CONSULTING GEOLOGIST

INTRODUCTION

The present report is a summary of the objectives and results of an exploration program conducted by Advance Murgor Explorations Limited and supervised by the writer, on the company's Fancamp township property located in northern Quebec, Canada, during the period December, 1980 to March, 1981. In it, the writer also draws certain conclusions based on a preliminary assessment of the exploration data and makes recommendations for further work. A final report will be submitted in the near future.

PROPERTY

The Advance Murgor Explorations Limited property is situated in Fancamp township, in the Chibougamau Mining Division, Quebec, Canada. It is easily accessible by means of paved highway and good gravelled logging roads from the mining towns of Chibougamau-Chapais, being about 36 road miles from the former.

The property consists of 52 contiguous mining claims comprising 2,080 acres (832 hectares). 12 of these claims were staked in November, 1980 to protect ground adjoining the southeastern portion of the property. All of the claims are currently in good standing.

GEOPHYSICAL SURVEYING

During December, 1980 and January, 1981, a small amount of ground geophysics, comprising approximately 5.5 line miles of magnetic and horizontal-loop electromagnetic surveying was performed by Flanagan, McAdam and Co. for Advance Murgor Explorations Ltd. on a small grid extending from the "A" gold-bearing area southward across Island Lake. The magnetic survey indicates that the prominent magnetic anomaly, along which the A and B gold-bearing zones occur, extends for about 1,400 feet southwestward under the lake from its north shore. The electromagnetic survey did not indicate any anomalies.

DIAMOND DRILLING

The objectives of the limited drilling program were to 1) establish continuity of the A and B gold-bearing zones by fill-in drilling between holes put down in 1974; 2) test for the extension of the zones to the northeast and south, and 3) further test interesting zinc mineralization encountered in a 1974 drill hole.

The drilling was contracted to Contact Drilling Ltd. of Chibougamau, Quebec. One wireline machine, recovering AQ core was employed. Drilling commenced on January 30 and had to be terminated on March 20, 1981 due to impending break-up conditions. During that period, 16 holes,

totalling 5,462 lineal feet were completed for an average length of 341.4 feet. Split (halved) core was assayed by Bourlamaque Assay Laboratories Ltd. in Val d'Or, Quebec. Analysis for gold was done by the fire assay method. Selected pulps and rejects will be checked by two different laboratories. The drill core is stored in Chibougamau.

DISCUSSION OF RESULTS

The reader is referred to the accompanying drill hole compilation map which shows previous 1974 and 1981 drill holes, gold intersections and the trace of the gold-bearing and zinc-bearing mineralized zones.

The gold mineralization, consisting of native gold, is intimately associated with pyrite mineralization which occurs in variable amounts within zones of shearing, silicification, carbonatization and quartz-carbonate-tourmaline veining hosted by basic to acid tuffaceous volcanic rocks near the contact of a large intrusive granite-granodiorite stock. Gold may occur within fractures of pyrite cubes, or more rarely, interstitially between such crystals.

All of the holes drilled in the 1981 program intersected zones of sulfide mineralization within which gold has been found to occur. These vary in width from a few feet to about 35 feet. Although the majority of the drilling tested the zones to a maximum vertical depth of 150 feet,

several holes (AM-81-1, 81-2) intersected mineralization and gold values at a depth of 300 to 450 feet (vertical), indicating vertical continuity of the zones. Only on four sections of the entire length of the gold-bearing zones was a bank of two holes drilled previously and in the 1981 program, mostly to shallow depth. The remaining drilling consisted of shallow tests for lateral continuity of the zones.

An interpretation of previous and 1981 drilling results indicates that there are two main gold-bearing zones of mineralization. Of these, the most extensive and persistent appears to be the B-1 - B-2 - A-2 zone (interpreted to be one zone) which seems to have a strike-length of at least 2,700 feet (it is still open in both directions). In area B, this "zone" consists of two parallel zones (B-1 and B-2) which are located from 25 feet to about 75 feet apart. The A-1 zone, occurring closer to the intrusive contact, has been traced by drilling for some 1,400 feet and is open to the south. To the northeast, there are indications (hole AM-81-5) that it may extend intermittently for at least another 1,400 feet (except for holes AM-81-10, 81-6 and 81-5, no other holes in the northern portion of the area have tested for this zone). Continuity of the gold-bearing zones between areas A and B was established by hole AM-81-10. Shorter gold-bearing zones appear to parallel the two main

zones in area A.

The best gold intersections obtained in the 1981 program were 1) 0.16 oz./ton Au over 8.0 feet (weighted average) from 88.0 to 96.0 feet in hole AM-81-9 at a vertical depth of 65 feet. The intersection in this hole correlates with that of previous hole G-74-6 at a vertical depth of about 20 feet (0.15 oz./ton over 11.0 feet) and indicates depth continuity of the zone and a more or less consistent width and grade. The AM-81-9 intersection included a 1.5-foot interval which assayed 0.50 oz./ton in gold; 2) an intersection of 0.17 oz./ton Au over 2.0 feet (weighted average) obtained in AM-81-13 under Island Lake, immediately upon entering bedrock. Included in this section was 1.0 foot which assayed 0.29 oz./ton Au, containing visible gold.

Other significant intersections were in holes AM-81-3 and AM-81-5, the latter being the most northeasterly hole drilled on the zones in area B. Values ranging up to 0.16 oz./ton Au over 1.0 to 1.65 feet were obtained in these holes.

Of the holes drilled in 1981, 25% intersected values greater than 0.1 oz./ton Au. Most of the remaining holes obtained low but still significant gold values.

Two holes (AM-81-1 and 81-2) were drilled to further test the zinc mineralization encountered by previous hole G-74-7. Both holes intersected uneconomic but significant

zinc mineralization, best values being 0.310% Zn over 3.0 feet from 379.0 to 382.0 feet in hole AM-81-1 and 0.580% Zn over 2.0 feet from 45.0 to 47.0 feet in hole AM-81-2.

Significant copper mineralization, previously not intersected, was encountered in most of the holes drilled. The best copper mineralization was intersected in area B. It occurs within the volcanic rocks, the main granite-granodiorite body and certain quartz-carbonate veins as disseminations and stringers. Best values intersected were: 1.22% Cu over 1.5' from 180.9 to 182.4 feet (AM-81-7) 0.79% Cu over 1.0' from 253.5 to 254.5 feet (AM-81-6) 0.45% Cu over 2.5' from 306.75 to 309.25 feet (AM-81-6) 0.61% Cu over 1.0' from 668.5 to 669.5 feet (AM-81-1).

CONCLUSIONS

The 1981 winter exploration program conducted by Advance Murgor Explorations Limited on its Fancamp township, Quebec property has produced decidedly encouraging results. Gold-bearing zones of sulfide mineralization associated with shearing, silicification, carbonatization and quartz-carbonate-tourmaline veining have been traced by a limited amount of mainly shallow drilling over a strike-length of about 3,000 feet. Although only 25% of the 1981 drill holes intersected gold values of probable economic significance, it should not be construed that the zones

carry only sporadic gold values. The nature of the gold mineralization is such that diamond drilling fails to assess the average grade of the zones. It can be visualized that since the gold is not uniformly distributed with the pyrite, a narrow drill hole can miss altogether, but if drilled only a few inches in either direction, may cut significant gold mineralization. Also, some, and possibly in certain instances all of the gold may be ground up in the holes and washed away. At best, drilling on the Fancamp property, as well as on numerous other gold occurrences in the Canadian Shield, is only of value in defining the lateral and vertical extent of the zones that have been identified as hosting the gold mineralization. The only way to properly determine the actual gold content of the zones would be to 1) sink test pits in a number of places along the zones, take bulk samples of sufficient size and run mill tests, or 2) do underground development involving detailed sampling and bulk sample mill testing. Since alternative 2) is obviously the more costly, the former procedure would be preferred initially.

The potential for outlining a gold deposit with significant tonnage remains good - there is at least one mile of strike length which remains untested, following a prominent magnetic anomaly along which the gold mineralization occurs in the drill-tested areas. Deeper drilling to test for vertical continuity of the zones along with confirmation

of currently economic grade from bulk sampling would be required before a feasibility study could be undertaken.

There are other indications on the property (gold values associated with a major shear zone to the northwest of areas A and B and an intriguing magnetic anomaly about 1,000 feet south of the B zones) that are prime exploration targets for gold, and should be followed up on as soon as possible.

The significant zinc mineralization in area B northwest of the gold-bearing zones still has to be properly evaluated as an indicator of a possible massive sulfide type deposit. Only two holes tested this zone in the 1981 program. A preliminary interpretation of the results suggests that the geometry and attitude of the zone is considerably more complex than previously believed. Detailed geophysics should be conducted over the target area before further drilling is undertaken.

The interesting copper mineralization within the volcanics and especially in the granitic intrusive complex warrants further work. It is possible that a "porphyry" type copper deposit occurs within the granitic intrusive. The copper mineralization in the volcanics, particularly in area B, along with the zinc occurrence, are strong indicators for a possible economic base-metal deposit with volcanogenic affinity.

It is concluded that the work conducted by Advance

Murgor Explorations Limited during the winter of 1981 has produced encouraging results which warrant a continuing program of exploratory work.

RECOMMENDATIONS AND COST ESTIMATE

PHASE 1 of a recommended extensive exploration program was completed in March, 1981.

The following exploratory work is recommended by the writer:

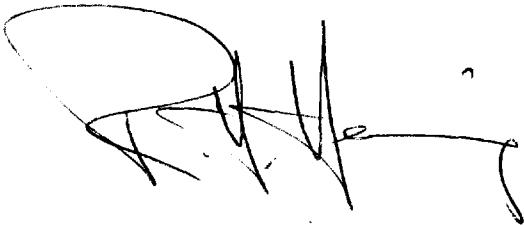

INITIAL PHASE 2: June 1 - October 31, 1981 - as outlined in the attached "Proposed 1981 Summer Exploration Program and Cost Estimate" - cost estimate \$ 400,000

FINAL PHASE 2: November 1, 1981 - April 15, 1982 - Approximately 25,000 feet of diamond drilling to provide for testing of the vertical extent of gold-bearing mineralized zones and further testing for gold-bearing zones under Island Lake, especially west of the holes drilled in 1981 - cost estimate \$ 600,000 (including drill contract work, consulting fees, salary for assistant, assaying, transportation, miscellaneous expenses)

TOTAL COST ESTIMATE, PHASE 2 \$ 1,000,000

Depending on the results of Phase 2, PHASE 3 could consist of feasibility studies and underground development work with considerable expenditures foreseen.

Respectfully submitted,

Toronto, Ontario, Canada

R. H. HENNING, P. Eng.

ATTACHMENTS

1. Proposed 1981 Summer Exploration Program and Cost Estimate
2. Plan showing Location of Drill Holes and Au, Zn - bearing Mineralized Zones

ADVANCE MURGOR EXPLORATIONS LIMITED

PROPOSED 1981 SUMMER EXPLORATION PROGRAM
AND COST ESTIMATE

PERIOD: June 1 - October 31, 1981

1. LINE CUTTING

- a) Lines to be cut 100 feet apart and chained at 50-foot intervals in areas "A" and "B" (approximately 15 line miles, including base and tie lines);
- b) Lines to be cut 400 feet apart and chained at 100-foot intervals on the remaining portion of the property (approximately 55 line miles, including base and tie lines).

To be contracted - to commence immediately after break-up.

2. GEOPHYSICAL SURVEYING

- a) Magnetic surveys employing a proton precession magnetometer at 25-foot intervals on the detail grid in areas "A" and "B" and at 50-foot intervals elsewhere;
 - b) VLF electromagnetic surveys over the entire property at 50 or 100-foot intervals;
 - c) Horizontal-loop electromagnetic surveys employing a Max-Min II EM unit with 2 frequencies (high and low) and 300-foot coil spacing over the entire property;
 - d) Induced Polarization (IP) surveys on a trial basis in order to determine the capability of the method to detect disseminated pyrite mineralization with which gold is associated.
- (a,b and c to be performed by Advance Murgor personnel, d to be contracted)

3. GEOLOGICAL MAPPING, PROSPECTING AND GEOCHEMICAL SURVEYING

Detailed geological mapping and prospecting of the entire property; geochemical surveys involving sampling and analysis of overburden, lake bottom and stream sediments.

To be performed by Advance Murgor personnel.

4. DIAMOND DRILLING

10,000 feet of core drilling employing one B.B.S. 1 or smaller machine; to test for lateral continuity of the "A" and "B" gold-bearing zones; further follow-up on base-metals (copper-zinc) target areas and testing of additional gold-bearing areas and geophysical anomalies.

To be contracted.

5. Overburden stripping and sinking of pits in gold areas "A" and "B"; bulk sampling for mill test.
