# EXECUTIVE SUMMARY

The Nam Ngiep 1 Hydropower Project (NNP1 Project) involves construction and operation of a 290 megawatt (MW) hydroelectric power generation facility on a build-operate-transfer basis at the Nam Ngiep River, Lao PDR. The Project will generate 262 MW of its capacity for export to Thailand and 20MW for domestic supply.

The purpose of this report is to provide an updated baseline assessment (following submission of the Project environmental impact assessment) of the biodiversity values relevant to the Project in response to the Terms of Reference (ToR) provided by ADB.

### The Project area

The Project area is defined as the area potentially directly and indirectly affected by the Project components. The components include two reservoirs each impounded by a separate dam serving two separate power stations, transmission line and resettlement area. The main power station is designed to re-regulate and stabilise the Nam Ngiep River discharge from the main power station for the safety to the downstream area of the re-regulation dam. The main dam inundation area is 70 km in length, and includes a total surface area of 66.9 km<sup>2</sup>. The transmission line will span between the main powerhouse and the Ban Nabong substation near Vientiane.

The proposed Project lies on the Nam Ngiep River which flows in a southsoutheast direction through a mountainous region to the gorge at Hat Gniun village where the topography changes to a hilly landscape before entering the Mekong River at Pakxan. The gorge is the location for the construction of the proposed dam.

Terrestrial ecoregions are natural ecological communities with shared species, dynamics and environmental conditions and offer a useful way of understanding the biodiversity within an area (ADB & UNEP, 2004). The ecoregion associated with the Project area is characterised by a variety of forest associations including montane hardwoods, mixed conifer-hardwood forests, open montane forests, and open conifer forests (Wikramanayake *et al.*, 2002). These forests have been subject to heavy logging pressure and much of the forest cover of central Lao PDR is subject to existing forestry operations, or occurs within approved forest leases. Slash and burn agriculture is a land use that is still practiced widely in central Lao PDR, including the Project area (ERM 2013b).

This report uses available information (from desktop, preliminary field surveys, targeted field surveys and consultation with species specialists) to describe the biodiversity values in accordance with the requirements of ADB Environmental Safeguard Policy. A combination of field survey, desktop review, village interview, consultation with species specialists and geospatial analysis was undertaken to describe the existing characteristics of the Project area of influence. Preliminary field sampling was undertaken in 2007 and in the wet and dry seasons of 2013. Additional targeted surveys were undertaken specific to threatened primate species and fast water aquatic habitats in 2013/2014. Based on the outcomes further assessment specific to one fish species is scheduled.

The vegetation within the Project area is dominated by forest (natural habitat) and fallow land vegetation (modified habitat). The deciduous forest land cover dominates the Project area, representing approximately 36 per cent of the footprint. Young and old fallow land is also highly represented with 16 and 21 per cent respectively. Condition assessment of the Project area indicated that over 80 per cent of the Project area is classified as moderate or high NDVI (or photosynthetic capacity).

Flora and fauna species diversity was recorded to be high in comparison to other areas in the region. A total of thirteen flora and thirty-five fauna species listed as critically endangered, endangered or vulnerable on the IUCN Red List of Threatened Species were reported (by interview, secondary data or direct observation) as known or may occur within the Project area. This includes the critically endangered flora species *Dipterocarpus turbinatus* and the Northern white-cheeked gibbon (*Nomascus leucogenys*).

Aquatic ecology surveys were also undertaken in 2007, 2013 and 2014. In general, river habitats were fast flowing with greater water depth and flows during the wet season. Dry season river habitats exhibited riffle zones which were flooded during the wet season. The river bed was generally dominated by sand and gravel. Villagers use the river environment for fishing and other activities and cattle were observed in the waterbody.

The fish community of the Mekong River is one of the largest in the world with most of the production based on migratory river species (Poulsen et al., 2004). Fish migration is an important component for many fish species life cycle. The EIA (ERI, 2009) noted that the fish community detected in 2007 contains species common to the Mekong tributaries and was dominated by Cyprinid species. Cyprinid family species were reported to adapt to different environments in various sections of the river, and this family was also the dominant group detected during 2013 survey. The EIA assessment noted that of the larger species detected, many are migratory species of the lower Mekong basin that move upstream during the wet season spawning activities (EIA citing Poulsen et al., 2004). These larger species, such as mud carp (*Cirrhinus molitorella*) and Asian red tailed catfish (*Hemibagrus wyckioides*) were detected in 2007 and 2013 surveys. The surveys noted a number of juvenile individuals of the migratory species suggesting that the Nam Ngiep River plays a role in providing habitat for these species' reproductive cycle (EIA citing Lowe-McConnell, 1995).

It is evident that villagers in the Project area regularly use local terrestrial and aquatic biodiversity – e.g. as a food source. However, the dependence on natural resources varies by village and is largely associated with accessibility. For example, remote villages tend to rely more heavily on medicinal plants as access to pharmaceuticals is limited. The biodiversity values of the area provide ecosystem services such as hunting and gathering, medicinal plants and materials, timber products, fishing and cultural services.

### ADB SPS Habitat Categories

Land cover mapping for the Project area identified a number of vegetated cover classes. The grassland, old fallow land, young fallow land, rice paddy, slash and burn land, and urban classes are considered to be modified habitats while bamboo, deciduous forest and evergreen forest areas are considered to be natural habitats in accordance with the ADB SPS habitat categories assessment.

Assessment for critical habitat within the Project area was undertaken for species considered to be candidates based on desktop and field survey review. Using baseline data and consultation with species experts the species were screened against the determination criteria and quantitative thresholds. No flora species or terrestrial fauna species were determine likely to have critical habitat within the Project area. One fish species, *Luciocyprinus striolatus*, was determined to have critical habitat within the main dam inundation area and a number of endemic and potential endemic species were detected. The area downstream of the Project area is recognised for the large river and floodplain habitat values for migratory fish species.

# Candidate Offset Sites

Four candidate offset sites have been identified in the Biodiversity Offset Design Report for the Project. This report investigated the biodiversity values of each of the candidate offset sites such that their ecological suitability to provide a biodiversity offset can be assessed. The sites described include parts of the Nam Ngiep catchment (Upper Nam Ngiep), stretches of the Nam Xan River between Nam Lao and Bolikhan, the Huay Ngua PPA and Phou Khao Kouay Protected Area. The candidate sites have been identified as part of the offset design process and details are provided in the related report.

The candidate offset sites vary in site and character. Each site has been described in terms of land cover, vegetation condition, flora species, fauna species and threatened species. In general, a number of the sites display characteristics similar to the Project area biodiversity.

#### 1 INTRODUCTION

### 1.1 BACKGROUND

The Nam Ngiep 1 Hydropower Project (NNP1 Project) involves construction and operation of a 290 megawatt (MW) hydroelectric power generation facility on a build-operate-transfer basis at the Nam Ngiep River, Lao PDR. The NNP1 Project site is located on the Nam Ngiep River, in the provinces of Vientiane, Xieng Khouang and Bolikhamxay, approximately 145 kilometres (km) northeast from the city of Vientiane or 50 km north from Pakxan District, as shown in *Figure 1.1*.

The Project will generate 262 MW of its capacity for export to Thailand and 20MW for domestic supply. The Project will be funded predominantly by private sector funds. The Nam Ngiep 1 Power Company (NNP1PC) is the proponent of the proposal.

An Environment Impact Assessment (EIA) was compiled for the Project in 2012 to identify and quantify the potential impacts of the Project, assess their significance and consider mitigation measures. Following reviews, the Kansai Electric Power Company Inc. (Kansai) was requested by the Asian Development Bank (ADB) and the Project's Independent Advisory Panel (IAP) to investigate the biodiversity offset requirements for the NNP1 Project and has contracted Environmental Resources Management ERM-Siam Co. Ltd (ERM) to undertake these studies.

The investigation for biodiversity offsets has been triggered by the Policy Principles of *ADB Safeguard Policy Statement, Environmental Safeguards* (ADB, 2009). The ADB requirements include the design of appropriate biodiversity offset measures to achieve at least a "no net loss" of biodiversity values.

The ADB provided a Terms of Reference (ToR) specific to the preparation of a *Baseline Biodiversity Assessment Report* and *Biodiversity Offset Design Report* for the Project. This report is the *Baseline Biodiversity Assessment Report*.

#### 1.2 **PROJECT DESCRIPTION**

NNP1 consists of two reservoirs each impounded by a separate dam serving two separate power stations. The Project components are shown in *Figure 1.2*.

The Project will operate a main power station and a re-regulation power station. The main power station is designed to re-regulate and stabilise the Nam Ngiep River discharge from the main power station for the safety to the downstream area of the re-regulation dam. The re-regulation power station is designed to generate 19.6 MW per annum.

The main dam creates a reservoir with the normal water level at 320 m and minimum operating level at EL 296.0 m. The effective storage capacity is 1192 Mm<sup>3</sup> at normal water level 320 m. The dam inundation area is 70 km length, and includes a total surface area of 66.9 km<sup>2</sup>.

The project components and the location where each biodiversity assessment is present is summarised in *Table 1.1*.

| 115 kV<br>transmission line   | Transmission line between the re-<br>regulation powerhouse and Pakxan<br>substation being developed by<br>Electricite du Laos (EdL).  | Assessment is the responsibility of EdL. When available, a revised project description and timeline for preparation of environmental assessments will be included in the IEE for the 230 kV transmission line. |
| Areas and<br>communtiies<br>potentially<br>affected by<br>cumulative<br>impacts | Communities within Nam Ngiep<br>catchment, to the confluence of<br>NPP1 River with Mekong River.  | EIA (including cumulative impact<br>assessment)  |

The NNP1 project has been developed on a 'Built Operate and Transfer' basis with the Government of Lao PDR. The project will generate and sell electricity to EGAT and EDL for 27 years under a concession provided by Government of Lao PDR and the Power Purchase Agreements with EGAT and EDL respectively.

### 1.3 ADB TERMS OF REFERENCE

The ADB provided ToR identified four key objectives:

- 1. *Provide updated baseline biodiversity data in NNP1 project affected* areas covering the: inundation area, downstream of the reservoir, downstream of the regulating and construction quarry site.
- 2. *Provide comprehensive baseline biodiversity data* covering Nam Xan River (140 km-stretch) and a nearby National Protected Area (NPA) as the potential biodiversity offset area;
- 3. Assess the suitability of a biodiversity offset to address any residual impacts on biodiversity and associated natural habitats from the NNP1 projects in order to achieve "no net loss or a net gain of the affected biodiversity". This will take into consideration the ecological, social, legal, institutional and financial viability and value of establishing a biodiversity offset at the target sites.
- 4. *Recommend and design biodiversity offset measures*. This will include identifying suitable sites/areas, designing biodiversity offsetting activities, quantifying conservation benefits and gains, developing operational management plans and associated legal, institutional arrangements, roles and requisite capacities, calculating budgets and designing suitable financial arrangements, developing stakeholder participation programs, benefit mechanisms and compensation requirements, and establishing appropriate monitoring and evaluation arrangements.

# 1.4 PURPOSE OF THIS REPORT

The purpose of this report is to provide an updated baseline assessment of the biodiversity values relevant to the Project in response to the Terms of Reference (ToR) provided by ADB. This report is intended to meet the first two objectives of the ToR, by describing the biodiversity of NNP1 affected areas as well as the biodiversity of candidate offset sites (including Nam Xan River as described in objective two).

This report will document updated baseline biodiversity assessment required to revise the Project EIA and finalise the Biodiversity Offset Design Report. The Biodiversity Offset Design Report will be compiled to satisfy the final two objectives of the ADB ToR.

This report should be read in conjunction with the EIA for the Project. The remainder of the EIA provides additional detail on a number of assessment components which are not necessarily provided in detail in this report. In particular:

- EIA Appendix B Biodiversity Offset Design Report;
- EIA Appendix C Cumulative Impact Assessment Report;

- Appendix D Environmental Flow Assessment Report; and
- Appendix F1 IEE for Transmission Line.

## 2 BIODIVERSITY VALUES ASSESSMENT METHODS

### 2.1 RELEVANT ASSESSMENT STANDARDS

## 2.1.1 Asian Development Bank

The ADB Safeguard Policy Statement (SPS) (June 2009) outlines the requirements that the borrower/clients are required to meet when delivering environmental safeguards for project supported by the ADB.

Environmental assessment requirements are identified, including the basis for the assessment process. Specific to biodiversity conservation and sustainable natural resource management the borrower/client:

'will assess the significance of Project impacts and risks on biodiversity and natural resources as an integral part of the environmental assessment process.... The assessment will focus on the major threats to biodiversity, which include destruction of habitat and introduction of invasive alien species, and on the use of natural resources in an unsustainable manner. The borrower/client will need to identify measures to avoid, minimise, or mitigate potentially adverse impacts and risks and, as a last resort, propose compensatory measures, such as biodiversity offsets, to achieve no net loss or a net gain of the affected biodiversity.'

Primarily the revised EIA documents the significance of Project impacts and management of potentially adverse impacts, with this report providing the baseline data to facilitate the impact assessment.

The policy statement describes habitat area categories to be considered including modified habitat, natural habitat and critical habitat. This baseline assessment describes the modified and natural habitats in accordance with the SPS and undertakes an assessment to identify the presence of critical habitat that may directly or indirectly impacted by the Project. The assessment identifies critical habitat in accordance with the definitions of the SPS and draws upon the criteria thresholds defined by international guidelines.

# 2.1.2 International Finance Corporation Performance Standard 6

The International Finance Corporation (IFC) Performance Standards establish a range of social and environmental obligations to be met by recipients of IFC financing. Governance of the Performance Standards is the responsibility of the IFC. There are eight IFC Performance Standards of which Performance Standard 6 (PS6) is relevant to this biodiversity assessment.

IFC PS6 defines the parameters of biodiversity and ecosystem services which will be considered when assessing the Project against the IFC Performance Standards. This includes the identification and consideration of biodiversity values that include habitat values, threatened species, ecosystem services, protected areas and invasive species. PS6 outlines the objective of no net loss of biodiversity in natural and modified habitats and a net gain of biodiversity in Critical Habitats, where feasible. The PS6 also identifies the need to consider use of offsets to compensate for residual impacts to biodiversity as a result of the Project, but only after the mitigation hierarchy has been applied to the fullest extent practicable.

# Threatened Species

Threatened species are identified in PS6 as those listed on the IUCN Red List of Threatened Species. The IUCN Red List of Threatened Species provides taxonomic, conservation status and distribution information on plants and animals that have been evaluated using the IUCN Red List categories and criteria. The criteria identify three categories of threatened species:

- Critically Endangered (CR);
- Endangered (EN); and
- Vulnerable (VU).

Five additional categories of plants and animals are included in the IUCN Red List including:

- Extinct;
- Extinct in the Wild;
- Near Threatened (NT);
- Least Concern (LC);
- Those for which data is insufficient Data Deficient (DD); and
- Those which have not been evaluated (NE).

Species categorised as CR, EN and VU are considered to be at a heightened risk of extinction and are awarded an elevated level of consideration under the IFC Performance Standards.

# Critical Habitat

One of the key provisions of IFC PS 6 is the identification of 'Critical Habitat'. IFC PS6 defines Critical Habitats as areas with high biodiversity value, including (i) habitat of significant importance to Critically Endangered and/or Endangered species; (ii) habitat of significant importance to endemic and/or restricted-range species; (iii) habitat supporting globally significant concentrations of migratory species and/or congregatory species; (iv) highly threatened and/or unique ecosystems; and/or (v) areas associated with key evolutionary processes. Critical Habitat may not be limited to pristine or highly biodiverse areas but rather may include modified and natural habitats across the broader landscape that supports the biodiversity values that trigger the Critical Habitat designation.

### 2.2 REGIONAL BIODIVERSITY CONTEXT

The proposed Project is located in central Lao PDR within the Mekong River basin in the Luang Prabang Montane Rainforest Ecoregion (IM0121), as defined by the Worldwide Fund for Nature (WWF) (WWF, 2003a).

Terrestrial ecoregions are natural ecological communities with shared species, dynamics and environmental conditions and offer a useful way of understanding the biodiversity within an area (ADB & UNEP, 2004). The Luang Prabang Montane Rainforests ecoregion comprises areas largely above 800 m in north-central Lao PDR and is globally recognised for its diversity in bird species (some 540 different species of birds have been recorded) despite more than 70 per cent of the original forest cover being lost as a result of shifting cultivation. The remaining forests contain a rich mix of tree and non-timber species including hardwoods, conifers, rhododendron, ferns, orchids and lichens (WWF, 2003b). No endemic species have been recorded in this ecoregion but this is thought to be due to the lack of biological surveys rather than a true lack of endemics.

The ecoregion is characterised by a variety of forest associations including montane hardwoods, mixed conifer-hardwood forests, open montane forests, and open conifer forests (Wikramanayake *et al.*, 2002). These forests have been subject to heavy logging pressure and much of the forest cover of central Lao PDR is subject to existing forestry operations, or occurs within approved forest leases. Humid evergreen forest occurs at lower elevations around 800 m with *Dipterocarpus turbinatus* and *Toxicodendron succedanea* as the dominant over storey species. The low stature of trees in this community and open understory with an abundance of broad-leaved monocots and grasses suggest severe past impacts from burning and clearance (Wikramanayake *et al.*, 2002). Slash and burn agriculture is a land use that is still practiced widely in central Lao PDR, including the Project area (ERM, 2013b).

Large tracts of remnant and intact forest are reported to occur in less accessible parts of the ecoregion housing several large mammals such as Northern White-cheeked Gibbon (*Nomascus leucogenys*), Tiger (*Panthera tigris corbetti*), Asian Elephant (*Elephas maximus*) and Asiatic Black Bears (*Ursus thibetanus*); all of which are considered to be under continued threat due to habitat loss and hunting/ poaching (WWF, 2003b).

The ecoregion, and the biodiversity housed within it, continues to be threatened by intensive land use pressures, such as cultivation, agriculture, mining and hydropower. As of 2004, the remaining forest cover in Lao PDR was considered to be approximately 41.5 per cent, which is a significantly less than the 1940 estimation of approximately 70 per cent (World Bank, 2005).

These pressures are coupled with use by local communities pose additional threats to the biodiversity values of the area. This includes hunting of small mammals and firewood collection in nearby forests and fishing in local waterways. Much of what is caught and/ or collected is consumed locally (i.e. within household) rather than sold at market.

#### 2.3 INVESTIGATION AREAS

A number of locations, summarised below, were assessed as part of this baseline biodiversity assessment. Within this report the following terminology applies:

- Study area the area encompassing all areas assessed for biodiversity values. This includes the Project area and candidate offset sites and surrounds (*Figure 2.1*).
- Project area the area potentially directly and indirectly affected by the Project (*Section 3*). This area is consistent with the Project 'area of influence' in accordance with the ADB SPS. It includes the footprint of disturbance of the various project components (direct impact area) as well as areas of the wider Nam Ngiep catchment (indirect impacts).
- Candidate offset sites the areas investigated to provide potential offset sites. This included consideration of the biodiversity values at four locations: the Upper Nam Ngiep River, Nam Xan River, Huay Ngua Provincial Preserved Area (PPA) and the Phou Khao Kouay (PKK) National Protected Area (NPA). The extent and characteristics of these areas is further described in *Section 4*.

The study area components are described in *Table 2.1* and shown in *Figure 2.1*.

Note that areas shown in *Table 2.1* estimate the area of direct impact or coverage (in the case of candidate offset sites). The area of influence includes the wider Nam Ngiep catchment and has less defined extent. The impact assessment considers the magnitude and significance of both direct and indirect impacts in order to assess impact to the area of influence.

| Study Area       |   | Area (ha)          |
|------------------|---|--------------------|
| Project area     | Main Dam site and inundation area                     | 6,798              |
| ,                | Resettlement Site                                     | 467                |
|                  | Re-regulation Dam                                     | 699                |
|                  | Access Road network (estimated footprint of 4.75      | 521 (Length 58 km) |
|                  | m from centreline)                                    |                    |
|                  | Lower Nam Ngiep (downstream of the dams)              | -                  |
| Candidate Offset | Upper Nam Ngiep River (outside inundation area)       | 127,176            |
| Sites            | Nam Xan River   | Length – 85 km     |
|                  | Huay Ngua PPA   | 5,860              |
|                  | Phou Khao Kouay NPA                                   | 181,306            |
| 1. Based on      | length of 58 km, and width of 4.75 m from centreline. |                    |

# Table 2.1Summary of Study Area

### 2.4 BASELINE BIODIVERSITY SURVEY

The baseline biodiversity values of the Study area have been determined using a number of information sources including:

- Flora and fauna survey across the Study area;
- Desktop sources (published and grey literature, available reports, geospatial datasets and species profiles);
- Geospatial datasets including remote sensing data;
- Species expert consultation;
- Detailed flora survey of the access road corridor; and
- Targeted threatened species survey.

These sources provide description of vegetation communities and habitats, and species that may occur in the Project area. The data collated for the purposes of this report can be categorised into two types:

*Direct:* Species recorded during biodiversity field surveys undertaken during 2007 and 2013 are considered direct counts. In general the location and details of this data has been recorded and a higher level or certainty can be inferred.

*Indirect:* Species reported from village surveys or within reports (secondary data) using a more regional study area are considered indirect records. These data sources provide a valuable understanding of the biodiversity of the locality and region however should be afforded further analysis or applicability considered. Data obtained from village surveys can contain errors in some instances, especially when considering identification of species with more challenging diagnostic features.

The reliability of the records has been considered throughout the report and the data category of species records is denoted.

The direct and indirect data sources are described in this section.

# 2.4.1 Direct Biodiversity Data Sources

# NNP1 Environmental Impact Assessment 2012

The NNP1 Project EIA document was completed in 2012, which included an ecological investigation undertaken by the Environmental Research Institute, Chulalongkorn University (ERIC). The investigation included studies on the biological environment of the Project area covering terrestrial ecology and wildlife, forest and vegetation cover, aquatic biota and wetlands.

ERIC surveyed the Project area in March and October 2007 in order to identify threatened species occurring in or near the Project area, and whether the

project has potential to impact their habitats. The assessments were carried out through visual inspection (direct data), interviews with villagers (indirect data) and utilisation of secondary data sources. Detailed survey methodology for this component is provided in *Annex A*. Results of the surveys reported that current clearing and general habitat disturbance has resulted in many species not occurring in the Project area.

The forest types within the project sub-catchment were classified according to the classifications and definitions from Forest Inventory and Planning Division, Department of Forestry (DoF). The forest and land use data used for the study was based upon imagery (the Assessment of Forest Cover and Land Use during 1992-2002 (Department of Forestry, 2005)) that has now been superseded by land cover mapping data prepared by the Department of Forest and Resource Management (DFRM) in 2010 (DRFM, 2010).

# Thailand Institute of Scientific and Technological Research Biodiversity Survey

Field investigations were undertaken in March and July 2013 by the Thailand Institute of Scientific and Technological Research (TISTR) to collect data representative of wet and dry season biodiversity conditions. The TISTR team as a subcontractor to ERM were engaged to undertake survey design, field survey and deliver a field survey biodiversity report to inform the development of offset design. The TISTR report has been used in the development of this biodiversity baseline assessment report.

Surveys were undertaken by teams targeting separate taxa: vegetation (team of 7 people), terrestrial wildlife (team of 6 people) and aquatic biota (team of 5 people). The surveys incorporated detailed assessments that included forest and vegetation cover survey and assessment, wildlife survey and assessment, and aquatic ecology survey and assessment.

Surveys were undertaken at four of the investigation areas that include:

- The Project area (main dam site and inundation area, re-regulation dam site (including inundation area), resettlement site/lower Nam Ngiep);
- Upper Nam Ngiep River;
- Upper and lower Nam Xan River; and
- Huay Ngua Provincial Preserved Area.

Sampling locations are shown in *Figure 2.2*. Detailed survey methodology for this component is provided in *Annex B*.

# Forest and Vegetation Survey

The forest survey team surveyed for species diversity along trails and in sampling plots. Unknown plants were collected and three duplicates of leave with flowers or fruits for further analysis in the laboratory. Botanists recorded necessary information i.e. morphology, habit, colour of flowers and ecology, georeferenced location, and compiled photographic records.

Across the survey the sampling plots consisted of 3 types of temporary plots:

- A circular sample plot with a radius of 17.85 meters (or 0.1 ha);
- Square plots of 5x5 meters (25 square meters or 0.0025 ha); and
- Square plots of 2x2 meters (4 square meters or 0.0004 ha).

Analyses of the data collected included specialised laboratory investigations to establish identification of voucher specimens.

# Terrestrial Fauna Survey

The terrestrial fauna survey aimed to describe the baseline wildlife diversity of the NNP1 Project area impact zones for the purposes of assessing the potential Project impacts to terrestrial wildlife. Survey and sampling work involved developing an inventory of wildlife species (amphibians, reptiles, birds, and mammals).

The inventory for each fauna group was collected through direct and indirect counts.

Direct counts were carried out to determine numbers of amphibians, reptiles, birds, and mammals by sightings during the field surveys at each survey station. Observations and records of animal signs such as tracks, nets, burrows, droppings, hair and feathers, were also recorded. Details of the techniques used for each group include:

- Amphibians and reptiles: species searches were undertaken in habitats such as under logs, rocks, bark as well as digging in the buttress of trees. At night, spotlighting was used to detect nocturnal species along rivers, around poundages, and within tree canopies.
- Birds: were directly observed using binoculars during day time. Some species of birds were identified using call identification during the morning or evening, when they are the most active. Birds were also caught using mist-nets under tree canopies or cross the creeks these were identified, photographed, and released.
- Mammals: were observed from their signs such as tracks, scats, scratches on trees, burrows, etc. small mammals, were captured using live-traps or Sherman's traps. Bats were surveyed at night using mist-net and harp traps

placed under tree canopies or cross creeks. Some species of mammals were identified from local hunters.

For all wildlife species the habitats were recorded. In the case of unidentified individuals these were collected and preserved and later analysed at the laboratory in the Natural History Museum-Nation Science Museum, Pathum Thani, Thailand.

Indirect counts were used to obtain supplementary information on fauna by interviewing local residents who lived in or near by the area. Some local villagers may hunt animals for food or for sale. Local households as well as local markets were also sampled.

Relative abundance of wildlife was calculated from numbers obtained in the direct and indirect counts, species were assigned as abundant, common, and less common using a calculation formulated by Pettingil (1969).

# Aquatic Biota Survey

Aquatic biota sampling was conducted at different locations in Nam Ngiep, Nam Xan, Huay Ngua PPA and the resettlement area. Survey techniques included:

- collection of phytoplankton and zooplankton species using multiple plankton net surveys at each location, followed by preservation, identification and laboratory analysis at TISTR;
- collection of benthos at multiple replicate sites using an Ekmann dredge, followed by identification and abundance counts at the TISTR laboratories; and
- capture and identification of fish species within the main rivers and their tributaries using the help of local fishermen using multi-mesh gillnets, electrofishing, cast nets, gun and hook, as well as discussions with fishermen and other information sources.

# National University of Laos Ground-truth of Natural Habitat Survey (Access Road Corridor)

Specific to the proposed disturbance area for the access road network Nam Ngiep 1 Power Company engaged Pheng Phengsintham, a botanist and lecturer of the National University of Laos (NUL) to undertake survey to ground-truth flora species and delineate natural/modified habitat.

The November 2013 assessment aimed to identify areas of natural and modified habitat within the Proposed Road. Some stretches of temporary and permanent roads in the vicinity of the re-regulation dam were not able to be assessed. The assessment involved survey at 53 temporary sampling plots where the vegetation type and tree species were recorded each side of the proposed access road. The temporary sample plots were set within the proposed access road area with the ten closest trees recorded and measured. The outcomes of NUL assessment have been incorporated in baseline data and description.

# Dr Phaivanh Phiapalath Endangered Primate Survey

Targeted survey of the inundation area, in particular potential habitat areas for the Northern White-cheeked Gibbon (*Nomascus leucogenys*, Critically Endangered), Red-shanked Douc Langur (*Pygathrix nemaeus*, Endangered) and Phayre's Leaf Monkey (*Trachypithecus phayri*, Endangered) were undertaken in December 2013. The survey aimed to identify habitats for the species, confirm if the species is present and assess the significance of the area for these primate species. The survey area included the inundation area with four survey clusters established and surveyed by five sub-survey teams.

The survey was conducted by establishing listening posts for gibbons and reconnaissance surveys for non-vocal primate species. Additional data was captured from village interviews with boat men, hunters and elders of Ban Pou, Ban Sop Phouan and Ban Sop Youak.

# Dr Kottelat Fast Water Habitat Survey

Aquatic survey targeting fast water habitats was undertaken in February 2014 to meet a knowledge gap in fish species data recognised for this habitat type. Most sampling was undertaken using a battery-powered electric fish shocker or using ichtyocides. Other methods used included push-net and seine, as well as inspection of villager catches and restaurant kitchens.

Fish were sampled or observed at 21 sites in the Nam Ngiep draninge upstream of the dam site, 14 of them in fast water habitats in the inundation area of the main dam. Eight locations were sampled in the Nam Xan drainage, one in the Nam Mang and six in the Nam Xao.

# Mr Terry Warren Critically Endangered Fish Species Habitat Survey

To further understand the extent of habitat and distribution of *Luciocyprinus striolatus* in the Nam Ngiep catchment and adjacent sub-catchments, a team led by Mr Terry Warren undertook field survey from 3 to 8 April 2014. The survey aimed to collected evidence of critical habitat presence or absence associated with the life-cycle of the species (namely spawning locations), the hydro-geomorphic characteristics of rivers where the species is reportedly found and identify any practical measures that might be used to protect the species with regard to the Nam Ngiep catchment.

Villages and accessible river stretches were visited by the team and anecdotal information collected specific to the species.

# 2.4.2 Indirect Biodiversity Data Sources

# Desktop Review

Desktop review was undertaken to collate and assess other data sources. The desktop review included an assessment of:

- Online reports relating to the Project area and biodiversity of Lao PDR;
- Threatened species profiles and online species distribution information; and
- Published literature relating to threatened species and Lao PDR biodiversity.

Information collated through desktop review was used to provide additional background information relating to the biodiversity values associated with the Study area. Key desktop documents included:

- Houay Ngua Provincial Preserved Area Management Plan (MP) 2011-2015 by the Provincial Agriculture and Forestry Office of Bolikhamxay (PAFO) (December 2010) – species identified have been considered to have potential to occur in habitat associated with the Access road (indirect data). The management plan reports species based on some field survey and village interview results;
- Nam Ngum 3 Hydropower Project: Final Environmental Impact Assessment, October 2011 prepared by NN3 Power Company;
- The Status and Distribution of Freshwater Biodiversity in Indo-Burma compiled by D.J. Allen, K.G. Smith and W.R.T. Darwall for the International Union for Conservation of Nature (IUCN);
- Wildlife in Lao PDR, 1999 Status Report compiled by J.W. Duckworth, R.E. Salter and K. Khounboline for the IUCN, Wildlife Conservation Society and Centre for Protected Areas and Watershed Management;
- Significant Wildlife and Wildlife Habitats of Bolikhamxay Province April 2011, Integrated Ecosystem and Wildlife Management Project: Bolikhamxay Province Provincial Agriculture and Forestry Office and the Wildlife Conservation Society

# Geospatial Analysis

Geospatial analysis was undertaken to assist in understanding the biodiversity values in the Project area and candidate offset sites. Primarily this was based on interpretation of a variety of spatial layers provided by DFRM and Rapideye Imagery. The analysis included land cover mapping, production forest and vegetation community mapping that delineates land cover types. In order to further understand the biodiversity values represented within the Project area and candidate offset sites, remote sensing analysis was undertaken to map the variation in vegetation condition. Rapideye Imagery was used to identify the normalised difference vegetation index (NDVI) across the area. NDVI is a remote sensing indicator that provides a measure of vegetation density and condition by indicating the photosynthetic capacity of the land surface cover.

The imagery outputs provide a NDVI in grid formation (5m x 5m) across the Project area and candidate offset sites. For the Project condition classes (for a range of NDVI) were defined and applied to each forest type. The condition classes are shown in *Table 2.2*. These condition classes were used to refine land cover calculations. Area within the Impacted NDVI range was removed from the habitat area calculations.

# Table 2.2Condition Class NDVI Range

| Condition | NDVI Range |
|-----------|------------|
| Benchmark | 0.8 to 1.0 |
| High      | 0.6 to 0.8 |
| Moderate  | 0.4 to 0.6 |
| Low       | 0 to 0.4   |
| Impacted  | -ve to 0   |
|           |            |

#### Limitations

For this Project NDVI has been used as a remote sensing tool to indicate vegetation condition. As with all remote sensing techniques there are limitations associated and all information has not been ground-truthed. The outcomes of this assessment should be interpreted on a regional scale and note that the data is based on image capture at one specific time. Similarly, as discussed NDVI is an indicator of photosynthetic capacity of the surface and does not distinguish between vegetation communities.

The inherent benefit of utilising NDVI relates to the remote sensing accessibility of information from areas that may be difficult to access on the ground or when considering larger areas for a local and regional context. The index allows for comparison of vegetation photosynthetic capacity along the length of the corridor in the context of the surrounding landscape.

The NDVI and land cover calculations are based on 5 metre square pixels. The Rapideye satellite imagery provided was at 5 metre square pixels and this same level of accuracy was used in generating the NDVI and land cover calculations presented in this report.

#### Species Specialist Consultation

In addition to desktop sources, a number of species specialists were consulted to assist in developing an understanding of the importance of the Project area for the critical habitat candidate species. Each specialist contacted provided advice via email response to queries clearly identified as related to this Project. The specialists that provided advice are listed in *Annex C* and advice is referenced as appropriate.

Key input was provided by Dr J.W Duckworth, Dr M Kottelat, Dr P Phiapalath and Mr T Warren. Comment was provided on some species texts however it is acknowledged that the final content remains the responsibility of the report compilers.

A number of primate species were determined candidates for critical habitat and Dr Phiapalath of the IUCN SSC Primate Specialist Group was engaged to undertake further site survey and advice relating to critical habitat for primate species. The method of assessment and discussion relating to habitat value is provided in *Annex D* and the advice has been incorporated into the critical habitat assessment. Similarly, Dr Kottelat was engaged to undertake additional fast water habitat fish surveys and Mr Warren was engaged to undertake additional targeted village interviews. The results of which have been incorporated into the critical habitat assessment and summary reports provided in Annex *E*.

# Social and Cultural Surveys

An assessment of the ecosystem services was undertaken to supplement the biodiversity assessment completed for the NNPI project. The aim was to provide a social context to the establishment of biodiversity offsets.

It should be noted that the ecosystem services assessment in this report does not replace the consultation or social assessment undertaken for the project, rather draws upon findings of consultation for the purposes of identifying ecosystem services only.

The assessment included two field visits. The first visit was conducted in February and March 2013. It involved engagement with key government and non-government officials to understand current land use and tenure as well as use and threats to biodiversity in the Nam Ngiep River catchment and potential offset site. In addition, village and market surveys were undertaken. These were used to gather data on the utilisation of ecosystem services by project affected people (PAP), including the use of threatened flora and fauna. The village surveys included focus group discussions and in-depth interviews with relevant community representatives (e.g. hunters, gatherers); while the market surveys involved visual surveys and informal discussions with stall operators.

The second field visit was conducted in July 2013. The focus was on understanding and assessing the ecosystem services in the potential offset site as well as community acceptance of the proposed offset measures. The survey approach was similar to that conducted in the first field visit – e.g. focus group discussions, in-depth interviews and visual surveys.

In total, 18 villages and four markets were surveyed. The outcome was an understanding of stakeholder opinions and concerns as they relate to the potential offset site and proposed offset measures and an understanding of ecosystem services utilised by local community members.

Other sources reviewed included:

- NNP1 Social Impact Assessment Draft Report, which provided initial baseline information for the Project area (2012);
- Physical Cultural Resources: Preliminary Archaeological Survey in the proposed Nam Ngiep 1 Hydropower Project (NNHP-1), an archaeological survey report written in October 2007 provided by Mr Viengkeo Souksavatdy, Deputy Head of the Archaeology Department, MICT;
- Village surveys to determine the socio-economic context for the biodiversity offsets. This included focus groups and in-depth interviews with relevant representatives from communities in the Project area and proposed offset catchment;
- Market surveys in the Project area and proposed offset catchment to further understand and quantify the threat to flora and fauna; and
- Engagement with relevant stakeholders (e.g. representatives from government and non-governmental organisations) to confirm local land use activities, including the presence and use of biodiversity.

## 3 PROJECT AREA BIODIVERSITY VALUES

# 3.1 OVERVIEW

The following section summarises the key biodiversity values identified during in the baseline assessment of the Project area. It provides an overview of the biodiversity values associated with the Project area to enable determination of impact assessment associated with the project activities and for the determination of biodiversity offsets. The impact assessment is documented in Chapters 6 and 10 of the EIA.

Specifically, a description of habitats within the Project area in accordance with the terminology defined by the ADB Safeguard Policy Statement is provided. The Project area is made up of the components described in *Section 1.2* and shown in *Figure 1.2*.

Lao PDR is approximately 41 per cent covered by forest and is considered one of the most biodiversity rich countries in Southeast Asia (World Bank, 2005). In general, the main dam inundation area (inundation area approximately 6798 ha) is located in mountainous terrain with some intermittent narrow plains. There are high mountains on both sides of the river. Downstream of the main dam is a valley with slopes less steep than the upstream reaches as the river widens and the relief flattens downstream of the re-regulation dam (approximately 700 ha). Forest vegetation dominates the Lao PDR and the Project area.

# 3.2 TERRESTRIAL BIODIVERSITY VALUES

# 3.2.1 Vegetation

# Land Cover

Using land cover mapping (DFRM, 2010), natural and modified habitats can be identified within the Project area. *Table 3.1* summarises the land cover shown in *Figure 3.1* and identifies the habitat category of each land cover type.

Natural habitat is an environment where the biological communities are largely formed by native plant and animal species and where human activity has not modified the areas primary ecological functions (ADB, 2012). The natural habitats within the Project area include deciduous forest, evergreen forest and bamboo vegetation.

Modified habitat is altered natural habitat, often formed by the removal of native species for harvesting, land conversion and/or introduction of alien flora and fauna species (ADB, 2012). The modified habitats within the Project area include young and old fallow land, slash and burn, rice paddy, grassland and urban areas. The Project EIA (ERI, 2009) identified during field reconnaissance and village interviews that a large portion of the main dam and re-regulation dam inundation areas has already been disturbed by

conversion of forest land to other land use types (predominantly agriculture) as well as burning for hunting and illegal logging.

Overall, the vegetation within the Project area is dominated by forest (natural habitat) and fallow land vegetation (modified habitat). The deciduous forest land cover dominates the Project area, representing approximately 36 per cent of the footprint. Young and old fallow land is also highly represented with 16 and 21 per cent respectively.

Within the main dam inundation area, approximately 50 per cent is mapped as natural habitat with deciduous forest the dominant land cover type. Patches of natural habitat are dispersed throughout the main dam inundation area though it is the narrower stretches of the inundation area where the majority of the deciduous forest and evergreen forest is mapped. The fallow lands and rice paddy areas dominate the lower third of the inundation area, in particular in large patches where the dam inundation will be its widest at Vang Naxay and Na Nhao.

Within the re-regulation dam area, approximately 40 per cent is mapped as natural habitat with high proportions of deciduous forest and bamboo, mainly located on the southern bank of the Nam Ngiep River. These land cover types are located in the upper re-regulation dam area as the lower reach is dominated by fallows lands.

The resettlement site is mapped with approximately 40 per cent natural habitat which is primarily bamboo and a small area of deciduous forest. The bamboo is distributed throughout the fallow lands, though the deciduous forest is generally restricted to the edges of the proposed resettlement area.

|                               |                         |   |                        | Area (ha)                          | 1                 |                 |               |               |

#### Forestry Classification Mapping

Forestry classification mapping identifies both protection forest and production forest across the Project area. *Figure 3.2* depicts the extent of protected and production forest within the Project area and shows that greater than half of the Project area is mapped as National Protected Forest. Protection forest is described as:

'forest and forest land classified for the protection of watershed areas and the prevention of soil erosion. It also includes areas of forest land significant for national security, areas for protection against natural disaster and protection of the environment and other areas.'

The protection forest extends from the resettlement site upstream in the catchment of the Nam Ngiep River. The upper area of the main dam inundation area is mapped as production forest. Production Forests are natural forests and planted forests classified for the utilization purposes of areas for production, and wood and forest product businesses to satisfy the requirements of national socio-economic development and people's living. Production forests are primarily managed for the production of timber resources. The Forestry Law provides the basis for the management of production and conservation forests in Lao PDR outside of the protected area system. It enables the possible reclassification of production forests to protection forests to enable long-term conservation of potential biodiversity offset areas.

#### Vegetation Condition

The NDVI features recorded in Rapideye Imagery provides an index of vegetation density and condition at the time of image capture. It indicates the photosynthetic capacity of the land surface cover and has been used to refine the vegetation type extents into an additional level of detail. The NDVI across the Project area is shown in *Figure 3.3* and the area of each classification is summarised in *Table 3.2, Table 3.3, Table 3.4* and *Table 3.5*.

Over 80 per cent of the Project area is classified as moderate or high NDVI. Up to 5 per cent of the Project area is classified as impacted NDVI. The following tables summarise the vegetation condition for each Project area component.

| Forest type       | Code | Impacted<br>(- to 0) | Low<br>(0 - 0.4) | Moderate<br>(0.4 - 0.6) | High<br>(0.6 - 0.8) |
|-------------------|------|----------------------|------------------|-------------------------|---------------------|

#### Ground-truthed Vegetation Communities/Habitat

Detailed ground-truthing was undertaken within the proposed access road corridor only in preparation for construction activities. In general detailed ground-truthing determined, with respect to the representation of natural habitat, that the landcover mapping provides an over-estimate of the extent of natural habitat.

Ground-truthing results for the access road corridor for the Ban Nomsomboun to Ban Hat Gniun section of the proposed road identified substantially less natural habitat (47% natural habitat) than detected in land cover mapping (61% natural habitat). Similarly, ground-truthing of the JICA Road results (11% natural habitat) were less than indicated on land cover mapping (22% natural habitat).

The flora survey undertaken of the access road by NUL, ground-truthed the land cover mapping to confirm the presence of natural or modified habitat in accessible areas of the access road network. *Table 3.6* summarises the habitat description for segments of the access road, as provided in the draft field report from the corridor flora survey (Phengsintham 2013). *Table 3.4* of the Access Road IEE report summarises the modified and natural habitat areas.

| <b>Road Segment</b> | Vegetation Description   |
|---------------------|--|
| Ban                 | Primarily modified habitat on left and right sides, except TSP no5 on the      |
| Nomsomboun to       | left hand side, where regeneration forest occurs across for approximately      |
| Huay Ngua PPA       | 500 m of the access road.  |
| Inside Huay         | Huay Ngua PPA primarily consisted of lower mixed deciduous fores               |
| Ngua PPA            | (LMD). Within the corridor, the average DBH in LMD is 38 cm and                |
|                     | average distance 9.3 m. In comparison, outside the corridor, the average       |
|                     | DBH was 34.5 cm and the average distance 7.8m.                                 |
|                     | A total of 114 Mai Yang Khao (Dipterocarpus turbinatus - Critically            |
|                     | Endangered, IUCN list) have previously been recorded. 21 items were            |
|                     | cleared by the EDL (pole installation), 29 exist within the road corridor      |
|                     | and the remaining will be preserved by NNP1PC and PAFO.                        |
|                     | Removal of Mai Yang Khao could be replaced by replanting the specie            |
|                     | inside the PPA, supporting the provincial office to improve Huay Ngu           |
|                     | PPA through reforestation and providing a check point during road              |
|                     | construction.  |
| JICA road           | JICA road passes through Ban Hat Gnuim and Hatsaykham villages.                |
|                     | The sections is primarily modified forest, except two points (TSP no35 and     |
|                     | no40), which are small patches of UMD. The Average DBH 43 cm and               |
|                     | average distance 7.08 m for TSP no35.  |
|                     | This vegetation type represented the dense vegetation (UMD) at the site        |
|                     | but the forest was disturbed by historical logging activities, shiftin         |
|                     | cultivation (ray) and other agricultural activities.                           |
| P2 and T12          | Three TSPs were established. The area between ICA road and TSP no4             |
|                     | was primarily Fallow Forest. Between TSP no43 and TSP no45 vegetation          |
|                     | was primarily disturbed UMD to the right of the road, and Fallow Forest t      |
|                     | the left of the road.  |
|                     | This vegetation represented the highest quality dense vegetation, however      |
|                     | the forest was disturbed by historical logging activities, shifting cultivatio |
|                     | (ray) and fired in May 2013.   |

#### Table 3.6Vegetation descriptions from road corridor flora survey (Phengsintham 2013)

| Road Segment   | Vegetation Description   |  |  |  |  |
|--|--|--|--|--|--|
| T7, T8 and T9  | Eight TSPs were surveyed in these access roads. The area included young  |  |  |  |  |
| Access Road  | fallow forest, plantation area and mixed deciduous forest. The average   |  |  |  |  |
|  | DBH in UMD was 44.8 cm and the average distance 9.48m. In comparison,    |  |  |  |  |
|  | outside the corridor the average DBH was 28 cm and distance about 6.36m. |  |  |  |  |

| botanist and Lectur  | er of the National University of Laos) (November 2013).                  |  |  |  |  |

#### 3.2.2 Flora Species

Thirty-five sample plots were assessed in the main dam inundation area during the 2007 survey by ERI with an additional 113 survey plots assessed across the main dam inundation, re-regulation dam inundation, resettlement area and candidate offset sites during the 2013 TISTR survey.

Sampling undertaken during the 2013 survey by TISTR recorded the diversity of vascular plants in the main dam inundation area (upper Nam Ngiep) was greater in comparison to all other areas sampled for the Project, with at least 509 species recorded. The primary vegetation types at each of the components of the Project is summarised in *Table 3.7* based on the 2013 TISTR survey results. A full species list is provided in *Annex F*.

| Surv          | rey  | Forest Type Description   |  |  |  |  |
|---------------|------|---|--|--|--|--|
| Locat         | ion  |   |  |  |  |  |
| Main          | Dam  | Mixed deciduous forest located in the steep valley. Nearby the forest is        |  |  |  |  |
| Inundatio     | on   | mixed with some species of dry evergreen forest. Canopy cover is                |  |  |  |  |
| Area          |      | approximately 60-70%. Top canopy height is 20-40 m.                             |  |  |  |  |
| Resettlen     | nent | Secondary growth of mixed deciduous forest. Canopy cover is                     |  |  |  |  |
| Site          |      | approximately 40%. The average height of the upper canopy is                    |  |  |  |  |
|               |      | approximately 15 m.   |  |  |  |  |
| Re-regulation |      | Lower mixed deciduous forest and mixed deciduous forest on one river            |  |  |  |  |
| Dam           |      | bank. Canopy cover is approximately 50-60%. Top canopy height is 10 m. On       |  |  |  |  |
| Inundatio     | on   | other river bank is Eucalyptus plantation. Canopy height is 15 m under          |  |  |  |  |
| Area          |      | which is densely covered by seedlings of the original mixed deciduous forest    |  |  |  |  |
|               |      | type.   |  |  |  |  |
| Lower         | Nam  | Dominated by disturbed mixed deciduous forest. Canopy cover is                  |  |  |  |  |
| Ngiep         |      | approximately 60-70%. Top canopy height is 20-30 m.                             |  |  |  |  |
| Access        | Road | Dominated by mixed deciduous forest with some areas of mixed evergreen          |  |  |  |  |
| (Huay         | Ngua | forest and secondary growth of mixed deciduous forest. Canopy cover is          |  |  |  |  |
| PPA)          |      | approximately 60-70%.   |  |  |  |  |
| Transmis      | sion | Secondary growth of mixed deciduous forest with canopy cover of 40%.            |  |  |  |  |
| Line          |      | Forest condition and species diversity is similar to the Resettlement site. The |  |  |  |  |
|               |      | average height of the upper canopy is approximately 15 m.                       |  |  |  |  |

Table 3.7Primary Forest Type at Project area

For the forest types the forest canopies are divided in 3 classes. The dominant species for each survey locations are summarised in *Table 3.8*.

| Canopy class                                    | Dominant species  |  |  |  |  |  |  |
|---|---|--|--|--|--|--|--|
| Main Dam Inundation Area Mixed Deciduous Forest |   |  |  |  |  |  |  |
| Top canopy                                      | Pometia pinnata, Duabanga grandiflora, Lagerstroemia calyculata, Toona ciliata,     |  |  |  |  |  |  |

#### IUCN Listed Species

A total of thirteen species of plants listed as critically endangered, endangered or vulnerable under the IUCN Red List were recorded within the Project area during 2007 ERI and/or 2013 TISTR surveys. These include one species listed as critically endangered, seven as endangered and five as vulnerable (*Table 3.9*).

#### 3.2.3 Fauna Species

The main dam inundation area was surveyed for fauna during the 2007 survey by ERI with additional data collected in 2013 by TISTR at eight key survey locations (including the candidate offsets sites).

The diversity of fauna in the main dam inundation area (upper Nam Ngiep) was high in comparison to other areas sampled in 2013 by TISTR. Habitats varied in condition with human disturbance evident in areas downstream of the main dam. The habitat and species detected at each of the main surveyed areas are summarised in *Table 3.10*. A full list of flora species is provided in Annex F, and a list of fauna species is provided in Annex G. Threatened species are discussed separately below.

#### Table 3.10Fauna Habitat in the Surveyed Areas

| Surv<br>Loca | 5    | Forest Type Description  |  |  |  |  |  |  |
|--------------|------|--|--|--|--|--|--|--|
| Main         | Dam  | The upper area of the Nam Ngiep River is dominated by primary forest. Site     |  |  |  |  |  |  |
| Inundation   |      | surveys detected (through interviews with villagers or direct observation) at  |  |  |  |  |  |  |
| Area         |      | least 46 mammals species, 50 bird species, 28 reptiles species and 10          |  |  |  |  |  |  |
|              |      | amphibian species.   |  |  |  |  |  |  |
| Resettler    | ment | The resettlement area is mostly and heavily disturbed as a result of slash and |  |  |  |  |  |  |
| Site         |      | burn activities. There is evidence of some regeneration and secondary          |  |  |  |  |  |  |

| Survey    | Forest Type Description  |  |  |  |  |  |  |
|-----------|--|--|--|--|--|--|--|
| Location  |  |  |  |  |  |  |  |
|           | growth. Site surveys detected (through interviews with villagers or direct     |  |  |  |  |  |  |
|           | observation) at least 9 mammals species, 24 birds species, 19 reptiles sp      |  |  |  |  |  |  |
|           | and 8 amphibian species.   |  |  |  |  |  |  |
| Lower Nam | This area is mostly disturbed and dominated by agricultural landuse. There     |  |  |  |  |  |  |
| Ngiep     | is high human activity in this area. Site surveys detected (through interviews |  |  |  |  |  |  |
|           | with villagers or direct observation) at least 12 mammals species, 27 birds    |  |  |  |  |  |  |
|           | species, 21 reptiles species and 7 amphibian species.                          |  |  |  |  |  |  |

#### Restricted Species

Species listed as Restricted under the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF includes wild animals and fish which are rare, endangered, high conservation value, and special significance to the economy and national environment.

The Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF identifies wildlife into two categories, restricted species (List I), and protected species (List II). Restricted species are wild species which are rare, endangered, high conservation value and species significance to the economy/society and national environment in Lao. Activities relating to this group require permission from the Lao Ministry of Agriculture and Forestry.

A number of these species were recorded during field surveys in the Project area undertaken by ERI (2007) and TISTR (2013). Species listed as Restricted are considered candidates for critical habitat (Section 3.5).

The recent surveys (TISTR 2013) in main dam inundation area (upper Nam Ngiep), lower Nam Ngiep, resettlement site and access road detected the following terrestrial species listed as restricted in the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF:

- fifteen mammal species;
- six bird species;
- three reptiles; and
- no amphibians.

Annex *G* shows the results.

 $\checkmark$  = Direct record; x = Indirect record

#### **IUCN Listed Species**

The fauna species have been categorised by the IUCN (2012) and a number listed on the IUCN Red List have been recorded within the Project area. The 2013 (TISTR) surveys recorded one species, the Northern white-cheeked gibbon listed as critically endangered within the Project area at the main dam inundation area. A number of other species were reported through indirect records. Species listed as critically endangered or endangered are considered candidates for critical habitat and these species records have been investigated further in *Section 3.5*.

Overall, the direct and indirect records identified:

- Twenty-one mammal species (1 critically endangered, 7 endangered, 13 vulnerable);
- Five bird species (1 critically endangered, 2 endangered, 2 vulnerable);
- Nine reptile species (2 endangered, 7 vulnerable);
- No amphibian species.

Table 3.12 summarises the species recorded.

#### 3.4 AQUATIC BIODIVERSITY VALUES

#### 3.4.1 Hydrological Features

The proposed Project lies on the Nam Ngiep River which flows in a southsoutheast direction through a mountainous region to the gorge at Hat Gniun village where the topography changes to a hilly landscape before entering the Mekong River at Pakxan. The gorge is the location for the proposed dam construction.

The flow regime of an aquatic ecosystem plays a role in the health and productivity of the system and for some species, flows can trigger movement during some periods. The Nam Ngiep River has a catchment area of 3700 km<sup>2</sup> with the river approximately 160 km in length (Kansai, 2012). Flows of the river are influenced by the monsoon dominated weather which divides the year into clearly defined wet and dry periods. Peak discharges (200-325 m<sup>3</sup>/s) occur between June and September with lowest discharge volumes (50-75 m<sup>3</sup>/s) in February to April.

Upstream of the main dam site is mountainous terrain with intermittent narrow plains which are inhabited. High mountains are found on both sides of the Nam Ngiep River and tributaries, providing continuous supply of large amounts of water throughout the year.

Between the main dam and the re-regulation dam, the terrain on both sides of the river widens and consequently forms flatter plains. Downstream of the reregulation dam, the terrain is predominately flat and slopes gradually towards the Mekong River. In this area, the Nam Ngiep River runs parallel to the Nam Xan before it merges with the Mekong River at Pakxan.

#### 3.4.2 Aquatic Habitats

Aquatic riverine and tributary habitats were assessed during TISTR 2012 site surveys. Seasonal variation was observed in terms of water depth, clarity, flow and wetted width. Habitat characteristics recorded are summarised in *Table 3.13*.

In general, river habitats were fast flowing with greater water depth and flows during the wet season. Dry season river habitats exhibited riffle zones which were flooded during the wet season. The river bed was generally dominated by sand and gravel. Villagers use the river environment for fishing and other activities and cattle were observed in the waterbody.

Tributary habitats were surveyed in the Upper Nam Ngiep River and Resettlement Area (as well as Huay Ngua PPA). These habitats were generally shallower and slower flowing than riverine habitats with some areas drying to isolated pools in the dry season.

Aquatic plants were not recorded at all sites and when recorded were noted to be sparse.

| Sampling Area                   |            | Aquatic habitat features   |
|---------------------------------|------------|--|
| Main Dam Site (Upper Nam Ngiep) |            | <ul><li>main river and tributary habitats</li><li>in tributary areas, the watercourse is dried to small pools in the dry</li></ul>   |
| Dry Season                      | Wet Season | <ul> <li>In tributary areas, the watercourse is dried to small pools in the dry season</li> <li>the main river current flows rapidly in the wet and dry season</li> <li>river depth in dry season 1-3m (shallower in riffle zone where water flows fastest), wet season 3-5m</li> <li>river bed is sand and gravel with some boulders</li> <li>aquatic plants present sparsely</li> <li>water level is high during the wet season flooding all banks and vegetation</li> <li>riparian zone is mainly original forest with agriculture close to communities</li> <li>water is clear with greenish brown colour in the dry season, turbic and reddish brown in the wet season</li> <li>surrounding landuse is agriculture and communities</li> <li>villagers use waterbody for fishing, cattle swim</li> </ul> |

| Dry Season                      | Wet Season | <ul> <li>river depth in dry season 2-3 m (shallower in riffle zone where wate flows fastest), wet season 4-5m depth</li> <li>width of the river is approximately 50-100 m in dry season, 100-156 during wet season</li> <li>river bed is sand and small gravel</li> <li>aquatic plants present sparsely on the river bank in the dry season</li> <li>water is turbid and reddish brown in wet season</li> <li>riparian zone is mainly covered by big trees and bamboos</li> <li>upper zone has communities where people and cattle share the rive in terms of swimming and washing. People always fishing</li> </ul>   |

# Table 3.13TISTR Aquatic Ecology Sampling Area Habitat Characteristics

Sampling Area

#### **Resettlement Area**

Dry Season

Wet Season

#### Aquatic habitat features

- tributary habitat
- water is approximately 1m depth in the dry season and 5m wetted width
- bed is clay
- no aquatic plants
- riparian zone is covered by big trees left after shifting and burning
- landuses around the creek are agricultural areas, and secondary growth

#### Fish

Three separate fish surveys have been undertaken (ERIC 2007, TISTR 2013, Kottelat 2014), a targeted habitat survey and a number of village interviews have been undertaken to inform the understanding of the fish biota within the Nam Ngiep River and its tributaries.

During the 2007 ERIC survey of the main dam inundation area, 42 species were detected. The community detected included relatively similar proportion of surface feeder, column feeder and bottom feeder species. Survey within the main dam inundation area during the 2013 TISTR survey detected 75 species.

The EIA noted that the fish community detected by ERIC in 2007 contains species common to the Mekong tributaries and was dominated by Cyprinid species. Cyprinid family species are reported to adapt to different environmental conditions in various sections of the river, and this family was also the dominant group detected during the 2013 TISTR survey. Species detected in 2007 in juvenile phase included Mackerel barb (*Opsarius pulchellus*), Swamp barb (*Puntius brevis*), *Rasbora borapetersis*, Slender rasbora (*Rasbora danioconius*), Salmon carp (*Raimas guttatus*) and *Poropuntius spp*. A full species list is provided in *Annex H*.

Targeted fast water survey in the Nam Ngiep detected 56 species (53 within the main dam inundation area and 34 outside the main dam inundation area). Among the 53 species of the main dam inundation area, two species are new to science and an additional four species are potentially new to science (confirmation required) (Kottelat 2014). The new species must be considered as endemic to the Nam Ngiep in the absence of any other data. Although endemic, each of the species was also detect outside the main dam inundation area.

The species detected considered to be endemic to Nam Ngiep include:

- *Schistura sp.* n. 'Nam Youak';
- *Schistura sp.* n. 'slender';
- Danio sp. n.;
- Poropuntius sp. n.;
- Oreoglanis delacouri; and
- Schistura crabro.

Additional details relating to the endemic species identified is provided in Annex *E* and *I*.

### IUCN Listed Species

Aquatic surveys across the Project area detected ten species listed as critically endangered, endangered or vulnerable on the IUCN Red List (summarised in

*Table 3.14*). Species listed as critically endangered or endangered are considered candidates for critical habitat and these species records have been queried further in *Section 3.5* Species listed a Restricted under the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF or endemic are also considered candidates for critical habitat and as such *Wallago leeri* has also been included as a candidate species.

#### Table 3.14IUCN Listed Fish Species reported within the Project area

Fast water survey: I = detected within the inundation area; O = detected outside the inundation area

IUCN Status: CR - Critically Endangered; EN - Endangered; VU - Vulnerable;

counts = Direct record; x = Indirect record; blue x = noted within Huay Ngua PPA Area MP

#### Migratory Species

The fish community of the Mekong River is one of the largest in the world with most of the production based on migratory river species (Poulsen *et al.*, 2004). Fish migration is an important component for many fish species life cycle. In the Mekong catchment, fish migration can be generally described in terms of (Poulsen *et al.*, 2004):

- Annual movement between inundated floodplains (where most fish production originates) and dry season refuges;
- Movement into spawning areas within the river system (usually upstream) from dry season refuges, generally upon start of flooding; and
- Passive migration of fish fry downstream from spawning areas.

The ERIC 2007 assessment noted that of the larger fish species detected, many are migratory species of the lower Mekong basin that move upstream during the wet season spawning activities (EIA citing Poulsen *et al.*, 2004). These larger species, such as mud carp (*Cirrhinus molitorella*) and Asian red tailed catfish (*Hemibagrus wyckioides*) were detected in 2007 (ERIC) and 2013 (TISTR) surveys. The surveys noted a number of juvenile individuals of the migratory species suggesting that the Nam Ngiep River plays a role in providing habitat for the reproductive cycle (EIA citing Lowe-McConnell, 1995).

During the targeted fast water survey, two of the species recorded are known to be long distance migrators (i.e. into other tributaries of the Mekong River). This included *Labeo pierrei* and the mud carp.

#### 3.5 ADB SPS HABITAT CATEGORIES

#### Modified Habitat

Modified habitat is altered natural habitat, often formed by the removal of native species for harvesting, land conversion and/or introduction of alien flora and fauna species (ADB, 2012).

Land cover mapping for the Project area identified a number of vegetated cover classes. The grassland, old fallow land, young fallow land, rice paddy, slash and burn land, and urban classes are considered to be modified habitats. *Figure 3.1* shows the distribution of these modified landuses within the Project area.

Natural HabitatNatural habitat is an environment where the biological communities are largely formed by native plant and animal species and where human activity has not modified the area's primary ecological functions (ADB, 2012).

Land cover mapping for the Project area identified a number of vegetation cover classes. The bamboo, deciduous forest and evergreen forest areas are considered to be natural habitats for the purposes of this assessment. *Figure 3.1* shows the distribution of these natural habitat landuses within the Project area. Bamboo is a native species in Lao however it is noted that it can be invasive and used for commercial purposes. For the purposes of this assessment, the precautionary approach has been applied and bamboo areas have been considered as natural habitat.

#### Critical Habitat

Critical habitat is an area that has high biodiversity value. It includes:

- habitat required for the survival of critically endangered or endangered species;
- areas having special significance for endemic or restricted-range species;
- sites that are critical for the survival of migratory species;
- areas supporting globally significant concentrations or numbers of individuals of congregatory species;
- areas with unique assemblages of species or that are associated with key evolutionary processes or provide key ecosystem services; and
- areas having biodiversity of significant social, economic, or cultural importance to local communities.

For this Project, critical habitat criteria described in the IFC PS6 Guidance Note have been used to guide the determination of critical habitat for each candidate species. The criteria include:

• Criterion 1: Critically endangered and or endangered species (Tier 1 and Tier 2 sub-criteria for habitat for these species). Tier 1 sub-criteria relate to a proportion of the population and known and regular occurrences. Tier 2 sub-criteria relate to nationally/regionally important concentrations;

- Criterion 2: Endemic and/or restricted-range species (Tier 1 and Tier 2 subcriteria for habitat for these species). Tier 1 and 2 sub-criteria relate to the proportion of the global population;
- Criterion 3: Migratory and/or congregatory species (Tier 1 and Tier 2 subcriteria for habitat for these species). Tier 1 and 2 sub-criteria relate to the proportion of the global population;
- Criterion 4: Highly threatened and/or unique ecosystems;
- Criterion 5: Key evolutionary processes.

Assessment of the Project area has not identified any highly threatened and/or unique ecosystems, or key evolutionary processes. As such the assessment focusses on the relevance of Criterion 1-3. Each of the candidate species has been assessed for the critical habitat determination criteria 1-3 using the literature and field survey data collected in the Project area as well as expert advice.

*Table 3.16* provides the threshold criteria used (IFC 2012).

| Criterion   |          | Tier 1  |          | Tier 2   |
|---|----------|---|----------|--|
| 1. Critically<br>endangered<br>(CR) /<br>Endangered<br>(EN) species | a)<br>b) | Habitat required to sustain ≥10<br>percent of the global population<br>of a CR or EN the<br>species/subspecies where there<br>are known, regular occurrences<br>of the species and where the<br>habitat could be considered a<br>discrete management unit for<br>that species<br>Habitat with known, regular<br>occurrences of CR or EN species<br>where that habitat is one or 10 or<br>fewer discrete management sites<br>globally for that species | c)<br>d) | Habitat that supports the regular<br>occurrence of a single individual<br>of a CR species and/or habitat<br>containing regionally- important<br>concentrations of a Re-listed EN<br>species where that habitat could<br>be considered a discrete<br>management unit for that<br>species/subspecies<br>Habitat of significant importance<br>to CR or EN species that are<br>wide-ranging and/or whose<br>population distribution is not<br>well understood and where the<br>loss of such a habitat could<br>potentially impact the long-term<br>survivability of the species<br>As appropriate, habitat |
|   |          |   | -)       | containing nationally/regionally<br>important concentrations of an<br>EM, CR or equivalent<br>national/regional listing.   |
| 2. |                |    |  |    |   |

The species information was collated and analysed against the relevant critical habitat criteria (individual species detail provided in *Annex l*). A summary of the analysis is provided below. The summary includes an identification of the landcover types likely to be suitable habitat for the species, estimate of the extent of habitat within the direct impact area of the Project, and summary of the assessment.

The species screened against the determination criteria and quantitative thresholds include IUCN listed species, species considered endemic or listed as Restricted in the Regulation of the Ministry of agriculture and Forestry No. 0360/MAF and species considered to be migratory.

Throughout the assessment it was identified that a number of species, although candidates according to the above criteria, are not native species to Lao PDR. Although the conservation status of these species is recognised globally, they are not necessarily considered priorities for conservation efforts outside their native distribution.

|--|--------------------------|----------|--------|-----------|---|---|------------------------------------|--|---|
| Species  | Habitat<br>Type<br>Codes | Criteria | Direct | In-direct | -<br>Record Location  | Habitat<br>within<br>project<br>area (ha) | Key Threats                        | Critical<br>Habitat<br>in<br>Project<br>area | Assessment Outcome  |
| Buceros bircornis<br>Great hornbill                | EF, DF                   | 1        |        | ~         | Huay Ngua PPA, Nam Xan  | 3410                                      | Hunting                            | No   | Great hornbill plausibly still occurs in the Project area but probably<br>only in low numbers. Its status is similar across large parts of Lao<br>PDR. The Project area is only a small proportion of the nation's total<br>such habitat and as such would not be expected to constitute one of 10<br>discrete management units (Tier 1) or an area of significant<br>importance (Tier 2).  |
| <i>Cairina scutulata</i><br>White winged<br>duck   | W                        | 1        |        | ~         | Upper Nam Ngiep, Huay<br>Ngua PPA   | 410                                       | Hunting,<br>habitat<br>degradation | No   | White winged duck might possibly still occur in the Project area but<br>at best only in very low numbers. Despite major loss of habitat in the<br>last half century, tracts similar in extent and condition to the Project<br>area remain in many parts of Lao PDR. The Project area is only a<br>small proportion of the nation's total such habitat and as such would<br>not be expected to constitute one of 10 discrete management units<br>(Tier 1) or an area of significant importance (Tier 2). |
| <i>Centropus</i><br>sinensis<br>Greater coucal     | EF, DF,<br>SB, G,<br>U   | 1        | ~      | ~         | Upper and lower Nam<br>Ngiep, resettlement site,<br>Huay Ngua PPA, upper<br>and lower Nam Xan | 3933                                      | Hunting                            | No   | Greater coucal is probably abundant over the deforested and<br>degraded parts of the Project area. This is so across Lao PDR so the<br>Project area is only a small proportion of the nation's total such<br>habitat and as such would not be expected to constitute one of 10<br>discrete management units (Tier 1) or an area of significant<br>importance (Tier 2).  |
| <i>Gyps bengalensis</i><br>White backed<br>vulture | SB, U,<br>G              | 1        |        | ~         | Upper Nam Ngiep   | 523                                       | Hunting,<br>veterinary<br>drugs    | NA   | Given the ease of finding this species when present and the high<br>levels of survey in the general region of Lao PDR within which lies<br>the Project area, there is no chance that the interview reports collected<br>in fact refer to a resident population of this or any other vulture.  |

|  |                          |          | Rec    | cord      | _                      |   |                       | Likely                                       |   |
|--|--------------------------|----------|--------|-----------|------------------------|---|-----------------------|--|---|
| Species  | Habitat<br>Type<br>Codes | Criteria | Direct | In-direct | Record Location        | Habitat<br>within<br>project<br>area (ha) | Key Threats           | Critical<br>Habitat<br>in<br>Project<br>area | Assessment Outcome  |
| <i>Lophura diardi</i><br>Siamese<br>fireback             | EF, B,<br>SB             | 1        |        | ~         | Huay Ngua PPA, Nam Xan | 1390                                      | Habitat<br>conversion | No   | Siamese fireback is very likely to occur, perhaps widely, in the Project<br>area. Nonetheless, the Project area constitutes an insignificant<br>proportion of suitable habitat across Lao PDR, so does not constitute<br>critical habitat.  |
| Lophura<br>nycthemera<br>Silver pheasant                 | EF                       | 1        |        | V         | Huay Ngua PPA, Nam Xan | 514                                       | Habitat<br>conversion | No   | Silver Pheasant is very likely to occur, perhaps widely and commonly,<br>in the Project area. Nonetheless, the Project area constitutes an<br>insignificant proportion of suitable habitat across Lao PDR, so does<br>not constitute critical habitat.  |
| Pavo muticus<br>Green peafowl                            | EF, DF,<br>B, G, SB      | 1        |        | V         | Huay Ngua PPA          | 4394                                      | Hunting               | No   | Assuming that the interview reports are in error, there is no reason to<br>consider that the Project area constitutes critical habitat. However, the<br>rather anomalous survival of the small population around Ban<br>Nakhaty, Phou Khao Khoay NPA, emphasises the possibility that<br>other remnants may also survive, and it cannot be excluded that the<br>Project area might support one. Such a population could be significant<br>at the national level rather than a global level. |
| Polyplectron<br>bicalcaratum<br>Grey peacock<br>pheasant | EF                       | 1        |        | V         | Huay Ngua PPA, Nam Xan | 514                                       | Habitat<br>conversion | No   | Grey Peacock Pheasant is very likely to occur, perhaps widely and<br>commonly, in the Project area. Nonetheless, the Project area<br>constitutes an insignificant proportion of suitable habitat across Lao<br>PDR, so does not constitute critical habitat.  |
| Psittacula<br>alexandri<br>Red-breasted<br>parakeet      | DF                       | 1        |        | V         | Huay Ngua PPA          | 2896                                      | Trade                 | No   | Accepting the likelihood of this species' occurrence in the Project area,<br>it is however unlikely, that in the context of the much larger numbers<br>remaining in parts of Central and South Lao PDR, that the Project area<br>could comprise critical habitat.   |

|  |                          |          | Rec    | cord      | _   |   |                           | Likely                                       |   |
|--|--------------------------|----------|--------|-----------|---|---|---------------------------|--|---|
| Species  | Habitat<br>Type<br>Codes | Criteria | Direct | In-direct | Record Location   | Habitat<br>within<br>project<br>area (ha) | Key Threats               | Critical<br>Habitat<br>in<br>Project<br>area | Assessment Outcome  |
| <i>Ichthyophaga<br/>humilis</i><br>Lesser fish eagle     | W                        | 1        |        | r         | -   | 410                                       | Habitat loss, persecution | No   | With no information on the status in the Project area no firm decision<br>can be made. Numbers, if any, in the Project area are probably too few<br>for the area to constitute critical habitat; but if there are surprisingly<br>large numbers there, then it possible would be critical habitat.  |
| Reptiles   |                          |          |        |           |   |   |                           |  |   |

| Species                   | Habitat<br>Type<br>Codes | Criteria | Direct | In-direct | Record Location | Habitat<br>within<br>project<br>area (ha) | Key Threats  | Critical<br>Habitat<br>in<br>Project<br>area | of the Nam Ngiep downstream of the dam infrastructure. The<br>nigratory species detected a generally species requiring large river of<br>loodplains habitats. Due to the nature of the gorge where the dam is   |  |
| Migratory fish<br>species | W                        | 3        | ~      | ~         |                 |   | Restriction of<br>movement<br>and access to<br>habitat | Unlikely                                     | Potential habitat for Mekong migratory species may occur in reaches<br>of the Nam Ngiep downstream of the dam infrastructure. The<br>migratory species detected a generally species requiring large river or<br>floodplains habitats. Due to the nature of the gorge where the dam is<br>located the majority of this habitat is located downstream of the dam<br>rather than within the inundation areas. Indirect impacts to<br>downstream habitats relating to environmental flows will need to be<br>considered during impact assessment. |  |

The outcomes of the assessment identified that the downstream environment will require consideration for indirect impacts to aquatic species and that the Project area is potential critical habitat for the predatory fish species *Luciocyprinus striolatus*. Habitat for *L. striolatus* has been identified through a number of survey and interviews in the Nam Ngiep and neighbouring catchments. During these surveys a number of spawning locations were identified and anecdotal evidence of the species in the Nam Ngiep River as well as tributaries (Nam Chain and Nam Siam) that are unlikely to be impacted. While the habitat within and upstream of the FSL may be of importance to the species, the distribution of the species is not well understood and as such additional survey is planned to assess the distribution and inform the design of a species action plan. Further detail on this species is provided in Annex *I*.

The downstream aquatic biodiversity has been highlighted within the critical habitat assessment as an area where indirect impacts may be of significance. The impact to this area, downstream biodiversity and fish biomass will require consideration in the impact assessment.

No likely critical habitat was identified within the terrestrial environment (resettlement area, access road or inundation areas).

## 3.6 ECOSYSTEM SERVICES

It is evident that villagers in the Project area regularly use local terrestrial and aquatic biodiversity – e.g. as a food source. However, the dependence on natural resources varies by village and is largely associated with accessibility. For example, remote villages tend to rely more heavily on medicinal plants as access to pharmaceuticals is limited.

The following section describes the uses and cultural values placed on (and/ or associated with) biodiversity by local villagers in the Project area. Much of the data is from village and market surveys undertaken by ERM in February and March 2013. *Annex J* contains the results of the socio-economic survey that have been used to inform the assessment of ecosystem services.

# 3.6.1 Hunting and Gathering

Villagers, both Loa and Hmong people, hunt and gather. This is done primarily for household consumption. However, when surplus exists, it is sold within the village or neighbouring villages.

Although the norm is to consume the materials locally, there are a small number of species that are collected for sale. Access to markets from villages is limited due poor road access, so external sales are to intermediaries who travel to the villages.

Hunting for small animals is common across all villages. Villagers rarely admitted to hunting larger animals as all were aware this is illegal. Bamboo

traps are predominantly used for capturing squirrels and rats, though hunting dogs, firearms and knives are also reportedly used.

Hmong families tend to hunt together while lowland Lao hunt individually or in small groups of either men or women. Hunting activity is no longer a daily activity, and is only triggered when a change from chicken or fish is desired or a ceremony requires it (i.e. a wedding or Hmong New Year). Villagers will generally travel as far as the need to hunt and gather though based on survey data this is unlikely to be further than 3-5 kilometres from the village (i.e. walking distance).

Villagers have noted that availability of naturally occurring resources, especially forest animals and fish, has been declining in recent years.

# 3.6.2 *Medicinal Plants and Materials*

Usage, and therefore dependence, appears to be predicated on access to health services - the easier the access to pharmaceuticals, the lower the usage of natural medicines. In the Project area, villages have indicated a preference for pharmaceuticals but said natural medicines were generally used in the first instance.

# 3.6.3 *Timber Products*

Timber products are actively sourced from the forests by villagers and commercial operators. For instance the local villagers were observed sourcing and processing hardwood into planks near the proposed dam site.

# 3.6.4 Fishing

When compared to hunting, fishing occurs on a more regular basis. This is largely because of the close proximity of villages to waterways.

Fishing may have been more important for income generation in earlier times though with greater availability of alternative protein sources and reported reduction in stock availability and size, villages have adapted.

Fish is generally caught only for household consumption, but it is also a common item used in inter-household exchange and transactions. Surplus fish tends to be sold at below market rates suggesting such transactions may more likely be part of a local gift economy rather than a commercial transaction. This being said, it was common to hear that small fish are eaten at home while big fish, when found, are sold.

The most common fishing method is with a cast weighted net, an item commonly seen in most houses. Larger nets are used during the rainy season to catch larger fish that swim up river from the Mekong River. At Hatsaykham, the survey team observed other methods such as scaring fish into a net hung across a short section of the river and gathering by hand. Other equipment observed in villages included lines, hooks and spear guns. Fishing takes place at established riverside sites at which small shelters are built.

#### 3.6.5 *Cultural Services*

Most of the villages surveyed in the Project area have been settled only relatively recently signalling a lesser dependence on cultural services provided within proximate ecosystems. While length of residence is not an exclusive factor in determining usage and dependence, the less time people have to form attachments to aspects of an ecosystem, the less significant these features are likely to be. Indeed the relatively new nature of the villages acts to sever any bonds that people may have with prehistoric features within the environment such as tangible objects (i.e. stone tools, brass or ceramic objects) and intangible knowledge (i.e. creation myths or site specific rituals). This is not to say that the cultural values villagers derive from the ecosystem are insignificant, it is to signal that what values they do use are likely severable and reproducible elsewhere.

Numerous locally collected polished stone tools have been found in the Project area indicating human occupation in the area occurred between 4,000 and 12,000 years ago. However, most of the existing villages were settled in the early-1980s and 1990s.

The most significant social, religious and cultural sites people were able to identify (during the surveys) in villages in the Project area were grave sites. Reflecting the severable nature of connections people have with grave sites, villagers indicated that the ancestor spirits associated with such grave sites are transferrable to a new location through the performance of a complex ceremony conducted by the village shaman (called a Yao in the surveyed villages).

Each of the Hmong villages visited in the lower reservoir zone had a shaman residing there. Each house has a small shrine that is used by the shaman for ceremonies. The shaman is essentially a conduit between the human and spirit worlds. Sickness among Hmong is believed to be the result of contact with evil spirits. At risk of overgeneralising, the shaman's role is to free a person's spirit (or soul) from the malevolence brought through this contact with spirit world. The shaman was identified in these villages as the person most dependent on the naturally occurring forest though little detail was able to be collected about the extent of this dependence.

Naturally occurring bamboo is used by both Lao and Hmong to make an animist symbol that is hung above doorways to ward off evil spirits.

#### 4 CANDIDATE BIODIVERSITY OFFSET SITES

#### 4.1 OVERVIEW

This section discusses the biodiversity values of each of four candidate offset sites which have been proposed for this Project including parts of the Nam Ngiep catchment (Upper Nam Ngiep), stretches of the Nam Xan River between Nam Lao and Bolikhan, the Huay Ngua PPA and Phou Khao Kouay Protected Area (PKK) (*Figure 4.1*). The candidate offset sites have been described such that their ecological suitability to provide a biodiversity offset can be assessed. The suitability assessment is documented in the Biodiversity Offset Design Report for the Project.

#### 4.2 UPPER NAM NGIEP

## 4.2.1 Overview

The biodiversity values of the Upper Nam Ngiep investigation area are similar to those described in the Project area (*Section 3*). Sampling locations for the baseline field surveys in 2007 and 2013 were restricted to adjacent to the waterway and, as such, it is considered that many terrestrial species detected during these surveys may utilise the habitats outside the inundation area and in the wider Nam Ngiep catchment area. Many of the fauna species identified during survey are highly mobile and habitat preferences are not restricted to riparian areas. These species have potential to move to forested and other natural habitats locally.

## 4.2.2 Vegetation

#### Land Cover

Using land cover mapping (DFRM, 2010), natural and modified habitats, in accordance with IFC definition, can be identified within the Upper Nam Ngiep candidate offset site. The Upper Nam Ngiep is dominated by natural habitat (76 per cent) with almost half of the area deciduous forest land cover. There is limited urban area. *Table 4.1* summarises the land cover shown in *Figure 4.2* and identifies the habitat category of each land cover type.

## Table 4.1Land Cover within the Upper Nam Ngiep Candidate Offset Site

| Land Cover        | IFC Habitat Class | Total Area (ha) | % of Total |
|-------------------|-------------------|-----------------|------------|
| Deciduous Forest  | Natural           | 59,078          | 46%        |
| Evergreen Forest  | Natural           | 37,666          | 30%        |
| Bamboo            | Natural           | 5,735           | 5%         |
| Old Fallow Land   | Modified          | 15,165          | 12%        |
| Young Fallow Land | Modified          | 3,496           | 3%         |

| Grassland         | Modified          | 3,900           | 3%         |
| Urban Area        | Modified          | 7               | <1%        |
| Rock              | Natural           | 161             | <1%        |
| Cloud             | -                 | 30              | <1%        |
| Shadow            | -                 | 149             | <1%        |
|                   | Total             | 127,178         |            |

#### Forestry Classification Mapping

Forestry classification mapping identifies both protection forest and production forest in the Upper Nam Ngiep. *Figure 4.3* depicts the extent of protected and production forest and shows that greater than half of the offset site is mapped as National Protected Forest.

#### Vegetation Condition

The NDVI across the Upper Nam Ngiep is shown in *Figure 4.4* and the area of each classification is summarised in *Table 4.2*.

Over 96 per cent of the Project area is classified as moderate or high NDVI. Almost 65 per cent of the area is mapped as high NDVI. Less than 1 per cent of the area is classified as impacted NDVI.

| Forest type       | Impacted (- to<br>0) | Low<br>(0 - 0.4) | Moderate (0.4<br>- 0.6) | High<br>(0.6 - 0.8) |
|-------------------|----------------------|------------------|-------------------------|---------------------|
| Deciduous Forest  | 16                   | 1209             | 19,614                  | 38,240              |
| Evergreen Forest  | 11                   | 1008             | 13,447                  | 23,200              |
| Old Fallow Land   | 2                    | 370              | 3148                    | 11,643              |
| Young Fallow Land | 2                    | 265              | 1493                    | 1735                |
| Bamboo            | 5                    | 181              | 1526                    | 4021                |

#### 4.2.3 Flora Species

As described, the Upper Nam Ngiep is the area adjacent to the main dam inundation and re-regulation dam inundation areas which have been surveyed (see Section 3.2.2). The land cover mapping shows similar vegetation covers across the catchment area and, as such, it is likely that many flora species recorded during surveys (2013) within the Project area will also occur within the wider Upper Nam Ngiep area.

Deciduous forest types were recorded during Project area surveys and this vegetation is likely to be similar to the Upper Nam Ngiep. The deciduous forest types were present in terms of mixed deciduous forest and lower mixed deciduous forest at the main dam inundation and re-regulation dam inundation areas. The dominant species recorded within these forest types during the 2013 survey by TISTR within the Project area are summarised in *Table 4.3* and are considered likely to occur within the Upper Nam Ngiep.

# Table 4.3Dominant Flora Species in vegetation communities similar to the Upper Nam<br/>Ngiep Candidate Offset Site

| Canopy class      | Dominant species   |  |  |  |  |  |
|-------------------|--|--|--|--|--|--|
| Mixed Deciduou    | Mixed Deciduous Forest   |  |  |  |  |  |

#### IUCN Listed Species

A total of nine species of plants listed as critically endangered, endangered or vulnerable under the IUCN Red List were identified within the upper Nam Ngiep area during 2007 and/or 2013 surveys. These include one species listed as critically endangered, five as endangered and three as vulnerable (*Table 4.4*).

# Table 4.4IUCN Listed Flora Species recorded in the Upper Nam Ngiep Candidate Offset<br/>Site

## 4.2.4 Fauna Species

As identified for the flora species, many of the fauna species detected during TISTR surveys of the main dam inundation area have potential to utilise the habitat of the Upper Nam Ngiep. The diversity of fauna is expected to be high given the large intact area of habitat and the results obtained from surveys of the Project area. The Upper Nam Ngiep River is dominated by primary forest. The fauna habitat in this area is in good condition in comparison to other areas surveyed. Site surveys during 2013 (TISTR) detected (through interviews with villagers or direct observation) at least 46 mammals species, 50 bird species, 28 reptiles species and 10 amphibian species.

#### **IUCN Listed Species**

The fauna species have been categorised by the IUCN (2012) and a number have been recorded within the Project area. The 2013 TISTR surveys recorded one species, the Northern white-cheeked gibbon (*Nomascus leucogenys*) listed as critically endangered within the Project area and as such it is considered possible these species may also inhabit the Upper Nam Ngiep.

Overall, the direct and indirect records identified:

- Twenty-one mammal species (1 critically endangered, 7 endangered and 13 vulnerable);
- Five bird species (1 critically endangered, 2 endangered and 2 vulnerable);
- Nine reptile species (2 endangered and 7 vulnerable);
- Two fish species (2 endangered); and
- No amphibian species.

*Table 4.5* summarises the species recorded.

#### 4.3 NAM XAN

## 4.3.1 Overview

The Upper Nam Xan River, on the west bank of the river, is covered by primary forest, deciduous forest. On the east bank of the river is the production forest, where the larger trees have been previously harvested and there is evidence of re-succession recovery. There are stretches of the river that are currently mostly vegetated with a relatively low population density, poor vehicular access, and steep riparian terrain.

The Nam Xan candidate offset site has been the subject of consultation with Lao PDR representatives and following consultation the option of this area as use for offsetting has been discounted. The area is predominantly mapped as production forest which is an important resource for Lao PDR and unlikely to be suitable for conversion to reserve status.

Field surveys collected some species information summarised below however it is unlikely this site will be investigated further.

#### 4.3.2 Flora

The Nam Xan River area consists of upper mixed deciduous forest, mixed with dry evergreen forest species in the upper area. Canopy cover in the upper Nam Xan area recorded 80-90 per cent while the lower Nam Xan area recorded 50-60per cent canopy cover. Surveys undertaken by TISTR in the area in 2013 identified at least 468 species.

For the forest types the forest canopies are divided in 3 classes. The dominant species for each survey (2013) locations are summarised in *Table 4.6*.

## Table 4.6Dominant Flora Species in Nam Xan Candidate Offset Site

| Canopy class                                     | Dominant species   |  |  |  |
|--|--|--|--|--|
| Upper Nam Xan River Upper Mixed Deciduous Forest |  |  |  |  |
| Top canopy                                       | Consists of large trees such as Palaquium poilanei, Duabanga grandiflora,            |  |  |  |
| (22-30m)   | Pterospermum litorale, Lagerstroemia calyculata,                                     |  |  |  |
| Middle canopy                                    | Contains saplings of the higher canopy or small trees such as <i>Crateva magna</i> , |  |  |  |
| (8-15m)  | Alangium chinense, Shorea roxburghii, Vatica odorata,                                |  |  |  |
| Lower canopy                                     | Saplings and seedling of the trees in the higher canopies, for example,              |  |  |  |
| (<15m)   | Elaeocarpus sphaericus, Litsea glutinosa, Baccaurea ramiflora, Stereospermum         |  |  |  |
|  | fimbriatum   |  |  |  |
| Lower Nam Xan                                    | River Disturbed Mixed Deciduous Forest   |  |  |  |
| Top canopy                                       | Lagerstroemia calyculata, Tetrameles nudiflora, Hopea ferrea, Castanopsis            |  |  |  |
| (20-30m)   | 30m) argyrophylla, Garuga pinnata, Parkia sumatrana, Crudia chrysantha, Calleya      |  |  |  |
|  | atropurpurea, Toona ciliata  |  |  |  |
| Middle canopy                                    | Crateva magna, Trewia nudiflora, Carallia brachiata, Albizia lucida, Dalbergia       |  |  |  |
| (10 <b>-</b> 20m)                                | cultrata   |  |  |  |
| Lower canopy                                     | Consist of saplings and seedling of the higher canopies. Some species belong         |  |  |  |
| (~10m)   | to dry evergreen forest, such as Murraya paniculata, Streblus ilicifolius, Leea      |  |  |  |
|  | rubra, Caryota mitis   |  |  |  |

#### **IUCN Listed Species**

A total of ten plant species listed under the IUCN Red List were recorded during vegetation surveys in Nam Xan in 2013. These are shown in *Table 4.7*. This includes:

- Two species listed as critically endangered;
- Five species listed as endangered; and
- Three species listed as vulnerable.

## Table4.7IUCN Listed Flora Species Recorded within Nam Xan Candidate Offset Site

| Scientific Names         | Status |

| Morinopsis capillaris    | VU     |
| Ternstroemia wallichian  | VU     |

#### 4.3.3 Fauna

The upper Nam Xan area contains the second highest species diversity in comparison to the other surveyed areas during 2013 surveys (TISTR). A total of 123 species of wildlife including 39 species of mammals, 43 species of birds, 28 species of reptiles, and 13 species of amphibians. In this area the river bank is dominated by deciduous forest while the east bank is production forest where trees are being harvested.

The lower Nam Xan area recorded at least 110 species including 35 mammal species, 40 bird species, 24 reptile species and 11 species of amphibian.

Common fish species detected in the Nam Xan River during surveys in 2013 (TISTR) included Golden poropuntius (*Poropuntius normani*), Dwarf snakehead (*Channa gachua*), Swamp barb (*Puntius brevis*), Sikuk barb (*Sikukia gudgeri*) and Sidestripe rasbora (*Rasbora paviana*).

A full fauna species list is provided in *Annex G*.

#### **Restricted Species**

The recent surveys (TISTR 2013) in Nam Xan detected the following species listed in the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF:

- Twenty-seven mammal species (12 restricted (List I), 15 protected (List II));
- Nine bird species (6 restricted (List I), 3 protected (List II));
- Nine reptiles (3 restricted (List I), 6 protected (List II));
- One fish (protected (List II)); and
- No amphibians.

Annex G provides a description of the results.

## IUCN Listed Species

The recent surveys (TISTR 2013) in Nam Xan detected the following species listed as critically endangered, endangered or vulnerable on the IUCN Red List:

- Thirteen mammal species (1 critically endangered, 3 endangered and 9 vulnerable);
- Five reptiles (1 endangered and 4 vulnerable); and
- Four fish species (2 endangered and 2 vulnerable).

#### 4.3.4 Aquatic

The Nam Xan River surveyed in 2013 habitats exhibited a gravel substrate with variety in depth and flow seasonally. During the wet season water was approximately 1-3m depth and up to 150 m wide in area where the wetted width is 100m during the dry season. Reaches recorded areas with larger rock and riffle zones as well as beach and island areas where aquatic plants grow sparsely. In general the substrate is dominated by gravel. In the upper area there are settlements with fish cultivation in the lower area. Sand and gravel is harvested in some reaches. *Figure 4.5* shows the habitat within the Nam Xan River.

#### 4.4 HUAY NGUA PPA

## 4.4.1 Overview

The Huay Ngua PPA (the PPA) was established in 2010 and is located to the east of the Nam Ngiep River between Borikham and Hat Kham. The preserved area is approximately 5,430 ha. There are five villages with a total population of 4,302 made up of Laoloum, Laosoung and Keummou ethnic groups. The groups are located in scattered settlements living near highland rice fields and rivers. The villagers use local terrestrial and aquatic biodiversity however dependence varies (Provincial Conservation Division, 2010).

The PPA is an important part of a wildlife corridor between PKK and along the Nam Ngiep River. The area is considered significant for aquatic and wildlife habitat (Provincial Conservation Division, 2010) as well as providing a research site of Province Agriculture and Forestry School. The PPA currently does not have any formal management arrangements in place to facilitate its management. A management committee under Central, Provisional or District levels of government has not been established. A Management Plan for the PPA has been prepared but it has not been implemented as no funding currently exists to pay for the management actions it contains. The priority actions to manage the PPA included in the plan are related to:

- raising community awareness to increase participation in sustainable uses;
- improving community livelihoods in and around the PPA to assist in management of natural resources;
- law enforcement and patrolling;
- biodiversity research and monitoring; and
- development of ecotourism opportunities.

The forest and wildlife is considered a high value resource with increasing demand in Lao PDR and neighbouring countries. The PPA is abundant in these resources. Some fauna species have been impacted by hunting and trapping for local and regional market and there is harvesting for rosewood and agar wood (*Aquilaria crassna*) (Provincial Conservation Division, 2010).

Forest resources have played an important role in the economics of the surrounding province contributing to almost 30% of the total province economy in 2000. Although production of forest products is important for the province, environmental values remain important and the forest is considered a place for production and collection of food for the rural population as well as a source of traditional medicine (Provincial Conservation Division, 2010).

#### 4.4.2 Vegetation

#### Land Cover

Using land cover mapping (DFRM, 2010), natural and modified habitats, in accordance with the IFC definition, can be identified within the Huay Ngua candidate offset site. The Huay Ngua is dominated by natural habitat (83 per cent) which is mapped as deciduous forest. *Table 4.9* summarises the land cover shown in *Figure 4.7* and identifies the habitat category of each land cover type.

| Table 4.9Land Cover within the Huay Ngua Candidate Offset S | ite |
|---|-----|
|---|-----|

|                  | IFC Habitat Class | Total Area (ha) | % of Total |

#### Vegetation Condition

The NDVI across the Huay Ngua PPA is shown in *Figure 4.8* and the area of each classification is summarised in *Table 4.10*.

Over 94 per cent of the Huay Ngua is classified as moderate or high NDVI. The majority of the area is classified as moderate (71 per cent). Less than 0.1 per cent of the area is classified as impacted NDVI.

## Table 4.10Vegetation Condition within the Huay Ngua Candidate Offset Site

| Forest type      | Impacted<br>(- to 0) | Low<br>(0 - 0.4) | Moderate<br>(0.4 - 0.6) | High<br>(0.6 - 0.8) |

#### Aquatic Habitats

The Huay Ngua aquatic habitats can be described as tributary habitat. The aquatic habitats sampled were very shallow during the dry season. No aquatic plants were observed. The substrate is dominated by sand and small gravel. The riparian zone in this area is original forest dominated by bamboo. No disturbance was observed.

#### 4.4.3 Flora Species

The climatic conditions (low temperature, high humidity and high winds) have led to dense growth of several plant species such as rosewood, mai kebe, mai ngang (*Dipterocarpus alatus*), maid tae (*Sindora cochinchinensis*), mai peuy (*Lagerstroemia calyculata, Lagerstroemia floribunda*) and mai bark (*Anisoptera costata*) (Provincial Conservation Division, 2010).

Sampling undertaken during 2013 surveys by TISTR recorded 451 species of vascular plants in the Huay Ngua PPA sampling locations. Vegetation is dominated by mixed deciduous forest with some areas of mixed evergreen forest and secondary growth of mixed deciduous forest. Canopy cover is approximately 60-70 per cent. The forest canopies are divided in 3 classes. The dominant species are summarised in *Table 4.11*.

## Table 4.11Dominant Flora Species in Huay Ngua Candidate Offset Site

| Canopy class  | Dominant species   |
|---------------|--|
| Top canopy    | Anisoptera costata, Lagerstroemia calyculata, Shorea roxburghii, Irvingia malayana |
| (20-35m)      | Alstonia glaucescens, Schima wallichii, Vitex pinnata, Stereospermum fimbriatum    |
| Middle canopy | Acronychia pedunculata, Peltophorum dasyrachis, Nauclea orientalis, Microcos       |
| (10-20m)      | tomentosa, Mallotus paniculatus, Gonocaryum lobbianum, Cratoxylum formosum         |
| Lower canopy  | Croton cascarillicdes, Breynia glauca, Ardisia helferiana, Glycosmis pentaphylla,  |
| (<10m)        | Melicope pteleifolia, Allophylus cobbe, Salacia chinensis                          |

#### IUCN Listed Species

A total of 11 plant species listed under the IUCN Red List were recorded during vegetation surveys in Huay Ngua in 2013. These are shown in *Table* 4.12. This includes:

- One species listed as critically endangered;
- Six species listed as endangered; and
- Five species listed as vulnerable.

## Table 4.12IUCN Listed Flora Species Recorded within Huay Ngua Candidate Offset Site

## 4.4.4 Fauna Species

A total of 38 terrestrial species of fauna from 19 families, and 31 genera were recorded from the field surveys in 2013 surveys in Huay Ngua PPA by TISTR. This includes one species of mammal, 29 species of birds, three species of reptiles, and six species of amphibians. Species diversity of animals in this area is lowest among the total study areas due to the lack of secondary data, all records were obtained by direct observation during the field surveys.

Common fish species detected in the Nam Xan River during surveys in 2013 included Spiny barb (*Mystacoleucus marginatus*), Sikuk barb (*Sikukia gudgeri*), Horseface loach (*Acantopsis choirorhynchos*), and Long fin mystus (*Mystus singaringan*). Of these species the Sikuk barb and Long fin mystus are known full migrant species.

The Houy Ngua Provincial Preserved Area Management Plan reports (indirect data) fauna species occurring within the PPA to include wild pig, munjac, clouded leopard (*Pardofelis nebulosa*), civet, flying squirrel as well as Green peafowl (*Pavo muticus*), Hill myna (*Gracula religiosa*), Red junglefowl (*Gallus gallus*) and the Siamese fireback (*Lophura diardi*).

Overall, the TISTR surveys and indirect data reported:

- Nine amphibian species;
- Fifty-nine bird species;
- Twenty-seven mammal species;
- Nine reptile species; and
- Thirty-nine fish species (including twelve species considered to be migratory).

A full species list is provided in *Annex G* (*terrestrial fauna*) and *Annex H* (*aquatic biota*).

# Restricted Species

Species listed as Restricted under the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF includes wild animals and fish which are rare, endangered, high conservation value, and special significance to the economy and national environment.

The 2013 TISTR surveys (direct data) and indirect data sources identified the following species listed as Restricted in the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF:

- Two mammal species;
- Six bird species;
- One reptile;
- One fish;
- No amphibians.

*Annex G* and *Annex H* provide a description of results for terrestrial fauna and aquatic biota, respectively.

## IUCN Listed Species

Three IUCN Red Listed critically endangered, endangered or vulnerable fauna species were recorded within the Huay Ngua PPA area during 2013 surveys by TISTR while PAFO surveys identified 16 species listed as critically endangered, endangered or vulnerable on the IUCN Red List that may occur within the Huay Ngua PPA.

#### 4.5 *PHOU KHAO KOUAY*

#### 4.5.1 Overview

Phou Khao Kouay, or 'Buffalo Horn Mountain', is a Protected Area near Vientiane in central Laos. The area spans 2000 square kilometres over three provinces, with an elevation range of 200m - 1761m. The landscape ranges from sandstone cliffs and river gorges to rugged mountain slopes. Layered sandstones are visible as linear outcrops and large boulders along steep slopes. There are also extensive flat uplands of exposed sandstones with little or no soil development (Salter & Bouaphanh, 1990). The PKK NPA has a monsoonal climate similar to the rest of Central Laos with a mean annual temperature of 26.6 C. The wet season extends from May to October with a distinct dry season during from November to April.

#### 4.5.2 Vegetation

#### Land Cover

Using land cover mapping (DFRM, 2010), natural and modified habitats, in accordance with the IFC definition, can be identified within the PKK candidate offset site. The PKK is dominated by natural habitat (73 per cent) which is a mixture of deciduous forest, evergreen forest, coniferous forest, mixed coniferous forest, scrub and bamboo. *Table 4.14* summarises the land cover shown in *Figure 4.9* and identifies the habitat category of each land cover type.

| Forest Type                            | IFC Habitat Class | Total Area (ha) | % of Total |
|--|-------------------|-----------------|------------|
| Deciduous Forest                       | Natural           | 76,001          | 42%        |
| Evergreen Forest                       | Natural           | 43,262          | 24%        |
| Coniferous Forest                      | Natural           | 1,563           | 1%         |
| Mixed Coniferous/Broadleaved<br>Forest | Natural           | 702             | <1%        |

Vegetation Condition

The NDVI across the PKK is shown in *Figure 4.10* and the area of each classification is summarised in *Table 4.15*.

Over 87 per cent of the PKK is classified as moderate or high NDVI. Less than 2 per cent of the area is classified as impacted NDVI.

#### 4.5.3 Flora Species

The central portion of the park contains the lower basins of the Nam Leuk and Nam Mang. This area is predominantly upper dry evergreen forest. This forest has plant families and genera typical for other parts of Southeast Asia, such as the genera Dipterocarpus and Shorea. Mixed deciduous forest is found on lighter, shallow soils. Large stands of coniferous forest, usually monospecific stands of *Pinus merkusii*, grow on shallow, nutrient deficient, sandy soils, particularly in the western portion of the park, where it occurs in association with extensive, fire-climax grasslands.

#### 4.5.4 Fauna Species

#### **IUCN Listed Species**

Information regarding the PKK identified a number of IUCN Red List species to occur including:

• Ten mammal species (1 critically endangered, 4 endangered and 5 vulnerable).

#### 4.6.1 Hunting and Gathering

Hunting is generally done for household consumption; while any surplus is sold to intermediaries. However, from time to time, hunting is done to generate money, when required to cover household expenses such as clothing and education. It is typically the smaller species that are consumed within the household, while the larger animals are sold to intermediaries.

Male hunters normally go hunting individually, unless big animals such as cow or deer are needed for events (e.g. weddings) during which males will hunt in groups of four to five to hunt big animals. Females usually hunt in groups of four to five.

Hunting frequency ranges from two to three times per week to once a month in most villages. However, male hunters from Ban Don mentioned that they have not hunted for the past six years – i.e. since hunting become illegal.

Frequently caught species include small animals such as squirrels, birds, bamboo rats and the lesser mouse deer; however, once in a while larger animals such as the Rusar Unicolor, Southern Red Munjak and Pangolin are caught.

According to villagers, the most prized mammal species is the Pangolin, the price for which ranges from 100,000 KIP (13 USD) to 1 million KIP (130 USD) per kilogram. This is because of its rarity and medicinal purpose – it is believed to have sexual stimulation powers and is preferred alive.

Hunters reported that the availability of resources has been declining since around 2000. The villagers believe that the cause of the decline is the increasing number of new settlers who have migrated to the village areas and started accessing the existing natural resources.

In addition to hunting, many women collect materials from the forests (i.e. gather). A number of species are collected, including mushrooms and bamboo shoots, and are collected baseon their growing season d. Female gatherers reported that they visit forests more often at the start of the rainy season (i.e. May) given that the bamboo shoots and ground vegetation are abundant and ripe at this time of year.

Flora species were, again, primarily used for household consumption and only surplus is sold to intermediaries. However, from time to time, specific species will be requested by intermediaries, such as Nor boon (1,000 KIP (15 cent) per piece) and Nor Xang (50,000 KIP (7 USD) per kilogram). These are the most prized plants due to their taste.

Instead of selling materials collected, females typically engage in other activities, such as planting rice or textile production, in order to provide family income.

#### ENVIRONMENTAL RESOURCES MANAGEMENT AUSTRALIA

#### 4.6.2 Fishing

Villagers indicated that fishing is mainly the role of females rather than males. The majority of fish caught are consumed within household. Only surplus or the prized species are sold to intermediaries. Hence, family income derived from selling fish is relatively low - ranging from 0 to 20 per cent.

In terms of species, female hunters typically catch cat fish and scale fish. The Pla Pann is reported to be the most prized species – it can attract up to 130,000 KIP (17 USD) per kilogram at market.

Females indicated that they go fishing more often during the rainy season as species that dwell in Mekong River flow downstream to the Nam Ngiep and Nam Xan rivers during this period.

Regarding availability of fish, villagers indicated that resources have been declining due to the increasing number of people fishing. Villagers noted many of these people are fishing for commercial purposes, not household consumption.

#### 4.6.3 *Cultural services*

Most of the villages identified two specific cultural sites deemed important to their way of life - village temples and cremation sites. The cultural sites are typically located in close proximity to the village, but are communally owned by the village. For example, Ban Don reported to have village temple named Ban Don Chaiyaram. Religious ceremonies are held at the site from time to time. The villagers reported to do in Buddhist merits such as release fish, turtles at the temple.

When asked, the villagers indicated that the sites can be moved elsewhere or destroyed and rebuilt elsewhere. In order for this to occur, compensation in the form of land or money is required. The only exception was the Ban Hat Seung Tom, a historic cultural site where artefacts are buried, in Ban Pakheaung. The site was established prior to the founding of the village itself.

As for intangible heritage, no significant sites were identified. This is partly due to the fact that the village residences were largely lowland Laos who are Buddhist; accordingly, religious ceremonies are conducted in village temples. Another possible underlying factor is that the villagers did not settle in the area until after the Laotian Civil War (1953 – 1975).

#### 5 CONSERVATION SIGNIFICANT VALUES SUMMARY

#### 5.1 **PROJECT AREA**

The Project area is located along the Nam Ngiep River which is a major watercourse draining into the Mekong River. The Nam Ngiep River flows through a mountainous region to a gorge at Hat Gniun, which is the proposed location for the main dam wall. Surrounding the river the vegetation is dominated by deciduous forest land, representing approximately 36 per cent of the footprint. Young and old fallow land is also highly represented with 16 and 21 per cent respectively. In terms of vegetation condition the Project area is dominated by vegetation cover that shows moderate to high photosynthetic capacity.

The vegetation present provides habitat for a number of flora and fauna species, including species listed on the IUCN Red List as Critically Endangered, Endangered or Vulnerable, species listed as Restricted in the Lao PDR Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF, and species that are migratory and endemic. These species have been considered as candidates for critical habitat in accordance with SPS.

As part of the baseline assessment each candidate species has been assessed against the quantitative thresholds of the performance standard for the relevant criteria. Species information sourced from desktop review, field survey results, village interviews and specialist consultation was used to determine the importance of the Project area for each candidate species, and in turn the likelihood of the Project area be considered critical habitat.

The outcomes of the assessment and specialist consultation did not identify any areas of critical habitat for terrestrial flora or fauna species. One fish species, *Luciocyprinus striolatus*, was determined to have critical habitat within the main dam inundation area and a number of endemic and potential endemic species were detected. The area downstream of the Project area is recognised for the large river and floodplain habitat values for migratory fish species.

#### 5.2 CANDIDATE OFFSET SITES

Four candidate offset areas were investigated to determine the biodiversity values represented. Following impact assessment for the Project, an appropriate offset site, or combination of, will be selected. The Biodiversity Offset Design Report will document this process.

In comparison to the biodiversity values of the Project area, the candidate offset sites demonstrate biodiversity values similar to the candidate offset sites. The table below summarises some key biodiversity features for comparison. As would be expected given the proximity to the Project area the

Upper Nam Ngiep candidate offset site exhibited biodiversity values most similar to the proposed disturbance area.

| Feature                   | Project  | Upper      | Nam     | Huay     | РКК        |

# Environmental Research Institute 2007 Survey Method

The following method is an excerpt from Chapter 3 of the Nam Ngiep 1 Hydropower Project Environmental Impact Assessment Draft Report prepared by: Environmental Research Institute, Chulalongkorn University, October 2009.

#### A.1 TERRESTRIAL ECOLOGY/WILDLIFE

Blockage in a waterway to create a large reservoir as well as other activities associated with the construction and operation of a large dam like the NNP-1 can cause abrupt changes in the environment. It may affect plants and animals in either positive or negative ways. Some animals may respond positively to the changes, hence increasing their populations. Other animals may not be able to withstand the abrupt changes and must either seek a new place to live or die out.

#### A.1.1 Objectives of Study

- 1. Investigate the diversity, abundance, and distribution of wildlife in the Project area, and any use of the wildlife by local residents.
- 2. Assess environmental impacts that the proposed project may have on wildlife, their food sources, and their habitat.
- 3. Draw up appropriate mitigating measures to protect against probable negative impacts on wildlife.

#### A.1.2 Method of Study

The surveyed area is broadly defined as the area north of the dam site extending to the northern margin of the reservoir, covering the proposed inundation area. The surveys were conducted to provide baseline information on the distribution of wildlife and wildlife habitats to determine likely impacts of the project on such fauna and to assess how any such impacts might be mitigated through appropriate interventions.

After a review of available literature, a field survey was conducted in both wet (October 2007) and dry (March 2007) seasons to collect primary field data concerning all wildlife species including mammals, reptiles, amphibians and birds.

Within and around the survey areas, wildlife conditions were surveyed and assessed by visual inspection and interviews with villagers, as well as from secondary data and information gathered from available sources such as authorities concerned with wildlife. Local villagers within and around the Project area were interviewed regarding wildlife conditions within and around their villages. Additionally, wildlife within circular sample plots for forest collection were recorded, such as the sighted animals, foot-prints, nests, burrows, hair or feathers, molts, sounds and any other evidence.

Status of the wildlife species is then assessed according to the current IUCN classification (IUCN, 2009):

- CR = Critically Endangered
- EN = Endangered
- VU = Vulnerable
- NT = Near Threatened
- LC = Least Concern
- DD = Data Deficient

(IUCN 2009. IUCN Red List of Threatened Species. Version 2009.1. <www.iucnredlist.org>. Downloaded on 09 June 2009.)

#### A.2 FOREST, VEGETATION COVER

The Nam Ngiep Hydropower Project will affect forest resources and ecosystems by clearing some forest to be replaced by the dam and reservoir.

#### A.2.1 Objectives of Study

- 1. Study forest characteristics particularly tree species, density, and timber volume as well as saplings and seedlings in the inundation area and in the resettlement area.
- 2. Assess the economic value of timber to be cut in the reservoir and the resettlement areas.
- 3. Evaluate impacts on forest resources that may be caused by the project.
- 4. Recommend mitigating measures to minimize impacts on forest resources and ecosystems.

#### A.2.2 Method of Study

The surveyed area is broadly defined as the area north of the dam site extending to the northern margin of the reservoir, covering the proposed inundation area. The surveys were conducted to provide baseline information on the distribution of forest types and vegetation to determine likely impacts of the project on such flora and to assess how any such impacts might be mitigated through appropriate interventions.

The methodology involved in assessing the forest and vegetation cover was to compile maps and available literature on the land and water resources of the region and in particular the survey area. Based on these maps and literature, the field survey was conducted in October 2007 to collect primary data concerning tree and vegetation species, density and estimated volume per hectare for big tree species with diameter at breast height (DBH) of more than 10 centimetres.

The main method used in this survey is similar to that used for the wildlife survey including interviews with villagers, especially senior persons who have experience with the types of vegetation and non-timber forest products in their vicinity. The villagers were questioned on land use as well as lists of vegetation and NTFPs.

Primary data was collected from 35 temporary sample plots that were set in the form of line plot system covering the inundation area according to land use, geographic conditions and forest types. The sample plots were set in the dominant area or good sample areas located where the reservoir will be located. There were 3 types of temporary sample plots, and the data collected depended on their shapes and size:

- 1. A circular sample plots with a radius of 17.85 meters (0.1 hectare total area) from which data on trees of DBH equal to and above 10 centimeter were collected. Other significant information recorded included tree species, their diameter and height, and bamboo types, including number of clumps and stems per clump found in the plot.
- Square plots of 5x5 meters (25 square meters) were established in the middle of the circular plots. Information on small trees and/or saplings (trees whose DBH is less than 10 centimeters and whose height exceeds 1.3 meters), tree species, number of tree and their average height as well as NTFP species was recorded from these plots.
- 3. Square plots of 2x2 meters were established within the larger square plots of 5x5 meters. Data concerning plants and vegetation including sapling or seedlings (all undergrowth vegetation), focusing on species of trees or seedlings of each species as well as NTFPs were recorded in these plots. The main concern was on the diversity of plants and NTFPs species, not the numbers or density of the saplings and seedling or plants, since the time available for field data collection was limited, and also since some of the data, especially that on NTFPs were being collected through interviews with villagers.

#### A.2.3 Forest and Vegetation Classification

Several forest classification schemes have been proposed for the Lao PDR. The classification of forest types for this study is based on the classification used by the Forest Inventory and Planning Division, Department of Forestry since 1982, and the preliminary national forest record. Box 1 shows the classification and definition of each forest or land use type.

Box 1 Definition of Land Use and Forest Types

#### 1. <u>Current Forest</u>:

Current Forest includes natural forests and plantation forests. It is used to refer to land with a tree canopy cover of more than 20% and area of more than 0.5 ha. The trees should be able to reach a minimum height of 5 m. The basis for the distinction between forest and other land use groups is the

crown density. Natural forests are classified into forest types, which are Upper and Lower Dry Evergreen Forests, Upper and Lower Mixed Deciduous Forests, Gallery Forest, Coniferous Forest, Mixed Broadleafed and Coniferous Forest, and Dry Dipterocarp Forest.

- <u>Dry Evergreen Forest (DE)</u>: The Dry Evergreen Forest type has a lower proportion of evergreen trees than the Evergreen type, 50% -80%. Except in disturbed stands there is very little bamboo. Soil is usually deep. The forest consists of a considerable number of species, of which 2 to 3 species tend to be predominant.
- <u>*Mixed Deciduous Forest (MD):*</u> In the Mixed Deciduous Forest, deciduous tree species represent more than 50% of the stand. The forest storeys are not as dense as those of evergreen types and most of the seedlings and saplings are deciduous trees. Bamboo often occurs in this type of forest.
  - <u>Upper Mixed Deciduous Forest (UMD)</u>: This type of forest is located at an altitude above 200 m. In moist areas there might be many climbers, and it could be difficult to distinguish this forest from the Dry Evergreen type. In dry regions the difference can be clearly seen. This forest type appears quite open with a considerable amount of bamboo and undergrowth.
  - *Lower Mixed Deciduous Forest (LMD):* This type of forest is located at an altitude below 200 m.
- *Dry Dipterocarp Forest (DD):* This type of forest occurs in open stands. The tree diameter is comparably small and the height of the stand varies from 8 to 25 m. The crowns do not spread out widely. It is normally found in places with shallow soil, where the hard pan emerges above the ground, and on latirized soil. On the most poor and shallow soils the trees are crooked and do not exceed 10 m in height: If the crown cover is less than 20% and the stand is undisturbed the vegetation type should be classified as Savannah.

Many species characteristic for the Dry Dipterocarp forests are fire resistant and have a thick bark. Mai Sabeng (*Dipterocarpus intricatus*), Mai Chick (*Shorea obtusa*), Mai Sat (*Dipterocarpus obtusifolius*), Mai Seuak (*Terminalia tomentosa*) and Mai Hang (*Shorea siamensis*) are among these species.

• *Coniferous Forest (S):* The Coniferous Forest is usually single storied and open but the young growth may sometimes form a dense second storey. This forest type occurs in higher elevations with a cool climate. The characteristic species of this type are pines (*Pinus kesiya* or *Pinus merkusii*) but other coniferous trees such as Cunninghammia may also be predominant.

• <u>Mixed Broadleaved and Coniferous Forest (MS)</u>: The MS Forest is a transition type between the coniferous and the broadleaved forest types. The coniferous trees could be mixed with either deciduous or evergreen trees. It is also found in higher elevations.

# 2. <u>Potential Forest</u>:

Previous forest areas where the crown cover has been reduced below 20% (whether from logging or shifting cultivation) are classified as Potential Forest. The potential forest includes Bamboo, old shifting cultivation areas (young secondary forests) and Temporary Unstocked areas. Potential Forest is consisted of Unstocked, Bamboo and Ray.

- <u>Unstocked Forest (T)</u>: Unstocked Forest Areas are previous forest areas in which the crown density has been reduced to less than 20% because of logging, shifting cultivation or other heavy disturbance. If the area is left to grow undisturbed it becomes forest again. Abandoned ray and disturbed stands with a crown density less than 20% should be classified as Unstocked Forest Areas. Old ray in which seedlings, sapling and trees cover more than 20% of the area should be classified as some type of Current Forest.
- <u>Bamboo (B)</u>: If an area is covered with bamboo and the over storey has a crown cover less than 5% it should be classified as Bamboo Forest.
- <u>Swidden (Ray) (RA)</u>: Ray is an area where the forest has been cut and burnt for temporary cultivation of rice and other crops. The area should be classified as Ray from the time it is clear cut until one year after it has been abandoned. Areas being prepared but not yet clear-cut and areas that have been abandoned for more than 1 year should not be classified as Ray.

## 3. <u>Other Land Use Types</u>:

- <u>Savannah (SH)</u>: is an area where the soil conditions are unsuitable for tree growth as well as for agriculture production. The tree cover in the Savannah should be at least 1% but not more than 20%. The trees are drought resistant and mostly short with graminaceous and herbaceous plants forming an under storey. Savannahs should not be confused those grass covered areas that sometimes occur after shifting cultivation. Normally, the Savannah does not occur on steep slopes but in plains.
- *Scrub Forest (SR):* This is an area covered with scrub and stunted trees. The soil is shallow and rocky.
- <u>Barren Land and Rock (R)</u>: Unfertile or seriously degraded land on shallow soil and rocky areas on which neither trees nor grasses can grow.
- <u>Grassland (G)</u>: Unfertile or degraded land on which no trees or shrubs grow. It might be an area that is too dry for tree growth that has been covered by grasses. It could also be an area that has originally been

covered by trees, but has been heavily disturbed by cutting and fire and gradually depleted. One reason for the absence of trees could be that larger areas have been deforested and the seed supply from surrounding forest has ceased. Areas burnt every year to grow fodder or for hunting purposes could also be classified as Grassland. That type of Grassland can be found on higher elevations in the Northern part of Laos. Grassland can also occur on deep sand with a high moisture content.

• <u>Swamp (SW)</u>: Swamps are areas where the soil is saturated with water. The soil may basically be fertile but the lack of oxygen limits its agriculture or forest capacity. The Swamp could have a high ecological or environmental value and the flora and fauna may be rich.

The typical tree species found in the Swamps are trees which can grow in water, such as *Adina cordifolia*, *Rhus succedanea* and *Barringtonia acutangula*.

## 4. <u>Other Agricultural Land (OA)</u>:

Land being used for agricultural purposes other than crop cultivation, such as cattle grazing, should be classified as Other Agricultural Land, unless the tree cover exceeds 20%. In that case it should be classified as some type of Current Forest depending on the tree species composition.

• <u>*Rice Paddy (RP):*</u> Areas permanently being used for rice cultivation. Old paddy that has been abandoned and not in use for more than one year should not be classified as Rice Paddy.

Source: Report on the Assessment of Forest Cover and Land Use (MAF, DOF, July 2005)

#### A.3 AQUATIC BIOTA

Reservoir impoundment and effluent discharge from the power plant and from other activities during construction and operation will affect the surrounding water bodies, including aquatic life in local canals and rivers. Therefore, a study on aquatic biota and habitats is necessary to assess present conditions and possible project impacts, and as a basis for possible plans for future utilization or development of their aquatic resources by local communities.

#### A.3.1 Objectives of Study

- 1. Review secondary data of aquatic biota and habitats from preliminary reports and the collect primary data from the field.
- 2. Assess potential impacts on aquatic biota in the Project area and downstream.
- 3. Recommend mitigation measures, including monitoring programs.

#### A.3.2 Method of Study

#### Sampling Station

Dry season survey along Nam Ngiep River was conducted in January 2008 at ten stations: six located downstream from the proposed dam and the other four located upstream (Table 6.1 and Figure 3-2).

#### Table A.1Fish and Fisheries Survey Locations along the Nam Ngiep River

| Name |            | Location    |          |               | Coordinate  |              |

#### Figure A.1 Fish and fisheries survey locations along the Nam Ngiep River

Examination of aquatic fauna and flora included distribution of indigenous fish species and their abundance in particular areas of the river. Plankton, benthos and aquatic plants, which provide nutrients to young fish, were also examined. The aim of the survey was mainly to determine the existence of aquatic life in the river. Study results and other relevant data (hydrology, water quality) were used to predict possible changes in aquatic life after project development and its effect on peoples' livelihood.

#### Fish Sampling

Fish were collected using sampling seine net with the size of 430 x 160 cm with 5 mm mesh size. At the site, the seine net was equipped with bamboo pole at each end that was at least equal to the height of the net. Haul seine was operated and fished parallel to the river bank. Fish samples were preserved in a plastic bottle or a jar containing 10% formalin solution. The bottle was labeled with information such as date of sampling, station code, name of collector and time of collection. The samples were sent to a laboratory for species identification. In the laboratory, fish sampled from each station were identified by using a magnifier, a dissection microscope and classification guidance books (Kottelat, 2001 and Rainboth, 1996). Their productivity in the river was recorded

#### Plankton Sampling

Plankton sampled from those stations was conducted using a plankton net of 70  $\mu$ m mesh size and a 2-litter beaker (Gajaseni, 1993). Sampling depth of water was taken at 30 cm below the water surface. Ten litters of sample were preserved in a plastic bottle containing 5% formalin solution. Information such as the code of sampling station and date were marked on the bottle. The specimens were sent to a laboratory for species identification as well as their density.

#### **Benthic Sampling**

Benthic fauna at each station was sampling using an Ekman dredge (Gajaseni, 1993). The samples were sieved by using a 1 m-mesh sieve. Each specimen was preserved in a separate bottle containing 7% formalin solution. Necessary information was labeled on the bottle. They were delivered to a laboratory for specie identification and density assessment.

#### A.4 WETLAND

A wide range of inland wetland habitats are found in Laos PDR. The Mekong River and its tributaries, paddy fields, small ponds, swamps, and flooded forests are among them. These habitats provide a fundamental source of food for local people as well as shelters for wildlife species such as native catfish and large waterbirds (Giant ibis and Sarus crane). Although the Lao PDR has not yet ratified the Ramsar Convention on Wetlands for the protection of wetlands of international importance as of March 2009, it well recognizes the importance of wetlands. Therefore, any significant adverse impact on wetland habitat caused by this project should be identified. In addition, the rehabilitation and restoration of any damaged wetland ecosystem should be promoted.

#### A.4.1 Objectives of Study

- 1. Identify location and pattern of wetlands found in the Project area. This information serves as baseline data for future comparison of land cover changes or wetland habitat losses due to the project.
- 2. Detect changes of location and patterns of wetlands and the impacts of project development on wetlands. This is useful for assessment of impact on the wetlands after project development.
- 3. Propose mitigation measures to reduce adverse impacts on wetlands. The proposed measures are helpful to establish future rehabilitation and restoration programs for damaged wetlands during and after the project development.

#### A.4.2 Method of Study

- 1. Compile information on wetlands from Lao and international literatures.
- 2. Acquire both primary and secondary data to evaluate wetlands in the Project area.
- 3. Assess possible impacts of the project on identified wetlands.
- 4. Prepare protection and mitigation measures and propose monitoring plans

Annex B

Thailand Institute of Scientific and Technological Research Biodiversity 2013 Survey Method The following method was provided by The Thailand Institute of Scientific and Technological Research.

#### B.1 SURVEYS

Field investigations were undertaken in four key areas associated with the Project:

- NNP1 Project area;
- Nam Xan River Catchment;
- Huay Ngua Provincial Preserved Area; and
- Houy Soup Resettlement Site.

Surveys were undertaken by three teams comprising 25 people targeting separate taxa: vegetation (two teams of 7), terrestrial wildlife (one team of 6) and aquatic biota (one team of 5).

#### B.1.1 Forest and Vegetation Survey

The Forest and Vegetation Survey was designed to assess the overall status, quality, and conservation significance of existing forest/vegetation types, taking into consideration global, national and local conservation priorities; and to assess the diversity and availability of Non Timber Forest Products (NTFPs). In summary, the Forest and Vegetation Survey included the study of species diversity and the conservation status of vascular plants based on field survey and literature review. Specifically it included:

- review of literature obtained from secondary sources, including flora journals and reports on other surveys of the area;
- a vascular plant survey of 9 Study Sites (the main dam inundation, reregulation dam inundation, resettlement site, Huay Ngua Provincial Preserved Area, Upper Nam Ngiep River and Lower Nam Ngiep River, the Upper Nam Xan River, Lower Nam Xan River, and Transmission line);

#### B.1.2 Methods

The forest survey team specifically surveyed for species diversity along trails and in the sampling plots. Intensive surveys were conducted on the transect lines and covered all vegetation types. Unknown plants were collected and three duplicates of leave with flowers or fruits for further analysis in the laboratory. Botanists recorded necessary information i.e. morphology, habit, colour of flowers and ecology, georeferenced location, and compiled photographic records.

The sampling plots consist of 3 types of temporary plots:

- A circular sample plot with a radius of 17.85 meters (or 0.1 ha): data of trees which are diameter at breast height (DBH) ≥ 10 centimeters were recorded. Other significant information were recorded and measured such as tree species, DBH, total height, timber quality, number of log (1 log = 5 m timber), and bamboo species, including number of clumps and stems per clump.
- 2) Square plots of 5x5 meters (25 square meters or 0.0025 ha) were established in the middle of the circular plots. Information of small trees and/or saplings (trees whose DBH < 10 centimeters and whose height >1.3 meters), tree species, number of tree, and height, as well as NTFP species were recorded from these plots.
- 3) Square plots of 2x2 meters (4 square meters or 0.0004 ha) were established within the larger square plots of 5x5 meters. Data concerning plant species, number of seedling, and undergrowth vegetation was recorded.

Analyses of the data collected included specialised laboratory investigations to establish identification of voucher specimens. Quantitative analysis of the data included analysis of tree density, frequency, volume, of tree species and was determined as per Curtis and McIntosh (1950). Timber volume ( $\overline{V}$ ) per survey plot was estimated using Thannarin (1999). Relative density ( $RD_i$ ), Relative dominance ( $RB_i$ ) and Relative frequency ( $RF_i$ ) of a given species were also calculated. Important value Index ( $IVI_i$ ) was used to determine the overall importance of each species in the community structure was calculated from the (Curtis, 1959). A Complex index of a particular forest type (CI) was also calculated and Species diversity and dominance of a given species were evaluated using Shannon-Weaver (1963) index of diversity) H').

A forest status assessment was undertaken considering the environmental factors within the forest including forest impact assessment including wood density, volume, composition, functions of the forest, and ecological value of forests and external factors. External factors include areas of forest cover, conservation and management, and anthropogenic activities in the study areas.

#### B.1.3 Timing

Surveys were completed during the dry season March 2013 and wet season July 2013.

#### B.1.4 Terrestrial Wildlife Survey

The Terrestrial Wildlife survey aimed to describe the baseline wildlife diversity of the impact zones for the purposes of assessing the potential Project impacts to terrestrial wildlife. Survey and sampling work involved developing an inventory of wildlife species (amphibians, reptiles, birds, and mammals).

#### B.1.5 Locations

A total of eight study areas were assessed for the Wildlife Surveys and included, the Resettlement site, Huay Ngua Provincial Preserved Area, Nam Ngiep River, Nam Xan River, Upper Nam Ngiep River, Lower Nam Ngiep River, Upper Nam Xan River, and Lower Nam Xan River.

| Locations                         | Name of Stations | Co-ordination (Zone 48 –<br>WGS84 |         |  |
|-----------------------------------|------------------|-----------------------------------|---------|--|
|                                   |                  | X                                 | Y       |  |

#### B.1.6 Methods

The methodology adopted in the wildlife survey was included a literature review of previous publications, papers, reports, internet, etc., relating about wildlife within the study areas. The Wildlife inventory of each group was collected through the following techniques:

- 1) Direct count: This method was carried out to count directly numbers of amphibians, reptiles, birds, and mammals by sightings during the field surveys at the survey stations. Observations and records of animal signs such as tracks, nets, burrows, droppings, hair and feathers, were also recorded. Details of the techniques used for each group include:
  - i. Amphibians and reptiles: species searches were undertaken in habitats such as under logs, rocks, bark as well as digging in the buttress of trees. At night, spotlighting was used to detect nocturnal species along rivers, around poundages, and within tree canopies.
  - Birds: were directly observed using binoculars during day time.
     Some species of birds were identified using call identification during the morning or evening, when they are the most active.
     Birds were also caught using mist-nets under tree canopies or cross the creeks these were identified, photographed, and released.
  - iii. Mammals: were observed from their signs such as tracks, scats, scratches on trees, burrows, etc. small mammals, were captured using live-traps or Sherman's traps. Bats were surveyed at night

using mist-net and harp traps placed under tree canopies or cross creeks. Some species of mammals were identified from local hunters.

For all wildlife species the habitats were recorded. In the case of unidentified these were collected and preserved and later analysed at the laboratory in the Natural History Museum-Nation Science Museum, Prathum Thani, Thailand.

2) Indirect count: was used to obtain supplementary information on wildlife by interviewing local residents who lived in or near by the Project area. Some local villagers may hunt animals for food or for sale. Local households as well as local markets were also sampled.

Habitat evaluation: was undertaken recording information on plant species acting as the sources of food and cover. Plants used for foraging and their frequency of observation will be utilised from the forest inventory.

Species Diversity: Wildlife identification of each group using keys and descriptions from the standard references (Corbet & Hill (1992), Francis (2008), and Lekagul & McNeely (1988); avian species were mainly referred to Lekagul & Round (1991) and Robson (2002); reptiles species were identified base on Taylor (1963) and Cox *et al.*, (1998); and amphibian species were classified using Taylor (1962) and Chan-ard (2003).

Relative abundance of wildlife: was calculated from numbers obtained in the direct and indirect counts, species were assigned as abundant, common, and less common using a calculation formulated by Pettingil (1969).

#### B.1.7 Timing

Surveys were completed during the dry season March 2013 and wet season July 2013.

#### B.1.8 Aquatic Biota Survey

The Aquatic Biota survey aimed to determine the baseline fish biodiversity and aquatic resources of the Project Affected Area and the proposed offset sites. Sampling was conducted at different locations in Nam Ngiep, Nam Xan, Huay Ngua PPA and the Houy Soup resettlement area. This included 5 sampling sites (NNg1 through to NNg5) upstream of the proposed main dam and 3 sampling sites (NNg6 through to NNg8) downstream of the proposed main dam in the Nam Ngiep Catchment, 5 sampling sites (NX1 through to NX5) in the Nam Xan Catchment, 2 sampling sites (HN1 and HN2) in the Huay Ngua PPA and 2 sampling sites (RA1 and RA2) in the Houy Soup resettlement area.

In summary, the Aquatic Biota Surveys included:

- Collection of phytoplankton and zooplankton species using multiple plankton net surveys at each location, followed by preservation, identification and laboratory analysis at TISTR;
- Collection of benthos at multiple replicate sites using an Ekmann dredge, followed by identification and abundance counts at the TISTR laboratories; and,
- capture and identification of fish species within the main rivers and their tributaries using the help of local fishermen using multi-mesh gillnets, electrofishing, cast nets, gun and hook, as well as discussions with fishermen and other information sources.

# 1. Introduction

This report has been compiled to present results of surveys undertaken from 14 December 2013 to the 18 December 2013 for the presence, distribution and populations of endangered primate species within the inundation area of Nam Ngiep 1 Project (NNP1).

The NNP1 project is located in the triangle of Bolikhamxay, Xiengkhuang and Vientiane Province. This survey is a targeted survey to provide additional information to the EIA report as requested by the ADB to ensure that the endangered primate species and their associated habitats are identified and understood to allow for appropriate mitigation measures if any adverse impacts are identified.

Nam Ngiep Project 1 (NNP1) has an output of approximately 269 MW, the main project component consist of a relatively small reservoir (ca. 7,000 ha) with a width (0.5 km) and a length of the reservoir (ca. 70 km). The Nam Ngiep hydropower dam has its reservoir level of ca. 75 m above the river base or ca. 320 m above sea level. It is high terrace dam but narrow reservoir. There are only 6 villages and ca. 2,500 people to be resettled which is considered small population.

Nam Ngiep River flows through rocky mountain valleys as steep valleys in most parts. The river has four main tributaries, the Nam Chae, Nam Phong, Nam Siam and Nam khai as key watersheds. Another seven small tributaries have also been identified as important watersheds for NNP1. Along the river itself the proposed inundation area topography and land uses varies from section to section.

The majority of the project area is mixed deciduous forest and evergreen forest in upper mountains. The lower areas or foothills especially the upstream of Nam Chae and downstream of Nam Houy Keng Ngon are dominated by fallows, current slash and burn practice, and logging activities. According to the riparian forest characteristic the whole inundation area can be classified into 5 sections as following:

| Section | Name of location | Habitat description   |
|---------|------------------|---|
|         | range            |   |
| 1       | Upstream of      | Degraded habitat, fallows, bananas leaves, weeds              |
|         | Nam Chae         |   |
| 2       | Nam Chae to      | Some fallows, degraded habitat due to previous and current    |
|         | Ноиу Као         | logging activity.   |
| 3       | Houy Kao to      | Quite good habitat, hilly valley, healthy riparian forest and |
|         | Houy Keng Ngon   | also uphill mountains of both sides                           |
| 4       | Houy Keng Ngon   | Some fallows and new slash and burn on the left bank and      |
|         | to Houy heuafan  | mid-lower mountain, all fallows in right bank, some logging   |
|         |                  | activity.   |
| 5       | Downstream of    | Degraded habitat presence of grassland due to over slash      |

Table 1. Habitat description by sections

| Houy heuafan | and burn, some logging activity. |
|--------------|----------------------------------|
|--------------|----------------------------------|

There are 11 villages located within the proposed inundation area, mainly in the upper part of the reservoir but only three villages in the lower reservoir. Due to these settlements the forest habitats of upper and lower reservoir have been modified.

NNP1 is situated in a remote area and as such a number of endangered species have been identified as potentially occurring within the project locality. Three endangered primate species have been identified from the previous biodiversity survey work as potentially occurring within the proposed inundation area of the NNP 1. This survey was conducted to establish the presence of these species and their related habitats within the inundation area.

# 2. Objective

- To conduct survey of Northern white cheeked Gibbon, Red-shanked Douc Langur and Phayre's Leaf Monkey in the inundation area;
- To obtain a population of the target primate species in the inundation area;
- Identify critical habitat that suitable for the target species in the project area.

# 3. Survey Species

Lao PDR is considered one of richest countries in terms of biodiversity in Southeast Asia. There are 24 National Protected Areas (NPAs) declared that are of conservation significance (see Fig. 1). The national protected area covers 15% of the country. Also, 49 national protection forests and over 100 provincial and district protected areas. These conservation forests support populations of critically and endangered wildlife species. Apart from these designated protected areas and protection forest it has production forest and also non-protected area. The NNP1 project area is within a non-protected area.

The Nam Ngiep project 1 area is a remote area that has been identified as potential habitat for three endangered primate species including Northern White-cheeked Gibbon, Red-shanked Douc Langur and Phayre's Leaf Monkey.

Figure 1. Map of three forest types in Lao PDR

#### Northern White-checked Gibbon (Nomascus leucogenys) - Critical Endangered

Globally: this species is critically endangered, found only in Lao DPR, China and Vietnam. Lao PDR holds nearly all of the world's remaining wild Northern White-cheeked Gibbons and may hold all the viable populations. In southern China, Xishuanbanna, Yunnan Province, close to Luang Namtha Province (Fan Pengfei *et al.* 2009) was confirmed but very low as it is probably on the verge of extinction in the wild. While, in Vietnam it has recently only

been recorded in a few forests close to the Lao border, but the viability of all remaining populations is questionable. As such it is an outstanding global priority for conservation of this species.

Regionally: this species is endemic to southern China especially in Lao PDR. Within Laos, the species has been exist from northern part of Nam Kading NPA in Bolikhamxay Province which a range crossing from west at Mekong to northeast at Annamite Mountain Range as around northern Nam Kai Nam Theun NPA. Entirely this section up the northern country wide is believed to have only Northern white-cheeked Gibbon except the west of Mekong River where the distribution of White-handed Gibbon and Western Black crested Gibbon. Nationally: the population of Northern white-cheeked Gibbon in Lao PDR is guite large as globally important population. It has a distribution range from the far north east of Lao PDR to the area of the Nam Kading River in Nam Kading NPA (Thinh et al., 2010). There are several National Protected Areas (NPA) that the species' range within Lao PDR including Nam Et-Phou Louey NPA representing surely the largest patch of little-encroached and effectively managed habitat for the species. It is reported about 15 groups (WCS, 2010) found in a small proportion of the NPA but the entire gibbon population has not been estimated. Nam Kading may also hold considerable populations of this species. In both Nam Kading and Nam Et-Phou Louey NPAs the crested gibbons are key species for management and ongoing conservation is confirmed through donor support and technical input from the Wildlife Conservation Society (WCS). Populations of this species is persist in the Nam Xam NPA. The small numbers in Phou Den Din NPA, Phou Khao Khoay NPA, Phou Sabot Pongchong and Phou Phanang NPA. In addition, Thinh et al. (2010a) considered that N. *leucogenys* still exists outside the NPA system in northern Lao PDR in Oudomxay Province, Vangvieng District and also northern Bolikamxay Province that joins with Vientiane Province.

This species spends most time in trees and prefer most in evergreen forest. They give song in early morning and most active from November to March. They need the habitat, canopies connected for traveling. They feed on wild fruits as *Ficus* tree is best but they do rarely descend on the ground. Where a wide river that has no gallery forest of both sides closing to each other is a barrier for the species to cross so most a wide river such as Nam Ngiep River is already a barrier for the gibbon groups present in both river sides. It has a home range of ca. 40 ha but depends on habitat quality. Where best habitat quality and high density of gibbon groups their home range is smaller than other site with low habitat quality. Estimated records of groups size of gibbons in Laos are at Hin Namno NPA is 3.8 (Phiapalath, 2009) and 3.6–3.8 for the Western Black crested Gibbon in Nam Kan NPA (Geissmann, 2007).

#### Red-shanked Douc Langur (Pygathrix nemaeus) - Endangered Species

Globally: this species is endemic to Indochina as only Lao PDR, Vietnam and Cambodia. In Vietnam, Red-shanked Douc Langur was found in Bach Ma National Park (Pham, 1993b), Phong Nha Ke Bang National Park (Pham *et al.*, 2000), Phu Mat Nature Reserve (Lippold, 1998), Kong Cha Rang Nature Reserve, Kon Khi Kinh Nature Reserve (Lippold, 1995), and Son Tra Nature Reserve (Lippold, 1977; 1995). These places are mainly in Vietnam's

Central Highlands with altitude between 500–1,000 m above sea level (Timmins and Duckworth, 1999).

Regionally: this species is just the same status as the global status since it is endemic to only the Indochina which cannot be found elsewhere in the world.

Nationally: In Lao PDR, their habitats lie between 14°25′ and 18°25′ N as Nam Kading NPA is the most northern range of the species (Timmins and Duckworth, 1999). By province, the species distribution is in Bolikhamxay Province toward southern provinces. They can be found along the Vietnam border in the east, from Nam Chat catchment to the Cambodian border in the south (Timmins and Duckworth, 1999). Recently, the species has been recorded in Laos and that confirmed at 12 locations ranging from 200 to 1,500 m a.s.l., (Timmins and Duckworth, 1999). Specifically, Nakai-Nam Theun National Protected Area and Hin Namno National Protected Area support the largest population of the species in the world (Duckworth *et al.*, 1999; Timmins and Duckworth, 1999). A small to medium population of Red-shanked Douc Langur has also been reported at other eight sites in Laos including Nam Kading National Protected Area in Bolikhamxay Province, Phou Xang He and Dong Phouvieng in Savannakhet Province, Xe Bang Nuan and Sesap in Saravanh Province, Dong Hua Sao in Champasak Province, Dong Ampham and Nam Kong in Attapeu Province, and Phou Ahyon in Sekong Province (Duckworth *et al.*, 1999; Timmins and Duckworth, *1*999).

Red-shanked Douc Langur is found in similar habitats to Vietnam including limestone habitats (Duckworth *et al.*, 1999; Timmins and Duckworth, 1999; Walston and Vinton, 1999). The Red-shanked Douc Langur is mainly found in primary forests but also in secondary forests. They can adapt to variety of forest types including semi-evergreen, hill evergreen, sub-montane evergreen, mixed deciduous, mixed evergreen and closed broad-leaved tropical forests (Lippold, 1998).

Red-shanked Douc Langur is diurnal and arboreal, as is normally found in the group of colobids, spending a major proportion of their daytime for feeding in the wild (Lippold, 1995) – both leaves and fruits. Also, the species mainly lives in the mid to upper levels of the forest canopy. Groups of Red-shanked Douc Langurs reportedly move through the forest canopy along established routes. An adult male is the group leader and all group members follow when he moves. Females and infants are often found in the center and juvenile males bring up the rear during their locomotion (Lippold, 1995; 1998).

This species spends most time in trees and prefer most in evergreen forest. They need the habitat with connected canopies for crossing. Where a wide river it is a barrier for the species to cross from one to another side because this specie is usually not descending on the group. This species is reported they descend on ground for feeding on ground in begin dry season (Phiapalath, 2009) and also use mineral licks (Rawson et al., 2011). Group size of Red-shanked Douc Langur varies depending on habitat and human disturbance. In the past, they lived in groups of 30–50 individuals (Lippold, 1995) in Vietnam. Groups as large as 50 individuals have been reported in Kong Cha Rang Nature Reserve and Kon Khi Kinh Nature Reserve (Lippold, 1995). It is normally a group size ranging18-40 in Lao PDR (Phiapalath, 2009). Nevertheless, in areas with high pressure of human activity, the group size is much smaller, with as few as 4-5 individuals (Lippold, 1998). The home range of the species ranges is ca. 250 ha (Phiapalath, 2009).

#### Phayre's Leaf Monkey (Trachypithecus phayri) - Endangered Species

Globally: this species is found in many countries including India, Bangladesh, China, Thailand, Laos and Vietnam (Bleisch, 2008; Ruggeri and Timmins, 1996). Population of this species is quite large as expand beyond Southeast Asia.

Regionally: this species is quite good population in the region and distributed in all countries except Cambodia. Thailand has three areas that this species reported (Houy Khakhaeng and Phou Khieo National Park and northern country (Borries et al. 2011). It is also found in central and northwest Vietnam.

Nationally: although Phayre's leaf Monkey live in evergreen forest and mixed deciduous forest. This species distributes in central to northern Laos (Timmins *et al.*, 2011) as reported in 7 NPAs, mainly Phou Dendin, Nam Et-Phou Loey, Nam Phoui, Nam Kan NPA, Phou Phanang, Phou

Kha Ya (Duckworth et al. 2009, Phiapalath, 2012).

This species spends a majority of time in trees and descend to the ground for using mineral licks usually once for every two weeks. The species feed on leaves including bamboo buds and wild fruits. A group size of this species is quite large as ca. 30 individuals in Nam kan NPA but range 15-30. The home range according to the study group in Phou Kieo National Park is about 80 ha (Pages et al. 2011).

## 4. International Standard and Requirement

As to ensure sustainable investment and development there are several key international environmental standards for which the NNP1 project must follow:

- IFC Performance Standard 6
- ADB Environment and Social Safeguard (2009)
- World Bank Safeguard Policy

Under these environmental standards a project area must determine the presence of three habitat categories *Modified habitat, Natural habitat, Critical habitat.* These habitats may contain a large population of some or more fauna and flora as the habitat may support some critical ecosystem.

The international standards are concerned about the loss of critical habitats that could result in a reduction of a population of critically or endangered species. The IFC standard 6 recognizes that protecting and conserving biodiversity; maintaining ecosystem services and; sustainably managing living natural resources are fundamental to sustainable development.

Critical habitat are areas with High biodiversity value or High Conservation Value (HCV), including habitat required for the survival of critically endangered or endangered species according to IUCN Redlist 2013. It can be areas having special significance for endemic or restricted-range species; sites that are critical for the survival of migratory species; supporting globally significant concentrations, evolutionary processes or provide key ecosystem services; and areas having biodiversity of significance. Also, it is about those areas of international recognition such as Ramsar Site, World Natural Heritage including National Parks and National Protected Areas. Similarly, ADB and World Bank safeguards have to ensure the environmental soundness and sustainability of projects and to support the integration of environmental considerations into the project decision-making process (reference?).

No project activities should be undertaken unless;

(i) there are no measurable adverse impacts such as critical habitat;

- (ii) the project is not anticipated to lead to a reduction in the population of any recognized endangered or critically endangered species;
- (iii) (iii) no mitigation measures are designed to achieve at least no net loss of biodiversity and;
- (iv) any lesser impacts are mitigated.

If a project is located within a legally protected area, implement additional programs to promote and enhance the conservation aims of the protected area. In an area of natural habitats, there must be no significant conversion or degradation, unless;

- (i) alternatives are not available;
- (ii) (ii) the overall benefits from the project substantially outweigh the environmental costs, and
- (iii) (iii) any conversion or degradation is appropriately mitigated. A combination of actions, such as post-project restoration of habitats, offset of losses through effective conservation action.

## 5. Survey Methods

#### 5.1 Survey Area and Locations

The survey area was the proposed inundation area with a focus on potential habitats of the target species starting from Nam Chae to the proposed dam site. The survey area for each site was within 1-2 km from the inundation area or the river. Four survey clusters were established in the proposed inundation area and surveys were conducted by five sub-survey teams (see Fig. 2).

Specific survey routes designed where potential habitats, mineral licks and where the species have been reported by local hunters. The survey was designed to cover all potential habitats associated with the inundation area.

Figure 2. Map of the survey clusters

## 5.2 Survey Technique

Primate survey was conducted through direct field establishing listening post for gibbons and reconnaissance surveys for non-vocal primate. Additional data from village interviews was collected with boat men, hunters and elders in Ban Pou, Ban Sop phouan and Ban Sop Youak.

The surveys undertaken for other primate species which are quite different for gibbons as non-vocalization primates such as Red-shanked Douc Langur and Phayre's Leaf Monkey.

For the gibbon survey a listening post was established by each sub-team at predetermined locations that were selected based on vegetation type prior to the field trip. A total of 20 listening surveys were conducted in 5 listening posts. Each sub-team survey site were separated by about 2 km and camps were set at determined locations, waypoints to be recorded in their GPS. A short training session took place prior to departure at Ban Pou. All the sub-teams moved from the first survey cluster at Nam Chae down to the first survey cluster at downstream of Ban Sop Youak. The technique is to listen to gibbon song in early morning from 5.50 am to 7.30 am, using listening post data form. Song types and times, bearing from listen post and approximate distance were recorded. In areas with high

gibbon population more than one group would be heard. When gibbon songs are heard coming from different directions they are considered to be different groups if they start in different time. If from the same direction and same distance although more than one song, we will consider that it would be just one group. If a good call is heard we conclude that it is a group, otherwise a solo song is considered likely individual male. The distance of gibbon song locations are roughly estimated based upon how loud the song is heard, but no more than 2 km.

Given a small reservoir along the river straight, the survey for Douc Langur and Phayre's Leaf Monkey was for the total count technique as each sub-team to search for the target animals in their areas of responsibility within 1-2 km. In early morning while two persons recording gibbon song and other two people were surveying within 2 km around the camp. We used 7 sub-survey teams per day made a total of 28 sub-survey team days. Encounter a group of the target animals the site location, species and individuals of the group were recorded.

Figure 3. A sub-team 2 on listening post

Also, the two persons who had finished listening post they then started survey walk which each sub-team agreed who to go which direction from the camp and returned at 10.30 am. Direct observation, using binoculars for scanning through forest canopies or detect from seeing trees moving. Any evidence of the target species was recorded such as feeding at mineral licks by Phayre's Leaf Monkey. Data forms and guidebooks were used for the survey.

The distance from camp to camp was 2 km. Each team arrived next camp before 4.00pm and prepared their camp. Noise at camp was minimised to not disturb gibbons in the area as this would result in animals not singing in the morning.

A team wrap up was conducted in Ban Sop Youak on Dec 18, 2013 to the sub-teams findings. Each sub-team checked local names and recorded key waypoints.

Figure 4. Data summary and wrap up at Ban Sop Youak

#### 5.3 Data Analysis

#### Gibbon population

In principle, a number of groups recorded and average group size of the gibbon groups as the group size to be recorded from at least two cross-lines by two sub-teams. However, the survey found only two gibbon records at single listening post so we did not necessarily analyze the data.

#### Douc langur and Phayre's Leaf Monkey

As the total count technique for rare species which is based on a sum of total number of groups and individuals counted by sub-teams. However, we found only one evidence of the Phayre's Leaf Monkey but no douc langur was recorded nor reported during the survey.

#### 5.4 Survey schedule

The field work started in Dec 13-18, 2013 as 4 days used for forest survey work.

| Date   | Activity   | Location                           |
|--------|--|------------------------------------|
| Day 1  | Travel to Paksan                                   | Paksan town                        |
| Day 2  | Travel to Ban Pou, conducted short training and    | Ban Pou                            |
|        | left for fieldwork by boat.                        |                                    |
| Day 3  | First camp, conducted listening post and survey    |                                    |
|        | walk. Completed the first survey cluster, continue |                                    |
|        | to other survey clusters                           |                                    |
| Day 4  | Field survey continued                             |                                    |
| Day 5  | Field survey continued                             |                                    |
| Day 6  | Field survey continued, travel to Ban Sop Youak,   |                                    |
|        | wrap up and then Vientiane                         |                                    |
| Day 7  | Debrief to technical team of NNP1                  | NPP1 Office                        |
| Day 8  | Present results to senior and manager teams of     | NPP1 Office, video Conference with |
|        | NNP1   | ERM team                           |
| Day 9  | Prepared technical report                          | VTE                                |
| Day 10 | Prepared technical report                          | VTE                                |
| Day 11 | Present results of the surveys to ADB teams        | NPP1 Office, video Conference with |
|        |  | ADB                                |
|        | Revise the draft report                            |                                    |
| Jan 9  | Submit the report                                  | ERM,                               |

Table 2. Itinerary

#### 5.5 Participants

There are about 49 participants include boatmen and from 6 organisations including Wildlife Conservation Association (WCA) as main technical assistance, ERM, NNP1, government officers (Thathom District, Xiengkhuang), solders of Thathom District, local villagers including boatmen.

| Iub | Tuble 5. List of participants |                         |                                   |  |  |  |  |

## 6. Results

#### 6.1 Description of habitats

Majority of the habitats along the reservoir straight have been modified to agricultural land especially the upper and lower reservoirs. The area that is far from settlement such as from Houy Kao to Houy Keng Ngon remains good riparian forest.

### 6.1.1 Habitats in the inundation areas

According to the field observation and reconnaissance surveys the habitats along the reservoir straight can be classified into 5 sections (see Fig. 2) as following:

Section 1: Upstream of Nam Chae, this section is large but not in our survey cluster due to existing habitats have been seriously degraded by conversion to agricultural area. Various ages of fallows including existing hill rice field were observed. This section is quite gentle so both foothills and upper mountain have been totally converted. Bananas trees were observed scattered along the section.

Figure 6. Degraded riparian habitat and fallows

Section 2: Nam Chae to Houy Kao where the first survey cluster took place. This section is small and considered degraded habitat as the foothills were converted to agricultural land and change in forest canopies due to logging. Old logging road was observed in Upper Mountain of this section. It is mixed deciduous as highly dominated by bamboo forest. One mineral lick (Pong Chae) was found in this section. However, no evidence of wildlife using this mineral lick were identified and that consequently was overgrown with weeds. One small area of salt soil was found in this section.

Figure 7. Degraded forest habitats

Figure 8. Degraded forest canopies and old logging road

Figure 9. Old mineral licks (Pong Chae) and salted soil

Section 3: Houy Kao to Houy Keng Ngon where the second survey cluster took place. This section is large and considered good forest habitat as mixed deciduous forest in lower valley and evergreen in Upper Mountain. Riparian forest is still in good condition and also Upper Mountain although some old logging road was found in this section. The left bank of this section, a high density of fig trees were found as this tree is critically important for any wild animals by providing fruits all year round, fig trees were found along the survey routes of the team 1 of day 2 (T1.2). Also, the right bank a portion of evergreen forest away in uphill mountains was reported a presence of gibbons and Phayre's Leaf Monkey.

Figure 10. Good riparian forest

Figure 11. Good forest habitat

Figure 12. Fig tree (Ficus, Moraceae)

Section 4: Houy Keng Ngon to Houy huafan where the third survey cluster took place. This section is considered degraded forest habitat as portion of hill rice fields and fallows was found especially the right bank of the river has been totally converted to agricultural land while only new hill rice field found in scatter in the left bank. Evergreen in Upper Mountain remain some good habitat in the left bank such as Pha Phanong which team 3 reached the area and considered good evergreen forest (UTM 2081230/334861).

Figure 13. Portions of hill rice filed and fallow

Figure 14. Portion of forest habitat conversion

Section 5: Houy Huafan to Damsite where the fourth survey cluster tool place. This section is large and considered degraded forest habitat due to slash and burn practice such as the team 3 camped at Phou Khapha (UTM: 2068418/334585) certified as all follow in the

lower area. Most lower valleys were converted to agricultural land but some portion of evergreen forest can be found in Upper Mountains. Logging was observed in this section.

Figure 15. Degraded forest habitat

Figure 16. Habitat conversion, grassland

In conclusion, the proposed flooded area is not considered natural habitat, and consists of mainly old fallows, agricultural land and some riparian forest. There was no critical habitats or terrestrial ecosystem identified in the project area. The mineral licks are considered part of critical habitats, however, evidence of recent use was not recorded. Upper Mountain areas where the distribution of evergreen forest species was more abundant would be classed as a critical habitat if a number of endangered wildlife species are present, however given the lack of species presence and the relative condition of these areas only small population of endangered species is found in the area.

#### 6.1.2 Records of the Endangered Primate Species

No Red-shanked Douc Langur was found nor reported. Nam Ngiep Project 1 is not in the distribution range of the species. the survey map is found in Annex.

Two records of gibbons during the survey from songs in morning. The first record by subteam 2 at Houy Kao area heard gibbon song from northeast for about 1.5 km away and second record by sub-team 1 Houy Chili area heard gibbon song from northeast for about 2 km away. The local villagers believed that the second song would be from Phou Phahua. These groups were heard from upper mountains of the left bank.

| Date       | Location   | Coord   | linates | Time of song |        | Time of song |         | Direction, | Distance |
|------------|------------|---------|---------|--------------|--------|--------------|---------|------------|----------|
|            | name       | Ν       | Е       | start        | finish | Bearing      | (km)    |            |          |
| 17/12/2013 | Houy Kao   | 2069000 | 337719  | 6.10         | 6.30   | NE, 60°      | >1.5 km |            |          |
| 18/12/2013 | Houy Chili | 2074329 | 334263  | 7.05         | 7.20   | NE, 44°      | 2 km    |            |          |
|            |            |         |         |              |        |              |         |            |          |

Table 5. Listing post records of Northern White-cheeked Gibbon

According to the provisional data, 5 groups of this species were reported throughout the project area – both sides but predominately in the upper mountain areas which are away from the inundation area. There will be two groups in evergreen forest of Phou Thin and Phou Sam Liem of the far right bank and other three groups in evergreen forest of Phou Phahua and Phanoy of the left bank. Populations of this species are already fragmented by the river and habitat conversion.

One evidence of Phayre's Leaf Monkey was recorded on December 16, 2013 by sub-team 5 at Pong Chor (mineral lick) UTM: 2096370/342601 from hand prints as were found on the bamboo tree. The hand print of this animal is smaller and longer hand print compared to other sympatric primate. During the survey this species was well reported and that it was shot occasionally by hunters. One was shot last year at Houy Khai which a picture of the dead animal was taken.

Figure 17. Handprint of Phayri

According to the provisional data, there are about 10-13 groups present in the NNP1 watershed as below:

| Location               | Estimate Group | Left or right bank |
|------------------------|----------------|--------------------|
| 1. Houy Chae area      | 1              | left               |
| 2. Houy San area       | 1              | right              |
| 3. Houy Khai area      | 3              | right              |
| 4. Houy So area        | 1              | left               |
| 5. Houy Lang Nong area | 1              | right              |
| 6. Pong Chor area      | 2              | left               |
| 7. Houy Wai area       | 1              | right              |
| 8. Pong Dinkhao area   | 1              | left               |
| 9. Phou Phaheua        | 2              | left               |
| 10. Phou Phanoy        | 2              | left               |

About 6 groups of Phayri were reported in the right bank and other 7 groups in the left bank. The populations of Phayre's Leaf Monkey in both sides of Nam Ngiep River have already been fragmented.

Phayre's Leaf Monkey used mineral licks as part of its behavior ecology. The animal uses a mineral lick for food digesting. Mineral licks were surveyed and identified along the river. There are 10 mineral licks, of which 3 mineral licks are used by wild animals including Pong Xang, Pong Chor, and Pong Din kao. These mineral licks are known by local villagers. The mineral licks that are not used by wild animals today are due to the habitats surrounding the mineral licks being converted. Mineral lick is not only important for this langur but also other wildlife species particularly ungulate group.

Figure 18. Pong Sa, old mineral lick

| No | Name of mineral licks | Coordinates (UTM) | Elevation (m) | Remarks |
|----|-----------------------|-------------------|---------------|---------|
| 1  | Pong Chae             | 2101417/0342528   | 319           | flooded |
| 2  | Pong Sa               | 2101338/0342220   | 320           | flooded |
| 3  | Pong Xang             | 2096370/0342601   | 316           | flooded |
| 4  | Pong Chor             | 2096591/0343145   | 314           | flooded |
| 5  | Pong Din deng         | 2099057/0342108   |               | flooded |
| 6  | Pong Lang nong        | 2092468/0337406   |               | flooded |
| 7  | Pong Houy hok         |                   |               |         |
| 8  | Pong Din kao          | 2078410/0329472   |               | flooded |
| 9  | Pong Keua             | 2005021/0334840   |               | flooded |
| 10 | Pong Houy Chili       |                   |               |         |

These mineral licks will be flooded but some mineral licks were reported in Phou Thin and Sam Liem area of the right bank will remain after inundation. It is believed that another

side of Phou Phanoy and Phou Phaheua around Nam Ma River may have some mineral licks. The mineral licks in these areas that are not flooded will be used by the animals.

### 6.2 Records of some vulnerable species

There are three vulnerable species were recorded by chance during the survey including Stump-tailed Macaque, Northern Pig-tailed Macaque and Sambar Deer. There are 2 records of Stump-tailed Macaque from feeding sites (UTM 2100721/0342698; 2069692/0337253), 2 records of Northern Pig-tailed Macaque from hand print in soft soil UMT 20941432/0339279; 2080048/0331580. One Northern Pig-tailed Monkey was shot dead during the survey by local hunter on 17 December, 2013. Sambar Deer was recorded 4 times (UTM 2101338/0342220; 2096591/0343145; 20941432/0339279; 2088511/0341116).

Figure 19. Pictures of vulnerable species

Figure 20. Evidence of Stumped-tailed Macaque and Northern Pig-tailed Macaque

#### 6.3 Key wildlife habitats

The key wildlife habitats that the gibbons and Phayre's Leaf Monkey were reported are in Phou Thin, Phou Pha Noy, Phou Pha hua, Phou Sam Liem. These locations are mainly evergreen forest and some mixed deciduous forest. Also, important watershed for NNP1.

Figure 21. Map of the important wildlife habitat

### 6.4 Threats

Threat to wildlife and wildlife habitat is high in the area. Logging camps were found at Nam Chae, upstream of Ban Sop Phouan, downstream of Ban Sop Youak. According to the village interviews, Lao private firm receive quota for logging from the government but Vietnamese Loggers are hired to do log in the area. Hunting is common and that we found a number of gun man still holding a local gun. Hunting Phayre's Leaf Monkey is well reported in the area so the pressure from hunting is high in the area. Most hunters are local hunter, the Hmong people mainly in Sop Phouan, Sop Youak, and also Ban Pou and Ban Phiangta. Slash and

burn practice is an issue which made most forest habitat of upstream and downstream reservoir converted.

Figure 22. Logging camp of Vietnamese

## 7. Discussions

Nam Ngiep Project 1 hydropower project area has low biodiversity value. There has no particular critical habitats identified in the project area. Although gibbons are present in the project area their habitats are not be relevant to the inundation area. Population of this species remains very low in the area.

Phayre's Leaf Monkey has some minor impact due to their mineral licks will be flooded but mitigation measures are possible. The Phayre's Leaf Monkey population in Nam Ngiep project area is considered low. The global population of this species is large and distributed in many countries including India and Bangladesh. Therefore, the population of this monkey in the Nam Ngiep Project 1 is not significant. Apart from this in Lao PDR, the species is recorded in 7 National Protected Areas (NPAs) and some outside NPAs particularly the northern country. Once, the species will not impact by the development of Nam Ngiep 1 project. With availability of biodiversity offset plan by enhancing forest habitat and ban on wildlife hunting in the area will help better protect the species.

## 8. Recommendations

- Habitat rehabilitation as to make connectivity by leaving fallows to naturally grow and enrich where necessary.
- Artificial mineral licks to be established where possible especially in the area close to water body, mud flat etc. The potential location should be further identified and that the area is closed to the important habitats of Phayre's Leaf Monkey.
- Ban on wildlife hunting wildlife in the project area which regulation of wildlife and forest management should be developed.
- Develop a biodiversity offset plan for watershed protection, forest management and to support relevant local government departments for effective management of the Nam Ngiep watershed

• Ensure soil erosion protection in place (Kok kkai)

Figure 23. Mai Khai, as natural bank protection tree

Ensure maintaining flows of the main tributaries as to maintain fish breeding site when most part of Nam Ngiep is lost to the inundation.

Figure 24. Nam Hok, the small tributary of Nam Ngiep

## 9. Conclusion

NNP1 is a small and long reservoir thus is considered good dam according to the World Bank publication (Ledec & Quintero 2003) due to its small reservoir, narrow and length with minor impacts on natural habitats. Minor impacts would occur on only Phayre's Leaf Monkey and there would be no impact on the gibbons within the project area due to the low populations in the project area, and those populations being predominately located outside of the inundation area. Therefore, the development of Nam Ngiep 1 hydropower project will comply with international standard of IFC and safeguard policies of the World Bank as well as the ADB regarding *terrestrial biodiversity*.

# Executive Summary

The Nam Ngiep catchment / drainage has been identified as an important area for the development of hydropower, and construction at several sites is already underway or has already been completed.

Populations of a large species of predatory Cyprinid (*Luciocyprinus striolatus*) have been identified by fish taxonomy experts within the boundaries of the Nam Ngiep catchment / drainage. It is placed in the IUCN red list category of endangered (EN) and as such runs a very high risk of becoming extinct in the wild.

*L. striolatus* populations are not confined only to the Nam Ngiep catchment in the Lao PDR and have in fact been positively identified in at least three other major catchments in the northern, central and southern parts of the country (Figure 1). It is known to live in large deep pools in upland areas.

Very little information is available on this fish species and much of what is known about its occurrence, distribution and biology within the Lao PDR is presented in this report. According to Kottelat (2014) it was recorded in the literature from the Nam Tha, Nam Ou, Nam Ngum, Nam Kading (Nam Theun and Nam Gouang Xe Kong and Xishuangbanna, China, (Cui & Chu, 1986; Kottelat, 1999, 2001; Rainboth *et al.*, 2013). It is thought to exist in river systems on the Vietnamese side of the Annamite mountain range that forms the border with the Lao PDR (Tyson Roberts, pers. com.).

This report recommends that protection and conservation efforts focus on the middle and upper Nam Kading / Theun mainstreams and their tributaries.

## 1. Introduction

### 1.1 Description of *Luciocyprinus striolatus*

*Luciocyprinus striolatus* is a large predatory fish belonging to the family Cyprinidae (Kottelat, 2009a) and was first described in Xishuangbanna Prefecture, Yunnan Province, China (Cui and Chu, 1986). Kottelat (2001) states that *L. striolatus* is distinguished from the only other known member of the genus by having five to eight longitudinal black stripes on the body in adults, 78 to 89 (+ three to four) lateral line scales and 40 to 46 predorsal scales. Local fishers in Laos have reported that individual specimens can attain lengths of up to 1500 mm Standard Length. Chu (1986) states that the genus Luciocyprinus shares common characteristics with members of the subfamily Barbinae. The characters include 1) Anal fin without spine but with five branched rays. 2) Lower pharyngeal teeth in three rows. 3) Pharyngeal process with the posterior end compressed. 4) Neural complex simple, without free interspine. 5) Transverse process on the first vertebra is located in front of the second vertebra and its transverse process. Luciocyprinus was long recognized as a monotypic genus, but since the description of *L. striolatus* in 1986 (Cui & Chu, 1986) this status has now become questionable.

#### 1.2 IUCN conservation status of *L. striolatus* and legislation

Under the IUCN Red List system, L. striolatus is placed in the category of Endangered (EN). A taxon is endangered when the best available evidence indicates that it meets any of the criteria A to E for Endangered, and it is therefore considered to be facing a very high risk of extinction in the wild. Under Lao law (Forestry law 1996) aguatic animals and wildlife living naturally in the territory of Lao PDR are the property of the national community. It is the responsibility of the State, as representative of the people, to determine the conditions of access, protection, propagation and use of these animals and wildlife (Article 39) (Cacaud and Latdavong 2009). The Wildlife and Aquatic Animals Act 2008 was adopted by the National Assembly in 2008. Under this Act, exists the right to hunt wildlife and aquatic animals is provided to any individual or legal entity within the limits of the law (Article 9). Hunting certain species is prohibited or restricted. It is strictly prohibited to hunt species listed in Category I except for research or propagation purposes, whereas catching species of species under Category II is allowed with an authorization and during certain periods. Species listed in Category III may be taken for customary purposes and to some extent for commercial puposes with an authriztion from PAFO (Article 9) Species of wildlife and aquatic animals are classified into three categories a) Category I lists species that are considered to be rare, endangered or highly valuable in socio-economic terms. L. striolatus, therefore fits into Category I classification.

### 1.3 Purpose of this report

A population of L. striolatus is believed to exist in the Nam Ngiep catchment of the Lao PDR. This catchment has been earmarked for hydropower development and at least two dams are being considered. Given that this species has been placed on IUCN's Red List as endangered (EN), what is required at present is bring together all relevant information on the species to establish a broad picture of the current status of populations within the Nam Ngiep catchment and those outside it but with the Lao PDR. This it is hoped will provide some indications of the threats that *L. striolatus* populations face in general and this will allow an assessment to be made of the proportional impact from the Nam Ngiep dam and then look at conservation opportunities.

# 2. Methods

The methodology used to formulate this report is based on the author's past fieldwork, hardcopy library resources, papers, documents and books collected by the author, and internet searches. Almost all references used in this report are based on published material, and personal communication only appears once in the report. All photographs that appear in this report were taken by the author over the past two decades.

# 3. Results based on field observations and anecdotal reports

## 3.1 Known distribution range within the Lao PDR

Kottelat (2009a) identified specimens of *L. striolatus* from three major Mekong tributaries: the Nam Ou in the northern part of Lao PDR (Kottelat, 2009b), the Nam Kading in central Lao PDR (Kottelat, 1996a), the Nam Gnouang (Kottelat, 1996a), and in the Xe Kong (Kottelat, 2009a; Kottelat, 2011) in the southern part of the Lao PDR (Figure 1 and Table 1).

Baird *et al.*, (1999) identified *L. striolatus* in the Xe Kong mainstream in Kaleum District, Xe Kong Province in May 1996. Baird *et al.*, (1999) point out that it is not common in the lower part of Xe Kong in Lamam District, Xe Kong Province and is not found at all in the lower part of the Xe Kong in Attapeu Province. Baird *et al.*, (1999) report that juvenile *L. striolatus* were identified from the upper Xe Kaman in Saysettha District in Attapeu Province in 1996 (Figure 1 and Table 1).

Figure 1 Map showing where populations are known to exist within the Lao PDR based on confirmed identification of *L. striolatus* and referenced in this report over the past two decades.

Warren (1995) identified and photographed three juvenile specimens of *L. striolatus* (< 45 cm Total Length) from a market at Ban Thabac where Route 8 now passes over the Nam Theun via a road bridge (Figure 2 and Figure 3). All three specimens were caught in the Nam Theun within close proximity to Ban Thabac. Warren (2010) identified and photographed one specimen of *L. striolatus* bought at Phongsaly City market, Phongsaly Province that was caught in the Nam Ou upstream from Ban Hat Sa (Figure 4), and another juvenile specimen caught in Huay En (Figure 5), a small tributary of the Nam Ou that runs alongside Ban En on the right-hand bank of the Nam Ou, Phongsaly Province (Figure 1 and Table 1).

**Figure 4** A photograph of *L. striolatus* (< 60 cm) purchased from the city market at Phongsaly. Its condition had deteriorated during travel time to market (Warren and Phommavong, 2010).

**Figure 5** A juvenile (< 20 cm) *L. striolatus* caught live in a basket trap at a small weir on Huay En (Nam Ou tributary) next to Ban Huay En (Warren and Phommavong, 2010).

3.2 Anecdotal reports of the presence and local descriptions of *L. striolatus* within the Lao PDR

Kottelat (1996b) reported that local fishers at Ban Thabac on the Nam Theun considered that *L. striolatus* was found more frequently in the Nam Gnouang than in the Nam Theun. Warren (1995) conducted surveys on the Nam Theun between Ban Thabac and Ban Huay Gan Ya and interviewed local fishers over a distance of approximately 4 kilometers. Fishers reported that within the last two years they had caught a large fish measuring somewhere between one and two meters in total length and that it was known locally as "*Pba Nuuak*". *L. striolatus* is usually given the local vernacular name of *Pba Kang* on the upper Nam Theun, so it is possible that the fish that was described by fishers in 1995 was another species. Previous to the 1995 survey, Mr. Phouthalom of Burapha Development Consultants, who had been involved with the 1992 Aquatic Life Survey of the Nam Theun, referred to a fish very similar to the description provided by Nam Theun fishers between Ban Thabac and Ban Huay Gan Ya.

Baird *et al.*, (1999) report that in the southern part of the Lao PDR, *L. striolatus* is known by the local name "*Pa Sak*". According to local villager fishers it can attain maximum lengths of between 150 and 200 cm and reach weights of between 70 and 100 kilograms. Interviews with villagers revealed that *L. striolatus* prefers to remain in middle to surface waters and inhabits large clear rivers flowing at mid to high altitudes. Villagers reported that it prefers rivers with small stones on the bottom or large slabs of rock.

Baird *et al.*, (1999) report that juvenile *L. striolatus* are rarely seen in the lower parts of the Xe Kong in Kaleum District, but larger individuals occasionally venture into those areas. *L. striolatus* is not found in the lower parts of the Xe Kong in Attapeu Province. According to Baird *et al.*, (1999) *L. striolatus* eat mainly fish, and villagers from Kaleum District have noted a significant decline in population numbers of this species compared to the past.

During fishery surveys conducted by Warren in 1997, a total of 21 potential hydropower sites were visited by helicopter from northern Lao P.D.R. to the very south of the country. During that survey, local communities were visited along the banks of the Nam Mouan, a major tributary flowing into the Nam Kading approximately 40 km downstream of the Theun-Hinboun dam. A number of villagers said that they knew *L. striolatus* when shown photographs of it and referred to it with the Lao vernacular name of "*Pba Kang*". They described it as a fish reaching a maximum length of 2.0 meters and weighing up to around 60 kg. They reported that in 1997, *L. striolatus* of that size were no longer being caught in the Nam Mouan and the largest fish caught then were approximately 1.0 meter in total length and weighed up to and around 10 kg maximum.

3.3 Anecdotal and observed reports of preferred aquatic habitat for L. striolatus

Warren (1995) surveyed a section of the Nam Theun stretching from what was then the ferry point at Ban Thabac upstream to Ban Huay Gan Ya, a distance of

approximately 4 kilometers. It should be remembered that this was a time prior to the completion of the Theun-Hinboun dam and no reservoir was present. In 1995, to get to Ban Huay Gan Ya by boat from Ban Thabac, it was necessary to traverse a number of rocky rapids. Once over the rapids, the Nam Theun changed into a series of wide (40 to 50 meters), slow-flowing deep pools as observed during the survey. Riparian vegetation along the deep pool river sections consisted mainly of dense bamboo forests on opposite sides of the river. Local people, including the boat driver, reported that this was the habitat where *L. striolatus* could be found and caught using gillnets (Figure 6).

**Figure 6** This photograph shows one of the large deep pools that local fishers claim is where *L. striolatus* prefers to live. The photograph was taken at a point somewhere between Ban Thabac and Ban Huay Gan Ya prior to closure of the Theun-Hinboun dam (Warren, 1995).

The following is a direct quote from a final report I wrote whilst employed as Fisheries Specialist for the Theun-Hinboun Power Company (THPC), Vientiane, Lao P.D.R. (1999).

"According to local villagers, 13 rapids along the Nam Theun and five rapids along the Nam (Ngouang) Gnouang were submerged following the closure of the Theun dam in December 1997. At least one rapid, approximately 500m upstream of the Nam Gnouang / Theun confluence was identified by local villagers as a spawning site of the predatory cyprinid species *Luciocyprinus striolatus*. Because of its large size,

and the fact that it spawns during the dry-season months in January / February when water clarity is greatest, its spawning behavior can be observed relatively easily".

### 3.4 Anecdotally reported spawning behavior of *L. striolatus*

In 1997, a joint venture was launched between Lahmeyer International GmbH, Frankfurt, Germany, Worley International Ltd and the Government of the Lao P.D.R. to provide consulting services required for the execution of the Nam Theun 2 Study of Alternatives. The Study was carried out in cooperation with the Hydropower Project Office of the Ministry of Industry and Handicraft in Vientiane. I was given responsibility for the fisheries part of the study.

At one point during the survey, it was agreed that interviews should take place with local communities at a strategic village point along the Nam Mouan, a major Nam Kading tributary. Interviews took place regarding the importance of village-level fisheries to local communities. One fisher described how he had witnessed the natural spawning event of L. striolatus. He said that from a secluded position, he saw a large fish that he recognized as L. striolatus (Pba Kang) appearing in shallows either in the Nam Mouan itself, or in a small tributary close to the Nam Mouan mainstream, and said that water was flowing guite swiftly. Most importantly, he said that it was during the low water period and the depth of the water was no more than an estimated 20 cm. He said that shortly after he saw the large L. striolatus move into the shallows, a large number of smaller L. striolatus suddenly appeared from downstream and gathered around the large fish in mid-stream. Following this, he described the large fish as moving erratically from side to side. Then after another short period, the water turned milky and the smaller L. striolatus were seen zig zagging around the large fish, and then slowly all the fish started moving back downstream again and out of sight. Those observations made by the Nam Mouan villager, and translated into English here, probably represent one of the very few records available, or perhaps the only one, of the spawning behavior of *L*. striolatus.

Baird *et al.*, (1999) report that local illagers from Kaleum District, Xe Kong Province believe that *L. striolatus* spawn in shallow water in the upper parts of the Xe Kong mainstream and in smaller streams during May and June. During this time *L. striolatus* is apparently vulnerable to capture.

Kottelat (1996a) reports that informants in Ban Thabak on the Nam Theun said that *L. striolatus* lives all year round in deeper areas of the river and that it spawns in January-February in rapids.

3.5 Anecdotal reports of the feeding behavior of *L. striolatus* 

Undoubtedly, *L. striolatus* is a predatory species and its diet probably consists mostly of fish and perhaps some amphibians. However, during the course of the Nam Theun 2 Study of Alternatives, our team received at least three reports that it will attack small primates that enter shallows in the Nam Theun / Kading and some of its major tributaries such as the Nam Gnouang and the Nam Mouan.

#### 3.6 Risk assessment and conservation significance (Table 2 below)

Given the paucity of data on the distribution of *L. striolatus* within major river catchments throughout the Lao PDR, only subjective comments can be made regarding *management units* with the aim of protecting this species. Specifically, this report draws on the field work experiences and educated prediction of where populations are in three major catchment areas where this species is known to exist outside of the Nam Ngiep catchment area. All *values* listed under columns two and three are arbitrary. They are based on intuitive and intimate knowledge of the river catchments concerned. They are not based on any survey work that was specifically designed to gather information on *L. striolatus*.

Information on this particular fish species was gathered incidentally, together with data on many other aspects of fish populations and fisheries in all three major catchments apart from Nam Ngiep during previous studies. These are already referenced in this report but they are: 1) Nam Theun / Kading studies in 1995, 1997 and 1998, 2) Nam Ou studies in 2010 and 3) Xe Kong studies in 2011. During the Nam Theun / Kading studies and those in the Nam Ou, specimens of *L. striolatus* were obtained and photographs of this fish species were taken and are presented in this report (Figures 2, 3, 4 and 5). Columns two and three in Table 2 are not based on any type of pre-determined methodology; they are the author's best intuitive attempt, based on field experience, to allocate various categories to column's two and three.

Table 2 Risk assessment and conservation significance to *L. striolatus* populations in the Lao PDR

| Management Unit  | Habitat<br>Sensitivity /<br>Value | Magnitude<br>of Effect | Discussion on Key Threats  | Discussion on Conservation<br>Opportunities  |
|--|-----------------------------------|------------------------|--|--|
| Middle Nam Ngiep<br>mainstream and tributaries (N<br>Ngiep1 dam site upstream to<br>Thathom) | - Medium                          | - Medium               | - NN1 Project impacts may only be medium<br>after completion of the Project. But these may<br>rise to a higher level after completion of NN2<br>Project. First steps must be to establish if the<br>species is in the area. Kottelat (2014) did not<br>observe the species during his January 2014<br>survey.  | <ul> <li>- L. striolatus can only really be managed if<br/>stretches of mainstreams and large tributaries<br/>where the species has been reported from or<br/>observed in markets etc can be preserved,<br/>and this includes suitable spawning habitats.</li> <li>- Fishery Conservation Zones (FCZs) may be</li> </ul> |
|  |                                   |                        | <ul> <li>However, anecdotal evidence provided by villagers from Ban Pou, Ban Thaviang, Ban Viengta and BanXomxeun indicates that it does exist in these areas at least.</li> <li>Mining activities always pose a potential threat to aquatic ecosystems and the flora and fauna that reside in them.</li> <li>Human population expansion and over exploitation of all aquatic resources is always a possibility especially in areas close to the capital.</li> </ul> | effective in conserving not only the species in question, but also fish that undoubtedly form part of its diet.<br>Use of modern technology and "state of the art" pollution protection systems may help to protect <i>L. striolatus</i> populations.  |
| Upper Nam Ngiep<br>mainstream and tributaries<br>(Thathom upstream to<br>headwaters)         | High                              | Medium                 | - NN2 Project impacts may be greater than NN1<br>due to habitats that may be more suited to the<br>species.  | - What must be established is just how small a stream is that might be able to maintain viable populations of <i>L. striolatus</i> .   |

Table 2 contiuned .....

# 4. Discussion and recommendations

Clearly, there are a number of catchments / drainages outside of the Nam Ngiep that support or supported viable populations of *L. striolatus*. What is also apparent is that these populations face a wide range of potential and actual threats throughout the length of the Lao PDR (Table 2). In the light of limited funds and other vital resources, conservation efforts aimed at protection must focus on those catchments outside of the Nam Ngiep basin where they are most likely to succeed.

Population numbers of *L. striolatus* must be described as low within the Lao PDR. This makes studying its habits very difficult and almost all information on it is based on anecdotal reports only. Reports by elderly people in villages seem to suggest that much larger specimens of *L. striolatus* did exist up to 30 or 40 years ago. There are almost no reports of large specimens (60, 70 to 100kg) living now.

As has happened in what is now the Nam Ngum cascade of dams, releases from projects further upstream (NN2 Project) may affect fishery resources and fish populations in the river bed between the end of the NN1 Project reservoir and the NN2 Project dam. The effects that altered hydrology might have on the populations of many fish species, including *L. striolatus* below NN2 Project can only be guessed at until more details are known.

As a final comment / recommendation and based on available information and data, I would recommend that protection and conservation efforts focus on the middle and upper Nam Kading / Theun mainstreams and their tributaries.

#### Acknowledgements

I would especially like to thank Mr. Souksavanh (Boey) from the Nam Ngiep Hydropower Company Offices in Pakxan, Mr. Vongphet Vilahoun from District Agriculture and Forestry Offices at Thathom and driver Mr. Pradith for all their helpful assistance during the field work part of this study. I also gratefully acknowledge the help and assistance provided to me by many members of the Nam Ngiep Hydropower Company Offices in Vientiane, including Mr. Cliff Massey, Mr. Apirat Lamsiri from Electricity Generating Authority of Thailand and Mr. Suksumek from the Vientiane Offices. Finally I would like to thank all of the villagers who gave their time for interviews and took us to see special habitats and features of a number of river systems.

#### Executive summary

Under the present day situation hydropower dams in the upper Nam Ngiep catchment area (NN1, NN2 and NN3) and several projects in other sub catchments in Xieng Khouang, Bolikhamsy and Vientiane Prefecture are under construction phase and rivers are still free-flowing prior to impoundment within the next few years of this decade.

Although impossible to gain precise statistics over such a short survey period, viable populations of *L. striolatus* (further referred to in this report as L.s) have been recorded based on anecdotal reports from interviews with villagers in the Nam Ngiep upstream from NN1 FSL (close to Ban Pou) to Ban Poucafe (see Table 1). L.s has been recorded from the Nam Siam at Ban Nam Sia (photo 3423 / 3424) and Ban Chanam (3379). The Nam Siam is to be impounded by the NN2 Main Project just upstream from its confluence point with the Nam Ngiep.

Between Ban Pou and Ban Xiengthong (Table 1 and photo 3553) on the Nam Ngiep mainstream, a total of seven villages have cumulatively established 11 Fishery Conservation Zones (FCZs). These have been set up under village rules that invariably ban all fishing activity using all fishing gears all year round and are almost always established over deep pools areas. Three villages at Ban Hat Sam Khon, Ban Viengthong and Ban Xiengkhong have established FCZs over deep pools close to the villages (Table 1 and photos 3580, 3594 and 3553). The downstream end of each deep pool / FCZ ends in a series of rapids. It is in precisely this environment that L.s reportedly spawns. The actual spawning event has been witnessed by numerous villagers over the past decade and always involves a period of gathering / shoaling of up to 30 individuals prior to spawning taking place both during the nighttime and during the daytime period. The spawning takes place in quite shallow waters and there were several reports of dorsal fins sticking out of the water surface. Eggs are apparently sticky and large numbers of them can be seen in the area following spawning.

Our study team was taken to see one FCZ on the Nam Siam and Ban Nam Siam (Table 1 and photos 3423 / 3424). Villagers explained that this deep pool was where L.s prefers to live in the early dry season months, but that all L.s migrate back downstream at the flood recession period back to the Nam Ngiep and its deeper pools.

Other rivers that reportedly hold populations of L.s were the reaches of the Nam Xan around and downstream from the road bridge on route 1D (Table 1 and photo 3600 / 3606). Once the Nam Xan becomes a series of strong rapids upstream from the road

bridge, L.s can no longer be found. It is found downstream to Muang Thathom, but it is not clear downstream past Thathom (Table 1 and photos 3355) that the range of L.s extends to. L.s is not known in the areas around Project's 3B and 3A (Table 1 and photos 3618 / 3623) neither in any of the areas around Phouvieng where final interviews were carried out above both these Projects (Table 1 and photos 3621 / 3626 and 3631).

The Nam Chian (pronounced Nam Jey) is a major tributary of the Nam Ngiep and our study team received numerous reports that a population of L.s were present from the Nam Ngiep confluence point upstream to the base of a series of steep rapids (Table 1 and photos 3518, 3520 and 3528). These rapids (*Dtut heah*) form a zoogeographical barrier to L.s.

A series of rapids and waterfalls (*Tad-a-Tong*) on the Nam Ngiep acted as a zoogeographical barrier to upstream movement of L.s even before the construction of the NN3 Project (Table 1 and photos 3444 / 3449).

Critical life-cycle habitats for L.s remain in the areas of the Nam Jey between NN1 FSL that are not inundated and the base of the *Dtut heah* rapids and waterfalls. Critical spawning sites between Ban Pou and Ban Xiengthong may be impacted depending on how NN2 Main Project is to be operated. Altered dry season hydrology and water quality may be key issues. The section of the Nam Ngiep between NN2 Main Project and NN2 Tributary Project may face dewatering because of water diversion, but Ban Keokoang (Table 1 and photo 3544), Ban Phapheung and Ban Sanlouang (Table 1) do not know L.s and the Nam Ngiep is a long distance away. The only village likely to be impacted by dewatering is Ban Poucafe (Table 1). Populations of migratory L.s will almost certainly not be able to exist in that river after the completion of the NN2 main Project.

### 1. Introduction

*Field* survey work has been conducted in the upper Nam Ngiep catchment from Thursday April 3 to Tuesday April 8 2014 specifically to gather more information and data on the distribution and habits of *Luciocyprinus striolatus* throughout the Nam Ngiep catchment and various adjacent sub-catchments. The survey also aimed to record critical habitat presence or absence associated with the life-cycle of L.s, the hydro-geomorphic characteristics of rivers where L.s is reportedly found and identify any practical measures that might be used to protect the species with regard to the Nam Ngiep catchment. It should also be remembered that it is the construction of hydropower infrastructure that influenced where and how interviews took place. This may have introduced a level of bias in the village-interview sampling methodology because it is mainly tributaries of considerable size that have received attention from fishery researchers / taxonomists.

### 1.1 Anecdotal information

Much of the evidence provided here in this final report is based on anecdotal information presented by local people during interviews. Anecdotal evidence can be divided into two main types: 1) That information that is presented based on something that a third party saw, heard or did, and 2) Information that the interviewee actually experienced or witnessed first hand. Clearly the latter type of information is more reliable and this report is mostly based on this type of information. To actually

witness a capture or observe a spawning event of a species that must be considered as generally uncommon over such a short survey time and covering a vast geographical area would be extremely fortunate.

#### 1.2 Purpose and justification of this report

A survey of the upper Nam Ngiep catchment and adjacent sub-catchments was required to better understand the likely extent of *L.s* the habitat (s) that might be affected by the Nam Ngiep Project, and the likely extent of cumulative impacts of all three (or four) hydropower Projects and other catchment uses. The main purpose of the report is to ascertain population condition in relation to IFC Critical Habitat threshold limits.

#### 1.3 Study team

The study team consisted of:

- Mr. Souksavanh (Nam Ngiep Project Officer, Pakxan based.
- Mr. Vongphet Vilahoun from the District Agriculture and Forestry Offices at Thathom.
- Mr. Pradith (Nam Ngiep Project driver, and
- Mr. Terry J. Warren, independent fishery advisor.

### 2. Methodology

A literature study was carried out prior to beginning field work. A short report was prepared by the author based on the literature study (Warren 2014). The field work was planned / based on 1) previous field studies, 2) the likely Project / inundation area footprint, 3) the un-regulated parts of the upper Nam Ngiep catchment and 4) selecting areas where it was thought that *L.s* might be found based experience of habitat type in other rivers in the Lao PDR where it is known to exist (the Nam Theun / Kading, the Nam Mouan, the Nam Ngouang, the Nam Ou and the Xe Kong are examples).

At each of the villages where interviews took place the village chief was contacted and asked if it would be convenient to carry out the interview with five or six people that had knowledge of fishing and fishery issues. This took place on every occasion. A detailed description of *L.s* was provided to interviewees prior to showing any photographs of the fish. It is quite an easy fish to describe because of its size (adult fish weighing up to 30kg), shape and habits (spawning behavior, predatory nature). It was easy to see from interviewee reaction whether they knew the fish or not. Some were able to say that they knew it, but it was not found in the river / stream near their village; Ban Nam Siam for example (Table 1). After the description was provided all interviewees were shown photographs of the fish previously taken by the author from the Nam Theun and the Nam Ou and one taken by Dr. Maurice Kottelat (see appendix 1). All information was recorded in notebooks and typed up each day. Each interview took anything up to 45 minutes to complete.

**Figure 1** Map of the Lao PDR showing where populations of *L. striolatus* have been positively identified.

## 3. Survey results

Table 1 below provides details of GPS coordinates, category and elevation and any notes or comments on specific sites and locations of relevance

| Coordinate<br>East | Coordinate<br>North | Category and elevation   | Notes  |
|--------------------|---------------------|--|--|
| 0352694            | 2100847             | Thathom DAF Offices<br>(253m)  | Next to DAF Offices and Nam<br>Xan – water very brick-red<br>orange.   |
| 0323250            | 2115610             | Base camp for NN2 main Project (373m).   | Taken from road (1D) opposite it.  |

| 0313805            | 2115603             | Ban Chanam on right-<br>hand bank of Nam Siam<br>(497m).   | Village where all interviewees<br>knew <i>L. striolatus</i> and on the<br>Nam Siam (NN2 Main Project).   |
| 0327358            | 2121436             | Ban Poucafe on left-<br>hand bank of Nam Ngiep<br>(554m)   | A village on the Nam Ngiep (1D road) above NN2 main Project.   |
| 0319877            | 2128351             | NN2 Tributary Project (844m).  | Seventeen kilometers after left turn off main 1D road.   |
| 0297261            | 2125206             | Ban Nam Siam or better<br>pronounced in English as<br>Nam <i>Seeam</i> (833m).                         | This village is near to the upper<br>areas of the Nam Siam. Exact<br>source of Nam Siam is not known<br>at present, and is anyway<br>irrelevant to this study. L.s not<br>seen or caught here, but one<br>person knew it.  |
| 0301048            | 2119144             | Ban Nam Sia. <i>L.s</i> is<br>caught at this village,<br>especially on downstream<br>migration (801m). | This village is about 10km<br>downstream from Ban Nam Siam<br>and about 20 to 25km upstream<br>from Ban Chanam (row four after<br>title). They are very familiar with<br><i>L</i> .s. Villagers estimate that eight  |
| 0301945            | 2118192             | Coordinates of the FCZ at<br>Ban Nam Sia ( <i>Wang Nam</i><br><i>Dong</i> ) -700m)                     | to ten fish are caught per year. A<br>one kilometer walk down the<br>valley brings one to an FCZ<br>(village established). Villagers<br>here report that <i>L.s</i> live in this<br>deep pool (FCZ) but all <i>L.s</i> move<br>away at the end of the dry<br>season back to the Nam Ngiep. |

Table 1 continued...

| Coordinate<br>East | Coordinate<br>North | Category and elevation  | Notes   |
|--------------------|---------------------|---|---|
| 0327334            | 2139265             | An FCZ on the Nam<br>Ngiow (1079m)  | After the top of the <i>Tad-a-Tong</i><br>waterfall, the Nam Ngiap is<br>known as the Nam Ngiow. There<br>is an FCZ about 200m from Ban<br>Sang below.  |
| 0326601            | 2132819             | Ban Sang – village<br>(1128m).  | A point about four or five<br>kilometers above the NN3<br>Project. Here the name of Nam<br>Ngiep changes because of a 20m<br>high waterfall ( <i>Tad-a-Tong</i> ). Ban<br>Sang is on the stretch of the Nam<br>known as the Nam Ngiow. <i>L.s</i><br>cannot pass the waterfalls. It is a<br>zoogeographical barrier (not<br>climate or habitat). <i>L.s</i> is not<br>known in the Nam Ngiow<br>according to an interview at Ban<br>Sang. |
| 0325829            | 2133724             | Base of the Tad-A-Tong<br>waterfall and also the site<br>of the NN3 Project<br>powerhouse (914m).                                       | A zoogeographical barrier to fish migration approximately 20 meters high and very steep.  |
| 0326398            | 2134629             | A water release point<br>from the NN3 Project.<br>The water flows to the<br>Nam Ngiep when FSL<br>water levels are too high<br>(1064m). | Large water gates.  |
| 0326818            | 2134811             | NN3 Project dam site (1061m).   | One end of the dam.   |
| 0325829            | 2133724             | NN3 Project powerhouse (914m).  | NN3 Project powerhouse is at the base of the <i>Tad-a-Tong</i> waterfall.   |
| 0355124            | 2130375             | Ban Nabong. Villagers<br>here say they know <i>L.s</i><br>and that it is in the Nam<br>Xan at Ban Thaenphoun<br>(1225m).                | Not to be confused with the<br>Nam Xan in the southern part of<br>the Nam Ngiep Project (Topo.<br>Map). The Nam Xan in question<br>(column 3) flows into Vietnam.   |
| 0351702            | 2126204             | Ban Khek is below Ban<br>Nabong (1193m).  | Villagers here say that they know<br>L.s. but that it is caught below a<br>200m section of waterfalls (Dtut<br>heah) on the Nam Jey. Road to<br>Nam Jey is too difficult to pass.<br>We decide to visit Ban<br>Thaenphoun on the Nam Xan<br>and try to get to Nam Jey the<br>next day by a different route.   |

Table 1 continued...

| Coordinate<br>East | Coordinate<br>North | Category and elevation  | Notes  |
|--------------------|---------------------|---|--|
| 0362995            | 2137687             | Ban Thaenphoun (782m).  | Villagers here on the Nam Xan<br>(no confusion with the other Nam<br>Xan that flows to the Mekong) do<br>not know <i>L.s</i> and say it is not in<br>their river.  |
| 0347300            | 2120368             | Low bridge over the Nam<br>Chian (Topo. Map). Bad<br>vernacular translation.<br>The name of the river is<br>much more like the Nam<br>Jey, or Nam Jay. <i>L.</i><br><i>striolatus</i> is found in the<br>lower Nam Jey below the<br>waterfalls before it<br>discharges into the Nam<br>Ngiep (1076m). | This is a large Nam Ngiep<br>tributary. There is a sizeable<br>hydropower dam being built quite<br>close (about one kilometer above<br>where the Nam Jey flows down<br>through rapids that are perhaps<br>200m long). This is a<br>zoogeographical barrier for<br>almost fish and definitely <i>L</i> .<br><i>striolatus</i> . The best vernacular<br>translation I can produce for the<br>waterfalls is <i>Dtut heah</i> (see next<br>row). |
| 0337111            | 2132716             | Top of hills overlooking<br>the Nam Phouan Valley<br>(1602m)  | This was an alternative route to try to reach the Nam Jey.   |
| 0344376            | 2126271             | Nam Dtun, a sizeable<br>river running close to Ban<br>Dtun Tai. The GPS was<br>taken next to a new<br>bridge under construction<br>(1204m).   | Villagers at this place did not<br>know <i>L.s</i> and said that it was not<br>found in the Nam Dtun.  |
| 0344633            | 2124167             | Ban Pakhing at next<br>village past the Nam Dtun<br>(1196m)   | Villagers at Ban Pakhing do not know <i>L.s.</i>   |
| 0347300            | 2120368             | A low bridge is under<br>construction over the<br>Nam Jey at Ban Boong<br>(1076m)   | Local people said they knew <i>L.s</i> from the Nam Jey, but that it was below the <i>Dtut heah</i> waterfalls.  |
| 0348126            | 2117801             | This is the site of the<br>Nam Jey HPP. But<br>nobody was prepared to<br>provide an exact name. It<br>does not block the Nam<br>Jey, but impounds<br>tributaries that flow into<br>the Nam Jey (1068m).   |  |
| 0347302            | 2119477             | This reference is what<br>appears to be the top of<br><i>Dtut heah</i> waterfalls<br>(1069m).   | Cannot be sure. Wild territory.  |
| 0347205            | 2119403             | This reference is what<br>seems like the middle<br>part of the falls (1113m).   | Cannot be sure. Wild territory. No tracks or ways of navigating.   |

# 3.1 What was found during this study when set against the ToR proposed

a) What is the status of *L. striolatus* population above NN1 FSL to NN2 wall?

As far as is known at present the NN1 reservoir tail waters will end at Ban Pou (route 1D). Currently there is a seemingly healthy population of *L.s* from NN! FSL to Ban Phoucafe as anecdotally reported to the study team during the present survey. *L.s* almost certainly exists in the Nam Ngiep beyond these two locations. It is an uncommon fish and probably lives out most of its life as a solitary predatory species. It is found in other rivers that all confluence with the Nam Ngiep in the middle and upper sections of the Nam Ngiep mainstream.

**b**) What is the status of *L*.*s* population above in the Nam Chait (major left bank tributary and with Nam Sen – NN2 – forms Nam Ngiep?

The Nam Chait (much confusion about the vernacular spelling of this river, i.e. the Nam Chian and the Nam Chait). The only river that is probably being considered here is the Nam Jey. It is a large tributary and confluences with the Nam Ngiep within the study area. If the spelling of Nam Jey is not correct then I think the Nam Chait was probably outside of our study area.

If the Nam Chait is the Nam Jey, then it can be reported that the population of L.s is important. There was anecdotal evidence to support its presence in the Nam Jey. From its hydro-geomorphological appearance the Nam Jey appears a suitable habitat for L.s before major rapids become a zoogeographical obstacle to its range.

c) What is the geomorphic range of the habitat in the upper Nam Ngiep?

In terms of elevation, this fish lives between 325m and about 800m based on the results of this brief survey. The Nam Siam (Nam Seeam) was the smallest river where *L.s* migrate into for spawning or feeding or both from the Nam Ngiep that was found during this survey. Tributaries that are less than about five meters wetted width, and perhaps too steep do not appear to be a suitable habitats for this species.

**d**) Where are the most likely locations of *L*.*s* based on the geomorphic character of the Nam Ngiep?

*L.s* can grow to a large size (just over 30kg) in the Nam Ngiep, and larger in other river systems; but this is exceptional and most fish that are caught in the Nam Ngiep are about one kilogram or less.

Geomorphic characteristics of the Nam Ngiep represent a suitable habitat for L.s based on the author's other studies in the Nam Ou, Nam Theun-Kading and the Xe Kong. L.s is one of a small number of large fish species that spawn in the dry season (January to April). Most Cyprinid species are wet season spawners (May to June – July) when rivers are swollen with fresh rains. It may be the case that L. striolatus spawns twice; once in the dry

season and again in the wet season. We do not know this for sure, and it would be unusual.

Adult *L.s* (two or three kilogram fish) has a preferred habitat of deep pools of about two to six meters in depth in the dry season. As an adult fish, it can live in these deep pool environments in the Nam Ngiep at any time of the year; but for sure this is their dry season habitat. During the onset of the flood season, it moves upstream (May to July). After rains cease in October and November it moves back downstream again to dry season refuge habitats in main streams like the Nam Ngiep. The upstream migration for juveniles (<1kg) may represent a trophic migration, but for larger fish, this may represent a spawning migration.

**e**) Where is the known spawning sites of *L.s* and in what month does it breed? Are these based on actual observations or anecdotal reports? Detailed descriptions of reproductive habits and spawning. The sizes of the fish and how many were involved?

The places where *L.s* is known to breed are at the downstream end of three large pools between Ban Pou and Ban Xiengkhong. These are based on my discussions with many local people, but all based on personal witness accounts and observations. From my experience of conducting such interviews, there is no question that this is valid information.

f) What are the operational and design aspects of NN2 that will impact on L.s?

1) It is NN1, NN2 and NN3 that will impact on *L.s* populations in the Nam Ngiep, and not just on any one Project. What must always be remembered is that, all three (or perhaps four Projects) will have a cumulative effect on the aquatic environment, but in there own different ways.

2) Major concerns are:

2a) Possible poor water quality (sulphides and nitrites / ammonia) spilling from NN2 reservoir in particular, but perhaps NN3 also, but to a lesser extent.

2b) A reduction in essential life-cycle habitat (flooding of spawning grounds). This fish needs deep-pool habitats and downstream rapids where it can gather and shoal to breed. Sometimes up to 30 individual specimens are involved according to anecdotal reports.

3) Detailed design elements of all three (or four) Projects are required before it can be related to fisheries and fish population aspects.

**g**) What is the accumulative impact of NNP1 and NNP2, including impact that may occur before NNP1 commences and for which the NN1PC Project cannot be held accountable for viz proportional responsibility?

1) It is possible that the Nam Ngiep Project may bring about the extirpation (this means over its localized range within the Nam Ngiep where it is known from). But all three Nam Ngiep Projects will definitely not produce the extinction of this fish species because it is known from many other catchments.

**h**) Data gaps for each *L.s* population. What we don't know but should know? What we don't know about, and is of major importance is the status of *L.s* populations outside of the Nam Ngiep catchment.

a) We now have a lot of information about *L.s* in the Nam Ngiep catchment at least. We have information on where it lives and breeds, and general life-cycle on a seasonal basis.

b) What we don't know about are the populations outside of the Nam Ngiep catchment. It is very important to record this information so that strategies can be put in place to protect this species of freshwater fish elsewhere.

#### 1 Summary

The fishes of fast water habitats of the Nam Ngiep inundation zone were surveyed in January– February 2014. Samples were also obtained in adjacent drainages (Nam Mang, Nam Xan and Nam Xao) to obtain information on the distribution of the endemic species.

The survey recorded 53 fish species in the NNP1 inundation zone. Two species were not observed, but reliably reported. The survey found 4 species new to science (unnamed), two of them in the inundation zone and 2 above FSL. An additional 4 species present difficulties of identification and are potentially new to science too..

Five species are known only from the Nam Ngiep drainage. The identity of four additional species is still not clear and they are potentially endemic to the Nam Ngiep drainage. For three of them, the same or a similar species (unnamed) is known from the Nam Ngum and/or Nam Mang drainages. None of the observed species is known only from the area to be inundated.

Four of the species of concern are known in the inundation zone and headwaters, or only in headwaters. The species are expected to survive the impacts of NNP1 project, provided that significant areas of their habitats (torrents, hill streams and small forest streams) remain intact. For species known only from the inundation zone or also until about FSL, they are expected to survive if stretches of several of the main tributaries remain intact at and above FSL for some distance.

*Schistura crabro* was earlier considered to be endemic to the Nam Ngiep. The survey did not observe it in the Nam Ngiep but was found at two sites in the Nam Xan.

The giant pike-carp *Luciocyprinus striolatus* is present in the inundation zone. It is assessed as EN (endangered) in IUCN's Red List. Work must now be undertaken to determine whether or not the Nam Ngiep is a Critical Habitat for the species; work should consider the number of populations globally, the number of 'discrete management units' and their environment quality and threats. Mitigation to the impact of NNP1 project on this species could include research to increase knowledge on the biology of the species and habitat requirements, develop methods for artificial reproduction, and possibly habitat modification to protect or create spawning sites.

#### **2** Introduction

The diversity of inland fishes in Southeast Asia is very high, with more than 1000 species known from western Indonesia (Kottelat et al., 1993; Kottelat & Whitten, 1996a) and some 900 known from mainland Southeast Asia (Kottelat, 1989). Despite this high diversity and their importance for humans, our knowledge of fish biology over most of Asia is still very incomplete and often is restricted to mere lists (Kottelat & Whitten, 1996b). Large areas are still unsurveyed.

The information on Laotian fishes published in the scientific litterature is still limited. Scientific surveys of the fish diversity started in the mid 1990s in conjunction with hydropower development. Unfortunately most of this information is of limited quality and not openly available.

Hydropower projects are usually installed on rivers with a high gradient and the inundated stretches of rivers are mainly characterized by fast to very fast waters, with rapids and waterfalls. These fast water habitats (= rheophilic habitats) are inhabited by aquatic animals specialised for these strong current conditions; most of them are unable to adapt to slow flowing or standing water and will disappear with inundation of the reservoir and reduced flow downstream. However, EIAs often neglect this rheophilic fauna, mainly because the sites are difficult to access and to sample.

This report presents the observations on fish diversity made during surveys conducted in January and February 2014 in the Nam Ngiep 1 project area and discusses impacts of the project in the rheophilic fauna and possible mitigations.

**3.1 Survey participants** Dr Maurice Kottelat, fish taxonomist Mr Thavone Phommavong, Living Aquatic Resources Research Center, Vientiane Mr Soukhsavan \_\_\_\_\_, NNP1PC Mr Adam Greenhalgh, ERM Mr \_\_\_\_\_, Division of Fisheries, Vientiane

#### 3.2 Methods and terminology

Most fish samples were obtained with a GrassI IG200/2 battery-powered electric fish shocker and with ichthyocides. Additional material was obtained by push-net and seine, and by inspecting catches of villagers and kitchens of restaurants. Ichthyocides were used to obtain samples from habitats that could not be sampled by other means (crevices, rapids, etc.); they were used only where their effect could be entirely controlled and where the river topography allowed an immediate dilution below toxicity level immediately downstream of the sampled area.

The sites were accessed by boat or by car. The Nam Ngiep itself could not be sampled between the dam site and Ban Sopyouak as it cannot be travelled by boat and there is no access by car. Access to tributaries on the west side was not possible upstream of Ban Pouan for security reason.

Identifications and nomenclature follow mainly Kottelat (2001), updated with knowledge acquired posteriorly (compiled in Kottelat, 2012, 2013).

Species are recorded only under their scientific names; these are made of two words, written in italics, and follow the International Code of Zoological Nomenclature. For species that present identification problems, the term 'cf.' is added between the generic name (the 'first name' written with a capitalised initial) and the species name ('second name') to refer to populations which are likely to belong to the species referred to but whose identification is not yet certain because of unresolved taxonomic problems. For example, what is referred to as *Oreoglanis* cf. *delacouri* is possibly *Oreoglanis delacouri* but a soubt subsists and more work, or more material, or more populations are needed to be absolutely sure. The term 'aff.' (for 'affinis') denotes populations that cannot be identified with any species known to me, or which probably are new species (that is unnamed, without scientific name). The use of 'aff.' is to ally this possibly new taxon with what is possibly its closest species. For example, *Schistura* aff. *ephelis* indicates that the species is distinct but close to *Schistura ephelis*. 'sp. n.' is used for species new to science, that is, species that have not yet received a formal name. For example *Glyptothorax* aff. *zanaensis*.

The term "sp." means an unidentified species. For example *Schistura* sp. indicates a species of *Schistura*, which cannot be identified at the species level, for example very small juveniles or mutilated individuals.

Spelling of names of villages and streams follow the 1985 1:100,000 Lao P.D.R. topographic maps, when feasible. Co-ordinates were obtained with four different GPS (two of them mounted in camera) and, in a few cases, from the maps. Datum: WGS 84, UTM zone 48. *Altitudes listed below are only indicative*; they were measured with these two GPS; they often differed and they also differed from those indicated in other documents and maps, or those obtained from Google Earth. The amplitude of the differences varied between 1 to 20 meters. As a result, some samples obtained around FSL may be somewhat above or below.

In the discussion, the word *endemic*, used as either a noun or an adjective, means: whose distribution is restricted to a geographically limited area. For example, a species endemic to the Nam Ngiep is a species that has been observed only in the Nam Ngiep drainage.

#### 4 Results of survey

#### 4.1 Collecting sites and observed species

Sampling sites are numbered in chronological sequence. The sites are organised in the following order: NNP1 inundation zone; Nam Ngiep drainage above FSL of NNP1; and sites outside NNP1 project area (Nam Mang, Nam Xan, Nam Xao). Species are listed in alphabetical order of families, genera and species.

#### 4.1.1 Nam Ngiep in NNP1 inundation zone

**14-001** Nam Chae, immediately upstream of confluence with Nam Ngiep, about 7.5 km downstream of Ban Pou; 18°59'39.5"N 103°30'00.0"E, 300 masl; 28 Jan 2014.

| Balitoridae   | Homaloptera yunnanensis         |
|---------------|---------------------------------|
| Cyprinidae    | Onychostoma aff. gerlachi       |
| Cyprinidae    | Scaphiodonichthys acanthopterus |
| Nemacheilidae | Schistura aff. ephelis          |
| Sisoridae     | Glyptothorax horai              |
| Sisoridae     | Glyptothorax laosensis          |
| Sisoridae     | Glyptothorax aff. zanaensis     |
| Sisoridae     | Pseudecheneis sympelvica        |

**14-002** Houay None, immediately upstream of confluence with Nam Ngiep, about 9 km downstream of Ban Pou; 18°59'06.9"N 103°29'39.8"E, 279 masl; 28 Jan 2014.

| Channidae     | Channa gachua                   |
|---------------|---------------------------------|
| Cyprinidae    | Barbodes aurotaeniatus          |
| Cyprinidae    | Danio acrostomus                |
| Cyprinidae    | Esomus metallicus               |
| Cyprinidae    | Opsarius pulchellus             |
| Cyprinidae    | Osteochilus striatus            |
| Cyprinidae    | Poropuntius aff. carinatus      |
| Cyprinidae    | Puntius brevis                  |
| Cyprinidae    | Rasbora atridorsalis            |
| Cyprinidae    | Rasbora rubrodorsalis           |
| Cyprinidae    | Scaphiodonichthys acanthopterus |
| Cyprinidae    | Systomus jacobusboehlkei        |
| Cyprinidae    | Tor laterivittatus              |
| Nemacheilidae | Nemacheilus platiceps           |
| Nemacheilidae | Schistura defectiva             |
| Nemacheilidae | Schistura dorsizona             |

**14-003** Houay Hok, about 300 m uspstream of confluence with Nam Ngiep, which is about 15 km downstream of Ban Pou; 18°56'25.7"N 103°29'58.2"E, 295 masl; 29 Jan 2014.

| Balitoridae    | Hemimyzon confluens             |
|----------------|---------------------------------|
| Cyprinidae     | Bangana lippa                   |
| Cyprinidae     | Garra theunensis                |
| Cyprinidae     | Onychostoma aff. gerlachi       |
| Cyprinidae     | Opsarius pulchellus             |
| Cyprinidae     | Poropuntius aff. carinatus      |
| Cyprinidae     | Raiamas guttatus                |

#### 4.2 Fish fauna

#### 4.2.1 Diversity, endemism

Fish were sampled or observed at 21 sites in the Nam Ngiep drainage upstream of the dam site, 14 of them in fast water habitats in the inundation zone of NNP1 reservoir. A total of 56 species were recorded in the surveyed part of the drainage (Table 1), 53 of them present in the inundation zone, and 34 species were observed in the samples from outside the inundation zone.

Although not observed during the survey, interviews with villagers in Ban Pou, Ban Thaviang, Ban Viengta abd Ban Xomxeun indicate the presence of *Luciocyprinus striolatus* (see Annex 1). In 2013 I have seen in a restaurant in Ban Vanglouang (Hom District; Nam Ngum drainage) a specimen of *Labeo pierrei* that had been brought from Ban Sopyouak; the species has not been obtained by the survey but the origin of the observed specimen is reliable and conforms with what is known of the species in other drainages (Nam Ou, Nam Ngum, Xe Bangfai, Xe Kong). The two species are included in the fish fauna of the Nam Ngiep in Tables 1–2.

Among the 53 species in the inundation zone (Table 1), 2 are new to science (*Schistura* sp. n. 'Nam Youak', *Schistura* sp. n. 'slender'). A further 4 species are potentially also new to science but this cannot be established within the time available for this report (*Schistura* aff. *ephelis*, *Schistura* sp. 'compact', *Schistura* aff. *defectiva*, *Poropuntius* aff. *carinatus*). Awaiting clarification, I adopt a precautionary approach and treat them here as if they effectively are new species. These new species have been discovered by the survey in the Nam Ngiep drainage and therefore they must be treated as endemic to the Nam Ngiep. For 3 of these species there is, however, suspicion that some (or similar-looking species) also exist in adjacent drainages (*Poropuntius* aff. *carinatus*, *Schistura* aff. *ephelis*, *Schistura* aff. *ephelis*, *Schistura* aff. *ephelis*, *Schistura* aff. *ephelis*.

A further 2 new species were discovered in a small hill stream of the Nam Ngiep drainage (site 14-30), but far above FSL (*Danio* sp. n., *Poropuntius* sp. n.). *Glyptothorax* aff. *zanaensis* and *Onychostoma* aff. *gerlachi* are also unnamed species obtained by the survey but they were already known from surveys in other areas of Laos.

All the endemic species found in the inundation zone have also been found above FSL. Some have a wide distribution in the inundation zone (*Schistura* sp. n. 'slender', *Schistura* aff. *ephelis*, *Schistura* sp. 'compact', *Poropuntius* aff. *carinatus*) but others seem to have a restricted range, but this might result from a sampling bias because most of the tributaries of the reservoir are not accessible.

Eight sites were sampled in the Nam Xan drainage, one in the Nam Mang and six in the Nam Xao, a tributary ofv the Nam Ngiep entering it downstream of NNP1 dam site.

Schistura crabro was earlier known only from an unspecified locality in the Nam Ngiep drainage. The survey observed it at two sites in the Nam Xan and therefore the species is no longer to be treated as endemic of the Nam Ngiep. The habitat in which it was observed (riffles on a substrate of gravel to small stones) was rare in the surveyed stretch of the Nam Ngiep and the species possibly does no occur in the NNP1 inundation zone.

#### 4.2.1.3 Other drainages

The sampling in the adjacent drainages yielded 55 species (Table 2). 30 of them are also present in the surveyed parts of the Nam Ngiep drainage. These species will not be further mentioned here unless relevant to the discussion of the NNP1 project area.

#### 4.2.2 Migrations

Only two of the recorded species are known to be long distance migratory in other tributaries of the Mekong: *Labeo pierrei* and *Cirrhinus molitorella*. Both species were observed in restaurants and said to come from the Nam Ngiep.

Labeo pierrei is known to undertake long migrations. This has been documented in the Xekong River, where it moves between the middle Xekong (for spawning) and the Mekong. Such long migrations will not be possible in the Nam Ngiep after construction of the NNP1 dam. However, a survey of the Nam Ngum in 2013 observed that juveniles 1-2 years old were present upstream of Nam Ngum 1 and Nam

Ngum 2 reservoirs. They were at about FSL of Nam Ngum 2, in rapids exposed in the dry season. This shows that reproduction was possible without access to the Mekong, but this observation may not be informative for long term evolution since Nam Ngum 2 dam was commissioned in 2011.

#### 4.2.3 Conservation status

The threat status of all the named freshwater fishes of mainland Southeast Asia has been assessed in the IUCN Red List of Endangered Species (www.iucnredlist.org) (Allen et al., 2012). 46 of the 56 species recorded in the Nam Ngiep drainage upstream of NNP1 dam site have already been assessed (see Table 3). The Red List rating indicates the risk of extinction based on precisely defined criteria. The threat categories are: Critically Endangered (CR), Endangered (EN) and Vulnerable (VU). All species, even those not threatened, have been rated. Least Concerned (LC) are species not threatened; Near Threatened (NT) are species not in any of the threatened category but for which small changes in the habitat or population would immediately move them in a threat category. Data Deficient (DD) are species for which the available data did not allow to objectively rate them. Most of the DD species are newly discovered or rare species. The fate of DD species is not to remain DD but to eventually be evaluated; experience shows that once evaluated a fair number of the DD species are rated as threatened. Note that the assessment is based on the global range of a species, which means that a wide-ranging species could be locally abundant in a given area but globally threatened, or the reverse.

Among the 46 species observed by the survey and that had already been evaluated, none is CR, 1 is EN (*Luciocyprinus striolatus*), 3 are VU, 2 are NT, 29 are LC, and 11 are DD.

#### 5 Species of concern, threats and mitigation

#### 5.1. Endemics

#### 5.1.1 Schistura sp. n. 'Nam Youak'

This is a new species discovered by the survey. It was observed in a small fast flowing stream tributary of the Nam Ngiep near Ban Soppouan (site 14-009) in the inundation zone, in the Nam Youak at about FSL (site 14-015) and in a small tributary of the Nam Youak about 100 m above FSL (site 14-016). It was most abundant at the last site where most individuals were obtained in the stretches with the fastest current. It is expected to be present in adjacent headwaters and its presence in the inundation zone is expected to be restricted to small tributaries. Most of the habitat of the species is expected to be above FSL.

The species is not directly threatened by the project. Indirect impacts will be the construction of access roads that will damage the streams and attract human activity, logging activity (road, camps, etc.) that result in deforestation, siltation, pollution and overfishing. Site 14-016 was along the road, about 1 km from village, in secondary forest, with some impact but still had a good fish population.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors are small stream with fast water on large stones (torrent-type), with riparian forest cover, clear water and absence of siltation. An important point should be the absence of cause of siltation in the upper part of the catchment. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. It will require knowing better the distribution of the species to ensure that it will be present in some of the protected areas.

#### 5.1.2 Schistura sp. n. 'slender'

This is a new species discovered by the survey. It was observed in two tributaries of the Nam Ngiep on the west side (Nam Khai, site 14-006; Nam Pouan, site 14-008), in the inundation zone, and in the Nam Ngiep upstream of FSL of NNP1 reservoir (site 14-019). It was found on and in a substrate of coarse sand, gravel and small stones. Its preferred habitat seems to be stretches with moderate flow (in the dry season), which is not frequent in the inundation zone but makes most of the observed stretch of the Nam Ngiep upstream of FSL until at least Ban Naxong (site 14-019); the extent of its range upstream is not known. The upstream of the Nam Khai and Nam Pouan could not be

researched because of access difficulties and security reasons.

The species has not been collected in the main stream of the Nam Ngiep in the inundation zone but it was present in two tributaries. Species of the genus *Schistura* have not been observed to adapt to reservoir conditions and it is expected *Schistura* sp. n. 'slender' will disappear from the inundation zone. It is expected to subsist in the Nam Ngiep between NNP1 reservoir and NNP2 dams, if the substrate of gravel and stones is not covered by sediment resulting from construction and human activity further upstream.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors seems to be the presence of a substrate of coarse sand, gravel and small stones and that this remain free from sediments or siltation. It would be better if such habitat could be located in tributaries located in protected areas for other animals and forest.

#### 5.1.3 *Danio* sp. n.

This is a species new to science. It was found only at site 14-030, which is a small stream draining to the Nam Ngiep, in the hills almost at the divide between Nam Ngiep and Nam Xao, about 100 m above FSL. It is probably present in other headwaters; site 14-030 is along one of the only two tracks on which it was possible to cross the divide between the Nam Ngiep and the Nam Xao (near Ban Muang Bo). The species was not observed in the inundation zone and probably occurs only in small headwaters.

The species is not directly threatened by the project. Indirect impacts will be the construction of access roads that will damage the streams and attract human activity, logging activity (road, camps, etc.) that result in deforestation, siltation, pollution and overfishing. It was found together with *Poropuntius* sp. n. (see below).

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors are riparian forest cover, clear water, absence of siltation and human disturbance. An important point should be the absence of cause of siltation in the upper part of the catchment. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. It will require knowing better the distribution of the species to ensure that it will be present in some of the protected areas.

#### 5.1.4 Poropuntius sp. n.

This is a species new to science. It was found only at site 14-030, which is a small stream draining to the Nam Ngiep, in the hills almost at the divide between Nam Ngiep and Nam Xao, about 100 m above FSL. It is probably present in other headwaters; site 14-030 is along one of the only two tracks on which it was possible to cross the divide between the Nam Ngiep and the Nam Xao (near Ban Muang Bo). The species was not observed in the inundation zone and probably occurs only in small headwaters.

The species is not directly threatened by the project. Indirect impacts will be the construction of access roads that will damage the streams and attract human activity, logging activity (road, camps, etc.) that result in deforestation, siltation, pollution and overfishing. It was found together with *Danio* sp. n. (see above).

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams with where the species is presentretain intact aquatic habitats. Key factors are riparian forest cover, clear water, absence of siltation and human disturbance. An important point should be the absence of cause of siltation in the upper part of the catchment. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. It will require knowing better the distribution of the species to ensure that it will be present in some of the protected areas.

#### 5.1.5 Oreoglanis delacouri

This species is endemic to the Nam Ngiep drainage (Ng & Kottelat, 1999; Kottelat, 2001). It was earlier recorded only from the headwaters of the Nam Ngiep. It was found in the Nam Ngiep in the inundation zone and from several small tributaries, above FSL. It inhabits very fast flowing water, especially headwaters and torrents. One sample from the Nam Xan (site 14-018) looks similar to *Oreoglanis delacouri*; since it includes only juveniles, adults are needed to confirm the identification.

Most of the habitat of the species is above FSL. Outside of the inundation zone, it will not be directly threatened by the project. Indirect impacts will be the construction of access roads that will damage the streams and attract human activity, logging activity (road, camps, etc.) that result in deforestation, siltation, pollution and overfishing. It was found together and abundant with *Schistura* sp. n. 'Nam Youak' (see below).

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams with where the species is presentretain intact aquatic habitats. Key factors are riparian forest cover, clear water, absence of siltation and human disturbance. An important point should be the absence of cause of siltation in the upper part of the catchment. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. It will require knowing better the distribution of the species to ensure that it will be present in some of the protected areas.

#### 5.1.6 Schistura crabro

Schistura crabro was earlier known only from an unspecified locality in the Nam Ngiep drainage. The survey observed tzhe species at two sites in the Nam Xan and therefore it is no longer to be treated as endemic to the Nam Ngiep. The habitat in which it was observed (riffles on a substrate of gravel to small stones) was rare in the surveyed stretch of the Nam Ngiep and the species possibly does no occur in the NNP1 inundation zone.

#### **5.2 Potential endemics**

#### 5.2.1 Poropuntius aff. carinatus

This species has been observed at most sampling sites in the Nam Ngiep drainage, in the inundation zone as well as above FSL. It is possibly new to science. A similar or the same species is also present in the middle and upper Nam Ngum to the west; the time available for this report was not sufficient to confirm that hypothesis. The species has affinities with *Poropuntius carinatus*, a species known from the Mekong drainage in Laos and Xishuangbanna (Yunnan, China).

The species is apparently present everywhere in the main stream of the Nam Ngiep and its tributaries and headwaters. Species of the genus *Poropuntius* have not been observed to adapt to reservoir conditions and it is expected that *Poropuntius* aff. *carinatus* will disappear from the inundation zone. It will subsist in tributaries, will probably subsist in the Nam Ngiep between NNP1 reservoir and NNP2 dams, and may subsist in the stretches of streams immediately below FSL and emerged during most of the year.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams with where the species is presentretain intact aquatic habitats. Key factors are riparian forest cover, clear water, absence of siltation and human disturbance. An important point should be the presence of relatively deeper areas to provide shelter during the dry season and gravel and stones along the shores in some stretches for spawning. The presence of dams operating at peak hours upstream could have negative impact in daily exposing gravel beds and shore vegetation in which eggs are deposited. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest.

#### 5.2.2 Schistura aff. ephelis

This species has been observed at most sampling sites in the Nam Ngiep mainstream in the inundation zone as well as above FSL. It was also observed in tributaries near their confluence with Nam Ngiep (but these tributaries could not be sampled away from the main river for access or security

reasons). In the Nam Youak it was observed at about FSL and similar habitat exist further upstream but could not be accessed. A similar or the same species is also present in the middle Nam Ngum drainage to the west; the time available for this report was not sufficient to confirm that hypothesis. The species has similarity with *Schistura ephelis*, a species present in the Nam Ngum and Nam Xan drainages, but still is very distinct.

The species apparently occupies stretches of the Nam Ngiep and its tributaries with fast current and stone substrate. Species of the genus *Schistura* require moving, clear and well oxygenated water and do not adapt to reservoir conditions and it is expected that *Schistura* aff. *ephelis* will disappear from the inundation zone. It will subsist in larger tributaries with sufficient discharge and stone, will probably subsist in the Nam Ngiep between NNP1 reservoir and NNP2 dams, and may subsist in the stretches of streams immediately below FSL but emerged during most of the year.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors are clear water, absence of siltation and absence of dayly variation of discharge (as typical downstream of dams operating at peak hours) that would exposed part of the habitat everyday and kill fish trying to occupy that part of the river bed. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. Lower parts of tributaries immediately above FSL should be primary target areas (as our sampling site on the Nam Youak).

#### 5.2.3 Schistura aff. defectiva

This species has been observed at two sites, one in the Nam Ngiep mainstream in the inundation zone (site 14-004) and one in the Nam Ngiep above FSL (site 14-019). The identity of the species is not clear. Only few individuals were observed and it still cannot be excluded that these are aberrant specimens of *Schistura defectiva*, a species present at both sites and widely distributed in the Nam Ngiep and Nam Ngum. A similar or the same species is also present in the Nam Mang (site 14-014) and in the middle Nam Ngum drainage to the west; the small number of individuals collected by the survey is not sufficient to reach a definitive conclusion.

With the presence of this species in only two samples and its unclear identity, it is difficult to make hypotheses on the preferred habitat. The two sites have in common a long run on a substratum of stones about 10-20 cm diameter, about 50 cm deep. This may not be the preferred habitat but the habitat where it is most easily captured. Species of the genus *Schistura* require moving, clear and well oxygenated water and do not adapt to reservoir conditions and it is expected that *Schistura* aff. *defectiva* will disappear from the inundation zone. It is expected to subsist in tributaries, will probably subsist in the Nam Ngiep between NNP1 reservoir and NNP2 dams, and may subsist in the stretches of streams immediately below FSL and emerged during most of the year. It might also be possible that most of the habitat of the species is above FSL and that its presence in the inundation zone is only marginal.

**Mitigations.** No mitigation may be proposed until the identity of the samples can be clarified, especially its identity with the species of the Nam Mang and Nam Ngum drainages. Generally, the most efficient way to manage such small species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Considering the doubts about the identity of the species and its presence at only two sites, it is not possible to speculate on the key characteristics of the habitat. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. At both sites it was collected with *Schistura* aff. *ephelis*.

#### 5.2.4 Schistura sp. 'compact'

This species has been observed in the Nam Ngiep mainstream in the inundation zone (site 14-004). It was also observed in tributaries near their confluence with Nam Ngiep (but these tributaries could not be sampled away from the main river, because of access and security reasons) (sites 14-007, 14-008, 14-009, 14-012). In the Nam Youak it was observed at about FSL (site 14-015) and similar habitat exist further upstream but could not be accessed. The specific distincness is still not clear. Only few individuals were observed and it still cannot be excluded that these are aberrant specimens of *Schistura coruscans*, a species present at most sites and widely distributed in the Nam Ngiep and

#### Nam Ngum.

The species apparently occupies stretches of the Nam Ngiep and its tributaries with fast current and stone substrate. Species of the genus *Schistura* require moving, clear and well oxygenated water and do not adapt to reservoir conditions and it is expected that *Schistura* sp. 'compact' will disappear from the inundation zone. It will subsist in larger tributaries with sufficient discharge and stone, and it may subsist in the stretches of streams immediately below FSL but emerged during most of the year.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors are clear water, absence of siltation and absence of cyclical variation of discharge (as typical downstream of dams operating at peak hours) that would exposed part of the habitat everyday and kill fish trying to occupy that part of the river bed. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. Lower parts of tributaries immediately above FSL should be primary target areas (as our sampling site on the Nam Youak). At most sites it was collected with *Schistura* aff. *ephelis*.

#### 5.3 Luciocyprinus striolatus

*Luciocyprinus striolatus* is recorded in the literature from Nam Tha, Nam Ou, Nam Ngum, Nam Kading (Nam Theun and Nam Gnouan), Xe Kong and Xishuangbanna (China) (Cui & Chu, 1986; Kottelat, 1998, 2001; Rainboth et al., 2013) The survey recorded for the first time its presence in the Nam Ngiep and obtained information suggesting it is also present in the Nam Xan. No specimen could be obtained but the identification seems reliable. The summaries of interviews are in Annex 1.

*Luciocyprinus striolatus* reaches a large size (at least 1.5 m, reportedly up to about 2 m) and lives in deep pools and adjacent rapids in fast flowing stretches of large rivers. It is absent in the Mekong floodplain and is only recorded from the middle and upper part of its main tributaries. It spawns downstream of rapids, along shores made of pebble and small stones. It is a predatory fish, feeding on aquatic animals and reported to also capture small mammal that enter the water (monkeys, dogs, etc.) although this is probably only exceptional behavior of very large individuals.

Most populations of the species are impacted or will be impacted by a variety of projects, mainly hydropower and/or mining. In theory, only the population in Nam Theun drainage upstream of the Nam Theun reservoir, in Nakay NBCA, is not threatened by impacts happening upstream.

**Mitigations.** The available information on the biology of the species is very limited and does not allow at this stage to propose concrete actions. The first steps to the management of the species is to confirm the identity, to establish its present distribution in the Nam Ngiep and outside and to obtain biological data.

Because of its size, spectacular appearance, and stories about its feeding habits, *Luciocyprinus striolatus* has a potential to attract attention from the general public and the visibility of the company's attention (or lack of) to conservation issues.

Main points to consider:

#### 1) Distribution

Document the exact distribution of the species, identify exact river stretches, in the inundation zone and between NNP1 reservoir and NNP2 dams

Survey the inundation zone with villagers and identify sites where they have caught or observed the species, especially ripe females. To be done with villagers from Ban Pou, Ban Soppouan and Ban Sopyouak. Although these habitats will be lost at inundation, mapping and describing them may allow to identify geomorphological parameters that can be used later for identification of sites for potential stocking, or provide information for the creation of new, substitution habitats. This should include collection of data on wet-season parameters of these sites.

Survey upstream, of the inundation zone will document the exact distribution of the species. Villagers interviews indicate that very large individuals do not occur upstream of Ban Pou and but villagers are

not certain about the possible existence of spawning sites. Given that the species is not migratory, if large individuals and small juveniles are present, spawning sites may be expected. This needs confirmation from inhabitants of villages upstream.

In regard to ADB Critical Habitat policies, the size and quality of the Nam Ngiep population should be assessed relative to the global population. The 'discrete management units' of the species must be identified as their number, size and habitat quality and integrity may modify the classification.

#### 2) Biological data

Obtain biological data on the species in the project area and outside. Sound management requires to know the basic requirements of the species and the characteristics of its life cycle: feeding, growth, habitat at different stages of life cycle, age and size at maturity, spawning sites and habits, ecology of eggs and fry, incubation, growth and feeding of fry, local movements, etc.

The project might join effort with other projects in which the species is also present in order to conduct or fund the research. Nam Theun 2 could be a potential partner; the drainage of their reservoir includes what is apparently the population in the safest conditions; the existence on site of an hydrobiology lab and researchers might ease the setting up of a research program.

As the species is not very abundant (as is the case for most large predatory animals), methods should be used that require to sacrifice only a limited number of individuals.

#### 3) Fishing activity

Capture of the species should be managed in the Nam Ngiep. Fishing methods that specifically target the species should be banned. Individuals caught alive should be released; admittedly this is far from local customs. Some conservation pools should be established or, if there are already some, they should be extended where needed (this traditional management method is used at community level in the country).

Non-specific fishing methods can probaby not be controlled.

#### 4) Captive breeding

In parallel to the collection of biological data in (2) above, a small captive or semi-captive stock should be established in a safe area. It could be used to study the artificial reproduction of the species. The aim should not be to maintain a permanent captive stock but to develop the knowledge and capacity to quickly produce a large number of juveniles if the need appears. This way, should the need arise the information will already exist and can be used immediately; it will not need to be develop in emergency.

The production of a large number of individuals could be, for example, for stocking in the river to stengthen the local population (at the beginning of flooding, or following a heavy pollution upstream) or to create a new population.

#### 5) Identity

Confirm the identity\_of the species present in the Nam Ngiep. Considering the number of disjunct populations reported as *Luciocyprinus striolatus*, it cannot be totally ruled out that more than one species are confused under that name. Apparently, there has been no attempt to scientifically compare individuals of the different populations, because the material for comparison is not available. A DNA test could be useful; however, it should be kept in mind that while a great difference at DNA level usually indicate species distinctness, the absence of difference or a very small difference does not automatically mean that only one species is involved.

The conservation status of the Nam Ngiep population will be better if all the disjunct populations effectively belong to a single species. If more than one species is involved, the conservation actions must be drastically adapted.

Before possibly stocking individuals obtained by artificial reproduction (see (4) above), if the stocked material originates from another population/drainage, it may become necessary to check that this does not impact genetic integrity of the receiving population. However, there will always be some genetic

difference between isolated populations and in some situations the loss of genetic integrity is a minor concern compared to the loss of a population.

#### 6) Habitat modifications

The survival of the species will depend of the presence of habitats were it can complete its life cycle. It also depends of the continued presence of the preys it feeds on. The habitat components identify during the interviews (Annex 1) and in earlier observations of the species in the Nam Theun drainage (Kottelat, 2002) indicate that adults live in deep pools, with a possible preference for the upper and lower parts, near rapids, riffles and runs. For spawning, it moves to shallow areas with stone and gravel banks along the shores; this is the wet season morphology of the sites since the species spawns in November, not in the dry season.

These habitats will disappear in most of the reservoir. Some will emerge for a few months in the drawdown zone of the Nam Ngiep and its main tributaries. In the stretches immediately below FSL rapids and deep pools may be functional (at least hydrologically) part of the year. However, the reported spawning season is in November (but some villagers gave dates as late as March, which seemed less reliable), which is in the period in which the reservoir is at FSL. Even the two most ustream spawning sites identified by villagers in Ban Pou and Ban Viengta will be submerged at that time (Wang Mon, Kaen Tao).

The status of this last-mentioned sites calls for some reservation. Maps indicate they will will be below FSL and the rapids would not be functional in November. This is the dry season situation. It is not known what the current morphology is during the wet season. The water is certainly some meters higher and what appears as rapids in the dry season are no longer rapids in the wet season, other rapids may appear, and the spawning sites described as in shallow water on pebble banks are not in the position of the dry-season pebble banks. It might well be that the current wet-season topography of these spawning sites remain after inundation, or that inundation of the reservoir might create wet-season situation further upstream comparable to the current wet-season situation in the inundation zone.

Observation of the spawning sites identified under (1) above is needed during the spawning season to observe the wet season topography and the position actually occupied by the fish.

Depending of these observations, it might be desirable or possible to modify some sites in the Nam Ngiep and main tributaries, above or close to FSL, to mimic the identified spawning sites and that could possibly be adopted by the fish. Without information, further speculations on the kind of modifications is premature.

#### 7) Upstream impacts

The discharge from NNP2 project upstream of NNP1 may have impacts on the population of *Luciocyprinus striolatus* downstream. The main impacts will be caused by the increase of the dry-season discharge, the reduced discharge at the beginning of the wet season, and, if it operates at peak hours, the daily fluctuations of the discharge.

Daily fluctuations of the water level downstream of dams/powerhouses is a well-know cause of destruction of fish habitats, and especially of spawning sites. Eggs typically hatch in a few days. Those eggs attached to vegetation or deposited in the sand or in gravel in shallow water become exposed and die in a few minutes. Most fish species spawn this way and it has been observed that *Luciocyprinus striolatus* spawns in shallow water on stone or gravel banks. These stone and gravel banks will be impacted by the daily variation in water level. Here again, without data on the wet-season conditions of the spawning sites, and the planned discharge from NNP2, it is not possible to speculate on the real impact of NNP2.

Further, the impact of NNP2 on the aquatic fauna in the drawdown zone of NNP1 will be very different before and after inundation of the NNP1 reservoir. There will also be specific, short but intense impacts at the end of the construction and during the testing phase of NNP2. This potentially can be devastating for the aquatic fauna downstream.

Information on operation model and planned discharge of NNP2 is needed for management of the aquatic fauna in NNP1 inundation zone. NNP2 has a potential to annihitated mitigation measures taken by NNP1 to support *Luciocyprinus striolatus* and other fish species.

#### **6** General recommendations

Four of the endemic species have been observed mainly or only in small streams and headwaters (*Schistura* sp. n. 'Nam Youak', *Danio* sp. n., *Poropuntius* sp. n., *Oreoglanis delacouri*). The most efficient way to manage these species is to ensure that stretches of streams remain intact, under forest cover, and especially to avoid disturbance of the stream morphology and to avoid siltation in these stretches and upstream. The main cause of siltation is road construction, logging, mining and agriculture. Conservation of habitats for these species can be achieved in conjunction with the establishment of protected areas for other animals and forest. This conservation areas should extend to the uppermost part of these streams to avoid any siltation originating upstream. *Schistura* sp. n. 'Nam Youak and *Oreoglanis delacouri* inhabit torrent habitats. *Danio* sp. n. and *Poropuntius* sp. n. were found in a slower flowing forest stream.

Four of the endemic species and potentially endemic species have been observed mainly in the inundation zone, including close to FSL (*Schistura* sp. n. 'slender', *Schistura* aff. *ephelis*, *Schistura* aff. *defectiva*, *Schistura* sp. 'compact'). They apparently do not occur in headwaters and seem to require larger stream and stone substrate, which is most common in the main river and the lower parts of the main tributaries. However, site 14-009 was a small torrent-type stream and both *Schistura* aff. *ephelis* and *Schistura* sp. 'compact' were present. The efficient way to manage these species is to ensure that stretches of the Nam Ngiep and main tributaries above FSL remain intact for some distance and especially to ensure that no sediment covers the bottom of the streams.

The most interesting streams would be the Nam Youak, Nam Pouan and Nam Chae, but of these last two streams, the Nam Chae is already impacted by the construction of the Nam Chae dam, and the Nam Pouan will be impacted by the construction of the Nam Pouan dam. Smaller tributaries in the project area might have suitable habitats. The species were found near their confluence but access or security reasons did not allow to sample them further away from the main river (Houay Hok, site14-003; Nam Khai, site 14-006; Houay San, site 14-007).

Judging from maps, these species should also occur further upstream on the Nam Ngiep and other tributaries upstream of the surveyed area, for example the Nam Siam upstream of the NNP2 power house. Again, security reasons do not allow to sample this area.

Poropuntius aff. carinatus occurs in both stream types.

#### Annex 1. Luciocyprinus striolatus, data from interviews

Interviews were conducted upstream of FSL in Ban Thaviang, Ban Viengta and Ban Pou, and downstream of the dams site in Ban Xomxeun.

Luciocyprinus striolatus is called Pa Kouan Say upstream and Pa Ern downstream. The name Pa Kharm earlier reported in Ban Thathom is erroneous and resulted from confusion with Raiamas guttatus.

#### **Ban Viengta**

Information obtained from a fisherman usually working between Ban Viengta and Ban Soppouan.

*Luciocyprinus striolatus (L. s.)* extends upstream to Sop Syem [7 km upstream of Ban Thaviang, near NNP2 power house]. He has fished in Sop Syem and in the Nam Ngiap upstream but has not seen *L. s.* upstream. He thinks it is not present because the river is too steep and the water too cold.

According to him, *L. s.* is present in Nam Chae. He guesses that its distribution extends downstream to Mekong because he sees more individuals downstream near Sop Pouan but in fact he has never been further downstream). Maybe *L. s.* migrates because it is rare in dry season in Ban Viengta. At an usual fishing site about 8-10 km dowstream of Ban Pou, the fish is also rarer at the same time as in the village.

L. s. is usually caught in sectors about 2 m deep, between rapids and pools.

*L. s.* breeds in November. He knows it because he has seen a pair spawning, he caught one by net. The fish caught was a female that released eggs when brought out of the water. This is the only time he obsrved actual spawning. This spawning site was about 1 km downstream of village (not clear whether Ban Viengta or Ban Pou), at Wang Mon 'beach', on sand, in very shallow water, the back of the fishes was outside the water. Several pairs were observed at the same time on this 'beach'.

#### Ban Pou

Information obtained from three fishermen, fishing mainly between Nam Chae and Ban Pou.

*L. s.* lives in deep water, downstream of strong current but before deep pools. The depth is at least 2 m.

The distribution of *L. s.* extends upstream to Ban Sop Syem. They guess that *L. s.* is not present upstream because the river is too small and not deep enough. (But they do not go fishing upstream of Sop Syem; they have seen the river and think the fish cannot live there).

They guess that *L. s.* might go downstream to the Mekong, because the water is deeper downstream, but they do not go fishing downstream of Ban Sopppouan, because their boats cannot pass the rapids. They fish in the Nam Chae but they do not catch *L. s.* in that river. They know that villagers in Ban Soppouan go fishing in Nam Pouan, but they have never seen *L. s.* among the catches obtained from that river.

*L. s.* spawns only in December. They observed it at Kaen Tao 'beach', about 4 km downstrean of Ban Pou. Kaen Tao is about opposite sampling site 14-005. Only one of them has seen actual spawning and only once. The water was 40-50 cm deep and the back of the fish was out of the water. They have seen a small group spawning; they counted 4 but there were probably more. They killed one by gun. It was about 1.5 m long (when carried by two people on a pole, the tail was touching the ground). It was a female, 22 kg, of which 1 kg of eggs. Females grow larger than males.

Juveniles live in whirl pools downstream of rapids. At around 40 cm they are caught by gill nets, with 40-50 mm meshes. The fishermen guess that smaller juveniles also inhabit the same area.

*L. s.* moves downstream to big pools from November to May.

The fishermen think that there are also some large *L. s.* in Sop Syem, but they cannot be as big as downstream. Large individuals are not known from Ban Pou; they occur only from Kaen Tao downwards.

#### **Ban Thaviang**

Information obtained from villagers who catch between Sop Pouan and Ban Houay Pa Mom.

In the dry season, the river upstream of Ban Thaviang is too shallow for L. s.

*L. s.* spawns in shallow, flowing water. Mentioned supposed spawning sites are Keng Mai and Keng Mgoua near Sop San (site 14-007). *L. s.* spawns in January-March. It breeds in groups of about 10 individuals (they know because they hunt them with guns when they see groups of big fish). The fishes make a group in very close contact.

The maximum size is 1.5 m, up to 16 kg.

*L. s.* is also known from upstream until the upper part of Thaviang, but it only reaches a smaller size and there they are caught by net. The maximum known upstream extent is Sop Syem (Ban Sop Syem).

#### Ban Xomxeun.

Information obtained from 3 fishermen.

This village is located on the Nam Ngiep, it is the second village downstream of the dam site. *L. s.* is recognised on the photograph as Pa Ern. It is caught in October-November at Hat Nguen, below the confluence of Nam Ngiep and Nam Xao. They never catch *L. s.* at other times of the year.

*L. s.* is caught with 'drifting gill net'. The fish caught are about 60 cm. They never catch larger individuals, but this might be because the meshes they use (80 mm) would not allow to catch bigger fish. They have never see smaller individuals, although they also catch with smaller meshes. The fish they catch never have eggs or sperm.

#### Conclusions

Fish are observed downstream only at the end of the rainy season, when the discharge is highest; these are apparently vagrant individuals that came downstream with the current. This does not seem to be migrating individuals. This is very few km upstream of the confluence with the Mekong. If this species were migrating to the Mekong, it would certainly already have been noted by surveys and fisheries studies in Laos and Thailand.

The maximum extent of the species upstream is Sop Syem, about 15 km upstream of Ban Thaviang, near NNP2 power house. The species is reported not to grow as big as downstream, but there are still large individuals, and possibly spawning locally. Larger individuals and higher density are downstream of Ban Pou.

*L. s.* inhabits fast water between rapids and large pools. For spawning, it comes towards the shore, along beaches of pebbles, gravel or sand. These are shallow water habitats in the wet season, probably several meters above river level in the dry season.

Largest recorded individuals are females, about 1.5 m long. Males are smaller. On spawning sites, they form small groups and spawn (apparently as pairs) in shallow water, about 40-50 cm deep.

Spawning time is November-December. The mention of spawning in January-March seems less well informed. However, there might be local variation. For comparison, the information I obtained in the Nam Theun was that the species spawns in January-February in rapids (Kottelat, 1996); in 2002 I was told that in the Nam Kading drainage it spawns in October-December.

In the inundation zone, the two mentioned sites close to FSL are Kaen Tao 'beach', about 4 km downstrean of Ban Pou, opposite site 14-005 (19°00'00.4"N 103°28'50.0"E) and Wang Mon 1 km downstream of Ban Pou.

#### Annex 2. Fishes of Nam Ngiep drainage, upstream of damsite

Note: Not all species are figured. Material suitable for photography was not obtained for all species (small juveniles, individuals already cut in pieces for cooking, etc.).

#### Bagridae

Hemibagrus nemurus, 98 mm SL

Hemibagrus wyckioides, about 400 mm SL

### Balitoridae

Balitora lancangjiangensis, 62 mm SL

Hemimyzon confluens, 57 mm SL

Homaloptera yunnanensis, 58 mm SL

#### Channidae

*Channa gachua*, 89 mm SL

#### Clariidae

Clarias batrachus, 102 mm SL

Cyprinidae

Bangana lippa, 110 mm SL

Barbodes aurotaeniatus, 62 mm SL

Cirrhinus prosemion, about 500 mm SL

Danio acrostomus, 40 mm SL

*Danio* sp. n., 55 mm SL

Esomus metallicus, 36 mm SL

*Garra cambodgiensis*, 77 mm SL

Garra theunensis, 121 mm SL

Hampala macrolepidota, 65 mm SL

Mystacoleucus greenwayi, 86 mm SL

*Mystacoleucus marginatus*, 82 mm SL

Neolissochilus blanci, 80.0 mm SL

Onychostoma aff. gerlachi, 126 mm SL

*Opsarius pulchellus*, 88 mm SL

*Osteochilus striatus*, 58 mm SL

Poropuntius aff. carinatus, about 250 mm SL

Poropuntius normani, 88 mm SL

Poropuntius sp. n., 80 mm SL

Puntius brevis, 50 mm SL

Rasbora atridorsalis, 50 mm SL

Rasbora rubrodorsalis, 15 mm SL

Scaphiodonichthys acanthopterus, 95 mm SL

Systomus jacobusboehlkei, 73 mm SL

#### Gobiidae

Papuligobius ocellatus, 56 mm SL

*Rhinogobius albimaculatus*, male, 56 mm SL (above) and female, 49 mm SL (below)

#### Mastacembelidae

Mastacembelus armatus, 270 mm SL

Nemacheilidae

*Nemacheilus platiceps*, 52 mm SL

Schistura coruscans, 68 mm SL

*Schistura defectiva*, 49 mm SL

Schistura dorsizona, 33 mm SL

Schistura aff. defectiva, 33 mm SL

Schistura aff. ephelis, 65 mm SL

Schistura sp. 'compact', 47 mm SL

Schistura sp. n. 'Nam Youak', 38 mm SL

#### Sisoridae

*Glyptothorax horai*, 90 mm SL

Glyptothorax laosensis, 57 mm SL

*Glyptothorax* aff. *zanaensis*, 74 mm SL

Oreoglanis delacouri, 104 mm SL

Pseudecheneis sympelvica, 40 mm SL

#### Synbranchidae

Monopterus albus, 295 mm SL

Tetraodontidae

Pao turgidus, 60 mm SL

Remarks:

## \* = Introduced species X = occurrence

- VC = very common
- C = common

<sup>1</sup>Abundance:

LC = Less common

<sup>2</sup>Conservation Status: refers to the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF, dated 8th Dec. 2003

- <sup>3</sup>IUCN Red List Status: IUCN (2013)
- CR = critically endangered
- EN = endangered
- VU = vulnerable
- NT = near threaten
- LC = least concern

Annex I

Critical Habitat Candidate Species Profiles

| Species      | Afzelia xylocarpa   |
|--------------|---|
| Candidate    | Criterion 1 – The species is listed as Endangered on the IUCN Red List  |
| Criteria     |   |
| Record       | Direct  |
|              | TISTR 2013 survey recorded the species at the main dam inundation, re-  |
|              | regulation dam inundation, resettlement area, transmission line, Huay Ngua  |
|              | and upper and lower Nam Ngiep sampling plots.   |
|              | NUL ground-truthing of the access road did not detect the species within the  |
|              | search areas.   |
|              | Indirect  |
|              |   |
| Distribution | The species is native to Cambodia, India, Lao PDR, Myanmar, Thailand and  |
|              | Viet Nam. TISTR survey detected the species at a number of locations  |
|              | throughout the Nam Ngiep catchment and it was also detected in upper and  |
|              | lower Nam Xan sampling plots. Specialists advice from Dr Pheng  |
|              | Phengsintham indicates that the distribution in Lao PDR includes Vientiane  |
|              | capital, Phouhin Namno National Biodiversity Conservation Area (pers.   |
|              | comm. 7/12/2013).   |
| Population   | Limited information is available regarding the population size of the species   |
|              | locally and globally however the direct data indicates a number of records  |
|              | locally.  |
| Habitat      | This tree is reported to grow in dense forest habitats and in transitional areas  |
|              | between evergreen and dry open dipterocarp forest. Altitude range of 100-   |
|              | 650m in areas with uniform rainfall range, 1000-1500mm/year, a dry season of  |
|              | 5-6 months, mean annual temperature of 20-32°C is listed. Flowers March-  |
| Threats      | April, fruiting September-December.   |
| Threats      | In Viet Nam the timber is values for carpentry. Other reports suggest the tree<br>is hervested for medicinal numerous pulp for cigarettee as well as wood |
|              | is harvested for medicinal purposes, pulp for cigarettes as well as wood turning  |
| Summary      | This species has been noted within a number of sampling plots during survey   |
| Summary      | of the Nam Ngiep and Nam Xan catchment hence it appears that the species is   |
|              | disturbed across the region. The species is also known from Vientiane and a   |
|              | protected area in the south of Lao PDR. Given the distribution of known   |
|              | records it is considered <b>unlikely that the Project area sustains &gt;10 per cent of</b>  |
|              | the global population (Tier 1), or, habitat of significant important or   |
|              | containing nationally important concentrations (Tier 2). Measures such as   |
|              | planting and management of harvesting threats locally will assist in managing   |
|              | the local population of the species.  |

| Species               | Anisoptera costata   |
|-----------------------|--|
| Candidate<br>Criteria | Criterion 1 - The species is listed as Endangered on the IUCN Red List   |
| Record                | Direct<br>TISTR 2013 survey recorded the species in a sampling plot within the Huay<br>Ngua PPA survey in lower mixed deciduous forest habitat. The species was<br>also detected in the lower Nam Xan survey location.<br>DFRM road corridor survey identified 254 stems of the species.<br>NUL ground-truthing survey identified the species within and outside of the<br>proposed access road corridor.<br><i>Indirect</i> |
| Distribution          | The species is native to Brunei, Cambodia, Indonesia, Malaysia, Myanmar,<br>Philippines, Singapore, Thailand and Viet Nam (Ashton, 1998c). It is not<br>reported to be native to Lao PDR. TISTR survey detected the species at a<br>number of locations throughout the Nam Ngiep catchment.  |
| Population            | Limited information is available regarding the population size of the species locally and globally however the recent survey noted the species as a dominant tree species within the proposed access road and in the adjacent area.  |
| Habitat               | It is reported to grow in semi-evergreen dipterocarp, evergreen and humid lowland forest.  |
| Threats               | The species is an economic tree and used for house construction.   |
| Summary               | This species was detected in the Huay Ngua PPA survey locations (by TISTR 2013) and more recently during ground-truthing of the disturbance corridor (by NUL 2013).<br>The species is not native to Lao PDR and as such is not considered a priority biodiversity value. <b>The species is not a candidate for critical habitat within the Project area.</b>   |

| Species      | Dalbergia oliveri  |
|--------------|--|
| Candidate    | Criterion 1 – The species is listed as Endangered on the IUCN Red List         |
| Criteria     |  |
| Record       | Direct   |
|              | TISTR 2013 survey recorded the species within the main dam, re-regulation      |
|              | dam, resettlement area, transmission line, upper Nam Ngiep, Huay Ngua amd      |
|              | upper Nam Xan survey areas.  |
|              | NUL ground-truthing of the access road did not detect the species within the   |
|              | search areas.  |
|              | Indirect   |
|              | -  |
|              |  |
|              |  |
| Distribution | This species is not native to Lao PDR. It is native to Myanmar, Thailand and   |
|              | Viet Nam. TISTR survey detected the species at a number of locations           |
|              | throughout the Nam Ngiep catchment.  |
| Population   | Limited information is available regarding the population size of the species  |
|              | locally and globally.  |
| Habitat      | It is reported to be scattered among dense evergreen and semi-deciduous        |
|              | forest of up to 1200 m elevation.  |
| Threats      |  |
| Summary      | The species is not native to Lao PDR and as such is not considered a priority  |
|              | biodiversity value. The species is not a candidate for critical habitat within |
|              | the Project area.  |
| References   | Nghia, N.H. 1998. Dalbergia oliveri. In: IUCN Red List of Threatened Species.  |

| Species               | Dipterocarpus alatus  |
|-----------------------|---|
| Candidate<br>Criteria | Criterion 1 – The species is listed as Endangered on the IUCN Red List  |
| Record                | Direct<br>TISTR 2013 survey recorded the species in upper and lower Nam Ngiep<br>survey locations as well as Huay Ngua and lower Nam Xan survey locations.<br>NUL ground-truthing survey identified the species along the JICA Road and<br>outside of the access road corridor.<br>Indirect   |
| Distribution          | This species is not native to Lao PDR. It is native to Bangladesh, Cambodia,<br>India, Myanmar, Philippines, Thailand and Viet Nam. The species is common<br>in Southeast Asian countries. Phengsintham (2013) notes recording the species<br>in several Lao PDR provinces including Vientiane capital, Bolikhamxay,<br>Khammouane, Savannekhet, Saravane, Champasak and Attapeu. |
| Population            | Limited information is available regarding the population size of the species locally and globally however the NUL survey noted the species both within the proposed access road and in the adjacent area.  |
| Habitat               | In Indo-China and Thailand the species occurs gregariously along river banks,<br>and in the Philippines it is found in mixed dipterocarp forest. It is a tropical<br>tree of dense evergreen and mixed dense forest.  |
| Threats               | The major threat to the species is habitat loss. In Cambodia it is a valued construction timber and resin used for proofing and traditional medicine.   |
| Summary               | This species was detected in the Project area at a number of survey locations.<br>The species is not native to Lao PDR and as such is not considered a priority<br>biodiversity value. <b>The species is not a candidate for critical habitat within<br/>the Project area.</b>  |
| References            | Ashton, P. 1998. <i>Dipterocarpus alatus</i> . In IUCN 2013. IUCN Red List of Threatened Species Version 2013.1. <u>www.iucnredlist.org</u> . Downloaded on 21 August 2013.   |

| Species      | Dipterocarpus turbinatus   |
|--------------|--|
| Candidate    | Criterion 1 – The species is listed as Critically Endangered on the IUCN Red     |
| Criteria     | List   |
| Record       | Direct   |
|              | TISTR 2013 survey recorded the species at main dam, re-regulation dam,           |
|              | upper Nam Ngiep and the Huay Ngua PPA as well as lower Nam Xan survey            |
|              | locations.   |
|              | NUL ground-truthing of the proposed assess road did not detect the species       |
|              | within the search areas.   |
|              | ERI 2007 survey recorded the species in dry evergreen forest, mixed deciduous    |
|              | forest and unstocked forest in the main dam survey area.                         |
|              | Indirect   |
|              | -  |
|              |  |
|              |  |
| Distribution | The species is native to Bangladesh, Cambodia, India, Lao PDR, Myanmar,          |
|              | Thailand and Viet Nam. TISTR survey detected the species at a number of          |
|              | locations throughout the Nam Ngiep catchment. Hossain and Nath note that in      |
|              | Bangladesh the species scattered in the tropical ever-green forests and tropical |
|              | semi-evergreen forests of Chittagong, Chittagong Hill Tracts, Cox's Bazar and    |
|              | Sylhet while in Myanmar the species has a comparatively wide distribution in     |
|              | tropical semi-evergreen forests and tropical moist deciduous forest. Dr Pheng    |
|              | Phengsintham indicated that the distribution in Lao PDR includes Vientiane       |
|              | province (pers. comm. 7/12/2013).  |
| Population   | Limited information is available regarding the population size of the species    |
|              | locally and globally.  |
| Habitat      | The species is found in mixed deciduous, evergreen and semi-evergreen            |
|              | forests. It is reported to often occur in wet dense forest.                      |
| Threats      | In some countries the resin of the tree is used to prepare torches.              |
| Summary      | This species has been noted within a number of the Project area survey           |
|              | locations and affords a distribution across a number of countries outside Lao    |
|              | PDR. Given the distribution of known records it is considered unlikely that      |
|              | the Project area sustains >10 per cent of the global population (Tier 1), or,    |
|              | habitat of significant important or containing nationally important              |
|              | concentrations (Tier 2). Measures such as planting and management of             |
|              | harvesting threats locally will assist in managing the local population of the   |
|              | species.   |

| Species      | Hopea ferrea   |
|--------------|--|
| Candidate    | Criterion 1 - The species is listed as Endangered on the IUCN Red List         |
| Criteria     |  |
| Record       | Direct   |
|              | TISTR 2013 survey recorded the species in upper Nam Ngiep survey locations     |
|              | however the species was not detected in other survey areas.                    |
|              | ERI 2007 survey recorded the species in mixed deciduous forest and unstocked   |
|              | forest in the main dam survey area.  |
|              | Indirect   |
|              | -  |
|              |  |
|              |  |
| Distribution | The species is native to Cambodia, Malaysia, Myanmar, Thailand and Viet        |
|              | Nam. This species is not native to Lao PDR.                                    |
| Population   | Limited information is available regarding the population size of the species  |
|              | locally and globally.  |
| Habitat      |  |
| Threats      | The species is commercially traded as an important timber tree.                |
| Summary      | This species was detected in the Project area at a number of survey locations. |
|              | The species is not native to Lao PDR and as such is not considered a priority  |
|              | biodiversity value. The species is not a candidate for critical habitat within |
|              | the Project area.  |

| Species      | Shorea roxburghii, White Meranti  |
|--------------|---|
| Candidate    | Criterion 1 – The species is listed as Endangered on the IUCN Red List                |
| Criteria     |   |
| Record       | Direct  |
|              | TISTR 2013 survey recorded the species in resettlement, transmission line,            |
|              | upper and lower Nam Ngiep and Huay Ngua PPA as well as upper and lower                |
|              | Nam Xan survey locations.   |
|              | The NUL ground-truthing survey (2013) of the proposed access road did not             |
|              | detect the species within the search areas.   |
|              | Indirect  |
|              | -   |
|              |   |
| Distribution | The species is native to Cambodia, India, Lao PDR, Malaysia, Myanmar,                 |
| Distribution | Thailand and Viet Nam. TISTR survey detected the species at a number of               |
|              | locations throughout the Nam Ngiep catchment. Phengsintham (2013) notes               |
|              | recording the species in several Lao PDR provinces including Vientiane                |
|              | capital, Savannekhet and Road no 13.  |
| Population   | Limited information is available regarding the population of the species,             |
| 1            | though healthy regenerating subpopulations are reported in the south of India.        |
| Habitat      | The species is considered unusual for its adaptation to withstand adverse             |
|              | climatic conditions and soil types. It occurs in dry evergreen or deciduous           |
|              | forest and bamboo forest, often on sandy soils.                                       |
| Threats      |   |
| Summary      | This species has been noted within a number of the Project area survey                |
|              | locations and affords a distribution across a number of countries outside Lao         |
|              | PDR. Given the distribution of known records it is considered <b>unlikely that</b>    |
|              | the Project area sustains >10 per cent of the global population (Tier 1), or,         |
|              | habitat of significant important or containing nationally important                   |
|              | concentrations (Tier 2). Measures such as planting and management of                  |
|              | harvesting threats locally will assist in managing the local population of the        |
| Defens       | species.  |

| Species      | Vatica cinerea  |
|--------------|---|
| Candidate    | Criterion 1 – The species is listed as Endangered on the IUCN Red List          |
| Criteria     |   |
| Record       | Direct  |
|              | TISTR 2013 survey did not record the species.                                   |
|              | A survey undertaken by the Department of Forestry Resource Managemen            |
|              | along a section of the proposed access road detected one individual.            |
|              | NUL ground-truthing did not detect the species within the search area.          |
|              | Indirect  |
|              | -   |
|              |   |
|              |   |
| Distribution | This species is not native to Lao PDR. Is native to Cambodia, Malaysia          |
|              | Myanmar, Thailand and Viet Nam.   |
| Population   | Limited information is available regarding the size of the population of the    |
|              | species and habitat preferences.  |
| Habitat      | This small species is reported to flourish in exposed areas, occurring on rocky |
|              | dry land and in bamboo forest.  |
| Threats      |   |
| Summary      | The species is not native to Lao PDR and as such is not considered a priority   |
|              | biodiversity value. The species is not a candidate for critical habitat within  |
|              | the Project area.   |
| References   | Ashton, P. 1998. Vatica cinerea. In IUCN 2013. IUCN Red List of Threatened      |
|              | Species Version 2013.1. www.iucnredlist.org. Downloaded on 12 Septembe          |
|              | 2013.   |

| Species      | Aonyx cinerea, Asian small-clawed otter   |
|--------------|---|
| Candidate    | Criterion 1 – The species is listed as Restricted in the Regulation of the Ministry   |
| Criteria     | of Agriculture and Forestry No. 0360/MAF.   |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey did not record the species.  |
|              | ERI 2007 biodiversity survey did not record the species.  |
|              | T 1' /  |
|              | Indirect  |
|              | Biodiversity village surveys in 2013 apparently recognised the species in the   |
|              | upper Nam Ngiep area.   |
|              | Note: Verbal village information on otters is close to impossible to assign to  |
|              | species despite the often overconfident presentation in interview reports.  |
|              | These reports are thus no more than weakly indicative of Small-clawed otter presence in the Project area. However, otters as a group are readily recognised |
|              | and because no otter species remains widespread or common in Lao PDR, the   |
|              | information at group level remains of value. Reports of otters may also include   |
|              | Eurasian otter <i>Lutra lutra</i> as well as the two species treated here.  |
| Distribution | The species has a large distribution range, extending from India, eastward  |
| 210010 ution | through south-east Asia to the Philippines, and north to Taiwan and southern  |
|              | China.  |
| Population   | A reliable population estimate of the Asian Small-clawed otter is lacking.  |
| - r          | Duckworth et al (1999) noted that the species was then probably widespread in   |
|              | Lao PDR with populations considered to be of moderate global significance. In   |
|              | northern Lao PDR, records have been noted in Nam Kading and Nam Theun,  |
|              | with other records in central and southern Lao PDR (Duckworth et al 1999).  |
|              | Since then, massive declines in otters across northern southeast Asia render it   |
|              | likely that the species has disappeared from, or been reduced to non-viably   |
|              | low populations within, some or many of the Lao PDR catchments it formerly  |
|              | inhabited.  |
| Habitat      | Habitat use apparently varies across its wide range. In Indonesia, the typical  |
|              | habitats of the species in are wetland systems having pools and stagnant  |
|              | water, including shallow stretches, with depths less than one metre. In the   |
|              | Western Ghats of India, it seems tied to streams through forest and tree  |
|              | plantations in evergreen and semi-evergreen areas, with no records from the   |
|              | sort of agricultural and urban landscapes it typically uses in Java. Original   |
|              | habitat use in Lao PDR is unknown; recent hunting is likely to have removed it  |
|              | from accessible and even some remote areas. Asian small-clawed otters have a  |
|              | high climatic and trophic adaptability in south and south-east Asian tropics,   |
| <b>11</b>    | occurring from coastal wetlands up to mountain streams.   |
| Threats      | Throughout Asia the main threat to the species is trade-driven hunting. The   |
|              | drivers and dynamics of this are poorly understood, particularly in southeast   |
|              | Asia. Habitat destruction due to development activities may be a local threat,  |
|              | but the species remains widespread in Java in, for example, towns and paddy-  |
|              | dominated landscapes. Other threats might include degradation of water<br>quality due to the use of agrochemicals in catchments, and reduction in prey      |
|              | due to over-exploitation. In Lao PDR over the last 15 years these have all been,  |
|              | if relevant at all, dwarfed by the effects of hunting.  |
| Summary      | The general patterns in northern southeast Asia suggest it is unlikely that   |
| C aminiar y  | hunting will not have reduced this species to very low numbers in the Project   |
|              | area. There is no situational reason to expect an anomalously high survival in  |
|              | the Project area (which could potentially now qualify as critical habitat) and  |
|              | the record is a weak indication of the species, but this cannot be excluded. The  |
|              | key threats relate to hunting and degradation of aquatic environments and   |
|              | although current information does not confirm critical habitat, the   |
|              | precautionary approach should be considered and the threats to the species  |
|              | should be managed throughout the Project construction and operation and   |
|              | should be hunded unoughout the froject construction and operation and   |

| Species    | Aonyx cinerea, Asian small-clawed otter  |

| Species      | Canis aureus, Golden jackal   |
|--------------|---|
| Candidate    | Criterion 1 - The species is listed as Restricted in the Regulation of the Ministry   |
| Criteria     | of Agriculture and Forestry No. 0360/MAF.   |
| Record       | Direct<br>TISTR 2013 biodiversity survey did not record the species.  |
| Distribution | Indirect<br>Biodiversity village surveys in 2013 apparently recognised the species in the<br>upper Nam Ngiep area.<br>Stakeholder village surveys in 2013 apparently recognised the species<br>reporting it as very common at Ban Xomxuen, Ban Kanyong and Ban<br>Pakheuang thugh never encountered at Ban Pou, Ban Pakyong or Ban Don.<br>The Project EIA (2007) notes the species occurrence within and outside the<br>Project area based on a secondary data source though no location is specified.   |
| Distribution | The species is widespread in north and north-east Africa, occurs in the Arabian Peninsula, parts of Europe, Turkey, Syria, Iraq, Iran, Central Asia, the entire Indian subcontinent, and east and south to Sri Lanka, Myanmar, Thailand and parts of Indo-China. The species is fairly common throughout its range. Duckworth et al. 1999 noted the species to occur in southern Lao PDR (Xe Pian and Dong Khanthung) though there are provisional records in northern and central Lao PDR. It has since been found on the Nakai plateau (before inundation) and Phou Phanang NPA northwest of Vientiane. |
| Population   |   |
| Habitat      | All records in Lao PDR and surrounding areas come from deciduous dipterocarp forest and other open, deciduous forests, and also, in areas where hunting is relatively low, cleared evergreen areas. There are no records from interior evergreen forest. As such, the species is highly restricted in Lao PDR, because most suitable habitats are too heavily hunted for it to survive. It seems, for example, to be on the brink of extinction on the Nam Ngum plain.  |
| Threats      | Hunting, apparently primarily as by-catch or in retaliation for livestock-killing<br>is the main threat in Lao PDR; there is no evidence of any trade demand. Given<br>its tolerance of habitat degradation (and, in fact, it is likely to have benefitted<br>in southeast Asia from encroachment into evergreen forest areas, where<br>hunting is relatively low, as indicated by the recent colonisation of Khao Yai<br>NP and environs, Thailand), the Lao PDR population could be much higher<br>than it presently is.  |
| Summary      | The species has a large global range; Lao PDR is on the edge of this. Numbers<br>in the Project area are likely insignificant given the much larger, and growing<br>populations in Thailand and probably Cambodia. Although numbers in Lao<br>PDR are now probably small, there is no reason to indicate the Project area has<br>any particular role for conserving the species compared with the many other<br>landscapes of similar habitat in the country. <b>As such the Project area is</b><br><b>considered unlikely to be critical habitat for the species.</b>                                    |

| Species      | Capricornis milneedwardsii, Southwest China serow                                    |
|--------------|--|
| Candidate    | Criterion 1 - The species is listed as Restricted in the Regulation of the Ministry  |
| Criteria     | of Agriculture and Forestry No. 0360/MAF.  |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not record the species.                           |
|              | ERI 2007 biodiversity survey did not record the species.                             |
|              | Indirect   |
|              | Biodiversity village surveys in 2013 apparently recognised the species in the        |
|              | upper Nam Ngiep area.  |
|              | Stakeholder village surveys in 2013 apparently recognised the species                |
|              | reporting it as very common at Ban Xomxuen, common at Ban Pakyong                    |
|              | though never encountered at Ban Pou, Ban Kanyong, Ban Pakheuang or Ban               |
|              | Don.   |
| Distribution | This species occurs in much of Myanmar, Cambodia, south and central China,           |
|              | Lao PDR, Thailand, and Viet Nam.   |
| Population   | No total estimates of population size have been made, however in Lao PDR,            |
|              | this species is still widespread, and despite heavy hunting, it is consistently      |
|              | present in areas of suitable habitat.  |
| Habitat      | Accounts from throughout the species range report the species inhabits rugged        |
|              | steep hills and rocky places, especially limestone regions up to 4,500 m.            |
|              | However, the species is also routinely recorded (by camera-trapping) in hill         |
|              | and mountain forest areas with gentler terrain.                                      |
| Threats      | Threats to the species include hunting, to which it seems remarkably resilient.      |
|              | Habitat loss for agricultural expansion, and habitat degradation from clearance      |
|              | for firewood and timber, are also negatively affecting the population                |
|              | somewhat, in large parts through fragmenting and increasing accessibility to         |
|              | areas of remaining unconverted habitat.  |
| Summary      | Serows plausibly remain widespread and locally common in the Project area,           |
|              | but this is equally true of much of hilly north and central Lao PDR. The Project     |
|              | area is only a small proportion of the nation's total such habitat and as such       |
| <b>D</b> (   | would not be expected to constitute critical habitat.                                |

|              |   |
|              | Indirect  |
|              | Biodiversity village surveys in 2013 apparently recognised the species in the     |
|              | upper Nam Ngiep area.   |
|              | Stakeholder village surveys in 2013 apparently recognised the species             |
|              | reporting that it is very commonly encountered in Ban Pou, Ban Xomxuen, Ban       |
|              | Pakyong and Ban Don though never encountered in Ban Kanyong and Ban               |
|              | Pakheuang villages.   |
|              | The Project EIA (2007) notes the species occurrence within and outside the        |
|              | Project area based on a secondary data source though no location is specified.    |
| Distribution | The species is native to Bangladesh, Bhutan, Cambodia, China, India,              |
|              | Indonesia, Kazakhstan, Kyrgyzstan, Lao PDR, Malaysia, Mongolia, Myanmar,          |
|              | Nepal, Russian Federation, Tajikistan, Thailand and Viet Nam. The species is      |
|              | thought to have ranged over most of Lao PDR, Cambodia, Viet Nam and               |
|              | Thailand although reliable site-specific information is scarce. Duckworth et al   |
|              | 1999 note the species to occur in north Lao (Phou Khaokhoay) and in southern      |
|              | Lao (Dong Hua Sao, Xe Pian and Dong Khanthung) and there are more recent          |
|              | records from various other survey areas such as the Nakai plateau and Nam Et      |
|              | Phou Louey NPA.   |
| Population   | It is estimated that fewer than 2,500 mature individuals remain in the wild       |
|              | with a declining population trend. The Lao PDR population is not known,           |
|              | although the species evidently remains considerable more widespread in Lao        |
|              | PDR than do the big cats.   |
| Habitat      | The species is found in a wide variety of vegetation types including primary,     |
|              | secondary and degraded tropical dry and moist deciduous forest, evergreen         |
|              | and semi-evergreen forests, dry thorn forests, grassland scrub forest mosaics     |
|              | and alpine steppe. Habitat selection factors include the availability of medium   |
|              | to large ungulate prey, water, presence of other large carnivores, suitability of |
|              | breeding sites and human population levels.                                       |
| Threats      | The most important threat in Lao PDR is likely to be hunting, although this is    |
|              | usually as by catch in retaliation for livestock killing; as yet there is no      |
|              | evidence of significant trade demand. Secondary threats include habitat loss,     |
|              | depletion of prey population, interspecific competition, persecution and          |
|              | possibly disease.   |
| Summary      | Dholes plausibly remain widespread and perhaps even locally common in the         |
|              | Project area; but this is equally true of much of hilly north and central Lao     |
|              | PDR. The Project area is only a small proportion of the nation's total such       |
|              | habitat and as such would not be expected to constitute critical habitat.         |

| Species      | Elephas maximus, Asian elephant  |
|--------------|--|
| Candidate    | Criterion 1 - The species is listed as Endangered on the IUCN Red List and is  |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and  |
|              | Forestry No. 0360/MAF.   |
| Record       | <i>Direct</i> TISTR 2013 biodiversity survey did not record the species.   |
|              | TISTR 2015 bloulversity survey the not record the species.   |
|              |  |
|              | Indirect   |
|              | The Huay Ngua MP (2010) notes presence of the species within the provincial  |
|              | preserved area.  |
|              | Stakeholder village surveys in 2013 recognised the species reporting it is not<br>commonly encountered in Ban Pakyong and never seen in Ban Pou, Ban           |
|              | Xomxuen and Nam Xan villages.  |
|              | The Project EIA (2007) notes the species occurrence within and outside the   |
|              | Project area based on a secondary data source though no location is specified.   |
| Distribution | The species is native to Bangladesh, Bhutan, Cambodia, China, India,   |
|              | Indonesia, Lao PDR, Malaysia, Myanmar, Nepal, Sri Lanka, Thailand and Viet   |
|              | Nam (Choudhury et al. 2008). Populations in Lao PDR are now numerically  |
|              | insignificant compared with those of south Asia, but in the context of even  |
|              | steeper declines in Vietnam and China and similar ones in Cambodia, they are<br>highly significant in the maintenance of ancestral range.                      |
|              | The species in Lao PDR is reported to be widely, but very patchily distributed   |
|              | in forested areas (highlands and lowlands) with potentially important  |
|              | populations Nam Phouy west of the Mekong and in northern Lao PDR; in   |
|              | Phou Phanang and Phou Khao Khoay in Vientiane Province; Nakai Nam  |
|              | Theun NPA and surrounding in Khammouane Province; Phou Xang He NPA   |
|              | in Savannakhet Province; Dong Ampham, Dong Khanthung, Xe Pian, close to  |
|              | Cambodian border; and Nam Et, Nam Xam, Phou Dendin, and Nam Ha in the north, close to the Vietnamese and Chinese borders. However recent                       |
|              | information on most of these areas is sparse.  |
|              | Near the Project area, potentially important elephant populations have been  |
|              | reported at Phou Phanang and Phou Khao Khoay to the west (approximately  |
|              | 20 km) and Nam Xan.  |
|              | An area to the east (approximately 20 km) of Huay Ngua PPA is considered   |
|              | important for a population of elephants that links to Nam Kading National  |
| Population   | Protected Area (pers comm. Kham khoun Khounboline 19/11/2013).   |
| Population   | It was estimated in 2003 that the global population of the species is between 41,410 and 52,345 (however this has been contested) which includes between       |
|              | 500 and 1000 in Lao PDR.   |
|              | Estimate of national population is expected to be larger than the 200-500  |
|              | estimated in Lair (1997) and the Lao PDR population has been considered to be  |
|              | the most important national population for conservation in Indochina.  |
|              | However, ongoing declines in Lao PDR and recent discoveries in Cambodia  |
| Habitat      | suggest this statement may require modification.   |
| Habitat      | The species is found in many habitat types up to at least 1200 m, remaining widely distributed in forested, hilly areas. The species is a generalist occurring |
|              | in grassland, evergreen forest, semi-evergreen forest, moist deciduous forest,   |
|              | dry deciduous forest, dry thorn forest, scrublands and cultivated and  |
|              | secondary forests.   |
|              | The Asian elephant is an herbivore requiring large amounts of food per day.  |
|              | Their dung contributes to germinating seed dispersal. The home range varies  |
|              | but is considered to be large with ranges in excess of 60,000 ha recorded in   |
| Thurst       | India and only 16,000 ha range in Sri Lanka.   |
| Threats      | The overwhelming threat to the species in Lao PDR and surroundings is<br>hunting both for trade and resulting from crop destruction. Subsidiary threats        |
|              | hunting, both for trade and resulting from crop destruction. Subsidiary threats  |

| Species    | Elephas maximus, Asian elephant  |
|------------|--|
|            | include habitat loss, degradation and fragmentation, chiefly because these         |
|            | increase the likelihood of human-elephant conflict and enhance the ease of         |
|            | poaching. Large areas of prime elephant habitat in Lao PDR have already lost       |
|            | the species.   |
| Summary    | The location of the indirect records is mainly to the east of the Project area and |
|            | to the north, outside the Project area. Similarly there are a number of locations  |
|            | noted for the species other countries. As such, the Project area is not            |
|            | considered likely to be part of one of 10 or fewer habitat areas or required to    |
|            | sustain greater than 10 per cent of the global population (C1 Tier 1). The         |
|            | Project area is not a known important area in Lao PDR for the species however      |
|            | suitable habitat exists.   |

| Malaysia; Myanmar; Thailand; Viet Nam).Sun bears occur in mainland south-east Asia as far west as Bangladesh and<br>north-eastern India, as far north as southern Yunnan Province in China, and<br>south and east to Sumatra and Borneo, respectively. The species now occurs<br>very patchily through much of its former range.<br>Duckworth et al 1999 note the species to occur in central Lao PDR (Nakai-Nam<br>Theun) and in southern Lao (Phou Ahyon, Dong Ampham, Nam Ghong<br>Provincial PA, Dong Hua Sao and Xe Pian); at this stage there had been few<br>relevant surveys in northern highlands of Lao PDR. Subsequent records from,<br>e.g., Nam Et-Phou Louey NPA; suggest a former wide occurrence in that part<br>of the country.PopulationReliable estimates of sun bear populations are lacking.HabitatSun bears rely on tropical forest habitat and in mainland south-east Asia<br>inhabit seasonal ecosystems with a long dry season (3–7 months), during<br>which rainfall is 1,000m.ThreatsThe major threat to sun bears in Lao PDR is commercial hunting.SummarySun bears plausibly occur in the Project area; but this is equally true of much of<br>Lao PDR. The Project area is only a small proportion of the nation's total<br>such habitat and as such would not be expected to constitute critical habitat.ReferencesFredriksson, G., Steinmetz, R., Wong, S. & Garshelis, D.L. | Management.  |              | Conservation Society/Centre for Protected Areas and Watershed                               |
|  |              | Management.   |

| Species      | Lutrogale perspicillata, Smooth-coated otter   |
|--------------|--|
| Candidate    | Criterion 1 – The species is listed as Restricted in the Regulation of the Ministry  |
| Criteria     | of Agriculture and Forestry No. 0360/MAF.  |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not record the species.   |
|              | ERI 2007 biodiversity survey did not record the species.   |
|              |  |
|              | Indirect   |
|              | Biodiversity village surveys in 2013 apparently identified the species to occur in   |
|              | the upper Nam Ngiep area.  |
|              | Note: Verbal village information on otters is close to impossible to assign to   |
|              | species despite the often overconfident presentation in interview reports. These   |
|              | reports are thus no more than weakly indicative of Smooth-coated otter presence  |
|              | in the Project area. However, otters as a group are readily recognised and   |
|              | because no otter species remains widespread or common in Lao PDR, the  |
|              | information at group level remains of value. Reports of otters may also include  |
| Distribution | Eurasian Otter ( <i>Lutra lutra</i> ) as well as the two species treated here.   |
| Distribution | The species is distributed through much of south Asia and south-east Asia. Its distribution is largely continuous from Indonesia, through south-east Asia, and     |
|              | westwards from southern China to India and Pakistan, with an isolated  |
|              | population in Iraq.  |
| Population   | Reliable estimates of its population are not available (Hussain 2008b).  |
| ropulation   | Duckworth et al (1999) notes records from Xe Pian and Nam Ghong PPA as well  |
|              | as many signs of large otters in various localities. Duckworth et al (1999) noted  |
|              | that the species was probably widespread in Lao PDR with populations   |
|              | considered to be of moderate global significance. Since then massive declines in   |
|              | otters across northern southeast Asia render it likely that the species has  |
|              | disappeared from, or been reduced to non-viably low populations within, some   |
|              | or many of the Lao PDR catchments it formerly inhabited.   |
| Habitat      | Habitat use may vary across its wide range, but in general it seems mostly to  |
|              | occur in areas of gentle terrain, in both flowing and standing wetlands.   |
| Threats      | Throughout Asia the main threat to the species is trade-driven hunting The   |
|              | drivers and dynamics of this are poorly understood, particularly in SE Asia.   |
|              | Habitat destruction due to development activities may be a local threat but the  |
|              | species occurs in significant numbers in south India and – where not yet hunted  |
|              | out - north and central India in reservoirs and on major rivers flowing amid   |
|              | purely agricultural landscapes. Other threats might include degradation of   |
|              | water quality due to the use of pesticides in catchments, and reduction in prey  |
|              | due to over-exploitation. In Lao PDR over the last 15 years these have all been if   |
| Cummo arra   | relevant at all, dwarfed by the effects of hunting.  |
| Summary      | The general patterns in northern southeast Asia suggest it is likely that hunting will have reduced this species to very low numbers in the Project area. There is |
|              | no situational reason to expect an anomalously high survival in the Project area   |
|              | (which could potentially now qualify as critical habitat), and the record is a   |
|              | weak indication of the species, but this cannot be excluded. The key threats   |
|              | relate to hunting and degradation of aquatic environments and although current   |
|              | information does not confirm critical habitat, the precautionary approach should   |
|              | be considered and the threats to the species should be managed throughout the  |
|              | Project construction and operation and within any Biodiversity Offset Design.  |

| Species      | Manis javanica, Sunda pangolin  |
|--------------|---|
| Candidate    | Criterion 1 - The species is listed as Endangered on the IUCN Red List and is   |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF.  |
| Record       | Direct<br>TISTR 2013 biodiversity survey did not directly record the species.<br>One was photographed in the lower Nam Ngiep area in early 1999 that had<br>reportedly been collected 30 minutes' walk in a village from the village of Ban<br>Sopyouk; two more unidentified pangolins were seen then in Ban   |
|              | Houaypamom, reportedly collected a few hours' walk away. Specific location information is unavailable.  |
|              | <i>Indirect</i><br>The Huay Ngua MP (2010) notes presence of pangolins, assumed to be the species within the preserved area.  |
|              | Stakeholder village surveys in 2013 recognised pangolins, assumed to be the species is commonly encountered in Ban Pou (of Nam Ngiep) and Ban Pakheuang (of Nam Xan) and less common in Ban Xomxuen, Ban Pakyong and Ban Kanyong. He species is noted as very common at Ban Don village. The Project EIA (2007) notes the species occurrence within and outside the Project area based on a secondary data source though no location is specified.  |
|              | Note: There is some uncertainty associated with these indirect data sources for<br>the species as there can be confusion between <i>Manis javanica</i> and the other<br>pangolin species of Lao PDR, Chinese pangolin <i>M. pentadactyla</i> . However,<br>pangolins as a group are readily recognised and because no pangolin species<br>remains widespread or common in Lao PDR, the information at group level<br>remains of value.  |
| Distribution | The species ranges of much of mainland Southeast Asia, including southern<br>Myanmar through central and southern Lao PDR, Thailand, central and<br>southern Viet Nam, Cambodia, Peninsular Malaysia, Sumatra, Java and<br>Borneo. In Lao PDR it is expected that the species is restricted to the Mekong<br>plain and adjacent foothills to around 900 m, with potential occurrence in the<br>Bolaven Plateau. Duckworth et al 1999 noted records from many survey areas<br>in the 1990s. However very high levels of trade-driven hunting since hen |
|              | suggest that pangolins are likely now to be very rare and plausibly widely<br>extirpated from suitable habitat in Lao PDR.  |
| Population   | The species is rarely observed and as such population size information is<br>unavailable. The species is noted as common in parts of Singapore and<br>relatively common Sabah though reports of substantial declines are noted in<br>areas of Viet Nam and Lao PDR.   |
| Habitat      | Found in primary and secondary forest as well as cultivated areas, gardens<br>and plantations. The species inhabits hollows for sleeping and den sites and as<br>such primary forest might occupy more individuals because they contain<br>higher numbers of older, larger trees with suitable hollows. The species is<br>largely nocturnal and solitary, feeding on ants and termites. Home range size<br>has been estimated at 6.97 ha.   |
| Threats      | The overwhelming threat to the species is hunting for (formerly) local use and (now, almost entirely) international trade (skins, scales, meat). Pangolins are highly adaptable to some modified habitats (those with sufficient food), where not hunted.   |
| Summary      | There is some uncertainty associated with the indirect data sources for the species as there can be confusion between <i>Manis javanica</i> and other pangolin species.<br>The key threat to the species is hunting and although current information does not confirm critical habitat, the precautionary approach should be considered and the threats to the species should be managed throughout the Project   |
|              | and the threats to the species should be managed throughout the Proj<br>construction and operation and within any Biodiversity Offset Design.   |

| Species    | Manis javanica, Sunda pangolin  |

| Species      | Nomascus leucogenys, Northern white-cheeked gibbon                                  |
|--------------|---|
| Candidate    | Criterion 1 - The species is listed as Critically Endangered on the IUCN Red        |
| Criteria     | List. It also has an elevated protection status nationally and is listed as         |
|              | Restricted in the Regulation of the Ministry of Agriculture and Forestry No.        |
|              | 0360/MAF.   |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey recorded a vocalisation of a gibbon assumed to       |
|              | be the species in the upper Nam Ngiep survey area in the main dam                   |
|              | inundation area.  |
|              | Targeted primate survey was undertaken in November 2013 by Dr Phaivanh              |
|              | Phiapalath of the IUCN SSC/Primate Specialist Group which reported two              |
|              | records (vocalisation) of gibbons in uphill mountain area outside the               |
|              | inundation area.`   |
|              | Indirect  |
|              | -   |
| Distribution | The species is native to Lao PDR and Viet Nam and (now very much reduced)           |
|              | in China. In Lao gibbons probably of this species have been recorded widely in      |
|              | the northern highlands, potentially south into the northern Annamites in            |
|              | Nakai-Nam Theun and Nam Kading NPAs. However, ongoing challenges in                 |
|              | identifying gibbons to species render many claims provisional. The gibbons of       |
|              | the Nam Ngiep catchment may include this species, but may also include, or          |
|              | even be entirely comprised of Southern white-cheeked gibbon N. siki.                |
| Population   | Population numbers are highest in Lao PDR due to larger tracts of natural           |
|              | habitat remaining in comparison to Viet Nam and China where forest habitat          |
|              | is much more fragmented and hunting has been in general, at higher levels for       |
|              | longer.   |
| Habitat      | The species is strictly arboreal though there is very little behavioural ecology    |
|              | information, including home range extent. Habitat includes tall primary and         |
|              | heavily degraded evergreen and semi-evergreen forest. The diet is dominated         |
|              | by fruits and some small amounts of leaves and insects. Anecdotal reports           |
|              | suggest group sizes of 3-4 individuals.   |
|              | Targeted primate survey identified a number of key habitat areas for the            |
|              | species, though located outside the inundation area.                                |
| Threats      | Hunting has been so heavy in much of Lao PDR that many forest blocks have           |
|              | now lost gibbons entirely or support only tiny numbers. However, in some            |
|              | areas local traditional beliefs have resulted in the survival of potentially viable |
|              | numbers in areas where almost all other wildlife species of similar, or even        |
|              | much lower, sensitivity to offtake have been seriously reduced. These areas are     |
|              | particularly important in retaining gibbons in the northern half of Lao PDR,        |
|              | but general erosion of these beliefs is high threat to these remnant populations.   |
| Summary      | Key habitat areas for the species are reported by Dr Phaivanh Phiapalath at         |
|              | Phou Thin, Phouru Pha Noy, Phou Pha hua and Phou Sam Liem. These                    |
|              | locations are outside the Project area though must be considered for indirect       |
|              | impact. As such the Project area is not considered to be critical habitat           |
|              | however threat management should be considered.                                     |

| Species      | Nycticebus bengalensis, Bengal slow loris   |
|--------------|---|
| Candidate    | Criterion 1 - The species is listed as Restricted in the Regulation of the Ministry   |
| Criteria     | of Agriculture and Forestry No. 0360/MAF.   |
| Record       | <i>Direct</i> TISTR 2013 biodiversity survey did not record the species.  |
|              | <i>Indirect</i><br>Biodiversity village surveys in 2013 apparently recognised the species to occur<br>in the upper Nam Ngiep area.<br>Stakeholder village surveys in 2013 apparently recognised lorises, reporting to   |
|              | be as very common at all the villages surveyed: Ban Pou, Ban Xomxuen, Ban Pakyong, Ban Kanyong, Ban Pekheuang and Ban Don.  |
|              | The Project EIA (2007) notes the species occurrence within and outside the Project area based on a secondary data source though no location is specified.   |
| Distribution | The species has a broad distribution in south-east Asia and occurs in:<br>Bangladesh, Cambodia, southern China, north-eastern India, Lao PDR,<br>Myanmar, Thailand, and Viet Nam (except the south).  |
| Population   | In Lao PDR, the population seems to be large and occurs in both large forest tracts and in degraded and fragmented areas. In the 1990s large lorises were among the most common species seen during spotlight surveys in much of central and southern Lao PDR (the north had no comparable surveys), and – in the absence of repeat survey – the limited credible village information gathered since then suggests no major declines within remaining suitable habitat.                                       |
| Habitat      | The species is arboreal and nocturnal, and inhabits tropical evergreen rainforest, semi-evergreen forest, and moist deciduous forest (Streicher 2008b).   |
| Threats      | The species is hunted and traded for food, traditional medicine, sport and as pets. Presently, in Lao PDR, this seems to be at lower levels than in countries such as Cambodia, although an escalation of hunting pressure may occur. The species' habitat is being reduced by farming, human settlement, infrastructure development (roads, dams and transmission lines) and fires, but very large areas remain in Lao PDR and the species is not yet anywhere close to being threatened by habitat factors. |
| Summary      | This loris plausibly remains widespread and common in the Project area, but<br>this is equally true of much of Lao PDR. The Project area is only a small<br>proportion of the nation's total such habitat and as such would not be<br>expected to constitute critical habitat.  |
| References   | Streicher, U., Singh, M., Timmins, R.J. & Brockelman, W. 2008b. <i>Nycticebus bengalensis</i> . In: IUCN 2013. IUCN Red List of Threatened Species. Version 2013.1. < <u>www.iucnredlist.org</u> >. Downloaded on <b>07 November 2013</b> .   |

| Species      | Nycticebus pygmaeus, Pygmy slow loris   |
|--------------|---|
| Candidate    | Criterion 1 – The species is listed as Restricted in the Regulation of the Ministry   |
| Criteria     | of Agriculture and Forestry No. 0360/MAF.   |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey did not record the species.  |
|              |   |
|              | Indirect  |
|              | Biodiversity village surveys in 2013 apparently recognised the species to occur   |
|              | in the upper Nam Ngiep area.  |
|              | Stakeholder village surveys in 2013 recognised lorises, apparently this species,  |
|              | as very common at all the villages surveyed: Ban Pou, Ban Xomxuen, Ban  |
|              | Pakyong, Ban Kanyong, Ban Pekheuang and Ban Don.  |
|              | The Project EIA (2007) notes the species occurrence within and outside the  |
| Distribution | Project area based on a secondary data source though no location is specified.  |
| Distribution | This species is found east of the Mekong River in eastern Cambodia, southernmost China (south-eastern Yunnan), Lao PDR, and Viet Nam. In              |
|              | China it is not clear if individuals recorded are wild animals or captured  |
|              | animals brought into China from Viet Nam.   |
| Population   | In Lao PDR, the population seems to be large and occurs both in large forest  |
|              | tracts and in degraded and fragmented areas. In the 1990s small lorises were  |
|              | among the most common species seen during spotlight surveys in some parts   |
|              | of central and southern Lao PDR (the north had no comparable surveys), and –  |
|              | in the absence of repeat surveys – the limited credible village information   |
|              | gathered since then suggests no major declines within remaining suitable habitat.   |
| Habitat      | This species has been sighted in a wide variety of habitats, including primary  |
|              | evergreen and semi-evergreen forest, forest on limestone, secondary and   |
|              | highly degraded habitats, and bamboo thickets. It seems to be more common   |
|              | below 600 m.  |
| Threats      | In Viet Nam and Cambodia the species is threated by exploitation for  |
|              | medicinal purposes. Levels of exploitation in Lao PDR are significantly lower   |
|              | so far, but escalation may occur. Habitat loss, due to agriculture (woody   |
|              | plantations, annual crops and so forth), and human settlement, may be resulting in localized declines.  |
| Summary      | This loris plausibly remains widespread and common in the Project area, but   |
|              | this is equally true of much of Lao PDR. The Project area is only a small   |
|              | proportion of the nation's total such habitat and as such would not be  |
|              | expected to constitute critical habitat.  |

| Species      | Panthera pardus, Leopard   |
|--------------|--|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is  |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and  |
|              | Forestry No. 0360/MAF.   |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not directly record the species.  |
|              |  |
|              | Indirect   |
|              | The Huay Ngua MP (2010) notes presence of the species within the protected   |
|              | area.  |
|              | Biodiversity village interviews in 2013 apparently recognised the species has  |
|              | been seen in the upper Nam Ngiep area.   |
|              | The Project EIA (2007) does not note the species.  |
|              | Note: Verbal village information on cats is close to impossible to assign to   |
|              | species despite the often overconfident presentation in interview reports.   |
|              | These reports are thus no more than weakly indicative of Leopard presence in   |
|              | the Project area.  |
| Distribution | The species also occurs across most of sub-Saharan Africa, as remnant  |
|              | populations in north Africa, and in the Arabian peninsula and Sinai/Judean   |
|              | Desert (Egypt/Israel/Jordan), south-western and eastern Turkey and through   |
|              | southwest Asia and the Caucasus into the Himalayan foothills, India, China   |
|              | and the Russian Far East as well as Java and Sri Lanka. The species distribution   |
|              | includes Lao PDR. In the 1990s there were rather few confirmed records   |
|              | during extensive surveys (Duckworth et al. 1999) but methods were not very   |
|              | suitable for finding the species. There have been few records since (again in  |
|              | part reflecting the limited application of suitable methods). However, the   |
|              | extreme rarity with which big cat signs are now found in most of Lao PDR   |
|              | means that the species's distribution in the country is probably now highly  |
| Population   | fragmented.  |
| ropulation   | There is no reliable global population estimate, and population estimates for<br>India and Africa are considered unreliable. Many populations west of    |
|              | southeast Asia are believed to be increasing, and there are high levels of   |
|              | human-leopard conflict.  |
|              | In Lao PDR the identification of the species by local reports and signs is   |
|              | challenging and many claims are over-confident (as proven almost whenever  |
|              | skins or other relicts are available to be examined). The species might still be   |
|              | widespread in the Bolikhamxay province though at very low density (IEWMP   |
|              | 2006).   |
| Habitat      | In south-east Asia, the species is found in all forest types, from tropical  |
|              | rainforest to the temperate deciduous and alpine coniferous (up to 5,200 m in  |
|              | the Himalaya), and also in dry scrub and grasslands.   |
| Threats      | The massive declines in Indochina have been driven at least almost entirely by   |
|              | hunting. Suitable habitat remains widespread in Lao PDR but mostly no longer   |
|              | supports the species, at least at potentially viable levels.   |
| Summary      | Given the large range of the species, certainty of records and secondary   |
|              | information from local village representatives it is <b>unlikely that the Project</b>  |
|              | area and immediate surrounds supports greater than 10 per cent of the  |
|              | global population or habitat of significant importance.  |
|              | The key threat to the species is hunting and although current information does   |

|            | Management.   |

| Species      | Panthera tigris, Tiger  |
|--------------|---|
| Candidate    | Criterion 1 – The species is listed as Endangered on the IUCN Red List. It also   |
| Criteria     | has an elevated protection status nationally and is listed as Restricted in the   |
|              | Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF.  |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey did not directly record the species.   |
|              |   |
|              |   |
|              | Indirect  |
|              | Biodiversity village interviews in 2013 apparently recognised the species has   |
|              | been seen in the upper Nam Ngiep area and stakeholder village surveys in  |
|              | 2013 noted the species is less common in Ban Pou (upper Nam Ngiep area) and   |
|              | never seen in Ban Xomxuen, Ban Pakyong, Ban Kanyong, Ban Pakheuang and  |
|              | Ban Don.  |
|              | The Project EIA (2007) notes the species occurrence within and outside the  |
|              | Project area based on a secondary data source though no location is specified.  |
|              | Note: Verbal village information on cats is close to impossible to assign to  |
|              | species despite the often overconfident presentation in interview reports.  |
|              | These reports are thus no more than weakly indicative of Tiger presence in the  |
| Distribution | Project area.<br>There are thirteen range countries for the tiger including Bangladesh, Bhutan,   |
| Distribution | Cambodia, China, India, Indonesia, Lao PDR, Malaysia, Myanmar, Nepal,   |
|              | Russia, Thailand and Viet Nam. Duckworth et al. (1999) presented confirmed  |
|              | or plausible records from many areas of Lao PDR in the 1990s, but very heavy  |
|              | hunting in the interim cautions against assuming that Tigers persist in these   |
|              | sites (mostly not subsequently surveyed). It is possible that only one  |
|              | population remains in Lao PDR, in Nam Et-Phou Louey NPA, and those other  |
|              | recent Tiger indications, where not based on misidentification, are wandering   |
|              | animals.  |
| Population   | Population size estimates in 42 protected source sites are 2154 individuals and   |
| -            | estimates outside protected areas is poorly known. Global Tiger Recovery  |
|              | program estimates the population as 3948 across range countries. The Lao PDR  |
|              | population is likely to be a few dozen at most and possible already much  |
|              | smaller than that.  |
| Habitat      | The availability of sufficient prey base or large ungulates is a major habitat  |
|              | requirement for the species. It is estimated a tiger needs to kill 50 large prey  |
|              | animals per year. The species is generally solitary. Home range is dependent  |
|              | on prey availability but can be up to 10,000 ha.  |
| Threats      | Main threats to the species include illegal trade and habitat loss.   |
| Summary      | Given the large range of the species, certainty of records and secondary  |
|              | information from local village representatives it is unlikely that the Project  |
|              | area and immediate surrounds supports greater than 10 per cent of the   |
|              | global population or habitat of significant importance.   |
|              | The key threat to the species is hunting and although current information does  |
|              | not confirm critical habitat and there is uncertainty of the relevance of the   |
|              | village interview data, the precautionary approach should be considered and   |
|              | the threats to the species should be managed throughout the Project   |
| Roforoncos   | construction and operation and within any Biodiversity Offset Design.   |

| Species      | Pardofelis temminckii, Asiatic golden cat   |
|--------------|---|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is       |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and           |
|              | Forestry No. 0360/MAF.  |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey did not record the species.                          |
|              | A shot individual was photographed in the lower Nam Ngiep in early 1999             |
|              | that had reportedly been killed in a village near chickens, though specific         |
|              | location details are unavailable.   |
|              | Indirect  |
|              | The Huay Ngua MP (2010) notes presence of the species within the protected          |
|              | area.   |
|              | Biodiversity village interviews in 2013 apparently recognised the species in the    |
|              | upper Nam Ngiep area.   |
|              | Stakeholder village surveys in 2013 apparently recognised the species,              |
|              | reporting it is common at Ban Kanyong however never encountered at all              |
|              | other villages surveyed: Ban Pou, Ban Xomxuen, Ban Pakyong, Ban Pekheuang           |
|              | and Ban Don.  |
|              | The Project EIA (2007) notes the species occurrence outside the Project area        |
|              | based on a secondary data source though no location is specified.                   |
|              | Note: Verbal village information on cats is close to impossible to assign to        |
|              | species despite the often overconfident presentation in interview reports.          |
|              | These reports are thus no more than weakly indicative of Asian golden cat           |
|              | presence in the Project area. However, the 1999 record from in/near the area,       |
|              | the species' known use of such habitats and its somewhat higher resilience to       |
|              | human activities than of the big cats all suggest it should be in the Project area, |
|              | and may perhaps be widespread.  |
| Distribution | The species occurs from the Himalayan foothills into China and south-east           |
|              | Asia, and is native to: Bangladesh; Bhutan; Cambodia; China; India; Indonesia       |
|              | (Sumatera); Lao PDR; Malaysia; Myanmar; Nepal; Thailand; Viet Nam.                  |
| Population   | In 1990s surveys in Lao PDR Golden Cat was the second-most widely recorded          |
| -            | cat species, with several records from outside the protected area system,           |
|              | suggesting a high population. However, recent camera-trapping in Nakai-Nam          |
|              | Theun NPA suggests that a decade of heavy snaring has now greatly depleted          |
|              | populations in the surveyed parts of that protected area. While Golden Cat          |
|              | evidently remained common in Nam Et-Phou Loeuy until at least few years             |
|              | ago, this exceptional area retained even Tigers. Nakai-Nam Theun NPA is             |
|              | likely to be a better predictor for the typical situation in Lao PDR, and it may    |
|              | be that numbers across Lao PR are typically now much lower than in the 1990s.       |
| Habitat      | The species is primarily found in forest habitats ranging from tropical and         |
|              | subtropical evergreen to mixed and dry deciduous forest; it is evidently very       |
|              | tolerant of degradation and perhaps, where not hunted, of fragmentation.            |
| Threats      | The species is threatened in Lao PDR by indiscriminate snaring and other            |
|              | forms of hunting, driven largely by illegal trade in the species' pelt and bones.   |
| Summary      | This cat plausibly persists, perhaps widely, in the Project area, but this is       |
|              | equally true of much of Lao PDR. The Project area is only a small proportion        |
|              | of the nation's total such habitat and as such would not be expected to             |
|              | constitute critical habitat.  |

|              |   |

| Species               | Prionailurus bengalensis, Leopard cat  |
|-----------------------|--|
| Candidate<br>Criteria | Included at request  |
| Record                | <i>Direct</i><br>TISTR 2013 biodiversity survey did not record the species.  |
|                       | <i>Indirect</i><br>Biodiversity village interviews in 2013 apparently recognised the species has in<br>the upper Nam Ngiep area.<br>Stakeholder village surveys in 2013 apparently recognised the species,<br>reporting it as very common at Ban Pakheuang and Ban Don, common at Ban<br>Xomxuen and Ban Kanyong however never encountered at Ban Pou or Ban<br>Pakyong.   |
|                       | The Project EIA (2007) notes the species occurrence within and outside the Project area based on a secondary data source though no location is specified. Note: Verbal village information on cats is close to impossible to assign to species despite the often overconfident presentation in interview reports. These reports are thus no more than weakly indicative of Leopard Cat presence in the Project area. However, the species' wide distribution in Lao PDR, its known use of habitats similar to those in the Project area, and its high resilience to human activities all suggest it should be in the Project area, and is plausibly widespread and common. |
| Distribution          | The species occurs from the India into northeast and south-east Asia.  |
| Population            | Generally distributed and common across its south-east Asian range, and<br>typically the most commonly encountered small cat on recent surveys. Its<br>current status in Lao PDR is unclear, but all indications are that it remains<br>widespread and common.   |
| Habitat               | The species is found widely in forest habitats (ranging from tropical and subtropical evergreen to mixed and dry deciduous forest) and is highly tolerant of deforestation provided some dense low-level cover remains, being common, for example, in various plantations, and even persisting in peri urban Bangkok and Hanoi, far from any forest.   |
| Threats               | The species is apparently not threatened, at least in southeast Asia. In areas of very heavy hunting, such as much of Lao PDR, numbers are doubtless much reduced, but there is no evidence yet for significant extirpation.   |
| Summary               | Leopard cat plausibly remains widespread and perhaps locally common in the Project area; but this is equally true of much of Lao PDR. The Project area is only a small proportion of the nation's total such habitat and as such would not be expected to constitute critical habitat.   |

| Species      | Prionailurus viverrinus, Fishing cat   |
|--------------|--|
| Candidate    | Criterion 1 – The species is listed as Endangered on the IUCN Red List and is  |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and  |
|              | Forestry No. 0360/MAF.   |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not record the species.   |
|              |  |
|              |  |
|              | Indirect   |
|              | The Huay Ngua MP (2010) notes presence of the species within the provincial  |
|              | preserved area.  |
|              | Stakeholder village surveys in 2013 apparently recognised the species,   |
|              | reporting it is common in Ban Kanyong and Ban Don of Nam Xan while noted   |
|              | the species as less common Ban Pou and Ban Pakyong of Nam Ngiep River.   |
|              | The Project EIA (2007) notes the species occurrence within and outside the   |
|              | Project area based on a secondary data source though no location is specified.<br>Note: Verbal village information on cats is close to impossible to assign to |
|              | species despite the often overconfident presentation in interview reports.   |
|              | Fishing cat is so widely misidentified in South-east Asia (e.g. Duckworth <i>et al.</i>  |
|              | 2010) yet so universally reported in verbal village information that these   |
|              | reports should not be taken as even weakly indicative of Fishing cat presence  |
|              | in the Project area. In fact, there is no confirmation that the species occurs in  |
|              | Lao PDR at all. Most of the valid recent records from southeast Asia are from  |
|              | coastal areas, and while there are historical specimens from a few inland areas,   |
|              | there are too few inland records to make a habitat-based prediction of Fishing   |
|              | cat's likely status in the Project area.   |
| Distribution | The species is native to Bangladesh, Bhutan, Cambodia, India, perhaps  |
|              | Indonesia, perhaps Lao PDR, Myanmar, Nepal, Sri Lanka, Thailand and Viet   |
|              | Nam. The species is primarily found in wetland habitats, which are   |
|              | increasingly being settled, degraded and converted; its occurrence may now be  |
|              | highly localised in southeast Asia, and is almost certainly so, away from the  |
|              | coast. The species has not been seen captive or in trade in Lao PDR suggesting   |
|              | that it is extremely rare or not likely to occur (pers comm. Will Duckworth  |
|              | 15/11/2013).   |
| Population   | Population estimates are not well understood. There are very few reports from  |
|              | Lao, all either certain or plausible errors. It is possible that the species is extinct  |
|              | or never occurred in Lao PDR; it is inconceivable that, if present, it is other  |
|              | than extremely rare. This is also true of Cambodia even though a sizeable  |
|              | number of captive animals have been reported in this latter country. In  |
|              | southeast Asia recent records are infrequent suggesting a decline in populations.  |
| Habitat      | Past statements on habitat use in SE Asia are confounded by incorporation of   |
|              | information from misidentified animals. Almost all recent SE Asian records are   |
|              | from the coast, although a few historical specimens prove inland occurrence.   |
|              | All such latter records seem to have been from the level lowlands, in areas  |
|              | with many standing waterbodies. The species is thought to feed mainly on fish  |
|              | but also small rodents, reptiles and amphibians. Home ranges reported in   |
|              | Nepal ranged between 400 and 1600 ha.  |
| Threats      | Main threats to the species include wetland destruction and degradation.   |
| Summary      | There is no reason to think that Fishing cat inhabits the Project area, but  |
| 2            | equally it cannot be excluded that it does so. However, the Project area's   |
|              | habitat is not distinct in any way from typical Lao hill-country, and so there is  |
|              | no reason to conclude that the Project area could be considered critical   |
|              | habitat for the species. This assessment remains particularly provisional given  |
|              | the uncertainty surrounding the species' distribution and habitat use in inland  |
|              | SE Asia.   |
|              |  |

| Species      | Pygathrix nemaeus, Red shanked douc langur                                       |
|--------------|--|
| Candidate    | Criterion 1 - The species is listed as Endangered on the IUCN Red List           |
| Criteria     |  |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not record the species.                       |
|              | Targeted primate survey was undertaken in November 2013 by Dr Phaivanh           |
|              | Phiapalath of the IUCN SSC/Primate Specialist Group which detected no douc       |
|              | langur.  |
|              | Indirect   |
|              | Stakeholder village surveys in 2013 identified that the villagers indicated to   |
|              | never encounter this species at any of the villages surveyed.                    |
|              | The Project EIA (2007) notes the species occurrence outside the Project area     |
|              | based on a secondary data source though no location is specified.                |
| Distribution | The species is native to Lao PDR and Viet Nam, and perhaps Cambodia. The         |
|              | IUCN mapped distribution does not include the Study area. Timmins and            |
|              | Duckworth (1999) and Coudrat et al. (2012) traced no records northwest of        |
|              | Nam Kading NPA (where the species is rare and localised) so it is quite          |
|              | plausible the Project area lies outside the species's range. There are a few     |
|              | verbal reported from Pho Khao Khoay NPA (west of the Project area) but these     |
|              | may reflect mistaken interpretation, e.g. from people who saw them elsewhere.    |
|              | However, the area between Nam Kading NPA and Phou Khao Khoay NPA                 |
|              | (and even the latter protected area itself) remains poorly surveyed and the true |
|              | status of the doucs in it is open to question.                                   |
| Population   | IUCN reports the population of the species in Lao is likely to be larger than in |
|              | other areas. In Lao the largest and most important global population occurs in   |
|              | Nam Theun basin and surrounds which includes a number of protected areas         |
|              | and is to the south of the Project area.   |
| Habitat      | The species is found in primary and secondary evergreen and semi-evergreen       |
|              | broadleaf forest. It is mainly folivorous.                                       |
| Threats      | Main threats to the species include hunting for subsistence use and traditional  |
|              | medicine as well as, probably now only to a low extent, the pet trade.           |
| Summary      | The Project area is outside the range of the species and targeted primate survey |
|              | in 2013 did not detect the species.  |

| Species               | Rusa unicolor, Sambar  |
|-----------------------|--|
| Candidate<br>Criteria | Criterion 1 – The species has an elevated protection status nationally and is<br>listed as Restricted in the Regulation of the Ministry of Agriculture and   |
| Cillella              | listed as Restricted in the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF.   |
| Record                | Direct<br>TISTR 2013 biodiversity survey did not record the species.   |
|                       | <i>Indirect</i><br>The Huay Ngua MP (2010) notes presence of the species within the protected area.  |
|                       | Biodiversity village interviews in 2013 apparently recognised the species in the upper Nam Ngiep area.   |
|                       | Stakeholder village surveys in 2013 apparently recognised the species<br>reporting it as very common at Ban Pou, Ban Kanyong and Ban Pakheuang,<br>common at Ban Pakyong and Ban Don, however less commonly encountered<br>at Ban Xomxuen. Note: There is some uncertainty associated with these   |
|                       | indirect data sources for the species, in particular with respect to the frequency of encounters.  |
|                       | The Project EIA (2007) notes the species occurrence within and outside the Project area based on a secondary data source though no location is specified.  |
| Distribution          | The species occurs from India and Sri Lanka in the west, along the southern<br>Himalayas and through south China to Taiwan. Further south it occurs in<br>Bangladesh, throughout mainland south-east Asia and many of the main<br>islands of the Greater Sundas (Timmins et al. 2008). Duckworth et al 1999  |
|                       | noted that the species occurred in numerous survey areas in north Lao, central<br>and southern Lao. However with ongoing very heavy hunting since then in the<br>country, many local extirpations may have occurred.   |
| Population            | In Lao PDR, Sambar was described as very common in 1940 and widespread at<br>low numbers in the 1990s. Sites surveyed between 2004 and 2007 have shown<br>major declines. The remaining Lao populations are centred around areas with<br>extensive open, or at least broken, habitat amid forest (Timmins et al. 2008).  |
| Habitat               | Habitat is reported as wooded areas, more commonly in broken areas amid<br>semi-evergreen forest but also open deciduous forest and unbroken evergreen<br>forest.  |
| Threats               | There are major, ongoing, declines in Viet Nam, Lao PDR, Cambodia and<br>Thailand which can plausibly only be driven by hunting, because suitable<br>habitat for Sambar is abundant in these countries but is almost or actually<br>bereft of the species (Timmins et al. 2008).   |
| Summary               | If the reports that Sambar is locally common in the Project area are accurate, the area may be important habitat on a national scale rather than a global scale. There are large remaining populations in some other countries. As such the <b>Project area is not considered to be critical habitat for the species</b> however measures should be employed to understand the importance of the population on a national level.   |

| Species      | Trachypithecus phayrei, Phayre's leaf monkey  |
|--------------|---|
| Candidate    | Criterion 1 – The species is listed as Endangered on the IUCN Red List. Its   |
| Criteria     | treatment in the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF is ambiguous; it is not mentioned by English or scientific name, but is best seen as listed as Restricted, taking the entity translated as Silvered Langur to in fact refer to all grey langurs (=leaf monkeys).   |
| Record       | Direct<br>TISTR 2013 biodiversity survey did not record the species.<br>Targeted primate survey was undertaken in November 2013 by Dr Phaivanh<br>Phiapalath of the IUCN SSC/Primate Specialist Group which reported one<br>record (vocalisation) and three mineral licks were found within the area.<br>A shot individual was photographs in the lower Nam Ngiep in early 1999<br>however specific location information is unavailable.  |
|              | Indirect<br>Biodiversity village surveys in 2013 suggested the species in the main dam<br>inundation area.<br>Stakeholder village surveys in 2013 apparently recognised the species,<br>reporting that it is very common in Ban Pou, common at Ban Xomxuen and<br>Ban Kanyong however is never encountered at Ban Pakyong, Ban Pakheuang<br>or Ban Don.   |
|              | The Project EIA (2007) notes the species occurrence within and outside the Project area based on a secondary data source though no location is specified. Note: Although interviews cannot reliably distinguish the various taxa of <i>Trachypithecus</i> inhabiting Lao PDR, on geographical grounds Indochinese Silvered Leaf Monkey <i>T. germaini</i> can be eliminated, and the Project area seems to support little if any habitat rugged enough for François's Leaf Monkey (sensu lato) <i>T. fancoisi</i> .   |
| Distribution | The species is native to Bangladesh, China, India, Lao PDR, Myanmar,<br>Thailand and Viet Nam (Bleisch et al., 2008b). In Lao PDR the species has been<br>confirmed only in the northern parts (including the Project area), perhaps<br>extending marginally into central Lao PDR. Viet Nam records are from less<br>than five areas. In Thailand there are good populations in Nam Nao National<br>Park and Phukhio Wildlife Sanctuary and Western Forest complex. In Lao<br>PDR, Timmins et al. (2013) note the species to occur from the Mekong Valley<br>up to at least 800m, with one record (at a mineral lick) at 1125m. |
| Population   | Populations are generally small and isolated. China has reported healthy<br>populations in a number of reserves though overall the species population is<br>reported on serious decline globally.<br>Timmins et al. (2013) noted recent Lao records only from ten survey areas (in<br>some, merely objectively identified as grey leaf monkeys, but which on range<br>can be assumed to be this species), with little evidence for large numbers in<br>any survey area.   |
| Habitat      | The species inhabits primary and secondary evergreen and semi-evergreen<br>forest, mixed moist deciduous forest as well as bamboo areas, light woodlands<br>and near tea plantations. In Lao it seems to be particularly occurring in edge<br>and degraded areas, which suggest high tolerance to habitat perturbation, but,<br>because such areas are often on the margins of wilderness areas, elevated rick<br>from hunting. It is a predominantly arboreal species that is folivorous. Home<br>range extent not reported.   |

| Species    | Trachypithecus phayrei, Phayre's leaf monkey                                      |
|------------|---|
| Threats    | The main threat to the species In Lao PDR is hunting, its effects may be          |
|            | exacerbated by the species' habitat use. Most of the areas within the species'    |
|            | geographic range large enough to have remotes cores with relatively lower         |
|            | hunting have such areas above 800m, and thus probably support few if any of       |
|            | this species. However, the numbers of records from outside the protected area     |
|            | system and fairly close to heavy human activity suggest higher resilience to      |
|            | hunting than shown by, for example, Red-shanked douc langur.                      |
| Summary    | This species is probably among the mammal species for which the Project area      |
|            | provides a significant contribution to national conservation prospects.           |
|            | However, even at the national level it is implausible that the Project area       |
|            | supports close to 10 per cent of the population, given that it comprises far less |
|            | than 10% of the species' presumed present area of occupancy in today's Lao        |
|            | PDR. As such the Project area is not considered to be critical habitat for the    |
|            | species. Key habitat areas for the species are reported by Dr Phaivanh            |
|            | Phiapalath at Phou Thin, Phouru Pha Noy, Phou Pha hua and Phou Sam Liem.          |
|            | These locations are outside the Project area though must be considered for        |
|            | indirect impact.  |

|            | -   |

| Species      | Ursus thibetanus, Himalayan black bear  |
|--------------|---|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is   |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and   |
|              | Forestry No. 0360/MAF.  |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey did not record the species.  |
|              | Indirect  |
|              | The Huay Ngua MP (2010) notes presence of the species within the protected  |
|              | area.   |
|              | Biodiversity village interviews in 2013 recognised bears apparently this species  |
|              | as been seen in the upper Nam Ngiep area.   |
|              | Stakeholder village surveys in 2013 apparently recognised the species,  |
|              | reporting it is common in Ban Kanyong and Ban Pakheuang however less  |
|              | common in Ban Pou, Ban Xomxuen and Ban Pakyong and never encountered  |
|              | at Ban Don.   |
|              | The Project EIA (2007) notes the species occurrence outside the Project area  |
|              | based on a secondary data source though no location is specified.   |
|              | Note: Verbal village information on bears is close to impossible to assign to   |
|              | species despite the often overconfident presentation in interview reports.  |
|              | These reports are thus no more than weakly indicative of Sun bear presence in   |
|              | the Project area. However, the species' wide distribution in Lao PDR, its   |
|              | known use of habitats similar to those in the Project area, and its level   |
|              | resilience to human activities all suggest it could well inhabit the Project area.  |
| Distribution | The species is native to numerous countries (Afghanistan; Bangladesh; Bhutan;   |
|              | Cambodia; China; India; Iran, Islamic Republic of; Japan; Korea, Democratic   |
|              | People's Republic of; Korea, Republic of; Lao People's Democratic Republic;   |
|              | Myanmar; Nepal; Pakistan; Russian Federation; Taiwan, Province of China;  |
|              | Thailand; Viet Nam).  |
|              | The species occupies a narrow band from south-eastern Iran eastward through   |
|              | Afghanistan and Pakistan, across the foothills of the Himalayas, to Myanmar.  |
|              | It occupies all countries in mainland south-east Asia except Malaysia.  |
|              | Duckworth et al. (1999) traced few certain records from 1990s surveys which,  |
|              | however, used methods unsuitable to generate records confirmed to species   |
|              | level (as distinct from as unidentified bears). More recent information   |
|              | (suggested by a number of captive cubs_ suggests a surprising wide  |
|              | occurrence in Lao PDR's northern highlands, including outside the protected   |
| Demoletter   | area system.  |
| Population   | No rigorous population estimates exist for this species in Lao PDR, but it can  |
|              | safely be assumed to be much reduced even if not yet very widely extirpated.  |
|              | Estimates available include 8-1400 bears in Japan (though perhaps no longer valid) 5 6000 in Russia 7 9000 in India 1000 in Pakistan and 15 46000 in        |
|              | valid), 5-6000 in Russia, 7-9000 in India, 1000 in Pakistan and 15-46000 in   |
| Habitat      | China, however here are concerns regarding the reliability of these estimates.<br>The species occupies a variety of forested habitats in Lao PDR, including |
| maniai       | highly degraded landscapes.   |
| Threats      | The overriding threat to the species in Lao PDR is commercially driven  |
| Theats       | hunting for skins, paws and gall bladders.  |
| Summary      | The Project area's habitat is not distinct in any way from typical Lao hill-  |
| Juninary     | country, and so there is no reason to conclude that the Project area could be   |
|              | considered critical habitat for the species.  |

| Species      | Buceros bircornis, Great hornbill  |
|--------------|--|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is  |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and  |
|              | Forestry No. 0360/MAF.   |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not record the species.   |
|              |  |
|              |  |
|              | Indirect   |
|              | The Huay Ngua MP (2010) notes presence of the species within the provincial  |
|              | preserved area.  |
|              | Biodiversity village survey apparently recognised the species, reporting it as   |
|              | less commonly encountered in the upper and lower Nam Xan only.   |
|              | Note: Verbal village information on hornbills is difficult to assign to species  |
|              | despite the often overconfident presentation in interview reports. These   |
|              | reports are thus no more than weakly indicative of Great Hornbill presence in  |
|              | the Project area. In most of Lao PDR Great Hornbill is much more declined  |
|              | than Wreathed Hornbill, and most village reports of 'great hornbills' and taken  |
|              | by the interviewers to mean Great Hornbill in fact probably refer to Wreathed<br>Hornbill.   |
| Distribution | The species has a wide distribution, occurring in China, India, Nepal, Bhutan,   |
| Distribution | Bangladesh, Myanmar, Thailand, Lao PDR, Vietnam, Cambodia, Malaysia and  |
|              | Indonesia. Surveys in the 1990s recorded the species in a fair number in areas   |
|              | across Lao PDR, although almost invariably in small numbers (Duckworth et  |
|              | al. 1999); there is recent information only from few areas, reflecting patchy  |
|              | survey but some local extirpations are likely to have occurred in the  |
|              | intervening period.  |
| Population   | Although the species has a large range it occurs at low densities and is patchily  |
| - op         | distributed. In Lao PDR, the species was formerly common but now (although   |
|              | still widespread) is scarce. Based on population estimates in India, the species   |
|              | global population is estimated at 10,000 to 70,000 individuals. It is probably   |
|              | best placed in the band 20,000-49,999 individuals.   |
| Habitat      | This species frequents evergreen, semi-evergreen and mixed deciduous forests,  |
|              | ranging out into open deciduous areas to visit fruit trees and ascending slopes  |
|              | to at least 1,560 m. The species is perhaps most common in unlogged forest.  |
| Threats      | The primary threat to the species in Lao PDR is hunting; many large tracts of  |
|              | prime habitat support only small numbers, or none, because of this threat.   |
| Summary      | Great hornbill plausibly still occurs in the Project area but probably only in low   |
| 5            | numbers. Its status is similar across large parts of Lao PDR. The Project area is  |
|              | small in proportion to the nation's total suitable habitat and as such is most   |
|              | unlikely to constitute critical habitat.   |

Indirect

The Huay Ngua MP (2010) notes presence of the species within the provincial preserved area.

Stakeholder village surveys in 2013 apparently recognised the species, reporting it as common in Ban Xomxuen and Ban Pakyong of the Nam Ngiep River though never seen in Ban Pou. In Nam Xan River villagers responded that the species is common in Ban Kanyong and Ban Don and very common in Ban Pakheuang.

The Project EIA (2007) notes the species occurrence outside the Project area based on a secondary data source though no location is specified.

Note: Verbal village information on ducks and other swimming birds is impossible reliably to assign to species despite the often overconfident presentation in interview reports. In particular, inept interview teams almost invariably record White-winged Duck almost anywhere in Lao PDR that villagers report ducks of any species. Given that the considerable specific search effort for White-winged Duck in the 1990s and to a lesser extent in the 2000s found only few areas to support the species, and that competently executed interview surveys very rarely find reports that conform in morphological and behavioural aspects with White-winged Duck, it is obvious that most purported White-winged Duck interview claims are in error. The same is assumed to hold here. However, the habitat is suitable for the species, and would surely have held it previously, and it cannot be excluded that small numbers remain.

| Distribution | The species is native to Bangladesh, Cambodia, India, Indonesia, Lao PDR,         |
|--------------|---|
|              | Myanmar, Thailand and Viet Nam. Duckworth et al (1999) note 2 - 3                 |
|              | population centres for the species in Lao PDR. There are no recent (post-1950)    |
|              | records or convincing reports of the species in Lao PDR from north of the         |
|              | Nakai plateau, there are also no historical reports, but in the light of highly   |
|              | limited survey efforts, the species is assumed to have been overlooks in the      |
|              | many Mekong tributary systems upstream of the Nam Kading to at least the          |
|              | Nam Sang. Recent intensive activity in the Nam Theun catchment suggests           |
|              | that very small numbers may survive for some years in areas where                 |
|              | conventional survey under practical levels of effort cannot guarantee to find     |
|              | then, even by sign. Therefore, the actual status (extirpated vs reduced to very   |
|              | small numbers) in north Lao PDR in and since the 1990s cannot be determined.      |
| Population   | Estimates of global population report 450 individuals in India, low hundreds      |
|              | in Myanmar, 100 in Cambodia and 150 in Indonesia. Precautionary estimates         |
|              | places the global population between 350 and 1500 individuals. Total numbers      |
|              | in Lao PDR are likely to be no more than a few dozen, and probably now are        |
|              | many fewer.   |
| Habitat      | The species occur in stagnant or slow-flowing wetlands (natural and artificial)   |
|              | within or adjacent to evergreen, deciduous or swamp forest. Individuals roost     |
|              | and nest in the tree hollows. The species is secretive and forages at night on    |
|              | seeds, aquatic plants, grain, rise, small fish and invertebrates. Duckworth et al |
|              | (1999) note records from slower moving stretches of forested streams and          |
|              | rivers, and pools in forests, up to 600 m.  |
| Threats      | The primary threat to the species in Lao PDR is hunting, apparently mainly for    |
|              |   |

The primary threat to the species in Lao PDR is hunting, apparently mainly for local use; many large tracts of prime habitat support only small numbers, or none, because of this threat. The threat from hunting is exacerbated by the

| Species    | Cairina scutulata, White winged duck   |
|------------|--|
|            | species' habitat use: riverine and riparian forest habitats, and are among those               |
|            | most heavily used and degraded by human activity. Thus, although there                         |
|            | seems to be no trade demand for the species in Lao PDR,  |
|            | incidental/opportunistic hunting occurs throughout its Lao PDR range at                        |
|            | levels sufficient for widespread local extirpation.  |
| Summary    | White winged duck might possibly still occur in the Project area but at best                   |
|            | only in very low numbers. Despite major loss of habitat in the last half century,              |
|            | tracts similar in extent and condition to the Project area remain in many parts                |
|            | of Lao PDR. The Project area is only a small proportion of the national's total                |
|            | suitable habitat and as such it is <b>unlikely to constitute critical habitat</b> .            |

|            | Management.  |

| Species      | Centropus sinensis, Greater coucal   |
|--------------|--|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is  |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and  |
|              | Forestry No. 0360/MAF.   |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey recorded the species in Huay Ngua PPA the   |
|              | upper and lower Nam Ngiep, resettlement site, and upper and lower Nam  |
|              | Xan.   |
|              | Indirect   |
|              | The Huay Ngua MP (2010) notes presence of the species within the provincial  |
|              | preserved area.  |
|              | The Project EIA (2007) notes the species occurrence within and outside the   |
| Distribution | Project area based on a secondary data source though no location is specified.   |
| Distribution | This species has an extremely large distribution and is native to: Bangladesh,<br>Bhutan, Brunei Darussalam, Cambodia, China, India, Indonesia, Lao PDR,     |
|              | Malaysia, Myanmar, Nepal, Pakistan, Philippines, Singapore, Sri Lanka,   |
|              | Thailand, and Viet Nam.  |
| Population   | The global population size has not been quantified, but the species is reported  |
| •            | to be common almost everywhere throughout its range. National population   |
|              | sizes have been estimated at c.100-10,000 breeding pairs and c.50-1,000  |
|              | individuals on migration in China; and c.100-10,000 breeding pairs in Taiwan.  |
|              | It is widespread and generally abundant, including in areas with very heavy  |
|              | human use and bird hunting pressure, across Lao PDR.   |
| Habitat      | Habitat is noted to be forest edge, scrub, tall secondary growth and grassland   |
|              | including ponds and villages.  |
| Threats      | There are no threats to Greater coucal populations in Lao PDR. Although it is  |
|              | often hunted, it seems resilient to current levels, and while populations may by   |
|              | below carrying capacity in heavily settled areas, there has been no significant  |
|              | contraction of range. The species has doubtless benefitted hugely from the   |
| Cummany      | major conversion and degradation of Lao PDR's forests over the last century.   |
| Summary      | Greater coucal is probably abundant over the deforested and degraded parts of<br>the Project area. <b>This is so across Lao PDR however the Project area</b> |
|              | constitutes an insignificant proportion of the nation's total suitable habitat   |
|              | and as such does not constitute critical habitat.  |

|              | Management.  |

| Species      | Gyps bengalensis, White backed vulture   |
|--------------|--|
| Candidate    | Criterion 1 - The species is listed as Critically Endangered on the IUCN Red   |
| Criteria     | List   |
|              | Criterion 3 - The species may be considered congregatory   |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not record the species.   |
|              | Indirect   |
|              | The Project EIA (2007) notes the species occurrence outside the Project area   |
|              | based on a secondary data source though no location is specified.  |
|              | Note: Despite their distinctive physical appearance and habits, and unique Lao   |
|              | name, vultures are surprisingly widely reported by incompetent interviews  |
|              | across parts of Lao PDR from where they have been extirpated for many  |
|              | decades. Extensive field observation and careful interview shows that resident   |
|              | vultures are extirpated from all but the southernmost two provinces of Lao   |
|              |  |
|              | PDR. Himalayan griffon <i>G. himalayensis</i> and Cinereous vulture <i>Aegypius</i>  |
|              | <i>monachus</i> are erratic vagrants from the north which presumably could occur   |
| Distribution | anywhere in Lao PDR, although so far there have been no record of either.  |
| Distribution | The species is native to Afghanistan, Bhutan, Cambodia, India, Iran, Lao PDR,<br>Myanmar, Nanal, Pakistan, Thailand and Viot Nam (BirdLife International   |
|              | Myanmar, Nepal, Pakistan, Thailand and Viet Nam (BirdLife International 2012a). In Leas PDR Dural worth at al 1000 parts that historically the america was |
|              | 2012a). In Lao PDR Duckworth et al 1999 note that historically the species was   |
|              | widespread and common however recent records come only from Champasak  |
|              | and Attapu provinces. There have been no records or credible reports since   |
| Demulation   | 1999 from any other province in Lao PDR.   |
| Population   | The global population of the species is estimated between 2500 and 9999  |
|              | mature individuals which equates to between 3,500-15,000 individuals. Viable   |
|              | populations in South-east Asia are known in Myanmar and Cambodia. The  |
|              | IUCN mapped distribution identifies the species is 'possibly extinct' in Lao   |
| Ttabitat     | PDR and much of Thailand and Cambodia.   |
| Habitat      | The species occurs mainly in plains and less commonly in hilly regions. It is  |
|              | known to utilise light woodland, villages, cities and open areas. The species is   |
|              | thought to forage over a vast range, primarily on carrion. Vultures play a role  |
|              | in the wider landscape as providers of ecosystems services, relied upon to   |
|              | dispose of animal and human remains in India. The species is reported to form  |
|              | considerable aggregations when feeding, and use communal roosting sites,   |
| These        | breeding in colonies and as such may be considered a congregatory species.   |
| Threats      | Major decline in the south Asian population has been attributed to veterinary  |
|              | drugs used to treat domestic livestock poisoning individuals. However, the   |
|              | southeast Asian population has declined hugely before the introduction of  |
|              | these drugs, apparently through declines in food supply: hunting driven  |
|              | collapse of wild large mammal populations and changes in livestock carcase   |
|              | disposal practices. Remaining use of Lao PDR by this species may depend  |
|              | entirely on ranging from Cambodia, where birds are maintained by specific  |
| C            | feeding ('vulture restaurants').   |
| Summary      | Given the ease of finding this species when present and the high levels of   |
|              | survey in the general region of Lao PDR within which lies the Project area,  |
|              | there is no chance that the interview reports collected in fact refer to a resident  |
|              | population of this or any other vulture. This the Project area does not  |
| Deference    | constitute critical habitat  |

| Species      | Lophura diardi, Siamese fireback   |
|--------------|--|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is                  |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and                      |
|              | Forestry No. 0360/MAF.   |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not record the species.                                     |
|              |  |
|              |  |
|              | Indirect   |
|              | The Huay Ngua MP (2010) notes presence of the species within the protected                     |
|              | area.  |
|              | Biodiversity village surveys in 2013 apparently recognised the species,                        |
|              | reporting it is less common in upper and lower Nam Xan however did not                         |
|              | recognise its presence in Nam Ngiep and Huay Ngua visited areas.                               |
|              | Stakeholder village surveys in 2013 recognised the species as very common in                   |
|              | Ban Pou and Ban Xomxuen of the Nam Ngiep River though common in Ban                            |
|              | Pakyong. In Nam Xan River villagers responded that the species is very                         |
|              | common in Ban Kanyong, Ban Pakheuang and Ban Don.  |
|              | The Project EIA (2007) notes the species occurrence within and outside the                     |
|              | Project area based on a secondary data source though no location is specified.                 |
|              | Note: Verbal village information on pheasants in Lao PDR is difficult to assign                |
|              | to species despite the often overconfident presentation in interview reports.                  |
|              | These reports are thus no more than weakly indicative of Siamese fireback                      |
|              | presence in the Project area. However, the area contains suitable habitat in its               |
|              | lower-lying parts, and the species is extremely resilient to hunting and forest                |
|              | degradation (it may even benefit from some level of the latter). Thus, it is                   |
|              | highly likely that Siamese fireback inhabits the area.   |
| Distribution | The species occurs in Thailand, Lao PDR, Cambodia and Vietnam. 1990s                           |
|              | surveys recorded the species widely across lower-lying parts of Lao PDR.                       |
| Population   | The species is locally common in much of its range. The total population is                    |
|              | suspected to number 20,000-49,999 individuals based on a conservative                          |
|              | estimate of c.2,000 individuals in Cambodia and an estimate of c.5,000                         |
|              | individuals in Thailand; the Lao PDR population is likely to dwarf both of                     |
|              | these.   |
| Habitat      | The species occurs in evergreen, semi-evergreen and bamboo forest, secondary                   |
|              | growth and scrub, often near roads and tracks through the forest, chiefly in the               |
|              | plains and foothills to 500 m, but occasionally much higher.                                   |
| Threats      | This species is declining in Lao PDR in proportion to wholesale conversion of                  |
|              | lowland and lower-hill forest to plantations and other uses. However, very                     |
|              | large areas of suitable habitat persist, and there are a sufficient number of                  |
|              | records in the last decade to be sure that the species is not threatened in Lao                |
|              | PDR. Despite earlier concerns, it is now clear the species is highly resilient to              |
|              | hunting, perhaps including large-scale snaring, although this largely takes                    |
|              | place in forests above it main altitudinal range.  |
| Summary      | Siamese fireback is very likely to occur, perhaps widely, in the Project area.                 |
|              | Nonetheless, the Project area constitutes an insignificant proportion of                       |
|              | suitable habitat across Lao PDR, so does not constitute critical habitat.                      |

|              | recognise its presence in Nam Ngiep and Huay Ngua visited areas.                               |
|              | The Project EIA (2007) notes the species occurrence within and outside the                     |
|              | Project area based on a secondary data source though no location is specified.                 |
|              | Note: Verbal village information on pheasants in Lao PDR is difficult to assign                |
|              | to species despite the often overconfident presentation in interview reports.                  |
|              | These reports are thus no more than weakly indicative of Silver pheasant                       |
|              | presence in the Project area. However, the area contains suitable habitat in its               |
|              | higher-lying parts, and the species is extremely resilient to hunting and forest               |
|              | degradation in Lao PDR. Thus, it is highly likely that Silver pheasant inhabits                |
|              | the area.  |
| Distribution | The species occurs broadly across south-east Asia. The species is native to                    |
|              | Thailand, Myanmar, Lao PDR, Vietnam, Cambodia and southern China.                              |
| Population   | The global population size of the Silver Pheasant has not been quantified, but                 |
|              | the species is reported to be widespread and seemingly common in suitable                      |
|              | habitat. The population size in China has been estimated at c.10,000-100,000                   |
|              | breeding pairs (BirdLife International 2013). Lao PDR supports large                           |
|              | populations as the species is widespread and locally common.                                   |
| Habitat      | Occurs in hill and montane forest (mainly evergreen) and tall secondary                        |
|              | growth. Generally found between 500m and 2020m although occasionally                           |
|              | down to 200m.  |
| Threats      | Silver pheasant is declining in Lao in proportion to wholesale conversion of                   |
|              | occupied hill forest to plantations and other uses. However, very large areas of               |
|              | suitable habitat persist, and there are a sufficient number of records in the last             |
|              | decade to be sure that the species is not threatened in Lao PDR. Despite earlier               |
|              | concerns, it is now clear the species is highly resilient to hunting, perhaps                  |
|              | including large-scale snaring (most of which occurs in this species' main                      |
|              | altitudinal range), although this is so far not well assessed.                                 |
| Summary      | Silver Pheasant is very likely to occur, perhaps widely and commonly, in the                   |
|              | Project area. Nonetheless, the Project area constitutes an insignificant                       |
|              | proportion of suitable habitat across Lao PDR, so does <b>not constitute critical</b>          |
|              | habitat. This remains so even if one treats the various morphologically                        |
| D.(          | distinctive races as separate conservation units.  |

| Species      | Pavo muticus, Green peafowl  |
|--------------|--|
| Candidate    | Criterion 1 – The species is listed as Endangered on the IUCN Red List                         |
| Criteria     | I I I I I I I I I I I I I I I I I I I  |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not record the species.                                     |
|              | , , , , , , , , , , , , , , , , , , ,  |
|              |  |
|              | Indirect   |
|              | The Huay Ngua MP (2010) notes presence of the species within the provincial                    |
|              | preserved area.  |
|              | Note: Verbal village information on pheasants in Lao PDR is difficult to assign                |
|              | to species despite the often overconfident presentation in interview reports.                  |
|              | This is so even for the morphologically distinctive Green peafowl, which is                    |
|              | often confused/amalgamated with Crested argus (Rheinardia ocellata) but also                   |
|              | often is 'reported' from outside the plausible present-day range of either. In the             |
|              | context of huge range contraction of Green peafowl in Lao PDR in the last 60                   |
|              | years and the great rarity of surviving remnant populations outside of                         |
|              | Savannakhet, these interview reports are most sensible taken as in error.                      |
| Distribution | The IUCN mapped distribution across the Project area is mapped as 'possibly                    |
|              | extinct'. Birdlife International recognises almost 2,500 ha on the south-western               |
|              | periphery of PKK as an Important Bird Area (IBA) where individuals have                        |
|              | been heard at a roosting site in 1994, 1995 and 2002, and were credibly                        |
|              | reported as still present in 2009. All other remnant populations of Green                      |
|              | peafowl confirmed in Lao PDR since 1990 are al far to the south of the Project                 |
|              | area.  |
| Population   | The estimates of global population size are 15,000-30,000 individuals. Birdlife                |
| -            | International (2003) notes while the population is of moderate to high national                |
|              | significance, it is of low global significance given the larger populations in                 |
|              | parts of Cambodia. Duckworth et al 1999 report five areas that are likely to                   |
|              | retain populations large enough to be viable in Lao PDR, including PKK.                        |
| Habitat      | The species has been reported to occupy a variety of habitats including                        |
|              | primary and secondary, tropical and subtropical, evergreen and deciduous                       |
|              | forest types, mixed coniferous forest, swamp forest, open woodland, forest                     |
|              | edge, bamboo, grasslands, savannah, scrub and farmland edge.                                   |
| Threats      | The main threat to the species in Lao PDR is hunting, including egg collection.                |
|              | Habitat modification and fragmentation may locally compound the problem.                       |
|              | These threats have led to widespread extirpation across Lao PDR and adjacent                   |
|              | countries.   |
| Summary      | Assuming that the interview reports are in error, there is <b>no reason to consider</b>        |
| 5            | that the Project area constitutes critical habitat. However, the rather                        |
|              | anomalous survival of the small population around Ban Nakhaty, Phou Khao                       |
|              | Khoay NPA, emphasises the possibility that other remnants may also survive,                    |
|              | and it cannot be excluded that the Project area might support one. Such a                      |
|              | population could be significant at the national level.   |

|              |  |

| Species      | Polyplectron bicalcaratum, Grey peacock-pheasant  |
|--------------|---|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is   |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and   |
|              | Forestry No. 0360/MAF.  |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey did not record the species.  |
|              | Indirect  |
|              | The Huay Ngua MP (2010) notes presence of the species within the provincial   |
|              | preserved area.   |
|              | Biodiversity village surveys in 2013 apparently recognised the species,   |
|              | reporting it is less common in upper and lower Nam Xan however did not  |
|              | recognise its presence in Nam Ngiep and Huay Ngua visited areas.  |
|              | Note: Verbal village information on pheasants in Lao PDR is difficult to assign   |
|              | to species despite the often overconfident presentation in interview reports.   |
|              | These reports are thus no more than weakly indicative of Grey peacock-  |
|              | pheasant presence in the Project area. However, the area contains extensive   |
|              | suitable habitat, and the species is extremely resilient to hunting and forest  |
|              | degradation. Thus, it is highly likely that Grey peacock-pheasant inhabits the  |
| Distribution | area, and it is quite probably common.<br>The species is native to Bangladesh, Bhutan, Cambodia, China, India, Lao PDR, |
| Distribution | Myanmar, Thailand and Viet Nam.   |
| Population   | The population size has not been quantified however it is not believed to be  |
| ropulation   | <10,000 mature individuals. The species is reported to be locally common to   |
|              | fairly common and rare. The population is suspected to be declining owing to  |
|              | habitat loss and degradation and, locally, overexploitation. It remains   |
|              | widespread and common almost across the Lao PDR.  |
| Habitat      | Occurs in evergreen forest from lowlands to 1850 m. The species is reported to  |
|              | be tolerant to degradation of forest.   |
| Threats      | As with other evergreen forest pheasants in Lao PDR, although hunting is very   |
|              | high within this species' habitats, it seems highly resilient to offtake. There are                                     |
|              | thus no serious threats to the species in Lao PDR presently, although its   |
|              | population is presumably declining in proportion to the conversion of forest to   |
|              | plantations and other non-forest habitats.  |
| Summary      | Grey Peacock Pheasant is very likely to occur, perhaps widely and commonly,   |
|              | in the Project area. Nonetheless, the Project area constitutes an insignificant   |
|              | proportion of suitable habitat across Lao PDR, so does not constitute critical  |
|              | habitat.  |

|              | Management.   |

| Species      | Psittacula alexandri, Red-breasted parakeet  |
|--------------|--|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is                  |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and                      |
|              | Forestry No. 0360/MAF.   |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey recorded the species in Huay Ngua PPA. The                      |
|              | survey did not detect the species the Nam Ngiep, Nam Xan or resettlement site                  |
|              | areas.   |
|              | Indirect   |
|              | Biodiversity village surveys in 2013 apparently recognised the species,                        |
|              | reporting it is common in Huay Ngua.   |
|              | The Project EIA (2007) notes the species occurrence within and outside the                     |
|              | Project area based on a secondary data source though no location is specified.                 |
|              | Note: Verbal village information on parakeets in Lao PDR is difficult to assign                |
|              | to species despite the often overconfident presentation in interview reports.                  |
|              | These reports are thus no more than weakly indicative of Red-breasted                          |
|              | parakeet presence in the Project area. However, the area contains some suitable                |
|              | habitat and there are recent records from relatively nearby (lower Nam Kading                  |
|              | plain; Pakxan wetlands) so it is quite plausible that Red-breasted parakeet                    |
|              | inhabits the area, although, given general recent trends in its population in Lao              |
|              | PDR, it is unlikely to be common.  |
| Distribution | The species has a broad distribution and is native to Bangladesh; Bhutan;                      |
|              | Cambodia; China; India; Indonesia; Lao PDR; Myanmar; Nepal; Thailand; and                      |
|              | Viet Nam.  |
| Population   | The global population size has not been quantified; however the species is                     |
|              | reported to be generally common. The species has been heavily traded, and                      |
|              | 125,695 wild-caught individuals have been recorded in international trade                      |
|              | since 1981. In Lao, Duckworth et al 1999 report flocks exceeding 1000 to occur                 |
|              | (recorded in southern Lao PDR) but in most areas rarely number more than 20-                   |
|              | 30. The species has particularly declined in the northern half of the country,                 |
|              | and has been widely extirpated.  |
| Habitat      | In Lao the species occurs in deciduous forests and adjacent secondary growth,                  |
|              | mostly below 400m.   |
| Threats      | Four species of parakeets occur in Lao PDR the populations of all of them have                 |
|              | probably declined hugely although this is based on status documented in                        |
|              | neighbouring countries (where flocks are typically much larger than in Lao                     |
|              | PDR, especially in Cambodia, China and, locally, in Vietnam) rather than on                    |
|              | direct evidence of decline: historical Lao information is insufficiently precise.              |
|              | Declines have been particularly severe in the northern half of the country,                    |
|              | where suitable habitat is naturally more fragmented and in smaller patches.                    |
|              | The decline is assumed to have been driven by the cagebird trade, because                      |
|              | there is no evidence of other trade in significant volumes, and ample suitable                 |
|              | habitat remains widespread but supporting only very small numbers.                             |
| Summary      | Accepting the likelihood of this species' occurrence in the Project area, it is                |
| -            | however unlikely, that in the context of the much larger numbers remaining                     |
|              | in parts of Central and South Lao PDR, that the Project area could comprise                    |
|              | critical habitat.  |

| Species      | Anhinga melanogaster, Darter  |
|--------------|---|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is   |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and   |
|              | Forestry No. 0360/MAF.  |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey recorded the species in the upper Nam Xan: at  |
|              | least two birds.  |
|              | Indirect  |
|              | Verbal village information on large waterbirds in Lao PDR is difficult to assign  |
|              | to species despite the often overconfident presentation in interview reports.   |
|              | These are particular problems with Darter in that name assigned to it (on what  |
|              | basis is apparently undocumented), <i>nok kho ngou</i> (snake-necked bird) is widely  |
| Distribution | assigned by rural lowland Lao to Purple Heron <i>Ardea purpurea</i> .   |
| Distribution | The species occur widely in South and South-east Asia. In Lao it was<br>historically widespread and common, but suffered a massive decline during       |
|              | the latter 20th century, so that during the 1990s it was recorded in few survey   |
|              | areas, and only in small numbers. Effective protection of major breeding  |
|              | colonies in Cambodia has resulted in a rapidly rising number of visitors to Lao   |
|              | PDR usually in the late dry season and wet season; however, some birds can  |
|              | apparently now be seen all year. There seems to be no evidence of re-   |
|              | establishment of breeding in Lao PDR, but this may not be far away (if indeed   |
|              | it has not already happened, undocumented).   |
| Population   | In Lao PDR and surrounding countries, numbers are low except for Cambodia,  |
|              | which supports large breeding numbers. These disperse widely during non-  |
|              | breeding season. Numbers now using Lao PDR are unclear; in the 1990s there  |
|              | were probably no more than a few dozen per year, but now there are likely to  |
|              | be in the hundreds or perhaps even the low thousands.   |
| Habitat      | In Lao PDR a wide variety of waterbodies, from forest streams to large ope  |
|              | reservoirs, is used. This is typical of the species elsewhere in its range. The   |
| Threats      | species is probably independent of forests.   |
| Threats      | Overharvest evidently drove the major declines in mainland SE Asia and when<br>the large numbers breeding around the Great Lake of Tonle Sap were given |
|              | effective protection in the early 2000s, the decline rapidly reversed. Pot-hotting  |
|              | of visitors to Lao PDR is likely to be widespread, but presently an insignificant   |
|              | proportion of the Cambodian population visits the country. Breeding re-   |
|              | establishment in Lao PDR may well be severely restrained by this factor:  |
|              | almost all waterbodies and -course used by the species are navigable.   |
| Summary      | Darters in Lao PDR's forest rivers are presently widely scattered in small  |
|              | numbers. The Project area would support only a small proportion of the  |
|              | number visiting Lao PDR presently, which are moreover, mobile (much   |
|              | suitable habitat remains unoccupied); and in any case the reservoir might   |
|              | actually improve Darter habitat in the Project area. <b>Thus, the Project area does</b>   |
| Deferrer     | not comprise critical habitat.  |

|              | 1999 Status Report. Vientiane: IUCN-The World Conservation Union/Wildlife<br>Conservation Society/Centre for Protected Areas and Watershed              |
|              | Conservation Society/Centre for Protected Areas and Watershed Management.   |
|              |   |

| Species      | Ichthyophaga humilis, Lesser Fish Eagle   |
|--------------|---|
| Candidate    | Criterion 1 - The species has an elevated protection status nationally and is   |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and Forestry No. 0360/MAF.  |
| Record       | <i>Direct</i> None: but the species is easily overlooked unless specifically searched for.  |
|              | <i>Indirect</i><br>None: but the species cannot be detected by village reports.<br>The Project area holds some potentially suitable habitat (see below), but it is probably fairly localised in the Project area, if it occurs at all.  |
| Distribution | Widespread in tropical Asia. In Lao PDR, formerly widespread but now reduced to a few centres of population; still occurs from the far north (Nam Ou) to the far south.   |
| Population   | Now much reduced in Lao PDR to a few centres of population, each probably with only about a dozen pairs at maximum.   |
| Habitat      | Rivers with good fringing forest. Photographs of the Nam Gniang look similar<br>to some of the other streams inhabited by the species in Lao PDR, other<br>streams of similar width, flow an flanking habitat seem to lack the species (e.g.<br>the Nam Kading). Although in some areas this doubles because of persecution,<br>this explanation is implausible for the Nam Kading within Nam Kading NPA.<br>Without clearer understanding of the species' habitat use in Lao PDR it is not<br>possible to predict the suitability of the Project area for the species. |
| Threats      | Loss of riverine forest and persecution; the relative importance of the two is<br>unclear. All remaining populations in Lao PDR are in relatively remote areas<br>(really remote areas lack streams of sufficient width) in landscapes retaining a<br>high proportion of forest.  |
| Summary      | With no information on the status in the Project area no firm decision can be made. Numbers, if any, in the Project area are probably too few for the area to constitute critical habitat; but if there are surprisingly large numbers there, then it possible would be critical habitat.   |
| References   | Duckworth, J.W., Salter, R.E. and Khounboline, K. 1999. Wildlife in Lao PDR<br>1999 Status Report. Vientiane: IUCN-The World Conservation Union/Wildlife<br>Conservation Society/Centre for Protected Areas and Watershed<br>Management.  |

| Species      | Other possible species:   |
|--------------|---|
| operes       | Aceros nipalensis, Rufous-necked hornbill   |
|              | Rheinardia ocellata, Crested argus  |
|              | Bubo nipalensis, Spot-bellied eagle owl   |
|              | Picus rabieri, Red-collared woodpecker  |
|              | Upupa epops, Hoopoe   |
| Candidate    | Criterion 1 - These species have an elevated protection status nationally and             |
| Criteria     | are listed as Restricted in the Regulation of the Ministry of Agriculture and             |
|              | Forestry No. 0360/MAF.  |
| Record       | Direct  |
|              | None  |
|              | Indirect  |
|              | Based on habitat and geographical location, these bird species surely                     |
|              | (Hoopoe), may well (Red-collared woodpecker, Spot-bellied eagle owl) or                   |
|              | might (Crested argus) occur in the Project area, or might have done so                    |
|              | (Rufous-necked hornbill).   |
| Distribution | Various.  |
|              | None is endemic to Lao PDR. In Lao PDR, Crested argus is naturally restricted             |
|              | to eastern parts, but the others are or (Rufous-necked hornbill) were                     |
| Denvilation  | widespread.   |
| Population   | Various.  |
|              | Rufous-necked hornbill is now localised and rare; the breeding Hoopoe                     |
|              | population is now localised and scarce; the others remain common within suitable habitat. |
| Habitat      | Various.  |
| Habitat      | Rufous-necked hornbill - occupies hill forest   |
|              | Red-collared woodpecker - occupies lowland forest   |
|              | Crested argus – occupies wet evergreen forest with marginal extension into                |
|              | adjacent areas.   |
|              | Suitable habitat for these three species is naturally restricted or possibly absent       |
|              | in the Project area.  |
|              | Spot-bellied eagle owl and hoopoe occupy a range of habitats.                             |
| Threats      | Various.  |
|              | Hunting has severely reduced Lao PDR populations of Rufous-necked                         |
|              | hornbill, the breeding Hoopoe population and, probably to some extent, Spot-              |
|              | bellied eagle owl. Crested argus may also have been locally affected, especially          |
|              | where suitable habitat is naturally or anthropogenically fragmented.                      |
|              | Suitable habitat remains extensive for all species, although ongoing conversion           |
|              | of lowland forest to plantations is probably much reducing suitable habitat for           |
|              | Red-collared woodpecker. Migrant populations of Hoopoe are probably not                   |
|              | threatened in Lao PDR, although many individuals are probably killed.                     |
| Summary      | Although some, perhaps all of these species are likely to inhabit the Project             |
|              | area, it forms only an insignificant part of the habitat in Lao PDR for all of            |
|              | them and it is <b>implausible it could be critical habitat</b> for any of them.           |

|--------------------|---|
| Candidate          | Criterion 1 - The species has an elevated protection status nationally and is   |
| Criteria           | listed as Restricted in the Regulation of the Ministry of Agriculture and   |
|                    | Forestry No. 0360/MAF.  |
| Record             | Direct  |
|                    | TISTR 2013 biodiversity survey did not record the species.  |
|                    | Indirect  |
|                    | The Huay Ngua MP (2010) notes presence of the species within the protected  |
|                    | area.   |
|                    | Biodiversity village surveys in 2013 apparently recognised the species,   |
|                    | reporting it is less common in upper and lower Nam Ngiep, resettlement site   |
|                    | and upper and lower Nam Xan however did not recognise its presence in   |
|                    | Huay Ngua.  |
|                    | Stakeholder village surveys in 2013 recognised the species as very common in<br>Bon Boy, Bon Yamuyan and Bon Balwang of the Nam Naion Biyar as well as                  |
|                    | Ban Pou, Ban Xomxuen and Ban Pakyong of the Nam Ngiep River as well as<br>Ban Pakheuang and Ban Don of the Nam Xan River. Ban Kanyong of the Nam                        |
|                    | Xan River noted the species as common.  |
| Distribution       | The species occurs in Indonesia, Timor-Leste, Bangladesh, Brunei Darussalam,  |
| 2 10 11 2 10 10 11 | Cambodia, India, Lao PDR, Malaysia, Myanmar, Philippines, Singapore,  |
|                    | Thailand and Vietnam.   |
| Population         | The species is considered to be widespread in Lao PDR, and populations are  |
| -                  | considered to be of low global significance.  |
| Habitat            | Duckworth et al (1999) noted the species is expected to occur in most forest  |
|                    | types though it is also documented to inhabit humid forests and is typically  |
|                    | found in riparian areas (Raffles Museum of Biodiversity Research 2013). It also   |
|                    | occurs in agricultural areas, scrubland, mangroves and urban areas (Raffles   |
|                    | Museum of Biodiversity Research 2013).  |
| Threats            | It is threatened by commercial exploitations for the skin trade.  |
| Summary            | Given that the Lao PDR population is not considered to be of global   |
|                    | significance and that is it widespread it is <b>unlikely that the Project area</b><br><b>sustains greater than 10 per cent of the global population or is one of 10</b> |
|                    | discrete management sites globally for the species (C1 Tier 1). The baseline  |
|                    | information <b>does not provide an indication that the habitat is of significant</b>  |
|                    | importance, or that records are part of an important concentration (C1 Tier   |
|                    | 2).   |

| Platysternon megacephalum, Big-headed turtle  |
|---|
| Criterion 1 - The species is listed as Endangered on the IUCN Red List  |
|   |
| Direct  |
| TISTR 2013 biodiversity survey did not record the species.  |
|   |
|   |
| Indirect  |
| The Huay Ngua MP (2010) notes presence of the species within the provincial   |
| preserved area.   |
| Biodiversity village surveys in 2013 apparently recognised the species,   |
| reporting it is less common in upper Nam Ngiep and upper Nam Xan.   |
| The species is native to China, Lao PDR, Myanmar, Thailand and Viet Nam.  |
| The species has been reported to occur in PKK to the west of the Project area as  |
| well as other records in Annamite mountains and southern Lao PDR in 1999  |
| (Duckworth et al 1999).   |
| There is limited information regarding the size of the population of the species.   |
| In 1999 Duckworth et al. reported that Lao PDR populations are considered to  |
| be of moderate global significance with the species being widespread. In 2006   |
| IEWMP reported the species probably occurs widely in the Bolikhamxay  |
| Province with known records from the Ban Nape area, Nam Nouang and  |
| NNT.  |
| The species inhabits fast flowing, cool, rocky mountain brooks and streams,   |
| usually narrower than 1 m and less than 10 cm deep. There are a number of   |
| low order streams that the Project area intersects. The species is thought to be  |
| nocturnal when it forages along the stream bottom and stream edge. It is a  |
| carnivorous species.<br>A key threat to the species will be improved access to the area for illegal   |
| wildlife collectors, either via the reservoir itself, or via project access roads   |
| The key threat to the species is hunting and although current information does  |
| not confirm critical habitat, the precautionary approach should be considered   |
| and the threats to the species should be managed throughout the Project   |
| construction and operation and within any Biodiversity Offset Design.   |

| Species      | Laubuca caeruleostigmata, Flying minnow   |
|--------------|---|
| Candidate    | Criteria 1 - The species is listed as Endangered on the IUCN Red List               |
| Criteria     |   |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey recorded this species in surveyed of the upper       |
|              | Nam Ngiep and lower Nam Xan sites.  |
|              | Indirect  |
| Distribution | The species has been recorded from Thailand in the Mae Khlong and Chao              |
|              | Phraya basins, and from the Mekong in Cambodia, Lao PDR and Thailand.               |
| Population   | There is limited information on the population size of the species. In Thailand     |
|              | 60% of populations extirpated in 10 years due to loss of habitat. It is likely that |
|              | the species is rare in Lao PDR.   |
| Habitat      | Found in large rivers and flooded forest.   |
| Threats      |   |
| Summary      | Species profile information identifies the importance of flood areas and large      |
|              | river environments. If the species is present downstream of the reservoir, the      |
|              | alteration of the flow pattern (especially disruption of daily and annual cycle)    |
|              | may have an indirect impact. Environmental Flows Assessment identifies flow         |
|              | release regime to manage downstream flows for maintaining normal river              |
|              | functions.  |
| References   | Vidthayanon, C. 2011. Laubuca caeruleostigmata. In IUCN 2013. IUCN Red List         |
|              | of Threatened Species. Version 2013.2. www.iucnredlist.org Downloaded on 16         |
|              | January 2014.   |

| Species      | Pangasianodon hypophthalmus, Striped catfish  |
|--------------|---|
| Candidate    | Criterion 1 – The species is listed as Endangered on the IUCN Red List  |
| Criteria     | Criterion 3 – The species is migratory  |
| Record       | Direct<br>TISTR 2013 biodiversity survey did not record the species.  |
|              | <i>Indirect</i> The Huay Ngua MP (2010) notes presence of the species within the provincial preserved area.   |
| Distribution | There is limited information regarding the size of the population of the species  |
|              | however the species remains common and popular aquaculture species. It is used in aquaculture.  |
| Population   | The species is native to Cambodia, Lao PDR, Thailand and Viet Nam.  |
| Habitat      | It inhabits main channels and floodplains, moving off-channel for feeding and<br>nursing. The species feeds mainly on algae, plants, zooplankton, insects, fruits,<br>crustaceans and fish. |
|              | The species is reported to move seasonally from main channels floodplains of  |
|              | large rivers to floodplains and marshland for feeding and nursing. The species  |
|              | is capable of migration in excess of 300 km.  |
| Threats      | Major threats to the species globally include overexploitation, habitat   |
|              | degradation, and changes in water quality and flow. Plans to dam the Mekong   |
|              | may disrupt the species life cycle as the migratory requirements appear to rely   |
|              | on flow or water quality to facilitate migration, cue spawning, and aid dispersal of young.   |
| Summary      | Species profile information suggests that the species utilises main or larger   |
|              | river channels and floodplain areas and undertakes long distance migrations   |
|              | and as such more confirmation of presence of the species is required. In the  |
|              | event there is spawning area downstream of the dam, the area may be   |
|              | considered critical habitat.  |
|              | Environmental Flows Assessment identifies flow release regime to manage   |
|              | downstream flows for maintaining normal river functions to manage this threat to notantial habitat  |
|              | threat to potential habitat.  |

| Species      | Probarbus labeamajor, Thicklipped barb   |
|--------------|--|
| Candidate    | Criterion 1 - The species is listed as Endangered on the IUCN Red List                     |
| Criteria     | Criterion 2 – The species is endemic to the Mekong   |
|              | Criterion 3 – The species is migratory   |
| Record       | Direct   |
|              | TISTR 2013 biodiversity survey did not record the species.                                 |
|              | Indirect   |
|              | The Huay Ngua MP (2010) notes presence of the species within the provincial                |
|              | preserved area.  |
| Distribution | The species is endemic to the Mekong and reported only from the Mekong                     |
|              | mainstream from Nakorn Phanom Province (Thailand) and Sambor District,                     |
|              | Kratie District (Cambodia). It has also been found in Sesan, Sekong and Srepok             |
|              | tributaries of the Mekong.   |
| Population   | Population size is not well understood though it is noted to be decreasing and             |
|              | a population decline of at least 50% is inferred across the global population.             |
| Habitat      | The species inhabits the deep, slow reaches of the main channel of large rivers            |
|              | with a sand or gravel substrate and abundant mollusc population. It is known               |
|              | to undertake short distance migrations for spawning in November and                        |
|              | January. The species feeds on aquatic plants, insects and shelled molluscs.                |
|              | The species is reported to undertake short distance migrations for spawning in             |
|              | November and January.  |
| Threats      | Threats to the species include overfishing, habitat destruction and large dams.            |
| Summary      | Specialist input (Dr Maurice Kottelat pers comm 11/11/2013) indicated that                 |
|              | the species is not known to occur in the Project area part of the catchment and            |
|              | the record would require verification. The species is very distinctive and                 |
|              | identification is generally unproblematic, as such the record is likely valid.             |
|              | Species profile information suggests that the species utilises main or larger              |
|              | river channels. Should the record be correct, the habitat in the lower reaches of          |
|              | the Nam Ngiep River may be susceptible to indirect impacts from the propose                |
|              | dam, however the area is unlikely to represent >10% of the habitat within the              |
|              | Mekong. The Project area is not considered to be critical habitat for the                  |
| Deferrer     | species.   |
| References   | Baird, I. 2011a. <i>Probarbus labeamajor</i> . In IUCN 2013. IUCN Red List of              |
|              | Threatened Species. Version 2013.1. www.iucnredlist.org Downloaded on 12<br>Sontambar 2013 |
|              | September 2013.  |

| Species      | Wallago leeri   |
|--------------|---|
| Candidate    | Criterion 1 – The species has an elevated protection status nationally and is           |
| Criteria     | listed as Restricted in the Regulation of the Ministry of Agriculture and               |
|              | Forestry No. 0360/MAF.  |
| Record       | Direct  |
|              | TISTR 2013 biodiversity survey did not record the species.                              |
|              |   |
|              | Indirect  |
|              | The Huay Ngua MP (2010) notes presence of the species within the provincial             |
|              | preserved area.   |
| Distribution | The distribution of the species reaches from the Mekong delta to northern Lao           |
|              | PDR and Thailand. Other sources note that reports of the species from the               |
|              | Mekong River basin are mis-identifications of Wallago micropogon. W. leeri is           |
|              | restricted to western Indonesia and Malay Peninsula where in the Mekong                 |
|              | River W. micropogon occurs.   |
| Population   | No information available  |
| Habitat      | W. micropogon is found in rivers and smaller streams. It moves to flooded               |
|              | forests during high water levels and migrates from rivers to smaller steams to          |
|              | spawn.  |
| Threats      | Threats to <i>W. micropogon</i> are likely related to loss of riverine forest and       |
|              | possibly changes to flow regimes.   |
| Summary      | Wallago micropogon is listed as data deficient on the IUCN Red list, it has been        |
|              | previously misidentified as <i>W. leeri</i> in the Mekong. As such the species is not a |
|              | candidate for critical habitat.   |
| References   | Allen, D. 2011. Wallago micropogon. In: IUCN 2013. IUCN Red List of                     |
|              | Threatened Species. Version 2013.1. www.iucnredlist.ord. Downloaded on 20               |
|              | November 2013.  |

| Species               | Migratory Fish Species   |
|-----------------------|--|
| Candidate<br>Criteria | Criterion 3 – These species are migratory  |
| Record                |  |
| General               | <ul> <li>Acantopsis choirorhynchos (Horseface loach) – potamodromous, occurs in swift, clear streams with sand or gravelly substrate, also large rivers. IUCN distribution does not include Lao PDR (Ng 2012a).</li> <li>Barbonymus gonionotus (Java barb) – potamodromous, occurs in rivers, streams, floodplains and occasionally reservoirs. Prefers standing water habitats. Local migrant from the Mekong to small streams and flooded areas (Thinh et al 2012). The species is widely distributed and cultivated.</li> <li>Henicorhynchus lineatus – occurs mainly in medium to large-sized rivers and enters flooded fields (Allen 2011).</li> <li>Henicorhynchus ornatipinnis</li> <li>Hypsibarbus venayi</li> <li>Luciosoma bleekeri (Shark minnow) – occurs in rivers and tributaries, moving to floodplains in the rainy season (Vidthayanon 2012a).</li> <li>Mystacoleucus atridorsalis – occurs in lowland rivers and submontane streams and tributaries (Vidthayanon 2012c).</li> <li>Oxyeleotris marmorata (Marbled goby) – occurs in wetlands, rivers, ponds, reservoirs, canals, swamps and flooded forest. Prefers little to no water movement (Allen 2011b). Conflicting evidence regarding the migratory nature of this species.</li> <li>Scaphognathops bandanensis</li> <li>Sikukia gudgeri (Sikuk barb) – common throughout its range, potamodromous, migrates from Cambodia to southern Lao PDR and</li> </ul> |
| Summary               | north-eastern Cambodia between November and February (Baird 2012).<br>For species where the aquatic habitats up and downstream of the access road<br>crossings may play a role in migration pathways, the area may be considered<br>critical habitat. Further investigation into the migratory species relevant to the<br>Project area is scheduled.   |
|                       | Environmental flows release from the proposed dam will be required to<br>consider the requirements of migratory species.   |

#### INTRODUCTION

1

The Nam Ngiep 1 Hydropower Project (the Project) involves construction and operation of a hydroelectric power generation facility on the Nam Ngiep River, Lao PDR. The Project site is located in the provinces of Vientiane, Xieng Khouang and Bolikhamxay, approximately 145 kilometres (km) northeast from the city of Vientiane or 50 km north from Pakxan District. Project details are reported in the Nam Ngiep 1 Hydropower Project Environmental Impact Assessment (EIA) along with the assessment of other terrestrial and aquatic biodiversity values.

The proposed Project lies on the Nam Ngiep River which flows in a southsoutheast direction through a mountainous region to the gorge at Hat Gniun village where the topography changes to a hilly landscape before entering the Mekong River at Pakxan. The gorge is the location for the proposed dam construction.

This report focusses on collating available information from specialist reports and literature sources for *Luciocyprinus striolatus* such that critical habitat determination can be undertaken, mitigation options can be identified and offsetting strategies can be developed. It describes the biological aspects, distribution and threats to the species to support the conclusions. The species is not previously known for the Nam Ngiep catchment however during biodiversity studies undertaken to inform the EIA, anecdotal evidence of the species was collected and sub sequential studies have in turn been undertaken the population and its distribution. The species is listed as Endangered on the IUCN Red List of threatened species.

This report is informed by expert advice documented and provided in Annex A - D provided by Mr Terry Warren (Annex *A* and *B*), Dr Maurice Kottelat (Annex *C*), and Mr Sinthavong Viravong and Mr Thavone Phommavong (Annex *D*). The information collated combines known records and anecdotal reports where appropriate.

#### 1.1 INFORMATION LIMITATIONS

This report collates information derived from literature, field sampling, habitat surveys, village interviews and other observations. As such some information presented is based on anecdotal evidence provided by local people during interview.

Anecdotal evidence has been used in the absence of more detailed survey data in sections of this report. Warren (2014b) notes that, over the limited survey period, capturing an individual or witnessing spawning behaviour would be challenging, as the species lives in low abundance. During Warren's village interview, measures were employed to maximise confidence in valid species identification and the anecdotal nature of the data has been considered when drawing conclusions.

#### ENVIRONMENTAL RESOURCES MANAGEMENT AUSTRALIA

Through collection of data for this report, it is also noted that a substantial amount of the information for the species has been collected to inform hydropower Project assessments and as such there is survey bias. The distribution of the species shown in the literature is likely to be biased toward these targeted locations, i.e. fewer surveys are likely to have been undertaken in areas not being considered for hydropower infrastructure and the presence of the species in such areas is less well known.

#### 2 BIOLOGICAL PROFILE

*Luciocyprinus striolatus* is a large predatory fish of the family Cyprinidae (Kottelat 2011). The species is differentiated from the other species of the genus by the presence of five to eight longitudinal black stripes on the body of adults, 78 to 89 lateral line scales, and 40 to 46 predorsal scales.

The species is reported to reach up to 70-100 kg in weight, however there are almost no recent reports of large specimens (greater than 60 kg) (Warren 2014a). Females have been recorded growing to about 1.5 m (reportedly up to 2 m) long, and males are reported to be smaller. A fisherman from Ban Pou described one female fish caught as about 1.5 m long and weighing 22 kg, 1 kg of which was eggs (Kottelat 2014).

The species lives in upland areas (Warren 2014a). Interviews with local fishermen and observations of the species in the Nam Theun drainage indicate that adults live in deep pools, with a possible preference for the upper and lower parts of the pool, near rapids, riffles and runs (Kottelat 2014). Interviews by Baird *et al.* (1999, cited in Warren 2014a) indicate that the species occupies middle to surface water strata and prefers rivers with small stones substrate or large slabs of rock. Deep pools of between two and six metre depth during dry season conditions are expected to be preferred (Warren 2014b).

The species is reported to spawn in shallow, flowing water (approximately 40 – 50 cm deep) along beaches of pebbles, gravel or sand (Kottelat 2014). One fisherman reported that water was no more than approximately 20 cm deep at a spawning site (Warren 2014a), and others noted that fish dorsal fins were out of the water (Kottelat 2014). These shallow habitats are likely several meters above the dry season water level (Kottelat 2014). Based on anecdotal observations, the species forms small groups (reportedly around ten individuals) and apparently spawn in pairs (Kottelat 2014).

Spawning is believed to occur in November-December, however there may be local variation. Fishermen interviewed have reported spawning in January-March. Information obtained by Kottelat in Nam Theun in 1996 indicated spawning in January-February, and information obtained by Kottelat in Nam Kading in 2002 indicated spawning in October-December (Kottelat 2014). Baird has reported the fish breeds in May and June (Warren 2014a).

The species is not known to migrate (Kottelat 2011), although fishermen provided anecdotal evidence of local seasonal movements (Kottelat 2014). Fishermen in Ban Pou reported that the species moves downstream to large pools from November to May (Kottelat 2014).

The species is predatory and feeds on aquatic animals (mainly fish and perhaps some amphibians) (Kottelat 2014; Warren 2014). The species has also been reported to capture small mammals that enter the water, such as dogs and monkeys, however this is likely to be exceptional behaviour of very large individuals (Kottelat 2014). The species is not very abundant and this is typical of large predatory animals (Kottelat 2014).

#### 3 DISTRIBUTION

#### 3.1 GLOBAL AND NATIONAL

*L. striolatus* has been recorded in Lao PDR and China, although it is not known if the species persists in China currently (Kottelat 2014).

In Lao PDR, the species is reported to been found in upper Xe Kong, upper Nam Kading (Nam Theun and Nam Ngouang), upper Nam Ou, the upper Xekaman, Nam Ngum and upper Nam Tha rivers (Kottelat 2014). The species is absent from the Mekong floodplain. *Figure 3.1* indicates the catchments where the species has been found in Lao PDR according to Warren (2014). Kottelat (2014) also notes anecdotal evidence of the species in the Nam Tha catchment though location information is unavailable.

A recent survey of fast water habitats by Kottelat (2014) (Annex *C*) identified the first anecdotal evidence of the species in the Nam Ngiep catchment, and the first information suggesting its presence in the neighbouring Nam Xan catchment. Although no specimens were obtained during the survey, the identifications appear reliable. Subsequent target survey by Warren (2014b) also recorded anecdotal evidence of the species in the Nam Ngiep and Nam Xan catchments during village interviews. Further detail specific to the distribution in the Nam Ngiep and surrounding catchments is provided in Section *3.2*.

*Table 3.1* summarises the available information on the occurrence of *L. striolatus* in each catchment in which it is known to occur in Lao PDR.

The species is listed as Endangered on the IUCN list due to suspected and inferred population declines of 50% or more over the past 30 years (Kottelat 2011). The listing is due to a decline in the quality and availability of habitat resulting from hydro-power development throughout the species' range, as well as the removal of individuals through recreational and illegal fishing and poaching. Other reported impacts to the species' habitat include soil erosion, sedimentation and chemical pollution associated with logging, deforestation and agriculture within the species' distribution (Kottelat 2011).

| Catchment                      | Description of occurrence   |
|--------------------------------|---|
| Nam Ou (Lao PDR)               | <ul> <li>Warren (2010, cited in Warren 2014a) identified an individual at a<br/>market that was caught in Nam Ou, upstream of Ban Hat Sa, and<br/>another juvenile specimen caught in Huay En, a tributary of Nam Ou<br/>(Phongsaly Province).</li> </ul>   |
| Nam Theun/<br>Kading (Lao PDR) | <ul> <li>Individuals identified by Warren (1995, cited in Warren 2014a) were identified as being sourced from Nam Theun, near Ban Thabac.</li> <li>Local fishers at Ban Thabac on the Nam Theun considered the specie was found more frequently in Nam Gnounang (a tributary of Nam Kading) than Nam Theun (Warren 2014a).</li> <li>There is anecdotal evidence of much larger <i>L. striolatus</i> being found between Ban Thabac and Ban Huay Gan Ya in 1995 (now the Theun Hinboun head-pond) (Warren 2014a).</li> <li>There is anecdotal evidence of observed spawning behaviour of <i>L striolatus</i> prior to the closure of the Theun-Hinboun dam in December 1997 and subsequent submergence of rapids (Warren 2014a).</li> <li>Local people interviewed in 1997 noted that the largest individual caught in Nam Mouan were approximately 1.0 m in length and weighing up to around 10 kg (Warren 2014a).</li> <li>In theory, the population in Nam Theun drainage, upstream of the Nam Theun reservoirs, in Nakay NBCA, is the only population no threatened by impacts happening upstream and is possibly the population in the safest condition (Kottelat 2014).</li> </ul> |
| Xe Kong (Lao PDR)              | <ul> <li>Juvenile <i>L. striolatus</i> were identified from the upper Xe Kaman in Saysettha District in Attapeu Province in 1996 (Baird et al. 1999, cited in Warren 2014).</li> <li>Juveniles are rarely seen in the lower parts of Xe Kong in Kaleum District, although juveniles are rarely seen (Baird et al. 1999, cited in Warren 2014).</li> <li>It is not common in the lower part of Xe Kong in Lamam District, X Kong Province and is not found at all in the lower part of the X Kong in Attapeu Province (Baird et al. 1999, cited in Warren 2014a).</li> </ul>   |
| Nam Ngiep (Lao<br>PDR)         | • Further description of the species' presence in this catchment i provided in <i>Section 3.2</i> .   |
| Nam Xan (Lao<br>PDR)           | <ul> <li>Anecdotal evidence identifies a population of the species near Muany Thathom (Warren 2014b)</li> <li>Anecdotal evidence during Kottelat (2014) survey, though ne specimen collected.</li> </ul>  |
| Nam Ngum (Lao<br>PDR)          | Photograph listed from Nam Ngum reservoir (Rainboth et al. 2012)  |

| Xishuang Banna<br>(China)      | <ul> <li>The species was originally described in Xishuang Banna, China, and<br/>is known from the Nala and Buyuan rivers. However, it is uncertain<br/>as to whether this species still occurs in China (Kottelat 2014).</li> </ul>   |

# Table 3.1Description of occurrence in each known catchment

#### 3.2 NAM NGIEP AND SURROUNDING CATCHMENTS

The survey undertaken by Kottelat (2014) (Annex *C*) revealed the first evidence of the species in the Nam Ngiep catchment. Given the evidence is the first from the catchment, the habitat must be considered for its importance to the species.

The full distribution of the species is not well understood hence to obtain an understanding of the distribution within Nam Ngiep, three village interview surveys were undertaken as part of the additional targeted studies for the L. striolatus.

- Viravong and Phommavong (2014) held interviews between the upper Project full supply level (FSL) and near NN2 (incorporated Nasong, Viengthong, Nasay and Xiengkhong villages) (Annex *D*);
- Kottelat (2014) reported interviews upstream of the FSL in Ban Thaviang, Ban Viengta and Ban Pou (Annex *C*); and
- Warren (2014b) undertook interview in the upper Nam Ngiep catchment and various adjacent sub-catchments (Annex *B*).

*Figure 3.2* shows the location of the villages interviewed, location of spawning sites reported, fish conservation zones (FCZ) identified and key landmarks.

Kottelat (2014) reported fishermen working in the Nam Ngiep noted that the species occurs as far upstream as Sop Syem (approximately 7 km upstream of Ban Thaviang, near the NN2 Powerhouse). It was reported that this stretch of the river, upstream of Ban Thaviang, is too shallow for the species to occur during the dry season. The individuals in the upstream section of the river are said to be smaller, with large fish believed to occur downstream of Kaen Tao (Kottelat 2014). Interviews by Warren (2014b) also reported the species in this region with anecdotal evidence from the Nam Siam and between Xiengkhong and Nasong. The results of the survey suggested the species occupies habitats between 325m and 800m elevation with the Nam Siam the smallest river where the species was reported to migrate for spawning or feeding (Warren 2014b).

Warren (2014b) also reported evidence of the species in lower Nam Chian (or Nam Jey) and the neighbouring Nam Xan catchment.

Fishermen suggested that the species may occur as far downstream as the Mekong, but have not fished that far downstream. Fishermen from Ban Xomxuen report catching the species at Hat Nguen, below the confluence of Nam Ngiep and Nam Xao in October-November, but not at any other time of the year (Kottelat 2014).

A fisherman working between Ban Viengta and Ban Soppouan reported that the species is present in Nam Chae although other fishermen indicated they had not caught the species in Nam Chae (Kottelat 2014). Two spawning sites were reported within the inundation zone: Kaen Tao 'beach', about 4 km downstream of Ban Pou, and Wang Mon 1 km downstream of Ban Pou (Kottelat 2014). Warren (2014b) reported three additional spawning locations between Xiengkhong and Nasong, and Viravong and Phommavong (2014) noted it is highly likely that more spawning habitats occur in the river.

The outcomes of the surveys suggest the habitat may be of importance to the species. Further work is scheduled to obtain additional information regarding the distribution of the species and its habitat.

#### 4 THREATS TO THE SPECIES

#### 4.1 THREATS IN LAO PDR

The main threats to freshwater fish biodiversity in Indo-Burma region relate to alteration of river morphology (from hydropower, irrigation and navigation), pollution, mining, exploitation and invasive species (Kottelat *et al.* 2008). The *L. striolatus* population is vulnerable to dams, exploitation and habitat degradation through impacts to the aquatic environment associated with mining, deforestation and agriculture. Kottelat (2014) notes that most populations of the species in Lao PDR are impacted, or are likely to be impacted, by hydropower and/or mining projects.

Hydropower and other dam development result in physical blockage of upand downstream fish movement. *L. striolatus* is not a long-distance migrator however is expected to move within river basins to access feeding and spawning habitat areas (as described in Section 2). The barrier induced by dam infrastructure has potential to limit natural movements and interrupt reproductive behaviours.

Similarly, the water flow barrier leads to an alteration in the hydrological pattern and volume to downstream. This is likely to include an increase in dry-season discharge, reduction in discharge at the beginning of the wet season and potentially daily fluctuations of discharge. Specific to the Nam Ngiep population, the discharge from the NN2 project and NN3, located upstream of the spawning locations identified, may already threaten the downstream habitat. Daily fluctuation in water level is a well-known cause of destruction of fish habitat, especially spawning sites (Kottelat 2014). Eggs attached to vegetation or deposited in sand/gravel (as observed for L. striolatus) become exposed and die within a few minutes. The extent of this potential impact is unknown with additional detail regarding the wet-season condition of the spawning sites and the planned discharge from NN2. The testing phase of NN2 also presents a threat to the habitats within the Nam Ngiep with the short but potentially intense discharge flows. These threats are likely to be associated with all dam installations in L. striolatus inhabited rivers.

Fishing using illegal fishing techniques and exploitation of the fisheries resource for sale is also a threat to the species. Fishing using explosives ichthyocides and ichthyoanesthetics used to be common in some catchments in the 1990s. The rate of use of these techniques currently is not well understood. With development occurring across Lao PDR there is a rapidly expanding human population and as such fishing is no longer only for subsistence but also for income. The high market food commodity and fuel cost encourage local people to exploit local resources.

Large scale changes to the landscape, for example rubber plantations, mining and other agricultural conversion, have been associated with declines in fish population and diversity (Kottelat et. al. 2008). Consequences such as pollution from activities (for example herbicide or mining chemical pollution) as well as siltation and river bed and bank disturbance, destroys and degrades habitat for fish species.

#### 5 CRITICAL HABITAT STATUS

#### 5.1 CRITICAL HABITAT CRITERIA

The Asian Development Bank Environmental Safeguards Good Practice Source Book (the 'Source Book') (ADB 2012) contain specific requirements for different habitat types that relate to their likely conservation value. Relevant to *L. striolatus*, the Source Book describes critical habitat as:

'an area that has high biodiversity value, including habitat required for the survival of critically endangered or endangered species; areas having special significance for endemic or restricted-range species; ...'

L. striolatus is an Endangered species on the IUCN Red List.

In order to identify if the Project is located within critical habitat for a species, the available information is screened against the International Finance Corporation (IFC) critical habitat criteria and thresholds. The criteria for Critically Endangered and Endangered species are considered in two tiers (IFC Performance Standard 6 Guidance Note 2012):

Tier 1

- a) Habitat required to sustain >10 percent of the global population of a CR or EN species/subspecies where there are known, regular occurrences of the species and where that habitat could be considered a discrete management unit for that species.
- b) Habitat with known, regular occurrences of CR or EN species where that habitat is one of 10 or fewer discrete management sites globally for that species.

#### Tier 2

- c) Habitat that supports the regular occurrence of a single individuals or a CR species and/or habitat containing regionally-important concentrations of a Red-listed EN species where that habitat could be considered a discrete management unit for that species/subspecies.
- d) Habitat of significant importance to CR or EN species that are wideranging and/or whose population distribution is not well understood and where the loss of such a habitat could potentially impact the longterm survivability of the species.
- e) As appropriate, habitat containing nationally/regionally important concentrations of an EN, CR or equivalent national/regional listing.

#### 5.2 **POPULATION MANAGEMENT UNITS**

The criteria for critical habitat reference discrete management units for species. For the purposes of this assessment each catchment where the species has been reported is considered to be a management unit. It is recognised that there may be more than one management unit within each catchment however the available information is insufficient with confirm this aspect.

Specific to known Lao PDR *L. striolatus* population locations, the main threats in those catchment areas are summarised in *Table 5.1*. Warren (2014a) reports the relative risks to each population based on specialist knowledge of the sensitivity of the population locations and magnitude of threats. More recent information supports the suggestion that the species also occurs in the Nam Xan catchment. Habitat for the species in this catchment also exhibits threats from dam infrastructure.

| Management Unit  | Habitat<br>Sensitivity/<br>Value | Magnitude of<br>Effect | Key Threats   | Key Conservation Opportunities   |
|--|----------------------------------|------------------------|---|--|
| Middle Nam Ngiep<br>mainstream and<br>tributaries (Nam Ngiep 1<br>dam site upstream to<br>Thathom) | Medium                           | Medium                 | <ul> <li>NNP1 Project impacts may only be medium after completion of the Project. But these may rise to a higher level after completion of NN2 Project. First steps must be to establish if the species is in the area. Kottelat (2014) did not observe the species during his January 2014 survey.</li> <li>However, anecdotal evidence provided by villagers from Ban Pou, Ban Thaviang, Ban Viengta and Ban Xomxuen indicates that it does exist in these areas at least.</li> <li>Mining activities always pose a potential threat to aquatic ecosystems and the flora and fauna that reside in them.</li> <li>Human population expansion and over exploitation of all aquatic resources is always a possibility especially in areas close to the capital.</li> </ul> | <ul> <li><i>L. striolatus</i> can only really be managed if stretches of mainstreams and large tributaries where the species has been reported from or observed in markets etc. can be preserved, and this includes suitable spawning habitats.</li> <li>Fishery Conservation Zones (FCZs) may be effective in conserving not only the species in question, but also fish that undoubtedly form part of its diet.</li> <li>Use of modern technology and "state of the art" pollution protection systems may help to protect <i>L. striolatus</i> populations.</li> </ul> |
| Upper Nam Ngiep<br>mainstream and<br>tributaries (Thathom<br>upstream to headwaters)               | High                             | Medium                 | • NN2 Project impacts may be greater than NNP1 due to habitats that may be more suited to the species.  | • What must be established is just how small a stream is that might be able to maintain viable populations of <i>L. striolatus</i> .   |

# Table 5.1Threats to L. striolatus populations in the Lao PDR (Warren 2014a)

| Management Unit   | Habitat<br>Sensitivity/<br>Value | Magnitude of<br>Effect | Key Threats   | Key Conservation Opportunities   |
|---|----------------------------------|------------------------|---|--|
| Middle Nam Ou<br>mainstream and<br>tributaries (Muang Khua<br>upstream to Muang<br>Phongsaly) | High                             | High                   | <ul> <li>The Nam Ou is earmarked for at least seven hydropower dams and work on three projects has begun already.</li> <li>Widespread semi-commercial mining of gold using up to and around 100 back-hoe diggers over the last 10 to 15 kilometers of the Nam Ou before it confluences with the Mekong (2010)</li> <li>Some artisanal gold mining taking place also, but not much mining activity takes place in the middle and upper reaches of the Nam Ou.</li> <li>Fishing with explosives not very common throughout most of the Nam Ou valley because it is easily observed and not tolerated by local communities (2010 survey)</li> <li>Fishing with ichthyocides and ichthyoanesthetics was common in the river sections of the Nam Ou upstream from Ban Hat Sa all the way up to Ban Sop Kang beyond proposed site of the Hat Hin HPP (2010 survey)</li> <li>Not much evidence of fishing using electrical devices during surveys in 2010</li> </ul> | <ul> <li>It is necessary to establish exactly if the populations are isolated and if a single species only is involved.</li> <li>There was a move by the GoL to prevent any more licenses to prospective semi-commercial gold mining operators in 2010 because of the environmental damage that was taking place.</li> <li>Fishing with ichthyocides can using other illegal fishing methods can only addressed through education programs.</li> </ul> |

#### 5.3 CRITICAL HABITAT ASSESSMENT

*Table 5.1* summarises the outcomes of screening against the critical habitat assessment criteria. The information collated identifies that the species potentially meets the threshold for the Tier 1 criteria.

| IFC PS6 Criterion/Threshold   | Comment   |
|---|---|
| Tier 1  |   |
| Habitat required to sustain >10<br>percent of the global population of a<br>CR or EN species/subspecies where<br>there are known, regular occurrences<br>of the species and where that habitat<br>could be considered a discrete<br>management unit for that species. | Species population size is not well documented. The<br>specialist studies undertaken identified a number of<br>locations where the species is known by local villagers<br>that have not been previously reported in literature.<br>As this species is not considered a long distance<br>migrator, rather undertakes local seasonal movements,<br>the upper and middle Nam Ngiep may be considered<br>a management unit. Village interviews indicate that<br>although rare there are regular occurrences of the<br>species within the Nam Ngiep. |
| Habitat with known, regular<br>occurrences of CR or EN species<br>where that habitat is one of 10 or<br>fewer discrete management sites<br>globally for that species.   | Collation of information regarding the distribution of<br>the species, and as such the location of populations,<br>identified at least 8 river basins where there are<br>known records of the species occurring. Village<br>interviews indicate that although rare there are<br>regular occurrences of the species in the Nam Ngiep.<br>As such this population may be one of 10 or fewer<br>discrete management sites globally for the species.  |

The ADB SPS notes that no project activity is permitted in critical habitat area unless (ADB 2012):

- There are no measurable adverse impacts, or likelihood of such, on the critical habitat that could impair its high biodiversity value or ability to function;
- The project is not anticipated to lead to a reduction in the population of any recognized endangered or critically endangered species, or a loss in the area of habitat of concern such that the persistence of a viable and representative host ecosystem will be compromised; and
- Any lesser impacts are mitigated to achieve at least no let loss to biodiversity.

The information collated in this report has characterised the distribution of the species (in terms of discrete management units) to be wider than previously documented. The recent habitat surveys (Warren 2014b) identified a number of Nam Ngiep tributaries where the species has been reported and habitat is suitable. Some of these, for example Nam Chain and Nam Siam are unlikely to be impacted by the NNP1. While the habitat within and upstream of the

FSL may be of importance to the species, the distribution of the species is not well understood and as such additional survey work is planned to assess the distribution and inform the design of a species action plan.

Mitigation and management options have been investigated that target maintaining the population size for the species and managing the potential impacts and threats to habitat areas upstream of the FSL. These are described in Section *6*.

### 6 PROPOSED MITIGATION MEASURES

#### 6.1 APPROACH

Mitigation has been considered for *L. striolatus*. The purpose of the mitigation is to recommend approaches to minimise the magnitude of the impact to the species.

The impacts from the project as defined include:

- Loss of habitat, including spawning habitat (potential critical habitat);
- Permanent fragmentation of habitat; and
- Degradation of habitat.

#### 6.2 WATERSHED MANAGEMENT ABOVE FULL SUPPLY LEVEL

The key threats identified in the Nam Ngiep River above FSL include: impacts from water releases from the Nam Ngiep 2 Hydro Scheme; fishing and poaching; and impacts on habitat associated from soil erosion, sedimentation and chemical pollution associated with logging, deforestation and agriculture.

The approach proposed for watershed management to protect the species habitat necessary for its lifecycle and mitigate against the threats identified. An adaptive management framework would be necessary to be designed to aid in mitigation against these impacts from the threats. The approach is outlined in *Table 6.1*.

Implementation of this management framework will require a close working relationship with landholders, Ministry of Natural Resources and Environment (MoNRE) and the Nam Ngiep 2 Hydro Power Scheme.

| Activity   | Action  | Respon                             | sibility |
|------------|---|------------------------------------|----------|
| Research   | <ul> <li>Undertake research into the biology of the species, including population size, breeding cycle and habitat requirements.</li> <li>Undertake a comprehensive assessment of key threats to the species.</li> <li>Map the suitable deep pools and spawning habitats upstream of the NNP1 FSL, including in the Nam Ngiep tributaries in order to target habitat management in these areas.</li> </ul>  | NNP1 on association<br>with LaRREC |          |
| Management | <ul> <li>Develop a management plan for the species in the Nam Ngiep aligned with conservation outcomes for the species and peer reviewed by relevant scientists.</li> <li>Manage key threats, including impacts to spawning and deep pool habitats from landuse impacts such as forestry and agriculture.</li> <li>Incorporate key actions into the Watershed Management Plan being prepared by MoNRE.</li> <li>Approach and discuss management actions with NN2 Hydro Power Scheme and NN3 to investigate opportunity for coordinated release. Coordinated release could aim to maintain suitable seasonal depth in key habitat areas.</li> <li>Align the watershed management program with the captive breeding program (See Section 6.2.1).</li> </ul> | NNP1;<br>MoNRE                     | LaRREC;  |
| Education  | • Undertake an education program with local villagers regarding the species, including informing them of the declining population and the requirement for conservation.   | NNP1;<br>MoNRE                     | LaRREC;  |
| Monitoring | • Monitoring of the species presence in the Nam<br>Ngiep River (and tributaries) including:<br>population size; threats; effectiveness of<br>education programs; location of spawning sites<br>and water quality should occur on a regular<br>basis.  | NNP1;<br>MoNRE                     | LaRREC;  |
| Governance | • NNP1 Offset Advisory Committee to oversee the implementation of the management framework, including reporting and adaptive management approaches to the species conservation.   | NNP1PC;<br>MoNRE                   | LaRREC;  |

Estimated costs for this program are in the vicinity of \$20,000 USD per annum. It is recommended that further analysis of the specific costs for mitigation occurs once the management plan is developed. These actions would be built into the Watershed Management Plan to be prepared by MoNRE. Consultation with the Nam Ngiep 2 Hydropower scheme should occur as a matter of priority.

#### 6.3 CAPTIVE BREEDING

Captive breeding of *L. striolatus* would have the objective of preserving the genetic resource of the population as well as ensuring that the population could be restocked in the Nam Ngiep River. This measure would guard against future population decline in the river due to threats. This measure is not intended to occur in isolation and will be undertaken with strategic watershed management activities to protect and enhance the habitat with the Nam Ngiep for the species.

Contact has been made with fisheries experts to determine the suitability of captive breeding for the population of *L. striolatus* in the Nam Ngiep River. Dr Morioka from the Japan International Research Center for Agricultural Sciences (JIRCAS) has provided initial advice on the practicality of captive breeding for the species. Contact has also been made with Dr Philippe Cacot from the French Agricultural Research Centre for International Development (CIRAD). Dr Cacot has provided a recommended approach for a scoping study to investigate the potential to captive breed *L striolatus* (See *Annex E*). Both of these scientists work with the Living Aquatic Resources Research Centre (LaRREC) in Lao PDR.

The recommendations from Dr Morioka suggest that captive breeding for the species is feasible. The approach would require further ecological assessment of the species lifecycle, including information on the biology of the species and its breeding triggers and population size in the Nam Ngiep River. Capture of mature individuals would then be required to form a captive population of both sexes. For genetic diversity, the number of individuals captured should be representative of the population size (10 or more of each sex has been recommended. Dr Morioka believes that LaRREC has the resources available to undertake the research and captive breeding of the species at their facilities in Vientiane.

The estimated timeframe for research and establishment of breeding stock is around 5 years. An estimated cost for this to occur would be \$20,000 USD per annum.

#### 7 IMPACT TO THE SPECIES

#### 7.1 IMPACT ASSESSMENT

Specific to *L. striolatus*, the Project has the potential to impact the population in the Nam Ngiep River in terms of:

- Loss of habitat, including spawning habitat (potential critical habitat);
- Permanent fragmentation of habitat; and
- Degradation of habitat.

There are also threats associated with the hydropower infrastructure upstream (Nam Ngiep 2 Hydro Scheme) of NNP1 that may also impact other spawning areas that may occur, though the extent of these effects is unknown.

Approximately 73 km of the Nam Ngiep River will be inundated and the existing lotic habitat will be transitioned to lentic habitat (within the inundation area). The habitat within FSL includes two known spawning areas. Village interviews identified six spawning areas upstream of the FSL and suggest it is likely others would occur. Two are currently known to be within designated fish conservation pools. The interviews also reported the species to occur in the Nam Siam and Nam Chain tributaries of the Nam Ngiep catchment which are unlikely to be impacted by the Project. Section 2 indicates that spawning habitat is characterised to be shallow, flowing and pebble, gravel or sand. As such inundation is likely to transition these areas to deeper water not necessarily suitable for spawning.

Impact to a breeding area has potential to lead to an adverse impact to the population by limiting opportunity for reproduction and thus survival of the population. Current information indicates a limited number of populations are known across the species distribution and as such loss of a population in conjunction with threats to other populations may have severe impacts to the survival of the species.

Consistent with the Project EIS, risk to the species is assessed using the risk assessment matrix shown in *Table 7.1*.

The species is listed as endangered and as such is assigned a sensitivity of *High*. Given that the Project has potential to remove two spawning sites this may have a *Medium* impact to the species population. Removal of spawning habitat is likely to reduce opportunity for recovery of the species. Without any management or mitigation the risk to the species is considered to be *Major*.

|                           |  | Magnitude of Effect |                    |          |          |
|---------------------------|--|---------------------|--------------------|----------|----------|
| Species Sensitivity/Value |  | Negligible          | Small              | Medium   | Large    |
| Low                       | Species which are included on the IUCN Red<br>List of Threatened Species as Least Concern<br>(LC) (IUCN 2011).   | Not<br>significant  | Not<br>significant | Minor    | Moderate |
| Medium                    | Species included on the IUCN Red List of<br>Threatened Species as Vulnerable (VU), Near<br>Threatened (NT) or Data Deficient (DD)<br>(IUCN 2011). | High                      | Species included on the IUCN Red List of<br>Threatened Species as Critically Endangered<br>(CR) or Endangered (EN) (IUCN 2011).<br>Species having a globally Restricted Range<br>(i.e. plants endemic to a site or found<br>globally at fewer than 10 sites, fauna having<br>a distribution range (or globally breeding<br>range for bird species) less than 50,000 km <sup>2</sup> .<br>Internationally important numbers of<br>migratory or congregatory species. Key<br>evolutionary species. | Not<br>significant  | Moderate           | Major    | Critical |
| Magnitud                  | e of Effect Definition   |                     |                    |          |          |
| Negligible                | Effect is within the normal range of variation.  |                     |                    |          |          |
| Small                     | Affects a small proportion of a population, but does not substantially affect other species dependent on it, or the populations of the species itself  |                     |                    |          |          |
| Medium                    | Affects a sufficient proportion of a species population that it may bring about a substantial change in abundance and /or reduction in distribution over one or more generations, but does not threaten the long term viability of that population or any population dependent on it.  |                     |                    |          |          |
| Large                     | Affects an entire population or species at sufficient scale to cause a substantial decline in abundance<br>and/or change in distribution beyond with natural recruitment (reproduction, immigration from<br>unaffected areas) may not return that population or species, or any population or species dependent<br>upon it, to its former level within several generations, or when there is no possibility of recovery.   |                     |                    |          |          |

# Table 7.1Assessment of risks to Species

#### 7.2 RESIDUAL IMPACT

Section *6* describes the recommended mitigation specific to the potential impact to *L. striolatus* in the Nam Ngiep River. The mitigation recommendations focus on maintaining reproduction of the species and protecting the remainder of habitat in the Nam Ngiep River catchment.

A captive breeding program (Section 6.2) aims to establish a program that preserves the genetic resource while facilitating restocking of the Nam Ngiep River. Given the threats to other known populations of the species as well as potential threats to habitat associated with infrastructure upstream of NNP1, the approach is designed in attempt to guard against future population decline.

The watershed management (Section 6.3) would work toward protection of Nam Ngiep River habitat outside the inundation area from impact associated with habitat degradation, pollution (sedimentation and chemical) and exploitation. This approach would complement the breeding program by maintaining or improving the Nam Ngiep River habitat quality for the sustainability of the population and suitability of the habitat for any released individuals.

These approaches would reduce the magnitude of the effect by contributing to the long term viability of the Nam Ngiep River population (and potential contribute to other populations) resulting in impact to a smaller proportion of the population affected and as such maintaining biodiversity value. Through maintaining suitable habitat in Nam Ngiep tributaries the ecosystem would continue to support the persistence of the species in the catchment.

Additional conservation efforts are recommended as in-kind offsets. These measures are described in Section 7.3 and play a role in compensating the loss of critical habitat for *L striolatus*.

#### 7.3 ADDITIONAL CONSERVATION ACTIONS

In-kind offsetting can be used where significant residual losses exist for the species following mitigation. These conservation actions would need to occur to ensure the survival and persistence of the species across its range by improving scientific information on the species lifecycle, managing threats and conserving viable populations.

### 7.3.1 Species Recovery Coordination

To assist in planning of recovery actions for the species across Lao PDR, it is recommended that a species recovery taskforce for *L. striolatus* be established. This approach would work with Government of Lao to establish a framework for coordination across government agencies to facilitate research and conservation for the species. The recovery taskforce would be led by MoNRE and include key members from DESIA, Department of

Forestry and Resource Management, Department of Finance and LaRREC. The key objectives of the committee would be to: coordinate research on the species biology; establish a framework to raise awareness of the species within GoL and the community; work with hydropower companies to promote conservation; coordinate captive breeding programs; and undertake education campaigns across the species range to raise awareness of the conservation status of the species and methods to assist conservation.

The cost of establishing and funding the actions of the task force are estimated at \$25,000USD per annum.

#### 7.3.2 Co-management of Nam Theun Population

To offset any residual impacts on the species and to ensure the long term persistence of the species, it is recommended that a co-management program occur in conjunction with the Nam Theun 2 HydroPower Company (NT2).

*L. striolatus* is not threatened upstream of the NT2 Reservoir as the majority of the watershed is contained within a protected area. During fish population monitoring, young and adult specimens were found 4 years after impoundment upstream of the Reservoir and downstream of the Nakai Dam. The presence of this species upstream of the Reservoir is mainly due to the configuration of the dams.

Preliminary discussions have occurred with Dr Maud Cottet from NT2 regarding potential co-management of the species within the Nam Theun and Nam Ggouang watersheds. The focus of the co-management will be to fund research into the biology of the species; education within the Nam Theun/Nam Ngouang watershed to protect the species from fishing; and establishment or extension of the conservation area.

The potential cost of the co-management is yet to be determined and would need further discussion with NT2.

#### 7.4 RISK AREAS

There are risks associated with the success of each of the approaches identified which must be considered in assessing the suitability of the recommended measures. The risks of each approach are summarised in *Table 7.2.* 

These risks are expected to be consistent with mitigation and offset measures of this nature. Through recognising these risks at this stage of planning, it is recommended the mitigation and offset approach incorporate additional measures to manage the risk of potential for failure.

| Mitigation /<br>offset measure      | Key risks   | Safeguards  |
|-------------------------------------|---|---|
| Coordination of<br>species recovery | • There is not currently a species<br>recovery plan or taskforce for this<br>threatened species in Lao PDR. Risks<br>of failure of this approach relate to the<br>capacity of the Taskforce to be able to<br>implement activities to fulfil the<br>objectives of the recovery plan.   | <ul> <li>To minimise risk of<br/>failure clear objective<br/>must be set for the<br/>taskforce with realisting<br/>timeframes and<br/>funding.</li> </ul>   |
| Watershed<br>management             | • This approach relies on good relationships and cooperation with NN2, landholders and MoNRE. If these relationships and negotiations are unsuccessful it will be difficult to fulfil the aims of this measure.   | <ul> <li>A strategy for<br/>developing and<br/>maintaining stakeholder<br/>relationships will be<br/>developed for<br/>implementation. This<br/>may include input from<br/>specialists. Commanagement<br/>arrangements may be<br/>required</li> </ul>                           |
| Captive<br>Breeding                 | <ul> <li>Preliminary consultation indicates that<br/>captive breeding <i>may</i> be possible<br/>however there are limited examples of<br/>captive breeding for this species to<br/>draw upon. There are however<br/>examples of captive breeding for other<br/>large freshwater predatory fish species<br/>available. There are facilities and<br/>technical specialists suitable to<br/>undertake the program locally in<br/>Vientiane however additional<br/>biological and behavioural<br/>information is required prior to<br/>trialling the captive breeding. As with<br/>all breeding programs there is a risk<br/>that the species is difficult to breed in<br/>captivity.</li> </ul> | <ul> <li>This is an inherent ris<br/>of captive breeding. To<br/>minimise this risk it is<br/>recommended that the<br/>program is run by<br/>experienced specialist<br/>and the appropriat<br/>level of biologica<br/>information is obtained<br/>prior to inception</li> </ul> |
|                                     | • Mature individuals of both sexes are<br>required to form the captured<br>population and further ecological<br>assessment of the lifecycle is required.<br>These activities will need to be<br>completed prior to commencement of<br>the Project. Similarly, given threats to<br>habitat associated with NN2<br>operations it will be a priority to<br>obtain the necessary fish stock and<br>information while available.   | • Early negotiations with<br>NN2 will be required to<br>establish a cooperative<br>working relationship<br>whereby information<br>exchange and<br>collaboration is the<br>foundation. A strateg<br>for maintaining the<br>relation will be required                             |

# Table 7.2Mitigation and Offsetting Risks

| Mitigation /<br>offset measure                  | Key risks   | Safeguards                    |
|---|---|-------------------------------|
| Co-<br>management of<br>Nam Theun<br>population | This approach relies on good<br>relationships and cooperation with<br>NT2. If these relationships and<br>negotiations are unsuccessful it will be<br>difficult to fulfil the aims of this<br>measure. | • As for watershed management |

#### CONCLUSION

9

*Luciocyprinus striolatus* is a large predatory fish listed as Endangered on the IUCN Red List of threatened species. Recently collected anecdotal evidence (Kottelat 2014; Warren 2014b) for NNP1 EIA biodiversity studies suggest a population of the species occurs in the upper Nam Ngiep area and the Nam Xan catchment, as well as a number of other catchments in Lao PDR.

Globally the species is known from Lao PDR and China however it is unknown if the species persists in China today. In Lao PDR, the species has been found in upper Xe Kong, upper Nam Kading (Nam Theun and Nam Ngouang), upper Nam Ou, the upper Xekaman, Nam Ngum and upper Nam Tha rivers (Kottelat 2014).

Detection of the species in Nam Ngiep River by Kottelat (2014) is the first evidence of the species in this catchment. Village interview has identified two spawning locations for the species within the Nam Ngiep and it has been noted that it is highly likely that more occur in the area. Further work is scheduled in 2014 to obtain additional information regarding the distribution of the species.

Threats to the species relate to alteration of river morphology (including hydropower dams), pollution and exploitation. An assessment of these threats in the context of the known populations of the species identified that all known populations are currently under threat from these activities, including the Nam Ngiep population. The proposed NNP1 Project is an additional threat to spawning habitat for the species. The main dam FSL will inundate the two known spawning habitat areas.

Screening against the IFC critical habitat assessment criteria highlighted the overall paucity of information regarding the population and in particular distribution of the species. Already reported, and additional information collated in the report suggest that the Nam Ngiep River may be potential critical habitat for the species based on the Tier 1 criteria. There is ongoing field assessment to further understand species distribution and this will inform the design of species mitigation, design of a species action plan and any offsets initiatives. Mitigation and management options have been identified to limit the likelihood of impact to the species, maintain the population of the species and manage impacts to biodiversity. Implementation of these approaches is considered to reduce the residual impact to the species. In addition to the mitigation measures, conservation actions are also recommended in the form of in-kind offset programs. There are risks associated with the success of each of the mitigation and conservation action proposed and strategies will need to be included during planning phases to manage the risk of potential failure.

#### 9.1 **RECOMMENDATIONS**

The following recommendations are made regarding *L striolatus* in relation to the NNP1 Project:

- 1. It is recommended that further work proceed to define the extent of populations in Lao PDR. This work should proceed to screen other river basins to determine the likely presence of habitat within the country and then proceed with in-field villager interviews to determine likely presence within target river basins;
- 2. To better define the habitats within the Nam Ngiep River, a geomorphic study of the Upper Nam Ngiep River and its tributaries should occur. This will better define the likely presence on habitat for the species;
- 3. Contact should be made with NN2 Hydro power Scheme regarding opportunities for co-management of the species within the Nam Ngiep watershed;
- 4. Contact with MoNRE and the Lao PDR Fisheries Department should be made regarding the preparation for a Species Recovery Plan for *L. striolatus* within Lao PDR; and
- 5. Conduct a scoping study into the opportunities for captive breeding as recommended by Dr Phillippe Cacot

## Executive Summary

The Nam Ngiep catchment / drainage has been identified as an important area for the development of hydropower, and construction at several sites is already underway or has already been completed.

Populations of a large species of predatory Cyprinid (*Luciocyprinus striolatus*) have been identified by fish taxonomy experts within the boundaries of the Nam Ngiep catchment / drainage. It is placed in the IUCN red list category of endangered (EN) and as such runs a very high risk of becoming extinct in the wild.

*L. striolatus* populations are not confined only to the Nam Ngiep catchment in the Lao PDR and have in fact been positively identified in at least three other major catchments in the northern, central and southern parts of the country (Figure 1). It is known to live in large deep pools in upland areas.

Very little information is available on this fish species and much of what is known about its occurrence, distribution and biology within the Lao PDR is presented in this report. According to Kottelat (2014) it was recorded in the literature from the Nam Tha, Nam Ou, Nam Ngum, Nam Kading (Nam Theun and Nam Gouang Xe Kong and Xishuangbanna, China, (Cui & Chu, 1986; Kottelat, 1999, 2001; Rainboth *et al.*, 2013). It is thought to exist in river systems on the Vietnamese side of the Annamite mountain range that forms the border with the Lao PDR (Tyson Roberts, pers. com.).

This report recommends that protection and conservation efforts focus on the middle and upper Nam Kading / Theun mainstreams and their tributaries.

## 1. Introduction

### 1.1 Description of Luciocyprinus striolatus

*Luciocyprinus striolatus* is a large predatory fish belonging to the family Cyprinidae (Kottelat, 2009a) and was first described in Xishuangbanna Prefecture, Yunnan Province, China (Cui and Chu, 1986). Kottelat (2001) states that *L. striolatus* is distinguished from the only other known member of the genus by having five to eight longitudinal black stripes on the body in adults, 78 to 89 (+ three to four) lateral line scales and 40 to 46 predorsal scales. Local fishers in Laos have reported that individual specimens can attain lengths of up to 1500 mm Standard Length. Chu (1986) states that the genus Luciocyprinus shares common characteristics with members of the subfamily Barbinae. The characters include 1) Anal fin without spine but with five branched rays. 2) Lower pharyngeal teeth in three rows. 3) Pharyngeal process with the posterior end compressed. 4) Neural complex simple, without free interspine. 5) Transverse process on the first vertebra is located in front of the second vertebra and its transverse process. Luciocyprinus was long recognized as a monotypic genus, but since the description of *L. striolatus* in 1986 (Cui & Chu, 1986) this status has now become questionable.

### 1.2 IUCN conservation status of *L. striolatus* and legislation

Under the IUCN Red List system, L. striolatus is placed in the category of Endangered (EN). A taxon is endangered when the best available evidence indicates that it meets any of the criteria A to E for Endangered, and it is therefore considered to be facing a very high risk of extinction in the wild. Under Lao law (Forestry law 1996) aguatic animals and wildlife living naturally in the territory of Lao PDR are the property of the national community. It is the responsibility of the State, as representative of the people, to determine the conditions of access, protection, propagation and use of these animals and wildlife (Article 39) (Cacaud and Latdavong 2009). The Wildlife and Aquatic Animals Act 2008 was adopted by the National Assembly in 2008. Under this Act, exists the right to hunt wildlife and aquatic animals is provided to any individual or legal entity within the limits of the law (Article 9). Hunting certain species is prohibited or restricted. It is strictly prohibited to hunt species listed in Category I except for research or propagation purposes, whereas catching species of species under Category II is allowed with an authorization and during certain periods. Species listed in Category III may be taken for customary purposes and to some extent for commercial puposes with an authriztion from PAFO (Article 9) Species of wildlife and aquatic animals are classified into three categories a) Category I lists species that are considered to be rare, endangered or highly valuable in socio-economic terms. L. striolatus, therefore fits into Category I classification.

### 1.3 Purpose of this report

A population of L. striolatus is believed to exist in the Nam Ngiep catchment of the Lao PDR. This catchment has been earmarked for hydropower development and at least two dams are being considered. Given that this species has been placed on IUCN's Red List as endangered (EN), what is required at present is bring together all relevant information on the species to establish a broad picture of the current status of populations within the Nam Ngiep catchment and those outside it but with the Lao PDR. This it is hoped will provide some indications of the threats that *L. striolatus* populations face in general and this will allow an assessment to be made of the proportional impact from the Nam Ngiep dam and then look at conservation opportunities.

# 2. Methods

The methodology used to formulate this report is based on the author's past fieldwork, hardcopy library resources, papers, documents and books collected by the author, and internet searches. Almost all references used in this report are based on published material, and personal communication only appears once in the report. All photographs that appear in this report were taken by the author over the past two decades.

# 3. Results based on field observations and anecdotal reports

### 3.1 Known distribution range within the Lao PDR

Kottelat (2009a) identified specimens of *L. striolatus* from three major Mekong tributaries: the Nam Ou in the northern part of Lao PDR (Kottelat, 2009b), the Nam Kading in central Lao PDR (Kottelat, 1996a), the Nam Gnouang (Kottelat, 1996a), and in the Xe Kong (Kottelat, 2009a; Kottelat, 2011) in the southern part of the Lao PDR (Figure 1 and Table 1).

Baird *et al.*, (1999) identified *L. striolatus* in the Xe Kong mainstream in Kaleum District, Xe Kong Province in May 1996. Baird *et al.*, (1999) point out that it is not common in the lower part of Xe Kong in Lamam District, Xe Kong Province and is not found at all in the lower part of the Xe Kong in Attapeu Province. Baird *et al.*, (1999) report that juvenile *L. striolatus* were identified from the upper Xe Kaman in Saysettha District in Attapeu Province in 1996 (Figure 1 and Table 1).

**Figure 1** Map showing where populations are known to exist within the Lao PDR based on confirmed identification of *L. striolatus* and referenced in this report over the past two decades.

Warren (1995) identified and photographed three juvenile specimens of *L. striolatus* (< 45 cm Total Length) from a market at Ban Thabac where Route 8 now passes over the Nam Theun via a road bridge (Figure 2 and Figure 3). All three specimens were caught in the Nam Theun within close proximity to Ban Thabac. Warren (2010) identified and photographed one specimen of *L. striolatus* bought at Phongsaly City market, Phongsaly Province that was caught in the Nam Ou upstream from Ban Hat Sa (Figure 4), and another juvenile specimen caught in Huay En (Figure 5), a small tributary of the Nam Ou that runs alongside Ban En on the right-hand bank of the Nam Ou, Phongsaly Province (Figure 1 and Table 1).

**Figure 4** A photograph of *L. striolatus* (< 60 cm) purchased from the city market at Phongsaly. Its condition had deteriorated during travel time to market (Warren and Phommavong, 2010).

**Figure 5** A juvenile (< 20 cm) *L. striolatus* caught live in a basket trap at a small weir on Huay En (Nam Ou tributary) next to Ban Huay En (Warren and Phommavong, 2010).

3.2 Anecdotal reports of the presence and local descriptions of *L. striolatus* within the Lao PDR

Kottelat (1996b) reported that local fishers at Ban Thabac on the Nam Theun considered that *L. striolatus* was found more frequently in the Nam Gnouang than in the Nam Theun. Warren (1995) conducted surveys on the Nam Theun between Ban Thabac and Ban Huay Gan Ya and interviewed local fishers over a distance of approximately 4 kilometers. Fishers reported that within the last two years they had caught a large fish measuring somewhere between one and two meters in total length and that it was known locally as "*Pba Nuuak*". *L. striolatus* is usually given the local vernacular name of *Pba Kang* on the upper Nam Theun, so it is possible that the fish that was described by fishers in 1995 was another species. Previous to the 1995 survey, Mr. Phouthalom of Burapha Development Consultants, who had been involved with the 1992 Aquatic Life Survey of the Nam Theun, referred to a fish very similar to the description provided by Nam Theun fishers between Ban Thabac and Ban Huay Gan Ya.

Baird *et al.*, (1999) report that in the southern part of the Lao PDR, *L. striolatus* is known by the local name "*Pa Sak*". According to local villager fishers it can attain maximum lengths of between 150 and 200 cm and reach weights of between 70 and 100 kilograms. Interviews with villagers revealed that *L. striolatus* prefers to remain in middle to surface waters and inhabits large clear rivers flowing at mid to high altitudes. Villagers reported that it prefers rivers with small stones on the bottom or large slabs of rock.

Baird *et al.*, (1999) report that juvenile *L. striolatus* are rarely seen in the lower parts of the Xe Kong in Kaleum District, but larger individuals occasionally venture into those areas. *L. striolatus* is not found in the lower parts of the Xe Kong in Attapeu Province. According to Baird *et al.*, (1999) *L. striolatus* eat mainly fish, and villagers from Kaleum District have noted a significant decline in population numbers of this species compared to the past.

During fishery surveys conducted by Warren in 1997, a total of 21 potential hydropower sites were visited by helicopter from northern Lao P.D.R. to the very south of the country. During that survey, local communities were visited along the banks of the Nam Mouan, a major tributary flowing into the Nam Kading approximately 40 km downstream of the Theun-Hinboun dam. A number of villagers said that they knew *L. striolatus* when shown photographs of it and referred to it with the Lao vernacular name of "*Pba Kang*". They described it as a fish reaching a maximum length of 2.0 meters and weighing up to around 60 kg. They reported that in 1997, *L. striolatus* of that size were no longer being caught in the Nam Mouan and the largest fish caught then were approximately 1.0 meter in total length and weighed up to and around 10 kg maximum.

3.3 Anecdotal and observed reports of preferred aquatic habitat for L. striolatus

Warren (1995) surveyed a section of the Nam Theun stretching from what was then the ferry point at Ban Thabac upstream to Ban Huay Gan Ya, a distance of

approximately 4 kilometers. It should be remembered that this was a time prior to the completion of the Theun-Hinboun dam and no reservoir was present. In 1995, to get to Ban Huay Gan Ya by boat from Ban Thabac, it was necessary to traverse a number of rocky rapids. Once over the rapids, the Nam Theun changed into a series of wide (40 to 50 meters), slow-flowing deep pools as observed during the survey. Riparian vegetation along the deep pool river sections consisted mainly of dense bamboo forests on opposite sides of the river. Local people, including the boat driver, reported that this was the habitat where *L. striolatus* could be found and caught using gillnets (Figure 6).

**Figure 6** This photograph shows one of the large deep pools that local fishers claim is where *L. striolatus* prefers to live. The photograph was taken at a point somewhere between Ban Thabac and Ban Huay Gan Ya prior to closure of the Theun-Hinboun dam (Warren, 1995).

The following is a direct quote from a final report I wrote whilst employed as Fisheries Specialist for the Theun-Hinboun Power Company (THPC), Vientiane, Lao P.D.R. (1999).

"According to local villagers, 13 rapids along the Nam Theun and five rapids along the Nam (Ngouang) Gnouang were submerged following the closure of the Theun dam in December 1997. At least one rapid, approximately 500m upstream of the Nam Gnouang / Theun confluence was identified by local villagers as a spawning site of the predatory cyprinid species *Luciocyprinus striolatus*. Because of its large size,

and the fact that it spawns during the dry-season months in January / February when water clarity is greatest, its spawning behavior can be observed relatively easily".

### 3.4 Anecdotally reported spawning behavior of *L. striolatus*

In 1997, a joint venture was launched between Lahmeyer International GmbH, Frankfurt, Germany, Worley International Ltd and the Government of the Lao P.D.R. to provide consulting services required for the execution of the Nam Theun 2 Study of Alternatives. The Study was carried out in cooperation with the Hydropower Project Office of the Ministry of Industry and Handicraft in Vientiane. I was given responsibility for the fisheries part of the study.

At one point during the survey, it was agreed that interviews should take place with local communities at a strategic village point along the Nam Mouan, a major Nam Kading tributary. Interviews took place regarding the importance of village-level fisheries to local communities. One fisher described how he had witnessed the natural spawning event of L. striolatus. He said that from a secluded position, he saw a large fish that he recognized as L. striolatus (Pba Kang) appearing in shallows either in the Nam Mouan itself, or in a small tributary close to the Nam Mouan mainstream, and said that water was flowing guite swiftly. Most importantly, he said that it was during the low water period and the depth of the water was no more than an estimated 20 cm. He said that shortly after he saw the large L. striolatus move into the shallows, a large number of smaller L. striolatus suddenly appeared from downstream and gathered around the large fish in mid-stream. Following this, he described the large fish as moving erratically from side to side. Then after another short period, the water turned milky and the smaller L. striolatus were seen zig zagging around the large fish, and then slowly all the fish started moving back downstream again and out of sight. Those observations made by the Nam Mouan villager, and translated into English here, probably represent one of the very few records available, or perhaps the only one, of the spawning behavior of *L*. striolatus.

Baird *et al.*, (1999) report that local illagers from Kaleum District, Xe Kong Province believe that *L. striolatus* spawn in shallow water in the upper parts of the Xe Kong mainstream and in smaller streams during May and June. During this time *L. striolatus* is apparently vulnerable to capture.

Kottelat (1996a) reports that informants in Ban Thabak on the Nam Theun said that *L. striolatus* lives all year round in deeper areas of the river and that it spawns in January-February in rapids.

3.5 Anecdotal reports of the feeding behavior of *L. striolatus* 

Undoubtedly, *L. striolatus* is a predatory species and its diet probably consists mostly of fish and perhaps some amphibians. However, during the course of the Nam Theun 2 Study of Alternatives, our team received at least three reports that it will attack small primates that enter shallows in the Nam Theun / Kading and some of its major tributaries such as the Nam Gnouang and the Nam Mouan.

#### 3.6 Risk assessment and conservation significance (Table 2 below)

Given the paucity of data on the distribution of *L. striolatus* within major river catchments throughout the Lao PDR, only subjective comments can be made regarding *management units* with the aim of protecting this species. Specifically, this report draws on the field work experiences and educated prediction of where populations are in three major catchment areas where this species is known to exist outside of the Nam Ngiep catchment area. All *values* listed under columns two and three are arbitrary. They are based on intuitive and intimate knowledge of the river catchments concerned. They are not based on any survey work that was specifically designed to gather information on *L. striolatus*.

Information on this particular fish species was gathered incidentally, together with data on many other aspects of fish populations and fisheries in all three major catchments apart from Nam Ngiep during previous studies. These are already referenced in this report but they are: 1) Nam Theun / Kading studies in 1995, 1997 and 1998, 2) Nam Ou studies in 2010 and 3) Xe Kong studies in 2011. During the Nam Theun / Kading studies and those in the Nam Ou, specimens of *L. striolatus* were obtained and photographs of this fish species were taken and are presented in this report (Figures 2, 3, 4 and 5). Columns two and three in Table 2 are not based on any type of pre-determined methodology; they are the author's best intuitive attempt, based on field experience, to allocate various categories to column's two and three.

Table 2 Risk assessment and conservation significance to *L. striolatus* populations in the Lao PDR

| Management Unit  | Habitat<br>Sensitivity /<br>Value | Magnitude<br>of Effect | Discussion on Key Threats  | Discussion on Conservation<br>Opportunities   |

# 4. Discussion and recommendations

Clearly, there are a number of catchments / drainages outside of the Nam Ngiep that support or supported viable populations of *L. striolatus*. What is also apparent is that these populations face a wide range of potential and actual threats throughout the length of the Lao PDR (Table 2). In the light of limited funds and other vital resources, conservation efforts aimed at protection must focus on those catchments outside of the Nam Ngiep basin where they are most likely to succeed.

Population numbers of *L. striolatus* must be described as low within the Lao PDR. This makes studying its habits very difficult and almost all information on it is based on anecdotal reports only. Reports by elderly people in villages seem to suggest that much larger specimens of *L. striolatus* did exist up to 30 or 40 years ago. There are almost no reports of large specimens (60, 70 to 100kg) living now.

As has happened in what is now the Nam Ngum cascade of dams, releases from projects further upstream (NN2 Project) may affect fishery resources and fish populations in the river bed between the end of the NN1 Project reservoir and the NN2 Project dam. The effects that altered hydrology might have on the populations of many fish species, including *L. striolatus* below NN2 Project can only be guessed at until more details are known.

As a final comment / recommendation and based on available information and data, I would recommend that protection and conservation efforts focus on the middle and upper Nam Kading / Theun mainstreams and their tributaries.

#### Acknowledgements

I would especially like to thank Mr. Souksavanh (Boey) from the Nam Ngiep Hydropower Company Offices in Pakxan, Mr. Vongphet Vilahoun from District Agriculture and Forestry Offices at Thathom and driver Mr. Pradith for all their helpful assistance during the field work part of this study. I also gratefully acknowledge the help and assistance provided to me by many members of the Nam Ngiep Hydropower Company Offices in Vientiane, including Mr. Cliff Massey, Mr. Apirat Lamsiri from Electricity Generating Authority of Thailand and Mr. Suksumek from the Vientiane Offices. Finally I would like to thank all of the villagers who gave their time for interviews and took us to see special habitats and features of a number of river systems.

### Executive summary

Under the present day situation hydropower dams in the upper Nam Ngiep catchment area (NN1, NN2 and NN3) and several projects in other sub catchments in Xieng Khouang, Bolikhamsy and Vientiane Prefecture are under construction phase and rivers are still free-flowing prior to impoundment within the next few years of this decade.

Although impossible to gain precise statistics over such a short survey period, viable populations of *L. striolatus* (further referred to in this report as L.s) have been recorded based on anecdotal reports from interviews with villagers in the Nam Ngiep upstream from NN1 FSL (close to Ban Pou) to Ban Poucafe (see Table 1). L.s has been recorded from the Nam Siam at Ban Nam Sia (photo 3423 / 3424) and Ban Chanam (3379). The Nam Siam is to be impounded by the NN2 Main Project just upstream from its confluence point with the Nam Ngiep.

Between Ban Pou and Ban Xiengthong (Table 1 and photo 3553) on the Nam Ngiep mainstream, a total of seven villages have cumulatively established 11 Fishery Conservation Zones (FCZs). These have been set up under village rules that invariably ban all fishing activity using all fishing gears all year round and are almost always established over deep pools areas. Three villages at Ban Hat Sam Khon, Ban Viengthong and Ban Xiengkhong have established FCZs over deep pools close to the villages (Table 1 and photos 3580, 3594 and 3553). The downstream end of each deep pool / FCZ ends in a series of rapids. It is in precisely this environment that L.s reportedly spawns. The actual spawning event has been witnessed by numerous villagers over the past decade and always involves a period of gathering / shoaling of up to 30 individuals prior to spawning taking place both during the nighttime and during the daytime period. The spawning takes place in quite shallow waters and there were several reports of dorsal fins sticking out of the water surface. Eggs are apparently sticky and large numbers of them can be seen in the area following spawning.

Our study team was taken to see one FCZ on the Nam Siam and Ban Nam Siam (Table 1 and photos 3423 / 3424). Villagers explained that this deep pool was where L.s prefers to live in the early dry season months, but that all L.s migrate back downstream at the flood recession period back to the Nam Ngiep and its deeper pools.

Other rivers that reportedly hold populations of L.s were the reaches of the Nam Xan around and downstream from the road bridge on route 1D (Table 1 and photo 3600 / 3606). Once the Nam Xan becomes a series of strong rapids upstream from the road

bridge, L.s can no longer be found. It is found downstream to Muang Thathom, but it is not clear downstream past Thathom (Table 1 and photos 3355) that the range of L.s extends to. L.s is not known in the areas around Project's 3B and 3A (Table 1 and photos 3618 / 3623) neither in any of the areas around Phouvieng where final interviews were carried out above both these Projects (Table 1 and photos 3621 / 3626 and 3631).

The Nam Chian (pronounced Nam Jey) is a major tributary of the Nam Ngiep and our study team received numerous reports that a population of L.s were present from the Nam Ngiep confluence point upstream to the base of a series of steep rapids (Table 1 and photos 3518, 3520 and 3528). These rapids (*Dtut heah*) form a zoogeographical barrier to L.s.

A series of rapids and waterfalls (*Tad-a-Tong*) on the Nam Ngiep acted as a zoogeographical barrier to upstream movement of L.s even before the construction of the NN3 Project (Table 1 and photos 3444 / 3449).

Critical life-cycle habitats for L.s remain in the areas of the Nam Jey between NN1 FSL that are not inundated and the base of the *Dtut heah* rapids and waterfalls. Critical spawning sites between Ban Pou and Ban Xiengthong may be impacted depending on how NN2 Main Project is to be operated. Altered dry season hydrology and water quality may be key issues. The section of the Nam Ngiep between NN2 Main Project and NN2 Tributary Project may face dewatering because of water diversion, but Ban Keokoang (Table 1 and photo 3544), Ban Phapheung and Ban Sanlouang (Table 1) do not know L.s and the Nam Ngiep is a long distance away. The only village likely to be impacted by dewatering is Ban Poucafe (Table 1). Populations of migratory L.s will almost certainly not be able to exist in that river after the completion of the NN2 main Project.

### 1. Introduction

*Field* survey work has been conducted in the upper Nam Ngiep catchment from Thursday April 3 to Tuesday April 8 2014 specifically to gather more information and data on the distribution and habits of *Luciocyprinus striolatus* throughout the Nam Ngiep catchment and various adjacent sub-catchments. The survey also aimed to record critical habitat presence or absence associated with the life-cycle of L.s, the hydro-geomorphic characteristics of rivers where L.s is reportedly found and identify any practical measures that might be used to protect the species with regard to the Nam Ngiep catchment. It should also be remembered that it is the construction of hydropower infrastructure that influenced where and how interviews took place. This may have introduced a level of bias in the village-interview sampling methodology because it is mainly tributaries of considerable size that have received attention from fishery researchers / taxonomists.

#### 1.1 Anecdotal information

Much of the evidence provided here in this final report is based on anecdotal information presented by local people during interviews. Anecdotal evidence can be divided into two main types: 1) That information that is presented based on something that a third party saw, heard or did, and 2) Information that the interviewee actually experienced or witnessed first hand. Clearly the latter type of information is more reliable and this report is mostly based on this type of information. To actually

witness a capture or observe a spawning event of a species that must be considered as generally uncommon over such a short survey time and covering a vast geographical area would be extremely fortunate.

### 1.2 Purpose and justification of this report

A survey of the upper Nam Ngiep catchment and adjacent sub-catchments was required to better understand the likely extent of *L.s* the habitat (s) that might be affected by the Nam Ngiep Project, and the likely extent of cumulative impacts of all three (or four) hydropower Projects and other catchment uses. The main purpose of the report is to ascertain population condition in relation to IFC Critical Habitat threshold limits.

### 1.3 Study team

The study team consisted of:

- Mr. Souksavanh (Nam Ngiep Project Officer, Pakxan based.
- Mr. Vongphet Vilahoun from the District Agriculture and Forestry Offices at Thathom.
- Mr. Pradith (Nam Ngiep Project driver, and
- Mr. Terry J. Warren, independent fishery advisor.

### 2. Methodology

A literature study was carried out prior to beginning field work. A short report was prepared by the author based on the literature study (Warren 2014). The field work was planned / based on 1) previous field studies, 2) the likely Project / inundation area footprint, 3) the un-regulated parts of the upper Nam Ngiep catchment and 4) selecting areas where it was thought that *L.s* might be found based experience of habitat type in other rivers in the Lao PDR where it is known to exist (the Nam Theun / Kading, the Nam Mouan, the Nam Ngouang, the Nam Ou and the Xe Kong are examples).

At each of the villages where interviews took place the village chief was contacted and asked if it would be convenient to carry out the interview with five or six people that had knowledge of fishing and fishery issues. This took place on every occasion. A detailed description of *L.s* was provided to interviewees prior to showing any photographs of the fish. It is quite an easy fish to describe because of its size (adult fish weighing up to 30kg), shape and habits (spawning behavior, predatory nature). It was easy to see from interviewee reaction whether they knew the fish or not. Some were able to say that they knew it, but it was not found in the river / stream near their village; Ban Nam Siam for example (Table 1). After the description was provided all interviewees were shown photographs of the fish previously taken by the author from the Nam Theun and the Nam Ou and one taken by Dr. Maurice Kottelat (see appendix 1). All information was recorded in notebooks and typed up each day. Each interview took anything up to 45 minutes to complete.

**Figure 1** Map of the Lao PDR showing where populations of *L. striolatus* have been positively identified.

### 3. Survey results

Table 1 below provides details of GPS coordinates, category and elevation and any notes or comments on specific sites and locations of relevance

| Coordinate<br>East | Coordinate<br>North | Category and elevation   | Notes  |
|--------------------|---------------------|--|--|
| 0352694            | 2100847             | Thathom DAF Offices<br>(253m)  | Next to DAF Offices and Nam<br>Xan – water very brick-red<br>orange.   |
| 0323250            | 2115610             | Base camp for NN2 main Project (373m).   | Taken from road (1D) opposite it.  |
| 0322177            | 2116873             | NN2 dam, the main<br>Project (389m).   | Looking straight at the dam construction.  |
| 0317579            | 2115939             | Nam Siam valley (471m).  | Point at where Nam Pot (stream) joins the Nam Siam.  |
| 0313805            | 2115603             | Ban Chanam on right-<br>hand bank of Nam Siam<br>(497m).   | Village where all interviewees<br>knew <i>L. striolatus</i> and on the<br>Nam Siam (NN2 Main Project).   |
| 0327358            | 2121436             | Ban Poucafe on left-<br>hand bank of Nam Ngiep<br>(554m)   | A village on the Nam Ngiep (1D road) above NN2 main Project.   |
| 0319877            | 2128351             | NN2 Tributary Project (844m).  | Seventeen kilometers after left turn off main 1D road.   |
| 0297261            | 2125206             | Ban Nam Siam or better<br>pronounced in English as<br>Nam <i>Seeam</i> (833m).                         | This village is near to the upper<br>areas of the Nam Siam. Exact<br>source of Nam Siam is not known<br>at present, and is anyway<br>irrelevant to this study. L.s not<br>seen or caught here, but one<br>person knew it.  |
| 0301048            | 2119144             | Ban Nam Sia. <i>L.s</i> is<br>caught at this village,<br>especially on downstream<br>migration (801m). | This village is about 10km<br>downstream from Ban Nam Siam<br>and about 20 to 25km upstream<br>from Ban Chanam (row four after<br>title). They are very familiar with<br><i>L</i> .s. Villagers estimate that eight  |
| 0301945            | 2118192             | Coordinates of the FCZ at<br>Ban Nam Sia ( <i>Wang Nam</i><br><i>Dong</i> ) -700m)                     | to ten fish are caught per year. A<br>one kilometer walk down the<br>valley brings one to an FCZ<br>(village established). Villagers<br>here report that <i>L.s</i> live in this<br>deep pool (FCZ) but all <i>L.s</i> move<br>away at the end of the dry<br>season back to the Nam Ngiep. |

Table 1 continued...

| Coordinate<br>East | Coordinate<br>North | Category and elevation  | Notes   |
|--------------------|---------------------|---|---|
| 0327334            | 2139265             | An FCZ on the Nam<br>Ngiow (1079m)  | After the top of the <i>Tad-a-Tong</i><br>waterfall, the Nam Ngiap is<br>known as the Nam Ngiow. There<br>is an FCZ about 200m from Ban<br>Sang below.  |
| 0326601            | 2132819             | Ban Sang – village<br>(1128m).  | A point about four or five<br>kilometers above the NN3<br>Project. Here the name of Nam<br>Ngiep changes because of a 20m<br>high waterfall ( <i>Tad-a-Tong</i> ). Ban<br>Sang is on the stretch of the Nam<br>known as the Nam Ngiow. <i>L.s</i><br>cannot pass the waterfalls. It is a<br>zoogeographical barrier (not<br>climate or habitat). <i>L.s</i> is not<br>known in the Nam Ngiow<br>according to an interview at Ban<br>Sang. |
| 0325829            | 2133724             | Base of the Tad-A-Tong<br>waterfall and also the site<br>of the NN3 Project<br>powerhouse (914m).                                       | A zoogeographical barrier to fish migration approximately 20 meters high and very steep.  |
| 0326398            | 2134629             | A water release point<br>from the NN3 Project.<br>The water flows to the<br>Nam Ngiep when FSL<br>water levels are too high<br>(1064m). | Large water gates.  |
| 0326818            | 2134811             | NN3 Project dam site (1061m).   | One end of the dam.   |
| 0325829            | 2133724             | NN3 Project powerhouse (914m).  | NN3 Project powerhouse is at the base of the <i>Tad-a-Tong</i> waterfall.   |
| 0355124            | 2130375             | Ban Nabong. Villagers<br>here say they know <i>L.s</i><br>and that it is in the Nam<br>Xan at Ban Thaenphoun<br>(1225m).                | Not to be confused with the<br>Nam Xan in the southern part of<br>the Nam Ngiep Project (Topo.<br>Map). The Nam Xan in question<br>(column 3) flows into Vietnam.   |
| 0351702            | 2126204             | Ban Khek is below Ban<br>Nabong (1193m).  | Villagers here say that they know<br>L.s. but that it is caught below a<br>200m section of waterfalls (Dtut<br>heah) on the Nam Jey. Road to<br>Nam Jey is too difficult to pass.<br>We decide to visit Ban<br>Thaenphoun on the Nam Xan<br>and try to get to Nam Jey the<br>next day by a different route.   |

Table 1 continued...

| Coordinate<br>East | Coordinate<br>North | Category and elevation  | Notes  |
|--------------------|---------------------|---|--|
| 0362995            | 2137687             | Ban Thaenphoun (782m).  | Villagers here on the Nam Xan<br>(no confusion with the other Nam<br>Xan that flows to the Mekong) do<br>not know <i>L.s</i> and say it is not in<br>their river.  |
| 0347300            | 2120368             | Low bridge over the Nam<br>Chian (Topo. Map). Bad<br>vernacular translation.<br>The name of the river is<br>much more like the Nam<br>Jey, or Nam Jay. <i>L.</i><br><i>striolatus</i> is found in the<br>lower Nam Jey below the<br>waterfalls before it<br>discharges into the Nam<br>Ngiep (1076m). | This is a large Nam Ngiep<br>tributary. There is a sizeable<br>hydropower dam being built quite<br>close (about one kilometer above<br>where the Nam Jey flows down<br>through rapids that are perhaps<br>200m long). This is a<br>zoogeographical barrier for<br>almost fish and definitely <i>L</i> .<br><i>striolatus</i> . The best vernacular<br>translation I can produce for the<br>waterfalls is <i>Dtut heah</i> (see next<br>row). |
| 0337111            | 2132716             | Top of hills overlooking<br>the Nam Phouan Valley<br>(1602m)  | This was an alternative route to try to reach the Nam Jey.   |
| 0344376            | 2126271             | Nam Dtun, a sizeable<br>river running close to Ban<br>Dtun Tai. The GPS was<br>taken next to a new<br>bridge under construction<br>(1204m).   | Villagers at this place did not<br>know <i>L.s</i> and said that it was not<br>found in the Nam Dtun.  |
| 0344633            | 2124167             | Ban Pakhing at next<br>village past the Nam Dtun<br>(1196m)   | Villagers at Ban Pakhing do not know <i>L.s.</i>   |
| 0347300            | 2120368             | A low bridge is under<br>construction over the<br>Nam Jey at Ban Boong<br>(1076m)   | Local people said they knew <i>L.s</i> from the Nam Jey, but that it was below the <i>Dtut heah</i> waterfalls.  |
| 0348126            | 2117801             | This is the site of the<br>Nam Jey HPP. But<br>nobody was prepared to<br>provide an exact name. It<br>does not block the Nam<br>Jey, but impounds<br>tributaries that flow into<br>the Nam Jey (1068m).   |  |
| 0347302            | 2119477             | This reference is what<br>appears to be the top of<br><i>Dtut heah</i> waterfalls<br>(1069m).   | Cannot be sure. Wild territory.  |
| 0347205            | 2119403             | This reference is what<br>seems like the middle<br>part of the falls (1113m).   | Cannot be sure. Wild territory. No tracks or ways of navigating.   |

Table 1 continued...

| Coordinate<br>East | Coordinate<br>North | Category and elevation   | Notes   |
|--------------------|---------------------|--|---|
| 0344934            | 2113629             | At some point down the<br>Nam Jey valley towards<br>the confluence with the<br>Nam Ngiep. Probably<br>about half way down<br>(690m)  | New road and thick forest along both banks.   |
| 0330895            | 2106225             | Ban Thaviang Sai on<br>route 1D. Interview with a<br>restaurant owner and the<br>place where Mr. Boey<br>had asked for the<br>restaurant owner to<br>refrigerate any <i>L</i> .s that<br>was brought to her<br>(325m). | Interview held at the restaurant<br>(Nang Pawn's restaurant). She<br>provided a very good description<br>of a local venue where the<br>spawning of <i>L.s</i> takes place each<br>year. |
| 0330802            | 2106127             | This is a reference for a<br>position at Ban Thaviang<br>Sai on the banks of the<br>Nam Ngiep opposite<br>Nang pawn's restaurant<br>(326m)   | A two minute walk across fields<br>from the road (route 1D) and<br>restaurant.  |
| 0328773            | 2129165             | Ban Keokoang. The<br>residents of this village<br>are Hmong people, and<br>do not normally go<br>fishing. They do<br>sometimes. The village is<br>on route 1D (1201m).   | This village does not know <i>L.s.</i> ,<br>the reasons are not least of<br>which is because it across hilly<br>country and takes a long time to<br>get to.                             |
| 0328218            | 2126918             | Ban Sanlouang. The residents here are Hmong ethnicity (1007m).   | This village does not know <i>L.s</i><br>and like Ban Keokoang they<br>rarely or almost never go fishing<br>there because it would involve<br>travelling over sizeable hills.           |
| 0325632            | 2112784             | Ban Xiengkhong. This<br>reference is for the village<br>next to route 1D (361m).<br>It was one of three<br>villages where LARReC<br>carried out interviews.  | The FCZ, and spawning site of <i>L.s</i> ( <i>Wang Khouak</i> ) was a short distance away.  |
| 0326443            | 2112467             | This is the reference for<br>the <i>Wang Khouak</i> FCZ<br>referred to in the above<br>column (344m).  | The FCZ is near Ban Xiengthong,<br>but not actually at the village.   |
| 0326888            | 2109003             | Ban Viengthong. This is a<br>reference for the village<br>next to route 1D.<br>Interviews were carried<br>out here by LARReC<br>(345m).  |   |

| Coordinate<br>East | Coordinate<br>North | Category and elevation   | Notes                                       |
|--------------------|---------------------|--|---|
| 0329916            | 2106979             | This is a reference for the<br>village of Ban Naxong<br>where LARReC carried<br>out its third interview.<br>During this interview, we<br>were informed about the<br><i>Wang Ngiow</i> FCZ. |   |
| 0329194            | 2106856             | This reference is the reference for the <i>Wang Ngiow</i> FCZ and spawning site of <i>L.s</i> (334m).  |   |
| 0335830            | 2103908             | This is a reference for<br>Wang Hat Sam Khon<br>FCZ and spawning site of<br>L.s (338m).  | Reference for Ban Hat Sam Khon is missing!! |
| 0342179            | 2105809             | At the road bridge on<br>route 1D on the Nam Jey.<br>An FCZ has been<br>established here (366m)  |   |
| 0352124            | 2104284             | This is a reference along<br>the lower part of the road<br>to the Nam Xan 3B and<br>3A Projects (292m).  |   |
| 0354851            | 2110929             | This reference taken at<br>the Nam Xan 3B Project<br>(647m).   |   |
| 0357454            | 2113520             | This reference was taken<br>on a high point quite<br>close to the Nam Xan 3A<br>Project (1370m).   |   |
| 0359249            | 2115479             | This reference was taken<br>at the site of the Nam<br>Xan 3A Project (1373m)   |   |
| 0360544            | 2117692             | This is a reference at a position that was close to the Nam Xan close to the top of the mountain (1427m).  |   |
| 0360823            | 2117946             | This reference was taken close to rapids on top of the plateau (1427m).  |   |
| 0362565            | 2118739             | This is a reference for<br>Ban Phouvieng where the<br>last interview took place<br>(1444m).  | End of GPS readings.                        |

# 3.1 What was found during this study when set against the ToR proposed

a) What is the status of *L. striolatus* population above NN1 FSL to NN2 wall?

As far as is known at present the NN1 reservoir tail waters will end at Ban Pou (route 1D). Currently there is a seemingly healthy population of *L.s* from NN! FSL to Ban Phoucafe as anecdotally reported to the study team during the present survey. *L.s* almost certainly exists in the Nam Ngiep beyond these two locations. It is an uncommon fish and probably lives out most of its life as a solitary predatory species. It is found in other rivers that all confluence with the Nam Ngiep in the middle and upper sections of the Nam Ngiep mainstream.

**b**) What is the status of *L*.*s* population above in the Nam Chait (major left bank tributary and with Nam Sen – NN2 – forms Nam Ngiep?

The Nam Chait (much confusion about the vernacular spelling of this river, i.e. the Nam Chian and the Nam Chait). The only river that is probably being considered here is the Nam Jey. It is a large tributary and confluences with the Nam Ngiep within the study area. If the spelling of Nam Jey is not correct then I think the Nam Chait was probably outside of our study area.

If the Nam Chait is the Nam Jey, then it can be reported that the population of L.s is important. There was anecdotal evidence to support its presence in the Nam Jey. From its hydro-geomorphological appearance the Nam Jey appears a suitable habitat for L.s before major rapids become a zoogeographical obstacle to its range.

c) What is the geomorphic range of the habitat in the upper Nam Ngiep?

In terms of elevation, this fish lives between 325m and about 800m based on the results of this brief survey. The Nam Siam (Nam Seeam) was the smallest river where *L.s* migrate into for spawning or feeding or both from the Nam Ngiep that was found during this survey. Tributaries that are less than about five meters wetted width, and perhaps too steep do not appear to be a suitable habitats for this species.

**d**) Where are the most likely locations of *L*.*s* based on the geomorphic character of the Nam Ngiep?

*L.s* can grow to a large size (just over 30kg) in the Nam Ngiep, and larger in other river systems; but this is exceptional and most fish that are caught in the Nam Ngiep are about one kilogram or less.

Geomorphic characteristics of the Nam Ngiep represent a suitable habitat for L.s based on the author's other studies in the Nam Ou, Nam Theun-Kading and the Xe Kong. L.s is one of a small number of large fish species that spawn in the dry season (January to April). Most Cyprinid species are wet season spawners (May to June – July) when rivers are swollen with fresh rains. It may be the case that L. striolatus spawns twice; once in the dry

season and again in the wet season. We do not know this for sure, and it would be unusual.

Adult *L.s* (two or three kilogram fish) has a preferred habitat of deep pools of about two to six meters in depth in the dry season. As an adult fish, it can live in these deep pool environments in the Nam Ngiep at any time of the year; but for sure this is their dry season habitat. During the onset of the flood season, it moves upstream (May to July). After rains cease in October and November it moves back downstream again to dry season refuge habitats in main streams like the Nam Ngiep. The upstream migration for juveniles (<1kg) may represent a trophic migration, but for larger fish, this may represent a spawning migration.

**e**) Where is the known spawning sites of *L.s* and in what month does it breed? Are these based on actual observations or anecdotal reports? Detailed descriptions of reproductive habits and spawning. The sizes of the fish and how many were involved?

The places where *L.s* is known to breed are at the downstream end of three large pools between Ban Pou and Ban Xiengkhong. These are based on my discussions with many local people, but all based on personal witness accounts and observations. From my experience of conducting such interviews, there is no question that this is valid information.

f) What are the operational and design aspects of NN2 that will impact on L.s?

1) It is NN1, NN2 and NN3 that will impact on *L.s* populations in the Nam Ngiep, and not just on any one Project. What must always be remembered is that, all three (or perhaps four Projects) will have a cumulative effect on the aquatic environment, but in there own different ways.

2) Major concerns are:

2a) Possible poor water quality (sulphides and nitrites / ammonia) spilling from NN2 reservoir in particular, but perhaps NN3 also, but to a lesser extent.

2b) A reduction in essential life-cycle habitat (flooding of spawning grounds). This fish needs deep-pool habitats and downstream rapids where it can gather and shoal to breed. Sometimes up to 30 individual specimens are involved according to anecdotal reports.

3) Detailed design elements of all three (or four) Projects are required before it can be related to fisheries and fish population aspects.

**g**) What is the accumulative impact of NNP1 and NNP2, including impact that may occur before NNP1 commences and for which the NN1PC Project cannot be held accountable for viz proportional responsibility?

1) It is possible that the Nam Ngiep Project may bring about the extirpation (this means over its localized range within the Nam Ngiep where it is known from). But all three Nam Ngiep Projects will definitely not produce the extinction of this fish species because it is known from many other catchments.

**h**) Data gaps for each *L.s* population. What we don't know but should know? What we don't know about, and is of major importance is the status of *L.s* populations outside of the Nam Ngiep catchment.

a) We now have a lot of information about *L.s* in the Nam Ngiep catchment at least. We have information on where it lives and breeds, and general life-cycle on a seasonal basis.

b) What we don't know about are the populations outside of the Nam Ngiep catchment. It is very important to record this information so that strategies can be put in place to protect this species of freshwater fish elsewhere.

Annexes

Annex 1. *Luciocyprinus striolatus*, data from interviews Annex 2. Fishes of Nam Ngiep drainage, upstream of damsite

#### 1 Summary

The fishes of fast water habitats of the Nam Ngiep inundation zone were surveyed in January– February 2014. Samples were also obtained in adjacent drainages (Nam Mang, Nam Xan and Nam Xao) to obtain information on the distribution of the endemic species.

The survey recorded 53 fish species in the NNP1 inundation zone. Two species were not observed, but reliably reported. The survey found 4 species new to science (unnamed), two of them in the inundation zone and 2 above FSL. An additional 4 species present difficulties of identification and are potentially new to science too..

Five species are known only from the Nam Ngiep drainage. The identity of four additional species is still not clear and they are potentially endemic to the Nam Ngiep drainage. For three of them, the same or a similar species (unnamed) is known from the Nam Ngum and/or Nam Mang drainages. None of the observed species is known only from the area to be inundated.

Four of the species of concern are known in the inundation zone and headwaters, or only in headwaters. The species are expected to survive the impacts of NNP1 project, provided that significant areas of their habitats (torrents, hill streams and small forest streams) remain intact. For species known only from the inundation zone or also until about FSL, they are expected to survive if stretches of several of the main tributaries remain intact at and above FSL for some distance.

*Schistura crabro* was earlier considered to be endemic to the Nam Ngiep. The survey did not observe it in the Nam Ngiep but was found at two sites in the Nam Xan.

The giant pike-carp *Luciocyprinus striolatus* is present in the inundation zone. It is assessed as EN (endangered) in IUCN's Red List. Work must now be undertaken to determine whether or not the Nam Ngiep is a Critical Habitat for the species; work should consider the number of populations globally, the number of 'discrete management units' and their environment quality and threats. Mitigation to the impact of NNP1 project on this species could include research to increase knowledge on the biology of the species and habitat requirements, develop methods for artificial reproduction, and possibly habitat modification to protect or create spawning sites.

#### 2 Introduction

The diversity of inland fishes in Southeast Asia is very high, with more than 1000 species known from western Indonesia (Kottelat et al., 1993; Kottelat & Whitten, 1996a) and some 900 known from mainland Southeast Asia (Kottelat, 1989). Despite this high diversity and their importance for humans, our knowledge of fish biology over most of Asia is still very incomplete and often is restricted to mere lists (Kottelat & Whitten, 1996b). Large areas are still unsurveyed.

The information on Laotian fishes published in the scientific litterature is still limited. Scientific surveys of the fish diversity started in the mid 1990s in conjunction with hydropower development. Unfortunately most of this information is of limited quality and not openly available.

Hydropower projects are usually installed on rivers with a high gradient and the inundated stretches of rivers are mainly characterized by fast to very fast waters, with rapids and waterfalls. These fast water habitats (= rheophilic habitats) are inhabited by aquatic animals specialised for these strong current conditions; most of them are unable to adapt to slow flowing or standing water and will disappear with inundation of the reservoir and reduced flow downstream. However, EIAs often neglect this rheophilic fauna, mainly because the sites are difficult to access and to sample.

This report presents the observations on fish diversity made during surveys conducted in January and February 2014 in the Nam Ngiep 1 project area and discusses impacts of the project in the rheophilic fauna and possible mitigations.

#### 3.2 Methods and terminology

Most fish samples were obtained with a GrassI IG200/2 battery-powered electric fish shocker and with ichthyocides. Additional material was obtained by push-net and seine, and by inspecting catches of villagers and kitchens of restaurants. Ichthyocides were used to obtain samples from habitats that could not be sampled by other means (crevices, rapids, etc.); they were used only where their effect could be entirely controlled and where the river topography allowed an immediate dilution below toxicity level immediately downstream of the sampled area.

The sites were accessed by boat or by car. The Nam Ngiep itself could not be sampled between the dam site and Ban Sopyouak as it cannot be travelled by boat and there is no access by car. Access to tributaries on the west side was not possible upstream of Ban Pouan for security reason.

Identifications and nomenclature follow mainly Kottelat (2001), updated with knowledge acquired posteriorly (compiled in Kottelat, 2012, 2013).

Species are recorded only under their scientific names; these are made of two words, written in italics, and follow the International Code of Zoological Nomenclature. For species that present identification problems, the term 'cf.' is added between the generic name (the 'first name' written with a capitalised initial) and the species name ('second name') to refer to populations which are likely to belong to the species referred to but whose identification is not yet certain because of unresolved taxonomic problems. For example, what is referred to as *Oreoglanis* cf. *delacouri* is possibly *Oreoglanis delacouri* but a soubt subsists and more work, or more material, or more populations are needed to be absolutely sure. The term 'aff.' (for 'affinis') denotes populations that cannot be identified with any species known to me, or which probably are new species (that is unnamed, without scientific name). The use of 'aff.' is to ally this possibly new taxon with what is possibly its closest species. For example, *Schistura* aff. *ephelis* indicates that the species is distinct but close to *Schistura ephelis*. 'sp. n.' is used for species new to science, that is, species that have not yet received a formal name. For example *Glyptothorax* aff. *zanaensis*.

The term "sp." means an unidentified species. For example *Schistura* sp. indicates a species of *Schistura*, which cannot be identified at the species level, for example very small juveniles or mutilated individuals.

Spelling of names of villages and streams follow the 1985 1:100,000 Lao P.D.R. topographic maps, when feasible. Co-ordinates were obtained with four different GPS (two of them mounted in camera) and, in a few cases, from the maps. Datum: WGS 84, UTM zone 48. *Altitudes listed below are only indicative*; they were measured with these two GPS; they often differed and they also differed from those indicated in other documents and maps, or those obtained from Google Earth. The amplitude of the differences varied between 1 to 20 meters. As a result, some samples obtained around FSL may be somewhat above or below.

In the discussion, the word *endemic*, used as either a noun or an adjective, means: whose distribution is restricted to a geographically limited area. For example, a species endemic to the Nam Ngiep is a species that has been observed only in the Nam Ngiep drainage.

#### 4 Results of survey

#### 4.1 Collecting sites and observed species

Sampling sites are numbered in chronological sequence. The sites are organised in the following order: NNP1 inundation zone; Nam Ngiep drainage above FSL of NNP1; and sites outside NNP1 project area (Nam Mang, Nam Xan, Nam Xao). Species are listed in alphabetical order of families, genera and species.

#### 4.1.1 Nam Ngiep in NNP1 inundation zone

**14-001** Nam Chae, immediately upstream of confluence with Nam Ngiep, about 7.5 km downstream of Ban Pou; 18°59'39.5"N 103°30'00.0"E, 300 masl; 28 Jan 2014.

| Balitoridae   | Homaloptera yunnanensis         |
|---------------|---------------------------------|
| Cyprinidae    | Onychostoma aff. gerlachi       |
| Cyprinidae    | Scaphiodonichthys acanthopterus |
| Nemacheilidae | Schistura aff. ephelis          |
| Sisoridae     | Glyptothorax horai              |
| Sisoridae     | Glyptothorax laosensis          |
| Sisoridae     | Glyptothorax aff. zanaensis     |
| Sisoridae     | Pseudecheneis sympelvica        |

**14-002** Houay None, immediately upstream of confluence with Nam Ngiep, about 9 km downstream of Ban Pou; 18°59'06.9"N 103°29'39.8"E, 279 masl; 28 Jan 2014.

| Channidae     | Channa gachua                   |

#### 4.2 Fish fauna

#### 4.2.1 Diversity, endemism

Fish were sampled or observed at 21 sites in the Nam Ngiep drainage upstream of the dam site, 14 of them in fast water habitats in the inundation zone of NNP1 reservoir. A total of 56 species were recorded in the surveyed part of the drainage (Table 1), 53 of them present in the inundation zone, and 34 species were observed in the samples from outside the inundation zone.

Although not observed during the survey, interviews with villagers in Ban Pou, Ban Thaviang, Ban Viengta abd Ban Xomxeun indicate the presence of *Luciocyprinus striolatus* (see Annex 1). In 2013 I have seen in a restaurant in Ban Vanglouang (Hom District; Nam Ngum drainage) a specimen of *Labeo pierrei* that had been brought from Ban Sopyouak; the species has not been obtained by the survey but the origin of the observed specimen is reliable and conforms with what is known of the species in other drainages (Nam Ou, Nam Ngum, Xe Bangfai, Xe Kong). The two species are included in the fish fauna of the Nam Ngiep in Tables 1–2.

Among the 53 species in the inundation zone (Table 1), 2 are new to science (*Schistura* sp. n. 'Nam Youak', *Schistura* sp. n. 'slender'). A further 4 species are potentially also new to science but this cannot be established within the time available for this report (*Schistura* aff. *ephelis*, *Schistura* sp. 'compact', *Schistura* aff. *defectiva*, *Poropuntius* aff. *carinatus*). Awaiting clarification, I adopt a precautionary approach and treat them here as if they effectively are new species. These new species have been discovered by the survey in the Nam Ngiep drainage and therefore they must be treated as endemic to the Nam Ngiep. For 3 of these species there is, however, suspicion that some (or similar-looking species) also exist in adjacent drainages (*Poropuntius* aff. *carinatus*, *Schistura* aff. *ephelis*, *Schistura* aff. *ephelis*, *Schistura* aff. *ephelis*, *Schistura* aff. *ephelis*.

A further 2 new species were discovered in a small hill stream of the Nam Ngiep drainage (site 14-30), but far above FSL (*Danio* sp. n., *Poropuntius* sp. n.). *Glyptothorax* aff. *zanaensis* and *Onychostoma* aff. *gerlachi* are also unnamed species obtained by the survey but they were already known from surveys in other areas of Laos.

All the endemic species found in the inundation zone have also been found above FSL. Some have a wide distribution in the inundation zone (*Schistura* sp. n. 'slender', *Schistura* aff. *ephelis*, *Schistura* sp. 'compact', *Poropuntius* aff. *carinatus*) but others seem to have a restricted range, but this might result from a sampling bias because most of the tributaries of the reservoir are not accessible.

Eight sites were sampled in the Nam Xan drainage, one in the Nam Mang and six in the Nam Xao, a tributary ofv the Nam Ngiep entering it downstream of NNP1 dam site.

Schistura crabro was earlier known only from an unspecified locality in the Nam Ngiep drainage. The survey observed it at two sites in the Nam Xan and therefore the species is no longer to be treated as endemic of the Nam Ngiep. The habitat in which it was observed (riffles on a substrate of gravel to small stones) was rare in the surveyed stretch of the Nam Ngiep and the species possibly does no occur in the NNP1 inundation zone.

#### 4.2.1.3 Other drainages

The sampling in the adjacent drainages yielded 55 species (Table 2). 30 of them are also present in the surveyed parts of the Nam Ngiep drainage. These species will not be further mentioned here unless relevant to the discussion of the NNP1 project area.

#### 4.2.2 Migrations

Only two of the recorded species are known to be long distance migratory in other tributaries of the Mekong: *Labeo pierrei* and *Cirrhinus molitorella*. Both species were observed in restaurants and said to come from the Nam Ngiep.

Labeo pierrei is known to undertake long migrations. This has been documented in the Xekong River, where it moves between the middle Xekong (for spawning) and the Mekong. Such long migrations will not be possible in the Nam Ngiep after construction of the NNP1 dam. However, a survey of the Nam Ngum in 2013 observed that juveniles 1-2 years old were present upstream of Nam Ngum 1 and Nam

Ngum 2 reservoirs. They were at about FSL of Nam Ngum 2, in rapids exposed in the dry season. This shows that reproduction was possible without access to the Mekong, but this observation may not be informative for long term evolution since Nam Ngum 2 dam was commissioned in 2011.

#### 4.2.3 Conservation status

The threat status of all the named freshwater fishes of mainland Southeast Asia has been assessed in the IUCN Red List of Endangered Species (www.iucnredlist.org) (Allen et al., 2012). 46 of the 56 species recorded in the Nam Ngiep drainage upstream of NNP1 dam site have already been assessed (see Table 3). The Red List rating indicates the risk of extinction based on precisely defined criteria. The threat categories are: Critically Endangered (CR), Endangered (EN) and Vulnerable (VU). All species, even those not threatened, have been rated. Least Concerned (LC) are species not threatened; Near Threatened (NT) are species not in any of the threatened category but for which small changes in the habitat or population would immediately move them in a threat category. Data Deficient (DD) are species for which the available data did not allow to objectively rate them. Most of the DD species are newly discovered or rare species. The fate of DD species is not to remain DD but to eventually be evaluated; experience shows that once evaluated a fair number of the DD species are rated as threatened. Note that the assessment is based on the global range of a species, which means that a wide-ranging species could be locally abundant in a given area but globally threatened, or the reverse.

Among the 46 species observed by the survey and that had already been evaluated, none is CR, 1 is EN (*Luciocyprinus striolatus*), 3 are VU, 2 are NT, 29 are LC, and 11 are DD.

#### 5 Species of concern, threats and mitigation

#### 5.1. Endemics

#### 5.1.1 Schistura sp. n. 'Nam Youak'

This is a new species discovered by the survey. It was observed in a small fast flowing stream tributary of the Nam Ngiep near Ban Soppouan (site 14-009) in the inundation zone, in the Nam Youak at about FSL (site 14-015) and in a small tributary of the Nam Youak about 100 m above FSL (site 14-016). It was most abundant at the last site where most individuals were obtained in the stretches with the fastest current. It is expected to be present in adjacent headwaters and its presence in the inundation zone is expected to be restricted to small tributaries. Most of the habitat of the species is expected to be above FSL.

The species is not directly threatened by the project. Indirect impacts will be the construction of access roads that will damage the streams and attract human activity, logging activity (road, camps, etc.) that result in deforestation, siltation, pollution and overfishing. Site 14-016 was along the road, about 1 km from village, in secondary forest, with some impact but still had a good fish population.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors are small stream with fast water on large stones (torrent-type), with riparian forest cover, clear water and absence of siltation. An important point should be the absence of cause of siltation in the upper part of the catchment. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. It will require knowing better the distribution of the species to ensure that it will be present in some of the protected areas.

#### 5.1.2 Schistura sp. n. 'slender'

This is a new species discovered by the survey. It was observed in two tributaries of the Nam Ngiep on the west side (Nam Khai, site 14-006; Nam Pouan, site 14-008), in the inundation zone, and in the Nam Ngiep upstream of FSL of NNP1 reservoir (site 14-019). It was found on and in a substrate of coarse sand, gravel and small stones. Its preferred habitat seems to be stretches with moderate flow (in the dry season), which is not frequent in the inundation zone but makes most of the observed stretch of the Nam Ngiep upstream of FSL until at least Ban Naxong (site 14-019); the extent of its range upstream is not known. The upstream of the Nam Khai and Nam Pouan could not be

researched because of access difficulties and security reasons.

The species has not been collected in the main stream of the Nam Ngiep in the inundation zone but it was present in two tributaries. Species of the genus *Schistura* have not been observed to adapt to reservoir conditions and it is expected *Schistura* sp. n. 'slender' will disappear from the inundation zone. It is expected to subsist in the Nam Ngiep between NNP1 reservoir and NNP2 dams, if the substrate of gravel and stones is not covered by sediment resulting from construction and human activity further upstream.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors seems to be the presence of a substrate of coarse sand, gravel and small stones and that this remain free from sediments or siltation. It would be better if such habitat could be located in tributaries located in protected areas for other animals and forest.

#### 5.1.3 Danio sp. n.

This is a species new to science. It was found only at site 14-030, which is a small stream draining to the Nam Ngiep, in the hills almost at the divide between Nam Ngiep and Nam Xao, about 100 m above FSL. It is probably present in other headwaters; site 14-030 is along one of the only two tracks on which it was possible to cross the divide between the Nam Ngiep and the Nam Xao (near Ban Muang Bo). The species was not observed in the inundation zone and probably occurs only in small headwaters.

The species is not directly threatened by the project. Indirect impacts will be the construction of access roads that will damage the streams and attract human activity, logging activity (road, camps, etc.) that result in deforestation, siltation, pollution and overfishing. It was found together with *Poropuntius* sp. n. (see below).

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors are riparian forest cover, clear water, absence of siltation and human disturbance. An important point should be the absence of cause of siltation in the upper part of the catchment. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. It will require knowing better the distribution of the species to ensure that it will be present in some of the protected areas.

#### 5.1.4 Poropuntius sp. n.

This is a species new to science. It was found only at site 14-030, which is a small stream draining to the Nam Ngiep, in the hills almost at the divide between Nam Ngiep and Nam Xao, about 100 m above FSL. It is probably present in other headwaters; site 14-030 is along one of the only two tracks on which it was possible to cross the divide between the Nam Ngiep and the Nam Xao (near Ban Muang Bo). The species was not observed in the inundation zone and probably occurs only in small headwaters.

The species is not directly threatened by the project. Indirect impacts will be the construction of access roads that will damage the streams and attract human activity, logging activity (road, camps, etc.) that result in deforestation, siltation, pollution and overfishing. It was found together with *Danio* sp. n. (see above).

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams with where the species is presentretain intact aquatic habitats. Key factors are riparian forest cover, clear water, absence of siltation and human disturbance. An important point should be the absence of cause of siltation in the upper part of the catchment. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. It will require knowing better the distribution of the species to ensure that it will be present in some of the protected areas.

#### 5.1.5 Oreoglanis delacouri

This species is endemic to the Nam Ngiep drainage (Ng & Kottelat, 1999; Kottelat, 2001). It was earlier recorded only from the headwaters of the Nam Ngiep. It was found in the Nam Ngiep in the inundation zone and from several small tributaries, above FSL. It inhabits very fast flowing water, especially headwaters and torrents. One sample from the Nam Xan (site 14-018) looks similar to *Oreoglanis delacouri*; since it includes only juveniles, adults are needed to confirm the identification.

Most of the habitat of the species is above FSL. Outside of the inundation zone, it will not be directly threatened by the project. Indirect impacts will be the construction of access roads that will damage the streams and attract human activity, logging activity (road, camps, etc.) that result in deforestation, siltation, pollution and overfishing. It was found together and abundant with *Schistura* sp. n. 'Nam Youak' (see below).

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams with where the species is presentretain intact aquatic habitats. Key factors are riparian forest cover, clear water, absence of siltation and human disturbance. An important point should be the absence of cause of siltation in the upper part of the catchment. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. It will require knowing better the distribution of the species to ensure that it will be present in some of the protected areas.

#### 5.1.6 Schistura crabro

Schistura crabro was earlier known only from an unspecified locality in the Nam Ngiep drainage. The survey observed tzhe species at two sites in the Nam Xan and therefore it is no longer to be treated as endemic to the Nam Ngiep. The habitat in which it was observed (riffles on a substrate of gravel to small stones) was rare in the surveyed stretch of the Nam Ngiep and the species possibly does no occur in the NNP1 inundation zone.

#### **5.2 Potential endemics**

#### 5.2.1 Poropuntius aff. carinatus

This species has been observed at most sampling sites in the Nam Ngiep drainage, in the inundation zone as well as above FSL. It is possibly new to science. A similar or the same species is also present in the middle and upper Nam Ngum to the west; the time available for this report was not sufficient to confirm that hypothesis. The species has affinities with *Poropuntius carinatus*, a species known from the Mekong drainage in Laos and Xishuangbanna (Yunnan, China).

The species is apparently present everywhere in the main stream of the Nam Ngiep and its tributaries and headwaters. Species of the genus *Poropuntius* have not been observed to adapt to reservoir conditions and it is expected that *Poropuntius* aff. *carinatus* will disappear from the inundation zone. It will subsist in tributaries, will probably subsist in the Nam Ngiep between NNP1 reservoir and NNP2 dams, and may subsist in the stretches of streams immediately below FSL and emerged during most of the year.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams with where the species is presentretain intact aquatic habitats. Key factors are riparian forest cover, clear water, absence of siltation and human disturbance. An important point should be the presence of relatively deeper areas to provide shelter during the dry season and gravel and stones along the shores in some stretches for spawning. The presence of dams operating at peak hours upstream could have negative impact in daily exposing gravel beds and shore vegetation in which eggs are deposited. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest.

#### 5.2.2 Schistura aff. ephelis

This species has been observed at most sampling sites in the Nam Ngiep mainstream in the inundation zone as well as above FSL. It was also observed in tributaries near their confluence with Nam Ngiep (but these tributaries could not be sampled away from the main river for access or security

reasons). In the Nam Youak it was observed at about FSL and similar habitat exist further upstream but could not be accessed. A similar or the same species is also present in the middle Nam Ngum drainage to the west; the time available for this report was not sufficient to confirm that hypothesis. The species has similarity with *Schistura ephelis*, a species present in the Nam Ngum and Nam Xan drainages, but still is very distinct.

The species apparently occupies stretches of the Nam Ngiep and its tributaries with fast current and stone substrate. Species of the genus *Schistura* require moving, clear and well oxygenated water and do not adapt to reservoir conditions and it is expected that *Schistura* aff. *ephelis* will disappear from the inundation zone. It will subsist in larger tributaries with sufficient discharge and stone, will probably subsist in the Nam Ngiep between NNP1 reservoir and NNP2 dams, and may subsist in the stretches of streams immediately below FSL but emerged during most of the year.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors are clear water, absence of siltation and absence of dayly variation of discharge (as typical downstream of dams operating at peak hours) that would exposed part of the habitat everyday and kill fish trying to occupy that part of the river bed. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. Lower parts of tributaries immediately above FSL should be primary target areas (as our sampling site on the Nam Youak).

#### 5.2.3 Schistura aff. defectiva

This species has been observed at two sites, one in the Nam Ngiep mainstream in the inundation zone (site 14-004) and one in the Nam Ngiep above FSL (site 14-019). The identity of the species is not clear. Only few individuals were observed and it still cannot be excluded that these are aberrant specimens of *Schistura defectiva*, a species present at both sites and widely distributed in the Nam Ngiep and Nam Ngum. A similar or the same species is also present in the Nam Mang (site 14-014) and in the middle Nam Ngum drainage to the west; the small number of individuals collected by the survey is not sufficient to reach a definitive conclusion.

With the presence of this species in only two samples and its unclear identity, it is difficult to make hypotheses on the preferred habitat. The two sites have in common a long run on a substratum of stones about 10-20 cm diameter, about 50 cm deep. This may not be the preferred habitat but the habitat where it is most easily captured. Species of the genus *Schistura* require moving, clear and well oxygenated water and do not adapt to reservoir conditions and it is expected that *Schistura* aff. *defectiva* will disappear from the inundation zone. It is expected to subsist in tributaries, will probably subsist in the Nam Ngiep between NNP1 reservoir and NNP2 dams, and may subsist in the stretches of streams immediately below FSL and emerged during most of the year. It might also be possible that most of the habitat of the species is above FSL and that its presence in the inundation zone is only marginal.

**Mitigations.** No mitigation may be proposed until the identity of the samples can be clarified, especially its identity with the species of the Nam Mang and Nam Ngum drainages. Generally, the most efficient way to manage such small species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Considering the doubts about the identity of the species and its presence at only two sites, it is not possible to speculate on the key characteristics of the habitat. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. At both sites it was collected with *Schistura* aff. *ephelis*.

#### 5.2.4 Schistura sp. 'compact'

This species has been observed in the Nam Ngiep mainstream in the inundation zone (site 14-004). It was also observed in tributaries near their confluence with Nam Ngiep (but these tributaries could not be sampled away from the main river, because of access and security reasons) (sites 14-007, 14-008, 14-009, 14-012). In the Nam Youak it was observed at about FSL (site 14-015) and similar habitat exist further upstream but could not be accessed. The specific distincness is still not clear. Only few individuals were observed and it still cannot be excluded that these are aberrant specimens of *Schistura coruscans*, a species present at most sites and widely distributed in the Nam Ngiep and

#### Nam Ngum.

The species apparently occupies stretches of the Nam Ngiep and its tributaries with fast current and stone substrate. Species of the genus *Schistura* require moving, clear and well oxygenated water and do not adapt to reservoir conditions and it is expected that *Schistura* sp. 'compact' will disappear from the inundation zone. It will subsist in larger tributaries with sufficient discharge and stone, and it may subsist in the stretches of streams immediately below FSL but emerged during most of the year.

**Mitigations.** The most efficient way to manage the species is to ensure that stretches of streams where the species is present retain intact aquatic habitats. Key factors are clear water, absence of siltation and absence of cyclical variation of discharge (as typical downstream of dams operating at peak hours) that would exposed part of the habitat everyday and kill fish trying to occupy that part of the river bed. Conservation of habitats for the species can be achieved in conjuction with the establishment of protected areas for other animals and forest. Lower parts of tributaries immediately above FSL should be primary target areas (as our sampling site on the Nam Youak). At most sites it was collected with *Schistura* aff. *ephelis*.

#### 5.3 Luciocyprinus striolatus

*Luciocyprinus striolatus* is recorded in the literature from Nam Tha, Nam Ou, Nam Ngum, Nam Kading (Nam Theun and Nam Gnouan), Xe Kong and Xishuangbanna (China) (Cui & Chu, 1986; Kottelat, 1998, 2001; Rainboth et al., 2013) The survey recorded for the first time its presence in the Nam Ngiep and obtained information suggesting it is also present in the Nam Xan. No specimen could be obtained but the identification seems reliable. The summaries of interviews are in Annex 1.

*Luciocyprinus striolatus* reaches a large size (at least 1.5 m, reportedly up to about 2 m) and lives in deep pools and adjacent rapids in fast flowing stretches of large rivers. It is absent in the Mekong floodplain and is only recorded from the middle and upper part of its main tributaries. It spawns downstream of rapids, along shores made of pebble and small stones. It is a predatory fish, feeding on aquatic animals and reported to also capture small mammal that enter the water (monkeys, dogs, etc.) although this is probably only exceptional behavior of very large individuals.

Most populations of the species are impacted or will be impacted by a variety of projects, mainly hydropower and/or mining. In theory, only the population in Nam Theun drainage upstream of the Nam Theun reservoir, in Nakay NBCA, is not threatened by impacts happening upstream.

**Mitigations.** The available information on the biology of the species is very limited and does not allow at this stage to propose concrete actions. The first steps to the management of the species is to confirm the identity, to establish its present distribution in the Nam Ngiep and outside and to obtain biological data.

Because of its size, spectacular appearance, and stories about its feeding habits, *Luciocyprinus striolatus* has a potential to attract attention from the general public and the visibility of the company's attention (or lack of) to conservation issues.

Main points to consider:

#### 1) Distribution

Document the exact distribution of the species, identify exact river stretches, in the inundation zone and between NNP1 reservoir and NNP2 dams

Survey the inundation zone with villagers and identify sites where they have caught or observed the species, especially ripe females. To be done with villagers from Ban Pou, Ban Soppouan and Ban Sopyouak. Although these habitats will be lost at inundation, mapping and describing them may allow to identify geomorphological parameters that can be used later for identification of sites for potential stocking, or provide information for the creation of new, substitution habitats. This should include collection of data on wet-season parameters of these sites.

Survey upstream, of the inundation zone will document the exact distribution of the species. Villagers interviews indicate that very large individuals do not occur upstream of Ban Pou and but villagers are

not certain about the possible existence of spawning sites. Given that the species is not migratory, if large individuals and small juveniles are present, spawning sites may be expected. This needs confirmation from inhabitants of villages upstream.

In regard to ADB Critical Habitat policies, the size and quality of the Nam Ngiep population should be assessed relative to the global population. The 'discrete management units' of the species must be identified as their number, size and habitat quality and integrity may modify the classification.

## 2) Biological data

Obtain biological data on the species in the project area and outside. Sound management requires to know the basic requirements of the species and the characteristics of its life cycle: feeding, growth, habitat at different stages of life cycle, age and size at maturity, spawning sites and habits, ecology of eggs and fry, incubation, growth and feeding of fry, local movements, etc.

The project might join effort with other projects in which the species is also present in order to conduct or fund the research. Nam Theun 2 could be a potential partner; the drainage of their reservoir includes what is apparently the population in the safest conditions; the existence on site of an hydrobiology lab and researchers might ease the setting up of a research program.

As the species is not very abundant (as is the case for most large predatory animals), methods should be used that require to sacrifice only a limited number of individuals.

### 3) Fishing activity

Capture of the species should be managed in the Nam Ngiep. Fishing methods that specifically target the species should be banned. Individuals caught alive should be released; admittedly this is far from local customs. Some conservation pools should be established or, if there are already some, they should be extended where needed (this traditional management method is used at community level in the country).

Non-specific fishing methods can probaby not be controlled.

### 4) Captive breeding

In parallel to the collection of biological data in (2) above, a small captive or semi-captive stock should be established in a safe area. It could be used to study the artificial reproduction of the species. The aim should not be to maintain a permanent captive stock but to develop the knowledge and capacity to quickly produce a large number of juveniles if the need appears. This way, should the need arise the information will already exist and can be used immediately; it will not need to be develop in emergency.

The production of a large number of individuals could be, for example, for stocking in the river to stengthen the local population (at the beginning of flooding, or following a heavy pollution upstream) or to create a new population.

### 5) Identity

Confirm the identity\_of the species present in the Nam Ngiep. Considering the number of disjunct populations reported as *Luciocyprinus striolatus*, it cannot be totally ruled out that more than one species are confused under that name. Apparently, there has been no attempt to scientifically compare individuals of the different populations, because the material for comparison is not available. A DNA test could be useful; however, it should be kept in mind that while a great difference at DNA level usually indicate species distinctness, the absence of difference or a very small difference does not automatically mean that only one species is involved.

The conservation status of the Nam Ngiep population will be better if all the disjunct populations effectively belong to a single species. If more than one species is involved, the conservation actions must be drastically adapted.

Before possibly stocking individuals obtained by artificial reproduction (see (4) above), if the stocked material originates from another population/drainage, it may become necessary to check that this does not impact genetic integrity of the receiving population. However, there will always be some genetic

difference between isolated populations and in some situations the loss of genetic integrity is a minor concern compared to the loss of a population.

### 6) Habitat modifications

The survival of the species will depend of the presence of habitats were it can complete its life cycle. It also depends of the continued presence of the preys it feeds on. The habitat components identify during the interviews (Annex 1) and in earlier observations of the species in the Nam Theun drainage (Kottelat, 2002) indicate that adults live in deep pools, with a possible preference for the upper and lower parts, near rapids, riffles and runs. For spawning, it moves to shallow areas with stone and gravel banks along the shores; this is the wet season morphology of the sites since the species spawns in November, not in the dry season.

These habitats will disappear in most of the reservoir. Some will emerge for a few months in the drawdown zone of the Nam Ngiep and its main tributaries. In the stretches immediately below FSL rapids and deep pools may be functional (at least hydrologically) part of the year. However, the reported spawning season is in November (but some villagers gave dates as late as March, which seemed less reliable), which is in the period in which the reservoir is at FSL. Even the two most ustream spawning sites identified by villagers in Ban Pou and Ban Viengta will be submerged at that time (Wang Mon, Kaen Tao).

The status of this last-mentioned sites calls for some reservation. Maps indicate they will will be below FSL and the rapids would not be functional in November. This is the dry season situation. It is not known what the current morphology is during the wet season. The water is certainly some meters higher and what appears as rapids in the dry season are no longer rapids in the wet season, other rapids may appear, and the spawning sites described as in shallow water on pebble banks are not in the position of the dry-season pebble banks. It might well be that the current wet-season topography of these spawning sites remain after inundation, or that inundation of the reservoir might create wet-season situation further upstream comparable to the current wet-season situation in the inundation zone.

Observation of the spawning sites identified under (1) above is needed during the spawning season to observe the wet season topography and the position actually occupied by the fish.

Depending of these observations, it might be desirable or possible to modify some sites in the Nam Ngiep and main tributaries, above or close to FSL, to mimic the identified spawning sites and that could possibly be adopted by the fish. Without information, further speculations on the kind of modifications is premature.

### 7) Upstream impacts

The discharge from NNP2 project upstream of NNP1 may have impacts on the population of *Luciocyprinus striolatus* downstream. The main impacts will be caused by the increase of the dry-season discharge, the reduced discharge at the beginning of the wet season, and, if it operates at peak hours, the daily fluctuations of the discharge.

Daily fluctuations of the water level downstream of dams/powerhouses is a well-know cause of destruction of fish habitats, and especially of spawning sites. Eggs typically hatch in a few days. Those eggs attached to vegetation or deposited in the sand or in gravel in shallow water become exposed and die in a few minutes. Most fish species spawn this way and it has been observed that *Luciocyprinus striolatus* spawns in shallow water on stone or gravel banks. These stone and gravel banks will be impacted by the daily variation in water level. Here again, without data on the wet-season conditions of the spawning sites, and the planned discharge from NNP2, it is not possible to speculate on the real impact of NNP2.

Further, the impact of NNP2 on the aquatic fauna in the drawdown zone of NNP1 will be very different before and after inundation of the NNP1 reservoir. There will also be specific, short but intense impacts at the end of the construction and during the testing phase of NNP2. This potentially can be devastating for the aquatic fauna downstream.

Information on operation model and planned discharge of NNP2 is needed for management of the aquatic fauna in NNP1 inundation zone. NNP2 has a potential to annihitated mitigation measures taken by NNP1 to support *Luciocyprinus striolatus* and other fish species.

### **6** General recommendations

Four of the endemic species have been observed mainly or only in small streams and headwaters (*Schistura* sp. n. 'Nam Youak', *Danio* sp. n., *Poropuntius* sp. n., *Oreoglanis delacouri*). The most efficient way to manage these species is to ensure that stretches of streams remain intact, under forest cover, and especially to avoid disturbance of the stream morphology and to avoid siltation in these stretches and upstream. The main cause of siltation is road construction, logging, mining and agriculture. Conservation of habitats for these species can be achieved in conjunction with the establishment of protected areas for other animals and forest. This conservation areas should extend to the uppermost part of these streams to avoid any siltation originating upstream. *Schistura* sp. n. 'Nam Youak and *Oreoglanis delacouri* inhabit torrent habitats. *Danio* sp. n. and *Poropuntius* sp. n. were found in a slower flowing forest stream.

Four of the endemic species and potentially endemic species have been observed mainly in the inundation zone, including close to FSL (*Schistura* sp. n. 'slender', *Schistura* aff. *ephelis, Schistura* aff. *defectiva, Schistura* sp. 'compact'). They apparently do not occur in headwaters and seem to require larger stream and stone substrate, which is most common in the main river and the lower parts of the main tributaries. However, site 14-009 was a small torrent-type stream and both *Schistura* aff. *ephelis* and *Schistura* sp. 'compact' were present. The efficient way to manage these species is to ensure that stretches of the Nam Ngiep and main tributaries above FSL remain intact for some distance and especially to ensure that no sediment covers the bottom of the streams.

The most interesting streams would be the Nam Youak, Nam Pouan and Nam Chae, but of these last two streams, the Nam Chae is already impacted by the construction of the Nam Chae dam, and the Nam Pouan will be impacted by the construction of the Nam Pouan dam. Smaller tributaries in the project area might have suitable habitats. The species were found near their confluence but access or security reasons did not allow to sample them further away from the main river (Houay Hok, site14-003; Nam Khai, site 14-006; Houay San, site 14-007).

Judging from maps, these species should also occur further upstream on the Nam Ngiep and other tributaries upstream of the surveyed area, for example the Nam Siam upstream of the NNP2 power house. Again, security reasons do not allow to sample this area.

Poropuntius aff. carinatus occurs in both stream types.

### Annex 1. Luciocyprinus striolatus, data from interviews

Interviews were conducted upstream of FSL in Ban Thaviang, Ban Viengta and Ban Pou, and downstream of the dams site in Ban Xomxeun.

Luciocyprinus striolatus is called Pa Kouan Say upstream and Pa Ern downstream. The name Pa Kharm earlier reported in Ban Thathom is erroneous and resulted from confusion with Raiamas guttatus.

### **Ban Viengta**

Information obtained from a fisherman usually working between Ban Viengta and Ban Soppouan.

*Luciocyprinus striolatus (L. s.)* extends upstream to Sop Syem [7 km upstream of Ban Thaviang, near NNP2 power house]. He has fished in Sop Syem and in the Nam Ngiap upstream but has not seen *L. s.* upstream. He thinks it is not present because the river is too steep and the water too cold.

According to him, *L. s.* is present in Nam Chae. He guesses that its distribution extends downstream to Mekong because he sees more individuals downstream near Sop Pouan but in fact he has never been further downstream). Maybe *L. s.* migrates because it is rare in dry season in Ban Viengta. At an usual fishing site about 8-10 km dowstream of Ban Pou, the fish is also rarer at the same time as in the village.

*L. s.* is usually caught in sectors about 2 m deep, between rapids and pools.

*L. s.* breeds in November. He knows it because he has seen a pair spawning, he caught one by net. The fish caught was a female that released eggs when brought out of the water. This is the only time he obsrved actual spawning. This spawning site was about 1 km downstream of village (not clear whether Ban Viengta or Ban Pou), at Wang Mon 'beach', on sand, in very shallow water, the back of the fishes was outside the water. Several pairs were observed at the same time on this 'beach'.

### Ban Pou

Information obtained from three fishermen, fishing mainly between Nam Chae and Ban Pou.

*L. s.* lives in deep water, downstream of strong current but before deep pools. The depth is at least 2 m.

The distribution of *L. s.* extends upstream to Ban Sop Syem. They guess that *L. s.* is not present upstream because the river is too small and not deep enough. (But they do not go fishing upstream of Sop Syem; they have seen the river and think the fish cannot live there).

They guess that *L. s.* might go downstream to the Mekong, because the water is deeper downstream, but they do not go fishing downstream of Ban Sopppouan, because their boats cannot pass the rapids. They fish in the Nam Chae but they do not catch *L. s.* in that river. They know that villagers in Ban Soppouan go fishing in Nam Pouan, but they have never seen *L. s.* among the catches obtained from that river.

*L. s.* spawns only in December. They observed it at Kaen Tao 'beach', about 4 km downstrean of Ban Pou. Kaen Tao is about opposite sampling site 14-005. Only one of them has seen actual spawning and only once. The water was 40-50 cm deep and the back of the fish was out of the water. They have seen a small group spawning; they counted 4 but there were probably more. They killed one by gun. It was about 1.5 m long (when carried by two people on a pole, the tail was touching the ground). It was a female, 22 kg, of which 1 kg of eggs. Females grow larger than males.

Juveniles live in whirl pools downstream of rapids. At around 40 cm they are caught by gill nets, with 40-50 mm meshes. The fishermen guess that smaller juveniles also inhabit the same area.

*L. s.* moves downstream to big pools from November to May.

The fishermen think that there are also some large *L. s.* in Sop Syem, but they cannot be as big as downstream. Large individuals are not known from Ban Pou; they occur only from Kaen Tao downwards.

### **Ban Thaviang**

Information obtained from villagers who catch between Sop Pouan and Ban Houay Pa Mom.

In the dry season, the river upstream of Ban Thaviang is too shallow for L. s.

*L. s.* spawns in shallow, flowing water. Mentioned supposed spawning sites are Keng Mai and Keng Mgoua near Sop San (site 14-007). *L. s.* spawns in January-March. It breeds in groups of about 10 individuals (they know because they hunt them with guns when they see groups of big fish). The fishes make a group in very close contact.

The maximum size is 1.5 m, up to 16 kg.

*L. s.* is also known from upstream until the upper part of Thaviang, but it only reaches a smaller size and there they are caught by net. The maximum known upstream extent is Sop Syem (Ban Sop Syem).

### Ban Xomxeun.

Information obtained from 3 fishermen.

This village is located on the Nam Ngiep, it is the second village downstream of the dam site. *L. s.* is recognised on the photograph as Pa Ern. It is caught in October-November at Hat Nguen, below the confluence of Nam Ngiep and Nam Xao. They never catch *L. s.* at other times of the year.

*L. s.* is caught with 'drifting gill net'. The fish caught are about 60 cm. They never catch larger individuals, but this might be because the meshes they use (80 mm) would not allow to catch bigger fish. They have never see smaller individuals, although they also catch with smaller meshes. The fish they catch never have eggs or sperm.

#### Conclusions

Fish are observed downstream only at the end of the rainy season, when the discharge is highest; these are apparently vagrant individuals that came downstream with the current. This does not seem to be migrating individuals. This is very few km upstream of the confluence with the Mekong. If this species were migrating to the Mekong, it would certainly already have been noted by surveys and fisheries studies in Laos and Thailand.

The maximum extent of the species upstream is Sop Syem, about 15 km upstream of Ban Thaviang, near NNP2 power house. The species is reported not to grow as big as downstream, but there are still large individuals, and possibly spawning locally. Larger individuals and higher density are downstream of Ban Pou.

*L. s.* inhabits fast water between rapids and large pools. For spawning, it comes towards the shore, along beaches of pebbles, gravel or sand. These are shallow water habitats in the wet season, probably several meters above river level in the dry season.

Largest recorded individuals are females, about 1.5 m long. Males are smaller. On spawning sites, they form small groups and spawn (apparently as pairs) in shallow water, about 40-50 cm deep.

Spawning time is November-December. The mention of spawning in January-March seems less well informed. However, there might be local variation. For comparison, the information I obtained in the Nam Theun was that the species spawns in January-February in rapids (Kottelat, 1996); in 2002 I was told that in the Nam Kading drainage it spawns in October-December.

In the inundation zone, the two mentioned sites close to FSL are Kaen Tao 'beach', about 4 km downstrean of Ban Pou, opposite site 14-005 (19°00'00.4"N 103°28'50.0"E) and Wang Mon 1 km downstream of Ban Pou.

# Annex 2. Fishes of Nam Ngiep drainage, upstream of damsite

Note: Not all species are figured. Material suitable for photography was not obtained for all species (small juveniles, individuals already cut in pieces for cooking, etc.).

## Bagridae

Hemibagrus nemurus, 98 mm SL

Hemibagrus wyckioides, about 400 mm SL

# Balitoridae

Balitora lancangjiangensis, 62 mm SL

Hemimyzon confluens, 57 mm SL

Homaloptera yunnanensis, 58 mm SL

## Channidae

*Channa gachua*, 89 mm SL

#### Clariidae

Clarias batrachus, 102 mm SL

## Cyprinidae

Bangana lippa, 110 mm SL

Barbodes aurotaeniatus, 62 mm SL

Cirrhinus prosemion, about 500 mm SL

Danio acrostomus, 40 mm SL

*Danio* sp. n., 55 mm SL

Esomus metallicus, 36 mm SL

*Garra cambodgiensis*, 77 mm SL

Garra theunensis, 121 mm SL

Hampala macrolepidota, 65 mm SL

Mystacoleucus greenwayi, 86 mm SL

Mystacoleucus marginatus, 82 mm SL

Neolissochilus blanci, 80.0 mm SL

Onychostoma aff. gerlachi, 126 mm SL

*Opsarius pulchellus*, 88 mm SL

*Osteochilus striatus*, 58 mm SL

Poropuntius aff. carinatus, about 250 mm SL

Poropuntius normani, 88 mm SL

Poropuntius sp. n., 80 mm SL

Puntius brevis, 50 mm SL

Rasbora atridorsalis, 50 mm SL

Rasbora rubrodorsalis, 15 mm SL

Scaphiodonichthys acanthopterus, 95 mm SL

Systomus jacobusboehlkei, 73 mm SL

### Gobiidae

Papuligobius ocellatus, 56 mm SL

*Rhinogobius albimaculatus*, male, 56 mm SL (above) and female, 49 mm SL (below)

## Mastacembelidae

Mastacembelus armatus, 270 mm SL

Nemacheilidae

Nemacheilus platiceps, 52 mm SL

Schistura coruscans, 68 mm SL

Schistura defectiva, 49 mm SL

Schistura dorsizona, 33 mm SL

Schistura aff. defectiva, 33 mm SL

Schistura aff. ephelis, 65 mm SL

Schistura sp. 'compact', 47 mm SL

Schistura sp. n. 'Nam Youak', 38 mm SL

# Sisoridae

*Glyptothorax horai*, 90 mm SL

Glyptothorax laosensis, 57 mm SL

*Glyptothorax* aff. *zanaensis*, 74 mm SL

Oreoglanis delacouri, 104 mm SL

Pseudecheneis sympelvica, 40 mm SL

# Synbranchidae

Monopterus albus, 295 mm SL

Tetraodontidae

Pao turgidus, 60 mm SL

Annex D

NNP1 to Nam Xieng and Nam Sieme Rivers (Viravong and Phommovong 2014)

# Biological/Ecological survey of Nam Ngiep River *Luciocyprinus* striolatus between NNP1 northern most reservoir and the conjunction of the two rivers meet (Nam Xieng and Nam Sieme Rivers)

By Sinthavong VIRAVONG and Thavone PHOMMAVONG

The survey was conducted in Nam Ngiep River, the part laying within the distance of about 15 km, starting from upper most part of NNP1 reservoir and go further upwards to north to just downstream of NNP2 where the two rivers (Nam Xieng and Nam Sieme rivers) form a conjunction and become one river. The conjunction where the two rivers join together we call "Sop Sieme" (it means: "Mouth of Sieme river"). From this point downwards to the south of the river is given name and called "Nam Ngiep River" (Figure 1).

Figure 1. Location of the villages where the interview was conducted over *Luciocyprinus striolatus* population status

From this conjunction to north of both rivers such Sieme and Xieng Rivers are the areas inside the NNP2 project, so that the villages located in these two rivers are not conducted in this survey.

<sup>@ -</sup> Viengthong village is currently combined in one by the two villages such Viengthong and Nasay villages. The new name called "Vienthong village". For Nasay village we call "Vienthong village Nasay cluster"

Three villages were conducted the survey by the team that starting on 20 March 2014: Nasong (N19<sup>o</sup>02'55.4",E103<sup>o</sup>22'59.8"), Viengthong<sup>®</sup> (Viengthong (N19<sup>o</sup>03'57.7", E103<sup>o</sup>21'23.2"), Nasay cluster (N19<sup>o</sup>03'31.7",E103<sup>o</sup>3'31.7")) and Xiengkhong villages (19<sup>o</sup>06'37.4",E103<sup>o</sup>20'09.0"). Through the coordination among the surveyed team with Provincial and District; DAFO has requested chief of each village to provide experience fishers/villagers to join the interview for at least 5 to 6 people/village. And the date and time of appointment had made arrangement according to the time appropriate of the villagers. In consequence, the additional survey in the specific locations has been conducted in order to elaborate detail information which obtained from fishers during the interview process(Figure 2).

(a) Fishers at Nasay cluster explain over Ls Behavior and the catch

(b) Nasong village office, in which the interview conducted

@ - Viengthong village is currently combined in one by the two villages such Viengthong and Nasay villages. The new name called "Vienthong village". For Nasay village we call "Vienthong village Nasay cluster"

(d) Explanation on the fishing gear type for Ls and season of spawning

(d) Fishers explain spawning behavior and their critical habitats

<sup>@ -</sup> Viengthong village is currently combined in one by the two villages such Viengthong and Nasay villages. The new name called "Vienthong village". For Nasay village we call "Vienthong village Nasay cluster"

# **Characteristic of River**

Leaving the conjunction of the two rivers (Xieng and Sieme Rivers), Nam Ngiep follows downwards its course through the three villages (between Xiengkhong and Nasong villages) over the distance of 15 km long before passing Thavieng village. The river along this stretch located maximum level at 368 m to minimum level at 329 m above sea level. Topography of the Nam Ngiep here is hillock along which the river forms many of riffles and pools in dry season (in March) and some Rapids. Based on the interview and sites visit found 16 pools, 14 riffles and 4 rapids that located nearby the villages. Different pools have difference in depth and vary from 2 to 8 meters, but the pools with the medium depth of 2-4 meters are dominated. Riffles are form by the deposition of the big to small gravel bars in a characteristic alternation from one side to another of the river. Riffle areas displays regular shallow water with 30 to 35 cm depth and high velocity of the flow by 1-2 m/sec. The river, along which still have found many different size of islands emerging in the dry seasons (see annexes 1-6).

# Instantaneous fish distribution

Result from the survey found that LS has the name popular for this four village and fish has known the name as "Pa kouane Say". Based on the specific characteristic of river in this stretch, Nam Ngiep plays host for about 30 fish species (this number is identified by villagers or local Ecological knowledge) of which, *Luciocyrpinus striolatus* is one that found in this stretch of the river including adult and juvenile individuals. *Luciocyprinus striolatus* is reported been the biggest fish in the river reaching to or more than 20 kg. It is characterized as very strong fish comparing to other species. The occurrence of big size of *Luciocyprinus striolatus* in the river was found seasonally, especially during the spawning season. For small size fish was reported found in the pools all round the year although they are considered now as rare specie.

# Fishing and fishing gears

When after 1975 some villages had been re-established and many moved from Xiengkhouang Province deciding to dwell in this area. At that time fishing was a part of livelihood for villagers. Fishing every day before dusk was aims to get food for the dinner other than selling. Most popular fishing gears were cast net, stationary gill net and hooks. Fishing gear such Lee trap was also used at time but during September to October. These kinds of fishing gears could not able to catch the big like *Luciocyprinus* 

<sup>@ -</sup> Viengthong village is currently combined in one by the two villages such Viengthong and Nasay villages. The new name called "Vienthong village". For Nasay village we call "Vienthong village Nasay cluster"

*striolatus* except Lee trap. Only two fishes of *Luciocyprinus striolatus* of 60 kg/fish were reported catching by Lee trap since before 1991. And Lee trap had been identified as destructive fishing gear and prohibited to use since 1994.

Currently, ttrong,he most fishing gears that fishers used are cast net, gill net and hook and line. Only hook and line can sometime be able to catch LS with the big size but in small amount of number. Two week ago, one fisher in Viengthong village caught LS of 17kg weigh with hook and line. Other fisher in the same village caught one juvenile of LS with 30 cm long by gill net. Juvenile less than 20 cm long also found in this stretch line of the river reporting by Vienthong villager.

# Current Status of LS

*LS* is reported as rare specie in the Nam Ngiep around the villages. Villagers were not able to catch them with such traditional fishing gear types such cast net, gill net, because fishes are very so strong, especially the big size fish of LS. All these fishing gears can be destroyed by LS. Villagers do not know how much number of eggs contained in fish due to never caught them. Based on the villager information, Number of LS caught by fisher each year was less than 60 fishes for the whole four villages dominating by juvenile in size.

# Spawning season of *LS*

During March of each year, fishes were migrated down from deep pools "Vang Kva" to riffle area "Hat Kva" (as reported by fishers in Xiengkhong village) where the shallow with flowing water that fishers can see even their dorsal fin emerged from the water during their spawn due to shallow water. More than 30 years ago, fisher in Xiengkhong reported that about 10 pairs of fishes were migrated to spawn in this riffle. Now the number remaining one to two pairs of fish found in the same riffle (kvav riffle) during the spawning season. During February 2014 fisher of Xiengkhong had caught 1 Ls of 3 kg weigh, fish was observed the eggs but not found.

Another village such Nasong village, fishers also mentioned about finding big *LS* at deep pool "Vang Song" and riffle "Hat Song" during the spawning season in March this year (2014).

# Fish and fisheries management

<sup>@ -</sup> Viengthong village is currently combined in one by the two villages such Viengthong and Nasay villages. The new name called "Vienthong village". For Nasay village we call "Vienthong village Nasay cluster"

Result from interview found that each village territory belong to many deep pools and riffles. So each village (Three villages carrying interview) had set up their own deep pool as be a conservation pool to save all type of fishes. Fishing in this conservation zone is prohibited for year round. Attempt to establish a new conservation pool "Vang Peuai pool" by Xiengkhong villager and the company "Xayakheue company" is in the process. They will manage and save the aquatic resources together including LS and other fish species. The use of illegal fishing gear in the river is prohibited. Some destructive fishing gears such Lee traps were not allowed to use since 1994. The rule is remained used in each village. Although, a number of riffles have been recognized as spawning habitats, they were not taken into account into the fisheries management planning in village level (Annex 1).

# **Critical habitats**

As result from interview and sites survey along the river of 15 km long pertain complexity of critical habitats such refuge habitat, spawning habitat, feeding habitat. There initially found 7 deep pools, 8 seven riffles and 2 rapids (annex 1). LS is the fish specie has been reported found using the nearest riffles close to deep pools where they refuge as spawning habitat. Juvenile of Ls with the size of 20-30 cm are currently found the pool around the village. We strongly expected that there are more than two spawning habitats for LS in this stretch line of the river (See annex 1). Because some part of the river course is far off the village, and fishers were not access to that area of the river, as a result fisher has provided less information on LS critical habitats that expect to be existing in Nam Ngiep.

# Recommendation and suggestion from this survey

- Based on classification guide of Dr. Kottelat 2001, LS is fish specie belonging to family Cyprinidae.
- Referring to information obtained from villagers/fishers, LS found living in the river (Nam Ngiep) at 329m to 368m above sea level.
- Deep pools where Ls found swelling have 2m to 6m deep.
- Ls prefers to spawn at the riffle with shallow water of 30-35 cm deep and water current flow between 1-2 m/sec.

<sup>@ -</sup> Viengthong village is currently combined in one by the two villages such Viengthong and Nasay villages. The new name called "Vienthong village". For Nasay village we call "Vienthong village Nasay cluster"

# How to save Ls population in the future when the NNP1 and NPP2 existed.

- Need to find Ls critical habitat in Nan Ngiep tributary such Nam Theng River
- Need to save the river water in certain level to save the riffle for fish to spawn
- Continue to manage effectively the fish conservation zone in each village, advising by PAFO<sup>1</sup> and DAFO<sup>2</sup>

<sup>@ -</sup> Viengthong village is currently combined in one by the two villages such Viengthong and Nasay villages. The new name called "Vienthong village". For Nasay village we call "Vienthong village Nasay cluster"

Annex J

# Socio-economic Survey Results

# J.1 PROPOSED OFFSET AREA SOCIO-ECONOMIC AND CULTURAL RESULTS

# J.1.1 Introduction

ERM undertook an assessment of the ecosystem services to supplement the biodiversity assessment completed for the NNPI project. The aim is to provide a social context to the establishment of biodiversity offsets.

The assessment included two field visits to collect relevant social data. The first visit involved engagement with key stakeholders (e.g. government officials) and village and market surveys to understand utilisation of ecosystem services by project affected people (PAP). The results of the first visit are presented in the *Inception Report*, prepared by ERM in July 2013.

The following sections present the results from the second field visit, which was undertaken 24 to 29 July 2013 in Bolikham District, Lao PDR. The focus of the second field was twofold:

(1) An assessment of provisioning and cultural ecosystem services in the proposed offset area. The field team mapped natural resources and cultural site locations as well as undertook a significance ranking exercise to prioritize natural and cultural resources. The focus was on prioritizing the species and resources to be conserved.

(2) Stakeholder engagement to determine the level of community acceptance of offset measures in the area. The field team conducted focus group discussions and indepth interviews with hunters and gatherers from six villages (both male and female representatives) along Nam Ngiep River and Nam Xan River. The aim was to generate inputs to the *Biodiversity Offset Report*. The list of villages is provided in *Table 1.2*.

The villagers interviewed were largely lowland Lao, which differ from highland Laos in a number of ways. The Lao government classify the population by their location of residence for this reason Lao people can be categorized into three main groups - lowland Laos, highland Laos and upland Lao. The lowland Lao refer to groups of Lao people who reside in the lower part of mountains or on the flat areas. The lowland Laos practice Buddhism and engage in agricultural farming as a way of sustaining their livelihood. The majority of Lao population is the lowland Lao.

The highland Lao refer to those who reside in the mountainous region of the country. The highland Laos consist of different tribal groups, such as the Hmong, Kamoon and Yaoo. The highland Laos speak their own dialects and practice animism. In this report, no upland Laos were identified.

### ENVIRONMENTAL RESOURCES MANAGEMENT AUSTRALIA

# J.1.2 Stakeholder Engagement Outcomes

Based on the focus group discussions, villagers are aware that the Project is being constructed and may adversely impact their livelihood.

During the focus groups, villagers were asked about the concept of 'biodiversity offset'. Villagers appear to understand the concept as a conservation area that is like or similar to the one that is being used impacted (by the Project). The villagers are aware that areas located around their residence may be utilized as biodiversity offset areas.

In addition, villagers were informed, and appeared to be accepting, that the biodiversity offset proposal, is still in its initial stages of development by the NNP1PC. Villagers were aware that biodiversity offset will not be established without consent from villagers.

Villagers were aware that biodiversity offset areas, once established, may restrict their use of natural resources as well as access to significant cultural or spiritual sites that are frequently used or owned by the villagers.

Although villagers expressed concerns regarding the implementation of biodiversity offset areas, no villagers were openly opposed to the establishment of the biodiversity offset area. Instead most villagers interviewed appeared to have a neutral position. This may be due to the fact that villagers do not perceive the biodiversity offsets as a threat to their livelihood.

Much of the understanding within local villages comes from existing experience. According to the villagers in the Thatom district, including Ban Pou and Ban Pakyong, they were already conserving community forest in nearby areas through the Village Forest Committee. This was a result of a duty allocated by the Thatom District in which the villages are asked to manage and oversee their community forests and natural resources. Therefore, potential impacts from the implementation of biodiversity offset were understood by the villagers from Ban Pou and Ban Pakyong.

Similar to Ban Pou and Ban Pakyong, the lower villages including Ban Kanyong, Ban Pakheaung, Ban Don and Ban Xomxeun have also developed village police groups to oversee both legal and illegal doings, such as hunting and gathering related to the Provincial Protective Forests.

Based on their experience with conservation, villagers indicated that if their forests are used as conservation areas there should be other areas established where key activities can continue to occur, such as hunting and gathering. In this manner, villagers can continue to sustain their subsistence living and/ or livelihood without altering their way of life. This was the preferred to financial compensation.

The villagers indicated that the existing village forest committees could help manage the biodiversity areas. The committees, which have been set-up to oversee forest use, consist of village headmen, respected older male representatives from the Lao youth committee, and female representatives from the women's union.

Furthermore, the villagers suggested that the Lao government should be an actor in deciding which areas will be conserved. In addition, villagers indicated that they (and others) would be more willing to comply with the decision (e.g. prohibition on hunting in a conservation area) if the Lao government was the decision-maker.

# J.1.3 Results Of Market Surveys

Two markets were surveyed (see Table I.1). This included the Bolikham and Thabok markets. The market surveys at Ban Pou and Pakxan markets indicated no signs of wildlife sales. The Bolikham and Thabok markets were selected to widen the pool in order better understand the potential sale of wildlife species.

The Bolikham market is located between Ban Don and Xomxeun and includes a stop for Laos's public transportation. From visual observations, there are approximately 50 stalls of fresh vegetables, 20 stalls of fresh meats (e.g. chicken and pork), and 60 general commodity stores, such as manufactured household products and clothes. Several of the stalls sell NTFP, including mushrooms and bamboo shoots.

The Thabok market is located in the Thapabrad district, next to the Phou Khao Kouay National Protective Area. Based on observations, there are approximately 60 stalls of fresh produce and 20 stalls for general household merchandises, such as manufactured food and clothes. Some of the fresh produce stalls also sold wild species such as wild boar, wild chicken, and frogs. However, not always were the species on site, instead the species are stored at the vendor's residence and can be ordered.

Mr. Fongsalee Chaiyasarn, a government official from the Agriculture and Forestry Department, informed the survey team that vendors in local village markets were highly unlikely to be selling endangered species sourced from protected areas as it is prohibited in Loa. The field team observations align with the officer's comments as no endangered species were observed at the vendors' stalls at the Bolikham market. This may be because the market is located near the district's central administration office and government officers visit the market frequently.

# Table J.1Market Surveys

| Market   | Notable species observed       |  |
|----------|--------------------------------|--|
| Bolikham | No notable species observed    |  |
| Thabok   | Wild boar, wild chicken, frogs |  |

# *Figure J.1* Stalls at Bolikham Market

Fresh produce stall

Fresh produce stall

Selling of small frogs

# Figure J.2 Stalls at Thabok Market

Commodity stalls at Thabok market

Fresh produce stall

Wrapped wild chicken

Sale of endangered species (A leg of wild boar was stored in the blue storage)

#### J.1.4 Results of the Village Surveys

In addition to stakeholder engagement and market surveys, focus groups were run with village representatives (*Table I.2.*).

Table J.2Villages Surveyed

| Location      | Focus groups and In-depth interviews |
|---------------|--------------------------------------|
| Ban Pou       | 25 <sup>th</sup> July 2013           |
| Ban Pakyong   | 25th July 2013                       |
| Ban Kanyong   | 26th July 2013                       |
| Ban Pakheaung | 26th July 2013                       |
| Ban Don       | 27th July 2013                       |
| Ban Xomxeun   | 27th July 2013                       |

Villagers were aware of a number of proposed developments for the local area, including Nam Ngiep 1, Nam Ngiep 2 and the Nam Xan project. (The Nam Xan project is a proposed weir, which will serve to generate electricity for village consumption.) Villagers at Ban Kanyong mentioned construction of Keang Tong and Keang Dao dam, which will generate electricity. The villagers did not identify any proposed mining projects.

Villagers also commented on unexploded ordnance (UXO) contamination. In most villages ordinances have been cleared. The exception is Ban Kanyong, where a small number of remaining UXOs exist. Government officers regularly visit the village to terminate UXOs.

### J.1.5 Provisioning Services

#### Fauna

A flipbook was used during the focus groups to guide the discussion and generate dialogue. The flipbook included photographs of species that have been reported to exist in the Project area by the Environmental Research Institute Chulalongkorn University (ERIC) in 2011. Detailed information about the species found by villagers is contained in *Table I.3*, including species name and sight frequency.

# *Table J.3*Sight frequency of reported species

ENVIRONMENTAL RESOURCES MANAGEMENT AUSTRALIA

Most of the villagers identified the areas where the above-mentioned species are seen in and around their village and along Nam Ngiep and Nam Xan Rivers (*Table 1.4*). In a number of instances, the reported locations align with the community forests, which are located adjacent to the villages.

| Table J.4 | Biodiversity areas reported by each village |
|-----------|---|
|-----------|---|

#### Figure J.3 Map with identified biodiversity areas

ENVIRONMENTAL RESOURCES MANAGEMENT AUSTRALIA

During the focus group discussions a significance ranking exercise was conducted. Results of this activity led to a prioritized list of significant species which hold relative importance to the villagers.

For the mammal species, the villagers viewed big animals as the most important species due to their tracks (i.e. footprints). The villagers reasoned that the tracks, when hunting, lead them to areas rich in biodiversity. When asked to prioritize species that should be conserved, the villagers ranked large mammals in the following order Asian Elephant, Southern Red Muntjak, Tiger, Gaur, Bears, Pangolin and Red-shanked Douc Langur.

As for reptiles and amphibian species, the villagers did not identify any of the flipbook species as significant (i.e. that need to be conserved). However, they mentioned a soft-shelled turtle (*Trionyx cartilageneus*) as a valuable amphibian species. Since the soft-shelled turtle draws a high price at market, which means that if caught it will be sold for income. Apart from market value, the soft-shelled turtle does not hold other significant values to villagers.

For avian species, the Hornbill, including the Rufous-necked Hornbill and Helmeted Hornbill, were identified as important species that should be conserved. The villagers indicated that these species have gradually disappeared from the areas around the villages, which means that they are now rare. In order to conserve the Hornbills, the villagers suggested maintaining and growing Hornbill habitat (e.g. areas where Hornbills nest).

Generally, villagers agreed that endangered species, and if possible, all species should be conserved for future generations (e.g. to see and consume).

In terms of locations, the species are typically found around the villages as well as in the provincial protective forests. The village areas are owned by the villagers.

The provincial protective forests are owned by the Lao government. The forests are divided into reserved and productive areas. Villagers are allowed to access the productive areas, while access to the reserved lands is strictly prohibited. The productive areas are allocated on an annual basis to villagers to ensure that the land is used on a rotation basis. The boundaries are delineated by poles placed around the productive areas by government and announced by the village headman to ensure compliance.

As for private areas, or areas which are privately owned by individual villagers the lands are normally utilized by planting crops. The villagers then know that these areas have ownership and they are not allowed to hunt in such areas.

#### ENVIRONMENTAL RESOURCES MANAGEMENT AUSTRALIA

#### Terrestrial

*Male:* Male hunters generally hunt species primarily for household consumption; any surplus is sold to intermediaries. Approximately, 10% to 50% of species are sold to the market. The money generated by this activity is spent on household expenses such as buying food from markets, clothes and education.

Male hunters normally go hunting individually, unless big animals such as cow or deer are needed for events, such as weddings. Male hunters then go hunting in groups of four to five to hunt big animals. They typically hunt in the designated productive forest areas.

Hunting frequency ranges from two to three times per week to once a month in most villages. However, male hunters from Ban Don mentioned that they have not hunted for the past six years, which is when hunting became illegal. Enforcement has been strictly implemented around Ban Don

A variety of weapons are used. This includes gun, knife, rubber band, traps and nets were also impounded by the district officials.

Typically, male hunters tend to catch what they see, rather than a predetermined species. Frequently caught species include small species such as squirrels, birds and lesser mouse deer; however, once in a while big animals such as Rusa Unicolor, Southern Red Muntjak and Pangolin are caught. The villagers explained that small species, if caught, will be consumed in the household. Big species, on the other hand, are sold to intermediaries. According to male hunters, the most prized mammals species is the Pangolin, the price for which ranges from 100,000 KIP (13 USD) to 1 million KIP (130 USD) per kilogram. (The price correlates to the availability of the species – e.g. in areas where the species is more readily available the price is lower.) This is because of its rarity and medicinal purpose – it is believed to have sexual stimulation powers and is preferred alive.

In terms of cultural importance, male hunters did not identify any species which possess culture or spiritual value.

Hunters reported that the availability of resources has been declining since around 2000. The villagers believed that the cause of such decline is the increasing number of new settlers who have migrated to the village areas and started accessing the existing natural resources.

*Female:* Similar to males, female villagers also hunt; however, females hunt smaller species such as squirrels, bamboo rats, reptiles, and birds. These species are hunted primarily for household consumption; any surplus is sold to intermediaries.

Female hunters usually go hunting in groups of four to five. Female hunters are less likely to go to forests alone.

Hunting frequency ranges from daily to once a once a month. The frequency largely depends on the season and the villager's desires for dinner.

In the same manner with the male hunters, female hunters when they go hunting, they do not have specific species in mind. They claimed to catch whatever species they see. In terms of location, female hunters hunt in the government's designated productive forest areas.

Similar to male hunters, female hunters mentioned that the availability of the existing resources has been declining since 2000. This was attributed to the increasing numbers of people coming into the area to hunt.

In context of cultural importance, female villagers did not identify any animal or plant species which hold significant values to them.

#### Aquatic

Villagers indicated that fishing is mainly the role of females rather than males. Female hunters claimed to go fishing in groups of three to four at a frequency of daily to two to three times per week (depending on, again, on what they want for dinner).

Females indicated that they go fishing more often during the rainy season. This is largely because species that dwell in Mekong River flow downstream to the Nam Ngiep and Nam Xan rivers during the rainy season.

Fishing primarily occurs along the Nam Ngiep and Nam Xan rivers (and their tributaries). Female hunters use nets, baits and traps to fish year round (*Figure 1.4*).

## Figure J.4 Female fishing method

Female fishing

Catch of the day

Female fishing with net

Female fishing

The majority of fish caught are consumed within household. Only surplus or the prized species are sold to intermediaries. Hence, family income derived from selling fish is relatively low - ranging from 20% to zero.

In terms of species, female hunters typically catch cat fish and scale fish. Scale fish are reported to be the most prized species – it can attract up to 130,000 KIP (17 USD) per kilogram at market.

Regarding availability of fish, female hunters mentioned that such resources have been declining due to the increasing number of people fishing. In addition, villagers noted many of these people are fishing for commercial purposes, not household consumption.

The villagers noted that the fish catch are unlikely to be found only in the Project area. Instead, the fish can be caught elsewhere.

#### Flora

Information regarding flora species was also investigated during the focus groups. Females are responsible for gathering flora species and usually operate in groups of three to four in the productive forest areas. They typically use knifes and basket when collecting species.

Female gatherers reported that they visit forests more often at the start of the rainy season (i.e. May) given that the bamboo shoots and ground vegetation are abundant and ripe at this type of year.

No specific flora species were identified during the focus group discussions. This included no specific plant species for medicinal or ceremonial purposes. This aligns with the information obtained about cultural practices – i.e. villagers do not hold any particular important ceremonies.

In terms of non-timber forest products (NTFPs), a number of species are collected, including mushrooms and bamboo shoots, which are gathered at different times of the year, depending on the species' growing season.

Flora species were, again, primarily used for household consumption and only surplus is sold to intermediaries. However, from time to time, specific species will be request by intermediaries, such as Nor boon (1,000 KIP (15 cent) per piece) and Nor Xang (50,000 KIP (7 USD) per kilogram). These are the most prized plants due to their taste.

Female gatherers tend to engage in other activities, such as planting rice or textile production, in order to provide family income (instead of gathering flora species for income).

In terms of availability of existing resources, similar to fauna species, it was reported that flora species have been declining due to the increasing number people settling in the area.

#### J.1.6 Cultural Services

During the village surveys, information was collected on histories and migration stories. Most of the villages have common stories that involve involuntary migration as the result of the Laotian Civil War (1953-1975).

Ban Pou was settled in 1975 after the Civil War for strategic reasons. The villagers mainly migrated from the Xaysomboon province. At present, the villager consists of 70 percent Hmong people, while the remaining 30 percent is lowland Laos.

Ban Pakyong was founded in 1987 with the old name of Ban Nayae. The villagers moved back and forth between Thatom and Bolikham to avoid the Civil War before finally settling in the current location in 1987. The village consists of equal numbers of lowland Laos and Kamoo tribe people.

Villagers in Ban Kanyong, similar to other villages, moved back and forth due to the Civil War. The village was officially founded in 1989. The composition of the villagers is 100 percent lowland Lao.

The villagers in Ban Pakheaung migrated back and forth along the Nam Xan River as required by the Lao government before finally settling the village in 1977. The composition of the villagers is 100 percent lowland Lao.

Ban Don was founded in 1975. Prior to settlement, villagers migrated from Kumkerd, which was located Bolikhamxay province but no longer exists, and the Xiangkwang province. The village proportionally consists of both highland and lowland Laos.

Ban Xomxeun is believed to be over 100 years old with the former name of Ban Meung Mai. The composition of the villagers is 100 percent lowland Lao.

#### J.1.7 Tangible Cultural Heritage

In terms of tangible cultural heritage, most of the villages identified two specific cultural sites deemed important to their way of life - village temples and cremation sites. The cultural sites are typically located in close proximity to each of the villages, but are communally owned by the village.

For example, Ban Don reported to have village temple named Ban Don Chaiyaram, which is located at the centre of the village. Religious ceremonies are held at the site from time to time. The villagers reported conduct religious activities, such as release fish, turtles at the temple.

Ban Xomxeun identified *Tad Jaokumheaung*, a place where Buddhist relics are located. Villagers go to the location to pay respects to the remains of Ban Xomxeun's founder or Jao Kam Heaung. Another cultural site identified is Buddha's footprint was located between Nam Xan and Nam Ngiep River since 1974.

When asked, the villagers indicated that the sites can be moved elsewhere or destroyed and rebuilt elsewhere. In order for this to occur, compensation in the form of land or money is required. The only exception was the Ban Hat Seung Tom, a historic cultural site where artefacts are buried, in Ban Pakheaung. The site was established prior to the founding of the village itself.

#### Figure J.5 Cultural sites at Ban Xomxeum

Tad Jaokumheaung at Xomxeun

ປະຫວດສ້າງພຸດທະບາດສາຮອງ ມັງໃໝ່ເບລັກັນ

Pagoda next to Buddha's footprint

#### Intangible Cultural Heritage

As for intangible cultural heritage, no significant sites were identified. This is partly due to the fact that the village residences were largely lowland Laos who are Buddhist. Accordingly, religious ceremonies are conducted in village temples. Another possible underlying factor is that the villagers have migrated many times prior to settling after the Laotian Civil War. Hence, concerns of originality and native lands are of low importance.
