16

17 **Key Points**

18

- 19
- 20 • We present the release of 64 aerogeophysical datasets (including gravity, magnetic, bed-pick,
21 and radar data) obtained from 24 surveys flown by the British Antarctic Survey over West
22 Antarctica, East Antarctica, and the Antarctic Peninsula between 1994 and 2020.
 - 23 • The published datasets have been standardised according to the FAIR (Findable, Accessible,
24 Interoperable and Re-Usable) data principles and integrated into a user-friendly data interface,
25 the Polar Airborne Geophysics Data Portal, to further enhance the interactivity of the datasets.
 - 26
 - 27 • We discuss how the data were acquired and processed and, using a layer-continuity method,
28 show potential avenues for future studies attempting to extract further information from the
29 englacial architecture of the ice using the radar data.
- 30

31 **Abstract**

32

33 Over the past 50 years, the British Antarctic Survey (BAS) has been one of the major acquirers of
34 aerogeophysical data over Antarctica, providing scientists with gravity, magnetic and radar datasets that
35 have been central to many studies of the past, present, and future evolution of the Antarctic Ice Sheet.
36 Until recently, many of these datasets were unpublished in full, restricting further usage of the data for
37 different applications such as gravity inversions, bed-reflectivity analysis, and englacial-layer tracking.
38 Starting in 2020, scientists and data managers at the British Antarctic Survey have worked on
39 standardising and releasing large swaths of aerogeophysical data acquired during the period 1994-2020,
40 including a total of 64 datasets from 24 different surveys, amounting to ~450,000 line-km (or 5.3 million
41 km²) of data across West Antarctica, East Antarctica, and the Antarctic Peninsula. Amongst these are
42 the extensive surveys over the fast-changing Pine Island (BBAS 2004-05) and Thwaites (ITGC 2018-
43 20) glacier catchments, and the first ever surveys of the Wilkes Subglacial Basin (WISE-ISODYN
44 2005-06) and Gamburtsev Subglacial Mountains (AGAP 2007-09). Considerable effort has been made
45 to standardise these datasets to comply with the FAIR (Findable, Accessible, Interoperable and Re-
46 Usable) data principles, as well as to create the Polar Airborne Geophysics Data Portal
47 (<https://www.bas.ac.uk/project/nagdp/>), which serves as a user-friendly interface to interact with and
48 download the newly published data. This paper reviews how these datasets were acquired and
49 processed, presents the methods used to standardise them, and introduces the new data-portal
50 infrastructure and interactive tutorials that were created to improve the accessibility of the data. Lastly,
51 we exemplify future potential uses of the datasets by extracting information on the continuity of
52 englacial layering from the fully processed radar data. We believe this newly released data will be a
53 valuable asset to future geophysical and glaciological studies over Antarctica and will extend
54 significantly the life cycle of the data. All datasets included in this data release are now fully accessible
55 at: <https://data.bas.ac.uk>.

61 1. Introduction

62 As one of the fastest changing environments on Earth, Antarctica has been at the epicentre of
63 scientific research since the early 1960s. Understanding the past, present, and future of the Antarctic
64 Ice Sheet is of special interest, particularly in the context of rapid climatic changes already affecting
65 large parts of the Antarctic Peninsula and threatening the stability of the West Antarctic Ice Sheet
66 (IPCC, 2021). One way to quantify how the ice sheet will respond to these changes is to conduct
67 surveys of the ice and bedrock underneath using geophysical techniques such as gravity, magnetic,
68 and radar. By studying the bed beneath an ice sheet, we can better estimate where a retreating ice
69 stream is more likely to stabilise or de-stabilise further (Holt et al., 2006; Morlighem et al., 2020;
70 Ross et al., 2012; Tinto and Bell, 2011; Vaughan et al., 2006) and how topography or subglacial
71 water-routing systems can affect the flow-regime of ice streams (Ashmore and Bingham, 2014; Bell et
72 al., 2011; Schroeder et al., 2013; Siegert et al., 2014; Wright et al., 2012; Young et al., 2016). By
73 studying the subglacial geology underlying the ice, we can better understand magmatic, tectonic and
74 sedimentary influences on ice flow over timescales of hundreds, thousands or even millions of years
75 (Bamber et al., 2006; Bell et al., 1998; 2006; Bingham et al., 2012; Blankenship et al., 2001; Jordan et
76 al., 2010; Studinger et al., 2001), and quantify the influence of geothermal heat flux on ice dynamics
77 (Jordan et al., 2018; Schroeder et al., 2014). Finally, the use of gravity techniques enables us to better
78 understand the bathymetry beneath fast-changing ice shelves and ice-stream fronts and quantify areas
79 of high sensitivity (Greenbaum et al., 2015; Jordan et al., 2020; Millan et al., 2017; Tinto et al., 2019).

80 Since the mid-1960s, the British Antarctic Survey (BAS) has been involved in acquiring
81 aerogeophysical data with a particular focus on radar-data acquisition using a 35- and 60-MHz radio-
82 echo sounder developed at the Scott Polar Research Institute (Robin et al., 1970), and, in collaboration
83 with the Technical University of Denmark, using slightly improved versions of the same analogue
84 radar system until the early 1990s (Robin et al., 1977). The subsequent development of an in-house
85 digital radar system at BAS in 1993-94 (Corr and Popple, 1994), and accompanying gravity and
86 magnetic instruments, allowed for the first surveys over West Antarctica's Evans Ice Stream to be
87 conducted in 1994-95, marking the start of modern aerogeophysical surveying of the Antarctic by
88 BAS. Further improvements in survey techniques and instruments have allowed BAS to develop its
89 aerogeophysical capabilities further and become one of the leaders in aerogeophysics over the
90 Antarctic.

91 Since the mid-1990s, aerogeophysical datasets acquired by BAS have been playing a vital
92 role in understanding past and current ice-dynamical and lithospheric processes over the Antarctic Ice
93 Sheet. In total, BAS flew 24 survey campaigns between 1994 and 2020, representing a total of
94 ~450,000 line-km of aerogeophysical data over the Antarctic Peninsula and the West and East
95 Antarctic Ice Sheets (hereafter abbreviated to WAIS and EAIS respectively) (Fig. 1, Table 1). The
96 total cumulative survey coverage since 1994 is 5.3 million km², equivalent to > 30 % of the total area
97 of the Antarctic Ice Sheet (14.2 million km²). Many of these surveys were acquired as part of large
98 international collaborative projects such as the International Polar Year AGAP project, the European
99 Space Agency (ESA) PolarGAP project, and the US-UK International Thwaites Glacier Collaboration
100 (ITGC), amongst others, while much of the data have been central to the output of large international
101 science groups, such as the SCAR-funded (Scientific Committee on Antarctic Research) BEDMAP
102 (I/II/III), ADMAP (I/II), AntArchitecture, and IBCSO projects (Arndt et al., 2013; Fretwell et al.,
103 2013; Golynsky et al., 2018; Lythe et al., 2001).

104

105 **Figure 1. Map showing all the published datasets included in this data release.** The colours are the
106 same as those used on the data portal interface. Abbreviations are as follows: EV: EVANS (1994-95); BC:
107 Black Coast (1996-97); CI: Charcot Island (1996-97); JRI: James Ross Island (1997-98); LA: Larsen Ice Shelf
108 (1997-98); DF: DUFEEK (1998-99); AC: AFI Coats Land (2001-02); M: MAMOG (2001-02); TO: TORUS

110 IMAGE (2006-07); AG: AGAP (2007-09); AD: Andriill HRAM (2008-09); AI: Adelaide Island (2010-11); IM:
111 IMAFI (2010-11); PI: Pine Island Glacier Ice Shelf (2010-11); IG: ICEGRAV (2012-13); F15: FISS 2015
112 (2015-16); PG: PolarGAP (2015-16); F16: FISS-EC-Halley 2016 (2015-16); T18: ITGC Thwaites (2018-19);
113 T19: ITGC Thwaites (2019-20). The background image is from the Landsat Image Mosaic of Antarctica
114 (LIMA; Bindschadler et al., 2008).

115 Despite the importance of these surveys to understanding the Antarctic cryosphere and
116 tectonics, until now the underlying data have been relatively inaccessible to the wider geophysical and
117 glaciological communities due to the scale of the data-management task required. As a result, this lack
118 of accessibility has hampered the ability of the wider research community to extract further valuable
119 information from these datasets. In 2020, a collaborative project between the UK Polar Data Centre
120 (PDC, <https://www.bas.ac.uk/data/uk-pdc/>) and the BAS Airborne Geophysics science team was set
121 up to improve the FAIR-ness (Findability, Accessibility, Interoperability and Re-Usability; Wilkinson
122 et al., 2016) of these data. The main objectives of this collaboration were to comply with national and
123 international policies on data sharing and accessibility, foster new collaborations, and allow the
124 further re-use of these data beyond the lifespan of the science projects.

125 This paper presents the result of this successful collaboration between data managers and
126 scientists to standardise and release most of BAS' aerogeophysical data acquired to date using modern
127 instruments from 1994 onwards. Data acquired prior to this, while particularly useful to long-term
128 monitoring of ice sheet conditions, are much more challenging and time-consuming to bring up to
129 modern standards (see Schroeder et al., 2019; Sect 5.3), and are thus not included in the data release
130 discussed here. Section 2 of this paper reviews the main scientific findings from each survey flown
131 between 1994 and 2020. Section 3 describes the various instruments and techniques used to acquire
132 and process the data. Section 4 outlines the format and data publishing strategy for our datasets
133 following the FAIR data principles, as well as the creation of a new data portal and interactive, open-
134 access tutorials. Finally, Section 5 discusses potential avenues for future data analyses, focusing
135 primarily on extracting further information from the radar data.

136

137 2. Background

138 The following section reviews the main scientific findings related to the acquisition of
139 aerogeophysical data from BAS for the period 1994-2020 and is divided into two sections: findings
140 from surveys conducted pre-2004 using older aerogeophysical instruments, and surveys conducted
141 post-2004 using the PASIN- (Polarimetric Airborne Survey INstrument) 1 (2004-2015) and PASIN-2
142 (2015-2020) radar systems and more modern data acquisition methods. Figures 2-3 demonstrate that
143 the surveys discussed in these sections have been used progressively to build up wide-ranging datasets
144 of gravity and magnetic anomalies, bed elevation and ice thickness, and 2-D radar profiles that we
145 release with this paper.

146 2.1. Aerogeophysical Surveys for the Period 1994-2004

147 The first surveys conducted by BAS since the mid-1990s involved extensive gravity and
148 magnetic surveying of the western and eastern Antarctic Peninsula and Weddell Sea Embayment.
149 Surveys over Evans Ice Stream (1994-95), Black Coast (1996-97), Charcot Island (1996-97), and
150 James Ross Island (1997-98) (Fig. 1, Table 1) provided new insights into the history of crustal
151 boundaries between the eastern Antarctic Peninsula and the Filchner Block (Ferris et al., 2002),
152 evidence of crustal thinning below Evans Ice Stream (Jones et al., 2002), and new understanding of
153 the magmatic and tectonic processes around the Mount Haddington stratovolcano on James Ross
154 Island (Jordan et al., 2009). A further study covering the Larsen Ice Shelf (Antarctic Peninsula) was
155 conducted conjointly by BAS and Instituto Antártico Argentino in 1997-98. The radar data acquired
156 during this survey was used in ocean (Holland et al., 2009) and firn-density (Holland et al., 2011)
157 models to improve our understanding of ice-ocean interactions and ice-surface elevation change on
158 the ice shelf. In 1998-99, extensive aeromagnetic surveying of the Dufek Massif (West Antarctica)
159 revealed the presence of a Jurassic dyke swarm that likely acted as a magma transport and feeder
160 system to the Ferrar Large Igneous Province (Ferris et al., 2003). In 2001-02, an additional survey
161 was flown over the Rutford Ice Stream basin as part of the TORUS (Targeting ice-stream Onset
162 Regions and Under-ice Systems) initiative, acquiring gravity, magnetic and radar data in a high-
163 resolution grid with ~10-km across-track spacing between radar lines. The SPARC (Superterranes of
164 the Pacific Margin Arc) campaign of 2002-03 over Northern Palmer Land (Antarctic Peninsula) used
165 gravity and magnetic instruments to reveal subglacial imprints of crustal growth linked with the
166 Gondwana margin (Ferraccioli et al., 2006).

167 Over East Antarctica, two surveys conducted in 2001-02 acquired detailed gravity, magnetic
168 and radar measurements over Slessor Glacier (AFI; Antarctic Funding Initiative Coats Land survey)
169 and Jutulstraumen Ice Stream (MAMOG; Magmatism as a Monitor of Gondwana break-up). The AFI
170 Coats Land survey provided the first accurate measurements of ice thickness and bed elevation in the
171 area (Rippin et al., 2003a) (Fig. 2), and led to the discovery of a ~3-km thick sedimentary basin

172 associated with a weak till layer at the bed which enhances basal motion and affects the flow regime
 173 of this part of the EAIS (Bamber et al., 2006; Rippin et al., 2003a; Shepherd et al., 2006). The
 174 MAMOG survey revealed the presence of a subglacial Jurassic continental rift in the area of western
 175 Dronning Maud Land, providing early evidence for the initial Gondwana break up (Ferraccioli et al.,
 176 2005a; 2005b).

177 2.2. Aerogeophysical Surveys for the Period 2004-2020

178 Building from the surveys prior to 2004 which were relatively small in coverage, BAS began
 179 surveying larger areas from the mid-2000s onwards (Table 1), primarily due to enhanced international
 180 collaborations and improvements in data acquisition and instruments which led to data being acquired
 181 both at higher resolution and over larger spatial scales (Fig. 4-5). The acquisition strategy was to
 182 collect data from multiple geophysical sensors mounted on BAS' Twin Otter aircraft across every
 183 survey, giving a holistic view of vast and previously unsurveyed regions. The core sensor suite
 184 included gravity and magnetic instruments used to understand the sedimentary nature of the basins
 185 and their tectonic structure, alongside the radar system used to map ice thickness and bed
 186 elevation. The development of a new radar system, the Polarimetric Airborne System Instrument
 187 (PASIN) (PASIN-1, 2004-2015) (see Sect. 3.1.3), and an improved version of the same system
 188 (PASIN-2, 2015-16 onwards), allowed for the efficient collection of high-quality digital radar data for
 189 BAS-led campaigns in the Antarctic.

190 We describe the findings from these surveys in more details below, starting with the
 191 campaigns conducted between 2004-2015 (Sect. 2.2.1), and then followed by the campaigns
 192 conducted between 2015-2020 (Sect. 2.2.2).

193 2.2.1 2004-2015

194 The first mission to utilise the PASIN-1 radar system was the 2004-05 BBAS survey of Pine
 195 Island Glacier (Vaughan et al., 2006). This survey provided two key findings: a) the discovery of a
 196 deep subglacial trough, 500 m at its deepest point and 250 km long, through which Pine Island Glacier
 197 flows; and b) the existence of well-constrained valley walls which would likely provide a buffer
 198 against a potential catastrophic collapse of the WAIS via Pine Island Glacier (Vaughan et al., 2006).
 199 Further studies utilising this dataset focused primarily on bed characteristics and the subglacial
 200 hydrology of the catchment (Chu et al., 2021; Napoleoni et al., 2020; Rippin et al., 2011), as well as
 201 tracking englacial layers and quantifying past-accumulation rates (Bodart et al., 2021; Corr and
 202 Vaughan, 2008; Karlsson et al., 2009; 2014). The survey was also conducted simultaneously with
 203 another covering the Thwaites Glacier catchment led by the University of Texas Institute for
 204 Geophysics and the National Science Foundation of the United States (Holt et al., 2006), enabling a
 205 comparison of the surveying capabilities where the surveys overlapped (e.g. Chu et al., 2021).

206 **Table 1. Information on the period, region, sub-region, type of data acquired, total line-coverage**
 207 **(km), total coverage area (km²), and key reference for each survey included in this data release.** For
 208 "Data", the abbreviations are as follows: Gravity (G), Magnetic (M), Radar (R). For "Regions", abbreviations
 209 are as follows: APIS (Antarctic Peninsula Ice Sheet), EAIS (East Antarctic Ice Sheet), WAIS (West Antarctic
 210 Ice Sheet). "DML" stands for Dronning Maud Land and "PIG" for Pine Island Glacier. The total area in km² is
 211 calculated as a cumulative total area of the spatial footprint of the survey's minimum and maximum extent.

212

213 Following on from the BBAS survey, the suite of geophysical instruments on board the BAS
 214 Twin Otter aircraft were used to survey Wilkes Subglacial Basin, Dome C, and the Transantarctic
 215 Mountains as part of the 2005-06 WISE-ISODYN survey between BAS and the Italian Programma

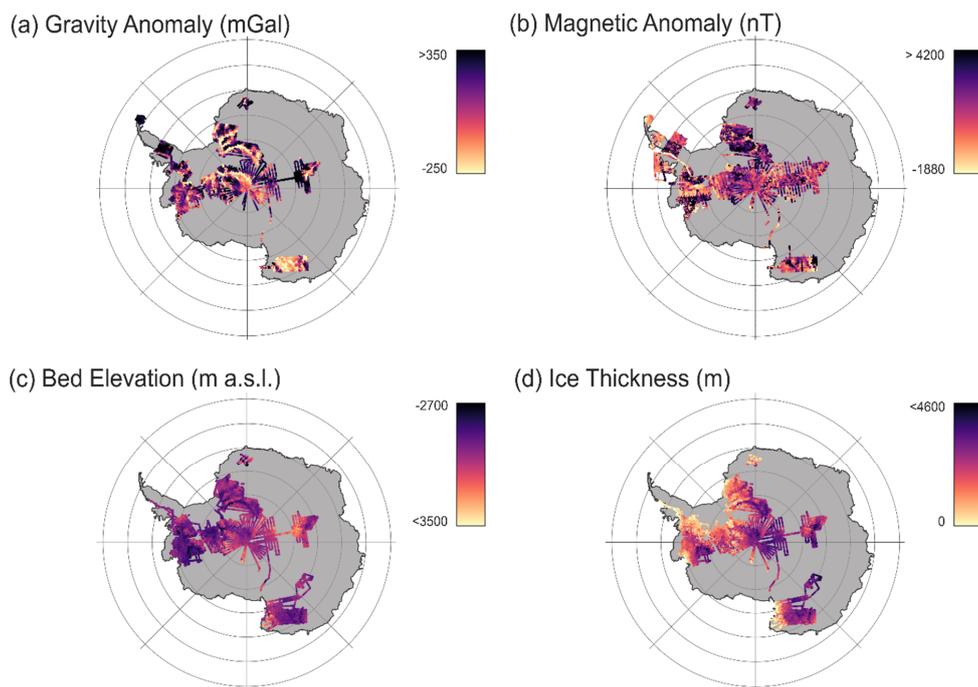

216 Nazionale di Ricerche in Antartide (Bozzo and Ferraccioli, 2007; Corr et al., 2007; Ferraccioli et al.,
217 2007; Jordan et al., 2007). This project revealed, for the first time, the crustal architecture of the
218 Wilkes Subglacial Basin (Ferraccioli et al., 2009; Jordan et al., 2013) and the distribution of a well-
219 preserved subglacial sedimentary basin underlying the Wilkes catchment (Frederick et al., 2016). The
220 following year, the 2006-07 GRADES-IMAGE (Glacial Retreat in Antarctica and Deglaciation of the
221 Earth System - Inverse Modelling of Antarctica and Global Eustasy) survey, comprising surveys over
222 the transitional area between the Antarctic Peninsula and the WAIS, provided detailed information on
223 subglacial properties of Evans Ice Stream (Ashmore et al., 2014), ice-thickness measurements along
224 the grounding line were used as key calibration for the Landsat-derived “ASAIID” grounding-line
225 product (Bindschadler et al., 2011), and englacial layers through Bungenstock Ice Rise were used to
226 assess ice-divide stability and the wider ice-flow history and stability of the WAIS’s Weddell Sea
227 sector during the Holocene (Siebert et al., 2013).

228 Over two austral field seasons from 2007 to 2009, the AGAP (Antarctica’s Gamburtsev
229 Province Project) survey, coordinated as part of the fourth International Polar Year between the UK,
230 USA, Germany, Japan, Australia and China, comprised a comprehensive survey of the interior of the
231 EAIS, yielding important aerogeophysical data used to interrogate the origin and geophysical
232 characteristics of the Gamburtsev Subglacial Mountains. Significant scientific discoveries generated
233 by the AGAP survey included observations of widespread freeze-on at the bottom of the ice which
234 leads to thickening of the EAIS from the base (Bell et al., 2011), a thick crustal root formed during the
235 Proterozoic aeon (1 Gyr ago) surrounded by a more recent ~2,500-km-long rift system (Ferraccioli et
236 al., 2011), and the existence of ancient pre-glacial fluvial networks at the present ice bed which
237 confirmed the presence of the Gamburtsevs prior to the start of glaciation at the Eocene–Oligocene
238 climate boundary (ca. 34 Ma) (Creys et al., 2014; Rose et al., 2013).

239 Between 2008 and 2011, three surveys utilised the magnetic and radar instruments on board
240 the BAS Twin Otter to conduct high-spatial resolution surveying of Coulman High on Ross Ice Shelf
241 as part of the ANDRILL HRAM (Antarctic Drilling - High Resolution Aeromagnetic) project,
242 Adelaide Island (Antarctic Peninsula), and Pine Island Glacier Ice Shelf (West Antarctica). The 2010-
243 11 Adelaide Island survey provided high-resolution aeromagnetic data to underpin a better
244 understanding of the complex magmatic structure of the Antarctic Peninsula Cenozoic arc/forearc
245 boundary (Jordan et al., 2014). The Pine Island Glacier Ice Shelf survey of the same year revealed a
246 network of sinuous subglacial channels, 500- to 3000-m wide and up to 200-m high, in the ice-shelf
247 base, which, combined with surface and basal crevasses formed as a result of the basal melting, could
248 lead to structural weakening of the shelf in the future (Vaughan et al., 2012).

Figure 2. Maps of gravity, magnetic, and radar (bed elevation and ice thickness) point measurements for all surveys published as part of this data release. (a) Gravity anomaly points (in milligal, or mGal), (b) Magnetic anomaly points (in nanotesla, or nT), (c) Bed elevation points from radar data (in metres above sea level, or m a.s.l.), (d) Ice thickness points from radar data (metres). In total, this data release contains 3.62 million gravity, 7.41 million magnetics, and 14.5 million ice-thickness and bed-elevation data points. Note that no correction such as downward continuation has been applied to compile the gravity data shown in (a).

258

259

260

The early 2010s saw the deployment of the PASIN system used as part of two large collaborative projects, namely the 2010-11 Institute-Möller Antarctic Funding Initiative (IMAFI) survey over Institute and Möller ice streams of West Antarctica, and the 2012-13 ICEGRAV survey over the Recovery and Slessor region of East Antarctica.

267

268

269

270

271

272

273

274

The 2010-11 IMAFI project was designed to assess the ability of the subglacial sedimentary structure to control the flow of two large ice streams draining the WAIS into the Weddell Sea Embayment, and the potential stability of this sector of West Antarctica (Ross et al., 2012). Radar data revealed the presence of a reverse-bed slope with a 400-m decline over a 40-km distance away from the grounding line and that this region was relatively close to flotation, indicating the potential instability of this sector in the light of future grounding-line migration upstream of its current position (Ross et al., 2012). Additional analysis using gravity and magnetic data revealed the extent of the Weddell Sea Rift, adding further evidence for the early-stages of Gondwana break-up and Jurassic extension in the region (Jordan et al., 2013). Further analysis of the radar data acquired during the IMAFI survey led to a new digital elevation model of the bed underlying the ice streams of the Weddell Sea Embayment at 1-km resolution, revealing deep subglacial troughs between the ice-sheet interior and the grounding line and well-preserved landforms associated with alpine glaciation (Jeofry et al., 2018; Ross et al., 2014), as well as evidence for a temperate former WAIS via the discovery of extensive subglacial meltwater channels (Rose et al., 2014). The data have also been used to assess

275 bed roughness (Rippin et al., 2014) and englacial properties across the catchment in order to elucidate
276 past ice-flow dynamics (Ashmore et al., 2020; Bingham et al., 2015; Winter et al., 2015).

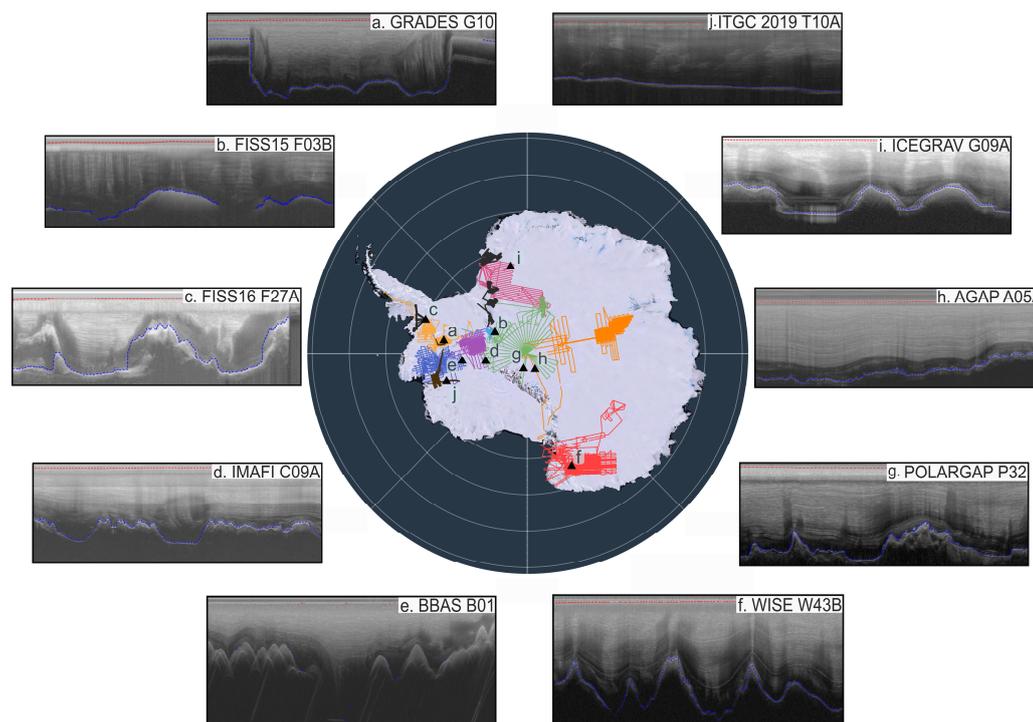

277 The 2012-13 ICEGRAV survey, the product of an international collaboration between BAS
278 and the Technical University of Denmark, National Science Foundation, Norwegian Polar Institute,
279 and the Instituto Antártico Argentino, carried out aerogeophysical surveys over the poorly explored
280 Recovery Glacier catchment and Recovery Subglacial Lakes (Forsberg et al., 2018), revealing a deep
281 800-km trough underlying Recovery Glacier, with evidence for subglacial water controlling the fast
282 flow in the upstream portion of the ice stream (Diez et al., 2018).

283 2.2.2 2015-2020

284 The 2015-16 PolarGAP survey, the first to deploy a further upgraded radar system, PASIN-2
285 (see Sect. 3.1.3), was a major international collaboration funded by the European Space Agency
286 (ESA) and led by BAS, Technical University of Denmark, Norwegian Polar Institute and the National
287 Science Foundation designed primarily to fill a gap in global gravity surveying that the European
288 Space Agency GOCE (Gravity field and steady-state Ocean Circulation Explorer) satellite network
289 was unable to cover. Alongside the large swath of gravity surveying, opportunistic magnetic and radar
290 data were also acquired over the South Pole and parts of Support Force, Foundation, and Recovery ice
291 streams. Additional funding from the Norwegian Polar Institute also allowed for a number of
292 dedicated flights over the subglacial Recovery Lakes. The acquired data have led to major scientific
293 findings, such as the presence of anomalously high geothermal heat flux near the South Pole (Jordan
294 et al., 2018) and the delineation of two active subglacial lakes (Recovery Lakes A and B) totalling
295 ~4,320 km² in size and composed of saturated till, with evidence of bed lubrication and enhanced flow
296 downstream of their location as a result of water drainage (Diez et al., 2019). Additional evidence
297 showed that the Pensacola-Pole Basin is characterised by a topographic depression of ~0.5 km below
298 sea level and contains a thick sedimentary layer of 2-3 km in the southern part of the catchment
299 (Paxman et al., 2019). The radar data from the PolarGAP survey have also revealed large troughs at
300 the bottleneck between East and West Antarctica, suggesting that drawdown of the EAIS via the
301 WAIS is unlikely (Winter et al., 2018).

302 In the austral summers of 2015-16 and 2016-17, two surveys were flown as part of the
303 Filchner Ice Shelf System (FISS) project with support from the Alfred-Wenger Institute, Germany,
304 with the aim to investigate the potential contribution of the Filchner Ice Shelf system to sea-level rise.
305 The 2015-16 survey acquired ~7,000 line-km of aerogeophysical data over Foundation Ice Stream and
306 Bungenstock Ice Rise. In 2016-17, ~26,000 line-km of aerogeophysical data were acquired over
307 Filchner and Brunt ice shelves (West Antarctica), as well as over outlet glaciers of English Coast
308 (western Palmer Land, Antarctic Peninsula). Early findings from the 2016-17 aerogeophysical survey
309 revealed subglacial drainage channels beneath Support Force Glacier (Hofstede et al., 2021), provided
310 evidence for a large ~80 x 30 x 6 km mafic intrusion likely resulting from mantle melting during
311 Gondwana break-up (Jordan and Becker, 2018), and helped to delineate the subglacial bathymetry
312 beneath Brunt Ice Shelf (Hodgson et al., 2019).

313 During the 2018-19 and 2019-20 seasons, BAS was involved in aerogeophysical surveying of
314 Thwaites Glacier as part of the UK-US International Thwaites Glacier Collaboration (ITGC)
315 initiative. The 2018-19 survey acquired ~9,900 km of aerogeophysical data over lower Thwaites
316 Glacier and Thwaites Glacier Ice Shelf, and the 2019-20 survey acquired ~4500 line-km over lower
317 Thwaites Glacier, the WAIS Divide ice-core site, and Rutford Ice Stream. These surveys contributed
318 to a new bathymetric map of Thwaites, Crosson and Dotson ice shelves from gravity measurements,
319 revealing a deep (>800 m) marine channel extending beneath the ice shelf adjacent to the front of
320 Thwaites Glacier (Jordan et al., 2020). These datasets have also contributed to a new bathymetry
321 model of George VI Sound (Constantino et al., 2020) and Thwaites Glacier (Hogan et al., 2020).

322

323 **Figure 3. Sample radargrams from the ten 2-D radar datasets released with this paper.** The
324 colours for each survey on the map are the same as in Fig. 1 and the data portal. The location of each radargram
325 (a-j) is marked on the map by black triangles. The red and blue dashed lines on the radargrams are the surface
326 and bed picks respectively. A description of each radargram is provided as follows: (a) Flightline G10
327 (GRADES-IMAGE) showing well-defined subglacial valleys through which Evans Ice Stream flows (ice flow is
328 approximately out of page), with stable layering at the onset and in the middle of the topographic low; (b)
329 Flightline F03B (FISS 2015) showing undulating bed topography and disrupted layering at the onset of
330 Foundation Ice Stream; (c) Flightline F27A (FISS 2016) showing variations in subglacial topography at the
331 divide between the Antarctic Peninsula and West Antarctica, with potential evidence of basal freeze-on at the
332 start of the segment; (d) Flightline C09A (IMAFI) showing evidence of preserved layering despite changes in
333 local topography at the bottleneck between East and West Antarctica; (e) Flightline B01 (BBAS) over Ellsworth
334 Subglacial Mountains showing a ~1.5 km trough in the ice sheet bed and one of the deepest points in the PIG
335 basin with ~3km of ice underlying the surface; (f) Flightline W43B (WISE-ISODYN) showing internal layers
336 draping over the highs and lows in the local Wilkes Subglacial Basin topography, with two particularly bright
337 reflectors in the middle and bottom of the ice column; (g) Flightline P32 (PolarGAP) showing the onset of a
338 topographic high near the Transantarctic Mountain Range with internal layering visible down to the ice-bed
339 interface; (h) Flightline A05A (AGAP) showing stable internal layering characteristic of the interior of the
340 EAIS; (i) Flightline G09A (ICEGRAV) showing evidence of a bright reflector likely associated with a
341 previously unidentified subglacial lake in the region; and (j) Flightline T10A (ITGC 2019) showing a section of
342 inland-sloping bed from a profile in the main trunk of Thwaites Glacier, >200 km from the current grounding
343 line position (ice flow is right to left).

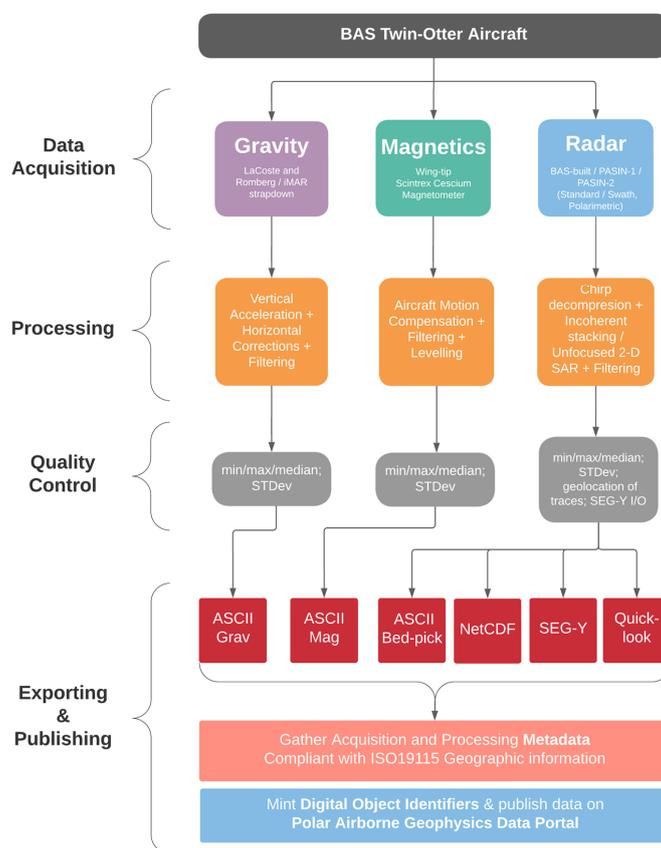

344

345 3. Data Acquisition and Processing

346 The typical acquisition and processing workflow for the aerogeophysical data is shown in
347 Figure 4. Generally, the aircraft is set up systematically to acquire gravity, magnetic, and radar data
348 together, except in situations where surveying objectives are not compatible with the acquisition of all

349 three datasets at once (i.e. flying at constant terrain clearance for the radar data affects the quality of
 350 the gravity data which is better flown at constant altitude, and vice-versa); although novel gravity-
 351 acquisition methods are increasingly making this issue redundant (see 3.1.1). As shown in Table 1, the
 352 conventional gravity-magnetic-radar set-up was used in 19 out of 24 surveys, with the remaining 6
 353 campaigns using either a magnetic-radar- or gravity-magnetic-only set-up. The data acquisition steps
 354 for each type of data are described in Sect. 3.1, and the processing of the data is described in Sect. 3.2.

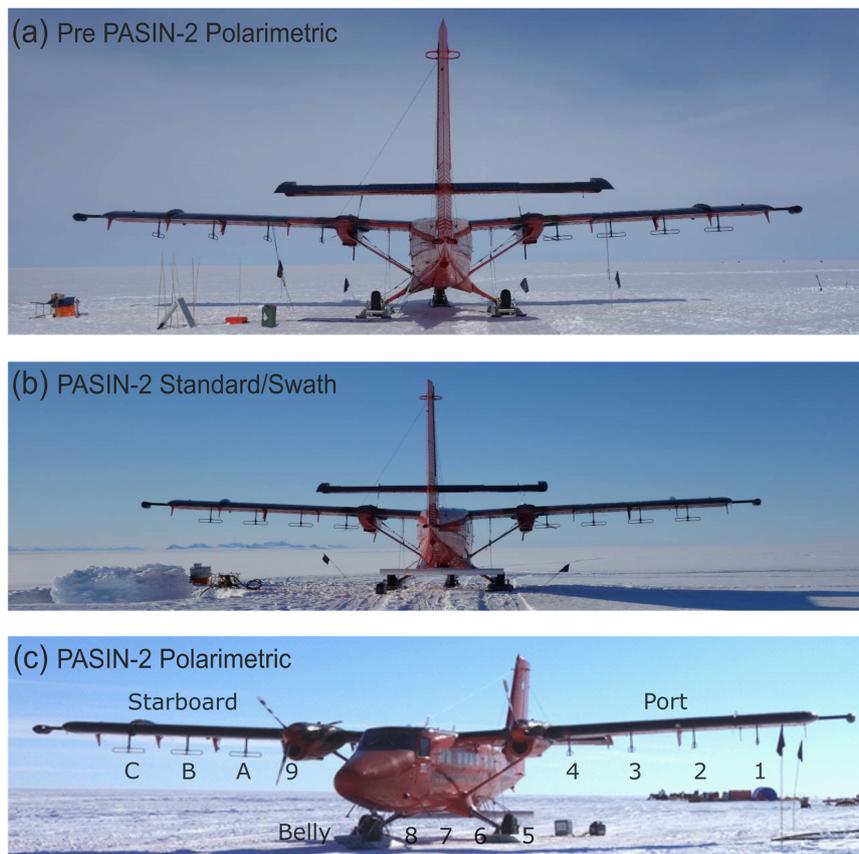

355

356 **Figure 4. Workflow describing the data acquisition, processing, and publishing for the BAS**
 357 **aerogeophysical data included in this data release.** “STDev” stands for standard deviation, whilst “I/O” refers
 358 to the output of the SEG-Y files and the import of the files into seismic-interpretation software for quality check.

359 3.1. Data Acquisition and Instrumentation

360 All of BAS aerogeophysical data acquisition is conducted using Twin Otter aircraft due to
 361 their remote capabilities, long fuel range (up to 1,000 km), and operability. The aircraft’s twin turbo-
 362 prop engines enable it to conduct rapid take-off and landing and operate in small and remote airfields
 363 commonly covered in snow and icy terrains using mounted skis. All data acquisition since the early
 364 1990s has been conducted using the BAS DeHavilland Twin Otter aircraft “VP-FBL” (Fig. 5). The
 365 aircraft typically flies at a nominal speed of ~60 m/s, which results in an along-track distance between
 366 each stacked radar trace of 0.2 m (prior to processing). The following sections describe the acquisition
 367 of the data for the gravity (3.1.1), magnetic (3.1.2), radar (3.1.3), and GPS and lidar (3.1.4)
 368 instruments on board the aircraft.

369

370 **Figure 5. Photographs of the aerogeophysical set-up on the BAS Twin Otter aircraft “VP-FBL”**
371 **for PASIN-2.** The radar antennae and wing-tip magnetometers are visible on the wings. (a) The pre-PASIN-2
372 (used in 2015-16 PolarGAP only) configured to mimic the set-up of PASIN-1 data collection in polarimetric
373 mode. The eight folded dipole transmitting and receiving antennae are fixed under the wings (two transmit and
374 two receive antennae on each wing) with the port configured as V (vertical) and starboard as H (horizontal). (b)
375 The PASIN-2 set-up in standard/swath mode. The twelve folded dipole transmitting and receiving antennae are
376 fixed under the wings and inside the aircraft and are operated using an RF (Radio Frequency) switch, and an
377 additional four receiving antennae are situated in the belly enclosure. When in standard swath mode, all
378 antennae are configured in H orientation with the starboard and belly antennae also in H orientation. The
379 PASIN-1 set-up in standard mode (not shown here) had a similar configuration as shown in (b) bar the belly
380 antenna (i.e. only four transmit on port and four receive on starboard in H orientation) (c) The PASIN-2 set-up
381 in polarimetric mode. The twelve folded dipole transmitting and receiving antennae are fixed under the wings
382 and inside the aircraft and are operated using an RF switch, and an additional four receiving antennae are
383 situated in the belly enclosure. When in polarimetric mode, the port antennae are configured in V orientation
384 and the starboard and belly antennae in H orientation. The PASIN-1 set-up in polarimetric mode (not shown
385 here as rarely flown) had the two pairs of outboard antennas rotated to V and the inboard in H configuration.
386 Photo credit: Carl Robinson.

387 **3.1.1 Gravity**

388 Until 2012, BAS aerogravity measurements were acquired with a LaCoste and Romberg air-
389 sea gravimeter modified by Zero Length Spring Corporation (ZLS). The gravimeter was mounted in a
390 gyro-stabilised, shock-mounted platform at the centre of the aircraft to minimise the effect of
391 vibrations and rotational motions.

392 Starting with the 2015-16 PolarGAP survey, aerogravity data began to be acquired using a
393 novel strapdown method which, unlike traditional surveys using a stabilised gravity platform, allow
394 for the collection of gravity data during draped or turbulent flights (Jordan and Becker, 2018). For this
395 survey, both the LaCoste and Romberg and the strapdown systems were operated together with results
396 from the two systems merged to provide an optimum data product with the long-term low and
397 predictable drift of the LaCoste and Romberg system and dynamic stability of the strapdown system.
398 Subsequent surveys used a strapdown sensor alone, removing the need to prioritise the quality of the
399 gravity data over the radar data and allowing for flights at a constant terrain clearance for optimal
400 radar-data collection. The optimum resolution of the system is approximately 100 s along-track
401 (Jordan and Becker, 2018).

402 The first strapdown sensor deployed by BAS was the iMAR RQH-1003 provided by
403 Technical University (TU) Darmstadt, and consisting of three Honeywell QA2000 accelerometers
404 (mounted in mutually perpendicular directions) and three Honeywell GG1230 ring laser gyroscopes.
405 The subsequent 2018-19 and 2019-20 ITGC surveys over Thwaites Glacier used the iMAR iCORUS
406 strapdown airborne gravimeter systems from Lamont-Doherty Earth Observatory and BAS
407 respectively, which have approximately equivalent internal components to the TU Darmstadt system.

408 **3.1.2 Magnetics**

409 The Twin Otter is configured for fixed wing magnetometer operation. The aircraft
410 modifications include inboard-positioned wingtip fuel pumps, pod-boom hard points and a
411 demagnetised airframe to maximise magnetic-data collection. Scintrex CS3 Cesium sensors are used
412 due to their high sensitivity, high cycling rates, excellent gradient tolerance, fast response and low
413 susceptibility to the electromagnetic interference. The resolution of the magnetometers has greatly
414 increased over time, with the current systems having a measurement accuracy of 0.2 pT compared
415 with the older systems used between 1991-2003 (10 pT; Sintrex H8 Cesium) and 1973-1990 (500 pT;
416 Geometrics G-803 Potassium).

417 **3.1.3 Radar**

418 Prior to 2004, BAS deployed a custom-built, 8-array element radar system, referred here as
419 “BAS-built” (Corr and Popple, 1994). This was a coherent radar system operating at a centre
420 frequency of 150 MHz and using a transmit power of 1,200 W (Rippin et al., 2003a). The radar
421 system was equipped with eight folded dipole transmitting and receiving antennae fixed under the
422 wings (four transmitting on port wing, four receiving on starboard wing). Similar to the current
423 systems, the “BAS-built” system transmitted both a conventional narrow-sounding pulse mode of
424 0.25 μ s and a deep-sounding 4 μ s, 10-MHz chirp (Table 2). As developments in digital acquisition
425 became commercially available, several technical upgrades were applied to the radar system. These
426 ranged from using a LeCroy scope to acquire logarithmic detected waveforms to complex coherent
427 acquisition, as well as the replacement of the LeCroy oscilloscope by a low sample-frequency 12-bit
428 dual ADC (analogue-to-digital converted) card in the later years of operation (see Fig. S1). During
429 this time, the dynamic range of the system was extended by the interleaved transmission of different
430 waveform, which were conventional short wavetrain pulses at the centre frequency.

431 After operating for ten successive field seasons, the “BAS-built” radar system was retired and
432 replaced by a more modern radar system, the Polarimetric Airborne Survey Instrument (PASIN). In
433 contrast to the “BAS-built” system, PASIN was designed to sound ice much deeper (up to 5 km
434 compared with 3.3 km for the earlier system) thanks to improved digital electronics and added power

435 in the transmitting antennae (see Table 2). Additionally, the modern digitisation enabled by the use of
436 ADC cards rather than a digitising scope allowed phase and not just power to be recorded in greater
437 resolution on PASIN, which eventually allowed for the use of more advanced processing techniques
438 such as Synthetic-Aperture-Radar to be applied to the data (see Sect. 3.2.3).

439 The older PASIN-1 (2004-2015) and the newer PASIN-2 (2015-Present) systems are bi-static
440 radars operating at a 150-MHz centre frequency and configured as follows: (a) PASIN-1: 10-MHz
441 bandwidth system with eight folded dipole transmitting and receiving antennas fixed under the wings
442 (four transmitting on port wing, four receiving on starboard wing) operating in H (horizontal)
443 orientation when in standard mode and more rarely with the port (transmit) and starboard (receive)
444 antennae positioned in both H and V (vertical) orientation when in polarimetric mode (see similar
445 PASIN-2 set-up in Fig. 5a); and (b) PASIN-2: 13-MHz bandwidth system with twelve folded dipole
446 transmitting and receiving antennas fixed under the wings and inside the aircraft and operating using
447 an RF switch and an additional four receiving antennae in the belly enclosure (see Fig. 5b-c; Table 2).
448 When in standard/swath mode, the antennae are configured in H orientation (Fig. 5b), whereas in
449 polarimetric mode the port antennae are configured in V orientation and the starboard and belly
450 antennae in H orientation (Fig. 5c). The main difference between the PASIN-1 and -2 systems is the
451 ability for across-track swath processing to be applied to the PASIN-2 data by allowing both transmit
452 and receive on the folded dipole antenna via the use of RF switches.

453 In further contrast with PASIN-1, the PASIN-2 radar has a very flexible configuration, with
454 the standard configuration being a twelve channel swath radar (with eight transmit and twelve
455 receive). However, other configurations are also possible, including a polarimetric mode to give H
456 and V data where the port antennas are rotated 180 degrees (see Table S1). A final configuration is a
457 mixed antenna gain path for areas where ice is heavily disrupted where the starboard signal can be
458 attenuated by several decibels. Since 2016, the radar system has undergone minor modifications to
459 reduce noise and improve system operations, including low-pass filters in the RF switches, the use of
460 a 10-GHz waveform generator, and new 1 kW solid-state power amplifiers which have lowered
461 transmit system noise and increased transmitter and receiver isolation.

462 Data are received using sub-Nyquist digitisation and stacking and stored on removable solid-
463 state disks or tapes, and then copied to duplicate spinning disks for data archiving. On average, a 4.5-
464 hour flight will generate ~150-200 GB of data for PASIN-1 and up to 3 TB of data for PASIN-2. The
465 systems systematically acquire a shallow-sounding 0.1 μ s pulse (PASIN-1) / 1 μ s short-attenuated
466 chirp (PASIN-2), and a deep-sounding 4 μ s, 10- (PASIN-1) /13- (PASIN-2) MHz linear chirp (Table
467 2). The shallow-sounding pulse/short-attenuated chirp product is best used to assess internal layering
468 in the upper ~1.5-2 km of the ice sheet, whereas the deeper-sounding chirp is best suited to assess
469 englacial layering and bed characteristics in deep-ice conditions (Fig. 6 a-b). The radar is capable of
470 sounding ice to depths of up to 5 km with a horizontal resolution of 10 cm (before processing) and a
471 depth resolution in the vertical direction of 8 m.

472 **Table 2. Radar Parameters for the three radar systems deployed by BAS between 1994 and the**
473 **Present.** Note that PASIN-1/2 have a number of programmable settings for flight-specific objectives (e.g. 1 to 8
474 waveforms programmable for PASIN-2), and the numbers provided here are for the most commonly used
475 settings. For PASIN-2, a standard set-up consists of 5 waveforms as follows: 4 μ s H (0°), 4 μ s V (0°), 4 μ s H
476 (90°), 4 μ s V (90°), 1 μ s H (Table S1). Abbreviations in the table are as follows: ADC = Analogue to Digital
477 Converter; FPGA = Field Programmable Gate Array; SF = Sample Frequency; SI = Sample Interval; PRF =
478 Pulse-Repetition Frequency; PRI = Pulse Repetition Interval. *BAS-built and PASIN-1 systems used RF
479 combiners on the receiver to produce a single RF input-to-sample, with PASIN-1 splitting these into a high and
480 low gain channel for standard mode (2 ADC channels) and combining these for pairs of H and V in polarimetric
481 mode (4 ADC channels). **Radar Range Resolution is calculated using a radiowave velocity in ice of 168
482 m/microseconds and does not include the effect of the processing on the vertical resolution of the system which
483 is expected to be ~50% greater than the values provided in the table, thus these numbers should be interpreted as

484 the theoretical system performance. Diagrams showing the configurations of the three radar systems are
 485 provided in the Supplementary Information (Figures S1-3).

Radar Parameters	BAS-built (1994-2004)	PASIN-1 (2004-15)	PASIN-2 (2015-Present)
Antennae Configuration	8x folded dipole (4 Tx / 4 Rx)*	8x folded dipole (4 Tx / 4 Rx)*	12x folded dipole + 4x belly (12 Tx/Rx / 4 Rx only)
Centre Frequency	150 MHz	150 MHz	150 MHz
Transmitted Pulse Width	0.25 μ s (pulse) 4 μ s linear (chirp)	0.1 μ s (pulse) 4 μ s linear (chirp)	1 μ s (Tukey envelope chirp) 4 μ s linear (Tukey envelope chirp)
Chirp Bandwidth	4 MHz (pulse) 10 MHz (chirp)	10 MHz	13 MHz
Antenna Gain	11 dBi	11 dBi	11 dBi
PRF / PRI	20,000 Hz (PRI: 50 μ s)	15,635 Hz (PRI: 64 μ s)	15,635 Hz (PRI: 64 μ s)
Peak Transmit Power	300 W / antennae (1.2 kW total)	1 kW / antennae (4 kW total)	1 kW / antennae (8 kW total)
Receiver SF	25 MHz (scope max single shot)	88 MHz	120 MHz
Receiver FPGA decimation	-	4	-
Receiver Effective SF	25 MHz (SI: 40.0 ns)	22 MHz (SI: 45.5 ns)	120 MHz (SI: 8.3 ns)
Receiver Trace Stacking	64	25 (standard) 50 (polarimetric)	25
Effective PRF (post- stacking)	312.5 Hz	312.5 Hz (standard 2 waveforms)	125.1 Hz (5 waveforms) 208.5 Hz (3 waveforms)
ADC Resolution	12-bit	14-bit	16-bit
Equivalent Sustained Data Rate per ADCs (FPGA)	100 MB/s	176 MB/s (standard) 352 MB/s (polarimetric)	960 MB/s (system: 2.88 GB/s)
Average Data Storage Rate for Full PRI	~1 MB/s	11 MB/s (maximum)	173 MB/s (all arrays)
Radar Range Resolution**	21.0 m (pulse) 8.4 m (chirp)	8.4 m	6.5 m

486

487 The pulse repetition frequency of the PASIN system is 15,635 Hz and hardware stacking is
 488 typically set to 25 in standard mode, which results in an effective pulse-coded waveform acquisition
 489 rate of 312.5 Hz for each transmit pulse (Table 2). The sample period is 64 μ s and the peak
 490 transmitted power of the radar system is 4 kW for PASIN-1 and up to 8 kW of possible power for
 491 PASIN-2 (1 kW through each transmitting antenna), or 66 dBm. Following stacking, the final
 492 sampling frequency of PASIN-1 is 22 MHz and PASIN-2 is 120 MHz (Table 2).

493 3.1.4 GPS and lidar

494 Since 1978, navigation has transitioned from basic aircraft data, imagery, and dead reckoning
 495 to more modern means, including the use of carrier-phase Global Positioning System (GPS) systems.

496 Between 1994 and 2004, the BAS Twin Otter aircraft was equipped with a Trimble GPS
 497 system (1994-95 surveys: Trimble 4000SSE; 1996-2003 surveys: Trimble 4000SSI). Since 2004, the

498 aircraft is equipped with two, 10-Hz GPS receivers (Leica 500 and ASHTEC Z12 for 2004-18
499 surveys; Javad Delta and Novatel Span for post-2018 surveys) installed on board the aircraft. On the
500 ground, two Leica 500 GPS base stations (replaced by Javad TRIUMPH-2 for post-2018 surveys) are
501 positioned and equipped with choke-ring antennas set up specifically to obtain an unobstructed view
502 of the sky above. Aircraft turns are typically limited to 10-degree banking angles in order to avoid
503 losing connection with the receivers on the ground. The estimated accuracy of the absolute position of
504 the aircraft is 10 cm or less, with the relative accuracy approximately one order of magnitude better.
505 Since 2010, the aircraft altitude and inertial information has been provided by an iMAR FSAS inertial
506 measurement unit (IMU), with the data logged on a Novatel Span receiver. Additional attitude
507 information from the strapdown gravity system is also available for post processing of other datasets.

508 For all modern surveys, the aircraft was also equipped with a Riegl Q240i-80 laser altimeter
509 system (or lidar) in the floor camera hatch to accurately detect the ice surface. The lidar data used for
510 correction of the radar data are typically extracted from the nadir point value with no correction for
511 aircraft altitude. The system has a repetition frequency up to 2 kHz which results in an along-track
512 measurement every 3 cm with an accuracy of up to 5 cm. The lidar is used up to altitudes of 700 m
513 and is constrained by cloud/fog-free conditions.

514 **3.2. Data Processing**

515 **3.2.1 Gravity**

516 The raw aerogravity data are processed to obtain levelled free-air gravity anomalies.
517 Although additional survey-specific processing might have been applied to the data, general
518 processing steps for the LaCoste and Romberg system include the calculation of the observed gravity
519 and a range of corrections and filtering functions as described in Jordan et al. (2007; 2010) and
520 Valliant (1992). In particular, corrections for vertical acceleration, Eotvos horizontal motion (Harlan,
521 1968), latitude (Moritz, 1980), and free air (Hackney and Featherstone, 2003) were applied to obtain
522 the final free-air anomalies before subsequent 9-12 km low-pass filtering. As the free-air values refer
523 to the WGS84 ellipsoid, they are defined in geodesy as gravity disturbance.

524 The strapdown gravity method adopted from 2015-onwards directly combined observations
525 of acceleration in all three axes, with orientation and GPS observations combined in a Kalman filter to
526 solve simultaneously for aircraft position and variations in Earth's gravitational field (Becker et al.,
527 2015). For subsequent strapdown-acquisition surveys, some amount of levelling/correction for
528 thermal drift are required. Spectral analysis suggests that the strapdown system can resolve
529 wavelengths on the order of ~5 km (Jordan et al., 2020). Error estimates for the gravity data can be
530 found in the respective survey metadata (see Table 3), or in specific studies utilising the BAS
531 aerogravity data (e.g. Ferraccioli et al., 2006; Forsberg et al., 2018; Jordan and Becker, 2018).

532 Additional processing has, at times, been applied, including the use of masks to remove
533 aircraft turns, start and end of lines, and other regions of noisy data, or producing an upward
534 continued free-air anomaly by upward continuing each line segment from the collected flight altitude
535 to the highest altitude in the survey. The first level of free-air anomaly for all published BAS data is
536 shown in Figure 2a, although it is worth noting that no correction such as downward continuation has
537 been applied to compile the data shown in Figure 2a. It is considered that at the scale of the map, the
538 vertical gradient of residual gravity anomalies at flight altitude is inferior to 2 mGal. Additionally, as
539 the gravity surveys are acquired over the ice sheet, the distance to the bedrock is not only dependent
540 on the flight altitude but also on the ice thickness.

541 **3.2.2. Magnetism**

542 The raw aeromagnetic data have been processed using the SCAR ADMAP2 data-release
543 protocols (Golynsky et al., 2018). Data were collected at 10 Hz, allowing for modelling and removal

544 of aircraft dynamic movements using a so-called compensation correction (Ferraccioli, et al. 2007).
545 This correction typically requires a dedicated calibration flight in the direction of the survey lines and
546 tie-lines to have been flown. For some surveys with radial design, or where magnetic-data acquisition
547 was opportunistic, logistical constraints meant no calibration flight could be conducted. In these cases,
548 the generally large depth-to-source due to the thick ice allowed for a 10- to 15-second filter to be
549 applied to minimise noise generated by aircraft motion without compromising the geological signal.
550 Given the redundancy of collecting 10 Hz (~6 m spaced) observations over thick ice, most surveys
551 were down-sampled to 1 Hz (~60 m) prior to further processing.

552 After magnetic compensation, the magnetic data were corrected for the International
553 Geomagnetic Reference Field (IGRF), which is a standard mathematical description of the Earth's
554 main magnetic field. Data impacted by operation of aircraft systems such as pumps and heaters were
555 manually determined. Typically such data were discarded, but survey design and lack of alternative
556 data sources mean that sometimes important signatures may be present. In some cases the
557 contaminated data were therefore corrected using an offset correction, accepting that the data segment
558 may be more noisy.

559 The data were then corrected for diurnal variations in the magnetic field using observations at
560 a fixed base station, typically filtered with a 30-minute filter to remove short-wavelength noises
561 potentially not seen on the aircraft. Further statistical levelling of the data based on internal
562 intersections and crossovers with previous surveys was carried out at times to remove systematic
563 errors associated with flight direction (i.e. heading corrections) and additional long-wavelength errors
564 associated with incomplete removal of diurnal variations. In some cases, continuation to a fixed
565 altitude above the ice-sheet bed and a final grid-based micro-levelling procedure was applied
566 (Ferraccioli et al. 1998). The magnetic anomaly map shown in Figure 2b provides an insight of the
567 data coverage and magnitude of magnetic data available. Errors in the data are typically presented as
568 the standard deviation of the crossover errors and can be found in the respective survey metadata (see
569 Table 3).

570 3.2.3. Radar

571 All data acquired with the earlier “BAS-built” radar system (1994-2004) were read using a C
572 code software to convert the LeCroy data to formats readable by Halliburton Landmark’s seismic-
573 processing software SeisSpace ProMAX, hereafter just referred as ProMAX. Basic processing was
574 applied to the data in the hardware analogue domain and later using ProMax, including power
575 normalisation and final SEG-Y export. Following the transition from the LeCroy oscilloscope to ADC
576 cards on the “BAS-built” system (see Sect. 3.1.3), MATLAB replaced the IDL language for data
577 processing.

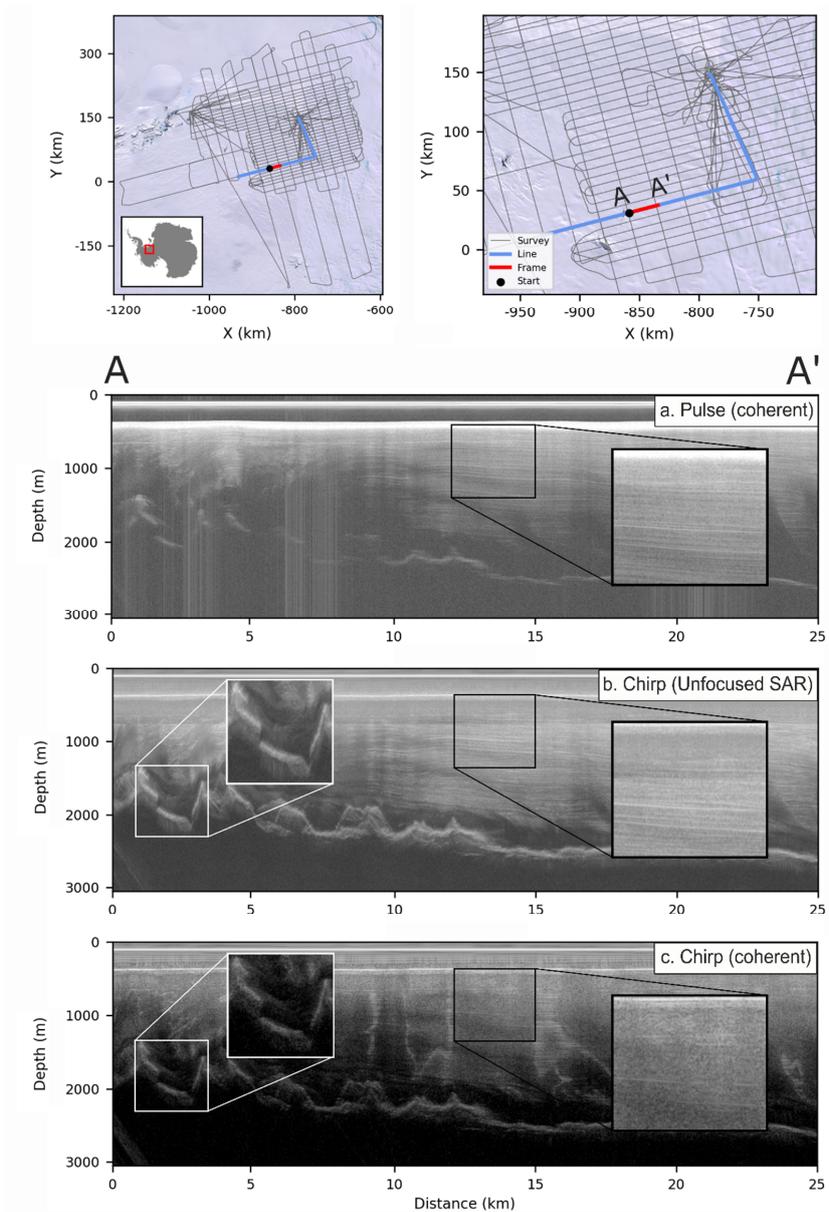

578 As opposed to the “BAS-built” system which, by design, had some level of processing done
579 on the raw data internally, the PASIN system is designed to retain much of the sampled data in the
580 rawest form possible to allow for evolving processing techniques to be applied to the data in the
581 future. For all PASIN data (2004-onwards), the first high-level step was to extract the raw data from
582 the tape drives, convert the three-byte values to conventional four-byte integers, combine the
583 waveforms associated with each pulse transmit type, and then export the data into MATLAB-
584 formatted binary files. Following on from this first step, a chirp-decompression technique using a
585 Blackman window to minimise sidelobe levels was applied using a custom-built MATLAB toolbox,
586 resulting in a processing gain of ~10 decibels (dB).

587 The next step was to apply processing techniques both to enhance along-track resolution and
588 improve the signal-to-noise ratio. For the 2004-05 BBAS survey, incoherent stacking of 10
589 consecutive traces was applied and a moving-average window filter used, however no Synthetic
590 Aperture Radar (SAR) techniques were applied to these data. First tested on previously acquired

591 PASIN radar data (Hélière et al., 2007), 2-D SAR processing based on the Omega-K algorithm and
592 subsequently improved versions using Doppler-beam sharpening were applied systematically to all
593 the deep-sounding chirp data from 2005-2006 onwards to increase spatial resolution and remove
594 backscattering hyperbolae in the along-track direction (Corr et al., 2007; Jeofry et al., 2018). The
595 benefit of using unfocused along-track SAR processing is that it resolves the bed in much finer detail
596 compared with non-SAR focused data (see Fig. 6 b-c); however SAR-processing can also lead to
597 distortions of the amplitude of the ice structure and bed reflection in unhomogenous areas of the ice
598 sheet (e.g. near grounding line; see Hélière et al., 2007) and thus might not always be appropriate for
599 assessing internal layering or absolute amplitudes such as required for bed-reflectivity analysis.
600 Additional moving-average filters of varying lengths have also been applied to enhance englacial
601 reflections and improve visualisation of the radar data.

602 Figure 6 shows the three processed radar products provided for the 2010-11 IMAFI survey
603 over West Antarctica, with Figure 6a showing the shallow-sounding pulse, and Figure 6b-c the deep-
604 sounding chirp radar data using the unfocused SAR-processing technique from Hélière et al. (2007)
605 (Fig. 6b) and a version of the chirp product processed with coherent summations but with no SAR-
606 processing applied (Fig. 6c). Internal layering is more clearly visible in the upper part of the ice
607 column on the pulse data compared with the chirp data (see black-bordered insets in Fig. 6a and 6c),
608 however deeper internal layering is much more visible on the SAR-chirp than the non-SAR chirp
609 (Fig. 6b-c). Additionally, the peak amplitude of the bed is better resolved in the SAR-processed chirp
610 than the non SAR-processed chirp (see white-bordered inset in Fig. 6b-c).

611

612 **Figure 6. A 25-km segment for flightline 15d of the 2010-11 IMAFI survey showing the three**
 613 **radar products and processing attributes.** The top two panels show an overview map of the entire survey
 614 with an inset over Antarctica and a zoomed-in map over the specific flightline with the 25-km radar segment
 615 (defined as A-A') shown in red. The background satellite image in the upper two maps is from the Landsat
 616 Image Mosaic of Antarctica (LIMA) (Bindschadler et al., 2008). The bottom three radargrams show a 25-km
 617 segment of the data for the three products provided for the 2010-11 IMAFI survey as follows: (a) the coherently
 618 processed, shallow-sounding pulse, (b) the unfocused 2-D SAR-processed, deep-sounding chirp, and (c) the
 619 coherently processed, deep-sounding chirp. The black-bordered insets zoom to the internal layering in the upper
 620 portion of the ice column for the three radar products and the white-bordered insets show the difference in bed
 621 characteristics between the two processed chirp products.

622 Note that further processing of the PASIN data has also been applied by others using simple
623 image-processing techniques such as moving-average filters to enhance the internal layering of the ice
624 and reduce incoherent noise (Ashmore et al., 2020; Bodart et al., 2021), or by applying more complex
625 SAR processing techniques such as over previously incoherently processed radar data (Chu et al.,
626 2021). Additional techniques have also been employed in areas where side-echos from steep valley
627 walls lead to ambiguous bed reflections and thus may affect ice thickness estimates, as previously
628 employed over Flask Glacier (Antarctic Peninsula) using PASIN SAR-processed data and a
629 combination of velocity and digital elevation models to obtain more accurate ice thickness estimates
630 (Farinotti et al., 2013).

631 Following on from the processing of the radar data, the last step was to “pick” the bed and
632 ice-surface reflectors. It is worth stating that picking the onset of the basal echo (i.e. where the echo
633 amplitude is greater than the noise floor) as done on the BAS data is not a universal method applied
634 by all institutes, who, may pick the half-amplitude delay or the peak value, leading in turn to
635 measurement biases across institutes and data products (e.g. Chu et al., 2021; Peters et al., 2005).

636 We picked the bed in ProMax, using a semi-automatic first-break pick algorithm on the chirp
637 data below a top-mute window (generally ~100 samples above the bed reflection) to locate the precise
638 bed return. This was followed by manual checks and re-picking to exclude any unrealistic spikes. In
639 areas where multiple closely spaced reflectors were sounded at the bed, the shallowest reflection was
640 assumed to be the bed as off-axis reflectors would likely appear lower down in this section. However,
641 in some cases, reflectors which appeared deeper were chosen, with shallower weak reflectors assumed
642 to reflect entrained debris, accreted ice, or uncompensated refraction hyperbolae close to the bed.

643 Since the PASIN system does not resolve the ice surface well due to errors in the phase centre
644 of the pulse in reflections from the firn layer, the surface reflector as imaged by the radar was only
645 rarely used on its own to calculate the actual ice surface location on the radargrams. However, to
646 estimate ice thickness and hence correct for bed elevation, the location of the surface reflector in the
647 radargram must be known accurately. Thus, range-to-surface from coincident on-board-acquired lidar,
648 or alternatively if lidar was not available (i.e., due to clouds or ground clearance higher than 750 m),
649 using surface elevation from an accurate Digital Elevation Model (DEM) (i.e. REMA 8-m DEM for
650 latest surveys; Howat et al., 2019), was used to calculate the “theoretical” surface pick, as follows:

651 Firstly, the same semi-automatic picker used for picking the bed was used on a subset of the
652 shallow-sounding pulse data with a bottom-mute window set at ~100 samples below the surface
653 reflection. Secondly, once aircraft-to-surface range was obtained from lidar, a linear trend between the
654 surface pick from the radar and the surface range from the lidar was calculated, and a resulting slope
655 and offset was used to calculate the theoretical location of the surface. Where possible, the range-to-
656 ground value was derived from the lidar data or interpolated from the mean lidar elevation within
657 ~700 m. In those rare cases where the surface reflection was picked directly from the radar, a
658 regression, local to the data gap, was used to fit the radar range to terrain clearance. For older surveys
659 where on-board lidar or accurate DEMs were not available to calculate range-to-ground, the height of
660 the aircraft above the surface was obtained by the aircraft’s radar altimeter which was then converted
661 into a radar delay time. This conversion was done after a two-stage calibration process which
662 involved recording the terrain clearance over a sea surface with the two instruments, and then
663 correction for the penetration depth of the radar altimeter was obtained from the difference in the
664 height above ellipsoid of a surveyed ‘flat’ snow surface and the aircraft. Where possible, the reference
665 surface was chosen to be in the centre of the targeted area.

666 Once bed and surface reflectors were picked, ice thickness was obtained by calculating the
667 difference between the bed and surface pick in range samples (relative to the BAS system). The
668 picked travel time was then converted to depth in metres using a radar wave speed of 168
669 m/microseconds and a constant firn correction of 10 m. Bed and surface elevations were then

670 integrated with a high-precision kinematic dual-frequency GPS position solution to provide the final
 671 point dataset of elevations relative to the WGS84 Ellipsoid. To ensure best accuracy of satellite-orbit
 672 definitions and atmospheric corrections, the interpolated survey locations and aircraft elevations were
 673 processed from 10-Hz coupled Precise Point Positioning (PPP) GNSS/INS solutions one month after
 674 data acquisition. Measurement errors were typically calculated from crossover analysis for an entire
 675 survey using the root-mean-square deviation of the surface, bed and ice thickness at intersection
 676 transects, and can be found in the various studies utilising the PASIN data (see Jeoffrey et al., 2018;
 677 Rose et al., 2013; Ross et al., 2012; Vaughan et al., 2006), or alternatively in the respective survey
 678 metadata (see Table 3).

679

680 4. FAIR Data Publishing

681 In total, we have published 64 datasets from 24 surveys as part of this data release,
 682 representing ~566 GB of data and ~1800 files. This amounts to a total of 3.62 million gravity and 7.41
 683 million magnetic data points, as well as 14.5 million ice-thickness and bed-elevation measurements.
 684 The complete list of published datasets is provided in Table 3, including the short Digital Object
 685 Identifiers (DOI) which redirect to the metadata sheets and download folders for each respective
 686 dataset archived on the PDC Discovery Metadata System (DMS) data catalogue
 687 (<https://data.bas.ac.uk/>).

688 **Table 3. Short Digital Object Identifiers for the gravity, magnetic, bed-pick, and 2-D radar**
 689 **datasets for each survey flown by BAS and included in this data release.** Abbreviations used are the same as
 690 in Table 1. The links in this table can also be accessed by adding the short DOI preceded by ‘<https://doi.org/>’.
 691 “*”For the PolarGAP survey, data can be downloaded from both the ESA and BAS data catalogues, but the DOI
 692 for the gravity and magnetic data (<https://doi.org/10.5270/esa-8ff003e>) belongs to ESA. If using the PDC data
 693 catalogue, the PolarGAP gravity and magnetic data can be downloaded from [https://data.bas.ac.uk/full-](https://data.bas.ac.uk/full-record.php?id=GB/NERC/BAS/PDC/01583)
 694 [record.php?id=GB/NERC/BAS/PDC/01583](https://data.bas.ac.uk/full-record.php?id=GB/NERC/BAS/PDC/01583) and [https://data.bas.ac.uk/full-](https://data.bas.ac.uk/full-record.php?id=GB/NERC/BAS/PDC/01584)
 695 [record.php?id=GB/NERC/BAS/PDC/01584](https://data.bas.ac.uk/full-record.php?id=GB/NERC/BAS/PDC/01584) respectively. “**” indicates that the data are not held at BAS, but
 696 instead are available on the CReSIS data portal (<https://data.cresis.ku.edu/>).

697

698 Below, we discuss the release of the datasets centered around the four FAIR data principles
699 (i.e. Findable, Accessible, Interoperable and Re-Usable; Wilkinson et al., 2016), starting with the
700 formats and attributes used to store and describe the data (Interoperability; Sect. 4.1), the metadata
701 and Digital Object Identifiers assigned to each dataset (Findability; Sect. 4.2), the data-portal
702 infrastructure and functionalities (Accessibility; Sect. 4.3), and finally the creation of a user guide and
703 open-access tutorials written in Python and MATLAB for reading the data programmatically (Re-
704 usability; Sect. 4.4).

705 4.1. Interoperability: Data Formats and Attributes

706 In order to make our data as interoperable as possible, the choice of an open format for all our
707 datasets was a priority. We followed the best practices of the geophysics community and used
708 common data formats and naming conventions to describe the variable names. These are detailed
709 further here.

710 The gravity, magnetic, and bed-pick data are stored in open ASCII data formats, namely XYZ
711 and CSV files, to ensure long-term access and unrestricted use of the data in the future (Fig. 4).
712 Additionally, we followed the SCAR ADMAP2 data-release protocols (Golynsky et al., 2018) for the
713 naming convention of the channels for the magnetic data. For the radar data, we chose to release the
714 bed-pick data separately from the full radar data (Fig. 4), although the full radar product contains most
715 of the information stored in the ASCII bed-pick files. Publishing the bed-pick data separately from the
716 radar data was a deliberate choice: it alleviates the need for users to download the full radar datasets
717 to access light-weight tabular data, and improves the accessibility of the point data for large gridded
718 products such as SCAR's BEDMAP (Fretwell et al., 2013) and NASA's BedMachine (Morlighem et
719 al., 2020) projects. The bed-pick data are stored as ASCII-formatted files (namely XYZ and CSV),
720 whereas the full radar data are stored as SEG-Y and NetCDF files, reasons for which are described
721 below.

722 The SEG-Y format has been used extensively by radar scientists since the early 1980s to store
723 radar data. This is primarily due to the lack of a radar-specific format, SEG-Y having been developed
724 primarily to store seismic data. The advantage of using SEG-Y files is that data can be readily
725 imported into seismic-interpretation software for data interpretation and analysis. The drawbacks of
726 using SEG-Y, however, are numerous, making this option unsuitable for long-term data storage.
727 These include: (1) limited space for metadata, (2) the choice of byte-information to store the radar
728 data is subjective due to the nature of the SEG-Y format, (3) until recently, the byte stream structure
729 which includes the geolocation of each radar trace (i.e. the X and Y positions) was restricted to integer
730 format leading to large inaccuracies in the actual trace position despite the use of high-resolution, sub-
731 metre GPS data (see Sect. 3.1.4). Recognising, however, the need from the geophysical community to
732 view and analyse the radar data in conventional data formats, we have decided to continue producing
733 SEG-Y files for each flightline and acquisition mode (e.g. pulse and chirp). The SEG-Y files were
734 produced using the Revision 1.0 SEG-Y format and georeferenced using the navigational position of
735 each trace from the GPS on board the aircraft in Polar Stereographic (EPSG: 3031) projection. Each
736 SEG-Y file contains the following byte-information: trace number (byte: 1-4 and 5-8), PRI-Number
737 (byte: 9-12), Cartesian X-coordinate (byte: 73-76), Cartesian Y-coordinate (byte: 77-80), number of
738 samples for each SEG-Y trace (byte: 115-116), and the sampling interval (byte: 117-118).

739 As a result of the issues mentioned above, we also exported the radar data in NetCDF-
 740 formatted files. We chose the NetCDF format due to its portability and array-oriented structure, the
 741 ability to store large amounts of metadata and variables into one portable file, its machine-readable
 742 capability, and to harmonise our data products with other fields such as climate science (e.g. ECMWF
 743 ERA5 reanalysis products; NCAR climate data), glaciology (e.g. Lei et al., 2021; Le Brocq et al.,
 744 2010; Morlighem et al., 2017) and, increasingly, radar geophysics itself (e.g. Blankenship et al., 2017;
 745 Paden et al., 2014), which already all make use of this data format effectively. The NetCDF files we
 746 produced contain extensive metadata relating to the acquisition and processing of the radar data, as
 747 well as a set of CF-compliant (Climate and Forecast; <https://cfconventions.org/>) variables that are tied
 748 to the radar data (Table 4). As a minimum, each NetCDF file contains a radar data variable (one for
 749 the pulse and/or one for the chirp if both exist) in 2-D format, and a set of 1-D variables relating
 750 directly to the radar data, such as the trace number, PRI number, fast time, and the X and Y
 751 coordinates (Table 4). We also provided additional radar-related variables which were extracted from
 752 the radar data following processing, such as the surface and bed picks, the surface and bed elevation,
 753 the ice thickness, longitude and latitude, time of the trace, and the elevation of the aircraft (Table 4).
 754 Additional 1-D variables include the source of the surface pick (from lidar or radar) if this exists, the
 755 range between the aircraft and the ice surface, and in case the pulse- and chirp-radar variables do not
 756 have the same length, we provide two sets of variables for the trace number and PRI number.

757 **Table 4. Attributes for each variable stored in the NetCDF files.** For each attribute name, we
 758 provide the long name, the dimension (1- or 2-D, x- or y-axis), the short or CF-compliant standard name, and
 759 the unit of the measurement. The standard name is only provided if it exists as part of the CF convention
 760 (<https://cfconventions.org/>), otherwise a short name is provided. “dBm” stands for decibel-milliwatts and “a.s.l.”
 761 stands for above sea level. Note that the surface and bed pick data are referenced to the sampling time of the
 762 BAS radar systems across the 64 microseconds pulse repetition interval window, and digitised according to the
 763 receiver sampling frequency (see Table 2).

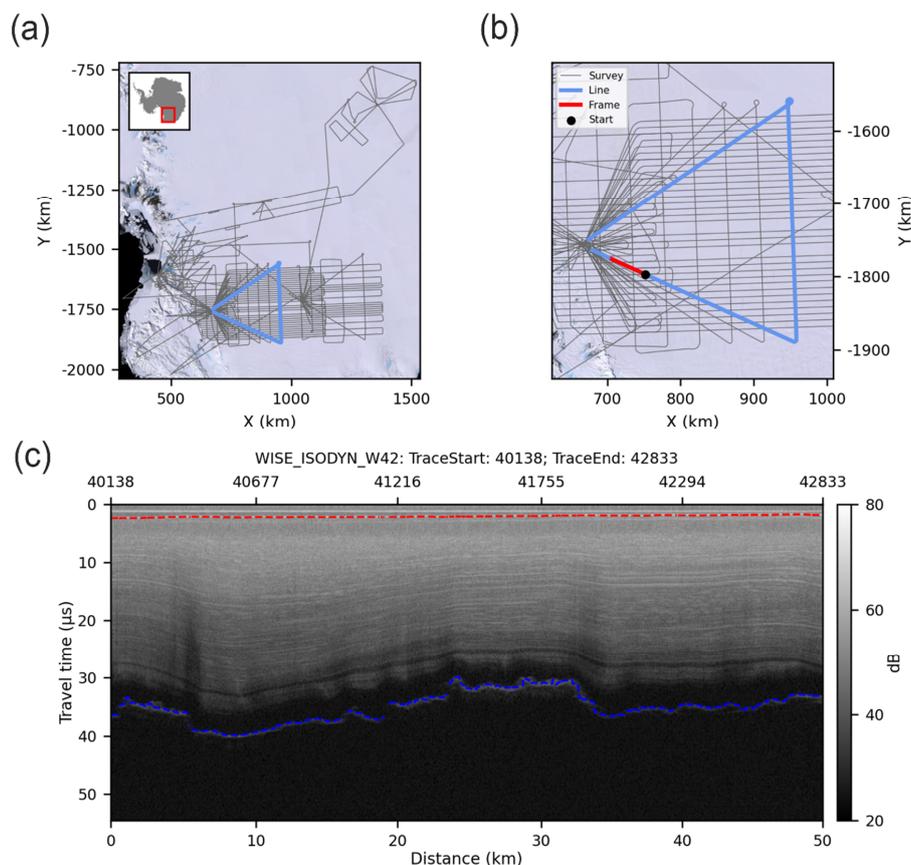

NetCDF Attributes	Long Name	Dimension	Short / Standard Name	Unit
traces	Trace number for the radar data	1-D (x-axis)	traceNum	integer count (unitless)
fast_time	Two-way travel time	1-D (y-axis)	time	microseconds
x_coordinates	Cartesian x-coordinates for the radar data	1-D (x-axis)	projection_x_coordinate	meters (WGS84 EPSG: 3031)
y_coordinates	Cartesian y-coordinates for the radar data	1-D (x-axis)	projection_y_coordinate	meters (WGS84 EPSG: 3031)
chirp_data	Radar data for the processed chirp	2-D (x- and y-axis)	-	power (dBm)
pulse_data	Radar data for the processed pulse	2-D (x- and y-axis)	-	power (dBm)
longitude_layerData	Longitudinal position of the trace number	1-D (x-axis)	longitude	degree_east (WGS84 EPSG: 4326)
latitude_layerData	Latitudinal position of the trace number	1-D (x-axis)	latitude	degree_north (WGS84 EPSG: 4326)
UTC_time_layerData	Coordinated Universal Time (UTC) of trace number	1-D (x-axis)	resTime	seconds of the day

PriNumber_layerData	Incremental integer reference number related to initialisation of the radar system	1-D (x-axis)	PriNum	integer count (unitless)
terrainClearance_layerData	Terrain clearance distance from platform to air interface with ice, sea or ground	1-D (x-axis)	resHt	meters
aircraft_altitude_layerData	Aircraft altitude	1-D (x-axis)	Eht	meters a.s.l. (WGS84 ellipsoid)
surface_altitude_layerData	Ice surface elevation for the trace number	1-D (x-axis)	surface_altitude	meters a.s.l. (WGS84 ellipsoid)
surface_pick_layerData	Location down trace of surface pick (BAS system)	1-D (x-axis)	surfPickLoc	time sample (microseconds)
bed_altitude_layerData	Bedrock elevation for the trace number	1-D (x-axis)	bed_altitude	meters a.s.l. (WGS84 ellipsoid)
bed_pick_layerData	Location down trace of bed pick (BAS system)	1-D (x-axis)	bedPickLoc	time sample (microseconds)
land_ice_thickness_layerData	Ice thickness for the trace number	1-D (x-axis)	land_ice_thickness	meters

764

765 Lastly, to aid visualisation and improve efficiency in navigating the datasets, we created
 766 lightweight quick-look PDF files of the radar data for each flightline of each survey (Fig. 7). Each
 767 quicklook file contains three plots: an overview map of the specific survey with an inset of its position
 768 over Antarctica and the specific flightline highlighted in blue (Fig. 7a), a closer zoomed-in version of
 769 the specific flightline with the frame footprint and start point for the segmented radargram shown as a
 770 red line and black dot respectively (Fig. 7b), and the segmented ~25 or ~50-km segment shown in
 771 Figure 7b as a 2-D radargram of the chirp radar data, with the surface and bed pick shown as a red and
 772 blue dashed lines respectively (Fig. 7c). The x-axes in Figure 7c show the trace number (top) and
 773 distance in kilometers (bottom) respectively. The choice of ~25 or ~50-km length for the 2-D
 774 radargram was chosen based on clarity of the image and varies from survey to survey. The quick-look
 775 PDF files are stored alongside the SEG-Y and NetCDF files and are accessible using the links
 776 provided in Table 3.

777

778 **Figure 7. Example of a segmented quick-look image from the 2005-06 WISE-ISODYN survey.** (a)
779 Overview map of the entire survey with an inset over Antarctica. (b) Zoom to version to which the segment
780 belongs with the frame footprint and start point for the radargram shown. The background satellite image in (a-
781 b) is from the Landsat Image Mosaic of Antarctica (LIMA) (Bindschadler et al., 2008). (c) 50-km segmented
782 radar image of the chirp data with distance in kilometres shown in the bottom x-axis and the trace number
783 shown in the top x-axis. The format of the title in (c) is as follows: Survey Name and Flight ID, First Trace of
784 Segment, Last Trace of Segment. The red and blue dashed lines on the radargram (c) are the surface and bed
785 pick respectively.

786 4.2. Findability: Metadata and Digital Object Identifiers

787 ISO 19115/19139 Geographic Information metadata are provided for each data type of each
788 survey and is archived alongside the datasets onto the PDC DMS catalogue (<https://data.bas.ac.uk/>;
789 see Table 3). Each metadata record provides detailed information about the dataset, including an
790 abstract, list of personnel involved in the acquisition or analysis of the dataset, and detailed lineage
791 information on the acquisition and processing steps used to produce the dataset amongst others. All
792 our data are covered under the UK Open Government License
793 (<http://www.nationalarchives.gov.uk/doc/open-government-licence/>), enabling the re-use of the data
794 freely and with flexibility, whilst at the same time ensuring acknowledgment of those involved in the
795 collection and processing of the data. In addition, we use Earth Science-specific keywords and
796 vocabularies from the Global Change Master Directory (GCMD, 2021) to describe our data in a

797 consistent and comprehensive manner in accordance with ISO 19115 standards. Lastly, a Digital
798 Object Identifier is minted for each dataset so that it can be discoverable and adequately cited. The
799 end goal is to provide all the information necessary for effective, long-term data re-use.

800 The data are shared via the web-based RAMADDA (Repository for Archiving and MANaging
801 Diverse DATA; <https://geodesystems.com/>) data repository system which is an open-source content
802 and data management platform. The download of the data is done through a standard HTTP-protocol
803 where no login account is required. In the backend, the data are stored following a simple folder
804 structure on the PDC server that is mirrored onto RAMADDA. This simple structure allows us to
805 maintain a balance between the services we can provide and our ability to move away from specific
806 tools – RAMADDA in this case - and potentially adopt more performant systems in the future. The
807 goal is to stay as independent of the platform we use as possible while providing the most effective
808 service possible.

809 4.3. Accessibility: Polar Airborne Geophysics Data Portal

810 To increase the accessibility and discoverability of our data, we developed a new data portal,
811 the Polar Airborne Geophysics Data Portal (<https://www.bas.ac.uk/project/nagdp/>). The portal allows
812 to showcase interactively the wide coverage of aerogeophysical datasets collected by BAS and
813 enables users to easily discover and download the published datasets via a series of widgets and
814 functionalities aimed at enhancing the user experience.

815 The portal is divided into five layer-menus: “Aerogravity”, “Aeromagnetics”, “AeroRadar”,
816 “Boundaries & Features”, and “Basemaps”. The first three menus contain shapefile layers for the
817 gravity, magnetic, and radar datasets respectively. The “Boundaries & Features” menu contains a set
818 of specific boundary layers, such as the Antarctic Coastline and Ice Drainage boundaries amongst
819 others, and the “Basemaps” menu contains background maps such as ice thickness, surface and bed
820 elevations, magnetic anomaly and geothermal heat flow maps amongst others.

821 The track lines for each dataset correspond to individual polyline shapefiles (either segmented
822 in 25 or 50-km, or by flightline) which contain key statistics such as the minimum, maximum, and
823 median gravity and magnetic anomalies, and minimum, maximum, and median ice surface, bed
824 elevation, and ice thickness. The shapefiles also contain direct links to the survey’s metadata and to
825 direct links to download the data via the RAMADDA interface.

826 A powerful functionality of the portal is the ability to view the aerogeophysical data rapidly
827 via the creation of quick-look gravity, magnetic, and radar plots for each flightlines (see Sect. 5.2;
828 Figure 7c). For the magnetic and gravity data, graphs showing the magnetic or free-air anomaly along
829 straight lines were created in the direction Westernmost-Easternmost if the profile is mainly in the
830 direction of the longitude, or Northernmost-Southernmost if the profile is predominantly in the
831 direction of the latitude. For the radar data, the segmented images were produced in a similar format
832 to Figure 7c and split into ~25 and ~50 km segments depending on the survey.

833

834 **4.4. Re-Usability: User Guide and Tutorials**

835 To increase further the re-usability of our data, we provided a user guide for the data portal as
836 well as interactive, open-source Jupyter Notebook tutorials written in Python and MATLAB for
837 reading in the gravity, magnetic, and radar datasets and conducting first-order analyses on the data.
838 These are archived on the BAS GitHub repository and provided via an interactive web interface using
839 Jupyter Book (https://antarctica.github.io/PDC_GeophysicsBook). We believe these to be particularly
840 beneficial for ensuring accessibility and re-usability of our data to as wide of a range of users as
841 possible, primarily as a result of the complexity around reading in aerogeophysical data formats.
842 Section 5.1 discusses further the potential re-usability of the radar data.

843

844 **5. Discussion**

845 This final section exemplifies the potential re-usability of the newly released radar data via
846 the interrogation of the englacial architecture of the ice as sounded by BAS ice-penetrating radars. We
847 also explore the future use of the new data portal and discuss opportunities in terms of data release
848 and further potential re-use of the BAS aerogeophysical data.

849 **5.1. Internal Layering Continuity Index**

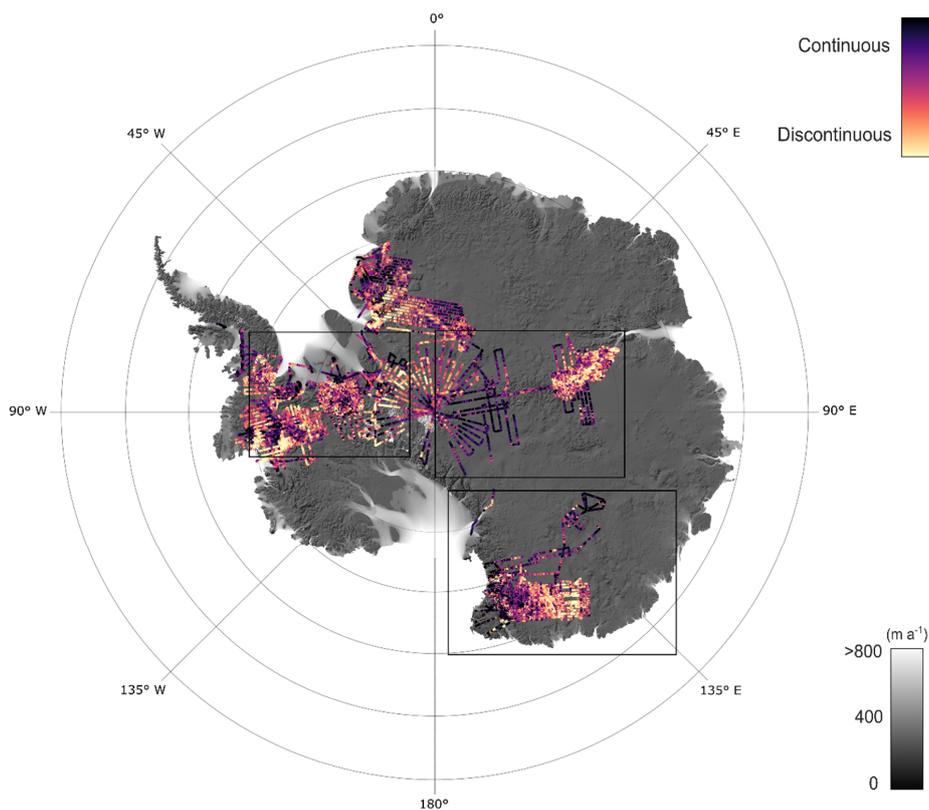

850 Englacial layering, as imaged by ice-penetrating radars, is a powerful means of extracting
851 information on past ice-dynamical processes (Bingham et al., 2015; Siegert et al., 2003) amongst
852 others. For example, the presence of well-preserved and continuous englacial layering may reflect
853 stable ice conditions and suggest changes in past ice-flow conditions, ice divide migration, or melting
854 within or at the base of an ice sheet are limited (Karlsson et al., 2012). In contrast, poor continuity in
855 englacial layering, primarily characterised by buckled or absent layering, may be indicative of past
856 ice-flow switching or increased englacial stress gradients (Bingham et al., 2015; Siegert et al., 2003).
857 Thus, quantifying the continuity of englacial layering is essential in our understanding of past and
858 current ice dynamical conditions, and can also be used for selecting ice-core drilling sites (Karlsson et
859 al., 2018), or to identify areas which could benefit from being re-surveyed in more detail with more
860 modern systems or acquisition strategies.

861 Several methods have been developed for mapping the continuity of englacial layering from
862 ice-penetrating radar data (e.g. Delf et al., 2020; Karlsson et al., 2012; Sime et al., 2014). One such
863 technique, the Internal Layer Continuity Index (or ILCI; Karlsson et al., 2012) is the first to provide
864 an automated tool for quantitatively assessing the continuity of englacial layering based on A-scope
865 radar profiles. This method has the advantage of being much less laborious than manual methods (e.g.
866 Bingham et al. 2007; Rippin et al., 2003a; Siegert et al., 2003) and removes the potential subjectivity
867 in assessing layer continuity. Additionally, the large amount of radar data now available precludes the
868 ability to identify layer continuity manually, making the ILCI a powerful tool in our ability to extract
869 this valuable metric. By design, the ILCI is sensitive to the number and strength of internal
870 reflections, such that low values indicate discontinuity and high values indicate high continuity. First
871 tested over selected 2004-05 BBAS flightlines covering the Pine Island Glacier (Karlsson et al.,
872 2012), the ILCI was subsequently employed over Institute and Möller Ice Stream (Bingham et al.,
873 2015; Winter et al., 2015) and East Antarctica (Karlsson et al., 2018; Luo et al., 2020). Using the ILCI
874 previously calculated for the 2010-11 IMAFI radar data, Ashmore et al. (2020) further demonstrated
875 that the ILCI was statistically higher where manually picked internal layers could be traced, thus
876 showing for the first time that this method has the potential to be applied at a larger scale with reliable
877 results. However, until now, this approach had not been tested at a regional scale over Antarctica and
878 with the use of multiple radar datasets.

879 Here, we have calculated the ILCI on the ten PASIN radar datasets that have been published
880 as part of this data release (Fig. 8-9). This includes a total of ~300,00 line-km of 2-D radar data from
881 the BBAS-AGASEA (2004-05), WISE-ISODYN (2005-06), GRADES-IMAGE (2006-07), AGAP
882 (2007-09), IMAFI (2010-11), ICEGRAV (2012-13), FISS (2015-17), PolarGAP (2015-16), and ITGC
883 Thwaites (2019-20) surveys (see Table 3). Since we were primarily interested in regional changes in
884 layer continuity, the ILCI was smoothed using a horizontal window of 1000 samples (representing
885 ~25-45 km distance depending on the dataset) to remove any small-scale anomalies in the data and
886 only making use of the deep-sounding chirp product due to its capability of imaging deeper internal
887 layers. The upper and lower 20% of the ice were also omitted in the calculations to avoid surface
888 noise affecting the result in the upper part of the ice column, and because internal layering is typically
889 absent near the ice-bed interface (Karlsson et al., 2012).

890

891

892 **Figure 8. Internal Layer Continuity Index for the ten PASIN datasets for which the fully**
893 **processed 2-D radar data was released as part of this paper (see Table 3).** The background map shows ice-
894 flow velocities from the In-SAR MEaSURES dataset (Rignot et al., 2017) superimposed over a hill-shade from
895 the BedMachine bed elevation dataset (Morlighem et al., 2020). The black and white colour bar shows ice-flow
896 velocities in metres per annum, and the magma colour bar shows the continuity of internal layers throughout the
897 radar dataset (low ILCI values = yellow; high ILCI values = dark purple). The black-bordered rectangles are
898 shown in more detail in Figure 9a-c.

899 An important consideration in employing the ILCI over multiple datasets is that the results
900 will vary based on data acquisition (i.e. radar frequency, system resolution) and processing applied
901 (i.e. incoherent vs 2-D SAR), thus a pan-Antarctic comparison of internal layer continuity must be

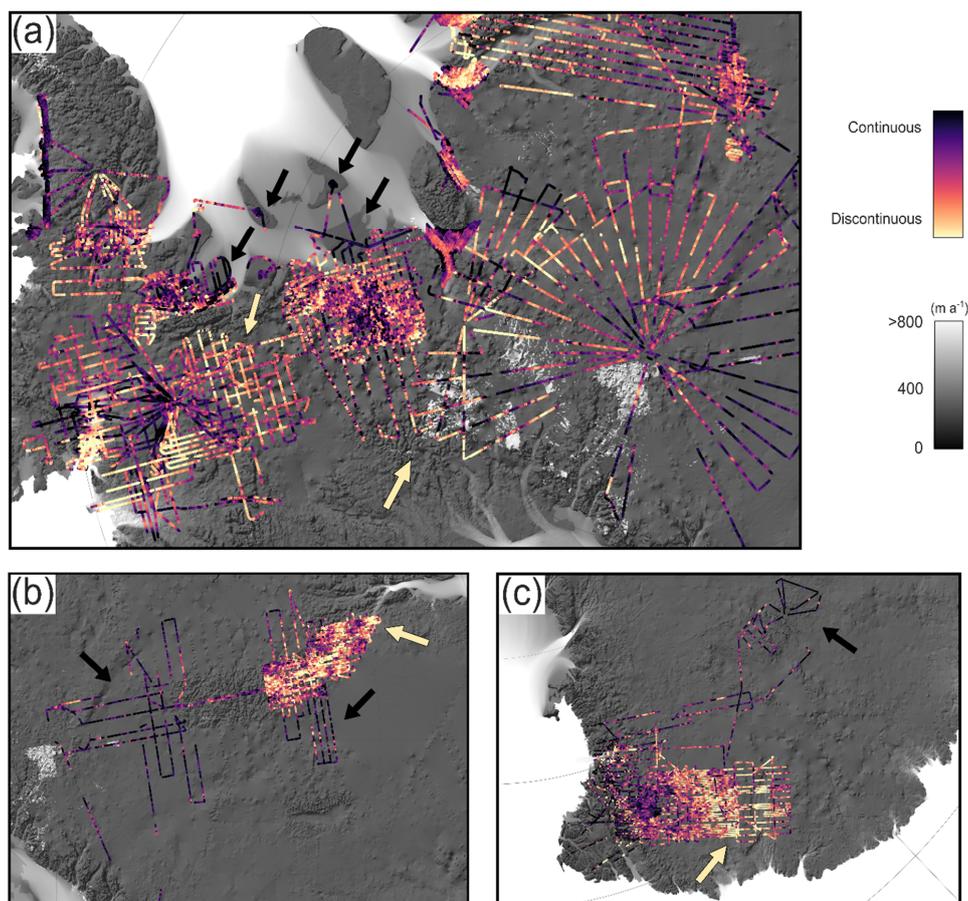

902 analysed in this context. This is especially the case here, where we have applied the ILCI to data
903 acquired over a period of >15 years with two different systems (namely PASIN-1 and PASIN-2) and
904 using different processing regimes. Therefore, care must be taken when interpreting the results from
905 different surveys together, as for example, a low level of layer continuity in the main trunk of Pine
906 Island Glacier on the BBAS survey may not reflect the same level of discontinuity on the low-
907 continuity areas of the AGAP survey. This caution noted, the results presented here offer an
908 opportunity to identify some regional patterns of potential value for future work, as we now discuss.

909 Figure 8 shows that there is a good correspondence between discontinuous layering where ice
910 flow is fast ($> 200 \text{ m a}^{-1}$) such as over Foundation Ice Stream (FISS) and the main trunk of Pine Island
911 Glacier (BBAS) and Slessor Glacier (ICEGRAV) (Fig. 8 and 9a). Whilst layer discontinuity is mainly
912 present over the WAIS due to the high concentration of fast-flowing ice streams in this region, several
913 sections covering the EAIS also show signs of layer discontinuity, particularly in the upstream
914 portions of the fast-flowing Lambert Glacier (AGAP), as well as over David and Ninnis glaciers
915 (WISE-ISODYN) (yellow arrows in Fig. 9b-c).

916 Unsurprisingly, areas of high continuity are mainly observed over the interior of the EAIS,
917 particularly on flightlines extending deep into East Antarctica and South Pole (Fig. 8 and 9a-b), as
918 well as into the deeper parts of the Wilkes Subglacial Basin and Dome C where deep ice-cores have
919 been drilled (black arrow in Fig. 9c). Areas of high layer continuity over the WAIS include numerous
920 ice-rises (i.e. Bungenstock, Fletcher, Henry, and Skytrain) as imaged on the GRADES-IMAGE and
921 FISS surveys (black arrows in Fig. 9a), the deeper sections of the southern Pine Island Glacier basin
922 on the BBAS data, as well as on PolarGAP survey lines upstream of the FISS grids covering
923 Foundation Ice Stream (Fig. 9a).

924 Also visible are the disruptive effects of local bed topography on the continuity of internal
925 layering, such as over the Ellsworth Subglacial Mountains (BBAS) and at the onset of the Pensacola
926 and Transantarctic Mountains as seen on the IMAFI and PolarGAP survey flightlines (yellow arrows
927 in Fig. 9a), with relatively flat bed topography in the deep interior of the EAIS allowing layering to
928 remain relatively undisturbed (Fig. 8 and black arrows in Fig. 9b).

929
930 **Figure 9. Zoomed-in sections of the Internal Layer Continuity Index shown in the black-**
931 **bordered rectangles on Figure 8.** The basemap datasets and colour scales are the same as in Figure 8. (a) ILCI
932 results over the WAIS (including Pine Island Glacier, Rutford Ice Stream, Institute-Möller Ice Stream, and
933 Foundation Ice Stream) and bottleneck with the EAIS (including South Pole, Pensacola Mountains and Slessor
934 Glacier), (b) ILCI results for the AGAP survey over East Antarctica's Dome A and South Pole, (c) ILCI results
935 for the WISE-ISODYN survey over East Antarctica's Wilkes Subglacial Basin and Dome C. Arrows refer to
936 locations mentioned in the text, with black arrows highlighting examples of high layer continuity and yellow
937 arrows low layer continuity.

938
939 Together, the results presented in Figures 8 and 9 show the potential for the yet-unexplored
940 radar datasets to be further exploited in the future, particularly with regards to tracking or otherwise
941 characterising the englacial architecture of the ice and as motivated by the SCAR AntArchitecture
942 group. At present, only two BAS radar datasets (BBAS and IMAFI) have been comprehensively
943 assessed for deep englacial layers (Ashmore et al., 2020; Bodart et al., 2021; Karlsson et al., 2009).
944 Thus, the release here of large swaths of additional radar datasets, including over the more stable
945 regions of the EAIS (namely the AGAP, ICEGRAV, PolarGAP, and WISE-ISODYN datasets), and
946 the evidence indicated here by the ILCI of large regions of continuous englacial layering in the region
947 will likely offer more promising opportunities for englacial work to be conducted on these datasets. In
948 particular, the close proximity of deep ice cores to the ITGC Thwaites surveys (i.e. WAIS Divide ice-
949 core; Buizert et al., 2015 and Sigl et al., 2016) and the WISE-ISODYN survey (i.e. EPICA Dome C
ice-core; EPICA Community Members, 2004) provide ready opportunities for these layers to be

950 dated, increasing significantly their use for wider applications such as estimating past accumulation
951 rates and constrain changes in past ice-flow dynamics (c.f. Cavitte et al., 2018; Parrenin and
952 Hindmarsh, 2007; Siegert and Payne, 2004; Sutter et al., 2021).

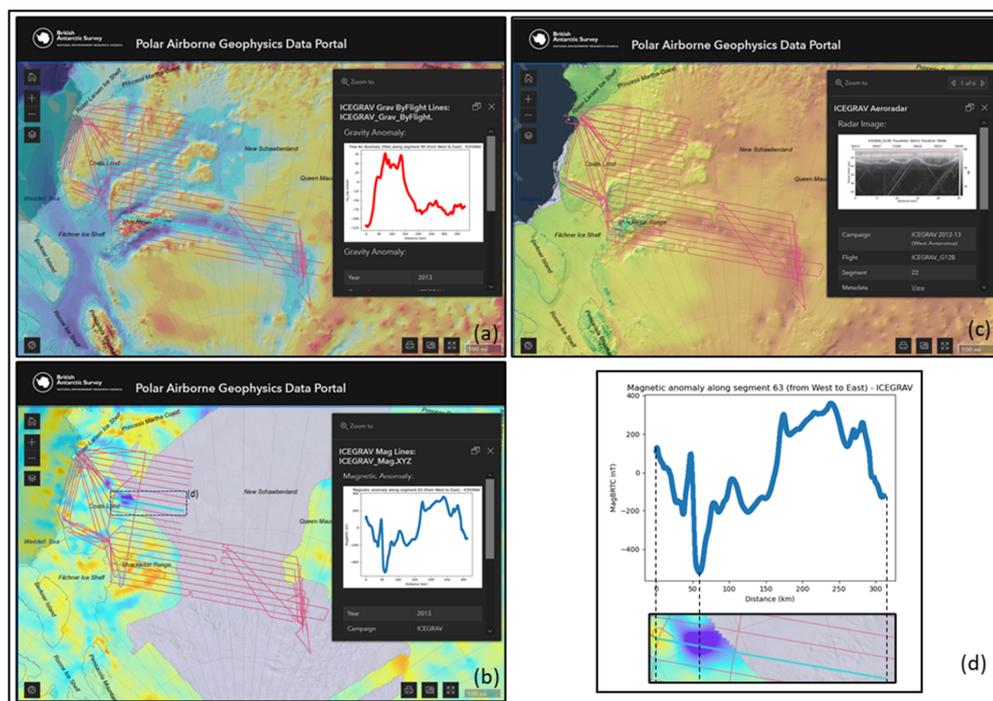

953 We also expect this data release to be useful in a series of other ice-dynamical applications in
954 the future. Examples applied to individual BAS datasets so far include calculating balance velocities
955 from dated englacial layers (Rippin et al., 2003b), analyses of water routing systems and bed
956 reflectivity (Chu et al., 2021; Rippin et al., 2006), as well as assessments of the bed roughness and
957 local topography (Rippin et al., 2003a; 2011; 2014), amongst others. It is our aspiration that this data
958 release will enable further such studies in the future.

959 5.2. Polar Airborne Geophysics Data Portal

960 One specificity of the platform is that it offers three types of geophysical datasets - namely
961 gravity, magnetic and radar - at the same time geospatially. Although some surveys were acquired
962 over 25 years ago, they may never have been exploited or analysed fully in a form that reached peer-
963 reviewed publications, nor combined with other geophysical data before, increasing in turn their re-
964 usability. By publishing this resource, we anticipate that the portal and datasets will foster new
965 research and discoveries related to our understanding of ice-sheet processes and crust and lithosphere
966 heterogeneity beneath the Antarctic Ice Sheet.

967 Additionally, the portal enables users to combine the published line datasets with gridded
968 products to compare the ability of the interpolated datasets to match the direct observations. For
969 instance, as shown in Figure 10 for the 2012-13 ICEGRAV survey, the portal allows users to readily
970 investigate the free-air gravity anomaly with the bed topography from BEDMAP2 or assess the
971 consistency between the measured ICEGRAV magnetic anomalies and the gridded aeromagnetic
972 product (Fig. 10). Alternatively, the quick-look radargrams can be compared with the ice-thickness
973 and bed-elevation grid cells from BEDMAP to assess sub-km variations in along- and across-flow on
974 the radar data which may have been smoothed out in the 1-km gridded product.

975 With its ~207,000 line-km of gravity, ~338,000 line-km of magnetic, and ~352,000 line-km
976 of radar data published, the Polar Airborne Geophysics Data Portal provides a robust platform for the
977 dissemination of the BAS aerogeophysical data. Further opportunities offered by the data portal are
978 the potential for the platform to be used to plan future field surveys or encourage future compilation
979 efforts based on gaps in the data coverage or quality of the data.

Figure 10. Screenshots of the Polar Airborne Geophysics Data Portal showing the three aerogeophysical products for the 2012-13 ICEGRAV survey with different basemaps. (a) ICEGRAV aerogravity survey with the BEDMAP2 bed elevation basemap (b) ICEGRAV aeromagnetic survey with the magnetic anomaly basemap from Goodge and Finn (2010), (c) ICEGRAV aeroradar survey with the ice thickness basemap from BEDMAP2. (d) Magnetic anomaly along the profile highlighted in (c) with a comparison with the aeromagnetic anomaly map from Goodge and Finn (2010).

988 5.3. Future Work

989 Although most of data published here have already been incorporated into previous data
990 compilations such as BEDMAP2 or ADMAP2, the more recent datasets presented here will provide
991 useful additions to future editions of such initiatives. Examples of this are the data acquired as part of
992 the 2012-13 ICEGRAV aeromagnetic campaign in Dronning Maud Land where the last compilation
993 effort of magnetic anomalies had shown a large gap (Goodge and Finn, 2010; Fig. 10), or the new ice-
994 thickness and bed-elevation data acquired over Thwaites Glacier (2018-20), South Pole (2015-16),
995 and Filchner Ice Shelf (2015-17) which are expected to be added to the new BEDMAP3 compilation.

996 Even though most of the gravity, magnetic and bed-pick data acquired since the mid-1990s
997 are now fully published, radar data from older surveys (1994-2004) for which the bed-pick data are
998 published and already integrated into larger gridded products (e.g. BEDMAP; Fretwell et al., 2013)
999 are yet to be published in full as per the more modern surveys (2004-2020) released here (see Table
1000 3). This is primarily due to poorer data management practices at times of acquisition and less well-
1001 documented processing procedures which restrict the re-usability of these older radar dataset. Much
1002 older analogue radar data acquired on films and video tapes prior to the deployment of digital radars
1003 (i.e. pre-1994) also offer additional opportunities, although the necessity for manual digitisation
1004 makes this task much more time consuming and challenging. It is worth noting, however, that many
1005 of the regions broadly covered by these older surveys have recently been re-flown using more modern

1006 instruments, much as part of NASA's Operation IceBridge programme (MacGregor et al., 2021),
1007 although reprocessing and modernising older radar data can bring substantial benefits, as already
1008 demonstrated by Schroeder et al. (2019). Additional reprocessing of older radar data using modern 2-
1009 D SAR techniques would also be beneficial, as recently demonstrated by Chu et al. (2021).

1010 Lastly, and as a result of the very flexible configuration of the PASIN-2 system, much more
1011 data can be extracted from the raw radar files already acquired, including fully polarised data used to
1012 image ice crystal-fabric orientation for estimating ice deformation processes (i.e. Young et al., 2021),
1013 or 3-D swath radar data used to reconstruct the sub-surface at finer resolution and without
1014 compromising on across-track resolution as for conventional 2-D data (Holschuh et al., 2020; Arenas-
1015 Pingarron et al., 2022).

1016 Combined, these will likely add further opportunities for future data releases, alongside our
1017 intention to publish newly acquired data regularly via the data portal and following the procedures
1018 detailed in this paper.

1019

1020 6. Conclusion

1021 We have presented here the release of 64 aerogeophysical datasets from 24 surveys flown by
1022 the British Antarctic Survey between 1994 and 2020 over the Antarctic Peninsula and East and West
1023 Antarctica. Altogether, the data release consists of ~450,000 line-km (or ~5.3.million km²) of
1024 aerogeophysical data on gravity, magnetic and radar measurements (including bed-pick and the fully
1025 processed 2-D radar data) which have all been standardised according to the FAIR (Findable,
1026 Accessible, Interoperable and Re-Usable) data principles. A new data portal, the Polar Airborne
1027 Geophysics Data Portal (<https://www.bas.ac.uk/project/nagdp/>), and interactive, open-access tutorials
1028 written in Python and MATLAB have also been created to improve the interactivity and user-
1029 accessibility of our datasets.

1030 Aside from discussing the data acquisition and processing steps, we have demonstrated that
1031 much more information can be extracted from the full radar datasets by assessing the continuity of
1032 englacial layering along ~300,000 line-km of the newly released radar data. Using an automated layer
1033 continuity extraction method on all ten fully published 2-D radar datasets, we have shown that large
1034 volumes of radar profiles contain well-preserved englacial layering from which further information
1035 such as past accumulation rates and ice-dynamical processes can be extracted.

1036 Although all of the datasets released here have so far made a significant contribution to our
1037 understanding of past and current ice-dynamical and lithospheric influences, partly through their
1038 contributions to major international collaborative projects such as the SCAR BEDMAP and ADMAP
1039 programmes, they have until now largely remained unpublished in their full form thus restricting the
1040 further usage of the data beyond the life cycle of the science projects. It is our hope that these newly
1041 released data will offer further research opportunities and enable the wider geophysical and
1042 glaciological community to benefit from the abundance of newly published aerogeophysical data over
1043 Antarctica, particularly within the context of recently established international projects such as the
1044 SCAR AntArchitecture and RINGS Action groups.

1045 Reflecting on our collaboration between data managers and scientists, we believe that this
1046 project sets a positive example for further release of aerogeophysical data, particularly for future
1047 international initiatives that are aiming to harmonise the availability and findability of
1048 aerogeophysical data collected across Antarctica. A full list of all available datasets can be found in
1049 Table 3 of this paper, or via the BAS Discovery Metadata System (<https://data.bas.ac.uk/>).

1050

1051 **Data Availability Statement**

1052 All the data included in this manuscript are freely available via the BAS Discovery Metadata System
1053 (<https://data.bas.ac.uk>), with direct links to the datasets found in Table 3 of this paper. The user guide
1054 for the data portal and the Jupiter Notebook tutorials designed for reading in the gravity, magnetic,
1055 and radar data in Python and MATLAB are freely accessible on the Jupyter Book interface
1056 (https://antarctica.github.io/PDC_GeophysicsBook) or via the BAS GitHub repository
1057 (https://github.com/antarctica/PDC_GeophysicsBook). The code used to produce the Internal Layer
1058 Continuity Index over the whole BAS radar dataset (Fig. 8-9) is available on the GitHub page of
1059 J.A.B. (<https://github.com/julbod>).

1060

1061 **Competing Interests**

1062 The authors declare that they have no conflict of interest.

1063

1064 **Contribution Statement**

1065 A.C.F. and J.A.B. co-led this data release. A.C.F. initiated the collaboration between the Polar Data
1066 Centre and the BAS Airborne Geophysics science team, with input from H.J.P. A.C.F. quality-
1067 checked and published the gravity, magnetic and bed-pick datasets, with input from T.A.J., F.F. and
1068 J.A.B. J.A.B. re-processed, quality-checked, and published the fully processed radar datasets and
1069 accompanying files, with input from A.C.F., T.A.J. and C.R. The three BAS radar systems and
1070 accompanying radar processing software libraries were designed by H.F.J.C. The aerogeophysical
1071 data were primarily acquired and processed by H.F.J.C, C.R., F.F. and T.A.J. J.A.B. created the data
1072 portal, with input from A.C.F., T.A.J. and F.F. A.C.F. and J.A.B. populated the data portal with the
1073 gravity, magnetic, and radar track-lines. A.C.F. created the Jupyter Notebook tutorials, with input
1074 from J.A.B. for the radar tutorials and user guide. J.A.B. wrote the code and analysed the results for
1075 the layer continuity index. J.A.B. wrote the initial manuscript and created the figures, with input from
1076 A.C.F. All authors commented and contributed to the final edits of the manuscript prior to publication.

1077

1078 **Acknowledgments**

1079 We would like to thank the many BAS personnel involved over the last three decades in developing
1080 and maintaining the aerogeophysical instruments and in acquiring and processing the data presented
1081 in this paper. In particular, we would like to credit and acknowledge Hugh Corr and Nick Frearson for
1082 designing the PASIN radar systems. We are also especially grateful to the many pilots that flew the
1083 BAS Twin Otter aircraft “VP-FBL” throughout the years, including Lee Proudfoot, Greg Harris, Pete
1084 Buckley, Doug Pearson, Mark Beasley, Doug Cochrane, Andy Vidamour, Oli Smith, and particularly
1085 David Leatherdale and Ian Potten who flew most of the survey km. Many campaigns that BAS
1086 conducted were also in partnership with international collaborators and institutes from around the
1087 world, which we would also like to acknowledge more widely. J.A.B. was partly funded by the NERC
1088 Doctoral Training Partnership (grant reference number: NE/L002558/1) hosted in the Edinburgh E³
1089 DTP program. We would also like to acknowledge the help from the BAS PDC and MAGIC
1090 (Mapping and GIS) teams for their valuable input throughout this project.
