban tertiary hospital with cardiac surgery (Spain) were included.
Results: Nineteen cases of IE were detected (10/19 definite IE; 9/19 possible IE). Epidemiological and clinical characteristics of the patients are detailed in Table 1. The most frequent location was the mitral valve (4/19) and Contegra-type devices (3/19). Etiological diagnosis was achieved in 14/19 (74%) of the cases. The majority were bacterial: S. epidermidis (4/13), S. aureus (3/13), S. viridans (2/13), E. faecalis (2/13), K. kingae (1/14) and S. pneumoniae (1/14); one case of C. albicans (1/14) was also detected. The most common diagnostic test was transthoracic echocardiography (TTE) (11/19). PET-CT allowed definitive diagnosis in 3 cases (3/19), all with high clinical suspicion but TTE without alterations. Median treatment duration was 6 weeks (p25-75; 5-9). In five cases (5/19) PET-CT was used to guide the end of treatment: 4 were negative and allowed treatment to be discontinued. Seven patients (7/19) required surgery. No patient died (median follow-up: 2.9
years).

Table 1. Clinical and epidemiological characteristics and complementary examinations of patients with IE.

	Acute NV IE	Subacute NV IE	Early VP IE	Late VP IE	All
N°	5	5	5	4	19
Epidemiology					
Woman	3 (60%)	1 (20%)	2 (40%)	2 (50%)	8 (42,1%)
Age	2,3 (0,5-10,9)	8,4 (4,1-12,5)	1,1(0,2-14,5)	5,1 (2,4-7,2)	5 (0,8-9,9)
History of heart disease	1 (20%)	2 (40%)	5 (100%)	4 (100%)	12 (63%)
Previous surgical intervention	0 (0%)	1 (20%)	5 (100%)	4 (100%)	10 (52,6%)
Cardiac device carrier	0 (0%)	0 (0%)	5 (100%)	4 (100%)	9 (47,4%)
Clinical					
Fever	5 (100%)	5 (100%)	5 (100%)	4 (100%)	19 (100%)
Tachycardia	2 (40%)	2 (40%)	3 (60%)	1 (25%)	8 (42,1%)
Heart murmur (new or changed)	1 (20%)	2 (40%)	0 (0%)	0 (0%)	3 (15,7%)
Heart failure signs	2 (40%)	2 (40%)	2 (40%)	1 (25%)	7 (36,8%)
Extracardiac infection.	2 (40%)	0 (0%)	0 (0%)	1 (25%)	3 (15,7%)
Embolism or infarction	3 (60%)	1 (20%)	2 (40%)	0 (0%)	6 (31,6%)
Diagnosis					
Altered TTE	5/5 (100%)	3/5 (60 %)	2/5 (60%)	1/4 (25%)	11 (57,9%)
Altered PET-CT	0/0 (0%)	0/0 (0%)	1/1 (100%)	2/2 (100%)	3/3 (100%)
Positive blood cultures	0,8 (0 - 1,5)	0,8 (0 - 1,5)	1,8 (1 - 2,5)	0,75 (0,5 - 1)	1 (0 - 2)

IE: infective endocarditis; NV: native valve; PV: prosthetic valve; TTE: transthoracic echocardiography.

Conclusions/Learning Points: Most of the patients in our series who developed IE had a history of operated congenital heart disease. The use of PET-CT has proven to be useful in the diagnosis of cases with clinical suspicion, but normal conventional diagnostic tests and/or to verify the resolution of the infection.

KINGELLA KINGAE - A RARE COMPLICATION OF A COMMON PATHOGEN

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Gonçalo Vale[1], Filipa Marujo[2], Marcia Bonfadini[2], Rita Valsassina[3], Catarina Gouveia[4], Susana Abreu[5], Conceição Trigo[5], João Estrada[2]
[1]Centro Hospitalar Barreiro-Montijo, Pediatrics, Barreiro, Portugal, [2]Hospital Dona Estefânia, Centro Hospitalar Universitário Lisboa-Central, Pediatrics, Lisboa, Portugal, [3]Hospital Dona Estefânia - Central Lisbon Universitary Hospital Center, Paediatrics Infectious Diseases Unit, Lisbon, Portugal, [4]Hospital Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatric Infectious Diseases Unit, Lisbon, Portugal, [5]Hospital Santa Marta, Centro Hospitalar Universitário Lisboa-Central, Cardiology, Lisboa, Portugal

Title of Case: KINGELLA KINGAE - A RARE COMPLICATION OF A COMMON PATHOGEN
Background: Kingella kingae is a gram-negative coccobacillus belonging to the HACEK group and a common oropharyngeal colonizer of healthy young children. Occasionally, it may cause severe invasive infections, including infective endocarditis.
Case Presentation Summary: A 11-month-old boy, with no past medical history, was hospitalized for 10 days of fever (39.5ºC every 4hours), associated to 3 days of diarrhea and cough. At admission he was prostrated, pale, tachycardic but normotensive, with grade III/VI holosystolic heart murmur and normal pulmonary auscultation, without hepatomegaly or oral ulcers. Laboratory evaluation revealed leukocytosis with neutrophilia. C-reactive protein of 92.8mg/L and procalcitonin 5.23 ng/ml. Positive respiratory virus panel for enterovirus and parainfluenza 1. Kingella kingae was isolated in the blood culture. Transthoracic ultrasound identified a mitral valve vegetation, with perforation of the anterior leaflet, causing moderate-severe regurgitation. Treatment with ceftriaxone 100mg/kg/day, furosemide and captopril was started. On the 3rd day of admission, he presented with generalized hypotonia, inability to remain seated and left hemiparesis. No cranial nerves change. Cranial CT showed cortico-subcortical hypodensity in right frontoparietotemporal, inferior frontal and insular topography translating recent multifocal ischemic lesions. He was admitted to ICU, without respiratory or cardiovascular compromise or new neurological deficits, being apyretic after the 4th day of antibiotic. Anticoagulant therapy was delayed due to the risk of hemorrhagic transformation. He was subsequently transferred to a Cardiology unit and submitted to vegetationremoval surgery with mitral valve repair.
Learning Points/Discussion: We report a severe, fulminant K. kingae infective endocarditis that led to severe life-threatening complications. Although rare, the proportion of K. kingae endocarditis is rising, as reported in Israel, and occurs more frequently in young boys without a previous structural cardiopathy.

PV0512 / #1387

A CASE SERIES OF INVASIVE PNEUMOCOCCAL DISEASE (IPD) IN THE ERA OF PNEUMOCOCCAL CONJUGATE VACCINE (OCTOBER 2022-JANUARY 2023)

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Dimitra Grammenou, Ioanna Tassiou, Angeliki Spartinou, Mirsini Kopanou, Ismini Oikonomou, Anastasia Anastasiou-Katsiardani
GENERAL HOSPITAL OF VOLOS, Paediatric, VOLOS, Greece

Backgrounds: Background: Although successive pneumococcal conjugate vaccines 7 and 13 (PCV) implementations have led to a significant reduction of pneumococcal disease burden including IPD, Streptococcus pneumoniae (pneumococcus) remains an important pathogen and a major cause of morbidity and mortality worldwide in childhood.
Methods: Aims: The presentation of patients' characteristics and pneumococcal treatment. Methods: We retrospectively analyzed data from the medical records of 5 patients with IPD treated in our Pediatric Department from October 2022 till January 2023.
Results: Five patients were included with a diagnosis of pneumococcal bacteremia and meningitis.2/5 were male,2 were siblings with a median age17months(range:5 months-9 years).Four out of 5 were hospitalized in our department with a milder course of disease. One patient presented with cardiac arrest due to septic shock and died at the emergency department.Four were fully vaccinated with PCV-13.All presented with fever, 50%with opthalmitis and one of them with vomiting,confusion and dehydration, while1/5had headache and nuccal rigidity.3/5had leukocytocis,1/5 significant anemia(Hemoglobin: 6,7gr/dl)1/5 elevated procalcitonin and5/5had elevated CRP values.Pneumococcus was isolated via blood culture or PCR in4/5patients and1/5from CSF. Its serotype was24B in2 and in the rest is still under investigation. One of the survived patients received a total of14days of iv and po antibiotic treatment (5/5 3rd generation cephalosporin, 2/5 combined with vancomycin) and 3 patients received10 days.
Conclusions/Learning Points: Conclusions: With the appearance of 13-valent pneumococcal conjugate vaccine (PCV13) the incidence of IPD has decreased dramatically, but at the same time serotype replacement was observed, with the appearance of new pneumococcal serotypes not included in the vaccines. A high index of suspicion is required to recognize the non-specific clinical manifestations of IPD so that the right treatment is administered. Prevention of the disease using newer PCVs is vital.

PV0513 / #404

THE OUTCOME OF CHILDREN ADMITTED WITH A NON-BLANCHING RASH

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Rachel Hammett, Renee Erasmi, David Pace
Mater Dei Hospital, Child And Adolescent Health, Msida, Malta

Backgrounds: The differential diagnosis of a non-blanching rash in well appearing children is wide with the most sinister being bacterial sepsis. Approximately 10% of children with a non-blanching rash have meningococcal septicaemia. We aimed to study the diagnosis and outcome of children who were hospitalised with a non-blanching rash.
Methods: The clinical presentation, diagnosis, management, vaccination status and Length of stay (LOS) of children (0-16 years) admitted to Mater Dei Hospital, Malta between 2019-2021 with a non-blanching rash were analysed retrospectively. Comparisons were made using Chi-Square and Independent t-tests.
Results: Out of 140 children recruited, 23 were excluded due to incomplete data. Their mean age was 4.33 years (IQR = 1.17-5.50) and 66.67% were male. Febrile children most commonly had a viral illness (69.7%), whilst Henoch Schönlein purpura (23.5%) and immune thrombocytopenia (23.5%) were the most common diagnoses in afebrile children. None had septicaemia. The average LOS was 2.3 days (95%CI 1.46-3.13). There were no significant differences in LOS, management and meningococcal and pneumococcal vaccination status between febrile and afebrile patients. Similarly, there was no significant difference in blood results between febrile and afebrile children except for the mean CRP which was 22.88 (95%CI 13.6-32.2) and 6.54 (95%CI 1.62-11.5) respectively (p-value < 0.00001).
Conclusions/Learning Points: Well appearing children presenting with petechiae remain challenging to manage. Fever and a high CRP help distinguish infective from non-infective causes. Febrile children with petechiae would still merit a period of observation to exclude underlying septicemia.

PV0514 / #903

LEMIERRE SYNDROME WITH AN ATYPICAL PRESENTATION

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Alicia Hernanz-Lobo[1], Laura García[1], Laura Torres Soblechero[1], Begoña Santiago García[1], Elena Rincón López[1], María Slocker Barrio[2]
[1]Gregorio Marañón University Hospital, Infectious Diseases Department, Madrid, Spain, [2]Gregorio Marañón University Hospital, Paediatric Intensive Care Unit, Madrid, Spain

Title of Case: Lemierre syndrome with an atypical presentation
Background: Lemierre Syndrome (septic thrombophlebitis of the internal jugular vein) is a rare complication of an otorhinolaryngological infection that may lead to severe secondary lesions.
Case Presentation Summary: A previously healthy 15-year-old male presented with a 7-day history of fever, sore throat, and jaundice. Physical examination revealed swollen tonsils and hepatosplenomegaly. Laboratory analysis showed elevated acute phase reactants, cholestasis, thrombocytopenia, and coagulopathy. Microbiology tests for SARS-CoV-2, hepatitis, and Streptococcus pyogenes were negative. Urinalysis showed leukocyturia and nitrites and treatment with cefotaxime was started. The patient developed thoracic, cervical, and lumbar pain and his respiratory status
worsened requiring oxygen therapy. A new asymmetric tonsillar enlargement was detected, and blood cultures were positive for Fusobacterium necrophorum. A computed tomography (CT) scan showed a peritonsillar abscess of 3,3 x 2,9 x 5,5 cm, thrombosis of the internal jugular vein, and septic pulmonary embolisms.
After surgical drainage, the patient was changed to amoxicillin/clavulanate plus metronidazole and admitted to the Paediatric Intensive Care Unit. Magnetic Resonance Imaging (MRI) showed two extensive cervical and lumbar epidural abscesses, L5-S1 arthritis, and infiltration of paravertebral muscles. The patient respiratory status worsened requiring mechanical ventilation. A new CT scan showed progression of the septic embolisms without other long-distance complications. Antibiotic therapy was changed to meropenem, and anticoagulation was started. The patient gradually improved allowing extubation and a follow-up MRI showed improvement of musculoskeletal complications. After 32 days of hospital admission, he was discharged on oral amoxicillin and subcutaneous anticoagulation therapy.
Learning Points/Discussion: Few Lemierre Syndrome cases with musculoskeletal complications have been reported. Treatment should combine surgical source control if possible and long-term antibiotic therapy. Clinical suspicion, early diagnosis, and multidisciplinary management become essential to deal with this potentially lethal entity.

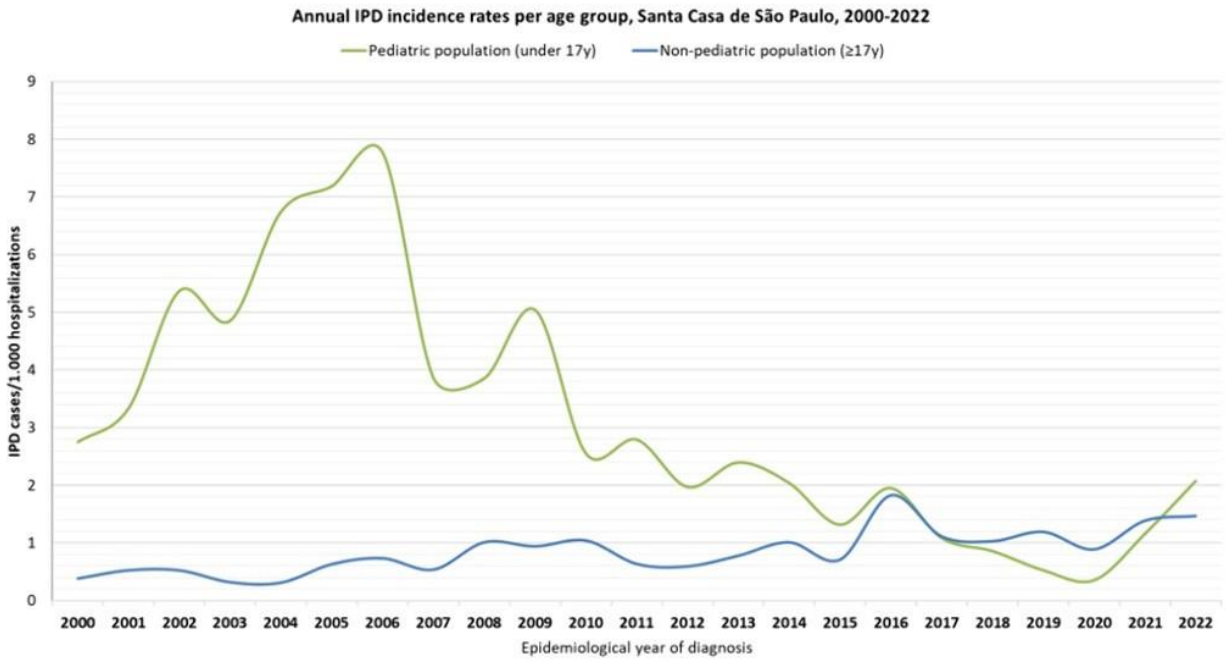
PV0515 / #1926

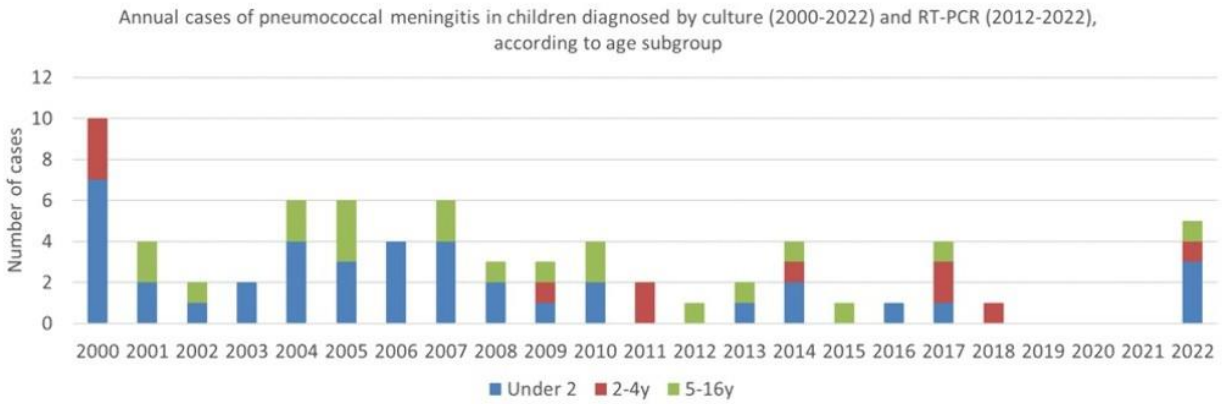
A PANORAMIC VIEW OF INVASIVE PNEUMOCOCCAL DISEASE OVER MORE THAN TWO DECADES: THE EFFECT OF VACCINATION AND COVID-19 ON PEDIATRIC CASES IN A SINGLE BRAZILIAN CENTER

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Daniel Jarovsky[1], Cely Barreto Da Silva[2], Emmanuella De Jesus D'Elia[1], Flavia Almeida[1], Marco Aurelio Safadi[1], Eitan Naaman Berezin[1]
[1]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [2]Santa Casa de São Paulo, 3. hospital Infection Control Unit, São Paulo, Brazil

Backgrounds: Pneumococcal conjugate vaccine (PCV10) was introduced in the Brazilian National Vaccination Program in 2010 to all children under 2 years. We describe the effect of PCV10 vaccination and the COVID-19 pandemic on IPD over the last 22 years in a single tertiary center in Brazil.
Methods: In this hospital-based study, all cases of IPD (S. pneumoniae isolated in sterile fluids) from January 1st, 2000, through December 31st, 2022, were evaluated. Incidence rates per 1000 hospitalizations were analyzed according to age group and pre-vaccination period (2000-2009) versus post-vaccination period (2011-2022). RT-PCR was added as a routine diagnostic tool for meningitis in 2012.
Results: A total of 736 IPD episodes were evaluated. Incidence rates per 1000 hospitalizations dropped substantially among children after PCV10 until 2020 (2.79 to 0.4, average 1.53), but a sharp increase occurred during the 2nd and 3rd pandemic years (1.2 and 2.1, respectively). Seven years after PCV10 introduction, the incidence of adult IPD exceeded the pediatric, but rates trends drastically and unusually reverted in 2022. Since PCV10, 18.1% (62/342) of IPD episodes occurred in children, while 64.5% (231/358) of cases during the pre-vaccine era were pediatric. Among 170 meningitis cases, 21 occurred in children during the post-vaccine period – numbers in 2022 reached a 15-years record following COVID-19, exceptionally and exceedingly high among children under 2. Detection rates were significantly increased using RT-PCR in
CSF.





Conclusions/Learning Points: During this 22-year surveillance on IPD, IPD incidence shifted towards an evident adult predominance after the use of PCV10, but rates drastically and unusually reverted in 2022. Pneumococcal meningitis in children unusually increased after COVID-19, with molecular assay playing a substantial role in diagnosis.

Title of Case: Infantile Invasive MSSA infection: a good outcome is possible
Background: Invasive methicillin susceptible Staphylococcus aureus (MSSA) infections are an important cause of mortality and morbidity in neonates. Colonization of virulent strains of the mother or spread through NICU may provoke iMSSA infections to the newborn, usually through hematogenous dissemination. We present a complex case of a 22days old boy.
Case Presentation Summary: Our patient with a history of a 3day hospitalization in NICU for respiratory distress, was admitted for a 3day purulent umbilical secretion, without fever. The mother presented skin abscess. His vital signs were normal and he was in perfect general state. At the clinical examination, he presented reduced mobility of the right arm and left leg and eight reddish palpable nodules on his left thigh. His initial work up on admission revealed high inflammatory markers and the blood culture and the umbilical cord pus were positive for MSSA PVL negative. Ultrasounds and MRIs revealed multiple subcutaneous abscesses on the areas of left leg and right arm, septic arthritis of the right shoulder and an inferior spinal intracanal abscess. After multidisciplinary discussion, only the abscess of the right shoulder was evacuated on the 8th day of hospitalization. He received a 4week course of clindamycin and a 6week course of cloxacilline. At discharge, his physical examination and radiological control were strictly normal. Patient’s and his mother’s immunological work up were normal.
Learning Points/Discussion: Disseminated early life staphylococcal infections with a benign evolution are rare. The complexity of the genome, the role of its superantigens and toxins of SA are still understudied. Efficient screening and decolonization programs of pregnant women could possibly decrease invasive staphylococcal disease in neonates. Efficacy and cost effectiveness are yet to be studied.

[1]Hospital de Braga, Paediatrics, Braga, Portugal, [2]Hospital de Braga, Orthopaedics, Braga, Portugal, [3]Hospital de Braga, Pediatric Intermediate Care Unit, Braga, Portugal

Title of Case: Invasive Group A Streptococcal Infection in an 8-Month-Old Infant: A Case Report
Background: Streptococcus pyogenes (S.pyogenes), also known as group A streptococcus, causes a wide range of infections, including noninvasive and invasive diseases. Invasive infections are the most severe forms of presentation and are more common in younger children.
Case Presentation Summary: An 8-month-old, previously healthy boy was seen at the emergency department with a 2-day-history of fever, erythematous rash, irritability and poor oral intake. On examination, he was pale, had a maculopapular rash on the trunk, palms and soles, and scattered petechiae. After admission, the patient's condition worsened with hypoactivity, tachycardia and hypotension, requiring a fluid bolus. Later, erythematous lesions and swelling appeared on the third finger of the right hand, and the left wrist and arm. Blood tests revealed high inflammatory markers and treatment with ceftriaxone and clindamycin was started. S.pyogenes was isolated in the blood culture and the patient was diagnosed with S.pyogenes sepsis. As the antimicrobial susceptibility test revealed sensitivity to penicillin and clindamycin, ceftriaxone was switched to penicillin. On the first-day after admission, he presented signs consistent with arthritis of the right-knee confirmed by MRI. A diagnostic and therapeutic arthrocentesis was performed. S.pyogenes was also isolated in the synovial fluid. By day-11, due to persistent inflammatory signs, an MRI was done and showed multiarticular involvement, but no complications. The patient was discharged home 21 days after presentation, with oral amoxicillin to complete 4-weeks of antimicrobial therapy. Total resolution of the articular changes was observed in follow-up appointments.
Learning Points/Discussion: This case illustrates the importance of early identification and treatment of S.pyogenes infections in children, in order to prevent complications, postinfectious sequela and the high morbidity and mortality associated with invasive infections.

LONG-TERM FOLLOW-UP OF INVASIVE MENINGOCOCCAL DISEASE SEQUELAE IN CHILDREN: UPDATE ON SEINE STUDY

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Camille Jung[1], Corinne Levy[2], Annie Elbez-Rubinstein[2], Alexiane Baloche[3], Genevieve Monguillot[2], Ines Layouni[1], Stéphane Béchet[2], Muhamed Kheir-Taha[4], Robert Cohen[5], Michael Levy[6]
[1]CHI Créteil, Crc, Créteil, France, [2]ACTIV, Infectious Disease, Créteil, France, [3]5UR 4129, Parcours Santé Systémique (p2s), Lyon, France, [4]Institut Pasteur, National Reference Center For Meningococcus, Paris, France, [5]ACTIV, Pediatric, Créteil, France, [6]Robert Debré Hospital, Intensive Care Unit, Paris, France

Backgrounds: Few studies have considered the long-term (>1year) sequelae of invasive meningococcal disease in children. The SEINE study aims to include patients <18 years old who had invasive meningococcal disease (IMD), meningitis or purpura fulminans when <15 years old and >1 year before the date of inclusion. To establish a pathway for care, enrolled participants undergo a thorough medical, neurocognitive, and sensory evaluation.
Methods: Through the ACTIV meningococcal disease active surveillance network, 135 children who had IMD between 2010 and 2020 were identified at 32 hospitals in Paris area.
Results: Of these 32 sites, 6 are active centers accounting for 53 children eligible for inclusion; the remaining sites have deferred study participation, primarily due to the unavailability of their medical staff, who are busy managing major winter epidemics. Among these 53 children, 19 have been lost to follow-up—underscoring the challenge of maintaining contact with study participants' families—while records are missing for 7. At this time, 20 patients have been enrolled, some of whom are still undergoing examinations. While one child has a severe disability, the others attend regular schools. The preliminary data reveal frequent sensory impairments (i.e., loss of vision [7/17: 41%] or hearing [2/17: 12%]) as well as learning disabilities (attention disorders [4/17: 23%] and difficulties with spelling [10/16: 62%], reading [5/16: 31%], or logical/mathematical tasks [3/16: 19%]), despite WPPSI-IV and WISC-V scores indicating normal cognitive abilities.
Conclusions/Learning Points: The update of the SEINE study underlines the difficulties of implementing a study that requires recontacting families at a distance from the IMD and when the children are often no longer followed in hospital. The preliminary results illustrate the importance of neurocognitive and sensory follow-up and of screening for learning disabilities.

[1]Queen Mary Hospital, Department Of Paediatrics And Adolescent Medicine, Hong Kong SAR, Hong Kong PRC, [2]The University of Hong Kong, Department Of Paediatrics And Adolescent Medicine, Hong Kong, Hong Kong PRC, [3]Queen Mary Hospital, Department Of Otolaryngology, Hong Kong, Hong Kong PRC, [4]Queen Mary Hospital, Division Of Neurosurgery, Department Of Surgery, Hong Kong, Hong Kong PRC

Title of Case: INVASIVE GROUP A STREPTOCOCCUS AND INFLUENZA CO-INFECTION IN A 13-YEAR-OLD GIRL LEADING TO TOXIC SHOCK SYNDROME, SUBDURAL EMPYEMA, MENINGITIS, PAN-SINUSITIS AND PHARYNGITIS
Background: Streptococcus pyogenes, or group A Streptococcus, can cause a multitude of illnesses, of which acute pharyngitis is the most common. Invasive group A Streptococcal disease (iGAS) affecting otherwise sterile sites is rarer and associated with severe complications and deaths. WHO has recently reported increasing incidences of pediatric iGAS in Europe since late 2022.
Case Presentation Summary: A 13-year-old previously healthy Chinese girl who recently returned from United Kingdom presented with 3-days of coryzal symptoms, headache and otalgia, followed by right periorbital and facial swelling, incoherent speech and photophobia. Empirical ceftriaxone, vancomycin, metronidazole and oseltamivir was started. She required inotropic support in PICU. WBC was raised ($17.23x10^9$/L), with neutrophilia ($16.78x10^9$/L) and lymphopenia ($0.31x10^9$/L). CT brain and orbit revealed pan-sinusitis, preseptal cellulitis, subdural empyema and cerebral edema. MRI brain showed leptomeningeal enhancement. CSF cell count was $360x10^6$/L (91% neutrophils) and opening pressure was 54cmH2O. Emergency bilateral functional endoscopic sinus surgery, drainage of subdural empyema and external ventricular drain (EVD) insertion was performed. Cultures yielded Streptococcus pyogenes and PCR detected influenza A. CSF reassessment 6 days later on removal of EVD showed cell count $<1x10^6$/L. These findings were compatible with Streptococcal toxic shock syndrome (STSS), subdural empyema, meningitis, pan-sinusitis, pre-septal cellulitis and pharyngitis. Neurocognitive sequelae included left hemiplegia, frontal lobe and swallowing dysfunction. She completed course of oseltamivir and 6 weeks cefotaxime. Neurorehabilitation and reassessment MRI brain was arranged.
Learning Points/Discussion: iGAS disease can progress rapidly, causing life-threatening conditions and severe morbidity, especially when STSS occurs and PICU care is required. Timely initiation of antimicrobials and management of co-infections and complications was life-saving for this child.

AN ENTEROCOCCUS FAECALIS RE-INFECTION IN A NEWBORN

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Cláudia Magalhães[1], Mariana Pereira[1], Raquel Oliveira[1], Carla Moreira[1], Eduarda Abreu[2], Cátia Leitão[2], Joana Alves[3], Joana Teixeira[2], Almerinda Pereira[2]
[1]Hospital de Braga, Paediatrics, Braga, Portugal, [2]Hospital de Braga, Neonatal Special Care Unit, Braga, Portugal, [3]Hospital de Braga, Infectious Diseases, Braga, Portugal

Title of Case: AN ENTEROCOCCUS FAECALIS RE-INFECTION IN A NEWBORN
Background: Enterococcus faecalis is a rare agent for neonatal sepsis and is an important cause of morbidity in neonates. The timing of the diagnosis and the treatment is of paramount importance to prevent complications in the short and long term.
Case Presentation Summary: A 2 months-old female, presented to the emergency room (ER) with a history of fever and irritability. She had been previously hospitalized at 15 days old with acute VSR bronchiolitis and Enterococcus faecalis urosepsis with meningitis and treated for 7 days with Cefotaxime, 10 days Gentamicin and 14 days Ampicillin. She was released 3 days before. At the ER she was hemodynamically stable, with vigorous crying, normal anterior fontanelle and no neurological deficit. At admission her blood test revealed leukocytosis with predominance of neutrophils, normal C-Reactive protein, urine and blood cultures revealed an Enterococcus faecalis. The cerebrospinal fluid (CSF) had 10949 cells (82% neutrophils) and the culture was positive to Enterococcus faecalis. She was hospitalized for 21 days, treated with ampicillin and gentamicin. During the hospitalization she did a cerebral MRI that was normal. She presented analytical improvement and repeated the lumbar puncture the day before being discharged, which revealed 31 cells and CSF and blood culture negative. At 5 months she is growing and developing well. She is waiting for immunological study results.
Learning Points/Discussion: Enterococcus faecalis is a Gram positive bacteria that normally acts as an opportunistic pathogen. Normally causes infection in patients that are hospitalized for a long time or that received antibiotic therapy. It is not the case of our patient. Therapy with broad spectrum antibiotics, during 21 days, resulted in complete recovery.

[1]12 de Octubre University Hospital, Paediatric Infectious Diseases, Madrid, Spain, [2]12 de Octubre University Hospital, Paediatric Cardiology, Madrid, Spain, [3]12 de Octubre University Hospital, Microbiology, Madrid, Spain, [4]12 de Octubre University Hospital, Cardiothoracic Surgery, Madrid, Spain, [5]12 de Octubre University Hospital, Paediatric Intensive Care Unit, Madrid, Spain, [6]12 de Octubre University Hospital, Infectious Diseases, Madrid, Spain

Backgrounds: Infective endocarditis(IE) is a rare disease in children and is associated to significant morbimortality. We describe the epidemiological, microbiological, and clinical features of IE episodes from a Spanish tertiary hospital in a 10-years' period.
Methods: A descriptive observational retrospective study was performed, including paediatric patients <16 years old with a definite or possible IE admitted to a tertiary hospital between January/2012-December/2021.
Results: 32 IE episodes were identified. Twenty-eight(87.5%) had congenital heart disease, 8(25.0%) were preterm neonates, 1(3.1%) immunocompromised and 6(18.8%) had other chronic disorders; in 11(34.4%) episodes >1 underlying condition was associated. Twenty(62.5%) patients had a central venous line. Microbiologic isolates were: 7(19.4%) coagulase-negative staphylococci, 6(16.7%) S.aureus, 4(11.1%) E.faecalis, 3(8.3%) viridans streptococci, 10(27.8%) non-HACEK Gram-negative bacteria, 1(2.8%) HACEK-group bacterium, 4(11.1%) fungi and 1(2.8%) C.burnetii. 30%(3/10) of IE episodes of patients colonized by multiresistant bacteria (MRB) were caused by those. There were echocardiographic findings in 27(84.4%) episodes: 21(65.6%) were right IE and 6(18.8%) left IE. The most common complication was septic embolism: 11(34.4%) episodes (9 pulmonary and 2 cerebral). 11(34.4%) episodes required surgical management. Inhospital mortality was 6.3%, all of them due to underlying condition and not to IE or its complications. Clinical features and complications of IE episodes caused by non-HACEK Gram-negative bacteria and caused by Gram-positive bacteria were compared, finding no significant
differences(Table1).

Table 1. Complications of IE episodes caused by non-HACEK Gram-negative bacteria and Gram-positive bacteria.

	Gram-positive bacteria (n=18*)	Non-HACEK Gram-negative bacteria (n=9*)	*p*
PICU admission, n (%)	13 (72,2)	9 (100)	0,080
Surgical management, n (%)	5 (27,8)	3 (33,3)	0,766
Septic embolisms, n (%)	4 (22,2)	3 (33,3)	0,535
Local extension of infection, n (%)	1 (5,6)	1 (11,1)	0,603
Heart failure, n (%)	2 (11,1)	3 (33,3)	0,161
Residual valve regurgitation, n (%)	5 (27,8)	1 (11,1)	0,091
Heart rhythm disturbances, n (%)	1 (5,6)	0 (0)	0,471
Neurological complications, n (%)	1 (5,6)	2 (22,2)	0,194
Acute renal failure, n (%)	3 (16,7)	1 (11,1)	0,702
Recurrences, n (%)	2 (11,1)	2 (22,2)	0,444
Mortality, n (%)	1 (5,6)	1 (11,1)	0,603

***4 IE episodes had >1 bacteria isolated (2 isolates per episode).**

Conclusions/Learning Points: Risk factors for developing IE, proportion of embolic complications and mortality were similar to those previously published. Proportion of IE episodes caused by non-HACEK Gram-negative bacteria was higher. A high percentage of children colonized by MRB had an IE episode due to those bacteria. There were no differences in clinical features and complications when comparing IE episodes caused by non-HACEK Gram-negative bacteria and those caused by Gram-positive bacteria.

Title of Case: Fever, limp and skin lesions: when the clue is at home.
Background: Endocarditis is a serious infection with a challenging diagnosis and treatment. Cases have been rising due to the increased survival in patients with heart diseases, immunodeficiencies or catheter carriers. However, 8-10% of these don't have any risk factor.
Case Presentation Summary: A 4-year-old female, healthy and properly vaccinated, presented fever and limp for 6 days and palm and soles lesions in the last 48 hours. She received treatment with amoxicillin-clavulanate for 3 days. Her mother had been recently discharged from the hospital due to an oncologic disease. She presented weakening, ecchymotic lesions in palm and soles, heart murmur and hypotension. Blood test showed leukocytosis 20000/ul, neutrophilia 15340/ul, thrombocytopenia 99900/ul, C-reactive protein 25.45mg/dl, procalcitonin 4.39ng/ml, troponin I 16.7ng/ml and NT-proBNP 1524pg/ml. With the presumptive diagnosis of osteoarticular infection and endocarditis, ceftriaxone and cloxacillin were started. Electrocardiogram, chest x-ray and hips ultrasound were normal. Echocardiography revealed a 10x15mm vegetation at mitral valve with mild to moderate mitral regurgitation. In the blood culture, Staphylococcus aureus grew and MALDI-TOF and FilmArray tests revealed methicillin resistance (MRSA). Therefore, treatment was changed to ceftaroline and daptomycin. Brain and hips magnetic resonance showed left hemicortex microinfarction and ilyopubic osteomyelitis. After obtaining the antibiogram, treatment was changed to vancomycin. The vegetation was surgically removed and MRSA grew in its culture. Treatment with vancomycin was completed for 6 weeks since the surgery, with periodic optimization of the antibiotic dose. Carriers study was performed, and MRSA was isolated in the mother's.
Learning Points/Discussion: Endocarditis must be suspected even in the absence of risk factors. It's important to monitor antibiotic levels to optimize treatment and remember MRSA in patients or relatives with epidemiological risk factors.

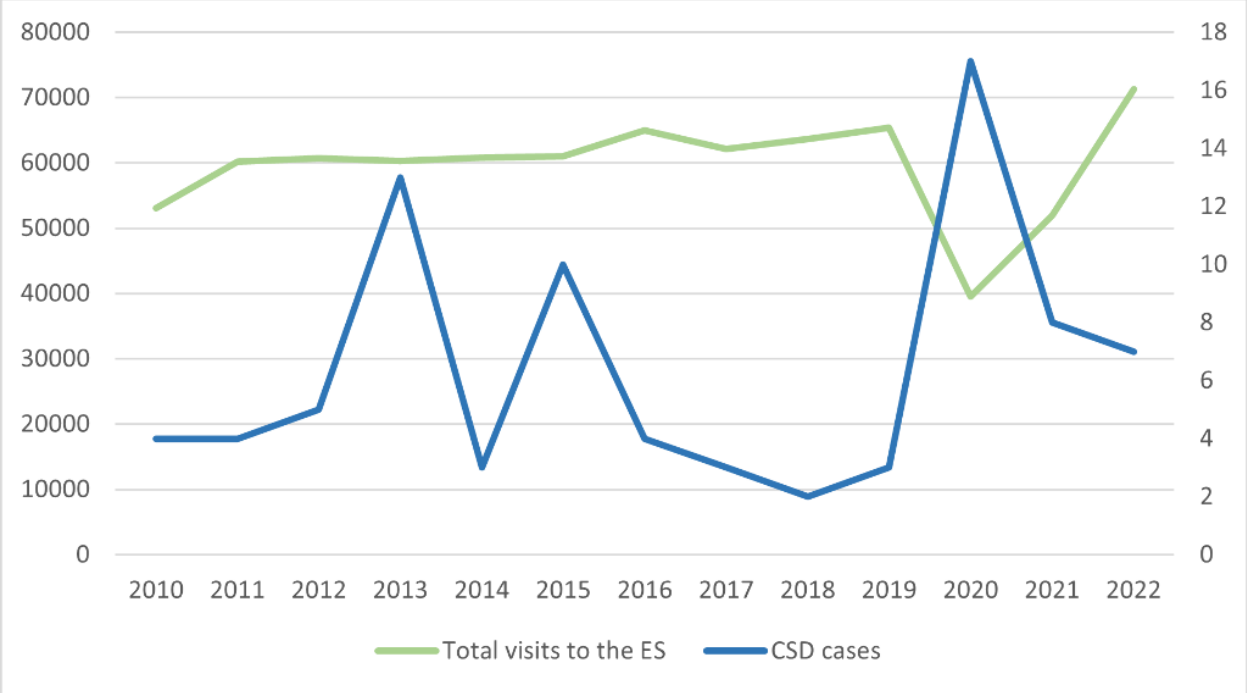
PV0523 / #2090

CAT SCRATCH DISEASE THROUGHOUT THE COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Cátia Martins[1], Margarida Camacho Sampaio[1], Catarina Leuzinger-Dias[1], Mariana Ferreira[1], Catarina Pereira[1], Ana Teresa Gil[1], Lia Gata[1], Mariana Domingues[1,2], Ana Brett[1,2], Fernanda Rodrigues[1,2]
[1]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Universidade de Coimbra, Faculty Of Medicine, Coimbra, Portugal

Backgrounds: Cats serve as the natural reservoir for B. henselae and Cat Scratch Disease (CSD) can result from a scratch or bite from an infected cat, as well as from exposure to cat fleas or via contact of cat saliva. Rare cases have occurred after exposure to dogs. An increase in CSD cases was observed in our community in 2020, probably related to increased time at home due to the COVID-19 pandemic restrictions. Our aim was to assess its incidence after progressive lifting of the restrictions and compare to pre-pandemic period.
Methods: Retrospective observational study of all cases of CSD diagnosed in a tertiary paediatric hospital from 2010 to 2022.
Results: 83 cases were identified, with annual distribution presented in figure, with a peak incidence in 2020. The median age was 8.9Y (0.6-17Y), 89.2% had contact with cats (in 70% kittens) with 50% having a scratch. Most presented with regional lymphadenopathy (88%), 71.2% of which with several enlarged lymph nodes. Ten had atypical presentation (median age 5Y), 3 in 2020: hepatosplenic disease with microabscesses (n=6), prolonged fever (n=3) and Parinaud's oculoglandular syndrome (n=1). All had a good
outcome.



Conclusions/Learning Points: An increase in CSD cases was observed in 2020, in contrast with the dramatic reduction of most infectious diseases and Emergency Service visits. The progressive lifting of the restrictions was accompanied by a reduction in the number of cases, similar to the prepandemic period.

PV0524 / #1405

HYPEREOSINOFILIA IN AN ASSYMPTOMATIC CHILD DUE TO VISCERAL LARVA MIGRANS: A PEDIATRIC CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Inês Mazeda[1], Inês Vivas[1], Sofia Branco[1], Beatriz Vieira[1], Maria Tavares[2], Inês Falcão[1]
[1]Centro Hospitalar da Póvoa de Varzim e Vila do Conde, Department Of Pediatrics, Póvoa de Varzim, Portugal, [2]Centro Hospitalar S João, Pediatrics, Porto, Portugal

Title of Case: Hypereosinofilia in an assymptomatic child due to visceral larva migrans: a pediatric case report
Background: Hypereosinophilia (≥1500 eosinophils/microL) may be present by allergic, infectious, inflammatory or neoplastic conditions. Toxocariasis is a common cause of eosinophilia caused by migrating Toxocara spp larvae, with humans being accidental hosts. Clinical manifestations range from asymptomatic to severe organ injury.
Case Presentation Summary: 3-year-old boy with global developmental delay, from a rural area, presented with incidental hypereosinophilia (5400/microL). He remained asymptomatic. Four weeks later the work-up revealed rising eosinophils (8500/microL), without cytopenias or other findings on peripheral blood smear. Stool exams and allergic screening were unremarkable. The hypothesis of toxocariasis was raised and diagnosis was confirmed by ELISA IgG for Toxocara canis and confirmatory immunoblot test. Hypereosinophilia persisted after 5 days of albendazole and a second course was administered. Systemic involvement was investigated with normal biochemical parameters, chest x-ray and echocardiogram. Abdominal ultrasound showed mild hepatomegaly, with slight hypertrophy of the left lobe, without focal lesions or splenomegaly. Eye evaluation was requested. Echinococcus and fascioliasis were excluded. He remained asymptomatic and the eosinophil count decreased. Reassessment 6-months later revealed worsening of hypereosinophilia (10000/microL) and hypoechoic hepatic lesions. Public Health and Pediatric Infecciology expert opinion were asked. After a longer treatment with anthelminthic therapy (5-day course mebendazole followed by 4 weeks albendazole) with no side effects, three smaller areas of signal change on MRI were detected and a new longer course of albendazole was performed. Hepatic focal lesions disappeared and eosinophil count slowly normalized.
Learning Points/Discussion: The main concern is the progression to visceral or ocular larva migrans. Public Health must be involved. Longer anthelminthic treatment may be required. Blood count eosinophils may have a delay to normalize.

PV0525 / #1128

CHARACTERISTICS OF STREPTOCOCCUS SPP. OTHER THAN STREPTOCOCCUS PNEUMONIAE CAUSING PEDIATRIC SEPSIS IN THE PAST 10 YEARS.

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Masaaki Minami[1], Syunsuke Akahori[2]
[1]Nagoya City University Graduate School of Medical Sciences, Bacteriology, Nagoya, Japan, [2]Nagoya City University, Medicine, nagoya, Japan

Backgrounds: Streptococcus spp. is one of the most common pathogens causing sepsis in pediatric infections, but other than Streptococcus pneumoniae, streptococci have not been reported to be well studied in clinical microbiology. We try to determine the clinical characteristics of streptococci other than Streptococcus pneumoniae isolated from pediatric sepsis patients in Japanese general hospitals during the past decade.
Methods: A cross-sectional study was conducted on 29 patients diagnosed with pediatric sepsis at a Japanese general hospital between 2013 and 2022.Medical records added to the clinical species were used for clinical characteristics. Streptococcus spp. isolated from children were identified by standard laboratory procedure. Antimicrobial susceptibility testing was performed by microdilution assay.
Results: The gender of the infected people was eleven males and eighteen females. By age group, fourteen were in the 0-1 age group, seven in the 1-3 age group, three in the 4-6 age group, and five in the 7-12 age group. The number of sepsis patients by year averaged 1 from 2013 to 2017. However, the number of patients increased to 6 in 2018, 4 in 2019, 5 in 2021, and 7 in 2022. The most frequently isolated Streptococcus species were Streptococcus mitis, Streptococcus agalactiae, and Streptococcus parasanguinis. Antimicrobial susceptibility testing showed thirteen penicillin-insensitive, twenty erythromycin-insensitive, eight clindamycin-insensitive, twelve minocycline-insensitive, and eight ciprofloxacin-insensitive resistant Streptococcus spp.
Conclusions/Learning Points: Our results suggest that the isolation of Streptococcus spp. in pediatric patients with sepsis is on the increase and that the non-susceptibility to antimicrobial agents, including penicillin, tends to be high. Thus, the trend of Streptococcus spp. in the clinical microbiology field should also be kept in focus in the future.

PV0526 / #1397

IMPACT OF SARS-COV-2 PANDEMIC ON PEDIATRIC INPATIENTS WITH INVASIVE GROUP A STREPTOCOCCAL INFECTIONS (IGAS)

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Anita Niederer-Loher, Christian Kahlert
Children's Hospital of Eastern Switzerland, Infectious Diseases And Hospital Epidemiology, St.Gallen, Switzerland

Backgrounds: To investigate the incidence, possible risk factors and clinical characteristics of iGAS, a potentially severe disease in children in Switzerland, over time, a national registry has been created.
Methods: Since 01.12.2017, inpatients < 17 yrs. with iGAS are reported to a national registry, the Swiss Pediatric Surveillance Unit (SPSU). Demographic data, clinical characteristics including outcome are collected via detailed questionnaire.
Results: In total, 165 iGAS-patients were reported between 01.12.2017 and 30.11.2022. Median age was 62 months (range 18 days to 16 11/12 years) and 55/165 (33%) were female. During pandemic, cases substantially decreased from 41 in 2019, to 18 and 16 cases in 2020 and 2021, respectively. After discontinuation of nonpharmaceutical interventions, a resurgence to a total of 29 cases was recorded in 2022 by end-November. Severe illness occurred in 76/165 (46%) iGAS-cases with need for ICU treatment, 41/77 (53%) patients required temporary ventilation, 44/77(57%) had catecholamines to maintain circulation and 90/165(55%) required surgery. A risk factor was identified in 32/165 (19%), with previous varicella infection being the most prevalent in 21 cases. Of 165 patients, 121(73%) had complete cure. Residuals occurred in 32/165(19%) and one death was reported in a 26-month-old previously healthy infant, representing a case fatality rate of 0.6 %. Risk factors or frequency and severity of residuals did not differ in the years before and during the pandemic.
Conclusions/Learning Points: In Switzerland, iGAS is again increasing after incidence had dropped during the SARS-CoV-2 pandemic. It mainly affects previously healthy children and is severe in almost half of the cases, though severity was comparable in both periods. Further surveillance is needed to determine changes in the incidence, severity and clinical presentation of iGAS.

E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Pınar Önal[1], Deniz Aygun[1], Gözde Apaydin Sever[1], Beste Eren[1], Gülşen Kes[1], Fatih Aygün[2], Haluk Çokuğraş[1]
[1]Istanbul University-Cerrahpaşa Medical Faculty, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department Of Pediatric Intensive Care, Istanbul, Turkey

Title of Case: A CRITICAL CASE OF MULTIFOCAL PYOMYOSITIS CAUSED BY METISILINE SENSITIVE STAPHYLOCOCCUS AUREUS TOGETHER WITH PERICARDITIS, SACROILEITIS AND ACUTE GENERALIZED EXANTHEMATOUS PUSTULOSIS IN A PREVIOUSLY HEALTHY ADOLESCENT

Background: Pyomyositis which is predominantly caused by staphylococcus aureus, is primary pyogenic infection of the skeletal muscles. It can be seen at any age group and previously healthy children.Staphylococcus aureus is the most important cause of community-acquired skin, soft tissue or bone infections

Case Presentation Summary: This case represents an adolescant girl with pyomyositis of multiple muscles, causing sacroileitis and multiorgan failure because of sepsis. There was no medical history of trauma, infection, surgery or immunsupression.She described these progressive complaints for 1 week. Her physical examination revealed decreased breath sounds on basal areas of bilateral lungs, abdominal distension, edematous extremities. The pus aspirated from the abscess tested positive for meticilline sensitive Staphylococcus aureus. Despite proper treatment with parenteral antibiotics and surgical drainge, patient's fever persisted, and sepsis triggered hemophagocytic syndrome. The patient has transferred to pediatric intensive care unit with the diagnosis of hemophagocytic syndrome related to sepsis and received plasmapheresis, iv corticosteroid, broad spectrum antibiotics and renal replacement therapy. Also a new maculopapuler rash on her trunk and limbs was observed after meropenem infusionand and diagnosed with acute generalized exanthematous pustulosis , After clinical improvement the patient has transferred to pediatric infectious diseases ward back

Learning Points/Discussion: In conclusion, diagnosis of pyomyositis is generally difficult because of subtle symptoms and its low incidence, therefore treatment delay can rapidly cause fatal outcomes. Also, the absence of a comorbid disease should not mislead the physician if there is a suspicion of pyomyositis.

PV0528 / #2711

CENTRAL LINE-ASSOCIATED BLOODSTREAM INFECTIONS DUE TO GRAM-NEGATIVE BACTERIA IN CHILDREN WITH SHORT BOWEL SYNDROME – A RETROSPECTIVE STUDY FROM A UNIVERSITY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Veronika Osterman[1,2], Ana Prislan[1]
[1]University Medical Centre Ljubljana, Department Of Paediatric Surgery, Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Hospital Infection Control And Prevention Services, Ljubljana, Slovenia

Background: Children with short bowel syndrome (SBS) receiving parenteral nutrition (PN) are predisposed to central line-associated bloodstream infections (CLABSI), which are often polymicrobial and more likely caused by gram-negative bacteria from the gut, suggesting a central causative role of intestinal translocation. Gram-negative bacteremia is known to carry a high rate of morbidity and mortality.
Methods: A 10-year (January 2012 – December 2022) descriptive single-centre retrospective chart review of all episodes of microbiologically confirmed Gram-negative CLABSIs in children with SBS on PN.
Results: In the analysed period, 16 children had 26 episodes of microbiologically confirmed gram-negative CLABSIs, of which 65.4% (17/26) were present in children with SBS. Out of all children with SBS, 62.5% (5/8) had more than one gram-negative CLABSI (2.1 per child). Of all CLABSIs, 19.2% (5/26) were polymicrobial, with 80% (4/5) of them occurring in children with SBS, with an incidence of 23.5% (4/17). The most frequently isolated pathogen was Klebsiella pneumoniae (29.2%, 7/24), followed by Klebsiella oxytoca (16.6%, 4/24), Escherichia coli (16.6%, 4/24), Raoultella (Klebsiella) ornithinolytica (8.3%, 2/24), Enterobacter cloacae (8.3%, 2/24), Proteus mirabilis (8.3%, 2/24), Proteus vulgaris (4.2%, 1/24), Enterobacter ausburiae (4.2%, 1/24) and Pseudomonas aeruginosa (4.2%, 1/24). Twenty-nine percent (5/17) of CLABSIs in children with SBS presented with signs of septic shock. The mean duration of antibiotic therapy was 21.3 ±9.3 days. No deaths were recorded.
Conclusions/Learning Points: Children with SBS had more gram-negative and more polymicrobial CLABSIs than other children, with more CLABSI recurrences. The need for long-term central venous access and the intestinal dysfunction associated with SBS drive the need for an intestinal failure-specific approach to prevent and treat infections in patients with SBS.

Title of Case: MULTIPLE CAUSES OF BELL PARALYSIS IN A TODDLER: WHICH ONE IS TO TREAT?
Background: Facial nerve palsy in children is uncommon. Management depends on etiology (bacterial, viral, inflammatory, neoplastic, traumatic or idiopathic).
Case Presentation Summary: We present a previously healthy and immunized 16-months boy admitted to hospital for elevated fever. During hospitalization he developed bilateral secretory otitis and progressive neurologic signs (left peripheral facial palsy, nystagmus); no clinical signs of otomastoiditis. Laboratory findings included positive EBV, HSV, CMV and Paramyxovirus IgM; only EBV infection was confirmed by PCR on blood. Blood count and inflammatory markers were always normal. Head CT showed signs of bilateral otitis media complicated with mastoiditis. Brain MRI showed a voluminous mass in the parotid region which according to the US was recognized as inflammated parotid gland with increased dimension and multiple lymphadenopathies. Linear impregnation of the left facial nerve was also shown by MRI. Otomastoiditis was treated with Ceftriaxone, Vancomycin and Prednisone with progressive improvement of clinical conditions and resolution of nystagmus. Due to impossibility to rule out HSV co-infection and in the attempt to treat EBV infection, acyclovir was also administered. Even though physiotherapy rehabilitation with the Cabot method was promptly started, the paralysis partially persisted four weeks after hospital discharge.
Learning Points/Discussion: Facial nerve palsy in children has multiple causes. Differential diagnosis is essential to establish proper treatment. In case of viral infections, the role of antiviral treatment is still unclear. Few cases of facial palsy by EBV infection have been described, but none of them with identification of etiopathogenesis. In our case, there was radiological evidence of inflammation of the VII nerve in its intraparotid portion as result of gland inflammation due to EBV infection. Rehabilitation outcomes are unpredictable.

Backgrounds: The global burden of S. aureus community-acquired and healthcare-associated infection poses a significant challenge for clinicians worldwide. The aim of this study was to characterize invasive disease by this agent in Portuguese children from a clinical and microbiological point of view.
Methods: 7-year, observational, retrospective, multicentric study of infected children with identification of S. aureus in a biological sample from a usually sterile site. Clinical survey and microbiological characterization.
Results: Total of 394 cases (reported from 20 hospitals), with S. aureus isolated more frequently in blood cultures (295; 74.3%), followed by abscess drainage (58; 14.6%) and synovial fluid (15; 3.7%). Global incidence – 21.1 cases/100 000 children. Main clinical presentations were bacteremia/sepsis (36%), osteoarticular infection (21%) and skin abscess (14%). Male predominance (60.7%), median age of 3.9 years (30.8% < 1YO, 45.2% ≥ 5YO), 36% with comorbidities, hospital admission in 92.2%, 14.7% in critical care. There were reported complications in 53 cases (13.3%) with 7 deaths. Oxacillin resistance rate was 30.3 vs. 10.1% and clindamycin 30.5 vs. 20.6%; respectively, in healthcare-associated and community-acquired species. Susceptibility testing influenced antibiotic therapy change in 33.7% of methicillin susceptible staphylococcus aureus (MSSA) species. MRSA infections occured more frequently in healthcare-associated infections and in younger children. Molecular characterization is being undertaken.
Conclusions/Learning Points: Invasive disease by S. aureus was present in every age bracket, predominantly in children with or above 5 years old and in skin and soft tissue and osteoarticular infections. Antibiotic therapy was adjusted by the antibiogram result in only 1/3 of MSSA cases. Oxacillin resistance rate in community-acquired infections was higher than reported in other European countries.

Backgrounds: Invasive pneumococcal disease (IPD) is a common cause of morbidity and mortality among children, with a case fatality rate of about 10% in children under 5 years. The frequency of primary bacteremia is 20% of the IPD in children under 2 years.
Methods: Observational, descriptive, longitudinal study. Data were obtained from medical records of patients under 18 years diagnosed with primary bacteremia by pneumococcus and treated in Neumocolombia network hospitals in 2017-2022 (10 hospitals of Bogotá, and 4 hospitals of Cali, 2 of Medellín and 1 of Cartagena). A univariate analysis was performed using frequency and bivariate tables with non-parametric Kruskal-Wallis (preliminary data).
Results: 344 cases of IPD, 74(21.5%) diagnosed with primary bacteremia. 55.4% of the patients were male. Median age was 30 months (IQR 9 - 55). 40.5% of the patients were under the age of 2; lethality was 10.8% (8/74) under 18 years and 20%(6/30) under 2 years of age, 39% had complete immunization with PCV10 (schedule 2+1) and 58% had at least one dose. Serotyping was obtained in 44(59%). The most frequent serotype was 19A, followed by 6C and 23B, (43%, 11.3% and 6.8%, respectively). Resistance to erythromycin was 50%, to clindamycin 33.8%, penicillin 20.5% and ceftriaxone 10%. 33.7% of the children were admitted to the ICU. The average hospital stay was 12.3 days, and 9.2 days in the ICU.
Conclusions/Learning Points: Primary bacteremia by S. pneumoniae in Colombia has a 20% case fatality rate in children under 2 years, the most frequent serotype being 19A, high resistance to antibiotics was found. Colombia changed to PCV 13 in July 2022

LISTERIOSIS AT AN ATYPICAL AGE, WHAT TO THINK ABOUT ?

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Adriana Romano, Inês Candeias, Ivo Miguel Neves, Maria Augusta Gonçalves
Hospital de Braga, Paediatrics, Braga, Portugal

Title of Case: Listeriosis at an atypical age, what to think about?
Background: Listeriosis is a rare but serious invasive infection with a case-fatality rate of 16-20%. It is caused by Listeria monocytogenes and is usually transmitted by ingestion of contaminated food. It typically affects pregnant women, newborns, the elderly and immunosuppressed patients. It is very rare in immunocompetent persons.
Case Presentation Summary: We present a case of a 6-year-old female with a pathological history of recurrent respiratory infections. She was brought to the emergency department due to fever associated with frontal headache and decreased appetite. No respiratory symptoms associated. Later on she began to have liquid diarrhea, without blood, mucus or vomiting. No epidemiological context or suspicious food/water consumption was identified. Due to clinical signs of dehydration, a blood analysis and culture were performed and revealed mild hypokalemia(3,4mmol/L), leukocytosis(13200/uL) with a predominance of neutrophils and an elevated C-Reactive Protein(53,30mg/L). Subsequently, the blood culture isolated Listeria monocytogenes and antibiotic therapy with ampicillin and gentamicin was started for 14 days, following the exclusion of central nervous system involvement. The infection was reported to public health authorities. After both clinical and analytical improvement, she was discharged with instructions for follow-up, at which time she initiated treatment with immunoglobulin for suspected Common Variable Immunodeficiency.
Learning Points/Discussion: The authors consider it extremely important to share their findings as the number of Listeria infections is increasing in Europe. In these cases early initiation of antibiotic therapy is crucial and, in order to protect those at risk of severe illness, promptly notifying is essential. Given the rarity of this condition in immunocompetent children, the exclusion of immunodeficient children is mandatory. The authors also aim to highlight the importance of food safety.

CYTOKINE PROFILE IN SEPSIS IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Katsiaryna Serhiyenka[1], Oxana Romanova[1], Elena Fomina[2], Veranika Zverko[2]
[1]Belarussian State Medical University, Children Infections Diseases, Minsk, Belarus, [2]Republican Scientific and Practical Center of Epidemiology and Microbiology, Laboratory For Immunology And Cell Biotechnology, Minsk, Belarus

Backgrounds: The first barrier of immune defense against pathogens is the complement system, acute phase proteins, cytokines, monocytes, macrophages, neutrophils and NK cells, etc.
Methods: Purpose of the study: to determine the cytokine profile (IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, TNF-α) in patients with sepsis and to evaluate the possibility of using the studied immunological parameters in the early diagnosis of bacterial sepsis. The study included 18 patients with sepsis (main group) who were treated at the City Children's Infectious Clinical Hospital and the 3rd City Children's Clinical Hospital in Minsk in 2022. In patients of the main group, the study of cytokines was carried out twice - at the diagnosis of "sepsis" (n=18) and in dynamics after 7 days (n=16).
Results: It was found that in the group of children with sepsis, the initial period of the disease proceeds against the background of a significant increase in the concentration of cytokines in the blood - TNF-α, IL-6 and IL-8 ($p<0.05$ compared with the control). The greatest changes were found in IL-6 values, the values of which exceeded the control values by 10 times, the median of which was 108.6 pg/ml (in the control group - 7.25 pg/ml). Studies in the dynamics of the course of sepsis against the background of antibiotic therapy revealed a significant decrease in the median of inflammatory cytokines: TNF-α, IL-6, $p<0.05$
Conclusions/Learning Points: The study revealed an immune imbalance, manifested by an increase in the blood concentration of some inflammatory cytokines (TNF-α, IL-6 and IL-8) in the absence of growth of others (IL-1β, IL-2, ID-4, IL- 10), which undoubtedly requires further detailed study and comparison with other markers of bacterial inflammation.

CLINICAL PRESENTATION OF EBV INFECTION IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Elda Skenderi
University Hospital Center, General Pediatrics, Tirana, Albania

Backgrounds: Epstein-Barr virus(EBV) is a human herpesvirus that is ubiquitous in nature, and most of the world population is infected. Infectious Mononucleosis(IM) is the most common clinical syndrome caused by EBV. IM most often begins insidiously, with vague malaise, followed several days later by fever, sore throat, swollen posterior cervical lymphnodes and fatigue. Some patients experience an abrupt influenza-like onset with fever, chills, body-aches and sore throat.
Methods: Because primary EBV infection is usually asymptomatic in children or produces an acute illness that is often not recognized as being to EBV, a study was conducted to explore clinical presentation of primary EBV infection in albanian children. In the study were enrolled 107 children aged 0-14years old, hospitalized in the Pediatric Infectious Disease Ward in the University Hospital Center "Mother Teresa" in Albania, during 2015-2018. Diagnosis was performed based on positive immunoglobulin M of EBV viral capsid antigen. In the typical presentation of IM were included all cases presented with the classic triad(fever, pharyngitis, lymphadenopathy), all other cases were considered atypical.
Results: 63% of children presented with typical IM and 37% presented with atypical IM. In the age-group 0-2years 56%of cases were typical IM, and 44% of cases were atypical IM. In the age-group 2-6years 57% of cases were typical IM, and 43% of cases were atypical IM. In the age-group 6-14years 74% of cases were typical IM, and 26% of cases were atypical IM. Median age in typical IM was 5.7years and median age in atypical IM was 4.9years.
Conclusions/Learning Points: The risk of developing Infectious Mononucleosis after primary EBV infection correlates with the age of the child. Young children often present with atypical or a partial IM syndrome. Although classic IM occurs too.

DENGUE-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN A MICHIGAN TODDLER: THE IMPORTANCE OF TRAVEL HISTORY

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Sandeep Sohal[1], Sindhu Manjunath[2], Daniel Domijan[2], Nidal El-Wiher[2], Maxim Yankelevich[2], Bishara J Freij[2]
[1]Beaumont Royal Oak, Infectious Disease, Royal Oak, United States of America, [2]Beaumont Children's Hospital, Pediatrics, Royal Oak, United States of America

Title of Case: DENGUE-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN A MICHIGAN TODDLER: THE IMPORTANCE OF TRAVEL HISTORY
Background: Hemophagocytic lymphohistiocytosis (HLH) is a potentially fatal hyperinflammatory syndrome causing progressive immune-mediated organ damage. It can be inherited (familial) or acquired (infectious or cancerous triggers). Dengue afflicts 390 million people annually, but it is rarely complicated by HLH. In the 2012-2013 dengue epidemic in Puerto Rico, HLH incidence was 0.56/100,000 children/year; 80% were dengue-associated. This is very rarely diagnosed in the contiguous United States.
Case Presentation Summary: A three-year-old boy developed persistent fever, chills, and a back rash two weeks after returning from an extended stay in India where he had several undiagnosed febrile illnesses. He was hospitalized on day 8 of fever and had hyponatremia, hypoxemia, hepatosplenomegaly, hepatitis, and thrombocytopenia, with progressive declines in his white blood and neutrophil cell counts, high ferritin, and low fibrinogen. Interleukin-2 receptor level was 8690 pg/mL on day 13. He met the HLH-2004 diagnostic criteria and had an H-score of 264 (Table). Dexamethasone 10 mg/m²/day was started on day 12 of fever and gradually tapered over 5 weeks, with complete clinical recovery and gradual laboratory parameter normalization within 4-6 weeks. Dengue IgM and IgG were first measured on day 10 of fever and were positive at 7.84 and 23.34 immune status ratio (ISR), respectively (threshold positive >2.84). When repeated on day 39, IgM and IgG levels were 3.26 and 23.7 ISR, respectively. Serum dengue NS1 antigen was negative when tested on day 18 of fever. Familial HLH gene tests and a search for other infectious triggers were unrevealing.

Table. H-SCORE CALCULATIONS FOR HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

	Laboratory/Clinical Parameter (H=highest; L=lowest)	Points
Hemoglobin (g/dL)*	7.8 (L)	+34
White blood cell count (bil/L)	2.6 (L)	
Platelet count (bil/L)*	36 (L)	
Aspartate aminotransferase (U/L)	3437 (H)	+19
Ferritin (ng/mL)*	19675 (H)	+50
Fibrinogen (mg/dL)*	62 (L)	+30
Triglycerides (mg/dL)*	273 (H)	+44
Hepatosplenomegaly*	Present	+38
Known immunosuppression	Absent	+0
Temperature*	40.1°C (H)	+49
Bone marrow examination*	Not done	+0
Interleukin-2 receptor (pg/mL)*	8690 (H)	Not included in H-score calculation

Total H-Score: 264 points; HLH probability >99%
*Findings that meet the HLH-2004 diagnostic criteria
https://www.mdcalc.com/calc/10089/hscore-reactive-hemophagocytic-syndrome

Learning Points/Discussion: Dengue as an HLH trigger should be considered in those with history of travel to endemic areas. Early recognition and treatment allows for faster recovery.

PV0536 / #2108

AGE AND PATHOGEN DISTRIBUTION IN COMMUNITY BLOODSTREAM INFECTIONS AMONG PEDIATRIC PATIENTS: CENTRAL GREECE, 2010-2022

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Aspasia Michoula[1], Stelios Xytsas[2], Eleftheria Chatzi[1], Athanasios Gkoutzourelas[1], Ioulia Boulogianni[1], Efthymia Petinaki[2], George Syrogiannopoulos[1], Ioanna Grivea[1]
[1]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department Of Pediatrics, Larissa, Greece, [2]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department Of Microbiology, Larissa, Greece

Backgrounds: Management of bloodstream infections (BSI) among pediatric patients depends, along with the severity of disease, on age and etiologic agent.
Methods: This is a study among pediatric patients hospitalized due to BSI at the University General Hospital of Larissa, Greece, from January 1st 2010 to December 31st 2022.
Results: During the 13-year study period, a total of 25,522 children were hospitalized; 161 children had ≥1 positive blood cultures within the first 48 hours after admission that indicated true bacteremia. The median age of the patients was 18.9 months [Interquartile range (IQR): 2.8 -72.8 months]. The median incidence rate of hospitalized bacteremia cases was 6.7 per 1000 admissions per year. Pathogens which were considered as "contamination", such as coagulase negative Staphylococcus or Streptococcus viridans, were not included in the study unless detected in two subsequent blood samples obtained during hospitalization. In two cases two different pathogens were isolated from the same blood sample; in total 163 pathogens were analyzed. The proportion of the isolated pathogens by age group revealed characteristic variability, mainly among children aged 3 months-<5 years old.
(Table).

	0-2 mos n=40	3-11 mos n=29	12-59 mos n=43¶	5-11 yrs n=32	≥12 yrs n=17
Staphylococcus aureus, n=32	6 (15.0)	4 (13.8)	7 (15.6)	8 (25.0)	7 (41.2)
Escherichia coli, n=26	14 (35.0)	4 (13.8)	5 (11.1)	1 (3.1)	2 (11.8)
Streptococcus pneumoniae, n=20	1 (2.5)	4 (13.8)	7 (15.6)	8 (25.0)	
Brucella spp., n=19			6 (13.3)	8 (25.0)	5 (29.4)
Streptococcus agalactiae, n=15	13 (32.5)	1 (3.5)	1 (2.2)		
Streptococcus pyogenes, n=10			5 (11.1)	4 (12.5)	1 (5.9)
Klebsiella pneumoniae, n=8	4 (10.0)	2 (6.9)	2 (4.4)		
Neisseria meningitides, n=7		3 (10.3)	2 (4.4)	2 (6.3)	
Salmonella spp., n=7	1 (2.5)	3 (10.3)	3 (6.7)		
Enterobcter spp., n=5		1 (3.5)	4 (8.9)		
Haemophilus influenzae, n=4		1 (3.5)	2 (4.4)	1 (3.1)	
Pseudomonas aeruginosa, n=4		4 (13.8)			
Yersinia enterocolitica, n=2		1 (3.5)	1 (2.2)		
Enterococcus faecalis, n=1		1 (3.5)			
Campylobacter spp., n=1	1 (2.5)				
Staphylococcus haemolyticus, n=1					1 (5.9)
Candida kefyr, n=1					1 (5.9)

¶*Two pathogens isolated in the same blood culture in two patients*

Conclusions/Learning Points: Knowledge on the most common etiologic agents according to their age,

along with the severity of the clinical manifestations, constitutes the most crucial guide for the empiric management of bacteremia cases prior to isolation of the specific pathogen.

PV0537 / #2075

INVASIVE GROUP A STREPTOCOCCUS DISEASE, TWO RECENT CASES

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Madalena Torrado Malato[1], Inês Pereira Soares[1], Vera Lúcia Da Costa Pereira Brites Alpendre[2], Sofia Almeida[3], Helena Sousa[1], Ana Catarina Fernandes[1], Inês Vaz Silva[1], Florbela Cunha[1]
[1]Hospital de Vila Franca de Xira, Pediatrics, Lisboa, Portugal, [2]Hospital Dona Estefânia- Centro Hospitalar Lisboa Central, Pediatrics, Lisboa, Portugal, [3]Hospital Santa Maria- Centro Hospitalar de Lisboa Norte, Pediatrics, Lisboa, Portugal

Title of Case: Two recent cases
Background: Group A Streptococcus (GAS) is commonly associated with pharyngitis/scarlet fever. Sometimes, it can cause a severe infection: invasive GAS disease (iGAS). Since September/2022, European countries have been reporting an increase of these cases among children.
Case Presentation Summary: 1: A healthy 5-year-old boy, presented with four days of viral upper airway symptoms and one hour of fever and stridor. Physical examination revealed severe upper respiratory distress. Oxygen, corticosteroid, adrenaline, and ceftriaxone were administered. Intubation was very difficult and only an ETT 3 could be placed with the sensation of airway obstruction without apparent epiglottitis. Laboratory values showed leukocytosis, neutrophilia, and renal dysfunction. The blood culture (BC) isolated GAS. A neck-CT was performed. to exclude parapharyngeal abscess but a subglottic stenosis was identified. Later, a micropapular rash appeared on his thorax and furfuraceous desquamation on his fingers. Laryngitis complicated with sepsis was assumed. Recovery took 10 days. 2: A healthy 2-year-old girl, presented with three days of fever and breathing difficulty. Physical examination revealed respiratory distress, hypoxemia, and a decrease in the vesicular murmur with crepitations. She was diagnosed with pneumonia and started on ceftriaxone, vancomycin and oxygen. She became prostrated, tachycardic, with petechial rash. Laboratory values showed leukopenia, neutropenia, lymphopenia, hyponatremia, hypokalaemia, thrombocytopenia, coagulation dysfunction and metabolic acidosis. The BC was negative. She developed sepsis and was transferred to the UCI. A chest-ultrasound showed an empyema. The pleural fluid culture was negative, and the PCR detected GAS. She improved in the following days.
Learning Points/Discussion: iGAS should be suspected in children with severe respiratory syndromes, especially if a preceding viral infection is present. Negative BC should not exclude the diagnosis as it can also be achieved through PCR of other sterile sites.

BORRELIOSIS: AN EMERGING ZOONOSIS IN PORTUGAL

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Lara Torres, Alexandra Rodrigues, Sónia Santos, Pedro Carvalho
ULS Guarda, Pediatria, Guarda, Portugal

Title of Case: BORRELIOSIS: AN EMERGING ZOONOSIS IN PORTUGAL
Background: Lyme disease (LD) is a spirochaetal infection caused by the Borrelia burgdorferi (Bb) sensu lato complex, transmitted by Ixodes ticks. Typical symptoms include fever, headache, fatigue, and a characteristic skin rash called erythema migrans. It is more prevalent in regions with moderate climates; however, its geographic distribution is expanding, and cases have been reported throughout Europe, which can, in part, be explained by the increase in migratory movements and trips to endemic areas. In Portugal, LD incidence seems to be rising, particularly in northern and central regions.
Case Presentation Summary: A healthy two-year-old boy living in Portugal was brought to an Emergency Department due to appearance of non-pruritic erythematous skin lesions on the legs, arms, abdomen and face. Lesions had been expanding gradually over the previous week. Fever and other systemic symptoms were denied and parents did not recall a history of insect bite. The mother reported that they had been in Brittany about 2 weeks before the appearance of the lesions. On physical examination, the boy presented several erythematous annular lesions, flat and without scale, with a central macula: the first to appear was on the left knee, with 15 cm in diameter, the remaining were also annular, with around 10 cm in diameter. The lesions found on the patient were compatible with erythema migrans. Diagnosis was later supported by IgM and IgG antibody positivity on ELISA serology testing and treatment with oral amoxiciline was initiated for 14

days.

Learning Points/Discussion: LD has a broad spectrum of clinical manifestations which, associated with its low incidence in Portugal, requires a high level of clinical suspicion for diagnosis. This case highlights the importance of epidemiologic history as a diagnostic clue.

BRAND NEW HABITS, SAME OLD DISEASES

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Piero Veronese, Valentina Maffini, Monica Rubini, Beatrice Ruozi, Alessandra Giacometti, Marco Pappalardo, Pietro Lazzeroni, Claudio Ruberto, Laura Bianchi, Icilio Dodi
Pediatric Hospital of Parma, Pediatric Infectious Disease Unit, Parma, Italy

Title of Case: BRAND NEW HABITS, SAME OLD DISEASES
Background: Typhoid or typhoid fever is the most severe and systemic manifestation of Salmonella typhi infection.
Case Presentation Summary: S., 17 years old girl, went to Emergency department because of abdominal pain, fever and diarrhea after consumption of raw fish. Blood exams revealed marked increase of C-reactive protein (CRP 123 mg/L) and the ultrasound (US) of the abdomen showed dilation and thickening of bowel loops. Prescribed Azithromycin for 6 days, with no benefit and appearance of severe bloody diarrhea. Because of worsening, exams were repeated and revealed leukocytosis (WBC 29260/ul), low platelets (PLT 35000/uL), mild anemia (Hb 7,3 gr/dL), hyponatremia (Na 121 mEq/L) and hypoalbuminemia (2,3 gr/dL). The CT scan showed ascites with marked thickening of the colon. Antibiotic therapy with Piperacillin-Tazobactam and Metronidazole was promptly started, with Albumin, Furosemide, total parental nutrition and two blood transfusion. Bilateral pleural effusion with atelectasis required pleural drainage and high-flow oxygen therapy. Cardiac US revealed mild dilatation of coronary arteries with normal functionality. Abdomen CT-scan and color-doppler US showed a non-occluding thrombosis at the origin of the superior mesenteric vein. Acetylsalicylic acid therapy was undertaken for 30 days. After 48 hours of intensive care, girl was transferred to our unit and showed clinical and laboratory improvement, reduction of pleural and ascitic effusions and apyrexia. Stools slowly improved, although bloody evidence remained until 15 days from discharge. Microbiological tests revealed positive anti-typhoid antibodies (O-positive antigen 1:640); cultures from stools and blood samples resulted negative along with antibodies against Brucella, Epstein-Barr virus, Adenovirus and Coxsackievirus.
Learning Points/Discussion: Salmonella typhi infection must be considered in the differential diagnosis when clinical presentation (fever, hematic diarrhea, abdominal pain) and anamnesis (raw fish ingestion) are suspected for typhoid fever also in low-incidence countries.

CASE SERIES OF INVASIVE SALMONELLOSIS IN A TERTIARY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS07.D. SEPSIS, SYSTEMIC AND MULTI-ORGAN INFECTIONS

Isabel Viñuela Díaz-Moro[1], Paula Cueto-Felgueroso[2], Irene Rodríguez[2], Jaime Carrasco-Colom[1], Lidia Ciudad Aguilar[1], Enrique Ruiz De Gopegui Bordes[3], Lluis Galmés Rosselló[1], Joaquín Dueñas Morales[1]
[1]Hospital Universitario Son Espases, Paediatric Infectious Diseases, Palma de Mallorca, Spain, [2]Hospital Universitario Son Espases, Paediatrics, Palma de Mallorca, Spain, [3]Hospital Universitario Son Espases, Microbiology, Palma de Mallorca, Spain

Title of Case: CASE SERIES OF INVASIVE SALMONELLOSIS
Background: Salmonella enterica, a common pathogen in gastrointestinal infections, can also cause invasive infections such as bacteraemia or focal infections. We retrospectively reviewed invasive Salmonella enterica infections in children under 18 years from June 2012 to October 2022.
Case Presentation Summary: We obtained 14 cases (64% male) with a median of 11 years. 9 cases were non-typhoidal serotypes (NTS) and 5 typhoidal serotypes (TS). Of the latter, 3 had travelled to endemic areas. 4 had sickle cell disease, 1 advanced HIV and 1 suspected chronic granulomatous disease. Fever (12/14) was associated in 8 cases with digestive symptoms and in 5 with osteoarticular symptoms. 4 cases were diagnosed with bacteraemia due to NTS and 4 due to TS. The second most frequent diagnosis was osteoarticular infection (6/14). Third generation cephalosporin was the empirical treatment in 8/14 and targeted treatment in 12/14, switching to amoxicillin-clavulanic acid in case of oral therapy. 11/14 were sensitive to the tested antibiotics, 2 resistant to ampicillin and co-trimoxazole, and 1 to quinolones.
Learning Points/Discussion: An increased incidence of invasive Salmonella infections has been described. In our series, it's striking that almost half of the cases (6/14) occurred in 2022. The number of patients with risk factors (9/14) is also noteworthy. Regarding the history of travel to an endemic area, it is to be noted that none had received vaccination against typhoid fever. It could be an option in patients with underlying pathology travelling to endemic areas, especially in those visiting friends and relatives. Resistance to antibiotics has increased, most troublingly to quinolones and third generation cephalosporins in Southeast Asia. In our series we have detected few resistances: of those found, 2 out of 3 were imported TS.

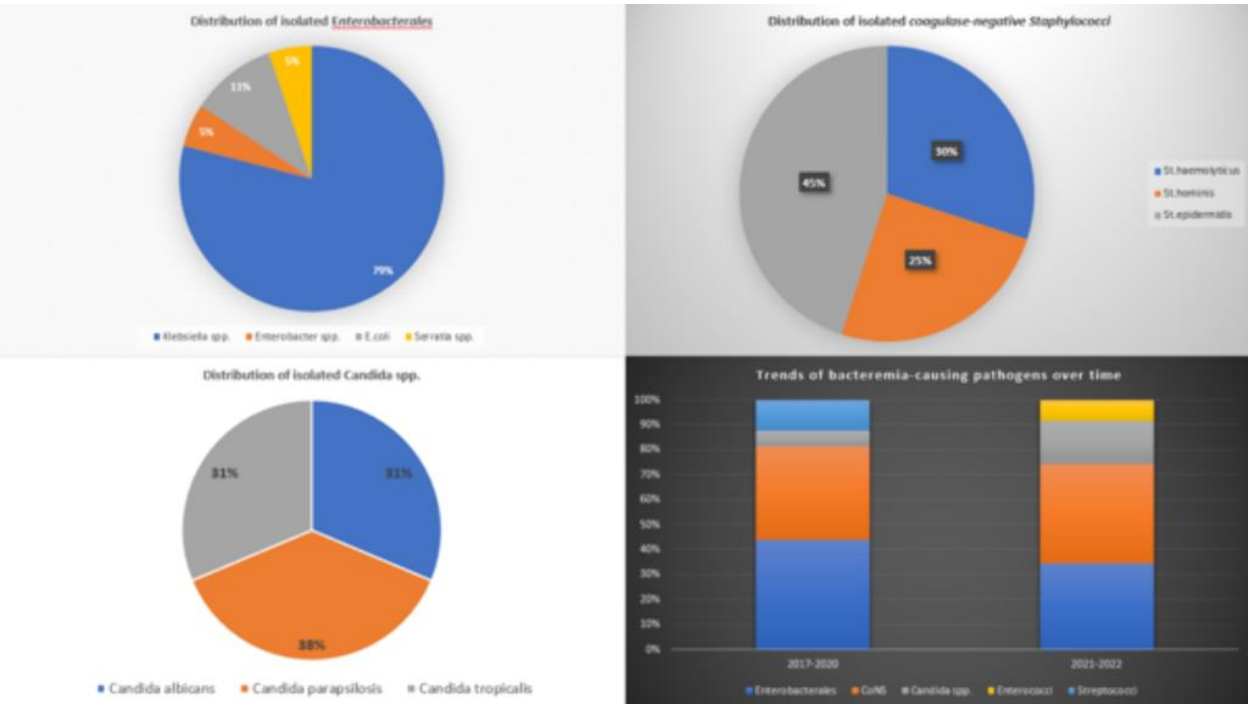
[1]General Hospital of Thessaloniki Hippokration, 3rd Department Of Pediatrics, Thessaloniki, Greece, [2]Aristotle University of Thessaloniki, Hippokration Hospital of Thessaloniki, 3rd Dept Of Pediatrics, Thessaloniki, Greece

Backgrounds: Although parenteral nutrition (PN) is life-saving in children with SBS, it possesses risks for central venous catheter-associated BSI. We investigated the incidence of such infections and possible risk factors in our department.
Methods: We reviewed the medical records of patients with SBS hospitalized between 1/1/2017-31/12/2022. Variables recorded were sex, primary cause of SBS, presence of ileocecal valve, length of remnant small bowel (percentage of the predicted, according to postconceptional age/weight at the time of surgery), duration of ileostomy/parenteral nutrition/central venous catheterization. Episodes of BSI (bacteremia/fungemia) per 1000-inpatient-days (in the presence of central venous catheter) and their trends over time were also recorded.
Results: Eight patients (4 males) were included. Mean age was 3.3 years (SD: 2.4). Ileocecal valve was removed from all cases. Mean length of remnant bowel was 44% (SD: 35) of predicted, whereas mean duration of ileostomy / parenteral nutrition / central venous catheterization was 128.6 (SD: 134.9) / 236.1 (SD: 165.1) / 262.6 (SD: 165.3) days respectively. A total of 51 bloodstream infections and a mean of 6.4 infections per patient (SD: 1.475) were recorded. Mean number of confirmed BSIs per 1000-inpatient-days was 30 (SD: 26). Median number of central-venous catheter changes was 2 (IQR:3). Isolated microorganisms were Enterobacterales [19/51(37.3%)], coagulase-negative staphylococci (CoNS) [20/51(39.2%)], Candida spp. [7/51(13.7%)], Enterococcus spp. [3/51(5.9%)], Streptococcus spp. [2/51(3.9%)]. A 2-fold-increase in BSIs was noted from 2021 to 2022, compared to 2017-2020, with concomitant statistically significant increase of CoNS and Candida infections. Strong correlation was found between number of BSIs and duration of ileostomy/PN [correlation coefficient: 0.776 (p-value: 0.024)/0.898 (p-value: 0.002) respectively].



Conclusions/Learning Points: Catheter-related BSIs in patients with SBS are common and potentially life-threatening complications. Protracted dependence on PN and ileostomy are associated with recurrent episodes.

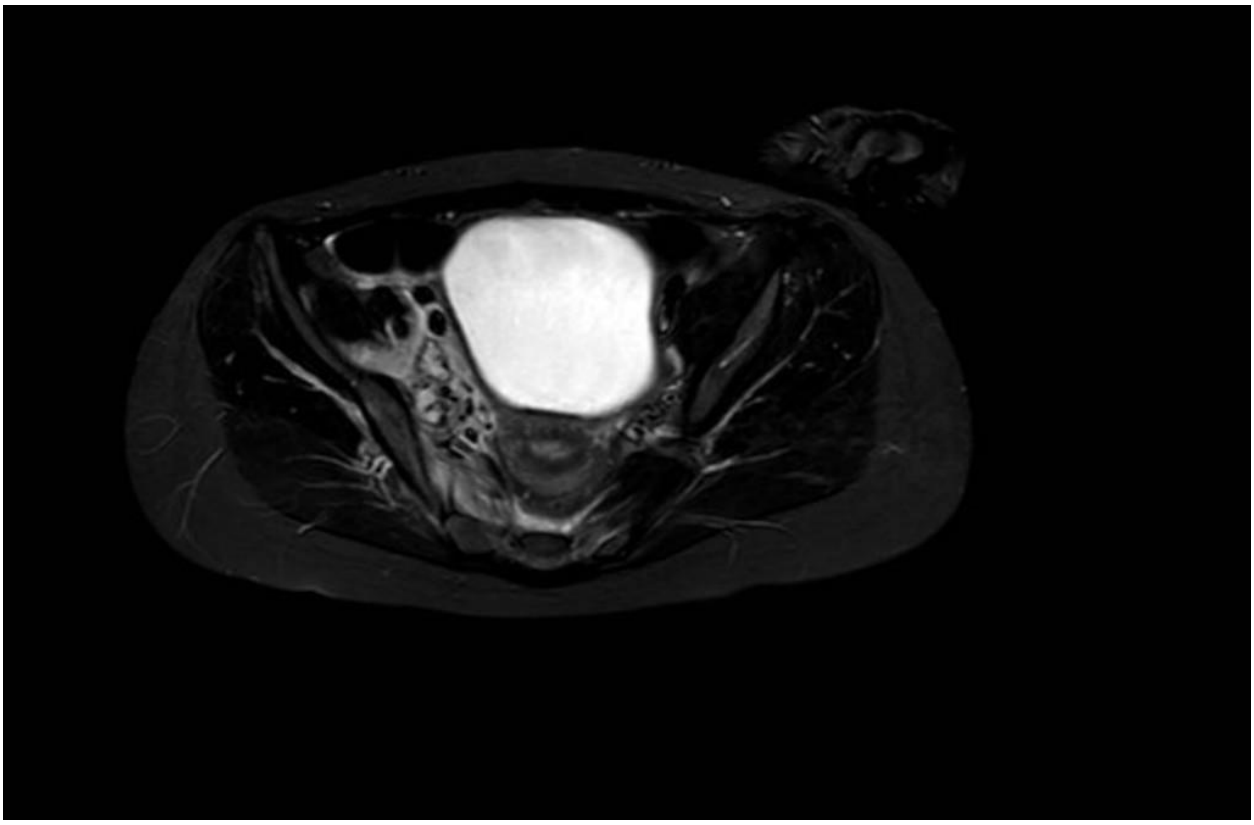
Title of Case: Pyomyositis associated with abscess formation caused by streptococcus pneumoniae in children: a case report
Background: Pyomyositis is an unusual and potential severe bacterial infection in children. Staphylococcus Aureus is the first causative agent (70-90%), following by Streptococcus Pyogenes. Streptococcus Pneumoniae rarely caused invasive muscular infections. We describe a case of complicated pyomyositis caused by Streptococcus Pneumonia in a healthy 12 year old female.
Case Presentation Summary: Patient presented hypothensive with a high fever for five days associated with right hip and abdominal pain. The blood exams showed neutrophilic leukocytosis with high level of inflammatory markers (CRP 46,17 mg/dl; Procalcitonin 25,8 ng/ml). The abdomen ultrasonography was unremarkable. Computed tomography (CT) of the abdomen and right hip revealed complicated pyomyositis of iliopsoas, piriformis and internal shutter muscles associated with marked signs of suppuration (figure 1). The patient was admitted to our paediatric care unit and initially treated with intravenous Ceftriaxone (100mg/kg/die) and Vancomycin (60mg/kg/die). On day 2, a multisensitive Streptococcus Pneumoniae was isolated from the blood culture, and Vancomycin was discontinued. She was successively treated with IV Ceftriaxone for 3 weeks, then continued with oral Amoxicillin for a total of 6 weeks of therapy. The follow up showed a complete resolution of the pyomyositis and iliopsoas abscess after 2
months.



Learning Points/Discussion: Pneumococcus pyomyositis associate with muscular abscess is a rare deep muscular infection in healthy children. Clinical presentation can mimic other pathologies (like osteomyelitis or septic arthritis), so many times is hard to identify. The risk factors include story of recent trauma and immunodeficiency, not present in our case report. The treatment of choice is IV antibiotic, although in literature there is no agreement regarding duration of therapy, and when indicated abscess drainage.

Title of Case: 2 1/2-MONTH-OLD MALE WITH COUGH, CORYZA AND INABILITY TO EXTEND THE RIGHT LOWER LIMB
Background: Septic arthritis though presents infrequently in infancy, still can be challenging in terms of diagnosis and treatment.
Case Presentation Summary: A 2 1/2 month-old boy was admitted with inability to extend the right lower limb.Symptoms presented five hours prior to the emergency department attendance.He had cough and coryza for a week and low grade fever(maximum temperature of 37.7oC) five days prior to the presentation.He had normal hip radiograph,but the ultrasound of right hip revealed fluid in the joint. On admission, the patient was clinically well, with right hip being on flexion,abduction, external rotation,with decreased range of movements and tender on handling. The inflammatory markers were not raised (WBC: 16,470/μL, CRP:13mg/L, ESR:18).He was started on intravenous cefotaxime and clindamycin. On day four of admission, a repeat ultrasound and an arthrocentesis were performed.The blood culture revealed methicillin-sensitive Staphylococcus aureus (MSSA) and antibiotic therapy was switched to cloxacillin. The synovial fluid microscopy showed raised white cell count with neutrophilia, but there was no bacterial growth. The patient completed 14 days of intravenous antibiotic therapy and during the admission remained clinically very well, afebrile, with progressive improvement of the range of motion of right lower limb.He was discharged with oral co-amoxiclav in order to complete 6 weeks of antibiotic treatment in total. Orthopedic team has reviewed the patient two weeks post-discharge and during the clinical examination the right hip had full range of motion.
Learning Points/Discussion: The prompt diagnosis and appropriate management of septic arthritis is of outmost importance, as it can prevent significant complications of the joint involved.

Title of Case: PYOMYOSITIS: A CASE SERIES
Background: Pyomyositis is a primary infection of the skeletal muscle commonly affecting the lower limbs. It occurs by seeding in the muscle, during transient bacteremia.
Case Presentation Summary: Our aim was to characterise pyomyositis' epidemiology, diagnosis setting, treatment and outcome in paediatric patients. Retrospective, unicentric study of children and adolescents diagnosed with pyomyositis in a tertiary care paediatric hospital, from June 2008 to June 2022. Predisposing factors, clinical, laboratory and radiological results, treatment and evolution were analysed. 27 patients were identified, 74% male, median age of 8 years old [2;13]. The most common predisposing factors were trauma (33%) and intense physical activity (33%). Pain (100%), fever (63%) and limited range of movement (ROM) (59%) were the most frequent symptoms, with a median onset of 6 days [2;10] and 52% were diagnosed at the first Emergency Department visit. The lower limb was the most affected site (86%), specially the hip muscles (46%). All patients had altered inflammatory parameters (median CRP 98.8 mg/L; median ESR 40 mm/h). MRI had 100% sensitivity, whereas 40% of ultrasounds were inconclusive. Blood cultures were positive in 36%, MSSA was the most common organism isolated (28%), but in 60% of patients no agent was identified. Most patients were treated with intravenous flucloxacillin plus clindamycin (52%) for a median 14 days [9;17] and median total duration of 28 days [19;39]. Drainage was performed in 6 patients. All patients improved without ROM limitation at 6-month follow-up.
Learning Points/Discussion: Pyomyositis is difficult to diagnose, since symptoms can be nonspecific. Nevertheless early diagnosis and treatment were essential. MSSA was the most isolated organism, as in other series, but in 60% no agent was identified, probably related to low drainage rate.

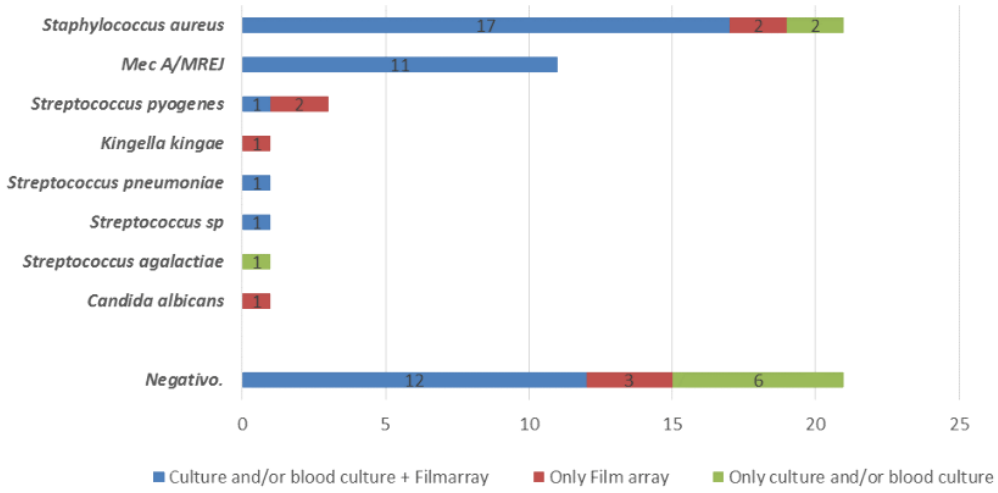
CORRELATION BETWEEN THE RESULT OF CULTURES AND MOLECULAR PANEL FILM ARRAY™ IN A COHORT OF PEDIATRIC PATIENTS WITH BONE AND JOINT INFECTIONS IN BOGOTA (COLOMBIA).

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Germán Camacho-Moreno[1,2], Enrique Vergara Amador[1,2], Tomas Martinez Villegas[1], Luz Romero[1], Francisco Lores[1], Yefry Aragon Joya[1], Vivian Moreno[2], Aura Leal[1]
[1]Universidad Nacional de Colombia, Bogotá, Bogotá, Colombia, [2]HOMI Fundación Hospital Pediátrico la Misericordia, Bogota, Bogotá, Colombia

Backgrounds: Bone and Joint Infections (BJI) have high morbidity. Staphylococcus aureus meticilin resistent(MRSA) has increased. Culture-based diagnosis is limited to recovering fastidious bacteria and in detecting polymicrobial infections. Alternatively, molecular methods offer a promising improvement for the diagnosis of BJI with reduced time to result. The aim of the study was to determine the correlation between culture results and the Film array™(FA) molecular panel in a cohort of pediatric patients with BJI.
Methods: Descriptive study. Patients admitted with BJI between July 1, 2019 and 31 December 2020 at HOMI, Fundación Hospital pediatrico La Misericordia, in Bogotá(Colombia). Blood cultures and synovial fluid samples were taken. Samples were kept at -70°C. On September 2022, BJI panel Film array™ was performed in sinovial fluid.
Results:

Graphic 1: Microorganisms isolated in culture/blood culture and/or film array™



38 patients were included. 23(60%) were positive by culture/Blood culture. The most frequent microrganism were Staphylococcus aureus 19(82,6%), 11(57,9%) were MRSA. Other microorganisms isolates were Streptococcus pyogenes, Streptococococcus pneumoniae, Streptococcus viridans, Streptococcus agalactiae. 24(63%) were positive by FA, 20 positive detections were concordant with culture, there were 6 additional isolates (2 S. aureus, 2 S. pyogenes, 1 Kingella kingae and 1 Candida spp) and 3 false negative (2 S. aureus and 1 S. agalactiae). Two patients with coinfection were detected, one with methicillin-susceptible Staphylococcus aureus(MSSA) + Streptococcus sp and another with MSSA + Streptococcus pyogenes. All MRSA were detected. (Graphic 1). In 27(71%) patients the etiology was documented by any method.
Conclusions/Learning Points: These results showed overall good correlation between BJI panel Film array and culture. Moreover, compared to culture, the BJI panel allowed the detection of more positive

samples (+11%) and more polymicrobial samples. There was adequate correlation of resistance genes (Mec A).

Title of Case: Cervical arthritis: An Unusual Presentation of Bartonella henselae infection
Background: Cat scratch disease (CSD) is usually caused by Bartonella henselae and is typically benign, commonly presenting with regional lymphadenopathy. Skeletal involvement is rare in CSD and most commonly involve the vertebrae.
Case Presentation Summary: A previously healthy 10-year-old immunocompetent female, presented with 8 days of high-fever, cervicalgia and torticollis. At examination, she presented good general condition, slightly reddened tonsils, left painful cervical tumefaction, no hepatomegaly or palpable adenomegalies. Initial laboratory evaluation showed no leukocytosis and CRP of 74mg/L. Neck ultrasound showed cellulitis and a right intramuscular paravertebral collection. Neck CT excluded parapharyngeal infection. Neck MRI evidenced posterior C4-C5 septic arthritis, piomyositis and small abscesses on the semispinalis capitis muscle. She was treated with flucloxacillin and clindamycin for 14 days with gradual improvement, but torticollis and cervical adenomegalies persisted. Bartonella henselae infection was confirmed by serology in two consecutive samples with IgG titer1024 and negative IgM) after 1 and 5 weeks of the onset of symptoms PCR was performed after antibiotic treatment and was negative. She reported frequent contact with kittens, and in one of the cats Bartonella infection was also confirmed. Antibiotherapy was switched to doxycycline and rifampicine with an improvement of the clinical condition.
Learning Points/Discussion: B. henselae C4-C5 osteoarthritis is rare, and should be considered in patients with unusual presentation, with systemic symptoms, back pain and cat contact. Diagnosis, antibiotic choice and duration of therapy remain challenging. MRI is essential for early diagnosis and complication prevention. The prognosis is generally good.

Title of Case: HEXAPOD EXTERNAL FIXATOR INFECTIONS IN CHILDREN. DESCRIPTIVE STUDY 2014-2022.
Background: Correction of limb deformity or shortening and complex fractures in children can be managed with distraction osteogenesis technique using hexapod external fixators. Retrospective descriptive and inferential study of all pin site infections in hexapods placed in children <18 years from 2014 to 2022.
Case Presentation Summary: Forty-seven hexapod external fixators were placed in 38 patients, 22 (46.8%) were female. The mean age at placement was 13.1 (± 3.1) years, involving tibia+fibula in 27 (57.4%) of the cases. The median number of pins/needles per hexapod was 7.00 [6.0;10.5] and the median treatment length was 191 [156;251] days. In 37/47 (78.7%) an infection was suspected on 1 or more occasions; a statistically significant higher infection rate was observed in those with longer hexapod treatment (196 vs 152 days; P=0.026). Empirical antibiotics were started on 53 occasions, mainly first generation cephalosporins. Fifty cultures showed growth in 42 (84.0%), MSSA isolated in 29/42 (69.0%) and coagulase-negative staphylococci in 7/42 (16.7%). MRSA was not identified in any case. The time from surgery to the first infection was 34.0 [27.0;57.0] days. Most infections were grade 2 (81.1%). The empirical antibiotic was changed on 15/50 (30.0%) occasions, due to poor clinical response in 6/50 (12.0%) and resistance in 4/50 (8.0%). The median time on antibiotics was 21.0 [16.0;35.0] days. The hexapod was removed due to infection in 1/37 (2.7%) case and in 3/37 (8.1%) a pin had to be removed.
Learning Points/Discussion: Infections in hexapods are very frequent, in general they are mild with a good response to oral antibiotics. MSSA is the most frequent causative microorganism in our setting, therefore a first-generation cephalosporin is an adequate empirical therapy.

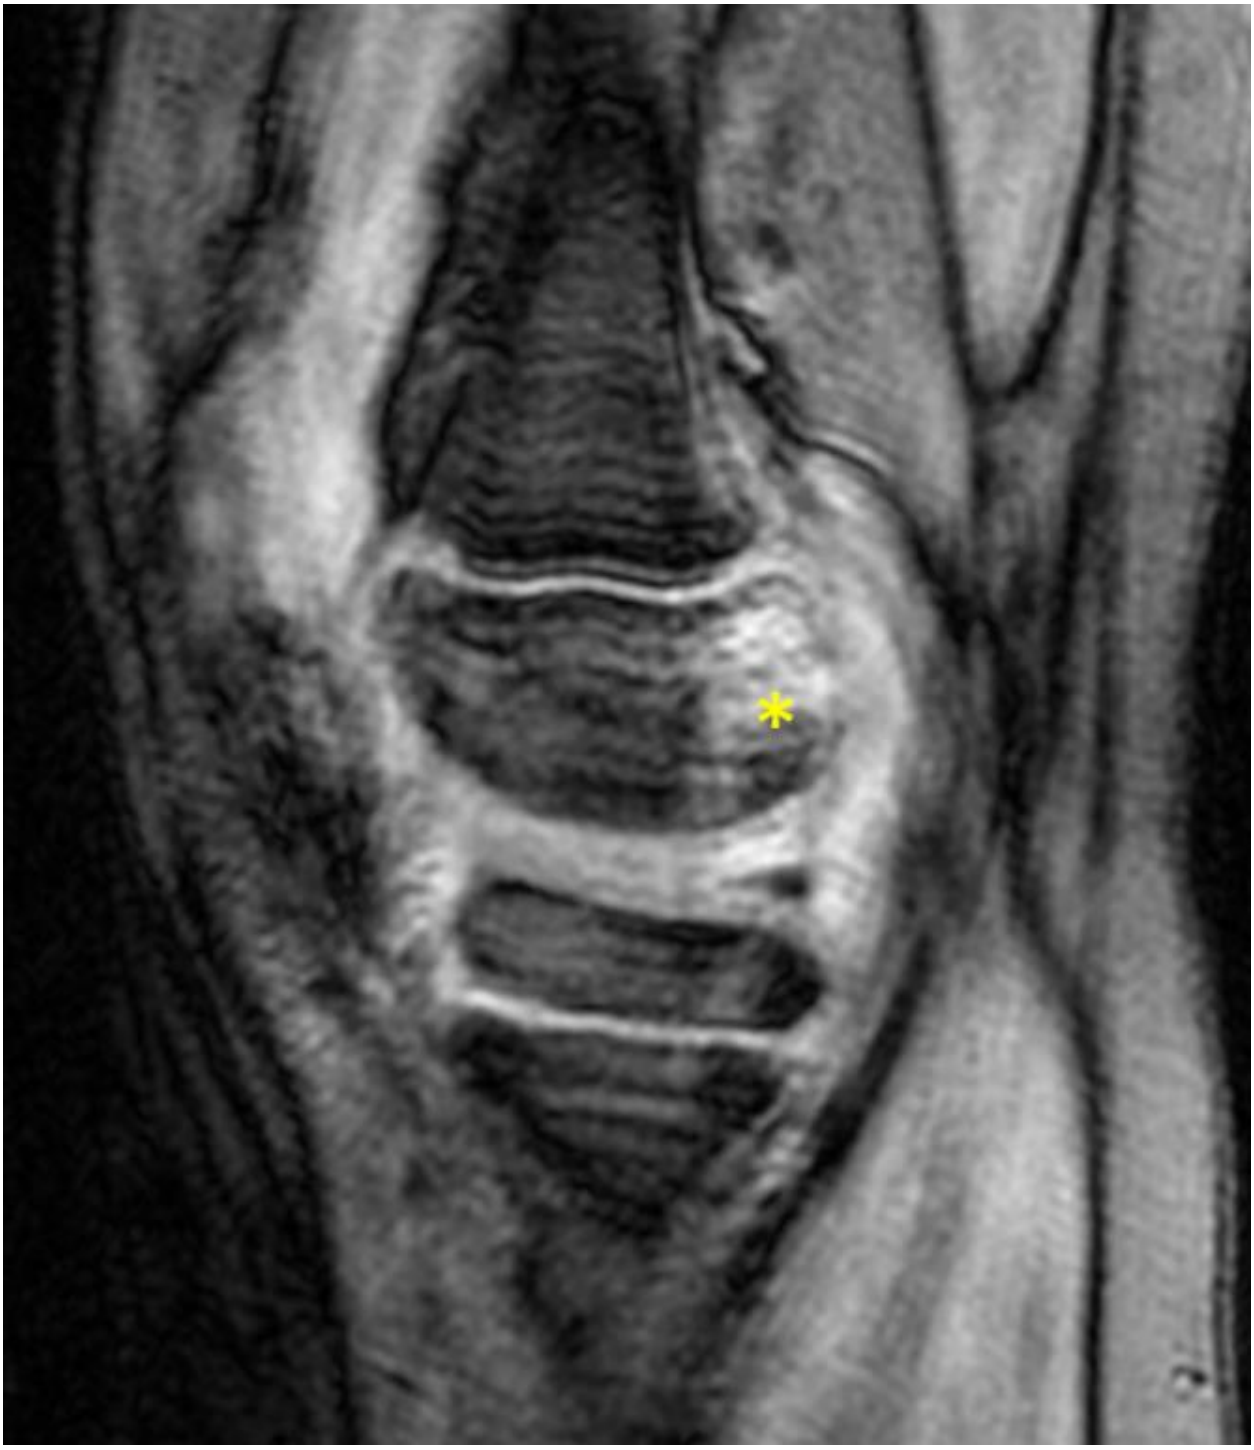
PV0548 / #1305

Q FEVER CHRONIC OSTEOMYELITIS IN A PEDIATRIC PATIENT AND ADVERSE EFFECTS OF TREATMENT WITH FLUOROQUINOLONES: A CASE REPORT.

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Maria Garcia Acevedo[1], Irene Gutierrez Rosa[2], Ana Sánchez Sánchez[2], María Sánchez Codez[2], Estrella Peromingo Matute[2]
[1]HOSPITAL UNIVERSITARIO PUERTA DEL MAR, Pediatria, CADIZ, Spain, [2]Puerta del Mar Hospital, Division Of Pediatric Infectious Diseases, Puerta Del Mar, Cadiz, Spain, Cádiz, Spain

Title of Case: Q FEVER CHRONIC OSTEOMYELITIS IN A PEDIATRIC PATIENT AND ADVERSE EFFECTS OF TREATMENT WITH FLUOROQUINOLONES: A CASE REPORT.
Background: Q fever chronic osteomyelitis is a rare (1-2% of infections by Coxiella burnetti) and underreported disease. Although the clinical spectrum includes a wide range of manifestations, most patients are asymptomatic. Farm animals are the main reservoirs, and transmission to humans usually occurs via inhalation of contaminated aerosols.
Case Presentation Summary: A previously healthy 8-year-old female patient came to hospital in February 2022 with swelling and pain in her left knee and a 2-week intermittent fever. She had a history of septic arthritis on the same knee in 2019. Despite living in a rural environment, she had no contact with livestock nor drinking unpasteurized milk. Blood test revealed negativity of acute phase reactants (6890 leukocytes, 2330 neutrophils, 271.000 platelets, CRP 2.3mg/L, ESR 14mm/h). Results of CT showed compatible signs with chronic osteomyelitis. The diagnosis was confirmed by detecting an elevated anti-phase I IgG titer (1:16384) in serological tests. On the second day of treatment with Ciprofloxacin and Rifampicin, she experienced acute pain in her right achilles tendon. In suspicion of tendinitis as an adverse side effect, treatment was replaced by Cotrimoxazole, with good clinical evolution afterwards. Currently, anti-phase I IgG titers have decreased
(1/1024).



Learning Points/Discussion: This diagnosis should be discarded in cases of chronic relapsing or multifocal osteomyelitis, particularly if there is a history of exposure to livestock. The optimum treatment is challenging, although the combination of two antimicrobials, one of them being a fluoroquinolone, is considered the best choice. Due to fluoroquinolone´s disabling adverse side effects, such as tendinopathies, the European Medicines Agency recommends the discontinuing of treatment at the first sign of any adverse effect.

CHRONIC OSTEOMYELITIS IN FRONTAL BONE AS A COMPLICATION OF GUNSHOT WOUND: A CASE REPORT.

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Ana Sánchez Sánchez[1], Irene Gutierrez Rosa[1], Maria Garcia Acevedo[2], María Sánchez Codez[1], Estrella Peromingo Matute[1]
[1]Puerta del Mar Hospital, Division Of Pediatric Infectious Diseases, Puerta Del Mar, Cadiz, Spain, Cádiz, Spain, [2]HOSPITAL UNIVERSITARIO PUERTA DEL MAR, Pediatria, CADIZ, Spain

Title of Case: CHRONIC OSTEOMYELITIS IN FRONTAL BONE AS A COMPLICATION OF GUNSHOT WOUND: A CASE REPORT.
Background: Gunshot wounds (GSW) are rare in Paediatrics. Therapeutic management and their complications are not well established, since there are hardly any cases described. Very limited review of the literature is focused on military scenarios and countries at risk of war. We describe a case of osteomyelitis secondary to a GSW in a developed country.
Case Presentation Summary: A previously healthy 14-year-old patient was admitted to hospital after a head trauma caused by a GSW. CT showed multiple fractures of both frontal bones and the left frontal sinus with a parenchymal hematoma (Figure 1A). A left frontal lobectomy and a bone graft were performed through a decompressive frontal craniectomy. Amoxicillin-clavulanic was used as surgery prophylaxis with favorable evolution. Five months later, he was readmitted due to leakage of purulent fluid through the surgical wound. Clinically afebrile, he presented a generalized seizure. The blood test showed leukocytosis (12.630uL) with neutrophilia (8890uL) and CRP 13.3mg/L. CT revealed signs of osteomyelitis in the frontal graft and a sub-periosteal abscess (Figure 1B). After craniectomy, bone resection, and a drainage, empirical ceftazidime and vancomycin were started. Methicillin-sensitive S.aureus was isolated in the bone culture. Therefore, treatment was optimized with intravenous cloxacillin during a month, with good clinical evolution afterwards. Currently, he is pending of a cranial prosthesis.
Learning Points/Discussion: Chronic osteomyelitis as result of a GSW is uncommon. The duration of antibiotic therapy ranges from 4-6 weeks if the resection of the grafted material is complete. Treatment can be sequenced orally if adequate bioavailability of the

antimicrobial.

EPIDEMIOLOGIC STUDY OF PEDIATRIC PYOGENIC ARTHRITIS (RECENT 20 YEARS): AN UPDATE

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Seungmin Jeong, Jaeho Cho, Taehun Kim, Jong Wha Lee
Ajou University Hospital, Department Of Orthopedic Surgery, Suwon, Korea, Republic of

Backgrounds: Although septic arthritis is rare disease, it is very important to keep the possibility of septic arthritis in mind. The doctors have to diagnose and manage the disease without delay because of various complications; destruction of the growth plate or cartilage, sepsis, death. The author presents the epidemiology of pediatric septic arthritis in the last 20 years.
Methods: Between March 1997 and December 2019 for 22 years, all patients under 17 years of age hospitalized Ajou Hospital with a diagnosis of septic arthritis were treated by surgical operation. Firstly, we select the patients who complain of the clincal symptoms. Among the patients, we apply inclusion criteria. We include the patients at least satisfied 2 inclusion criteria; 1) wbc≥10,000/μl, 2) CRP≥1.2mg/dL, 3) fever(≥37.8 ˚C). We define the septic arthritis that the patients' official image reading (MRI) is closely septic arthritis or identification of bacteria in patients' joint fluid or blood is positive.
Results: Among 92 subjects, as there were 55 boys and 37 girls(the gender ratio 1.48 to 1). The highest ratio in incidence of the septic arthritis was in age category of 1-6 years (29.3%). In the anatomical location of septic arthritis, we demonstrated the hip as the most common(52.2%), followed by knee(27.2%). When analyzing the frequency of causative bacteria, the Methicillin sensitive staphylococcus aureus group (MSSA) was the most common(19.8%), followed by MRSA(12.1%). When osteomyelitis was accompanied, the course of treatment was longer by about 10 days.
Conclusions/Learning Points: Septic arthritis is rare disease at a young ages, but pediatrician always has to keep the possibility of septic arthritis in mind because of severe sequela. Therefore, When treating a patient who complained of joint pain, the doctor must be taken for septic arthritis.

EVALUATION OF PEDIATRIC SEPTIC ARTHRITIS AND OSTEOMYELITIS CASES

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Yalçın Kara[1], Mahmut Kızıl[2], Merve Işeri Nepesov[3], Nidai Dalokay[4], Mustafa Kavak[5], Ömer Kiliç[1], Ener Çağrı Dinleyici[3]
[1]Eskişehir Osmangazi University, Pediatric Infectious Disease, ESKİŞEHİR, Turkey, [2]Eskişehir Osmangazi University, Pediatric Infectious, Eskişehir, Turkey, [3]Eskişehir Osmangazi University, Pediatric Infectious Disease, Eskişehir, Turkey, [4]Eskişehir Osmangazi University, Pediatric, Eskişehir, Turkey, [5]Eskişehir Osmangazi University, Ortopedics, Eskişehir, Turkey

Backgrounds: Childhood septic arthritis and osteomyelitis is an emergency clinical condition that can cause irreversible damage.The aim of this study was to evaluate the clinical and epidemiological features of pediatric patients presenting with septic arthritis and osteomyelitis.
Methods: Pediatric patients who were followed up at Eskişehir Osmangazi University Faculty of Medicine between 2017-2022 due to septic arthritis and osteomyelitis were included in the study. Epidemiological and clinical features were evaluated retrospectively.
Results: The mean age of 23 pediatric cases were 102(13-204) months and fifteen (65%) of the cases were male. 13 of the cases had septic arthritis and 10 of them had osteomyelitis.In septic arthritis cases, 61% had involvement in the knee joint, 30% in the hip joint, and 9% in the elbow joint. In osteomyelitis cases, 50% had ankle involvement, 30% had knee joint involvement, and 20% had hip joint involvement.While joint puncture was performed in 9 of 13 septic arthritis cases, leukocyte count of joint fluid was 67,340(8000-146,000)/mm3. In the joint fluid culture of septic arthritis cases, Staphylococcus aureus growth was found in 2 cases and mycobacterium tuberculosis in 2 cases. In the cultures of osteomyelitis cases; Staphylococcus aureus in 1 case, S.pyogenes in 1 case, and enterobacter in 1 case. Antibiotic treatment was given to all 23 cases, brucellosis treatment was given to 3 cases, and anti-tuberculosis treatment was given to 2 cases. The mean duration of treatment was 14 days (7-28) parenterally and 21 (7-42) days orally.
Conclusions/Learning Points: Septic arthritis and osteomyelitis in children are emergencies that require prompt diagnosis and treatment. For this reason, septic arthritis and osteomyelitis should be kept in mind, especially in children presenting with monoarthritis, and their diagnosis and treatment should be done quickly.

[1]"P.& A.Kyriakou" Childrens' Hospital of Athens, Second Department Of Pediatrics, National And Kapodistrian University Of Athens, Athens, Greece, [2]"P.& A. Kyriakou" Childrens' Hospital of Athens, First Department Of Orthopaedics, Athens, Greece, [3]"P.& A. Kyriakou" Childrens' Hospital of Athens, Microbiology Department, Athens, Greece

Title of Case: We present a toddler with severe skeletal infection by methicillin-susceptible S.aureus(MSSA), associated with bacteremia, which manifested features of Staphylococcal scalded skin syndrome(SSSS) and Kawasaki disease(KD).
Background: Staphylococcus aureus can cause a multitude of different diseases, either by direct tissue invasion or toxin-mediated. Some strains produce superantigens, leading to an activation of the host immune system.
Case Presentation Summary: A previously healthy 3-year-old male, with a recent history of leg injury, presented with high-grade fever for five days and rash. On admission, physical examination was remarkable for polymorphous rash, erythema and edema of palms and soles, erythematous lips and strawberry tongue. The patient had elevated CRP, anemia, hypoalbuminemia and hyponatremia. Blood cultures developed MSSA and the patient presented progressive, cutaneous erythema and desquamation, considered to be a toxin-mediated manifestation; thus, he was treated with intravenous cloxacillin and clindamycin. After 24hours of treatment, clinical examination revealed antalgic position of the left lower limb and restriction of motion of the hip. Ultrasonography and MRI demonstrated septic arthritis of the hip joint with femur pandiaphysitis. The patient underwent multiple surgical drainages. Because of persistent fever and the severity of skeletal infection, rifampicin was added and intravenous immune-globulin(IVIG) was administered, on high clinical suspicion of PVL-positive strain infection. In the 15th day of fever, incomplete KD was suspected as he developed periungual desquamation of the hands and feet, alongside with thrombocytosis. The echocardiogram revealed Z-score of the coronary arteries>2 and the patient was treated with IVIG 2g/kg and aspirin to which he immediately responded. The patient was discharged after 40 days of hospitalization with cardiologic, rheumatologic and orthopedic follow-up.
Learning Points/Discussion: This case shows the complexity of differential diagnosis and the consequent necessity of constant vigilance and review in clinical practice.

Title of Case: Pyomyositis: An uncommon cause of hip pain
Background: Pyomyositis is an uncommon bacterial infection of striated muscle, usually acquired by hematogenous route and most frequently caused by Staphylococcus aureus. If not treated properly, it can progress rapidly to a high-risk clinical situation and, possibly, death.
Case Presentation Summary: We present a 5-year-old healthy boy who presented to the Pediatric Emergency
Department (ER) with a 4-day history of fever, up-to 38.8ºC every 8h, as well as cough and rhinorrhea. On the 3 rd day he started complaining of left hip pain, which firstly resolved with non-steroidal anti-inflammatories. Over the last 24h, pain began worsening, and the child refused to walk, which led him to the ER.
At admission, physical exam showed worsening pain with external rotation movement of the hip and wide-based gait, as well as swollen tonsils. The rest physical exam was unremarkable.
Investigation began with a hip ultrasound, that showed no signs of synovitis. Analytically, white-blood-cell count was normal, but erythrocyte sedimentation and C-reactive protein were elevated (71mm/h and 37.4mg/L respectively). Given the suspicion of osteoarticular infection, an Magnetic resonance (MRI) was performed, revealing pelvic myositis, which affected the gluteus maximus and extended to the trochanteric bursa, with am hypoenhanced lesion of 14x11mm.
He was admitted to the Pediatric ward for endovenous flucloxacillin and clindamycin, completing 4 weeks of treatment.
On day 21 of treatment, we performed another MRI, showing size reduction of the lesions. Before discharge, an ultrasound was performed, with complete resolution of the infection.
Learning Points/Discussion: Given the rarity of pyomyositis, diagnosis requires a high suspicion, particularly in
healthy individuals, and must be confirmed by MRI. Treatment requires long courses of antibiotics, and the prognosis is usually favorable.

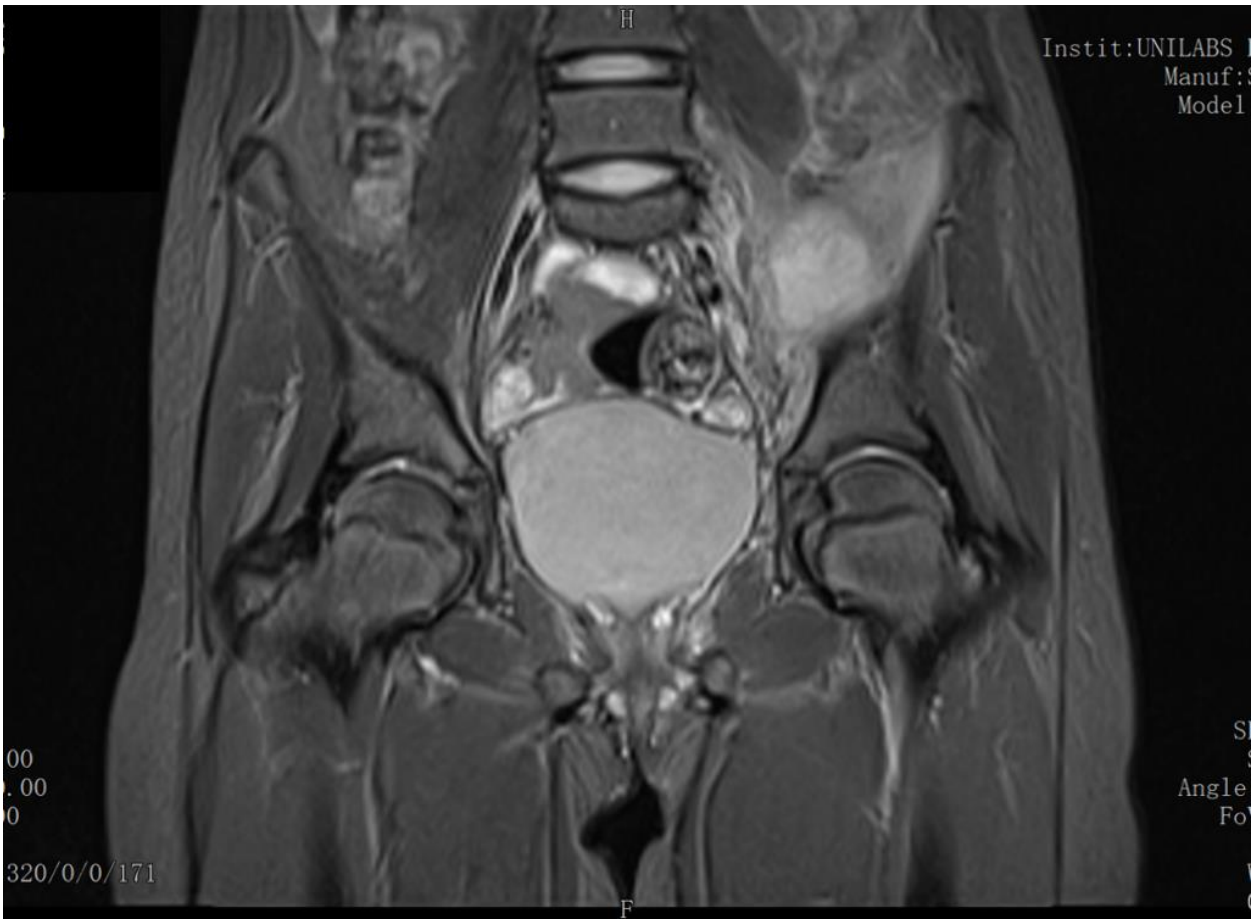
Title of Case: CLAUDICATION IN PAEDIATRIC AGE - A RARE CAUSE
Background: Claudication is a relatively common complaint in childhood and its etiology ranges from benign and self-limiting to potentially life-threatening conditions that must be identified and managed promptly.
Case Presentation Summary: A previously healthy 11-year-old girl was taken to the emergency department for gait claudication, progressively worsening pain in the left gluteal region for 4 days and 1 day of fever, maximum 39.0ºC. There was no history of local trauma or recent infections. On physical examination, she presented a reasonable general appearance and pain with left thigh movements. The blood sample revealed leukocytes of 12990/uL, an absolute neutrophilia and CRP of 201.8 mg/L. Two blood cultures were collected. The hip CT scan revealed a slight effusion of both hip joints, without liquid periarticular collections. She was evaluated by Orthopaedics and admitted in the Paediatric ward for multidisciplinary surveillance, pain control and intravenous antibiotic therapy with flucloxacillin due to a suspected diagnosis of sacroiliitis. The MRI confirmed a left sacroiliitis as well as a psoas abscess with a maximum diameter of 4.0 cm. A methicillin-sensitive Staphylococcus aureus was isolated from the blood culture. Given the good clinical response 96 hours after antibiotic therapy initiation, it was decided to maintain a conservative approach through 3 weeks of intravenous treatment, with a favorable clinical and analytical evolution. The reassessment MRI showed total regression of the abscess.



Learning Points/Discussion: There are few cases described showing a conservative approach in the management of psoas abscess, with most cases being managed through percutaneous surgical approach. The diagnosis requires a high degree of clinical suspicion, a multidisciplinary assessment and prompt empiric antibiotic therapy initiation. Clinical and analytical evolution may guide the need for surgical intervention.

Title of Case: Methicillin-Susceptible Staphylococcus Aureus (MSSA) as the cause of a severe and complicated osteoarticular infection (OAI) presented in an 11-year old patient.
Background: S.aureus is the main etiologic agent of OAIs in paediatric patients. MSSA and MRSA - notably PVL–positive - are a leading cause of morbidity.
Case Presentation Summary: An 11-year-old male without prior medical history presented to our Paediatric's Department due to 3-day history of fever, left knee pain and limping. On admission, he had left thigh and knee inflammation signs and a generalized pustular rash. Left lower limb MRI revealed femoral pandiaphysitis. Abdominal and chest CTs showed multiple lung and intestinal septic emboli. Triplex vascular ultrasound detected extensive thrombosis of left deep femoral vein. An MSSA lukF/S-PV (-), clfA (+), hla (+), sea (+), sec (+), seb (-), eta (-), etb (-), hlb (-), fnb (-) strain was isolated from multiple blood, synovial fluid and intraoperational bone specimens cultures. Clinical response to cloxacillin and clindamycin was poor with fever for four weeks and treatment was enriched with linezolid. The patient had undergone repeated surgical management. Due to the severe and non responsive to treatment infection, an immunology workup was presented and celiac disease was serologically diagnosed. The patient was discharged after 45 days of IV antibiotics and PO cloxacillin was to be continued for 3 months. Due to a recurrence of fever and inflammation signs, a repeat plain X ray and MRI showed involucrum formation of the femoral diaphysis.
Learning Points/Discussion: Although PVL - negative S.aureus infections could have a favorable prognosis, there are difficult cases to handle due to host's comorbidities and other than PVL toxin profiles. Unlike adults, literature does not support that celiac disease could lead to immunosuppression in children.

Title of Case: A CASE SERIES OF CHILDREN DIAGNOSED WITH BRODIE ABSCESS IN A SINGLE INSTITUTION
Background: Brodie abscess (BA) is a subacute osteomyelitis characterised by intraosseous abscess formation. The number of paediatric patients with BA reported in the literature is low and the therapeutic approach varies among healthcare professionals. We describe the clinical characteristics, treatment and outcomes of children with BA in our setting.
Case Presentation Summary: The 12 children in this study were diagnosed with BA between January 2010 and November 2022 in St. Joan de Déu Hospital, a tertiary care paediatric hospital in Barcelona, Spain. Figure 1 shows the clinical characteristics of the patients. Nine (75%) were female and median age was 7 years (interquartile range (IQR) 2.5 - 10.5). Median time to diagnosis was 5 months (IQR 1 - 9). Pain was the most frequent symptom (75%) and tibia the most frequent location (50%). All patients had a plain radiography and an additional imaging study (computed tomography or magnetic resonance). All patients received antibiotic therapy and all but one had surgery as first approach. Seven (58.3%) intraoperative cultures were positive, six of them with Staphylococcus aureus (one methicillin-resistant). Antibiotic regimes were mainly anti-staphylococcal penicillins and first generation cephalosporins. Median duration of antibiotic treatment was 5 weeks (IQR 4.0 - 7.1), and median time to switch-to-oral treatment was 6 days (IQR 3.5 - 10). No patient required a second surgery.
Learning Points/Discussion: Clinical presentation and microbiology were similar to that reported in the literature. The combination of surgical and medical treatment was successful in all cases. Parenteral treatment was shorter in most recent patients, but total antibiotic course duration was variable. The optimal antibiotic treatment of BA after surgery needs to be

clarified.

Year of diagnosis	Gender	Age (years)	Time-to-diagnose (months)	Bone	Bone segment	Symptoms	Diagnose CRP (mg/L)	Diagnose ESR (mm/hr)	Invasive procedure	ATB bead	Intraoperative Culture	Total ATB duration (weeks)	Switch to oral (days)	Complication

PASTEURELLA MULTOCIDA: FROM CAT'S MOUTH TO OSTEOARTICULAR INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Joana Neto[1], Pedro Pereira[2], Ana Melo[1], Maria Tavares[1]
[1]Centro Hospitalar S João, Pediatrics, Porto, Portugal, [2]Centro Hospitalar Universitário S João, Orthopedics, Porto, Portugal

Title of Case: A case of Pasteurella multocida osteoarticular infection
Background: Skin and soft tissue infections are frequent in children. Although uncommon, Pasteurella multocida is a microorganism to consider specially after dog and cat bites or scratches.
Case Presentation Summary: A previously healthy and fully immunized 12-yo female was observed in Emergency Department (ED) due to intense pain, inflammatory signs, and difficulty in mobilizing the right hand's 4th finger after being bitten by her domestic cat. After a normal hand radiography she was discharged with oral flucloxacillin and ambulatory dressing care. After two weeks, she returned to ED due to fever, progressive worsening of inflammatory signs and frequent purulent collections' drainage, even after changing the antibiotic therapy to amoxicillin-clavulanate. Laboratorial workup did not show elevated inflammatory parameters. Due to suspected proximal interphalangeal joint (PIA) septic arthritis, she underwent surgical cleaning and debridement and intravenous ceftriaxone and clindamycin, with a very favorable clinical and laboratorial evolution. After isolation of a multi-sensitive P. multocida, on the purulent drainage, antibiotherapy was de-escalated to Benzylpenicillin. She completed three weeks of intravenous antibiotic therapy and was discharged with oral amoxicillin-clavulanate. After an MRI documenting osteomyelitis, she prolonged antibiotherapy completing two months. Serial clinical, laboratorial, and radiological evaluations demonstrated progressive recovery. Currently, she has no limitation on her daily activity, but maintains PIA ankylosis due to bone destruction in consequence of osteoarticular infection.
Learning Points/Discussion: Animal bites are usually self-limiting and easily treated with oral antibiotics. When the bite is deeper, as in case of cat's sharper teeth, it can cause deeper infections by penetrating inoculation. This case demonstrates that P. multocida osteoarticular infection should be considered in cases of direct animal contact. Prompt intravenous antibiotics and surgery, have an important role in prognosis and long-term sequelae.

TEMPORO-MANDIBULAR JOINT ANKYLOSIS OF INFECTIOUS ORIGIN AT THE YAOUNDE UNIVERSITY TEACHING HOSPITAL: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Zilefac Brian Ngokwe, Nokam Kamdem Gimel Stephane, Ntep Ntep David Bienvenue, Kwedi Karl Guy, Tamoh Stive Fokam, Bengondo Messanga Charles
University of Yaounde I, Oral Surgery, Maxillofacial Surgery And Periodontology, Yaoundé, Cameroon

Title of Case: TEMPORO-MANDIBULAR JOINT ANKYLOSIS OF INFECTIOUS ORIGIN AT THE YAOUNDE UNIVERSITY TEACHING HOSPITAL: A CASE REPORT
Background: Temporomandibular joint (TMJ) ankylosis is a pathologic condition in which the mandible is fused to the mandibular fossa by bony or fibrotic tissues. The most common cause of TMJ ankylosis is trauma; however, other causes exist, including infectious (which has decreased since the advent of antibiotics), inflammatory, and congenital.
Case Presentation Summary: A 09-year-old girl was referred to us for management of a significant reduction in the mouth opening. Four years ago, the patient had several teeth extracted, which would have been followed by a local infection and suppuration and a progressive reduction of the mouth opening. Clinically the patient presented with a mandibular hypoplasia and a limited mouth opening A CT scan revealed a bilateral fibrous TMJ ankylosis with Topazian classification type 1. The diagnosis retained was a post-infectious Bilateral fibrous TMJ ankylosis
Learning Points/Discussion: Infections of dental origin might contaminate the joint both through the hematogenous route and through diffusion from close proximity, particularly from a secondary jaw osteomyelitis. Treatment of pediatric cases of TMJ ankylosis involves a lot of factors among which patient motivation and mandibular growth Given that the main complication is a re-ankylosis, Postoperative rehabilitation is essential and has to be started early.

SECONDARY MANDIBULAR OSTEOMYELITIS WITH A PATHOLOGICAL FRACTURE: A CLINICAL CASE

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Zilefac Brian Ngokwe, Ntep Ntep David Bienvenue, Nokam Kamdem Gimel Stephane, Bengondo Messanga Charles
University of Yaounde I, Oral Surgery, Maxillofacial Surgery And Periodontology, Yaoundé, Cameroon

Title of Case: SECONDARY MANDIBULAR OSTEOMYELITIS WITH PATHOLOGICAL FRACTURE: A CLINICAL CASE
Background: Pathological mandibular fractures, which occur in areas where bone has been weakened by an underlying pathological process, are uncommon, accounting for less than 2% of all mandibular fractures. Pathological fractures are typically determined by surgical interventions (third molar removal and implant placement), occur as a result of osteomyelitis, osteoradionecrosis (ORN), and bisphosphonate-related osteonecrosis of the jaw (BRONJ), are idiopathic, or are facilitated by cystic lesions, benign, malignant, or metastatic tumors
Case Presentation Summary: We present a case of a 13-year-old male patient who developed right facial swelling and limited mouth opening after a tooth infection, as well as multiple purulent cutaneous fistulas and a bird's profile (mandibular hypoplasia) An intraoral examination revealed generalized calculus and dental mobility in quadrants 3 and 4. We carried out an orthopantomography which revealed a mandibular body fracture and the diagnosis of secondary mandibular osteomyelitis with pathological fracture was retained. Sequestrectomy was performed, along with the placement of a reconstruction plate and sutures.
Learning Points/Discussion: Pathological mandibular fractures are complicated and difficult to treat due to their varied etiology and peculiar local and general conditions. Clinicians are frequently confronted with patients who have severely infected bone. Early detection and treatment are critical for reducing patient morbidity.

MAXILLARY OSTEOMYELITIS AND ORBITAL CELLULITIS IN A CHILD WITH OSTEOPETROSIS: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Danang Setyo Nugroho[1], Mulki Angela[1], Resna Sary[1], Oktrian Oktrian[2], Resita Sehati[3], Haryanti Wulandari[3], Nina Dwi Putri[3]
[1]Paediatric Resident, Department Of Child Health, Faculty Of Medicine University Of Indonesia, Cipto Mangunkusumo Hospital, Jakarta, Indonesia, [2]University of Indonesia, Faculty Of Medicine, Jakarta, Indonesia, [3]Paediatrician, Department Of Child Health, Faculty Of Medicine University Of Indonesia, Cipto Mangunkusumo Hospital, Jakarta, Indonesia

Title of Case: MAXILLARY OSTEOMYELITIS AND ORBITAL CELLULITIS IN A CHILD WITH OSTEOPETROSIS: A CASE REPORT
Background: Osteopetrosis is a rare hereditary bone disorder characterized by an increase in bone density and reduction of marrow spaces. Maxillary osteomyelitis and orbital cellulitis are uncommon complications.
Case Presentation Summary: A 7-year-old boy was brought to hospital due to swelling on the left side of face and eye for 1 month before admission. Patient had fever accompanied by pain when chewing. Physical examination showed pale, left orbital proptosis and edema on left side of face, palatal defect, gangrene of radix and pulp. Laboratory examination revealed pancytopenia, increased CRP and procalcitonin level. Culture obtained from necrotic palatal defect revealed growth of Citrobacter freundii and Streptococcus alpha-hemolytic which were sensitive to ampicillin sulbactam. Skeletal survey showed sclerotic and increased density of skull, spine, pelvis, and appendicular bone; Erlenmeyer flask deformity of both femur; “bone-in-bone” appearance of metacarpal bone; “hair-on-end” appearance in bilateral ilium superior; and “sandwich” vertebrae. Computed tomography of the paranasal sinuses was suggestive of maxillary osteomyelitis and left orbital cellulitis. Treatment included high-dose intravenous ampicillin sulbactam and debridement of necrotic bone. After 2 months, the patient came without active infection.
Learning Points/Discussion: Diagnosis of osteopetrosis is often delayed due to rarity of the disease, lack of clinical suspicion, and depends mainly on radiographic examination. Maxillary osteomyelitis and orbital cellulitis are serious complications of osteopetrosis related to odontogenic infection and its management is challenging.

SPONDYLODISCITIS: A CLINICAL AND IMAGING PITFALL IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Angele Bec, Antoine Ouziel, Luc Panetta, Dominique Ploin
Hôpital Femme Mère Enfant - Hospices Civils de Lyon, Emergency - Infectious Disease, Bron, France

Title of Case: Spondylodiscitis: a clinical and imaging pitfall in children
Background: Spondylodiscitis (SD) is an uncommon disease in children, with a significant risk of complications when diagnosis is delayed.
Case Presentation Summary: Three cases, aged from 18 months to 3 years, were lately diagnosed in our department with lumbosacral SD in which the clinical diagnosis were challenging and radiological findings misleading. The clinical presentations were evocative of SD. They presented with limping, lumbar or tight pain. Refusal of the potty was found in each of them but none had fever neither inflammatory syndrome. First, a negative bone scintigraphy (BS) ruled out BJI diagnosis. In front of the persistence of symptoms, MRI was then performed, and confirmed SD. A 7.7-day-mean delay was observed between negative BS and antibiotic start.
Learning Points/Discussion: The objective of the cases was to discuss respective strengths and weaknesses of clinical pictures, BS, and MRI for the diagnosis of SD in children. Blood samples are known to be non-contributive. For imaging strategies, BS is rather easily available for children, and is very useful when the clinical examination signs and/or pain are poorly localized, and thus should not be excluded from the diagnostic tree. Possibility of false negative results are demonstrated in our cases. When the clinical picture is evocative, the risk of false negative makes MRI imperative. As stated by ESPID guidelines, MRI remains the reference diagnostic tool for SD, despite limited availability and frequent requirement of a general anesthesia. Precise and careful physical examination justifies going further than BS, and going beyond MRI accessibility difficulties. In our cases initial BS have misguided the diagnostic approach. The delay in diagnosis confirmation created diagnostic wandering, major anxiety in the parents and postponement of treatment

DIPLOPIA IN A 10-YEAR-OLD BOY WITH RETROPHARYNGEAL ABSCESSES

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Valeria Rubinacci[1], Cristina Epalza[2], Judit Jiménez-Betancort[2], Pablo Rojo[2], Daniel Blázquez-Gamero[2], Ángela Manzanares[2], Luis Prieto[2], Serena Villaverde[2], Cinta Moraleda[2], Ignacio Jimenez[3], Ana Martinez De Aragòn[4], Elisa Fernandez-Cooke[2]
[1]Hospital 12 de Octubre, Madrid- University of Milan, Pediatric Infectious Diseases, Madrid, Spain, [2]12 de Octubre University Hospital, Pediatric Infectious Diseases, Madrid, Spain, [3]Hospital 12 de Octubre, Madrid, Spain, Ent, Madrid, Spain, [4]Hospital 12 de Octubre, Madrid, Spain, Radiology, Madrid, Spain

Title of Case: DIPLOPIA IN A 10-YEAR-OLD BOY WITH RETROPHARYNGEAL ABSCESSES
Background: Retropharyngeal abscesses may extend to adjacent sites and cause serious complications. Clival involvement is extremely rare.
Case Presentation Summary: A 10 year-old boy, presented with frontal oppressive headache, photophobia, posterior neck pain and stiffness. Afebrile. He was hospitalized for suspected meningitis and empirical antibiotherapy (cefotaxime and vancomycin) was started after a failed LP. Diplopia appeared 48 hours later, due to bilateral sixth nerve paralysis. CT scan and MRI revealed retropharyngeal abscesses with prevertebral extension and probable clival osteomyelitis, later confirmed by scintigraphy. Metronidazole was added and surgery with transoral approach was performed; the purulent drainage resulted positive for Streptococcus intermedius. A second LP ruled out meningitis while showing a high opening pressure. In the following 2 weeks, due to clinical and radiological worsening, he was operated twice, via both cervical and transoral access. Mycotic and mycobacterial infections were ruled out. Afterwards, he remained afebrile, with persistent, yet improving, sixth nerve paralysis, and evidence of glossopharyngeal nerve involvement, of uncertain post-surgical or infectious nature. Last follow-up MRI, after 6 weeks of IV therapy, revealed reduction until disappearance of the abscesses, and improving clival involvement. Therefore, oral switch to amoxicillin and metronidazole was made to complete 3 to 6 months of treatment.
Learning Points/Discussion: Our case is noteworthy given the little evidence regarding clival osteomyelitis as a complication of retropharyngeal abscess particularly in children. Clinicians must remain alert and consider this eventuality especially when documenting cranial nerves involvement. Since this is an area of difficult surgical access, a multidisciplinary management and early treatment with antibiotics with optimal bone penetration are crucial, as well as strict follow-up given the high risk of complications and relapses.

German Trias i Pujol, Pediatrics, Barcelona, Spain, [19]Hospital Josep Trueta, Paediatrics, Girona, Spain

Backgrounds: Primary pyomyositis (PP) is not frequently diagnosed in children since it often accompanies osteoarticular infections (secondary pyomyositis-SP). Therefore, there is a scarce of guidelines for its management in children. The aim of this study was to evaluate epidemiological, clinical and microbiological characteristics of children with PP and compared them with those with SP.
Methods: Retrospective, multicenter study to evaluate children with PP admitted to 12 hospitals in Spain from 2015-2022. Medical charts were reviewed and children with the diagnosis of PP were included. SP were obtained from the RioPed network database located in a RedCap Platform from the same period of time. Children with PP were compared with those with SP.
Results: 180 children with pyomyosytis were evaluated (68 PP; 112 SP). Children with PP were younger (39.0[17.3-91.0] vs 76.0[22.0]134.0 months). There was a trend of higher rate of risk factors (54.5% vs 40.6%; p=0.077) and decrease mobility (89.0 vs 79.4%;p=0.084) in children with SP. A bacterial isolate was obtained in 49.7% (80/161) of cases (PP 26.9% vs SP 65.0%;p<0.001), being MSSA (62.5%), S. pyogenes (11.3%) and MRSA (10.0%) the most common isolates. SP received more frequently an MRI (96.4 vs 74.6%; p<0.001) and surgical treatment (83.9 vs 16.1%;OR 95% CI:5.03[2.33-10.82]). They also recieved more days of hospitalization (13[9-19] vs 8[7-15];p<0.001) and antibiotic therapy (38.0[28.0-42.7] vs 28[21.0-36.0];p<0.01). Sequelae were more often reported in the SP group (21.0 vs 4.4%;OR 95% CI:5.75[1.65-20.03]).
Conclusions/Learning Points: In this study children with PP were younger than those with SP, but with better clinical outcome, less surgery and less rate of sequelae.An isolate was more frequent in SP, being S. aureus/S. pyogenes the most common bacteria . These findings may help the clinicians to better manage these rare infections.

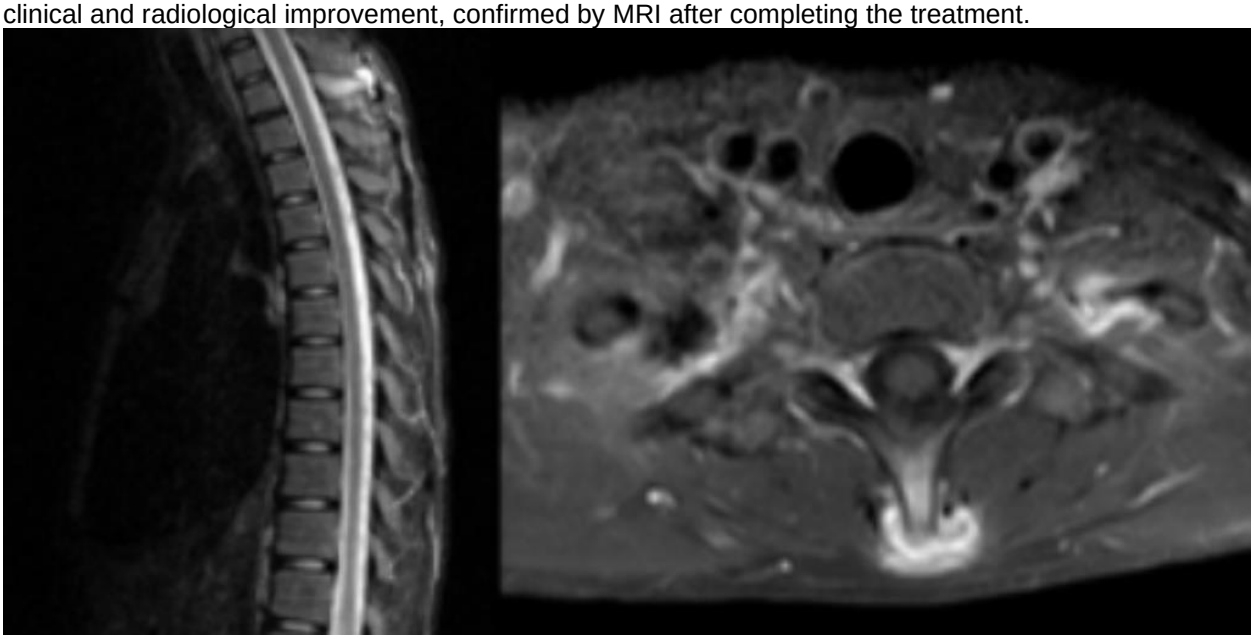
WHEN ACNE GOES FURTHER THAN THE SKIN: AN UNEXPECTED CASE OF NATIVE CHRONIC VERTEBRAL OSTEOMYELITIS CAUSED BY CUTIBACTERIUM ACNES.

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Gisela Pérez Gil[1], Vanessa Laveglia[1,2], Nathalia Joaqui[1,2], Iván García Pérez[1], María Gratacós De Aguilera[1], Ivet Bou Figueras[1], Pere Sala Castellvi[1,2]
[1]Hospital Universitari General de Catalunya, Department Of Paediatrics, Barcelona, Spain, [2]Hospital Universitari General de Catalunya, Paediatric Infectious Disease Department, Barcelona, Spain

Title of Case: When acne goes further than the skin: an unexpected case of native chronic vertebral osteomyelitis caused by Cutibacterium acnes.
Background: Cutibacterium acnes (C. acnes) is an anaerobic gram-positive bacteria that is a part of the normal flora of skin. It is mainly known for its pathogenesis in acne vulgaris, but has also been recognized as a cause of medical device-related infections, and most common in immunocompromised patients.
Case Presentation Summary: A 14-year-old male with a medical history of juvenile acne and autoimmune neutropenia, presented to the emergency department with a 4-week history of pain in the upper dorsal region, without fever. Comedonal acne on face and back, without any other signs around the painful area. Blood test showed neutropenia (ANC 1.000/uL) with normal values of CRP and ESR. A cervical and thoracic spine MRI showed a nodular image of soft tissue at the tip of the spinous process of D1 (14x18x17mm), that eroded the cortex of the spinous process, associating mild underlying bone edema, indicative of osteomyelitis in D1 spinous process. Bone and nodule biopsies were performed guided by CT scan. Two samples of the nodule culture were positive for C. acnes, and the bone histology showed bone trabeculae surrounded by fibrous tissue and chronic inflammatory cellularity. The patient received a single dose of G-CSF and ampicillin, continuing with amoxicillin for a total of 3 months, with clinical and radiological improvement, confirmed by MRI after completing the treatment.



Learning Points/Discussion: Risk factors for vertebral osteomyelitis caused by C. acnes are usually associated with a history of surgical intervention. Nevertheless, immunocompromised patients including neutropenia should be taken into consideration, especially as the clinical manifestations could be more subtle and inflammatory markers are usually negative.

OROPHARYNX KINGELLA KINGAE PCR AND OSTEOARTICULAR INFECTIONS

E-Posters Viewing
E-POSTER VIEWING: AS07.E. SKELETAL INFECTIONS

Madalena Torrado Malato, Inês Pereira Soares, Inês Azevedo Carvalho, Maria Beatriz Morais, Mafalda Casinhas Santos, Florbela Cunha
Hospital de Vila Franca de Xira, Pediatrics, Lisboa, Portugal

Backgrounds: Kingella Kingae (KK) is the most common cause of septic arthritis and osteomyelitis in children aged 6 to 48 months. Osteoarticular infections (OAI), are a challenging diagnosis due to subtle clinical and laboratory findings. If untreated, OAI can evolve into serious complications for the child's bone development.
Methods: We analyzed the relationship between the identification of oropharynx KK polymerase chain reaction (PCR) and the diagnosis of acute OAI in children at a level 2 hospital. This retrospective descriptive study included all children which, between June/2018 and December/2022, underwent KK survey in the oropharynx and presented symptoms of OAI. Data analysis was done using Microsoft Excel and Software R.
Results: Twenty-seven children with average age of 2.9 years were studied (40.7% female, 59.3% male). The lower limbs were the most affected (92.6%), especially the knee (7), the coxofemoral (7) and tibiotarsal (6) joints. The prevalent symptoms were gait claudication (88.9%), pain (66.7%) and fever (63%). Hospitalization was required in 16 cases (59%) where a significant majority were females (p-value=0.0076). We found statistically significant relationship between children with positive oropharynx KK and OAI diagnosis (p-value=0.085). All these children were treated with antibiotics for an average of 21 days.
Conclusions/Learning Points: OAI have an impact on children's lives leading to hospitalization in the majority of cases. The primary affected joints were the extremities of the long bones, namely the lower limbs, which is in accordance with the literature. Oropharynx KK PCR is an accessible method that confirms the etiological diagnosis and should be routinely performed in all children younger than 4 years with clinical manifestations of OAI.

WHEN CHICKENPOX IS NOT SO BENIGN

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Daniela Araújo[1,2], Sandra Catarina Ferraz[2], Joana F. Pires[2,3], Sara Geraldes Paulino[2,4], Vera Teixeira[5], Pedro Marinho[2], Hugo Rodrigues[2]
[1]Hospital de Braga, Paediatrics Department, BRAGA, Portugal, [2]Unidade Local de Saúde do Alto Minho, Paediatrics Department, Viana do Castelo, Portugal, [3]Centro Hospitalar Vila Nova de Gaia/Espinho, Paedicatrics Department, Vila Nova de Gaia, Portugal, [4]Centro Hospitalar e Universitário do São João, Paedicatrics Department, Porto, Portugal, [5]Unidade Local de Saúde do Alto Minho, Dermatology Department, Viana do Castelo, Portugal

Title of Case: When chickenpox is not so benign
Background: Chickenpox usually runs a benign course. Although, rarely, complications may occur.
Case Presentation Summary: A previously healthy 6-year-old boy presented to the emergency department (ED) with fever for the last five days. Six days prior he had developed a papulovesicular rash in his chest and abdomen that later progressed to his legs, arms and face. He was examined by his primary-physician 3 days before admission and, based on previous contact with a child with chickenpox and in the absence of immunization against varicella-zoster virus (VZ), was started on oral acyclovir. On admission, skin lesions with a necrotic centre and surrounding erythema were noted (Fig 1A,B). Micropapular and crusted lesions were also present. Laboratory investigation showed no major findings. The patient was started on oral and topical antibiotic therapy and discharged. He returned to the ED 3 days later for maintaining the complaints. On admission he appeared ill and uncomfortable and had multiple infected postulated painful lesions (Fig 1C,D). His blood tests showed elevated inflammatory markers, anaemia and hypoalbuminemia. The patient was admitted to the ward and started on intravenous flucloxacillin, clindamycin and acyclovir. In the absence of any clinical improvement, flucloxacillin was switched to linezolid and the patient improved. Serological and DNA testing were positive for VZ. Staphylococcus aureus was isolated from the purulent material collected from an abdominal lesion. Patient was discharged after completing 10 days of intravenous antibiotic and antiviral therapy.

Learning Points/Discussion: Varicella gangrenosa, a type of necrotizing fasciitis, is a complication of chickenpox. Recommended treatment includes acyclovir and antibiotics with effective streptococcal and staphylococcal coverage. Debridement is often required. Although rare, it is potentially life-threatening, and therefore its recognition and timely treatment are crucial.

ORBITAL CELLULITIS – AN EXUBERANT MANIFESTATION WITH POSSIBLE OPHTHALMOLOGICAL ENVOLVMENT

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Rita Calejo[1], Joana Carvalho Queirós[2], Joaquim Cunha[1], Sandra Teixeira[1]
[1]Centro Hospitalar Tâmega e Sousa, Department Of Pediatrics And Neonatology, Penafiel, Portugal, [2]Centro Materno Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatrics, Porto, Portugal

Title of Case: ORBITAL CELLULITIS – AN EXUBERANT MANIFESTATION WITH POSSIBLE OPHTHALMOLOGICAL ENVOLVMENT
Background: Orbital cellulitis is an infection that affects the orbital fat and extraocular muscles and is more common in young children. One of the main differential diagnosis is periorbital cellulitis, which can have similar clinical manifestations. However, the correct diagnosis is crucial, since orbital cellulitis can have severe consequences, especially ophthalmological and intracranial.
Case Presentation Summary: We present a case of a male 9 years-old child, with Attention Deficit and Hyperactivity Disorder. He presented to the Emergency Department with fever and bilateral eyelid swelling and erythema with 30 hours evolution. He was firstly evaluated at the beginning of clinical manifestations, medicated with flucloxacillin and completed one day of treatment. At observation, he presented exuberant bilateral upper and lower eyelid swelling and erythema, more evident in the right side with incapacity to open the eye, and swelling and erythema of the right malar area (Figure 1). Computed Tomography Scan showed acute pansinusitis, fat densification and postseptal extension of the infectious process in the right side, with superior ophthalmic vein dilation. He was observed by Ophthalmology with no apparent ocular involvement and with daily evaluation needed. He was admitted to the pediatric ward and started treatment with Ceftriaxone, Clindamycin and systemic corticotherapy. He was apyretic since the beginning of treatment and showed progressive improvement of the swelling and erythema. No other ophthalmological alterations were detected. He completed 10 days of intravenous treatment and 14 in total.

Learning Points/Discussion: In all cases of orbital cellulitis, a correct diagnosis and prompt beginning of treatment is essential to a favorable clinical evolution and absence of severe complications. Ophthalmological involvement and its potential consequences should always be one of the major concerns.

EXUBERANT MANIFESTATION OF VARICELLA – A CLINICAL CASE

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Joana Carvalho Queirós[1], Rita Calejo[2], Bárbara Costa Correia[2], Joaquim Cunha[2], Rosa Barbosa[2], Carla Brandão[2]
[1]Centro Materno Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatrics, Porto, Portugal, [2]Centro Hospitalar Tâmega e Sousa, Paediatrics And Neonatology, Penafiel, Portugal

Title of Case: EXUBERANT MANIFESTATION OF VARICELLA – A CLINICAL CASE
Background: Chickenpox is a common infectious disease in childhood caused by primoinfection with the varicella-zoster virus (VZV). Although generally considered a benign and self-limited disease, complications can occur in 2 to 5% of cases, being bacterial over-infection the most frequent.
Case Presentation Summary: We describe a case of a female 13-months-old child, with a diagnosis of chickenpox 10 days prior to the observation. Portuguese National Vaccination Programme is updated without other vaccines. Evaluated at the Emergency Department (ED) with large erythematous lesions in both axillae and right inguinal region with 4 days of evolution (Fig 1) and 24 hours of fever. The previous chickenpox lesions had a favorable evolution until then. Well appearing at physical examination and with multiple scattered lesions with a pink base, exudative at the centre and desquamative at the edges. The two largest had a major diameter of 10 cm with more erythematous areas, located in the left axillae and right inguinal area. Multiple vesicles in healing phase scattered over the body. She was admitted to the pediatric ward with intravenous amoxicillin/clavulanic acid and topical bacitracin. The exudate of the lesion was positive for VZV. Apyretic since day 3 and favorable evolution of the lesions, with adequate healing. Completed 7 days of intravenous antibiotherapy and 10 in total. A follow-up consultation was scheduled.

Learning Points/Discussion: This case shows an exuberant manifestation of a common pathology in pediatric age. Although the majority of over-infections only require oral treatment, the more severe ones involve intravenous treatment and exclusion of the main differential diagnosis.

Title of Case: Actinomyces Timonensis sp. in a healthy child with recurrent cutaneous abscesses
Background: Actinomyces Timonensis is a novel species of the genus Actinomyces that was isolated in humans only once in a 13-year-old girl with sacroiliitis and long history of osteo-articular condition.
Case Presentation Summary: We present the case of a 2-year-old girl with 5-months history of recurrent cutaneous abscesses resistant to multiple antibiotic therapy. Before our assessment a subcutaneous mass of 30 mm x 25 mm in left cervical region required surgical drainage. Personal and family medical history was non-significant. She was afebrile and systemically well, physical examination showed multiple furuncles on her chest and neck, impetiginized skin lesion of the scalp and cutaneous infection of distal phalanges of hand’s
fingers.

White blood cell count was in the normal range and C-reactive protein level was negative. No alteration was found in immunological exams. The cultural analysis performed on a superficial swab of the lesion revealed the presence of A. Timonensis. The identification was performed with mass spectrometry, MALDI-tof MS. A. Timonensis was susceptible to clindamycin, meropenem, penicillin G, piperacillin-tazobactam and vancomycin, but resistant to metronidazole, similarly to the strain previously isolated. Conditions predisposing to cervicofacial actinomycosis like dental caries, trauma or immunocompromised state were not found in our patient. Infection was treated with three weeks of intravenous antibiotic therapy with teicoplanin, replaced by meropenem after determination of antimicrobial susceptibility, followed by two weeks of oral clindamycin, with total regression of skin lesions and no recurrence observed for a six-month follow-up period.

Learning Points/Discussion: Actinomycosis due to novel strain such as A. timonensis may represent a novel antimicrobial entity involving even immunocompetent children with recurrent abscesses. A prompt diagnosis may ensure an appropriate therapeutic management.

ORIGIN AND METABOLIC REWIRING OF DERMAL MACROPHAGES DRIVE IMMUNITY AND IMMUNE MEMORY IN BACTERIAL INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Philipp Henneke[1], Aaron Forde[2]
[1]University Medical Center Freiburg, Cci, Freiburg, Germany, [2]University Medical Centerr Freiburg, Cci, Freiburg, Germany

Backgrounds: The skin needs to tune immunity to colonizing, sporadically invading and chronically infecting bacteria. Conceptionally, a flexible response machinery is required to accommodate the dynamic challenges of efficient antimicrobial defence and restoration of tissue homeostasis. Dermal macrophages critically provide immunity against the skin colonizer and opportunistic pathogen Staphylococcus aureus, as well as to Mycobacterium spp. causing chronic infections.
Methods: Here, we dissected the impact of origin, cell-intrinsic mechanisms and micro-environmental cues on macrophages in localized dermal infections by adapting metabolic profiling, single-cell transcriptomics, fate mapping, and high resolution imaging.
Results: We found that in acute staphylococcal infection, cell intrinsic metabolic rewiring is required for the resolution of infection and acquisition of innate immune memory– largely irrespective of macrophage origin. This rewiring program relied on GM-CSF produced by distinct T-cell subsets and hypoxia conditioning the dermal microenvironment, thus metabolically diverting macrophages away from a homeostatic M-CSF and HIF-1alpha dependent program. Mechanistically, the expression of IRG1 and generation of itaconate were essential for tight immune control. In contrast, dermal (and soft tissue) immunity to chronic infection with Mycobacterium spp. heavily depended on incoming, i.e. monocyte-derived macrophages and their intrinsic differentiation programs, which steered antibacterial activity, diversification of macrophage subsets and tissue repair. This contrasts homeostasis, where barrier tissue macrophages display profound plasticity in filling microanatomical niches even in the absence of incoming macrophages.
Conclusions/Learning Points: In summary, during bacterial skin infections dermal macrophages receive complex, and infectious agent specific exogenous and endogenous cues that allow for cycling between fierce antimicrobial activity, resolution of inflammation and immune memory.

QUANTIFYING THE RATE OF VARICELLA ASSOCIATED COMPLICATIONS

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Hiral Shah[1], Anne Meiwald[2], Alex Hirst[2], Chamath Perera[2], Yunni Yi[2], Hadisa Awan[2], Pratishtha Khanduri[3], Nicolas Jamet[4]
[1]GSK, Value Evidence And Outcomes, London, United Kingdom, [2]Adelphi Values PROVE, Health Economics And Data Analysis, Bollington, United Kingdom, [3]Evidera, Modelling & Simulation, London, United Kingdom, [4]GSK, Value Evidence And Outcomes, Paris, France

Backgrounds: Varicella (chickenpox) is an infectious disease caused by the varicella-zoster virus (VZV) affecting both children and adults. Varicella symptoms are usually considered mild, however differing complications with widespread and systemic manifestations can occur. This study systematically reviews and quantifies varicella complication rates.
Methods: Two databases (Embase and MEDLINE), congress abstracts, and reference lists of systematic reviews were searched to identify evidence on varicella complications. Healthy/immunocompetent/immunocompromised individuals who developed viral/breakthrough varicella infection were included. Outcome of interest was the percentage of patients with varicella-associated complications. Proportional meta-analyses were performed using a random-effects model. Subgroup analysis, sensitivity analysis, and heterogeneity and publication bias tests were performed.
Results: Of the total 2030 records identified, 78 papers fulfilled the meta-analysis eligibility criteria. Complications were categorized into 14 clinically relevant sub-groups. Overall, the percentage of patients with any varicella complication was 25.29% (95% confidence interval [CI] 22.09–28.64). The most frequent types of complication in patients with varicella were severe varicella (22.42%; 95% CI, 10.13–37.77), skin-based complications (20.12%; 95% CI, 15.48–25.20) and infection-based complications (10.03%; 95% CI, 7.47–12.90) (Table 1). All other pooled complication subgroup rates ranged from 0.5% to 10%. Observations suggested that complications were generally more prevalent in children and patients hospitalized for varicella. There was substantial heterogeneity in all subgroups (94%–100%) (Table 1) and publication bias was
observed.

Table 1. All complications summary table

Complication Category	Related studies (reference number)	Sample size	Complication rate, % (95% CI)	Heterogeneity

ONYCHOMADESIS IN CHILDREN AS A LATE COMPLICATION OF HAND-FOOT-MOUTH DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Malvina Javakhadze[1,2], Manana Kachlishvili[2], Irma Korinteli[3], Tamar Didbaridze[4]
[1]Tbilisi State Medical University, Infectious Diseases Departament, T'bilisi, Georgia, [2]Acad.V.Bochorishvili clinic, Pediatric, T'bilisi, Georgia, [3]Tbilisi State Medical University, Pediatric, T'bilisi, Georgia, [4]Tbilisi State Medical University, Microbiology, T'bilisi, Georgia

Title of Case: Onychomadesis in children as a late complication of hand-foot-mouth disease
Background: Hand, foot, and mouth disease (HFMD), caused by an enterovirus is common in children under 5 years, especially in the last decade. The illness is usually not serious, but is very contagious and it spreads very easily. It is characterized by clinical diversity, the severity varies from mild to severe. Complications are not common, although there is a rare but noteworthy complication - Onychomadesis. Nail abnormalities range from leukonychia and Beau lines to partial or complete nail shedding. The pathogenesis is not fully understood.
Case Presentation Summary: The patient, a 4-year-old girl, came to us with complaints-changes in her nails. The patient referred to different doctors, but an accurate diagnosis was not given. In dynamics, the situation became complicated, the damage increased and spread to other fingers as well and later resulted in complete nail shedding. The temperature was normal. Objective examination showed no changes in the internal organs (Fig.N1, 2, 3) According to the parent's narration and description, 5 weeks ago she had HFMD (Fig. N4,5). After 3 days of fever, the condition improved, she had rash of medium intensity, which disappeared without a trace in 8 days. Symptomatic therapy had been administered. It was re-examined after 80 days, when the process was completely resolved and the child had healthy nails. In the case of Onychomadesis of other etiology, long-term local therapy is considered.

Learning Points/Discussion: Onychomadesis is a rare complication of HFMD which appears 5 weeks after the onset of the disease, and should be known to pediatricians and family physicians, as well as to dermatologists, because in this case, no additional special treatment is considered, since it is a self-limiting process.

PARINAUD OCULOGLANDULAR SYNDROME

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Maria Beatriz Morais, Inês Azevedo Carvalho, Vanessa Albino, Tânia Carvalho, Florbela Cunha
Hospital de Vila Franca de Xira, Pediatrics, Vila Franca de Xira, Portugal

Title of Case: Parinaud Oculoglandular Syndrome
Background: Parinaud Oculoglandular Syndrome is an atypical presentation of Cat Scratch Disease (CSD), described in 2 to 8 percent of patients. It is characterized by unilateral granulomatous follicular conjunctivitis and ipsilateral preauricular, submandibular or cervical lymphadenopathy. It should be considered in differential diagnosis of preauricular, submandibular or cervical lymphadenopathies for early antibiotic treatment, resulting in faster time-to-recovery and fewer visits to emergency room.
Case Presentation Summary: A healthy 9-year-old boy presented with 2 days left conjunctival injection with no purulent discharge. Viral conjunctivitis was assumed and he was treated with symptomatic measures. After 7 days, the was a worsening of conjunctivitis with additional left-sided palpebral and facial edema, pain and night sweats, associated with a palpable painful preauricular lymphadenopathy. Lab results showed no alterations and assuming reactive lymphadenopathy he was treated with anti-inflammatory medication. One week later presented with no improvement. Neck ultrasound revealed intraparotid enlarged lymph nodes without parotid gland alterations. Given the history of kittens at home and the preauricular lymphadenopathy with previous ipsilateral conjunctivitis, the diagnosis of CSD was considered. A 5-day course of azithromycin was empirically performed. Serologies showed positive IgM and IgG for Bartonella henselae. One month later he presented clinically well, the ocular alterations and the majority of the lymphadenopathies had resolved, with only the persistence of a small lymphadenopathy of about 1-2cm.
Learning Points/Discussion: Parinaud Oculoglandular Syndrome is a treatable pathology, without sequels, that should always be considered in a child or adolescent with preauricular lymphadenopathy and ipsilateral conjunctivitis. The diagnosis is confirmed by serology and the treatment consists in azithromycin in immunocompetent patients, which shortens the course of the disease.

DERMATOPHYTOSES AMONG PAEDIATRIC OUTPATIENTS

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Amina Obradović Balihodžić[1], Šejla Kotorić Keser[2]
[1]Institute for public health of Canton Sarajevo, Microbiology Department, Sarajevo, Bosnia and Herzegovina, [2]Clinical center University of Sarajevo, Microbiology Department, Sarajevo, Bosnia and Herzegovina

Backgrounds: Dermatophytoses are caused by keratinophilic fungi belonging to the genera Microsporum, Trichophyton, and Epidermophyton. Transmission of dermatophytes may occur by direct contact with infected humans or animals or indirectly, by contact with contaminated fomites. Most common clinical manifestations are tinea capitis, tinea corporis, tinea pedis, and tinea unguium (onychomycosis).
Methods: This is a descriptive analytical study. We used laboratory records of outpatients in Canton Sarajevo whose samples were analysed for dermatophytes in the Microbiology Laboratory of the Institute for public health of Canton Sarajevo in the period 01.01.2022-31.12.2022. The samples were examined under microscope for hyphae and conidia, and cultured on Sabouraud dextrose agar and Dermatophyte agar (Liofilchem).
Results: Among 92 positive dermatophyte cultures of outpatients, 21 (22,8%) were among paediatric population aged <18 years old, more often females (n=13, 61,9%). The predominant sample was skin scraping (12 cases, 57,1%) followed by scalp scraping (6 cases, 28,6%) and nail scraping (3 cases, 14,3%). The most common isolated dermatophyte was Microsporum canis (n=11, 52,4%). Median age was 9 years old (min. 1, max. 18 years old).
Conclusions/Learning Points: It is necessary to improve the surveillance of dermatophytoses, especially in the paediatric population.

UNDERSTANDING DIAPER DERMATITIS: IN THE BEGINNING WAS UREASE

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Emily Owen, A. Toby Jenkins
University of Bath, Chemistry, Bath, United Kingdom

Backgrounds: Diaper dermatitis (DD) / Incontinence Associated Dermatitis (IAD) is skin inflammation caused by urinary/faecal exposure. DD is the most common dermatologic disorder of infancy: at least one episode occurs for most children. Mechanistically, there are several gaps in understanding of the pathogenesis of DD, involving a complex interaction of infective agents (Figure 1). Urease-positive faecal bacteria, including Proteus mirablis (P. mirabilis), catalyse the conversion of urea into ammonia. The resulting increase in skin pH activates faecal enzymes and can cause infections, predominately by Candida albicans and Staphyloccous aureus. Furthermore, pro-inflammatory cytokines are released. It is hypothesised that by inhibiting urease activity, the positive feedback of pathogenic agents may be halted. Impedance Spectroscopy, a non-invasive measure of skin barrier function, was applied in an in vivo human model
(EP22107).

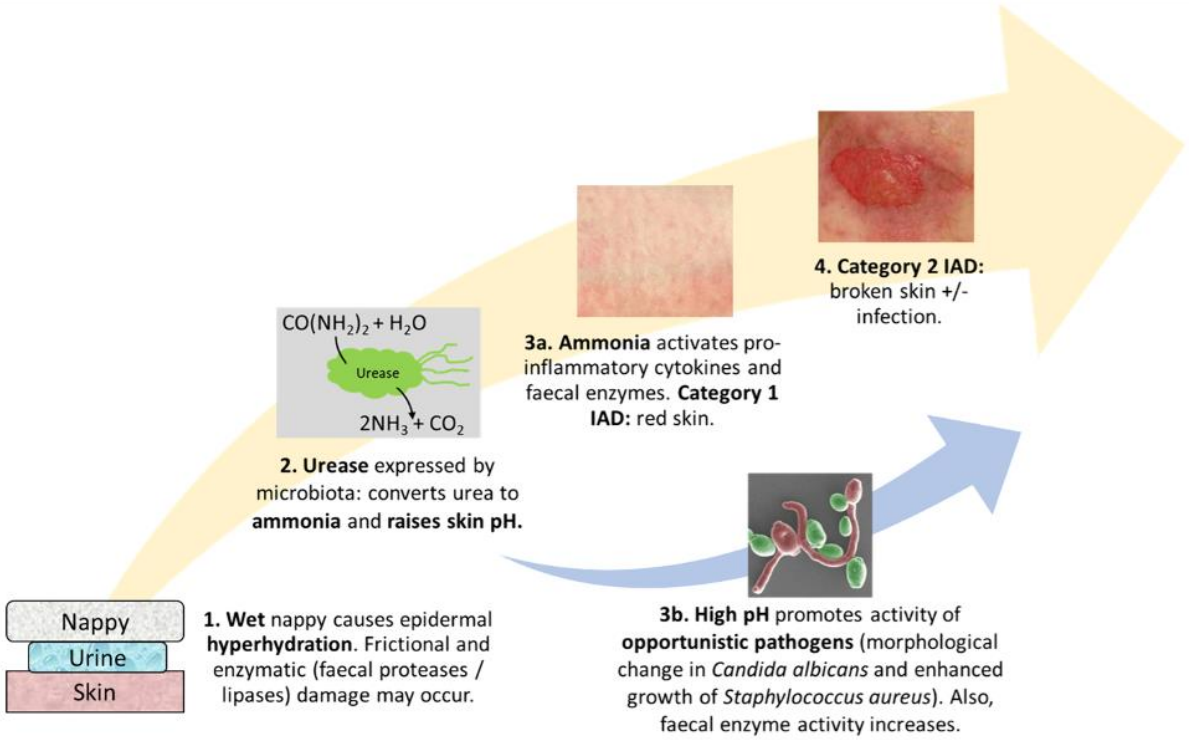

Figure 1. Schematic showing the contributing factors in Diaper Dermatitis (DD) / Incontinence Associated Dermatitis (IAD). Wet skin is susceptible to hyperhydration and frictional/enzymatic damage. Commensal bacteria express urease which catalyses the conversion of urea to ammonia, raising the skin pH. The high pH promotes further bacterial growth and increases protease activity. This also causes morphological change in commensal *Candida albicans* and increased growth rate of *Staphylococcus aureus*, promoting skin degradation.

Methods: Healthy human volunteers (N = 8) were inoculated with artificial urine, urease-positive P. mirablis (B4) and urease inhibitors (25% v/v Nasturtium officinale, 5 mM Lithostat - a urease inhibiting drug). After 4 h, skin integrity was assessed using impedance spectroscopy, pH, transepidermal water

loss (TEWL), stratum corneum moisture and erythema.
Results: Skin impedance decreased ($p < 0.001$) and pH increased ($p < 0.0001$) in the presence of P. mirablis. Lithostat reduced the changes in impedance ($p < 0.001$) and pH ($p < 0.001$) caused by P. mirabilis, preventing ammonia-induced damage. Nasturtium officinale may serve as an anti-inflammatory.
Conclusions/Learning Points: DD is a common, complex condition which involves the interplay of faecal/dermal bacteria, yeasts, and enzymes. This work attempts to further our understanding of DD pathogenesis; urease was identified as a potential pharmacological target for inhibition. Skin impedance spectroscopy may have future value in objectively diagnosing DD, including darker skin tones where erythema is less visible.

HERPES ZOSTER WITH AN UNCOMMON DISTRIBUTION IN A CHILD

E-Posters Viewing
E-POSTER VIEWING: AS07.F. SKIN INFECTIONS

Mariana Pereira, Rita Lages Pereira, Rita Aldeia Da Silva, Carla Moreira
Hospital de Braga, Paediatrics, Braga, Portugal

Title of Case: HERPES ZOSTER WITH AN UNCOMMON DISTRIBUTION IN A CHILD
Background: Varicella-zoster virus(VZV) is a member of the herpesvirus family and causes varicella after primary infection. The virus then establishes latency in the dorsal root ganglia and its reactivation results in herpes zoster(HZ), with a typical distribution along a specific dermatome. Although the rash can occur in any dermatome, thoracic and lumbar dermatomes are most often involved.
Case Presentation Summary: A previously healthy 4-year-old boy presented to the emergency department(ED) with history of a painful rash for 3 days. The rash started on the right shoulder and progressed down the arm to the forearm. On the day of presentation to the ED, he also complained of headache and vomiting. No history of fever or other symptoms. No history of recent contact with anyone with a rash or varicella-like illness. History of varicella at 1 month of age without complications. On ED, he had a vesicular rash on his right shoulder and anterior side of the right arm and forearm, with few scattered vesicles on the thenar region of the right hand, consistent with involvement of C5/C6 dermatome. No evidence of meningeal irritation or any neurologic deficit. The diagnosis of HZ was assumed. The child improved with analgesia, oral ondansetron and rehydration solution. He was discharged and treated with acyclovir 20mg/kg every 6 hours during 7 days, with complete regression of the lesions.
Learning Points/Discussion: HZ can be found in all age groups, but its incidence increases with age. Exposure to the VZV during the first year of life is a risk factor for the development of HZ during childhood. The authors bring this case to aware to this unusual distribution that can be found in HZ.

Title of Case: A CASE OF MASTOIDITIS CAUSED BY STREPTOCOCCUS INTERMEDIUS WHEREIN EARLY DIAGNOSIS OF LUPUS ANTICOAGULANT-HYPOPROTHROMBINEMIA SYNDROME ALLOWED PROMPT SURGICAL DRAINAGE
Background: Lupus anticoagulant (LA) is transiently produced in children following viral infection, and rarely bacterial infection, and results in abnormal coagulation. In particular, the presentations of patients with lupus anticoagulant-hypoprothrombinemia syndrome (LAHPS), which is LA-positive, range from asymptomatic to presenting with severe bleeding.
Case Presentation Summary: A 3-year-old girl presented with no specific medical history. Her left posterior ear was swollen, and she was on an oral antibiotic therapy that was prescribed by a local doctor. A contrast-enhanced CT scan of her head and face showed mastoiditis, an abscess in the posterior part of the auricle, and destruction and lysis of the pyramidal bone. Apuncture culture revealed Streptococcus intermedius and anaerobic bacteria. Although considered an indication for emergency otolaryngological surgery, the patient’s coagulation test showed a marked prolongation of activated partial thromboplastin time, which is a contraindication for surgical intervention. A cross-mixing test showed a positive LA pattern, which ruled out the possibility of coagulation factor deficiency. Furthermore,since no abnormal bleeding tendency was noted, surgical drainage could be performed promptly without neurological sequelae.
Learning Points/Discussion: LAHPS is often reported to occur after viral infections, but in the present patient, it was thought to have occurred after a bacterial infection. When prolonged coagulation is observed in a child with an infection that requires surgical intervention, it is important to promptly rule out coagulation factor deficiency through a cross-mixing test, to avoid delayed surgical intervention.

Title of Case: Staphylococcal scalded skin syndrome due to methicillin resistant Staphylococcus aureus: a case report.
Background: Staphylococcal scalded skin syndrome (SSSS), also known as Ritter disease, is a rare, toxin-mediated desquamating skin disease caused by Staphylococcus aureus strains, affecting children up to five years old. Diagnosis is essentially clinical, and early onset of anti-staphylococcal drug therapy is required.
Case Presentation Summary: A five-year-old boy, previously healthy, presented to an emergency room (ER) with odynophagia and serous rhinorrhea for three days, and a maculopapular rash, affecting axillary and inguinal folds for a day. He was apyretic. Rapid-antigen detection test for group A Streptococcal was positive and he was discharged with Amoxicillin. The next day, he returned to the ER because he was not tolerating antibiotics, showing generalized erythema, skin pain, and erythematous blisters on the forehead and perioral region. At the admission, he was afebrile, looking ill and complaining of pain at the touch. Vital signs were normal. Despite vast skin lesions, inflammatory markers were not elevated. SSSS was considered, and antibiotic treatment was initiated intravenously with penicillin G, flucloxacillin and clindamycin, after hemoculture and nasopharyngeal swab culture collections. He remained stable, and the pain was manageable. The culture from the nasopharyngeal swab grew methicillin-resistant Staphylococcus aureus, and hemoculture was negative. Penicillin G and flucloxacillin were discontinued after five days. The patient was treated for ten days with clindamycin and showed progressive clinical improvement with lesion regression.
Learning Points/Discussion: Although with appropriate treatment, signs and symptoms of SSSS usually resolve completely within three weeks without long-term sequelae, it might also have a severe clinical course due to loss of skin barrier. A high index of suspicion is essential for making an accurate diagnosis so that the treatment is started promptly and appropriately.

Title of Case: A RARE CASE OF PRIMARY CUTANEOUS ASPERGILLOSIS IN A PREMATURE INFANT
Background: Primary cutaneous aspergillosis (PCA) is a rare and a life-threatening fungal infection in premature infants. Various predisposing factors increase the risk of neonatal PCA, including extreme prematurity, low birthweight, immature immune system, use of broad-spectrum antibiotics, and immature skin barrier. We herein present a rare case of PCA caused by Aspergillus flavus in a premature infant.

Case Presentation Summary: A male preterm infant was delivered by cesarean section at 23^{+6} weeks of gestation with a birth weight of 595g.On the 7th day of life, he developed erythematous plaques covered with thick, white scales on his back.These lesions enlarged and extended to the entire back of the patient within 24 h.Laboratory studies were unremarkable.The white skin scales were removed from his back, and treatment with empirical intravenous piperacillin-tazobactam and amphotericin B deoxycholate was started for presumed nosocomial sepsis and fungal infection. Direct microscopic examination of skin scraping lesion revealed branched fungal septate hyphae. Blood, cerebrospinal fluid, and endotracheal aspirate cultures were negative. There was no evidence of disseminated fungal infection in echocardiogram, ophthalmologic examination, abdominal and cranial ultrasound. Skin samples were inoculated on Sabouraud dextrose agar. After 48 hours of incubation, mold colonies were observed in all culture plates. The mold was eventually identified as Aspergillus flavus.All skin lesions resolved after 21 days of amphotericin B treatment, with no scarring. A search for possible sources of infection in our NICU was undertaken by the hospital infection control team, with no positive results.
Learning Points/Discussion: PCA may cause extensive tissue destruction and systemic illness in premature infants.Our case highlights that early diagnosis and treatment are of critical importance in reducing progressive and systemic infection.

[1]Klinik Ottakring, Department Of Paediatrics And Adolescent Medicine, Vienna, Austria, [2]UCL Great Ormond Street Institute of Child Health, University College London, Department Of Infection, Immunity & Inflammation,, London, United Kingdom, [3]Royal Children's Hospital Melbourne, University of Melbourne, Department Of Paediatrics, Melbourne, Australia

Title of Case: PRIMARY CYTOMEGALOVIRUS INFECTION IN AN INFANT PRESENTING WITH ISOLATED VESICULAR SKIN LESIONS
Background: Cytomegalovirus (CMV) infection can cause diverse clinical presentations, from asymptomatic infection to life-threatening disease, occasionally resulting in long-term disability. Neonates infected during pregnancy and immunocompromised individuals tend to have the most severe disease manifestations. Currently, there are only few reports of isolated cutaneous CMV, especially in children.
Case Presentation Summary: A five-month-old male infant was admitted to our hospital with yellow, crusting skin lesions on the right ear and scalp. The patient was born at 30+0 weeks-of-gestation, and was discharged in good condition after an uncomplicated 9-week NICU stay. The infant was fed with non-pasteurised breast milk and showed no signs of infection in the first weeks following discharge. At five months, the baby developed vesicular lesions on the scalp without any systemic features. PCRs on viral swabs of the vesicular fluid were negative for herpes simplex virus (HSV) and varicella zoster virus, but positive for CMV. Bacterial culture of the fluid showed co-infection with Staphylococcus aureus, treated with topical fusidic acid. Ophthalmologic examination, cranial ultrasound and brainstem evoked response audiometry revealed no abnormalities. Serial blood tests did not show raised inflammatory markers. The skin lesions resolved after 3 weeks without CMV-specific treatment. Additionally, the mother had CMV IgG antibodies (92U/ml) at the child's birth, which slightly increased after five months (114U/ml).
Learning Points/Discussion: CMV infection should be considered in infants presenting with vesicular skin lesions that morphologically resemble HSV infection. It remains uncertain whether the patient had acquired the CMV infection congenitally via the haematogenous route, or in the postnatal period via breastmilk. Currently, most immunological investigations are still pending, but to date laboratory results did not suggest an underlying immunodeficiency.

Ciberinfec, Madrid, Spain, [7]Hospital Gregorio Marañón. Instituto de Investigación Sanitaria Gregorio Marañón (IisGM). CIBERINFEC. RITIP., Paediatric Infectious Diseases, Madrid, Spain

Backgrounds: Sexually transmitted infections (STI) have increased in recent years becoming a growing public health issue. Its incidence in adolescents has doubled in Spain. Objective: to describe STI diagnosed in patients younger than 18 years attended in our setting over the last 6 years.
Methods: Retrospective multicenter study, including STI diagnosed in two tertiary hospitals in Madrid, between 2016-2022. Clinical-epidemiological data were collected from medical-history. Microbiological tests, performed according to symptoms/exposure history, included: PCR for N.gonorrhoeae(NG) and C.trachomatis(CT) in urethral/cervical/oral/rectal/pharyngeal samples; PCR for herpes simplex-1/2 (HSV) or human papilloma virus (HPV) in scrapped samples and syphilis serological test.
Results: There were 185 STI diagnosed in 140 adolescents, as shown in table 1. A 33.5% were asymptomatic, diagnosed after sexual risk behaviors. All HSV and HPV consulted for skin lesions. CT was detected more frequently in females than males (70 vs 31, $p<0.05$), while NG was more frequent in men (43 vs 32, $p<0.05$). No significant differences in age were found. Twenty females (24%) were admitted because of pelvic inflammatory disease (PID): median age 16 years(RIC16-18); 7 NG, 7 CT and 6 CT-NG coinfections. Only 64 (45.7%) adolescents were followed up in pediatric infectious disease consultation, median of 6 months(RIC 3-12). An upward trend was observed with higher number of STI diagnosed between 2019-2022 (excluding 2020 due to COVID lockdown) (114 cases) as compared to 2016-18 (63
cases).

Table 1. Sexually transmitted infections characteristics

Patient´s Characteristics (N 140)	
Age	
Median (RIC)	17 years old (RIC 16-17)
< 15 years old	19 (14%)
Female	84 (60%)
Place of Birth	
Spain	67(47.8%)
Latin America	42 (30%)
STI diagnosed (N 185)	
C trachomatis	101
N gonorrhoeae	75
Syphilis	5
HSV	3
HPV	1
Coinfections	
CT-NG	43
Coinfection with *Ureaplasma urealyticum*	13
Coinfection with *Mycoplasma hominis*	12

Conclusions/Learning Points: C.trachomatis and N.gonorrhoeae are the main STI diagnosed in adolescents in our setting, but other preventable STI have occurred. To note, one in four adolescent females had a severe STI (PID), requiring hospitalization. In addition, one third of STI were asymptomatic, reflecting a larger number of STI undiagnosed in adolescents.

PV0582 / #1965

THE IMPORTANCE OF SEXUALLY-TRANSMITTED INFECTIONS IN ADOLESCENT GIRLS

E-Posters Viewing
E-POSTER VIEWING: AS07.G. STDS

Javier López Pequeño[1], Javier Brincau[1], Inés Ojeda Velázquez[1], Paula Cabrera[2], Elena Medina[2], Irene Mingueza De La Paz[1], Maria Palomo[3], Jimena Pérez[1], Leticia Llamas Santos[4], Maria Del Carmen Viñuela[4], Jose Tomas[2], Arantxa Berzosa Sánchez[2], Marisa Navarro[1]
[1]Hospital Gregorio Marañón, Pediatrics, Madrid, Spain, [2]Hospital Clínico San Carlos, Pediatric Infectious Diseases Unit, Department Of Pediatrics, Madrid, Spain, [3]Hospital Gregorio Marañón, Microbiology, Madrid, Spain, [4]Hospital Gregorio Marañón, Gynecology, Madrid, Spain

Backgrounds: Pelvic inflammatory disease (PID) is a complication frequently seen in women with sexual transmission infections (STI). If not treated, PID can cause women's reproductive health problems. The aims of this study were to describe the characteristics and the management of PID cases in patients under 18 over the last six years in Madrid.
Methods: Retrospective multicentric study including all STI diagnosed in two tertiary hospitals in Madrid, Spain, between 2016-2022. Clinical and epidemiological data were collected, as well as PID management and follow-up. Microbiological test included PCR for N. gonorrhoeae (NG), C. trachomatis (CT), Mycoplasma hominis (MH), Ureaplasma urealyticum (UU) and Mycoplasma genitalium (MG) in cervical samples and serological test for HIV and T. pallidum infections.
Results: Out of 84 female patients diagnosed with a STI over the study period, 23.8% (n=20) developed PID (median age 16 years [RIC 15-17]). All patients were symptomatic, most commonly presenting with abdominal pain (70%), genital pain (50%) and abnormal vaginal discharge (25%). Only 10% had fever. There were 13 NG infections and 13 CT infections (6 were NG-CT co-infections). Other detected pathogens in co-infection included 5 MH, 4 UU and 2 MG. There were no cases of HIV or syphilis. Imaging tests were performed in 90% of patients, 72% were abnormal. All patients received combined antibiotic therapy, 10% required surgery. There were complications in 35%: 4 bilateral tubo-ovarian abscesses, 2 pyosalpinx, 1 peritonitis, 1 ileocolitis. 70% were followed-up in Paediatric Infectious disease unit, having 10% of them STI recurrence.
Conclusions/Learning Points: PID is a serious complication of STI, usually due to NG and/or CT infections, with a high risk of hospitalization and secondary complications. High clinical suspicion is needed for early diagnosis and prevention of new STI.

PELVIC INFLAMMATORY DISEASE – AN INCREASING INCIDENCE OR IMPROVED DIAGNOSIS?

E-Posters Viewing
E-POSTER VIEWING: AS07.G. STDS

Mariana Eiras Dias, Marta Pelicano, Ana Pereira, Catarina Albuquerque, Inês Pinto Ferreira, Rita Morais, Paula Nunes
Centro Hospital Lisboa Ocidental, Pediatra Hospital São Francisco Xavier, Lisbon, Portugal

Backgrounds: Pelvic inflammatory disease (PID) is an infection of the female upper genital tract. Sexually active adolescents present the highest risk and diagnosis is challenging due to nonspecific or absent symptoms. In 2022 we implemented a hospital protocol regarding PID. We report the prevalence and characteristics of PID in adolescents at a general hospital.
Methods: Retrospective study of clinical files of adolescents aged 11-18 years diagnosed with PID in the Emergency Department between 2015-2022.
Results: Pelvic Inflammatory Disease was diagnosed in 6 adolescents, 1 in 2015, 6 in 2022. Median age was 16,6 years-old [16-17]. All presented abdominal pain (n=7), 4 had cervical purulent discharge and 3 had fever. A sexually transmitted disease (STD) agent was detected in all cases, 6 by urine PCR and 1 by vaginal/endocervical swab culture. Co-infection was detected in 4 cases (3 with Neisseria gonorrhoeae and Chlamydia trachomatis; 1 with N. gonorrhoeae, C. trachomatis and Ureaplasma urealyticum), 2 cases had solely N. gonorrhoeae and 1 had C. trachomatis. As per protocol, serologies for other STD were requested in all cases, one of which was positive for syphilis. 5 patients were hospitalized, with variable empiric antibiotic therapy. Complications included 3 tubo-ovarian abscesses and 1 Fitz-Hugh-Curtis Syndrome. Median time of hospitalization was 4.6 days [2-8]. All adolescents were referred to Adolescent and Gynecology appointments, with a favorable outcome.
Conclusions/Learning Points: PID diagnosis clearly rose in 2022 which may have been due to increased awareness from clinicians, reinforcing the relevance of hospital protocols. Other factors may have contributed, like a higher prevalence of STD and increased diagnostic sensitivity with PCR methods. Co-infections were frequent, emphasizing the importance of a broad spectrum empiric therapy and screening for other STD to avoid missed testing opportunities.

PELVIC INFLAMMATORY DISEASE IN ADOLESCENTS – EXPERIENCE OF A PORTUGUESE HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS07.G. STDS

Inês Foz, Joana Bastos, Maria Inês Marques, Margarida Pinto, Paulo Calhau
Hospital Garcia de Orta, Pediatria, Almada, Portugal

Backgrounds: Pelvic inflammatory disease (PID) is an infection of the upper genital tract in females, including endometritis, salpingitis, tubo-ovarian abscesses, and pelvic peritonitis. Sexually transmitted infections (STIs), such as Chlamydia trachomatis and Neisseria gonorrhoeae, cause most PID cases. Sexually active adolescents are at higher risk for developing PID and subsequent sequelae.
Methods: Retrospective observational study of paediatric patients hospitalized at a secondary care paediatric department diagnosed with PID between January/2015-December/2022. Data included patient risk factors and symptoms; clinical, laboratory and imagological findings; STIs testing and treatment.
Results: We identified 10 patients hospitalized with DIP, 1 of them with 2 admissions, with a median length of 5 days. Median age was 16 years. All adolescents were sexually active, without or inconsistently using barrier methods. The most frequent symptoms were lower abdominal pain (91%), fever (82%), increased vaginal discharge (73%), vomiting (54%) and dysuria (45%). The bimanual pelvic examination was positive in 91% of the adolescents. All had leucocytosis with increased CRP (median 12,6 mg/dL). The ultrasound established the diagnostic in 9 cases, 1 required abdominal TC and 1 laparoscopy. An infectious agent was identified in 36% of the cases (2 Chlamydia trachomatis, 3 Neisseria gonorrhoeae). All were tested for STIs, 1 presenting with condyloma lata. 54% were complicated PID, all tubo-ovarian abscesses. Most completed triple antibiotic treatment for at least 14 days. In 4 cases the partner was treated.
Conclusions/Learning Points: DIP is associated with long-term sequelae, including infertility and chronic pelvic pain, requiring a high level of clinical suspicion and appropriate patients and their partners' treatment. The results point out some risk behaviours in adolescence. Clinicians should provide counselling regarding safe sexual behaviours and STIs prevention and screening, including Chlamydia trachomatis and Neisseria gonorrhoeae.

ANTIMICROBIAL RESISTANCE AND NEISSERIA GONORRHOEAE TREATMENT IN PEDIATRICS: A CONCERN AS OF RIGHT NOW?

E-Posters Viewing
E-POSTER VIEWING: AS07.G. STDS

David Gomes[1,2], Tiago Silva[2], Ana Margarida Garcia[2], Catarina Gouveia[2]
[1]Hospital do Espírito Santo de Évora, Paediatrics Unit, Woman And Child's Department, Évora, Portugal, [2]Hospital Dona Estefânia, Paediatric Infectious Diseases Department, Lisboa, Portugal

Backgrounds: Neisseria gonorrhoeae infections are a serious health problem worldwide. Increasing resistance levels to azithromycin and ceftriaxone are being reported in multiple studies.
Methods: Patients with confirmed Neisseria gonorrhoeae infections were included, from a tertiary Paediatric Hospital between 2017 and 2021. Demographic, clinical and microbiological data were collected.
Results: Thirty cases were identified, 24 (80%) were males. The mean age was 16.6 ± 0.97 years. In males, dysuria was the most common symptom (79.1%). Females were mostly asymptomatic (66.7%). Co-infections were frequent (60%), most commonly with Chlamydia trachomatis (n=17), followed by Syphilis (n=2). Cultural testing, with antimicrobial sensitivity studies, were only possible in 13 of the 30 cases. Resistant to quinolones was found in 5/13 (38%) cases, 1 with concomitant resistance to azithromycin. No isolates were resistant to cefixime or ceftriaxone.
Conclusions/Learning Points: Neisseria gonorrhoeae infections can be asymptomatic, especially in females, raising the question about the need for periodic testing, especially of risk populations. Culture identification of strains is fundamental for establishing the epidemiological picture of each territory and establishing the best empirical treatment in each case.

5 YEARS OF SEXUALLY TRANSMITTED INFECTIONS IN ADOLESCENTS IN TWO PAEDIATRIC UNITS IN PORTUGAL – TWO CASE SERIES

E-Posters Viewing
E-POSTER VIEWING: AS07.G. STDS

Inês Hormigo[1], Madalena Torrado Malato[2], Rosa Figueiredo[1], Carolina Albuquerque[2], Ana Margarida Garcia[1], Tiago Silva[1], Florbela Cunha[2]
[1]Hospital Dona Estefania, Centro Hospitalar Universitario lisboa Central, Infectious Diseases Unit, Lisbon, Portugal, [2]Hospital Vila Franca de Xira, Paediatric Unit, Vila franca de xira, Portugal

Title of Case: 5 YEARS OF SEXUALLY TRANSMITTED INFECTIONS IN ADOLESCENTS IN TWO PAEDIATRIC UNITS IN PORTUGAL – TWO CASE SERIES
Background: Sexually Transmitted Infections (STIs) are a health care concern worldwide. Adolescents are at special risk as they are prone to high-risk sexual behaviors. Objectives/methods: We aim to describe two pediatric populations from a level two and a level three Paediatric Hospitals in Portugal, with confirmed STI between January 2018 and November 2022 (5 years).
Case Presentation Summary: Tertiary hospital: 53 adolescents, ages between 12 and 18 (median of 17 year old), 33 (62%) of them male. The most prevalent STI was Chlamydia trachomatis (CT) n=33 (62%), followed by Neisseria gonorrhoeae (NG) n=30 (57%). Other STIs also identified were syphilis n=6, hepatitis B virus n=3, human immunodeficiency virus (HIV) n=1 and Trichomonas vaginalis (TV) n=1. Coinfection was identified in 19 cases (36%): CT/NG n=15, CT/NG/syphilis n=2, CT/syphilis n=1 and NG/TV n=1 Level two hospital: 25 adolescents, ages between 13 and 18 (median of 17 years old), 16 of them female (64%). The most prevalent STI was also CT n=13 (50%), followed by NG n=10 (38%). Coinfection CT/NG was diagnosed in 4 cases (15%). Other STIs also identified were syphilis n=4, HIV n=1 and TV n=1.
Learning Points/Discussion: These two case series show similarities regarding the types and distribution of the STIs identified, reflecting similarities in sexual practices between adolescents from two different social contexts. It also underlines the importance of the consideration of STIs in early age groups, as some infections were diagnosed before 14 years old. Prevention and early diagnosis and treatment of STIs should be the focus of future discussion in order to decrease the impact of these diseases.

Sadjia Mahrane, Selma Nouar, Radia Boushaki, Habiba Ait Belkacem
Chu hussein dey faculté of pharmacy, Pharmacie, Alger, Algeria

Title of Case: Neonatal conjunctivitis due to Neisseria gonorrhoeae: a case study
Background: In this study, two cases of neonatal conjunctivitis are reported. The cases appeared as a result of maternal transmission following a sexually transmitted infection in the mother.
Case Presentation Summary: The study concerns two newborn babies aged 22 and 25 days old consulting at the level of the pediatric emergency room of the hospital Nafissa Hamoud Algiers. The newborns have been reported as not reponsding to any antibiotic or medical treatment. Conjunctival swab samples were received at the Biology laboratory of the CHU Hussein dey The samples received were subjected to microscopic examination after staining and culture according to the usual techniques. The test results have shown Cocci in the form of coffee beans, the infection with Neisseria gonorrhoeae is, therefore, strongly suspected, the two newborns are put on ceftriaxone while awaiting the bacteriological results After 48 hours a fine culture is obtained, the Gram, the orientation examinations as well as the gallery confirm the diagnosis of conjunctivitis due to Neisseria gonorrhoeae, the antibiogram is then carried out according to CLSI standards, the reading of the latter finds a association of resistance of isolated strains to Penicillin G, tetracycline and ciprofloxacin, only ceftriaxone remains active against these strains The evolution was favorable for the 1st newborn under ceftriaxone, while the 2nd newborn presented an abscess of the cornea engaging his visual prognosis
Learning Points/Discussion: Self-medication of sexually transmitted infections has increased the resistance of Neisseria gonorrhoe and raised fears of the appearance of toto-resistant strains

Title of Case: SECONDARY SYPHILIS IN AN ADOLESCENT – THE IMPORTANCE OF RECOGNIZING SIGNS AND SYMPTOMS
Background: Syphilis is a predominantly sexually transmitted infection of worldwide importance caused by the bacterium Treponema pallidum. Within the last few years, an increase in its incidence has been reported in Europe, including among adolescents. It develops in different stages classified as primary, secondary, latent, and tertiary syphilis. Of those, secondary syphilis, which is characterized by the presence of systemic symptoms, appears within weeks after an untreated and often asymptomatic primary infection. If not properly treated, long-term health consequences are possible.
Case Presentation Summary: A 15-year-old female adolescent, diagnosed with borderline personality disorder and medicated with fluoxetine, quetiapine, lamotrigine, and lorazepam, presented to our pediatric emergency department with one-month history of left vulvar swelling and macular palmar rash. Additional symptoms were nausea, vomiting, and feeling fatigued over the course of two weeks. When questioned, she recalled a painless vulvar lesion a few weeks prior to the onset of symptoms and confirmed being sexually active and having multiple partners. On physical examination, a condyloma lata was observed on the left labia majora, as well as multiple macular lesions on both palms. The patient was diagnosed with secondary syphilis after positive treponemal and nontreponemal tests and treated with intramuscular penicillin. Other sexually transmitted infections were excluded.
Learning Points/Discussion: Early diagnosis and prompt treatment of syphilis are crucial to avoid complications and prevent its progression to irreversible stages. In an adolescent with a high-risk sexual behavior, it is important to consider this diagnosis and take an active role in preventing the spread of this disease, educating patients on safer practices, promoting testing, and providing treatment to partners.

THE ROLE OF HOST IMMUNITY AND PATHOGEN VIRULENCE IN THE “NEW” RSV EPIDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Inês Aires Martins[1], Inês Paiva Ferreira[2], Joana Carvalho Queirós[1], Rita Calejo[2], Marvin Oliveira[3], Tiago Branco[2], Abílio Oliveira[2], Nuno Ferreira[2]
[1]Centro Materno Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatrics, Porto, Portugal, [2]Centro Hospitalar Tâmega e Sousa, Paediatrics And Neonatology, Penafiel, Portugal, [3]Centro Hospitalar Tâmega e Sousa, Clinical Pathology, Penafiel, Portugal

Backgrounds: Respiratory syncytial virus (RSV) is an important pathogen of early childhood, with significant morbidity and mortality. The COVID-19 pandemic reduced the transmission of viral respiratory pathogens, which may result in the increase of an immunologically naïve population and lead to more severe RSV epidemics.
Methods: Retrospective cohort study including hospitalized RSV respiratory infections in four time periods: April 2019 to March 2020 (group 1), April 2020 to March 2021 (group 2), April 2021 to March 2022 (group 3), and April 2022 to March 2023 (group 4), in a level II Portuguese hospital.
Results: Until December 2022, a total of 270 patients were included, 61 in group 1, 0 in group 2, 78 in group 3, and 131 in group 4. No statistical differences were found between demographic and clinical characteristics at admission, including WARM score. Hypoxemia was significantly higher in group 3 ($p=0.018$; $\eta 2=0.030$ vs group 4). There were no differences regarding ICU transfer or type of respiratory support needed, with the exception of high flow nasal cannula that was more used in group 4 when compared to both group 1 ($p=0.004$) and 3 ($p=0.036$), with a medium effect size ($\eta 2=0.045$).
Conclusions/Learning Points: Hospitalization roughly doubled in group 4 despite no changes seen in disease presentation. This increase can more likely be explained by immunological factors of the host rather than by the pathogen’s virulence. Therefore, the reported increase in health services burden caused by RSV infections appears to be related to a higher disease incidence. In line with literature reports, there were no RSV hospitalizations during the peak of the COVID-19 pandemic (group 2).

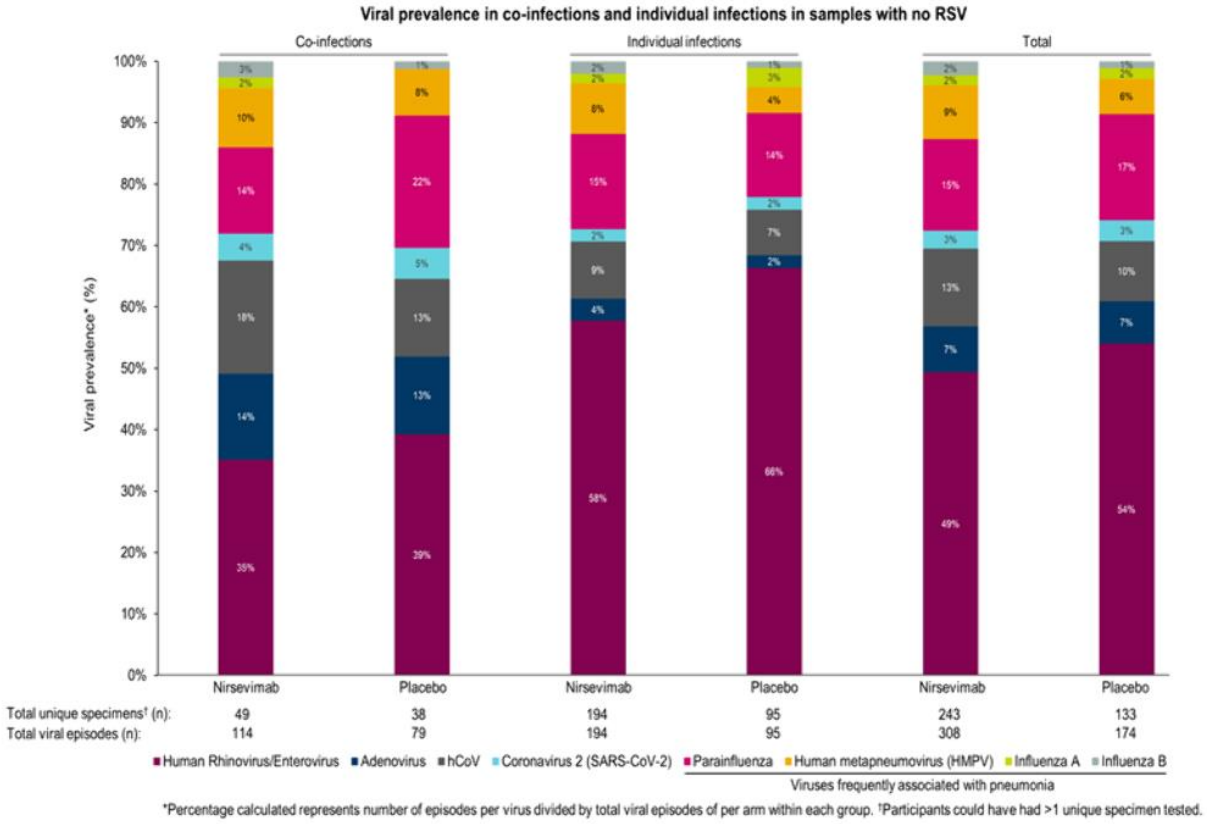
[1]AstraZeneca, Vaccines & Immune Therapies, Biopharmaceuticals R&d, Gaithersburg, United States of America, [2]Faculty of Health Sciences of the Ben-Gurion University of the Negev, The Shraga Segal Dept. Of Microbiology, Immunology And Genetics, Beer-Sheva, Israel, [3]Johns Hopkins University, Department Of International Health, Baltimore, United States of America, [4]AstraZeneca, Vaccines & Immune Therapies, Biopharmaceuticals R&d, Durham, United States of America, [5]AstraZeneca, Discovery Sciences, R&d, Gaithersburg, United States of America

Backgrounds: Nirsevimab, an extended half-life monoclonal antibody to the respiratory syncytial virus (RSV) fusion protein reduced medically attended (MA) RSV lower respiratory tract infection (LRTI) by 74.5% in MELODY (primary cohort), a pivotal trial in healthy late-preterm and term infants. A post-hoc analysis showed nirsevimab reduced the risk of all-cause MA LRTI by 51.5%. Given the already well-characterised benefit of nirsevimab in preventing RSV disease, we examined the distribution of other respiratory viruses between nirsevimab and placebo participants.
Methods: MELODY randomised 3012 participants 2:1 to nirsevimab or placebo. Infants were dosed prior to their first RSV season and followed for up to 530 days. Nasal swabs were collected from infants presenting with an LRTI. All samples were tested in the Biofire® Respiratory 2.1 Panel for 21 non-RSV pathogens.
Results: As of August 2022, 518 MA-LRTI specimens from 418 infants harboured respiratory viruses. Excluding the 142 cases associated with RSV, 127/376 were associated with ≥1 virus frequently associated with pneumonia: Parainfluenza, Human metapneumovirus (HMPV), and Influenza . These were balanced by treatment arm and represented 15%, 9%, and 4%, of episodes among nirsevimab and 17%, 6%, and 3% among placebo recipients respectively. Specimens were detected with a single virus more frequently than multiple co-occurring non-RSV viruses and were balanced between nirsevimab (194/243 [79.8%]) and placebo (95/133 [71.4%]). The most frequently detected non-RSV viruses were rhinovirus/enterovirus, parainfluenza, and seasonal coronaviruses, regardless of treatment arm. Frequency of specific viral infections, particularly Influenza and HMPV may have been reduced by the COVID-19 pandemic occurring during the
study.



Conclusions/Learning Points: This multinational clinical dataset to characterise non-RSV LRTIs in infants and young children suggests that distribution of non-RSV viruses was not impacted by nirsevimab.

ADENOVIRUS INFECTIONS, A MIMIC OF BACTERIAL INFECTIONS?

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Beatriz Andrade[1], Carolina Curto[2], Ana Feio[1], João Faria Dias[1], Filipa Almeida[1]
[1]Centro Hospitalar do Médio Ave, Pediatrics, Vila Nova de Famalicão (new), Portugal, [2]Centro Materno Infantil do Norte, Pediatrics, Porto, Portugal

Background: Adenovirus is a common cause of respiratory infections in children. This infection can cause significant morbidity and develop into severe complications. Some clinical presentations can mimic bacterial infection making difficult to distinguish between the two which can lead to unnecessary antibiotic use and hospitalizations.
Methods: Retrospective study of paediatric patients with acute respiratory infections in whom nasopharyngeal aspirate samples were collected and came positive for adenovirus. We included data between January 1sts 2019 and December 31st, 2022. Demographic information, symptoms, laboratory findings, therapeutics and clinical outcomes were analysed.
Results: Adenovirus was detected in 87 samples; median age was 1.6 years old. Viral coinfection was detected in 68%, with RSV, rhinovirus and influenza being the most commonly found. The main clinical symptoms were fever and cough. Fever presented in 78% and lasted more than 5 days in 22% of cases. The main diagnoses were upper airway infections, bronchiolitis and pneumonia. X-ray was performed in 69%, with 45% showing bilateral infiltrate and 15% lobar hypodensity. Laboratory tests were performed in 72 cases, 42% showing PCR >5 mg/dl and 43% leucocytosis (>15000/uL). There were 61% admissions into the paediatric department, 19% receiving antibiotic treatment for suspected bacterial infection: four cases had otitis, four pneumonia sobreinfection and seven were initially treated for occult bacteremia. There were two cases transferred for intensive care.
Conclusions/Learning Points: This study demonstrates that the heterogenous presentation and laboratory findings can often mimic bacterial infections. The findings merit further studies that offer paediatricians an informed decision to proceed with early diagnosis and appropriate management of adenovirus infections. In order to improve outcomes and reduce risk of complications, making it essential for paediatricians to have access to accurate and timely diagnostic tools.

[1]Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Marmara University School of Medicine, Medical Microbiology, İstanbul, Turkey

Backgrounds: The Human Bocavirus (HBoV) is one of the most commonly detected virus, causing mild to severe upper or lower RTI in children mainly under 5-year-old. It may also present with gastroenteritis, conjunctivitis and rarely encephalitis. The present study aimed to o describe the clinical profile of HBoV infections, estimate the prevalence of co-infection with other respiratory viruses, evaluate the non-respiratory signs and symptoms in children.
Methods: The characteristics of patients aged 0-18 years who admitted to the Marmara University Departments of Pediatrics in two years and HBoV was detected in nasopharyngeal samples were analyzed retrospectively. We investigated the demographic features, the frequency of coinfections and their effects on the clinic, and the rate of non-respiratory symptoms.
Results: Forty-five children were enrolled. There were 21 (46.7%) males and 26 24 (53.3%) females with the median age of 31 months (min-max:2-205 months). The coinfection rate with other respiratory viruses was 28.9% (n:13). Co-infection with RSV was 6.7% and Human Metapneumovirus was 6.7%. Pneumonia was found to be significantly higher in patients with coinfection (p=0,038)(Table 1). The most common complaints were fever (73.3%, n:33), cough (60%, n:27), rinorrhea (22%, n:10) and diarrhea (13%, n:6).The need for inhaler therapy was associated with prolonged hospital stay (p: 0.026). Encephalitis developed in one case and dilate cardiomyopathy in one case.

Table 1. Coinfeciton and pneumonia relation

		Pneumonia		Total Number	p
Co-infeciton		Yes	No		
	Yes	8	2	10	0,038
	No	20	6	26	
Total Number		28	8	36	

Conclusions/Learning Points: In children, HBoV usually presents with upper respiratory tract symptoms, but patients who have co-infection with other viruses are more likely to develop lower respiratory tract infections.

[1]Robert Debre University Hospital, General Pediatrics And Infectious Diseases, PARIS, France, [2]ACTIV, Activ, PARIS, France, [3]Robert Debre University Hospital, Hematology, PARIS, France

Backgrounds: Acute chest syndrome (ACS) is a life-threatening complication of sickle-cell disease (SCD). Although respiratory pathogens are usually detected in children admitted for ACS, their role in triggering the disease is unknown. The aim of this study was to take advantage of the unprecedented recent dynamics of respiratory pathogens following nonpharmaceutical interventions (NPIs), to unravel their respective role in ACS epidemiology.
Methods: This cohort study used an interrupted time-series analysis of patient records from a national surveillance system. All children younger than 18 years with SCD hospitalized for ACS in France between January 2015 and May 2022 were included. The monthly incidence of ACS per 1,000 children with SCD over time was analyzed by quasi-Poisson regression model. The circulation of 12 respiratory pathogens in the general pediatric population over the same period was included in the quasi-Poisson regression model to assess the fraction of ACS attributable to each respiratory pathogen.
Results: Among the 55,941 hospitalizations of children with SCD, 2306 episodes of ACS were included. We observed a significant decrease in ACS incidence after NPIs implementation in March 2020 (-29.5%; 95% CI, -46.8% to -12.2%; P = .001), and a significant upraise after NPIs lifting in March 2021 (24.4%; 95% CI, 7.2% to 41.6%; P = .007). Over the study period, Streptococcus pneumoniae accounted for 30.9% (95% CI, 4.9% to 56.9%; P = .02) of ACS incidence, and influenza 6.8% (95% CI, 2.3% to 11.3%; P = .004), while other respiratory pathogens had a minor role.
Conclusions/Learning Points: This COVID-19 pandemic related NPIs allowed us to unravel the important contribution of respiratory pathogens, mainly S. pneumoniae and influenza, to the burden of childhood ACS, highlighting the potential benefit of vaccine prevention in this vulnerable population.

Backgrounds: Adenovirus infection is common in childhood. However little is known of the clinical characteristics of children admitted to hospital as both inpatient and outpatient.
Methods: Between Jan 2020-Feb 2022, hospitalized pediatric cases detected Adenovirus by PCR in respiratory tract samples were enrolled in the present study. Clinics and diseases courses of the patients were analyzed.
Results: During the study period, 199 children with adenovirus infection were admitted to our hospital. While 21 (10.5%) patients were inpatients, 178 (89.5%) patients were outpatients. The median age was 3 years (IQR:1-7) in inpatient group and 2 years (IQR:1-4) in outpatient group. Of the outpatients, 76.4% had no underlying diseases whereas 71.4% had underlying diseases in inpatient group (p=0.001). The common diagnosis was respiratory tract infection in both groups. Gullian barre syndrome (n=1), myocarditis (n=1), and multisystemic inflammatory syndrome (n=1), were detected in inpatient group. Two patiens had severe, seven patients had moderate and four patients had mild liver injury. The median white blood cell, CRP, sedimentation, thrombocyte count, procalcitonin level were not statisticaly different between inpatient and outpatient groups. Of all, 5 (23.8%) patients in inpatient group had multiple viral infection, 57 patient (32%) among outpatient group had viral coinfection (p=0.30). Rhinovirus (15%) and bocavirus (9.5%) were the most common pathogens responsible for co-infection. No patient died in this

Table 1: Demographic and clinical data of all patients

	Inpatient group (n=21)	Outpatient group (n=178)	p value

EPIDEMIOLOGY OF RESPIRATORY SYNCYTIAL VIRUS-RELATED HOSPITALIZATION OVER A 8-YEAR PERIOD IN ITALY: EVALUATION OF SEASONALITY, AGE DISTRIBUTION AND COMPARISON BETWEEN PRE AND POST-PANDEMIC ERA

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Federica Barbati, Lorenzo Lodi, Valentina Guarnieri, Laura Pisano, Francesca Lippi, Silvia Ricci, Chiara Azzari, Clementina Canessa
Meyer Children's Hospital IRCCS, Pediatric Immunology, Firenze, Italy

Backgrounds: Underlying comorbidities increase the risk of contracting severe RSV infection, but most infections still occur in previously healthy children. The outbreak of COVID-19 contributed to modify the natural epidemic course of common respiratory infections. We aimed to evaluate the epidemiologic data of the pediatric population hospitalized due to RSV in the pre and post COVID-19 pandemic years to support the development of the best preventive strategies.
Methods: This observational study retrospectively evaluated all children aged 0-18 years old hospitalized in Florence, Empoli, Prato and Pistoia with a diagnosis of RSV infection from September 2014 to April 2022. The study analyzed and compared the RSV seasonal trend, its distribution according to age and the clinical and laboratory data in two different period: before the COVID-19 pandemic (September 2014-March 2020) and after the beginning of the pandemic (March 2020-May 2022).
Results: In the pre-pandemic period 834 children were hospitalized, while in the post-pandemic period 433. In the pre-pandemic period RSV started in November, had a peak in January and had a variable end in spring. In 2020-2021 season no cases of RSV were detected until May 2021. The 2021 epidemic spread of RSV started in mid-September, with a number of cases 3 times higher than the previous years. More than 70% of children in pre-pandemic season were under 1 year old. In post-pandemic population, 56.8% of the children were under 1 year old.
Conclusions/Learning Points: Most of the hospitalizations happened in previously healthy children, underlining the need to protect all infants. Since the post-pandemic data showed that infection can affect also older children, pediatricians should search for RSV in all children with respiratory symptoms. Epidemiological studies are needed to evaluate which prevention strategy might be the most useful.

RESPIRATORY VIRUSES IN CHILDREN BEFORE AND DURING THE COVID-19 PANDEMIC IN A PORTUGUESE HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Carla Barbosa Mendes[1], Luís Silva[1], Ana Mendes[1,2], Ana Castro[1]
[1]Centro Hospitalar Universitário do Porto, Serviço De Microbiologia, Porto, Portugal, [2]Centro Hospitalar Universitário do Porto, Unidade De Biologia Molecular, Porto, Portugal

Backgrounds: The emergence of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) in 2020, seems to have changed the frequency and seasonality of some of the other respiratory viruses. The aim of this study is to analyze the pattern of respiratory viruses in the pediatric respiratory samples of a portuguese tertiary hospital before and during de coronavirus disease (COVID-19) pandemic.
Methods: Polymerase chain reaction results of influenza virus A (FluA), influenza virus B (FluB), respiratory syncytial virus (RSV), rhinovirus (RhinoV), bocavirus (BocaV), adenovirus (AdenoV), human metapneumovirus (MPV), enterovirus (EnteroV) and parainfluenza virus (PIV) 1-4 of pediatrics respiratory samples between 2019 and 2022 were retrospectively analyzed.
Results: There was a decrease in the frequency of all respiratory viruses from March 2020 until the Spring of 2021. During this period there were no positive samples for most of the viruses surveyed, except for AdenoV and RhinoV. The variations observed between 2019 and 2022 were significant ($p<0,005$) for FluA, FluB, RSV, BocaV and RhinoV. There was a change in the seasonality of RSV and BocaV. Of the total RSV positive samples in 2021 (n=168), 50.6% were in the second and third quarters of the year. In 2019, the lowest number of positive samples (6.6%) were in this period. For BocaV positive samples in 2021 (n=35), 80% of them were in the third and fourth quarters, while in 2019 the majority of positive samples (68.75%) were in the first and second quarters.
Conclusions/Learning Points: In the pediatric population analyzed there was a change in the dynamics of respiratory viruses with the emergence of SARS-CoV-2, which is in line with other studies. Further research is needed to understand the consequences in the clinical presentation of children.

SEVERE VIRAL LOWER RESPIRATORY TRACT INFECTIONS IN A TUNISIAN PEDIATRIC INTENSIVE CARE UNIT SENTINEL SARI CENTRE: EPIDEMIOLOGICAL AND CLINICAL FEATURES

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Oumaima Barkallah Jemai[1], Ahmed Ayari[1], Ahmed Hajji[1], Assaad Louati[1], Shatila Hadj Hassine[1], Asma Bouziri[1], Aida Borgi[1], Salma Abid[2], Latifa Maazaoui[3], Khaled Menif[1]
[1]BÉCHIR HAMZA CHILDREN'S HOSPITAL, Pediatric Intensive Care Unit, Tunis, Tunisia, [2]Charles Nicolle HOSPITAL, Microbiology Laboratory, Virology Unit, Tunis, Tunisia, [3]Ministry Of Health, Primary Health Care Direction, Tunis, Tunisia

Backgrounds: Severe acute respiratory infection (SARI) is a leading cause of morbidity and mortality in children world wide. It can take a severe clinical form that needs a management in pediatric intensive care unit (PICU). The aim of this study is to identify the pathogen profile of children admitted in intensive care.
Methods: Prospective study in which were enrolled all patients hospitalized for SARI during the period between octobre 2021 and Mai 2022.
Results: During the study period, 155 infants were admited to the PICU for SARI which represent 36.4% of all hospitalized patients. Median age was 40 days and sex ratio was 1.76. Forty four patients (28%) had comorbidities. The median value of the Wang score was 10. In 72.2% of participants (n= 112), the causative viral pathogen was Respiratory Syncytial Virus, followed by Rhinovirus 23.8% (n=37) and non COVID Human Corona virus 12.2% (n=19). The detection rate of two or more viruses was 30.3% (n= 47). Bacterial co-infection was recorded in 21.2% of patients (n= 33), and the mostly detected bacterial agents were Heamophilus Influenzae (8.3%, n= 13), Moraxella Catarrhalis (5.1%, n= 8) and Streptocoque Pneumonae (4.5%, n= 7). Staphylocoque Aureus was only recorded in 3 patients (1.9%). Mechanical ventilation was performed in 91 patients (58.7%) with median duration of ventilation of 5 days and median duration of stay in PICU was 6 days. The overall mortality rate was 2.5% (deceased= 4).
Conclusions/Learning Points: Viral infection is the leading cause of SARI with a predominance of RSV. Our population study is very young (median age: 40 days) which may explain that SARI is associated with an increased morbidity (Mechanical ventilation rate 58.1%).

[1]University of Florence, Department Of Health Sciences, Florence, Italy, [2]University of Florence, Medical Specialization School Of Hygiene And Preventive Medicine, Florence, Italy, [3]Sanofi, 14 Espa. Henry Vallée, Lyon, France, [4]Sanofi, Viale L. Bodio, 37/b, Milan, Italy

Backgrounds: Respiratory syncytial virus (RSV) is the leading cause of hospitalizations due to respiratory infections. All infants are at risk of severe disease and hospitalization due to RSV, while this risk is even higher in premature infants and those having co-morbidities (i.e., congenital heart disease). The aim of this systematic review is to assess the burden of RSV-related hospitalizations in children aged 0-5 years old in Italy.
Methods: A search string was applied to PubMed, Embase, Scopus and International HTA databases in the time frame January 2000 - July 2022 concerning studies in English/Italian languages.
Results: From initial 20,845 records, 8 articles were selected and analysed. Among the general population, 88.8% of RSV-positive hospitalization involved patients <1 year of age. In another study, among RSV-positive hospitalized children 0-5 years old, 81.6% were <1 year, 62.5% were <3 months and 41% were <30 days old. In a retrospective study involving children ≤1 year of age, the proportion of infants admitted for RSV-induced ALRI in the three RSV epidemic seasons was 71.6%-80.8% in full term infants aged <6 months, while it was 48.2%-63.3% in those <3 months. Instead, the proportion of infants admitted for RSV infection was 50%-81.8% in preterm infants aged <6 months and <3 months. RSV-A and RSV-B infections varied across the epidemic seasons considered, although RSV-A seemed to be more frequent (particularly in preterms).
Conclusions/Learning Points: All infants at their first RSV season showed to be at higher risk of severe infection and hospitalization, regardless gestational age at birth, compared to older children (1-5 years old). Collected data on hospital-related RSV infection among children in Italy may enrich the understanding about this disease, being a useful tool to assess the most effective preventive measures.

SOME INFECTIONS AND AUTOIMMUNE HEMOLYTIC ANEMIA – TWO CASES PRESENTATIONS

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Amelia Blescun[1], Ileana Popescu[1], Alexandra Nicolescu[1], Smaranda Arghirescu[2]
[1]Emergency Clinical Hospital for Children "Louis Țurcanu", Pneumology/infectious Diseases, Timișoara, Romania, [2]University of Medicine and Pharmacology Victor Babes, Pediatric Department, Timișoara, Romania

Title of Case: Some infections and autoimmune hemolytic anemia – two cases presentations
Background: Autoimmune hemolytic anemia is an acquired form of hemolytic anemia in which autoantibodies target red blood cell membrane antigens, inducing cell rupture (lysis). Is rare in children with an estimated incidence of 0.2 per million individuals below 20 years of age.
Case Presentation Summary: Case presentation: two cases without history of present illness addmitted in our hospital for hemolytic anemia triggerd by infectious disease. First case is a 17 years girl, hospitalised initialy with fever, hepatosplenomegaly, laterocervical adenopathy, tonsilitis. She presented positive serology for Ebstein barr infection (IgM VCA > 160 Ui/ml). After 3 days she presented sudently extreme skin pallor, jaundice, astenia, tachycardia and repeted hemoglobin was 6 g/l from 11 g/l three days earlier, indirrect bilirubin elevated. She was refered to hour hospital. Biological examination revealed elevated ferritin, LDH, low haptoglobin, negative IgM parvovirus B19 serology, and positive IgM mycoplasma. Indirect Coombs test was negative. Evolution after red blood cell transfusion, corticotherapy and antibiotherapy (macrolides) was favorable. The second case is a 3 years boy with a recent episode of acrocianosis a frigore treated with hydrocortizon hemisuccinat for 5 days. After another 5 days of acalmia he presented fever, extrem skin pallor, was tested positive for influenza A with hemoglobin 4.7 g/L (from 11 g/L one week earlier) and referenced to our hospital. SARS COV2 IgG were positive. No compatible red blood cells packages could be found. The corticotherapy was started (dexamethasone). He recoveres slowly. After 5 days hemoglobin was 7.8 g/L.
Learning Points/Discussion: Conclusion: Double infection (Epstein Barr and mycoplasma) or Influenza after covid increases the risk of haemolitic anemia. This cases respond to corticotherapy.

Henry Vallée, Lyon, France, [4]Sanofi, Viale L. Bodio, 37/b, Milan, Italy

Backgrounds: Respiratory syncytial virus (RSV) is a frequent cause of acute lower respiratory infection that leads to a significant global disease burden for children under 5 years of age. Infants with RSV infection often require hospitalization, admission to intensive care units (ICU) and mechanical ventilation. Healthcare utilization and economic expenses due to RSV could be considerably high, impacting workload and normal functioning of neonatal/paediatric wards during RSV season. The aim of this systematic review is to describe the economic burden and healthcare management of RSV bronchiolitis in inpatients aged 0-5 years old in Italy.
Methods: A specific search string was applied to PubMed, Embase, Scopus and International HTA Database. Inclusion criteria comprised English/Italian languages and publication date between January 2000 and July 2022. Studies were subdivided into groups considering the reported symptoms/diagnosis (bronchiolitis, acute respiratory infections, …).
Results: Among the 20,845 records retrieved, 12 articles resulted eligible for our study and referred to bronchiolitis. Most of the reported costs for bronchiolitis are related to hospitalisation, diagnostic tests, and other medical procedures. The mean cost per inpatient for bronchiolitis was higher in case of RSV-positive infants (5,753.43 ± 2,041.62 euros), while children <3 months of age accounted for most of the annual cost. The length of stay in hospital ranged from 3.4 to 5.8 days, higher in case of ICU admission. Comparing severity of disease, a tendency toward longer hospitalization and longer oxygen therapy were detected in RSV-positive patients when compared with RSV-negative children.
Conclusions/Learning Points: The collection of evidence on healthcare utilization for RSV bronchiolitis could be crucial for an appropriate prevention strategy to manage paediatric RSV-related disease in the future in Italy.

[1]Sanofi Pasteur, Vaccines, Lyon, France, [2]Fisabio, Vaccine Research Department, Valencia, Spain

Backgrounds: Presence of comorbidities are associated with higher risk of complications and poorer clinical outcomes related to respiratory illnesses. However, available data among pediatric population are limited. We investigate the characteristics of paediatric hospitalizations considering viral aetiology and frequency of complications by presence of comorbidities
Methods: A multicentre prospective observational study within the Valencia Hospital Surveillance Network for the Study of Influenza and Other Respiratory Viruses Diseases (VAHNSI) framework was conducted during 8 pre-COVID influenza seasons (2011/2012 to 2018/2019) in 4-10 hospitals covering 21-46% of total inhabitants of the Valencia Region of Spain (around 5M). Patients <18 years hospitalized with respiratory complaints were included in the study if they met the ECDC ILI-case definition (≥5 years) or if the respiratory symptoms had an onset within 7 days prior to admission (<5 years) and were tested by RT-PCR for 8 respiratory viruses. Demographics and clinical information were used to describe the cases, with Chi-square or non-parametric tests were used to compare patients by presence of comorbidity
Results: 26% of children reported at least one comorbidity at admission. The majority (80.9%) had at least one complication during the hospitalization, regardless the presence of underlying conditions. Children with comorbidities were twice as likely to be admitted to ICU. RSV was the main detected pathogen (23.1%).
Conclusions/Learning Points: Most children hospitalized for respiratory illness did not have pre-existing risk conditions. The use or availability of treatments and vaccines are currently limited for most respiratory viruses. Additional efforts are needed for greater dissemination of evidence-based recommendations to prevent respiratory illness and their complications among the pediatric population.

THE POST PANDEMIC RESURGE OF RESPIRATORY SYNCYTIAL VIRUS

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Elena Bozzola[1], Vittucci Anna Chiara[1], Livia Antilici[1], Rosanna Recupero[1], Hana Zeric[1], Giordana Mattana[2], Cristina Russo[2], Maria Marchili[1], Carlo Federico Perno[2], Alberto Villani[1]
[1]Bambino Gesù Children's Hospital, Pediatric, Roma, Italy, [2]Bambino Gesù Children's Hospital, Unit Of Microbiology And Diagnostic Immunology, Roma, Italy

Backgrounds: After COVID-19 restrictive measures relaxing, increased hospitalization for bronchiolitis in 2021-2022 season was observed. Aim of the study is analyzing RSV hospitalization among infants during the actual epidemic season in Italy.
Methods: We enrolled children aged less than 12 months admitted for bronchiolitis to Pediatric Unit, Bambino Gesù Children's Hospital, Rome, Italy from 1st October- 31 December 2022.
Results: 103 patients entered the study. In 95% there was no prematury or comorbidities. RSV was the main agent (64,1%), followed by Rhinovirus (33,0%), Parainfluenza (11,7%), Influenza (11,73%). Main findings were: - length of hospitalization (LOS) was 6 days, higher in RSV-patients compared to non-RSV ones (mean 6,68 ±3,19 days vs 5,08 ±3,89 days; p 0,001). - oxygen supplementation in 79 patents (76,6%), mostly RSV-patients ($p < 0.00001$). - Intensive Care Unit (ICU) occupation by 11 patients (10,6%) mostly RSV-patients (p 0,049). Comparing this actual season to our previous pre-pandemic data, main findings were: - LOS, higher in 2022 (mean 6,11 ±3,52 days vs 4,68 ±2,24 days, p 0,001) as well as oxygen supplementation (76,6% vs 37,2% $p < 0.00001$) and in particular the use of high-flow nasal cannulas (30,09% vs 19,56%, p 0,017). -percentage of patients admitted to ICU , higher in 2022 (11,65% vs 3,58% p 0,0019), as well as the ICU occupation time (mean 9,73 ±2,45 days vs 6,53 ±1,89 days, p 0,001). This data are even more evident in RSV group (93,93% vs 44,28%, $p< 0.00001$). -age, as patients in 2022 were older than in 2017 (mean 99,82 ±71,88 days vs 48,95 ±67,41 days p 0,007).
Conclusions/Learning Points: During the actual epidemic season, RSV seems to be more virulent and aggressive on infants. Extensive protection for infants is advisable.

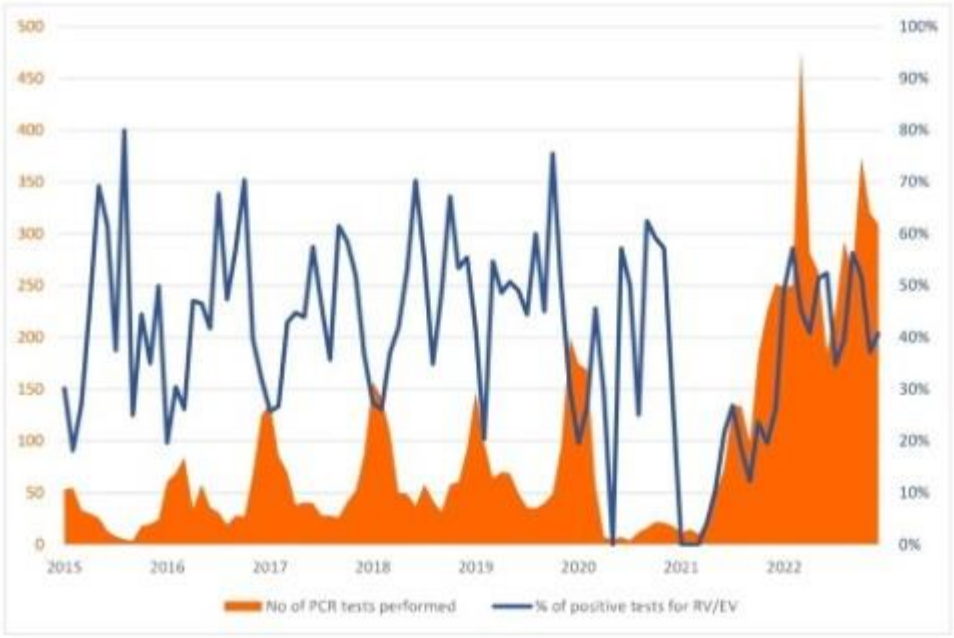
PV0603 / #1826

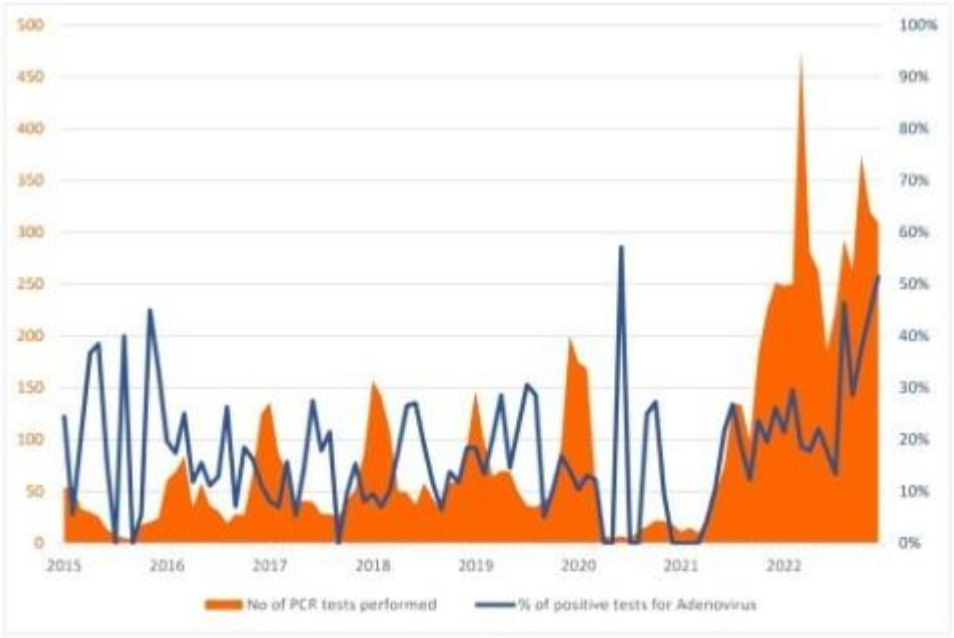
NONENVELOPED RESPIRATORY VIRUSES THROUGHOUT THE PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Mariana Bravo[1], Raquel Palha Martins[1], Miguel Lucas[1], Mariana Costa[1], João Pereira Vaz[2], Lurdes Correia[2], Lia Gata[1], Fernanda Rodrigues[1,3]
[1]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Clinical Pathology Service, Coimbra, Portugal, [3]Universidade de Coimbra, Faculty Of Medicine, Coimbra, Portugal

Backgrounds: The implementation of non-pharmacological interventions to decrease transmission of respiratory viruses (RV) during the pandemic led to a marked reduction of respiratory infections, although with some reports that not all RV were affected in the same way, with some persistence of non-enveloped viruses (adenovirus, rhinovirus). The timing of resurgences of RV was also very heterogeneous. The aim of this study is to describe adenovirus and rhinovirus/enterovirus detection before and throughout the pandemic.
Methods: Retrospective and descriptive analysis of all adenovirus and rhinovirus/enterovirus detections by PCR (FilmArray respiratory panel) in nasopharyngeal samples, from children with acute respiratory infections as part of routine care, in a paediatric tertiary hospital, from January 2015 to December 2022.
Results: The proportions of positive tests for adenovirus and rhinovirus/enterovirus over time are presented (figure). Co-infection was a frequent finding for





both.

Conclusions/Learning Points: Unlike other respiratory viruses that normally have a clear seasonality, despite a reduction, adenovirus and rhinovirus/enterovirus infections did not disappear with the COVID-19 pandemic and there was an early return to pre-pandemic levels, although with less fluctuation. Even greater enhancement of infection prevention strategies would be required to prevent transmission of these viruses.

INFLUENZA A INFECTION AND NEUTROPENIA IN AN INFANT

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Martin Brizuela, Fernanda Ponzio, Romanette Hurtado Latapiat, Sandra Barreiro
Hospital General de Agudos Velez Sarsfield, Pediatrics, Buenos Aires, Argentina

Title of Case: Influenza A infection and neutropenia in an infant
Background: Several infections can cause transient neutropenia in children otherwise healthy. Viral infections such as influenza is an important etiology of neutropenia with spontaneous recovery in children. We present the case of a child with transient neutropenia associated with influenza A.
Case Presentation Summary: A 3-months-old male infant presented at the emergency room in September 2022 with a one day history of fever (39°C), cough and coryza. 39 weeks of gestational age with 3,560 grams of weight at birth. He has the diagnosis of interventricular communication. Vaccinations were up to date according to the Argentinian calendar. His mother had received influenza vaccine during the pregnancy. Physical exams revealed a systolic murmur 2/6, heart rate 135 pm, respiratory rate 40 pm, oxygen saturation 98% with room air. Laboratory test: leukocytes 3310/µL (neutrophils 496/µL, 15%; lymphocytes 1423/µL, 43%) , procalcitonin <0.05 ng/mL. A nasopharyngeal aspirate was performed at the emergency room. X-Ray chest with no lung infiltration. Because of severe neutropenia he was admitted to the pediatric floor, blood cultures were drawn and ceftriaxone was started at 80 mg/kg. On the first day of hospitalization, we received a positive PCR- Influenza A and oseltamivir treatment was started. A second blood test showed leukocytes 5600/µL (neutrophils 280/µL, 5%; lymphocytes 4592/µL, 82%). Blood smear and abdominal US were normal. No abnormal findings suspect oncology disease were present. Because he had no clinical abnormal findings and had a favorable evolution, he was discharged six days later with ambulatory follow- up. In a hemogram at two weeks, neutropenia was resolved spontaneously.
Learning Points/Discussion: Influenza infection is a differential diagnosis of transient neutropenia in healthy children during flu season.

ACUTE MYOSITIS CAUSED FOR INFLUENZA B: REPORT OF TWO CASES

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Martin Brizuela, Jimena Bergilli, Antonella Magnano, Luciana Pedretti, Leandro Carambia, Fernanda Ponzio, Romanette Hurtado Latapiat, Sandra Barreiro
Hospital General de Agudos Velez Sarsfield, Pediatrics, Buenos Aires, Argentina

Title of Case: Acute myositis caused for influenza B: report of two cases
Background: Acute myositis is a common condition in children. It can be caused by some viruses such as influenza A and B. Generally, children have a history of upper respiratory symptoms in the last week, associated with headache, fever, and malaise with a favorable evolution. We present two cases of myositis associated with influenza B.
Case Presentation Summary: Case 1: a 14-year-old girl with no clinical history of interest who consulted in October 2022 for fever and myalgia with difficulty walking for 3 days, associated with cough and runny nose. The admission laboratory showed an increase in CPK 8,788 U/L, thrombocytopenia, lymphopenia and increased transaminases. Aspiration of nasopharyngeal secretions was performed with detection of influenza B virus. She remained hospitalized for five days for symptomatic treatment (pain and hyperhydration) with good clinical evolution, with no complications. Case 2: a 10-year-old girl with no pathological history who consulted in October 2022, due to a two-day history of symptoms consisting of fever, arthralgia, myalgia, and nasal congestion. Laboratory was requested, which reported CPK 1,311 U/L, platelet count in the lower limit, mild increase in ALT. A nasopharyngeal aspirate with influenza B isolate was requested. Due to a mild clinical picture, outpatient management with oral analgesia and hyperhydration was decided. After six days, there was clinical resolution of the condition and normalization of CPK values.
Learning Points/Discussion: Influenza B infection should be taken into account as a differential diagnosis of myositis in pediatrics. The probable modification of the viral seasonal pattern must be taken into account. Management can be performed on an outpatient or hospital basis, taking into account the clinic and the laboratory.

RHABDOMYOLYSIS DUE TO INFLUENZA TYPE B AND RSV TYPE B CO-INFECTION: A CLINICAL CASE

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Valentina Burzio, Lina Cimminelli, Mohammad Reza Eshraghy, Bruna Loperfido, Stefano Maccario, Anna Perona, Roberta Spola, Eleonora Tognato, Paolo Manzoni
Nuovo Ospedale Degli Infermi, Ponderano (Biella), Division Of Paediatrics And Neonatology, University Of Torino. Department Of Maternal-infant Medicine, Biella, Italy

Title of Case: Rhabdomyolysis due to Influenza type B and RSV type B co-infection: a clinical case
Background: Paediatric rhabdomyolysis is related to different aetiologies, nonetheless viruses remain the most common cause. Timely diagnosis is critical for a proper clinical management.
Case Presentation Summary: A previously healthy eight-years-old boy presented to our paediatric emergency department with a five days history of fever associated with coryza, vomiting, headache, myalgia with limited extension of lower limbs, painful walking, and cough. At home, he was treated with ibuprofen, steroids and cefpodoxime, with scarce fluid and food intake. At arrival, he showed normal vital signs, croup, pale skin, dry mucosae, normal cardiac and abdominal examination, painful lower limbs with limited walking, without signs of arthritis. He was initially treated with adrenaline inhalers, and performed laboratory investigations which showed significant increased creatine phosphokinase (CPK 9334 U/l, normal value 38-174), liver enzymes (aspartate aminotransferase, AST 564 U/l – normal value 1-38, alanine aminotransferase, ALT 156 U/l – normal value 1-41), with renal function, cardiac enzymes, electrolytes and coagulation in normal ranges. He was therefore admitted to our ward to perform intravenous hyper-hydration (NaCl 0.9%) and cardiac monitoring. The anti -inflammatory treatment and steroids were suspended. A respiratory virus panel performed on nasal swab resulted positive for Influenza type B and RSV type B. The muscles enzymes progressively decreased until normalisation and he improved until full recover.
Learning Points/Discussion: Rhabdomyolysis is a potentially life threatening condition. Most common causes are infective, usually showing good prognosis. Viral infections combined with overuse of ibuprofen, steroids and decreased oral intake can trigger this condition. Criteria for admission to an intensive care unit are signs of acute kidney injury, electrolytes imbalances, abnormal ECG and disseminated intravascular coagulation, not present in this boy.

PV0607 / #1943

SEVERITY OF RSV BRONCHIOLITIS BEYOND THE COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Ana Cláudia Cavadas-Almeida[1], Joana Gama Jardim[1], Beatriz Garcia[2], Mariana Domingues[1,2], Ana Brett[1,2], João Pereira Vaz[3], Lurdes Correia[3], Fernanda Rodrigues[1,2]
[1]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Universidade de Coimbra, Faculty Of Medicine, Coimbra, Portugal, [3]Clinical Pathology Service, Centro Hospitalar E Universitário De Coimbra, Portugal, Coimbra, Portugal

Backgrounds: The COVID-19 pandemic changed the seasonality of respiratory infections, including RSV bronchiolitis. The aim of this study is to assess changes in the severity of RSV bronchiolitis, before (2016-2020) and throughout (2021; 2022) the pandemic.
Methods: Retrospective observational study of all children < 24 months, with bronchiolitis and a positive PCR test for RSV in nasopharyngeal secretions, attending a tertiary paediatric emergency service, from 2016-2022, comparing demographics, clinical characteristics and management.
Results: RSV was not detected from April 2020 to May 2021. The 2021 season occurred between June and October and the 2022 season started in September. The characteristics and comparison of the 3 groups are presented in the
table.

Table. Demographics, clinical characteristics and management of RSV bronchiolitis cases before (2016-2020) and throughout (2021; 2022) the COVID-19 pandemic.

	2016-2020 n=401	2021 n=231	2022 n=179	p
Median age (months)	2.0±4.7	9.0±6.7	5.0±5.4	**p<0.01**
Sex (female)	197 (49%)	112 (48%)	79 (44%)	p=0.525
Comorbidities				
Prematurity	41 (10%)	6 (3%)	14 (8%)	**p=0.010**
Congenital heart disease	10 (2%)	2 (1%)	0	**p=0.010**
Admitted cases	341 (85%)	70 (30%)	75 (41%)	**p<0.001**
Median age (months)	2.0±4.4	3.5±6.2	3.0±4.7	**p=0.014**
Median duration (days)	3±3.6	2.0±6.1	3.0±4.2	p=0.189
Oxygen therapy	240 (70%)	43 (61%)	49 (65%)	p=0.284
Laboratory tests	147 (43%)	16 (23%)	13 (17%)	**p<0.001**
X-Ray	139 (41%)	25 (36%)	17 (23%)	**p=0.013**
Antibiotic treatment	39 (12%)	12 (17%)	10 (13%)	p=0.424
PICU	41 (12%)	2 (3%)	5 (7%)	**p=0.039**

Conclusions/Learning Points: In the 2021 epidemic, that occurred outside the usual season, children with bronchiolitis were older, with fewer comorbidities and admitted cases seemed to be less severe. In 2022, the season started earlier and, despite being closer to the prepandemic pattern, cases were still less severe.

FIRST REPORT OF TRANSIENT HEPATIC TRANSAMINASE ELEVATION DURING METAPNEUMOVIRUS INFECTION IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Ismahan Celep[1], Sare Ilbay[2,3], Kubra Aykac[2], Ali Cengiz[3], Yasemin Ozsurekci[2]
[1]Hacettepe University, Faculty of Medicine, Paediatrics, Ankara, Turkey, [2]Hacettepe University Faculty of Medicine, Pediatric Infectious Diseases, Ankara, Turkey, [3]Hacettepe University Faculty of Medicine, Pediatric Infectious Diseases, ankara, Turkey

Backgrounds: Human metapneumovirus (MPV) is known as one of the leading causes of viral respiratory tract infections in children. There are limited number of studies mentioning hepatic transaminase elevations in adults during disease course of MPV infection. Here, we want to draw attention to increase in transaminases that may possibly be associated with MPV in our pediatric cohort.
Methods: Pediatric cases who admitted to our tertiary care hospital between January 2020-January 2022 and whose nasopharyngeal swab samples positive for MPV were included. Respiratory tract multiplex polymerase chain reaction panel was used to isolate respiratory viruses. Clinical and laboratory characteristics were collected from the hospital recording system.
Results: Of all 149, median age was 35 months (Q1-Q3: 18.5-65). Presenting clinical diagnosis was upper respiratory tract infection in 78 (52.3 %) and pneumonia in 56 (37.6%) of the patients. Underlying disease was recorded in 52 (34.8%) patients. Twenty-two cases (14.7%) were hospitalized with median length of stay 9 days (Q1-Q3: 4-15) and 15 (10%) of them needed respiratory support. There were 5 (3.3%) cases with increased alanine (ALT) and aspartate (AST) transaminases; however, 2 of them had previously known transaminase elevations, they were above 2x and 4x the upper limit of normal (ULN). During MPV infection, they increased to 6x ULN in both of the patients. Transaminases were above <2x the upper limit of normal (ULN) in 2 patients, >5x ULN in a patient who had 1113 and 1413 U/L values of ALT and AST, respectively with spontaneous resolution.
Conclusions/Learning Points: MPV is a relatively new respiratory pathogen and may cause hepatic transaminase elevations in children, especially with underlying diseases. Close monitorization of ALT and AST is needed to demonstrate the actual relation between MPV and hepatic involvement.

RESPIRATORY SYNCYTIAL VIRUS INFECTION, BEFORE AND AFTER COVID-19 – TRENDS AND CHALLENGES

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Rodica Chirilă[1], Laura-Mariana Olaroiu[1], Raluca Vlad[1,2], Daniela Păcurar[1,2]
[1]"Grigore Alexandrescu" Emergency Children's Hospital, Paediatrics, Bucharest, Romania, [2]"Carol Davila" University of Medicine and Pharmacy, Paediatrics, Bucharest, Romania

Backgrounds: Respiratory syncytial virus (RSV) is the main cause of bronchiolitis in children. Morbidity is significantly higher in premature infants and patients with pre-existing comorbidities. We aimed to identify epidemiological changes in RSV infection trends during COVID-19 pandemic.
Methods: We conducted a retrospective study from March 2018 to June 2022 assessing RSV infection prior to and during the COVID-19 pandemic (sex distribution, age of admission, seasonal peak, hospital length of stay and prevalence of respiratory failure).
Results: 486 patients were included: 309 pre-pandemic (March 2018- February 2020) and 177 during COVID-19 pandemic (March 2020- June 2022). We report a significant reduction in RSV incidence in the second group and a significant statistical increase during summer and autumn in the pandemic period ($p<0.01$) - most likely caused by the lifting of restrictions in Romania. There was no statistical difference in sex distribution (57.9% vs 60.5% boys) between these two groups, but the average age was significantly higher during the pandemic period (5.76 vs 7.83 months, $p=0.054$). A possible explanation might be a significantly higher admission rate for older patients with neurologic comorbidities, patients which were particularly challenged in terms of respecting control measures for SARS-CoV-2 transmission. The average length of hospital stay (7.59±5.25 vs 7.49±3.99 days, $p=0.82$) and the prevalence of respiratory failure (69.6% vs 77.4%, $p=0.074$) were similar. Premature birth was associated with a significant risk for both.
Conclusions/Learning Points: During the COVID pandemic, the RSV infection was significantly less common, was not modified according to gender, hospital stay and associated respiratory failure, but the incidence increased with age. Our study also highlights the importance of spacing measures in the prevention of other respiratory infections as RSV, not only SARS-CoV2 infection.

REGIONAL DISEASE BURDEN ESTIMATE OF RESPIRATORY SYNCYTIAL VIRUS IN CHILDREN IN WESTERN PACIFIC AND SOUTH EAST ASIA REGIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Young June Choe[1], Jiseon Park[1], Sangshin Park[2], Hyun Jung Kim[3], Lorenzo Bertizzolo[4]
[1]Korea University Anam Hospital, Department Of Pediatrics, Seoul, Korea, Republic of, [2]University of Seoul, Graduate School Of Urban Public Health, Seoul, Korea, Republic of, [3]Sanofi, Medical Affairs, Seoul, Korea, Republic of, [4]Sanofi, 14 Espa. Henry Vallée, Lyon, France

Backgrounds: Respiratory syncytial virus (RSV) is an important cause of bronchiolitis and pneumonia in infants globally. In Western Pacific and South East Asia Regions, RSV has been shown to be one of the most important pathogens among lower respiratory tract infection (LRTI) in children, however, its burden is largely underestimated.
Methods: We conducted a systematic review and meta-analysis examining the incidence of RSV in infants in Western Pacific and South East Asia Regions using random effects models. Included in this analysis were original observational studies involving infants <5 years and reporting the proportion of RSV among children with acute respiratory infections (ARI), and/or incidence.
Results: A total of 4,403 studies were identified from the initial search, after screening titles, abstracts, and full-text review, a total of 143 studies met pedefined eligibility criteria and were included in the analysis. The proportion of RSV among all respiratory trac infection was 21.4% (95% CI, 17.9-25.1), while the proportion of RSV among lower respiratory tract infection was 27.7% (95% CI, 6.3-25.4) in children in Western Pacific and South East Asia Regions between 1970 and 2021. By countries, the highest proportion was in Myanmar (50.0%; 95% CI, 47.5-52.4%) and New Zealand (45.3%; 95% CI, 37.2-56.4%), followed by Singapore (37.1%; 95% CI, 36.0-28.3%), Vietnam (35.5%; 95% CI, 19.3-53.6%) and South Korea (31.7%; 95% CI, 18.2-47.1%).
Conclusions/Learning Points: The burden of RSV-associated respiratory infection among children in Western Pacific and South East Asia Regions is substantial. While new prophylactic interventions will target the children for protection in coming years, efforts to improve preventive strategies and expand immunoprophylaxis in Western Pacific and South East Asia Regions could lead to increase protection against RSV-associated diseases.

AUTUMN 2022, UNPRECEDENTED BRONCHIOLITIS PEAK IN FRANCE SUPPORTS THE IMMUNITY DEBT CONCEPT

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Robert Cohen[1], Alexis Rybak[1], Andreas Werner[2], Stéphane Béchet[1], Françoise Gebhard[2], Karine Picard[2], Alain Wollner[1], Antoine Mercier[2], Morched Zouari[2], Florence Beaufils-Philippe[2], François Angoulvant[3], Naim Ouldali[4], Bruno Frandji[5], Corinne Levy[6]
[1]ACTIV, Pediatric, Créteil, France, [2]AFPA, Pediatrics, Créteil, France, [3]CHUV, Pediatrics, Lausanne, Switzerland, [4]Robert Debré Hospital, Pediatrics, Paris, France, [5]CGM, Public Health, Paris, France, [6]ACTIV, Infectious Disease, Créteil, France

Backgrounds: Non pharmaceutical interventions (NPIs) implemented during the COVID- 19 pandemic have led also to a dramatic decrease of many pediatric infectious diseases. Early, the concept of immunity debt raised concerns about a rebound of the diseases after lifting barrier measures and many polemics in social media ensued.
Methods: The Pediatric and Ambulatory Research in Infectious diseases (PARI) study, with 125 pediatricians using the same software, was set up in France to appraise the trends of infectious diseases. From July 2017 to November 2022, the electronic medical records of children with an infectious disease were automatically extracted. Point-of-care tests such as combo tests (SARS-CoV-2, RSV, and influenza) were distributed to participating pediatricians.
Results: From the beginning of the surveillance, we observed for the year 2022, a deep and 6-week earlier outbreak of bronchiolitis. During the week 46/2022, the highest weekly number of bronchiolitis cases (n=401) was reported. During this outbreak, RSV positive rapid test accounted for 65.4% CI95% [61.7, 69.0]. No significant change in the age distribution between 2017 and 2022 was observed, children aged ≤3 months, 4-6, 7-12 and ≥13 months accounted for 11.2%, 26.4%, 30.7% and 31.7%, respectively.
Conclusions/Learning Points: In the context of new epidemic patterns of bronchiolitis and overload of hospital emergencies, wards and intensive care units, the health care system responses should be quickly adapted. Targeted NPIs around the youngest children should be implemented to protect them and counterbalance the consequences of immune debt. Our data underline the interest of implementation of immunoprophylaxis and/or RSV

vaccines.

CLINICAL AND VIROLOGICAL SURVEILLANCE OF ENTEROVIRUS D68 IN PAEDIATRIC PATIENTS ATTENDED IN A TERTIARY HOSPITAL BETWEEN 2021-2022 IN BARCELONA (CATALONIA, SPAIN)

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Anna Creus-Costa[1], Jorgina Vila[1], Cristina Andrés[2], Ariadna Carsi Durall[1], Maria Piñana[2], María Carmen Martín[2], Pere Soler-Palacín[3], Andrés Anton[2]
[1]Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Paediatric Hospitalisation Unit, Department Of Paediatrics, Barcelona, Spain, [2]Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Respiratory Viruses Unit, Microbiology Department, Barcelona, Spain, [3]Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Paediatric Infectious Diseases And Immunodeficiencies Unit, Barcelona, Spain

Backgrounds: Enterovirus D68 (EV-D68) has been linked to outbreaks of lower respiratory tract infections (LRTI) and neurological complications. An increase in EV-D68 cases has been observed during 2021-2022. This study aims to describe clinical and virological characteristics of paediatric patients with EV-D68 laboratory-confirmed infection in a tertiary hospital in Barcelona (Catalonia, Spain).
Methods: Between September 2021-November 2022, respiratory samples from <16-year-old patients with a suspected viral infection that attended a tertiary hospital in Barcelona were collected. Detection of EV and other respiratory viruses was performed by a specific real-time multiplex reverse transcription assay (Allplex Respiratory Panel Assay, Seegene, South Korea), and phylogenetic analysis of the partial viral protein 1 coding region (WHO protocol) was carried out for genetic EV characterisation. Clinical information was retrospectively retrieved after EV-D68 laboratory-confirmation.
Results: A total of 13,142 specimens were received, of which 1,192 (9.1%) were laboratory-confirmed for enterovirus. Up to 230 (19.3%) viruses were typed as EV-D68, majorly belonging to the B3-clade (226/230; 98.3%). Median age was 3 years (IQR 1-4) and 60.0% were male. The most common clinical presentation was LRTI (139/230, 60.4%) followed by upper respiratory tract infections (70/230, 30.4%). Overall, 73/230 (31.7%) EV-D68 cases required hospitalisation, with LRTI as the main cause of hospital admission (56/73, 76.7%). Seven cases required intensive care admission, all of them due to LRTI. One patient (0.4%) presented with myelitis and remains with sequelae. Viral co-detections were observed in 112/230 (48.7%) samples, most commonly with rhinovirus (79/112, 70.5%) followed by adenovirus (17/112, 15.2%).
Conclusions/Learning Points: Respiratory EV-D68 infection was most commonly associated with LRTI in our series. Despite its low frequency, the concern of neurological complications underlines the importance of a continued enterovirus surveillance.

PV0613 / #2079

ARE POST-PANDEMIC BRONCHIOLITIS MORE FREQUENT AND SEVERE?

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Gonçalo Croca, Catarina Mendonça, Teresa Magalhães, Mariana Viegas, Catarina Gomes
Centro Hospitalar do Oeste, Caldas da Rainha, Pediatrics, Caldas da Rainha, Portugal

Backgrounds: Acute bronchiolitis is one of the main causes of hospitalization in Pediatrics, especially in infants. Typical infection outbreak occurs during the winter months and can cause severe symptoms, especially in small infants. Post COVID 19 pandemic, the epidemiology and severity of bronchiolitis were affected. The aim of our study is to compare the frequency and severity of pre and post-pandemic admissions for acute bronchiolitis.
Methods: Retrospective study of hospitalized pediatric patients with bronchiolitis in 2019 (pre pandemic) and 2022 (post pandemic) in a level II hospital. Demographic, clinical, and microbiological data were collected. Patients with immunodeficiency and chronic heart, neurologic or systemic disease were excluded.
Results: In 2019 81 children were admitted for bronchiolitis (0,3% of all emergency department visits) versus 101 in 2022 (0,3%). In our sample 44% were girls, median age 3 months (9 days-2 years), with similar age distributions between both groups. The median length of stay was 4 days. RSV was identified in 84 patients total (46,52%). In 2022 more infants needed supplemental oxygen (73,3% vs 39,5%, $p<0,0001$), there was a higher need of CPAP (8,9% vs 1,2%, $p=0,023$) and mechanic ventilation (2,0% vs 1,2%, $p=0,645$). [GC1] In 2022, 88,9% of patients that required CPAP were 3 months or younger. Furthermore, there was increased admission to intensive care in 2022 (8,9% vs 2,5%), with the majority being one month or younger (63,6%).
Conclusions/Learning Points: In our sample post-pandemic infants hospitalized with bronchiolitis had a higher need of oxygen and non-invasive ventilation, but there was no statistical difference in mechanical ventilation. Our results are similar to the few previous published studies. It is hypothesized that the pandemic restrictions led to an immunological debt, resulting in increased frequency and severity of bronchiolitis.

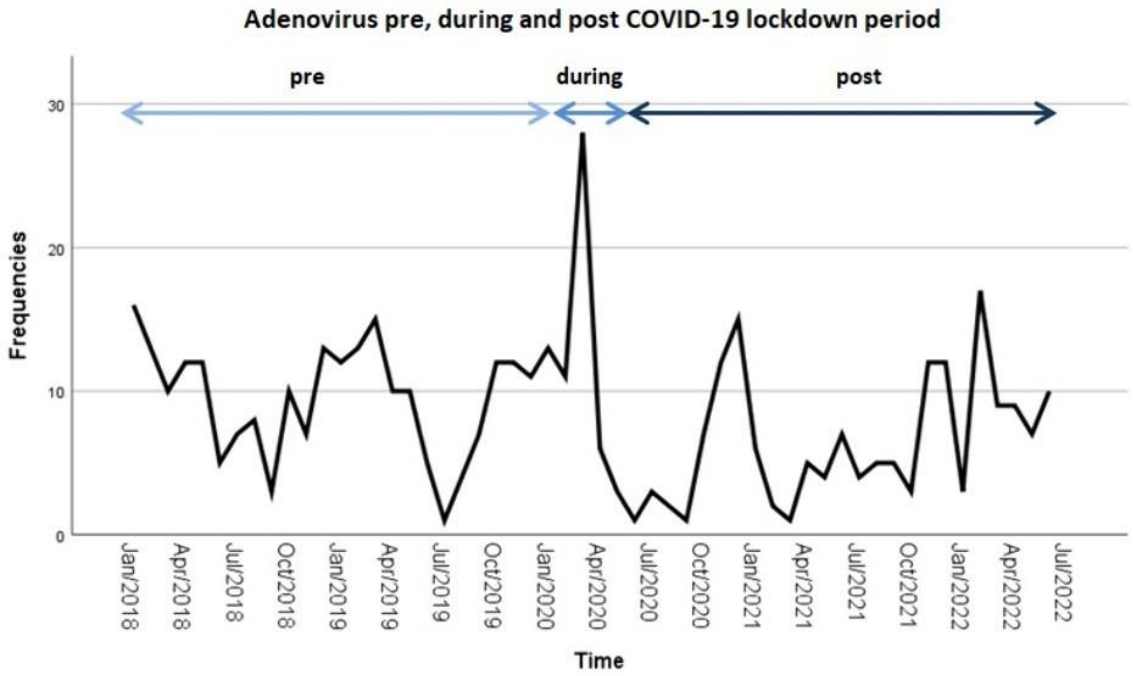
PV0614 / #2085

THE CHANGING PATTERN OF ADENOVIRUS INFECTION AMONG CHILDREN ADMITTED IN PORTUGUESE HOSPITAL: BEFORE AND AFTER COVID-19 LOCKDOWN PERIOD

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Raquel Da Costa Neves[1], Nina Berdianu[1], Rita Valsassina[1], Tiago Silva[1], Rita Corte Real[2], Paula Palminha[3], Catarina Gouveia[1]
[1]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatric Infectious Diseases Unit, Lisbon, Portugal, [2]Hospital São José - Centro Hospitalar Universitário Lisboa Central, Molecular Biology, Lisbon, Portugal, [3]Instituto Nacional de Saúde Dr Ricardo Jorge, Virology, Lisbon, Portugal

Backgrounds: Human adenoviruses (AdV) can cause infections at any age but most commonly in pediatric population. We aim to study the impact of COVID-19 lockdown period on AdV infection in children admitted in a Portuguese tertiary hospital.
Methods: Single center, retrospective, study of AdV identification in respiratory samples collected from children admitted from Jan/2018 to Jun/2022. Demographic, clinic, laboratorial and evolution data were analyzed and compared in 3 groups: pre, during (Feb/2020 – May/2020) and post COVID-19 lockdown period.
Results: We identified 451 children with AdV-positive, with median age of 20 months [P25;P75], 55,9% male, 85,8% <5 years, 53,4% in pre-lockdown, 10,6% during and 35,9% in post-lockdown. Most (83,8%) had co-infection with another agent. Positivity rate of AdV-infection significantly decreased after lockdown (p-value <.001), with 13,8% pre-COVID-19 and 9,0% post-COVID-19, more significantly in the female group (p-.01). There was no significant difference between age groups. Median length of stay was 5 days before COVID-19 and 4 days after COVID-19. Regarding seasonality, we observed an increase of AdV infections from October to March in both periods. During COVID-19 lockdown the rate of nosocomial AdV infections decreased (2,1%) when compared with pre (14,5%) and post (15,4%) COVID-19 (p < .01). Respiratory symptoms were less frequently reported post lockdown (p-.006), however gastrointestinal symptoms increased (p-.019), without difference in transaminases values. Also, no difference was shown in clinical presentation such as fever and neurological symptoms among patients before and after nonpharmaceutical interventions (NPIs)
launched.



Conclusions/Learning Points: Children under 5 years old were the main population for AdV infections in inpatients. The NPIs significantly decreased the transmission of community respiratory viruses, as well as AdV-infections. Clinical presentation with less respiratory and more gastrointestinal symptoms appears to have been influenced by COVID-19.

[1]Hospital Clínico Universitario de Santiago de Compostela, Translational Pediatrics And Infectious Diseases, Santiago de Compostela, Spain, [2]Instituto de Investigación Sanitaria de Santiago, Genetics, Vaccines And Infections Research Group (genvip), Santiago de Compostela, Spain, [3]Instituto de Salud Carlos III, Centro De Investigación Biomédica En Red De Enfermedades Respiratorias, Madrid, Spain, [4]Unidade de Xenética, Instituto de Ciencias Forenses, Facultade De Medicina, Universidade De Santiago De Compostela, Santiago de Compostela, Spain

Backgrounds: Respiratory Syncytial Virus (RSV) is the principal cause of acute lower respiratory infections (ALRI) in young children, and it is associated with significant morbidity and mortality in childhood. The majority of infants with RSV admitted to the hospital are healthy and lack identifiable predisposing risk factors for severe disease. The main aim of the present study is to disentangle the host molecular factors associated with RSV infection severity using an epigenomics approach to non-invasive samples.
Methods: We recruited 16 infants admitted to the hospital for an RSV infection. Eight of them had a severe infection requiring PICU admission and mechanical ventilation, while the remaining eight infants presented mild symptoms, with only few days of hospitalization. DNA was extracted from saliva samples collected upon admission and the Illumina methylation EPIC BeadChip was performed for epigenetic analyses
Results: A linear model adjusted for age was used to examine the association between DNA methylation and RSV disease severity. We identified a panel of differentially methylated positions (DMPs) that allows clustering infants suffering a severe infection from those having mild symptoms. The gene set analysis, performed with all CpGs and with CpGs within promoters revealed significant enrichment for pathways involved in the expression and translocation of olfactory receptors (FDR<10^{-5}), olfactory signaling and transduction pathways (FDR<10^{-4}), and biological processes involved in olfactory receptor activity (FDR<10^{-3}).
Conclusions/Learning Points: DNA methylation pattern in the saliva of infants with RSV infection may discriminate severe (PICU) from mild (hospitalized) impairment. Saliva as an accessible proxy of the host response may be useful for further investigation and search for biomarkers.

CIBERIFNEC. RITIP. Universidad Autonoma de Madrid, Paediatric Infectious Diseases, Madrid, Spain

Backgrounds: Antibiotics are frequently prescribed to children with atypical pneumonia, although viruses cause the majority of cases. Our aims are to describe the aetiology of atypical pneumonia in children, using molecular biology techniques, and to analyze whether these techniques influence antibiotic consumption and hospital stay.
Methods: Prospective study of children under 14 years admitted for atypical pneumonia and tested with a respiratory panel (FilmArray® 2plus) in October 2019-June 2022 (except March-November 2020), in the first 72 hours of admission. Patients with positive RT-PCR for respiratory syncytial virus (RSV), influenza, or SARS-CoV-2 were excluded. Comparison with historical controls (2017-18), with similar clinical characteristics but no etiological study.
Results: We included 64 patients and 50 controls, with a median age of 26 months in both groups. The respiratory panel was positive in 58 patients (91%), 27 of which (47%) were coinfections (Table). Most children (92% cases, 84%controls, p=0.237) had hypoxemia. Seven cases (11%) and five controls (10%) were admitted to the Intensive Care Unit. The median length of stay (IQR) was 4 (3-6) days in cases and 3 (2-4.3) in controls (p<0.001). There were no differences in total antibiotic consumption (83% of cases and 86% of controls). Antibiotics were prescribed to 41% of cases and 72% of controls at hospital discharge (p=0.001). Ampicillin was the most commonly prescribed antibiotic among patients (44%, vs. 18% in controls, p=0.005), whereas azithromycin was the most common in the control group (19% in patients vs. 48% controls,
p=0.001).

Table. Respiratory panel results in chilren with atypical pneumonia

Microorganism	Positive samples (%)*	Coinfections (%)
Rhinovirus	25 (39)	21 (84)
Metapneumovirus	22 (34)	11 (50)
Enterovirus	13 (20)	13 (100)
Parainfluenza	10 (16)	3 (30)
Adenovirus	10 (16)	9 (90)
Bocavirus	7 (11)	4 (57)
VRS	6 (9)	3 (50)
Coronavirus OC43	4 (6)	3 (75)
Coronavirus HKU1	3 (5)	2 (67)
Influenza	1 (1,5)	1 (100)
Bordetella parapertussis	1 (1,5)	1 (100)
Mycoplasma pneumoniae	1 (1,5)	1 (100)

Conclusions/Learning Points: We detected at least one respiratory virus in more than 90% of children admitted for atypical pneumonia. In addition to molecular diagnosis, other interventions are needed to reduce antibiotic consumption in these patients.

PV0617 / #596

INFLUENZA MORBIDITY AND MISSED OPPORTUNITIES FOR INFLUENZA VACCINATION IN HIGH-RISK CHILDREN: EXPERIENCE FROM A TERTIARY PEDIATRIC CLINIC

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Panagiota Diamantopoulou[1], Sofia Karagiannidou[2], Garyfallia Syridou[2], Vassiliki Papaevangelou[2]
[1]"ATTIKON" UNIVERSITY HOSPITAL, Third Department Of Pediatrics, Athens, Greece, [2]"ATTIKON" UNIVERSITY HOSPITAL, Third Department Of Pediatrics, ATHENS, Greece

Backgrounds: Influenza is a highly infectious acute respiratory viral infection. Influenza serious sequelae and hospital admissions, more common in high-risk populations, can be prevented by vaccination. We aimed to describe morbidity during the current seasonal influenza wave in a pediatric population and estimate the “missed” opportunities of vaccination in a subgroup of high-risk children.
Methods: An ongoing prospective observational study was conducted. Children (<18 years) with confirmed Influenza (A / B) that presented at the Pediatric ER of “Attikon” University Hospital (Athens, Greece) during the period 1/10/2022 – 10/01/2023 were enrolled, irrespectively to whether they were hospitalized or not. Influenza infection was confirmed by either antigenic or molecular assay in nasal swab. Demographic and clinical characteristics were recorded.
Results: 122 children (48.4% male) were included, with a mean (SD) age of 9.34 (4.06) years, while 18/122 (14.8%) had underlying diseases. Ten children (8.2%) were hospitalized, with a mean (SD) length of hospital stay of 4.7 days (2.67); 30% of them were diagnosed with pneumonia and hypoxia. Among non-immunized children, hospitalization rate was 7.7% among healthy and 17.6% among those with underlying disease (p=0.196). None of the vaccinated children required hospitalization. Overall, 7/104 (6.7%) healthy children and 2/18 (11.1%) children with underlying diseases presenting with influenza were previously vaccinated (p=0.6). Univariate analysis indicated that children with underlying diseases in which, according to NIP, vaccination was indicated, had longer mean hospitalization length of stay (8.83 vs 4.07 days, p=0.01), as did children younger than 2 years old (8.25 vs 4.07, p=0.023).
Conclusions/Learning Points: Missed opportunities of influenza vaccination among high-risk children were identified indicating that more educational efforts are needed. Additionally, vaccination of young children 6months – 2 years needs to be discussed.

HUMAN METAPNEUMOVIRUS INFECTION IN CHILDREN HOSPITALIZED WITH RESPIRATORY TRACT DISEASE - CLINICAL FEATURES AND MANAGEMENT

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Joao Dias[1], Ana Feio Azevedo[2], Ana Santos[2], Adriano Pereira[2], Ezequiel Moreira[2], Fernanda Carvalho[2]
[1]Centro Hospitalar do Medio Ave, Pediatria, Porto, Portugal, [2]Centro Hospitalar do Medio Ave, Pediatria, Vila Nova Famalicão, Portugal

Backgrounds: Human metapneumovirus (hMPV) is a leading cause of acute respiratory illness among children worldwide. We aim to describe demographic characteristics, impact of the disease, and therapy used in this population.
Methods: Retrospective study conducted at a secondary hospital, including children < 5 years of age hospitalized between 2018 and 2022 with acute respiratory infection caused by hMPV. Data were collected from medical records and analyzed through SPPS; p values <0.05 were considered statistically significant
Results: Included 22 patients, 13 male, mean of age 15,1 months (SD 13,6; interquartile range IQR 1-59.0). Mean hospitalization time 5,6 days (SD 3,6). Comorbidities (prematurity, recurrent wheezing, Trisomy 21 and cardiovascular disease) among 12 (54,5%). Most frequent cause of hospitalization: hipoxemia (9, 40,9%) and eating difficulties (8, 36,4%). More than 50% presented with cough, fever, eating difficulties and respiratory distress. Most common diagnosis were bronchiolitis (14; 63,3%) and pneumonia (7; 31,8%). 18 (81,8%) were treated with salbutamol, 14 (63,6%) supplemental oxygen, 10 (45,5%) corticosteroids, 10 (45,5%) antibiotics and 6 (27,3%) chest physiotherapy. Mean hospitalization time was statistically significant in patients who realized supplemental oxygen (p=0,002) and chest physioterapy (p=0,001). Viral co-infection presented in 8 patients; complications in 11 (50%), namely acute otitis media, atelectasis and bacterial superinfection. There was no statistically significant association between patients with previous comorbidities and development of complications or with patients with viral co-infection.
Conclusions/Learning Points: This study showed information about the effects of hMPV infections in young children. In this group, the therapeutic intervention as well as the mean hospitalization time with supplemental oxygen and chest physioterapy longer than other therapies, highlight to the severity of this pathogen and its high morbidity in respiratory infections.

SENTINEL SURVEILLANCE OF SEVERE ACUTE RESPIRATORY INFECTIONS IN SERBIA IN 2021-2022 INFLUENZA SEASON

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Dragana Dimitrijevic[1], Verica Jovanovic[2]
[1]Institute of Public Health of Serbia,,Dr Milan Jovanovic Batut,,, Department Of Epidemiological Surveillance, Belgrade, Serbia, [2]Institute of Public Health of Serbia, Centre For Disease Control, Belgrade, Serbia

Backgrounds: Sentinel surveillance of severe acute respiratory infections (SARI) was implemented in Serbia in November 2009. Six sentinel hospitals in 3 cities participated in the SARI surveillance system. Three of them are child hospitals. The aim of this study is to provide a review of sentinel surveillance of SARI among children population in Serbia in 2021-2022 influenza season.
Methods: Both epidemiological and virological data were collected on a weekly basis during all round of year. Influenza surveillance has been done in accordance with professional and methodological guidance for epidemiological surveillance of influenza for the current season. Intensive care units (ICUs), pediatric and respiratory disease wards were all represented. For laboratory confirmation of influenza, Real time polymerase chain reaction (RT-PCR) was used.
Results: Start of influenza season was registered in week 50/2021 Influenza activity peaked between weeks 12/2022 and 15/2022, with the positivity rate higher than 35%. A total of 143 SARI cases were reported with 100% recorded age. Of these, 59% were 0-4 years old and 41% were 5-14 years old. Among these cases, 130 (91%) respiratory specimens were collected during the surveillance period. The number of positive samples was 34 (26%). The highest proportion of laboratory-confirmed influenza cases was 47% in week 14/2022. All three influenza viruses were confirmed: A(H1)pdm09, A(H3) and type B. A(H3) viruses predominated, accounting for 53% of all sentinel SARI detections. There no were death associated to influenza.
Conclusions/Learning Points: Existing the high match between SARI hospitalizations and the percentage of influenza testing and influenza positive samples indicates the adequacy of sentinel SARI surveillance in Serbia. Integration epidemiological with laboratory surveillance highlights the importance of maintaining and improving national influenza surveillance capacity especially in the frame of International Health Regulations.

INFLUENZA-RELATED HOSPITALIZATIONS IN CHILDREN DURING THE OMICRON WAVE

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Anca Cristina Draganescu[1], Oana Sandulescu[2,3], Anuta Bilasco[4], Victor Daniel Miron[1], Anca Streinu-Cercel[2], Roxana Sandu[2], Simona Paraschiv[5], Ovidiu Vlaicu[5], Dragos Florea[5], Adrian Streinu-Cercel[2]
[1]Carol Davila University of Medicine and Pharmacy, Pediatrics, Bucharest, Romania, [2]Carol Davila University of Medicine and Pharmacy, Infectious Diseases, Bucharest, Romania, [3]National Institute for Infectious Diseases "Prof. Dr. Matei Bals", Bucharest,Romania, Infectious Diseases, Bucharest, Romania, [4]National Institute for Infectious Diseases "Prof. Dr. Matei Bals", Bucharest,Romania, Pediatrics, Bucharest, Romania, [5]National Institute for Infectious Diseases "Prof. Dr. Matei Bals", Bucharest,Romania, Medical Laboratory, Bucharest, Romania

Backgrounds: The COVID-19 pandemic has significantly changed the circulation of respiratory viruses and especially influenza viruses. The aim of this study was to monitor and characterize pediatric cases hospitalized for influenza since the onset of the omicron wave in Romania.
Methods: We present data from a multicenter prospective epidemiological study monitoring influenza virus circulation among patients hospitalized for ILI/SARI. We included in the analysis all non-COVID-19 pediatric cases tested for influenza by RT-PCR between January and May 2022 and hospitalized in the largest infectious disease hospital in Romania.
Results: A total of 135 children, non-COVID-19, were hospitalized for ILI/SARI symptoms. Median age was 4 years (IQR:2-9years), and male predominated (56.3%,n=76).The influenza positivity rate was 29.6%(n=40). The A/H3 subtype predominated in 36 of the cases (only 3 A/H1 cases and 1 A/no subtype ca0se).The majority of influenza cases were identified in March (28 cases/52 children tested) and April (10 cases/27 children tested). We identified 5 cases of co-infection: rhinovirus (4) and adenovirus (1). In addition 21.5%(n=29) of children tested were negative for influenza but positive for other respiratory viruses: rhinovirus (n=16), respiratory syncytial virus (n=7), adenovirus (n=3), metapneumovirus (n=2), parainfluenza (n=1). All influenza cases had a favourable outcome, with a median duration of hospitalisation of 5 days (IQR:4-6days). This was significantly higher compared to that of patients tested negative ($p<0.05$). Age under 2 years increased need for hospitalization by 1 day ($p=0.008$).
Conclusions/Learning Points: We identified a 29.6% positivity rate of influenza among children hospitalized for influenza in the first 5 months of 2022. Continuous monitoring of viral circulation, especially in the pediatric population, is essential and the use of multiplex PCR testing can be a useful tool for diagnostic and therapeutic as well as epidemiological purposes.

PV0621 / #1548

IMMUNOPROPHYLAXIS WITH PALIVIZUMAB IN A LEVEL II HOSPITAL.

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Inês Eiras, Luciana Abelha, Sandra Catarina Ferraz, Inês Correia Magalhães, Ana Isabel Sequeira, Armando Laranjeira, Dalila Rocha, Mariana Costa
Unidade Local de Saúde do Alto Minho, Paediatrics, Viana do Castelo, Portugal

Backgrounds: Respiratory syncytial virus (RSV) is a highly contagious virus that can lead to severe infections, particularly in children who are at high risk. Palivizumab, a monoclonal antibody, is used to prevent severe lower respiratory tract disease caused by RSV in high-risk children. Objective: characterize cases of prophylaxis with palivizumab in high-risk children under 2 years at a level II hospital, and determine the incidence of RSV respiratory disease in these children.
Methods: Retrospective descriptive study that included patients under 2 years who were indicated for prophylactic immunization with palivizumab over a period of 10 seasons (2012-2013 to 2021-2022).
Results: A total of 42 patients were included, with male predominance (54.8%) and within the age range 0-5 months (69%). The primary reason for performing immunoprophylaxis was gestational age $\leq 28^{+6}$ weeks in 42.9% of cases, followed by congenital heart disease in 28.6% of cases. The season with the highest number of infants undergoing immunoprophylaxis was 2012-2013 with 9 (21.4%) individuals. No respiratory disease was detected in the months following inoculation in 26 (61.9%) cases. Of the 16 (38.1%) individuals who developed an infection, a nasopharyngeal aspirate was performed using polymerase-chain-reaction (PCR) in 12 (75%), and of these 2 (12.5%) tested positive for RSV. Admission to the pediatric service was required in 10 (62.5%) cases, with one case requiring intensive care.
Conclusions/Learning Points: The majority of individuals didn't contract respiratory disease in the following months. Those who did develop an infection, hospitalization was required, mostly caused by an agent other than RSV. Since the risk of infection in these children remains high, complementary environmental control measures are recommended. Future studies are also needed to optimize timing of palivizumab's administration as the seasonality of RSV appears to have modified.

Backgrounds: Screening tests for early detection of SARS-CoV-2 infections in asymptomatic children and child care workers (CCW) in day care centers (DCC) were frequently established during the pandemic. Non-pharmaceutical measures directed against SARS-CoV-2 affected the circulation of other viral pathogens. We investigated screening samples in DCC for the presence of SARS-CoV-2 and other respiratory viruses.
Methods: Respiratory samples from asymptomatic children aged 1-6 years and CCW were collected in DCC in Würzburg (Germany) at one day each in October and November 2020, and in February, May, June and July 2021. Samples were tested for SARS-CoV-2 and 17 other respiratory virus using PCR/multiplex PCR (FTD-21™). The cycle threshold value indicated viral load (<25 high/25-35 medium/>35 low).
Results: A total of 474 samples were collected, including 336 (70.9%) samples from 150 children and 138 (29.1%) from 58 CCW. Overall, 79/474 (16.7%) samples were virus-positive (19.6% in children, 9.4% in CCW), with 87 detections overall (50.6% rhinovirus, 26.4% adenovirus, 8.0% endemic coronavirus, 4.6% enterovirus, 3.4% parainfluenzavirus, 2.3% RSV, 2.3% bocavirus, 1.1% parechovirus, 1.1% SARS-CoV-2; no influenzavirus or human metapneumovirus [hMPV]). Children showed a higher proportion of rhinovirus than CCW (11.9% vs. 2.9%; p=0.001). RSV, bocavirus, parechovirus and SARS-CoV-2 were found only in children. Parainfluenzavirus, RSV and parechovirus were detected only during the summer season. Viral load was high/medium/low in 1.1%/41.4%/57.5% of 87 detections.
Conclusions/Learning Points: Respiratory viruses were detected in 17% of samples from asymptomatic DCC participants, despite pandemic preventive measures. Rhinovirus and adenovirus predominated. Unusually, RSV, influenzavirus, hMPV and parainfluenzavirus were not detected during the winter season 2020/21. Further studies are needed on the relevance of high/medium/low viral load in asymptomatic children regarding virus transmission.

ACUTE RESPIRATORY INFECTIONS IN THE PRE-PANDEMIC ERA: ANALYSIS OF EMERGENCY ROOM SURVEILLANCE DATA IN A REFERRAL HOSPITAL FOR CHILDREN IN ITALY

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Allegra Ferrari[1], Erica Baldoni[1], Silvia Allegretti[1], Lucia Massolo[1], Peter Postma[1], Matilde Ogliastro[1], Raffaella Sibilio[1], Stefano Mosca[2], Andrea Orsi[1,2,3], Giancarlo Icardi[1,2,3]
[1]University of Genoa, Department Of Health Sciences (dissal), Genoa, Italy, [2]Interuniversity Research Center on Influenza and Other Transmissible Infections, Ciri-it, Genoa, Italy, [3]Ospedale Policlinico San Martino IRCCS, Hygiene Unit, Genoa, Italy

Backgrounds: In order to reduce the burden of acute respiratory illness in the community, the implementation of clinical-epidemiological surveillance systems is strongly recommended by the World Health Organization and the European Center for Disease Control and Prevention.
Methods: Since 2007, an Emergency Department Syndrome surveillance system has been active at “IRCCS G. Gaslini”, the children's Reference Hospital in the Liguria region (Northwest Italy). Influenza-Like Illness (ILI) and Lower Respiratory Tract Infections (LRTI) are the two monitored syndromes. In this study, we performed a comprehensive analysis of the surveillance data collected over a period of 7 years (2013-19) in the pre-pandemic era.
Results: During the study period, there were an average of 1190 ILI and 830 LRTI annually (Figure 1). The window of maximum incidence of respiratory infections was between December and March, with a peak in December (13.73%) and February (12.60%) for ILI and LRTI, respectively. Most cases were registered between 1 and 3 years of age (55.77% of ILI and 46.77% of LRTI) and among male children (55.59% of ILI and 55.43%). With regards to hospital admissions, most of them were registered among children with LRTI (24.28% vs. 4,62%). Multivariate logistic regression showed that, in comparison to those with ILI, they had 4 times the chances of being admitted at the hospital (aOR 4.16 95% CI 3.66-4.73; p<0.001). Age and sex were not statistically significant predictors of hospital

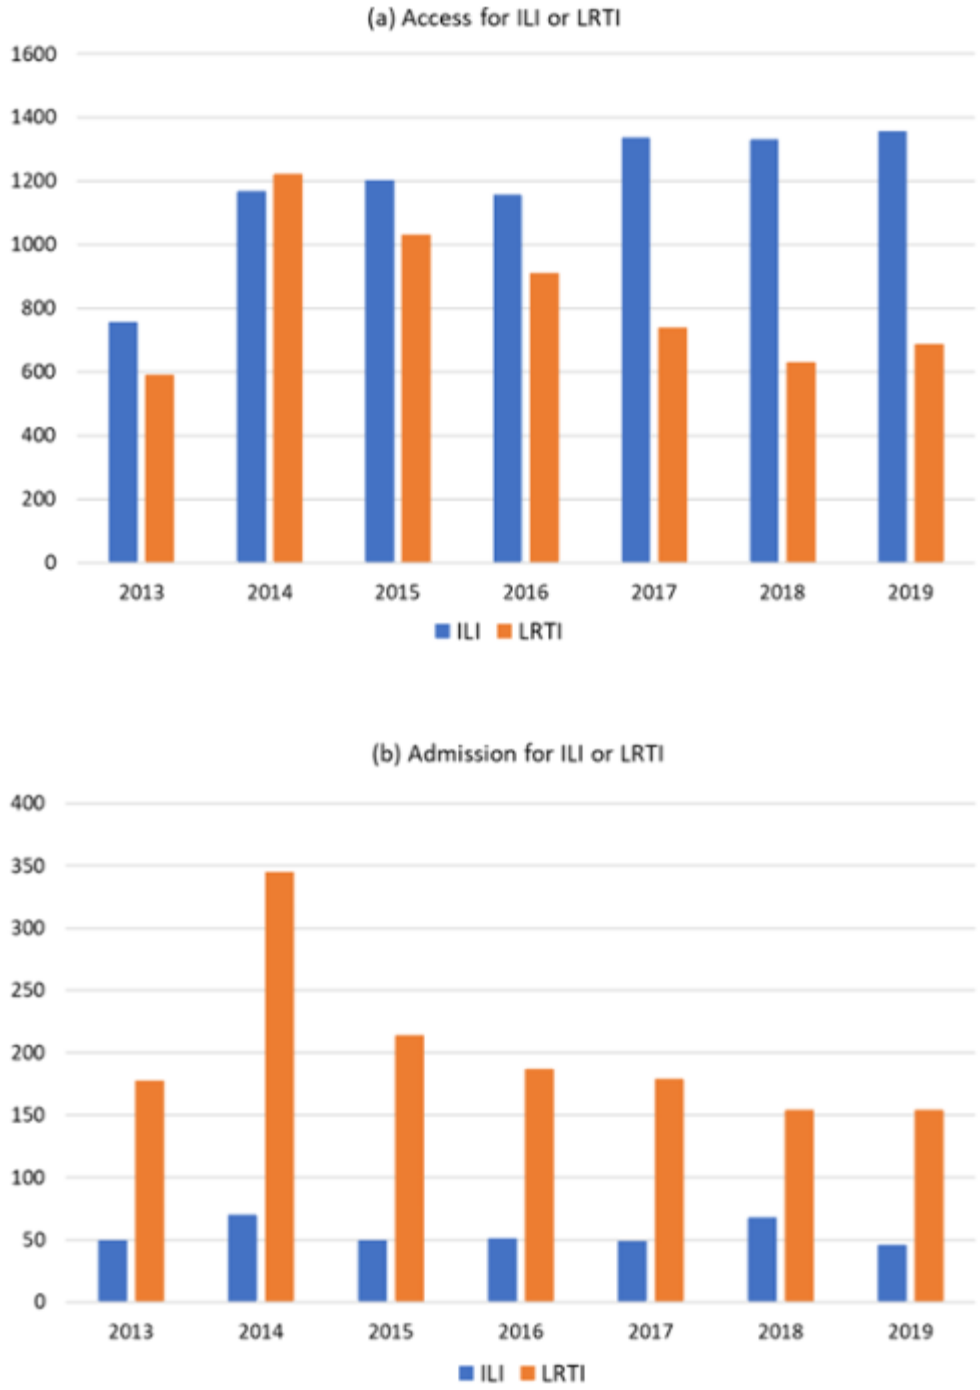

Figure 1 - IRCCS G. Gaslini syndromic surveillance, 2013-2019

admission.

Conclusions/Learning Points: Syndromic surveillance systems worldwide need to be adapted to new COVID-19 indicators. However, an accurate analysis of the pre-existing epidemiological panorama is necessary in order to draw accurate comparisons and understand the additional burden that this pandemic has placed on pediatric hospitals.

[1]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Universidade de Coimbra, Faculty Of Medicine, Coimbra, Portugal, [3]Centro Hospitalar e Universitário de Coimbra, Clinical Pathology Service, Coimbra, Portugal

Backgrounds: Influenza virus (IV) is a major cause of infection in children. The COVID-19 pandemic led to a dramatic reduction in respiratory infections but, with the lifting of non-pharmaceutical interventions, there was a resurgence of many pathogens. The aim of this study was to characterise the resurgence of IV in the paediatric population.
Methods: All cases of IV infection detected by PCR in nasopharyngeal samples collected as part of routine testing in the ER of a tertiary pediatric hospital, from 2015 to 2022, were analysed.
Results: There were 1173 detections (952 IV type A, 320 H1N1, 624 A(H3) and 221 type B). The distribution by month and year is shown in figure 1. The beginning of the pandemic interrupted the 2019-20 epidemic, with IV remaining undetectable until February 2022, when a new epidemic started, dominated by
A(H3).

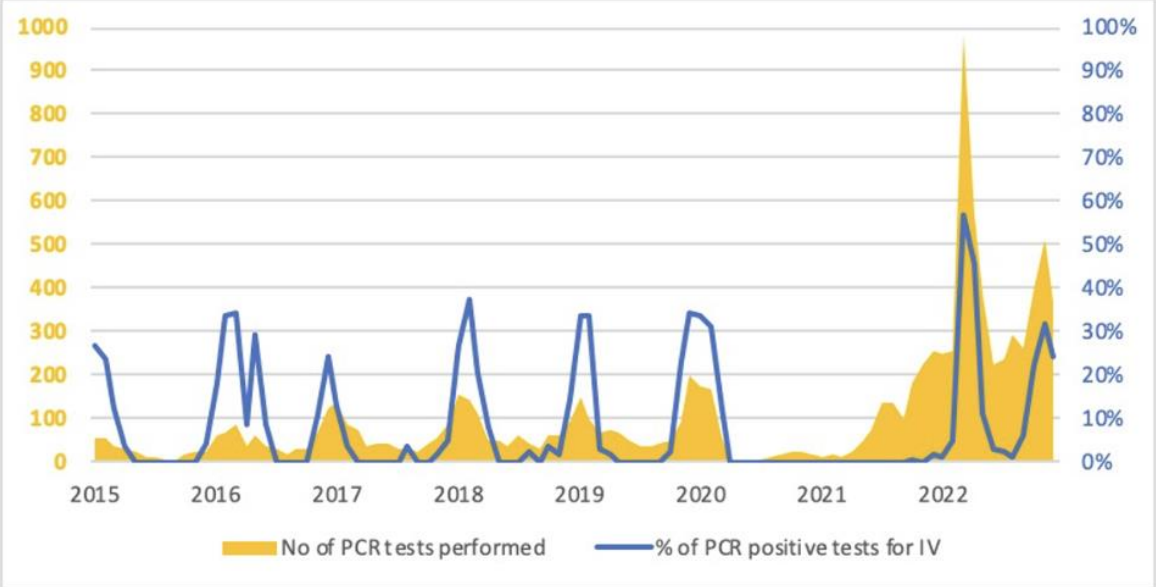

Figure 1. Number of PCR tests performed and proportion of positive tests for IV.

Conclusions/Learning Points: The COVID-19 pandemic interrupted IV circulation for 2 years. The resurgence occurred later than for other viruses, with an unusually late epidemic, of shorter duration, and with exceptionally high proportion of positive samples, followed by a further epidemic, 6 months later, earlier than observed in previous epidemics in this community.

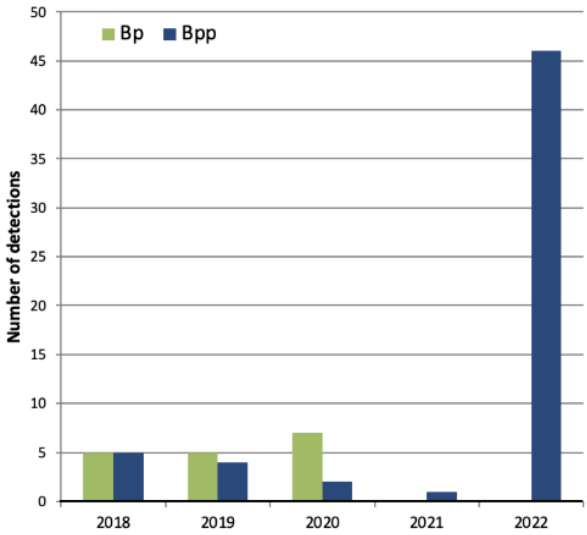
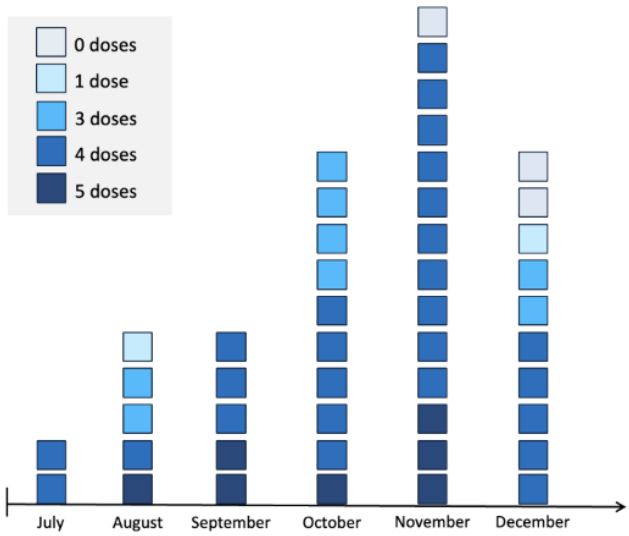
Backgrounds: Bordetella parapertussis (Bpp) can cause a pertussis-like illness, but less severe or asymptomatic, with < 5% following the classic disease symptoms. Pertussis maternal vaccination was introduced in the Portuguese NIP in 2017, with coverage rates >90% and with infant vaccination rates >95%. It is unclear whether acellular pertussis vaccines provide any protection against Bpp infection.
Methods: Observational, retrospective, descriptive study, including all cases with Bordetella detection by PCR in nasopharygeal samples from 2018 to 2022, in a tertiary paediatric emergency service that admits an average of 60,000 children/year. The decision to perform the test was made by the physician who observed the patient. A more detailed analysis of Bpp cases was performed.
Results:



Distribution of Bp and *Bpp* cases between 2018 and 2022



Distribution of *Bpp* cases in 2022 and vaccination status

Since 2018, there were 75 Bordetella detections: 17 B. pertussis (23%) and 58 Bpp (77%), with distribution shown in the figure. In 2022, there was an unusual number of detections of Bpp; with distribution presented in the figure. All children were appropriately vaccinated for their age, and 3 were aged <2M. The mean age was 2,9Y (≤6M n=6; 7-18M n=12 and >18M n=40). 40% cases lived in the hospital's county. Co-detection with respiratory viruses occurred in all but one child, mainly rhinovirus/enterovirus (63.8%), adenovirus (58.6%) and parainfluenza virus (27.6%). The most frequent diagnosis were nasopharyngitis (n=24, 41.4%), bronchopneumonia (n=9, 15.5%) and cough (n=6, 10.3%, two with whooping cough). Most children had no comorbidities. 22% (n= 13) were admitted, with a mean hospital stay of 2.9 days.
Conclusions/Learning Points: An increase in incidence of Bpp in central Portugal in 2022 was

observed, mainly in children fully vaccinated. Only two patients presented with whooping cough. Co-detection of Bpp with other respiratory viruses questions its clinical significance.

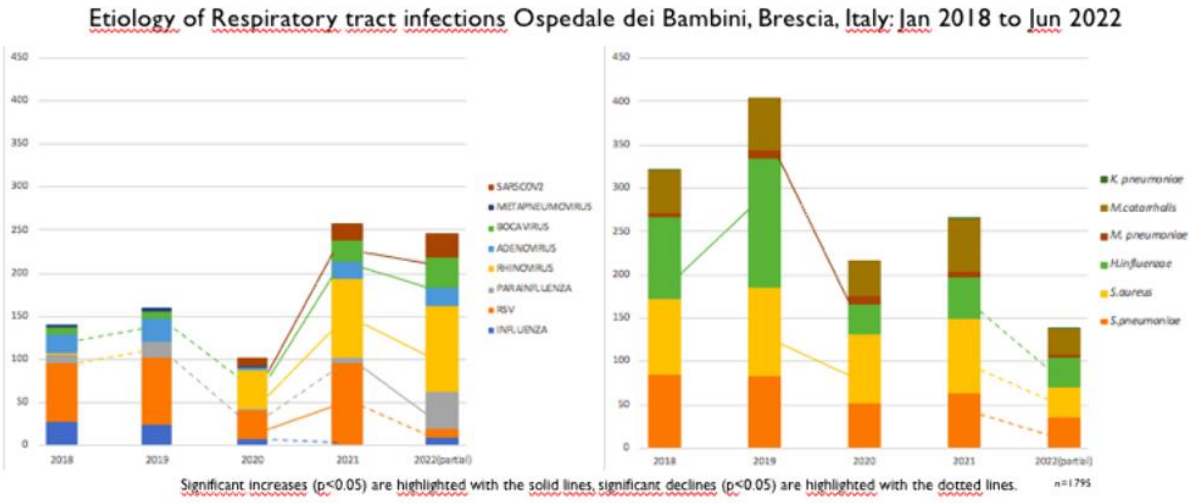
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Luisa Giannone[1], Sara Roversi[2], Parveen Saini[3], Arnaldo Caruso[2], Raffaele Badolato[4], Richard F Schumacher[5]
[1]University Children's Hospital "Ospedale dei Bambini", ASST Spedali Civili di Brescia, Italy, Department Of Pediatric, Brescia, Italy, [2]University of Brescia, Department Of Molecular And Translational Medicine, Section Of Microbiology, Brescia, Italy, [3]University of Brescia, Department Of Pediatric, Brescia, Italy, [4]University of Brescia, Molecular Medicine Institute "angelo Nocivelli" And Department Of Clinical And Experimental Sciences, Brescia, Italy, [5]ASST Spedali Civili, Brescia, Hematology-oncology,ospedale Dei Bambini, Brescia, Italy

Backgrounds: Recent scientific literature has shown that the preventive and control measures used during the COVID19 Pandemic impacted heavily on the spread of other pathogens causing acute respiratory tract infection in children.
Methods: We retrospectively analyzed data from all patients admitted to the University Children's Hospital in Brescia between January 2018 and June 2022, who had at least one respiratory pathogen identified (PCR or culture) on nasopharyngeal swab or aspirate.
Results: Hospitalizations, gender and age distribution, and comorbidities of the 1795 children included remained constant over the study-period. While the most frequent bacteria, S.pneumoniae, S.aureus, H.influenzae and M.catarrhalis, decreased slowly but significantly over time, the incidence of viral pathogens increased showing a much more differentiated variation pattern during the study period: RSV peaked between October and December 2021, while Influenza since the beginning of the SARS-CoV-2 Pandemic was not observed until June 2022. The most frequent viruses in 2018 and 2019 were RSV, Influenza Virus, and Adenovirus, whereas from 2020 there was a marked increase of Rhinoviruses. Also, Bocavirus, so far rarely identified, was the third most frequent pathogen in 2021 and 2022, preceded only by Rhinovirus and RSV in 2021 and by Rhinovirus and Parainfluenza Virus in the first six months of 2022. A significant increase in co-infections was also
observed.



Conclusions/Learning Points: We observed significant changes in the etiology of acute respiratory infections, especially the absence of the Influenza, and the increase of RSV, rhinovirus, whose increase has already been described, or bocavirus about which little is published to date. It will be important to

study the new epidemiology of respiratory infections to better understand community transmission and to establish timely and effective preventive measures.

PV0627 / #2471

COMPARISON OF MODERATE AND SEVERE CHICKENPOX CASES IN POST-COVID-19 ERA: A RETROSPECTIVE STUDY.

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Aniket Sharma[1], Mark Grigoryan[2], Violeta Manukyan[2], Lernik Martirosyan[2], Roza Kishoyan[2], Hasmik Yeghiazaryan[2], Suren Brutyan[2], Vigen Asoyan[2], Hripsime Apresyan[2]
[1]Yerevan State Medical University, General Medicine, yerevan, Armenia, [2]YSMU, Infectious Diseases, Yerevan, Armenia

Background: Chickenpox is an infection caused by the varicella-zoster virus. It causes an itchy rash with small, fluid-filled blisters. Complications include bacterial infections of the skin, soft tissues, joints, sepsis, dehydration, pneumonia, encephalitis, toxic shock syndrome, Reye's syndrome in children taking aspirin during chickenpox.
Methods: We retrospectively used medical records of patients infected with varicella zoster virus from the Isolation Unit of Muratsan University Hospital from 2021 and 2022. Overall, we included 87 patients with chickenpox and shingles.
Results: Of 87 cases 54(62%) were from 2022 and other 33(38%) from 2021. Severity of the disease was moderate in 51(58.6%) patients, severe in 31(35.6%), and extremely severe in 5(5.8%) patients. Male-to-Female was 3:2(52/36). Total number of complicated cases were 26 (30%) of which 19 were in 2022 and 7 in
2021.

COMPLICATIONS	NUMBER OF CASES
Superficial Skin Infection	10
Phlegmon	5
Cellulitis	5
Cerebellitis and Ataxia	2
Pneumonia	1
Immune thrombocytopenia	1
Respiratory failure	1
Meningism	1

In 2021, Cases of skin infections were 2(6%), and 16(29.6%) in 2022. Of 26 complicated cases, 18 were male. Average length of hospital stay was 7.1 days and for complicated cases 9.2 days vs non-

complicated cases 6.2
days.

Averages of laboratory data during admission are depleted in the table below.

Lab	Severe/extremely severe	Moderate	P-value
HGB, g/l	125	122	<0.436
Neutrophils, $x10^9$/l	7.25	3.89	**<0.004**
Lymphocytes, $x10^9$/l	2.90	4.13	**<0.003**
PLT, $x10^9$/l	297	280	<0.561
ESR, mm/h	18.4	15.7	<0.273
CRP (at admission), mg/l	51.2	19.8	**<0.029**
CRP (at discharge), mg/l	3.68	7.80	<0.110
Glucose, mmol/l	5.59	5.31	<0.319
ALT, U/l	32.7	19.80	<0.265
AST, U/l	40.7	33.9	<0.364
Albumin, g/l	32.0	34.1	<0.518

Treatment: 69 out of 87 received Acyclovir, with an average of 5.33 days of treatment. We added antibacterial treatment to 50 complicated cases: Ceftriaxone-22cases(average-6.4 days), Metronidazole-15 cases (severe-11.4days, moderate-7.25days), Amoxicillin-Clavulanate-12cases (severe cases-6.5days,moderate-3.7 days), Azithromycin-12 cases, Amikacin, Cephalexin-4 cases each, TMP-SMX, Cefepime, Ciprofloxacin, Meropenem, Vancomycin-2 cases each. in six cases surgery was required. 7 (14%) Antibiotic resistance cases had received hyperbaric oxygen therapy(average-15.6days).
Conclusions/Learning Points: Comparing complications of chickenpox in the post-covid-19 era we have noted a dramatic increase in skin infection after varicella zoster infection. High absolute neutrophil and CRP counts were associated with these complications as suspected. Antibiotic resistance cases have longer duration of stay. Hyperbaric oxygen therapy is an option for treatment in these cases.

PV0628 / #1658

UTILITY OF THE RSV-CLASS CLINICAL ASSESSMENT SEVERITY SCORE FOR THE ASSESSMENT OF VIRAL AND HOST RSV DISEASE SEVERITY RISK FACTORS.

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Julia Gsenger[1], Britta Manuel[2], Clara Ihling[1,3,4], Paul Schnitzler[1], Julia Tabatabai[1,4,5]
[1]Centre for Infectious Diseases, Virology, University Hospital Heidelberg, Heidelberg, Germany, [2]Kinderarztpraxis, Kunterbunt, Heidelberg, Germany, [3]Dr. von Haunersches Kinderspital, University Hospital of the LMU Munich, Pediatrics, München, Germany, [4]German Centre for Infection Research, (dzif), Heidelberg, Germany, [5]Center for Childhood and Adolescent Medicine, University Hospital Heidelberg, General Pediatrics, Heidelberg, Germany

Backgrounds: Despite the substantial burden of respiratory syncytial virus (RSV) infections in infants and young children, validated tools for the systematic assessment of disease severity are lacking. We recently developed the RSV-CLASS Clinical Assessment Severity Score. This study aims to validate the score for assessing host and viral risk factors for severe disease.
Methods: Data of 339 RSV-positive children <3 years collected in winter seasons 2017-2020 was used for validation. RSV infection was confirmed with RT-PCR. Clinical data was obtained using a standardised questionnaire. The RSV-CLASS was calculated assigning one point each for clinical symptoms cough, rales, tachypnoea, and wheezing. The outcome LRTI was chosen as a proxy for severe disease
Results: The median age was 3.2 months, and 55.5% were male. With an RSV-CLASS score value of three or four, 97.9% and 100% of the children, respectively, were admitted with LRTI and classified correctly. The respective Area under the curve (AUC) was 0.87. More than half of the patients (64.3%) were aged <6 months, and their RSV-CLASS AUC was 0.82. Most children were previously healthy, but 14.2% had one or more diagnoses associated with a higher risk for severe disease. These children were younger ($p<0.001$), hospitalised longer ($p<0.002$), and had lower RSV-CLASS values ($p<0.003$), and their RSV-CLASS AUC was 0.86. We recently investigated the correlation of viral risk factors with disease severity and did not report significant correlations with the length of hospitalisation or signs of respiratory failure. The RSV-CLASS supports this, with no correlation of RSV subtype ($p=0.588$) and viral load ($\rho=-0.037$, $p=0.492$) with disease severity.
Conclusions/Learning Points: The RSV-CLASS is a tool for the assessment of RSV disease severity with a very convincing AUC when calculated for host and viral risk factors.

WHAT COULD WE IMPROVE IN BRONCHIOLITIS MANAGEMENT? CHANGES WITH COVID-19 PANDEMIA

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Antonio Correro Almagro[1], María Sánchez Codez[2], Irene Gutierrez Rosa[2], Maria Garcia Acevedo[3], Ana Sánchez Sánchez[4], Estrella Peromingo Matute[2], Veronica Fernandez Puentes[2], Almudena Alonso-Ojembarrena[5]
[1]Puerta del Mar University Hospital, Paediatrics, Cadiz, Spain, [2]Puerta del Mar Hospital, Division Of Pediatric Infectious Diseases, Puerta Del Mar, Cadiz, Spain, Cádiz, Spain, [3]HOSPITAL UNIVERSITARIO PUERTA DEL MAR, Pediatria, CADIZ, Spain, [4]Hospital Puerta del Mar, División De Enfermedades Infecciosas Pediátricas, Puerta Del Mar, Cádiz, España, Cádiz, Spain, [5]Hospital Puerta del Mar, Pediatrics, Cadiz, Spain

Backgrounds: Systematic use of genome amplification tests has modified the diagnostic and therapeutic management of bronchiolitis. One of its main advantages is the appropriate use of antimicrobials and reduction of complementary tests performed. We compared management of bronchiolitis before and after COVID-19 pandemic.
Methods: Retrospective cross-sectional study of patients with bronchiolitis were stratified in two groups according to COVID-19 pandemic: pre-pandemic period (PREP) and post-pandemic period (POSTP). Respiratory panel was performed on all patients POSTP. Only RSV antigen test was used in PREP. We compared disease severity and differences in diagnosis and treatment between both periods.
Results: 155 patients were included: 100/155 (64.5%) PREP and 55/155 (35.5%) POSTP. Severity score of POSTP was higher (median IQR: 7 [6-8]) than PREP (median IQR: 6.2 [4-8]; p=0.009). The frequency of RSV detections was higher in PREP (69/116 [59.5%] vs 47/116 [40.5%]; p=0.002) than POSTP. Chest radiograph (61% vs 39%), blood test (31% vs 69%) and blood culture (56 vs 44%) were used less in POSTP than PREP, with no significant differences. Although no differences were observed in use of albuterol, epinephrin and hypertonic saline were used less in PREP (97% vs. 3%; p=0.0001 and 88.4% vs. 11.6%; p=0.0001, respectively). Duration of hospitalization, oxygen requirement, type and duration were comparable between both groups.
Conclusions/Learning Points: Severity of bronchiolitis was higher in POSTP. Use of epinephrin and hypertonic saline has been lower in this group following the recommendations of the latest clinical practice guidelines. RSV detection was lower in POSTP, possibly due to changes in respiratory viruses circulation. Despite the innumerable advantages of respiratory panels, lager sample size is needed in our center to evaluate its diagnosis and therapeutic utility.

Backgrounds: Human bocaviruses (HBoVs) are recently described as human emergent viruses, so there is limited information on the clinical characteristics. This study aimed to investigate the clinical features of HBoVs infections in children.
Methods: Between May 2021-2022, hospitalized pediatric cases detected HBoV by PCR in respiratory tract samples were enrolled in the present study. Clinics and diseases courses of the patients were analyzed.
Results: Human bocavirus was detected in 77 children. While 10 (13%) patients were admitted in to the pediatric intensive care unit (PICU), 67 (87%) patients were hospitalized in inpatient wards. The median age was 2.5 years (min-max 0-7) in PICU group and 2 years (min-max 0-9) in others. All of the patients had underlying diseases in PICU group. The common diagnosis was pneumonia (85.7%). The mean absolute neutrophil count was 7300 cell/mL in non-PICU and 12500 cell/mL in PICU groups (p=0.005). The mean procalcitonin level was 0.12 ng/mL (IQR: 0.74-0.41) in non-PICU group and 1.44 ng/mL (IQR: 0.6-3.8) in PICU group (p=0.01). Of all, 35 (52.2%) patients in non-PICU group had multiple viral infection, only one patient (10%) among PICU group had viral coinfection (p=0.01). Rhinovirus (24.7%) and influenza (2.5%) were the most common pathogens responsible for co-infection. One patient died in PICU

Mortality	0	1 (10)	NA

group.

Conclusions/Learning Points: Human bocavirus infection is predominantly affects infants and the rate of PICU admission is high. Coinfections with HBoVs seem likely reduce the risk of PICU admission. More studies with large populations are needed to evaluate the impact of viral coinfections.

VIRAL PATHOGENS OF ACUTE LOWER RESPIRATORY TRACT INFECTIONS IN OUTPATIENT INFANTS

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Katharina Hecker[1], Hanna Bethe[1], Géraldine Engels[1], Kerstin Knies[2], Benedict Weißbrich[2], Johannes Liese[1], Andrea Streng[1]
[1]University Hospital Wuerzburg, Department Of Paediatrics, Wuerzburg, Germany, [2]Julius-Maximilians-University Würzburg, Institute For Virology And Immunobiology, Würzburg, Germany

Backgrounds: Up-to-date population-based data on viral etiology of acute lower respiratory tract infections (LRTI) in outpatient infants are lacking in Germany. Non-pharmaceutical preventive measures during the SARS-CoV-2 pandemic led to strong fluctuations in the circulation of viral pathogens, including RSV. This study aims to determine the incidence and etiology of acute LRTI in outpatient infants during the winter season 2022/2023.
Methods: Since November 2022, all infants <2 YOA from Würzburg diagnosed with acute LRTI are recorded in seven (44%) pediatric primary care practices in Würzburg. Oropharyngeal swabs for PCR testing on SARS-CoV-2 and 17 other viruses are collected on a pre-defined day every week.
Results: During the first 8 weeks of surveillance, 197 infants with acute LRTI were registered (on average 3-4 infants per practice and week); 52 infants provided respiratory samples. Median age was 14 months (IQR 8-18). Acute LRTI was diagnosed most frequently by abnormal auscultation (84.3%) and stridor/wheezing/grunting (53.8%); 97% of the children had bronchitis/bronchiolitis, 5.6% laryngotracheitis and 1.5% pneumonia. Overall, 73 viral pathogens were detected in 49/52 (94.2%) infants: RSV (32; 43.8%), endemic coronavirus (12; 16.4%), influenza virus (11; 15.1%), rhinovirus (7; 9.6%), adenovirus (5; 6.8%), bocavirus (3; 4.1%), parainfluenza virus (2; 2.7%), human metapneumovirus (1; 1.4%). Co-detections were observed in 19/49 (39%) infants (15x 2 viruses, 3x 3 viruses, 1x 4 viruses).
Conclusions/Learning Points: With the current population of 5500 infants in Würzburg, the monthly incidence of acute LRTI was estimated as 40/1000 infants <2 YOA (95% CI 37-44); 44% of the LRTIs were associated with RSV. SARS-CoV-2-associated LRTI were not detected so far, despite the contagious omicron variant and reduction of preventive measures.

Backgrounds: Respiratory Syncytial Virus (RSV) is the most frequent cause of childhood lower respiratory tract infections (LRTI). Surveillance data of bronchiolitis found 4.6% infants <1 year old attend hospital leading to 1:10 PICU admissions. Data on i) laboratory confirmed RSV cases (in primary, secondary and tertiary care) including hospital Emergency Department discharges, ii) health economic impact and iii) burden to families, are needed to inform strategies for preventive therapies.
Methods: The STOP-RSV study (ISRCTN:41075797) recruits children <3 years old with LRTI symptoms from primary, secondary and tertiary care. A nasal swab is tested on a multiplex respiratory viral panel using Biofire/Panther systems. On days 14 and 28 after inclusion parents complete EQ5 D3L and PeDS QL questionnaires and medical records are collected. In this mid-term analysis (n= 723, December 2021 - August 2022) results on prematurity, co-morbidities, healthcare utilization and medication prescription are presented. This study is funded by a collaborative agreement with Sanofi / AstraZeneca.
Results: Recruits: n=723 of which 18% were born premature <37 weeks (7% <35 weeks) Proportion Underlying Co-morbidity: 22% (78% no underlying co-morbidity noted) Health Care Utilization: 92% of hospital attendances had a previous Primary Care Consultation. Medication: (at time of symptoms): 25% antibiotics, 29% inhalers and 14% corticosteroids. 3% previously administered Palivizumab.
Conclusions/Learning Points: A high proportion of children <3 years old with LRTI symptoms in primary, secondary and tertiary care with confirmed RSV do not have any significant co-morbidity. Medication was frequently prescribed including antibiotics – this is a significant cost and AMR burden. The majority of those attending hospital had a prior primary care consultation indicating the high healthcare burden of this diagnosis.

CHILDREN HOSPITALIZED WITH INFLUENZA IN A PEDIATRIC HOSPITAL IN ARGENTINA DURING THE YEARS 2019-2022: WHAT CHANGED AFTER THE COVID-19 PANDEMIC?

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Ximena Juarez, Maria Causarano, Carmen Burundarena, Patricia Dondoglio, Emilce Haleblian, Luciana Montoto Piazza, Gretel Wenk, Rial Jose, Aldo Cancellara
Hospital General de Niños Pedro de Elizalde, Infectologia, Buenos Aires, Argentina

Backgrounds: During 2020 and 2021, influenza detection remained below expectations in all regions of the world. In Argentina, in 2022 we observed an uninterrupted circulation of influenza throughout the year with a large increase in cases in spring and summer. Our objetive was describe patterns of circulation during the last 4 years and the clinical characteristics and evolution of children hospitalized with Influenza.
Methods: Observational, retrospective study that included all patients hospitalized in a third level pediatric hospital in Argentina with detection of influenza virus by Inmunofluorescense or real time polymerase chain reaction (PCR) during 2019-2022.
Results: Data from 136 patients were analized. In 2019: 39 cases (92% Influenza A, FLU A), in 2022: 97 (56% FLU A). In 2020 and 2021 there were no influenza hospitalizations. In 2019, 87% of hospitalizations occurred in autumn-winter while in 2022 only 38% occurred in those months. Age: 55 months (SD 46). Comorbilidities for influenza: 58%, of this only 25% were vaccinated for Influenza. The most frequent clinical form was acute lower respiratory infection in 63%, 12.5% had atypical manifestations. 14.7% of patients required intensive care, it was more frequent in younger children ($p = 0.002$). The length of stay was 9.7 days (SD 9.9) and was longer in unvaccinated compared with vaccinated children ($p=0.04$). 18% had experienced complications, one patient died.
Conclusions/Learning Points: Our study shows that in 2022 there were 2.5 more hospitalizations because of influenza compared to 2019. In 2019 most infections occurred in winter and in 2022 most occurred in spring-summer. FLU A largely predominated in 2019, while in 2022 the detection of FLU A and Influenza B (FLUB) was similar. Most hospitalized children had comorbidities and most were not vaccinated for influenza.

INFLUENZA A IN CHILDREN COMPLICATED BY ENCEPHALITIS – CASE PRESENTATION

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Borcos Bianca Rybana[1], Elena Gheorghe[1], Mihaela Safta[1], Madalina Merisescu[1], Andreea Panciu[1], Ana Maria Popescu[1], Madalina Manole[1], Luminita Marin[1], Vasile Magda[1], Gheorghita Jugulete[1,2]
[1]Institute of Infectious Diseases Professor Doctor "Matei Bals", Paediatric, Bucharest, Romania, [2]University of Medicine and Pharmacy Carol Davila Bucharest, Pediatric Infectious Diseases, Bucharest, Romania

Title of Case: Influenza A in children Complicated by Encephalitis – case presentation
Background: Influenza is an acute respiratory illness caused by influenza viruses type A, B, rarely C, which occurs in annual epidemics. Although it is generally a self-limiting and uncomplicated illness in healthy children, it can be burdened by severe complications and high mortality in immunocompromised children.
Case Presentation Summary: This paper presents the case of a girl aged 5 years,with a history of previous neurological impairment, admitted to the Institute of Infectious Diseases Professor Doctor"Matei Bals" for14 days, with the diagnosis of Influenza type A complicated with acute encephalitis.The onset of the disease was 5 days prior to admission with respiratory manifestations, to which she associated in evolution fever and eating disorders.She was evaluated at the on-call room, where the diagnosis of influenza type A was established (rapid test - antigen) and she received home treatment with Oseltamivir and symptomatic. Because in evolution she presents bradylalia, bradiphsia, drowsiness, she was admitted in to our clinic.The neurological consultation revealed a child with partial temporo-spatial disorientation, who responds with delay to simple questions, does not recognize family members, bradylalic, bradypsychic, with repetitive gestures, maintaining orthostatism, showing wide-based gait and imbalance, with absence seizures lasting less than 30 seconds. EEG is performed, which shows a slow EEG with presence of symmetrical delta waves and lumbar puncture shows clear, hypertensive CSF with normal parameters. The diagnosis of influenza is confirmed by RT-PCR from nasal secretions. The treatment instituted was: etiological, brain depleting, pathogenic, human immunoglobulins and symptomatic under which the patient's evolution is slowly favourable.
Learning Points/Discussion: The favourable response to immunoglobulins and corticosteroids supports the involvement of an immune mechanism in the encephalopathic
reaction in this case.

CHARACTERISTICS OF CHILDHOOD INFLUENZA – SEASON 2022 - 2023

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

National Institute for Infectious Diseases Matei Bals, Pediatric Infectious Diseases, Bucharest, Romania

Backgrounds: With the decline in the number of COVID-19 cases and the abandonment of most epidemiological preventive measures, in the autumn of 2022 we are witnessing an explosion in the number of cases of childhood viroid. Influenza is a condition we are currently facing being responsible for the majority of paediatric viroid admitted.
Methods: In this presentation we aim to analyse the clinical and epidemiological features of influenza in children in the 2022 - 2023 season. We conducted a retrospective clinical study of pediatric cases of influenza admitted to the Clinical Section IX Infectious Diseases-Pediatrics of the National Institute of Infectious Diseases "Prof. Dr. Matei Balș" in the period November 2022 - January 2023. In these cases we analysed demographic parameters (age, sex), clinical picture of the disease, clinical form of the disease as well as the type of influenza virus. The diagnosis of influenza was established on clinical, epidemiological and laboratory criteria (RT-PCR from nasopharyngeal secretions).
Results: During the period analysed we recorded 284 cases of influenza in children. The majority of cases were influenza type A (84.8%), originating from family or community outbreaks (91.9%) in the age group 1-4 years (35.9%). We did not record any deaths in the cases studied and the most common clinical form of illness was moderate, complicated with interstitial pneumonia. Severe forms of disease were recorded in infants (0 - 1 year) complicated with acute respiratory failure, sepsis and acute dehydration syndrome.
Conclusions/Learning Points: Influenza is a condition that can take on severe clinical forms of disease especially in young children, where complications can evolve rapidly with risk of death. Vaccination is the most effective method of prevention alongside epidemiological measures (avoidance of crowding, wearing a mask).

E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Menucha Jurkowicz[1], Ilana Fratty[2], Hilda Sherbany[2], Nathan Keller[3], Eugene Leibovitz[1], Gilad Sherman[1], Or Kriger[1], Ella Mendelson[2,4], Michal Mandelboim[2,4], Michal Stein[1]
[1]Edmond & Lily Safra Children's Hospital, Chaim Sheba Medical Center, Pediatric Infectious Diseases Unit, Ramat Gan, Israel, [2]Ministry of Health, Central Virology Laboratory, Ramat Gan, Israel, [3]Ariel University, Faculty Of Medicine, Ariel, Israel, [4]School of Public Health, Sackler Faculty of Medicine, Department Of Epidemiology And Preventive Medicine, Tel Aviv, Israel

Backgrounds: Data regarding disease characteristics of patients hospitalized with human metapneumovirus (hMPV) infection across different age groups is limited.
Methods: This is a single-center, retrospective cohort study, including all pediatric and adult patients hospitalized with laboratory confirmed hMPV at Sheba Medical Center during January 2015-August 2021. The case analysis was completed according to patient age (four groups; 0-2, 3-17, 18-59 and ≥60 years), and to defined time periods (pre and during the COVID-19 pandemic). Univariate analysis was conducted to compare age groups and to identify differences in demographics, comorbidities and clinical characteristics during hospitalization.
Results: 990 patients diagnosed with hMPV were enrolled, of them 253 (25.6%), 105 (10.6%), 121 (12.2%) and 511 (51.6%) belonged to age groups 0-2, 3-17, 18-59 and ≥60 years, respectively. Male patients constituted a majority in age groups <18. Patients <18 years experienced high levels of comorbidities with immunodeficiency (14.4%) and malignancies (29.9%). The majority (37/39, 94.9%) of all bronchiolitis cases were diagnosed in patients aged 0-2 years. A greater proportion of patients >18 years were diagnosed with pneumonia, while no differences between the age groups were recorded in patients with asthma exacerbation. A greater proportion of patients diagnosed with viral coinfection were <18 years and were more likely to be co-infected with RSV and adenovirus. The highest percentages of ICU admission were recorded among patients <18 years, with 13.8% of patients aged 0-2 and 17.1% of patients aged 3-17.
Conclusions/Learning Points: While acute bronchiolitis was diagnosed mainly in very young patients, pneumonia was more likely to be diagnosed in older patients. Patients < 18 experienced high levels of ICU admission.

EVALUATION OF THE CHANGE IN THE EPIDEMIOLOGY OF RESPIRATORY VIRUSES WITH THE PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Ömer Kiliç[1], Mahmut Kızıl[1], Yalçın Kara[2], Ebru Kaçmaz[3], Gürkan Bozan[4], Eylem Kiral[4], Tercan Us[5], Ener Çağrı Dinleyici[3]
[1]Eskişehir Osmangazi University, Pediatric Infectious Disease, ESKİŞEHİR, Turkey, [2]Eskişehir Osmangazi University, Pediatric Infectious Disease, Eskiehir, Turkey, [3]Eskişehir Osmangazi University, Pediatric Intensive Care, Eskişehir, Turkey, [4]Eskişehir Osmangazi University, Pediatric Infectious Disease, Eskişehir, Turkey, [5]Eskişehir Osmangazi University, Microbiology, Eskişehir, Turkey

Backgrounds: Acute respiratory tract infections are one of the leading causes of childhood death and morbidity. Seasonal respiratory viruses are the most common cause. The COVID-19 pandemic has altered the epidemiological distribution and clinical characteristics of respiratory viruses. We wanted to look into the epidemiological and clinical changes in pandemic respiratory tract virus infections.
Methods: Between December 2018 and February 2022, Eskişehir Osmangazi Patients with nasopharyngeal PCR samples who were followed up on with a diagnosis of respiratory tract infection at the University of Medicine's Pediatrics Clinic were evaluated retrospectively. The cases were evaluated before the pandemic (before March 2020), during the first year of the pandemic (March 2020-March 2021), and after the pandemic (March 2021-February 2022) when the restrictions were relaxed
Results: The study included 567 cases in which nasopharyngeal PCR was performed. There were 320 (56.4%) male cases and mean age was 41 months. Fever (72%), cough (65%), and respiratory distress (23%) were the most common presenting symptoms.In the pre-pandemic group (n:257), the most common viral agents were; Influenza A/B 95 (36%), Rhinovirus 87 (34%), RSV 46 (18%), Prainfluenza virus 14 (7%). Although the number of viral agents detected in the 1st year of the pandemic has decreased (n:57); the most frequently viral agents are Rhinovirus (72%), RSV (10%), and Parainfluenza virus 2 (0.7%). In the second year of the pandemic (n: 253), the most common viral agents were Rhinovirus (44%), RSV (46%) and Bocavirus (17%)
Conclusions/Learning Points: During the pandemic period, a decrease was observed in all viruses, especially influenza, with isolation measures. With the relaxation of the post-pandemic measures, there was an increase in all viral agents, similar to the pre-pandemic period.

UNEXPECTED SEVERE BOCAVIRUS INFECTIONS AMONG HOSPITALIZED CHILDREN DURING THE COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Ömer Kiliç[1], Gürkan Bozan[2], Eylem Kiral[2], Yalçın Kara[3], Mahmut Kızıl[3], Nidai Dalokay[4], Tercan Us[5], Ener Çağrı Dinleyici[2]
[1]Eskişehir Osmangazi University, Pediatric Infectious, Eskişehir, Turkey, [2]Eskişehir Osmangazi University, Pediatric Intensive Care, Eskişehir, Turkey, [3]Eskişehir Osmangazi University, Pediatric Infectious Disease, ESKİŞEHİR, Turkey, [4]Eskişehir Osmangazi University, Pediatric, Eskişehir, Turkey, [5]Eskişehir Osmangazi University, Microbiology, Eskişehir, Turkey

Backgrounds: Acute respiratory tract infections are among the most important causes of childhood mortality and morbidity. The most frequently isolated viruses in respiratory tract infections are respiratory syncytial virus, influenza virus, parainfluenza virus, adenovirus, coronavirus, metapneumovirus, and bocaviruses. Here, we aimed to evaluate Bocavirus (HBoV) cases presenting with severe respiratory tract symptoms during the pandemic period.
Methods: Patients who were followed up with the diagnosis of respiratory tract infection in Eskişehir Osmangazi University Faculty of Medicine Pediatrics Clinic between September 2021 and March 2022 were evaluated retrospectively. Patients detected HBoV by nasopharyngeal PCR included in the study. The clinical and epidemiological features of the cases were reviewed retrospectively.
Results: Fifty-four cases with HBoV in nasopharyngeal PCR samples were included in the study.The mean age of the cases was 25 months(1 month-72 months).The most common symptoms at presentation were cough, fever, and respiratory distress. In the chest X-ray; hyperinflation 48%, pneumonic consolidation 42%, and pneumothorax-pneumomediastinum 7% were detected.54% of the cases were followed up in the intensive care unit.HBoV and other viral coinfection were present in 20(37%) cases, and bacterial coinfection was in 7(17%) cases. 57% of all cases were given oxygen support via a mask, 24% high-flow oxygen, 7% non-invasive ventilation, and 9% mechanical ventilator support. Antibiotics were given to 34(63%) cases and steroid treatment was given to 41(76%) cases
Conclusions/Learning Points: The COVID-19 pandemic changed the epidemiology of seasonal respiratory viruses and the clinical course of the diseases. Although HBoV infections are not as common as other seasonal respiratory viruses, they are among the viruses that cause respiratory symptoms in children. Although it usually causes mild symptoms, severe respiratory symptoms can also lead to serious life-threatening clinical findings that require intensive care admission

TREATMENT OF RESPIRATORY INFECTIONS IN CHILDREN AGED LESS THAN 1 YEAR: A DESCRI PTIVE RETROSPECTIVE STUDY FROM TERTIARY-LEVEL PEDIATRIC HOSPITAL IN FINLAND

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Sallamaria Kelloniemi, Paula Heikkilä, Sauli Palmu
Tampere University, Faculty Of Medicine And Health Technology, Tampere, Finland

Backgrounds: Viral respiratory infections are accountable for a vast amount of health care visits annually. Treatment guidelines of different respiratory tract infections and their symptoms vary. We aimed to determine how children aged <1 year presenting with fever and symptoms of a respiratory infection were treated, as well as the response to the treatment, in Tampere University Hospital Pediatric Unit. The secondary purpose was to describe the specific diagnosis beyond the respiratory symptoms.
Methods: This descriptive, retrospective study was conducted in the pediatric unit of Tampere University Hospital (Tays), Finland, using background and medical data relating to the outpatient and inpatient episodes from the electronic patient records of Tays. We documented demographics, clinical findings at arrival to the hospital, and the medication and other treatments given to the children during their hospital stay. If the child was given the same medication multiple times, only the first dosage and response to that medication were documented.
Results: Total of 119 episodes (117 children) were included, and 50 children (42%) were hospitalized. Symptom-relieving medications were used frequently. For example, paracetamol was given to 82 children (69%), with good response and salbutamol to 21 children (18%) with 14 children having response. Most children (59%) were administered antibiotics, the most common indication being otitis media. Most common primary or secondary diagnosis were bronchiolitis or bronchitis (43%), otitis media (38%) and upper respiratory tract infection (27%).
Conclusions/Learning Points: We found that nearly half of the children needed hospitalization. We also found that symptom-relieving medications, such as analgetics were a key form of treatment with commonly good response. Antibiotics were also used frequently, supporting the previous understanding that viral respiratory infections are often complicated by secondary bacterial infections.

Backgrounds: Numerous viruses are known to be the predominant pathogens of acute respiratory tract infections (ARIs). They present with non-pathogen-specific symptoms, and only microbiological studies can establish the correct diagnosis. Using a syndromic approach, we aimed to investigate respiratory pathogens in children with ARIs admitted to a university hospital.
Methods: In this ongoing study, a total of 100 nasopharyngeal specimens from children with ARIs were tested between January 2018 and February 2022. The commercial kit FilmArray Respiratory panel (bioMerieux, France), which detects 23 targets (4 bacteria and 19 viruses), was used.
Results: Out of the cases, 71% were diagnosed with lower ARIs infections. Their median age was 10 months. Among the patients, 94 were admitted to the wards, and 6 were seen in the emergency department. Respiratory pathogens were detected in 77 % (77/100) of specimens, including 105 viruses and 8 bacteria, such as Bordetella pertussis and B. parapertussis. However, an unsuspected case of B.pertussis infection was found, and the patient was then isolated. The prevailing viruses were Human Rhinovirus/Enterovirus (51.95%) and Respiratory syncytial virus (RSV) (33.77%). One-third (26/77) of the positive specimens were coinfected with two or more pathogens. Human Rhinovirus/Enterovirus was the most common companion virus in mixed infections, while RSV plus Human Rhinovirus/Enterovirus was the most frequent combination. SARS-CoV-2 was detected in 7 samples, 2 of them as coinfection with RSV. In one of these associated infections, SARS-CoV-2 was an incidental finding. The child was also isolated, local health authorities were notified, and an epidemiological investigation commenced.
Conclusions/Learning Points: Our results have shown diverse diagnostic yields. Moreover, rapid mPCR testing has aided in the timely therapeutic management and prevention of hospital outbreaks that are challenging to recognize.

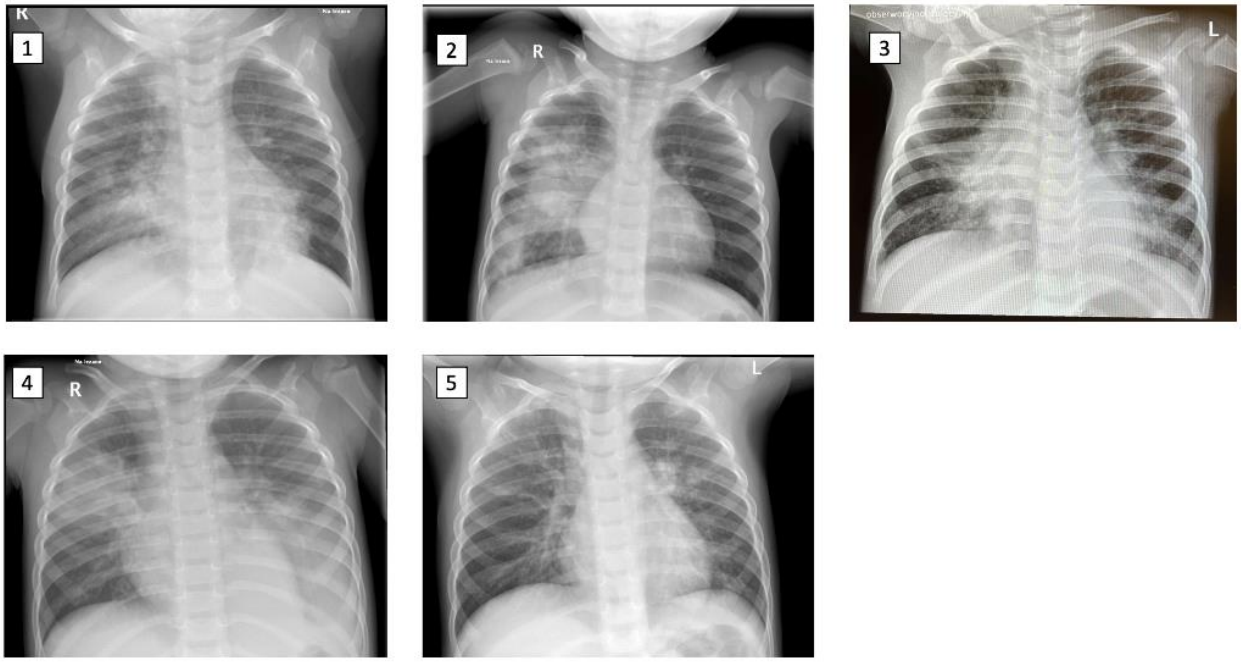
PARTICULARLY SEVERE COURSE OF ADENOVIRUS RESPIRATORY INFECTION IN SIX CHILDREN, INCLUDING FIVE UKRAINIAN REFUGEES

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Magdalena Okarska-Napierała, Joanna Mańdziuk, Edyta Podsiadły, Ernest Kuchar
Medical University of Warsaw, Department Of Paediatrics With Clinical Assessment Unit, Warsaw, Poland

Title of Case: PARTICULARLY SEVERE COURSE OF ADENOVIRUS RESPIRATORY INFECTION IN SIX CHILDREN, INCLUDING FIVE UKRAINIAN REFUGEES
Background: Coronavirus disease 2019 pandemic, associated with various infection prevention measures, led to a transient reduction in other seasonal infections, followed by an unusually high circulation of respiratory viruses. Moreover, the Russian invasion of Ukraine led to the massive migration to other countries, mostly to Poland (1.4 million registered refugees as of 10/2022). Many refugees still stay in overcrowded humanitarian hubs.
Case Presentation Summary: We present six otherwise healthy children (four boys, aged 0.7-2.7 years) admitted to our hospital between 10th Oct and 10th Nov 2022. Five of them were Ukrainian refugees. All children had fever lasting up to 13 days and respiratory signs (5/6 had otitis media, 5/6 were oxygen-dependent, and 5/6 had abnormal chest X-rays [see the picutre]). All but one were substantially lethargic for a prolonged time, irrespective of rehydration and other treatment measures. Three children had mucocutaneous lesions. The only child with no dyspnea and the shortest disease course was Polish. Blood tests showed a varying degree of inflammation (median C-reactive protein 5 mg/dL, procalcitonin 14.1 ng/mL, leukocytes 10.7 x 10^3/uL) with high ferritin (up to 5867 ng/mL) and high D-dimer (up to 43475 ug/L) in all children tested. All patients received antibiotics, and two received intravenous immunoglobulins and steroids. All recovered, but three were discharged with slight dyspnea. Among five children tested, all had adenovirus infection. The boy who was not tested, was admitted as the first one, from the same hub and in the same week as two
others.



Learning Points/Discussion: Adenovirus respiratory disease may have a particularly severe, prolonged course in young children, with fatigue, poor living conditions and crowding being possible risk factors.

[1]Teaching Institute of Public Health and School of Medicine University of Zagreb, Molecular Microbiology Department, Zagreb, Croatia, [2]Children's Hospital Zagreb and Faculty for Dental Medicine and Healthcare/School of Medicine, Josip Juraj Strossmayer University of Osijek, Department Of Pulmonology, Allergy, Immunology And Rheumatology, Zagreb, Croatia, [3]Children's Hospital Zagreb and School of Medicine University of Zagreb, Microbiology Department, Zagreb, Croatia, [4]Teaching Institute of Public Health, Department For Respiratory Infection, Zagreb, Croatia, [5]Croatian Institute of Public Health and School of Medicine University of Zagreb, Microbiology Department, Zagreb, Croatia

Backgrounds: Non-pharmacological measures (NPMs) introduced to prevent the spread of SARS-CoV-2 affected the incidence of respiratory viruses, but not with the same effect on all types of respiratory viruses. The aim of our research was to compare the incidence of enveloped versus naked respiratory viruses before and during NPMs in Croatia.
Methods: In four years period (5/2017-3/2021), specimens obtained from 957 children up to 18 years of age which were hospitalized due to respiratory infection were collected and tested for fifteen respiratory viruses using multiplex PCR.
Results: One or more respiratory viruses were detected in 739 (77.2%) patients, of which one virus in 496 (67.1%) and two or more viruses in 243 (32.8%) cases. The most frequently detected was rhinovirus (343; 35.8%), followed by: respiratory syncytial virus type A and B (162; 16.9%), adenovirus (145; 15.2%), parainfluenza viruses types 1-4 (101; 10.6%), bocavirus (73; 7.6%), influenza viruses type A and B (69; 7.2%), enterovirus (61; 6.4%), coronaviruses OC43 and 229E/NL63 (54; 5.6%) and metapneumovirus (30; 3.1%). Incidence of all tested viruses did not differ between seasons 2017/18, 2018/19 and 2019/20, while significantly dropped in 2020/21 when NPMs were in use ($P<0.05$). However, while the incidence of enveloped viruses (i.e., respiratory syncytial virus, influenza and parainfluenza viruses, seasonal coronaviruses, metapneumovirus) was practically zero, the non-enveloped viruses (i.e., rhinovirus, bocavirus, adenovirus and enterovirus) showed activity of quarter of the value compared to previous seasons despite NPMs.
Conclusions/Learning Points: The spread of enveloped respiratory viruses is effectively prevented with NPMs. To completely prevent the spread of non-enveloped respiratory viruses, NPMs such as distance and wearing masks are not sufficient, specific pharmacological measures should be developed and considered.

CLINICAL SEVERITY OF RSV DISEASE IN INFANTS AND YOUNG CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Tânia Lopes[1], Rute Monteiro[1], Manuela Lopes[1], Ana Cláudia Cavadas-Almeida[1], Ana Manuela Silva[1], Joana Gama Jardim[1], Joana Sousa[1], Raquel Palha Martins[1], Mariana Bravo[1], Ana Fradique[1], Ana Rita Jesus[1], Joana Oliveira[1], Mariana Sebastião[1], Mariana Costa[1], Miguel Lucas[1], Miguel Félix[1], Fernanda Rodrigues[1,2]
[1]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Universidade de Coimbra, Faculty Of Medicine, Coimbra, Portugal

Backgrounds: RSV causes substantial morbidity in infants and young children. Studies comparing the severity of infections caused by RSV with other viruses are inconclusive. The aim of this study was to evaluate clinical characteristics of infants and young children with RSV infection and compare it with respiratory infections caused by other viruses.
Methods: This is a prospective observational study including hospitalised children under 24 months of age with acute respiratory infection (with symptoms lasting <5 days), from March 2021 to December 2022. A nasopharyngeal sample was taken and submitted to PCR detection (FilmArray respiratory panel). Clinical data were recorded. The ReSVinet Scale, a clinical score for the assessment of respiratory difficulty in infancy was applied. The cohort was divided based on the virus detected: RSV, RSV with another virus or other viruses and groups were compared.
Results:

Table 1. Demographic and clinical characteristics of children with respiratory infections
* Justicia-Grande AJ et al. PLoS One.2016;11(6):e0157665

	RSV only (n = 70)	RSV with other viruses (n = 56)	Other viruses (n = 53)	*p value*
Gender Male – n (%)	38 (54,3)	32 (57,1)	24 (45,3)	0.424
Median age – months (IQR)	2 (4)	6 (7)	8 (13,5)	<0.001
Median duration of admission – days (IQR)	3 (5)	3 (6)	1 (2)	0.002
Final diagnosis – n (%)				
Rhinopharyngitis	2 (2,9)	3 (5,4)	20 (37,7)	< 0.001
Bronchiolitis	62 (88,6)	40 (71,4)	23 (43,4)	< 0.001
Pneumonia	5 (7,1)	9 (16,1)	5 (9,4)	0.326
Laryngitis	0	0	3 (5,7)	
Bronchitis	1 (1,4)	0	1 (1,9)	
Acute otitis media	0	1 (1,8)	0	
Wheezing	0	3 (5,4)	1 (1,9)	
ReSVinet Score – n (%)				
Mild	12 (17,1)	6 (10,7)	27 (50,9)	< 0.001
Moderate	50 (71,4)	47 (83,9)	25 (47,2)	
Severe	8 (11,4)	3 (5,4)	1 (1,9)	

Data were collected from 179 children: 70 with RSV only, 56 with RSV with other virus and 53 with other viruses (Rhinovirus/Enterovirus 33%, Human Coronavirus 10.6%, Human Metapneumovirus 10.5%, Parainfluenza virus 10%, others). The comparison between groups is presented in Table 1. Children with RSV infection differ significantly in age, duration of admission, final diagnosis and ReSVinet Score, which is higher in children with RSV only.

Conclusions/Learning Points: Children with RSV associated infections were younger, mostly with bronchiolitis and with higher clinical severity when compared to infections caused by other viruses.

CLINICAL IMPACT OF PANDEMIC RELATED CHANGES ON THE EPIDEMIOLOGY OF RESPIRATORY TRACT INFECTIONS

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Nicole Maison[1,2,3], Sophia Rinderknecht[1], Jimmy Omony[2], Melanie Meyerbuehn[4], Erika Von Mutius[1,2,3], Johannes Hübner[4,5], Ulrich Von Both[4,5]
[1]Dr von Hauner Children's Hospital, Ludwig Maximilians University, Munich, Department Of Asthma And Allergy, Munich, Germany, [2]Helmholtz Zentrum Munich, German Research Center for Environmental Health, Institute For Asthma- And Allergy Prevention, Neuherberg, Germany, [3]German Center for Lung Research (DZL), Comprehensive Pneumology Center Munich (cpc-m), Munich, Germany, [4]Dr. von Hauner Children's Hospital, University Hospital, LMU Klinikum, Division Of Pediatric Infectious Diseases, Department Of Pediatrics, Munich, Germany, [5]German Center for Infection Research (DZIF), Partner Site Munich, Munich, Germany

Backgrounds: Following lockdown periods and restricting public health measures, an increase of respiratory infections was observed worldwide. Consequently, several reports highlighted an increased burden on children's hospitals compromising medical care of acutely and chronically ill children. This study aimed to characterize changes in the epidemiological pattern of circulating viral infections.
Methods: We assessed the number of patients with respiratory infections and the annual distribution of virus detections between 2019 and 2022 based on 4809 clinical samples of 4131 patients in a German pediatric tertiary care center. We then investigated the impact of lockdown periods on spectra of circulating viruses, pattern of coinfections, age and seasonality of these infections in children.
Results: A fourfold increase in the total number of respiratory virus detections was observed in 2022 vs 2019 with a doubling comparing 2021 to 2022. In contrast to previous years, constant high rates of Rhinovirus infections with no typical seasonal pattern were observed all over 2022 while other viruses showed fewer changes in terms of seasonality. SARS-CoV-2, parainfluenza- and human metapneumovirus detections increased significantly in 2022 (2019 vs 2022 $p < 0,01$). Coinfections with multiple viruses occurred significantly more often since 2021 as compared to prepandemic years, especially in very young children (2019 vs 2022 $p < 0,01$).
Conclusions/Learning Points: Compared to pre-pandemic years, we demonstrate a dramatic increase in pediatric respiratory tract infections with an incrementing spectrum of viruses and an outstanding gain in Rhinovirus infections leading to a high rate of hospital admissions, particularly in conjunction with other viruses. This is acutely causing a shortage of medical care and increases the risk of chronic respiratory diseases such as asthma, thus leading to a long-lasting burden on the health system.

ETIOLOGY OF VIRAL RESPIRATORY TRACT INFECTIONS IN CHILDREN IN THE PRE-PANDEMIC PERIOD

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Thangam Menon[1,2], Anusha Hindupur[2]
[1]Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences, Microbiology, Chennai, India, [2]Dr ALM PG Institute of Basic Medical Sciences, University of Madras, Microbiology, Chennai, India

Backgrounds: Viruses are a common cause of acute respiratory infections (ARI) in the paediatric population and the epidemiology of these infections have changed after the pandemic. We report the viral aetiology of ARI in children, during the pre-pandemic period 2016-2018.
Methods: Nasal swabs were collected from 343 children, aged one month to 17 years. RNA was extracted, subjected to reverse transcription, and analysed for human respiratory syncytial virus (HRSV), influenza viruses, human metapneumovirus (hMPV), human rhinovirus (hRV) and human parainfluenza viruses (HPIV). The presence of HRSV subtypes (HRSV A and B) was confirmed by real time RT-PCR (rRT-PCR). Influenza A and B viruses (INF A and B) were detected by simplex nested real-time PCR (nRT-PCR) targeting the matrix gene of influenza A virus and nucleoprotein gene of influenza B virus. hMPV was detected using nRT-PCR and confirmed with rRT-PCR using primers and probe targeting the nucleoprotein gene of hMPV. Human rhinovirus (hRV), human parainfluenza virus types 1, 2, 3 and 4 (HPIV 1 - 4) were detected by simplex conventional RT-PCR.
Results: HRSV B (10.9%) was the most commonly detected virus, followed by INF A (9.1%) and HRSV A (6.3%). hMPV, hRV, HPIV 3 and HPIV 4 were present in 4%, 3.7%, 4.2% and 2% of the samples respectively, while none were positive for HPIV 1 and HPIV 2. INF B was detected in 1.7% samples, with equal numbers of Victoria lineage and Yamagata lineage strains. Dual infections were found in 4% of samples with HRSV A and INF A virus being the most frequently encountered combinations.
Conclusions/Learning Points: HRSV subtype B and influenza A were the most common etiological agents of ARI in children during the pre-pandemic period.

LONG-READ WHOLE GENOME SEQUENCING OF THE RESPIRATORY SYNCYTIAL VIRUS IN SOUTH KOREA

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Bonhyang Na[1,2], Yu Jin Park[3], Miri Park[3], Ji Yeon Baek[1], Ji Young Lee[1], Sung Min Lim[1], Minyoung Kim[1,2], Jong Gyun Ahn[1,2], Seung Tae Lee[3], Jiman Kang[1,2]
[1]Yonsei University College of Medicine, Department Of Pediatrics, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Institute For Immunology And Immunological Disease, Seoul, Korea, Republic of, [3]Yonsei University College of Medicine, Department Of Laboratory Medicine, Seoul, Korea, Republic of

Backgrounds: Respiratory syncytial virus (RSV) has been the leading cause of lower respiratory tract infection (LRTI) in children, with seasonal epidemics in temperate regions. However, in Korea, the occurrence of RSV in the 2020-2021 season was close to zero, and it is prevalent again from the 2021-2022 season. We investigated whether there were significant changes in the genotypic patterns of RSV strains in Korea before and after the COVID-19 pandemic.
Methods: This prospective study was conducted at Severance Children's Hospital in Seoul, Korea from September 2019 to December 2022. Residual respiratory specimens from children hospitalized with RSV LRTI were collected. Whole genome sequencing (WGS) analysis was performed using the PacBio Circular Consensus Sequencing platform. Due to time constraints, we preferentially analyzed samples in the pre-pandemic era.
Results: A total 168 samples in 168 children were collected. The median age at sample collection was 0.9 years (interquartile range, 0.3 to 1.9 years), and 87 subjects (52%) were male. Seven children received at least one dose of palivizumab prior to RSV infection during the RSV season. Of these, RNA extracts from 84 samples (A type: 52 and B type: 32) were available for analyses. Genotypes showed close clustering with NA1, ON1 and GA2 in RSV-A and BA in RSV-B, respectively. When analyzed only for the G protein genotype, all RSV-A strains were close to ON1 or NA1, and all RSV-B strains were BA. No mutations have been found for palivizumab resistance.
Conclusions/Learning Points: Our NGS method can not only quickly track these genotypic trends, but also provide information on the clinical effectiveness of existing and/or recently developed RSV-specific agents. Continuous monitoring of genotypic changes in RSV strains is required.

GLOBAL CLINICAL BURDEN OF HUMAN METAPNEUMOVIRUS INFECTIONS IN CHILDREN IN GIPUZKOA (BASQUE COUNTRY, SPAIN)

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Eider Oñate[1], Luis Piñeiro[2], Pedro Vallejo[2], Mila Montes[2]
[1]Donostia University Hospital, Paediatric Intensive Care Unit, Donostia/San Sebastián, Spain, [2]Donostia University Hospital, Microbiology, Donostia/San Sebastián, Spain

Backgrounds: Human metapneumoviruses (hMPV) are commonly detected in nasopharyngeal aspirates (NPAs) from children with respiratory tract infections (RTIs) but the real burden remains poorly defined.
Methods: Observational and retrospective study carried out by reviewing the medical records of patients up to 14 years old who tested positive for hMPV in the outpatient oncology clinic, emergency department and inpatient departments [general pediatrics and hematology/oncology units, neonatal intensive care units and pediatric intensive care units. It was performed in a tertiary hospital of a Spanish province between January 2018 and June 2022.The virus hMPV was detected using a commercial real-time multiplex PCR platform (AllplexTM Respiratory panel assays, Seegene). Epidemiological, clinical and analytical variables were analyzed.
Results: hMPV was detected in 291 samples from 2050 children(14,2%). We excluded three patients with no symptoms related to hMPV with a surgical diagnosis. One-hundred-twenty(41.6%) episodes occurred in infants aged<1 year. Viral co-infections were detected in 85 episodes(29.5%). The mean-age of single infections was similar to coinfected children (24.5±25.3/24.3±28.1months;p=NS). In addition to causing upper respiratory disease (29.1%), the virus was associated with bronchiolitis(18.4%), asthma exacerbation(24.3%), pneumonia(14.6%), high fever(5,9) bronchitis(3.8%) febrile seizures(1,7%) and croup(1,4%). In total 143(49.6%) children were hospitalized. The mean-length of stay was 7.2 days(range 2–24 days). Twenty-three children required admission to the PICU. The hospitalization of monoinfections was similar to coinfections (48.7%vs.51.7%) but they needed less respiratory support (9.3%vs.5.30%;p=NS) and PICU admissions (6.4% vs. 11.8%; p=NS). The use of aerosoltherapy (50.2%vs.62.3%;p=NS),corticotherapy (32.01%vs.35.3%;p=NS) and antibiotics (6.4% vs. 11.8%;p=NS) was similar in both.
Conclusions/Learning Points: hMPV is a significant pathogen that contributes to the hospitalization of children being a leading cause of respiratory tract infections. Coinfections of hMPV and other respiratory viruses were associated with severe respiratory syndromes more frequently than Hmpv single-infections.

VIRAL INTERFERENCE BETWEEN RESPIRATORY VIRUSES: A SYSTEMATIC REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Sergio Huerta-Barberá[1], Javier Díez-Domingo[2], Alejandro Orrico-Sánchez[2]
[1]Hospital General Universitario Castellón, Pediatrics, Castellón, Spain, [2]Fisabio, Vaccine Research Department, Valencia, Spain

Backgrounds: The COVID-19 pandemic has placed new urgency on examining the underlying mechanisms that influence the epidemic spread of respiratory viruses (RV) and their interactions due to the dramatic decrease in epidemic virus incidence. Viral interference is an interaction which occurs between different viruses, producing an alteration in viral replication when a host is infected at a certain time probably due to primary immunity activation. We evaluated the evidence published about viral interference in RV in the last 10 years.
Methods: A systematic review was conducted in the electronic database MEDLINE of all preclinical and observational studies between 2013 and 2023. Two reviewers performed title/abstract, full-text review, and data extraction.
Results: We identified 596 studies and 256 were eligible after inclusion and exclusion criteria. Finally, 24 articles were accepted for qualitative synthesis. 8 contained information about >3 RV; 11 about 2 RV and 5 studies about 1 RV (influenza) and their linages. Preclinical studies demonstrated the interaction Influenza-coronavirus, SARS-CoV-2-influenza, SARS-CoV-2-RSV, Rhinovirus-influenza, RSV-Human Metapneumovirus and Rhinovirus-SARS-CoV-2. Observational studies showed that influenza, SARS-CoV2 and Rhinovirus reduce other respiratory virus presence.
Conclusions/Learning Points: There is current scientific evidence related to viral interference in observational and preclinical studies, but it is necessary to carry out clinical trials in humans to provide more information.

BURDEN OF JUVENILE RECURRENT RESPIRATORY PAPILLOMATOSIS: A SYSTEMATIC LITERATURE REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Olga Ovcinnikova[1], Elizabeth Russell[2], Meenu Verma[3], Rishabh Pandey[4], Edith Morais[5]
[1]MSD UK, Vad, London, United Kingdom, [2]Merck & Co, Epidemiology, Boston, United States of America, [3]Parexel International, Access Consulting, Mohali, India, [4]Parexel International, Access Consulting, Bangalore, India, [5]MSD France, Core, Puteaux, France

Backgrounds: Juvenile-onset recurrent respiratory papillomatosis (JoRRP) is a human papillomavirus (HPV)-induced disease characterized by the growth of papillomas in the respiratory tract, especially the larynx to effect voice and restrict breathing. Transmission of JoRRP occurs from the mother to the child either in utero or at the time of birth. The objectives of this systematic literature review (SLR) were to assess the disease clinical, epidemiological and economic burden of this non curable and life-threatening disease.
Methods: The SLR was conducted according to the guidelines from the Cochrane Group and PRISMA. MEDLINE, Embase and Cochrane Library databases and conference proceedings published in last 4years. The outcomes of interest were clinical (i.e., patient characteristics, risk factors, symptoms, treatment and procedures); humanistic, epidemiological (i.e., incidence, prevalence, HPV genotype, frequency of RRP recurrences, tumour progression and mortality) and economic (i.e., costs, indirect costs, resource use and utility data) burdens.
Results: This SLR identified data from publications that described generally narrow populations. These results include data from 64 clinical, 8 humanistic, 35 epidemiologic, and 13 economic burden full-text articles. Most of HPV infections were due to HPV type 6 and 11. Diagnosis of the disease is challenging in children and usually around 3 years old. The treatment largely consists of multiple surgical management, including tracheotomy for the most aggressive cases. Due to the non-curable aspect, the humanistic and economic burden is significant.
Conclusions/Learning Points: The published data are limited in scope. JoRRP is a rare non-curable disease mainly due to HPV 6 and HPV 11 with high clinical and economic burden through lifetime treatment. Further research is crucial to obtain more robust data that will help address the information gap in clinical, epidemiological and economic burden.

CHARACTERISTICS OF THE RSV (RESPIRATORY SYNCYTIAL VIRUS) WAVE OF NOVEMBER-DECEMBER 2022

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Andreea Panciu[1], Madalina Manole[2], Ana Maria Popescu[1], Mihaela Safta[1], Elena Gheorghe[1], Borcos Bianca Rybana[3], Madalina Merisescu[2], Luminita Marin[1,4], Gheorghita Jugulete[2,4]
[1]National Institute of Infectiouse Disease, 9th Pediatric Department, Romania, Romania, [2]National Institute for Infectious Diseases Matei Bals, Pediatric Infectious Diseases, Bucharest, Romania, [3]Institute of Infectious Diseases Professor Doctor "Matei Bals", Paediatric, Bucharest, Romania, [4]University of Medicine and Pharmacy Carol Davila Bucharest, Pediatric Infectious Diseases, Bucharest, Romania

Backgrounds: In the months of autumn and winter 2022, there was an increase in RSV (respiratory sincicial virus) infection cases around the world. RSV infection symptoms appeared earlier and in much greater numbers. Hospitalizations were higher than in previous years.
Methods: We did a retrospective study on the children hospitalized with confirmed diagnosis of RSV infection on the 9 th Pediatric Department of the National Institute of Infectious Disease„Prof. Dr. Matei Bals”in the period November 2022- December 2022.Diagnosis was confirmed by positive rapid tests for RSV or PCR.
Results: We had a total number of 36 cases of RSV infection in children.22% were <1 year old , 55% - 1-3 years old ,16 % - 4-6 years old and 5% were older than 7 years.49% were female and 51% male.55% of cases were mild forms and 27% were moderate forms.All patients presented with high grade fever, productive cough and nasal obstruction.An important number of patients (27%) developed acute respiratory failure.Supplemental oxigenotherapy was necesary,with a median duration of 2 days,and a median value of 2 liters O2/min.No invaziv ventilation was required.The most frequent complications were acute interstitial pneumonia (83%) , dehydration syndrome((52%),gastrointestinal symptoms (27%) and anemia (27 %).Additionally, there were 3 cases of acute otitis media, 2 related sepsis episodes and coinfections with influenza A virus and rhinovirus .Median period of hospitalisation was 5 days,and all the patients had favorable outcomes.
Conclusions/Learning Points: RSV can cause serious health complications, particularly for young children.This year case numbers have peaked early. Also as we can see in our study there were more sever cases,which can be explained by the fact that children were exposed to RSV earlier in the pandemic due to masking and social distancing.

THE IMPACT OF UNIVERSAL VARICELLA VACCINATION IN ISRAEL: AN INTERRUPTED TIME-SERIES ANALYSIS, 2000-2020

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Noga Fallach[1], Stephanie Kujawski[2], Pieralessandro Lasalvia[3], Gabriel Chodick[1], Manjiri Pawaskar[2]
[1]Kahn-Sagol-Maccabi Research and Innovation Institute, Epidemiological Research, Tel Aviv, Israel, [2]Merck & Co., Inc., Center For Observational And Real-world Evidence, Rahway, United States of America, [3]NeuroEconomix, Neuroeconomix, Bogota, Colombia

Backgrounds: In Israel, a 2-dose universal varicella vaccination (UVV) program was implemented in 2008, with a first dose recommended for children at 12 months of age and a second dose at 6–7 years of age. This study examined the impact of 2-dose UVV on varicella incidence in Israel.
Methods: This retrospective observational study obtained data from Maccabi Healthcare Services, a nationwide health plan in Israel. Electronic medical record data from January 2000–December 2020 were included, with the pre-UVV period spanning from January 2000–December 2007 and the post-UVV period from January 2010–December 2020. Incidence rates were calculated per time period (pre-UVV, post-UVV) and by age group: target vaccinated population (1–7 years), non-target population (<1 year, >7 years), and overall population (all age groups). Time series analyses with autoregressive integrated moving average (ARIMA) modeling were used to predict varicella incidence in the absence of UVV in the post-UVV period by age group. Predicted and observed incidence rates post-UVV were compared to estimate UVV impact.
Results: Mean annual incidence rates per 100,000 population declined from 5,459 pre-UVV to 1,065 post-UVV in the target population, from 438 to 331 in the non-target population, and from 1152 to 426 in the overall population. In the post-UVV period, observed varicella incidence was 81.7% (95% prediction intervals [PI]:65.7%-87.5%), and 68.2% (95% PI:2.2%-81.1%) lower than predicted incidence in the target and overall populations, respectively. The reduction in observed vs. predicted incidence was highest in 1-2 year olds (90.7%; 95% PI:82.9%-93.7%) followed by 6–7 year olds (74.8%, 95% PI:49.6%-83.2%).
Conclusions/Learning Points: In Israel, varicella burden of disease reduced substantially following implementation of the 2-dose UVV program.

RESULTS OF A NEW COST-UTILITY MODEL ASSESSING PALIVIZUMAB FOR THE PREVENTION OF RESPIRATORY SYNCYTIAL VIRUS INFECTION IN ITALIAN INFANTS BORN AT 29-35 WEEKS' GESTATIONAL AGE

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Paolo Manzoni[1], Xavier Carbonell-Estrany[2], Bosco Paes[3], Barry Rodgers-Gray[4], John Fullarton[4], Ian Keary[4], Jean-Eric Tarride[3], Roberto Ravasio[5], Marcello Lanari[6]
[1]University of Torino school of medicine, Division Of Pediatrics And Neonatology, Ponderano, Italy, [2]Hospital Clinic, ., Barcelona, Spain, [3]McMaster University, ., Hamilton, Canada, [4]Violicom Medical Limited, ., Aldermaston, United Kingdom, [5]HEOR & RWE Lead, Ma Provider, Milan, Italy, [6]IRCCS-Policlinico di Bologna, Pediatric Emergency Unit, Bologna, Italy

Backgrounds: To undertake a cost-effectiveness analysis of palivizumab versus no prophylaxis in healthy Italian infants born at 29-35 weeks gestational age (wGA) using a newly developed cost-utility model that includes medically-attended respiratory syncytial virus (RSV) infections (MARI) and ascribes RSV hospitalisation (RSVH) risk using the International Risk Scoring Tool (IRST).
Methods: Data for all infants born at 29-31wGA and 32-35wGA identified as moderate- or high-risk of RSVH by the IRST were analysed. Infants entered a semi-Markov process whereby they experienced RSVH, MARI, or remained uninfected/non-medically attended. Palivizumab (average cost per infant 29-31wGA: €2,978; 32-35wGA: €3,422) reduced the RSVH rate by 63.3% in 29-31wGA (baseline rate: 5.9%) and by 82.2% in moderate-high risk 32-35wGA infants (baseline: 6.3%). Likelihood of RSV-related intensive care unit (ICU) admission was 8.7% in those receiving palivizumab and 20% in unprophylaxed infants, with 0.43% ICU mortality applied. MARI (emergency room visit without RSVH), 18 years of long-term respiratory morbidity and indirect costs were included in the reference case, without vial sharing. A lifetime time horizon with 3% discounting was utilised. Deterministic (±20% on main variables) and probabilistic (10,000 iterations) sensitivity analyses were conducted.
Results:

Table: Cost-effectiveness of palivizumab *versus* no prophylaxis

	29-35 wGA*	29-31 wGA	**32-35 wGA***
- Difference in costs (€)	2,134	1,959	2,193
- Difference in QALYs	0.144	0.130	0.149
- **Cost *per* QALY** (€)	14,799	15,078	14,717

*32-35 wGA infants assessed at high- and moderate-risk by the International Risk Scoring Tool. QALY: quality-adjusted life year; wGA: weeks' gestational age

The incremental cost per quality-adjusted life year (QALY) gained with palivizumab versus no prophylaxis

was €14,799 (€15,652 excluding indirect costs) for 29-35wGA infants (Table). The probability of being cost-effective was 89.7% at a €40,000 willingness-to-pay threshold. The incremental cost/QALY was €15,078 and €14,717 for 29-31wGA and 32-35wGA infants, respectively. The model was most sensitive to long-term respiratory morbidity rates, health utility scores, palivizumab efficacy and palivizumab cost. **Conclusions/Learning Points:** This new analysis, the first to incorporate the IRST and MARI in the Italian setting, found palivizumab to be highly cost-effective in otherwise healthy 29-35wGA infants (vs no prophylaxis).

CORRELATION OF FACTORS DETERMINING THE NEED OF OXYGEN SUPPLEMENTATION IN RESPIRATORY SYNCYTIAL VIRUS INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Kalliopi Rodolaki[1], Irene Tzovara[1], Thanasis Sarigiannidis[1], Georgios Dionysopoulos[1], Maria Eleni Bompou[1], Danai Sofianou-Petraki[2], Ioanna Farakla[1], Christina Kanaka-Gantenbein[2], Evanthia Botsa[1]
[1]Aghia Sophia Children's Hospital, First Department Of Pediatrics - University Of Athens, Athens, Greece, [2]"Agia Sophia" Children's Hospital, Athens, Greece, First Department Of Pediatrics, University Of Athens, Athens, Greece

Backgrounds: Bronchiolitis is a common pediatric disease which affects children under 2 years and accounts for multiple hospitalizations. Rigorous measures are needed to prevent further deterioration of the disease and to ensure the least possible hospitalization duration. In the present study we investigate the factors that determine disease outcomes.
Methods: We evaluated neonates, infants and toddlers admitted in our institution for respiratory syncytial virus infection between September 2022 until January 2023. We documented patients age, duration of infection prior to admission, C-reactive protein (CRP), white blood cells (WBCs) levels, as well as the ratios of neutrophil to lymphocytes(NLR), monocyte to lymphocyte(MLR) and monocyte to neutrophils(MNR), and the use of oxygen supplementation and correlated them to the duration of hospitalization.
Results: Overall, 103 patients were enrolled in this study, aged 1-70 months and admitted between the first and 11thday of symptoms. The median duration of hospitalization was 4 days (1-11). Neither patient age (p-value=.403), nor the duration of infection prior to hospitalization (p-value=.291) influenced the need for oxygen supplementation. Similarly, CRP, WBC, NLR, MLR and MNR levels did not differentiate among those that required oxygen and those that did not (p-value .471, .988, .879, .931 and .763 respectively). Of all the laboratory parameters, only CRP admission levels correlated with the duration of hospitalization (rho=.192). Patients with concurrent infections had significantly higher CRP levels (p-value=.002) and a lower MNR (p-value=.012).
Conclusions/Learning Points: Admission laboratory parameters of patients with respiratory syncytial virus infection cannot help distinguish those that will require oxygen supplementation during hospitalization, nor the length of hospital stay; hence, their use should be restricted on the presence of concurrent infections.

PV0654 / #1248

PREDICTORS OF COMPLICATED INFLUENZA INFECTION IN CHILDREN PRESENTING IN A TERTIARY HOSPITAL IN A TROPICAL COUNTRY: A CASE-CONTROL STUDY.

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Sudipta Roy Chowdhury[1], Chia Yin Chong[2], Koh Cheng Thoon[2], Karen Nadua[2], Kai Qian Kam[2], Jiahui Li[2], Natalie Woon Hui Tan[2], Chee Fu Yung[2]
[1]KK Women's and Children's Hospital, General Pediatrics, singapore, Singapore, [2]KK Women's and Children's Hospital, Singapore, Paediatrics, Infectious Disease Service, Singapore, Singapore

Backgrounds: Influenza causes significant health-care burden world-wide with highest mortality and morbidity in children and the elderly. We aim to compare the characteristics of patients with complicated influenza infections admitted to high-dependency (HD) or intensive care unit (ICU) and influenza-related mortality in hospitalized children and identify the risk factors associated with these cases.
Methods: A retrospective case-control study was conducted amongst laboratory-confirmed influenza infections amongst pediatric patients admitted to KK Women's and Children's Hospital, Singapore between January 2011 to October 2017. Patients were defined as cases if they were admitted to HD or ICU for complicated influenza infection needing closer monitoring; controls were patients admitted for an uncomplicated influenza infection within 3 days of these cases. We compared demographic, clinical and laboratory data between cases and controls and between mortality cases and survivors.
Results: We identified 209 patients, 55 (26.3%) cases and 154controls (1:2.8 ratio) between the ages of 22 days to 15 years (median age 2.9 years). There were 17 deaths (8.1%)amongst the cohort studied. Cases requiring HD/ICU admission were older compared to controls (4.5 years versus 2.6 years). By univariate analysis, significant risk factors for HD/ICU admission or death were respectively: drowsiness(OR 5.8, p <0.001; 10.49, p<0.001), any co-morbidities (OR 4.46, p<0.001; 3.14, p 0.02) and viral co-infections (OR 7.34, p=0.001; 6.26, p=0.002). Additional significant risk factors for HD/ICU admission were age >5 years old (OR 2.17, p=0.02), presence of seizure (OR 3.00, p=0.01) or tachypnea (OR 6.86, p<0.001) at initial presentation in hospital. By multivariate analysis; risk factors for HD/ICU admissionwere: initial presentation with tachypnea (multivariate OR 9.27, p<0.001) and concurrent viral co-infections(multivariate OR 10.42, p=0.002). Multivariate analysis showed greatest risk factor for influenza-related mortality to be presence of drowsiness (multivariate OR 7.97, p<0.001).
Conclusions/Learning Points: Patients with underlying co-morbidities should be recommended for routine influenza vaccination. Initial presentations of tachypnea, seizures or drowsiness in suspected influenza infections should be monitored closely for progression and complications that may cause significant morbidity or mortality and should alert the attending physician to consider admission to HD/ICU for more intensive care and treatment.

SEVERE INFLUENZA VIRUS AND RSV INFECTIONS IN PEDIATRIC INTENSIVE CARE IN THE LAST 15 YEARS

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Inês Rua[1], João Diogo[2], Gustavo Januário[3], Rita Moinho[1], Leonor Carvalho[1], Patrícia Mação[4]
[1]Pediatric Hospital, CHUC, Pediatric Intensive Care Service, Coimbra, Portugal, [2]Faculty of Medicine of the University of Coimbra, Faculty Of Medicine Of The University Of Coimbra, Coimbra, Portugal, [3]Pediatric Hospital, Pediatric Ambulatory Service, Coimbra, Portugal, [4]Pediatric Hospital, Pediatric Emergency Service, Coimbra, Portugal

Backgrounds: Influenza virus is a common agent of pediatric infection. Most cases are mild, but severe illness and death can occur. The aim of this study was to analyze severe cases associated with influenza virus and compare it with RSV.
Methods: We retrospectively studied children 0-17years old, admitted to pediatric intensive care unit (PICU) over the last 15years (2008-2022) due to influenza virus at a tertiary hospital in Portugal. Clinical presentation, severity and evolution were analyzed. Comparison of children with RSV infection admitted in the same period was performed (excluding coinfections; n=11).
Results: We identified 46 cases of influenza virus infection (24% coinfection with RSV, 15% with other viruses), with a median age of 2,3years (IQR 6,8) and 52% had comorbidities. The median admissions were 3/year, with a peak of 11 cases in 2019. Influenza subtype A was identified in 93%. Clinical presentation was with respiratory symptoms in 96%, neurologic 39% and sepsis 28%. The main reason for admission was respiratory failure (67%). Mean Paediatric Index of Mortality 2 (PIM2) at admission was 9% (SD 16). Ventilatory support was used in 65% (invasive 45%, non-invasive 30%). Vasoactive support and blood products were required in 17% each. The median length of stay was 4days (IQR 5,5). There were 3 (7%) deaths. During this period there were 171 admissions related to RSV infection. Comparison with cases of RSV infection is present at Table
1.

Type of viral infection	Influenza virus (n=35)	RSV (n=171)
Age (y), median (IQR)	3,3 (IQR 7,9)	0,1 (IQR 0,2)
Newborn (n, %)	1 (2,9%)	57 (33,3%)
Male (n, %)	19 (54,3%)	100 (58,5%)
Comorbidities (n, %)	20 (57,1%)	57 (33,3%)
Influenza vaccination (n, %)	2 (0,06%)	3 (0,02%)
PIM2 (mean, SD)	11,2 (SD 17,9)	1,7 (SD 17,6)
Length of stay (days), median (IQR)	5 (IQR 7)	5 (IQR 4)
NIV (n, %)	12 (34,3%)	49 (28,7%)
MIV (n, %)	15 (42,8%)	38 (22,2%)
Length (hours) of MIV, median (IQR)	108 (IQR 192)	12,5 (IQR 94)
Blood products (n, %)	8 (22,9%)	6 (3,5%)
Mortality (n, %)	3 (8,6%)	0 (0%)

Conclusions/Learning Points: The number of RSV infections admitted to PICU was much higher than with influenza virus. However, influenza was more severe (higher PIM2 at admission and need of supportive care) and responsible for all deaths registered. An important number of patients were previously healthy.

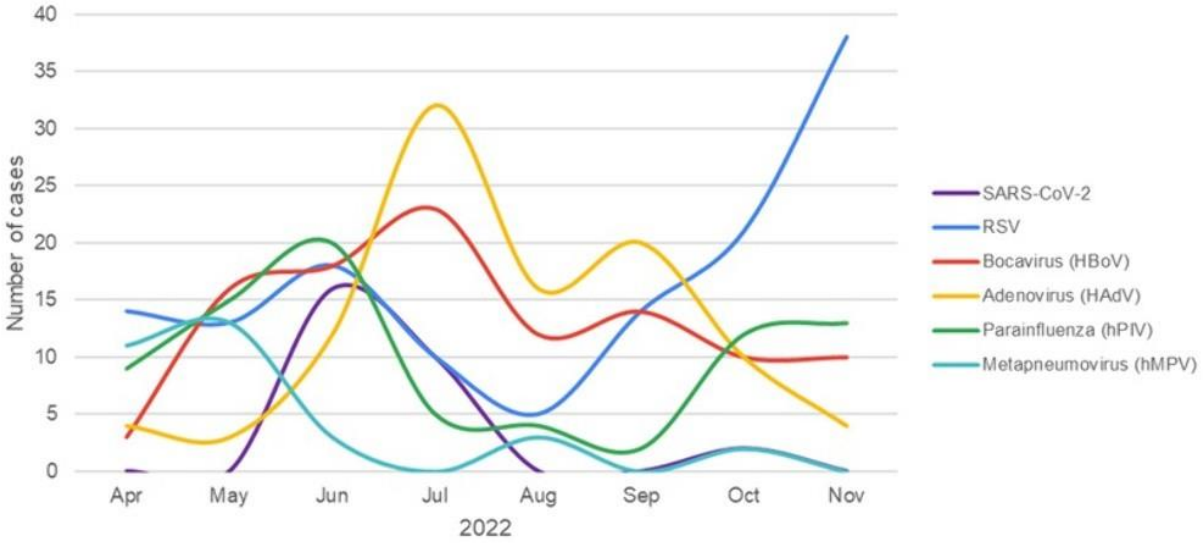
SEASONALITY TRENDS OF COVID-19, RSV, AND OTHER RESPIRATORY VIRUSES DURING THE COVID-19 PANDEMIC IN SÃO PAULO, BRAZIL: A SINGLE-CENTER PASSIVE SURVEILLANCE STUDY

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Flavia Almeida[1], Emmanuella De Jesus D'Elia[1], Natalia Saori Nakata[2], Giovanna Guerra[1], Daniel Jarovsky[1], Marco Aurelio Safadi[3], Eitan Naaman Berezin[1]
[1]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [2]Santa Casa de São Paulo, Department Of Pediatrics, Sao Paulo, Brazil, [3]Santa Casa de Sao Paulo School of Medical Sciences, Pediatric Infectious Diseases, Sao Paulo, Brazil

Backgrounds: Significant changes in the circulation of respiratory viruses were seen during and following the COVID-19 pandemic years. All pediatric cases admitted to a referral university hospital due to respiratory disease were evaluated. The prevalence of the different respiratory viruses causing hospitalization is provided herein.
Methods: From 2020 to 2022, we collected nasopharyngeal specimens from all pediatric inpatients under 15 years old with respiratory diseases. A multiplex RT-PCR assay was performed, and the early and mid-pandemic periods (2020 and 2021) were compared to 2022.
Results: 2053 patients were screened, and 1974 samples were evaluated – 278 were collected in 2020, 724 in 2021, and 972 in 2022; 40% were younger than 5 years old. The most frequent viruses found in 2020 were SARS-CoV-2 (10%; 28/278) and RSV (5.7%; 16/278). In 2021 RSV was the leading pathogen (22.8%; 165/724), followed by parainfluenza (7.3%; 53/724) and bocavirus (4.4%; 32/724). During 2022 RSV was the most frequent virus (13.7%; 133/972), followed by bocavirus (10.9%; 106/972) and adenovirus (10.4%; 101/972). Most patients were admitted with severe respiratory symptoms (SARS) – RSV was the leading pathogen in this group. In addition, most children with RSV (41%) were hospitalized from August to November in both 2021 and
2022.



Conclusions/Learning Points: RSV has been a leading cause of hospitalization in pediatric patients, even during early and mid-pandemic periods. The seasonality of this virus differed in 2021 and 2022 since the circulation peaked in March-July before COVID-19.

BACTERIAL CO-INFECTIONS IN BRONCHIOLITIS: ANTIBIOTIC PRESCRIPTION IN SPECIFIC CASES

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

María Sánchez Codez[1], Estrella Peromingo Matute[1,2], Veronica Fernandez Puentes[1], Irene Gutierrez Rosa[1], Ana Sánchez Sánchez[1]
[1]Puerta del Mar Hospital, Division Of Pediatric Infectious Diseases, Puerta Del Mar, Cadiz, Spain, Cádiz, Spain, [2]Puerta del Mar Hospital, Paediatrics, Cádiz, Spain

Backgrounds: Most recent guidelines do not recommend antimicrobials therapy in bronchiolitis. However, antibiotics are indicated if there is evidence of a coexisting or secondary bacterial infection. We sought to define the incidence of bacterial infections in children with bronchiolitis caused by different viruses.
Methods: Retrospective cross-sectional study of children ≤ 2 years old with bronchiolitis admitted at a referral hospital from June to December 2022. Patients hospitalized in ICU were excluded. Acute otitis media (AOM), urinary tract infection (UTI), pneumonia and bacteremia were considered as bacterial infections. Respiratory viral co-infections and severity clinical outcomes were compared between patients with bacterial infections and those with uncomplicated bronchiolitis.
Results: 6/57 (10%) children presented bacterial concomitant infections. Of those, 3/6 (50%) were pneumonia, 2/6 (33%) AOM and 1/6 (17%) UTI. All patients were RSV positive. No differences in age or immunizations (included flu vaccine) administered were detected according to bacterial infections. No different history of family smoking, atopia, prematurity or having a sibling less than 5 years old based on bacterial co-infections was reported. Respiratory viral co-infections were similar between both groups. C-reactive protein was higher in bacterial concomitant infection group than those without bacterial complication (median IQR: 71 [47-102] mg/L vs. 17[3.5-22] days; p =0.004). No differences in severity score of bronchiolitis, duration of hospitalization or oxygen requirement were detected according to bacterial co-detections. Amoxicillin/clavulanic acid was the most commonly used antibiotic 3/6 (50%), followed by amoxicillin 1/6 (16.6%) and ceftriaxone12/6 (33.3%). Median IQR of antimicrobial duration was 6.4 [6-7] days.
Conclusions/Learning Points: Bacterial infections complicating bronchiolitis in our center were higher than reported by other studies, being essential to detect and treat specifically these patients.

THE ASSOCIATION BETWEEN CHRONIC COMORBIDITIES AND RHINOVIRUS DISEASE SEVERITY IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

María Sánchez Codez[1], Isabel Benavente Fernandez[2], Katherine Moyer[3], Amy Leber[4], Octavio Ramilo[5], Asuncion Mejias[4]
[1]Puerta del Mar Hospital, Division Of Pediatric Infectious Diseases, Puerta Del Mar, Cadiz, Spain, Cádiz, Spain, [2]Puerta del Mar University Hospital, 2department Of Paediatrics, Puerta Del Mar University Hospital, Cadiz, Spain, [3]Inova Children's Hospital, Falls Church, VA,USA, Division Of Pediatric Infectious Diseases, Virginia, United States of America, [4]Department of Laboratory Medicine, Nationwide Children's Hospital, Columbus, Oh, Usa, Columbus, United States of America, [5]St Jude Children's Research Hospital, Memphis, TN, USA, Division Of Pediatric Infectious Diseases, Tennessee, United States of America

Backgrounds: Human rhinoviruses (RVs) are known triggers of asthma attacks, but the role of RV infections in children with other chronic medical conditions (CMC) is not fully described. We sought to define the frequency of CMC in a large cohort of patients with RVs infection, and the impact of RV infections on clinical outcomes according to the type of CMC.
Methods: Retrospective cross-sectional study of patients ≤21 years of age with a symptomatic PCR-confirmed RVs infection at a referral hospital or associated outpatient clinics from 07/2011 to 12/2013. RV semiquantitative loads was reported as cycle threshold values. Clinical outcomes (need and duration of hospitalization, ICU and oxygen administration) were compared between patients with asthma (CMC-A), other comorbidities (CMC-O) and those previously healthy.
Results: 1,899 children had a symptomatic RV infection: previously healthy(22%),CMC-O (41%), and asthma (37%)(Table 1). Within CMC-O the most common condition was prematurity(208; 11%). Median age was higher for CMC-A(23 mo), followed by CMC-O (11 mo) and healthy (4.7 mo); p=0.0001. No differences in RV viral loads or RV/viral coinfections were identified based on the presence or type of CMC. However, need for hospitalization was higher in children with CMC vs those healthy (86% vs.77%; p=0.0001), with no differences between CMC-A(88%) and CMC-O(84%). In CMC children supplemental oxygen(CMC-A, 65%; CMC-O, 50%) and PICU requirement(CMC-A 43%; CMC-O, 27%) were higher compared to healthy children(35% and 17% respectively; p=0.001). Length of stay was also higher in children with CMC vs healthy (2.6 vs.1.9 days; p
=0.0001).

Table. 1. Patient population and distribution of Underlying chronic conditions

Data presented as frequency (percentage). Numbers in bold indicate significant p values. * Values expressed as median [interquartile range]. [a] Prolonged duration of supplemental oxygen if greater than median O2 supplementation that was 4 days. [b] Prolonged pediatric intensive care unit (PICU) stay if greater than the median length of PICU stay, which was 1.9 days. [c] Prolonged hospital stay if greater than the median length of stay, which was 1.8 days. NIV, non-invasive ventilatory support; PICU, pediatric intensive care unit. Other CMC included: prematurity (n=208); genetic syndromes (n=132); gastrointestinal diseases (n=70); congenital heart diseases (n=70); respiratory tract morbidity (n=41); neurological disorders (n=36); immunodeficiencies (n=27); cystic fibrosis (n=17), hematologic disease (n=17) and other (n=169).

Conclusions/Learning Points: Clinical outcomes were significantly worst in both CMC-A and CMC-O vs healthy irrespective of RV viral loads. Defining the clinical phenotype of RV infection in children will help identify the patients that may benefit from targeted interventions.

RESPIRATORY SYNCYTIAL VIRUS (RSV)- ASSOCIATED HOSPITALIZATIONS IN A TERTIARY PEDIATRIC DEPARTMENT: A 5-YEAR REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Parthena Savvidou, Petrina Vantsi, Elpis Hatziagorou, Fotios Kirvassilis, Charalambos Antachopoulos, Elias Iosifidis, Emmanuel Roilides
Aristotle University of Thessaloniki, Hippokration Hospital of Thessaloniki, 3rd Dept Of Pediatrics, Thessaloniki, Greece

Backgrounds: Respiratory Syncytial Virus(RSV) is a leading cause of hospitalization for acute respiratory tract infections(ARI), especially in young infants. The aim of this study is to review the characteristics of RSV pediatric patients hospitalized in a 5-year period, including the COVID-19 pandemic.
Methods: A retrospective study was conducted from Jan 2018 to Dec 2022 in a General tertiary level Pediatric department in North Greece. Hospitalized children with a diagnosed RSV infection were included. Demographic, epidemiology, clinical data, treatment, and outcome were analyzed.
Results: Sixty-five(65) children were included, 33(50.7%) males, with mean age 8.23mo (IQR 6, 70% <6 months of age). In 2018-2020, seasonal peaks were observed Jan-March, while in 2021-2022 peaks were observed Oct-Dec, indicating an earlier season onset. In early December 2022, there was a cluster of RSV cases within 15 days, in children that were hospitalized for other reasons. Nineteen patients(29%) had a history of chronic conditions (16% of prematurity). Two patients had received at least one dose of Palivizumab. Fifty-five patients(84%) were diagnosed as bronchiolitis, with main symptoms cough(89%), rhinitis(86%) and respiratory distress(76%). Forty-two(64%) patients were diagnosed with a rapid antigen test, 25(38%) with multiplex PCR, while three patients had a co-infection with Human Rhinovirus-Enterovirus. All patients received iv fluids, 49(75%) needed oxygen therapy, and 8(12%) were admitted to PICU/NICU. Half patients were treated with antibiotics, 61% had nebulizers, and 53% had corticosteroids. Four patients presented complications . No deaths were recorded.
Conclusions/Learning Points: In this cohort of hospitalized patients with RSV infection, most patients were young infants with a good clinical course. The seasonality of RSV hospitalizations seems to be altered due to COVID-19 pandemic. An RSV outbreak in the department was detected.

ASTHMA, VIRUSES AND THE ENVIRONMENT: A SPATIO-TEMPORAL ECOLOGICAL ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Rana Sawires[1], Jim Buttery[2], Hazel Clothier[2], Michael Fahey[3], David Armstrong[4]
[1]Monash University, Paediatrics, Clayton, Australia, [2]Murdoch Children's Research Institute, Health Informatics, Melbourne, Australia, [3]Monash Children's Hospital, Neurology, Clayton, Australia, [4]Monash Children's Hospital, Respiratory And Sleep Medicine, Clayton, Australia

Backgrounds: Asthma is a heterogenous respiratory condition characterised by chronic airway inflammation, affecting 300 million people globally and predominating in children five years and older. The aetiopathophysiology of asthma is complex, with various environmental triggers leading to exacerbations, including respiratory viral infections, pollen levels, thunderstorm incidence and humidity.
Methods: We conducted a spatiotemporal ecological analysis of state-wide hospital data in Victoria, Australia, from July 2011 to June 2022. Spatiotemporal trends of state-wide datasets of emergency department and hospital-admitted asthma episodes occurring in children 5-19 years, environmental triggers and respiratory multiplex PCR tests performed at two large hospital networks were examined through negative binomial regression analysis.
Results: RSV, hMPV, Influenza A and B and pollen levels were associated with increased risk of asthma incidence before the COVID-19 pandemic (1.18 RR, 1.08 RR, 1.05 RR, 1.03 RR, 2.14 RR, respectively). Decreasing humidity was also associated with increased asthma risk before the pandemic. In 2020-2022, RSV and pollen levels were all associated with an increased risk of asthma (1.07 RR and 2.44 RR, respectively).
Conclusions/Learning Points: In addition to non-infective triggers, ongoing associations of asthma with RSV through the COVID-19 pandemic suggest an important role for this virus in exacerbations. Having identified changes to asthma associations in the wake of the COVID-19 pandemic, ongoing investigation of the role of these variables is warranted to provide further insight into asthma exacerbations in a post-pandemic world. If these results are confirmed, they can serve as the foundation for a multi-faceted asthma exacerbation forecasting system for healthcare providers and public use.

SOUTHERN AUSTRIA RESPIRATORY SYNCYTIAL VIRUS (RSV) INPATIENT INVESTIGATION (ARNI STUDY)

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Gülsen Sever Yildiz[1], Bernhard Resch[2,3]
[1]Medical University of Graz, Department Of Paediatrics And Adolescent Medicine, Graz, Austria, [2]Medical University of Graz, Department Of Paediatrics And Adolescent Medicinemedicine, Graz, Austria, [3]Division of Neonatology, Medical University of Graz, Department Of Paediatrics And Adolescent Medicine, Graz, Austria

Backgrounds: RSV-Bronchiolitis is one of the main causes of hospitalization in infants and young children, especially in premature newborns and the presence of pre-existing disorders. Aim of this study was to document the burden of disease during the last 7 RSV seasons in Southern Austria.
Methods: Retrospectively all infants and children ≤ 5 years of age hospitalized due to RSV infection between October 01, 2015, and April 30, 2022, were analysed. Demographics, medical history, incidence, severity, treatment, complications, and mortality of RSV infection, as well as hospital costs, were documented. Hospitalization rate for RSV to all acute respiratory illnesses (ARI) and to other diseases were estimated.
Results: 976 hospitalized infants and children were identified due to RSV infection during the study period. 79% hospitalized infants were younger than 12 months, 60% of infants were born during the RSV season. 87 % were healthy term infants. Highest hospitalization occurred in February (239 children). In the 2nd year of life, 59 % children with severe RSV infection had underlying diseases and prematurity. RSV accounted for 19% of hospitalizations due to ARI in children ≤ 5 years of age, 37% of all ARI <6 months of age, 28% of all ARI<12 months of age and 6.3% of all infections <12 months. Mortality rate was 0.3%. RSV-related hospital costs were about € 2 million per year.
Conclusions/Learning Points: Infants are disproportionally affected by RSV with the majority of hospitalizations being healthy term. RSV hospitalization accounted for about 1/5 of all hospitalization respiratory cause in children ≤ 5 years of age and were associated with high morbidity and costs. Prematurity and pre-existing conditions played a major role in older children resulting in comparably severe courses of disease

PV0662 / #1796

MICROBIOLOGICAL DATA OF RESPIRATORY INFECTIONS IN HOSPITALIZED CHILDREN DURING SEPTEMBER 2021-MARCH 2022.

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Angeliki-Eleni Sfetsiori[1], Aikaterini Georgakaki[1], Marialena Mani[1], Nektaria Rekleiti[2], Apostolia Salampasi[1], Chris Karakos[1], Olympia Zarkotou[2], Georgios Triantafyllidis[1]
[1]Tzaneio, General Hospital of Piraeus, Pediatric Department, Piraeus, Greece, [2]Tzaneio, General Hospital of Piraeus, Department Of Microbiology, Piraeus, Greece

Backgrounds: Novel rapid diagnostic methods are crucial for prompt identification of a wide range of respiratory pathogens and their clinical utilization may potentially improve patients' outcome.
Methods: Data from medical records of all hospitalized children during the study period (1/9/2021-13/3/2022) were documented and statically analyzed with SPSS 25.0.
Results: During the study period a total of 240 children were hospitalized, of which 62/240 (25.8%) presented symptoms indicative of respiratory infection. A percentage of 65% of children was found to be less than one year of age (range: 2 months-6 years), while boys accounted for 65% of study population. Emergency department complaints included: Symptoms indicative of acute bronchiolitis (52,5%), fever (32,5%), respiratory distress (10%), croup (2,5%) and other reasons (2,5%). In 64,5% of cases, rapid novel microbiological diagnostics methods were performed: RT- PCR (42,5%), FilmArray Respiratory panel (35%) or Lateral flow immunoassay (9%). Table 1 shows the microbiological data of diagnostic testing. RSV rapid diagnostic methods were proven to be accurate with high positive predictive value: 93,8% for RSV RT-PCR and 77,8% for RSV immunoassay.

Table 1

RESULT	POSITIVE	NEGATIVE
FILMARRAY (FA) Respiratory panel	11/14 (78,6%)	3/14 (21,4%)
	RSV: 3/11	
	Parainfluenza: 3/11	
	Rhinovirus/Enterovirus: 2/11	
	Metapneumonovirus: 1/11	
	Rhinovirus & Metapneumonovirus: 1/11	
	Corona0C43 & Rhinovirus & RSV: 1/11	
RT-PCR RSV	15/16 (93,8%)	1/16 (6,2%)
RSV Lateral flow Immunoassay	7/9 (77,8%)	2/9 (22,2%)
RT-PCR INFLUENZA	1/1 (100%)	
RT-PCR SARS CoV2	2/2 (100%)	

Conclusions/Learning Points: This study shows that the majority of hospitalized children with respiratory infections are under one year of age, highlighting the need for raising public awareness regarding prevention of respiratory infections in infants. Rapid novel microbiological methods for RSV are proven to be cost-effective point-of-care testing with high accuracy and potentially positive impact on clinical outcome of children.

Backgrounds: Acute respiratory viral infections are a leading cause of morbidity and mortality worldwide, especially among children. Although a small proportion of pediatric patients requires intensive care, it is crucial to understand risk factors for severe course among these patients. We aimed at assessing risk factors for severe course among children hospitalized in the pediatric intensive care unit (PICU).
Methods: A retrospective cohort study in a tertiary care center in northern Israel, during 2010-2021. All pediatric patients admitted with a laboratory-confirmed respiratory viral infection were included. Data regarding age, sex, underlying conditions, clinical manifestations and complications were collected. Severe course considered to be hospitalization >7 days, mechanical ventilation, pneumonia and death in the first month.
Results: A total of 312 patients were included comprising 10% of the patients admitted to the PICU during the study period. The median age was 13.2 months. Fifty-five percent were males, and 18.3% were born preterm. Almost quarter were transferred from surrounding hospitals. The most common pathogen was RSV (37.5%), followed by adenovirus (28%), influenza (19%), parainfluenza (11.5%) and Human metapneumovirus (HMPV)(11%). During the COVID-19 pandemic, there were 14 cases of SARS-CoV-2. Nearly half required mechanical ventilation and another 25% required other respiratory support. Mortality rate was 12%, half of them in the first month after admission. In a multivariate analysis, background illness (p=0.004; OR-2.11 95% CI 1.27-3.53), HMPV (p=0.049; OR-2.56 95% CI 1.01-6.51) and referral from another hospital (p=0.023;OR-1.99 95% CI 1.10-3.61) were found as independent risk factors for the severe course.
Conclusions/Learning Points: Although respiratory viral infections are not the main cause of admission to PICU, morbidity and mortality are not negligible, especially among patients with underlying conditions, those with HMPV and refereed from surrounding hospitals.

PROFOUND CHANGES IN THE EPIDEMIOLOGY OF RESPIRATORY VIRUSES AFTER THE COVID-19 PANDEMIC IN A LATIN AMERICAN PEDIATRIC ONCOLOGY CENTER.

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Adriana Silva[1], Luara Pignati[2], Janaina Sodre[3], Priscila Germano[3], Gustavo Zamperlini[4], Luciana Domingues[4], Maria Gabriele Matos[4], Lais Quintino[4], Fabianne Carlesse[1]
[1]Institute of Pediatric Oncology - GRAACC/UNIFESP, Pediatric Infectious Diseases, Sao Paulo, Brazil, [2]State University of Sao Paulo, Clinical Research Center, Sao Paulo, Brazil, [3]Institute of Pediatric Oncology - GRAACC/Federal University of Sao Paulo, Hospital Infection Control Service, Sao Paulo, Brazil, [4]Institute of Pediatric Oncology-GRAACC/Federal University of Sao Paulo, Pediatric Oncology, Sao Paulo, Brazil

Backgrounds: The COVID pandemic has turned the spotlight on the importance of the diagnosis of respiratory virus infections. Immunocompromised patients remain vulnerable to respiratory viral infections and there are still doubts regarding the true incidence of respiratory infections in these patients. We aimed to evaluate in pediatric oncology patients the impact of not SARS-CoV-2 respiratory virus in pandemic time, by comparing their detection with pre-pandemic.
Methods: We analyzed all respiratory specimens collected between Jan, 2017 and Dez, 2022 from symptomatic patients. Immunofluorescence test detected: Influenza, Adenovirus, Parainfluenza, and Respiratory Syncytial Virus (RSV). We compared results from 2017-2019 (pre-pandemic) to 2020-2022 (pandemia).
Results: In the pre-pandemic period, 1,421 tests were collected, versus 2,451 during the pandemia, a 72.5% increase. There were 53 positive tests 2017-2019 and 43 in 2020-2022 (4% vs. 2%, respectively; $p<0.001$). RSV was the most commonly isolated virus in the pre-pandemic period (55%; $p<0.001$), followed by Parainfluenza (32%), Influenza (11%), and Adenovirus (2%). During the pandemic period, Parainfluenza was the most commonly isolated virus (63%; $p=0.005$), followed by RSV (19%), Influenza (14%), and Adenovirus (5%). During 2017-2019, RSV incidence peaked in April-June. During 2020-2022, Parainfluenza had two separate peaks, during August-September and November-December, 2022.
Conclusions/Learning Points: The pandemic has led to profound changes in the circulation of non-SARS-CoV-2 respiratory viruses. Our study observed a reduction in RSV incidence and increase in Parainfluenza infections. The number of tests has significantly increased, probably due to increased awareness, allowing earlier diagnoses, prompt initiation of isolation and supportive measures to decrease morbidity and mortality in our pediatric oncology patients.

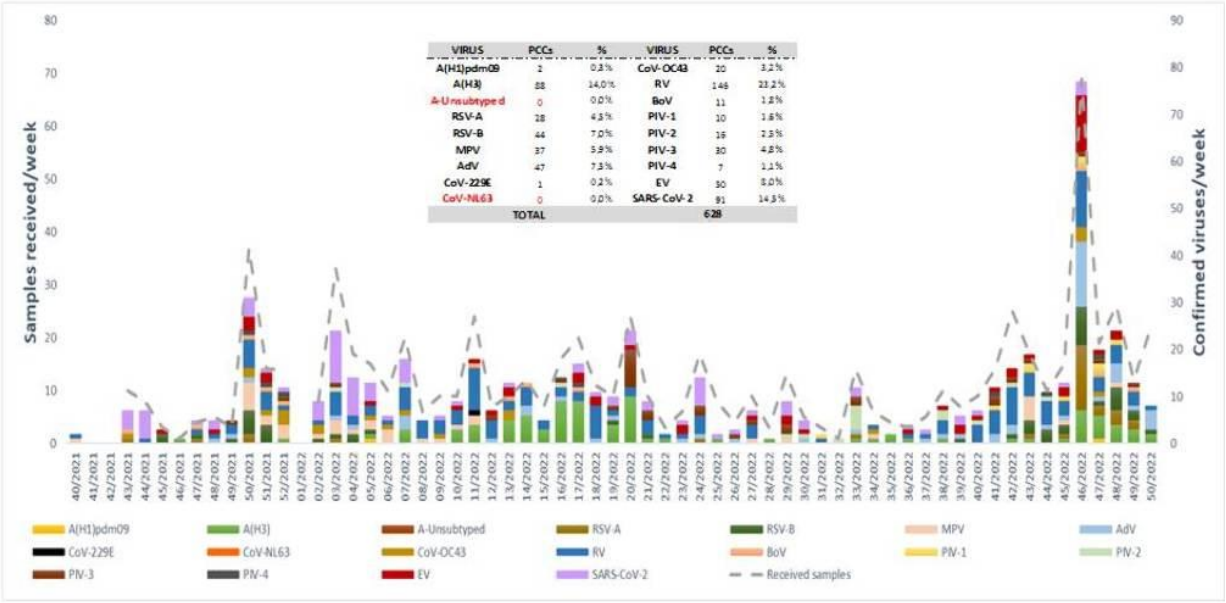
Backgrounds: We aimed to monitor and to characterize respiratory viral infections among paediatric population attended at Primary Care (PC) setting in Catalonia (Spain), comparing them with those detected among general population attended at the largest tertiary hospital in this area.
Methods: Naso/oropharyngeal swabs from children with a suspected acute respiratory tract infection were randomly collected at 25 PC participating centres of the COPEDICAT network (up to two per centre weekly) in Catalonia (Spain) between September/2021 and December/2022. Laboratory confirmation of respiratory viruses was performed at the referral microbiology laboratory. Detection of viruses was performed by transcription-mediated amplification and real-time multiplex RT-PCR assays for SARS-CoV-2 and other respiratory viruses, respectively. Molecular characterisation was carried out for influenza viruses, SARS-CoV-2, enterovirus (EV) and adenovirus (AdV) by partial or complete genome sequencing.
Results: A total of 734 specimens were received, mostly from 5 to 14-year-old children (335, 46%), and 628 (86%) different viruses were detected (Figure). Rhinoviruses were the most prevalent (23%), followed by SARS-CoV-2 (14.5%), influenza A(H3) virus (14%), EV (8%), AdV (7.5%), RSV-B (7%), and MPV (6%). These prevalences were similar to the observed at the referral hospital for COPEDICAT network, except for seasonal coronaviruses and parainfluenza virus type 3. Genetic characterisation revealed that: all influenza A(H3) and one A(H1)pdm09 viruses belonged to a similar clade of the current recommended vaccine strain; most AdV were from genetic clades B3 (15; 41%) and C2 (16; 43%); up to 12 different EV types were distinguished, being EV-D68 the most common; and finally, different SARS-CoV-2 lineages were detected, mostly Omicron
variants.



VIRUS	PCCs	%	VIRUS	PCCs	%
A(H1)pdm09	2	0.3%	CoV-OC43	20	3.2%
A(H3)	88	14.0%	RV	146	23.2%
A-Unsubtyped	0	0.0%	BoV	11	1.8%
RSV-A	28	4.5%	PIV-1	10	1.6%
RSV-B	44	7.0%	PIV-2	16	2.5%
MPV	37	5.9%	PIV-3	30	4.8%
AdV	47	7.5%	PIV-4	7	1.1%
CoV-229E	1	0.2%	EV	50	8.0%
CoV-NL63	0	0.0%	SARS-CoV-2	91	14.5%
TOTAL				628	

Conclusions/Learning Points: The good correspondence observed in viral detections between hospital and PC makes this paediatric surveillance worthy to implement as a sentinel network from paediatric PC clinics.

DIVERSITY OF RESPIRATORY VIRAL CO-INFECTIONS IN AUSTRIA DURING SEASONS 2021/2022 AND 2022/2023

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

David Springer, Jeremy Camp, Stephan Aberle, Judith Aberle, Monika Redlberger-Fritz
Medical University of Vienna, Center For Virology, Vienna, Austria

Backgrounds: During the SARS-CoV-2 pandemic, the circulation of RSV, Influenza and other respiratory viruses declined significantly due to pandemic measures and changes in behavior. In the current season, a seasonally atypical re-emergence of RSV, Influenza and other respiratory viruses could be observed.
Methods: In Austria, annual sentinel surveillance of circulating respiratory viruses is coordinated on a nation-wide level. Nasopharyngeal samples are collected year-round from over 200 sentinel physicians (including pediatricians, family doctors and hospitals) from patients presenting with acute respiratory illness and tested by PCR for SARS-CoV-2, RSV-A/-B, Influenza-A/-B/-C, Rhinovirus, Metapneumovirus and other viruses at the Center for Virology of the Medical University of Vienna. Here, we report the incidence data for infections and co-infections with those viruses for two pandemic seasons (2021/2022 and 2022/2023) in children (0-6 and 6-18 years) and adults (>18 years).
Results: In summary, the 2021/2022 season was characterized by a strong SARS-CoV-2 activity in adults, low overall Influenza activity and a moderate to high RSV-A incidence in children. In comparison, strong Influenza-A and RSV-B circulation was observed in the 2022/2023 season with only low co-circulation of SARS-CoV-2. Children under 6 years showed a more diverse pattern of viral infections and viral co-infections compared to adults. Notably, SARS-CoV-2- and RSV-infected children (< 6a) were co-infected with another virus in up to 50 % and 25 % of the observed cases in the current 2023/2023 season, respectively. Interestingly, co-infections with RSV and Influenza-A were less commonly observed than other combinations such as RSV and SARS-CoV-2.
Conclusions/Learning Points: In conclusion, the unusual predominance of RSV-B as well as the overall strong respiratory virus circulation in the current 2022/2023 season warrant further epidemiological and mechanistic investigation.

MUMPS VIRUS INFECTION IN CHILDREN IN BULGARIA

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Radostina Stefanova, Chiydem Ismailova, Petia Genova-Kalou, Elica Golkocheva-Markova, Marina Doncheva, Stefka Krumova
National Center of Infections and Parasitic Diseases, Virology, Sofia, Bulgaria

Backgrounds: Mumps (MuV) is a common childhood disease worldwide, especially in developing countries that usually makes a child have a fever and swollen salivary glands in his mouth and near his ear. MuV may also affected the central nervous system and caused viral meningitis.
Methods: In the present study, 108 serum samples, 39 urines and 39 buccal swabs from 108 children with possible MuV infection were tested, for the period 2018-2022. Patients are aged from 0 to 18 years of age. Serological tests were performed using a commercial enzyme-linked immunosorbent assay (indirect ELISA test to prove specific mumps IgM/IgG antibodies in sera). Molecular methods with a target amplifying the highly variable small hydrophobic (SH) gene of MuV genome by a One-step RT-PCR in urines and buccal swabs were used. The study was supported by the European Regional Development Fund through Operational Program Science and Education for Smart Growth 2014–2020, Grant BG05M2OP001-1.002-0001-C04.
Results: Of all tested patients (n=108), in 50 (46%) serological confirmation of acute MuV infection (positive IgM result) were found. The distribution by age groups shows the most frequent infection of children aged 5-9 years (27/50, 54%). Positive MuV PCR signals in 28 urines and 23 buccal swabs were detected. The resulting mumps symptoms quickly subsided and the outcome of the disease was good. In 70/108 (65%) of the tested patients, evidence for MuV protective immunity (IgG antibodies) were shown.
Conclusions/Learning Points: Despite vaccination strategies, recent outbreaks in European countries highlight the need for rapid diagnosis of MuV. The most affected persons are children between the ages of 2 and 12 and the unimmunized.

RESPIRATORY SYNCYTIAL VIRUS EPIDEMIC IN YOUNG CHILDREN IN A TROPICAL COUNTRY: EFFECTS FROM COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Piyarat Suntarattiwong[1], Jiratchaya Trijitwatanakoon[1], Amornwadee Chudaeng[2]
[1]Queen Sirikit National Institute of Child Health, Pediatric Department, Bangkok, Thailand, [2]Queen Sirikit National Institute of Child Health, Department Of Pathology, Bangkok, Thailand

Backgrounds: Respiratory syncytial virus (RSV) is the most important respiratory pathogen of young children. During the COVID-19 pandemic, reports from temperate countries demonstrated RSV seasonal patterns changes, information were limited from tropical areas. We did the study to define RSV seasonal pattern and compare clinical characteristics of young children before and during the pandemic.
Methods: A cross-sectional study was done from January 1, 2019, to December 31, 2021, at Queen Sirikit National Institute of Child Health, Bangkok, Thailand. Children aged 0-5 years with RSV PCR or antigen test positive were enrolled. We collected the children's demographic and clinical information and analyzed data using SPSS software.
Results: There were 2143, 1912, and 356 RSV testing and the rate of positive for RSV were 15, 28, and 4% in 2019, 2020, and 2021 respectively. Comparing between pre-pandemic (2019) and during Covid-19 pandemic (2020), the RSV peak was shifted from August-September in 2019 to October-November in 2020. The mean age was significantly lower in children with RSV enrolled in 2019 compared to 2020-2021 (15.7 ± 13.0 versus 21.8 ± 16.4 months, p=0.001). Clinical diagnosis was also different, in 2019, 84% presented with lower respiratory tract infections including pneumonia, bronchiolitis, and bronchitis compared to 77% in 2020-2021 (p=0.022). In contrast, in-patient treatment was significantly higher in 2020-2021 compared to 2019 (63.9 versus 52.1%, p=0.038).
Conclusions/Learning Points: RSV season was delayed by 2 months, which was corresponded to delayed school starting during Covid-19 pandemic in Thailand. RSV affected older children during the pandemic and may explain the clinical presentations of less pneumonia and bronchiolitis. The higher admissions may reflect higher concern of Covid-19 among young children presented with respiratory infections during the pandemics.

THE IMPACT OF THE SARS-COV-2 PANDEMIC ON THE SEASONALITY OF HUMAN RESPIRATORY SYNCYTIAL VIRUS AMONGST HOSPITALIZED CHILDREN IN HEIDELBERG/GERMANY

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Julia Tabatabai[1,2,3], Julia Gsenger[4], Clara Ihling[2,3,5], Sarah Klemm[2], Paul Schnitzler[2]
[1]Center for Childhood and Adolescent Medicine, University Hospital Heidelberg, General Pediatrics, Heidelberg, Germany, [2]Center for Infectious Diseases, Virology, Heidelberg, Germany, [3]German Centre for Infection Research, (dzif), Heidelberg, Germany, [4]Centre for Infectious Diseases, Virology, University Hospital Heidelberg, Heidelberg, Germany, [5]Dr. von Haunersches Kinderspital, University Hospital of the LMU Munich, Pediatrics, München, Germany

Backgrounds: The SARS-CoV-2 pandemic had an impact on the circulation of common respiratory viruses. We evaluated changes in the seasonality of respiratory syncytial virus (RSV) infection amongst hospitalized children.
Methods: Nasopharyngeal swabs are obtained from hospitalized children (<3 years) who present with clinical symptoms of acute respiratory tract infection (ARTI) at the Paediatric Department of the University Hospital Heidelberg/Germany during winter seasons. We compared three pre-pandemic seasons (2017/18, 2018/19, 2019/20) with three pandemic SARS-CoV-2 seasons (2020/21, 2021/22, 2022/23 (ongoing investigation)). Nasopharyngeal swabs were screened for RSV using point-of-care molecular testing (Abbott IDnow®), and RT-PCR (Altona Diagnostics) was performed to identify RSV subtypes. Clinical data was collected using a standardized questionnaire.
Results: Pre-pandemic during winter seasons 2017/18, 2018/19, 2019/20, a total of n=146/461 (31.7%), n=193/397 (48.6%) and n=121/313 (38.7%) hospitalized children were RSV positive, respectively. RSV-B predominated 2017/18 and 2018/19 with 56.4% and 84.0%, respectively, whereas RSV-A mostly circulated in season 2019/20 with 80.0%. The seasonal peaks were February/March 2018, January/February 2019 and February 2020. During the SARS-CoV-2 pandemic, in the first winter season 2020/21 only few patients (n=30) presented with ARTI and none was RSV positive. During season 2021/22, a total of n=214/481 (44.5%) patients tested RSV-positive (64.2% male; median age 4.4 months (IQR 1.6-16.0)) with the majority presenting with RSV-A (77.4%). Whereas in the currently ongoing season 2022/23, n=145/270 (53.7%) children were RSV positive and 85.3% were allocated to RSV-B. Both seasonal peaks were earlier in November/December 2021 and 2022, respectively and in 2021 first RSV positive cases were found in July.
Conclusions/Learning Points: RSV seasonality changed substantially with the introduction of non-pharmaceutical measures during the SARS-CoV-2 pandemic reporting no RSV cases in 2020/21 whereas displaying an early onset and high incidence in 2021/22.

ALICE IN WONDERLAND SYNDROME ASSOCIATED WITH INFLUENZA INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Teresa Tavares[1], Sérgio Alves[1], Cristina Garrido[2], Carla Teixeira[1,3], Laura Marques[1,3], Alexandre Fernandes[1,3], Ana Ramos[1,4]
[1]Centro Materno-Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatrics, Porto, Portugal, [2]Centro Materno-Infantil do Norte, Centro Hospitalar Universitário do Porto (CMIN - CHUPorto), Paediatric Neurology Unit, Porto, Portugal, [3]Centro Materno-Infantil do Norte, Centro Hospitalar e Universitário do Porto, Infectious Diseases And Immunodeficiencies Unit, Paediatric Department, Porto, Portugal, [4]Centro Materno-Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatric Department, Pulmonology Unit, Porto, Portugal

Title of Case: ALICE IN WONDERLAND SYNDROME ASSOCIATED WITH INFLUENZA INFECTION
Background: Alice in Wonderland Syndrome (AIWS) is characterized by distortions of visual perception (macropsia or micropsia), the body schema, and the perception of time. It is often associated with migraines, brain tumours, the use of psychoactive drugs, and viral infections, with Epstein-Barr virus infection being the most common. Here we present a case of AIWS associated with Influenza infection.
Case Presentation Summary: A healthy 10-year-old boy presented with a 2-day history of fever, headache, rhinorrhoea, cough and vomiting. He had two afebrile self-limited episodes of altered visual perception, where he described seeing everything too large. He did not take any recent medications or immunizations, he had no contact with animals, no recent travel or history of trauma. Neurological and systemic examination were normal. His blood test results revealed lymphopenia (640/uL). Cerebrospinal fluid obtained by a non-traumatic lumbar puncture revealed 200 erythrocytes/uL and 3 leukocytes/uL, with normal glucose and proteins and without microbial identification. Influenza A/H3 was identified on respiratory secretions. Brain CT scan and electroencephalogram were normal. The diagnosis of AIWS associated with Influenza A infection was assumed and the patient was given oseltamivir. He had no fever after day 2 of treatment, with no new episodes. Three months after the episode he had a good general and mental health, without relapse.
Learning Points/Discussion: AIWS is a rare presentation in paediatric patients. In the presence of AIWS, Influenza virus infection should be considered as a possible cause. The clinician's awareness of this complication of influenza infections might prevent extensive diagnostic procedures.

HOSPITALIZATIONS IN THE LAST 5 YEARS DUE TO INFLUENZA INFECTIONS IN A TERTIARY PEDIATRIC HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Teresa Tavares[1], Helena Ferreira[1], Carla Teixeira[1,2], Laura Marques[1,2], Alexandre Fernandes[1,2], Ana Ramos[1,3]
[1]Centro Materno-Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatrics, Porto, Portugal, [2]Centro Materno-Infantil do Norte, Centro Hospitalar e Universitário do Porto, Infectious Diseases And Immunodeficiencies Unit, Paediatric Department, Porto, Portugal, [3]Centro Materno-Infantil do Norte, Centro Hospitalar Universitário do Porto, Paediatric Pulmonology Unit, Porto, Portugal

Backgrounds: Seasonal influenza virus' burden seems to have changed due to COVID-19 pandemic. We aimed to characterize influenza hospitalizations in children, and evaluate the pandemic impact.
Methods: Cross-sectional observational retrospective study of patients under 18 years, hospitalized in a tertiary paediatric hospital with Influenza, from January 2018 to December 2022. Cases were divided before the beginning of the COVID-19 pandemic (before march 2020) and after. Statistical univariate analysis was performed.
Results: There were 94 hospitalizations due to influenza (54.3% male, median age 26 months), mostly influenza A (75.5%). Half of the children had a co-infection, mainly RSV. The majority (71,3%; 67) were younger than 5 years old (45.7%;43 younger than 2 years). 50% (47) had a chronic condition, the most common being asthma (30%). Nine (9,6%) were vaccinated, all of them with chronic conditions. The main reason for hospitalization was hypoxemia (52,1%; 49), followed by feeding difficulties (31.9%; 30). Eight (8.5%) required ICU, and there were no deaths. The year with more hospitalizations was 2019 (36.2%), followed by 2022 (31.9%). More cases occurred before COVID-19 pandemic (67.0%; 63). Before the pandemic, infections were more common in winter (77.8% vs 9.7%), and after in the autumn (61.3% vs 6.3%; $p<0.001$). There were no differences in ages and chronic conditions. After the pandemic there were more neurological complications (32.3% vs 6.3%, $p<0.001$) and a higher mean length of hospital stay (9,67 vs 5,71, $p<0.005$).
Conclusions/Learning Points: Restrictive measures during COVID-19 pandemic changed the epidemiology of infections. During last year, Influenza infections raised to pre-pandemic levels, occurring earlier in the year. The burden of influenza infection in younger and healthy children should allow reflection on the role of different immunization strategies at that age.

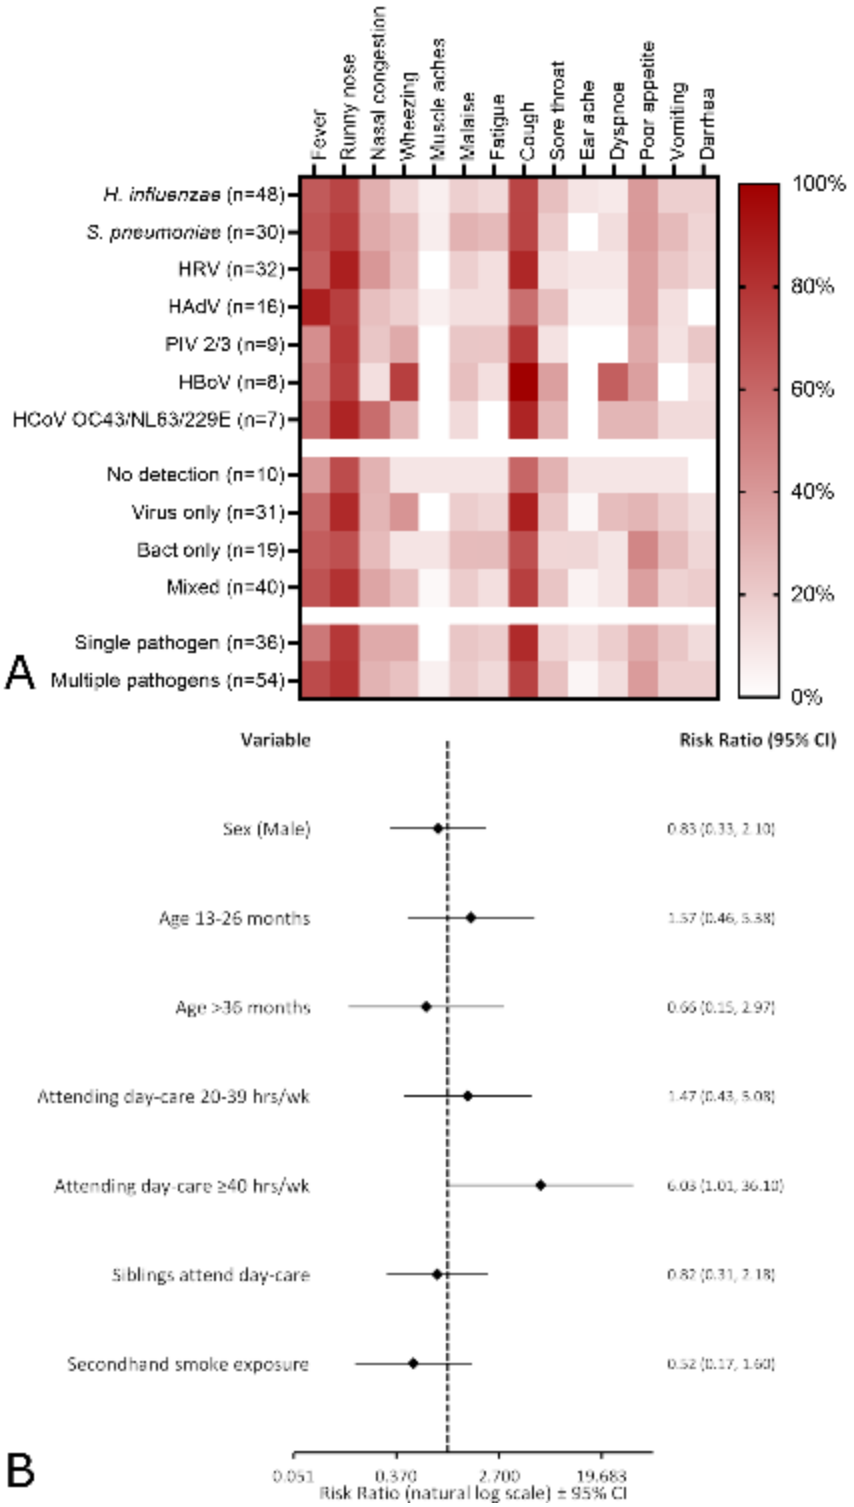
THE USEFULNESS OF MULTIPLEX PCR PANELS IN ACUTE RESPIRATORY INFECTIONS IN CHILDREN: A PROSPECTIVE CASE-CONTROL STUDY

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Katarzyna Zdanowicz[1], Dawid Lewandowski[2], Piotr Majewski[3], Kinga Polkosnik[1], Nikolina Liwoch-Nienartowicz[2], Joanna Reszec[4], Dariusz Lebensztejn[1], Artur Sulik[2], Kacper Toczylowski[2]
[1]Medical University of Bialystok, Department Of Pediatrics, Gastroenterology, Hepatology, Nutrition, Allergology And Pulmonology, Bialystok, Poland, [2]Medical University of Bialystok, Department Of Pediatric Infectious Diseases, Bialystok, Poland, [3]Medical University of Bialystok, Department Of Clinical Molecular Biology, Bialystok, Poland, [4]Medical University of Bialystok, Department Of Medical Pathomorphology, Bialystok, Poland

Backgrounds: Acute respiratory tract infections (ARIs) are common in pediatric patients. Since these infections are caused by a wide spectrum of viral and bacterial pathogens, proper antibiotic use in ARI patients is difficult. The aim of the study was to identify respiratory pathogens in nasopharyngeal swabs by multiplex PCR in ARI children in the context of the clinical picture of the infections.
Methods: We prospectively recruited children under 5 years of age with ARI who were hospitalized (n=54) or consulted in the primary care clinic (n=46), and tested negative for SARS-CoV-2. Nasopharyngeal swabs were collected between October 2021 and April 2022 and tested with RT-PCR screening for 19 viruses and 7 bacterial strains.
Results: A virus was detected in 67% of outpatients and 74% of hospitalized children. Bacteria were detected in 59% of children. The most common detections were H. influenzae (49%), human rhinovirus (32%), and S. pneumoniae (30%). The fluA virus was detected in 2% children in March 2022 only. RSV was detected in 5%. Single detection was seen in 36%, dual in 27%, triple in 15%, and quadruple in 2%. No correlation was found between the number of detected pathogens, the co-detection of bacterial pathogens and the clinical picture of the infection (Fig.A). Multiple detections were more common in children spending over 40 hours in a day-care weekly (OR, 6.03; 95%CI, 1.01-36.1)(Fig.B).



Conclusions/Learning Points: Viral and bacterial pathogens were commonly detected in ARI children. Clinical symptoms were similar regardless of the pathogens detected in the nasopharyngeal swabs, questioning the usefulness of multiplex PCRs. Our results also show that RSV and the flu viruses were still circulating in the early 2022, providing a reservoir for the flu and RSV outbreaks in the late 2022.

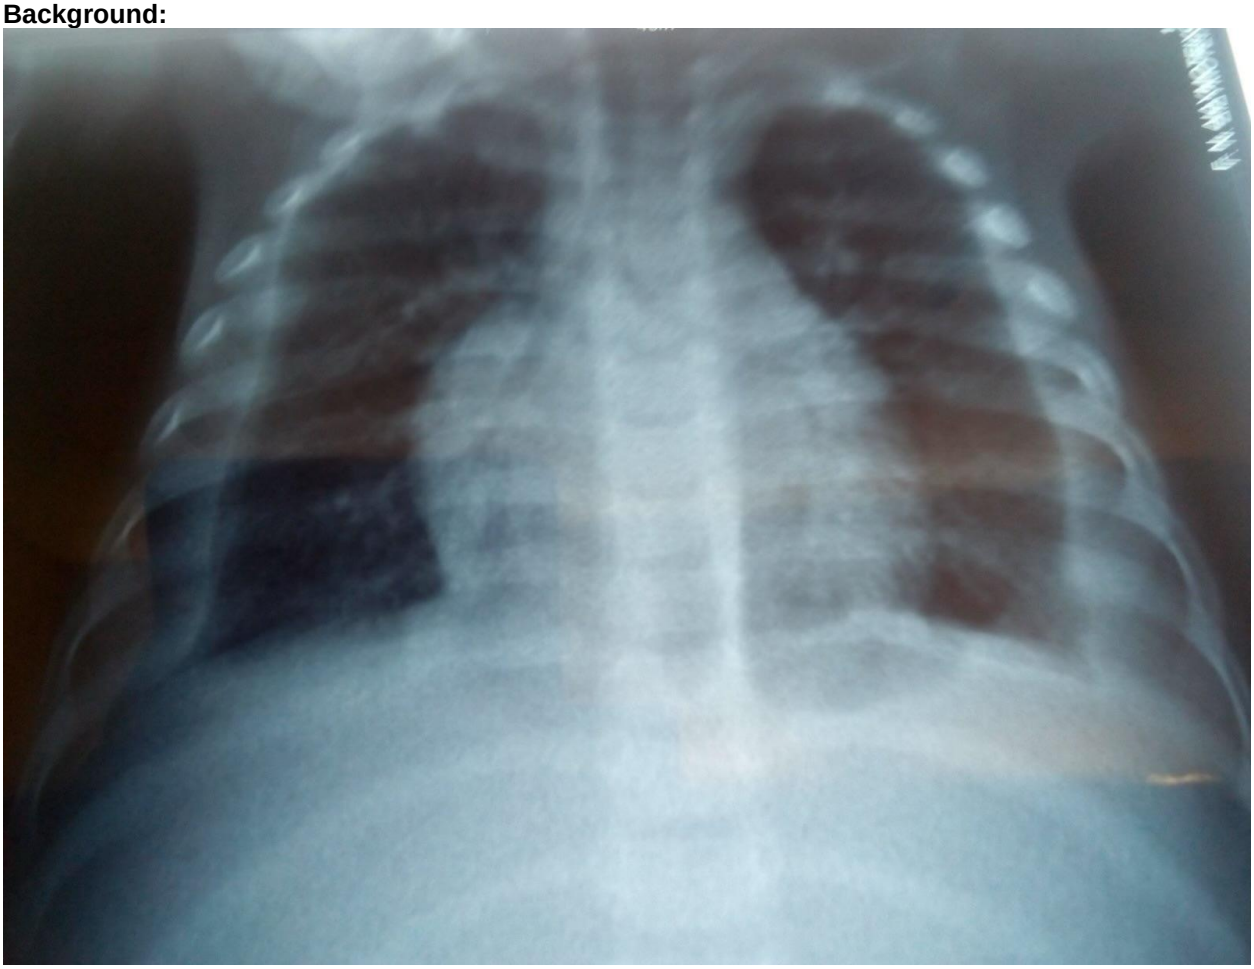
TODDLER WITH BILATERAL PLEURAL EFFUSION CAUSED BY INFLUENZA A

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Pelagia Tsitsani, Evdokia Psaroulaki, Georgios Katsaras
GENERAL HOSPITAL OF PELLA-HOSPITAL UNIT OF EDESSA, Peadiatric Department, EDESSA, Greece

Title of Case: Toddler with bilateral pleural effusion caused by Influenza A.
Background:



Bilateral pleural effusion in children is attributed to different infectious agents (Streptococcus pneumoniae), or non-infectious factors (congestive heart failure, malignancies). Clinical features of pulmonary complications of Influenza are mild lower respiratory tract infection, secondary bacterial pneumonia, progressive severe hemorrhagic pneumonia and concomitant viral and bacterial pneumonia.
Case Presentation Summary: A 2 years-old boy presented to emergency department afebrile with respiratory distress. Physical examination revealed bronchospasm and clinical symptoms of acute bronchitis of moderate severity. CBC depicted WBC: 17,520 x10^6/L (LY: 80%), negative inflammatory biomarkers (CRP: 0.15 mg/dL, procalcitonin: 0.07 ng/ml) and negative rapid tests for SARS-CoV-2, Influenza A + B, RSV and Adenovirus. Treatment with oxygen and nebulized salbutamol was initiated. On the 3rd day of admission, patient presented fever (T: 38.4^{o}C) and severe grunting. CXR was performed and revealed bilateral pleural effusion. Diagnostic thoracentesis was performed; pleural fluid was

exudative (according to Light's criteria). A blood culture was collected and empirical treatment with intravenous ceftriaxone was administered. Repeated CBC, biochemical profile revealed a decrease in WBC: 2,860 $x10^6$/L(LY 90%), and elevation in inflammation markers (CRP: 27.2 mg/dL and PCT: 2.5 ng/ml). The rapid test for Influenza A became positive the 4^{th} day of hospitalization. Oseltamivir was added to the treatment. After 20 days of hospitalization, clinical improvement was observed with gradual absorption of pleural effusion.

Learning Points/Discussion: Influenza A virus may cause severe respiratory infection and invasive complications, such as pleural effusion. Prognosis of the latter is highly related to the underlying disorder and early drainage of fluid may dramatically reduce the rate of mortality and morbidity. Rapid test should be repeated when clinically indicated, as early administration of oseltamivir is associated with better outcomes .

PREVALENCE AND COMPLICATIONS OF RESPIRATORY SYNCYTIAL VIRUS INFECTIONS IN CHILDREN HOSPITALIZED WITH ACUTE LOWER RESPIRATORY TRACT INFECTIONS IN AN EMERGENCY CHILDREN HOSPITAL DURING 2018-2022

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Alexandru Ulmeanu[1], Carmen Zapucioiu[2]
[1]Carol Davila University of Medicine and Pharmacy, Paediatric Pulmonology, Bucharest, Romania, [2]Grigore Alexandrescu Emergency Children Hospital, Paediatric Pulmonology, Bucharest, Romania

Backgrounds: Respiratory syncytial virus (RSV) represents an important cause of lower respiratory tract infections in infants and children Aim: To investigate the prevalence of RSV infections, complications, and impact on hospitalizations during a 5-year period (2018-2022) in an Emergency Children Hospital
Methods: Retrospective analysis of cases of RSV associated lower respiratory tract infections (LRTI) in children admitted to a tertiary care centre from Romania. RSV was detected by rapid antigen tests or RT-PCR from nasal swabs.
Results: 627 children were admitted for RSV LRTI during the 5-year period, representing 13% of the total LRTIs treated in the Paediatrics Department. 53% of RSV LRTIs were diagnosed in infants (<1 year) and 44% in pre-schoolers (<6 year). Most of the patients were admitted during the classic season (November-April) except for 2021 when the RSV season started during summer and lasted until April 2022,probably due to non-pharmacologic measures taken during the COVID-19 pandemic. The main identified complications were respiratory failure in 52% of cases, hypovolemia in 28%, and otitis media in 4,5% of cases. For both all-age children and under 3 months old infants, the average length of stay (ALS) for RSV LRTI was longer than for non-RSV LRTI (7.4 days and 8.25 days, compared with 5.5 days and 6 days, respectively). The total cumulative days of hospitalization for RSV infection was 4000 days.
Conclusions/Learning Points: RSV bronchiolitis and pneumonia are an important cause of hospitalization in infants and young children and frequently associates respiratory failure and dehydration requiring prolonged hospital stay and additional costs for the health system. RSV LRTI is most likely underdiagnosed in this study because testing is not performed routinely.

PV0675 / #810

RSV AND OTHER RESPIRATORY INFECTIONS AMONG CHILDREN DURING THE SECOND COVID-19 PANDEMIC WINTER SEASON

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Peter Voitl[1,2], Lena Strassmayr[2], Angela Riepl[2], Paulina Ehlmaier[2], Julian Voitl[2], Klara Langer[2], Ulrike Kuzio[2], Bernhard Muehl[3], Susanne Diesner-Treiber[2]
[1]Sigmund Freud University, -, Vienna, Austria, [2]First Vienna Pediatric Medical Center, -, Vienna, Austria, [3]Vienna Medical Innovation Center, -, Vienna, Austria

Backgrounds: Background: In the first Covid-19 winter season respiratory pathogens such as RSV, influenza and metapneumovirus were not observed in pediatric patients due to the impact of non-pharmaceutical measures. This prospective, longitudinal analysis aimed to identify the pathogen profile in children during the second Covid-19 winter season with less strict measures.
Methods: 678 children (0-36 months) presenting with an acute respiratory infection at Vienna's largest pediatric primary healthcare center were enrolled in this study from September 2021 to the end of March 2022. Nasal swabs were performed and tested by multiplex PCR for 23 respiratory pathogens. Clinical features, treatment recommendations and hospitalization were documented. The effect of lockdown on the pathogen prevalence was analysed.
Results: The 815 smears of 678 children revealed rhino-/enterovirus (38.5%), RSV (26.7%), and metapneumovirus (7.2%) as most prevalent pathogens. The early RSV onset was interrupted by the only lockdown in this winter season (RR 0.367, CI (0.184-0.767), p=0.003). Metapneumovirus circulated in January. Influenza was only sporadically found. Compared to last season, the hospitalization rate was significantly higher and was associated with RSV (OR 4.089, 95%CI (1.414-11.827), p-adj=0.05).
Conclusions/Learning Points: Less strict Covid-19 measures led to the surge of RSV in the second winter season. RSV was associated with a high hospitaliziation rate, and was abruptly interrupted by the only lockdown.

INCIDENCE OF MINIMALLY SYMPTOMATIC WINTERTIME RESPIRATORY VIRAL INFECTIONS IN FRONTLINE PAEDIATRIC EMERGENCY HEALTHCARE WORKERS IS SIMILAR TO THAT IN OFFICE AND LABORATORY WORKER CONTROLS

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Jonathan Vowles[1], Teresa Almeida Lopes[2], Chloe Farren[1], Dylan Thomas[1], Jacob Symanowski[1], Kaltun Duale[1], Louise Setter[1], Marta Marta Mergulhão[1], Mohar Chattopadhyay[1], Nellie Farhoudi[1], Rosa Rosa Aldridge[1], Tom Long[1], Will Healy[1], Begonia Morales-Aza[1], Adam Finn[1,3], Fernanda Rodrigues[2], Anna Koi[1]
[1]University of Bristol, School Of Cellular And Molecular Medicine, Bristol, United Kingdom, [2]Centro Hospitalar e Universitário de Coimbra, Hospital Pediátrico, Coimbra, Portugal, [3]University of Bristol, Cellular And Molecular Medicine, BS TD, United Kingdom

Background: Wintertime acute viral respiratory tract infections are common in children. Clinical staff in frequent contact with children presenting to emergency services may be frequently exposed via exhaled aerosols and contact with fomites. We compared rates of infection in these staff during the peak virus season with those in staff in the same hospital without patient contact duties.
Methods: 56 frontline healthcare workers (HCW) (doctors and nurses) with daily contact with acutely infected children and 56 control hospital staff without direct patient contact provided 5 weekly nasal swab and saliva samples in December 2019 - January 2020, just before the start of the COVID-19 pandemic. Staff on sick leave were not sampled. Masks were not routinely worn at this time. Samples were analysed by RT-qPCR multiplex panel (Certest Biotec) for respiratory viruses: Influenza A, Influenza B, Respiratory Syncytial Virus (RSV), Adenovirus, Human Metapneumovirus, Bocavirus, Rhinovirus, and Parainfluenza 1-4.
Results: Positive results are shown in the table. The numbers of cases detected were very similar for all viruses apart from influenza, with a cluster of 4 cases of influenza B detected in the HCWs. Saliva yielded fewer positives than nasal swabs and only 2 cases of influenza B were detected in saliva only. 5/6 influenza and 2/3 RSV cases had
symptoms.

	HCW (n=56)	Controls (n=56)
Influenza	5 (1A, 4B)	1 (1A)
RSV	1	2
Parainfluenza	2	2
Rhinovirus	15	12
Adenovirus	1	0
Total	24	17

Conclusions/Learning Points: During a period of high incidence of respiratory viral disease, including influenza and RSV, despite increased occupational exposure and during the pre-pandemic period, before enhanced infection control precautions were introduced, HCWs in frequent contact with sick children did not have enhanced numbers of mild or asymptomatic viral infections apart from a cluster of cases of influenza B.

THE RELATIONSHIP BETWEEN RSV VIRAL LOAD AND BRONCHIOLITIS SEVERITY AMONG CHILDREN AGED LESS THAN 12 MONTHS

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Alessandro Rocca[1], Giulia Piccirilli[2], Camilla Totaro[3], Caterina Borgatti[2], Luca Pierantoni[1], Marta Leone[2], Michele Di Marzio[3], Martina Franceschiello[2], Daniele Zama[1], Tiziana Lazzarotto[3], Marcello Lanari[1]
[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, 40138 Bologna, Italy, Pediatric Emergency Unit, bologna, Italy, [2]St. Orsola-Malpighi University Hospital, Operative Unit Of Clinical Microbiology, Laboratory Of Virology, Bologna, Italy, [3]Alma mater studiorum, University of Bologna, Specialty School Of Paediatrics, bologna, Italy

Backgrounds: Respiratory syncytial virus (RSV) is the most common cause of bronchiolitis which is the main cause of hospitalization in infants under 1 years of age. It has still not been clarified if a correlation exists between VRS viral load (VL) and disease severity.
Methods: Our objective was to define this correlation in hospitalized infants. We analyzed 116 nasopharyngeal aspirates (NPAs) from 38 infants admitted to hospital with RSV bronchiolitis between March 2018 and August 2021. NPAs were taken at admission, every 48 h, at discharge. VL was detected with a real-time PCR. Results were normalized for the presence of human DNA and expressed as Log10 copies/ng human DNA (h DNA). Disease severity was assessed considering the need for supplemental oxygen therapy, its delivery devices (low-flow and high-flow), length of stay and clinical score including poor feeding.
Results: At admission infants who required oxygen therapy (n=24) showed on average a higher VL compared to those who didn't (n=14) (4,71 ± 0,87 vs 4,04 ± 0,93 Log10 copies/ng h DNA; p=0,031). In 18 patients out of 24 (75%) treated with oxygen, the highest VL was found at admission, whereas for the remaining 6 (25%) at 48h from admission. On average, VL was greater among infants who required high-flow oxygen therapy (n=5) in comparison to those who received low-flow oxygen therapy (n=19), (5,49 vs 4,76 Log10 copies/ng h DNA; p=0,044). No statistically significant difference was found between VL at different time points and within parameters of disease severity.
Conclusions/Learning Points: Our data shows that virus replication plays an important role in defining the clinical picture demonstrating a significant correlation between VL at admission and the need for oxygen therapy, especially for those who required high-flow therapy.

MEASLES CLINICAL MANIFESTATION IN DIFFERENT AGE CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Alina Zaretska, Yuriy Kharchenko, Hanna Pitel, Olena Buiko
Odessa National Medical University, Children Infectious Diseases, Odesa, Ukraine

Backgrounds: Measles is an acute respiratory infection that occurs at any age in children without vaccination. Typically measles outbreaks happened once in 5-10 years when the public immunity response decreases. The last measles outbreak affected Europe and the USA in 2017-2018.
Methods: The 239 case histories of children from one month to 18 years with confirmed measles were analyzed during 2017-2018.
Results: The obtained data indicate that the course of measles in children retains its typical manifestation but has features depending on the child's age. So in children up to 12 months more often, measles occurs in a severe form (29.41±6.09)% with manifestations of intoxication (95.59±2.49)%, a typical rash (100%), fever (91.18±3.44)%, dry cough (94.12±2.85)%, runny nose (89.71±3.68)% and with the development of complications (48.53±6.06)%, mainly in the form of pneumonia (32.40±5.67)%, $p<0.05$.
The most diverse manifestations of measles were in children aged 1-3 years. Thus, in most of them, fever (94.12±3.29)% and dry cough (96.08±2.72)% were determined against the background of a typical rash (100%) and, in every third child, complications (33, 33±6.60)%, more often in the form of pneumonia (16.28±5.17)% and bronchitis (18.60±5.45)%.
4-6 years old, children characterized by the course of moderate severity (82.61±2.90)% with intoxication (76.09±6.29)%, fever (95.65±3.01)%, rash (100%), dry cough (97.83±2.16)% and bronchitis (19.57±5.85)%.
Typical rash (100%), intoxication (88.89±4.68)%, fever (97.78±2.19)%, conjunctivitis in every second child (51.11±7.45) %, and a severe course (31.11±6.19)% characterize measles in children aged 7-12 years, $p<0.05$.
At the same time, typical manifestations for children aged 13-17 were intoxication (86.21±6.40%), fever (96.55±3.38%), rash (100%), dry cough (100%), conjunctival hyperemia (72.41±8.29)%, runny nose (58.62±9.15)%, and facial swelling (51.72±9.28)%, $p<0.05$.
Conclusions/Learning Points: The age younger than 12 months (29.41±6.09) %, the presence of concomitant diseases (35.71±6.40)%, and lack of vaccination (82.14±5.12)% are the risk factors of measles severe manifestation.

PATTERNS OF SEASONAL RESPIRATORY INFECTIONS IN PEDIATRICS BEFORE AND DURING THE COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS08.A. VIRAL RESPIRATORY INFECTIONS

Omar Zuhdi[1], Claudia Gaviria-Agudelo[2]
[1]Central Michigan University, College Of Medicine, Mount Pleasant, United States of America, [2]University of South Florida Morsani College of Medicine, Pediatric Infectious Diseases, Tampa, United States of America

Backgrounds: During the COVID-19 pandemic, an interesting phenomenon was observed consisting in the disruption of regular circulation of common respiratory pathogens across the US and the world. We aim to describe the prevalence of respiratory patterns in hospitalized children during the COVID-19 pandemic.
Methods: A retrospective analysis of the prevalence of respiratory pathogens was performed using BioFire respiratory panels among hospitalized patients (ages 0-18) from January 2019 to December 2022. A total of 2,670 specimens were obtained from 2,456 patients at a tertiary university hospital in Tampa, FL. Pathogen detection rates were analyzed by age group, gender, calendar year, season, co-infection, and clinical presentation.
Results: Overall positivity rates were 51.7% in 2019, 32.1% in 2020, 39.9% in 2021, and 42.8% in 2022. In 2019, prior to the COVID-19 pandemic, rhinovirus was the most prevalent pathogen (31.7% positivity rate), followed by influenza B (14.7%) and influenza A (14.0%). Starting 2020 circulation patterns changed dramatically. Influenza A decreased to 7.30% in 2020, 2.90% in 2021, and bounced back at 23.9% in 2022. RSV declined from 7.90% in 2019 to 1.80% in 2020, rising back up to 8.30% in 2021 and 9.3% in 2022. The prevalence of SARS-COV-2 was noted at 3.20% in 2020, 10.10% in 2021 and 5.4% in 2022. The most frequent initial clinical manifestations prompting testing were fever, cough, and respiratory distress.
Conclusions/Learning Points: We noted a significant decrease in respiratory viruses such as influenza and RSV earlier in the COVID-19 pandemic. The year 2022 was marked by rebounds in influenza and RSV detection. Continuous surveillance of these circulation patterns is important as COVID-19, influenza, and RSV appear to have formed a triple threat taxing healthcare systems worldwide.

PREDICTIVE FACTORS OF THE NEED FOR INTENSIVE TREATMENT IN CHILDREN WITH PNEUMONIA

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Dhany Irvandi, Eggi Arguni, Amalia Setyati
Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Department Of Child Health, Yogyakarta, Indonesia

Background: Pneumonia is a major cause of morbidity and mortality in children. Some children with pneumonia require intensive treatment. Several predictors of the need for intensive treatment have been studied previously but showed inconsistent results. The objective of our study was to determine whether the age of onset at diagnosis, severe malnutrition, hypoxemia, high neutrophil-lymphocyte ratio (NLR), high platelet-lymphocyte ratio (PLR), and comorbidities are the predictive factors of the need for intensive treatment in children with pneumonia.
Methods: A retrospective cohort of children aged 1 month-18 years with pneumonia that was admitted to Dr. Sardjito Hospital in January 2020-December 2020 and who met the inclusion and exclusion criteria. Samples were taken by convenience sampling. Bivariate analysis to calculate p-value and multivariate analysis with logistic regression was conducted. The relationship between variables was presented as odds ratio (OR), 95% confidence interval (95% CI), and statistical significance level $p < 0.05$.
Results: One hundred and six children with pneumonia were included, with a median age of 24 (1-206) months. 36.8% need intensive treatment. Multivariate analysis showed hypoxemia (adjusted OR=6,849; 95%CI=2,692-17,429; p<0,001) was an independent predictor of the need for intensive treatment in children with pneumonia.
Conclusions/Learning Points: Hypoxemia was an independent predictor of the need for intensive care in children with pneumonia

THE AUSTRIAN SYNDROME: HIGHLIGHTING PNEUMOCOCCAL INVASIVE POTENTIAL

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Omar Escobar[1], Andres Arias[2], Maria Guerrero[2], Juan Betancur[2], Camilo Acosta[2]
[1]Universidad CES, Antioquia, Medellín, Colombia, [2]Erasmo Meoz University Hospital, Norte De Santander, Cucuta, Colombia

Title of Case: THE AUSTRIAN SYNDROME: HIGHLIGHTING PNEUMOCOCCAL INVASIVE POTENTIAL
Background: A 2-year-old Latin-American male with no relevant previous history, with full vaccine scheme 2+1 of 10 serotypes pneumococcal conjugate vaccine (PCV10)
Case Presentation Summary: He presented to the ER with 15 days of runny nose, dry cough, and intermittent fever up to 39°C, otalgia was present with no response to cephalexin and oral azithromycin prescribed in the ambulatory setting. 3 days before consultation he developed a fever of up to 40°C. On admission, generalized tonic-clonic movements and gaze deviation without resolutions, the Glasgow scale was 9/15 and was admitted to the PICU. The blood count at admission was WBC18x10e9/L, N15x10e9/L, L1,9x10e9/L, Hb113g/L, Plq41x10e9/L, and bilateral lung infiltrates compatible with pneumonia in chest X-ray (Figure1. A). Vancomycin and ceftriaxone were started for suspected meningitis. Abnormal CSF exam: leukocytosis (240) with neutrophilia (70%), hypoglycorrhachia (10mg/dl), hyperproteinorrhachia (560mg/dl), and a multiplex PCR positive for S. pneumoniae, as well as blood cultures with susceptibility to PEN y CRO. A contrasted cerebral MRI identified multiple hyperintense lesions suggesting inflammatory and ischemic lesions, predominantly in temporal, frontal, and basal ganglia lobes (figure 1,C and D), in addition to pansinusitis. The first echocardiography noted infective mitral valve endocarditis, vegetation 10x7 mm, and mild to moderate mitral insufficiency requiring surgery for extraction a valvular reconstruction (Figure1. B). The second blood count showed WBC51x10e9/L, N43x10e9/L, L4,8x10e9/L, Hb150g/L, Plq26x10e9/L and CSF culture identified S. pneumoniae PEN (R) and CRO susceptible (MIC <0.12mcg/L). Despite of medical treatment, he develops generalized CNS compromise and secondary infective vasculitis that leading to confirmed brain death; serotype 19A was later
confirmed.

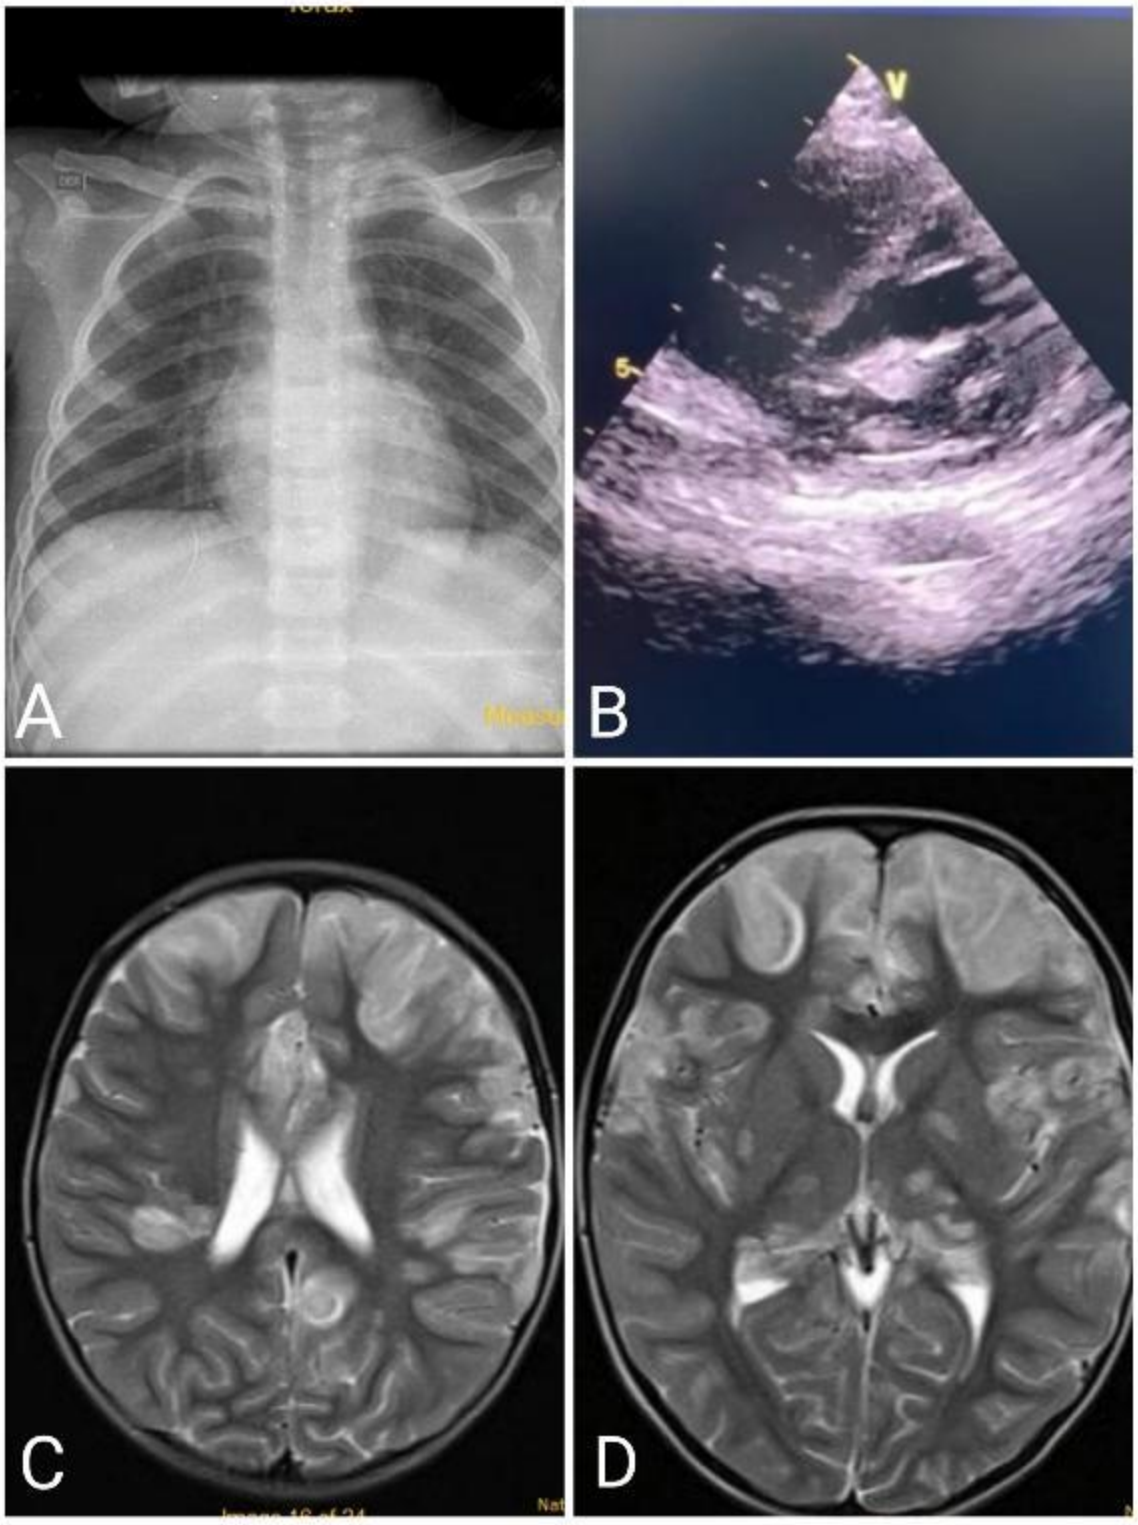

Figure 1

Learning Points/Discussion: Pneumonia, meningitis with endocarditis due to S. pneumoniae is rare, especially in the pediatric age.

EVALUATION OF VIRUS-BACTERIA CO-INFECTION IN PEDIATRIC COMMUNITY-ACQUIRED PNEUMONIA

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Eitan Berezin[1], Emmanuella D`Elia[1,2], Ana Assis[3], Daniel Jarovsky[2], Flavia Almeida[2]
[1]santa casa sp, Pediatric, sao paulo, Brazil, [2]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [3]Santa Casa SP, Public Health, São Paulo, Brazil

Title of Case: Evaluation of virus-bacteria co-infection in pediatric community-acquired pneumonia
Background: As diagnostic methods evolve, the detection of coinfection in pneumonia becomes more frequent and can impact antibiotic prescription and hospitalization length. We aim to describe the etiology of CAP in pediatric patients, including cases of virus-virus and virus-bacteria co-infection.
Case Presentation Summary: Methods: We retrospectively screened patients aged under 7 years of age from March to December 2022 at a tertiary referral hospital in São Paulo, Brazil. All those admitted due to severe CAP were included. Blood samples (culture and RT-PCR), respiratory secretion (multiplex RT-PCR assay), and pleural fluid (RT-PCR) were evaluated. Results: 18 patients were included: 61% (11/18) were female, with ages ranging between 4 months and 6 years old. S. pneumoniae was the most frequently identified bacteria identified by RT-PCR or culture (n=8). Streptococcus pyogenes and H. influenzae were also detected in the blood culture. Two patients had a viral infection (Adenovirus and Bocavirus, respectively) and six bacterial infections – one with Haemophilus influenzae and five with .S. pneumoniae Virus-bacteria coinfection was present in 4 cases: two associated with Adenovirus, one with Bocavirus, and one with metapneumovirus. 67% (4/6) of patients with isolated bacteria and all patients with virus-bacteria coinfection were admitted to the PICU.
Learning Points/Discussion: – In general, virus-virus coinfection does not seem to significantly impact the severity of the disease. Conversely, virus-bacteria co-infection is generally associated with increased severity due to the synergy mechanism in the nasopharyngeal epithelium. Pneumococcus is a major pathogen causing CAP in children, both as an isolated agent and in co-infection with viruses. RT-PCR in pleural fluid was essential for its identification.

Backgrounds: Pneumonia and bronchiolitis/bronchitis are the most common lower respiratory tract infections (LRTI) in children and accounts for 13% of all infectious illnesses in infants younger than 2 years of age.
Methods: Retrospective cohort study in a single tertiary hospital on 91 children with pneumonia hospitalized from October 2022 to December 2022.
Results:

1st IV Treatment							
Total n=91 Female=46 Male=45	Ampicillin	Ampicillin/ Sulbactam	Ceftriaxon or Cefotaxin	Teicoplanin/ and Piperacillin/ Tazobactam	Dalacin	No Rx	Average days of hospitalization
1-24 months n=31	11	9	6	4		2	6,6
2-5 years old n=38	22	7	4	0	0	1	6,6
>5 years old n=22	14	4	3	0	2	0	6,5

Out of 450 patients hospitalized with LRTI, 91 patients had pneumonia (46 female, 45 males, average age 6 years old). Major symptoms were cough and fever. Seventeen patients reported recurrent LRTI and 15/91 had prematurity history. Viral co-infections of RSV or FLU A/B was identified in 20 patients during December, while 19/91 reported COVID-19 infection during the last 12 months. Complicated pneumonia, with pleural infusion occurred in 14/91 (16%). Nine patients were treated with intravenous antibiotics while 5 patients underwent interventional pleural infusion drainage. Film-array of pleural infusion revealed Strept.pneumoniae in 80%. Two patients had single pneumococcal infection, 2/5 had co-infection with rhino/entero and parainfluenza virus and 1/5 adenovirus and Flu Type A virus. Pneumonia panel Film-array revealed rhino/entero/parainfluenza in 2 patients, FLU A/B in 1 and Sars-Cov-2 in one. In 4 patients with pneumonia without pleura infusion, Haemophilus influenzae with viral co-infection (adeno, rhino/entero or corona-virus) was identified in pneumonia Film-array panel. Median duration of hospitalization was 6,6 days regardless of patients age. Prolonged stay was observed in 17 patients due to supportive care (16/17) and antibiotic step up (12/17). Need of supplemental oxygen or nebulizers was noticed in 45 out of 91 patients.

Conclusions/Learning Points: Elevation of pneumonia incidence compared to the same period of 2021 when only 3 patients were hospitalized in our department, with Strept.pneumoniae being the main pathogen in complicated pneumonias.

RISK FACTORS ASSOCIATED WITH NONINVASIVE PNEUMOCOCCAL INFECTION AND ANTIMICROBIAL RESISTANCE OF ISOLATED STRAINS IN CHILDREN UNDER 5 YEARS OF AGE

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Dina Bujor[1], Ninel Revenco[1], Ana-Mihaela Balanuta[2], Adela Horodisteanu-Banuh[3], Olga Cirstea[2], Ala Holban[1], Oxana Burac[4]
[1]State University of Medicine and Pharmacy "Nicolae Testemitanu", Pediatric Department, Chisinau, Moldova, [2]"Nicolae Testemitanu" State University of Medicine and Pharmacy, Pediatric Department, Chisinau, Moldova, [3]Mother and Child Institute, Pediatric Scientific Laboratory, Chisinau, Moldova, [4]National Agency for Public Health, The Microbiological Laboratory, Chisinau, Moldova

Backgrounds: Streptococcus pneumoniae is a commensal bacterium that colonize human nasopharynx in asymptomatic carriers or may determine a variety of manifestations, such as sinusitis, otitis, conjunctivitis or invasive infections including meningitis, bacteremia, complicated pneumonia and pleural empyema. The objective of our study was to identify risk factors associated with symptomatic pneumococcal infection and antibiotic resistance profile of the isolated strains.
Methods: The proposed study is a descriptive, prospective laboratory-based survey of children with acute respiratory infections, hospitalized in the period 2021-2022. Patients included in the study were aged from 2 to 59 months. All 138 biological samples were taken using the nasopharyngeal aspirate technique before the initiation of antibiotic therapy. The study was carried out in the framework of the project 20.80009.8007.08 „The impact of immunization on the morbidity and mortality of children with respiratory diseases in the Republic of Moldova" supported by the National Agency for Research and Development.
Results: S. pneumoniae was identified in 7.7% of cases. It was resistant to benzylpenicillin (80%), amoxicillin/clavulanate (75%), trimethoprim/ sulfamethoxazole (70%), amoxicillin, ampicillin and cefatoxime (66%), cefepime, ceftriaxone, cefuroxime, carbapenems (33%), and to macrolides in 42% of cases. Also, the results of our study showed that children's exposure to passive smoking is a risk factor for pneumococcal infection (RR – 2.4, OR – 2.6, CI 95%: 0.66 – 10.30, $\rho<0.05$), while immunization with the pneumococcal conjugate vaccine (PCV13) is a protective factor (RR – 0.25, OR – 0.22, CI 95%: 0.05 – 0.88, $\rho<0.05$).
Conclusions/Learning Points: Although, the study showed a relatively high rate of antibiotic resistance, the rate of pneumococcal infection was low. Identifying and understanding factors that influence pneumococcal infection is important for strengthening measures to prevent infections of lower airways in young children.

E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Giacomo Campisi Frascà[1], Irene Raffaldi[2], Marco Denina[2], Emanuele Castagno[2], Manuela Pagano[2], Angelo Giovanni Delmonaco[2], Silvia Garazzino[3], Fabrizio Gennari[4], Antonia Versace[2], Claudia Bondone[2]
[1]Regina Margherita Children's Hospital and University of Torino, Pediatric And Public Health Sciences, Turin, Italy, [2]Regina Margherita Children's Hospital, Paediatric Emergency, turin, Italy, [3]Regina Margherita Children's Hospital, Paediatric Infectious Disease, Turin, Italy, [4]Regina Margherita Children's Hospital, Pediatric General Surgery, Turin, Italy

Backgrounds: The acute management of paediatric complicated community-acquired pneumonia (PCCAP) can be challenging. Patients may experience poor outcomes, such as PICU admission, prolonged hospitalization and invasive procedures. The aim of this study is to identify possible predictors of poor outcomes in PCCAP.
Methods: In this retrospective study, we collected demographic, clinical, laboratory, instrumental and therapeutic data of all paediatric patients hospitalized in our Centre from 1st May 2017 to 31st May 2022 with a diagnosis of PCCAP. We considered as complications: parapneumonic effusion, empyema, lung abscess, necrotizing pneumonia, pneumatocele and pneumothorax. We searched correlations between variables and poor outcomes, using univariate and multivariate analysis. We considered as "poor outcomes": PICU admission, invasive procedures, and hospitalization longer than twenty days.
Results: We selected eighty-five patients with PCCAP. Twenty-seven patients had a prolonged hospitalization, nine patients were admitted to PICU and twenty patients underwent invasive procedures. Effusion size on lung ultrasound on admission showed a correlation with poor outcomes. Among biomarkers, CRP levels on admission and after 48-72 hours were significantly higher in children admitted to PICU; CRP levels at admission and WBC count, neutrophils count, CRP and PCT after 48-72 hours from admission showed a correlation with both invasive procedures and prolonged hospitalization. Multivariate analysis showed that chest and abdominal pain at admission are significantly associated to invasive procedures, and duration of fever before admission is associated to both PICU admission and invasive procedures.
Conclusions/Learning Points: PCCAP are infrequent but serious clinical conditions: therefore, knowing possible predictors of poor outcome could help physician in the management of them. The integration of different parameters that are easily available at early stages of hospitalization, such as chest or abdominal pain is essential.

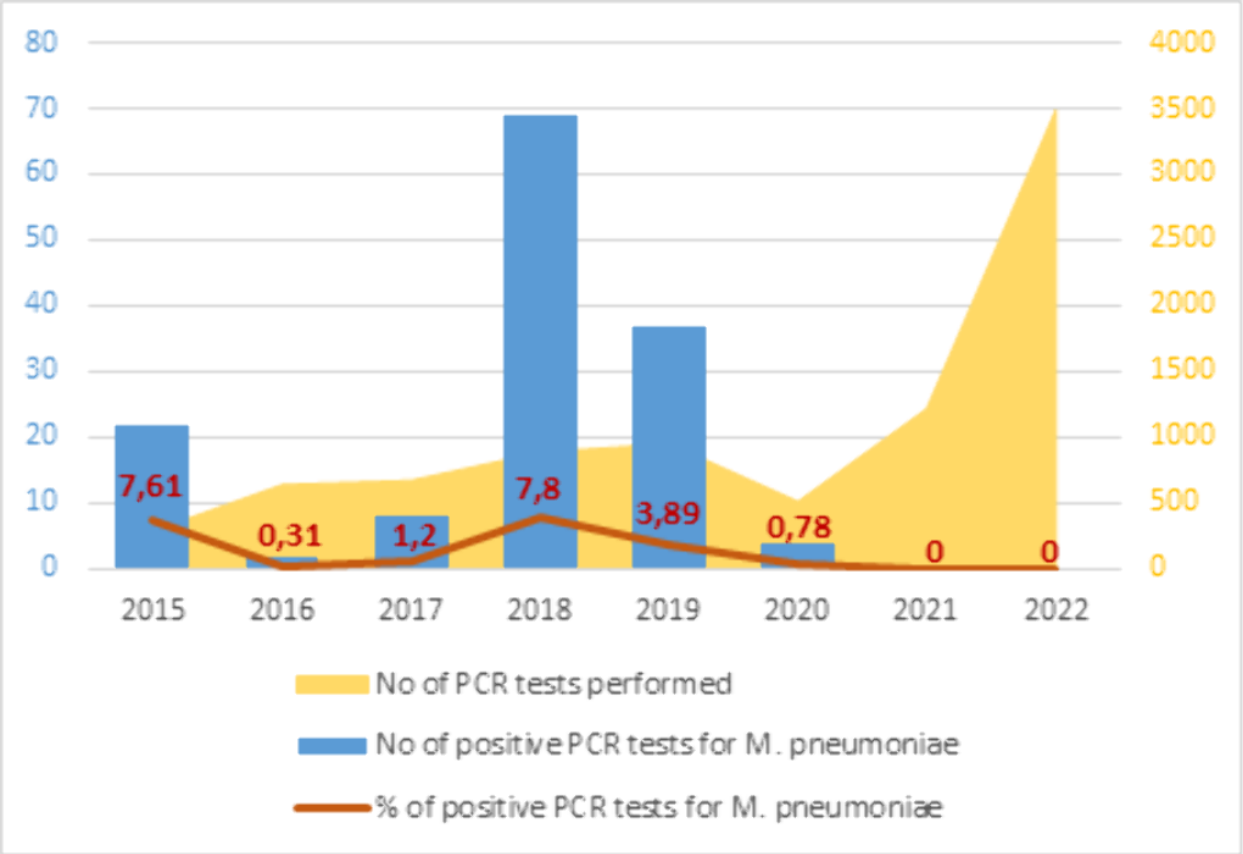
WHERE IS MYCOPLASMA PNEUMONIAE?

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Mariana Costa[1], Miguel Lucas[2], Lia Gata[2], João Pereira Vaz[3], Lurdes Correia[3], Fernanda Rodrigues[4,5]
[1]Hospital Pediátrico, Centro Hospitalar Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [3]Centro Hospitalar e Universitário de Coimbra, Clinical Pathology Service, Coimbra, Portugal, [4]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [5]Universidade de Coimbra, Faculty Of Medicine, Coimbra, Portugal

Backgrounds: Mycoplasma pneumoniae is a cause of community acquired paediatric respiratory infections. The COVID-19 pandemic led to a dramatic reduction of illness due to viral and bacterial respiratory pathogens, including M. pneumoniae, with subsequent resurgences of most of them, although at different times. The aim of this study was to evaluate the detection of M. pneumoniae during and beyond the COVID-19 pandemic and compare it to previous years.
Methods: We performed an observational study evaluating all the detections of Mycoplasma pneumoniae through PCR in nasopharyngeal samples (FilmArray respiratory panel), from children with acute respiratory infections, attending an Emergency Service of a level III pediatric hospital, that has received an average of 60 000 children/year, from January 2015 to December 2022. The decision to perform the test was up to the physician who observed the patient.
Results:



Despite some variation of M. pneumoniae detection from year to year before the pandemic, these data

show its disappearance and ongoing absence in this community since the beginning of the pandemic.
Conclusions/Learning Points: Despite the progressive reduction of non-pharmacological interventions and the high number of samples submitted to PCR in the last two years, M. pneumoniae remains undetectable to date, in contrast to what was observed for respiratory viruses, as an indicator of community transmission. The reasons for this sustained suppression are not clear and continuous surveillance is necessary to monitor when and how this pathogen will come back.

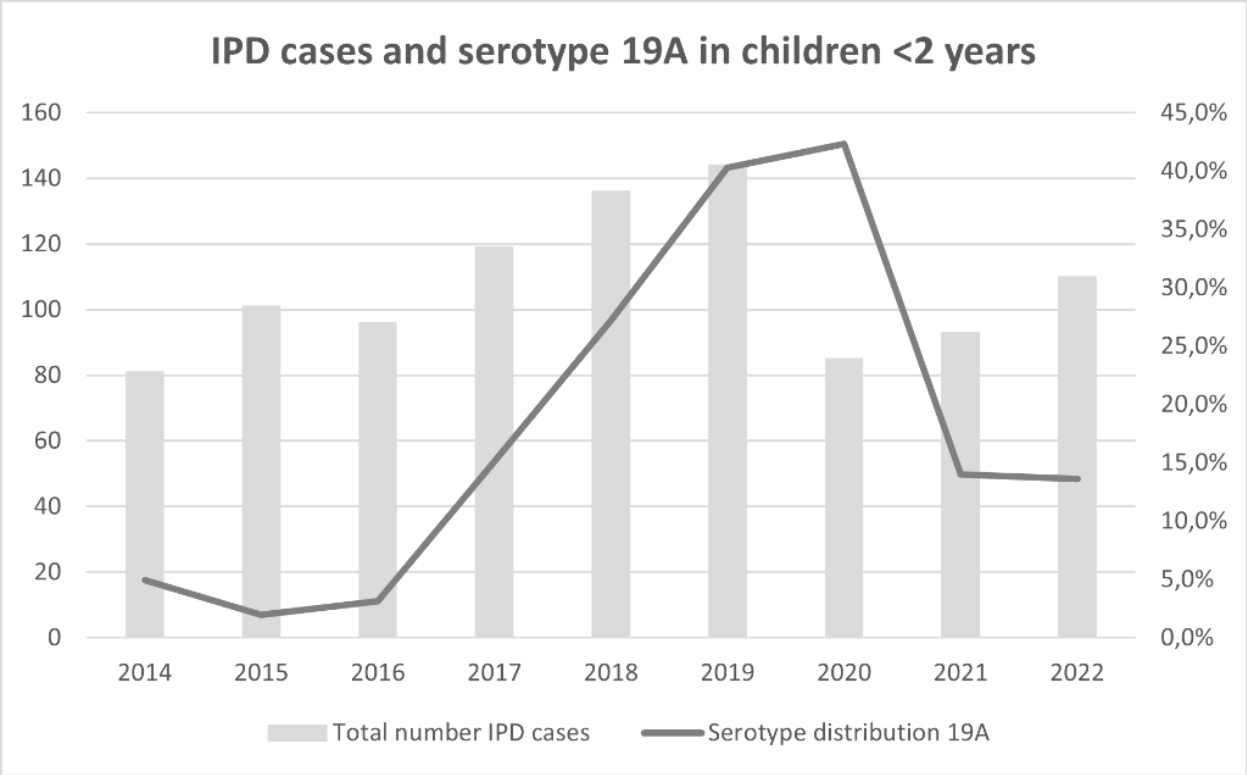
LIFTING DISTRUPTION OF INVASIVE PNEUMOCOCCAL DISEASE (IPD) CASES FOLLOWING THE COVID-19 PANDEMIC: IPD IN THE YOUNGEST CHILDREN IN BELGIUM AFTER RE-SWITCH FROM PCV10 TO PCV13

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Lize Cuypers[1,2], Stefanie Desmet[1,2]
[1]UZ Leuven, Department Of Laboratory Medicine, Leuven, Belgium, [2]KU Leuven, Department Of Microbiology, Immunology And Transplantation, Leuven, Belgium

Backgrounds: Due to the restrictive measures to contain the COVID-19 pandemic, a signficant and sustained reduction in invasive pneumococcal disease (IPD) cases in children (<2 years) was observed in 2020-2021. The 13-valent pneumococcal conjugate vaccine (PCV13) was reinstalled in 2019 in the childhood vaccination programme, after a re-emergence of serotype 19A IPD in children following the switch from PCV13 to PCV10 in 2015-2016 in Belgium.
Methods: Surveillance of IPD in Belgium is based on a stable laboratory-based system involving yearly around 100 laboratories, evenly spread over the country, sending their strains to the National Reference Centre for Invasive Pneumococci, for capsular typing by Quellung reaction.
Results:



While the total of 110 IPD cases in children for 2022 is a reduction of 23.6% compared to the pre-COVID year 2019, numbers have increased compared to 2020 and 2021 (respectively +29.4% and +18.3%), and exceeded cases of the years 2014 to 2016. Although capsular typing determined 19A as most prevalent serotype (13.6%) in young children for 2022, similar to 2021 (14.0%), this entails a continued reduction of 19A cases following the re-switch from PCV10 to PCV13 in 2019 as serotype 19A accounted for 40.3% and 42.4% of cases in children in 2019 and 2020. Serotypes 33F (10.0%), 10A (9.1%), 11A (9.1%) and 23B (7.3%) complete the top 5 of most frequently detected serotypes in 2022. Serotype coverage of pneumococcal vaccines PCV13, PCV15 and PCV20 based on IPD cases is 19.1%, 30.9% and 57.3%,

respectively.
Conclusions/Learning Points: For 2022, IPD epidemiology is no longer heavily disturbed by the COVID-19 pandemic, characterized by increasing cases, although still lower compared to 2019. Furthermore, three years post PCV10 to PCV13 switch, a further reduction of the proportion of serotype 19A was observed.

T HE IMPACT OF PNEUMOCOCCAL PNEUMONIA IN A BRAZILIAN PEDIATRIC HOSPITA

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Lilian Diniz[1], Fernanda Lopes[2], Laura Coelho[2], Gabriela Gouvêa[2], Beatriz De Freitas[1], Pedro De Castro[1], Carolina Carvalho Carvalho[1], Talitah Candiani[2], Daniela Teixeira[1], Aline Bentes[1], Cristiane Dias[1]
[1]Federal University of Minas Gerais, Pediatrics, Belo Horizonte, Brazil, [2]Fundação Hospitalar de Minas Gerais, Hospital Infantil João Paulo Ii, Belo Horizonte, Brazil

Backgrounds: Pneumococcal infection is the main cause of pneumonia in children. The impact of COVID-19 pandemic on pneumococcal pneumonia is still unknown. The aim of this study was to describe the epidemiology and sensitive profile of pneumococcal pneumonia from 2018-2022.
Methods: Data were collected from medical records of patients admitted to a reference pediatric hospital in Brazil.
Results: 56 cases of pneumococcal pneumonia were identified, 36 (64%) during the years of COVID-19 pandemic (2020-2022). 37 (66%) patients were admitted to an intensive care unit (ICU). Younger age was associated with a higher risk of ICU admission (p=0.021). In total, 36 (64%) patients had pulmonary complications. The main complication was pleural effusion (28, 77,7%). The year of 2022 had the highest prevalence of complications (47,2%) (p< 0.001). Overall mortality rate was 8.92% (n=5). There was no difference in mortality between the studied periods. Penicilins were the antibiotic of choice with a mean treatment duration of 9 (±4) days. All pneumococci were 100% sensitive to penicillin. Greater resistance was noted for sulfamethoxazole (53%), erythromycin (50%) and clindamycin (46%).
Conclusions/Learning Points: The immune debt caused by social restriction measures and exposure to respiratory pathogens has led to higher pneumococcal pneumonia compications in 2022, when lockdown was ended. This study also reinforces the recommendation to use penicillins as a first-line treatment for pneumonia.

BACTEREMIA IN CHILDREN DIAGNOSED WITH PNEUMONIA IN EMERGENCY DEPARTMENTS: A MULTINATIONAL PROSPECTIVE COHORT STUDY

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Mark Neuman[1], Nathan Kuppermann[2], Daniel Tancredi[2], Lilliam Ambroggio[3], Franz Babl[4], Stuart Dalziel[5], Michelle Eckerle[6], Santiago Mintegi[7], Amy Plint[8], Norma-Jean Simon[9], Todd Florin[9]
[1]Boston Children's Hospital, Pediatric Emergency Medicine, Boston, United States of America, [2]UC Davis, Emergency Medicine And Pediatrics, Davis, United States of America, [3]Children's Hospital of Colorado, Emergency And Hospital Medicine, Aurora, United States of America, [4]Royal Children's Hospital, Paediatric Emergency Medicine, Melbourne, Australia, [5]Starship Children's Hospital, Children's Emergency Department, Auckland, New Zealand, [6]Cincinnati Children's Hospital Medical Center, Pediatric Emergency Medicine, Cincinnati, United States of America, [7]Biocruces Bizkaia Health Research Institute, Hospital Universitario Cruces, Pediatric Emergency Medicine, Bilbao, Spain, [8]Children's Hospital of Eastern Ontario, Paediatric Emergency Medicine, Ottowa, Canada, [9]Ann and Robert H. Lurie Children's Hospital of Chicago, Pediatrics (emergency Medicine), Chicago, United States of America

Backgrounds: Globally, blood cultures are commonly obtained in children presenting to emergency departments (ED's) with community-acquired pneumonia (CAP). The current prevalence and etiology of bacteremia are not well described for this population. We sought to assess the prevalence and etiology of bacteremia among children diagnosed with CAP in a global cohort of ED's.
Methods: This was a prospective cohort study of children 3 months to <14 years old with CAP at 69 ED's in a global consortium, the Pediatric Emergency Research Network. We excluded children with hospitalizations within the previous 7 days, hospital-acquired pneumonias, or chronic complex conditions. Bacteremia was defined by pathogen detection in blood culture. Patient demographics, clinical characteristics, radiographic findings, and laboratory testing results were compared between children with and without bacteremia.
Results: A total of 2,540 children (median age 3.8 years) with CAP were enrolled. Blood cultures were obtained from 790 (31.1%) patients, and 16 (2.0%) demonstrated growth of a pathogen. Streptococcus pneumoniae accounted for 13 (81.3%) cases of bacteremia, Staphylococcus aureus was identified in 2 patients, and Group A streptococcus in 1. Clinical and radiographic findings did not significantly differ between children with and without bacteremia; however, inflammatory markers were significantly higher among children with bacteremia. (Table) Eight children with bacteremia had complicated pneumonias, 6 had moderate-to-large pleural effusions, and 4 underwent pleural drainage.

Table 1. Characteristics of children with CAP, stratified by bacteremia (n=790).

Characteristic	No bacteremia (n=774)	Bacteremia (n=16)	P-value
Demographics			
Age (yr), median (IQR)	2.0 (1.0, 5.0)	2.5 (1.0, 4.0)	0.95

Any virus detected	228 (29.5%)	3 (18.8%)[2]	
RSV	111 (14.3%)	0 (0%)	0.10
Influenza A	31 (4.1%)	0 (0%)	0.41
Influenza B	19 (2.5%)	0 (0%)	0.53
Clinical course			
Hospitalized	671 (86.8%)	14 (87.5%)	0.94
ICU >48 hours	81 (10.5%)	3 (18.8%)	0.24
Death	1 (0.1%)	0 (0%)	0.89
Complicated pneumonia[3]	47 (6.1%)	8 (50.0%)	<0.001
Oxygen use	410 (53.0%)	8 (50.0%)	0.81
Non-invasive positive pressure ventilation[4]	115 (28.8%)	3 (30.0%)	0.93
Mechanical ventilation	54 (13.5%)	1 (10.0%)	0.75
Vasopressors	14 (3.5%)	1 (10.0%)	0.28
Extracorporeal membrane oxygenation	2 (0.5%)	0 (0%)	0.83
Pleural drainage	35 (4.5%)	4 (25%)	<0.01

IQR interquartile range, CXR chest xray

[1] Includes CXRs read as favoring pneumonia or definite pneumonia on CXR performed in ED

[2] Parainfluenza 3 (n=1), Rhinovirus/enterovirus (n=2)

[3] Defined by the presence of empyema, abscess, necrotizing pneumonia, or pneumothorax

[4] Includes high-flow nasal cannula, continuous positive airway pressure, bi-level positive airway pressure

Conclusions/Learning Points: Bacteremia is uncommon among children diagnosed with CAP in the ED globally. Although our study demonstrates clinical and radiographic findings are similar between children with and without bacteremia, inflammatory markers are significantly higher among children with bacteremia.

STICKING TO THE FACTS - AN UNUSUAL BACK SWELLING

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Deirdre Foley[1], Claire Connellan[2], Fiona Healy[2], Patrick Gavin[1]
[1]Children Health Ireland Crumlin and Temple Street hospitals, Infectious Disease And Immunology, Dublin, Ireland, [2]CHI at Temple Street, Department Of Paediatric Respiratory Medicine, Dublin, Ireland

Title of Case: STICKING TO THE FACTS - AN UNUSUAL BACK SWELLING
Background: A, a 7-year-old female of African ethnicity presented with a tender swollen mass to the left mid-back. She reported a three-day history of cough and fever, and three weeks of intermittent back pain, reduced appetite, and weight loss prior to admission. She also reported that she was ‘hit with a stick' to her back by a guardian the day previous to admission.
Case Presentation Summary: Examination of the respiratory system was normal and there was a tender, non-erythematous swelling to the right mid-back,10cm in length. She had an underlying diagnosis of Autistic Spectrum Disorder (ASD) and a sibling had passed away in early childhood following a prolonged illness abroad with a 'neck lump', but his final diagnosis was unclear. Investigations on admission included a of CRP 126 mg/L, neutrophilia and a chest radiograph demonstrating a confluent area of opacification within the right peripheral lower zone and small pleural effusion. CT reported two large enhancing and infiltrative lesions, in the right thorax (5x 2.9 x 3.9cm) and the right posterior lower ribs (7.4 x 3.4 x 9.4cm), and disseminated lymphadenopathy. This extended to adjacent musculature and retroperitoneally into the right posterior renal space. Tissue sampling for microbiology and histology were conclusive for actinomycosis, and she had a full recovery following a prolonged course of oral amoxicillin.
Learning Points/Discussion: Invasive actinomycosis is rare. This diagnostic journey was clouded by suspicion of non-accidental injury (NAI) and concern regarding her sibling's unusual illness. Though there was an invasive bacterial pneumonia, her respiratory signs were mild. A thorough investigation is warranted in those with an atypical history and presentation, and full investigation of any case suspicious for NAI to both safeguard the child and to ensure no underlying medical cause for symptoms.

PV0691 / #71

EFFECT ON NASAL HEALTH OF NUTRITION IN CHILDREN IN HOMA BAY COUNTY, KENYA (ENRICH): AN EXPLORATORY STUDY

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

[1]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, United Kingdom, [2]Kenya Medical Research Institute, Centre For Global Health Research, Kisumu, Kenya, [3]University of Oxford, Department Of Paediatrics, Oxford, United Kingdom, [4]Radboud Center for Infectious Diseases, Laboratory Of Medical Immunology, Nijmegen, Netherlands, [5]Lancaster University, Lancaster Medical School, Lancaster, United Kingdom, [6]Murdoch Children's Research Institute, Infection And Immunity, Melbourne, Australia, [7]University of Melbourne, Department Of Microbiology And Immunology, Melbourne, Australia

Backgrounds: Malnutrition contributes to 45% of deaths in children under five, with malnourished children at greater risk of severe pneumonia. Stunted children may have higher rates of pneumococcal carriage, a prerequisite for pneumococcal disease, but the underlying biological mechanisms are unknown.
Methods: The ENRICH study was nested within the PROSYNK study in Homa Bay County, Kenya and enrolled asymptomatic infants from the PROSYNK control arm and their household contacts under five. Weight and height were measured for each child, then paired nasopharyngeal swabs and synthetic absorptive matrix (SAM) samples were collected. Respiratory bacteria and viruses were detected in swabs by species-specific qPCR. Cytokine and metal concentrations in nasal fluid were measured using Luminex and Inductively Coupled Plasma Mass Spectrometry (ICP-MS), respectively. Results were grouped according to Weight-for-Height (WHZ, a measure for wasting) or Height-for-Age (HAZ, a measure for stunting) Z-scores.
Results: 27 PROSYNK control group children and 56 compound contacts were recruited in early 2022. 72 (88%) children asymptomatically carried a respiratory bacterial pathogen, and 15 (18%) children were asymptomatically infected with a respiratory virus, the most common being SARS-CoV-2. Nasal levels of GCSF, IL-10, eotaxin, IL-17A, MCP1, HGF, VEGFα, IFNγ, TNFα, IL-2, IL-2R and IL-7 were higher in children with lower WHZ scores when carrying bacteria but not virus. In children with lower HAZ scores, IL-13 and RANTES levels were higher and IL-1RA lower when carrying bacteria but no virus, whereas IL-2 concentrations were higher in the absence of any respiratory pathogen. Concentrations of calcium and magnesium were positively correlated with HAZ score.
Conclusions/Learning Points: This study provides preliminary insights into changes at the nasal mucosa in malnourished children. Differences in nasal cytokine and micronutrient levels could alter susceptibility to respiratory pathogens.

[1]Nepean Hospital, Infectious Diseases, Kingswood, Australia, [2]Nepean Hospital, Neonatal Intensive Care Unit, Kingswood, Australia, [3]Sydney Children's Hospital, Infectious Diseases, Randwick, Australia

Title of Case: THE USE OF CEFIDEROCOL TO TREAT A MULTIRESISTANT STENOTROPHOMONAS MALTOPHILIA VENTILATORY ASSOCIATED PNEUMONIA IN AN EXTREME PRETERM NEONATE.
Background: Ventilator-associated pneumonia (VAP), a complication of mechanical ventilation caries a morbidity and mortality risk in the pre-term neonate. Cefiderocol, a siderophore cephalosporin, has broad gram-negative antimicrobial activity, and CNS penetration and is licensed for the treatment of hospital-acquired or VAP in adults. There are no published data on neonates.
Case Presentation Summary: A female neonate born at 26+6/40 gestation developed apnoeas, abdominal distention and raised inflammatory markers on day 14 of life, requiring mechanical ventilation and broad-spectrum antibiotics (meropenem and vancomycin). Her clinical symptoms and inflammatory markers improved over 72 hours, but she developed an increasing oxygen requirement and pneumonia on a chest x-ray. Two endotracheal aspirates cultured a pure growth of Stenotrophomonas maltophilia, resistant to trimethoprim/sulfamethoxazole, ceftazidime and ciprofloxacin. Cerebrospinal fluid showed an elevated white cell count but was culture negative; as were serial blood cultures. Given the extensive antibiotic resistance and ongoing clinical deterioration, cefiderocol monotherapy was given at 30 mg/kg/tds for 10 days. Within 72 hours of starting cefiderocol, the neonate was extubated with clinical improvement. Further antimicrobial susceptibility testing of the S. maltoophilia isolate revealed a 28mm disk zone to cefiderocol (susceptible >/=17mm as per CLSI guidance).
Learning Points/Discussion: Cefiderocol was integral for the care of our critically-unwell premature neonate with multidrug-resistant VAP. We provide the first published data on its off-label use in this population. No immediate adverse safety consequences were evident. Dosing data were obtained from conference proceedings and expert consensus. The paucity of evidence is concerning given the high rates of infections due multidrug-resistant pathogens in neonates worldwide, frequently resulting in prolonged hospital stay and significant morbidity and mortality.

NON RESPONDING COMMUNITY ACQUIRED PNEUMONIA, CONSIDER DRSP

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Pramod Kulkarni
KEM Hospital Research Centre Pune, Pediatrics, PUNE, India

Title of Case: Non responding Community Acquired Pneumonia, consider DRSP.
Background: CAP not responding to appropriate first line antibiotic is a therapeutic challenge for clinician and significant health threat for a child patient. Structured clinical review and timely imaging usually suffice, microbiology needed occasionaly. Presented herewith a case of non responding CAP due to MDRSP, responding to antimicrobial escalation.
Case Presentation Summary: A 9 years old boy referred for persistent fever of 6days, early vomiting, cough with streaks of blood , inspite of oral co amoxy-clav 3days, cefuroxime 3days. Examination revealed severe, hypoxic CAP . Empiric IV ceftriaxone 100mg/kg/day, cloxacillin 100 mg/kg/day, oral Azithromycin,oseltamivir with supportive treatment was started. Hb 11, TWBC1900/cmm,P75,L21,E0,M4, platelets1.32L/cmm, ESR65mm, CRP327mg/L, Xray chest Rt. middle, lower lobe homogenous opacity,air bronchogram.USG chest-consolidation, no pleural fluid. After marginal clinical improvement over 48hours, hypoxia, fever, tachypnoea, retractions increased with vomiting and lethargy. Hb10.4, TWBC 5900, P68, L 20, E4,M8, platelets 1.74L, CRP67mg/L. USG chest- Consolidation Rt.middle, lower lobe, minimal non-tappable pleural effusion., sputum PC 25/hpf ,gram, ZN stains, geneXpert negative. Blood culture D1 Streptococcus Pneumoniae Susceptible to penicillin,cefotaxime, Quinolones,Clindamycin,vancomycin,Linezolid,tetracycline rifampicin; Resistant to Erythromycin,TMP SMX.(MDRSP-PSSP) As per structured analysis of persistent /non responding CAP 1) wrong diagnosis-confirmed pneumonia 2) complications- Local- significant pleural effusion, abscess, necrotizing pneumonia, Distant- TSS, Metastatic infections excluded 3) wrong bug- TB excluded 4) Wrong antibiotic-selection, route, dose, duration- excluded 5) Immunocompromise - no background & normal WBC-reasonably excluded 6) Resistant Organism- MDRSP sensitive to penicillin & ceftriaxone With clinical antimicrobial failure, vancomycin was started to which child responded in 48 hours with complete resolution in 8days Vi tek Advanced Expert System flagged red of Beta lactam resistance (modification of PBP)
Learning Points/Discussion: Growing AMR is becoming clinically relevant in non invasive pneumococcal disease.

COMPLICATED PNEUMONIA IN CHILDREN/A PICU EXPERIENCE IN THE FIRST POST-COVID YEAR

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Anna Maria Spanaki[1], Fani Ladomenou[2], Theonymphi Tavladaki[1], Eleni Michailidou[3], Evaggelos Blevrakis[4], Marianna Miliaraki[1], Stavroula Ilia[1]
[1]University Hospital of Heraklion, Pediatric Intensive Care Unit, Heraklion, Crete, Greece, [2]Venizeleion Hospital, Pediatric Infectious Diseases Clinic, Heraklion, Crete, Greece, [3]University Hospital of Heraklion, Crete, Greece, Dpt Of Pediatrics, Heraklion, Crete, Greece, [4]University Hospital of Heraklion, Dpt Of Pediatric Surgery, Heraklion, Crete, Greece

Backgrounds: Complicated pneumonia (CP) is an uncommon but severe condition in children, with an increasing incidence after post-COVID-19 lockdown strategies discontinuation. Managing patients with CP is challenging as no definite guidelines exist. Antibiotics alone, chest tube drainage +/- fibrinolytics, video-assisted thoracoscopy (VATS) and open thoracotomy (OT) with decortications are among accepted treatment with significant variability and different modalities. The aim of this study is to present children with CP treated in our department, in the first post-covid year.
Methods: A retrospective analysis of patients (age ≤18 years) managed with CP, between January 2022 to December 2022, in our department in a tertiary-level teaching hospital.
Results: 9 children with CP with a mean age of 7.04 years old, were admitted to our unit from January to December 2022 (5 boys, 4 girls). All had high temperature, respiratory distress with elevated inflammation markers, abnormal x-rays, US and CT of the chest. Six underwent thoracostomy and 2 received fibrinolytics. Streptococcus pneumonia was the pathogen most commonly detected by polymerase chain reaction (PCR) of blood and/or pleural fluid (6/9), followed by Staphylococcus aureus (1/9). One respiratory viral PCR panel detected rhinovirus/enterovirus. COVID19 was not detected in any of the samples. One patient, a 11.5-year old girl, with an underlying comorbidity remained intubated for 20 days. PICU hospitalization duration was 3-30 days (mean 3.62). Only 2 children needed additional surgical treatment. All patients survived.
Conclusions/Learning Points: The majority of CPs in children can be successfully treated with a conservative approach. Some of them may need surgery. Indications and timing of surgical procedures are controversial. Further studies are required for children's best treatment management. [1]The University of Hong Kong, School Of Nursing, Li Ka Shing Faculty Of Medicine, Pokfulam, Hong Kong PRC, [2]The University of Hong Kong, Centre For Safe Medication Practice And Research, Department Of Pharmacology And Pharmacy, Li Ka Shing Faculty Of Medicine, Pokfulam, Hong Kong PRC, [3]MSD, Global Medical And Scientific Affairs, Hong Kong, Hong Kong PRC, [4]Hong Kong Science and Technology Park, Laboratory Of Data Discovery For Health (d24h), NT, Hong Kong PRC, [5]The University of Hong Kong, School Of Public Health, Li Ka Shing Faculty Of Medicine, Pokfulam, Hong Kong PRC

Backgrounds: Streptococcus pneumoniae(Sp) is one of the aetiology for paediatric infections. The pathogen can cause pneumonia, invasive pneumococcal disease(IPD) and otitis media(OM), which might lead to bacteraemia and meningitis. This study aims to identify the characteristics of antimicrobial resistance(AMR) and serotypes for the Sp isolated.
Methods: Data were retrieved from the population-wide Clinical Data Analysis and Reporting System(CDARS), for hospitalisation episodes with IPD, invasive infections, and OM from 2012 – 2019. Patients aged <18 years diagnosis were defined by International Classification of Diseases, 9th Revision, Clinical Modification(ICD-9-CM). Collected data include patient demographics, diagnoses, and microbiological culture and laboratory test results – including antimicrobial sensitivity and serotyping. Laboratory results were captured within ±28 days from the date of admission. Hospital admissions within ±28 days of the index hospitalization were considered as the same episode. Descriptive statistics were tabulated by each hospitalisation episode for (1)antimicrobial susceptibility (Sensitive/Intermediate/Resistance); and (2)serotype of the isolate.
Results: Of all 40503 episodes identified from 37661 patients, 64% had pneumonia. Other manifestations include bacteraemia(23%) and OM(9%). Sp isolates from 723 episodes were tested for antimicrobial susceptibility. Among the tested isolates, 12% had no evidence of antimicrobial resistance, another 38% were resistant to 2 antibiotics. Of the antibiotics tested, some notable antibiotics with non-susceptibility include Tetracycline(94%), Azithromycin(87%), Erythromycin(86%), Penicillin(28%). For isolates from 85 episodes, serotype information was available. Serotype 3 was the most prevalent serotype, accounting for 41% of all tested isolates and 40% among isolates with evidence of AMR (intermediate/resistance).
Conclusions/Learning Points: AMR is found common in pneumococcal diseases in kids and adolescents. Despite the high uptake of pneumococcal vaccines among children, serotype 3 remains the dominant serotype among patients with AMR. Future vaccine development should address efficacy against infection by serotype 3.

INVASIVE GROUP A STREPTOCOCCAL INFECTION: RAPID DIAGNOSIS IN CHILDREN WITH PARAPNEUMONIC EFFUSION BY PCR

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Marie Cecilie Lawaetz, Anja Poulsen, Ulrikka Nygaard
Copenhagen University Hospital, Rigshospitalet, Department Of Pediatrics And Adolescent Medicine, DK Copenhagen Ø, Denmark

Background: Parapneumonic effusion is a complication of severe pneumonia in children, and will require prolonged antibiotics. During the latest increase in invasive Group A Streptococcal (GAS) infections in children most of the severe pneumonia with effusion is caused by GAS infection. However, identification of the pathogen can be difficult, as cultures of upper respiratory tract specimens in children often will reflect throat and upper colonization. Multiplex PCR assays has not been approved for pleural fluid and can only identify a selected group of pathogens. However, it has been used in children with complicated pneumonia at our department since 2021.
Methods: This year, until 8th of March, we identified 11 patients with pleuraeffusion due to invasive GAS infection and severe pneumonia. All the included patients were treated with pleural drainage, at Department of pediatrics at Rigshospitalet, which is a tertiary care referral center for chest tube drainage for eight pediatric departments (2.6 million inhabitants). This is a high increase. Medical records were reviewed for clinical and laboratory data, including microbiological results.
Results: All 11 patients identified with parapneumonic effusion due to GAS infection were investigated with multiplex PCR (BioFire FilmArray Pneumonia Panel; Biomerieux). In 27 % (3/11) og the patients GAS was also found in blood culture, 36% (4/11) in pleural fluid culture. 7 patientes had a respiratory tract specimen made, and of these 71% (5/7) GAS was also found here. (table1) (The results are partly and among others, included in report submitted to Acta
Paed.)

TABLE 1 Patients aged 0-17 years with Invasive GAS pneumonia and parapneumonic effusion treated with chest tube drainage at Copenhagen University Hospital, Rigshospitalet 1st Jan – 8th March 2023.

No	YEAR	AGE	CAUSATIVE BACTERIA	CULTURE			MULTIPLEX PCR[1]		ANTIBIOTICS[2]	VIRUS[3]
				Blood	Pleural fluid	Respiratory tract specimen	Pleural fluid			Respiratory tract specimen
							Bacteria	Copies/mL	Hours	
1	2023	0	Group A *Streptococcus*	+	+	NI	+	10^6	3	hMPV, adeno- and rhinovirus
2	2023	2	Group A *Streptococcus*	-	-	NI	+	10^5	96	hMPV
3	2023	3	Group A *Streptococcus*	-	-	+	+	10^5	240	VZV
4	2023	4	Group A *Streptococcus*	-	+	NI	+	10^4	7	hMPV
5	2023	1	Group A *Streptococcus*	-	+	NI	+	$\geq 10^7$	30	Influenza A
6	2023	2	Group A *Streptococcus*	-	-	+	+	$\geq 10^7$	59	hMPV
7	2023	5	Group A *Streptococcus*	-	-	-	+	10^4	192	hMPV
8	2023	8	Group A *Streptococcus*	-	-	+	+	10^6	120	-
9	2023	5	Group A *Streptococcus*	+	+	+	+	$\geq 10^7$	5	Influenza B
10	2023	1	Group A *Streptococcus*	+	-	-	+	$\geq 10^7$	32	hMPV
11	2023	1	Group A *Streptococcus*	-	-	+	+	$\geq 10^7$	11	VZV

'-' = Pathogen *not identified*; '+' = Pathogen *identified*; MRSA = methicillin-resistant *Staphylococcus aureus*; MSSA = methicillin-sensitive *Staphylococcus aureus*; NA = not available; NI = not investigated; RSV = respiratory syncytial virus; VZV = varicella-zoster virus; hMPV= human metapneumovirus

[1] The assay identifies 18 bacterial pathogens with semi-quantitative results, seven antimicrobial resistance genes, and eight viruses (https://www.biofiredx.com/products/the-filmarray-panels/filmarray-pneumonia). Semi-quantitative concentrations were given as 10^4, 10^5, 10^6, and $\geq 10^7$ genome counts/mL

[2] The duration of antibiotics covering the pathogen before pleural fluid investigation

[3] Viral co-infection was identified in upper airway secretion by either SeeGene Allplex™ Respiratory Panel Assays (Roche cobas Liat influenza/RSV assay) or BioFire FilmArray Respiratory Panel 2/Pneumonia Panel.

Conclusions/Learning Points: PCR on pleural fluid has the advantage of delivering a test result within a few hours, and will help clinicians with early targeted antibiotic treatment, in contrast to more conventional cultures and respiratory tract specimens.

[1]Helsinki University Hospital, Children's Hospital, Helsinki, Finland, [2]University of Helsinki, Faculty Of Medicine, Helsinki, Finland, [3]Hospital Pediátrico David Bernardino, -, Luanda, Angola, [4]Department of Pediatrics, Center for Vaccines and Immunity Nationwide Children's Hospital, Columbus, OH, USA, Division Of Infectious Diseases, Columbus, United States of America, [5]St Jude Children's Research Hospital, Memphis, TN, USA, Division Of Pediatric Infectious Diseases, Tennessee, United States of America

Backgrounds: In previous studies the prevalence of bacteremia in paediatric community acquired pneumonia (CAP) has been shown to be low globally. The reported rates have ranged between 1.1-11.4%. Our objectives were to (1) to determine the rate of bacteremia in Angolan children hospitalized with pneumonia and (2) to observe if any demographic/ clinical characteristics or outcomes were associated with positive blood cultures.
Methods: This is a prospective, observational study of children hospitalized with pneumonia in Hospital Pediátrico David Bernardino, Luanda. Patients were previously healthy and aged between 2 months-13 years. Children with sickle cell disease or HIV were not excluded. Blood cultures were performed at the study hospital.
Results: 372 children with admission diagnosis of pneumonia and a lung x-ray were enrolled between September 2019 and May 2021. Blood cultures were performed in 328/372 (88%) cases. 66/328 (20%) of the cultures were positive. Mortality was higher (8% vs 3%), and median age lower (2.4 vs 3.4y) in bacteremic children compared with cases with negative bacterial cultures, but the differences were not statistically significant. No significant differences were either found in breastfeeding, fever duration/antibiotic treatment before admission, PICU admissions, pleural complications, need of respiratory support, C-reactive protein values or white blood cell counts. Table 1. Staphylococcus aureus was the most common pathogen identified (n=23) followed by Klebsiella (n=14). 40/66 (61%) of the identified pathogens were gram-
negative.

MASSIVE PROGRESSIVE EMPYEMA DESPITE PROPER ANTIBIOTHERAPY AS A COMPLICATION OF STREPTOCOCCUS PYOGENES PNEUMONIA.

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Jennifer Moortgat, Céline Mignon, Sarah Jourdain
HUDERF, Infectious Diseases, Brussels, Belgium

Title of Case: Massive progressive empyema despite proper antibiotherapy as a complication of Streptococcus pyogenes pneumonia.
Background: Community-acquired pneumonia is a common cause of pediatric hospitalization, especially in children under five. Most of them are easily treated with narrow-spectrum antibiotics, but some develop complications, with especially parapneumonic effusions.
Case Presentation Summary: We report here the case of a previously healthy four-year-old boy treated conservatively for a right pneumonia with parapneumonic effusion. After four weeks of antibiotics (three of intravenous penicillin and one of oral amoxicillin) with initial improvement, CRP and fever increased again. A chest CT demonstrated a voluminous mass occupying the middle, anterior and posterior part of the mediastinum. A malignant tumor was initially suspected on the basis of radiological images. A thoracoscopy for biopsy was performed and an abundant purulent discharge was observed in the pleural spaces. A massive empyema had developed. The pus was analyzed and a 16S pan-bacterial PCR identified a Streptococcus pyogenes. This patient finally recovered after 6 weeks of post-drainage antibiotics, including two given
intravenously.

Learning Points/Discussion: This case reminds us that even if prolonged fever is frequent with empyema, close follow-up is key to ensuring complete resolution. It also highlights that although Streptococcus pneumoniae is the most common cause of pneumonia in children, pneumonia and empyema due to Streptococcus pyogenes are increasing. Empyema due to Streptococcus pyogenes seems to be associated with higher risk of complications compared with Streptococcus pneumoniae, with larger effusion, longer hospital stay, but also longer time before defervescence, even with adequate antibiotherapy.

CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS IN CHILDREN WITH COMMUNITY-ACQUIRED PNEUMONIA: A 10 YEAR MULTICENTRIC RETROSPECTIVE STUDY IN PORTUGAL

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Catarina Nunes[1], Joana Bastos[2], Maria Ravara[1], Catarina Franquelim[2], Bárbara Saraiva[3], Rita Marques[2], Francisca Costa[1], Paula Correia[1]
[1]Hospital Professor Doutor Fernando da Fonseca, Paediatrics, Amadora, Portugal, [2]Hospital Garcia de Orta, Paediatrics, Almada, Portugal, [3]Hospital Dona Estefânia, Paediatrics, Lisboa, Portugal

Backgrounds: Community-acquired pneumonia (CAP) represents significant burden in children's health. The aim of this study was to characterize the demographic and clinical features of children admitted for CAP.
Methods: Retrospective descriptive study of children admitted to the hospital aged 0-18 y-old with diagnosis of CAP from 2011 to 2021 in two level II hospitals in Lisbon, Portugal. CAP diagnosis was based upon clinical and imagiological evidence. Statistical analysis was conducted in SPSS®.
Results: In a total of 512 children, 362 were uncomplicated CAP (UCAP), 85 uncomplicated pleural effusions, 46 empyemas, 14 necrotizing pneumonias and 5 pulmonary abscesses. Median age was 3 y-old (interquartil range: 1,7-7,0). 48% of the UCAP and 32% of the complicated CAP (CCAP) had PCV13. 135 children had comorbidities, the most frequent was sickle cell disease (SCD). Fever was the main symptom (92%), 38% had gastrointestinal symptoms. 20% of the UCAP had normal breath sounds. The C-reactive protein (CRP) was statistically different between UCAP and CAP (p-value<0,001, mean value for UCAP 13,8mg/dl, CCAP 18,9mg/dl). 32% CCAP had an agent identified (46% S.pneumoniae). There were 39 CAP in the SCD group, 33% had normal breath sounds, 9 were CCAP with mean CRP value 11,1mg/dl, whilst in the UCAP was 8,9mg/dl.
Conclusions/Learning Points: Most of the data are according to the scientific literature. Nevertheless, gastrointestinal symptoms and normal breath sounds were frequent, raising the need for clinical suspicion for its diagnosis. SCD patients, a rare disease, yet frequent amongst our population, were paucisymptomatic. The CRP is tendentially lower in patients with UCAP, but it is not enough to distinguish between UCAP and CCAP.

STREPTOCOCCAL DISEASE CAUSING EMPYEMA AND CATECHOLAMINE RESISTANT SHOCK

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Omotakin Omolokun[1], Malcolm Gajraj[2]
[1]CWM TAF UNIVERSITY HOSPITAL HEALTH BOARD, Paediatrics, Merthyr Tydfil, CF DT, United Kingdom, [2]University Hospital of Wales, Picu, CF XW, United Kingdom

Backgrounds: We report a case of a four year old with invasive Group A Streptococcal disease manifesting as Pneumonia and Empyema.
Methods: He had presented to ED with fever, lethargy, blanching erythematous rash and cold extremities. His capillary refill time was prolonged at 7s, with HR of 172b/min and systolic BP of 60mHg. Following 60ml/kg of fluid resuscitation, he was ventilated, and transferred to PICU on inotropic support. In spite of maximal doses of Adrenaline and Noradrenaline infusions, his MAP was not maintained above 55 mmHg. He received 120ml/kg of Hartman solution, 20ml/kg each of Packed cells and FFP and a septic dose of Hydrocortisone. Following CXR, (figure 1) a chest drain released 420ml of purulent fluid. An Echocardiogram revealed poor myocardiac function but no pericardial effusion. Following addition Vasopressin, his MAP improved to above 60mmHg. He required some active cooling for a core temperature of 42.4^{o}C. Vasopressin was weaned slowly and replaced with Milronone on Day 2 on PICU admission.
Results: Pleural fluid isolated group A streptococcus (emm type 6.0). Antibiotics was switched to high dose Benzyl Penicillin and Clindamycin. Inotropes were weaned off slowly until Day 6 of admission. He developed some dark discoloration and blisters on his toes but this did not result in necrosis or limb amputation. He required hemofiltration for seven days for a renal failure. He made good recovery and was discharged on the third week for follow
up.

Figure 1.

x-rays showing a Right Pneumonia and Empyema on admission.

x-rays with chest drain following thoracocentesis of purulent fluid.

Conclusions/Learning Points: Our case highlights the virulence of GAS infection and how clinicians need to be familiar with uncommon presentation of invasive disease in children. Early recognition of group A streptococcus as a cause of empyema and shock can result in good outcomes.

PV0701 / #1421

PNEUMONIA? IT'S COMPLICATED...

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Ana Pereira[1], Mariana Eiras Dias[2], Filipa Cirurgião[3], Inês Ferreira[3], Sara Marcos[3]
[1]Centro Hospitalar Lisboa Ocidental - Hospital de Sao Francisco Xavier, Pediatrics, Lisboa, Portugal, [2]Hospital São Francisco Xavier - Centro Hospitalar Lisboa Ocidental, Pediatrics, Lisboa, Portugal, [3]Centro Hospitalar Lisboa Ocidental - Hospital de Sao Francisco Xavier, Paediatrics, Lisboa, Portugal

Title of Case: Pneumonia status? It's complicated...
Background: Although complicated community-acquired pneumonia is rare in paediatric patients, it's the most frequent cause of morbidity and mortality in children between 28-days and 5-years of age. Despite some studies have been done to establish the better therapeutic approach, the treatment is still a challenge.
Case Presentation Summary: A previously healthy 2-year-old boy with updated routine vaccination, presented to the emergency department with 4 days of high fever, cough and anorexia. X-ray was performed and he was discharged with oral amoxicillin for pneumonia. 4 days later he returned for persistent fever, dyspnea, and groaning. At observation he had infracostal retraction and decreased left breath sounds. X-ray revealed a hypotransparency on the middle/upper right lobe and inferior left lobe and blood tests a PCR increase (5.9 mg/dL), without leucocytosis. He was admitted with the diagnosis of bilateral lobar pneumonia and started ampicillin. 72 hours later, a new x-ray and thoracic ultrasound were performed for persistent fever and demonstrated a small pleural effusion. Ampicilin was switched to ceftriaxone plus clindamycin. After 72 hours of no clinical and laboratorial improvement, thoracic CT was performed, revealing an extended consolidation on the right and left side, signs of necrotizing pneumonia with pneumatoceles, 2 small abscesses and bilateral mild pleural effusion. Vancomycin was added and he was afebrile in 24 hours. He was discharged after 3 weeks of intravenous antibiotics, with radiologic, analytic, and clinical improvement. Thoracic CT was performed 4 months later, showed a significant improvement, without sequels.
Learning Points/Discussion: Complicated community-acquired pneumonia should be suspected in any child with pneumonia not responding to appropriate antibiotic treatment within 48-72h. In this case, conservative treatment was sufficient, without need to resort to surgical intervention, with complete clinical recovery.

INVASIVE NON-TYPABLE HAEMOPHILUS INFLUENZAE IN A PREVIOUSLY HEALTHY MALE ADOLESCENT

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Daniela Pestana, Marta Marques, Marta Cabral, João Neves
Hospital Luz Lisboa, Departamento De Pediatria, Hospital Da Criança E Do Adolescente, Lisboa, Portugal

Title of Case: INVASIVE NON-TYPABLE HAEMOPHILUS INFLUENZAE IN A PREVIOUSLY HEALTHY MALE ADOLESCENT

Background: The introduction of the Haemophilus influenzae (Hi) type b vaccine has had a significant impact on Hi invasive disease worldwide. Non-typeable Hi (NTHi) usually causes acute otitis media and sinusitis, but an increase in NTHi invasive disease has been reported in the last decade, especially in the elderly and children before the age of 5 years-old.

Case Presentation Summary: A previously healthy 15-year-old male adolescent, who had returned from a 3-week Costa Rica vacation, came to the paediatric emergency room reporting general malaise, high fever and shivers. He had been immunized with hepatitis A and typhoid fever vaccines prior to the trip. The remaining vaccine schedule was updated. He was pale, febrile and the remaining vital signs and physical examination were normal. Blood count revealed WBC 4500/Ul (N 34.9%, Ly 49.1%) with a C-reactive protein 4,63mg/dL. An x-ray was performed showing a bilateral perihilar infiltrate and no condensations. Blood cultures were pending, and he was discharged on azithromycin. A non-typeable Haemophilus influenzae was isolated in the blood culture and he was summoned for observation. He had improved and his fever was lower, but he was still started on ceftriaxone completing a 5-day course of treatment, with complete recovery. Primary and secondary immunodeficiencies were ruled out, and there was no functional or anatomic asplenia.

Learning Points/Discussion: Carriage of NTHi has been increasing after the introduction of pneumococcal and Hib conjugated vaccines, and probably underlies the higher rates of invasive NTHi. We report a healthy adolescent with NTHi bacteremia, highlighting the importance of timely blood cultures in patients presenting fever and shivers, irrespective of the age.

Backgrounds: Each year, Streptococcus pneumoniae disease causes approximately 14% of all deaths in children aged under 5 years worldwide (WHO, 2021), with most deaths occurring in low- or middle-income countries. S. pneumoniae causes a spectrum of diseases, from mucosal infections such as acute otitis media and non-bacteremic pneumonia to severe invasive pneumococcal disease (IPD), including septicemia, meningitis, and bacteremic pneumonia. However, there is limited evidence regarding the demographics, clinical characteristics, and outcomes of children in Thailand presenting with IPD. The objective of this study was to describe the risk condition status and clinical outcomes among Thai children hospitalized with pneumococcal disease.
Methods: In this retrospective analysis, pediatric patients with invasive pneumococcal disease (IPD) or X-ray confirmed non-bacteremic pneumococcal pneumonia (NBPP) were identified from nine hospitals from 2010-2019 in Thailand. Data on risk factors and outcomes were extracted from medical records.
Results: In total, 413 cases were identified, 319 IPD and 94 NBPP. Overall, 133 (32.2%) patients were admitted to the intensive care unit and 11/406 (2.7%) died. Twenty-seven percent of IPD cases had at-risk conditions; 15% had high-risk conditions. Most IPD cases (32.9%) occurred in children aged 2-4 years and most NBPP cases (28.7%) occurred in infants aged 0-11 months. Of 51 Streptococcus pneumoniae isolates collected, 41 (80%) were PCV13 serotypes. Only 5.1% of children had received a pneumococcal vaccine.
Conclusions/Learning Points: Most children with IPD and NBPP had no risk condition, while 42% of the children had at-risk or high-risk conditions for pneumococcal disease. Very few children in the cohort had received any type of pneumococcal vaccine. Increasing the availability of pneumococcal conjugate vaccines should be considered to reduce the burden of pneumococcal disease among children in Thailand.

PEDIATRIC NON-INVASIVE PNEUMOCOCCAL PNEUMONIA IN PORTUGAL (2017-2022): DOMINANCE OF SEROTYPES 11A AND 23B AND THE CONTINUED IMPORTANCE OF VACCINE SEROTYPES 3 AND 19F

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Catarina Silva-Costa, Joana Gomes-Silva, Mário Ramirez, José Melo-Cristino, . The Portuguese Group For The Study Of Streptococcal Infections, . The Portuguese Study Group Of Invasive Pneumococcal Disease Of The Pediatric Infectious Diseases Society
Faculdade de Medicina de Lisboa, Instituto De Microbiologia, Lisboa, Portugal

Backgrounds: Although pediatric invasive pneumococcal disease (IPD) is well characterized, less is known regarding the epidemiology of non-invasive pneumococcal pneumonia (NIPP). The aim of this work was to characterize the pneumococcal population causing NIPP in children (<18 years) in Portugal in 2017-2022.
Methods: A total of 167 respiratory tract isolates recovered in 62 hospitals between January 2017 and December 2022 were characterized by serotyping.
Results: A decrease in reporting of NIPP cases was noted, possibly due to the COVID-19 pandemic. Overall, 79 isolates expressed serotypes not included in any conjugate vaccine (47%). Serotypes included in PCV7 accounted for 13% of the isolates (n=21), while PCV13 serotypes were found in 39 isolates (23%). The serotypes included in PCV15 accounted for 44 isolates (26%). Slightly more than half of the isolates (53%, n=88) expressed serotypes included in PCV20. Serotype 11A was the most frequent, accounting for 17% (n=29), followed by serotype 23B (11%). Vaccine serotypes 3 and 19F were responsible for 8% of NIPP cases (each). Throughout the study period, the proportion of infections caused by non-PCV20 serotypes and PCV7 serotypes decreased from 58.6% to 37.5% and from 17.2% to 12.5%, respectively, while the opposite trend was detected for serotypes included in PCV13 and PCV15 (27.6% to 37.5% both) and in PCV20 serotypes (from 41.4% to 62.5%), all non-significant.
Conclusions/Learning Points: Despite more than 2 decades of conjugate vaccine use, serotype 19F is still an important serotype in pediatric NIPP, along with serotype 3, which is a very important serotype also in IPD. Serotypes included in PCV20 are becoming important causes of disease, reinforcing the potential usefulness of higher valency vaccines in the pediatric population.

Background: Streptococcus pneumoniae (Spn) is a leading cause of a wide range of bacterial infections including otitis media, community-acquired pneumonia, meningitis and bacteremia, with considerable morbidity and mortality worldwide. Current prophylaxis is based on capsular polysaccharide vaccines, plain or conjugated to protein carriers, that are periodically updated to cover for the circulating serotypes. Young children under 2 years of age, the elderly and individuals with weakened immune systems are still vulnerable to infection due to emerging serotypes not covered by current vaccines. To circumvent the need for new vaccines composition and to provide broad serotype coverage, we are developing V-212, a peptide-based vaccine candidate based on a small number of well-conserved antigenic epitopes presented on a synthetic nanoparticle (Virometix SVLP platform).
Methods: The antigenic epitopes, parts of Spn virulent surface protein domains shared among serotypes, were synthesized using solid-phase peptide synthesis and subsequently conjugated to a lipopeptidic backbone carrying elements to activate innate and adaptive immune responses.
Results: V-212 is immunogenic in mice and rabbits with durable epitope-specific antibody responses. In two lethal sepsis mouse models, administration of V-212 prevents pneumococcal disease by reducing bacterial presence in lungs, and extends animal survival by blocking bacterial dissemination in blood, both after intranasal challenge with serotypes 3 and 8. Moreover, antibodies triggered upon V-212 immunization recognize and bind whole bacterial cells of various PCV13 vaccine and non-vaccine serotypes.
Conclusions/Learning Points: V-212 is a novel vaccine candidate against Spn. Additional efficacy studies and studies to elucidate the mechanism of protection conferred by V-212 will allow us to further proceed to the candidate’s non-clinical development.

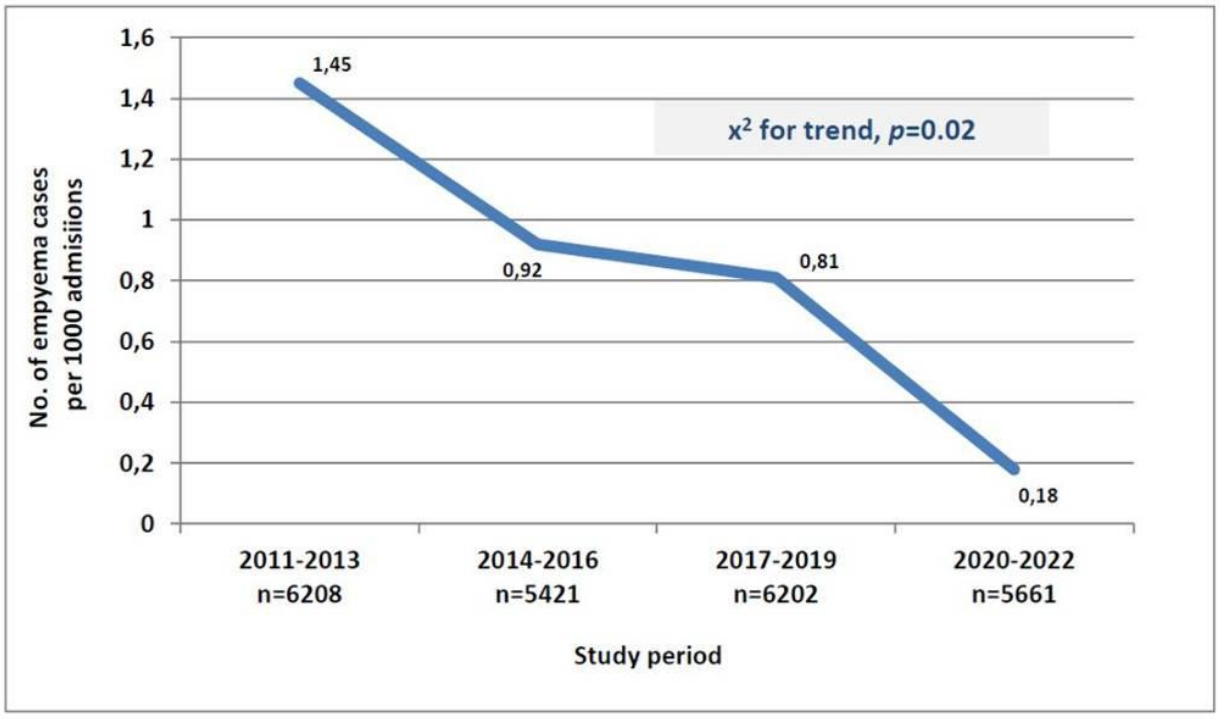
DECLINE IN THE INCIDENCE OF PNEUMOCOCCAL EMPYEMA AMONG PEDIATRIC PATIENTS DURING COVID-19 PANDEMIC: CENTRAL GREECE, 2011-2022

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Georgia Gazeti[1], Aspasia Michoula[1], Eleni Papadimitriou[1], Theoni Syrogiannopoulou[2], Paraskevi Rozou[1], Maria Garefi[1], George Syrogiannopoulos[1], Ioanna Grivea[1]
[1]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department Of Pediatrics, Larissa, Greece, [2]National and Kapodistrian University of Athens, Medical School, Athens, Greece

Backgrounds: Pleural empyema is a complication of pediatric community-acquired pneumonia mostly due to Streptococcus pneumoniae. In Greece, the 13-valent pneumococcal conjugate vaccine (PCV) was introduced in June 2010 and since July 2010 it has been the most used PCV. The first case of SARS-CoV-2 infection was announced on February 26th resulting initially in a full lockdown, followed by several non-pharmacological interventions. Previously reported experience of viral epidemics has shown the increase of bacterial coinfections or post-viral superinfections, such as sepsis and/or pneumonia.
Methods: We studied all pediatric pneumococcal empyema cases admitted to the University General Hospital of Larissa before and during Covid-19 pandemic (2011-2022).
Results: There were 20 cases of empyema due to S. pneumoniae among children aged 2.3-9.7 years (median age: 4.4 years). The rate of empyema cases significantly declined from 1.45 cases per 1000 admissions during the period 2011-2013, to 0.18 cases during the Covid-19 period, 2020-2022 (Figure). The identified serotypes were: 3, 19A, and 9N/L in descending order. Serotype 3 emerged as the predominant pathogen of pneumococcal empyema (15 of 20 cases). There were not any cases of serotype 1 reported, whereas serotype 19A was not recovered after 2011.



Conclusions/Learning Points: In Greece, currently, there is a major withdrawal of non-pharmacological interventions. Surveillance of the pneumococcal empyema cases is ongoing to assess whether a rebound of the empyema cases will occur.

Title of Case: INVASIVE GROUP A STREPTOCOCCAL EMPYEMA: AN EMERGING CLINICAL PRESENTATION?
Background: Group A Streptococcus (GAS) is a common cause of acute pharyngitis and cutaneous infections. Multiple countries have reported the resurgence of rarer cases of invasive GAS (iGAS) infections since the end of 2022.
Case Presentation Summary: A previously healthy 15-month-old boy presented with 7 days of high fever, cough and rhinorrhea. Two days before he had become lethargic and presented papule-vesicular rash. There were cases of chickenpox at his school. At admission, he looked ill, was febrile, tachycardic, SpO2 of 93%, presenting signs of breathing difficulty and diminished breathing sounds on the right hemithorax, as well as enanthema. Laboratory results were notable for leukocytosis (18390/uL) with neutrophilia (12250/uL), high CRP (236mg/L) and PCT (44ng/mL). Chest x-ray showed increased lucency on the right and subsequent ultrasound a voluminous non-loculated pleural effusion occupying the right hemithorax with collapse of the left lung. A thoracic drain was inserted in ICU with aspiration of 685mL of purulent fluid compatible with empyema in the first 24h. GAS was isolated in blood culture and detected in pleural fluid PCR. Adenovirus and chickenpox co-infection were also confirmed. GAS pleural empyema was treated with 21 days of penicillin drug and clindamycin and he completed 5 days of acyclovir due to concomitant chinckenpox. On the 6th day, due to clinical deterioration he performed ultrasound that showed multiloculated pleural effusion, requiring 3 additional days of fibrinolytics in ICU, with latter good evolution, being discharged after 20 days.
Learning Points/Discussion: Pleural empyema following chickenpox or presenting with rash may be due to GAS, therefore prompt addition of an antitoxin drug is advised. As recently reported, we describe a difficult to treat severe case of iGAS pneumonia with empyema.

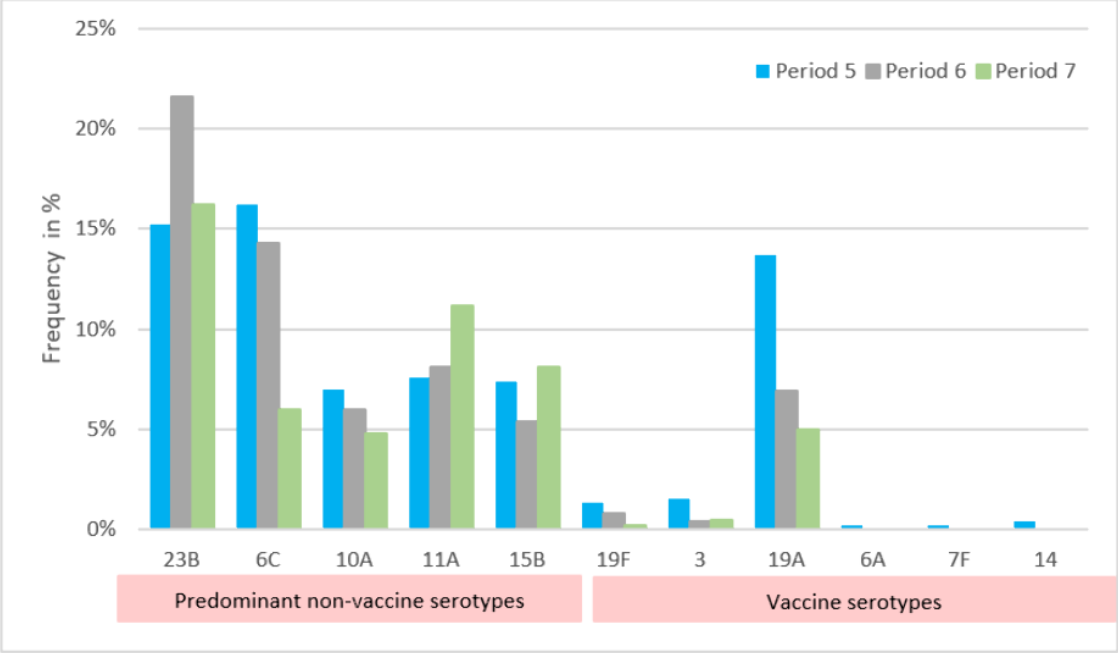
[1]University of Antwerp, Vaccine And Infectious Disease Institute - Centre For Evaluation Of Vaccination (vaccinopolis), Antwerp, Belgium, [2]UZ Leuven, Department Of Laboratory Medicine, Leuven, Belgium, [3]KU Leuven, Department Of Microbiology, Immunology And Transplantation, Leuven, Belgium, [4]University of Antwerp, Laboratory Of Medical Microbiology, Antwerp, Belgium, [5]University of Antwerp, Centre For Health Economics Research And Modelling Infectious Diseases, Antwerpen, Belgium

Backgrounds: Following a switch from 13-valent (PCV13) to 10-valent pneumococcal conjugate vaccines (PCV10) in the Belgian infant vaccination program in 2016, we started monitoring nasopharyngeal carriage of pneumococcal serotypes (STs) in children (6-30 months) attending day-care centers (DCC). Here, we report data collected in November 2021-June 2022 (P7) and in November 2020-July 2021 (P6) to evaluate the continuing impact of reverting to PCV13 in September 2019 when 19A carriage was 13.7%.
Methods: In P6 and P7 respectively, 700 and 709 nasopharyngeal samples were cultured for Streptococcus pneumoniae (SP), which were consecutively serotyped (Quellung reaction) and tested for antimicrobial susceptibility. Differences between P6 and P7 were evaluated using Chi^2.
Results:

Figure 1: Frequency of pneumococcal serotypes carried by young children at three consecutive collection periods



Frequency of predominant non-vaccine serotypes 23B, 6C, 10A, 11A, and 15B and of vaccine serotypes 19F, 3, and 19A in period5 (blue bars), in period 6 (grey bars) and in period 7 (green bars).

The proportion of age-appropriately vaccinated children with exclusively PCV13 increased from 39.2% (P6) to 95.6% (P7), while children vaccinated with a mixed schedule decreased from 40.1% to 0.4%. SP carriage was 68.7% in P6 and 59.1% in P7 ($p>0.05$). PCV13-vaccine serotype carriage decreased from 8.1% in P6 to 5.7% in P7 ($p>0.05$), only serotypes 3, 19A, and 19F remained. Carriage of frequently-occurring (>5%) non-vaccine serotypes did not significantly change except serotype 6C (14.3% (P6); 6.0% (P7) – $p<0.001$) and 23B (21.6% (P6); 16.2% (P7) - $p<0.05$)(Figure1). Antimicrobial non-susceptibility to tetracycline (22.9% (P6); 22.4% (P7)), erythromycin (22.5% (P6); 21.9% (P7)), penicillin (23.7% (P6); 28.4% (P7)) and cotrimoxazole (23.7% (P6); 21.9% (P7)) did not change significantly. However, non-susceptibility of strains to at least one of those antibiotics markedly decreased (43.4%; 70.9% (P6); 43.4% (P7) - $p<0.001$).

Conclusions/Learning Points: In Belgian children attending DCC, the overall carriage of PCV13-vaccine serotypes (non-significantly) as well as the carriage of frequently-occurring non-vaccine serotypes 6C and 23B (significantly) decreased between 1−2 years after the switch back from PCV10 to PCV13.

E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Pelagia Tsitsani, Evdokia Psaroulaki, Georgios Katsaras
GENERAL HOSPITAL OF PELLA-HOSPITAL UNIT OF EDESSA, Peadiatric Department, EDESSA, Greece

Title of Case: Unvaccinated pre-school girl with community-acquired pneumonia
Background: Streptococcus pneumoniae is the most commonly identified bacteria causing community-acquired pneumonia. The disease is associated with significant morbidity and mortality in young children, particularly those under the age of two

years.

Case Presentation Summary: A 4.5 years-old girl presented to the emergency department with cough, shortness of breath and low-grade fever. The patient came from the Roma ethnic minority group and was completely unvaccinated. Physical examination revealed crackles and decreased breath sounds in the right lower lobe on chest auscultation, and dullness to percussion. She was admitted for further observation and investigation. CBC depicted elevation of WBC: 24,000 x 10^6/L (NEU: 80%), PLT 600,000/μL, increased inflammatory biomarkers (CRP: 15,2 mg/dL, procalcitonin: 1 ng/ml), and negative

rapid tests for SARS-CoV-2, Influenza A, Influenza B, RSV, and Adenovirus. CXR was performed showing segmental consolidation of the right lobe. Furthermore, pneumococcal urinary antigen test was found positive. Serum cold agglutinin test was negative. Therapy included administration of intravenous ampicillin (100 mg/kg/d), and oxygen due to mild respiratory distress. On the 3rd day of hospitalization, she became afebrile and respiratory distress gradually improved. The patient was discharged on the 7^{th} hospitalization day with per os amoxicillin (90mg/kg) for 7 days.

Learning Points/Discussion: Urinary antigen tests have emerged as a promising alternative for improving the diagnosis of respiratory infections caused by Streptococcus pneumoniae. Vaccination programs in developed countries have significantly decreased the incidence of Streptococcus pneumoniae infections. Nevertheless, in the last two decades the anti-vaccine movement has led to an escalation of lung infections, especially in the post Covid era. Moreover, targeted health policies need to be developed aiming to prioritize vaccinations in vulnerable communities.

THE ACTIVITY OF CERAGENIN CSA-13 AGAINST MULTISPECIES BIOFILMS ASSOCIATED WITH CHRONIC INFECTIONS IN CYSTIC FIBROSIS SUBJECTS

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Urszula Wnorowska[1], Dawid Łysik[2], Ewelina Piktel[3], Magdalena Zakrzewska[1], Tamara Daniluk[1], Krzysztof Fiedoruk[1], Robert Bucki[1]
[1]Medical University of Bialystok, Department Of Medical Microbiology And Nanobiomedical Engineering, Bialystok, Poland, [2]Bialystok University of Technology, Department Of Materials Engineering And Production, Bialystok, Poland, [3]Medical University of Bialystok, Independent Laboratory Of Nanomedicine, Bialystok, Poland

Background: Opportunistic pathogens such as P. aeruginosa, S. aureus, and C. albicans are usually growing in biofilm form in which increased antibiotic resistance was noted. The development of such biofilms triggers life-threatening infections in cystic fibrosis patients, which are associated with impaired response to antibiotic therapy, rapid decline in lung function, and poor clinical outcomes. An additional key factor in the development of drug-resistant phenotypes and the persistence of chronic lung infections in cystic fibrosis patients is the high viscosity of biofilms developed by mucoid (alginate-producing) strains of P. aeruginosa, which considerably impairs the diffusion of antimicrobials within biofilm matrix and thus, hampers the eradication of biofilm-embedded bacteria.
Methods: This study was designed to evaluate the ability of ceragenin CSA-13, being a lipid analog of endogenous antimicrobial peptides to eradicate multispecies biofilms associated with lung infection development in cystic fibrosis subjects. The mass of multispecies biofilms developed in the presence of CSA-13 was measured using crystal violet staining. Rheological properties of bacterial biofilms exposed to the different concentrations of ceragenin were investigated using a rheometer in a plate-plate arrangement.
Results: We observed considerable reductions in single- and multi-species biofilm masses upon treatment with CSA-13. Alterations in the viscoelastic properties of biofilms developed in the presence of CSA-13 were also noted.
Conclusions/Learning Points: The observed effects of CSA-13 strongly suggest the possibility to develop novel lung infection therapies for cystic fibrosis subjects based on lipid antimicrobials from the ceragenin family. This work was financially supported by grant from the National Science Center, Poland: UMO-2018/30/M/NZ6/00502 (RB).

Backgrounds: Since 2010, Kazakhstan has gradually started mass vaccination against pneumococcal infection for children. The present study is the first analysis that aims to study the prevalence of pneumonia and pneumonia as a cause of mortality in children under 1 year of age.
Methods: An analytical study of the official data of the statistical collection of the National Scientific Center for Health Development (Kazakhstan) for 2010 to 2020 was carried out.
Results: From 2010 to 2020, the incidence of pneumonia in children under 1 year of age tends to decrease in absolute numbers. In 2010, this indicator was 17,761 cases of morbidity, and in 2020, the indicator decreased by 52.1% compared to 2010, i.e. 8493 cases. Mortality from pneumonia in children under 1 year of age in the Republic of Kazakhstan in 2010 was 0.6% of the total mortality of children under 1 year of age. In general, there is a steady decrease in pneumonia as a cause of death. In the final 2020 study, mortality from pneumonia in children under 1-year-old was recorded as 0.1%.

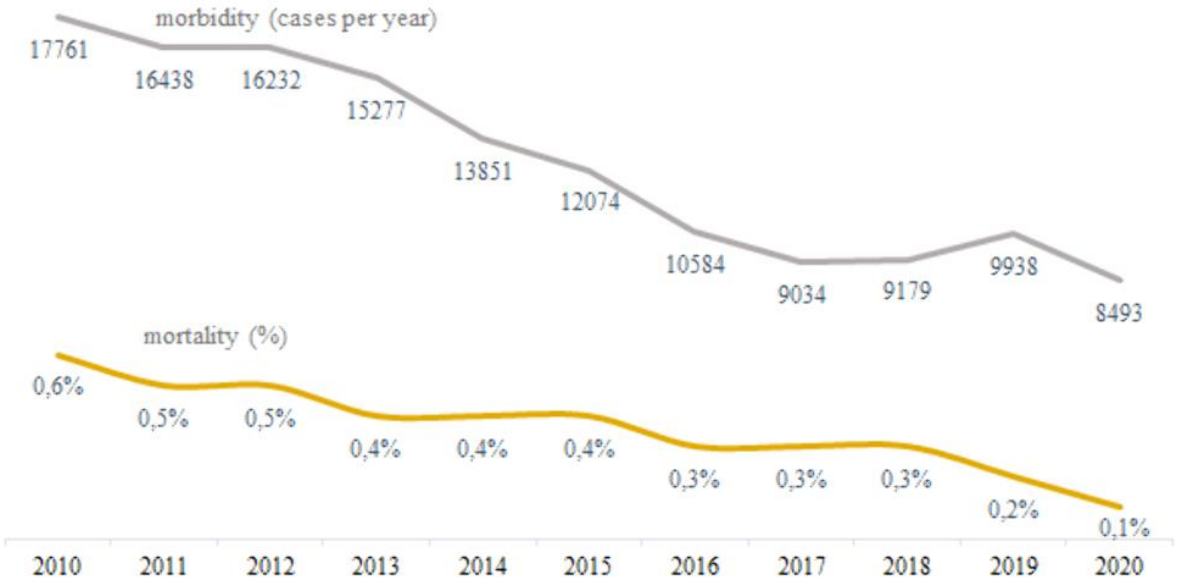

Figure 1. The number of confirmed pneumonia cases per year and percentage of mortality from pneumonia in children under 1-year-old in the Republic of Kazakhstan (2010-2020)

Conclusions/Learning Points: Vaccination against pneumococcal infection was included in the national vaccination schedule of the Republic of Kazakhstan in 2010. In general, in the Republic of Kazakhstan, there is a decrease in the incidence of pneumonia in children under 1 year of age.

GALACTO-OLIGOSACCHARIDES POSSESS ANTIMICROBIAL AND ANTI-INFLAMMATORY PROPERTIES: POTENTIAL TREATMENT FOR MACROLIDE-RESISTANT AND -SENSITIVE MYCOPLASMA PNEUMONIAE

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Hongzhen Zhu[1], L.J.M. Slimmen[1], Yang Cai[2], A.C.J.M. De Bruijn[1], Gert Folkerts[2], Annemarie Van Rossum[3], Saskia Braber[2], W.W.J. Unger[1]
[1]Erasmus MC University Medical Centre Rotterdam - Sophia Children's Hospital, Department Of Pediatrics, Laboratory Of Pediatrics, Rotterdam, Netherlands, [2]Utrecht University, Pharmacology, Utrecht, Netherlands, [3]Erasmus MC University Medical Centre Rotterdam-Sophia Children's Hospital, Department Of Pediatrics, Division Of Paediatric Infectious Diseases And Immunology, Rotterdam, Netherlands

Backgrounds: Effective treatment of bacterial infections is threatened by antibiotic resistance. Antibiotic resistance reduces treatment efficiency and often results in increasing morbidity and mortality. Mycoplasma pneumoniae (MP) are frequent causes of respiratory infections in children, and known for increasing resistance rates against macrolide antibiotics. Evidently, alternative treatments are warranted. Non-digestible oligosaccharides (NDOs), a diverse group of carbohydrates have recently gained profound interest due to their direct anti-infective and bactericidal effects on pathogens. Here, we evaluated the potential of galacto-oligosaccharides (GOS) and fructo-oligosaccharides (FOS) as therapeutic options for macrolide-resistant (MR) MP and MP infections.
Methods: Minimum inhibitory concentrations (MICs) and minimum bactericidal concentrations (MBCs) were determined on MP and MRMP isolates. Effect of NDOs on bacterial adhesion and viability was evaluated in co-cultures with A549 alveolar cells. Cytokines in co-culture supernatants were detected by ELISA. Untreated cultures served as control.
Results: MIC and MBC of GOS for MRMP and MP was 4%. MIC and MBC of FOS was 16% for all strains. GOS reduced adhesion of MRMP and MP to A549 in a dose-dependent manner, with 8%GOS respectively inhibiting 65% of MRMP and 54% of MP adhesion as compared to control. Analysis of culture supernatants revealed that 91% MRMP and 59% MP were killed. Additionally, the production of bacteria-induced IL-6 and IL-8 was significantly suppressed by 8%GOS. Remarkably, FOS did not show anti-adhesion, anti-inflammatory and anti-microbial effects on MRMP and MP.
Conclusions/Learning Points: These results indicate that GOS, but not FOS, acts as an anti-infective and anti-microbial agent and also has anti-inflammatory properties. Therefore, GOS may be useful for treatment of MRMP and MP infections.

PV0713 / #697

EXPERIMENTAL ASYMPTOMATIC MYCOPLASMA PNEUMONIAE CARRIAGE ACCELERATES BACTERIAL CLEARANCE BUT INCREASES IMMUNOPATHOLOGY DURING SUBSEQUENT MYCOPLASMA PNEUMONIAE PNEUMONIA

E-Posters Viewing
E-POSTER VIEWING: AS08.B. BACTERIAL PNEUMONIA

Ruben De Groot[1], L.J.M. Slimmen[1], Silvia Estevão[1], Hongzhen Zhu[1], Ad C.J.M. De Bruijn[2], Ana Belo[1], Annemarie Van Rossum[1], W.W.J. Unger[1,2]
[1]Erasmus MC - Sophia Children's Hospital, Pediatrics, Rotterdam, Netherlands, [2]Erasmus MC University Medical Centre Rotterdam - Sophia Children's Hospital, Department Of Pediatrics, Laboratory Of Pediatrics, Rotterdam, Netherlands

Backgrounds: Mycoplasma pneumoniae causes 3-7 yearly epidemics of pneumonia in children and can be preceded by asymptomatic upper respiratory tract carriage. Vaccine-enhanced disease have been described, but how previous M. pneumoniae exposure affects the host response during infection is unknown. We thus studied the effects of experimental M. pneumoniae carriage on immunity during a subsequent M. pneumoniae infection.
Methods: We have developed a murine model of asymptomatic M. pneumoniae upper respiratory tract carriage using intranasal installation of 10^6 CFUs of the M129 M. pneumoniae strain.
Results: We found that prior M. pneumoniae carriage led to accelerated bacterial clearance in the lungs during subsequent M. pneumoniae infection, but also increased lung histopathology scores and weight loss when compared to infection in non-carrier controls. Repeated infections with M. pneumoniae showed even faster bacterial clearance in the lungs and similar increases in immunopathology when compared to infection in M. pneumoniae carriers. Lung histopathology coincided with increased levels of inflammatory cytokines, but not with lung bacterial load, and was associated with increased weight loss [Spearman's rho -0.5171, 95%CI: -0.7920 - -0.06782]. Both pneumonia in M. pneumoniae carriers and repeated infection in non-carriers led to rapid recall responses of M. pneumoniae-specific immunoglobulins in bronchoalveolar lavage fluid and serum, which associated with bacterial clearance in the lungs [Spearman's rho: -0.7670, 95%CI: -0.9142 - -0.4411]. Previous exposure also induced accelerated clearance of M. pneumoniae from the upper respiratory tract, however this could not be attributed to antibody responses.
Conclusions/Learning Points: Previous M. pneumoniae upper respiratory tract carriage and M. pneumoniae infection improve bacterial clearance during subsequent M. pneumoniae infection, but this comes at the cost of increased lung immunopathology and does not benefit mouse body weight loss during M. pneumoniae infection.

NECK STIFFNESS IN A TODDLER, NOT ALWAYS A LUMBAR PUNCTURE IS NEEDED

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Ángela Bonilla Tramoyeres, Noelia Guevara Sanchez, Ana María Reguillo Lacruz, Ivan Domenech Mañez, Marta Dapena Archiles
Hospital General Universitario de Castellón, Paediatrics, Castellón de la Plana, Spain

Title of Case: Neck stiffness in a toddler, not always a lumbar puncture is needed
Background: Neck stiffness is generally associated with meningoencephalitis in paediatrics and should be so, however, other diagnostic possibilities must be considered.
Case Presentation Summary: We present a 10-month-old male infant referred to the emergency department with fever, cough and irritability on several occasions. The patient was examined and discharged home with several diagnosis; upper respiratory tract infection and suspicion of pneumonia and a course of empirical antibiotics with amoxicillin clavulanic was prescribed. He presented an insidious evolution with persistent fever and on examination a left submandibular adenopathy was observed associating neck stiffness. Tests showed leukocytosis (38,500), neutrophilia (21,400) and elevated CRP (136 mg/L). Meningitis was ruled out with a normal lumbar puncture (normal CSF biochemistry and negative meningoencephalitis panel), and a cervical ultrasound showing a 2.6 cm left laterocervical abscess. He was admitted to the hospital and intravenous amoxicillin clavulanic was continued. Dysphagia, drooling, and respiratory distress were observed 48 hours after admission. Contrast-enhanced cervical and mediastinal CT was performed and the presence of a left retropharyngeal abscess (36x24x64 mm) with airway compromise was confirmed and surgical drainage was performed. Bacterial culture showed positivity for K. pneumoniae, MSSA, S. mitis, and S. constellatus. Intavenous antibiotic regimen was modified to cefotaxime and clindamycin for 7 days and continued orally with amoxicililn-clavulanic at home during 1 more week with full
recovery.

Learning Points/Discussion: Retropharyngeal abscesses are a rare complication in children presenting with fever, odynophagia, sialorrhea, trismus and neck pain. In this clinical case the neck stiffness was one of the main concerns. Deep suppurative ENT area complications must be taken into consideration when meningitis is rule out at this range of age.

ORBITAL CELLULITIS: AN 8 YEAR REVIEW IN A PEDIATRIC DEPARTMENT

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Marta Figueiredo, Ana Pereira, Mariana Eiras Dias, Ana Teresa Soares, Laura Azurara, Rita Belo Morais
Hospital São Francisco Xavier - Centro Hospitalar Lisboa Ocidental, Pediatrics, Lisboa, Portugal

Backgrounds: Periorbital (PC) and orbital cellulitis (OC) are common in pediatric age and include infections of the ocular adnexal and orbital tissues with different management and potential complications.
Methods: Retrospective descriptive analysis of pediatric patients admitted to a general hospital diagnosed with PC or OC between 2013-2021.
Results: Sixty-five children were admitted with PC (82%) or OC (18%), mainly unilateral (97%). Most occurred in wintertime, in under 5-year-olds (54% PC, 58% OC), 50.8% in males. Rhinosinusitis was present in 53% of PC; 83% in OC; acute conjunctivitis in 17% of PC and 16.7% of OC. Symptoms included periorbital edema and erythema (> 80% of PC and OC), fever and eye pain (50% of OC), proptosis (n=1 PC) and chemosis (n=2 OC). Median leukocyte count was 12,600/uL (4,600-32,400) in PC, 11,750/uL (6,000-17,900) in OC; median C-reactive-protein (CRP) was 8.1mg/L (1-181) in PC; 28.7mg/L (1-119) in OC. All cultures were negative. Intravenous amoxicillin-clavulanate was the first line empirical therapy (PC=OC). Contrast CT (n=52;80%) revealed complications in 7.5% of PC (n=4), 33% of OC (n=4): subperiosteal abscess (n=6), orbital abscess (n=1) and epidural empyema (n=1). 5 patients needed antibiotics change. Mean duration of systemic therapy was 4.9 days (1-10; OC minimum 4 days). Mean duration of hospital stay was 5.6 days in PC and 6.8 days in OC. All recovered well.
Conclusions/Learning Points: As previously described, PC was more frequent, incidence was higher in wintertime and rhinosinusitis was a major risk factor, especially for OC. OC didn´t always present with proptosis, ocular pain, higher leukocyte count or CRP, so the diagnosis required a high degree of suspicion. Amoxicillin-clavulanate was mainly an effective treatment. OC had slightly higher mean duration of stay and complications, but overall, prognosis was good.

PERIORBITAL CELLULITIS: WHEN THINGS LOOK BAD, THEY MAY GET WORSE

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Marta Figueiredo, Madalena Sales Luís, Rita Morais
Hospital São Francisco Xavier - Centro Hospitalar Lisboa Ocidental, Pediatrics, Lisboa, Portugal

Title of Case: PERIORBITAL CELLULITIS: WHEN THINGS LOOK BAD, THEY MAY GET WORSE
Background: Orbital (OC) and periorbital cellulitis (PC) both present with sudden onset of eyelid swelling and erythema, but with different clinical implications. PC does not involve the contents of the orbit and usually has a better prognosis with lower risk of complications. Acute rhinosinusitis is the most frequent predisposing factor, followed by skin lesions.
Case Presentation Summary: A previously healthy 4 year-old male, was admitted with a 3-day history of high fever, headache and right conjunctival purulent discharge, followed by right palpebral edema and eye pain. He had no diplopia, skin lesions, respiratory symptoms or vomiting. Examination revealed marked edema and erythema of the right eyelid, with closure of the palpebral fissure, without proptosis, altered eye movements, relative afferent pupillary defect or chemosis. Blood tests revealed 32,400 leukocytes/uL, 84.7% neutrophils and CRP 12.3mg/dL. Cranial CT scan revealed pansinusitis with right preseptal cellulitis. He was started on IV Amoxicillin+Clavulanic Acid. Due to clinical and analytical worsening after 3 days, cranial CT scan was repeated, which revealed worsening of the PC, epidural empyema and frontal subperiosteal abscess. Antibiotics were changed to IV ceftriaxone and metronidazole and bilateral ethmoid-maxillary sinusotomy was performed with external drainage of the frontal subperiosteal collection. He completed 4 weeks of antibiotic treatment, with full recovery. Cultures of the exudate from the paranasal sinuses and subperiosteal abscess were negative.
Learning Points/Discussion: Despite usually having a better prognosis, PC has potential serious complications such as subperiosteal and orbital abscess or intracranial empyema, even in the absence of postseptal involvement. Exuberant inflammatory signs or absent improvement after 24-48 hours of adequate antibiotics should lead to clinical and imaging assessment to exclude complications that may require surgical intervention.

EPSTEIN-BARR VIRUS (EBV) INFECTION IN PEDIATRICS: EXPERIENCE OF A PORTUGUESE HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Catarina Franquelim[1], Inês Monteiro[1], Inês Foz[1], Marta Almeida[1], Ana Lemos[2], Paulo Calhau[1]
[1]Hospital Garcia de Orta, Pediatria, Almada, Portugal, [2]Hospital Garcia de Orta, Patologia Clinica, Almada, Portugal

Backgrounds: EBV infection is usually subclinical or associated with infectious mononucleosis. Diagnosis is based on clinical suspicion complemented with laboratory data. Complications can occur, with a wide variety of symptoms that can lead to hospital admission. It can also be associated with long-term morbidity.
Methods: Retrospective observational study of pediatric patients with positive EBV serology and/or heterophile antibody test between January/2018-June/2022. Clinical and analytic data were collected and findings of admitted vs non-admitted patients were compared.
Results: Identified 107 patients (51,4% female) with acute infection, median age 12,8 years (IQR 5,7-15,8). The most frequent clinical manifestations were fever (78,5%), tonsillitis (78,5%), adenomegalies (62,6%), fatigue (26,8%), hepatomegaly (25,2%), splenomegaly (18,7%) and cutaneous rash (16,8%). Heterophile antibodies were found in 87,1% of tested patients, the remaining being diagnosed with serology. 53% had leukocytosis, 90% lymphocytosis (median of maximum absolute count 7900/uL, IQR:5090-11260/uL), 92% monocytosis (median of maximum absolute count 960/uL, IQR:550-1300/uL) and 89% stimulated lymphocytes. C-reactive protein was elevated in 88,6% of cases (median 1,62mg/dL, IQR:0,2-
28,2mg/dL) and transaminases in 81%. Complications included hepatitis (n=4), bacterial superinfection (n=3), severe cutaneous rash (n=2), febrile neutropenia, lupus flare, parotiditis, immune thrombocytopenia, Guillain-Barré syndrome and hemorrhagic gastritis. There were 20 hospitalizations (median age 7 years, IQR:2-15,7) with a median length of 3 days. Corticosteroids (n=8), antibiotics (n=4) or intravenous fluids (n=9) were administrated in some of the patients. Hospitalized patients had higher C-reactive protein measures (p=0,045). No differences were observed in admitted vs non-admitted patients regarding remaining analytic data.
Conclusions/Learning Points: This is the largest identified national casuistic of pediatrics' EBV infections. One-fifth of our patients required hospitalization, but C-reactive protein measure was the only significant difference found. More investigation is needed for a better understanding of complications risk.

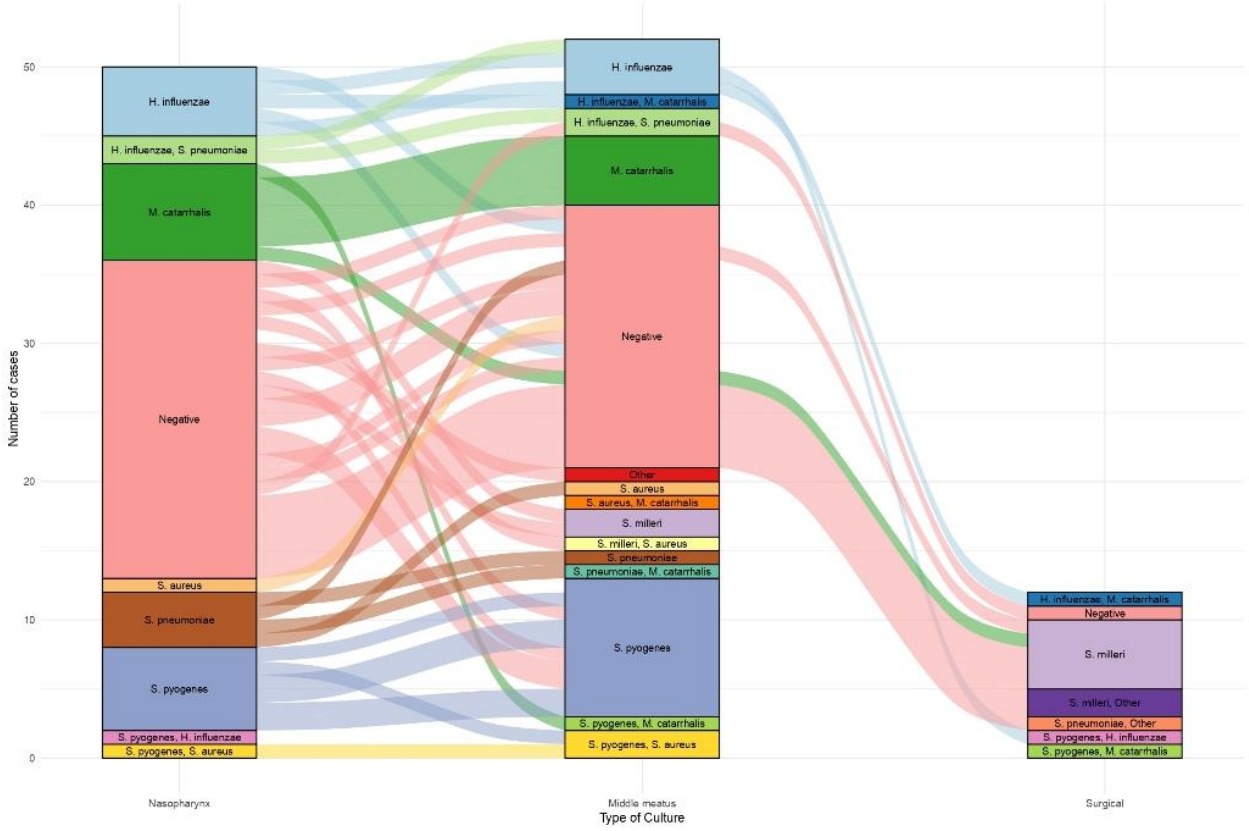
COMPLICATIONS TO ACUTE BACTERIAL RHINOSINUSITIS IN CHILDREN - A PROSPECTIVE STUDY; BACTERIAL CULTURES, VIRUS DETECTION, ALLERGY SENSITIZATION AND IMMUNOGLOBULINS

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Olof Hertting, Sofia Dennison
Paediatric Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden

Backgrounds: There are few prospective studies of complications due to acute bacterial rhinosinusitis (ABRS) in children. Microbial etiology is difficult to establish, and viral infection has been implicated in the pathogenesis of ABRS. The aim was to compare the bacterial findings from different anatomic sites, and to investigate the rate of concomitant viral infection.
Methods: Children up to 18 years of age, hospitalized due to acute bacterial rhinosinusitis, from April 1st, 2017 to April 1st, 2020 were prospecively included. Bacterial cultures from nasopharynx (NPH) and nasal middle meatus (MM), blood cultures, multiplex viral PCR swab from all and bacterial cultures and broad-range 16S rDNA PCR from the children undergoing surgery were obtained.
Results:



55 children were included. The MM cultures were positive for bacterial growth to a greater extent (69% compared to 54%) and showed a different set of bacteria compared to NPH cultures (Figure1). In 20 cases (36.4%). We found an association between S. pyogenes and maximum CRP ($p<0.01$). The most common bacteria found in surgical cultures was S. milleri (7/12 cases),S. pyogenes in middle meatus cultures (13/52 cases), and S. pyogenes and H. influenza in the nasopharyngeal cultures (8/50 cases respectively). 50% of surgical cases had negative nasal cultures and broad-range 16S rDNA PCR increased the number of positive results compared to cultures. Viral nasopharyngeal PCRs were positive

in 51% of the cohort and Influenza A was the most common. There was a significant association between influenza A/B and growth of S. pyogenes ($p<0.05$).
Conclusions/Learning Points: There seem to be differences in the patterns of bacterial growth in NPH, MM and surgical cultures in children with complications to ABRS. Viruses seem to play a role in complications to acute bacterial rhinosinusitis in children.

EOSINOPHILIC INFILTRATION OF THE LUNGS, ASSOCIATED WITH FASCIOLA HEPATICA

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Malvina Javakhadze[1,2], Irma Korinteli[3], Irina Korinteli[3], Karaman Pagava[3]
[1]Tbilisi State Medical University, Infectious Diseases Departament, T'bilisi, Georgia, [2]Acad.V.Bochorishvili clinic, Pediatric, T'bilisi, Georgia, [3]Tbilisi State Medical University, Department Of Pediatrics And Adolescents Medicine, T'bilisi, Georgia

Title of Case: EOSINOPHILIC INFILTRATION OF THE LUNGS, ASSOCIATED WITH FASCIOLA HEPATICA
Background: Eosinophilic infiltration of the lungs associated with parasitic diseases is rare.Only a few cases are described in the literature
Case Presentation Summary: We aimed to describe a case of eosinophilic infiltration of the lungs, associated with Fasciola hepatica. A 10-year-old boy was admitted to the pediatric emergency medicine department. The patient had a fever for 12 days. Cough developed later. The prenatal, birth, and neonatal period was without pathologies. For clinical assessment, It was presented: Tachypnea, shortness of breath, and dry cough. Decrease of breathing sounds in the right lower lobe for auscultation. The abdomen was soft for palpation. Other organ systems were presented without pathological changes. In laboratory studies, it was noted: leukocytosis ($21.3*10^9$/L), Neutropenia ($5.1*10^9$/L) Lymphopenia ($4.1*10^9$/L) Eosinophilia ($10.4*10^9$/L), ESR- 39mm/hr and CRP- 39mg/L.On the chest X-ray detected infiltration of the right lower lobe. Abdomen USE without pathologic changes.2 possible diseases were selected for differential diagnosis according to the patient's clinical and laboratory tests: Hematologic malignancy, Parasitic infection. A serological test was conducted on common parasites and Anti-Fas2 IgM F.Hepatica become positive. The egg was not found in stools. The primary diagnosis was eosinophilic infiltration of the lungs associated with F.hepatica.The patient continued treatment in a specialized clinic with triclabendazole. Broncho alveolar lavage was performed and eosinophils were detected (Eos-41%) 3-4 days after treatment F.hepatica eggs were found in stool. The patient's symptoms improved and he left the hospital.
Learning Points/Discussion: Conclusion: Eosinophilic infiltration of the lungs associated with F.hepatica is a rare condition and Parasitic diseases should be considered in etiology. Early diagnosis is important for rational anthelmintics treatment. serologic testing for common parasites may be more informative than stool analysis.

EMM TYPES OF BIOFILM-FORMING PHARYNGEAL ISOLATES OF GROUP A STREPTOCOCCI IN SCHOOL CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Thangam Menon[1], Divya Bajoria[2]
[1]Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences, Dept Of Microbiology, Chennai, India, [2]Dr ALM PG Institute of Basic Medical Sciences, University of Madras, Dept Of Microbiology, Chennai, India

Backgrounds: Group A Streptococci (GAS) are responsible for a diverse spectrum of diseases, including pharyngotonsillitis. Persistent asymptomatic GAS throat carriage is due to streptococcal internalization in epithelial cells or biofilm formation. Several virulence factors play an important role in biofilm formation in GAS, particularly the M protein, which is required for initial cell-surface interactions. The objective of this study was to detect slime production and biofilm forming ability of GAS isolated from children with pharyngotonsillitis and asymptomatic carriers and to determine their emm types.
Methods: Fifty strains of GAS isolated from school children (21 from pharyngotonsillitis and 29 from asymptomatic pharyngeal carriers) were screened for their ability to produce slime and biofilm. Slime formation was detected by the Congo Red agar method and biofilm formation was assayed by the crystal violet microtiter plate method. The strains were emm typed according to the standard CDC protocol(http://www.cdc.gov/ncidod/biotech/strep/protocol_emm-type.htm).
Results: All the 50 isolates tested were slime producers of which 92% were strong slime producers. Seventeen of the 50 isolates (34%) were biofilm producers.The isolates from pharyngotonsillitis belonged to 12 emm types showing 57.14% heterogeneity, while the carrier isolates belonged to 19 emm types showing 65.51% heterogeneity. Thirteen out of the 50 isolates (26%) were emm89.0b. Eleven different emm types were observed among the 17 biofilm positive isolates. The most common emm type was emm89.0b. Many of biofilm positive emm types were also found among the biofilm negative strains.
Conclusions/Learning Points: The most common emm type reported in our study was emm89.0b. The emm-types associated with biofilm positive strains in our study were extremely heterogenous. Hence biofilm formation appeared to be an inherent property of individual GAS isolates rather than a general attribute of the serotype.

ADENOVIRUS INFECTION IN CHILDREN. A DESCRIPTIVE STUDY

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Carmen García Malagón[1], Jose Gil Arenas[1], Alvaro Villarejo Perez[1], Walter Goycochea Valdivia[1], Dolores Falcon Neyra[1], Peter Olbrich[1], Laura Fernandez Silveira[1], Marisol Camacho Lovillo[1], Maria Muñoz Vilches[1], Laura Merino Diaz[2], Jose Antonio Lepe Jimenez[2], Pedro Camacho Martinez[2], Olaf Neth[1]
[1]Hospital Universitario Virgen del Rocío, Servicio De Infectología, Reumatología E Inmunología Pediátrica, Sevilla, Spain, [2]Hospital Universitario Virgen del Rocío, Servicio De Enfermedades Infecciosas, Microbiología Y Parasitología. Hospital Universitario Virgen Del Rocío, Sevilla., Sevilla, Spain

Backgrounds: Adenovirus infection (AI) in children commonly presents with a wide variety of clinical presentations, including high fever and increased acute phase reactants (APR). Differential diagnosis includes bacterial infections and frequently, these patients receive a short-course empirical antibiotic therapy. This study aims to describe the spectrum of AI.
Methods: Review of clinical and analytical features of AI diagnosed with RT-PCR from nasopharyngeal exudates of children with symptoms in a tertiary hospital, between February 2021 and October 2022.
Results: • Clinical specimens from 175 pediatric children with symptoms compatible with AI were studied. 73 (41.7%) samples were detected by RT-PCR (29 girls/ 44 boys) with a median age of 36 months (IQR: 16-55). Most frequent symptoms were: fever (95.9%), ear, nose and throat related symptoms (60.3%), upper respiratory symptoms (58.9%), vomiting and/or diarrhea (57.6%), conjunctival injection (28.8%), respiratory distress (12.3%) or cutaneous rash (11%). The median duration of fever was 4 days (IQR: 2-5). Median rise in APR was: 13440 leukocytes (IQR: 10400-16797), 8600 neutrophils (IQR: 6330-11610), 2600 lymphocytes (IQR: 1555-4160), C-reactive protein (CRP) 77 mg/L (IQR: 36.75-143). • 44 children (60.3%) required hospital admission, with a median length of stay of 3 days (IQR: 1.5-5), and up to 52.3% children received empirical antibiotic therapy (more frequently cephalosporins [34.1%]) with a median duration of 3 days (IQR: 2-4.5). Viral and bacterial coinfection was identified in 19.3 % and 4.1%, respectively.
Conclusions/Learning Points: AI often presents with an APR response, similar to bacterial infections, with CRP values above 70mg/l in our series. More than a half of these patients were hospitalized and received antibiotics, thereby unnecessarily increasing antibiotic pressure and hospital stays. Further studies are needed to develop accurate diagnostic and management algorithms.

LYMPHOCYTOSIS AND ADENOMEGALY: THE CHALLENGE OF THE DIFFERENTIAL DIAGNOSES

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Joana Neto, Alice Martins, Beatriz Carmo, Íris Ascenção, Irene Carvalho
Centro Hospitalar S João, Pediatrics, Porto, Portugal

Title of Case: Distinguishing haemato-oncological cancer from infectious mononucleosis
Background: In pediatric age, peripheral lymphadenopathies are frequent, particularly when associated with changes in the white blood count. Differential diagnoses are numerous, and it is imperative to exclude serious and potentially treatable causes, from those that are benign and do not need targeted therapy.
Case Presentation Summary: A 2-year-old male child is admitted at the Emergency Department for rhinorrhea, dry cough and painless, mobile, and elastic cervical, axillary, and inguinal adenomegalies for the last 24 hours. He also had bilateral tonsillar hypertrophy and hyperemia, without hepatosplenomegaly. He completed the seventh day of amoxicillin-clavulanate due to acute otitis media, diagnosed in the previous week. The analytical study showed leukocytosis 13620/uL with lymphocytosis (8200/uL, atypical lymphocytes 286/uL) and cells suggestive of lymphoblasts (1185/uL) in the peripheral blood smear (PBS). He was admitted into the Paediatrics Department to continue the etiological study. The PBS was repeated and revealed reactive lymphocyte and monocyte population with no lymphoblasts therefore excluding haemato-oncological disease. An abdominal ultrasonography was performed, which showed the already known adenopathy with reactive characteristics. From the etiological study, positive IgM for the Epstein Barr Virus stood out, which allowed the diagnosis of Infectious Mononucleosis. The child was discharged without directed therapy and was reassessed in consultation with complete resolution of the clinical picture.
Learning Points/Discussion: Infectious Mononucleosis is a common disease in pediatric age and the differential diagnosis with the haemato-oncological diseases is not always straight. Invasive and unnecessary exams should be avoided and carefully weighted as they can harm more than benefit. This case also highlights that malignant diagnosis should not be communicated to the patients and their families, when not for certain because they can carry unnecessary burden and impact on their lives.

UNUSUAL PRESENTATION OF SCARLET FEVER – CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Ana Sofia Nunes, André Morais, Cláudia Gonçalves, Sofia Miranda, Joana Macedo
Hospital de Braga, Paediatric Department, Braga, Portugal

Title of Case: UNUSUAL PRESENTATION OF SCARLET FEVER – CASE REPORT
Background: Scarlet fever is caused by an endotoxin produced by group A Streptococcus (GAS). Usually presents as a confluent, rough textured maculopapular rash associated with fever and pharyngitis. However, atypical presentations are described in literature.
Case Presentation Summary: Previously healthy 2-year-old boy was admitted in our emergency department with a 36-hour history of fever, rash, joint swelling and vomiting. Loss of consciousness, respiratory distress and angioedema were denied. No known history of allergies.
At presentation, he was apiretic and hemodynamically stable. We observed erythema of the pharynx and a blanchable, confluent, rough textured maculopapular rash, more prominent in the trunk and skin folds, sparing palms and soles. Furthermore, he presented a non-painful oedema and redness on knees, elbows and hands. Some purpuric lesions were noticed in both legs. No gait impairment was noticed. Blood tests revealed a slight increase of inflammatory markers (RCP 84.50 mg/L), prothrombin time (15.5 seconds) and INR (1.34), but normal complete blood count. Serology testing was negative to Epstein-Barr virus, cytomegalovirus and adenovirus. Rapid antigen detection test to GAS was positive. Therefore, this case was interpreted as an unusual presentation of scarlet fever and the child was treated with benzylpenicillin and clemastine, with joint swelling improvement. Discharged under desloratadine. After 24 hours he became apyretic and the rash started to fade 2 days later with light desquamation.

Learning Points/Discussion: Unusual presentations of scarlet fever can be misdiagnosed with other entities leading to treatment delaying and potential major complications. This case highlights the relevance of early identification, particularly when cases of invasive GAS are increasing. Thereby, the knowledge of toxin-producing strains could be a useful tool to better understand the variation of clinical presentation.

[1]Universitas Indonesia Hospital, Department of Child Health, Faculty of Medicine Universitas Indonesia, Department Of Child Health, Depok, Indonesia, [2]Universitas indonesia, Universitas Indonesia Hospital, Child And Health Department, Depok, Indonesia

Title of Case: PERTUSSIS MANIFESTING AS RECURRENT COUGH AND HYPERLEUKOCYTOSIS WITH COMPLICATION OF SEIZURE IN AN INCOMPLETELY VACCINATED 12-MONTH-OLD- INFANT
Background: The COVID-19 pandemic has affected healthcare services and access globally, including vaccination coverage in children, contributing to the rising incidence of vaccine-preventable diseases (VPDs). Pertussis, one of the VPDs, is an acute respiratory illness caused by Bordetella pertussis, showing a re-emergence in developed countries.
Case Presentation Summary: We reported a case of 12 months old boy who was referred to our hospital due to a history of seizures and hyperleukocytosis with a white blood count (WBC) of 75.000/mL predominantly by lymphocytes. A brain computed tomography scan was performed with hypoxic encephalopathy as a result. A blood smear showed a 3% of blast hence bone marrow puncture was performed. A 21% blast was found in the peripheral blood smear that supports the suspicion of acute leukemia but the immunophenotyping showed otherwise. We found a history of recurrent cough since the age of 2,5 months old and pneumonia at the age of 3,5 months old. Several kinds of antibiotics were given including beta-lactam antibiotics but no macrolides had been prescribed until that point. The patient only received 1 dose of pertussis vaccination at 2 months old. Several episodes of cyanosis during the cough made us consider a potential diagnosis of pertussis in the patient. The polymerase chain reaction from the nasopharynx swab was then performed and showed positive for Bordetella pertussis. The patient was given azithromycin considering the clinical suspicion and once the diagnosis of pertussis was confirmed the therapy was administered for 7 days and the infant recovered completely.
Learning Points/Discussion: Pertussis can manifest through an atypical course of disease in infants and as a high-risk population, herd immunity is needed.

[1]Alma Mater Studiorum, University of Bologna, Specialty School Of Pediatrics, Bologna, Italy, [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, 40138 Bologna, Italy, Pediatric Emergency Unit, bologna, Italy, [3]IRCCS Azienda Ospedaliero-Universitaria di Bologna, 40138 Bologna, Italy, Pediatric Emergency Unit, Bologna, Italy

Backgrounds: Acute otomastoiditis (AOM) is a severe infection potentially developing from an acute otitis media. AOM could be responsible for severe life-threatening complications. Aim of the study: To describe the epidemiology of AOM in our tertiary care Centre and to evaluate risk factors for possible complications.
Methods: We enrolled children admitted to our Pediatric Unit in the past 20 years, diagnosed with AOM according to the ICD-11th Revision codes. We collected demographic and clinical data and compared clinical outcomes between children with and without complications and children younger and older than 2 years. We performed a multivariate logistic regression to identify risk factors for complications of AOM, including clinical and laboratory predictors as independent variables.
Results: We enrolled 214 patients for a total of 222 cases. Mean (SD) age was a 5.2 (3.9) years. Earache was the main symptom (n=173, 78%), followed by fever (n=155, 70%). The most common findings were erythema (n=166, 75%) and edema (n=157, 71%) in the retroauricolar area. All patients received antibiotics, mainly ceftriaxone (n= 206, 93%). Imaging was performed in 52 (23%) cases, mostly CT (40/52 cases). Intracranial complications of AOM occurred in 29 (13%) patients and subperiosteal abscess was the most frequent finding. Surgery was necessary in 22 (10%) patients. In spite of a more prolonged parenteral treatment, children younger than 2 years had a similar incidence of complications of older patients. A positive blood culture was found as an independent risk factor for complications in the multivariate logistic regression.
Conclusions/Learning Points: Our study describes the clinical and laboratory characteristics of a large pediatric population with AOM. Blood culture should be obtained in these patients, to identify children at higher risk for complications.

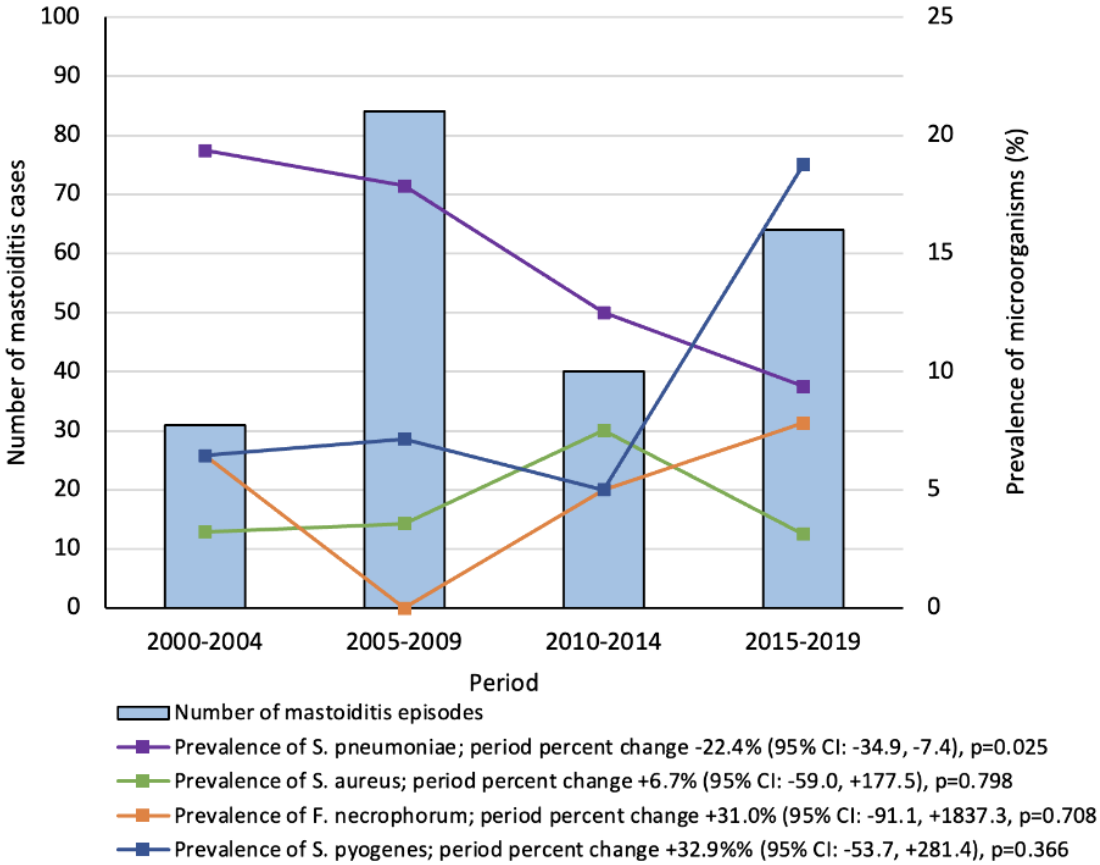
CHANGES IN THE EPIDEMIOLOGY OF ACUTE MASTOIDITIS AFTER THE IMPLEMENTATION OF PNEUMOCOCCAL VACCINATION IN A SPANISH POPULATION.

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Ángela Manzanares[1], David Aguilera-Alonso[2], María Del Mar Santos Sebastián[3], María Escobar[2], Sara Vigil-Vázquez[2], Felipe González-Martínez[2], Gracia Aránguez Moreno[2], Emilia Cercenado[4], Jesus Saavedra-Lozano[5]
[1]12 de Octubre University Hospital, Pediatric Infectious Diseases, Madrid, Spain, [2]Hospital Universitario, Gregorio Marañón, Madrid, Spain, [3]Gregorio Marañón University Hospital, Infectious Diseases Department, Madrid, Spain, [4]Hospital Universitario Gregorio Marañon, Microbiology, Madrid, Spain, [5]Hospital Universitario Gregorio Marañón, Infectious Diseases Unit, Madrid, Spain

Backgrounds: The aim of our study was to describe changes in the epidemiology and etiology of acute mastoiditis (AM) over a 20-year period in relation to the implementation of pneumococcal conjugated vaccines (PCV).
Methods: Retrospective study at Gregorio Marañón Hospital (Madrid). Episodes of AM in children <16 years from 2000-2019 were included. Demographics, clinical and microbiological variables were collected from the medical charts. The study was grouped into four 5-year periods. The percentage change (PC) in the incidence rate and in the prevalence of each microorganism isolated within the study periods were estimated to characterize trends.
Results: 219 episodes from 209 patients were included: 125(59.8%) males; median age 19(IQR 13-35) months. The incidence rate of AM remained stable (PC:+27.2%[95%CI:2.6; +139.8];p=0.163). Ninety-one (41.6%) episodes had some microbiological isolation. S. pneumoniae was the most common (32/91,35.2%), although its prevalence decreased from 19.4% in the first, to 9.4% in the last period (PC:-22.4%[95%CI:−34.9,-7.4];p=0.025). Serotypes were identified in 18/32(54.5%) isolates, and 19A was the most frequent (11/18;61.1%). PCV13 serotypes significantly decreased in the post-PCV13 period (p=0.022). Non-susceptibility to standard-dosing penicillin (75%vs.27.2%;p=0.022) and cefotaxime (62.5%vs.9%;p=0.08), and resistance to erythromycin (68.8%vs.27.3%;p=0.034) significantly decreased within the study period, and were associated with serotype 19A (p=0.002;p=0.013;p=0.002, respectively).



Conclusions/Learning Points: The incidence of AM remained stable in our study with significant changes in its etiology. Thus, whereas the prevalence of S. pneumoniae significantly decreased in the post-PCV era, S. pyogenes emerged as the main etiological agent after the implementation of PCV13.

OTOGENIC LEMIERRE'S-LIKE SYNDROME SECONDARY TO COMPLICATED, DISSEMINATED BACTEROIDES FRAGILIS GROUP INFECTION IN A CHILD WITH BILATERAL CHRONIC SUPPURATIVE OTITIS MEDIA

E-Posters Viewing
E-POSTER VIEWING: AS08.C. ENT INFECTIONS

Natalie Yap[1], Grace Butel-Simoes[2,3], Natasha Ching[1], Kimberly Davis[1], Matthew O'Brien[1], Jeremy P Carr[1,4]
[1]Monash Children's Hospital, Department Of Infection And Immunity, Clayton, Australia, [2]Monash Health, Department Of Infectious Diseases, Clayton, Australia, [3]Monash Health, Department Of Microbiology, Clayton, Australia, [4]Monash University, Department Of Paediatrics, Clayton, Australia

Title of Case: Otogenic Lemierre's-like syndrome secondary to complicated, disseminated Bacteroides fragilis group infection
Background: Lemierre's syndrome is a rare but potentially life-threatening infection resulting in septic thrombophlebitis of the internal jugular vein(IJV) often complicated by multifocal, septic emboli. The classic form follows Fusobacterium necrophorum pharyngitis however, it may follow mastoiditis or sinusitis. We report a case of otogenic Bacteroides fragilis Lemierre's-like syndrome.
Case Presentation Summary: A 9-year-old boy with chronic suppurative otitis media was admitted to PICU with septic shock following eight days of fevers, otorrhoea and neck pain. Investigations demonstrated bilateral mastoiditis, subdural empyema and occlusive thrombus(sigmoid sinus to the IJV) with pleural effusions and multiple embolic, cavitary pulmonary abscesses. He underwent bilateral mastoidectomies and drainage of the subdural empyema and pleural fluid. Bacteroides fragilis group was isolated in the blood culture and pleural fluid. Meropenem and vancomycin were rationalised to ceftriaxone and metronidazole upon clinical improvement. Susceptibility testing performed by gradient MIC strip method at two different laboratories using different anaerobic breakpoints(EUCAST or CLSI) revealed different susceptibilities(Table 1). Despite reported resistance according to EUCAST breakpoints, there was significant improvement with meropenem and/or metronidazole prior to the availability of susceptibility testing. Oral moxifloxacin was changed to amoxicillin/clavulanic acid to complete 6 weeks of antibiotics following source control with an excellent clinical outcome.

Table 1. Minimum Inhibitory Concentrations for *Bacteroides fragilis group* blood culture and pleural isolates

	Interpretation / Minimum Inhibitory Concentration mg/L (MIC)		
	Blood culture isolate 23/9/22 (CLSI breakpoints)	**Pleural isolate 5/10/22 (CLSI breakpoints)**	**Pleural isolate 5/10/22 (EUCAST breakpoints)**
Antibiotic			
Amoxycillin/Clavulanic acid	Susceptible (MIC 2)	Susceptible (MIC 2)	No interpretable breakpoint (MIC 1)
Meropenem	Susceptible (MIC 4)	Intermediate (MIC 8)	Resistant (MIC 2)
Metronidazole	Susceptible (MIC 4)	Intermediate (MIC 16)	Resistant (MIC 8)
Moxifloxacin	Resistant (MIC 16)	Susceptible (MIC 0.5)	No interpretable breakpoint (MIC 0.38)

Learning Points/Discussion: Lemierre's syndrome may extend beyond the classic form and should be considered in complicated or severe mastoiditis, with systemic features. Susceptibility testing of anaerobic isolates should be considered in severe infections however clinical correlation is not always clear.

Bacteroides fragilis resistance to meropenem and metronidazole is described but gold standard in-vitro testing is often not available to confirm the MIC. Different methodologies may lead to variability in the MIC and the categorisation of susceptibility.

A CASE OF TUBERCULOUS LYMPHADENITIS INFECTION PRESENTING MAINLY AS A SINGLE SUPRACLAVICULAR ADENOPATHY IN A PATIENT FROM A HIGH TUBERCULOSIS INCIDENCE COUNTRY

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Madalena Afonso[1], Ana Pereira[1], Marta Pelicano[1], Inês Belo[1], Ana Margarida Garcia[2], Rita Morais[1], Paula Nunes[1]
[1]Centro Hospitalar Lisboa Ocidental - Hospital de São Francisco Xavier, Serviço De Pediatria, Lisboa, Portugal, [2]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatrics Infectious Diseases Unit, Lisbon, Portugal

Title of Case: Cervical Lymphadenopathy: Remember the Old Foe
Background: Tuberculosis is one of the most widespread infectious diseases worldwide. Since 2015, Portugal is considered a low incidence country. Extrapulmonary tuberculosis is more frequent in children and tuberculous cervical lymphadenitis is the most common presentation.
Case Presentation Summary: A 16-year-old Bangladeshi girl, living in Portugal for six months, was admitted with a 1-month history of fatigue, 2-week history of a progressively enlarging right supraclavicular mass, intermittent headache, cough and nocturnal fever. She denied weight loss. Physical examination showed a hard, painful, right supraclavicular mass 5cm wide, adherent to underlying tissue, with undefined borders and no inflammatory signs. She had no other palpable masses. Computed tomography scan revealed a heterogeneous supraclavicular adenopathy conglomerate, with central necrosis and densification of surrounding fat, without other adenopathies, pulmonary or abdominal lesions. Fine needle aspiration showed inflammatory cells and no evidence of malignancy. Search for possible viral and bacterial causes was negative. Tuberculin skin test read at 48 hours and interferon gamma release assay were positive, pointing towards tuberculosis infection. Lymphnode incisional biopsy was performed with nucleic acid amplification test and mycobacterial culture, which was positive for M. tuberculosis, confirming the diagnosis of tuberculous lymphadenitis. The patient started antituberculosis therapy (with isoniazid, rifampin, pyrazinamide and ethambutol for two months followed by isoniazid and rifampin for four months) and monthly follow-up. Family members were screened.
Learning Points/Discussion: While investigating a patient with supraclavicular adenopathy, excluding neoplastic etiology is of paramount importance. Nevertheless, infectious diseases should always be contemplated. Due to the significant rate of immigrants from high incidence countries, clinicians should consider tuberculosis when these children present with cervical adenopathy.

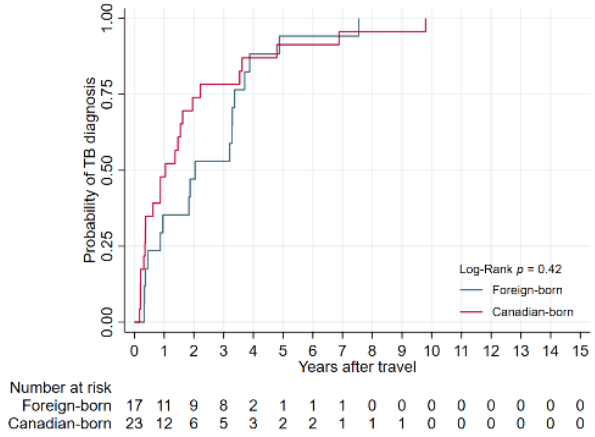
PV0729 / #942

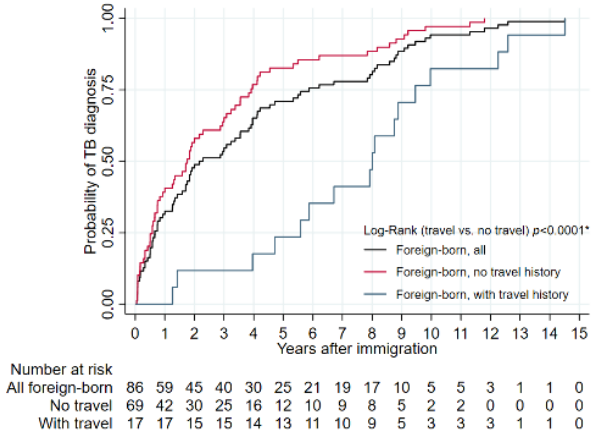
EPIDEMIOLOGY OF INTERNATIONAL TRAVEL AS A MODE OF DISEASE ACQUISITION AMONG CANADIAN- AND FOREIGN-BORN CHILDREN WITH TUBERCULOSIS — TORONTO, ONTARIO, 2002–2018

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Mohsin Ali[1], Melanie El Hafid[1], Daniel Farrar[2], Haifa Kourdi[1], Shaun Morris[2], Valerie Waters[1], Ray Lam[1], Ian Kitai[1]
[1]The Hospital for Sick Children, Paediatrics, Division Of Infectious Diseases, Toronto, Canada, [2]Hospital for Sick Children, Centre For Global Child Health, Toronto, Canada

Backgrounds: In most low-burden settings, travel data is not routinely collected for tuberculosis (TB) case notification. We analyzed travel-related epidemiologic risk factors for disease transmission among children with TB.
Methods: We reviewed data for all children treated for TB disease in Toronto's regional pediatric TB program from 2002–2018. Birthplace, migration, and travel histories were prospectively obtained at clinic enrolment. Countries with annual TB incidence over 20 cases per 100,000 population, matched to year of travel departure, were considered endemic. Travel-related epidemiologic risk factors were analyzed among source-negative patients.
Results: Of 221 children with TB disease, 110 (50%) were foreign-born and 111 (50%) Canadian-born, among whom 95% had at least one foreign-born parent. 71 (32%) patients travelled to a TB-endemic country, 61 (86%) of whom to a country of either parent's birth. Among 122 source-negative patients, 23/35 (66%) Canadian-born versus 17/87 (20%) foreign-born children had travelled to a TB-endemic country (p<0.001); 66% of trips departed in June, July, December, or January, coinciding with summer and winter school holidays. Median (interquartile range) time from travel to diagnosis was 1.0 (0.4–2.2) years for Canadian-born children and 2.0 (0.9–3.4) years for foreign-born children (p=0.42; Figure 1A). Time from immigration to diagnosis was substantially longer among foreign-born patients with a post-immigration travel history than those without (8.0 [5.6–9.5] vs 1.7 [0.5–3.9] years, p<0.0001, Figure 1B), supporting travel as the likely source of TB in this subgroup.





Conclusions/Learning Points: Travel to a TB-endemic country plausibly accounted for about one in three source-negative cases and one in five cases overall. Epidemiologic patterns among both domestic- and foreign-born children suggest that travelers were likely visiting friends and relatives. Clinical and public-health measures to prevent travel-related pediatric TB disease should be developed and evaluated.

DIFFERENCES BETWEEN NON-TUBERCULOUS MYCOBACTERIAL PULMONARY AND CERVICAL LYMPH NODE INFECTIONS.

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Marina Ascunce Abad[1], Alejandra Coccolo Góngora[1], Yasmina Mozo Del Castillo[2], Paula Rodríguez-Molino[3], Fernando Baquero-Artigao[3], Carlos Toro Rueda[4], Paloma Garcia Clemente[4], Cristina De Manuel Gómez[5], Marta Ruiz De Valbuena[5], Cristina Calvo[3], Carlos Grasa[3], Ana Méndez Echevarría[3], Talia Sainz[3], Dolores Corral Sanchez[2], David Bueno Sánchez[2], Luisa Sisini[2], Antonio Pérez-Martínez[2], Teresa Del Rosal[3]
[1]La Paz University Hospital, Paediatrics, Madrid, Spain, [2]La Paz Universitary Hospital, Paediatrics Haemato-oncology, Madrid, Spain, [3]La Paz Universitary Hospital, Pediatric Infectious Diseases, Madrid, Spain, [4]La Paz Universitary Hospital, Microbiology, Madrid, Spain, [5]La Paz Universitary Hospital, Paediatric Pulmology, Madrid, Spain

Backgrounds: Incidence of nontuberculous mycobacterial (NTM) infections has risen during the past years. While the most frequent presentation in children is cervical adenitis, pulmonary and disseminated infections are less common. There are few paediatric studies comparing these infections.
Methods: Retrospective comparative study of culture-confirmed NTM pulmonary and lymph node infections in patients aged 0-18 years, from 2013 to 2022, in a tertiary hospital.
Results: 34 patients were included: 12 (35%) pulmonary infection, 22 cervical lymphadenitis. Median age was lower in lymphadenitis (22 months [IQR 19.7-28.2] vs 169.5 months [IQR 98-192.5], p<0, 01). All patients with lung disease had chronic conditions, mainly immunodeficiency (n=5, 42%) or cystic fibrosis (n=6, 50%), whereas all patients with adenitis were previously healthy. The most common pathogen in respiratory infection was Mycobacterium avium (n=6, 50%), while in lymph node infection was Mycobacterium lentiflavum (n= 16, 72%). All patients with lung disease and the majority of patients (86%) with lymphadenitis received combined antibiotic therapy. Therapy was longer in pulmonary infections (median of 48 weeks [IQR 8-54] vs 16 weeks [IQR 3.3-24], p 0.238). Fifteen patients with adenitis (68%) underwent surgery. Four patients with pulmonary disease had a relapse after eradication, without any lymph node infection relapsing (p 0.01). Four patients died (12%), being all immunocompromised patients with NTM lung disease. NTM infection contributed to two deaths.
Conclusions/Learning Points: Lymphadenitis is the most common presentation of NTM infection, affecting young and healthy children, and has an excellent prognosis. Pulmonary infections affect older children with immunodeficiency or cystic fibrosis and can recur despite longer treatments. In our setting, the most frequent pathogens are M. avium in pulmonary infection and M. lentiflavum in adenitis.

TREATMENT OF MULTIDRUG-RESISTANT TUBERCULOSIS IN THE CHILD PRESENTING WITH ITP-LIKE CLINIC AND IN CHILDREN LIVING TOGETHER

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Burcu Parlak[1], Seyhan Yılmaz[1], Sevgi Aslan Tuncay[1], Zeynep Ergenç[2], Ela Eralp[1], Duygu Yılmaz[1], Aylin Babalık[3], Yasemin Gökdemir[1], Eda Kepenekli[1]
[1]Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Marmara University School of Medicine, Pediatric Infectious Diseases, Istanbul, Turkey, [3]Health Sciences University, Süreyyapaşa Chest Diseases and Thoracic Surgery Training and Research Hospital, Chest Diseases, İstanbul, Turkey

Title of Case: Treatment of multidrug-resistant tuberculosis in the child presenting with ITP-like clinic and in children living together
Background: Multidrug-resistant tuberculosis (MDR-TB) is the resistance of the tuberculosis bacillus to both isoniazid and rifampicin. It is estimated that approximately 25,000–32,000 children develop multidrug-resistant or rifampicin-resistant tuberculosis each year. Mortality is reported to be approximately 22% in children with multidrug-resistant tuberculosis
Case Presentation Summary: In June 2021, the oldest child first applied with the complaint of bleeding from the mouth and nose. In the foreground, ITP (immune thrombocytopenic purpura) was accepted as the diagnosis and steroid treatment was administered. She did not benefit from intravenous immunoglobulin treatment. On the 2nd day of steroid treatment, platelets still did not increase. Platelets increased with platelet replacement. Then, the information that the mother had tuberculosis and MDR-TB came. Contact screening was performed on four more children, the mother's three other children and a niece living in the same household. All of the children were girls and their ages were 15,13,12, six and one and a half years old. The symptoms, findings, treatment and side effects of the patients are given in the table.
Learning Points/Discussion: Diagnosis and treatment may be delayed due to the non-specificity of tuberculosis symptoms in children, the difficulty of microbiological tests and the low sensitivity of diagnostic tests. MDR-TB should be considered in children with adult contact known to have MDR-TB, although isoniazid and rifampicin resistance were not detected by culture result. Management of MDR-TB in pediatric patients is a process that requires patience and dedication. The use of unapproved second-line drugs in children is necessary to treat life-threatening MDR-TB, but careful monitoring is required to recognize dose- and duration-dependent drug adverse events quickly.

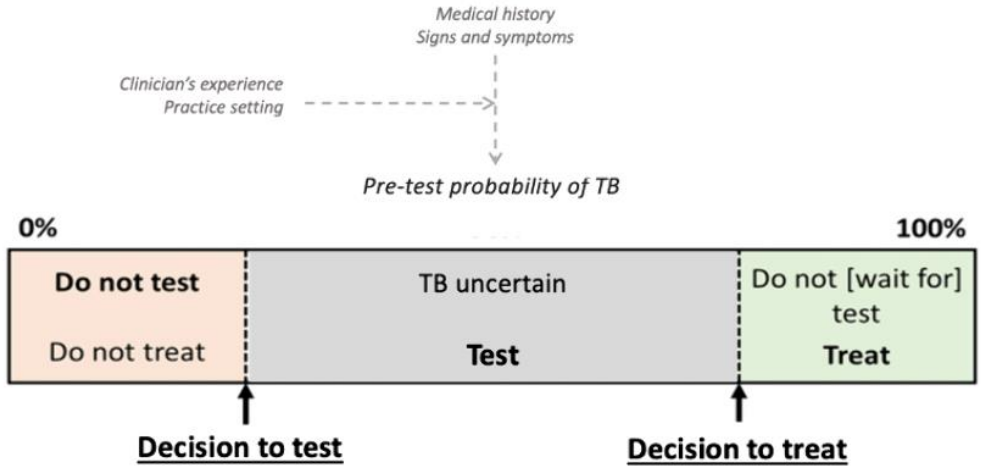
UNCERTAINTY IN PEDIATRIC TUBERCULOSIS CLINICAL DECISION-MAKING: FINDINGS FROM A SYSTEMATIC UMBRELLA REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Francesca Wanda Basile[1], Sedona Sweeney[2], Else Bijker[1], Maninder Pal Singh[2], Ted Cohen[3], Nicolas Menzies[4], Anna Vassall[2], Pitchaya Indravudh[2]
[1]University of Oxford, Paediatrics, Oxford, United Kingdom, [2]London School of Hygiene and Tropical Medicine, Faculty Of Public Health And Policy, London, United Kingdom, [3]Yale School of Public Health, Department Of Epidemiology Of Microbial Diseases, New Haven, United States of America, [4]Harvard T H Chan School of Public Health, Department Of Global Health And Population, Boston, United States of America

Backgrounds: In clinical decision-making, the threshold model represents test/treatment decisions based on pre- and post-test probabilities of disease. In resource-limited settings, additional contextual factors may influence thresholds, contributing to uncertainty in the decisional process. This umbrella review aimed to identify factors influencing pediatric TB decision-making and underlying sources of uncertainty.
Methods: Systematic reviews were searched in seven databases (MEDLINE, CINAHL®Complete, Embase, Scopus, Cochrane, PROSPERO, Epistemonikos) and selected using predetermined criteria. Results were thematically analyzed based on sources of uncertainty (patient, provider, health system, diagnostic test) and classified as barriers and facilitators for testing or treatment decisions.
Results: 24 reviews were included. Study designs and primary aims were heterogeneous, with seven meta-analyses and three qualitative evidence syntheses. Provider-level facilitators for test decisions included an advanced professional qualification and confidence in tests. Important diagnostic test characteristics included automation, non-sputum-based assays, and quick turnaround times. Main barriers for testing included poor provider TB knowledge and lack of diagnostic, infrastructural, and administrative resources. Fear of acquiring TB through respiratory sampling, complexity, and invasiveness of collection technique (e.g., gastric aspirate) were additional barriers for testing. Facilitators for empiric treatment included patients' young age, severe sickness, and test inaccessibility. Barriers to treatment included a history of previous TB, unknown TB exposure, providers' high confidence in negative test results (irrespective of true negative predictive value) and fear of TB drugs side effects.
Conclusions/Learning Points: Complex determinants of uncertainty influence pediatric TB decision-making. Provider and health system factors, in addition to patient and diagnostic test factors, should be addressed to optimize testing and treatment decision-making. Pragmatic trials at the point-of-care are needed to ensure that provider characteristics and the operating context are considered early during the development of diagnostic tests and decision

algorithms.



Facilitators	**Provider:** public sector employment, high level of qualification, confidence in diagnostic tests **Health system:** public/urban facility **Diagnostic test:** automation/computer-based technology, good sensitivity, non-sputum-based test, short waiting time for results	**Patient:** young age, sick hospitalized child **Health system:** high testing costs, lack of diagnostic resources **Diagnostic test:** low sensitivity in paucibacillary TB, invasiveness
Barriers	**Provider:** low TB knowledge, informal provider, private sector employment, fear of acquiring TB, TB/HIV stigma **Heath system:** undertrained staff, diagnostics and PPE stock-outs, poor infrastructure, peripheral setting, no local guidelines **Diagnostic test:** invasiveness, sample collection complexity	**Patient:** previous TB diagnosis, no known TB exposure **Provider:** high confidence in negative test result (even if low NPV), fear of TB drugs side effects

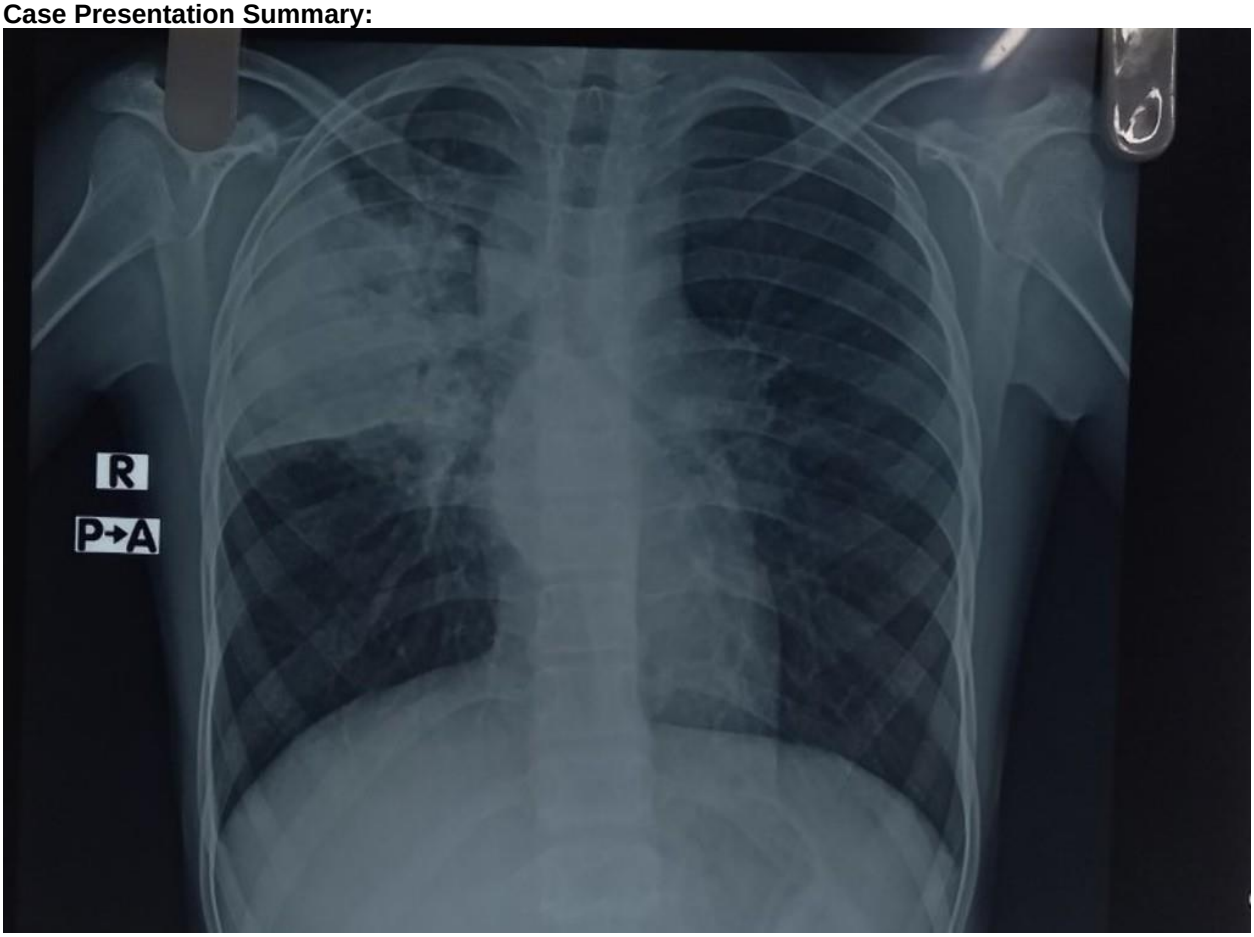
13 YEAR OLD WITH DELAYED DIAGNOSIS OF PULMONARY TUBERCULOSIS

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Gunjan Baweja, Rajdeep Singh
J. P. Medical Centre, Pediatrics, Chandigarh, India

Title of Case: 13-YEAR-OLD GIRL WITH DELAYED DIAGNOSIS OF PULMONARY TUBERCULOSIS
Background: With a burden of disease that accounts for more than 10 million new cases per year, of which less than two-thirds are reported, tuberculosis (TB) continues to be a major global health threat. Once infected with TB bacteria, children are more likely to get sick with TB disease and to get sick more quickly than adults. Diagnosis and treatment of the disease may be missed sometimes in the early stages and symptoms may mimic other conditions like Asthma, especially in children and it may flare up with the use of steroids. Limited access to healthcare, high treatment cost, and the social stigma of TB have contributed to delayed detection and poor treatment uptake.
Case Presentation Summary:



The 12-year-old child presented with a history of cough from 6 months on and off. She was treated as persistent asthma for which she was given steroids for the exacerbations twice and was also started on inhalers. At presentation, she had a high-grade fever for 1 week with an increased cough. On examination, she had Bronchial breathing on the right side and a chest x-ray was done at admission, shown in figure 1. She was admitted and started on injectable antibiotics and her sputum was sent for Acid fast bacilli (AFB), which was positive she was started on Anti-tubercular drugs and she responded

well to the treatment.
Learning Points/Discussion: In children with prolonged cough, tuberculosis should always be ruled out. Sometimes wheezing may be an initial symptom and the use of steroids may flare up up the disease. Early referral whenever needed should always be done.

TWENTY THREE YEARS OF DRUG-RESISTANT TUBERCULOSIS IN ARGENTINIAN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Griselda Berberian, Maria Jose Izaguirre, Soledad Gonzalez, Vanesa Reijtman, Nadia Miño, Lidia Casimir, Claudia Sarkis, Mariana Gatto, Cintia Kobashigawa, Andrea Monaco, Guadalupe Perez, Maria Teresa Rosanova
Hospital de Pediatria JP Garrahan, Pediatric Infectious Diseases, Ciudad Autonoma deBuenos Aires, Argentina

Backgrounds: The emergence of strains of Mycobacterium tuberculosis (MT) that are resistant to antimycobacterial agents (DR-TB) is a worldwide problem, which the magnitude has not been well described specially in pediatric patients (p).
Methods: We performed a retrospective review of all mycobacterial samples send from 1998-2022 at Hospital Garrahan for microbiological evaluation. Drug resistance tests to first line drugs:Isoniazid(INH), Rifampicin(R), Pirazinamide(PZ), Ethambutol(EMB), Streptomycin(STO) were performed on Lowenstein-Jensen medium according to the proportion method or/and Bactec 460/MGIT960 TB system. We defined DR-TB at those strains of MT resistant to one or more first-line drugs. Strains divided into monoresistant or resistant to 2 or more drugs:multidrug resistant TB strains (MDR-TB, those resistant to at least INH+R) and poliresistant TB strains. We analyzed medical records of p with microbiological confirmation of DR-TB.
Results: We included 1880 TB p during 23 years: 760 p had bacteriologically positive confirmed culture (40%). Fifty nine (7,8%) had DR-TB. Primary resistance was found in 49p (83%).The median age at diagnosis was 124 months (r:4-204), 18p (30%) were immunocompromised, 15/18p (84%) HIV positive. Pulmonary disease was the most common presentation:40p (68%). Nineteen p (32%) had extra-pulmonary localization. Of 59 DR-TB cultures 39(66%) were monoresistant and 20(34%) resistant to 2 o more drugs. Thirteen were MDR-TB, 10p of who had HIV infection. Monoresistance for INH, R, PZ, EMB and STO were 2.1% 0,4%, 0%, 0,13% and 2,5% respectively. Global INH resistance was 4,7%. Twenty two p (37%) had TB contact, 11p (18%) had previous hospital admission, and 9p (15%) previous TB treatment. Three p (5%) died because of TB disease; all of them had central nervous system infection.
Conclusions/Learning Points: INH resistant is increasing and MDR-TB was associated with HIV status. Mortality was low.

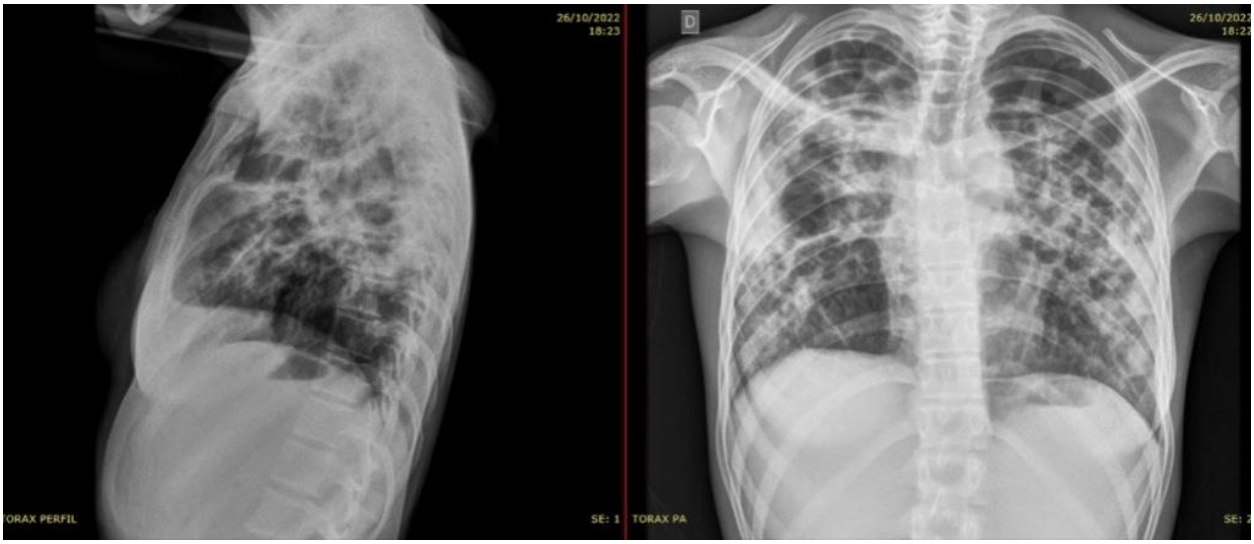
Title of Case: Severe and persistent tuberculosis in a healthy adolescent
Background: Tuberculosis is a transmissible disease considered one of the main causes of death worldwide. It is caused by the Mycobacterium tuberculosis bacillus, with the pulmonary form being the most prevalent.
Case Presentation Summary: A 13-year-old patient with family contact diagnosed with pulmonary tuberculosis in 2020. The patient received treatment for latent infection, ending the scheme in April 2021. After 8 months, she evolved with respiratory symptoms, fever and weight loss. Diagnosis of pulmonary tuberculosis was made in January 2022 (bacilloscopy and sputum culture positive), supervised treatment with Rifampicin + Isoniazid + Pyrazinamide + Ethambutol was initiated. She evolved with periods of improvement followed by worsening, fever, cough and maintenance of weight loss. Readmitted in October 2022, for the difficult-to-regress disease. He received treatment with RIPE associated with levofloxacin due to the possibility of secondary infection, maintaining positive bacilloscopy and, therefore, intravenous treatment was associated with Amikacin and Linezolid. Sputum cultures did not show drug resistance. She was discharged in December 2022, after 50 days of hospitalization with RIPE + Ciprofloxacin, afebrile and with clinical improvement. During outpatient follow-up, bacilloscopy was repeated 10 days after hospital discharge, with negative result. The scheme was maintained until obtaining 2 new consecutive negative sputum samples and then moving on to the second phase of treatment with Rifampicin and
Isoniazid.



Learning Points/Discussion: The RIPE regimen for 2 months, followed by 4 months of Rifampicin + Isoniazid is the recommended treatment. The evolution is usually favorable in immunocompetent patients. The patient met these criteria, without resistance to medications, but evolved unsatisfactorily. One of the hypotheses for such an evolution was the presence of multiple pulmonary cavitations that hindered the effectiveness of the medication.

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, Instituto da Criança e do Adolescente, Departamento De Pediatria, Unidade De Infectologia Pediátrica, São Paulo, Brazil, [2]Instituto da Criança e do Adolescente - FMUSP, Departamento De Pediatria, Unidade De Gastroenterologia E Hepatologia Pediátrica, São Paulo, Brazil

Title of Case: Disseminated tuberculosis with intestinal involvement in teenager.
Background: Tuberculosis (TB) has suffered a major impact during the pandemic period with COVID-19 globally. According to the World Health Organization (WHO), the progress made so far with global goals has significantly regressed. Mainly associated with the investigation and reporting of cases. In WHO epidemiological data until 2019, Tuberculosis was responsible for leading deaths associated with only one infectious agent, being surpassed by COVID-19 since 2020. During this period, approximately 9.9 million people worldwide were affected, with 1 .3 million deaths without HIV co-infection. In Brazil, in 2021, the incidence was 32/100,000 population (68,271 new cases). The pediatric population (under 15 years old) corresponds to 3.0%, especially those under five years old who represent 40.1%. Regarding the clinical forms, the extrapulmonary presented the highest percentage in its historical series in 2020 with 23.9%.
Case Presentation Summary: We describe a case of disseminated tuberculosis in an adolescent. A 14-year-old male patient presenting weight loss and fatigue for six months, with sweating and cervical lymph node enlargement in the last month. Exams showed pancytopenia (Hemoglobin: 6.4 g/dl / Leukocytes: 908 cells / Platelets: 67,000). Tomography of the thoracoabdominal, evidenced presence of lymph node clusters in bilateral cervical and mediastinal chains, and diffuse consolidations in the right lung. The colonoscopy showed multiple active ulcers in colon and rectum and distal rectal fistula. Pulmonary and ganglionic involvement, whose differential diagnoses transited between Tuberculosis, Lymphoma, HIV and Inflammatory Bowel Disease (Crohn's). Cultures, PCR for MTB and smear microscopy disclosed Mycobaterium tuberculosis. The patient had excellent response to treatment and complete recovery.
Learning Points/Discussion: This case report shows the importance of investigating tuberculosis in cases of fatigue, weight loss and multisystemic involvement.

PROSPECTIVE EVALUATION OF TB-LAM IN HIV NEGATIVE CHILDREN WITH PRESSUMPTIVE TB IN A DISTRICT HOSPITAL IN MOZAMBIQUE.

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Lucia Carratala Castro[1], Alberto García-Basteiro[1], Sozinho Acácio[2], Shilzia Munguambe[3], Belén Saavedra[1], Elisa Lopez-Varela[4]
[1]ISGlobal - Barcelona Institute of Global Health, Tuberculosis Research, Barcelona, Spain, [2]Centro de Investigação em Saúde de Manhiça, -, Manhiça, Mozambique, [3]Centro de Investigação em Saúde de Manhiça, Tb Laboratory, Manhiça, Mozambique, [4]ISGlobal, Hiv, Barcelona, Spain

Backgrounds: Novel accurate, reliable and rapid point of care (PoC) diagnostic methods which are non sputum based, are needed to narrow the large childhood TB case detection gap POC tests that detect the mycobacterial lipoarabinomannan (LAM) antigen in urine, are currently recommended by WHO for TB diagnosis in people living with HIV, but further evidence-based data is needed regarding broader applications including those HIV negative populations.
Methods: We prospectively evaluated the performance of the Urine TB-LAM Ag test in a prospective cohort of children <8 yr with presumptive TB in rural Mozambique living with and without HIV. Enrolled participants were evaluated clinically, radiologically and microbiologically (urine TB LAM, two respiratory samples tested through Xpert Ultra and culture and one stool sample tested through Xpert Ultra). Diagnostic accuracy was estimated against microbiological confirmation (excluding TB LAM) and NIH clinical case definiton (TB confirmed, unconfirmed and unlikely TB).
Results: Of the 71 presumptive TB cases enrolled, 8 (11.2%) were HIV positive, 3 (4,2%) had a positive LAM and 16 (22%) started ATT. Among those starting ATT, 5 (7%) were confirmed TB. The Sensitivity and specificity of TB LAM was 25 and 100% against the clinical definition in the HIV positive and 16.7% and 100% in the HIV negative. Sensitivity and specificity against Confirmed TB it was 25% and 98.3% respectively for HIV negative
children.

HIV positive	Confirmed	Unconfirmed	Unlikely TB	Total
LAM +	0	1	0	1
LAM -	1	2	4	7
Total	1	3	4	8

HIV negative	Confirmed	Unconfirmed	Unlikely TB	Total
LAM +	1	1	0	2
LAM -	3	7	51	61
Total	4	8	51	63

Conclusions/Learning Points: Until recently there are few studies that try to establish the accuracy of TB-LAM in HIV-negative children, therefore our study presents new evidence in this regard. The results of the study are limited, but the positivity of TB-LAM in two HIV negative children that are considered TB cases, suggests that there is room to further study this topic.

CERVICAL LYMPHADENOPATHY AND POSITIVE INTERFERON-GAMMA RELEASE ASSAY (IGRA) - NOT ALWAYS TUBERCULOSIS

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Rita Carvalho[1], Ana Lemos[1], Helena Peres[2], Anabela Silva[3], João Neves[4], Catarina Gouveia[1]
[1]Hospital Dona Estefânia - Centro Hospitalar Universitário de Lisboa Central, Paediatric Infectious Diseases Department, Lisbon, Portugal, [2]Hospital Dona Estefânia - Centro Hospitalar Universitário de Lisboa Central, Microbiology Department, Lisbon, Portugal, [3]National Institute of Health Doutor Ricardo Jorge, Infectious Diseases Department, Oporto, Portugal, [4]Hospital Dona Estefânia - Centro Hospitalar Universitário de Lisboa Central, Paediatric Immunodeficiencies Department, Lisbon, Portugal

Title of Case: CERVICAL LYMPHADENOPATHY AND POSITIVE INTERFERON-GAMMA RELEASE ASSAY (IGRA) - NOT ALWAYS TUBERCULOSIS
Background: Nontuberculous mycobacteria (NTM) are an important cause of cervical lymphadenitis in immunocompetent children. Most cases are caused by Mycobacterium avium complex. However,Mycobacterium kansasii remains one of the most relevant species of NTM.
Case Presentation Summary: A previously healthy 6-year-old girl was referred to our institution due to a 3-month history of hard adherent unilateral cervical lymphadenopathy. Other symptoms were absent,animal contact or recent travel were denied, and her immunizations did not include BCG. Blood work showed elevated erythrocyte sedimentation rate (25 mm/h),with normal complete blood cell count,C reactive protein and aminotransferases. HIV,CMV, EBV,toxoplasmosis were excluded. QuantiFERON®-TB gold test (QTF) was positive,chest X-ray was unremarkable,and the neck ultrasound revealed a right adenopathic conglomerate (52 mm) and the abdominal ultrasound mesenteric adenopathies (7 mm) and small bowel intussusception. Lymph node's biopsy revealed a caseous granuloma and acid-fast bacilli smear and nucleic acid amplification tests were negative. Tuberculous lymphadenitis was considered,and isoniazid, rifampicin, pyrazinamide, ethambutol [HRZE] were initiated. Biopsy's cultural exam isolated M. kansasii,sensitive to rifampicin,moxifloxacin and clarithromycin, which motivated pyrazinamide discontinuation and treatment with HRE,so far for five months, with gradual improvement. Immunological study is ongoing.
Learning Points/Discussion: The clinical syndromes and radiologic findings of M. kansasii infection are usually indistinguishable from those of M. tuberculosis, so microbiological confirmation is required. Furthermore, QTF may be positive in patients infected with M. kansasii, confounding the diagnosis, as it firstly happened in this case. There is limited evidence to guide treatment of M. kansasii extra-pulmonary disease. We decided to treat this presumed immunocompetent child with extrapulmonary disseminated infection with HRE for a minimum of six months, being the duration decided according to clinical and imagiological evolution.

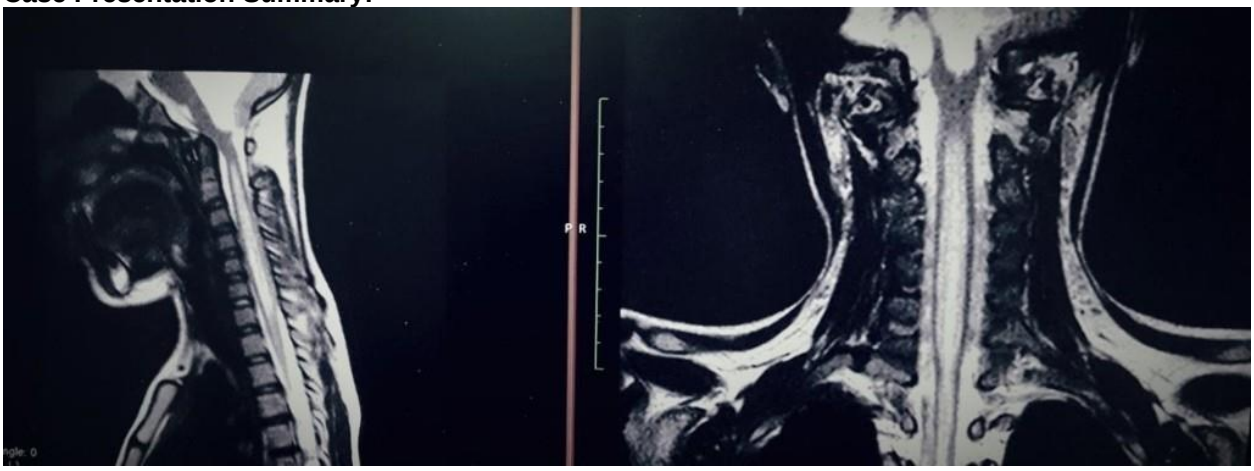
Title of Case: Tuberculous meningitis in a girl with acquired internal occlusive post-hemorrhagic hydrocephalus, right-side hemiparesis
Background: Tuberculous meningitis is a serious and often fatal disease in children and ranges between 1-10% of all TB cases. We want to present a case of tuberculous meningitis in a girl with acquired internal occlusive post-hemorrhagic hydrocephalus, right-side hemiparesis.
Case Presentation Summary:



Our patient is an 8-year-old girl with complaints of prolonged febrile fever, severe headache in the occipital region, vomiting. Disease history. A CSF shunt system was installed to treat hydrocephalus at the age of 1 year. Three months ago there was contact with a bacteriopositive case of lung tuberculosis. The examination showed the following changes: CSF - cytosis of 206 cells, protein 3.32%, glucose 1.9 mmol/l, lymphocytes 80%, MBT Gene Expert CFL was negative. QFT plus was positive. SCT of the thoracic and abdominal organs was nornal. MRI result-signs of increased internal occlusive hydrocephalus with mass effect causing on the brain stem, with the threat of lateral and axillary insertion of the brain stem, increased signals from the hard and soft membranes of the brain, pronounced hydromyelia of the cervical and thoracic spine. The child underwent surgical intervention-revision and removal of the distal end of the CSF shunt system. Antituberculosis drugs were started. Patient improved with follow up MRI showing positive dynamics with Mass effect causing resolution, without the threat of wedging and reducing hydromyelia.
Learning Points/Discussion: 1.Tuberculous etiology should be suspected, although rare, in children with hydrocephalus and prolonged fever, when other causes are excluded. 2. Prognosis can improve with early diagnosis and prompt treatment.

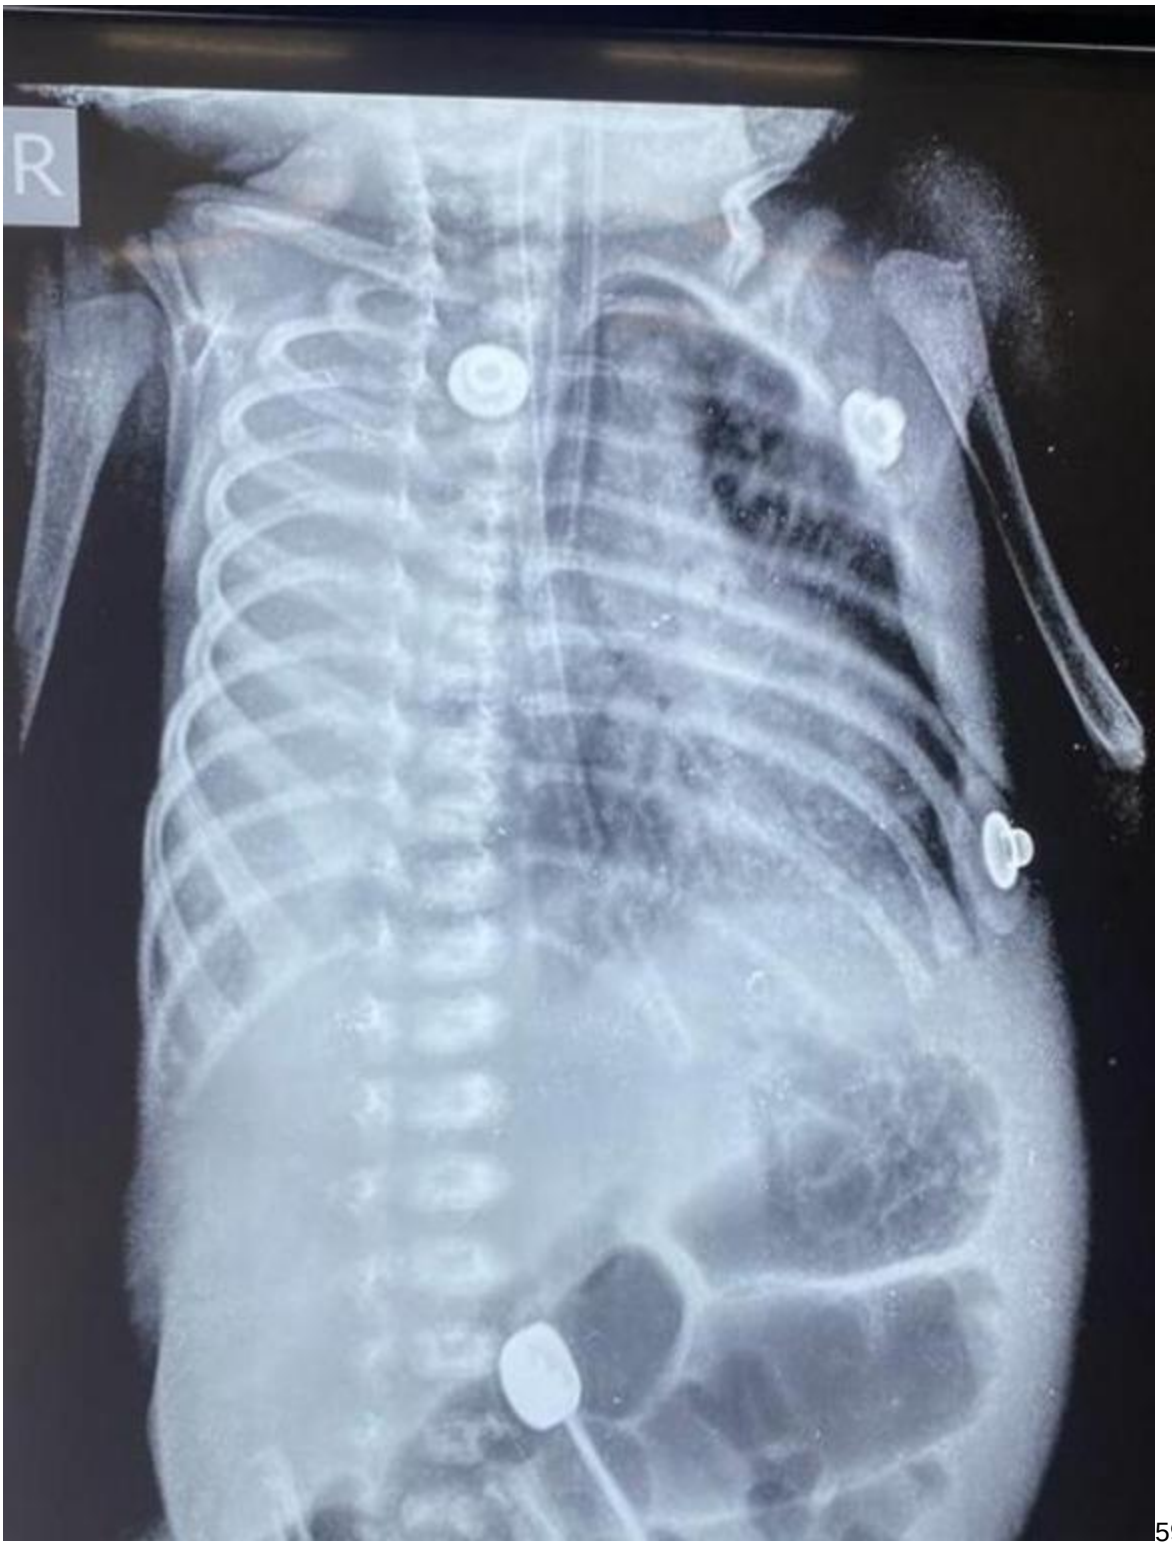
DISSEMINATED TUBERCULOSIS WITH RENAL INVOLVEMENT IN A PARANEONATE

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Meenakshi Dey, Maithili Joshi, Ira Shah
Bai Jerbai Wadia Hospital for Children, Pediatric Infectious Diseases, mumbai, India

Title of Case: DISSEMINATED TUBERCULOSIS WITH RENAL INVOLVEMENT IN A PARANEONATE
Background: Renal tuberculosis (TB) accounts for 14-41% of all cases of pulmonary tuberculosis (PTB) in developed countries. Renal TB in paraneonatal age group is not reported previously.
Case Presentation Summary:



59 day old male born by vaginal delivery at 38 weeks of gestation with a birth weight of 2kg,brought with fever,cough for 7-8 days. On presentation weight was 1.9 kg with anasarca,respiratory distress and hypoxemia.Initially suspected to have late onset sepsis and required non-invasive ventilation,subsequently intubated and put on mechanical ventilation. Started with intravenous antibiotics piperacillin tazobactum and amikacin.CT chest showed consolidation of entire right lung as well as posterior segment of left upper lobe and most of left lower lobe, Nodular infiltrates with tree in bud

distribution in left lung. Hemoglobin of 8.2 gm/dL,white cell count of 19,100 cells/cumm (63% polymorphs, 33% lymphocytes),C-reactive protein(CRP) 260 mg/L,AST 617 U/L,ALT 136 U/L,Total bilirubin 0.8 mg/dL,Total protein 3.1g/dL,albumin of 1.9g/dL. Blood cultures had no growth. HIV serology was negative.Mother was admitted to another hospital for abdominal Tuberculosis the same time. Endotracheal secretions revealed mycobacterium tuberculosis (MTB) on Xpert MTB/RIF assay without resistance to rifampicin. Started on anti-tubercular therapy (ATT).In view of polyuria and abdominal distension,ultrasound abdomen done which showed raised renal echogenicity with ascites, internal echoes and normal liver echotexture.Urine routine had 1-2 pus cells/ high power field,urine culture was negative. Urine Xpert MTB/RIF ultra showed MTB without resistance to rifampicin. Inspite of all efforts baby succumbed due to respiratory failure.

Learning Points/Discussion: Renal tuberculosis is usually a secondary tubercular infection which is causes by hematogenous dissemination during primary infection or reactivation. High index of suspicion should be kept in patients with primary infection and unexplained renal signs and symptoms.

[1]University of Padua, Department Of Women's And Children's Health, Padua, Italy, [2]University of Padua, Division Of Paediatric Infectious Diseases, Department Of Women's And Children's Health, Padua, Italy, [3]Hospital of Bolzano, Department Of Pediatrics, Bolzano, Italy

Title of Case: Abdominal tuberculosis in children: a diagnostic challenge
Background: Tuberculosis disease (TB) is a relevant public health problem, especially in high-prevalence areas. Intestinal TB (ITB) is a rare entity, characterized by non-specific symptoms and signs and a difficult microbiological diagnosis. We present two different cases of ITB.
Case Presentation Summary: CASE 1-A 13-year-old Peruvian male was admitted for a 3-day history of fever, nausea and abdominal pain. Abdominal US showed diffuse ascites. Abdominal CT reported a widespread peritoneal thickening and multiple mesenteric adenopathies. Tuberculin skin test and QuantiFERON were negative. Multiple microscopic samples and PCR for Mycobacterium tuberculosis (MTB) DNA resulted negative in gastric and urine specimens. A laparoscopic peritoneal biopsy reported epithelioid and Langhans cells and caseous necrosis areas. PCR for MTB in the histological sample was positive. Antitubercular treatment was started with clinical improvement. CASE 2-A 12-year-old female was hospitalized for fever and lower abdominal tenderness with a recent travel history in Kosovo. Abdominal US showed ascites, and abdominal CT revealed diffuse peritoneal thickening. A chest CT described a single non-specific pulmonary lesion. Microbiological and PCR for MTB assays performed on urinary, nasopharyngeal, peritoneal fluid and stool samples were negative, but QuantiFERON and tuberculin skin test returned positive. A diagnosis of intestinal tuberculosis was confirmed by positive PCR for MTB in gastric specimens, and a specific treatment regimen was started.
Learning Points/Discussion: ITB is challenging in children, especially in the absence of pulmonary disease. ITB mimics inflammatory bowel disease, malignant neoplasia or other infectious diseases. Therefore, ITB should be included in the differential diagnosis in patients who come from endemic areas and develop abdominal complaints. Imaging tests, QuantiFERON and microbiological tests for TB in biological specimens lead to establishing diagnosis and treatment.

Title of Case: LARYNGEAL TUBERCULOSIS
Background: Laryngeal tuberculosis (LT) is a rare chronic granulomatous infectious disease caused by Mycobacterium tuberculosis (MT), that affects mainly adults in developing countries. It can either be primary or secondary. This article has the objective to report a case of LT in an adolescent and convey the importance of the differential diagnosis among others granulomatous diseases (GD).
Case Presentation Summary: Healthy 12-year-old male was admitted with a history of dry coughing for the past 6 months, 2 months of progressive hoarseness and painless, enlarged, mobile lymph node. The patient also presented with fragile lesions in the larynx and oropharynx, raising suspicions of a GD. The Computed tomography of the neck had showed diffuse submucous thickening of the larynx, causing significant stenosis of the lumen. He had IgM serologies and sputum AFB tests negative, PPD tests with 15mm (48h) and 18mm (72h), hematological PCR for MT negative. A biopsy of the lesion was performed and PCR tests for MT were found at low levels. LT was confirmed and the patient was started on a regimen of rifampicin, isoniazid, pyrazinamide, ethambutol and corticosteroids for treatment. One week later, showed a slight decrease in swelling in the larynx, an improvement in hoarseness, and a reduction in coughing. After 4 months, the patient still had diffuse granulomatous lesions in the arytenoids, blurring of the aryepiglottic folds, but had his epiglottis and vocal folds free of erosive lesions and unimpaired mobility.
Learning Points/Discussion: This case report highlights the importance of considering LT as a possible differential diagnosis for chronic GD in children and must maintain a high level of suspicion and initiate appropriate treatment, even if test results are negative, in order to prevent poor outcomes.

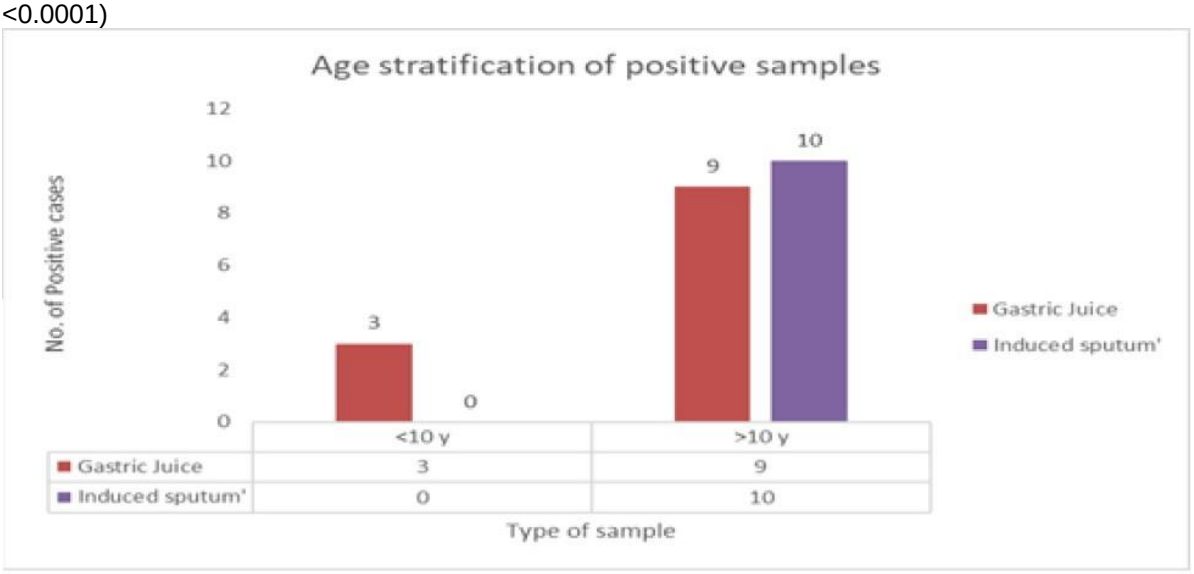
[1]CHRISTIAN MEDICAL COLLEGE, VELLORE, Child Health 3, VELLORE, India, [2]CHRISTIAN MEDICAL COLLEGE, Clinical Microbiology, VELLORE, India, [3]CHRISTIAN MEDICAL COLLEGE, Biostatistics, VELLORE, India, [4]CHRISTIAN MEDICAL COLLEGE, Pulmonary Medicine, VELLORE, India, [5]CHRISTIAN MEDICAL COLLEGE, Paediatric Infectious Diseases, VELLORE, India

Backgrounds: Gastric juice aspiration has been the preferred method of sampling for the diagnosis of pulmonary TB in children. However, induced sputum collection is less invasive, does not require in-patient admission, causes less discomfort and does not require overnight fasting. Hence this study was carried out to evaluate induced sputum collection against gastric juice aspiration in the diagnosis of Tuberculosis using XpertMTB/RIF and MGIT(culture) in children between 2 to 15 years of age.
Methods: This is a cross-sectional, prospective study including both in-patients and out-patients who were suspected cases of Tuberculosis between 2 and 15 years of age. Sequential samples of gastric juice and induced sputum were collected and both were sent for XpertMTB/RIF and MGIT.
Results: We recruited 138 children for the study who were suspected to have Tuberculosis. Pulmonary TB accounted for 13 cases (9.4%). The overall diagnostic yield by GJ aspiration was 12/138 ie. 8.6% (5-14.5%), while that for Induced sputum was 10/138 ie. 7.2% (3.9-12.8%). Above 10 years of age, there were 10 cases detected by Induced sputum and 9 cases by GJ aspiration. Less than 10 years, 3 cases were detected by Gastric juice aspirate and none by IS. Using the Wong-Baker visual analogue scale GJ aspiration had a median score of 8 while Induced sputum production had a median score of 2, suggesting that IS production was associated with significantly lower levels of discomfort compared to GJ aspiration. (p value
<0.0001)



Conclusions/Learning Points: In children less than 10 years, gastric juice aspiration should be used for

the diagnosis of TB. However, in children aged 10 years and above induced sputum should be done owing to better yield and tolerability.

REPORT ON THE RESULTS OF TB CONTACT HEALTH EXAMINATIONS OF CHILDREN IN JAPAN OVER THE PAST 12 YEARS.

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Kenji Gotoh[1], Atsushi Miyake[2], Kiyohito Okumiya[2]
[1]Kurume University School of Medicine, Department Of Infection Control And Prevention, Kurume Fukuoka, Japan, [2]Kurume University School of Medicine, Department Of Pediatrics And Child Health, Kurume Fukuoka, Japan

Backgrounds: In 2021, the number of newly registered TB cases in Japan was 9.2/100,000, classifying Japan as a low endemic country for the first time. Kurume University Hospital has been carrying out TB contact person health examinations in children, and we report on the status of TB infection in children.
Methods: We reviewed the medical records of TB contact health check-ups over a 12-year period from 1 April 2009 to 31 March 2021at Kurume University Hospital retrospectively, and investigated the background, family history of cases judged to have established TB infection, contact status, TB test results at health check-ups and anti-tuberculosis drug administration status.
Results: In this study 192 children were examined for TB contact health examinations and 29 patients(15.1%) were judged to have TB infection (pulmonary TB: 3, lymph TB:4, latent TB:21, pulmonary TB after treatment for latent TB:1). Family and contact history: 15 patients lived together and 12 had contact 1-2 times a week. The main tests leading to the diagnosis were positive tuberculin test in 16 cases, positive IGRA in 6 cases and imaging tests in 2 cases. Treatment was INH+RFP+PZA in pulmonary and lymph node TB cases and INH in latent TB cases.
Conclusions/Learning Points: Among cases in which a family member living with the patient developed pulmonary TB, TB infection was established in all cases. In addition, we found pulmonary TB cases during the check-up after the completion of treatment for latent TB, and it is considered necessary to follow up regularly on cases treated for TB infection. In two cases of pulmonary TB, the tuberculin test was strongly positive and IGRA was negative, so it is necessary to make a comprehensive diagnosis of TB in children, including imaging tests.

RITIP, Paediatric Infectious Diseases, Madrid, Spain, [10]Hospital Universitario 12 de Octubre, Paediatric Infectious Diseases, Madrid, Spain, [11]Hospital Universitario La Paz, Pediatrics, Madrid, Spain, [12]Hospital Joan XIII, Pediatrics, Tarragona, Spain

Backgrounds: In low-endemic regions, most children have nonsevere tuberculosis (TB). The SHINE Trial has shown that treatment for children with nonsevere TB can be safely reduced from six to four months. We aimed to assess the prevalence and characteristics of nonsevere TB among patients in the Spanish Pediatric TB Research Network cohort.
Methods: We conducted an observational study in children aged ≤16 years diagnosed with TB. Nonsevere TB cases included smear-negative children with respiratory TB confined to one lobe, with no significant airway obstruction, no complex pleural effusion, no cavities, and no signs of miliary, or children with peripheral lymph-node disease. Children not fulfilling these criteria were considered to have severe TB. We estimated the prevalence of nonsevere TB in our cohort, and compared the clinical presentation, diagnostic findings, and outcomes between children with nonsevere and severe TB.
Results: Seven hundred and eighty patients were included (46.9% males, median age 5.5 years [IQR:2.6-11.1]); 477 (61.1%) had nonsevere TB. Nonsevere TB was less frequent in children <1 year of age (4.8% vs 15.2%; p<0.01), and >10 years of age (25.2% vs 35.3%; p<0.01), mostly diagnosed in contact tracing (60.4% vs 29.2%, p<0.01) and more frequently asymptomatic (38.3% vs 17.7%; p<0.01). There was no difference in interferon-gamma release assay tests performance. TST positivity rates and mean induration diameters were greater in nonsevere patients (p<0.01 in both cases). TB confirmation in nonsevere TB was less frequent by culture (27.0% vs 57.1%, p<0.01) and by molecular tests (18.2% vs 48.8%, p<0.01).
Conclusions/Learning Points: In our cohort, two-thirds of the children had nonsevere TB, most of them with benign clinical presentation and negative microbiologic results. In low-burden countries, a large number of children with nonsevere TB might benefit from shorter treatment regimens.

Title of Case: A FATAL M. TUBERCULOSIS AND S. PNEUMONIAE MIXED MENINGITIS IN A HEALTHY INFANT
Background: Streptococcus pneumoniae and Mycobacterium tuberculosis are major vaccine-preventable pathogens causing meningitis, including severe sequelae and fatal outcomes. We describe a rare form of pneumococcal and tuberculous mycobacteria coinfection causing meningitis in a previously healthy child.
Case Presentation Summary: A previously healthy 8-month-old girl presented to the ER with a cough, runny nose, vomiting, diarrhea, and recurrent high fever (up to 39°C) for 7 days, but with significant worsening of the general condition, drowsiness, and irritability and respiratory pattern during the last 24h. CSF was obtained from the lumbar tap: 42 cells (63% neutrophils; 37% lymphocytes), protein=512 mg/dl, glucose=20 mg/dl; red cells=103/mm^3), negative culture. Due to progressive drowsiness and a sudden 12-minute cardiac arrest, orotracheal intubation and vasoactive support were required, and empiric antimicrobial treatment with high-dose ceftriaxone, vancomycin, and acyclovir was initiated. Necrosis of the extremities developed soon after, and, despite these efforts, she remained unresponsive, hypoactive, and with fixed middle pupils even after weaning off sedatives and vasoactive drugs. She died after 18 days of hospitalization in PICU after brain death was confirmed. Streptococcus pneumoniae was identified by multiplex RT-PCR in the CSF from a control lumbar puncture. Acid-alcohol fast bacilli were absent using fluorescent microscopy, and Mycobacterium tuberculosis was subsequently grown in culture after 3 weeks; the organism is sensitive to the drugs used in treatment.
Learning Points/Discussion: Mixed pneumococcal and tuberculous meningitis is a rare combination that occurs most frequently in young infants and results in fatal infections. Diagnostic difficulties are frequent, and delay in treatment is considerable.

Title of Case: CASES OF PULMONARY TUBERCULOSIS WITH PLEURISY IN SIBLINGS WHO REFUSED LATENT TUBERCULOSIS TREATMENT
Background: Latent tuberculosis infection (LTBI) is defined as a state in which Mycobacterium tuberculosis infected a host but has not caused a disease. According to the Korean Guidelines for Tuberculosis, children with LTBI are recommend being treated with isoniazid for 9 months or with isoniazid plus rifampin for 3 months. We hereby present cases of pulmonary tuberculosis with pleurisy in siblings who refused the LTBI treatment.
Case Presentation Summary: Case 1. A 13-year-old girl visited ER for dyspnea that started 3 days ago. Her chest x-rays showed a massive left side pleural effusion. She was previously diagnosed with LTBI for her father had active pulmonary tuberculosis 7 months ago and 9-month isoniazid treatment was recommended. However, the parents refused the treatment then. Active pulmonary tuberculosis was confirmed with chest CT and sputum exam. The effusion was removed via percutaneous catheter drainage (PCD) and antituberculosis medication was started. She completed a course of 2 months of isoniazid, rifampin, ethambutol, and pyrazinamide (2HREZ) followed by 4 months of isoniazid, rifampin, ethambutol (4HRE). Her symptoms and abnormal findings in chest x-rays improved with the treatment. Case 2. An 11-year-old boy, the brother of case 1, was also diagnosed with LTBI 7 months ago but was not treated. He had no symptoms but his repeated chest x-rays showed active pulmonary tuberculosis with right side pleural effusion. He underwent a course of 2HREZ and 4HRE and recovered completed.
Learning Points/Discussion: LTBI treatment of children could be bothersome and their caregivers would ignore its necessity. However, healthcare professionals should provide confident information about both the benefits and risks of LTBI treatment. The present sibling cases may show its importance.

Kyriakou Children's Hospital National and Kapodistrian University of Athens, Second Department Of Paediatrics, Athens, Greece

Title of Case: A case of bronchial tuberculosis in a 15-year-old female adolescent
Background: Introduction: Bronchial tuberculosis (BTB) refers to Mycobacterium tuberculosis (MT) infection of the trancheobronchial tree. BTB is either a complication or a specific type of pulmonary tuberculosis (TB). It is mainly seen in young females. It occurs in about 10-40% in patients with active TB, but it is likely to be undiagnosed. This case illustrates an adolescent with BTB.
Case Presentation Summary: Case presentation: We present a 15-year-old female adolescent, living in Greece, refugee from Ghana admitted due to multiple episodes of hemoptysis since the same day and cough since 2 weeks ago. The clinical examination and the chest X-ray showed no pathological findings. The chest CT revealed bronchiectasis, atelectasis, a ''tree-in-bud'' appearance and ground glass opacity of the left lower lobe with calcified mediastinal lymph nodes. The tuberculin skin test, the sputum test for acid-fast bacilli and the GeneXpert were all negative, however the Quantiferon - TB Gold was positive, so a bronchoscopy was performed and a blood clot was found in the entrance of the left main bronchus. The biopsy revealed granulomas with multinucleated giant cells compatible with TB, the GeneXpert of the tissue, the Lowenstein Jensen culture and MGIT culture of the washing and the mini bronchoalveolar lavage were positive. The Mycobacterium tuberculosis isolated was sensitive to all first line anti-TB drugs. The patient was finally treated with Isoniazid, Rifampin, Ethambutol and Pyrazinamide for 2 months and then with Isoniazid and Rifampin for 4 months.
Learning Points/Discussion: Discussion: Although our patient is a typical BTB case, a bronchoscopy had to be performed to confirm the diagnosis, since direct isolation of MT is the gold diagnostic standard.

THE DIAGNOSTIC YIELD OF NASOPHARYNGEAL ASPIRATE FOR PAEDIATRIC PULMONARY TUBERCULOSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Nisreen Khambati[1], Emily Maclean[2], Mikashmi Kohli[3,4], Laura Olbrich[5], Rinn Song[1], Else Bijker[1]
[1]University of Oxford, Paediatrics, Oxford, United Kingdom, [2]Central Clinical School, Faculty Of Medicine And Health, Sydney, Australia, [3]McGill International TB Centre, Tb, Montreal, Canada, [4]FIND, Diagnostics, Geneva, Switzerland, [5]Ludwig-Maximilians University, Division Of Infectious Diseases And Tropical Medicine, Munich, Germany

Backgrounds: Diagnosing pulmonary tuberculosis (TB) is challenging in young children who cannot expectorate sputum spontaneously. Nasopharyngeal aspirate (NPA), an alternative respiratory sample, may be more easily collected than gastric aspirate or induced sputum. However, data on its diagnostic yield is lacking.
Methods: We systematically reviewed and meta-analysed the diagnostic yield of one NPA for testing by either culture or nucleic acid amplification testing (NAAT) to detect Mycobacterium tuberculosis. Three bibliographic databases and two trial registers were searched until 24th November 2022. Microbiological confirmation based on culture and/or WHO-endorsed NAAT on a respiratory specimen was the reference standard. The incremental yield of two NPA samples compared to one was estimated and operational aspects of NPA collection and processing were summarised.
Results:

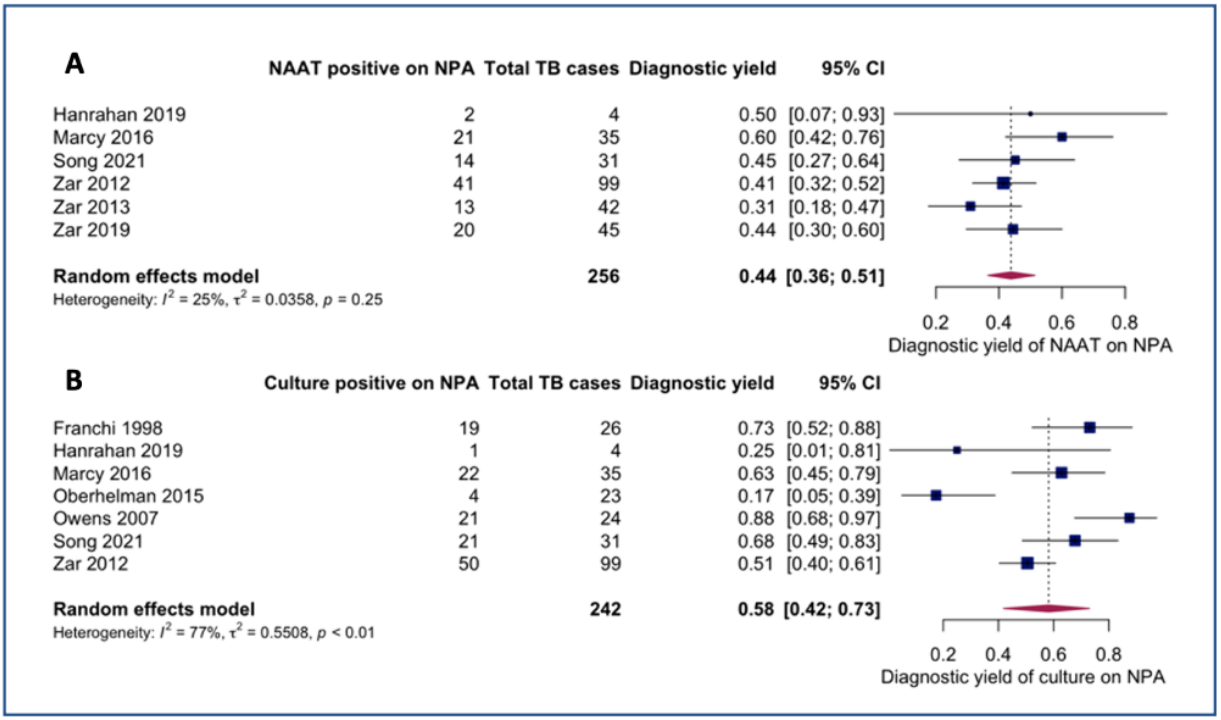

Figure 1: *Forest plots of diagnostic yield of nasopharyngeal aspirate (NPA) using NAAT (A) and culture (B) compared to a microbiological reference standard, based on culture and/or WHO-endorsed NAAT on any of the following respiratory specimens: gastric aspirate, induced sputum, stool, string test, expectorated sputum, bronchoalveolar lavage and NPA.*

From 1492 citations, 54 underwent full-text review and nine were included. Based on six studies

including 256 children with microbiologically confirmed TB, the diagnostic yield of NAAT on one NPA ranged from 31-60%, (summary estimate 44%, 95% CI 36-51%) (Figure 1A). From seven studies including 242 children with microbiologically confirmed TB, the diagnostic yield of culture was 17-88%, (summary estimate 58%, 95% CI 42-73%) (Figure 1B). Testing of a second NPA increased the yield by 8-19% for NAAT and 4-35% for culture. NPA collection procedures varied between studies, although most children had NPA successfully obtained (96-100%), with a low rate of indeterminate results (<5%). Results specifically for children under five years, as well as data on NPA acceptability and contamination rates were limited.

Conclusions/Learning Points: This review confirms that NPA is a suitable and feasible specimen for diagnosing paediatric TB. Studies focused on children under five years and research into how to standardise NPA collection are needed.

PV0750 / #1462

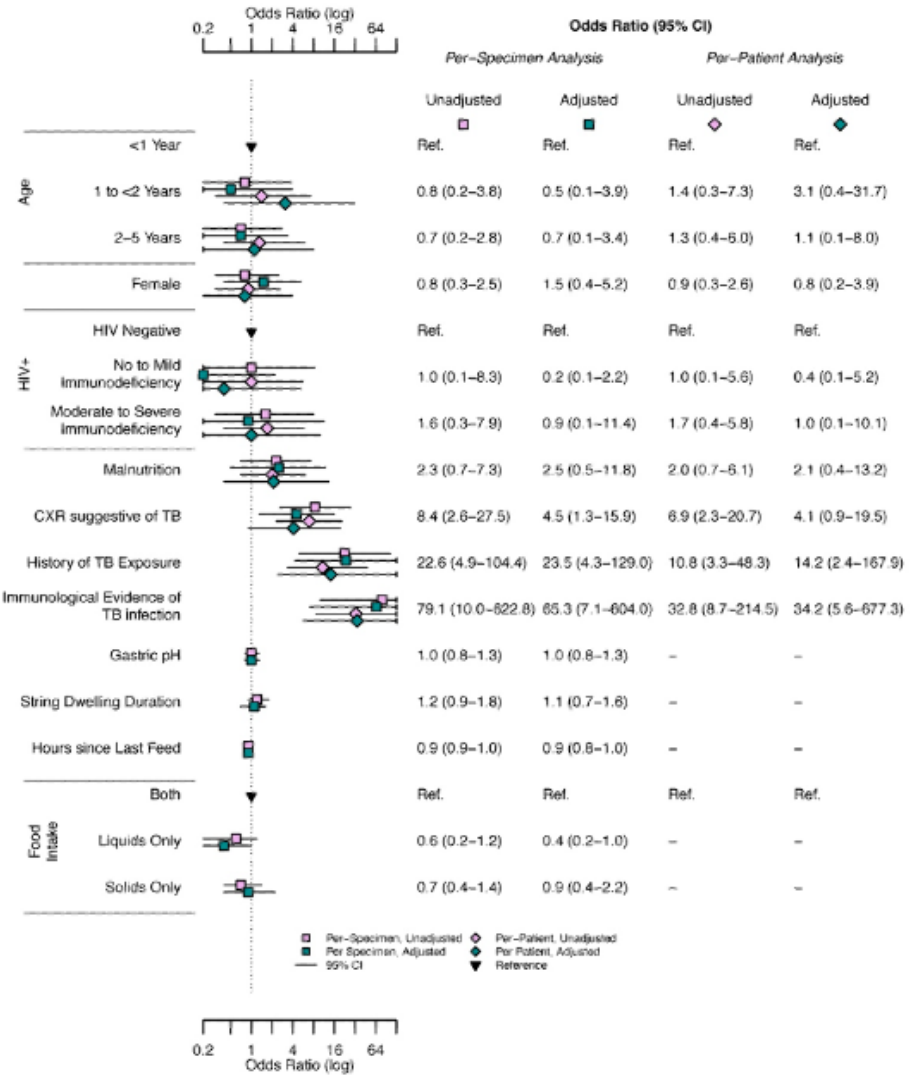
FEASIBILITY AND DIAGNOSTIC UTILITY OF THE COMBINED-NASOGASTRIC-TUBE-AND-STRING-TEST FOR DIAGNOSIS OF PULMONARY TUBERCULOSIS IN YOUNG CHILDREN - KENYA

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Nisreen Khambati[1], Rinn Song[1], Jonathan Smith[2,3], Else Bijker[1], Kimberly Mccarthy[2], Eleanor Click[2], Walter Mchembere[4], Albert Okumu[4], Susan Musau[4], Elisha Okeyo[4], Kevin Cain[2], Carlos Perez-Velez[5]
[1]University of Oxford, Paediatrics, Oxford, United Kingdom, [2]Division of Global HIV and Tuberculosis, Centers For Disease Control And Prevention, Atlanta, United States of America, [3]Department of Health Policy and Management, Yale School Of Public Health, New Haven, United States of America, [4]Kenya Medical Research Institute, Center For Global Health Research, Kisumu, Kenya, [5]University of Arizona, College Of Medicine, Tucson, United States of America

Backgrounds: Alternative diagnostic specimens with high real-world feasibility are needed for TB in young children. We examined the procedural feasibility and microbiologic yield of the Combined-NasoGastric-Tube-and-String-Test (CNGTST), a NGT with a thread wrapped around it that affords the collection of two specimens simultaneously: gastric aspirate (GA) and a string test (ST).
Methods: We conducted a prospective cohort study of children under five with presumptive PTB in Kisimu, Kenya between 2013 and 2015, and obtained demographic, clinical and radiologic information. Using the CNGTST device, up to two samples of GA and ST were collected and tested with Xpert-MTB/RIF and culture. We estimated unadjusted and adjusted odds ratios (ORs) and 95% confidence intervals (CIs) between positive ST samples and covariates using logistic regression implemented through generalized estimating equations.
Results: 294/300 (98%) participants underwent CNGTST; 285/294 (97%) had one or more ST samples successfully collected (545 ST samples total, 541 (99%) interpretable). 38/541 (7%) GA samples and 23/541 (4%) ST samples were positive by Xpert or culture. 23/281 (8%) and 15/281 (5%) children had positive GA and ST results respectively. The median string dwelling time was 34 minutes. Covariates associated with a positive ST included chest radiography suggestive of TB (OR: 8.4; CI: 2.6-27.5), household TB exposure (OR: 22.6, CI: 4.9-104.4) and immunological evidence of TB infection (OR: 79.1; CI: 10.0-622.8). Associations remained significant after adjustment (Figure One).

Figure 1: Unadjusted and adjusted odds ratios of factors associated with a positive Mtb finding on string test samples, by per-specimen analysis (n = 1082) and per-patient analysis (n = 296). Per-specimen analyses implemented logistic regression through generalized estimating equations to account for repeated measurements on the same patient. CI: confidence intervals; CXR: chest X-ray; Mtb; *Mycobacterium tuberculosis*; HIV, human immunodeficiency virus; TB; tuberculosis



Conclusions/Learning Points: The CNGTST procedure was feasible in nearly all children under five years with symptoms of TB. Although microbiologic yield of ST was slightly lower than GA, the CNGTST could be a viable method for detecting TB in situations where GA is already being undertaken. Further research is required to optimise yield of ST.

CLINICAL SIGNIFICANCE OF TUBERCULIN SKIN TEST VERSUS INTERFERON-GAMMA RELEASE ASSAY IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Jihong Kim[1], Minsun Ryu[2], Jong Gyun Ahn[2]
[1]Gangnam Severance Hospital, Yonsei University College of Medicine, Pediatrics, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Department Of Pediatrics, Seoul, Korea, Republic of

Backgrounds: Diagnostic tools for tuberculosis(TB) infection include the tuberculin skin test(TST) and interferon-gamma release assay(IGRA). TST and IGRA can give discordant results and this make it difficult to diagnose TB. In this study, we investigated concordance and discordance rate in children who tested both TST and IGRA. Additionally, when IGRA was used as the reference standard, risk factors associated with discordance of results between IGRA and TST were investigated, and sensitivity and specificity according to the induration threshold of TST were analyzed.
Methods: We retrospectively reviewed the medical records of children(aged ≤ 18 years) who underwent both TST and IGRA from Mar 2010 to Dec 2020 at Severance Children's Hospital. Quantiferon Gold In-Tube test (QFT-GIT) was used as IGRA method.
Results: A total of 289 children were included and the concordance rate of TST and IGRA was 91.1%. The 0-4 age group had the lowest concordance rate at 83.3%. Only the TST induration size showed a significant difference between the positive concordant group and the TST false negative group. Sensitivity and specificity of TST were 48% and 96% for TST 10mm threshold, which is the current positive standard. In 5mm positive threshold of TST, the sensitivity increased to 61%, the specificity decreased to 89%. In 15 mm positive threshold of TST, the sensitivity was lowered to 35% and the specificity rose to about 98%.
Conclusions/Learning Points: TST and IGRA have a discordance rate of 8.9%, which was highest in 0-4yrs group. For the 10mm threshold of TST, the false positive rate may increase in the younger age group, and the false negative rate may increase in the adolescent age group. Therefore, a backup of the IGRA is needed in suspicious situations of TB infection.

EXTRAPULMONARY TUBERCULOSIS: A CASE OF ORCHITIS REQUIRING ORCHIECTOMY

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Mahmut Kızıl[1], Yalçın Kara[1], Ömer Kiliç[2], Ener Çağrı Dinleyici[2]
[1]Eskişehir Osmangazi University, Pediatric Infectious Disease, ESKİŞEHİR, Turkey, [2]Eskişehir Osmangazi University, Pediatric Infectious Disease, Eskişehir, Turkey

Title of Case: EXTRAPULMONARY TUBERCULOSIS: A CASE OF ORCHITIS REQUIRING ORCHIECTOMY
Background: The clinical manifestations of extrapulmonary tuberculosis involvement are very different, causing delays in diagnosis and treatment. In our case, a male patient who had chronic orchitis due to testicular tuberculosis in the childhood age group and underwent orchiectomy is mentioned.
Case Presentation Summary: 17-year-old male who underwent right orchiectomy due to chronic orchitis and fistula and pathology was interpreted as tuberculosis. It was learned that he had no tuberculosis contact and no active complaints. No pathological finding was detected in the physical examination. and the blood tests studied. Microscopy, culture and PCR analysis were performed for tuberculosis from urine and sputum samples for 3 consecutive days and results were negative. Ppd test was evaluated at 72th hour and the result was 17 mm. Patient was started on antituberculosis quadruple therapy with isoniazid,rifampicin, pyrazinamide, ethambutol.
Learning Points/Discussion: In childhood, tuberculosis is an infectious disease that can involve all organs and tissues, although it most often affects the lymph nodes except the lungs. The gold standard in diagnosis is the production of bacillus in culture. Tuberculosis should definitely be investigated in the differential diagnosis of patients presenting with different complaints and findings in regions with a high incidence of tuberculosis.

Title of Case: NEUROLOGICAL DEFICITS DUE TO BRAIN ABSCESSES CAUSED BY DISSEMINATED INFECTION WITH MYCOBACTERIUM BOVIS
Background: Mycobacterium bovis, usually causing tuberculosis (TB) in cattle and other animals can lead to TB disease in humans following infection via ingestion of contaminated, unpasteurized dairy products. Whereas cases are rare in developed countries, they still occur in certain developing countries.
Case Presentation Summary: A 16-year-old previously healthy girl whose family originates from East Africa presented with increasing headache, nausea and vomiting, experiencing flashes of light and temporary unilateral body numbness. Cerebral magnetic resonance imaging showed multiple intracranial abscesses. The critically ill girl required ICU care and external CSF drainage in view of a massively raised intracranial pressure. Further diagnostics included LP and a stereotactic biopsy that tested positive for "MTB complex" on PCR. For presumed TB, she was started on quadruple treatment (Isoniazid, Rifampicin, Pyrazinamide, Prothionamide) and steroids. However, cultures from CSF and gastric aspirate eventually yielded a positive result for Mycobacterium bovis demonstrating disseminated disease. Clinical course was complicated by a relevant intracerebral vascular stenosis (middle cerebral artery) in close proximity of severely affected and inflamed brain tissue requiring systemic anticoagulation. The girl, though born in Germany, had recently spent a 7-year-period in Ethiopia living according to local standards, including consumption of unpasteurized cow's milk.
Learning Points/Discussion: Though M. tuberculosis accounts for the majority of tuberculosis cases in developed countries, M. bovis may be responsible for TB disease in selected populations exposed to contaminated unpasteurized dairy products. Even while responding well to treatment, cerebral involvement may cause severe complications such as vascular stenosis. PCR detects multiple species of the "MTB complex", including M. bovis. Hence, mycobacterial culture remains the gold standard and is of critical importance to tailor the most efficient antimycobacterial regimen.

TB CLUSTER IN THE PASIFIKA COMMUNITY IN SYDNEY, AUSTRALIA

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Archana Koirala[1], Katherine Smith[2], Annaleise Howard-Jones[3], Vitali Sintchenko[3], Ben Marais[4], Philip Britton[4]
[1]Nepean Hospital, Infectious Diseases, Kingswood, Australia, [2]Nepean Hospital, Tuberculosis Control, Kingswood, Australia, [3]NSW Health Pathology, Centre For Diseases And Microbiology, Westmead, Australia, [4]Sydney Children's Hospital Network, Infectious Diseases, Westmead, Australia

Title of Case: TB cluster in the Pasifika community in Sydney, Australia
Background: Australia has one of the lowest tuberculosis (TB) incidence rates in the world (case rate of 5.8 per 100,000 in 2018) and the majority of reported cases has been within the overseas-born population. Australia is located however in close proximity to many high TB incidence countries, including some the Pacific island nations.
Case Presentation Summary: We describe a cluster of 20 TB cases among an ethnically Samoan family living in Western Sydney, Australia; 14 cases were genotypically linked by whole genome sequencing and 6 through epidemiological linkage. The cluster included cases identified over a 10 years period. The 20 TB episodes included 15 adults and 3 children (2 children were infected and were diagnosed with disease twice), aged from 11 months to 61 years.
Learning Points/Discussion: We highlight a paediatric TB case within this family, who was exposed to her birth mother in in 2019 and her grandmother in 2021, requiring 2 prolonged courses of treatment for TB disease before the age of 5 years. Treatment was complicated and highlights a need for Pasifika cultural engagement (talanoa), methods to improve health literacy, difficulties in access to directly observed treatment during the COVID-19 pandemic, the role of child protection services when required, and recent changes to Australian recommendations regarding BCG vaccination.

MULTIFOCAL MUSCULOSKELETAL TUBERCULOSIS, AN UNUSUAL CHILDHOOD PRESENTATION.

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Pramod Kulkarni
Deenanath Mangeshkar Hospital Research Centre, Pediatric Infectious Diseases, PUNE, India

Title of Case: Multifocal musculoskeletal Tuberculosis, an unusual childhood presentation
Background: Skeletal Tuberculosis is a less common form of Extra Pulmonary Tuberculosis in childhood. Multifocal musculoskeletal disease by Drug Sensitive MTB in an immunocompetent girl is presented.
Case Presentation Summary: A 13.5 old girl presented with seqential multiple body swellings since 18months. First one right scapular discharged & healed with a scar ove 6months. Left elbow, right foot, left forearm, left buttock, left anterior thigh swellings followed sequentially. These swellings were variably but mildly painful & dicharging over months with few healing with scar. She had significant limitation of posture & body movements but no fever, cough, chest pain. she had breathlessness since 2months relieved by Inhaler therapy. she had lost 5kg weight over last year. She was a frequent wheezer, had contact with a relative having active pulmonary TB 4years ago. Her investigations- normal WBC, microcytic hypochromic anemia,raised ESR & CRP, positive Tuberculin Skin Test, x ray limbs with osteomyelitis with soft tissue swellings & chest xray with fusiform paravertebral swelling. MRI confirmed multifocal osteomyelitis, thoracic Pott's spine & soft tissue cold abscesses. The wound discharge had AFB on ZN stain and GeneXpert confirmed MTB with Absent Rifampicin resistance. Primary immunodeficiency screening and HIV serology was negative. With 4drug Antitubercular therapy over next months she recovered well & continues so. Soft tissue swellings reduced markedly, wound and sinuses healed, gained 6kg weight and movements restored.
Learning Points/Discussion: Musculoskeletal TB is a late & less common childhood presentation of extrapulmonary tuberculosis. Our case is unusual for multifocal musculoskeletal involvement in an immunocompetent girl, caused by DSTB and resolving well with standard DSTB treatment.

CONGENITAL TUBERCULOSIS: IS IT MDR STRAIN?

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Ajay Kumar[1], Gunjana Kumar[1], Videesh Chinna[1], Sushma Nangia[1], Kamal Singhal[2]
[1]Lady Hardinge Medical College and Assoc. Kalawati Saran Children Hospital, Neonatology, Delhi, India, [2]Lady Hardinge Medical College and Assoc. Kalawati Saran Children Hospital, Pediatrics, New Delhi, India

Title of Case: CONGENITAL TUBERCULOSIS: IS IT MDR STRAIN?
Background: Congenital Tuberculosis is rare and usually misdiagnosed as sepsis, pneumonia or hepatitis resulting in poor prognosis. Aim of the current presentation is to share our experience in diagnosing and managing a newborn with congenital tuberculosis.
Case Presentation Summary: The baby born to 29 years 3rd gravida was admitted on D22 of life with fever. Mother had herpes zoster and facial palsy 20 days before delivery and recieved Acyclovir. Delivery and initial course was uneventful. On admission he had PR of 168/min, RR of 68/min and SPO2 of 91% on room air. Chest was clinically clear. There was moderate hepatosplenomegaly. X ray revealed bronchopneumonia. Baby's respiratory distress continued to worsen and repeat X ray on D29 showed development of pleural effusion (Fig). USG abdomen showed moderate ascites. Ascitic fluid and pleural fluid analysis was suggestive of exudate. Baby's clinical course prompted investigations for Tuberculosis in mother. Her chest X ray revealed miliary mottling (Fig). Gastric lavage of the baby and sputum of the mother revealed Rifampicin Sensitive Mycobacterial tuberculosis on CBNAAT. Baby was started on Streptomycin, Levofloxacin and Ethambutol in view of deranged LFT which could be changed to RZEH when LFT became normal. After 2 months of intensive treatment gastric lavage is still positive for Mycobacterium tuberculosis. As BACTEC MGIT report for drug sensitivity is awaited, it has been decided to extend intensive phase by 4 weeks. Meanwhile mother's sputum has become AFB negative. Baby has shown clinical and radiological
improvement.

Baby

Mother

Learning Points/Discussion: High index of suspicion led to diagnosis in the mother. Debatable points in

management are, starting modified anti-tuberculous treatment, no steroids, extending intensive phase by 1 months, and what should be the total duration of ATT?

M.AVIUM CAUSING CHRONIC CERVICAL LEMPHADENOPATHY IN AN IMMUNOCOMPETENT CHILD

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Chrysanthi Lazarou[1], Maria Theohari[1], Maria Berikopoulou[1], Panagiota Drosatou[1], Chrysi Aikaterini Georgokosta[2], Vana Spoulou[2], Anna Messaritaki[1]
[1]'Aghia Sophia' Childrens Hospital, 2nd Pediatric Clinic, Athens, Greece, [2]National and Kapodistrian University of Athens, First Department Of Pediatrics, Division Of Infectious Diseases, Athens, Greece

Title of Case: M.AVIUM CAUSING CHRONIC CERVICAL LEMPHADENOPATHY IN AN IMMUNOCOMPETENT CHILD
Background: Backgrounds: Nontuberculous mycobacteria (NTMs) are opportunistic environmental pathogenic bacteria transmitted to humans through respiratory, gastrointestinal system and skin. In the last three decades the prevalence of disease in immunocompetent children caused by NTMs has increased with annual incidence ranging from 0.8 to 4.5 children /100,000. Cervical lymphadenitis is the most common NTM clinical entity, particularly affecting patients aged 1–5 years.
Case Presentation Summary: Methods: We present the case of an 8-year-old immunocompetent boy presenting only with unilateral cervical lymphadenopathy, starting two months before his admission. The diagnosis of atypical mycobacterium was reached after biopsy of the extracted lymph node. Extensive work-up for underlying hematological and/or immunological disorders was negative. Results: While the ultrasound findings were non-conclusive, a lymph node biopsy was scheduled immediately, and tissue samples were sent for cultures for bacteria, including mycobacteria, and histological examination. In the histological exam there was no evidence of malignancy or granulomas. The lymph node culture was positive for Mycobacterium avium. The child was initially treated with clarithromycin and amoxicillin-clavulanate with no clinical improvement. The treatment was altered to intravenous cefotaxime –per os rifampicin, which the patient received for 15 days with no further improvement Excision of the affected lymph node was conducted after unsuccessful antibiotic treatment, and was considered as sufficient by the Department of Infectious Diseases. No further antibiotic treatment was required.
Learning Points/Discussion: Conclusions: The report of the case aims to highlight atypical mycobacteria as pathogens in healthy children. Suspicion of NTMs should be raised in the setting of chronic cervical lymphadenopathy regardless the immune status. Surgery is the gold standard treatment for cervical lymphadenitis following a usually unsuccessful antibiotic course.

PV0758 / #1095

MANAGEMENT OF BCG COMPLICATIONS: THE EXPERIENCE OF A TERTIARY HOSPITAL IN LONDON

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Giulia Lorenzetti[1], Elizabeth Whittaker[2,3]
[1]University of Rome Tor Vergata, Bambino Gesù Children's Hospital IRCCS, Academic Department Of Paediatrics, Rome, Italy, [2]Department of Paediatric Infectious Diseases, St Mary's Hospital, Imperial College Nhs Healthcare Trust, London, United Kingdom, [3]Imperial College, Paediatric Infectious Diseases, London, United Kingdom

Backgrounds: Bacille Calmette-Guérin (BCG) vaccine is administered in countries where tuberculosis is endemic to prevent disseminated and meningeal tuberculosis. Albeit uncommon, BCG vaccine complications can occur and there is no clear consensus on their management. The aim of this study was to review the experience of a tertiary care hospital in London (UK).
Methods: We retrospectively reviewed children with BCG complications managed at St Mary's Hospital, London between January 2016 and November 2022. Data on type of complications (localized [injection site reaction, lymphadenitis, or both] or systemic [disseminated BCG disease], management (watch and wait, antimicrobials, surgery) and outcome (complete resolution or healing with complication) were collected.
Results: Thirty-six patients experienced BCG vaccine complications. Demographic and clinical characteristics are shown in Table 1. Thirty-two (88.9%) children presented with localized complications (mainly lymphadenitis 71.9%), and 4 (11.1%) patients had disseminated BCG disease. Patients with localized disease were managed conservatively in the majority of cases (78%); 2 (6.3%) patients were prescribed with antimycobacterial treatment, 3 (9.4%) patients underwent surgery (i.e. incision and drainage), and 2 (6.3%) patients received both medical and surgical treatment. All patients with systemic complications were treated with a long course of antimicrobials, and 3 of them underwent surgery as well (Table 1). All patients with disseminated BCG disease and patients with slow healing/persistent lymphadenitis (total N=19), were investigated for possible underlying immunodeficiency: among them, six (31.6%) patients were diagnosed with immunodeficiency (Table 1). All patients eventually healed without

Demographic and clinical characteristics of the population	
Total number of patients - N	36
Gender - N (%)	
Male	16 (44.4)
Female	20 (55.6)
Ethnicity - N (%)	
Asian or Asian British	13 (36.1)
Black, African, Caribbean, Black British	2 (5.6)
Mixed of multiple ethnic groups	2 (5.6)
Other ethnic group	2 (5.6)
White	17 (47.1)
Comorbidities - N (%)	12 (33.3)
Immunodeficiency	6 (16.7)
Parental consanguinity - N (%)	2 (5.6)
Age at vaccination in days - median (IQR)	2 (0 - 13.5)
Age at symptoms onset in months - median (IQR)	3 (2 - 6)
Age at presentation at tertiary hospital in months - median (IQR)	6 (4 - 9.75)
Localized disease - N (%)	32 (88.9)
Injection site reaction	9 (28.1)
Injection site reaction + Lymphadenitis	3 (9.4)
Lymphadenitis only	20 (62.5)
Non-Suppurative lymphadenitis	11 (47.8)
Suppurative lymphadenitis	12 (52.2)
Disseminated disease - N (%)	4 (11.1)
Bone	2 (50)
Abdomen	1 (25)
CNS + Abdomen + Chest	1 (25)
Management of localized and disseminated disease	
Management of localized disease - N (%)	
Watch and wait	25 (78)
Antimycobacterial treatment	2 (6.3)
Surgery	3 (9.4)
Antimycobacterial treatment + Surgery	2 (6.3)
Management of disseminated disease - N (%)	
Antimycobacterial treatment only	1 (25)
Antimycobacterial treatment + Surgery	3 (75)

Clinical features and management of patients with immunodeficiency

Patient number	Type of Immunodeficiency	Type of complication - Details	Management
1	CGD	Localized - Suppurative lymphadenitis	Antimycobacterial treatment (4 drugs)
2	RAG1 deficiency	Localized - Injection site reaction + Lymphadenitis	Antimycobacterial treatment (4 drugs)
3	IFN-γ/IL-12 pathway defect	Systemic - Bone	Antimycobacterial treatment (2 drugs) + Surgery
4	IFN-γ/IL-12 pathway defect	Localized - Suppurative lymphadenitis	Antimycobacterial treatment (4 drugs) + Surgery
5	Syndromic immunodeficiency (Danon syndrome Xq24 deletion)	Systemic - Abdomen	Antimycobacterial treatment (5 drugs) + Surgery
6	Undefined immunodeficiency	Systemic - CNS, Abdomen, Chest	Antimycobacterial treatment (5 drugs)

sequelae.

Conclusions/Learning Points: The management of BCG complications is nowadays controversial. Our data show that localized disease can be safely managed conservatively. Immunological workup remains of utmost importance in children with disseminated BCG disease or slow healing/persistent lymphadenitis.

PERITONEAL TUBERCULOSIS IN A PEDIATRIC PATIENT: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Júlia Machado[1], Vitória Schinneider Muller[2], Wilson Hoshino[1], Ana Isabel Monteiro[1], Aida De Fátima Gouveia[1], Fabiana Carmo[1], Daisy Maria Machado[1], Kelly Cunegundes[1], Maria Aparecida Ferrarini[1]
[1]universidade federal de são paulo, Departament Of Pediatric Infectology, São paulo, Brazil, [2]universidade federal de são paulo, Infectologia Pediátrica, São paulo, Brazil

Title of Case: Peritoneal Tuberculosis in a Pediatric Patient: a case report
Background: peritoneal tuberculosis is a very rare condition in children representing about 6% of extrapulmonary cases of TB. Usually occurs due to reactivation of a latent focus in the peritoneum or after a pulmonary/miliary condition with a hematogenous dissemination. This paper aims to report a case with microbiological confirmation in a pediatric patient.
Case Presentation Summary: Patient R.S.F, 9 years old, previously healthy. Presented with 2 months of weight loss, progressive abdominal pain, mild diarrhea, nausea and lack of appetite, in addition to daily low fever at night. Physical exam show na ascitic abdomen and no other findings. Normal chest X-ray and Tuberculin test = 8mm. Abdominal CT scan with free fluid in the cavity and peritoneal nodular thickening. Peritoneal fluid: ADA 73, negative BK PCR, negative culture for bacteria and BK, absence of neoplastic cells. Blood cultures and gastric fluid negative for TB. Laparoscopy with biopsy of nodular lesion in the peritoneum with positive PCR for Mycobacterium tuberculosis. Treatment was initiated with rifampicin isoniazid and pyrimethamine. The child presented good clinical response, coursed with rapid weight gain and complete resolution of ascites.
Learning Points/Discussion: Peritoneal tuberculosis is a challenging entity, rarely diagnosed in children, with a nonspecific clinical history and difficult microbiological confirmation. The disease has high morbidity and mortality if not correctly treated and high clinical suspicion is required to enable early diagnosis in this population.

PRELIMINARY DATA OF THE EXPERIENCE OF TOSAMAGANGA HOSPITAL IN TANZANIA IN IMPLEMENTING THE SIMPLE ONE-STEP METHOD FOR XPERT ON STOOL IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Anna Hermine Markowich[1], Maria Francesca Dalla Porta[2], Emanuel Pillas[3], Elias Nindwa[3], Martina Borellini[4], Paolo Belardi[4], Andrea Pietravalle[5], Sara Chiurchiù[6], Laura Lancella[7]
[1]Bambino Gesù Children's Hospital, Infectious Diseases, Rome, Italy, [2]University of Modena and Reggio Emilia, Post-graduate School Of Pediatrics, Department Of Medical And Surgical Sciences Of The Mother, Children And Adults, Modena, Italy, [3]Tosamaganga Hospital, Laboratory, Tosamaganga, Tanzania, [4]CUAMM - Doctors with Africa, Tosamaganga Hospital, Tosamaganga, Tanzania, [5]CUAMM - Doctors with Africa, Padova, Padova, Italy, [6]Bambino Gesù Children's Hospital IRCCS,, Infectious Disease Unit, Rome, Italy, [7]Bambino Gesù Children's Hospital, Infectious Disease Unit, Roma, Italy

Backgrounds: The diagnosis of tuberculosis in children is a challenge, especially in low-income countries. The increase use of rapid molecular testing has improved the microbiologic yield, yet respiratory sample collection in young children may be still difficult. According to WHO, stool is an alternative sample that can be collected non-invasively. We present preliminary data of the experience of Tosamaganga Hospital in Tanzania in implementing the Simple One-Step method for Xpert on stool in children.
Methods: At the Tosamaganga Hospital diagnosis of TB in children unable to produce sputum is achieved through a national clinical score. The hospital laboratory was already equipped with the Xpert MTB/RIF instrument and software, and the personnel was trained to test sputum, CSF and other biological fluids. In November 2022 the laboratory staff received additional training on the Simple One-Step method through the SOP. In order to assess the efficacy of the training, the staff performed the Xpert on stool and sputum of the same adult patients, and the results were concordant.
Results: In December 2022, the Xpert on stool was then performed in 5 children with severe acute malnutrition (a risk factor for TB) who were not able to produce sputum. The characteristics of patients are summarized in table 1. All tests resulted negative, likewise the Tanzanian clinical score. The laboratory technicians reported the test as being intuitive and not time-consuming.

Patient	Age (months)	Sex	HIV	TB contact	Fever	Cough	Xpert on stool Result
1	20	F	negative	no	yes	no	negative
2	17	F	negative	no	yes	no	negative
3	15	F	negative	no	no	yes	negative
4	16	F	negative	no	no	yes	negative
5	15	M	negative	no	yes	no	negative

Conclusions/Learning Points: The SOS method for Xpert on stool is simple and can be extremely useful in the diagnosis of TB in young or severely ill children. In our setting it was easy to implement since Xpert was already in use. We expect this non-invasive test to become routine when assessing a child with suspected tuberculosis.

PV0761 / #1884

NEURO TUBERCULOSIS IN A YOUNG INFANT: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Camila Morais[1], Flavia Almeida[1], Daniel Jarovsky[1], Carolina Santos[1], Clicia Bispo De Oliveira[1], Janaína Poy[1], Juliana Oliveira[1], Manuela Bessen[1], Mariana Zanata[1], Rebecca Luguera Copin Tenorio Tenorio[1], Samantha Matos[1], Giovanna Guerra[1], Emmanuella De Jesus D'Elia[1], Marco Aurelio Safadi[1], Eitan Berezin[2]
[1]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [2]santa casa sp, Pediatric, sao paulo, Brazil

Title of Case: Neuro tuberculosis in a young infant: a case report
Background: Tuberculosis remains an endemic disease in Brazil. In 2022 there were more than 49.000 new confirmed cases. In 2018, 8.3% of the total cases occurred in children under 19 years of age – an unchanged rate to be seen in 2022 (7.6%). Seventeen percent of these cases had some form of extrapulmonary involvement. In addition, we present a case of TB meningoencephalitis with rapid and unfavorable evolution.
Case Presentation Summary: a previously healthy 4-month-old male infant was admitted with dyspnea, altered neurological examination, and signs of sepsis. He presented epidemiology and CSF analysis suggestive of TB, and treatment with RIP and dexamethasone was immediately started. Despite the therapy, the patient developed re-entrant seizures, and imaging revealed intense ischemia with the brainstem and diencephalon involvement. Due to the extension and irreversibility of the condition, complete palliative care was bilaterally instituted. Unfortunately, after 2 months of hospitalization, the patient died.
Learning Points/Discussion: epidemiological surveillance plays a fundamental role in controlling TB-related morbidity and mortality. In a country like Brazil, it cannot fail to be considered among the differential diagnoses in countless clinical conditions.

QUINQUENNIAL STUDY OF PAEDIATRIC TUBERCULOSIS IN INDIA – EXPERIENCE OF A SOUTH INDIAN TERTIARY CARE HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Geetha Nagaraj[1], Seeta Reddy[2], K Ravikumar[3]
[1]Central Research Laboratory, Molecular Biology, Bangalore, India, [2]Kempegowda Institute of Medical Sciences, Dept Of Pulmonology, Bangalore, India, [3]Central Research Laboratory, Microbiology, Bangalore, India

Backgrounds: One of the top ten killers of children globally today is tuberculosis (TB). The true burden of paediatric tuberculosis (TB) is frequently underestimated and underdiagnosed in India. The ability to diagnose paediatric TB is improved by the availability of the Xpert MTB/RIF assay. We aimed to evaluate the clinical characters, diagnosis, treatment regime given and outcome of the treatment among paediatric cases.
Methods: Data of 191patients diagnosed with paediatric TB between 2017-2022 were analysed. Demographic and clinical characteristics, diagnostic methods, commenced treatments and clinical follow up of patients were listed from medical records
Results: 6.4%(n=191) of the total clinically diagnosed TB positive cases was constituted by paediatric age group (0-15yrs). Highest TB cases were reported in 2019(24%, n=46). Extra pulmonary TB was predominant (63%), while pulmonary TB was 37%. One patient was reactive to HIV test and none of the patients were diabetic, alcoholic and tobacco user. 27/46(58%) samples were tested on positive using GeneExpert MTB/RIF in 2019. 32/320 were positive for TB during 2022. INH resistance (low level) was observed in one patient and no RIF resistance case. Until 2020, paediatric TB patients were treated using HRE drugs for 6months. From 2017-2019, 110 patients received HRE drugs. Among them, 23cured, 78Treatment-complete, 2 Treatment-regimen changed, 7Untraceable. 2FDC and 3FDC drug tablets were dispensed from 2020. 81 (2020-22) patients received 2FDC, 3FDC, 4FDC, Ethambutol drug combinations. One patient with INH resistance was treated with extra Pyrazinamide and Levofloxacin drugs. Among 81 patients– 14cured, 1died, 46treatment complete, 1treatment regimen changed, 19– Diagnosed on treatment.
Conclusions/Learning Points: The results of our study advance knowledge of pediatric tuberculosis, and the continuing
Xpert MTB/RIF campaign for pediatric tuberculosis increases diagnostic yield

XPERT MTB/RIF ULTRA VERSUS XPERT MTB/RIF FOR THE DIAGNOSIS OF EXTRA PULMONARY TUBERCULOUS: A PROSPECTIVE, SINGLE CENTRE STUDY FROM INDIA

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Santhanam Naguthevar, Deepak Kumar, Kuldeep Singh, Jagdish Prasad Goyal, Sarika P Kombade, Akshatha Ravindra, Subhashree Samantaray, Shivang Sharma, Gopal Krishna Bohra, Mk Garg
AIIMS, Infectious Disease, Jodhpur, India

Backgrounds: Extrapulmonary tuberculosis (EPTB) prevalence in India ranges from 8.3-13.1%. EPTB diagnosis more challenging due to paucibacillary nature of the specimen. Xpert MTB/RIF Ultra (Xpert Ultra) might have higher sensitivity than its predecessor, Xpert MTB/RIF (Xpert). This study, we aimed to compared utility of Xpert MTB/RIF and Xpert MTB/RIF Ultra in EPTB
Methods: In this prospective study, we included the suspected cases of EPTB with age <18 years based on the composite reference standard (CRS) criteria. Specimen was sent for Acid fast stain (AFB), Xpert, Xpert Ultra and Mycobacterial culture. Test performance (sensitivity, specificity, and positive and negative predictive values) was calculated for Xpert Ultra and Xpert and compared against CRS.
Results: Between January 16, 2021 to December 10, 2021, 84 patients were randomly assigned to Xpert Ultra (n=52) or Xpert (n=32). The sensitivities of Xpert Ultra and Xpert for tuberculous meningitis diagnosis against a reference standard of mycobacterial culture were 97.22% for Xpert Ultra and 50% for Xpert specificities was 53.3% & 0% respectively.

Analysis (total)	Sensitivity	Specificity	Positive predictive value	Negative predictive value
Xpert ultra	97.22%	53.33%	54.55%	94.12%
Xpert	50%	0%	18.52%	0%

Total cases (no)	Xpert ultra	Xpert
Lymph node	12	14
TB meningitis	29	10
Pleural	4	4
Others	7	4
Total	52	32

Conclusions/Learning Points: Our results suggest that Xpert Ultra might perform better than Xpert in EPTB samples in pediatric population & could be preferably used in detection of paucibacillary TB. Xpert Ultra showed a high negative predictive value 0f 94%, which can be of clinical use. Both the methods detects Rifampin sensitivity which is important for initiation of appropriate antitubercular drug. We need further studies with larger sample size to confirm the utility of Xpert Ultra.

ISOLATED TUBERCULOS ARTHRITIS OF THE ANKLE : A CASE REPORT FROM IGIMS HOSPITAL PATNA

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Zeba Najeeb
Igims patna, Microbiology, Patna, India

Title of Case: Isolated tuberculos arthritis of the ankle : a case report from IGIMS hospital Patna
Background: Isolated ankle joint Tuberculos arthritis is extremely rare , comprising an incidence lower than 5% of skeletal tuberculosis.
Case Presentation Summary: We present an unusual case of isolated tubercular arthritis of the ankle in a 30 year old non diabetic , normotensive male , where the definitive diagnosis was difficult to be reached . The clinical examination revealed slight edema and a slight increase in local skin temperature . Based on magnetic resonance imaging performed the finding was suggestive of hyperintense marrow edema was noted involving navicular bone , anterior middle band inferior aspect of talus bone with significant reduction of talonavicular joint space . Arthoscopic synovial biopsy was carried out in which a sample from the synovial lesions was taken for histopathological examination along with synovial fluid analysis . The histopathological findings showed granulomatous arthritis (histocytes and multinucleatd langerhans type gaint cells with surrounding lymphocytes . The microscopy , MGIT culture and CBNAAT (xpert MTB /RIF) of synovial fuid suggestive of Mycobacterium Tuberculosis bacilli.
Learning Points/Discussion: A high index of suspicion and inclusion of TB in the differential diagnosis of inflammatory arthritis is needed to achieve early diagnosis of the disease and appropriate treatment.

DISTRIBUTION OF SEX IN TUBERCULOSIS DISEASE IN CHILDREN, ADOLESCENTS, AND ADULTS IN SWITZERLAND

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Daniela Neudecker[1], Nora Fritschi[2], Nicole Ritz[2,3,4], Ekkehardt Altpeter[5]
[1]University Children's Hospital Basel, Department Of Clinical Research, Basel, Switzerland, [2]University Children Hospital Basel and University Basel, Department Of Clinical Reserach, Basel, Switzerland, [3]Children's Hospital Lucerne, Paediatric Infectious Diseases, Luzern, Switzerland, [4]The Royal Children's Hospital Melbourne, Paediatric Infectious Diseases Unit, Melbourne, Australia, [5]Federal Office of Public Health, Transmissible Id, Bern, Switzerland

Backgrounds: Sex distribution of individuals with tuberculosis (TB) disease shows a male dominance in adults, whereas in adolescents current data suggest a female dominance. The aim of this study was to assess the sex distribution in individuals with TB disease in Switzerland, and particularly in adolescence.
Methods: Notification of TB disease cases to the Swiss Federal Office of Public Health (FOPH) is mandatory for laboratories and physicians. For this study surveillance data from 2000 to 2021 was used. TB disease was defined as the detection of Mycobacterium tuberculosis by culture or molecular assays or when a treatment with ≥3 antimycobacterial drugs was initiated. Absolute TB disease cases and incidence rates stratified by sex were calculated. Adolescence was divided into and defined as early adolescence 10-14 years and late adolescence 15-19 years.
Results: A total of 11'872 individuals were notified during the 22 years observation of whom 832 were adolescents. Throughout the entire age range of adolescence, the male sex dominated with a male to female ratio (M:F) of 1:0.5 (incidence 5.7 per 100'000 and 3.0 per 100'000 for males and females, respectively). In early adolescence the female sex dominated with a M:F ratio of 1:1.2 (incidence 7 per 100'000), while in late adolescence the male sex dominated with a ratio of 1:0.4. The increase of TB incidence in females compared to males was seen at an early age.
Conclusions/Learning Points: We observed a female dominance only in early adolescence, while in late adolescence there is clear dominance of male sex in TB cases in Switzerland. The dominance of males in late adolescence likely results from a higher rate of male refugees arriving in Switzerland in this age

group.

SHOW ME YOUR LEFT ARM - STUDENTS' PROJECT TO INVESTIGATE THE KNOWLEDGE AND RISK PERCEPTION REGARDING TUBERCULOSIS IN DIFFERENT COUNTRIES

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Lioba Niesmann, Wanda Ambrosius, Laura Pohl, Anna Küper, Melissa Szmukala, Lea Zylla, Leszek Szenborn, Kamila Ludwikowska
Wroclaw Medical University, Department Of Pediatric Infectious Diseases, Wrocław, Poland

Backgrounds: Globally, the incidence of tuberculosis (TB) is falling at about 2% per year, but it is still one of the most important threats for public health. The incidence of TB is varied and 30 high TB burden countries account for nearly 90% of new cases. The strategy for vaccination depends on the disease epidemiology. Increased human mobility in recent years might impact the TB incidence, however, and doctors should be aware of TB regardless of the country. The aim is to research and evaluate the current awareness and knowledge about TB in future doctors. We hypothesized that the knowledge on TB and perception of TB risk might depend on the country of origin as well as the country in which one gets medical education.
Methods: To investigate that, a group of students from English Department from our University created an online questionnaire and distributed it to multiple universities in different European countries. The study group would be medical students. Except for the demographic information, the questionnaire includes questions that will allow us to evaluate the knowledge of TB epidemiology, presentation, prevention, as well as subjective risk perception. We would compare the results obtained from the students of countries with relatively low epidemiological rates of tuberculosis, to those studying in countries with a higher incidence.
Results: The study is ongoing, by the time of the ESPID meeting we would gather enough data to be presented.
Conclusions/Learning Points: We hope that the study will let us evaluate if there are any differences in knowledge as well as subjective sense of threat connected with TB depending on country, and if there is a need to adjust education on TB accordingly.

[1]Kurume University School of Medicine, Department Of Pediatrics And Child Health, Kurume Fukuoka, Japan, [2]Kurume University School of Medicine, Department Of Infection Control And Prevention, Kurume Fukuoka, Japan

Backgrounds: Bacille Calmette-Guérin (BCG) lymphadenitis occurs after BCG vaccination and usually results in swelling of the axillary lymph nodes on the side of vaccination. Most cases resolve spontaneously, but there are often cases of abscess formation or even fistulae. Few reports for BCG lymphadenitis specify which cases require therapeutic intervention, and there are limited reports summarizing the course of treatment of BCG lymphadenitis and its underlying diseases.
Methods: Thirty-eight patients who visited the Kurume University Hospital between 2013 and 2022 with the complaint of lymphadenopathy after BCG vaccination were included in the study. Lymph node size at the time of visit, course of local lesion, treatment details, prognosis, and underlying disease were investigated retrospectively based on medical records.
Results: Of the 38 patients, 24 had spontaneous regression. Fourteen patients had suppurative lymphadenitis, of which nine bursts spontaneously, and four had lymph node biopsies. Six patients had pus or biopsied tissue with BCG Tokyo strains. Two patients were diagnosed as tuberculous lymphadenitis. Eight patients were treated with rifampicin (RFP) ointment application and two with oral isoniazid (INH), all of which regressed within 6 months. 1 patient with underlying Mendelian Susceptibility to Mycobacterial Disease (MSMD) recovered after RFP and INH administration, 1 patient with chronic granulomatous disease (CGD) developed disseminated BCG infection and was treated for a prolonged period.
Conclusions/Learning Points: Most cases of BCG lymphadenitis resolve spontaneously, but some cases of suppurative lymphadenitis include immunocompromised patients with CGD, MSMD, or tuberculosis infection. In case of suppurative lymphadenitis, it is important to search for underlying disease.

Backgrounds: Tuberculosis (TB) is a major cause of paediatric morbidity and mortality, with most deaths occurring in children undiagnosed. Mycobacterial culture and more recently Xpert® MTB/RIF Ultra (Ultra) are the reference standard for confirmation in children.
Methods: RaPaed-TB was a diagnostic accuracy study enrolling children (<15yrs) with suspected TB from 5 lower-middle income countries. Two respiratory specimens (sputum or gastric lavage) were collected, and one nasopharyngeal aspirate (NPA) if <5yrs. Extrapulmonary specimens were collected according to local guidelines where possible. Children with M. tuberculosis (MTB) confirmed by Ultra and/or culture were categorised as confirmed TB.
Results: Among 965 children enrolled with valid microbiological results, 2299 samples were collected. In total 93.8% (2157) of samples were pulmonary; most were induced sputa (IS) (59%, 1273/2157), spontaneous sputa (SS) (18%, 389) and NPAs (15%, 332). Of 527 children treated for TB, MTB was confirmed in only 45% (239); 46.0% (110) on Ultra and culture, 36% (86) on Ultra alone, and 18% (43) on culture alone. Semi-quantitative results “trace”, “very low” and “low” together accounted for 78% of all Ultra results. 41% (98) of confirmed cases were confirmed on IS, 21% (49) on extrapulmonary specimens and 15% (36) on SS. Few (15%, 35) were confirmed on more than one specimen type; most on IS and NPA (5%, 13), and on IS and SS (3%, 8). Incremental yield was calculated in children with two serial samples collected for culture. Additional yield was 5% for IS, 4.3% for any two specimen types combined and 3.7% for SS.
Conclusions/Learning Points: This study confirms the paucibacillary nature of TB in children and the added diagnostic value of Ultra “trace” detection. In addition, it highlights the need for improved diagnostic tests for paediatric TB.

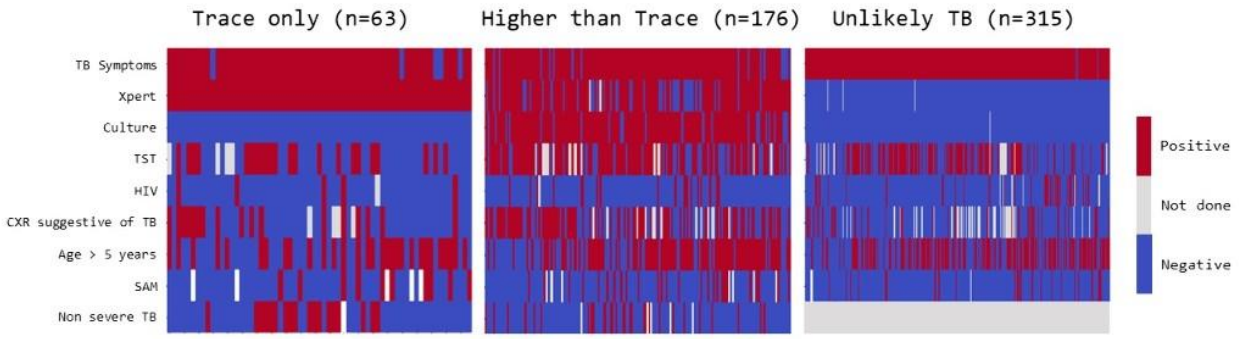
Backgrounds: Microbiological detection of tuberculosis (TB) remains challenging in children. Xpert®MTB/RIF Ultra (Ultra) has greater sensitivity than alternative cartridges. Due to lower specificity, however, WHO recommends considering Ultra Trace results (the lowest semi-quantitative positive) as true positive only for HIV-positive adults, children, and extrapulmonary specimens.
Methods: RaPaed-TB was a multi-centre prospective diagnostic validation study including five countries. Children (<15 years) with presumptive TB provided at least two (induced) sputum samples at enrolment and one nasopharyngeal aspirate if <5 years.
Results: Of 974 participants, 842 were eligible for diagnostic case classification and 28.4% (239/842) met definitions for microbiologically confirmed TB, including 46.0% (110/239) confirmed by both Ultra and culture, 18.0% (43/239) by culture only, and 36.0% (86/239) by Ultra only. Of note, 26.4% (63/239) were confirmed by Ultra Trace only. Children confirmed by Ultra Trace only were younger (4.9 years [IQR 1.3-9.8]) than children confirmed otherwise (7.1 years [2.0-12.0]) with higher BCG-vaccination (100%, [58/58] vs 89.2% [141/176]), and less likely to have positive tuberculin skin test (TST; 37.3% [22/63] vs 70.0% [112/176]), chest Xray consistent with TB (27.0% [17/63] vs 51.7% [81/176]), or severe TB disease (16.4% [29/176] vs 28.6% [18/23]) (Figure 1). On multivariate binomial regression, older age (RR 0.56, 95%CI 0.35-0.89), positive TST (RR 0.42, 0.27–0.65) and chest Xray consistent with TB (RR 0.52, 0.32-0.84) remained significantly less likely for children confirmed by Trace alone.



Conclusions/Learning Points: Ultra Trace results increased the numbers of microbiologically confirmed children, disproportionately impacting children of younger age, less clear radiology, and lower TST positivity. Possible explanations include both false positives, and greater increase in sensitivity for less severe TB disease, warranting further in-depth analyses. Case-by-case review is ongoing by an expert panel.

Backgrounds: Paediatric Tuberculosis (TB) is associated with significant morbidity and mortality. Microbiological confirmation of disease can be challenging. Diagnosis relies on non-specific clinical and radiological features.
Methods: RaPaed-TB study was a prospective study of new diagnostics, enrolling children (<15years) with suspected TB from 5 lower-middle income countries. Baseline demographic, clinical and chest radiograph data, and specimens for microbiological testing were collected. Participants were categorised as confirmed, unconfirmed or unlikely TB, according to adapted NIH consensus definitions. Clinical characteristics in the confirmed and unlikely TB groups were compared.
Results: Of 974 children enrolled, 842 (86.4%) could be categorised; 28.4% (239) had confirmed TB, 34.2% (288) unconfirmed TB, and 37.4% (315) unlikely TB. Children with confirmed TB were older (6.2 [IQR 1.8-1.6] vs 4.8 years [IQR 2.1-7.2]), with lower weight-for-length (in <5years) or BMI-for-age (in >5years) z-scores (-0.6 [SD 1.6] vs -0.1 [SD 1.5]). Both groups had similar percentages of children living with HIV (10.0% [24/239] vs 10.2% [32/315]), however, a higher proportion of confirmed cases was antiretroviral naïve at baseline (52%, 13 vs 21%, 7). Similar frequencies of TB symptoms were observed, however, the confirmed group reported a higher mean number of symptoms (4.0 [SD 2.4] vs 3.2 [SD 1.7]). More children in the confirmed than unconfirmed group had a positive Tuberculin Skin Test, TST (61% [134/239] vs 42% [125/315]) and chest radiograph findings attributable to TB (45% [108/239] vs 13% [41/315]). Multivariate regression analysis supported the associations between confirmed TB and TST positivity (OR 6.36, 95%CI 3.52-11.50), chest radiography (OR 2.57, 95%CI 1.33-4.97) and number of symptoms (OR 1.27 95%CI 1.05-1.52 for each additional symptom reported).
Conclusions/Learning Points: In one of the largest cohorts in recent years, findings reflected the well-described symptomology of paediatric TB.

ACTIVATION OF LATENT TUBERCULOSIS BY A COVID-19 INFECTION: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Omotakin Omolokun, Jessica Perry
CWM TAF UNIVERSITY HOSPITAL HEALTH BOARD, Paediatrics, Merthyr Tydfil, CF DT, United Kingdom

Title of Case: Activation of latent tuberculosis by a COVID-19 infection: A case report
Background: Few case reports have suggested the possibility of activation of latent pulmonary tuberculosis in COVID-19 patients. To date, there has however been little described in the paediatric population.
Case Presentation Summary: We report a case of a 15-year-old male who presented with shortness of breath, night sweats and weight loss, following a recent PCR confirmed COVID-19 infection. His initial COVID-19 infection was mild, not requiring treatment. Three months later, he presented with constitutional symptoms and shortness of breath, for which his GP had arranged a chest x-ray and review by the Paediatric team. Chest imaging showed significant upper lobe consolidation in keeping with a diagnosis of active pulmonary tuberculosis. Screening test four months prior to arrival at the United Kingdom including TB screen was negative. on examination, there was reduced air entry with scattered crepitations to the right side and bronchial breathing but saturating 98% in air. He had a few cervical Lymph nodes but no organomegaly. During his admission, he had multiple high grade fevers. Chest x-rays showed bilateral airspace opacification throughout the right lung (figure 1). Sputum cultures were sent which later showed acid fast bacilli were present on both ZN and Auramine staining. He responded well to treatment with Rifinah, Ethambutol, Pyrazinamide and Pyroxidine as par guidelines.

Figure 1 showing Pulmonary Tuberculosis.
Learning Points/Discussion: Our case highlights an unusual presentation of PTB in a child previously fit and well. Given his previous negative screening for TB and the sequence of events, we suggest that COVID-19 may have played a role in activating a latent TB for this child.

INFANTILE TUBERCULOSIS. HOW IMPORTANT IS THE SCREENING?

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Inês Pereira Soares[1], Madalena Torrado Malato[1], António Sampaio Mesquita[1], Joana Carvalho[2], Florbela Cunha[1]
[1]Hospital de Vila Franca de Xira, Pediatrics, Vila Franca de Xira, Portugal, [2]Centro de Diagnóstico Pneumológico, Tuberculosis, -, Portugal

Backgrounds: Estimating the burden of tuberculosis (TB) in children is challenging due to lack of standard case definition, low public health priority, and difficulty in establishing a diagnosis. Since 2015, Portugal is a low incidence country. In 2021 there were 1504 cases reported, 2% in children <15 years.
Methods: Retrospective analysis of children referenced to an infectious disease outpatient clinic in a level II hospital in the past 2 years for “close contact” with adults with respiratory TB. Statistical analysis in Excel2013®.
Results: There were identified 22 children, 13 girls. The average age was 4,2 years. Six children had been vaccinated with BCG. The “close contact” was the mother in eight children and a family member in 11; in one child it was unknown. The index case was Portuguese in nine children and foreign-born in 11: Guinean (3), Angolan (3), Indian (3), Spanish (2). Most children were asymptomatic with a normal chest x-ray. One child presented with an abnormal chest-CT and a positive Lowenstein culture of the gastric aspirate for Mycobacterium tuberculosis complex with negative smear and nucleic acid amplification tests. Screening tests for latent TB infection (LTBI) were positive in ten children: three positive tuberculin skin tests (TST), three TST conversions, two positive interferon-gamma release assays (IGRA) and two IGRA conversions. Eleven children were offered chemoprophylaxis, nine were treated for LTBI and one for TB disease (TBD).
Conclusions/Learning Points: Amongst the identified children 47,6% were treated for LTBI/TBD. Most contacts were a household with mothers as the main spread source. TB remains a public health problem, with that being verified in the residential areas of our hospital. Screening tests remain essential for identifying TB in asymptomatic children that were “close contacts” of contagious adults.

Backgrounds: Cytomegalovirus (CMV) and tuberculosis (TB) are highly prevalent pathogens with similar epidemiological characteristics. Recent evidence suggests that CMV-TB co-infection affects the risk for TB infection and TB disease progression. We here assess the burden of CMV-TB co-infections in children with presumptive TB and describe their immunological response against CMV antigens.
Methods: RaPaed-TB was a prospective, multi-center paediatric TB diagnostic accuracy study conducted in five countries. Case definition for TB disease followed NIH-consensus classification. T-cell activation marker CMV assay (TAM-CMV) is a blood based immunological assay using flow-cytometry to measure functional and phenotypic markers on CMV-specific CD4 T-cells (CD38 and CD27). CMV-viral load (VL, blood and urine) and serology were captured alongside TAM-CMV at baseline, month 1, 3, and 6.
Results: At point of writing, preliminary results for CMV-serology and CMV-VL were available for 19/300 children with defined TB disease status, 57.9% (11/19) of which were CMV-IgG positive (mean AU 388.5437). Median CMV-IgG in children with confirmed TB was lower (n=9, 217.6 AU; IQR 47.71-250.5) compared to children with unlikely TB (n=10, 371.7 AU; 204.2-999). A considerable proportion of children was VL-positive, particularly children under the age of 5 (9/10). 576 TAM-CMVs captured at multiple time points from 316 children with a defined TB case definition are available and descriptive analysis of the immunological CMV-specific T-cell response is currently underway. Further testing and analysis are ongoing.
Conclusions/Learning Points: Our preliminary results show a high prevalence of CMV-VL and serology positive children under the age of 5. This is the first study to investigate functional changes of CMV-specific T-cells and other determinants of the CMV-immune response and will contribute to a better understanding of the immunological and clinical implications of TB-CMV coinfections.

Title of Case: Challenges in diagnosing TBM
Background: Tuberculous meningitis (TBM), a severe manifestation of tuberculosis in children, is associated with high risk of death and disability. After cervical lymphadenitis, TBM is the commonest form of extrapulmonary tuberculosis in children. Diagnosing TBM is often challenging due to its commonly insidious onset with non-specific symptoms, and the lack of highly sensitive diagnostic tests. Diagnostic and resulting treatment delays increase the risk of poor clinical outcome.
Case Presentation Summary: A 2.5-year-old boy of African descent presented with fever without focus for two weeks. Initial blood tests showed unremarkable inflammatory parameters. A broad viral panel performed on a pharyngeal sample and blood cultures were negative. Chest x-ray and abdominal ultrasound were unremarkable. Three weeks after symptom onset, when the patient developed reduced consciousness, a cranial MRI scan revealed symmetrical ventricular dilatation. Cerebrospinal fluid (CSF) showed: WBC 254 cells/µl (93.9% lymphocytes), low glucose and high protein levels. CSF Gram stain and PCR for common viruses were negative. Despite an indeterminate IGRA result (QuantiFERON-TB Gold), TBM was suspected due to the CSF changes, and empiric TBM treatment was started. PCR for Mycobacterium tuberculosis was performed on three gastric aspirates and three CSF samples, but only positive in one CSF sample. After four weeks only one gastric aspirate and one CSF culture grew M. tuberculosis.
Learning Points/Discussion: This case illustrates the difficulties in diagnosing TBM in children. Published data show that indeterminate IGRA results, which convey no information about the TB infection status of the respective patient, are more common in TBM than other forms of TB. MTB PCR can expedite the diagnoses compared to culture, but has comparatively poor sensitivity in TBM. Therefore, multiple clinical samples should be examined whenever possible.

[1]Hospital 12 de Octubre- University of Milan, Pediatric Infectious Diseases, Madrid, Spain, [2]Hospital 12 de Octubre, Pediatrics, Madrid, Spain, [3]12 de Octubre University Hospital, Pediatric Infectious Diseases, Madrid, Spain

Title of Case: TRACHEOBRONCHIAL STENOSIS IN A CHILD UNDERGOING ANTITUBERCULOUS TREATMENT: A DIAGNOSTIC AND THERAPEUTIC CHALLENGE
Background: Differential diagnosis, while facing clinical/radiological worsening at the beginning of antituberculous treatment, must include paradoxical reaction as well as treatment failure or coinfections. Management can be challenging when vital structures are affected.
Case Presentation Summary: 4-year-old child, living in Spain, arrived to ER with 5-days fever after a 6 weeks-stay in Morocco. Mediastinal lymphadenopathies at chest X-ray, 10 mm skin-test, positive IGRA test and positive PCR for Mycobacterium Tuberculosis in stool, led to Tuberculosis diagnosis. Treatment with HRZE, with paediatric formulations, was started, followed by fever resolution. Three weeks later, he was hospitalized for stridor at rest. Chest X-ray and CT scan showed mediastinal lymphadenopathies significantly increased in size with tracheal and bronchi compression (minimum diameter 3 mm). Paradoxical reaction was suspected and iv methylprednisolone at 2 mg/kg/d was started. Concurrently, drug dosage and formulations were adjusted, respiratory viral coinfection and drug resistance, through detection of mutations with PCR in stool, were excluded. Oral switch was made after 7 days of iv steroids followed by clinical and radiological worsening.Multidisciplinary diagnostic and therapeutic alternatives were discussed: transbronchial lymphadenopathies' decompression was ruled out for high anaesthetic risk as well as infliximab, administered to date only in meningeal paradoxical reactions. Eventually, conservative approach was preferred using iv methylprednisolone, with slow tapering, obtaining gradual improvement.
Learning Points/Discussion: Our case describes how paradoxical reactions can be a real challenge both in the diagnosis and treatment of TB. Poor evidence exists regarding their management in children, especially in life threatening situations. Non-standardized microbiological tests like PCR in stool as well as a strict multidisciplinary follow-up can be crucial. Nevertheless, more studies are needed for the pediatric population.

TUBERCULOSIS OR CANCER? TWO CASES WITH A CHALLENGING DIFFERENTIAL DIAGNOSIS

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Giulia Meraviglia, Anna Sala, Caterina Peri, Valeria Rubinacci, Gianvincenzo Zuccotti, Vania Giacomet
Università degli Studi di Milano, Department Of Biomedical And Clinical Sciences, Buzzi Children's Hospital, Milan, Italy

Title of Case: Tuberculosis or cancer? Two cases with a challenging differential diagnosis
Background: Clinical and radiological findings in tuberculosis often present analogies with neoplastic disease, making the differential diagnosis challenging. Here we present two cases followed at our Unit.
Case Presentation Summary: 16 years-old girl from Pakistan. Subacute onset of night fever and vomiting. Chest CT scan revealed mediastinal and peritracheal adenopathy. Abdominal MRI showed ascitic effusion with peritoneal thickening and mesenteric adenopathy. QuantiFERON resulted positive while tumour markers were negative. Ascitic fluid was negative for both tumour cells and detection of Mycobacterium tuberculosis (MT) by microscopy, culture, and RT-PCR. FDG-PET showed multiple thoracic and abdominal lymphadenopathies, suspicious for neoplastic lesions. Exploratory laparoscopy with peritoneal biopsies was performed, revealing epithelioid cell granulomas with necrotizing multinucleated giant cells referable to MT infection. 14 years-old boy from Philippines. Due to abdominal pain and vomiting, abdominal ultrasound was performed, showing hyperechoic mesenterial adipose tissue and ascites. MRI revealed pleural and peritoneal effusion with thickening of mesenteric adipose tissue. Chest CT scan showed pleural effusion, lingular consolidation and intrathoracic lymphadenopathy. Mantoux was positive while QuantiFERON and tumour markers tested negative. In pleural fluid from thoracentesis no malignant cells were found and RT-PCR for MT was negative. Exploratory laparoscopy with peritoneal biopsies was performed, showing necrotizing chronic granulomatous inflammation with multinucleated giant cells. In both cases treatment with HRZE was started with improvement.
Learning Points/Discussion: Our cases show that before doubtful inflammatory lesions, it is essential to consider tuberculosis in the differential diagnosis, investigating the epidemiological links and bearing in mind the poor sensitivity of PCR for MT on fluids other than sputum. Histological investigations play a crucial role in complex cases, where both possible diagnoses are potentially life-threatening when not promptly treated.

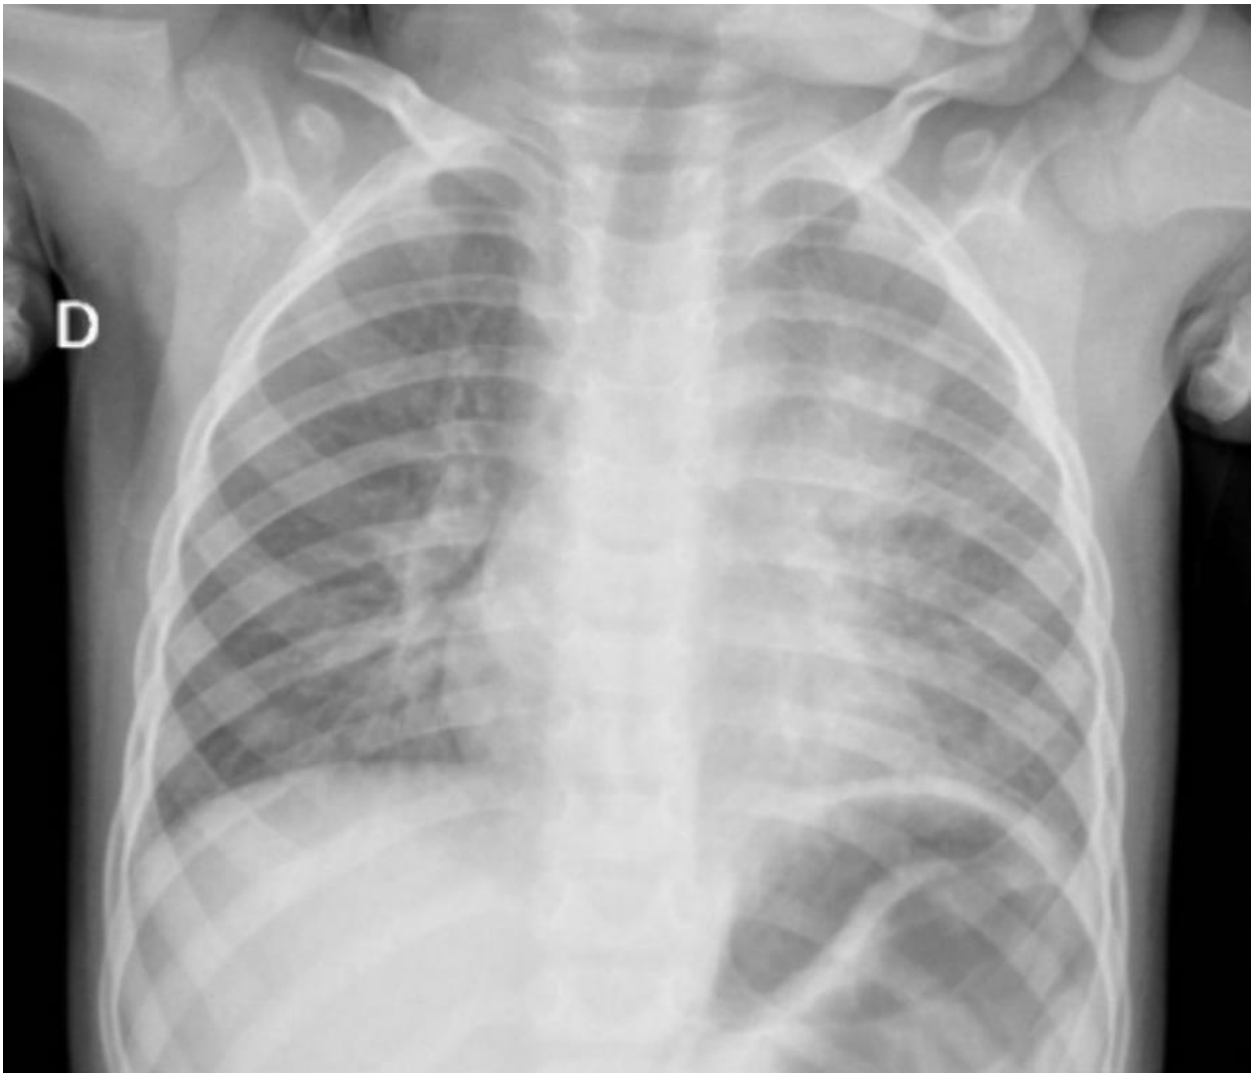
NOT ALWAYS DRINKING RAW MILK IS THE CAUSE: PULMONARY TUBERCULOSIS DUE TO MYCOBACTERIUM BOVIS.

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Gisela Pérez Gil[1], Vanessa Laveglia[1,2], Nathalia Joaqui[1,2], Iván García Pérez[1], María Gratacós De Aguilera[1], Ivet Bou Figueras[1], Pere Sala Castellvi[1,2]
[1]Hospital Universitari General de Catalunya, Department Of Paediatrics, Barcelona, Spain, [2]Hospital Universitari General de Catalunya, Paediatric Infectious Disease Department, Barcelona, Spain

Title of Case: NOT ALWAYS DRINKING RAW MILK IS THE CAUSE: PULMONARY TUBERCULOSIS DUE TO MYCOBACTERIUM BOVIS.
Background: Diseases caused by Mycobacterium bovis (M. bovis) are exceptional in our environment due to livestock control and pasteurization of dairy products. However, in recent years there has been an increased incidence due to immigration from highly endemic countries. The epidemiological environment is fundamental for the diagnosis.
Case Presentation Summary: A previously healthy 2-year-old boy presented with a 2 week history of coughing and rhinorrhea, associating fever in the last 48 hours. A chest X-ray showed pulmonary infiltrates with incipient consolidation in the left lung. Blood tests revealed neutrophilia (7,800/mm3) with an elevated CRP (4.8 mg/dl). He had lived with his 4-year-old cousin who is under treatment for abdominal tuberculosis. Chemoprophylaxis with isoniazid was given for 4 weeks, withdrawing due to poor tolerance after a negative tuberculosis skin test. His father has been diagnosed with miliary tuberculosis due to M. bovis, currently under standard treatment. They have not traveled abroad with no intake of unpasteurized dairy products either. A positive tuberculosis skin test response was indicated by 12 mm of induration with blister formation and gastric aspirate was collected. Initial phase treatment with isoniazid, rifampicin and ethambutol was started and the patient was discharged home. Both culture and PCR results were positive for M. bovis and a 9 month course treatment was completed with a favorable clinical course.



Learning Points/Discussion: Tuberculosis due to M.bovis is a rare zoonosis in our environment and human-to-human transmission infection occurs rarely. Extrapulmonary involvement is more frequently seen than the pulmonary. A close contact screening is very important to determine the index case (usually an adult) and therefore establish an early diagnosis to guide the specific treatment.

THINK RENAL, THINK WISE

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Dina Sallam
Faculty of Medicine, Ain Shams University, Pediatrics & Pediatric Nephrology, Cairo, Egypt, Egypt

Title of Case: Think Renal, Think wise
Background: A 6-year-old boy was diagnosed as steroid resistant nephrotic syndrome, with renal biopsy MPGN type 2. He treated with pulse steroid & Cytoxan with no improvement. During which, he had an attack of focal convulsions, CT brain showed right leuco-encephalomalacia. Brain MRI showed multiple brain masses for differential diagnosis, pyogenic abscess, cysticercosis, Tuberculomas versus Fungal lesions. MRS was done and showed pattern suggestive of TB, but Revision of MRI with senior staff suggesting more cysticercosis. Serological markers of cysticercosis, tuberculin test, & QuantiFERON were negative. Broad spectrum antibiotic & antifungal were started with no improvement of brain masses. Oral Albendazole was started but with no improvement. Masses were increasing in sizes, so triple antituberculosis medications were started empirically for 2 months but follow up MRI & MRS brain showed no changes in size & new lesions Patient had uncontrolled convulsions, so an open biopsy was sone & revealed yellowish white cheesy like caseous materials, that confirmed by pathology to be chronic necrotizing granulomatous inflammatory reaction & diagnosis of Tuberculomas was confirmed. Quadruple antituberculosis therapy was started, but with no improvement & patient had passed away 2 months later
Case Presentation Summary: A male patient who was diagnosed as steroid resistant nephrotic syndrome & received immunosuppressive medications, developed uncontrolled convulsion owing to brain masses that was difficult for diagnosis & treatment, & finally proved to be a resistant to treatment brain tuberculoma
Learning Points/Discussion: An enemy that changed strategy

XPERT MTB/RIF ULTRA IN TONGUE SWAB AND SPUTUM SAMPLE COLLECTION IN CHILDREN WITH SUSPECTED PULMONARY TUBERCULOSIS

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Ivaine Sauthier, Gabriela Zavaglia, Luciane Kern, Muriel De Barros, Thais Azevedo, Fernanda Varela, Ingrid Fernandes, Shirlei Ribeiro, Caroline David, Marcia Polese-Bonatto, Marcelo Scotta, Renato Stein
Hospital Moinhos de Vento, Social Responsibility, Porto Alegre, Brazil

Backgrounds: Introduction: Mycobacterial culture for tuberculosis (TB) diagnosis remains the “gold standard” method despite having a lower sensitivity in children due to the paucibacillary nature of TB. Development of rapid diagnostic TB tests is recognized as essential of the World Health Organization (WHO) End TB Strategy, to allow early initiation of TB treatment and reduce mortality. WHO endorse the use of Xpert MTB/RIF Ultra (GeneXpert® Cepheid) as the initial diagnostic test in all children suspected of having TB. Availability of alternative, noninvasive sample collection would increase the TB testing. This work was supported by the PROADI-SUS in collaboration with Hospital Moinhos de Vento.
Methods: Cross-sectional study in 22 Brazilian local sites. Children between 6 months to <15 years old were prospectively enrolled in two different types of health services (hospital and specialized outpatient clinics) from December 2021 to December 2022. All participants underwent tongue swab and sputum collection, analyzed by Ultra. Diagnostic accuracy was calculated using the epiR package to estimate sensitivity and specificity values. Exact method was used to calculate 95% confidence intervals for all estimates.
Results: 161 participants were screened and 123 were included. 88/123 (71.5%) had tongue swab and sputum Ultra results. No detection of TB occurred in all tongue swab samples, while in sputum, four participants were diagnosed positive for TB (positivity of Ultra was defined as: detected or trace-positive). Specificity was 100.0% (95%CI, 95.5-100.0) and the sensitivity was 0.0% (95%CI, 0.0-60.2).
Conclusions/Learning Points: Conclusion: These partial results indicated, at the moment, that the noninvasive tongue swab samples are not as sensible as the sputum sample. However, this is an ongoing study and more participants will be included.

Title of Case: IS IT REALLY COVID-19?
Background: COVID-19 pandemic had a substantial effect on tuberculosis (TB) diagnosis and treatment worldwide both due to reduced accessibility of medical services and overlapping clinical presentations of these respiratory infections. We present a case of TB that was misdiagnosed as an acute SARS-CoV-2 infection more than once.
Case Presentation Summary: A 17-year-old teenager presented with a history of recurrent upper respiratory infections (rhinitis, dry cough, subfebrile fever) lasting for a year. During this time the boy was diagnosed twice with SARS-CoV-2 infection. As the cough continued and lung auscultation was always unremarkable, he was first treated for a gastroesophageal reflux and later considered to have post-COVID syndrome. Only after a year (on the 7th visit to the family doctor) the boy finally had a chest X-ray that revealed bilateral infiltrates with a necrotic cavitation on the right. He had no known TB contacts and lived with a mother who worked as a teacher and had yearly chest X-rays that were always normal. Subsequent chest CT scan of the patient showed multiple various size cavitations bilaterally characteristic for TB. Additionally, the boy had positive Mantoux tuberculin skin test as well as positive microscopy for AFB and positive GeneXpert assay for Mycobacterium tuberculosis DNA on gastric lavage aspirate, susceptable to rifampicin. After confirming pulmonary TB, the patient was isolated and received treatment with oral rifampicin, isoniazid, pyrazinamide and ethambutol that was later changed to intravenous rifampicin and isoniazid due to extensive pulmonary damage. After a month of treatment the patient developed toxic hepatitis and treatment had to be interrupted. At the moment he continues his TB treatment in adult TB department.
Learning Points/Discussion: If acute SARS-CoV-2 infection presents with prolonged or severe symptoms, TB should always be ruled out in endemic countries.

TUBERCULOSIS OF THE CENTRAL NERVOUS SYSTEM IN CHILDREN: A 12-YEAR SINGLE INSTITUTION RETROSPECTIVE REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Beatriz Sousa Nunes[1], Ana Margarida Garcia[2], Ana Lemos[2], Rita Valsassina[2], Tiago Milheiro Silva[2], Carla Ribeiro Da Conceição[3], Rita Lopes Da Silva[4], José Pedro Vieira[4], Maria João Brito[2], Catarina Gouveia[2]
[1]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatrics, Lisboa, Portugal, [2]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatric Infectious Diseases Unit, Lisbon, Portugal, [3]Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal, Neuroradiology, Lisbon, Portugal, [4]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal, Paediatric Neurology Unit, Lisbon, Portugal

Backgrounds: Central Nervous System Tuberculosis (CNSTb) has the highest morbidity of all tuberculosis manifestations. Neurological sequelae are described in more than 50%. Our aim is to characterise children with CNSTb admitted to a tertiary-level children's hospital in Portugal, and compare patients with and without neurological sequelae.
Methods: Retrospective review of pediatric patients with CNSTb (diffuse and/or focal), admitted over a 12-year period (2011-2022). Severity of disease was classified according to the Modified Medical Research Council score. We defined neurological sequelae as any motor, sensory, cognitive or behavioural impairment that emerged during illness and persisted 12 months after.
Results: Eleven children with CNSTb were identified. Median age was 10.0 years [0.5-16.0]; 2 (18%) were immigrants and 2 (18%) were not immunized with BCG. One patient had a definitive diagnosis; 6 were classified as probable cases, and 4 as possible cases; 64% had a severity score II or III. Fever, headache, meningism, and altered consciousness were the most frequent presentations (61%). TST was negative/indeterminate in all and 3 (27%) had a positive IGRA test. Mycobacterium tuberculosis was isolated in 3 (27%). The mean duration of antituberculosis therapy was 12 months [9-18]. No deaths were registered. 5 (45%) had neurological sequelae: 2 epilepsy, 1 hemiparesis, 1 ataxia, 1 global development delay, 1 learning disabilities, and 1 behavioral disorder. Patients with sequelae presented with a higher severity score at admission (p=0.02). No statistical difference was observed between groups regarding previous BCG vaccination.
Conclusions/Learning Points: CNSTb is difficult to diagnose, as signs and symptoms are nonspecific, and diagnostic tests are often negative. Although no mortality was registered, a substantially high proportion of patients had sequelae. Sequelae was associated to a higher severity score at presentation.

THE PARADOX OF MEDICAL THERAPY IN TUBERCULOUS LYMPHADENITIS

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Marta Stracuzzi, Vania Giacomet
università degli studi di milano, Pediatric Infectious Disease, Luigi Sacco Hospital, Milan, Italy

Title of Case: THE PARADOX OF MEDICAL THERAPY IN TUBERCULOUS LYMPHADENITIS
Background: We report a case of a 5-year-old Pakistan male with persistent fever and enlargement of laterocervical lymphnodes on the left side. A positive Mantoux skin test, the DNA amplification by polymerase chain reaction and the culture from fine needle aspiration confirmed the diagnosis of Mycobacterium tuberculosis. He started medical treatment with isoniazid, rimpaficin, pyrazinamide. There was an initial remission of the fever and general conditions, while the characteristics of the affected lymphnodes did not change. After 1 month of therapy, he came back to our observation for increased lateral cervical swelling, redness of the overlying skin and pain, in addition to the reappearance of serotin fever and night sweats. Therapy was then modified by discontinuing the isoniazid, adding ethambutol, prednisone and levofloxacin.
Case Presentation Summary: After another month, due to no clinical improvement, a magnetic resonance was performed: marked deformation of the laterocervical region was found with voluminous confluent necrotic-colliquative adenopathies (88x72 mm). We therefore decided to subject the child to surgery to remove the colliquate laterocervical lymphnodes and to proceed with histological examination, with confirmation of M. tuberculosis. A drug resistance was ruled out by antibiogram. He continued therapy with isoniazid, rimpaficin, pyrazinamide and ethambutol. At the 2-month ultrasound examination, only a few immunoreactive lymphnodes were found, without necrotic-colliquative phenomena. Clinically, the child was in well-being, with excellent therapy compliance and good tolerance.
Learning Points/Discussion: Excluding drug resistance and the presence of immunodeficiencies, paradoxical upgrading reaction (PUR) to the medical therapy offer a plausible explanation for this phenomenon.

TRENDS IN EPIDEMIOLOGY OF CHILDHOOD TUBERCULOSIS IN GREECE IN THE LAST DECADE

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Angeliki Syngelou, Nikos Spyridis, Ioannis Kopsidas, Nikoletta Brouskaki, Kiriaki Benetatou, Irini Eleftheriou, Maria Tsolia
National and Kapodistrian University of Athens, 2nd Department Of Pediatrics, Athens, Greece

Backgrounds: Tuberculosis (TB), with 9.9 million new cases and 1.3 million deaths in 2020, is still one of the major causes of mortality and morbidity worldwide, especially in low- and middle-income countries.Childhood TB is of particular importance as it is a marker of TB activity in the community. This study aims at analyzing the epidemiology of pediatric TB patients enrolled at our major referral clinic over the past decade.
Methods: We retrospectively reviewed the medical records of patients aged <16 years treated for active TB and TB infection between January 2010 and December 2019 at our pediatric TB clinic and compared the results with the patient turnover during the previous decade (2000–2009). Data on demographic and clinical characteristics were analyzed.
Results: A total of 1.110 children <16years of age (median age 6.5 years, 58% males) with positive TST were examined. Seventy two children (6.4%) were diagnosed with active TB, while 496/1.110 (39%) had TB infection. Almost half of children with active TB (49/72) originated from areas where TB was previously recognized to be highly endemic. Eighteen children (25%) had extra-pulmonary TB. Bacteriological confirmation was obtained in 40% of patients: 2 (5%) strains were multidrug-resistant. The average annual TB incidence of pediatric TB in the greater Athens area declined from 5.37/100 000 to 4.5/100.000. Time trend analysis for the 20- year- period was also performed.
Conclusions/Learning Points: Childhood TB is decreasing among native Greek children and the epidemiology of the disease is strongly influenced by immigration from endemic countries, including those with high resistance rates. Future efforts to control TB in children should especially target the high-risk immigrant population by successfully treating both adults and children with infectious TB and those with TB infection.

PULMONARY TUBERCULOSIS IN THE PEDIATRIC POPULATION – STILL A HOT TOPIC DURING THE SARS COV2 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Alina Turenschi, Irina Elena Nedelea, Simona Mosescu, Gabriela Otel
"Grigore Alexandrescu" Emergency Hospital for Children, Bucharest, Romania, Pediatrics, Bucharest, Romania

Title of Case: Pulmonary tuberculosis in the pediatric population – still a hot topic during the SARS COV2 pandemic
Background: Pulmonary tuberculosis in pediatric population remains a current issue even during the SARS COV 2 pandemic. Romania has one of the highest incidence of tuberculosis (TB) in Europe. Difficult access to healthcare system during the pandemic period has led to underdiagnosed cases and patients developed severe forms of the disease.
Case Presentation Summary: We present three cases of pulmonary TB from the Pediatrics Department of "Grigore Alexandrescu" Hospital with polymorphic clinical and imaging presentation. Case 1: A 17-year-old patient admitted with dry cough, weight loss, fever and shortness of breath. Pulmonary computed tomography (CT) described a left upper lobe consolidation, pulmonary cavities in the right upper lobe and right inferior lobe that communicate with satellite bronchiectasis and right pleural effusion. Case 2: A 14-year-old patient presented with fever, dry cough and chest pain. Pulmonary radiography reveals a right-sided pleural effusion with a condensation area in the base of the right lung. Case 3: A 16-year-old patient with a history of asthma admitted for fever, productive cough and weight loss. Pulmonary radiography revealed an atelectatic left lung with shifting of the mediastinal structures towards the left side. The CT showed a complete collapse of the left lung due to atelectasis, with bronchiectatic lung parenchyma associated with parenchymal calcifications.
Learning Points/Discussion: The diagnosis of TB in children is challenging due to the paucibacillary forms and to the polymorphism of the clinical and imaging presentation. We observed that all the patients had severe pulmonary disease due to delayed presentation at the hospital during the pandemic period. In only one case the epidemiological investigation identified the source of the disease.

CHEST X-RAY OUTCOMES IN SOUTH AFRICAN CHILDREN PRESENTING WITH PRESUMPTIVE PULMONARY TUBERCULOSIS AFTER 6-MONTHS OF FOLLOW-UP

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Carla Mckenzie[1], Megan Palmer[1], Isabelle Dewandel[1], Anneke Hesseling[1], H Schaaf[1], Pierre Goussard[1,2], Marieke Van Der Zalm[1]
[1]Stellenbosch University, Desmond Tutu Tb Centre, Department Of Paediatrics And Child Health, Cape Town, South Africa, [2]Stellenbosch University, Department Of Paediatrics And Child Health, Cape Town, South Africa

Backgrounds: Little is known about end of treatment CXR outcomes in children treated for pulmonary tuberculosis (PTB). The aim of this study was to assess residual abnormalities in end of treatment CXRs of children who present with presumptive PTB.
Methods: In this prospective observational cohort study, we enrolled children (0-13 years) with presumptive PTB from November 2017 to November 2021, in Cape Town, South Africa. Treating clinicians decided on initiation of TB treatment. Both children treated for TB and symptomatic controls were followed up intensively for 6 months including CXRs taken at baseline and end of treatment. CXRs read was done retrospectively and blinded by an expert in paediatric TB.
Results: A total of 348 children with presumptive PTB were enrolled, 133 were excluded due to early withdrawal, incomplete baseline data or missing CXRs. Median age was 24.8 months (IQR 12.1-57.2), 112 (52.1%) were male and 13 (6%) children were living with HIV. TB treatment was initiated in 72/215 (33.8%) children. Of the 72 children treated for TB, 48 (66.7%) had abnormal CXRs at baseline; 30/48 (62.5%) abnormal CXRs were typical of TB, 16 (53.3%) of these deemed severe TB disease. At end of TB treatment, 23/72 (31.9%) children had residual CXR abnormalities (compared to 21/141 (14.9%) symptomatic controls (p=0.008)). Of these 23, 10 (43.5%) were confirmed and 13 (56.5%) were unconfirmed TB. Five of 21 (23.8%) symptomatic controls with residual CXR abnormalities, were classified as having TB retrospectively (1 confirmed, 4 unconfirmed).
Conclusions/Learning Points: Residual CXR abnormalities at the end of TB treatment are common in children. These findings require further investigation for the impact on diagnosis of subsequent recurrent TB episodes and for any clinical morbidity in terms of post-TB lung disease.

DOWNSTREAM CONSEQUENCES OF LATE DIAGNOSIS OF TUBERCULOSIS IN A BONE MARROW TRANSPLANT UNIT

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Stephanie Zahradnik[1], Ray Lam[1], Laurie Streitenberger[2], Tal Schechter-Finkelstein[3], Joerg Krueger[3], Valerie Waters[1], Ian Kitai[1], Michelle Science[1]
[1]The Hospital for Sick Children, Paediatrics, Division Of Infectious Diseases, Toronto, Canada, [2]Hospital for Sick Children, Infection Prevention And Control, Toronto, Canada, [3]Hospital for Sick Children, Oncology, Toronto, Canada

Backgrounds: Tuberculosis is a possible complication of haematopoietic stem cell transplantation (HSCT) in those with latent Mycobacterium tuberculosis infection (LTBI). Identification of patients with LTBI and treatment prior to starting immunocompromising therapy is effective to prevent transplant recipients from progressing to active disease. We describe the impact of a late diagnosis of paediatric pulmonary and disseminated tuberculosis three months following HSCT at a paediatric tertiary healthcare centre in Canada.
Methods: Outbreak summaries and outbreak meeting notes from 2017-2018 were reviewed. Actions taken at a unit level were described.
Results: The index patient was born in a TB-endemic country. They reactivated post engraftment while in a positive pressure room. They were identified when a secondary site was biopsied and sent for M. tuberculosis testing. There were no respiratory symptoms; sputum was AFB 3+. On the HSCT unit, patients are cared for in private positive pressure ventilation rooms following HSCT until engraftment as standard of care. This resulted in multiple patients, caregivers and staff potentially exposed. In total, there were 148 exposed staff and 61 exposed caregivers. Screening with tuberculin skin tests (TST) was offered. Of caregivers, 10/11 were negative, 1/11 was positive. This caregiver was foreign born and the positive result was deemed unlikely related to this exposure. There were 29 exposed HSCT patients; TST and interferon-γ release assays were presumed unreliable, while drug interactions inhibited empiric treatment. Monitoring was undertaken; none developed disease. Collaboration with public health strengthened outbreak management.
Conclusions/Learning Points: The late diagnosis of disseminated tuberculosis following HSCT had substantial implications in the care of the index case, other children, families and staff. This case illustrates the importance of having a screening program in place for LTBI prior to immunocompromise to identify patients at risk.

ADVERSE EVENTS IN INDUCED SPUTUM SAMPLE COLLECTION IN CHILDREN WITH SUSPECTED PULMONARY TUBERCULOSIS

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Ivaine Sauthier, Gabriela Zavaglia, Luciane Kern, Muriel De Barros, Thais Azevedo, Fernanda Varela, Ingrid Fernandes, Shirlei Ribeiro, Caroline David, Marcia Polese-Bonatto, Marcelo Scotta, Renato Stein
Hospital Moinhos de Vento, Social Responsibility, Porto Alegre, Brazil

Backgrounds: Introduction: Childhood tuberculosis (TB) is an increasingly important public health problem, particularly in developing countries. The diagnosis of tuberculosis, especially the bacteriological confirmation of pulmonary TB is notoriously difficult in children. Sputum induction is viewed as a safe and tolerable procedure, and the major advantage of this specimen is that it comes directly from the site of infection and reflects the lung microbiological organisms. We aimed to describe the adverse events in sputum induction in children with suspected pulmonary TB.
Methods: Cross-sectional study in 22 Brazilian local sites. Children between 6 months to <15 years old were prospectively enrolled in two different types of health services (hospital and specialized outpatient clinics) from December 2021 to December 2022. The main inclusion criteria for hospitalized participants was admission for lower respiratory tract infection, and for clinical ones the referral of suspected tuberculosis. All participants underwent sputum collection and were analyzed by Xpert MTB/RIF Ultra (GeneXpert® Cepheid). The hospitalized participants had a second sputum collection during the admission. The subjects who were unable to spit spontaneously had the collection done by induced sputum. This work was supported by the PROADI-SUS in collaboration with Hospital Moinhos de Vento.
Results: 161 participants were screened and 123 were included. 149 procedures of induced sputum were done (96 procedures in admitted subjects and 53 procedures in ambulatorial ones). 109/149 (73.2%) sputum aspiration procedures were done. Adverse events occurred in 3 ambulatorial subjects (2%, 3/149), two epistaxis and one vomiting.
Conclusions/Learning Points: Conclusion: These preliminary results reinforced that induction and aspiration sputum collection present few and minor adverse events, the procedures are tolerable and feasible in childrens in outpatients clinics and hospitals.

DIAGNOSIS PROFILE OF TUBERCULOSIS IN BRAZILIAN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS09.A. TUBERCULOSIS AND OTHER MYCOBACTERIAL INFECTIONS

Ivaine Sauthier, Gabriela Zavaglia, Luciane Kern, Muriel De Barros, Thais Azevedo, Fernanda Varela, Ingrid Fernandes, Shirlei Ribeiro, Caroline David, Marcia Polese-Bonatto, Marcelo Scotta, Renato Stein
Hospital Moinhos de Vento, Social Responsibility, Porto Alegre, Brazil

Backgrounds: Introduction: The 2022 Brazilian tuberculosis (TB) epidemiological bulletin reported that 72.3% of individuals positive for TB had a diagnosis through one of these methods of analysis (rapid molecular test, bacilloscopy or sputum culture). From the 68.271 new TB cases, 2.077 (3%) occurred in children under 15 years old. Children are considered a priority, as they are more likely to progress from the latent to active forms, have a higher incidence of severe extrapulmonary forms, and can be a long-term reservoir for the disease.
Methods: Cross-sectional study in 22 Brazilian local sites. Children between 6 months to <15 years old were prospectively enrolled in two different types of health services (hospital and specialized outpatient clinics) from December 2021 to December 2022. The main inclusion criteria for hospitalized participants was admission for lower respiratory tract infection, and for clinical ones the referral of suspected tuberculosis. All participants underwent sputum collection for Mycobacterium tuberculosis detection. Samples were analyzed by Xpert MTB/RIF Ultra (GeneXpert® Cepheid) and liquid culture (LC). The positivity of Ultra was defined as: detected or trace-positive. The presumptive diagnosis refers to a patient who presents with symptoms or signs suggestive of TB, despite the negative Ultra and LC results. This work was supported by the PROADI-SUS in collaboration with Hospital Moinhos de Vento.
Results: 161 participants were screened and 123 were included. 20/123 (16.3%) were TB positive (bacteriological or presumptive diagnosis). 6/20 (30.0%) were laboratory confirmed while the other 14 participants had presumptive TB diagnosis, despite the negative results (Ultra and LC).
Conclusions/Learning Points: Conclusion: These preliminary results indicated that Ultra presented higher sensitivity than LC in the analyzed samples.

[1]Hospital de Santa Maria, Paediatrics, Lisbon, Portugal, [2]Hospital Santa Maria, Pediatric Infectious Diseases Unit, Lisbon, Portugal, [3]Centro Hospitalar Lisboa Norte, Paediatric Infectious Diseases And Immunodeficiencies Unit, Lisboa, Portugal

Title of Case: HIV Patients Transition from Paediatric to Adult care: The experience of a Tertiary Hospital in Lisbon: 2015-2020 Case Series and Outcomes
Background: Advancements in paediatric antiretroviral therapy(ART) have enabled an increasing number of adolescents living with HIV(ALHIV) to survive into adulthood. Despite that, ALHIV are the only age group with a rising HIV-related mortality. Transition to adult care has been associated with high rates of loss of follow up, virologic failure(VF) and immunological deterioration with a subsequent increase in morbidity and mortality.The aim of this study was to evaluate the impact of transition on health outcomes of a cohort of ALHIV.
Case Presentation Summary: We reviewed medical records of ALHIV followed in a tertiary hospital, at transition, and one and three years after transition to adult care, between 2015 and 2020. 38 ALHIV, 89,5% perinatally infected, were transferred at the median age of 19,5 years. At transition 52,6% had undetectable viral load(UVL), normal CD4 cell count and were 100% adherent to therapy; 68,4% had at least 3 different ART regimens. After one and three years of follow-up, retention rate, viral suppression(VS) and immunosuppression were respectively 32/38 vs 29/38; 19/32 vs 19/29 and 14/32 vs 11/29. Of the 18 ALHIV who had positive viral loads before transition, three achieved and maintained UVL three years later and two died with AIDS. Of the 20 ALHIV with UVL at transition, 15 maintained VS during the follow-up period, two had VF and three lost follow-up.
Learning Points/Discussion: Almost half of our ALHIV didn't met the ideal objectives of ART at transition to adult care, retention rate decreased overtime and two patients died from AIDS. There is a need for new ways of intervention to support ALWH during this vulnerable period.

FACTORS INFLUENCING ADHERENCE TO PAEDIATRICS ANTIRETROVIRAL THERAPY AT ROYAL HOSPITAL IN OMAN

E-Posters Viewing
E-POSTER VIEWING: AS09.B. HIV/AIDS

Basma Al Jabri
Royal Hospital /Oman, Clinical Pharmacist, Oman/Muscat, Oman

Backgrounds: In Oman 3060 is the total number of Omanis diagnosed with HIV between 1984 -2018, of which 77 patients were aged 0-4 years,120 patients were aged 5-14 years at time of diagnosis. There was a noticed reduction in the percentage of patients aged below 14 years of age at the time of diagnosis from 14.2 % in 1984-1996 to 2.9 % in 2013-2018.
Methods: ¬ Study design
Cross sectional study ¬ Characteristics of study area and target population
This study is conducted in pediatrics infectious disease clinic of Royal hospital which is a tertiary care institution. Patients are referred to this clinic from all around Oman. Our target population will be all children with HIV infection attending this clinic from August 2021 to July 2022. Patients who lost follow up will be excluded. ¬ Sampling We is include all children with HIV on ART following at Royal Hospital from August 2021 to July 2022. ¬ Variable definitions and measurements
This is include demographic data, lab investigations, ART and the questionnaire. ¬ Data collection tools and methods
♣ interview the participants in a private environment using a questionnaire and adherence assessment tool
♣use AlShifa system to access patient records to collect demographic, clinical, lab and medications data
Results: Significant results of factors affecting adherence categorized : Caregiver related factor :Age , Educational level Socioeconomic: Transportation, Income Medication: Drug finished , bad taste, lack of trust on the efficacy of medication , child not feeling sick , school schedule , missed refill (available stock at home) Appointments :

Backgrounds: A specific approach of HIV in adolescence is of global concern. Data about new HIV diagnoses in adolescents are scarce, especially in Europe. Describing UNAIDS 2020 targets (90-90-90) in this population will contribute to better approach this problematic situation.
Methods: Description of the continuum of care in newly HIV-diagnosed adolescents 12-20 years-old included in CoRIS (adult) and CoRISpe (pediatric) Spanish cohorts, until 2019. The cascade of care was analysed for the first 12 and 24 months after enrolment: (i)active HIV care (a CD4 or viral load measurement), (ii)on ART, (iii)virologically suppressed (<200 copies/ml or undetectable) and (iv)good immune status (CD4>350 cells/mm^3).
Results: From the 410 adolescents diagnosed, 75% were male, the median age was 18.8 years (IQR17.9-19.5). The main infection risk was sexual (79%), 59.5% were born in Spain and 35% presented late to care (CD4<350 cells/mm^{3}or AIDS at diagnosis). Data for the first 12 and 24 months after diagnosis were available for 393 (96%) and 368 (90%) of global cohort and thus, selected for first and second year-cascade analysis, respectively. The cascade of care improved during the study period (Table1). Nevertheless, the proportion of patients on active care significantly decreased from the first to the second year (92%vs82%;p=0.034). In addition, for the most recent period 2015-2019, UNAIDS target was reached only for patients on ART but not for those virologically suppressed for the first year (87%) or the second year (79%). Good immune status rate was also <90% both for the first and second year.

Table 1: Continuum of care in HIV newly diagnosed adolescents in Spain in the first and second year after enrolment.

Year of HIV diagnosis	<1989	1990-1994	1995-1999	2000-2004	2005-2009	2010-2014	2015-2019

[1]Centro de Investigaçao em Saude da Manhiça, Hiv, Manhiça-Maputo, Mozambique, [2]ISGlobal, Hiv, Barcelona, Spain, [3]Hospital Clínic, Preventive Medicine, Barcelona, Spain, [4]Faculty of Medicine, University Eduardo Mondlane, Infectious Disease, Maputo, Mozambique, [5]University of Washington, Department Of Global Health, Seattle, Washington, United States of America

Backgrounds: Health-Related Quality of Live (HRQoL) may be affected in children living with HIV (CLHIV). Research on the HRQoL among CLHIV in low-and middle-income countries is limited and with contradictory results. This study assessed HRQoL among CLHIV in Mozambique for the first time and compared it to children without HIV infection.
Methods: We conducted a cross-sectional study from May-2021 to February-2022 at the Manhiça District Hospital, in southern Mozambique. CLHIV aged 2-10 years on ART for 12-36 months were recruited at their routine HIV visit. Children in the same age range attending either the triage with minor acute ailments or the healthy-child consultation, and with a negative HIV result in the previous 30 days were recruited as controls. HRQoL was measured using the parent-proxy version of the PedsQL™4.0 questionnaire. Mann-Whitney U test was used to compare the HRQoL scored between groups and the interquartile range ratio to compare data dispersion.
Results: A total of 49 CLHIV and 33 children without HIV infection were included. We found a good parent-reported HRQoL (Total PedsQL™score > 90/100 points) for all age groups. Although we did not find statistical differences between groups, we observed that 10% of the 2-4- and 8-10-years age groups of CLHIV had total HRQoL below 80 points, whereas none of the children without HIV infection did. HRQoL scores among CLHIV were poorer when reported by their parents compared to those reported by other non-parent relatives (p=0.018).
Conclusions/Learning Points: CLHIV in care had an overall good HRQoL. Future research is needed to elucidate determinants of lower scores in the social domain among preschooler and preadolescent CLHIV and to compare HRQoL to the general pediatric population, in order to ensure a good HRQoL beyond their viral suppression.

INCREMENTAL NUTRITION STATUS AMONG CHILDREN WITH HIV ON ANTIRETROVIRAL THERAPY WITHIN 12 MONTHS AT TERTIARY REFERRAL HOSPITAL IN INDONESIA

E-Posters Viewing
E-POSTER VIEWING: AS09.B. HIV/AIDS

Nida Ghitha[1], Nia Kurniati[2], Dina Muktiarti[2], Rizqy Amalia[2]
[1]Universitas Indonesia, Faculty Of Medicine, Jakarta, Indonesia, [2]Cipto Mangunkusumo Hospital, Child Health Department, Faculty Of Medicine, Universitas Indonesia, Jakarta, Indonesia

Backgrounds: Indonesia still has high perinatal HIV transmission rate and late presentation of positive cases is still a problem. Early antiretroviral (ART) treatment has been shown to increase survival. However, whether treatment at all change the nutrition status in the face of stunting is still unknown. This study is to describe increment of nutritional status during ART within 12 months.
Methods: This is a cohort observational data developed in Cipto Mangunkusumo Hospital Indonesia. Children first diagnosed with HIV within 2019-2021 were eligible. Data collected were clinical stage, initial hemoglobin, CD4, ART, weight and height measurements every 3 months for 12 months after received first ART. Nutritional status was determined using Z-score calculation (WHO-AnthroPlus) and analysed with SPSS.
Results: 81 subjects were eligible. The mean (SD) WAZ, HAZ, and BAZ at baseline were -3.00 (1.81), -2.55 (1.44), and -1.89 (1.72). Initial hemoglobin and CD4 were 10.27 mg/dL and 336.4 cells/mm^3 (69.3% <750 cells/mm^3). There were 89% on first-line; 11% on second-line ART. Proportion for severely underweight, severely stunted, and severely wasted children at baseline were 44%, 32%, and 27% and decrease to 10%, 13%, and 3% after 12 months on ART. WAZ was significantly increased from the month 0, 3rd, 6th, 9th, to 12th (3.00, -2.49, -2.17, -1.79 to -1.64); p<0.001. BAZ was increased (-1.89, -1.22, -0.93, -0.66 to -0.40); p<0.001.WAZ and BAZ mean change were significant. However, HAZ was not good (-2.55, -2.39, -2.28, -1.96 to -2.00);
p=0.331.

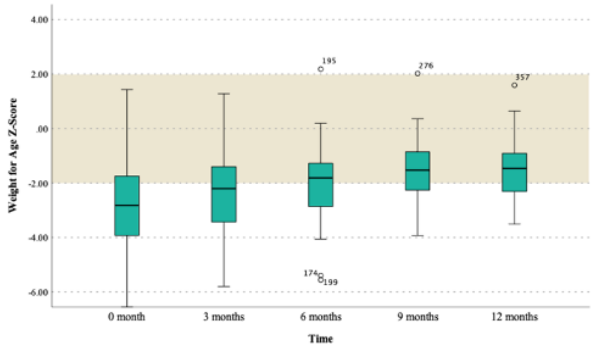

Figure 1: The mean z-score for weight for age

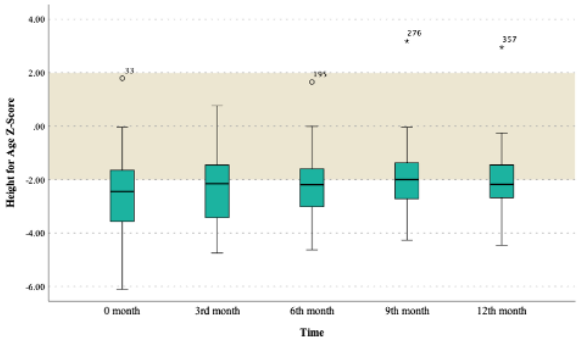

Figure 3: The mean z-score for height for age

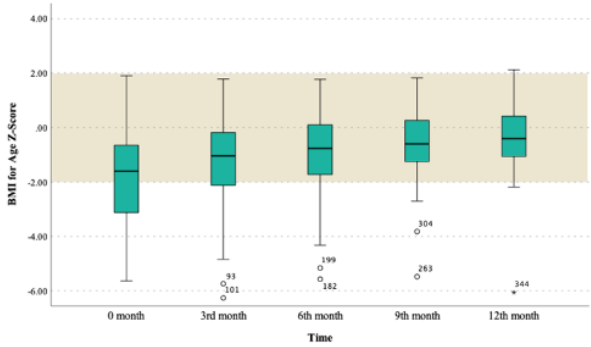

Figure 2: The mean z-score for BMI for age

Conclusions/Learning Points: ART showed to improve body weight and BMI over 12 month ART, regardless of ART type and other baseline data. However height increment did not show the same effect. This could contribute to stunting problem in the nation.

PROFUSE LOWER GASTROINTESTINAL BLEEDING OF HIV CHILD IN DR. SOETOMO HOSPITAL SURABAYA

E-Posters Viewing
E-POSTER VIEWING: AS09.B. HIV/AIDS

Leny Kartina[1], Dominicus Husada[1,2], Dwiyanti Puspitasari[1], Parwati Basuki[2], Ismoedijanto Moedjito[1]
[1]Faculty of Medicine Airlangga University, Pediatrics, Surabaya, Indonesia, [2]Soetomo General Hospital, Pediatrics, Surabaya, Indonesia

Title of Case: PROFUSE LOWER GASTROINTESTINAL BLEEDING OF HIV CHILDREN IN DR SOETOMO HOSPITAL SURABAYA
Background: Human immunodeficiency virus infection is still a difficult problem in developing countries in the era of antiretroviral treatment. Opportunistic infection (OI) leads to severe condition that brings fatal consequence. Tuberculosis, pneumonia, candidiasis esophagus, and cytomegalovirus infection are common OI that caused severe complications. Lower gastrointestinal (GI)bleeding in HIV children, even rare, can be correlated with this OI and be associated with mortality. We report a fatal case of HIV infection in children with profuse lower GI bleeding.
Case Presentation Summary: A 9-year-old girl was referred for HIV in the second month of ARV treatment, tuberculosis, pneumonia, chronic diarrhea, and severe malnutrition. There was a history of uncomplying with ART of zidovudine, lamivudine, and nevirapine. Chest x-ray showed a massive infiltrate on both lungs, high CRP, Ig M CMV positive, and sterile blood culture. We gave her antibiotics, antifungal, and ganciclovir besides continued ARV and other supportive treatment. On the second week of admission, she suffered profuse lower GI bleeding until a total of about 1800 ml for 3 days. Abdominal sonography showed normal results but a colonoscopy cannot be done because of her condition. The whole blood transfusion was given but she passed away due to hypovolemic shock.
Learning Points/Discussion: Poor ART compliance plays a role in the incidence of opportunistic infections. Lower GI bleeding in HIV is rare and the study reported it is associated with OI such as CMV colitis, mycobacterium avian complex, and candidiasis esophagus. CMV colitis should be confirmed by colonoscopy and biopsy but it is challenging in limited resources. The gancyclovir for CMV colitis, in this case, is based on CMV IgM serology, and the bleeding needs more aggressive management.

E-POSTER VIEWING: AS09.B. HIV/AIDS

Anna Hermine Markowich[1], Maria Francesca Dalla Porta[2], Stella Mtera[3], Glory Tawa[3], Martina Borellini[4], Paolo Belardi[4]
[1]Bambino Gesù Children's Hospital, Infectious Diseases, Rome, Italy, [2]University of Modena and Reggio Emilia, Post-graduate School Of Pediatrics, Department Of Medical And Surgical Sciences Of The Mother, Children And Adults, Modena, Italy, [3]Tosamaganga Hospital, Ctc, Tosamaganga, Tanzania, [4]CUAMM - Doctors with Africa, Tosamaganga Hospital, Tosamaganga, Tanzania

Title of Case: EX JUVANTIBUS CRITERIA FOR DIAGNOSIS OF HSV ENCEPHALITIS IN AIDS PATIENT IN A RESOURCE-LIMITED SETTING
Background: In 2020 there have been 1.7 million new diagnosis of HIV infection, 150.000 were in children. Perinatal transmission is responsible for most HIV infections in children. AIDS is associated with many complications, which require a correct diagnosis and treatment. We present a child with HIV diagnosed in AIDS stage.
Case Presentation Summary: A 10-year-old child was brought to Tosamaganga Hospital in Tanzania due to fever for one week. The patient also reported loss of body weight over the previous months. He was ill-looking, wasted and markedly pale. FBP showed Hb 1.9 g/dl and raised WBC. MRDT was negative. HIV antibody test positive. CD4 count was 12/mcl. The child was therefore diagnosed with AIDS. After detailed history the mother revealed being HIV+ and in ART since 5 years; the patient had never been tested. The patient received blood transfusion and started on cotrimoxazole, ceftriaxone and ART (Dolutegravir and ABC Lamivudine). The fever gradually improved and the hemoglobin increased. After 1 week of treatment the patient developed confusion associated with hallucinations, followed by catatonic state. Lumbar puncture was performed, all tests available in our setting (cell count, GRAM stain, Xpert for MTB, cryptococcal antigen) resulted negative. Since HSV encephalitis could not be excluded, empiric treatment with acyclovir was started. The neurological status of the patient quickly improved and he was discharged.
Learning Points/Discussion: In HIV high burden countries, screening and treatment of pregnant women is fundamental in preventing new HIV infections in children. Diagnosis of HSV encephalitis can be difficult in the absence of clear clinical signs, but it should be considered as a possible complication of AIDS. In low resources settings, where diagnostic tests availability is limited, clinicians may have to rely on empiric treatment.

KAPOSIS SARCOMA IN PEDIATRIC HIV PATIENT: CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS09.B. HIV/AIDS

Liana Punzi, Fabio Castellano, Sara Maria Scarano, Margherita Del Bene, Cristina Moracas, Davide Cagno, Martina Mancuso, Marco Poeta, Francesco Nunziata, Andrea Lo Vecchio, Eugenia Bruzzese
University of Naples, Federico II, Department Of Translational Medical Sciences - Section Of Pediatrics, Naples, Italy

Title of Case: KAPOSIS SARCOMA IN PEDIATRIC HIV PATIENT: CASE REPORT
Background: Kaposi's Sarcoma is a malignancy associated with HIV infection in Sub-Saharan Africa where HHV-8 is endemic and the access to antiretroviral therapy is limited.
Case Presentation Summary: We describe the case of a 16-month-old girl with multiple compressive lymphadenopathies (the largest measuring 54 x 23 mm), declivous edema, anemia and severe thrombocytopenia refractory to immunoglobulins infusion and steroids therapy. Although diagnosed with HIV infection at two months of age she lived for a long period in an HHV-8 endemic area without starting the antiretroviral therapy. The patient's symptoms, signs, and laboratory findings did not improve after the start of HAART and the immune reconstitution induced a fast worsening of lymphadenopathies with compression of mediastinal structures, the emergence of life threatening conditions with the need of intensive care. FNAB of the major lymphadenopathy showed the presence of spindle cells compatible with Kaposi's Sarcoma. Given the severity of the clinical condition, empiric therapy for Kaposi's Sarcoma with liposomal doxorubicin was started before the immunohistochemical confirmation. Subsequently, the diagnosis was confirmed at immunohistochemistry and HHV-8 was detected in blood and lymph node specimens. The patient rapidly improved after the first chemotherapy with the normalization of hemoglobin and platelet values and a significant reduction of lymph node volume.
Learning Points/Discussion: The expected survival of an HIV-positive patient with Kaposi's Sarcoma on exclusive antiretroviral therapy is 3-4% and increases to >90% if antiretroviral therapy is combined with suitable and rapid chemotherapy. Therefore, it is imperative to include HIV in the differential diagnosis of lymphadenopathies, to consider Kaposi's Sarcoma in HIV patients who have lived in an HHV-8 endemic area and to start chemotherapy as soon as possible.

HOW BEST TO ASSESS COGNITIVE FUNCTION IN YOUNG PEOPLE LIVING WITH HIV IN SUB-SAHARAN AFRICA? A PILOT STUDY

E-Posters Viewing
E-POSTER VIEWING: AS09.B. HIV/AIDS

Annalie Shears[1], Nyasha Dzavakwa[2], Vicky Simms[2], Rashida Ferrand[3], Panashe Black[2], Debson Munemo[2], Modeste Mpofu[2], Rumbi Marambo[2]
[1]Stepping Hill Hospital, Paediatrics, Manchester, United Kingdom, [2]The Health Research Unit Zimbabwe, Research, Harare, Zimbabwe, [3]London School of Tropical Medicine & Hygiene, Hiv, London, United Kingdom

Backgrounds: Neurocognitive dysfunction impacts on learning, education and mental health in affected children, and early accurate diagnosis is essential. There are few validated neurocogitive assessment tools for adolescents in Sub-Saharan Africa. We conducted a pilot study, to compare the feasibility and acceptability, of delivering paper and electronic cognitive assessments, among adolescents (aged 11-19 years) living in Harare, Zimbabwe, aiming to inform a future study investigating the impact of HIV on cognitive function.
Methods: Participants were selected by snowball sampling at Sally Mugabe Central Hospital outpatient clinics from August-September 2022. Participants completed three cognitive assessments: the paper-based Kaufmann Assessment Battery for Children Second Edition (KABC-II), and the tablet-based PLUS-EF and NIH Toolbox Cognition Battery (NIH-CB). The KABC-II was the designated gold standard, it requires trained assessors and takes 90 minutes to complete versus 15 for the PLUS-EF and 30 for the NIH-CB.
Results: 42 HIV negative participants (20 M, 22 F) aged between 11-19 (mean 15 years) attended for cognitive assessments. Acceptability and percived comprehension was high across all three tools. Significant positive skewing of individual subtest and total scores was seen on the PLUS EF, indicating that it was too easy for our cohort. NIH-CB scores were well distributed around the mean and demonstrated a degree of correlation with Kaufmann Mental Processing Index ($r^2 = 0.414$) and Non-Verbal Index ($r^2 = 0.4$) scores.
Conclusions/Learning Points: Cognitive assessments using the NIH-CB and KABC were acceptable to participants and feasible in a Zimbabwean hospital setting. A larger study is required to determine if they have equal sensitivity in evaluating HIV associated neurocognitive dysfunction in adolescents. Both tools will be used in a larger cross-sectional study of cognitive function and mental health in young people living with HIV.

EPICARDIAL ADIPOSE TISSUE IS INCREASED IN HIV INFECTED ADOLESCENT AND YOUNG ADULTS

E-Posters Viewing
E-POSTER VIEWING: AS09.B. HIV/AIDS

Marta Stracuzzi[1], Azzurra Marceca[2], Gianvincenzo Zuccotti[3], Alberto Barosi[2], Vania Giacomet[1]
[1]università degli studi di milano, Pediatric Infectious Disease, Luigi Sacco Hospital, Milan, Italy, [2]Luigi Sacco Hospital, Cardiology Unit, Milan, Italy, [3]Università degli Studi di Milano, Department Of Pediatrics, V. Buzzi Children's Hospital, Milan, Italy

Backgrounds: The association between antiretroviral therapies in HIV positive subjects and the cardiovascular risk is already known in literature. To date, there are few studies investigating this association in adolescents and young adults with vertically transmitted HIV; it appears to be urgent to stratify as earlier as possibile cardiovascular risk in these patients.
Methods: In our study we enrolled 20 (mean 20 years, 10 male) vertically transmitted HIV patients aged at least 14 years with good immunovirological control. They underwent echocardiography with the evaluation of the following parameters: biventricular systolic function (LVEF, RVEF); biventricular global longitudinal strain (LVGLS, RVGLS); left ventricular diastolic function (E / A-MV, E / e ', TR, BSA); epicardial adipose tissue (EAT). The cohort thus identified was compared with a cohort of HIV-negative healthy controls matched for age and sex.
Results: Comparing HIV infected cohort to healthy controls, no statistically significant differences emerged except for the EAT, which appears to be greater in the HIV infected cohort, although the values detected are within normal limits. Using Sperman's linear correlation statistical function we evaluated whether the parameters of BMI, age and gender were related to EAT: no correlation was identified.
Conclusions/Learning Points: Our study revealed an increased thickness of EAT in the HIV infected cohort, while remaining within the normal range. Further data are needed to support these preliminary data.

CAROTID INTIMA MEDIA THICKNESS IS INCREASED IN HIV INFECTED ADOLESCENT AND YOUNG ADULTS

E-Posters Viewing
E-POSTER VIEWING: AS09.B. HIV/AIDS

Marta Stracuzzi[1], Francesco D'Amario[2], Gianvincenzo Zuccotti[3], Tiziano Porretta[2], Vania Giacomet[1]
[1]università degli studi di milano, Pediatric Infectious Disease, Luigi Sacco Hospital, Milan, Italy, [2]Luigi Sacco Hospital, Vascular Surgery Unit, Milan, Italy, [3]Università degli Studi di Milano, Department Of Pediatrics, V. Buzzi Children's Hospital, Milan, Italy

Backgrounds: To date, there are few studies investigating this association in adolescents and young adults with vertically transmitted HIV; it appears to be urgent to stratify as earlier as possibile cardiovascular risk in these patients.
Methods: In our study we enrolled 33 (mean age 25 years, 12 male) vertically transmitted HIV patients aged at least 14 years with good immunovirological control. They underwent ultrasound of the supra-aortic trunks with the evaluation of the thickness of the carotid intima-media (IMT). The cohort thus identified was compared with a cohort of HIV-negative healthy controls matched for age and sex.
Results: Comparing HIV infected cohort to healthy controls, we found a statistically significant difference in IMT both for right and left carotid, which appears to be greater in the HIV infected cohort, although the values detected are within normal limits. Spearman's correlation index was calculated between the mean right and left IMT value and weight, height, BMI, abdominal circumference, systolic and diastolic blood pressure in ortho and supine position, cholesterol (total, LDL, HDL, non-HDL), triglycerides, fasting blood glucose, basal insulin, HOMA-index, glycated hemoglobin, CD4+ lymphocyte count and average over the years elapsed since the initiation of ART therapy. No correlation was found for the left IMT value. There was a significant correlation with abdominal circumference ($r = 0.42$) (p value 0.012) and BMI ($r = 0.36$) (p value 0.03) with right IMT.
Conclusions/Learning Points: Our study revealed an increase of IMT in the HIV infected cohort, while remaining within the normal range, apparently related to the patient's metabolic state. Further data are needed to support these preliminary data.

USE OF INFORMATION AND COMMUNICATIONS TECHNOLOGY AS A NEW PUBLIC HEALTH SURVEILLANCE TOOL DURING COVID-19 PANDEMIC IN THE STATE OF SÃO PAULO, BRAZIL

E-Posters Viewing
E-POSTER VIEWING: AS10.A. DECISION SUPPORT TOOLS

Tatiana D`Agostini[1], Rosana Tamelini[2], Eliane Augusto[3], Raphael Ramos[3], Regiane De Paula[4]
[1]State Health Department of São Paulo, Epidemiological Surveillance Center, Brazil, Brazil, [2]State Health Department of São Paulo, Regional Health Department, São Paulo, Brazil, [3]State Health Department of São Paulo, Sanitary Surveillance Center, Brazil, Brazil, [4]State Health Department of São Paulo, Health Surveillance Center, Brazil, Brazil

Background: In Brazil, the Covid-19 surveillance is based on case/deaths notification by Severe Acute Respiratory Syndrome (SARS) and Influenza-like illness. The pandemic brings the importance of using information and communications technology (ICT) as a new public health surveillance resource for monitoring and integration between databases in real time. This study aims to describe the introduction process of ICT as a public health tool during the Covid-19 pandemic in the State of São Paulo (SSP).
Methods: This is a descriptive study about the implementation of CENSO Covid-19 since the health services notification to issuing epidemiological alerts.
Results: Due to the need to update in real time suspected/confirmed cases of COVID-19 in wards and Intensive Care Units, all health centers must fill the form available on http://censocovid19.saude.sp.gov.br/ (Resolution SS nº. 42/2020) developed by the technical advisors of epidemiological surveillance. Both public and private health services have informed daily the quantitative and follow-ups. Along 6 months, an information system was developed with programming language and dashboards, using many variables, such as hospitalized adults and pediatrics patients, hospital beds for Covid-19/non-Covid-19, new and discarded cases and exits, and different colors to facilitate filling out the form. The CENSO Covid-19 has been an important tool for monitoring the Covid-19 outbreak in the SSP in the short, medium, and long term, giving real time information about hospital occupancy, support many studies about structures for pandemic service and planning of distribution of inputs, medicines, and protective equipment for professionals.
Conclusions/Learning Points: New ICTs allow improving the epidemiological surveillance and the analytical capacity of the system at the regional level, strengthening the Health Care Network helping to detect or prevent changes in individual or collective health patterns of the population.

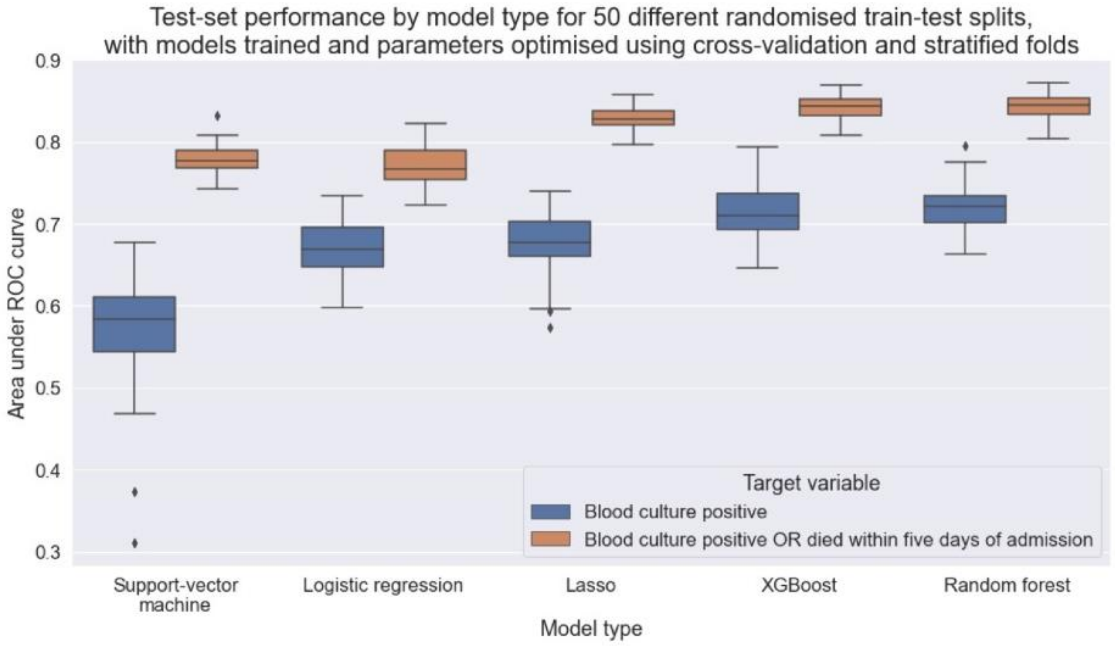
A MACHINE-LEARNING APPROACH TO PREDICTING RISK OF SEPSIS IN LOW-RESOURCE NEONATAL UNITS USING ROUTINE HEALTHCARE DATA FROM NEOTREE

E-Posters Viewing
E-POSTER VIEWING: AS10.A. DECISION SUPPORT TOOLS

Felicity Fitzgerald[1], Ed Lowther[2], Nushrat Khan[3], Gwendoline Chimhini[4], Mario Cortina Borja[3], Sanaz Jabbari[2], Nel Swanepoel[2], Samuel Neal[5], Marcia Mangiza[6], Michelle Heys[3], Simbarashe Chimhuya[4]
[1]Imperial College London, Infectious Diseases, London, United Kingdom, [2]UCL, Centre For Advanced Research Computing, London, United Kingdom, [3]UCL, Ucl Gos Institute Of Child Health, London, United Kingdom, [4]University of Zimbabwe, Paediatrics, Harare, Zimbabwe, [5]University of Edinburgh, Neonatology, Edinburgh, United Kingdom, [6]Ministry of Health and Child Care, Paediatrics, Harare, Zimbabwe

Backgrounds: Neonatal sepsis is a major cause of morbidity and mortality in low-resource settings. Where microbiological diagnostics are scarce, clinical prediction models developed using local data are potentially useful alternatives. We assessed the performance of clinical prediction models derived using machine learning from routine clinical data in Zimbabwe.
Methods: We included data from 7,126 neonates admitted to the neonatal unit in Sally Mugabe Central Hospital, a tertiary teaching hospital in Zimbabwe and 2,390 neonatal blood culture results. Data were collected using the Neotree app, a digital quality improvement tool from February 2020-September 2022. We assessed two outcomes: 1. Positive blood culture results for early onset neonatal sepsis (within 72 hours of admission) 2. Positive blood culture results or death within 5 days of admission, as blood cultures were not consistently available for the study duration. Performance of support vector machine, lasso, extreme gradient boosting and random forest algorithms were tested compared with a baseline logistic regression model, using area under the ROC curve (AUC) as an accuracy metric.
Results: Overall Lasso (AUC=0.68; 0.82), XGBoost (0.69; 0.83), and Random Forest (0.70; 0.83), performed better than the baseline model (AUC=0.66; 0.78) for outcomes 1 and 2 respectively, with Random Forest the most computationally efficient (Figure). The AUC remained similar for neonatal deaths between 3 and 8 days of admission. Use of larger datasets may result in more robust models as model performance varied across random splits of training and test datasets
(Figure).



Conclusions/Learning Points: We have demonstrated proof of concept for using machine learning techniques to derive clinical prediction models from routine clinical data to predict early onset sepsis and/or neonatal death with a good degree of accuracy. External validation of this model is now required.

RECURRENT SKELETAL AND GASTROINTESTINAL INFLAMMATIONS WITH PAIN AND FEVER: CHALLENGES FACED BY A TUNISIAN FAMILY

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Nouha Bouayed Abdelmoula, Balkiss Abdelmoula
Medical University of Sfax, Genomics Of Signalopathies At The Service Of Medicine, Sfax, Tunisia

Backgrounds: In response to diverse triggers, inflammasome sensor proteins are activated leading to caspase-1 activation and pro-inflammatory cytokines release. Mutations in the components of inflammasome complexes are implicated in multiple hereditary periodic fever syndromes. Irregularly repeated acute episodes of fever and tissues inflammation (joints, gut, chest, etc.) related to these syndromes are clinically challenging, as they sometimes lead to different misdiagnosis. Here, we report the clinical management scheme of a three-generation Tunisian family, in which recurrent gastrointestinal inflammations led to inappropriate surgical interventions.
Methods: During our genetic counselling for reproduction failure and congenital disorders as well as genetic conditions, a 30-year-old Tunisian woman were explored because of recurrent gynecological infections with secondary infertility. Suspecting periodic fever syndrome, she was investigated at the molecular level. Using multiplex PCR, screening of 12 mutations of the MEFV gene, that codifies for pyrin, and which is located at 16p13, was conducted. Subsequently, genetic exploration and counselling were undertaken for the three-generation family members of our patient.
Results: The investigated Tunisian female was born in Sfax (Tunisia) from a consanguineous couple. Homozygous single nucleotide substitution of exon 10 of MEFV gene (c.2040 G>C) was confirmed. Homozygous and heterozygous M680I mutations were found in symptomatic and asymptomatic members of the three-generation Tunisian pedigree. Adult patients reported their first episode at the age of 20-25 years, whereas in children the first episode happened at an earlier age. Clinical management of all mutated patients, was planned individually, according to results of the genetic testing.
Conclusions/Learning Points: Mediterranean fever is an autosomal recessive auto inflammatory disease that should be differentiated from infections and other autoimmune disorders. We emphasize on the importance of MEFV molecular testing to avoid the challenges of the clinical management .

RECURRENT ARTHRITIS IN A PEDIATRIC PATIENT: A DIAGNOSTIC CHALLENGE WITH A GENETIC SOLUTION

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Balkiss Abdelmoula, Nouha Bouayed Abdelmoula
Medical University of Sfax, Genomics Of Signalopathies At The Service Of Medicine, Sfax, Tunisia

Background: Recurrent arthritis can be caused be a variety of factors. While infections are a frequent cause, autoimmune, genetic and hereditary rheumatic disorders are also common. One such disorder is Familial Mediterranean Fever (FMF), which can present with a range of symptoms making it difficult to diagnose. Here, we present a diagnostically challenging case of a Mediterranean female child from Libya, who underwent multiple surgical interventions for recurrent arthritis episodes.
Methods: A nine-year-old female was referred to our genetic counselling by her pediatrician for a suspected genetic origin of her paroxysmal inflammatory symptoms associated to febrile episodes. The patient had a history of three arthritis episodes in the hip and knee, which were surgically managed. Despite radiographic investigations revealing arthritis of infective or inflammatory origin, no microbes were detected in joint aspiration analysis. Cytogenetic and MEFV molecular investigations were carried out to set up the diagnosis of a suspected FMF.
Results: Cytogenetic analysis revealed a 46,XX formula, without any structural abnormalities in chromosome 16, which harbors the FMF responsible gene. However, molecular screening of the 12 most frequent mutations of the MEFV gene confirmed the diagnosis of FMF. In fact, the condition was related to the most severe mutation, which was a homozygous point mutation in exon 10 of the MEFV gene: M694V.
Conclusions/Learning Points: FMF needs to be considered in juvenile recurrent arthritis. Family history and ethnic background should thus be taken into consideration. While the most severe forms of FMF are associated with exon 10 MEFV mutations (M694V and M680I), it appears that patients with homozygous M694V mutation tend to have an earlier onset of FMF, manifesting during childhood. Early genetic molecular testing is therefore crucial to avoid unnecessary medication and surgical interventions for children with recurrent arthritis.

IMMUNOASSAY ON THE MEMEDKEY INSTRUMENT CAN DIFFERENTIATE BACTERIAL AND VIRAL INFECTIONS IN CHILDREN WITH POTENTIAL TO IMPACT ON PATIENT PATHWAYS WHEN USED POINT OF CARE

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Eliza Alexander[1], Rhea Escriba[2], Mazeda Akhtar[1], Kathryn Harris[3]
[1]Barts Health NHS Trust, Virology, London, United Kingdom, [2]Barts Health NHS Trust, Children's Clinical Research Facility, London, United Kingdom, [3]Barts Health NHS Trust, Virology, Royal London Hospital, United Kingdom

Backgrounds: Differentiating between bacterial and viral infections is challenging based on clinical findings alone, especially in younger children and infants or those with complex medical conditions. This can lead to children being admitted to hospital and started on empiric antibiotics. The MeMed BV® Test is an immunoassay that measures three host response proteins in serum: TNF-related apoptosis-inducing ligand (TRAIL), Interferon gamma-induced protein-10 (IP-10) and C-reactive protein (CRP). These three quantitative measurements are combined with an algorithm to generate a score (0 – 100) that predicts the likelihood of bacterial infection.
Methods: Twenty paediatric patients were identified as having a known or suspected bacterial or viral infection and their residual serum samples were stored at -80 °C. Samples (0.1 ml) were tested retrospectively. Not all patients met the test's intended for use criteria.
Results: MeMed scores for 20 patients are presented in Table 1, alongside the clinical and laboratory findings. Eleven had a score > 70 (high or moderate likelihood of bacterial infection), seven of these had a confirmed bacterial infection, one had a confirmed fungal infection and the remaining three had no pathogens detected in the laboratory. One patient with a result in the equivocal range had confirmed viral and bacterial infection. Five patients had a score < 35 (high or moderate likelihood of non-bacterial infection), two had confirmed viral infections, two had no pathogens detected and one had a confirmed bacterial infection.
Conclusions/Learning Points: The MeMed test could differentiate bacterial infections in the majority of samples tested with a rapid (< 15 minutes) time to result. We are currently evaluating the impact of this point of care test on patient pathways within the paediatric department of our

hospital.

Sample	Clinical history	MeMed Score	Clinical Findings	Laboratory Findings
1	no infection	0	Low suspicion of infection	No pathogens detected
2	fever and vomiting	7	Suspected infection	Confirmed viral infection
3	viral URTI	16	Suspected viral infection	Confirmed viral infection
4	fever and rash	20	suspected viral infection	Confirmed bacterial infection
5	fever and rash	24	suspected viral infection	No pathogens detected
6	chickenpox/necrotising fasciitis	35	Confirmed viral infection & suspected bacterial infection	Confirmed viral and bacterial infection
7	LRTI in complex patient	53	Upper respiratory tract infection	confirmed viral infection
8	LRTI in complex patient	60	Lower respiratory tract infection	confirmed viral infection
9	tonsillitis and rash	61	suspected bacterial infection	Confirmed viral infection
10	complex patient/fever/IV line	70	suspected bacterial infection	Confirmed fungal infection
11	complex patient/fever/IV line	71	suspected bacterial infection	Confirmed bacterial infection
12	complex patient/fever/IV line	72	suspected bacterial infection	No pathogens detected
13	complex patient/sepsis/IV line	87	Probable bacterial infection	Confirmed bacterial infection
14	periorbital cellulitis	92	probable bacterial infection	Confirmed bacterial infection
15	sacroilitis	95	probable bacterial infection	Confirmed bacterial infection
16	complex patient/sepsis/line infection	96	probable bacterial infection	Confirmed bacterial infection
17	complex patient/sepsis	96	Suspected bacterial infection	No pathogens detected
18	febrile seizure	97	Probable bacterial infection	No pathogens detected
19	severe sepsis/line	98	Probable bacterial infection	Confirmed bacterial infection
20	cerebral empyema	100	Probable bacterial infection	Confirmed bacterial infection

Table 1: Twenty serum samples were tested on the MeMed Key generating a score for each sample. A qualitative interpretation of the result is generated by placing the scores into the following "bins": 0-9: High likelihood of viral infection or other non-bacterial etiology (light blue); 10-34: Moderate likelihood of viral infection or other non-bacterial etiology (dark blue); 35-65: Equivocal (grey); 66-90: Moderate likelihood of bacterial infection or co-infection (light orange); 91-100: High likelihood of bacterial infection or co-infection (dark orange).

PV0805 / #632

IN FEBRILE CHILDREN FOR MORE THAN FIVE DAYS, SERUM CONCENTRATIONS OF SOLUBLE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR FAIL TO IDENTIFY THOSE WITH KAWASAKI DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Ahmed Alsuwaidi, Junu George, Hassib Narchi
United Arab Emirates University, Pediatrics, Al Ain, United Arab Emirates

Backgrounds: SuPAR, the soluble form of the urokinase plasminogen activator receptor, separates from the cell membrane of immunologically active cells during inflammation. It plays a role in the plasminogen activating pathway, inflammation, cell adhesion and migration. It has been used in the diagnosis and prognosis of multiple inflammatory, infectious and autoimmune conditions. We aimed, in this study, to establish if suPAR serum concentrations in febrile children can distinguish those with Kawasaki disease (KD) from those with infections, and if they are associated with the development of coronary artery complications in KD.
Methods: SuPAR was measured in children admitted to hospital with fever > 5 days and without suggestive diagnostic signs on admission using commercial Enzyme-Linked Immunosorbent Assay kits (suPARnostic™ assay, Virogates, Copenhagen, Denmark).
Results: We enrolled 17 children (median age 25 months, interquartile range 18, 53 months). Seven children had KD, of whom one developed coronary artery aneurysm (CAA) and ten had febrile infections (one bacterial pneumonia, one scarlet fever, three viral respiratory infections and five viral gastroenteritis). There was no significant difference (p=0.84) in suPAR concentrations between children with KD (5.35 ± 2.76 ng/mL) and febrile infections (5.57 ± 1.69 ng/mL), (Fig. 1). SuPAR concentrations were not significantly different (p=0.47) between bacterial and viral infections (4.75 ± 1.07 ng/mL vs 5.78 ± 1.81 ng/mL), nor between sexes (p=0.61), age groups (p=0.47) or duration of fever prior to admission (p=0.61). In KD, suPAR concentration was 4.69 ng/mL in one child who developed a CAA, compared to 5.47 ± 1.04 ng/mL in the
others.

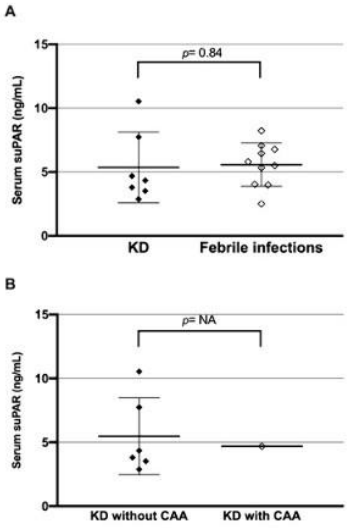

Figure 1. Soluble Urokinase Plasminogen Activator Receptor concentrations in children with Kawasaki disease and febrile infections. **Panel A**: KD and febrile infections. **Panel B**: KD with and without CAA.
Footnote: suPAR: Soluble Urokinase Plasminogen Activator Receptor ; KD: Kawasaki disease ; CAA: coronary artery aneurysm; NA: could not be computed. Horizontal lines represent mean values ± standard deviations. *P* values calculated by the 2-sided unpaired Student t-test.

Conclusions/Learning Points: In our study, serum suPAR concentrations on admission to hospital failed to distinguish between children with KD and those with febrile infections, or to predict the development of CAA in KD.

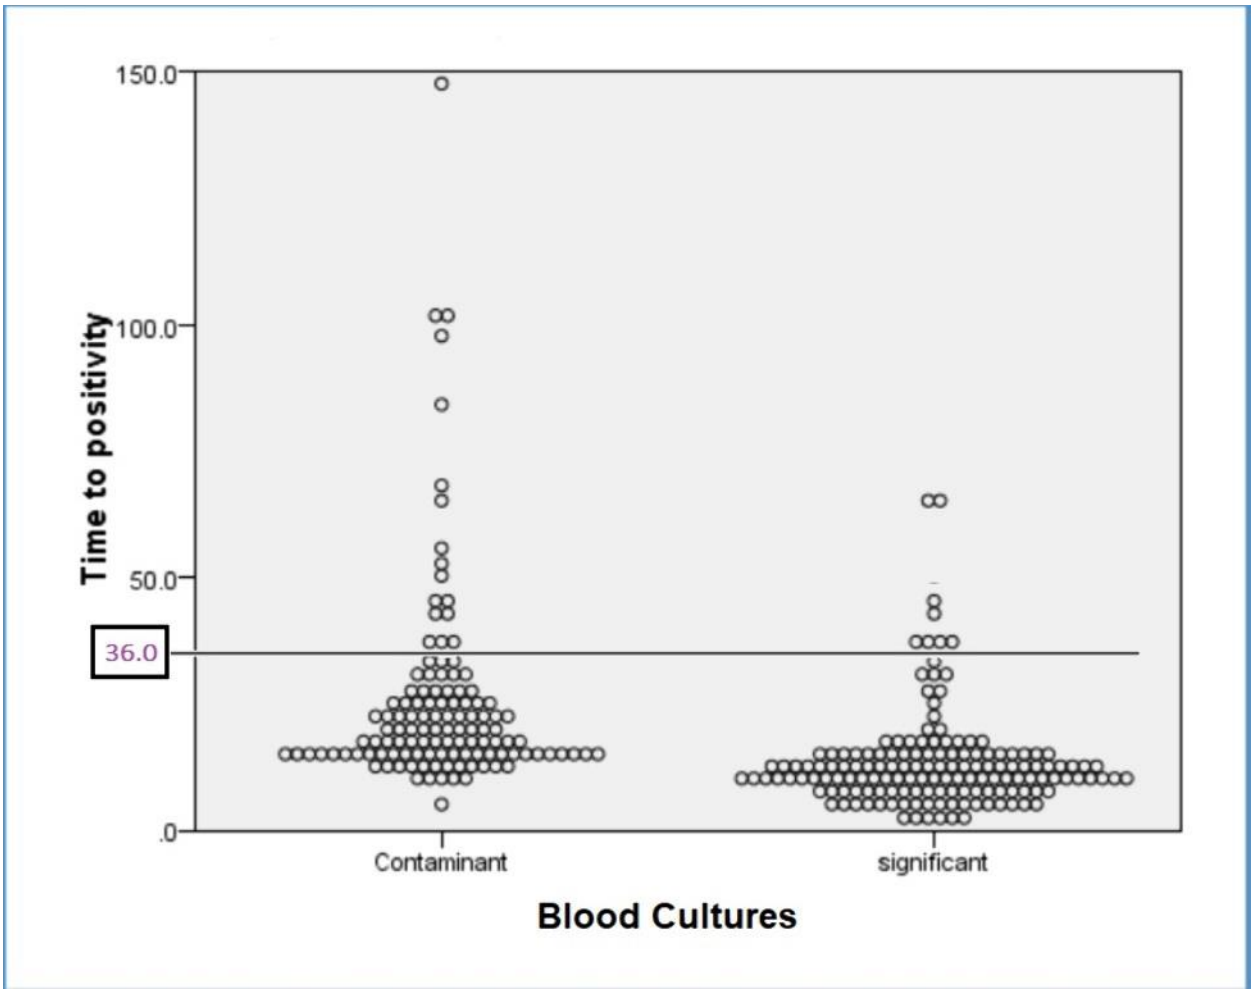
PV0806 / #1155

EVALUATION OF EARLIER PRELIMINARY NEGATIVE BLOOD CULTURE REPORTING AT 36 HOURS IN CHILDREN AGED 0-16 YEARS OLD: A UK TEACHING HOSPITAL'S EXPERIENCE.

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Sharon Koo, Kashif Aziz
University Hospitals of Leicester NHS Trust, Microbiology, Leicester, United Kingdom

Backgrounds: Blood cultures remain the gold standard in the diagnosis of bloodstream infections. Negative preliminary blood culture reporting assist clinicians in reviewing the diagnosis of sepsis and antimicrobials initiated on admission. UK guidance recommends 36 hours blood culture reporting in neonates but no specific standards are available for children in other age groups. Historically in our centre, preliminary negative blood cultures were reported at 48 hours as with adults. We aim to review the usefulness of earlier preliminary blood culture reporting at 36 hours in children aged 0-16 years old.
Methods: All blood cultures recieved in the microbiology lab at University Hospitals of Leicester NHS Trust from patients aged 0-16 years old over a period of 1 year were included in this review. Time to positivity (TTP) of blood cultures and organisms grown were reviewed alongside clinical details available from the laboratory information system and patient's clinical notes. Blood cultures growing skin-type organisms were deemed as contaminants unless there was presence of prosthetic material and clinical suspicion of infection at the time of blood culture collection. Data was analysed using SPSS v22.
Results:



A total of 4,114 blood cultures were received, of which 274 showed positive growth. Mean TTP in contaminated blood cultures was 25.4 ± 20 hours whilst for significant blood cultures TTP was 13.6 ± 10 hours(p-value 0.017). Blood culture positivity rates at 12, 24, 36 and 48 hours were 58%, 89.5%, 94.1% and 95.3%. The sensitivity and specificity for significant cultures at 36 hours were 94% and 97%.
Conclusions/Learning Points: This review suggests that preliminary reporting at 36 hours was sensitive and specific in the detection of significant bloodstream infections in children, allowing for earlier review of patients and antimicrobials.

Backgrounds: Studies on procalcitonin (PCT) for identifying sepsis were published as early as 1993 and since then, PCT has been the topic of over 8,500 studies, including several systematic reviews showing its adequate diagnostic value in febrile children. Several studies show PCT to be superior to CRP in differentiating paediatric sepsis from viral infections, especially early in the disease course. However, its actual use in clinical practice is poorly documented. Our aim was to study the use of PCT in febrile children attending the ED across Europe and compare this to the use of CRP.
Methods: The MOFICHE/PERFORM study, a prospective multicentre study, took place at 12 European EDs in eight countries and included febrile children <18 years. Descriptive analyses were performed, describing the use of PCT in all febrile children and for different age groups, foci of fever and fever duration.
Results: Nine settings used PCT in children attending the ED, leading to 31,612 paediatric febrile episodes for analyses. CRP was used in 49% of these, while PCT was used 2% of the time. When blood tests were done, CRP was performed in 98% (range 80-100%) and PCT in 4% (range 0.2-86%). PCT was most often performed in children below 3 months (8.6% versus 1.8% in older children, $p<0.001$) and in children with sepsis/meningitis (12%), inflammatory illness (8.9%) and undifferentiated fever (5.1%). PCT was used slightly more often in children with fever less than 24 hours (2.3%) than in children with longer duration of fever (1.8%, $p<0.05$).
Conclusions/Learning Points: Actual PCT use in febrile children at the ED is limited and varies largely between hospitals. Guidelines could aid in a more targeted and evidence-based approach.

RAPID MOLECULAR POINT-OF-CARE TEST FOR STREP A PHARYNGITIS IN REMOTE-LIVING SCHOOL AGED CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Janessa Pickering[1], Dylan Barth[1], Bernadette Wong[1], Rebecca Famlonga[1], Delia Lawford[2], Robyn Macarthur[3], Shelley Kneebone[3], Narelle Ozies[3], Abbey Ford[1], Gelsa Cinnani[1], Slade Sibosado[1], Liam Bedford[1], Jonathan Carapetis[1], Asha Bowen[1]
[1]Telethon Kids Institute, Wesfarmers Centre For Vaccines And Infectious Diseases, Nedlands, Australia, [2]Broome Regional Aboriginal Medical Service, Medical Clinic, Broome, Australia, [3]Derby Aboriginal Health Service Council, Health Clinic, Derby, Australia

Backgrounds: Accurate and timely diagnosis of Strep A pharyngitis in remote settings can be challenging. The availability of molecular point-of-care testing (PoCT) for Strep A pharyngitis may revolutionise primary prevention strategies in children at high risk of acute rheumatic fever. We aimed to evaluate the performance of a rapid molecular PoC test for Strep A pharyngitis in remote-living children in the Western Australia (WA).
Methods: Our primary school-based prospective surveillance program evaluated the epidemiology of Strep A infection in two towns within the Kimberley WA, comprising: (1) cross-sectional screening two times a year, and (2) weekly active surveillance visits once a week. Between April 2021 and September 2022, consented children were screened for pharyngitis and provided throat swabs for gold standard microbiological culture and PoCT using the Strep A ID NOW machine. We calculated the sensitivity, specificity, positive (PPV) and negative predictive values (NPV). PoC test performance was compared to the microbiological culture results
Results: Strep A PoCT was performed on 122 instances of sore throat. Twenty-nine (24%) tests were positive by PoCT, of which ten also produced positive culture results. One culture positive result was not detected by PoCT. We calculated a POCT sensitivity of 90.1%, specificity of 82.9%, PPV 34.5% and NPV 98.9%. Potential false positive results due to detection of other Streptococcal species (e.g. S. dysgalactiae) warrants further molecular investigation.
Conclusions/Learning Points: The high sensitivity of molecular Strep A tests may represent an advantage in detection and early treatment of pharyngitis. We confirm the value and feasibility of molecular PoC testing in remote Australian settings to improve diagnosis and treatment of Strep A pharyngitis.

UTILITY OF FEBRIDX POINT OF CARE TEST TO FACILITATE THE DECISION-MAKING PROCESS IN THE PEDIATRIC EMERGENCY DEPARTMENT AT PADUA UNIVERSITY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Raimondo Junior Castaldo[1], Giulia Brigadoi[2], Sara Rossin[3], Liviana Da Dalt[4], Daniele Donà[5]
[1]University of Padua, Department For Women's And Children's Health, Padua, Italy, [2]Padua University, Department Of Women's And Children's Health, Padua, Italy, [3]Padua University, Pediatric Emergency Department, Department Of Women's And Children's Health, University Of Padua, Padua, Italy, Padua, Italy, [4]University of Padua, Pediatric Emergency Department, Padua, Italy, [5]University of Padova, Division Of Pediatric Infectious Diseases, Department For Women's And Children's Health, Padova, Italy

Background: Acute respiratory infections are the most frequent cause of Emergency Department (ED) visits but is not always easy to differentiate between viral and bacterial infection, thus resulting in the execution of blood tests to help the clinical decision. We evaluated the usefulness of a rapid point-of-care test, FebriDx, that simultaneously measures two key infection biomarkers, C-reactive protein and Myxovirus resistance protein A, in facilitating the decision-making process in our Pediatric Emergency Department (PED) and in reducing the time spent in the room visits.
Methods: This case-control retrospective study evaluated patients aged more than one year with fever and respiratory symptoms with no antibiotic treatment in the previous month. Patients tested with FebriDx from 03.11.2022 to 31.01.2023 (cases) were compared with patients of the same age and same duration of fever evaluated from 2016 to 2021 (between October and April) and subjected to blood tests (controls).
Results: Of the 34 cases, the mean age was 5,03 years, the mean duration of fever was 4,11 days. No one of them underwent blood tests. Twenty-three patients had a viral result (one received antibiotic for suspected urinary tract co-infection), one patient had a bacterial result, and ten patients had a negative result (one of them received antibiotic for streptococcal pharyngitis).Of the 34 controls, the mean age was 4,91 years, the mean duration of fever was 4,2 days. No one of them received an antibiotic prescription at discharge.The mean time spent in PED was 2.1 hours in the FebriDx groups and 3.12 hours in the control group ($p<0.005$).
Conclusions/Learning Points: FebriDx seems to have helped facilitate clinician decisions in reducing the time spent in the ED visits and to avoid the invasiveness due to blood tests.

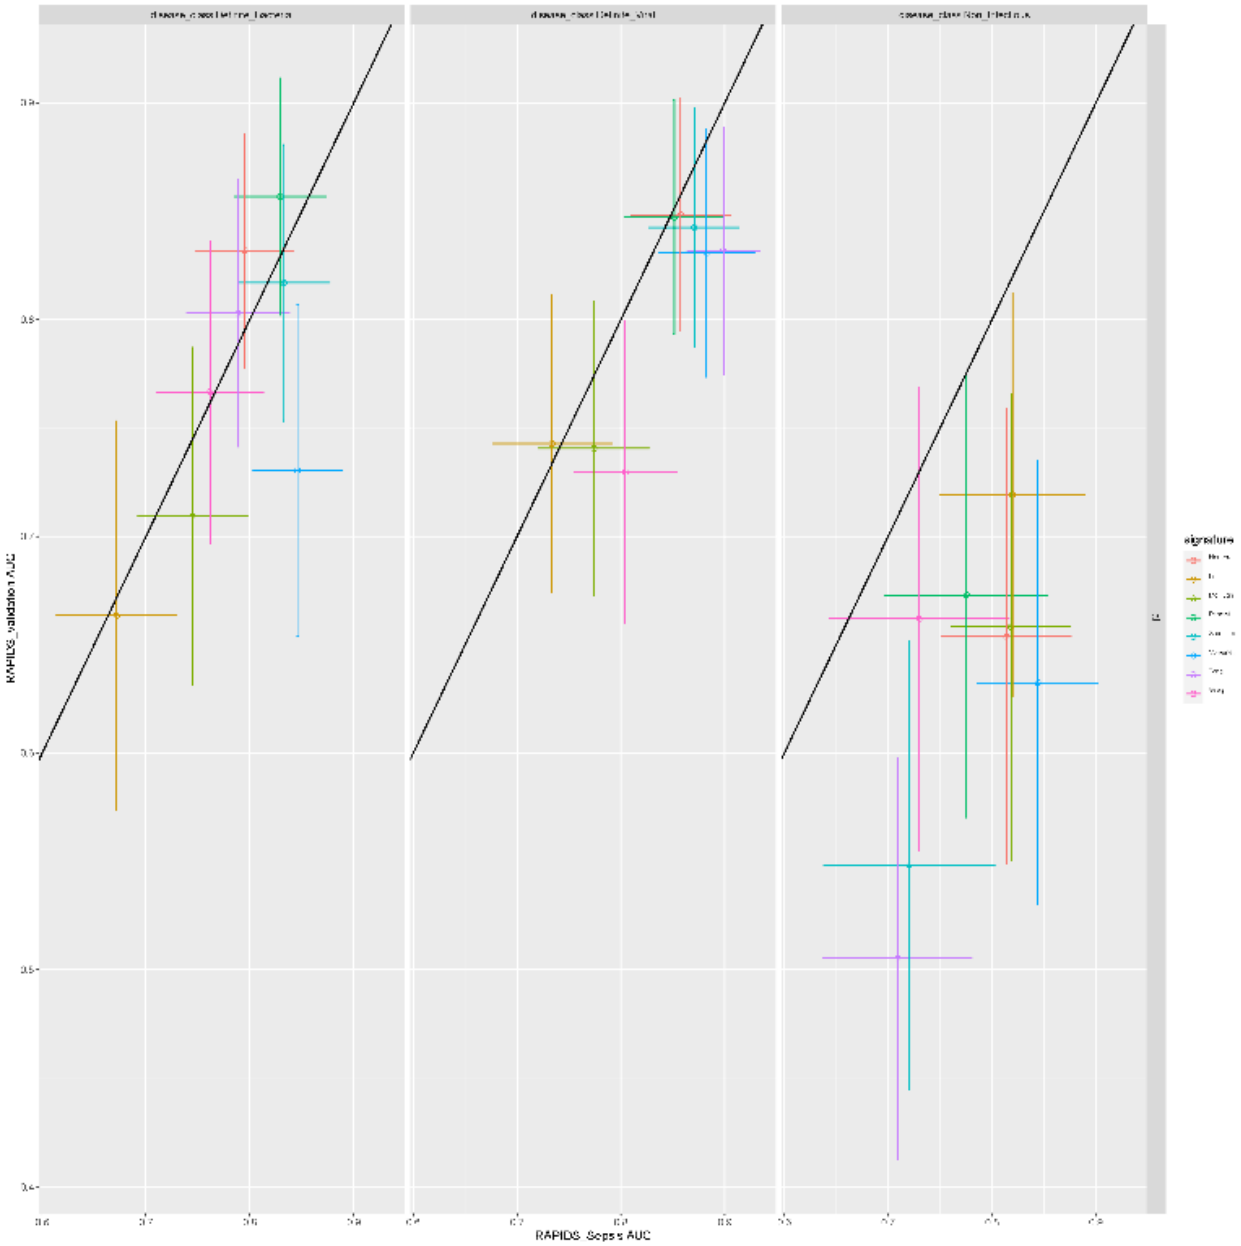
A UNIFIED FRAMEWORK FOR DISCOVERY, VALIDATION AND RE-TRAINING OF MINIMAL GENE SIGNATURES FOR DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Lachlan Coin[1], Luregn Schlapbach[2], Devika Ganesamoorthy[3]
[1]University of Melbourne, Microbioloogy And Immunology, Melbourne, Australia, [2]Children's Research Center, University Children's Hospital Zürich, Neonatal And Pediatric Intensive Care Unit, Zurich, Switzerland, [3]University of Queensland, Childrens Health Research Centre, Brisbane, Australia

Backgrounds: Gene expression signatures have been developed for many applications, including distinguishing bacterial from viral infection; identifying specific types of infections, such as Tuberculosis and also for distinguishing severe from mild disease. The development of small gene signatures which can be deployed on rapid, low-cost, platforms for measuring gene expression has been particularly promising. However, relatively little work has been undertaken on developing tools for rapid validation of existing biomarker signatures on both new and pre-existing datasets; nor on defining frameworks for specification and sharing of models.
Methods: We have developed a web-server, and associated R package for validation and re-fitting of gene signatures (http://coinlab.mdhs.unimelb.edu.au/fspls/), coupled with a format for full model specification The model supports both binary as well as multi-class outcomes. The webserver uses encryption to enable cross-validation by different groups without requiring sharing of models or data, and can securely and efficiently access data stored in the cloud.
Results: We used a newly collected dataset comprising whole blood RNA sequencing on 911 RNA samples from children with suspected sepsis which were assigned as having a viral, bacterial or non-infectious disease based on clinical and pathology lab data, split into discovery (n=595) and validation (n=312) cohort. We used the FSPLS webserver to investigate the performance of 8 previously described signatures. These signatures generated validation AUCs up to 86% , 85% and 72% for Bacterial, Viral and non-infectious categories, respectively (Fig.
1).



Conclusions/Learning Points: The framework we have developed can be used to standardise validation of minimal gene signatures in infectious disease, leading to more robust signatures. Application of this framework to a paediatric sepsis cohort higlighted the difficulty in classification of non-infectious disease using existing models.

RESPIRATORY DIAGNOSTIC TEST PERFORMANCE IN PAEDIATRIC PRIMARY CARE CLINICS AND RELATION WITH PCR CYCLE THRESHOLDS AND DURATION OF ILLNESS

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Maria Dominguez-Villoria[1], Teresa De La Calle-Cabrera[2], Maria Concepcion Vega-Hernández[3], Nieves Gutierrez-Zufiaurre[4], Claudia Sanchez-Villares[5], Pilar Aparicio-Rios[6]
[1]Gerencia de Atencion Primaria de Zamora, Pediatria, Salamanca, Spain, [2]Centro de Salud de Tamames, Gerencia De Atención Primaria De Salamanca, Salamanca, Spain, [3]University of Salamanca, Estadística Multivariante Aplicada, Salamanca, Spain, [4]Hospital Universitario de Salamanca, Microbiología, Salamanca, Spain, [5]Centro de Salud de Ciudad Rodrigo, Gerencia De Atención Primaria De Salamanca, Salamanca, Spain, [6]Centro de Salud de Peñaranda, Gerencia De Atención Primaria De Salamanca, Salamanca, Spain

Backgrounds: Rapid diagnostic test (RDTs) for respiratory viruses have had massive development due to the pandemic but the performance of immunocromatographic test for viruses other than COVID has rarely been evaluated. PCR cycle thresholds (CTs) have also been evaluated mainly in this setting, where the findings are that CT values correlate strongly with cultivable virus. Other factor which has been found to be involved in the RDT performance is the duration of illness.
Methods: Prospective study in primary care paediatrics in Salamanca, Spain. Paediatricians recruited patients with respiratory infections from November´21 to April´22, and performed two nasopharyngeal swabs simultaneously, for RDT (Certest – RSV, Influenza A+B and Adenovirus) and for PCR viral panel which included RSV, Influenza A+B and SARS-CoV-2. A questionnaire was completed with signs and symptoms, length of illness, age and sex. CT for the PCRs was obtained from the microbiology laboratory. Statistical analysis was performed for sensitivity, specificity and association with positivity/time of illness/PCR CT. Ethical approval was obtained.
Results:

	RSV	Influenza A	Influenza B
Sensibility	45.8%	54.2%	0
Specificity	98.9%	97.1%	96.3%
Positive predictive value	89.8%	88.3%	0
Negative predictive value	89.3%	84.2%	99.8%
Prevalence	17.9%	28.5%	0.2%
Eficacy	89.4%	84.9%	96.1%
True Positives	44 (8.1%)	83 (15.2%)	0 (0.0%)
False Positives	5 (0.9%)	11 (2.0%)	20 (3.7%)
False Negatives	52 (9.5%)	70 (12.8%)	1 (0.2%)
True Negatives	435 (79.7%)	372 (68.1%)	515 (94.3%)

546 children up to age 14 were recruited, 261 under 2 years of age. Performance of the test for 3 viruses is described in Table 1. Statistical difference is found in PCR CTs between true positives and false negatives (p value<0.001). There was no evidence of differences based on the duration of illness.
Conclusions/Learning Points: Sensitivity of the respiratory viruses RDT test was generally poor but false negatives are mainly related with higher CTs. Specificity was very good for all test. More studies on

the performance of RDTs introduced in the clinics are needed in real life settings, and the results should be taken into account when interpreting the results of these tests.

PV0812 / #1601

ASSESSING THE CLINICAL VALUE IN THE USE OF PET CT/FDG IN IDENTIFYING INFECTION FOCI IN PAEDIATRIC PATIENTS WITH CONFIRMED BACTERAEMIA – A NARRATIVE REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Sarah Dowsell[1], Alice Packham[2], Anna Goodman[1]
[1]Guy's and St Thomas' NHS Trust, St Thomas' Hospital - Infectious Diseases, London, United Kingdom, [2]University Hospitals Birmingham Foundation Trust, Infectious Diseases, Birmingham, United Kingdom

Backgrounds: Bacteraemia of unknown source has been associated with higher mortality risk in a paediatric population. The diagnostic value of PET CT has begun to be assessed in children presenting with fever of unknown origin. However, there is sparse literature available regarding the clinical value of PET CT in identifying an infective focus in paediatric bacteraemia.
Methods: A structured search was completed in PUBMED and Embase. Inclusion and exclusion criteria were applied. Inclusion criteria; patients with confirmed bacteraemia, English speaking papers, paediatric patients (≤18 years) and PET CT as imaging modality. Exclusion Criteria; other imaging modalities, patients >18 years and fever of unknown origin with no confirmation of bacteraemia. Final papers were systematically reviewed and corresponding results were
collated.

Search Design for Embase and Pubmed
child* OR infant OR adolescent OR pediatr* OR paediatr* OR baby OR babies OR teen
bacteraemia OR bacteremia
pet ct OR pet OR positron emission tomography OR FDG OR fluorodeoxyglucose

Results: A search of PUBMED and Embase highlighted 29 and 57 papers respectively, published between 2013-2021. After application of exclusion criteria, 6 papers were identified that included a confirmed total of 23 children. Number of paediatric participants remained undisclosed for one paper. PET CT was found to have diagnostic value in identifying infection foci where other imaging modalities could not for 4/23 patient cases where information was available. It is reported to have a high diagnostic yield leading to changes in clinical management but with varying sensitivity. Reported limitations in imaging modality include the duration of imaging and image quality due to the limits in technology.
Conclusions/Learning Points: PET CT appears to have diagnostic value for children with bacteraemia of unknown source or infection foci. However, further research is paramount for greater quantification.

BENEFIT OF THE IMPLEMENTATION OF A PROTOCOL TO DECREASE THE TIME TO PERFORM A MAGNETIC RESONANCE IMAGING IN HOSPITALIZED CHILDREN WITH OSTEOARTICULAR INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Eduardo Rodríguez Pascual[1], Jesus Saavedra-Lozano[1,2,3], Alicia Hernanz-Lobo[1,4], María Del Mar Santos Sebastián[1], Marisa Navarro[1], Begoña Santiago García[1], David Aguilera-Alonso[5]
[1]Gregorio Marañon Hospital, Gregorio Marañon Hospital, Madrid, Spain, [2]Gregorio Marañon Hospital, Pediatrics, Madrid, Spain, [3]Hospital Universitario Gregorio Marañón, Infectious Diseases Unit, Madrid, Spain, [4]Gregorio Marañón University Hospital, Infectious Diseases Department, Madrid, Spain, [5]Fundación para la Investigación Hospital 12 de Octubre, Hospital 12 De Octubre, Madrid, Spain

Backgrounds: Recent guidelines recommend the use of MRI for the diagnosis of acute osteomyelitis (AOM) and esponylodiscitis (ED) in children. The main objective of this study was to evaluate the time until an imaging study was performed in children with OAI after the implementation of a collaborative protocol.
Methods: In 2013, a collaborative OAI protocol was established between the Pediatric Infectious Diseases and the Pediatric Radiology to decrease the time until MRI in children hospitalized with OAI. Single center, retrospective, comparative study performed by reviewing the medical charts OAI between January 2008-March 2020. The cohort was divided in two groups (GroupPre 2008-2013; GroupPost 2014-2020) to determine possible changes after the protocol was implemented.
Results: 136 children were identified; 89 with AOM or ED (55 from GroupPre and 37 from GroupPost), with no differences in terms of demographics and clinical presentation. The rate of scintigraphy (77.8 GroupPre vs 17.1% GroupPost; p<0.001) and MRI (48.1 vs 85.3%; p<0.001) were different between the study groups. No difference in time until an imaging study was done was observed according to the study group (overall median time: 5 days). However, there was a significant reduction in the number of days until MRI in the GoupPost (5.0 vs 8.0 ; p=0.002) (Figure). When only children with SA were analyzed (n=46) there was a non-significant increase in the rate of MRIs performed in the GroupPost, without an increased rate of diagnosed AOM-S.
Conclusions/Learning Points: After the implementation of an imaging study protocol for children with OAI, there was a significant increase in the rate of MRI performed. The time to obtain an MRI in these children was significantly decreased. This increased rate of MRI performed did not rise the diagnosis of OAM-SA.

REDUCING BLOOD CULTURE CONTAMINATION RATES IN CHILDREN: A PRACTICAL APPROACH AND EXPERIENCE IN A LARGE TEACHING HOSPITAL IN THE EAST MIDLANDS, UK.

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Sharon Koo[1], Deepa Panjwani[2], Marie Hubbard[2], Anoj Oommen[2], Osama Diab[3]
[1]University Hospitals of Leicester NHS Trust, Microbiology, Leicester, United Kingdom, [2]University Hospitals of Leicester NHS Trust, Neonatology, Leicester, United Kingdom, [3]University Hospitals of Leicester NHS Trust, Paediatrics, Leicester, United Kingdom

Backgrounds: Blood cultures are important in the management of bloodstream infections. Blood culture contamination rates reported in children varies and is thought to be as high as 22% in some centres. A previous audit found that paediatric blood culture contamination rate in our centre was 3.36%.
Methods: In an attempt to reduce our paediatric contamination rate, a quality improvement project using multi-disciplinary team approach was implemented. A literature search was performed looking at best practices in paediatric specific blood culture collection and techniques. A review of current practices against best practice reported in literature was done.
Results: Unlike in adults, we could not find agreed standards nationally or internationally in paediatric blood culture collection. Blood volume guidance varied across different organisations and between authors of published articles. We implemented an e-learning package focussed mainly on standardisation of blood culture collection technique specifically aimed at staff who takes blood cultures from paediatric patients. An age-specific blood volume recommendation was introduced within the e-learning. A paediatric hospital-wide education and roll-out was done. A re-audit found that our contamination rate in paediatric cohort has reduced to 2.9% in our centre.
Conclusions/Learning Points: A multi-faceted approach was used to reduce blood culture contamination rates in children at our centre. Standardisation of technique, optimising blood volume, education and engagement was crucial in ensuring success.

USE OF MYXOVIRUS RESISTANCE PROTEIN A (MXA) AS A BIOMARKER FOR THE DIFFERENTIAL DIAGNOSIS BETWEEN VIRAL AND BACTERIAL INFECTIONS IN FEBRILE INFANTS WITHOUT SOURCE (FWS)

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Vasiliki Korentzelou[1], Irini Eleftheriou[2], Mersyni Mavrikou[1], Maria Tsolia[2], Nikos Spyridis[2]
[1]P&A Kyriakou Childrens Hospital, First Paediatric Department, Athens, Greece, [2]National and Kapodistrian University of Athens, Second Department Of Paediatrics, Athens, Greece

Backgrounds: Febrile infants without a source are often over-investigated and overtreated while awaiting for culture results. A reliable biomarker that can distinguish between viral and bacterial infection can improve therapeutic decisions. We aimed to determine the sensitivity and specificity of FebriDx, a rapid point-of-care test that combines MxA and C-reactive protein, in the diagnosis of viral and bacterial infections in infants with FWS.
Methods: This prospective controlled study enrolled infants aged 29 days - 12 months old admitted to a tertiary care children's hospital with FWS between November 2021 and December 2022. We included 66 infants with fever (≥38°C) for <72 hours who had no source of infection on physical examination. The control group formed by 55 infants hospitalized for non-infectious cause.
Results: Among 66 infants with FWS, 34 (51,6%) proved to have a bacterial infection and 32 a viral infection; urinary tract infection was the most common bacterial infection (76,4%) while SARS-CoV-2 (31%) and rotavirus (15,6%) were the predominant viruses isolated. For bacterial infections, the sensitivity of FebriDx was 94% and the specificity was 100%. Positive predictive value (PPV) and negative predictive value (NPV) were 100% and 96,4% respectively. For viral infections, the sensitivity was 96,8% and the specificity was 92,7%. PPV and NPV were 88,5% and 98% respectively. 25% of infants with viral infection and positive MxA protein were initially treated with antibiotics.
Conclusions/Learning Points: FebriDx has been used for the management of acute respiratory infections in adults and children. This is the first prospective study on febrile infants with FWS showing high sensitivity and specificity in differentiating between viral and bacterial infections. FebriDx could potentially reduce diagnostics and antimicrobial use in this population.

PV0816 / #600

PSEUDO-OUTBREAK OF ROTAVIRUS INFECTION IN A NEWBORN NURSERY

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Minsung Kim, Jin Lee
The Catholic University of Korea Incheon ST. Mary's Hospital, Department Of Pediatrics, Incheon, Korea, Republic of

Backgrounds: Newborns under the age of rotavirus vaccination coverage are still vulnerable to this infection and rotavirus may cause outbreaks in neonatal units. Rapid antigen tests for rotavirus are done in many newborn nurseries as a screening test for early detection of rotavirus infection. A significant increase in stool samples testing positive for rotavirus antigens in the newborn nursery of a university hospital was observed without any suggestive clinical features. We strengthened infection control measures and conducted additional tests to confirm the diagnosis.
Methods: A rotavirus reverse transcription polymerase chain reaction (PCR) test was performed on stool samples that were positive in the rotavirus rapid antigen test immunochromatographic assay (ICA).
Results: From October 2021 to June 2022, 28 newborn infants were detected positive for rotavirus ag ICA kit. Repeated tests for the same stool samples using a PCR test showed negative results in all 28 neonates. All false positive test results were derived from the rotavirus rapid test device from the same company.
Conclusions/Learning Points: Rotavirus antigen rapid test is easy to perform and provides quick results. However, interpretation of the results should be done with caution. In the case of an increase in rotavirus rapid antigen test positivity without clinical symptoms or epidemiological relevance, false positives and pseudo-outbreaks should be considered. False-positive rapid antigen test results may be related to the timing of the test, prevalence of disease, or product issues.

LONGITUDINAL ANALYSIS OF QUANTIFERON TEST IN PEDIATRIC POPULATION

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Patricia Martínez Paz[1], Sandra Moya Herranz[1], Ana Méndez Echevarría[1], Milagros García López-Hortelano[1], Teresa Del Rosal[2], Fernando Baquero-Artigao[3], Cristina Calvo[4], Miguel González Muñoz[1], Jara Hurtado-Gallego[1], Sonia Alcolea[1], Rocío Sanchez[1], Talia Sainz[5], Paula Rodriguez Molino[6]
[1]Hospital Universitario La Paz, Paediatrics, Madrid, Spain, [2]La Paz University Hospital, Pediatric Infectious Diseases, Madrid, Spain, [3]La Paz Universitary Hospital, Pediatric Infectious Diseases, Madrid, Spain, [4]La Paz Universitary Hospital, Paediatrics, Madrid, Spain, [5]Hospital Universitario la Paz, Pediatric Infectious Diseases, Madrid, Spain, [6]Hospital Universitario La Paz, Pediatrics, Madrid, Spain

Backgrounds: Children are at higher risk of developing tuberculosis, severe and disseminated forms. However, diagnosis is more difficult than in adults. The performance of QuantiFERON® test (QFT) is lower in children, and there is little data regarding their results' long-term evolution. Our aim is to perform a longitudinal analysis of the results of the QFT test in children.
Methods: An ambispective longitudinal study in a tertiary hospital in Madrid was performed between February 2012-January 2023. Patients with history of tuberculosis disease (TB) or latent tuberculosis infection (LTI), <18 years at the time of diagnosis, and a first positive result of QFT test were offered to repeat the test. Results with an interval of >6 months were included.
Results: Fourteen patients with a median age of 8.10 years [IQR (3.78-2.86)] were included: 8 TB, 6 LTI. All completed anti-tuberculosis treatment with good adherence, except one with a loss of follow-up. The 2º QFT was performed with a median interval of 4.86 years [IQR (1.63-6.86)]. In 5/14 (35.7%) the test became negative and in 9/14 (64.3%) remained positive, regardless of the time between tests. In patients with persistently positive results, the median time (4.56 years [1.42-6.05]) between determinations was lower than those that revert to negative (6.84 years [2.85-8.89]). There were no differences in the reversal rate between patients with LTI (2/5) or TB (3/5).
Conclusions/Learning Points: It is essential to know the trend and evolution of QFT in different age ranges, especially in pediatric population. In our work, more than half of the patients still have positive test after almost 8 years. This fact requires more investigation to be interpreted properly, particularly in high burden-settings where there is an increased risk of exposure to the disease.

PV0818 / #1295

ONCOSTATIN M: A NOVEL BIOMARKER FOR BACTERIAL PNEUMONIA IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Clare Mills[1], Cathal Roarty[1], Oenone Rodgers[1], Hannah Norman-Bruce[2], Peter Cosgrove[2], Thomas Waterfield[1]
[1]Queen's University Belfast, Wwiem, Belfast, United Kingdom, [2]Royal Belfast Children's Hospital, Paediatric Department, Children's Ed, BT BA, United Kingdom

Backgrounds: Oncostatin M (OSM), a cytokine belonging to the interleukin 6 cytokine family, is a potential biomarker of pneumonia in adults. There have been no studies investigating the role of OSM in paediatric pneumonia. The aim of this study was to assess the diagnostic accuracy of OSM in diagnosing bacterial pneumonia in children admitted to the paediatric intensive care unit (PICU).
Methods: Children with clinician diagnosed pneumonia confirmed on chest radiograph were recruited from the Royal Belfast Hospital for Sick Children between April 2020 and December 2022. Detailed clinical data was recorded including the paediatric sequential organ failure assessment (pSOFA), treatments given, levels of care, length of stay and survival. Blood plasma was collected and OSM tested by ELISA. A final diagnosis of bacterial, viral or mixed viral and bacterial pneumonia was provided by an independent paediatric intensivist based on clinical data and results from blood culture, broncheoalveolar lavage and sputum.
Results: A total of 27 children were included in the study. The median age was 1.7 (IQR: 0.5-6.8) years and 48% were male. 22/27 (81%) received invasive ventilation, and 3/27 (11%) died. There were 15/27 (56%) cases of viral pneumonia, 9/27 (33%) cases of bacterial or mixed pneumonia and 3/27 (11%) with an unclear aetiology. OSM demonstrated excellent diagnostic test accuracy for identifying bacterial pneumonia with an area under the curve (AUC) of 0.89(95% CI 0.72-1.1). The optimum cut-off for OSM was 5.3pg/ml with a sensitivity of 0.93 (95%CI 0.68 to 0.99) and specificity of 0.78 (95%CI 0.45 to 0.96).
Conclusions/Learning Points: This small cohort study provides the first evidence that OSM could be used as a blood biomarker of bacterial pneumonia in children.

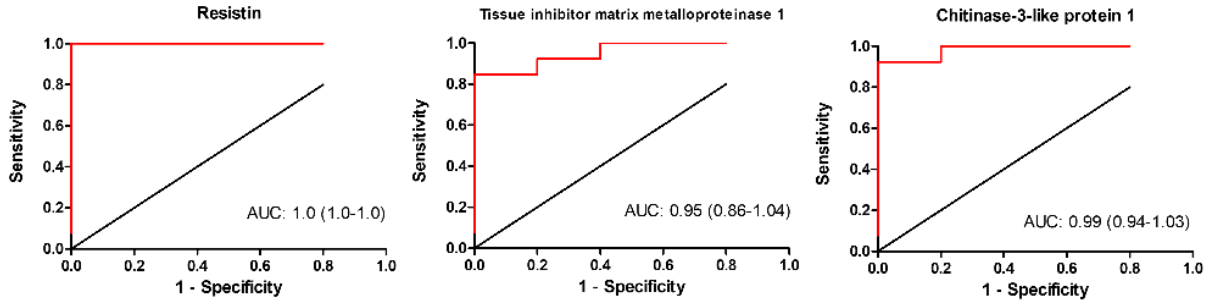
NOVEL HOST BIOMARKERS COULD HELP TAILOR ANTIBIOTIC USE IN CHILDREN ADMITTED TO PICU WITH PNEUMONIA

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Clare Mills[1], Cathal Roarty[1], Oenone Rodgers[1], Hannah Norman-Bruce[2], Peter Cosgrove[2], Thomas Waterfield[1]
[1]Queen's University Belfast, Wwiem, Belfast, United Kingdom, [2]Royal Belfast Children's Hospital, Paediatric Department, Children's Ed, BT BA, United Kingdom

Backgrounds: Much research has been carried out to identify novel host biomarkers that can accurately discriminate between bacterial and viral pneumonia in children. However, pneumonia biomarker discovery has not been carried out in a paediatric intensive care unit (PICU) setting, where children have high rates of co-morbidities and relatively indiscriminate administration of antibiotics. This study aims to identify robust novel biomarkers of bacterial pneumonia in this population.
Methods: Children with clinician-diagnosed pneumonia, confirmed on chest radiograph, were recruited from the PICU at the Royal Belfast Hospital for Sick Children between April 2020 and December 2022. Blood plasma was collected and analysed using two O-Link proteomic multiplex proximity extension assays. An independent paediatric intensivist provided a final diagnosis of bacterial, viral or mixed viral and bacterial pneumonia based on clinical data and results from blood culture, bronchoalveolar lavage and sputum.
Results: A total of 27 children were included in the study. The median age was 1.7 (IQR: 0.5-6.8) years and 48% were male. There were 15/27 (56%) cases of viral pneumonia, 9/27 (33%) cases of bacterial or mixed pneumonia and 3/27 (11%) with an unclear aetiology. Bacterial (n=5) and viral (n=13) samples were analysed by O-Link. 126 proteins were found to be differentially expressed between the two groups. Statistical analysis and correlation with published literature identified three promising biomarkers: Resistin, Tissue inhibitor matrix metalloproteinase 1 and Chitinase-3-like protein 1, AUCs are shown below.



Conclusions/Learning Points: Additional biomarkers could help clinicians tailor antibiotic prescribing for pneumonia in the PICU. Technical verification of biomarkers is ongoing in our remaining samples and larger validation studies will be needed to assess the use of biomarkers in this group of patients.

IMPACT OF PCR-BASED DIAGNOSTIC TESTING IN RESPIRATORY INFECTIONS

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Joana Monteiro[1], Jorge Rodrigues[2], Ana Matos[2], Mariana Vieira Da Silva[2], Joana Pimenta[2], Cristina Faria[2]
[1]Centro Hospitalar Tondela Viseu, Pediatrics, Viseu, Portugal, [2]CH Tondela-Viseu EPE, Pediatric Department, Viseu, Portugal

Backgrounds: Lower respiratory tract infections (LRTI) are a significant cause of morbidity in children. Viruses are one of the most frequent etiologies of community-acquired pneumonia (CAP), especially in younger children. Early and quick identification of viral agents in respiratory samples could result in a decrease in antibiotic use, although several studies show contradictory results. The aim of this study was to analyze the impact of a positive viral detection in children admitted with LRTI.
Methods: Single center, 5-year, retrospective analysis of hospitalized children who underwent respiratory sample collection to perform a multiple-target RT-PCR diagnostic panel.
Results: A total of 166 patients were included, median age of 1.75 years (IQR 0.4-3), with identification of a respiratory virus in 164 (98.8%) cases. Most frequently isolated pathogens were rhinovirus-enterovirus (56%), followed by adenovirus (21%), respiratory syncytial virus (RSV) (20%) and metapneumovirus (10%). A diagnosis of CAP was considered in only 33.1% of patients, with chest radiography performed in 56% (92.7% of CAP) and antibiotic therapy prescribed in 46.4% (100% of CAP). Interestingly, identification of RSV or influenza did not influence decision on antibiotic therapy nor length of stay. Additionally, we found a stronger association between adenovirus and onset of empirical antibiotic therapy (63.1% vs. 36.8%, p-value 0.018) and CAP (32.7% vs. 67.2%, p-value 0.034).
Conclusions/Learning Points: Despite a high yield of viral identification, the use of multiple-target RT-PCR panel in our cohort did not make a significant impact in decision-making regarding antibiotic use or length of stay. However, its use was focused primarily on children with protracted clinical resolution or fever of unknown origin. Further studies must be considered to assess if children with mild illness share the same impact.

MICRORNA PROFILING IN PATIENTS CO-INFECTED WITH CHRONIC HEPATITIS B VIRUS (CHBV) AND HUMAN IMMUNODEFICIENCY VIRUS (HIV) IN A HIGH PREVALENCE SETTING.

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Lulama Mthethwa
University of KwaZulu-Natal, Department Of Virology, mayville, durban, South Africa

Backgrounds: HBV and HIV/HBV co-infection are significant public health issues, despite the availability of an effective HBV vaccine for nearly three decades. HBV and HIV both modulate microRNA (miRNA) expression to support viral replication. It has been estimated that 2.7 million people are co-infected with HBV and HIV worldwide. South Africa is an endemic setting for HBV and HIV infections. The role played by microRNAs in HBV replication and pathogenesis is being increasingly recognized.
Methods: Plasma microRNA, specific to HBV, were measured by reverse-transcription quantitative polymerase chain reaction (qRT-PCR) in HBV and HIV negative healthy controls (n = 23) and in patients coinfected with chronic HBV-HIV (n = 50). MicroRNA expression levels were measured and compared between patients with high vs low HBV viral load. Data were analysed using unpaired Mann-Whitney U test, Spearman's correlation coefficient (r) and the false discovery rate was corrected by using the Benjamini–Hochberg FDR method.
Results: Significantly higher expression levels of hsa-miR-122-5p, hsa-miR-192-5p and hsa-miR-193b-3p were observed in samples with high HBV viral load. A significant moderate positive correlation was observed between HBV viral load and the expression levels of hsa-miR-122-5p, hsa-miR-192-5p and hsa-miR-193-3p.
Conclusions/Learning Points: Our study was able to demonstrate the potential role of hsa-miR-122-5p, hsa-miR-192-5p and has-miR-193b-3p in being prognostic and diagnostic markers in chronic HBV disease progression.

QUALITY IMPROVEMENT OF THE PRE-LABORATORY PHASE OF BLOOD CULTURE PROCESSING IN A TERTIARY HOSPITAL IN ZIMBABWE

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Felicity Fitzgerald[1], Tinashe Mwaturura[2], Katharina Kranzer[3], Gwendoline Chimhini[4], Mutsa Bwakura[4], Svitlana Austin[5], Cecilia Ferreyra[6], Birgitta Gleeson[6]
[1]Imperial College London, Infectious Diseases, London, United Kingdom, [2]Biomedical Research and Training Institute, Clinical Research, Zimbabwe, Zimbabwe, [3]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom, [4]University of Zimbabwe, Paediatrics, Harare, Zimbabwe, [5]Ministry of Health and Child Care, Paediatrics, Zimbabwe, Zimbabwe, [6]FIND Diagnostics, Medical Affairs, Geneva, Switzerland

Backgrounds: Accurate identification of pathogens causing sepsis in low-resource settings is crucial for reducing morbidity and mortality. We conducted a quality improvement programme to improve the pre-analytic phase of blood culture processing at a tertiary hospital in Zimbabwe (Sally Mugabe Central Hospital, SMCH).
Methods: Issues raised at initial stakeholder meetings highlighted lack of stock availability as a barrier to taking blood cultures. With clinicians from Neonatology and Paediatrics departments, we developed Standard Operating Procedures (SOPs) for blood culture collection to reduce contamination and increase blood volumes. We then trained rotating junior doctors bimonthly, collecting contemporaneous feedback, and performed stock checks. Blood culture bottles were weighed pre/post-collection of blood. We introduced a Laboratory Blood Culture Logbook to improve documentation of sample receipt.
Results: The programme ran from 10.3.22-10.10.22. Thirteen, half-hour trainings were conducted with 8-15 junior doctors in each session. Feedback was collected from 37 participants, Trainees reporting themselves 'confident' in collecting blood cultures increased from 18/37(48%) to 34/37(92%) pre/post-training. Consensus was that the training was very useful, particularly the demonstration of aseptic techniques. Most stock was consistently available, excepting butterfly needles. 55% of samples had blood volumes <0.01ml. Contamination rates were high and did not change over time: neonatology 26% (196/761 cultures) overall, and paediatrics: 26% (303/1169 cultures) overall (Table). 1490 samples were recorded in the logbook over 4
months.

Table of Blood Culture Contamination Rate by Month, 2022

	Neonatal Unit		Paediatrics	
	n/N[1]	% Contamination [95% Confidence Interval]	n/N	% Contamination [95% Confidence Interval]
Overall	196/761	25.8 [22.7 - 29.0]	303/1169	25.9 [23.4 - 28.5]
June	40/146	27.4 [20.3 - 35.4]	33/138	23.9 [17.1 - 31.9]
July	46/178	25.8 [19.6 - 32.9]	54/236	22.9 [17.7 - 28.8}
August	46/181	25.4 [19.2 - 32.4]	103/342	30.1 [25.3 - 35.3]
September	49/204	24.0 [18.3 - 30.5]	86/347	24.8 [20.3 - 29.7]
October	15/52	28.8 [17.1 - 43.1]	27/106	25.5 [17.5 - 34.9]

1. Contaminated blood culture/ total cultures taken

Conclusions/Learning Points: Despite the appetite for improvement and training, high contamination rates and low blood volumes persisted. Incorrect beliefs that stock were unavailable might lead to fewer cultures being taken. Improving pre-laboratory blood culture processing is a multifaceted and complex issue requiring contextual intervention and long term monitoring.

Backgrounds: Since rapid and accurate diagnosis of pneumonia and the determination of its severity are challenging, especially in childhood, we aimed to evaluate the role of toll-like receptors (TLRs) in pneumonia, the investigation of which has been limited in animal and adult studies.
Methods: TLR-2, TLR-4, interleukin (IL)-1β, IL-4, IL-6, IL-10, interferon (IFN)-α, and tumor necrosis factor (TNF)-α levels were evaluated in the serum samples of 67 pediatric patients with community-acquired pneumonia (CAP) (43 inpatients and 24 outpatients) and 22 healthy pediatric controls. Saliva samples from 30 pediatric patients with CAP (19 inpatients and 11 outpatients) and 20 healthy pediatric controls were also investigated.
Results: In saliva samples obtained at the time of diagnosis, the threshold levels were 1.16 $2^{-(\Delta\Delta Ct)}$ for TLR-2 and 1.28 $2^{-(\Delta\Delta Ct)}$ for TLR-4 to differentiate patients with and without pneumonia, respectively. The sensitivity of salivary TLR-2 and TLR-4 assessment was 0.80 and 0.86, respectively. In the serum samples, TLR-2, TLR-4, IL-1β, IL-4, IL-6, IL-10, IFN-α, and TNF-α levels were significantly decreased in patients with novel coronavirus disease 2019 (COVID-19) compared with other viruses ($p<0.05$ for all). In the serum samples of patients with pneumonia due to COVID-19, IL-6 and IFN-α levels were significantly lower than in the control group ($p<0.05$ for
all).

THE SUCCESSFUL DESIGN OF A POINT-OF-CARE DIAGNOSTIC TEST FOR RESPIRATORY VIRAL INFECTIONS

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Ivana Pennisi[1], Michael Levin[2], Myrsini Kaforou[3], Pantelis Georgiou[4], Jesus Rodriguez-Manzano[5], On Behalf Of Protondx[1]
[1]Imperial College, London, Infectious Disease, london, United Kingdom, [2]Imperial College London, Department Of Infectious Disease, London, United Kingdom, [3]Imperial College London, Faculty Of Medicine, Department Of Infectious Disease, Section Of Paediatric Infectious Disease, London, United Kingdom, [4]Imperial College, Electric And Electronic Engineering, London, United Kingdom, [5]Imperial College, Infectious Disease, London, United Kingdom

Backgrounds: The most common acute conditions resulting in general practitioner consultations and antibiotic prescriptions are respiratory tract infections, despite the fact that 70% of these infections are viral, and many others are minor self-limiting bacterial infections. Antibiotics should therefore be preserved rather than used indiscriminately in such circumstances. As part of our efforts to accomplish this goal, we have developed a diagnostic platform capable of identifying and distinguishing SARSCoV2, FluA, FluB, RSV, and HRV.
Methods: Using a UKAS accredited independent laboratory, we were able to validate the diagnostic kit's performance by comparing it with an authorized extraction kit (alphaPrepTMViral DNA/RNA Extraction Kit) and RT-qPCR assay (PROmate COVID-19 RT-qPCR assay). A total of 435 archived clinical nose and throat swabs were obtained and subsequently classified as 163 positives and 265 negatives using the comparator RT-qPCR.
Results: The results obtained when compared to the reference standard PROmate® COVID-19 CE-IVD RT-PCR kit, showed 99.35% (95% CI: 96.46% -99.98%) sensitivity for Ct values < 34.71 (< 800 copies/mL) and 97.35% (95% CI: 93.80% -99.32%) sensitivity including Ct values <37.66 (>120 copies/mL). Among the 435 clinical samples tested, 265 were negative by both platforms, and no sample amplified beyond 37.66 Ct limit of the blank cut-off. Accordingly, the calculated specificity for our platform was 100.00% (95% CI: 98.62% -100.00%). Precision of measurement experiments showed a LoD of 500 copies/mL for SARS-CoV-2, 25,000 copies/mL for Flu A/B and RSV, and 822 copies/mL for HRV.
Conclusions/Learning Points: The validation results showed high sensitivity and a low limit of detection (LOD). This allows patients to receive prompt diagnosis and treatment. Speed and ease of diagnosis contrast with the standard PCR approach that is generally processed over the course of a 24-hour period in laboratory settings.

Backgrounds: Fever is one of the most frequent presenting complaints. A European study, DIAMONDS (2020-2025), aimed to characterise febrile children attending Emergency Departments (ED), exploring appropriateness of diagnosis and management.
Methods: Children <18years with fever or suspected infection and diagnostic venepuncture attending EDs of DIAMONDS network (22 hospitals in 11 European countries, plus Gambia, Nepal and Taiwan), between April 2020-December 2022. Demographic, clinical and routine laboratory data were collected and analysed.
Results: 5800 cases included in this interim analysis. Median age: 5.4years (SD:7.5 years). 55.8% males. 36.1% had comorbidities. Main presenting symptoms: fever (71.0%), gastrointestinal (43.0%) and respiratory (26.1%). 31.5% ill appearance at presentation. Abnormal results were found in 10.6% (N=130/578) of rapid pathogen detection tests, 47% (N=1032/2192) of X-rays and 10.6% (N=223/2106) of urine analysis. Main clinical syndromes: 16.5% COVID-related inflammation, 12.9% lower respiratory infections (pneumonia) and 11.9% gastrointestinal infections. 10.5% had bacteremia or septic shock. Pathogens were identified in 3076 (53%) cases, but a definite causative agent could be assigned to only 1439 cases [definite bacteria (N=662), definite viral (777)]. Main causative bacteria were: E.coli (18.9%,N=148), S.aureus (11.6%,N=91) and Coagulase Negative Staphylococcus (8.3%,N=65). Main causative viruses were: SARS-COV-2 (33.3%,N=339), rhinovirus (10.3%,N=105), and enterovirus (8.9%,N=91). 59.9% admitted, 9.8% directly to pediatric intensive care unit(PICU). 0.8% died. 22.5% received antibiotics at discharge from ED, 56.7% on admission to the ward and 91.2% on admission to PICU. Furthermore, 52.2% (N=3025) cases were prescribed antibiotics, although only 35.1% (N=1062/3025) of these had bacterial-related phenotypes.
Conclusions/Learning Points: Despite application of best standard diagnostic investigations, a causative pathogen was identified in half of the patients. Antibiotics remains excessively and inadequately used in children presenting with fever.

CMV-RNA, A NEW MARKER FOR FOLLOW UP CMV INFECTION AFTER HEMATOPOIETIC STEM CELL TRANSPLANTION IN PEDIATRIC PATIENTS

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Cristina Russo[1], Leonarda Gentile[1], Pietro Merli[2], Francesco Quagliarella[2], Franco Locatelli[3], Carlo Federico Perno[1]
[1]Bambino Gesù Children's Hospital, Unit Of Microbiology And Diagnostic Immunology, Rome, Italy, [2]Bambino Gesù Children's Hospital, Hematopoietic Transplantation And Cell Therapies, Rome, Italy, [3]Bambino Gesù Children's Hospital, Experimental And Precision Medicine, Rome, Italy

Backgrounds: Letermovir blocks CMV infection by inhibiting the viral terminase and the virion maturation, without blocking viral-DNA production. Approved in adults, it represents an attractive alternative for CMV-treatment also in children. Effective lab tests for monitoring the drug efficiency are missing, mostly because the CMV-DNA is unable to properly evaluate antiviral efficacy. We present preliminary data on CMV monitoring by a new assay for CMV-RNA detection and quantitation in a cohort of hematopoietic stem cell transplanted children after antiviral treatments.
Methods: Between July-to-November 2022, 53 children were treated with Letermovir after HSCT at the Bambino Gesù Children's Hospital. Thirty-six received primary or secondary prophylaxis, 17 pre-emptive or treatment therapy (median dosage 240 mg/mq, range 120-480). CMV-DNAemia was evaluated twice a week (artus® CMV-TM-PCR_Qiagen_ Hilden, Germany). In 30/53, CMV-RNA was also investigated in plasma samples using CMV-RNA ELITe MGB® (Kit-ELITe_InGenius System: ELITechGroup).
Results: 61 samples, referred to 30 patients (median age 10, IQR 1-21 years), were collected to perform simultaneously CMV-DNAemia and CMV-RNAemia. In 54/61 samples (88.5%) CMV-DNA was persistently present (median 848 copies/mL, IQR 314-3995), while only in 16/61 (26.2%) CMV-RNA was detected (median 23 copies/mL, IQR 6-150). When CMV-DNAemia was quantified <1000 copies/mL (26/54 samples including 11 samples pre-treated with DNAsi), RNA-CMV resulted not detected or below 30 copies/mL. Under pre-emptive therapy/treatment of infection, all patients achieved CMV-DNA negativization in blood within 20 days.
Conclusions/Learning Points: Despite the presence of positive CMV-DNA, the clinical evolution was compatible with the absence of CMV activity thus suggesting that the undetectability of CMV-RNA is driven by the infection evolution and not by the lack in the method sensitivity. The CMV-RNA may represent an accurate marker to monitor clinical antiviral efficacy, more than CMV-DNA.

[1]Tzaneio, General Hospital of Piraeus, Pediatric Department, Piraeus, Greece, [2]Tzaneio, General Hospital of Piraeus, Department Of Microbiology, Piraeus, Greece

Backgrounds: BIOFIRE® FILMARRAY® (FA) Respiratory panel (bioMerieux, USA) allows the rapid simultaneous detection of a wide number of pathogens causing acute respiratory infections in children. The aim of this study was to identify predictive factors for positive FA Respiratory panel results.
Methods: Clinical and laboratory characteristics of children with respiratory infection, for which FA Respiratory panel was performed, were recorded retrospectively and correlated with the result of the method.
Results: FA Respiratory panel was performed in 45 children. Respiratory viruses were detected in 30/45 (66,7%) cases. Shortness of breath (60% in positive results versus 20% in negative, p=0,011), cough (80% versus 33,3% respectively, p=0,002) or rhinitis (90% versus 66,7% respectively, p=0,05) were strongly correlated with positive results in FA Respiratory panel. In addition, clinical symptoms indicative of acute bronchiolitis were suggestive of detection of pathogens in FilmArray (57,1% in positive tests versus 0% in negative, p=0,001). Parameters such as the season (winter versus summer, p=0,399), gender (p=0,826) or presence of fever (p=0,737) were not correlated with the result of the method. Finally, CRP levels and white blood cell count (WBC) were not found to be predictive of the result of FA Respiratory panel.
Conclusions/Learning Points: This study suggests that clinical suspicion of acute bronchiolitis may be predictive of positive results in FA Respiratory panel, which indicates the need for optimizing communication between physicians and medical laboratory scientists. Predictive factors of positive FA results should be identified in order to establish a cost-effective approach in the rapid diagnosis of respiratory infections.

[1]St Jude Children's Research Hospital, Infectious Diseases, Memphis, United States of America, [2]St Jude Children's Research Hospital, Bone Marrow Transplantation, Memphis, United States of America, [3]St Jude Children's Research Hospital, Diagnostic Imaging, Memphis, United States of America

Title of Case: Incidental Detection of Alternaria Sinusitis in a pediatric HCT patient via FDG-PET scan: A Case Report
Background: Pediatric patients who undergo hematopoietic cell transplant (HCT) are at high risk for serious, invasive infection. However, identifying infection in this population remains a diagnostic challenge. Recently, limited data advocates for the utility of fluorodeoxyglucose-positron emission tomography (FDG-PET) scans in detecting infection in febrile immunocompromised patients. This is a case report of a pediatric HCT patient who had incidental detection of invasive fungal sinusitis, later identified as Alternaria, during a 100-day post-transplant disease evaluation FDG-PET scan.
Case Presentation Summary: A four-year-old male with history of relapsed acute myeloid leukemia, presented with new non-neutropenic fever day +92 post haploidentical HCT. Enterococcus faecium bacteremia was identified and treated with 10 days of vancomycin and line removal. Despite appropriate therapy, he remained intermittently febrile with rising c-reactive protein. On day 100 post-transplant he underwent an FDG-PET scan for disease evaluation. A small focus of uptake was noted in the left anterior nasal cavity which prompted ENT evaluation and surgery. Histopathology of biopsy from the left middle turbinate revealed numerous fungal hyphae with tissue invasion and he was started on posaconazole. His fevers resolved and Alternaria species grew on tissue culture.
Learning Points/Discussion: Immunocompromised pediatric patients with prolonged fever will often experience a delay in diagnosis of infection or have prolonged exposure to antimicrobials without an infectious etiology identified. This case report highlights the need to explore the utility of FDG-PET scans over other diagnostic methods in detecting infections in this population.

SERUM YKL-40 AS A POTENTIAL BIOMARKER FOR SEPSIS IN TERM NEONATES – A PILOT STUDY.

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Evangelia Steletou[1], Dimitra Metallinou[2], Theodoros Giannouchos[3], Athanasios Michos[4], Ioannis Papassotiriou[5], Alexandra Margeli[5], Tania Siahanidou[6]
[1]University General Hospital of Patras, Department Of Pediatrics, Rio, Patras, Greece, [2]University of West Attica, Department Of Midwifery, Athens, Greece, [3]University of South Carolina, Department Of Health Services Policy And Management, Arnold School Of Public Health, Columbia, United States of America, [4]NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, Paediatric, ATHENS, Greece, [5]Agia Sofia Children's Hospital, Department Of Clinical Biochemistry, Athens, Greece, [6]National and Kapodistrian University of, Neonatal Unit Of The First Department Of Pediatrics, School Of Medicine, Athens, Greece

Backgrounds: To determine the diagnostic value of serum YKL-40 levels in term neonates with sepsis and to compare YKL-40 with other biomarkers already used in clinical practice.
Methods: 45 term neonates, aged between 4 to 28 days old, were included in this prospective study conducted in a single tertiary hospital. 30 septic neonates comprised the case group and 15 healthy neonates the control group. Sepsis was diagnosed according to the International Pediatric Sepsis Consensus Conference criteria. Blood samples were obtained from the septic neonates at admission (acute phase of sepsis – day 1) and remission of sepsis (day 7-10) while from the healthy neonates only once at admission. Routine laboratory tests included complete blood count, C-reactive protein (CRP) and cultures. Measurements of YKL-40 levels were performed by Elisa.
Results: In septic neonates, 7 blood and 13 urine cultures were positive. Serum YKL-40 levels [median (25th-75th percentile)] were significantly higher at the acute phase of sepsis [35.5 (27.9-54.2) pg/ml] than in remission [24.1 (18-35.5) pg/ml; p=0.004] and in controls [21.5 (18.9-31.2) pg/ml; p=0.003]. Serum YKL-40 levels did not differ significantly between patients in remission and controls (p=0.431). Serum YKL-40 levels at the acute phase of sepsis were also higher in patients with positive cultures [38.6 (31-63.1) pg/ml] compared to those with negative cultures [31.5 (21.3-35.9) pg/ml; p=0.061]. Positive correlations between serum YKL-40 levels and white blood count, absolute neutrophil count and CRP levels at enrollment were also observed. In ROC analysis, YKL-40 levels at admission resulted in significant area under the curve (AUC) to identify patients with sepsis [AUC=0.771 (95%CI 0.632-0.911); p=0.003].
Conclusions/Learning Points: Serum YKL-40 might be considered as a potential biomarker for the diagnosis and monitoring of neonatal sepsis.

Kyriakou Children's Hospital, Athens, Greece, [5]P & A. Kyriakou Children's Hospital, Second Pediatric Department, Athens, Greece

Title of Case: METHICILLIN-SUSCEPTIBLE S. AUREUS -ASSOCIATED SEVERE AND INVASIVE INFECTIONS. A CASE SERIES
Background: Methicillin-susceptible S.aureus(MSSA) is a major cause of severe infections and its morbidity is largely attributed to various toxins including Panton-Valentine leukocidin(PVL).Herein we describe the clinical, microbiological and molecular characteristics of MSSA strains in a case series with severe and complicated infections.
Case Presentation Summary: Clinical characteristics of 3 non-immunocompromised children hospitalized within 2 months due to severe MSSA infections are presented. Species identification and susceptibility testing were performed with Phoenix (BD) automated system.MecA/C and virulence genes including pvl (lukF/S-PV), enterotoxins (sea,seb,sec), exfoliative toxins (eta, etb), hemolysins (hla, hlb) and adhesion factor genes (fnbA, fnbB, clfA) were detected by PCR.The first 3,5 year-old boy was hospitalized with MSSA bacteremia, and extensive hip arthritis and osteomyelitis of the right femur. The second 11 year-old boy was hospitalized with left hip arthritis, femoral pandiaphysitis, MSSA bacteremia, lung septic emboli and femoral vein thrombosis. Both children underwent repeated surgical management and extended due to non-responsive clinical picture treatment. The 3rd boy was a 22-days old neonate with MSSA bacteremia, omphalitis, and skin abscesses.Susceptibility testing revealed PEN and PEN/SXT resistance of strains isolated from the two cases with osteoarticular (OA) infections. All isolates were mecA/C, lukF/S-P,V seb, eta, etb, hlb and fnbA negative and clfA and hla positive. Strains from the 1st and 2nd OA cases carried sec and sea genes respectively, while strain from the 3rd case carried fnbB gene.
Learning Points/Discussion: PVL genes are not the only highly virulent ones. A combination of genes including enterotoxin sea and sec appear to be associated with higher immunological responses leading to host tissue damage and prolonged infections, as in the two complicated OA infections. Literature supports this finding.

PV0831 / #2701

DIAGNOSTIC VALUE OF A MODERN MARKER IN DETECTING EARLY NEONATAL SEPSIS

E-Posters Viewing
E-POSTER VIEWING: AS11. DIAGNOSTICS AND BIOMARKERS

Olena Vlasova[1], Kateryna Vlasova[2], Olena Koloskova[1]
[1]Bukovynian State Medical University of Ukraine,, Department Of Pediatrics And Children's Infectious Diseases, Chernivtsi, Ukraine, [2]Bukovynian State Medical University of Ukraine,, Department Of Medical Biology And Genetics, Chernivtsi, Ukraine

Background: The use of markers in the diagnosis of neonatal sepsis for early verification during the "golden hour", the appointment of timely antibacterial therapy, and subsequently the establishment of the prognosis are extremely important.
Methods: A comprehensive examination of 260 newborns with neonatal sepsis was conducted. The control group consisted of 17 children who were in the ward for follow-up examination without signs of an infectious process.The content of presepsin (Human sCD14, ng/ml) in blood serum was investigated using the reagent: Hycult Biotech NK 320, Netherlands.
Results: The level of presepsin in the blood serum has a positive correlation with the severity of the condition (SNAPII) and, accordingly, the length of the bed-day ($p<0.05$). High concentrations >800 pg/ml indicated a severe course of the disease ($p<0.05$).The study of the risk indicators of immunological markers in the detection of neonatal sepsis showed that the relative risk indicator (RR) for presepsin is 21.8 (95%CI: 12.97-36.6) and the absolute risk is 0.8. Based on the obtained data, a 21-fold increase in the risk of detecting neonatal sepsis has presepsin at a breakpoint of 300 ng/ml.
Conclusions/Learning Points: The research results showed that presepsin is an effective and reliable marker of early neonatal sepsis.

LEAD LEVELS IN DOMESTIC WATER AND BREAST MILK OF LACTATING MOTHERS

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Raafat Abdeldayem
mansoura university, Toxicology, mansoura, Egypt

Backgrounds: Lead acts as anti-essential trace element in the human body. Breast milk is the ideal nutrient for the newborn, lead reach into breast milk through passive transfer.The aim of the present work is to correlate between the lead levels in domestic water and breast milk of lactating mothers.
Methods: this study was performed on fifty-two drinking tap water samples collected from different districts and fifty-two breast milk samples from lactating mothers hosted in different hospitals. Drinking water and breast milk samples were analyzed for lead levels using Zeeman (USA) 4100 ZL atomic absorption spectrophotometer with graphite furnace unit.
Results: Lead level in drinking groundwater showed higher levels than in drinking surface water. In addition, an elevation of lead levels in breast milk of mothers drinking groundwater was noticed when compared with that of mothers drinking surface water. The comparison between mean lead levels in drinking water and mothers' breast milk samples showed positive relationship. Lead concentrations in breast milk of the studied samples were elevated by exposure to smoking.
Conclusions/Learning Points: Lead is excreted in breast milk and may reach high levels in women living in polluted areas, and those exposed to passive smoking compared to non exposed women. This may exceed the daily hazard to suckling infants. Prolonged contact with lead plumbing can increase the lead content in tap water with subsequent increase of lead burden in infant fed formula and infant blood. the chemical analyses must be carried out periodically to ensure the water suitability for domestic purposes. Passive exposure to smoking during lactation should be avoided. Children should be screened at least at their first birthday, unless the community in which these children live does not have a childhood lead poisoning problem.

EXPERIENCES OF COMPLIANCE WITH HAND HYGIENE AMONG PEDIATRIC INTENSIVE CARE NURSES: A QUALITATIVE STUDY

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Anas Alsharawneh[1], Murad Sawalha[2]
[1]The Hashemite University, Nursing, Zarqa, Jordan, [2]THE HASHEMITE UNIVERSITY, Maternal, Child And Family Health Nursing, Zarqa, Jordan

Background: Pediatric intensive care nurses can be exposed to a greater risk of occupational exposure to microorganisms and acquiring infections especially in emergency situations. The primary strategy to prevent and control microorganisims transmission is compliance with Hand Hygiene (HH). However, previous research has indicated that compliance with HH is low among nurses. Most studies regarding infection control practice are quantitative and have identified some barriers to good infection control practice. However, these studies do not explain why and how those factors affect compliance with HH by paediatric nurses'. Neither has the literature provided a clear and fundamental rationale for the lack of compliance with infection control guidelines. The aim of the study was to study the factors that influence pediatric intensive care nurses' experiences of being compliant with HH in order to avoid occupational exposure to pathogens, by employing a qualitative research approach.
Methods: A descriptive qualitative study was conducted in two Jordanian hospitals and used purposive sampling of 12 pediatric intensive care nurses who had at least one year of work experience in pediatric critical care. Data were gathered from face to face semi-structured interviews which were audio-taped. Data were analyzed using thematic analysis.
Results: Barriers and facilitators that influence nurses' compliance with HH were identified by participants. Barriers included; conflict in emergency situations; shortage of staff and equipment; and lack of knowledge. While facilitators included; risk perception; reminder system; and good communication.
Conclusions/Learning Points: Changing current behavior of pediatric intensive care nurses requires knowledge of the factors that may influence their compliance with HH. The findings of this study could inform infection control programs and training that targets pediatric intensive care nurses.

ROLE OF CARBAPENEM-RESISTANT ENTEROBACTERIACEAE COLONIZATION/INFECTION IN CHILDREN ATTENDED IN PEDIATRIC HOME CARE SERVICE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

André Ricardo Araujo Da Silva[1], Izabel Leal[2], Cristina Souza[2], Cristiane Teixeira[3], Mirian Cardoso[2]
[1]Universidade Federal Fluminense, Materno Infantil, Niterói, Brazil, [2]Prontobaby, Infection Control Comittee, Rio de Janeiro, Brazil, [3]Prontobaby Group, Infection Control Committee, Rio de Janeiro, Brazil

Backgrounds: Carbapenem-resistant Enterobacteriaceae (CRE) is one of most important group of concern to development of new antibiotics and treatment, according to the World Health Organization (WHO). Few data are available in children attended in pediatric home care services. Our aim is to measure the importance of CRE in children attended in pediatric home care service.
Methods: We performed a retrospective descriptive study in all patients attended in a pediatric home care service of Rio de Janeiro city, Brazil during four years of follow-up (2019-2022). We analysed all cultures collected, respiratory samples (tracheal aspirate and bronchoalveolar lavage) and urinocultures.
Results: We analyse 188 patients, with 383 positive cultures, being 296/383 (77.3%) Gram-negative bacteria, 79/383 (20.6%) Gram-positive bacteria and 8/383 (0.8%) funghi. CRE were isolated in 6/383(1.6%), Carbapenem-resistant Pseudomonas aeruginosa (CRPa) in 14/383 (3.7%) and Carbapenem-resistant Acinetobacter baumannii in 4/383 (1%). When we analysed urinocultures, 91 samples were positive, being 78/91 (85.7%) Gram-negative bacteria, 4/91 (4.4%) were funghi and 3/91 (3.3%) were Gram-positive bacteria. CRE represented 3/91 (3.3%) of positive urinocultures and CRPa 2/91 (2.2%). We detected 159 positive respiratory samples, being 144/159 (90.6%) due to Gram-negative bacteria, 13/159 (8.2%) Gram-positive bacteria and 2/159 (1.3%) funghi. CRPa were isolated in 12/159 (7.5%), CRAb in 3/159 (1.9%) and CRE in 1/159 (0.6%).
Conclusions/Learning Points: Gram-negative bacteria were the most common group in positive cultures of admitted children in home care services. CRE, CRPa and CRAb were uncommon, even in this population, but an expressive percentual of CRPa were detected in respiratory samples.

CASE REPORT: PINWORM INFECTION AS A CAUSE OF IRON DEFICIENCY

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Ana Bandeira Santos[1], Adriano Pereira[1,2], Paula Fonseca[1]
[1]Centro Hospitalar do Médio Ave, Paediatrics, Vila Nova de Famalicão, Portugal, [2]Centro Hospitalar do Médio Ave, Paediatrics, VNF, Portugal

Title of Case: CASE REPORT: PINWORM INFECTION AS A CAUSE OF IRON DEFICIENCY
Background: Iron deficiency is the most prevalent nutritional disorder globally and the main cause of anemia associated with dietary errors, blood loss or rapid growth, being a common and underdiagnosed condition in adolescence. This deficit impairs neuropsychomotor development, learning ability, appetite, growth and immune response, making it crucial to determine its etiology and appropriate treatment.
Case Presentation Summary: 16-year-old caucasian male referred to the Outpatient Clinic for Adolescents due to iron deficiency anemia. At anamnesis, he presented clinically asymptomatic, without objective blood loss, without relevant personal or family history. He mentioned a nutritionally balanced diet, practice of federated football 2-3 times a week and restful sleep. Physical examination showed good general condition, slightly discolored mucous membranes, no palpable adenopathies, no significant weight loss, height at P50 (WHO growth curves), no other particularities. He started oral iron at a therapeutic dosage and blood analysis follow-up, at 3, 6 and 9 months, showed initial improvement and subsequent worsening of anemia, persistence of iron deficiency, as well as new eosinophilia. Vitamin B12, C and D deficiencies, as well as thyroid and celiac disease screenings were negative. Other laboratory data, such as inflammation markers were normal. A gastrointestinal endoscopic study revealed multiple small live worms, compatible with pinworms. Adequate treatment with Albendazole, continued iron supplementation and implementation of hygienic-dietary measures resulted in resolution of both anemia and iron deficiency.
Learning Points/Discussion: Anemia and iron deficiency are prevalent and serious problems in pediatric age. Intestinal parasites should be included in its possible etiologies list, particularly when the condition is refractory to iron therapy. Awareness of this entity is important because intestinal parasitic infection is common and easily curable with proper treatment.

SEVERE DIABETIC KETOACIDOSIS WITH AN ACUTE MEDIASTINITIS COMPLICATING A FUNGAL BRONCHOPNEUMONIA: A PEDIATRIC CASE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Salma Bellaftouh, Anas Erragh, Amine Afif, Kaoutar Elfakhr, Wissal Aissaoui, Samira Kalouch, Abdelaziz Chlilek
CHU Ibn Rochd, Anesthesiology-intensive Care Medicine Department, Casablanca, Morocco

Title of Case: Severe Diabetic Ketoacidosis with An Acute Mediastinitis Complicating A Fungal Bronchopneumonia: A Pediatric case
Background: Type 1 diabetes mellitus (T1DM) is the most common metabolic disorder occurring in childhood with significant morbimortality. Uncontrolled diabetic patients are exposed to fatal hyperglycemic emergencies such as Diabetic ketoacidosis (DKA) characterized by hyperglycemia, acidosis, and ketosis. Although infections remain the predominant precipitating factors for (DKA), its association with mediastinitis is, to date, a rare situation. The objective of this study was to bring the importance of diagnosing the underlying etiological precipitants during DKA to enhance the management of this complication and reduce its mortality.
Case Presentation Summary: The authors report during this article the case of a 7-year-old male patient, known type 1 diabetic on insulin therapy for 3 years, admitted to the pediatric intensive care unit in A.H hospital in Casablanca for severe diabetic ketoacidosis with febrile reparatory distress and in whom the non-improvement of the symptomatology leads us to diagnose an acute mediastinitis complicating its fungal bronchopneumonia.
Learning Points/Discussion: This report will review the precipitant factors, relayed by literature, associated with acute metabolic decompensation of diabetes in pediatric patients and the incidence of fungal lung infection in the diabetic population. The authors also highlight the lack of scientific data concerning the mediastinitis complicating pulmonary infections, especially in the pediatric population. To conclude Acute mediastinitis is a serious medical condition, commonly misdiagnosed due to the polymorphic and unspecific clinical presentation that can be related to the bronchopneumonia itself. This fatal complication being an etiological factor of a DKA considerably increases its mortality as reported in our case.

PV0837 / #1262

RHEUMATIC FEVER IN EUROPE NOT GONE NOR FORGOTTEN: TWO CASES OF SYDENHAM'S CHOREA

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Catarina Belo[1], Margarida Vicente Ferreira[1], Sofia Granja[2], Raquel Sousa[3], Ana Maia[1]
[1]Centro Hospitalar Universitário de São João, Serviço De Pediatria Da Uag Da Mulher E Criança, Porto, Portugal, [2]Centro Hospitalar Universitário de São João, Serviço De Cardiologia Pediátrica, Porto, Portugal, [3]Centro Hospitalar Universitário de São João, Unidade De Neuropediatria, Porto, Portugal

Title of Case: Sydenham's chorea
Background: Group A β-haemolytic Streptococcus (GABHS) is one of the most frequent infectious agents in children. Although pharyngitis is the most common presentation, unusual manifestations such as acute rheumatic fever (ARF) may exist. Sydenham's chorea is the most common form of acquired chorea in children and one of the major criteria of ARF; 20 to 35% of patients may present with hemichorea. In these two cases, hemichorea was the main clinical manifestation.
Case Presentation Summary: Case 1: A six-year-old portuguese boy was brought for consultation due to a three-week history of migratory arthralgia, asthenia, and involuntary movements of the right limbs associated with fever and odynophagia. He presented with a systolic heart murmur and chorea of the right limbs. Laboratory tests showed elevated antistreptolysin O titres (ASLO) - 1824 U/mL. Echocardiogram revealed moderate mitral insufficiency and mild aortic insufficiency. Case 2: A seven-year-old boy was brought to the emergency department due to trunk ataxia, involuntary movements of the right arm and leg and emotional lability in the previous week. He came from Switzerland where he was treated for an ulnar osteomyelitis. He presented involuntary movements of the right upper and lower limbs and right-sided muscle weakness. Laboratory tests revealed elevated ASLO - 399 U/mL. Echocardiogram showed mild aortic insufficiency and moderate mitral insufficiency. Both cases were treated with haloperidol for two months and maintained furosemide, captopril and benzathine penicillin. On long term follow-up, both showed resolution of chorea and improvement of cardiac changes.
Learning Points/Discussion: These cases highlight the necessity of a GABHS vaccine in the infant population in order to avoid long term neurologic and cardiac complications. Despite the low incidence of ARF in developed countries, the disease and its manifestations cannot be neglected.

[1]Sanofi, Health Economics And Value Assessment, Lyon, France, [2]Vaccines & Immune Therapies, AstraZeneca, Health Economics And Value Assessment, Gothenburg, Sweden, [3]Sanofi, Health Economics And Value Assessment, Toronto, Canada, [4]Sanofi, Health Economics And Value Assessment, Reading, United Kingdom

Backgrounds: Respiratory syncytial virus (RSV) is a leading cause of hospitalization in infants. Several preventative interventions will soon be available and the assessment of their impacts on healthcare resource utilization is critical to inform future recommendations. The objective of this modeling study was to estimate the impact of nirsevimab and maternal vaccine on RSV medically attended lower respiratory tract infections (RSV MA-LRTI) in a UK birth cohort compared to the current standard of practice (SoP).
Methods: We used a static decision analytic model to estimate health outcomes related to RSV under SoP and with prophylaxes. Assumptions for interventions were documented based on clinical results for nirsevimab, and top-line data of Ph3 global trial for maternal vaccine. Implementation was defined year-round for maternal immunization, and seasonal for nirsevimab, considering equal coverage rate.
Results: We estimated 249,927 MA LRTIs under SoP over the first RSV season of infants, including 24,381 hospitalizations. RSV MA-LRTIs was predominantly observed among infants born before the season (67%), whereas hospitalizations were equally distributed between infants born before and during the season. Nirsevimab prevented consistently 64% of RSV MA-LRTIS across the birth cohort. Maternal vaccine prevented overall 29% of events, with 20% avoided in infants born before the season, and 48% in infants born during the RSV season.
Conclusions/Learning Points: Our model estimates that nirsevimab is most effective at reducing the number of MA-RSV LRTI. With timely immunization and durable protection over time, the RSV disease burden can be addressed in the full birth cohort.

ROTAVIRUS GASTROENTERITIS PREVENTION INTO THE ITALIAN NATIONAL IMMUNIZATION PLAN (NIP): COMPARISON BETWEEN OFFICIAL RECOMMENDATION AND IMMUNIZATION COVERAGE TRENDS IN EUROPE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Paolo Bonanni, Angela Bechini, Sara Boccalini
University of Florence, Department Of Health Sciences, Florence, Italy

Backgrounds: Rotavirus (RV) is the leading cause of severe gastroenteritis in children, and it is responsible for approximately 30% of diarrhea deaths among children aged <5 years. Two effective oral live attenuated vaccines (2-dose monovalent and 3-dose pentavalent vaccines) are available since 2006 to prevent RV disease. The aim of this study is to describe the Italian recommendations for RV prevention, to provide an overview of the current European RV vaccine offer and to compare vaccination coverage (VC) rates in Europe.
Methods: The Italian National Immunization Plan and the “ECDC-vaccine scheduler” were consulted to retrieve information on the European schedules; Rotavirus VC data were collected through the WHO/UNICEF and the Italian Ministry of Health websites (years 2008-2021).
Results: Since 2017, RV vaccination is recommended in Italy for all infants starting from the 6th week of life and vaccination cycle should be completed no later than 8 months of age. It can be co-administered with the other vaccinations of the first year of life. RV vaccination is not universally recommended in Europe, some countries offered it only to specific risk groups (pre-term and low weight at birth infants). VC vary between EU countries, ranging from 20% in Greece to 96% in Norway in 2021. There has been an increase in the annual VC in Europe from 12% in 2014 to 34% in 2021. Italian VC reached its peak (63%) in 2021, while it settled to 70.4%, according to Italian national data.
Conclusions/Learning Points: Italy has recently started a national universal program against RV and VC exceeds, almost two folds, the annual average VC data at European level. Efforts should be done to increase VC and to extend RV vaccination in Europe.

MANAGEMENT OF FEVER IN SICKLE CELL DISEASE IN THE PEDIATRIC EMERGENCY WARDS (PEW) ACCORDING TO FRENCH GUIDELINES

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Isaline Boudaud[1], Jean-François Brasme[2], Oussama Gasmi[3], Christèle Gras-Le Guen[3], Elise Launay[3]
[1]Lyon University Hospital (CHU), Pediatrics Emergency And Infectiology, Bron, France, [2]Angers University Hospital (CHU), Hemato-pediatric, Angers, France, [3]Nantes University Hospital (CHU), Pid, Nantes, France

Background: Main complication of Sickle cell disease (SCD) is infection susceptibility related to functional asplenia. The French guidelines recommends encapsulated-germs-optimized vaccination, early V-penicillin-prophylaxis, and criteria for outpatient/hospitalization management of fever. The aim of this restrospective study was to describe the population of children visiting the pediatric emergency wards (PEW) with fever, and to describe compliance of hospitalization and broad-spectrum IV-antibiotic prescription according to the French guidelines.
Methods: Historical cohort study of children with SCD visiting the PEW (hospital of Angers-France), for fever (January 2015-June 2022).
Results: Out of 128 febrile episodes seen in PEW visits, 33 visits (26%) lead to ambulatory management; 1 toddler was further hospitalized with pneumonia (guideline deviation for inadequate age range), and 94 (74%) lead to hospitalization. In the latter, 24 severe bacterial infections (SBI, 26%) were found: 17 pneumonia/acute thoracic syndrome, 6 pyelonephritis, and 1 soft tissue infection. Median age of the hospitalized children (n=94) was 5,4 years, sex ratio was 1.41, and the French guideline compliance for preventive measures was 75% for vaccines and was 95% for antibioprophylaxis. Four children required PICU-ventilatory support. Neither clinical factors nor guideline criteria were significantly associated to SBI. Only CRP was significantly higher in children with SBI.
Conclusions/Learning Points: The French guidelines allow to safely ambulatory manage children when criteria are followed. The prevalence of SBI was 26% despite prophylactic measures. Early detection of SBI stay a high priority. Reliable criteria to rule-out children seem a priority to safely avoid hospitalization and systematic IV-antibiotherapy. They still need to be strengthen to manage febrile children with SCD, and we will carry out further research to development and validation of a decision tree to guide physicians in the clinical management.

BOTULISM – CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Carolina Castro, Joana Machado Morais, Ana Luísa Correia, Rui Almeida, Sérgia Soares
Hospital Pedro Hispano, Paediatrics, Matosinhos, Portugal

Title of Case: BOTULISM – CASE REPORT
Background: Botulism is a rare and life-threatening syndrome of diffuse, flaccid paralysis caused by a neurotoxin produced by Clostridium botulinum. It results from an irreversible blockage of pre-synaptic cholinergic receptors at the neuromuscular junction. It presents by early involvement of the cranial nerves with progressive muscle weakness, descending and symmetrical.
Case Presentation Summary: A 3 years-old boy with developmental delay was admitted to the Emergency Department with prostration, eating difficulties with dysphagia for liquids and solids, and bilateral eyelid ptosis lasting 24 hours. Parents reported vomiting and diarrhea the day before the admission and soil consumption one week before the onset of symptoms. History of fever, honey, or unpasteurized dairy product consumption was denied. At presentation, physical examination revealed prostration, bilateral eyelid ptosis, and sialorrhea. No limitations in eye movements or facial asymmetries were observed, osteotendinous reflexes were present and symmetrical, and the child was hemodynamically stable. There was no clinical worsening, including respiratory compromise or proximal muscle weakness. On day two, as deficits persisted without an established cause (normal brain imaging and negative anti-acetylcholine receptor antibody), botulism was considered, and heptavalent botulinum antitoxin was administered. There was gradual improvement in eating difficulties and ptosis. Although the search for botulinum toxin in serum, gastric aspirate, and feces was negative, a clinical diagnosis of botulism was assumed since there was an improvement in neurological deficits after specific therapy. The recovery was complete.
Learning Points/Discussion: A careful history and physical examination are essential for the diagnosis of botulism, which can be made based on clinical and epidemiological findings. Early administration of botulinum antitoxin neutralizes free neurotoxin and should not be delayed until diagnostic confirmation. This approach may reduce the severity, duration, and mortality of this disease.

MANAGEMENT AND OUTCOME OF CARBAPENEM-RESISTANT BACTERIAL (CRB) INFECTIONS IN A TERTIARY PEDIATRIC SURGERY UNIT

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Charis Lampada[1], Konstantina Charisi[1], Chrysovalantis Mariorakis[2], Eleftheria Georgiou[2], Christos Stefanidis[2], Charalambos Antachopoulos[1]
[1]Hippokration General Hospital of Thessaloniki, 3rd Dept Of Pediatrics, Thessaloniki, Greece, [2]Hippokration General Hospital of Thessaloniki, Pediatric Surgery Unit, Thessaloniki, Greece

Backgrounds: Carbapenem resistance rates in pediatric patients are increasing. Their management is challenging and may include the use of newer antibiotics such as ceftazidime-avibactam (CAZ-AVI) or older ones, such as the aminoglycosides, colistin and fosfomycin, alone or in combination. We herein describe our clinical experience with CRB infections in pediatric surgical patients.
Methods: Review of medical records of consecutive patients with confirmed CRB infections hospitalized in a tertiary pediatric surgery unit from 1/1/2022 till 12/31/2022. Carbapenem susceptibility was assessed with Vitek®2 system using EUCAST breakpoints.
Results: Five patients with CRB infections were included [median age 11 months (5-18 months), 4 males]: 2 with bacteremia and 3 with urinary tract infection (UTI). Three of these patients had short gut syndrome and central venous catheter. All isolated microorganisms were Klebsiella pneumoniae. 3 of these patients had received meropenem (2) or cefepime (1) as initial empirical treatment with no response. Based on susceptibility results, the 2 patients with bacteremia received CAZ-AVI plus colistin and those with UTI received: CAZ-AVI plus fosfomycin, gentamicin plus fosfomycin, or gentamicin plus ciprofloxacin, respectively. Antimicrobial dosages were CAZ-AVI, 150 mg/kg/d of ceftazidime divided 8-hourly; colistimethate sodium, 300,000 IU/kg/day (equivalent to 9.9 mg colistin base activity/kg/d) divided 8-hourly; fosfomycin, 400 mg/kg/day divided 6-hourly; gentamicin, 6 mg/kg/d q24hr; ciprofloxacin, 30 mg/kg/d divided 8-hourly. The duration of treatment was 14 days for bacteremia and 10 days for UTI. All patients had a favorable outcome with no relapse and no adverse events.
Conclusions/Learning Points: Successful treatment of CRB infections in pediatric surgical patients was accomplished using a combination of two in vitro active agents in high doses.

HOSPITAL-ACQUIRED MEASLES: A SYSTEMATIC REVIEW USING THE OUTBREAK REPORTS AND INTERVENTION STUDIES OF NOSOCOMIAL INFECTION (ORION) STATEMENT

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Young June Choe[1], Jiseon Park[1], Erdenetuya Bolormaa[2]
[1]Korea University Anam Hospital, Department Of Pediatrics, Seoul, Korea, Republic of, [2]Korea University College of Medicine, Department Of Preventive Medicine, Seoul, Korea, Republic of

Backgrounds: Several outbreaks of nosocomial measles with rapid dissemination and increased severity in developed countries have been reported; therefore, there is a need for a comprehensive review of hospital-acquired measles.
Methods: The Outbreak Reports and Intervention Studies of Nosocomial Infection (ORION) statement provides standardized methodology for transparent reporting of nosocomial outbreaks. This statement aids in the comparison of nosocomial investigations and assimilation of evidence as well as provides consensus guidelines, which can increase our understanding of the outbreak and limit the consequences of hospital-acquired infections in terms of morbidity, mortality, and cost. Publications related to measles infection in hospital settings were selected. We then evaluated the quality of outbreak reports of nosocomial measles infection worldwide using the ORION statement findings and recommendations.
Results: We reviewed 24 studies in accordance to the ORION statement. Measles transmission in healthcare settings is a significant burden on the morbidity, mortality, and economy of measles. The healthcare workers' booster vaccination guidelines should be monitored and enhanced during the post-elimination period of measles. The outcomes of infections must be explicit for outbreak reports.
Conclusions/Learning Points: Our findings highlight that the ORION statement can improve the quality of reporting and provide strong evidence for infection control policies in hospitals.

PERITONSILLAR ABSCESS IN COVID-19 PEDIATRIC PATIENTS-PRESENTATION OF TWO INTERESTING CASES

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Konstantina Chrysouli
PENTELI CHILDREN HOSPITAL, Ent, ATHENS, Greece

Title of Case: PERITONSILLAR ABSCESS IN Covid-19 PEDIATRIC PATIENTS-PRESENTATION OF TWO INTERESTING CASES
Background: The SARS-CoV-2 usually causes symptoms related to the lower respiratory system (fever, cough, pneumonia, ARDS), however it can also affect the upper respiratory system (anosmia, nasal congestion, runny nose). In the year 2021 at the ENT clinic of General Children's Hospital Penteli two active Covid-19 children presented with ENT symptomology.
Case Presentation Summary: A 15-year-old female patient (suffering from Covid-19 for a week) presented to our Hospital due to sore throat, dysphagia and fever since two days. During the clinical examination, peritonsillar cellulitis was found (with a negative fine needle aspiration) and the patient was placed on intravenous antibiotic treatment. On the 2nd day of her hospitalization, persistent tachypnea was observed and the patient complained of chest pain. Laboratory testing revealed elevated serum troponin, and after pediatric and cardiology evaluation, a diagnosis of Covid-19 myocarditis was made. A second case of a 16-year-old female patient presented to the ENT Clinic due to sore throat, mandibular trismus and fever since 24 hours. During the clinical examination, a peritonsillar abscess was found (2nd episode). A surgical drainage of the abscess was performed. During the standard molecular testing for Covid-19, a positive PCR test was found. The patient was hospitalized for intravenous antibiotic treatment and 45 days after her discharge, she underwent a tonsillectomy.
Learning Points/Discussion: Our cases dictate the need for vigilance by the medical community for SARS-CoV-2 -related ENT manifestations, including peritonsillar cellulitis and abscess. Considering that new data are constantly appearing in the pathological spectrum of the disease, more studies are undoubtedly needed to draw safe conclusions.

CANDIDURIA IN A 5-MONTH-OLD INFANT

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Anthi Damianaki[1,2]
[1]National and Kapodistrian University, “P & A Kyriakou” Athens Children’s Hospital, Second Department Of Pediatrics, ATHENS, Greece, [2]National and Kapodistrian University, “P & A Kyriakou” Athens Children’s Hospital, Second Department Of Pediatrics, Athens, Greece

Backgrounds: Upper urinary tract fungal infections are uncommon and are predominantly diagnosed in neonates,infants with severe underlying conditions and in immunosuppressed individuals.Fungal bezoar (ball) formation is rare and management options include intravenous antifungal agents and percutaneous nephrostomy with antifungal instillation of antifungal agents.
Methods: A 3-month-old boy,antenatally diagnosed with left hydronephrosis and hydroureter,was initially admitted to a local Hospital due to pyelonephritis.No culture was available.He was treated with intravenous ceftazidime, ceftazoline and amikacine for 3 weeks.Ultrasound (US) and voiding cystourethrogram (VCUG) demonstrated hydronephrosis grade II with megaureter due to ureterovesical junction obstruction and reflux grade I.A urine catheter was implemented monitoring urine function.He was discharged with cotrimoxazole prophylaxis.On a 2-week follow up,he received asymptomatic oral 3rd generation cephalosporin for 10 days due to pyuria.1 week after antibiotic cessation,he was admitted to our Hospital due to fever.
Results: Urine analysis showed basically yeasts besides leukocytes.Culture showed Candida albicans sensitive to fluconazole.Blood cultures were negative.US demonstrated several mobile echogenic masses suggesting fungal balls without parenchymatic involvement.Inflammation markers and renal parameters were normal.He started on antifungal therapy for 4 weeks.Follow-up US showed complete eradication of fungal balls.He was discharged with cotrimoxazole and fluconazole prophylaxis and he was referred to the Urologic Department for further evaluation of his obstructive uropathy and for surgical circumcision.
Conclusions/Learning Points: We believe that the main high risk factors for the renal fungal bezoar formation in our patient were the bladder catheterization and the prolonged broad-spectrum antibiotic use.The aim of this case is to underline the necessity of prudent antimicrobial use in patients with urinary tract abnormalities, mostly obstructive uropathies, and the cautious use of urinary tract drainage devices in order to reduce the possibility of opportunistic infection by fungus.

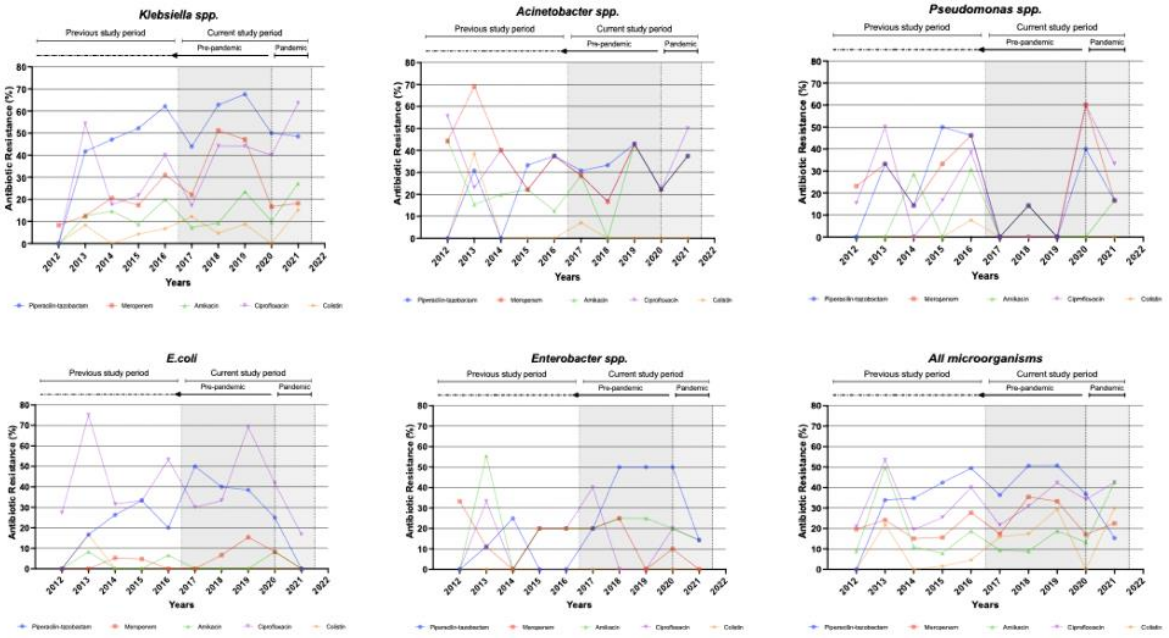
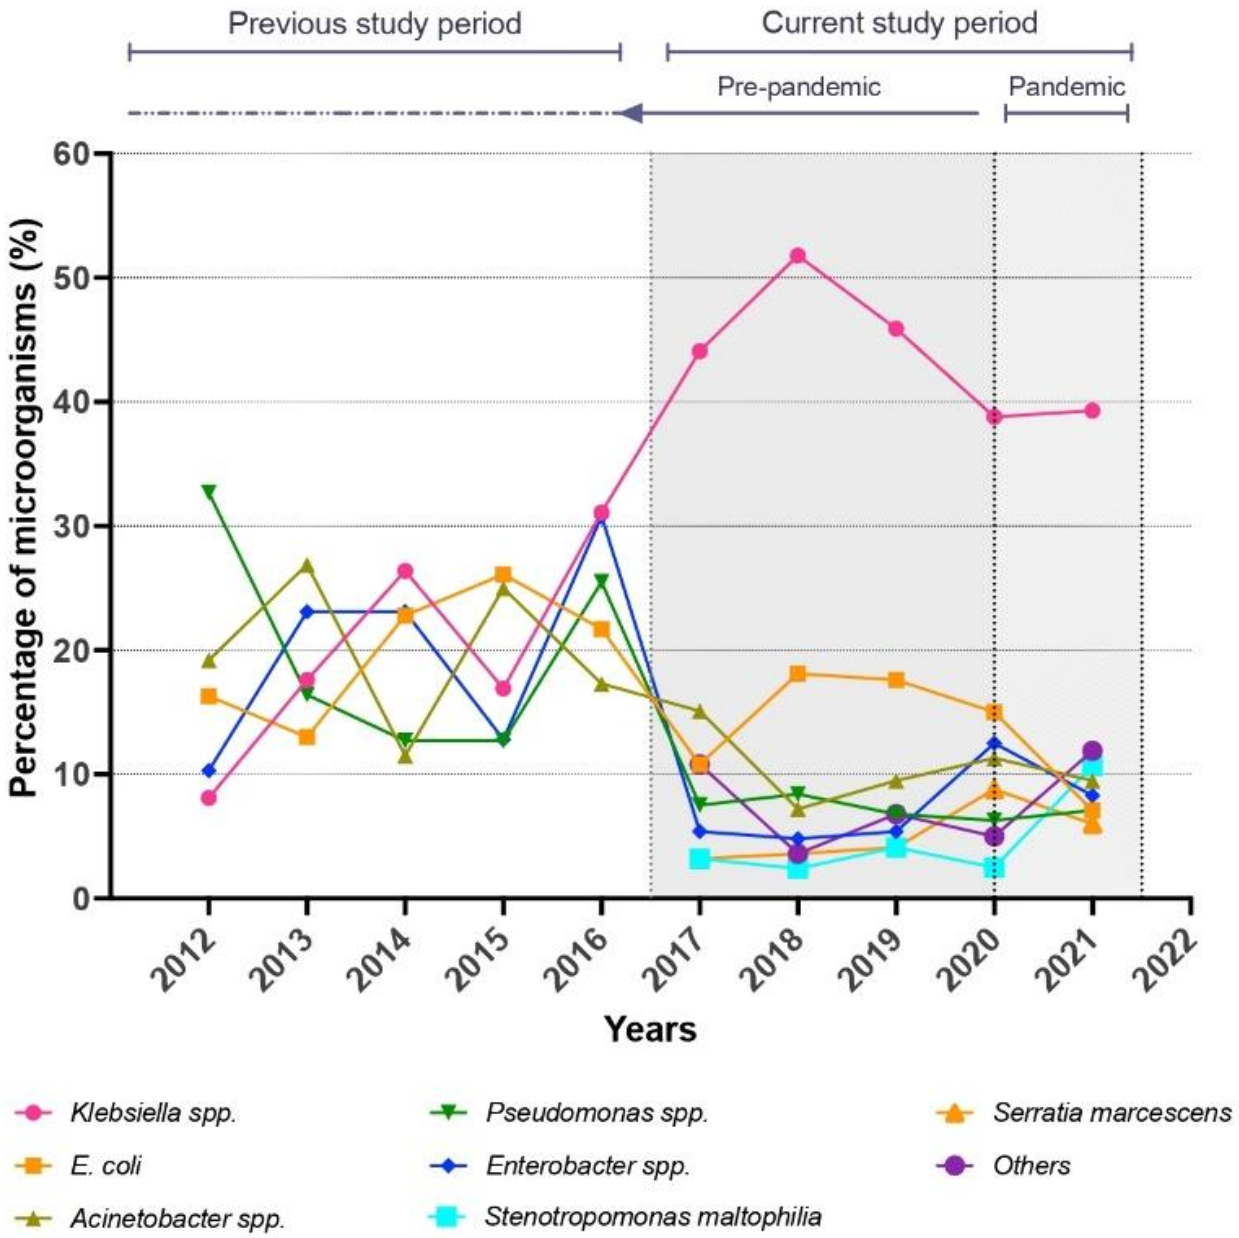
[1]Hacettepe University Faculty of Medicine, Paediatrics, Ankara, Turkey, [2]Hacettepe University Faculty of Medicine, Pediatric Infectious Diseases, ankara, Turkey, [3]Hacettepe University Faculty of Medicine, Biostatistics, ankara, Turkey, [4]Hacettepe University Faculty of Medicine, Medical Microbiology, ankara, Turkey

Backgrounds: Bloodstream infections caused by gram-negative bacteria emerge as an important cause of mortality and morbidity in pediatric clinics. In this study, we aimed that to determine the isolated gram-negative bacteria from blood cultures, their resistance patterns and the epidemiologic changes over the years, clinical status of the patients according to bacteria, the risk factors and outcome.
Methods: In the study, 412 episodes of 349 children aged 0-18 years and were hospitalized in a Turkish tertiary care university hospital with the diagnosis of Gram-negative bacteriemia between 2017 and 2021 were retrospectively analyzed. In addition, the data were compared with our previous findings.
Results:





The most common microorganisms were Klebsiella spp. (43.9%), followed by E. coli (13.5%) and Acinetobacter spp. (10.6%). Klebsiella spp were persistent and predominant causative agents over the years. Carbapenem resistance (CRGN) was revealed in 27.6% of all Gram-negative bacteria and 41.2% of the bacteria were multi drug resistance (MDR), 13.5% were extensively drug resistance (XDR) and 0.4% were pan-drug resistance (PDR). In addition, it was determined that carbapanem and colistin resistance increased over the years. The most common risk factors were the presence of a central venous catheter (77%), hospitalization in the intensive care unit (67%) and the use of broad-spectrum antibiotics within the last month (45.6%). Clinical response and infection-related mortality were 74% and 15.7%, respectively in cases infected with CRGN.

Conclusions/Learning Points: The increase in multi-resistant Klebsiella spp. seems to be one of the biggest obstacles ahead in our fight against nosocomial infections. Increasing CRGN bacteria over the years affects both the clinical response of bloodstream infections and mortality. Close follow-up of these local data is very important both in the determination of resistance patterns and the ideal empiric antimicrobial treatments.

INFECTIONS ASSOCIATED WITH KAWASAKI DISEASE IN QATAR

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Sohair Elsiddig[1], Ahmed Khalil[2], Maisaa Elzain[1], Manasik Hassan[3], Blgeis Elgadra[3]
[1]Hamad medical corporations, Pediatric Department, Doha, Qatar, [2]hamad medical corp, Pharmacy, Doha, Qatar, [3]Hamad Medical Corporation, Pediatric, Doha, Qatar

Backgrounds: Infectious agents have been considered a predisposing factor for KD. Although both viral and bacterial agents may be related to the onset of KD, the actual mechanism remains unknown. It has been hypothesized to be secondary to the activation of cytokine production. Aim To identify the common infection associated with KD in Qatar's children under five.
Methods: In a cross-sectional retrospective study done in Qatar from 2009 -2019, two hundred children confirmed to have KD were included, their records reviewed, and children were included based on confirmed infection Positive culture (blood, urine or throat culture) Pneumonia proved by clinical or radiological Positive blood virology or respiratory panel PCR Lymphadenitis proven by clinical or radiological
Results: Among the 200 cases of KD, 32% were proven to have associated infections. Among all diagnosed patients, 22.5% had a viral infection, and 14 % had a bacterial infection. EBV virus was found in 24.4%, followed by 13% of Adino virus. Influenza, rhino, and CMV were equal to around 11.1 %. RSV was found in 6% of patients; Other viruses' percentage was less than 5%. Step pyogen throat infection was the most common bacterial infection among all KD patients. Followed by Ecoli UTI at 25%.
Conclusions/Learning Points: Conclusion : Infection was associated with one-third of all children with KD in Qatar, EBV was the most common virus, and strep pyogen was the most common bacterial infection. Infection was not affecting the prognosis or the outcome of the disease.

DRUG RESISTANCE AMONG WOMEN ATTENDING ANTENATAL CLINICS IN THE ERA OF COVID-19 IN THE NORTHERN PART OF GHANA

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Philip Enyan
University of Ghana, School Of Public Health And Administration, Accra, Ghana

Backgrounds: Background:
Initial evidence from resource-limited countries using the WHO HIV drug resistance (HIVDR) threshold survey suggests that transmission of drug-resistance strains is likely to be limited. However, as access to ART is expanded, increased emergence of HIVDR is feared as a potential consequence. We have performed a surveillance survey of transmitted HIVDR among recently infected persons in the geographic setting of Northern Ghana.
Methods:
As part of a cross-sectional survey, 2 large voluntary counseling and testing centers in Temale enrolled 50 newly HIV-diagnosed, antiretroviral drug-naive adults aged 18 to 25 years. Virus from plasma samples with >1,000 HIV RNA copies/mL (Roche Amplicor v1.5) were sequenced in the pol gene. Transmitted drug resistance-associated mutations (TDRM) were identified according to the WHO 2009 Surveillance DRM list, using Stanford CPR tool (v 5.0 beta). Phylogenetic relationships of the newly characterized viruses were estimated by comparison with HIV-1 reference sequences from the Los Alamos database,
Results::
Subtypes were predominantly D (39/70, 55.7%), A (29/70, 41.4%), and C (2/70; 2, 9%). Seven nucleotide sequences harbored a major TDRM (3 NNRTI, 3 NRTI, and 1 PI- associated mutation); HIVDR point prevalence was 10.0% (95%CI 4.1% to 19.5%). The identified TDRM were D67G (1.3%), L210W (2.6%); G190A (1.3%); G190S (1.3%); K101E (1.3%), and N88D (1.3%) for PI.

Conclusions/Learning Points: Conclusion; In Northern Ghana, we found a rate of transmitted HIVDR, according to the WHO threshold survey method, falls into the moderate (5 to 15%) category. This is a considerable increase compared to the rate of <5% estimated in the 2006-7 survey among women attending an antenatal clinic. As ART programs expand throughout Africa, incident infections should be monitored for the presence of transmitted drug resistance.

PV0849 / #1576

IMMUNIZATION STATUS AND CLINICAL OUTCOME OF PATIENTS ADMITTED WITH PEDIATRIC COMMUNITY ACQUIRED PNEUMONIA, COVID-19 SUSPECT AT OSPITAL NG MAYNILA MEDICAL CENTER FROM MARCH 2020 TO SEPTEMBER 2021

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Isabel Rafaela Espinosa, Jennie Wong
Ospital Ng Maynila Medical Center, Pediatrics, Manila, Philippines

Backgrounds: Pneumonia remains to be one of the main leading causes of morbidity and mortality among children worldwide, accounting for 17% of deaths in children under the age of five. In the Philippines, 11% of deaths were caused by pneumonia making this disease the major cause of mortality in this age group. Routine immunization against vaccine-preventable childhood illnesses has been recognized as one of the most effective public health approaches to prevent pneumonia. However due to COVID-19 pandemic, vaccination services were interrupted because of limited access to transportation and fear of parents in bringing children to health facilities for fear of exposing themselves to the COVID-19 virus. GENERAL OBJECTIVE: To determine the immunization status and clinical outcome of patients admitted with Pediatric Community Acquired Pneumonia (PCAP), COVID-19 Suspect
Methods: SETTING: Tertiary government hospital STUDY DESIGN: Retrospective cross-sectional study MATERIALS AND METHODS: Charts of pediatric patients aged 2 months to 18 years old admitted with PCAP C or D, COVID 19 suspect from March 2020 to September 2021 were retrieved. Data gathered included: Age, Sex, Place of residence, Immunization status, Disease severity, COVID status, Length of hospital stay and Disposition. SPSS version 10 was utilized for data analysis.
Results: The prevalence of patients with PCAP-D was significantly higher among those with incomplete immunization status versus those with complete immunization status based on Expanded Program on Immunization (EPI), with 34% and 15.9% respectively. Higher mortality rate was noted among those with incomplete EPI status (17%) than those with complete EPI status (3.2%).
Conclusions/Learning Points: Complete Expanded Program on Immunization (EPI) status play a significant role in improving clinical outcomes for pediatric patients admitted with PCAP. No significant association was noted between immunization status and COVID-19 infection.

PV0850 / #1452

COVID-19 VACCINATION HESITANCY AMONG PARENTS OF CHILDREN AGED 5 TO 11 YEARS OLD AT A TERTIARY HOSPITAL IN MANILA, PHILIPPINES

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Isabel Rafaela Espinosa, Jennie Wong
Ospital Ng Maynila Medical Center, Pediatrics, Manila, Philippines

Backgrounds: While the COVID-19 vaccine roll-out is still ongoing, parental vaccine hesitancy, defined as “delay in acceptance or refusal of vaccination despite the availability of vaccination services,” serves as a significant barrier to its success, making it a major predicament for achieving herd immunity. Studies regarding COVID vaccine hesitancy among parents in the Philippines is limited hence we embark on this study, aiming to determine reasons behind parental COVID vaccination hesitancy.
Methods: SETTING: Tertiary government hospital
STUDY DESIGN: Prospective cross-sectional study
MATERIALS AND METHODS: Parents of patients 5 to 11 years old at Ospital ng Maynila Medical Center were asked to answer an adopted structured questionnaire. Pilot testing was also done to ensure validity. SPSS version 23 for Windows was used for data analysis.
Results: Parents who have not vaccinated their children due to vaccine hesitancy were noted at 59.7%, majority of which was attributed due to fear of side effects of the vaccine. Results revealed vaccine hesitancy was significantly higher proportion in females, parents with children <8 years old, who had preexisting comorbidities and with incomplete Expanded Program for Immunization (EPI) status. Lastly, parents with no or incomplete COVID-19 vaccination were also vaccine
hesitant.

Association Between Sociodemographic Profiles & COVID Vaccine Hesitancy of Parents of Children Aged 5-11 Years Old in Ospital ng Maynila Medical Center (n=164)

	n	Vaccine Hesitancy		*p-value**
		Yes (n=103)	**No** (n=61)	
Sex				
Male	15	6 (40.0%)	9 (60.0%)	0.05 (S)†
Female	149	97 (65.1%)	52 (34.9%)	
Age of Child				
5	33	25 (75.8%)	8 (24.2%)	
6	37	28 (75.7%)	9 (24.3%)	
7	24	18 (75.0%)	6 (25.0%)	
8	28	15 (53.6%)	13 (46.4%)	0.008 (S)†
9	18	7 (38.9%)	11 (61.1%)	
10	12	6 (50.0%)	6 (50.0%)	
11	12	4 (33.3%)	8 (66.7%)	
Preexisting Comorbidities of Children	26	21 (80.8%)	5 (19.2%)	0.03 (S)†
Yes	138	82 (59.4%)	56 (40.6%)	
No				
Covid Vaccination status of Parent				
Yes, one dose	3	3 (100%)	0	
Yes, two doses or more	151	90 (59.6%)	61 (40.4%)	0.01 (S)†
No	10	10 (100%)	0	
Complete EPI of Children				
Yes	136	79 (58.1%)	57 (41.9%)	0.006 (S)†
No	28	24 (85.7%)	4 (14.3%)	

Conclusions/Learning Points: COVID-19 vaccine hesitancy among parents of 5-11 years old children is prevalent. The sex of the parent, age of children, preexisting comorbidities and EPI status of children and COVID-19 vaccination status of parent were noted to be significantly associated with vaccine hesitancy. Perceptions on the susceptibility and severity of COVID-19 infection, also the barriers and benefits of COVID-19 vaccination play a crucial role in the acceptance of the parents on vaccination. The main reason for vaccine hesitancy is due to fear of side effects of the vaccine.

PV0851 / #2147

CHARACTERISTICS AND OUTCOMES OF THE PATIENTS ON THE PAEDIATRIC ENVIN-HELICS DATABASE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Jose Carlos Fernández[1], Mireia Mor-Conejo[2], Ariadna Rigalos-Cases[1], Raquel Garcia-Romero[1], Carme Alejandre-Galobardes[2], Monica Balaguer-Gargallo[2], Elena Fresan-Ruiz[2], Iolanda Jordan[3], Paediatric Envin-Helics Study Group[1,4]
[1]Hospital Sant Joan de Déu, Paediatrics Department, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Déu, Paediatric Intensive Care Unit, Esplugues de Llobregat, Spain, [3]Hospital Sant Joan de Deu, Pediatric Intensive Care Unit, Esplugues de Llobregat (Barcelona), Spain, [4]Hospital Vall d'Hebron, Epidemiology, Barcelona, Spain

Backgrounds: The aim of this study is to describe the epidemiological characteristics and outcomes of the patients with healthcare-associated infections (HAI) diagnosed in Paediatric Intensive Care Units (PICU) from the annual Spanish registry Paediatric-ENVIN-HELICS in 2021.
Methods: Multicentre, prospective and observational study about HAI diagnosed in 25 Spanish PICUs, during a three-month period (April-June 2021). The characteristics and outcomes were analysed with Epidat 4.1 software.
Results: There were 1986 patients recruited with a mean of 79 per unit. The median age was 39 months (58.1% under 5 years), predominantly male (58.91%). 46.98% of admissions came from the operating room (80.81% programmed surgeries), predominantly postoperative cardiac surgery (21,15%) and neurosurgery (19.4%). 48.79% of the patients were non-surgical (79.9% from the emergency department and 4.9% were trauma patients). Predominating respiratory (26.49%), neurological (22.56%) and haemodynamic pathologies (21.85%). 30.46% of patients had previous comorbidities, with a mean of 1.4 comorbidities and 2.71 risk factors for HAI per patient. The mean PRISM-III was 3.11 (2.63-3.57). Invasive devices were present in 62.8%, with a 2.4% rate of HAI. The mean PICU length of stay has decreased over the years of the registry from 7.82 to 5.55 days (5.22-5.68), with 81.7% of patients staying for less than a week. Mortality at PICU discharge was 1.21% which has also decreased (3.6% to 1.21%). It was significantly related to PRISM-III on admission, emergency surgeries, and the presence of comorbidities or risk factors for HAI or presenting HAI ($p<0.01$).
Conclusions/Learning Points: The Paediatric-ENVIN-HELICS registry, which has been operating since 2013, is a useful tool to evaluate different patient types, infections and its evolution. The results showed a significant decrease over the years in the length of stay and mortality.

CHALLENGES TO AND RESOURCES NEEDED FOR KANGAROO MOTHER CARE (KMC) FOR SMALL AND SICK NEWBORNS IN AFRICA

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Irene Frantzis[1], Stéphanie Levasseur[1], Workeabebe Abebe[2], Ezekiel Mupere[3], Philip Larussa[1], Maitry Mahida[1], Lawrence Stanberry[1], Lisa Saiman[1]
[1]Columbia University Irving Medical Center, Pediatrics, New York, United States of America, [2]Addis Ababa University, Pediatrics, Addis Ababa, Ethiopia, [3]College of Health Sciences, Makerere University., Paediatrics And Child Health, Kampala, Uganda

Backgrounds: Newborn deaths from healthcare-associated infections (HAIs) occur disproportionately in low and middle-income countries. As KMC can significantly reduce HAIs as well as severe respiratory illnesses,[1] we assessed KMC practices in African hospitals caring for small and/or sick newborns to identify strategies to improve KMC. [1] doi:10.1002/14651858.CD002771.pub3
Methods: The study team, including African collaborators, developed an infection prevention and control (IP&C) practice survey that included questions assessing KMC resources and challenges and created a virtual assessment tool to 'visit' the KMC areas. African hospitals caring for small and/or sick newborns <30 days old were eligible to participate. Survey items for KMC were analyzed using descriptive statistics.
Results: The survey was administered from May 2021-October 2022; 45 hospitals from 20 countries (11 Francophone) participated, including 8 smaller district hospitals. KMC was available in 42 (93%) hospitals; 33/42 (79%) had a separate KMC area. Respondents reported KMC challenges and support needed to further improve KMC (Table 1). The virtual assessments found that 23 (52%) hospitals had KMC in crowded conditions. Table 1: Support Needed to Improve and Challenges to Providing KMC

Educational material/training	35 (78%)
Maternal medical condition	31 (69%)
Infant medical condition	28 (62%)
Adequate space	27 (60%)
Maternal comfort/access to necessities	24 (53%)
Staff knowledge/support	14 (31%)
Maternal knowledge	12 (27%)
Family/staff support	7 (15%)
Other[1]	5 (11%)

[1] Financial (n=2), distance to hospital (n=2), infant monitoring equipment (n=1)
Conclusions/Learning Points: Most hospitals adopted KMC. In addition to previously described challenges[2], respondents also identified previously unrecognized needs, i.e., providing maternal comfort and necessities. Furthermore, efforts to address cultural barriers and develop educational materials could improve KMC in African hospitals.
Funded by the Bill and Melinda Gates Foundation. [2] doi: 10.1186/s12913-021-07086-9.

ASSESSMENT OF WATER, SANITATION AND HYGIENE (WASH) PRACTICES IN AFRICAN HOSPITALS CARING FOR SMALL AND SICK NEWBORNS

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Irene Frantzis[1], Stéphanie Levasseur[1], Workeabebe Abebe[2], Ezekiel Mupere[3], Philip Larussa[1], Maitry Mahida[1], Lawrence Stanberry[1], Lisa Saiman[1]
[1]Columbia University Irving Medical Center, Pediatrics, New York, United States of America, [2]Addis Ababa University, Pediatrics, Addis Ababa, Ethiopia, [3]College of Health Sciences, Makerere University., Paediatrics And Child Health, Kampala, Uganda

Backgrounds: Compared with higher-income countries, neonatal mortality from healthcare-associated infections (HAIs) is 10-15 times higher in low- and middle-income countries (LMIC) and disproportionately caused by multi-drug resistant Gram-negative organisms. To combat HAIs, WHO has increasingly emphasized infection prevention and control (IP&C), including WASH practices.[1] We assessed WASH practices in African hospitals caring for newborns. [1]https://www.who.int/publications/i/item/9789240051164
Methods: The study team, including African collaborators, developed a survey to assess IP&C, including WASH practices, in African hospitals caring for small and/or sick newborns <30 days old. Survey responses for WASH practices were analyzed using descriptive statistics.
Results: From May 2021-October 2022, 45 hospitals from 20 countries (11 francophone) participated. Thirty-eight (84%) hospitals taught staff how and when to perform hand hygiene (HH) using posters and demonstrations; 34 did not monitor HH adherence and 9 did not teach HH after touching environmental surfaces. Tap water was used to prepare infant formula and clean reusable respiratory therapy equipment in 15 and 16 hospitals, respectively. Many hospitals reused/shared pulse oximeters (96%), nasal cannula (85%), thermometers (76%) and CPAP equipment (50%). Most used chlorine-based solutions to clean environmental surfaces at least daily as per CDC recommendations for LMIC (Table).[2] [2] https://www.cdc.gov/hai/pdfs/resource-limited/environmental-cleaning-RLS-H.pdf Table: Cleaning agents for selected surfaces

Agent	Floors	Counters
Chlorine-based	84%	75%
Soap/water	9%	18%
Alcohol-based	4%	7%
Adequate cleaning supplies available		
Yes	78%	78%
Frequency of cleaning		
At least daily	93%	75%

Conclusions/Learning Points: Many hospitals had implemented WHO and CDC guidelines, but opportunities to improve WASH practices were identified. Future learning collaboratives could be used to expand evidence-based IP&C and WASH practices in African Hospitals. Funded by the Bill and Melinda Gates Foundation.

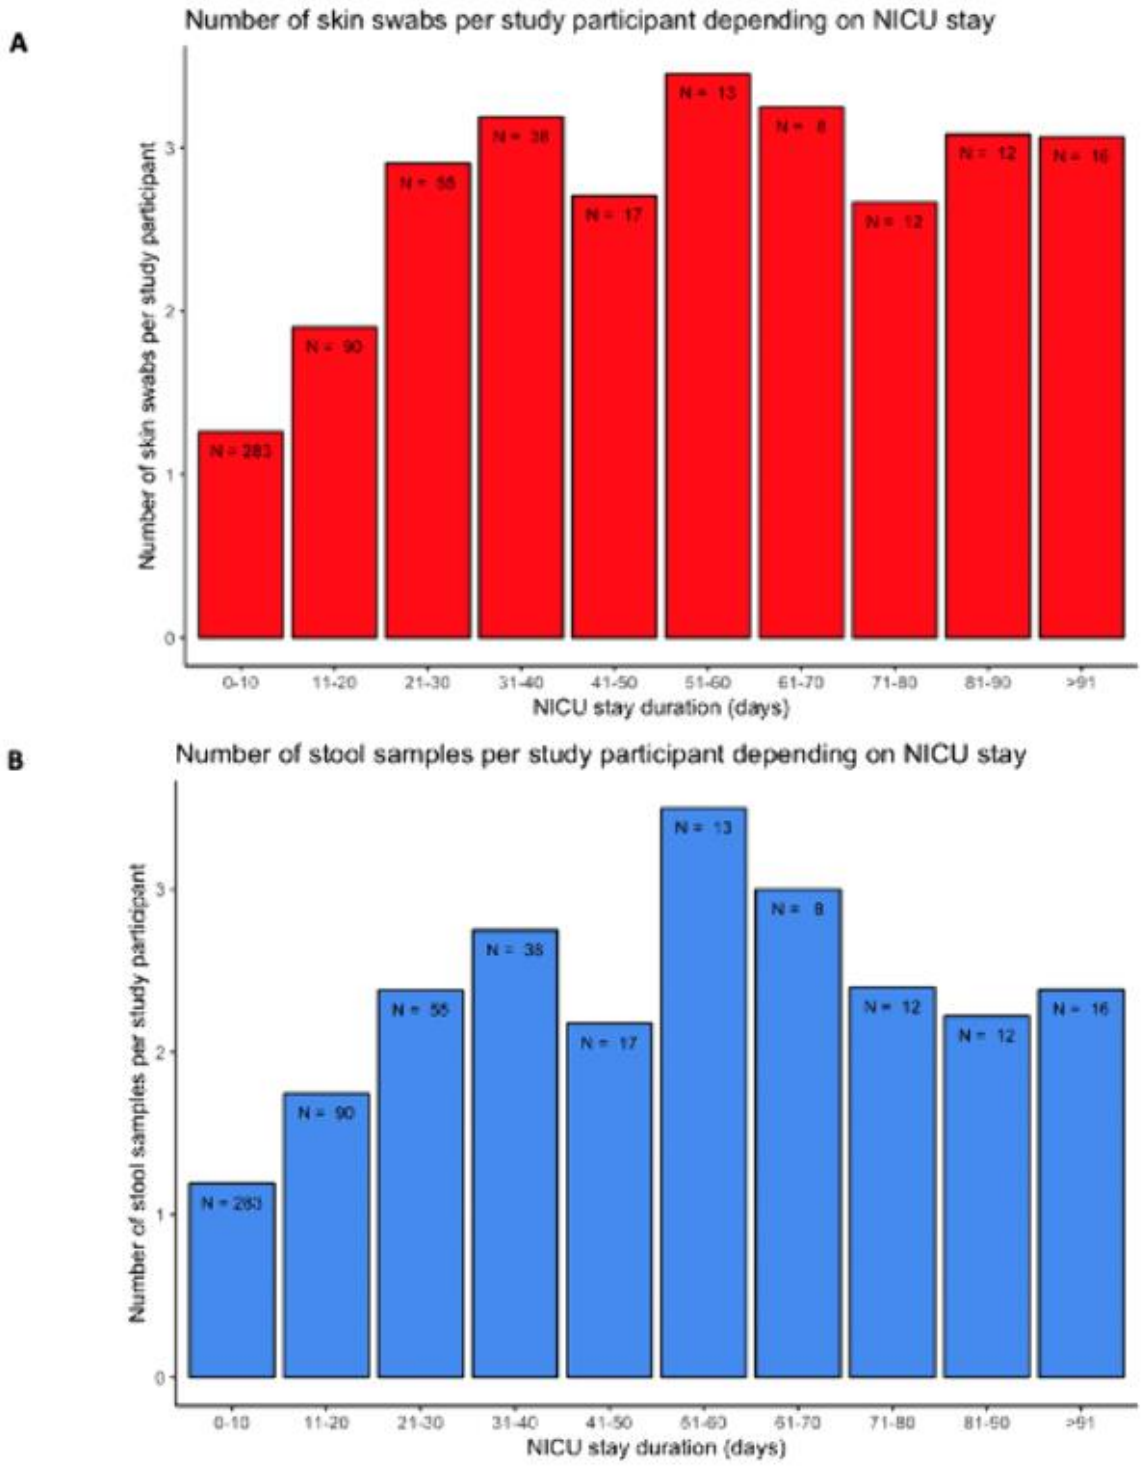
DESCRIPTIVE INTERIM ANALYSIS OF THE SAMPLING STRATEGY IN ANONYMOUS REPEATED CROSS-SECTIONAL SAMPLES IN EUROPEAN NEONATAL INTENSIVE CARE UNITS (NICU)

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Klervi Golhen[1], Verena Gotta[1], Marc Pfister[1], Julia Bielicki[2]
[1]University of Basel Children's Hospital (UKBB), Department For Paediatric Pharmacology And Pharmacometrics, Basel, Switzerland, [2]St. George's, University of London, Antimicrobial Resistance Research, Centre For Neonatal And Paediatric Infection, London, United Kingdom

Backgrounds: The NeoIPC Unit Level Resistant Bacterial Colonization Surveillance project aims to foster infection prevention and control implementation in the high risk setting of European NICU to reduce resistant bacterial colonization and infection. The main objective of this study is to assess feasibility of a proposed tailored sampling strategy for skin swabs and stool samples in neonates.
Methods: This is an initial descriptive analysis of the sampling strategy in anonymous repeated cross-sectional non-invasive samples from neonates. The proposed strategy consisted of 4 colonization point prevalence surveys of skin swabs and stool samples per infant (minimum of 4 and maximum of 14 days apart) to capture the main breaks in the cumulative colonization curve having a colonization pressure >20%.
Results: By November 15th 2022, 546 neonates were included in 15 European study sites. There were 6 to 78 participants per study site. A total of 969 skin swabs and 767 stool samples were collected. A proportion of 24.0% of neonates had ≥4 stool samples collected and 30.5% had ≥4 skin swabs. A total of 283 neonates remained in the NICU for <10 days and had at least one skin or stool sample drawn, while 16 stayed for >3 months. Neonates remaining in the NICU between 51 and 60 days had >3 stool samples collected. The interval between two consecutive samples per infant was mainly 4, 7 and 14 days. Figure 1 – Mean number of skin swabs (A) and stool samples (B) per study participant depending on NICU stay.



Conclusions/Learning Points: Allowing for sampling time intervals rather than fixed timepoints allows for more variability enhancing scientific and clinical usefulness of results. Colonization data will enable to assess resistant bacterial colonization pressure and model infant colonization dynamics.

HEPATOSPLENIC CAT-SCRATCH DISEASE - FASTER RECOVERY WITH STEROIDS?

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Cristel Gonçalves[1], Rebeca Santos[1], Inês Pereira[2], Filipa Briosa[1], José Gonçalo Marques[2]
[1]Hospital Beatriz Ângelo, Pediatrics, Loures, Portugal, [2]CHULN - Hospital Santa Maria, Pediatrics, Lisboa, Portugal

Title of Case: Hepatosplenic cat-scratch disease - faster recovery with steroids?
Background: Cat scratch disease (CSD) is a Bartonella henselae granulomatous infection that typically presents with regional lymphadenopathy associated with a papule in the scratched skin area. Disseminated bartonellosis with organ involvement such as bone, heart, liver, spleen, and central nervous system may present even in immunocompetent children.
Case Presentation Summary: We report a previously healthy 2-year-old boy who presented to the emergency department with fever and a tender left inguinal lymphadenopathy for the last 3 days. Laboratory tests showed mildly elevated CRP (4.68 mg/dL) and ESR (37 mm/h). Firstly, he was prescribed amoxicillin/clavulanate plus clindamycin, and was noted regression of inflammatory signs of the inguinal lesion, but no fever improvement occurred. New data when interviewing parents was a history of regular exposure to kittens. The chest radiograph was unremarkable. The abdominal CT scan showed multiple hepatic hypodense nodules, a maximum of 5mm sized. EBV, CMV, toxoplasma, HIV, HBV, HCV, Brucella, Borrelia, and Rickettsia were ruled out. Bartonella-PCR in blood, IGRA, and tuberculin skin tests were negative. The inguinal ganglion excision biopsy demonstrated a granulomatous inflammatory reaction without necrotic areas. Results of Bartonella serology IgM <1/20 and IgG 1/256 were interpreted as systemic CSD presentation. He received azithromycin, rifampicin for 10 days, and prednisolone for 14 days with clinical improvement and apyrexia from day one.
Learning Points/Discussion: This case reinforces the importance of epidemiologic contextualization during complete medical history. Serology is used for the diagnosis of CSD and IgG titers ≥ 1/256 strongly suggest active or recent infection. There is no consensual management for hepatosplenic cat-scratch disease but a double antibiotic regimen associated with steroids may provide a safe and faster resolution of the disease.

[1]Children's Emergency Clinic Hospital Brasov, Paediatrics, Brasov, Romania, [2]Edmond & Lily Safra Children's Hospital, Chaim Sheba Medical Center, Pediatric Infectious Diseases Unit, Ramat Gan, Israel, [3]Ben Gurion University, Faculty Of Health Sciences, Beer Sheva, Israel, [4]Soroka University Medical Center, Pediatric Infectious Disease Unit, Beer Sheva, Israel, [5]Transylvania University, Faculty Of Medicine, Brasov, Romania

Backgrounds: The aim of this study was to analyze all Streptococcus pneumoniae isolates from mucosal and invasive pneumococcal diseases, in children admitted at the Clinical Children's Hospital Brasov Romania after the introduction of PCV-13 in our National Immunization Program (NIP) and during COVID-19 pandemic.

Methods: A prospective on-going study was designed in our hospital and 216 S. pneumoniae isolates were collected between October 2019 throughout June 2022, from children with mucosal and invasive disease.

Results: The majority (70.8%) came from rural areas, 41.2% had low income and poor life conditions, 26.3% had more than 3 siblings, 15.2% were exposed to passive smoking and 51.8% had a recent medical history. Only 33.3% completed our NIP vaccination schedule. The most common serotype was 23F (14.8%), followed by 19F (14.3%), 11A (9.25%), 6B (7.87%), 3 (6.48%), 19A (5.55%) and 23A (4.64%). Antimicrobial resistance pattern was high, with 76.8% at penicillin (minimal inhibitory concentration (MIC) ≥2.0µg/ml), 62.9% at ceftriaxone (MIC values ≥0.5µg/ml), 65.5% at oxacillin, 31.3% at tetracycline, 57.7% at trimethoprim-sulfamethoxazole, 45.8% at erythromycin, 43.5% at clindamycin and 28.2% at cotrimoxazole. The susceptibility to chloramphenicol was 100%. More than a half, 55.0% of the isolates were multidrug resistant (MDR) with a predominance of 19F, 6B, 11A, 19A, 6A. PCV-13 coverage for the isolates in this study is 58.3%, PCV-15 – 59.7% and PCV-20 – 77.3%, while for MDR isoltaes PCV-13, PCV-15 is 90.7% and PCV-20 - 100%.

Conclusions/Learning Points: At 5 years after the introduction of PCV-13 in our NIP, most of the isolates are covered by PCV-13 while the best coverage rate is offered by PCV-20, including MDR isolates.

HIGH RESISTANCE PATTERN OF INTESTINAL MICROORGANISMS TRANSLOCATED TO BLOODSTREAM INFECTION IN PEDIATRIC ONCOLOGY AND HEMATOLOGY PATIENTS

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Lauryna Aukstikalne[1], Barbara Avizenis[2,3], Inga Ivaskeviciene[2,3], Goda Vaitkeviciene[3,4]
[1]Vilnius University Hospital Santaros Klinikos, Department Of Biomedical Research, Vilnius, Lithuania, [2]Vilnius University Hospital Santaros Klinikos, Paediatrics Centre, Vilnius, Lithuania, [3]Faculty of Medicine, Vilnius University, Clinic Of Children Diseases, Institute Of Clinical Medicine, Vilnius, Lithuania, [4]Vilnius University Hospital Santaros Klinikos, Center For Pediatric Oncology And Hematology, Vilnius, Lithuania

Backgrounds: Immunocompromised oncology/hematology patients have high risk of infection-related mortality. It is of importance to evaluate intestinal colonization with resistant pathogens which might be a source for bloodstream infections.
Methods: Data of positive stool cultures, collected routinely at admission for identification of intestinal colonization, and positive blood cultures, collected during febrile episodes from pediatric patients (<18 years) treated at the tertiary center for pediatric oncology and hematology during the 2018-2022 period, were retrospectively analyzed. Cases with matching microorganisms in blood and stool cultures were identified and further investigated.
Results: In total, 420 positive stool (n=224) and blood (n=196) cultures from 120 patients were identified. Predominance of gram-negative bacteria in stool and gram-positive bacteria in blood was documented (n=164 (74%) and n=128 (66%), respectively). In 22 (11% of all positive blood cultures) episodes of bacteremia, the same pathogen was identified in the stool. Severe neutropenia (ANC <0.5x10^9/l) was present in 16/22 cases (73%) of positive blood cultures. Most of the matched pathogenes, identified in both stool and blood cultures (Klebsiella pneumoniae, n=9/22, Eschericia coli, n=5/22, Pseudomonas aeruginosa, n=4/22, Staphylococcus haemolyticus, n=1/22) showed highly antimicrobial resistant pattern with ≥50% of tested cultures being resistant to one or more of: piperacillin-tazobactam, second or third generation cephalosporins or fluoroquinolones, or other first-line or alternative tratment. However, all tested cultures were susceptible to amikacin. Other less frequently detected pathogens (Stenotrophomonas maltophilia, n=1/22, Enterobacter cloacae, n=1/22, Candida albicans, n=1/22) did not exhibit significant resistance.
Conclusions/Learning Points: Screening for intestinal colonization of resistant pathogens is of importance for individualization of empirical febrile episodes treatment to reduce infection-related mortality risk.

EVALUATION OF PEDIATRIC HYDATID CYST CASES: A SINGLE CENTER TEN-YEAR EXPERIENCE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Yalçın Kara[1], Mahmut Kızıl[1], Merve Işeri Nepesov[1], Çiğdem Öztunalı[2], Mehmet Arda[3], Hüseyin Ilhan[4], Ömer Kiliç[1], Ener Çağrı Dinleyici[5]
[1]Eskişehir Osmangazi University, Pediatric Infectious, Eskişehir, Turkey, [2]Eskişehir Osmangazi University, Radiology, ESKİŞEHİR, Turkey, [3]Eskişehir Osmangazi University, Pediatric Surgery, Eskişehir, Turkey, [4]Eskişehir Osmangazi Medical University, Pediatric Surgery, Eskişehir, Turkey, [5]Eskişehir Osmangazi University, Pediatric Intensive Care, Eskişehir, Turkey

Backgrounds: Hydatid cyst is a zoonotic disease caused by echinococcal tapeworms. Hydatid cysts can occur in any place such as the liver, lung, spleen, kidney, brain, and soft tissue. We aimed to present the demographic characteristics, clinical symptoms and type of surgery of patients with hydatid cysts.
Methods: Eighty-four pediatric cases followed between 2012-2022 in Eskişehir Osmangazi University Medical Faculty Hospital were included. The epidemiological, clinical features, laboratory and radiological findings and treatment of the cases were evaluated.
Results: Fifty (59.5%) of 84 patients were male, mean age was 137(15-216) months .48(47.1%) of the cases lived in rural areas and 38 (45.2%) of them had animal contact. While 16.7% of the cases had anaphylaxis, 14.3% had lung and liver rupture. Indirect hemagglutination assay test was positive in 54.8% of the cases and 48.8% had eosonophilia. While 41.7% of the cases had lung cysts, 32.1% liver, 23.8% had lung and liver cysts, bladder in one patient, ovary in one patient and heart in one patients. According to Gharbi scoring, 60.5% of the patients had Type-3 hydatid cysts, 18.5% had Type-2, 11.1% had Type-1, 6.2% had Type-5 and 3.7% had Type-4 hydatid cysts. Cysts were >5 cm in 58% of cases, and <5 cm in 42%. As treatment, albendazole and surgery were used in 73.8% of the cases, only albendazole in 25% and PAIR in 1 case.
Conclusions/Learning Points: Our country is one of the endemic regions for hydatid cyst, and it may cause very different clinical findings and various organ involvements. For this reason, hydatid cyst should be kept in mind in patients who apply with prolonged clinical findings and have a history of living in rural areas and animal contact

PV0859 / #660

ETIOLOGICAL EVALUATION OF LYMPHADENOPATHIES IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Nurhayat Karakaya[1], Yalçın Kara[2], Mahmut Kızıl[2], Merve Işeri Nepesov[3], Özcan Bör[4], Ömer Kiliç[2], Ener Çağrı Dinleyici[5]
[1]Eskişehir Osmangazi University, Pediatric, Eskişehir, Turkey, [2]Eskişehir Osmangazi University, Pediatric Infectious Disease, ESKİŞEHİR, Turkey, [3]Eskişehir Osmangazi University, Pediatric Infectious Disease, Eskişehir, Turkey, [4]Eskişehir Osmangazi University, Pediatric Hematology, Eskişehir, Turkey, [5]Eskişehir Osmangazi University, Pediatric Intensive Care, Eskişehir, Turkey

Backgrounds: Lymphadenopathies are one of the most common causes of hospital admission in childhood. Many reasons such as infections, malignancies and rheumatological diseases play a role in its etiology. Here, it is aimed to evaluate the clinical and epidemiological features of pediatric cases presenting with lymphadenopathy
Methods: Patients followed up in Eskişehir Osmangazi University Pediatric Infection Clinic between 2012 and 2022 due to lymphadenopathy were included in the study. The clinical and epidemiological features of the cases were evaluated retrospectively.
Results: Of the 249 patients included in the study, 157(60.9%) were male and the mean age was 7.5 years. The most common symptoms were neck swelling(74%), fatigue(29.5%), fever(21.3%) and anorexia(14.2%). 80.2% of the cases were cervical, 10.7% submandibular, 4.7% axillary, 3.1% inguinal region.In etiology; Ebstein-barr virus in 13.9% of cases,Cytomegalovirus in 4.9%, group A beta-hemolytic streptococcus in 4.8%, malignancy in 2.5%(2 lymphomas, 1 leukemia, 1 langerhans cell lymphohistiocytosis,1 rhabdomyosarcoma),tuberculous lymphadenitis in2%, mumps in 1.6%,cat scratch in 1.2%,PFAPA syndrome in 1.2%, congenital cyst in 1.2% ,kawasaki disease in 0.8% , brucella in 0.8%,toxoplasma in 0.4%, tularemia in 0.4%, and sarcoidosis in 0.4%.While biopsy was performed in 13.1% of the cases,most common pathological findings were; granulomatous infections, congenital cysts, tuberculous lymphadenitis and malignancy.While antibiotic treatment was given to 38% of the cases, 2 cases were operated due to deep neck infection.
Conclusions/Learning Points: Although lymphadenopathy often develops after viral infections and upper respiratory tract infections in childhood, rarer chronic infections such as tuberculosis and cat scratch, malignancy and rheumatological diseases should be kept in mind. Especially the cases that last for a long time and unresponsive to treatment or accompanied by systemic symptoms should be examined in detail, so that early diagnosis and treatment should be arranged.

PV0860 / #1628

COMPARED IMPACT OF NIRSEVIMAB AND MATERNAL VACCINE FOR THE PREVENTION OF RSV MA-LRTI IN A US BIRTH COHORT EXPERIENCING THEIR FIRST RSV SEASON

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

[1]Sanofi, Health Economics And Value Assessment, Lyon, France, [2]Sanofi, Health Economics And Value Assessment, Reading, United Kingdom, [3]Vaccines & Immune Therapies, AstraZeneca, Health Economics And Value Assessment, Gothenburg, Sweden, [4]Sanofi, Health Economics And Value Assessment, Toronto, Canada

Backgrounds: Respiratory syncytial virus (RSV) is the leading cause of hospitalization in infants. Several preventative interventions will soon be available and the assessment of their impacts on healthcare resource utilization is critical to inform future recommendations. The objective of this modeling study was to estimate the impact of nirsevimab and maternal vaccine on RSV medically attended lower respiratory tract infections (RSV MA-LRTI) in a US birth cohort compared to the current standard of practice (SoP).
Methods: We used a static decision analytic model to estimate health outcomes related to RSV under SoP and with prophylaxes. Assumptions for interventions were documented based on clinical results for nirsevimab, and top-line data of Ph3 global trial for maternal vaccine. Implementation was defined year-round for maternal immunization, and seasonal for nirsevimab, considering equal coverage rate.
Results: We estimated 528,872 MA LRTIs under SoP over the first RSV season of infants, including 46,880 hospitalizations. RSV MA-LRTIs was predominantly observed among infants born before the season (69%), whereas hospitalizations were equally distributed between infants born before and during the season. Nirsevimab prevented consistently 54% of RSV MA-LRTIS across the birth cohort. Maternal vaccine prevented overall 25.6% of events, with 20% avoided in infants born before the season, and 38% in infants born during the RSV season.
Conclusions/Learning Points: Our model estimates that nirsevimab is most effective at reducing the number of MA-RSV LRTI. With timely immunization and durable protection over time, the RSV disease burden can be addressed in the full birth cohort.

PV0861 / #1730

A REVIEW ON THE COMPREHENSIVE BURDEN OF GONORRHOEA IN EUROPE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Zeki Kocaata[1], Linda Hortobagyi[2], Shahina Begum[1]
[1]GSK, Value Evidence & Outcomes, Wavre, Belgium, [2]Freelance c/o GSK, Na, London, United Kingdom

Backgrounds: Emerging evidence on the 4CMenB vaccine's gonorrhoea cross-protection raised hopes for targeted gonorrhoea prevention. Whilst incidence is increasing, men-having-sex-with-men (MSM) and individuals between 15-25 years are disproportionally affected, particularly in the United Kingdom (UK). This targeted literature review synthesized the burden of gonorrhoea in selected European countries to understand the comprehensive disease burden and inform decision-making on the potential delivery of the vaccine.
Methods: Findings reported here for the UK, France, Germany, Italy and Spain were part of a global search where observational, health-economic and review studies in MEDLINE were screened from 2012 to 30/06/2022. Excluding grey literature and global reviews, relevant local studies were reviewed by title/abstract and synthesised by medical, humanistic, and economic burden.
Results: Five medical (3 German, 1 French, 1 UK) and one humanistic burden study (UK) were identified. Two German studies showed increasing azithromycin antimicrobial resistance (AMR) (5.6% of analysed samples). Another German study reported prevalence ranges (7.4-14.8%) for MSM, highest among HIV-negative pre-exposure prophylaxis users. The French study showed most patients were diagnosed symptomatic (women-having-sex-with-men 53.3%, men-having-sex-with-women 90%). MSM had the highest HIV-coinfection level (13.9%). The UK (Brighton) study found 12% of samples collected >1 year were genetically related, suggesting long-term asymptomatic carriage of gonorrhoea. No local studies assessing infections per anatomical sites, sequelae, AMR beyond MSM and co-infections beyond HIV were captured. Gaps in humanistic burden in patients and spillovers to others remain, a UK study assessed quality-of-life of only 2 patients. No economic burden studies were captured in relevant geographies. Overall, no studies were identified in Italy and Spain.
Conclusions/Learning Points: To better understand the role and target of emerging prevention options against gonorrhoea, more local disease burden evidence is needed.

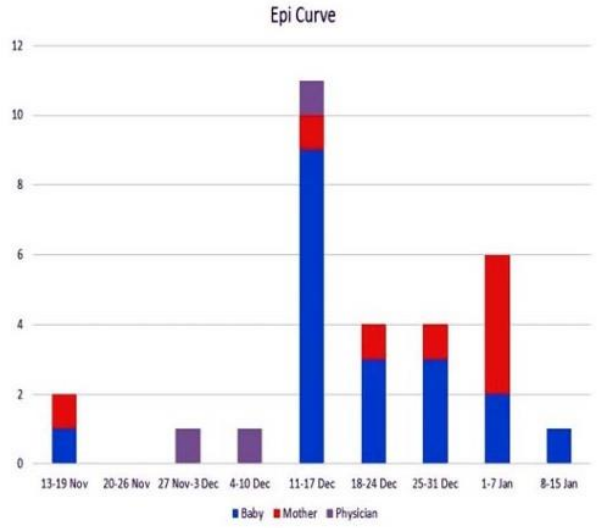
[1]Lady Hardinge Medical College and Assoc. Kalawati Saran Children Hospital, Neonatology, Delhi, India, [2]Lady Hardinge Medical College, Microbiology, New Delhi, India, [3]All India Institute of Medical Sciences, Virology, Microbiolgy, New Delhi, India

Title of Case: ADENOVIRUS CONJUNCTIVITIS OUTBREAK IN A NEONATAL UNIT IN NEW DELHI
Background: Nosocomial spread of Adenovirus has been reported in adult and pediatric medical units. This hardy virus is resistant to numerous disinfectants and has potential to cause outbreaks. In this communication we present our experience in evolution, investigation and control of an Adenovirus conjunctivitis outbreak in our unit.
Case Presentation Summary: Outbreak occurred in 50 bedded NICU between 13th November 2022 to 15 January 2023. Once outbreak was suspected infection control team was informed and data collected, regarding gender, weight, gestation, clinical signs and symptoms, mother's involvement. Conjunctival swabs were sent for bacterial cultures and in VTM for real time PCR for Adenovirus. A total of 19 babies, 8 mothers and 3 physicians had conjunctivitis (Fig). Conjunctival swabs could be sent for 17 babies out which 4 were positive for Adenovirus. Swab from one physician and mother was also positive. During the middle of the outbreak we realised that the most of the babies had prior ROP examination. It was noted that there was frequent rotation of the ROP screening team and each team had only one set of instruments which they were washing with soap and water. Eye congestion, purulent discharge and lid edema were the common presentations. Five patients had pseudomembrane (Fig). A meeting of all stakeholders was held. Five new sets of instruments were immediately procured. ROP team was requested to use only autoclaved instruments. Infected babies and mothers were cohorted and hand hygiene among all patient attendants, doctors and nurses was
reinforced.



Profile of affected babies

Parameter	Number (N=19)
Weight	
<1000 gm	6
1000-1500 gm	2
1500-2500 gm	5
>2500 gm	6
Prior ROP Examinations	11
Interval ROP and symptoms days M(IQR)	6 (3) Range 1-20
Eye Symptoms	
Congestion	19
Purulent Discharge	16
Lid edema	18
Papillary Hypertrophy	2
Pseudomembrane	5
Corneal Involvement	0
Mother infected after baby	6 (2 before)
Interval between baby's and mother's symptoms days M(IQR)	5 (13) Range 3-18
Conjunctival Swab Report (N=17)	Adenovirus 4, Adenovirus + Enterococcus 1 and Klebsiella sp 2

Learning Points/Discussion: In an outbreak of conjunctivitis Adenovirus should be considered. Instruments used for ROP examinations should be properly sterilized. Infection control practices especially hand hygiene should be followed rigorously.

THUNDERSTRIK-ING YEAR. A THREE-FOLD INCREASE OF FEBRILE SEIZURES INCIDENCE IN 2022 COMPARED TO 2021.

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Domniki Kyriakou
Regiomed Klinikum Coburg, General Pediatrics, Coburg, Germany

Title of Case: Influenza one of the most common pathogen, highest CrP, longest hospitalization, a positiv case with complex seizure. Should vaccination be considered for children with a history of reccurent febrile seizures?
Background: Febrile Seizures are one of the most common emergency department presentations. Nevertheless is a devastating experience for the family members resulting to parental anxiety in any future fever episodes. In our study we noticed a three-fold increase on the admitted cases of febrile seizures in the year 2022 compared to 2021. Data of patient age, date of admission, seizure characteristic, fever focus, isolated pathogen, C-reaktive Protein, WBC, Monocytes, Neutrophil to Lymphocyte Ratio. Metabolic parameters ammoniac and phosphate, CSF inflammatory parameters Initially 32 patients for the year 2021, and 105 for the year 2022 were admitted for further investigation and treatment in our hospital due to seizures secondary to fever or infect. Following definition criteria for febrile seizures patients above the age of 6, preexisting neurologic abnormality, and CNS infection were excluded leaving 28 patients for the year 2021 and 92 patients for the year 2022.
Case Presentation Summary::

Seasonal Variation of most common Viruses

	Adeno-	Rota-/Norovirus	Rhino-/Enterovirus	Influenza	Sars-Cov-2	RSV
Autumn 2022	2	0	1	0	2	0
Winter 2022	0	1	2	5	4	3
Spring 2022	1	1	3	0	6	0
Summer 2022	0	0	2	1	1	0

Seasonal Variation of Complex Seizures

Autumn 2022	6
Winter 2022	2
Spring 2022	0
Summer 2022	2

Learning Points/Discussion: Seasonal distribution similar to those of community acquired respiratory infections. Influenza Vaccine should be recommended for all children aged 6 months and above especially with predisposition to febrile seizures. Influenza

is highly pyrogenic with the ability to induce neuronal excitability and reduce convulsion threshold.

PV0864 / #1936

SHORT-TERM PERIPHERAL VENOUS CATHETER–RELATED STAPHYLOCOCCUS AUREUS BLOODSTREAM INFECTIONS IN PEDIATRIC PATIENTS, MADRID 2017-2021

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Almudena Lagares[1], Valeria Rubinacci[1], Emilia Cercenado[2], María Ángeles Orellana[3], Serena Villaverde[4], Alicia Hernanz-Lobo[1], Ángela Manzanares[5], Jesus Saavedra-Lozano[1], Cristina Epalza[6], David Aguilera-Alonso[1]
[1]Hospital Gregorio Marañón, Pediatric Infectious Diseases Unit, Madrid, Spain, [2]Hospital Universitario Gregorio Marañon, Microbiology, Madrid, Spain, [3]12 de Octubre University Hospital, Microbiology, Madrid, Spain, [4]Hospital Universitario 12 de Octubre, Pediatric Infectious Diseases Unit, Madrid, Spain, [5]Hospital Universitario 12 de Octubre, Pediatric Infectious Diseases Unit, Madrid, Spain, [6]Hospital Universitario 12 de Octubre, Paediatric Infectious Diseases Unit, Madrid, Spain

Backgrounds: Despite the widespread use of peripheral venous catheters (PVCs) in hospitalized pediatric patients, infectious complications, such as PVC-related bloodstream infections (PVCR-BSIs), are commonly underestimated. Among the different microorganisms, Staphylococcus aureus shows high morbidity.
Methods: Retrospective descriptive study including pediatric patients diagnosed with PCVR-BSIs by S. aureus 2017-2021 in two tertiary hospitals in Madrid (Spain). An adapted definition of catheter-related BSI was used, defining confirmed (PVC tip's culture) or probable (phlebitis or resolution of symptoms after catheter removal).
Results: A total of 17 episodes of PCVR-BSIs by S. aureus in 17 patients were identified (8.5% of total S.aureus bacteremias). PCV tip was not cultured in any case. Ten (58%) were males, with a median age of 51 days (IQR:30-199). All but one patient were <1 year. The median time of hospital admission at PCVR-BSI was 8 days (IQR:3-32). The most common reasons for the admission were a respiratory infection (n=5;29%), prematurity (n=5;29%) and congenital heart disease (n=4;24%). None of them had a central line. The PVC responsible for the BSI was considered not necessary for patient's management in 24% of the patients. One (6%) of the cases was due to methicillin-resistant S. aureus. A metastatic infection was diagnosed in 6 (35%) cases: skin and soft tissues(n=4), pneumonia(n=2), osteoarticular(n=2), and endocarditis(n=1). Ten (59%) patients required PICU admission because of PCVR-BSI. One patient died related to the PCVR-BSI and another had osteoarticular sequelae.

Total of bacteriemias due to *S.aureus*	201
PVC-related bloodstream infections	17 (8.5%)
Type of PCVR-BSI	Confirmed: 0 Probable: 17
Concomitant use of a central line	0
Sex	Male: 10 (58%), Female: 7 (42%)
Age	<1 year 16 (94%), ≥1 years: 1 (6%) Median age: 51 days (IQR:30-199)
Income unit	General Pediatrics: 6 (35%) Neonatology: 6 (35%) Pediatric Intensive Care: 4 (24%) Others: 1 (6%)
Reason for admission	Respiratory infection: 5 (29%) Prematurity: 5 (29%) Cardiopathy: 4 (24%) Other causes: 3 (18%)
Presence of comorbidities	No: 4 (24%), Yes: 13 (76%)
Type of comorbidity	Prematurity <27 weeks: 6 (46%) Cardiopathy: 4 (30%) Solid organ neoplasm: 1 (8%) Pierre-Robin sequence: 1 (8%) Metabolic disease: 1 (8%)
Median time of hospital admission at PCVR-BSI	8 days (IQR:3-32)
Metastatic infection	No: 11 (65%) Yes: 6 (35%) Locations: Endocarditis: 1, Lung: 2, Osteoarticular: 3, Skin and soft parts: 4.
Median of total antibiotherapy time	10 days (IQR:6-21)
Need for ICU due to bacteremia	No: 10 (59%), Yes: 7 (41%)
Need for inotropics	No: 13 (43%), Yes: 4 (57%)
Need for oxygen therapy	No: 0 (0%), Yes: 7 (100%)
Need for noninvasive mechanical ventilation	No: 0 (0%), Yes: 7 (100%)
Need for invasive mechanical ventilation	No: 2 (29%), Yes: 5 (71%)
Sequelae related to the PCVR-BSI	1 patient (6%), osteoarticular
Death related to the PCVR-BSI	1 patient (6%)

Conclusions/Learning Points: Our study describes a relevant morbidity of PCVR-BSIs in children, with high proportion of metastatic infections and PICU admissions. Patients were mainly infants <1year old. PVCR-BSI diagnosis is challenging as PVC tips are not usually sent for culture. Training on the care of PVC, decreasing its use if not indicated, seems relevant.

RISK FACTORS ASSOCIATED WITH AN INCREASE IN ESBL ENTEROBACTERIA CARRIAGE IN A PEDIATRIC HEMATOLOGY-ONCOLOGY UNIT

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Camille Bréhin[1], Guillaume Le Balle[1], Anne Isabelle Bertozzi[2], Damien Dubois[2], Caroline Viard[2]
[1]CHU de Toulouse, Hôpital Des Enfants, Toulouse, France, [2]CHU Toulouse, Hôpital Des Enfants, Toulouse, France

Backgrounds: An increase in the carriage of extended-spectrum betalactam enterobacterial (ESBLE) in the pediatric population has been observed. Following the observation of an increase in ESBLE carriage in the pediatric hematology oncology unit, the hypothesis of a causal link between exposure to antifungal treatment and ESBLE carriage was put forward. The objectives of this study was to describe patients with ESBL and to determine possible risk factors associated with carriage of ESBLE.
Methods: A single-center retrospective observational study was conducted. Patients under 18 years of age hospitalized in the pediatric hematology oncology department with ESBL carriage were included between January 1, 2017 and December 31, 2020. The factors possibly involved in the acquisition of ESBL germs were extracted from the medical record data.
Results: Of the 242 patients screened over the four years, 61 children were included. The median age was 7.5 years (1-17). The two predominant ESBL bacterial species were Escherichia coli and Klebsiella pneumoniae. Among the patients screened, the proportion of ESBL carriers has increased from 18% in 2017 to 33% in 2020 (p=0.007). No difference was identified between each year concerning the number of central venous lines, exposure to antibiotic treatment (prophylaxis or treatment) in the last 3 months, hospitalization with or without stay in intensive care in the last 3 months, origin or stay in a country with high ESBL endemicity, presence of mucositis, previous history of urinary tract infection. Only exposure to an anti-fungal drug increased from 56% in 2017 to 79% in 2020.
Conclusions/Learning Points: Exposure to antifungal therapy appears to be a risk factor associated with the increase of EBLSE carriage. Larger studies looking at the impact of antifungal prescription on the microbiota of children should be conducted.

PV0866 / #1418

PAEDIATRIC INVASIVE PNEUMOCOCCAL DISEASE: A 30-YEAR STUDY FROM A TERTIARY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Joana Lima[1], Luis Salazar[1], Alexandre Fernandes[2], Carla Teixeira[2], Laura Marques[2]
[1]Centro Materno Infantil do Norte - Centro Hospitalar Universitário do Porto, Paediatrics' Department, Porto, Portugal, [2]Centro Materno-Infantil do Norte, Centro Hospitalar e Universitário do Porto, Infectious Diseases And Immunodeficiencies Unit, Paediatric Department, Porto, Portugal

Backgrounds: Streptococcus pneumoniae (SP) is the leading cause of morbidity due to pneumonia, meningitis, and bacteremia worldwide. Pneumococcal 13-valent conjugate (Pn13) vaccines are part of the Portuguese National Vaccination Program (PNV) since 2015, conferring protection against invasive pneumococcal disease (IPD). However, these vaccines have a limited serotype coverage and are associated with serotype replacement. The aim of this study was to characterize IPD in a tertiary paediatric hospital over the last 30 years.
Methods: A retrospective study was performed including all the patients under 18 years-old with a diagnosis of IPD at our department between 1993-2023. The identification occurred by culture and/or molecular biology in products obtained from sterile sites.
Results: A total of 74 patients were included, with a median age of 25 months (1m–17y) and a male predominance (63.5%). Analyzing by 5-year periods, the number of infections were similar. The most frequent diagnosis were pneumonia (31.1%), meningitis (28.4%), bacteraemia (27.0%) and sepsis (24.3%). There was a reduction in meningitis ($p=0.036$) with an increase in pneumonia ($p<0.01$). The SP identification was predominantly in blood culture (48.6%), followed by cerebrospinal fluid (28.4%) and pleural fluid (27.0%). Twenty-three patients (31.1%) had serotype identification - serotype 3 was the most frequent (10.8%). After 2015, there was a reduction in sepsis and bacteraemia ($p=0.002$; $p=0.010$).
Conclusions/Learning Points: There was a reduction in sepsis and bacteraemia after introduction of Pn13 vaccine in the PNV, but not in the overall number of IPD. This may be related with serotype replacement and improved molecular biology diagnosis in the last decade. The high prevalence of serotype 3, in complicated pneumonia, may be caused by the low protection from Pn13 vaccine to this serotype as previously reported.

FREQUENCY OF RESISTANT MICROORGANISMS IN PATIENTS TRANSFERRED TO THE NEONATAL UNIT AT HOSPITAL UNIVERSITARIO SAN IGNACIO

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Juan Carlos Lopez, Laura Beltran, María Suarez, Ana Bertolotto, Adriana Bohorquez, Yaris Vargas
Hospital Universitario San Ignacio, Infectious Diseases, ., Colombia

Backgrounds: Infections by Multidrug-resistant organisms have increased in the population, strategies have been developed for the control and prevention of these infections, such as taking rectal swabs. Objective: Evaluate the incidence and prevalence of multiresistant microorganisms that were transferred or had a previous admission to the neonatal unit at Hospital Universitario San Ignacio during a 40 month timeframe.
Methods: Chart review and univariate analysis descriptive statistics. Bivariate analysis between colonization and infection by multiresistant organisms. Logistic regression analysis to evaluate association between baseline characteristics and colonization by multiresistant organisms.
Results: A Total of 722 patients were included in the study. 68 of them were colonized with multiresistant organisms (9.42%). The main resistant microorganisms found were enterobacteriaceae ESBL not E Coli. The prevalence of infections associated with multiresistant organisms was 2.94%. The only statistically significant association between baseline characteristics and mutiresistant organism colonization was the previous use of antibiotics. OR 2,149 (IC 1,139 - 4,053, p 0.000).
Conclusions/Learning Points: Multiresistant organisms infections are more frequent in patients colonized with multiresistant organisms and this is more frequent in patients with previous antibiotic therapy.

COMPARISON BETWEEN TWO GROUPS OF CHILDREN WITH INFLUENZA FROM BRASOV, CENTRAL ROMANIA

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Ioana Luca[1], Ioana Arbanas[1], Anca Ilea[2], Laura Bleotu[2], Oana Falup-Pecurariu[1,3]
[1]Children Hospital of Brasov, Pediatrics, Brasov, Romania, [2]Children Hospital of Brasov, Laboratory Medicine, Brasov, Romania, [3]Transylvania University, Faculty Of Medicine, Brasov, Romania

Backgrounds: Background: The dramatic increase in the number of influenza cases constitutes a burden to the Romanian healthcare system. Despite this fact, flu vaccination rates among Romanian children remain low (< 3%.) Aim of the study: to compare different flu strain characteristics of children that were evaluated at the Children Hospital of Brasov during two consecutive flu seasons.
Methods: A retrospective-observational study which enrolled a total of 1831 children who presented at the ER department of Children Hospital of Brasov. All children had positive rapid antigen tests for influenza. Group 1 is represented by 309 children who presented during January-April 2019, and group 2 enrolled 1522 children, from January-April 2020.
Results: All studied children were aged between 0-17 years old (SD=4.63), came from urban or rural areas of Brasov county and both genders were included. Boys were slightly more prevalent - 54.5% in 2019 and 52,3% in 2020 in the studied groups. Differences arose when checking the demographic characteristics- in 2019, more patients from rural areas presented in the ER (54.5%), while in 2020 urban areas were better represented (64.7%) (p=0.039). In both groups, respiratory symptoms and fever were prevalent (p=0.0003), while gastrointestinal symptoms were less common (p=0.002). Influenza A was prevalent in group 1-97.7%, while in the second group, more patients presented with Influenza B-61.5% (p=0.037)
Conclusions/Learning Points: Conclusions: There were differences in the prevalent influenza strain in these two groups. The demographic backgrounds of these two groups varied.

A CASE OF VARICELLA COMPLICATED BY IMPETIGO AND PERIORAL CELLULITIS

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Teresa Magalhães, Mariana Viegas, Catarina Mendonça, Daniel Soares
Centro Hospitalar do Oeste, Caldas da Rainha, Pediatrics, Caldas da Rainha, Portugal

Title of Case: A Case of Varicella Complicated by Impetigo and Perioral Cellulitis
Background: Varicella has been known to be a harmless childhood disease. However, it has been reported that severe complications have taken place following varicella infection. Bacterial superinfection of skin and soft tissues are the most frequent complications in both immunocompetent, as well as immunocompromised, individuals.
Case Presentation Summary: A healthy 2-year-old male patient was initially presented with 2-day-history of a papulovesicular rash all over his body, and varicella was clinically diagnosed. Three days later he was referred to emergency service with fever (maximum of 40ºC), food refusal and swelling, redness, and pain around the mouth, with purulent exudate. He presented edema surrounding the mouth, erythema, purulent exudate and widespread rash consistent with chickenpox. The diagnosis was varicella with perioral cellulitis and impetigo, which results in eating difficulties leading to patient hospitalization. There was no evidence of immunodeficiency or chronic disease. Seven days before he was diagnosed with acute otitis and NSAIDs (Ibuprofen) were prescribed for pain. The laboratory parameters results were within normal limits (Leukocytes 9800/uL, Neutrophils 5760/uL, Platelets 511000/uL, CRP 0.6 mg/dL). The patient was treated with intravenous flucloxacillin and glucose solution until the second day of hospitalization, which resulted in progressive improvement in fever, skin lesions and food tolerance.
Learning Points/Discussion: Varicella could cause serious complications including hospital admission. Previous studies demonstrated an increased risk of severe skin and soft tissue infectious complications associated with the use of NSAIDs, such as Ibuprofen, in children with chickenpox. In this case, the consumption of NSAIDs prior to the cutaneous manifestations of chickenpox may have been responsible for the exuberant skin condition. Therefore, fever and pain associated with varicella should be treated with paracetamol, not a NSAIDs.

SERRATIA MARCESCENS ENDOCARDITIS. ARE GRAM-NEGATIVE BACTERIA A NEW PARADIGM IN PAEDIATRIC INFECTIVE ENDOCARDITIS?

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Inés Marín-Cruz[1], Arantxa Berzosa Sánchez[1], Marta Illán-Ramos[1], Belén Joyanes-Abancens[2], Enrique Criado[3], Paloma Merino[4], Jose Ramos[1]
[1]Hospital Clínico San Carlos, Paediatric Infectious Diseases, Madrid, Spain, [2]Hospital Clínico San Carlos, Paediatric Intensive Care Unit, Madrid, Spain, [3]Hospital Clínico San Carlos, Neonatal Intensive Care Unit, Madrid, Spain, [4]Hospital Clínico San Carlos, Microbiology, Madrid, Spain

Title of Case: SERRATIA MARCESCENS ENDOCARDITIS. ARE GRAM-NEGATIVE BACTERIA A NEW PARADIGM IN PAEDIATRIC INFECTIVE ENDOCARDITIS?
Background: Infective endocarditis (IE) is a rare disease in children associated with significant morbimortality. The most frequent aetiological agents for paediatric IE are Staphylococcus aureus and viridans streptococci but, in recent years, other previously rare causative organisms are increasing such as coagulase-negative staphylococci, non-HACEK Gram-negative bacteria and fungi. We describe two cases of Serratia marcescens endocarditis, which has seldom been reported in children.
Case Presentation Summary: 4 months-old female infant with a polymalformative syndrome (ventricular septal defect, renal hypoplasia, cleft palate, polysplenia) admitted to the PICU due to RSV-bronchiolitis. A central venous line was placed. After 2 months of PICU admission, she presented with sepsis symptoms and S. marcescens was isolated in 8 different blood cultures in a 2-weeks period. Echocardiogram showed severe mitral regurgitation and 2.7x3.5mm mitral vegetation. IE was complicated with an apical myocardial abscess. Roth's spots were found on fundoscopy. She received cefepime(20 days)/meropenem(4 weeks) and ciprofloxacin(6 weeks IV, 2 weeks PO) after first negative blood culture. No surgical management was required. 6 weeks-old female infant admitted to the NICU (with central venous line placement) due to preterm birth at 24 weeks gestational age. She presented with haemodynamic instability and S. marcescens was isolated in 6 different blood cultures in a 7-days period. Echocardiogram showed intracavitary vegetation at right atrium. She received a 6 weeks-course meropenem+ciprofloxacin after first negative blood culture, with uneventful recovery.
Learning Points/Discussion: Due to increasing complexity of health care in our setting, there had been changes in paediatric IE microbiological aetiology and risk factors (such as venous central line placement, NICU/PICU admission or immunosuppression). Paediatricians attending patients with suspected IE should be aware of these changes.

OUTBREAK OF CANDIDA PARAPSILOSIS IN NEONATAL INTENSIVE CARE UNIT: INFECTION CONTROL AND CHARACTERISTICS OF BIOFILM

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Atsushi Miyake[1], Kenji Gotoh[1], Kiyohito Okumiya[2], Hiroshi Watanabe[1], Yushiro Yamashita[2]
[1]Kurume University School of Medicine, Department Of Infection Control And Prevention, Kurume Fukuoka, Japan, [2]Kurume University School of Medicine, Department Of Pediatrics And Child Health, Kurume Fukuoka, Japan

Backgrounds: We dealt with the occurrence of an outbreak of Candida parapsilosis in a neonatal intensive care unit (NICU) in September 2020. Though there have been several reports of C. parapsilosis outbreaks in NICUs, both the transmission rout and the characteristics of biofilm are not often uncleared. In this study we describe our investigation into the transmission route and the biofilm.
Methods: C. parapsilosis strains were detected in three inpatients and in two environmental cultures in our NICU. One environmental culture was isolated from the incubator used by a fungemia patient, and another was isolated from the humidifier of an incubator that had been used by a nonfungemia patient. The humidifier had not been cleaned after using. To prove their identities, we tested them by micro satellite analysis. We used two methods, dry weight measurements and observation by electron microscopy, to confirm biofilm.
Results: Microsatellite analysis showed the five C. parapsilosis cultures were of the same strain. Dry weight measurements and electron microscopy showed C. parapsilosis formed biofilms that amounted to clumps of fungal cells by massive extracellular matrix.
Conclusions/Learning Points: We concluded that the outbreak happened due to horizontal transfer through the humidifier of the incubator and that the C. parapsilosis had produced biofilm, which promoted an invasive and infectious outbreak. After the outbreak, we suggested that NICUstaff should check all the humidifiers of incubators during daily rounds in order to prevent next outbreak. Additionally, biofilm is closely associated with pathogenicity.

E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Geetha Nagaraj[1], Varun S[2], Muthumeenakshi Bhaskaran[1], Sravani Dharmavaram[1], K Ravikumar[3]
[1]Central Research Laboratory, Molecular Biology, Bangalore, India, [2]Central Research Laboratory, Microbial Informatics And Genomics, Bangalore, India, [3]Central Research Laboratory, Microbiology, Bangalore, India

Backgrounds: Staphylococcus aureus(SA) is recognized as an important cause of invasive disease in children. Methicillin resistant Staphylococcus aureus(MRSA) is endemic in India and is a dangerous pathogen for hospital acquired infections among children. Data on the prevalence of SA infection among children are scarce in India. This study was aimed at elucidating genomic epidemiology of SA strains in childhood and explore associations of antimicrobial resistance genes and virulence factors with clinical phenotypes
Methods: 57 paediatric non-repetitive MRSA isolates obtained from nine states of India mainly from pus samples of inpatients from 2014-2019 were studied. Phenotypic ID/AST was performed on Vitek-2 platform. Sequencing was performed in Illumina MiSeq Platform and data was analyzed following GHRU bioinformatic pipeline. Isolates carrying novel SCCmec cassettes were further characterized using long-read sequencing
Results: ST22, ST772 & ST2371 were the major clones identified with CC22 (42%) and CC1 (28%) predominant among MRSA isolates. Varied diversity of 22 different spa types was identified, with predominant spa-t657 type and was present solely in CC1-MRSA isolates (n=14). The CC22 MRSA strains carried SCCmec types IVa (54%) & IVc (46%) and belonged to spa types t005(n=8), t852(n=7) and t309(n=3). Fifteen MRSA isolate carried a novel SCCmec type V and four isolates had type IIIa. The luk-PV and tsst-1 genes were present in 76% and 24.5% of MRSA isolates, respectively. Phylogeographic analysis of the collection performed revealed that the major STs(ST22 and ST772) were present across the entire country for entire duration of the study
Conclusions/Learning Points: The present multicentric study provides crucial current knowledge about the epidemiology of MRSA in the paediatric population in India. Applying a clinical-genomic surveillance technique in India can enhance current infection control and antibiotic stewardship procedures

EPIDEMIOLOGICAL DATA OF STREPTOCOCCAL INFECTIONS IN HOSPITALIZED CHILDREN IN ALBANIA

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Bashkim Nezaj[1], Geogina Kuli-Lito[2], Raida Petrela[3], Ferit Zavalani[1], Blerina Gjoni[3], Diana Shtembari[2], Sosjana Baja[4], Marsida Kurti[5], Sara Zavalani[6]
[1]University Hospital Center "Mother Theresa", Pediatric Infectious Diseases, Tirana, Albania, [2]University Hospital Center: 'Mother Theresa', Tirana, Albania, Infectious Diseases, Tirana, Albania, [3]University Hospital Center "Mother Thereza", Pediatric Infectious Disease, Tirana, Albania, [4]University Hospital "Mother Theresa", Neonatology, Tirana, Albania, [5]Primary Health Care, Pediatrics, Mat, Albania, [6]University Hospital "Mother Theresa", Endocrinology, Tirana, Albania

Backgrounds: All members of the streptococci genus are Gram-positive, catalase-negative cocci that grow in pairs or short chains and are classified mainly according to the type of hemolysis and their clinical importance
Methods: This is a retrospective and descriptive study which describes epidemiological data in 467 children, hospitalized with streptococcal infection, in the Pediatric Infectious Disease Service, QSUT, during the period January 2017 - December 2021
Results: The incidence of streptococcal infections in hospitalized children in Albania has undergone continuous changes. The highest percentage of hospitalized cases is observed in 2017. The largest number of cases resulted in Tirana in 83.94%. of the cases. The most frequent clinical manifestation was purulent tonsillitis in 80.08% of the cases. Streptococcal infection appear to be more frequent in the spring season (March, April, May) and in the cold months of the year (November, December, January). The most frequently hospitalized age group is 1-5 years old with an average age 4 years old. Men predominate with 58.45% of the cases. 12.41 % of the cases had concomitant diseases but the predominance of a particular pathology as co-morbidity is a random finding. The minimum hospitalization day is 1 and the maximum 21 days, with an average of 5.97 hospitalization days. 10.06% of the cases, resulted with positive culture and 17.77% resulted with high titer of ASO (from the total number of these, cases with a positive throat culture are 42.16%)
Conclusions/Learning Points: Streptococcal infections remain a daily challenge for general pediatricians. Evidence of epidemiological and demographic data are an added help to diagnose and treat these infections at the right time, reducing so the contagiousness and avoiding complications

POOR STATUS OF THE PRIMARY HEALTH CARE IN NIGERIA-IMPLICATION FOR CHILD HEALTH

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Oliver Odikamnoro
Ebonyi State University, Applied Biology, Abakaliki, Nigeria

Title of Case: POOR STATUS OF THE PRIMARY HEALTH CARE IN NIGERIA-IMPLICATION FOR CHILD HEALTH
Background: In Nigeria, most heath policies are poorly implemented. One of the worst affected is the primary health care, widely regarded as the cornerstone of essential healthcare, Access to Universal Health Care, and the attainment of health-related Sustainable Development Goals, SDGs, and health security remain a mirage.
Case Presentation Summary: Summary: The Primary Healthcare Centres, PHCs, which are the first point of contact with the healthcare system, are not meeting the needs of Nigerians for essential health services as a result of years of neglect and poor funding
Learning Points/Discussion: Investigations revealed that many of the PHCs especially in rural communities in the six geo-political regions of the country are overwhelmed by challenges of poor staffing, inadequate equipment, substandard infrastructure, shortage of health workers, and lack of essential drug supply among others. Several of the health centres are in bad state and not providing the required comprehensive health care, maternal and child healthcare services, essential drugs and diagnostic services or referrals to secondary and tertiary healthcare institutions. This survey revealed poor implementation of the Primary Health Care as it concerns child health. The remoteness of some rural communities and lack of easy accessibility makes it difficult for health progrmmes to get to the grassroot. There is the need to train a large number of Village-Based Health Volunteers, who should step up community mobilizaion and health education campaigns.

PAEDIATRIC SCHISTOSOMIASIS IN RURAL COMMUNITIES OF SOUTHEAST NIGERIA-A NEGLECTED HEALTH CHALLENGE OF CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Oliver Odikamnoro
Ebonyi State University, Applied Biology, Abakaliki, Nigeria

Backgrounds: Background: Human schistosomiasis is an important and widespread infection in the tropics. It gives rise to a complex of acute and chronic diseases with widely differing signs and symptoms. It is the second most prevalent parasitic disease after malaria in the developing world with a huge impact on public health and socio-economic development. It is classified by the World Health Organization as a neglected tropical disease.
Methods: Aggregated studies were carried out in selected primary schools to establish the prevalence and intensity of Schistosoma haematobium infection in some rural communities of Ebonyi state, southeast Nigeria, using the filtration quantitative technique. Primary school children were used as tracers.
Results: Results;The results showed a high prevalence of urinary schistosomiasis among primary school children in the study area.In Abakaliki urban, out of the 800 pupils examined from Afikpo north and Ezza south respectively, 182 (29.5%) and 160 (40.0%) were infected with S. haematobium respectively,.In the 13 locations surveyed, the prevalence of urinary schistosomiasis ranges from 3.97% to 59%.. There was a gradual increase in the disease prevalence with increasing age of the study subjects. About 90% of the infected persons were aged 8 – 14 years. Statistical analysis revealed that the prevalence, intensity and visible haematuria were significantly higher ($P > 0.05$) in subjects between the age 8 and 14 years than subjects below 8 years of age. Results from other endemic areas of the state showed similar trends.Some of the water bodies found in the area that predispose people to the site of infection are streams, ponds, rivers, well. Humans are infected through water contact activities.
Conclusions/Learning Points: Conclusions: Urinary schistosomiasis has a low mortality, its morbidity has great impact on the health of children

BACTERIAL COLONIZATION IN A NEONATAL INTENSIVE CARE UNIT

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Carolina Oliveira Gonçalves[1], Catarina Garcia[2], Elzara Aliyeva[3], Marta Ferreira[2], Rosalina Barroso[2]
[1]Hospital Prof. Doutor Fernando Fonseca, EPE, Child And Youth Department, Amadora, Portugal, [2]Hospital Prof. Doutor Fernando Fonseca, EPE, Neonatal Intensive Care Unit, Amadora, Portugal, [3]Hospital Prof. Doutor Fernando Fonseca, EPE, Clinical Microbiology, Amadora, Portugal

Backgrounds: Newborns admitted to Neonatal Intensive Care Units (NICU) are highly vulnerable to colonization and infection by multi-drug resistant bacteria (MDRB). Healthcare associated infections due to MDRB are an emerging threat, associated with significant morbidity and mortality. We aimed to analyse the MDRB colonization rate and its associated risk factors, as well as the subsequent development of infection.
Methods: Case review of clinical files of all newborns admitted to a level III NICU, between November 2018 and November 2019. Rectal and nasal swabs were performed upon admission and weekly until discharge for detection of MDRB. Demography, colonization status and infection were recorded. Statistical analysis was performed with SPSS, version 25.0.
Results: 294 newborns were included: median gestational age was 35 weeks (IQR 32-38) with a prematurity rate of 61,2%, 8,2% being extremely preterm. The median birth weight was 2175 grams (IQR 1498,8-3090). The overall MDRB colonization rate was 28,2% (83/294). The most frequent MDR colonizer was ESBL-producing Enterobacteriaceae (n=48). Colonization with MDRB was associated with mothers' admission at least one week prior to delivery (p=0,009), infants' lower gestational age (p<0,001) and birth weight (p<0,001), longer hospitalization (p< 0,001), antibiotic therapy upon admission (p<0,001), mechanical ventilation (p<0,001) and central line (p<0,001). Colonization with a MDRB was an important risk factor for subsequent infection during hospitalization, as 31,3% (26/83) of colonized-infants developed late-onset sepsis, compared to 5,2% of non-colonized ones (p<0,001).
Conclusions/Learning Points: The increase of MDRB in NICUs is a growing concern and the prevention of colonization among hospitalized infants is key to minimize infection. Early detection of colonized patients through screening with subsequent implementation of strict contact precautions and cohorting of patients and healthcare staff helps controlling the spread of MDRB.

[1]Children Health Ireland Crumlin and Temple Street hospitals, Infectious Disease And Immunology, Dublin, Ireland, [2]Children Health Ireland Crumlin, Paediatric Haematology, Dublin, Ireland, [3]Children Health Ireland Crumlin, Antimicrobial Pharmacy, Dublin, Ireland, [4]Children Health Ireland Crumlin, Microbiology Laboratory, Dublin, Ireland, [5]Children Health Ireland Crumlin and Temple Street hospitals, Microbiology, Dublin, Ireland, [6]Children Health Ireland Crumlin, Pharmacy, Dublin, Ireland, [7]Children Health Ireland Crumlin, Oncology, Dublin, Ireland

Backgrounds: Antifungal prophylaxis is recommended in patients with a >10% risk of developing invasive fungal disease (IFD) during anti-cancer therapy. Oral azoles are popular but effective therapeutic levels can be difficult to attain mandated therapeutic drug monitoring (TDM). The aim was to assess rates of effective azole prophylaxis, compliance with existing guidelines for TDM and bottlenecks to delivery of effective coverage at our institution.
Methods: This was a retrospective audit of eligible patients from July - December 2021. The main outcomes were compliance to TDM guidelines with additional bottleneck analysis using a Tanahashi model. Data was collected from pharmacy and laboratory databases and inpatient records.
Results: There were 16 eligible patients, 12 males, and four females. The median age 11 years (range 1-16 years). Fifteen out of the 16 patients received doses according to the hospital formulary at the start of prophylaxis. Therapeutic levels were all checked at or after 7 days. Fourteen patients achieved the therapeutic level with one requiring switching to Posaconazole from Voriconazole. The median duration to reach the therapeutic range was 4 weeks (range 1 week to 48 weeks) with a mean of 16 weeks with Itraconazole and 9 weeks with Posaconazole. The only patient on Voriconazole achieved the level after 1 week. There was no breakthrough IFD. Bottleneck analysis identified a slow turnaround time for reporting therapeutic levels (median 7 days, range 1-19 days) and inappropriate dose adjustment as barriers to effective coverage.
Conclusions/Learning Points: While compliance with initial dosing and TDM strategies was good, effective coverage was negatively impacted by available drug preparations and health system barriers. Our methods could be replicated in similar institutions to support local interventions to optimize effective coverage.

E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Rita Amorim[1], Ana Luísa Correia[2], Marisa Pereira[3], Ana Correia-Costa[3,4], Ana Reis-Melo[5,6], Maria Tavares[6]
[1]Centro Hospitalar Universitário de São João, Pediatrics, Porto, Portugal, [2]Hospital Pedro Hispano, Unidade Local de Saúde de Matosinhos, Pediatrics, Matosinhos, Portugal, [3]Centro Hospitalar Universitário de São João, Pediatric Cardiology Department, Porto, Portugal, [4]Faculty of Medicine, University of Porto, Gynecology-obstetrics And Pediatrics, Porto, Portugal, [5]Faculty of Medicine of University of Porto, Biomedicine Department, Porto, Portugal, [6]Centro Hospitalar Universitário de São João, Pediatric Infectious Diseases And Primary Immunodeficiencies Unit, Pediatrics, Porto, Portugal

Backgrounds: Infective endocarditis (IE) is a challenging diagnosis with high morbidity and mortality. Furthermore, life-saving medical interventions like the use of implanted prosthetic material lead to a higher incidence of these infections. This study aimed to analyse all admissions for IE in a tertiary hospital.
Methods: A retrospective study examining pediatric IE cases treated between 2008 and 2021 at our hospital was conducted. Clinical presentation, treatment, complications, outcome of IE and underlying microorganisms were reviewed.
Results: During this period, there were 25 admissions for pediatric IE. The last years had higher numbers, with 3-fold magnification from 2008 to 2021. The median age was 8.8 years (Q1-Q3:4-14), hospital admissions had a median duration of 43 days (Q1-Q3:25-56) with a maximum of 113 days, and 2 deaths occurred. Heart disease was present in 88%(n=22) of patients which 95%(21/22) was congenital, 50%(11/22) had prosthetic material and of these, 45%(5/11) had mechanical valve. Moreover, 8% of patients had primary immunodeficiency disease. Only one patient did not have fever at presentation. Regarding diagnosis, 36% of patients had no vegetations in imaging exams. In 24% of cases, positron emission tomography was performed. Complications occurred in 44% of patients, with 32% having cerebral or pulmonary emboli. Regarding underlying organisms, Staphylococcus aureus (48%), epidermidis (16%), and streptococcus (16%) were the most frequent. There were no culture negative IE. The mean duration of antibiotic therapy was 6.8 weeks, and 32% were submitted to surgery.
Conclusions/Learning Points: The number of IE diagnoses increased over the years in our hospital. Streptococci are still described as the most prevalent aetiology but Staphylococci are known to becoming more frequent, as shown in our sample. Awareness of IE in patients with heart disease and implanted prosthetics material is crucial.

MICROORGANISMS AND ANTIMICROBIAL RESISTANCE OF HEALTHCARE-ASSOCIATED INFECTIONS ON THE PAEDIATRIC ENVIN-HELICS DATABASE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Ariadna Rigalos-Cases[1], Mireia Mor-Conejo[2], Jose Carlos Fernández[1], Raquel Garcia[1], Monica Balaguer-Gargallo[2], Sara Bobillo-Perez[2], María Slocker Barrio[3], Elena Fresan-Ruiz[2], Iolanda Jordan[4], Paediatric Envin-Helics Study Group[1]
[1]Hospital Sant Joan de Déu, Paediatrics Department, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Déu, Paediatric Intensive Care Unit, Esplugues de Llobregat, Spain, [3]Gregorio Marañón University Hospital, Paediatric Intensive Care Unit, Madrid, Spain, [4]Hospital Sant Joan de Deu, Pediatric Intensive Care Unit, Esplugues de Llobregat (Barcelona), Spain

Backgrounds: To describe the etiology and antimicrobial resistance pattern of device-associated infections in Paediatric Intensive Care Units (PICUs).
Methods: Multicentre, prospective and observational study based on the Paediatric-ENVIN registry in 25 PICUs. Device-associated infections were analysed in patients admitted for more than 24 hours, during a three-month period (April-June 2021).
Results: From 1986 patients 47 (2.4%) developed 182 infections, and 60 were device-associated: 12(20%) ventilator-associated pneumonia, 17 (28%) catheter-associated urinary tract infections, and 31(52%) catheter-related bloodstream infections/bacteriemia of unknown origin. The causative micro-organism was isolated in 51 infections. The most common microorganisms were Gram-negative bacteria (GNB) 35 cases (62.5%) followed by Gram-positive bacteria (GPB) 14 (25%) and 5 fungal (8.9%), without differences with 2013-2020.

GNBs	Escherichia coli (9; 16%) Pseudomonas aeruginosa (8; 14.3%) Klebsiella pneumoniae (4; 7.1%) Enterobacter cloacae (3; 5.3%) Stenotrophomonas maltophilia (3; 5.3%) Klebsiella spp (2; 3.5%) Serratia marcescens (2; 3.5%).
GBPs	Enterococcus faecalis (5; 8.9%) Staphylococcus aureus (4; 7.1%) Staphylococcus coagulase negative (3; 5.3%)
Fungal	Candida parapsilosis (2; 3.5%) Candida lusitaniae (2; 3.5%) Candida albicans (1 case; 3.5%)

Table 1. Most common isolated micro-organisms Eighty-eight patients (4.4%) were previously colonized by a multidrug-resistant microorganism (MRM). Thirteen patients (1.4%) had an MRM infection. No extended-spectrum β-lactamase or carbapenemase-producing microorganisms were isolated. One case of Pseudomonas aeruginosa was resistant to 4th generation cephalosporins, 2 to quinolones, and one to piperacillin-tazobactam. One Serratia marscescens was resistant to 3rd generation cephalosporins and aminoglycosides. GPB were sensitive to vancomycin and teicoplanin (except one case teicoplanin resistant).

Conclusions/Learning Points: The most frequently isolated microorganisms in device-associated infections in PICUs during the studied period were GNB, most of them being sensitive to standard antibiotics. This profile of micro-organisms remains similar to previous years.

BLOOD CULTURE CONTAMINATION IN CHILDREN: CHARACTERIZATION OF A CHALLENGING ISSUE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Montserrat Ruiz-García[1], Maria Navarro Aguirre[2], Anna Vilamala Bastarras[2], Judit Serra-Pladevall[2], Anna Besolí Codina[2], Neus Roca Saladrigues[1], Maria Vinyoles Tolosa[1], Marta Rodríguez González[1], Estel Castany Capdevila[1], Tània Cosp Gomà[1], Meritxell Torrabías Rodas[1]
[1]Hospital Universitari de Vic, Paediatrics, Vic, Spain, [2]Hospital Universitari de Vic, Microbiology Department, Vic, Spain

Backgrounds: The rate of contaminated blood culture (CBC) represents an individual healthcare quality indicator. The aim of this study is to describe the characterization of the patients with a CBC in our center.
Methods: We conducted a retrospective observational study, including all patients <15 years who had a blood culture performed in our center during 2021. We defined CBC as the growth of a commensal microorganism in a blood culture. We calculated the contamination rate and analyzed the clinical, epidemiological, and technical characteristics of CBC cases.
Results: CBC rate: from 459 cultures performed, 71 were contaminated (15.5%). The median age of the CBC group was 14 months and the median weight 11.5kg. 63.7% were male. The main organism identified was Coagulase-negative Staphylococci (80.6%), followed by Streptococcus sp (5.3%) and Bacillus sp (4.3%). Technical characteristics: 88.7% of CBC samples were collected at the Emergency Department. The highest rates of CBC ocurred in winter (December) and summer (June-July). Only 65.5% were taken during the fever peak. Clinical features and management: the main symptom to indicate the test was fever (89.2%), higher than 38ºC on the 72.3%. Only 42.6% had a blood test with bacterial infection signs according to Rochester criteria.
The 64.7% of the patients were admitted with a medium stay of 5 days. The 48% received antibiotic (26.1% intravenously). The leading diagnosis was viral infection (30%), followed by low respiratory tract infection (20.5%).
Conclusions/Learning Points: Our center has a higher rate of CBC (15.5%) than recommended by main guidelines (3%). Most of them were collected at the Emergency Department during work peak periods. A deeper study focused on the pediatrician healthcare team is needed to identify points of improvement and establish an effective intervention plan.

Lurie Children's Hospital of Chicago, Pediatrics, Chicago, United States of America, [4]Seattle Children's Hospital, Pediatrics, Seattle, United States of America, [5]Johns Hopkins University School of Medicine, Pediatrics, Baltimore, United States of America, [6]Children's Hospital at Montefiore, Pediatrics, Bronx, United States of America, [7]Merck & Co., Inc., Center For Observational And Real-world Evidence, Rahway, United States of America

Backgrounds: Although HA-RSV infections increase morbidity and healthcare utilization, surveillance strategies are not standardized. We assessed existing surveillance definitions in children with HA-RSV infections and calculated infection rates.
Methods: From October-April 2016-2017, 2017-2018, and 2018-2019, and from October 2020-November 2021, HA-RSV infections were identified in hospitalized children with new-onset respiratory symptoms and RSV-positive PCR tests >=72 hours after admission to six U.S. children's hospitals. We determined the proportion of children with HA-RSV infection who met the U.S. CDC's surveillance definitions for upper respiratory tract infections (URTI) and pneumonia (PNA). To compare HA-RSV infection rates over time, we calculated the respiratory viral infection transmission index (number of HA-RSV infections per 100 hospitalized community-acquired RSV infections).
Results: We identified 122 children with sporadic HA-RSV infections; no outbreaks were identified. Overall, 39% and 10% children with HA-RSV met URTI and PNA definitions, respectively. Infants =<12 months old were less likely to meet the URTI definition than older children (9.4% vs. 52.2%, p<0.001). The median transmission index was stable over time, but varied among sites (Table 1). Table 1: HA-RSV Infection Transmission Index during Three Respiratory Viral Seasons

Respiratory Season April-October	Median, (Interquartile Range, IQR) Transmission Index of HA-RSV per 100 C
2016-2017	0.79 (IQR 0.52, 1.73)
2017-2018	0.63 (IQR 0.46, 1.53)
2018-2019	1.06 (IQR 0.70, 1.70)

Conclusions/Learning Points: Revising surveillance definitions could improve detection of HA-RSV infections and likely other respiratory viral infections. Longitudinal trending of the transmission index could help assess HA-respiratory infection prevention efforts. Mitigation strategies for HA-respiratory viral infections should be prioritized to decrease patient harm. Funded by Merck Sharp & Dohme LLC, subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS EPIDEMIOLOGY - A 6-YEAR ANALYSIS IN A PEDIATRIC HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Luis Salazar[1], Joana Lima[1], Carla Teixeira[1], Alexandre Fernandes[1], Paulo Pereira[2], Laura Marques[1]
[1]Centro Materno-Infantil do Norte, Centro Hospitalar e Universitário do Porto, Infectious Diseases And Immunodeficiencies Unit, Paediatric Department, Porto, Portugal, [2]CHUPorto, Microbiology, Porto, Portugal

Backgrounds: Staphylococcus aureus (SA) is responsible for common infections, mainly in the skin/soft tissue, but it can occasionally cause more severe ones. Resistant SA, namely Methicillin-resistant Staphylococcus aureus (MRSA) have been arising, making clinical challenges to its approach.
Methods: Retrospective cohort study including pediatric patients with positive cultures for SA, performed at a tertiary pediatric center, from 2017 to 2022.
Results: There were 328 identifications of SA, obtained from 147 patients (51.7% males), with median age of 13 years-old (YO) (IQR 11-15 YO). Most patients (78.2%) presented chronic diseases, the most frequent being cystic fibrosis (21.1%). The majority of these samples were from respiratory secretions (64.3%), or from skin/soft tissue lesions(26.8%). About a third (35.6%) were associated to health-care settings. The most frequent therapeutic option was amoxicilin-clavulanate (21.6%). MRSA was detected in 21 samples (6.4%), collected from 18 patients (55.6% males), with median age of 14 YO (IQR 14-15 YO). Prevalence of chronic pathologies was 88.9%. Most samples were obtained from skin/soft tissue lesions (55.6%) and a third (33.3%) had a antibiotic use in the last 3 months. Vancomycin was the most frequent therapeutic option (41.2%). One case of health-care associated MRSA was also resistant to vancomycin.
Conclusions/Learning Points: MRSA prevalence in our sample was similar to previous studies in Portugal/Europe (~7%). MRSA detection was high in chronic diseases, and with recent antibiotic use. MRSA prevalence has been arising owing to decades of unnecessary antibiotic use, and should be considered when initial therapies are not effective.

HEPATITIS A: A CASE REPORT WITH IMPORTANT ANALYTICAL CHANGES – THE IMPORTANCE OF THINKING ABOUT THE MOST PREVALENT INFECTIONS OF IMMIGRANT'S ORIGIN COUNTRIES

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Filomena Santos, Inês Rodrigues, Artur Bonito Vitor, Julieta Morais
Centro Hospitalar do Médio Tejo, Serviço De Pediatria, Torres Novas, Portugal

Title of Case: Hepatitis A: a case report with important analytical changes – the importance of thinking about the most prevalent infections of immigrant's origin countries
Background: The incidence of hepatitis A infection has decreased with the improvement of sanitary conditions and accessibility to immunization. Nowadays, the majority of cases reported in Portugal are imported from other countries. The main transmission route is fecal-oral.
Case Presentation Summary: The authors report a case of a previous healthy 11-years-old boy, who recently emigrated from Angola, observed in the emergency department due to abdominal pain. Mentioned fever since the previous day to admission, was well malaise, anorexia, vomiting, jaundice and choluria with one day of evolution. The blood analysis demonstrated elevation of bilirubin (total bilirubin 15.64mg/dL; direct bilirubin 14.58mg/dL); alkaline phosphatase 405 IU/L; gamma-glutamyl transferase 251 IU/L; aspartate aminotransferase 4465 U/L; alanine aminotransferase 4581 U/L; lactate dehydrogenase 2390 IU/L; prothrombin time 23.20 seconds; activated partial thromboplasmin clotting time 33.2 seconds. Hepatitis A serologies positive for immunoglobin M and negative immunoglobin G. Acute hepatitis A infection was presumed. The treatment was supportive, focusing on symptoms control and fluid therapy. During hospitalization, the maximum total bilirubin was 44.46 mg/dL and direct bilirubin 33.42mg/dL. A mild hepatomegaly and bilateral pleural effusion was showed by abdominal ultrasound. On the 10th hospitalization day, the patient has been discharged with good clinical and analytical evolution.
Learning Points/Discussion: In recent years, the rate of immigration to Portugal has increased and with that the number of less frequent disorders, in particular infectious diseases. Given this endemic context, the authors agree that it is necessary to value the child's history and cover all diagnostic hypotheses, improving the quality of health care and limiting outbreaks.

COMPLIANCE WITH HAND HYGIENE IN PAEDIATRIC WARDS: A LITERATURE REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Murad Sawalha
THE HASHEMITE UNIVERSITY, Maternal, Child And Family Health Nursing, Zarqa, Jordan

Backgrounds: Healthcare Associated Infections (HCAI) are a major issue in clinical practice worldwide that increase patient morbidity and mortality. It is clear that healthcare professionals' compliance with hand Hygine (HH) is the cornerstone of reducing HCAI. However, it is commonly understood that non-compliance with HH remains and negatively impacts on paediatric patients by increasing their hospital stay and exposing them to the complications of infections. This literature review has been designed to explore and critically analyses existing studies on paediatric nurses' compliance with HH. This review focuses on understanding the factors that affect compliance with HH among paediatric nurses.
Methods: A systematic approach was used to review the literature. The literature as a whole is critically searched, through the use of inclusion and exclusion criteria. The search strategy was designed to retrieve studies from 2010 to 2020, using CINAHL, PsycINFO, Academic Search Premier, Medline, and Cochrane Database of Systematic Reviews.
Results: The literature suggests that the reliable use of HH can prevent transmission of HCAIs and improve patient and healthcare safety. However, compliance to HH among healthcare professionals is suboptimal. Existing studies have evaluated compliance rate and examined factors that influence compliance with guidelines in different clinical areas such as availability of sinks and hand washing agents, and insufficient time and personnel. However, these studies do not fully address the views and perceptions of paediatric nurses in relation to infection control practice, and the factors that affect their compliance with HH.
Conclusions/Learning Points: It is necessary that we have a thorough understanding of the factors influencing compliance with HH. It is especially important that we understand why paediatric nurses sometimes choose not to comply with HH. It is suggested here that further research is necessary to explore this issue.

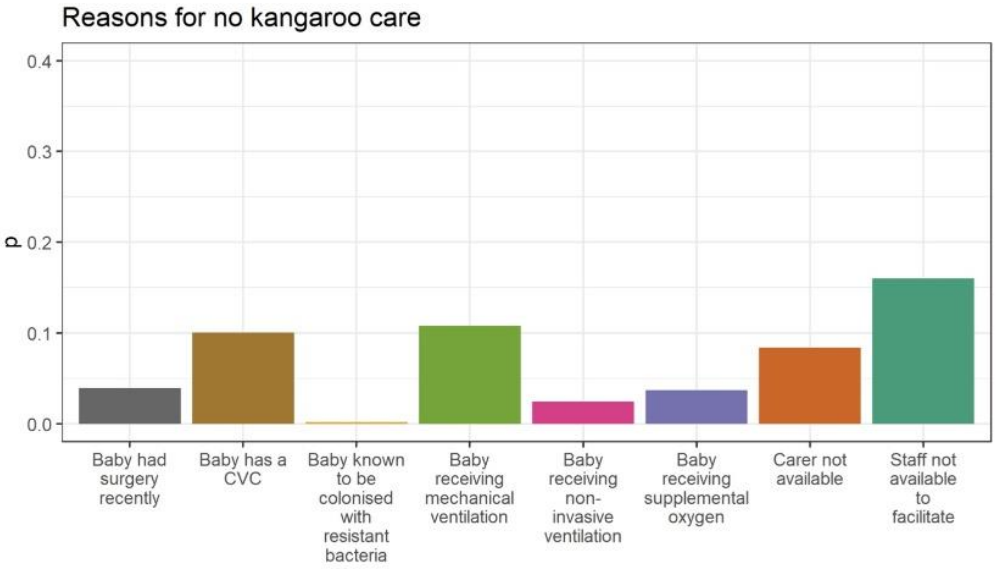
KANGAROO CARE AS A POTENTIAL INFECTION PREVENTION AND CONTROL (IPC) MEASURE IN NEONATAL INTENSIVE CARE UNITS

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Chloé Schlaeppi, On Behalf Of Neoipc
University of Basel Children's Hospital (UKBB), Paediatric Infectious Diseases, Basel, Switzerland

Backgrounds: Kangaroo care (KC) has been shown to be protective against hospital-acquired neonatal sepsis. One suggested mechanism includes the reduction in neonatal bacterial colonisation through skin-to-skin contact, as previously shown for Methicillin-Oxacillin-Resistant Staphylococcus aureus, thus leading to fewer invasive bacterial infections.
Methods: The NeoIPC colonisation assessment is an EU Horizon 2020 (No 965328) funded multi-centre study characterizing bacterial colonisation in hospitalised neonates. KC practices were captured for each participating centre in a standardized questionnaire which included general and neonatal-specific IPC aspects. In addition, actual receipt of KC was collected in up to 4 colonisation surveys for each participant.
Results: By December 2022, 16 European NICUs had completed the IPC questionnaire. 11/16 (69%) units indicated offering KC, mainly to mothers and fathers. Overall median duration of a session was 105 min (IQR 60-165min). Barriers to KC indicated by the units were mostly surgery (8/11), mechanical ventilation (5/11) and carer known to be colonised with resistant bacteria (3/11). Written guidance and training were available in 7/11 units. The colonisation assessment had 545 participants contributing to 1062 surveys. 307/545 (56%) received KC at some point during their hospitalisation up to the last survey they were included in. Overall in 1062 surveys, 510 participants (48%) had received KC in the 24 hours prior to the survey, these rates were similar in neonates < 32 weeks and >=32 weeks. Most common reasons for not receiving KC included presence of central lines, mechanical ventilation and unavailability of staff/carers (Figure
1).



Conclusions/Learning Points: While KC is potentially an effective neonatal specific IPC intervention, the results indicate that real-world implementation of KC varies strongly across European NICUs thus offering the potential to optimise this technique as an IPC strategy.

CANDIDA AURIS AS THE PREDOMINANT SPECIES CAUSING NOSOCOMIAL CANDIDEMIA IN NEONATES AND CHILDREN IN MUMBAI, INDIA

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Tanu Singhal, Sweta Shah, Pooja Thakkar, Shweta Ladi
Kokilaben Dhirubhai Ambani Hospital and Medical Research Institute, Paediatrics, Mumbai, India

Title of Case: Candida auris as the predominant species causing nosocomial candidemia in neonates and children in Mumbai, India
Background: Candida is an important cause of nosocomial blood stream infections in neonates/ children. C. auris is currently one of the most important candida species to reckon with.
Case Presentation Summary: This is a retrospective chart review of all newborns and children who had nosocomial candidemia between 2015-2022 at a private tertiary care hospital in Mumbai India. Identification and susceptibility testing was done on VITEK-2 (Biomerieux, France). Data related to risk factors, species distribution, antifungal susceptibility and outcomes were extracted and analysed. There were 19 patients who met the criteria for nosocomial candidemia during the study period. These included 9 newborns (age < 90 days), 7 infants (3-12 months) and 3 children. The risk factors were cardiac surgery in 12 children, prematurity in 3 and pediatric critical care admission in 4 patients. Candida auris was the commonest species accounting for 37% of the isolates (7 cases, 6 neonates) followed by C. parapsilosis (4 isolates), Candida tropicalis/ C. albicans/ Candida pelliculosa in 2 each and Candida famata/krusei in 1 each. The overall fluconazole and amphotericin B susceptibility rates of the candida isolates were 50% and 70% respectively. All the isolates were susceptible to the echinocandins. The C. auris isolates were uniformly resistant to fluconazole and voriconazole/ amphotericin B and flucytosine susceptibility was seen in only 2/7 isolates. CSF examination was abnormal in 1 baby with C.parapsilosis but none with C. auris. The overall crude mortality rate was 21% (4 deaths) while the mortality rate in those with C. auris candidemia was 30% (2/7 deaths).
Learning Points/Discussion: Emergence of C. auris in neonates/children poses significant challenges in treatment and infection control.

THE MOLECULAR EPIDEMIOLOGY OF METHICILLIN-SENSITIVE STAPHYLOCOCCUS AUREUS IN A NEONATAL INTENSIVE CARE UNIT

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Yudai Toyama, Hiroaki Tanaka, Tamaki Ikuse, Ken Hisata, Kaoru Obinata
Juntendo University School of Medicine, Department Of Pediatrics, And Adlescent Medicine, Tokyo, Japan

Backgrounds: Isolation rates of methicillin-resistant Staphylococcus aureus (MRSA) have decreased due to disseminated infection control in neonatal intensive care units (NICUs). In contrast, the frequency of isolation of methicillin-sensitive Staphylococcus aureus (MSSA) has not decreased. Therefore, the control of MSSA infection is expected to contribute to the improvement of neonatal prognosis in the future. We performed a molecular epidemiological analysis of isolated MSSA strains in the NICU and attempted to elucidate their genetic characteristics.
Methods: Samples were collected from neonates admitted to the NICU at Juntendo University Hospital, their parents, and healthcare workers of the NICU. DNA was extracted from the isolated MSSA, and whole genome analysis was performed using a next-generation sequencer. Multilocus sequence typing (MLST) and search of resistance genes and pathogenic genes were performed based on whole genome information.
Results: MSSA was detected in 69 cases, including 16 neonates. In the Clonal Complex classification by MLST, CC30 was the most common with 13 samples (12 strains), followed by CC45 with 11 samples (6 strains), and CC1 with 7 samples (4 strains). There was no obvious difference in distribution between neonates and adults. In the search for pathogenic genes, tst was detected in 17 samples and eta in 5 samples.
Conclusions/Learning Points: The distribution of major CCs was similar between adults and neonates, and no bias in resistance or toxin genes was observed. From this, it is speculated that MSSA isolated from neonates is not circulating in the NICU, but is transmitted to neonates from adults carrying MSSA. Additionally, many strains with the tst gene, which encodes a superantigen toxin (TSST-1) that causes neonatal TSS-like eruption (NTED), have been identified. This result suggests that more stringent infection control measures are needed in NICUs.

CENTRAL-LINE ASSOCIATED BLOODSTREAM INFECTIONS IN CHILDREN WITH INTESTINAL FAILURE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Madalena Von Hafe[1], Ana Melo[2], Raquel Marques[3], Susana Corujeira[1], Paula Guerra[1]
[1]Centro Hospitalar Universitário de São João, Pediatrics, Porto, Portugal, [2]Centro Hospitalar Universitário de São João, Pediatric Infectious Diseases And Primary Immunodeficiencies Unit, Porto, Portugal, [3]Centro Hospitalar Universitário de São João, Pediatric Cardiology, Porto, Portugal

Backgrounds: Children with intestinal failure (IF) on parenteral nutrition (PN) are at high risk for bacteremia. Pediatric central line–associated bloodstream infections (CLABSIs) cause morbidity and increased health care use.
Methods: A retrospective review of the medical records of pediatric patients who are or were dependent of home PN. Medical records were evaluated from January 2004 to December 2022.
Results: A total of 39 patients with IF were selected, 21 (53.8%) were male. After excluding the 5 deceased patients, 34 patients were included. Median age was 8 years (IQR 3-11). Sixty five percent of the patients had short bowel syndrome and 14.7% chronic intestinal pseudoobstruction. The median time on parenteral nutrition was 39 months (IQR 12-108), with a median number of CVC of 3.5 per patient (IQR 2-5.5). Each patient was hospitalized in our center an average of 1.5 times per year (IQR 1-2.25) with a median of 8,5 days (IQR 4-16). 79 CLABSIs were registered, with a ratio of 1.3 CLABSIs per 1000 days of catheter. 51% were caused by gram-positive bacterias, 47% were gram-negative and 2 fungal infections were recorded. The most prevalent bacteria isolated was Staphylococcus epidermidis (n=20), followed by Pseudomonas aeruginosa (n=10), Staphylococcus aureus (n=5) and Klebsiella pneumoniae (n=5). Antibiotics were adjusted to antibiotic susceptibility testing. Even though the number of patients with IF and CVC is increasing the percentage of infection per year is decreasing.
Conclusions/Learning Points: The diagnosis of CLABSIs is challenging and has a great impact on the quality of life of these patients. Although patients dependent of devices such CVC are increasing, education of CVC management with the practice of consistent guidelines is important to reduce CLABSIs.

A CASE OF TOXOCARIASIS IN AN 11 YEAR OLD GIRL IN URBAN AREA OF CENTRAL GREECE

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Kalliopi Tanou[1], Athanasios Michos[2], Ioanna Tassiou[1], Eleni-Ioanna Vourli[1], Sofia Makri[1], Anastasia Anastasiou-Katsiardani[1]
[1]GENERAL HOSPITAL OF VOLOS, Paediatric, VOLOS, Greece, [2]NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, Paediatric, ATHENS, Greece

Title of Case: A CASE OF TOXOCARIASIS IN AN 11 YEAR OLD GIRL IN URBAN AREA OF CENTRAL GREECE
Background: Parasitic nematodes of Toxocara are important zoonotic pathogens. The parasites are usually directly transmitted to the human host via the faecal-oral route causing toxocariasis. Toxocariasis can be associated with severe neural, ocular and visceral larva migrans disease.
Case Presentation Summary: An 11-year old girl presented with a 3 day history of abdominal pain, nausea and loose stools. On examination she was afebrile, with no abdominal tenderness. Laboratory tests revealed leukocytosis with eosinophilia (12400 eosinophils/ml), normal hematocrit and platelets, normal CRP and liver biochemistry and elevated IgE (1230 IU/ml). Parasitosis was suspected and chest x-ray and ophthalmologic examination were performed with no abnormal findings. On abdominal ultrasound marginally enlarged liver and spleen, as well mesenteric lymph nodes were found. She was started on oral mebendazole for a 3 day course. Serology tests were sent for echinococcus, toxocara spp, leishmania, cysticercus, trichinella and dirofilaria. Parasitology stool testing was negative. Serology testing initially was positive for echinococcus. Our patient was clinically well, asymptomatic on follow-up and blood eosinophilia was gradually improving on oral mebendazole. Serology tests were repeated twice with positive IgG and IgM antibodies (+3) for toxocara canis and negative for echinococcus. She had another 3-day course of mebendazole 15 days after the first. She had no relapse of symptoms and blood eosinophils were in normal range on follow-up.
Learning Points/Discussion: Toxocara is a worldwide human helminthiasis. The disease is mostly asymptomatic. In cases of eosinophilia toxocariasis should be included in the differential diagnosis. Serology tests can give false positive cross reactions with other parasites and need to be repeated and correlated to the clinical presentation.

ANALYSIS OF A SEROLOGICAL STUDY OF PERTUSSIS AMONG CHILDREN AND ADOLESCENTS IN THE REPUBLIC OF KAZAKHSTAN

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Lyazzat Yeraliyeva[1], Ainagul Kuatbayeva[2]
[1]National scientific center of phtisiopulmonology Ministry of Health of the Republic of Kazakhstan, Almaty, Kazakhstan, Deputy Director Of Clinical And Scientific Work, Almaty, Kazakhstan, [2]Branch Scientific and Practical Center for Sanitary and Epidemiological Expertise and Monitoring «National Center for Public Health» of the Ministry of Health of the Republic of Kazakhstan, Director, Almaty, Kazakhstan

Background: In 2018 over 151 000 cases of whooping cough were reported worldwide. In the Republic of Kazakhstan the incidence of whooping cough has always remained relevant. The incidence is recorded mainly among children under 14 years of age, whose share is 96–100% of the total incidence in certain years. It should also be noted that 82,9–96% of sick people are not vaccinated against whooping cough.
Methods: For the study included medical organizations in the cities of Aktobe, Karaganda, Taldykorgan, Shymkent. Participants aged 10–14 years who were hospitalized in children's hospitals and 15–18 years old who visited polyclinics were invited to participate in the study.
Results: Among 520 participants aged 10–14 years – 200 (38.5%) and 15–18 years – 320 (61.5%), including boys – 284 (54.6%), girls – 236 (45.4%). Just over half of the children (276 or 53.1%) also received the whooping cough vaccine at age 6. In biological blood samples of 17 participants (3.3%) antibodies of the IgA class were detected in 245 samples (47.1%) – antibodies of the IgG class. Of the 17 participants with IgA antibodies, 15 also tested positive for IgG. In total antibodies of the IgA and IgG classes were detected in 247 participants which amounted to 47.5%.
Conclusions/Learning Points: Thus an increase in whooping cough and a decrease in protective vaccine immunity among older age groups can be stated which raises concerns about transmission of the infection in the home to vulnerable children and the need to strengthen vaccination strategies.

EPIDEMIOLOGY OF CARBAPENEMASE-PRODUCING ENTEROBACTERALES COLONIZATION IN A PAEDIATRIC TERTIARY HOSPITAL IN CANADA

E-Posters Viewing
E-POSTER VIEWING: AS12. HEALTH ASSOCIATED INFECTIONS, INFECTION PREVENTION AND CONTROL

Stephanie Zahradnik[1], Mohsin Ali[2], Adriana Airo[3], Ana Blanchard[4], Sandra Isabel[3], Kayur Mehta[1], Laurie Streitenberger[5], Renee Freeman[5], Yvonne Yau[3], Aaron Campigotto[6], Manal Tadros[6], Michelle Science[1]
[1]The Hospital for Sick Children, Paediatrics, Division Of Infectious Diseases, Toronto, Canada, [2]Hospital for Sick Children, Infectious Diseases, Paediatrics, Toronto, Canada, [3]The Hospital for Sick Children, Microbiology, Toronto, Canada, [4]Hospital Ste Justine, Infectious Disease, Montreal, Canada, [5]Hospital for Sick Children, Infection Prevention And Control, Toronto, Canada, [6]Hospital for Sick Children, Division Of Microbiology, Toronto, Canada

Backgrounds: Infections caused by carbapenemase-producing Enterobacterales (CPE) are associated with high mortality rates and treatment is complicated by limited antibiotic therapy options. Guidelines recommend patient CPE screening and use of additional precautions for CPE-colonized patients to prevent transmission in healthcare settings. Knowledge of CPE epidemiology in hospitalized children is limited. We aimed to describe CPE colonization in a paediatric tertiary healthcare centre in Canada.
Methods: Hospital-wide point-prevalence CPE screens of inpatients were completed in April of 2017, 2019, and 2022. Families provided verbal consent. If CPE was identified in stool/rectal swab, medical charts were reviewed for history of travel or hospitalization outside of Canada.
Results: In 2017, specimens were obtained from 242 of 270 inpatients (89.6%). CPE was isolated in one patient (0.4%): with an OXA-48-like gene Escherichia coli. This patient had prolonged hospitalizations in Lebanon, where OXA-48 outbreaks have been reported. In 2019, specimens were obtained from 278 of 299 inpatients (93.0%). CPE were isolated in two patients (0.7%): both E. coli with OXA-48-like genes. These patients were Canadian born with histories of long-term travel to India the prior year. In 2022, 220 specimens were obtained from 236 inpatients (93.2%). CPE were isolated in two patients (0.9%). One carried NDM-positive E. coli and Klebsiella pneumoniae with OXA-48-like genes with prior hospitalization in Turkey. The other had NDM-positive E. coli and history of travel to Afghanistan and Pakistan.
Conclusions/Learning Points: This study highlights the importance of periodic CPE surveillance in Canadian paediatric hospitals. Identified risk factors included receiving healthcare or living outside Canada. T Targeted screening programs should include these risk factors to identify colonized patients and prevent transmission in hospital.

[1]Techinvention Lifecare Private Limited, Na, Mumbai -, India, [2]Techinvention Lifecare Private Limited, Research And Development, Mumbai, India, [3]Indian Institute of Science Education and Research, Biological Sciences, Bhopal, India, [4]Techinvention Lifecare Private Limited, Medical Affairs, Mumbai, India

Backgrounds: Therapeutic application of scFv antibodies can be a suitable alternative to costly full IgG monoclonal antibodies. Neutralization of different SARS-CoV-2 variants can be achieved by scFv antibodies isolated from antibody libraries constructed from convalescent plasma of COVID-19 recovered patients. The objective of this study was to evaluate the neutralizing activity of anti-SARS-CoV-2 scFv antibodies isolated from phage display antibody library against different SARS-CoV-2 variants.
Methods: Phage displayed antibody library was constructed from ten COVID-19 recovered patients of Indian origin. Biopanning was done against SARS-CoV-2 proteins viz. S1, S2, and RBD. Phage ELISA screened binders were evaluated for virus neutralizing assay by transducing spike pseudotyped virus to ACE2 + HEK293T cells and corelated with luciferase assay. Neutralizing activity of different scFv antibodies was investigated against SARS-CoV-2 wild-type and different variants. ACE2-IgFc microbody was used a positive control for neutralization assay. DNA sequencing of these scFv antibodies was performed to determine the novelty of CDRs.
Results: As a result of stringent biopanning and primary screening by phage ELISA, 15 scFv clones were identified as suitable candidates for DNA sequencing and based on novel CDR sequences, 7 were shortlisted for neutralization assay of SARS-CoV-2 (Wuhan-wild type, Alpha, Delta, and Omicron). Two clones were found to neutralize all 4 strains of SARS-CoV-2 and can be considered as suitable candidates for future therapeutic applications.
Conclusions/Learning Points: Neutralizing activity of Wuhan-wild type and SARS-CoV-2 variants (Alpha, Delta, and Omicron) was successfully demonstrated by two scFv antibodies isolated from phage displayed antibody library constructed from convalescent plasma of COVID-19 recovered patients from Indian population.

MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN: AN OVERVIEW

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Shoaa Aldhahri, Suzanne Kutbi
fakeeh hospital, Pediatric, jeddah, Saudi Arabia

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection was first identified in China in late 2019 and has quickly spread across the world, with subsequent epicenters being recognized in Europe and the U.S. As per the previous reports of SARS-CoV-2 infection, it was not seen very commonly in young children. This could be due to a lack of detection because of predominantly asymptomatic or mild disease in this age group. In the latter part of April 2020, a new syndrome in children and adolescents termed "multisystem inflammatory syndrome in children" (MIS-C) with likely relation to SARS-CoV-2 infection was first described.
Methods: Methodology: The review is a comprehensive research of PUBMED, Google Scholar, and WHO official page from the year 2005 to 2021.
Results: In a very short duration of time, a lot has been learned about MIS-C temporally associated with COVID-19; however, numerous uncertainties still exist. It is a rare disease and consists of a variable spectrum of symptoms and severity. It may have a turbulent course consisting of multiple organ failure and the need for intensive care. Causality with SARS- CoV-2 cannot be proven, but the temporality associated with COVID-19 is remarkable, emphasizing the importance of conducting serology and viral research.
Conclusions/Learning Points: Conclusion: In a very short duration of time, a lot has been learned about MIS-C temporally associated with COVID-19; however, numerous uncertainties still exist. It is a rare disease and consists of a variable spectrum of symptoms and severity. It may have a turbulent course consisting of multiple organ failure and the need for intensive care. Causality with SARS- CoV-2 cannot be proven, but the temporality associated with COVID-19 is remarkable, emphasizing the importance of conducting serology and viral research.

THE INFLUENCE OF COVID-19 PANDEMIC ON INFLUENZA IMMUNIZATION IN ALHASA REGION: CROSS-SECTIONAL STUDY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Mansoor Alnaim
King Abdulaziz National Guard Hospital, Family Medicine, Hofuf, Saudi Arabia

Backgrounds: Influenza vaccination is the primary control measure for severe complications caused by influenza viruses. Moreover, in the face of the COVID-19 pandemic, Saudi Arabia recommends vaccinating people at risk against influenza to minimise co-infection risk with SARS-CoV2. Therefore, this study aims to assess the Saudi population's knowledge, attitude, and practice toward influenza vaccination during the COVID-19 pandemic. Moreover, we evaluate the impact of the COVID-19 pandemic on seasonal influenza vaccination.
Methods: This cross-sectional study was conducted using an online survey in AlHasa region between March 2022 to Novmber 2022. Participants were invited to complete the questionnaire through a survey link sent to social media platforms.
Results: A total of 3240 participants were included in this study. Our data demonstrate a lack of practice, attitude, and knowledge, especially on the influenza virus's symptoms, viral transmission, and vaccine efficacy. Moreover, this study showed that the COVID-19 pandemic significantly impacted seasonal influenza vaccination in the AlHasa region population by 1.3-times compared to the previous years.
Conclusions/Learning Points: COVID-19 pandemic has increased the hesitancy of participants in influenza vaccination due to the lack of knowledge. As the pandemic of COVID-19 is fading, awareness campaigns are needed to encourage the public about the importance of receiving the influenza vaccine, especially for those at high risk each year.

FIRST-LINE TREATMENT OF MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN RELATED TO COVID-19 - A SYSTEMATIC REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Inês Alves[1], Ana Rita Faísca[2]
[1]Universidade da Beira Interior, Faculdade De Ciências Da Saúde, Portugal, Portugal, [2]Centro Hospitalar Universitário da Cova da Beira, Infecciologia, Covilhã, Portugal

Backgrounds: MIS-C associated with COVID-19 is a rare and severe complication, that usually occurs up to 4 weeks after of SARS-CoV-2 infection. Consensus has no been on the best treatment strategy has not yet been reached. The present review aims compare the outcomes of the currently most used treatment options: intravenous immunoglobulin (IVIG), corticosteroids and their combination.
Methods: This systematic review followed PRISMA 2020 guidelines. Initial search was conducted until december 2022, through EBSCOhost databases (including MEDLINE and Cochrane), as well PubMed. The algorithms used were constructed with strategically chosen MESH terms. Studies eligible for inclusion were randomized controlled trials, case-control and cohort studies of patients diagnosed according to WHO, CDC or RCPCH criteria and treated with either or both drugs. The included studies' quality of evidence and risk of bias were assessed using the Newcastle-Ottawa Scale and ROBINS-I tool, respectively.
Results: Of 445 papers identified in the search, 10 retrospective cohort studies were included. Of the five studies that used cardiovascular dysfunction as an outcome, four found that using a combined treatment as first-line therapy resulted in a significantly shorter time to recover from cardiovascular disfunction when compared to only IVIG. Concerning the subsidence of fever, four of five studies, that analysed this outcome, concluded it occurs more rapidly in patients on an initial treatment containing corticosteroids from the beginning.
Conclusions/Learning Points: Although most included studies suggest addition of corticosteroids to initial MIS-C treatment leads to better outcomes, we still found many disparities. Randomized controlled trials are needed to come to a clearer conclusion.

Backgrounds: Both statistically and clinically significant association between COVID-19 and KD was shown in many trials. Those cases were clinically similar to incomplete Kawasaki disease and that's why called Kawasaki-like syndrome (nowadays: COVID-19-associated Multisystem Inflammatory Syndrome in Children, MIS-C).
Methods: A retrospective analysis was performed of medical files in a period from July 2020 to January 2021. Sixteen patients were included.
The aim of our study is to analyze the clinical and laboratory data of patients with MIS-C treated in the Isolation Unit.
Results: The male-to-female ratio was 11 to 5. A definitive diagnosis of MIS-C was made among 15 patients. Only 1 out of 16patients has a negative test for COVID-19 antibodies(6.25%). Of 15(93.75%)patients presented to the clinic with a fever. Only one patient has no fever at presentation due to belated admission (9^{th}day of the disease). Of 14(87.5%) complained of rash, another 2 developed rashes during 2-3days of hospital stay. Enlarged lymph nodes were seen in 13 and conjunctivitis in 11patients at presentation but, later, the other 5patients had conjunctivitis too. Gastrointestinal symptoms like diarrhea and vomiting were reported among 5patients(31.25%). The results of laboratory investigations are depicted in Table 1 and Table

COVID-19 Ab	1,05	69.5	152.4	-	-	-	< 1

Blood cultures were negative(n=16). Cardiovascular involvement were totally reported in 10(62.5%)patients. IVIG was administered to 15(93.75%) patients, of 12(80%) with clinically good responses to therapy. Two of three IVIG-treatment-resistant patients were treated with Methylprednisolone pulse therapy and one with Infliximab. Dexamethasone was given to 15(93.75%), Aspirin to 16, and antibiotics to 9(56.25%)patients.

Conclusions/Learning Points: The absence of a rash cannot exclude COVID-19-associated MIS-C. High platelet levels were also seen among our patients during the last days of hospitalization. Low-dose Aspirin and surveillance is good measures for these patients.

TREATMENTS FOR PEDIATRIC COVID-19 IN ADMITTED CHILDREN IN BRAZIL. A THREE-YEAR FOLLOW UP

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

André Ricardo Araujo Da Silva[1], Jackson Miranda[1], Julia Cherene[1], Maria Vaz[1], Leonardo Pereira[1], Vitória Pires[1], Felipe Pittan[1], Clara Lopes[1], Cristiane Teixeira[2], Cristina Souza[3]
[1]Universidade Federal Fluminense, Materno Infantil, Niterói, Brazil, [2]Prontobaby Group, Infection Control Committee, Rio de Janeiro, Brazil, [3]Prontobaby, Infection Control Comittee, Niterói, Brazil

Backgrounds: Introduction/Aim: Despite of improving in pediatric COVID-19 care remains the necessity of analysis of treatments for admitted children in the “real life”, The aim of the manuscript is to describe treatments used in hospitalized children with confirmed COVID-19
Methods: We performed a temporal serie of confirmed pediatric COVID-19 cases. All children less than 18 years admitted in two pediatric hospitals of Rio de janeiro city, Brazil were included. We analysed the folowwing treatments: antimicrobials, corticosteroids, immunoglobulin and anticoagulants. A descriptive analysis was conducted.
Results: We analyse 333 patients, being 95/333 (28.5%) in 2020, 150/333 (45%) in 2021 and 88/333 (26.4%) in 2022. One-hundred twenty seven (38.1%) were younger than 2 years, 67/333 (20.1%) had between and 2 and 5 years, 70/333 (21%) had between and 5 and 10 years and 69/333 (20.7%) had between 10 and 18 years. One-hundred ninety (57.1%) were admitted in pediatric intensive care units and 143/333 (42.9%) in wards. At least one antimicrobial was prescribed in 282/333 (84.7%) patients being 262/333 (78.7%) of them antibiotics, two antimicrobials in 169/333 (50.8%), three or more antimicrobials in 108/333 (32.4%) children. Corticosteroids were prescribed in 142/333 (42.6%) children, imunnoglobulin in 19/333 (5.7%) patients, tocilizumab in 3/333 (0.9%) and anticoagulants in 7/333 (2.1%) patients. Of 88 children admitted in 2022, 82 (93.25) didn’t receive any dose of COVID-19 vaccine.
Conclusions/Learning Points: Antimicrobials were extensively used for children with COVID-19 in this temporal serie, especially antibiotics, probably to initial difficulty to diffentiate associated bacterial infections. Corticosteroids were prescribed for almost half of patients.

EPIDEMIOLOGY AND CHARACTERISTICS OF MISC IN CYPRUS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Maria Koliou-Mazeri[1], Athina Aristidou[2], Elia Avraam[3], Margarita Onoufriou[3]
[1]University of Cyprus, Medical School, Nicosia, Cyprus, [2]Archbishop Makarios Hospital, Paediatrics, Nicosia, Cyprus, [3]Archbishop Makarios Hospital, Paediatrics, nicosia, Cyprus

Title of Case: EPIDEMIOLOGY AND CHARACTERISTICS OF MISC IN CYPRUS
Background: Multisystem inflammatory syndrome in children(MISC) is a rare but severe complication of SARS-CoV2 infection in children, and typically occurs 2-6 weeks after acute infection. MISC can present with three main distinct phenotypes: Kawasaki-like disease, cases admitted with shock and cases with fever and inflammation. The aim of this study is to evaluate the burden and clinical characteristics of MISC in Cyprus.
Case Presentation Summary: We reviewed the medical records of patients, younger than 16-year-old admitted to hospitals in Cyprus with MISC, that fulfilled the criteria of Center for Disease Control US between May 2020 and May 2022. 34 children were hospitalized with MISC, during the 2 year-period. The incidence of MISC was higher during the domination of Alpha(55/100000) and Delta(51/100000), in contrast to Omicron variant(16/100000). The median age of children was 5 years(3 months to 13,6 years). MISC occurred equally in males and females. Only one adolescent had vaccination history. Despite no death, 26% of children required intensive care. Children who presented with shock(38%), had a median age 8 years. Patients with the phenotype of fever and inflammation(32%) had a similar median age. Kawasaki-like phenotype(29%), had a median age 2,5 years-old. In acute phase, 38% of children developed coronary artery dilatations, 24% mitral valve regurgitation and 12% affected myocardial function. Temporary acute kidney injury was reported in 3 cases. All the children received treatment, most of them(56%) IVIG and low dose prednisolone for initial treatment.
Learning Points/Discussion: The epidemiological and clinical features of MISC in Cyprus is in accordance with studies in other European countries and USA. MISC remains a rare but possibly life-threatening complication of covid-19 in children. Vaccination appears to be protective in many studies.

ATTITUDES OF PARENTS AGAINST COVID19 VACCINATION IN CYPRUS.

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Athina Aristidou[1], Maria Koliou-Mazeri[2]
[1]Archbishop Makarios Hospital, Paediatrics, Nicosia, Cyprus, [2]University of Cyprus, Medical School, Nicosia, Cyprus

Backgrounds: Covid-19 vaccines have been approved for children ≥12 and 5-11 years since September 2021 and December 2021, respectively. However, many parents still hesitate to vaccinate their children against covid-19. The aim of this study is to investigate the parents' attitudes to offer the vaccine to their children.
Methods: This is a cross-sectional study, in which questionnaires were distributed to parents whose at least one child was 5 to 18 years, and who visited a primary care paediatrician's office across all regions of Cyprus. Data on demographic characteristics and parental beliefs for routine and covid-19 vaccinations were collected.
Results: A total of 600 questionnaires were completed. 80.8% of participants were female, and the majority were 30-49 years (85.1%). 45.4% of participants were educated at bachelor and 32.9% at master/doctoral level. 30.2% of parents have already vaccinated their children, 9.3% intended to do so, 24.2% have not decided yet and 35.6% refused to offer the vaccine. The main reason for which parents were not willing to vaccinate their children, were concerns regarding related adverse events (68%). However, the history of recent covid-19 infection of the child was the most common reason which positively affected parents who intended to vaccinate but they have not done yet. The top factors which affected parents' decisions against vaccination were the internet (41.3%) and social media (20.6%), whereas the majority of participants whose children have been vaccinated answered that their decisions were affected by their paediatrician (65.2%).
Conclusions/Learning Points: Vaccination in childhood is a very important tool which protects children from acute disease and its complications. According to our findings, one third of parents in Cyprus vaccinated their children, whereas the majority were against or have not decided yet.

THE ASSOCIATION OF NEONATAL SARS-COV-2 ANTI-SPIKE PROTEIN RECEPTOR-BINDING DOMAIN ANTIBODIES AT DELIVERY WITH INFANT COVID-19 INFECTION UNDER AGE 6 MONTHS: A PROSPECTIVE COHORT STUDY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Liat Ashkenazi-Hoffnung[1,2], Lital Oz-Alkalay[3]
[1]Schneider Children's Medical Center, Departement Of Day Hospitalization, Petah Tikva, Israel, [2]Tel Aviv University, Sackler Faculty Of Medicine, Tel Aviv, Israel, [3]Schneider Children's Medical Center, Pediatrics A, Petah Tikva, Israel

Backgrounds: To assess the association between neonatal SARS-CoV-2 antibody level at delivery and infant COVID-19 infection under age 6 months, and to identify predictive factors for neonatal antibody level at delivery.
Methods: In a prospective observational study, conducted between September 2021 and mid-February 2022, cord blood sera were tested for SARS-CoV-2 anti-spike receptor-binding domain antibodies after maternal BNT162b2 vaccination or infection. Infants were followed for 6 months for COVID-19 infection.
Results: Sixty-seven mother-infant dyads were enrolled; nine did not meet eligibility criteria. Of the 58 included, 6-month follow-up data were available for 57. The mean log SARS-CoV-2 anti-spike antibody level at delivery was lower among infants who were COVID-19-positive versus negative during follow-up (3.41±0.74 AU/mL, n=12 vs 3.87±0.84 AU/mL, n=46, p=0.036); a log titre ≥4.07 AU/mL (11,750) at delivery was associated with a significantly lower likelihood of infant infection [OR 0.54 (95%CI: 0.32, 0.90), p=0.018]. A spline curve model showed a linear decrease in antibody levels when the last dose was administered at ≤30 weeks' gestation (50 days before delivery), after which the antibody levels increased (R^2=0.50). In multivariate analysis, more vaccine doses, prior maternal infection and last administered dose at ≥31 weeks' gestation were associated with higher antibody level at delivery.
Conclusions/Learning Points: Higher anti-spike antibodies at delivery were associated with decreased risk for COVID-19 infection at age <6 months; the antibody level decreased linearly when the last dose was administered at ≤30 weeks' gestation. Future research should assess the effectiveness of a second booster during pregnancy against infant infection.

TUBERCULOUS OSTEOMYELITIS IN A PATIENT WITH FORMER HISTORY MIS-C

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Adrian Papa[1], Oana Falup-Pecurariu[2,3], Denisa Atanasiu[3]
[1]Children's Clinic Hospital, Paediatric Surgery, Brasov, Romania, [2]Transylvania University, Faculty Of Medicine, Brasov, Romania, [3]Children's Clinic Hospital, Paediatrics, Brasov, Romania

Title of Case: Tuberculous osteomyelitis in a patient with former history MIS-C
Background: Extrapulmonary tuberculosis in children tends to be severe, while in infants it is rarely described. Due to the late diagnosis, correct treatment is delayed, and there is a high mortality rate.
Case Presentation Summary: We report a case of an 8-month-old infant, with a former history of MIS-C, admitted at the Childrens Clinic Hospital, Brasov, Romania for fever with an onset of 2 days before admittance. Physical examination revealed a lump on the left thigh. The ultrasound of the soft-tissues shows a 3/3 cm abscess in the left thigh, while CRP=35.91 mg/dl (N=0-1 mg/dl). Surgical drainage was performed with aspiration, culture and testing for TB being requested. Patients evolution was initially favorable, with CRP=16.7 mg/dl. His general condition worsened, with an increase in CRP=36.05 mg/dl, while chest x-ray showed a typical image for TB. CT examination revealed multiple osteolytic lesions, with a suggestive aspect for bone septic dissemination, left thigh abscess, and bilateral pulmonary septic dissemination. Drain tube was placed at the level of the bone abscess in the left iliac wing after surgery. Cultures came positive for TB. Mixed pulmonary and bone tuberculosis was diagnosed. He received the first line TB treatment (HRZE scheme) with complex therapy. Three weeks later, he developed a pathological fracture at the left humerus. The patient worsened respiratory acidosis and oro-tracheal intubation mechanical ventilation were initiated, but he presented cardiac arrest and died.
Learning Points/Discussion: We present a case report of disseminated TB at an infant 8 month old with previous history of MIS-C.

THE CALCULUS OF RISK: PARENTAL PERSPECTIVES AND DECISION-MAKING ON SARS-COV-2 VACCINES FOR THEIR CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Anushka Ataullahjan[1,2], Pierre-Philippe Piche-Renaud[3,4], Elahe Karimi-Shahrbabak[5], Sarah Abu Fadaleh[5], Costanza Di Chiara[4], David Avelar Rodriguez[4], Shaun Morris[3,4,5,6]
[1]University of Toronto, Social And Behavioural Health Sciences,dalla Lana School Of Public Health, Toronto, Canada, [2]Western University, Faculty Of Health Sciences, London, Canada, [3]University of Toronto, Department Of Pediatrics, Faculty Of Medicine, Toronto, Canada, [4]Hospital for Sick Children, Division Of Infectious Diseases, Toronto, Canada, [5]Hospital for Sick Children, Centre For Global Child Health And Child Health Evaluative Sciences, Toronto, Canada, [6]Dalla Lana School of Public Health, Division Of Clinical Public Health And Centre For Vaccine Preventable Diseases, Toronto, Canada

Backgrounds: Increasing the uptake of SARS-CoV-2 vaccine in children presents unique challenges. Understanding what shapes parental decision-making to vaccinate their children can provide important insights into vaccine hesitancy to ultimately optimize vaccination programs and campaigns. We performed a qualitative study to understand what influenced parents' decision-making on SARS-CoV-2 vaccination for their child(ren).
Methods: We conducted a qualitative study that included online focus group discussions (FGDs) with caregivers of children aged 5-11 years. Data was collected between July 26th to November 8th, 2022. A total of seven FGDs were conducted. The FGDs were audio-recorded and transcribed verbatim. Thematic analysis was conducted by the first author, and peer debriefing was used to ensure methodological rigor.
Results: Findings revealed that both parents of vaccinated and unvaccinated children employed language of cost-benefit analysis to inform their decision-making. For parents of unvaccinated children, the perception of the risk posed by COVID-19 to their child was not considered as harmful compared to potential vaccine side effects. Parents of vaccinated children were concerned about the health of family members, decreasing the risk of spread in the community and the potential risk of long COVID-19 in their child. Participants also perceived a lack of transparency from the government and public health agencies, highlighting inconsistent messaging which had fractured their trust in COVID-19-related recommendations and mandates.
Conclusions/Learning Points: Our results point to the need for clear and accessible evidence about the benefits of vaccines, the risk of COVID-19, and further transparency of what is underlying shifting in messaging as the science evolves.

Backgrounds: The long-term persistence of symptoms after the acute phase of COVID-19 has been observed also in the pediatric population. In accordance with the definitions provided by WHO and CDC, long-COVID consists of symptoms occurring or persisting after 3 months from the infection and lasting for at least 2 months. Long-term neurological symptoms have been observed in 80% of cases. The aim of the study was to describe the clinical features of pediatric patients affected by long COVID with neurological manifestations.
Methods: This prospective multicenter study enrolled patients aged less than 17 years with a previous confirmed SARS-CoV-2 infection. Clinical manifestations were investigated using a previously validated questionnaire at median time-points of 2.4 (range 2.0-2.9), 5.4 (range 5.0-5.9) and 8.4 (range 8.0-8.8) months after the infection. The first survey was conducted during a medical examination.
Results: The study enrolled 925 patients and 252 (27.2%) presented at least one neurological symptom in the first 3 months. Prevalence of neurological symptoms at 6 and 8 months was 33.7% and 28.2%, respectively. Patients reporting neurological symptoms were significantly older (9.7 ± 3.3 vs 7.4 ± 4.3 years; $p<0.001$), more often female (57.5% vs 44.3%; $p< 0.001$) and more frequently affected by comorbidities (44.0% vs 34.9%; $p=0.01$). Patients who later developed neurological forms of long COVID experienced more frequently headache (56.8% vs 32.5%; $p<0.001$) and "cognitive fog" (3.6% vs 0.3%; $p<0.001$) during the acute phase. Headache and impaired concentration were the main symptoms reported in all evaluations.
Conclusions/Learning Points: Neurological symptoms involve ¼ of children with long COVID. The main factors associated with the onset of neurological forms of long-COVID are the presence of comorbidities and the occurrence of neurological symptoms during the acute phase.

PV0905 / #2227

COMPARISON OF CLINICAL CHARACTERISTICS OF ADULT AND PEDIATRIC PATIENTS AFFECTED BY LONG COVID AND EVALUATION OF AGE AND GENDER AS ASSOCIATED RISK FACTORS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Giovanni Autore[1], Matteo Puntoni[2], Susanna Esposito[3], Laura Patrizi[2], Chiara Palo[2], Michela Deolmi[3], Greta Ramundo[3], Valentina Fainardi[1], Francesca Cusenza[3], Caterina Caminiti[2]
[1]Pediatric Clinic, University of Parma, Medicine And Surgery, Parma, Italy, [2]Medicine and Surgery, University of Parma, Clinical And Epidemiological Research Unit, Parma, Italy, [3]Pediatric Clinic, Medicine And Surgery, University Of Parma, Parma, Italy

Backgrounds: Long COVID is defined as symptoms occurring or persisting 3 months after the infection and lasting for at least 2 months and has been observed in both adult and pediatric patients. The pathophysiological mechanisms and predisposing factors are still poorly understood. The aim of the study was to describe and compare the clinical characteristics of adults and children affected by long COVID and to investigate the role of age and gender.
Methods: This study analyzed data from two independent prospective cohorts of adult and pediatric patients with prior confirmed SARS-CoV-2 infection. The adult cohort consisted of patients hospitalized while pediatric patients were enrolled regardless of the severity of the infection. Clinical data collection was performed using adult- and child-specific versions of previously validated questionnaires. The mean time points of the surveys were 2.5-3.3 months, 5.4-6.9 months, and 8.4-9.9 months in the two cohorts.
Results: The study enrolled 425 adults and 925 children. Overall, adults experienced at least one symptom more frequently than children (62% vs. 85%; p<.001), with no significant differences between males and females but with a clear association with increasing age (0-5 years: 59%; 6-11 years: 64%; 12-50 years: 71%; > 50 years: 85%, p<0.001). Analyzing age subgroups, female gender represents a significant protective factor for children aged < 5 years (HR: 0.64; 95%CI: 0.45-0.91, p=0.012) and a risk factor in patients aged 12-50 years (HR: 1.39; 95%CI: 1.04-1.86; p=0.025).
Conclusions/Learning Points: The clinical manifestations of long COVID in childhood are overall less frequent than in adulthood. Increasing age represents a significant risk factor while the role of the female gender seems limited to patients aged 12-50 years, probably due to specific hormonal factors.

A RETROSPECTIVE REVIEW OF PAEDIATRIC COVID-19 ADMISSIONS TO AN IRISH TERTIARY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Amir Bachari[1], Sheiniz Giva[2], Cilian Omaoldomnaigh[2], Patrick Gavin[2]
[1]Royal College of Surgeons in Ireland, Department Of Medicine, Dublin, Ireland, [2]Children Health Ireland Crumlin and Temple Street hospitals, Infectious Disease And Immunology, Dublin, Ireland

Backgrounds: While children are considered as susceptible to SARS-CoV-2 infection as adults, they reportedly constitute a small proportion of COVID-19 hospital admissions. We aimed to characterize COVID-19 admissions to a tertiary hospital in Dublin, Ireland.
Methods: Paediatic admissions to Children's Health Ireland (CHI) Temple Street, tested for SARS-CoV-2 from March 2020 to December 2022 were identified using an electronic hospital enquiry database. Patients >18years old or with incomplete data were excluded. Data on demographics, presentation (symptomatic/asymptomatic), presenting complaint, ventilation requirement, and length of stay (LOS) were collected and analysed using Jamovi and Microsoft Excel. Symptomatic patients were defined as SARS-CoV-2 PCR test positive AND ≥ at least one COVID-19 defining symptom or identification of COVID-19 as causative by the admitting paediatrician.
Results: A total of 3761 paediatric admissions to CHI Temple Street were tested for SARS-CoV-2 over the 33-month study. 365 (9.7%) tested positive and 2659 (89.1%) negative for SARS-CoV-2. 252 (69.6%) SARS-CoV-2 positive admissions were <6years of age, with a primarily (172, 47.5%) <1year age. Among positive cases, male (56.2%) and female (43.8%) presentations were similar. 244 (68%) SARS-CoV-2 positive admissions were symptomatic: respiratory symptoms (128, 52.5%), isolated fever (48, 9.6%) and GI symptoms (30, 12.3%). Median LOS of SARS-CoV-2 positive admissions was 2 days (IQR 1, 6); median LOS was prolonged in 10-12 year olds (5.5 days, IQR 1.25, 10). Median LOS was longer in asymptomatic SARS-CoV-2 positive cohort (3 days, IQR 1-11.5). 51 (20.9%) symptomatic and 10 (8.4%) asymptomatic patients required ventilation.
Conclusions/Learning Points: In keeping with international experience, symptomatic SARS-CoV-2 cases constituted a relatively small proportion of total paediatric admissions to our single tertiary centre during the pandemic. In additon, the majority presented with respiratory symptoms and/or isolated fever.

CLINICODEMOGRAPHIC PROFILE AND OUTCOME OF NEWBORNS BORN TO COVID-19 CONFIRMED MOTHERS IN A TERTIARY GOVERNMENT HOSPITAL IN BATAAN FROM AUGUST 2020 TO SEPTEMBER 2021

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Cristina Marie Barruga, Lorraine Marie Item, Glenn Tolentino, Suzette Perfecto
Bataan General Hospital and Medical Center, Pediatrics, Balanga City, Bataan, Philippines

Backgrounds: Little is known about the impact of COVID-19 virus on vulnerable population like pregnant women and their fetuses and newborn. This study aimed to determine the clinical and demographic characteristics, and outcome of newborns of COVID-19 confirmed mothers.
Methods: All charts of newborns born to COVID-19 confirmed mothers at a tertiary government in Bataan from August 2020 to September 2021 were reviewed from electronic medical record. The following data were collected: demographic characteristics, clinical profile as to manner of delivery, APGAR score, birthweight, age of gestation, appropriateness of weight based on gestational age, signs and symptoms and initial laboratory evaluation. Length of hospital stay, disposition, associated complications and mortality rate were also documented.
Results: Majority were delivered via NSD (64.3%), term (92%), birthweight more than 2,500grams (84.9%) and good APGAR score (97.7%). Only 4.5% were symptomatic presenting with difficulty of breathing and vomiting. COVID-19 RT PCR results done at 24th and 48th hour of life showed that majority (99%) tested negative, however three (0.7%) and four (0.9%) revealed positive results respectively but asymptomatic. Hemoglobin, leukocyte level, CRP, AST, ALT and chest xray were requested mostly revealing normal results. COVID-19 protocol continued to evolve leading to decrease of tests requested for these newborns. Median length of stay was 5 days. Majority (9.5%) of comorbidities was neonatal hyperbilirubinemia. Eight newborns succumbed to death of which, three (30%) was due to respiratory distress syndrome. Vast majority (98.9%) of mothers presented with mild symptoms but two mothers with concomitant disease expired and were categorized as severe COVID-19 infection.
Conclusions/Learning Points: Newborn outcomes were affected by underlying illness rather than degree of COVID-19 infection. Perinatal transmission is greatly reduced with strict adherence to infection prevention measures.

SARS-COV-2 INFECTIONS AMONG CHILDREN AND STAFF IN 69 DAY-CARE CENTERS DURING PERIODS OF DIFFERENT TEST CONCEPTS IN THE COVID-19 PANDEMIC IN GERMANY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Jesper Bendig[1], Géraldine Engels[1], Viktoria Rücker[2], Johannes Forster[3], Monika Kraft[4], Barbara Finkenberg[5], Peter Heuschmann[2,6], Christoph Härtel[1], Oliver Kurzai[3,7], Andrea Streng[1], Johannes Liese[1]
[1]University Hospital Wuerzburg, Department Of Pediatrics, Würzburg, Germany, [2]University of Wuerzburg, Institute Of Clinical Epidemiology And Biometry, Würzburg, Germany, [3]University of Würzburg, Institute Of Hygiene And Microbiology, Würzburg, Germany, [4]City of Wuerzburg, Youth, Family And Social Department, Würzburg, Germany, [5]City and District Wuerzburg, Health Department, Würzburg, Germany, [6]University Hospital Wuerzburg, Clinical Trial Center Wuerzburg, Würzburg, Germany, [7]Hans-Knoell-Institute, Leibniz Institute For Natural Product Research And Infection Biology, Jena, Germany

Backgrounds: Closures of day-care centers (DCC) were frequently used non-pharmaceutical interventions during the COVID-19 pandemic. We analyzed SARS-CoV-2 infections and associated closures in DCC during periods with or without mandatory SARS-CoV-2 surveillance testing.
Methods: From October 2020 to January 2022, we collected data on DCC closures due to SARS-CoV-2 infections among children and childcare workers (CCW) at 69 DCC in Würzburg, Germany. SARS-CoV-2-infections of children and CCW, the number of secondary infections (SI), the number of closures and the applied test concept were recorded.
Results: The 69 DCC comprised a total of 4750 children and 814 CCW. During the 15-months observation period from October 2020 to December 2021 (period without mandatory testing) there were 104 (2.2%) infections in children and 56 (6.9%) in CCW, corresponding to an average of 11 infections/month. These resulted in 89 closures with 0-11 SI (Median 0, IQR 0-1) including 57 closures without SI. From January 2022 to beginning of February 2022 (period with mandatory testing) there were 260 (5.5%) infections in children and 95 (11.7%) in CCW with 36 associated closures with 0-39 SI (Median 5, IQR 0-16); this corresponded to approximately 284 infections/month. During mandatory testing, no differences regarding the proportion of closures (4/7 vs. 32/62) or median of SI (4 vs. 5) were observed between DCC applying pooled PCR-tests (7 DCC) or rapid-antigen-tests (62 DCC).
Conclusions/Learning Points: Infection rates in DCC children were lower than for CCW. Before January 2022, only few SARS-CoV-2 infections were detected, followed by a 26-fold increase in SARS-CoV-2 infections and associated DCC closures, presumably due to the emergent, more infectious omicron variant. The applied mandatory SARS-CoV-2 surveillance method had no impact on DCC closure rate or number of SI.

MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN (MIS-C) DUE TO COVID-19 WITH SEVERE DENGUE PRESENTING AS SEVERE LEFT VENTRICULAR DYSFUNCTION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Deepak Bhat[1], Gurdeep Singh Dhooria[2], Shruti Kakkar[2]
[1]DAYANAND MEDICAL COLLEGE LUDHIANA, Pediatrics, LUDHIANA, India, [2]DAYANAND MEDICAL COLLEGE, LUDHIANA, PUNJAB, INDIA, Pediatrics, Ludhiana, Punjab, India

Title of Case: MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN (MIS-C) DUE TO COVID-19 WITH SEVERE DENGUE PRESENTING AS SEVERE LEFT VENTRICULAR DYSFUNCTION
Background: Multisystem inflammatory syndrome in children (MIS-C) associated with COVID 19 , has many manifestations similar to dengue.Like both type of infections may have fever, erythematous rash, vomiting, abdominal pain and shock.Timely identification as well as management is often a challenge.
Case Presentation Summary: A 5 year old child was brought to our hospital emergency with complaints of fever and pain abdomen for last 4 days,vomiting,bodyaches and congestion of eyes for 2 days.On examination child was lethargic with cold peripheries and a prolonged capillary refill time.Her vitals were : pulse rate of 138/mt,respiratoryrate of 38/mt and a blood pressure of 80/60 mmHg.Child was managed initially as a case of hypotensive shock with a possibility of MIS-C.Laboratory investigations revealed a WBC of 7600/dl with 87.2% polymorps and 7.1% lymphocytes and a platelet count of 560000/dl.D-Dimer levels were greater than 1000ng/ml,CRP of 288mg/L,ferritin of 390 ng/ml,IL-6 of 5000 pg/ml.Anti SARS COV-2 antibody levels were 106.8.2D echocardiography revealed an ejection fraction of 22 % with normal coronaries.Patient was given a single 2gm/kg dose of intravenous immunoglobulin along with a 3 days pulse therapy with inj methylprednisolone.Child became afebrile in 48 hours .However the platelet counts started falling to a low of 28000/dl.Suspecting dengue fever,dengue serology was done which subsequently came out to be positive.Progressive D-Dimer levels also showed a falling trend and repeat echocardiography done showed improved left ventricular function.
Learning Points/Discussion: Covid 19 infection although not a big problem in children but MIS-C poses a diagnostic as well as management challenge in children.As dengue infection is more prevalent in India and many features overlap with MIS-C,managing such coinfections becomes more problematic.

ATAXIA IN A CHILD WITH COVID-19: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Martin Brizuela, Julieta Chalup, Romanette Hurtado Latapiat, Fernanda Ponzio, Sandra Barreiro
Hospital General de Agudos Velez Sarsfield, Pediatrics, Buenos Aires, Argentina

Title of Case: Ataxia in a child with COVID-19: a case report
Background: SARS-CoV-2 confirmed cases could have neurological symptoms and complications. Some common disorders related to CNS are encephalomyelitis- like changes, myelitis and cranial nerve enhancement.
Case Presentation Summary: A 10-year-old boy, previously healthy, with complete vaccinations according to the Argentinian immunization schedule, is taken to the emergency room due to a one-day history of gait disturbance. No medication or toxins exposure. He had not received any vaccinations in the previous month. He was afebrile (36.5°), with normal vital signs. All cranial nerves were intact, and there was no speech or sensory dysfunctions. Muscle tone, strength, and deep tendon reflexes were normal. Cerebellar examination revealed impaired finger to nose, heel to shin, and rapid alternative movements. Gait was ataxic and he could not walk without help. Laboratory tests: WBC 7,800 (70% neutrophils, 22% lymphocytes), liver enzymes, renal functioning, inflammatory markers including erythrocyte sedimentation rate and C reactive protein were normal. Toxics in urine, amphetamines, barbiturates, benzodiazepines, cocaine, phencyclidine, marijuana, methylenedioxymethamphetamine, morphine, opiates were negative. Nasopharyngeal swabs with antigen and PCR-SARS-CoV-2 were positive. A lumbar puncture was performed, and CSF with glucose 67 mg/dl, proteins <10 mg/dl, leukocytes 4/ul, 100% mononuclear was obtained. Bacteriological culture and viral PCR for enterovirus, varicella zoster virus and SARS-CoV-2 were negative. Brain MRI with gadolinium showed no pathological finding. The patient was diagnosed with ataxia associated to COVID-19 according to the result of the test performed and the neurologist criteria. He was hospitalized for 4 days, with good clinical evolution, presenting a clear improvement in his admission condition.
Learning Points/Discussion: COVID-19 causes neurological manifestations such as ataxia in children. Workout to exclude this infection is necessary in patients with march disturbances.

CLINICAL AND LABORATORY CHARACTERISTICS OF COVID-19 AND INFLUENZA PATIENTS 2021/2022

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Sigita Burokiene, Ausra Steponaviciene, Inga Ivaskeviciene, Indre Staceviciene, Daiva Vaiciuniene, Augustina Jankauskiene
Vilnius University, Clinic Of Children's Diseases, Faculty Of Medicine, Vilnius, Lithuania

Backgrounds: Seasonal epidemics of respiratory viruses cause significant morbidity among children worldwide. The aim of the study was to compare the most important clinical and laboratory characteristics and outcomes of COVID-19 and influenza pediatric patients.
Methods: A single-center observational study was performed at the Pediatric emergency department in Vilnius University Hospital Santaros Klinikos from 1 October 2021 to 30 April 2022.
Results: In total 5127 children with respiratory symptoms were tested for SARS-CoV-2 and influenza A/B by reverse transcription-polymerase chain reaction (RT-PCR) tests. We found 997(19.4 %) SARS-CoV-2-positive and 827(16.1 %) influenza-positive (influenza A - 99.2 %) patients. The median age of COVID-19 patients was 1.5 (0.7–4.5), influenza patients - 6.6 (4.2-9.6) years. Respiratory distress symptoms (6.9% vs 1.3%, p<0,001) and the need of prolonged supplemental oxygen (1.5% vs 0.4%, p<0,001) were significant more frequent in COVID–19 patients compare to influenza patients. White blood cell count (7.6 (5.5-11.0) vs 6.3 (4.6-8.3), p<0,001), lymphocites count (2.36 (1.20-4.14) vs 1.37 (0.83-2.30), p<0,001) and platelets level (262 (218-320) vs 221 (188-260), p<0,001) were higher for COVID-19 patients compared to influenza patients with opposite for hemoglobin level (122 (115-129) vs 126 (120-133), p<0,001) beings higher for influenza patients. The hospitalization (17.1% vs 6.2%, p<0,001) and admission to PICU rate (2.9% vs 0.6%, p<0,001) were higher for COVID-19 patients compared to influenza patients. There was no significant difference in neutrophil level and length of hospital stay. The peak of patient visits to emergency department for influenza was in April, while for SARS-CoV-2 in February.
Conclusions/Learning Points: Pediatric patients with COVID-19 were younger, had more severe respiratory symptoms, reflected by more frequent hospitalization and need for respiratory support and PICU assistance compared to influenza patients.

COVID-19, HERPES-6 OR ANTIBIOTIC – WHOSE FAULT IS IT?

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Beatriz Carmo[1], Diana Simões[1], Tatiana Moreira[1], Diana Bordalo[1,2], Ana Maia[1,2]
[1]Centro Hospitalar S João, Pediatrics, Porto, Portugal, [2]Faculty of Medicine of Porto University, Department Of Gynecology/obstetrics And Paediatrics, Porto, Portugal

Title of Case: Covid-19, Herpes-6 or Antibiotic – Whose fault is it?
Background: Cutaneous rashes in paediatrics may occur associated with multiple clinical conditions. The final diagnosis demands a comprehensive clinical history and physical examination, along with clinical and analytical investigation to the most probable cause.
Case Presentation Summary: A previously healthy six-month-old boy was brought to the Emergency Department (ED) with a two-day fever; he was diagnosed with acute otitis media and was treated with amoxicillin (for the first time). On the 3rd day of antibiotic, maintaining fever and having productive cough and rhinorrhea, he was re-evaluated in the ED and tested positive for Covid-19. He completed 7 days of amoxicillin; 24 hours after discontinuing it, a non-pruritic, morbilliform erythematous rash on the chest and abdomen appeared, without any other symptoms, which resolved spontaneously in 3 days. From the study performed in a follow-up paediatric appointment, he had positive Sars-Cov2 IgG antibodies, negative Herpes-6 DNA and negative total and specific IgE for amoxicillin (5kU/L and 0,15kU/L, respectively). He was later referred to an allergy appointment, and a drug provocation test for amoxicillin was performed - negative.
Learning Points/Discussion: Covid-19 infection in children is characterized by a myriad of clinical manifestations, with skin lesions being among the most common. These may mimic several diseases (like the exanthem subitum) since lesions present with the same distribution and appearance and appear in apyrexia. They can also resemble an antibiotic hypersensitivity reaction. It is, therefore, often necessary to refer the patient to a consultation, to reach a definitive diagnosis and to exclude, with certainty, an allergy to amoxicillin, since a hasty diagnosis can compromise therapeutic options in the future.

A CASE REPORT OF MIS-C IN A 34 MONTH OLD CHILD

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Inês Carvalho, Carolina Simão, Ana Luísa Rodrigues, Augusta Arruda, Ana Lúcia Maia, Paula Maciel
Hospital do Divino Espírito Santo de Ponta Delgada, Pediatrics Department, Ponta delgada, Portugal

Title of Case: A CASE REPORT OF MIS-C IN A 34 MONTH OLD CHILD
Background: Since 2020 there has been an increasing number of cases resembling a Kawasaki-like syndrome regarding SARS-CoV-2 positive diagnostic testing. This new entity named by the Center for Disease Control, Multisystem Inflammatory Syndrome in Children (MIS-C), shows an average diagnosis age of 9 years. A positive diagnostic is considered with current or recent SARS-CoV-2 infection by RT-PCR, serology, or antigen test. The diagnostic criteria include an individual <21 years with fever, laboratory evidence of inflammation, clinically severe illness requiring hospitalization, with multisystem organ involvement.
Case Presentation Summary: This is a case of a 34 month old child, previously healthy, without known contact with SARS-CoV-2 infection or COVID-19 vaccination. He presented in the emergency room with 24h of high fever and conjunctival hyperemia and was discharged with supportive care. He returned within 72h, maintaining previous symptoms, with prostration and ill appearance. Analytically showing lymphopenia, thrombocytopenia, hypoalbuminemia, elevated d-dimer and inflammatory markers. He also presented with cardio-renal dysfunction, with glomerular filtration rate of 62 ml/min/1.73m2 and an echocardiogram showing cardiac abnormalities. The child was admitted to the intensive care unit with hypotensive shock requiring vasopressors. He became apyretic 36h after immunoglobulin. The final diagnosis of MIS-C was made by serology.
Learning Points/Discussion: With this case, we aim to emphasize the young age of MIS-C presentation of our patient and that SARS-CoV-2 infection may be asymptomatic, making this a demanding diagnosis. Although clinically it may be similar to Kawasaki disease, laboratory values present differences that can help guide the diagnosis. We should remember this entity in a patient with persistent fever and multisystemic organic dysfunction, even in younger age groups, as prompt recognition may alter the final outcome.

CHANGE IN SEVERITY AND CLINICAL MANIFESTATION OF MIS-C OVER SARS-COV-2 VARIANT OUTBREAKS IN KOREA

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Eun Hwa Choi[1], Young June Choe[2]
[1]Seoul National University College of Medicine, Pediatrics, Seoul, Korea, Republic of, [2]Korea University Anam Hospital, Department Of Pediatrics, Seoul, Korea, Republic of

Background: There is a difference in the incidence of MIS-C in patients with different variants of SARS-CoV-2, however, little is known about the epidemiology in Asian countries. We investigate and compare the epidemiology of the MIS-C during Omicron-dominant period with that of previous periods in South Korea.
Methods: We obtained clinical, epidemiological and laboratory data on MIS-C cases from national MIS-C surveillance in South Korea. We defined Pre-Delta period as Jan 2020 - May 2021; Delta period as Jun 2021 - Dec 2021; and Omicron period as Jan 2022 - Apr 2022. We describe the clinical characteristics and outcomes of MIS-C patients by period.
Results: A total of 91 cases were assessed to be MIS-C cases. Number of MIS-C cases have increased from six cases during Pre-Delta period to 66 cases during Omicron period, while incidence rate has decreased from 38.5 cases per 100,000 (95% CI, 14.1-83.9) during Pre-Delta period to 1.6 cases per 100,000 (95% CI, 1.2-2.0) during Omicron Periods. During Pre-Delta period, 66.7% and 100% had hypotension and gastrointestinal involvement, respectively; while during Omicron period, 12.1% and 6.1% had such clinical manifestations. 50% of Pre-Delta MIS-C patients were taken ICU cares, while 10.6% of patients during Omicron periods were in ICUs.
Conclusions/Learning Points: Omicron period was associated with less severe clinical manifestation compared to Pre-Delta and Delta periods. Although the incidence rate of MIS-C was lower for the Omicron period than Pre-Delta and Delta periods, a number of patients reported with MIS-C may pose a substantial clinical burden.

VACCINE EFFECTIVENESS OF CORONAVAC AND BNT162B2 AGAINST SEVERE OUTCOMES AMONG CHILDREN AND ADOLESCENT PATIENTS WITH SARS-COV-2 OMICRON

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Ka Chun Chong[1,2], Yuchen Wei[1], Eng Kiong Yeoh[1]
[1]The Chinese University of Hong Kong, Centre For Health Systems And Policy Research, Hong Kong, Hong Kong PRC, [2]The Chinese University of Hong Kong, School Of Public Health And Primary Care, Hong Kong, Hong Kong PRC

Backgrounds: Hong Kong is providing two types of vaccines for citizens - the inactivated and mRNA vaccines, while the population, particularly in children and adolescent had limited protection from natural infections before the Omicron epidemic. In this study, we used real-world data to estimate the vaccine effectiveness (VE) against hospitalization caused by the Omicron variant among children and adolescent patients.
Methods: A case-control design was employed using administrative registered data of COVID-19 patients aged >18 years in Hong Kong. The analyses were restricted to an Omicron-predominated period from January 1, to November 27, 2022. A propensity score matching was conducted for all case-control matches. Vaccine effectiveness was determined as 1 minus the adjusted odds ratio obtained by conditional logistic regression adjusted with covariates.
Results: Totally 3,208 hospitalizations and 12,684 matched controls were included the study. Of the patients aged 12 to 17 years, the VE against hospitalization of CoronaVac increased from 46.4% (4.3-70.0) at the first dose to 52.9% (33.2-66.7) at the second dose, and to 51.8% (22.4-70.1) at the third dose, whereas that of BNT162b2 changed from 73.7% (62.4-81.6) at the first dose to 73.7% (65.6-79.8) at the second dose, and to 66.2% (49.1-77.5) at the third dose. A similar change of VE by the number of doses is observed among the patients aged 5 to 11 years. However, two doses and three doses of CoronaVac only had a VE of 23.3% (10.0-34.7) and 34.0% (9.4-51.9) respectively.
Conclusions/Learning Points: Our analyses demonstrated that the CoronaVac had a lower VE than BNT162b2 in general, and its protection against hospitalization was insufficient among children patients. A revision of vaccination programmes in this subpopulation involving inactivated CoronaVac vaccines warrants a further consideration.

[1]sanatorio mater dei, Pediatria Cardiologia Infantil, CABA, Argentina, [2]sanatorio mater dei, Pediatria Cardiologia Infantil, Caba, Argentina

Title of Case: Unusual symptoms of pediatric patients with MIS-C and Covid-19: Presentation of three cases in a private hospital in Buenos Aires, Argentina.
Background: Although pediatric age presents a lower risk of serious infection and they usually undergo fewer diagnostic tests than adults, the infection incidence by Covid-19 is similar to adults patients. It is associated with MIS-C in less than 1%.
Case Presentation Summary: Analyze different types of uncommon clinical symptoms of MIS-C in a private hospital in Buenos Aires
Learning Points/Discussion: Every patient with clinical and epidemiological criteria for SARS-CoV-2 infection was swabbed between March 16, 2020 and December 15, 2021, according to the public health authority's protocol using the PCR-RT method. Those who met criteria for MIS-C were analyzedResults: From samples of 4,713 patients, 538 were confirmed as positive (11.4%). Just three of them developed MIS-C. First Case: Male, 186 months old. Fever during 6 days and chest pain, ECG with repolarization disorder. Second Case: Male, 85 months old. Fever during 4 day. Stomach ache, conjunctival injection, erythematous rash and palmar-plantar desquamation. Third Case: Male, 136 months old, fever during 5 days. Apendicitis. Serology for SARS COV2+, myalgia, headache, edema and bipalpebral erythema. Positive PCR-RT were present in the first and the second cases by SARS-CoV-2. The three of them showed increasing parameters for Troponin, D-dimer, ferritin and atrial natriuretic peptide. Treatment given: 2g/kg/dose of intravenous immunoglobulin and an initial dose of 80 mg/kg/day of acetylsalicylic acid. Two of them also have received corticosteroids. Conclusion: Even through the incidence of MIS-C and Covid-19 in our hospital was in a low rate, we think that cardiology and gastrointestinal symptoms should be considered as suspicious of MIS-C in Covid-19 patients

Instituto de Investigación Sanitaria Gregorio Marañón (IisGM). CIBERINFEC. RITIP., Paediatric Infectious Diseases, Madrid, Spain, [7]University of Padua, Paediatric Infectious Diseases, Padua, Italy

Backgrounds: We aimed to describe the prevalence of persistent COVID in hospitalised paediatric population 1 year after admission compared to a control group.
Methods: Prospective observational study, in 2 hospitals. We included patients aged 0-18 years hospitalised for acute COVID-19 more than 1 year ago and controls, matched by age and sex, hospitalised for causes other than COVID-19, and with no history of COVID-19 at recruitment or during the follow-up. Families were contacted and a standardised survey was conducted. Persistent disease was defined as the presence of symptoms with onset in the first 3 months after admission and with persistence for more than 2 months.
Results: 50 cases and 46 controls were analysed, 58.3% male, 35.9% £5 years. Families were interviewed a median of 1.89 years (interquartile range; 1.25-2.07) after hospitalisation. The definition of persistent disease was met in 34% of COVID-19 cases vs. 37% of controls (p=0.767). Symptoms persisted >=11 months in 24% (12/50) of cases vs. 13% (6/46) (p=0.182), with no differences by age group. The most frequent symptoms at 1 year among cases were fatigue (8%), headache (6%), poor appetite (6%), abdominal pain (6%) and variations in heart rate (6%). In controls, persistent symptoms were abdominal pain (6%) and poor appetite (6%). Readmissions occurred in 11/50 (22%) in cases and 6/46 (13%) in controls (p=0.267). On emotional/behavioural items, 16/50 (32%) of cases reported that their state was worse or much worse than before admission, compared to 16/46 (34.7%). No risk factors associated with the development of persistent symptoms were found, except the length of hospitalisation (p=0.043).
Conclusions/Learning Points: In this study, the prevalence of persistent symptoms 1 year after hospitalization was not different in hospitalized patients who had COVID-19 than in controls.

MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN: SINGLE-PEDIATRIC CENTER EXPERIENCE

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Guliz Erdem[1], Diego Cruz Vidal[2], Simon Lee[2], Stacy Ardoin[2], Shoghik Akoghlanian[2]
[1]Nationwide Children's Hospital, Pediatrics, Columbus OH, United States of America, [2]Nationwide Children's Hospital, Pediatrics, Columbus, United States of America

Backgrounds: Multisystem inflammatory syndrome in children (MIS-C) is a hyperinflammatory condition associated with preceding severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) infection. In this single center study, we wanted to determine MIS-C clinical and laboratory characteristics that may be associated with cardiac involvement and severe clinical presentation. We also analyzed whether there were differences in clinical presentations coinciding with change in viral variants reported in the US.
Methods: This prospective observational study included all MIS-C patients diagnosed and treated at Nationwide Children's Hospital between June 2020 and January 31, 2022. We reviewed clinical and laboratory findings and treatment outcomes of the patients.
Results: 146 patients were diagnosed with MIS-C. Sixty-six (45.2%) patients had evidence of cardiac dysfunction, 26 (17.8%) had coronary artery abnormalities (CAA) and 15 (10.2%) had both cardiac dysfunction and coronary artery abnormalities. Cardiac dysfunction, intensive care admission rates, vasopressor use were significantly higher in older patients, and in those presenting with abdominal pain. Lower absolute lymphocyte (ALC) and platelet counts; elevated C-reactive protein (CRP), procalcitonin (PCT), ferritin, fibrinogen, d-dimer, interleukin-6 (IL-6); and lower serum albumin levels were associated with cardiac dysfunction. All patients had improved cardiac function in their follow up evaluations while we have observed possible steroid associated side effects in few patients.
Conclusions/Learning Points: We found patients with cardiac involvement had lower ALC, higher inflammatory markers. We have identified possible complications of utilized treatments. Identification of clinical and laboratory characteristics as well as treatment complications could aid in appropriate management of patients with MIS-C.

PV0919 / #1634

IN CHILDREN LOW BIRTH WEIGHT MAY CONTRIBUTE TO THE DEVELOPMENT OF SEVERE COVID-19

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Zsofia Csizek[1], Matyas Bukva[2], Cintia Petes[3], Attila Szabo[1], Tamas Kiss[1]
[1]Semmelweis University, Department Of Paediatrics, Budapest, Hungary, [2]Data Science and Me Limited Liability Company, -, Kecskemet, Hungary, [3]Semmelweis University, Department Of Public Health, Budapest, Hungary

Backgrounds: It was previously recognised that patients with high cardiovascular risk or established cardiovascular disease have a greater chance to develop severe COVID-19. Low birth weight (LBW) is knownt to be associated with increased risk of cardiovascular disease. Our goal was to investigate whether LBW can contribute to the development of severe COVID-19 in children.
Methods: In our single center observational study 325 COVID-19 patients hospitalized between September 1, 2020 and July 31, 2022 were identified. Infants under 1 year were excluded from our study. Data on 213 patients were retrospectively collected, among them 142 children had birth weight data available and enrolled in our study. We used Fisher's exact testto assess the representation of LBW among the admitted patients compared to the national average. Kaplan-Maier method and Cox proportional-hazards model was used to test the relationship between the length of hospital stay and birth weight.
Results: LBW children were significantly overrepresented among patients needed hospital admission (12.58% vs. 8,37% nationwide, p = 0.0464*). LBW was also associated with a longer hospital stay (+3 days median value, p = 0.00083*). Obese patients were not hospitalized longer (p = 0.094). Chronic conditions including chronic kidney failure (p = 0.16), chronic liver disease (p = 0.7), cystic fibrosis (p = 0.15) and developmental disorders (p = 0.086) had no significant impact on length of hospital stay.
Conclusions/Learning Points: We conclude that LBW is associated with a higher probability and longer hospital admission so it may contribute to the development of severe COVID-19 in pediatric patients.

Stefan Zeromski Specialist Hospital in Krakow, Department Of Paediatrics, -, Poland

Backgrounds: The symptoms of an ongoing SARS-CoV-2 infection are well known. Atypical manifestations from various systems that begin after recovery fremain the subject of research. The aim of the study was to assess the state of health of children who underwent COVID-19.
Methods: The reported complaints, abnormalities on physical examination, laboratory and imaging tests were analyzed. The study group contained 106 subjects – 49 girls(46%) and 57 boys(54%) aged 9 months to 17 years, hospitalized between March and June 2022. The time between the end of the infection and the onset of symptoms ranged from 2 weeks to 18 months. The inclusion criterion was: history of SARS-CoV-2 infection confirmed by positive PCR or antigen test or the presence of IgG-class antibodies. Children with PIMS/MIS-C multisystem inflammatory syndrome were excluded from the analysis.
Results: The main manifestations involved the respiratory(45%), cardiovascular(30%), nervous(19%) and gastrointestinal system. The most commonly reported symptoms were cough, rhinitis, chest pain, palpitations, fainting, feeling of cardiac arrhytmia, weakness, fatigue headaches, concentration and behavioral disorders, depression. Lung ultrasound and chest X-rays examinations has revealed lung lesions in 31% and 47% x-ray respectively. FeNO test levels were found in 47%, abnormal FOT values in 46% of children. There were abnormalities in ECG(21%) and 24-hour Holter-ECG(63%). Additional tests has shown elevated values of d-dimers, lactate dehydrogenase, creatinine kinase and reduces values of ferritin and vitamin D3 levels.
Conclusions/Learning Points: The analysis has shown that children, who recovered form SARS-CoV-2 infection presented a wide spectrum of long term health complications, especially from the respiratory, cardiovascular and nervous systems, as well as psychological problems. It should be remembered that these may be late complications of COVID-19. Electrocardiography, 24-hour Holter-ECG, lung ultrasound and chest X-ray are helpful diagnostic methods.

THE IMPACT OF MIS-C ON CHILDREN'S PHYSICAL ACTIVITY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Alicja Czyżyk[1], Klaudia Wójtowicz[1], Leszek Szenborn[1], Justyna Kawa-Szeląg[2], Natalia Dudek[2], Katarzyna Herjan[3], Kamila Ludwikowska[1]
[1]Wroclaw Medical University, Department Of Pediatric Infectious Diseases, Wrocław, Poland, [2]Medical University of Warsaw, Department Of Paediatrics With Clinical Assessment Unit, Warsaw, Poland, [3]Medical University of Warsaw, Medical University Of Warsaw, Warsaw, Poland

Backgrounds: Multisystem inflammatory syndrome in children (MIS-C) is a rare but severe systemic complication of SARS-CoV-2 infection. A considerable number of affected children develop acute but reversible heart failure, and many also have myocarditis features. Most of the children showed adequate response to treatment and good recovery. Long-term follow-up seems favorable but current data are limited. We have been tracking reports of MIS-C in Poland since May 2020 (MOIR CoR Study). In this study, we investigated how MIS-C affected children's physical activity.
Methods: Telephone surveys with parents of patients with MIS-C history were collected. Comparison of the demographical data and the assessment of the child's physical activity before and a median of 1,4 years (505 days) after MIS-C was performed.
Results: 84 children (aged median 9 years old, 69.4% males; hospitalized due to MIS-C between 26/05/2020 and 27/10/2022) were enrolled. In general, children in our cohort were very active before MIS-C and by the time of the survey majority of them regained their activity as presented in Figure 1. 63.1% of children before MIS-C and 56.0% after were attending extra sports classes. In total, before MIS-C children spent a median of 225 hours/week on physical activity, and two years after MIS-C it was a median of 195 hours/week. They gained weight more than expected with age with a median of 0.3 z-score for BMI increase. Analysis of the recommendations they received from doctors considering physical activity after having MIS-C were very inconsistent and often imprecise.

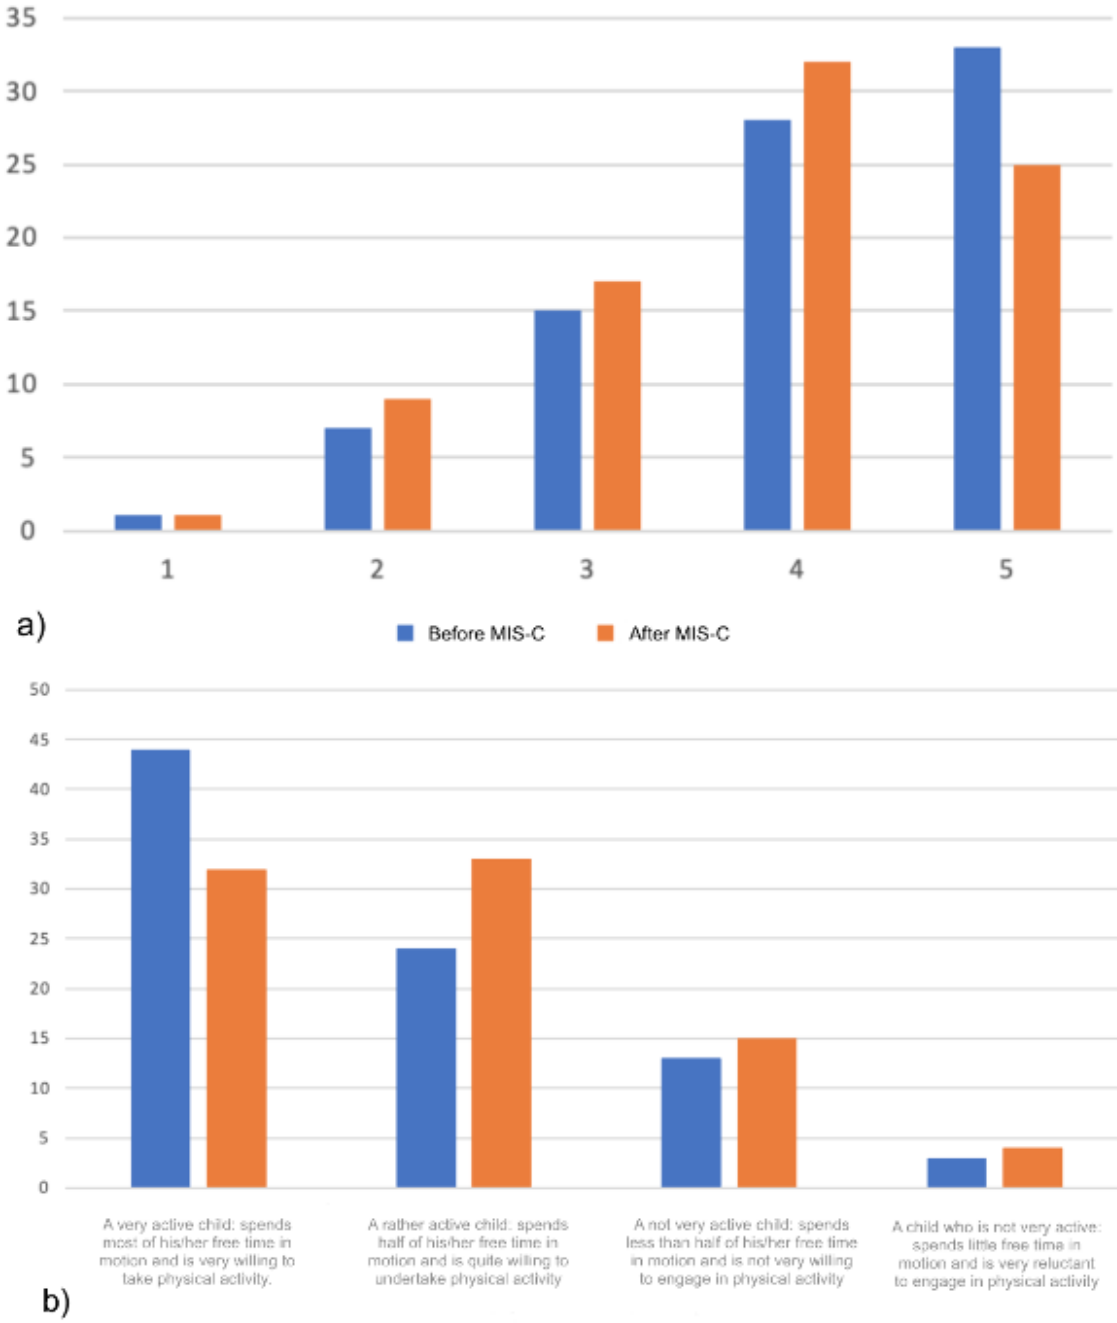

Figure 1.

a) Parent's assessment of the child's physical activity before and after MIS-C on a numerical scale from 1 (lack of activity) to 5 (child constantly physically active).

b) Parent's verbal assessment of the child's physical activity before and after MIS-C.

Conclusions/Learning Points: MIS-C impacted children's physical activity in long-term observation.

COVID-19 VACCINATION COVERAGE AMONG CHILDREN AND MINORS IN THE STATE OF SÃO PAULO, BRAZIL

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Tatiana D`Agostini[1], Nathália Cristina De Moraes[1], Alessandra Franco[1], Thiago Brumatti[1], Fernanda Florencia Zambom[1], Jéssica Camargo[2], Regiane De Paula[2]
[1]Secretaria Estadual de Saúde de São Paulo, Epidemiological Surveillance Center, Brazil, Brazil, [2]Secretaria Estadual de Saúde de São Paulo, Health Surveillance Center, Brazil, Brazil

Background: Covid-19 vaccination campaign has advanced throughout the state of São Paulo (SSP), considering priority groups (health professionals, immunosuppressed and elderly). Although minors (people under 18 yo) and children had been vaccinated after August 2021, because of the gradual vaccine's availability and sanitary recommendations, these groups represent a high percentage of the vaccinated population. This study aims to describe the schedule of vaccination in the people under 18yo and show the vaccination coverage (VC) for this group in the SSP and how it impacts the health of this population.
Methods: This is a descriptive study using the VaciVida database, the official system for registration of Covid-19 vaccination of SSP, managed by São Paulo State Health Department (SHD-SP).
Results: VaciVida sends the dose records to the Ministry of Health within 24 hours, and it has been allowed that SHD-SP monitoring in real-time the VC among children and minors, available vaccine used (Sinovac/Butantan, AstraZeneca/Oxford University/Fiocruz and Pfizer/Wyeth), how many doses were administered (one/second/booster) and the percentages of complete schedule and absentees. By February 2023, there were vaccinated with 1 booster dose over 60% of 12-17yo, over 4% of 5-11yo and 0.6% of 6monts-2yo. The VaciVida system has been being very important for epidemiological surveillance for monitoring the Covid-19 VC, especially among under 18yo, and it has been useful to analyze VC and encourage adherence, avoid serious cases, hospitalizations, and deaths, in addition to prevent new variants of SARS-CoV-2.
Conclusions/Learning Points: VaciVida shows an increase on the applied doses of the Covid-19 vaccine in children and minors. For children between 5 to 12yo the campaign goal (90%) was reached, for the first dose, and the VC for this group and under have been also progressing over time.

HEPATIC INVOLVEMENT IN CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME RELATED TO SARS-COV-2

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Gurdeep Singh Dhooria
DAYANAND MEDICAL COLLEGE, LUDHIANA, PUNJAB, INDIA, Pediatrics, Ludhiana, Punjab, India

Background: In both acute SARS-CoV-2 infection and MIS-C, gastrointestinal manifestations may represent a relevant aspect of the clinical picture. In MIS-C, diarrhea, vomiting and abdominal pain represent the most frequent gastrointestinal manifestations. Less typically, acute liver injury (ALI) in a wide range of children with Multisystem Inflammatory Syndrome related to SARS-CoV-2 (MIS-C) has been reported.
Methods: We analysed 51 cases of MIS-C patients for hepatic involvement and their correlation with severity. Demographic, clinical, laboratory and imaging features of children with MIS-C were prospectively collected. ALI was defined in presence of ALT elevation > 40 U/L. ALI was defined as severe in case of ALT >200 U/L.
Results: Mean age of cases were 7.89 ± 4.61 years. Gastrointestinal system was involved in 78.4% cases. Presenting GI symptoms were fever, 51 cases (100%), abdominal pain, 20 cases (39.2%), vomiting, 22 cases (32%), and diarrhoea 10 cases (19.6%). Ultrasound abdomen findings seen were moderate ascites (35.3%), gall bladder oedema (5.9%), hepatomegaly (2%), renal echogenicity, mesenteric adenopathy, and splenomegaly (2% each). Raised serum bilirubin (> 1.5 mg/dL) was seen in 7/51 cases (13.7%). ALI was seen in 30/51 cases (58.8%), while severe ALI was seen in 11/51 cases (21.6%). The mean max AST in MIS-C with shock cases were higher, 1213.05 ± 2104.17 compared to without shock 36.92 ± 167.73 (P = 0.016),
Conclusions/Learning Points: Hepatic involvement were commonly observed in the cohort of MIS-C patients. However, liver impairment was not severe in the majority of cases, and did not seem to be correlated with poor prognosis.

Background: mRNA vaccines trigger a higher humoral response to SARS-CoV-2 in adults after a previous infection. This study aimed to profile the early and long-term humoral response to the BNT162b2 vaccine in children with or without a previous COVID-19.
Methods: A multicentre prospective study was conducted on 5-11 years old children attending the University Hospital of Padua and Bambino-Gesù Hospital in Rome (Italy) between Dec-2021 to Dec-2022. Blood samples were collected pre-, 1-, and 6 months after vaccination. Neutralizing antibodies (NAbs) and anti-S-RBD IgG titers were analyzed through Plaque Reduction Neutralization Test (PRNT) and chemiluminescent immune-enzymatic assay (CLIA), respectively. Geometric mean titers (GMTs) and median of variables were compared according to pre-existing confirmed COVID-19.
Results: Sixty children (43% female, median age=9.2 years [IQR=7-10.7]) were enrolled in the study, including 46 subjects with a molecular-documented previous COVID-19 (Group-A) and 14 “naïve-vaccinated” peers defined as the absence of antigen-specific antibodies before vaccination (Group-B). Forty children were healthy [HC], while 8, 4, and 8 subjects had underlying immunomodulant conditions [IM], solid organ transplant [SOT], and a previous MIS-C [MIS-C]. Overall, Group-A recorded higher antibody titers than Group-B, at both 1 and 6 months after vaccination ($p<0.001$ for each antibody titer). However, antibody titers appeared depressed in SOT recipients in each Group at both times. Both Groups recorded a decrease in antibody titers of ~100-250% from 1-6 months. However, all individuals in Group-A, except SOT recipients, showed higher antibody titers at 6 months post-vaccination than those detected at pre-vaccination
(table).

Table. *Neutralizing antibodies (NAbs) and anti-receptor-binding-domain IgG antibodies (anti-S-RBD IgG) titers in children with (Group A) and without a previous SARS-CoV-2 infection (Group B) at pre-, 1, and 6 months after mRNA vaccination: overall and stratifying according to pre-existing pathologies (healthy children. [HC], children with a condition that can potentially affect the immune system [IM], solid organ transplant recipients [SOT], and children with a previous diagnosis of Multisystem inflammatory syndrome in children [MIS-C]).*

[§]Anti-S-RBD IgG titer was considered negative <4.33 kBAU/L;

[§]The neutralization titer was defined as the reciprocal of the highest dilution resulting in a reduction of the control plaque count >50% (PRNT50). The neutralization titer was estimated for the Parental and Omicron BA.2 variants. Samples recording titers equal to or above 1:10 were considered positive. Log2 of fold dilution of PRNT50 was used for the analyses.

*IM includes: juvenile idiopathic arthritis and nephrotic syndrome.

Conclusions/Learning Points: Vaccines trigger a higher humoral response in children with previous COVID-19. Inferior antibody titers were observed in SOT recipients. These findings provide insight into boosting preexisting immunity and the need for additional preventive strategies in immunocompromised children.

SARS-COV-2 ANTIBODY KINETICS IN UNVACCINATED HOSPITALIZED CHILDREN WITH COVID-19

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Dimitra Dimopoulou[1], Marietta Charakida[2], Antonios Marmarinos[3], Dareilena Karaviti[2], Margaritis Avgeris[3], Dimitrios Gourgiotis[3], Maria Tsolia[2]
[1]National and Kapodistrian University of Athens, Second University Department Of Pediatrics,/ Athens, Greece, [2]National and Kapodistrian University of Athens, Second Department Of Paediatrics, Athens, Greece, [3]National and Kapodistrian University of Athens, Laboratory Of Clinical Biochemistry-molecular Diagnostic, Second Department Of Pediatrics, Athens, Greece

Backgrounds: Antibody levels decline a few months post-acute COVID-19, but humoral memory persists in adults. Age and disease severity may affect antibody responses. This study aims to evaluate the presence and durability of antibody responses in children with COVID-19.
Methods: A prospective, single-center study, involving unvaccinated children aged 0-16 years old, hospitalized with COVID-19 between October 2020 and December 2021, was conducted. Children with a history of reinfection were excluded. COVID-19 severity was defined according to the NIH classification. Serological testing for anti-Spike SARS-CoV-2 IgG and neutralizing antibodies was performed at diagnosis and at 1, 3, 6 and 12 months post-infection. Analysis was performed using mixed effects models and random effects on time. The antibodies were naturally logged transformed to approximate normality.
Results: A total of 65 immunocompetent children were enrolled [mean age(+/-SD):6.7(+/-6.4) years; males:56.9%]. At 3 months, 40/44 (91%) children were seropositive; seropositivity persisted in 22/26 (85%) children at 6 months and in 10/12 (83%) children at 12 months. There was no evidence that age was modifying the prediction of variance of SARS-CoV-2 IgG levels. In contrast, SARS-CoV-2 IgG levels varied with time and disease severity. The association with time was non-linear, so that with increasing time there was significant reduction in SARS-CoV-2 IgG levels (coef-.044 [95%CI:0.061-0.028], $p<0.001$). For each increment of time the higher disease severity group was associated with 0.9 lower SARS-CoV-2 IgG levels. Each individual varied from the average effect of time with a SD of 0.01, suggesting that individuals may have different trajectories across time.
Conclusions/Learning Points: Disease severity but not age has an effect on antibody titers among children hospitalized with COVID-19. SARS-CoV-2 infection induces durable seroconversion in these children with detectable IgG levels at 1 year after infection.

RISE OF NEUROLOGICAL MANIFESTATIONS DURING SARS-COV-2 OMICRON WAVE IN CHILDREN WITH COVID-19

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Dimitra Dimopoulou[1], Foteini- Eleni Dasoula[2], Marianthi Liaska[2], Irini Eleftheriou[3], Despoina Maritsi[2], Nikos Spyridis[2], George Vartzelis[2], Maria Tsolia[2]
[1]National and Kapodistrian University of Athens, Second University Department Of Pediatrics,/ Athens, Greece, [2]National and Kapodistrian University of Athens, Second Department Of Paediatrics, Athens, Greece, [3]P. and A. Kyriakou Children's Hospital National and Kapodistrian University of Athens, Second Department Of Paediatrics, Athens, Greece

Backgrounds: Omicron variant wave is characterized by less severe, but more contagious infection, resulting in higher rates of community transmission and pediatric COVID-19 hospitalizations. Omicron variant may present a more epileptogenic profile. This study aims to evaluate the frequency and clinical characteristics of children with neurological COVID-19-related symptoms during Omicron period and compare them with the previous waves.
Methods: A retrospective, single-center study, involving children aged 0-16 years of age with COVID-19, admitted to a tertiary Children's hospital, was conducted. Clinical characteristics and incidence of neurological manifestations were compared between the two study periods, the first one before the emergence of Omicron variant (March 2020-December 31st, 2021) and the second one, when Omicron variant was predominant (January 1st, 2022-April 15th, 2022).
Results: A total of 571 children were enrolled (first period: 311 children; second period: 260 children). COVID-19-related neurological manifestations were observed in 25 children (8%) during the pre-Omicron period and in 58 children (22.3%) during the second period ($p<0.0001$). Febrile seizures significantly increased during the Omicron wave ($p=0.012$), while headache was more frequent during the pre-Omicron period ($p=0.002$). Electroencephalogram was performed in 9 children during the second period and it was abnormal in 4 of them, while brain MRI was performed in 5 children and it was normal in all of them. Treatment with anticonvulsants was administered for 3 months in 12 children and it was discontinued without complications during the follow-up period in all.
Conclusions/Learning Points: The period of Omicron variant predominance was characterized by an increased rate of neurological manifestations, and especially febrile seizures, among children with COVID-19. Further collaborative studies are required to determine the prevalence and the full spectrum of neurological manifestations among SARS-CoV-2 infected children.

Backgrounds: The Omicron variant is associated with increased transmissibility, but evidence regarding the impact of Omicron in seropositivity of children is limited. The purpose of this study is to evaluate SARS-CoV-2 seroprevalence in children during the different variants' periods.
Methods: A prospective multicenter study was conducted in Greece. Children from different age groups admitted to the hospital or examined in outpatient clinics for reasons other than COVID-19 and their parents were tested for anti-Spike SARS-CoV-2 IgG in serum. The study period was divided into three different subperiods: 01/03/2021-30/6/2021 (Alpha predominance), 1/11/2021-31/1/2022 (Delta predominance) and 01/02/2022-30/06/2022 (Omicron predominance).
Results: A total of 2054 children (0–16 years) were enrolled. In the first period with alpha variant predominance, 414 children (males: 219/414 (52.9%); median age (IQR): 8.1 (5.4)) were included. In the second period with delta variant predominance, 468 children (males: 262/468 (55.9%); median age (IQR): 6 (6)), while in the third period with omicron predominance, 1172 children (males: 670/1172 (57.2%); median age (IQR): 4.9 (5)) were included. Seropositivity rate increased significantly from Alpha to Delta period (59/414 (14.3%) vs 157/468 (33.5%) seropositive children, respectively) (P-value<0.0001), as well as from Delta to Omicron period (157/468 (33.5%) vs 750/1172 (63.9%) seropositive children, respectively) (P-value<0.0001). Seropositivity increased for all age groups (P-value<0.0001). No significant differences were observed in seropositivity with respect to gender, origin, or hospitalization status.
Conclusions/Learning Points: During the Omicron period, seropositivity significantly increased in the paediatric population, as a result of higher transmissibility or reinfection rates. Continuous surveillance seroprevalence studies are needed in children, in order to determine the true extent of SARS-CoV-2 in this population.

National and Kapodistrian University of Athens, First Department Of Pediatrics, Infectious Diseases And Chemotherapy Research Laboratory, Medical School, Athens, Greece

Backgrounds: Cellular immunity after SARS-CoV-2 infection or immunization may be important for long-lasting protection against severe COVID-19 disease. We investigated cellular immune responses after SARS-CoV-2 infection and/or vaccination with an interferon (IFN)-γ release assay.
Methods: Children and adults who were convalescent and/or vaccinated for COVID-19 were included. Whole blood with heparin samples were obtained for the evaluation of cellular immune responses using the SARS-CoV-2 QuantiFERON assay (QFN). Serum samples were also obtained and measured for SARS-CoV-2 anti-Nucleocapsid (Abs-N), anti-Spike (Abs-S) and Neutralizing (NAbs) antibodies against SARS-CoV-2 wild type and Omicron variant.
Results: In the study were included 41 participants; unvaccinated children (6) and adults (5) and vaccinated uninfected (16) or vaccinated convalescent adults (14). All vaccinated adults had received three doses of the BNT162b2 COVID-19 vaccine at 6.2-10.9 months prior to their inclusion to the study. All the unvaccinated participants were tested negative with QFN. Regarding the vaccinated population, 50% (8/16) of the vaccinated uninfected adults and 57.1% (8/14) of the vaccinated convalescent adults were tested positive. Among the QFN positive individuals, a reactive response to antigen (Ag) 1 ($CD4^+$ epitopes) and to Ag2 ($CD4^+$ and $CD8^+$ epitopes), was detected in 68.8% (11/16) and 87.5% (14/16) respectively, while 56.3% (9/16) had a reactive response to both antigens. Ag1 IFN-γ values correlated with Abs-S ($P<0.001$) and NAbs against wild type ($P=0.039$) levels, but not with NAbs against Omicron variant ($P=0.09$) and Ag2 IFN-γ values correlated only with Abs-S ($P=0.009$).
Conclusions/Learning Points: The SARS-CoV-2 QFN assay did not detect cellular responses in unvaccinated individuals and in a significant number of vaccinated individuals. Further comparative studies with different immunology assays are required to elucidate whether this is the result of waning immunity or low sensitivity of the assay.

CLINICAL FEATURES IN INFANTS HOSPITALIZED WITH COVID-19 (OMICRON)

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Anca Cristina Draganescu[1], Victor Daniel Miron[2], Oana Sandulescu[2,3], Anca Streinu-Cercel[2], Anuta Bilasco[4], Roxana Sandu[2], Adrian Streinu-Cercel[2]
[1]Carol Davila University of Medicine and Pharmacy, Pediatrics, Bucharest, Romania, [2]National Institute for Infectious Diseases "Prof. Dr. Matei Bals", Bucharest,Romania, Infectious Diseases, Bucharest, Romania, [3]Carol Davila University of Medicine and Pharmacy, Infectious Diseases, Bucharest, Romania, [4]National Institute for Infectious Diseases "Prof. Dr. Matei Bals", Bucharest,Romania, Pediatrics, Bucharest, Romania

Backgrounds: The omicron variant has resulted in a large number of pediatric cases of COVID-19 worldwide, including Romania. The aim of this study was to characterize the clinic of infants hospitalized with omicron in the largest infectious disease hospital in Romania.
Methods: We performed a retrospective analysis of the clinical characteristics of all infants hospitalized with RT-PCR-confirmed SARS-CoV-2 infection in 2022. Infants with other co-infections and those without complete data were excluded from the analysis.
Results: A total of 613 infants (58.9% male) with median age of 5 months (IQR:3-8 months) required hospitalization. Fever was the most common clinical manifestation (96.4%, n=591), followed by cough (64.8%, n=397) and loss of appetite (63.3%, n=388). Digestive manifestations were present in 49.6% of infants, being more common in infants older than 7 months ($p<0.001$). Overall, 11.3% of infants had dyspnea. Median length of hospital stay was 4 days (IQR:3, 5 days) being significantly higher by 1 day in infants under 3 months ($p<0.001$). The outcome was favourable in all cases.
Conclusions/Learning Points: We identified a high number of infants hospitalized with omicron. Although the outcome was favorable in all cases, the burden of disease was significant. Continuous monitoring of circulating variants of SARS-CoV-2 is a necessity for taking appropriate measures to limit the spread of infection including in infants.

PV0930 / #1205

IS D-DIMER A USEFUL DIAGNOSTIC TEST FOR MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN?

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Amedine Duret[1], Harsita Patel[1], Joy Obianyo-Onwuagha[1], Robin Basu Roy[2], Elizabeth Whittaker[1]
[1]St Mary's Hospital, Department Of Paediatric Infectious Diseases, London, United Kingdom, [2]Queen Mary University of London, Blizard Institute, London, United Kingdom

Backgrounds: D-dimer have been used along with other clinical indicators to aid diagnosis of MIS-C. However, there is limited published data on D-dimer values in acutely unwell children with febrile and non-febrile illnesses. We describe the range of D-dimer values and association with severity markers in children admitted to intensive care to assess whether D-dimers are uniquely raised in MIS-C or whether it is a nonspecific marker of acute disease.
Methods: Retrospective observational study of pseudo-anonymised, routinely collected data from electronic health records of paediatric (<18 years) patients admitted to PICU with a D-dimer request between 01/05/2017 – 01/06/2020.
Results: Fifty-seven patients were included, 22/57 (38%) were female, median age 5.9 years (IQR 1.0–11).10/57 (17%) were managed as MIS-C; 6/10 met the WHO MIS-C criteria. Other primary diagnoses included: bacterial infections (11/57, 19%), viral infections (10/57, 17%), status epilepticus or autoimmune encephalitis (9/57, 16%) and other (17/57, 29%). D-dimer levels did not discriminate between gender (p=0.9) or ethnicity (p=0.6); a weak positive correlation was seen with age (R2=0.29, p=0.03). The median D-dimer in MIS-C was 3329ng/mL (IQR 2192–7173), vs 3307ng/mL (IQR 1064-15577) in other diagnoses (p=0.61). When comparing D-dimer levels in febrile illnesses, no significant differences were seen (p=0.1) (Figure1a). One patient had confirmed deep venous thrombosis - their D-dimer was below the median at 2223ng/mL. Raised D-dimers were associated with shock (median levels: shock - 5407ng/mL, no shock - 1714ng/mL, p=0.0004), cardiac involvement defined as abnormal echocardiogram/electrocardiogram (median levels: cardiac involvement - 5542ng/mL, no cardiac involvement - 2363ng/mL p=0.05), but not mechanical ventilation (median levels: MV-2227, No MV-4787, p=0.6)
(Figure1b).

Figure 1a: D-dimer levels by febrile illness

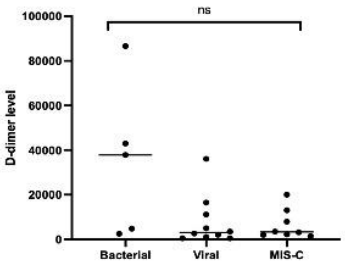

Figure 1b: association of d-dimers with markers of severity

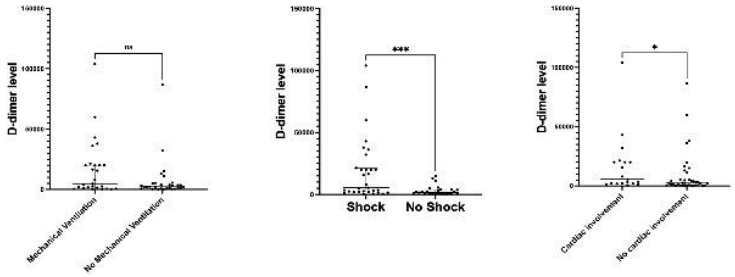

Conclusions/Learning Points: In our cohort, raised D-dimer levels were not specific for MIS-C and were a marker of severe disease regardless of aetiology.

LONG COVID SYMPTOMS IN EXPOSED AND INFECTED CHILDREN, ADOLESCENTS AND THEIR PARENTS ONE YEAR AFTER SARS-COV-2 INFECTION: A PROSPECTIVE OBSERVATIONAL COHORT STUDY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Anneke Haddad[1], Ales Janda[2], Maximilian Stich[3], Hanna Renk[4], Alex Dulovic[5], Klaus Kaier[6], Anna Willems[1], Philipp Henneke[7], Roland Elling[1]
[1]Freiburg University Medical Center, Center of Pediatrics and Adolescent Medicine, Pediatric Infectious Diseases And Rheumatology, Freiburg, Germany, [2]University Ulm, Department For Pediatrics And Adolescent Medicine, Ulm, Germany, [3]University Children's Hospital Heidelberg, Department Of Pediatrics I, Heidelberg, Germany, [4]University Children's Hospital Tuebingen, Pediatric Infectious Diseases, Tübingen, Germany, [5]University of Tuebingen, Nmi Natural And Medical Sciences Institute Reutlingen, Reutlingen, Germany, [6]Freiburg University Medical Center, Institute Of Medical Biometry And Statistics, Freiburg, Germany, [7]University Medical Center Freiburg, Cci, Freiburg, Germany

Backgrounds: There is a lack of understanding on long COVID in children, particularly due to a lack of well-controlled studies with long-term follow-up. In addition, the impact of the family context on persistent symptoms following SARS-CoV-2 infection is unknown. Here, we examined long COVID symptoms in a cohort of infected children, adolescents, and adults and their exposed but non-infected household members approximately 1 year post-infection and investigated clustering of persistent symptoms within households.
Methods: 1267 members of 341 households (404 children, 140 adolescentsand 723 adults) were prospectively enrolled across 4 centers and categorized as having had either a SARS-CoV-2 infection or household exposure to SARS-CoV-2 with-out infection, based on three serological assays and history of laboratory-confirmed infection. Participants completed questionnaires assessing the presence of long COVID symptoms 11-12 months after infection in the household using online questionnaires.
Results: The prevalence of moderate or severe persistent symptoms was statistically significantly higher in infected than in exposed women (36.4% [95% CI: 30.7-42.4%] vs 14.2% [95% CI: 8.7-21.5%]), infected men (22.9% [95%CI: 17.9-28.5%] vs 10.3% [95% CI: 5.8-16.9%]) and infected adolescent girls (32.1% 95% CI: 17.2-50.5%] vs 8.9%[95%CI: 3.1-19.8%]) while infected adolescent boys and children did not show a higher frequency of persistent symptoms. In addition, we found clustering effects within households, meaning that the risk that a participant experienced one additional moderate or severe persistent symptom increased by 12% for every additional symptom present in this household.
Conclusions/Learning Points: In this controlled, multi-centre study, infected men, women and adolescent girls were at increased risk of negative outcomes 11-12 months after SARS-CoV-2 infection. Amongst non-infected adults, persistent symptoms were also frequent. Prolonged symptoms tended to cluster within families, suggesting family-level interventions for long COVID could prove useful.

CONCORDANCE OF UPPER AND LOWER RESPIRATORY TRACT SARS-COV-2 RT-PCR RESULTS IN PEDIATRIC PATIENTS ADMITTED AT A TERTIARY REFERRAL HOSPITAL IN MANILA, PHILIPPINES

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Giselle Mikhaela Enriquez-Briones, Anna Lisa Ong-Lim
Philippine General Hospital, Infectious And Tropical Diseases In Pediatrics, Ermita, Manila, Philippines

Backgrounds: Nasopharyngeal swab SARS-CoV-2 RT-PCR remains the standard for COVID-19 diagnosis. Efforts to improve yield given its moderate sensitivity and the implications of a missed diagnosis led to our institution's protocol of routine paired upper (URT) and lower (LRT) respiratory tract sampling. The resulting delays in disposition, substantial increase in cost, conflicting data in published literature on the optimal specimen for testing, have made determining the concordance of these two samples and comparing the clinical profiles of positive patients with concordant versus discordant results a worthwhile endeavor.
Methods: This is a retrospective cross-sectional study that reviewed the medical records of pediatric patients admitted to the largest COVID-19 referral hospital in the Philippines from May 1, 2020 to May 31, 2022 with URT and LRT SARS-CoV-2 RT-PCRs performed within 24 hours of each other.
Results: A total of 241 paired tests obtained during the 1st week of illness from 171 unique patients displayed moderate concordance (k = 0.45). Two hundred and eleven (88%) were concordant, with 195 (81%) testing negative and 16 (7%) positive. Meanwhile, 30 (12%) were discordant, of which 23 (77%) were positive on URT, and 7 (23%) on LRT sampling. Test positivity was higher for URT (84.8%) compared to LRT (50%) specimens. Concordant positives had lower cycle threshold values. Majority (33, 72%) of all positive cases were categorized as severe or critical, but a greater number of non-severe cases had discordant results. Otherwise, the groups were similar.
Conclusions/Learning Points: The moderate concordance of URT and LRT SARS-CoV-2 RT-PCRs, and higher test positivity rate of URT sampling suggest that routine paired testing is unnecessary for patients on the 1st week of illness. LRT testing can be considered for URT negative cases suspicious for COVID-19.

IMMUNOLOGICAL PECULIARITIES IN CHILDREN WITH SARS-COV2 INFECTIONS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Rodica Eremciuc, Elena Dolapciu, Dina Bujor, Ala Holban, Ninel Revenco
State University of Medicine and Pharmacy "Nicolae Testemitanu", Pediatric Department, Chisinau, Moldova

Backgrounds: Children and adolescents exhibit a broad range of clinical outcomes from SARS-CoV-2 infection, with the majority having minimal to mild symptoms. The incidence rate of pediatric COVID-19 cases ranges between 1%–5% of all COVID-19 cases worldwide. However, this rate is likely to be underestimated, given the high proportion of underdiagnosed mild symptomatic and asymptomatic cases. Host immune responses to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), especially in children, are still under investigation.
Methods: Our study aim was to compare the association of clinical presentation of the disease with the development of IgG antibodies against SARS-CoV-2 in children.
Results: Our study included 47 study subjects with a positive RT-PCR test result for SARS-CoV-2. Mean age of our subjects was 6.53 ±0.98 years. Most reported cases of infected children were attributed to contact with an infected family member. Of all cases, 2% presented mild forms, 60% of cases - moderate forms, 38% of cases were severe. Febrile syndrome was present in 89% of children. Signs and symptoms in children were similar to tadults, but were lower in frequency. Children often experience robust antibody production within the first 3 weeks post infection and an estimated seroconversion time to IgG antibodies in the first week. Additionally, there is an increase in IgG specific B-cell rates in children with SARS-CoV-2, indicating a rapid humoral immune response. It was found that children with antibodies more frequently had chronic pathologies (41% vs 17% of cases), more frequently developed pneumonia (82% vs 70%) and dyspnea (53% vs 33%)).
Conclusions/Learning Points: Children who developed antibodies showed a more severe course of the disease. The spread of viral variants among unvaccinated pediatric populations could change the spectrum of disease in children.

BAROTRAUMATIC COMPLICATIONS DURING COVID 19 IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Anas Erragh[1], Karima Amanzoui[1], Marouane Elharit[1], Houssam Salem[1], Amine Afif[2], Samira Kalouch[2], Abdelaziz Chlilek[2]
[1]CHU IN ROCHD, Anesthesia Resuscitation, casablanca, Morocco, [2]CHU Ibn Rochd, Anesthesiology-intensive Care Medicine Department, Casablanca, Morocco

Backgrounds: The start of 2020 was marked by the outbreak of the COVID-19 pandemic. The first cases were identified in December 2019. The pandemic is secondary to an infection with the severe acute respiratory syndrome coronavirus 2, known as SARS-COV-2. Patients with COVID-19 are also susceptible to barotraumatic complications, such as pneumomediastinum, pneumothorax, and subcutaneous emphysema. The objective was to identify the profile of patients with COVID-19 who developed these barotraumatic complications for effective management.
Methods: We report cases concerning 3 patients under five years old, suffering from COVID-19 hospitalized in the pediatric intensive care unit of EL HAROUCHI hospital of the CHU IBN ROCHD in Casablanca during the period from 09/15/2022 to 15/ 10/2022, and who presented on admission or during hospitalization, one of the following complications: pneumomediastinum; pneumothorax or subcutaneous emphysema
Results: The mean time to onset of these complications was 3 days after patient admission. The average age was 3 years with a male predominance. 2 patients did not have a pathological history, with one patient presenting with a notion of neonatal asphyxia with viral bronchiolitis. The chest scanner objectified lesions very suggestive of COVID-19 with the presence of pneumothorax in one patient, pneumomediastinum and subcutaneous emphysema in 2 patients. Regarding ventilation, 3 patients were on invasive ventilation. Evolution was favorable in 2 patients, with worsening of one patient and death after 24 hours of hospitalization. The main cause of death was related to profound hypoxemic respiratory failure
Conclusions/Learning Points: The presence of barotraumatic complications in patients with COVID-19 poses a problem of ventilatory management. Better recognition of the natural history of this disease and multidisciplinary care between emergency physicians, resuscitators, pulmonologists and radiologists will offer better care and improve survival.

ANTIBIOTIC USE IN HOSPITALIZED CHILDREN WITH COVID-19 DURING THE THREE YEARS OF PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Paraskevi Farmaki, Ioanna Maligianni, Maria Noni, Efrossini Briassouli, Maria Mandrapylia, Konstantina Sveroni, Athanasios Michos, Vana Spoulou
National and Kapodistrian University of Athens, First Department Of Pediatrics, Division Of Infectious Diseases, Athens, Greece

Backgrounds: COVID -19 in pediatric population is thought to be asymptomatic or mild. However, antibiotic administration is not uncommon especially among pediatric patients with underlying conditions.Our aim was to study the antibiotic use among hospitalized children with COVID-19 in our hospital.
Methods: A retrospective study was performed among children hospitalized with COVID-19 in the largest tertiary Children's Hospital in Greece during March 2020-December 2022. Demographic, clinical and laboratory data were collected.
Results: Of the 1497 hospitalized children, 250 (16.7%) received antibiotic treatment. Patients' age ranged from 1 day to 20 years old. Seventy-two (28.8%) patients had confirmed bacterial or viral coinfection. Among them, 21 patients (29%) had a urinary tract infection and 7(9.7%) had bacteremia. Antibiotic use was quite common among patients with increased inflammatory markers (n=120, 48%) and underlying comorbidities (n=69, 27.6%) including malignancy (n=14), prematurity (n=5), respiratory (n=7), or hematological (n=7) disease. However, coinfection was detected only in 37/120 and 14/69 respectively. Moreover, antibiotic treatment was initiated in patients aged less than 90 days old (n=66, 26.4%)and those who received oxygen supplementation (n=25, 10%). Coinfection was detected in 19/66 and 4/25 respectively.
Conclusions/Learning Points: Children with COVID-19 even those with an underlying disease have low rates of bacterial or viral coinfection; therefore, antibiotics should be used with caution. Clinicians should apply diagnostic criteria to avoid overprescribing antibodies for COVID-19.

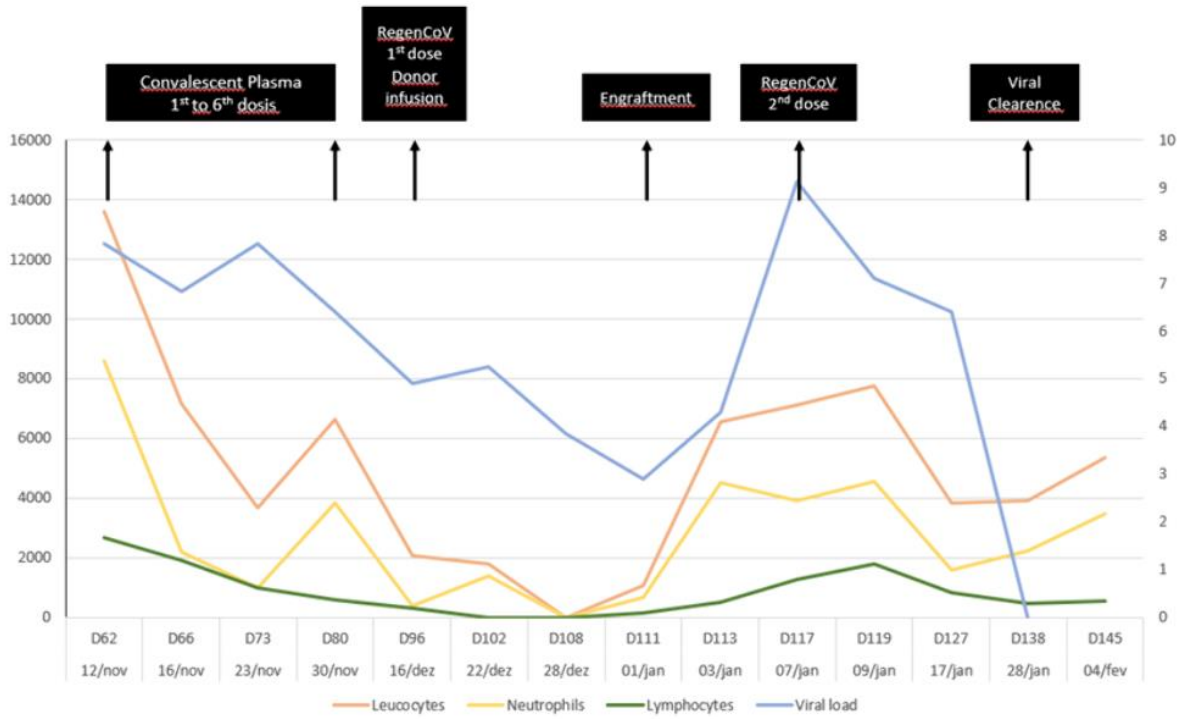
Title of Case: Convalescent plasma and monoclonal antibody on a persistent COVID-19 infection in a severe combined immunodeficiency (SCID) infant in a pre-allogeneic hematopoietic stem cell transplantation scheduling.
Background: We aim to assess clinical and virological effects of convalescent plasma and monoclonal antibody in SARS-CoV-2 infected infant with inborn error of immunity without viral clearence after more than 60th days in a hematopoietic stem cell transplant program.
Case Presentation Summary: We report a COVID-19 infection with long time shedding in a 17-month-old patient with SCID in transplantation program. The mieloablative conditioning could made this pacient a high risk for severe COVID-19 due to high viral load in nasopharyngeal samples and his infective capacity confirmed after Vero CCL-81 cells culture. Sanger sequencing of part of S gene revealed a infection caused by a gamma variant which persists in all detections. Initially five doses of convalescent plasma were administrated with no improve in viral load and in sixth infusion had a anaphylactic reaction with his suspension. Then, monoclonal antibody (REGEN-COV) was used to allow mielossupression regimen with a slightly viral load decrease and still no control. During all the time he remains assymptomatic and a full clearence was only possible after immune recovery in post-transplantation status.



Learning Points/Discussion: In SCID children a complete absence lymphocytes reduces inflammatory damage in target organs and innate response promotes infection containment which promoves mild infection as seen in our patient and a delayed resolution would be explained due to absence of memory cells and no sustained specific antibody response. The presence of neutralizing antibodies after convalescent plasma and REGEN-COV could guarantee the absence of symptoms, but no clearence was achieved before a immune reconstitution. So, this case highlights the importance of cellular immunity in viral clearance.

MULTISYSTEM INFLAMMATORY SYNDROME (MIS-C) IN CHILDREN, THE NEW DISEASE OF A THOUSAND FACES - ABOUT A CLINICAL REPORT

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Catarina Guerreiro Ferreira[1], Filipa Lima[1], Adelina Sitari[1], Cláudia Calado[2], Luísa Gaspar[2], Maria João Virtuoso[1], Elsa Rocha[1]
[1]Centro Hospitalar Universitário do Algarve, Pediatrics, Faro, Portugal, [2]Centro Hospitalar Universitário do Algarve, Pediatric And Neonatal Intensive Care Unit, Faro, Portugal

Title of Case: Multisystem inflammatory syndrome (MIS-C) in children, the new disease of a thousand faces - about a clinical report
Background: MIS-C is a severe inflammatory syndrome following recent infection with SARS-CoV-2, similar to Kawasaki disease or toxic shock syndrome. However MIS-C can have multiple presentations in children.
Case Presentation Summary: A previously healthy 4-year-old boy, whose mother had COVID-19 3 weeks earlier, presented with a 6-day history of fever and sore throat, aggravated with right cervical swelling and erythematous rash. Blood tests showed 21 × 109 white blood cells/L, 19 × 109 neutrophils/L, 1.3 × 109 lymphocytes and a C-reactive protein level of 244 mg/L. Because of a suspected retropharyngeal abscess, he was started on amoxicillin/clavulanic acid and clindamycin. There was clinical worsening with persistent fever, abdominal pain, progression of the rash, right cervical erythema, painful neck stiffness and trismus. Computed tomography (CT) of the neck showed multiple adenopathies, but excluded retropharyngeal abscess or cellulitis. Abdominal CT showed peritoneal and right pleural effusion. On day 8, he became tachycardic and hypotensive, and was started on peripheral dobutamine. Echocardiogram showed decreased ventricular contractility, with mitral and tricuspid insufficiency. This led to further workup that was suggestive of MIS-C (elevated ferritin, NT-proBNP, troponin, and positive COVID-19 IgG). There was clinical improvement following treatment with dobutamine, immunoglobulin and methylprednisolone. Repeated echocardiograms showed gradual increase of ventricular function and inflammatory markers trended down to normal.
Learning Points/Discussion: MIS-C can be a challenging diagnosis, even mimicking other diseases. We report a clinical case where the initial presentation resembled a retropharyngeal abscess. The unfavorable clinical progress, with multisystemic compromise, led us to consider MIS-C. We therefore emphasize the importance of early considering this diagnosis when faced with prolonged fever.

SAFETY AND DURABILITY OF MRNA-1273-INDUCED SARS-COV-2 ANTIBODY RESPONSES IN ADOLESCENTS

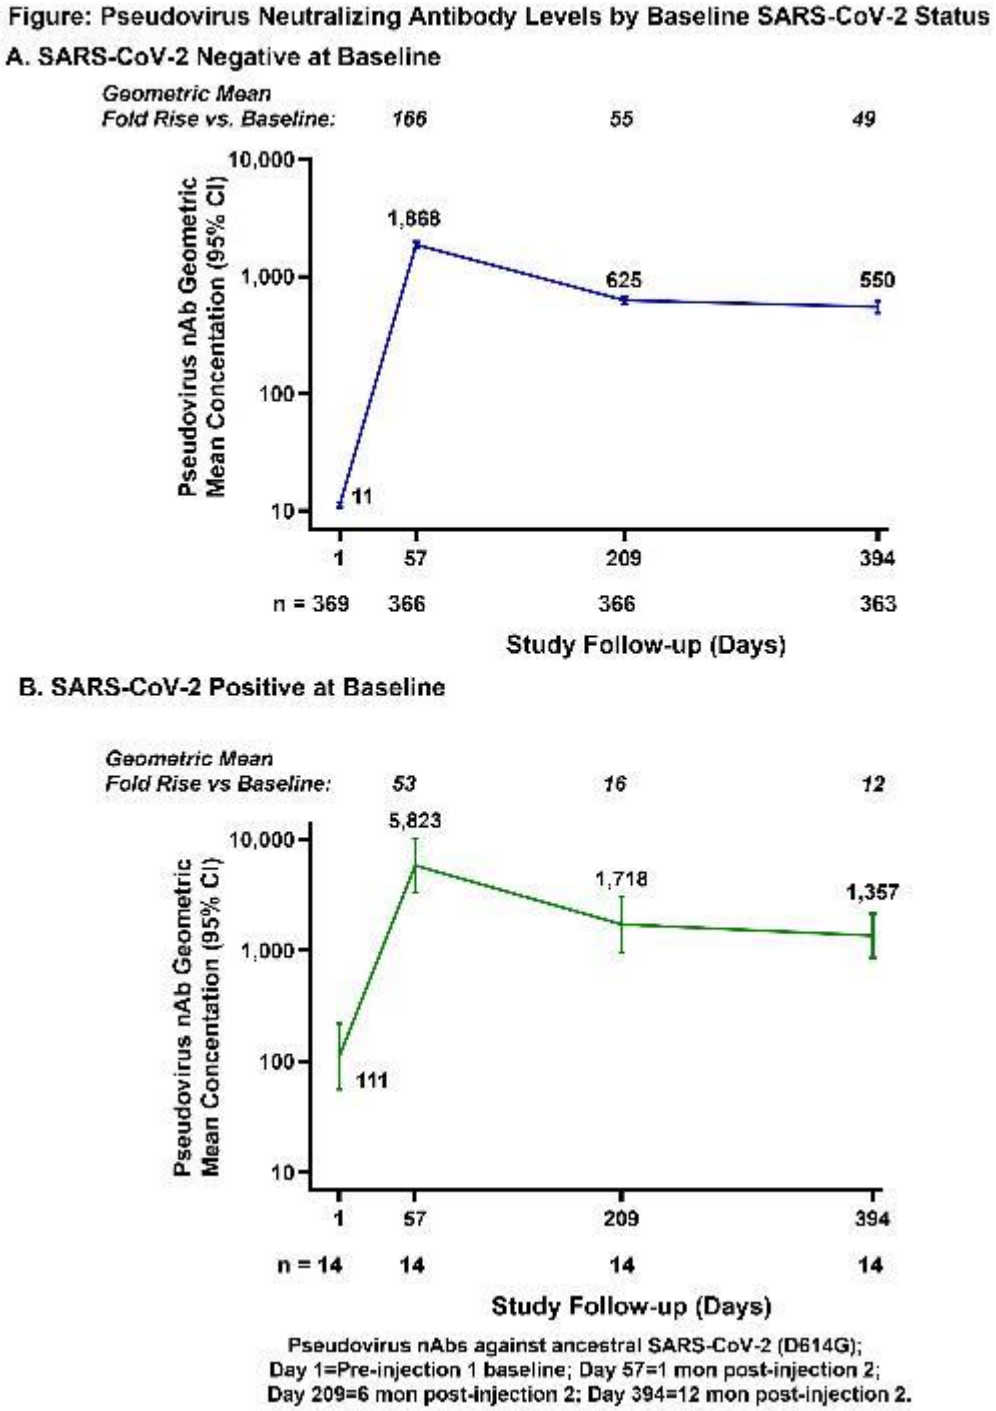
E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Amparo Figueroa[1], Kashif Ali[2], Gary Berman[3], Honghong Zhou[4], Weiping Deng[4], Bethany Girard[5], Frank Dutko[1], Anne Yeakey[6], Karen Slobod[1], Jacqueline Miller[1], Rituparna Das[1]
[1]Moderna, Inc., Clinical Development, Cambridge, United States of America, [2]Kool Kids Pediatrics, Dm Clinical Research, Houston, United States of America, [3]Clinical Research Institute, Allergy And Immunology, Minneapolis, United States of America, [4]Moderna, Inc., Biostatistics And Programming, Cambridge, United States of America, [5]Moderna, Inc., Clinical Biomarkers, Cambridge, United States of America, [6]Moderna, Inc., Pharmacovigilance, Cambridge, United States of America

Backgrounds: TeenCove is a Phase 2/3 randomized, observer-blind, placebo-controlled study in adolescents aged 12-17 years randomized to receive two injections of 100-µg mRNA-1273 vaccine (n=2490) or saline placebo (n=1243), 28 days apart. After authorization of COVID-19 vaccines in adolescents, placebo recipients were offered to receive mRNA-1273. Here, we present the long-term safety, immunogenicity, and antibody persistence results up to 12 months post-mRNA-1273 primary series.
Methods: 2486 mRNA-1273 recipients and 91 placebo recipients who received mRNA-1273 were monitored for COVID-19 and AEs (leading to discontinuation, SAEs, medically-attended, and AEs of special interest). Up to 12 months post-injection 2, we measured neutralizing (nAb) and binding antibodies (bAb) against ancestral SARS-CoV-2 spike protein; and bAb against alpha, beta, delta, and gamma variants.
Results: In SARS-CoV-2 baseline-negative adolescents(n=366), mRNA-1273 induced robust nAb responses 28 days post-injection 2, (Geometric Mean Concentration [GMC] 95% confidence interval [95% CI]=1868[1759,1985) vs. baseline (11[11,12]); strong nAb persistence was observed at 6 months [625[583,670] and at 12 months (550[490,618]) (Figure). Similar trends were observed in bAb including responses to variants. Robust nAb and bAb responses were also observed in participants who were SARS-CoV-2 baseline-positive. Overall, COVID-19 incidence rates were low through 1-year post-injection 2 (8.735/1000 person-months). During the Omicron wave, COVID-19 incidence rates increased in Dec 2021 (23.443/1000 person-months) and Jan 2022 (92.616/1000 person-months). mRNA-1273 was generally well-tolerated and the reactogenicity profile was consistent with that observed in thePhase 3 COVE study in adults. There were no deaths, investigator-reported vaccine-related SAEs, or MIS-C. One reported case of nonserious, moderate, probable acute myocarditis resolved by 8 days from symptom onset.
Conclusions/Learning Points: Antibody responses were durable through 12 months after mRNA-1273

primary series vaccination. The overall benefit-risk profile of mRNA-1273 remains favorable in

Figure: Pseudovirus Neutralizing Antibody Levels by Baseline SARS-CoV-2 Status



Pseudovirus nAbs against ancestral SARS-CoV-2 (D614G);

[1]National and Kapodistrian University of Athens, First Department Of Pediatrics, Infectious Diseases And Chemotherapy Research Laboratory, Medical School, Athens, Greece, [2]Agia Sofia Children's Hospital, Department Of Clinical Biochemistry, Athens, Greece

Backgrounds: Limited prospective long-term SARS-CoV-2 serosurveillance data have been reported in children. We investigated COVID-19 seropositivity in children between 1/5/2020-31/12/2022, representing SARS-CoV-2 Wuhan (Wh), Alpha, Delta and Omicron variants predominance periods in Greece.
Methods: Serum samples from children who presented to the emergency department or were hospitalized to the major tertiary Greek pediatric hospital “Aghia Sophia” for any cause, except for COVID-19, were randomly collected monthly and tested for SARS-CoV-2 nucleocapsid protein antibodies. Study periods were divided as: 1/5/2020-31/12/2020 (Wh), 1/1/2021-30/7/2021 (Alpha), 1/8/2021-31/12/2021 (Delta) and 1/1/2022-31/12/2022 (Omicron).
Results: A total of 1412/4963 (28.5%) seropositive children were detected. Their mean (±SD) age was 87.6(±63.4) months and males were 759/1412 (53.8%). Seropositivity rates in Wh, Alpha, Delta and Omicron periods were 1.7%, 12.7%, 23.8%, and 62.4%, respectively (P-value<0.001). The lowest seropositivity was detected in August 2020 (0.0%) and the highest were detected in October 2022 (80.6%) with statistical dependency between seropositivity and month detected (P-value<0.001). Seropositivity significantly increased from Wh to Omicron period for all age groups (P-value<0.001), reaching 44.1% in 0–1-year-old, 55.0% in 1-4 years, 65.4% in 4-6 years, 71.6% in 6-12 years and 67.2% in 12-16 years in Omicron period. No significant differences were detected between males and females (P-value=0.528). Seropositivity was not significantly higher in hospitalized (28.6%) than in non-hospitalized children (28.1%) (P-value=0.730). However, seropositivity was significantly higher in non-Greek (31.7%) compared to Greek children (27.3%) (P-value=0.003).
Conclusions/Learning Points: In Omicron period, SARS-CoV-2 seropositivity in pediatric population considerably increased suggesting either enhanced transmissibility or reinfection rates. Continuous surveillance of seroepidemiological data in children is required to estimate the true extent of pediatric COVID-19 prevalence.

SHORT-TERM OUTCOMES OF ELECTIVE PAEDIATRIC ORTHOPAEDIC SURGERY DURING THE COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Emma Fossett, Jagmeet Bhamra, Arash Afsharpad
Evelina London Children's Hospital, Paediatric Orthopaedics, London, United Kingdom

Backgrounds: The COVID-19 pandemic has posed significant challenges on healthcare services. The impact on safe delivery of surgical care remains uncertain, due to the unknown nature of the coronavirus and its future impact on surgical patients. There is a sparsity of reliable data in the paediatric population, given their potential to remain asymptomatic despite exposure. In our unit, the median COVID-19 admission rates per day was 1.4 (S.D 1.3), between December 2021 to September 2022, therefore our study assessed the effect of COVID-19 exposure in children, on post-operative complications.
Methods: We report on 60 elective cases admitted to our unit between January and September 2022. Vaccinated patients, equivocal results and loss to follow up, formed our exclusion criteria. All were consented for a SARS-CoV-2 antibody blood test pre-operatively, after obtaining research ethics and governance approval. Clinical reviews occurred up to three months and any complications noted. Data was collected through electronic patient records.
Results: Surgical procedures varied from metalwork removal to complex hip reconstruction. 53 patients were included, with 43 (81.1%) testing antibody positive and 10 (18.9%) testing antibody negative. We report no COVID-19 related complications in our cohort. 2 children (4.7%) in the antibody positive group and 1 (10%) in the antibody negative group developed post-operative pyrexia, requiring antibiotics. Statistical analysis using Fisher's Exact Test (95% C.I.), demonstrated no statistically significant association between SARS-CoV-2 antibody result and post-operative complication rate (0.47, $p>0.05$).
Conclusions/Learning Points: Our study demonstrates that although a large proportion of the paediatric population have had peri-operative exposure to COVID-19, in the absence of respiratory symptoms and active infection, early post-operative complication rate was not increased and the elective paediatric orthopaedic operations were safely carried out.

PV0941 / #1285

CERVICAL INVOLVEMENT IN MULTISYSTEM INFLAMMATORY SYNDROME – A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Ema Freitas[1], Rita Valsassina[2], Catarina Gouveia[2], Tiago Silva[2]
[1]Hospital Dona Estefania - Central Lisbon University Hospital Center, Paediatrics, Lisbon, Portugal, [2]Hospital Dona Estefania – Central Lisbon University Hospital Center, Pediatrics Infectious Diseases Unit, Lisbon, Portugal

Title of Case: Cervical Involvement in Multisystem Inflammatory Syndrome – A Case Report
Background: Multisystem inflammatory syndrome in children (MIS-C) is a severe but rare complication of coronavirus disease 2019 (COVID-19). It has various clinical features, mainly fever and a rash, as well as cervical involvement.
Case Presentation Summary: A 13-year-old white boy, presented with a 5-day history of high fever, vomiting and anterior neck pain with edema, erythema and an enlarged (3cm), tender left anterior cervical lump. He referred a cervical sunburn the previous week when surfing. Workup revealed normal leucocyte count, increased C-reactive-protein (119,3 mg/L). Cervical US showed multiple bilateral mainly left posterior adenopathies with no retropharyngeal involvement on CT. He was admitted on intravenous amoxicillin plus clavulanic acid and clindamycin for presumed cervical adenophlegmon. At day 5 of antibiotics fever persisted, bilateral conjunctival hyperemia was noted, neck erythema progressed to generalized macular exanthema and he became ill-appearing and hypotensive. Subsequent workups excluded cervical complications and showed hepatosplenomegaly (US), cardiac involvement (troponin I 19,3pg/mL, NT-proBNP 3.357pg/mL), elevated inflammatory biomarkers (sedimentation velocity 38mm/h, ferritin 777 ng/mL, procalcitonin 2,6 ng/mL and D-dimers 3.825 ug/L), with negative blood cultures. Taking into account he was diagnosed with COVID-19 8 weeks before, MIS-C was considered. He was treated with IV immunoglobulin (1g/kg/day 2 days) with complete resolution of fever after 1 day and improvement of inflammatory parameters and was discharged 2 days later.
Learning Points/Discussion: MIS-C may initially present with localized cervical symptoms. This case highlights the need to maintain MIS-C in our differential diagnosis when managing ill-appearing children with presumed cervical infection and a history of recent COVID-19 exposure or infection, that does not respond to antimicrobial therapy.

PV0942 / #1309

COVID-19 ANTIBODIES IN ADOLESCENTS LIVING WITH PERINATALLY ACQUIRED HIV: AN INTERIM ANALYSIS OF PARTICIPANTS FROM THE CHER TRIAL IN SOUTH AFRICA

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Lisa Frigati[1], Leonore Greybe[2], Shaun Barnabas[2], Mark Cotton[2], Helena Rabie[2]
[1]Tygerberg Hospital, Department Of Paediatrics, Cape Town, South Africa, [2]Stellenbosch University, Department Of Paediatrics, Cape Town, South Africa

Backgrounds: There is limited data on adolescents with HIV and COVID-19 co-infection. In an ongoing study on cardiometabolic risk factor in adolescents living with perinatally acquired HIV we reviewed clinical and antibody data related to COVID-19 in adolescents originally enrolled in the Children with HIV early antiretroviral therapy (CHER) study.
Methods: This study was nested in an ongoing prospective cohort study based at Tygerberg Hospital's paediatric infectious diseases clinic. Evidence of prior COVID-19 infection was based on SARS-COV-2 nucleocapsid and spike II antibodies. The study was funded by NIH 1D43TW010937-01.
Results: 33 participants, median age 16.4 years (IQR: 16.2-16.8), were enrolled. 18 (54.6%) were male and 28 (85%) had a viral load of <50 copies/ml. The median CD4 count was 753 cells/mL (IQR: 622-891). Median time on antiretroviral treatment (ART) was 16.1 years (IQR: 15.9-16.7). Median BMI was 21.6 kg (19.5-25.2) and no participant reported smoking cigarettes although 18 (54.6%) smoked cannabis. All participants had no laboratory documentation of COVID-19 testing prior to study enrolment. One had a history of mild COVID-19. Seven reported having received COVID vaccination. Sixteen (48.5%) had SARS-COV-2 nucleocapsid antibodies. SARS-COV-2 Spike II antibodies were found in all 10 participants tested. Table 1 Characteristics of participants with a history of having had COVID vaccine

	CD4 count	Viral load
Participant 1	863	undetectable
Participant 2	893	undetectable
Participant 3	735	undetectable
Participant 4	374	undetectable
Participant 5	690	undetectable
Participant 6	827	undetectable
Participant 7	736	undetectable

Conclusions/Learning Points: This limited analysis of a small number of ALPHIV on ART suggests that asymptomatic SARS-COV-2 infection is common.

PV0943 / #773

MULTISYSTEM INFLAMMATORY SYNDROME IN NEONATES (MIS-N)

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Anahit Grigoryan, Karine Simonyan
Muratsan University Hospital, Pediatric N1, Yerevan, Armenia

Title of Case: Multisystem inflammatory syndrome in neonates (MIS-N)
Background: MIS-N is emerging as a new disease in the newborn population, similar to MIS-C. It is hypothesized that either the following transplacental transmission of SARS-CoV2 antibodies or antibodies developed in neonate after the infection with SARS-CoV-2 are caused.
Case Presentation Summary: A 12-day-old full-term female infant was referred to our Pediatric Department with the history of one-day fever, rhinitis and SARS-CoV2 RT-PCR positive. Perinatal anamnesis is unremarkable. On admission, he had normal vital signs, low-grade fever and cough. Laboratory evaluation revealed mildly elevated PLT, low WBC and CRP levels. He received supportive care but on the 6th day of hospitalization developed poor feeding, tachypnea and hypoxia, suprasternal-subcostal retractions and dynamic bowel obstruction pattern. Laboratory tests changes are shown in the table and chest X-ray showed bilateral alveolar infiltration.She received oxygen, IV antibiotics and dexamethasone. Due to the increased oxygen requirement, he was transferred to NICU, where he underwent an invasive-mechanical ventilation the following day. Bronchial specimen and blood culture were negative for bacterial pathogens. During one day in NICU respiratory distress worsened, ECHO showed myocardial dysfunction, DIC syndrome was developed and the patient died.

	1^{st} day
WBC	$9.97 * 10^9/L$
HGB	162 g/l
NEU	17%
LYM	55.5%
PLT	$604 * 10^9/L$
CRP	7.85 mg/l
AST/ALT	
LDH	
FERRITIN	

Learning Points/Discussion: In consistent with the current literature, we had all the criteria to diagnose this case as MIS-N. The common presentation of MIS-N included cardiorespiratory compromise with the possibility of high mortality. The identification

of suspected MIS-N cases are necessary to perform specific lab tests and ECHO screening on time to decrease the mortality rate.

PREDICTORS OF OUTCOMES FOR PATIENTS WITH PAEDIATRIC INFLAMMATORY MULTISYSTEM SYNDROME TEMPORALLY ASSOCIATED WITH SARS-COV-2 (PIMS-TS) IN NORTHERN IRELAND

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Naomi Kirk[1], Hannah Mitchell[2], Lisa Mcfetridge[2], Sharon Christie[1], Paul Moriarty[1], Lynne Speirs[1], Helen Groves[3]
[1]Royal Belfast Hospital for Sick Children, Infectious Diseases, Belfast, United Kingdom, [2]Queen's University Belfast, School Of Mathematics, Belfast, United Kingdom, [3]Queen's University Belfast, Wellcome Wolfson Institute For Experimental Medicine, Belfast, United Kingdom

Backgrounds: Paediatric inflammatory multisystem syndrome temporally associated with SARS-CoV-2 (PIMS-TS) was first described in April 2020 and is recognised as a rare, post-infectious complication of SARS-CoV-2 infection in children.
Methods: We conducted a retrospective review of all children (ages <18 years) in Northern Ireland who met the UK Royal College of Paediatrics and Child Health (RCPCH) diagnostic criteria for PIMS-TS for the period March 2020 to February 2022 inclusive. Univariate and multivariable analyses were performed to evaluate the association of demographic, clinical and laboratory characteristics with outcomes including; duration of hospital stay, intensive care unit (ICU) admission, inotropic support requirement and echocardiogram abnormalities.
Results: 47 children (median age 104 months) were identified, 30 (64%) were male and 9 (19%) had comorbidities. Median fever duration prior to presentation was 3 days (range 1-13). Other common presenting symptoms included; rash (72%), vomiting/abdominal pain (67%) and conjunctivitis (63%). Median duration of hospital stay was 7 days (range 2-16), 16 (34%) patients were admitted to ICU and 14 (30%) required inotropic support. Initial echocardiogram showed coronary artery abnormalities in 11 (24%) and abnormal ejection fraction in 17 (38%). There were no deaths. Older age, evidence of renal dysfunction and shock at presentation were significantly associated with ICU admission, inotrope use and abnormal ejection fraction. ICU versus non-ICU patients also had significantly lower blood platelet, lymphocyte and albumin counts, with higher troponin, pro B-type natriuretic peptide, ferritin and D-dimer levels. On multivariable logistic regression analysis, only lower blood albumin level remained significantly associated with ICU admission (OR 0.59, P=0.02).
Conclusions/Learning Points: We present the first description of patients with PIMS-TS in Northern Ireland highlighting factors associated with outcomes, with lower blood albumin predictive of ICU admission.

CHILDREN'S KNOWLEDGE AND PRACTICES REGARDING COVID-19

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Shaher Hamaideh
The Hashemite University, Community And Mental Health, Zarqa, Jordan

Background: The knowledge and practices regarding infectious diseases would greatly affect whether children could follow the control measures or not. The COVID-19 pandemic puts children at higher risk for getting the infection because they usually have less ability to understand and practice healthy measures. Therefore, the aims of this study were to assess children's levels of knowledge and practices regarding COVID-19, and to determine the sources of knowledge obtained about COVID-19.
Methods: A cross-sectional, correlational design was used. After getting the required approvals, data were collected from a convenience sample of children aged between 13-15 yeas from six schools that chosen randomly from Zarqa Governorate, Jordan. The questionnaire consisted of demographics, Knowledge and Practices regarding COVID-19, and source of knowledge regarding COVID-19. Data were collected through an online questionnaire sent to 440 students through WhatsApp groups in the selected schools (classes of 7^{th}, 8^{th}, and 9^{th} grades).
Results: The final sample consisted of 180 students (response rate=41.0%). Children had poor knowledge (48.5%) and low practices (54.2%) toward COVID-19. There were statistically positive relationships between knowledge and age, gender, grade, and family income. Female students have better knowledge and practices regarding COVID-19 than their male counterparts. Similarly, there were statistically positive relationships between practices and age, gender, grade, and family income. Children's receive knowledge about COVID-19 from TV (65.0%), social media (73.0%), and from parents (45.0%).
Conclusions/Learning Points: Conclusions: Teachers and parents could provide health education to improve children's understanding of signs of symptoms and practices for protecting infection with COVID-19. Current results are informative to health care policymakers and mental health authorities in helping identify target populations such as school children for prevention and education about infectious diseases such as COVID-19.

PV0946 / #1877

ACUTE RESPIRATORY CORONAVIRUS DISEASE IN A CHILD WITH TYPE 1 DIABETES: A CLINICAL CASE

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Mykola Haras[1], Roman Tkachuk[2]
[1]Bukovinian State Medical University, Pediatrics And Pediatric Infectious Diseases/Chernivtsi, Ukraine, [2]Chernivtsi Pediatric Regional Hospital, Pediatric Intensive Care, Chernivtsi, Ukraine

Title of Case: Acute respiratory coronavirus disease in a child with type 1 diabetes: a clinical case
Background: It is known that children with type 1 diabetes mellitus are at increased risk for severe respiratory symptoms and COVID-19 related complications, compared to patients without the specified premorbid condition. For unknown reasons, SARS-CoV-2 may trigger new-onset diabetes.
Case Presentation Summary: The 4 years old female patient upon admission confirmed severe neurological symptoms as sopor caused by ketoacidosis, dehydration, as well as respiratory infection. The patient was lethargic, hypodynamic, accessible to verbal contact, but with delayed responses. The patient felt ill suddenly, her condition was rapidly worsening. The blood work of the patient revealed hyperglycemia, hyperstenuria, glycosuria, ketonuria, hypertransferasemia, elevated levels of glycated hemoglobin and decreased levels of C-peptide. The patient has been receiving fluid replacement treatment intravenously, short-acting insulin to correct hyperglycemia followed by symptomatic treatment therapy. The patient responded well to the treatment plan and was discharged from the hospital after 8 days continuing treatment from home.
Learning Points/Discussion: This article describes a clinical case of COVID-19 in adolescent patient with a new onset type 1 diabetes mellitus. Despite subtle respiratory symptoms, the patient presented with severe dehydration and ketoacidosis. This case highlights the need for clinical awareness of acute respiratory presentations of confirmed COVID-19 as they may result in ketoacidosis. It is advised to test glucose levels during acute stage of infection. At the moment, it is not enough data to conclude whether type 1 diabetes mellitus in pediatric population can cause serious complications from COVID-19. However, we do believe that in this particular case, COVID-19 triggered new onset type 1 diabetes mellitus in this young patient who had not had any symptoms of type 1 diabetes mellitus before COVID-19.

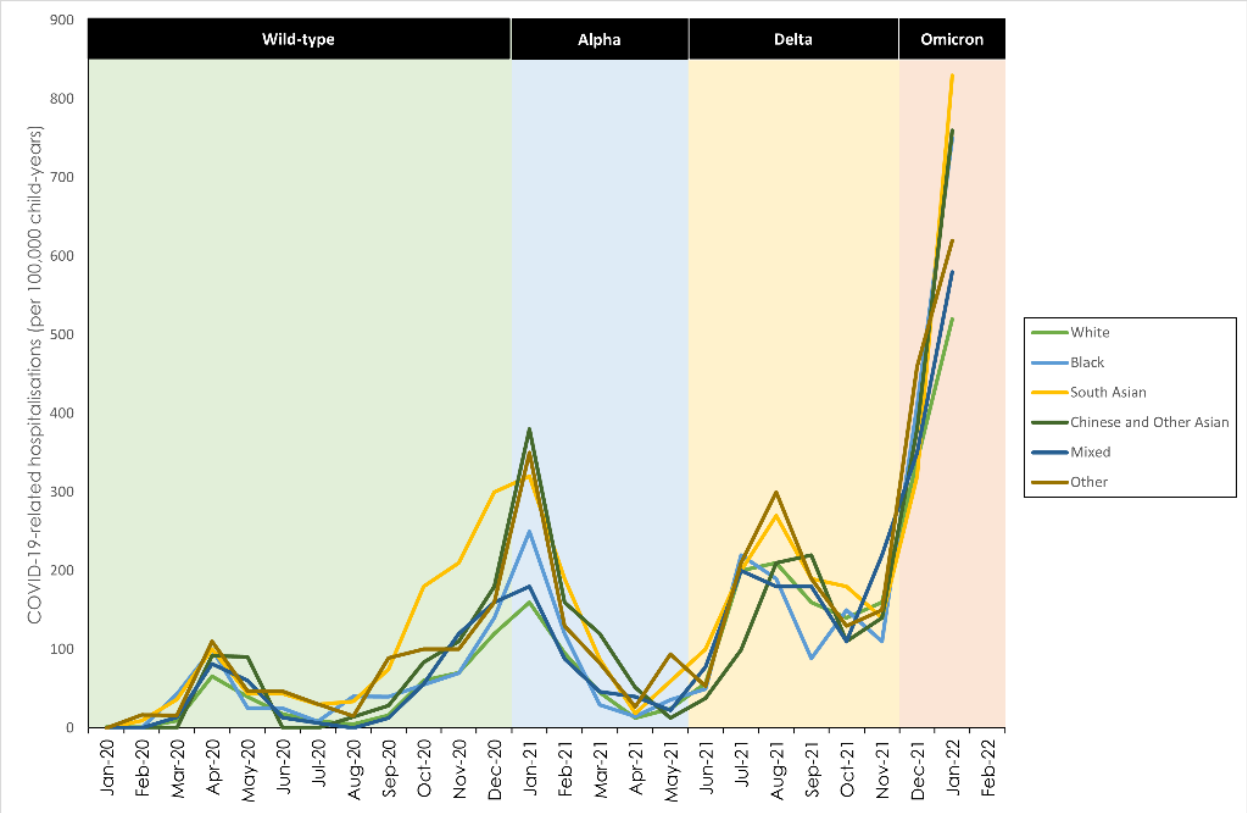
ETHNIC GROUP DIFFERENCES IN RATES OF SARS-COV-2 TESTING, PCR-CONFIRMED INFECTIONS AND COVID-19-RELATED HOSPITALISATIONS IN YOUNG CHILDREN BY COVID VARIANT: NATIONAL BIRTH COHORT STUDY.

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Fariyo Abdullahi, Pia Hardelid, Vincent Nguyen, Claire Thorne, Linda Wijlaars
UCL GOSH Institute of Child Health, Population, Policy And Practice, WCN EH, United Kingdom

Backgrounds: COVID-19-related-hospitalisation rates in children increased during the Omicron variant wave. Substantial inequalities in SARS-CoV-2 infection outcomes across different ethnic groups are reported in adults.
Methods: We used a national birth cohort of all singleton children under 5 years, born in England between 01/2015-01/2022, linked to national SARS-CoV-2 testing and hospitalisation data, to calculate and compare rates of testing (lateral flow and PCR), primary PCR-confirmed SARS-CoV-2 infections per 1000 child-years (06/2020-01/2022), and COVID-19 related-hospitalisation rates per 100,000 child-years (01/2020-01/2022) by ethnic group and dominant variant wave.
Results: We included data for 4,095,233 children. Black children had the lowest testing rates, ranging from 185.2 per 1000 child-years (95%CI:182.1-188.4) during the wild-type wave to 1261.6 per 1000 child-years (95% CI:1247.9-1275.5) during the Omicron wave. South Asian (Indian, Pakistani, and Bangladeshi) children had the highest rate of PCR-confirmed infections during the wild-type and Alpha variant waves, 42.0 (95%CI:40.4-43.7) and 115.7 (95%CI:112.8-118.7) per 1000 child-years, respectively, despite higher testing rates in White children. COVID-19-related hospitalisation rates were highest during the Omicron wave across all ethnic groups. South Asian children had the highest hospitalisation rate during the wild-type, Alpha, and Delta waves (71.3, 179.1 and 163.9 per 100,000 child-years). Black children had the greatest rate of hospitalisations (589.8 per 100,000 child-years [95%CI:530.2-654.4]) during the Omicron
wave.



Conclusions/Learning Points: Ethnic differences in COVID-19 outcomes in children under 5 years were found. Ethnic minority children were infected at greater rates during the earlier variant waves. The substantial increase in hospitalisation rates in all ethnic groups can be linked to the Omicron variant. Future work will assess factors explaining variations of COVID-19 outcomes by ethnic group and monitor ethnic group differences in outcomes as COVID-19 restrictions ended during 2022.

EASING OF SARS-COV-2 PREVENTIVE MEASURES LEAD TO A RAPID AND SEQUENTIAL INCREASE OF PEDIATRIC RSV AND SARS-COV-2 ACUTE RESPIRATORY INFECTIONS IN PEDIATRIC PRIMARY CARE PRACTICES

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

André Haufschild[1], Géraldine Engels[1], Johanna Sack[1], Kerstin Knies[2], Benedikt Weißbrich[2], Christoph Härtel[1], Lars Dölken[2], Andrea Streng[1], Johannes Liese[1]
[1]University Hospital Wuerzburg, Department Of Pediatrics, Wuerzburg, Germany, [2]University of Wuerzburg, Institute Of Virology And Immunobiology, Wuerzburg, Germany

Backgrounds: As a side effect of non-pharmaceutical measures directed against SARS-CoV-2, considerable fluctuations of other respiratory viral infections were observed in pediatric primary care practices in winter 2020/21 (Engels et al. 2022). We investigated the prevalence and clinical manifestations of respiratory infections in the same setting during winter 2021/22, after easing of pandemic measures.
Methods: From October 2021 to May 2022, children aged 0-14 years presenting with acute respiratory infection (ARI) in one of five pediatric practices in Würzburg (Germany) were included. On one day per week and practice, an oropharyngeal swab was taken from up to 8 patients and tested for SARS-CoV-2 (PCR) and 17 other respiratory viruses (multiplex-PCR FTD-21™). Sociodemographic and clinical data of the patients were collected.
Results: 521 children (52% males) were recruited (median age 3.3 years; IQR 1.7-5.5); 11% had an underlying disease, mainly “recurrent obstructive bronchitis“ [8%]. 143 (27%) children presented with lower respiratory tract infection (82%/143 only bronchitis/bronchiolitis, 9%/143 only pneumonia); four (0.8%/521) required hospitalization. In 444/521 (85%) children, at least one virus species was detected: rhinovirus (30%); RSV (22%); SARS-CoV-2 (16%); human metapneumovirus (14%); bocavirus (11%); adenovirus (9%); endemic coronaviruses (7%); parainfluenza viruses (6%); influenza A (1%); parechovirus (1%). RSV was detected mainly in October–December 2021 (112/114) whereas SARS-CoV-2 was found only in January–May 2022 (82/82). Rhinovirus and adenovirus were consistently detected throughout the study period. Co-detections were found in 156 (29,9%) children (children <2 years of age (YOA) 37%, 2-4 YOA 34%, 5-11 YOA 19%, 11-14 YOA 6%).
Conclusions/Learning Points: After easing of non-pharmaceutical preventive measures RSV-associated ARI increased rapidly and unusually early in autumn 2021 and were followed by strong SARS-CoV-2 ARI increase in early 2022.

PV0949 / #654

SIMILARITIES AND DIFFERENCES BETWEEN MULTISYSTEMIC INFLAMMATORY SYNDROME IN CHILDREN (MIS-C) AND SEPSIS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Maria Hernandez-Garcia[1], Elies Roldan-Berengue[2], Carmina Guitart[3], Monica Girona-Alarcon[3], Guillermo Argüello[4], Rosa Pino[1], Mariona F De Sevilla[1], Juan Jose Garcia-Garcia[1], Iolanda Jordan[3]
[1]Hospital Sant Joan de Deu, Paediatrics Hospitalization, Esplugues de Llobregat, Barcelona, Spain, [2]Universitat Internacional de Catalunya, Medicina, Barcelona, Spain, [3]Hospital Sant Joan de Deu, Pediatric Intensive Care Unit, Esplugues de Llobregat (Barcelona), Spain, [4]Universitat Oberta de Catalunya, Faculty Of Computer Science, Multimedia And Telecommunications, Barcelona, Spain

Backgrounds: MIS-C is the most severe presentation of SARS-CoV-2 infection in children. Its differential diagnosis with other causes of systemic inflammatory response such as sepsis is complex.
Methods: Case-control study that compared the demographic, clinical, diagnostic and therapeutic data between paediatric patients with MIS-C (cohort 2020-2022) and sepsis (cohorts 2010-2014 and 2017-2018) admitted to a Paediatric Intensive Care Unit (PICU) of a tertiary care paediatric hospital. A predictor score was developed to help better distinguish between the two entities.
Results: 29 patients with MIS-C were identified, who were matched 1:3 with patients with sepsis (n=87). Patients with MIS-C were older (10 vs. 4 years old), and most of them were men (69%). Clinical characteristics that demonstrated statistically significant differences between the two groups were prolonged fever and signs and symptoms affecting skin-mucosa and gastrointestinal system. Leukocytes, PCT and ferritin were higher in the sepsis group, while thrombocytopenia and elevated adrenomedullin were more frequent in the MIS-C group. Patients with MIS-C presented greater myocardial dysfunction ($p<0.01$). 5 selected variables were introduced in a multivariate logistic regression model, and after scaling the coeficients and the intercept of the regression to integer values the next predictor score was developed: - (4 * Hours of fever) + Platelets - (84 * Abdominal pain) - (43 * Conjunctival erythema) - (2 *Vasoactive Inotropic Score (VIS)) + 120 The interpretation is: when the score is negative the model is predicting a patient with MIS-C, and when is positive a patient with Sepsis.
Conclusions/Learning Points: MIS-C phenotype overlaps with sepsis. The use of predictor scores, such as the one designed in our study, could be useful to distinguish between both entities and direct specific treatment.

Instituto de Investigación Sanitaria Gregorio Marañón (IisGM). CIBERINFEC. RITIP., Paediatric Infectious Diseases, Madrid, Spain

Backgrounds: The aim of this study was to compare humoral and cellular response to SARS-CoV-2 mRNAs vaccines in paediatric heart transplant recipients (HTR) compared with healthy controls (HC).
Methods: Prospective cohort study including paediatric HTR (n=12) and HC (n=14) vaccinated against SARS-CoV-2 in a tertiary hospital between December 2021-July 2022. The humoral response was measured by quantifying antibody titers against SARS-CoV-2 protein S (anti-S IgG). T-cell-phenotype and SARS-CoV-2-specific T-cell response was studied by quantifying intracellular cytokine production (IFN-γ/TNF-α/IL-2) after SARS-CoV-2 peptides stimulation by flow cytometry on cryopreserved peripheral blood mononuclear cells.
Results: Patients' characteristics are shown in Table 1. Anti-S IgG levels (UA/mL) were significantly lower in HTR group (3960, IQR 985-11,915) compared to HC (19,170, IQR 13,131-32,852) after vaccination ($p<0.005$). Twelve children had been previously infected by SARS-Cov-2. Overall, there was not a significant difference in the humoral response between these children and those not previously infected. In terms of cellular response, no significant differences were observed in the magnitude of response in HTR compared to HC groups. However, participants previously infected by SARS-CoV-2 showed increased SARS-CoV-2 specific T-cell response and rate of responders (individuals with a SARS-CoV-2 specific response threshold ≥0.05%) despite no significant differences. Direct correlations were shown between anti-S IgG levels and SARS-CoV-2-specific IFN-γ+ and TNF-α+ production in total and memory CD8 T-cells. Notably, anti-S IgG levels inversely correlated with activation markers' expression on CD4 T-cells (HLA-DR+CD38+ and CD25+). The expression of degranulation marker, CD107a+, inversely correlated with the expression of CD25+ on CD4 memory T-cells.

Table 1. Clinical characteristics of the study groups.

	HTR n=12	HC n=14	*p*
Age (years)	13.2	8.7	>0,05
Sex (male), n (%)	6 (50)	7 (50)	>0,05
Immunosuppressive treatment, n (%)			
Tacrolimus	11 (91.7)	0	
Mycophenolate	6 (50)	0	
Sirolimus	1 (8.3)	0	
Corticosteroids	3 (25)	0	
Doses of vaccine, n (%)			***<0,05***
Two doses	3 (25)	14 (100)	
Three doses	9 (75)	0	
Time from last dose of vaccine to follow-up sample collection, in months (IQR)			**<0,05**
	4.3 (1.7-4.9)	0.6 (0.6)	
Previous SARS-CoV-2 infection			>0,05
	5 (41.6)	11 (78.5)	

HTR: heart transplant recipients; HC: healthy controls; IQR: interquartile range.

Conclusions/Learning Points: In our study, paediatric HTR responded adequately to SARS-CoV-2 mRNA vaccination, although they had lower antibody titers than HC. We did not found differences in the cellular response between HTR and HC.

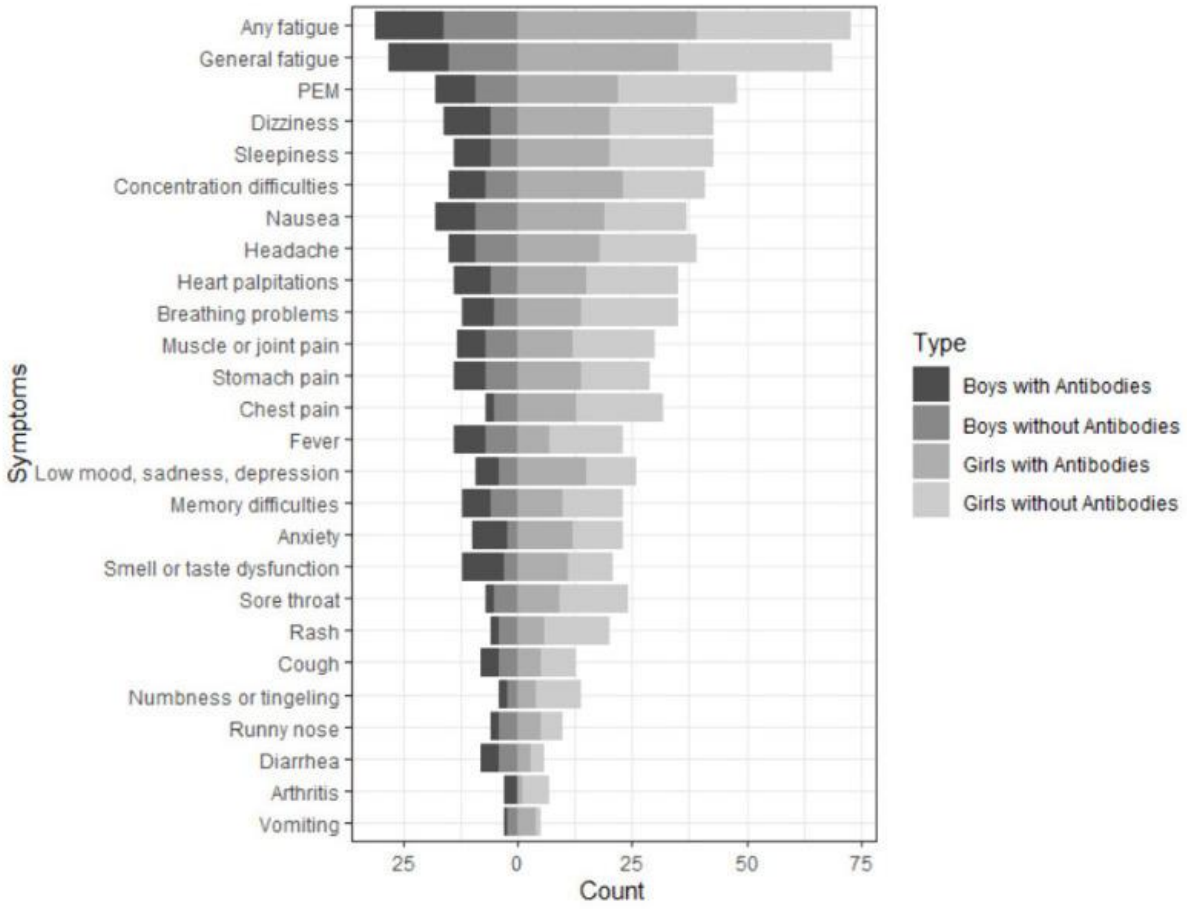
POOR RELATION BETWEEN TYPICAL POSTCOVID SYMPTOMS AND PROOF OF SARS-COV-2 INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Olof Hertting, Selma Åkerfeldt, Joachim Luthander, Malin Ryd Rinder
Paediatric Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden

Backgrounds: The COVID-19 pandemic has had a significant impact on children's health despite their typically mild course of infection. Long-term symptoms after COVID-19 in the pediatric population is gaining increased attention. We organized a multi-disciplinary specialist pediatric outpatient post-COVID clinic and standardized the patient management. Here, we aim to describe our group of patients and compare clinical presentation and characteristics in SARS-CoV-2 antibody positive or negative children.
Methods: The cohort of children and adolescents attending our clinic was managed within a standardized multidisciplinary program, involving multiple standardized tests and interviews by a team pediatrician, nurse, physiotherapist, psychologist and medical social worker. SARS-CoV-2 spike antibodies were measured.
Results:



In 114 children aged 6-18 years, a confirmed serological link to SARS-CoV-2 infection was found in 52%. The most common symptoms were fatigue, post-exertional malaise, dizziness, nausea, headache and concentration difficulties (Figure 1). The type of symptoms were unrelated to antibody status. Children lacking SARS-CoV-2 antibodies had a higher number of individual symptoms. Self-reported health was low in both groups (EQ5DY VAS scale 54 in seropositive children vs 48 in seronegative children). 37% of seropositive children and 48% of seronegative children had other family members suffering from post-COVID.

Conclusions/Learning Points: This cohort of children attending a specialist pediatric post-COVID clinic experienced multiple different symptoms, poor self-reported health and often had other family members with similar problems. Children with positive SARS-CoV-2 antibodies did not report symptoms more often than those without. The situation for children during the pandemic may have caused similar symptoms regardless of exposure to SARS-CoV-2. A multidisciplinary assessment was essential in light of the broad spectrum of symptoms displayed and the need of individualized support.

Title of Case: CASES OF PEDIATRIC MULTISYSTEM INFLAMMATORY SYNDROME (MIS-C) LINKED TO SARS-COV2 TREATED AT A THIRD LEVEL HOSPITAL IN SOUTHERN SPAIN
Background: MIS-C is a multisystem inflammatory syndrome that began to be diagnosed on May 2020 in pediatric patients after 2-6 weeks of suffering an acute infection with SARS-Cov2. The most frequent symptoms were fever, gastrointestinal, cardiovascular and hematological symptoms. In a high percentage of cases admission to pediatric intensive care was required for monitoring and treatment. Below, we describe the cases treated in our hospital:
Case Presentation Summary: 1. 10-year-old patient with fever, abdominal pain, vomiting and diarrhea. Within 48 hours, he presented biventricular dysfunction that required admission to the ICU. He received treatment with glucocorticoids, immunoglobulins, anakinra and anticoagulants with full recovery after 2 mo 2. 11-year-old patient with fever, abdominal pain, exanthema and diarrhea. Progressive hemodynamic worsening that required vasoactive treatment. He received therapy with glucocorticoids, immunoglobulins, anakinra and anticoagulants, recovery with neurological sequelae. 3. 8-year-old patient with fever, conjunctival hyperemia, and abdominal pain. In 72 hours, he presented systolic dysfunction that required admission to the ICU. He receives treatment with glucocorticoids, immunoglobulins, anakinra and anticoagulants with full recovery after a month. 4. 12-year-old patient with fever and abdominal pain. Within 48 hours, he presented biventricular systolic dysfunction that required going into the ICU. He received treatment with glucocorticoids, immunoglobulins and anticoagulants with full recovery after three months. 5. 6-year-old and 10-year-old patients with fever, abdominal pain, and palmoplantar exanthema. No cardiac involvement. They receive treatment with glucocorticoids and immunoglobulins without requiring ICU admission.
Learning Points/Discussion: All presented positive serology for SARS-COV2, leukopenia and a significant increase in acute phase reactants. None had a personal background of interest, nor had they received vaccination against SARS-COV2.

ANTIBODY LEVEL OF SARS-COV-2 AMONG PEDIATRIC ONCOLOGY PATIENTS IN DR. SOETOMO HOSPITAL, SURABAYA, INDONESIA

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Dominicus Husada, Mellisa Hosea, Andi Cahyadi, Alpha Attiyah, Leny Kartina, Neurinda Kusumastuti
Faculty of Medicine Universitas Airlangga/Dr. Soetomo General Hospital, Pediatrics, Surabaya, Indonesia

Backgrounds: During the Covid-19 pandemic, among all children, pediatric oncology patients were one of the most severe victims. In Indonesia, the Covid vaccination program for children only covers 6-17 years age group. There is no national data regarding the antibody level among those oncology patients. This study aimed to analyze the SARS-CoV-2 antibody level among children with oncology diseases in Dr. Soetomo Hospital Surabaya
Methods: This cross-sectional study was performed in a tertiary academic teaching hospital, the largest hospital in the eastern part of Indonesia. Recruited subjects had aged at least 6 years old and suffered from pediatric malignancy. IgG level was determined from 3 ml of venous blood. The antibody examination using Chemiluminescent Microparticle Immunoassay (CMIA) was done at a commercial international accredited laboratory in Surabaya.
Results: There were 50 children during the study, with 76% having hematological malignancy. Most of these subjects were on chemotherapy, uninfected with Covid-19, and unimmunized. Boys outnumbered girls, and the majority was Javanese ethnicity. Among those with hematological malignancy and solid tumor, the antibody levels were 968.3 (range 1.7 – 29091.4) and 572.7 (range 16.1 – 1066.1), respectively. Three (hematological malignancy) and one (solid tumor) patients showed nonreactive results.
Conclusions/Learning Points: Children with hematological malignancy showed higher antibody levels of SARS-CoV-2 than the solid tumor patients. Despite the low level of immunization, a high percentage of positive results in children indicated the high number of infections during this pandemic.

SIGNS OF SEVERITY ASSOCIATED TO LIMPHOPENIA IN CHILDREN HOSPITALIZED WITH COVID 19 IN BUCHAREST, ROMANIA

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Niculae Ion Nedelcu, Petre Iacob Calistru
Bd Mihai Bravu 281 Sector 3 Bucharest, Infectious Diseases, Bucharest, Romania

Backgrounds: Lymphopenia associated with Covid 19 is considered a prognostic sign of severe evolution in adults - however this association is not clear in children In this study, our aim was to explore the possible associations of lymphopenia with other signs of disease severity in children hospitalized for Covid 19 in our clinic
Methods: All children aged 0-18 years treated for SARS-CoV-2 infection in our hospital in the first semester of 2022 were included in the study. For each patient, relevant clinical and laboratory data were retrived from the electronic register and entered into an EpiInfo 7 database. Statistical comparison have been used to show correlations between lymphopenia and other signs of disease severuty.
Results: The prevalence of children with limphopenia at hospital admission was 44.5% (95% CI: 37.5% - 51.7%), similarely distributed ($p > 0.05$) by age group. No deaths or ICU admission were encountered in patients within study group; however the followimg signs of severuty were associated with limphopenia: mean duration of hospital stay was significantly higer in children with lymphopenia (3.12 days) compared with those of children without limphopenia (1.86 days) Kruskal-Wallis H = 12.7239 df=1 p: 0.0004 prevalence of elevated blood coagulation markers (53.99 %) was significantely higer in patients with limphopenia compared with only 20.72 % in children without limohopenia : RR:2.60; 95%CI (1.72 – 3.92); p : 0000006016.
Conclusions/Learning Points: Our results provide evidences of prognostic value of limphopenia detected at the hospital admission of children with Covid 19.

URTICARIA MULTIFORME: CUTANEOUS MANIFESTATION OF COVID-19 INFECTION- A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Joseph Carolin Jeyanthi, Khin Myo Yi, Chia Shi Yun
KK women's and Children's Hospital, Paediatrics, Singapore, Singapore

Title of Case: URTICARIA MULTIFORME: CUTANEOUS MANIFESTATION OF COVID-19 INFECTION - A CASE REPORT
Background: Recent literature has reported a variety of dermatologic manifestations associated with COVID-19 infection among children. Although urticarial lesions are commonly reported, urticaria multiforme, a morphological subtype of acute urticaria, is under-recognized and not commonly described as a dermatologic manifestation of COVID-19 infection. A case of urticaria multiforme associated with COVID-19 infection is detailed in this case report.
Case Presentation Summary: A 9 year 4 month old boy with no significant past medical history presented with a pruritic rash, sore throat, and rhinorrhoea of 5 days duration. The rash initially began as raised erythematous papules and then evolved to form annular, polycyclic, erythematous wheals affecting the limbs, hands, and feet. Clinically, the child remained haemodynamically stable and physical examination revealed annular urticarial rashes with a dusky, ecchymotic center affecting the extremities without any mucosal involvement. The child was eventually confirmed to be COVID-19 PCR positive. Based on the above clinical findings, a diagnosis of urticaria multiforme was made. The patient was treated symptomatically with antihistamines, with complete resolution of symptoms.
Learning Points/Discussion: The cutaneous manifestations of COVID-19 are diverse and may reflect the range of host immunological responses to the virus. Although the majority of them are self-limiting, dermatologic manifestations can also be observed in hyperinflammatory states such as multisystem inflammatory syndrome in children (MIS-C). The authors feel that further characterisation and classification of COVID-19 associated dermatologic manifestations will aid clinicians in risk stratification and early identification of patients with MIS-C.

PV0956 / #1288

DEMOGRAPHIC, CLINICAL AND LABORATORY DIFFERENCES BETWEEN PAEDIATRIC COVID-19 AND PIMS-TS – RESULTS FROM A SINGLE CENTRE STUDY IN THE UK

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Prince Jiju[1], Michail Matalliotakis[2], Clare Pain[2,3], Waison Wong[4], Christian Hedrich[2,3]
[1]Alder Hey Children's NHS Foundation Trust, Department Of Paediatric Medicine, Liverpool, United Kingdom, [2]Alder Hey Children's NHS Foundation Trust, Department Of Paediatric Rheumatology, Liverpool, United Kingdom, [3]Institute of Life Course and Medical Sciences, University of Liverpool, Department Of Women's And Children's Health, Liverpool, United Kingdom, [4]Alder Hey Children's NHS Foundation Trust, Paediatric Infectious Diseases And Immunology, Liverpool, United Kingdom

Backgrounds: Paediatric symptomatic SARS-CoV-2 infections associate with two presentations, acute COVID-19 and paediatric inflammatory multisystem syndrome temporally associated with SARS-CoV-2 (PIMS-TS). Phenotypic comparisons, and reports on predictive markers for disease courses are sparse.
Methods: A chart review of COVID-19 and PIMS-TS patients (≤19 years) admitted to Alder Hey Children's NHS Foundation Trust, a tertiary centre in the North-West of England, was performed (02/2020-09/2022).
Results: Of 848 children testing positive for SARS-CoV-2, 687 (81%) were not admitted for PIMS-TS or COVID-19. Remaining 161 COVID-19 and 50 PIMS-TS patients were included in this study. PIMS-TS cases presented approximately 4 weeks after COVID-19 (figure 1). The incidence of PIMS-TS reduced over time, and there were no admissions after 02/2022. PIMS-TS were older than COVID-19 patients (median: 10.3 versus 2.03 years; $p<0.001$). There were no differences in gender distribution, but minority ethnicities were over-represented among PIMS-TS patients. Regional ethnic distribution was reflected more amongst COVID-19 patients (66.7% versus 84.4% Caucasian, $p=0.01$). Pre-existing comorbidities were more common among COVID-19 patients (54.7% versus 8%, $p<0.001$). Respiratory symptoms were more common in COVID-19. PIMS-TS associated with abdominal symptoms, headaches, skin rashes, mucositis, lymphadenopathy, and arthritis ($p\leq0.05$). PIMS-TS more frequently required intensive care admission (64% versus 16.8%), oxygen supplementation (48% versus 29.8%), fluid resuscitation (68% versus 19.9%) and inotropic support (64% versus 9.32%) ($p<0.05$). More deaths occurred among COVID-19 patients (0 versus 7 (4.35%)). When compared to COVID-19, PIMS-TS patients exhibited more lymphopenia and thrombopenia, a more pronounced acute phase reaction, and more hyponatraemia ($p<0.05$).

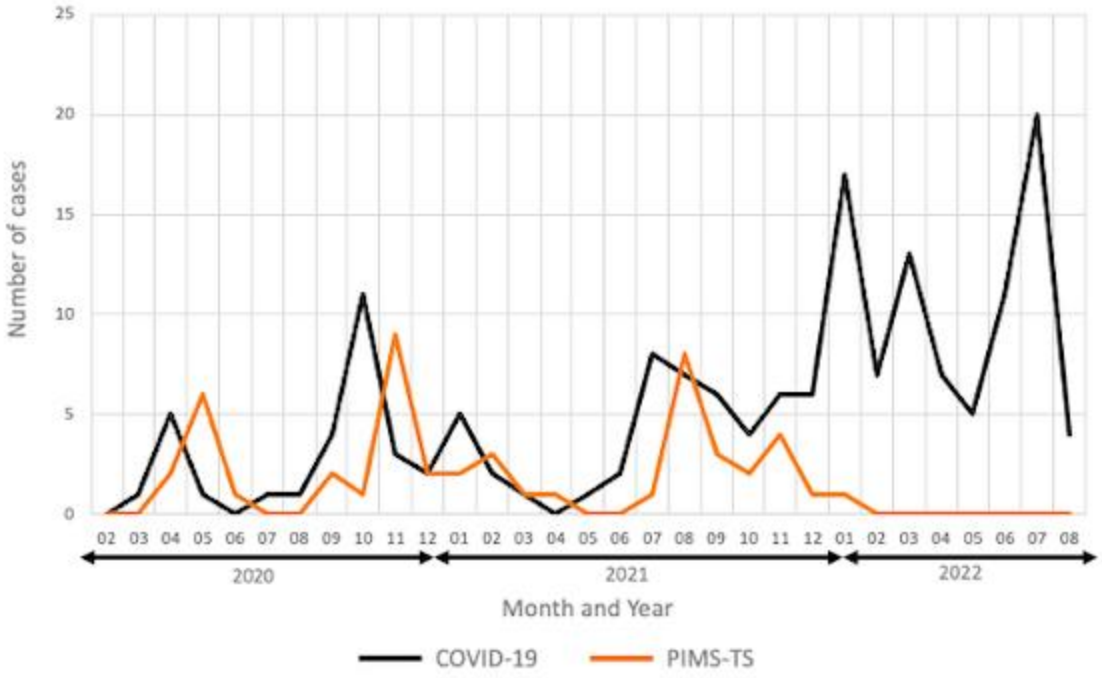

Figure 1: Hospital admissions for PIMS-TS and COVID-19 between 10/02/2020 and 31/08/2022. PIMS-TS: *n=50;* acute COVID-19: *n=161.*

Conclusions/Learning Points: Young age and pre-existing comorbidities predispose to paediatric COVID-19. While PIMS-TS may present more acutely, mortality is higher in COVID-19. Clinical and laboratory signs of cytokine storm syndrome at diagnosis may predict PIMS-TS.

PV0957 / #1116

SEROPREVALENCE OF SARS-COV-2 IN CHILDREN IN PREVACCINE ERA

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Piia Jõgi[1], Paul Naaber[2], Sirje Leedo[3], Elo Saue[4], Jevgenia Epštein[5], Irja Lutsar[6]
[1]Children Clinic of Tartu University Hospital, Acute Infections, Tartu, Estonia, [2]SYNLAB Eesti, Oy, Tallinn, Estonia, [3]Tartu University Hospital, United Laboratories, Tartu, Estonia, [4]Tallinn Children´s Hospital, Laboratory, Tallinn, Estonia, [5]Health Board of Estonia, Department Of Communicable Diseases, Tallinn, Estonia, [6]University of Tartu, Department Of Medical Microbiology, Tartu, Estonia

Backgrounds: At the end of 2021, the seroprevalence of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection among adults in Estonia was about 80% (1). Limited prospective seroprevalence data in children regarding SARS-CoV-2 have been reported. Our aim was to determine SARS-CoV-2 seroprevalence in children before paediatric SARS-CoV-2 immunisation and compare it to the registered notification and hospitalisation rates of SARS-CoV-2.
Methods: The leftover sera of 310 children (aged 0-11years) were collected by the laboratories of children hospitals in Estonia between December 21, 2021 and January 12, 2022 (prevaccine era for this age-group). Anti-SARS-CoV-2 S-RBD IgG concentration was measured by CMIA (Abbott). The antibody titres ≥50AU/ml were considered suggestive to SARS-CoV-2 infection. The notification and hospitalisation rates of SARS-CoV-2 were derived from the database of the Health Board of Estonia.
Results: A total of 136 children (median age 5 years; IQR 3-8) were seropositive (43.9%; 95%CI 28.8-49.6), similar in all yearly ages. The seroprevalence was lower among pre-kindergarten children aged 0-2years (36%; 95%CI 24.5-48.5) and kindergarten children aged 3-6years (36%; 95%CI 28.1-45.4) than in schoolchildren aged 7-11years (57%; 95%CI 47.4-66.3) (Figure 1). The SARS-CoV-2 notification rate was highest among schoolchildren 21.6%, followed by kindergarten (11.0%) and pre-kindergarten children 5.2% (Figure 1). In contrast, the hospitalisation rate was highest among pre-kindergarten children (0.4%) and equal in other age-groups (Figure
1).

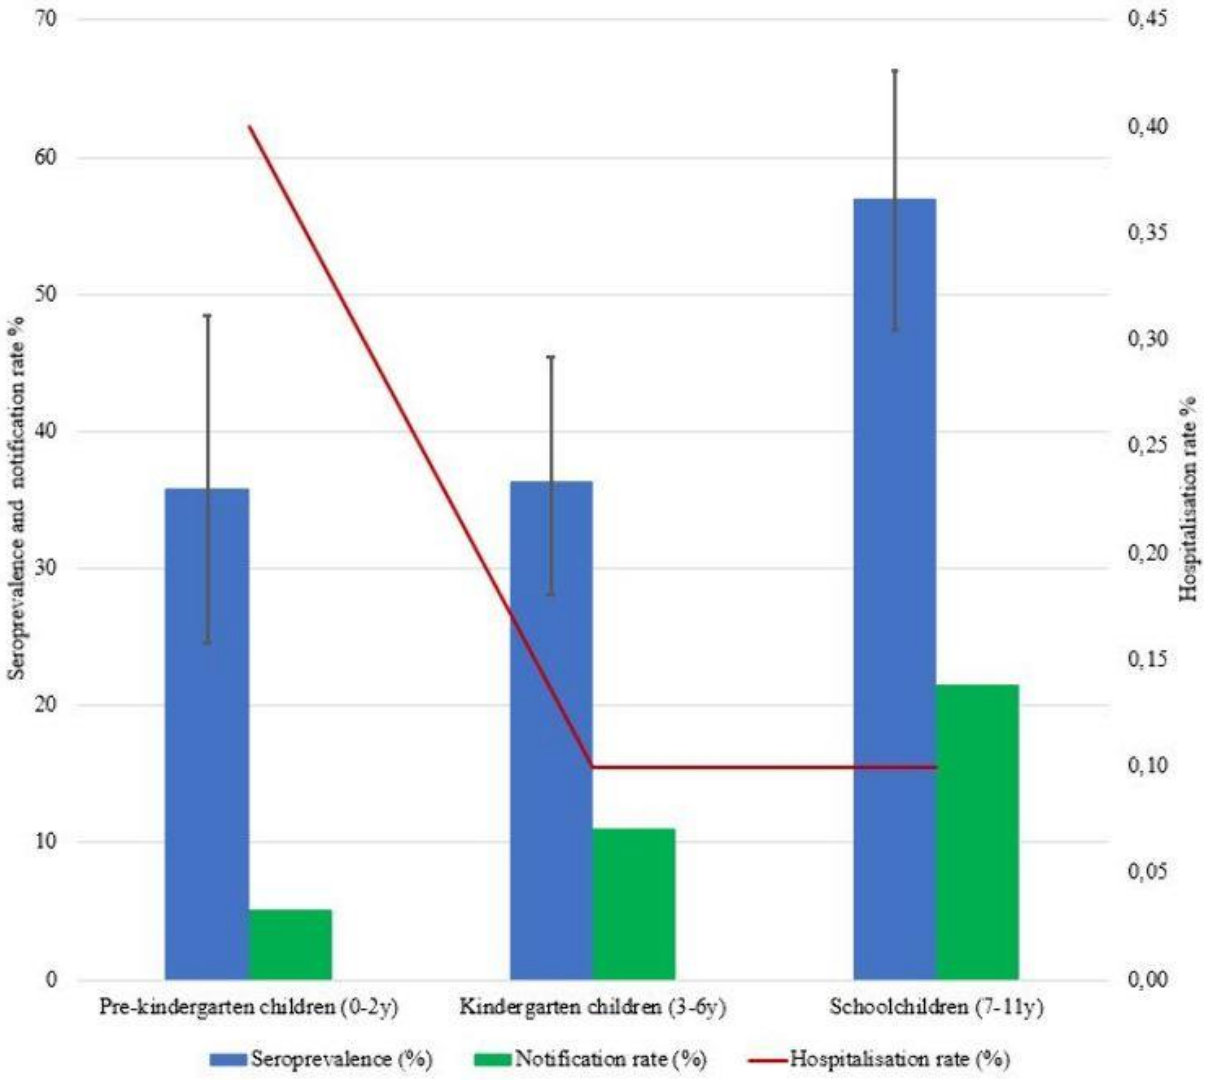

Figure 1: SARS-CoV-2 seroprevalence (%) with CI (blue, primary y-axis), notification rate (%, green, primary y-axis) and hospitalisation rate (%, red, secondary y-axis) in pre-kindergarten, kindergarten and schoolchildren in prevaccine era.

Conclusions/Learning Points: Natural seroprevalence of SARS-CoV-2 among children was half of that in adults. However, among children it was significantly higher than the reported incidence. This together with low hospitalisation rates suggests that COVID-19 in children is mostly mild or asymptomatic.

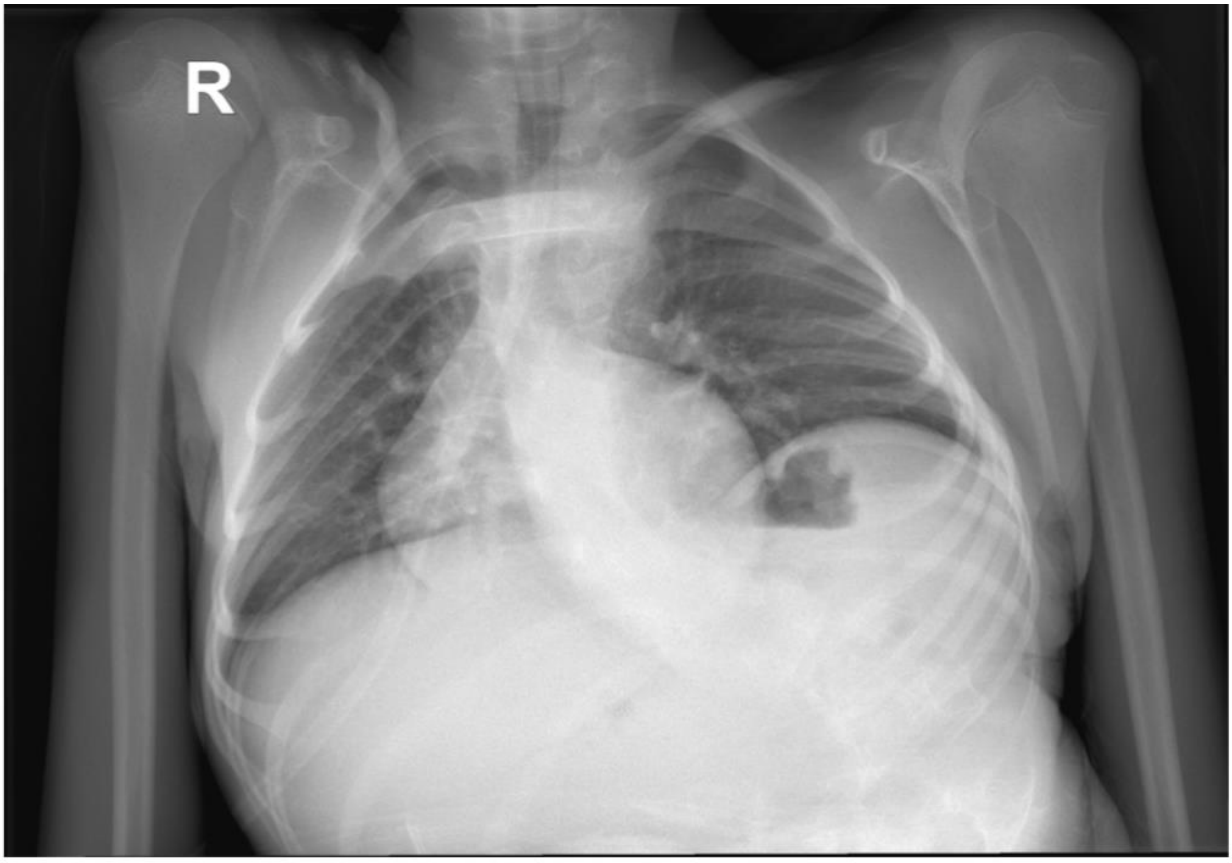
SARS-COV-2 INFECTION IN PEDIATRIC PATIENTS WITH CYSTIC FIBROSIS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Daniela Gabdullina, Monica Luminos, Daniela Ceptureanu, Gheorghita Jugulete, Madalina Merisescu
National Institute for Infectious Diseases Matei Bals, Pediatric Infectious Diseases, Bucharest, Romania

Backgrounds: SARS-CoV-2 infection has the potential of causing severe forms of COVID-19, especially in patients with comorbidities and other associated diseases prior to the infection. Pediatric patients with cystic fibrosis represent a special category at-risk to develop acute respiratory failure as well as the possibility of exacerbation of their underlying chronic pulmonary condition.
Methods: During SARS-CoV-2 pandemic period, from January 2022 to January 2023, in Matei Bals Hospital from Bucharest, Romania, were hospitalized 4 pediatric patients with cystic fibrosis, who were undergoing background treatment with aerosols and pancreatic enzymes.The patients were aged between 7 months and 15 years old, the oldest one presented the most severe form of cystic fibrosis associated with a significant form of scoliosis.
Results: Albeit all these patients were known with a chronic pulmonary disease, one of them of 15 years old, also presenting significant bone deformities, which means an additional risk of developing severe lung infections, they were admitted to our pediatric clinic with medium forms of COVID-19. They developed mild breathing failure without the necessity of high-flow oxygen therapy or monitoring at the intensive care unit. During hospitalization they received antiviral treatment with Remdesivir for 5 days, antibiotherapy, nebulizations with bronchodilatators, supplemental oxygen therapy through non-invasive ventilation and symptomatic treatment. All the patients had a favorable outcome and were dischardged after 5-7 days of hospitalization. There were no deaths
registered.



Chest X-ray, National Institute for Infectious Diseases Matei Bals, Bucharest, Romania.

Conclusions/Learning Points: Despite the fact that cystic fibrosis represents a risk factor for an acute exacerbation of the respiratory function in COVID-19, during the 2022-2023 pandemic period at Matei Bals Hospital, we have not registered severe cases of SARS-CoV-2 infection in pediatric patients with this chronic pulmonary disease.

SARS COV2 INFECTION COMPLICATED WITH STAPHYLOCOCCUS AUREUSSEPSIS ON A CHILD WITH SELECTIVE IG A DEFICIENCY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Borcos Bianca Rybana[1], Elena Gheorghe[1], Mihaela Safta[1], Madalina Manole[1], Ana Maria Popescu[1], Andreea Panciu[1], Luminita Marin[1], Madalina Merisescu[1,2], Gheorghita Jugulete[1,2]
[1]Institute of Infectious Diseases Professor Doctor "Matei Bals", Paediatric, Bucharest, Romania, [2]University of Medicine and Pharmacy Carol Davila, General Medicine, Bucharest, Romania

Title of Case: SARS CoV2 infection complicated with Staphylococcus aureus sepsis on a child with selective Ig A deficiency
Background: SARS-CoV-2, the virus responsible for COVID-19, primarily affects the respiratory system, with most cases in children presenting as mild and requiring only supportive care. However, there are exceptions, and further research is needed to fully understand the clinical presentation and management of COVID-19 in pediatric populations.
Case Presentation Summary: A 1 year and a seven-month-old child was admitted to the Pediatric Department at The National Institute of Infectious Diseases "By Prof. Dr. Matei Bals" for presenting fever, vomiting, diarrhea, and oligoanuria. Upon admission, the child tested positive for SARS-CoV-2 antigen, and laboratory investigations revealed discrete lymphocytosis (5500/mm3), minimal hypochromic microcytic anemia, and no biological inflammatory syndrome. The stool analysis was negative. The child was initiated on antiviral therapy with Remdesivir i.v. And symptomatic treatment, with an initially favorable evolution. On the fourth day of hospitalization, the child developed high fever and chills, and chest radiography revealed bilateral hiliolaterobasal alveolointerstitial infiltrates. Laboratory investigations revealed leukocytosis (16,560/mm3) with neutrophilia (9,330/mm3) and significant biological inflammatory syndrome (CRP=46.1 mg/L), procalcitonin = 25.14 ng/mL. Antibiotic therapy was initiated with Ceftriaxone and Linezolid for seven days. Blood culture was positive for Staphylococcus aureus MSSA, and the immunogram revealed that the IgA level was below the standard limit. The patient's clinical and biological evolution was favorable, and after ten days of hospitalization, the patient was discharged from the hospital.
Learning Points/Discussion: The simultaneous occurrence of SARS CoV2 infection and selective IgA deficiency results in a heightened susceptibility to infections due to a compromised immune system. This phenomenon can explain the development of complications, such as staphylococcus aureus sepsis, in a patient with both conditions.

VIRAL CO-INFECTIONS OF COVID-POSITIVE PATIENTS, IN THE PEDIATRIC POPULATION OF THE OMICRON PANDEMIC WAVE

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Madalina Merisescu, Gheorghita Jugulete, Daniela Gabdullina, Daniela Ceptureanu, Monica Luminos
National Institute for Infectious Diseases Matei Bals, Pediatric Infectious Diseases, Bucharest, Romania

Backgrounds: SARS-Cov2 infection is an immunosuppressive infection for the pediatric population, which can cause a severe form of the disease when other viruses overlap. Although the clinical picture of the disease was digestive, viral co-infections most often caused acute respiratory failure.
Methods: In the “Matei Bals” hospital, were admitted, a number of 1423 children with SARS-CoV-2 infection, between January 2022 and January 2023.The majority were represented by children with Sars-cov2, but 55 of them presented co-infections with other viruses.
Results: Among the patients, 43 presented Influenza A infection and Covid, 12 of them presented Sars-Cov2 associated with RSV and 4 of them presented triple viral infection represented by Sars-cov2, Influenza and Rotavirus. The age of these patients was between 0-5 years. Those who presented Sars-RSV co-infection were in the age group 0-1 years while the patients who had the flu and Sars were in the age group of preschool children, 4-5 years old.96% of the patients presented signs of acute respiratory failure, high fever, cough, laryngitis, or digestive manifestations, represented by vomiting or diarrhea.Their treatment was complex, including antiviral - Remdesivir with Oseltamivir in patients with flu, for at least 3 up to 7 days depending on the severity and complexity of the cases, oxygen therapy, cortisone, nebulization with bronchodilators.The clinical evolution of all children was favorable. 70% of the forms were moderate, 12% were severe. There were no deaths among children in the “Matei Bals” clinic.
Conclusions/Learning Points: Viral co-infections with the Covid-19 infection can represent an important cause of morbidity in pediatric clinics in Romania, especially with the appearance of the Omicron variant, which particularly interested children, causing prolonged forms of the disease with acute respiratory failure, which required oxygen therapy

PV0961 / #1892

THE IMPACT OF SARS-COV2 INFECTION IN IMMUNOCOMPROMISED PEDIATRIC PATIENTS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Madalina Merisescu, Gheorghita Jugulete, Monica Luminos
National Institute for Infectious Diseases Matei Bals, Pediatric Infectious Diseases, Bucharest, Romania

Backgrounds: With the reporting of the first case of Sars-cov2 omicron variant B.1.1.529 infection, the pediatric population was increasingly affected. Throughout the year, the circulating variants were BA.2, BA.4 and BA.5, the clinical forms of the disease determined by them being similar. Children with immunosuppression represented a special category that required additional care.
Methods: At the “Matei Bals Institute”, a number of 1433 cases were admitted in the pediatric wards between January 2022 and January 2023. 450 children with Sars-Cov2 infection were hospitalized on ward number 10, an important part of which was represented by immunosuppressed patients, representing 9.77% of the total.
Results: Out of the total number of patients, 44 presented various concurrent pathologies at admission, most of them were represented by severe haemato-oncological diseases, already extremely serious pathology previously caused by Sars-Cov2 virus infection.Among them: 4 children with chronic lung disease - cystic fibrosis, 11 patients with lymphoma in various stages of evolution, 7 patients with acute leukemia undergoing chemotherapy, 3 patients with sarcoma and a 17-year-old patient with adenocarcinoma of the intestinal type and peritoneal metastases, vasculopathies 3 cases, 9 children with thalassemia major.The treatment of these patients was complex, it included Remdesivir antiviral treatment, monoclonal antibodies when the age and weight of the patients allowed this treatment, antibiotics for bacterial co-infections, pathogenic and symptomatic treatment.The evolution was favorable in all cases, no deaths were recorded, in some situations it was necessary to interrupt or postpone the chemotherapy or cortisone therapy.
Conclusions/Learning Points: Although the patient’s comorbidities were multiple and severe, the evolution of the patients was favorable. Although the response to monoclonal antibodies in known to be around 25% to the Omicron version, the evolution of the children that received it, was good.

TREATMENT WITH MONOCLONAL ANTIBODIES FOR PATIENTS WITH HEMATO-ONCOLOGY DISEASES

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Daniela Ceptureanu, Monica Luminos, Daniela Gabdullina, Gheorghita Jugulete, Camelia Kouris, Madalina Merisescu
National Institute for Infectious Diseases Matei Bals, Pediatric Infectious Diseases, Bucharest, Romania

Backgrounds: The SARS-CoV-2 infection has represented a challenge for the oncology patients under chemotherapy. The pediatric patients with acute leukemia which presented the COVID-19 had a much higher risk of complications, compared to the immunocompetent. One of the revolutionary treatments for SARS-CoV-2 was the monoclonal antibody. Five biological anti-COVID-19 products which were given the emergency use authorization from the FDA were:Bebtelovimab,Tixagevimab/Cilgavimab,Bamlanivimab/Etesevimab, Sotrovimab,Casirivimab/Imdevimab.
Methods: In the timespan between January 2021- January 2023, 1433 children were hospitalized at the „Matei Bals Hospital", 44 of which presented different kinds of immunosuppression, and 7 of them had acute leukemia, which underwent chemotherapy. The age group for hospitalized children was 10-15 years.
Results: The blood test shows an severe pancytopenya to all patiens. For them, the treatment was challenging, consisting of the administration of the antiviral treatment of Remdesivir and biological therapy with– Casirivimab/Indevimab - available in the clinic at that time. Half of the children were over 12 years old, weight >40 kg. The evolution of the patients was favorable, the response to the associated treatment was very good, all children evolving favorably, without registering any deaths.
Conclusions/Learning Points: Although monoclonal antibody treatment with Casirivimab/Imdevimab is about 25% effective. At the clinical level, the evolution of the patients treated in combination with Remdesivir was favorable, and the tolerability was excellent. The administration of biological therapy was possible both prophylactically, also in the initial phases of the infection. Once the Spike protein is permanently mutated, biological therapy requires a new approach, namely the targeting of the nucleocapsid protein, with an eventual association of 2 monoclonal therapies.

CENTRAL NERVOUS SYSTEM COMPLICATIONS ASSOCIATED WITH SARS-COV-2 INFECTION IN HOSPITALIZED PEDIATRIC PATIENTS DURING THE COVID-19 PANDEMIC IN ISRAEL

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Menucha Jurkowicz[1], Michal Mandelboim[2,3], Nathan Keller[4], Eugene Leibovitz[1], Or Kriger[1], Gilad Sherman[1], Bruria Ben-Zeev[5], Michal Stein[1]
[1]Edmond & Lily Safra Children's Hospital, Chaim Sheba Medical Center, Pediatric Infectious Diseases Unit, Ramat Gan, Israel, [2]Ministry of Health, Central Virology Laboratory, Ramat Gan, Israel, [3]School of Public Health, Sackler Faculty of Medicine, Department Of Epidemiology And Preventive Medicine, Tel Aviv, Israel, [4]Ariel University, Faculty Of Medicine, Ariel, Israel, [5]Edmond & Lily Safra Children's Hospital, Chaim Sheba Medical Center, Pediatric Neurology, Ramat Gan, Israel

Backgrounds: The epidemiology and outcomes of central nervous system (CNS) complications associated with Sars-Cov-2 infection in hospitalized pediatric patients in Israel has not yet been described.
Methods: The study population consisted of 755 children and adolescents <18 years of age hospitalized at Sheba Medical Center, Ramat Gan, Israel, with laboratory confirmed Sars-Cov-2 from March 2020 through July 2022. A comparative cohort consisted of 314 pediatric patients diagnosed with influenza during the 2018-19 and 2019-20 influenza seasons.
Results: Overall, 5.8% (n=44) of the pediatric Sars-Cov-2 population exhibited CNS complications; 2.6% (n=20) experienced non-febrile convulsions, 1.1% (n=8) febrile convulsions and 0.7% (n=5) were diagnosed with status epilepticus. 0.4% (n=3) of patients experienced Guillain-Barre syndrome, 0.4% (n=3) meningitis, 0.1% (n=1) facial nerve paresis, 0.1% (n=1) encephalopathy, 0.1% (n=1) acute transverse myelitis and 0.1% (n=1) had hemiplegia. More patients with CNS complications experienced convulsions during the Omicron wave (77.8%) compared with patients in prior waves (41.2%), p=0.03. Fewer patients were admitted to the ICU in the Omicron wave (7.4%) compared with prior waves (41.2%), p=0.02. Fewer patients infected with Sars-Cov-2 experienced CNS complications (5.8%), compared with patients infected with influenza (9.9%), p=0.03. A greater proportion of Sars-Cov-2 patients experienced non-febrile convulsions (2.6% compared with 0.6% in influenza patients, p=0.06), while a greater proportion of influenza patients experienced febrile convulsions (7.3% compared with 1.1% in Sars-Cov-2 patients, p<0.01).
Conclusions/Learning Points: Pediatric Sars-Cov-2 patients experienced fewer CNS complications compared with influenza patients. Sars-Cov-2 patients were more likely to experience non-febrile convulsions, while influenza patients were more likely to experience febrile convulsions. The Omicron wave was characterized by more convulsions and fewer ICU admissions than in previous waves.

PEDIATRIC CRITICAL DISEASE RELATED TO SARS-COV-2 IN THE BRAZILIAN AMAZON: SURVIVING ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Maria Cleonice Justino[1], Emmerson De Farias[2], Susan Sales[2], Luciana Nascimento[2], Manoel Pavão Junior[2], Mary De Mello[2], Patricia Assunção[2], Gleice Clemente[3], Maria Terreri[3]
[1]Instituto EVANDRO CHAGAS, Virology Section, Belém, Pará, Brazil, [2]Fundação Santa Casa de Misericórdia do Pará, Division Of Pediatric Intensive Care, Belém, Pará, Brazil, [3]Universidade Federal de São Paulo, Department Of Rheumatology, São Paulo, Sâo Paulo, Brazil

Backgrounds: SARS-CoV-2 infection in children is usually asymptomatic or mild. However, some patients develop critical forms of this disease. Our aim was to evaluate independent risk factors associated with mortality in children with critical diseases related to SARS-CoV-2.
Methods: This multicenter prospective cohort study included all critically ill children (1 month and 18 years) admitted due to confirmed critical disease related to SARS-CoV-2 between April 2020/July 2022, from patients to three tertiary Amazonian pediatric intensive care units (PICU). The main outcome was the in-hospital mortality. Independent risk factors associated with mortality were evaluated using multivariable Cox proportional regression.
Results: After a median follow-up of 277 days (range, 2-759), 208 patients (median age, 33 months) were assessed, with 37 (18%) deaths, most non-survivors were men (20 [54.1%]) and 34 (91.9%) had at least one comorbidity. Higher drive pressure levels (12 cmH 2 O vs 9 cmH 2 O, p<0.001), hypoxemia (oxygen index:7.3 vs. 4.1, p=0.03), and lymphopenia at admission (1,133 vs. 2,125, p<0.001) were more frequent in non-survivors. Independent risk factors associated with mortality were underweight status (HR, 6.64; p=0.01), acute respiratory distress syndrome (HR, 8.63; p=0.02), erythrocyte sedimentation rate in mm/hour >18 (HR, 3.95; p=0.03), and vasoactive inotropic score > 120 (HR, 4.76; p=0.05). Patients with hospital stays of longer than 19 days presented a lower survival time in days (mean 465.6, CI95%, 367.54- 563.72).
Conclusions/Learning Points: The risk of death at any time during follow-up was clearly higher in underweight individuals with ARDS, higher erythrocyte sedimentation rate, and higher vasoactive inotropic score.

CARDIAC INVOLVEMENT IN CHILDREN WITH COVID-19

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Dimitrios Kapnisis[1], Angeliki Karatza[1], Aggeliki Vervenioti[1], Anastasia Varvarigou[1], Gabriel Dimitriou[1], Despoina Gkentzi[1,2]
[1]Patras Medical School, Department Of Paediatrics, Rio, Greece, [2]General University Hospital of Patras, Department Of Paediatrics, Patras, Greece

Title of Case: Cardiac involvement in children with COVID-19
Background: Cardiac involvement in children with COVID-19 can manifest as acute myocardial injury with elevated plasma troponin I concentration. We report COVID-19 paediatric cases with elevated HS-Troponin I values, which were hospitalized in our Tertiary Paediatric Department during a two-year period (2020-2022) and presented no signs of clinical myocarditis or electrocardiographic and echocardiographic abnormalities.
Case Presentation Summary: HS-TnI levels were measured in 216 COVID-19 cases (listed in Table 1) without known cardiac disease,which were tested positive with nasal PCR testing. Troponin-I was elevated in 17 patients (7,8%). None of these 17 patients had ECG or ECHO abnormalities. Troponin levels gradually decreased in follow up laboratory testing and patients recovered completely without any complications.Two COVID-19 cases with the maximum measured HS-TnI values are presented in more detail.The first case was an eight-day old male neonate with rhinitis,which was tested positive in follow-up for jaundice evaluation. At the admission, he had an elevated HS-TnI value (216 pg/ml).The maximum value of HS-TnI recorded was 524,3 pg/ml. The neonate has been hospitalized for 43 days,with a HS-TnI value at 109,4 pg/ml on day of discharge.The second case was a 14-year old female adolescent,which was admitted to the Emergency Department with chest pain. Laboratory tests at admission revealed lymphopenia, elevated transaminases (AST: 231 IU/l , ALT: 219 IU/l) and elevated HS-TnI: 839,3 pg/ml. No treatment was given.On day of discharge,she was completely asymptomatic with a HS-TnI value of 67,80
pg/ml.

Age	Total	Boys	Girls	Mean HsTnI (pg/ml)	Max HsTnI (pg/ml)	No over upper limit (>34,2 pg/ml)
Neonates (1-28 days)	20	10	10	53,48	524,3	5
Infants (29 days – 12 months)	99	55	44	18,17	173,3	10
Children (1-10 years)	50	26	24	2,21	20	0
Adolescents (10-16 years)	47	22	25	20,97	839,3	2
TOTAL	**216**	**113**	**103**	**18,35**	**839,3**	**17**

Learning Points/Discussion: These cases highlight that elevated HS-TnI values can indicate some degree of myocardial injury, but not necessarily myocarditis and that further work up with cardiac magnetic resonance may be required in selected cases for an accurate description of myocardial involvement in paediatric COVID-19.

PV0966 / #1391

INFLAMMATORY AND ENDOTHELIAL BIOMARKERS ASSOCIATED WITH POST COVID-19 INFECTION IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Dareilena Karaviti[1], Marietta Charakida[1], Dimitra Dimopoulou[1], Irini Eleftheriou[1], Despoina Maritsi[1], Antonios Marmarinos[2], Margaritis Avgeris[2], Dimitrios Gourgiotis[2], Nikos Spyridis[1], Maria Tsolia[1]
[1]National and Kapodistrian University of Athens, Second Department Of Paediatrics, Athens, Greece, [2]National and Kapodistrian University of Athens, Laboratory Of Clinical Biochemistry-molecular Diagnostic, Second Department Of Pediatrics, Athens, Greece

Backgrounds: Previous studies conducted in adults have suggested the presence of endothelial dysfunction following SARS-CoV-2 infection which might be related to chronic inflammation. This study aims to evaluate differences in lipids, inflammatory and endothelial biomarkers in children who had experienced SARS-CoV-2 infection in comparison to healthy controls.
Methods: We studied 234 children; 155 had a history of COVID-19 (Group 1) [105 had mild disease and recovered at home, 40 with severe/moderate disease required hospitalization and 10 had multisystem inflammatory syndrome (MIS-C)]. The second group (Group 2) was composed of the remaining healthy controls with negative SARS-CoV-2 IgG antibodies. In all children, we obtained full lipid profile and inflammatory markers(IL-6, TNF-a, INF-γ, CRP). The endothelial marker soluble intercellular adhesion molecule-1 (sICAM-1) was assessed in a subgroup of 40 children with history of severe/moderate disease and 40 age-matched controls. Normally distributed variables are expressed as mean (±SD).
Results: Group 1 participants were studied from 2 months to 1 year following SARS-CoV-2 infection (median time:6.8 months post infection). They were older (10.8+/-3.2 vs 8.5+/-2.8 years, $p<0.001$) and had increased body mass index (20.3+/-5.6 vs 18.4+/-3.5 $kg/m^{2,}$ $p=0.01$) compared to children in Group 2. Levels of sICAM-1 were higher in children with history of moderate/severe COVID-19 infection compared to controls (555.8+/-113.2ng/ml vs 428+/-42.6ng/ml, $p<0.001$). Inflammatory markers and cholesterol levels were comparable between groups. Additionally, SARS-CoV-2 IgG levels did not differ by type of SARS-CoV-2 disease severity.
Conclusions/Learning Points: This study demonstrates that children with a history of moderate/severe COVID-19 infection compared to unaffected controls had evidence of endothelial activation in the absence of chronic inflammation as demonstrated by increased sICAM-1 levels. Although this is an isolated finding, it possibly suggests persistent endothelial dysfunction following moderate/severe COVID-19 infection.

IMPACT OF COVID-19 LOCKDOWN ON LOWER RESPIRATORY TRACT INFECTION ADMISSIONS IN PUBLIC SECTOR FACILITIES IN THE WESTERN CAPE PROVINCE OF SOUTH AFRICA (2019-2021)

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Kathleen Kehoe[1], Erna Morden[2], Theuns Jacobs[2], Nesbert Zinyakatira[2], Alexa Heekes[2], Jaco Murray[3], Heloise Buys[4], Brian Eley[4], Hayley Jones[5], Theresa Redaniel[6], Mary-Ann Davies[1]
[1]University of Cape Town, Centre For Infectious Disease Epidemiology & Research, School Of Public Health And Family Medicine, Cape Town, South Africa, [2]Western Cape Government, Health Intelligence Directorate, Cape Town, South Africa, [3]Paarl Hospital, Department Of Paediatrics & Neonatology, Paarl, South Africa, [4]University of Cape Town, Department Of Paediatrics And Child Health, Cape Town, South Africa, [5]University of Bristol, Population Health Sciences, Bristol Medical Schoo, Bristol, United Kingdom, [6]University Hospitals Bristol and Weston NHS Foundation Trust, The National Institute For Health Research Applied Research Collaboration West (nihr Arc West) A, Bristol, United Kingdom

Backgrounds: To mitigate COVID-19 virus transmission, the South African government implemented strict lockdown strategies to encourage physical distancing and de-escalate routine services. There were several unintended consequences including reduced access to routine healthcare services for other illnesses such as lower respiratory tract infections (LRTI). We aimed to assess the impact of the COVID-19 lockdown from April 2020 on LRTI hospitalisations among children under five years from January 2019 – November 2021 in the pubic sector in the Western Cape.
Methods: We identified LRTI admissions captured, integrated and linked by the Western Cape Provincial Health Data Centre using a comprehensive list of International Classification of Diseases 10th revision. Using an interrupted time series analysis, we estimated the change in rate and trend of LRTI admissions post-lockdown compared to those pre-lockdown. The model was adjusted for sex, age, patients length of stay, child's residence, childhood immunisation, LRTI seasonality and COVID-19 case burden. We presented incidence rate ratios (IRR) with 95% confidence intervals (CI).
Results: Of the 36,340 total LRTI admissions, 52% (18,671 admissions) occurred from April 2020 – November 2021. The median rate of LRTI admissions decreased by 19% from 1.78 (IQR 1.14-2.46) for January 2019 – March 2020 to 1.44 (IQR 0.99-2.20) for April 2020 – November 2021. The COVID-19 lockdown immediately decreased LRTI admissions by 17% (IRR 0.83, 95% CI 0.79-0.88). Thereafter, LRTI admissions increased on average by 3% per month (IRR 1.03, 95% 1.02-1.03).
Conclusions/Learning Points: The immediate impact of the COVID-19 lockdown may due to social distancing, decreased population mobility and hesitancy to access healthcare services. However, over time, as lockdown levels were altered, there was a gradual increase in LRTI admissions suggesting changes in population mobility and their health seeking behaviour.

MITIGATING FROM COVID-19 DURING INTERCOLLEGIATE SPORTS MATCH

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Yun-Kyung Kim[1,2], In Han Song[3], Young June Choe[4]
[1]Korea University College of Medicine, Pediatrics, seoul, Korea, Republic of, [2]eulji university hospital, Pathology, seoul, Korea, Republic of, [3]yonsei university, Social Welfare, seoul, Korea, Republic of, [4]Korea University Anam Hospital, Department Of Pediatrics, Seoul, Korea, Republic of

Backgrounds: The recovery of college match has become an important issue that drew attention after the ease of COVID-19 pandemic quarantine measures. We evaluated the infuence of an annual intercollegiate sports match on COVID19 epidemic in college.
Methods: We retrospectively assessed the number of COVID-19 cases before and after the intercollegiate match taking place on October 28 and 29, 2022. We collected the community-onset COVID-19 cases from the government's database, and calculated the 7-day average incidence per 100,000 of COVID-19 cases in the community and in the universities
Results: In total, 59,500 tickets were sold in all sports matches and 40,000 spectators in the main stadium. In the 1st week of Oct 2022, the community-onset COVID-19 cases ranged 48/100,000 (95% CI, 44-51/10^5) and 51/10^5 (95% CI, 48-54/10^5); whereas the university-onset COVID-19 cases was 25/10^5 (95% CI, 22-28/10^5). During one week after the intercollegiate match, the community-onset and university-onset cases were 93/10^5 (95% CI, 90-96/10^5) and 100/10^5 (95% CI, 97-104/10^5), respectively. During the 4th week after match, the community-onset and university-onset cases were 108/10^5 (95% CI, 105-111/10^5) and 34/10^5 (95% CI, 31-37/10^5), respectively. There was no notified critical infections nor deaths attributable to COVID-19 following the match. The intercollegiate sports match was concluded with surge of incidence rate for a very short period, followed by leveling off of the outbreak, which was lower than that of community-level. There was no second wave of outbreak or sustained outbreak in the school provoked by big intercollegiate sports match.
Conclusions/Learning Points: Sustainable and safe intercollegiate sports match that we experienced shows that operating of mass-gathering sports event is feasible during the era of COVID-19 vaccination and in the predominance of Omicron variant.

TOCILIZUMAB IN THE MANAGEMENT OF CRITICALLY ILL CHILDREN WITH COVID PNEUMONITIS: RESULTS FROM A SINGLE-CENTRE OBSERVATIONAL STUDY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Arangan Kirubakaran[1], Elizabeth Whittaker[2], Lucy Crossman[3]
[1]Royal Brompton Hospital, Paediatric Intensive Care, London, United Kingdom, [2]Department of Paediatric Infectious Diseases, St Mary's Hospital, Imperial College Nhs Healthcare Trust, London, United Kingdom, [3]St Mary's Hospital, Paediatric Intensive Care, London, United Kingdom

Backgrounds: Tocilizumab is currently licensed for use in the UK to treat paediatric rheumatological conditions. Recently it has been used in the management of severe paediatric COVID-19 despite a lack of supporting data. We aimed to characterise the disease course of critically ill children in our unit with COVID pneumonitis and evaluate outcomes following tocilizumab use.
Methods: A retrospective analysis of computerised medical records and laboratory data was conducted for all patients requiring high-dependency care for COVID pneumonitis at St Mary's Hospital, London between January 2019 to March 2022. Data on presenting symptoms, demographics, treatment and outcomes at discharge was recorded.
Results: Fifteen out of 526 COVID positive patients (3%) were hospitalised. All 15 had pre-existing comorbidities including obesity (28%), neurological (22%) or genetic disorders (17%). Eight patients received conventional care as defined by RCPCH guidelines (dexamethasone, antibiotics and remdesivir), with 7 receiving additional tocilizumab. Baseline CRP values were mildly elevated (median 17.9 mmol/L; IQR 8.7-54) with a raised ALT observed in tocilizumab recipients (median 93 U/L; IQR 50.8-124.8). Four patients (50%) were screened for hepatitis before tocilizumab therapy. Tocilizumab patients had lower baseline albumin levels (p=0.02) with no other significant differences between blood results. Seven patients (47%) required intubation with no deaths recorded. There were no significant differences in length of stay, respiratory support or clinical complications.
Conclusions/Learning Points: Our data suggests that severe COVID pneumonitis is rare, affecting children with significant comorbidities. Conventional care led to favourable outcomes with no benefits observed with tocilizumab. Our data is greatly limited by temporary service reconfigurations between January and February 2021 leading to adult COVID admissions within our unit. Although safety and dosing data already exist for tocilizumab, further research is needed to aid clinical decision-making.

PV0970 / #480

QUANTITATIVE BENEFIT AND RISK ANALYSIS OF MONOVALENT BNT162B2 VACCINE FOR CHILDREN AGED 6 MONTHS TO 4 YEARS USING QUALITY-ADJUSTED LIFE YEAR

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Taito Kitano[1], David Thompson[1], Lilly Engineer[1], Matthew Dudley[2], Daniel Salmon[2]
[1]Johns Hopkins Bloomberg School of Public Health, Health Policy And Management, Baltimore, United States of America, [2]Johns Hopkins Bloomberg School of Public Health, Institute For Vaccine Safety, Baltimore, United States of America

Backgrounds: The vaccine coverage rate for young children is low in many countries. The quantitative risk and benefit analysis on a single health outcome such as quality-adjusted life year (QALY) for this age group can guide the decision making on the COVID-19 vaccination.
Methods: Using QALY, a model to calculate benefit and risk of primary series (3 doses) for of monovalent BNT162b2 was developed for children aged 6 months to 4 years. Both benefits and risks by receiving the vaccination was calculated as QALY change/100,000 vaccinees for 60 days after completion of the primary vaccine series to calculate benefit/risk ratio. Published and gray literatures as of the end of 2022 were used to identify indicators. For indicators without available data for this age group, the data of older children or adult were referred.
Results: The average QALY loss due to COVID-19 over 2 months were 65.1, 57.6, 62.1 and 54.8/100,000 children aged 6 months to 4 years for males with comorbidity, males without comorbidity, female with comorbidity and female without comorbidity, respectively. The QALY loss due to primary series of BNT162b2 were 0.5/100,000 vaccinees for both males and females. Benefit risk ratios for males with comorbidity, males without comorbidity, female with comorbidity and female without comorbidity were 38.5, 34.0, 38.6 and 34.0 with 30% vaccine effectiveness and 102.6, 90.8, 102.8 and 90.8 with 80%[t1] vaccine effectiveness, respectively.
Conclusions/Learning Points: Although there are some limitations, including the use of data in older age group for some indicators (e.g., health utility and incidence of myocarditis[t1]), this study suggests that the benefits of receiving BNT162b2 for children aged 6 months to 4 years outweigh its risk.

PV0971 / #1596

INFECTIOUS AGENTS AS RISK FACTORS FOR NEW-ONSET TYPE 1 DIABETES IN COVID-19 PANDEMIC: A RETROSPECTIVE STUDY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Lizete Klavina[1,2], Viktorija Truskova[1,2], Anda Kivite-Urtane[3], Jana Pavare[1,4], Iveta Dzivite-Krisane[1,4]
[1]Children's Clinical University Hospital, Department Of Paediatrics, Riga, Latvia, [2]Riga Stradins University, Department Of Continuing Education, Paediatrics, Riga, Latvia, [3]Riga Stradins University, Department Of Public Health And Epidemiology, Riga, Latvia, [4]Riga Stradins University, Faculty Of Medicine, Riga, Latvia

Backgrounds: As multiple centres from different countries have reported increase in incidence of type 1 diabetes (T1D) since the beginning of COVID-19 pandemic, no doubt SARS-CoV-2 has been suspected as potential cause of that. The aim of this research was to analyze exposure to SARS-CoV-2 and most common infectious agents that are already proven as potential inducers of T1D.
Methods: This was a retrospective research including patients up to 18 years old with new-onset T1D who were hospitalized from August 2022 till January 2023. Data about previous infectious diseases were gathered in interviews, serology testing was performed to estimate seroprevalence of infectious agents.
Results: In total, 42 patients (54.8% boys) with mean age 8.64 (±4.52) years were included in this study. By the time of hospitalization, all of them were tested negative for SARS-CoV-2 and 8 (19%) patients had been vaccinated against COVID-19. According to parent questionnaire, 25 (59.5%) patients had laboratory approved SARS-CoV-2 infection, 5 (11.9%) had epidemiological data of possible COVID-19 infection before T1D manifestation, whereas serology testing showed positive SARS-CoV-2 antibodies in 90.5% (n=38) of included patients. From the group of patients with known COVID-19 infection before, 48.3% have been infected within 6 months, but 96.5% - within 12-month period before T1D, with median time 28 (24-40) weeks before T1D. Serology testing revealed, that besides SARS-CoV-2 virus, next most commonly detected were Epstein-Barr virus (54.8%), Parvo-B19 virus (45.2%), Cytomegalovirus and Influenza A (35.7%), but less frequently – enteroviruses (ECHO, Coxsackie, 16.7%).
Conclusions/Learning Points: Although SARS-CoV-2 has been detected as most common virus that patients with new-onset T1D have been exposed, it’s role in possible influence of T1D development is not clear, and further studies, including other risk factor analysis, should be continued.

PV0972 / #738

EPIDEMIOLOGY AND CLINICAL FEATURES OF SARS-COV-2 INFECTION IN CHILDREN UNDER 18 YEARS IN THE PRE-OMICRON ERA: A GLOBAL SYSTEMATIC REVIEW AND META-ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Durga Kulkarni[1], Nabihah Binti Ismail[1], Fuyu Zhu[2], Xin Wang[2], Graciela Morales[3], Kristen Allen[4], Julia Spinardi[5], Ehsanur Rahman[1], Moe Kyaw[6], Harish Nair[1]
[1]University of Edinburgh, Centre For Global Health, Edinburgh, United Kingdom, [2]Nanjing Medical University, School Of Public Health, Nanjing, China, [3]Pfizer, Vaccines, San Jose, Costa Rica, [4]Pfizer, Vaccines, Minneapolis, United States of America, [5]Pfizer, Vaccines, Sao Paulo, Brazil, [6]Pfizer, Vaccines, Reston, United States of America

Backgrounds: Data on paediatric SARS-CoV-2 infection are limited. We conducted a systematic review to estimate the SARS-CoV-2 infection rate, risk factors, and disease severity in children aged <18 years prior to the Omicron era.
Methods: The review protocol was registered on PROSPERO (CRD42022327680). We searched MEDLINE, Embase, Global Health, CINAHL, three Chinese language databases, and WHO COVID-19 databases for primary studies recruiting children aged <18 years with a confirmed SARS-CoV-2 infection by PCR or antigen tests. The Joanna Briggs Institute critical appraisal tools were used to appraise the study quality. Random effects meta-analyses were conducted for all the outcomes.
Results: A total of 250 studies, each reporting at least one of the study outcomes, were included. Based on data from 12,974,850 children from 105 studies, of all individuals aged <18 years who were tested for SARS-CoV-2, we estimated that the positivity rate was 9 (95% CI = 7 to 12) percent [12 (95% CI = 2 to 27) percent when restricted to good quality studies]. Having a comorbidity was identified as a risk factor for SARS-CoV-2 infection [RR = 1.75 (95% CI = 1.43 to 2.14)]. Most cases in the population included in this review were asymptomatic or presented with mild disease. However, around 26% of paediatric SARS-CoV-2 infections were hospitalized, and 7%, 5%, and 4% required oxygen support, intensive care, and mechanical ventilation, respectively. The case fatality rate was 1 (95% CI = 1 to 1) percent.
Conclusions/Learning Points: Our data showed that children were at-risk for SARS-CoV-2 infection and severe COVID-19 outcomes in the pre-Omicron period. These findings underscore the need for effective vaccination strategies against SARS-CoV-2 in the paediatric population.

EVALUATION OF POST-COVID SYMPTOMS OF THE SARS-COV-2 DELTA AND OMICRON VARIANT IN CHILDREN: A PROSPECTIVE STUD

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Sema Yıldırım Arslan, Gulhadiye Avcu, Zumrut Bal, Asli Arslan, Zafer Kurugol, Ferda Özinay
Ege University Faculty of Medicine, Pediatric İnfectious Diseases, İzmir, Turkey

Backgrounds: The post-COVID-19 syndrome is a new syndrome defined in patients with a history of probable or confirmed SARS-CoV-2 infection, usually within three months of the onset of COVID-19, with symptoms and effects lasting at least two months. This study aimed to comprehensively compare symptoms of the post-COVID-19 syndrome in children with delta and omicron variants.
Methods: This prospective study included children with COVID-19 followed in hospitalized or outpatient clinics in tertiary hospital. We used a special questionnaire to ask about the presence of persistent symptoms more than 12 weeks after the initial diagnosis. Patients with positive SARS-CoV-2 PCR were selected randomly and grouped according to the dominant variants in our country at that time as follows;Omicron group (after 16 December 2021); Delta (B.1.617.2) group (August 15, 2021, and December 15, 2021).
Results: This study included 200 children, 71 of whom were in the delta group, 129 of whom were in the omicron group. Weakness (8.5% vs.1.6%; p=0.017), the impact of physical efforts (5.6% vs.3.9%; p=0.020), fatigue (22.5% vs. 8.5%; p=0.009), anxiety disorder (12.7% vs. 0.8%; p=0.001), and gastrointestinal changes (12.7% vs.4.7%, p=0.050) were statistically significantly higher in patients with the delta variant compared to patients with the omicron variant. There were no differences between the groups regarding anorexia, anosmia/ageusia, arthralgia, influenza-like symptoms, sleeping disorders, decreased physical activity daily, headache, need for analgesia, concentration and memory disorder, and weight loss (p>0.05).
Conclusions/Learning Points: This study showed that weakness, impact of physical efforts, fatigue, anxiety disorder, gastrointestinal changes were more frequent in the delta group. The incidence of post-COVID-19 syndrome is high in children as well as adults and affects several systems; therefore, it should be kept in mind that children should be followed for post-COVID-19 syndrome.

Backgrounds: Children infected with SARS-CoV-2 displayed milder symptoms than adults. A nationwide vaccination program has been implemented for children aged ≥12 years of age since August 2021 in Turkey. Therefore, we aimed to evaluate the national vaccination program to hospitalization numbers and compare it with the previous year. The second aim was to compare the characteristics, severity, and outcomes of COVID-19 among vaccinated and unvaccinated adolescents.
Methods: We conducted a retrospective multicentre cohort study of 15 hospitals including hospitalized SARS-CoV-2 ınfected patients aged 12-18 years between September 1, 2021, and September 1, 2022, in Turkey. Two periods (September 1, 2021- September 1, 2022; second period), (September 1, 2020-August 31, 2021; first period) were compared.
Results: During the first period, 3967 children (0-18 years) were hospitalized, and 5143(0-18 years) were hospitalized in the second period. Of them, 35.4% of the patients were aged 12-18 years old, and this rate was 18.6% in the second period; the incidence rate ratio was 1.9. Breakthrough infection was detected in 43 (4.47%) of 961 patients. 25 children have been vaccinated with a single dose and 18 children were fully vaccinated. Eighteen children (41.9 %) had mild, 10 (23.3%) had moderate, and 15 (34.9%) had severe disease. Twenty-one (48.8%) children had at least one underlying comorbidity, and 8/21 were obese (18.6%). The incidence rate ratios were 1.9 and 2.33 for PICU admission and respiratory support among the unvaccinated group.
Conclusions/Learning Points: The hospitalization incidence ratio was 1.9-fold higher in adolescents during period 1 when compared with 2. Nearly, half of the patients with breakthrough infection had an underlying disease; every 1 of 3 was obese. PICU admission and respiratory support need were 1.9 and 2.33 fold higher among unvaccinated adolescents.

RE-INFECTIONS IN THE PEDIATRIC COHORT- A SINGLE CENTER EXPERIENCE

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Asli Arslan[1], Gulhadiye Avcu[1], Ece Erci[1], Sema Yıldırım Arslan[1], Nimet Melis Bilen[1], Zumrut Bal[2], Ferda Özinay[1], Zafer Kurugol[1]
[1]Ege University Faculty of Medicine, Pediatric İnfectious Diseases, İzmir, Turkey, [2]Medical School of Ege University, Pediatrics, Izmir, Turkey

Backgrounds: This study focused on timelines of COVID-19 re-infection episodes and aimed to determine the dominant variants, disease severity and outcome of the pediatric patients with reinfection.
Methods: This study retrospectively evaluated the medical records of the hospitalized and/or outpatients aged 0-18 years old with a positive SARS-CoV-2 Polymerase Chain Reaction (PCR) between March 2020 and September 2022 at Ege University Children's Hospital. Reinfection was defined in patients with at least 90 days between two SARS-CoV-2 PCR positivity.
Results: 91 pediatric patients with reinfection with SARS-CoV-2 were included.There was an underlying condition in 26.4%. The median time between the two episodes was 184 days.18 patients' (19.7%) first infection was in pre-Delta period and second in Omicron BA.1 period. 49 patients (53.8%) were infected initially in Delta period; 35 patient (38.4%) was reinfected in Omicron BA.1 period while 14 patient (15.3%) was reinfected in Omicron BA.4/BA.5 period. 24 patients' (26.3%) first infection episode in Omicron BA.1 period and then reinfected in Omicron BA.4/BA.5 period. There was a significant increase in symptomatic patients in the second episode (84.6% vs. 94.5%, p=0.03). The hospitalization rate significantly declined in the second infection (15.3% vs. 7.6%, p= 0,03). Severe disease, treatment needs, and steroid use were decreased in the second episode, but no significant difference was found. PICU admission was not altered.

Steroid use	*2 (2.2)*	*1 (1.1)*	*0,5*

Conclusions/Learning Points: As the pandemic surveys, the struggle against COVID-19 continues with the changing features of the virus and vaccine response against new variants. This study revealed that reinfections frequently develop in previously healthy children, but reinfections do not cause more severe outcomes. Although the fact about protection after the first infection, the risk of symptomatic reinfections is still high due to the effect of the Omicron variant.

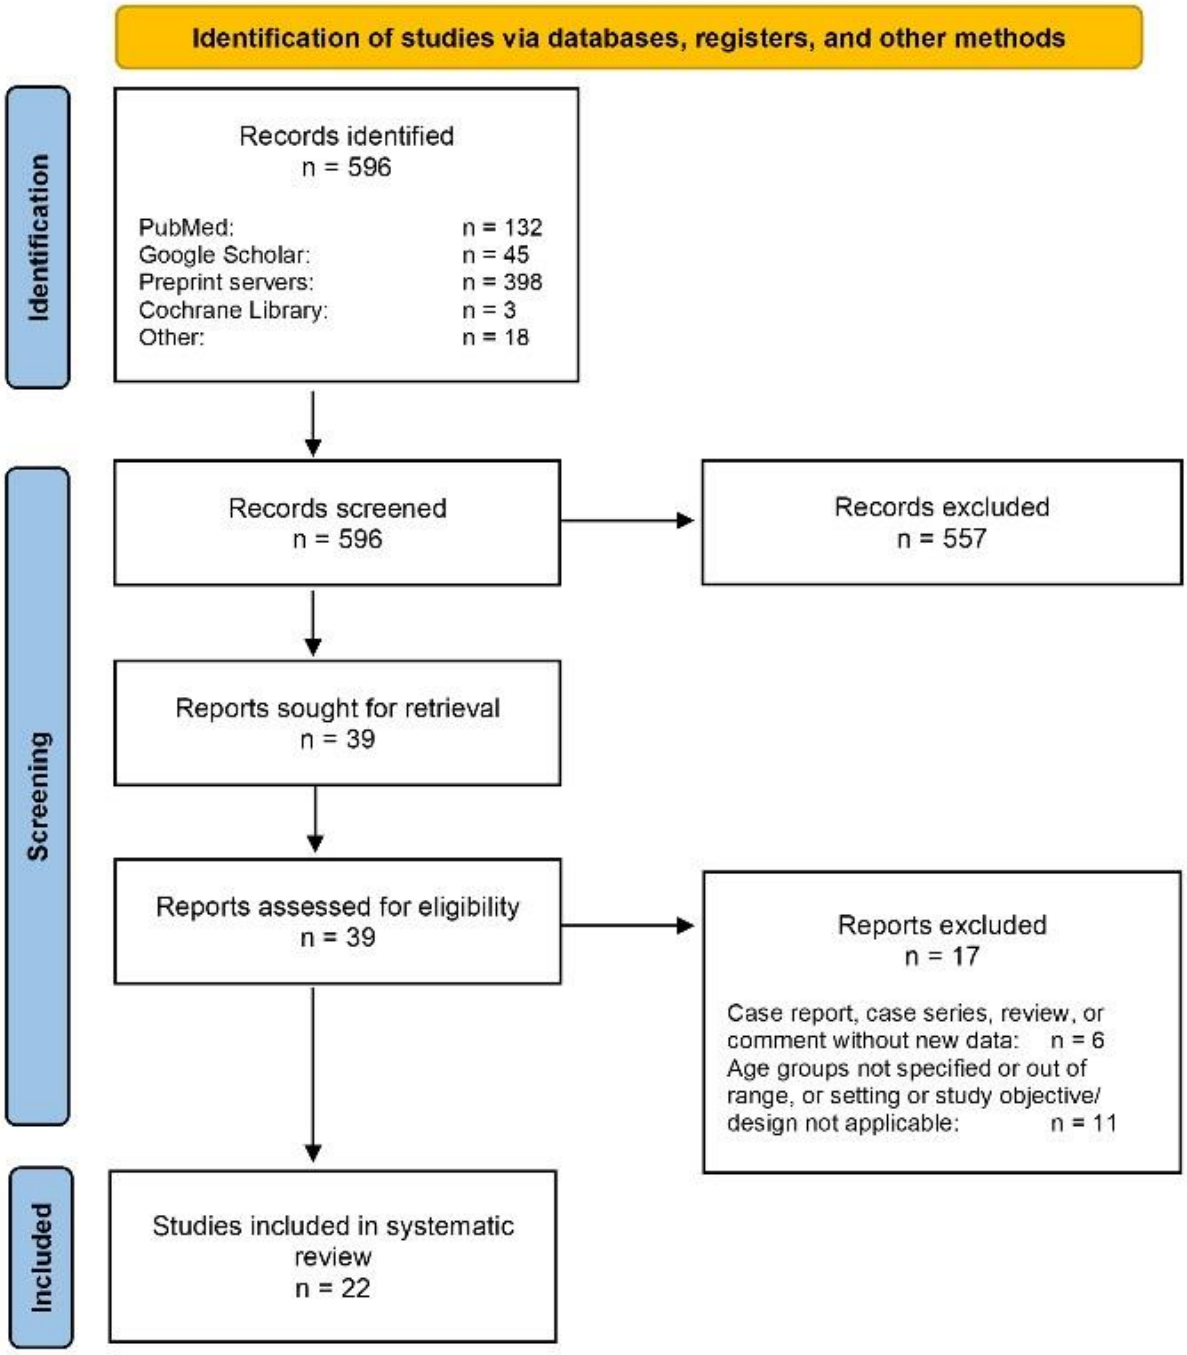
CHILD MASK MANDATES FOR SARS-COV-2: A MIXED-METHOD AND SYSTEMATIC REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Johanna Sandlund[1], Ram Duriseti[2], Shamez Ladhani[3,4], Kelly Stuart[5], Jeanne Noble[6], Tracy Høeg[7]
[1]Independent, Independent, Alameda, United States of America, [2]Stanford University Medical Center, Department Of Emergency Medicine, Palo Alto, United States of America, [3]St George's, University of London, Centre For Neonatal And Paediatric Infection, London, United Kingdom, [4]UK Health Security Agency, Immunisations And Vaccine Preventable Diseases Division, London, United Kingdom, [5]SmallTalk Pediatric Therapy, Smalltalk Pediatric Therapy, San Diego, United States of America, [6]University of California San Francisco, Department Of Emergency Medicine, San Francisco, United States of America, [7]University of California San Francisco, Department Of Epidemiology & Biostatistics, San Francisco, United States of America

Background: Children have to varying degrees in different locations been subject to mask mandates during the COVID-19 pandemic and a risk-benefit analysis of this intervention has not yet been performed.
Methods: Using mixed methods, we performed a systematic review to assess the effectiveness of face masks against SARS-CoV-2 infection or transmission in children alongside a narrative review of evidence of potential harms of masking in children.
Results: We screened 596 studies and included 22 studies in the systematic review. There were no randomized controlled trials in children assessing the effectiveness of face masks against SARS-CoV-2 infection or transmission. Six observational studies reporting negative association between mask mandates and transmission or SARS-CoV-2 antibody seropositivity were significantly biased and/or were shown to have non-significant effects in follow-up studies, while sixteen observational studies found no effect of masking on SARS-CoV-2 infection and/or transmission rates. The largest studies (n=3) with the lowest risk of bias showed minimal to no benefit from masking policies for children or their households. The one study with the most robust internal control of comparable vaccination and community transmission rates showed no benefit from the school mask mandate. Identified harms of masking include affected speech, language, ability to learn, and emotional and trust development, as well as physical discomfort contributing to reduced time and intensity of exercise.



Conclusions/Learning Points: Real-world effectiveness of child mask mandates has not been demonstrated with high-quality evidence. There is extensive evidence of potential harms of mask mandates in children. The current body of scientific data of mask mandates in children fails to meet basic risk-benefit analysis for protection against SARS-CoV-2.

CHARACTERISTICS AND OUTCOMES OF NEONATAL SARS-COV-2 INFECTION: A DOUBLE-CENTER EXPERIENCE

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Kleanthi Voutsadaki[1], Fani Ladomenou[1], Emmanouil Chatzakis[2], Georgios Patsouras[3], Emmanouil Karavitakis[3], Marina Koropouli[2]
[1]Venizeleion General Hospital, Department Of Pediatrics, Heraklion, Greece, [2]Venizeleion General Hospital, Neonatal Intensive Care Unit, Heraklion, Greece, [3]Agios Georgios General Hospital, Neonatal Unit, Chania, Greece

Title of Case: CHARACTERISTICS AND OUTCOMES OF NEONATAL SARS-CoV-2 INFECTION: A DOUBLE-CENTER EXPERIENCE
Background: The rate of COVID-19 infection in neonates is lower than in adults and children. Most neonates remain asymptomatic or develop mild disease. Aim of this study was to examine the epidemiology, clinical presentation, laboratory findings and outcomes of neonatal SARS-CoV-2 infection.
Case Presentation Summary: A double-center observational study was conducted from March 2020 to December 2022, involving neonates admitted to NICU with SARS-CoV-2 infection. COVID-19 was diagnosed in 23 neonates (52.17% males, mean gestation age 38+5weeks, mean birth weight 3400gr, mean age at diagnosis 15.3days, mean weight at admission 3670gr). No vertical transmission was found. All neonates were previously healthy with no comorbidities instead of one patient with right aortic arch. Commonest signs of infection were fever (78.26%), rhinitis (21.74%) and poor feeding (21.74%), followed by gastrointestinal symptoms (13%). Most neonates received only supporting therapy. One patient needed supplemental oxygen (4.35%). 9/23 (39.13%) received antibiotics, whereas no anticoagulants, corticosteroids, remdesivir, immunoglobulin were used. 7/23 (30.43%) patients presented with lymphopenia, whereas no leukocytosis nor thrombocytopenia were observed. Liver function tests, coagulation tests and c-reactive protein levels were normal. 3/20 (15%) neonates had increased troponin levels . They were evaluated by a pediatric cardiologist, and electrocardiography and echocardiography were performed, with normal findings. Mean length of stay was 5.9days. All neonates were discharged home.
Learning Points/Discussion: Our results suggest that most neonates present with mild COVID-19 symptoms, maintain spontaneous respiration and have good prognosis. In most cases symptomatic treatment alone is needed. In our cohort, elevated troponin levels were observed in some cases without clinical significance. The role of troponin levels on myocardial function is not well established in neonates with COVID-19 and further studies are needed.

SEVERE NEUROLOGICAL DISORDERS IN CHILDREN AFTER SARS-COV-2 INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Adam Łęcki, Alina Ciach, Leszek Szenborn, Kamila Ludwikowska
Wroclaw Medical University, Department Of Pediatric Infectious Diseases, Wrocław, Poland

Title of Case: Severe neurological disorders in children after SARS-COV-2 infection
Background: SARS-COV-2 infection in adults predisposes to neurologic complications, including strokes. In children such complications are sporadic.
Case Presentation Summary: We present 3 cases of central nervous system vascular involvement that occurred in previously healthy children after SARS-COV-2 infection. First case considers direct COVID-19 complication, while two next cases present atypical course of a different disease that might have been modified by recent SARS-CoV-2 infection (with positive antibodies in both cases). Case 1. A 7.5-month-old girl was hospitalized because of COVID-19 with bilateral otitis media and vomiting. She developed right-sided tremors followed by hemiparesis and pathological sleepiness. A head CT scan revealed ischaemic lesions in the left frontal. MR imaging indicated vasculitis with multiple micro-impacts. Case 2. An 18-month-old girl presented with acute onset of left-sided hemiparesis and status epilepticus. Imaging studies diagnosed massive hemorrhagic lesions in the frontal region (Figure 1) . HSV infection was confirmed. As hemorrhagic form of HSV encephalitis is extremely rare in small children and the outcome is usually worse than observed, we hypothesized that recent SARS-CoV-2 Case 3. A 3-year-old boy with VII,VI and III nerve paresis with confirmed neuroborreliosis and proof of preceding SARS-COV-2 infection. Neuroimaging revealed not only mononeuritis multiplex but also thrombosis of the superior sagittal sinus. Thrombosis in course of neuroborreliosis in children is extremely rare. All the symptoms in all three cases resolved under the treatment.
Learning Points/Discussion: expect unexpected, new clinical situations to occur that are beyond the scope of known algorithms, remember to make a broad differential diagnosis and look for analogies to known disease entities, but maintain an individualized approach to the patient. Passing a Covid infection can modify the disposition of neurological diseases.

PV0979 / #509

IMMUNOGENICITY OF BNT162B2 AND CORONAVAC IN HEALTHY CHILDREN AND ADOLESCENTS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Daniel Leung, Jaime Rosa Duque, Yu Lung Lau
The University of Hong Kong, Department Of Paediatrics And Adolescent Medicine, Hong Kong, Hong Kong PRC

Backgrounds: BNT162b2 and CoronaVac are COVID-19 vaccines with the highest number of doses distributed worldwide. Their efficacy and immunogenicity profiles differ. Age-dependent differences in immune response to vaccines may also lead to different efficacy in children. We aim to compare the immunogenicity of the two vaccines, and between children and adults.
Methods: We evaluate immunogenicity of BNT162b2 and CoronaVac in a nonrandomized study. Healthy adolescents and children who received 3 doses of COVID-19 vaccine (11-17 years for BNT162b2 and 3-17 years for CoronaVac) with no prior infection history were included, and compared against adults with non-inferiority margin of 0.60. Binding and neutralizing antibody responses, including S-RBD IgG, S IgG, FcR binding, avidity, and surrogate and authentic live-virus neutralizing antibody, as well as T cell responses against SARS-CoV-2 proteins S (and N and M for CoronaVac) were tracked as primary objectives. Cross-variant reactivity was studied as secondary objective.
Results: Antibody and T cell responses were non-inferior to those of healthy adults. BNT162b2 elicited higher antibody responses while CoronaVac induced multiprotein T cell responses against S, N and M. For BNT162b2, 96% of adolescents could neutralise BA.1 5 months after two doses of BNT162b2. After 3 doses, adolescents had preserved binding IgG against BA.2 and moderate neutralisation levels against BA.1, BA.2, and BA.5. FcR binding was paradoxically blunted after dose 3 BNT162b2. For CoronaVac, T cell frequencies to BA.1 S, N, and M mutation pools were similar, increased, and halved compared to reference pools.
Conclusions/Learning Points: Both BNT162b2 and CoronaVac induced robust immune responses in children. Reactivity against Omicron subvariants was preserved, suggesting maintained efficacy in children. Testing for hybrid immunity and cross-neutralization of emerging Omicron subvariants is underway.

PV0980 / #1161

DIFFERENCES IN SMELL DYSFUNCTIONS, LABORATORY FEATURES, DISEASE SEVERITY AND TREATMENT OF PEDIATRIC COVID-19 BETWEEN SARS-COV-2 VARIANTS.

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Dawid Lewandowski[1], Kacper Toczylowski[1], Kamil Grubczak[2], Artur Sulik[1]
[1]Medical University of Bialystok, Department Of Pediatric Infectious Diseases, Bialystok, Poland, [2]Medical University of Bialystok, Department Of Regenerative Medicine And Immune Regulation, Bialystok, Poland

Backgrounds: Since COVID-19 outbreak, we have experienced several waves of infections caused by various variants of the virus. The new variants also differed in the severity and infectivity, but also in frequency of smell dysfunctions. In our study we compared the severity of smell disturbances, but also we aimed at evaluating correlations between cytokine levels in pediatric patients infected with different variants of SARS-CoV-2.
Methods: Eighty-five children (aged 7-17y) were included. The Polish version of the 40-odorant standardized multiple-choice scratch-and-sniff UPSIT test was used. Based on the predominance of SARS-CoV-2 variant in the period when the study was done,10 children had British, 51 Delta, and 24 Omicron variant. We measured concentrations of vitamin D and IL-1beta, IL-6, IL-17, TNF-alpha, IFN-gamma, IL-10, TGF-beta. Based on WHO criteria we assessed the severity of the disease caused by each variant, as well as remdesivir and antibiotic use.
Results: Patients with the Omicron variant had less severe smell dysfunctions, milder COVID-19 course and spent less days in hospital than patients with other variants. They rarely received antibiotics (42% vs. 50% British; 59% Delta) and remdesivir (0% vs. 50% British; 16% Delta). Radiological evidence of pneumonia was present in 21% of patients with Omicron (vs. 70% British; 59% Delta). Severe smell dysfunctions were present in 25% of children with Omicron, 69% with Delta and 80% with the British variant. There were no differences between variants in cytokines and Vitamin D levels.
Conclusions/Learning Points: The emergence of new SARS-CoV-2 variants resulted in change of clinical features and severity of COVID-19 as well as clinicians' attitude towards treatment of the disease. Smell dysfunctions were the hallmark of the SARS-CoV-2 infections during British and Delta waves, but became a rare symptom in the times of the Omicron.

HOSPITALIZATIONS OF NEWBORNS IN POLAND BEFORE AND DURING COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Krzysztof Kanecki[1], Katarzyna Lewtak[1,2], Piotr Tyszko[1,3], Paweł Goryński[4], Irena Kosińska[1], Aneta Nitsch-Osuch[1]
[1]Medical University of Warsaw, Department Of Social Medicine And Public Health, Warsaw, Poland, [2]National Institute of Public Health NIH - NRI, Department Of Health Promotion And Prevention Of Chronic Diseases, Warsaw, Poland, [3]Institute of Rural Health in Lublin, , Lublin, Poland, [4]National Institute of Public Health NIH - NRI, Department Of Population Health Monitoring And Analysis, Warsaw, Poland

Background: The COVID-19 pandemic affected the health situation and health systems functioning in many countries, and it could also be associated with changes in paediatric hospitalizations. The aim of the study was to show up-to-date information on newborns' hospitalizations in Poland.
Methods: A retrospective, population-based study was conducted using data from hospital discharge records of patients hospitalized in 2017-2021 registered in the Nationwide General Hospital Morbidity Study maintained by the National Institute of Public Health in Poland and covered hospitalization records of newborns requiring in-hospital care immediately after birth. A main disease as well as comorbidities significant in the case of those hospitalizations were analyzed in accordance with ICD-10 codes.
Results: The study group consisted of 105,130 newborns, out of which male patients accounted for 51.5%. Annual hospitalization rate for newborns were estimated at 50.3-51.9 per 1000 in 2017-2019, 55 per 1000 in 2020 and rose to 77 per 1000 in 2021. In the pre-COVID-19 period in relation to the pandemic period there were no significant differences in the incidence of infectious diseases among newborns. During COVID-19 pandemic the prevalence of SARS-CoV2 infections was 4.3 per 1000. Among the most often noted causes of hospitalizations during the COVID-19 era, we observed significantly more newborns affected by: maternal renal and urinary tract diseases ($P<0.001$), premature rupture of membranes ($P<0.001$), complications of placenta, cord and membranes ($P<0.001$), neonatal jaundice due to other excessive hemolysis ($P<0.001$) compared to the time before the pandemic.
Conclusions/Learning Points: The COVID-19 pandemic and restrictions implemented throughout health care system could have significantly contributed to qualitative and quantitative changes in hospital care among newborns. The results of this study may be useful for taking effective and focused public health actions.

COVID-19-ASSOCIATED ACUTE MOTOR-SENSORY AXONAL NEUROPATHY IN AN 11-YEAR-OLD BOY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Qin Ying Lim[1], Jaime Rosa Duque[2], Sophelia Chan[2], Winnie Tso[2], Christy Chau[1]
[1]Queen Mary Hospital, Department Of Paediatrics And Adolescent Medicine, Hong Kong SAR, Hong Kong PRC, [2]The University of Hong Kong, Department Of Paediatrics And Adolescent Medicine, Hong Kong, Hong Kong PRC

Title of Case: COVID-19-ASSOCIATED ACUTE MOTOR-SENSORY AXONAL NEUROPATHY IN AN 11-YEAR-OLD BOY
Background: Guillain-Barre syndrome (GBS), the most common cause of acute flaccid paralysis, is an uncommon COVID-19-associated complication. Acute motor-sensory axonal neuropathy (AMSAN), a rare GBS variant, was found to be more commonly associated with COVID-19 infection in adults with 20 reported cases. We present the first case of paediatric COVID-19-associated AMSAN.
Case Presentation Summary: An 11-year-old previously healthy boy presented with 3-weeks of ascending weakness, inability to walk or raise arms, weak hand grip and swallowing difficulties, beginning 2 weeks after COVID-19 infection. Upon admission, he had hypotonia, areflexia and muscle weakness but no sensory deficit. CSF revealed cytoalbuminologic dissociation (protein 1.86g/L, cell count $1x10^6$/L). [SC1] MRI showed cauda equina contrast enhancement. Nerve conduction study showed axonal motor-sensory polyneuropathy, compatible with AMSAN. He required PICU admission after developing respiratory failure necessitating non-invasive ventilation (NIV) support. He received 2 courses of 2g/kg IVIG and 9 courses of plasmapheresis. He had transient sphincter dysfunction requiring urinary catheterization, and developed depressed moods from concerns of potential permanent immobility, improving with sertraline and psychological counseling. Intensive inpatient rehabilitation including motor and oromotor training was started early and continued during his 6-months inpatient stay. Motor performance significantly improved and swallowing problem resolved. His respiratory condition improved on lung function tests, no longer requiring NIV. He will continue outpatient rehabilitation with regular review.
Learning Points/Discussion: AMSAN, the rare GBS variant, can present in children like our patient, and must be considered when weakness or sensory symptoms occur after COVID-19 infection. Early diagnosis and treatment can improve clinical outcome. Care of AMSAN requires multidisciplinary team, including intensivists, neurologists, respirologists, psychiatrists, rehabilitation physicians and allied health professionals. Longer rehabilitation training is anticipated for full motor recovery.

SHORT-TERM OUTCOMES OF SOUTH AFRICAN CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN: A PROSPECTIVE COHORT STUDY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Juanita Lishman[1], Deepthi Abraham[1], Barend Fourie[1], Nurea Yunis[1], Andrew Redfern[1], Marieke Van Der Zalm[2], Helena Rabie[3]
[1]Stellenbosch University, Paediatrics And Child Health, Cape Town, South Africa, [2]Desmond Tutu TB Centre, Paediatrics, Cape Town, South Africa, [3]Stellenbosch University, Department Of Paediatrics, Cape Town, South Africa

Backgrounds: Despite the life-threatening presentation of MISC in children, the overall prognosis is favourable in first world centers. In this study we investigate the short-term outcomes in children with MIS-C in Cape Town, South Africa.
Methods: This prospective observational cohort study included children <13 years who fulfilled the World Health Organization (WHO) case definition of MIS-C and were admitted to Tygerberg Hospital (Cape Town, South Africa) between 1 June 2020 and 31 October 2021. Clinical features were recorded at baseline and at follow-up at the 6-week cardiology and 3-month rheumatology-immunology clinics respectively.
Results: Fifty-three children with MIS-C were included. The median age was 7.4 years (interquartile range (IQR) 4.2-9.9). There was a slight male predominance (30/53; 56,6%) and the majority was of mixed-race (28/53; 52,83%) or black African ancestry (24/53; 45,3%). Fourteen children (14/53; 26,4%) had co-morbid disease. The median length of hospital stay was 8 days (IQR 6-10). All children had an echocardiogram performed at baseline of which 39 were abnormal (39/53; 73,6%). The majority had elevated markers of inflammation, lymphopenia, anaemia, renal impairment, hyponatremia, and elevated cardiac enzymes during the acute phase. All children were discharged alive. Eleven children (11/41; 26,8%) had a persistently abnormal echocardiogram at cardiology follow-up. Systemic inflammation and organ dysfunction resolved in most.
Conclusions/Learning Points: Although the short-term outcomes of MIS-C in our cohort were generally good, the cardiac morbidity needs further characterization and follow-up. This high morbidity highlights access of COVID 19 vaccines in children <12 years in LMICs.

[1]University of Naples, Federico II, Department Of Translational Medical Sciences - Section Of Pediatrics, Naples, Italy, [2]University of Naples, Federico II, Department Of Translational Medical Sciences - Section Of Pediatrics, Napoli, Italy

Backgrounds: Respiratory syncytial virus (RSV) infection is the most common cause of bronchiolitis. SARS-CoV-2 spreading and the implementation of restrictive measures led to a dramatic reduction of RSV together with rare and mild clinical bronchiolitis induced by SARS-CoV-2. Aims of our study are to describe clinical respiratory picture of SARS-CoV-2 infection and to evaluate the frequency and the severity of SARS-CoV-2 bronchiolitis comparing it with other respiratory viral infections in children less than two years of age.
Methods: Respiratory involvement and severity of bronchiolitis were assessed evaluating the duration of hospitalization and the need of oxygen therapy, intravenous hydration, systemic corticosteroid and antibiotic therapies. A retrospective study was conducted enrolling children below two years of age, hospitalized for respiratory symptoms. Diagnosis of SARS-CoV-2 and others respiratory viral infections were performed by a multiplex PCR on nasal swab.
Results: 138 children were enrolled:60/138 (43,5%) had SARS-Cov2 infection and 78/138 (56,5%) had RSV infections. In the group of SARS-CoV-2 infected children 13/60 (21%) received a diagnosis of co-infection showing at least one other respiratory virus at nasal swab. Among the enrolled children, 87/138 (63%) received a diagnosis of bronchiolitis. We compared children with respiratory symptoms due to SARS-CoV-2, RSV and co-infection. Children with RSV infection or co-infection had higher risk of oxygen therapy (RR 9.14;6.83;1.24), intravenous hydration (RR5.87;4.3;1.26), systemic corticosteroid (RR 5.22;7.33;0.74) and antibiotics (RR 2.17;2.32;0.94). When we compared only children with clinical diagnosis of bronchiolitis no difference were observed between groups in terms of need for oxygen therapy and hospital stay.
Conclusions/Learning Points: These date confirm that SARS-Cov2 infection in pediatric age is generally milder than in adults and SARS-CoV-2 induced bronchiolitis is rare. Despite this, SARS-CoV2 induced bronchiolitis may be associated with a severe clinical course.

University of Naples, Federico II, Department Of Translational Medical Sciences - Section Of Pediatrics, Napoli, Italy

Title of Case: Multisystem Inflammatory Syndrome in children with acute Influenza A infection resulted negative for SARS-CoV-2 infection
Background: Multisystem Inflammatory Syndrome in Children (MIS-C) is a severe condition characterized by fever, inflammation, and multiorgan dysfunction and described for the first time in children with recent SARS-CoV-2 infection. We hereby report two children with acute influenza A infection who fulfilled the inclusion criteria for MIS-C but resulted negative for SARS-CoV-2 nasopharyngeal swabs, serology and previous history of contact.
Case Presentation Summary: Two toddlers were admitted to our department with a 2-day history of fever and feeding refusal. Patient#1 presented with diarrhea, cough, interstitial pneumonia on chest CT and respiratory failure requiring High-Flow Nasal-Cannula Oxygen Therapy. Patient#2 presented with cough and severe diarrhea with the presence of enlarged lymphnodes and mesenteric inflammation at abdominal ultrasound. Both children had increased markers of inflammation and myocardial injury, liver enzymes and amylases, and signs of coagulopathy (Table). A thorough microbiological examination of blood, stools and urine resulted negative with the exclusion of a positive molecular test for Influenza A virus on nasal swab. Patient#1 did well on steroid therapy, while Patient#2 recovered with no specific therapy.

Characteristics	Patient#1	Patient#2
Age, years	2.5	2.8
WBC, cells/ul	15600	2060
CRP, mg/L(0-5)	42.8	17
PCT, ng/ml(<0.09)	4	56.29
Ferritin, ng/ml(15-160)	815	6550
ALT, U/L(0-55)	2486	1052
Amylases, U/L(25-101)	820	452
INR(0.8-1.2)	1.43	1.43
D-dimer, ng/ml(0-500)	15743	2224
Troponin, pg/ml(<16)	1756	60
CK-MB, ng/ml(0-7.2)	12.4	16.6
BNP, pg/ml(0-73)	1429	na
NT-proBNP, pg/ml(<125)	na	535

Learning Points/Discussion: The observation of two children with Influenza A infection showing systemic inflammation and multiorgan involvement (fulfilling criteria for MIS-C except for SARS-COV-2 infection), raises the hypothesis that MIS-C might be a condition related also to viruses other than SARS-CoV-2.

PREVALENCE AND ASSOCIATING FACTORS OF LONG COVID IN PEDIATRIC PATIENTS DURING THE DELTA AND THE OMICRON VARIANTS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Tananya Lokanuwatsatien[1], Araya Satdhabudha[2], Auchara Tangsathapornpong[2], Pornumpa Bunjoungmanee[2], Pakatip Sinlapamongkolkul[2], Chanapai Chaiyakulsil[1], Paskorn Sritipsukho[2], Pichaya Tantiyavarong[3]
[1]Thammasat university hospital, Pediatrics, Pathumthani, Thailand, [2]Faculty of medicine, Thammasat university, Pediatrics, Pathumthani, Thailand, [3]Faculty of Medicine, Thammasat University, Clinical Epidemiology, Pathumthani, Thailand

Backgrounds: The number of pediatric COVID-19 infections is increasing; however, the data on long COVID conditions in children is still limited. Our study aimed to find the prevalence of long COVID in children during the Delta and Omicron waves, as well as associated factors.
Methods: A single-center prospective cohort study was conducted. We included 802 RT-PCR-confirmed COVID-19 pediatric patients in the Delta and Omicron periods. Long COVID was defined as having symptoms for ≥3 months after infection. Parents and/or patients were interviewed by phone. Multivariable logistic regression was performed to find associated factors with long COVID.
Results: The overall prevalence of long COVID was 30.2%. The Delta period had more prevalence than the Omicron (36.3% vs. 23.9%). Common symptoms for patients 0-3 years' old were loss of appetite, rhinorrhea, and nasal congestion. Conversely, patients 3-18 years' old had hair loss, dyspnea on exertion, rhinorrhea, and nasal congestion. Most symptoms improved after a 6-month follow-up. Factors associated with long COVID-19 conditions were infection during the Omicron period (adjusted OR 0.54; 95% CI 0.39-0.74, P < 0.001), fever (adjusted OR 1.51, 95% CI 1.03-2.23, P = 0.04) and rhinorrhea (adjusted OR 1.47, 95% CI 1.06-2.02, P = 0.02).
Conclusions/Learning Points: Infection during the Omicron wave has a lower prevalence of long COVID. The prognosis is generally good, and symptoms are obscure over time. However, pediatricians may schedule appointments to surveil long COVID in children with fever or rhinorrhea as an initial symptom.

MULTISYSTEM INFLAMMATORY SYNDROME - A 3 YEARS PORTUGUESE MULTICENTRIC STUDY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Rita Valsassina[1], Caroline Lopes[1], Teresa Lopes[2], Maria Tavares[3], Filipa Prata[4], Laura Marques[3], Fernanda Rodrigues[5], Catarina Gouveia[1]
[1]Hospital Dona Estefania – Central Lisbon University Hospital Center, Pediatrics Infectious Diseases Unit, Lisbon, Portugal, [2]Hospital Pediátrico do Centro Hospitalar e Universitário de Coimbra, Paediatric Infectious Diseases Department, Coimbra, Portugal, [3]Centro Hospitalar Universitário de São João, Pediatric Infectious Diseases And Primary Immunodeficiencies Unit, Pediatrics, Porto, Portugal, [4]Centro Hospitalar Lisboa Norte, Paediatric Infectious Diseases And Immunodeficiencies Unit, Lisboa, Portugal, [5]Centro Hospitalar e Universitário de Coimbra, Pediatrics Infectious Disease Unit, Coimbra, Portugal

Backgrounds: Multisystem inflammatory syndrome (MIS-C) is a rare but potentially severe complication of SARS-CoV-2 infection. This study was conducted to characterize clinical presentation, and outcome, according to the SARS-CoV-2 circulating variant.
Methods: Retrospective, multicenter study at 49 Portuguese hospitals over a three-year period (2020-2022). Children/adolescents with MIS-C diagnosis were included. Data regarding epidemiology, symptoms, management, and outcomes were collected.
Results: A total of 172 patients were included, with an average annual incidence of 3.08/100,000 and a mean of 1.4 admissions per week (peak 11 cases/week 22/02/2020 to 07/03/2020). The mean age was 8.3 years (±4.6), 144 (83.7%) caucasians. Most cases (93;54.1%) occurred during the dominant circulation of the alpha variant ($p<0.01$), followed by the wild (31;18%), delta (42;24.4%) and omicron (6;3.5%). Clinical and laboratory presentations are described in table 1. The phenotype was Kawasaki-like (116;67.4%) and unspecific (56;32.6%). Shock occurred in 48 (27.9%), 40/48 (88.9%) needed inotropes, and 7/116 (6%) had coronary artery abnormalities. Most (116;68%) were treated with immunoglobulin and corticosteroid combination. Thirteen (7,6%) needed mechanical ventilation, and there was no death; At 3-4 weeks follow-up, 15/137 (10,9%) had cardiac involvement, mostly minimal myocardial scars, and 7/90 (10,1%) maintained those changes at 6-8 weeks. We didn't find any association between shock, phenotype or SARS-CoV-2 variant. Those that needed inotropes had a lower mean value of lymphocytes, platelets and albumin and higher neutrophils, D-dimers, ferritin, troponin, NT-proBNP, ALT, CRP and PCT($p< 0.05$).
Conclusions/Learning Points: There was a clear decrease in the incidence of MIS-C with the Omicron variant, which may be due to the lower pathogenicity and immunity induced by previous infection or, in some cases, by vaccination. Despite the severe acute presentation most patients had a good short-term outcome.

NEONATAL MULTISYSTEMIC INFLAMMATORY SYNDROME (MIS-N) ASSOCIATED WITH CORONAVIRUS DISEASE. EXPERIENCE FROM A FOURTH-LEVEL HOSPITAL IN BOGOTA, COLOMBIA

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Juan Carlos Lopez[1,2], María Suarez[1], Yaris Vargas[1], Angie Sierra[1]
[1]Hospital Universitario San Ignacio, Infectology Department, Bogota, Colombia, [2]Hospital Universitario San Ignacio, Infectious Diseases, ., Colombia

Title of Case: Neonatal Multisystemic Inflammatory Syndrome (MIS-N) associated with coronavirus disease. Experience from a fourth-level hospital in Bogota, Colombia.
Background: This study describes the diagnostic challenges of multisystemic inflammatory syndrome associated with postnatally acquired coronavirus disease
Case Presentation Summary: Retrospective observational study describing the characteristics of patients reported with MIS-C associated with positive RT-PCR for SARS-CoV-2 between April 2020 and March 2022. An adjustment was made to the criteria proposed by the CDC for MIS-C (Multisystem Inflammatory Syndrome in Children), in the absence of fever described in the neonatal population, excluding other pathologies such as neonatal sepsis and perinatal asphyxia. We documented a total of 32 cases of SARS-CoV-2 infection of which 4 (12.5%) met MIS-N or MIS-C criteria. The cases occurred at the end of the third epidemiological peak between April and July 2021. All cases were preterm infants between 30- and 34 weeks gestational age. 2 cases with a mother with an asymptomatic infection and 2 with documented symptomatic infection after delivery, all with positive RT-PCR for SARS-CoV-2. The onset of symptoms between 8 days and 8 weeks of chronological age. Cardiac involvement (elevated troponins and proBNP (100%), one case with electrocardiographic alteration and pericardial effusion), ventilatory failure (50%), fever (25%), elevated inflammatory markers (100%), deep vein thrombosis (25%). 4 received immunoglobulin, 3 methylprednisolone. 1 case of mortality with a need for ECMO therapy.
Learning Points/Discussion: MIS-C or MIS-N should be considered in the differential diagnosis of patients with unusual signs of multisystem inflammation, having a high index of suspicion, due to the diversity of manifestations in their clinical presentation

Title of Case: CHALLENGES IN DIFFERENTIATING KAWASAKI DISEASE FROM MIS-C IN THE COVID ERA; THE CASE OF AN INFANT WITH GIANT ANEURYSMS FORMATION
Background: Kawasaki disease is a vasculitis, typically affecting young children, and importantly associated with coronary artery aneurysms (CAAs) formation.[1] MIS-C has been reported in older children, in association with exposure to SARS-COV2. However, MIS-C has been also described in infants, in which cardiac sequelae are commonly observed.[2]
Case Presentation Summary: A 4 month-old infant presented with a 2-day history of fever and diarrhea, as well as diffuse maculopapular rash and bilateral conjunctival injection. The infant had no confirmed history of COVID-19. Clinically, the patient presented marked irritability, while the laboratory and imaging findings included increased inflammatory markers and NT-proBNP, pericholecystic edema, abnormal coagulation profile, sterile pyuria, as well as positive SARS-COV2 serology. Based on the clinical and laboratory findings, a diagnosis of MIS-C presenting with atypical Kawasaki features was made and treatment with IVIG, intravenous corticosteroids and aspirin was initiated. However, at the 10th day, fever recurred, and periungual desquamation and thrombocytosis were observed, so a 2nd IVIG infusion was administered. Even though repeated echocardiography was normal initially, on the 16th day medium sized aneurysms were depicted in both right and left coronary arteries, which rapidly evolved to giant aneurysms, while on the 26th day a thrombus was formed inside the giant aneurysm of the right coronary artery, despite timely initiation of anticoagulation. Thrombolysis was attempted, a 3rd IVIG infusion was administered and treatment with Anakinra was initiated, resulting to gradual thrombus resolution and aneurysms reduction.
Learning Points/Discussion: This case illustrates the challenge in differentiating Kawasaki disease from MIS-C in young infants, as well as the importance of prompt diagnosis and treatment in this high-risk population.

Paolo, Palidoro, San-ta Marinella And Arrhythmology, Rome, Italy, [4]Bambino Gesù Children Hospital, Department Of Cardiac Surgery, Cardiology And Heart Lung Transplant, Division Of Sports Medicine, Rome, Italy, [5]Bambino Gesù Children's Hospital, IRCCS, Department Of Pediatric Cardiac Surgery, Cardiology, Heart Failure And Heart Lung Trasplantation, Rome, Italy, [6]Bambino Gesù Children's Hospital IRCCS, Advanced Cardiovascular Imaging Unit, Department Of Imaging, Rome, Italy

Background: Multisystem inflammatory syndrome in children (MIS-C) is a serious health condition that imposes a long-term follow-up. The multi-faceted nature of the disease course and various presentations underlines the need for prompt approach by specialists in several areas. In this study we aim to evaluate the early and long-term outcomes of MIS-C.
Methods: This is a longitudinal 12-months cohort study of children admitted and treated for MIS-C at Bambino Gesù Children Hospital from November 2020 to December 2022. Patients were followed 4-6 weeks, 4-6 months, and 9-12 months postadmission.
Results: We enrolled 40 patients. 28 patients have completed the 12 months follow-up. Acutely 10 patients required intensive care with vasoactive support, 18 had left ventricular (LV) systolic dysfunction, 7 had coronary abnormalities. The gastrointestinal and respiratory involvement was showed respectively in 29 and in 31 subjects. All patients received immunomodulatory treatment. At 4-6 weeks postadmission 1 patient had persistent dilated coronary artery. By 4-6 weeks through 6 months all patients returned to functional baseline. At 4-6 months follow-up the cardio pulmonary exercise testing (CPET) was carried out in 20 patients and showed some changes despite normal electrocardiogram (ECG), echocardiogram and 24-hour Holter-ECG monitoring. In these patients spirometry was normal. The cardiac magnetic resonance (CMR) performed in patients with LV dysfunction and/or with hs-TnT elevated, revealed no myocardial edema or fibrosis. The 28 patents who reached the 9-12 months follow-up continued to show stable clinical condition with normal cardiologic findings.
Conclusions/Learning Points: Treatment with immunomodulators drugs in MIS-C patients provide favorable outcomes with full recovery. The anomalies observed at CPET during the 4-6 months follow-up could be related to the state of complete physical detraining of children. These findings may help guide clinical management and outpatient monitoring.

[1]Bambino Gesù Children's Hospital, Unit Of Clinical Immunology And Vaccinology, Rome, Italy, [2]University of Rome Tor Vergata, Chair of Pediatrics, Department Of Systems Medicine, Rome, Italy, [3]Bambino Gesù Children's Hospital, Unit Of Microbiology And Diagnostic Immunology, Rome, Italy, [4]Bambino Gesù Children's Hospital, IRCCS, Department Of Pediatric Cardiac Surgery, Cardiology, Heart Failure And Heart Lung Trasplantation, Rome, Italy, [5]Bambino Gesù Children's Hospital IRCCS, Advanced Cardiovascular Imaging Unit, Department Of Imaging, Rome, Italy

Backgrounds: Multisystem inflammatory syndrome in children(MIS-C) is a rare but severe complication of SARS-CoV-2 infection.There is currently limited evidence on whether the severity of MIS-C differs when occurred after different Variant Of Concern(VOC).Here we described the clinical characteristics of MIS-C during the waves pre-Omicron and Omicron.
Methods: Between November 2020 and October 2022 we enrolled patients admitted to Bambino Gesù Children Hospital meeting the MIS-C CDC criteria.We defined the variant period according to the data from the Italian National Institute of Health(pre-Omicron waves November 2020-December 2021,Omicron wave January 2022-October 2022).
Results: During the pre-Omicron waves and the Omicron wave we observed a comparable number of MIS-C cases, respectively 20 and 19.The age and sex were homogeneous.No major clinical differences were observed in MIS-C enrolled in the pre-Omicron compared to the Omicron wave period. However in the Omicron wave the incidence of conjunctivitis, lymphadenopathy and mucocutaneous involvement was higher than in pre-Omicron wave (Table).In pre-Omicron waves 90% of patients received intravenous immunoglobulins (IVIG) and steroids and the 10% only IVIG (2gr/kg).The 15% of subjects were treated with anti-IL1 in combination with other therapies.No differences were observed regarding the treatment (Table) during the omicron wave.No MIS-C cases occurred among patients with reinfections.During the Omicron wave, among patients eligible for vaccination (=11), all cases of MIS-C but one weren’t fully vaccinated.

	NO. (%)	
PHENOTYPE OF PATIENTS WITH MIS-C	pre-Omicron (n=20)	Omicron (n=19)
Sex		
Male	10 (50)	9 (47)
Female	10 (50)	10 (53)
Age, median (range)	8 (2-16)	9 (2-15)
Clinical characteristics		
Cardiac involvement		
- Cardiac dysfunction	8 (40)	9 (47)
- Elevated troponin	8 (40)	10 (53)
- Coronary artery aneurysm/dilatation	5 (25)	2 (11)
Gastrointestinal involvement	16 (80)	14 (74)
Dermatologic involvement	8 (40)	8 (42)
Conjunctivitis	5 (25)	10 (53)
Lymphadenopathy	3 (15)	6 (32)
Any mucocutaneous involvement	2 (10)	6 (32)
Neurologic involvement	5 (25)	5 (26)
Respiratory involvement	15 (75)	16 (84)
Intensive care unit admission	4 (20)	4 (21)
Treatment		
IVIG	2 (10)	2 (11)
IVIG+Steroids	18 (90)	(84)
Anti-IL1+other therapies	3 (15)	3 (16)
Total days in hospital, median (range)	13 (7-33)	15 (10-20)
Vaccination status		
Eligible	1	11
Fully vaccinated	0	1
Partially vaccinated	0	2
Vaccination not received	1	8

Conclusions/Learning Points: We don’t find clear evidence that different variants influenced the presentation of clinical picture or the risk of MIS-C.Continuous evidence will be needed over the next COVID19 waves to monitor changes in clinical presentation and possible complication of this condition.Our data further confirm the pivotal role of COVID19 vaccination in reducing the incidence of MIS-C and highlight the benefits of immunization in children.

PV0992 / #2175

CASE REPORT: POST COVID BLEPHAROPTOSIS IN A CHILD OF 2 YEARS OLD

Title of Case: Case Report: Post COVID blepharoptosis in a child of 2 years old
Background: Neurological manifestations during or after SARS-Cov-2 infection are largerly common in children under 18years old and vary from febrile seizures, abnormal eye mouvements, encephalopathy, meningeal signs to non specific such as headache, fatigue, anosmia. Data suggest that the pathophysiological mechanisms are complex and can consist into direct CNS invasion and infection, immune system dysregulation, autoimmune mechanisms and/or microvascular damage.
Case Presentation Summary: A previous healthy 2year old boy, with family history of grandfather suffering from myasthenia, was admitted for unilateral blepharoptosis, evolving since ten days. Fifteen days before admission, he was treated with amoxicilline for an unidentified upper respiratory infection. The ophtalmological exam confirmed third nerve palsy. The brain MRI demonstrated some small lessions on the pons whereas the MRA was normal. CSF and blood were positive for oligoclonal bands type IV. A complete blood and CSF work up excluded associated metabolic diseases, autoimmune encephalitis and myasthenia Gravis. The SARS-COv2 blood IgG protein was extremely high, indicating a recent infection whereas all other viral serologies were negative. The patient received a 5day course of immunoglobulines and progressively the symptom resolved.At two month follow up, his neurological examination is normal and a control MRI has been programmed.
Learning Points/Discussion: We report a rare to our knowledge case of a very young boy who presented third nerve palsy- after a SARS-Cov2 infection with great outcome after receiving immmunoglobulines.. Whether the virus revealed or aggravayed an underlying condition or whether the SARS-Cov-2-induced immune system dysregulation is responsable are questions that demand more standardized studies, especially in children where the symptoms and pathophysiological mechanisms differ from those in adults and are not related to the severity of the SAR-Cov2 infection.

A CASE OF EOSINOPHILIC PLEURAL EFFUSION IN A 9-YEAR-OLD BOY AFTER ASYMPTOMATIC COVID-19

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Vasiliki Korentzelou, Konstantina Patouni, Efstathia-Danai Bikouli, Foteini Markantoni, Andriani Vazeou, Mersyni Mavrikou
P&A Kyriakou Childrens Hospital, First Paediatric Department, Athens, Greece

Title of Case: A case of eosinophilic pleural effusion in a 9-year-old boy after asymptomatic COVID-19
Background: Eosinophilic pleural effusion (EPE) is defined as a pleural effusion with eosinophilic count exceeding 10% of white blood cells. It has been attributed to a wide range of causes such as infections, rheumatological diseases, malignancies, drugs or it could be idiopathic. This case illustrates asymptomatic COVID-19 as a potential cause of EPE.
Case Presentation Summary: We present a previously healthy 9-year-old boy from Greece who was admitted with a 3-day history of cough. No other symptoms such as chest pain, dyspnea or fever were reported. Clinical and radiological examination revealed a left-sided pleural effusion with normal lung parenchyma; from the thoracentesis nearly half of the exudate pleural fluid (540ml) was removed. The white blood cells in the fluid were 1980/microL (71% lymphocytes, 26% neutrophils and 15% eosinophils). Laboratory results revealed peripheral blood eosinophilia (3.500/microL) solely. The rest of the workup was negative. Asymptomatic Covid-19 in remission was detected by polymerase chain reaction (PCR) from nasopharyngeal swabs; SARS-Cov-2 was detected at 38 and 40 cycles on day 1 and 2 of admission respectively and a new PCR test on day 5 was negative. Other infectious diseases, TB, malignancies and rheumatological diseases were ruled out. Clarithromycin was administered for 10 days. The remaining pleural fluid showed a gradual decrease with a corresponding gradual improvement of the clinical findings and a progressive reduction of the peripheral eosinophilia.
Learning Points/Discussion: In our case the only finding suggesting a potential cause of eosinophilic pleural effusion was COVID-19, although it is considered a rare manifestation especially in asymptomatic patients.

Backgrounds: Multisystem Inflammatory Syndrome in Children associated with COVID-19 (MIS-C) is a late and potentially severe complication of SARS-CoV-2 infection. Emerging data implicate dysregulated B cell responses in the pathogenesis of MIS-C, importantly through autoantibody production. Yet a comprehensive analysis of how B cell activation pathways are impacted in MIS-C is yet to be conducted. We carried out profiling of B cells in a cohort of MIS-C patients and healthy children post COVID-19 to address this knowledge gap.
Methods: Participants that meet the WHO criteria for MIS-C diagnosis are recruited at 3-6 months following the onset of disease. As the control group, we are enrolling children that have fully recovered from acute COVID-19. Peripheral blood is collected, the assessment of B cell activation is carried out by flow cytometry, using antibodies against CD19, CD27, IgD, IgM, CD21 and CD38. This enables the identification of transitional (IgMhiCD38hi), naïve (IgD+CD27-), switched (IgD-CD27+) and unswitched memory (IgD+CD27+), activated (CD21loCD38lo) as well as double negative B cells (IgD-CD27-) and plasmablasts (IgM-CD38++).
Results: The enrolment of participants is ongoing, but our preliminary data of 4 MIS-C patients and 4 controls indicates trends for the increased B cell activation via the extrafollicular pathway. This pathway has been previously extensively characterised in autoimmunity. Specifically, we observe a trend for MIS-C-associated expansion of IgD-CD27- double negative B cells and IgM-CD38++ plasmablsts. Nevertheless, none of the results reached statistical significance.
Conclusions/Learning Points: As more study participants are recruited, we aim to delineate the functional significance of potential alterations in B cell activation pathways. In the light of the extrafollicular B cell activation giving rise to de novo autoreactive antibody production following severe COVID-19, it will be important to address differences in underlying mechanisms of pathogenesis.

PV0995 / #265

FACTORS ASSOCIATED WITH ADVERSE OUTCOMES AMONG SARS-COV-2 POSITIVE CHILDREN IN A TERTIARY GOVERNMENT COVID-19 REFERRAL HOSPITAL IN THE PHILIPPINES

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

[1]University of the Philippines College of Medicine, Pediatrics, Manila, Philippines, [2]Philippine General Hospital, Expanded Hospital Research Office, Manila, Philippines

Backgrounds: Pediatric COVID-19 epidemiology and factors associated with adverse outcomes – mortality, need for invasive mechanical ventilation, and ICU admission, are largely unstudied. We described the clinico-demographic characteristics of Filipino pediatric COVID-19 patients and determined which were associated with adverse outcomes.
Methods: This is a retrospective cohort study of 180 hospitalized SARS-CoV-2-confirmed cases 0-18 years old from April 2020 to August 2021. Crude associations were determined using chi-squared or Fisher's exact test; medians were compared by Mann-Whitney test. Factors predictive of mortality were determined using Cox proportional hazards regression. Survivor functions were depicted in graphs.
Results: About 41.67% had mild disease, 58.33% were males, 39.4% aged 0-4 years, and 69.44% had at least one comorbidity. About 9.44% died, 17.78% needed invasive mechanical ventilation, and 20% needed ICU admission. Independently, severe-critical COVID-19 (HRc 11.51, 95% CI), retractions (HRc 10.30, 95% CI), alar flaring (HRc 4.39, 95% CI), cyanosis (HRc 4.39, 95% CI), difficulty of breathing (HRc 7.99, 95% CI), poor suck/appetite (HRc 4.46, 95% CI), ferritin (HRc 1.01, 95% CI), IL-6 (HRc 1.01, 95%), aPTT (HRc 1.05, 95%), IVIg (HRc 4.00, 95% CI) and corticosteroid (HRc 6.01, 95% CI) were significant hazards for mortality. In adjusted Cox analysis, only retractions (HRa 34.96, 95% CI), seizure (HRa 9.98, 95% CI), and corticosteroids (HRa 8.21, 95% CI) were significantly associated with mortality while alar flaring appeared to be protective (HRa 0.10, 95% CI).
Conclusions/Learning Points: Majority of hospitalized pediatric COVID-19 patients were very young, males, had mild disease, and had at least one comorbidity. Mortality, invasive mechanical ventilation, and ICU admission were relatively low. Except for alar flaring which appeared to be protective, retractions, seizure, and use of corticosteroids were associated with adverse outcomes.

EARLY TREATMENTS OF FRAGILE CHILDREN WITH COVID-19. RESULTS OF CLEVER (CHILDREN COVID EARLY TREATMENT), A RETROSPECTIVE, OBSERVATIONAL STUDY.

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Chiara Minotti[1], Daniele Mengato[2], Marica De Pieri[3], Sabrina Trivellato[2], Andrea Francavilla[4], Costanza Di Chiara[1], Cecilia Liberati[1], Raffaele Mattera[5], Alessandra Biffi[5], Carlo Giaquinto[1], Francesca Venturini[2], Daniele Donà[1]
[1]University of Padua, Paediatric Infectious Diseases, Padua, Italy, [2]University Hospital of Padua, Hospital Pharmacy Department, Padua, Italy, [3]University Hospital of Padua, Paediatric Infectious Diseases, Padua, Italy, [4]University of Padua, Unit Of Biostatistics, Epidemiology And Public Health, Department Of Cardiac, Thoracic, Vascular Sciences And Public Health, Padua, Italy, [5]University of Padua, Division Of Pediatric Hematology, Oncology And Stem Cell Transplant, Padua, Italy

Backgrounds: SARS-CoV-2 infection is notably mild in children, though comorbidities may increase the risk of hospitalization and may represent a risk for increased disease severity. There is an urgent need for targeted therapies with an acceptable efficacy and safety profile. To date, most of the medicines for COVID-19-specific treatment are prescribed off-label for children due to a lack of clinical trials and consequent evidence in this population.
Methods: This was a retrospective, observational study investigating the safety of treatments for the prevention of severe COVID-19 in fragile pediatric patients who received monoclonal antibodies and antivirals for mild to moderate symptoms between December 2021 and July 2022.
Results: Thirty-two patients were included. Monoclonal antibodies were prescribed to 62%, intravenous antivirals to 22%, and oral antivirals to 16% of children. Sotrovimab was the most frequently prescribed drug among monoclonal antibodies and overall (59%). The second most prescribed drug was remdesivir (22%). No severe adverse drug reaction was reported. There were no progression to severe disease and no death cases due to COVID-19 or drug administration. At drug type stratification, resolution of symptoms and swab positivity time showed no difference between the two groups at 7 and 28 days. Off-label prescriptions were 84% overall, in similar proportions between the two groups.
Conclusions/Learning Points: In this small sample, antivirals seemed safe and showed no differences in safety as compared to MAbs for the early treatment of COVID-19 in fragile children, thus representing a valuable choice, even administered off-label.

GUILLAIN-BARRE SYNDROME AS MANIFESTATION OF MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN (MIS-C)

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Aliyyah Mohammad Khuzaini[1,2], Halimah Abdul Halim[1,2]
[1]Universiti Sains Islam Malaysia, Paediatric Department, Nilai, Malaysia, [2]Hospital Ampang, Paediatrics, Ampang, Malaysia

Title of Case: GUILLAIN-BARRE SYNDROME AS MANIFESTATION OF MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN (MIS-C)
Background: Guillain-Barre Syndrome (GBS) is characterised by rapidly-progressing, ascending symmetrical weakness with loss of muscle proprioceptive reflexes. It is typically an autoimmune post-infectious process damaging the myelin sheath. Coronaviruses have been shown to be neurotropic, causing varied neurological symptoms. GBS is not an established manifestation of Covid-19 infection or MIS-C in children. We report a case of GBS associated with multisystem inflammatory syndrome in children (MIS-C).
Case Presentation Summary: A previously well 4-year-old child presented with sudden onset of bilateral lower limb weakness and inability to bear weight. There was no fever, no bowel or urinary incontinence and no other neurological symptoms. He had an upper respiratory tract infection a week earlier. Lower limb neurological examination upon admission revealed absent power with areflexia and hypotonia. A magnetic resonance imaging of the whole spine showed thickening with diffuse enhancement of cauda equina nerve roots. Lumbar puncture showed elevated protein levels with no pleocytosis. He was started on intravenous immunoglobulin. However, after 24 hours, he developed weakness and painful paresthesia of bilateral upper limbs with acute urinary retention, complicated with altered consciousness and myocarditis later that day. Inflammatory markers and N-terminal-prohormone BNP (NT-proBNP) were raised with positive covid antibodies, suggestive of MIS-C. He completed a course of methylprednisolone and intravenous immunoglobulin. He was discharged after two weeks with mild lower limb weakness without cardiac or central nervous system sequelae.
Learning Points/Discussion: Association between Covid-19 and GBS has been shown in adults, however it is limited to case reports in children. The mechanism is still uncertain, but it has been attributed to post-infectious syndrome, nerve damage by T-cell activation, and hyperinflammatory response to COVID-19 virus.

[1]Federal University of Sao Paulo, Paulista Nursing School, Sao Paulo, Brazil, [2]Federal University of Uberlandia, Technical School Of Health, Uberlandia, Brazil, [3]Federal University of Uberlandia, Institute Of Biomedical Science, Uberlandia, Brazil, [4]University of Florence, Department Of Experimental And Clinical Medicine, Florence, Italy, [5]University of Hong Kong, Faculty Of Medicine, Hong Kong, China, [6]University of Sao Paulo, Institute Of Tropical Medicine Of Sao Paulo, Sao Paulo, Brazil, [7]Federal University of Sao Paulo, Paulista Medical School, Sao Paulo, Brazil

Background: With the emergence of the COVID-19 pandemic, it has become urgent to understand its pathophysiology, especially inpopulations that cannot comply with measures of social distancing, such as hemodialysis patients. The objective was to verify the prevalence of SARS-CoV-2 in children and adolescents on hemodialysis and compare the serological andsalivary detection in this population and their companions.
Methods: Prospective cohort conducted with individuals aged 0-18 years on Hemodialysis at the Pediatric Nephrology Service ofHospital São Paulo, Brazil. Saliva and blood samples were collected from the patient and his companion in two moments,T0 (initial) and T1 (30 to 60 days after). Serological and RT-PCR tests were performed for SARS-CoV-2. Grant #2021/04492-1, São Paulo Research Foundation (FAPESP).
Results: We included 10 patients and their companions, in the period prior to vaccination against COVID-19. Among the patients,the mean age was 10.6 years, 70% male. Serology in T0 was reactive in 2 (20%) and remained so in T1. The companionswere women (100%), with a mean age of 37.5 years. Serology in T0 was reactive in 3 (30%) and 4 (40%) in T1. The RT-PCR for SARS-CoV-2 was negative for all participants, in both moments.
Conclusions/Learning Points: The importance of knowing serological status is demonstrated to provide greater health safety for all involved intreatment, especially when there are only non-pharmacological prevention measures. The fact that he found both positiveand asymptomatic patients and companions, the need for change of care protocols for prevention and infection control is evidenced, with the inclusion of companions in the screening.

SARS-COV-2 IN CHILDREN AND ADOLESCENTS SUBMITTED TO KIDNEY TRANSPLANTATION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Richarlisson Morais[1,2], Isis Arruda[2], Karen Hiraki[3], Simone Giannecchini[4], Kelvin To[5], Rodrigo Zerbinati[6], Suelen Stopa[7], Paulo Henrique Braz-Silva[6], Monica Taminato[2]
[1]Federal University of Uberlandia, Technical School Of Health, Uberlandia, Brazil, [2]Federal University of Sao Paulo, Paulista Nursing School, Sao Paulo, Brazil, [3]Federal University of Uberlandia, Institute Of Biomedical Science, Uberlandia, Brazil, [4]University of Florence, Department Of Experimental And Clinical Medicine, Florence, Italy, [5]University of Hong Kong, Faculty Of Medicine, Hong Kong, China, [6]University of Sao Paulo, Institute Of Tropical Medicine Of Sao Paulo, Sao Paulo, Brazil, [7]Kidney and Hypertension Hospital, Nephrology, Sao Paulo, Brazil

Background: With the emergence of the COVID-19 pandemic, it has become urgent to understand its pathophysiology in different clinical situations, especially in populations of higher risk and vulnerability, such as immunosuppressed. The objective was to verify the prevalence of SARS-CoV-2 in renal transplant children and adolescents and to compare the serological and salivary detection of SARS-CoV-2 in this population and its companions.
Methods: Cross-sectional, analytical, descriptive study with individuals from 0 to 18 years of age submitted to kidney transplantation at the Kidney and Hypertension Hospital, Sao Paulo, Brazil. Blood and saliva samples were collected from the patient and his companion for serological and RT-PCR testing for SARS-CoV-2. Grant #2021/04492-1, São Paulo Research Foundation (FAPESP).
Results: Thirty patients and their companions were included. Among the patients, the mean age was 14 years, 50% male. Serology was reactive in 23 (79.3%), while RT-PCR was positive in 12 (40.0%). 83.3% of the companions were women, with a mean age of 38 years. Serology was reactive in 29 (100%), while RT-PCR was positive in 8 (26.6%). 1 patient and 1 companion did not collect blood sample for serology. At the time of collection, only 1 patient reported flu-like symptoms.
Conclusions/Learning Points: A high prevalence of COVID-19 is demonstrated in the sample studied. The importance of using protective measures such as masks, social distancing and hand hygiene is emphasized, since 95% of cases of active infection were asymptomatic. This finding highlights the need to maintain surveillance and prevention protocols for COVID-19, especially in populations with greater vulnerability.

ADVERSE EFFECTS OF SARS-COV-2 VACCINE IN CHILDREN, IS IMMUNOSUPPRESSION OR COVID-19 INFECTION A FACTOR?

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Ángela Manzanares[1], Irati Gastesi[1], Álvaro Ballesteros[1], Sara Villanueva[1], David Aguilera-Alonso[2], Jaime De Inocencio[1], María Baro[1], Carlota Pinto[3], Ana Esteban Romero[4], María López Luengo[4], Pablo Gómez Roca[4], Cinta Moraleda[1], Alfredo Tagarro[4]
[1]Fundación para la Investigación Hospital 12 de Octubre, Hospital 12 De Octubre, Madrid, Spain, [2]Hospital Universitario, Gregorio Marañón, Madrid, Spain, [3]Universidad Europea de Madrid, Facultad De Medicina, Alcobendas, Spain, [4]Fundación para la Investigación Hospital Universitario Infanta Sofía y del Henares, Hospital Infanta Sofía, San Sebastián de los Reyes, Spain

Backgrounds: Our objectives are to describe the adverse effects of SARS-CoV-2 vaccines in children, and to compare children with and without COVID-19 infection, and healthy and immunosuppressed children.
Methods: Healthy and immunocompromised children aged 5-11 years (vaccination group 7) who had received at least 1 dose of Pfizer-BioNTech SARS-CoV-2 vaccine between December 2021-May 2022 were included. A 6-month telephone follow-up was conducted with a standardized questionnaire on adverse effects after each dose, and COVID-19 infections prior to and during vaccination.
Results: Forty-eight children were included, 28 (58.3%) healthy and 20 (41.6%) immunosuppressed. The mean age was 9.1 (7.5-10.6) years. 28 (58.3%) had adverse effects after the first dose, mostly local adverse effects (26/28; 92.8%), with a mean duration of 1 day. 40 (83.3%) received a second dose 2 (1.9-2.4) months later. 19 (47.5%) had adverse effects, mostly (15/19; 78.9%) local. 7 (14.8%) received a third dose 1.5 months later. None had adverse effects. 15/48 (31.2%) children had had a COVID-19 infection prior to vaccination, being more frequent in healthy than immunosuppressed children (p=0.046); 7/48 (14.6%) children had COVID-19 infection between the first and second dose. There were no significant differences in adverse effects between healthy and immunosuppressed children at the first (p=0.704) and second (p=0.162) doses. There were no significant differences in adverse effects in children who had COVID-19 prior to immunization (OR=0.34 [0.09;1.22]) or between the first two doses of vaccination (OR=0.81 [0.13;4.47]).
Conclusions/Learning Points: Adverse effects of the SARS-CoV-2 vaccine in children were frequent, local and of short duration. COVID-19 infection or immunosuppression did not influence the frequency or intensity of adverse effects.

PERSISTENCE OF SYMPTOMS ONE YEAR AFTER MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Cinta Moraleda[1], Sara Villanueva[2], Olga Aldecoa Jiménez[3], Blanca Díaz Fuentes[3], Luis Prieto[4], Daniel Blázquez[4], Cristina Epalza[1], Elisa Fernandez-Cooke[1], Ángela Manzanares[1], Pablo Rojo[4], Serena Villaverde[1], Álvaro Ballesteros[2], Sara Domínguez[2], Alfredo Tagarro[2]
[1]12 de Octubre University Hospital, Pediatric Infectious Diseases, Madrid, Spain, [2]Fundación para la Investigación Hospital 12 de Octubre, Hospital 12 De Octubre, Madrid, Spain, [3]Complutense University, Faculty Of Medicine, Madrid, Spain, [4]Hospital Universitario 12 de Octubre. Instituto de investigacion imas12. Universidad Complutense de Madrid. RITIP, Paediatric Infectious Diseases, Madrid, Spain

Backgrounds: Long term evolution of Multisystem Inflammatory Syndrome (MIS-C) is poorly understood. We described the frequency of persistent symptoms after one-year in a cohort of MIS-C patients.
Methods: Prospective observational study in under-18-aged patients diagnosed with MIS-C in October 2020-April 2021 in a tertiary hospital. Data from initial episode was obtained from the national database. A standardized phone questionnaire was done one year after the acute episode. As controls, patients with history of acute COVID-19 and with peritonitis, pared by age and sex, were included. Data was collected using REDCap and analysed with R. Ethics committee approval was obtained.
Results: 48 patients were included, 16 in each group. Characteristics at admission are shown in Table 1. MIS-C patients presented high frequently 94% (15/16) cardiological complications during hospitalization, in contrast with 19% (3/16) of acute COVID-19 patients and 25% (4/16) of peritonitis group ($p<0.01$). All of them resolved after a year except the ones associated to hypoxic ischemic encephalopathy in a patient with MIS-C. After one-year follow-up, 88% MIS-C patients suffered ≥1 symptoms, more frequently: headache (44%), fatigue (38%), insomnia (38%) and concentration problems (38%). A total of 56% of COVID-19 patients presented persisted symptoms, mainly fatigue and concentration problems (19%), and 31% in peritonitis group (19% loss of appetite and abdominal pain), ($p<0.001$). MIS-C patients visited more frequently medical professionals due to emotional change after the disease [4/16 (25%) in MIS-C vs. 0/16 (0%) in both control groups, p=
0.028].

Features		All N=48	MIS-C N=16	COVID-19 N=16	Peritonitis N=16	*p*

THE IMPACT OF THE COVID-19 PANDEMIC ON SELF-HARM REFERRALS IN CHILDREN AND ADOLESCENTS PRESENTING TO CAMHS EMERGENCY SERVICES IN SOUTH WEST LONDON

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Nighat Nadeem
South West London and St George's Mental Health NHS Trust, Child And Adolescent Mental Health, SW DJ, United Kingdom

Backgrounds: The COVID-19 pandemic has had a significant negative impact on child and adolescent mental health with direct consequences on child and adolescent mental health emergency care services (CECS). This study aimed to explore the impact of the COVID-19 pandemic on number and reasons for referral to the South West London CECS team. As the COVID-19 pandemic has placed additional strain on CAMHS emergency services, it is imperative that relevant data is analysed to inform ongoing CECS service development.
Methods: Data was extracted from electronic medical records of all young people who had been referred to the South West London CECS team over a 4 year period between 1.3.2018-1.3.2022. Data was analysed quantitatively using Strata 16 and SPSS programs.
Results: 4155 referrals were received by CECS between 1.3.2018-1.3.2022. 1901/4155 were referred because of self harm. There was an increase in self-harm referrals from 534 pre-pandemic to 1367 post-pandemic and self harm constituted a larger proportion of total referrals (29.3% pre-pandemic and 58.7% post-pandemic). All values were statistically significant, $p<0.05$. Both total and self-harm referrals were increasing monthly pre-pandemic (+1.05 and +2.50 respectively). CECS self harm referrals increased from +0.50 pre-pandemic to +0.84 post-pandemic. Immediately following the first lockdown (March 2020), there was a rise of +13.26 referrals for self harm which stabilized over 2 years.
Conclusions/Learning Points: The COVID-19 pandemic has had a negative impact on child and adolescent mental health with increased self harm presentations to CECS. This study provides data on the impact of the COVID-19 pandemic on referral patterns to CECS.

Hospital Universitario Virgen Del Rocío, Sevilla., Sevilla, Spain, [3]Hospital Universitario Virgen del Rocío, Servicio De Hematología Infantil., Sevilla, Spain, [4]Hospital Universitario Virgen del Rocío, Instituto De Biomedicina De Sevilla (ibis), Sevilla, Spain

Title of Case: NIRMATRELVIR/RITONAVIR USE IN PEDIATRIC PATIENTS WITH RISK OF PROGRESSION TO SEVERE DISEASE DUE TO SARS-COV-2
Background: The use of nirmatrelvir-ritonavir in adults with mild-moderate COVID-19 and risk factors of progression to severe disease (RF-SD), has demonstrated to reduce the risk of hospitalization and mortality. Data in children are limited. We present three children with leukemia / GATA2 deficiency and SARS-CoV-2 infection who received compassionate use of nirmatrelvir-ritonavir.
Case Presentation Summary: 6-year-old girl with acute lymphoblastic leukemia (ALL) developed mild COVID-19 (cough) on day +12 of chimeric antigen receptor T cell therapy. SARS-CoV-2 blood viral load (BVL): 2470 copies/ml She received nirmatrelvir-ritonavir (300mg/100mg/12h) for five days, with no adverse events and clerarance of viremia. 11-year-old girl with ALL and an allogeneic hematopoietic cell transplantation. On day +90 (receiving corticosteroids and JAK-kinase inhibitors for acute graft-versus-host disease), presented with mild SARS-CoV-2 infection (cough). BVL: 3730 copies/ml. A five-day course of nirmatrelvir-ritonavir was given with no side effects, symptom resolution and clearance of viremia. 10-year-old girl with acute myeloid leukemia in remission and GATA2 deficiency, with severe COVID-19 infection (bilateral pneumonia, hypoxia). She received corticosteroids, IL-1 inhibitors and remdesivir with poor evolution and persistence of high BVL (2790 copies/ml). Five-day course of nirmatrelvir-ritonavir resulted in viral clearance, however viremia rebound was observed after two weeks, requiring a second cycle with equal results. A second viremia rebound prompted compassionate maintenance use of nimatrelvir-ritonavir attempting viral suppression without success. Subsequently she sadly died due to pulmonary Nocardia and Aspergillus infections and multiple organ failure.
Learning Points/Discussion: Early use of nirmatrelvir-ritonavir was safe and effective achieving viral clearance and symptom resolution in our patients with COVID-19 and RF-SD. Rebound viremia was observed in one patient, who suffered from GATA2 deficiency plus immunosuppression.

E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Lieke Noij[1], Mirjam Van Den Brink[2,3], Caroline Brackel-Kosterink[1], Coen R. Lap[4], Giske Biesbroek[1,5], Marlies Van Houten[5], Anke-Hilse Maitland-Van Der Zee[6], Simone Hashimoto[1], Suzanne Terheggen[1]
[1]Emma Children's Hospital, Amsterdam Medical Centre, Department Of Paediatric Pulmonology And Allergy, Amsterdam, Netherlands, [2]Maastricht University, Laboratory Of Behavioural Gastronomy, Centre For Healthy Eating And Food Innovation, Venlo, Netherlands, [3]Prinses Maxima Center, Pediatric Oncology, Utrecht, Netherlands, [4]Spaarne Gasthuis, location Hoofddorp and Haarlem, Department Of Pediatrics, Hoofddorp, Netherlands, [5]Spaarne Gasthuis Hospital, Department Of Vaccines And Immunology, Hoofddorp, Netherlands, [6]Amsterdam University Medical Center, location AMC, Department Of Respiratory Medicine, Amsterdam, Netherlands

Backgrounds: Introduction. The SARS-CoV-2 virus is known to cause olfactory dysfunction in the acute phase and long-term [Rao et al. JAMA Pediatr. 2022], but quantification of loss of smell in children is lacking. Therefore, our aim was to assess long-term olfactory dysfunction in children with post-COVID syndrome as defined by the WHO guidelines. Hypothesis. A validated, objective tool has added value in screening and quantification of olfactory dysfunction in children with post-COVID syndrome.
Methods: . Participants were children (6-18 years) with diagnosed post-COVID condition, seen at the Amsterdam UMC hospital >3 months after infection. Long-term olfactory dysfunction was assessed in two ways: 1) by the U-Sniff test, and 2) by self-reported loss of smell. The U-Sniff test is validated and standardized, with high sensitivity and specificity, measuring the odor identification ability in children [Schriever et al. J Pediatr. 2018]. Outcome scores range from 0 to 12, cut-off values are age-dependent.
Results: Results. From 94 children included, 21% had abnormal U-Sniff scores at 15.7 (±7.0) months after infection. Children with abnormal scores were older and more frequently had self-reported loss of smell (table 1). However, the test also suggests olfactory dysfunction in 10 (17%) children with no self-reported loss of smell.
Conclusions/Learning Points: Conclusion. Long-term olfactory dysfunction is a frequent condition in children with post-COVID syndrome. Screening through a validated test suggests a higher impairment than through patient self-reported complaints, which can play a role in further clinical evaluation.

[1]National and Kapodistrian University of Athens, First Department Of Pediatrics, Division Of Infectious Diseases, Athens, Greece, [2]Aghia Sophia Children's Hospital, Department Of Microbiology, Athens, Greece

Title of Case: RESPIRATORY SYNCYTIAL VIRUS AND SARS-COV-2 COINFECTION IN HOSPITALIZED PEDIATRIC PATIENTS: CASE SERIES
Background: While SARS-CoV-2 continue to circulate in Greek population, the 2022–23 RSV season shows an early rise in pediatric RSV-associated hospitalization. Although both RSV and SARS-CoV-2 can contribute to substantial pediatric morbidity, whether coinfection increases disease severity compared with that associated with infection with one virus alone is unknown.
Case Presentation Summary: We report a case series of 12 pediatric hospitalized patients with RSV/SARS-CoV-2 coinfection from March 2020 to December 2022. RSV/SARS-CoV-2 coinfection was detected through FilmArray Respiratory Panel, PCR assays or rapid antigen testing. Half of the patients had high viral load for SARS-CoV-2 (Ct <20). Patients' age ranged from 1.5 months to 13.5 years old and 7 (58%) were males. Patients presented with silent hypoxia (n=2), tachypnea (n=6), cough (n=11), rhinorrhea (n=5), feeding difficulties (n=6) and fever (n=8). Pulmonary disease was reported as underlying medical condition in 2 patients. Ten (83%) patients received oxygen supplementation from 3 to 9 days. Management included nebulized treatment with budesonide (n=6), salbutamol (n=10) and intravenous corticosteroids (n=6). Two patients received antiviral treatment with remdesivir. A 3- month-old infant required intensive care unit (ICU) admission. Chest x-ray revealed diffuse interstitial infiltration in all of them. Hospitalization lasted from 4 to 10 days.
Learning Points/Discussion: According to our recent experience, patients with RSV/SARS-CoV-2 coinfection had high oxygen requirements indicating potentially more severe disease. Further studies are needed to better understand the interplay between SARS-CoV-2 and RSV and the mechanisms associated with disease severity.

COVID-19 IN HOSPITALIZED INFANTS LESS THAN 90 DAYS OLD; THREE YEARS' EXPERIENCE

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Maria Noni[1], Maria Stavropoulou[1], Paraskevi Farmaki[1], Maroula Tritzali[1], Efrossini Briassouli[1], Maria Eleni Liagkaki[1], Ifigeneia Matara[1], Eleni Karapati[1], Vana Spoulou[2], Athanasios Michos[1]
[1]National and Kapodistrian University of Athens, First Department Of Pediatrics, Division Of Infectious Diseases, Athens, Greece, [2]Aghia Sophia Children's Hospital, First Department Of Pediatrics - University Of Athens, Athens, Greece

Backgrounds: Although children are generally mildly affected from SARS-CoV-2, a higher risk for progression to severe COVID-19 has been reported in infants and children with underlying medical conditions. Data on age-related poor prognosis and especially on very young age are still debated. The aim of our study was to present our experience on COVID-19 in infants less than 90 days old.
Methods: A retrospective study was performed on infants less than 90 days old hospitalized with COVID-19 in the largest tertiary Children's Hospital in Greece during March 2020-December 2022. Confirmed cases were defined through nasopharyngeal swabs tested positive for SARS-CoV-2 RT-PCR. Demographic, clinical, laboratory and radiological data were also collected.
Results: Three hundred twenty-nine infants were enrolled in our study. Mean age was 49 days (range 3-89) and 56.8% were males. Only 29.7 % of the mothers were vaccinated against SARS-CoV-2. Most frequent symptoms were fever (84.8%), cough (20.9%), gastrointestinal complications (8.8%) and feeding difficulties (33.4%). Fifty-one (15.5%) infants presented with neutropenia and 239 (72.6%) with monocytosis. Chest x-ray was performed in 67.5% infants and only 18.8% of them had normal findings. Sixty-six infants (20%) received antibiotic treatment. However, only 28.7% of them had a confirmed coinfection including bacteremia, urinary tract infection, acute otitis media, cutaneous infection and perianal abscess. Three infants had a SARS-CoV-2/RSV coinfection and 1 experienced aSARS-CoV-2/rhinovirus/enterovirus coinfection. Two premature infants experienced severe respiratory disease and treatment with remdesivir was initiated. One infant was administered to ICU and died after prolonged hospitalization. The vast majority (267 infants; 81.2%) was hospitalized for less than 4 days.
Conclusions/Learning Points: Infants aged less than 90 days old with COVID-19 usually present with mild symptoms. However, a possible coinfection needs to be evaluated and excluded, accordingly.

ASSESSMENT OF PEDIATRIC CANCER PATIENTS WITH COVID 19 INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Yasemin Ersözlü[1], Cengiz Canpolat[2], Metehan Ozen[3]
[1]Acibadem University, Department Of Pediatric Infectious Diseases, istannbul, Turkey, [2]Acibadem University, Pediatric Hematology Oncology, istanbul, Turkey, [3]Acibadem University, Department Of Pediatric Infectious Diseases, İstanbul, Turkey

Background: Coronavirus Disease 2019 (COVID-19) still remains a health problem by the SARS-CoV-2 virus, which causes significant mortality and morbidity in risk groups. While the symptoms are severe in the elderly with co-morbidities, children usually survive milder. Malignant patients are voicing their concerns about COVID-19 as they are immunosuppressed by both the underlying disease and the treatments they receive(1).
Methods: During the follow-up of the Pediatric Hematology Oncology Unit, patients with positive SARS CoV-2 PCR test until January 2023 were screened prospectively
Results: Twenty-eight patients with SARS-CoV-2 PCR positive were included in the study. 3 patients had recurrent COVID-19; 1 patient was re-infected twice and 2 patients became infected three times. A total of 33 incidents were detected. The patients did not require mechanical ventilation and intensive care follow-up.
Conclusions/Learning Points: While the COVID 19 pandemic has spread rapidly all over the world, publications and information for pediatric patients have been relatively limited. It has been reported that the prevalence of COVID-19 infection in adult cancer patients (1%) is higher than that of the general population (0.29%). While the prevalence is 0.8% in general pediatric patients, it is estimated to be 1.3% in pediatric cancer patients (2). When the clinical features of pediatric cancer patients followed up in our center for COVID-19 were examined, the disease was found to be less common in boys (39.4), since the reinfected patients were mostly girls. Similarly, the most common accompanying cancer was found to be leukemia (42.3%). No patient required respiratory support. There was no death due to COVID 19 but three patients died due to complications related to their primary diseases.

HEALTH SURVEILLANCE: THE SARS-COV-2 INFECTION AND VACCINATION COVERAGE IN THE SCHOOLS OF MODENA PROVINCE, ITALY.

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Stefania Paduano[1], Lucia Borsari[2], Maria Chiara Facchini[1], Alessandra D'Alterio[1], Laura Iacuzio[2], Antonella Greco[2], Elisabetta Fioretti[2], Giacomo Creola[2], Giovanni Casaletti[2], Annalisa Bargellini[1], Tommaso Filippini[1]
[1]University of Modena and Reggio Emilia, Department Of Biomedical, Metabolic And Neural Sciences - Section Of Public Health, Modena, Italy, [2]Local Authority of Modena, Department Of Public Health - Public Hygiene Service, Modena, Italy

Backgrounds: In Italy, the COVID-19 pandemic has caused over 4.8 million cases in individuals aged 0-19 years. The role of the school reopening on the spread of SARS-CoV-2 infection is still under investigation. The aim of our study was to assess the influence of vaccination coverage against SARS-CoV-2 on the reduction the virus spread in the schools of Modena province.
Methods: We performed a retrospective cohort study in the period 1 September-15 December 2021, involving students aged 0-19 years and teachers, screened for SARS-CoV-2 infection by nasopharyngeal swab following the detection of an index case within their classroom.
Results: A total of 12534 students and 1400 teachers were tested. We identified 1373 cases (594 index cases and 779 secondary cases) from 594 different classes: 9.8% (1225 cases) of students tested and 10.6% (148 cases) of teachers. Regarding vaccination coverage, 32.7% (4562) of entire population was vaccinated with at least one dose of the anti-SARS-CoV-2 vaccine at the test time. In detail, 64.9% of teachers and 29.2% of students were vaccinated. Among secondary cases only 7.7% (60 out of 779) was vaccinated compared to 35.1% (4408) among negative tested subjects. The highest ratio of secondary cases on index cases rate (2.19) was found among students attended primary school, while the lowest values were among subjects attended high school (0.40) and nursery school (0.37).
Conclusions/Learning Points: Our results highlight the differential spread of SARS-CoV-2 among different age groups and show that the vaccination may have mitigated virus diffusion in high and middle schools, as it was available only for the population aged≥12 in the study period. Of note, in infant and nursery schools the low virus spread could have been mitigated by small classes.

PV1009 / #2642

IMPACT OF THE COVID19 PANDEMIC IN PAEDIATRIC EMERGENCY VISITS OF A SMALL PRIVATE HOSPITAL: WHERE ARE THE CHILDREN AND THE RESPIRATORY INFECTIONS?

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Ana Rosalina Partidas, Inés Hernandez Salvador, David Rivera, Raquel Fernandez
Hospital Quironsalud Erandio, Pediatrics, Erandio, Spain

Background: Respiratory tract infections (RTI) are a major cause of morbidity and mortality in children. Most of the episodes occur during the winter, where influenza and respiratory syncytial virus (RSV) cause a rise in paediatric emergency department (ED) visits. However, since the beginning of the COVID19 pandemic, several countries have reported a decrease in ED visits, specially RTIs.
Methods: This is a retrospective study including all the ED visits in children 0 to 14 years old, during the months of October 2019-March 2021 (P1) and October 2020 and March 2021 (P2). The data was classified into 7 groups according to the main complaint at admission. The respiratory symptoms group was further analysed for age, sex, and diagnosis. Results were analysed via Chi-square and Fisher exact test using Sigma Plot v.11 for windows.
Results: An overall reduction of 38% was seen in the total number of ED visits of both study periods (7103 vs 4837). A statistically significant decrease from 30.33% to 19.14% (P <0.001) in the respiratory symptom group was described, whereas the trauma group showed an increase of 8.4% (P <0.001) and urinary tract complaints remained unchanged. Subgroup analysis showed a rise in URTI (47.3% vs 49.6%). In contrast, bronchiolitis, pneumonia, AOM and flu/flu-like episodes dropped.

	Respiratory	Trauma	Fever	Gastrointestinal	Skin	Urinary tract	Other
P1	30.4	27.1	13.4	9.5	6	1.7	11
P2	19.1	35.4	11.1	12.2	4.3	2.6	15.3

Fig 1. Percentage of ED visits according to main complaint in both periods, showing a reduction in respiratory complaints, increase in trauma and almost no change in urinary tract symptoms (P <0.001).

Conclusions/Learning Points: An overall reduction of 38% in ED visits was described with a major impact on episodes of RTIs, but not in other infections such as urinary tract infections or trauma. This may imply that the measures set in place due to the COVID19 pandemic, may not be the only cause for the change in the seasonality of winter viruses and supports the possibility that other causes may play a role.

PV1010 / #1247

PREDICTORS OF SARS-COV-2 SEROPOSITIVITY PRIOR TO VACCINE ELIGIBILITY AMONG CANADIAN CHILDREN AGED 1–11 YEARS AT A PEDIATRIC TERTIARY REFERRAL HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Dara Petel[1], Mohsin Ali[2], James Wright[3], Aaron Campigotto[4], Michelle Science[5], Shelly Bolotin[3,6]
[1]The Hospital for Sick Children, Infectious Diseases, Toronto, Canada, [2]Hospital for Sick Children, Infectious Diseases, Paediatrics, Toronto, Canada, [3]Public Health Ontario, Epidemiology, Toronto, Canada, [4]Hospital for Sick Children, Division Of Microbiology, Toronto, Canada, [5]The Hospital for Sick Children, Paediatrics, Division Of Infectious Diseases, Toronto, Canada, [6]Dalla Lana School of Public Health, Public Health, Toronto, Canada

Backgrounds: Pre-vaccine seroprevalence studies of SARS-CoV-2 may help identify groups at particular risk of infection. In this study, we sought to estimate SARS-CoV-2 seroprevalence among children prior to vaccination eligibility, and to analyze demographic and clinical predictors of seropositivity.
Methods: We used a convenience sample of residual sera at The Hospital for Sick Children from October–November 2021. Patient characteristics were reviewed retrospectively from electronic medical records. Infants and patients who received plasma or intravenous immunoglobulin were excluded. Anti-spike IgG were detected using EUROIMMUN Anti-SARS-CoV-2 ELISA. Exact 95% confidence intervals were calculated around seroprevalence estimates, and seropositivity predictors modelled using logistic regression.
Results: Of 324 patients, 301 were eligible, including 118 (39.2%) inpatients, 58 (19.3%) outpatients, 76 (25.2%) emergency room patients, and 49 (16.3%) referred by community providers for laboratory testing. Median age was 4 (IQR, 2–7) years; 163 (54.2%) were male. 188 (62.5%) had a chronic medical condition, and 42 (14.0%) were immunocompromised. Overall seroprevalence was 22.3% (95% CI, 17.7–27.4%); only 6 (9%) had documented prior SARS-CoV-2 infection. In univariable analyses, seroprevalence was higher among males (27.0%; 95% CI, 20.3–34.5%), inpatients (29.7%; 95% CI, 21.6–38.8%), immunocompromised patients (40.5%; 95% CI, 25.6–56.7%), and patients with documented prior SARS-CoV-2 infection (83.3%; 95% CI, 35.9–99.6%); all predictors remained statistically significant in multivariable logistic regression.
Conclusions/Learning Points: In this hospital-based sample prior to vaccine eligibility and the Omicron wave, almost one in four children aged 1–11 years had evidence of prior SARS-CoV-2 infection. This higher-than-expected seropositivity may reflect children's susceptibility to subclinical infections. Higher risk, in particular among immunocompromised inpatients, may hold relevance for clinical and public health measures for the current and future pandemics.

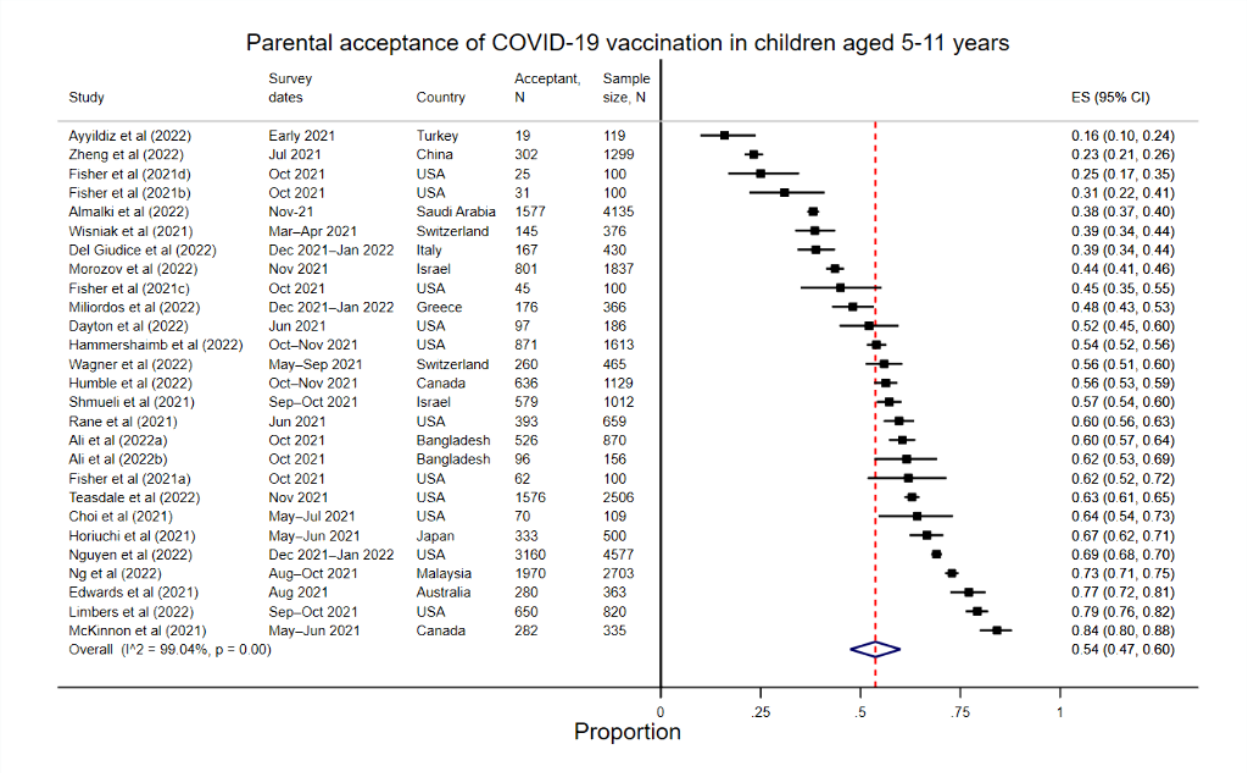
COVID-19 VACCINES ACCEPTANCE IN CAREGIVERS OF 5-11-YEAR-OLD CHILDREN: A SYSTEMATIC REVIEW AND META-ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Costanza Di Chiara[1], Caitlyn Hui[2], Pierre-Philippe Piche-Renaud[2], Joelle Peresin[1], Elahe Karimi-Shahrbabak[1], Ciobha Okelly[2], Andrea Macikunas[2], Tingting Yan[3], Lauren Tailor[1], Daniel Farrar[1], Shaun Morris[4]
[1]Hospital for Sick Children, Centre For Global Child Health And Child Health Evaluative Sciences, Toronto, Canada, [2]Hospital for Sick Children, Division Of Infectious Diseases, Toronto, Canada, [3]University of Toronto, Temerty School Of Medicine, Toronto, Canada, [4]Dalla Lana School of Public Health, Division Of Clinical Public Health And Centre For Vaccine Preventable Diseases, Toronto, Canada

Backgrounds: COVID-19, COVID-19 vaccine hesitancy (VH) among caregivers of children aged 5 to 11 has contributed to low uptake in this group. This study aimed to assess the acceptance of COVID-19 vaccines and identify determinants of vaccine willingness and hesitancy among caregivers of children aged 5-11 years.
Methods: A systematic review of Medline, Embase, Cochrane, and CINAHL was performed to identify relevant studies published between October 29, 2021, and September 12, 2022. A random-effects meta-analysis and a qualitative analysis of the primary and secondary outcomes were conducted respectively.
Results: A total of 1571 records were identified for full-text screening, of which 30 were included. Twenty-four studies were conducted in high-income countries, three in upper-middle-income countries, and three in low- to middle-income countries. The pooled effects size for caregivers' vaccine acceptance was s 54% (95% CI 47–60%), with considerable between-study heterogeneity (I^2 of 99.04%). The most frequent reasons for vaccination willingness identified in the studies included caregivers' SARS-CoV-2 vaccination coverage (27%), collective responsibility (27%), perceived risk of COVID-19 in children (23%), having older children already vaccinated (17%), return to normal life (17%), higher parental education (17%), and having received flu vaccine (17%). Common reasons for VH consisted of vaccine safety/efficacy concerns (77%), misconceptions about childhood COVID-19 severity (43.3%), and low knowledge about vaccine approval processes
(33%).



Conclusions/Learning Points: Our findings showed a low proportion of caregivers being acceptant of the SARS-CoV-2 vaccine for their children aged 5-11 years. Since vaccine safety/efficacy concerns and misperception about children's susceptibility to severe disease were the common drivers of VH, studies documenting the safety and benefits of vaccination in children will potentially strengthen vaccine confidence and uptake in this age group.

Backgrounds: While serious adverse events following immunization (AEFI) following COVID-19 vaccines remain rare, cases of post-vaccination myocarditis and pericarditis have now been well described. This study reports on cases of cardiac AEFI assessed in the Special Immunization Clinic (SIC) Network in Canada. The study objective was to describe clinical characteristics of patients with cardiac AEFI and their outcomes following revaccination.
Methods: Ten SIC sites accepted referrals for children and adults with suspected cardiac AEFI following COVID-19 vaccination. Cases were classified as per the Brighton Collaboration Case Definition for mutually exclusive diagnoses of myocarditis, myopericarditis or pericarditis. Patients who experienced chest pain but had a normal cardiac workup (troponins, ECG and/or echocardiogram) and no alternate diagnosis were categorized as having nonspecific chest pain. Recommendations for revaccination were based on SIC physician judgment, informed by national guidelines. After patient or parental consent, de-identified data were transferred to a central database for analysis.
Results: Between April 1, 2021 and July 11, 2022, 94 participants with cardiac AEFI were enrolled and included in the analysis (see Table). Seventy-six (80.9%) had myocarditis/myopericarditis, 10 (10.6%) pericarditis and 8 (8.5%) nonspecific chest pain. Most cases occurred after mRNA vaccination (n=92, 97.9%). Thirty-nine (41.5%) required hospitalization and two (2.1%) required intensive care unit admission. Following SIC assessment, 16 patients (17.0%) were revaccinated and had at least one follow-up appointment. There were two recurrences (12.5%) of cardiac AEFI after revaccination; one pericarditis (milder severity, no hospitalization required) and one myocarditis (same severity,

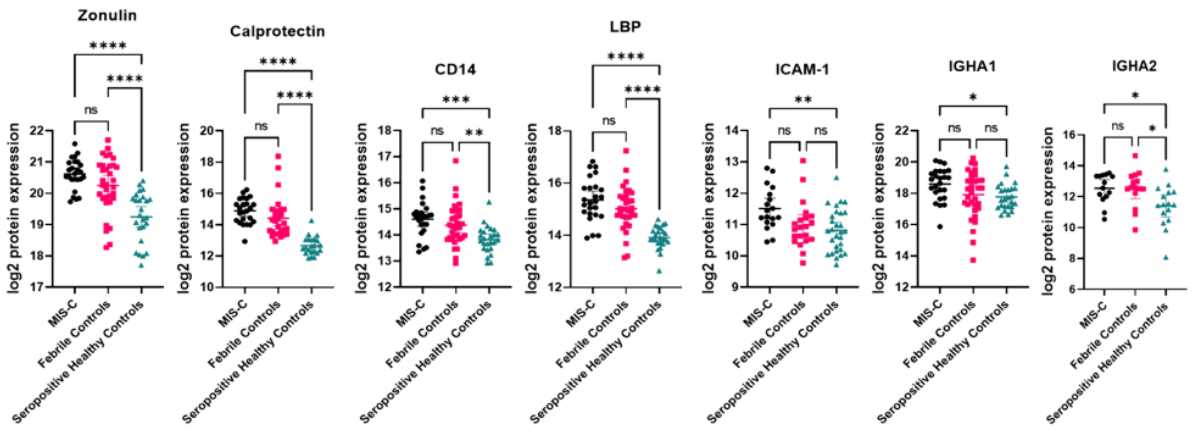
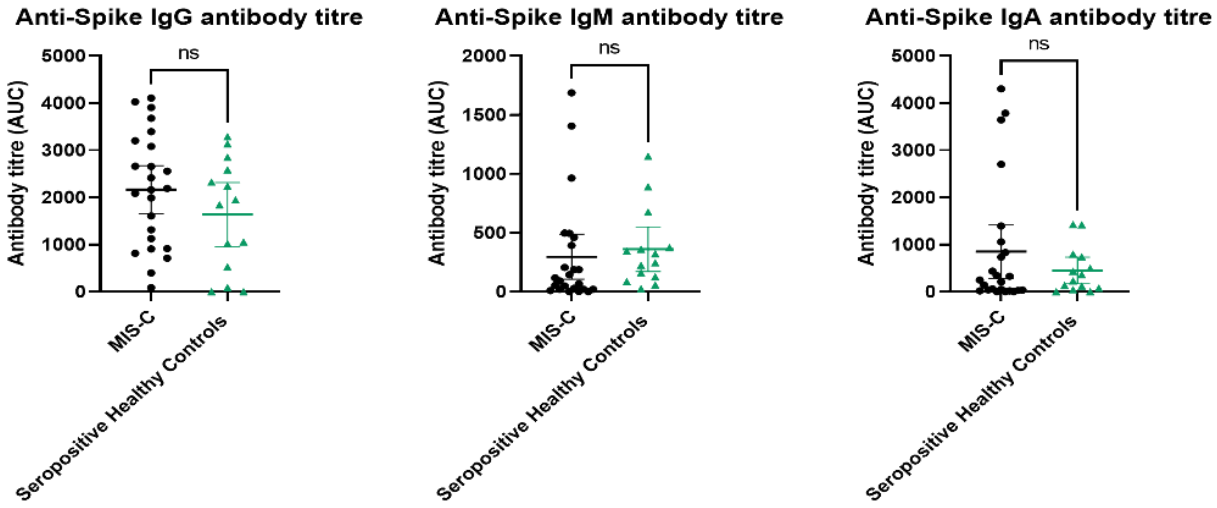
MIS-C AND LEAKY GUT: INVESTIGATION OF MARKERS OF INTESTINAL PERMEABILITY AND PERSISTENT ANTIGENAEMIA IN A UK MIS-C COHORT.

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Cathal Roarty, Claire Tonry, Clare Mills, Chris Watson, Thomas Waterfield
Queen's University Belfast, Wwiem, Belfast, United Kingdom

Backgrounds: It has been suggested that MIS-C development is driven by increased permeability of the intestinal epithelium leading to SARS-CoV-2 viral proteins leaking into the bloodstream. We investigated evidence for this hypothesis in a cohort of UK MIS-C patients.
Methods: We utilised LC-MS to measure the levels of proteins associated with intestinal permeability in the plasma of 25 children with MIS-C and age and gender matched controls, both febrile (34) and healthy SARS-CoV-2 seropositive (25). We further quantified the spike protein antibody titres in MIS-C and healthy controls who were previously infected with SARS-CoV-2 within a similar timeframe.
Results:





Levels of Zonulin, lipopolysaccharide binding protein(LBP) and other proteins associated with increased gut permeability were all significantly increased in MIS-C compared to seropositive healthy controls ($p<0.0001$). However, there was no significant difference between levels of any of these proteins between MIS-C and febrile controls($p>0.05$). We found no significant difference in the titres of either IgG, IgM or IgA to the RBD portion of spike protein between the MIS-C cohort and seropositive healthy controls. Further, there was no correlation between levels of any of the proteins associated with increased intestinal permeability and any of the antibody subclass titres in MIS-C.

Conclusions/Learning Points: There is evidence of increased circulating markers of intestinal permeability in MIS-C relative to healthy controls , however we found no difference in markers of intestinal permeability between our MIS-C and febrile cohorts. This suggests that an increase in gut permeability in MIS-C is not unique to this condition and occurs in other unwell children. We found no evidence of a humoral response to persistent viral antigenaemia in our MIS-C cohort, with antibody titres similar to that of seropositive healthy controls.

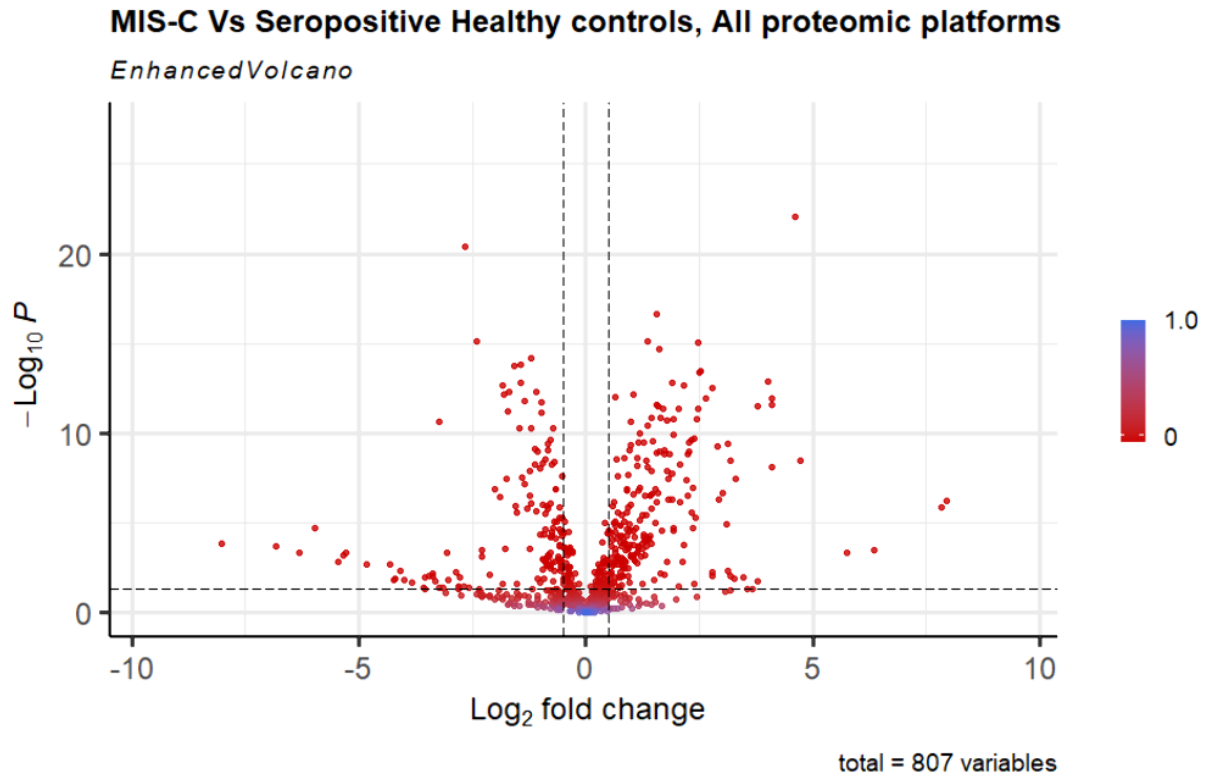
PV1014 / #402

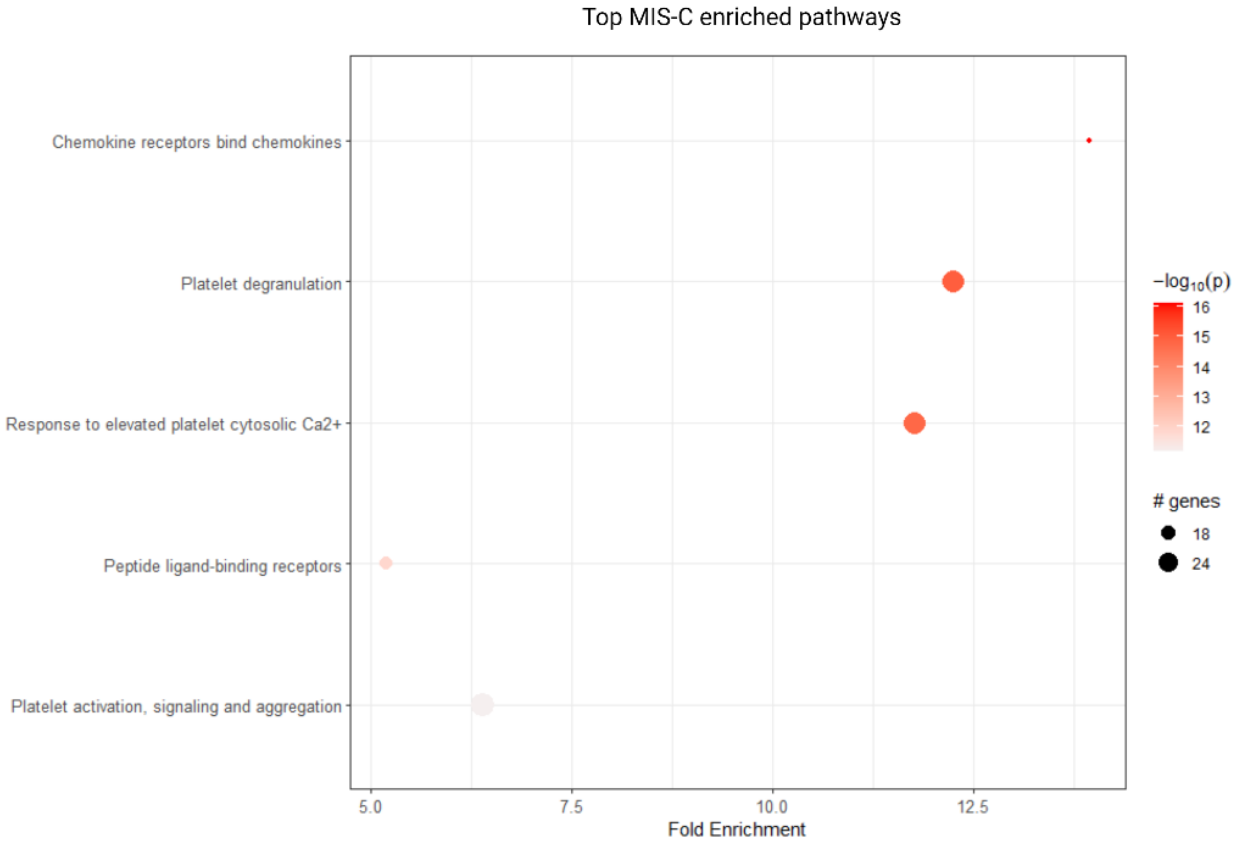
PROTEOMIC CHANGES IN PAEDIATRIC SARS-COV-2 INFECTION AND IN MIS-C

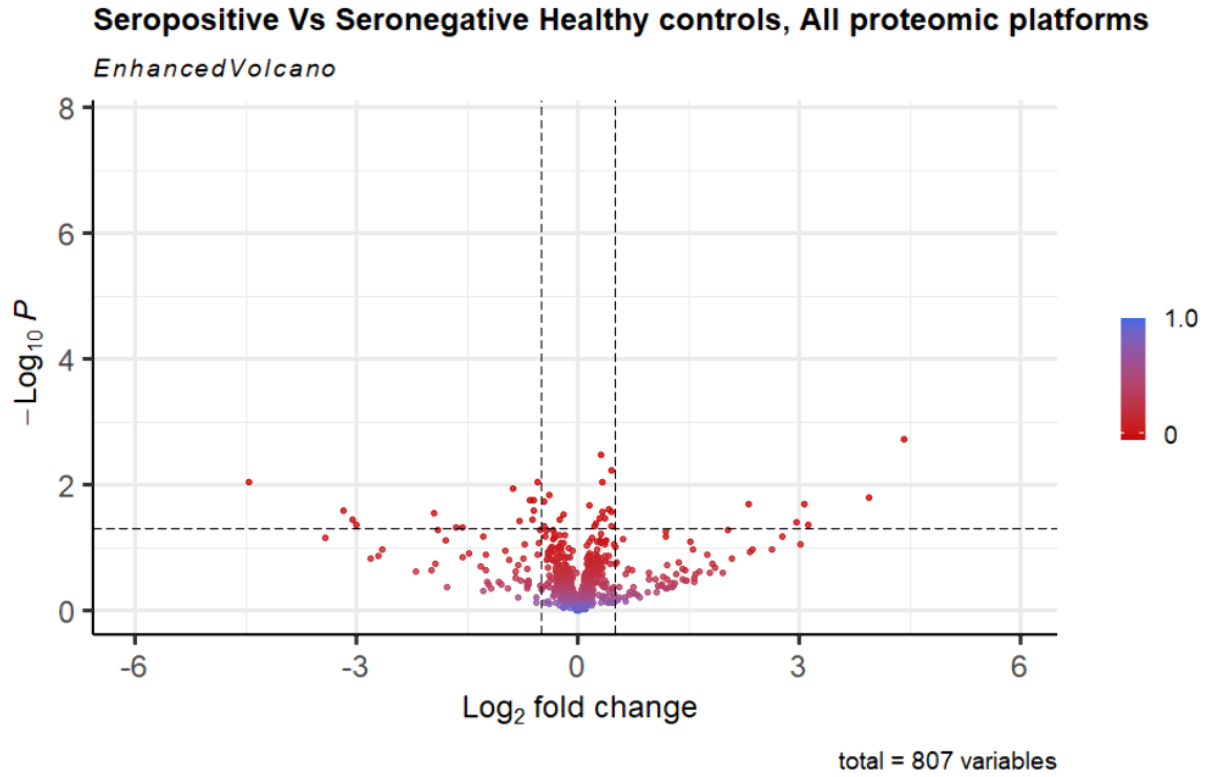
E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Cathal Roarty, Claire Tonry, Thomas Waterfield, Chris Watson
Queen's University Belfast, Wwiem, Belfast, United Kingdom

Backgrounds: Most children infected with SARS-CoV-2 experience mild symptoms , however a small proportion develop Multisystem Inflammatory Syndrome in Children (MIS-C) several weeks after SARS-CoV-2 infection. It's unkown if there are major changes in the proteome of healthy children who have recovered from mild or asymptomatic SARS-CoV-2 infection, and whether there are similarities between the proteome of MIS-C and this group.
Methods: We prospectively recruited a cohort of children hospitalised due to COVID-19 related illness, including MIS-C(n=25). Age and sex matched children (n=25) with both a seronegative and later seropositive result for SARS-CoV-2 antibodies were used as healthy controls. LC-MS was used to analyse the proteome of these groups and identify differences.The results from LC-MS were used to perform pathway enrichment analysis to identify biological pathways potentially driving disease.
Results:







There was a clear difference in the circulating proteome of MIS-C and that of seropositive children with

441 differentially expressed proteins (fdr <0.05). Likewise, there was a number of differentially expressed proteins between seropositive and seronegative children. There was 140 enriched pathways in MIS-C, with the top 5 enriched pathways differing from those enriched in the seropositive group.
Conclusions/Learning Points: The circulating proteome of children with MIS-C differs from that of children who have previously been infected with SARS-CoV-2, and this reflects an underlying difference in pathways activated. We have identified pathways enriched in MIS-C which correspond with the hyperinflammatory clinical presentation of the syndrome. Further investigation of the pathways unique to MIS-C may lead to greater insights into the disease pathogenesis.

[1]Riga Stradins University, Department Of Continuing Education, Paediatrics, Riga, Latvia, [2]Riga Stradins University, Department Of Public Health And Epidemiology, Riga, Latvia, [3]Riga Stradins University, Department Of Paediatrics, Riga, Latvia, [4]Riga Stradins University, Faculty Of Medicine, Riga, Latvia

Background: Multisystem inflammatory syndrome in children (MIS-c) is a potentially life-threatening condition, which emerged during the COVID-19 pandemic and is temporally associated with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). While data about the acute conditions' epidemiology, clinical manifestations, and treatment pathways have been studied, the short and long-term impact of MIS-c on children's health is unknown.
Methods: Prospective longitudinal cohort study. Children under age of 18 years, fulfilling the Centers for Disease Prevention and Control (CDC) diagnostic criteria for MIS-c, and admitted to Children's Clinical University Hospital of Latvia (CCUH), between July 1, 2020, and April 15, 2022, were enrolled. All patients were evaluated at various time points: 2 weeks, 2 months (1-3 months), and 6 months (5-7 months) after MIS-c diagnosis.
Results: 21 patients with confirmed MIS-c were included. In acute phase all children had multi-organ involvement, including muco-cutaneious, gastrointestinal, cardiovascular, and neurological symptoms. At two-week follow-up half of children (N=10, 47.6%) reported exercise intolerance with provoked tiredness after exercise. In laboratory tests increase in blood cell count was observed, with a near doubling of leukocyte and neutrophil counts, and tripling of thrombocytes. Considerable decline in inflammatory and organ-specific markers was seen. The cardiological examination showed significant improvement with gradual resolution of acute phase pathological findings. Within two-month time improvement in exercise capacity was observed with five-fold reduction in physical intolerance (N=2, 9.5%) and two-fold reduction in physical activity induced fatigue (N=5, 23.8%). Normalisation of all blood cell lines was seen, and cardiological examination showed no persistent changes. At 6 months visit further improvement in children's exercise capacity was seen, laboratory and cardiological testing showed no pathological changes.
Conclusions/Learning Points: Abnormal clinical and laboratory findings were seen in patients 2 weeks after MIS-C with significant improvement in following weeks.

Backgrounds: COVID-19 in children is often asymptomatic or paucisymtomatic compared to the adults, however long term consequences such as Long Covid (LC) may occur. Reports about LC in children are conflicting regarding its prevalence, duration. We describe a cohort of children affected by LC evaluated in a hospital setting focusing on clinical presentation, cardiopulmonary function and immunology screening.
Methods: From October 2021 and November 2022 children with confirmed previous COVID-19 were evaluated in a dedicated LC Day Hospital. Inflammatory markers, immunological tests and SARS-CoV-2 serology were assessed. The cardiopulmonary evaluation for each patient was based on electrocardiogram (ECG), spirometry, and lung ultrasound.
Results: Of 273 children, almost 30% did not meet the criteria for LC. The clinical evaluation was performed after a median of 93 days after COVID-19 (IQR 68, range 7 – 324). The 50.3% with criteria for LC had comorbidities: allergy and/or asthma (24.1%), NPI disorder (11.3%), obesity (4.6%), headache (4.6%). The most frequent symptoms were: fatigue (48.2%), cough (25.1%), headache (20.0%), dyspnea (9.2%) mainly after excercise (66.7%), myalgia (7.2%), sleep disturbances (6.2%). Comparing LC with the non-LC, the significant differences were that former were older, more symptomatic during COVID-19 but less admitted to hospital (Table 1). A greater number of non-LC patients were competitive sports children. No difference for SARS-CoV-2 Ab were found. Cardiopulmonary evaluation was not significantly different between the two
subgroups.

Table 1. Characteristics of the study sample	
Total	273
Long Covid	195 (71.4)
Age (years) – mean (SD, range)	8.8 (4.6, 0.3 – 17.7)
Sex (male) – no. (%)	142 (52.4)
Caucasian ethnicity – no. (%)	262 (96.0)
Comorbidities – no. (%)	132 (48.4)
- Allergy and/or asthma	61 (22.3)
- NPI disorder	28 (10.3)
- Obesity	10 (3.7)
- Headache	9 (3.3)
Sport – no. (%)	143 (52.4)
- Competitive sport	16 (5.9)
Symptoms – no. (%)	
- Fatigue	94 (34.4)
after exercise	8 (8.5)
- Cough	51 (18.7)
- Headache	40 (14.7)
- Dyspnea	19 (7.0)
after exercise	13 (68.4)
- Myalgia	14 (5.1)
- Sleep disturbances	12 (4.4)
- Chest pain	11 (4.0)
- Fever	11 (4.0)
- Impaired concentration	11 (4.0)
- Arthralgia	10 (3.7)
New symptoms after negative test – no. (%)	125 (45.8)
Persistence of symptoms after negative test – no. (%)	95 (34.8)
SARS-CoV-2 vaccination – no. (%)	58 (21.2)
White blood cells (cells/mcl) – mean (SD, range)	6798 (2157, 2760 – 17149)
Neutrophils (cells/mcl) – mean (SD, range)	3150 (1353, 350 – 9020)
Lymphocytes (cells/mcl) – mean (SD, range)	2792 (1283, 340 – 9370)
Hemoglobin (g/dl) – mean (SD, range)	13.3 (1.0, 10.5 – 17.9)
Platelets (10*3 cells/mcl) – mean (SD, range)	298 (849, 138 – 671)
LDH (U/L) – mean (SD, range)	225 (50, 13 – 433)
ALT (U/L) – median (IQR, range)	14 (6, 3 – 163)
AST (U/L) – median (IQR, range)	24 (9, 6 – 81)
Creatinine (mg/dl) – mean (SD, range)	0.5 (0.2, 0.2 – 1.0)
Azotemia (mg/dl) – mean (SD, range)	13 (3, 4 – 23)
CPK (U/L) – median (IQR, range)	108 (57, 32 – 67)
CRP (mg/dl) – median (IQR, range)	0.03 (0.1, 0.03 – 6.4)
hsTnT (pg/ml) – median (IQR, range)	3 (1, 3 – 40)
NT-proBNP (pg/ml) – median (IQR, range)	49 (62, 5 – 273)
Ferritin (ng/ml) – median (IQR, range)	30 (21, 6 – 283)
Positive anti-N antibodies – no. (%)	264 (96.7)
Anti-S antibodies (BAU/mL) – median (IQR, range)	196 (980, 0.8 – 5000)
Pathological findings	12 (4.4)
Electrocardiogram – no. (%)	6 (2.2)
Spirometry – no. (%)	112 (41.0)
Lung ultrasound – no. (%)	

Table 2. Comparison of LC and not LC patients			
	LC	non-LC	p-value
Total	195	78	
Age (years) – mean (SD, range)	9.2 (4.4, 0.5 – 17.7)	7.6 (4.8, 0.3 – 17.5)	0.008
Sex (male) – no. (%)	104 (53.3)	39 (50.0)	0.618
Caucasian ethnicity – no. (%)	188 (96.4)	74 (94.9)	0.559
Comorbidities – no. (%)	98 (50.3)	34 (43.6)	0.319
- Allergy and/or asthma	47 (24.1)	14 (17.9)	0.270
- NPI disorder	22 (11.3)	6 (7.7)	0.377
- Obesity	9 (4.6)	1 (1.3)	0.185
- Headache	8 (4.6)	1 (1.3)	0.238
Sport – no. (%)	106 (54.4)	37 (47.4)	0.771
- Competitive sport	10 (9.4)	6 (16.2)	0.001
Symptomatic at 1° swab – no. (%)	188 (96.4)	67 (85.9)	<0.001
Admission – no. (%)	4 (2.1)	8 (10.3)	0.003
SARS-CoV-2 vaccination – no. (%)	51 (26.2)	7 (9.0)	0.020
White blood cells (cells/mcl) – mean (SD, range)	6774 (2113, 2760 – 15190)	6859 (2279, 2900 – 17140)	0.773
Neutrophils (cells/mcl) – mean (SD, range)	3212 (1369, 1240 – 9020)	2993 (1325, 350 – 7800)	0.232
Lymphocytes (cells/mcl) – mean (SD, range)	2697 (1170, 840 – 9370)	3034 (1512, 1120 – 8800)	0.051
Hemoglobin (g/dl) – mean (SD, range)	13.3 (0.9, 10.5 – 16.1)	13.3 (1.3, 10.6 – 17.9)	0.707
Platelets (10*3 cells/mcl) – mean (SD, range)	295 (281, 142 – 671)	305 (91.7, 138 – 594)	0.396
LDH (U/L) – mean (SD, range)	220 (49, 13 – 433)	239 (51, 107 – 429)	0.002
ALT (U/L) – median (IQR, range)	14 (7, 3 – 168)	15 (6, 9 – 42)	0.067
AST (U/L) – median (IQR, range)	23 (9, 11 – 81)	27 (10, 6 – 48)	<0.001
Creatinine (mg/dl) – mean (SD, range)	0.5 (0.2, 0.2 – 1.0)	0.4 (0.2, 0.2 – 1.0)	0.045
Azotemia (mg/dl) – mean (SD, range)	13 (3, 5 – 23)	13 (3, 4 – 21)	0.854
CPK (U/L) – median (IQR, range)	103 (55, 32 – 673)	121 (64, 41 – 411)	0.006
CRP (mg/dl) – median (IQR, range)	0.03 (0.1, 0.03 – 6.4)	0.03 (0.1 (0.03 – 1.6)	0.030
hsTnT (pg/ml) – median (IQR, range)	3 (1, 3 – 29)	3 (3, 3 – 40)	0.060
NT-proBNP (pg/ml) – median (IQR, range)	42 (55, 5 – 262)	64 (53, 7 – 278)	0.038
Ferritin (ng/ml) – median (IQR, range)	42 (29, 6 – 256)	37 (33, 6 – 283)	0.347
Pathological findings			0.679
Electrocardiogram – no. (%)	8 (4.1)	4 (5.1)	0.155
Spirometry – no. (%)	6 (3.1)	0 (0)	0.993
Lung ultrasound – no. (%)	81 (41.5)	31 (39.7)	

Conclusions/Learning Points: Our data suggest that patients with LC, despite the persistent or appearance of symptoms after the negativization, did not showed either cardiopulmonary anomalies or immunology alteration. This discrepancy might support the need of high quality studies to better understand the pathogenesis of LC in order to avoid the over diagnosis and mislabel of some pediatric patients.

Title of Case: Use of Remdesivir in children with COVID-19: report of an Italian multicenter study
Background: COVID-19 is generally milder in children than in adults, however severe infection has been described. Data on use of Remdesivir (RDV) in children are still limited. We report a multicenter study to investigate the safety of RDV in children affected by COVID-19.
Case Presentation Summary: Fifty children were included, with a median age of 12.8 years. Many patients had at least one comorbidity (78%), mostly obesity. Symptoms were fever (88%), cough (74%) and dyspnea (68%). Most patients were diagnosed with pneumonia of either viral and/or bacterial etiology. Blood test showed leukopenia in 66% and increased C-reactive protein (CRP) levels in 63% of cases. Thirty-six patients received RDV for 5 days, nine patients up to 10 days. Most children who received RDV longer were admitted to the PICU (67%). Treatment with RDV was well tolerated with rare side effects (Table 1): bradycardia was recorded in 6% of cases. A mild elevation of transaminases was observed in 26% of cases, however for the 8%, it was still detected before the RDV administration. Patients who received RDV for more than 5 days waited longer for its administration after pneumonia diagnosis. The presence of comorbidities and the duration of O2 administration significantly correlated with the duration of RDV
therapy.

Table_ RDV administration, safety measures

RDV administration	
Dose of RDV	
Duration of therapy (days) - median ± IQR (range)	4 ± 1 (1 - 10)
≤ 5 days - no. (%)	32 (78)
> 5 days - no. (%)	9 (22)
Time from symptoms onset to administration (days) - median ± IQR	6 ± 3 (0 - 15)
(range)	2 ± 2 (0 - 8)
Time from pneumonia to administration (days) - median ± IQR (range)	
Safety evaluation of RDV administration	
AST (U/L, max value) - median ± IQR (range)	43 ± 47.3 (19 - 164)
ALT (U/L, max value) - median ± IQR (range)	54 ± 108 (6 - 350)
Creatinine (mg/dl, max value) - median ± IQR (range)	0.6 ± 0.4 (0.1 - 0.9)
eGFR (ml/min, max value)* - median ± IQR (range)	120 ± 91 (79 - 236)
Ipertransaminasemia - no. (%)	14 (44)
Bradicardia - no. (%)	2 (4)
Rash - no. (%)	3 (6)
Renal insufficiency (according to eGFR) - no. (%)	0 (0)

Learning Points/Discussion: Our experience indicates that RDV against SARS-CoV-2 is safe and well-tolerated in pediatric populations at high risk of developing severe COVID-19. Our data suggest that delaying RDV therapy after diagnosis of pneumonia may be associated with a longer duration of antiviral therapy, especially in patients with comorbidities.

EFFECTIVENESS OF BNT162B2 AND CORONAVAC IN CHILDREN AND ADOLESCENTS AGAINST SARS-COV-2 INFECTION DURING OMICRON BA.2 WAVE IN HONG KONG

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Jaime Rosa Duque, Daniel Leung, Ka Man Yip, Hung-Kwan So, Wilfred Wong, Yu Lung Lau
The University of Hong Kong, Department Of Paediatrics And Adolescent Medicine, Hong Kong, Hong Kong PRC

Backgrounds: The SARS-CoV-2 Omicron BA.2 subvariant replaced BA.1 globally in early 2022, and caused an unprecedented tsunami of cases in Hong Kong, resulting in the collapse of elimination strategy. Vaccine effectiveness (VE) of BNT162b2 and CoronaVac against BA.2 is unclear.
Methods: We utilize an ecological design incorporating population-level vaccine coverage statistics and territory-wide case-level SARS-CoV-2 infection surveillance data, and investigate the VE against infection during the Omicron BA.2 wave between January 1 to April 19, 2022, in Hong Kong for children and adolescents.
Results: We estimate VE to be 33.0% for 1 dose of BNT162b2 in children aged 5-11 and 40.8% for 2 doses of CoronaVac in children aged 3-11. We also estimate 54.9% VE for 2 doses of BNT162b2, and 55.0% VE for 2 doses of CoronaVac in adolescents aged 12-18.
Conclusions/Learning Points: Our findings support preserved VE against infection by variants of concerns for children and adolescents in settings with extremely low levels of prior SARS-CoV-2 circulation.

MIS-C IN A RECENT ONSET OF DIABETES MELLITUS TYPE 1

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Virginia Rossi[1], Gabriella Guida[1], Francesca Chiara Redaelli[1], Maddalena Macedoni[1], Agnese Petitti[1], Chiara Mameli[1,2], Gianvincenzo Zuccotti[1,2]
[1]University of Milan, Department Of Pediatrics, Buzzi Children's Hospital, Milan, Italy, [2]University of Milan, Department Of Biomedical And Clinical Sciences, Milan, Italy

Title of Case: MIS-C in a recent onset of diabetes mellitus type 1
Background: Multisystem inflammatory syndrome in children (MIS-C) is a rare but severe clinical entity characterized by a dysregulated response of the immune system, that can occur 2-6 weeks after SARS-CoV-2 infection.
Case Presentation Summary: C.C., a 7-year-old male, presented with onset of type 1 diabetes (T1D) without ketoacidosis and with low insulin requirement in September 2022 during paucisymptomatic SARS-CoV-2 infection. Approximately three weeks after, C.C. came to our emergency department because of 4-day fever and conjunctivitis. Blood tests showed neutrophilia (8164/mmc), lymphocytopenia (860/mmc), increased inflammatory markers (C-reactive protein 197 mg/l, nv <10 mg/l; erythrocyte sedimentation rate 28 mm/h), fibrinogen 700 g/l, D-dimer 2351 mcg/l, TroponinT 62 ng/l, proBNP 3511 ng/l, IL-6 1098 pg/ml. MIS-C was suspected. Echocardiography showed globular left ventricle, lower wall hypokinesis and septum with dyskinetic appearance, reduced ejection fraction (42%), mitral and tricuspid insufficiency, dilated inferior vena cava and right atrium. Immediately we started intravenous immunoglobulin and steroid therapy, furosemide and intravenous adrenaline. Contextually, glycemic profile showed severe persistent hyperglycemia, with progressive increase in insulin requirements (from 0.2 up to 1 U/kg/day). Serial cardiological evaluations were performed, showing biventricular function normalization and good cardiovascular balance; blood tests showed negativization of inflammatory markers, with normalization of cardiac function values in 10 days. Besides, glycemic profile required a longer time to correct, likely due to steroid therapy. Eventually, 20 days after hospital admission, C.C. reached euglycemic values. Three months after, insulin requirement is 0.5 U/kg/day.
Learning Points/Discussion: We describe a case confirming how MIS-C prompt treatment with high dose anti-inflammatory therapy is essential for achieving better outcomes. However, in some cases this may provoke severe metabolic derangement in patients with comorbidities such as T1D.

PREVALENCE OF SARS-COV-2 ANTIBODIES AMONG HEALTHCARE PROFESSIONALS AT A HOSPITAL IN SÃO PAULO

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Rachel Leirner Argelazi[1], Carolina Mira Bergamini[1], Danielle Oliveira[2], Edison Luiz Durigon[2], Denis Cavalcante[3], Flavia Almeida[3], Marco Aurelio Safadi[4]
[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, Faculdade De Ciências Médicas Da Santa Casa De São Paulo, São Paulo, Brazil, [2]Universidade de São Paulo, Molecular And Clinical Virology Laboratory, São Paulo, Brazil, [3]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [4]Santa Casa de Sao Paulo School of Medical Sciences, Pediatric Infectious Diseases, Sao Paulo, Brazil

Backgrounds: This study aimed to compare seroprevalence and antibody titers to SARS-CoV-2 between professionals who had a previous Covid-19 history and those who did not, and the different vaccines applied.
Methods: A cross-sectional descriptive study was carried out through anonymous questionnaires and collection of Neutralizing Antibodies (VNT) to the Wuhan variant of SARS-CoV-2.
Results: A total of 117 professionals participated in the study. Before vaccination, 56 had a confirmed diagnosis of Covid-19. All participants were vaccinated: 27 with two doses of Oxford/AstraZeneca, 88 with two doses of CoronaVac, 1 with a dose of Janssen and 1 with two doses of Pfizer. After vaccination, 10 participants had a confirmed diagnosis of Covid-19 by PCR.
Conclusions/Learning Points: Our study showed that previous Covid-19 infection is related to greater positivity of VNT (p=0.0028). This was ratified when analyzing the participants who received the two doses of CoronaVac (p=0.013). However, this was not ratified in participants who received the two dose AstraZeneca (p=0.7). Professionals who received AstraZeneca had higher positivity (88.9%) compared to CoronaVac (68.2%), confirming the greater immunogenicity of the vaccine. The mean antibody titers of patients who had a history of previous SARS-Cov-2 infection and were vaccinated with the AstraZeneca vaccine was 3.79 times higher than the same group with a history of infection and vaccinated with the CoronaVac vaccine. When comparing the groups that had no history of previous infection, participants who received the vaccine CoronaVac had mean antibody titers 1.38 times higher than the group that received the AstraZeneca vaccine. All 70 participants who received the complete vaccination schedule and the booster dose with Pfizer showed VNT for SARS-CoV-2.

THE PREVALENCE OF REINFECTION BY SARS-COV2 VIRUS AMONGST HEALTHCARE WORKERS FROM SANTA CASA DE SÃO PAULO

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Carolina Mira Bergamini[1], Rachel Leirner Argelazi[1], Edison Luiz Durigon[1], Danielle Oliveira[1], Denis Cavalcante[2], Flavia Almeida[2], Marco Aurelio Safadi[3]
[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, Paediatrics, São Paulo, Brazil, [2]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [3]Santa Casa de Sao Paulo School of Medical Sciences, Pediatric Infectious Diseases, Sao Paulo, Brazil

Backgrounds: The COVID 19 most commonly affects young adults leading to a mild illness marked by anosmia. In light of the failure to produce a fool proof therapy to alleviate the symptoms that COVID can cause, the natural history of the virus was only hindered by the development of the vaccines. After several countries reported numerous COVID waves following the initial one, it's been put into question whether the other waves happen due to a "viral resurgence" after an inappropriate viral clearance or due to reinfections
Methods: Through Google forms, 65 healthcare workers that had already had at least one previous SARS-CoV2 infection anonmiously informed how many times they've had COVID, when they had COVID so that the team could infere what was the COVID variant more common when the infection took place and what and how many vaccines they got.
Results: Out of the 65 patients invited to join the study, only 62 replied to all the questions, so this study considers a total of 62 patients.
Out of the 62 patients, 8 (12,9%) of them reported reinfection. When the number of patients that reported reinfections was analysed as to what vaccines they got, 5 (62,5%) got two initial doses of Sinovac-Coronavac whilst 3 got the AstraZeneca-Oxford.
Conclusions/Learning Points: Even though the patients that got COVID 19 still got reinfected the most, Sinovac-Coronavac continues being pivotal in the pandemic, because although it doesn't stop the actual infection, it has led to a better clinical outcome, lowering the death rates due to SARS-CoV2 infection.

CASE REPORT OF A SELF-LIMITED PEDIATRIC INFLAMMATORY MULTISYSTEM SYNDROME TEMPORALLY ASSOCIATED WITH A SARS-COV-2 INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Raquel Santos, Carolina Quintela, Joana Pinto Oliveira, Aida Sá, Vanessa Gorito
Centro Hospitalar de Trás-os-Montes e Alto Douro, EPE - SNS, Serviço De Pediatria E Neonatologia, - Vila Real, Portugal

Title of Case: Case report of a self-limited Pediatric Inflammatory Multisystem Syndrome Temporally associated with a SARS-CoV-2 Infection
Background: Pediatric Inflammatory Multisystem Syndrome temporally associated with COVID-19 (PIMS-Ts) is a rare condition that occurs weeks after the infection and causes multiorgan dysfunction. The authors report a case of PIMS-Ts that was successfully managed only with supportive therapy.
Case Presentation Summary: A three-year-old boy, previously healthy, with a COVID-19 infection five months before, came to the Emergency Department with a two-day-fever, prostration, abundant diarrhea, vomiting, and total food refusal. On physical examination, he was prostrated, with dehydration signs, and an unspecific rash. He became hypotensive, tachycardic, and oliguric, responsive to fluid boluses. Blood samples showed lymphopenia, hyponatremia, hypoalbuminemia, and increased urea, creatinine, transaminases, lactate dehydrogenase, C-reactive protein, procalcitonin, ferritin, prothrombin time, fibrinogen, d-dimer, and BNP. Blood, urine, stool, and cerebrospinal fluid cultures and a nasal viral panel were negative. He was hospitalized with intravenous fluids and antibiotics. Afterwards, a positive SARS-CoV-2 IgG (2628AU/mL), established the diagnosis of PIMs-Ts with an undefined inflammatory presentation. During hospitalization, he had transient conjunctival hyperemia and a progressive clinical improvement, with normalization of hepatic, renal, and cardiac function. He was discharged after six days, asymptomatic. Since then, it was maintained an uneventful follow-up.
Learning Points/Discussion: This patient met all PIMS-Ts diagnostic criteria, such as age, clinical presentation, laboratory findings, and evidence of a prior SARS-CoV-2 infection, without other identified causes. Usually, the treatment relies on immunomodulators (immunoglobulin, methylprednisolone, biological drugs), and antiplatelet agents. Despite this, in this patient, no immunomodulators were used and there was a full recovery only with support measures. We highlight the possibility of diagnosing PIMS-TS with an undefined inflammatory presentation, characterized by self-limited course and improvement without an immunomodulatory approach, overlapping with recent literature.

PV1023 / #2045

PSYCHOSOCIAL IMPACT AND COPING STRATEGIES OF THE COVID-19 PANDEMIC AMONG SCHOOL AGE CHILDREN IN JORDAN

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Murad Sawalha, Jamila Abuidhail
THE HASHEMITE UNIVERSITY, Maternal, Child And Family Health Nursing, Zarqa, Jordan

Backgrounds: Millions of people's health and lives worldwide have been jeopardized by the coronavirus disease 2019 (COVID-19) pandemic. Although children's physical health is less harmed by the disease, their psychosocial health is not. Children are dealing with many stressors resulted from COVID-19 and quarantine and their perception of risk and stress may differ than adult that expose them to many psychosocial problems.
This study aims to examine the psychosocial impact of the COVID-19 pandemic on Jordanian primary school age children and explore their coping strategies to alleviate this impact.
Methods: A descriptive cross sectional was followed to assess the psychosocial impacts of COVID-19 among Jordanian school age children (6-12 years) and their coping strategies. The data were collected electronically from a convenient sample of 200 children through google form (permission was required from their parents, and some help in filling the questionnaire). The online questionnaire composed from two main parts: the first one was the demographic sheet. The second was the instrument that measured the psychosocial impacts of COVID-19 and coping strategies.
Results: The results revealed that staying at home by force leads to negative physical, social and psychological effects among school age children such as anxiety, stress, and depression. These problems mainly related to losing opportunities for play, physical contact and physical education. Therefore children felt confused and at loss with the current situation, leading to frustration and anxiety, which will only increase with the over exposure to mass and social media.
Conclusions/Learning Points: The results of this study will aid in the development of effective educational training program and targeted interventions to alleviate the impacts of COVID-19 pandemic among school age children, and to reduce the risk of future psychosocial problems during similar crisis.

THE RELATIONSHIP BETWEEN ELEVATED LIVER ENZYMES AND THE SEVERITY OF LUNG INVOLVEMENT IN CHILDREN WITH COVID-19 INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Shirin Sayyahfar[1], Azizollah Yousefi[2], Afsaneh Kaboudani[2], Elham Zarei[3]
[1]Research Center of Pediatric Infectious Diseases, Institute of Immunology and Infectious Diseases, School of Medicine, Iran University of Medical Sciences, Tehran, Iran, Pediatrics, Tehran, Iran, [2]School of Medicine, Iran University of Medical Sciences, Tehran, Iran, Pediatrics, Tehran, Iran, [3]Department of Radiology, Ali asghar Children's Hospital, School of Medicine, Iran University of Medical Sciences, Tehran, Iran, Radiology, Tehran, Iran

Backgrounds: The aim of this study is identifying the frequency of elevated liver enzymes in children with covid-19 and investigating the type and severity of lung involvement in chest CT scan in order to identify any relationship between abnormal liver enzymes and the severity of lung involvement based on imaging findings.
Methods: All patients one month to 18 years of age referred to Hazrat Ali Asghar Children's Hospital from March 2020 to the end of September 2022, who were infected with Covid-19 were enrolled in a descriptive-cross-sectional study. Normal laboratory values for AST and ALT was 8-33 U/L and 10-40 U/L respectively. Mild, moderate and severe levels for ALT were 40-200 U/L, 200-800 U/L, and more than 800 U/L respectively.
Results: The present study was conducted on 319 patients. Out of 319 patients, 185(58%) cases were male and 134(42%)patients were female. There was no case of clinical hepatitis during this study. Based on ALT, 263(82.5%) cases had normal ALT while 56 (17.5%)patients had subclinical hepatitis [51(16%) mild, 4(1.2%) moderate. and 1(0.3%) severe]. All patients had improvement in AST and ALT during treatment. Chest CT scan was performed in 192 (60.18 %) cases. A normal CT scan was reported in 110 patients (57.3%) while 47(24.5%),22(11.5%)and 9(4.7%)cases had mild, moderate and severe pulmonary involvement. Totally, 4 (2%) cases had pleural effusion. Based on type of involvement, 27(14%), 37(19.3%) and 18(9.4%) cases had typical, indeterminate and atypical presentation in the chest CT. There was no significant relationship between changes in liver enzymes and severity of lung involvement based on imaging findings.
Conclusions/Learning Points: It seems that liver enzyme value cannot predict the severity of lung involvement in pediatric covid 19 cases.

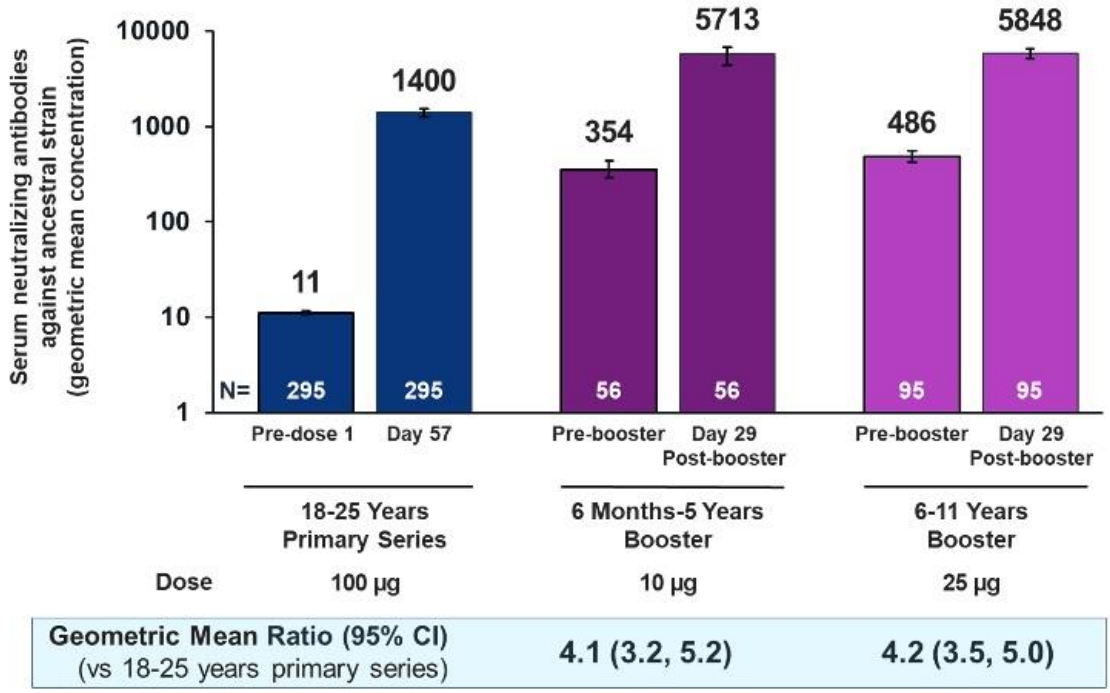
SAFETY AND IMMUNOGENICITY OF A SARS-COV-2 BOOSTER (MRNA-1273) IN CHILDREN AGED 6 MONTHS TO 11 YEARS FROM THE PHASE 2/3 KIDCOVE STUDY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Sabine Schnyder Ghamloush[1], Vladimir Berthaud[2], C. Buddy Creech[3], Evan Anderson[4], Weiping Deng[1], Xiaoping Zhao[1], Honghong Zhou[1], Mollie Brown[1], Anne Yeakey[5], Karen Slobod[6], Bethany Girard[1], Rituparna Das[1]
[1]Moderna, Inc., Clinical Development, Cambridge, United States of America, [2]Meharry Medical College – Clinical and Translational Research Center, Infectious Diseases, Nashville, United States of America, [3]Vanderbilt University Medical Center, Paediatric Infectious Diseases, Nashville, United States of America, [4]Emory University School of Medicine, Paediatrics, Atlanta, United States of America, [5]BioPoint Contracting, Pharmacovigilance, Wake Forest, United States of America, [6]Cambridge ID & Immunology Consulting, Clinical Development, Somerville, United States of America

Backgrounds: Among children aged 6 months-11 years, a 2-dose primary series of an mRNA-based SARS-CoV-2 vaccine (mRNA-1273) was well-tolerated and immunogenic in the phase 2/3 KidCOVE study (NCT04796896). We present data from KidCOVE participants who received an mRNA-1273 booster dose.
Methods: Safety and immunogenicity against SARS-CoV-2 were assessed in participants who received a booster dose of mRNA-1273 (10 µg for 6 months-5 years of age; 25 µg for 6-11 years of age) administered ≥6 months after dose 2 of the primary series. Non-inferiority of booster immune responses against ancestral SARS-CoV-2 in children (Day 29) to those after primary series dose 2 (Day 57) in young adults aged 18-25 years was evaluated in participants without prior SARS-CoV-2 infection.
Results: 145 children younger than 6 years and 1294 children aged 6-11 years received a booster dose. No new safety concerns were identified. Pain was the most common solicited local adverse reaction (AR); irritability/crying and fatigue were the most frequent systemic ARs among those aged <36 months and 37 months-11 years, respectively. A booster dose elicited high serum neutralizing antibodies against ancestral SARS-CoV-2 at Day 29 (Figure); a similar effect was observed in participants with prior SARS-CoV-2 infection. Booster immune responses in pediatric age groups were non-inferior to those observed in young adults aged 18-25 years after completing an mRNA-1273 primary series.

Figure. Serum neutralizing antibodies against SARS-CoV-2



Per-protocol immunogenicity population included participants with pre-dose 1 negative status for SARS-CoV-2 (young adults aged 18-25 years; COVE trial) or participants with pre-booster negative status for SARS-CoV-2 (children aged 6 months to 11 years; KidCOVE trial). Non-inferiority was declared when (1) the lower bound of the 95% CI of the geometric mean ratio (geometric mean concentration [GMC] post-booster Day 29 [children] over GMC post-dose 2 Day 57 [young adults]) was >0.667 (or >1/1.5) and (2) the lower bound of the 95% CI of the seroresponse rate difference between age groups was >-10%.

Conclusions/Learning Points: An mRNA-1273 booster dose raised no new safety concerns and effectively boosted serum neutralizing antibodies against ancestral SARS-CoV-2 in children aged 6 months-11 years. Neutralizing titers were non-inferior to those in young adults after the primary series. These data support the administration of a SARS-CoV-2 booster vaccine to children aged 6 months-11 years regardless of prior SARS-CoV-2 infection.

SWISSPED RECOVERY TRIAL – DESCRIPTION AND INTERPRETATION OF INTERCURRENT EVENTS IN AN OPEN-LABEL RANDOMISED TRIAL

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Nina Schöbi[1], Carlos Sanchez[2], Tatjana Welzel[3], Andrew Atkinson[2], Luregn Schlapbach[4], Julia Bielicki[5]
[1]University Children's Hospital, University Bern, Inselspital, Paediatric Infectious Diseases, Paediatrics, Bern, Switzerland, [2]University of Basel Children's Hospital (UKBB), Pediatric Research Center, Basel, Switzerland, [3]University of Basel Children's Hospital (UKBB), Pediatric Rheumatology, Basel, Switzerland, [4]Children's Research Center, University Children's Hospital Zürich, Neonatal And Pediatric Intensive Care Unit, Zurich, Switzerland, [5]University of Basel Children's Hospital (UKBB), Department For Infectious Diseases And Vaccinology, Basel, Switzerland

Backgrounds: Swissped RECOVERY is an open-label randomised trial comparing iv methylprednisolone 10 mg/kg 3 days and IVIG 2 g/kg single dose for PIMS-TS. Given the pragmatic nature, the expected occurrence of post-randomisation treatment modifications, i.e., intercurrent events (ICEs), was high.
Methods: Patients from the cohort with one or more ICE were considered and characteristics reviewed in relation to the whole cohort. The blinded endpoint review committee (BERC) consisted of four international PIMS-TS experts. The primary objective of the BERC was to adjudicate the chronologically first ICEs based on blinded case vignettes with two key questions a) disease classification and b) likelyhood of clinical indication: i) definitely (>80%), ii) probably (51-80%, iii) unlikely (21-50%), iv) no (< 21%).
Results: Between May 2021 and April 2022 75 patients were recruited. In 41 patients ICEs were observed; 24/37 (64.9%) in the iv methylprednisolone compared to 17/38 (44.7%) in the IVIG arm (most commonly oral corticosteroids). Baseline characteristics associated with ICEs were inotropic support 19/41 vs 6/34, p=0.017; more severe lymphocytopaenia (*10^9/L) 0.66 [0.47, 1.03] vs 1.00 [0.64, 1.42], p=0.041; and thrombocytopaenia (*10^9/L) 127 [100, 166] vs 180 [142, 261], p=0.004. According to the BERC, in 14/41 (34.1%) patients, rescue treatment was clinically not indicated (unlikely, no), corresponding to 11/24 of patients in the iv methylprednisolone and 3/17 in the IVIG arm.
Conclusions/Learning Points: In patients at the severe end of the clinical spectrum clinicians are more likely to add immunomodulatory treatment. Working in adherence to local guidelines (e.g. tapering corticosteroids) might lead clinicians to abandon trial protocol. An RCT for an emerging disease requires a pragmatic approach, e.g. an open-label setting. To improve understanding of the data and to identify factors that potentially lead to ICEs a BERC can be considered.

TIXAGEVIMAB–CILGAVIMAB PROPHYLAXIS IN A 3-YEARS OLD CHILD WITH SEVERE APLASTIC ANEMIA

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Stefano Rossi, Giulia Baresi, Elena Soncini, Veronica Maria Folsi, Marianna Maffeis, Giulia Albrici, Andrea Castagna, Carmelita D'Ippolito, Fulvio Porta, Richard F Schumacher
Asst Spedali Civili of Brescia, Children Bmt Unit And Hematology And Oncology Unit, Brescia, Italy

Title of Case: TIXAGEVIMAB–CILGAVIMAB PROPHYLAXIS IN A 3-YEARS OLD CHILD WITH SEVERE APLASTIC ANEMIA
Background: SARS-CoV-2 infection represents an extremely harmful complication of children affected by severe hematologic diseases or malignancies. Neutralizing antibodies may offer a chance for both treatment and prevention of infection and disease manifestations. Among these, the combination of the two two Fc-modified human monoclonal antibodies Tixagevimab–Cilgavimab has been proposed for prophylaxis in patients with Immunocompromising Conditions or not eligible for COVID-19 vaccinations. Unfortunately, the combination is only licensed for patients ≥ 12 years old.
Case Presentation Summary: Here we report on a 3-years old child affected with severe aplastic anemia that was successfully treated with Tixagevimab–cilgavimab after exposure to SARS-Cov-2. The index patient is a 3-years old female child of African ethnicity diagnosed with severe aplastic anemia. The patient had not been vaccinated against SARS-CoV-2. According to the severity of the disease the patient was candidate for bone marrow transplantation (BMT) and was admitted to our Unit and in order to perform pre-BMT examinations. At the time of the admission a nasal swab performed both on the patient and on her mother (caregiver of the child) revealed a positivity of the latter, while the test performed on the patient ended up negative.After multidisciplinary discussion we decided to treat the child with a single dose of the combination Tixagevimab–cilgavimab as a post-exposure prophylaxis. We identified a dose of 100 mg as appropriate for the patient. The infusion was well tolerated with no acute or late adverse event reported. The patient did not showed a positivity for SARS-CoV-2 and remained always asymptomatic.
Learning Points/Discussion: Tixagevimab–cilgavimab is well tolerated in children and can ben a useful tool in the prophylaxis of SARS-Cov-2 infection.

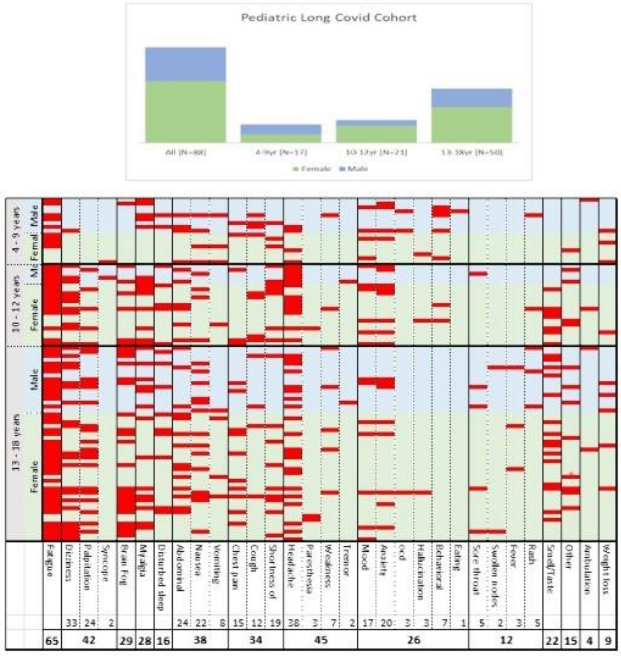
PEDIATRIC LONG COVID ACROSS AGE GROUPS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Bazak Sharon[1,2]
[1]University of Minnesota, Pedaitrics, Minneapolis, United States of America, [2]university of minnesota, Pediatrics, Minneapolis, United States of America

Title of Case: Pediatric Long Covid
Background: Pediatric infection with SARS-CoV-2 may cause long term sequalae and there is a need to describe this disease, allowing for standardized guidelines for diagnosis and management. The aim of this case series is to to describe the pathology observed in children with Long Covid.
Case Presentation Summary: We present the clinical disease observed in 88 children who were diagnosed with Long Covid at the University of minnesota pediatric Covid clinic. The series is composed of 57 females (assigned at birth) and 31 male, age 4 to 18 years. The majority of patients were teenagers (50 children older than 13yr). The most common symptoms identified were fatigue (65, 74%), followed by autonomic dysfunction (42, 48%), headache (38, 43%), gastrointestinal (38, 43%), respiratory (34, 38%), cognitive (29, 33%), pain (28, 32%), and psychiatric (26, 30%) symptoms. Persistent abnormalities in smell and taste were also common (22, 18%). Some of the symptoms had very different distribution based on age, particularly autonomic dysfunction (12% in ages 4-9yr / 56% in ages 10-18yr), cognitive dysfunction/brain fog (6% in 4-9yr / 40% in 10-18yr), Abnormal smell/taste (0% in 4-9yr / 25% in 10-18yr), and psychiatric symptoms (45% in 4-12yr / 18% in 13-18yr). Figure 1 summarized the demographic and symptoms of the cohort and the different age
groups.



Learning Points/Discussion: Children may develop persistent illness following SARS-CoV-2 infection that is reminiscent of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME.CFS). Fatigue, headache, gastrointestinal, and pulmonary symptoms as well as generalized pain, and sleep disturbances are common across age groups. Younger children are at risk for acute neuropsychiatric

syndrome, while teenagers are more commonly experiencing autonomic dysfunction and cognitive impairment. Prompt recognition is crucial and management should follow ME/CFS guidelines.

ANTIBODY RESPONSE IN PREVIOUSLY NAÏVE CHILDREN AFTER PRIMARY SARS-COV-2 OMICRON VARIANT INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Ching-Fen Shen[1], Chao-Min Cheng[2], Ching-Chuan Liu[1], Chi-Chang Shieh[1]
[1]National Cheng Kung University Hospital, Pediatrics, Tainan, Taiwan, [2]Institute of Biomedical Engineering, National Tsing Hua University, HsinChu, Taiwan

Backgrounds: Antibody production after SARS-CoV-2 infection is essential for the prevention of re-infection. However, information regarding the antibody response in infection naïve and unvaccinated children after primary infection remains scarce.
Methods: Children under 18 years visiting National Cheng Kung University Hospital, Tainan, Taiwan due to COVID-19 and associated complications during the first wave of domestic outbreak (April – August 2022, mainly caused by Omicron BA.2 variant) were invited into this study. Anti-SARS-CoV-2 S (spike) IgM/IgG total antibody (Roche Elecsys), anti-SARS-CoV2 neutralization antibody titers (cPass, GeneScript) toward wildtype and variants were measured using serum collected one month after infection.
Results: One hundred thirty patients with a mean age of 3.4 years (from 0.3 ~13.6 years) were recruited. Most of the clinical diagnoses are upper respiratory tract infections. The anti-SARS-CoV-2 S antibody ranges from 0.4 IU/ml to 604.6 U/ml, and there is no significant difference between age groups. But the neutralizing antibody against Omicron BA.2 variant is higher in children aged 3 months- 2 years than those aged 5-12 years (inhibition: 51.9 ± 13.2% in 3 months-2 years, 32.2 ± 17.2% in 5-12 years, $p < 0.05$). These primary Omicron BA.2 infected children generated sub-optimal cross-reactive neutralizing antibodies against wildype (inhibition: 32.9±18.4%), Delta variant (16.1±20.6%), and Omicron BA.1 variant (37.4±19.6%). There are 87.5% of children failed to generate adequate neutralizing activity against Delta variant (inhibition < 30%), followed by 43.8% against wildtype and 40.6% against Omicron BA.1 variant.
Conclusions/Learning Points: Younger children generate higher neutralizing activity toward the infected SARS-CoV-2 variant than older children during the early phase post-infection. Primary infection-induced antibody in naïve children is not robust and does not provide sufficient cross-reactivity against other variants. Further vaccination is still warranted.

ADOLOSCENT WITH FEVER – THINK OUT OF THE BOX

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Bhaskar Shenoy, Pooja Doddikoppad, Devesh Joshi
Manipal Hospital, Pediatrics, Bangalore, India

Title of Case: ADOLOSCENT WITH FEVER – THINK OUT OF THE BOX
Background: Fever in an adolescent can be challenging situation .An adolescent with fever should be investigated for common tropical binfections . In situations where we dont get any diagnostic clue ,look beyond infections .
Case Presentation Summary: 11 years old girl came with rashes noticed over lower limbs, progressed to upper limbs. History of fever since 3 days with headache and myalgia. History of travel to Maldives,, treated empirically with hydrocortisone for 3 days. , child had continuous fever spikes with neck pain and conjunctival congestion for first 3 days child was worked up for infectious cause of fever and treated with IV Ceftriaxone . Iinvestigation showed a high CRP 154 mg /dl Blood culture showed no growth .work up for infectious cause of fever -dengue, Leptospira, scrub typhus was negative. Day 8, Echo - small aneurysm in LAD with dilatation of coronary artery (LMCA) Z score 3.9mm, LAD 3.9mm, RCA 3.3mm) repeat inflammatory markers, CRP - 174.98, procalcitonin - 0.098 ng/ml, Serum Ferritin- 454.2, NT pro BNP 664 pg./ml, Fibrinogen 696 2 LDH of 236. Provisionally diagnosed to have ATYPICAL KAWASAKI DISEASE vs MISC Child was started on IVIG at 2 g/kg over - 48hours with IV methyl prednisolone for 3 days . Child was afebrile for next 72 HOURS Investigation showed decreasing trend of inflammatory markers with - CRP 38 mg/ dl REPEAT ECHO no further worsening of aneurysm with same changes Discharged with aspirin 3 mg /Kg and regular plan to follow up.
Learning Points/Discussion: Think beyond infections in a child with persistent fever Empiric use of steroids in early in the course of fever without establishing the cause does more harm than good by masking the clinical picture.

PV1031 / #2187

CHARACTERISTICS AND RISK FACTORS OF POST-COVID CONDITIONS IN CHILDREN.

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Erika Silvestro[1], Elisa Barisone[2], Giulia Pruccoli[1], Federica Mignone[1], Carlo Scolfaro[1], Elisa Funiciello[1], Francesca Robasto[2], Marco Denina[1], Silvia Garazzino[1]
[1]Regina Margherita Children's Hospital, Paediatric Infectious Disease, Turin, Italy, [2]University of Turin, Science Of Public Health And Pediatrics, Turin, Italy

Backgrounds: Post-COVID conditions (PCC) are an important recent public health concern. However, they are still a widely debated entity in adults and even more in the pediatric population.
Methods: This retrospective, observational study included all the children admitted to Regina Margherita Children's Hospital (Turin, Italy) with SARS-CoV-2 infection, from the beginning of the COVID-19 pandemic up to September 2022. Patients with recently diagnosed oncologic diseases and preexisting severe neurologic impairment were excluded. A subset of children underwent a close clinical follow-up; the remaining were followed up through questionnaires by phone calls. The primary aim was to investigate PCC epidemiology, and the second was to evaluate characteristics and risk factors.
Results: Overall 510 children were enrolled. Among these, 122 (23.9%) patients underwent periodic clinical assessments with a mean duration of follow-up of 8.28 months. 36.9% (45/122) had concomitant chronic diseases. At 3 months from COVID-19, 24 children (24/510, 4.7%) presented at least one symptom consistent with PCC: asthenia and easy fatigue (13), arthromyalgias (5), headache (3), residual respiratory distress (3), heart-pounding and chest pain (2). At 6 months 13 patients (2.5%) still complained of symptoms. No patient required a second hospital admission due to SARS-CoV-2 infection, including PCC. Children with PCC were significantly older than those without mean age of 10.04 years vs 6.97, respectively ($p < 0.01$). Sex, chronic diseases, moderate or complicated course of COVID-19, and ICU admission were not significantly associated with a higher risk of PCC.
Conclusions/Learning Points: In our cohort of hospitalized children, PCC was rare compared to the literature (Lopez-Leon et al. estimated a prevalence of 25.24%) and independent of infection severity. To recognize and improve PCC management early, finding a standardized definition is mandatory.

PV1032 / #1977

REMDESIVIR IN SARS-COV-2 PNEUMONIA IN CHILDREN: SINGLE-CENTER EXPERIENCE

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

João Simões[1], Joana Melo[2], Ana Lemos[1], Rita Valsassina[1], Ana Margarida Garcia[1], Tiago Silva[1], Catarina Gouveia[1], Maria João Brito[1]
[1]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatric Infectious Diseases Unit, Lisbon, Portugal, [2]ULSBA - Hospital José Joaquim Fernandes, Beja, Pediatrics, Beja, Portugal

Backgrounds: The role of Remdesivir in pediatric COVID-19 hospitalizations is still discussed. Recent evidence has shown it to be safe in children, allowing the expansion of indications to >4 weeks-old and >3 kilograms. We describe our experience using remdesivir in pediatric hospitalized patients.
Methods: Single-center, retrospective, descriptive study of pediatric patients (< 18 years-old) with COVID-19 admitted to a third level Pediatric Center in Portugal, treated with remdesivir, from May/2020 to December/2022. Demographic and clinical data were collected.
Results: 32 patients were included, 24 (75%) males, median age of 36 months [10-108]. Sixteen (50%) presented comorbidities, most frequently cardiac insufficiency/cardiomyopathy (n=4), asthma/recurrent wheezing (n=4), medullary aplasia (n=3), cerebral palsy (n=2) and obesity (n=2). Twenty-two (68,7%) were from late 2021/2022 and 10 (31,3%) from 2020/early 2021. Remdesivir treatment was initiated at a median 4 day [3,00-5,75] of disease onset. The most common indication was hypoxic pneumonia (n=26). Treatment duration was 5 days (n=27) or 10 days (n=5) and 19 (59,4%) were concomitantly treated with corticosteroids. The duration of admission had a median of 7,5 days [5,25-12,75]. Eight (25%) were admitted to pediatric ICU, 4 (12.5%) needed mechanical ventilation and 1 (3,1%) ECMO. Two patients died during acute illness (1 previously healthy, 1 cardiac insufficiency). Complications attributed to remdesivir occurred in 3 (9,4%) previously healthy patients (bradycardia (n=2), hepatitis (n=1)) and were self-limited.
Conclusions/Learning Points: Remdesivir is the only approved pediatric antiviral for SARS-CoV-2 infection, both in established severe disease and prophylaxis, appearing to be safe. In adults, if used early, it shows reduction in hospitalization risk and complications in high-risk groups. Large scale randomized controlled trials enrolling pediatric patients are still needed to measure the impact on disease progression/prevention.

LONG TERM CARDIAC OUTCOMES IN A COHORT OF CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME IN MUMBAI, INDIA

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Tanu Singhal, Tanuja Karande, Prashant Bobhate, Preetha Joshi
Kokilaben Dhirubhai Ambani Hospital and Medical Research Institute, Paediatrics, Mumbai, India

Title of Case: Long term cardiac outcomes in a cohort of children with Multisystem inflammatory syndrome in Mumbai, India
Background: MIS-C has emerged as one of the most dramatic consequences of COVID-19 in children. Data on long term cardiac outcomes of MIS-C is emerging.
Case Presentation Summary: All children diagnosed with MIS-C at our centre in 2020 and 2021 were included. The diagnosis and treatment was as per standard guidelines. All patients underwent ECHO at baseline and 48 hours, 2 weeks, 4-6 weeks and then every 3-6 months till normal. The patients were followed up till December 2022. A total of 27 patients were diagnosed with MIS-C (10 &17 in 2020 and 2021 respectively) with ages between 1-17 years (mean 7 years). Fifteen had a Kawasaki disease phenotype while 12 had a toxic shock phenotype. Twenty one patients were treated with IVIG and steroids while eight with only steroids. The baseline ECHO was abnormal in 15 (55%) patients. While 30% patients in 2020 had abnormal ECHO, it was 70% in 2021. The ECHO abnormalities included reduced ejection fraction in 10, coronary artery dilatation (Z score > 2) in 7 while 3 had both reduced ejection fraction (REF) and coronary artery dilatation. The lowest EF was 35% and the z score ranged from 2-2.5. The EF normalized at 2 weeks in 5 patients and at 3, 6, 12 and 18 months in 1 each. Only 1 patient had abnormal myocardial function as low voltage QRS complex at 18 months. The coronary artery dilatation resolved by 2 weeks in 4 patients and by 6 weeks, 3 and 12 months in 1 each.
Learning Points/Discussion: MIS-C appeared to be more severe following the delta wave in India. The long term cardiac outcomes of MIS-C are excellent.

PV1034 / #1012

THE SAFETY AND TOLERABILITY OF REMDESIVIR IN INFANTS AND CHILDREN WITH COVID-19

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Tanu Singhal, Juhi Mehrotra, Santanu Sen
Kokilaben Dhirubhai Ambani Hospital and Medical Research Institute, Paediatrics, Mumbai, India

Title of Case: The safety and tolerability of remdesivir in neonates, infants and children with COVID-19
Background: COVID-19 is generally associated with mild illness in children and symptomatic therapy is all that is required. Antiviral therapy is indicated in children with COVID-19 pneumonia or those with risk factors for disease progression. Remdesivir and monoclonal antibodies are the only approved anti virals for children. There is limited data on the safety, tolerability of remdesivir in neonates, infants and children
Case Presentation Summary: This retrospective study included all children below 18 years who received remdesivir for treatment of COVID-19 infection at our centre from 2020-2022. Information regarding demographics, indications, adverse effects and outcomes was abstracted and analysed. A total of 21 children with age ranging from 1 month to 18 years (mean age 8 years) were included in the study. The indications were moderate COVID-19 pneumonia in 4 previously healthy children, neonates with COVID-19 pneumonia post cardiac surgery (2), mild COVID-19 infection in a) hematologic stem cell transplant recipients (5 patients), b) hematologic malignancy on chemotherapy (5 patients), c) neonate with complex congenital heart disease (1) and finally 4 patients with CT evidence of pneumonia. The treatment was well tolerated in all except 1 patient where therapy was interrupted due to elevation of liver enzymes. The patients with moderate pneumonia improved completely. None of the cancer chemotherapy/ stem cell transplant recipients had progression of COVID-19 disease. Two neonates who were diagnosed with COVID-19 infection following congenital heart surgery died due to progressive cardiorespiratory failure but causal relationship with COVID-19 could not be established.
Learning Points/Discussion: Remdesivir is safe and well tolerated in children. The absence of a control group precludes interpretation of its efficacy in our cohort.

PARENTAL ATTITUDES TOWARDS COVID-19 VACCINATION FOR CHILDREN: RESULTS FROM A NATIONWIDE SAMPLE IN GREECE

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Evangelia Steletou[1], Theodoros Giannouchos[2], Kyriakos Souliotis[3], Gabriel Dimitriou[1], Despoina Gkentzi[1]
[1]University General Hospital of Patras, Department Of Pediatrics, Rio, Patras, Greece, [2]University of South Carolina, Department Of Health Services Policy And Management, Arnold School Of Public Health, Columbia, United States of America, [3]University of Peloponnese, Department Of Social And Education Policy, Corinth, Greece

Backgrounds: To estimate the association between parents' intention to vaccinate against COVID-19 and child and parental characteristics and parental attitudes associated towards COVID-19 vaccination.
Methods: We conducted a random, nationwide questionnaire-based cross-sectional survey from October to December 2022 in Greece and included parents with at least one child under 17 years old.
Results: Overall, 497 parents completed the survey (97.1% - 497/512). Of those, 243 (48.9%) had not or did not intent to vaccinate their children against COVID-19, 188 (37.8%) had or intended to vaccinated them, and 66 (13.3%) were uncertain. Among parents with definitive views on children's COVID-19 vaccination (n=431), the majority of parents were females, aged 40 to 54 years, with college education, employed and married, and had one or two children under the age of 18. About 65% of these parents were vaccinated against COVID-19 but had not received a booster, and more than half (56.8%) supported vaccination mandates for adults. Among parents with children < 5years, around 20% intended to vaccinate their children against COVID-19, while among those with children > 5 years about half (47.3%) had already or intended to vaccinate them against COVID-19. The most common reasons against vaccination were fear of side effects (32.9%), short length of clinical trials (29.2%), and the child already having had COVID-19 in the past (12.0%). Stratified analyses by the two children age groups (<5 and 5-17) yielded similar estimates. Among parents who had not or did not intend to vaccinate their children, about 10% would do so if recommended by a pediatrician.
Conclusions/Learning Points: Our findings highlight the need to incentivize healthcare professionals and pediatricians in particular to inform parents about vaccines, clarify misconceptions and address concerns.

RELATIONSHIP OF AGE OF MISC PEDIATRIC PATIENTS' WITH PICU ADMISSION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Laura Stendelyte[1], Ausra Snipaitiene[2], Aurelija Sirataviciene[2], Rima Sileikiene[2], Leila Varoneckaite[2], Lina Jankauskaite[2]
[1]Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Department Of Pediatrics, Kaunas, Lithuania

Backgrounds: Multisystem Inflammatory Syndrome in Children (MIS-C) is characterized by overwhelming systemic inflammation, fever, hypotension, and cardiac dysfunction. SARS-CoV-2-associated disorder starts at 2-6 weeks after SARS-CoV-2 infection. Our aim was to investigate MIS-C cases and compare children admitted to ward versus pediatric intensive care unit (PICU).
Methods: We conducted a retrospective data analysis. All pediatric patients diagnosed with MIS-C were included into the study. We recorded patient's demographic, COVID data,complaints, symptoms, lab records, and length of stay (LOS). Data were analyzed with SPSS 28.0; p-value <0.05 was considered significant.
Results: In total, 43 patients' data were included. The mean age-8 years. Only seven children were identified as positive for COVID infection (majority-lack of data). 46.5% had contact with COVID-19. 21 patients were admitted to PICU. The majority PICU patients complained of gastrointestinal symptoms (abdominal pain, diarrhea, vomiting); 15 children had rash, and 12 presented with conjunctivitis. As expected, the total LOS admitted to PICU was longer compared to those treated in the ward and (13.1+/-5.5 vs 9.1+/-5.4 (p=0.009). None of the complaints or symptoms, except for signs of shock, were associated with PICU admission. MIS-C severity score did not differ between admitted to PICU or ward. However, age was linked to PICU admission (mean age for admitted children 9.6+/-4.3 vs 6.8+/-3.5y; p=0.012). All pediatric patients received same MIS-C-specific diagnostic tests and none of them were associated with admission to the PICU.
Conclusions/Learning Points: In total, 43 children were diagnosed and treated for COVID-19-associated MIS-C, with half of them admitted to PICU with a longer total LOS. Older children were more likely to be admitted to PICU.

LONG COVID SYNDROME IN CHILDREN: A CONTINUOUS FOLLOW-UP PROGRAM

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Laura Stendelyte[1], Ausra Snipaitiene[2], Ugne Kubiliute[1], Ryte Monterroso[1], Edita Hansted[2], Giedre Kojeliene[2], Jolita Statkuviene[2], Kristina Ganzijeva[2], Goda Laucaityte[2], Greta Venckute[2], Dovydas Burkojus[3], Jonas Andreikenas[3], Milda Dubininkiene[4], Darius Leskauskas[4], Rasa Pakanaviciute[4], Rimantas Kevalas[2], Lina Jankauskaite[2]

Backgrounds: Children who have contracted COVID are at risk of experiencing a variety of long-lasting symptoms collectively known as prolonged COVID syndrome. According to world data, about 30% of children infected with SARS-CoV-2 will experience certain symptoms. In this study, we aimed to create a continuous follow-up program for children after COVID infection. Moreover, our aim was to improve long-term periodic communication with the patient's parents to discuss her/his condition and timely recognize the signs of prolonged COVID. In addition, provide individualized assistance, monitoring of the patient and symptoms, assessment of the persistence of symptoms, and provide specific treatment.
Methods: Continuous follow-up program in the frame of a prospective observational study was created and is conducted in our hospital. The program started in March 2022. Criteria for the inclusion: 1 month up to 18 years of age, diagnosed with COVID-19, or have been diagnosed with MIS-C syndrome according to the clinical criteria. After the inclusion, in a period of one year, 5 medical assessments of the state of health are planned to be carried out. In case of specific symptoms, a patient is referred to a specialist.
Results: Currently, ~40 children with their caregivers are included into the program. The median age for inclusion – 9y, 42%-female. Nine children required additional consultation with a pediatric neurologist with the most frequent complaint of headaches. 4 children have ongoing consultations with a psychiatrist and continuous visits are planned. Six children were referred to a pediatric rheumatologist complaining of prolonged joint aches and the assessment regarding autoimmune diseases is ongoing.
Conclusions/Learning Points: Our further plans are to collect more data and analyze the symptoms and signs according to age and gender.

Backgrounds: Down syndrome (DS) leads to alterations in the immune system. Previously, we found that adults with DS have a lower antibody response to routine SARS-CoV-2 mRNA vaccination compared to healthy controls (HC). In this study, we attempted to translate this finding prospectively to children in the PRIDE study.
Methods: Antibody concentrations were measured at baseline (T=1), 21-28 days after first vaccination (T=2) and 28 days (21-42 range) after second vaccination (T=3) by multiplex immunoassay in 5-17 year old children with DS and HC. Previous SARS-CoV-2 exposure was defined by the presence of antibodies against the N protein.
Results: All participants (DS N= 52, HC N= 9) showed a normal increase in antibody concentration after primary SARS-CoV-2 vaccination with age-specific recommended doses. At T=3 there were similar geometric mean antibody concentrations (GMC) in DS (4.6 kBAU/ml) and HC (4.5 kBAU/ml, NS). The GMC in SARS-CoV-2 naïve participants at T=3 was also similar between DS (N=33, 3.4 kBAU/ml) and HC (N=5, 3.9 kBAU/ml, NS). SARS-CoV-2 naïve participants at T=3, showed a higher antibody concentration with increasing age (DS=Pearson r=0.409, p=0.018, HC=Pearson r=0.317, p=0.028).
Conclusions/Learning Points: This is the first report on antibody responses after primary SARS-CoV-2 vaccination (BNT162b2) in children with DS. In contrast to adults with DS, our results show that children with DS are able to produce normal antibody concentrations in response to mRNA vaccination.

DIFFERENCES IN SERUM LEVELS OF MATRIX METALLOPROTEINASES IN CHILDREN WITH COVID-19 AND MULTISYSTEM INFLAMMATORY SYNDROME (MIS-C)

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Artur Sulik[1], Dawid Lewandowski[1], Diana Martonik[2], Marta Sawicka[1], Ewa Bojkiewicz[1], Marta Wozinska[1], Kacper Toczylowski[1]
[1]Medical University of Bialystok, Department Of Pediatric Infectious Diseases, Bialystok, Poland, [2]Medical University of Bialystok, Department Of Infectious Diseases And Hepatology, Bialystok, Poland

Backgrounds: SARS-CoV2 infection in children may rarely manifest with an inflammatory condition classified as multisystem inflammatory syndrome in children (MIS-C). Symptoms of MIS-C are largely similar to Kawasaki disease. MIS-C is characterized by activation of the immune system and extensive damage to the endothelial system. Matrix metalloproteinases (MMPs) and their inhibitors, known as tissue inhibitors of MMP (TIMPs), play central roles in the process of the extracellular matrix synthesis and breakdown. Little is known about the role of MMPs and TIMP in the pathophysiology of MIS-C.
Methods: 16 children with MIS-C and 9 children with acute COVID-19 hospitalized between October 2020 and December 2021 were included in the study. Serum samples were collected on admission. Concentrations of 9 different matrix metalloproteinases, their inducers (TNF-α and EMMPRIN), and 4 tissue inhibitors (TIMP 1-4) were assessed using the microbead-based Luminex assay.
Results: Children with MIS-C had higher concentrations of TIMP-1 (459.2±246.1 vs. 268.0±45.4 ng/mL; p=0.032), TIMP-4 (2.6±0.9 vs. 1.3±0.4 ng/mL; p<0.001), TNF-α (60.5±30.3 vs. 26.7±16.3 pg/mL; p=0.008), MMP-3 (15.7±16.4 vs. 3.4±2.2 ng/mL; p=0.038), and MMP-8 (60.4±42.6 vs. 8.3±5.9 ng/mL; p=0.001), and lower MMP-2 (385.4±103.2 vs. 472.1±95.6 ng/mL; p=0.05), compared to acute COVID-19. The total concentration of TIMP did not differ between the groups. Concentrations of MMP-3 and MMP-8 correlated with TNF-α (respectively: R=0.64, p=0.001; R=0.63, p=0.001).
Conclusions/Learning Points: Inflammatory cytokines stimulate the production of MMP-3 and MMP-8 in MIS-C. MMP-8 was previously shown to promote extravasation of polymorphonuclears from blood vessels during inflammation, whereas MMP-3 causes endothelial injury and accumulation of inflammatory cells in the cardiovascular system. Our findings suggest that MMPs play an important role in the pathogenesis of MIS-C.

PV1040 / #1867

CLINICAL FEATURES OF CHILDREN ADMITTED WITH COVID-19 DISEASE TO A TERTIARY HOSPITAL IN CENTRAL GREECE

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Stavroula Kontogianni[1], Eftychia Svarna[1], Theoni Syrogiannopoulou[2], Michail Papamichalis[3], Evangelia Angeli[1], Ioanna Grivea[1], George Syrogiannopoulos[1]
[1]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department Of Pediatrics, Larissa, Greece, [2]National and Kapodistrian University of Athens, Medical School, Athens, Greece, [3]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department Of Cardiology, Larissa, Greece

Backgrounds: SARS-CoV-2 spread quickly around the world causing a global pandemic. As pediatric patients have been mostly asymptomatic or with mild symptoms, the true prevalence of clinical features of Covid-19 disease in children is underestimated.
Methods: This is a retrospective study of the clinical manifestations and outcome of pediatric patients with SARS-CoV-2 infection admitted to the University General Hospital of Larissa in Central Greece between June 1st 2020 and December 31st 2022.
Results: During the 31-month study period, 581 patients (52.2% male), with a positive SARS-CoV-2 PCR, aged 2 days-17 years (median: 8 months; IQR:2-72 months) were hospitalized and close contact of 405 (69,7%) with ≥1 infected persons within the family or the school, was identified. 51 children (8,8%) had an underlying condition, mainly a chronic neurologic/metabolic disease (15/51). Very young age (neonates, infants), fever, fatigue, or dehydration, and/or the underlying disease were the main reasons for hospitalization. At the time of admission, most patients (559 of the 581 patients) were symptomatic, mainly with mild symptoms of upper respiratory tract system. Four children of those initially asymptomatic exhibited mild symptoms soon after admission. In 261 (44.9%) of those admitted chest x-ray was performed; peribronchial or alveolar infiltrates were revealed only in 15 (5.7%). The median duration of hospitalization was 3 days (IQR: 3-5 days). Favorable outcome of Covid-19 disease was noted in 100% of patients
(Table).

	n/N (%)
Clinical manifestations	
Fever ≥38°C	430/581 (74.0)
Upper respiratory system's symptoms (rhinorrhea or/and nasal congestion)	284/581 (48.9)
Lower respiratory system's symptoms	37/581 (6.4)
Gastrointestinal symptoms (abdominal pain or/and vomiting or/and diarrhea)	139/581(23.9)
Headache reported by children >5 years old	23/167 (13.8)
Severity of the disease	
O_2 supplementation by nasal cannula or mask	14/581 (2.4)
n-CPAP[¶] or high-flow oxygen therapy	2/581 (0.3)
Mechanical ventilation	0
Transfer to I.C.U.[¥]	0
Death	0

[¶]n-CPAP: nasal continuous positive airway pressure; [¥]I.C.U.: intensive care unit

Conclusions/Learning Points: A low severity of Covid-19 disease was observed in hospitalized children. The low frequency of co-morbidities and/or the fact that the immune response to SARS-CoV-2 appears to differ from that of adults, have probably contributed to this observation.

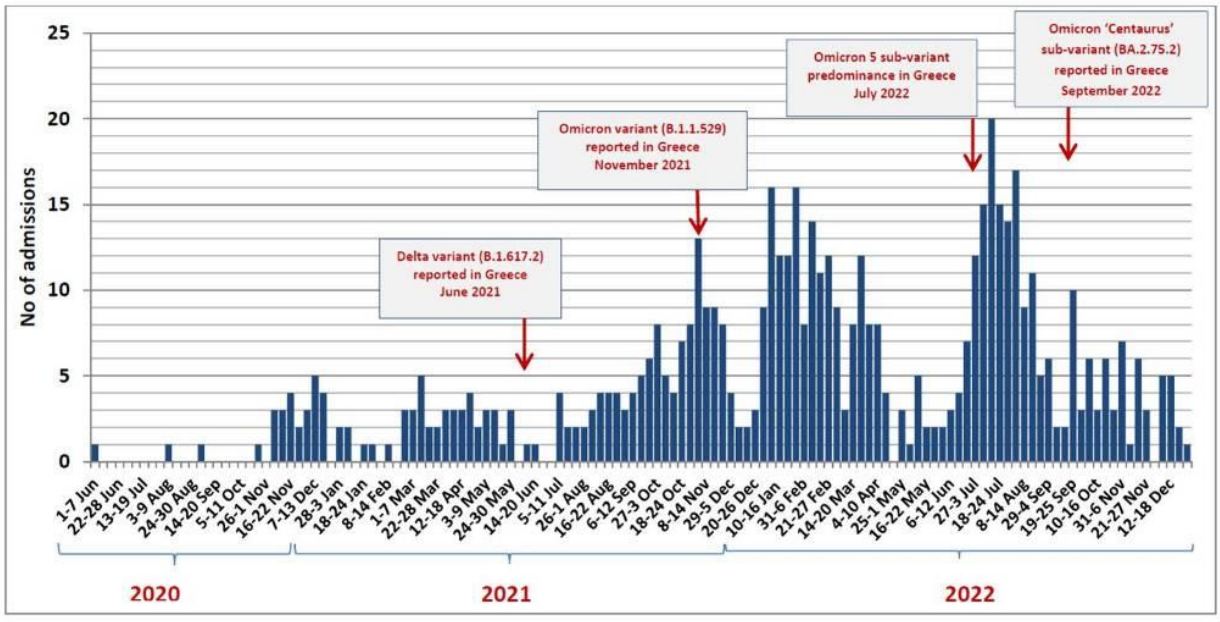
PV1041 / #1989

EPIDEMIC WAVES OF COVID-19 DISEASE AMONG PEDIATRIC PATIENTS IN CENTRAL GREECE FROM JUNE 2020 THROUGH DECEMBER 2022

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Eftychia Svarna[1], Stavroula Kontogianni[1], Theoni Syrogiannopoulou[2], Michail Papamichalis[3], Ioulia Sirina[1], George Syrogiannopoulos[1], Ioanna Grivea[1]
[1]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department Of Pediatrics, Larissa, Greece, [2]National and Kapodistrian University of Athens, Medical School, Athens, Greece, [3]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department Of Cardiology, Larissa, Greece

Backgrounds: Although SARS-CoV-2 infection has predominated in adults, many cases have also been noted in children during the pandemic. The aim was to identify the epidemiological characteristics of pediatric patients admitted with COVID-19 disease between June 1st 2020 and December 31st 2022.
Methods: This is a retrospective study, among children <17 years old, admitted to the University General Hospital of Larissa, in Central Greece, during the first 31 months of SARS-CoV-2 pandemic.
Results: Among 581 patients aged 2 days-17 years old (median=8 months), 303 (52.2%) were male. Age group distribution was: neonates (n=65), 29 days to 5 months (n=194), 6 to 11 months (n=66), 1 to 4 years (n=89), 5 to 11 years (n=90) and ≥12 years old (n=77). The weekly rates of admissions were highest in November 2021, January – February 2022 and July – August 2022 (Figure). In the three consecutive waves, the decision for hospitalization was most frequent among infants 29 days to 5 months old (35.9%, 27.9% and 40.9%
respectively).



Conclusions/Learning Points: During the study period, June 1st 2020 - December 31st 2022, due to SARS-CoV-2 variants and sub-variants spread and extend of the non-pharmacological interventions applied, variability in the incidence of the Covid-19 pediatric admissions incidence was noted. The highest admission rates occurred during Delta and Omicron variants/sub-variants predominance periods.

Backgrounds: Little is understood about which comorbidities are associated with severe outcomes in children hospitalized with acute COVID-19.
Methods: Data from 2 multicenter (116 hospitals) prospective cohort studies of hospitalized children (aged 0-18 years) with confirmed SARS-CoV-2 in Spain and Colombia were combined for this analysis. Outcome was classified as (in decreasing order of severity): death, mechanical ventilation (MV), pediatric intensive care unit (PICU) admission, high flow/CPAP, oxygen therapy with nasal prong (NP) and hospitalization without respiratory support. Risk factors for severity, adjusting for age and gender, were identified using multinominal logistic regression and a backwards selection process.
Results: A total of 1,753 patients were included, 734 (41.8%) in Spain and 1,019 (58.1%) in Colombia. The most frequent comorbidities were asthma (9.0%), chronic neurological disorder (NRL) (7.4%), immunosuppressive medication (7.2%), malignant neoplasms (5.4%) and chronic lung disease (not asthma) (CLD) (4.5%). Asthma was associated with a significantly increased risk of death (OR: 4.17; 95%CI 1.34-12.97), MV (OR: 7.94 (3.59-17.56)), PICU admission (OR: 3.37 (1.91-5.96)), high flow/CPAP (OR: 6.65 (2.69-16.46)), and NP (OR: 3.85 (2.57-5.77)) compared to hospitalization without respiratory support. NRL was associated with increased risk of death (OR: 7.34 (3.01-17.90)), MV (OR: 3.07 (1.20-7.82)) and high flow/CPAP (OR: 4.36 (1.68-11.29)). CLD was associated with increased risk of death (OR: 6.22 [2.28-16.94]) and NP (OR: 3.1 (1.74-5.58)) and in addition, chronic cardiac disease was associated with increased risk of MV (OR: 5.21 (1.76-15.41)) and PICU (OR: 2.78 (1.27-6.08)). Risks of death (OR: 4.49 (2.03-9.05)), MV (OR: 2.97 (1.52-5.81)), PICU (OR: 4.27 (2.89-6.33)), and NP (OR: 4.67 (3.64-5.99)) were higher in the Colombia
Cohort.

Comorbidity	Death	MV	PICU	CPAP/High flow therapy	O2
Chronic cardiac disease	1.36 [0.29;6.49]	5.21 [1.76;15.41]	2.78 [1.27;6.08]	3.28 [0.87;12.32]	1.73 [0.92;3.26]
Chronic pulmonary disease	6.22 [2.28;16.94]	2.60 [0.73;9.22]	1.14 [0.41;3.17]	2.97 [0.83;10.59]	3.12 [1.74;5.58]
Asthma or recurrent wheezing	4.17 [1.34;12.97]	7.94 [3.59;17.56]	3.37 [1.91;5.96]	6.65 [2.69;16.46]	3.85 [2.57;5.77]
Chronic neurological disorder	7.34 [3.01;17.90]	3.07 [1.20;7.82]	1.52 [0.79;2.96]	4.36 [1.68;11.29]	1.10 [0.68;1.76]
Malignant Neoplasm	5.03 [2.09;12.12]	0.00 [-;-]	1.15 [0.59;2.21]	1.00 [0.22;4.41]	0.15 [0.06;0.37]
Chronic hematologic disease	2.67 [0.85;8.37]	1.44 [0.32;6.40]	0.68 [0.27;1.69]	0.75 [0.10;5.86]	0.35 [0.15;0.80]
Diabetes	2.99 [0.29;30.70]	0.00 [0.00;0.00]	5.67 [1.84;17.47]	0.00 [-;-]	1.19 [0.33;4.24]

Conclusions/Learning Points: Asthma, chronic neurological disease and belonging to the Colombia cohort were associated with multiple severe outcomes of COVID-19.

A GOOD PROGNOSIS ASSOCIATED WITH ACUTE MYOCARDITIS DUE TO MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN (MIS-C) FOLLOWING SARS-COV-2 INFECTION IN CRITICALLY ILL PRESENTING CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Gajanand Singh Tanwar, Divya Mohta, Palak Patel, Sushil Bana, Meenakshi Rani, Shanta Choudhary
S. P. Medical College,, Pediatrics, BIKANER, India

Backgrounds: Acute myocarditis with intense systemic infammation is an emerging severe pediatric disease following SARS-CoV-2 infection as a common component of multisystem inflammatory syndrome in children (MIS-C). Early and prompt recognition of this disease is needed and referral to an expert center is recommended.
Methods: This prospective cohort study was conducted from September 2020 to August 2021. The MIS-C myocarditis was defined as per the Centers for Disease Control and Prevention case definition of MIS-C. The ethical committee approval for the study and informed consent from the parents and attendants had been obtained as per regulations.
Results: We encountered 9 children admitted to PICU with shock. The chief complaints were high grade fever (n=9), breathlessness (n=9), intense abdominal pain (n=8), skin rash (n=4), conjunctivitis (n=4); oral mucosal congestion (n=3); adenitis (n=2). All children had highly elevated C-reactive protein (97.8 ± 32.4 mg/dl), ESR (46.2 ± 22.2 mm) and procalcitonin (6.8 ± 2.4 ng/mL). The most prominent hematologic derangements were lymphopenia with leukocytosis, thrombocytopenia, and anemia. 2D echocardiography showed acute myocarditis (mean left ventricular ejection fraction, 38.2 ±10.4%; troponin I, 369.8 ± 204.6 ng/ml; and NT –pro BNP, 1932.4 ± 986.6 pg/mL) and pericardial effusion (n=6/9; 66.6%). SARS-CoV-2 PCR was positive in 4 children while 5 had positive serology. All children needed vasoactive drug support. All children received intravenous immunoglobulin with adjuvant corticosteroids. All children survived and were afebrile with a full left ventricular function recovery at PICU discharge on 14.8±4.4 days.
Conclusions/Learning Points: Compared with classic myocarditis, children with MIS-C had a greater likelihood of full recovery of cardiac function with a faster time, even when they presented with more fulminant course.

PV1044 / #168

ANTIBODY RESPONSE IN CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME RELATED TO COVID-19 (MIS-C) COMPARED TO CHILDREN WITH UNCOMPLICATED COVID-19

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Anaïs Thiriard[1], Benjamin Meyer[2], Christiane Eberhardt[2], Natasha Loevy[3], Serge Grazioli[3], Arnaud L'Huillier[3], Claire-Anne Siegrist[3], Arnaud Marchant[1], Arnaud Didierlaurent[3], Géraldine Blanchard Rohner[4]
[1]Université Libre de Bruxelles, Institute Of Medical Immunology, Brussels, Belgium, [2]center for vaccinology, Pathology And Immunology, Geneve, Switzerland, [3]University Hospitals of Geneva, Department Of Woman, Child And Adolescent, Genève, Switzerland, [4]University Hospitals of Geneva, Department Of Woman, Child And Adolescent, Genève, Switzerland

Backgrounds: The exact cause leading to MIS-C remains unclear. In this study, we analyzed the quality of the antibody response between children with MIS-C and age-matched controls one month after SARS-CoV-2 exposure.
Methods: Serum from 20 MIS-C children at admission, and 14 control children were analyzed. Antigen specific antibody isotypes and subclasses directed against various antigens of SARS-CoV-2 as well as against human common coronavirus (HCoVs) and commensal pathogens were assessed by a bead-based multiplexed serological assay and by ELISA. The functionality of these antibodies was also assessed using a plaque reduction neutralization test, an RBD-specific avidity assay, a complement deposition assay and an antibody-dependent neutrophil phagocytosis (ADNP) assay.
Results: Children with MIS-C developed a stronger IgA antibody response in comparison to children with uncomplicated COVID-19, while IgG and IgM responses are largely similar in both groups. We found a typical class-switched antibody profile with high level of IgG and IgA titers and a measurable low IgM due to relatively recent SARS-CoV-2 infection (one month). SARS-CoV-2-specific IgG antibodies of MIS-C children had higher functional properties (higher neutralization activity, avidity and complement binding) as compared to children with uncomplicated COVID-19. There was no difference in the response to common endemic coronavirus between both groups. However, MIS-C children had a moderate increase against mucosal commensal and pathogenic strains, reflecting a potential association between a disruption of the mucosal barrier with the disease.
Conclusions/Learning Points: Even if it is still unclear why some children develop a MIS-C, we show here that MIS-C children produce higher titers of IgA antibodies, and IgG antibodies with higher functionality, which could reflect the local gastro-intestinal mucosal inflammation potentially induced by a sustained SARS-CoV-2 gut infection leading to continuous release of SARS-CoV-2 antigens.

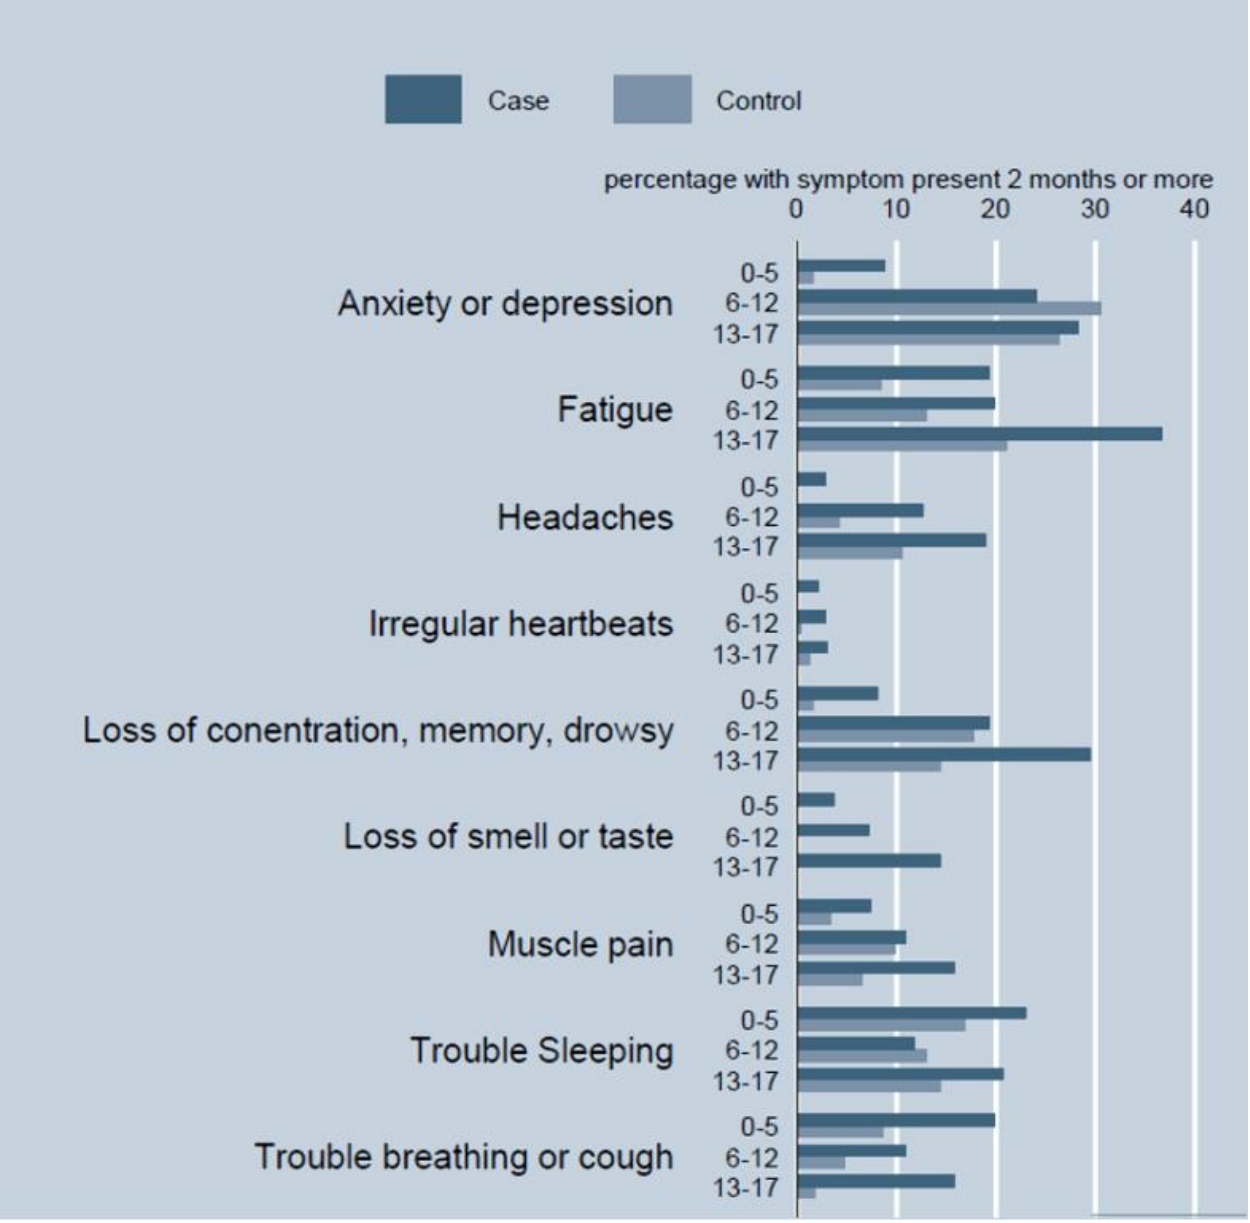
LONG COVID IN ICELANDIC CHILDREN

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Valtyr Thors[1], Asgeir Haraldsson[2], Thorvardur Love[3]
[1]Children´s Hospital Iceland, Infectious Diseases, Reykjavik, Iceland, [2]Children´s Hospital Iceland, Immunology, Reykjavik, Iceland, [3]Landspitali University Hospital, Internal Medicine, Reykjavik, Iceland

Backgrounds: Paediatric SARS-CoV-2 infections are usually mild but long term complications have been recognised and may include neurological sequalae but also “Long-COVID syndrome” has been described. These symptoms may be severe and significantly impact the quality of life of children of all ages.
Methods: We obtained identifiers of all 837 Icelandic children who were diagnosed with SARS-CoV-2 by PCR between March 2020, and June 2021. We asked about the presence of at least twice weekly of ten physical and mental symptoms and if any symptoms had been present we asked about the duration and severity of symptoms (a little, somewhat, much). For all subjects who completed the questionnaire, an age and sex matched control without SARS-CoV-2 infection, was found through the National citizen registry - Iceland.
Results:



Responses from 601 cases and controls were analysed. Overall, children who had been infected with SARS-CoV-2 were more likely to report any symptoms apart from anxiety/depression where there was no difference. Fatigue and loss of concentration was evidently more common in cases than controls among teenagers (37 vs 21% and 29 vs 15%, both $p<0.05$). In all comparisons more participants in the COVID group reported more severe symptoms and this difference was significant for fatigue, headaches, muscle pain and breathing difficulties. Also of the children reporting long lasting symptoms >70% report them as severe or somewhat severe. No associations between Ct-values at diagnosis and Long-COVID symptoms were found.

Conclusions/Learning Points: To conclude, symptoms of Long COVID in children are evident and are likely to impact the quality of life of millions of children. The importance of further unravelling the pathophysiology of acute and long term symptoms of the disease in children is very important as well as potential preventive measures.

Joseph Tonge[1], Olivia Stevens[1], Jeremy Dawson[2], Daniel Hawley[3], Caroline Kerrison[4], Nils Krone[5], Sarah Maltby[3], Anne-Marie Mcmahon[3], Fiona Shackley[4], Rupa Talekar[6], Carmen Gonzalez-Martinez[4], Neil Lawrence[5]
[1]University of Sheffield, The Medical School, Shefffield, United Kingdom, [2]The University of Sheffield, Management School, Sheffield, United Kingdom, [3]Sheffield Children's NHS Foundation Trust, Paediatric Rheumatology, Sheffield, United Kingdom, [4]Sheffield Children's NHS Foundation Trust, Infectious Diseases & Immunology, Sheffield, United Kingdom, [5]University of Sheffield, Oncology & Metabolism, Sheffield, United Kingdom, [6]Sheffield Children's NHS Foundation Trust, Paediatric Cardiology, Sheffield, United Kingdom

Backgrounds: The relationship between inflammatory markers and anti-inflammatory medication in Paediatric inflammatory multisystem syndrome temporarily associated with SARS-CoV-2 infection (PIMS-TS) is unknown. We sought to investigate the relationship between demographics, biomarkers, treatment, and length of stay (LOS) in this novel disease.
Methods: We reviewed the case notes and investigations of all patients that met the Royal College of Paediatrics diagnostic criteria for PIMS-TS at a large tertiary centre in the United Kingdom. Biomarker trajectories were modelled using log linear mixed effects, and factors affecting LOS were evaluated using multiple regression.
Results: Between March 2020 and May 2022, 56 patients attended Sheffield Children's Hospital with PIMS-TS, 70% male. Mean age was 7.4 ± 3.7 years and mean LOS 8.7 ± 4.5 days with 50% requiring intensive care and 20% requiring inotropes. Older males had shorter LOS than younger males (p=0.04), not seen in females. Treatment included intravenous glucocorticoids in 93%, intravenous Immunoglobulins in 77%, Anakinra in 11% and infliximab in 1.8%. Biomarkers correlated poorly with trajectories that peaked at different times. C-reactive protein peaked first after median 1.3 days post-admission: amylase last after 5.1 days. Age had a large effect on some biomarkers, with older children having larger troponin and ferritin, and lower lymphocytes and platelets. Cumulative dose of glucocorticoids and IVIG had a statistically significant effect on some biomarkers, but effect size was small.
Conclusions/Learning Points: The heterogenous nature of PIMS-TS highlights the importance of a multidisciplinary approach. Worse inflammatory markers in older children may be an indication of a different disease process occurring at different ages. Future work to investigate the association between age and troponin and ferritin in hyperinflammatory states is warranted.

Title of Case: Extensive cerebral venous sinus thrombosis in a child after presumed SARS-CoV-2 infection
Background: Several guidelines concerning SARS-CoV-2 thromboembolic complications in adult patients have been published whereas data in children are limited. Molecular pathways and coagulation dysregulations have been proposed which differ among adult and paediatric patients.
Case Presentation Summary: A previously healthy 4-year old boy, with no family medical history, was admitted to the ER due to a five day frontal headache associated with emesis. A febrile upper respiratory infection preceeded ten days prior to his admission. At the ER, the patient was dehydrated and was suffering from intense headache. The urgent fundoscopy revealed bilateral papilledema with normal visual acuity. Opening CSF pressure was elevated. MRI venography revealed extensive thrombosis of the left sigmoid and transverse sinus, the upper part of the left jugular vein, the superior and inferior parts of sagittal sinus and the straight sinus. Regarding admission labs, D-dimer and fibrinogen were elevated with otherwise normal coagulation parameters and negative inflammatory markers. A subsequent work up of thrombophilia identified an homozygous state of MTHFR (C677T) mutation. SARS-CoV-2 PCR on admission was negative but IgG SARS-CoV-2 S protein value was particularly high,indicative of recent infection. He received acetazolamide for 3 months and tinzaparine for 7 months, with complete resolution of his symptoms. Control brain MRI showed partial venous recanalization and patient remains asymptomatic at the one-year follow up.
Learning Points/Discussion: Except in the MIS-C, unlike adults, thrombotic complications seem uncommon in children with SARS-CoV-2. To our knowledge, this is the first case of severe extended brain venous thrombosis presented in a child with MTHFR mutation after SARS-COV-2 infection Further studies are needed to define thrombotic risk factors among children with COVID-19 in order to develop specific guidelines.

EVALUATION OF THE IMMUNE RESPONSE TO MRNA VACCINES AGAINST COVID-19 IN HIGH-RISK PEDIATRIC POPULATIONS: A NARRATIVE REVIEW OF THE CURRENT LITERATURE AND FUTURE PROSPECTS

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Panagiota Tsagkli[1], Ioanna Papadatou[1], Theano Lagousi[1,2], Maria Geropeppa[1], Vana Spoulou[1,2]
[1]National and Kapodistrian University of Athens, Immunobiology And Vaccinology Research Laboratory, First Department Of Paediatrics, Athens, Greece, [2]"Agia Sophia" Children's Hospital, Athens, Greece, First Department Of Pediatrics, University Of Athens, Athens, Greece

Background: Immunocompromised children/adolescents may be in higher risk for severe COVID-19 and related complications because of immune system's suppression attributable to the primary disease or concurrent treatment. Novel mRNA-vaccines against SARS-CoV-2 have played a key-role in protection. However, data on the immune-response to COVID-19-vaccines in this population remain scarce.
Methods: A PubMed search was performed to identify studies that include evaluation of humoral/cellular immunity to mRNA-vaccines against SARS-CoV-2 in immunocompromised children-adolescents. Key-words such as "Covid-19", "vaccination", "immunogenicity", "cellular", "immunity", "immunocompromised" were used.
Results: A total of 27 studies were identified:8/27 on patients with inflammatory-bowel-diseases(IBDs), 7/27 with rheumatic-diseases(RDs), 6/27 on solid-organ-transplant-recipients, 3/27 with solid/hematological malignancy, 2/27 on ART-treated-HIV patients and 1/27 with IEIs. Regarding humoral immunity, 20/27 studies measured anti-spike-IgGs and 8/27 neutralizing-antibodies. Two doses were immunogenic in most groups. Solid-organ-transplant-recipients displayed the highest proportion of non-responders, but seroconversion was established after a 3rd dose. High antibody-titers elicited in patients with IBDs and RDs on immunosuppressive-therapy, approximately 1month post 2nd dose. However, 5/15 studies have highlighted the combined therapy of an anti-TNFα+MMF/methotrexate as a risk-factor for a significantly reduced immune response compared to monotherapy. Five studies evaluated the durability of humoral-immunity and demonstrated a significant waning at 3-6months-post 2nd dose. Cellular immunity was examined in 4/27 studies by ELISPOT(n=3/4) and flow-cytometry(n=1/4). Cellular response had not significant differences in patients with RDs on anti-TNF±MTX compared to healthy-controls. Solid-organ-transplant-recipients, malignancy-patients on intensive chemotherapy and ART-treated-HIV-patients showed a suboptimal cellular-response indicating the need for additional doses.
Conclusions/Learning Points: mRNA COVID-19 vaccines induce high antibody responses in most high-risk children/adolescents at 1month post a 2-dose-schedule. However, antibodies may wane rapidly and cellular immunity is attenuated in severe immunosuppression. A booster dose may offer additional protection in these patients at risk.

[1]UNIVERSITY OF ATHENS, 1st Gencological Clinik, ATHENS, Greece, [2]MEDICAL SCHOOL OF SHEFFIELD, Medical School, Sheffield, United Kingdom

Background: BACKGROUND: The aim of the study was to study the relation of Vaccination coverage rate of COVID-19 vaccine in pregnancy with the Flu vaccination and Pertussis coverage rate in Pregnancy during the last season of Influenza (1 October 2022 -28 February 2023)
Methods: METHOD : The present study is a prospective cross-sectional study conducted in the last Flu season from October 1, 2022, until March 2023 to 200 pregnant women receiving prenatal care at a tertiary University Hospital. Data was gathered through a face-to-face questionnaire.
Results: The vaccination coverage rate against COVID -19 was 54 %. The Influenza vaccination coverage rate was 65% and the pertussis vaccination coverage rate was 8%. We investigated the relation of Covid-19 Vaccination with the acceptance of Influenza and pertussis vaccination in pregnancy. Vaccination against influenza during past pregnancy was statistical significantly positively associated with vaccination against Covid -19 ($p < 0.001$) and vaccination in present pregnancy was also significant at level $p < 0.001$.Vaccination against pertussis during present pregnancy was statistical significantly positively associated with vaccination against Covid -19($p < 0.001$)
Conclusions/Learning Points: Conclusion: In conclusion we need to improve the face-to-face communication with pregnant women, focusing more on safety and effectiveness data, sharing information about surveillance programs, using clinical experience from other maternal vaccination, and presenting the benefits from vaccination to the mother and the offspring.

Backgrounds: The acute presentation of PIMS-TS is now well known, but data on longer term outcome, particularly cardiac, are scarce.
Methods: This national prospective observational cohort study includes children less than 18 years of age who were hospitalised with PIMS-TS in Switzerland between 03.2020 and 03.2022. Data was recorded from 29 paediatric hospitals through the Swiss Paediatric Surveillance Unit (SPSU) during hospitalisation and six weeks after discharge. Data was analysed stratified into three groups according to admission to intensive care unit (ICU) (non-ICU, ICU-moderate) and requirement of invasive ventilation and/or inotropic support (ICU-severe).
Results: 204 children were included of whom 194 (95.1%) had follow-up data available. Median age was 9.0 (IQR 6.0 to 11.5) years and 142 (69.6%) were male. 105 (51.5%) required ICU admission, of whom 55 (52.4%) were in the ICU-severe group. Echocardiography was performed in 201 (98.5%) children; 132 (64.7%) had a cardiac abnormality including pericardial effusion (50 [24.9%]) and mitral valve regurgitation (60 [29.9%]). Left ventricular systolic dysfunction was present at admission in 62 (30.8%) children and appeared during hospitalisation in 11 (5.5%) children. Coronary artery abnormality was detected at admission in 29 (14.2%) children and developed during hospitalisation or at follow-up in 13 (6.5%) and three (1.5%), respectively. None of the children had left ventricular systolic dysfunction at follow-up, but coronary abnormality and pericardial effusion were found in 12 (6.6%) and 3 (1.7%) children, respectively. School absenteeism at follow-up was more frequent in ICU-moderate (10.4%) and ICU-severe group (17.6%) compared to non-ICU group (2.5%) (p-value 0.011).
Conclusions/Learning Points: Irrespective of initial severity, rapid resolution of left ventricular systolic dysfunction is observed. Most coronary artery aneurysms regress, however, some are still present at follow-up, emphasising the need for prolonged cardiac evaluation.

REKAMLATINA NETWORK AND MIS-C IN LATIN AMERICA: THE ROLE OF A PEDIATRIC INFECTIOUS DISEASE NETWORK FROM THE SOCIEDAD LATINOAMERICANA DE INFECTOLOGIA PEDIATRICA (SLIPE) DURING COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Rolando Ulloa-Gutierrez[1], Gabriela Ivankovich-Escoto[2], Pio López[3], Roberto Debbag[4], Maria Avila-Aguero[1], Adriana Tremoulet[5], The Rekamlatina-3 Study Group Investigators[6]
[1]Hospital Nacional de Niños Dr. Carlos Sáenz Herrera, Servicio De Infectologia Pediatrica, San Jose, Costa Rica, [2]Hospital Nacional de Niños "Dr. Carlos Sáenz Herrera", Servicio De Inmunología Y Reumatologia Pediatrica, San Jose, Costa Rica, [3]Universidad del Valle, Centro De Estudios En Infectología Pediatrica Ceip.department Of Pediatrics, Cali, Colombia, [4]Sociedad Latinoamericana de Infectología Pediátrica, Slipe, Santo Domingo, Argentina, [5]Rady Children's Hospital and University of California San Diego, La Jolla, California, Department Of Pediatrics, La Jolla, United States of America, [6]Sociedad Latinoamericana de Infectología Pediátrica, Slipe, Santo Domingo, Dominican Republic

Backgrounds: A decade ago, REKAMLATINA (Red de Enfermedad de Kawasaki en América Latina) was launched to study the epidemiology of Kawasaki disease (KD) in Latin America (LA). The main core of this research group has been pediatric infectious disease specialists from SLIPE. The objective of this work is to describe the role of a multinational multispecialties network during COVID-19 pandemic in the surveillance of pediatric Multisystem Inflammatory Syndrome (MIS-C).
Methods: A retrospective and prospective descriptive study of hospitalized children and adolescents with MIS-C was undertaken and continues at the main referral pediatric and general hospitals in Latin America. Researchers were invited to participate through personal communications, research groups databases, e-mails from SLIPE and other participant societies, webinars, lectures, Twitter and other social platforms. Approval by an ethics research committee was required from each site.
Results: From Jan-1-2020 to Dec-31-2022 a total of 1,425 children have been enrolled at 86 main pediatric referral and general hospitals of 18 LA countries. Major enrollment by country has been the following: Mexico (34.1%), Colombia (16.1%), Argentina (8.6%), Peru (8.4%), Panama (7.1%), Brasil (4.7%), Honduras (4%), and Costa Rica (3.4%)pts, among others. Among 269 participant researchers, the following background was identified: pediatric infectious disease specialists and fellows, 90(33.4)% and 4(1.5)% respectively; pediatric cardiology 53(19.7%); pediatricians 32(11.9%); pediatric rheumatology 26(9.7%); pediatric critical care 22(8.2%); pediatric emergency 6(2.2%); and pediatric immunology 7(2.6%); among others.
Conclusions/Learning Points: REKAMLATINA is one of the largest multinational multicenter multispecialty networks studying KD and MIS-C in children and adolescents. Having a multidisciplinary solid research network of this kind before the pandemic, allowed us to integrate promptly and study better the behavior of a life-threating, newly discovered, and uncommon condition such as MIS-C.

OPINIONS AND ATTITUDES TOWARDS SARS-COV-2 VACCINATION IN EIGHT SOUTH AMERICAN COUNTRIES

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Analia Urueña[1,2], Ricardo Machado[3], Juarez Cunha[3], Clara López Colmano[2], Carolina Rancaño[2], Renato Kfouri[3], Catalina Pírez[4], Pablo Bonvehí[2,5], Mario Calvo[6], Robinson Cuadros[7], Greta Muñoz[8], Mónica Rodríguez[9], Jaime Torres[10], Florencia Cahn[2], Isabella Ballalai[3]
[1]Universidad Isalud, Centro De Estudios Para La Prevención Y Control De Enfermedades Transmisibles, Ciudad Autónoma de Buenos Aires, Argentina, [2]Sociedad Argentina de Vacunología y Epidemiología, Save, Ciudad Autónoma de Buenos Aires, Argentina, [3]Sociedade Brasileira de Imunizações, Sbim, São Paulo, Brazil, [4]Sociedad Uruguaya de Pediatría, Comité De Infectología Y Vacunas, Montevideo, Uruguay, [5]Hospital Universitario CEMIC, Servicio De Infectología, Ciudad Autónoma de Buenos Aires, Argentina, [6]Universidad Austral de Chile, Profesor Asociado, Santiago de Chile, Chile, [7]Asociación Internacional de Gerontología y Geriatría, Comité Latinoamericano Y Del Caribe, Bogotá, Colombia, [8]Sociedad Ecuatoriana de Pediatría, Sep, Quito, Ecuador, [9]Instituto de Previsión Social, Hospital Central, Asunción del Paraguay, Paraguay, [10]Universidad central de Venezuela, Profesor, Caracas, Venezuela

Backgrounds: During 2022, 2 years after the Covid-19 Pandemic was declared, SARS-CoV-2 continued mutating and representing a public health concern in South America and globally. Although vaccination was available and demonstrated to be the most effective tool to prevent severe forms and deaths, adherence was still incomplete, and misinformation and doubts persisted. This research aimed to analyze opinions and attitudes towards SARS-CoV-2 vaccination and the factors that influence its acceptance or rejection in eight South American countries.
Methods: A cross-sectional study was performed through an online self-administered questionnaire to 6555 participants >15 years old from Argentina, Brazil, Chile, Colombia, Ecuador, Paraguay, Uruguay, and Venezuela during February-April 2022. Sample was stratified by regions and age groups (15-19;20-29;30-39;40-49;50-59;>60) and weighted to express the real population proportionality of each segment and country in the global context of the study.
Results: Overall, respondents agreed that Covid-19 vaccines were necessary (86.4%), effective (79.8 %), and safe (79.1 %). Additionally, 64 % agreed vaccination should be mandatory. The agreement was lowest and highest among Chilean and Brazilian respondents, respectively (53.3%, 50.9%, 49.4%, 40.3% and 92.2%, 83.2%, 82.7%, 72.5% regarding necessity, safety, effectiveness and mandatory, respectively). Of the total, 83.4% accepted vaccination and received at least one dose, 12.3% refused it completely, and 3.2% preferred not to complete vaccination. Main rejection reasons were safety (65.8%), efficacy (54.9%), and rushed development and approvals (49.1%). Three most used sources of information regarding Covid-19 pandemic were social networks (52.8%), TV/radio (51.7%) and portal news (47.8%).
Conclusions/Learning Points: Although vaccine confidence remains high in this South American sample, a significant proportion remains reluctant. Communication campaigns in social networks stressing safety issues are key since they are the main source of information and concern among hesitant people.

SARS-COV-2 INFECTION IN CHILDREN AND ADOLESCENTS WITH COMORBIDITIES

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Joana Vasconcelos[1], Beatriz Andrade[1], Filipa Durão[2], Pedro J. Miguel[1], Miguel Palha[3], Filomena Pereira[4], Filipa Prata[5], Ana Mouzinho[5], José Gonçalo Marques[5]
[1]Centro Hospitalar Lisboa Norte, Paediatric Department, Lisboa, Portugal, [2]Centro Hospitalar Lisboa Norte, Paediatric Nephrology And Renal Transplantation Unit, Lisboa, Portugal, [3]Child Development Centre, DiferenÇas, Lisboa, Portugal, [4]Portuguese Oncology Institute of Lisbon Francisco Gentil, Paediatric Department, Lisboa, Portugal, [5]Centro Hospitalar Lisboa Norte, Paediatric Infectious Diseases And Immunodeficiencies Unit, Lisboa, Portugal

Backgrounds: New drugs already approved for risk groups for severe COVID-19 lack evidence of clinical benefit in paediatrics. It's important to increase the knowledge about the clinical course of SARS-CoV-2 infection in those groups. Objectives: To characterize SARS-CoV-2 infections in paediatric at-risk groups for severe COVID-19, according to vaccination and previous infection history.
Methods: Retrospective longitudinal observational study of patients <18 years-old with SARS-CoV-2 infection and comorbidities considered at risk for severe illness. Data was collected through a paper-questionnaire.
Results: Seventy-two patients were included: 51.4% female; average age 12 years; 55.6% under immunosuppressive therapy, 31.9% with solid organ transplant, 23.6% neoplasia, 20.8% under renal replacement technique, 12,5% obesity, 12.5% Down syndrome, 11.1% HIV-positive, and 9.7% with hemodynamically significant heart disease. No patient received pre-exposure prophylaxis and 65% had been vaccinated. Diagnosis was done from January 2022 onwards in 78%, when the most predominant strains in circulation were OMICRON_BA.1, BA.2 and BA.5_non_BQ.1. Average symptom duration was 3 days [0-17 days]; 81.9% had mild to moderate disease; one patient had severe infection (16y, acute myeloid leukaemia, pneumonia with hypoxemia, previously vaccinated) and the remaining cases were asymptomatic (33,3% previously vaccinated). Change in regular medication was performed in 8.3%; 6.9% had decompensation of their chronic disease; 4.2% were hospitalized. There were no reported admissions to ICU, deaths or sequelae. There were 11 cases of reinfection (mild symptoms, no change in regular medication or hospitalization).
Conclusions/Learning Points: SARS-CoV-2 infection was not severe in 98.6% of our 72-case series of children and adolescents that are considered at risk for severe disease, irrespective of vaccine status, and reinfection was mildly symptomatic. More comprehensive knowledge of the disease in children should be obtained before recommending monoclonal antibodies and antivirals in this age group.

CLINICAL PRESENTATION AND OUTCOME OF ACUTE RESPIRATORY ILLNESSES IN SOUTH AFRICAN CHILDREN DURING THE COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Andrew Redfern[1], Marieke Van Der Zalm[2], Juanita Lishman[1], Pierre Goussard[1], Liezl Smit[1], Ron Dagan[3], Mm Barday[1], Minette Mare[1], Gert Van Zyl[4], Matilda Claasen[4], Helena Rabie[1], Lilly Verhagen[1,5]
[1]Stellenbosch University, Department Of Paediatrics, Cape Town, South Africa, [2]Stellenbosch University, Desmond Tutu Tb Centre, Paediatrics And Child Health, Cape Town, South Africa, [3]Ben-Gurion University of the Negev Faculty of Health Sciences, The Shraga Segal Dept. Of Microbiology, Immunology And Genetics, Beer Sheva, Israel, [4]Stellenbosch University, Division Of Medical Virology, Cape Town, South Africa, [5]Radboud University Medical Center, Section Of Pediatric Infectious Diseases,, Nijmegen, Netherlands

Backgrounds: Data from low- and middle-income countries (LMICs) show higher morbidity and mortality in children with acute respiratory illness (ARI) from Severe Acute Respiratory Syndrome Coronavirus – 2 (SARS-CoV-2). However, whether SARS-CoV-2 infection is distinct from other causes of ARI in this regard is unclear. We describe clinical characteristics and outcomes of South African children with SARS-CoV-2 and non SARS-CoV-2 ARIs.
Methods: We performed a cross-sectional study including children aged 0-13 years admitted to Tygerberg Hospital in Cape Town, South Africa, between May and December 2020 with an ARI. All children underwent SARS-CoV-2 polymerase chain reaction (PCR) testing. Multivariable logistic regression models were built to determine factors associated with SARS-CoV-2 infection and severity.
Results: Data for 176 children were available, 38 (22%) children were SARS-CoV-2 PCR positive and 138 (78%) were negative. SARS-CoV-2 positive children were more likely to be female (OR 2.68, 95% CI 1.18-6.07), had lower weight for age Z scores (OR 0.76, 95% CI 0.63-0.93), presented more frequently with fever (OR 3.56 95% CI 1.54-8.24), and less often with cough (OR 0.27 95% CI 0.11-0.66). SARS-CoV-2 infection was associated with significantly longer duration of oxygen treatment (median 8 vs 3 days, OR 1.1, 95% CI 1.01-1.20). Overall, 66% of children had viral co-infection, with no significant difference between groups. In total, 18% of SARS-CoV-2 positive children were readmitted within 3 months for a respiratory reason, compared to 15% SARS-CoV-2 negative (p 0.64).
Conclusions/Learning Points: ARIs from SARS-CoV-2 were associated with a higher morbidity compared to ARIs from other causes in South African children. The long-term implications of severe SARS-CoV-2 pneumonia in young children in LMICs requires further study.

SAFETY OF COVID-19 VACCINATION IN CHILDREN PREVIOUSLY HOSPITALIZED BY MULTISYSTEM INFLAMMATORY SYNDROME

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Rodolfo Villena[1], Karina Saravia[1], Josefina Hojman[1], Javier Troncoso[1], Paula Leal[2], Cecilia Piñera[1], Giannina Izquierdo[1]
[1]Universidad de Chile, Infectious Diseases, Santiago, Chile, [2]Hospital de niños Dr Exequiel González Cortés, Infectious Diseases, Santiago, Chile

Backgrounds: Multisystem inflammatory syndrome associated to Covid-19 (MIS-C) is one of the most severe manifestations of SARS-Cov-2 in children. Covid-19 vaccines safety after MIS-C have not been fully evaluated. Chile implemented a vaccination strategy in children using inactivated and/or mRNA platforms. The aim of this study was to describe the safety of Covid-19 vaccination in children with a history of MIS-C
Methods: Descriptive study of unvaccinated subjects at the time of MIS-C diagnosis, admitted in the 2020-2022 period at a tertiary children's hospital. Clinical, vaccination and safety data were obtained from medical and national immunization records; and a standardized interview with parents.
Results: 50 patients were enrolled, median age 5.2 years, 58% males, 38% had comorbidities, 68% required PICU admission, 82% received at least 1 dose of a Covid-19 vaccine, 70% 2, 46% 3, and 8% 4 doses. For priming and booster doses, vaccine platforms were 92% inactivated and 87% mRNA, respectively. Median time between MIS-C onset and first dose was 15 months (0-24); 1 month between 1^{st}-2^{nd} doses; 6.2 months between 2^{nd}-3^{rd}; and 5 months between 3^{rd}-4^{th} doses. No serious adverse events were reported in no doses for priming nor for boosters. Any adverse events were reported in 27% of subjects, all of them were mild and self-limited (fever, headache, myalgias, gastrointestinal, itching and rash) mainly with 1st dose. MIS-C symptoms like fever for >3 days, gastrointestinal or rash were reported in 14.6%, 24.3% and 4.8% respectively, without recurrence of MIS-C
Conclusions/Learning Points: Covid-19 vaccination was safe in patients with history of MIS-C, regardless of age, clinical manifestation or evolution, type of vaccine and interval between the disease and the vaccination. No recurrence of MIS-C was reported.

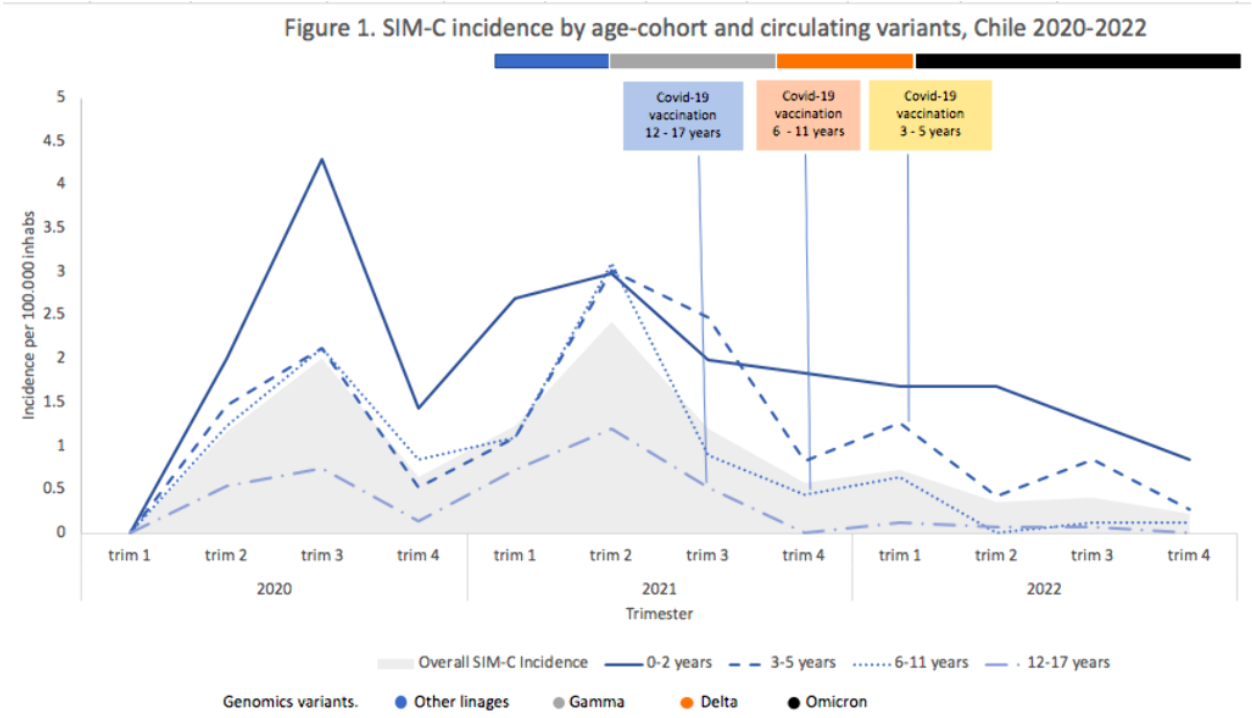
PV1056 / #866

DYNAMICS OF MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN ASSOCIATED TO COVID-19 IN CHILE: EPIDEMIOLOGIC TRENDS DURING PANDEMIC AND AFTER CHILDREN VACCINATION

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Rodolfo Villena[1], Giannina Izquierdo[2], Juan Pablo Torres[1], Jan Wilhelm[3], Pia Riquelme[4], Marco Acuña[4], Christian Garcia[4], Sylvina Alvarado[4]
[1]Universidad de Chile, Infectious Diseases, Santiago, Chile, [2]Universidad de Chile- Hospital Barros Luco Trudeau - Hospital Exequiel Gonzalez Cortés, Infectious Diseases Unit, Santiago, Chile, [3]Hospital de niños Dr Luis Calvo Mackenna, Infectious Diseases, Santiago, Chile, [4]Ministry of Health, Epidemiology, Santiago, Chile

Backgrounds: Multisystem inflammatory syndrome associated to Covid-19 (MIS-C) is one of the most severe outcomes of SARS-Cov-2 in children. Covid-19 vaccines were successfully implemented in Chile and effectiveness against MIS-C has been suggested. During 2021, mRNA and inactivated vaccines for the pediatric population were introduced in the country. The aim of this study was to describe the epidemiologic trends of MIS-C in Chilean children during the pandemic and after children vaccination
Methods: Analytic study of MIS-C cases from April 2020 to October 2022. Epidemiologic, SARS-CoV-2 variants and vaccination uptake data were obtained from the National Surveillance Program (Department of Epidemiology), Public Health Institute and National Immunization Program, respectively.
Results: 487 cases were reported, 58% males. Median age was 5 years (0-2 years:32%; 3-5years:21%; 6-11years:34% and 12-17years:13%). Incidence rates were 3.8, 5.4 and 1.6 per 100,000-inhabitants in 2020, 2021 and 2022 respectively. 73% required PICU admission and case fatality rate (CFR) was 1%. 97% of cases occurred in unvaccinated subjects. On those previously vaccinated, all but one case were in subjects receiving inactivated vaccines. No association among circulating variants and incidence was observed. Incidence risk rate (IRR) comparison between 2020 and 2021-2022 period was 0.72 (CI95% 0.65-0.81, $p<0.05$) for the overall; 0.86 for 0-2years (CI95%:0.71-1; $p=0.12$); 0.88 for 3-5years (CI95%:0.69-1.11; $p=0.28$); 0.61 for 6-11years (CI95%: 0.50-0.75; $p<0.05$); and 0.64 for 12-17years (CI95%:0.47-0.89; $p<0.05$). Vaccination uptake was 63% for 3-5years, 91% for 6-11years, and 99% for 12-
17years.



Conclusions/Learning Points: A decline of MIS-C incidence and age distribution shifting to younger population overtime have been observed. CFR was low but with high PICU admission. IRR only decreased in the cohorts of children who were vaccinated, but with high COVID-19 immunization coverage

COVID-19 VACCINE HESITANCY IN TUTORS OF CHILDREN IN A SOUTH-AMERICAN COUNTRY

E-Posters Viewing
E-POSTER VIEWING: AS13. COVID 19 AND MIS-C

Daisy Cedillo[1], Maria Jesus Godoy[1,2], Paula Leal[3], Rodolfo Villena[2]
[1]Universidad de Chile, Pediatrics, Santiago, Chile, [2]Universidad de Chile, Infectious Diseases, Santiago, Chile, [3]Hospital de niños Dr Exequiel González Cortés, Infectious Diseases, Santiago, Chile

Background: COVID-19 vaccine hesitancy varies according to the population studied worldwide. Concerns regarding the safety and the fear of adverse effects are one of the drivers for it. Uptake of COVID-19 vaccines in Chile have been high, mainly in adult and adolescent population, however is lower in children <6 years. Data on factors associated with reluctance are scarce. The aim of this study was to identify the factors associated with COVID-19 vaccine hesitancy in tutors of children between 3 and 15 years old, in Chile
Methods: Analytical cross-sectional study. Data was obtained through a survey applied online or face-to-face to tutors in the metropolitan region of Chile, in February-March 2023. The sample was selected by convenience, considering a confidence interval (CI) of 95% and a precision of 5%.
Results: 334 surveys were answered. 9% of tutors responded that they had not vaccinated their child. Main reasons: 56.7% "do not want to vaccinate", 26.7% "want to vaccinate, but have not yet done so", and 16.7% "have not yet decided whether to vaccinate". A 13.8% of tutors manifested that they wouldn't vaccinate their children against COVID-19 if it were annual, 54.3% because they "believe they are sufficiently protected", and 39.1% because "COVID-19 is not a fatal disease". 15% of respondents believe that COVID-19 vaccine is not much important for the child-health, 14.4% believe it is not safe at all, and 55.8% are very or moderately concerned of serious adverse events for their children.
Conclusions/Learning Points: COVID-19 vaccine uptake is high for priming, however hesitancy for booster doses could be foreseen. Main factors associated with hesitancy are the lacking of risk-perception and fear of vaccine adverse events.

Backgrounds: We compared age-stratified SARS-CoV-2 symptomatology of wild-type/Alpha versus Omicron BA.1/BA.2 variant infected individuals, and the impact of COVID-19 booster vaccination on Omicron symptom burden.
Methods: Data from three European prospective household cohorts were used (April 2020 to April 2021 and January to March 2022). Standardized outbreak protocols included (repeated) PCR testing, paired serology and daily symptom scoring for all household members. Comparative analyses was performed on 346 secondary household cases from both periods.
Results: Children< 12 years (all unvaccinated) experienced more symptoms and higher severity scores during Omicron compared to wild-type/Alpha period ($p \leq 0.01$). In adults, Omicron disease duration and severity were reduced ($p \leq 0.095$). Omicron was associated with lower odds for loss of smell or taste (Adjusted Odds Ratio [aOR]: 0.14; 95%CI 0.03-0.50) and higher, but non-significant odds for upper respiratory symptoms, fever and fatigue (aORs:1.85-2.23). No differences were observed in disease severity or duration between primary versus booster series vaccinated adults ($p \geq 0.12$).
Conclusions/Learning Points: The Omicron variant causes higher symptom burden in children compared to wild-type/Alpha and lower in adults, possibly due to prior vaccination. A shift in symptoms occurred with reduction in loss of smell/taste for Omicron. No additional effect of booster vaccination on Omicron symptom burden was observed.

YSMU, Infectious Diseases, Yerevan, Armenia

Title of Case: Two complications of two viruses
Background: Multisystem inflammatory syndrome in children is a novel, life-threatening hyperinflammatory condition that develops in children a few weeks after infection with SARS-CoV-2. This disease has been likened to Kawasaki disease and shock syndrome.This case refers to COVID-19 and chickenpox with their complications- MIS-C and cellulitis accordingly.
Case Presentation Summary: A 4-year-old girl presented on the 8th day of illness with fever, weakness, sleepiness, swelling of right side of the neck, vesicular rash.
Physical examination revealed skin pallor, cheilitis, irritability, strawberry tongue, spotted rash on the trunk and extremities, cervical lymphadenopathy, and swelling, hyperemia, tenderness of the right half of the neck, hepatosplenomegaly. The cervical movement to right was restricted. CBC showed leukocytosis with high neutrophil count(WBC-22.73x10^9/L,NEUT-12.92x10^9/L,LYMPH-7.45x10^9/L), anemia(RBC-3.07x10^9/L,HGB-80g/L,MCV-77.2fL) and thrombocytopenia(PLT-51x10^9/L). Biochemistry profile included high LDH levels(395U/L), low Total Protein(56.6g/L) and Albumin(31.62g/L) levels. Anti-COVID-19 antibodies were positive(79U/L). The coagulation studies were normal. Ferritin level was 409.7ng/ml and D-dimer
8.4ng/ml.

During admission	12.07.2022	15.07.2022	23.07.2022
WBC	22.73	24.96	9.59
NEUT	12.92	10.11	1.51
LYMPH	7.45	12.49	7.19
PLT	51	270	679
RBC	3.07	3.22	3.43
HGB	80	83	88
MCV	77.2	79.5	81.0

Imaging:EchoCG showed mild pericardial effusion. Chest X-ray: moderate right pleural effusion. Cervical ultrasonography:subcutaneous infiltration on the right, bilateral enlarged hypoechoic lymph nodes(0.9-1.3cm). Considering clinical and laboratory data the child was diagnosed with chickenpox, COVID-19-associated MIS-C and cervical cellulitis. After a surgical intervention a purulent fluid from the lesion was cultured. Alpha-hemolytic streptococci has been grown. The child received Acyclovir for chickenpox, antibacterial therapy for cellulitis(Meropenem, Vancomycin, Metronidazole, Clindamycin). MIS-C was treated with IVIG and symptomatic therapy.
Learning Points/Discussion: Sometimes it is challenging to treat children with multiple diseases. Two different viral infections with their complications potentiate duration of the disease and makes it hard to treat the patient. Although there was a high risk of thrombosis because of MIS-C (high platelet number), Aspirin was not used in this case to avoid Reye syndrome.

Background: This multi-center point prevalence study evaluated children diagnosed with coronavirus disease 2019 (COVID-19).
Methods: On 2nd February 2022, inpatients and outpatients infected with severe acute respiratory syndrome-coronavirus-2 (SARS-CoV-2) were included in the study from 12 cities and 24 centers in Turkey.
Results: Of 8605 patients on 2nd February 2022 in participated centers, 706 (8.2%) had COVID-19. The median age of 706 patients was 92.50 months, 53.4% were female, and 76.7% were evaluated as inpatients. The three most common symptoms of the patients with COVID-19 were fever (56.6%), cough (41.3%), and fatigue (27.5%). The three most common underlying chronic diseases (UCD) were asthma (3.4%), neurologic disorders (3.3%), and obesity (2.6%). The SARS-CoV-2-related pneumoniae rate was 10.7%. The COVID-19 vaccination rate was 12.5% in all patients. Among patients older than 12 years with vaccine accessibility given by the Republic of Turkey Ministry of Health was 38.7%. Patients with UCD presented with dyspnea and pneumoniae more frequently than those without UCD ($p<0.001$ for both). The rates of fever, diarrhea and pneumoniae were higher in the patients without COVID-19 vaccination ($p=0.001$, $p=0.012$, $p=0.027$).
Conclusions/Learning Points: To lessen the effects of the disease, all eligible children should receive the COVID-19 vaccine. The illness may specifically endanger children with UCD.

Title of Case: EVALUATION OF 601 CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME
Background: The aim of this study is to compare the clinical and laboratory characteristics and outcomes of MISC patients who did and did not require admission to an intensive care unit (ICU).
Case Presentation Summary: Methods: This study was carried out between June 11, 2021, and January 01, 2022. The demographics, complaints, laboratory results, system involvements, and outcomes of the patients were documented. Results: A total of 601 patients were enrolled; 157 patients (26.1%) required hospitalization in the intensive care unit. The proportion of Kawasaki disease-like features in the ICU group was significantly higher than in the non-ICU group (56.1% vs. 43.2% p=0.006). The ICU group had considerably lower counts of both lymphocytes and platelets (lymphocyte count 900 vs. 1280 cells × μL, platelet count 153 vs. 212 cells × 10^3/ μL, all for $p < 0.001$). C- reactive protein, procalcitonin, and ferritin levels were significantly higher in the ICU group (CRP 164 vs. 129 mg/L, procalcitonin 9.2 vs. 2.2 μg/L, ferritin 644 vs. 334 μg/L). Being between ages 5-12 and older than 12 increased the likelihood of hospitalization in the ICU by four [95% CI 1.971-8.627] and six times (95% CI 2.575-14.654), respectively, compared to being between the ages 0-5. A one-unit increase in log D-dimer and log troponin was also demonstrated to increase the need for intensive care by 1.8 (95% CI 1.079-3.233) and 1.4 times (95% CI 1.133-1.789), respectively.
Learning Points/Discussion: Patients requiring an ICU stay had considerably higher levels of procalcitonin, CRP, and ferritin but significantly lower levels of lymphocyte and thrombocyte. In particular, high levels of procalcitonin in the serum might serve as a valuable laboratory marker for anticipating the need for intensive care.

Backgrounds: The intestinal microbiome, which plays a critical role in host immunity, might be a key factor in explaining the significant variation between individuals in vaccine responses.
Methods: We searched MEDLINE and EMBASE without language or location restrictions to identify observational studies and clinical trials in humans which investigated the association between the intestinal microbiome composition and humoral or cellular vaccine responses.
Results: We included 10 studies (3 in adults, 7 in infants) from both developed and developing countries. A higher relative abundance of different taxa from the phylum Actinobacteria was consistently associated with stronger vaccine responses, and a higher abundance of the phylum Bacteroidetes (Bacteroides and Prevotella) with weaker vaccine responses. The association between the relative abundance of the phylum Firmicutes and Proteobacteria and vaccine response varied with different genus and species. Three studies found no association between the intestinal microbiome composition and vaccine responses. Study designs were highly heterogenous, with disparities in vaccine type studied, vaccine efficacy measurement, stool analysis timing and methods, and reporting.
Conclusions/Learning Points: Current data support the concept that the intestinal microbiome composition impacts vaccine responses. Further adequately powered studies are necessary to confirm this association and inform potential microbiome-targeted interventions to optimise vaccine responses.

WHICH IMPACT DO CFTR MODULATORS HAVE ON THE LUNG MICROBIOME OF PEDIATRIC PATIENTS WITH CYSTIC FIBROSIS? A MONOCENTRIC RETROSPECTIVE STUDY WITH REVIEW OF LITERATURE

E-Posters Viewing
E-POSTER VIEWING: AS14. MICROBIOME

Giulia Cassol[1], Giulia Paiola[2], Sonia Volpi[2], Marco Cipolli[2]
[1]Azienda Ospedaliera Universitaria Integrata, Ospedale Della Donna E Del Bambino - Pediatria, Verona, Italy, [2]Cystic Fibrosis Center, Cystic Fibrosis, Verona, Italy

Backgrounds: The lung microbiome of patients with cystic fibrosis (pwCF) has a characteristic, anaerobic and poorly heterogeneous flora, dominated by methicillin-susceptible and resistant S. aureus (MSSA, MRSA), P. aeruginosa, H. influenzae and Aspergillus spp. They are often subject to pulmonary exacerbations, that gradually worsen their respiratory capacity throughout life. In 2020 EMA approved Kaftrio®, a new modulator of the Cystic Fibrosis Transmembrane Regulator protein (CFTR), that has been introduced as treatment for people from 12 years with at least one Δ-F508 allelic mutation. Since that, the result is a great improvement in their quality of life.
Methods: Ours is a monocentric retrospective study, involving 20 pediatric patients aged from 12 to 18, who had been starting Kaftrio® for at least 10 months. They went to periodic control, with pulmonary sputum collection, before and after therapy (T0-T1-T2). The sputum culture sampled the bacteria present, their number in order of decimals, any resistance to antibiotics.
Results: We observed that after a transient significant reduction in the load and number of pathogens, mostly after 3-6 months, around 12 months there is a stabilization of the number of colonies. The antibiotic resistance does not change, on the contrary it decreases slightly.
Conclusions/Learning Points: The aim of our study is to underline the key role of the sputum control, that can be introduced as a long-term follow-up of pwCF treated with Kaftrio®, to stage the disease progression. In the future, it will be possible to better understand whether the CFTR modulators have beneficial implications for the innate and adaptive immune response, how it influences the individual microbiome, and whether there is the prospect of a standardized synergistic treatment with modulators and antibiotic, to promote the pwCF quality of life.

MICROBIOME IN AUTISM SPECTRUM DISORDER - THE KEY TO ALL SYMPTOMS OR A DEAD END?

E-Posters Viewing
E-POSTER VIEWING: AS14. MICROBIOME

Zuzanna Lewandowska-Pietruszka, Magdalena Figlerowicz, Katarzyna Mazur-Melewska
Poznan University of Medical Sciences, Department Of Infectious Diseases And Child Neurology, Poznań, Poland

Backgrounds: Autism spectrum disorder is a complex neurodevelopmental disorder of complex and not full understood etiology. There is increasing evidence of an imbalance in the gut microbiome that can potentially exacerbate core and gastrointestinal symptoms of autism.
Methods: We performed a systematic literature review according to PRISM Checklist to analyse the current state of knowledge in gut microbiota abnormalities in children with autism spectrum disorder. We searched PubMed Central database using the following search query: (((((((autism) OR ASD) OR autistic) AND microbiome) OR microbiota) AND microflora) NOT murine) NOT mice) NOT rat and obtained 10983 results. We included only the original studies, meta-analyses and systematic reviews on microbiota, excluding those performed on animal models, and finally selected 26 papers – 4 meta-analyses and 22 original manuscripts - to be included. The data from analysed manuscripts comes from 628 patients in total.
Results: The results concerning the diversity and the composition of microbiota differed between analysed papers, however we observed a visible tendency for patients with autism to present with lower abundance in Bacteroidetes and Firmicutes, with abnormal Bacteroidetes/Firmicutes ratio. The autistic patients had also lowered Bifidobacterium, Actinobacteria and Proteobacteria abundance. While some researchers suggested the positive influence of galactooligosacharyde or microbial intervention (probiotics or faecal microbiota transplant), others show no difference in patients' functioning.
Conclusions/Learning Points: The results of the analysis suggest that the subject requires further research on a larger group of patients. The authors currently conduct a research on oral and stool microbiota in children with autism.

SMALL INTESTINAL BACTERIAL OVERGROWTH IN CHILDREN WITH SHORT BOWEL SYNDROME – A RETROSPECTIVE STUDY FROM A UNIVERSITY HOSPITAL

E-Posters Viewing
E-POSTER VIEWING: AS14. MICROBIOME

Ana Prislan[1], Veronika Osterman[1,2]
[1]University Medical Centre Ljubljana, Department Of Paediatric Surgery, Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Hospital Infection Control And Prevention Services, Ljubljana, Slovenia

Background: Children with short bowel syndrome (SBS) have abnormal intestinal anatomy, secretion, or motility, which can lead to small intestinal bacterial overgrowth (SIBO). Reduction of the bacterial burden with antibiotic therapy is the mainstay of SIBO treatment.
Methods: A 5-year (January 2018 – December 2022) descriptive single-centre retrospective chart review of all episodes of clinically suspected SIBO in children with SBS on parenteral nutrition (PN).
Results: Of all patients with SBS, 31.2% (5/16) had at least one episode of clinically suspected SIBO, with a total of 25 episodes (5 episodes/child, range 1–14). The most common clinical presentation was diarrhoea (76%, 19/25), followed by meteorism (56%, 14/25), inappetence (48%, 12/25), flatulence (48%, 12/25), weight loss (36%, 9/25), abdominal pain (25%, 4/16), and vomiting (12%, 3/25). The mean laboratory values were 7.2 ±5.7 mg/L for CRP and 9.5 ±3.9 $x10^9$/L for WBC. Acidosis was present in 12% (3/25). All children received antibiotics, with 56% (14/25) receiving monotherapy, 36% (9/25) a combination of two, and 8% (2/25) of three antibiotics. TMP/SMX was prescribed most commonly (68%, 17/25), followed by metronidazole (48%, 12/25), amoxicillin/clavulanic acid (20%, 5/25), rifaximin (8%, 2/25), vancomycin (8%, 2/25) and gentamicin (4%, 1/25). The mean duration of antibiotic therapy was 11 ±4.5 days. In 20% (1/5) additional serial transverse enteroplasty procedure was needed. Fifty percent of all SBS managed to achieve bowel autonomy. Of the remaining, 62.5% (5/8) had SIBO.
Conclusions/Learning Points: Children with SBS are at high-risk for SIBO, affecting their ability to successfully wean off PN. SIBO is suspected on the basis of clinical presentation, with inflammatory markers remaining normal. Diagnostic tests have innate challenges, and a strong index of clinical suspicion is paramount. Empirical oral antibiotic treatment is efficient in most cases.

PV1066 / #735

DIVERSITY OF EARLY LIFE RESPIRATORY MICROBIOTA IS ASSOCIATED WITH LOWER RESPIRATORY TRACT INFECTIONS IN FIRST YEAR OF LIFE IN INFANTS WITH CYSTIC FIBROSIS

E-Posters Viewing
E-POSTER VIEWING: AS14. MICROBIOME

Ruth Steinberg[1], Markus Hilty[2], Kathryn Ramsey[1], Philipp Latzin[1], Insa Korten[1]
[1]Inselspital, Bern University Hospital, Department Of Paediatrics, Division Of Paediatric Pneumology And Allergology, Bern, Switzerland, [2]University of Bern, Institute For Infectious Diseases, Bern, Switzerland

Backgrounds: Lower respiratory tract infections (LRTI) are a driving force for pulmonary exacerbations and lung function decline in people with cystic fibrosis (CF), leading to recurrent antibiotic treatment. Over the last years, it could be shown that the respiratory microbiota is closely related to the pathogenesis of LRTIs. While several studies could show these associations in healthy infants, data in infants with CF is scarce. However, early life is an especially vulnerable period for later lung development.
Methods: We analyzed the microbiota in biweekly nasal swabs in 50 infants with CF and 30 healthy controls from two prospective birth cohorts followed throughout the first year of life. We assessed respiratory symptoms, antibiotic treatment and changes in the environment at time of swab via standardized telephone interviews.
Results: We analyzed 1557 data points (963 in CF). The respiratory microbiota differed between healthy and CF infants as expected, but differed also within the CF group. Healthy infants suffered only rarely LRTIs (n= 6). In infants with CF having more frequent LRTIs (n=15 infants, 300 swabs) α-diversity (measured via Shannon diversity index) was lower compared to those with no or few LRTIS (n=35 infants, 633 swabs) (Coef -0.42; SE 0.099; $p<0.0001$). Interstingly, this difference was already present before first respiratory symptoms occurred (Coef -0.612; SE 0.22; $p<0.01$). This finding was independent from antibiotic treatment.
Conclusions/Learning Points: We found that α–diversity of the respiratory microbiota is lower in infants with CF with frequent LRTIs. Importantly, the lower α- diversity was already present before first respiratory symptoms occurred and independent of antibiotic treatment. Thus, a disbalanced composition of the respiratory microbiota in early life might contribute in susceptibility towards respiratory tract infections. Next, we will investigate strain level microbiota profiles to detect potential pathogenic microbes in more detail.

KAWASAKI DISEASE – STILL AN UNDERRECOGNIZED ENTITY?

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Ana Rita Albuquerque Costa, Ana Rita Matos, Mariana Silva, Jorge Rodrigues, Joana Pimenta, Maria José Cálix, Cristina Faria
Centro Hospitalat Tondela-Viseu, Pediatria, Viseu, Portugal

Backgrounds: Kawasaki Disease (KD) is a systemic vasculitis of unknown etiology that mainly affects young children. Diagnosis is based on characteristic clinical signs and laboratory abnormalities that can occur in other childhood febrile illnesses, making it challenging to promptly recognize and treat it. We aimed to explore the clinical characteristics of a cohort of children with KD admitted to our hospital and assess challenges in their approach.
Methods: Single-center, 10-year, retrospective analysis of children admitted for KD.
Results: In this period, 13 children were diagnosed with KD (53.9% male, median age of 3.0 years). The time from fever onset to treatment was a median of 5 days, during which 81.8% of patients required multiple medical evaluations and 53.8% started antibiotic treatment. Two of them already had positive criteria for KD listed in medical records before diagnosis. During the course of disease, a rash appeared in 100% of patients, 76.9% displayed mucosal involvement, 61.5% showed extremity changes and 46.1% had lymphadenopathies. Gastrointestinal and osteoarticular symptoms were described in 30.7% and 23.1%, respectively. Of the cohort, 61,5% met the criteria for classic KD and 38.5% for atypical or incomplete KD. After establishing the diagnosis, every patient was treated with immunoglobulin and acetylsalicylic acid, 15.3% after day 8 of disease. Coronary involvement occurred in 1 patient (7.7%). The mean period of hospitalization was 7.42 days.
Conclusions/Learning Points: From our analysis, diagnosing KD was challenging and never achieved in the first medical evaluation. The underreporting in this study also emphasizes the need for a systematic review of organ involvement in systemic disease. KD should always be suspected in the presence of fever of unknown etiology, so that the appropriate treatment is not delayed.

PV1068 / #2192

KAWASAKI DISEASE – A REFRACTORY CASE

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Ana Carolina Alves[1], Mariana Gouveia Lopes[1], Patrícia Vaz Silva[2], Ester Gama[1], Maria Manuel Zarcos[1]
[1]Hospital de Santo André, Pediatria, Leiria, Portugal, [2]Hospital Pediatrico de Coimbra, Cardiologia Pediátrica, Coimbra, Portugal

Title of Case: Kawasaki Disease – A refractory case
Background: Kawasaki disease (KD) is one of the most common vasculitides of childhood and its main complication is coronary artery aneurysms (CAA). Its etiology remains unknown. Early treatment with intravenous immune globulin (IVIG) is recommended and decreases the risk of CAA development. It is mandatory to identify risk factors which may contribute to IVIG resistance - refractory KD.
Case Presentation Summary: A 4-months-old male-infant, whose parents were born in Uzbekistan, without relevant medical history, was admitted because of a 3-day fever, left cervical swelling, diarrhea and irritability. Blood analysis revealed elevation of acute-phase reactants with C-reactive protein 115mg/L; procalcitonin 85ng/mL, erythrocyte sedimentation rate 33mm and enterovirus was detected by PCR-assay. Cervical ultrasonography showed a lymph node conglomeration on the left side. Because of lymphadenitis, it was initiated intravenous antibiotic treatment. On the fourth-day of illness, he developed a diffuse erythematous maculo-papular rash. On the fifth-day of fever, he presented bilateral conjunctival injection and redness and crust formation at the site of BCG inoculation. Following KD suspicion, transthoracic echocardiography was performed which showed small CAA. The patient was treated with a combination of IVIG (2g/kg) and oral aspirin. Since the fever persisted for longer than 48 hours after IVIG administration, he was given a second dose of IVIG combined with intravenous methylprednisolone, with clinical and laboratory improvement. He was discharged with aspirin and an oral corticosteroid slow tapering off.
Learning Points/Discussion: This case illustrates an incomplete KD, with more than 5 days of fever, 3 clinical diagnostic criteria and laboratory and echocardiography criteria. Enterovirus isolation in blood supports the evidence that several infectious agents may trigger the immunopathogenesis of KD. Persistent fever after IVIG administration, should raise concern for refractory KD.

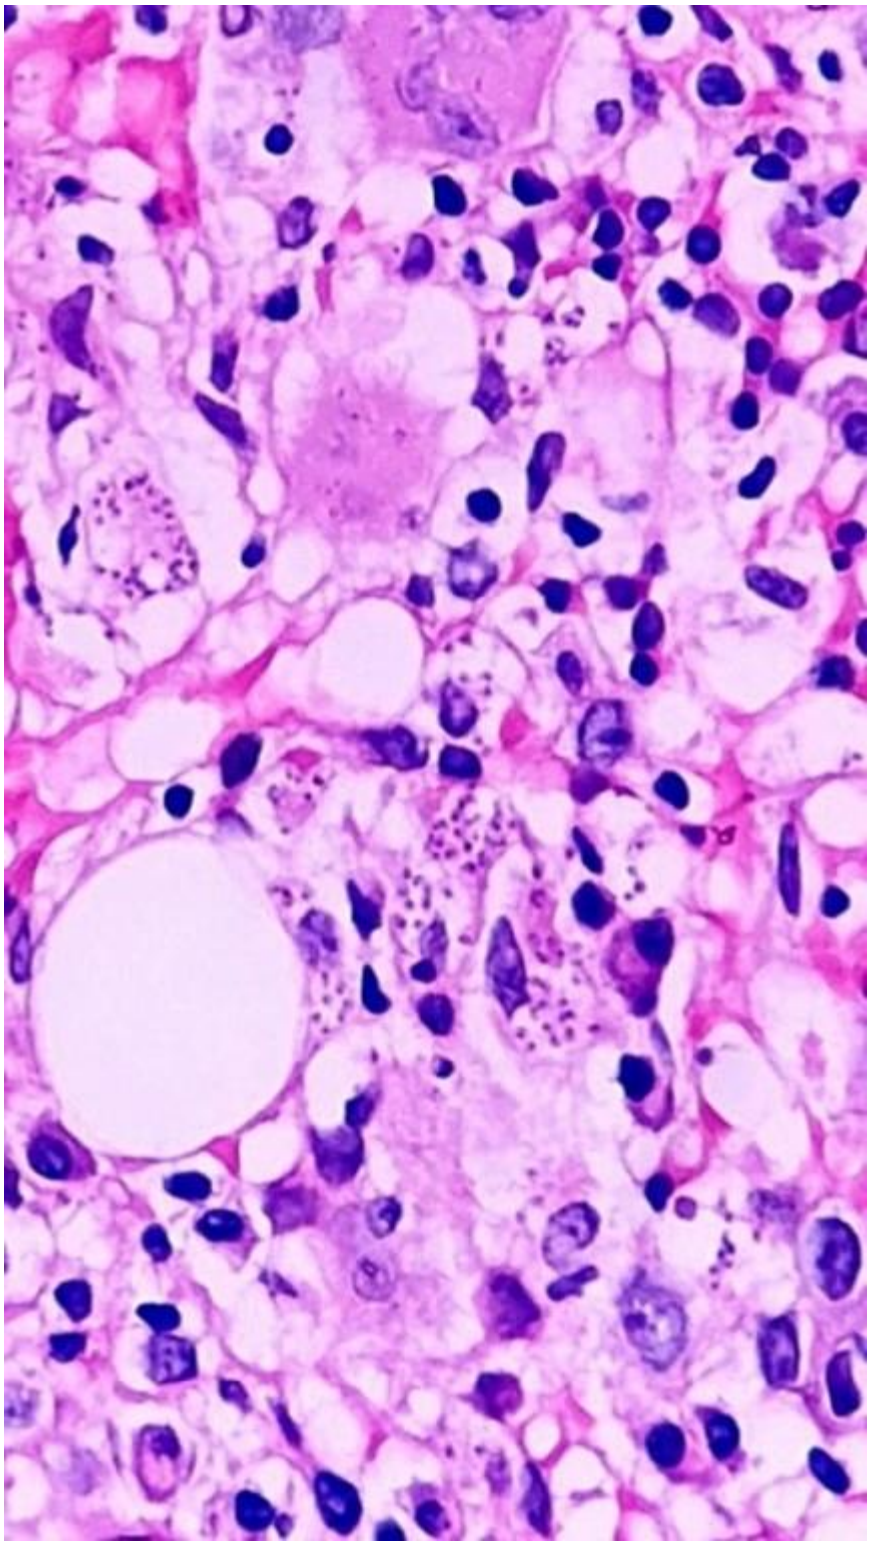
PV1069 / #2267

VISCERAL LEISHMANIASIS IN PEDIATRICS MIMICKING BACTERIAL SEPTIC SHOCK

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Andres Arias[1], Omar Escobar[2], Leonardo Escobar[1], Krisell Contreras[1], Martha Flórez[1]
[1]Erasmo Meoz University Hospital, Norte De Santander, Cucuta, Colombia, [2]Universidad CES, Antioquia, Medellín, Colombia

Title of Case: VISCERAL LEISHMANIASIS IN PEDIATRICS MIMICKING BACTERIAL SEPTIC SHOCK
Background: A Venezuelan male 16-year-old without medical history, presented to the ER for a 1-week history of fever of up to 39.5°C, predominantly in the afternoon with diaphoresis associated with chills, asthenia, adynamic, and retroocular pain.
Case Presentation Summary: On admission, the patient described intermittency for the previous five months without specific treatment. The physical examination consisted of hepatomegaly and pale appearance. blood count showed leukopenia (WBC: 1520 cells/mm3), hypochromic microcytic anemia (HB: 8.5 g/dL), moderate thrombocytopenia (110,000 cells/mm3), elevated acute phase reactants (PCR 160 mg/L). Invasive Salmonella infection was suspected, and ceftriaxone was started empirically, clinical deterioration with persistent pancytopenia needing admission to ICU for septic shock, meropenem and vancomycin were started. Peripheral blood smear red blood cells with moderate anisocytosis with microcytes (++) and macrocytes (+), moderate polychromatophilia; ovalocytosis (++), leukocytes with marked leukopenia; IgM dengue negative, IgM Leptospira negative, IgG Trypanosoma cruzi negative, blood smear for malaria negative, serology for Hepatitis B and C negative, HIV not reactive, rapid treponemal test negative. Abdominal ultrasound shows mild hepatomegaly and splenomegaly grade II. Due to the previous findings, the clinical progression and the persistence of fever without recovery of blood cultures. Bone marrow biopsy reported: histiocytes with hemophagocytosis and intracellular forms of Leishmania amastigotes (VL) (Figure 1.) Liposomal amphotericin B was started at 3 mg/kg IV every day during the first 5 days due to candidemia coinfection, subsequent doses on day 14 and 21 was



administered.

Learning Points/Discussion: VL is considered a neglected disease, and has a broad spectrum of signs and symptoms, without suspicion it is often misdiagnosed with a delay in treatment, more severity, and progress to systemic multiorgan dysfunction, mimicking bacterial septic shock.

PROLONGED FEVER DUE TO CHRONIC MENINGITIS AND SPINAL ARACHNOIDITIS: A DIAGNOSTIC CONUMDRUM

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Si Min Chan[1,2], Rie Aoyama[1], Olivia Leow[1], Furene Wang[1,2], Belinda Quek[1], Vincent Nga[3], Pamela Palasanthiran[2,4,5]
[1]National University Health System, Khoo Teck Puat-national University Children's Medical Institute, Singapore, Singapore, [2]National University Singapore Yong Loo Lin School of Medicine, Singapore, Department Of Paediatrics, Singapore, Singapore, [3]National University Hospital, Division Of Neurosurgery, Department Of Surgery, Singapore, Singapore, [4]Sydney Children's Hospitals Network, Randwick, Department Of Immunology And Infectious Diseases, New South Wales, Australia, [5]University of New South Wales, School Of Women's And Child Health, Sydney, Australia

Title of Case: PROLONGED FEVER DUE TO CHRONIC MENINGITIS AND ARACHNOIDITIS: A DIAGNOSTIC CONUMDRUM
Background: Chronic meningitis often remains undiagnosed. Immunological status, radiological findings and epidemiological exposure are important diagnostic clues.
Case Presentation Summary: We report a 3 year 10 month old previously healthy Bangladeshi boy with possible tuberculous meningitis (TBM) and confirmed Aspergillus meningitis. He presented in Dhakar with fever, vomiting, photophobia, after 1 month of headaches and lethargy. Cerebrospinal fluid (CSF) was turbid with significant pleocytosis, low glucose, high protein. No bacterial, fungal or mycobacterial pathogen was identified. He had prolonged hospitalisation for chronic meningitis and hydrocephalus requiring ventriculo-peritoneal (VP) shunt insertion, broad-spectrum antibiotics, empiric 4-drug anti-tuberculous therapy (ATT), steroids and levetiracetam. He then presented to Singapore after 2 months of unresolved fever, intermittent lower back pain, and bilateral lower limb weakness. Further imaging showed basal cistern meningitis and spinal arachnoiditis. L5/S1 laminectomy and spinal lesion biopsy revealed a fibroinflammatory lesion adherent to dura and nerve root clumping. Histology showed no granulomas or malignancy. Extensive infectious workup was done. Investigations for other organ involvement were normal. ATT was changed to include ethionamide and steroids increased. CSF showed galactomannan >5.0; Aspergillus flavus PCR positive. He received liposomal amphotericin followed by voriconazole. VP shunt was changed. CSF pleocytosis normalised; galactomannan remained elevated. Immunodeficiency investigations showed IFN-γ/IL-12p70 pathway non-responsiveness; whole genome sequencing did not detect mutations. He was discharged 6 weeks later, afebrile and walking, with Cushingoid features and mood/behavioural change.
Learning Points/Discussion: TBM is an elusive diagnosis with low CSF culture yield, and reliance on suggestive radiological findings of hydrocephalus and basal meningeal enhancement. TB arachnoiditis causing myeloradiculopathy may cause concomitant, paradoxical, or late lower limb symptoms. Aspergillus meningitis can rarely mimic TBM or occur as VP shunt infection.

PV1071 / #1510

PRESENTATION OF KAWASAKI DISEASE IN A 12-YEAR-OLD MALE PATIENT, DIFFERENTIAL DIAGNOSIS AND LACK OF ETIOLOGICAL DEFINITION: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Diana Duessmann[1], Adilaeti Lopes[1], Kathielen Rösler[2], Cássio Solano[2], Giovani Petró[2], Claudia Vallandro[2], Maria Clara Valadao[2]
[1]Federal University of Santa Maria, Medicine, Santa Maria, Brazil, [2]Federal University of Santa Maria, Pediatrics, Santa Maria, Brazil

Title of Case: KAWASAKI DISEASE IN A 12-YEAR-OLD MALE PATIENT, DIFFERENTIAL DIAGNOSIS AND LACK OF ETIOLOGICAL DEFINITION: A CASE REPORT
Background: The diagnostic criteria for Kawasaki disease (KD) consists in clinical features that are common in many other typical febrile illnesses in childhood. KD predominantly affects children between six months and five years of age. The purpose of this report is to present a case of KD in an adolescent and highlight its similarity to scarlet fever (SF).
Case Presentation Summary: Healty, 12-year-old healthy boy was admitted with a 7-day history of widespread erythema on the face, fever (38-39ºC), and a previous diagnosis of SF. He didn't have symptoms of exudative pharyngitis and was being treated with benzathine penicillin but showed no improvement. The patient presented with symptoms of a "bumpy raspberry" tongue,dysphagia, bilateral conjunctivitis without exudate, bilateral cervical lymph node enlargement, edema of hands and feet with subsequent desquamation of the skin, which closed criteria for diagnosis of KD. IgM serologies and SARS-CoV-2 tests were negative, he was previously vaccinated. On D7, an echocardiogram revealed dilation of the anterior descending and right coronary arteries, as well as insufficiency of the mitral and tricuspid valves. Human immunoglobulin (IVIG) treatment was initiated along with Aspirin and he responded positively to the treatment, D27 there was full resolution.
Learning Points/Discussion: This case highlights that clinical symptoms can lead to confusion as it may resemble other viral exanthematous diseases and SF. It's important to be aware of the clinical signs and diagnostic criteria, even if the age of the patient is differes from what's typically seen in the disease's epidemiology, as early treatment with IGIV within the first 10 days can change the course of the disease and prevent complications.

PV1072 / #2083

NASAL PORTAGE OF STAPHYLOCOCCUS AUREUS IN A RARE CASE OF WEGENER GRANULOMATOSIS IN A CHILD

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Rodica Eremciuc, Olga Gaidarji, Dina Bujor, Ala Holban, Ninel Revenco
State University of Medicine and Pharmacy "Nicolae Testemitanu", Pediatric Department, Chisinau, Moldova

Title of Case: Interrelationships between granulomatosis with polyangiitis, carriage of Staphylococcus aureus and acute infections – a case report
Background: Granulomatosis with polyangiitis, also known as Wegener's granulomatosis, is a systemic vasculitis affecting small and medium vessels. It is characterized by granulomatous inflammation of the upper and lower respiratory tract, pauci-immune necrotizing glomerulonephritis, and vasculitis involving other organs.
Case Presentation Summary: The 10-year-old patient presents with febrile syndrome, refractory to treatment lasting 3 weeks, headache, ataxia, non-inflammatory joint syndrome. Previously, during the last month, the patient diagnosed with maxillary sinusitis and pneumonia. Septic workup revealed repeated positive blood cultures for St.aureus.In spite to adequate antibiotic treatment child's condition gradually worsened. Nasal crusting and epistaxis was reported by patient. Sanguineous crusts present an entrance gate for staphylococcus, which in conditions of immune dysfunction can lead to severe complications from the internal organs. An repeated X-ray of the chest showed multiple nodules and cavities in the lungs. Lung biopsy was taken and the diagnosis of GPA was confi rmed. Considering the persistence of symptoms, but also the presence of 4 criteria for granulomatosis with polyangiitis, it was decided to initiate immunosuppressive treatment to induce remission. On heart ultrasound vegetations were revealed. The diagnosis of infective endocarditis was made. After the treatment of active infection, an alternative regimen of GPA treatment was chosen (biological therapy with rituximab). No relapse of lung disease was reported in 3 months follow-up.
Learning Points/Discussion: Patients presenting with upper respiratory tract pathology and chronic carriage of Staphylococcus aureus may be eligible for topical antibiotic treatment to prevent exacerbations and generalization of staphylococcal infection. GPA is an important diagnostic option in patients with upper respiratory tract involvement (especially non-responsive to treatment) and the presence of Staphylococcus aureus carriage.

KEEP CALM: IT'S KIKUCHI!

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Joana Glória[1], Adelina Sitari[2], Catarina Guerreiro Ferreira[2], Filipa Lima[2], Guida Gama[2], Luísa Gaspar[2]
[1]Centro Hospitalar Universitário Lisboa Norte, Pediatria, Lisboa, Portugal, [2]Centro Hospitalar Universitário do Algarve, Pediatria, Faro, Portugal

Title of Case: Keep Calm: It's Kikuchi!
Background: Fever of undetermined origin can be a diagnostic challenge. It is usually caused by common disorders, often with an unusual presentation. Many differential diagnoses course with adenopathies. Most common etiologies are infectious, connective tissue diseases and neoplasms, the latter, due to their severity, must be excluded.
Case Presentation Summary: Fourteen y.o boy with worsening cervical lymphadenopathies for 2 months, non responsive to NSAIDs. Three weeks prior to hospitalization he had fever with chills, fatigue, weight loss (4kg), headache with nocturnal awakening. He had several visits to the Emergency Department, and was tested negative for EBV and CMV. On the last admission he was emaciated, extremely tired, with cervical, axillary and supraclavicular adenopathies. Diagnostic workout showed anemia, leukopenia (with reactive lymphocytes), increased transaminases, ferritin and LDH, normal CRP. Serologies for infectious diseases, Mantoux, Igra and ANAs negative. Cervical-CT showed reactive adenopathies and Cranioencephalic and thoraco-abdomino-pelvic CT were normal. He was referred to the Oncology Center. Had a normal medulogram and ganglionic aspirate flow cytometry. Aspiration citology couldn't exclude Hodgkin's Lymphoma, so an excisional biopsy was performed and was suggestive of Kikuchi lymphadenitis(KL). During hospital stay, he became afebrile and clinically improved so was discharged home after 6 days. Two months later, he is clinically well, afebrile, recovered his usual weight, with no adenopathies and normal blood tests.
Learning Points/Discussion: The clinical presentation raised serious concern of neoplastic disease. Only excisional biopsy allowed to exclude linfoma and to establish KL. It is described as a self-limiting condition, and no effective treatment has been established. When symptoms are severe or persistent, glucocorticoids or immunoglobulin may help. This case illustrates how conservative treatment with active surveillance can spare the patient to high doses of corticoids.

PV1074 / #1821

DISSEMINATED HISTOPLASMOSIS IN EARLY CHILDHOOD

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Giovanna Guerra[1], Camila Morais[1], Samantha Matos[1], Emmanuella D`Elia[1], Eitan Naaman Berezin[1], Marco Aurelio Safadi[2], Daniel Jarovsky[1], Flavia Almeida[1]
[1]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [2]Santa Casa de Sao Paulo School of Medical Sciences, Pediatric Infectious Diseases, Sao Paulo, Brazil

Title of Case: Disseminated histoplasmosis in early childhood
Background: Histoplasmosis is a systemic fungal disease that can range from asymptomatic illness to mild to disseminated disease,that can course with death. The disseminated form most often occurs in immunocompromised patients,but not only,it can also occur at extremes of age.Infection commonly disseminates to the skin and gastrointestinal tract, but can occur anywhere.
Case Presentation Summary: An 8-month-old infant, previously healthy, is admitted with a history of fever, pallor and increased abdominal volume for 20 days, evolving with progressive worsening of the general condition.Epidemiology: he is from the rural area of Mata Verde,Minas Gerais, Brazil. The mother reported contact with animals (chicken, pig, horse, cow and bats).On physical exam, he looked pale, tachypneic, prostrated.He had globose,distended abdomen, normal hydro-air noise, diffusely painful on palpation, with the presence of enlarged liver and spleen.His spleen was almost at the left iliac crest.Laboratory tests revealed pancytopenia: hemoglobin 5.2 g/dL; leukocytes 1100/µL (704 neutrophils; 228 lymphocytes); Platelets 6.000/µL.A myelogram was performed and showed an increase in macrophages full of parasites with crescent-shaped nuclei,characteristic of Histoplasma, and the diagnosis of disseminated Histoplasmosis was made.The patient evolved with respiratory failure,attributed to restriction due to the large abdominal volume,requiring orotracheal intubation.Treatment was made with liposomal amphotericin B for 30 days,followed by itraconazole for 12 months.Clinical improvement was gradual,the fever ceased after one month of treatment and the liver and spleen were improved,return on the normal size after 6 months.Primary immunodeficiencies, neoplasms and HIV infection were excluded.
Learning Points/Discussion: Acute disseminated histoplasmosis can occur in early childhood,in some endemic areas and in patients with severely impaired cellular immunity,with lethal outcome. A quick diagnostic suspicion to initiate treatment is essential for the outcome of the case.

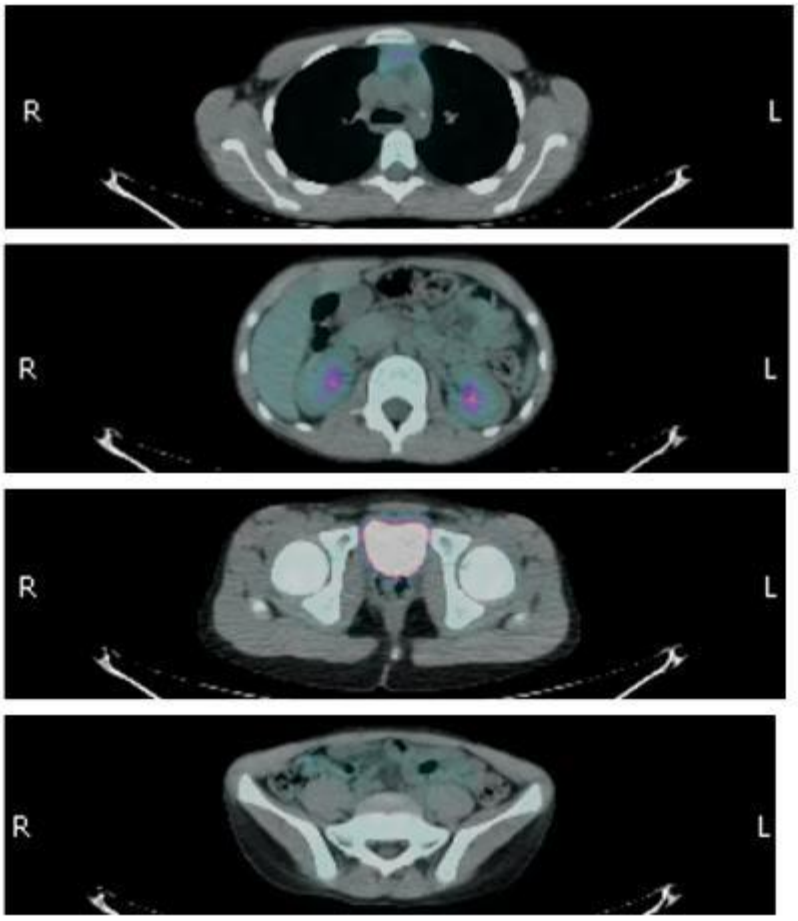
Title of Case: A MONTH-LASTING HIGH-GRADE INTERMITTENT DAILY FEVER ASSOCIATED WITH SPLENOMEGALY, LYMPHADENOPATHIES AND CYTOPENIAS IN AN OTHERWISE HEALTHY 10-YEARS-OLD BOY WITH A MISDIAGNOSED COMMON PEDIATRIC VIRAL INFECTION
Background: FUO is defined by daily temperature of ≥38.0°C for at least 14 days, defying explanation after anamnesis, physical examination, and basic laboratory tests. It represents a diagnostic challenge.
Case Presentation Summary: A 10 years-old boy referred to the emergency-room for high-grade intermittent twice-daily fever spikes, started 14 days before with a 48-hours lasting ankle arthralgia. Cefprozil and clarithromycin were ineffective. Laboratory tests excluded EBV and Group-A Streptococcus infections, showing mildly increased phlogosis indexes; the child was discharged with oral prednisone with subsequent 48-hours lasting defervescence. He was re-hospitalized for recurrence of intermittent once-daily fever spikes. Echocardiography, fundus oculi, thorax/abdomen CT excluded infectious foci, showing axillar reactive lymphadenopathies and splenomegaly. Blood/urine/faecal cultures, parasites research, Legionella urinary antigen, Mantoux/Quantiferon tests, nasopharyngeal aspirate PCR for respiratory viruses/bacteria, serology and blood PCR for Leishmania, Toxoplasma, Borrelia, Brucella, Salmonella, Bartonella, Mycoplasma, Rickettsia, Coxiella, Francisella, Babesia and Anaplasma spp., CMV, EBV, HHV6, Adenovirus, Enterovirus, Parvovirus, HBV and HCV showed positive Parvovirus IgG with <250 copies/ml of Parvovirus DNA on peripheral blood consistent with a quiet remote infection. TSH, phlogosis indexes, ANA, anti-CCP antibodies, RF, C3/C4, lymphocyte typization, IgG/IgA/IgM levels excluded immuno-rheumatological disorders. Peripheral blood smears confirmed mild leukopenia with worsening anemia, bone marrow aspirate showed intermediate cellularity consistent with ongoing viral infection. 5408 copies/ml of Parvovirus DNA were detected on bone marrow aspirate, confirming ongoing Parvovirus infection, supported by total body FDG-

Figure 1. Total body 18-FDG PET/CT



No areas of hyperaccumulation of the radiopharmaceutical frankly referable to heteroplastic lesions with high glucose metabolism, nor inflammatory-infectious foci in the active phase.

Diffuse hyperfixation in the thymic lodge, probably referable to physiological thymic uptake.

Small gastric fixation, probably of an inflammatory or non-specific nature.

PET. Fever lasted 44 days.

Learning Points/Discussion: Parvovirus is a potential cause of FUO with hematotropism. Molecular infectivological analysis on bone marrow aspirate should be considered in case of serological-molecular inconclusive results on peripheral blood.

16 YEARS OLD BOY WITH RECURRENT FEVER

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Eka Nakhutsrishvili, Tinatin Kutubidze
TSMU G. Zhvania's Pediatric Academy Clinic, Pediatrics, Tbilisi, Georgia, Georgia

Title of Case: 16 YEARS OLD BOY WITH RECURRENT FEVER
Background: The patient was born from a physiological pregnancy. Physical and psycho-emotional development corresponded to age. At preschool age-several episodes of infections. Since 2013_6-7 cases of acute tonsillitis treated with antibiotics. Tonsillectomy was performed in April 2015. Until the summer of 2016, the child periodically had a sore throat and fever up to 39-40^{o}C. Since the autumn of 2016_high temperature almost 1-2 per month, complains of sore throat, general weakness. He was hospitalized several times, laboratory and instrumental studies were conducted, the cause of fever couldn't be determined. In March 2019 an immunological study was conducted - without pathology, a genetic for FMF- the disease was ruled out. It should be noted that when the patient has a fever, segmental neutrophils, ESR, and C-reactive protein are always elevated at >100. Consultations of otolaryngologist, rheumatologist, infectious disease specialist, hematologist were conducted. Parasitic tests - without significant changes, blood bacteriology during fever - sterile. In May 2021, a cytological examination of the lymph nodes was performed _hyperplastic lymphadenitis. Abdominal ultrasound was done several times - no hepatosplenomegaly. Echocardiography - slight prolapse of the anterior leaflet of the mitral valve, with trivial mitral regurgitation.
Case Presentation Summary: The condition has so far been assessed as PFAPA syndrome, Medrol (Methylprednisolone) has been prescribed for high temperature, after giving this medicine the temperature is normalizing. The patient continues to have fever once or twice per month, the interval between fevers has decreased, during fever he has a sore throat, general weakness, immediate response to single dose of Glucocorticoid.
Learning Points/Discussion: Are we really dealing with PFAPA? How to manage frequent episodes? What should be assessed, what risks we might be
dealing with?

PV1077 / #617

A CLINICAL CASE OF RECURRENT FEVER, NEUTROPENIA AND ARTHRITIS IN AN INFANT

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Eka Nakhutsrishvili[1], Tinatin Kutubidze[2]
[1]TSMU G. Zhvania's Pediatric Academy Clinic, Pediatrics, Tbilisi, Georgia, Georgia, [2]TSMU G. Zhvania's Pediatric Academy Clinic, Pediatrics, Tbilisi, Georgia

Title of Case: CLINICAL CASE OF RECURRENT FEVER, NEUTROPENIA AND ARTHRITIS IN AN INFANT
Background: Neutropenia is a challenging issue for pediatricians. Neutropenia results from four basic mechanisms:decreased production, ineffective granulopoiesis, shift of circulating polymorphonuclear cells to vascular endothelium or tissue pools, or enhanced peripheral destruction. The most common type of childhood arthritis is juvenile idiopathic arthritis. Here we are presenting the case of the infant with fever, severe neutropenia, anemia and arthritis
Case Presentation Summary: Patient is 2-year-old. Second child in the family, born full term, weight 3300 gr. The mother was diagnosed with SARS-CoV-2 infection in the first trimester of pregnancy. At the age of 6 months after scheduled vaccination, the patient experienced high fever which lasted for 1 month, followed by moderate anemia, agranulocytosis. Child was hospitalized in the hematology department for anemia. Numerous investigations were performed, including immunodeficiency assessment, bone marrow aspiration-no abnormalities. Treatment included antibiotic therapy with Ceftriaxone, and cefixime p.o was continued, after stopping the antibiotic, the fever recurred, so medication was continued for the following 4 months. From March 2022, the patient expressed pain and swelling in numerous joints. Peripheral blood analysis revealed severe anemia and agranulocytosis, Intravenous antibiotic therapy was initiated, hemotransfusion was performed. During the last hospitalization there were episodes of fever, severe malaise, weight deficiency, swelling, pain, limitation of movement in joints, without hepatosplenomegaly, lymphadenopathy or skin rash. ANA was 1:2560, anti-ds DNA was negative, glucocorticosteroid therapy with high doses of i.v. was prescribed.
Learning Points/Discussion: There are two very important questions regarding this patient: whether maternal SARS-Cov-2 infection may have caused innate immune dysregulation and the resulting unusual presentation of chronic arthritis and hematological abnormality. Can this condition be classified as sJIA even if the ANA is positive?

PV1078 / #1038

CASE OF AUTOIMMUNE HEPATITIS FOLLOWING EPSTEIN-BARR VIRUS INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Sinam Papyan[1], Lia Andreasyan[1], Tatevik Shahinyan[2], Astghik Hakobyan[1]
[1]Arabkir Medical Center, Isolation Unit, Yerevan, Armenia, [2]Arabkir Medical Center, Department Of Gastroenterology And Hepatology, Yerevan, Armenia

Title of Case: CASE OF AUTOIMMUNE HEPATITIS FOLLOWING EPSTEIN-BARR VIRUS INFECTION
Background: Autoimmune hepatitis type 1 (AIH 1) is a disease of unknown etiology, that in some cases can be triggered by Epstein-Barr virus (EBV) infection. The diagnosis of AIH in the setting of EBV infection is very challenging and requires close monitoring.
Case Presentation Summary: A twelve-year-old girl was admitted to the hospital with low-grade fever and fatigue for one month. Physical examination showed moderate hepatosplenomegaly, laboratory tests revealed increased levels of aspartate aminotransferase 479 IU/L and alanine aminotransferase 478 IU/L. The level of bilirubin, albumin, and GGT was within normal ranges. Complete blood count and coagulation tests were also normal. After extensive workup HIV, hepatitis A, B, C, and CMV infections were excluded. Other causes of hepatitis (e.g drug-induced hepatitis, Wilson disease, alpha-1-antitrypsin deficiency) were also excluded. However, EBV capsid antigen was positive. During 2 weeks of hospitalization, the child was closely monitored, and liver enzyme levels were fluctuating. A serological workup was also done, and high levels of ANA antibodies and anti-smooth muscle antibodies were detected, whereas antinuclear, anti-mitochondrial, and anti-liver -liver/kidney microsomal-1 antibodies were absent. Parents refused liver biopsy, hence histological examination was not done. Considering all the above-mentioned test results, AIH type 1 was diagnosed, and the treatment with steroids was initiated, however, later therapy was switched to azathioprine. The general condition of the child improved, and the laboratory normalized.
Learning Points/Discussion: There are a number of case reports discussing the association between EBV and AIH 1. In the case of EBV infection, if the patient continues to have a high level of liver enzymes, other causes of hepatitis should be ruled out and a differential diagnosis of AIH is essential for further management.

PV1079 / #51

AN UNCOMMON CAUSE OF PERSISTENT FEVER

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Nicola Sardi, Paolo Cussino, Cristina Cravero, Paola Musso, Maria Eleonora Basso
ASL CN1 - Ospedale SS Annunziata Savigliano, Department Of Paediatrics, Savigliano, Italy

Title of Case: AN UNCOMMON CAUSE OF PERSISTENT FEVER
Background: Acute lobar nephronia (ALN) is a localized, non-liquefactive, renal interstitial bacterial infection, affecting one or more renal lobules. The disease is considered as an intermediate stage between acute pyelonephritis (APN) and renal abscess. This condition is probably underdiagnosed. Diagnosis is relevant since ALN requires longer antibiotic treatment and is associated with more complications.
Case Presentation Summary: A 7-year-old girl presented with a 48 hours history of high fever with chills. Physical examination was normal. Laboratory tests showed neutrophilic leucocytosis and high CRP and procalcitonin. Urinalysis revealed the presence of leucocytes and nitrites. Urine culture was positive for a multisensitive strain of E.coli (negative blood culture). Chest X-ray and abdominal US were normal. Abdomen MRI revealed multiple areas with restricted diffusion in the left kidney, compatible with ALN. Amoxicillin/clavulanate iv was started; after 48 h the patient was still febrile, therefore treatment was switched to piperacillin/tazobactam + amikacin + vancomicin. After 72 h, the fever disappeared. Amikacin and vancomycin were discontinued. Piperacillin/tazobactam iv was continued for 10 days, then switched to cefotaxime iv for 7 days. Cefpodoxime proxetil was given orally for additional two weeks after discharge. Abdomen MRI, performed one month after discharge, showed an improvement of lesions in left kidney. VCUG revealed a bilateral grade 1 reflux.
Learning Points/Discussion: ALN is probably not a rare condition in children, but difficult to diagnose due to lack of specific symtoms and laboratory findings. ALN, compared to APN, has a prolonged and more severe clinical course; the antibiotic treatment should be initially intravenous and for at least 3 weeks of overall duration. CT scanning represents the diagnostic gold standard for ALN, but MRI could be considered in order to limit irradiation.

SYSTEMIC BARTONELLA HAENSELE INFECTION IN AN IMMUNOCOMPETENT ADOLESCENT- CASE PRESENTATION

E-Posters Viewing
E-POSTER VIEWING: AS15. PROLONGED / RECURRENT FEVER

Ramona Stroescu[1], Flavia Chisavu[1], Adela Icleanu[2], Ruxandra Steflea[1], Amelia Blescun[2], Gabriela Doros[1], Mihai Gafencu[1]
[1]University of Medicine and Pharmacy "V. Babes", Pediatrics, Timisoara, Romania, [2]Emergency Clinical Hospital for Children “Louis Țurcanu”, Iiird Pediatric Clinic, Timișoara, Romania

Title of Case: Systemic bartonella haensele infection in an immunocompetent adolescent- case presentation
Background: Systemic clinical presentations of infection caused by Bartonella henselae are rare in immunocompetent children.
Case Presentation Summary: We report a case of a 12 years old girl with splenic, hepatic and bone involvement, presented as prolonged fever of unknown origin and sacroiliac pain. Physical examination was unremarkable; lymph nodes, liver, and spleen were not enlarged. ESR and CRP were elevated. Ultrasound revealed multiple hypoechoic splenic lesions with well-defined thick margins. Bone marrow aspiration excluded lymphoma. HIV serology was negative, negative tuberculin test with normal immunoglobulins. Serologic testing was negative for sarcoidosis and cystic echinococcosis but positive serology for Bartonella henselae (IgM and IgG), cytomegalovirus (IgM and IgG), Epstein barr (VCA IgM, IgG and EBNA) and Toxoplasmosis gondii (IgG). MRI shown multiple hepatic, splenic and bone lessions (right iliac bone, femoral neck, pubic bone and L1 L2 vertebrae) with central necrosis and diffuse edema, characteristic for Bartonella disease. Despite a prolonged QT treatment with doxycline and rifampicin was started with good evolution with strict cardiologic assessment.
Learning Points/Discussion: Bartonella henselae is mostly asymptomatic in the immunocompetent host or localized as regional adenopathy. Prolonged fever of unknown origin should raise suspicion of cat-scratch disease

PV1081 / #376

PYRIDOXIN TOXICITY IN PEDIATRIC PATIENT WITH ESRD ON PERITONEAL DIALYSIS. CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Nawras Al Hadi[1], Badria Al Ghaithi[1], Hilal Al Hashami[2]
[1]Royal Hospital, Child Health, Muscat, Oman, [2]Royal Hospital, Child Health, -AL Rusial, Oman

Title of Case: Pyridoxin Toxicity in pediatric patient with ESRD on peritoneal dialysis. Case report
Background: Pyridoxine induced toxicity was first described in 1984 in 58 years old female patient with carpal tunnel syndrome. Later on, couple of case report also reported different forms of neurosensory toxicity in adult patients on high doses and/or long-term therapy of pyridoxine. We present first case of pyridoxine toxicity in pediatric patient received[B1] therapeutic dose of pyridoxine of 1 mg/kg/day once daily who presented with low blood pressure, headache and hypersomnia.
Case Presentation Summary: A 4-year-old child with end stage renal disease secondary to Caroli syndrome. He has been on peritoneal dialysis for two years. He presented with 5 days history of a sudden onset headache, hypotension, numbness of all limbs, sleepiness and lethargy. Parents also gave a history of unsteady gait for two days. Parents denied any history of trauma, animal exposure and sick contact. Mantoux test was done recently as part of pre-transplantation work up. The test was positive and hence started on isoniazid and pyridoxine does of 20mg OD (1-2mg/kg/day, Weight: 17Kg) for treatment of latent TB. On initial examination, child was alert, conscious and Vitaly stable. Motor, sensory exam were normal. Reflex examination was normal in all extremities, and his gait was normal. Other systemic examinations were unremarkable. Laboratory investigations were insignificant for possible cause. CT head scan was done considering the acuity of child presentation and was normal. Possibility of pyridoxine induced neurotoxicity was considered yet pyridoxine level couldn't be sent because of lack of availability. Therefore, child was admitted for observation and pyridoxine was put on hold. Child showed clinical improvement subsequently
Learning Points/Discussion: In certain circumstances usage of pyridoxine supplementation should be used with cautions as in our patient.

A RARE CASE OF GASTROINTESTINAL BASIDIOBOLOMYCOSIS IN AN IMMUNOCOMPETENT CHILD: A CASE REPORT AND LITERATURE REVIEW

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Bandar Albaradi, Abdalazeem Hamad, Hanan Kanani
King Fahad Specialist Hospital, Pediatric Infectious Diseases, Dammam, Saudi Arabia

Title of Case: A RARE CASE OF GASTROINTESTINAL BASIDIOBOLOMYCOSIS IN AN IMMUNOCOMPETENT CHILD: A CASE REPORT AND LITERATURE REVIEW
Background: Basidiobolus ranarum (B. ranarum) is a fungus of zygomycetesclass found in decaying vegetation, skin of insects, and dung of reptiles and amphibians. The mode of transmission for B. ranarum is assumed to be through minor trauma. These fungi typically affecting immunocompetent host causing subcutaneous infection, with rare gastrointestinal (GI) manifestations.
Case Presentation Summary: 7 -year-old previously healthy girl presented with a four-month history of abdominal pain and abdominal distention associated with anorexia, weight loss and bloody diarrhea. The examination showed a huge lower abdominal mass. The full blood count had 18.9 10∧9/L white blood cells, with 55 % neutrophils and 40.9% eosinophils. Contrast enhanced computed tomography scan of the abdomen showed (figure 1) a large heterogeneous ill-defined mass within the right side of the mesentery measuring 6.8 cm x 10.2 cm x 10.5 cm in AP with central necrosis. She underwent an imaging-guided abdominal mass biopsy. Histopathology showed infiltration of eosinophils, special stains highlighted elements with thin walls and broad hyphae surrounded by eosinophilic material , positive for fungal microorganisms with morphological features consistent with basidiobolomycosis (SPLENDORE-HOEPPLI PHENOMENON) (figure 2) The patient started on intravenous voriconazole without surgical intervention. After 8 weeks, intravenous voriconazole shifted to oral . Abdominal mass cultures for TB and fungal were negative. Serial abdomen US showed a regression in the size of the mass (figure 3). The patient has gained weight with no bloody diarrhea and no palpable abdominal mass. The patient is still on Voriconazole with regular follow-up.
Learning Points/Discussion: To highlight the importance of clinical suspicion for early diagnosis and treatment of Gastrointestinal Basidiobolomycosis to optimize the patient's outcomes.

PULMONARY TUBERCULOSIS AND INVASIVE PENICILLIUM SINUSITIS IN PEDIATRIC PATIENT WITH ACUTE LYMPHOBLASTIC LEUKEMIA. CASE REPORT AND LITERATURE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Bandar Albaradi, Abdalazeem Hamad, Kawthar Mubayedh, Waad Alharthi
King Fahad Specialist Hospital, Pediatric Infectious Diseases, Dammam, Saudi Arabia

Title of Case: Pulmonary Tuberculosis and Invasive Penicillium sinusitis in Pediatric Patient with Acute Lymphoblastic Leukemia. Case report and literature report
Background: Tuberculosis (TB) diagnosis in immunocompromised host patients is challenging, mainly because of atypical presentation and increased likelihood of negative tuberculin skin tests (TST) and interferon-gamma release assays (IGRAs). The incidence of mycobacterial infections is higher in patients with hematological malignancies than in the general population. Infections caused by Penicillium spp. are rare but devastating in immunocompromised hosts.The treatment presents special problems because of the interactions between immunosuppressive drugs and antituberculous therapy as well as antifungal therapy.
Case Presentation Summary: A 2 year-11-month-old girl, High risk B-Cell Acute Lymphoblastic Leukemia, presented with prolonged non-neutropenic fever. A non-enhanced CT scan of the chest showed multiple bilateral pulmonary nodules and cavities, the largest in the left upper lobe, measuring 1.5 cm in diameter (figure 1). CT paranasal sinuses showed right maxillary antrum rounded soft tissue intensity lesion (figure 2). The patient underwent Broncho alveolar Lavage (BAL), Acid-fast bacilli (AFB) smear was positive. BAL for GeneXpert Mycobacterium tuberculosis (MTB) / Rifampicin (RIF) Real Time PCR Assay was positive , but Rifampicin resistance has not been detected. Functional endoscopic sinus surgery (FESS) was done, the culture grew Penicillium spp. with the following susceptibility (table 1). The patient started on standard therapy for pulmonary tuberculosis including isoniazid (INH), rifampin (RIF), pyrazinamide (PZA), and ethambutol (EMB).Treatment was modified as per susceptibility pattern (table 2),in addition to Liposomal amphotericin B for fungal sinusitis. Currently, infection is controlled with anti-TB and Anti-fungal therapy.
Learning Points/Discussion: Although co-infections are rare, pulmonary tuberculosis and Penicillium sinusitis require a high clinical index of clinical suspicion, early diagnosis, and prompt management to optimize the patient's outcome.

PV1084 / #1314

SHORT VERSUS PROLONGED COURSES OF ANTIBIOTIC THERAPY FOR CHILDREN WITH UNCOMPLICATED GRAM-NEGATIVE BACTEREMIA; A SYSTEMATIC REVIEW AND META-ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Afaf Ghunaim, Jawaher Aloatibi, Mona Aldabbagh
King Abdulaziz medical city, Pediatrics, Jeddah, Saudi Arabia

Backgrounds: There is no consensus on the optimal duration of antibiotic therapy in children with gram-negative bacteremia. Thus, the objective of this study was to compare the short (7- 10 days) vs. long-term (> 10 days) course of intravenous antibiotic therapy in those patients.
Methods: A literature search of PubMed, EMBASE, Scopus, and Cochrane databases was performed with the keywords " short-term antibiotic therapy, prolonged antibiotic therapy, gram-negative bacilli, bacteremia, bloodstream infection, treatment failure, relapse, and complications" in children (<18Years) . Screening of titles/ abstracts, data extraction, and quality assessment were done by two independent reviewers. Data were pooled using random effect model and compared using risk difference (RD) and its 95% confidence interval (CI).
Results: Eight studies were included in the analysis; 5 were clinical trials and 3 observational studies. The total number of patients was 807; 395 were in the short course group, and 412 were in the prolonged course group. Eight studies reported data about relapses [24 vs. 20 in short vs. prolonged course groups]. The overall RD was 0 (95% CI: -0.03- 0.02). Five studies reported data related to the dissemination of infection with no difference between both groups [RD: -0.01 (95% CI: -0.03- 002)]. Five studies reported data about all-cause mortality, with a RD of 0 and 95% CI of (-0.02- 0.02). Two studies reported antibiotic-related side effects, with no significant difference, however, there was a trend towards increased risk of candidemia in the prolonged therapy group, but this did not reach statistical significance [RD: 0.05 (95% CI: -0.10 – 0.00)].
Conclusions/Learning Points: Short course of Intravenous antibiotic therapy should be sufficient for treating uncomplicated gram negative Bacteremia in children with no apparent increased risk of relapse, infection spread, or mortality.

Title of Case: Disseminated Candidiasis In A Case Dıagnosed With Aplastic Anemia
Background: Aplastic anemia is a bone marrow failure disease characterized by hypocellular bone marrow and pancytopenia without abnormal infiltration and reticulin fiber increase. Clinical findings develop depending on cytopenias. Fungi can cause infections that are difficult to treat and have high mortality in patients with aplastic anemia.
Case Presentation Summary: A 13-year-old girl, who was followed up in an external center with the diagnosis of aplastic anemia, was sent to our pediatric intensive care unit with a preliminary diagnosis of septic shock. His general condition was poor, he was hypotensive, tachycardic, and his body temperature was 38 degrees. In the examinations, acute phase reactants were found to be high, neutrophil: 0 /mm3. Due to the pain in the left eye, which was around the eye, a fundus examination was performed by the ophthalmologist. Upon detection of lesions compatible with fungal endophthalmitis, anterior chamber paracentesis and intravitreal Amphotericin B injection were performed, and systemic amphotericin B was started. In the follow-up, the patient had nasal congestion and severe pain. In the ear, nose and throat examination, a necrotic crusty appearance compatible with invasive fungal sinusitis was detected. Untypeable mold was detected in the culture of the debridement material, and Candida was grown in the blood cultures of the patient. Micafungin was added to the amphotericin B treatment because the general condition of the patient was very poor and his fever was persistent. The patient, whose neutropenia persisted during the follow-up, and whose general condition was poor, died due to fungal sepsis.
Learning Points/Discussion: Although bacterial agents are frequently seen in long-lasting neutropenia, it should not be forgotten that fungal agents may be mortal.

EARLY ENTERAL FEEDING IN PRETERM INFANTS EXPOSED TO RISK FACTORS OF BRAIN DAMAGE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Hanifa Arfi[1], Nadia Cherfi[1], Samira Abrouk[2], Djamil Lebane[1]
[1]university of Algiers, Medecine, Algiers, Algeria, [2]university of Algiers, Biostatistics, Algiers, Algeria

Background: Early enteral nutrition is correlated with beneficial effects in healthy or sick premature infants. However, the protective effects of breast milk on the damaged brain are not yet sufficiently studied. Objectives Estimating the beneficial effect of breast milk in prematures at high risk of brain damage.
Methods: Case control study at the neonatal service of CHU Mustapha of Algiers from 01/12/2007 to /12/2012. Population : 801 in born prematures aged between 24 to 36 GA +6 days. -Cases : infants early fed with breast milk -Controls : infants fed with articficial milk. Exams : -CUS within the 72 hours of birth followed by weekly controls until the acquired term. - Late MRI for the 32 weeks born or less and after 40 post natal weeks if abnormal neurological exam.- -EEG : during the first week of life. - Statistical method : bi-varied analysis, logistic regression. P < to 0.05 was considered significant.
Results: Brain lesions frequency was 27.3%. The lesions included peri-intraventricular hemorrhages, cystic and non-cystic leukomalacia and the sequelae (post hemorrhagic hydrocephalus, hypotrophy or atrophy of corpus callosum, and cortical atrophy). The frequency of the breastfed infants was 83,4% (Cases: 20,12% and Controls: 79;87%). In bivaried: OR=0,14 (0,09-0,22) p<10-6 After adjustment by logistic regression ,early breast milk was an independent protector factor, ORa = 0,475 (0,25-0,90) p =0,022
Conclusions/Learning Points: In our study, breast milk was a protective factor against the occurrence of early brain damage. However, more specific studies are needed to better understand the mechanisms of this beneficial effect and its impact on distant cerebral development.

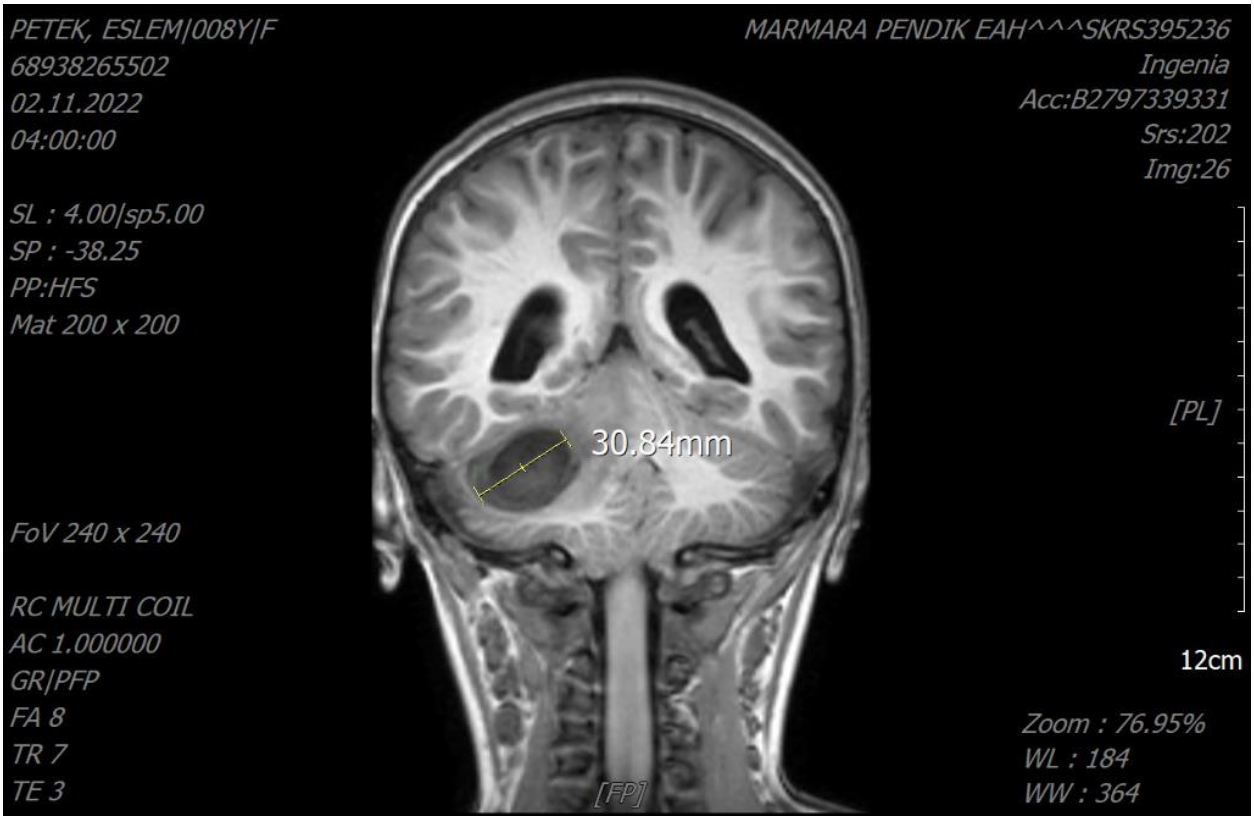
INCREASED INCIDENCE OF INVASIVE PNEUMOCOCCAL DISEASES (IPDS) AMONG CHILDREN AFTER COVID-19 PANDEMIC

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Sevgi Aslan Tuncay[1], Zeynep Ergenç[1], Seyhan Yılmaz[1], Burcu Parlak[1], Pınar Canizci Erdemli[1], Aylin Dizi Işık[1], Eda Kepenekli[2]
[1]Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Marmara University School of Medicine, Pediatric Infectious Diseases, Istanbul, Turkey

Title of Case: Increased Incidence of Invasive Pneumococcal Diseases (IPDs) among Children after COVID-19 Pandemic
Background: After lifting COVID-19 restrictions, an increase has been reported in childhood IPD that exceeded prepandemic levels. Here we present three children with the diagnosis of IPD.
Case Presentation Summary: Case 1 A 31-month-old male patient admitted with swelling and tenderness behind the left ear. He had bilateral cochlear implant for one year. There was no mastoiditis sign in computed tomography, an abscess was detected. Streptococcus pneumonia was identified in the culture of drained abscess material. Ceftriaxone and vancomycin was started. The antibiogram resulted as cefotaxime sensitive (mic: 0.047), than vancomycin was discontinued. The patient's symptoms resolved and he was discharged at 21st day of treatment. Case 2 A ten-month-old male patient presented with swelling and redness behind the left ear following otitis media. Computed tomography showed mastoiditis, and cortical mastoidectomy was performed. Meropenem and vancomycin combination therapy was started. Streptococcus pneumonia was idintified in the tissue culture and antibiogram resulted as cefotaxime sensitive (mic: 0.125). Vancomycin and meropenem were stopped and ceftriaxone was started. Ceftriaxone was stopped on the 14th day. Case 3 A nine-year-old female patient admitted with the headache following otitis media. Cranial MRI was showed an 30 mm abscess in the right cerebellar hemisphere (Figure
1).



The abscess was drained and the patient was started on metronidazole, cefepime, and vancomycin. Streptococcus pneumonia and Methicillin-resistant coagulase negative Staphylococcus spp were identified in the abscess culture. Treatment was switched to ceftriaxone and vancomycin. The abscess regressed significantly and treatment was completed to six weeks.

Learning Points/Discussion: The increased incidence of IPDs in this post-pandemic season highlights the importance of adequate immunization against S. pneumonia and the active surveillance for pneumococcal serotyping.

A CASE OF ACTINOMYCOSIS PRESENTING WITH A MEDIASTINAL MASS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Seyhan Yılmaz[1], Zeynep Ergenç[1], Sevgi Aslan Tuncay[1], Burcu Parlak[1], Pınar Canizci Erdemli[1], Aylin Dizi Işık[1], Gürsu Kıyan[2], Ayten Bakır[2], Eda Kepenekli[1]
[1]Marmara University School of Medicine, Pediatric Infectious Diseases, İstanbul, Turkey, [2]Pediatric Surgery, Marmara University School Of Medicine, İstanbul, Turkey, İstanbul, Turkey

Title of Case: A CASE OF ACTINOMYCOSIS PRESENTING WITH A MEDIASTINAL MASS
Background: Aktinomyces, a member of the Actinomycetaceae family may affect the bronchopulmonary, pleural, and thoracic wall and can spread from oropharynx into the deep organs. Here we present a case who was evaluated for mediastinal mass and thought to have malignancy but was diagnosed with actinomycosis.
Case Presentation Summary: A 12-year-old boy presented with back pain. The patient was admitted to pediatric surgery with presume diagnosis of malignancy when a mediastinal mass was found in the thorax magnetic resonance imaging (MRI). Magnetic resonance showed a mass lesion in the paretracheal region of the left hemithorax, extending from the T3-T4 level to the T7 level. A biopsy was obtained. In Periodic acid-Schiff (PAS) staining, microorganisms that resemble Actinomycetes forming filamentous groups were found. Pulmonary actinomycosis was diagnosed. The patient received intravenous of penicillin G. Following one month of antimicrobial therapy the mass was resolved. Immunoglobulins, the Dihidrorodamin (DHR) test and Flow cytometry analysis were normal. The antimicrobial therapy switched to the amoxicillin and was continued for one year.
Learning Points/Discussion: In conclusion, pulmonary actinomycosis lack of distinct symptoms and radiological similarities to other lung infections and cancers are significant. The diagnosis can be made by tissue sampling and special staining methods.

PV1089 / #868

FIRST FEVER AND BLOOD, THEN RASH

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Diana-Georgiana Basaca[1,2], Amelia Blescun[3], Otilia Mărginean[1,2]
[1]Emergency Clinical Hospital for Children “Louis Țurcanu”, Ist Pediatric Clinic, Timișoara, Romania, [2]University of Medicine and Pharmacy "Victor Babeș", Department Of Pediatrics, Timisoara, Romania, [3]Emergency Clinical Hospital for Children “Louis Țurcanu”, Iiird Pediatric Clinic, Timișoara, Romania

Title of Case: First fever and blood, then rash
Background: Fever is the single most common reason for children to present to the emergency department. When paired with a rash, it can lead to a dilemma in the diagnostic, given the broad spectrum of diseases that present these clinical symptoms, therefore the history and the physical examination are crucial. Febrile rashes are most of the time self-limited and with favorable prognostic, but some represent a public health concern.
Case Presentation Summary: A male patient, 16 years old, presented fever, cough, headache, rhinorrhea, and two loose stools, then 12 hours later he presented multiple episodes of hematemesis (fresh blood and clots) after minimal coughing. He was brought to the ED where laboratory analysis revealed an elevated CRP (152mg/L) and mild thrombocytopenia (123.000/ul). He was admitted to the Gastroenterology Department and antibiotic and supportive treatment was initiated, He underwent multiple procedures and investigations (gastroscopy, laryngeal endoscopy, chest CT, abdominal ultrasound, ENT consult) and a small portion of the tracheal mucosa was found to be congested and with accentuated vascularization, showing signs of recent bleeding. After 48 hours since the first symptoms, a generalized maculopapular rash appeared and the patient was transferred to the Infectious Disease Department. Screening for viral rashes (measles, rubella, EBV, CMV, HIV, Toxoplasma, Mycoplasma pneumoniae, Parvovirus) was performed, with negative results. He was discharged after 4 days, with clinical improvement and no further episodes of hematemesis, which was interpreted as vascular hyperpermeability linked to the viral infection.
Learning Points/Discussion: This case report demonstrates the importance of treating the patient, not just the disease. The multidisciplinary team approach is essential in allowing for a more comprehensive evaluation and management of the patient's condition, leading to early diagnosis and treatment.

COWPER SERINGOCÉLE, MISSED ETIOLOGY OF RENAL FAILURE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Hammou Benslimane
faculty of medecine, Pediatric Urology Department, oran, Algeria

Title of Case: Cowper seringocéle, missed etiology of renal failure
Background: The cowper's gland is a small gland located on either side of the membranous urethra, which produces mucus which it drains into the urethral lumen through these two ductThe cowper's gland cyst is a dilation of the gland, commonly called cowper's syringocele , is a disease that effects children but is unfortunately diagnosed in adulthood by missed diagnosis.
Case Presentation Summary: 5-year-old child admitted to the emergency department for urinary retention ,neonatal period unremarkable ,no history of neurological symptoms , history of repeated urinary tract infections one time every 3 month with dysuria and dribbling , managed by antibiotic and a history of feeling incomplete urination.Physical examination found a bladder globe,retention with sub pubic swelling with guarding and pain.Urinalysis found leukocytes and nitrites.The culture confirms the urinary tract infection with Escherichia coli.Blood test finds a creatinine level of 20 mg / l and urea at 0.65 g / l.Ultrasound: bladder with diverticular wall with bilateral ureterohydronephrosis and dilation.Retrograde urethrocystography: show dilated prostatic urethra and bilateral vesicoureteral refluxTherapeutic interventions: Patient relieved by placement of urinary catheter.Cystoscopy was done in peripheral hospital : stenotic urethra with demonstration of a bladder diverticulum.
Learning Points/Discussion: Suspected in the presence of a clinical or paraclinical symptomatology of urinary obstruction and confirmed by an endoscopic examination where the syringocele appears as a protrusion of a cyst in the intaurethral in the event of a closed syringocele or a defect on the posterior surface of the membranous urethra in case of ruptured syringocele.Unknown pathogenesis, congenital in children,.Several classifications used, the current trend is the use of a simple classification, ruptured syringocele and enraptured syringocele.

SALMONELLA PARATYPHI URINARY TRACT INFECTION IN AN INFANT-A RARE MANIFESTATION OF PARATYPHOID FEVER

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Deepak Bhat
DAYANAND MEDICAL COLLEGE LUDHIANA, Pediatrics, LUDHIANA, India

Title of Case: SALMONELLA PARATYPHI URINARY TRACT INFECTION IN AN INFANT-A RARE MANIFESTATION OF PARATYPHOID FEVER

Background: Salmonella is primarily known to affect the gastrointestinal tract but can rarely cause infections at uncommon sites like the urinary tract. It is known that Salmonella can infect the urinary tract directly by blood, fecal contamination of urethra, urolithiasis, or secondary intraluminal ascending infection. We present a case of 8 month old infant who presented with fever caused by Salmonella paratyphi further leading to urinary tract infection

Case Presentation Summary: An eight month old female child was admitted in the pediatrics department of our hospital with complaints of fever,irritability,refusal to feed and increased frequency of micturition for past 8 days.Fever was high grade,intermittent and associated with rigors.Baby was being given milk with a bottle which was not properly sterilized.Routine laboratory investigations were sent along with blood culture and a urine culture.Child was started on intravenous fluids and injection cefuroxime for suspected urinary tract infection.Hematological parameters were in normal range except for raised CRP levels.In liver function tests ALT as well as AST levels were raised and so was serum LDH.Urine analysis showed increased leukocytes and proteins.Urine culture showed growth of Salmonella paratyphi A which was resistant to cefuroxime .As per sensitivity reports antibiotic was changed to ceftriaxone.Child continued to have fever upto 102^0F.In the meantime blood culture also grew Salmonella paratyphi A.As fever persisted ispite of giving intravenous ceftriaxone for 5 days,oral Azithromycin was added in a dose of 20 MG/Kg/day.Within 48 hours defervescence took place and child was discharged home on 10^{th} day of hospitalization.Child received further 4 days of oral Cefixime.

Learning Points/Discussion: Salmonella paratyphi A is a rare cause of UTI.Patients who develop S.paratyphi bacteriuria should be evaluated further for underlying urinary tract abnormalities.

PROTEIN-LOSING ENTEROPATHY AS UNUSUAL COMPLICATION OF GIARDIASIS IN CHILDREN: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Margarida Caldeira, Filipa Sutre, Alexandra Gavino, Aldina Lopes
Hospital Distrital de Santarém, Pediatria, Portugal, Portugal

Title of Case: PROTEIN-LOSING ENTEROPATHY AS UNUSUAL COMPLICATION OF GIARDIASIS IN CHILDREN: A CASE REPORT
Background: Giardiasis is an intestinal infection caused by Giardia lamblia, a protozoan parasite. The infection may be asymptomatic or present with a wide spectrum of clinical manifestations. Malabsorption is a well-known complication of giardiasis, however, selective protein-losing enteropathy (PLE) is rare. In cases of severe hypoproteinemia edema, ascites and/or pleural/pericardial effusion may occur.
Case Presentation Summary: A previously healthy, indian, 17-month-old girl presented to an emergency department with a one-week history of fever, watery diarrhea, vomiting and face, hands and feet swelling. At the admission she was apyretic and hemodynamically stable, with pale skin and generalized pitting edema without ascites, organomegaly or pleural/pericardial effusions. Laboratory results showed iron deficiency anemia, hypoproteinemia (2.9 g/dL) and hypoalbuminemia (1.4 g/dL). Biochemical examinations, urinalysis and 12-hours urinary protein excretion excluded proteinuria and hepatic dysfunction. Serum immunoglobulin G, vitamin D, calcium and ferritin levels were low. Celiac disease was excluded. Although stool cultures failed to reveal pathogenic organisms, stool analysis for Giardia lamblia antigen were repeatedly positive in three samples. The patient was managed with fluid-restriction and a high protein content diet. Vitamin D, calcium and iron were also supplemented. After five days of Albendazole (400 mg/day), the edema decreased progressively and she was discharged from hospital 13 days after admission. Four weeks later, she was asymptomatic, physical examination was entirely normal and serum total protein, albumin and immunoglobulins levels were in the normal range.
Learning Points/Discussion: Giardiasis is a treatable cause of PLE, which can be associated with severe comorbidities. An epidemiological investigation, early recognition and treatment of Giardia infection presenting with PLE, allows rapid clinical and laboratory recovery thus preventing malnutrition, particularly in growing children.

AN AUDIT EVALUATING THE USE OF A LOCAL PAEDIATRIC SEPSIS SCREENING TOOL COMPARED TO THE NICE STRATIFICATION TOOL IN IDENTIFYING PAEDIATRIC SEPSIS CASES

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Sapphire Cartledge[1], Ezgi Seager[2], Steven Welch[2]
[1]University of Birmingham, School Of Medicine, Birmingham, United Kingdom, [2]Heartlands Hospital, Department Of Paediatrics, University Hospitals Birmingham, Birmingham, United Kingdom

Backgrounds: An effective screening tool to identify cases of paediatric sepsis is paramount to ensuring prompt recognition, and management of sepsis. At Heartlands University Hospitals Birmingham (UHB) there is a screening tool for paediatric sepsis based off NICE guidelines. This audit aims to compare how many children admitted to paediatric assessment unit (PAU) triggered the sepsis pathway on the UHB screening tool compared to the NICE stratification tool, and of these how many had a final diagnosis of sepsis.
Methods: We collected data from 147 PAU admissions in a period of 18 days from August to September 2022. Outcomes recorded include completion of the UHB sepsis screening tool at admission; if the sepsis pathway was triggered by the UHB screening tool, or NICE tool; and number of final diagnoses of sepsis along with time for senior review and antibiotic administration.
Results: 94 children presenting to PAU out of 147 (64%) had sepsis forms completed. Four children (3%) triggered the sepsis pathway via the UHB tool whereas 32 children (22%) triggered via the NICE tool. Of these, 27 children (18%) triggered due to age-specific tachycardia. In total, no children had a final diagnosis of sepsis.
Conclusions/Learning Points: In our 147 PAU admissions, we found only 64% had sepsis forms completed. Of these, over seven times the number of children triggered the sepsis pathway for urgent senior review via the NICE stratification tool compared to our local UHB sepsis screening tool; no children had a final diagnosis of sepsis. This suggests more emphasis should be placed on completion of the sepsis form in our PAU, and more research should be undertaken evaluating the sensitivity of the NICE stratification tool in PAU.

ACUTE LYMPHOCYTIC LEUKEMIA - AN UNEXPECTED DIAGNOSIS: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Mariana Castro[1], Mariana Sebastião[2]
[1]Unidade de Saúde Familiar Araceti, General And Family Medicine, Coimbra, Portugal, [2]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal

Title of Case: ACUTE LYMPHOCYTIC LEUKEMIA - AN UNEXPECTED DIAGNOSIS: A CASE REPORT
Background: Leukemia is the most common cancer in children and teens, accounting for almost 1 out of 3 cancer cases, the most common type being acute lymphocytic leukemia (ALL). In this clinical case, asthenia and recurrent infections were the symptoms that motivated the patient to seek professional help, but the overall nonspecific clinical presentation created a diagnostic challenge.
Case Presentation Summary: Three-year old male is brought to the hospital with fever (maximum 39,3ºC, 4/4 hours, resolves with antipyretic and without signs of hypoperfusion), productive cough and odynophagia with 3 days of evolution. A physical examination presented with paleness, normal breath sounds, no dyspnea, 99% oxygen saturation and hyperemic tonsils. Rapid antigen detection test for group A streptococcus negativity lead to the assumption of viral respiratory infection. Paleness was attributed to breastfeeding and the mother was advised to start weaning in order to prevent iron absorption deficits and related anemia. A week later is brought again to the hospital due to asthenia and hypoactivity, noticed by the mother and teacher, and to recurrent respiratory infections over the last month. Analytical assessment showed severe anemia (Hb 4.9) – 2 blood units were transfused, mild leuko- and thrombocytopenia, elevated ferritin and reticulocytes, and a peripheral blood smear with 7% blasts of apparent lymphoid lineage. Bone marrow examination confirmed precursor B-acute lymphoblastic leukemia.
Learning Points/Discussion: Early diagnosis of ALL is essential for proper treatment. Nonspecific symptoms might be overlooked and misguide clinical investigation. Hemogram is a simple but valuable diagnostic tool and its routine use can hasten diagnosis, improving patients' prognosis.

MURINE TYPHUS IN CHILDREN IN CYPRUS BETWEEN 2007 AND 2021

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Myria Charalambous[1], Maria Koliou[2]
[1]Archbishop Makarios Hospital, Paediatrics, Nicosia, Cyprus, [2]University of Cyprus, Medical School, Nicosia, Cyprus

Title of Case: MURINE TYPHUS IN CHILDREN IN CYPRUS BETWEEN 2007 AND 2021
Background: Murine typhus is caused by the intracellular bacterium Rickettsia typhi and is usually transmitted by the rat-flea Xenopsylla cheopis. In Europe the disease is endemic in Southern European countries. This study aims at defining the epidemiological and clinical characteristics of murine typhus in children in Cyprus.
Case Presentation Summary: In this retrospective cohort study, the medical records of patients under 15 years old, admitted to three public hospitals in Cyprus were reviewed. Cases were diagnosed as confirmed or possible based on the Ministry of Health definitions of Notifiable diseases 2018. Thirty children were diagnosed with murine typhus between 1/1/2007 to 31/12/2021. 15 of them were males (50.0%). Median age 10 yrs. Most of cases occurred between July and September. Median duration of fever before admission was 7 days. The most common clinical findings were fever 100%, rash 60.0%, chills 50.0%, headache 46.7%, myalgias 36.7%, lymphadenopathy 30.0%, splenomegaly 30.0%. Most common laboratory abnormalities were elevated C-reactive protein 93.3%, low albumin 63.2% and elevated transaminases 63.3%. Complications such as meningitis and nephritis occurred in 20% of cases, mostly in patients above 10 years old. No patient was admitted in Intensive care unit or died. Treatment regimens included doxycycline (73.3%) and azithromycin (16.6%).
Learning Points/Discussion: Murine typhus is a rare but important cause of fever and hospitalization in Cyprus. Complications occur mostly in patients above the age of 10 years. Murine typhus should be considered in children with fever and rash during summer and autumn months in Cyprus. Improved physician awareness will lead to early recognition of R. typhi infection in children and will prevent unnecessary use of non-effective antibacterials and prolonged morbidity.

SEROPREVALENCE OF TOXOPLASMA GONDII AND PEDIATRIC TOXOPLASMOSIS IN SOUTH KOREA: A SINGLE CENTER RETROSPECTIVE STUDY DURING 2010-2022

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Donghyun Shin, Soo-Han Choi
Pusna National University Hospital, Department Of Pediatrics, Busan, Korea, Republic of

Backgrounds: Primary Toxoplasma gondii infection in pregnant women or reactivation of chronic infection in immunocompromised patients can result in severe consequences. We investigated the seroprevalence of Toxoplasma in South Korea.
Methods: A retrospective review was conducted on individuals of all ages who underwent serologic testing for Toxoplasma gondii at Pusan National University Hospital from January 2010 to December 2022. We analyzed the seroprevalences of Toxoplasma by age group, age group, and periods.
Results: Data on 4,921 Toxoplasma IgM and 3,635 Toxoplasma IgG were collected. The overall seroprevalence of Toxoplasma IgM and IgG was 1.4% and 16.6%, respectively. Of 2,669 individuals who underwent Toxoplasma IgM and IgG, 2.2% tested positive for both. The seroprevalence of Toxoplasma IgM was the highest in individuals aged 30-39 (3.6%). As the age increased, the seroprevalence of Toxoplasma IgG showed a significant upward trend (P <0.001). The seroprevalence of Toxoplasma IgG was the highest among individuals aged ≥70 years old (27.3%). In females of reproductive age (15-49 years), the seroprevalence of Toxoplasma IgM was 2.6% (3.1%, aged 20-29; 3.8%, aged 30-39). There were no significant differences by gender (male vs. female): 1.3% vs. 1.5% (P = 0.623) in IgM and 16.1% vs. 15.4% in IgG (P = 0.604). Over the study period, the seroprevalence of Toxoplasma IgG noted a significant upward trend over time (P = 0.036). Among the infants, the seroprevalence of Toxoplasma IgM and IgG was 0.2% (3/1,531; all congenital toxoplasmosis) and 8.6% (7/81; 5, transplacental transmission related to maternal toxoplasmosis), respectively. In children aged 1-18, the seroprevalence of Toxoplasma IgM and IgG was 0.5% (4/812) and 8.0% (12/150).
Conclusions/Learning Points: The seroprevalence of Toxoplasma IgM was relatively high among young adults, and monitoring for congenital toxoplasmosis is needed.

SEVERE RHABDOMYOLYSIS IN A PATIENT WITH MALARIA

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Ana Luísa Correia[1], Rita Amorim[2], Marta Grilo[3], Teresa Campos[4], Ana Reis-Melo[5], Maria Tavares[5]
[1]Hospital Pedro Hispano, Unidade Local de Saúde de Matosinhos, Pediatrics, Matosinhos, Portugal, [2]Centro Hospitalar Universitário de São João, Pediatrics, Porto, Portugal, [3]Centro Hospitalar Universitário de São João, Pediatric Intensive Care Unit, Pediatrics, Porto, Portugal, [4]Centro Hospitalar Universitário de São João, Reference Center Of Hereditary And Metabolic Diseases, Pediatrics, Porto, Portugal, [5]Centro Hospitalar Universitário de São João, Pediatric Infectious Diseases And Primary Immunodeficiencies Unit, Pediatrics, Porto, Portugal

Title of Case: Severe rhabdomyolysis in a patient with malaria
Background: Rhabdomyolysis in Plasmodium falciparum (PF) malaria is reported occasionally in the literature, and it can lead to severe metabolic and renal complications.
Case Presentation Summary: A 14-year-old boy, natural from Ivory Coast, had no relevant medical history, other than non-complicated malaria 2 years before. During his vacation in Portugal he went to an emergency department with complaints of fever, headache, and myalgias, with 3 days of evolution. He had already taken a dose of artemether/lumefantrine at home. At admission he was prostrated and drowsy. Initial blood workout revealed a creatine-kinase (CK) of 15427 U/L, creatinine of 1.24 mg/dL, and CRP of 75 mg/L. P. falciparum malaria was diagnosed, with a parasitemia of 0.12%.
He started IV artesunate, ceftriaxone and fluid therapy. There was a global clinical improvement, however, his urine was dark-colored and he referred significant leg pain. Analytically, there was myoglobinuria (with choluria), exacerbation of CK and myoglobin values (117668 U/L and 5585.2 ng/ml, respectively). He was admitted in intensive care, with renal insufficiency and rhabdomyolysis. During hospitalization, CK and myoglobin values progressively increased, reaching maximum values of 345139 U/L and >12000 ng/mL, respectively; with normalization of kidney function. Besides antimalarial drugs, he was treated with intravenous hyperhydration and sodium bicarbonate boluses. After 2 weeks of treatment, he was discharged with normal CK and myoglobin levels. He has an ongoing genetic study to determine if there is an individual susceptibility to justify these extremely elevated CK levels.
Learning Points/Discussion: In patients with Falciparum malaria presenting with severe myalgia and black-colored urine, rhabdomyolysis should be considered. This is a particular and rare case, due to these extremely high levels of CK, compared to other published case reports.

PV1098 / #1472

SPLENIC ABSCESS AS A CLUE TO DIAGNOSIS OF ENTERIC FEVER: A CASE SERIES

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Nabaneeta Dash[1], Navpreet Kaur[2], Lakhinana Kaliprthap[2], Ashish Agarwal[2], Anmol Bhatia[3], Sanjay Verma[4]
[1]PGIMER, Telemedicine, Chandigarh, India, [2]PGIMER, Paediatrics, Chandiagrh, India, [3]PGIMER, Radiodiagnosis, Chandigarh, India, [4]PGIMER, Pediatrics, Chandigarh, India

Title of Case: SPLENIC ABSCESS AS A CLUE TO DIAGNOSIS OF ENTERIC FEVER: A CASE SERIES
Background: Salmonella infection is a major public health problem in low-middle income countries. India accounted for nearly 50% of 14.3 million global cases of enteric fever in 2017. Typhoidal Salmonella rarely cause abscesses in different organs as opposed to non-typhoidal strain; isolated splenic abscess, in particular is uncommon. Here we report 3 children who presented with non-localizing fever and splenic lesions.
Case Presentation Summary: A 12-year-old boy presented with 3-weeks history of fever with chills and pain in left upper abdomen. Ultrasound (US) examination of abdomen revealed 3 anechoic to hypoechoic lesions in spleen, that were aspirated under US guidance. Pus culture grew Salmonella paratyphi A. He recovered completely with 3 weeks of ceftriaxone. A 5-year old girl presented with 10 days history of fever, pain abdomen, vomiting and loose stool. Blood culture showed growth of Salmonella typhi (pan-sensitive). She was started on intravenous ceftriaxone. Despite 7-days therapy, fever did not defervesce hence an US was done that showed solitary splenic abscess. Aspiration & drainage of pus while continuing antibiotics helped in her complete recovery over 3 weeks. Another 4-year-old girl was admitted with complaints of fever with chills, pain abdomen and vomiting for 10-days. US done as a part of evaluation for fever showed multiple splenic granulomas. Her blood culture grew Salmonella typhi at 48 h incubation. She had complete resolution following 14-days of systemic antibiotics without any additional intervention.
Learning Points/Discussion: Splenic abscesses/lesions in typhoidal Salmonella infection are not as uncommon. Non-resolution of fever despite sensitive antibiotic therapy in enteric fever cases should raise the suspicion of intraparenchymal abscess particularly in spleen. Ultrasound guided pus aspiration may help in diagnosis and treatment.

COVID-19 VACCINATION IN CHILDREN OVER 3 YEARS OLD. CROSS-SECTIONAL STUDY OF PEDIATRICIANS' AND PARENTS' PERCEPTIONS AND VACCINE ACCEPTANCE IN COLOMBIA.

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Mauricio Guerrero Roman[1], Claudia Patricia Beltrán Arroyave[2], Andrea Puentes Díaz[3], Gloria Zuccardi[1], Silvia Enrique[4], Roberto Debbag[5]
[1]Sociedad Colombiana de Pediatría, Cundinamarca, Bogotá, Colombia, [2]Universidad de Antioquia. Clínica del Prado, Antioquia, Antioquia, Colombia, [3]Tecnofarma, Tecnofarma, bogotá, Colombia, [4]Sociedad Latinoamericana de Infectología Pediátrica, Slipe, Santo Domingo, Dominican Republic, [5]Sociedad Latinoamericana de Infectología Pediátrica, Slipe, Santo Domingo, Argentina

Backgrounds: COVID-19 vaccine is indicated in children over 3 y.o. in Colombia, vaccination coverage rate in the 3-11 y.o. age group was 67% for the second booster, as of Dec 6, 2022. Vaccine acceptance is one of the main factors impacting coverage; little is known about it in Colombia. Our goal was to assess pediatricians' and parents' perception and acceptance of COVID-19 vaccines in children in the country.
Methods: From January 2-15, 2023 we carried out two cross-sectional online surveys among pediatricians and parents of children of COVID-19 vaccination age in Colombia.
Results: 767 physicians completed the questionnaire (52.1% from private practice; 81.2% > 5 years of clinical practice). The risk of COVID-19 was perceived as low both for adults and children (16.8% and 37.0%, respectively) while vaccine acceptance was higher for adults (96.4%) than for healthy children (69.4%); 23.0% would only indicate the vaccine to children at risk. Lack of scientific information (57.3%), fear of immediate and long-term side effects (20.8% and 33.3%, respectively), and non-severity of the disease in children (21.8%) were the main reasons impacting vaccine hesitancy. Of the 646 parents who answered the survey, 82.6% were mothers over 35 y.o.; 57.7% had postgraduate degrees; 89.4% had vaccinated their children against COVID-19. The main reason for non-vaccination was concern about vaccine safety (36.6%). 71.2% of participants had received information from their pediatricians about how vaccines work, and 64.8% about the risks of COVID in children.
Conclusions/Learning Points: Acceptance of COVID-19 vaccines is high in Colombia, as shown by the results of this study and the vaccination coverage rates. However; evaluating and designing strategies to revert vaccine hesitancy should not be overseen in light of the current global and regional antivaccine moment.

COVID-19 VACCINATION IN CHILDREN OVER 6 MONTHS OF AGE. CROSS-SECTIONAL STUDY OF PEDIATRICIANS' AND PARENTS' PERCEPTIONS AND VACCINE ACCEPTANCE IN ARGENTINA.

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Ximena Juarez[1], Paula Pertzov[2], José Brea[3], Silvia Enrique[4], Roberto Debbag[5]
[1]Hospital General de Niños Pedro de Elizalde, Infectologia, Buenos Aires, Argentina, [2]Laboratorios RAFFO, Pediatría, caba, Argentina, [3]Facultad de medicina del Instituto Tecnológico de Santo Domingo, Facultad De Medicina, Santo Domingo, Dominican Republic, [4]Sociedad Latinoamericana de Infectología Pediátrica, Slipe, Ciudad Autónoma de Buenos Aire, Argentina, [5]Sociedad Latinoamericana de Infectología Pediátrica, Slipe, Santo Domingo, Argentina

Backgrounds: COVID-19 vaccine is indicated in children over 6 months of age in Argentina, vaccination coverage rate is 62% in children over 3 yo, and it is low in the 6 mo-3 yo age group. Vaccine acceptance is one of the main factors impacting coverage; little is known about it in Argentina. Our goal was to assess pediatricians' and parents' perceptions and acceptance of COVID-19 vaccines in children in the country.
Methods: From January 2-15, 2023 we carried out two cross-sectional online surveys among pediatricians and parents of children of COVID-19 vaccination age in Argentina.
Results: 919 physicians completed the questionnaire (68.1% from public hospitals and primary health care; 90.2% > 5 years of clinical practice). The risk of COVID-19 was perceived as moderate in adults (54.9%) and low in children (52.6%), vaccine acceptance was higher for adults (91.5%) than for healthy children (68.2%); 17.1% would only indicate the vaccine to children at risk. Lack of scientific information (29.0%), concern about long-term side effects (19.9%), and non-severity of the disease in children (9.7%) were the main reasons impacting vaccine hesitancy. Of the 2,692 parents who answered the survey, 97.3% were mothers, 87.2% over 30 y.o., 46.0% had university studies and 59.7% had not yet vaccinated their children against COVID-19. The main reason for non-vaccination was their concern about vaccine safety (50.1%); 63.7% of participants had received information from their pediatricians about how vaccines work, and 55.3% about the risks of COVID in children.
Conclusions/Learning Points: Acceptance of COVID-19 vaccines is still low in Argentina, as shown by vaccination coverage rates and the results of this study. Evaluating and designing strategies to revert vaccine hesitancy and improve vaccine uptake is essential in the current global and regional antivaccine moment.

INTENSIVE TRAINING PROGRAM IN VACCINOLOGY AND VACCINES POLICIES: A LATIN AMERICAN INITIATIVE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Roberto Debbag[1], Carlos Espinal Tejada[2], Francisco Becerra[2], Jaime Torres[3], Carlos Torres Martinez[4], Rolando Ulloa-Gutierrez[5], Silvia Enrique[6]
[1]Sociedad Latinoamericana de Infectología Pediátrica, Slipe, Santo Domingo, Argentina, [2]Florida International University, Global Health Consortium, Robert Stempel College Of Public Health And Social Work, Miami, United States of America, [3]Universidad Central de Venezuela, Infectious Diseases And Tropical Medicine, Caracas, Venezuela, [4]Universidad del Bosque, Pediatría, Bogota, Colombia, [5]Hospital Nacional de Niños Carlos Sáenz Herrera, Servicio De Infectologia Pediatrica, San Jose, Costa Rica, [6]Essentia-Medical, Office Of The Ceo, Buenos Aires, Argentina

Backgrounds: Several Vaccinology courses are offered worldwide. Language and costs are barriers to access international education for Latin American physicians. We describe a training initiative aimed at filling this gap.
Methods: We designed an 8 days' training on Vaccines and Vaccination Policies in Spanish language, directed to Latin American (LATAM) physicians, members of governmental agencies, the academia, and the industry. Top-notch experts were invited as professors and lecturers. Participants' selection criteria was based on academic and professional background. The agenda included a comprehensive insight on vaccine development, economics, production, vaccination programs and policies, through lectures, workshops, master classes, coached peer groups, and digital tools.
Results: 423 inquiry forms and 96 applications were received; 52 participants from 11 LATAM countries were selected (81% physicians; 35% infectious diseases; mean age 41; public/private practice ratio 50/50, male/female ratio 20/32). The program took place on September 18-25, 2022 in Miami, Florida, USA, during 8 days (70 class hours, 50 sessions, 140 educational objectives, 30 professors). Before joining, participants were asked to agree to a "digital silence" policy (no use of personal devices during sessions) and attended a virtual leveling course during the 9 weeks prior to the training. The online program platform included interactive tools, all presentations, videos, and suggested readings; iPads with access to the platform were provided to be used during digital silence. In the post-training survey, 89.1% of participants ranked the agenda as excellent and gave high scores to all academic activities and faculty; 100% confirmed to have gained new knowledge, and would recommend the program to their colleagues.
Conclusions/Learning Points: This training program fills in an educational gap, and might become a new opportunity to identify and develop future leaders in Vaccinology and Vaccines Policies in LATAM.

VIRTUAL MEDICAL EDUCATION IN PEDIATRIC INFECTIOUS DISEASES: A LATIN AMERICAN EXPERIENCE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Pio López[1], Eduardo López Medina[1], Diana Davalos[2], Daniela Torres[3], Roberto Debbag[4]
[1]Sociedad Latinoamericana de Infectología Pediátrica, Slipe, Santo Domingo, Dominican Republic, [2]Universidad del Valle, Centro De Estudios En Infectología Pediatrica Ceip.department Of Pediatrics, Cali, Colombia, [3]Universidad del Valle, Department Of Pediatrics, Cali, Colombia, [4]Sociedad Latinoamericana de Infectología Pediátrica, Slipe, Santo Domingo, Argentina

Backgrounds: Discussion of difficult or controversial cases is a traditional tool to update medical knowledge. Virtual case discussion meetings (VCDM) also allow knowledge exchange at regional and global levels. Since 2020, our PID scientific society in Latin America holds a regional weekly VCDM. We describe this educational initiative and the participants' feedback.
Methods: We revised the diagnoses, attendance and participants' profile, and designed a survey to assess their feedback on the activity.
Results: From January 11 to December 13, 2022 we hosted 44 VCDM. Society members were invited to attend via email campaigns. Presenters were selected by the medical education committee. Average attendance was of 115 physicians from 229 institutions in 20 Latin American countries. The most frequent pathologies were infections in ICH (20%), infrequent invasive bacterial infections (18%), endemic mycosis (10%), and neonatal infections (10%). 72 participants completed the survey (78.5% PID specialists, 14.2% PID fellows, and 7% others); 65.28% had over 5 years of clinical practice. 50% stated that they had changed their agendas to attend the meetings, 20% did not attend but watched the videos. Most participants (91.5%) agreed that these meetings contribute to their daily clinical practice, provide opportunities for networking and update (35.7% and 34.3%, respectively). Most prefer to discuss frequent pathologies with unusual clinical manifestations (77.1%); everyone stated that they will continue participating in 2023.
Conclusions/Learning Points: Our VCDM allowed specialists and fellows in training to interact and learn from diverse clinical cases presented by their peers throughout the region. Scientific societies promoting this type of forums contribute to improve medical knowledge on the epidemiology, presentation, diagnosis and management of diseases, and favor academic and scientific networking.

FIRST CASE OF CONGENITAL VISCERAL LEISHMANIASIS IN MONTENEGRO

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Snezana Dragas, Bojan Koprivica
Clinical Centre, Clinic For Infectious Disease, Podgorica, Montenegro

Title of Case: First case of congenital visceral leishmaniasis in Montenegro
Background: Occurence and outcome of congenital Visceral Leishmaniasis (VL) is rare publishing. The disease is endemic in some Countries including Montenegro with annually incidence of 3-5 cases. The aim of the case was to present the first case of congenital VL in our Country.
Case Presentation Summary: A 29 years female was hospitalized at the Clinic for Infectious disease, Podgorica, Mongenegro in the March 2017. 10 days after natural childbirth. Three days after giving birth she develope symptoms of fever, weakness, and abdominal pain with conjuctival hyperemia, generalised lymhadenopathy, hepatomegalia and spleen enlargment (up tp 25 cm cranio-caudal diameter) at physical examination. Laboratory analysis revealed pancytopenia, mild elevated of liver function tests, increased in inflamatory markers and hypergammaglobulinemia. Microbiology results incluing blood and urine culture and other viral and bacterial infections were negative. Hematologic, rheumatologic, and autoimmune disorders were ruled out. Positive antibodies agains Leishmania Donovani confirmed by bone marrow biopsy and finding the amastigote form of the parasite in cells confirmed the diagnosis of VL. She was treated with liposomal Amphotericin B within 28 days with resotions of symtoms, imrovement of laboratory markers decrease of spleen enlargement (up to 16 cm). Three months after mothers disharge, the newborn boy developed the same symtoms as mother has and the diagnosis of VL suggesting congenital transmission. He was hospitalized at the Pediatric Clinic, Podgorica, Montenegro and treated with Amphotericin B with complete resolution of symptoms and improvement of clinical and laboratory parameters.
Learning Points/Discussion: Despite the fact that the occurence of congenital Vl is rare it could be considered in endemic Countries uncluding Montenegro and routine testing of pregnant women should be recommended.

COMPLICATIONS OF INFECTIOUS MONUNUCLEOSIS IN CORRELATION WITH SPLEEN ENLARGEMENT AMONG HOSPITALIZED CHILDREN IN MONTENEGRO

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Snezana Dragas, Bojan Koprivica
Clinical Centre, Clinic For Infectious Disease, Podgorica, Montenegro

Backgrounds: Infrctious mononucleosis (IM) is an infective disease coused by Epstein Barr Virus (EBV) with differences in clinical features and complications. This study aimed to determine corelation of complications with spleen enlargement in hospitalized children with IM.
Methods: This retrospective study included 160 children aging from 3-16 years with acute IM confirmed by finding specific anti EBV VCA IgM antibodies, hospitalized at the Clinic for Infectious Disease, Podgorica, Montenegro from 2014-2019. Collecting data included epidemiological, clinical and laboratory parameters and ultrasound examination of the abdomen on addmition with dividing subjects into study group 105 patients with spleen enlargment, and control group 55 patients, without spleen enlargement.
Results: Mostly of included patients mostly aged between 7-16 years 61.25%. The most common symptoms and finding at addmition were fever, sore throat and fatigue, with tonsillopharyngitis, hepatosplenomegaly and lymphadenomegaly mostly founded in study compared to control group 90.5% vs 87.2%. Statistically significant lenght of hospital stay and complications were founded in study compare to control group: bacterial superinfection of the throath founded in 35 (33.3%) vs 15 (27.3%) patients, Mononucleous hepatitis 52.3% vs 20.4%, anaemia 26.7% vs 10.9%, uper airway obstruction 10.5% vs 5.4%, peritonsillar abscess and jaundice founded in 1.9% each and accute meningitis in one patient in study group. Other complications: pneumonia, leukopenia and exanthema: 7.1%, 27.5%, 6.5% respectivally, showed no statistical significance between the study groups.
Conclusions/Learning Points: In our study statistically significant difference was founded of respiratoray hematological, and liver complications as well as lenth of hospital stay in the group with enlarged spleen which in conclusion may predict the severity and complications of the disease.

RECURRENT PAROTITIS: CLINICAL CASE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Inês Eiras[1], Luciana Abelha[1], Inês Correia Magalhães[1], Sandra Catarina Ferraz[1], Sofia Miranda[1], Cátia Silva[1], Bernardete Rodrigues[2], Dalila Rocha[1]
[1]Unidade Local de Saúde do Alto Minho, Paediatrics, Viana do Castelo, Portugal, [2]Unidade Local de Saúde do Alto Minho, Radiology, Viana do Castelo, Portugal

Title of Case: RECURRENT PAROTITIS: CLINICAL CASE
Background: Recurrent parotitis is defined as the occurrence of two or more episodes of parotid gland inflammation. Several etiologies must be considered when approaching these patients.
Case Presentation Summary: Male child, 4 years old, with history of repeated tonsillitis and viral pharyngitis. Updated national vaccination plan. At 2 years of age, he presented with fever and inflammatory signs on the right hemiface, which resolved after treatment with anti-inflammatory drugs. After 6 months, he experienced a similar episode of fever and right facial swelling. This pattern repeated 8 months later, leading to an outpatient ultrasound of the salivary glands, showing a slight prominence of the right parotid gland with heterogeneity, but no circumscribed focal lesions. At 4 years of age, right facial swelling again, accompanied by slight effacement of the ipsilateral mandible angle. An acute context ultrasound was performed, with a diagnosis of acute right parotitis, with no evidence of ductal ectasia or collections. He was referred for pediatric consultation to further investigate the etilogy of the recurrent parotitis. A subsequent ultrasound of the parotid glands was performed, revealing echostructural alterations on the right, with a heterogeneous texture and numerous infracentimetric nodularities, indicative of chronic parotitis. An analytical study was carried out, including viral serologies, which revealed reactivity for IgG cytomegalovirus, IgG Epstein-Barr virus and IgG paramyxovirus.
Learning Points/Discussion: The prognosis depends on the underlying etiology. Recurrent idiopathic parotitis is a common cause, often associated with spontaneous epidodes' resolution by early adulthood (90% of cases). Infectious cause is also important, with complications of orchiditis and oopharitis after puberty. However, despite the positive viral serologies, given the patient's background and vaccination status, they may not necessarily indicate a causal relationship with the recurrent parotitis.

Backgrounds: Introduction: Intracranial abscesses and empyemas are rare and constitute a medical-surgical emergency Objective: The objective of our study was to describe the clinical, microbiological, therapeutic characteristics and evolution of intracranial abscesses and empyemas in children
Methods: This is a retrospective study of cases collected over a period of 9 years (2013-2022) in the emergency department and pediatric resuscitation in sfax.
Results: 8 cases were included. The mean age was 1 year 5 months with extremes of 3 months to 3 years. The Sex ratio was 1.6. We observed 5 cases of abscesses and 3 cases of empyema. Among the 3 cases of empyema 1 case of extra dural empyema was observed. The portal of entry in 6 cases was post meningitis in 3 cases, ENT infection in 2 cases and skin infection in 1 case. The germs isolated from the patients were: pneumococcus (3 cases), SAMS (1 case) and pseudomonas aeruginosa (1 case). Empirical broad-spectrum antibiotic therapy was initiated in all patients. Surgical treatment was indicated in 5 children. The evolution was favorable in 7 patients with only 1 case of death.
Conclusions/Learning Points: Conclusion: Intracranial abscesses and empyemas in children are a therapeutic emergency. It is necessary to insist on an early diagnosis and an adequate and rapid management in order to avoid the various dreadful complications.

CLINICAL FEATURES OF RICKETTSIAL INFECTION IN CHILDREN IN TUNISIA: A REPORT OF 9 CASES

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Amal Elleuch[1], Cyrine Kharrat[2], Khaoula Mekki[3], Taycir Cheikrouhou[4], Asma Ben Hlima[3], Mahdi Ben Dhaou[4], Lamia Gargouri[3], Abdelmajid Mahfoudh[3]
[1]Faculty of Medicine of sfax Tunisia, Pediatric Emergency And Resuscitation Service Department; University Hospital Hedi Chaker, SFAX, Tunisia, [2]faculty of medecine of sfax, Infectious Department Hospital Hedi Chaker De Sfax, SFAX, Tunisia, [3]Faculty of medecine of sfax, Pediatric Emergency And Resuscitation Service Hospital Hedi Chaker Sfax, SFAX, Tunisia, [4]faculty of medecine of sfax, Pediatric Surgery Departement Hedi Chaker Hospital Sfax Tunisia, SFAX, Tunisia

Backgrounds: INTRODUCTION Rickettsial infections are an under-recognized cause of acute fever because of their non-specific clinical presentation.
Methods: MATERIAL AND METHODS This 13-year (2010 to 2022) retrospective study of children with serologically confirmed rickettsial infections was performed at a pediatric emergency department in Tunisia.
Results: RESULTS There were 9 pediatric cases during the study period. The mean age at presentation was 6.3 years (1 year 7 months–11 years). The sex ratio was 0,8. At presentation, the most frequent complaints were fever (9 cases). A maculopapular rash involving palms and soles was noted in 8/9 (88%), and eschars were identified in two cases. Cough (4 cases), nausea and vomiting (5 cases), and myalgia (4 cases) were common. Examination showed hepatomegaly (2 cases), edema (3 cases), arthritis (3 cases), conjunctival congestion (3 cases), and lymphadenopathy (2 cases). Elevated CRP (9 cases), hyponatremia (4 cases), and elevated transaminases (3 cases) were the most frequent laboratory abnormalities. Thrombocytopenia occurred in 2 cases, and leukopenia in one case. The diagnosis was based on serologic tests which detected IgM and IgG antibodies to conorii rickettsial antigens (6 cases) and to typhi rickettsial antigens (3 cases). Azithromycin was prescribed in 5 cases and Doxycycline in 4 cases. All children had good outcomes.
Conclusions/Learning Points: CONCLUSION Rickettsial infections have a relatively benign clinical course in children. It should be thought in any case where fever, rashes, and arthropods are involved. Clinical response to treatment often gives a clue to the diagnosis before serological test results are available.

[1]Faculty of Medicine of sfax Tunisia, Pediatric Emergency And Resuscitation Service Department; University Hospital Hedi Chaker, SFAX, Tunisia, [2]Faculty of medecine of sfax, Pediatric Emergency And Resuscitation Service Hospital Hedi Chaker Sfax, SFAX, Tunisia, [3]faculty of medecine of sfax, Infectious Department Hospital Hedi Chaker De Sfax, SFAX, Tunisia, [4]faculty of medecine of sfax, Pediatric Surgery Departement Hedi Chaker Hospital Sfax Tunisia, SFAX, Tunisia

Backgrounds: Introduction Sepsis is a common, complex condition that requires early recognition and aggressive management to improve outcomes. Objective To describe clinical manifestations, diagnostic testing, management options, and outcomes of sepsis in children.
Methods: This is a retrospective study conducted in the pediatric emergency and resuscitation department over a 3-year period (January 2019 - October 2022).
Results: There were 20 cases of sepsis : 11 girls and 9 boys. The mean age was 7 months with extremes ranging from 1 month to 3 years. A recent hospitalization was noted in 6 cases. These were mainly nosocomial sepsis (53.9%). The main clinical features observed in the infected patients were: fever (16 cases); respiratory distress (12 cases); altered general condition (10 cases) and neurological disorders (7 cases). The biology showed hyperleukocytosis (14 cases), thrombocytosis (9 cases), and positive CRP in all cases. The majority of infections causing sepsis were cutaneous (5 cases), urinary (4 cases), and respiratory (2 cases). The most common infecting organism was Serratia marcescens (6 cases) followed by pneumococcus (3 cases), staphylococcus (3 cases), enterobacter cloacae (3 cases), and pantoea spp (2 cases). The respiratory tract was the most common secondary location of infection (8 cases), followed by central nervous system (1 case). Antibiotic treatment was initially empirical and then adapted to the results of the antibiogram. The most prescribed class of antibiotics was cephalosporins (61.6%). The mean length of stay was 15 days. 14 patients required an intensive care unit stay. The death rate was 23.1%.
Conclusions/Learning Points: Pediatric sepsis remains a significant cause of morbidity and mortality worldwide. Early recognition and diagnosis of sepsis, together with appropriate management has been shown to reduce mortality.

Backgrounds: Introduction Postoperative infections (PI) are common cause of mortality and morbidity in children with esophageal atresia (EA). Aim: To determine the impact of surgical timing on PI, the results of patients with delayed surgery and those with early surgery were compared.
Methods: Medical records of children who underwent primary esophageal repair from 2007 to 2020 were retrospectively reviewed. A delay of more than 48 hours from birth was defined as delayed surgery. Statistical significance was assigned to p-values <0.05.
Results: Results 55 cases were included. The male-female ratio was two to one. The mean gestational age was 38 weeks (33–42 weeks) and the mean birth weight was 2649 grams (1250–3550 g). The average time to surgery was 43 hours, with 30.9% of patients having a delayed surgery (delay > 48 hours). The incidence of PI was 36.3%. The most common infections were pneumonia (n = 12, 21.81%), wound infections (n = 6 cases, 10.90%), blood stream infections (n = 4, 7.27%), and urinary tract infections (n = 1). Microbiologic evaluations revealed that five cases had staphylococcus spp, four cases had streptococcus spp, and two cases had mixed bacteria. Gram-positive bacteria were found in 64% of the cases. Four of the patients died as a result of sepsis. There was no difference in the incidence and risk of PI between cases with delayed surgery and those with early surgery (p > 0.05).
Conclusions/Learning Points: Conclusion PI can be seen in 36.3% of cases after EA repair. Delayed surgery wasn't found to be a risk factor for postoperative infections. More large studies are needed to confirm these findings.

Backgrounds: Introduction Salmonella infections are a major cause of gastroenteritis worldwide.
Methods: Our study was conducted from January 2013 to October 2022. Cases were children who were hospitalized in the pediatric emergency department because of diarrhea and found to have a culture-proven nontyphoidal Salmonella infection.
Results: Results Nine children with Salmonella infection were identified. The mean age at presentation was 4 years (6 months-9 years). The sex ratio was 2; Presenting complaints included fever (7 cases), diarrhea (6 cases), vomiting (5 cases), and febrile seizures (2 cases). Stools were bloody in 1 case. Elevated CRP (9 cases), and hyperleukocytosis (3 cases) were the most frequent laboratory abnormalities. Salmonella was identified in stool cultures (3 cases), and in blood cultures (one case). Serologic tests were positive in 5 cases. Two different Salmonella species were isolated, including Salmonella spp and Salmonella entertidis. All children benefited from supportive treatment (fluids and rest). Antibiotics were prescribed in 4 cases. All children had good outcomes.
Conclusions/Learning Points: Conclusion Salmonella infections are the cause of significant morbidity and mortality worldwide. The most important measures to prevent the spread and outbreaks of these infections are adequate sanitation protocols for food processing and handling as well as hand hygiene.

A CASE OF HAND, FOOT, AND MOUTH DISEASE WITH ATYPICAL COURSE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Burak Ütük[1], Zeynep Ergenç[2], Sevgi Aslan Tuncay[2], Seyhan Yılmaz[2], Eda Kepenekli[2]
[1]Marmara University School of Medicine, Pediatrics, Istanbul, Turkey, [2]Marmara University School of Medicine, Pediatric Infectious Diseases, Istanbul, Turkey

Title of Case: A Case Of Hand, Foot, And Mouth Disease With Atypical Course
Background: Hand, foot, and mouth disease is an enteroviral infection usually in children younger than five years, and it is caused by Coxsackievirus A16. Patients typically present with fever, deeply located oval vesicles on the palms and soles, and erosive areas on the buccal mucosa and tongue. Eczema coxsackium is a manifestation of the disease especially in children with atopic dermatitis. Here we report a case of eczema coxsackium presented with atypical lesions.
Case Presentation Summary: A three-and-a-half-year-old boy presented with a rash that started 2 days ago. He had a fever and sore throat that started 1 week ago and resolved spontaneously. Physical examination revealed numerous, unfading, raised, and itchy vesicles, some with honey-colored crusts on the distal four extremities. (Picture 1-

2) 

Lesions were less numerous on the feet and hands and were absent in the mouth. Laboratory tests detected white blood cell count: 8100/mm3, absolute neutrophile count: 2000/mm3, absolute lymphocyte count: 5500/mm3, hemoglobin: 10.8 g/dL, platelet count: 259000, C-reactive protein: 9 mg/L. The diagnosis of eczema coxsackium and impetigo was considered in the patient, and he was followed up closely with oral co-amoxiclav therapy. His lesions regressed on the 5th day(Picture 3), and returned to normal without leaving a

trace.

Learning Points/Discussion: Eczema coxsackium is an atypical presentation of hand, foot, and mouth disease, and can cause secondary skin infections. Eczema coxsackium should be considered in the differential diagnosis in children presenting with fever and vesicular rash.

PV1112 / #1483

SINUS DRAINAGE IN ORBITAL CELLULITIS TREATMENT: A CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Özge Günal[1], Zeynep Ergenç[2], Sevgi Aslan Tuncay[2], Seyhan Yılmaz[2], Eda Kepenekli[2]
[1]Marmara University School of Medicine, Pediatrics, Istanbul, Turkey, [2]Marmara University School of Medicine, Pediatric Infectious Diseases, Istanbul, Turkey

Title of Case: Sinus Drainage In Orbital Cellulitis Treatment: A Case Report
Background: Orbital cellulitis results from the spread of infection from structures adjacent to the orbit, like dental infections or sinusitis, or direct inoculation of the infectious agent as a result of trauma or surgery. Here we present a severe case of orbital cellulitis, which was a complication of sinusitis, refractory to medical treatment, and required sinus drainage surgery in follow-up.
Case Presentation Summary: A ten-year-old girl presented with a swollen left eye and left-sided head and eye pain. In the physical examination, the left eyelid was edematous and eye movements were painful (Picture

1).  Laboratory examination revealed white blood cell count: 7800/μL, absolute neutrophile count: 6800/μL, absolute lymphocyte count: 600/μL, and C-reactive protein: 307 mg/L. Intravenous ampicillin-sulbactam and clindamycin and local moxifloxacin treatments were started with the diagnosis of orbital cellulitis. In the follow-up, the eyelid edema increased, the eye-ache worsened, and the patient had a significant chemosis under the eyelid. Parenteral antibiotics were changed to vancomycin and meropenem. Orbital computerized tomography (Picture 2) and Magnetic Resonance Imaging (MRI) scans detected left

dacryoadenitis and maxillary, ethmoid, and frontal sinusitis.

Maxillary sinus drainage surgery was performed by the otolaryngology and 15 ccs of pus were drained with Streptococcus intermedius growth. The meropenem treatment was completed 28 days after the surgical intervention. The patient was discharged with oral co-amoxiclav treatment without any sequelae.

(Picture 3). 

Learning Points/Discussion: In cases of preseptal/orbital cellulitis that do not respond to appropriate antibiotic therapy, radiological imaging should be performed to detect the source of infection such as sinusitis or sinus abscess, and if detected, surgical intervention should be performed.

PV1113 / #910

SEVERE CUTANEOUS CONDITION WITH SHOCK SYNDROME: CHALLENGES IN RECOGNIZING AND MANAGEMENT

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Vinicius Fernandes[1], Rafael Azevedo[2], Felipe De Oliveira[2], Mirela Castro[2], Priscila Cursi[2], Mariana D'Avila[3], José Junior[2]
[1]Hospital Alvorada, Paediatric Infectious Disease, São Paulo, Brazil, [2]Hospital Alvorada, Picu, São Paulo, Brazil, [3]Hospital Alvorada, Paediatric Ward, São Paulo, Brazil

Title of Case: SEVERE CUTANEOUS CONDITION WITH SHOCK SYNDROME: CHALLENGES IN RECOGNIZING AND MANAGEMENT
Background: We discuss about a 3-year-old boy presenting fever and sudden multiorgan system involvement that mimics a lot of syndromes, from MIS-C and Kawasaki to shock toxic syndrom and Stevens-Johnson. His clinical course was severe and all hypotheses and therapies were considered until the final diagnosis.
Case Presentation Summary: We describe the evolution of a 3-year-old boy, born in Russia, living in Brazil since 2019, previously healthy, admitted to the emergency department with fever and respiratory distress that started 1 day ago. Physical examination showed diffuse erythema on trunk, back and face, mucosal lesions, purulent ocular discharge and purulent urethritis. Initially, in hypothesis of toxic shock syndrome, received ceftriaxone and clindamycin and, in the intensive care unit (ICU), associated vancomycin for MRSA cover. After admission he developed distributive shock requiring vasoactive drug and mechanical ventilation. He also received immunoglobulin and corticosteroid therapy for three days to manage clinical conditions with pro-inflammatory response. On etiologic evaluation cultures remain negative and inflammatory biomarkers rapidly lowered, viral sorologies was not negative for active disease and infectious causes was discarded. After fourteen days from admission a skin biopsy made definitive diagnosis of Stevens-Johnson Syndrome. The patient had satisfactory evolution being discharged from the ICU after 22 days of hospitalization and discharged home on the 36th day.
Learning Points/Discussion: We aim to discuss importance of considering all infectious syndromes that mixes skin lesions and multi-organ envolvment. In the current times physicians could just focus on MIS-C syndrome and forget about classical conditions like staphylococcal toxic shock syndrome and mucocutaneous reactions. Also pointed use of antibiotic treatment, corticosteroids and immunoglobulin in a not defined management and importance of skin biopsy to final diagnosis.

RITIP, Paediatric Infectious Diseases, Madrid, Spain, [5]12 de Octubre University Hospital, Madrid, Spain, Pediatric Infectious Diseases, Madrid, Spain, [6]12 de Octubre University Hospital, Paediatric Infectious Diseases, Madrid, Spain, [7]12 de Octubre University Hospital, Pediatric Infectious Diseases, Madrid, Spain

Title of Case: An stroke code of infectious etiology
Background: Sinusitis is rarely complicated by a subdural empyema. We present a case of a “Code Stroke” activation in a patient that developed sudden hemiplegia in the context of sinusitis
Case Presentation Summary: A previously healthy, 14-year-old boy developed a sudden muscle strength loss of the left side of his body. Around 48 hours earlier he had consulted in A&E for a cold that associated fever and retroocular headache that worsened with valsalva maneuver, he was discharged under antipyretic treatment. In the Emergency Department he presented paresis of his lower left limb, paratonia of the upper left limb and preference to right ocular deviation. The blood tests showed leukocytosis (19,000/uL) with a neutrophil count of (10,000/uL), PCR 31mg/dL, PCT 0,21ng/mL and coagulopathy with an INR of 1,4. The brain CT scan revealed right subdural and subarachnoid hemisphere occupation consistent with hemorrhage vs purulent collection. The “Code stroke” was activated. An urgent MRI was performed showing a complicated pansinusitis with subdural empyema, associating a 6mm abscess in frontal parenchyma. Empirical antibiotics were initiated with Cefotaxime, Metronidazole, and Vancomycin, alongside dexamethasone, vitamin K and fresh frozen plasma. An urgent surgical approach was performed by neurosurgery and ENT, draining the sinuses and the subdural empyema. The culture of the drained pus grew S.intermedius.
Learning Points/Discussion: Intracranial complications of sinusitis are rare; however, we are attending to an increased incidence in the last six months in our center. The consequences and sequelae are severe. Empirical treatment must cover microorganisms that cause sinusitis and must have a high central nervous system penetration. The multidisciplinary care of these patients as well as the early drainage of intracranial empyema and sinus collections improve the prognosis and outcomes.

A CASE OF STEVENS-JOHNSON SYNDROME - FINDING THE CULPRIT

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Catarina Guerreiro Ferreira[1], Filipa Lima[1], Adelina Sitari[1], Luísa Gaspar[2], Maria João Virtuoso[1]
[1]Centro Hospitalar Universitário do Algarve, Pediatrics, Faro, Portugal, [2]Centro Hospitalar Universitário do Algarve, Pediatric And Neonatal Intensive Care Unit, Faro, Portugal

Title of Case: A case of Stevens-Johnson syndrome - finding the culprit
Background: Stevens-Johnson syndrome (SJS) is a rare and severe immunologic phenomenon characterized by rash and mucous membrane disease, that can result in severe morbidity from scarring of mucosal surfaces, leading to blindness as well as urethral and esophageal strictures. It may be triggered by medications and, less frequently, by infections such as Mycoplasma pneumoniae (Mp). Less than 1% of Mp infections can lead to SJS. It is not clear that treatment with intravenous immunoglobulin, corticosteroids or macrolide antibiotics can improve the outcome.
Case Presentation Summary: A 7-year-old boy, presented with a 8-day history of rhinorrhea, cough and fever, diagnosed on day 3 with pneumonia, treated with amoxicillin/clavulanic, ibuprofen, paracetamol and carbocisteine (which was taken for the first time). On day 5, new perioral swelling and erythematous ulcerations were found, leading to desquamation around the mouth and anogenital regions, compatible with SJS. Blood tests showed 9 × 109 white blood cells/L, 7.6 × 109 neutrophils/L and a C-reactive protein level of 14 mg/L. Initial Mp serologies were negative. He got better without any specific treatment. Repeat serologies showed a positive IgM and IgG for Mp. Specific IgE was negative for amoxicillin/clavulanic. Follow-up showed no recurrence.
Learning Points/Discussion: Similar to our case, literature states that Mp-associated SJS has a distinct clinical presentation that includes evidence of a preceding respiratory infection and less extensive skin disease than non–Mp-associated SJS. Our case supports this finding of mucositis-predominant disease. There is no established standardized treatment guideline that has been shown to reduce hospitalization duration and/or disease progression.

Backgrounds: Invasive bacterial infection (IBI) remains a major cause of morbidity and mortality in children. COVID-19 pandemic caused changes in the epidemiology of several infectious diseases. We aimed to characterize hospitalizations in children due to IBI in the last 5 years and a half and assess the impact of the COVID-19 pandemic.
Methods: We retrospectively analysed all IBI related hospitalizations occurring in patients under 18-years-old in our tertiary center between July 2017 and December 2022. Trends in hospitalization and microbiological agents were compared in the 2 year and 9 month period immediately before and after the start of the COVID-19 pandemic (March 2020).
Results: In our cohort of 69 IBI related hospitalizations, 39 (56.5%) were female, median age was 8 months (IQR 1.5-34). S. pneumoniae was the most common microorganism (17.4%), followed by E. coli (13%), S. aureus (10.1%) and N. meningitidis (5.8%). In infants < 3 months E. coli was the most frequent pathogen (29.1%), whereas in children > 2 years it was S. pneumoniae (38.4%). 2020 was the year with fewer hospitalizations (3, 4,3%). IBI hospitalizations were significatively less frequent after the start of the pandemic (64% vs 36%, p=0.029). We found four invasive meningococcal infections in the period preceding the pandemic, and none after its beginning. As for pneumococcal invasive infections, 9 were observed before March 2020 and only 3 after this time point. IBI due to S. aureus and S. agalactiae remained stable (3vs4, 2vs1, respectively).
Conclusions/Learning Points: The occurrence of IBI was reduced during the COVID-19 pandemic probably in consequence of the containment policies introduced. Further investigation is needed to assess post-pandemic epidemiology of IBI.

Backgrounds: Differences between NIC presentation in LMICs vs HICs (high income countries) have been previously reported. NIC is associated with high-risk neonates (birth weights <1500 g or gestational age <28 weeks) in HICs, but an increasing number of studies from LMICs have described NIC in older neonates. Whereas Candida spp. resistances in neonates remain low in HICs, fluconazole-resistant isolates seem to emerge in LMICs.
Methods: A systematic review was conducted including original articles about microbiologically confirmed NIC in LMICs until April 2022. Data on epidemiological characteristics, fungal prophylaxis, treatment, and species distribution were presented. Results from the English literature are presented here.
Results: A total of 198 articles were eligible for inclusion, reporting 8037 NIC-cases from 36 LMICs. The mean (standard deviation) for gestational age and birth weight were 31.6 (3.3) weeks and 1500.9 (652.1) g respectively. 14.9% (n=1198) were high-risk neonates. The species isolates distribution was C. parapsilosis (n=1742, 34.8%); C. albicans (n=1686, 33.9%); C. tropicalis (n=776, 15.7%); C. krusei (n=382, 7.7%); C. glabrata (n=306, 6.2%); C. auris (n=82, 1.7%). Susceptibility testing results were available in 21 countries (58.3%); with a total of 1080/3961 (27.3%) isolates resistant to fluconazole. Prophylactic antifungals were reported in 288 cases (3.6%). Treatment for NIC (specified in 1726 cases, 21.5%) was dominated by amphotericin B (712; 41.3%) and fluconazole (546; 31.6%). The overall mean treatment duration was 21.9(8.0) days.
Conclusions/Learning Points: Our results have demonstrated differences in disease profiles of NIC in LMICs compared to HICs. Future studies are required to evaluate preventive measures in these neonates, together with management strategies tailored to increasing rates of resistant isolates.

NEONATAL ANTIFUNGAL PROPHYLAXIS USE IN LOW- AND MIDDLE INCOME COUNTRIES (LMICS): DATA FROM THE NEOOBS STUDY.

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Laura Ferreras-Antolin[1,2,3], Aislinn Cook[3], On Behalf Of The Neoobs Consortium[3]
[1]St. George's University Hospital NHS Foundation Trust, Paediatrics, London, United Kingdom, [2]University of Exeter, Mrc Centre Medical Mycology, London, United Kingdom, [3]St George's, University of London, Centre For Neonatal And Paediatric Infection, London, United Kingdom

Backgrounds: Antifungal prophylaxis targeted to neonates at high risk of NIC (<1000g birth weight and/or <28 weeks' gestation) is recommended in neonatal units in High Income Countries (HICs). In LMICs, antifungal prophylaxis might be compromised due to access to antifungals, fluconazole-resistant isolates or different epidemiology of NIC with neonates not in the high-risk category as in HICs. We aimed to describe the extent of antifungal prophylaxis use, patient profile and agents included in the NeoOBS study.
Methods: Secondary data on antifungal prophylaxis use were extracted and analysed from the NeoOBS study, a global, prospective, longitudinal, observational cohort study of hospitalised infants <60 days postnatal age with sepsis. It enrolled 3204 infants at 19 hospitals (11 countries) in 5 WHO regions between August 2018 and February 2020.
Results: Complete antimicrobial data were available from 2986/3204 (93%) infants. 61/2986 infants (2%) received antifungal prophylaxis in the 7 days before a blood culture was taken. For those on prophylaxis, median gestation age was 28 weeks (IQR: 27-30) and median birthweight was 985g (IQR: 860-1130g). There were 215/2986 (7,2%) high risk neonates; from those, 19/215 (9%) received antifungal prophylaxis. Fluconazole was used in 59/61 (97%). Antifungal prophylaxis was reported in 9/19 hospitals with 80% (49/61) infants from 4 hospitals in 2 countries (AFRO, SEARO). Overall, 15/2986 (5%) infants had Candida spp. isolated from blood culture; 2/61 (3%) from those who were on previous antifungal prophylaxis and in 13/2925 (4%) infants who were not on prophylaxis.
Conclusions/Learning Points: The optimal method to target antifungal prophylaxis in the LMICs settings, including choice of drug dose, duration and cost-effectiveness, needs to be better defined. Further studies are required.

Medical University of Bialystok, Department Of Medical Microbiology And Nanobiomedical Engineering, Bialystok, Poland

Background: Pseudomonas aeruginosa filamentous bacteriophages (Pf) are essential virulence factors of this archetypal cystic fibrosis (CF) pathogen, which contribute to chronic infection via the promotion of biofilm formation, antibiotic resistance, and immune suppression. However, Pf phages constitute a heterogeneous group of viruses with distinct structural properties. Therefore, we aimed to determine the immune response of human lung epithelial cells after exposure to various Pf phages.
Methods: Pf phages were purified from P. aeruginosa strains isolated from CF patients using the standard PEG/NaCl precipitation method. In addition, Pf1 phage suspension (ASLA Biotech AB, Latvia) was used as the reference. Pf phages in concentrations ranging from 10^8 to 10^1 PFU/mL, alone and in combination with LPS, were used to stimulate A549 human lung epithelial cells. Subsequently, RNA was isolated from the cells to estimate the expression of the genes encoding immune response factors, including TNF-α, IL-6, IL-8, and IFNs, with SYBR Green RT-qPCR technique.
Results: Altered expression of several genes under the study was recorded in the presence of Pf phages, particularly at concentrations ranging from 10^6 to 10^4 PFU/mL. For instance, Pf1 phage-induced expression of the IFNB1 gene mostly at concentration of 10^4 PFU/mL. In addition, the expression of TNF-α gene was modulated by Pf phages in cells simultaneously stimulated with LPS compared with the cells treated with LPS only.
Conclusions/Learning Points: P. aeruginosa Pf phages interfere with the expression of the genes encoding immune factors controlling anti-bacterial and anti-viral responses, particularly at specific doses.
Research funding: HARMONIA 10 grant (2018/30/M/NZ6/00502) National Science Center (Poland).

STIEHM-DAMROSCH/NIKLASSON PROGNOSTIC SCORE – AN IMPORTANT TOOL IN MENINGOCOCCEMIA

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Bianca Balas-Maftei, Carmen Florea, Alexandra Georgiana Lacatusu, Ina Stratan, Doina Carmen Manciuc
Infectious disease Hospital, Infectious Diseases, Iasi, Romania

Backgrounds: Meningococcal infectious represents one of the most important health problem with a very high morbidity and mortality rate. The etiological agent of meningococcal infection is Neisseria meningitidis which can produce meningitis and meningococcemia, one of the most serious and life-threatening infectious disease during childhood.
Methods: We carried out an observational retrospective study of patients admitted in '' Saint Parascheva" Infectious Disease Hospital Iasi in period 2018-2022.Data were collected from medical file of the pediatric patients diagnosed with meningococcemia. We included 14 patients who met the selection criteria.We evaluated the Stiehm-Damrosch/Niklasson prognostic score of severity, clinical and paraclinical data and the period of the hospitalization.
Results: The prognostic score in all 14 hospitalized patients was above 3, fact that highlighted the degree of severity.One of the 14 patients (7,14%) had a fulminant evolution of the disease and died within the first hours of addmision. The age of the patients varied between 3 months and 18 years old, the averange being 6 years old. None of the patients were vaccinated against meningococcal infection.Petechials rash were present in 12 patients (85,7%), in the first 12 hours of the disease. All patients had more than 20 nuclear elements in the cerebrospinal fluid. The presence of leukocytosis in the peripheral blood was identified in 5 patients (35, 7%). Trombocytopenia was present in 2 patients (14,2%), the prognostic score for those 2 patients was 6, extremely severe, one of them died in the first hours after being addmited. The average length of hospitalization was 15 days.
Conclusions/Learning Points: Meningococcemia represents one of the biggest medical emergency, the using of Stiehm-Damrosch/Niklasson prognostic score represents an important tool in assessing the degree of severity.

STOOL CULTURES IN A PORTUGUESE PEDIATRIC EMERGENCY DEPARTMENT (ED): EXPERIENCE OF 5 YEARS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Catarina Franquelim[1], Mafalda Cabral[2], Andreia Romana[1], Leonardo Carneiro[3], Cristina Esteves[1], Rita Marques[1], Filipa Nunes[1]
[1]Hospital Garcia de Orta, Pediatria, Almada, Portugal, [2]Centro Hospitalar Lisboa Central, Hospital D. Estefânia, Lisboa, Portugal, [3]Hospital Garcia de Orta, Patologia Clínica, Almada, Portugal

Backgrounds: Although around 30% of acute gastroenteritis (AGE) worldwide have bacterial etiology, antibiotic treatment isn't routinely needed. Stool cultures should only be performed when specific criteria are met.
Methods: Longitudinal observational retrospective study of pediatric patients with acute bacterial gastroenteritis diagnosed between January 2017-December 2021 in a pediatric ED.
Results: Identified 8094 admissions in ED for diarrhea or AGE. 124 stool cultures were collected, 64 were positive (56,2% in males), median age 3,3 years (IQR 1,0-9,0). The median time of disease at stool collection was 4 days (IQR 2-6). Clinical manifestations included fever (84,4%), bloody diarrhea (62,5%), vomiting (40,6%), and dehydration (29,9%). Convulsions were described in 6,25%. Hospitalization was required in 23,4% (median length 1 day). Microorganisms isolated were Campylobacter spp (57,9%), Salmonella spp (31,9%), Aeromonas caviae (8,7%), Clostridium difficile (1,4%). Coinfections were identified in 7,8%. Multi-resistance was described in 6,9% of bacterias. Laboratory evaluation was requested in 35,9% of patients, 34,8% had leukocytosis and 47,9% neutrophilia. Median C-reactive protein level was 6,6mg/dL (IRQ 3,6-11,7mg/dL). Higher values were associated with Salmonella spp (p=0,05). When stool culture results were known 9,3% needed antibiotics. It was initiated in 4 Campylobacter spp infections and in 1 Salmonella spp infection in a 2-month-old child. The remaining Salmonella spp weren't medicated. Selected antibiotic was azithromycin except for the Clostridium difficile infection (vancomycin).
Conclusions/Learning Points: Campylobacter spp. and Salmonella spp. were responsible for most of the infections. The decision to start antibiotic therapy was based on microbiological and clinical findings associated with disease evolution and epidemiological context. Only 6 children required antibiotic therapy in 5 years. There were no records of invasive disease. Quicker stool culture results and locally validated guidelines would be useful in the uniformization of acute bacterial gastroenteritis management.

[1]National Institute of Health, Pediatrics, Yerevan, Armenia, [2]Wigmore Hospital for Children, Pediatrics, Yerevan, Armenia

Title of Case: A case of 10-years-old girl with compression fracture of Th7 vertebra due to Chronic Recurrent Multifocal Osteomyelitis
Background: ChronicRecurrentMultifocalOsteomyelitis(CRMO)/ChronicNonbacterialOsteomyelitis(CNO) is a rare autoinflammatory bone disorder that typically affects children, young adults and characterized by recurrent episodes of bone pain, inflammation, swelling, often affecting multiple bones.
Case Presentation Summary: A 10-years-old girl admitted to orthopedic department with complains of chest pain mostly at nights during the previous two months. General examination:difficulties in movements, painful and limited forward bending of torso, inability to walk tip-toes/pain in lower 3rd of left leg. Examination of other systems:unremarkable. Extensive laboratory work-up including CBC, CRP, Brucella and TB were negative. MRI revealed compression fracture of Th7vertebra, decreased height of Th6-Th7intervertebral discus, increased signal from Th12, bone marrow edema, L4-S1discs bulging. Biopsy from Th7 showed histological pattern of nonspecific osteomyelitis. Fixation of Th5-Th9 segments of spine with metal rods and screws was done, the child was discharged under the follow-up of orthopedic surgeons. After 2months the child was readmitted to the hospital with non-severe back pain. On examination she still had difficulties in movements, limited range of motion due to back pain in operated area, forward bending of torso was painful, limited. To differentiate from neoplastic disorders PET/CT scan was ordered:non-focal zones with high metabolic activity of the Th10,L1,L3vertebrae. The child was diagnosed with CRMO and treatment with Indomethacin 2mg/kg/day was initiated. On 3 and 6-months follow-up:no complains, returned to school, by scintigraphy no new foci of inflammation. Indomethacin was continued.
Learning Points/Discussion: Osteomyelitis can be manifestation of autoinflammatory bone disorders. CRMO remains a challenging and complex problem in pediatric medicine. With early diagnosis and appropriate treatment, patients with this condition are able to achieve a good outcome and return to normal activities

Title of Case: Case series of pediatric osteomyelitis S. Harutyunyan 1, L. Margaryan 1, A. Papikyan 1, H. Ghazaryan 1,2 1. Wigmore Hospital For Children, Yerevan, Armenia 2. NIH, Department of General Pediatrics and Pediatric subspecialities
Background: Background Pediatric osteomyelitis is a serious bone infection that can be caused by various factors. In this study, we analyzed six cases of pediatric osteomyelitis treated at Wigmore hospital for children, in Armenia. The Gram positive Staphylococcus aureus is the most frequently etiologic agent of the pediatric osteomyelitis.
Case Presentation Summary: Case presentation Biopsies were performed in all cases, and cultures identified Staphylococcus aureus as the most common pathogen. Surgery was required in four cases, and all patients underwent a prolonged course of antibiotic treatment, ranging from 6 to 8 weeks. In one case we have hematogenous spread of the bacteria. In four cases the empiric antibacterial therapy started with Ceftriaxone, Metronidasiole and Vancomicin, in one case with only Vancomicin and in one case with monotherapy with Ceftriaxone. After the puncture culture result, treatment continues with Co-Amoxi in 2 cases, with Ciprofloxacin and Clindamycin in two cases, in one case with CefuroxIme Comparing the cases, we found that younger patients tended to have better treatment outcomes, and those with trauma-related osteomyelitis had longer hospital stays and required more extensive surgical intervention. In contrast,patients with no trauma tended to respond better to antibiotics alone.

Case	1:	2:	3:	4
Sex	Female	Male	Female	F
Location	Left hip	Lower 1/3 of tibia	Calculus	L

Learning Points/Discussion: Conclusion Pediatric osteomyelitis is a complex disease that requires a multidisciplinary approach for successful management. Prompt diagnosis and appropriate treatment are essential for preventing long-term complications.

Estefânia - Centro Hospitalar Universitário Lisboa Central, Lisbon, Portugal, [3]Infectious Diseases Unit and Emergency Service, Hospital Pediátrico, Centro Hospitalar E Universitário De Coimbra, Coimbra, Portugal, [4]Instituto de Microbiologia - Instituto de Medicina Molecular, Faculdade De Medicina Da Universidade De Lisboa, Lisbon, Portugal, [5]Sociedade de Infeciologia Pediátrica, Sociedade Portuguesa De Pediatria, Lisbon, Portugal

Backgrounds: Streptococcus pyogenes (Group A Streptococcus, GAS) is associated with common throat and skin infections, but upsurges of severe invasive disease (iGAS) have been recently reported in Europe. This study performed a clinical, epidemiological, and molecular characterisation of pediatric iGAS in Portugal.
Methods: A national prospective surveillance of pediatric (<18yrs) iGAS infections from 2014-2022, collected demographic and clinical characteristics of cases. Whole genome sequencing was performed for all available isolates from 2014-2021 (n=109).
Results: 195 children were included, with an average annual incidence of 1.51/100,000 (3.09/100,000 <5 years old), marked by a significant reduction during the COVID-19 pandemic period of 2020-2021. Clinical information was available for 161 cases. The median age was 3.0 years (IQR 1-5 years), 53% males, 15% with underlying chronic conditions, and 51% with a preceding acute disease. The most frequent diagnosis were bacteraemia without focus (35%), skin/soft tissue infection (25%), osteoarticular infection (20%), pneumonia (15%), and sepsis (15%). Streptococcal Toxic Shock Syndrome (STSS) occurred in 13% and necrotizing fasciitis in 5% of cases. The case-fatality rate was 5%. Risk factors for mortality were hypotension at admission (p=0.009) and STSS (p=0.001). The predominant emm types were: emm1 (35%), emm3 (17%), emm12 (10%), and emm6 (9%). The new emm1 sub-lineage, $M1_{UK}$, emerged in 2015 and accounted for 33% of emm1 cases. There were no significant associations between individual emm types or clusters and STSS or mortality, although emm1 was associated with ICU admission.
Conclusions/Learning Points: The incidence of pediatric iGAS has been stable in Portugal and slightly lower than reported in other European countries, although with similar associated mortality and STSS. The new $M1_{UK}$ strains emerged in Portugal in 2015 and represented one-third of all emm1 cases.

WHEN KITTENS ARE NOT YOUR BEST FRIEND: AN ADOLESCENT GIRL WITH DISSEMINATED CAT-SCRATCH DISEASE IN A SECONDARY HOSPITAL OF CENTRAL GREECE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Dimitra Grammenou, Ioanna Tassiou, Kalliopi Tanou, Ismini Koletsi, Anastasia Anastasiou-Katsiardani
GENERAL HOSPITAL OF VOLOS, Paediatric, VOLOS, Greece

Title of Case: WHEN KITTENS ARE NOT YOUR BEST FRIEND: AN ADOLESCENT GIRL WITH DISSEMINATED CAT-SCRATCH DISEASE IN A SECONDARY HOSPITAL OF CENTRAL GREECE
Background: Cat scratch disease (CSD),caused by Bartonella henselae,is transmitted when infected kittens bite or scratch humans.CSD is usually presented as a self-limited regional lymphadenopathy. However,disseminated infection may occur in up to14%of patients with hepatosplenomegaly,bone, neurologicaland ocular involvement.We describe an atypical case of extended disease in an immunocompetent patient.
Case Presentation Summary: A previously healthy 12,5 year old female adolescent was admitted in our pediatric clinic due to tonsillitis with a 5-day history of high fever, rigor, upper respiratory tract symptoms and raised CRP (190mg/l) with normal CBC. Her serological tests were negative for EBV, CMV, Toxoplasma infection. She was treated with iv cefuroxime. On the 3rd day while she was still febrile, the physical examination showed a tender left-sided submandibular swelling and hepatosplenomegaly. Laboratory tests revealed normal CBC and lower CRP:122mg/l. he ultrasound of the cervical region showed bilateral multiple enlarged cervical lymph nodes and inflammatory left-sided submandibular lymph nodes (max diameter=2.7cm). Abdominal ultrasound demonstrated enlarged hepatic lymph nodes(diameter=2cm) and multiple hypoechoic splenic lesions. In the MR of the abdomen besides the splenic and hepatic abscesses, cysts in the lumbar vertebrae were revealed. Treatment was altered to iv cefotaxime, iv clindamycin and po azithromycin and the patient was transferred to a tertiary pediatric hospital for further investigation and treatment. The results of the IFA tests demonstrated infection with Bartonella henselae (IgG:>1/16.384,IgM:>1/320).
Learning Points/Discussion: Disseminated CSD is infrequent. Therefore, the diagnosis and management of the disease require a high rate of suspicion and the use of the appropriate diagnostic tools. There is no one single universal therapy for this infection, and treatment should be tailored individually.

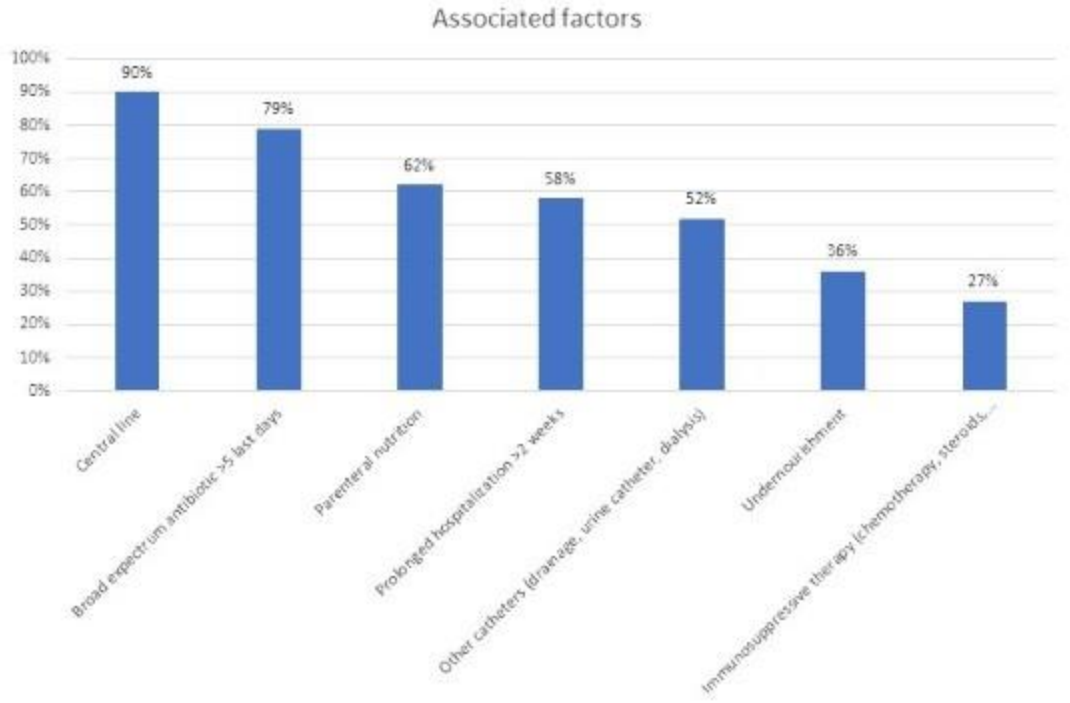
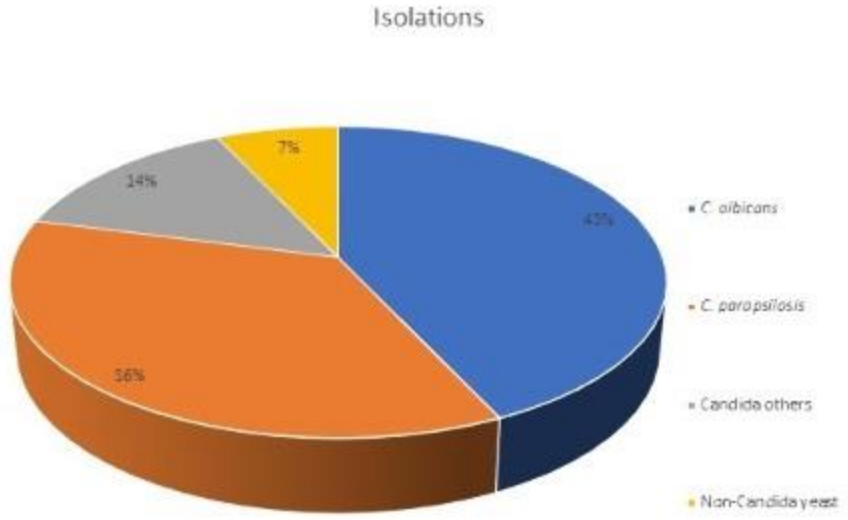
Backgrounds: Invasive fungal disease (IFD) is an important cause of morbi-mortality in at risk pediatric population. This study aims to describe characteristics of patients, fungal isolation, prophylaxis, treatment and the outcome of proven IFD in a tertiary pediatric hospital.
Methods: Retrospective observational study (January 2015-December 2021) focused on admitted pediatric patients who had a proven IFD with microbiological isolation of yeast from a sterile sample.
Results: 102 cases were identified. Median age at diagnosis was 6 months (IQR1.3-27 months); 52% were male. The main admission departments were neonatology (40/102,39%) of which 30/40,75% were preterm, and hemato-oncology (12/102,12%) of whom 7/12,58% had received hematopoietic stem cell transplantation, which means 7% of the total, 7/102. 11%(11/102) were solid organ transplant recipients. Up to 64%(65/102) of the isolations were from blood and 36%(37/102) from other sterile sites (cerebrospinal fluid(1/37,3%), ascitic fluid(5/37,13%), pleural fluid(1/37,3%), vitreous humour(2/37,5%) and urine(28/37,76%)). Figure 1 shows the most frequently associated risk factors(Figure1A) and the yeasts isolated(Figure1B). Thirty-three cases (33/102,32%) were breakthrough IFD. Fluconazole was the antifungal most frequently used as prophylaxis (14/33,42%). Median duration of treatment was 17 days (IQR14-30) and the main first-line antifungals were fluconazole (51/102,50%) and liposomal amphotericin-B(31/102,30%). In breakthrough IFD, 15/33(45%) maintained treatment used as prophylaxis. Related to outcomes: 76% were recovered, 4% had sequelae and 20% died, of which 20% (4/20) were attributed to IFD.



A



B

Conclusions/Learning Points: C. albicans was the most frequent yeast in IFD in our series and fluconazole the first-line treatment. The significant number of breakthrough IFD with fluconazole leads us to reconsider it as prophylaxis in some cases. The high proportion of patients who maintained the same antifungal used as prophylaxis during a breakthrough IFD leave us margin of improvement in the management of IFD.

Title of Case: INVASIVE FUNGAL DISEASES BY NON-CANDIDA YEASTS IN A TERTIARY HOSPITAL.
Background: Invasive fungal disease (IFD) is an important cause of morbi-mortality. IFD due to yeast fungi different from Candida are rare. The aim of this study is to describe a series of IFD cases caused by non-Candida yeasts.
Case Presentation Summary: Retrospective observational study in a tertiary pediatric hospital (January 2015-December 2021) of proven IFD by microbiological isolation from sterile samples of non-Candida yeasts fungi. Five of 102 cases of proven IFD (5%) were due to non-Candida yeasts: 2 Trichosporon asahii, 1 Trichosporon inkin, 1 Saccharomyces cerevisiae, and 1 Magnusiomyces capitatus. Four cases were breakthrough IFD. Median age was 24 months (range 1.4 months-14 years). All patients have received broad-spectrum antibiotics and carried central lines, and 4 received parenteral nutrition. Characteristics of the patients and the isolated species are shown in Table 1. Four yeasts were resistant to echinocandins; however 4 were sensitive to liposomal amphotericin B. Only T.inkin was sensible to fluconazole. Liposomal amphotericin B was part of initial therapy in all cases; 2 patients required a change of antifungal due to clinical impairment or drug toxicity. The mean duration of treatment was 17 days (range 5-30 days). Three patients died within the first 19 days after diagnosis of IFD (days 5, 17 and 19); being only attributable to IFD the case who died 5 days after IFD diagnosis.

Yeast	Age (years)	Isolation	Location at diagnostic	Co-morbidity	Antifungal profhylaxys	IFD treatment	Antifungal resistance	Treatment duration (days)
Trichosporon inkin	14	BC	PICU	HSCT	MFG PCZ	LA-B iv FLZ iv MFG	ADF CPF MFG	5
Trichosporon asahii	2	BC	PICU	Primary Inmunodeficiency	LA-B iv MFG	LA-B iv VO	ADF CPF FLZ MFG	15
Trichosporon asahii	1,7	Ascitic Fluid	PICU	SOT (liver)	LA-B iv	LA-B iv FLZ iv VO	ADF CPF FLZ MFG	30
Saccharomyces cerevisiae	2	BC	Pediatric ward	Short bowel syndrome	No	LA-B iv	FLZ	17
Magnusiomyces capitatus	1	Ascitic fluid	PICU	SOT (liver)	LA-B iv	LA-B iv VO FCT	ADF CPF FLZ MFG	17

Blood culture (**BC**) Pediatric Intensive Care Unit (**PICU**). Hematopoietic Stem Cell Transplant (**HSCT**). Solid organ transplant (**SOT**). Liposomal Amphotericin B (**LA-B**), intravenous (iv). Voriconazole oral (**VO**). Micafungin (**MFG**). Posaconazole (**PCZ**). Fluconazole (**FLZ**). Flucytosine (**FCT**). Anidulafungin **(ADF**). Caspofungin (**CPF**).

Learning Points/Discussion: IFD caused by non-Candida yeasts was infrequent in this series, but it was associated with high mortality rate. These fungi should be considered in patients under antifungal prophylaxis, particularly with fluconazole or echinocandins, due to their resistance pattern.

PV1128 / #827

HEPATOSPLENOMEGALY AND ANEMIA PROMPT TO INCLUDE VISCERAL LEISHMANIASIS IN THE LIST OF DIFFERENTIAL DIAGNOSIS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Violeta Manukyan[1], Mark Grigoryan[1], Lernik Martirosyan[1], Suren Brutyan[1], Hasmik Hakobyan[1], Armen Minasyan[2], Vigen Asoyan[1], Hripsime Apresyan[1]
[1]YSMU, Infectious Diseases, Yerevan, Armenia, [2]YSMU, Coloproctology, Yerevan, Armenia

Backgrounds: Visceral Leishmaniasis is fatal if left untreated in over 95% of cases. It remains one of the top parasitic diseases with outbreak and mortality potential.Leishmania parasites are transmitted through the bites of infected female phlebotomine sandflies, which feed on blood to produce eggs. Leshmania and is the second-largest killer in the worl(after malaria). Armenia is an endemic region for the visceral leishmaniasis caused by Leishmania infantum.
Methods: Medical records of 22 pediatric patients with Visceral and Cutaneous Leishmaniasis hospitalized during March2020 to January2021 period in Isolation Unit of Muratasan University Hospital Complex have been analyzed. The average age of patients was 4years old(46 months,max:11y.o.,min:8m.o.).Male to female ratio was approximately 3:2.
Results: The analysis shows 3 out of 22 patients were diagnosed Cutaneus Leshmaniasis and other 19 had Visceral Leshmaniasis.The average duration of onset of symptoms to hospital admission was 68.6 days (max300:min5).The vast majority of patients with VL(n=15) were severe ill at presentation. Hepatomegaly was seen in 16 and splenomegaly in 17 patients simultaneously.The average length of stay(ALOS) was 24 days(max:69,min:8). ALOS depends on the drug used during treatment, the complications of disease and the adverse events of treatment.Treatment of 3patients was continued after a short break because of QT prolongation. Laboratory data are presented in table.

	HGB	MCV	PLT	LYM	NEU	Albumin
min	$52*10^{12}$ g/l	$61.4*10^{12}$ fL	$19*10^{9}$g/l	$0.9*10^{9}$g/l	$0.09*10^{9}$g/l	17.3g/l
avereg	$87.2*10^{12}$ g/l	$72.2*10^{12}$ fL	$169.8*10^{9}$g/l	$5.4*10^{9}$g/l	$3.6*10^{9}$g/l	33.4g/l
max	$145*10^{12}$ g/l	$89.5*10^{12}$ fL	$571*10^{9}$g/l	$89.5*10^{9}$g/l	$54*10^{9}$g/l	49g/l

Conclusions/Learning Points: Severe illness associated with belated admission to the hospital is common among VL patients. Considering this fact reinforce bond between population and primary health care centers, and encourage and/or train medical stuff to be focused on children with hepatosplenomegaly and severe anemia.

PV1129 / #1394

HHV-6 ENCEPHALITIS IN AN INMUNOCOMPETENT PATIENT DUE TO REACTIVATION IN THE CONTEXT OF FLU SYNDROME

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Paula Hidalgo Cáceres[1], Marta Cano Cabrera[2], Sara Pérez García[2]
[1]Hospital Universitario Virgen de Valme, Pediatria, Sevilla, Spain, [2]Hospital Universitario Virgen de Valme, Pediatría, Sevilla, Spain

Title of Case: HHV-6 ENCEPHALITIS IN AN INMUNOCOMPETENT PATIENT DUE TO REACTIVATION IN THE CONTEXT OF FLU SYNDROME
Background: Human herpesvirus 6 belongs to the Herpesviridae family, so it shares the characteristics of DNA integration and reactivation. Its classic clinical manifestation is roseola infantum. The highest rate of seropositivity is between six months and two years of age. Other less frequent complications described are: encephalitis, hepatitis or myocarditis, which occur especially in immunocompromised patients.
Case Presentation Summary: A 7-year-old boy admitted for atypical febrile seizure with focal characteristics, associated with a 3-day febrile syndrome with cough, runny nose, headache and myalgia. On examination, tending to sleep, temporal-spatial disorientation, incoherent speech, mild dysarthria, with episodes of nervousness, visual hallucinations, symmetrical face, preserved strength and sensitivity, normal ROT, difficulty walking and pain on palpation of lower limbs. The following complementary tests are carried out: *PCR Influenzae A virus: Positive. *PCR Sars-cov2 virus: Negative. *Lumbar puncture: Cytochemical study of viral characteristics, negative gram stain, negative culture. PCR to neutrotrophic virus: Positive for human herpesvirus 6, along with determined in CSF, positive. *Cranial CT: No pathological findings. *Cranial MRI: No pathological findings. *EEG: Normal base rhythm. It was interpreted as encephalitis due to herpes virus 6, in an immunocompetent patient due to reactivation, in the context of flu syndrome. Treatment with ganciclovir was started for 14 days, and the patient was finally asymptomatic with no neurological sequelae.
Learning Points/Discussion: Like other herpesviruses, herpesvirus 6 can remain latent after primary infection. Being able to reactivate, producing complications such as encephalitis, especially in immunocompromised or post-transplant patients. Encephalitis due to this virus in immunocompetent patients without risk factors is rarely described, although cases with a good response to ganciclovir have been seen.

EXPERIENCE IN THE TREATMENT OF VISCERAL LEISHMANIASIS IN OUR HOSPITAL. CASE SERIES.

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Sara Pérez García[1], Marta Cano Cabrera[1], Paula Hidalgo Cáceres[2]
[1]Hospital Universitario Virgen de Valme, Pediatría, Sevilla, Spain, [2]Hospital Universitario Virgen de Valme, Pediatria/Sevilla, Spain

Title of Case: EXPERIENCE IN THE TREATMENT OF VISCERAL LEISHMANIASIS IN OUR HOSPITAL. CASE SERIES.

Background: Leishmaniasis is a parasitosis produced by a protozoan that infects through the mosquito bite. Its clinical manifestations moves in a wide range from asintomatic to severe systemic infection. We present our experience in handling this pathology through two cases with different regimens of the same treatment:

Case Presentation Summary: Patient 1: 2-year-old female with fever and pancytopenia.At physical examination she has skin and mucosa pallor with widespread bruising and splenomegaly were found.In blood smear we objectify anisocytosis and polychromasia of the red series and lymphocytosis of mature elements. In bone marrow biopsy we detected PCR positive to Leishmania donovani.The patient receives transfusion of red blood cells and treatment with intravenous liposomal amphotericin B at 7 mg/ kg/dose on the 1st-5th and 14th days. Patient 2: 2-year-old male with prolonged febrile syndrome, asthenia and anorexia.At physical examination we saw highlights cutaneous-mucosal pallor with palpebral and malleolar edema, splenomegaly and hepatomegaly.Blood smear show us pancytopenia, with activated lymphocytosis and red blood cells with tendency to form roulox.The results of serology were IgG positive to Leishmania Donovan at titer 1/1280.The patient receives treatment with amphotericin B Liposomal at 4 mg/kg/dose in a regimen of 1-5,10, 14 and 21 days. In both cases complete healing occurs without relapse.
Learning Points/Discussion: Due to its safety profile, liposomal amphotericin B has become the treatment of choice.Treatment with short-course liposomal Amphotericin B offers results similar to treatment with a long regimen, and both of them were equally effective.Currently, the trend is to make shorter guidelines to avoid side effects, although in this series of cases, it has not been shown that the long regimen produced side effects to our patients.

A CASE REPORT OF BLACKWATER FEVER IN A 5 YEAR OLD GIRL WITH HER THIRD MALARIA INFECTION IN JAYAPURA PAPUA

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Mathilda Irianti[1], Joue Abraham Trixie[2], Sandra Sianipar[3]
[1]RS Bhayangkara, Er, Jayapura, Indonesia, [2]University of Indonesia, Public Health, Jakarta, Indonesia, [3]RS Bhayangkara, Pediatrics, Jayapura, Indonesia

Title of Case: A CASE REPORT OF BLACKWATER FEVER IN A 5 YEAR OLD GIRL WITH HER THIRD MALARIA INFECTION IN JAYAPURA PAPUA
Background: A severe febrile illness accompanied by the passage of dark urine was documented by an English surgeon, Tidlie, in West Africa, given the condition name Blackwater fever in 1884. Black water fever itself is a rare manifestation of falciparum malaria characterized by sudden intravascular haemolysis followed by fever and haemoglobinuria.
Case Presentation Summary: A 5-year-old girl, who was born and raised in Papua admitted with fever, malaise, abdominal pain and dark coloured urine for 2 days. Liver was palpable at two to three fingerbreadths. The initial laboratory tests revealed severe anemia (Hb 6.2 g/dL). Colour of Urine dark-coloured; Blood in urine +3, Leukocytes in Urine +1, Microscopic finding listed Leukocytes 5-8/Visual Field, Erythrocytes 15-20/Visual Field. The thick and thin blood is confirmed. The patient has 2 times history of Malaria; Mixed and Tropicana. Anti-malaria was administered IV and single dose per oral. Red Blood Cell transfusion is given 3 times to overcome the Anemia. On the 14th day, the patient was discharged.
Learning Points/Discussion: Patients who have been repeatedly infected with malaria in endemic countries are still at risk for complications from malaria. Either the patient has re-infected; or the parasite is in dormant from the previous infection. Screening and early the diagnosis can lower the chance of life-threatening complication. For pediatricians, giving an aggressive approach in treatment also give the best result based on the patient condition.

SYPHILIS AND HIV IN ADOLESCENTS IN SOUTHERN MADRID, SPAIN (2018-2022)

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Judit Cecilia Jiménez Betancort[1], Arantxa Berzosa Sánchez[2], María Espiau Guarner[3], Marisa Navarro[4], Anna Gamell Fullà[5], Lola Falcón Neyra[6], Alfredo Pérez Rivilla[7]
[1]12 de Octubre University Hospital, Paediatric Infectious Diseases, Madrid, Spain, [2]Hospital Clínico San Carlos, Pediatric Infectious Diseases Unit, Department Of Pediatrics, Madrid, Spain, [3]Vall'd Hebron University Hospital, Paediatric Infectious Diseases, Barcelona, Spain, [4]Gregorio Marañon Hospital, Gregorio Marañon Hospital, Madrid, Spain, [5]Sant Joan de Deu Hospital, Paediatric Infectious Diseases, Barcelona, Spain, [6]Virgen del Rocío Hospital, Paediatric Infectious Diseases, Sevilla, Spain, [7]12 de Octubre University Hospital, Microbiology And Parasitology, Madrid, Spain

Backgrounds: The incidence of sexually transmitted infections (STI) is rising worldwide. Its incidence in Spain has doubled since 2016, including in the adolescents. Data about STI in this population could help tailoring preventive measures.
Methods: Retrospective descriptive study describing syphilis and HIV serologies requests in 2018-2022, to adolescents aged 10-19 years, in a health area in Southern Madrid, Spain (including hospital and primary care settings). The results and clinical records were reviewed.
Results:

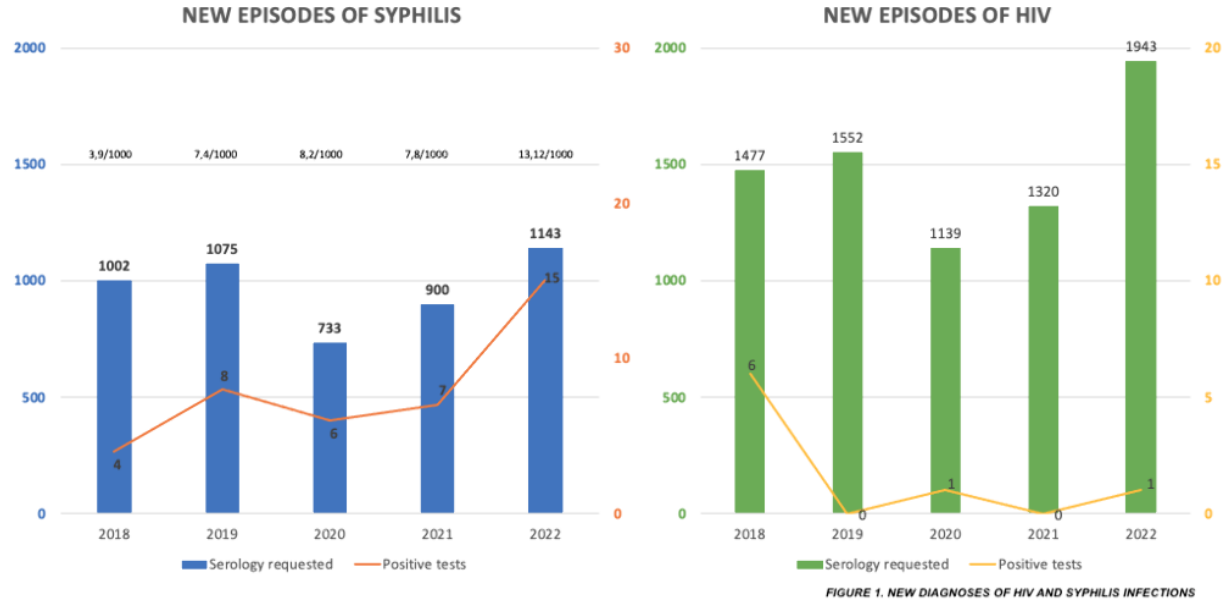

FIGURE 1. NEW DIAGNOSES OF HIV AND SYPHILIS INFECTIONS

From 4853 syphilis serologies analyzed, 40 new [C1] episodes occurred[C2] , from 2018 to 2022. The median age at diagnosis was 18 years (18-19 IQR); [C3] 31/40 (77.5%) in late adolescents (18-19 years) and 9/40 (22.5%) in middle adolescents (15-17 years). A significant increase in the annual incidence of the rate of syphilis was observed, from 0.39% in 2018 to 1.31% in 2022 (p=0.035) (Figure1). Regarding HIV, there were 8 new diagnoses in the study period, all in late adolescents (18-19 years). Likewise, our study showed the impact that health alerts had on STI screening. During the COVID-19 pandemic (2020), the minimal number of serologies were requested both for syphilis and HIV, while during the Monkeypox virus emergency (2022), the maximum requests were seen (Figure1).
Conclusions/Learning Points: Our data show an increase in the incidence of syphilis in adolescents in

Southern Madrid in recent years. In addition, this study reveals the impact that health emergencies have on the screening of these infections.

ANALYSIS OF MENINGOCOCCAL B IMMUNISATION IN CHILDREN UNDER 15 YEARS OF AGE. VALENCIAN REGION (SPAIN). YEARS 2018-2022.

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Juan Juaneda[1,2], Cristina Gimenez Lozano[1,3], Miriam Escrig-Collado[1], Miriam Paya-Canals[1], Inmaculada Notivoli-Marín[1], Eliseo Pastor-Villalba[1], Jose Lluch-Rodrigo[1]
[1]General Direction of Public Health and Addictions, Health Promotion And Prevention Programs Service, Valencian Region, Spain, [2]La Fe Hospital, Preventive Medicine & Public Health Service, Valencia, Spain, [3]Peset Hospital, Preventive Medicine Service, Valencia, Spain

Backgrounds: Meningitis B vaccine was allowed to be sold in pharmacies in 2015 and recommended by Paediatrics Associations, funded by parents. In November 2022 its funding was recommended for infants with a 2-4-12 months regimen besides already financed risk groups. The Valencian Region, with 35,000-37,000 births per year, registers through the Vaccine Information System over 97% of total vaccine doses sold in the region. This study aims to analyse evolution of vaccines administered in the region during 2018-2022 and assess pandemic influence over vaccination.
Methods: A descriptive analysis of meningococcal B vaccination trends was performed, by sex, age group, risk group and public/private centre, in children up to 14 years of age from 2018 to 2022.
Results: In 2018, 113,126 doses were reported compared to 80,017 in 2022. 99.74% doses were in children without risk factors in 2018. In 2022, distribution remained similar (99.83%). A total 448,854 children were vaccinated between 2018-2022 (55.04% under 1 year, 33.77% 1-4 years, 11.19% 5-14 years). Significant differences in age groups were observed in 2018 (45.2% <1 year, 33.76% 1-4 years, 24.84% 5-14 years) and 2022 (65.56% <1 year, 31.72% 1-4 years, 3.72% 5-14 years). Private centres administered 11.20% and 9.20% doses in 2018 and 2022 respectively. A decrease of 29.27% in vaccination was observed between 2018-2022, with a larger decrease in 2018-2019 (-27.53%) than in 2020-2022 (-9.41%) during pandemic years.
Conclusions/Learning Points: The number of vaccines has decreased due to fewer births. Most children vaccinated were not at risk. Vaccination was highest for children under 1 year, decreasing over time. No differences by sex. Vaccination in private centres remained around 10%. The largest decrease in vaccination was pre-pandemic in 2019, followed by the first pandemic year.

PV1134 / #1637

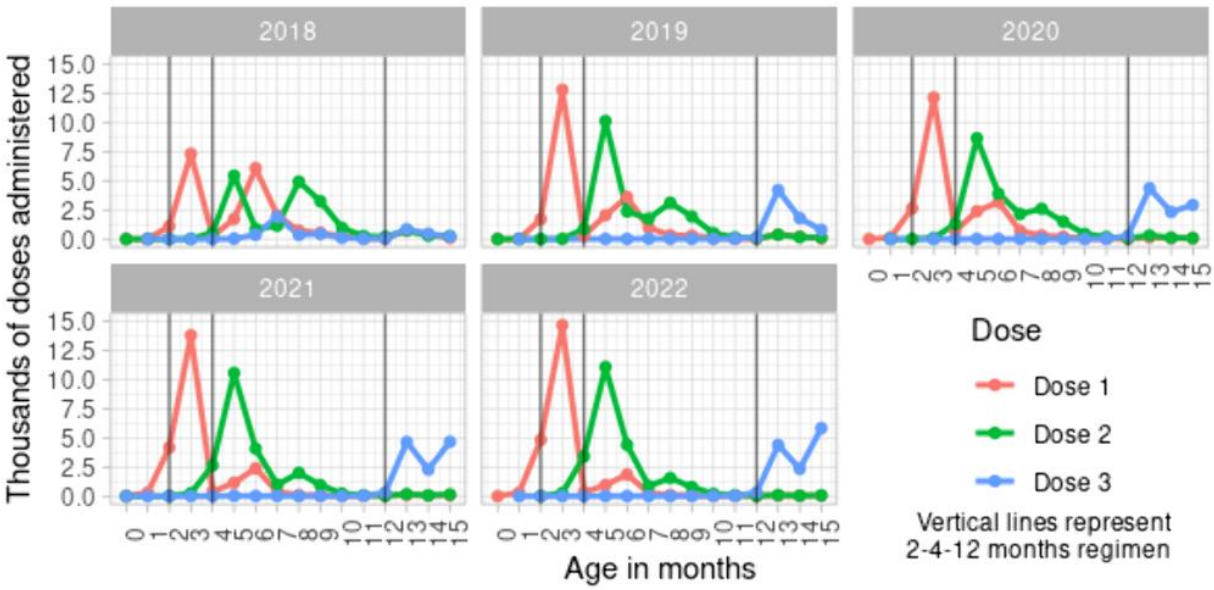
NON-FINANCED MENINGOCOCCUS B VACCINATION IN THE VALENCIAN REGION, SPAIN: ARE THE RECOMMENDATIONS BEING FOLLOWED?

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Juan Juaneda[1,2], Cristina Gimenez Lozano[1,3], Miriam Escrig-Collado[1], Miriam Paya-Canals[1], Inmaculada Notivoli-Marín[1], Eliseo Pastor-Villalba[1], Jose Lluch-Rodrigo[1]
[1]General Direction of Public Health and Addictions, Health Promotion And Prevention Programs Service, Valencian Region, Spain, [2]La Fe Hospital, Preventive Medicine & Public Health Service, Valencia, Spain, [3]Peset Hospital, Preventive Medicine Service, Valencia, Spain

Backgrounds: The B serogroup meningococcus vaccine (menB-v) was recommended in Spain in November 2022, with a 2-4-12 months regimen, emphasizing the importance of administering its doses on time. In the Valencian Region (VR), with around 36,000 births per year, menB-v has not been financed by the regional health system (RHS) until then, following heterogeneous administration guidelines. This study aims to evaluate on-time administration to understand non-RHS-financed vaccination behaviour.
Methods: A descriptive study using data from the Vaccine Information System (VIS) of the VR was conducted. The system records the vaccines administered in both public and private centres. All doses of menB-v administered to infants 0-15 months of age without risk factors during 2018-2022 were included. The study evaluated the number of first, second and booster doses given by age according to sex and year of administration.
Results: Mean doses (SD) administered per year during 2018-2022 were: 22774 (840) first doses, 21426 (1519) second doses and 9388 (3403)
boosters.

Figure 1. No. of doses administered by age and dose order



Most first doses were given in third month (53.3%) and only 12.7% were given on time (5.2% in 2018, 20.5% in 2022). Second doses were predominantly administered in fifth month (42.8%), only 8.2% administered on time (2.9% in 2018, 14.9% in 2022). The majority of third doses were given in thirteenth month (39.3%) and only 2.3% on time (1.1% in 2018, 2.4% in 2022). However, since 2020, an increase is observed in the administration of third doses in the fifteenth month. No differences in vaccination were found by sex.

Conclusions/Learning Points: Non-financed vaccinations did not conform to national recommendations, perhaps to decrease the number of injections per visit. To achieve maximum benefits, it is important to ensure vaccination at the minimum age allowed by the technical sheet.

PV1135 / #2000

AN OVERLOOKED AND LITTLE KNOWN CAUSE OF ACUTE CHEST PAIN

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Roza Kishoyan, Lernik Martirosyan, Viola Manukyan, Hasmik Yeghiazaryan, Mark Grigoryan, Suren Brutyan, Hripsime Apresyan, Vigen Asoyan
YSMU, Infectious Diseases, Yerevan, Armenia

Title of Case: An Overlooked and Little Known Cause of Acute Chest Pain
Background: Mediastinal fat necrosis (MFN) or epipericardial fat necrosis, as it is commonly referred to in the literature, is a rare self-limiting cause of chest pain of unclear etiology. MFN affects previously healthy individuals who present with acute pleuritic chest pain.
Case Presentation Summary: An otherwise healthy 9-year-old girl presented on the 2th day of illness with a pain in chest and right shoulder, especially while inspiration. The patient was fully alert. The patient's weight was 22kg, height 128cm. Her all vaccinations were up-to-date. There is no history about genetic disorders. The chest x-ray showed insignificant exudate in right pleural sinus. Ultrasound showed pleural effusion (exudate – 40ml) and after that child was admitted to the hospital. Laboratory findings:

During admission	First day	Last day
WBC	13.69	7.18
NEUT	10.01	3.02
LYMPH	2.49	3.42
PLT	279	361
RBC	5.02	4.90
HGB	128	130
MCV	79.0	76.1
CRP	7.24	0.69

Ultrasound of heart didn’t show any pathology Chest CT showed that in right cardio diaphragmal angle there is a 2.8 × 2.0 × 1.0 cm ovoid fat attenuation lesion delimited by a thin soft tissue. And also right sided hydrothorax without any pathology of pleura. There was no lymphadenopathy. Treatment The child received Ibuprofen 10mg/kg every 8 hours. Diagnosis Considering clinical and laboratory data the child was diagnosed with Mediastinal fat necrosis (MFN) or epipericardial fat necrosis.
Learning Points/Discussion: 1.There is not much information about mediastinal fat necrosis and patients are being diagnosed mostly after biopsy which is traumatic manipulation. 2.Because of its benign, self-limited nature, conservative treatment is preferred.

PV1136 / #2084

A CASE OF ACUTE DISSEMINATED ENSEPHALIT AFTER HHV-6 MENINGITIS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Mahmut Kızıl[1], Yalçın Kara[1], Ebru Kaçmaz[2], Eylem Kiral[3], Gürkan Bozan[3], Coşkun Yarar[4], Ömer Kiliç[5], Ener Çağrı Dinleyici[5]
[1]Eskişehir Osmangazi University, Pediatric Infectious Disease, ESKİŞEHİR, Turkey, [2]Eskişehir Osmangazi University, Pediatric Intensive Care, Eskişehir, Turkey, [3]Eskisehir osmangazi university, Pediatric Intensive Care, eskişehir, Turkey, [4]Eskisehir osmangazi university, Pediatric Neurology, Eskisehir, Turkey, [5]Eskişehir Osmangazi University, Pediatric Infectious Disease, Eskişehir, Turkey

Title of Case: A CASE OF ACUTE DISSEMINATED ENSEPHALIT AFTER HHV-6 MENINGITIS
Background: Many cases of viral meningitis are idiopathic, but increased utilization of polymerase chain reaction testing has enabled physicians to better recognize rare causes of viral meningitis. Patients who do not respond to supportive treatment and, if necessary, antiviral treatment can be challenging for the clinician. A case with ADEM (acute disseminated encephalitis) whose flaccid paralysis and confusion continues after HHV-6 meningitis will be discussed.
Case Presentation Summary: While a 9-month-old female baby was being followed up with signs of viral respiratory infection, we applied to our clinic after noticing circulatory disorder, altered consciousness, and decreased extremity movements. On physical examination, there were several crusted vesicular lesions on the anterior surface of the chest, and confusion was present. Laboratory tests revealed leukopenia and lymphopenia, and CRP was 11.2 mg/L . CSF glucose 81 mg/d L and simultaneous blood glucose was 110 mg/dL, CSF protein was 32 mg/dL, no cells were observed in CSF microscopy, HHV-6 was detected by CSF PCR. Empirically ceftriaxone, vancomycin and acyclovir was were given. In the follow-up, the patient had flaccid paralysis in 4 extremities and continued confusion. Considering the prediagnosis of acute disseminated encephalomyelitis (ADEM), intravenous immunoglobulin treatment was started for 5 days. The patient, who had a dramatic response with the first dose, was discharged after 14 days of acyclovir treatment.
Learning Points/Discussion: ADEM is an inflammation of the spinal cord and brain. Diagnosis of ADEM, due to its rare occurrence and lack of definite laboratory findings, is difficult and is never totally certain. Clinical criterion required for the diagnosis is presence of acute symptoms from the brain and/or spine with fever, occurring after viral or bacterial infection, vaccination or serum administration.

E-POSTER VIEWING: AS16. OTHERS

Maria Koliou-Mazeri[1], Margarita Onoufriou[2], Andreas Sergis[3], Antonis Cleanthous[3], Androulla Efstratiou[4], Athina Aristidou[3]
[1]University of Cyprus, Medical School, Nicosia, Cyprus, [2]Archbishop Makarios Hospital, Paediatrics, nicosia, Cyprus, [3]Archbishop Makarios Hospital, Paediatrics, Nicosia, Cyprus, [4]UKHSA, Reference Microbiology Division, London, United Kingdom

Title of Case: STREPTOCOCCAL GROUP A INVASIVE INFECTIONS IN CHILDREN IN A TERTIARY REFERRAL CENTER IN CYPRUS
Background: Beta-haemolytic streptococcus group A (GAS) causes common infections such as pharyngotonsillitis. Rarely, it can be the cause of invasive infections such as sepsis, meningitis, chest empyema and streptococcal toxic shock syndrome(STSS). In 2022 an increase in the number of invasive GAS infections (iGAS) was observed in many countries. The aim of this study is to evaluate the epidemiology, clinical characteristics and outcome of iGAS infections in Cyprus.
Case Presentation Summary: We reviewed the medical records of patients, younger than 16-year-old admitted with iGAS infection to Archbishop Makarios Hospital, the tertiary referral center for all Cyprus, between January 2021 and January 2023. Invasive cases were defined as cases with GAS isolated from a sterile site. A total of 8 cases were reported. The incidence rate of iGAS infections in 2022 was 2,6/100000 children. The median age of children was 3,5 years(1.3 to 8.6 years). 75% of cases were female. Two children suffered pneumonia with empyema, and GAS was cultured from pleural fluid. Six children had bacteraemia(75%), two of them without any focus, and four of them concurrent with focal infection ie endocarditis, meningitis, cellulitis, and septic arthritis. STSS also occurred in three patients(37,5%). Two children with STSS died within hours after admission(25%). A third child required ECMO. Median duration of hospitalization for survivors was 29 days.
Learning Points/Discussion: iGAS infections are rare, but severe as they carry substantial morbidity and mortality. There are no previous recorded cases in Cyprus in order to make comparisons to the current year. In case of iGAS cases strict adherence to preventive guidelines should be followed. Parents have to be educated on symptoms requiring urgent medical attention.

E-POSTER VIEWING: AS16. OTHERS

Konstantina Kontopoulou
GENERAL HOSPITAL G.GENNIMATAS OF THESSALONIKI, Laboratory Of Clinical Microbiology, THESSALONIKI, Greece

Title of Case: PRESENTATION OF A CASE OF WEST NILE VIRUS INFECTION IN A TERTIARY HOSPITAL DURING AUGUST 2022
Background: Outbreaks of West Nile virus concern the global medical community during the autumn and summer months. There is an increase in recorded cases in our country included pediatric patients in the year 2022.
Case Presentation Summary: The case concerns a West Nile infection in a 14-year-old pediatric patient, that was hospitalized at General Hospital of "G.GENNIMATAS", during August 2022, in Thessaloniki. The medical history and laboratory results were evaluated. The pediatric patient was a traveler from Russia and admitted to the hospital with fever, headache and characteristic skin rash. The laboratory diagnosis was confirmed in the Clinical Microbiology Laboratory of AUTH with the detection of IgM antibodies against West Nile virus in the serum and in the Cerebrospinal fluid.Commercial ELISA kits (WNV IgM capture DxSelect and WNV IgG DxSelect, Focus Diagnostics Inc, Cypress, California) were used for antibody detection. Magnetc resonance imaging showed thin meningeal hyperemia , while the general examination of cerebrospinal fluid was normal. IgM antibodies against West Nile virus in the serum and in the Cerebrospinal fluid were positive. The result was considered positive when the index value was >1.1 for IgM and >1.5 for IgG antibodies. The patient was discharged after five days of hospitalization in pediatric clinic. The diagnosis was suspected and confirmed within the first 24 hours of hospitalization.
Learning Points/Discussion: Continuous information and awareness among health professionals is a prerequisite for early differential diagnosis of West Nile virus cases. Climate change and the geographical location of Greece encourage vector-borne diseases.

PV1139 / #2716

BLOODSTREAM INFECTIONS IN PEDIATRIC PATIENTS

E-Posters Viewing

Konstantina Kontopoulou[1,2]
[1]GENERAL HOSPITAL G.GENNIMATAS OF THESSALONIKI, Laboratory Of Clinical Microbiology, thessaloniki, Greece, [2]GENERAL HOSPITAL G.GENNIMATAS OF THESSALONIKI, Laboratory Of Clinical Microbiology, THESSALONIKI, Greece

Background: Blood stream infection (BSI) is the leading cause of morbidity and mortality in pediatric patients and may present a diagnostic and therapeutic challenge. Objective:This study aims to describe the microbiological characteristics of BSI in pediatric patients.
Methods: Material for the study was blood samples(Pediatric vials, BACTEC, Becton Dickinson) from 453 pediatric patients, of whom 303(67%) were males and 150(33%) females. The study was conducted at General Hospital G.GENNIMATAS in Thessaloniki from January 2017 to January 2023.From the entire sample, 30 were positive for one microorganism. Positive blood culture samples were cultured on blood / Mc Conkey agar, chocolate agar in CO2 conditions and blood agar in anaerobic conditions. Identification and susceptibilty test were performed using VITEK-2 automated system(Bio Merieux, France).
Results: 30 (6,6%) blood samples were positive for one microorganism. Of them eleven 11(37%) were Gram positive bacteria included Staphylococcus aureus(72%) of which 25% were methicillin resistant, Streptococcus pneumoniae (18%), Streptococcus pyogenes (10%). Gram negative bacteria were also 11(37%) and included Escherichia coli(64%), Klebsiella oxytoca (9%) and Salmonella enteritidis(27%). One isolate was Candida parapsilosis. 75% of S.aureus were methicillin sensitive and 50% of S.pneumoniae were Penicillin resistant. All of the gram negative were ESBL negative and 43% of E.coli isolates were 57% resistant to amoxicillin/clavulanic acid. Patients with immuno- suppressive disorders with BSI had isolates such as Salmonella enteritidis, S. pneumoniae and Candida parapsilosis.
Conclusions/Learning Points: Detection of bacteria in blood has an important role in diagnosis for a febrile patient; to establish the presence of infection, to reassure the clinician about the chosen empirical therapy, and to provide up-to date information on the local etiologic patterns and antibiotic sensitivities as this will guide the clinician in the management of the patient.

DE NOVO ONSET OF CROHN'S DISEASE IN A 10 YEAR OLD GIRL SHORTLY AFTER COVID-19 INFECTION

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Ioanna Tassiou, Mirsini Kopanou, Dimitra Grammenou, Angeliki Spartinou, Anastasia Anastasiou-Katsiardani
GENERAL HOSPITAL OF VOLOS, Paediatric, VOLOS, Greece

Title of Case: DE NOVO ONSET OF CROHN'S DISEASE IN A 10 YEAR OLD GIRL SHORTLY AFTER COVID-19 INFECTION
Background: Introduction: The onset of autoimmune diseases may be generated by a variety of factors through the creating a hyper-stimulated state of the immune system. Infection from Sars-Cov-2 has been related to pathologic immune response even in children and could initiate various autoimmune diseases. These may present either during or shortly after resolution of disease.
Case Presentation Summary: A 10 year old girl was referred to our hospital due to daily low grade fever, diarrhea, anorexia and periodic epigastralgia, all initiating 10 days after infection from Sars-Cov-2. She wasn't vaccinated against Covid-19. Clinical findings included pallor and emaciation.Double antibiotic therapy was administered to our patient, immediately after laboratory tests were performed: Ht:30%, Hb:9.9g/dl, WBC:12.8 k/μL (N:70%),CRP:86,37mg/L, ESR:36mm/h,PCR panel for various viruses,antibodies for celiac disease,parasitological and stool cultures,C.difficile toxin,Widal-Wright, antibodies for autoimmune diseases.Each test was negative.Due to persistence of symptoms stool calprotectin was checked with upcoming results highly off normal values(1008,9 μg/g).Abdominal ultrasound revealed the presence of abnormal mesenteric lymph nodes(1cm),while X-rays of the abdomen were normal.Patient was transferred to a tertiary hospital where after gastro-colonoscopy and MR Enterography diagnosis of Crohn's disease was established and cortisone and azathioprine therapy was administered.
Learning Points/Discussion: Conclusions: According to up to date data, infection from Covid-19 can induce intestinal inflammation and lead to de novo onset of IBD, possibly due to disturbance of bowel barrier, mutations in genetic expression, intestinal dysbiosis and immunologic hyper-responsiveness. Nevertheless, more studies should be conducted in order to export safer results. Until then, the clinician should be vigilant for possible IBD manifestations after Covid-19 infection, and refer immediately any such patient to a pediatric gastroenterologist.

DE NOVO ONSET OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) DISEASE IN A 13Y OLD GIRL AFTER COVID-19 AND EPSTEIN-BARR VIRUS (EBV) COINFEC-TION

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Mirsini Kopanou, Ioanna Tassiou, Angeliki Spartinou, Anastasia Anastasiou-Katsiardani
GENERAL HOSPITAL OF VOLOS, Paediatric, VOLOS, Greece

Title of Case: DE NOVO ONSET OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) DISEASE IN A 13y OLD GIRL AFTER COVID-19 AND EPSTEIN-BARR VIRUS (EBV) COINFECTION
Background: SLE is caused by the interaction between genetic and environmental factors, however, its underlying triggers remain unknown. Among the environmental factors, the involvement of infections, as a trigger for SLE, especially those of viral etiology, has been widely reported. Viruses such as EBV have been documented to be involved in SLE pathogenesis and the new Sars-Cov-2 is now implemented in autoimmune and autoinflammatory disorders.
Case Presentation Summary: A 13 year old girl visited our outpatient clinics due to persistent arthralgia over the past trimester.At first only major joints were affected (knee and limb) but shortly after pain and oedema presented in smaller joints of upper and lower extremitities as well. Headache, hoarseness of voice,difficulty in climbing steps, weight loss and worsening hair loss were also mentioned. The above symptoms started3months after a laboratory-confirmed COVID-19and EBVcoinfection. Due to persistence of symptoms the patient admitted to hospital and extensive laboratory tests were performed and revealed:severe leukopenia, thrombocytopenia,elevated erythrocyte sedimentation rate(ESR),hypocomplementemia,hyperglobulinemia,positive ANA,anti-ds DNA markers, anti-cardiolipin IgM antibodies,anti-β2GPI IgM antibodies,Lac test and mild proteinuria.The patient fulfilled the classification criteria for SLE and was then referred to a rheumatologist and immunosuppressive treatment was started.
Learning Points/Discussion: Learning Points/ Discussion: There is a strong belief that EBV infection is involved in SLE pathogenesis. Covid-19 infection related autoimmune response has been documented as well. It would be interesting to observe any relationship between Covid and EBV coinfection and trigger of autoimmune diseases. Until then the clinician should be vigilant for possible infections or infectious reactivation that are potential triggers for initiation of autoimmunity and for SLE flares.

INTESTINAL MYIASIS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Pramod Kulkarni[1,2]
[1]KEM Hospital Research Centre Pune, Pediatrics, PUNE, India, [2]Deenanath Mangeshkar Hospital Research Centre, Pediatric Infectious Diseases, PUNE, India

Title of Case: Intestinal Myiasis- a rare tropical infestation
Background: Intestinal Myiasis is a condition when fly larvae accidentally inhabit human gastrointestinal tract and are passed out in faeces. Ingestion of food contaminated with eggs or larvae of various types of flies in human surroundings. Visible passage of live-wriggling or dead worms in faeces is the commonest manifestation variably associated with abdominal pain, diarrhoea, failure to thrive as clinical symptoms. Persistent passage of worms in spite of repeated anti helminthic courses is typically suggestive of myiasis which resolves over long time spontaneously or after bowel wash - intestinal decontamination.
Case Presentation Summary: A 2year old boy from countryside was referred for passage of worms 50-60/stool since 2months noted by parents. The worms were of 5-8mm length, blackish brown coloured, most live wriggling and few dead. Video recordings of freshly passed stools by parents and personal gross inspection confirmed the infestation. The child also had recurrent acute diarrhoea since last year variable in colour, volume, consistency with occasional blood. Recurrent significant colicky abdominal pain lasting for an hour was reported especially at night , responded to antispasmodics. Exaggerated gastrocolic reflex was of note. Multiple consultations and repeated various anti helminthic medication courses provided no relief. The toddler weighed 10.150kg with 1400 gm documented gain over last year. Physical examination was totally normal without any abnormal finding. CBC, Stool examination results were noncontributory. History unfolded food contamination risk factors- habitual overeating of bananas, livestock stable in close vicinity, fly menace at village family house. Colonic wash with oral Polyethylene Glycol and WHO ORS repeated 3 times at weekly interval resolved all symptoms.
Learning Points/Discussion: Intestinal Myiasis is a known yet least considered tropical infestation, inappropriately over treated with anti helminthic medications.

Title of Case: OLD FRIEND / NEW ENEMY? : INVASIVE STREPTOCOCCUS PYOGENES INFECTIONS IN CHILDREN
Background: An increasing trend in invasive Streptococcus pyogenes infections has been reported from many countries, causing alarm worldwide in the last months of 2022. We followed six patients with severe invasive Group A Streptococcus (iGAS) infection in the last three months. In this study, we aimed to reveal the characteristics of the patients with iGAS infection and draw attention to the increasing disease burden.
Case Presentation Summary: We retrospectively evaluated six children with iGAS infections; three were males with a mean age of 6 years. Two deep neck infections, two septic arthritis, one bacteremia, and one pyomyositis were included. All patients had fever and were ill-appearing. All patients' acute phase reactants were high. Five of 6 patients underwent surgical drainage. Ampicillin-sulbactam was administered in five patients; clindamycin was initiated in two cases for suspected streptococcal toxic shock syndrome. Crystalline penicillin G was administered to one patient.
Learning Points/Discussion: These recently observed infections within three months draw attention to the increasing invasive nature of S.pyogenes. Despite causing severe infections, we had an excellent response to appropriate and immediate treatment, as the pathogen is still susceptible to penicillin. Particularly in the post-COVID period, iGAS infections reemerged and continue to pose a threat with the change in the epidemiology of most viral and bacterial infections.

STAPHYLOCOCCAL SCALDED SKIN SYNDROME (SSSS) IN CHILDREN: A 4-YEAR RETROSPECTIVE STUDY IN A SINGLE INSTITUTION

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Kleanthi Voutsadaki, Fani Ladomenou
Venizeleion General Hospital, Department Of Pediatrics, Heraklion, Greece

Title of Case: STAPHYLOCOCCAL SCALDED SKIN SYNDROME (SSSS) IN CHILDREN: A 4-YEAR RETROSPECTIVE STUDY IN A SINGLE INSTITUTION
Background: Staphylococcal scalded skin syndrome (SSSS) is a toxin-mediated, blistering skin disorder, produced by certain strains of Staphylococcus aureus. Mortality is approximately 4%. The purpose of this study was to describe the epidemiology, clinical features, management and antibiotic-resistant patterns of pediatric SSSS.
Case Presentation Summary: We conducted a retrospective study of children with a clinical diagnosis of SSSS from January 2019 to December 2022 in the pediatric department of a tertiary general hospital. Epidemiologic, clinical, laboratory and microbiology data were obtained. 43 patients with SSSS were included; 23/43 (55.8%) were female. Mean age of diagnosis was 3.06years (range 3.5months-6.5years). Occurrence was more frequent during summer and autumn, 16/43 (37.2%) and 12/43 (27.9%) respectively. Fever, elevated white blood cell count and high C-reactive protein levels were uncommon. Staphylococcus aureus was isolated in 33/43 (76.7%) patients; higher positive culture rates were found in nasal swabs (25/33, 75.7%). All cases were due to methicillin-sensitive S.aureus (MSSA). Susceptibility tests for the rest of antibiotics showed zero resistance rates to vancomycin and trimethoprim/sulfamethoxazole, followed by clindamycin (1/33 strains, 3%), whereas all strains were highly resistant to mupirocin (31/32 strains, 96.9%) and tobramycin (20/31 strains, 64.52%). All patients were treated with cloxacillin and clindamycin. Mean hospitalization was 5.34days. Severe complications were seen in one patient (2,33%) whose course was complicated with bloodstream infection. No fatalities were observed.
Learning Points/Discussion: SSSS remains a pediatric emergency with good prognosis when treated appropriately. Staphylococcus aureus is more often isolated from nasopharyngeal/periorificial swabs. In our study most SSSS cases were due to oxacillin and clindamycin susceptible strains. High resistant rates of mupirocin and tobramycin were demonstrated, questioning their use.

[1]ACeS Baixo Mondego, Usf Araceti, Arazede, Portugal, [2]ACeS Baixo Mondego, Usf Nautilus, Figueira da Foz, Portugal, [3]ACeS Baixo Mondego, Usf Rainha Santa Isabel, Coimbra, Portugal, [4]Hospital Distrital da Figueira da Foz, Serviço De Pediatria, Figueira da Foz, Portugal

Title of Case: "Healthy helminth": an asymptomatic case report
Background: Ascaris lumbricoides is the most common helminthic infection worldwide. It is transmitted through the ingestion of embryonated eggs from contaminated soil or food. Predisposing factors include poverty, poor sanitation and bad personal hygiene. The prevalence is higher in children younger than 5 years. The majority of patients are asymptomatic, but it can appear as anorexia, nausea, recurrent abdominal pain, abdominal distension and diarrhea. The diagnosis is best established by detection of eggs on faeces. The treatment is mandatory, even in asymptomatics, to prevent complications from the parasite´s migration. The drugs of choice are albendazole or mebendazole and the average cure rate is more than 95%.
Case Presentation Summary: The case concerns an eleven-year-old child, with an body mass index of 18 (percentile 50-85), who presented an helminth in the stool, without any symptom. It should be noted that this is a child with access to adequate hygiene and sanitary care, who lives in an European country, but in a rural area. He made albendazole in single dose (SD), without new episodes.

Learning Points/Discussion: This case alerts us to the presence of helminthic infections even in children with proper hygiene and led us to make an approach on the treatment of helminthic infections. The literature revision points that the treatment for children is 400mg albendazole or 500mg mebendazole, in a SD. They are highly safe, but attention must be paid because hepatic toxicity may rarely occur. Other drugs may be used , but they need more studies. Helminthic infections are typical from tropical and subtropical areas, but we must keep in mind that this parasites are present in soil, so every children are potentially in risk of infection.

PNEUMOCCOCAL VACCINATION IN INFANTS UNDER 2 YEARS OF AGE – DID THE LOCKDOWN MEASURES DUE TO THE SARS-COV-2 PANDEMIC INFLUENCE VACCINATION RATES AND TIMELINESS OF VACCINATION IN GERMANY?

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Maren Laurenz[1], Christof Von Eiff[1], Kathrin Borchert[2], Karolin Seidel[2], Christian Jacob[2], Felicitas Kühne[1]
[1]Pfizer Pharma GmbH, Vaccines, Berlin, Germany, [2]Xcenda GmbH, Eu Real World Evidence, Hannover, Germany

Backgrounds: Pneumococcal conjugate vaccination (PCV) is recommended for infants <2 years of age in Germany. From 08/2006 to 08/2015, a 3+1 schedule was recommended (2, 3, 4, and 11-14 months); since 09/2015, a 2+1 schedule is recommended for term infants (2, 4, and 11-14 months [respectively 11 months since 08/2020]). In March 2020, the SARS-CoV-2 pandemic started to strongly influence daily life in Germany (e.g. nationwide lockdown measures). Study aim was to assess vaccination rates and timeliness of PCV for birth cohorts before and during the pandemic based on real-world data.
Methods: A retrospective claims data analysis was conducted using the InGef Research Database containing an age- and gender-representative sample of the statutory health insured population in Germany. The study population consisted of infants born in 2013, 2016, 2018 (birth cohorts before the SARS-CoV-2 pandemic) and 2020 (first cohort born during the SARS-CoV-2 pandemic) with an individual follow-up of 9 months (interim analysis).
Results: After 9 months 90.4% (89.7%/89.2%/89.2%) of the 2020 (2018/2016/2013) birth cohort had received at least one PCV dose. The basic PCV series (2 doses in 2016-2020; 3 doses in 2013) was administered in 83.3% (79.5%/77.9%/75.4%) of infants of the respective birth cohorts. If administered, the first dose was received within the recommended timeframe only in 57.6% (2020), 53.6% (2018), 51.9% (2016), and 44.9% (2013).
Conclusions/Learning Points: Although nationwide lockdowns due to the SARS-CoV-2 pandemic strongly influenced daily life in Germany, there is currently no evidence of a negative impact on PCV rates and timeliness of vaccination. The rate of unvaccinated infants remained constant at about 10%. Vaccinations were often delayed but a positive trend regarding timeliness of the first dose and basic PCV was observed from birth cohort 2013 to 2020.

POTENTIAL IMPACT OF TWO DIFFERENT RECOMMENDATIONS FOR PNEUMOCOCCAL AND HEXAVALENT VACCINATION IN PRETERM (3+1) AND TERM (2+1) INFANTS – A GERMAN CLAIMS DATA ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Maren Laurenz[1], Christof Von Eiff[1], Kathrin Borchert[2], Karolin Seidel[2], Christian Jacob[2], Felicitas Kühne[1]
[1]Pfizer Pharma GmbH, Vaccines, Berlin, Germany, [2]Xcenda GmbH, Eu Real World Evidence, Hannover, Germany

Backgrounds: In August 2020, the German Standing Committee on Vaccination (STIKO) changed the hexavalent (HEXA) vaccination schedule for term infants (TI) from a 3+1 (2, 3, 4, and 11-14 months) to a 2+1 scheme (2, 4, and 11 months). For preterm infants (PI), the 3+1 schedule remained unchanged. A respective recommendation change for pneumococcal vaccination (PCV) took place in August 2015. Study aim was to assess vaccination rates and timeliness of PCV and HEXA vaccination in PI after the change in recommendation for TI based on real-world data.
Methods: A retrospective claims data analysis was conducted using the InGef Research Database containing an age- and gender-representative sample of the statutory health insured population in Germany. The study population consisted of all PI in the database (identified by ICD-10-GM codes P07.2 and P07.3) born in 2013, 2016, 2018 or 2020 with an individual follow-up of 9 months (interim data analysis).
Results: After 9 months, 91.5% (91.8%/92.0%/89.7%) of PI born in 2020 (2018/2016/2013) had received at least one HEXA vaccination, but only 62.8% (74.9%/73.3%/70.7%) obtained the three recommended HEXA vaccinations. At the same age, 92.7% (92.3%/90.9%/91.5%) of PI had received at least one PCV dose, but only 57.5% (49.2%/43.3%/70.5%) obtained the basic PCV series (three recommended doses). Only 56.3% (57.7%) of 2020 born PI receiving the first dose of PCV (HEXA) were vaccinated on time.
Conclusions/Learning Points: Although STIKO still recommends a 3+1 schedule for PCV and HEXA vaccination for PI in Germany, a significant decrease in PI receiving the three recommended doses within the first 9 months of life was observed after the respective recommendation change for TI. More efforts are needed to improve the adherence to STIKO recommendation to protect this vulnerable group of PI.

[1]Hospital Dona Estefânia - Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal, Paediatric Infectious Diseases Department, Lisbon, Portugal, [2]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Paediatric Neurology Department, Lisbon, Portugal, [3]General Directorate of Health, Disease Prevention And Health Promotion Department, Lisbon, Portugal, [4]Hospital de Dona Estefânia, Centro Hospitalar Universitário de Lisboa Central, Pharmacy, Lisbon, Portugal, [5]National Institute of Health Doutor Ricardo Jorge, Infectious Diseases Department, Lisbon, Portugal, [6]National Institute of Health Doutor Ricardo Jorge, Food And Nutrition Department, Oporto, Portugal

Title of Case: A CASE OF INFANT BOTULISM DETECTED IN LISBON
Background: Infant Botulism (IB) is a rare potentially life-threatening disorder, caused by botulinum neurotoxins-producing Clostridium. In Portugal, botulism is a statutory notifiable disease since 1999 and the first case of IB occurred in 2009.
Case Presentation Summary: In October 2022 a previously healthy 6-month-old female infant, born in USA, living in Austria for 2 months and on vacation in Portugal for 2 days, presented with subacute generalized hypotonia. Two days before she had become lethargic and was feeding poorly, also being constipated for six days. On admission decompensated hypovolemic shock was treated. Flaccid tetraparesis with preserved tendon reflexes, bilateral facial involvement and asymmetrical ptosis without pupillary disfunction were latter noted. She remained stable, requiring a nasogastric tube for feeding due to decreased sucking and gag reflexes. Blood work was unremarkable. Further investigation included neuroaxis MRI, CSF analysis, EEG, EMG with repetitive stimulation and infectious and metabolic investigations, all negative. Despite the absence of known risk factors, IB was considered. In serum the ELISA assay was negative for detection of botulinum neurotoxins (BoNT). Type A BoNT was detected in stools by Mouse Bioassay and PCR was positive for the gene that encodes type A BoNT-producing Clostridium, isolated from the faecal sample. A thorough epidemiological enquiry showed a context of family consumption of honey from Austria and the child had been given a home nuts paste. Human-derived Botulism Immune Globulin was administered at day 8. One week after and with rehabilitation support there was a slow but progressive improvement.
Learning Points/Discussion: IB is an under-reported disease possibly due to its nonspecific presentation and diagnostic difficulties. In this case,early treatment,considering the clinical and epidemiological context,while waiting laboratorial confirmation,was essential to reduce morbidity/mortality.

PV1149 / #601

CONCOMITANT TRIGEMINAL HERPES ZOSTER AND RAMSAY HUNT SYNDROME: A PEDIATRIC CASE REPORT

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Antonia Leutert[1], Rehana Huber[1,2], Henrik Köhler[1], Florence Barbey[1,3]
[1]Kantonsspital Aarau, Children's Hospital, Aarau, Switzerland, [2]Kantonsspital Aarau, Division Of Pediatric Neurology, Aarau, Switzerland, [3]Kantonsspital Aarau, Division Of Pediatric Infectious Diseases, Aarau, Switzerland

Title of Case: CONCOMITANT TRIGEMINAL HERPES ZOSTER AND RAMSAY-HUNT-SYNDROME: A CASE REPORT
Background: Herpes zoster (HZ) infection results from reactivation of latent Varicella Zoster Virus (VZV) gaining access to the sensory ganglia during varicella infection. Ramsay-Hunt-Syndrome (RSH) includes the triad of facial palsy, ear pain, and vesicles in the auditory canal and reflects reactivation of latent VZV in the geniculate ganglion. Multiple cranial nerve involvement is rare.
Case Presentation Summary: A healthy 17-year-old adolescent presented with right ear and facial pain during 5 days. Vesicles developed in the area of the right second and third branch of the trigeminal nerve and on the right soft palate (facial nerve) during two days. Corneal involvement was excluded and intravenous Acyclovir was initiated assuming concomitant trigeminal HZ and RHS. The next day RHS was completed as he developed right-sided facial palsy. Prednisolon was commenced. PCR swab of the vesicles was VZV positive. Cerebrospinal fluid (CSF) was VZV PCR negative. The patient was discharged after five days with complete recovery of the facial palsy. Acyclovir was administered orally for another 5 days.
Learning Points/Discussion: Co-occurrence of trigeminal HZ and RSH is rare. Adult cases presenting with serial occurrence of VZV cranial nerve involvement have been reported, assuming transaxonal spread within the area of the spinal trigeminal nucleus and tract (corresponding MRI alterations) or spread through CSF. In our case trigeminal HZ and RHS occurred simultaneously and CSF VZV PCR was negative assuming concurrent reactivation in the gasserian and geniculate ganglions. To the best of our knowledge, this represents the first described case with multiple cranial nerve involvement in an immunocompetent child. It's important to recognize this phenomenon even in healthy children and to initiate prompt therapy in order to prevent sequelae.

WHAT'S COMMON IS NOT SO COMMON (FOLLOW THE HEART OR THE HEAD?)

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Shelly Lipman Arens
Technion-Israel Institute of Technology, Rappaport Faculty Of Medicine, Haifa, Israel

Title of Case: A rare presntation of brucellosis in a 12 year old child
Background: Brucellosis is a zoonotic disease. infection occure after contact with infected animals or animal products as raw unpasteurized dairy. The clinical presentation is not specific and usually include fever, arthralgia and hepatosplenomegaly. Some are pesented as fever of unknown origin. involvment of the cardiac system is rare and myocarditis is much rarer. A high level of suspicion lead to early treatment and good prognosis.
Case Presentation Summary: 12 years old, Muslim origin, generally healthy, vaccinated. Admitted due to fever and pain, weakness, fatigue, loss of appetite and vomiting. On admission – he is fully conscious, temperature 38.5 C, pulse 115 per minute, blood pressure 115/67, saturation 98% on room air. Physical examination - normal. Lab results- leucopenia and thrombocytopenia and elvetaed CRP. ECG: Inversion of T waves V1-V6, III, AV . Troponin- positive Readback from the laboratory on the identification of gram-negative rods in blood culture. In a second anamnesis: Regularly drinks and eats non-pasteurized dairy products that his family buys direct from a farm. Treatment with Ceftriaxone and Doxycycline was started. Identification by MALDI-TOF (direct from the bottle) of serratia spp. Serology for brucella is taken and returns negative. Despite the negative serology and detection by MALDI-TOF the treatment continued and gentamycin is added. Identification of Brucella melitensis in blood culture and serology is pusitive.
Learning Points/Discussion: Diagnosis of brucellosis is not so easy and there should be high index of suspicion in ethnic groups in risk. Negative serology does not exclude the diagnosis. One should be aware of the limitations of MALDI-TOF in detection brucella Brucella myocarditis is rare and there are no guidelines for treatment this manifestation.

SKULL BASE OSTEOMYELITIS IN AN ADOLESCENT GIRL CAUSED BY INFECTION VIA CANALIS BASALIS MEDIANUS – AN EMBRYOLOGIC REMNANT IN THE CLIVUS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Felix Maier[1], Matthias Schaal[2], Ales Janda[1], Verena Herbener[1]
[1]University Ulm, Department For Pediatrics And Adolescent Medicine, Ulm, Germany, [2]University Ulm, Department For Radiology, Ulm, Germany

Title of Case: SKULL BASE OSTEOMYELITIS IN AN ADOLESCENT GIRL CAUSED BY INFECTION VIA CANALIS BASALIS MEDIANUS – AN EMBRYOLOGIC REMNANT IN THE CLIVUS
Background: A healthy 16-year-old girl presents with fever, neck pain and headache since 3 days, followed by neck stiffness, left-sided exophthalmos and torticollis. Liquor pleocytosis and CrP elevation lead to suspicion of acute meningitis, therapy with cefotaxime and aciclovir is initiated. Clindamycin is added due to slow clinical response. MRI shows enlarged tonsils and edema of the neck muscles. Gentamicin and clarithromycin are added to the therapy due to further clinical deterioration. In the course, the patient develops palsy of abducens and hypoglossus nerve. Follow-up MRI shows pathologic contrast enhancement of cranial nerves, the clivus and occipital condyles congruent with basal meningitis and skull base osteomyelitis.
Case Presentation Summary: The origin of the osteomyelitis remains enigmatic, no pathogen is detected; antibiotic therapy with clindamycin and cefotaxime is continued. Under the therapy the cranial nerve palsies regresse completely. The contrast enhancement of the skull base disappers, follow-up MRI shows demarcation of an accessory canal in the clivus, corresponding to „canalis basilaris medianus“ (CBM) or “fossa navicularis“. CBM is believed to occur in up to 5% of individuals as anatomical variation either as persistence of several emissary veins passing through the clivus or as an embryological remnant of the notochord. Otherwise, several case reports reported on meningitis in association with CBM, most likely serving as an infection route connecting the pharynx with the skull base and CNS. Surgical treatment might be necessary; in our case conservative treatment was sufficient.
Learning Points/Discussion: We suggest that in cases of unclear pediatric basal meningitis or skull base osteomyelitis, MRI (or CT scans) should be carefully searched for signs of CBM.

NECROTIZING FASCIITIS: RISK FACTORS IN CHILDREN IN BAMAKO

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Diakité Mamoudou, Keita Lassine, Fofana Youssouf
Hospitol Dermatology of Bamako, Dermatology, Bamako, Mali

Backgrounds: Necrotizing fasciitis (NF) is a serious bacterial infection, fatal in approximately 30% of cases, and is a medical and surgical emergency. This disorder is rare in children, although it is complicated by severe septic shock in 74% of cases. The aim of this study was to investigate the risk factors for the occurrence of necrotizing fasciitis in children in Bamako.
Methods: This was a case-control study of children aged 0-15 years seen in dermatology consultations and included according to the study objectives for a given period of one year. Each case was matched to a control.
Results: In total, out of a total of 48979 children seen, 20 children had necrotising fasciitis, representing a hospital incidence of 0.04%. Boys accounted for 55% and the mean age was 11.7 years. Of our children, 75% were from rural areas and 25% from urban areas. The lower limb was affected 65%, the upper limb 20%, the trunk 15% and the head 5%. The risk factors sought were: intertrigo (OR: 0.4; 95% CI: 0.03-3.66), varicella (OR: 0.21; 95% CI: 0.00-2.50), traumatic wound (OR: 10.3; 95% CI: 1.04-484.58), obesity (OR: 1; 95% CI: 0.01-82.57), HIV (OR:2.11; 95% CI: 0.09-130.99), lymphedema (OR:4.75; 95% CI: 0.39-245.95), NSAIDs (OR:19; 95% CI: 2.01-866.53), herbal medicine (OR:4.88; 95% CI: 1.00626.52).
Conclusions/Learning Points: In our study, the risk factors associated with the occurrence of necrotising fasciitis in children were NSAIDs, herbal medicine, lymphoedema and traumatic wounds. A large-scale cohort study is needed to better describe these factors

INNOVATIVE AND AFFORDABLE HIV-1 DRUG RESISTANCE TESTING FOR RESOURCE LIMITED SETTINGS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Sontaga Manyana
University of KwaZulu-Natal, Virology, Durban, South Africa

Backgrounds: As use of dolutegravir (DTG) becomes more common in resource limited settings (RLS), affordable methods for genotyping all relevant HIV-1 pol genes (i.e., protease (PR), reverse transcriptase (RT) and integrase (IN)) are required to guide choice of future antiretroviral therapy (ART) regimens. We designed an in-house HIV-1 drug resistance (HIVDR) genotyping method that is affordable and suitable for use in RLS.
Methods: We obtained remnant plasma samples from CAPRISA 103 study and amplified HIV-1 PR, RT and IN genes, using an innovative PCR assay. We genotyped samples by Sanger sequencing and assessed HIVDR mutations using the Stanford University HIV drug resistance database. We compared PR and RT mutations to previous sample genotypes, calculated method cost-estimates, and performed phylogenetic analysis.
Results: From 96 samples processed, we obtained sequence data for 78 (81%), of which 75 (96%) had a least one HIVDR mutation, with no major-IN mutations observed. When compared to previous genotypes, 18/78 (23%) had at least one discordant mutation, but only 2/78 (3%) resulted in different phenotypic predictions that could affect choice of subsequent regimen. Overall genotyping cost per sample was estimated at ~US$43, with a processing time of ~2 working days. All sequence pairs clustered together in phylogenetic analysis.
Conclusions/Learning Points: We successfully designed an in-house HIVDR method that is suitable for genotyping HIV-1 PR, RT and IN genes, at an affordable cost and shorter turnaround time. This HIVDR genotyping method accommodates changes in ART regimens and will help guide HIV-1 treatment decisions in RLS.

A CASE OF A 3.5-YEARS OLD BOY WITH INVASIVE GROUP A STREPTOCOCCUS (IGAS)

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Sose Margaryan, Aida Papikyan, Davit Sekoyan, Hrachuhi Ghazaryan
Wigmore Hospital for Children, Pediatrics, Yerevan, Armenia

Title of Case: A CASE OF A 3.5-YEARS OLD BOY WITH INVASIVE GROUP A STREPTOCOCCUS (iGAS)
Background: During 2022 an increase of cases of iGAS was indicated. This is a case report of a 3.5-years old boy with iGAS.
Case Presentation Summary: A previously healthy child admitted to the "Wigmore Hospital" on 5th day of the following complains: fever, swollen right ankle. Five days before admission X-ray of right leg was normal after trauma. On next day fever, rash on back, dry lips and pain on right ankle was observed. On 3rd day after the injury the child refused to walk due to swollen and painful ankle. On admission: child was very anxious, fine erythematous punctate eruption on back, on inguinal region, skin around the anus is wrinkled, peeling of the skin in some areas, red strawberry tongue, red throat, right leg: on preventive position, right ankle: swollen, hyperemic, warm. Rapid strep test from throat was positive, elevated CRP, leukocytosis were detected, echocardiography was normal. Treatment with IV Amoxicillin-Clavulanate were prescribed. On 3rd day child's condition improved, but on day 11 clinical signs worsened and the MRI was performed: a picture of phlegmon was described. The antibacterial therapy replaced by combined therapy with Ceftriaxone+Vancomycin+Metronidazole. Phlegmon was removed. Rapid strep test from puncture was positive and by microscopy cocci were found, on 10th day by culture: GAS. After surgical intervention some clinical improvement was observed. By 2nd MRI synovitis, tenosynovitis was described. On 30th day of hospitalization antibacterial treatment changed to TMP-SMX and continued 3 weeks. Fiberglass splint fixed. After two months: defect of the talus on X-ray, walk on small destinations without help but with difficulty.
Learning Points/Discussion: Raising awareness among clinicians can reduce transmission of GAS, number of iGAS.

[1]University Hospital of Padova, Pediatric Infectious Diseases, Department For Woman's And Child's Health, Padua, Italy, [2]University of Padova, Division Of Paediatric Infectious Diseases, Department For Women And Children's Health, Padova, Italy, [3]University of Padua, Paediatric Infectious Diseases, Padua, Italy, [4]Division of Pediatric Infectious Diseases, Department For Women's And Children's Health,, Padova, Italy, [5]University of Padua, Department For Woman And Child Health, Hematology And Oncology Unit, Padova, Italy, [6]University of Padua, Division Of Pediatric Infectious Diseases, Department Of Women's And Children's Health, Padua, Italy

Title of Case: CHILDREN WITH SUSPECTED ACUTE LYMPHOBLASTIC LEUKEMIA: CHALLENGES OF VISCERAL LEISHMANIASIS
Background: Visceral leishmaniasis (VL) is a vector-borne infection caused by the parasite Leishmania. The infection is endemic in subtropical and tropical areas and is listed as one of WHO´s neglected tropical diseases. Italy is considered an endemiccountry for Leishmania infantum. The incidence of infantile VL in Italy is decreased to a few cases per year. We present a child initially evaluated for acute lymphoblastic leukemia due to his clinical and hematological presentation, but subsequently found positive and treated for L. infantum infection.
Case Presentation Summary: a 15- month-old boy was evaluated in the emergency department for fever and pallor. His family was originally from Macedonia, and he spent some months there during summertime. Clinical evaluation showed hepatomegaly and splenomegaly without other pathological findings at clinical examination. Laboratory results showed anemia, thrombocytopenia and neutropenia with elevated reactive C protein and procalcitonin. Acute lymphoblastic leukemia was suspected, and the patient was admitted to the Hematological ward of Padua Children Department. A
bone marrow aspirate was obtained, with no evidence of any leukemic form was cytologically detected. Morphology evidence and polymerase chain reaction on marrow blood and in peripheric blood confirmed the diagnosis of Leishmania infantum. Therapy with a standard doses of liposomal amphotericin B was administered with rapid improvement of clinical conditions.
Learning Points/Discussion: Prompt identification of VL is essential to prevent severe outcomes. It should always be considered in the differential diagnosis of patients presenting with fever, hepatosplenomegaly and peripheral blood cytopenia

Backgrounds: Prematurity is a term for the broad category of neonates born at less than 37 weeks' gestation. Preterm birth is the leading cause of neonatal mortality and the most common reason for antenatal hospitalization. The main purpose of the study to conclude epidemiologic correlation between way of delivery and weight of newborn among neonates with preterm birth admitted to NICU of Muratsan UHC, Yerevan, Armenia.
Methods: Retrospective study included patients admitted during 01.01-01.06.2017period. We divided patients by gestation age(28-36-week and 37-41-week) as well as by weight after delivery(<1500g,1500-1999g, 2000-2499g, ³2500g).
Results: Analysis showed physiologic delivery among 85patients, Caesarean delivery– 42patients and there is no data about other 6patients. In general, 45 out of 133patients were 28-36-week gestation age, 82patients -37-41-week and there is no data about other 6. The average gestation age was 36.9(min-28 and max-41). The mean weight of neonates after delivery was 2767grams(min-980, max-5200). In the group with <1500g weight there were 5patients(3mothers had complicated pregnancy, 2 of them undergone C-section), 1500-1999g– 10patients(9mothers had complicated pregnancy, 5 of them–C-section), 2000-2499g– 28patients(19mothers- complicated pregnancy, 13–C-section), ³2500g– 90patients (48mothers- complicated pregnancy and 23-C-section). Complications during pregnancy were mainly due to respiratory infections.
In this period 30cases with death outcome were registered, 20(66.67%) of them were preterms. Breastfeeding patients were 49(36.8%).
Conclusions/Learning Points: The portion of women with complicated pregnancy tend to be higher in preterm births with lower weight. The major way of delivery among mothers with complicated pregnancy of the group <2500g was C-section.

[1]Santa Casa de São Paulo, Pediatric Infectious Diseases, Sao Paulo, Brazil, [2]Santa Casa de Sao Paulo School of Medical Sciences, Pediatric Infectious Diseases, Sao Paulo, Brazil, [3]santa casa sp, Pediatric, sao paulo, Brazil

Title of Case: POTT'S PUFFY TUMOR: A FORGOTTEN COMPLICATION OF A COMMON INFECTION IN CHILDREN
Background: Pott's Puffy Tumor (PPT) is defined as a subperiosteal abscess of the frontal bone that appears as a localized swelling of the forehead, associated with frontal osteomyelitis. It's a rare condition more frequently seen as a complication of frontal sinusitis.
Case Presentation Summary: A previously healthy 10-year-old male child, presented to the emergency room complaining of frontotemporal stabbing headache, associated with fever without flu-like symptoms, for two weeks. An edema appeared in the forehead region, and he had an isolated episode of generalized tonic-clonic seizure. Cranial CT scan showed left pansinusitis with extension of the infectious process into the bone (acute osteomyelitis) and signs of empyema, highlighting the hypothesis of PPT. The patient was evaluated by the neurosurgery and otorhinolaryngology teams, who performed a maxillary antrostomy and anteroposterior ethmoidectomy with drainage of the subdural empyema and frontal purulent collection. In addition,empiricalbroad-spectrum antibiotic therapy, with vancomycin (60), ceftriaxone (100) and metronidazole (30), was started. The results of blood and drained fluid culture were negative. The patient remained hospitalized for twenty-one days for intravenous antibiotic therapy, maintaining nasal lavage with high volume and low pressure, followed by a 6-week course of oral amoxicillin-clavulanate. He evolved with progressive clinical and laboratory improvement.
Learning Points/Discussion: PPT is a rare condition that predominantly occurs in previously healthy children and adolescents, being more frequent as a complication of undiagnosed or inadequately treated frontal sinusitis. The diagnosis is made on the basis of a clinical history, physical examination and imaging. Early diagnosis and treatment with intravenous broad-spectrum antibiotics and surgical drainage are of paramount importance to avoid complications and reduce morbidity and mortality.

Title of Case: A rare case of disseminated cat scratch disease in an immunocompetent teenager presenting with hepatosplenic abscesses, vertebral osteomyelitis-paraspinal abscess and autoimmune thyroiditis
Background: Cat scratch disease has a wide spectrum of presentation. It can be accompanied by vertebral osteomyelitis which is a rare clinical manifestation and autoimmune thyroiditis, which, however, is extremely rare.
Case Presentation Summary: An 11-year-old girl was admitted with a two week history of fever, a cervical painful mass and a few days history of torticollis and upper back pain. On clinical examination, she had neck stiffness, pain upon palpation of upper thoracic vertebrae and a submandibular enlarged painful lymph node. Inflammatory markers were elevated. Ultrasound revealed splee and liver microabcesses and an impressive picture of enlarged, hypoechoic thyroid gland with increased vascularity. Thyroid function tests revealed autoimmune hypothyroidism. Medical history revealed that the child had frequent contacts and abrasions from kittens. Antibodies for bartonella henselae were positive. MRI of the spine revealed bone lessions in T4 vertebral body and a paraspinal soft tissue mass. With the diagnosis of disseminated cat scratch disease, our patient received oral doxycycline, rifampicin and iv gentamycin. Thyroxine was also started. Due to severe gastrointestinal symptoms doxycycline was discontinued on the 12th day and was replaced by ciprofloxacin. Gentamycin was administered IV for the first two weeks. Total duration of the antibiotic course was 6 weeks. The fever resolved within 2 days of initiation of antibiotic treatment and her backache completely disappeared within 10 days. Within 10 weeks, the anti-thyroid antibodies titer decreased significantly and thyroid ultrasound normalized.
Learning Points/Discussion: Cat-scratch disease can present with rare clinical manifestations as vertebral osteomyelitis and reversible autoimmune thyroiditis. The latter is extremely rare with only two cases reported in the literature.

Backgrounds: Introduction Peritoneal tuberculosis is a rare presentation of tuberculosis, especially for children with no debilitating disease. The diagnosis is usually difficult, unsuspected, and often delayed, especially in the pediatric patient, who frequently presents with nonspecific and insidious symptoms. Aim: To evaluate the contribution of laparoscopy in the positive diagnosis of peritoneal tuberculosis
Methods: Medical records of children who underwent laparoscopic approach for peritoneal tuberculosis between 2013 and 2021 were retrospectively reviewed
Results: Results Five patients (4 boys, and 1 girl) with a mean age of 5.5 years (1 year 8 months - 10 years) were diagnosed with peritoneal tuberculosis. All patients presented with abdominal pain. Fever was found in 80% of the patients. No cases of coexisting pleural efusionof pulmonary tuberculosis were found. The mean duration from symptoms to diagnosis was 19 days (15 days-1 month). CT scan showed ascites (5 cases), mesenteric lymph nodes (3 cases), and thickening of the peritoneum and mesentery (4 cases). In all cases a laparoscopy was performed and showed that whitish tuberculosis was the most common appearance. Adhesions were also seen in one case. Peritoneal biopsy was performed and the diagnosis of peritoneal tuberculosis was confirmed histopathologically in all the cases. Four patients completed the antituberculous therapy without complications and death occurred in one case.
Conclusions/Learning Points: Conclusion Laparoscopy with peritoneal biopsy is safe, feasible, and effective in the diagnosis of peritoneal tuberculosis in children.

Backgrounds: Introduction: A urinary tract infection (UTI) is a symptom of underlying urinary tract abnormalities that may be related to urolithiasis. Aim: The aim of this study was to determine the incidence and pattern of UTI in children with urolithiasis and urinary tract malformations.
Methods: We retrospectively reviewed the medical records of children (18 years old) with urolithiasis associated with urinary tract abnormalities.
Results: Results 36 patients (16 boys and 20 girls) of a mean age of 7 years (5 months–18 years) were diagnosed with urolithiasis and associated urinary tract abnormalities. UTI was the most common presentation in 21 patients (58.3%). It was repeated in more than two episodes in 53.7% of cases. The most common presentations were fever (83%) and dysuria (48%). The two most common causative agents were E. coli (78%) and Proteus (14%). Urinary tract abnormalities were primary obstructive megaureter in 15 (41.6%), pelvic ureteric junction obstruction in 13 (36.1%), primary vesicoureteral reflux in 6 (16.6%), and ureterocele in 2 cases. All patients underwent surgical treatment for their urinary abnormalities. Stones were analyzed by infrared spectroscopy. Struvite stones were found in 33.4% of cases. The incidence of postoperative UTI was 2.7%.
Conclusions/Learning Points: Conclusion UTI is found in 58.3% of children who have urinary tract abnormalities and associated urolithiasis. In those patients, untreated UTI and concurrent urinary obstruction may contribute to calculus formation. The treatment of underlying urinary tract abnormalities is essential for the regression of postoperative urinary tract infections, thus protecting the renal function.

RISK FACTORS FOR RENAL SCARRING IN CHILDREN WITH PRIMARY VESICOURETERAL REFLUX DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Taycir Cheikrouhou[1], Mahdi Ben Dhaou[1], Amal Elleuch[2], Mohamed Zouari[1], Khaoula Mekki[3], Manar Hbaieb[1], Hayet Zitouni[1], Riadh Mhiri[1]
[1]faculty of medecine of sfax, Pediatric Surgery Departement Hedi Chaker Hospital Sfax Tunisia, SFAX, Tunisia, [2]Faculty of Medicine of sfax Tunisia, Pediatric Emergency And Resuscitation Service Department; University Hospital Hedi Chaker, SFAX, Tunisia, [3]Faculty of medecine of sfax, Pediatric Emergency And Resuscitation Service Hospital Hedi Chaker Sfax, SFAX, Tunisia

Backgrounds: Background and aim Primary vesicoureteral reflux (VUR) may result in renal scarring and nephropathy due to reflux of the infected urine to the upper tract. At the time of diagnosis, 30-49% of children with VUR were reported to have renal parenchymal scarring at DMSA scans. The aim of this study was to determine the risk factors for development of renal scarring in patients with primary VUR.
Methods: Charts of patients with VUR operated in the department of pediatric surgery 2010 to 2020 were reviewed. Micturating cystourethrogram (VCUG) was performed to evaluate and graduate VUR using the International Reflux Study Committee grading system (IRSCGS): Grades from I to V. Renal scarring was assessed by DMSA performed minimally six months after the treatment of urinary tract infection (UTI).
Results: 56 children were included (the mean age was 2.21 years). The Sex ratio was 1.15. Grade I, II, III, IV, and V was found in 2(3.57%), 12(21.42%), 19(33.92%), 16 (28.57%), and 7(12.52%) children, respectively. Unilateral VUR was observed in 33 children (58.92%). Renal scars are present in 78.56% of patients. Renal scarring was not significantly different between the different reflux sites (P >0.05). The risk factors in the development of renal scars were: Male gender (p= 0.007), antenatal hydronephrosis (p= 0.005), and the number of UTI episodes (≥3) (p=0.041).
Conclusions/Learning Points: Conclusion: Considering that the higher rate of renal scarring may be attributed to delayed diagnosis of VUR and ineffective treatment of previous UTI episodes, the presence of scars, once detected, should alert the physician for UTI recurrence prevention in order to avoid progressive injury to the renal parenchyma and deterioration of function.

THE MANAGEMENT OF PARAPNEUMONIC PLEURAL EFFUSION IN CHILDREN: UNICENTRIC STUDY.

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Taycir Cheikrouhou[1], Mahdi Ben Dhaou[1], Amal Elleuch[2], Mohamed Zouari[1], Khaoula Mekki[3], Manar Hbaieb[1], Hayet Zitouni[1], Riadh Mhiri[1]
[1]faculty of medecine of sfax, Pediatric Surgery Departement Hedi Chaker Hospital Sfax Tunisia, SFAX, Tunisia, [2]Faculty of Medicine of sfax Tunisia, Pediatric Emergency And Resuscitation Service Department; University Hospital Hedi Chaker, SFAX, Tunisia, [3]Faculty of medecine of sfax, Pediatric Emergency And Resuscitation Service Hospital Hedi Chaker Sfax, SFAX, Tunisia

Backgrounds: Background: The management of parapneumonic pleural effusion is still a matter of controversy between surgical and non-surgical options. Therapeutic options include antibiotics, thoracentesis, thoracostomy tube drainage, fibrinolysis, video-assisted thoracoscopic surgery (VATS), and thoracotomy (2). Aim: To evaluate the clinical characteristics and pathological features of parapneumonic pleural effusion in children and to explore the feasibility and safety of thoracoscopic approach.
Methods: Medical records of children with parapneumonic effusion from 2007 to 2020 were retrospectively reviewed.
Results: Totally, 35 patients with a mean age of 5.14 ± 3.9 years were diagnosed with parapneumonic pleural effusion. All children were hospitalized in a Pediatric Continuing Care Unit. Antibiotic therapy was administrated in combination in all cases. Corticosteroid therapy was used in 2 patients. Thoracentesis was performed in 6 patients. Thoracostomy tube drainage were placed before surgery in 11 patients. In all cases, a thoracoscopic approach was performed with an average duration of drainage before VATS was 6 days ±4. VATS decortication and/or debridement was indicated as second-line in 23 patients. The average duration of the surgery was 51 minutes (20 min-115 min). There is no conversion to open surgery and no intraoperative procedure-dependent complication. There were 4 children who have early complications after the VATS and one patient had a late postoperative complication. There were no deaths during the hospital stay or during follow-up.
Conclusions/Learning Points: Conclusion: VATS is safe, feasible, and effective in the management of parapneumonic pleural effusion in children with excellent outcomes. Further large studies are required to confirm these findings.

SCHISTOSOMIASIS IN MIGRANT CHILDREN: DIAGNOSIS AND LONG-TERM MANAGEMENT CHALLENGES

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Isabel Mellado Sola[1], Paula Rodriguez Molino[2], Carlos Grasa[3], Lucía Escolano[4], Blanca Bravo Queipo De Llano[5], Jorge Bustamante[3], Iker Falces Romero[6], Milagros García López-Hortelano[2], Talia Sainz[6]
[1]Hospital Universitario La Paz, Pediatrics, Madrid, Spain, [2]Hospital Universitario La Paz, Paediatrics, Madrid, Spain, [3]Hospital Universitario la Paz, Pediatric Infectious Diseases, Madrid, Spain, [4]HOSPITAL UNIVERSITARIO LA PAZ, PediatrÍa, MADRID, Spain, [5]Hospital Universitario La Paz, Paediatric Infectious And Tropical Diseases Department, Madrid, Spain, [6]Hospital Universitario La Paz and La Paz Hospital Research Institute (IdiPAZ). CIBERIFNEC. RITIP. Universidad Autonoma de Madrid, Paediatric Infectious Diseases, Madrid, Spain

Backgrounds: Schistosomiasis is a parasitosis included among the tropical neglected diseases by the WHO. It is caused by a blood trematode, acquired through contact with contaminated fresh water via skin penetration. This study aims to describe our experience in the diagnosis, management and long-term follow-up of migrant children diagnosed with Schistosomiasis.
Methods: A retrospective, observational study in a National Reference Unit in Madrid, Spain, attending patients referred for the screening of imported diseases. Patients below 18 years of age and diagnosed with schistosomiasis from January 2014 to July 2021 and follow-up visits up to May 2022 were included.
Results: Seventy-seven children were included. Most were male adolescents from Sub-Saharan Africa and Asia, with a median age of 16,3 years (IQR 9 – 17,5), mainly unaccompanied migrants or internationally adopted children. 60.3% were asymptomatic. 28.8% were screened due to peripheral eosinophilia. All presented with positive serology. Parasitological urine analysis was performed in 52 patients and ova were visualized in only 2 cases (3.8%). All received praziquantel 40-60 mg/kg/day for 1-2 days, 25.4% requiring several cycles. Serological test for Schistosoma persisted positive in 82.8% and 65% in the first and follow-up visits, respectively . However, a progressive decline in ELISA optical density, total IgE and peripheral eosinophil count was identified.
Conclusions/Learning Points: This study describes a large series of children diagnosed with schistosomiasis in Europe and the longitudinal follow up. Schistosomiasis is frequently asymptomatic in children and the absence of eosinophilia does not rule out the disease. Our results suggest that schistosomiasis' serology is useful for the screening of children recently arrived from endemic areas, specially from Sub-Saharan Africa and Asia. Eosinophilia, total IgE and ELISA optical density may be useful to monitor treatment response during follow-up visits.

STIS IN UNACCOMPANIED MIGRANT MINORS: TO SCREEN OR NOT TO SCREEN.

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Isabel Mellado Sola[1], Paula Rodriguez Molino[1], Carlos Grasa[1], Jara Hurtado-Gallego[1,2], Sonia Alcolea[2], Blanca Bravo Queipo De Llano[3], Lucía Escolano[4], Iker Falces Romero[5], Milagros García López-Hortelano[1], Talia Sainz[1]
[1]Hospital Universitario La Paz, Pediatrics, Madrid, Spain, [2]Hospital Universitario La Paz, Paediatrics, Madrid, Spain, [3]Hospital Universitario La Paz, Paediatric Infectious And Tropical Diseases Department, Madrid, Spain, [4]HOSPITAL UNIVERSITARIO LA PAZ, PediatrÍa, MADRID, Spain, [5]Hospital Universitario La Paz and La Paz Hospital Research Institute (IdiPAZ). CIBERIFNEC. RITIP. Universidad Autonoma de Madrid, Paediatric Infectious Diseases, Madrid, Spain

Backgrounds: Sexually transmitted infections (STIs) are an increasing concern, especially among youths. Screening for STIs is key to prevent transmission and any contact with health care system might be an opportunity. Unaccompanied migrant minors (UMM) are a especially vulnerable population due to social determinants of health, language and cultural barriers. The inclusion of STIs screening in imported diseases' screening protocols is an opportunity for diagnosis and treatment.
Methods: Retrospective study including UMM screened for imported diseases at a pediatric reference unit for tropical and infectious diseases in Madrid, Spain (2020-2022). In 2020, collection of urine samples for STI screening was included in the protocol for the screening of imported diseases in adolescents. The multiple STIs-PCR included G. ureaplasma, C. trachomatis, M. genitalium, N. gonorroheae, T. vaginalis.
Results: Ninety-nine UMM were screened during the study period, with a mean age of 17.1 years (±0.8), all were male. The most common diagnosis was latent tuberculosis infection. Urine sample for PCR was obtained in 39/99 (39%) and resulted positive in one asymptomatic patient, with identification of C. trachomatis and M. genitalium. This patient referred unprotected sex in the initial anamnesis . Azitromycin was prescribed to treat C. trachomatis. Patient was lost to follow-up.
Conclusions/Learning Points: UMM first contact with the healthcare system is an opportunity for diagnosis and treatment in a vulnerable population with many barriers to care. We believe that opportunities should not be missed when it comes to screen STIs among adolescents. However, larger studies are needed to address the cost-effectiveness of the inclusion of STIs screening among UMM, a population with language and cultural barriers, and a vulnerable legal and social situation that challenge the management and limits follow-up.

RESPIRATORY TRACT DISEASES AND THE PERINATAL PERIOD

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Catarina Mendonça, Gonçalo Croca, Teresa Magalhães, Mariana Viegas, Bárbara Marques
Centro Hospitalar do Oeste, Caldas da Rainha, Pediatrics, Caldas da Rainha, Portugal

Backgrounds: Respiratory tract diseases(RTD) are one of the main causes of mortality and morbidity in children. Risk factors such as tobacco exposure, daycare and older siblings are well known. Nowadays, different studies have reported a correlation between other factors, such as type of birth(TB) and gestational age(GA), with the development of RTD. This study aims to demonstrate this correlation.
Methods: Retrospective/descriptive/analytical study of children admitted to the pediatric ward due to RTD in 2019 and 2022. Studied TB(vaginal delivery(VD), assisted vaginal delivery(AVD) or c-section(C)) and GA(preterm(PT), term(T) and post-term). Chi-square test was used and considered significant if $p<0.05$.
Results: A total of 362 children were included, ages between 9 days and 13 years. Were born by VD 43.8%, AVD 19.5% and C 31%; of these, 82.3% T and 12% PT. No correlation between TB/GA and the incidence or severity of the RTD was found. Nonetheless, a significant correlation was found for personal history of RTD such as wheezing/asthma. Chronic RTD are more common in preterm children (PT 45.7%, T 24.4%; $p< 0.002$) and in those born by c-section (VD21.4%, AVD26.7%, C35.3%; $p<0.034$). Bronchodilators are more frequently administered in children born by AVD(64%; $p<0.03$) and preterm(60.9%; $p<0.043$); corticotherapy is mainly administered in those born by AVD(48%; $p<0.025$).
Conclusions/Learning Points: Children born preterm and/or by AVD/c-section are at higher risk of developing long-term respiratory problems. A higher risk of more severe RTD was not possible to conclude. Preventive strategies aimed at protecting high-risk groups are essential.

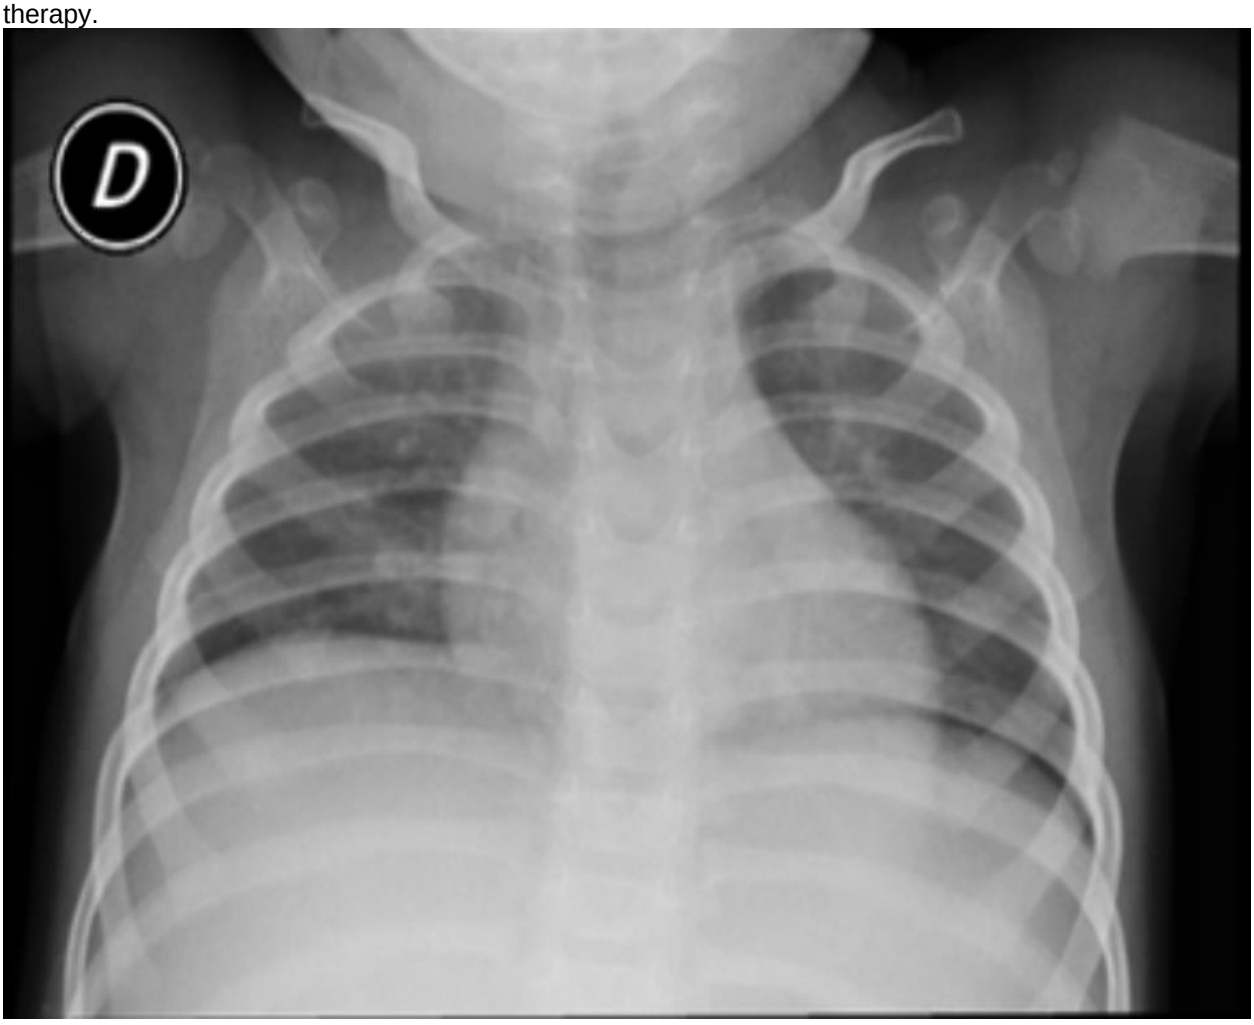
MELIOIDOSIS IN CHILDREN: DIFFERENT FACES OF THE SAME DISEASE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Laura Mendoza Rosado
OHI, Pediatrics, VALLEDUPAR, Colombia

Title of Case: Melioidosis in children: Different faces of the same disease
Background: Melioidosis is a disease caused by Burkholderia pseudomallei. It presents as a febrile illness, localized infection, or fulminant septicemia. Sporadic cases have been reported in Colombia. I report three cases in children without relevant past medical history reflecting the wide range of presentation.
Case Presentation Summary: Case#1. A 1-month-old boy presented with a history of 3-days fever and progressive respiratory symptoms. Acute bronchiolitis was suspected (Image 1) but blood culture was taken at admission because his age. Ceftazidime was started when microbiologists informed the growth of colonies suggestive to B. pseudomallei. The final report confirmed the isolation and antibiotic susceptibility. The patient continued improving, he completed 14 days and then switch to oral trimethoprim-sulfamethoxazole for eradication
therapy.



Case #2. A 3-year-old girl was admitted with acute fever and nonproductive cough, progressive

respiratory distress and finally ventilatory failure. A diagnose of complicated pneumonia (Image 2) was made and empiric antibiotics (ceftriaxone/Clindamycin) were started. She continued with septic appearance, multiorgan failure and died in 48 hours. Blood cultures were postmortem reported positive to B.
pseudomallei.

Case #3. Female Adolescent was hospitalized after several antibiotic courses without improvement due to a 5-weeks abscess located in herneck. A CT reported an organized abscess (Image 3). A percutaneous drainage was made and B. pseudomallei growth in culture. She received meropenem for 2 weeks and then switched to TMP/SMX with fully
recovery.

Learning Points/Discussion: Climate change has conditioned the emergence of certain pathogens in recent years as B. pseudomallei. It´s necessary a high suspicious level of this disease.

[1]Hospital Universitario Nuestra Señora de Candelaria, Paediatrics, Tenerife, Spain, [2]Complejo Hospitalario Universitario Insular Materno infantil, Paediatrics, Las Palmas de Gran Canaria, Spain, [3]Gerencia de Atención Primaria de Gran Canaria, Unidad Atención Al Menor Migrante-equipo De Intervención, Las Palmas de Gran Canaria, Spain, [4]Hospital Universitario Doctor Negrín de Gran Canaria, Microbiology, Las Palmas de Gran Canaria, Spain, [5]Complejo Hospitalario Universitario Insular Materno infantil, Microbiology, Las Palmas de Gran Canaria, Spain

Backgrounds: The number of surviving children arriving to Canary Islands from Africa in precarious boats (pateras) increased substantially over the last years. This has led to the implementation of analytical screening protocols adapted to this population, following the recommendations of the ECDC.
Methods: The objective of this descriptive retrospective observational study is to define the prevalence of HIV, hepatitis (A-C), syphilis, Strongyloides and Schistosoma spp infections in a sample of children under 18 years of age arriving from different African countries in ‘’patera’’ to Gran Canaria between January 2021 to October 2022. Analytical results collected in the electronic medical records were reviewed.
Results: 1977 blood samples were analyzed, 82.1% were male. 54.7% were Moroccans and 45,3% sub-Saharan Africans (SSA). Notably higher proportion of SSA population (almost 1/3) passed the infection naturally in comparison to Moroccans (p<0,001) and 51 patients presented a chronic form of HBV infection. 53,9% of the sample tested negative for anti-HBs, most of them Moroccans (62,86% vs 43,19%, p< 0,001). The global proportion of susceptible patients for HAV infection was 12%, majority Moroccan (71,3%). We identified 4 patients with HIV infection (all asymptomatic) and 6 with syphilis, none of them previously treated (83,3%, SSA). 1110 Strongyloides spp serologies were analyzed, 28 resulted positive (majority SSA, p= 0,002) out of which 57,6% presented eosinophilia. We observed statistically significant (p=0,004) association between relative eosinophilia (>5% eosinophils) and positive Strongyloides spp serology. Of the 768 urine samples analyzed in SSA, 88 (11,45%) revealed hematuria and in 32 of them (42%) S. haematobium eggs were found. In children diagnosed with Schistosomiasis, 95,8% had eosinophilia (p<0,001).
Conclusions/Learning Points: The implementation of analytical screening of African migrant children helps to detect potentially serious diseases in a highly vulnerable population.

THE ROLE OF PSEUDOMONAS AERUGINOSA IN CHILDREN WITH ACUTE APPENDICITIS; INCIDENCE, PREDICTORS, AND OUTCOMES

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Elias Nasrallah[1], Hussein Zaitoon[1], Marina Zeltser[2], Ran Steinberg[2], Ranaa Damouni Shalabi[1], Imad Kassis[1], Haleema Dabaja-Younis[1]
[1]Rambam Health Care Campus, Pediatric Infectious Disease Unit, Haifa, Israel, [2]Rambam Health Care Campus, Department Of Pediatric Surgery, Haifa, Israel

Backgrounds: Surgery and antibiotic treatment are the main treatment components for acute appendicitis. Some of the antibiotic regimens proposed for treatment may not cover Pseudomonas aeruginosa. The aim of this study is to determine the incidence, predictive factors and outcomes of Pseudomonas associated acute appendicitis in children.
Methods: A retrospective cohort study of children <18 years who presented with acute appendicitis, underwent surgery and had positive peritoneal cultures at a tertiary university hospital during 2007-2021. Patients with Pseudomonas isolated from peritoneal cultures were compared for predictors and outcomes with patients without Pseudomonas.
Results: Acute appendicitis with positive peritoneal cultures was documented in 338 patients, 77(22.8%) were positive for Pseudomonas, of whom 66(85.7%) were treated with anti-pseudomonas treatment on admission. Patients <5 years were more likely to have Pseudomonas than older patients (33.3% vs. 20.6%, p=0.032, OR=1.939, 95%CI:1.053-3.57). Pseudomonas was more prevalent in patients with polymicrobial compared to monomicrobial peritoneal cultures (29.6% vs. 8.3%, p<0.001, OR=4.617, 95%CI:2.206-9.666). Neither high intraoperative grading nor duration of symptoms were associated with prediction of Pseudomonas in peritoneal cultures (p=0.827 and 0.764 respectively). Patients with Pseudomonas had a longer median length of stay 8 days (IQR:7-10) compared to 7 days (IQR:5-9) in patients without Pseudomonas(p=0.004). However, median length of antibiotic treatment (p=0.893), admission to intensive care unit (p=0.197), readmission (p=0.760) and 30-day mortality (p=0.761) were similar.
Conclusions/Learning Points: Pseudomonas was found in high percentage of peritoneal cultures in pediatric acute appendicitis. Polymicrobial cultures and young age are predictors for Pseudomonas isolation. Empiric antibiotic regimens including anti-pseudomonal coverage should be highly considered in acute appendicitis in pedaitric

patients.

Backgrounds: Acute meningitis is a rapidly progressive disease caused by the inflammation of the tissues surrounding the brain and spinal cord. Incidence of the disease has been decreasing over the years, but it still remains a concern for state and public health institutions.
Methods: In this retrospective study, we enrolled 60 children diagnosed and hospitalized with acute meningitis in Pediatric Infectious Disease Service, for the period 2017-2019.
Results: The percentage of cases hospitalized with acute meningitis, compared to all children hospitalized in our service in the same time period, was 1.07% in 2017, 0.62% in 2018 and 0.92% in 2019. According to the causing agent, bacterial ones were found to be more frequent with 61.67% of cases. According to gender predominate males with 56.67% of cases.The average age is 4,7 years old. According to living area predominate urban area. According the sesonality, it is observed that the peak of cases are presented in the beginning of summer and in the last two months of winter. Clinical signs based on frequency are: drowsiness in 75% of cases, nuchal rigidity in 73.33%, vomiting in 68.33% , headache in 48.33% and 25% agitation. 7 children presented seizures, 7 photophobia, 6 children ataxia and 5 children had bombed fontanels. 23.3% developed complications during the disease with sepsis in 13.33% of cases, venous sinus thrombosis in 3.33% of cases and hemiparesis in 6.67% of cases. The average hospitalization days was 13.8 days
Conclusions/Learning Points: Great importance should be given to the prevention of acute meningitis, and when prevention fails, a diagnosis should be made as soon as possible and treatment should be started immediately to reduce the likelihood of long-term complications

ANGINA LUDWIG

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Ergena Neziri[1], Laureta Sadedini[1], Mirzana Kapllanaj[2], Georgina Kuli-Lito[3], Greta Haxhi[1], Perparim Shira[1], Albert Lama[1], Marsida Kurti[4], Numila Kuneshka[1]
[1]Mother Teresa University Hospital Center, Albania, Pediatric Emergency Department, tirana, Albania, [2]Mother Teresa University Hospital Center, Albania, Pediatric Onco-hematology Department, tirana, Albania, [3]Mother Teresa University Hospital Center, Albania, Pediatric Infection Disease Department, tirana, Albania, [4]Mother Teresa University Hospital Center, Albania, Pediatric Resident, tirana, Albania

Title of Case: ANGINA LUDWIG
Background: Angina Ludwig is an infection of odontogenic origin,with a rapidly progression affecting the soft tissues of the submandibular,sublingual and submental area.It can cause even the obstruction of the upper airways.
Case Presentation Summary:

5 years old boy presented to the ED with history of fever 39-40 from 4 days,swelling of the submandibular,sublingual and submental regions in 12 hours,trismus,dysphagia,odynophagia,sialorrhea,halitosis,impetigo in perioral region The boy was pale and nourished.High temperature 39.5.In the submandibular region was noted a large bilateral swelling with pain in palpation, redness,difficulties and reduction in opening the mouth,keilitis.His parents refered that the boy has done extraction of the bilateral molar and premolar teeth of the mandibula.Laboratoric findings:WBC 26.7 x 10^3 neutrofil 89%,PCR 45 mg/dl,ERS 35mm/h.Swab of the pus :mixed flora anaerob and aerob(streptococcus,staphylococcus aureus,epidermis,viridans) Neck ultrasound:inflamatory swelling of the subcutan connective tissues,increase vascularization,bilateral submandibular,sublingual limfonodules that suggested for celulits. Neck CT:through both the axial/coronal cuts was noted differentation of the density of soft tissues,likid in the submandibular region, inflammation of the deep

fascial tissues,swelling of the root of the tongue causing upper airways obstruction Treatment:Ceftriaxon 2x 1gr,Clindamicyn 3x 300mg,Metronidazol 3x 210mg.Imediately after the hospitalization he presented stridor,dyspnea and compromentation of the vital parameters SpO2 89-90%.In this condition he was transfered to the PICU,where is done the tracheostomy and the drainage for the decompression of the fascial spaces involved and the evacuation of the suppuration

Learning Points/Discussion: Fast evolution and aggressive power of dissemination assumes character of emergence treatment with an effective drug coverage and early surgical intervention to prevent the swelling of the fascial tissues and the obstruction of the upper airwayse obstruction of the upper airways.It is important the correct identification of the diagnosis based on careful clinical and complementary examination

FEBRILE SEIZURE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Ergena Neziri[1], Laureta Sadedini[1], Georgina Kuli-Lito[2], Mirzana Kapllanaj[3], Floreta Kurumi[1], Greta Haxhi[1], Marsida Kurti[4], Esmeralda Cuni[4], Numila Kuneshka[1]
[1]Mother Teresa University Hospital Center, Albania, Pediatric Emergency Department, tirana, Albania, [2]Mother Teresa University Hospital Center, Albania, Pediatric Infection Disease Department, tirana, Albania, [3]Mother Teresa University Hospital Center, Albania, Pediatric Onco-hematologic Department, tirana, Albania, [4]Mother Teresa University Hospital Center, Albania, Pediatric Resident, tirana, Albania

Backgrounds: Febrile Seizure are the most common neurological disordes in childhood,very similar to epileptic seizure and more manifested between 5 months -6 years old,especially during infection that do not affect central nervous system.Common factors that influence the first seizure are high fever positive familiar history,febrile seizure in the first and second family generation,delayed psychomotor development,perinatal disease
Methods: Aim of this study is to show the epidemiology of febrile seizure,to analyze the risk factors at the first febrile seizure.We conducted an retrospective study,involving all children with febrile seizure presented to Emergency Department at Tepelena Hospital from 1 January 2021-1 June 2022.Demographic and clinical data were collected,age,gender,time of the first,second,third or more episode,the duration of the attack and the presence of any of the risk factors during the seizure
Results: 120 children from 6 months age–5 years old were collected.72% had only one episode of febrile seizure,16%with two attacks,9%with three attacks,3%with four or more attacks.The age-group most affected 5m-2y 80%,followed by the age group 2y-4y 12% and the age group 4y-6y 8%.Both risk factors were present 35% of cases,55% of cases had only one risk factors mentioned 45% only high fever and 10% positive familiar history,10% had none of the two risk factors mentioned.79% male and 21% female.Average body temperature at the moment of the episode was 38.5.The peak of febrile seizure was during December- April,during winter season.The most common cause were upper and lower respiratory tract infection
Conclusions/Learning Points: Febrile seizures are common childhood illnesses and the great majority resolve spontaneously.They are result of the interplay of genetic and environmental factors,including viral infections.Although benign and requiring minimal management,the prevalence of febrile seizures and the possibility of long-term sequelae make them clinically important presentations in children.

Backgrounds: Acute OM is defined as an infection of the middle ear with acute onset,along with presence of effusion and signs of middle-ear inflammation,such as otalgia and distinct erythema of the tympanic membrane.The presence of middle-ear inflammation can be indicated by any of the following: bulging of the TM,limited or absent mobility of the TM with pneumatic otoscopy,air-fluid level behind the TM,or otorrhea.
Methods: Aim of the study was to show epidemiology of AOM,to analyze the risk factors,management and recurrence.We conducted an retrospective study, involving all children with AOM presented to ED Claud Bernard Hospital from 1 January 2022-31 December 2022.Demographic and clinical data were collected.Diagnosis of AOM meets all 3 following criteria:rapid onset,signs of MEE and signs and symptoms of middle-ear inflammation
Results: 420 children from 6 months age – 5 years old were collected.The age-group most affected 5m-2y(75%),followed by 2y-4y(20%) and the age group 4y-6y (5%).Peak incidence between ages 6 and 11 months.60% otalgia, 25%otalgia and temperature 39°C,15% only temperature at or above 39.5°C. 45% were OMA non-suppurative,35% OMA suppurative,20% OMA Recurrent.The pathogens most frequently associated with AOM are S.Pneumoniae 50%,H.influenzae 25%,M.Catarrhalis 15%,and group A streptococci 10%.The peak of AOM was during December- April, during winter season.60% are spontaneous resolved,40% treated with pain-killer and antibacterial agent
Conclusions/Learning Points: The natural course of acute otitis media is spontaneous resolution.However,the clinician must be aware of the potential complications of acute otitis media and bear in mind that if left untreated,it may rapidly progress with potentially life-threatening consequences.Recurrent episodes of otitis media may be prevented by applying environmental control measures such as decreased exposure to child care centers and secondhand smoking,and the use of prophylaxis antibiotics.Vaccines are known to be effective in preventing acute otitis media.

IS THE INCIDENCE OF INVASIVE STREPTOCOCCUS PYOGENES INFECTION INCREASING?

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Eider Oñate[1], Mikel Mata[1], Nora Catarineu[1], Miriam Alkorta[2], Maria Gomariz[2], Laura Sole[1], Ander Ceña[1]
[1]Donostia University Hospital, Paediatric Intensive Care Unit, Donostia/San Sebastián, Spain, [2]Donostia University Hospital, Microbiology, San Sebastián, Spain

Title of Case: INVASIVE STREPTOCOCCUS PYOGENES INFECTION
Background: Several European countries such as the UK, has detected an unusual increase in Streptococcus pyogenes invasive(ISP) infectios in children during the autumn and winter of 2022, perhaps related to the increased circulation of respiratory-viruses. Observational and retrospective study carried-out by reviewing computerized medical records of patients<14years-old with a diagnosis of ISP who required admission to the PICU from March- 2022 to March-2023. Demographic data, type of infection,risk factors,clinical presentation,tratment,microbiological data , hospital-stay and evolution were collected.
Case Presentation Summary: A total of 5 cases were collected(4.8/100,000 children/year), representing 2% of admissions to the PICU during this year; The median-age was 60 months (range1-108 months) and most were woman 3/5(60%). None of them presented previous risk-factors. 4 out of 5(80%) patients presented fever as a major sympton, poor general condition, and soft tissue infection (myositis,fascitis necrotizing and cellulitis). The last-one had progressive decreased cervical mobility and odynophagia due to retropharyngeal and mediastinal abscess. 4 out of 5(80%) children required respiratory support with intubation and mechanical ventilation, and 100% required hemodynamic support with inotropics. In 100% cases, SP was isolated in at least one sterile sample. At admission antibiotic-therapy was started with intravenous cefotaxime adding clindamycin when ISP was suspected. Surgery was required in 2 cases(40%). The medium hospital-stay was 8.3±4.72 days although one patient remains hospitalized. One patient presented sequels and none patient died.
Learning Points/Discussion: ISP has been a rare but serious reason for PICU admission. Skin and soft tissue oinfections together with septic shock were the most comon forms of ID. The mortality of our sample was cero despite the serious clinical manifestations.The ongoing supposed increase, combined with the severity warrants awareness among pediatricians, other clinicians, public health and parents.

MEDICAL ONLINE EDUCATION SIGNIFICANTLY IMPROVES PHYSICIAN KNOWLEDGE REGARDING THE IMPACT OF THE COVID-19 PANDEMIC ON MENINGOCOCCAL DISEASE AND VACCINE UPTAKE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Julia Duffey[1], Thomas O'Neil[2], Shanti Voorn[2], Saul Faust[3], George Kassianos[4]
[1]WebMD Global LLC, Clinical Strategy, Matlock, United Kingdom, [2]WebMD Global LLC, Clinical Strategy, New York, United States of America, [3]University Hospital Southampton NHS Foundation Trust and the University of Southampton, Pediatrics, southhampton, United Kingdom, [4]Royal College of General Practitioners, National Immunization Lead, London, United Kingdom

Backgrounds: Systemic infection with Neisseria meningitidis can rapidly lead to a serious, life-threatening disease or result in long-term sequelae.[1] The COVID-19 pandemic and containment measures was associated with decreasing incidence and burden of meningococcal disease. However, meningitis vaccine uptake also declined and has not yet returned to pre-COVID-19 levels. As physicians play a critical role in vaccine recommendation and uptake, we assessed whether an online independent medical education activity could improve the knowledge of Paediatricians and Public Health & Preventive Medicine Specialist (PHPMS) on the impact that the pandemic had on meningococcal disease and vaccine uptake
Methods: Educational effect was assessed using a repeated-pairs design with pre-/post-assessment. Three multiple choice questions assessed knowledge, and one question assessed confidence. Statistical tests to assess significance included: Paired samples t-test for overall average number of correct responses and confidence. McNemar's test for individual questions and learning objectives (P <.05). Cohen's d estimated the effect size impact on number of correct responses (<.20 modest, .20-.49 small, .59-.79 moderate, ≥.80 large). Data were collected from 7/26/2022 to 10/14/2022.
Results: From a total audience of 764 physicians, 149 were assessment completers. Overall, there was a significant increase (P<0.0001 for both specialities) with a large impact (paediatricians 0.80; PHPMS 1.1) in paediatrician and PHPMS knowledge gains. Both specialties reported an increase in confidence (paediatrician 66%; PHPMS 69%) with a total average confidence shift of 83% (paediatricians) and 114% (PHPMS), regarding the impact that the COVID-19 pandemic on meningococcal disease and vaccine uptake. Furthermore, both specialties had highly significant knowledge gains concerning carriage rates of Neisseria meningitidis (P <.001).
Conclusions/Learning Points: Online medical education significantly improved physician knowledge and confidence regarding epidemiology of meningococcal disease and vaccine uptake in the current COVID-19 era.

A CASE OF PULMONARY ASPERGILLOSIS IN A PATIENT WITH SOLID ORGAN TUMOR

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Yasemin Ersözlü[1], Cengiz Canpolat[2], Metehan Ozen[3]
[1]Acibadem University, Department Of Pediatric Infectious Diseases, Maltepe, Turkey, [2]Acibadem University, Pediatric Hematology Oncology, istanbul, Turkey, [3]Acibadem University, Department Of Pediatric Infectious Diseases, İstanbul, Turkey

Title of Case: A Case of Pulmonary Aspergillosis in a Patient with Solid Organ Tumor
Background: Invasive fungal infections originating from Aspergillus are an important cause of mortality and morbidity, especially in immunocompromised individuals such as cancer and transplant patients.
Case Presentation Summary: A 6.5-year-old girl with the diagnosis of medulloblastoma was hospitalized with febrile neutropenia at the 6th month of her treatment. On the 3rd day of the follow-up, her fever regressed, and on the 12th day, acute phase reactant elevation, abdominal pain and distension developed.Abdominal pathology was not detected in the abdominal tomography, but pneumonic infiltration and pleural effusion on the right were detected in the image area. The patient's treatment was gradually expanded upon the fever whose severe neutropenia continued.Voriconazole and amphotericin B were added to treatment because galactomannan and glucan were positive. Repeated lung imaging of the patient with increased galactomannan values was found to be compatible with pulmonary aspergillosis. No aspergillus focus was observed in the cranial imaging.The patient was evaluated in the Pediatric Chest Diseases department, while the follow-up was continued with oral voriconazole. No lesions were detected in bronchoscopy. Follow-up with oral voriconazole continues.
Learning Points/Discussion: Patients with hematological malignancies and bone marrow/solid organ transplant recipients are at risk for invasive pulmonary aspergillosis. In a retrospective single-center study, mortality was found to be 55% in pediatric hemato-oncology patients.When the incidence of underlying disease was examined in a single-center study, the highest recurrent acute myeloid leukemia (28%) and recurrent acute lymphoblastic leukemia (9%) were found in pediatric patients. Invasive aspergillus infection is not expected in our case, since there is no hematological malignancy, no bone marrow/organ transplantation.Pulmonary aspergillosis treatment was started before the disease progressed, response was seen with the increase in neutrophil count.

PV1176 / #443

EPIDEMIOLOGY AND CLINICAL CHARACTERISTICS OF NON-TYPHOID SALMONELLA BACTEREMIA IN KOREA

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Kyo Jin Jo, Sangjun Sohn, Yeoun Joo Lee, Su Eun Park
Pusan National University Children's Hospital, Pediatrics, Yangsan, Korea, Republic of

Backgrounds: We aimed to describe the epidemiology and clinical characteristics of non-typhoid Salmonella (NTS) bacteremia in Korean children and adults.
Methods: We retrospectively reviewed the medical records of children who were defined as the isolation of NTS from blood cultures in Pusan National University Yangsan Hospital during December 2008 to November 2022.
Results: Overall, 45 patients (17 children and 28 adults) were enrolled. The median age 2 years (range 0-12) and 12 (70.6%) patients were male in children, and the median age 65.5 years (range 31-81) and 20 (71.4%) patients were male in adults. The most common serogroup was serogroup D (47.1%) in children, and serogroup B (39.3%) in adult. The underling diseases were identified in 2 (11.8%) children and 23 (82.1%) adults (P<0.001). All children manifested with fever, but 11 (39.3%) adults manifested with fever (P<0.001). 13 (76.5%) children and 19 (67.9%) adults manifested with symptoms of acute gastroenteritis (P=0.780). Antibiotic susceptibility tests were performed in 14 children and 26 adults. In children, 11 (78.6%) patients were susceptible to ampicillin, 12 (85.7%) to ceftazidime, 12 (85.7%) to ciprofloxacin, 12 (85.7%) to cefotaxime, and 14 (100%) to trimethoprim/sulfamethoxazole (TMP/SMX). In adults, 15 (57.7%) patients were susceptible to ampicillin, 25 (96.2%) to ceftazidime, 22 (84.6%) to ciprofloxacin, 24 (92.3%) to cefotaxime, and 24 (92.3%) to TMP/SMX. There are two adults and two children who were resistant to both ampicillin and cefotaxime. There was no multi-drug resistance. Children were mainly treated with cefotaxime, and adults were mainly treated with cefotaxime or ciprofloxacin. The 30-day mortality rate was 0%.
Conclusions/Learning Points: Most NTS bacteremia have the presenting symptoms of gastroenteritis, and difference in presence of fever between children and adults. Antimicrobial resistance and mortality were low.

Backgrounds: Invasive Pneumococcal Disease(IPD) causes high mortality in children under 5 years. Colombia started administering PCV10 in 2012 and changed to PCV13 in July 2022. Neumocolombia network monitors IPD in pediatric patients throughout the country.
Methods: Case series study in deceased pediatric patients with IPD admitted to 10 hospitals of Bogotá, and 4 hospitals of Cali, 2 of Medellín and 1 of Cartagena in 2017-2022(preliminary data).
Results: 344 cases of IPD, 44(12.7%) deceased. Median age was 19 months (IQR 5 - 35); 29(66%) were younger than 24 months. The average hospital stay was 9.5 days; 43(98%) were admitted to the ICU. 22 cases (50%) presented pneumonia, 8(18%) primary bacteremia, 11(25%) meningitis and 3(6.8%) pneumonia plus meningitis. Case fatality rate was 10,6%(22/207) for pneumonia, 29.7%(11/37) for meningitis, 10.8%(8/74) for bacteremia, 60%(3/5) for meningitis plus pneumonia and 0% for other diagnosis IPD (0/21). 25 isolates(57%) were serotyped, the most frequent serotype was 19A, followed by 23B and 14 (48%, 16% and 8%, respectively), the case fatality rate by serotype were: serotype 10B,15B and 24 F 50%(1/2), serotype 23B 44%(4/9), serotype 8 33%(1/3), serotype 14 20%(2/10), serotype 16 20%(1/5),serotype 6A 12,5%(1/8), serotype 19A 12.1%(12/99) and serotype 3 5,8% (1/17). 15 cases(34%) had decreased susceptibility to penicillin.
Conclusions/Learning Points: Lethality from IPD is higher in children under two years. The highest lethality was found in patients with meningitis plus pneumonia, and the most frequent serotype was 19A and the most lethal serotype were 10B, 15B and 24F. Permanent monitoring of mortality by IPD after the implementation of mass vaccination with PCV is necessary.

CLINICAL AND ETIOLOGICAL PROFILE OF LIVER ABSCESS IN CHILDREN WITH SPECIAL REFERENCE TO THE OUTCOME

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Monali Rasal
Seth G S Medical College and K E M Hospital, Pediatrics, Mumbai, India

Title of Case: CLINICAL AND ETIOLOGICAL PROFILE OF LIVER ABSCESS IN CHILDREN WITH SPECIAL REFERENCE TO THE OUTCOME

Background: In developing countries liver abscess is still major cause of morbidity and no specific predisposing factors have identified. Despite of much known about etiopathogenesis, the gold standard treatment is debatable. Judicious use of different modalities of treatment is important. We aimed to study clinical and epidemiological characteristics with risk factor, microbiological etiology with special reference to outcome and its determinants in patients with liver abscess.

Case Presentation Summary: The mean age of presentation was 5.4 years with M: F ratio of 1:1. Fever was the most common presenting symptom found in 95% patients and hepatomegaly was present in 87.5%. 97.5% patients had anemia, 82.5% had leukocytosis.65% patients were underweight. 80% had single liver abscess and 20% had multiple liver abscesses, with 62.5 % had in right lobe. Blood culture was positive in 7.5% patients with growth of E.coli, Acinetobacter and Gram positive cocci and Pus culture was positive in 10% cases showing Methicillin sensitive staphylococcus aureus in two cases, Klebsiella pneumoniae in one case, E.coli and Staphylococcus aureus both in fourth case. The patients who were managed medically alone had mean duration of symptoms of 15.27 days and mean abscess size of 81.96 cc and those who required surgical intervention had mean duration of symptoms of 11.14 days and mean abscess size of 132.29 cc. 65% patients were managed medically alone and 35% patients underwent surgical intervention. Overall prognosis of liver abscess was better with 97.5 % recovery rate.

Learning Points/Discussion: Identification of children with larger liver abscess and choice of appropriate modality of treatment can have better prognosis and can reduce the morbidity.

ATYPICAL CASE OF MILLER-FISHER SYNDROME IN A YOUNG MALE PATIENT – CLINICAL CASE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Carolina Roldão[1], Marta Costa Cardoso[2], Joana Matos Silva[2]
[1]USF Araceti, Aces Baixo Mondego, Coimbra, Portugal, [2]USF Araceti, Aces Baixo Mondego, coimbra, Portugal

Title of Case: ATYPICAL CASE OF MILLER-FISHER SYNDROME IN A YOUNG MALE PATIENT – CLINICAL CASE
Background: Although typically associated with the triad ataxia, ophthalmoplegia and areflexia, an acute inflammatory demyelinating disease in children such as Miller-Fisher syndrome, may present with other symptoms, being confused with common infectious diseases. This clinical case is intended to draw attention to the importance of thinking about other diagnostic hypotheses and guide research accordingly.
Case Presentation Summary: 5-year-old boy already in study for a neurodevelopmental impairment (manipulation, social interaction and cognition), was brought to the emergency department with gait imbalance and frequent falls with 3 weeks evolution. No infectious context, fever, trauma, headache, drowsiness, gastrointestinal or genitourinary symptoms. On examination he showed a limping gait, worse on the right, slight shortening of the right lower limb, weakness of the pelvic muscles, absent tendon reflexes, slight imbalance when walking on the toes, inability to stand in one's foot and a dubious finger-nose testing. No fever, appendicular ataxia, ophthalmoplegia, facial weakness, dysarthria or dysphagia was documented. Laboratory tests were normal. Lumbar puncture showed albuminocytologic dissociation (3cells/mm3, protein level 150 mg/dL) and negative culture. Serogical tests for Borrelia, Campylobacter and SARS-CoV-2 were negative. The stimulation electroneuromyography revealed sensory axonal polineuropathy and MRI of the brain and spine revealed intense enhancement of the cauda equine. Admited to the hospital and started therapy with intravenous immunoglobulin and a rehabilitation program. Over time he showed a marked improvement in gait imbalance however maintains absent tendon reflexes.
Learning Points/Discussion: Miller Fisher syndrome is extremely rare in children and constitutes a diagnostic challenge. In atypical cases after investigation of differential diagnoses, the most appropriate treatment should be offered to aim for a clinical improvement. Although rare usually the prognosis is good.

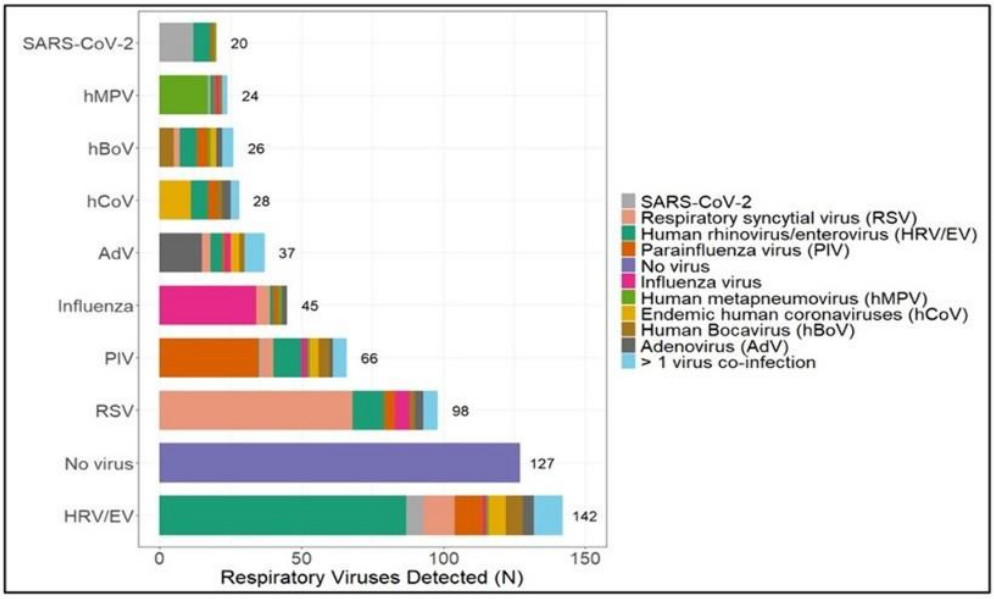
RESPIRATORY VIRUS SURVEILLANCE IN HOSPITALIZED CHILDREN LESS THAN 2-YEARS OF AGE IN KENEMA, SIERRA LEONE DURING THE COVID-19 PANDEMIC (OCTOBER 2020-OCTOBER 2021).

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Robert Samuels[1], Ibrahim Sumah[1], Foday Alhassan[1], Rendie Mchenry[2], Laura Short[2], James Chappell[2], Zaid Haddadin[2], Natasha Halasa[2], Donald Grant[1], John Schieffelin[3], Troy Moon[3]
[1]Kenema Government Hospital, Paediatrics And Lassa Fever Unit, Kenema, Sierra Leone, [2]Vanderbilt University Medical Center, Pediatrics, Nashville, United States of America, [3]Tulane University, Pediatrics, New Orleans, United States of America

Background: Acute respiratory tract infections (ARI) are a main cause of pediatric morbidity and mortality worldwide. Knowledge about the current causes of viral respiratory infections in low resource settings is limited, especially in COVID-19 era, which has impacted the seasonality of common respiratory pathogens. The aim of this study was to identify the viral pathogens associated with ARI in hospitalized children < 2 years of age in Sierra Leone.
Methods: We conducted a prospective, cohort study of children <24 months of age admitted to the Kenema Government Hospital (KGH) with acute respiratory symptoms between October 2020 to October 2021. Two nasal swabs were collected from each child at admission. Swabs were stored at KGH and then shipped to Vanderbilt University Medical Center for testing. Viral pathogen identification was performed using the NxTAG Respiratory Pathogen Panel + SARS-CoV-2 (Luminex) and real-time PCR assays. Descriptive statistics were used to summarize the pathogens detected.
Results: A total of 502 children were enrolled. 376 (75%) had at least 1 virus detected. The most common virus detected was HRV/EV (28.2%) followed by RSV (19.5%). Influenza and SARS-CoV-2 were identified in 9.2% and 3.9% of children, respectively. 97/376 (25.7%) of patients had more than one virus identified (Figure 1). Of the 213 children with a laboratory confirmed malaria diagnosis, 147 (69%) had a virus identified as well. All children admitted were treated with an antibiotic.

Figure 1: Total number of viral pathogens identified and their associated co-detected viruses



Conclusions/Learning Points: Viral pathogen detection was common, though SAR-CoV-2 was

infrequent. Further studies and laboratory capacity are needed to understand the epidemiology of respiratory viral pathogens in Sierra Leone, including any impact resulting from the ongoing COVID-19 pandemic.

FLU AND COVID-19, AN INFECTIOUS PROBLEM FOR PRESCHOOL CHILDREN?!

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Cristina Sapaniuc[1,2], Monica Terteliu-Baitan[1], Alina Mihailiuc[3], Olga Sturdza-Caliman[3], Loredana Corodescu[3], Alexandra Georgiana Lacatusu[1], Doina Carmen Manciuc[1,2]
[1]"Grigore T. Popa" University of Medicine and Pharmacy, Infectious Diseases, Iasi, Romania, [2]"Sf. Parascheva" Infectious Diseases Clinical Hospital, Infectious Diseases, Iasi, Romania, [3]"Sf. Ioan cel Nou" Emergency Hoapital, Infectious Diseases, Suceava, Romania

Backgrounds: Respiratory infections are common during the winter season, is the main reason for seeking medical care for children.
Methods: The study was conducted using comparative and statistical analysis of the medical files of the children admitted to an Emergency Hospital from the North of Romania over a period of 14th weeks.
Results: During this winter season, from 1st of October 2022 until 10th of January 2023, in our clinic were admitted 207 children. All children with respiratory symptoms were tested for COVID-19 and influenza by antigen test and polymerase chain reaction. Among 207 children assessed, 16 had SARS-CoV-2 infection, 17 had influenza A and one had Flurona (influenza A and SARS-CoV-2 infection). The ages varied from 21 days to 7 years old, 47% had 0 years (21 days to 12 months). During viral infection, bacterial adherence to epithelium is increased by viral glycoproteins which can lead to an increased risk for bacterial superinfection. Mixed viral-bacterial respiratory infections are relatively common in preschoolers, in our clinic, almost 21% of them had abnormalities at the chest x-ray (with suggestive images for pneumonia and bronchiolitis) which resolved after 1 week with antiviral and antimicrobial treatment. All patients were admitted with one of their parents (all of them presented respiratory symptoms). The evolution was good in all cases, none of them needed to be monitored in the intensive care unit.
Conclusions/Learning Points: All patients with respiratory symptoms, especially preschoolers should be monitored in a medical unit due to the complications that viral infections can include (viral or bacterial pneumonia, sinusitis, otitis, coinfections with bacterial agents). These complications not treated correctly can present a high risk of morbidity and mortality in children.

CHARACTERIZATION OF JAPANESE ENCEPHALITIS VIRUS GENOTYPE V ISOLATES FROM SOUTH KOREA

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Ah-Ra Lee, Sang-Uk Seo
The Catholic University of Korea, Department Of Microbiology, Seoul, Korea, Republic of

Backgrounds: Japanese encephalitis (JE) is a prevalent infectious disease with about 67,900 cases annually in 24 countries including the Republic of Korea (ROK). Children are most commonly affected worldwide and therefore children aged 3-4 years are starting to be given the JE vaccine. Since 2010, genotype V (GV) Japanese encephalitis virus (JEV) virus strains have been identified in the ROK but current vaccines are based on genotype III (GIII). Characterization of antigenic and pathologic properties of GV strains are required in order to minimize the risk for possible GV JEV outbreak.
Methods: We sequenced whole genome of two GV JEV isolates, NCCP 43279 and NCCP 43413 which were isolated from human patient and mosquito, respectively, and compared them with GV Muar (Malaysia) and XZ0934 (China) strains. We further characterized virus replication and cell toxicity in vitro and pathogenicity in vivo using a mouse model.
Results: We identified unique sequence substitutions from ROK isolates. ROK isolates exhibited slower growth in vitro and were less virulent in mice compared to GIII Nakayama strain. Importantly, GV strains were antigenically distinct from GIII Nakayama strain.
Conclusions/Learning Points: Our results suggest the need for a novel GV strain-based vaccine. Also, further study is required to reveal the molecular mechanism underlying the different pathogenicity of these strains.

PROGNOSTIC MODEL FOR DETERMINING THE PROBABILITY OF SEVERE RESPIRATORY DISORDERS DEVELOPMENT IN NEWBORNS FROM MOTHERS WITH DIABETES MELLITUS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Veranika Prylutskaya[1], Katsiaryna Serhiyenka[2]
[1]Belarussian State Medical University, Children Diseases, Minsk, Belarus, [2]Belarussian State Medical University, Children Infections Diseases, Minsk, Belarus

Backgrounds: The risk of adverse perinatal outcomes in patients with type 1 diabetes mellitus (DM1) is significantly higher compared to the general population of pregnant women. The aim of the study was to develop a predictive model for determining the likelihood of severe respiratory disorders in newborns from mothers with DM1.
Methods: We examined 101 newborns from mothers with DM1 who were born and treated at the RSPC "Mother and Child" in 2018–2021. Group 1 (n=45) included patients with severe respiratory disorders requiring respiratory support at the Neonatal Intensive Care Unit, group 2 (n=56) consisted of comparisons. Both groups were comparable in terms of sex (p=0.373), body weight (3860 (3440−4340) vs 3745 (3450−4000) g, p=0.268), and body length (53 (52−55) vs 53 (52−54) cm, p=0.467). We performed the analysis of 165 mothers' pregnancy and DM course anamnestic factors, anthropometric, clinical, laboratory, instrumental parameters, and newborns' metabolic status indicators. SPSS 26 was used for statistical analysis.
Results: According to the multivariate regression we established that the most significant respiratory disorders predictors were anemia in pregnancy, gestational age, emergency caesarean section, birth body weight Z-score, respiratory failure, hematological parameters (hemoglobin level lower than 202 g/l, immunological reactivity index (IRI) higher than 2.8). We developed a prognostic model for determining the probability of a severe course of respiratory disorders which contained 4 parameters and calculated its' threshold value (0.467). The diagnostic accuracy of the developed model was 84.1% (95% CI 76.2–91.9%).
Conclusions/Learning Points: The accuracy of the severe respiratory disorders in newborn from mothers with DM1 likelihood determining was ensured by the identified ante-, intra-, postnatal clinical and laboratory parameters comprehensive assessment.

HYPERACUTE CONJUNCTIVITIS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Ana Manuela Silva[1], Joana Sousa[1], José Alarcão[2], Ana Brett[1], Fernanda Rodrigues[1]
[1]Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Infectious Diseases Unit And Emergency Service, Coimbra, Portugal, [2]Hospital Pediátrico de Coimbra, Serviço De Urgência, Coimbra, Portugal

Title of Case: HYPERACUTE CONJUNCTIVITIS
Background: Clinical manifestations of meningococcal disease usually range from transient bacteraemia to fulminant disease. We present a rare manifestation of Neisseria meningitidis infection.
Case Presentation Summary: A previously healthy 16-month-old boy presented to the Emergency Room with bilateral ocular hyperaemia, photophobia, palpebral oedema with marked purulent discharge and irritability for the past 20 hours despite topical treatment. As clinical manifestations were very exuberant, culture of the eye discharge was done and topical treatment changed chloramphenicol. As no improvement was noticed, he was referred to the ophthalmologist 24 hours later and treatment was maintained. On the following day, the culture of the eye discharge was positive for N. meningitidis. Considering the risk of invasive disease (IMD), further investigation was done, showing a normal complete blood count (leucocytes 11700/mL, neutrophils 6720/mL), CRP 0.11 mg/dL, PCT 0,02ng/mL. CSF analysis was also normal and blood and CSF cultures negative. Ceftriaxone was given until negative cultures. Irritability and conjunctivitis improved rapidly with a good clinical outcome. Close contacts received chemoprophylaxis with ciprofloxacin.
Learning Points/Discussion: N. meningitidis is a very rare cause of hyperacute conjunctivitis. Given the possibility of serious complications, systemic antibiotic treatment was given until IMD was ruled out as it seems to significantly reduce its risk. Close contacts antibiotic chemoprophylaxis was given in order to reduce the risk of secondary IMD.

MANAGING LYMPHADENOPATHY IN THE PEDIATRIC EMERGENCY DEPARTMENT

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Mariana Silva[1], Ana Rita Albuquerque Costa[1], Joana Monteiro[2], Jorge Rodrigues[3], Joaquina Antunes[3], Cristina Baptista[3]
[1]Centro Hospitalat Tondela-Viseu, Pediatria, Viseu, Portugal, [2]Centro Hospitalar Tondela Viseu, Pediatria, Viseu, Portugal, [3]CH Tondela-Viseu EPE, Pediatric Department, Viseu, Portugal

Backgrounds: Lymphadenopathy (LA) is defined as an abnormality of one or more lymph nodes. It is a common presentation in childhood, associated with a wide spectrum of diseases including infectious, immunologic and neoplastic disorders. At present, there is no consensus in pediatric literature regarding a diagnostic and therapeutic algorithm, which can increase discrepancies in its management. The aim of this study was to describe the clinical features and outcomes of childhood LA admitted to our hospital.
Methods: Single center, 5-year, retrospective analysis of children and adolescents admitted for LA.
Results: Total of 222 patients, median of 7 years (IQR 3-11), 57.7% male. Head and neck, inguinal, axillary and supraclavicular LA were described in 87.4%, 6.3%, 2.3% and 1.4% of the patients, respectively. Constitutional signs were not reported in 76.1% of the clinical records. Clinical red flags were reported in 38.3% of patients. From those, ultrasonography was performed in 67.1%, laboratory tests in 48.2%, and chest radiography in 18.8%. In patients with LA without red flags, ultrasonography was performed in 35% and laboratory tests in 19.7%. Antibiotic therapy was prescribed in 5.6% of reactive LA without red flags and in 81.8% of adenitis/abscess. A specific diagnosis was achieved in 7.7%. The most common final diagnosis were reactive lymphadenitis (77%) and adenitis/abscess (14.9%). Follow-up evaluations were required in only 31.5% of cases.
Conclusions/Learning Points: LA is a benign condition in the majority of cases and does not require extensive investigation. A systematic approach for decision-making may help in identifying those lesions which require urgent attention. Generally, our study suggests a correct assessment of LA and the need for antibiotics and further investigation.

LYMPHADENOPATHY IN PEDIATRIC INFECTIOUS MONONUCLEOSIS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Elda Skenderi
University Hospital Center, General Pediatrics, Tirana, Albania

Backgrounds: Infectious Mononucleosis is the most common clinical manifestation of Epstein-Barr virus(EBV) infection. It is characterized by fever, sore throat, lymphadenopathy and hepato-splenomegaly. EBV infection is associated with a vigorous humoral and cellular immune response to rapidly proliferating EBV-infected B cells, which results in lymphadenopathy and other signs and symptoms of Infectious Mononucleosis.
Methods: As lymphadenopathy is a clinical sign that defines Infectious Mononucleosis, a study was performed to explore its anatomic location and age distribution in children. In the study were included 107 children aged 0-14years, hospitalized in the Pediatric Infectious Disease Ward of the University Hospital Center "Mother Teresa" in Tirana, Albania, during 2015-2018. Diagnose was made on base of a positive serology test for immunoglobulin M viral capsid antigen.
Results: Lymphadenopathy was found in 81% of cases. 57% of cases presented cervical lymphadenopathy and 24% of cases presented generalized lymphadenopathy. In 11% of cases it was the first presentig symptom. Cervical lymphadenopathy predominated in younger children whereas generalized lymphadenopathy in older children (p=0.001). Generalized lymphadenopathy was strongly associated with hepato-splenomegaly. Absolute lymphocytes number were more elevated in generalized lymphadenopathy than in cervical lymphadenopathy.
Conclusions/Learning Points: Lymph node enlargement both regional and generalized is common in pediatric Infectious Mononucleosis. Cervical lymphadenopathy is more prevalent in younger children whereas generalized lymphadenopathy predominates in older children. Lymphadenopathy is a common clinical finding in childhood and is frequently benign but sometimes raises fears about serious illnesses, so an accurate differential diagnosis should be performed.

Title of Case: Facial nerve palsy: diagnosis and treatment challenges in children – case report
Background: Facial nerve palsy is the most common cranial nerve dysfunction in children and adults, and in children under the age of 10 the incidence it is cited to be less than 3 per 100,000 annually.
Case Presentation Summary: We present the case of an 9 year old boy, with no significant medical history, witch presented in our hospital with headache, vertigo, fever , right lagophthalmos, facial asymmetry. The fever started 3 days prior to the admittance in our hospital. Because otitis media is the most frequent infectious cause of facial nerve paralysis we performed an ENT consult , witch excluded the otitis media. No significant changes were found in the initial blood workup , that is why he was tested for influenza A and B with negative results. Although the patient isn’t from an endemic area for Borrelia, because of the presenting symptoms we decided to test for Borrelia borgdoferi antibodies with positive results, later confirmed with Western Blot test. The herpes simplex antibodies were negative. We established the final diagnosis of: Lyme disease, early disseminated stage with right facial nerve palsy. Treatment with oral Cefuroxime was initiated for 21 days , in association with a short course of oral Prednison. We refrained from administering acyclovir until the test for herpes simplex antibodies came.
Learning Points/Discussion: Conclusion: Lyme disease in children is a rare occurrence in our country and although we didn’t identify the moment of the thick bite, Borrelia must be taken in consideration as a cause of facial nerve palsy.

CELLULITIS COMPLICATED BY NON-NECROTIZING FASCIITIS IN A CHILD CO-INFECTED WITH INFLUENZA VIRUS: A LIFE-THREATENING COMBINATION

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Giulia Sturniolo, Osvalda Rampon, Marica De Pieri, Daniele Donà
University of Padova, Division Of Pediatric Infectious Diseases, Department For Women's And Children's Health, Padova, Italy

Title of Case: CELLULITIS COMPLICATED BY NON-NECROTIZING FASCIITIS IN A CHILD CO-INFECTED WITH INFLUENZA VIRUS: A LIFE-THREATENING COMBINATION
Background: Skin and soft tissue infections represent a broad spectrum of disease processes, ranging from mild to fulminant, widespread necrosis, and systemic toxicity with high morbidity and mortality. Co-infection with the influenza virus has been linked to a worse prognosis.
Case Presentation Summary: A previously healthy two-year-old child was evaluated at ER for fever and respiratory symptoms. A papule on the umbilical region was observed during the physical examination, with diffuse, poorly demarcated skin erythema and edema of the abdomen, inguinal region and trunk. Soft-tissue US confirmed the diagnosis of diffuse cellulitis, and a nasopharyngeal swab tested positive for Influenza A (H3N2). The lab test showed leukocytosis, increased inflammatory markers, hepatic and muscle enzymes, hypoalbuminemia and hyponatremia. Blood cultures and skin swabs turn back negative. Despite one-week treatment with ceftriaxone and clindamycin, after initial improvement his clinical condition worsened with high fever, severe fatigue and underfeeding. A further increase in leukocytes and inflammatory markers (CRP and PCT) and new onset thrombocytosis was noted. MRI of the abdomen showed circumferential fasciitis of the abdomen without necrosis. A surgical approach was excluded. Hence, antimicrobial therapy escalation with piperacillin-tazobactam and linezolid was decided upon. Furthermore, due to a lack of clinical improvement after 48 hours, non-specific IVIGs were administered (1 gr/kg/die for two days) with rapid clinical response and restitutio ad integrum in the following week.
Learning Points/Discussion: Despite the negative culture, the clinical picture was highly suggestive of group A streptococcus with an influenza virus superinfection. This case highlights the importance of early recognition of possible complications and supports the early use of IVIGs in non-surgical patients who respond poorly to antibiotic treatment.

DOES EPSTEIN-BARR VIRUS INFECTION ASSOCIATED WITH CHILDHOOD ACUTE LYMPHOBLASTIC LEUKAEMIA? A SYSTEMATIC REVIEW AND META-ANALYSIS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Ni Made Adnya Suasti[1], Glazydia Juwita Rahma[2], Putu Gea Rini Dian Pertiwi[2]
[1]University of Oxford, Nuffield Department Of Clinical Medicine, Oxford, United Kingdom, [2]Faculty of Medicine Airlangga University, -, Surabaya, Indonesia

Backgrounds: Acute lymphoblastic leukaemia (ALL) is the most common type of leukaemia in childhood. Epstein-Barr virus (EBV) is a herpes virus that causes infectious mononucleosis. Studies have shown that children with ALL are more likely to have been infected with EBV in the past. The exact mechanism by which EBV infection increases the risk of ALL is not fully understood. This study aims to determine the association between EBV infection and childhood ALL.
Methods: A systematic search was conducted in multiple databases (Pubmed, Science Direct, Google Scholar) for publications until December 31st 2022. Random-effects meta-analyses were used to calculate pooled odds ratios (ORs) with 95% confidence intervals (CIs). The study selection process was carried out under PRISMA 2020 guidelines based on several eligibility criteria. The quality of the included study was further assessed using The Newcastle-ottawa Scale (NOS) for case control study. Funnel plot was used to assess the risk-of-bias for outcome studies.
Results: 5,982 literatures were retrieved, 1,025 were excluded due to duplication, 4,365 were due to inappropriate title and abstract, 24 unavailable full-text studies, and 568 with inappropriate method and outcome. Finally, 14 case control studies were included in this study involving 1,628 children with ALL. EBV infection is not associated with childhood ALL (p=0.28). The combined OR on ALL for EBV infection is 1.36 (95% CI: 0.77, 2.39; $I^2 = 72\%$). The studies were classified as good quality. The funnel plot showed that the studies spread quite dissymmetrical, therefore there is a possibility for publication bias.
Conclusions/Learning Points: Overall result depicted that there is no association between EBV infection and childhood ALL. Nevertheless, 4 studies suggests that EBV infection can significantly be a risk factor for the development of ALL in children.

NECROTIZING FASCIITIS CAUSED BY AN UNUSUAL ORGANISM AFTER SNAKE BITE

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Keang Suy
Angkor Hospital for Children, Microbiology Department, Siem Reap, Cambodia

Title of Case: NECROTIZING FASCIITIS CAUSED BY AN UNUSUAL ORGANISM AFTER SNAKE BITE
Background: Snake bite is a public health issue in many countries. Secondary bacterial infections occur infrequently. Here, we describe a case of severe, life-threatening soft tissue infection caused by an unusual organism after snakebite.
Case Presentation Summary: A 12 years old boy was referred to emergency department at Angkor hospital for children due to progressive left arm swelling after bitten by an unknown snake while catching fishes. His wound was cleaned at a nearby hospital. After two days, the wound became swollen and progress rapidly to his upper arm. He was brought back to the same hospital where he got admitted for 11 days. On arrival, his temperature was 35.7 C, heart rate 108beats/mn, respiratory rate 36/mn, and saturation O2 100% room air. Physical examination revealed a swollen, painful and pale left arm. He underwent fasciotomy and surgical debridement on the same day. Given the serious condition and history of prolonged hospital stay, vancomycin and meropenem were started. All three samples taken during the operation grew Edwardseilla tarda. The patient's condition improved after second operation and antibiotics were switch to ampicillin when sensitivity profile of the organism available. The patient was discharged after 10 days with oral amoxicillin for another 7days. On follow up at two weeks after discharge, the patient remained well and the wound was completely healed.
Learning Points/Discussion: Gastrointestinal disease is the most common reported infection caused by Edwardseilla tarda while extra-gastrointestinal disease is rare but with significant mortality rate. Microbiology laboratory is crucial and help us saved many doses of vancomycin and meropenem thus reducing cost, toxicity and resistance. Multi-disciplinary teams including medical, surgical, microbiology team improved the patient's outcome.

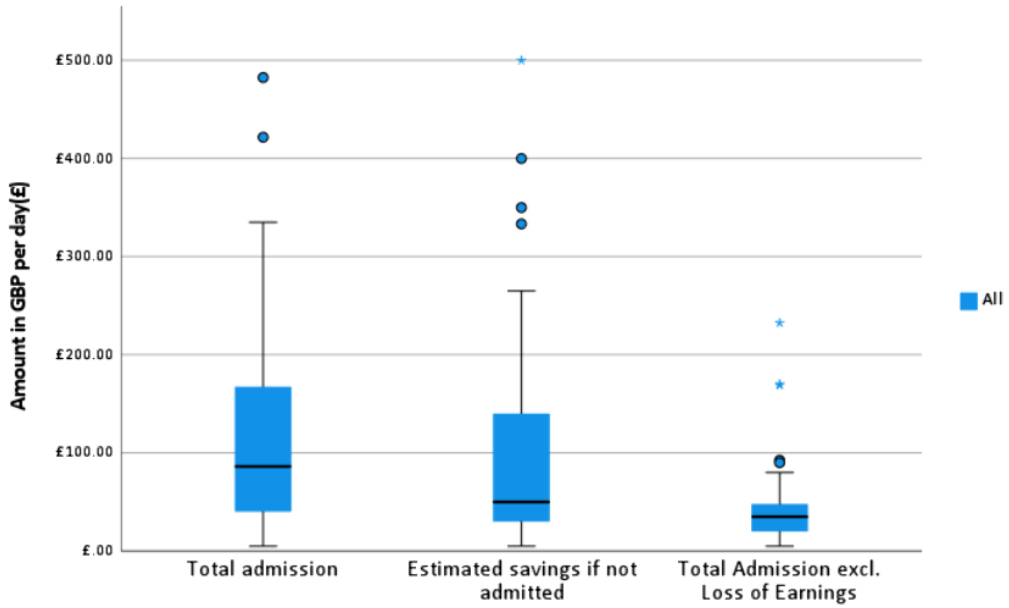
Backgrounds: Fever in children is a common reason to attend the emergency department (ED), and for hospitalisation pending microbiological diagnostics. The burden of financial and emotional costs of these admissions for families are not well studied. In the current cost of living crisis this burden is becoming increasingly important, especially in the North East of England, an area with relatively high levels of social deprivation.
Methods: A single-centre study between June and October 2022, utilising a structured questionnaire assessing financial and emotional costs of admissions to hospital for febrile illness via ED. Financial costs including travel, food, child care, loss of earnings and miscellaneous costs were estimated. Emotional costs were measured using the PHQ-4 and STAI-6 depression and anxiety questionnaires.
Results: 55 families of patients aged median 6.5 years (IQR 2-11 years) completed the questionnaire. 52 (94.5%) stated they had extra costs due to being in hospital. Most common costs were made for Travel and Food (N=49, 89.1% for either). Median costs per day were £85.25 (IQR £38.75-£168.25), or, adjusted for loss of income, median £35.00 (£19.70-£48.93) (Figure 1). Parents estimated they could save median £50.00 (IQR £27.50-£140) per day, if their child could have been safely discharged from ED. 47.3% of parents (N=26) experienced moderate to severe anxiety, secondary to their child's admission



Conclusions/Learning Points: Significant costs are incurred for parents of children attending hospital, with costs mainly made for travel and food. A large proportion of costs is due to loss of earnings. High levels of parental anxiety are not uncommon. As the cost-of-living crisis deepens, it is a task for health care providers to identify how to support those families most in need, and reduce these burdens.

VAGINITIS CAUSED BY CORYNEBACTERIUM AMYCOLATUM IN A PREPUBESCENT GIRL

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Álvaro Vázquez-Pérez[1], Elena Vicente Gutiérrez[2], Juan Luis Santos-Pérez[1], José Gutiérrez-Fernández[3]
[1]Hospital Universitario Materno-Infantil Virgen de las Nieves, Pediatrics- Pediatric Infectious Diseases/Granada, Spain, [2]Hospital Universitario Materno-Infantil Virgen de las Nieves, Pediatrics/Granada, Spain, [3]Hospital Universitario Virgen de las Nieves, Microbiology, Granada, Spain

Title of Case: Vaginitis Caused by Corynebacterium amycolatum in a Prepubescent Girl
Background: Vulvovaginitis is the most common gynecological symptom in prepubescent girls. Most cases have nonspecific causes and require only reassurance and improved perineal hygiene. Corynebacterium spp. are part of the normal flora of the skin and mucous membranes. However, Corynebacterium amycolatum (C.amycolatum) is increasingly being recognized as a significant pathogen with multidrug resistance to commonly used antibiotics. It has been implicated in endocarditis, sepsis, wounds, and urinary tract and respiratory tract infections, especially in immunocompromised patients. Its true clinical significance as an opportunistic pathogen has probably remained underestimated. Treating infections caused by C. amycolatum is challenging because infections are usually multidrug resistant.
Case Presentation Summary: A 9-year-old female virgin arrived at our hospital presenting with vaginal itching and frequent urination lasting for approximately 2 weeks. Although the patient had received repeated treatments such as potassium permanganate solution for the bath, her symptoms continued. The physical examination revealed an intact hymen with vulvitis with no visible vaginal discharge. Urinalysis was negative. A vaginal sample for microbiological culture was collected. The culture was positive for C. amycolatum resistant to penicillin, erythromycin, and clindamycin. Treatment was started with oral trimethoprim-sulfamethoxazole for 7 days. In a subsequent review, the resolution of the symptoms was verified. To the best of our knowledge, this is the first case report from Spain of C. amycolatum vaginitis in a prepubescent girl.
Learning Points/Discussion: Vulvovaginitis in prepubescent girls is most commonly attributed to poor hygiene or non-specific irritants; however, in some patients, recurrent or atypical vulvovaginitis is primarily caused by bacterial pathogens. In particular, Corynebacterium amycolatum is increasingly being recognized as an important pathogen with multidrug resistance to commonly used antibiotics.

FACKLAMIA HOMINIS URINARY TRACT INFECTION IN A PEDIATRIC PATIENT. AN UNDERRECOGNIZED PATHOGEN?

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Álvaro Vázquez-Pérez[1], Juan Luis Santos-Pérez[1], José Gutiérrez-Fernández[2]
[1]Hospital Universitario Materno-Infantil Virgen de las Nieves, Pediatrics- Pediatric Infectious Diseases/Granada, Spain, [2]Hospital Universitario Virgen de las Nieves, Microbiology, Granada, Spain

Title of Case: Facklamia hominis urinary tract infection in a pediatric patient. An underrecognized Pathogen?
Background: Facklamia species are a rarely reported etiology of clinical infection with few cases described in literature. Facklamia spp have been implicated in invasive infections, causing a range of illnesses such as sepsis, bacteremia, abscesses, peritonitis, meningitis, endocarditis, genitourinary infection, chorioamnionitis, and prosthetic joint infection. Its potential resistance to β-lactams may have significant clinical treatment implications. Only 2 cases of Facklamia infection in children have been reported. We add a case in which it was a likely contributor to a case of urinary tract infection (UTI).
Case Presentation Summary: Our first case is a 4-year-old girl, evaluated in the pediatric emergency room for fever without a source of up to 40ºC of 24 hours of evolution. He did not present voiding symptoms or other symptoms. He had presented a case of UTI due to E. coli the previous year, with no other history of interest. A mid-micturition urine study was performed with positivity for leukocytes, initiating empirical antibiotic therapy with cefixime. A positive urine culture (10,000-100,000 CFU) was received for multi sensitive F. hominis. He presented a good evolution, with the disappearance of the fever on the fourth day of treatment, which he received for 5 days.
Learning Points/Discussion: Facklamia spp are organisms whose true virulence and pathogenesis are poorly understood. They may cause infection in a susceptible host, but clarifying the risk factors has proven to be difficult based on the scarcity of literature. Due to challenges in its identification, the true burden of disease may be underrecognized. This case illustrates the requirement to standardize identification and treatment of care to avoid treatment failure and antimicrobial resistance, given its potential resistance to β-lactams.

ACTINOTIGNUM SCHAALII AND GENITAL ULCERS IN A MALE CHILD

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Álvaro Vázquez-Pérez[1], Alicia Herrera-Goicoechea[2], Juan Luis Santos-Pérez[1], José Gutiérrez-Fernández[3]
[1]Hospital Universitario Materno-Infantil Virgen de las Nieves, Pediatrics- Pediatric Infectious Diseases/Granada, Spain, [2]Hospital Universitario Materno-Infantil Virgen de las Nieves, Pediatrics/Granada, Spain, [3]Hospital Universitario Virgen de las Nieves, Microbiology, Granada, Spain

Title of Case: ACTINOTIGNUM SCHAALII AND GENITAL ULCERS IN A MALE CHILD
Background: The diagnosis of genital ulcers in children is of particular importance, as they can be an indication of pathologies that are either non-infectious or infectious, and in some cases may be associated with sexual abuse. Actinotignum schaalii (A. schaalii) is a gram-positive, facultative anaerobic bacillus that resides in the urogenital mucocutaneous epithelium. Its true clinical significance has probably continued to be underestimated due to the difficulty of isolating it in routine cultures. We present the first case to be described in the literature of genital ulcers associated with isolation of this microorganism.
Case Presentation Summary: The patient was a seven-year-old boy who presented with ulcers on the glans and balanopreputial region that had appeared 24 h earlier, without fever, history of trauma or recent use of new medications. The patient had been previously diagnosed with primary nocturnal enuresis and daytime wetting. During the examination, an ulcer of 4 mm was found on the glans and another of similar size, mirroring the first. The rest of the physical examination was normal. Blood test was normal. In the microbiological study, A. schaalii was identified using MALDI-TOF. The antibiotic sensitivity study showed: ampicillin, clindamycin and tetracycline sensitive, and metronidazole resistant. Urine culture and serology test were negative. Treatment was administered orally with amoxicillin, with a favourable clinical course.
Learning Points/Discussion: Although globally the most common cause of genital lesions is herpes simplex virus infection, in children and non-sexually-active adolescents, other non-infectious and infectious aetiologies should be considered. Opportunistic microorganisms such as A. schaalii must be taken into account in the differential diagnosis of genital ulcers, in particular, when there is prolonged exposure to moisture in the genital area.

EXTENSIVELY DRUG-RESISTANT SHIGELLA SONNEI INFECTION IN CHILDREN. A PEDIATRIC EMERGING THREAT? REPORT OF TWO CASES.

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Álvaro Vázquez-Pérez[1], Juan Luis Santos-Pérez[1], José Gutiérrez-Fernández[2]
[1]Hospital Universitario Materno-Infantil Virgen de las Nieves, Pediatrics- Pediatric Infectious Diseases/Granada, Spain, [2]Hospital Universitario Virgen de las Nieves, Microbiology, Granada, Spain

Title of Case: Extensively drug-resistant Shigella sonnei infection in children. A pediatric emerging threat? Report of two cases.
Background: Shigella sonnei (S. sonnei) is an emerging pathogen globally. Shigella infections is increasingly being associated with sexual transmission among men who have sex with men (MSM). Recently, the ECDC warned about the increase in extensively drug resistant (XDR) S. sonnei infections in MSM in Europe and the UK. We present two pediatric cases of XDR S. sonnei infections that to our knowledge are the first pediatric cases reported in Spain.
Case Presentation Summary: A previously healthy 4-year-old female patient presents to the emergency department with a febril seizure.She presented diarrhea and emesis; absence of a rigid abdomen and without focal neurologic symptoms. Laboratory test: CRP: 168 mg/L. PCT: 7.53 ng/mL. She was admitted and treatment with cefotaxime was started. S. sonnei was isolated from stool sample. It was resistant to ampicillin, cefotaxime, and trimethoprim-sulfamethoxazole and only susceptible to amoxicillin-clavulanate and carbapenems. She completed treatment with oral amoxicillin-clavulanate for 5 days with favourable evolution. The second case was detected in another 4-year-old girl, from the same healthcare centre. She had presented a fever of up to 39.5ºC for 24 hours, along with watery diarrheal stools for a week. S. sonnei was isolated in stool culture with the same antibiotic resistance profile, including resistance to levofloxacin. Symptoms had resolved by the time bacterial culture results were available.
Learning Points/Discussion: The majority of Shigella infections are self-limited but severe cases can be fatal if left untreated. The raise of this XDR S. sonnei in children should be a major concern for clinicians. It is necessary to strengthen the epidemiological surveillance of this infection in Europe, regarding the transmission, microbiological characterization and antimicrobial resistance.

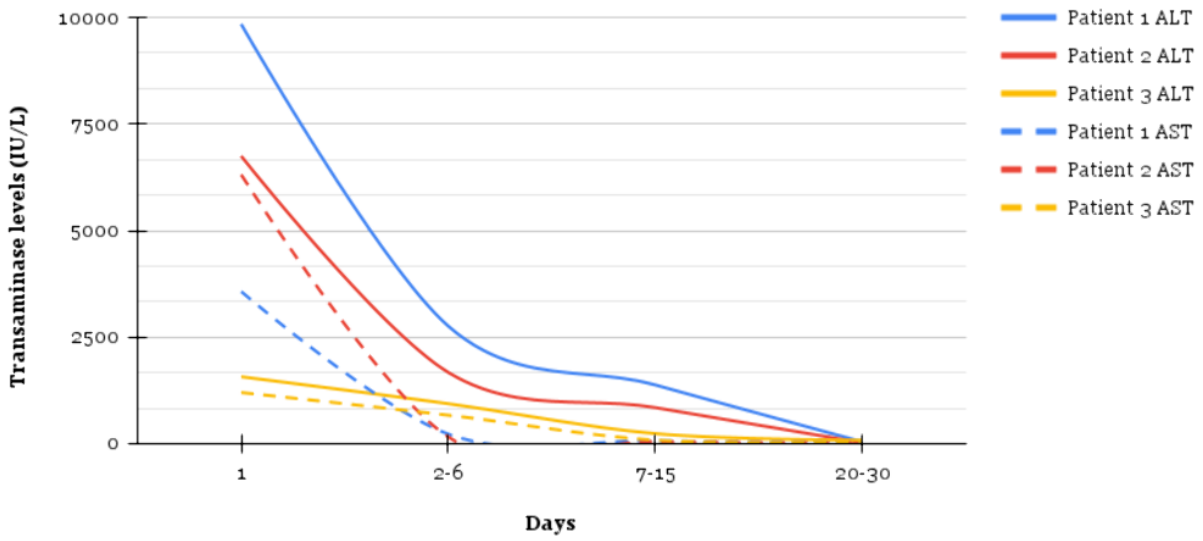
CASES OF ACUTE HEPATITIS OF UNKNOWN ORIGIN IN TEENAGERS

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Klaudia Wójtowicz, Kamila Ludwikowska, Leszek Szenborn
Wroclaw Medical University, Department Of Pediatric Infectious Diseases, Wrocław, Poland

Title of Case: Cases of acute hepatitis of unknown origin in teenagers
Background: In April 2022 Centers for Disease Control and Prevention released an alert about acute hepatitis of unknown origin (AHUO) in children. The first cases were reported in Alabama and involved children aged one through six, previously healthy. Then other cases were detected in Europe, especially in the United Kingdom.
Case Presentation Summary: Since the alert, we have carried out an increased vigilance for similar cases of AHUO in the Department of Pediatric Infectious Diseases in Wrocław, Poland. From February 2022 until September 2022 three children with AHUO were identified in our clinic. Differently than in the previous reports, our patients were all adolescent girls, aged fourteen through sixteen years old. All of them were previously healthy. In each case, a rapid onset of the disease with very high transaminases (Figure 1) but sustained liver function was observed. Two of these girls had episodes of intensive vomiting shortly preceding hepatitis diagnosis and the third one had a jaundice as a leading sign. Except for hypertransaminasemia, in two of these cases procalcitonin concentration was very high, while CRP - low. LDH activity was elevated as well. There were no prominent features of cholestasis. Broad differential diagnosis didn't reveal any cause for acute hepatitis, except for positive ANA results in two of these girls. No other laboratory features of autoimmune hepatitis were found, however. Two girls were treated symptomatically and one was treated with glucocorticosteroids in tempered doses for two weeks.



Learning Points/Discussion: In all cases, quick improvement was observed and transaminases came back to normal values in less than a month.

ENDOCARDITIS CASE SERIES IN A TERTIARY LEVEL CHILDREN'S HOSPITAL IN THE UNITED KINGDOM

E-Posters Viewing
E-POSTER VIEWING: AS16. OTHERS

Luca Zombori[1], Mohsin Shah[2], Quen Mok[1]
[1]Great Ormond Street Hospital, Paediatric Intensive Care Unit, London, United Kingdom, [2]Great Ormond Street Hospital, Project Drive Data Science, London, United Kingdom

Title of Case: Endocarditis case series in a tertiary level children's hospiral in the United Kingdom
Background: Endocarditis in children is a rare disease in the developed world, but it is associated with significant morbidity and mortality. Following the admission and death of a previously well 8-year-old girl and another case within a week, we performed a 10-year retrospective analysis of children with infective endocarditis in a tertiary children`s hospital in London, UK to check whether the trend of presentations with this diagnosis has been increasing.
Case Presentation Summary: Data was pulled using the electronic patient records and analyzed in Excel. 14 unique patients were identified, 50% male, 57% White. Median age was 4.9 years (IQR 1.1-8.5). 36% had congenital heart disease. All patients had an echocardiogram performed, and one patient had MRI of the heart. 66% (9/14) had a positive blood culture, 4 S.aureus and one each S.sanguinis, E.faecium, S.marcescens, C.koseri and C.parapsilosis. The patients were treated with intravenous antibiotics that were in line with current recommendations. Three patients (21%) did not survive to hospital discharge. Of the patients with an underlying cardiac condition, 40% died, and of those without a cardiac condition, 11% died. One patient who passed away had a severe immunodeficiency syndrome and acquired IE as a complication of a haemorrhagic chicken pox infection. The trend of admissions has been decreasing in the past 10 years.
Learning Points/Discussion: The ten-year case series in the study hospital fortunately did not show an increase in prevalence of paediatric IE cases. However the mortality in our cohort remains high despite appropriate therapy, probably due to a higher than average rate of background conditions.
