[1]Hokkaido University, Sapporo, Hokkaido, Japan, [2]National Institute of Agrobiological Sciences, Tsukuba, Ibaraki, Japan

Termites present complex caste differentiation systems, leading to a wide array of polymorphism patterns, which are adapted to specific social tasks. As in most other social insects, the termite caste differentiation is mainly triggered by juvenile hormone (JH), but its mode of action is still poorly understood.

In the damp-wood termite *Hodotermopsis sjostedti*, soldier caste differentiation can be induced from the totipotent caste called “pseudergates” by treatment with the JH analogue pyriproxyfen (JHA).

Focusing on this induced soldier caste differentiation, we used histological, physiological and molecular approaches to investigate how JH regulates specific caste morphogenesis.

During the soldier caste differentiation, fat body growth occurred rapidly after JHA treatment, accompanied by storage of protein granules, which were mobilized for morphogenesis prior to the presoldier molt. JHA also induced conspicuous changes in the corpora allata, and particularly hypertrophy of the molt gland.

Moreover, intrinsic JH titer was quantified by the LC-MS method during artificially induced soldier differentiation and also in all natural castes. The obtained JH titer patterns validate the previous model of termite caste determination for most pathways, with the exception of pseudergate stationary molt, which occurs after a peak of JH, prior to the molt.

Specific gene expression induced by JHA treatment was also investigated by differential display and suppressive subtraction, leading to the identification of several JH-regulated genes, such as P450, hexamerins and a putative nuclear protein. Those genes are suggested to participate in the regulation of JH titer and in the mechanism of response to JH.

Multidiscipline approach for studying the climate and molecular phylogeographic analysis of termites

Haidi Badawi, Amgad Elmahdi

[1]Biological Sciences, Flinders University, Adelaide, Australia, [2]CSIRO land and water, Adelaide, Australia

Global warming issue and increasing vulnerability of biodiversity are the main issues facing the world and particularly Australia, Australia has a rich fauna of termites mainly in mainland areas. Termites are primarily tropical and subtropical insects, and play an important role as an 'ecosystem engineers' because of their ability to decompose wood material. They have major effects as nutrients recyclers, and in influencing energy flow. Since Australia is facing sever drying conditions and reduced rainfall and precipitation which in turn reduced soil moisture and changed soil physical characteristics. Therefore, recently there are few study attempted to identify and establish the link between termites' distribution (phylogeographgy), invasions to climate and how this distribution might change with global warming and changes in drought frequency.

Hence, this study attempts to study the link between termites phylogenography and climatic conditions by applying molecular DNA bar-coding analysis for termites species from different climatic zones and states to develop a multidisciplinary integrated distributional model approach for Australian termite fauna in consideration of several factors such as vegetation type, ecosystem nature, temperature average, average rainfall, evaporation rate and soil type. This study can give answers for the major questions about Australian termite's fauna biodiversity. Preliminary results show there is a clear tradeoff between climate conditions and termite's distribution and biodiversity, the most sensitive parameters are rainfall, soil moisture, precipitation and temperature.

Multidiscipline approach for studying the climate and molecular phylogeographic analysis of termites

Preliminary investigations into a potentially new ant invader in Kruger National Park, South Africa

Hendrik Sithole, Catherine Parr, Izak Smit

[1]South African National Parks, Mpumalanga, South Africa, [2]Environmental Change Institute, Oxford University Centre for the Environment, University of Oxford, England, United Kingdom

Introduction: A rapid increase in the abundance of *Lepisiota incisa* (Forel) in residential areas of Kruger National Park (KNP) raised concerns that it might be exotic and invade KNP's ecosystems. This prompted this study to (i) explore current distribution and abundance of *L. incisa* around main residential area, (ii) assess ant diversity at *L. incisa*-dominated and non-dominated habitats, (iii) investigate mechanisms responsible for its dominance, and (iv) determine aggression levels among its nests.

Methods: Spread of *L. incisa* from residential area was determined by bait transects from the gardens' edge into undisturbed natural areas. Ant diversity and composition was determined by pitfall trapping in five habitats varying in disturbance. Aggression levels were assessed by introducing individual ants from one nest to another, and noting behaviour on a four-level aggression scale.

Results: *Lepisiota incisa* decreased in abundance when moving further away from the residential area. It was most abundant in gardens. Species richness of other ants was significantly lower in gardens. Ant assemblage composition varied significantly between all habitats. *Lepisiota incisa* recruited to baits significantly faster in gardens, and mostly coexisted with other species. Aggression level was low among eight nests, but high between the ninth and other eight nests.

Conclusions: *Lepisiota incisa* could be exotic. It remains confined to settlement but it may spread because it sustained itself on sites that are far from the residential area. There is unicoloniality among most nests. Its ability to exploit anthropogenic conditions, mostly coexist with other ants and unicoloniality among nests, cause it to dominate residential area.

Fruit fly population and damage in SIT and non-SIT treated deciduous fruit growing areas of the Western Cape Province, South Africa

Aruna Manrakhan, Pia Addison

University of Stellenbosch, Matieland, Western Cape, South Africa

Introduction: Two fruit fly species (Diptera: Tephritidae) that hamper production of commercial fruits in the Western Cape Province, South Africa, are Mediterranean fruit fly (Medfly), *Ceratitis capitata* (Wiedemann) and Natal fruit fly, *Ceratitis rosa* Karsch. Since 1999, a Sterile Insect Technique (SIT) programme was implemented and is ongoing to control Medfly populations in some deciduous fruit growing areas. In areas where SIT is not implemented, growers use mainly poisoned protein bait sprays to control fruit flies. A study was conducted from 2006 to 2008 to determine and compare fruit fly population levels and damage in areas under these two management practices.

Methods: Five study areas were selected: 3 under SIT and 2 under non-SIT control. In each area, 3-5 orchards were selected and in each orchard 4 traps baited with a food attractant, Biolure- 3 component, were placed. Traps were monitored on a fortnightly basis. At harvest, mature ripe fruits were examined on trees for fruit fly damage. All infested fruits were brought to the laboratory and incubated to determine species composition and degree of infestation.

Results: Medfly was the dominant species in traps and in infested fruits. Patterns of fruit fly population were similar in all study areas with a peak occurring between February and April, coinciding with the end of the fruiting season. There was no distinct association of Medfly adult population levels with management practices. Stone fruits and table grapes were the most susceptible hosts. Very low levels of damage (<1%) were recorded on pome fruits.

Developing a process-based population model for *Paropsis atomaria* Olivier, an emergent pest in subtropical hardwood plantations in Australia

Simon Lawson[1], Helen Nahrung[1], Mark Schutze[2], Anthony Clarke[2], Michael Duffy[2], Elizabeth Dunlop[2]

[1]Department of Primary Industries & Fisheries, Indooroopilly, Qld, Australia, [2]Queensland University of Technology, Brisbane, Qld, Australia

Introduction: The eucalypt leaf beetle, *Paropsis atomaria*, is an emerging pest of eucalypt plantations in subtropical eastern Australia, and potentially overseas, due to its wide host range of more than 20 eucalypt species and broad geographical distribution.

Methods: Low temperature thresholds, temperature-induced mortality, and day-degree requirements for immature stages were obtained in the laboratory using beetles sourced from temperate and subtropical zones and combined with field mortality estimates of these stages to produce a process-based population model, ParopSys, using DYMEX™. To validate the model, phenological data were obtained every two weeks between October 2005 and April 2006 from a field population of the beetle.

Results: ParopSys accurately predicted timing, duration and relative abundance of life-stages in the field and number of generations in a spring-autumn (September to May) field season. Two generations were predicted in the Australian Capital Territory, and up to four in Queensland, closely matching field observations.

Conclusions: ParopSys provides a basic tool enabling forest managers to: 1) use the number of generations and seasonal fluctuations in abundance to estimate the pest risk of *P. atomaria* prior to plantation establishment, 2) predict the occurrence and duration of damaging lifestages in the field, and 3) assist in decision making with regard to selection and timing of controls. Additionally, by using local climatic data the pest potential of *P. atomaria* can be estimated to predict the risk of establishment if accidentally introduced overseas. Improvements to the capability and complexity of ParopSys will be made as more biological data become available.

Biomimicry of termite engineering as solution for water and soil conservation

Amgad Elmahdi, Haidi Badawi

[1]Csiro land and water, Adelaide, Australia, [2]Biological Sciences, Flinders University, Adelaide, Australia

Nature has so much to offer to the current challenges facing societies and world, but unfortunately, societies tend to ignore or resort nature's offer/solution as the last option. Nowadays, world/mankind is facing a huge number of environmental problems. However, if researchers pay more attention to studying and understanding nature and nature's positive laws, it should help them play a critical role in overcoming and healing most of these problems. The main focus of this study is to present humanity and termites as design partners in the creation of a new dimension of water and soil conservation understanding. This understanding is based upon the likelihood that termites, as truly symbiotic detrivores, have developed optimal architecture and design for water and soil conservation in ecosystems over millions of years.

In this biomimicry concept study the objective is to present and discuss termite design for better water and soil management by government, industry and the public. Termites create environments that regulate and maintain near-constant moisture and temperature (green energy technology). Termites also create self-regulating energy systems that need no mechanical power for cooling and/or heating. In tropical climates, termites improve soil structure and moisture holding capacity and conserve water irrespective of changing environmental conditions. Thus, the focus/emerge question is can water and soil stakeholders mimic termite management systems in their bid to manage and sustain natural water and soil systems?

Heat and odour of *Macrozamia* cycad cones offer mixed cues to their host specific thrips pollinators

Irene Terry, Gimme Walter, Robert Roemer, Chris Moore

[1]University of Utah, Salt Lake City, UT, United States, [2]University of Queensland, Brisbane, QLD, Australia

The cones of Australian *Macrozamia* cycads are pollinated by host specific *Cycadothrips* species. Cones have daily thermogenic bouts during their pollination phase when male cones dehisce pollen and female cones are receptive. During a thermogenic event, cone odor emissions greatly increase and thrips leave their male host cones en masse. Later in the day the thrips recolonise male cones and some thrips enter females and pollinate them. Male cones serve not only as the sole food source for *Cycadothrips* (pollen) but also as a site for mating, oviposition, shelter and a nursery for their developing young. Why, then, do thrips leave such a suitable environment when there is ample pollen remaining and why do some of them visit female cones that offer little to no reward. Results of behavioural assays demonstrate that cone odors act in a concentration-dependent, push-pull, manner that drives thrips from cones at high concentrations and attracts them at lower levels. Female cones attract thrips by emitting the same chemical volatiles as their conspecific males, but at lower concentrations. Even though odour alone is sufficient to drive thrips out of cones, cone temperature and light are important modulators of thrips behaviour. Results suggest that either cone volatiles or thermogenic temperature increases drive thrips from cones, and only cone fragrances attract them.

Fatal attraction or just attraction? Evaluating alternative hypotheses on the occurrence of sexual cannibalism in praying mantids

Michael R. Maxwell[2], Katherine L. Barry[1], Shekar Viswanathan[2]

[1]Macquarie University, NSW, Australia, [2]National University, La Jolla, California, United States

Introduction: Sexual cannibalism, the consumption of the male by the female during or after courtship or copulation, occurs in many mantids. Explanations of the occurrence of sexual cannibalism have typically centered on ultimate considerations (fitness consequences to the sexes). In the North American mantid *Stagmomantis limbata,* we examine various proximate explanations (mechanistic, physiological) that address the question: how does a male come to be with a cannibalistic female? Field and captive experiments examine mechanisms of mate attraction and nutritional influences on female behavior.

Methods: Presence of female pheromone was analyzed via behavioral assays in the field and gas chromatography. Females were maintained on food-abundant and food-limited diets to examine male responses in field.

Results: Females appear to release tetradecanal as part of long-range pheromones. Male attraction is dependent on the female's nutritional status.

Conclusions: This study argues against a purely "Visual search" conducted by males, as well as against the notion that food-limited females attract males as part of a "Foraging" tactic. Two hypotheses concerning the expression of sexual cannibalism remain viable. The first is "Fatal mate", which posits that relatively well-fed females emit pheromones, and then attack males at some stage in the sexual encounter. The second is "Poaching" by poorly-fed females that do not emit pheromones, but may intercept males that are attracted to the pheromones of conspecific females.

Determination of *Lantana camara* L. (Verbanaceae) biotypes and evaluation of its biological control agents in Swaziland

Cebisile N. Magagula

University of Swaziland, Kwaluseni, Swaziland

Introduction: The study sought to ascertain the various *Lantana* biotypes in the country based on morphological features of the *Lantana* plants. Additionally, the existence of biological control agents which are known to have been introduced and established in South Africa, was to be determined.

Methods: Insects collected from *Lantana camara* by beating and visual inspections in three sites within the country were assessed and compared with natural enemies that have been released in South Africa. The study sites were located in the highveld (Hhohho), middleveld (Nhlambeni) and lowveld (Tambuti).

Results: Based on flower colour, three lantana biotypes were observed during the survey and these had varying distribution within the regions assessed. Six out of the nine natural enemies released in South Africa were found during the survey. Three of these, i.e. *Orthezia insignis,* a sap sucking bug; *Telionemia scrupulosa*,also a sap sucking bug and *Octotoma scabripennis,* a leaf mining bug were found only in the highveld. *Hypena laceratalis,* a leaf chewing moth caterpillar; *Ophiomyia camarae*, a seed feeding fly and *Ophyiomia lantanae,* the herringbone leafminer, were found in all three regions. The highveld had the highest number of natural enemies and the highest level of damage compared to the middleveld and the lowveld.

Conclusions: Due to the varying climatic conditions, further investigation on a suite of these agents in the country is needed to ensure that any natural enemies used are able to cope and compensate for each other and with any limiting factors which would negatively impact their individual impact.

Modelling the potential distribution of the Asiatic citrus psyllid, *Diaphorina citri* Kuwayama (Hemiptera: Psyllidae), in Australia under increasing temperatures predicted by climate change

Kyla Finlay[1], Jean-Phillipe Aurambout[2], Joanne Luck[1]

[1]Biosciences Research Division, Department of Primary Industries, Victoria. 621 Burwood Highway, Knoxfield, VIC 3180, Melbourne, Victoria, Australia, [2]Future Farming Systems, Department of Primary Industries, Victoria. 32 Lincoln Square North, Parkville, VIC 3052, Melbourne, Victoria, Australia

Introduction: Effects of climate change on Australian agriculture via impact on agricultural pests and diseases are virtually unknown. This paper assesses the impact of increasing temperatures on the behaviour, distribution and breeding potential of the exotic Asiatic citrus psyllid, *Diaphorina citri* Kuwayama (Hemiptera: Psyllidae), vector of the bacterial disease huanglongbing (citrus greening) and a major threat to the Australian citrus industry.

Methods: A combined plant physiology and pest development spatial model was developed to understand the effect of increasing temperatures on the behaviour, distribution and breeding potential of *D. citri* in relation to its citrus hosts. The model was then applied to scenarios of changing climatic conditions at a continental scale.

Results: Detection of potential *D. citri* infestations should start earlier in the season due to temperature effects on timing of the first flush (new tissue growth). As warmer temperatures shorten the psyllid life cycle and period of flush availability, an overall decrease in psyllid numbers is predicted throughout Australia. However results will be spatially heterogeneous with increasing temperatures in southern Australia presenting an increased threat from *D. citri.* The model has the potential to include variables such as increased growth of host due to elevated CO_2, presence of alternate hosts and reduced water availability.

Conclusions: Overall *D. citri* presents a reduced threat to Australian citrus under increasing temperatures but southern Australia will become more suitable to establishment and infestation of *D. citri.* Pest-host integrated models provide a powerful tool to assist in prioritizing biosecurity threats.

Novel associations between insects, ophiostomatoid fungi and tree hosts following anthropogenic spread

Michael J. Wingfield, Bernard Slippers, Wilhelm de Beer, Jolanda Roux, Brenda D. Wingfield

Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa

The ophiostomatoid fungi including species of *Ophiostoma sensu lato* and *Ceratocystis sensu lato* are well known associates of insects. While there are interesting exceptions, most *Ophiostoma* spp. are vectored by bark beetles whereas the majority of *Ceratocystis* spp. are associated with casual vectors such as nitidulid beetles and flies. The acquisition of novel vectors of the *Ophiostoma* spp. following anthropogenic spread has been well-known since the onset of Dutch Elm Disease, early in the last Century. As the movement of people and products around the world has grown, there has been a concomitant increase of new introductions of Ophiostomatoid fungi in many parts of the world. Intriguing and worrying associations between these fungi and unexpected insect associates are emerging. To define and understand these associations is complicated by a confused and incomplete taxonomy of the fungi. This is particularly true in the case of *Ceratocystis* spp., which are taxonomically less well known than *Ophiostoma* spp. However, DNA-based techniques allowing phylogenetic inference and population genetic analyses have contributed substantially to our understanding of these important fungi and their insect associates. It is thus likely that many new discoveries relating to the Ophiostomatoid fungi and their vectors will emerge in coming years. These in turn will lead to new concepts in forest protection and they will elevate our capacity to deal with the emerging pest and disease problems associated with a relatively poorly understood group of pathogens that threaten world forests.

Anhydrobiosis in the sleeping chironomid, *Polypedilum vanderplanki*: unique tactics to survive drought

Takashi Okuda[1], Takahiro Kikawada[1], Minoru Sakurai[2], Takao Furuki[2], Ken-ichi Akao[3], Yuichi Nakahara[1], Oleg Gusev[1], Ayako Saito[1], Masahiko Watanabe[1], Yasushi Kanamori[1], Daisuke Tanaka[1], Ken-ichi Iwata[1], Mika Fujita[1], Kanako Mitsumasu[1], Richard Cornette[1]

[1]National Institute of Agrobiological Sciences, Tsukuba, Ibaraki, Japan, [2]Tokyo Institute of Technology, Yokohama, Kanagawa, Japan, [3]JASCO Corporation, Hachioji, Tokyo, Japan

Polypedilum vanderplanki is a temporal pool dweller in the semi-arid regions of Africa. The small and shallow pools are easily dried up during dry season and *P. vanderplanki* larvae are also desiccated completely. They are however able to revive within an hour after rehydration by the next rain as if without ill effects. This developmental arrest with zero-metabolism is so called “cryptobiosis” or “anhydrobiosis” Our interest is to know the mechanism how *P. vanderplanki* larvae can stand complete desiccation. Larvae accumulated a great amount of trehalose (20% of larval dry weight) as compatible solute replacing water upon dehydration. LEA (late embryogenesis abundant) proteins (initially isolated from plant seeds) also occurred in *P. vanderplanki*. Physico-chemical analysis revealed that the anhydrobiotic larvae enter a vitrified state which is certainly stabilizing molecules and cell membranes of the larvae under complete dehydrartion, and both hydrophilic molecules (trehalose and LEA proteins) were importantly contributing to the glass formation. Other protective factors such as heat-shock proteins (HSPs) and anti-oxidative enzymes were also expressed for self-protection. Nevertheless, to our surprise DNA was damaged during anhydrobiosis. The mending of the damage should take place after rehydration.

Recently we isolated a trehalose transporter, *tret1* from *P. vanderplanki.* This gene has a great potential for application such as anhydro- and cryo-technology.

The success of biopesticides in Australian broadacre crops

Caroline Hauxwell[1], Patrick Buerger[2], Dave Murray[1]

[1]Department of Primary Industries & Fisheries, Queensland, Australia, [2]Ag Biotech Australia Pty Ltd, Richmond, New South Wales, Australia

Broadacre crop production in Australia was in crisis in the late 1990s due to high pest pressure from *Helicoverpa* spp. and escalating cost of and resistance to chemical insecticides. An integrated management strategy that included the use of baculovirus insecticides was introduced to break the cycle of insecticide resistance and maintain beneficial insects while reducing pest damage.

Biopesticides based on Nucleopolyhedrovirus (NPVs) have efficacy against insecticide resistant *Helicoverpa* spp. and low impact on natural enemies. They can be used in the early season to control spring flights of *H. punctigera* and emerging *H. armigera* populations, which reduces early season selection for insecticide resistance and further pest outbreaks by maintaining beneficial insects.

Research and development by the Queensland Department of Primary Industries (DPI&F) has supported the registration and manufacture of four commercial NPV insecticides: 'Gemstar', imported from the USA, and three domestic products, 'Vivus', 'Vivus Gold' and 'Vivus Max'. High quality, availability and viable pricing created a successful market in a broad range of commercial crops including sorghum, cotton, sweetcorn and lettuce. Further research in targeting, timing and formulation by DPI&F led to improved field efficacy. In grain sorghum, 95% of the sprayed crop area is NPV treatment.

Surveys have shown that mainstream growers and agronomists give top priority to efficacy, resistance management, maintaining beneficial insects and reducing secondary pest outbreaks. The success of NPVs has increased grower confidence in biopesticides as part of an integrated strategy, and led to a demand for similar 'soft' options against emerging sucking pests.

Improved formulation of *Baculovirus* insecticides against *Helicoverpa armigera* in Australian broadacre crops

Caroline Hauxwell[1], Andrew Reeson[2]

[1]Department of Primary Industries and Fisheries, Queensland, Australia, [2]CSIRO Sustainable Ecosystems, Canberra, ACT, Australia

Biopesticides based on Nucleopolyhedrovirus (NPV) are established tools in pest control and insecticide resistance management against *Helicoverpa* sp. in Australian cotton, sorghum and horticultural crops.

A range of commercial additives and reducing sugars, including mannitol, were tested for improvement of NPV efficacy on cotton. While many additives enhanced performance to some degree, there was a significant increase in efficacy with increased relative sweetness. Mannitol, thought to increase efficacy through neutralizing free radicals generated in the cotton leaves, was found to have limited enhancement effects relative to significant increases in efficacy with high sweetness additives.

Emulsified spray oils increased NPV efficacy at 2%, but with reduced enhancement with increasing concentrations. However, a combination of emulsified oil with high sweetness sugars resulted in a dramatic increase in viral potency on cotton plants. Ultra Low Volume application of NPV in oil with low cost, high-fructose sugar additives was more effective at controlling *Helicoverpa* in field trials than conventional spray application in water. The results demonstrate the benefits of practical, low-cost additives to enhance NPV field efficacy.

The ovo-pupal parasitoid *Fopius arisanus*, a promising biocontrol agent for the peach fruit fly, *Bactrocera zonata*, in Reunion Island

Serge Quilici[1], Pascal Rousse[1], Christophe Simiand[1], Antoine Franck[1], Frédéric Gourdon[1], Thomas Mangine[2], Ernest Harris[2]

[1]CIRAD, La Réunion, France, [2]USDA, Hawaii, United States

Introduction: The peach fruit fly, *Bactrocera zonata*, is a polyphagous tephritid which established in Reunion Island in 2000 and became dominant in the lowland areas. The ovo-pupal parasitoid *Fopius arisanus* was introduced from Hawaii in 2003, in collaboration with USDA. Studies were conducted to determine its survival and specificity on the tephritid species of economic importance present in Reunion Island. Releases were then conducted in various sites in order to obtain the acclimatization of the parasitoid.

Methods: Laboratory studies were conducted to determine the pre-imaginal development of the parasitoid on its different tephritid hosts. The response of adult female to host habitat and host odors was determined using a release-capture method in field-cages.

Results: Laboratory studies showed that this parasitoid could develop on several tephritids of economic importance, though *B. zonata* was the preferred host. The females positively responded to odours of various plants and to a kairomone present on tephritid eggs. In 2006, surveys revealed the presence of the parasitoid in various areas, on different host-fruits. On Indian almond (*Terminalia catappa*), on which *B. zonata* is the dominant species, the level of parasitism, though very variable, could at times reach 70-80 %.

Conclusion: The successful acclimatization of this parasitoid aims at decreasing the populations of the peach fruit fly in “reservoir areas” where huge populations used to develop in the absence of an effective biocontrol agent. Future studies will focus on defining the impact of this promising parasitoid in different ecological conditions and on different host fruits.

Codling moth and CpGV interactions: Resistance versus virulence

Marie Berling[1], Miguel lopez-ferber[1], Benoît Sauphanor[2], Antoine Bonhomme[3]

[1]EMA, ALES, France, [2]INRA, Avignon, France, [3]NPP, PAU, France

Introduction: The *Cydia pomonella Granulovirus* (CpGV) is widely used in codling moth control. Since 2004, after fifteen years of application, some CpGV resistant populations were detected in organic orchards in France, Germany and Italy. The resistance ratio can reach 50,000–fold in the laboratory. Virus formulations commercialized in Europe all derive from the same Mexican isolate and the resistance seems to be directed against this isolate.

Results: In a first step, various viral isolates were used to challenge both the susceptible (Sv) and the resistant (Rgv) laboratory colonies of codling moth. Among them, the NPP-R1 isolate was the most promising. Its efficiency on Sv larvae was similar to that of the Mexican isolate. On the Rgv colony, it presented the highest activity with a LC_{50} and LC_{90} respectively 6- and 18-fold higher than on the Sv colony. The success of the pest control in field could be tampered by this difference of efficiency between resistant and susceptible larvae. The second step was thus to try to improve the efficiency of NPP-R1 by successive cycles on Rgv larvae. After only four cycles of selection, this process led to a 30 % reduction in the LC_{50} on the Rgv strain. An even higher improvement was observed for the LC_{90} on this strain which was divided by three. No significant variation on the efficiency was observed on Sv larvae

The ancient origins, phylogeography and conservation of Hawaii's aquatic moths

Daniel Rubinoff, Patrick Schmitz

The University of Hawaii, Honolulu, Hawaii, United States

Introduction: The Cosmopterigid moth genus *Hyposmocoma* may be the most diverse endemic Hawaiian genus with nearly 400 recognized species though little research has been conducted. Amongst this diversity are aquatic moths, capable of remaining submerged for days. The evolution of this globally rare lifestyle in Hawaii has implications for the patterns and constraints of insect evolution. Because *Hyposmocoma* has endemic species from 20 million year old Hawaiian atolls, direct examination of lineage age and time of colonization is possible. Additionally, patterns of *Hyposmocoma* diversity can guide prioritization of regions and habitats on which conservation attention should be focused.

Methods: Aquatic and terrestrial moths were reared from across the Hawaiian Islands, including Northwest atolls. Phylogenies, based on sequence from two nuclear and one mitochondrial gene, are constructed using maximum parsimony, maximum likelihood and Bayesian models.

Results: Multiple invasions and reversions of the aquatic ecology are strongly indicated despite it being a globally rare evolutionary pathway due to the constraints of an aquatic lifestyle. Biogeographic patterns are presented. *Hyposmocoma* may be one of the oldest extant lineages in the archipelago. Species appear to be universally single-island endemics, some with very restricted ranges.

Conclusion: Aquatic *Hyposmocoma* are extremely diversified, and have rapidly evolved in and out of the aquatic environment. Riparian degradation appears to have limited the range of many populations, and aquatic *Hyposmocoma* may serve as indicator species for assessments of riparian habitat or water quality. Aquatic Lepidoptera are a global evolutionary anomaly, making Hawaii's radiation especially worthy of examination and preservation.

Allee effects and high dispersive behaviour: Antagonist forces in potentially invasive bark beetles

Jean-Claude Grégoire[1], Marius Gilbert[2]

[1]Université Libre de Bruxelles, Bruxelles, Belgium, [2]Fonds National de la Recherche scientifique, Bruxelles, Belgium

Introduction: Among the numerous records of Scolytine beetles established in new areas after having crossed a geographic barrier, there is no mention of aggressive, tree-killing *Ips* or *Dendroctonus* species. The continental European species, *Ips typographus*, in particular, has been regularly intercepted in the UK, the US and Canada but there is no record of successful establishment of this species.

Methods: An "invasion" experiment was performed within the distribution area of the species but in an area (Champagne, France) devoid of spruce and hence devoid of *Ips typographus*. 35 m³ of infested timber was introduced from Belgium in a pine and oak stand and beetle dispersal was followed using pheromone traps. In parallel, the reservoir of beetles in the air was followed in a 180 km transect of pheromone traps starting in spruce area and ending deep in the spruce-free area.

Results: Out of the estimated 300,000 insects released, only 5,000 were caught, mostly in the near vicinity of the infested timber. The catches along the transect steeply declined with the distance to the spruce area.

Conclusions: It is hypothetised that the conditions for success of highly dispersive species such as *Ips typographus* lie in the presence of population reservoirs fed by numerous sources, and which use pheromone communication to focus on susceptible host trees. In the absence of such population reservoirs, the chances of success of an invasive population appears extremely low.

Allee effects and high dispersive behaviour: Antagonist forces in potentially invasive bark beetles

Jean-Claude Grégoire[1], Marius Gilbert[2]

[1]Université Libre de Bruxelles, Bruxelles, Belgium, [2]Fonds National de la Recherche scientifique, Bruxelles, Belgium

Introduction: Among the numerous records of Scolytine beetles established in new areas after having crossed a geographic barrier, there is no mention of aggressive, tree-killing *Ips* or *Dendroctonus* species. In the absence of such population reservoirs, the chances of success of an invasive population appears extremely low.

Economic threshold for the management of *Plutella xylostella* with granulovirus in cauliflower

Sevgan Subramanian[1], R. J. Rabindra[2], Natarajan Sathiah[3]

[1]International Centre of Insect Physiology and Ecology, Nairobi, Kenya, [2]Project Directorate for Biological Control, Bangalore, India, [3]Tamil Nadu Agricultural University, Coimbatore, India

Introduction: Resistance to insecticides and some bio pesticides by *Plutella xylostella* (DBM) has resulted in the search for alternative options in its management. The *P. xylostella* granulovirus (PlxyGV) has emerged as an effective option for DBM management. However use of PlxyGV would be economical only when the pathogen is applied at the right crop stage and at economic threshold levels.

Methods: Field level economic threshold for application of PlxyGV at the reproductive phase of cauliflower was evaluated in two different sites of Tamil Nadu with application of virus at thresholds of >5, >10, >15 and >20 larvae per 10 plant. Observations on the DBM population and cauliflower yield in different treatments were undertaken.

Results: PlxyGV was very effective in the management of DBM and it was comparable to weekly application of Quinalphos 25EC. Due to higher cost of PlxyGV applications than Quinalphos, the benefit cost ratio with insecticide was much higher than the virus. The net returns from the virus application decreased both at lower thresholds due to higher cost of plant protection and at higher thresholds due to the increased damage by the pest. Based on net income per ha and plant protection cost, PlxyGV application at threshold of 10-12 larvae per 10 plant was optimum with the net return just equal to the plant protection cost.

Conclusion: An economic threshold level of 10 – 12 larvae per 10 plants in the reproductive phase is suggested for the use of PlxyGV in the management of DBM in cauliflower.

A geographic mosaic of selection in a generalized plant-pollinator-herbivore system

Jose M Gomez[1], Francisco Perfectti[1], Jordi Bosch[2], Juan P M Camacho[1]

[1]University of Granada, Granada, Andalusia, Spain, [2]CREAF, Barcelona, Catalunya, Spain

Selection mosaic is central to the Geographic Mosaic Theory of Coevolution. Most information on coevolving interactions, however, is coming from specialized organisms. In contrast, an accurate understanding of the effect of geographically varying evolutionary dynamics on the evolution of generalist organisms is still lacking, despite this kind of organisms are the most frequent at nature. In flowering plants, pollinators and herbivores are important selective agents driving the evolution of many floral traits. In this study we investigate the selection mosaic caused by pollinators and herbivores in the generalist herb *Erysimum mediohispanicum*, by quantifying in eight populations from SE Spain the selection exerted by these organisms on several plant traits (flower number, stalk height, corolla shape and diameter, and corolla tube length and width). We found that different populations were under different selective regimes, and the traits affected by selection depended on the predominant local pollinators and the intensity of mammal herbivory. This spatial variation in selection scenarios results in populations with strong selective regimes (hot spots) intermingled with populations with weak selective regimes (cold spots), suggesting the occurrence of a selection mosaic for *E. mediohispanicum*. Four important features characterized this geographic mosaic: 1) The interactions with generalist organisms, contrary to the conventional wisdom, produced strong selection; 2) There was divergent selection across populations as a consequence of spatial changes in main pollinators; 3) The outcomes of the geographic mosaic depended on a balance between mutualistic and antagonistic selection; 4) The selection mosaics operated at fairly small spatial scales**.**

Structures and uptake mechanisms of vitellogenins in cockroaches

Makio Takeda, Mohamed El-Sayed El-Mogy, Tufail Muhammad

Kobe University, Kobe, Hyogo-ku, Japan

The reproductive success of insects depends on vitellogenin (Vg, the major yolk protein precursor) biosynthesis and its internalization by Vg receptors (VgRs) into the developing oocytes. The Vg is synthesized extraovarially in the fat body cells and transported through hemolymph to the oocytes where it is deposited by membrane-spanning receptors, the VgRs, through receptor-mediated endocytosis. Once sequestered by growing oocytes, the Vg is sent to yolk bodies, where it is processed for storage, thus providing main nutritional reserves necessary for the embryo development.

We have characterized the molecular structures of four Vg molecules, the two (Vg1 and Vg2) being that of the American cockroach, *Periplaneta americana* (Tufail et al., 2000, 2001 2005), whereas, the two (Vg1 and Vg2) being that of the Madeira cockroach, *Leucophaea maderae* (Tufail and Takeda, 2002; Tufail et al., 2007). We also demonstrate the synthesis and expression pattern of both the transcript and the protein, and clarify, on molecular basis, that how Vgs undergo a complicated pattern of post-transcriptional processing. The data on phylogenetic analysis suggests that Vgs are still phylogenetically bound, although divergence exists among them, and can be used as a molecular marker.

Also, we report cloning/characterization of two VgRs from ovaries of the two cockroach species, *P. americana* (Tufail and Takeda, 2005) and *L. maderae* (Tufail and Takeda, 2007) and confirm that a ~7.3 kb transcript was specifically expressed in ovarian tissues at high levels throughout ovarian development, especially in previtellogenic ovaries and in ovaries before adult emergence. RNA *in situ* hybridization and immunocytochemistry localized VgR mRNA and the protein only in germ line-derived cells, the oocytes, and revealed that VgR gene transcription and translation begin very early during oocyte differentiation in the germarium. Furthermore, we observed the timing of uptake of both *Vg* genes products using immunoblotting in *P. americana*, and found that the receptor-endocytotic mechanism starts functioning soon after the ligand becomes available.

We will report the structure and functions of Rab5 protein, a small Ras-like GTPase, involved in Vg uptaking endocytosis in *P. americana* oocyte.

Ancient diversification and evolution of large circular dsDNA viruses of insects

Johannes A. Jehle[1], Monique M. van Oers[2], Regina G. Kleespies[3], Just M. Vlak[2], Yongjie Wang[1]

[1]Agricultural Service Center Palatinate, Neustadt/Wstr., Germany, [2]Laboratory of Virology, Wageningen University, Wageningen, Netherlands, [3]Institute for Biological Control, Julius Kuehn, Darmstadt, Germany

Numerous viruses have been identified in different insect species. Among these, the baculoviruses are one of the largest and most diverse groups of viruses. Presently, 43 baculovirus genomes have been sequenced. They share 29 homologous genes, which are considered as the baculovirus core genes. Their evolutionary relationship to other large circular dsDNA viruses infecting insects and crustacea has not been elucidated. Here we will provide new insight into the diversification and evolution of large circular DNA viruses based on comparative analyses of their genomes. The genomes of two nudiviruses, the beetle-infecting *Oryctes rhinoceros* nudivirus (OrNV) and the cricket-specific *Gryllus bimaculatus* nudivirus (GbNV), have been cloned and sequenced. They are 127,615 bp (OrNV) and 96,944 bp (GbNV) in size, respectively. In-depth genome sequence comparisons revealed that homologues of 20 baculovirus core genes are conserved in the genomes of OrNV, GbNV, and in *Heliothis zea* nudivirus 1. These 20 genes are associated with transcription (*p47*, *lef-8*, *lef-9*, *lef-4*, *vlf-1*, and *lef-5*), replication (*dnapol* and *helicase*), virion structure (*p74*, *pif-1*, *pif-2*, *pif-3*, *vp91*, *vp39*, *38K*, *19kda* and *odv-e56*), and with yet unknown functions (*ac68*, *ac81* and *p33*). The four *pif* genes (*p74*, *pif-1*, *pif-2* and *pif-3*) of baculoviruses are involved in virus binding to and in entry into midgut epithelial cells and hence are essential for successful infection of insect hosts *per os*. Genome wide analysis indicated that the baculoviruses and nudiviruses share a common ancestor and form monophyletic group. The phylogeny and evolution of these viruses will be discussed.

Comparative study on the morphology of egg pods, egg development and hatching of three *Hieroglyphus* species (Acrididae: Orthoperta)

Riffat Sultana, M.Saeed Wagan

Department of Zoology, Jamshoro, Pakistan

Comparative study of egg pods of agriculturally important grasshoppers were carried out in Pakistan between the years 2005-2006. Searches were made of oviposition sites under laboratory condition. The three principal grasshopper species found at these oviposition sites were *Hieroglyphus perpolita* (Uvarov), *H.oryzivorus* Carl and *H. nigrorepletus* I. Bolivar.

1. Female usually lays a heap of eggs in grounds, eggs usually enclosed in a sac, consisting of the hardened secretion cemented with grains of earth; such mass of eggs is called egg-pod. The pods are sub-cylindrical and slightly curved. The weight (3.64±0.60gm) and width (22.82±2.21mm) of *H.perpolita* is significantly greater than that of *H.oryzivorus* (1.30±0.03gm) and *H.nigrorepletus* (0.185±0.003gm) whereas length of *H.oryzivorus* (34.68±0.84mm) is significantly greater than that of *H.perpolita* (27.78±0.78mm) and *H.nigrorepletus* (18.38±1.15mm).

2. Eggs cylindrically elongated, large slightly bent in the middle and rounded at ends. The size, length (6.37±0.06mm) and weight (0.128±0.01mm) of eggs of *H.perpolita* is significantly greater than that of *H.oryzivorus* (0.0054±0.0001gm), (4.52±0.07mm) and *H.nigrorepletus* (0.005±0.00006gm), (4.55±0.0063mm) weight and length respectively. Similarly there was significant difference between the weight of dry eggs and fresh laid eggs of *H.perpolita.* The egg-pod is full of eggs without any empty space. There are more eggs at the base and their number decreased towards the top.

3. The major hatching occurred with in few weeks i-e 57.43to 100% in *H.perpolita* from June to August but mostly in the month of June, 76.85% to 100% in *H.oryzivorus* from July to September (mostly in August) and 69.09% in *H.nigrorepletus* from July to August mostly in mid July hatching then stopped.

The present study described the detailed of morphological variation in egg pods of these species although the genus is same, and examines some of the factors which influences egg laying in *Hieroglyphus* whose development has been dealt with elsewhere. Present study is being reported for the first time.

Introduction on a geometric approach in the study on the patterns of divergence in ecological relevant traits in an adaptively radiated wolfspider genus from Galapagos

Charlotte De Busschere, Léon Baert, Jean-pierre Maelfait, Frederick Hendrickx

University, Ghent, Belgium

Adaptive radiation is the process in which an ancestral species induces a range of species adapted to different niches and characterized by unique features to explore these niches. Although this is a well studied topic, there is still a lot of uncertainty about the underlying processes for example when the geographical distribution is not an adequate barrier to obstruct gene flow. Whether divergence in ecological traits is merely influenced by ecological processes (ecological opportunity) or rather by the potential of species to produce alternative phenotypes is crucial for understanding the mechanisms of speciation. This research is focused on the genus *Hogna.* On the Galapagos, populations of this genus are primarily diverged in function of the geographical position of the islands and secondly in function of the habitat in a repeated pattern. Populations are recently diverged and give the potential to get insight in the first steps of speciation. These populations are difficult to distinguish morphologically and constitute several species, until now 3 species are described *H. albemarlensis, H. galapagoensis* and *H. snodgrassi.*

The main goal is to contrast the degree of divergence in both ecological and molecular traits to explain the observed patterns of this differentiation. Furthermore we would like to know to what extent divergence in ecological traits can lead to reproductive isolation. Practically, this research involves morphometric methods, biometric measurements and genetic analyses. In this poster some preliminary morphometric methods are explained to analyze shape differences in carapax, epigynum and other structures.

Impacts of frost on beech (*Fagus sylvatica* L.) susceptibility to Scolytine ambrosia beetles

Sylvie La Spina, Charles De Canniere, Abdoul-Kader Sawadogo, François Mayer, Jean-Marc Molenberg, Jean-Claude Gregoire

Université Libre de Bruxelles, Brussels, Belgium

Introduction: Beech (*Fagus sylvatica* L.) stands in Southern Belgium have suffered in the early 2000S from a steady decline, puzzling by its geographical extent, gravity and suddenness. Bark exudations and necroses broke out on the trunks, along with fungi and the appearance of xylophagous insect galleries (the ambrosia beetles *Trypodendron* spp., *Anisandrus dispar*). These insects are generally considered secondary, normally attacking weakened or dead trees. The hypothesis of a sudden cold wave in November 1998 affecting trees not yet prepared to winter conditions is highly supported by meteorological (sudden drop of temperature in mid-November 1998), and symptomatological observations (orientation of the necroses, damages correlated with altitude and wind exposition).

Methods: Frost related injuries were artificially inflicted to beech trees, by application of different levels of cold shocks on the bark, using dry ice. Beech attractiveness to scolytids was studied by using interception traps established at the base of the trees. Volatile substances produced by necrotic zones were identified, after trapping on adsorbant substrates, by gas chromatography and mass spectrometry (GC-MS). Beech susceptibility to insect attacks was estimated by the colonization success of scolytids caged on the trunk.

Results: Ambrosia beetle attacks were observed in spring 2007 inside the treated zones. Results of year 2007 and 2008 will be presented and discussed.

Proteomic identification of parasitism-specific proteins in *Plutella xylostella* larvae

Kyung-Han Song, Min-Kyo Jung, Jai-Hoon Eum, Sung-Sik Han

Korea University, Seoul, Republic of Korea

Introduction: *Cotesia plutellae,* an endoparasitoid wasp of the diamondback moth *Plutella xylostella*, uses several strategies, such as the injection of viruses, venom, and serosal membrane-derived cells called teratocytes to overcome the innate immune system of the host; however, the proteome profiles related to these immune deficiency systems have not been clearly defined. This study was carried out to investigate the differently expressed proteins in parasitized *Plutella xylostella* larvae in order to determine the parasitism- specific proteins.

Methods: The parasitism-specific proteins in the host hemolymph were analysed by two-dimensional polyacrylamide gel electrophoresis and Q-TOF MS/MS. Real-Time PCR were performed to investigate mRNA expression level of pxSerpin 2.

Results: A total of 350 protein spots were detected in the 2-D gels, and approximately 50 spots were determined to have been differentially released into the parasitized DBM larvae every 48 h. Among them, 24 potential candidates, including translationally controlled tumor protein, apolipophorin-III, pxSerpin 2, fatty-acid binding protein, and signal transduction histidine kinase, were identified through quadrupole time-of-flight tandem mass spectrometry and sequence homology. These proteins were classified to 6 groups such as immunity, Signaling-related, lipid metabolism, enzyme metabolism, glycolysis, and structure. Among them, gene of pxSerpin 2 was cloned and investigated expression profile during parasitism. Real-time PCR analysis of pxSerpin 2 revealed that there was a poor correlation between the mRNA level and protein abundance.

Discussion: Our results suggested that these parasitic proteins were related to suppress the innate immune responses from host.

Female immunity, sperm length and sperm death

Luc Bussiere[2], Gioia Schwarzenbach[1], Andrew Pemberton[1], Paul Ward[1]

[1]University of Zurich, Zurich, Switzerland, [2]University of Stirling, Stirling, United Kingdom

Reproduction and immune defence are major fitness components, and they interact phenotypically. However, few studies have investigated genetic in addition to phenotypic correlations. We selected replicate lines of the yellow dung fly, *Scathophaga stercoraria*, for the expressed level of phenoloxidase (PO), an important enzyme in insect immune responses. There were correlated responses to selection: flies in high PO lines have shorter sperm and spermathecal ducts than flies in low PO lines. Although most of the theory linking immunity and reproduction has focussed on the potential for energetic trade-offs to regulate investment in each function, instead we found support for a direct role for PO in selecting on reproductive morphology. Specifically, we show that longer sperm are more susceptible to stress, and that they are more likely to die than short sperm within the sperm storage organs of wild-type females having high PO levels. This has implications for sexual conflict research and the relationship between immunity and sex, and may also help explain inconsistent findings on the adaptive significance of longer sperm.

The efficiency of regulation of brood size in securing resources for reproduction in the burying beetle, *Nicrophorus quadripunctatus*

Tomoyosi Nisimura, Masahiro Kon

The University of Shiga Prefecture, Hikone, Shiga, Japan

Introduction: In burying beetles, the adults are attracted to small vertebrate carcasses. After intra-sexual competition, a larger male-female pair remains to bury a carcass as a resource for their brood. They provide extensive parental care and adjust their brood size to match the carcass size. In the field, however, it was not examined whether regulation of brood size causes sufficient size of the offspring at the adult stage to secure a carcass.

Methods: In the burying beetle *Nicrophorus quadripunctatus*, the body size was measured for all adults collected with baited traps in the field. In baited traps with soil, moreover, a various size of carcasses were placed and the adults were allowed to breed.

Results: In the field, the sizes of breeding adults were larger than those of adults that searched carcasses. In the reproduction, a positive relationship was found between the brood size and the size of carcasses. When the carcass was small, however, the size of the grown adult on it would appear too small to secure carcasses for breeding. Moreover, it was revealed that the ratio of the total mass of brood to the carcass size was higher when the brood size on the carcass was larger.

Conclusions: In *N. quadripunctatus*, despite of the regulation of brood size, small carcasses caused that the offspring size would appear too small to secure a carcass, which might be concerned with the assimilation efficiency.

Molecular systematics of the genus *Dacus* Fabricius (Diptera: Tephritidae)

Massimiliano Virgilio[1], Marc De Meyer[1], Ian M. White[3], Thierry Backeljau[2]

[1]Royal Museum for Central Africa, Tervuren, Belgium, [2]Royal Belgian Institute of Natural Sciences, Brussels, Belgium, [3]Natural History Museum, London, United Kingdom

Introduction: The genus *Dacus* Fabricius includes economically important fruit flies distributed in the Afrotropical and Indo-Australian regions. A recent classification of the African fauna, based on morphological characters, resolved 177 species subdivided in seven subgenera. However, phylogenetic relationships within the genus still need to be fully clarified due to high levels of homoplasy in morphological characters.

Methods: 106 representatives of 34 African *Dacus* species (from five subgenera) were sequenced at one or more mitochondrial (COI, 16S) and nuclear (Period) gene fragments,. Phylogenetic relationships were inferred by Maximum Likelihood methods.

Results: Analyses of a concatenated dataset of representatives of 25 taxa resolved two major bootstrap supported clades. Clade A included species of the subgenera *Dacus* (n=12), *Leptoxyda* (n=3), *Didacus* (n=1) and *Psilodacus* (n=1). Clade B included other representatives of the subgenera *Leptoxyda* (n=6) and *Didacus* (n=2) and a species of the subgenus *Lophodacus* (*D. hyalobasis*). A number of bootstrap supported subclades was also resolved. *D. humeralis*, *D. chiwira*, *D. diastatus, D. durbanensis*, *D. famona* and *D. kariba* (all belonging to the group Humeralis of the subgenus *Dacus*) formed a subclade within clade A. However, specimens of *D. humeralis* from East (Kenya, Tanzania, Uganda) and West African locations (Benin, Congo D.R., Ivory Coast) formed separated clusters, possibly as a consequence of cryptic speciation.

Conclusions: The molecular phylogeny of 25 *Dacus* species shows a number of discrepancies with classifications based on morphological characters. Molecular taxonomy seems to represent a valuable complementary tool towards a more stable classification for the genus *Dacus* Fabricius.

Comparative efficacy of Ivermectin and Cypermethrin against *Hyalomma anatolicum* ticks (Acari: Ixodidae)

Muhammad Sajid, Muhammad Khan, Zafar Iqbal, Ghulam Muhammad

University of Agriculture, Faisalabad, Punjab, Pakistan

The objective of this paper is to describe the current status of the *in vitro* and *in vivo* effectiveness of the two acaricides viz; Ivermectin and Cypermethrin against prevalent tick species (*Hyalomma anatolicum*) of bovines. To this end, four hundred and eighty live engorged female *Hyalomma anatolicum* ticks were collected from the animals and separated into two equal groups viz; I & II for the efficacy trial of Ivermectin (Ivomec, Merial, France) and Cypermethrin pour-on (Cipermetriven, Ivan Labs, Spain), respectively. Each group was further divided into four sub-groups (A through D) to administer various concentrations of each drug. The ticks were counted after an immersion period in order to compare the efficacy of the two compounds. For an *in vivo* trial, three hundred and sixty bovines were selected on the basis of criteria as (i) having tick burden at the rate of >100 ticks per animal (ii) age of animals is more than 1year (iii) No history of application of acaricide to any of infested animals. The comparison of the two groups was done on day 0, 5, 10, 15 and 20 after treatment of the two test acaricides. The results of the study indicated better *in vitro* and in vivo efficacy of cypermethrin pour-on as compared to ivermectin against *Hyalomma* ticks. The results, thus obtained provide some useful tools in decision making of tick control providing the basis for testing the findings on provincial and national levels in future studies.

A complex world: Direct and indirect interactions between plants, decomposers and herbivores

Adela González Megías

Universidad de Granada, Granada, Spain

One of the main characteristics of food webs is their complexity. A myriad of organisms can interact direct and indirectly among them. In most systems plants interact with other plants and also with herbivores and decomposers. To fully understand food web complexity and functioning, it is important to determine the intensity of these interactions between all these organisms. Arid systems are ideal for this purpose because food webs are simpler than in other more productive ecosystems. I established a full factorial experiment in the field using an annual plant, *Moricandia moricandioides*, as a model system, and manipulating the presence of belowground decomposers, and above- and belowground herbivores. The manipulation of herbivores and decomposers affects other herbivores, parasitoids, and plant traits. Decomposers and herbivores negatively affect sap-suckers associated to *M. moricandioides*. There was also an important effect of decomposers and aboveground herbivores on flower visitors. Herbivore mortality due to parasitoids was lower in plants with decomposers. Plant size and reproductive output are affected positively by decomposers and negatively by herbivores. Therefore, decomposers and herbivores can affect antagonist and mutualist organisms associated to plants through direct and indirect effects. This experiment points out the importance of considering above- and belowground interactions in any system to fully understand the processes determining not only food web functioning but also complexity.

Comparison of different methods of bioassay for detecting Calypso and Spinosad susceptibility in *Leptinotarsa decemlineata* (Say)

Maryam Azimi[1], Aliasghar Pourmirza[1], Mohammad hasan Safaralizade[1], Nouraddin Shayesteh[2]

[1]Urmia university, Urmia/west Azarbijan, [2]Islamic Azad University, Branch of Mahabad, Mahabad, Islamic Republic of Iran

Introduction: The Colorado potato beetle, *Leptinotarsa decemlineata* (Say) is one of the most important pests of potato throughout the world. This pest cause seriously damages by defolation.

Methods: In this study susceptibility of CPB adults to Calypso and Spinosad as safe alternatives for conventional insecticides was determined through contact and dipping assay techniques.

Results: For Calypso LC_{50} and 95% confidence limits values with contact and dipping techniques were 0.12 (0.88 – 0.02) and 32.96 (71.86 – 19.16) ppm respectively. For Spinosad these criteria were 140.75 (328.06 – 93.61) and 1041.91 (2702.71 – 477) ppm in the same order. Contact technique, however, exhibited less variability in LC_{50} estimates and showed a higher degree of sensitivity than other method.

Conclusions: The results suggest that contact method is simple and sensitive test technique for measuring susceptibility of CPB adults to Calypso and Spinosad.

Compass orientation mechanisms in migratory butterflies

Rebecca Nesbit, Duncan Sivell, Jason Chapman

Rothamsted Research, Hertfordshire, United Kingdom

The butterflies *Vanessa cardui* (painted lady) and *V. atalanta* (red admiral) are frequent obligate migrants to northern Europe from the Mediterranean Basin. However, there remain significant gaps in our understanding of the behavioural mechanisms they have evolved to facilitate successful migrations.

We employed two different methods to investigate these mechanisms. Initially, we performed controlled flight-simulator experiments to test the ability of migrant *V. cardui* to orientate in a seasonally advantageous direction.

Our results provide convincing evidence that *V. cardui* reared under autumn day length conditions and flown with visual access to the sun exhibit a mutual SSW orientation. However, when the sun was not visible to butterflies in the simulators, their orientations were random. These results imply that *V. cardui* has an inherited preferred migration direction in the autumn (towards the SSW), and that it uses a sun compass to orientate its flight heading. Further experiments have been performed to test whether this sun-compass mechanism is time compensated.

In addition, we are using data from two vertical-looking entomological radars located in southern England. We have examined the displacement directions and flight headings of free-flying butterflies (likely to be *V. atalanta* and *V. cardui*) hundreds of metres above ground level. We provide evidence that they are migrating at altitude in seasonally adaptive directions.

Taken together, our results indicate that European migratory butterflies use a sun compass to direct their flight headings in seasonally-advantageous directions, and they frequently migrate at high altitudes, taking advantage of fast-moving, favourable winds.

Within host competition and virulence amongst pathogens: A race to the finish or a pound-for-pound fight.

Peter Staves, Rob Knell

Queen Mary University of London, London, United Kingdom

In nature multiple infections are the rule; when sampling hosts for pathogens often they are infected by a number of invaders. Coinfecting pathogen strains will vary in their respective virulences, and the competitive interactions between such strains are thought to drive the evolution of virulence within pathogen populations. While it has been suggested that a pathogens intrinsic virulence is correlated with competitive ability, there is a lack of empirical evidence to support this, as previous studies report. It is generally assumed that within host competition selects for increased virulence when competition is for a limited resource. The best competitor is the pathogen that makes the best use of a host and, as such, causes the most harm.

This assumption however is based on only one method of competition. Pathogens can compete within a host in a number of ways, indirectly or directly. When the competition between strains is direct (i.e. a pound-for-pound fight), the best competitor is the one that most successfully interferes with its opponent. As a result the “race” for host exploitation may suffer, leading to competitors that do less damage. Using the wax moth *Galleria mellonella*, the fungal pathogen *Metarhizium anisopliae* and the nematode *Steinernema feltiae* as a model coinfection system, we test these assumptions. We provide empirical data for both intra- and inter-specific coinfections, using multiple fungal strains of varied intrinsic virulence, and show how this relates to competition and competitive ability between these taxa.

The development of combined heat and controlled atmosphere quarantine treatments for phytosanitary pests of South African fruit crops

Shelley Johnson

University of Stellenbosch, Stellenbosch, South Africa

Phytosanitary pests of fruit crops grown in South Africa have lead to many rejections of fruit consignments presented for export to trading partners. Effective post-harvest non-chemical control treatments against these pests are required, as alternatives to chemical mitigation treatments such as fumigation with methyl bromide, and to sustain trade with other countries. The controlled atmosphere and temperature treatment system (CATTS) technology was developed in the United States and has been tested for commercial use against a number of phytosanitary pests affecting pome and stone fruit in the US. Developing CATTS treatments for specific pests on specific commodities is expensive since it requires infesting and treating large quantities of fruit. In order to determine the most tolerant pest species and developmental stage to CATTS, without the expense of in-fruit treatments, simulated-CATTS treatments using a water bath system have been developed by CATTS researchers. This controlled atmosphere water bath system (CAWB) was used to test combined heat and controlled atmosphere treatments on serious phytosanitary pests of South African export fruit, namely, *Macchiademus diplopterus*, (grain chinch bug), *Phlyctinus callosus*, (banded fruit weevil) and *Thaumatotibia leucotreta* (false codling moth). The effects of exposure to elevated levels of carbon dioxide and reduced levels of oxygen, combined with increasing temperature, on *M. diplopterus* and *P. callosus* adults, and *T. leucotreta* egg and larval stages are presented with a view to expand the testing of effective treatments on infested fruit in CATTS chambers and to evaluate fruit quality.

Phylogeny of apoid wasps

Michael Ohl, Volker Lohrmann, Silke Mosel

Museum of Natural History, Berlin, Germany

Apoid wasps, traditionally known as the family Sphecidae, is a morphologically and behaviorally highly diverse taxon of aculeate Hymenoptera. It comprises about 10,000 described species in about 280 genera. Apoid wasps share a number of plesiomorphic characters and can only be recognized by the unique combination of apomorphies of Apoidea (bees + apoid wasps) *and* the lack of the apomorphies of the bees. Cladistic analysis both based on morphological and molecular characters confirm that apoid wasps is paraphyletic with respect to bees. This is reflected in a newly proposed classification of Apoidea: Ampulicidae + (Sphecidae s.str. + (Crabronidae + bees)). Heterogynaidae is an enigmatic taxon of only eight described Old World species. It has been considered as the most basal taxon in Apoidea, but recent analyses have shown that it is a highly derived group of parasitic wasps deeply nested in Crabronidae. The Crabronidae, including about 9000 species of apoid wasps, is usually considered to be the sister group of bees, but this is weakly supported. Monophyly of Ampulicidae and Sphecidae s.str. has good support, but the relationships within the highly diverse Crabronidae is contradictory.

Rearing of codling moth *Cydia pomonella* (L.) for research purposes in South Africa

Matthew Addison, Dalene Stenekamp

Department of Conservation Ecology and Entomology, Faculty of AgriSciences, Stellenbosch University, Stellenbosch, South Africa

Codling moth is mass reared in South Africa for research purposes. Current maximum production is 250 000 individuals per week. The moths are primarily used in a sterile insect technique (SIT) program which involved the treatment of 120 Ha of commercial apple and pear orchards. Due to various constraints an agar and maize meal based diet was used. Research on the diet included the assessment of the impact of maize meal containing *Bacillus thuringiensis*, the use of wheat flour to replace maize meal and the testing of a number of gelling agents. The codling moth culture has allowed for research to be carried out on entomopathogenic nematodes and parasitic wasps (*Trichogrammatoidea* spp.). In addition the diet has been used to culture false codling moth *Thaumatotibia leucotreta* (Meyrick) and carnation worm *Epichoristodes acerbella* (Walker) for research purposes.

Climatic and biotic influences on the distributions of *Calliphora augur* and *Calliphora dubia* (Diptera: Calliphoridae)

Aidan P. Johnson[1], James F. Wallman[1], Melanie S. Archer[2]

[1]*Institute for Conservation Biology, School of Biological Sciences, University of Wollongong, NSW 2522, Australia,* [2]*Department of Forensic Medicine, Monash University, 57-83 Kavanagh St, Southbank Vic 3006, Australia*

Introduction: Documenting the known and potential distributions of insects is crucial to understanding their quarantine risk and role in agriculture, pest management, epidemiology and forensic entomology. This study focused on determining and interpreting the distributions of two endemic Australian blowflies, *Calliphora augur* (Fabricius) and *Calliphora dubia* (Macquart).

Methods and Results: We examined the effect of climatic factors on the maximal distributions of *C. augur* and *C. dubia*. Comparative laboratory and field experiments were used to derive parameters defining the distributions of these sister species, particularly in relation to temperature and moisture. The results showed that *C. dubia* had an increased tolerance to dry stress and high temperatures in comparison with *C. augur*. No difference was seen between species in the impact of cold temperatures on the development of maggots to the pupal stage. CLIMEX software was used to model the distributions of *C. augur* and *C. dubia* in relation to climate. Model parameters, determined from the literature, fieldwork and laboratory work, were entered into CLIMEX. The results accorded with those of a bait trapping transect extending from Berry (New South Wales) to Adelaide (South Australia). The distributions generated also greatly overlapped with distribution maps derived from insect collections and the literature, and extended these distributions significantly. Discrepancies are probably due to the inability of CLIMEX to accommodate non-climate related parameters, such as competition.

Conclusions: This study showed that distribution modelling software, such as CLIMEX, has great promise as a tool in forensic entomology.

Conservation priority setting and insects: How, where, how often?

Mar Cabeza, Anni Arponen, Heini Kujala, Astrid van Teeffelen, Ilkka Hanski

University of Helsinki, Helsinki, Finland

Choosing which areas to protect, or what to manage and how is no easy task. Many conservation implementations are a legacy of opportunistic actions, resulting from political and economic constraints that have led to inefficient, ineffective conservation. Systematic conservation planning has emerged in response to this reality, and has helped us move from ad-hoc decisions to a quantitative decision-making process. This process identifies conservation priorities that achieve explicit quantitative objectives in a cost-efficient manner. However, these tools are rarely applied to insects. This is perhaps because insects are rarely the target of large conservation plans or because we seldom have comprehensive data for groups of insects. But it is not because insects would not be suitable targets for such an approach. In this study we give an overview of a variety of available tools, applicable to different questions, scales, and numbers of species. We provide examples using Finnish butterflies: a national conservation priority map for 100 species, a regional plan for management options showing trade-offs between plant and butterfly species, and a local example with an endangered butterfly, assessing optimal management locations under different urban planning scenarios. There is no evidence to expect that targeting other taxa will simultaneously protect insects and therefore we encourage the inclusion of insects in large conservation priority assessments. This is possible by using quantitative conservation planning approaches and utilising modeling advances to cover for incomplete or biased data.

Mechanisms of odor information processing: Investigating representations of odor mixtures in the antennal lobe

Linda S. Kuebler, Shannon B. Olsson, Bill S. Hansson

Max Planck Institute for Chemical Ecology, Jena, Germany

Natural odors are often complex blends of several different compounds. Despite this fact, most studies concerning odor detection and coding in insects have focused on single components. The first olfactory neuropil in the insect brain, the antennal lobe (AL), modifies the final representation of odors in the assembly code carried by projection neurons to higher-order brain centers. The neural representation of odor mixtures in the AL may be simply the sum of its components or non-linear due to odor information processing. The phenomenon of a non-linear response to a mixture that is not predictable from the basis of responses to its components is called a mixture interaction. Our goal is to investigate interactions and different response characteristics in the AL in order to reveal relationships between host odor mixtures and single plant volatile components. Using a novel stimulus delivery system as well as coupled intracellular recording and calcium imaging experiments in the hawkmoth *Manduca sexta*, we addressed the question: what are the mechanisms of odor information processing at different levels in the antennal lobe? Preliminary results suggesting mixture interactions among host volatile odors in the general olfactory neuropil will be presented.

Factors influencing weather station ambient temperature corrections in forensic entomology

Aidan P. Johnson[1], Melanie S. Archer[2], James F. Wallman[1]

[1]Institute for Conservation Biology, School of Biological Sciences, University of Wollongong, NSW 2522, Australia, [2]Department of Forensic Medicine, Monash University, 57-83 Kavanagh St, Southbank Vic 3006, Australia

Introduction: Forensic entomologists use weather station data to retrospectively estimate the ambient temperatures at a death scene prior to discovery of the body. Correlation 'corrects' the weather station data, thus estimating scene temperatures. Archer (2004), in one of the first validation studies in forensic entomology, found a significant effect of time after body discovery on the accuracy of this technique.

Methods: We expanded Archer's study by examining additional factors that might influence weather station temperature corrections: 1) length of correlation period (2, 5, 10 days); and 2) distance between weather station and body discovery site (2 – 15 km). 24 hypothetical body discovery sites were clustered around four weather stations in New South Wales and Victoria, Australia. Temperature loggers at each site collected data every 30 minutes for approximately one month. This experiment was carried out twice: in early 2006 and 2007. We assumed that all hypothetical bodies lay *in situ* for five days before discovery.

Results and Conclusions: The results of this ongoing study so far indicate that neither correlation period length nor distance affects the accuracy of retrospective scene temperature estimation. This suggests that 1) forensic entomologists can use a shorter correlation period in the analysis of their data; and 2) at the distances examined here, weather stations closer to death scenes may not produce a more accurate result than those further away. We will also report on the results of a third factor, frequency of collection of weather station records, investigated using the same data set.

Influence of *Ageratum conyzoides* (L.) extract on the orientation of larvae and oviposition of adult *Helicovepra armigera* (Hüb.) (Lepidoptera: Noctuidae)

Ashok Singh, P. R. Ragesh

Department of Zoology, University of Delhi, Delhi-110 007, India

Introduction: *Helicoverpa armigera* is a pest of major economic concern worldwide. This insect has developed resistance against all the synthetic insecticides, and even against *Bt.* Plant derived products are viable alternative for the sustainable management this insect. *Ageratum conyzoides* (L.) is an annual plant having insecticidal property against agricultural pests. Present study was initiated to assess the effect of *Ageratum conyzoides* extract on the behaviour of this pest.

Methods: Hexane extract of dried aerial parts of *Ageratum conyzoides* was prepared in evaluated against *H. armigera*. The orientation response of the larvae was studied in a straight tunnel olfactometer. The ovipositional bioassay of adult females was conducted in a glass jar covered with muslin cloth. Test extract was applied on one half of the muslin cloth, and the other half was applied with hexane.

Results: Present study shows that hexane extract of *Ageratum conyzoides* elicit significant influence on orientation of larvae, and oviposition of adult *H. armigera.* Lower concentration of extract did not elicit response from larvae but repellency was significant for the higher concentration. Interestingly in choice situation, females laid significantly higher number of eggs on the surface treated with lower concentration but lower number of eggs was recorded at higher concentration as compared to control surface.

Conclusion: *A. conyzoides* contains non-polar chemicals that influence the orientation of larvae and oviposition of adult *H. armigera.* Further study is on progress to isolate and identify the deterrent compounds of *A. conyzoides,* which can be exploited in the management program of *Helicoverpa armigera*.

Nocturnal activity in carrion-breeding blowflies (Diptera: Calliphoridae) in south-eastern Australia

Bryan D. Lessard, James F. Wallman

Institute for Conservation Biology, School of Biological Sciences, University of Wollongong, NSW 2522, Australia

Introduction: The incidence of nocturnal activity in carrion-breeding blowflies is unclear. Limited studies, so far restricted to the northern hemisphere, have produced contradictory results. However, clarification of this topic is important because it is often assumed in forensic entomological casework that flies are not active and thus cannot oviposit at night. Estimates of time since death could be substantially affected in cases where such an assumption is incorrect.

Methods and Results: We investigated nocturnal oviposition in south-eastern Australia using piglet carcasses placed in the field. Night time experiments were carried out under conditions of new moon, full moon, and artificial light. Nocturnal oviposition did not occur on any carcass. Interestingly, the carrion beetle, *Ptomophila perlata* (Silphidae), was active at night in dense vegetation under both the full moon and artificial lighting. Even in the absence of flies, this species could therefore be a potential indicator of nocturnal corpse placement. Laboratory studies were also done to monitor diurnal and nocturnal blowfly activity under differing light intensities. A significant association was found between the time of day and degree of activity for all light intensities, as well as between activity and light intensity irrespective of time of day. We also investigated the influence of time of day and light intensity on oviposition in the laboratory.

Conclusions: Overall, our results support the general assumption that nocturnal oviposition is unlikely to occur in the field under typical circumstances in south-eastern Australia, However, laboratory data suggest that this may still be possible under certain scenarios.

Are oil palm plantations green deserts? Invertebrate biomass, diversity and function in oil palm plantations in Sabah, Malaysia.

Ed Turner, Jake Snaddon, William Foster

Department of Zoology, University of Cambridge, Cambridge, United Kingdom

Introduction: The area of oil palm plantations has expanded dramatically in recent decades and now covers approximately 10.7 million hectares worldwide: an increase of over 168% since 1960. Despite the threat to global biodiversity of oil palm expansion, remarkably few studies have assessed the impact on the environment of conversion of forest to oil palm plantation.

Methods: We studied the impact on overall invertebrate biomass and abundance, of forest conversion to oil palm in Sabah, Malaysia. The effect of habitat conversion was investigated for invertebrates living in the leaf litter, the canopy and common epiphytes by collecting arthropods using a variety of standard sampling techniques. We also investigated the impact of oil palm expansion on the diversity of leaf litter and epiphyte invertebrates and on leaf litter decomposition in these habitats.

Results: We found that oil palm expansion has a dramatic overall effect on the invertebrate community as well as on the rate of decomposition.

Conclusion: Our results highlight the overall negative effect that oil palm expansion has on invertebrates and demonstrates that more research needs to focus on management to enhance biodiversity and ecosystem functioning in plantations. We discuss our results with reference to plantation management and sustainability.

Post-campaign assessment of desert locust pesticide pollution at loading sites in West Africa

Wim C. Mullié[1], Gerrit van de klashorst[1], James W. Everts[2]

[1]FAO, Sub-regional Desert Locust Office, Dakar, Senegal, [2]FAO, AGPP, Rome, Italy

Introduction: During the 2003-2005 locust control campaign in West- and NW Africa, *c*. 13 million litres of pesticides were sprayed against Desert Locust, *Schistocerca gregaria* (Forsk.). Products used were mainly organophosphates. In 2006, an inventory was conducted in several Sahelian countries to assess soil pollution due to accidental spillage. The inventory and subsequent risk assessment was made by the so-called QUEST teams (QUality and Environment Survey of Treatments) in collaboration with the Africa Stockpiles Programme (ASP).

Methods: Targets in Niger, Mali, Mauritania and Senegal were large pesticide storage sites and aerodromes where spray planes were loaded. Assessments were visual and field officers were interviewed; recording on special forms. The ASP assessment method was adapted specifically for soil pollution. Field collected samples were transported refrigerated, then frozen until analysed. If needed, two depths were sampled to assess infiltration. Three pesticides (chlorpyrifos, fenitrothion and malathion) were analysed by gas chromatography (GC) and confirmed by GC-mass spectrometer.

Results: All sites examined by residue analysis were contaminated, ranging from slight (0.5-10 mg of pesticide/kg of soil to very heavy (> 1000 mg of pesticide/kg of soil). The size of polluted areas ranged from 1 - 3500 m^2. Some sites smelled badly up to 1500 m distance. Although most sites were fenced, no hazard warning signs were present, and many sites were close to habitations and accessible to humans and livestock.

Conclusion: Several heavily polluted sites need to be cleaned up and measures should be taken to prevent access by the general public and livestock.

Metabolic resistance to synthetic insecticides in the B and Q biotypes of *Bemisia tabaci* (Hemiptera: Aleyrodidae)

Shai Morin[1], Iris karunker[1], Michal Alon[1], Einat Laor[1], Juergen Benting[2], Ralf Nauen[3], Bettina Lueke[3], Tanja Ponge[3], Emmanouil Roditakis[4], John Vontas[5], Kevin Gorman[6], Ian Denholm[6]

[1]Hebrew University of Jerusalem, Rehovot, Israel, [2]Bayer AG, Corporate Development-Innovation, Leverkusen, Germany, [3]Bayer CropScience AG, Monheim, Germany, [4]Plant Protection Institute of Heraklion, Heraklion, Greece, [5]Agricultural University of Athens, Athens, Greece, [6]Rothamsted Research, Harpenden, United Kingdom

The two most damaging biotypes of *Bemisia tabaci*, B and Q, have evolved strong resistance to a range of synthetic insecticides. This resistance may result from changes in the sensitivity of insecticide target sites or increased rate of insecticides detoxification by metabolic enzymes. Here, we investigated the possible involvement of seventeen metabolic genes: the cytochrome P450 monooxygenases (P450s), the glutathione S-transferases (GSTs) and the carboxylesterases (COEs) in *B. tabaci* resistance to imidacloprid (neonicotinoid), pyriproxyfen (juvenile hormone analog) and chlorpyriphos (organophosphate). For studying imidacloprid resistance, the expression levels of 11 P450 genes were compared by real-time PCR (qPCR) across nine B and Q strains showing strong resistance, moderate resistance or susceptibility to imidacloprid. We found that constitutive over-expression (up to ~17-fold) of a single P450 gene, *CYP6CM1,* was tightly related to imidacloprid resistance in both biotypes. In studying pyriproxyfen resistance, we compared by qPCR the expression levels of 17 metabolic genes in two resistant and one susceptible Q biotype strains. We found that constitutive over-expression (up to ~35-fold) of a single GST gene, *GST_2*, was tightly related to pyriproxyfen resistance in both resistant strains. In studying chlorpyriphos resistance, our qPCR analysis showed that one COE gene, *coe1*, was over-expressed (~4-fold) in a chlorpyriphos B biotype resistant strain when compared to a susceptible strain. Taken together, these data show that metabolic resistance by over-expression of detoxification genes may be a major mechanism of resistance to synthetic insecticides in both the B and Q biotypes of *B. tabaci*.

Mimics and magnets: The importance of colour and ecological facilitation in floral deception

Craig I. Peter[1], Steven D. Johnson[2]

[1]Department of Botany, Rhodes University, P.O. Box 94, Grahamstown, 6140, South Africa, [2]School of Biological and Conservation Sciences, University of KwaZulu-Natal, Private Bag X01, Scottsville, 3209s, South Africa

Introduction: Plants that lack rewards can attract pollinators if they share attractive floral signals with rewarding plants. These deceptive plants should benefit from flowering in proximity to rewarding plants, because pollinators are locally conditioned on floral signals of the rewarding plants (mimic effect) and because pollinators are more abundant close to rewarding plants (magnet effect).

Methods and Results: We tested these ideas using the non-rewarding South African plant *Eulophia zeyheriana* (Orchidaceae) as a study system. Field observations revealed that *E. zeyheriana* is pollinated exclusively by a single species of *Lipotriches* (Halictidae) closely associated with the flowers of the rewarding sympatric plant *Wahlenbergia cuspidata* (Campanulaceae). The pale blue colour of the flowers of *E. zeyheriana* differs strongly from flowers of its congeners, but is similar to the flowers of *W. cuspidata.* Analysis of petal spectral reflectance using a bee vision model showed that bees are unlikely to be able to distinguish the flower colour of the two species. UV-absorbing sunscreen applied to the orchid flowers to alter their colour, resulted in a significant decline in pollinator visits indicating the importance of flower colour for attracting pollinators. Surveys of natural orchid populations, as well as a translocation experiment indicate that pollination success in the orchid was strongly affected by proximity to patches of *W. cuspidata.*

Conclusion: Flower colour and location of *E. zeyheriana* plants relative to rewarding magnet patches are key components of the exploitation by this orchid of the relationship between *W. cuspidata* and pollinating *Lipotriches* bees.

CpGV resistance of codling moth: new isolates with improved efficacy

Johannes A. Jehle, Karolin E. Eberle, Sabine Asser-Kaiser, Stefanie Schulze

Agricultural Service Center Palatinate, Neustadt/Wstr., Germany

The *Cydia pomonella* granulovirus (CpGV, Baculoviridae) is one of the most important biocontrol agents of the codling moth (CM) a worldwide pest of apples, pears and walnuts. It is worldwide used one more than 150,000 ha. Since 2003, CM populations with an up to thousand-fold decreased susceptibility to commercial CpGV products have been observed in Germany, France and several other countries. Meanwhile several CpGV isolates overcoming CpGV resistance have been identified. Here, we report the biological parameters describing their efficacy in CpGV susceptible and CpGV resistant codling moth larvae as well as their genetic differences to the conventionally used CpGV-M. A detailed genome comparison of two CpGV isolates overcoming CpGV resistance with the conventional CpGV-M will be provided. This comparison provide some clues about the potential factors influencing the virulence of CpGV.

Genetic variability of the sorghum plant bug, *Stenotus rubrovittatus* in Japan: its relationship with increasing populations in rice fields

Tetsuya Kobayashi[1], Tamito Sakurai[1], Mitsutaka Sakakibara[1], Tomonari Watanabe[2]

[1]National Agricultural Research Center for Tohoku Region, Daisen, Akita, Japan, [2]National Agricultural Research Center, Tsukuba, Ibaraki, Japan

Introduction: Since the first damage to rice by *Stenotus rubrovittatus* was reported in limited areas in the early 1980's, the area of rice fields infested by this species has been increasing. To determine whether new infestations originated from endemic populations or immigrants, the genetic structure and differentiation of *S. rubrovittatus* populations from across Japan was studied.

Methods: Samples were collected from 35 sites including undamaged areas in Japan. Sequence polymorphisms of mitochondrial COI genes and variations of six microsatellite markers on nuclear DNA were used to analyze genetic diversity, gene flow and phylogenetic relatedness of local populations.

Results: Northern (Tohoku) populations contained a unique group of mtDNA haplotypes at high frequencies of more than 50%. Haplotype diversity of mtDNA was high in northern populations, decreased toward the south and was quite low in southern populations. A neighbor-joining tree based on the microsatellite polymorphisms showed that northern populations are ancestral, and eastern (Kanto) and southernmost (Kyushu) populations diverged from them. Genetic differentiation between populations from highly damaged and undamaged areas was not detected.

Conclusions: Japanese populations of *S. rubrovittatus* are genetically differentiated along a geographical gradient, rather than in relation to the history of rice infestations. The increase in damage to rice caused by *S. rubrovittatus* is probably caused by increases in endemic populations and not by immigration from other regions.

Chemical mediation and organization of fig and fig wasp communities

Magali Proffit[1], Bertrand Schatz[2], Martine Hossaert-McKey[2], Steve Johnson[1]

[1]University of KwaZulu-Natal, Pietermaritzburg, South Africa, [2]CEFE-CNRS, Montpellier, France

Introduction: Encountering partners is a crucial phase in the functioning of highly specialized and obligatory interactions. All of the ~750 *Ficus* species (Moracea) are usually associated with at least one specific species of pollinating wasp (Chalcidoidea, Agaonidae), which also strictly depends on its host *Ficus* for reproduction. In these interactions pollinators use the chemical message produced by the plant to locate it. In addition, many non-pollinating wasp species, also specific, exploit this mutualism. In this study we investigated the role of chemical mediation in organisation of wasp communities associated with *Ficus* species.

Methods: By detailed monitoring of the species present on figs, we tried to establish the temporal succession of different species of non-pollinating fig wasps associated with two *Ficus* species. Using gas chromatography/mass spectrometry (GC-MS) we characterise and compare the chemical message produced at receptivity by several *Ficus* spp. to attract their pollinators. In addition, electroantennographic methods were used to detect the compounds within the message produced by figs at receptivity that elicit signals in the antennae of their pollinators.

Results: The temporal succession is associated with the production of different olfactory signals, to which the different species of wasps differentially respond.

Conclusion: Specialisation on different developmental stages of the fig is probably one of the principal mechanisms explaining the coexistence of different non-pollinating wasp species in association with a single pair of mutualists. Our work highlights the role of chemical mediation in fig and fig wasp communities.

New baculovirus products offer solutions for the biological control of *Cydia pomonella* and *Cryptophlebia leucotreta*

Philip Kessler, Daniel Zingg

Andermatt Biocontrol AG, Grossdietwil, Switzerland

Baculoviruses are insect pathogenic viruses that are ideal and valuable agents for biological insect pest control. They are very selective, do not produce toxins or residues, and are generally regarded as safe.

The *Cydia pomonella* granulovirus (CpGV), for example, is being applied worldwide not only in organic but also in IP orchards for the control of the codling moth (CM), *Cydia pomonella*. The development of resistance towards the CpGV-Mexican isolate has recently been reported to occur in isolated orchards after intensive sprayings over numerous years. Results are presented on the efficacy of the newly developed CpGV products “MADEX Plus” and “MADEX I12”. “Madex Plus” was developed through laboratory selection on larvae from a resistant CM population. Furthermore, a new Iranian isolate “I12” has been tested on resistant CM populations. Both products revealed good efficacy on resistant and on non-resistant codling moth populations both in the laboratory and in the field. CpGV is a good example of how baculoviruses can be used as an effective and sustainable control tool against insect pests.

Recently, a new product based on *Cryptophlebia leucotreta* granulovirus (CRYPTEX) has been approved for use against the false codling moth (FCM) (*Cryptophlebia leucotreta*) in citrus production in South Africa. Field trials demonstrated that the application of CRYPTEX reduces FCM below the damage threshold and therefore offers an alternative control measure against an economically important pest.

Factors influencing the Sirex-Pine interaction in South Africa

Brett Hurley[1], Bernard Slippers[1], Kier Klepzig[2], Mike Wingfield[1]

[1]FABI, University of Pretoria, Pretoria, South Africa, [2]Insects, Diseases, Invasive Plants (IDIP), USDA, Pineville, Louisiana, United States

The woodwasp *Sirex noctilio* and its fungal symbiont *Amylostereum areolatum* have been introduced and become established in many regions of the world where the pest is non-native. *Deladenus siricidicola*, a nematode parasitic to *S. noctilio* in its native range has been introduced as a biological control agent into many countries to reduce the impact of *S. noctilio*. Success with this nematode in these non-native environments has been variable. Research in the summer rainfall region of South Africa, where success with *D. siricidicola* has been poor, has shown that moisture content of the wood influences the success of the nematode. Moisture content of the wood at time of inoculation in this region is lower than in winter rainfall regions where *D. siricidicola* has been more effective. However, it was also apparent that moisture content is not the only factor determining nematode success. Incompatibility between *D. siricidicola* and *A. areolatum* strains has been observed in the laboratory and this could be a major barrier to nematode establishment in the field. Furthermore, bluestain fungi are commonly present in Sirex-infested trees. These fungi could compete with *A. areolatum* for resources and affect development of *D. siricidicola* populations. These barriers to the successful establishment of *D. siricidicola* in its non-native environment have not previously been investigated deeply. Their existence highlights the fact that a multi-faceted approach is needed to achieve effective control of *S. noctilio*, and this must include the introduction of multiple biological control agents.

The joint use of chemical and biological control agents: How the effects of pesticides on natural enemies can be elucidated?

Elisa Viñuela

Technical University of Madrid (UPM), Madrid, Spain

Introduction: In recent years, IPM programs based on the use of natural enemies and pesticides to control agricultural pests have rapidly increased in importance all over the world. In these programs pesticides used to manage a pest on a particular crop must be harmless to the biological control agent used in that crop. Studies to elucidate the effects of pesticides on biological control agents were first initiated in Europe by the IOBC in 1974. Today they are essential for registration of pesticides within the European Union.

Methods: Standard Methods have been developed by the IOBC to measure the effects of pesticides on different developmental stages of parasitoids and predators (see http://www-iobc-wprs.org.). The protocol first requires a natural enemy to be exposed to a pesticide on an inert surface and then on leaves in the lab. It then requires extended semi-field and field studies in a sequential scheme. Furthermore, persistence studies (aged residues) or exposure through different uptake routes are also performed. First tier laboratory studies require only two indicative species. On the other hand, further studies require an additional two more species to those used in the first tier.

Results: The safest pesticides are usually of natural origin or mimics of insect growth regulators. Eggs and pupae are generally more compatible with pesticides than the exposed stages (larvae of predators and adults of parasitoids).

Conclusions: As toxic effects depend on the mode of action of the pesticide to the natural enemy used, studies must be performed on a case-by-case basis.

Population dynamics and infestation levels of *Xylosandrus compactus* (Coleoptera: Curculionidae) on coffee in Hawaii

Elsie Burbano, Mark Wright

Department of Plant and Environmental Protection Sciences, University of Hawaii, Honolulu, Hawaii, United States

Introduction: The Asian black twig borer (BTB), *Xylosandrus compactus* (Coleoptera: Curculionidae), is among the most serious pests of coffee in Hawaii. This beetle attacks over 224 plant species including native forest trees. The control method used currently is sanitation by pruning. This tactic reduces vegetative plant material and many farmers do not use adequate methods to destroy infected material, thereby leaving an important reinfection source on the ground. Traps originally designed for the Japanese beetle, baited with ethanol 95 % can serve as a monitoring and research tool to assess seasonal phenology.

Methods: A series of ten Japanese beetle traps were deployed in twelve coffee farms in Kona, Hawaii at different elevations. The traps were baited with 95 % ethanol to monitor the BTB population and checked monthly for 19 months. Infested coffee branches were collected for each farm, number of borer tunnels per branch and populations of all BTB stages were quantified.

Results: There is a seasonal effect and plant stress effect on BTB population fluctuations. BTB populations show seasonal fluctuations throughout the year; populations are higher during the dry season.

Conclusion: BTB population levels are directly related to plant stress, including harvesting, dry season or lack of fertilizer. Traps baited with ethanol can be an important tool for monitoring adult insect populations as part of an integrated pest management program. These traps could also serve as a physical control tactic.

Population dynamics and infestation levels of *Xylosandrus compactus* (Coleoptera: Curculionidae) on coffee in Hawaii

Elsie Burbano, Mark Wright

1Department of Plant and Environmental Protection Sciences, University of Hawaii, Honolulu, Hawaii, United States

Introduction: The Asian black twig borer (BTB), *Xylosandrus compactus* (Coleoptera: Curculionidae), is among the most serious pests of coffee in Hawaii. This beetle attacks over 224 plant species including native forest trees. The control method used currently is sanitation by pruning. This tactic reduces vegetative plant material and many farmers do not use adequate methods to destroy infected material, thereby leaving an important reinfection source on the ground. Drosophila tracheal cells can sense hypoxia and induce terminal branch sprouting

L Centanin[1], A Dekanty[1], NM Romero[1], TA Gorr[2], P Wappner[1]

[1]Instituto Leloir, Universidad de Buenos Aires, CONICET, Buenos Aires, Argentina, [2]Institute of Veterinary Physiology, Vetsuisse Faculty and Zurich Center for Integrative Human Physiology, Zurich, Switzerland

The Drosophila tracheal system is a network of ramified tubes that deliver oxygen to every tissue in the organism. In larval stages, tracheal terminal branches are plastic and have the capacity to sprout-out projections towards oxygen-starved areas, in a process analogous to mammalian angiogenesis. It was reported that this oxygen-dependent effect relies on the upregulation of the fibroblast growth factor (FGF) homolog Branchless in hypoxic target tissues, which binds its receptor Breathless expressed in tracheal cells. Here, I will summarize our work with the group of P. Wappner on the role of the key mediator of survival during O_2 deprivation, the hypoxia-inducible transcription factor HIF, in tracheal sprouting and FGF signaling.

Transgenic, HIF-reporter expressing 3rd instar larva showed that terminal branches of tracheal cells can respond to hypoxia with a seemingly much higher sensitivity than any other cell type in the animal and, thus, are well endowed to sense incremental changes in oxygen tension via HIF. Moreover, the extra-sprouting phenotype was regulated by the Drosophila HIF-alpha homolog Sima, and antagonized by the oxygen sensing prolyl-4-hydroxylase product Fatiga (gene: *fga*). *fga* mutants displayed an extra-sprouting phenotype that was even stronger than that observed in wild type individuals exposed to hypoxia. This extra-sprouting phenotype is, to our knowledge, the first demonstration that loss-of-function of a HIF-prolyl hydroxylase can provoke an angiogenic-like phenotype. Thus, it seems reasonable to expect that conditional knock-down of mammalian prolyl-4-hydroxylase domain (PHDs) proteins in an appropriate cell type will promote angiogenesis. Upon Sima protein accumulation in tracheal cells of mildly hypoxic larvae, this transcription factor was able to induce the Breathless FGF receptor. Upregulation of Breathless, in turn, was sufficient to provoke extra sprouting. This cell-autonomous response enhances tracheal sensitivity to increasing levels of the ligand Branchless as a cardinal step in hypoxia-dependent sprouting of the fly respiratory system. Given the critical requirement of endothelial cell HIF for angiogenesis, it should now be tested if the autonomous and HIF-dependent induction of receptors for the vascular endothelial growth factor (VEGF) in these cells mediates a similar priming of the mammalian angiogenic response to hypoxia.

Circadian circuits in the fly's visual system

Elzbieta Pyza

Department of Cytology and Histology, Institute of Zoology, Jagiellonian University, Krakow, Poland

Introduction: In the fly's visual system, L2 interneurons in the first optic neuropil (lamina) show circadian changes in morphological plasticity. Their dendrites and axons change size and shape during the day and these rhythms are also maintained under constant darkness. Since the L2 cells do not express "clock genes" they must receive circadian information directly or indirectly from a circadian clock. To learn how circadian information is transmitted to target neurons in the visual system we examined terminals of clock neurons, containing pigment-dispersing factor (PDF), together with cells located next to them and L2 cells.

Methods: We used immunocytochemistry to examine the cyclical expression of with PDF and marker proteins specific for neurons and glial cells. For the same reason we also used *Drosophila* transgenic lines with expression of GFP targeted to different cell types. Flies were fixed at different times of the day, their brains sectioned and examined by confocal microscopy.

Results: The results obtained showed that accumulation of specific proteins detected in neurons in the lamina and medulla increases during the day, while in the glial cells neighbouring them the abundance of specific proteins is higher during the night.

Conclusions: Circadian information from the pacemaker seems to be delivered to neurons in the visual system through different types of glial cells, which synchronize the activity of neurons in modular units of the lamina and medulla.

Toxicity evaluation of Spinosyn, Chloropryfos methyl, Methoxyfenozide, insecticide Gel(IG), mineral oils (MO), insecticidal emulsion (IE) against *Phyllocnistis citrella* Stainton (Lepidptera: Gracillariidae)

Behnam Amiri-Besheli, Fatemeh Asgharnejad

Faculty of Agric. Univ. of Mazandaran, Sari/Mazandaran, Islamic Republic of Iran

Different methods have been used to control the citrus leafminer (*Phyllocnistis citrella*) but the bioinsecticides are realized to be the best and effective pesticides. The main aim of this experiment was to determine the efficacy of Spinosyn , Chloropryfos-methyl , Methoxyfenozide , insecticide Gel(IG), mineral oils (MO), Insecticidal emulsion (IE) on the control of citrus leafminer (CLM), *Phyllocnistis citrella* Stainton (Lepidoptera:Gracillariidae) in lab condition at 24, 48, 72 and 96 h post treatments. Leaves of Citrus with second and third instars of leafminer larvae were used in all tests and the larval mortality were monitored. Analysis of variance showed that there were significant differences between treatments and control, and also significant differences were found among treatments. LSD & Tukay-Test among above treatments has shown that Chloropryfos-methyl and Spinosyn and Methoxyfenozide with 86.7± 3. 2 and 80.5± 8.1 and 68.3± 7.1 percentage mortality were more effective than MO, IG and IE with 57.7 ± 8.3 and 54.8±7.5 and 30.6±4.2 percentage mortality and significant different with control (P< %1) respectively. LSD & Tukay-Test among 72 and 96 h post treatments with 60.5 ± 7 and 69.5 ± 7.5 percentage mortality are more effective than 24 and 48 h post treatments with 31.6 ±6 and 54.7 ± 7.7 percentage mortality respectively.

Toxicity evaluation of Spinosyn, Chloropryfos methyl, Methoxyfenozide, insecticide Gel(IG), mineral oils (MO), insecticidal emulsion (IE) against *Phyllocnistis citrella* Stainton (Lepidptera: Gracillariidae)

Behnam Amiri-Besheli, Fatemeh Asgharnejad

Faculty of Agric. Univ. of Mazandaran, Sari/Mazandaran, Islamic Republic of Iran

Different methods have been used to control the citrus leafminer (*Phyllocnistis citrella*) but the bioinsecticides are realized to be the best and effective pesticides. The main aim of this experiment was to determine the efficacy of Spinosyn , Chloropryfos-methyl , Methoxyfenozide , insecticide Gel(IG), mineral oils (MO), Insecticidal emulsion (IE) on the control of citrus leafminer (CLM), *phylocnistis citrella* Stainton (Lepidoptera:Gracillariidae) in lab condition at 24, 48, 72 and 96 h post treatments. Leaves of Citrus with second and third instars of leafminer larvae were used in all tests and the larval mortality were monitored. Analysis of variance showed that there were significant differences between treatments and control, and also significant differences were found among treatments. LSD & Tukay-Test among above treatments has shown that Chloropryfos-methyl and Spinosyn and Methoxyfenozide with 86.7± 3. 2 and 80.5± 8.1 and 68.3± 7.1 percentage mortality were more effective than MO, IG and IE with 57.7 ± 8.3 and 54.8±7.5 and 30.6±4.2 percentage mortality and significant different with control (P< %1) respectively. LSD & Tukay-Test among 72 and 96 h post treatments with 60.5 ± 7 and 69.5 ± 7.5 percentage mortality are more effective than 24 and 48 h post treatments with 31.6 ±6 and 54.7 ± 7.7 percentage mortality respectively.

A molecular phylogeny of Strepsiptera

Dino McMahon, Jeyaraney Kathirithamby

University of Oxford, Oxford, United Kingdom

The first molecular phylogeny of Strepsiptera is investigated using approximately 3 kb of genomic data, with representative taxa being taken from diverse genera across the major extant strepsipteran families. The resulting hypothesis is broadly consistent with traditional taxonomic classifications, although interrelationships between families are discordant with a recent cladistic analysis based on morphology. Tree shape is investigated with reference to key innovations that occurred during the evolution of this unique system, and in light of the pattern of host associations. The concept of morphological stasis as an order-wide phenomenon is also discussed.

Incidence of *Ceratitis capitata* (Wiedemann) (Diptera: Tephritidae) on native fruit trees of southern Mozambique: The role of habitat quality

Silvia Mausse, Romana Bandeira

Eduardo Mondlane University/Faculty of Agronomy and Forest Engineering/Department of Forestry, Maputo, Mozambique

Introduction: This study was conducted during the year 2003 and 2004 in three Districts of southern Mozambique aiming at assessing *Ceratitis capitata* incidence on native fruit trees per site and to determine sites similarity concerning insect species diversity.

Methods: Field surveys were performed by sampling 30 x 30 m quadrangular plots established in three locations per site. The locations were selected among those with natural occurrence of native fruit trees for sampling fruit insect pests. *Ceratitis capitata* population density was compared with that of other insect pests on same host tree species.

Results: *Ceratitis capitata* was one of the most constant fruit pest. Highest infestations of native fruit trees were caused by *C. capitata* on *Garcinia livingstonei* and *Annona senegalensis* fruits. Constance of *C. capitata* by site was higher in Manhiça, site that observed highest fruit infestation by this insect pest. Findings in the Matutuíne site gave indications of competition between insect pest species with low insect pest diversity and high numbers of the dominant curculionid *Endaeus floralis* on *A. senegalensis* fruits. The other sampling sites were divese in fruit insect pest species. We discuss implications of habitat condition on *C. capitata* incidence.

Structure of the arthropod community during flowering in mango, *Mangifera indica* L. (Anacardiaceae: Terebinthales) cv Ataulfo in the Soconusco region of Chiapas, Mexico

Ricardo Magallanes-Cedeno, Jorge Ulises Lopez-Ley, Amalia Concepcion Mejia-Barrios, Alfonso Perez-Romero, Martha Elena De Coss-Flores, Mario Ernesto Cabrera-Alvarado

Universidad Autonoma de Chiapas, Huehuetan, Chiapas, Mexico

Introduction: According to mango growers in Chiapas, the reduction in yield observed since 1996 is caused by thrips, therefore pesticides are regularly sprayed at blooming. Previous research indicate, however, that abundance of thrips has no relationship with fruit set. This research was conducted to obtain an understanding of the arthropod community in the mango flower habitat, required to support an IPM program.

Methods: Two different samplings were taken twice a week in six orchards around Huehuetan, Chiapas; the sampling unit was one panicle, and a sample size of 40 was obtained from ten trees in each orchard. Flying and non-flying arthropods were collected by different procedures. Specimens were identified by family and, up to this point, as morphospecies. Samplings started at beginning of blooming and continued until panicles were no longer visited by arthropods from December 2006 to January 2007.

Results: Arthropods visiting mango flowers integrate a community of three classes, Entognatha (Order Collembola), Insecta (Orders Odonata, Mantodea, Orthoptera, Psocoptera, Thysanoptera, Hemiptera, Diptera, Trichoptera, Lepidoptera, Neuroptera, Coleoptera and Hymenoptera) and Arachnida (Order Araneida) including about 72 families and 139 morphospecies. Differences in communities were found associated to the use of chemicals.

Conclusions: Only two species of Thysanoptera, one of Hemiptera and two of Hymenoptera are mentioned as potential pests by mango growers, but in communities as diverse like these perhaps none of them reach economical levels, although more research is needed to understand such interactions.

This research was partially supported by CONACYT and SAGARPA, Mexico.

Developing sampling systems for monitoring pest population levels on deciduous fruits in the Western Cape, South Africa

Kenneth Pringle

University of Stellenbosch, Stellenbosch, South Africa

Introduction: Sampling plans have been developed for monitoring pest population levels in apple orchards and table grape vineyards in South Africa.

Methods: The sampling plans are based on inspecting appropriate secondary sampling units for the presence of pests or their damage on a set number of evenly spaced primary units in blocks of apple orchards or vineyards. Operating characteristic curves were used to determine the precision of decisions regarding intervention. The results for *Eriosoma lanigerum* (woolly apple aphid) are used to illustrate the interpretation of the monitoring data on apples, while those for *Planococcus ficus* are used for illustrating interpretation of monitoring data on vines.

Results: Decisions regarding intervention against *E. lanigerum* were not markedly compromised by simply classifying the 25 trees as infested or uninfested, as opposed to counting colonies in leaf axils. The presence-absence system greatly reduced the time spent monitoring *E. lanigerum* population levels. In vineyards *P. ficus* cordon infestation preceded bunch infestation by three to five months. Therefore, cordon infestation can be used as a warning for pending bunch infestation. Control measures against *P. ficus* should be planned in the case of chemical control and initiated in the case of augmentative biological control at 2% cordon infestation.

Conclusions: A basic generic sampling plan can be used to monitor pest activity in apple orchards and table grape vineyards, the only difference being the definition of the primary and secondary sampling units.

Consortium for the Barcode of Life: An African perspective

Daniel Masiga

International Centre of Insect Physiology and Ecology (icipe), Nairobi, Kenya

Introduction: The Consortium for the Barcode of Life (CBOL) promotes DNA barcoding as a tool for identification of species. The primary objective of DNA barcoding is the adoption of a standardized gene targets for species identification. This provides a simple, but powerful tool for identifying known species and the discovery of new ones. The utility of such a scheme depends on agreed data standards that give confidence that data have been generated consistently and reliably.

Methods: Acquisition of DNA barcode data complies with a community consensus-developed BARCODE data standard, which has as key components: i) a DNA sequence ≥ 500 basepairs sequenced bidirectionally with less than 1% ambiguous base calls, (ii) a trace file, (iii) detailed collection records, (iv) a voucher specimen, with catalog numbers and details of holding institution, (v) identifier of specimen (vi) PCR primers, and (vii) digital image of the specimen. The Barcode of Life Data System (BOLD) is currently the main repository of primary DNA Barcode data, and the keyword "BARCODE" has been reserved by the International Nucleotide Sequence Database Collaboration (INSDC: DDBJ/EMBL/GenBank) for published sequence submissions that are compliant with the data standards, as collaboration with CBOL.

Results: A growing number of barcoding projects of relevance to Africa have been initiated. These include arthropods of medical and veterinary importance, crop pests and projects of interest to biodiversity and conservation. Although the numbers are relatively small, they already demonstrate the utility of DNA barcoding for identifying specimens.

Conclusions: Considering the small and falling number of experienced taxonomists in Africa, DNA barcoding provides a technology for more reliable understanding of the taxonomic status of several African taxa, including arthropods of major agricultural, veterinary and medical importance.

Inner anatomy of intercastes soldier-neotenic reproductives in *Prorhinotermes simplex* (Isoptera: Rhinotermitidae).

Jan Šobotník[1], František Weyda[2], Robert Hanus[1], Irena Valterová[1]

[1]Institute of Organic Chemistry and Biochemistry, Academy of Sciences of the Czech Republic, Praha, Czech Republic, [2]Institute of Entomology, Biology Centre, Academy of Sciences of the Czech Republic, Budějovice, Czech Republic

Introduction: After application of juvenile hormone analogue (JHA) to group of pseudergates (false workers), majority of treated specimen changes into intercastes pseudergate-soldier. We studied circumstances of occurrence of intercastes soldier-neotenic reproductive, and compared their inner anatomy with natural castes.

Methods: Intercastes soldier-neotenic reproductives moulted from pseudergates receiving JHA only by contact with treated specimen (and not being directly treated). Part of them was fixed and studied using methods of transmission electron microscopy; remaining individuals were kept living in group of nest-mates to evaluate their reproductive potential.

Results: Frontal gland is always quite small (compared to soldiers), present as sac-like organ in the head (never observed in neotenics). Labial glands are strongly modified, namely proportions of particular types of central secretory cells differ from all common castes. Epidermal glands are well-developed (more than in sterile castes) and of the same ultrastructure as observed in neotenics; unmodified epidermal cells always exist (while disappeare in neotenics). The size of corpora allata and gonades (both, testes and ovaries) is comparable to young neotenics - much larger than in sterile castes, but smaller than in functional reproductives. Neither gut nor fat body is influenced by JHA. Intercastes soldier-neotenic reproductive are not able to inhibit differentiation of further neotenic reproductives, and are not able to reproduce.

Conclusion: Although some intercastes show significant development of reproductive organs and other tissues specific to reproductives (e.g. epidermal glands), they are not able to fill reproductive role.

Financial support by Czech Science Foundation (project 206/06/1643) is gratefully acknowledged.

Bistrifluron: A new benzophenyl urea insecticide for both agricultural and non-agriculture use

Si Yong Kim, Chang Seop Cho, Tae-Joon Kim, Kyoung-Sung Kim

AgroLife Research Institute, Daejeon, Democratic People's Republic of Korea

Introduction: Bistrifluron inhibiting chitin biosynthesis is a new benzophenyl urea insecticide developed by Dongbu HiTek. Diverse field trials demonstrated that bistrifluron shows a very high control efficacy not only on agricultural insects, especially lepidopterous species, but on non-agricultural insects including mosquitoes and termites. Bistrifluron has good toxicological, environmental and eco-toxicological profiles, and it has been commercialized since 2006 in Korea for agricultural uses. Dongbu HiTek has tried to resister bistrifluron in 18 countries worldwide.

Methods: Many field trials have been conducted to determine the biological activity against various species of whiteflies and lepidopterous insects. The efficacy of bistrifluron has been evaluated against *Culex pipiens pallens* and *Reticulitermes speratus* under laboratory and field conditions.

Results: Bistrifluron showed a highly controlling efficacy to *Trialeurodes vaporariorum* and *Bemisia tabaci* at 50-100g ai/ha in greenhouse crops. Lepidopterous insects of *Spodoptera exigua* and *Plutella xylostella* were completely controlled at 75-150g ai/ha in vegetable crops. In orchard crops, *Stathmopoda masinissa* and *Phyllonorycter ringoniella* were effectively controlled at 100-400g ai/ha. More importantly, no cross-resistance to the organophosphorous insecticides was found. There have been no crop injuries detected to the wide range of crops. Showed LC_{90} of 0.0092 ppm under laboratory conditions, bistrifluron is able to control *C. piniens pallens* at 0.05 ppm under field conditions in 8 days. Special formulation, the above-ground-bait, could be required to control *Reticulitermes speratus* at 0.5%(w/w) of bistrifluron.

Conclusions: Bistrifluron is a new insecticide possessing a wide spectrum for both agricultural and non agricultural insects. For stand-alone application, Dongbu HiTek has introduced 10% EC bistrifluron with the trade name of HANARO® in the Korean market since 2006 for controlling lepidopterous insects for agricultural uses. Diverse efforts have been tried to commercialize bistrifluron for other crops and non-agricultural uses in the world.

Genetics of biological control: The diversity of *Teretrius nigrescens*, predator of the larger grain borer, *Prostephanus truncatus.*

Bonaventure Omondi Aman[1], Daniel Masiga[1], Fritz Schulthess[1], Johnnie van den Berg[2]

[1]International Centre of Insect Physiology and Ecology, Nairobi, Kenya, [2]North West University, Potchefstroom, South Africa

Introduction: The larger grain borer, an alien invasive post harvest pest, has spread to all regions of Africa, since its introduction two decades ago, becoming the single worst insect pest of stored maize in the continent. Biological control was considered a key tool in the integrated management of the pest and two populations of *Teretrius nigrescens,* from Costa Rica and Mexico were released in several areas between 1991 and 1996. However, the effectiveness of the predator has been inconsistent between populations and locations, with greater successes in hot-humid areas.

Methods: The genetic diversity among populations of the predator recovered from four agro-ecological zones in Mexico and Costa Rica and those recaptured from Africa was investigated. The cytochrome oxidase 1 (COI), COII and ribosomal Internal Transcribed Spacer (ITS1, 5.8S and ITS2) were amplified, and sequenced. Sequence alignment and analysis of potential diagnostic restriction sites were done.

Results: Two distinct clusters were detected, the cool highland and warm lowland populations clustered together irrespective of their geographical separation. The two genetic forms produced distinct profiles of the COI gene using *Rsa*I, *Bst*YI and *Aci*I enzymes. Intragenomic variation was detected in ITS1 and ITS2 while COII and 5.8S were monomorphic.

Conclusion: It is therefore possible that there exist ecological or geographical types of *T. nigrescens*, specialised to different environmental conditions. We propose a simple molecular identification procedure for strain-specific monitoring of the predator populations. Microsatellite markers have been developed for biotyping the populations.

Detection of plant DNA in the gut of omnivorous predators by molecular markers.

Nuria Agusti, Lorena Pumariño, Rosa Gabarra, Oscar Alomar

IRTA, Plant Protection, E-08348 Cabrils (Barcelona), Spain

Introduction: Identification of refuge plants that are source of natural enemies is a very important tool for the application of conservation biological control. This tool could allow studying crop colonization of either predator natural populations or pests. The main problem with the markers traditionally used (dyes, rubidium, proteins, etc.) is that only those individuals or plants that have specifically been marked can be identified but not others. The use of molecular markers to detect plant DNA in the gut of omnivorous natural enemies allows not only its detection, but also the identification of which plant species they have been feeding on.

Methods: *Macrolophus caliginosus* Wagner (Heteroptera: Miridae) is an omnivorous predator used in biological control of insect pests in horticultural crops. This study discusses the detection of plant DNA in the gut of this predator and other predator and pest species using the tomato plant as a model. For this purpose, two types of markers were tested: one tomato-specific and a universal one which amplifies all plants but giving different PCR product sizes.

Results: Both markers allowed amplification of DNA tomato fragments within the gut of *M. caliginosus* but not in all cases. Results are discussed depending on the type of material ingested, molecular marker used, and the feeding physiology of the insect.

Conclusions: The development of these techniques can facilitate the study of plant-insect interactions, conservation and crop colonization.

Cloning of vitellogenin gene of the giant water bug, *Lethocerus deyrollei*

Yoshiki Nagaba, Muhammad Tufail, Makio Takeda

Kobe University, Kobe, Japan

The Giant Water Bug, *Lethocerus deyrollei,* the largest aquatic insect in Japan is an endangered species. Nevertheless, basic biology of this bug is not well known. For conservation of this bug, the yolk protein precursor, Vitellogenin (Vg) was investigated. A 5865bp cDNA encoding 219.7kd Vg was cloned and sequenced from the fat body. The cleaved Vg polypeptide subunits were isolated from the female hemolymph and oocytes by SDS-PAGE, and their N-terminal sequences were decided by Edman degradation to determine the regions in the cleavage site. The developmental expressions around seasons and the temporal expressions in reproductive season of the Vg mRNA were investigated by Northern blot analysis. Similarly SDS-PHAGE was carried out for seasonal changes in the protein pattern.

Positional cloning of genes conferring pyrethroid resistance in *Anopheles funestus*, malaria vector in Africa

Charles Wondji[1], John Morgan[1], Helen Irving[1], Maureen Coetzee[2], Hilary Ranson[1], Janet Hemingway[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Vector Control Reference Unit, National Institute for Communicable Diseases, NHLS, Johannesburg, South Africa

Introduction: A major QTL *rp1* conferring pyrethroid resistance to the malaria vector *Anopheles funestus,* was previously identified. Here we present a fine-scale mapping of *rp1*, the identification and characterisation of the genes conferring this resistance.

Method: 650 F6 and F8 individuals from reciprocal crosses between susceptible and resistant strains were genotyped with SNPs and microsatellite markers for QTL mapping. A BAC clone containing *rp1* was sequenced and annotated. Quantitative PCR was carried out to study the expression pattern of the P450s genes and the *in vitro* metabolic activity of the candidate enzymes on pyrethroids was assessed.

Results: *rp1* was the major QTL explaining 85% of the genetic variance to pyrethroid resistance. Two other QTLs of minor effect *rp2* and *rp3* were detected. Fifteen genes were identified in the 120kb BAC clone containing the *rp1* QTL with a cluster of 10 P450 genes among which CYP6P9 and CYP6P4 were duplicated. These two genes were significantly differentially expressed between susceptible and resistant strains. Enzymes from these genes actively metabolise pyrethroid *in vitro*. Specific mutations associated with resistance were identified in CYP6P9 and CYP6P4. For each gene, two A/G SNPs were identified and genotyped for over 650 specimens. The G/G genotypes confer resistance at 100% and these could be used to design a diagnostic assay to detect this metabolic resistance.

Conclusion: CYP6P9 and CYP6P4 are the main genes conferring pyrethroid resistance in the laboratory strain FUMOZ-R and will now be analysed in field populations.

The landscape in agroecosystems and the ecological services provided by stingless bees

Vera L. Imperatriz-Fonseca, Judith E. Slaa, Marilda Cortopassi-Laurino, Denise de A. Alves, Jacobus C. Biesmeijer

[1]University of São Paulo, São Paulo, São Paulo, Brazil, [2]University of Leeds, Leeds, United Kingdom, [3]University of São Paulo, São Paulo, São Paulo, Brazil, [4]University of São Paulo, São Paulo, São Paulo, Brazil, [5]University of Leeds, Leeds, United Kingdom

The importance of pollination services provided by stingless bees (Meliponini) has been highlighted by several authors. Meliponini comprises many species that differ highly in body size, colony size and foraging strategy, which offers a wide range of pollinators for different floral species. Stingless bees can be managed in rational hives and several experiments have shown that they can be used for pollination of certain crops. However, Meliponiculture has not been developed on as large a scale as Apiculture, and only a fraction of all species is available in rational hives. The presence of natural nests close to the crop provides free pollination services. Most stingless bees require trees for nesting. Therefore, the landscape of the agroecosystem and the structure of the bordering area determine the nesting possibilities of these potential pollinators.

Using 50 Brazilian studies, we extracted the most commonly reported nest trees for several ecosystems, and analyzed the possibility of preferences for using tree species to nidify.

For each habitat, nests were found in many tree species. However, some trees were more commonly reported to house stingless bee nests, which could be used for selective reforestation in and around agroecosystems. Different stingless bee species have different habitat requirements, with some species requiring true forested areas, whereas others benefit from more open areas. Given the current problems in apiculture and the difficulty of quickly rearing large numbers of stingless bee hives, it is important to further develop this free pollination service in agricultural systems through habitat restoration and landscape recovering.

Pre-release monitoring of the larger grain borer *Prostephanus truncatus* and its predator *Teretrius nigrescens* in Kenya

Bonaventure Aman Omondi[2], Josephine Songa[3], Fritz Schulthess[1], Daniel Masiga[2], Johnnie van den Berg[1]

[1]International Centre of Insect Physiology and Ecology, Nairobi, Kenya, [2]North West University, Potchefstroom, South Africa, [3]Kenya Agricultural Research Institute, Nairobi, Kenya

Introduction: The larger grain borer, (LGB), *Prostephanus truncatus*, is the worst pest of farm stored maize in Africa since its introduction some 20 years ago. Biological control of the pest has been. Biological control of the pest was successful in West Africa and parts of Kenya initially. This study was a pre-release survey of *P. truncatus* and *T. nigrescens* in five ecological zones in Kenya.

Method: Twenty six-month monitoring and three month were done in 2005 - 2007 in five regions in Kenya pheromone baited flight traps. A second three-month life sample recovery was done around the first release area to recover *T. nigrescens.* Monthly flight patterns were determined and related to weather parameters based on regression models.

Results: In general, LGB flight activity increased with altitude. The predator was not recovered outside the warm lowland coastal and eastern regions. The strongest possible effects of respective mean monthly weather parameters and LGB flight activity were observed after two months delay. Temperature, relative humidity and vapour pressure deficit were the most important parameters determining LGB flight activity in all regions.

Conclusion: *T. nigrescens* established in the warm coastal areas of Kenya since last release. Its inability to disperse outside initial release region may be due to geographical barriers, unsuitable weather or independent introductions of LB into the hinterland. Biological control of the LGB in Kenya needs to incorporate focus on augmentative releases suitably adapted strains of natural enemies for respective agroecological zones.

What ecological niche models can tell us about invasive species' distributions

Mark Robertson[1], Marc De Meyer[2], Townsend Peterson[3], Mervyn Mansell[4]

[1]Department of Zoology & Entomology, University of Pretoria, Pretoria, South Africa, [2]Royal Museum for Central Africa, Entomology Section, Tervuren, Belgium, [3]Natural History Museum and Biodiversity Research Center, University of Kansas, Lawrence, United States, [4]United States Department of Agriculture, APHIS, Pretoria, South Africa

Introduction: Ecological niche models and species distribution models have been applied to a variety of problems in biology. Ecological niche models have considerable value in identifying regions that may be at risk from invasive species. These models can either be used to identify areas that are likely to be invaded by a species that has already been introduced to a region or in cases where a species has not yet been introduced. For these organisms, absence data are unreliable and thus cannot be used in model calibration or evaluation. This limits the type of modelling technique that can be used and has important implications for evaluation of the predictions. This study examines some of the advances and limitations in the application of ecological niche models to invasive species.

Methods: We used three correlative modelling approaches (GARP, Maxent and PCA) to generate ecological niche models for three invasive species of fruit fly. These models were used to predict the potential distributions of these species in regions that may be invaded in future.

Results: Ecological niche models were used successfully to identify regions that may be at risk of invasion by three fruit fly species. Model agreement was generally high and models performed well against test data.

Conclusions: Ecological niche models show considerable promise in assessing risks associated with invasive species but invasion risk cannot be determined directly from species potential distributions.

Life history patterns of an important predator in orchards, the common earwig, determines pest control efficacy

Bruno Gobin[1], Gertie Peusens[1], Kurt Jordaens[2], Rob Moerkens[2], Herwig Leirs[2]

[1]Zoology Department, pcfruit, Sint-Truiden, Belgium, [2]University of Antwerp, Antwerp, Belgium

Boosting populations of naturally occurring beneficial arthropods requires detailed knowledge on presence, life stages and interactions with orchard management. This is especially important in beneficials with a univoltine life cycle, which may suffer cumulative side-effects throughout their lifetime. Furthermore, correlation with pest life cycles and interaction with pesticides should be taken into account to optimize biological control potential.

Earwigs (*Forficula auricularia*) are important generalist predator of top fruit summer pests. Detailed population monitoring of earwigs revealed the presence of two molecularly distinct subspecies with different reproductive strategies –having a single or double brood per season. Both can occur either sympatric or allopatric, affecting the ensuing population dynamics and predatory impact. Different occurrence of egg-laying does not affect timing of appearance above ground. Migration from undergrowth to tree is steered by temperature rather than by prey seeking as we see no difference in orchards with specific pest spectra. The production of a small second brood in summer has an important effect on total population at the main mating and pair bonding period in September. We identified two critical periods in earwig phenology, during which earwig numbers reduce considerably. Winter mortality and the availability of nest sites are the main limiting factor in earwig population development and can be experimentally manipulated. A second loss of substantial amounts of earwigs occurs at the moult from 4th instar nymphs to adults. This reduction is density dependent and might be linked to intraspecific competition rather than predation or parasitism.

Spread of the invasive ladybird *Harmonia axyridis* in the Czech Republic and Denmark

Oldřich Nedvěd[1], Tove Steenberg[3], Susanne Harding[4]

[1]Faculty of Science, University of South Bohemia, Ceské Budejovice, Czech Republic, [2]Institute of Entomology, Biology Centre, Ceské Budejovice, Czech Republic, [3]Faculty of Agricultural Sciences, University of Aarhus, Lyngby, Denmark, [4]Faculty of Life Sciences, University of Copenhagen, Frederiksberg, Denmark

Introduction: *Harmonia axyridis* (Coleoptera: Coccinellidae) is an invasive alien ladybird in several continents. In late 2007, the established range in Europe extended to Denmark in the north and to the Czech Republic in the east.

Methods: Systematic field observations by professional entomologists, as well as random recordings by volunteer naturalists contributed to a database of records including site, date, environment, and colour morphs.

Results: By early 2008 the Czech database included 125 records, covering 57 (out of a possible 650) KFME grid squares (approximately 11x11 km). Most of these *H. axyridis* records were from large cities (probably introduced by transportation) and to the northwest of the country, where they probably spread naturally from Germany. There were 865 individuals recorded in total, 16% were melanics (12% *spectabilis*, 4% *conspicua*). Two individuals from the Czech Republic were identified as the nominal *axyridis* morph. In Denmark, large numbers of larvae and pupae has been recorded from Copenhagen in late 2007. Small numbers (8 records) of adults have been found in the southern parts of the country. 769 individuals have been recorded in total, 7% were melanics (6% *spectabilis*, 1% *conspicua*), Two individuals of *axyridis* morph were found.

Conclusions: We predict that *H. axyridis* will continue to spread rapidly in Europe, particularly northwards and eastwards. Although there may consequently be a reduction in pest insects, our records support that this species may have significant detrimental impact. The records of the *axyridis* colour morph in the Czech Republic and Denmark are unique within Europe and so this requires further study.

Assessing the effects of endosulfan, imidacloprid and indoxacarb on *Chrysoperla carnea* (Neuroptera: Chrysopidae) in laboratory using IOBC and life table methods

Golamreza Golmohammadi, Mir Jalil Hejazi, Shahzad Iranipour, Seyed Abolghassem Mohammadi

University of Tabriz, Tabriz, Islamic Republic of Iran

Introduction: Common green lacewing, *Chrysoperla carnea* (Stephens) is a polyphagous predator used in greenhouses. It is also very common in many agricultural systems. Compatibility of Insecticides with biological control agents is of most concern to practitioners of integrated pest management. Lethal and sublethal effects of imidacloprid, indoxacarb and endosulfan were assessed on *C. carnea* in laboratory, using the IOBC and life table methods.

Method: First instar larvae of *C. carnea* were treated with imidacloprid (12 mg ai/L), indoxacarb (86 mg ai/L) and endosulfan (181 mg ai/L) using glass petri dishes. Twenty four hours after treatment, the surviving larvae were individually transferred to 60 mm diameters plastic petri dishes and monitored daily until adults appeared. The resultant adults from the surviving treated larvae were kept separately in pairs of males and females; and their eggs were collected and counted daily. The total effects were estimated using IOBC and life table methods.

Results: All three insecticides tested showed significant adverse effects on the developmental time and survival of the 1st instar larvae ($p<0.01$). There were no significant differences in population growth parameters, namely gross reproductive rate, net reproductive rate, intrinsic rate of increase, doubling time, mean generation time and finite rate of increase among the treatments. Based on the IOBC classification method, imidacloprid, endosulfan and indoxacarb were classified as slightly harmful to 1st instar *C.* carnea.

Conclusion: If results similar to laboratory findings are obtained in field conditions, these insecticides might be suitable candidates for use in IPM programs.

Road-building and use in the western Amazon Basin, Part 2: Employing data from applied conservation research to address basic questions about species richness patterns of Neotropical Mordellidae (Coleoptera)

Christy Jo Geraci[1], Terry L. Erwin[1], Valeria Aschero[2]

[1]Smithsonian Institution, Washington, DC, United States, [2]Instituto Argentino de Investigaciones de Zonas Aridas, Mendoza, Argentina

Introduction: The terre firme forest of eastern Ecuador has very high tree and insect species richness. We predict that degree of host tree specialization is a factor governing phytophagous beetle diversity in the canopy, but this hypothesis remains to be tested. One of the by-products of the Ecuador Canopy Biodiversity Project (ECBP) is the discovery of a rich community of tumbling flower beetles (Mordellidae) in the two forest macroplots. Our objectives were to 1) describe morphospecies and classify them into genera using morphology and DNA, 2) build a geodatabase of Mordellidae and tree distributions within each macroplot, and 3) examine spatial and temporal patterns in morphospecies occurrences to identify generalists and host tree specialists.

Methods: A total of 2761 Mordellidae specimens were sorted into morphospecies, imaged, and databased. Two specimens (if available) of each species were chosen for DNA barcoding. Morphospecies were grouped into morphogenera based on gross morphology. The coordinates of both forest macroplots, along with the locations of all 200 sampling stations and the trees surrounding each station, were georeferenced using ESRI ArcGIS software. These data were used to find associations between beetles and trees.

Results and Conclusions: We designated 388 morphospecies based on morphological characters. There was a large turnover in morphospecies composition but no significant difference in species richness across seasons (Anova 1-way $p>0.05$). The majority of morphospecies showed limited distributions, but three (#004, 021, and 038) are widespread, abundant, and classified as generalist pollen vectors. DNA barcoding and evaluation of morphogenera monophyly is still underway.

Larval requisition behavior for food trophallaxis in the termite *Reticulitermes speratus*

Kazutaka Kawatsu[1], Kenji Matsuura[2], Kenji Fujisaki[1]

[1]Kyoto University, Kyoto, Japan, [2]Okayama University, Okayama, Japan

Introduction: Termite larvae may achieve higher fitness to increase trophallaxis by workers, since differentiation into nymphal line is considered to depend on their nutritional and hormonal conditions. Larvae have legs so that they can move by themselves, while they depend on workers for food. Therefore, some sort of behavior for trophallaxis can be expected in the larvae. We studied larval behavior in *Reticulitermes speratus* and hypothesized that larvae would try to control food intake by requisition to nursing workers to stimulate trophallaxis. We also investigated that intensity of requisition behavior is affected by larval nutritional conditions.

Methods: Larval behavior and trophallaxis were recorded by videotaping. To correlate larval behavior with their hungry level, we changed food availability of the larvae before experiment and set up three situations: uric acid or only distillation water with workers, complete isolation from workers. Larvae were then transferred to the observation nest with workers and filmed for 60 min.

Results: it was often observed that larvae actively and quickly approached workers (active approach). Trophallaxis was positively correlated with active approach and it was occurred after this behavior. Intensity of active approach significantly decreased with improvement of larval food availability.

Conclusion: Larvae require for trophallaxis by active approach. It would be expected that workers react against larval requisition, because it may results in producing more nymphs and bringing less ergonomic efficiency. We concluded, however, that the larval behavior is an important element of requisition for trophallaxis because it reflects larval nutritional condition.

Insects in the ancient Chinese custom and faith

Xue-xin Chen, Qiong Wu, Ya-ping Yao

Zhejiang University, Hangzhou, Zhejiang, China

There is no question that insects have shaped and molded human civilizations. Throughout history insects have managed to permeate our spiritual, cultural, and scientific endeavors. As China with a long history and many nationalities, ancient Chinese had made a great contribution to the knowledge of cultural entomology and the connotations of Chinese insect culture are of great diversity. Insects are used in a variety of ways to entertain, to evoke emotions, to convey ideas, and to amaze. Cricket-fighting is an ancient and very popular form of entertainment in China, and sound-making insects are kept as pets. There are many insect-associated love stories in Chinese literature, perhaps the most famous one is a story about a pair of lovers turning into butterflies and flying out of the control of their families (Liang Shan-bo and Zhu Ying-tai). The symbolic character of insects is ingrained in the ancient Chinese cultures. A mantis symbolized cruelty and mystery, the cicada a symbol of resurrection, a tettigoniid a symbol of more offspring, and the butterfly a symbol of joy. There are more than one hundred traditional festivals associated with insects in the history of China. A number of insects are used as or part of ancient Chinese names. Students are so-called “booklice”. The Chinese also believe the similarities of existence found ubiquitous throughout the living world including those between insects and humans.

Queen selection in the stingless bee *Scaptotrigona* aff*. depilis* (Hymenoptera: Apidae: Meliponini)

Cristiano Menezes, Tiago Maurício Francoy, Vera Lucia Imperatriz Fonseca

University of Sao Paulo, Ribeirao Preto, Brazil

Introduction: The selection of queens by colonies of eusocial bees is probably under strong selective pressures since the choice of an inadequate queen would considerably diminish the fitness of the colony. Due to the great size variability among virgin queens, this feature probably is under selection because it directly interferes with the reproductive capacity. This work aimed to investigate whether queen selection occurs in the stingless bee *Scaptotrigona* aff. *depilis*, and whether it is related to the size of the queens. Differences between the size of virgin queens and of chosen physogastric queens would be an important evidence for size selection.

Methods: We collected 30 virgin queens and 30 physogastric queens from 30 colonies of *S.* aff. *depilis*. Both the thoraces (three different measurements) and the heads (four different measurements) of the queens were taken as reference for the bees' size.

Results: Using a Principal Component Analysis, we found that the group of physogastric queens is more uniform and restricted in its distribution than the group of virgin queens. Besides an overlapping of the two groups, the physogastric queens are concentrated in a limited portion of virgin queens' distribution.

Conclusions: We postulate that this "concentration" is a consequence of queen selection. Experimental tests are being performed to investigate the importance of queen size for the colonies, and how colonies choose their queen.

Rapid radiations in vespoid Aculeata

Erik Pilgrim, James Pitts, Carol von Dohlen

Utah State University, Logan, UT, United States

Members of the vespoid lineages exhibit diverse lifestyles, from pollen feeding to parasitism to predatory behavior and from solitary to highly eusocial. Fossils indicate many lineages date to the early Cretaceous. While most vespoid families display multiple autapomorphies supporting their monophyly, solid synapomorphies to outline relationships among families are lacking. Analyses of our recently collected molecular data mirror the morphological characters, such that we find short internodes between lineages whose relationships have been ambiguous based on morphology, suggestive of a rapid radiation at the family/subfamily level. Maximum-parsimony analysis of a four-gene data set cannot resolve the radiation; however, likelihood-based Bayesian analysis of the combined-gene dataset, with genes modeled individually, resolves the radiation with confidence. Genes analyzed individually show a consistent pattern of short, deep internodes, suggesting the rapid radiation is true and not an artifact of conflict among gene partitions. The sampled genes show a range of variation that in combination provides signal from deep to shallow divergences. We subjected the molecular data with fossil-based calibrations to Bayesian relaxed molecular clock analyses to define the likely geological interval of the rapid radiation and correlate it with contemporary environmental/ecological variables, in an attempt to identify possible triggers for the radiation. In addition, we focus on the case of a single family, Pompilidae, in which morphology-based phylogenetics also has been difficult and our molecular data indicate a dramatic and rapid diversification; in this case, however, the radiation dates to a more recent period, most likely in the early Tertiary.

Temperature and starvation limit fig wasp abundance and distribution

Marié Warren

University of Pretoria, Pretoria, South Africa

Introduction: Determining what limits the distribution and abundance of a species is challenging. Two species of fig wasp utilise the flowers of *Ficus sycomorus* L. Both the pollinator (*Ceratosolen arabicus* Mayr) and the cuckoo wasp (*Ceratosolen galili* Weibes) are widely distributed across the range of *F. sycomorus*. However, it has been stated that *C. galili* is less abundant in drier areas. Here, we examine thermal tolerance, desiccation and starvation resistance of these two sympatric wasp species.

Methods: Figs that were close to releasing wasps were collected in Sukuza, Kruger National Park, South Africa. For each species, 30 freshly emerged female wasps were used for experiments examining critical thermal minima, maxima, desiccation and starvation resistance.

Results: Although the onset of chill coma is not significantly different between the species, recovery from chill coma is (faster and) at a lower temperature (by 2^{o}C) for *C. arabicus*. *C. arabicus* is also able to withstand higher temperatures than *C. galili*. Therefore, the thermal range of *C. arabicus* is greater than that of *C. galili*. Both species have similar survival times under desiccating conditions. However, *C. arabicus* appears to be more starvation resistant than *C. galili*.

Conclusion: Thermal tolerances and starvation resistance may determine the limits to the distribution and abundances of these fig wasp species.

Sperm precedence and its implication on evolution of prolonged copulation in *Dysdercus koenigii*

Kamal Gupta

Department of Zoology, Deshbandhu College, University of Delhi, Delhi, India

Introduction: Adults of *Dysdercus* exhibit certain unique features in their reproductive behaviour. Both males and females mate 5-7 times in their entire life span. Each mating lasts 2-3 days.. The females remain receptive to mating throughout their life span. Both males and females show relatively nonspecific mate selection behaviour.

Methods: A dose of Gamma radiation was selected which induced sterility in males but did not impair mating behaviour. In the first set of experiment the female was allowed to mate with normal and sterilized males in a sequence. The sperm utilization pattern in there females was assessed by calculating P_2 value. . In the second set of experiment the female was allowed to mate for 24 hr and then mating was forcefully terminated. The females were allowed to mate with normal or sterilized male.

Results: Our studies indicated that in *Dysdercus* insemination took place during first 24 hr of mating. However a female if mated for longer duration showed an enhanced fertility and an ordered oviposition behaviour. Studies pertaining to sperm utilization pattern of doubly mated females indicated sperm precedence behaviour. The P_2 value was 0.966. This reflected that sperms of last mating were utilized by the female for fertilization.P_2 value in the females of second set was 0.85 This indicated that a female if mated with two males in same mating cycle utilized the sperms contributed by the last male.

Conclusion: The significance of sperm precedence in evolution in prolonged copulation in *Dysdercus* was discussed.

Positional cloning of densovirus-resistance genes in *Bombyx mori*

Keiko Kadono-Okuda[1], Katsuhiko Ito[2], Kurako Kidokoro[1], Kimiko Yamamoto[1], Hideki Sezutsu[1], Keiro Uchino[1], Isao Kobayashi[1], Andrew Kalyebi[1], Toshiki Toshiki[1], Susumu Katsuma[2], Toru Shimada[2], Kazuei Mita[1]

[1]National Institute of Agrobiological Sciences, Tsukuba, Ibaraki, Japan, [2]The University of Tokyo, Bunkyo, Tokyo, Japan

Introduction: *Bombyx mori* densovirus (BmDNV) multiplies in the columnar cell nuclei of the midgut epithelia of the silkworm, *Bombyx mori*. It is classified into two species, BmDNV-1 and BmDNV-2 or Z (denso-like virus). Some silkworm strains are absolutely resistant against BmDNV-1 and/or BmDNV-2. Four unlinked mutations, *nsd-1*, *Nid-1*, *nsd-2* and *nsd-Z*, which were discovered in different *Bombyx* strains, control nonsusceptibility to infection by BmDNV-1 or 2. However, none of them had yet been isolated as responsible genes. The identification of these genes will provide important information for understanding the host- and tissue- specificity and infection mechanisms of the corresponding viruses. Since significant *Bombyx* genome information had accumulated, we undertook map-based cloning of the genes, *nsd-2, nsd-1 and Nid-1*.

Methods: Fine mapping of the genes and narrowing of the candidate regions were performed by linkage analysis of the virus-selected BC_1 populations. Germline transformation was adopted to prove the candidate genes.

Results and Conclusions: We isolated the *nsd-2* and *nsd-1* candidate genes, and narrowed the candidate region for *Nid-1* to 79 kb. The virus-resistance of *nsd-2* is caused by a 6 kb deletion in the ORF of a gene encoding a 12-pass transmembrane protein expressed only in midgut. Germline transformation with a wild type ($+^{nsd-2}$) transgene expressed in the midgut restored susceptibility, showing that the defective membrane protein is responsible for resistance. This is the first report of positional cloning of a mutant gene in *Bombyx* and the first isolation of an absolute virus resistance gene in insects.

Pollination by sexual deception in orchids

Florian Schiestl

Institute of Systematic Botany, Zürich, Switzerland

Sexually deceptive orchids mimic the sex pheromones of their insect-pollinator species, and pollination occurs when the males attempt to copulate with the orchid flowers. Pollination is highly specific and the floral odor is often of primary importance for pollinator attraction. Sexual deception is widely distributed, and can be found among terrestrial as well as epiphytic orchids, and in many floristic regions. My talk addresses the following topics: 1) What are the mechanisms of pollinator attraction? 2) Why has sexual deception evolved? 3) What are the evolutionary consequences? 1) Mechanisms of pollinator attraction are well understood in certain genera, and have proven to be surprisingly diverse. In the Australian genus *Chiloglottis,* few specific compounds attract the pollinators, thynnine wasps, whereas in many European *Ophrys* species, several more commonly found compounds are responsible for attraction of the pollinators, often solitary bees. 2) Since pollination via pollinia, a typical feature of orchids, is an efficient but also risky pollination mode, orchids may often suffer high pollen loss. In a comparative study, we have shown that sexually deceptive orchids have better pollen transfer efficiency than their related food deceptive species. This result can be explained by the high pollinator-specificity found in sexually deceptive orchids, a possible evolutionary driving force for the evolution of this pollination system. 3) This high specificity has consequences for the speciation within these orchids. As orchids evolve to mimic the sex pheromones of different pollinator species, reproductive isolation is a by-product of the adaptation towards specific pollinators, since sex pheromones often act on a species-specific basis.

Yield losses due to natural infestation of *Vicia faba* by l*iriomyza* spp., in Central Sudan

Faiza Salah[1], Elamin M Elamin[2], Elameen Eltoum[1], Dominique Bordat[3]

[1]Dept. Crop Protection, Faculty of Agricultues, Gezira University, Medani, Sudan; [2]Agricultural Research, Medani, Sudan; [3]CIRAD, Montpellier, France

The limiting factor for faba bean in the Gezira area proved to be the leaf miners (LM). This study was carried out at the Experimental Farm of the Faculty of Agricultural Sciences, University of Gezira, during the seasons, on two faba bean varieties: Shambat and SML. Two experiments were conducted: one for each variety where two treatments were laid out in a RCB design with six replicates. The first treatment was the natural infestation of LM (insecticide-untreated), and the second was protected by the IGR Trigard 75% W.P. (insecticide-treated). In both seasons, the untreated plots were heavily infested by the leaf miners, while the protected plots were lightly infested. Infestation resulted in yield losses of 22.8% and 42.2% for Shambat variety, in season I and II, respectively, and 29.1% and 27.6% for SML variety following the same order of seasons. Moreover, there were highly significant differences ($P<0.01$) in plant height and number of pods between the treated and the untreated plots. Negative correlations between the percentage of leaf infestation and plant height in the treated plots were detected.

Control of tomato pests under protected cultivation in the hot and seasonally humid tropics

Hans-Michael Poehling, Nasser Halaweh

Institute of Plant Protection and Plant Diseases, Leibniz Universität Hannover, Hannover, Germany

Introduction: Tomato production in the hot and seasonal humid tropics suffers from a number of detrimental pests. Thrips and white flies are of special importance because they damage by feeding activity and vector virus diseases such as Capsicum Chlorosis Virus or Tomato Yellow Leaf Curl Virus. All year round tomato production under those climatic conditions is only possible using protected cultivation systems, which was the topic of an international joint research project (see www.sus-veg-thai.de) located in Bangkok, Thailand.

Methods and Results: First basically we worked out life-table parameters for *Ceratothripoides claratris*, the most important thrips pest in the greenhouses, and we studied in detail its virus transmission capabilities and the heritability of its competence for virus transmission. A second set of experiments dealt with thrips and white fly control. Greenhouse cladding with UV absorbing plastics (roofs) and nets (side walls) inhibited immigration of thrips and white flies very efficiently. Thrips infestation and virus spread was reduced with an efficacy up to 90%. Accidental introduced thrips and white flies could be further controlled by a package of measures such as systemically plant translocation of neem ingredients and natural enemies, such as Entomopathogenic fungi.

A third focal point was the universal validity and mechanism of the UV effects, studied in laboratory experiments, with different herbivorous insects and natural enemies as well. Obviously most insects tested that search visually for hosts need a stimulation of UV sensitive photoreceptors to properly orientate in space and to differentiate colours.

Mating behaviour and evidence of the existence of a contact pheromone in *Monochamus leuconotus* (Pascoe) (Coleoptera: Cerambycidae)

Dumisani Kutywayo[2], David Hall[1]

[1]Natural Resources Institute, Chatham, Kent, United Kingdom, [2]Coffee Research Institute, Chipinge, Zimbabwe, Zimbabwe

Introduction: *M. leuconotus* is an important pest of coffee in several African countries currently controlled by uprooting and swabbing. New methods of control are required. Mating behaviour and evidence of the existence of a contact pheromone in *M leuconotus* were studied under laboratory conditions.

Methods: Behavioural interactions involved before, during and after mating were taken from twenty pairs of male and female *M leuconotus* in plastic boxes containing coffee twigs as food under laboratory ambient conditions over an eight-hour period. Male behavioural response within 10 minutes of exposure to dead unwashed female, dead hexane-washed female and dead hexane-extract recoated female in plastic box arenas was monitored.

Results: Males exhibited reproductive behaviour of licking, mounting, abdominal bending, copulation and mate guarding after initial antennal or tarsal contact with the females. Females were motionless during copulation but walked freely during pre-or post copulation mounting. Males mated more than once with same female and with different females. Males completed the full range of mating behaviour with dead unwashed and dead recoated females but did not recognise hexane-washed females

Conclusions: Mating behaviour in *M leuconotus* males is initiated after antennal or tarsal contact with conspecific females. Male recognition of dead unwashed and dead recoated females suggests the presence of a contact pheromone on the body surface

Plant damage to horticultural crops by zoophytophagous mirid predators

Cristina Castañé, Oscar Alomar, Jordi Riudavets, Judit Arnó, Rosa Gabarra

IRTA-Cabrils, 08348-Cabrils (Barcelona), Spain

Predatory mirid bugs have a mixed plant-prey diet in which the predatory aspect is principal in relation to their phytophagy, since most of them are unable of developing their immature stages and reproduce in a strict plant diet. However, these predators need the plant for oviposition and as a dietary complement to the prey.

The injuries they cause to plants are directly related with prey scarcity, although environmental conditions (temperature, humidity and impossibility to migrate) may have a synergistic effect. Two types of damage can be described: deformities of plant parts (pits and dimples on green tomato fruits or young zucchini fruits, and yellow spots on red tomato fruits by *Dicyphus tamaninii* or *Macrolophus caliginosus*; necrotic rings in tomato stems and shots by *Nesidiocoris tenuis*) and yield reduction due to nutrients extraction (*N. tenuis* in tomatoes).

They are important pest control agents in horticultural crops due to their high prey consumption and their polyphagy, despite the risk for causing damage to crops. It is important to have a deep understanding of the mechanisms implicated in crop damage in order to take advantage of their high biological potential.

Until recently, *N. tenuis* has been considered a tomato pest while nowadays it is commercially produced for *Bemisia tabaci* control. When confined in hermetic greenhouses with severe scarcity of prey it produces important yield loses. However, when there is enough prey and/or they can emigrate to search for it, only deformities as some necrotic rings appear in the crop.

Egg structures and embryological features of heel-walkers (Mantophasmatodea)

Ryuichiro Machida[1], Toshiki Uchifune[2], Koji Tojo[3], Tadaaki Tsutsumi[4], Mike D. Picker[5], Leonie Pretorius[6]

[1]Sugadaira Montane Research Center, University of Tsukuba, Sugadaira Kogen, Ueda, Nagano 386-2204, Japan, [2]Yokosuka City Museum, Fukadadai, Yokosuka, Kanagawa 238-0016, Japan, [3]Department of Biology, Faculty of Science, Shinshu University, Matsumoto, Nagano 390-8621, Japan, [4]Department of Environmental System Management, Faculty of Symbiotic Systems Science, Fukushima University, Fukushima, Fukushima 960-1296, Japan, [5]Zoology Department, University of Cape Town, Rondebosch 7700, Cape Town, South Africa, [6]ARC-Plant Protection Research Institute, Private Bag X 134, Queenswood, Pretoria 0121, South Africa

Egg structures: Eggs of *Karoophasma biedouwensis*, *Sclerophasma paresisensis*, *Hemilobophasma montaguensis*, and Austrophasmatidae gen. sp. were examined. The egg is ellipsoidal and more than 2 mm long. Anterior *ca*. 15% "cap region" and "body region" are distinguished. The egg membrane is composed of: 1) the fibrous thin outermost surface layer which forms a polygonal pattern on the egg surface, 2) the chorion which is composed of the exochorion with numerous long outer projections and endochorion vertically crossed by numerous striations, and 3) the fine vitelline membrane. The organization of egg membranes being specialized in the cap region, three zones 1-3 are distinguished: the posteriormost zone 1 is equipped with circular-arranged micropyles; the mid zone 2 is weak in structure, to be torn at hatching.

Embryonic development: As we have not succeeded in breaking the egg diapause yet, our knowledge on the mantophasmatodean embryology has not progressed after XXII ICE 2004, where we reported some prekatatrepsis stages of *Sclerophasma paresisensis*. The mantophasmatodean embryonic development is characterized by some features such as the typical short-germ-band embryogenesis and the special type of blastokinesis in which the embryo largely elongated at the egg surface shifts its position deeply into the yolk.

Phylogenetic remarks: Among the orthopteroid groups, it is only Grylloblattodea that possess a set of basic features of the egg membranes and the special manner of blastokinesis as shown in Mantophasmatodea, strongly suggesting the assemblage "Mantophasmatodea + Grylloblattodea."

Entomopathogenic fungus for the control of adult Anophelines in Tanzania

Tanya Russell[1], Ladslaus Mnyone[1], Dickson Lwetoijera[1], Gerry Killeen[2]

[1]Ifakara Health Research and Development Centre, Ifakara, United Republic of Tanzania, [2]Durham University, Durham, United Kingdom

Malaria is one of the most prevalent infectious diseases in the tropics. Annually, more than 500 million people become infected, with >1 million deaths. Malaria control efforts are limited by the development of *Plasmodium* resistance to drugs, *Anopheles* resistance to synthetic insecticides, the logistical difficulties in retreating insecticide-treated bednets and a general lack of funding in resource-poor countries. As such, there is an ongoing need for research into novel techniques which can be used to control vector mosquitoes. Our aim is to develop formulations of entomopathogenic fungi that can be incorporated into existing integrated malaria control programs. The fungal formulations will first be developed strategically. During laboratory trials we will identify the optimal fungal strain or co-formulation, concentration and delivery methods. This information will be used to design focused experimental hut trials to examine the efficacy of the most promising fungal formulations in the field. Sequentially, we plan to evaluate the efficacy of the newly developed technique at a village scale. The village scale trial will compare the biodemographics of the mosquito populations before and after the implementation of the fungus in two villages in rural Tanzania. The information derived from this work will highlight the efficacy of the formulations under real-life situations and provide essential information that will allow fungus formulations to be scaled up for use in national control programs.

Effects of environmental stress on efficacy of *Beauveria bassiana* for stored-product pest suppression

Jeff Lord

USDA-ARS, Manhattan, Kansas, United States

Manipulation of environmental conditions is perhaps the most benign of the pest control practices that are currently in wide use for stored-product insects. Several resulting changes favor the performance of *Beauveria bassiana* as a mycoinsecticide. Perhaps most surprising is that for many insects, the fungus's efficacy is best under dry conditions that are stressful to the insect. We have demonstrated this phenomenon for larval and adult *Rhyzopertha dominica* and *Tribolium castaneum*, larval *Plodia interpunctella*, and adult *Sitophilus oryzae* and *S. zeamais.* We did not find an efficacy enhancement with desiccation of adult *Cryptolestes ferrugineus*, larval *Lasioderma serricorne* or larval *Oryzaephilus surinamensis*. Temperatures from ca. 10-26°C favor the fungus primarily due to its lower temperature optimum for growth than those of the target insects. The effects of modified atmospheres are less clear. With *T. castaneum* as our test insect, oxygen reduction to 5% as opposed to CO_2 elevation to 40% for the first 72 h of fungus exposure resulted in greater larval mortality than fungus exposure under ambient atmospheres. Both treatments slowed beetle development, which would favor fungal efficacy. CO_2 elevation, but not O_2 reduction affected the mortality of adults that were exposed to the fungus. CO_2 elevation significantly reduced *B. bassiana*'s germination and growth rates, but oxygen reduction did not. Stresses are associated with a plethora of physiological effects, and determining those that influence fungal efficacy will be a long term venture

Incidence of *Ceratitis capitata* (Wiedemann) (Diptera: Tephritidae) on native fruit trees of southern Mozambique: the role of habitat quality

Silvia Mausse, Romana Bandeira

Eduardo Mondlane University/Faculty of Agronomy and Forest Engineering/Department of Forestry, Maputo, Mozambique

Introduction: This study was conducted in three Districts of southern Mozambique aiming at assessing *Ceratitis capitata* incidence on native fruit trees per site and to determine sites similarity concerning insect species diversity.

Methods: Field surveys were performed by sampling 30 x 30 m quadrangular plots in three locations per site. The locations were selected among those with natural occurrence of native fruit trees for sampling the fruit pests. *C. capitata* population density was compared with that of other insect pests on same host tree species.

Results: *C. capitata* was one of the most constant species. Highest infestations of native fruit trees were caused by *C. capitata* on *Garcinia livingstonei* and *Annona senegalensis* fruits. Constance of *C. capitata* by site was higher in Manhiça, site that observed highest fruit infestation by this insect pest. Findings in the Matutuíne site gave indications of competition between insect pest species with low insect pest diversity and high numbers of the dominant curculionid *Endaeus floralis* on *A. senegalensis* fruits. The other sampling sites were divese in fruit insect pest species. We discuss implications of habitat condition on *C. capitata* incidence.

Release of locust flight with neurochemicals

Stevenson Paul A., Buhl Edgar, Schildberger Klaus

University of Leipzig, Leipzig, Germany

Introduction: A central question in behaviour is how central pattern generators (CPGs) are activated? Our experiments refute the generally excepted notion that the CPG for insect flight is activated by octopamine and reveal an alternative, cholinergic mechanism.

Methods: Neurochemicals were applied to the deafferented thoracic ganglia of adult locusts in solution, or via micropipettes by pressure or ionophoresis. Flight activity was monitored by myograms. Amines were depleted using reserpine and this checked by immunocytochemistry.

Results: In addition to octopamine, the amines adrenaline, noradrenalin, dopamine, tyramine and histamine, but not serotonin, or the precursor amino acid tyrosine, all initiated fictive flight. Fictive flight was also initiated by acetylcholine's non-hydrolizable analogue carbachol, the muscarinic agonist pilocarpine and the acetylcholinesterase inhibitor eserine, but not by nicotine. While neither aminergic antagonists, nor amine depletion prohibited flight initiation by natural wind stimulation or cholinergic agonists, this was reversibly blocked by the muscarinic antagonist atropine. Finally, selective electrical stimulation of an identified descending giant interneurone (TCG) initiated flight within 25 ms, indicating direct activation of the CPG, and this action was selectively and reversibly blocked by atropine.

Conclusions: We suggest that flight initiating interneurones release acetylcholine which acts via muscarinic receptors to activate the flight CPG, various amines may facilitate this and tune the motor pattern, but are not essential.

Ecology of natural enemy-prey interactions: What can we learn for practical biocontrol?

Nick Birch

SCRI, Dundee, United Kingdom

The value of biocontrol as an 'ecological service' to agriculture is conservatively valued at around \$24/ha/year or approximately $\$4x10^{10}$ per year globally for all cropped land (Costanza et al., 1997). Globally, farmers spend c. $\$32 \times 10^9$/year (2004 figures) on pesticides, of which c. 25% are insecticides. Due to this intensive use of pesticides more than 500 species of insect and mite pests are now resistant to pesticides (FAO 1998) and more than 3 million pesticide-related poisonings to humans occur annually (WHO), highlighting the dangers of relying on this approach alone. As a result of environmental, economic and legislative pressures, pesticides are increasingly being used within IPM frameworks, with the aim to reduce pesticide inputs and increase and stabilise yields. IPM approaches should promote more sustainable crop protection by added value of components, although this is not always achieved (Pretty, 2005). Unfortunately, the rate of success (control target pests, reduce/replace pesticide use, provide economic and stable crop yields) for classical biocontrol initiatives as components of IPM is often only <10% (Gurr and Wratten, 1999), particularly in more variable open field environments.

In this review, possible reasons for failures and successes of biocontrol as a part of IPM will be examined. The role of genetics and evolution at three trophic levels (crop and uncultivated plants, herbivores, natural enemies), the need to understand complex interactions involving functional ecology at different scales (plant, field/farm, landscape) and the challenge to understand the 'black box' of multiple genotype x environment interactions will be discussed. Multidisciplinary case studies will be presented as examples which combine the use of molecular ecology, genetics, chemical ecology, insect behaviour, field experimentation and modelling. The aim is to build up an understanding of complex agro-ecosystems so that trophic interactions providing key 'ecological services' for biocontrol can be made more effective for farmers operating under diverse growing conditions and scales.

Adaptation to chronic nutritional stress in *Drosophila*

Tadeusz Kawecki, Munjong Kolss, Geraldine Schwaller

Department of Ecology and Evolution, University of Lausanne, Lausanne, Switzerland

Climate change does not only affect thermal and water regime experienced by insects, but many other aspects of insect ecology, including the quantity and quality of food. Adaptation to nutritional stress is thus an important aspect of evolutionary response to climate change. Using experimental evolution in Drosophila melanogaster we attempt to understand the physiological basis and life history consequences of adaptation to nutritionally poor food. During over 40 generations of selection for tolerance to chronic larval nutritional stress, our experimental fly populations significantly improved their egg-to-adult viability on poor food, without any reduction in viability on normal food. They evolved genetically smaller size and shorter developmental time. However, on both normal and poor food their relative pupal lipid content remained the same as that of unselected control populations. Despite their smaller size, the adults also show the same lifespan and no detectable decline in fecundity. This result contrasts with life history correlates of adaptation to survive periods of acute adult starvation. Our results also indicate an evolutionary trade-off between larval and adult tolerance to nutritional stress – the selected lines survive less well on poor food as adults. Finally, the selected lines show reduced associative learning performance. Thus, tolerance to nutritional stress is associated with a complex pattern of trade-offs, which may limit the potential of insect populations to adapt to climate change. We are currently studying the physiological and genomics basis of those trade-offs.

Studies on the external ultrastructure of the antennal sensilla of the adult female blackfly, *Simulium chutteri* Lewis (Diptera: Simuliidae)

Vuyisile L. Hobololo, Alan Hall, Chris Van Der Merwe

[1]ARC-Onderstepoort Veterinary Institute, Onderstepoort, 0110, South Africa, [2]University of Pretoria, Department of Veterinary Tropical Diseases, Faculty of Veterinary Sciences, Onderstepoort, 0110, South Africa, [3]University of Pretoria, Laboratory for Microscopy and Microanalysis, Pretoria, 0002, South Africa

Introduction: *Simulium chutteri*, endemic to Southern Africa, is the most important blackfly pest of livestock in South Africa. The ability of olfactory stimuli reception to influence blackfly host location behaviour has been confirmed by previous studies. However, sensory structures of *S. chutteri* responsible for stimuli reception, which elicit host location behaviour, have not yet been studied.

Methods: Wild populations of live adult female blackflies, *S. chutteri* were sweep-netted from sheep grazing in open fields along the Vaal River in the Christiana-Bloemhof area, South Africa. Live specimens were anaesthetized with diethyl ether and prepared for scanning electron microscopy (SEM) by fixation in 2.5% gluteraldehyde buffered at 0.075M sodium phosphate at pH of 7.4. After dehydration through a graded ethanol series, the specimens were critical point dried and mounted on SEM stubs with double-sided tape. Conductivity of the specimens was enhanced using RuOч vapour. Examination and micrography was done on a JEOL JSM 840 SEM, and a JEOL JSM 6000F SEM was used to obtain high resolution micrographs.

Results: Five types of sensilla were found on the antennal flagellum of *S.chutteri*, namely Type 1 sensilla chaetica (T1), Type 2 sensilla chaetica (T2), sensilla trichodea (ST), sensilla basiconica (SB) and the grooved sensilla basiconica (GSB). T1's are uniporous, thick-walled, outwardly curving sensilla protruding and occurring only around the antennal tip, whilst the T2 are thick-walled, grooved spines, outwardly curving, similarly structured as T1's, but shorter and located on the general flagellar surface. ST are thin-walled, porous, evenly distributed over the flagellum and most numerous and inwardly recurving sensilla. SB are thin-walled, consisting of two sub-types, some tapering and some club-like, shorter in the flagellomere ends than mid-region of antennal segments. GSB are thick-walled, multiporous, grooved and sparsely distributed on all flagellomeres mostly associated with SB at distal ends of flagellomeres.

Conclusions: Morphology of Type 1 and Type 2 sensilla chaetica have functional adaptations of contact chemoreceptors, whilst the structural adaptability of sensilla trichodea, sensilla basiconica and grooved sensilla basiconica is of olfactory reception.

Studies on the external ultrastructure of the antennal sensilla of the adult female blackfly, *Simulium chutteri* Lewis (Diptera: Simuliidae)

Vuyisile L. Hobololo, Alan Hall, Chris Van Der Merwe

[1]ARC-Onderstepoort Veterinary Institute, Onderstepoort, 0110, South Africa, [2]University of Pretoria, Department of Veterinary Tropical Diseases, Faculty of Veterinary Sciences, Onderstepoort, 0110, South Africa, [3]University of Pretoria, Laboratory for Microscopy and Microanalysis, Pretoria, 0002, South Africa

Introduction: *Simulium chutteri*, endemic to Southern Africa, is the most important blackfly pest of livestock in South Africa. The ability of olfactory stimuli reception to influence blackfly host location behaviour has been confirmed by previous studies. However, sensory structures of *S. chutteri* responsible for stimuli reception, which elicit host location behaviour, have not yet been studied.

Methods: Wild populations of live adult female blackflies, *S. chutteri* were sweep-netted from sheep grazing in open fields along the Vaal River in the Christiana-Bloemhof area, South Africa. Live specimens were anaesthetized with diethyl ether and prepared for scanning electron microscopy (SEM) by fixation in 2.5% gluteraldehyde buffered at 0.075M sodium phosphate at pH of 7.4. After dehydration through a graded ethanol series, the specimens were critical point dried and mounted on SEM stubs with double-sided tape. Conductivity of the specimens was enhanced using RuOч vapour. Examination and micrography was done on a JEOL JSM 840 SEM, and a JEOL JSM 6000F SEM was used to obtain high resolution micrographs.

Results: Five types of sensilla were found on the antennal flagellum of *S.chutteri*, namely Type 1 sensilla chaetica (T1), Type 2 sensilla chaetica (T2), sensilla trichodea (ST), sensilla basiconica (SB) and the grooved sensilla basiconica (GSB). T1's are uniporous, thick-walled, outwardly curving sensilla protruding and occurring only around the antennal tip, whilst the T2 are thick-walled, grooved spines, outwardly curving, similarly structured as T1's, but shorter and located on the general flagellar surface. ST are thin-walled, porous, evenly distributed over the flagellum and most numerous and inwardly recurving sensilla. SB are thin-walled, consisting of two sub-types, some tapering and some club-like, shorter in the flagellomere ends than mid-region of antennal segments. GSB are thick-walled, multiporous, grooved and sparsely distributed on all flagellomeres mostly associated with SB at distal ends of flagellomeres.

Conclusions: Morphology of Type 1 and Type 2 sensilla chaetica have functional adaptations of contact chemoreceptors, whilst the structural adaptability of sensilla trichodea, sensilla basiconica and grooved sensilla basiconica is of olfactory reception.

Assessment of blackfly (Diptera: Simuliidae) abundance along the Vaal and Orange Rivers in South Africa with reference to potential biological control approaches

Chantel de Beer, Solly Boikanyo, Karin Kappmeier Green

ARC-OVI, Pretoria, South Africa

Introduction: Blackflies (Diptera: Simuliidae) are major pests in the livestock and labour-intensive farming systems in South Africa. Presently blackflies are controlled with the larvicide *Bacillus thuringienses* var. *israelensis* (b.t.i.). As part of the establishment of an environmentally friendly and cost effective Integrated Pest Management program (IPM) against blackflies, investigations were initiated to support the present blackfly control strategy in South Africa. Emphasis was placed on potential predators and parasites of the blackflies' aquatic stages.

Methods: Thirteen sites along the Orange river, 12 along the Vaal river and one site along each of three tributaries to the Vaal river were monitored seasonally for one year. The abundance of the aquatic stages of blackflies and potential predators on rocks and vegetation in the river were determined using the 10-point visual ranking system of Palmer (1994) and the South African Scoring system (SASS 5), respectively. The abundance of algae, which may influence the efficacy of b.t.i, was also monitored.

Results: The four most abundant blackfly species were *Simulium damnosum* s.l,, *S. adersi*, *S. chutteri* and *S. nigritarse sl.* The most important families of predators identified were Coenagrionidae, Aeshnidae, Corydalidae, Hydropsychidae and Muscidae. Hydropsychidae was the only family recorded in high numbers. Nematode and Protozoan infection of the blackfly larvae and pupae were noted. The most abundant algae were species of *Baccillariophyceae* and *Chlorophyceae.*

Conclusion: The contribution of each of these potential predators and parasites needs to be evaluated for possible integration into an IPM approach.

Neonicotinoid resistance status of green peach aphid, *Myzus persicae* (Sulzer) (Hemiptera: Aphididae), in Turkey

A. Sibel Velioglu[1], Cem Erdogan[1], M. Oktay Gurkan[2], Graham D. Moores[3]

[1]Plant Protection Central Research Institute, Department of Physiology and Toxicology, Ankara, Turkey, [2]University of Ankara, Faculty of Agriculture, Department of Plant Protection, Ankara, Turkey, [3]Rothamsted Research, Harpenden, United Kingdom

Imidacloprid is the first authorized neonicotinoid in Turkey (1994). Following this, in 1996 acetamiprid, in 2000 thiamethoxam and in 2004 clothianidin were also authorized. Neonicotinoids are used heavily in vegetable, ornamental, cotton and similar important agro-ecosystems in green house and field conditions against aphids, whiteflies and other important pests. Related to their low cost advantage, usage rates are increasing more and more in Turkey, like in some other countries. Therefore, reduced susceptibilty rates are begun to monitor on pests in many agro-ecosystems.

Myzus persicae, is a polyphagous pest, which can easily found in many agro-ecosystems in Turkey. During this study, different populations that collected from heaviest insecticide used vegetable green houses and fields were assessed for cross-resistance risks refer to their LC_{50} values of authorized neonicotinoids of Turkey. Furthermore, same populations were also investigated on the relations of two metabolic enzymes - carboxylestrease and glutathione-S-transferase - with cross-resistance formation.

During our studies, 9 different populations from two important agricultural regions were used to determine LC_{50} values against imidacloprid, acetamiprid, thiamethoxam and clothianidin. Conducted systematic bioassay studies showed that; determined LC_{50} values for imidacloprid and acetamiprid has been higher than the values of thiamethoxam and clothianidin. The resistance rates of some populations were determined as follows; over than 200 fold in acetamiprid, 100 fold in imidacloprid, 10 fold in thiamethoxam and 20 fold in clothianidin. Related to the metabolic enzymes, carboxylesterase activity observed with both techniques the gel electrophoresis and the kinetic microplate assay. On the other hand the glutathione-S-transferase measured just with kinetic microplate assay.

Outbreak of erythrina gall wasps and control strategies based on their biology

Man-Miao Yang[1], Gene-Sheng Tung[2], Yen-Chiu Lan[3], En-Cheng Yang[4], Chia-Chin Hsu[2], Chun-Chern Fangjian[1]

[1]Department of Entomology, National Chung Hsing University, Taichung 402, Taiwan, [2]Division of Forest Protection, Taiwan Forestry Research Institute, Taipei 100, Taiwan, [3]Department of Resources and Environment, Tainan 709, Taiwan, [4]Department of Entomology, National Taiwan University, Taipei 106, Taiwan

Introduction: Since the report of erythrina gall wasp (EGW), *Quadrastichus erythrinae* (Hymenoptera: Eulophidae) in 2004, it has widely spread into various countries in Asia, pacific islands, and recently found in Florida. EGW form galls on the leaflets, petioles, and tender shoots of coral trees (*Erythrina* spp.). Heavy infestation causes curling of leaves and shoots, decline of plant health, defoliation, and possible death. Besides the emergent treatment, study of its basic biology is important for a better control of this significant invasive pest.

Methods: Various aspects of studies were conducted to understand basic biology of EGW, including life history, mating behavior, gall development, natural enemies, progressive stages of infestation, visual preference of adults, and investigation of population fluctuation in various regions of Taiwan. Further control strategies are recommended based on these results.

Results: The life cycle of EGW is 24.4 ± 1.2 days under 30℃ and 70-80% Rh. Significant differences were found in adult life between feeding with water and with diluted honey. Modifications of gall tissue from normal part only involve with increasing layers of cells but not obvious differentiation. At least four species of possible natural enemy are found, including a confirmed external parasitoid of EGW larvae which is well established in various populations in Taiwan. The sex ratio of male to female is slightly higher than one. The preference in wave-length using calibrated color paper shows a discrepancy between male and female. Four stages of damage levels are determined and treatment strategies are advised for each stage.

Conclusions: A better understanding of fundamental biology is essential for successful management of invasive pests. Our results cast some light on effective controlling strategies of EGW and further practical studies, such as biological control using parasitoids, are needed.

Hypersensitivity reactions in rice cultivars and effects on the morphology and development of the African rice gall midge, *Orseolia oryzivora* Harris and Gagné (Diptera: Cecidomyiidae)

Adebayo Omoloye

University of Ibadan, Ibadan, Oyo State, Nigeria

Introduction: Hypersensitivity responses (HR) in plants are physical, nutritional and allelochemical features that change in a plant's physiological, biochemical or morphological constituents following damage or stress by invasion of a herbivore. HR is presumed to be beneficial to the eliciting host plants since they hinder the performance and/or preference of invading herbivore. The relevance of HR as a mortality factor acting upon the African rice gall midge, *Orseolia oryzivora* in the resistant Africa (Tog) rice was investigated

Methods: Morphological changes after infestation in five different rice cultivars were recorded and data on rice reactions: gall length, colour, time to gall initiation, rate of gall development, period of development at each instar, number of pupae that emerged per treatment and number of larvae that survived to each instar were taken.

Results: Gall setting was the main morphological response to attack by the AfRGM and this occurred at the first instar. Many larvae may colonize a tiller but only one survives usually to 2nd instar in the field. Gall length was significantly suppressed in the resistant *O. glaberimma* cultivars compared to the *O. sativa* cultivars. Larval mortality (98%) in resistant cultivars was significantly higher at the first instar compared to the susceptible check. The female reproductive anatomy was negatively affected by HR causing reduced potential fecundity (32); morphological distortion, 70% reduction of egg size of F1 emergent in resistant cultivars.

Conclusion: The combined effects of hypersensitive reaction and probably other heritable factors of which type and amount phytosterol content are implicated.

Tentative phylogeny of Ditrysian Lepidoptera based on molecular data from mitochondrial and nuclear genes

Marko Mutanen[1], Lauri Kaila[2], Niklas Wahlberg[3]

[1]Zoological Museum, Department of Biology, University of Oulu, Oulu, Finland, [2]Finnish Museum of Natural History, Zoological Museum, University of Helsinki, Helsinki, Finland, [3]Laboratory Genetics, Department of Biology, University of Turku, Turku, Finland

Introduction: The Lepidoptera is one of the four megadiverse insect orders, yet the interrelationships between the superfamilies within it are poorly resolved. This situation is particularly true in the suborder Ditrysia, which comprises more than 99% of all Lepidopteran species. This study primarily aims at resolving the family-group relationships of the Ditrysian Lepidoptera using data from eight molecular markers.

Methods: One mitochondrial and seven nuclear genes (a total of 6472 basepairs) were sequenced from over 250 species representing ≈37 Lepidopteran superfamilies, ≈95 families and ≈195 subfamilies. Parsimony and Maximum Likelihood trees were constructed using TNT and RAxML, respectively

Results: The results further support the monophyly of Ditrysian Lepidoptera. Systematic placement of many previously unplaced Ditrysian lineages is clarified and several major lineages are reassigned. Insights into the phylogeny of most advanced non-Ditrysian Lepidoptera are gained as well.

Conclusions: Large molecular and morphological datasets combined with quantitative cladistic analyses are shedding new light to Lepidopteran phylogeny. It is foreseeable that the ongoing molecular and morphological Lepidoptera phylogeny projects will contribute at stabilizing the systematics of many poorly understood major Lepidopteran lineages.

Insecticide resistance status of *Trialeurodes vaporariorum* (Westw.) (Hemiptera: Aleyrodidae) in Turkey and resistance related biochemical markers

Cem Erdogan[1], A. Sibel Velioglu[1], M. Oktay Gurkan[2], Graham D. Moores[3], Ian Denholm[3]

[1]Plant Protection Central Research Institute, Department of Physiology and Toxicology, Ankara, Turkey, [2]University of Ankara, Faculty of Agriculture, Department of Plant Protection, Ankara, Turkey, [3]Rothamsted Research, Harpenden, United Kingdom

The greenhouse production in turkey mainly focused on vegetable production, which represents approximately 95% of total greenhouse production. A whitefly species, *Trialeurodes vaporariorum*, is very harmful to the greenhouse vegetable growing. Control of the whiteflies is very difficult because of their fast reproduction capacity, their ability to give several offspring in a agricultural production season, behavioural preferences of the both the adults and larvae to live on under surface of the leaf, and also having many host plant.

Therefore, the chemical control methods are heavily used in whitefly control. For the last 20 year, approximately, whitefly control is based on conventional insecticides as organophosphorus, carbamates and synthetic pyrethroids.

During our studies, insecticides from organophosphorus, synthetic pyrethroids and neonicotinoids were used. Eight different whitefly populations collected from the Turkey's heaviest insecticide used greenhouses, and compared regarding to their LC_{50} values by leaf dip and systemic bioassay methods. All populations showed higher resistance rates to the synthetic pyrethroids rather than other groups. During the studies, an evaluation of cross resistance was done according to different sorts of pesticide groups. Also, the activities of the metabolic enzymes (EST and GST), which were used as biochemical markers, are determined with microplate assay and then the relation between determined values and resistances discussed.

Tribolium species as models for chemical ecology and proteomic studies in insects

Taofic Alabi[1], Frederic Francis[1], Georges Lognay[2], Edwin Depauw[3], Eric Haubruge[1]

[1]Gembloux Agricultural University,Functional and Evolutionary Entomology, Gembloux, Belgium, [2]Gembloux Agricultural University,Analytical Chemistry, Gembloux, Belgium, [3]University of Liege, Mass Spectrometry Laboratory, Liege, Belgium

Introduction: Insects constitute pests in food products. Most of them received considerable attention from entomologists to reduce their damages and related economical impacts. Public criticisms, increasing of insect resistance and bad health and environmental effects of traditional chemical controls provided the need for novel and global patterns of insect control based on knowlegde of all biology aspects. Particularly, the stored product pests including Tribolium castaneum and related species were very studied for their response to several conventional chemical and innovative biological control methods. To investigate the relation between stored product pests and their environment, T. castaneum was selected to develop several complementary approaches including chemical ecology and molecular biology to better understand their behaviour and physiology and to be able to promote potential new control strategies such as the use of semiochemicals.

Methods: *Tribolium* species were selected as models to investigate an integrated view of insect communication by smell and taste. Beside behavioural assays and volatile compound analysis using gaz chromatography and electrophysiology to identify active infochemicals, complementary proteomic approach to identify active proteins in sensory organs by 2-D electrophoresis and mass spectrometry technics were performed.

Results: Behavioural and electrophysiological observations on T. castaneum and closed species were related volatile analysis and lead to the conclusion that several molecules were actively involved in the chemical communication of these species. Moreover, proteomic studies using very recent available genomic data's on antennae and legs of Tribolium species allowed us to identify proteins involved in the insect infochemical perception (CSP and OBP).

Phylogeny of Zygaenoidea and the evolution of larval locomotion, chemical defence and mimicry

Shen-Horn Yen[1], Marc Epstein[2], Oliver Niehuis[3]

[1]Department of Biological Sciences, National Sun Yat-Sen University, Kaohsiung, Taiwan, [2]Plant Pest Diagnostics Branch, California Department of Food & Agriculture, Sacramento, CA, United States, [3]School of Life Sciences, Arizona State University, Tempe, AZ, United States

The family-level classification and phylogeny of superfamily Zygaenoidea has been controversial for long. Currently it comprises 12 families: Heterogynidae, Zygaenidae, Lacturidae, Phaudidae, Himantopteridae, Somabrachyidae, Epipyropidae, Cyclotornidae, Megalopygidae, Dalceridae, Aididae, and Limacodidae plus several genera that have not been properly associated with any family. The monophyly of this superfamily are weakly supported by two morphological characters, the retractile head of the larva (at least in the later instars) and the second abdominal spiracle of the pupa, which is covered by the wings, but recent molecular phylogenetic studies have shown that the parasitic Epipyropidae and Cyclotornidae are more related to the cossoids. In the present study, we will address the research history of Zygaenoidea and in particular focus on the evolutionary trends of larval locomotion, chemical defence mechanisms and the complex mimetic coloration. We will also focus on the evolution of a peculiar functional and morphological replacement of male claspering apparatus by pregenital sternite and tergite, which is possibly one of the key innovations leading to diversification of several clades of this superfamily.

Ultrastructural and biochemical alterations in *Spodoptera litura* larvae treated with destruxin from *Metarhizium anisopliae* (Metch.)

Kandregula Sowjanya Sree, Vadlamani Padmaja

Andhra University, Visakhapatnam, Andhra Pradesh, India

Destruxin is a cyclodepsipeptidic mycotoxin produced by the entomopathogenic fungus, *Metarhizium anisopliae* and is of use in insect pest management with respect to its potent insecticidal properties. The crude destruxin treated *Spodoptera litura* larvae showed a decrease in thiol content and a hike in oxidation of glutathione to glutathione disulfide and ascorbate to dehydro ascorbate in a time (1, 24, 48 hours) and dose (LD_{30}, LD_{50}, LD_{90}) dependent manner. Apart from this evidence of the adverse effect of destruxin, an increase in the protein carbonyl levels which indicate the extent of protein oxidation or damage and the free radical levels (Hydrogen peroxide and hydroxyl radical) was also noted. These provide a clear indication of oxidative stress induced by crude destruxin on *S. litura* larvae. These biochemical changes in the larval body correlated with the ultrastructural alterations in the salivary glands of the larvae treated with LD_{50} (0.147 µg/g body wt.) of crude destruxin for 24 hours. These changes were noted from the transmission electron microscopic observations. The gradual detachment and damage of the microvilli from the epithelial cell surface was very clearly observed. Epithelial cell vacuolization, bleeding of the epithelial cells into the salivary gland lumen and disruption of the epithelial cell membrane were amongst the other major ultrastructural changes. The present investigation focuses salivary glands also as the target organ of destruxin apart from the already reported midgut, Malphigian tubules and haemocytes. The current study unravelled the role of larval innate antioxidant defence system in augmenting resistance or susceptibility against crude destruxin and the mode of action of this toxic metabolite on the larval body.

Pest risk analysis of importation of banana propagation materials from Uganda to Rwanda

Solomon Gebeyehu

Private, Africa, South Africa

The pest risk analysis of the importation of propagation materials from Uganda to Rwanda for the purpose of improving banana production was studied. A qualitative pathway-initiated pest risk analysis was done using the Crop Pest Compendium database compiled by the Common Wealth Agriculture Bureau International. The database provided several pests of potential quarantine importance to Rwanda, of which three were analyzed for their potential to enter, establish, spread and cause economic impact. The objective was to demonstrate the importance of doing pest risk analysis and decide appropriate phytosanitary measures by Rwanda before allowing importation of banana propagation materials from Uganda.

Individual risk factors were summarized as overall risk category for each of the insects. *Araecerus fasciculatus* had an overall high risk category as the banana propagation material could be a pathway for the entry of the pest into Rwanda, and favorable environmental conditions for its establishment as well as cultural practices that can aid its rapid spread would lead to significant yield loss to a wide range of major host plants which are of economic importance in Rwanda, once introduced. *Thrips hawaiiensis* showed medium risk as banana propagation materials are not direct pathway for this pest and the risk could be reduced by avoiding leaf materials in the consignment with which the insect is associated. Pest risk category for *Ceratitis capitata* was low as the pest only attacks fruits/pods and not banana propagation parts. The principles of pest risk analysis for trade with plants and plant materials is discussed.

Natural polymorphism affecting learning and memory

Tadeusz Kawecki[1], Frederic Mery[2], Amsale Belay[3], Marla Sokolowski[3]

[1]Department of Ecology and Evolution, University of Lausanne, Lausanne, Switzerland, [2]CNRS, Gif sur Yvette, France, [3]Department of Biology, University of Toronto, Toronto, Canada

Although numerous mutants with impaired learning have been identified, we know little about the genetic basis of natural variation in learning performance. Yet, it is on the basis of this variation that evolution moulds the learning ability and memory of a species. We have shown that a natural polymorphism in the gene *foraging* affects the ability of *Drosophila melanogaster* to learn which oviposition substrate is of high quality. Using a classical conditioning paradigm where flies are trained to avoid an odour associated with shock we could also show that the *foraging* polymorphism has antagonistic effects on two aspects of learning performance. Flies carrying the 'rover' allele have better short-term performance, but poorer long-term memory than flies homozygous for the 'sitter' allele. The *foraging* gene encodes a cGMP-dependent protein kinase (PKG). Using the GAL4-UAS system we could show that the effects of *foraging* on learning are mediated by the activity of PKG in the mushroom bodies of the fly brain. The *foraging* polymorphism has several pleiotropic effects and is thought to be maintained by balancing selection. This study thus offers insights into how ecology and genetics may combine to maintain variation for and create associations between behavioural traits.

Control of Colorado potato beetle, *Leptinotarsa decemlineata* Say (Coleoptera: Chrysomelidae), with the neonicotinoid thiamethoxam

Philippos M. Ioannidis[1], Zois D. Zartaloudis[1], Ioannis Papageorgiou[2]

[1]National Agricultural Research Foundation– Plant Protection Institute, P.O. Box 60324, ZIP 570 01,Thermi, Thessaloniki, Greece, [2]Syngenta Hellas SA, Anthousas Ave, Attiki, ZIP 153 49, Athens, Greece

Introduction: The Colorado potato beetle (CPB) is the most serious pest of potatoes in many regions of the world including Greece. This pest has an extraordinary ability to develop resistance almost to all groups of insecticides used to control it. Effective insecticide resistance management strategy aims to apply the least – insecticide amount on the population in order to conserve susceptibility. The method of spraying thiamethoxam directly on the potato tubers before sowing provides excellent protection.

Methods: Thiomethoxam (Cruizer 350 FS) which has a systemic action was sprayed (0.5lt water spray volume) just before sowing (beginning of May) at doses of 14, 20 and 28g of commercial product per 100 kg seeds tubers. Several preliminary trials and field experiments were conducted and the experimental design was a completely randomised block design with four replications. Harvesting was conducted in the middle of September.

Results: All the doses applied gave excellent control 45 days after sowing. Potato plants were satisfactorily protected even 60 days after sowing with less than 10% compared to the untreated control with more than 50% leaf damage.

Conclusions: This method gives a very good protection even from the early beginning of the growing season; keeps clear the plants from CPB damage even if the weather conditions are not ideal for alternative foliage spraying. This method has also an advantage of controlling early attacks of aphids and low impact on beneficial insects as well. This crop protection technique is strongly recommended particularly in regions where CPB severely damages potatoes.

Circadian plasticity of neurons and synaptic contacts in the fly's visual system

Elzbieta Pyza, Jolanta Gorska-Andrzejak

Department of Cytology and Histology, Institute of Zoology, Jagiellonian University, Krakow, Poland

Introduction: In the fly's visual system L2 interneurons show circadian plasticity in size of their axons. In addition the number of tetrad synapses formed between the photoreceptors and the L2 cells change during the day. We examined if morphology of the L2 dendrites, postsynaptic sites of the tetrads, and expression of their synaptic proteins are controlled by clock genes.

Methods: Flies were fixed at different times of the day and their brains sectioned. The L2 dendritic trees was examined by confocal microscopy. The L2 cells were visualized by expression of GFP in result of activation of a UAS-*gfp* reporter construct by the GAL4 enhancer-trap line 21D. Immunocytochemistry was used to detect pre- and postsynaptic proteins of tetrad synapses.

Results: The L2 dendritic trees were largest at the beginning of the day and of the subjective day in constant darkness. The rhythm was abolished in per^{01} but its pattern was changed in cry^{b} mutants. The tetrad presynaptic and postsynaptic proteins showed daily rhythms of their abundance. Only in case of the postsynaptic protein the rhythm was circadian.

Conclusions: The lamina L2 dendrites show circadian remodeling of their shape and this rhythm is controlled by clock genes. The presynaptic elements of tetrad synapses seem to be controlled by daily changes of light while the postsynaptic ones by a circadian clock.

Movement of non-native phytophagous Hymenoptera in Asia

Gene-Sheng Tung[1], Man-Miao Yang[2], Chia-Chun Hsu[3], Chia-Chin Hsu[1], Yuh-Shyong Yang[4]

[1]Division of Forest Protection, Taiwan Forestry Research Institute, Taipei 100, Taiwan, [2]Department of Entomology, National Chung-Hsing University, Taichung 402, Taiwan, [3]Division of Silviculture, Taiwan Forestry Research Institute, Taipei 100, Taiwan, [4]Department of Biological Science and Technology, National Chiao-Tung University, Hsingchu 300, Taiwan

Introduction: Various invasive phytophagous hymenopterans were reported in Asia and some cause severe damages to their hosts. Among these, the erythrina gall wasp (EGW), *Quadrastichus erythrinae* (Hymenoptera: Eulophidae) is a notorious one which forms galls and causes acute and severe damages on coral trees (*Erythrina* spp.). We reported the spread of EGW in Asia, and analyze the movement pattern of this pest geographically and biologically. Moreover, other cases of invasive wasps are reviewed.

Methods: The species distribution model was used to evaluate the potential distribution of EGW. Phylogenetic analysis was conducted based on molecular data for samples from various populations of Taiwan and different countries.

Results: The temporal distribution of EGW shows a progressive pattern geographically from west forward east direction or from Indian Ocean to Pacific Ocean. Models indicated EGW is confined to tropical area, and the Infection-unreported areas with the occurrence of host records are potential regions of EGW attack. Furthermore, prediction of the future expansion of is discussed. The molecular data confirm the con-specific status of EGW which occurred in various populations on different host species of Taiwan. The relationships of EGW from different countries are discussed based on molecular phylogeny.

Conclusions: The result of this analysis provides a better understanding of the movement of invasive EGW and an alert of its future expansion. It also offers a model for the study of other recently occurred invasive hymenopteran pests.

Xylosandrus germanus: A long established, but emerging invasive pest in U.S. nurseries

Christopher Ranger, Michael Reding

USDA-Agricultural Research Service, Wooster, OH, United States

Since first being detected in the U.S in 1932, the exotic ambrosia beetle *Xylosandrus germanus* is increasingly being recognized as a key pest of nursery trees, particularly deciduous hosts. Despite being mainly considered as a secondary attacker, a growing body of evidence indicates *X. germanus* will colonize apparently-healthy trees. A series of experiments were conducted to elucidate the influence of abiotic and biotic factors on the colonization strategy of *X. germanus*. The impact of prolonged winter dormancy on host-attraction to *X. germanus* was assessed using kousa dogwoods, *Cornus kousa*. Groups of dormant *C. kousa* trees were held for varying lengths of time in cold storage to experimentally-induce progressive phenological stages. *Cornus kousa* trees ranging from dormant to post-dormant were then simultaneously placed adjacent to woodlots just prior to *X. germanus* peak flight activity. The influence of phenological stage on host-attractiveness and colonization by *X. germanus* will be described. Complementary experiments focused on the interaction between flood stress and pathogenicity of *X. germanus* fungal symbionts. Sweetbay magnolia, *Magnolia virginiana*, trees under adequate and flood-stress irrigation conditions were inoculated with either *Ambrosiella hartigii* or a second unidentified *Ambrosiella* sp. isolated from the mycangium of *X. germanus*. Volatiles collected and identified from the *M. virginiana* treatments were subsequently assessed for their attractiveness to *X. germanus*. Fungal pathogenicity and the attractiveness of host-plant volatiles to *X. germanus* will also be described. Understanding the influence and interaction among these factors is critical to improving the management and detection of *X. germanus* in the nursery agroecosystem.

Immunization studies in rabbits using gut membrane-bound proteins derived from *Rhipicephalus appendiculatus, R. evertsi evertsi* and *Amblyomma variegatum* female ticks

Helen Lydia Kutima, Adepapo Amoo, Mabel Imbuga, Philip Kutima

Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

The objective of this study was to immunize rabbits with Gut Membrane-Bound Proteins (GMBP) derived from partially engorged *Rhipicephalus appendiculatus*, *R. evertsi evertsi* and *Amblyomma variegatum* female ticks and to assess whether the elicited immunity was protective against both homologous and heterologous tick instars and to isolate and identify the protective antigens.

Sodium dodecyl sulphate-polyacrylamide gel electrophoresis (SDS-PAGE) of the GMBP antigens demonstrated protein bands with molecular weights ranging from 16 to 140 KDa. Thirty-seven, 45 and 39 protein bands were fractionated from *R. appendiculatus*, *R. evertsi evertsi* and *A. variegatum* GMBP antigens, respectively, all possessing molecular weights ranging from 14 to 140 KDa. Twenty-two of the isolated proteins were shared among the three tick species. Immunized rabbits acquired resistance to challenge infestation by all instars of the three tick species. Resistance was manifested by prolonged feeding, reduction in engorgement weights, egg mass weights, moulting and percentage hatchability and increased mortality. Immunization of rabbits with GMBP antigens generated protection and cross-protection against challenge infestation with homologous and heterologous instars, respectively. Cross-protection was more pronounced in the homologous than heterologous systems.

Enzyme-Linked Immunosorbent Assay (ELISA) technique detected circulating antibodies in the anti-sera to GMBP from homologous and heterologous systems one week after the primary dose. Ouchterlony double immunodiffusion reactions with anti-tick GMBP sera formed 2 to 3 precipitin lines with homologous GMBP antigens and one to two precipitin line(s) with each heterologous GMBP antigens. A line of complete identity was observed when anti-sera to GMBP antigens reacted with GMBP from homologous and heterologous tick species, suggesting common antigenic epitopes.

Western blot analysis on GMBP of *R. appendiculatus*, *R. evertsi evertsi* and *A. variegatum* with sera from immunized rabbits detected protein bands specific to the homologous GMBP antigens, and revealed considerable cross-reactions in the heterologous systems. These results suggested further the presence of common antigens. The presence of cross-reacting antigens conferred cross-protection.

The influence and control of invasive pests in commercial forestry plantations in South Africa

Bernard Slippers[1], Brett P. Hurley[1], Jolanda Roux[2], Michael J. Wingfield[1]

[1]Department of Genetics, Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa, [2]Department of Microbiology and Plant Pathology, Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa

South Africa has approximately 1.5 million hectares of commercial plantations, consisting predominantly of *Pinus* spp., *Eucalyptus* spp. and their hybrids, and *Acacia mearnsii*. During the course of the past Century, a number of pests have impacted negatively on the productivity and sustainability of these plantations. These pests have included a large number of polyphagous native insects that have adapted to feed on the non-native plantation trees. Such pests include a number of Lepidopteran and Coleopteran defoliators and root feeders, the wattle mirid (*Lygidolon laevigatum*), the wattle bagworm (*Chaliopsis junodi*), and others. Most recently, the native cossid moth, *Coryphodema tristis*, has caused severe damage to *E. nitens* plantations. Despite the presence of natural enemies, sporadic outbreaks of these pests cause serious financial losses to the forestry industry. Of increasing concern is the introduction of non-native pests. Two of the earliest of these non-native pests to be detected in South African plantations were the Eucalyptus snout beetle (*Gonipterus scutellatus*) and the black pine aphid (*Cinara cronartii*), which caused extensive damage to *Eucalyptus* and *Pinus* plantations, respectively. In recent years, there appears to have been an increase in the number of introductions of non-native pests. Thus, three serious pests (*Sirex noctilio* on *Pinus* spp. and *Thaumastocoris peregrinus* and *Leptocybe invasa* on *Eucalyptus* spp.) have appeared in the last 15 years. Previously insecticides were typically used to control pests, but the negative environmental and financial considerations associated with this form of control has elevated the need and urgency for alternative management strategies. In this regard, biological control, host resistance and silvicultural measures are currently being applied and pursued.

The role of dopaminergic G protein coupled receptors (GPCRs) in the homeostatic regulation of the transient potassium current (I_A) in arthropod neurons

Deborah Baro, Merry Clark, Hongmei Zhang, Wulf-Dieter Krenz

Georgia State University, Atlanta, GA, United States

We are interested in how neuronal monoamine receptors transduce signals across time and space. Large, identified crustacean neurons provide excellent models for understanding the cellular properties of arthropod neurons in an intact network. The same neuron can be unambiguously identified and studied in every preparation, allowing for a detailed characterization of the spatiotemporal organization of neuronal GPCR transduction cascades. Unfortunately, because crustaceans are genetically intractable, tools for delving beyond the characterization of neuronal electrophysiological properties have been limited. Taking advantage of the extensive insect databases and the relatively close phylogenetic relationship between insects and crustaceans, we have cloned a variety of GPCRs and ion channels, including dopamine receptors and the shal channel, which mediates I_A. We study dopaminergic modulation of shal channels in two neurons, PD and LP, which exclusively express D2 and D1 receptors, respectively. Dopamine receptors are only located in a subset of nerve terminals where they modulate local proteins, as well as produce global biochemical signals that alter protein function in distant compartments, like the soma. In response to a brief application of dopamine, remote D2 and D1 receptors increase and decrease the density of the somatic I_A, respectively. On the other hand, prolonged exposure to DA induces a persistent, homeostatic adaptation in I_A that opposes the short term modulation (e.g., D2 activation decreases I_A density 10-12 hrs after DA is removed). We are currently testing the hypothesis that dopamine simultaneously and conversely alters shal channel phosphorylation and shal gene transcription to homeostatically regulate I_A density.

State-wide monitoring of mosquito insecticide resistance in Florida, USA

John Petersen

Florida A&M University, Panama City, Florida, United States

Introduction: Since 1999 a state-wide program of training workshops has increased the number of mosquito control programs that monitor mosquito response to pesticides currently in use in Florida. A standardized general procedure for insecticide resistance testing by the bottle bioassay has been published. The bioassay is based on exposure of adult mosquitoes to a diagnostic concentration of insecticide that is selected to discriminate between fully susceptible mosquitoes from those that show some level of genetic resistance.

Methods: 14 protocols have been developed detailing procedures for diluting "off-the-shelf" pesticides in A.C.S. acetone prior to testing by the bottle bioassay. Regional workshops were conducted in 37 locations throughout the state of Florida, contacting directly 46 different mosquito control programs that had not carried out insecticide resistance testing prior to our workshop.

Results: For each Active Ingredient (AI), dose response data obtained in our laboratory were subjected to probit analysis estimating the LC_{50} and LC_{95}. The diagnostic concentration we use for the bottle bioassay is defined as 2 times the LC_{95}. Baseline response of susceptible mosquitoes is determined using colony mosquitoes that have not been exposed to pesticides. Data from insecticide resistance bioassays by Florida mosquito control programs were posted to the Center's web site. This outreach program makes extensive use of the internet to disseminate standardized protocols and to share data that are the outcome of insecticide resistance testing.

Conclusions: Based on the outcome of bottle bioassays, operations supervisors can make informed, timely decisions about which products to use in mosquito control.

The efficacy of *Strychnos spinosa* (Lam.) and *Solanum panduriforme* (Incanum) fruit-extracts in controlling ticks in cattle

James Madzimure[1], Humphrey Hamudikuwanda[1], Brighton Mvumi[2], Thokozani Hove[3]

[1]Department of Animal Science, Faculty of Agriculture, University of Zimbabwe,, Harare, Southern Africa, Zimbabwe, [2]Soil Science & Agricultural Engineering, Faculty of Agriculture, University of Zimbabwe, Harare, Southern Africa, Zimbabwe, [3]Faculty of Veterinary Science, Paraclinical Veterinary Studies, University of Zimbabwe, P.O. Box MP 167, Mt Pleasant, Harare, Southern Africa, Zimbabwe

Introduction: Some Southern African farming communities have claimed that fruit-extracts of the plants *Strychnos spinosa* (Lam.) and *Solanum panduriforme* (Incanum) can be used to control ticks in cattle. In this study, the efficacy of these fruit-extracts for controlling ticks in cattle was evaluated.

Methods: Ripe *S. panduriforme* and mature but unripe *S. spinosa* fruits were pounded separately, soaked in cold water for 48 hours, and filtered through a muslin cloth to achieve concentrations of 5%, 10% and 20% (w/v). Treatments included the different concentrations of each plant species, Tickbuster (amitraz) spray (positive control) and no treatment (negative control). All the treatments were sprayed on 44 Mashona cattle at weekly intervals. Tick numbers were recorded before spraying and subsequently, daily for 43 days. Cattle blood samples were collected for piroplasms screening.

Results: Duration, post-treatment application, had an effect on tick numbers ($p < .0.05$) with tick numbers increasing with time after each spray. *S. panduriforme* was effective ($p < 0.05$) even at 5% concentration against the ticks *Rhipicephalus evertsi* and *Rhipicephalus appendiculatus*. The 10% *S. spinosa* was more effective ($p < 0.05$) than other extract concentrations against the tick *Boophilus decoloratus*. The treatments were ranked, in descending order of effectiveness, as Tickbuster, plant extract treatments, and untreated control. No piroplasms were detected implying that animals were not infected.

Conclusion: The results indicate that *S. panduriforme* and *S. spinosa* have some acaricidal effect on ticks in cattle with the former being more potent.

International activities related to Persistent Organic Pollutants (POPs) that are termiticides

Agneta Sundén Byléhn

UNEP/DTIE Chemicals, United Nations Environment Programme, Geneva, Switzerland

Introduction: Persistent organic pollutants (POPs) are chemicals of international concern since they undergo global environmental transport, persist for long periods in the environment, bio-accumulate and cause adverse effects to human health and wildlife. POPs include pesticides, industrial chemicals and unwanted by-products such as dioxins. Individual countries alone are unable to control the environmental pollution from these border crossing substances, which are found in regions where they have never been produced or used.

International Actions: Negotiations of a global legally binding instrument on POPs were started under the auspices of UNEP in 1998. The Stockholm Convention that entered into force in May 2004 aims at ultimate elimination of POPs. It presently covers twelve substances of which aldrin, chlordane, dieldrin, heptachlor, and mirex have, or are still, being used as termiticides. Other pesticides covered include DDT, endrin, hexachlorobenzene, mirex and toxaphene (camphechlor). Another set of pesticides are presently under review for inclusion under the Convention: chlordecone, endosulfane, alpha-and beta-hexachlorocyclohexane, lindane and pentachlorobenzene.

Results: UNEP / FAO collaboration on the POP termiticide issues in support of the Stockholm Convention resulted in 2000 in the establishment of the Global Termite Expert Group (GTEG), which presently has around 20 members from all regions of the world. GTEG has developed guidance and technical information to support states in implementing sustainable alternatives to POP termiticides. These and other materials are available at UNEP's website: http://www.chem.unep.ch/termites/Default.html.

Conclusion: The implementation of sustainable alternatives to POP pesticides depends heavily on guidance and technical support from the scientific and research communities.

Infection of ticks with borrelia cuts off olfactory orientation towards host kairomones

Torsten Meiners[1], Hans Dautel[2]

[1]Applied Zoology/Ecology, Free University of Berlin, Berlin, Germany, [2]Insect Services, Berlin, Germany

Nymphs of the blood-feeding tick *Ixodes ricinus* are known to move short distances towards host odour, although their main mode of host finding is ambushing passing vertebrates. Several chemicals have been identified that can mediate the olfactory orientation of the eyeless ticks that are vectors of *Borrelia sp.* causing Lyme borreliosis in humans. While tick nymphs parasitise both small and large vertebrates, large vertebrates like deer are incompetent as transmission reservoirs for *Borrelia sp.*. Thus, for borreliae transfer to a big mammal often means a dead end.

Here we investigate whether infested (*Borrelia afzelii*) ticks behave differently towards host (dogs, men) odours or certain volatile host compounds (CO_2; hexanoic acid) and whether differently infested ticks chose different heights for ambushing. We used a locomotion-compensator (servosphere) and CO_2-traps in the surroundings of Berlin, Germany, to test responses of uninfested and infested ticks to volatile kairomones. The choice of ambush heights was tested in semi-field stalk-arenas.

Uninfested ticks responded to all offered kairomones (but not to control air or plant volatiles) and chose a high ambushing position. Infested ticks on the contrary showed the same walking activity as uninfected ones, but did not orientate to any of the offered odours and chose a low ambushing position. Nymphs caught in the field by CO_2-traps showed a lower degree of infestation with *Borrelia sp.* than nymphs caught by flag sweeping. It is discussed how a possible “manipulation” of ticks by borreliae might contribute to enhance their chance of avoiding incompetent transmission reservoirs.

Fungus-growing termites maximize harvest and minimize host-symbiont conflict by growing *Termitomyces* fungi in monoculture

Duur K. Aanen[1], Henrik H. de Fine Licht[2], Alfons J.M. Debets[1], Niels Kerstes[1], Jacobus J. Boomsma[2], Rolf F. Hoekstra[1]

[1]Laboratory of Genetics, Wageningen, Netherlands, [2]Institute of Biology, Copenhagen, Denmark

Introduction: Although mutualistic symbiosis per definition provides a net benefit to the partners involved, these partners' interests are usually not completely identical. Also in the mutualistic symbiosis between fungus-growing termites and *Termitomyces* fungi, such conflicts of interest exist, for example over reproduction and the degree of symbiont mixing. Recently, a proximate mechanism on how these conflicts of interest are regulated has been proposed. The key to the proposed mechanism is the within-nest propagation mode of fungal symbionts by termites. The termites suppress horizontal fungal transmission by consuming modified unripe mushrooms (nodules) for food. However, these nodules provide asexual gut-resistant spores that form the inoculum of new substrate. This within-nest propagation implies that harvesting and inoculation are coupled. Furthermore, the inoculation of spores in high density ensures the fast establishment of a fungal colony in the new substrate.

Methods: I describe *in vitro* experiments to test the hypothesis that fusion between clonally related subcolonies, but not between non-clonally related subcolonies, leads to synergism. We compared the 'harvest' (number of nodules) of five monocultures (heterokaryons belonging to a single biological species of *Termitomyces* associated with *Macrotermes natalensis*) with the harvest of varying degrees of mixed cultures of these five strains (with two, three or five heterokaryons in all combinations) in a high density.

Results: In line with the prediction, we found a highly significant correlation between harvest and 'relatedness' (the chance to meet a clonally related subcolony in a mixture).

Conclusions: The results of these experiments imply that i) monoculture maximizes the harvest; ii) monoculture is self-maintaining as there is positive frequency-dependent selection; and iii) the termites and the resident fungus share the same short-term interest as the introduction of an unrelated fungus will initially lead to a lower harvest.

Chemical and behavioral ecology in insect parasitoids: How to behave in a complex odorous environment

Torsten Meiners, Monika Hilker

Applied Zoology/Ecology, Institute of Biology, Free University of Berlin, Berlin, Germany

Volatile cues released from the host habitat or the host itself play a key role in the foraging process of parasitoids. However, these resource-indicating odors encountered by parasitoids in their natural environment need to be detected within a huge variety of other environmental odors and are often both complex and variable mixtures themselves. Our studies address the question how egg parasitoids of herbivorous insects cope with the problems of complexity and variability of the infochemical web.

Two principal strategies to solve these problems will be shown. One strategy is to avoid areas with high odor complexity, and another one is to “dig through” all the odorous information. A successful way to disentangle complex odorous information is the combined use of innate odor preferences and learning which enhances the host finding success of a foraging egg parasitoid. A novel learning mechanism will be suggested where a chemical cue is “filtered” by a learning egg parasitoid in different odorous contexts, but a behavioral response to this cue occurs only when it is presented in a specific odourous context. Furthermore, our studies show that the spatial presentation of different volatile blends may substantially influence parasitoid orientation.

Research investigating how parasitoids actually cope with a very unstable infochemical environment can be utilised to improve the efficacy of current biological control programmes. This includes the development of novel approaches that manipulate plant diversity and environmental odor complexity and/or the use of infochemicals to control important agricultural and forest pests.

Interactions between the Bt-transgenic trait and inherent plant resistance mechanisms

Felix Wackers[1], Cristina Faria[1], Joerg Romeis[2]

[1]Lancaster University, LEC, Centre for Sustainable Agriculture, Lancaster, United Kingdom, [2]Agroscope Reckenholz-Tänikon Research Station ART, Zurich, Switzerland

Recent reports indicate that genetically modified cotton crops that express toxins derived from *Bacilus thuringiensis* (*Bt*) can suffer higher damage by *Bt*-insusceptible pests. While outbreaks of secondary pests in *Bt*-cotton have raised widespread concern, the underlying mechanisms remain poorly understood. Here we present a novel mechanism explaining increased susceptibility of *Bt* cotton to secondary pests. This will contribute to the sustainable use of transgenic varieties and effective resistance-management.

Techniques in determining the progressive stages of EGW infestation for galling pest control in Taiwan

Yen-Chiu Lan[1], Gene-Sheng Tung[2], Chia-Chin Hsu[2], Man-Miao Yang[3], En-Cheng Yang[4]

[1]Department of Resources and Environment, Leader University, Tainan, Taiwan, [2]Division of Forest Protection, Taiwan Forestry Research Institute, Taipei, Taiwan, [3]Department of Entomology, National Chung-Hsing University, Taichung, Taiwan, [4]Department of Entomology, National Taiwan University, Taipei, Taiwan

Introduction: The Erythrina Gall Wasp (EGW, *Quadrastichus erythrinae*), an Erythrina-specific galling species, has been first reproted in 2000 and listed in Global Invasive Species Database (GISD). EGW forms galls on the leaves, petioles, young shoots, and stems and has multivoltine and overlapping generations. Severe infestation causes obvious swelling and curling of young shoots, defoliation, and death of the tree. Field observation and experiments were proceeded to explore efficient pest control methods in Taiwan. Although the efficacy of chemicals is confirmed, the costs and labor are too intensive. Here we report a technique in the determination of progressive infestation stages and, therefore, better efficient strategies of pest control could be applied accordingly.

Methods: The experiments were performed from July 2006 to June 2007 in Taipei City and Tainan City. The number of galls and EGWs on the leaves and stems were counted from cut branches of infested Indian coral tree (*Erythrina variegata*). All the sampled branches were photographed. The number of galls and EGWs were plotted and the slops from liner regression were tested.

Results: Three significantly different regression lines were found. Contrast to the corresponding photograph, we may conclude that there are four progressive stages of infestation, the first three stages can be determined by gall numbers and symptoms of infested leaves and the fourth stages can be determined solely by the symptoms of infested branches.

Conclusions: The result provides a useful technique for field monitoring of infestation stages and field workers without expertise could implement it easily. The field information could be gathered instantly in determining strategies for pest control, once the infestation stage is determined, strategies for pest control could be decided.

Are neonicotinoid insecticides resistant to the evolution of resistance in aphids?

Steve Foster

Rothamsted Research, Harpenden, United Kingdom

Neonicotinoid insecticides now have widespread use for controlling insect pests. The commercial forerunner, imidacloprid, is active against species in the Hemiptera, Coleoptera, Diptera and Lepidoptera, but in agriculture is being used most intensively to control sucking pests (aphids, planthoppers, leafhoppers and whiteflies), and the Colorado potato beetle (CPB). Although resistance to imidacloprid is still relatively rare, it has evolved in tobacco and glasshouse whiteflies, CPB and brown planthoppers. Interestingly, there are no documented examples of neonicotinoid resistance, capable of causing control failures, in any aphid species even though these compounds have been in use for over fifteen years. Possible reasons for this lack of resistance are 1: neonicotinoids target the nicotinic acetylcholine receptors of nerve membranes, and these are thought to comprise complex heteropentamers of non-identical subunits that may well generate diverse binding sites for these insecticides in different sub-populations. As a result, a point mutation in one subunit may not be sufficient to confer insensitivity (resistance) across the entire population of nAChRs within the insect's nervous system. 2: in species carrying resistance it often appears to be mediated by increased activity of mixed function oxidases (MFOs) and this enzyme-based mechanism has not previously been implicated for resistance in aphids. Taken together, this may explain why resistance to neonicotinoids has been slow to evolve in aphids, although this should not lead to grower complacency since some species show a consistent low level reduced susceptibility to neonicotinoids, and this may represent the first steps toward the evolution of more potent resistance.

Analyzing complex trophic interactions in arthropod communities using DNA-based methods

Michael Traugott

University of Innsbruck, Innsbruck, Austria

DNA-based methods of parasitoid and prey detection have revolutionized the study of trophic interactions under natural conditions. For example, multiplex PCR-based parasitoid detection allows to effectively resolve the trophic connections occurring in a community of aphid parasitoids consisting of 12 primary and secondary parasitoid species. Besides determining host-parasitoid links, multiparasitism and primary parasitoid-hyperparasitoid links could be tracked at a species-specific level, providing unique insights into the trophic complexity of this parasitoid food web. Based on the parasitism rates found in field-collected aphids, another multiplex PCR system was developed to screen arthropod predators for aphid and parasitoid consumption. First results on spiders indicate, besides high levels of aphid predation, that these predators also extensively fed on adult parasitoids early in the season, revealing complex trophic interactions between the natural enemies of aphid pests.

DNA-based methods are also extremely valuable for resolving trophic links within soil food webs. For example, we have shown that besides predatory beetle larvae, centipedes (Geophilidae) are the main predators of eggs and larvae of scarabaeid beetles, serious pests within alpine grasslands. Moreover, scarab prey proved to be an important food source during summer, sustaining the predatory soil invertebrate community when earthworm prey was scarce.

Within a current project we take molecular approaches to determine trophic interactions one step further: using DNA-based gut content analysis trophic links between plants and elaterid larvae, soil-dwelling insects which feed on a variety of plants, will be determined to assess the impact of plant biodiversity on herbivore food choice.

The olfactory pathway in Attine ants

Christoph J. Kleineidam, Markus Ruchty

University of Wuerzburg, Wuerzburg, Germany

Temperature is decisive for brood development and social insects show behavioral adaptations to take care of their brood. Various behavioral responses to temperature fluctuations illustrate an amazing thermal sensitivity of e.g. ants. Recently, we showed that leaf-cutting ants can use thermal radiation for orientation and we searched for the sensillum receiving the adequate thermal stimulus.

In Sensilla coeloconica we found a very sensitive thermo-receptive neuron. Extracellular recordings of the neuronal activity revealed a phasic-tonic response and rapid adaptation. As thermal stimuli, we used both, convective heat (tempered air) and radiant heat (using a Peltier-Element) to describe the response properties. We found the sensillum to be direction sensitive to IR-radiation with best sensitivity in front of the sensillum. The sensory peg of the S. coeloconica is located in a chamber, embedded in the antennal cuticle (peg-in-pit sensillum), and only a tiny aperture within the thin apical cuticle of the sensillum connects it to the environment. This embedding probably attenuates rapid fluctuations of air temperature and results in the direction sensitivity to IR-stimuli. Based on both, response property of the receptor neuron and morphology, we conclude that the S. coeloconica of leaf-cutting ants are morphological IR-sensilla, suited to detect rapid changes in the thermal environment. This newly described IR-sensillum may allow ants to assess spatial information about their thermal environment.

Funding: DFG SFB 554/A6

Trick or treat - effects of an invasive plant on survival and resource sharing in Irish bumblebees

Anke Dietzsch, Jane Stout

Trinity College Dublin, Dublin, Ireland

Introduction: Invasive plant species have become a major concern in recent years because they alter native ecosystems and processes such as plant-animal interactions. Little is known about their impacts on pollinators. Pollinator communities may benefit if alien plants offer valuable resources or substitute declining native plants. Alternatively, they may be harmed by alien toxic secondary compounds, or by displacement of native plants.

Methods: We used *Rhododendron ponticum* as a model plant species to investigate its effects on native bumblebees. *R. ponticum* is severely invasive in Ireland and contains grayanotoxins. To test the suitability of alien floral rewards as bumblebee food we caged workers of *Bombus lucorum* and kept them under six feeding regimes. We also estimated and compared numbers of bumblebee colonies utilising invaded and uninvaded field sites by genotyping workers of *B. lucorum* and *B. pascuorum* at six microsatellite loci and reconstructing sisterhoods among the individuals.

Results: Neither nectar and pollen of *R. ponticum* nor food containing a toxin similar to grayanotoxin reduced the survival rate of bumblebee workers significantly compared to native nectar and pollen or commercial bee food. Invaded field sites were used by a higher number of colonies of both bumblebee species than uninvaded field sites.

Conclusions: Rewards of *R. ponticum* do not harm worker bumblebees, and represent a valuable foraging resource for native bumblebees. As a result, invaded plant communities can support more colonies of social bumblebees than native plant communities do, perhaps by the alien plant facilitating the establishment of bumblebee queens.

A largely unstudied wealth of galls, gall-inducers and associated insects on indigenous South African plants

Stefan Neser

Agricultural Research Council, Plant Protection Research Institute, Pretoria; and Forestry and Agricultural Reseach Institute, University of Pretoria, Pretoria, South Africa

Introduction: Despite a vast diversity of galls in both the unique Fynbos Floral Kingdom and in the Afrotropical Flora, southern Africa's gall fauna has received only little attention. Cecidomyiids on very diverse plant groups and eriophyoid mites seem to vie for the position as most speciose group of local gall formers.

Methods and results: Amongst galls from other groups recorded to date, the following are prominent: Lepidoptera (including some highly specialized cecidosids), Diptera other than gall midges (especially Tephritidae) and Coleoptera (mainly curculionoids, some also reported as inquilines). Galling thrips, psyllids, coccoids and aphids are probably poorly represented. A conspicuous near-absence of phytophagous cynipids and sawflies is balanced by a large number of members from at least six other hymenopteran families, often reared in species complexes from galls in which their actual roles remain unknown. Rearing insects from opportunistically collected galls and gall-like structures may lead to wrong conclusions about the initiators. This is especially true when the (primary) inducers may belong to uncommon groups of gallers, such as eriophyoids, non-soil inhabiting nematodes, and fungi. Complexes of several species may emerge from a single gall, and a variety of galls and gall inducers may occur on a single host-plant species.

Conclusions: There is a considerable backlog in collecting, studying, and describing galls and gall formers in southern Africa. Surveys by specialist collectors will no doubt yield a plethora of unknown and/or undescribed insect taxa, galls, and host associations, as well as possible surprises, especially within the endemic flora, succulents, and other desert plants.

Impacts of thinning ponderosa pine forests on pine bark beetles: Implications for mitigating climate change.

Monica Gaylord, Richard Hofstetter, Sky Stephens, Michael Wagner

Northern Arizona University, Flagstaff, Arizona, United States

Introduction: Most climate models predict that future droughts will become more frequent and severe in the southwestern United States and mitigating the impacts of climate change is an ongoing concern for forest managers. Thinning treatments in the southwestern United States are often suggested as an effective means of preventing bark beetle outbreaks by increasing water availability to remaining trees and by changing microclimate within stands. However, little research has been done across a range of stand densities to determine optimal basal area for tree resistance to bark beetle attacks.

Methods: Measurements on tree water stress and bark beetle resistance were collected from a range of thinning treatments (9.2– 34.4 m^2/ha) at two sites in ponderosa pine forests of northern Arizona. One site has been maintained at selected basal areas since 1962 and represents a long term thinning response. The second site was thinned in late fall of 2005 and represents a short-term thinning response.

Results and Conclusions: Stand resistance generally increased after thinning treatments. Water stress during the dry season was reduced in thinned stands at both sites. Our research suggests that thinning treatments mitigate water shortages in forest stands and decrease bark beetle associated mortality via immediate changes in microclimate and long-term changes in trees vigor. Stands with basal areas of < 23.0 m^2/ha appear to be less susceptible to bark beetle attacks. We will discuss how our results can be used to determine the impact of thinning treatments on forest stands under future climate change scenarios.

Cynipid–parasitoid interactions: Comparing three dog rose species along a geographical gradient

Annette Kohnen[1], Katrin Klinge[3], Volker Wissemann[2], Roland Brandl[1]

[1]University of Marburg, Marburg, Germany, [2]University of Giessen, Giessen, Germany, [3]University of Goettingen, Goettingen, Germany

Multitrophic interactions between plants, herbivores and natural enemies change with host species as well as geographic context. Thereby, the genetic variation between hosts affects not only herbivores but also the structure and dynamics of higher trophic levels.

In our study we examined interactions between the gall wasp *Diplolepis rosae* (L. (Hym.)) and its parasitoids on three dog rose species (*Rosa*, section Caninae) across Germany. Within 388 galls we found eight species of parasitoids (most common: *Orthopelma mediator* 18 %, *Glyphomerus stigma* 12 %, *Torymus bedeguaris* 9.1 %) and the inquilin *Periclistus brandtii* (12 %). Most galls were found on *R. rubiginosa* (mean: 5.9±1.4 bush^{-1}; *R. canina:* 1.8±0.1, *R. corymbifera*: 2.8±0.5; 133 bushes sampled). The abundance of galls bush^{-1} varied between sample localities ($F_{7,109}$=25, p<0.001), the rose species ($F_{2,109}$=25., p<0.001) and their interaction ($F_{14,109}$=2.9, p<0.001). The rate of parasitism and therefore the survival rate of *D. rosae* decreased with increasing gall volume ($F_{1,256}$=479, p<0.001) and varied between rose species ($F_{2,256}$=96, p<0.001). But in contrast to the abundance, the rate of parasitism was smallest for galls collected on *R. rubiginosa* (62 %, *R. canina*: 76 %, *R. corymbifera*: 76 %). Again the parasitism rate varied with sample locality ($F_{7,256}$=49, p<0.001), but showed no geographical gradient. Furthermore, host identity and locality showed a significant interaction ($F_{14,256}$=13, p<0.001). Overall our results show that host identity and geography interact in determining the structure of food webs.

The population dynamics of red date palm weevil *Rhynchophorus ferrugineus* Oliv. and other insects in date palm orchards in the Kharje area of Saudi Arabia

Hassan ALAyied, Hathal ALDafer

[1]King Abdulaziz City for Sicenec and Technology, Riyadh, Saudi Arabia, [2]King Saud University, Riyadh, Saudi Arabia

Introduction: Since long the red palm weevil, *Rhynchophorus frrugineus* Oliv is known to be the most serious pest of coconut and other cultivated palms in India and other South Asian countries. This insect entered the Gulf countries in mid 1980's and since then it has caused devastating impact on date palm cultivation. It has threatened the multi-million dollar date industry and has raised the question on the survival of a cultural icon of the Gulf countries. The larval stages of this insect feed voraciously within the trunk of the palms and kill the trees. There are a number of insects attacks the date palm tree trunks such as the longhorn date palm stem borer *Pseudophilus Testaceus* Gah. and *Oryctes* sp., besides red date palm weevil. Our study was conducted to understand the relationship between the red date palm weevil and the other two insects.

Methods: Twenty five fields were selected in al Kharje area (55 km South Riyadh, Saudi Arabia). Number of light traps and pheromone traps were distributed evenly in the selected fields. The study was started March 2007 and will end March 2008. The red date palm weevil, longhorn date palm stem borer and *Oryctes* sp adults were collected weekly for the study period by the traps and by dissecting the highly infested trees.

Results: Understanding the relationship is a critical component on integrated Pest Management (IPM) program.

Insect morphometrics: Trends and prospects in the postgenomic era

James S. Patterson[1], Casper J. Breuker[2], Christian Peter Klingenberg[3]

[1]University of Sussex, Brighton, United Kingdom, [2]Oxford Brookes University, Oxford, United Kingdom, [3]University of Manchester, Manchester, United Kingdom

Introduction: In addition to its traditional application in taxonomy and related areas, morphometrics has found new uses in many areas of entomology. In particular, morphometric studies of insects using genomic approaches have increased. Thanks to the availability of new resources such as collections of mutant stocks, microarrays, and new genotyping tools, considerable advances have been made in the understanding of the genetics of shape in insects. Moreover, the trend to high-throughput studies has made it necessary to consider automating steps in the data collection for morphometric studies.

Case study: We illustrate these trends with a study searching for genomic regions influencing wing shape in *Drosophila melanogaster*. We screened the Exelixis collection of *Drosophila melanogaster* stocks, each of which contains a different small chromosomal deficiency in an otherwise isogenic background. We found that many of the deficiencies have significant effects on wing shape, but that most of these effects are small. Furthermore, the magnitude of the effect is positively related to the size of the deleted genomic region and number of genes contained in it. Altogether, this analysis underscores that the genetic architecture of wing shape is highly polygenic, as there may be hundreds of loci that affect wing shape.

Perspective: This approach highlights the potential for linking the otherwise disparate disciplines of morphological variation and genomics. With the ascendance of more insect genomes on the horizon, and the potential for the subsequent development of comparative insect genomics it seems clear that morphometrics will have a key role to play.

Fighting ability in honeybee queens: Avoiding death and optimizing reproduction

Christian Pirk[1], Vincent Dietemann[1], Huo-Qing Zheng[2], Colleen Hepburn[3], Randall Hepburn[3], Sarah Radloff[4], Fu-Liang Hu[2], Robin Crewe[1]

[1]Department of Zoology and Entomology, University of Pretoria, Pretoria, South Africa, [2]College of Animal Sciences, Zhejiang University, Hangzhou, China, [3]Department of Zoology and Entomology, Rhodes University, Grahamstown, South Africa, [4]Department of Statistics, Rhodes University, Grahamstown, South Africa

Contests mediate access to reproductive opportunities in almost all species of animals. An important aspect of the evolution of contests is the reduction of the costs incurred during intra-specific encounters. Strategic decisions by individuals during contests are influenced by internal and external factors. Models based on game theory have considered the possibility that contestants gauge their own fighting ability (internal factor) and not that of their opponent (external factor), when assessing their behavioral options. Results from some species suggest that contestants indeed determine their fighting strategy solely based on self-assessment.

Although physical contests are widespread in social insects, they have rarely been used as model systems for the study of fighting strategies. Here we present a novel multi queen system to test the decision rules underlying the lethal fights between honeybee queens when competing for reproductive monopoly. By experimentally reducing their fighting abilities, we obtained evidence that queens without prior experience assess their own fighting ability and not that of their opponents. As a consequence, queens with reduced fighting ability refrain from engaging in fights. The presence of several of these queens in a colony results in their peaceful coexistence within the colony. Our results suggest that during contests for reproductive monopoly, honeybee queens make strategic decisions, based solely on the assessment of their own absolute fighting ability and that alternatives to lethal fighting can emerge.

Lethal and sublethal effects of endosulfan, imidacloprid and indoxacarb on green lacewing adults in laboratory

Mir Jalil Hejazi, Golamreza Golmohammadi, Shahzad Iranipour, Seyed Abolghassem Mohammadi

University of Tabriz, Tabriz, Islamic Republic of Iran

Introduction: Commonly, two types of toxicological assessments are made on natural enemies: Acute toxic and sublethal effects**.** In IPM programs, sublethal effects of insecticides are important in relation to the decrease in ability of entomophages in regulating their hosts or preys. Since *Chrysoperla carnea* is an important predatory insect in many crops that imidacloprid, indoxacarb and endosulfan are applied to, understanding the lethal and sublethal effects of these insecticides on it, would be very useful.

Methods: Glass petri dishes were sprayed with 2 ml of each concentration of the insecticides at a pressure of 0.5 bar using Potter tower**.** Fifteen adults (up to 24 h old) were transferred to each petri dish. Mortality was assessed 24 h after treatment**.** Each treatment was replicated at least four times at different days. To study the sublethal effects, adults were treated with LC_{25} of each of the insecticides. Twenty four hours after treatment, the surviving adults were kept separately as pairs of males and females; and the eggs were collected and counted daily.

Results: the LC_{50} values, for indoxacarb, imidacloprid and endosulfan were 11.2, 53.0, and 343.0 mg ai/L for males, and 19.2, 98.4 and 398.0 mg ai/L for females, respectively. All three insecticides tested produced significant adverse effects on fecundity, oviposition and longevity of both male and female adults ($p<0.01$).

Conclusion: the adult stage of *C. carnea* is very sensitive to indoxacarb, imidacloprid and endosulfan. Hence, these insecticides should not be applied when the density of adults is high in the field.

Lethal and sublethal effects of endosulfan, imidacloprid and indoxacarb on grren lacewing adults in laboratory

Mir Jalil Hejazi, Golamreza Golmohammadi, Shahzad Iranipour, Seyed Abolghassem Mohammadi

Conclusion: the adult stage of *C. carnea* is very sensitive to indoxacarb, imidacloprid and endosulfan. Hence, these insecticides should not be applied when the density of adults is high in the field.

Patterns of integration of *Drosophila* wing shape at multiple levels: From mutational potential to evolutionary divergence

Christian Peter Klingenberg[1], Casper J. Breuker[2], Nelly A. Gidaszewski[3], James S. Patterson[4]

[1]University of Manchester, Manchester, United Kingdom, [2]Oxford Brookes University, Oxford, United Kingdom, [3]University of Sheffield, Sheffield, United Kingdom, [4]University of Sussex, Brighton, United Kingdom

Introduction: Development plays a key role in the evolutionary process because it determines how genetic variation is expressed as observable phenotypic variation. The patterns of developmental integration influence evolution at multiple levels, from the distribution of new mutations through the standing genetic variation in contemporary populations to the patterns of divergence among evolutionary lineages. We combine the methods of geometric morphometrics with different experimental and comparative approaches to compare integration at these different levels.

Methods: We use a Procrustes fit of a constant set of 15 landmarks digitized on all wings to extract shape information in a consistent way. To characterize the integration of spontaneous variation in the developmental system, we analyze the fluctuating asymmetry in *Drosophila melanogaster*. Mutational integration is estimated from the distribution of average shapes of approximately 370 stocks of *Drosophila melanogaster* that carry small deficiencies but are otherwise isogenic. Standing genetic variation is estimated in three populations each of *Drosophila melanogaster* and *Drosophila subobscura*. Finally, the patterns of evolutionary divergence are from an analysis of the nine species of the *Drosopgila melanogaster* subgroup.

Analysis:.We establish the correspondence between the different levels of variation by comparison of the covariance matrices at the different levels and by comparing the directions of 'lines of least resistance'.

Conclusion: This study demonstrates the potential for analyses that use shape as a 'common currency' for comparing the results from different genetic experiments and comparative studies. This approach is feasible and promising not only for *Drosophila*, but for many other insects as well.

Metabolic insecticide resistance in field populations of the African malaria vector *Anopheles gambiae*

Pie Müller, Emma Warr, Bradley Stevenson, Patricia Pignatelli, Hilary Ranson, Mark Paine, Martin J. Donnelly

Vector Group, Liverpool School of Tropical Medicien, Liverpool, Merseyside, United Kingdom

Introduction: Pyrethroid-treated bednets and indoor residual spraying with pyrethroid insecticides are the mainstays of malaria vector control programmes in sub-Saharan Africa. Resistance to these insecticides threatens the sustainability of control. An understanding of the mechanisms conferring resistance facilitates the development of simple monitoring tools and may eventually lead to novel strategies to restore the efficacy of the insecticide, or the development of new compounds. These mechanistic studies have already led to the identification of novel genes associated with pyrethroid resistance in laboratory-reared mosquito colonies. However, laboratory colonies may not show the true picture of metabolic insecticide resistance in field populations, and hence investigation of field collected specimens is required.

Methods: We collected specimens from malaria endemic areas in Africa where pyrethroid resistance has previously been reported and evaluate the relationship between insecticide resistance phenotypes and gene expression levels. To identify genes conferring metabolic resistance we used microarray-based and multiplexed quantitative RT-PCR techniques to measure differential expression profiles between insecticide resistant and control mosquitoes collected from the field.

Results: We have identified several candidate cytochrome P450s which are associated with increased tolerance to pyrethroids and which were found at more than one field site in sub-Saharan Africa. These P450s are being characterised and preliminary data suggests some have a role in detoxifying pyrethroids.

Conclusions: Our current approach to screen for candidate loci associated with metabolic insecticide resistance in *A. gambiae* has yielded several candidates which will lead to genetic markers for the early detection of insecticide resistance in field populations.

Lack of effect of Bt-corn on the non-target arthropods

Oxana Habuštová, Hany Mohamed Mohamed Hussein, Petr Dolezal, Lukas Spitzer, Vlastimil Ruzicka, František Sehnal

Biology Centre, ASCR, Institute of Entomology, Ceske Budejovice, Czech Republic

Introduction: Genetically modified Bt-corn expressing *Bacillus thuringiensis* toxin Cry1Ab provides protection against the European corn borer. We examined if it does not affect other arthropods living on the corn field.

Methods: Bt-corn YieldGard® (MON 810) and a related non-Bt hybrid were grown each on 5 plots of 0.5 ha that were distributed checker-wise in a 14 ha field. The same type of corn was grown on identical plots for three successive years. Plants of the first crop were shred at the waxy stage of grain ripening and ploughed into the soil. ELISA was used to quantify the amount of Cry1Ab in the plants. Arthropod communities were examined on the plants (10 per plot and date) and sampled in pitfall traps every 2-3 weeks. Results were evaluated with Canoco statistics. Grant support: 1M06030.

Results: Bt maize expressed around 1 ppm Cry1Ab in the leaves and stem and undetectable amounts in the flowers and ears. The toxin provided full protection against the corn borer caterpillars, whereas the abundance of aphids, thrips, ladybirds and lacewings was statistically identical on the Bt and Non-Bt plants. As many as 23 species of spiders, 40 of Carabidae beetles, and 36 of Staphylinidae beetles were found on the field. The Bt and Non-Bt plots differed neither in the biodiversity nor in the abundance of these groups.

Conclusions: The expression of Cry1Ab provides protection against the European corn borer. No adverse effect was detected on other species dwelling on the corn plants or living on the ground.

A new baculovirus isolate that doesn't cause the liquefaction of the integument in *Spodoptera frugiperda* dead larvae

Fernando Valicente[1], Corina Macedo[2], José Wolff[3]

[1]Embrapa Maize and Sorghum Research Center, Sete Lagoas, Brazil, [2]Univeristy of Mogi das Cruzes, Mogi das Cruzes, Brazil, [3]Private, São Paulo, Brazil

Introduction: The *Spodoptera fruigiperda* nucleopolyhedrovirus (SfMNPV) can be very effective in controlling *S. frugiperda*, and has shown potential to be used in Brazil as a biopesticide. However, an important difficulty results from the disruption of the larvae integument due to SfMNPV infection (isolate 19). The liquefaction of the integument makes large scale production laborious because all larvae must be frozen before being harvested for polyhedra extraction.

Methods: One dead larva was found not disrupting the integument (isolate 6) and was multiplied during 5 generations in laboratory. Detection and sequencing of chitinase and cathepsin genes were performed as well as PIB production comparing the two isolates.

Results: The new Brazilian isolate 6 of *S. frugiperda* that doesn't disrupt the integument was confirmed to harbour cathepsin and chitinase genes. Restriction fragment analysis with *Bam*HI and *Hind*III did not show differences between isolate 19 and 6. PCR amplification of the regions encompassing the chitinase and the cathepsin genes produced an amplicon whose size was the same for the two isolates. Alignment of the sequence (isolate 6) obtained with the sequence of isolate 19 revealed a deletion of one base located within the chitinase gene. The framesift caused by this deletion resulted in appearance of a stop codon 15 base pairs downstream the mutation.

Conclusions: Isolate 6 proved to be very efficient to be used in a large scale baculovirus production. Using this isolate, the larval equivalent/ha could be lowered to 80 to 120 larvae/ha, which is equivalent to 10.75 and 13.86 g/ha, respectively

The effect of agri-environmental schemes on bumble bee abundance and diversity

Marika Mand, Reet Karise, Eneli Viik

Institute of Agricultural and Environmental Sciences, Estonian University of Life Sciences, Tartu, Estonia

Introduction: Habitat loss and the intensification of farming practices have lead to a rapid decline in the species-richness of bumble bees in Europe. In order to reverse this process, it is mandatory for the European Union member states to operate agri-environment schemes as part of the common agricultural policy. In Estonia, this policy has been in effect since 1997. The aim of the present study was to find out the impact of agri-environmental schemes on bumble bee abundance and diversity in Estonian agricultural landscapes.

Methods: The study was conducted in two regions with markedly contrasting landscape structures and proportions of semi-natural habitats. The number of bumble bees and the abundance of flowers were monitored on 66 field margins of three different farming types: organic farming, environmentally friendly farming and conventional farming.

Results: In mosaic agricultural landscapes, there were no differences in the abundance and diversity of bumble bees or in the abundance of flowers between the three different farming types. However, in the intensively used agricultural region, there were significantly more bumble bee species and higher density of flowers in organic farms and in farms that have joined the agri-environmental schemes. The number of bumble bees was very low on intensively managed cereal field margins.

Conclusion: In intensively used agricultural regions the number of compensation areas for pollinators is not sufficient and in this case the adopted agri-environment schemes enhance the species richness and abundance of bumble bees as well as pollination services on neighbouring intensively-managed farmland.

Origins of the push-pull concept as applied to pest management

James Miller

Michigan State University, East Lansing, Michigan, United States

Control of insect pests by either attractants/arrestants or repellents/deterrents used singly is difficult because the effects of behavioral modifiers are rarely overwhelming. Furthermore, the impacts of repellents/deterrents often diminish as pests become increasingly hungry or gravid. This dynamic nature of resource acceptance by insects was encapsulated in the rolling-fulcrum model of Miller and Strickler (1984), based largely upon our studies of the interactions of onion flies (*Delia antiqua*) with onions (*Allium cepa*). An important inference from this conceptual model was the sensibility of structuring a pest's environment so that positive outlets for feeding or oviposition (pull) are offered so as to sustain the effects of negative factors (push) applied to the valued resource. This "stimulo-deterrent diversion" concept was tested with limited success on onion fly in the late 1980s and formally introduced into peer-reviewed literature in 1990 (Miller and Cowles; *J. Chem. Ecol.*). The suggestion that this pest management principle might be more applicable to agriculture in developing rather than highly developed countries has proven true. This talk will summarize how the push-pull concept developed independently several times within entomology, as well as in various other fields like engineering, marketing, and politics, where it also thrives.

A phylogeny of genera of the *Pedaliodes* complex (Lepidoptera: Satyrinae: Pronophilini) based on morphological and molecular analyses

Mónica Higuera[1], Giovanny Fagua[1], Luz Angela Galindo Leva[2]

[1]Pontificia Universidad Javeriana, Bogotá, D.C., Colombia, [2]Cenicafé, Chinchiná, Caldas, Colombia

Introduction: The complex Pedaliodes Butler 1867 is a neotropical group of butterflies containing a high number of species distributed along a wide altitudinal range. This group is an interesting taxon to study the effects of orography and historic climate changes on speciation. This study was aimed to elucidate the phylogenetic relationships within the group.

Methods: 44 species of 12 genus of the complex were analyzed in the in-group. 12 species from the tribes Pronophiliini and Erebiini were employed as out-group. 76 morphological characters were used join to a fragment of 630 bases pair of cytochrome-c oxidase subunit I (COI). The resulting data matrix was analyzed by total evidence using PAUP and TNT packages.

Results: The complex *Pedaliodes* was a monophyletic group. Inside to complex, only *Praepronophila* was a monophyletic group while *Protopedaliodes*, *Punapedaliodes*, *Redonda* and *Steromapedaliodes* can be monophyletic groups. Several inner genera were paraphyletic or polyphyletic, such as *Altopedaliodes*, *Neopedaliodes*, *Panyapedaliodes, Phereopedaliodes*, *Pedaliodes* and *Praepedaliodes* among others. Into *Pedaliodes* were observed other species groups.

Conclusions: The complex *Pedaliodes* is a monophyletic group, but several inner genera are paraphyletic or polyphyletic. New morphological characters were described and some characters traditionally employed in Lepidoptera and particularly in the complex *Pedaliodes* were redefined.

Above- and belowground direct and indirect defense mechanisms of transgenic Bt maize and implications for biological control

Claudia Zwahlen, Lechot Géraldine, Ted Turlings

University of Neuchâtel, Institute of Biology, Neuchâtel, Switzerland

Herbivore-induced direct and indirect defense mechanisms are important for the plant's ability to combat attacking herbivores. Transgenic *Bacillus thuringiensis* (Bt) maize produces one or two Cry endotoxins against various pests, such as the European corn borer (Cry1Ab) and the corn rootworm (Cry3Bb1), which provides a highly effective direct defense mechanism against the target pests, but it is unclear whether the continuous production of these Cry proteins affects the plants' ability to allocate resources to fend off other, non-target attackers. Here we present results from our laboratory and field studies that determine the capacity of Bt maize to defend themselves using direct defense compounds and inducible volatile emissions that attract natural enemies, such as entomopathogenic nematodes (EPN) against corn rootworm larvae. So far, we have found that when Cry1Ab Bt maize and its near isogenic control were artificially induced to produce volatiles in a similar manner as corn rootworm feeding, they were equally attractive to EPNs. This suggests that Cry1Ab Bt maize is able to recruit natural enemies to combat its non-target belowground attackers similarly as non-Bt maize. However, artificially induced Bt maize produced significantly less Cry1Ab in their leaves and roots than untreated Bt maize. In a next step we will determine whether this has an effect on the plants' ability to fend off its aboveground target pests. Our studies will contribute to a better understanding of the resource allocation of plants under herbivore attack. Moreover, they provide a first step towards comparing transgenic plants with biological control systems.

Climate change and biological control: A multitrophic perspective

Nick Mills

University of California, Berkeley, CA 94720-3114, United States

Classical biological control is one of the most effective approaches for the management of invasive species through which specialized natural enemies from the region of origin of the invader are purposefully introduced to provide sustained long-term control. Although this approach is not without controversy, due to the potential for non-target impacts, it has provided some spectacular examples of large scale ecological experiments of the suppression and regulation of invaders by natural enemies. While classical biological control has been practiced for more than 100 years, with historical examples continuing to provide effective control, there is increasing concern regarding the future vulnerability of such systems to disruption through global climate change. As introduced populations show reduced genetic heterogeneity in comparison to source populations, due to founder effects, they may consequently have a reduced capacity to adapt to global climate change. Whether the capacity for genetic adaptation varies among trophic levels and whether climate change could disrupt classical biological control remain open to question. To explore these questions I will examine the frequency of regional variation in the outcome of classical biological control due to climatic factors using the historical record of natural enemy introductions for both arthropod pests and weeds. To understand the reasons for such variation and the potential for disruption of biological control through climate change, I will compare temperature tolerance data across trophic levels and consider the importance of synchronization of life cycle stages among trophic levels to the success of pest population suppression.

Hormonal regulation of larval diapause in a noctuid moth

Frantisek Sehnal, Matilde Eizaguirre, Christa Schafellner

Biology Centre, ASCR, Institute of Entomology, Ceske Budejovice, Czech Republic

Introduction: *Sesamina nonagrioides* overwinters in diapause as fully grown caterpillar that undergoes supernumerary larval molts. Their hormonal control was examined.

Methods: Development under short-day (SD) and long-day (LD) conditions was correlated with titre changes of juvenile hormones (JH) and ecdysteroids and the activity of JH esterase (JHE). Causality of correlations was verified with hormone agonists and a specific JHE inhibitor. Grant support: 522/06/1591.

Results: Larval development under LD conditions occurred at about 7 ng JH /ml hemolymph and was associated with ecdysteroid rises to over 300 ng/ml two days after each ecdysis (data for 4^{th} and 5^{th} instars). SD larvae contained nearly 15 ng JH /ml in the 4^{th} and 5^{th} instar and 5 ng/ml during subsequent diapause; ecdysteroids peaked in long (> 14 days) and irregular intervals. The transformation to pupa in LD 6^{th} instar larvae occurred at undetectable JH, while ecdysteroids rose to 600 ng/ml. JHE activity was negatively correlated with the ecdysteroid titre. Administration of JH agonist methoprene to 6^{th} instar LD larvae induced extension of typical larval development (molts in short intervals plus body growth), whereas in SD larvae it did not affect the slow diapause molting rhythm without growth. Ecdysteroid agonist RH-2485 stimulated both JH and ecdysteroid titres and evoked larval development in either type of larvae.

Conclusions: Larval diapause is induced by moderate JH and low ecdysteroid titers; feedbacks between these hormones prevent failures in the specification of larval development, metamorphosis, and diapause, respectively. JHE does play a significant role in JH titer regulation.

Insect species, landscapes and climate change: A northern hemisphere perspective

Juergen Ott

[1]L.U.P.O.GmbH, 67705 Trippstadt, Germany, [2]Dep. of Environmental Sciences, University of Landau, Landau, Germany

Introduction: In the past decades Europe faced a strong change in the distribution pattern of many insect taxa. Here a review on existing data is given, as well as the consequences for ecosystems and nature conservation are described.

Methods: Field data from several long-term monitoring projects in reference areas were analyzed and the literature on the ecology and nature conservation of several taxa is reviewed.

Results: A few decades ago a process started, which is still ongoing with an even increasing velocity: the invasion of Central and Northern Europe by Mediterranean insects, whereas recently in the Mediterranean also more and more African species are documented. This is in particular true for some mobile and easy to determine taxa like the Odonata. In the short term these invasions from the south may lead to an increase of biodiversity, in particular as euryoecious Odonata species are increasing their range. But in the medium term stenoecious mooreland and alpine species will disappear. In other taxa, like in the Trichoptera, this seems to be different: here, beside the Alpine species, mainly the diversity in the Mediterranean is under threat, as this area has the highest degree of endemism. Consequences for aquatic and terrestrial systems can be foreseen and new problems in nature conservation (e.g. new pests, invasions of alien species, the functioning of the European NATURA 2000 network) will arise.

Conclusions: Insects can be used very well as indicators for climate change and many effects on the different taxa can be registered, as well as on the coenosis and ecosystems can be expected. This may lead to new nature conservation strategies.

Grasshoppers, locusts, crickets and katydids of Mexico: A new synthesis

Ricardo Mariño-Pérez[1], Paolo Fontana[2], Filippo M. Buzzetti[2]

[1]Laboratorio de Protozoología, Departamento de Biología Comparada, Facultad de Ciencias, Universidad Nacional Autónoma de México, C.P. 04510, Ciudad Universitaria, Distrito Federal, Mexico, [2]Dipartimento Agronomia Ambientale e Produzioni Vegetali, Università di Padova Agripolis, Viale dell'Università, 16, I-35020, Legnaro (Padova), Italy

Introduction: The current knowledge of the Orthoptera of Mexico is scattered throughout literature, and is only available for the most part in old monographs. Also, only few genera have been reviewed recently and, in a global sense, little is known about Mexican Orthoptera. All the available information was grouped adding our new data.

Methods: Six entomological field expeditions (2004-2007) were conducted, also an intensive revision of the material of Ann Arbour (Michigan, USA) and CNIN (UNAM, Mexico) collections and literature was made.

Results: An updated checklist revised and integrated with new data numbers 978 species of Orthoptera (425 Ensifera and 553 Caelifera) actually known from Mexico, representing the 5 % of the about 20,000 species of Orthoptera worldwide known. During field expeditions many photos were taken to living specimens to create a photographic guide.

Conclusions: Current knowledge about Orthoptera biodiversity is far to be complete. Recently however, many species have been identified; some still have not been described officially, and many others have not been adequately studied. This new synthesis is the first step to start future researches on this group.

Structure of Orthoptera communities in an altitudinal gradient with Andean forest and oak forest.

Andrés Felipe Sandoval Mojica[2], Giovanny Fagua[1]

[1]Pontificia Universidad Javeriana, Bogotá, D.C., Colombia, [2]University of Florida, Gainesville, Florida, United States

Introduction: The study of distribution of animals and plants on natural gradients is useful for the determination of patters and process that govern the diversity. An Andean altitudinal gradient on the west of Cordillera Oriental (Colombia) has an interesting transition between Andean forests to oak forest. The incidence of both, altitude and vegetation, over diversity of Orthoptera was studied

Methods: The variation in abundance, richness, diversity, dominance and composition of the Orthoptera was studied along an altitudinal gradient, between 2000 and 3000 m, in an Andean forest at Santander (Colombia). Surveys were conducted at five places every 250 m in altitude. In each altitude was included four quadrants for manual sampling.

Results: The analysis defined two communities (2000–2250 m and 2750-3000 m) due possible to the structural differences across the vegetation on altitudinal gradient: an heterogenean Andean forest to oak grove with higher dominance of *Quercus humboldtii*. All altitudinal stations showed that species richness and diversity decreased gradually with increasing altitude, due to the reduced plant resource at high elevations. There was a positive correlation between altitude and dominance of Orthoptera species by higher proportion of the generalist species. However, the analysis without the altitudinal stations with dominance of *Q. humboldtii* showed that oak grove increased the slope of the declination in species richness and diversity, and the increasing of the dominance.

Conclusions: We conclude that oak grove exacerbate, by their homogeny composition and lowest complexity, the pattern of declination associated to the altitudinal effect.

Differential foraging response to racially-derived blends of brood pheromone in the honey bee, *Apis mellifera*

Bradley Metz, Tanya Pankiw

Texas A&M University, College Station, TX, United States

Introduction: Brood pheromone is a blend of ten fatty-acid methyl and ethyl esters extractable from the larval cuticle that has been shown to affect individual age of first foraging and foraging choice, and colony-level foraging investment. Most studies of brood pheromone have been performed using a synthetic blend formulated from a single race of honey bee, *Apis mellifera ligustica.* Bees in the United States, however, are primarily crosses of several different European honey bee races. Also present are Africanized bees which are crosses between European bees and *Am scutellata*.

Methods and Results: Using gas chromatography, we characterized BP esters from larvae selected from 8 colonies of Africanized and 8 colonies of European bees. We found that two BP components, methyl oleate and methyl stearate, differ significantly by race. We then formulated racially-derived blends of synthetic BP and performed a colony-level foraging bioassay using European bees. We observed that European BP released pollen foraging behavior, increasing proportional pollen foraging relative to control, while Africanized BP elicited the opposite response and suppressed pollen foraging.

Conclusions: *Am scutellata* evolved in a tropical climate and Africanized hybrids exhibit a characteristic foraging pattern of collecting large amounts of pollen, while temperate evolved bees characteristically forage preferentially for nectar. The divergent effects elicited by Africanized and European blends of brood pheromone may have evolved as a response to racial differences in foraging behavior.

Interaction between baculoviruses and midgut cells

Basil Arif, Jeffrey Slack

Great Lakes Forestry Centre, Sault Ste. Marie, Canada

Baculoviruses are a family of insect viruses that have been used for decades in biocontrol. Insects become vulnerable to infection when they ingest foliage contaminated with viral occlusion bodies (OBs). Liberated occlusion-derived virions (ODVs) initiate infection in epithelial cells when OBs dissolve in the alkaline environment of the larval midgut. While lepidopteran baculoviruses have been shown to synthesize two viral phenotypes, the budded virus (BV) and the ODV, genomics evidence revealed that hymenopteran baculoviruses are not likely to synthesize BV and this phenotype may not play a role in the biology of sawfly viruses. This observation is consistent with the fact that viruses of sawflies are confined to infecting midgut cells. It has been shown that the P74, present on the surfaces of ODVs, was essential for infection. A soluble form of the protein was generated and it was observed that it is cleaved when incubated with insect midgut tissues under alkaline conditions and that cleavage was prevented by soybean trypsin inhibitor (SBTI). Biological assays were carried out and suggested that SBTI inhibited baculovirus infection and that trypsin enhanced infectivity. This may be due to trypsin cleavage and activation of P74. Analysis of the peptide sequences of P74 homologues identified a highly conserved trypsin cleavage site that could generate the observed cleavage product. Further more; mutagenesis of the trypsin cleavage sites in P74 had an effect on the oral infectivity. We link molecular biology with practical biocontrol improvements and present evidence that plant products may affect baculovirus efficacy.

Interactions between colour pattern, temperature and life history traits in three coccinellid species (*Harmonia axyridis, Adalia bipunctata* and *Adalia decempunctata*)

Laura Jane Michie, Michael Majerus

University of Cambridge, Cambridge, United Kingdom

Many coccinellid species show conspicuous colour pattern polymorphism. It has been demonstrated that within these polymorphisms, the major forms are genetically controlled. This is the case in *Harmonia axyridis, Adalia bipunctata* and *Adalia decempunctata*, but comparatively little research has been carried out on the effect of environment on the detailed colour pattern variations within forms. Similarly, the effect that colour pattern has on life history traits in different environments has not been examined comprehensively. While there is some evidence of genetically controlled mating preferences for specific colour forms in *H. axyridis* and *A. bipunctata*, the effect of colour pattern on other life history traits has received very little attention. Here we present investigations of the effects of temperature during development on adult colour pattern in these three polymorphic coccinellids, and the impact of different temperatures on a variety of life history traits (activity, mating success, oviposition rate, fecundity) for melanic and non-melanic morphs of each species. We show that the interaction between morph and temperature differ between species in respect of both the effect of temperature on phenotype and its impact on life history traits.

Insect outbreaks viewed through a nutritional physiology framework

Spencer T. Behmer[1], Anthony Joern[2]

[1]Texas A&M University, College Station, TX, United States, [2]Kansas State University, Manhattan, KS, United States

Introduction: Food quality has important implications for insect performance, but the extent to which food quality and the nutritional landscape facilitate insect outbreaks is poorly understood. This is particularly true among grasshoppers.

Methods: Here we employ an experimental framework grounded in nutritional physiology to show what ratios and amounts of protein and carbohydrate different species of grasshoppers (including a range of North American species and two African locust species) prefer to eat.

Results: We demonstrate that among North American species coexistence may be facilitated by the existence of species-specific nutritional niches. We also show that performance by grasshoppers allowed the opportunity to mix their diets and thus regulate their protein–carbohydrate intake matches optimal performance peaks generated from no-choice treatments. Our results indicate the active nature of diet selection to achieve balanced nutritional intake can provide buffering capacity in the face of variable food quality.

Conclusions: Our results and experimental approach can be extended to generate and test predictions concerning the intensity of biotic interactions between species, the relative abundance of species, yearly fluctuations in population size, as well as the nature of interactions with natural enemies in tritrophic niche space.

Phylogenetic analysis of the *Zanchius*-group (Heteroptera: Miridae: Orthotylinae)

Dimitri Forero

[1]Cornell University, Ithaca, NY, United States, [2]American Museum of Natural History, New York, NY, United States

Miridae is the most diverse family of Heteroptera with more than 10.000 species described. Eight subfamilies are recognized in Miridae. Among these, Phylinae and Orthotylinae, which are considered to be sister groups, are the focal taxa of the Plant Bug Planetary Biodiversity Inventory project. Currently, three tribes within Orthotylinae are recognized: Orthotylini, Nichomachini, and Halticini. Orthotylini is the largest, including more than 200 genera. Schuh (1974) divided the tribe in several generic groupings: the *Orthotylus*, the *Sericophanes*, the *Falconia*, and the *Zanchius* groups, thus providing the most current concept of suprageneric categories.

Schuh proposed the Pantropical *Zanchius*-group to include 11 genera, identified by a flattened appearance, delicate body structure, usually hyaline hemelytra, and vesica without spicules. Additional genera have been proposed to be part of the *Zanchius*-group but until now no phylogenetic analysis have been performed in order to evaluate the limits of the group. The monophyly and generic relationships of the group were studied using several morphological character complexes, in particular male and female genitalia. Species of the *Sericophanes*, *Falconia*, and *Orthotylus* groups served as outgroups. About eighty percent of the genera ascribed to the group were examined. In addition, species of the yet undescribed Australian fauna were included. As result of the analysis, the initial diagnosis of the group is modified to include members with vesical spicules, although usually delicate; phallotheca with lateral protuberances; embolium of hemelytra with apically enlarged area; and eyes usually removed from the anterior margin of the pronotum, with a particular caudal structure.

Post-disturbance recovery of apple orchard spider communities

Viktor Markó, Balázs Keresztes, Jerry V. Cross

[1]Department of Entomology, Corvinus University of Budapest, Budapest, Hungary, [2]Institute for Plant Protection, University of Pannonia, Keszthely, Hungary, [3]East Malling Research, East Malling, United Kingdom

Introduction and methods: In our 4-year study the effect of two pest management strategies (i) 'zero pesticide residue integrated pest management program', where pesticides moderately harmful to natural enemies are applied only up to petal fall, but during the fruit development period pest control based on biocontrol agents (ii) a conventional pest management system (based on broad-spectrum insecticides) on apple orchard spider communities were compared. Pesticide free apple orchard plots served as a control. Special attention was paid to prey availability and post disturbance development of spider communities in the second part of the growing season.

Results: The 'zero pesticide residue' integrated pest management strategy results in higher spider abundance compared to the conventional pest management strategy in the first part of the fruit growing season. However, if the application of toxic pesticides to spiders is restricted up to first part of July the abundance of spider communities become identical in one month because of intensive immigration.

Apple orchard spider communities restructure after July probably because of habitat change of the juveniles and between-species differences in offspring and mortality. This re-structuring occurs both in non-disturbed and pesticide treated orchard plots and can help the post-disturbance recovery of the spider communities. The post-disturbance increase rate of spiders (immigration, within orchard reproduction) is tightly regulated by prey availability. Therefore post disturbance spider abundances saturate quickly to a point where they are in balance with their prey supply.

Goldenrod's resistance against gall flies may cost more than it's worth

Michael Wise, Warren Abrahamson

Bucknell University, Lewisburg, Pennsylvania, United States

Introduction: Arthropod-induced galls can be very detrimental to plant fitness. Even so, plant populations often have apparently suboptimal levels of resistance, despite the presence of substantial genetic variation. One constraint on the evolution of resistance is that increased resistance may cost more than it is worth.

Methods: We investigated costs and benefits of resistance of the goldenrod *Solidago altissima* to the gall-inducing tephritid *Eurosta solidaginis*. Goldenrods are genetically variable for a resistance response in which meristem cells become necrotic and kill fly larvae before gall induction. In a greenhouse study, we exposed replicates of 26 goldenrod genets to oviposition by *E. solidaginis* and followed gall development and plant performance.

Results: The presence of a gall cost plants an average of 1743 seeds, but the cost varied ten-fold across three environmental treatments. There was no evidence that resistance to gall formation carried an allocation cost. However, resistance carried a risk of autotoxicity, as necrosis killed the apex of 37% of the ungalled plants, which cost them an average of 5015 seeds. The risk was lowest in the highest resource treatment, with the result that resisting gall formation was 1.7 times more profitable than tolerating their presence. In the nutrient-stressed treatment, in contrast, tolerance was 3.0 times more profitable than resistance.

Conclusions: The potential for autotoxicity may constrain *S. altissima*'s resistance to *E. solidaginis* to an intermediate level, and spatial or temporal variation in environmental conditions may alter the relative costs and benefits of resistance, thus maintaining genetic variation for resistance.

Exploiting natural variation in ecologically relevant traits to improve natural enemies for biocontrol

Suzanne Lommen[1], Kees Koops[1], Peter de Jong[2], Paul Brakefield[1]

[1]*Evolutionary Biology, Institute of Biology, Leiden University, Leiden, Netherlands,* [2]*Laboratory of Entomology, Wageningen University, Wageningen, Netherlands*

Natural enemies of pest species are potential biological control agents but they may possess traits that prevent successful implementation of biocontrol. If there is heritable natural variation for these traits, suitability for biocontrol may be improved through artificial selection. We report on an example of a ladybird beetle where we used the principles of evolutionary ecology to improve suitability for biocontrol.

Ladybird beetles are important predators of aphids, one of the major pests in greenhouse crops. Because of their tendency to fly away soon after release, using these predators in augmentative control is problematic. Natural populations of the two-spot ladybird beetle, *Adalia bipunctata*, show heritable variation in flight ability. Therefore, we were able to rear a pure flightless stock. When released on aphid-infested plants, flightless beetles had a longer residence time and therefore they better controlled aphid pests compared with conspecifics that were able to fly.

We used artificial selection on ecologically relevant traits to further improve two methods for augmentative control by flightless beetles. One experiment focused on inundative control (mass-release of natural enemies) and we increased survival of flightless beetles by selecting on variation in wing morphology ($h^2 = 0.74 \pm 0.09$). The second experiment aimed to improve inoculative control (the offspring of the released enemies control the pest) by increasing early fecundity. Offspring number did not respond over ten generations of selection but reproduction became earlier and fertility increased. We suggest that these flightless phenotypes that have been selected for ecologically relevant traits improve aphid biocontrol.

Effect of pollen diet and primer pheromones on worker honey bee mandibular glands

Lizette Peters, Tanya Pankiw

Texas A&M University, College Station, United States

Introduction: Only two social insect primer pheromones have been chemically characterized: honey bee queen mandibular (QMP) and brood (BP) pheromones, communicating queen and larva presence, respectively (Pankiw, 1996; Le Conte, 1990). Primers gradually change endocrine, reproductive, and neurosensory systems of workers. Previous studies have shown an increase in hypopharyngeal gland protein content of worker bees in response to brood pheromone and pollen diet rearing environment (Hrassnigg and Crailsheim, 1998). However, effects on the mandibular gland, also involved in the production of brood food and in royal jelly, have not been examined in relation to primer pheromones and pollen diet. Learning what factors influence the development of these glands could improve brood rearing or increase colony fecundity.

Methods: Newly emerged bees were placed in cages and reared 12d with the following pheromone treatments: no primer pheromone, QMP, BP, and QMP + BP. Each pheromone treatment was conducted both with and without pollen resulting in a total of 8 treatments. Subsamples of 20 bees per treatment were collected every 3 days. Mandibular gland size, and mandibular and hypopharyngeal gland protein content were measured.

Results: This study indicated that regardless of pheromone treatment, pollen was the most influential factor regarding gland protein content and size.

Conclusions: The results of this study suggest that BP and QMP may regulate feeding behavior for provisioning royal jelly and worker brood food rather than gland physiologies. Further studies are needed to determine the physiological roles, if any, BP and QMP play on mandibular gland protein biosynthesis.

Landscape composition modulates population genetic structure of *Eriosoma lanigerum* (Hausmann) on *Malus domestica* Borkh in Central Chile

Blas Lavandero[1], Marcelo Miranda[2], Claudio Ramirez[1], Eduardo Fuentes-Contreras[1]

[1]Universidad de Talca, Talca, Maule, Chile, [2]Universidad Catolica de Chile, Santiago, Metro, Chile

Introduction: The woolly apple aphid *Eriosoma lanigerum* is an important pest of apple orchards worldwide. In North America this aphid seems to be holocyclic, with sexual forms on elm trees and asexual forms on apple. In other regions of the world this aphid has all year round asexual forms occurring on apple trees. Since genetic variability and structure of insect pest populations, associated with life cycle characteristics can provide some insights into the dispersal mechanisms of these, in the present study we tested whether geographical parameters affected genetic diversity and gene flow of this pests.

Methods: The individuals were collected on apple trees from different locations in a 400 km north-south transect trough central Chile. In order to determine if there was population structure, diversity and flow were assessed.

Results: A total of 215 individuals from these locations were analysed using Inter Simple Sequence Repeats (ISSR) markers. The percentage of molecular variation among locations was 18 %. Individuals were assigned to groups through different Bayesian methods, due to isolation-by-distance relationships detected in the data set. We inferred the presence of four genetic clusters in the study region. Clustering of individuals followed a pattern explained by some geographical barriers. Using partial Mantel tests, we detected barriers to gene flow other than distance, created by a combination of main rivers and mountains.

Conclusions: Although landscape genetics are rarely used in pest management, our results suggest that these tools may be suitable for the design of area-wide pest management programs.

Semiochemical-mediated fire ant-phorid fly interactions: GC-EAD response of *Pseudacteon tricuspis* to *Solenopsis* fire ants

Henry Fadamiro, Li Chen

Auburn University, Auburn, Alabama, United States

The decapitating phorid fly, *Pseudacteon tricuspis* has been released since the mid 1990s for biocontrol of imported fire ants, *Solenopsis* spp. in southern U.S. Little is known about the cues used by *Pseudacteon* phorid flies to locate fire ant hosts. We recently provided the first direct evidence of semiochemical-mediated attraction of *Pseudacteon* species to imported fire ants: *P. tricuspis* showed significant behavioral and electroantennogram (EAG) responses to body extracts imported fire ants. In this paper, we present the results of a follow-up study to determine the identity of the chemicals mediating this observed response of *P. tricuspis* to imported fire ants. Conventional silicon gel chromatography was utilized to purify and separate crude body extracts of three fire ant species (*S. invicta* = red, *S. richteri* = black, and *S. invicta* × *S. richteri* hybrid) into different fractions (e.g., alkaloids, cuticular hydrocarbons, etc). The principal fractions were then analyzed by GC followed by testing of EAG responses of *P. tricuspis* to the different fractions. Female *P. tricuspis* did not show significant EAG response to the cuticular hydrocarbon fraction, but other fractions (including the alkaloid fraction) did elicit significant EAG responses. The most EAG-active fractions were then subjected to further analyses by coupled gas chromatography electroantennogram detection (GC-EAD) to determine biologically-active peaks. The same 2-3 unknown compounds (peaks) from extracts of all three fire ant species were shown to consistently elicit significant GC-EAD responses in *P. tricuspis*, suggesting that these unknown compounds may play a role in mediating fire ant-phorid fly interactions.

Vector potential of stable flies (*Stomoxys calcitrans*) for transmission of Porcine Reproductive and Respiratory Syndrome Virus (PRRSv)

Kateryn Rochon[1], D. Wes Watson[1], Adalberto A. Pérez de León[2], Isabel M. Gimeno[3], Monte B. Mccaw[3], Rodney B. Baker[4]

[1]Department of Entomology, College of Agriculture and Life Sciences, North Carolina State University, Raleigh, North Carolina, United States, [2]Environmental Science Division, Valent Biosciences Corporation, Libertyville, Illinois, United States, [3]Population Health and Pathobiology, College of Veterinary Medicine, North Carolina State University, Raleigh, North Carolina, United States, [4]Department of Veterinary Diagnostic and Production Animal Medicine, College of Veterinary Medicine, Iowa State University, Ames, Iowa, United States

Introduction: Porcine Reproductive and Respiratory Syndrome (PRRS) is a globally significant swine disease. The virus (PRRSv) replicates in macrophages of infected pigs resulting in pneumonia and late-term abortions in sows. The link between outbreaks in separate farms within an area despite biosecurity measures remains unclear. House flies and stable flies are a common occurrence around swine facilities. House flies can transmit the virus from pig to pig under laboratory conditions. We have investigated the vectorial potential of stable flies in the transmission of PRRSv under laboratory conditions.

Methods: Groups of stable flies fed blood containing PRRSv or intrathoracically inoculated with the virus were sacrificed at different time intervals to determine virus persistence in the gut and haemolymph. Regurgitation and defecation of virus-fed or virus-inoculated stable flies were also monitored. In transmission experiments, groups of virus-fed flies were placed on naïve pigs for four subsequent blood meals.

Results: Active virus was recovered from stable fly guts up to 24 h post feeding. Detectable virus decreased with time, suggesting no virus replication in fly tissues. Flies shed virus for at least 6 h post-feeding. Intrathoracically inoculated stable flies had ~1,500 times more PRRSv copies/ml 48 h post inoculation compared to virus-fed flies. Transmission of the virus to naïve healthy pigs was unsuccessful under the current experimental conditions although all fly groups tested positive with virus isolation.

Conclusions: The potential for stable flies to transmit PRRSv to pigs under conditions conducive to infection remains to be determined.

Use of proteomics to investigate the respective role of insect and bacterial endosymbionts in aphid - plant interactions

Frederic Francis[1], Edwin De Pauw[2], Eric Haubruge[1]

[1]Gembloux Agricultural University, Functional and Evolutionary Entomology, Gembloux, Belgium, [2]University of Liege, Mass Spectrometry Laboratory, Liege, Belgium

Introduction: Proteomics found recent developments due to significant improvement and availability of both protein separation and identification methods. Moreover, functional information's linked to the studied proteins was brought when compared to genomic approach. For these reasons, molecular entomologists have now a panel of tools to determine the proteome patterns related to differential adaptation of insects to cope with plant defence mechanisms. The aphid-plant relations will be used as a case study. Indeed, aphids represent a wonderful model in the study of plant adaptation.

Methods: The adaptation and metabolic changes of aphids in relation to host plants focusing on the role of the bacterial endosymbionts was investigated. Use of artificial diet including diverse antibiotics but also the comparison of proteomes related to whole aphid and respective purified bacterial symbionts were studied to identify the respective origin and function of proteins constituting the studied proteomes. Diverse methods including traditional two dimension electrophoresis, 2D-Differencial In Gel Expression, liquid chromatography (LC) coupled with mass spectrometry (ESI-MS-MS and Maldi-Tof-MS-MS) and data bank investigations were developed.

Results: From the proteome investigation and identification from aphid fed with particular antibiotics but also from proteomes of whole aphid and related extracted bacterial endosymbionts, particular proteins of interest were selected and accurately characterised with both fundamental but also applied views. This broad proteomic approach will be discussed as an interesting and reliable tool to study the biologically involved proteins from aphids in response to several environmental changes, and particularly the insect - host plant interactions.

The enticing odour of fungi: Partner feedback in a primitive fungus gardener of Lymexylidae (Coleoptera)

Gerrit Holighaus, Stefan Schuetz

Buesgen Institute, Dept. of Forest Zoology and Forest Conservation, University of Goettingen, Goettingen, Germany

Introduction: In woodboring beetles, insect-fungus associations range from dispersal to true "gardening". Both partners evolved complex adaptations assuring their benefit without imbalancing the relationship. In a member of the primordial beetle superfamily *Lymexyloidea*, including fungal gardeners, we found a remarkable semiochemical based interaction with its main cultivar.

Methods: Chemoecological studies have been carried out for the Large Timberworm (*Hylecoetus dermestoides* L.; Col., *Lymexylidae*). Larvae feed mainly on an ascomycetous yeast within a fungus assemblage found in galleries of various tree species. We investigated host plant and fungal odours, their perception by the insect antenna by means of coupled gaschromatography and electroantennography (GC/MS-EAD).

Results: Behavioural field studies with thus identified chemicals showed effects of fungal volatiles on beetle behaviour. Fungus transfer to the beetles offspring is assured by genitalian mycetome and exploring uncolonized wood is regular. Thus, to our surprise, a single isoprenoid compound released exclusively by the main cultivar *Ascoidea hylecoeti* (Batra & Francke-Grosmann) strongly attracts female *H. dermestoides* on host search flight. The attraction of ovipositing females to volatiles of its cultivar inside conspecific galleries is remarkable.

Conclusions: The observed mechanism can be hypothesized as follows: The fungal odour compound acts like aggregation pheromones. Larval development benefits from reinfestation or vertical fungus transfer fails in some cases. Furthermore, horizontal cultivar transmission could be influenced to either benefit. Last, it is a persisting relict maintained during evolution of beetles adaptations as the mycetome. Chemoecological methods can enlighten the function of insect-fungal associations. Further insights might be identified by this chemotaxonomic data. Evolutionary studies on the interactions within *Lymexyloidea* seems promising.

Differences among populations in susceptibility of the grasshopper *Melanoplus sanguinipes* to a generalist fungal pathogen

Stefan Jaronski, Rob Schlothauer

USDA ARS NPARL, Sidney MT, United States

Introduction: While generalist entomopathogenic fungi such as *Beauveria bassiana* are understood to have broad host specificity, little is known about variations in the susceptibility of a host species, specifically among different, geographically separate, populations.

Methods: The model system consisted of the fungus *Beauveria bassiana* Strain GHA, five geographically separate populations and two different laboratory colonies of the Migratory Grasshopper, *Melanoplus sanguinipes*. Relative susceptibility of each population to the fungus was based on replicated, multiple dose, topical bioassays to yield a mean fungal LD50 and associated statistics for each population. Each population was tested 3-5 times over a three year period.

Results: The mean LD50 values for two Montanan, one Idahoan, one Alaskan population and the USDA colony were not significantly different from each other. The LD50 values ranged from 53,000 – 81,000 conidia per insect. A North Dakotan population was significantly less susceptible by a factor of 5-8, and a colony from Agriculture Agrifood Canada was significantly more susceptible by a factor of 5-7.5. This is first evidence for significant differences among host insect populations in their susceptibility to a generalist fungal pathogen.

Field response of *Steirastoma breve* (Sulzer, 1776) (Coleoptera: Cerambycidae) to odors of *Theobroma cacao* L.

Carmen V. Liendo-Barandiaran[1], Beatriz Herrera-Malaver[1], Franklin Morillo[2], Pedro Sanchez[2], José Vicente Hernández[1]

[1]Universidad Simón Bolívar, Caracas, Estado Miranda, Venezuela, [2]Instituto Nacional de Investigaciones Agrícolas, Caucagua, Estado Miranda, Venezuela

Introduction: *Steirastoma breve* is the most important insect pests in Neotropical cocoa plantations. Larvae and adults cause severe damage in stems and branches of infested plants. In the present work, field responses and olfactory behavior of *S. breve* to its host plant odors were evaluated.

Methods: Olfactory response of adults *S. breve* was evaluated using *Theobroma cacao* L. and *Bauhinia* sp. branches piles as odor source. In both cases, 60 kg of branches were placed under sunny and shade conditions in an experimental cocoa plantation. During 23 consecutively days, from 9:00 to 15:00 h, the sex and adults number of *S. breve* observed in the piles were recorded each hour. Approach behavior and other behavioral activities of *S. breve* towards *T. cacao* piles were recorded and described.

Results: Adults of *S. breve* are attracted towards *T. cacao* branches piles under sunny and shade conditions, contrary as occur with *Bauhinia* sp. Adults beetle average value to both sexes was higher in shade than in sunny conditions. In both conditions, males average value was higher than females one. Behaviors performed by this beetle on piles were classified as follow: resting, mating, flying, exploring and feeding. Three types of approach flight were observed towards the branches piles: zig-zag, direct and turns around branches pile.

Conclusions: All those results confirm kairomones presence emitted by *T. cacao*, they are involved in the chemical communication system of *S. breve*.

Transitions between respiratory patterns in sedentary insects is dependent on metabolic rates: A look into the respiratory patterns of *Rhodnius prolixus* and *Gromphadorhina portentosa*

Heidy Contreras

University of California, Irvine, Irvine, CA, United States

Relatively little is known about the response of insect respiratory pattern to changes in metabolism (i.e. aerobic demand) despite the fact that respiratory patterns of insects have been the subject of intense study. The reason for this is that any locomotory activity, which may accompany an increase in metabolic rate, tends to disrupt the observed respiratory pattern. We have sought to get around this problem by using insects that are highly sedentary and by adjusting metabolic rate in these poikilothermic animals using temperature. *Rhodnius prolixus,* a sit and wait bloodsucking insect, has a classic discontinuous respiratory pattern (closed, flutter and open phase). The hissing cockroach, *Gromphadorhina portentosa*, a relatively sedentary detritus feeder exhibits the classic active ventilatory pattern typical of cockroaches. We found that at low temperatures, both insects exhibit lengthy periods of spiracular closure reflecting a discontinuous pattern of respiration. As the temperature and metabolic rate increase, the insects show shortened closed periods, transitioning to the cyclical respiratory pattern. Finally, at the highest temperatures, the insects exhibit a continuous respiratory pattern. Our results suggest that the three described respiratory patterns in insects are not distinct but are instead a continuum of respiratory responses driven by the metabolic demand experienced by the insect.

A tritrophic view of diversity

Lee Dyer

Tulane University, New Orleans, LA, United States

Diversity is usually examined at single trophic levels, and many prominent diversity hypotheses, such as neutrality and intermediate disturbance, focus on primary producers. The focus of these diversity studies is also on species richness or a diversity index that utilizes species as the unit of interest. It is equally useful to view trophic chains as units of diversity and to focus on how the number of n-link chains varies across biotic or abiotic gradients. Utilizing collaborative data sets from large caterpillar rearing projects around the world and meta analyses from published studies, I tested the following assumptions about tritrophic (1 to 3-chain) diversity across a latitudinal gradient: 1) tritrophic diversity decreases with latitude, altitude, and disturbance, 2) consumer specialization decreases with latitude, and 3) pressure from natural enemies is more intense in the tropics and in predictable habitats. Tritrophic diversity, dietary specialization, and strength of trophic cascades all decreased significantly with increasing latitude. Gradients in disturbance and climatic variability were the best predictors of pressure from natural enemies, and this pressure did not vary consistently with latitude. Understanding mechanisms underlying these gradients in tritrophic diversity will contribute to clarifying issues about climate change, resiliency of tropical ecosystems, and the origin and maintenance of high tropical diversity.

Impact of invasive insect pests on eastern hemlock in the southern Appalachians, USA: Novel approaches to evaluating biological control agents for forest health management

Jerome Grant[1], Paris Lambdin[1], Gregory Wiggins[1], James Rhea[2]

[1]University of Tennessee, Knoxville, Tennessee, United States, [2]United States Department of Agriculture Forest Service, Southern Region, Asheville, North Carolina, United States

Introduction: Forest health in the southeastern USA is affected by numerous exotic insects, weeds, and plant diseases. Two invasive insect pests, elongate hemlock scale (EHS), *Fiorinia externa*, and hemlock woolly adelgid (HWA), *Adelges tsugae*, currently threaten forest health in the southern Appalachians, where HWA has caused high mortality of eastern hemlock (*Tsuga canadensis*). As part of a forest health management program, the feasible use of biological control agents against both invasive pests is underway. Large canopy enclosures (i.e., tree cages) were designed to evaluate their feasibility as tools to assess effectiveness and impact of introduced biological control agents in forest systems.

Methods: The impact of several established natural enemies of EHS was assessed; however, densities of HWA were not reduced by established natural enemies, emphasizing the need for the introduction and release of suitable biological control agents. Novel approaches to evaluating these introduced natural enemies were developed. Large screened cages (ca. 8 m tall x 24 m at base) were designed and placed over HWA-infested eastern hemlock trees in a forest setting. Densities of HWA were determined on each tree, and tree and HWA parameters were measured. One of three species of predatory beetles was placed in each cage. Predator and HWA densities were monitored to assess survival, establishment, reproduction, and impact on HWA.

Results: Impact of EHS on eastern hemlock was minimal in forest settings, due to the presence of numerous parasitoid and predator species. One parasitoid, *Encarsia citrina*, caused 20% mortality of EHS. Through trial and error, and resulting modification of cage strategy, a large tree cage that can withstand the various pressures placed upon it under field conditions was developed to better evaluate introduced natural enemies of HWA. These large cages have withstood rain, snow, and winds (some as high as 72 km/hr), with minimal damage. Results on the survival of each introduced biological control agent and its impact on HWA, as well as tree growth parameters, will be presented and discussed.

Conclusions: Large canopy enclosures provide a unique opportunity to assess introduced natural enemies of exotic pests of native trees in forest ecosystems. These cages have applicability to assessing the practicality of other forest pest/natural enemy systems.

Evolving out of conflict: Imperialism and altruism in gall-forming eusocial aphids

Patrick Abbot

Vanderbilt University, Nashville, TN, United States

The precise role of conflict in evolution of cooperation remains contentious. At debate are the conditions under which biological organization at more inclusive levels is promoted or inhibited by conflict and competition at lower levels. Eusocial, soldier producing aphids provide an interesting perspective, because they exhibit complex social organization in clonal societies. While admixture between clones occurs in some social species, clonality has been thought to be a necessary condition of social evolution in aphids. What is not known, however, is what role competition and conflict have played in these clonal societies. Here, we show that non-unitary relatedness evolved early in the radiation of the gall-forming North American genus *Pemphigus*, prior to the evolution of social behavior. Thus, social behavior evolved out of a more complex genetic group structure than previously known. These results update our understanding of social evolution in aphids, and provide a nuanced view of the evolution of conflict and cooperation in these insects. Namely, the function of aphid soldiers may not only be to ensure the survival of their resident kin group, but also the capacity of their clone to successfully exploit other clones. Because of their impressive dispersal abilities, all gallforming aphids - social or not - are probably clone-invading 'imperialists'. Eusocial aphids may not be so much 'fortress defenders' as they are 'fortified imperialists'.

Transdisciplinary approaches in documentation of biodiversity

Karl-Heinz Lampe

Zoologisches Forschungsmuseum Alexander Koenig (ZFMK), Bonn, Germany

Introduction: The traditional 'analogous' practice of documentation in Natural History museums is mainly based on more or less atomized entities which are often simple field names such as locality, collector or author. With modern approaches the documentation becomes more focused on processes and events. Thus the above mentioned entities what, who, where and when or respectively object/concept, person, place, time and activity have to be related to each other.

Methods: Information is modelled here with an ontology based on the CIDOC-Conceptual Reference Model (ISO 21127). In informatics, ontology is a formal specification of semantic concepts.

Results: As to be specified with some realistic examples taken from the field of biodiversity (collecting-, determination-, type creation-, expedition-, observation and painting events) the formal specification of semantic concepts makes scientific activities commonly understandable. In scientific (as well as scholarly) disciplines that should be an efficient way to document information in their full scientific depth rather than simply administering it. Thereby information content and handling can be improved by multiple instantiation, mutual verification and semantic enrichment.

Conclusions: A documentation of processes and events seems to be a prerequisite for trans-disciplinary information integration which is needed for developing knowledge networks and knowledge representation tools on the internet.

Neuronal organization of the trail pheromone pathway in Attine ants

Christoph J. Kleineidam, Christina Kelber

University of Wuerzburg, Wuerzburg, Germany

Leaf-cutting ants (genus *Atta*) are evolutionary-derived Attine ants with an extreme size polymorphism among workers and the most complex social organization. Body size is related to the behavior of workers and their assessment of the trail pheromone. Our behavioral experiments with *Atta vollenweideri* suggest that large workers primarily respond to the releaser component of the multi-component trail pheromone, whereas small workers rely more on blend-specific traits. We asked why the individuals behave differently and how neuronal information processing generates the inter-individual variance found in behavior. Using functional imaging, we found that the releaser component of the trail pheromone is represented in a substantially enlarged glomerulus (macroglomerulus) located in the antennal lobe. Only the antennal lobe of large workers contains a macroglomerulus, and correlating body size with glomerular volumes revealed two neuroanatomical sub-castes of workers (with or without macroglomerulus). The phenotypic plasticity found in the antennal lobe is probably the neuronal basis for the described differences in olfactory guided behavior.

In a comparative study across 24 species, we found a macroglomerulus only in the higher Attini (*Atta* and *Acromyrmex*) but not in any of the 10 investigated basal and intermediate Attini. This indicates that the macroglomerulus in the olfactory pathway of leaf-cutting ant workers is a derived trait. The neuroanatomical sub-castes of the polymorphic species lead to specialization and contribute to their complex social organization, whereas behavioral flexibility alone promotes division of labor in the species with less pronounced polymorphism and smaller colonies.

In addition to the genus-specific variation of glomerular volumes, we found an enormous variation in the number of glomeruli (288-630) indicating a strong selective pressure on the organization of the olfactory pathway.

Mass spectrometric analysis of neuropeptide-synthesizing neurons in the CNS of insects

Reinhard Predel, Susanne Neupert

Institute of Zoology, University of Jena, Jena, Germany

Neuropeptides are widespread signal molecules that display a great chemical and functional diversity. The predictions of neuropeptide cleavage from precursor proteins are not always correct and thus biochemical identification is essential. Particularly single cell analysis can be prerequisite for a better understanding of the complex functions of neuronal circuits. Currently, MALDI-TOF mass spectrometry is the method of choice to deal with that problem.

We present an overview of the methods that are used for cell identification and subsequent mass spectrometric analysis of peptidergic neurons in insects.

Insects with blue blood: On the occurrence of respiratory hemocyanins

Thorsten Burmester, Christian Pick

University of Hamburg, Hamburg, Germany

For a long time, respiratory proteins have been considered unnecessary in most insects because the tracheal system was thought to be sufficient for oxygen supply. Only a few species that dwell under hypoxic conditions were known exceptions and have hemoglobins. Other arthropods (crustaceans and chelicerates) harbour copper-containing hemocyanins in their hemolymph for transport of oxygen. No hemocyanins had been known from Hexapoda. However, recently we discovered a functional hemocyanin in the stonefly *Perla marginata*, which is present at high concentrations the hemolymph of nymphs and adults. *P. marginata* hemocyanin is a hexamer with two distinct subunit types of 659 and 655 amino acids, respectively. It has a moderate oxygen affinity (P_{50} ~ 8 torr) and displays cooperative oxygen binding. We further identified and cloned hemocyanin sequences from Collembola, Archaeognatha, Zygentoma, Phasmida, Dermaptera, Mantodea, Isoptera, Blattodea and Orthoptera. No hemocyanins could be identified by molecular or biochemical means in various representatives of Odonata and Ephemeroptera, suggesting its loss in these orders. Apparently, hemocyanin is also absent in Eumetabola (Hemiptera + Holometabola). Phylogenetic analyses show that there are two distinct hemocyanin subunit types (Hc1 and Hc2) in Hexapoda. While Hc1 groups with the copper-less, insect storage hexamerins, Hc2 is of more ancient evolutionary origin. The Pancrustacea hypothesis is supported by the hemocyanins. While the occurrence of hemocyanins adds further complexity to our view on insect respiration, there is currently no physiological or morphological character that could explain the presence or loss of hemocyanins in distinct taxa.

INOTAXA: open access, easy navigation and data mining of taxonomic literature on the web

Christopher Lyal[1], Anna Weitzman[2]

[1]The Natural History Museum, London, United Kingdom, [2]National Museum of Natural History, Washington, D.C., United States

Taxonomic literature produced over the past 250 years is required by all taxonomists, and contains a vast amount of information that is both of immense potential value and virtually inaccessible outside a few large libraries and collections. While progress has been made in producing digital versions of literature in formats such as PDF or JPEG and placing them on the web, these have drawbacks in terms of navigation, finding specific content or even finding the publication. The Biodiversity Heritage Library addresses some of these issues, but the content remains presented in a publication-centred manner rather than a user-centred way. INOTAXA (INtegrated Open TAXonomic Access) is a new way of making taxonomic literature and data available on the web. Using a purpose-designed XML schema interoperable with other TDWG standard schemas, and a purpose-built portal, a corpus of taxonomic literature can be searched using any term or set of terms, the search narrowed by restrictions such as geography, publication or higher taxon, or browsed by taxonomic classification, geography, person or publication. In addition to retrieving taxonomic treatments and keys, the content can be mined for specimen data, biological associations, classifications, people and much more. In addition to dealing with legacy literature, INOTAXA opens the door to much faster publication of new taxonomic information. Because of the use of standards data can be exchanged with resources such as GBIF, Catalogue of Life and the Encyclopedia of Life. A prototype of INOTAXA will be briefly shown and some of its functionality will be displayed.

Syngenta's approach to deploying transgenic insect resistance traits

Ryan Kurtz

Syngenta Biotechnology, Inc, Research Triangle Park, NC, United States

Syngenta currently has insect resistant transgenic maize and cotton products which are or are nearing commercialization in North and South America. Each of these products expresses one or more of three *Bacillus thuringiensis*-derived insecticidal proteins, Cry1Ab, Vip3A or mCry3A. The Cry1Ab protein provides protection against certain lepidopteran insect pests including *Ostrinia nubilalis, Diatraea grandiosella, Diatraea saccharalis, Heliothis virescens* and *Helicoverpa spp.* The Vip3A protein provides protection and a second mode of action against economically important lepidopteran pests including *D. grandiosella, D. saccharalis, Spodoptera frugiperda, Heliothis virescens* and *Helicoverpa spp.* The mCry3A protein provides protection against economically important corn rootworm pests such *Diabrotica virgifera virgifera* and *Diabrotica longicornis barberi*.

These proteins' high degree of specificity and demonstrated safety are the basis for their utility as plant incorporated protectants. The successful deployment of these products will provide substantial benefits to growers and to society. Consequently, it is essential that we foster the continued utility of this technology through the implementation of appropriate insect resistance management tactics. Syngenta's Vip3A toxin offers a distinct mode of action compared to Cry toxins. Pyramiding these two modes of action will reduce the risk of resistance in insects controlled by both events. In North America, Vip3A will only be offered as a pyramid with Cry1Ab in both maize (Bt11 x MIR162) and cotton (VipCot™). Vip3A and Cry1Ab will initially be offered singly in South America followed soon as pyramided in Bt11 x MIR162.

Taxonomic needs in managing invasive species: A global assessment

Christopher Lyal[1], Richard Smith[2]

[1]The Natural History Museum, London, United Kingdom, [2]BioNET-INTERNATIONAL, Egham, United Kingdom

Although taxonomy is recognized as important in managing invasive species there is little clarity on the overall priorities at a global policy level. The lack of explicit statements hinders access to taxonomic expertise and the development of protocols and practices to ensure taxonomic information and expertise are available when and where they are needed. An assessment of taxonomic needs in the context of Invasive Alien Species management at a global level showed that high prioritization was given by members of the IAS community to provision of names, their synonyms and their vernacular equivalents, to identification tools, and to the availability of expert taxonomists to provide identifications. The assessment provides recommendations to address the taxonomic impediment in IAS, and these are being made available both publically and to relevant policy and implanting bodies, such as the Convention on Biological Diversity and the Global Invasive Species Programme.

Vegetation management for biological control in annual crops: Spatial scale and meta-communities

Deborah Letourneau, Carol Shennan, Sara Bothwell, Tara Pisani-Gareau

University of California, Santa Cruz, CA, United States

Perennial vegetation in agricultural landscapes may contribute to ecological pest management by provision of critical habitat and food resources for arthropod parasitoids and predators of crop pests, especially in frequently disturbed, annual cropping systems. We determined the extent to which natural enemy abundance or diversity is predicted by the presence or relative cover of perennial vegetation at the field-level (vacuum samples on hedgerows adjacent to vegetable crops) and the landscape-level (Malaise trap samples in vegetable fields embedded in a range of vegetation and land-use mosaics). Landscape factors, within a 1.5km radius of each Malaise trap, were measured using manual aerial photo interpretation with GPS field-verification. We also measured parasitism rates of sentinel moth larvae (*Trichoplusia ni*) and aphids (*Brevicoryne brassicae*) to determine if diversity, abundance, or movement rates of natural enemies predict conservation biological control potential on farms. Robust results include: (1) a positive association between the amount of perennial vegetation cover and the richness of ichneumonid wasp species versus a negative association between annual cropland cover and species richness of ichneumonid wasps, (2) a positive association between parasitoid abundance and *Baccharis pilularis* shrubs in hedgerows versus a negative association between these factors on the landscape-scale, (3) differential hedgerow shrub usage by pests and natural enemies, and (4) a tenuous association between biodiversity and parasitism rates. We will discuss current evidence and experimental methodologies in the context of theoretical expectations regarding biodiversity and pest control as an ecosystem service.

Rapid and gradual shifts in tropical and temperate styles of herbivory from the North American Paleogene

Conrad Labandeira[1], Ellen Currano[3], Peter Wilf[3], Scott Wing[1]

[1]Smithsonian Institution, Washington, DC, United States, [2]University of Maryland, College Park, MD, United States, [3]Pennsylvania State University, University Park, PA, United States

Introduction: Comparisons of the intensity of tropical and temperate insect herbivory in the modern world show strong latitudinal patterns. These geographic patterns are mirrored in the paleontological record, such as the ~10^5 yr-long Paleocene-Eocene Thermal Maximum (PETM) occurring 55.8 million years ago.

Methods: Herbivore intensity and diversity are estimated from characteristic modes of insect feeding on fossil leaves. The units of analysis are damage types (DTs), which are diagnosable, stereotyped patterns of insect damage on fossil plants. Indices include the frequency and diversity of attack on bulk floras and specific, taxonomically identified plant groups.

Results: Pre-PETM floras from northern Wyoming, which were dominated by deciduous plants, had low levels of herbivory. During the PETM, a transient global temperature increase of ~5°C and tripling of atmospheric CO_2 was associated with a rapid increase in abundance and diversity of subtropical plant taxa and a major increase in total and specialized herbivory. Post-PETM climate and floras reverted to the previous state, as did levels of herbivory. Several million years later, as climates in northern Rocky Mountains became warmer and locally drier, the amount and character of herbivory changed again. During this interval there was a separation in herbivory style between more palatable deciduous taxa in wetter habitats versus highly defended, evergreen taxa in better drained and elevated areas.

Conclusion: The PETM is analogous to the modern rise of global anthropogenic in CO_2 and temperature. The PETM increase in insect herbivory is a preview for current managed and natural ecosystems.

Longitudinal studies on the emergence of dengue virus in Iquitos, Peru

Amy Morrison[1], Tadeusz Kochel[2], Gregor Devine[3], Moisés Sihuincha[4], Thomas Scott[5]

[1]University of California Davis, Davis, California, United States, [2]U.S. Naval Medical Research Center, Lima, Peru, [3]Rothamsted Research, Harpenden, United Kingdom, [4]Laboratorio Referencial, Iquitos, Peru, [5]University of California, Davis, California, United States

Dengue virus seroconversions were monitored among study populations of 2,000-3,000 residents in 3 prospective cohort studies carried out since 1999 in the Amazonian city of Iquitos, Peru. Study participants were tested by plaque reduction neutralization at 6 month intervals. Their homes and neighborhoods were also monitored regularly for *Aedes aegypti* vectors. In 1999, seroprevalence rates to dengue ranged from 65-89% and were correlated with vector densities ($r>0.5$). Under conditions of endemic transmission (prior to 2002) overall seroconversion rates ranged from 2-3 conversions/100 person-years at risk. In contrast, since the introduction of dengue-3, Iquitos has experienced 4 significant dengue outbreaks in which incidence rates ranged from 12 to 44 conversions per 100 person-years at risk. Dengue Hemorrhagic Fever cases were confirmed for the first time in 2004 and have occurred only when transmission rates were high over all. Only adult, not immature *Aedes aegypti* indices correlate with seroincidence rates; correlation rates were < 0.25 during inter-epidemic periods and 0.38-0.41 during periods of epidemic transmission.

House to house ULV pyrethroid spray applications consistently lowered vector populations to negligible levels and decreased dengue virus transmission significantly, whereas in a variety of controlled trials of larviciding strategies had minimal impact on vector populations. We will discuss the implications of these observations on dengue prevention and control strategies world-wide including the merits of strategies focused on preventing severe disease rather than complete suppression of virus transmission.

Spatially and temporally targeted vector-borne disease interventions

Thomas Scott, Amy Morrison

University of California, Davis, California, United States

Contemporary dengue prevention is based on the unvalidated assumption that a reduction in adult *Aedes aegypti* population densities will decrease risk of virus transmission. *Ae. aegypti* eradication is not considered feasible and there are no commercially available dengue vaccines or clinical cures. Mosquito vector control is the only currently available dengue prevention strategy. We will discuss the theoretical underpinnings and implications of temporally and spatially targeted vector control for dengue prevention in the context of four interrelated questions. What is an acceptable level of dengue risk? What are the mosquito densities necessary to achieve that goal? What is the best way to measure entomological risk? Because most dengue risk factors are likely to exhibit spatial dependence, at what geographic scale are the components of dengue transmission important?

Two important outcomes are necessary for meaningful improvement in dengue surveillance and control. First, there is an urgent need for field-based prospective longitudinal cohort studies on the relationships among measures of entomological risk (i.e. *Ae. aegypti* density), dengue incidence, and severity of disease. Second, new rapid, inexpensive, and operationally amenable methodologies are needed to evaluate and monitor the impact of vector control strategies on disease reduction. Unless mosquito vectors are eliminated entirely, predicting and evaluating success of dengue prevention programs will continue to require a more thorough understanding of the site specific relationships among effective disease prevention strategies, risk of human disease, and application of intervention strategies through time and space.

Different seasons, different reasons: Behavioral plasticity of the discriminating sex in mate choice

Kathleen Prudic, Antonia Monteiro

Yale University, New Haven, CT, United States

Introduction: *Bicyclus anynana* (Lepidoptera: Nymphalidae) displays seasonal variation in the size of its ventral eyespot patterns, a likely defensive adaptation against predators. This species also has dorsal eyespots that are stable in size across seasons, but little is still known about their function. Here we evaluate the role of dorsal eyespots in mate choice to understand why this character does not display the seasonal variation characteristic of other eyespots.

Methods: We designed experiments to evaluate mate preference of each sex from each season. We manipulated wing pattern by either applying opaque paint on top of UV-reflective scales in the center of the eyespots or away from the UV-reflective center. We observed the effect of eyespot treatment on first mating. We also recorded butterfly longevity as it related to mate seasonal form.

Results: Dry season males preferred females with intact dorsal eyespots while wet season males did not show a preference. Conversely, wet season females preferred males with intact dorsal while dry season females did not show a preference. Mating with a dry season male increased the longevity of both dry and wet season females, but mating with a wet season male did not affect female longevity.

Conclusions: Dorsal eyespots are vital for sexual signaling in *B. anynana*; however, the signaling sex changes between dry and wet season. This pattern can be explained by both species recognition mechanisms and seasonal resource availability. Behavioral plasticity appears to constrain morphological plasticity in the eyespots important for mate signaling.

Indirect host-related chemical kairomones for improving egg parasitoid efficacy in IPM

Stefano Colazza[1], Ezio Peri[1], Eric Conti[2], Gianandrea Salerno[2], Ferdinando Bin[2]

[1]Department of SENFIMIZO – Section of Entomology, Università di Palermo, Palermo Sicilia, Italy, [2]Department of DSAA – Section of Entomology, Università di Perugia, Perugia Umbria, Italy

Successful parasitism by Hymenoptera parasitoids of herbivores is arisen trough several phases of host searching behaviour, which eventually lead the wasp females close to, or in contact with their potential hosts. During the host location process, wasp females encounter and explore a great variety of stimuli, mainly chemical cues, named semiochemicals, that play a major role. In the last decades, semiochemicals have become a valuable tool for developing Integrated Pest Management (IPM) programs. However, applied approaches towards field use of semiochemicals as a mean for behavioural manipulation of insect parasitoids have rarely been considered. Attempts of kairomone employment in the field have been carried out with egg parasitoids, with the aim of retaining the parasitoids in the target area. Laboratory experiments on egg parasitoids belonging to the families *Trichogrammatidae* and *Scelionidae*, showed that scales shed by adults of lepidopterans, and chemical residues left on a substrate by true bugs while moving, represent a set of indirect host-related contact kairomones that induce arrestment and motivated searching behaviour. A comparative analysis of these results suggest that the active compounds of these contact kairomones can be sprayed over the plants to increase the probability of egg parasitoid encounters with the hosts, thus increasing parasitism rate. However a better understanding of plant surface - kairomone interactions is necessary to define how to apply these chemicals in the field and predict impact on natural enemies and biological control efficacy.

Ecology of fungi from Ascospherales and their association with social and solitary bees

Annette Bruun Jensen[1], Jørgen Eilenberg[1], Rosalind James[2]

[1]University of Copenhagen, Copenhagen, Denmark, [2]USDA-ARS, Logan, UT, United States

All known species of Ascosphaerales are associated with bees (Apoidea), social as well as solitary soil and twig nesting bees. Different fungal life cycle strategies can be found, some species are obligate pathogens of bee larvae/pupae and some are secondary pathogens, while others live as saprophytes on pollen, pollen provision or feces. The insect pathogenic Ascospharales differ significantly from most other insect pathogenic fungi with respect to their primary infection route – these fungi infect bee larvae through the gut upon ingestion of ascospores. We will discuss the biological significance of this exemplified by recent studies performed on the two most well known species *Ascosphara aggregate* and *Asco. apis*. These two species represent pathogens of important pollinators, *Asco. aggregate* infects the alfalfa leafcutting bee *Megachile rotundata*, *Asco. apis* infects the honey bee *Apis mellifera*, thus representing pathogens of a solitary and social bee, respectively.

Hygienic behaviour, removal of diseased larvae by worker bees is an important defence mechanism seen in social insects, and to eliminate this factor bioassays can be performed on *in vitro* reared larvae. We performed such bioassays to investigate susceptibility of different honey bee races to *A. apis*. *Megachile rotundata* is not known to have different races, but we have found the susceptibility of this bee to be affected by environmental temperature conditions, where cooler temperatures increase infection levels. Cool temperatures have previously been found to increase chalkbrood infection levels in honey bees and the blue orchard bee (*Osmia lignaria),* as well.

Current status of oak wilt disease in Korea

Kyung Hee Kim, Seung-Kyu Lee, Sang Tae Seo, Eunsung Oh, Won Il Choi

Korea Forest Research Institute, Seoul, Republic of Korea

Oak wilt disease in Korea was first reported in 2004. The causal agent was identified as *Raffaele*a sp. associated with an ambrosia beetle, *Platypus koryoensis*. There are six oak species in forests, and *Quercus mongolica* is the most susceptible. It shows the dying or dead symptom from July to October after infection. The trees attacked by the beetles resulted in 17~21% of mortality. The study sites were selected to observe the progress of disease on naturally damaged trees. There were no dead trees found in 2^{nd}~3^{rd} year after penetration of beetles in the sites. Also, the sites that were located over 600m elevation had less death of trees and slow spread of the disease. The damage was limited to central region between 2004 and 2005. However, it was widely distributed over the country in 2006. The oak forests with mainly *Q. mongolica* in the central region have been cut down once and grown from the sprouts. Because the oak wilt disease was predisposed to the central area, the area has been mostly damaged compare to other regions. Also, the sunny area had more infected trees than shade area. Overwintering adult beetles of *P. koryoensis* emerged from bark in early May and even early October. It was analyzed that the high peak of the emergence was dependent on environment conditions in different locations over year.

Non-target risk assessment of insect-resistant GM crops: an international, multi-stakeholder approach

Jörg Romeis[1], Detlef Bartsch[2], Franz Bigler[1], Marco P. Candolfi[3], Marco M.C. Gielkens[4], Susan E. Hartley[5], Richard L. Hellmich[6], Joseph E. Huesing[7], Paul C. Jepson[8], Raymond Layton[9], Hector Quemada[10], Alan Raybould[11], Roby I. Rose[12], Joachim Schiemann[13], Mark K. Sears[14], Anthony M. Shelton[15], Jeremy Sweet[16], Zigfridas Vaituzis[17], Jeffrey D. Wolt[18]

[1]Agroscope Reckenholz-Tänikon Research Station ART, Zurich, Switzerland, [2]Federal Office of Consumer Protection and Food Safety (BVL), Berlin, Germany, [3]BASF SE, Limburgerhof, Germany, [4]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [5]University of Sussex, Falmer, Brighton, United Kingdom, [6]USDA–ARS, Corn Insects and Crop Genetics Research Unit and Department of Entomology, Iowa State University, Ames, IA, United States, [7]Monsanto Company, St. Louis, MO, United States, [8]IPPC, Cordley Hall, Oregon State University, Corvallis, OR, United States, [9]DuPont Crop Genetics, Johnston, IA, United States, [10]Program for Biosafety Systems, Calvin College, Grand Rapids, MI, United States, [11]Syngenta, Jealott's Hill International Research Centre, Bracknell, Berkshire, United Kingdom, [12]USDA–APHIS Biotechnology Regulatory Services, Riverdale, MD, United States, [13]Julius Kuehn Institute, Federal Research Centre for Cultivated Plants (JKI), Institute for Biosafety of Genetically Modified Plants, Braunschweig, Germany, [14]Department of Environmental Biology, University of Guelph, Guelph, Ontario, Canada, [15]Department of Entomology, Cornell University/NYSAES, Geneva, NY, United States, [16]Environmental Consultant, Willingham, Cambridge, United Kingdom, [17]Biopesticides and Pollution Prevention Division, USEPA, Washington, DC, United States, [18]Biosafety Institute for Genetically Modified Agricultural Products and Department of Agronomy, Iowa State University, Ames, IA, United States

An international initiative is developing a scientifically rigorous approach to evaluate the potential risks to non-target arthropods (NTA) posed by insect-resistant, genetically modified (IRGM) crops. It adapts the tiered approach to risk assessment that is used internationally within regulatory toxicology and environmental sciences. The basic principles and rationale of this approach are outlined, and ways in which it has been refined by scientists from public, industrial and regulatory sectors, who have extensive experience with IRGM crops, are reported. The approach focuses on the formulation and testing of clearly stated risk hypotheses, making maximum use of available data and using formal decision guidelines to progress between testing stages (or tiers). It is intended to provide guidance to regulatory agencies that are currently developing their own NTA risk assessment guidelines for IRGM crops and to help harmonize regulatory requirements between different countries and different regions of the world. The approach will thus be of great benefit for regions that lack the capacities to conduct all the regulatory risk assessment studies themselves. It will also aid researchers developing IRGM crops as well as the funding agencies supporting their work by providing them a framework for organizing and planning regulatory studies in support of their products.

Edaphic factors influencing the performance of a root-feeding flea beetle, *Longitarsus bethae* (Coleoptera: Chrysomelidae), a biological control agent for *Lantana camara* (Verbenaceae)

David Simelane

Agricultural Research Council, Pretoria, Gauteng, South Africa

Adult preference and survival of the immature stages of the root-feeding flea beetle, *Longitarsus bethae* Savini and Escalona (Coleoptera: Chrysomelidae), a natural enemy of the weed, *Lantana camara* L. (Verbenaceae), were examined at four soil textures, three soil moisture levels, two soil surface conditions and at five levels of organic matter content under laboratory conditions. Both soil texture and moisture had no influence on leaf feeding and colonisation by adult *L. bethae*. Soil texture had a significant influence on oviposition, with adults preferring to lay on clayey and sandy soils to silty or sandy loam soils. However, survival to adulthood in clayey soils was significantly higher than in other soil textures. Although oviposition preference and depth of oviposition were not influenced by soil moisture, survival in moderately moist soils was significantly higher than in other moisture treatments. Development of immature stages in high soil moisture treatments was significantly slower than in low and moderate soil moisture treatments. There was a strong negative relationship between the percentage of organic matter in the soil and the number of eggs laid. There were no variations in the body size of beetles that emerged from different soil textures and moisture levels. Females laid almost three times more eggs on cracked than on non-cracked soils. It is predicted that clayey and moderately moist soils will favour the survival of *L. bethae*, and under these conditions, damage to the roots is likely to be high. This information will aid in the selection of suitable release sites where *L. bethae* would be most likely to become established.

The use of oil soluble dyes to mark *Eldana saccharina* Walker (Lepidoptera: Pyralidae) adults

Angela Walton, Des Conlong

[1]SASRI, Mount Edgecombe KZN, South Africa, [2]Stellenbosch University, Stellenbosch WC, South Africa

Two oil soluble dyes (Sudan red and Calco red) were incorporated into the diet used to rear *Eldana saccharina* at the SASRI Insect Rearing Unit. These dyes are taken up in the fat bodies of the target insect, which allow, upon dissection of these, the identification of laboratory-reared adults from wild counterparts caught in traps. However, the use of dyes such as these can have detrimental effects on the developmental biology, fecundity and fertility of *E. saccharina*. It was found that Sudan red reduced adult emergence by 38% and fecundity by 70% and prolonged development time. Development time was measured as % Pupation at the time of sampling. Pupation was reduced by 46% in the Sudan red treatment compared to the control. Calco red did not impact on the developmental and reproductive biology of this insect in any way.

This breakthrough allows these marked adults to be used in mating, field dispersion and population estimation studies. This information is important for the formulation of sterile insect technology and mating disruption control options for *E. saccharina*. The results will be discussed in the context of these area-wide management programmes.

Invertebrate conservation in Gauteng Province, South Africa: A retrospective overview

Ian Engelbrecht

Gauteng Dept. of Agriculture, Conservation and Environment, Johannesburg, Gauteng, South Africa

Gauteng Province has been championed as the economic development hub of South Africa, and the economic powerhouse of Africa. With this economic development has come extensive land transformation in the province, primarily for residential, industrial, and infrastructural purposes. This context provides significant challenges for biodiversity conservation. A systematic conservation plan, developed by the Department of Agriculture, Conservation and Environment, has provided the primary government regulatory tool for biodiversity conservation in the province. The invertebrates have featured significantly in the development of this conservation plan with six butterfly species, two beetle species, one scorpion species and twelve mygalomorph spider species included. These species were originally identified as conservation priorities through an expert consultation process, but evidence gathered subsequently indicated that their inclusion might not have been justified. As a result the decision was taken to apply the IUCN red list assessment criteria to these species in order to more objectively determine their likelihood of extinction, and hence more appropriately represent them in the conservation plan. This presentation will outline the mechanism by which the conservation plan is used as a regulatory tool in the province, the results of the Red List assessments and the implications for invertebrate conservation in Gauteng Province and elsewhere will be discussed.

Phenology modelling of major fruit tree pests: From biological basics to decision support

Jörg Samietz, Benno Graf, Heinrich Höhn, Hans Ulrich Höpli

Swiss Federal Research Station Agroscope Changins-Wädenswil ACW, Wädenswil, Switzerland

Introduction: Modern plant protection relies on precise timing of pest management. Forecasting tool are needed in order to optimize timing of monitoring and control of insect pests and growers or consultants have to be provided with according information. The system SOPRA has been developed to facilitate these needs by combining pest biology and behaviour, modelling, and modern internet technology.

Methods: Applying time-varying distributed delay approaches, phenology-models were developed driven by solar radiation, air temperature and soil temperature on hourly basis. Relationships between temperature and stage specific development rates for the relevant stages of the life cycles were established under controlled conditions for *Cydia pomonella*, *Grapholita lobarzewskii*, *Adoxophyes orana*, *Dysaphis plantaginea*, *Hoplocampa testudinea*, *Anthonomus pomorum*, *Cacopsylla pyri*, *Rhagoletis cerasi*.

Results: Validation of model predictions with independent field observations showed that, besides temperature-dependent processes, habitat choice of key stages needs to be regarded in order to achieve reliable results. On base of local weather data, age structure of the pest populations is simulated and crucial events for management activities are predicted. Simulation results are made available through the web-interface www.sopra.info covering all fruit growing regions of Switzerland. Phenology is directly linked to detailed decision support plus extended information about the pest insects, management strategies and plant protection products.

Conclusions: SOPRA is successfully applied as a simple to use decision support system in Switzerland, Southern Germany and beyond. It can serve as example for combining a wide range of information to establish a reliable and readily available information tool for growers and consultants.

Population management of cone- and seed insects in Norway spruce (*Picea abies* L. Karst.) seed orchards in Sweden

Olle Rosenberg, Jan Weslien

Skogforsk, UPPSALA, Sweden

Introduction: Seed orchards produce high-quality seeds for reforestation. Trees derived from these seeds have up to 20 % higher growth rate compared to trees derived from forest seeds, resulting in a high market value for orchard seeds. Several insect species have cones and seeds as their only/main food source. Different species have different flight periods which makes it difficult to decide when and for how long it is necessary to protect cones using e.g. insecticides.

Methods: By protecting branches during different development stages of flowers/cones, we studied at which time flowers/cones were susceptible to different insect species. We also monitored the flight time of one of the more serious pest insects, the lepidopterous species *Dioryctria abietella* using pheromone bated traps.

Results: Cones on branches protected during the whole season were undamaged. Protection during flowering to young cones (May-mid June) resulted in cones with very small damages, despite the fact that the monitoring of *D. abietella* showed that this pest species still were flying in August. Protection of young cones to mature cones (early June-October) resulted in heavily attacked cones from two lepidopterous species *Cydia strobilella* and *D. abietella* and the diptera *Strobilomyia anthracina*. Cones on branches that not were protected at all were damaged, although they had less damage compared to cones on branches protected during early June-October.

Conclusions: The infestation mainly occurs on flowers to young cones, a period of about one month. If cones are protected during this period they may remain healthy and thus produce viable seeds.

Invasive Hymenoptera: a global perspective

Michael Gates[1] and Michael Schauff[2]

[1]Systematic Entomology Laboratory, USDA, ARS, PSI, c/o National Museum of Natural History, Washington, D. C. 20013-7012, USA, [2]Plant Sciences Institute, USDA, ARS, 10300 Baltimore Ave., Beltsville, MD, USA

Introduction: Invasive arthropods cost governments and regulatory agencies billions of dollars annually in economic losses worldwide. Hymenoptera are an important component of many costly invasions requiring remediation by humans.

Methods: We intend to provide an introduction and brief overview of the role of Hymenoptera as invasive species, focusing especially on economic and ecological impacts. We evaluated published—electronic and paper based—records of Hymenoptera as invasive organisms worldwide during the past 25+ years in order to compose this overview, plus a short case study of a "beneficial invasive".

Results: While there are certainly numerous instances documenting the deleterious effects of invasions, there is also evidence that certain invasions have minimal or potentially beneficial effects. Larger aculeate Hymenoptera often capture the attention of the public and regulators, while smaller taxa may remain unnoticed initially. However, smaller taxa may cause plant damage through galling plant tissue, which serves to increase their apparency. We report on a case study in North America where previously undocumented parasitic Hymenoptera were detected during surveys of the emerald ash borer, an invasive buprestid from Southeast Asia.

Conclusions: Invasive Hymenoptera, in many cases, are here to stay. However, there are notable success stories in managing deleterious invasion events, ranging from active programs including eradication or partial mitigation via an integrated approach to passive "beneficial invasives" resulting from co-introductions with other arthropod invasives.

Population genetics of the eucalypt weevil; diversity and origin of Western Australian introductions

Tendai Mapondera, Mamoru Matsuki, Treena Burgess

School of Biological Sciences, Murdoch University, Perth, 6150, Australia

Gonipterus scutellatus is wide-spread in southeast Australia where it has limited impact. World-wide it has been introduced to most countries where eucalypts are grown and has become a significant defoliator of eucalypts. There are no early records of *G. scutellatus* occurring in Western Australia (WA). However, by 2002 it was the most abundant insect species collected in eucalypt plantations in WA. Unlike other regions of Australia where the pest is endemic, *G. scutellatus* causes significant damage to Western Australian plantations and in the absence of an effective biological control, chemical control has been routinely used in heavily impacted plantations. *G. scutellatus* was collected from 25 locations in eastern Australia (Tasmania, Victroia, New South Wales and South Australia) and several locations in WA. A 474 bp fragment of the mtDNA gene Cytochrome oxidase 1 was sequenced for 134 isolates, all sequences were converted to amino acid sequences to confirm they code for cytochrome oxidase 1. From the sequence data 46 haplotypes were revealed. Only one haplotype was found in WA, whilst collections from EA were very diverse, especially Tasmania. In the phylogenetic analysis, insects identified as *G. scutellatus* resided in five distinct and highly supported lineages strongly suggesting that this is a species complex rather than an individual species. Only one of these lineages have been introduced to WA. The distribution and biology of the different lineages needs to be determined. This data set will allow researchers world-wide to determine the identity and potentially origin of insects introduced into their countries.

Population genetics of the eucalypt weevil; diversity and origin of Western Australian introductions

Tendai Mapondera, Mamoru Matsuki, Treena Burgess

School of Biological Sciences, Murdoch University, Perth, Australia

Introduction: The stingless bees present large distribution, great diversity, very significant contribution as pollinator agents, and economic and medical value. Despite their biological and economic importance, basic aspects about their biology and evolution are still not elucidated. The multiple mate in Hymenoptera is relatively common, however in stingless bees only few studies on this subject have been published. To increase our understanding on this behavior the species *Plebeia remota* was choosen as experimental model. This species has a small body size and small number of individuals per nest. The literature has postulated that queens of *P. remota* mate once, however all these studies are based on just one temporal sample and one nest. The knowledge of queen mate number and the relationship degree among workers allows inferences on social evolution and conflict between queen and workers in the male production.

Methods: Workers and males from two colonies were collected monthly during one year, totalizing 123 individuals. Total DNA was extracted and used to PCR amplify microsatellite loci. Four loci were screening by using heterologous primers derived from *Melipona bicolor* (Mbi33, Mbi 215, Mbi 259 and Mbi278).

Results: The loci Mbi215, Mbi259 and Mbi278 presented two alleles each. By analyzing the males we could infer the queens genotypes, which were heterozygous for the three loci. Also most of the workers were heterozygous, however in different temporal samples we found workers homozygous for either alleles.

Conclusion: The data indicated that the queens likely were mated by at least two males.

Adaptive accuracy and evolution of morphological fit between flowers and insect pollinators

W Scott Armbruster[1], Thomas Hansen[2], Christophe Pelabon[3]

[1]University of Portsmouth, Portsmouth, United Kingdom, [2]University of Oslo, Oslo, Norway, [3]Norw Univ Sci Tech, Trondheim, Norway

Insects and their flowers participate in complex mutualisms based on four features: attraction, reward, fit, and pollination. Both reward and flower-pollinator fit depend on the interaction between morphological characteristics of plant and insect phenotypes, and in particular on genotype-phenotype mapping and adaptive accuracy. Insects collect nectar, pollen, oils, fragrances, or resins from flowers and must have appendages of appropriate length and shape to do so. Flowers, in turn, get pollinated by some of these floral visitors and must have the appropriate size and shape to benefit from their visitation. We can analyse these relationship in terms of visitation rate and pollination efficiency, employing the concept of adaptive accuracy. In this way we can consider simultaneously all sources of variance in how development translates genes into phenotype and how phenotype influences fitness. The two components of adaptive accuracy, precision and optimality (target deviance), are generated by different biological process and have different evolutionary dynamics in the context of plant-pollinator mutualisms.

Introduction of integrated pest management in hardy ornamentals: A good bug alone is not enough

Rob van Tol

Plant Research International, Wageningen, Netherlands

Introduction of IPM in hardy ornamentals in the Netherlands was initiated and intensively supported on several nurseries in the years 1991 to 1994 followed by an implementation project trying to extend IPM to larger areas within nursery industry. While the initial project was very successful in accomplishing the goal of reducing pesticide use the extension to other nurseries was much less successful. At best some single alternative pest control means were incorporated. The success of IPM depends, however, on the total concept of integrating all means (e.g. monitoring tools, pesticides, biologicals, labour, cultural means, planting schedule, etc.). The human factor as a key factor in success or failure of IPM is usually underestimated and may have limited successful spread of IPM. Complexity of management, knowledge support and risk assessment are only some of the factors involved in decision making of growers. In this presentation several key factors in decision making of growers are discussed.

The evolution of dorsoventral axis formation in insects

Siegfried Roth

University of Cologne, Cologne, Germany

The dorsoventral polarity in *Drosophila* is established during oogenesis when the asymmetric movement of the oocyte nucleus determines the dorsal side of the egg chamber. The mRNA of a TGFalpha-like ligand becomes restricted to the oocyte nucleus. From there the ligand is secreted and activates the EGF receptor in the overlaying follicle cells. This leads to dorsoventrally asymmetric gene expression within the follicular epithelium and subsequently to asymmetric spatial cues in the egg shell which are used to orient the embryonic dorsoventral axis. The embryonic dorsoventral axis depends on two major signalling cascades, the Toll/NF-kappaB and the BMP signaling cascade. This talk will review results form classical embryological and modern molecular-genetic studies which provide insights on how ovarian and embryonic dorsoventral axis formation have evolved in insects.

Juvenile hormone regulation of metamorphosis in the beetle *Tribolium castaneum*

Barbora Konopova, Marek Jindra

Biology Center ASCR, Institute of Entomology, Ceske Budejovice, Czech Republic

All recent winged insects undergo metamorphosis. Completion of wing development, besides sexual maturation, is the main metamorphic change. In holometabolan insects, metamorphosis transforms larval stages, which possess no external wings, into flying adults. A major part of wing development takes place during the pupal stage. Metamorphosis depends on the morphogenesis-promoting ecdysteroids and the morphostatic juvenile hormone (JH), whose presence precludes the metamorphic changes until the final larval instar. However, the mechanism of JH action remains poorly understood, mainly because JH signal transducers are unknown. Since JH has no robust effect on *Drosophila* larval-pupal transition, we chose to study JH regulation of metamorphosis in the red flour beetle *Tribolium castaneum*. Using systemic RNAi in *Tribolium*, we show that JH controls the entry into metamorphosis through the Methoprene-tolerant protein (Met). In contrast to *Drosophila*, where loss of *Met* causes resistance to ectopic JH but no developmental defects, *Tribolium* larvae lacking *Met* function enter the pupal program prematurely, developing wings and other pupal characters before reaching their final instar. Thus, Met is an essential transducer of the anti-metamorphic JH signal. We further show that in response to JH, Met regulates expression of the *Tribolium Broad-Complex* gene (*BR-C*), which is required for pupal development. Impaired function of *BR-C* blocks pupation and although it does not prevent cell proliferation within the wing primordia of the arresting *Tribolium* prepupae, it prevents their proper morphogenesis and elongation. Thus, Met and its downstream target *BR-C* play critical roles in the JH-dependent regulation of insect metamorphosis.

Red oak borer: History and population dynamics in Arkansas forests

Fred M. Stephen, Melissa K. Fierke, Laurel J. Haavik, John J. Riggins

University of Arkansas, Fayetteville, AR 72710, United States

In 2000, tens of thousands of dead and dying red oaks (*Quercus rubra* L.) were discovered in oak-hickory forests of northern and western Arkansas. A significant cause of tree mortality in this "oak decline event" was a population explosion of a previously innocuous, native wood-boring beetle, the red oak borer *Enaphalodes rufulus* (Haldeman) (Coleoptera: Cerambycidae). To obtain knowledge on population dynamics of this beetle and causes for this outbreak we have developed sampling methods for beetles within trees, stands and forests. We have shown, using dendrochonological methods, that from about 1940 until 1992 red oak borers were present in oaks but at consistently low levels. The recent outbreak on the Ozark National Forest appears to have begun in 1994 and peaked in 2000 and 2002, with population levels more than 100 times higher than at the beginning of the outbreak. Populations began to crash in 2004 and are now nearly as low as before the outbreak began. Hazard models predict that, of the different oak species, *Q. rubra* experiences the greatest mortality and that mortality is higher in dense stands on ridges than on north, east, west and south-facing benches or in forests with lower *Q. rubra* densities. Red oak borer populations are also highest on ridges. Preliminary studies of radial growth suggest that this oak decline event as well as the rise in red oak borer numbers is closely associated with reduced radial growth. Tree defense mechanisms and other factors affecting red oak borer mortality are discussed.

Effects of light intensity on pine engraver reproduction in ponderosa pine slash in northern Arizona

Christopher Hayes[1], Richard Hofstetter[2], Tom DeGomez[1], Michael Wagner[2]

[1]University of Arizona, Flagstaff, Arizona, United States, [2]Northern Arizona University, Flagstaff, Arizona, United States

Introduction: Within log abiotic conditions can affect pine engraver, *Ips pini* (Say), reproductive success, and slash management techniques often aim at reducing abiotic conditions. In this study, I investigate the affect of light intensity on phloem temperature and moisture in logs of two diameters and subsequent effects on pine engraver reproduction.

Methods: Thirty cm length logs with diameters of 10 and 15 cm were cut, left in the field for natural colonization by *I pini*, and then placed in an open meadow and under shade clothes of two densities. Phloem temperature and moisture were recorded over the duration of the experiment and, at the end of the field experiment logs were dissected and galleries were measured to gauge reproductive success.

Results: As sunlight exposure increased phloem temperatures increased and potentially lethal temperatures were often reached in the high light exposure but seldom in the low light. Smaller diameter logs were drier than larger diameter logs. All logs dried due to time in the field but sunlight level did not affect desiccation rates. *Ips pini* preferred attacking larger logs and on the bottom aspect of logs.

Conclusions: Sunlight exposure had a significant effect on net reproductive success in smaller diameter logs, with very little net reproductive success in high sunlight logs, and the highest reproductive success found in low and medium sunlight smaller diameter logs. Management implications of these results are discussed.

Effects of light intensity on pine engraver reproduction in ponderosa pine slash in northern Arizona

Christopher Hayes[1], Richard Hofstetter[2], Tom DeGomez[1], Michael Wagner[2]

[1]Univesity of Arizona, Flagstaff, Arizona, United States, [2]Northern Arizona University, Flagstaff, Arizona, United States

Introduction: Within log abiotic conditions can affect pine engraver, *Ips pini* (Say), reproductive success, and slash management techniques often aim at reducing abiotic conditions. In this study, I investigate the affect of light intensity on phloem temperature and moisture in logs of two diameters and subsequent effects on pine engraver reproduction.

Management implications of these results are discussed.

Species, morphology, and relationships of the African genus *Oreiscelio* Kieffer (Hymenoptera: Scelionidae)

Elijah Talamas, Norman Johnson

Ohio State University, Columbus, Ohio, United States

Oreiscelio Kieffer is a small group of egg parasitoids endemic to Africa and Madagascar. The genus is classified within the tribe Scelionini, the members of which, as far as is known, all attack the eggs of grasshoppers and locusts (Orthoptera: Acrididae). The generic and species concepts are reviewed and revised. The relationship of *Oreiscelio* with the closely related genera *Heptascelio*, from the Afrotropical and Oriental regions, and the Neotropical *Acanthoscelio* are analyzed. Additionally, morphological structures not previously known to exist within the Scelioninae are discussed. This work is part of the Platygastroidea Planetary Biodiversity Initiative, and the collaborative taxonomic methods developed for this international project are outlined.

Harmonia axyridis – top predator or invader? A critical examination

Pavel Kindlmann[1], Hironori Yasuda[2]

[1]Biodiversity Research Centre, Institute of Systems Biology and Ecology AS CR, Ceske Budejovice, Czech Republic, [2]Department of Agriculture, Yamagata University, Tsuruoka, Japan

Introduction: There is no doubt that *Harmonia axyridis* has recently been successful in suppressing many native species in North America and subsequently in Europe. It is not quite clear, however, what are the ecological traits that enabled it to be so successful. Critical studies are needed to evaluate, whether these traits include its ability to invade the aphid colony very quickly and efficiently, its competitive superiority, or something else.

Methods: Using published and some yet unpublished data, we critically examine all the above-mentioned possibilities. We assess the relative impacts of the interactions of *Coccinella septempunctata* (CS) and *Harmonia axyridis* (HA) on their larval survival, in particular cannibalism and intraguild predation (IGP) throughout larval development in relation to prey abundance. Then we compare incidences of cannibalism and IGP between HA and CS, and quantify attack and escape rates as the mechanisms, which possibly account for the difference in incidences of these interactions. Finally, we use key factor analysis to determine the critical life stages for CS and HA.

Results: HA is a strong competitor, which usually wins heterospecific contests. It arrives to the aphid colonies later than the other ladybird species, but is able to suppress larvae of other species. Its efficiency in conversion ladybird biomass in its own biomass is better than its efficiency in conversion aphids into its own biomass.

Conclusions: It seems that the most important factor that enabled the success HA in suppressing its intraguild competitors might be is evolutionary orientation into becoming a top predator.

Genetic based multi-species herbivore interactions in a eucalypt system

Julianne O'Reilly-Wapstra, Matthew Hamilton, Brad Potts

University of Tasmania, Hobart, Australia

Introduction: Plants are faced with attack from multiple herbivores during all life stages. The presence of multiple herbivore species may influence the direction and rate of evolutionary change in a plant species as a result of interacting selection pressures and in these instances, any evolutionary relationships that exist could do so in a diffuse rather than a pair-wise manner. *Eucalyptus globulus* is a dominant tree species in south eastern Australian forests and an important commercial species world-wide. It is browsed by multiple invertebrate and mammalian herbivores and in this paper we investigate the genetic correlations between *E. globulus* resistances to multiple herbivores.

Methods: Using a series of randomised common garden trials we assessed browsing damage by several invertebrate and mammalian herbivore species on up to 600 *E. globulus* families, comprising numerous provenances and geographically distinct races. We determined the genetic correlations between resistances to this array of herbivores.

Results: Results indicate clear genetic based resistance of *E. globulus* to numerous enemies, however, the genetic relationships in preference between these herbivores is varied. These complex genetic correlations match the display of defensive mechanisms used by *E. globulus* to deter its herbivores.

Conclusions: This paper provides insight into the complex evolutionary relationships that exist between a foundation species and its community of herbivores.

Conclusions: This paper provides insight into the complex evolutionary relationships that exist between a foundation species and its community of herbivores.

Effectiveness of different *Bacillus thuringiensis* additives on the greater wax moth *Galleria mellonella* L. (Lepidoptera: Pyralidae) larval feeding

Rasool Zareie, Ali Asghar Pourmirza, Nouradin Shayesteh, Shahram Aramideh

Urmia University, Urmia, Islamic Republic of Iran

Introduction: *Bacillus thuringiensis* Berline is a highly efficacious bioinsecticide that use to control of lepidopteran larvae in the field conditions. Nowadays different additives use in the B.t preparations to increase its effectiveness.

Methods: In this experiment, feeding effect of pre-gelatinized corn starch as an encapsulation matrix, sugar beet molasses as a phagostimulant, henna as a synergist, and congo red as a UV screener were indicated on the fifth instars of the greater wax moth *Galleria mellonella* L**.** For this purpose, each additive was mixed with artificial diet.

Results: The means of larval weight increasing were 122, 102, 98, 48, and 14 mg (after a week) for molasses, pre- gelatinized corn starch, control (artificial diet), congo red, and henna respectively. The larval weight increasing was analyzed by randomized complete block design.

Conclusions: The results were significant and indicated that sugar beet molasses by increasing preparations palatability, acted as a feeding stimulant, while henna and congo red were anti-feedants

Electron beam treatment as a phytosanitary measure for stored product pests

Nouraddin Shayesteh, Abbas Hosseinzadeh, Mohammad Reza Ardakani, Hamid Reza Zolfagharieh, Mohammad Babaii, Hadi Fatollahi, Hasan Zareshahi, Shahram Aramideh

Islamic Azad University, Mahabad, Israel

Introduction: Grains and pulses infested with insects such as *Tribolum castaneum* and *Plodia interponctella* may be disinfested with methyl bromide. Despite low residues, however, fumigation with MeBr may not to be desirable from the viewpoint of human health. More importantly, MeBr can deplet the ozon layer and on this basis it will be phased out for most uses. Development of an alternative treatment is urgently needed.

Methods: Developmental stages of two stored-product insect pests **viz.** *Tribolum castaneum* and *Plodia interponctella* were exposed directly to electrons using Rhodetron accelerator(tt200). Exposure doses on all stages were 0, 270, 380, 520, 700, 840, 1640, 2020, 2400, 2750 and 3130 Gy.

Results: The results of these studies indicate that inhibiting doses for eggs, larval, pupal and adults of *Tribolum castaneum* were 840, 380, 2020 and 3130Gy respectively. These criteria for *Plodia interponctella* were 840, 520, 1640 and 3130 respectively. Due to results eggs, larval and adults of *Tribolum castaneum* were sensitive than *Plodia interponctella*.

Conclusions: We suggest that it is possible to disinfest grains contaminated with these insects using high energy electrons at 3130Gy.

Lower herbivory in diverse forests due to semiochemical diversity? Tests in an artificially mixed forest

Hervé Jactel[2], Göran Birgersson[1], Fredrik Schlyter[1]

[1]Chemical Ecology, Dept. Plant Prot., SLU, Alnarp, Sweden, [2]Laboratory of Forest Entomology & Biodiversity, INRA, Cestas, Bordeaux, France

Introduction: The *semiochemical diversity hypothesis* (SDH), a new dimension and functional aspect of biodiversity, postulates a reduced searching efficiency of specialist herbivores in the face of non-host plant volatiles. A prediction from the SDH is that conifer specialists should avoid mixed habitats with non-host volatiles (NHV) from angiosperms like *Betula*.

Experimentally, however, tests have only shown modulation (inhibition) of attraction behaviour to point sources (traps) or their vicinity (2 –4m), mainly in conifer bark beetles.

Methods and Results: We show a population effect of density reduction in a moth on habitat scale by the EAD-active methyl salicylate, a synthetic birch volatile (no attractant sources involved). A replicated dose-response study (3 doses, >600 trees) at a scale of 50m pine forest edge sections show a dose-dependent reduction of larval winter nests of pine processionary moth (*Thaumetopoea pityocampa*). Mate location was similarly affected, as measured by male catches in pheromone traps.

Conclusions: Our data support a reduction of efficiency in both host and mate location by NHV. This is evidence for the SDH at the habitat-level in forest insects. However, the identities of chemical cues used by the conifer bark beetles and the pine moth to avoid angiosperms seem to differ drastically.

Multi-scale effects of humans on forest insect-microbe symbioses

Diana Six[1], Bernard Slippers[2]

[1]University of Montana, Missoula, MT, United States, [2]Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa

Humans exert considerable influence on forest ecosystems, both directly and indirectly. Direct effects occur through use for habitation, wildlife and biodiversity preserves, recreation, spiritual connections, and to extract wood, herbs, medicines, and food. Many of earth's natural forests have been cleared for human settlement, livestock grazing, fuel wood, and cropland. In other cases, afforestation efforts have attempted to restore croplands back to native forest conditions or to initiate plantations of exotic trees on previously un-forested lands to provide critical sources of wood and pulp. Indirect effects are also diverse and come through such varied sources as adjacent land use types, pollution drift, and climate change. Both direct and indirect effects affect forests at multiple scales on a continuum from the individual tree to the globe. While anthropogenic effects are often the focus of research on impacts on individual species, especially threatened or endangered species, or on economically important pests, little focus has been directed on investigating effects on outcomes of interactions among organisms, and fewer still on effects on symbioses. Many insects, for example, are drivers of forest structure, composition and function. These same insects are mostly, if not all, involved in symbioses with microbes that facilitate their ability to use trees as a resource. The potential for anthropogenic activities to enhance, suppress, or entirely decouple such symbioses across multiple scales should be of considerable concern.

The activity and effects of Indoxacarb on subterranean termites

Michael Rust[1], Raj Saran[2]

[1]University of California Riverside, Riverside, CA, United States, [2]MGK Corporation, Minneapolis, MN, United States

The novel semicarbazone insecticide, indoxacarb, applied to soils is active against the western subterranean termite, *Reticulitermes hesperus* Banks. When applied topically to termites, it is extremely toxic to termites with an LD_{50} of 1.6 ng/termite. When termites are confined to treated soils, brief 1-hour exposures of 100- and 200-ppm indoxacarb killed 100% of the workers in 7 days. The indoxacarb causes a delayed toxicity. Soils treated at ≥ 25 ppm prevent tunneling and kill 100% of the workers within 5 days. Termites exposed to 10 ppm indoxacarb tunnel < 0.3 cm, but some termites survive at this low dose. When donor termites were exposed to 100 and 200 ppm indoxacarb, they were killed within 7 days. Unexposed recipient termites held with the donors were also killed with 7 days. Indoxacarb horizontally transferred from donors to recipients. The delayed toxicity of indoxacarb assists in this horizontal transfer.

The scarab digestive tract as a target for microbial pathogens

Drion Boucias, Regina Kleespie, Trevor Jackson

[1]University of Florida, Florida, United States, [2]AgResearch Limited, Lincoln, New Zealand

Introduction: Microscopic studies were conducted to examine the cytological features of the various tissue, cellular, and sub-cellular domains comprising the alimentary tract of the root-feeding scarab *Costelytra zealandica*.

Methods: Digestive tracts were dissected from third instar larvae, placed in fixative, dehydrated, and either embedded in paraffin, in plastic resin, or subjected to critical point drying (CPD). Stained paraffin and thick sections were examined with light microscopy, thin sections were examined with TEM, and coated CPD dissected tissue preparations examined with SEM. Digital images were prepared and processed using conventional morphometric imaging software.

Results: The various imaging technologies provided an overview of the topography the alimentary tract, and detailed the different cells and structures that comprised the foregut, midgut, and hindgut regions. The foregut was relatively short and possessed a bulb-like crop whereas the midgut tissue extended throughout the entire body length. This tissue, compartmentalized with clusters of secretory or assimilatory cell domains, contained a well-developed fishnet-type peritrophic membrane. The well-muscled pyloric sphincter was designed to pull the peritrophic membrane posteriorly moving the food bolus into the hindgut. The scarab hindgut contained a unique fermentation sac that provided harborage to a plethora of microbes. The rectum and associated cryptonephridial complex was connected to the malpighean tubules.

Conclusions: The digestive tract has multiple unique morphological adaptations designed for digestion of plant roots. The different tissues contained unique domains that play a key role in the susceptibility/resistance of this insect to soil-borne microbes.

The physiological integration of simultaneously selected life history traits

Goggy Davidowitz[1], Derek Roff[2], Frederik Nijhout[3]

[1]University of Arizona, Tucson, Arizona, United States, [2]UC Riverside, Riverside, California, United States, [3]Duke University, Durham, North Carolina, United States

Body size and development time are complex, whole-organism traits, that require integration at multiple levels. Integration at the level of the whole organism is mediated by the endocrine system. We present a physiological / endocrine mechanism that regulates over 95% of the variation in body size and development time in the tobacco hornworm: growth rate (GR), the critical weight (CW) that measures the timing of the onset of the cessation of juvenile hormone secretion (which initiates the processes leading to pupation), and the time interval between attainment of the critical weight and secretion of ecdysteroids (the interval to cessation of growth, ICG). Knowledge of the physiological mechanism allows us to make explicit predictions, based on physiological first principles, as to how these life history traits should respond to simultaneous selection. Initial results support 11 of our 12 *a priori* predictions. When the two life history traits are selected in the same direction (both upwards or both downwards), the response to selection is determined primarily by the timing of the two hormonal events (CW and ICG). When the two life history traits are selected in opposite directions (one up, the other down) the response to selection is determined largely by growth rate (GR). These results indicate that, under simultaneous selection, the integration of complex traits differs depending on the direction of selection.

The Southern African Butterfly Conservation Assessment (SABCA) takes flight

Silvia Mecenero

Animal Demography Unit, Dept. Zoology, University of Cape Town, Cape Town, South Africa

The Southern African Butterfly Conservation Assessment (SABCA) is a four year project aimed at increasing understanding of the distribution and diversity of butterflies in the atlas region (South Africa, Lesotho and Swaziland), thereby contributing towards effective conservation planning and management. SABCA is a three-way partnership between the South African National Biodiversity Institute, the Lepidopterists' Society of Africa (LepSoc) and the Animal Demography Unit (University of Cape Town).

The project comprises three main activities: creating a comprehensive database of existing records in museum and private collections, field surveys prioritised in areas identified by gap analysis, and an online virtual museum which accepts photographic specimens from the public.

Almost all data in South African institutions have been digitised (~ 120 000 records). The data is reformatted, vetted and geo-referenced before being uploaded into the SABCA database. About 250 000 records reside with LepSoc members. Field surveys have begun in most provinces, and progress in filling in gaps is being made. The virtual museum has attracted great public interest, about 200 photographic submissions are received every month. Both the field surveys and virtual museum have made important new observations on threatened species and range expansions.

Data collected from these three activities will be used to assess the conservation status of each butterfly species according to the IUCN criteria. An updated Red Data Book and atlas will be produced to inform conservation planning, decision making and policy development for butterflies. The resultant project outputs will ultimately contribute towards understanding ecosystem health and climate change.

Species File Software and the Orthoptera Species File

David Eades[1], Daniel Otte[2], Piotr Naskrecki[3]

[1]Illinois Natural History Survey, Champaign, Illinois, United States, [2]Academy of Natural Sciences, Philadelphia, Pennsylvania, United States, [3]Conservation International, Cambridge, Massachusetts, United States

Species File Software was first developed as the computer programming needed to manage the Orthoptera Species File Online. It is now a set of programs that manage databases and websites for all the orders of Polyneoptera and for a few groups outside of Polyneoptera. A database is edited over the Internet, which allows multiple authors to share in managing the data. In addition to the usual nomenclatural information, databases may contain specimen level data and keys (both dichotomous and matrix-based). Integration of these items in a single database facilitates keeping current with new research. The program screens data as it is entered and blocks many errors including changes that would violate the International Code of Zoological Nomenclature. Users may indicate which kinds of data are of interest, and pages will then display only the kinds of data selected. Data from species files is passed on to Species 2000 and other data aggregators. Work is in progress to exchange data with ZooBank. An endowment that supports eight persons assures continuing development in the future. The software is useful for any group subject to the Zoological Code and is available free.

Fly as cancer model? Genomic analysis of Drosophila's hypoxia tolerance

J.M. Gomez[1], T. Tomita[2], N.M. Romero[1], K. Clough-Gorr[3], M. Gassmann[4], H.F. Bunn[5], P. Wappner[1], T. Gorr[4]

[1]Instituto Leloir, Universidad de Buenos Aires, Buenos Aires, Argentina, [2]National Cancer Institute, National Institutes of Health, Bethesda, Maryland, United States, [3]University Hospital Bern and Spital Netz Bern Ziegler, University of Bern, Bern, Switzerland, [4]Institute of Veterinary Physiology, Vetsuisse Faculty and Zurich Center for Integrative Human Physiology, Zurich, Switzerland, [5]Department of Medicine/Hematology, Brigham and Women's Hospital, Harvard Medical School, Boston, United States

To understand, on a genomic level, the remarkable ability of Drosophila to survive severe and prolonged deprivations of oxygen, transcriptome profiles of S2 cells from late stage fly embryos were recorded through microarray and Northern blot surveys as a function of graded hypoxia. Both, fruitflies and S2 cells express with the hypoxia-inducible factor (HIF) the key regulator protein for survival and adaptation during oxygen deprivation. When flies are exposed to a severe O_2 shortage they will switch from tracheal defenses to a reduction of metabolic activities in order to acquire a new energy steady state (hypometabolism) and, as such, resemble the angiogenic-to-quiescence transition of many hypoxic tumors.

Increasing severity of the hypoxic stress was reflected in rising numbers and magnitudes of hypoxia-responsive gene regulations. Entrance of S2 cells into the ultimate hypometabolic defense mode saw marked transcriptional regulations of 'hypometabolic factor (HMF)' candidate genes, in correlation with a progressive reduction of ATP-costly biochemical functions such as protein or DNA synthesis and cell cycle progression. The biological role of several of these protein synthesis inhibiting and cell cycle arresting molecules is currently being studied by collaborative in vitro and transgenic approaches. To this end, we are focusing our investigations on the highly hypoxia inducible *Drosophila* gene Thor, a single-copy homolog of the mammalian 4E-binding protein (4E-Bp) family that all act as repressor of the rate limiting mRNA translation initiation factor 4E. Seemingly mimicked in malignancy, 4E-Bp1 genes/proteins were also found to be induced and/or activated by low oxygen in several human cancer cell lines. In support of a pro-survival role of inhibited protein synthesis and conserved ATP resources from "critters to cancer", Thor null fly mutants show limited adaptability and slowed recovery, while 4E-Bp1 knockdown cancer cells died off in much greater proportion, in response to severe hypoxia when compared with wildtype controls. We are currently analyzing the energetic consequences of 4E-Bp/Thor manipulations. We will further apply expression interference studies to other HMF factors in both fly and cancer systems. That way, we hope to raise the susceptibility of these cells towards hypoxic stress and conventional treatment modalities by virtue of blocking their hypometabolic defenses and to promote fly as a metabolic cancer model.

Bracovirus mediated evasion of the insect immune response

Michael Strand

University of Georgia, Athens, Georgia, United States

Insects rely upon a well-coordinated innate immune system for protection against invading pathogens and parasites. Larger, multicellular parasites are usually killed by encapsulation which involves attachment of multiple layers of hemocytes to the foreign target. Smaller pathogens, in contrast, are killed by a combination of hemocyte-mediated phagocytosis and humoral defenses. Despite the fundamental importance of these responses, our understanding of their regulation in relation to the counter strategies pathogens use to evade host defense responses is limited. Viruses in the family Polydnaviridae are symbiotically associated with parasitoid wasps and are among the most virulent immunosuppressive pathogens of insects. Polydnaviruses are divided into two genera, bracoviruses (BVs) and ichnoviruses (IVs), on the basis of their association with wasps in the families Braconidae and Ichneumonidae. Functional analysis of *Microplitis demolitor* bracovirus (MdBV) has also identified several key genes involved in immunosuppression of encapsulation, phagocytosis and the phenoloxidase cascade. Notably, most of these virulence factors target signaling pathways rather than effector molecules themselves. Overall, current results provide important insight on the evolution of polydnaviruses and identify key virulence determinants underlying immunosuppression.

The use of life-shortening *Wolbachia* strains to reduce dengue transmission by *Aedes aegypti*

Scott L. O'Neill

The University of Queensland, Brisbane, Queensland, Australia

Insect age is a critical factor influencing the dynamics of a range of insect transmitted diseases. Its importance is linked to the extrinsic incubation period (EIP) of a given pathogen within the vector. Since the EIP of many pathogens is quite long relative to the natural insect lifespan only old insects are of epidemiological importance. We have successfully transferred life-shortening *Wolbachia* symbionts into *Aedes aegypti*, the primary dengue vector that halve adult lifespan in the laboratory. These bacteria are maternally inherited at high frequency and induce complete cytoplasmic incompatibility which may facilitate their natural spread into field populations. Interestingly the infection appears to influence the ability of these mosquitoes to successfully utilize the blood of certain hosts for egg production. Laboratory data suggest that this approach may be able to significantly reduce dengue transmission potential of *Aedes* populations. This potential will soon be evaluated in a field cage setting in Nth Queensland.

Biosystematics and Evolution of true land bugs (Insecta: Heteroptera)

M. Javahery

McGill University, Ste.Anne de Bellevue, QC, Canada

A comparative study has been done of the morphology and taxonomy of male and female reproductive system, development, and characteristics of eggs in representatives of five families in infraorder of Cimicomorpha and 11 families in infraorder of Pentatomomorpha. A total of 48 genera and 77 species were studied. They included examples of Miridae, Nabidae, Phymatidae, Reduviidae, Tingidae (Cimicomorpha), and Acanthosomatidae, Alydidae, Aradidae, Coreidae, Cydnidae, Lygaeidae, Pentatomidae, Pyrhocoridae, Scutelleridae, and Thyreocoridae, (Pentatomomorpha). Embryonic development was monitored by dissection of eggs in isotonic NaCl solution. The reproductive systems of both sexes were taken from fresh material and observation made in 50% alcohol. Materials were collected from southeastern Canada, as well as Palearctic regions. The studies were based on characters of true phylogenetic value of eggs (shape, chorion sculpture, presence of a true operculum, the number and position as well as shape of the micropilar processes, and shape of egg-burster) and the mechanisms of egg eclosion, morphology of both males and females reproductive system. The phylogram and distribution in superfamily Pentatomoidea indicate that the genera *Elasmucha* and *Sehirus* are primitive and they are considered the probable outgroups. The data collected supports the suggestion that various shapes of eggs in the above families have evolved independently, and along different pathways from an ovoid ancestral egg.

Pathogenicity of *Thripinema fuscum* Tipping & Nguyen (Tylenchida: Allantonematidae) infecting *Frankliniella fusca* (Hinds) (Thysanoptera: Thripidae)

Kelly Dunford[1], James Becnel[2], Joseph Funderburk[3], Drion Boucias[1]

[1]University of Florida, Gainesville, Florida, United States, [2]USDA/ARS, Gainesville, Florida, United States, [3]University of Florida, Quincy, Florida, United States

The insect parasitic nematode *Thripinema fuscum* Tipping & Nguyen (Tylenchida: Allantonematidae) is a key regulator of *Frankliniella fusca* (Hinds) (Thysanoptera: Thripidae) in agricultural peanut across the southeastern United States. Parasitism by *T. fuscum* causes a significant reduction in both the feeding and fecundity rates of adult female thrips, and as a result, reduces the vector competence (acquisition and transmission) of *F. fusca* to spread Tomato spotted wilt virus (Bunyaviridae: Tospovirus). The potential of *T. fuscum* to act as a biological control agent of *F. fusca* has been recognized; however, very few studies have investigated the pathological changes induced by the entomogenous parasite. Future elucidation of the mechanisms responsible for shutting off egg production in parasitized thrips may provide novel avenues for regulating the intrinsic rate of increase of this pest insect. Understanding the mechanism(s) leading to reduced Tospovirus competency in parasitized thrips may also provide targets that suppress disease spread. To determine how the parasitic *T. fuscum* modulates the physiology of the thrips host and how such alterations influence vector competence, the impact of *T. fuscum* on host thrips was examined using a combination of light and electron microscopy. Changes to *F. fusca* tissues affected by Thripinema invasion and replication were recorded and a possible explanation of the cause (mechanical vs. chemical) given.

An EST database for the lepidopteran forest insect, *Choristoneura fumiferana*

Lan Li[1], Tim Ladd[1], Sichun Zheng[3], Peter Kell[2], Basil Arif[1], Arthur Retnakaran[1], Daniel Doucet[1], David Basham[1], Qili Feng[1]

[1]Great Lakes Forestry Centre, Sault Ste. Marie, Ontario,, Canada, [2]Department of Molecular and Cellular Biology, University of Guelph, Guelph, Ontario, Canada, [3]School of Life Sciences, South China Normal University, Guangzhou, Guangdong, China

The Lepidoptera *Choristoneura fumiferana* is one of the most widely distributed and destructive defoliators of forests in North America. An expressed sequence tag (EST) project has been initiated three years ago as the first step to understand the genomics and transcriptomics and to search for possible gene targets for biocontrol strategies. The EST database reported here is the first result from this EST project. The database contains 63,203 high quality ESTs generated from cDNA libraries of the epidermis, fat body and midguts of the larvae molting from the 5th to 6th instar stage. These ESTs were assembled into 15,239 putative transcripts. Annotation of these putative transcripts was conducted against NCBI databases and Swiss-Prot/TrEMBL protein database. Information of the annotated ESTs sequences, gene description and gene ontology in molecular function, biological process and cellular component is available to be retrieved by users using blast, keyword or clone ID search. The database, which is publicly available from URL: http://www.pestgenomics.org/database.htm, provides an informative platform for the scientific community to conduct gene cloning and identification of this forest insect and genomic comparison with other insects.

Implications of international sanitary and phytosanitary regulations for the southern African citrus industry

Vaughan Hattingh, Elma Carstens

Citrus Research International at Universtiy of Stellenbosch, Stellenbosch, South Africa

The southern African citrus industry is the second largest fresh citrus export industry in the world and depends on access to international markets. The industry is a major source of foreign earnings, provides employment for a large labour force and is socio-economically important to the southern African region. Agriculture's importance as an export industry extends to other fresh produce industries in southern Africa and further through Africa. Dismantling tariff and subsidy barriers to trade prospectively provides opportunity for Africa to strengthen its agriculture and its participation in international trade. However, recent intensification of restrictions on international fresh produce trade, in the form of sanitary and phytosanitary (SPS) regulations, restricts these opportunities. The International Plant Protection Convention stipulates that phytosanitary regulations require appropriate technical justification, to avoid unnecessary disruption of trade. This provides an advantage to nations with access to the scientific support and resources required to challenge or defend phytosanitary regulations, but Africa's access to such resources is limited. SPS obstacles to retention and expansion of the southern African citrus industry's global export status are addressed by an industry-funded research portfolio. The research includes projects on bio-security, control and eradication strategies, pest risk assessment and risk mitigation measures and focuses on fruit flies, certain lepidopteran pests, mealybugs and disease vectors. Closer collaboration between trading nations with the objective of facilitating trade, while managing the risk of new pest incursions, rather than maintaining protectionism, has the potential to alleviate many of the constraints imposed by the increased focus on SPS issues.

A new artificial diet for the sugarcane stalk borer *Eldana saccharina* Walker (Lepidoptera: Pyralidae) includes an endophytic fungus and excludes dicotyledonous plant material

Sharon McFarlane, Stuart Rutherford

South African Sugarcane Research Institute, Mount Edgecombe 4300, South Africa

In the early 1980's a chickpea based diet was developed to support the production of large numbers of *E. saccharina* eggs for sugarcane resistance screening, and enough larvae and pupae to support parasitoid rearing for field release. More recently research into the application of the sterile insect technique (SIT) to *E. saccharina* control depends on the production of good quality irradiated male insects that are released in large numbers into target wild populations. Larval diet can have a major impact on the development, survival, and reproductive success of these insects. For the purpose of SIT, the chickpea diet formulation produces too variable a product, with many larvae remaining at pupal harvest.

Recent West African evidence has shown that *Fusarium verticillioides,* when present epiphytically or endophytically in maize, can positively affect survival of larvae and their development. A survey of wild host plant species in KwaZulu-Natal for fungal endophytes has revealed that *Fusarium* is isolated more frequently from these plants than are other fungi. Bioassays were developed to screen isolates for potential mutualistic interaction with *E. saccharina*. Attenuated isolates were incorporated into test artificial diets and isolates were determined to be beneficial, antagonistic or neutral in terms of larval survival and development. The most beneficial, an isolate of *F. pseudonygamai*, greatly increased survival and growth when incorporated into diet as a three-week culture on rice. In the final new diet monocotyledonous plant material comprised of whole-wheat flour and dried sugarcane powder in addition to fermented rice. Chickpea, the main protein source in the old diet, was replaced by a combination of non-fat milk powder and spray dried whole egg powder. This was done in consideration of the "chemical legacy hypothesis" which suggests that the response of adult parasitoids to the frass of their host larvae depends partly on a learning process involving plant cues. In other words, if field released parasitoids are to have a greater probability of success, an artificial host diet should contain similar plant cues as would be found in the field. The development of the new diet was an iterative process during which alternative genetic modification strategies for the control of *E. saccharina* in sugarcane became apparent.

Is *Eldana saccharina* Walker (Lepidoptera: Pyralidae) infected by *Wolbachia*, anywhere in Africa?

Stuart Rutherford[1], Des Conlong[2], Deborah Sweby[1]

[1]South African Sugarcane Research Institute, PBag X02, Mount Edgecombe 4300, South Africa, [2]Department of Conservation Ecology and Entomology, Stellenbosch University, Private Bag X01, Matieland, 7602, South Africa

Bacteria belonging to the genus *Wolbachia* are found in the reproductive tissues of a wide range of arthropod species and are associated with a variety of reproductive anomalies. The importance of this phenomenon is as a potential component of population control since infection by *Wolbachia* usually results in either a disruption of the sex ratio of the insect population by male-killing, or cytoplasmic incompatibility between differently infected individuals. In the latter case it is thought that infection can contribute towards speciation or at least to the maintenance of reproductive barriers between diverged lineages.

According to a recent phylogenetic study, African *E. saccharina* separate into three distinct groups (West and Southern African and an Ethiopian group), which also appear to have different preferred host plants, different guilds of parasitoids and slightly different behaviours. These guilds of parasitoids and *E. saccharina* populations overlap in Uganda (East Africa).

At the outset of this study it was not known whether *Wolbachia* infects *E. saccharina* in wild-host plant populations anywhere in Africa. A sampling strategy was developed based on the hypothesis that specimens, from the southern most limit of *E. saccharina* distribution in KwaZulu-Natal South Africa, would be least likely to be infected. Conversely, specimens from Uganda, the apparent centre of diversity, would be more likely to be infected. Detection of *Wolbachia* infection has been routinely conducted by allele-specific polymerase chain reaction (PCR). In a preliminary study *Wolbachia* has been detected in East African specimens using *Wolbachia*-specific primers targeting four genes. Amplified PCR fragments are of expected sizes and sequencing confirms that *Wolbachia* is present. Here we report on the extent of *Wolbachia* infection in *E. saccharina* specimens from West Africa (Benin), East Africa (Uganda, Kenya and Ethiopia) and Southern Africa (Mozambique and South Africa).

Biological and habitat interventions for Integrated Pest Management systems

Des Conlong[2], Stuart Rutherford[1]

[1]South African Sugarcane Research Institute, Mount Edgecombe, KwaZulu-Natal, South Africa, [2]Departement of Conservation Ecology and Entomology, Stellenbosch University, Stellenbosch, South Africa

Conventional Integrated Pest Management (IPM) systems have concentrated on controlling pests through informed use of cultural and biological control and host plant resistance characteristics to minimise pesticide interventions. The basic foundation of successful IPM systems is a thorough knowledge of the target pest's life cycle, and its ecological and behavioural interactions with the environment and natural controlling factors in both its indigenous and crop habitats. Through this basic knowledge, a number of new interventions can be added to the IPM arsenal. These include management of the habitat to make the crop less suitable for colonisation by potential pests, and to increase natural enemy foraging and abundance in the crop habitat, Thus increasing the efficacy of conservation, inoculative and augmentative biological control. In addition, more is known about the impact of plant and insect pathogens and symbionts on target pest populations by making potential host plants more or less suitable for colonisation, thus adding a fourth trophic level to agro-ecosystem dynamics. Furthermore, the impact of these on fertility and offspring sex ratios (eg. *Wolbachia* isolates in pest and natural enemy populations) makes their exploitation, in combination with interventions such as Sterile Insect Technology (SIT), a real and practical possibility. Modern IPM is thus not only about insect/plant interactions, it is about holistic agro-ecosystem interactions, in which knowledge about plants, pathogens, endophytes, symbionts and insects are all combined to provide effective crop protection in an area-wide and environmentally friendly manner.

Changes to citrus IPM strategy in southern Africa

Tim Grout[1], Hendrik Hofmeyr[2], Sean Moore[3]

[1]Citrus Research International, Nelspruit, Mpumalanga, South Africa, [2]Citrus Research International, Citrusdal, Western Cape, South Africa, [3]Citrus Research International, Port Elizabeth, Eastern Cape, South Africa

Introduction: The climate in the citrus-production regions of southern Africa supports a wide variety of pests and their natural enemies. Until the mid-1990s, most exporting citrus growers practiced a form of IPM that relied on the conservation of wild natural enemies through the judicious use of pesticides. Depending on the amount of chemical intervention required for vectors and cosmetic pests, growers were variably successful in keeping key pests such as red scale (*Aonidiella aurantii*) and citrus mealybug (*Planococcus citril)* under biological control. False codling moth (FCM) (*Thaumatotibia leucotreta*) was largely controlled with the use of chitin synthesis inhibitors (CSIs) and a few insectaries provided natural enemies for augmentation purposes that were utilised by some growers.

Changes: Since 2000, increasing market competition has led to lower tolerances for phytosanitary pests that are below levels required to sustain biological control. Simultaneously, the number of pesticides available for use on export fruit has declined. These pressures, together with an increase in resistance to CSIs in FCM, have led to the commercial use of a granulovirus, the introduction of Sterile Insect Releases (SIR) and mating disruption, for the control of FCM. The availability of inexpensive generic imidacloprid formulations has increased the biorational use of this product as a soil drench for the control of red scale and suppression of mealybug. This treatment, or stem applications of acetamiprid or methamidophos, are used for the control of citrus psylla (*Trioza erytreae*). Buprofezin and/or parasitoid releases are being used for citrus mealybug control, while generic abamectin formulations provide for inexpensive control of *Scirtothrips aurantii* and several mites. Bait stations are increasingly being used for fruit fly control.

Conclusion: Biorational control strategies such as microbial control, SIR, mating disruption, attract-and-kill and soil- and stem-applied systemics now define citrus IPM in South Africa.

Regulation of humidity in honeybee hives

Michael B Ellis, Sue W Nicolson, Robin M Crewe, Vincent Dietemann

University of Pretoria, Pretoria, South Africa

Introduction: Many insects are able to modify adverse microclimatic conditions rather than attempting to evade or tolerate them. Honeybees (*Apis mellifera)* are able to regulate the temperature in their nest to optimise brood development. Survival of brood is also affected by humidity. However, it is not known whether honeybees regulate this parameter. We investigated how nest material and behaviour of the workers influence humidity.

Methods: We determined the water absorption capacity of comb containing the hygroscopic cocoons spun by larvae within their cells. We also monitored the behaviour of workers exposed to different humidities in a set of interconnected linearly arranged chambers.

Results: Comb containing cocoons absorbs a mean of 11.1% of its mass in water. Honeybee workers exhibit a mild hygropreference for approximately 75% RH in the absence of brood, and this preference is further weakened by the presence of brood. Fanning behaviour of workers is significantly increased by a rise in humidity.

Conclusions: Our results indicate that the buffering properties of cocoons could ensure a stable high humidity within the cell, thus favouring brood development. The mild hygropreference of workers can be explained if their dispersal throughout a humidity gradient enables them to actively counteract sub-optimal conditions where they occur. Indeed, through fanning behaviour, workers can expel humid air, thus decreasing humidity for effective nectar evaporation. We obtained evidence that humidity in honeybee hives is affected by both passive and active mechanisms allowing for the maintenance of distinct optima in various parts of the hive.

Extraocular photoreceptors and frontal grooves in Criocerinae (Coleoptera: Chrysomelidae)

Michael Schmitt, Uta Heidenreich

Zoologisches Forschungsmuseum Alexander Koenig, Bonn, Germany

Introduction: Extraocular photoreceptors are described for several holometabolous insects, including some Chrysomelidae. They are persisting larval stemmata and could play a part in triggering circadian rhythms. Presence of such “brain eyes” in leaf beetles other than *Leptinotarsa decemlineata* has not been shown before. Since in two chrysomelid subfamilies (Criocerinae and Sagrinae) conspicuous frontal grooves are characteristic, but no function is known to date, we examined if they work as gates for incoming light.

Methods: Isolated brains of 5 leaf beetle species and 4 hemimetabolous insects have been checked under a dissecting microscope. Ultrathin sections were made of brains of *Lilioceris merdigera* and investigated under TEM. Head capsules of 12 leaf beetle species have been dissected and photographed under transillumination.

Results: The frontal grooves were permeable for long-waved light in two criocerine species with black heads (*Lilioceris lilii* and *Crioceris asparagi*). In all species with lighter head capsules the sulci appeared darker than the rest of the head. Extraocular photoreceptors were found in all species of leaf beetles, but not so in all hemimetabolous insects. Under TEM, rhabdomeres and screening pigments could be shown.

Conclusion: All beetles studied have „brain eyes“, which are persisting larval stemmata. Their ultrastructure is exactly that of an ocular retinula. In species with black pigmented head capsules, the frontal grooves can act as light gates. However, since these grooves transmit less light than the remaining head in species with lighter head capsules, the evolutionarily primary role of these grooves cannot have been light transmission.

Managing termite pests in Australia: The art of combining environmental sensitivities and economic rationalities

Theodore Evans

Commonwealth Scientific and Industrial Research Organisation, Canberra, ACT, Australia

Australia has around 20 species of wood-eating termites of economic significance, which are found all over Australia; with higher risk of termite infestation in the 30% of the country located in the tropics. There has been an almost 100 year continuous history of research into termite control and management in Australia; these methods have changed considerably in this time. Currently, there are many pest control methods; Australia now has one of the most diversified termite pest control markets in the world. This diversity is due, in part, to the readiness of pest control operators (PCOs) to change suppliers and methods to achieve most rapid control. This diversity is also due to environmental and economic concerns; in particular the potential toxic side effects of insecticides, and the availability of cheaper, generic insecticides. Termite pest control methods can be classified as either preventative or remedial treatments; most attempt to do both. These methods can also be classified according to the method used: physical, chemical or biological. Some methods were developed in other countries, usually by multinational companies, and so will be known elsewhere, but have required modification to Australian conditions. Other methods were developed in Australia, often by builders or PCOs, and so are not widespread. At this point in time in Australia, there no method or product dominates the pest control market, for several reasons: (1) all methods and products are effective; (2) methods can vary in ease of use and efficiency according to local conditions; (3) customer preferences.

Possibilities for biological control of the invasive spider mite *Tetranychus evansi* in Africa

David Bugeme[1], Knapp Markus[1], Nguya Maniania[1], Vitalis Wekesa[2], Imeuda Furtado[2], Gilberto de Moraes[2]

[1]ICIPE-African Insect Science for Food and Health, Nairobi, Kenya, [2]Departamento de Entomologia, Fitopatologia e Zoologia Agricola, Esalq, Universidade de Sao Paulo, Sao Paulo, Brazil

Introduction: The spider mite *Tetranychus evansi* is an invasive pest of tomatoes in Africa. It is causing severe yield losses in small-holder production systems. No effective natural enemies are present in the field in Africa.

Methods: Surveys for natural enemies of *T. evansi* were conducted in South-America for introduction into Africa. Elsewhere, the entomopathogenic fungi *Beauveria bassiana* and *Metarhizium anisopliae* isolates were investigated for their potential in the control of *T. evansi* in the laboratory, greenhouse and in the field.

Results: The predatory mite *Phytoseiulus longipes* was the most promising candidate and was imported into Kenya after extensive laboratory and greenhouse testing. A pilot release experiment did not lead to establishment in Kenya.

On another hand, in the laboratory *B. bassiana* and *M. anisopliae* isolates infested *T. evansi*, with the most pathogenic isolate inducing a mortality of up to 95.5%. In the greenhouse, fungal isolates in both water and oil formulations significantly reduced the population density of mites on tomato leaves, but conidia formulated in oil outperformed the ones formulated in water. Similar results were observed in the field at 3 weeks post-spraying. However, at 5 weeks post-spraying there were no significant differences between the two fungal formulations and the synthetic acaricide.

Conclusions: Further releases and trials are required to make a judgement about the potential of *P. longipes* as a classical biological control agent for *T. evansi*. However, this study underlines the potential of the *M. anisopliae* isolate ICIPE78 as an alternative to acaricides for *T. evansi* management.

The role of GBIF's ECAT programme in access to taxon names

David Remsen[1], Christopher Lyal[2]

[1]Global Biodiversity Information Facility, Copenhagen, Denmark, [2]The Natural History Museum, London, United Kingdom

Attempts to mobilize and serve biodiversity data are significantly hampered by retrieval impediments due to the 'names problem' in biology. This results from taxonomic and nomenclatural changes impacting on the names of species, imperfect penetration of those changes to the non-taxonomist users of the names, multiple co-occurring taxonomic views, and difficulty in mapping concepts and names used in one source to those employed in another. All biodiversity data mobilization initiatives find themselves challenged to reconcile problems of synonymy, orthography, and homonymy as it relates to basic search and retrieval of species information. This is particularly so for those operating at large scales, such as GBIF and the Biodiversity Heritage Library, where records number in the tens of millions, comprise a vast array of sources, and span the full taxonomic and temporal range of post-Linnaean biology. The GBIF ECAT program seeks to collectively access taxonomic and nomenclatural authority files and redirect their content into an applied informatics tool to address these access impediments.

Completing the Catalogue of Life for insects

Christopher Lyal

The Natural History Museum, London, United Kingdom

Over the past few years there has been an explosion in the number of databases and lists of insect species names being created and made available on the web and otherwise. Some have been presented in such a way that they can be accessed simultaneously through web portals, allowing searching of multiple datasets. Such portals include the major initiatives Species 2000 and ITIS, working together as the 'Catalogue of Life' and providing a single authoritative taxonomic view of species content to the Global Biodiversity Information Facility, GBIF. Currently the Catalogue of Life contains over 1 million species, but is by no means complete. A grant application is being presented this year to facilitate that completion by providing a 'nomenclator layer' of names and references, and tools to start building full synonymic databases. However, its ultimate success, and our success in building a catalogue of all insect names, will depend on the involvement of taxonomists around the world, and enabling their database to be linked to a global system. Future workshops will refine the process and the participation, but the completion of the Catalogue of Life for insects starts now.

Area-wide integrated pest management for tsetse flies: The role of sterile insects

Marc Vreysen[1], Udo Feldmann[1], Andrew Parker[2], Jorge Hendrichs[1]

[1]Insect Pest Control Sub-Programme, Joint FAO/IAEA Programme of Nuclear Techniques in Food and Agriculture, Department of Nuclear Applications, International Atomic Energy Agen, Vienna, Austria, [2]Joint FAO/IAEA Programme of Nuclear Techniques in Food and Agriculture, FAO/IAEA Agriculture and Biotechnology Laboratory, Entomology Unit, Seibersdorf, Austria

The concept of area-wide integrated pest management (AW-IPM) against specific tsetse populations has gained in significance during the last ten years. The approach targets entire populations of tsetse within a delimited geographical area and integrates in a phased manner a combination of control tactics that are best suited for the specific characteristics of the target area. AW-IPM aims at combining control tactics which are effective at high tsetse population densities, such as the SAT (sequential aerosol technique) with those that are effective at low population densities such as the sterile insect technique (SIT). In addition, it takes into account different favourable climatic, agroc-ecological and seasonal trends. The creation of sustainable tsetse-free areas on Africa mainland is feasible, provided the operations are carried out on an area-wide basis. The elimination of *Glossina pallidipes* from 11 000 km² in Zululand, South Africa in the 1950s, using a combination of aerial spraying of insecticides, game/habitat destruction, and mass-trapping, is a case in point. The area is to date still free of *G. pallidipes*.

New tools such as tsetse population genetics and geographic information systems/remote sensing are providing more evidence that the tsetse belt is not continuous, but is, in many instances, fragmented. These population islands offer opportunities for the creation of sustainable tsetse-free areas using AW-IPM principles. The role of sterile insects in these AW-IPM programmes should be carefully assessed and they should only be used in those topographical and ecological situations where they offer a comparative advantage over other control tactics.

DNA-based approaches to the identification of forensically important Australian *Chrysomya* (Diptera: Calliphoridae)

Leigh A. Nelson[1], James F. Wallman[2], Mark Dowton[1]

[1]*Centre for Medical Bioscience, School of Biological Sciences, University of Wollongong, NSW 2522, Australia,* [2]*Institute for Conservation Biology, School of Biological Sciences, University of Wollongong, NSW 2522, Australia*

Introduction: A DNA-based approach shows potential for the identification of taxa for which the use of morphology, or the association of different life stages, is problematic. The identification of several forensically important Australian *Chrysomya* species is hampered by their similar morphologies, even as adults.

Methods: Four DNA regions were tested for the identification of members of this genus, collected from the east coast of Australia: 1) the ribosomal 28S, 2) the second ribosomal internal transcribed spacer (ITS2), 3) the mitochondrial control region and 4) the 'barcode' region of the first subunit of the mitochondrial cytochrome oxidase I (COI).

Results and Conclusions: With the exception of the COI 'barcode', difficulties were experienced with amplification and sequencing, attributable to high intra-individual sequence variation (heteroplasmy) in those regions. The 658 bp fragment of the COI gene was sequenced from 56 specimens, representing all nine Australian *Chrysomya* and three calliphorid outgroups. The COI sequence divergences were calculated using the Kimura-two-parameter distance model, and a bootstrap neighbour-joining (NJ) tree was generated to provide a graphic display of the patterns of divergence among the species. The COI barcode successfully identified the Australian *Chrysomya,* with all species resolved as reciprocally monophyletic groups on the NJ tree, with strong bootstrap support. Intraspecific sequence divergences averaged 0.097% (range = 0-0.612%), while interspecific divergences averaged 6.499% (range = 0.458-9.254%). The overlapping sequence divergences for the *Chrysomya* is attributable to the low sequence divergence (mean = 0.484%) between the sister species *Chrysomya megacephala* and *Chrysomya saffranea.*

Spatial analysis of earthworm predation by generalist carabid predators using molecular analysis of gut contents

Andrew King[1], James Bell[2], David Bohan[2], William Symondson[1]

[1]Cardiff University, Cardiff, United Kingdom, [2]Rothamsted Research, Hertfordshire, United Kingdom

Earthworms have a key role in many soil processes, including soil turnover, aeration, drainage and the breakdown and incorporation of organic matter. As earthworms are a major component of the invertebrate biomass in European soils, they are a significant source of prey for many mammals, birds and invertebrate predators.

Carabid beetles, such as *Pterostichus melanarius* and *P. madidus*, are recognised predators of crop pests such as slugs and/or aphids, capable of affecting their temporal and spatial population dynamics.

Molecular approaches can be used to identify trophic links in agricultural food webs, to measure the responses of generalist predators to changes in prey diversity and density, and to assess the role of alternative prey, such as earthworms, in sustaining predators at times of low target prey abundance. Both monoclonal antibodies and general earthworm PCR primers have revealed significant proportions of *P. melanarius* populations testing positive for earthworm.

We have now developed species-specific, and in some cases lineage-specific, PCR primers for all the earthworm species at our field site. Extreme genetic divergence amongst two species, *Allolobophora chlorotica* and *Apporrectodea rosea*, necessitated the development of different primers for each lineage. The primers for all species and lineages were combined within a multiplex PCR to simultaneously screen for the presence all species of earthworm in the guts of each predator.

The application of this approach to the analysis of spatial and temporal interactions between carabids and multiple earthworm species in the field will be presented.

Vibratory signals in stingless bee recruitment: Investigations of transmission pathways allow the identification of potential receivers

Michael Hrncir

University of São Paulo, Ribeirão Preto, Brazil

When returning from profitable food sources, stingless bee foragers generate thoracic vibrations inside their nest, predominantly during trophallactic food transfers. Since it proves difficult to pinpoint the receivers of these putative signals (due to sometimes very subtle behavioral changes), the true meaning of these vibrations for recruitment processes is not entirely unscrambled. Yet, detailed analyses of the potential pathways, through which the thoracic vibrations are transmitted from the foragers to the hivebees, allow at least defining and confining the crowd of potential receivers. Assuming similar physiological properties of the mechanosensory organs in honeybees and stingless bees, (1) a "long-range", (2) a "medium-range", and (3) a "short-range" transmission pathway can be postulated. (1) *Substrate vibrations*. Thoracic vibrations are strongly attenuated on all natural substrates found within meliponine nests. Nevertheless, hivebees should be able to detect the substrate vibrations at distances of up to 3-5 cm from the vibrating forager (on entrance structure and involucrum). Consequently, substrate vibrations could be used by both food receivers and potential recruits to detect and approach a forager. (2) *Airborne sounds*. Most hivebees attending trophallaxes stay within 5 mm from the vibrating forager and (almost) touch her body with their antennae. Within this range, the forager-generated particle velocity is strong enough to be perceived by the hivebees. (3) The most efficient transmission is through *direct physical contact* during trophallaxis. Here, food-receivers are directly vibrated by the forager, and the frequency content and temporal pattern are directly passed on to the receiver bees. [FAPESP 06/50809-7 and 06/53839-4]

Phytosanitary constraints: South africa's export regulatory system

Isabella Bezuidenhout

Directorate Plant Health, Department of Agriculture, Pretoria, Gauteng, South Africa

As a result of agreements negotiated at the World Trade Organisation (WTO), traditional trade protection measures such as tariffs and quotas are falling away. But to some extent they are being replaced by domestic technical regulations that permit countries to bar products from entering their markets if the products do not meet certain standards. Arbitrary and restrictive sanitary and phytosanitary measures continue to represent a major obstacle to international trade of agricultural products. South Africa's entry into the international arena has been an area of tremendous change. In line with domestic liberalisation policies and export promotion strategies, South Africa has become an active member in international trade and a member of various international organisations. The new global environment for international trade places a huge responsibility on the National Plant Protection Organization of South Africa (NPPO) to facilitate safe agricultural trade with its international trading partners. Effective national export control systems are critical to enable a country to enhance its competitiveness and international market access of plants, plant products and other regulated articles. In South Africa an effective and efficient export regulatory system is undermined by the existence of inadequate and/or obsolete standards and standard operating procedures, absence or inadequate information on pests, insufficient human resources, inadequate pest surveillance, inspection and certification, pest free areas and areas of low pest prevalence not yet identified, smuggling through porous borders, and inadequate information sharing on pests.

The origin of the South African weed population of *Pereskia aculeata* (Cactaceae) and new potential biological control agents

Iain Paterson[1], Doug Downie[1], Stefan Neser[2], Martin Hill[1]

[1]Rhodes University, Grahamstown, South Africa, [2]ARC-Plant Protection Research Institute, Pretoria, South Africa

New biological control agents are required to control the invasive weed *Pereskia aculeata* Miller (Cactaceae) in South Africa. Identifying the regions of origin of weed biotypes has been important in a number of biological control programmes and is likely to affect the control of *P. aculeata* because of the plant's vast and distjunct native distribution. DNA sequencing of the TrnL-F intergenic spacer, the nuclear gene Phytochrome C and Inter-Simple Sequence Repeats using 14 primers indicate that the weed population originates from the southern part of the plant's native range in Misones Province, Argentina. South African plants are placed in a distinct clade which indicated either single or multiple introductions from this region. Surveys of the phytophagous insects associated with *P. aculeata* have been conducted in Misones Province and 4 other regions within the plant's native range. Misones Province had the largest diversity of phytophagous insects associated with *P. aculeata* followed by 3 regions in Brazil. It has been suggested that the Caribbean is the region of origin of the species but this region supported a depauperate insect fauna. As the origin of the South African weed population and the region with the most diverse insect fauna associated with *P. aculeata* Misones Province is the most appropriate region to survey for biological control agents. Of the 23 phytophagous insects associated with *P. aculeata* in this region 5 have potential and should be considered for host specificity testing based on their distributions and modes of damage.

Analysis of a market-focussed biorational product business

Sean Moore

Citrus Research International, Port Elizabeth, South Africa

Introduction: In 2003 the Citrus Growers Association formed a company – River Bioscience – to commercialise research innovations from its subsidiary, Citrus Research International.

The products: The first product commercialised by River Bioscience was the *Cryptophlebia leucotreta* granulovirus (CrleGV). Recently, River Bioscience acquired three other products. These are another baculovirus, the *Helicoverpa armigera* nucleopolyhedrovirus (HearNPV), a fruit fly bait station and a fruit fly monitoring system. The success of Cryptogran (the CrleGV product) can be attributed to: the dearth of other products in the market place at the time of launching; the high priority requirement to control the target pest; and the product's efficacy, which is comparable to that of existing chemical options. Helicovir (the HearNPV product) is fully developed but is awaiting registration. It is envisaged that acquiring market share with this product will be a lot more difficult than was the case with Cryptogran. This is due to the slow speed of kill of the product and the availability of chemical alternatives. Grower education will therefore be of paramount importance in obtaining acceptance of Helicovir.

The company: The success of the company can be attributed to: the market-focus rather than product-focus of the company; the relationship and credibility which the company has with its market; and the expertise of the company's distribution network. If River Bioscience had not acquired other products, in addition to Cryptogran, within three years from start up, the company would have been exposed to great risk.

Conclusions: The most influential factor in the success of the company and its products is the market focus of the company.

Polyandry or polygyny in the social Hymenoptera: two routes to genetic diversity

William Hughes[1], Francis Ratnieks[2], Madeleine Beekman[3], Ben Oldroyd[3]

[1]University of Leeds, Leeds, United Kingdom, [2]University of Sussex, Brighton, United Kingdom, [3]University of Sydney, Sydney, Australia

Understanding the evolution of multiple mating by females (polyandry) is an important question in behavioural ecology. A series of fitness benefits of polyandry for social insect queens have been suggested and significant progress has been made in providing experimental evidence for particular hypotheses in particular taxa. Here I will adopt for the social Hymenoptera, the potential powerful approach of a comparative analysis to examine the support it provides for the various hypothesised costs and benefits of polyandry. Many of the postulated fitness benefits of polyandry are based upon an increase in intracolonial genetic diversity, which also results from colonies having multiple queens (polygyny). I will therefore also examine the comparative relationship between polyandry and polygyny to see if it provides any support for the evolution of one or both traits having been driven by a benefit from intracolonial genetic diversity.

A case study of an invasive species: Why outbreak and why decline?

Zhen Zhang, Hongbin Wang, Xiangbo Kong, Pei-yi Zhang, Jun Liu

Research Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, The key Laboratory of Forest, Beijing, China

Abstract: The red turpentine beetle (RTB), *Dendroctonus valens* LeConte native in North and Central America, was introduced into China in early 1980's, and since 1998 it had caused severe damage to *Pinus tabulaeformis* in China, especially in an outbreak period from 1998 to 2002. The analyses indicated there were a few main factors which influenced the successful establishment of this species in China. (1) when RTB first attacked the pine there were no competitors, other borers infested the pine only after the tree became weak or dying by RTB; (2) RTB had high adaptation ability to the environment because of the wide distribution range, large host range and big body size; (3) the main host species, *Pinus tabulaeformis*, was attractive to the beetle; (4) RTB had a characteristics of low special aggregation;(5) there existed of huge pure pine stands or the mixed stands had limited resistance to infestation of RTB. The environmental or management factors caused the population outbreaks included drought in the spring, illegal cutting, heavy tapping and unsuitable management. The RTB population declined in recent years because there were more rainfall, the host attractiveness decreased, the local natural enemies were established, and various management measures were implemented, such as mass trapping using semio-chemicals, introduction of natural enemies, prohibition of illegal cutting, and also the treatment of stumps after cutting.

Forest inventory data: A basis for conservation of ground dwelling beetles in managed landscapes

Colin Bergeron[1], John Spence[1], Jan Volney[2]

[1]University of Alberta, Edmonton, Alberta, Canada, [2]Northern Forestry Centre, Edmonton, Alberta, Canada

Introduction: Ground dwelling beetles (Coleoptera: Carabidae) can teach us much about biodiversity conversation in managed landscapes. This study aims to quantify how ground beetles interact with different forest habitat components. It further seeks to determine if operational maps derived from air photo interpretation (1:20 000) adequately reflects these interactions in ways that allow the design of conservation strategies in managed landscapes.

Methods: A systematic grid of 200 sites was established on 84 km^2 of Boreal Mixedwood forest in Western Canada at the Ecosystem Management Emulating Natural Disturbance research site. Disturbance history, forest structure and composition, and ground dwelling beetles were sampled in every sites.

Results: Occurrence of most common ground beetle species was explained by the distribution of the most common tree species as is well reflected in forest inventory data (FID). Uncommon carabid species were associated with tree species uncommon on this landscape and these associations were not well reflected in the FID. The uncommon tree and beetle species occurred in places where the disturbance regime differs from the rest of the landscape.

Conclusions: FID predicted the occurrence of most common beetle species. They can therefore be used for conservation-oriented management planning. However, the occurrence of uncommon species in areas with long fire return intervals or frequent flooding is not well predicted by forest inventory data. Hence, other surrogates need to be investigated for use in conservation of the uncommon, and likely more vulnerable, species in managed landscapes.

Realities and prospects for microbial control of citrus pests in South Africa

Sean Moore[1], Antoinette Malan[2], Wayne Kirkman[1], Tim Grout[3], Tarryn Goble[4]

[1]Citrus Research International, Port Elizabeth, South Africa, [2]University of Stellenbosch, Stellenbosch, South Africa, [3]Citrus Research International, Nelspruit, South Africa, [4]Rhodes University, Grahamstown, South Africa

Introduction: Several pathogens have been recorded from citrus pests in South Africa. However, the exploitation of these pathogens on a commercial level is a relatively new practice in the southern African citrus industry.

Realities: Currently only *Bacillus thuringiensis kurstaki* (Bt) and the *Cryptophlebia leucotreta* granulovirus (CrleGV) are registered for use on citrus. Bt is used for controlling bollworm, *Helicoverpa armigera*, apple leafroller, *Tortrix capensana* and citrus butterflies, *Papilio* spp. CrleGV has been used commercially for control of the false codling moth, *Thaumatotibia leucotreta*, for four years now. An application for the registration of the *Helicoverpa armigera* nucleopolyhedrovirus (HearNPV) has also been submitted after several years of successful trials against *H. armigera*.

Prospects: In addition, several other projects to investigate and develop entomopathogens for control of citrus pests are underway. Entomopathogenic nematodes (EPNs) have shown great promise in laboratory biossasys for control of *T. leucotreta*. The integration of EPNs and CrleGV into a phenologically discerning programme for season-long control of *T. leucotreta* is discussed. EPNs could also be used for control of other pests which have a soil-borne stage in their life-cycle, such as fruit fly, *Ceratitis capitata* and *H. armigera*. Research projects are currently underway to investigate the use of hyphomycete fungi for control of final instar larvae and pupae of pests which occur in the soil. These include the pupae of *T. leucotreta*, *C. capitata* and the citrus thrips, *Scirtothrips aurantii*.

Conclusion: Much potential exists for further exploitation of entomopathogens for control of various pests on citrus. Microbial control options can form an integral part of a greater IPM strategy.

Composition and phenology of insect pests of *Capsicum baccatum* (Solanaceae) cultivated in the Makana District, Eastern Cape Province, South Africa

Colleen Hepburn, Sarah Radloff, Martin Villet, Martin Hill

Rhodes University, Grahamstown, South Africa

The composition and phenology of insects occurring on Cherry Peppers, *Capsicum baccatum*, grown in the Makana District was quantified during the study period, November 2005 to November 2006. Data from a pilot sampling trial were analyzed to establish the number of plants to be scouted per site and the most effective scouting techniques to use. Five different types of monitoring traps were placed in each of the eight study sites. Collection of trap catches and scouting of fifteen individual plants per site was undertaken on a weekly basis over the 52-week study period. The most commonly trapped potential insect pests were African Bollworm *Helicoverpa armigera* (Hübner), False Codling Moth *Thaumatotibia leucotreta* (Meyrick), Mediterranean Fruit Fly *Ceratitis capitata* (Wiedemann) and several species of thrips. The majority of damage caused to the *Capsicum baccatum* crop was due to *Ceratitis capitata* populations. Although *Helicoverpa armigera* and *Thaumatotibia leucotreta* adults were present in the monitoring trap catches, the scouting data showed larval counts of both species were nominal. Using the scouting data gathered and the mean number of pods per plant, a measure of plant damage was estimated. Statistical analyses established the efficacy of the monitoring traps for each pest and tested for differences among and between study sites. Surveillance programmes, Integrated Pest Management and intervention strategies are considered for application in *Capsicum baccatum* cropping systems.

Advances in the study of scent trails in stingless bees (Apidae: Meliponini)

Dirk Louis P. Schorkopf

University of Vienna, Vienna, Austria

Introduction: Meliponine bees are uniquely among flying insects for their scent trail laying behaviour: Bees of the worker caste of several species signalize food sources by scent marking them, therefore informing nest mates of its existence and position. Many interpretations and hypothesis concerning scent trail laying in meliponines are now in doubt and somewhat controversial when inspecting them in greater detail.

Methods: I first reviewed the advances of scent trail laying research in meliponines. I then compared the research methods and interpretations of the past on scent trail laying with the more recent outcomes and own observations. The following questions where treated in more detail: 1) which methods were used to challenge a particular question in respective studies 2) in which way did the methods of the past and recent studies differ 3) is it possible to explain some controversial hypothesis and interpretations between the studies merely by the use of different methods 4) where some methods particularly useful to answer a particular question regarding scent trail laying in meliponines?

Results: Since the discovery of scent trail laying in Meliponini several (however, less than 30) relevant studies have been published. Interestingly researchers in general preferred to use a new method or to change important aspects of already published methods when trying to answer the same questions which make a comparison difficult or in some cases even impossible. Some difference in methodology, however, was due to the use of sophisticated instruments rarely available in the past. Some controversial interpretations between the studies can possibly be explained by the use of different methods and the use of different species. Although some methods seem to be more efficient in answering a particular question on meliponine scent trail functionality, still much too few studies are available to draw secure conclusions.

Conclusions: Although some valuable insights on scent trail laying in meliponines are already available the study of scent trails in Meliponini has just begun. A more careful evaluation of the methodology, also as to their comparability to past studies will be very helpful to answer the many questions still remaining.

Insect rearing for commercial virus production

Sean Moore[1], Wayne Kirkman[2], Craig Chambers[1]

[1]Citrus Research International, Port Elizabeth, South Africa, [2]River Bioscience, Port Elizabeth, South Africa

Introduction: Since 2004 the *Cryptophlebia leucotreta* granulovirus (CrleGV) has been commercially produced in South Africa for use against the false codling moth, *Thaumatotibia leucotreta*, on various agricultural crops. This is the first baculovirus to be commercially produced in South Africa.

Host: The first requirement for successful production of the virus is an effective and efficient mass rearing process for the host, as virus production is *in vivo*. In order to achieve this, effective means for the following had to be established: surface sterilisation of eggs; production of a suitable artificial diet for larvae; and moth eclosion and oviposition systems. Quality control is of paramount importance. This entails regular recording of the host biology, cleanliness and environmental parameters. This enables rapid attendance to any unacceptable deviations.

Pathogen: Virus production must be spatially separated from host production, with no flow from the former to the latter. For virus production, the most suitable larval life-stage is inoculated with an LC_{90} concentration of virus and incubated for the optimal time period until harvesting. Great care must be taken to minimise contamination of larvae with bacterial and fungal pathogens. Quality control entails quantification of all important biological and environmental factors. Deviation from set standards may result in disqualification of virus from being formulated and bottled.

Conclusions: The most important factors in the successful production of a baculovirus in order to meet the demands of a commercial market are: documented protocols, well-trained staff and dedication to quality control.

Does *Xylaria* play a specific role in the fungus-growing termite mutualism?

Anna A. Visser[1], Vera D. Ros[1], Eline Hartog[1], Z. Wilhelm De Beer[2], Bernard Slippers[2], Michael Wingfield[2], Janette Mitchell[3], Thomas Lœssøe[4], Alfons J.M. Debets[1], Thomas W. Kuyper[5], Rolf F. Hoekstra[1], Duur K. Aanen[1]

[1]Laboratory of Genetics, Wageningen UR, Wageningen, Netherlands, [2]Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa, [3]Agricultural Research Council, Plant Protection Research Institute, Pretoria, South Africa, [4]Department of Biology, University of Copenhagen, Copenhagen, Denmark, [5]Department of Soil Quality, Wageningen UR, Wageningen, Netherlands

Introduction: Fungus-growing termites live in obligate mutualistic symbiosis with species of the basidiomycete genus *Termitomyces*, which is grown in monoculture on a substrate of dead plant material. When the termite colony dies, or when nest material is incubated without termites in the lab, often species of the ascomycete genus *Xylaria* appear and rapidly cover the fungus garden. Considering its high prevalence, is *Xylaria* specialized in occupying termite nests or is it just an opportunistic visitor? As a first attempt to answer this question, we tested specificity of *Xylaria* for fungus-growing termites at the termite genus, species, or single colony level.

Methods and Results: In South Africa, 120 nests of eight termite species from three termite genera were sampled for *Xylaria*. *Xylaria* appeared on 70% of the incubated combs. Using ITS and 28S sequences, and including non-termite associated *Xylaria* GENbank sequences, we show that one clade comprising 63% of all isolates is specific for fungus-growing termites. The remaining 37% strains possibly represent endophytes. The termite-specific *Xylaria* clade does not show strong specificity at subsequent lower taxonomic levels, viz. at the termite genus, species, or colony level.

Conclusions and Discussion: Our results suggest that *Xylaria* does not play a very specific role in the fungus-growing termite mutualism. We are currently testing if *Xylaria* is more specialized on the substrate of the fungus garden. This would explain why *Xylaria* is so prevalent in termite nests and does show specificity for fungus-growing termites in general, while lacking specificity for groups within fungus-growing termites.

Successful invasion of red turpentine beetle *Dendroctonus valens* LeConte (Coleoptera: Scolytidae): Evidence of the empty niche hypothesis

Zhen Zhang, Pei-yi Zhang, Jun Liu, Hong-bin Wang, Xiang-bo Kong

Research Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry The key Laboratory of Forest, Beijing, China

Abstract: The red turpentine beetle (RTB), *Dendroctonus valens* LeConte, originally distributed in North and Central America, was introduced into China in early 1980's and since 1998 it has caused great damage to Chinese pines, *Pinus tabulaeformis* Carr. The pine wood boring insect community structures in invaded area were studied to explore the reason of the successful invasion of the RTB. The results indicated that when RTB first attacked the pines there were no competitors, other borers came only after the pines became weak or dying by RTB. At later stages of attack RTB mostly coexisted and competed with *Melanophila farmanekin* and *Asemum amurense*. An important local natural enemy, *Temnochila sp*. was found which prefers RTB to other wood borers. There are also records of other local natural enemies which can prey or parasite on RTB. Thus, its successful invasion can not be explained by the lack of natural enemies while the empty niche hypothesis may provide a more likely explanation.

Effects of host and non-host volatiles on the behavior of red turpentine beetle *Dendroctonus valens* LeConte (Coleoptera: Scolytidae) and its natural enemies

Zhen Zhang[1], Hong-bin Wang[1], Li-xian Cui[2], Da-zhuang Huang[2], Xiang-bo Kong[1], Yong-jie Zhang[3], You-ju Jin[3]

[1]Research Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry The key Laboratory of Forest, Beijing, China, [2]Agricultural University of Hebei, Baoding/Hebei, China, [3]College of Biological Sciences and Biotechnology, Beijing Forestry University, Beijing, China

Red turpentine beetle (RTB), *Dendroctonus valens* LeConte (Coleoptera: Scolytidae), is an invasive species in China which originally distributed in North and Central America. Since 1998 it has caused grave damage to Chinese pines, *Pinus tabulaeformis* Carr in China. In door and field testing proved that (*S*)-(+)-3-carene was the most attractive host monoterpene to the Chinese population of RTB and its natural enemy, *Prostomis* sp. though other monoterpenes such as α-pinene, and β-pinene had also more or less their attractive effects. To the contrast, myrcene and (+)-limonene were repellents to RTB. Eight compounds (cis-3-hexen-1-o, trans-2-hexen-1-ol, nohyl aldehyde, 1-octen-3-ol, ethanol, 1-hexen-3-ol, benzaldehyde and salicylaldehyde) had significantly repellent effects on RTB, however, three other compounds(3-octanol, cis-2-hexen-1-ol, trans-2-hexenal) had been determined to have no significant repellent effects on RTB by the y-tube test. However, some of them were effective at lower concentration (1/1000), while others were more effective at higher concentration of 1/100. All the tested volatiles, except ethanol, were demonstrated to be effective repellents to RTB with rotor trap tests in the field.

Post-release evaluation of the seed feeding bruchid beetle *Sulcobruchus subsuturalis* in the biological control of *Caesalpinia decapetala* an invasive weed in South Africa

Faith Kalibbala, Edward Witkowski, Marcus Byrne

University of the Witwatersrand, Johannesburg, South Africa

Introduction: The release of the seed beetle *Sulcobruchus subsuturalis* for biological control of *Caesalpinia decapetala* in South Africa has been ongoing since 2000. This is the first post release evaluation of the efficacy of the agent against the weed.

Method: We assessed the phenology of *C. decapetala* and *S. subsuturalis* at two sites and the establishment of the beetle on the weed at 25 sites. In addition, the effects of *S. subsuturalis* on seed densities, seed germination and seedling recruitment were measured. Predation by native ants and attacks by native parasitoids were also examined at two release sites.

Results: Mature pods were available on the tree from spring to summer when the beetle is expected to be reproductively active. The proportion of beetle infested seeds collected from study sites was low (0 to 15.5%). Consequently high seed densities and seedling recruitment were observed in the field. In the laboratory, seed infestation levels were high and germination was less than 10% and seedling emergence as low as 2.1%. Predation by native ants (*Crematogaster* species, *Pheidole megacephala*, *Messor natalensis* and *Tetramorium avium*) reached 100% within 10 days. Egg parasitism ranged between 80 and 93.1%. The parasitic wasp *Dinarmus altifrons* was recovered developing inside a *C. decapetala* seed infested with *S. subsuturalis*.

Conclusion: Releases of *S. subsuturalis* against *C. decapetala* should continue, but improved by inundative rather than inoculative releases; every year between September and March (summer); and involve land owners, farmers and nature reserve authorities in release activities.

Molecular evolution and functional significance of *Drosophila* neuropeptide copies

Christian Wegener, Anton Gorbashov

Emmy Noether Neuropeptide group, Animal Physiology, Philipps-University, Marburg, Germany

Arthropod neuropeptides often occur in multiple sequence-related copies within a single prepropeptide. For example: the prepropeptide encoded by the *fmrf* gene contains 24 different FMRFa-like peptides in the cockroach *Periplaneta americana* [1], and 13 FMRFa-like peptides in *Drosophila melanogaster* [2].

A long-standing and unanswered question addresses the functional significance of these multiple sequence-similar copies. We choose a comparative genomic approach to this question and analyzed the amino acid sequence variability of neuropeptides in the 12 *Drosophila* species with fully sequenced genomes. To support the actual expression of predicted neuropeptides, we directly profiled major neuropeptide release sites of four species belonging to the main *Drosophila* subtaxa by MALDI-TOF mass spectrometry. This profiling provides the first biochemical identification of neuropeptides in *D. virilis, D. mojavensis, D. pseudoobscura*, and *D. sechellia*.

Our results show that the peptide hormone complement has been stable throughout the 60 million years of diversification within the genus *Drosophila*. They further suggest that all peptide copies are -to varying degrees- subjected to evolutionary constraints and do not neutrally mutate. Moreover, the degree of peptide sequence conservation correlates well with literature data on the pharmacological efficacy of individual peptide copies.

Taken together, our results suggest that multiple peptide copies are not mutually redundant, but have either specific functions or are important in line with the "more-of-the-same" concept.

Application of classification tree methods to the study of insect population dynamics

Chris J K MacQuarrie, D. Langor, John Spence

[1]University of Alberta, Edmonton, Alberta, Canada, [2]Canadian Forest Service, Northern Forestry Centre, Edmonton, Alberta, Canada

Introduction: One of the primary goals of insect population dynamics is to identify causes of mortality and quantify their relative impact. However, this task can be difficult if there are multiple potential causes for each insect death or specific causes cannot be identified. Often these problems can be resolved by rearing and rigorous experimentation. However, for many species, particularly aliens or invasives, this may be impractical or impossible. I show that via the application of classification trees to insect mortality data it is possible to perform detailed investigations of potential causes of insect mortality in a field setting.

Methods: I sampled larval populations during an outbreak of alien *Profenusa thomsoni* Konow in an urban birch (*Betula* L.) forest in Anchorage, Alaska, USA. The health (alive or dead) of each larvae was recorded as was the size of its host leaf; the amount of defoliation; the number of conspecifics; the crown position the larvae was collected from; and the time of sampling. I then used classification tree analysis to split the data into homogenous groups of live and dead larvae based on the values of the other variables as a way to associate biological processes with mortality. This procedure was repeated for each of *P. thomsoni*'s five larval instars that complete their development in the host leaf.

Results: Larval mortality of *P. thomsoni* was best explained by a combination of competition and resource exhaustion. However, the specific variables selected, and their magnitude differed among instars. Interestingly, the relationship between leaf area and survivorship observed in the classification trees suggested a novel hypothesis to explain overutilization of host leaf resources by leafminer females. These results suggest females may deposit too many offspring in host leaves as a way of minimizing the effect of plant defences. In addition, mortality was also associated with smaller leaves, a pattern than may reflect increased competition for limited resources, but also suggests that smaller-leaved birch varieties may be less susceptible to *P. thomsoni* damage.

Conclusions:. It is difficult to quantify the population dynamics of species like *P. thomsoni* that are not easy to rear or sample. Classification trees can be used to identify biologically important variables for poorly understood species and as way to generate hypotheses consistent with the data that should be given high priority for future experimentation.

The effect of predator and alternative prey density on cutworm survival, activity, and growth

Steven Frank[1], Paula Shrewsbury[2], Ellery Vodraska[2]

[1]Texas A&M University, College Station, Texas, United States, [2]University of Maryland, College Park, Maryland, United States

Introduction: Conservation biological control seeks to increase predator abundance to impose predation pressure on herbivores and prevent plant damage. However, many conservation biological control practices increase alternative food in addition to predator abundance. Moreover, research has demonstrated that predator activity or presence in a habitat can have negative indirect effects on herbivores by altering their behaviour and feeding efficiency. The objectives of the study were to 1) determine the effect of alternative food density on predation of cutworms by *H. pensylvanicus*; 2) determine the effect of predator density on predation of cutworms; 3) examine daily activity patterns of predators and cutworms; and 4) determine whether cutworm activity and growth is affected by predator density.

Methods: Experiments were conducted in PVC tubes on bluegrass turf maintained as a golf course fairway. Predator and cutworm activity was monitored every two hours on two nights of the experiment. After six days surviving cutworms were counted and weighed.

Results: Increasing alternative prey density reduced predation of cutworms. Predation was greatest at high predator density with no alternative food. However, cutworms were less active as predator density increased. In addition, when predator density was low cutworms were more active and grew faster than when predator density was high.

Conclusion: This research demonstrates that alternative food reduces the impact of predators on pest survival. However, high predator density is still detrimental to pest growth. Thus, indirect effects of predators on pest fitness deserve greater attention in pest management.

Cry2Ab resistance in *Helicoverpa armigera* and factors influencing the evolution of resistance to transgenic cotton in Australia

Rod Mahon, Karen Olsen, Sharon Downes

CSIRO, Canberra ACT, Australia

The transgenic cotton Bollgard II expresses the *Bacillus thuringiensis* toxins Cry1Ac and Cry2Ab. Bt-cotton is effective against many Lepidoptera including *Helicoverpa armigera* and *H. punctigera*. *H. armigera* has been able to evolve resistance to conventional insecticides and therefore threatens the long-term usefulness of Bt-cotton wherever this species is found. We have examined the frequency of alleles that confer resistance to Bt toxins in Australian populations of *H. armigera*. While Cry1Ac resistance has not been found, Cry2Ab resistance alleles occur at a frequency of 0.003. Resistance is the result of mutation(s) at a single autosomal locus and is recessive and is not cross-resistant to Cry1Ac. This is fortunate, as Bollgard II is grown extensively in Australia (>80% of all cotton). If both toxins are expressed at optimal levels, this variety should remain efficacious against Cry2Ab-resistant insects. However there is evidence that the titre of toxins vary throughout the growing season providing opportunities that favour rare homozygous Cry2Ab resistant insects. Nevertheless, we have no evidence that the frequency of resistance is increasing. We examined the hypothesis that Cry2Ab resistant insects suffer fitness costs that counters positive selection. We compared Cry2Ab resistant to near-isogenic susceptible insects under a variety of conditions. No fitness costs were found. Our present understanding of Cry2Ab resistance in *H. armigera* suggests that, because resistance is recessive, an increase in frequency of the resistance allele will be slow, but such an increase is inevitable.

Resource flow and digestion in the imported fire ant

Bradleigh Vinson, Asha Rao, Freder Medina, Karen Snowden

Texas A&M University, College Station, United States

Workers gather resources from the environment as well as cycle resources within the colony. But where these resources go depends on the type of resource (protein, lipid or carbohydrate), the nature of the resource (solid or liquid), and the source of the resource (directly from the environment or processed by worker or processed by larvae). For example, workers collect a variety of resources with the carbohydrates primarily going to and needed by workers. On the other hand, when they collect lipids or proteins, the liquids are fed mainly to the queens, alates and larvae. Particulates in the above resources are separated from liquids by workers and fed to larvae along with any collected solid resources. The larva processes these resources, but there are bacteria associated with the larvae that also appear to play an important role in processing these resources. In the larvae, some of these resources are extra–orally digested, others are regurgitated and yet others are passed as meconium prior to pupation. Some of these reprocessed resources are then redistributed to the colony. Here, we examined these various routes of resource flow and the manipulation involved along with the role of bacteria in fire ant resource utilization.

Termites as ecosystem engineers: increasing ecohydrological function and soil health in the savanna grazing lands of tropical northern Australia.

Tracy Dawes-Gromadzki, Adam Liedloff, Austin Brandis

CSIRO, NT, Australia

Healthy soils underpin healthy landscapes, through their effective capture, retention and recycling of water and nutrients. Declining soil health has become a critical issue within the Great Barrier Reef Lagoon catchments along north-east Queensland that primarily support cattle grazing. Symptoms include increased soil compaction, reduced water infiltration and increased sediment, nutrient and water run-off. Improving soil hydrological function is critical to reducing such effects. Termites are key drivers of this process through the creation and maintenance of macropores, which facilitate the capture and infiltration of rainfall. However, the activity and diversity of termites and other soil macroinvertebrates varies greatly across these landscapes in association with patchiness in perennial vegetation. Cattle grazing can also have marked effects on vegetation patch structure and dynamics and consequently on the structure of soil macroinvertebrate assemblages. Understanding these functional relationships and the consequences for soil health is critical to sustainable pasture and livestock production and the quality of water in run-off entering the Great Barrier Reef Lagoon. We are investigating the functional role of invertebrates in soil eco-hydrological processes and how this varies with vegetation patchiness and grazing management near Charters Towers, north Queensland. The results are also being used to feed into the Savanna.au computer simulation model to predict how changes in soil health affect soil water infiltration and runoff. We present an overview of results that suggest heavy grazing intensity leads to a decline in soil health through a reduction in macroinvertebrate activity, macropore density and the ability of these landscapes to capture rainfall.

Integration of neuropeptidergic signaling and stress behaviors via the AMP-activated kinase in *Drosophila*

Erik Johnson[1], Colin Bretz[1], Lindsay Williamson[1], Nevzat Kazgan[2], Jay Brenman[2]

[1]Wake Forest University, Winston-Salem NC, United States, [2]University of North Carolina, Chapel Hill, NC, United States

Introduction: Stress, defined as a challenge to homeostasis, can culminate in stereotypical behavioural and physiological changes. These alterations to behavioural and physiological programs are coordinated by a variety of neuropeptide and hormone transmitters. However, the mechanisms underlying stress perception and subsequent hormonal release are unclear. We have investigated the actions of the AMP-activated kinase (AMPK) in *Drosophila*, in pursuit of a better understanding of these mechanisms. AMPK signalling is thought to serve as an intracellular sensor of energetic status as it is activated by AMP and is allosterically inhibited by ATP.

Methods: The functional AMPK is a heterotrimer consisting of a catalytic alpha and regulatory beta and gamma subunits. By virtue of this assembly, we have generated specific mutations in the alpha subunit and displays dominant negative activity. We have employed the yeast binary system to manipulate AMPK signalling in a variety of different cellular and peripheral cellular populations.

Results: Ubiquitous expression of this dominant negative construct causes a dramatic hypersensitivity to starvation stress, as evaluated by lifespan. Furthermore, starvation conditions which generate hyperactivity in normal flies, leads to enhanced hyperactivity in this altered genetic background. However, expression of the dominant negative in neuroendocrine cells that express the Adipokinetic Hormone (AKH) leads to increased longevity and a reduction of starvation-induced hyperactivity, which is a similar phenotype as those reported for AKH cell ablation.

Conclusions: AMPK function is dependent upon cellular context and regulates starvation-induced behavioural and physiological changes. AMPK not only serves a role as an energy sensor, but also as a crucial link between stress hormone signalling and alterations in cellular and organismal physiologies under stress.

Community responses to multiple global change drivers

Jason Tylianakis

University of Canterbury, Christchurch, New Zealand

Introduction: All organisms are embedded in complex networks of feeding interactions with other species (food webs), and the structure of these networks may be critically linked to their stability and function. Empirical food webs necessarily require the pooling of interactions sampled over a given period and/or region, and thus provide a static representation of a dynamic community. The effects of global changes on this structure, and the extent to which pooled networks represent the structure of networks at smaller spatiotemporal scales are unclear.

Methods: Communities of cavity-nesting bees, wasps and their parasitoids were sampled over 17 months in 48 sites of five land use types in coastal Ecuador. Frequencies of parasitoid-host interactions were used to construct quantitative food webs, which were compared across habitats.

Results: Habitat modification significantly altered the structure of food webs, with webs in modified habitats having a more uneven structure. Modified webs also had reduced interaction turnover, and a greater proportion of potential interactions were actually realised.

Conclusions: Global change may have significant effects on food web structure and spatiotemporal variability in this structure. Such complex effects of individual global change drivers on network structure and interaction turnover become compounded when multiple interacting drivers operate simultaneously.

Cladistic analysis of assassin bugs (Heteroptera: Reduviidae): Morphological and molecular data

Christiane Weirauch, James Munro

Department of Entomology, University of California, Riverside, California, United States

Introduction: With more than 6600 species worldwide Reduviidae or assassin bugs are the second largest and one of the most diverse groups of True Bugs. Assassin bugs show remarkable morphological and biological diversity and an exceptional range of adaptations to prey capture. Despite these features, systematic studies on Reduviidae have been neglected over the past decades. Apart from the need for descriptive and revisionary work, the higher-level classification of Reduviidae is in poor condition. This is reflected in the fact that, depending on author, 21 to 32 subfamily-level names are recognized. Several subfamily-level taxa are poorly defined and their relationships are obscure.

Methods: A cladistic analysis of higher-level taxa of Reduviidae based on 162 morphological characters and 75 ingroup and outgroup species is presented. We are currently testing this hypothesis with a matching molecular data set for ~ 90 ingroup taxa, comprising 18 subfamilies and 28 tribes. The dataset comprises ~3000 base pairs of ribosomal mitochondrial and nuclear gene regions that are aligned using secondary structure models. The data are analyzed using parsimony, maximum likelihood and Bayesian methods.

Results;. The morphology-based hypothesis on higher-level groups of Reduviidae shows – to name only a few groups – the Phymatine Complex to be basal within Reduviidae, Triatominae as monophyletic and closely related to part of the Reduviinae and to Stenopodainae, Harpactorinae as monophyletic, and Reduviinae as polyphyletic. The analysis of molecular data corroborates most of these results, including a closer relationship of blood-feeding Triatominae with Stenopodainae and part of the Reduviinae.

Entomopathogenic fungi vs semiochemicals: Mutualistic affair against pests

Nguya Maniania[1], Felix Nchu[1], Susan Dimbi[2], Sunday Ekesi[1]

[1]International Centre of Insect Physiology and Ecology (icipe), Nairobi, Kenya, [2]Crop Protection Division, Tobacco Research Board, Harare, Zimbabwe

Introduction: Inundative and augmentative are the main methods employed for introduction of entomopathogenic fungi (EPF) into the ecosystem. However, a new strategy is currently being considered, whereby insect pathogens are disseminated (autodissemination) among target pest populations by using devices that attract insect pests into a focus of the pathogen. Contamination devices (Cd) have been developed for the introduction of EPF against a number of insects and the strategy relies largely on insect's semiochemicals.

Materials and Methods: Different Cds were tested for suppression of tsetse, fruit flies and ticks in the field. Cd was mounted on tsetse trap and flies that are attracted are forced to go through the Cd where they are contaminated with conidia before they exit. In the case of fruit flies, the Cd was baited with protein bait. In the case of ticks, an attraction-aggregation-attachment-pheromone trap was developed to infect tick attracted to the trap with different fungal formulations.

Results: Conidia applied in Cds significantly reduced tsetse and fruit fly populations in the field. A high level of mycosis was observed among tsetse and fruit fly samples brought to the laboratory. A reduction of ticks was also observed with the different fungal formulations tested. However, emulsifiable formulation was the best.

Conclusions: Semiochemicals and EPF have a mutual relationship that will go a long way. The availability of pheromones and other lures for the most important pests makes autodissemination technique an alternative that is less costly and effective than conventional method of application and deserves further studies.

The pest status of diamondback moth (Lepidoptera: Plutellidae) in South Africa: the role of parasitoids in suppressing the pest populations

Robert S. Nofemela, Morake S. Mosiane, Rami Kfir

ARC - Plant Protection Research Institute, Private Bag X134,, Pretoria 0001, South Africa

Introduction: Diamondback moth, *Plutella xylostella* (Lepidoptera: Plutellidae), is major pest of *Brassica* crops in South Africa. Investigations were carried out on the role of parasitoids in suppressing the pest populations.

Methods: Cabbage, *Brassica oleracea* var. *capitata* L. (Brassicaceae), seedlings were transplanted three consecutive times every year for five years (2003-2007) in a field in the North West Province of South Africa. At weekly intervals, 30 plants selected randomly were inspected and the numbers of *P. xylostella* larvae, pupae and parasitoid cocoons found in each plant were recorded. Three sex pheromone traps, placed around each field, were also monitored every week for the flight activity of male moths.

Results: Trap catches corresponded with infestations on the crop. Infestations were low during late spring to autumn (November - May) often fluctuating between zero and two larvae per plant. The only period that infestations were high was during late winter and spring (August - October). A negative correlation between infestations and parasitism levels was observed. Parasitism of *P. xylostella* larvae was high reaching 100% on several occasions during November – May each year, but lower (<50%) in winter and early spring. Eight indigenous parasitic Hymenoptera were reared from *P. xylostella* larvae, of which *Cotesia plutellae* (Braconidae) and *Oomyzus sokolowskii* (Eulophidae) were the most abundant.

Conclusion: Parasitoids suppressed *P. xylostella* populations during November – May, and in general the pest populations declined during the study period. However, additional control measures may be required during June – October to supplement low parasitism levels.

Bee perception of warmth as a floral reward

Adrian Dyer[1], Heather Whitney[2], Sarah Arnold[3], Beverley Glover[2], Lars Chittka[3]

[1]Monash University, Clayton, Vic., Australia, [2]University of Cambridge, Cambridge, United Kingdom, [3]Queen Mary University of London, London, United Kingdom

Introduction: Insects preferentially visit warmer flowers. Bumblebees (*Bombus terrestris*) do this even in the context of all flowers presenting equivalent nutritional rewards, potentially providing an evolutionary advantage for plants that present warmer flowers. Understanding why bees exhibit this behaviour requires separating factors including perceived flower warmth and sucrose concentration.

Methods: Exp 1: Bee visits to model flowers were tested in lab conditions considering temperature as a cue to make decisions to collect sucrose (20°C flowers) or avoid quinine (28°C flowers). Exp 2: Bee visits to feeders that varied in temperature (20°C or 28°C) or sucrose concentration (21.5%, 23%, 25% or 30%) were evaluated using a three way ANOVA.

Results: Exp 1: Bees had to land on flowers to perceive a temperature differences in stimuli. Once landed, bees rapidly learnt to use temperature as a cue to make correct decisions using either their antennae or tarsal receptors. Exp 2: With increasing sucrose concentration (at identical temperature) bees preferentially visit a sweeter feeder ($p=0.002$); and if a less sweet feeder is at a higher temperature this does not affect bee preferences for visiting a sweeter feeder ($p=0.672$).

Conclusions: Bees process the parameters of temperature and sucrose concentration separately. These cues are processed hierarchically by bees with sucrose concentration being the more important factor influencing choices. However, at an equal sucrose concentration bee preference for warmer flowers provides an effective way for plants, which can effectively modulate flower temperature, to maintain pollinators.

Evolution of odour coding in moths

Sonja Bisch-Knaden, Marco Schubert, Celine Heinl, Silke Sachse, Bill S. Hansson

Max-Planck Institute for Chemical Ecology, Department of Evolutionary Neuroethology, Jena, Germany

Introduction: Odour information is coded as an olfactory map in the antennal lobe glomeruli. Among different moth species there are similar numbers of glomeruli and thus probably similar numbers of receptor types. This concordance might have created also similar coding patterns in the antennal lobe.

Methods: By using calcium imaging to measure the representation of a diagnostic set of odours (aromatics, terpenes, alcohols, aldehydes, ketones) in different moth species we tested this hypothesis. We used low odour concentrations (0.5 µg to 5 µg) to determine the position of the most sensitive glomerulus for each odour. To compare the localization of this glomerulus within and between species, the size and orientation of the antennal lobes were normalized.

Results: We measured odour-evoked calcium responses in the antennal lobes of *Manduca sexta* (n=13, Sphingidae) and *Spodoptera littoralis* (n=9, Noctuidae) and found several similarities: e.g. within each species the response sites for the terpenes geraniol and linalool were indistinguishable ($p>0.9$) but both odours activated glomeruli at a different location than the aromatic phenyl acetaldehyde ($p<0.01$, repeated measures ANOVA plus Tukey-Kramer test). Furthermore, the between species comparison showed that these odours activated corresponding sites in the antennal lobe ($p>0.8$), as did the other seven odorants tested with the exception of octanol ($p<0.05$) and octanal ($p<0.001$). We are in the process of analyzing two more sphingid and noctuid moths respectively.

Conclusions: The spatial pattern of olfactory coding seems to be widely conserved between the two moth species investigated of the families Sphingidae and Noctuidae, separated by approximately 60 million years in evolutionary time.

The prohormone convertase AMONTILLADO represents a key enzyme in the production of bioactive peptide hormones

Christian Wegener[1], Cordelia Imig[1], Matthias Vömel[1], Jörg Kahnt[2], Jeanne Rhea[3], Michael Bender[3], R. Elwyn Isaac[4]

[1]Emmy Noether Neuropeptide group, Animal Physiology, Philipps-University, Marburg, Germany, [2]Max-Planck Institute of Terrestrial Microbiology, Marburg, Germany, [3]Department of Genetics, University of Georgia, Athens/Georgia, United States, [4]Institute of Integrative and Comparative Biology, University of Leeds, Leeds, United Kingdom

Subtilisin-like prohormone convertases (PCs) are major enzymes involved in the processing of bioactive peptides from larger precursor molecules. *amontillado* (*amon*) codes for *Drosophila* PC2 and is expressed in endocrine and nervous tissue. Flies deficient in *amon* show defects in growth, carbohydrate metabolism and ecdysis. This suggests that a deficiency in *amon* disrupts peptidergic endocrine pathways. It is, however, unknown if and which peptide hormones are affected.

We used direct MALDI-TOF mass spectrometric (MS) profiling. This technique allows to detect the whole peptide hormone complement up to 2.5 kDa in individual neurohemal organs of *Drosophila*. MS profiles of the ring gland from wildtype and heat-shock rescued *amon*-deficient larvae did not show significant differences. In *amon*-deficient larvae, peptide hormones were mostly undetectable. A deficiency in *amon* thus seems to impair the production of all peptide hormones in the detected mass range. In the adult brain, neuropeptides where also detectable in *amon*-deficient flies, but apparently at lower concentrations. We are currently conducting a more detailed analysis by quantifying peptide concentrations.

Our results so far suggest that *amon* is a key enzyme in the production of *Drosophila* neuropeptides. The general importance of this peptidase for peptide processing is being investigated by ectopic expression of neuropeptides using specific and pan-neuronal GAL4-drivers, and then by characterising their cellular distribution. The observed distribution is then correlated with that of *amon* and peptidergic neurons. In combination with MS, this will allow an assessment of whether *amon* is the only PC involved in neuropeptide processing, or whether other neuronal PCs may also have a role.

Female Sex Pheromone of Simao Pine Caterpillar Moth, *Dendrolimus kikuchii*: SPME Collection, Electrophysiological Analysis, and Field Evaluation

Xiang bo kong[1], Xiao ling Sun[2], Zhen Zhang[1], Hong bin Wang[1], Cheng hua Zhao[3]

[1]Research Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry; The Key Laboratory of Forest Ecology and Environment, State Forestry Administration, Beijing, China, [2]Tea research institute, Chinese Academy of Agricultural Sciences, Hangzhou,Zhejiang Province, China, [3]Institute of Zoology, Chinese Academy of Sciences, Beijing, China

Abstract - Sex pheromone components of *Dendrolimus kikuchii* Matsumura (Lepidoptera: Lasiocampidae) were demonstrated as (*Z,E*)-5,7-dodecadien-1-yl acetate (*Z*5,*E*7-12:OAc) and (*Z,E*)-5,7-dodecadien-1-ol (*Z*5,*E*7-12:OH) by means of solid phase microextraction (SPME) collection, electrophysiological tests, Coupled gas chromatography (GC)-mass spectrometry (MS) analyses, microchemical analyses, and field evaluations. GC and GC-MS analyses of solvent extracts determined that the average amount of *Z*5,*E*7-12:OAc and its corresponding alcohol per calling female gland extract was 1.2 ± 0.9 ng (± SD) and 0.2 ± 0.1 ng (± SD) (*N* = 30). In contrast, in solid phase microextraction (SPME) collection from calling females, *Z*5,*E*7-12:OAc (KIs: DB-WAX, 2,051; DB-5, 1,636) appeared as the single dominant peak, comprising13.5-33.4% (*N* = 3) of the sampled volatile. Whereas, *Z*5,*E*7-12:OH (KIs: DB-WAX, 2,147; DB-5, 1,511) comprises only1.3-2.3% of that (*N* = 3). Biological activities of pheromone candidates were assessed in GC-EAG and field bioassays. Males antennae were responsive strongly to *Z*5,*E*7-12:OAc, and weakly to *Z*5,*E*7-12:OH with synthetic compounds, and the same phenomena were observed from the solvent extracts of the pheromone glands. Further field trials determined that the complete fight behaviours were elicited by *Z*5,*E*7-12:OAc and *Z*5,*E*7-12:OH in a 5:1 ratio, and (*Z,E*)-5,7-Dodecadien-1-yl propionate and/or (*Z*)-5-dodecenyl acetate had a synergistic effect on male attraction to the acetate/alcohol pheromone blend.

Spatial distribution and movement of lesser grain borer, *Rhyzopertha dominica* F.

Godfrey Ching'oma, James Campbell, Sonny Ramaswamy

Kansas State University, Manhattan, United States Minor Outlying Islands

Information on spatial and temporal dynamics of the lesser grain borer, *Rhyzopertha dominica* (F.), in agricultural landscapes is not adequate. This research was undertaken with the objective of determining the flight capacity, seasonal patterns and spatial distribution. A mark-release-recapture study was undertaken on the Konza Prairie Biological Research Station, Kansas State University, Manhattan, Kansas during 2003 and 2004 to assess potential dispersal capacity of this species. The beetles were reared in the laboratory and one- to two-week-old unsexed beetles were released in the center of a grid of 46 Lindgren funnel traps placed in concentric circles at 50, 100, 200, 400, 600, 800, and 1,000 m from the center towards north, north-east, east, south-east, south, south-west, west, and northwest directions away from the release point. Of a total of 62,400 beetles released over multiple dates, 872 (1.4%) were recaptured. Beetles dispersed a mean (±SEM) distance of 380.4 ±10.5 m, with a range of 50 and 1,000 m (maximum distance in grid). However, Delta sticky traps placed as far away as 3.6 km from the release center recaptured a few (n=3) marked beetles suggesting that *R. dominica* is capable to fly significantly longer distances than our recapture grid. Beetles were also trapped at two- to three-week-intervals in an agricultural landscape in Dickinson Co., Kansas, using a grid of 203 aggregation pheromone baited sticky traps from May to November 2003 and April to November 2004, to assess the spatial-temporal distribution of beetles in relation to farm bins and other geographic features. During spring of both years, beetles were captured near wooded areas, whereas during summer beetles were trapped in both wooded areas and near farm grain storage locations and during fall were trapped predominantly in wooded areas.

Wasp-bracovirus associations: the grail quest for the ancestor virus

Annie Bézier[1], Marc Annaheim[2], Juline Herbinière[1], Christoph Wetterwald[3], Gabor Gyapay[4], Sylvie Bernard-Samain[4], Patrick Wincker[4], Isabel Roditi[2], Manfred Heller[2], Maya Belghazi[5], Jérôme Lesobre[1], Rita Pfister-Wilhem[2], Georges Periquet[1], Catherine Dupuy[1], Elisabeth Huguet[1], Nathalie Volkoff[6], Beatrice Lanzrein[2], Jean-Michel Drezen[1]

[1]IRBI CNRS, University of Tours, Tours, France, [2]Institute of Cell Biology, University of Bern, Bern, Switzerland, [3]Department of Clinical Research, University of Bern, Bern, Switzerland, [4]CEA/Genoscope, Evry, France, [5]Proteomic analysis center, Marseille, France, [6]BIVI INRA, University of Montpellier, Montpellier, France

Introduction: Comparative genomic studies have highlighted the role of symbiotic associations in biological evolution. However very few of these relationships involve viruses, except the remarkable associations of polydnaviruses (PDVs) with tens of thousand species of parasitic wasps that develop within the body of lepidopteran larvae. PDV particles, injected along with parasite eggs into the host body, act by manipulating host immune defences, development and physiology thereby enabling wasp larvae to survive in a potentially harmful environment. The virus is completely dependent on the wasp for particles production that occurs exclusively in specialized cells of the ovaries. Surprisingly, the genome enclosed in the particles encodes almost no viral structural protein but mostly factors used to manipulate the parasitized host. It was thus questioned whether PDVs were true viruses or a genetic secretion somehow created by the wasp.

Methods: Combined genomic and proteomic analyses were used to identify viral components of polydnaviruses in the braconid species *Chelonus inanitus* and *Cotesia congregata* which belong to the most distantly related subfamilies of bracovirus-associated wasps.

Results: We characterized a large set of virus genes encoding structural components of PDV particles in both species.

Conclusions: We demonstrated the viral nature of PDVs associated with braconid wasps

Deadly dosages: Tree killing as a life history in insect-fungal symbioses

Paal Krokene

Norwegian Forest and Landscape Institute, Ås, Norway

Combined bark beetle-fungus attacks are a key factor in conifer ecosystems in the Northern Hemisphere, where they regularly cause massive tree mortality. Central to the success of the bark beetle-fungus complex is the fact that bark beetles are among the few insects that are capable of breaching the potent anatomical and chemical defenses of healthy tree stems. These defenses include constitutive or preformed mechanical and chemical defenses, such as mechanically though sclerenchyma cells, cells specialized for synthesis and storage of phenolic compounds, and resin producing structures. Overlaid with these constitutive defenses is a capacity to up-regulate additional, inducible defenses in response to an attack, such as cell wall lignification and formation of traumatic resin ducts and wound periderms. In addition, acquired or systemic resistance, which may be considered a long-term consequence of induced defenses, may prime the tree for dealing more effectively with future attacks. The single most important characteristic of tree killing bark beetles is probably their ability to engage in pheromone-coordinated mass attacks that exhaust host resistance. However, since aggregation pheromones also occur in many bark beetles that do not kill trees pheromones can only be considered as a preadaptation for the evolution of tree killing. Other such necessary but insufficient conditions for tree killing is some degree of tolerance to host defenses, large contiguous forests with low host species diversity, and association with fungi that increase the virulence of each attack and help exhaust tree defenses.

Allatostatin A, a candidate peptide in olfaction driven behavior

Sabine Kreissl, Christine Strasser, Giovanni Galizia

University of Konstanz, Konstanz, Germany

Introduction: The growing number of known endogenous neuropeptides in insects adds to the complement of neuroactive substances contributing to network activities within central nervous systems. To study the role of neuropetides in coding of olfactory stimuli and in olfaction related behavior, we are mapping the peptide complement within the olfactory system of the honeybee *Apis mellifera.* Of several candidate peptides, we have here chosen Allatostatin A as one of the most prominent in olfactory neuropiles of the honeybee.

Methods: Brains were immunostained for Allatostatin A (AST), a family of neuropeptides sharing the c-terminal sequence YXFGLamide. Double labeling of GABA and Allatostatin and simultaneous staining of Allatostatin and antennal sensory neurons provided details on colocalisation and spatial arrangement. The wholemounts were scanned by confocal microscopy.

Results: The antennal lobes housed 20 somata of local AST neurons, all coexpressing GABA. Their neurites invaded the core regions of glomeruli T1-T3, and the entire glomeruli in T4. There was sparse overlap between AST neurites and receptor axons. In the mushroom bodies, which are multimodal second order neuropiles, we found AST stained neurites that likely originate from the A3 cluster of mushroom body extrinsic neurons.

AST was also present in the central body, optic lobes, tritocerebrum and subesophageal ganglion.

Conclusions: In all arthropods studied so far, AST exerted an inhibitory function. The distribution of AST neurites in bees suggests a role in shaping olfactory responses, maybe adding functional diversity to the network of inhibitory neurons within the olfactory system.

Predator trophic composition influences the relationship between predator diversity and herbivore suppression

Deborah Finke[1], Robert Denno[2]

[1]University of Missouri, Columbia, Missouri, United States, [2]University of Maryland, College Park, Maryland, United States

Introduction: Natural pest suppression is a valuable ecosystem service provided by insect natural enemies which may be threatened by declining biodiversity. However, the impact of the loss of predator diversity on pest populations may ultimately depend on the trophic relationships among enemies in the assemblage, specifically the occurrence of intraguild predation. In the absence of intraguild predation, declining predator diversity may, in fact, negatively impact herbivore suppression. However, if intraguild predators are present, predator diversity may relax the impact of predation on herbivores and dampen positive effects of predators on basal resources. Alternatively, habitat complexity, by providing a refuge from intraguild predation, might enhance the collective ability of predators to limit herbivore populations and thus indirectly benefit plant biomass.

Methods: Using a salt-marsh food web, we investigated the interactive effects of predator species richness (1-3 species) and trophic composition (strict predators, intraguild predators, or a mixture of the two) on prey suppression and primary production. We also assessed the effects of habitat vegetational complexity on the occurrence of intraguild predation and the ability of a diverse predator assemblage to control herbivore populations.

Results: We found that the trophic composition of the predator assemblage determined the impact of increasing predator species richness on natural pest suppression. Increasing the diversity of strict predator species additively enhanced herbivore suppression. Whereas, increasing intraguild predator species richness diminished herbivore control. However, complex-structured habitats enhanced prey suppression by the predator assemblage including intraguild predators by providing a refuge for predators.

Conclusions: The trophic composition of a predator assemblage may interact with habitat complexity to determine the impact of altered predator diversity on valuable ecosystem services such as natural pest suppression.

Analysis of the parameters improving oviposition of *Musca domestica* (Diptera: Muscidae) in a pig manure degrading pilot plant

Berta Pastor[1], Ana Isabel Martínez-Sánchez[1], Santos Rojo[1], Peter Takac[2], Milan Kozanek[2]

[1]Instituto Universitario CIBIO. Universidad de Alicante, Alicante, Spain, [2]Institute of Zoology. Slovak Academy of Sciences, Bratislava, Slovakia

Introduction: The intensive model of pig production in most Europe produces a huge volume of manure in very concrete areas, which makes the treatment of this waste very complicated. Inside this context appears ECODIPTERA (LIFE-environment UE project), which will try to prove that using larvae of dipterans to degrade pig manure is a reliable strategy. One of the main aspects of this technology is the volume of eggs required for the process. In order to obtain an optimal biodegradation it is required a continuous egg production, which can decompose big quantities of pig manure.

Methods: Two factors influencing the ovipositional behaviour were studied: a) maturation of adults with different diets (sugar, dried milk and yeast) and b) presentation of ovipositional substrate by the design of appropriate structures. For this purpose, four different treatments were compared: control (1), cross of paper placed on substrate (2), paper cover protecting the substrate (3) and a combination of the last two treatments (4).

Results & Conclusions: The diet that provided the highest volume of eggs was the mixture of sugar, dried milk and yeast one. Egg hatchability varied depending on the diet; after ten days hatchability decreased in sugar diet but was constant in the rest of diets. Substrate presentation affected the volume of eggs collected in each treatment: egg layings were bigger in treatment 4 (cross and cover), followed by treatment 3. The lowest quantities of eggs were recorded in uncovered treatments, 1 and 2.

Routes and modalities of invasion of *Harmonia axyridis*: a microsatellite-based population genetics survey

Eric Lombaert[1], Thibaut Malausa[1], Anne Loiseau[2], Benoit Facon[2], Thomas Guillemaud[2], Arnaud Estoup[2]

[1]INRA, Sophia Antipolis, France, [2]INRA, Montferrier sur Lez, France

Using standard population genetics inferential methods as well as more sophisticated ones (i.e. Approximate Bayesian Computation), we aim to retrace the routes of invasion of the Asian ladybird *H. axyridis* (*H.a*) in North and South America, South Africa and in northern Europe. This work is based on the analysis of the genetic variation of *H.a.* populations measured at microsatellite loci that have been recently optimized in the species. It should, amongst other things, allows understanding if the invasion is due to a single introduction of a particular commercialized strain or natural population of *H.a*., or if it is the consequence of many introductions with potential hybridization/introgression events between genetically differentiated strains/populations. This INRA research program benefits from a large sampling network based on national and international cooperation. We present here some unpublished results on *H.a* genetic variation based on a preliminary dataset including genotypes obtained at eighteen microsatellite markers.

Repellency, toxicity and tunneling activity of *Coptotermes heimi* (Wasmann) (Isoptera: Rhinotermitidae) in response to Biflex, Termidor and Tenekil

Farkhanda Manzoor, Nadeem Sheikh, Syed Nasir

1Department of Zoology, Lahore College for Women University, Lahore, Pakistan. Lahore, Punjab, Pakistan

In laboratory tests, repellency, toxicity and tunneling ability of field collected termite, *Coptotermes heimi* (Wasmann) was evaluated against three insecticides biflex (Bifenthrin), termidor (Fipronil) (Pyrazole) and tenekil (Polychlorinated petroleum hydrocarbon). For toxicity, different concentrations 0.78125, 1.5625, 3.125, 6.25, 12.5, 25, 50 ppm of biflex, termidor and tenekil were used to observe F-1 (0.97) mortality of termites. Biflex and termidor proved to be more toxic at 50 ppm in comparison with tenekil (after 8h exposure). LC_{50} values of biflex, termidor and tenekil against *Coptotermes heimi* were 1.78, 2.00 and 9.99 ppm respectively for 8h treatment. Similarly, LC_{50} values of biflex, termidor and tenekil against *Coptotermes heimi* were 14.6, 14.6 and 37.5ppm respectively for one month old treated soil. For repellency test, only biflex was repellent at 50 ppm in freshly treated and one month old treated soil. Termidor and tenekil did not prove its repellency at any concentration. These insecticides also affected survival and reduced the tunneling ability of termite workers in the treated soil. Results of the tunneling assay revealed that all termiticides (at every concentration) were able to stop termite penetration to the treated soil, either by killing or repelling them. Termite workers tunneled deeply in the lower concentrations (0.78125ppm) of these insecticides in comparison to the strong doses (50ppm). This study provided us some valuable information regarding their efficacy in the lab which could provide useful information for its field applications.

The *Tribolium* genome project: annotation and functional analysis of the first beetle genome

Marcé Lorenzen[1], Susan Brown[2], Yoonseong Park[3], Stephen Richards[4], Richard Beeman[1]

[1]USDA-ARS-GMPRC, Manhattan, KS, United States, [2]Division of Biology, Kansas State University, Manhattan, KS, United States, [3]Dept of Entomology, Kansas State University, Manhattan, KS, United States, [4]Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, United States

The genome of the red flour beetle, *Tribolium castaneum*, has been sequenced, and a working assembly (Tcas_3.0) will soon be released (www.hgsc.bcm.tmc.edu/projects/tribolium) and is being updated at NCBI. The addition of this insect to the genome club is of particular interest because *Tribolium* is both the first coleopteran and first pest insect to have its genome sequenced. The coverage is estimated to be ~96% of euchromatin, and 92% of the assembled genome (140/152 Mb) has been anchored to linkage groups via high-resolution recombinational mapping. GLEAN and NCBI RefSeq sets serve as the official gene predictions. The genome sequence and associated annotation tracks can be viewed in the Genboree genome browser (www.genboree.org); at NCBI; and in GBrowse at BeetleBase (www.bioinformatics.ksu.edu/BeetleBase), which will be the permanent curation/viewing site. Since *Tribolium* is an agricultural pest, we and our collaborators are interested in the identification of potential biopesticide targets. Specifically, we are employing transposon-based mutagenesis, RNA interference (RNAi) and microarray analysis to evaluate genes involved in chitin/cuticle metabolism, osmoregulation, neurotransmission, immunity, digestion and hybrid incompatibility. The status of the *Tribolium* genome project will be discussed and an overview of the available information, tools and resources will be presented.

Insect resistance management strategy for PTM-resistant 'Spunta' potatoes.

Walter Pett[1], David Douches[1], Diedrich Visser[2], Hector Quemada[1], Johan Brink[1], Kelly Zarka[1], Karim Maridia[1], Francisco Santos[1], Kobie de Ronde[2]

[1]Michigan State University, East Lansing, Michigan, United States, [2]ARC-Vegetable and Ornamental Plant Institute, Pretoria, South Africa

Introduction: We have developed a genetically modified 'Spunta' potato (Spunta G2) containing the *Bacillus thuringiensis* (Cry1Ia1) gene for the control of the potato tuber moth, *Phthorimaea operculella*, (PTM) in South Africa. To comply with South Africa's Genetically Modified Organisms (GMO) Act, 1997 (Act no. 15 of 1997) one of the components of a regulatory dossier should address insect resistance management.

Methods: Laboratory leaf bioassays studies evaluating PTM development and survival were conducted using solanaceous plants found in South Africa. The plants tested included; S*olanum melongena L.*, *Solanum elaeagnifolium Cav., Solanum incanum L., Solanum mauritianum Scop., Solanum. nigrum L.*, *Solanum sp., Datura ferox L., Physalis peruviana* L.*, Lycopersicum esculentum* Mill. PTM-resistant 'Spunta', non-transformed 'Spunta', and 'BP1' were also tested. Field trials were conducted to record the number of PTM damaged plants, mines, and larvae per plant on PTM-resistant 'Spunta', non-transformed 'Spunta', 'BP1', eggplant, and tomato.

Results: Greater than 60% PTM survival was observed on eight of the solanaceous plants tested in our laboratory feeding studies. PTM damage, mines, and larvae were detected on non-transformed 'Spunta', 'BP1', eggplant, and tomato in our field trial. No damage was detected on the PTM-resistant 'Spunta" plants.

Conclusions: Our results indicate that there are numerous solanaceous plant species that will serve as alternate hosts for PTM. Therefore, we propose a non-structured refuge as a strategy for managing the evolution of resistance in Spunta G2, relying on alternate hosts as well as non-transformed potatoes.

Insect resistance management strategy for PTM-resistant 'Spunta' potatoes.

Introduction: We have developed a genetically modified 'Spunta' potato (Spunta G2) containing the *Bacillus thuringiensis* (Cry1Ia1) gene for the control of the potato tuber moth, *Phthorimaea operculella*, (PTM) in South Africa. To comply with South Africa's Genetically Modified Organisms (GMO) Act, 1997 (Act no. 15 of 1997) one of the components of a regulatory dossier should address insect resistance management.

Methods: Laboratory leaf bioassays studies evaluating PTM development and survival were conducted using solanaceous plants found in South Africa. The plants tested included; S*olanum melongena L.*, *Solanum elaeagnifolium Cav., Solanum incanum L., Solanum mauritianum Scop., Solanum. nigrum L.*, *Solanum sp., Datura ferox L., Physalis peruviana* L.*, Lycopersicum esculentum* Mill. PTM-resistant 'Spunta', non-transformed 'Spunta', and 'BP1' were also tested. Field trials were conducted to record the number of PTM damaged plants, mines, and larvae per plant on PTM-resistant 'Spunta', non-transformed 'Spunta', 'BP1', eggplant, and tomato.

Results: Greater than 60% PTM survival was observed on eight of the solanaceous plants tested in our laboratory feeding studies. PTM damage, mines, and larvae were detected on non-transformed 'Spunta', 'BP1', eggplant, and tomato in our field trial. No damage was detected on the PTM-resistant 'Spunta" plants.

Conclusions: Our results indicate that there are numerous solanaceous plant species that will serve as alternate hosts for PTM. Therefore, we propose a non-structured refuge as a strategy for managing the evolution of resistance in Spunta G2, relying on alternate hosts as well as non-transformed potatoes.

G protein-coupled receptors from tick (*Rhipicephalus microplus*) and mosquito (*Aedes aegypti*): biological significance and peptidomimetic design for target validation

Patricia Pietrantonio[1], Ronald Nachman[2], Suparna Taneja-Bageshwar[1], Christopher Jagge[1]

[1]*Department of Entomology, Texas A&M University, College Station, TX, United States,* [2]*Southern Plains Agricultural Research Center, USDA, College Station, TX, United States*

Introduction: The female of the mosquito *Aedes aegypti* (Diptera: Culicidae) is a vector of arboviruses causing yellow fever and dengue fever. The tick *Rhipicephalus* (*Boophilus*) *microplus* (Acari: Ixodidae) is the principal tick vector in cattle worldwide. In both, transmission of disease agents is directly linked to the female's obligatory haematophagia for reproductive success. There is no vaccine for dengue, nor a recombinant vaccine against the *Babesia sp.* pathogen causative of bovine babesiosis. The G protein-coupled receptors putatively involved in water balance in these two arthropods are being characterized as potential targets for novel pesticide development.

Methods: Functional studies *in vitro* and *in vivo* are designed to elucidate receptor function and biological significance. RNAi of these receptors was attempted with variable results. The rational design of peptidomimetics based on the insect kinin analog FFSWGa is conducted for receptor target validation. Peptidomimetic design is improved through iterative calcium bioluminescence assays using tick and mosquito kinin receptors expressed in mammalian cells.

Results: We cloned the dih1 (DH_{44}) receptor (GPRdih1) from mosquito renal tubules and report evidence of temporal variation of the GPRdih1 transcript, suggesting that receptor biology (transcriptional expression) in the Malpighian tubule may be linked to hormone release during peaks of diuresis. Six insect kinin analogs were synthesized in which Ser, the primary peptidase hydrolysis site, was replaced with the bulky alpha-amino isobutyric acid (Aib) molecule, and in which the secondary peptidase hydrolysis site was also blocked for biostability. These mimetics were active on tick and mosquito kinin receptors.

Strategies for Insect Resistance Management (IRM) for Bt crops in Brazil and Argentina

Samuel Martinelli[1], Fabiano Ferreira[1], Odnei Fernandes[1], Graham Head[2], Gillermo Videla[3]

[1]Monsanto do Brasil Ltda., São Paulo, São Paulo, Brazil, [2]Monsanto Co., Saint Louis, Missouri, United States, [3]Monsanto LAS, Buenos Aires, Argentina

Genetically modified crops expressing *Bacillus thuringiensis* proteins (Bt crops) have been used for controlling certain lepidopteran and coleopteran pests in various countries. Bt crops provide benefits to farmers and the environment by reducing dependency on conventional chemical pesticides. Nevertheless, due to the continuous expression of these proteins, the evolution of resistance might occur and put at risk the use of this technology. Therefore, to prevent or delay the emergence of insect resistance to Bt crops, the biotechnology industry and farmers have been working together to develop insect resistance management (IRM) programs. Brazil and Argentina have been cropping Bt cotton, and Argentina also has a history of cultivating Bt maize. The plans currently in place in Brazil and Argentina are scientifically rigorous yet practical attempts to significantly delay the evolution of Bt resistance. The details of implementation, and resistance and compliance monitoring, will be covered in this presentation.

Training for biocontrol and sterile insect technique under the same roof: benefits of maintaining the two activities within the same industrial entity

Shimon Steinberg

Bio-Bee Sde Eliyahu Ltd., Bet Shean Valley, Israel

Bio-Bee has been mass producing and releasing natural enemies for biological control of pests since 1983. In 2004, Bio-Bee established a daughter company, Bio-Fly, to rear the Mediterranean fruit fly and supply sterile males for its control through Sterile Insect Technique (SIT). Examples are presented that demonstrate the added value of training for both biocontrol and SIT within the same industrial entity: (i) Pupal products are available for both biological control agents and the medfly. Therefore, quality assessment parameters, such as percent emergence and flight ability, can be determined for the aphid parasitoid, *Aphidius colemani*, and the medfly by using similar methods. These determinations enable adjustments to be made from the number of pupae produced to the number of functional adults released in the field, (ii) For pirate bugs and predatory mites, as well as the medfly, rates of emergence and mortality do not always correlate with adult fitness. This may be due to the same causes both in biocontrol and SIT, (iii) Possibly, the relationship between product control parameters and field performance of the end product can be predicted in both biocontrol and SIT, and (iv) The novel application of SIT to control leafminer flies, *Liriomyza* spp., synergizes with biocontrol of the pest. Bio-Fly produces and sterilizes males and females of the leafminer, *L. bryoniae*, and mass produces its parasitoid, *Diglyphus isaea*. Bio-Bee is a pioneering effort in mutual "fertilization" in education and training for biocontrol and SIT, emphasizing methods for mass production and quality assurance.

Critical oxygen responses in *Drosophila melanogaster* reared in hypoxia or hyperoxia

C Jaco Klok, Jon F Harrison

Arizona State University, Tempe, AZ, United States

Introduction: Atmospheric oxygen availability has long been hypothesized as having important historical effects on insect body size. In *Drosophila melanogaster* adult body size relates positively with rearing oxygen over multiple generations. By contrast leg tracheal dimensions relate, independent of size, negatively with oxygen. How do size and tracheal changes affect the matching of oxygen delivery capacity to oxygen needs? One prediction is that hypoxia reared flies would have lower critical PO_2 values ($CritPO_2$), due to reduced sizes and larger tracheal diameters.

Methods: Metabolic rates (MR) were recorded from adults and larvae reared for 9-11 generations in 10, 21 and 40% O_2. During respirometry % O_2 was steadily decreased, inducing activity (agitation) and an eventual drop in MR. We evaluated MR-$CritPO_2$ as % O_2 where MR drops, and activity-$CritPO_2$ as % O_2 inducing a sharp activity increase.

Results: All adults maintained steady MRs down to ≈2% O_2, before MRs dropped precipitously, independent of rearing O_2. The 40% O_2 reared adults' activity-$CritPO_2$ was 8% O_2 vs 6 to 5% for 21 and 10% O_2 reared adults. MR-$CritPO_2$ for 40% O_2 reared larvae was 8% and 4% for 21 and 10% O_2 reared larvae. Activity-$CritPO_2$ was ≈8% in 40% O_2 reared larvae while 10 and 21% reared larvae had no discernable activity increase. Amazingly, all larvae were able to continue activity even in 20 minutes of anoxia.

Conclusions: The adults' lower MR-$CritPO_2$'s and lack of rearing O_2 effects are consistent with adults having more extensive oxygen delivery capacities for flight. By contrast, the higher larval MR-$CritPO_2$'s and rearing O_2 effects are consistent with the oxygen induced diameter changes of their major longitudinal tracheae. Similarly, rearing oxygen had a narrow effect on adult activity-$CritPO_2$, while only the hyperoxic-reared larvae were noticeably more agitated by decreasing O_2. Continued larval activity despite 20 min of functional anoxia, suggests they have considerable capacity for anaerobic ATP generation.

Establishing the noxious/beneficial status of the zoophytophagous mullein bug, *Campylomma verbasci*

Olivier Aubry[1], Daniel Cormier[2], Gérald Chouinard[2], Timothy Work[1], Éric Lucas[1]

[1]Département des Sciences Biologiques, Université du Québec à Montréal, Montréal, Québec, Canada, [2]Institut de recherche et de développement en agroenvironnement, St-Hyacinthe, Québec, Canada

The mullein bug, *Campylomma verbasci* Meyer (Heteroptera : Miridae) can be an important pest in north American apple orchards. Initially, this zoophytophagous insect can be deleterious during the first larval instars since and can damage apple fruits. After that, it becomes beneficial by preying on mites (mainly *Panonychus ulmi* (Koch) (Acarina: Tetranychidae)). Here we 1) study *in situ* the link between mullein bug and red mite populations and 2) evaluate damage production of apple fruits according to fruits' diameter and cultivar. Densities of the bug in apple orchards were not correlated with densities of red spider mites. The number of feeding punctures did not differ between small (10-13mm) or large (14-17mm) fruits, however, the *Red Delicious* cultivar experienced more attacks than either *Ginger Gold* or *Honey Crisp* cultivars. The behaviour of this insect is discussed with regard to size and cultivar of apple fruits tested. Finally, we propose a new tool for establishing the noxious/beneficial status of the bug directly in orchards.

Anti-plasmodial, anti-trypanosomal and anti-parastic natural products of some selected Kenyan medicinal plants

Joseph Keriko[1], Elizabeth Kigondu[3], Mercy Githua[1], Mary Ndungu[1], Geoffrey Rukunga[3], Gathu Nyaga[1], Ahmed Hassanali[2], Isaiah Ndiege[4], Grace Murilla[5]

[1]Jomo Kenyatta University of Agriculture and Technology (JKUAT), [2]International Centre of Insect Physiology and Ecology (ICIPE), [3]Kenya Medical Research Institute (KEMRI), [4]Kenyatta University (KU), [5]Trypanosomiasis Research Centre (TRC), Nairobi, Kenya

Introduction: Protozoa disease including malaria,and leisimaniasis are a major threat to world health and are becoming more prevalent in developed World due to suppression of the immune system. Hazards associated with the continued use of conventional synthetic insecticides have also greatly hampered the control of protozoal diseases. Data shows that plants extracts have been used both in traditional medicine and in pest management practices for centuries with great success. Thus, extraction, separation and purification of the active principles from plants could produce template compounds for such control.

Methods: Plants parts such as the leaves, stems and root backs of some selected Meliaceae family of plants including some selected species of plants namely; *Suregada zanzibariensis*, *Albizia coriaria Aloe nyeriensis* were solvent extracted, fractionated, separated, purified and the isolated compounds structurally elucidated. Bioassay tests were carried out on both the fractions and pure compounds using various bioassay standard methods.

Results: Eighteen extracts from seven Meliaceae family of plants were tested in vitro against two strains of *Plasmodion falciparum*. Nine extracts were found to be active. Mathanol total extracts of the leaves of *S. Zanzibariensis* showed the highest anti-plasmodial activity. The same extract including the stem bark *of A. Coriaria* and *A. nyeriensis* exhibited good anti-leishmanial activity. Some active compounds were isolated.

Conclusion: In general Meliacese plants and related species of plants shows some potential as sources of anti-protozoal dungs. More *in vivo* activities tests are in progress in order to try to develop potential anti-plasmodial and anti-leishmanial dugs.

Genome-wide insertional mutagenesis in the red flour beetle, *Tribolium castaneum*

Marcé Lorenzen[1], Jochen Trauner[2], Teresa Shippy[3], Gregor Bucher[4], Ernst Wimmer[4], Richard Beeman[1], Martin Klingler[2], Susan Brown[3]

[1]USDA-ARS-GMPRC, Manhattan, KS, United States, [2]Department of Developmental Biology, University of Erlangen, Erlangen, Germany, [3]Division of Biology, Kansas State University, Manhattan, KS, United States, [4]Blumenbach Institute of Zoology and Anthropology, Dpt. of Dev. Biol., Georg-August-University, Göttingen, Germany

Introduction: Despite the fact that beetles are the most species-diverse eukaryotic order, the red flour beetle (*Tribolium castaneum*) genome is the first and so far only sequenced coleopteran genome (www.hgsc.bcm.tmc.edu/projects/tribolium/). Further progress in identifying and understanding the functions of the estimated 16,000 genes will require sophisticated methods of molecular dissection.

Methods: An *in vivo* system for generating new transposon insertions was used. This system utilizes transgenic strains generated using two different transposons (*piggyBac* and *Minos*). The *piggyBac*-based donor lines possess insertion-site-dependent reporter phenotypes dependent on enhancers flanking the insertion sites, as well as an insertion-site-independent reporter phenotype (eye-specific EGFP expression). Donor elements were remobilized via hybridization with *Minos*-based helper lines that supply a source of *piggyBac* transposase. Hybrid progeny (individuals carrying both elements in the same genome) were outcrossed and offspring carrying new insertions selected, as evidenced by loss of insertion-site-specific enhancer phenotype with retention of eye-specific EGFP expression. Insertion-site junctions were cloned, sequenced and their genomic locations determined.

Results: Depending on the donor/helper combination used, 75–100% of single-pair hybrid crosses produced new insertions. We have analyzed over 11,000 new transformants, of which at least 320 are recessive lethal, 24 recessive sterile, and over 200 possess new enhancer-trap phenotypes. Insertion junctions have been determined for many of these and often appear to be located within transcription units.

Conclusions: This highly efficient approach (synthetic hybrid dysgenesis) demonstrates that genome-wide, saturation mutagenesis is feasible in *Tribolium*, and perhaps in other economically important insects.

The *Tribolium* genome project and its potential impact on pest management

Marcé Lorenzen, Brenda Oppert, Richard Beeman

USDA-ARS-GMPRC, Manhattan, KS, United States

The genome sequence of the red flour beetle, *Tribolium castaneum*, a worldwide pest of stored products, has recently been determined (www.hgsc.bcm.tmc.edu/projects/tribolium/). *Tribolium* is the first agricultural pest insect and the first beetle for which the complete genome sequence has been described. *Tribolium* has become a powerful model for molecular genetic and functional genetic studies of pest biology and evolutionary/developmental biology. The *Tribolium* genome offers a rich source of potential targets for novel biopesticides. We have been mining the genomic data for candidate genes, as well as utilizing functional genomics (transgenics and RNA interference) to identify, characterize, and exploit physiological targets for pest control. Among the genes being considered as potential targets are those involved in chitin/cuticle metabolism, osmoregulation, neurotransmission, digestion and immunity. In *Tribolium*, RNA interference (RNAi) can be used to specifically inactivate any gene in all tissues after single injections of the appropriate double-stranded RNAs. The successful deployment of RNAi for pest control will depend on oral delivery of dsRNA produced in transgenic crops. Orally administered dsRNA has been shown to trigger gene silencing in several arthropods; *Ixodes scapularis* (tick), *Epiphyas postvittana* (moth), *Diabrotica virgifera virgifera* (beetle) and *Leptinotarsa decemlineata* (beetle). Continued work on this problem will lead to the identification of biopesticide target genes particularly amenable to oral RNAi-mediated knockout. Some examples of the results from our gene mining efforts will be presented along with an update on our progress towards functional analysis.

Lifting the historical impediment: BUGZonline, an electronic portal to the bibliography of New Zealand terrestrial invertebrates 1775-1993.

Stephen Pawson, Raphael Didham

[1]Scion, Christchurch, New Zealand, [2]University of Canterbury, Christchurch, New Zealand

The 'historical impediment' describes an inability to source early literature to assist in current research. This manifests as a lack of adequate indexing, or the lack of access to printed copies of publications. New Zealand is fortunate in that it has an almost complete bibliography of terrestrial invertebrate literature compiled over three decades. The BUGZ project began with the aim of lifting the historical impediment by utilising new OCR and database technology to provide free, full text, fully indexed access to the 16,043 references listed in the bibliography.

The resource now provides access to over 200,000 pages of invertebrate literature, including journal articles, books, monographs, theses, reports and popular literature. Content can be searched either by title, author, year, full-text or taxon, and articles can be browsed by title or author. Once found pages can be viewed individually as images or downloaded as a complete .pdf document (page range .pdf's are also available). A powerful feature of BUGZonline is the inclusion of UbiO's FindIT and LinkIT technologies; this allows users to select known taxonomic names associated with viewed pages and subsequently link them to external content from other providers such as Genbank and GBIF.

The BUGZ electronic portal is free to all users thanks to New Zealand's Terrestrial and Freshwater Biodiversity Information System who funded the project. Access to the portal is via www.bugz.org.nz – check it out today.

Effects of *Orius laevigatus* (Fieber) on the population dynamics of *Amblyseius swirskii* (Athias-Henriot) and *Bemisia tabaci* (Gennadius) in sweet pepper greenhouses

Hwang-Yong Kim, Jeong-Hwan Kim, Yong-Heon Kim, Yong-Hwi Lee

National Institute of Agricultural Science and Technology, Suwon, Kyung-gi, Republic of Korea

Introduction: In recent, *Bemisia tabaci* causes serious damage on sweet pepper in Korea. So the famers often release *Amblyseius swirskii* to control the whitefly. However, the predatory mite is also a prey to the other kind of predatory bug *Orius laevigatus* which is usually released to control thrips in sweet pepper greenhouse.

Methods: Filed experiment has been performed as follows. *A. swirskii* was released in sweet pepper greenhouse (10,000m^2), before the detection of *B. tabaci*. Every week, we have observed changes in population density of *A. swirskii* and *B. tabaci*. Later, to control the thrips on flowers, *O. laevigatus* was also released. And then the density of *O. laevigatus* has been monitored, too.

Results: Just one application of *A. swirskii* was effective to control *B. tabaci*. The predatory mite was settled down successfully on flowers and leaves. Just one application of *O. laevigatus* was also effective to control thrips. Although most of all *A. swirskii* has disappeared from the flowers after the application of *O. laevigatus*, the predatory bug has no significant influence over *A. swirskii* in the leaves. And consequently, *B. tabaci* has been continuously controlled in low density.

Conclusions: In the case of Korean sweet pepper greenhouse, combined application of *A. swirskii* and *O. laevigatus* was effective to control *Bemisia tabaci* and *Frankliniella occidentalis*.

Beyond barcoding: Genomic approaches to molecular systematics and diagnostics

Stephen Cameron

CSIRO Entomology, Canberra, ACT, Australia

DNA Barcoding has reinvigorated interest in molecular diagnostics however, despite the arguments of its proponents, barcoding does not provide solutions in all instances or for all groups. In instances where barcoding fails, genomic data is a rich source for alternative markers with higher accuracy or resolving power than the blind use of barcodes. Three approaches will be discussed:

1. mt genome mining to determine which genes have the optimal rates of variability;
2. functional barcoding by identifying gene variants responsible for resistance, virulence etc;
3. ecogenomics approaches to blind biodiversity assessments and comparisons between environments.

Collectively these approaches provide more experimentally verifiable approaches to three of the main goals of DNA barcoding – species level systematics, molecular diagnostics and biodiversity monitoring.

Respiration under high metabolic load in *Rhodnius*

Timothy Bradley

University of California, Irvine, California, United States

Three respiratory patterns have been described in insects: Discontinuous, Cyclic and Continuous. The Discontinuous Gas Exchange Cycle (DGC) can be distinguished by the presence of an open phase in which the spiracular valves are fully open, and a closed phase during which oxygen uptake into, and carbon dioxide release from, the insects are essentially precluded. The Cyclic pattern is characterized by cyclic carbon dioxide release with no evidence of a closed phase. The Continuous pattern shows no obvious cyclic pattern. I will discuss the effects of changing metabolic demand on the respiratory patterns of insects. In particular, one can differentiate the separate influence of oxygen demand and carbon dioxide accumulation on different portions of the respiratory control process. Examples from my own research will emphasize studies with the insect *Rhodnius prolixus*, but examples from other species will be discussed as well. The critical parameters influencing respiratory pattern are the size and design of the tracheal system and the rate of oxygen use (aerobic metabolic rate). The minute to minute balance between these two variables, one delivering oxygen, the other removing it, determines the pattern of respiration exhibited by the insect at any given time.

Genetic structure, origins, and evolution of biotypes in the *Bemisia tabaci* species complex

Margarita Hadjistylli[1], Judith Brown[2], George Roderick[1]

[1]University of California, Berkeley, Berkeley, California, United States, [2]University of Arizona, Tucson, Arizona, United States

Introduction: The sweetpotato whitefly, *Bemisia tabaci* (Gennadius) (Hemiptera: Aleyrodidae), is a cryptic species complex with its members (biotypes/haplotypes) exhibiting high genetic differentiation but no morphological variation. In this study, we examined genetic structure of worldwide populations and tested for evidence of allopatric diversification.

Methods: We genotyped individuals from 25 worldwide populations representing major biotypes/haplotypes at 15 microsatellite loci. We calculated pairwise genetic differentiation (F_{ST}) using the software Arlequin and assessed gene flow and genetic structure between populations using maximum likelihood and Bayesian inference approaches in the programs Migrate and Structure.

Results: Our analyses show significant genetic differentiation among most populations, especially between distinct geographic locations, suggesting allopatric divergence. High differentiation was detected even between biotypes overlapping in range, such as B and Q in the Mediterranean, suggesting strong reproductive isolation. Yet, biotypes B and Q seem to have diverged more recently than others, pointing to a common diversification center in the Mediterranean/North Africa/Middle East region that could explain the evolution of similar high pest attributes because of the long history of agriculture in the area. Our results are supported by the mitochondrial C01 gene phylogeny obtained for the same samples in a parallel study. Genetic data from biotypes B and Q are now used to understand how historical demography may have contributed to their diversification and worldwide expansion.

Conclusion: High genetic structure in the *B. tabaci* complex suggests that biotypes constitute genetic entities that are in the process of divergence into distinct species, especially when isolated by large geographic distances.

Odor representation in *Drosophila* local neurons

C Giovanni Galizia, Ana F Silbering

Universität Konstanz, Konstanz, Germany

Introduction: Olfactory coding is intrinsically combinatorial, involving the activity of several populations of neurons simultaneously. Furthermore, olfactory coding is hierarchical, with several processing steps leading from receptor neurons to central brain areas. We investigate odor representations both vertically and horizontally along these lines exploiting physiological and genetic tools in *Drosophila melanogaster*.

Methods: We recorded odor evoked responses in the antennal lobes of fruit flies, and characterized complete concentration-response curves. Using specific promotors, we expressed the calcium sensitive reporter GCaMP in olfactory sensory neurons, in three populations of local neurons, and in projection neurons. Data were recorded with a cooled 12-bit CCD camera, and further processed using IDL and R. Signals were evaluated in identified glomeruli across animals.

Results and Conclusions: The results indicate that the neural network within the antennal lobe is actively involved in shaping odor responses. In particular, both spatial and temporal aspects of odor-response profiles differed for the three populations of local neurons. Furthermore, responses in projection neurons could not be predicted by responses in sensory neurons alone. Also when all local neuron activity in that glomerulus was taken into account, no reliable prediction was possible. These results indicate that the responses in a glomerulus, at the level of projection neurons, is modulated both by single-glomerulus input and by network activity across glomeruli.

Eldana saccharina Walker (Lepidoptera: Pyralidae) assessment in the ZSAES sugarcane varieties' breeding and selection program: the road to ZN10 limited release in the Zimbabwe Sugar Industry

Audrey R.S Mutambara-Mabveni, Marvellous Zhou

[1]*ZSAES, Chiredzi, Zimbabwe,* [2]*ZSAES, Chiredzi, Zimbabwe*

Introduction: The sugarcane variety selection program in Zimbabwe was initiated in 1976 with the stated objective of increasing cane yield, quality and pest and disease resistance. About 100 crosses are made annually, under contract, by the South African Sugarcane Research Institute and the selections done in the southeast lowveld of Zimbabwe. The crosses series started in 1993 resulted in the limited release of cross 93-2317 (variety ZN10) in the Zimbabwe Sugar Industry in 2007. For this series, *Eldana saccharina* damage assessments were started in year 8 (pre-release variety trials stage) of the 13-year process.

Methods: Standard *E. saccharina* assessments were carried out in all pre-release variety trials with the 17 crosses/selections that reached year 8 of the 1993 series. Randomly selected sugarcane stalks were visually inspected for borer entry and exit holes, to determine the number of cane stalks bored. The stalks were then split longitudinally to determine the proportion of internodes bored per stalk. Larvae were collected and identified and damage ascribed to *E. saccharina* or any other borer. Data were analysed with SAS statistical software (SAS Institute Inc., 1999-2001).

Results: Statistical analysis indicated that there were significant differences ($p<0.001$) among the 17 crosses, in response to natural infestations by *E. saccharina.* Cross 93-2317 was among the least damaged crosses. The first ratoon crop was the most damaged, while crops harvested in the mid-season (June, July, August) were the least damaged. There were significant differences ($p<0.001$) in the performance of the crosses when grown in different localities. Cane older that 11.5 months had higher infestation levels compared to younger cane.

Conclusion: Cross 93-2317 has tolerance/resistance to *E. saccharina* damage among other desired attributes, such as high cane yield, high sucrose and tolerance to smut. Cross 93-2317 was recommended for limited release in the Zimbabwe Sugar Industry as variety ZN10. *E. saccharina* poses a threat to the growing of ZN10 in the Zimbabwe Sugarcane Industry, and infestation levels increase as the cane matures.

Peptidergic and monoaminergic mechanisms regulating circadian rhythms in insects

Makio Takeda, Susumu Hiragaki, Le Thi Duie Trang

Kobe University, Kobe, Hyogo, Japan

Recently, the molecular mechanism underlying circadian rhythm has been investigated in some model insects such as *Drosophila melanogaster,* cockroaches, and silkmoths. About a dozen of genes have been found in *D. melanogaster* .They form interlocked negative feedback loops. Homologous genes have been found in other insects but with some unique features to each species. The output pathways to regulate peripheral rhythms seem to vary. Unlike central cog mechanisms, the output pathway has not been worked out even in *D. melanogaster.* A convincing factor regulating this pathway is PDF, pigment dispersing factor in *D. melanogaster.* Since PDF-ir resides in the putative circadian pacemaker cells that express most of the clock gene products and that using mutants causing different degrees of optic lobe deformation, the number of PDF-expressing neurons and the strength of rhythmicity have a strong correlation. Also, a *pdf* mutant lost the rhythmicity. However, it is not likely that all output pathways are PDF-regulated, since *lark* mutant produces abnormal eclosion rhytms but locomotor activity rhythm is intact and pdf receptor is not expressed in neurosecretory cells.

Although surgical operations point to the accessory medulla region of the cockroach as the most critical locus to keep normal circadian rhythms, the IHCinvestigations have demonstrated that clock proteins-like antigens are not restricted to a particular part of the brain. We will show data indicating not only PDF but other factors are involved in circadian regulation. The classical scheme that the circadian pacemaker of the orthopteroid insects is located at the accessory medulla using PDF as an output messenger will be reappraised by focussing other factors, since this site expresses several other peptide-like immunochemical reactivities, such as BPP/NPF, glicentin, PHI, gastrin/CCK in *P. americana*, while some peptides like ATH, ASH and GABA caused phase shifts in *Leucopheae*. Melatonin and 5HT also are important in regulating circadian system in cockroaches and moths. There are several NAT genes but some have E-box in the regulatory region, and this is the access point of clock core mechanism to output pathway. I will show the neuroanatomical structure of peptides and indolamine mechanisms regulating circadian system and give its functional implications.

Dynamic of differentiation and hybridization in *Carabus solieri* : a comparison of morphological, genetic and colour variation throught a zone of genetic exchanges

Paul Alibert[1], Sabrina Gaba[2], Stéphane Garnier[1]

[1]CNRS-Université de Bourgogne UMR 5561 Biogéosciences, Dijon, France, [2]Unité de recherche Biologie et Gestion des Adventices-INRA Dijon, Dijon, France

Zones of genetic exchanges between differentiated entities provide valuable informations on the patterns of species distribution and the dynamic of divergence and speciation in time and space. Despite a rather restricted range (southern and Ligurian Alps in Europe) the ground beetle *Carabus solieri* exhibit significant morphological, genetic, and colour variations fitting with a clear geographical structuration. The present work focuses on a transition zone between two subspecies of *C. solieri* differing for all three features and examines their patterns of transition along a transect across the range of the subpecies and the zone of genetic exchanges. Morphological variation was assessed using outline analyses (Dual Axis Fourier Shape Analysis) of two external and genital characters: pronotum and aedeagus shapes, respectively. Genetic variation was appraised using 10 microsatellites loci and colour was captured, separately for the pronotum and the elytra, with a video camera and quantified using the position of the specimens in the RGB and HLS spaces. Variation along the transect of the morphological, genetical and colour caracters are fittet to maximum likelihood clines. Cline widths and position of cline centers are then estimated and compared between the different markers. A strong concordance and coincidence among clines is expected to reveal a selection acting on the whole genome whereas differences in cline positions and widths can suggest that selection operates differentially on the different characters (including between external and genital traits). Dynamic of introgression and selection of the putative hybrid zone are discussed in the light of these results.

Termites may be a friend to farmers: Ecosystem services in wheat paddocks in Australia

Theodore Evans[1], Tracy Dawes-Gromadzki[2]

[1]*Commonwealth Scientific and Industrial Research Organisation, Canberra, ACT, Australia,*
[2]*Commonwealth Scientific and Industrial Research Organisation, Darwin, NT, Australia*

Termites, along with ants and earthworms, the 'soil macrofauna', are known as ecosystem engineers' because of their ability to move soil and so affect mixing of soil layers by re-distributing soil types, aeration and water movement. These processes are known to be beneficial to other, smaller organisms and to plants in natural landscapes, which suggests that they may be desirable to have in production landscapes. However, soil macrofauna are vanishingly rare in Australian agricultural landscapes used for cropping, especially the very large areas used for wheat, barley, oats and canola, due to the regular disturbance to the soil from ploughing and other tillage – even some forms of seeding. Conservation tillage practices combined with stubble retention, originally implemented to minimize erosion of topsoil, have enabled the return of some termite species (and other soil organisms) to re-establish in these landscapes. The termite species are all grass harvesters belonging to *Amitermes*, *Drepanotermes*, *Nasutitermes* or *Tumilitermes*, which consume the stubble, dead leaves and roots of the crop plants. The effect of the soil macrofauna on the soil and productivity in wheat crop lands was examined in a two factor experiment, with insect exclusion (using a synthetic pyrethroid insecticide) and tillage as the factors. Soil macronutrients, water content and infiltration, and crop production are measured annually. The results to date for this preliminary experiment will be presented.

RNAi mediated silencing of essential multigenes of baculovirus induces higher level of resistance in transgenic silkworm, *Bombyx mori*

Subbiah Edupalli[1], Sriramana Kanginakudru[1], Corrine Royer[2], Vankadara Sivaprasad[3], - Chandrashekaraiah[3], Bernard Mauschamp[2], Gerard Chavancy[2], Pierre Couble[4], Javaregowda Nagaraju[1]

[1]Centre of Excellence for Genetics and Genomics of Silkmoths, Laboratory of Molecular Genetics, Centre for DNA Fingerprinting and Diagnostics,, Hyderabad 500 076, India, [2]Unité Nationale Séricicole,, 25 Quai, JJ Rousseau 69340, La Mulatière, France, [3]Andhra Pradesh State Sericulture Research and Development Institute,, Kirikera, Hindupur, Andhra Pradesh, India, [4]Centre de Genetique Moleculaire et Cellulaire, Universite Claude Bernard, 69622 Villeurbanne Cedex, France

Introduction: RNA interference (RNAi) approach has been used for anti-viral therapy with varied degree of success in different eukaryotic systems. In the study reported here we speculated that by simultaneously abrogating several essential genes of invading Bombyx mori Nuclear Polyhedrosis Virus (*Bm*NPV) it is possible to mount higher level of protective effect against viral infection in silkworm.

Methods: Towards achieving this goal, we constructed *piggybac* transposon-mediated transgenic silkworm strains that expressed double-stranded RNA (dsRNA) specific to four essential viral genes placed in tandem in flip-flop (MFF) orientation. We also obtained transgenic silkworms that expressed only *sense* (S) or *antisense* (AS) forms of these baculoviral genes.

Results: Our results show significant inhibition of baculovirus proliferation in MFF transgenic lines as compared to, *sense* , *antisense*, and their hybrids. The MFF harbouring transgenic lines registered significantly higher level of resistance to baculovirus infection as compared to the silkworm lines carrying single essential bauloviral target gene as reported in our earlier study (Kanginakudru et al. 2007 Insect Molecular Biology **16,** 635–644).

Conclusion: These results suggest that the RNAi pathway can be successfully exploited in developing baculovrus resistant silkworm strains which could find commercial applications in sericulture.

Study on the potential of native fungal isolates and *Metrahizium anisopliae* var. *acridum* for greater wax moth, *Galleria mellonella* (L) in Ethiopia.

Hellen Namusana, Emiru Seyoum, Bekele Jembere

Addis Ababa University, Addis Ababa, Ethiopia

Introduction: The greater wax moth is widely distributed in Ethiopia and various control measures had been used against the greater wax moth but use of pathogens in general and fungi in particular. It has been well documented that the entomopathogenic fungi, *Metarhizium* and *Beauveria* have proved to be potential candidates for many insect pests. Thus, this study investigated the potential of *Metarhizium anisopliae* var. *acridium* (IMI330189) and *Beauveria* (IITA 18) in comparison with two local isolates were compared against, adult wax moths. The possible effect of the fungal isolates on the honeybee colonies was also investigated.

Materials and methods: The effects of six fungal isolates including, DLCO-AA5, DLCO-AA14, DLCO-AA83, DLCO-AA 109, IITA 18 and IMI 330189 were evaluated in the laboratory for their pathogenicity to adult greater wax moths. Spore dilutions were prepared in 0.5% Tween 80. Adults were treated by spraying 2 ml of conidial suspensions ranging from $4x10^4$ to$4x10^7$ conidia /ml.

Results: Adult GWM were found to be susceptible to all isolates and concentrations used. Comparison of post treatment mortality of adult, greater wax moth (GWM) at the lowest concentration ($4x10^4$ conidia/ml) revealed that infection of $\geq$ 90% could be achieved by day 13 post inoculation. Investigations into effects of mycosis on percentage emergence of adults fungal from fungal treated pupae of the GWM showed no significant difference ($P>0.05$) between the different fungal isolates and controls. With all fungal concentrations (($4x10^4$ to $4x10^7$ conidia/ml) used, percentage emergence of over 86.1% was observed in adult GWM.

Implications of global environmental change for above- and belowground insect-insect and insect-plant interactions

Greg Masters[1], Felix Wackers[2], Alan Gange[3], Joanne Staley[4]

[1]CABI-LEC Alliance, Lancaster, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom, [3]Royal Holloway, Egham, United Kingdom, [4]Imperial, Ascot, United Kingdom

Interactions between species are a central tenet of entomology and ecology, but it is only relatively recently that we have started to understand the importance of the belowground system in such multitrophic communities. Recent advances have led to a greater understanding of the important role that insect-insect and insect-plant interactions have in driving the complex interplay between above- and belowground systems. The mechanisms and processes of such interactions potentially are numerous and can include changes in host-plants, in terms of overall level and allocation of water content, C, N and secondary metabolites, as well as altered plant phenology, stature, morphology and community structure. However, it is these same mechanisms and processes within communities and plants that will be affected by Global Environmental Change (GEC). We consider GEC to be primarily climate change but also to include pollution and changes in land-use. All of these environmental drivers, but particularly climate change, can affect physiological, autecological and population/community mechanisms underlying multitrophic interactions.

Although the implications of GEC for ecosystems, communities, populations and individual insect and plant species are increasingly understood, we know little about how such changes will affect multitrophic interactions, particularly between above and belowground systems.

Here, we examine the potential consequences of GEC for above- and belowground interactions by using conceptual and model laboratory and field above- and belowground insect herbivore systems, which manipulate temperature and water relations in line with climate change predictions. From this evidence, existing models of above-belowground interactions will be examined when subject to a climate manipulations. Although species may respond idiosyncratically, our aim is to seek general response patterns., limited evidence available.

Interactive auditory communication in mosquitoes

Ben Warren[2], Robbie Girling[1], Gabriella Gibson[1], Ian Russell[2]

[1]National Resources Institute, Chatham, United Kingdom, [2]University of Sussex, Brighton, United Kingdom

Introduction: It has been well documented that mosquitoes detect near field sounds (<10 cm away) using their Johnston's organ, an auditory structure located at the base of their antennae. Furthermore, male mosquitoes are known to be attracted by sound, within a frequency range similar to that of the females' flight tones, but nothing is known of female responses to sound. We investigated how males and females respond to one another's flight tones in species where male and female flight tones are similar (*Toxorhynchites brevipalpis*) and where they vary greatly (*Culex* spp.).

Methods: The sounds produced by tethered flying male and female mosquitoes were recorded using a particle velocity microphone (Knowles NR-3158) and analysed using Spectrogram 12 (Visualization Software, LLC) software. Flight tones were recorded from individuals of each sex, same-sex pairs and opposite-sex pairs.

Results: Individuals of *Tx brevipalpis* flown together in male-female pairs initially flew at their own endogenous wing beat frequencies, but in response to the other's flight tones they gradually converged on a common fundamental wing-beat frequency. In contrast, male-female pairs of *Culex* spp. converged not at their fundamental wing-beat frequencies but at higher harmonics, which are at frequencies outside their auditory range. Same-sex pairs of all the species tested did not converge either at a common fundamental or harmonic frequency.

Conclusions: We have discovered a form of auditory communication between male and female mosquitoes, which may be involved in mate recognition.

Botanical pesticides for stored grain protection: from the laboratory to the farm

Brighton Mvumi[1], Alex Chigoverah[1], Kenias Nyevedzanai[1], Phosiso Sola[2], Phillip Stevenson[4], Gudeta Sileshi[5], Steven Belmain[3], David Hall[3], Stephen Nyirenda[6], John Kamanula[7]

[1]University of Zimbabwe, Harare, Zimbabwe, [2]Southern Alliance for Indigenous Resources, Harare, Zimbabwe, [3]Natural Resources Institute, University of Greenwich, Chatham Maritime, Kent, United Kingdom, [4]Royal Botanic Gardens, Richmond, Surrey, United Kingdom, [5]World Agroforestry Centre (ICRAF), Lilongwe, Malawi, [6]Department of Agricultural Research Services, Mzuzu, Malawi, [7]Mzuzu University, Mzuzu, Malawi

Introduction: Storage insect pests remain one of the biggest threats to food security in sub-Saharan Africa where grain is usually stored for at least 6 months. Normally, farmers would use synthetic chemical pesticides but they are facing challenges in using these pesticides including unavailability, resistance development, high cost and adulteration. Therefore, farmers resort to using pesticidal plants which they have tried and tested over many years. Although much laboratory work has been conducted by many researchers, the results have been of limited use in the field.

Methods: Field trials were set-up in Zimbabwe using *Bobgunnia (Schwarztia) madagascarensis*, *Dichrostachys cinerea, Bauhunia thoningii, Lippia javanica* and *Aloe* spp. previously identified by the farming community. The plant materials were applied at 2% w/w on threshed maize and beans or cowpeas as fruit or leaf powder, except for *Aloe* spp. which was used as an ash. Actellic Super dust (at label rate) and neem, *Azadirachta indica* (at 2%w/w) were used as positive controls while untreated grain served as negative control. Grain was sampled from each treatment at the beginning of the experiment and at 8-week intervals subsequently, and analysed in the laboratory for insect numbers and species, and grain damage.

Results: Preliminary results indicate that the plant materials did have some effect but not sufficient to suppress grain damage and insect multiplication as much as Actellic Super dust or neem. Among the plants tested, *B. madagascarensis* showed the greatest pesticidal potential.

Conclusions: Considerable grain protection was achieved with *B. madagascarensis* applied at the rate of 2% w/w. Further studies are required to explore dose-response modelling and to identify the active ingredients so as to optimise the use of pesticidal plants.

Plant volatile and pheromone baited traps for the strawberry blossom weevil

Atle Wibe[1], Helena Bichão[2], Anna-Karin Borg-Karlsson[3]

[1]Bioforsk - Norwegian Institute for Agricultural and Environmental Research, Tingvoll, Norway, [2]NTNU - Norwegian University of Science and Technology, Trondheim, Norway, [3]KTH - The Royal Institute of Technology, Stockholm, Sweden

Introduction: The strawberry blossom weevil, *Anthonomus rubi*, is a major pest insect of cultivated strawberry in northern part of Europe. The weevils deposit eggs in the flower buds before it sever the buds from their stalks, leading to a direct loss of crop. The aim of this project is to develop an effective plant protection method without eradicants, to be used in both conventional and organic agriculture.

Methods: Volatiles emitted by the strawberry plants were collected using SPME and identified by GC/MS. To identify important volatiles for host location some compounds were tested as stimuli in electrophysiological studies of the insect antenna. In a field study using funnel traps two potential plant volatiles PV1 and PV2 and the pheromone blend Grandlure (Ph) were tested. The volatiles were tested separately and in mixtures.

Results: The chemical analysis of the host volatiles identified several compounds present in different quantities. Some of these compounds elicited electrophysiological responses in the insect antennae. In the field study traps baited with Ph caught more weevils than the traps baited with PV1 or PV2. Traps baited with PV1+PV2 or PV1+Ph caught about the same as traps baited with Ph. When the traps were baited with PV2+Ph or PV1+PV2+Ph a significant increase of caught weevils were recorded.

Conclusions: The results have shown that there may be a synergistic effect between PV2 and Ph when used as bait for trapping strawberry blossom weevils. This can be important knowledge for developing a new plant protection method for strawberry.

An integrated molecular and histological study on the impact of sublethal effects of Fenoxycarb on the European honeybee, *Apis mellifera*

Kevin Heylen[1], Johan Billen[1], Roger Huybrechts[1], Lutgarde Arckens[1], Bruno Gobin[2]

[1]Katholieke Universiteit Leuven, Leuven B-3000, Belgium, [2]Zoology Department, Sint-Truiden B-3800, Belgium

The aim of our research was to investigate if a synthetic Juvenile hormone (JH)-analog (the insecticide Fenoxycarb) potentially affects physiological processes in the honeybee. We evaluated effects on both the molecular level (gene and protein expression in the brain) and the organ level (hypopharyngeal gland development). Both mRNA and protein expression profiles were analysed in age-matched treated and control bees to identify relevant components using microarray and 2D-DIGE (2-dimensional fluorescence difference gel electrophoresis). Analysis of brains resulted in a list of 21 genes that were consistently differentially expressed in microarray experiments for 2 different colonies, while 7 differential protein spots were shared in 2D-DIGE experiments on 3 different colonies. So far, four protein spots were successfully identified using MS, of which two also appeared in the microarray list. When we focused on a specific gene involved in the transition from nurse to forager, bees treated with the JH-analog showed different expression to control bees. Moreover, histological studies on the important and JH-sensitive hypopharyngeal glands were also performed to look for morphological differences between treated and control bees. Age related degeneration of the hypopharyngeal gland progressed faster in bees, treated with Fenoxycarb, in comparison to control bees. Our data show that effects of JH-analogs on bees can be detected at the molecular and developmental level which provides a potential tool for side-effect evaluation.

Effects of potato viral infections in the biology and preference of aphid vectors and their epidemiological implications

Juan M. Alvarez, RajagopalBabu Srinivasan

University of Idaho, Aberdeen, Idaho, United States

Introduction: Virus infections influence the quality of plants directly affecting the performance of aphids feeding on these plants. PVY and PLRV are the two most economically important viruses in the potato crop in Idaho, the number one potato producing state in the United States. The two viruses can frequently be found on the same plant. The objective of this study was to determine the consequences of single and mixed infections on the insect vectors and how these infections in turn affect the vector dynamics and disease epidemiology.

Methods: Tissue culture plantlets were single and mix infected with PVY (including necrotic strains) and PLRV and the life histories (nymphal period, adult longevity, daily fecundity and intrinsic rate of increase) of the two most important aphid vector species were studied on these plants using leaf cages. Settling bioassays with alatae and apterae aphids were conducted on single and mixed infected plants.

Results: Aphid fecundity was significantly higher on mixed-infected plants than on singly-infected plants or non-infected plants. Both winged and wingless aphids preferentially settled on PVY-PLRV infected plants than on singly-infected plants or non-infected plants. Mixed-viral infected plants with these two heterologous viruses exhibited more severe symptoms than singly-infected plants.

Conclusions: Mixed infections have resulted in synergistic interactions, drastically altering plant viral-susceptibility and physiological status, which severely altered host plant symptom expression patterns as well as vector-preference behavior. Some of these interactions may provide an explanation for the recent spike in incidence of PVY necrotic variants in Idaho and some other regions.

Effects of potato viral infections in the biology and preference of aphid vectors and their epidemiological implications

Juan M. Alvarez, RajagopalBabu Srinivasan

University of Idaho, Aberdeen, Idaho, United States

Introduction: Virus infections influence the quality of plants directly affecting the performance of aphids feeding on these plants. PVY and PLRV are the two most economically important viruses in the potato crop in Idaho, the number one potato producing state in the United States. The two viruses can frequently be found on the same plant. The objective of this study was to determine the consequences of single and mixed infections on the insect vectors and how these infections in turn affect the vector dynamics and disease epidemiology.

Conclusions: Mixed infections have resulted in synergistic interactions, drastically altering plant viral-susceptibility and physiological status, which severely altered host plant symptom expression patterns as well as vector-preference behavior. Some of these interactions may provide an explanation for the recent spike in incidence of PVY necrotic variants in Idaho and some other regions.

Evolution of segmentation mechanisms in insects, as revealed by a study on the cricket *Gryllus bimaculatus*

Taro Mito, Taro Nakamura, Tetsuya Bando, Hideyo Ohuchi, Sumihare Noji

The University of Tokushima, Tokushima, Japan

The mode of segmentation in short and intermediate germ insects differs from that in *Drosophila*, a long germ insect. In order to elucidate segmentation mechanisms of short/intermediate germ insects, we have investigated functions of orthologues of the *Drosophila* segmentation genes as well as regulatory interactions among those genes, with a phylogenetically basal, intermediate germ insect, *Gryllus bimaculatus*. With RNAi-based analyses of gene functions in *Gryllus* embryogenesis, we previously demonstrated the divergent aspects of the segmentation mechanism in *Gryllus*, which are following: (1) Caudal (Cad) probably acts as a crucial morphogen with a posterior-to-anterior gradient, regulating the gap genes *hunchback* (*hb*) and *Kruppel* (*Kr*). (2) *even-skipped* regulates *hb* and *Kr* expression in a gap pattern. (3) *extradenticle* regulates *hb* and *eve* expression in the gnathal region, fulfilling a gap-like function. (4) Wingless/Armadillo signaling is involved in posterior elongation/segmentation, activating *cad* expression. Recently, we found that *Gryllus* has two *orthodenticle* (*otd*)-related genes, *Gb'otd1* and *Gb'otd2*, probably orthologous to *otd1* and *otd2* in other insects, respectively. *Gb'otd1* is expressed during blastoderm stage, whereas *Gb'otd2* expression starts later in a germband stage. An RNAi analysis revealed that *Gb'otd1* is required for patterning of the head and thorax, a larger domain than that regulated by *Drosophila otd,* through regulation of gap genes. Our findings indicate that the regulatory networks of segmentation genes and network components differ between *Gryllus* and *Drosophila*. This implies that molecular mechanisms of segmentation changed dynamically during insect evolution, whereas the segmented body plan itself remained substantially unchanged.

Activity of the homing endonuclease gene I-*Ppo*I in the germline of transgenic *Anopheles gambiae* mosquitoes

Nikolai Windbichler, Philippos Aris Papathanos, Andrea Crisanti

Imperial College, London, United Kingdom

Homing endonuclease genes are rare cutting DNA endonucleases that combine the capability to selectively disrupt specific gene sequences with the ability to spread from a few individuals to an entire population through homologous recombination repair events. Because of these properties HEGs are regarded as promising candidates to transfer genetic modifications from engineered laboratory mosquitoes to wild type populations including *Anopheles gambiae* the vector of human malaria. We have shown that the I-*Ppo*I homing endonuclease recognises and cleaves its highly conserved recognition site, located within the 28S rRNA genes on the X chromosome of *A. gambiae*, with high efficiency in cell lines, embryos and transgenic mosquitoes. We have proposed a gene drive system for mosquitoes that is based on this finding and aims to selectively incapacitate X-carrying spermatozoa. Such a system could be used to control the size of field populations by imposing severe sex biases or to drive transgenes through a population. We have generated a number of transgenic *A. gambiae* mosquito strains that express a fusion protein of the I-*Ppo*I homing endonuclease and the eGFP fluorescent marker under the control of the male germline specific beta2 tubulin promoter. We are measuring the effect on sex ratios and fecundity in male and female crosses of these transgenic lines to assess the potential of this system for mosquito vector control approaches.

Biology and larval feeding rate of *Scaeva albomaculata* (Diptera: Syrphidae) on *Macrosiphum rosae* (Linnaeus) (Homoptera: Aphididae) in laboratory conditions

Farzad Jalilian[1], Naser Moeeny Naghadeh[2], Seyed Mahdi Mahjoob[1], Mohammad Taghi Tohidi[1]

[1]Razi University, Kermanshah, Iran, [2]Agricultural research Center, Kermanshah, Iran

Introduction: Biological characteristics and larval feeding rate of hoverfly, *Scaeva albomaculata* (Macqaurt) were investigated on *Macrosiphum rosae* (L.) at laboratory conditions.

Material and Methods: The experiments were carried out in growth chamber at 27±2ºC, RH 60±5% and a photoperiod of 16:8 (L : D).

Results: The egg, 1st, 2nd, 3rd larval instars, prepupa and pupal developmental times were determined as 4.50 ± 0.42, 2.5 ± 0.22, 3.83 ± 0.37, 1.16 ± 0.16, 5.50 ± 0.71, 5.50 ± 0.71 days, respectively. Adult longevity was considerably increased (32.75 ± 2.78 days) when they fed with honey solution, while in food free conditions, they were alive only 4.33 ± 0.88 days. The results indicated that each female produce 110.5 ± 10.74, eggs during oviposition period, 88.50% of these eggs hatched to first instar larvae. There were significant differences ($P<0.01$) between daily feeding rate of the first, second and third instar larvae. Each larva fed 511.37 aphids during larval period and revealed a high potential of feeding on *M. rosae*. The third instar larvae had an important role in feeding rate of larval period and 78.32% of total larval feeding was due to this instar. Per capita daily feeding rate of the first, second and third instar larvae were 7.94, 33.06 and 104.48 , respectively.

Conclusions: Because of high feeding rate, the hoverfly, *S. albomaculata* can be used in biological control and integrated management programs of *M.rosae*.

Integration of growth and positional information by *Dachsous-Fat* signaling in leg regeneration of the two-spotted cricket *Gryllus bimaculatus*

Tetsuya Bando, Yuko Maeda, Fumiaki Ito, Taro Nakamura, Taro Mito, Hideyo Ohuchi, Sumihare Noji

University of Tokushima, Tokushima, Japan

Tissue regeneration, which is a mechanism recovering a lost part of tissue, is well known phenomenon in several animals and is classically categorized into two modes; morphallaxis and epimorphosis. Two-spotted cricket *Gryllus bimaculatus* recovers distal missing part in epimorphic manner. However, we do not know how regenerating cells know their positional information and how the regenerating cells know how many times they should divide to restore the lost part. Here we show that Fat signaling that widely regulate proximodistal patterning, planer cell polarity and cell proliferation in *Drosophila* is also involved in cell proliferation and positional information of leg regeneration in the cricket. Nymphal RNAi for *Gryllus* homologues of *fat*, *dachsous*, *expanded*, *merlin* and *warts* caused enlargement at blastemata of regenerating legs by over cell proliferation, while nymphal RNAi for *Gryllus* homologues of *fat*, *dachsous* and *dachs* recovered the lost part, but the lengths of regenerating legs were shortened depending on the amputated positions. These nymphs also showed defects in normal and reversed intercalary regeneration, showing loss of positional information in the balstemata. We found that in regenerated legs exhibiting nymphal RNAi for *fat*, *dachsous* and *dachs*, lost parts were recovered in a morphallactic manner. Our results suggested that different signaling cascades leading to cell growth and positional information are integrated by the Dachsous-Fat signaling during leg regeneration.

Effect of ionizing (gamma) and non-ionizing radiation (UV) on the development of *Trichogramma turkestanica*

Aydin S. Tuncbilek[1], Fahriye Sumer[2], Ulku Canpolat[3]

[1]Erciyes University, Seyrani Faculty of Agriculture, Department of Plant Protection,, Kayseri, Turkey, [2]Erciyes University, Faculty of Sciences and Literature, Department of Biology, Kayseri, Turkey, [3]Erciyes University, Faculty of Sciences and Literature, Department of Biology, Kayseri, Turkey

Introduction: Ionizing (gamma) and non-ionizing radiation (UV) were used to determine possible effectiveness on the development of *Trichogramma turkestanica*

Methods: Various instars of *Trichogramma turkestanica* (Hymenoptera: Trichogrammatidae) were exposed to gamma radiation for different doses (0-25 Gy) and ultraviolet (UV) radiation with 254nm wavelength (UV-C) for different durations (0-10 min) to assess their effect on each instars and their potential in breaking the developmental cycle of the egg parasitoid.

Results: The egg of *T. turkestanica* was more sensitive to gamma radiation and there was no adult emergence at the dose of 25 Gy. Pupal stage was more resistant to gamma radiation and adult emergence was not stopped within the investigated doses. The prepupa of *T. turkestanica* was more sensitive to UV radiation and there was no adult emergence at the duration of 4 minutes and above. Egg stage was more resistant to UV radiation and adult emergence was not stopped within the investigated doses. Longevity of irradiated adult was gradually decreased with increasing doses when compared with untreated control. Influence of irradiated host eggs on *T. turkestanica* will be discussed.

Conclusions: Biological effect of gamma radiation on *T. turkestanica* was different from UV radiation.

Invasion of Europe by the western corn rootworm, *Diabrotica virgifera virgifera*: multiple transatlantic introductions with various reductions of genetic diversity

Marc Ciosi[1], Nicholas J Miller[2], Kyung Seok Kim[2], Rosanna Giordano[3], Arnaud Estoup[4], Thomas Guillemaud[1]

[1]Equipe; Biologie des Populations en Interaction, UMR 1301 IBSV INRA-UNSA-CNRS, Sophia Antipolis, France, [2]USDA-ARS, CICGRU, Genetics Laboratory, Iowa State University, Ames, IA, United States, [3]Illinois Natural History Survey, Division of Biodiversity and Ecological Entomology, Champaign, IL, United States, [4]INRA, UMR CBGP (INRA / IRD / Cirad / Montpellier SupAgro), Montferrier-sur-Lez, France

The early stages of invasion involve demographic bottlenecks that may result in lower genetic variation in introduced populations than in the source populations. Previous population genetic studies of invasive species have reported very different levels of losses of genetic variability in comparisons of source and invasive populations. Descriptions of invasive species for which multiple introductions from a single source population have been demonstrated may be a particularly informative subject of study. The western corn rootworm (WCR), *Diabrotica virgifera virgifera*, native to Central America, is such a species as it has been shown to have been repeatedly introduced in Europe from North America. Using several genetic markers, we investigated within- and between-population variation, in WCR from North America and Europe, to investigate the possible routes by which the WCR was introduced into Europe and to assess the effect of introduction events on genetic variation. From 1992 to 2007, we detected five independent introductions from the northern US to Europe and four intra-European founder events. The loss of genetic diversity following these introductions differed considerably between events, suggesting substantial differences in the initial variation of colonizing individuals as well as foundation and/or establishment conditions. We also showed that as a result of multiple introductions, the nuclear genetic variability present in the US source population has been largely redistributed among the various introduction foci in Europe.

Differential gene expression patterns correlate with caste fate in the honey bee, *Apis mellifera*

Zilá Simões

FFCLRP of University of São Paulo, Ribeirão Preto, Brazil

Differential gene expression splits definitively the fate of the two female *Apis mellifera* morphs during specific moments of postembryonic development in a process denominated caste determination. The morphological, behavioral and physiological characters specific to each caste are outcomes of this process that initiates with the differential feeding of queen and worker larvae. Some traits are fixed for the rest of the life for these two morphs, however some characters still retain important traces of plasticity, at least in workers. One of the immutable traits established during metamorphosis is the differentiation of the corbicula, a pollen basket surrounded by strong bristles on the metathoracic leg of workers. We investigate how the development of this worker caste-specific structure relates to the expression of patterning genes, such as *Ubx* and *abd-A,* during specific moments of caste differentiation. More flexible life history traits relate to reproduction and division of labor. For example, the functionally sterile workers still retain the possibility to activate their ovaries and lay eggs, especially under queenless conditions, and this depends on the expression of specific genes. Important candidate genes for the regulation of fertility are *vitellogenin (vg)*, *lipophorin (lp*) and genes encoding their specific receptors. Analyzing the expression of these genes in honey bee queens and workers we observed a clear, albeit inverse relation to oogenesis.

Ancient agriculture in ants: exploring the complexity of social insect-microbe associations

Cameron Currie

University of Wisconsin, Madison, WI, United States

The formation of beneficial host-microbe symbioses have driven most major evolutionary transitions towards increased biological complexity, and the pervasiveness of these associations and their ecological dominance in virtually every ecosystem illustrates the importance of symbiosis as a form of evolutionary innovation. One textbook example is the fungus-growing ant-microbe symbiosis. This symbiosis includes the conspicuous leaf-cutters, and involves the obligate cultivation of fungus for food by ants. Over the last decade it has become clear that the ant-fungus mutualism includes two additional integral symbionts: i) specialized parasitic fungi in the genus *Escovopsis,* which exploit the ants' fungus garden and ii) mutualistic filamentous bacteria that produce antibiotics that inhibit the garden parasite. In this talk, I will present evidence for the presence of two more lineages of microbial symbionts associated with fungus-growing ants: i) black yeast that exploit the ant-bacteria mutualism, and ii) nitrogen-fixing bacteria that appear to fertilize the ants' fungus garden. The fungus-growing ant-microbe symbiosis illustrates the potential importance of microbes in shaping the biology of social insects.

Bacteria mediate insect-plant-fungal associations in leaf-cutting ants

Cameron Currie

University of Wisconsin, Madison, WI, United States

Since the origin of life on Earth ~4.6 billion years ago, microscopic organisms have shaped all levels of biological organization and have evolved into the most abundant and diverse life forms on the planet. However, the importance of microbes is perhaps best exemplified by their crucial role as symbionts with plants and animals, including mediating virtually every plant-insect association on the planet. For example, herbivorous insects depend on microbes to aid in the digestion of plant material, while fungal and/or bacterial symbionts can help plants defend themselves from herbivorous insects. Leaf-cutter ants in the tribe Attini represent a well-known example of microbes mediating insect-plant associations. The ants forage on fresh leaf material, which they use to manure their fungal garden. Leaf-cutting ant represents one of the most dominant herbivores in the Neotropics, illustrating the success of this obligate and ancient ant-fungus mutualism. Recent work has revealed that this association is composed of a complexity community of microbes, which includes microfungal pathogens that exploit the ants' fungal gardens. To help protect the health of the fungus garden the ants engage in a third mutualism with antibiotic-producing bacteria. Here I explore the role of additional microbial symbionts in altering tri-trophic insect-plant-microbe associations.

Medium range olfactory responses of the malaria vector, *Anopheles gambiae* to synthetic odour blends

Fredros Okumu, Sarah Moore

Durham University, Durham, United Kingdom

Background: The interaction between the malaria vector, *Anopheles gambiae* and its human hosts is mediated mainly by olfactory cues emanated from the host. Several compounds from whole body odour, sweat and breath are proven mosquito kairomones.

Methods: We evaluated medium range attractiveness of selected carboxylic acids to *An. gambiae s.s* in a semi field screen house system. The optimal concentrations at which these compounds are attractive to the vector were determined by a series of binary assays in competition with a standardized control blend.

Results: The behaviourally active odour compounds evaluated included l-Lactic acid, Propionic acid (C3), Octanoic acid (C8), Isopentanoic acid (3mC4), Pentanoic acid (C5), Butyric acid (C4), Heptanoic acid (C7) and Tetradecanoic acid (C14). Data was analysed by binary logistic regression to estimate the attractiveness of the test blends relative to the control blend. We determined that C3, C4, C5 and 3mC4, are attractive at low concentrations but repellent at higher concentrations. C7, C8 and C14 however remained attractive at high concentrations. The most attractive blend formulated from the test compounds was only of limited attractiveness compared to human foot odours trapped in worn socks.

Conclusion: Our results provide additional proof that apart from the carboxylic acids, there are other compounds essential for the mediation of *Anopheles* olfactory responses to humans. However, our system was evidently advantageous for rapid through assessment and optimization of behaviourally active compounds. Further discussion on the behavioural assay strategies and future work including recombination with insect repellents within a push-pull framework is discussed.

Two species of backswimmers (Notonectidae) and one species of water boatmen (Corixidae) as basibionts of some protozoan ciliates

Ricardo Mariño-Pérez, Rosaura Mayén-Estrada

Laboratorio de Protozoología, Departamento de Biología Comparada, Facultad de Ciencias, Universidad Nacional Autónoma de México, C.P. 04510, Ciudad Universitaria, México, D.F., Mexico

Introduction: Epibiosis is an association between an epibiont (organisms growing attached to a living surface) and a basibiont (substrate organism, which is the epibiont's host), this is a common interaction between aquatic animals and protozoans, nevertheless in arthropods has been reported mainly for crustaceans. The aim of this work is to present data concerning to the epibiosis between three species of water true bugs and ciliates, from central Mexico.

Methods: The aquatic bugs were collected in a freshwater pond in Hidalgo state, Mexico. Six samples were taken between February and August 2005. In order to examine and observe the ciliates, each basibiont was dissected, including the pairs of legs.

Results: Two species of backswimmers were found, *Notonecta unifasciata* and *Buenoa pallens,* and one species of water boatmen, *Corisella edulis*. All the three species presented epibionts. The peritrich *Orbopercularia* sp. and two species of suctorians (*Discophrya elongata* and *Acineta tuberosa*) were found attached to *Corisella edulis. Discophrya elongata* was found mainly in the middle legs, *Orbopercularia* sp. was observed mainly in legs, head and dorsal abdomen. For *A. tuberosa* data were not conclusive. On *Notonecta unifasciata* we observed *D. elongata* attached to legs. A third species of suctorian (*Periacineta notonectae*) was found only attached to *Buenoa pallens*, mainly in the anterior legs.

Conclusions: The epibionts were attached to certain exoskeleton areas, for which we conclude that the ciliates distribution is related to the appendage's architecture (very modified in Nepomorpha), and also to the hydrodynamic advantages implied in the nourishment activities.

Pseudopeptide and nonpeptide mimetic agonists and antagonists of diuretic insect kinin and diapause hormone neuropeptide classes

Ronald Nachman[1], Qirui Zhang[2], Suparna Taneja-Bageshwar[3], Pawel Zubrzak[1], Geoffrey Coast[4], Patricia Pietrantonio[3], David Denlinger[2]

[1]US Department of Agriculture, College Station, TX, United States, [2]Ohio State University, Columbus, OH, United States, [3]Texas A&M University, College Station, TX, United States, [4]University of London, London, United Kingdom

Insect neuropeptides regulate critical processes and behaviors in insects, though they are unsuitable as tools to arthropod endocrinologists and/or as pest management agents due to unsuitable biostability and/or bioavailability characteristics. Peptidomimetic analogs can overcome these limitations and either over-activate or block critical neuropeptide-regulated functions. The stereochemical and conformational aspects critical for the successful interaction of two broad classes of arthropod neuropeptides with their respective receptors is discussed, and exploited to design/discover mimetic analogs with enhanced biostability, bioavailability, and selectivity.

The diuretic insect kinin (IK) class of neuropeptides share the evolutionarily conserved C-terminal pentapeptide motif Phe-X^1-X^2-Trp-Gly-NH_2, where X^1 = His, Asn, Ser, or Tyr and X^2 = can be Ala but is generally Ser or Pro. Evaluation of restricted-conformation IK analogs incorporating such moieties as tetrazole and amino-pyroglutamate (APy), mimics of the *cis*Pro, type VI beta turn, indicate that this is the conformation adopted at the receptor site. A discussion follows on the design of non-peptide mimetic agonist/antagonist analogs with enhanced biostability in expressed tick and mosquito IK receptors.

The diapause hormone (DH) neuropeptide group shares the conserved C-terminal motif Trp-Phe-Gly-Pro-Arg-Leu-NH_2. The DH's induce embryonic diapause in *Bombyx mori*, and adult diapuse-break in Heliothines. Evaluation of DH analogs incorporating a *trans*Pro mimetic component in the diapause-break bioassay indicates that this configuration is associated with an agonist response. A discussion follows on the design of pseudopeptide mimetic DH agonists and antagonists with enhanced potency, biostability, and bioavailability that may prove of future utility for disruption of this important behavior in pest insects.

Resistance to human pathogens through the manipulation of mosquito immune pathways

Lindsey Garver, Jose Ramirez, Yuemei Dong, Zhiyong Xi, George Dimopoulos

Johns Hopkins School of Public Health, Baltimore, Maryland, United States

Introduction: Immune responses mounted by pathogen transmitting mosquitoes are largely regulated by the Toll and Imd pathways, which control the nuclear translocation of two NF-kappaB-like transcription factors, Rel1 and Rel2, respectively. Activation of Rel1 and Rel2 by these pathways is controlled by the negative regulators Cactus and Caspar.

Methods: We have used RNA interference to assays the effect of Toll and Imd pathway activation on pathogen infection and the regulation of the mosquito transcriptome.

Results: We found that Rel2 activation resulting from AgCaspar depletion rendered Anopheles gambiae mosquitoes resistant to the human malaria parasite *Plasmodium falciparum* at the pre-mature oocyst stage. In a similar analysis we found that Rel1 activation resulting from AeCactus depletion rendered *Aedes aegypti* mosquitoes less susceptible to the dengue virus. High-density microarray-based, genome-wide expression analyses in both mosquito species identified a plethora of genes that were regulated by the activation of the two Rel factors via Cactus and Caspar depletion. The Toll pathway displayed in general a significantly more diverse role in mosquito biology than did the Imd pathway, which was more immunity-specific. The Toll and Imd pathways are also implicated in anti-microbial defenses and we show that the mosquito's endogenous microbial flora play a role in limiting pathogen infection, possibly through a basal level immune gene stimulation.

A novel experimental hut assay to test spatial repellency

Sarah Moore[1], Nicodem Govella[1], Benjamin Fuhrer[1], John Grieco[3], Tanya Russell[1], Gerry Killeen[1], Nicole Achee[3]

[1]IHRDC, Ifakara, Tanzania, United Republic of, [2]Durham University, Durham, United Kingdom, [3]United States Uniformed Health Services, Bathesda, United States

The debate over the mode of action of excitorepellent insecticides still continues. Is toxicity or spatial repellency the reason that they are so effective in reducing vector-borne disease? Can a spatial repellent with limited toxicity ever be useful in large-scale vector control programmes? Only with the use of standard reproducible assays, similar to those WHO protocols employed to measure the lethal dose of residual insecticides can this question be answered.

In order to address this issue a standard experimental hut assay was devised. This assay uses a readily transportable kit form experimental hut with standardised interception traps specifically designed to capture Afrotropical malaria vectors entering and exiting the huts. The hut assay uses a novel design that brings together aspects of traditional experimental hut assays, and new innovations. Using standardised protocols the assays measure: reductions in proportions of mosquitoes entering treated versus control huts – spatial repellence; time spent in huts by mosquitoes that enter – contact irritancy; mortality of those mosquitoes that enter huts.

Baseline experiments to explore natural mosquito entry and exit behaviour were conducted. These were followed by assays using low-toxicity botanical spatial repellents *Nepata cataria* and para-menthane 3,8, diol to measure the differences in entering and exiting behaviour, and the results are discussed in relation. The kit-form huts are currently in use in four East African field sites, and will allow direct comparison of mosquito bionomics, the mode of action of residual insecticides, and the efficacy of malaria-control tools such as LLIN between those sites.

Dynamics of an eruptive herbivore in a novel habitat: consequences of climate-induced range expansion by the mountain pine beetle

Allan Carroll, Katherine Bleiker, Gregory Smith

Natural Resources Canada, Canadian Forest Service, Victoria, BC, Canada

For insect herbivores, the most commonly predicted/measured response to a warming environment is a latitudinal and elevational shift in their geographic range. However, due to their relatively high mobility, the rate of change in the distribution of herbivorous insects is expected to exceed that of virtually all other organisms in their original habitat . Thus, in many cases the short-term response to climate change by herbivorous insects will comprise habitat invasion. As a result of novel trophic interactions in new habitats the dynamics of an insect herbivore will likely differ from that associated with the originating habitat. Therefore, reliable predictions of the potential impacts of climate-induced range shifts by herbivorous insects are precluded. Using the recent expansion of the mountain pine beetle (*Dendroctonus ponderosae* Hopkins) across the northern Rocky Mountains in North America as a case study, this paper will examine the dynamics of an eruptive forest herbivore in novel habitats and assess the potential for continued range expansion.

Winners and losers in a transformed landscape: butterfly diversity in remnant Afrotropical forests.

Janice Bossart

Southeastern Louisiana University, Hammond, Louisiana, United States

In Ghana, West Africa, forest destruction has been pervasive. Existing forest cover is estimated to constitute only 15-25% of its original extent and what remains is highly fragmented and isolated. In 2001, I initiated systematic surveys of five small sacred forest groves and two larger forest reserves in the Ashanti Region of Ghana to investigate the impact of forest fragmentation on forest fruit-feeding butterfly species. Two to three, edge-to-interior transects were established in each forest and sampled regularly over a two year period (June 2001- July 2002 and August 2005 – May 2006). Sites were sampled from 27-58 times, resulting in ~16,000 specimens from more than 120 species. The largest forest reserve supported the highest diversity, although combined diversity across sacred groves was comparable to that of a much larger reserve. Smaller communities were also found to be nested subsets of larger communities, indicating that species loss from forest patches is non random. Although there were notable exceptions, species trapped only in the forest reserves were generally those associated with high quality forest, whereas those trapped only in the sacred groves were generally those tolerant of forest degradation. Although forest edges were found to significantly impact butterfly community diversity, species considered vulnerable to forest degradation were notably not restricted to forest interior habitat. Analysis of species' abundance patterns across fragments established that the *Bebearia*, *Euriphene*, and *Euphaedra* will be the biggest losers in terms of species persistence versus extinction in this fragmented landscape.

Mid-Southern USA regional evaluation of insecticide seed treatments on soybeans

Kelly Tindall[1], Angus Catchot[2], Scott Stewart[3], Roger Leonard[4], Gus Lorenz[5]

[1]University of Missouri, Portageville, MO, United States, [2]Mississippi State University, Mississippi State, MS, United States, [3]University of Tennessee, Jackson, TN, United States, [4]Louisiana State University, AgCenter, Winnsboro, LA, United States, [5]University of Arkansas, Lonoke, AR, United States

The adoption rate of seed treatments has increased over the last several years. In soybeans, the most common treatments are Cruiser and Gaucho. Treatments costs range from $6-8 per acre depending upon the product and rate used, and they are effective in controlling/suppressing some early season insect pests (i.e., thrips, bean leaf beetle, three cornered alfalfa hopper, grape colaspis, white grubs, wireworms, seedcorn maggot and others). Data have shown that the seed treatments at least pay for themselves 71-85% of the time and yields can be increased as much as 10+ bushels per acre but average around a three bushel per acre. What is not understood is the point at which profits result from seed treatment. Therefore, a regional effort involving five Mid-Southern states was made to investigate planting dates and tillage practices to determine if there are systems that are more prone to have yield increases as opposed to 'breaking even'.

Juvenile hormone and sexual maturation in migratory and non migratory populations of the true armyworm, *Pseudaletia unipuncta*

Jeremy McNeil

The University of Western Ontario, London, ON, Canada

Sexual maturation and migratory flight both require juvenile hormone (JH), yet most insects that undertake migration in response to habitat deterioration do so as sexually immature adults. To explain this apparent paradox, Rankin and Riddiford proposed that the levels of JH production, and the subsequent behavioural responses observed, would be modulated by external cues that provided reliable information with respect to habitat quality. Under conditions indicative of habitat decline (e.g. short days, low temperature) JH titres would remain low, resulting in the expression of migratory flight behaviour by sexually immature individauals. In contrast, conditions reflecting good habitat quality (e.g. long days. warm temperatures) would result in high JH titres leading to the onset of reproduction in the current habitat. Studies on a number of different migratory species have provided support for the general model, with a number of variations being observed that related to species specific life history traits.

We have been using the true armyworm, *Pseudaletia unipuncta* (Lepidoptera: Noctuidae) as a model species to investigate the underlying physiology related to both sexual maturation (including pheromone production) and seasonal migration. In recent years we have been carrying out studies, comparing migratory populations from North America with non-migratory ones found in the Azores, a volcanic archipelago in the Atlantic Ocean. There are significant differences in morphology and reproductive output (females from the Azores being smaller but with a higher total fecundity). Furthermore, there are marked differences in the temporal patterns of sexual maturation, as well as the rates of JH biosynthesis and JH haemolymph titres, when reared under identical temperature and photoperiod conditions . Results will be presented and the implications related to the costs associated with migration and reproductive success will be discussed.

Floral rewards for bats subsidize pollination, herbivory and biodiversity in an aridlands hawkmoth community

Jeffrey Riffell, Ruben Alarcon, Leif Abrell, Goggy Davidowitz, Judith Bronstein, John Hildebrand

University of Arizona, Tucson, Arizona, United States

Hawkmoths (Sphingidae, Lepidoptera) are nocturnal pollinators that typically visit fragrant, showy flowers with concealed nectar. In the arid grasslands and foothills of southern Arizona, USA, the presence of adult moths and the flowering of hawkmoth-adapted plants only partially coincide; furthermore, hawkmoth flowers are relatively scarce for the large hawkmoth populations. Analysis of pollen removed from the probosces of >500 individual hawkmoths attracted to blacklights at the base of the Santa Rita Mountains over two years indicate that 8 of 11 hawkmoth species heavily visit *Agave palmeri* (Agavaceae), a common species morphologically and chemically adapted for bat pollination. Behavioral experiments with both naïve and experienced *Manduca sexta* reveal that these hawkmoths learn to feed from *Agave* through olfactory conditioning, but readily switch to the hawkmoth-adapted flowers of *Datura wrightii* (Solanaceae) based on an innate odor preference. We show that these species emit similar concentrations of floral odor, but *Agave* provides six times more chemical energy per flower and scent composition, nectar chemistry, and flower reflectance are distinct. Pollen-load data indicate that the shift to the *Datura* occurs when this species is at its peak bloom. *Datura wrightii* is *M. sexta*'s nearly exclusive host plant in these habitats; *M. sexta* is simultaneously *D. wrightii*'s primary pollinator. Our results suggest that *Agave* populations subsidize both the mutualistic and antagonistic components of the *Datura/ Manduca* interaction, and are likely facilitating the persistence of the hawkmoth community as a whole in this desert grassland habitat.

Fire ants and native ants: A cautionary tale

Walter R. Tschinkel

Florida State University, Tallahassee, FL, United States

Community ecologists, especially those working on ants, have long believed that interspecific competition structures communities. Consequently, for half a century the dogma has been that the Argentinean fire ant, *Solenopsis invicta*, suppresses populations of native ants in its adopted home in North America (where it arrived around 1935). This belief was not based on experiments, but on negative correlations between fire ant populations and native ant populations, baiting studies and relative abundance data. Careful reanalysis of the data suggested that native ant populations were suppressed by habitat disturbance, whereas *S. invicta*, a disturbed-habitat specialist, was independently favored by the same disturbance. We removed *S. invicta* from pastures for 3 years, and found that removal had no effect on the abundance or species richness of other ants, suggesting this community is not structured by competition. We also subjected plots in a habitat normally devoid of *S. invicta* to disturbance (mowing, plowing, control), and combined these treatments with the transplantation of mature fire ant colonies and appropriate controls. Plowing greatly reduced native ant populations, but mowing had little effect. Transplantation of mature fire ant colonies, although very successful, had little effect on native ants. Therefore, even in this native habitat, the ant community is structured by the habitat rather than by competition, and disturbance is the cause of native ant suppression. We emphasize that competition cannot be inferred without experimentation, a caution for community ecologists. The degree to which our findings apply to other ant communities remains to be tested.

New technologies for tackling major challenges in border diagnostics.

Karen Armstrong[1], Shelley Ball[1], Alan Flynn[2]

[1]Lincoln University, Canterbury, New Zealand, [2]MAF Biosecurity New Zealand, Auckland, New Zealand

The accurate identification of exotic insect species detected at the border provides fundamental information on which to base subsequent biosecurity decisions; it is a critical component of any front-line defence against the potentially harmful invasion into economic or native ecosystems. However for many taxa there are barriers to their effective identification by traditional morphological means. This places a burden on the biosecurity system, and can result in conservative actions being taken with potentially social, economic or trading-partner consequences. Diagnostic barriers may be taxonomic in nature, such as the unavailability of appropriate expertise, or of keys for distinguishing immature life stages, closely related siblings or strains. Non-taxonomic barriers may reflect difficulties in confirming the vector status within a species or the viability of sessile forms, or confirming the geographic origin of an interception following an eradication to verify it as a new incursion rather than evidence of a remnant population. Research into new technologies that may alleviate each of these barriers is underway. An example is drawn from the development and implementation of DNA barcodes for species identification. Originally developed for high risk dipteran and lepidopteran species, subsequent research aims to build the DNA barcode dataset as a predictive tool, targeting 'taxonomic gaps' associated with actual border-intercepted material. It has also been used in an integrative taxonomy approach to resolve systematic complications revealed during such research. This method is now proposed as the basis of a sustainable diagnostic resource, to supplement both traditional and novel morphological technologies used at the border in the coming decades.

Does atmospheric oxygen limit insect size? Effects of oxygen on insect growth and tracheal morphology

Jon Harrison, C Jaco Klok, John VandenBrooks, Alex Kaiser, Jake Socha, Wah-Keat Lee

[1]Arizona State University, Tempe, Arizona, United States, [2]Midwestern University, Glendale, Arizona, United States, [3]Argonne National Laboratory, Argonne, IL, United States

Atmospheric oxygen has varied through the earth's history, and can vary in availability in different habitats. Rearing insects in atmospheres with different oxygen levels has revealed substantial diversity in responses among species; however, most insects are smaller when reared in hypoxic conditions. Moderate hyperoxia increases the size of some species, but extreme hyperoxia reduces size. In fruitflies, all life stages are sensitive to oxygen. The mechanism of oxygen effects on size are unclear and may be diverse, but are often at least partially mediated by affects on cell size. Multigenerational studies with fruitflies indicate that these insects evolve larger size in higher oxygen levels. However, when fruitflies are selected for large size, body sizes were similar whether the atmospheric oxygen level was 21% or 40% oxygen. Fruitflies selected for large size in 10% were smaller than those in higher oxygen levels, indicating that hypoxia does restrict body size in flies; when these flies are returned to 21%, their body sizes are similar to those raised at higher oxygen levels, confirming the constraining, plastic effect of hypoxia on size. Dimensions of larval longitudinal and adult leg tracheae are inverse to rearing oxygen levels, but adult abdominal and pupal "snorkel" tracheae do not seem to respond to atmospheric oxygen levels in flies. Comparative studies with beetles and ontogenetic studies with grasshoppers indicate that larger species have proportionally larger tracheae, especially in the legs. This trend could limit insect size via spatial limitations on tracheae or other tissues. Thus multiple lines of evidence suggest that atmospheric oxygen and tracheal oxygen delivery are important for determining the size of insects, and these experiments generally support the hypothesis that Paleozoic hyperoxia could have enabled insect gigantism. Supported by NSF IBN 0419704 to JFH.

Beauveria bassiana – lessons learnt regarding a fungal insecticide in a commercial environment.

Sias Leipoldt

Biological Control Products SA (Pty) Ltd., Pinetown, KwaZulu Natal, South Africa

Biological pest control makes use of the natural ability of certain organisms to parasitize and destroy others. A major advantage of this approach is the minimal effect of these agents on the environment as a result of their limited host range. In addition, the absence of mammalian toxicity, the non-invasive and non-systemic nature of the biological agents and the lack of necessity for any withholding period, allow their use on crops for immediate sale and also on crops intended for sale to regions and countries where pesticide residue regulations are very strict.

Beauveria bassiana is a soilborne fungus and is found worldwide. Efficacy does vary between different *Beauveria bassiana* strains, but this fungus is effective against a wide range of target pests. Although the BCP commercialised strain has not been registered against every target organism, it has been found effective against the following in laboratory and field trials. The list includes various ant species, army worm, African bollworm, various aphid species, crickets, cockroaches, diamond back moth, fleas, locusts, mealy bug, sugar cane borer, thrips, ticks, termites, weevils and white fly.

If used correctly, this organism can be highly effective in reducing a variety of target pests. This presentation will focus on the mode of action of *Beauveria bassiana*, how it should be applied and what to expect.

Initiation and scheduling of an innate behavioral sequence by central peptidergic ensembles

Young-Joon Kim[1], Dusan Zitnan[2], C. Giovanni Galizia[3], Kook-Ho Cho[2], Michael Adams[1]

[1]University of California, Riverside, Riverside, CA 92521, United States, [2]Slovak Academy of Sciences, Bratislava, Slovakia, [3]University of Konstanz, Konstanz, Germany

Introduction: Molting in insects is terminated by shedding of the old cuticle. This is accomplished by performance of the ecdysis behavioral sequence, an innate behavior under the control of steroid and peptide hormones. Sequential behaviors consisting of pre-ecdysis, ecdysis, and post-ecdysis are initiated and scheduled by neuropeptide signaling cascades in the CNS under the control of ecdysis triggering hormones (ETHs).

Methods: Primary neural targets of ETH in the CNS are identified by expression of ETH receptor (ETHR) transcripts. In *Drosophila*, ETHR neuron activity is monitored by calcium imaging. Necessary roles of these neurons are examined by cell ablation, overexpression of ETHR, or RNA silencing of ETHR.

Results: ETHR is expressed predominantly in "peptidergic ensembles", groups of neurons that release FMRFamides, eclosion hormone, kinins, CCAP, MIPs, and bursicon both centrally and peripherally. FMRFamide neurons are activated during all phases of the behavioral sequence. Eclosion hormone, CCAP and CCAP/MIP neurons become active prior to ecdysis, and activity of CCAP/MIP/bursicon neurons coincides with post-ecdysis. Ablation of kinin neurons causes variable defects in pre-ecdysis behaviors. Ablation of subsets of CCAP/MIP/bursicon neurons leads to defects in ecdysis and postecdysis. Overexpression or knockdown of ETH receptors alters scheduling of behavioral steps. For instance, overexpression of ETHR in CCAP/MIP neurons accelerates ecdysis onset, while ETHR knockdown in the same neurons delays ecdysis onset.

Conclusions: These findings offer insights into how innate behaviors are assembled and executed by central peptidergic ensembles. Supported by NIH grant GM067310.

Frequent habitat changes in Saprininae as revealed from a cladistic analysis.

Tomas Lackner

Hokkaido University, Sapporo/Hokkaido, Japan

Saprininae (Coleoptera: Histeridae), with approximately 700 species worldwide, are the second largest subfamily (after Histerinae) of the beetle family Histeridae. In the Palaearctic region, Saprininae comprises about 34 genera and subgenera, members of which are mostly found on carrion and in dung, where they prey on the larvae of other arthropods, especially cyclorrhapan flies. However, many genera are highly specialized and are inquilinous in the nests of birds, or in the burrows of rodents or even ants.

After scoring 68 morphological characters for 33 ingroup and 3 outgroup taxa, we performed a phylogenetic analysis and obtained surprising results. The following morphological characters proved to be phylogenetically most informative:

1) Male genitalia

2) Mouthparts

3) Reichardt's organ (specialized sensory organ of antenna)

Although our study dealt only with Palaearctic genera and subgenera, given the present phylogenetic hypothesis, it is tempting to make several inferences on the evolution of the subfamily Saprininae. It seems likely that Saprininae are the sister group to Dendrophilinae, whose members are likewise mostly inquilinous. Inquilinous taxa within Saprininae comprise the most basal 'grade,' suggesting that Saprininae evolved inside the nests of warm-blooded animals and have been a part of this biocenosis for a very long time. They probably subsequently entered open spaces, where they found ample food, speciated, and adapted to many stressful habitats such as deserts. This scenario contrasts with the most parsimonious evolutionary pathway, which should go the other way – from generalized to specialized. Unfortunately, there is little information on the life history, ecology, and distribution of many taxa. Further research on the subfamily worldwide will likely bring many interesting results and remains a high priority in my research.

Clearing the clutter: a life table analysis of the strain of *Anagyrus* sp. (near) *pseudococci* (Hymenoptera: Encyrtidae) found in vineyards of the Western Cape province, South African, and subsequent successful taxonomic specimen identification

Martin Wohlfarter[1], Jeanne De Waal[1], Carel Van Heerden[2], Pia Addison[1]

[1]University of Stellenbosch Deparment of ConsEnt, Stellenbosch, South Africa, [2]University of Stellenbosch, Department of Genetics, Stellenbosch, South Africa

Introduction: The potential of using the polyphagous parasitoid *Anagyrus pseudococci* (Girault) for the biological control of the vine mealybug, *Planococcus ficus* (Signoret) in South African vineyards is dependant on several factors. The objective of this study was to investigate the influence of temperature on the developmental time and fecundity of the strain *A. pseudococci* found in local vineyards and to furthermore ensure the correct taxonomic identification of the biological control agent, as these factors are essential to the success of the biological control programme.

Methods: A life table analysis of the wild type *Anagyrus* sp. isolated from vineyards throughout the Western Cape, South Africa, was carried out at five temperature intervals, 14, 21, 27, 32 and 34°C, with relative humidity below 60%. Specimens from this laboratory colony were identified to species level using both morphological keys and molecular methods.

Results: Laboratory temperature-trials indicated that the strain of *A. pseudococci* found in vineyards in South Africa performed differently regarding developmental time and fecundity when compared to similar work done in California using the same species, which raised the issue of species identification. Morphologically the wild type specimens were identified as *Anagyrus* sp. (near) *pseudococci* and molecular identification show that the sequence obtained match 99% with the sequence of *Anagyrus* sp. nr. *pseudococci* from Italy (GenBank library accession number: DQ667740.1).

Conclusion: Life tables aid in determining the optimum time of *Anagyrus* sp (near) *pseudococci* mass field release. The need for a survey of the grapevine growing areas is however paramount to surpass the discrepancies of historic identification of *Anagyrus* sp. in South Africa.

A microarray platform for genome-wide expression studies in the spruce budworm, *Choristoneura fumiferana*

Dayu Zhang[1], Susan Bowman[1], Qili Feng[3], Tim Ladd[1], Cailing Liu[1], Peter Krell[2], Basil Arif[1], Daniel Doucet[1]

[1]Great Lakes Forestry Centre, Sault Ste. Marie, Ontario, Canada, [2]University of Guelph, Guelph, Ontario, Canada, [3]South China Normal University, Guangzhou, China

Microarrays, also known as DNA chips, are extremely useful tools for the study of gene expression in many organisms. Owing to the decreasing costs of gene sequencing, DNA synthesis and other associated costs, microarrays have become progressively more accessible to investigate gene expression in insect species not belonging to "model systems" (*e.g. Drosophila*, *Bombyx*). We have constructed a microarray for the moth *Choristoneura fumiferana* (the spruce budworm, sbw), an important pest of fir and spruce in North America. The array contains over 3000 unique sbw DNA sequences, obtained by spotting PCR products from a sbw EST clone collection. The sbw array has been used to support two projects: i) an analysis of gene expression profiles in larvae molting from 5th to 6th instar stages and ii) a study of the impact of infection by a naturally-occuring and a recombinant baculovirus on the sbw transcriptome.

Results from the first project will be presented. Genes represented by over 300 ESTs showed at least three-fold difference in the expression level between molting and intermolting larvae. These genes are involved in several biological processes such as cuticle synthesis and degradation, chitin synthesis and degradation, cuticle pigmentation, myogenesis, transcription and translation regulation and catabolic pathways. Results from the second study indicate that virus infection kinetics affect the expression of several uncharacterized genes. These might be involved in cellular stress reaction and/or a redirection of vital cellular processes benefiting virus replication and propagation.

Ecology of insect hosts and entomopathogens

Ann Hajek

Cornell University, Ithaca, NY York, United States

There are many components of the host/pathogen system that act together to support pathogen populations and these interactions are especially critical to obligate pathogens. Pathogens are successfully transmitted to new hosts in a number of different ways, must grow within hosts and reproduce and also survive in the environment when hosts are not present or conditions are unfavorable. We know that pathogens, being microorganisms, can be very sensitive to abiotic conditions, both when free-living as well as when inside of hosts. Biotic conditions can also influence the success of pathogens; hosts can behaviourally defend themselves from pathogens although, alternatively, some pathogens can change host behavior to enhance transmission. Although relatively few studies of community-level effects on insect pathogens have been conducted, we know that some pathogens are influenced by the plants that herbivorous hosts eat. When conditions are excellent for pathogens, infection prevalence can increase quickly and epizootics will develop. Understanding the conditions under which prevalence of infection can increase to create epizootics has been central to studies of the epizootiology of insect diseases. Today, we are also exploring the spatial aspects of epizootiology, asking to what extent pathogens are able to recolonize areas where they have not been able to persist.

Sterile insects for the control of perennial crop insect pests in a time of global change

Marc Vreysen, Jorge Hendrichs, Rui Cardoso Pereira

Insect Pest Control Sub-Programme, Joint FAO/IAEA Programme of Nuclear Techniques in Food and Agriculture, Department of Nuclear Applications, IAEA, Vienna, Austria

Concerns about pesticide residues in food commodities are increasing, as well as resistance to pesticides, contamination of the environment and outbreaks of secondary pests. The use of the species-specific sterile insect technique (SIT), applied as part of an area-wide integrated pest management approach (AW-IPM), is gradually increasing to help address the demands for efficient, more specific, and cleaner pest control methods, and to facilitate international trade by the establishment of low prevalence and pest free areas. In addition, with international trade and travel expanding rapidly, the risk of exotic species invading new territories is increasing manifold. The SIT is a control tactic well suited to deal with incursions of invasive species when the infested areas are still small and the pest population density is still low. The release of sterile insects is currently being used to eradicate incursions of the invasive painted apple moth in New Zealand, to contain the spread of the cactus moth in the USA, and to prevent outbreaks of the Mediterranean fruit fly in California and Florida. The SIT package is also being developed against major pests, which have not invaded new territories but pose serious threats in case of an accidental introduction, e.g. the false codling moth. A brief overview of ongoing SIT activities against pests of perennial crops will be presented, as well as of new technological developments in this area.

Feeding performance of two lepidopteran herbivores on chitinase transgenic birches (*Betula pendula*)

Liisa Vihervuori, Päivi Lyytikäinen-Saarenmaa, Hanna-Leena Pasonen

[1]University of Helsinki, Department of Forest Ecology, Helsinki, Finland, [2]University of Helsinki, Department of Applied Biology, Helsinki, Finland

Introduction: A previous field trial with the chitinase transgenic Silver birch (*Betula pendula*) was continued by insect feeding tests in laboratory conditions. The aim was to provide new information on the interactions between GM-birch and insect herbivores. The additional aim was to study the effect of the artificial herbivory on the performance of the larvae and on the regrowth ability of GM-trees compared to the control trees.

Methods: The studies were conducted in 2003 and 2007. Transgenic birches carrying a sugar beet chitinase gene were used. Birches from the field trial and greenhouse grown trees were used. Trees were grouped according to their chitinase expression levels (high, intermediate, low). Insect feeding tests were conducted with larvae of *Orgyia antiqua* and *Phalera bucephala*. Larvae groups consumed birch leaves during one week. The larval performance was measured as relative growth rate (RGR) and efficiency of conversation of ingested food (ECI).

Results: The growth rate of the larvae on transgenic leaves decreased compared to those on control leaves. The amount of consumed food and the proportion of digested food was lowest within the group on leaves of high transgene expression. Expression level affected amount of consumed and digested food. However, this was not clear. No impact of artificial insect herbivory on the performance of the larvae or on the regrowth of the trees was observed.

Conclusions: Based to these results, the chitinase transgene may have negative effects on herbivorous lepidopterans. The present study provides basic knowledge about the interaction of GM-trees with defoliators.

Plant litter-detritivore interactions: links between the green and the brown part of ecosystems?

Stephan Hattenschwiler

CNRS, Montpellier, France

Introduction: Plant leaf chemistry is a key factor in plant-insect interactions. The same plant material, but chemically modified during leaf senescence, provides the food and energy source for soil arthropods. However, litter chemistry control over macro invertebrates is poorly studied, despite its potential far ranging consequences for litter breakdown rates and nutrient cycling, which in turn has important feedback effects on plant growth.

Methods: Using data from a series of different experiments from mainly tropical and Mediterranean forest ecosystems, the following questions are explored: (1) how does food quality differ between green leaves and leaf litter, (2) how do litter feeding animals influence mass loss of litter mixtures, and (3) to what degree are the “herbivore-plant” and the “detritivore-litter” systems comparable and how might they be linked.

Results: Data from many tropical forest tree species show that C:N:P stoichiometry changes drastically in leaf litter compared to green foliage, but that other components of tissue quality such as lignin and polyphenols remain quite similar. Litter-feeding animals are selective in food choice and interact with litter diversity in a way that major ecosystem processes, such as carbon and nutrient dynamics are influenced.

Conclusions: The herbivore-plant and the detritivore-litter systems are in so far comparable that the general nutritional constraints for the animals, and plant tissue quality control are similar. Litter quality control over detritivores and more generally, over decomposition, suggests the possibility that certain plant traits might be selected for their “afterlife” effects and their feedback on plant performance.

Probing behaviour of *Diuraphis noxia* on near-isogenic wheat lines with resistance ex PI 137739 and PI 262660.

Vicki Tolmay[1], Freddy Tjallingii[2], Charl Van Deventer[3]

[1]ARC-Small Grain Institute, Bethlehem, Free State, South Africa, [2]Wageningen Agricultural University, Wageningen, Netherlands, [3]University of the Free State, Bloemfontein, Free State, South Africa

Introduction: In the summer rainfall region of South Africa the most damaging pest of cultivated wheat , *Triticum aestivum* , is the Russian wheat aphid (RWA), *Diuraphis noxia.*

Methods: The DC EPG technique was used to characterise probing behaviour of RWA on near-isogenic, susceptible and resistant South Africa wheat genotypes.

Results: Distinct differences exist between the two susceptible genotypes Betta and Tugela in terms of the number of path periods and the time needed to attain sustained phloem ingestion. The influence of resistance in 1684/Tugela *ex* SA 1684 [PI 137739 (Dn1)] and 2199/Tugela *ex* SA 2199 [PI 262660 (Dn2)] on the probing behaviour of *D. noxia* is different. While resistance in 1684/Tugela was reflected in a lower proportion of time spent in phloem ingestion after attaining sustained phloem feeding, the resistance in 2199/Tugela was associated with a high number of probes shorter than three minutes prior to the first phloem activity denoting some host recognition or epidermal factor involved in the resistance of this genotype which was not evident in 1684/Tugela. In addition resistance in 2199/Tugela was associated with a significantly higher percentage of time spent in phloem ingestion after the first sustained phloem feeding had been attained. The mechanisms of resistance for these genotypes as reported in a previous study are consistent with the data from this investigation.

Conclusions: EPG data collected for *D. noxia* on two susceptible and two resistant host genotypes reveals that the interaction between the aphid and each host genotype is unique.

Collaborative Screening for Russian wheat aphid (*Diuraphis noxia*) resistance

Vicki Tolmay[1], Gary Puturka[2], Cheryl Baker[2], Robbie Lindeque[1]

[1]ARC-Small Grain Institute, Bethlehem, Free State, South Africa, [2]United States Department of Agriculture - Agricultural Research Service, Stillwater, Oklahoma, United States

Introduction: Russian wheat aphid (RWA) is the most damaging pest of wheat in the summer rainfall production region of South Africa. It also occurs in the USA where it causes severe crop losses in the Western Great Plains wheat production areas but the biotypes that occur in the USA differ from those found in South Africa. Host plant resistance (HPR) has been found to be a viable and economically sound approach to controlling this pest. South African germplasm was screened in the USA with two RWA biotypes to proactively identify lines with effective resistance against biotypes that might occur in South Africa in future.

Methods: Using a split plot design with three replicates, seedlings of 288 lines were screened against USA biotypes RWA1 and RWA2 using a 1-10 (resistant – susceptible) damage rating scale, in the greenhouse. Resistant seedlings were selected and grown to maturity.

Results: Thirty percent of the lines were susceptible to the USA biotypes. Of the 200 resistant lines, 134 lines potentially contain resistance from more than one resistance donor accession and 74 showed resistance to both biotypes tested. In total 647 single plants were selected with 174 and 473 resistant to RWA1 and RWA2 respectively.

Conclusions: Collaborative screening, exploiting different RWA biotypes from different regions in the world, proved effective in identifying resistant lines against potential biotypes, thus strengthening HPR breeding programmes.

What can social parasites tell us about cooperation and conflict in insect societies?

David Nash

University of Copenhagen, Copenhagen, Denmark

Social parasites exploit the resources and organization of social insect colonies. There are at least two fundamentally different routes to social parasitism: Social parasites can arise via exploitation of conspecific (or congeneric) social insects, or distantly-related organisms can evolve strategies to exploit social insect colonies. Both types of social parasitism can provide useful insights into cooperation and conflict within insect societies. Closely related social parasites are essentially the outcome of the breakdown of cooperation and the realisation of conflict, and the unique features of their evolution can provide information on how cooperation is normally maintained in insect societies. Distantly related social parasites must evolve de novo exploitation strategies without the benefit of shared ancestry of social traits with their hosts, so that their evolution can be used to examine how cooperation can be exploited independent of these traits. In this presentation I will examine both types of social parasitism in detail, and provide some examples of the insights they can bring to the study of cooperation and conflict.

Towards a gene drive system in *Anopheles* mosquitoes using homing endonuclease genes

Philippos Papathanos, Nikolai Windbichler, Andrea Crisanti

Imperial College, London, United Kingdom

Mosquito species of the *Anopheles gambiae* complex represent the major vectors of human malaria and they pose an enormous burden on global health. Molecular advances have made it possible to express genes that can block the transmission of *Plasmodium* in model systems. However, the translation of such achievements in suitable control measures still represents a major scientific and technical challenge. A mechanism must be developed to spread the desired genetic modification from a few laboratory-reared mosquitoes to a large fraction of the vector population. Homing endonuclease genes (HEGs) are selfish genes that promote their movement from one allele to the other by creating a double-strand break at a specific target site in an allele lacking the HEG. Homologous DNA repair then copies the HEG to the cut chromosome. The observation that HEGs can be engineered to cleave novel DNA sequences offers a multitude of opportunities to utilize these elements for mosquito control. We have demonstrated that naturally-occurring homing endonucleases, including the well - characterised I-*Sce*I*,* are active in *Anopheles gambiae* cells and embryos leading to target specific cleavage followed by HEG-induced homologous repair. We have characterized and isolated a number of promoter elements suitable for driving pre-meiotic expression of HEGs in the germline of *Anopheles gambiae*. We have generated reporter constructs and transgenic mosquito lines using those novel putative promoter elements to confirm their ability to direct expression early in the development of the germline. We have also completed the construction of a reporter system to determine HEG homing and activity rates in transgenic mosquitoes. The output of this system is a measurement of the functional activity of I-*Sce*I, expressed during spermatogenesis, on a modified eGFP reporter gene, harbouring the I-*Sce*I recognition sequence. HEG activity is scored as a loss of neuron-specific eGFP expression. Transgenic lines harbouring these reporter constructs using the novel promoter elements are being generated. Evaluation of HEG activity in this reporter system should allow us to determine the feasibility of invasive HEG constructs in mosquito populations.

Phylogenetic approaches to delimit baculovirus species based on single gene and whole genome data

Elisabeth Herniou[1], Timothy Barraclough[1], Jennifer Cory[2]

[1]Division of Biology, Imperial College London, Ascot, United Kingdom, [2]Department of Biology, Algoma University College, Sault Ste. Marie, Canada

Baculoviruses are among the best known insect pathogens and yet we know little of their diversity. The nomenclature of baculoviruses, by using the juxtaposition of host name and virus morphology, has long had the advantage of being simple, but it introduces a lot of confusion for taxonomic purposes. The wealth of available baculovirus sequences provides an excellent framework to test a new phylogenetic method that delimits clusters of individual sequences into independently evolving groups or species. We have assembled 3 datasets: 2 based on single genes, 293 *polyhedrin* and 221 *lef-8* sequences, and one based on 43 complete genomes. We use molecular phylogenies to reveal the interrelationships of individual viral isolates. In addition, the branching patterns within trees give further information on the evolution of the viruses, which is reflected in part by changes in branching rates during the history of the group. We have developed a new method that detects the transition from between-species to within-population branching in phylogenies. One of the benefits of this approach is the definition of groups of individuals with shared evolutionary histories. These clusters of isolates can be interpreted as species groups. This method provides an objective way to delimit species without *a priori* assumptions of host use. By comparing the 3 types of datasets, we aim to validate the method for baculoviruses and determine the most appropriate data to use to describe new baculovirus isolates. This method has also been successfully tested on a number of invertebrate and plant taxa.

Variation in resistance in willow against a gall-forming cecidomyiid

Stig Larsson, Solveig Hoglund

Swedish University of Agricultural Sciences, Uppsala, Sweden

Large genotypic variation in resistance against the gall midge *Dasineura marginemtorquens* is found in *Salix viminalis*. On resistant genotypes, neonate larvae die within 48 hours after egg hatch (no gall induction). Resistance is associated with rapid cell death at the site of attack, production of phenolic compounds, and induction of hydrogen peroxide – events frequently linked with the syndrome of hypersensitivity response (HR). However, certain resistant willow genotypes do not show any sign of HR (no necrotic spots or production of hydrogen peroxide), and larval mortality is still as high as on genotypes expressing typical HR symptoms. The complexity in the expression of HR in this system may have implications for many plant-insect interactions where HR is claimed to be the resistance factor. This and other apparent contradictions in the interaction between the willow and the gall midge will be discussed in the talk.

Trichromatic colour vision and alightment of a psyllid

Alan Urban

Rhodes University, Grahamstown, E. Cape, South Africa

Introduction: A study was made of the influence of colour on the locomotory responses of a 'yellow-sensitive' African psyllid, *Trioza erytreae* (Del Guercio) (Hemiptera: Triozidae).

Methods and results: Phototaxis of test populations of psyllids was measured by their rate of walking towards light emitted by a monochromator, the radiant flux of which was measured using a vacuum thermopile. Their phototactic action spectrum (against wavelength) was trimodal, with peaks in the yellow-green (YG) at wavelength ca. 550 nm, blue (B) ca. 450 nm, and ultraviolet (UV) ca. 350 nm. Rate of phototaxis was proportional to the logarithm of light intensity over 6 orders of magnitude, and was not influenced by bandwidth. In a very simple flight chamber incorporating a target of coloured light, YG and UV light each independently stimulated alightment, and their effects were approximately additive. Different response threshold light intensities indicated that the YG and UV receptor systems were separate. Blue light alone did not stimulate alightment, and was strongly alightment-inhibitory in combination either with YG or with UV light. On the basis of these physiological/behavioural findings, a formula was derived for describing/predicting the apparent manner of alightment-determining integration of the spectral reflectance of a coloured surface. The relative alightment stimulus (RAS) of a coloured surface was given by RAS = YG + UV – B, where the colour terms refer to the 'receptor'-sensitivity-weighted logarithm of the quantum flux from the target in the wavebands: YG = 480-670 nm, UV = 300-390 nm, B = 390-480 nm, minus the logarithm of the relevant colour threshold. The frequency of alightment on some series of differently coloured surfaces correlated slightly better and more consistently with the new formula than with previously available colour parameters.

Conclusions: The relative frequency with which this psyllid alights, is the result of neural integration of stimuli received by its three colour receptor systems from the spectral reflectance of differently coloured surfaces. Indications were obtained that a new alightment prediction formula developed here may be applicable to various other 'homopteran' pests, such as aphids.

Trichromatic colour vision and alightment of a psyllid

Alan Urban

Rhodes University, Grahamstown, E. Cape, South Africa

Introduction: A study was made of the influence of colour on the locomotory responses of a 'yellow-sensitive' African psyllid, Trioza erytreae (Del Guercio) (Hemiptera: Triozidae).

Methods and results: Phototaxis of test populations of psyllids was measured by their rate of walking towards light emitted by a monochromator, the radiant flux of which was measured using a vacuum thermopile. Their phototactic action spectrum (against wavelength) was trimodal, with peaks in the yellow-green (YG) at wavelength ca. 550 nm, blue (B) ca. 450 nm, and ultraviolet (UV) ca. 350 nm. Blue light alone did not stimulate alightment, and was strongly alightment-inhibitory in combination either with YG or with UV light. On the basis of these physiological/behavioural findings, a formula was derived for describing/predicting the apparent manner of alightment-determining integration of the spectral reflectance of a coloured surface. The relative alightment stimulus (RAS) of a coloured surface was given by RAS = YG + UV – B, where the colour terms refer to the 'receptor'-sensitivity-weighted logarithm of the quantum flux from the target in the wavebands: YG = 480-670 nm, UV = 300-390 nm, B = 390-480 nm, minus the logarithm of the relevant colour threshold. The frequency of alightment on some series of differently coloured surfaces correlated slightly better and more consistently with the new formula than with previously available colour parameters.

Conclusions: The relative frequency with which this psyllid alights, is the result of neural integration of stimuli received by its three colour receptor systems from the spectral reflectance of differently coloured surfaces. Indications were obtained that a new alightment prediction formula developed here may be applicable to various other 'homopteran' pests, such as aphids.

Potential efficacy of a candidate agent, *Cornops aquaticum* Brüner (Orthoptera: Acrididae) for biological control of water hyacinth, *Eichhornia crassipes* Mart. Solms-Laubach (Pontederiaceae) as influenced by water nitrate and phosphate levels

Angela Bownes[1], Martin Hill[2], Marcus Byrne[3]

[1]Agricultural Research Council, Pretoria, South Africa, [2]Rhodes University, Grahamstown, South Africa, [3]University of the Witwatersrand, Johannesburg, South Africa

The South African biocontrol programme against water hyacinth has had variable success, despite having released more agents than any other country with water hyacinth biocontrol projects. Agent efficacy is assumed to be constrained under particular nutrient conditions prevailing in South Africa, therefore, additional agents were sought in South America, resulting in the introduction of the water hyacinth grasshopper, *Cornops aquaticum*, into quarantine as a potential agent. Pre-release testing to evaluate the potential of *C. aquaticum* to contribute to water hyacinth control as influenced by water nutrient levels showed that herbivory by the grasshoppers at a density of one per plant, significantly reduced ($F = 66.02$; $P = 0.0000$) biomass accumulation in plants grown in eutrophic, mesotrophic and oligotrophic nutrient conditions compared with control plants. Plant growth and reproductive parameters were also significantly reduced in the presence of grasshopper feeding, however a density of more than one per plant would be needed to significantly reduce infestations in eutrophied environments. Herbivory by *C. aquaticum* resulted in a 99% reduction in the plant's competitive ability, in high nutrient conditions. Fecundity as measured by the number of egg packets per female ($F = 26.06$; $P = 0.0000$) and number of eggs per egg packet ($F = 8.57$; $P = 0.0048$) were significantly affected by water nutrient levels and suggested that higher grasshopper population densities would be attained where plants are growing in eutrophic water bodies. These results suggest that the grasshopper will be a valuable introduction into the S.A. water hyacinth biocontrol programme.

Impacts of ants (Hymenoptera: Formicidae) on vine mealybug parasitoids *Anagyrus* sp. near *pseudococci* (Girault) and *Coccidoxenoides perminutus* (Timberlake) (Hymenoptera: Encyrtidae) under laboratory conditions.

Nyembezi Mgocheki, Pia Addison

Stellenbosch University, Stellenbosch, South Africa

Introduction: *A.* sp. near *pseudococci* and *C. perminutus* are potential parasitoids that can be used for the biological control of the vine mealybug, *Planococcus ficus* (Signoret), a key pest in vineyards. Three ant species, *Anoplolepis steingroeveri* (Forel), *Crematogaster peringueyi* Emery and *Linepithema humile* (Mayr) forage for honey-dew from the vine mealybug in vineyards and promote the latter's infestations to unacceptable levels.

Methods: Ants and parasitoids were allowed to forage on vine mealybug infested butternuts. The number of ants and parasitoids was recorded for a one minute period at ten minute intervals for two hours after which parasitoids were allowed to forage for 24 hours. Parasitoid mortality and vine mealybug parasitism by the two parasitoids were then recorded in the presence and absence of the three ant species. Data were analysed using a repeated measures generalized linear model (GEE) approach in SAS.

Results: The mean number of *C. peringueyi* on the mealybug-infested butternuts was significantly higher than that of *A.steingroeveri* and *L. humile* between time intervals and parasitoid species ($p<0.0001$ in all cases). The mean number of *C. perminutus* foraging on the mealybug infested butternut was significantly higher than that of A. sp.nr. *pseudococci* over the two hour period, between ant species, and time intervals ($p<0.0001$ in all cases). *C. peringueyi* and *L. humile* caused significantly higher mortality of both parasitoids ($p<0.001$) than *A. steingroeveri* during the 24-hour exposure period. *C. perminutus* parasitised significantly more vine mealybugs than *A.* sp. near *pseudococci* for all treatments ($p < 0.0001$).

Conclusion: Ant control is essential before release of parasitoids for optimum biological control of the vine mealybug in South Africa.

Co-radiation of gall-inducing scale insects and their myrtaceous hosts.

Lyn Cook[1], Penny Gullan[2]

[1]The University of Queensland, Brisbane, Qld, Australia, [2]University of California, Davis, CA, United States

There have been multiple origins of galling among Australian scale insects (Hemiptera: Coccoidea), with two large (> 100 species) radiations of gall-inducing scale insects on Myrtaceae. One of these, *Apiomorpha*, is restricted to *Eucalyptus* but the other clade comprises radiations on several speciose genera such as *Eucalyptus*, *Corymbia*, *Melaleuca* and *Leptospermum*. Phylogenies indicate that the gall-inducing scale insects form host-specific clades that might have co-radiated with their hosts. There has been some duplication of scale insects on the one host group (speciation in the scale without concomitant speciation in the host) but no host-switching between host plant genera despite broad co-distributions. The latter observation suggests strong evolutionary constraints that differ from those of many non-galling scale insects, in which host switching is inferred to have been considerably more frequent.

Pollen nutritional content: We know everything but what it means

T'ai Roulston

Blandy Experimental Farm/University of Virginia, Boyce, Virginia, United States

Pollen is the most nutrient-rich and complex of floral rewards, ranging widely in protein content (2.5 – 61%) and starch content (0 – 22%). It also varies in amino acid content, with some pollen lacking essential amino acids and making pollen mixing a requirement for complete nutrition. Despite an abundance of information on the range of nutrients in pollen, and their taxonomic distribution across plant species, there is little consensus regarding the evolutionary forces responsible for this distribution, the evolutionary forces responsible for pollen use patterns among pollen-consuming animals, or the ecological consequences for plant-animal interactions of having pollen that differs in nutritional characteristics.

It is clear that pollen traits can affect the digestibility of pollen and the development or performance of organisms that eat it, but experiments thus far carried out lead to little or no predictability for which pollens are actually consumed. Because pollen is a critical resource for many invertebrates, including many pollinators, our current lack of understanding of the evolutionary and ecological drivers for pollen traits reveals a broad lack of understanding of a major area of ecology. Experiments that intentionally vary pollen traits to test for preference and performance among floral visitors are difficult to carry out, but they are critical to move our understanding of pollen forward.

Dissection of community structure reveals neutrality among tropical arthropods

Farnon Ellwood, William Foster, Andrea Manica

University of Cambridge, Cambridge, United Kingdom

Species are distributed according to deterministic factors including habitat gradients, competitive advantages and dispersal ability. In species-rich habitats, dispersal is limited and competitive interactions are weaker, which generates stochastic forces, ecological equivalence and neutrality. Here we dissect the structure of local communities, separate the effects of deterministic factors, and reveal the existence of hidden stochastic forces. By performing manipulative experiments using arthropod decomposers in an epiphytic fern, we establish that species are distributed at random among local communities in undisturbed ferns in both the high and low canopy of a tropical forest in Borneo. However, when we introduced habitat gradients by pooling ferns from different heights, the structure of the communities became non-random. We also partitioned the deterministic effects of ecological succession to reveal the existence of stochastic forces at discrete points in time and space. Our results show that stochastic and deterministic forces coexist and the scale of the investigation determines which forces predominate. Our study illustrates the difficulties of analyzing community structure with an imperfect knowledge of the history of the assemblages, and underlines the importance of empirical data.

Variation in the susceptibility of *Helicoverpa armigera* larvae to different *Bacillus thuringiensis* Cry proteins

Hua Li, Gustav Bouwer

School of Molecular and Cell Biology, University of the Witwatersrand., Johannesburg, South Africa

Introduction: The susceptibility of the most important pest in South Africa, *Helicoverpa armigera* Hübner (Lepidoptera: Noctuidae), to *Bacillus thuringiensis* Cry proteins was investigated and a local benchmark for *B. thuringiensis* insecticidal Cry protein toxicity to this pest was established.

Methods: Cry proteins were produced in *Escherichia coli* BL21 cells that were transformed with plasmids containing one of the six Cry proteins used in the study. Bioassays were performed using whole BL21 cells, with the concentration of the Cry protein in the BL21 cells determined by Protein Analysis Chip (Biorad). The toxicity of each of the Cry proteins to *H. armigera* larvae was determined using two bioassay methods (surface treatment and droplet method). The median lethal dose (LD_{50}) and median effective dose (ED_{50}; weight stunting) for each of the proteins were determined.

Results: There was no significant difference in the toxicities of untransformed BL21 cells and water controls for neonates or second instars of *H. armigera*. Second instars were consistently less susceptible to Cry proteins than neonates. The relative toxicities of Cry proteins ranked differently between neonates and second instar larvae. On the basis of LD_{50} analysis, three Cry proteins were found to be highly toxic to both neonates and second instar larvae. Cry protein with the lowest LD_{50} also produced the lowest ED_{50} value.

Conclusions: This study highlighted the feasibility of using *E. coli* strains as Cry protein producing hosts in bioassay to establish an initial benchmark of Cry protein toxicity to *H. armigera*. The dose response for mortality and weight stunting demonstrated that both *H. armigera* neonates and second instar larvae were most sensitive to the same Cry protein.

The difficult transition from good science to good business – a decade in review of the key drivers and restrainers in BCP's quest to commercialise microbial control products

Ken Neethling

BCP, Durban, KZN, South Africa

Biological Control Products (Pty) Ltd was founded in 1995 with the vision of developing promising technology primarily for the agricultural industry, using bio-pesticides as a viable alternative to synthetic chemicals. Over a decade later, BCP has a stable of products catering to the needs of sustainable agriculture. A rise in prominence of organic, pesticide-free, fresh produce has helped fuel demand for these products.

However, many valuable lessons have been learnt along the way and good science has not always materialised into good business. By looking at a case study of arguably BCP's most successful bio-pesticide, Green Muscle™, as well as doing a post-mortem on some that didn't make it, some of these lessons are shared. These lessons include the pro's & cons of research collaborations, the hidden costs and benefits to obtaining registrations, the importance of the voice of the customer, the power of the brand and the place for science in the business model.

Infochemicals for the management of the banana weevil, *Cosmopoilites sordidus*

William Tinzaara, Eldad Karamura, Cliff Gold, Marcel Dicke, Arnold Van Huis, Caroline Nankinga

Bioversity International, Kampala, Uganda

Infochemicals (pheromones and kairomones) play an important role in the biology of many insect species. An understanding of their role in plant-herbivore-carnivore interactions can be used in the development of tools for the enhancement of environmentally benign alternatives to synthetic pesticides. Infochemicals may potentially be used for control of the banana weevil *Cosmopolites sordidus* (Germar) (Coleoptera: Curculionidae), which is a major pest of East African highland banana and plantains in most banana growing regions of the world. The weevil produces an aggregation pheromone that attracts both males and females. The pheromone has been identified and synthesized and is being recommended as an effective method of trapping and controlling the weevil. In this overview, the use of the aggregation pheromone and host-plant kairomones as components of an integrated management approach of the banana weevil is presented. The use of the aggregation pheromone in mass trapping, enhancement of the pheromone with host plant volatiles (kairomones), and integration of the pheromone with predators and entomopathogenic fungus, for the control of the banana weevil are discussed. Further research areas that can provide information for the development of an infochemical-based trapping system for the management of banana weevil are discussed.

Can polyphagy explain geographic distribution? A phylogenetic analysis on butterfly subfamily Nymphalinae

Jessica Slove, Niklas Janz

Stockholm University, Stockholm, Sweden

Insects, in particular phytophagous insects, are highly diverse. The oscillation hypothesis focuses on transitional polyphagy as a source of variation for an increased speciation rate. According to the hypothesis, the increase in host range should enable an increase in geographic range. The larger distribution in turn increases the likelihood of divergent selection for local differences and speciation. Here we test the assumption that polyphagy is correlated with geographic distribution.

Previous studies have looked at correlations on local to regional scales but these processes are more likely on a larger scale. Nymphalinae are globally distributed and therefore well suited for this study. Geographic range was calculated from worldwide distribution maps, and the correlation with host range was then analysed by independent contrasts.

Towards a better insecticide-treated target for controlling *Glossina fuscipes fuscipes*

Jenny Lindh[1], Steve Torr[2], Glyn Vale[2], Mike Lehane[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Natural Resources Institute, University of Greenwich, Greenwich, United Kingdom

Introduction: Traps and insecticide-targets are used to control tsetse flies, the vectors of human and animal sleeping sickness. The performance of these catching devices can be improved by adding odour attractants and/or optimising their visual appearance. Here we focus on visual responses of *G. fuscipes*, a tsetse species for which the information on visual responses are scant.

Method: Studies were carried out on Chamaunga island in Lake Victoria, Western Kenya. Electric nets were used to estimate the numbers of tsetse attracted to and either captured or killed by a biconical trap or targets of various, colour, size, shape and height above ground.

Results: A biconical trap and a black target (1x1m) caught equal number of flies. However, catches from electric nets placed adjacent to the trap or target suggest that only 27% or 39% of tsetse attracted to the vicinity of the devices are captured or killed, respectively. Further experiments revealed that a blue-and-black target attracts up to 2x more tsetse than an all-black one. Moreover, increasing the height of the target from 0 to 1m above ground reduces the catch but increase the proportion of flies that land to 80%.

Conclusion: The above results suggest that a simple insecticide-treated target of blue-and-black flanked by a fine black netting panel would be 4x more effective than a biconical trap for half the price. Further studies of the visual responses of Palpalis group species of tsetse promise even greater improvements in the cost-effectiveness of using artificial baits to control sleeping sickness.

Diamondback moth choice in glucosinolate-containing plants, hosts and non-hosts

Francisco Badenes-Perez, Michael Reichelt, David Heckel

[1]Max Planck Institute for Chemical Ecology, Jena, Germany, [2]Max Planck Institute for Chemical Ecology, Jena, Germany, [3]Max Planck Institute for Chemical Ecology, Jena, Germany

Introduction: *Plutella xylostella* (L.) (Lepidoptera: Plutellidae) is a specialist of glucosinolate-containing cruciferous plants. Plants in the family Brassicaceae and other families containing a wide variety of glucosinolates (Caricaceae, Limnantheceae, Moringaceae, Phytolaccaceae, Resedaceae, and Tropaeolaceae) were studied as hosts for *P. xylostella*. Faba beans and peas (Fabaceae) were included as non-host plants. Three different strains of *P. xylostella* reared on artificial diet, cabbage, and peas were used to determine oviposition choices and survival on the different plants.

Methods: Ovipositional preference was studied in non-choice and two-choice tests. Larval survival on hosts was recorded. Glucosinolate and saponin contents in plants were determined with HLPC-UV and LC-MS, respectively.

Results and Discussion: Oviposition differences were often significant between plants of different genus, but not between species within the genus *Barbarea* despite qualitative and quantitative differences in glucosinolate and saponin composition and in absence/presence of trichomes. Oviposition and development also occurred in non-brassicaceous plants containing glucosinolates. Oviposition on non-hosts occurred in non-choice experiments. The role of glucosinolates and saponins in *P. xylostella* host choice is discussed.

Comparative genomic analysis of immunity-related genes in *Bombyx mori*

Hiromitsu Tanaka[1], Jun Ishibashi[1], Kosuke Fujita[1], Yoshiro Nakajima[1], Aki Sagisaka[1], Mikio Yoshiyama[1], kazuya Tomimoto[1], Yoichi Kaneko[2], Takashi Iwasaki[2], Tomoya Sunagawa[2], Ai Asaoka[1], kazuei Mita[1], Minoru Yamakawa[1]

[1]National Institute of Agrobiological Sciences, Tsukuba, Ibaraki, Japan, [2]University of Tsukuba, Tsukuba, Ibaraki, Japan

Comparative genome analysis of innate immunity-related genes was carried out using the lepidopteran insect, silkworm, *Bombyx mori*. Over 200 immunity-related genes were identified by searching genes encoding similar amino acids sequences to known defense proteins in *Drosophila melanogaster, Anopheles gambiae*, *Apis mellifera*, and *Tribolium castaneum*. *B. mori* had unique genes encoding antimicrobial peptides and a recognition protein, which was not present in other insects except for Lepidoptera, suggesting a lepidopteran specific gene evolution occurred in such genes. Our analysis also suggested that recognition, modulation and effectors mechanisms seemed not to be same between Lepidoptera and other insect species, because the similarity of the proteins involved in such mechanisms between *B. mori* and other insect species were not so high. On the other hand, the factors involved in the intracellular signal transduction pathways were well conserved, suggesting these immune signal transduction pathways were conserved between Lepidoptera and other insect species.

The emerald ash borer invasion of North America: how can a secondary pest threaten the existence of an entire tree genus?

Daniel Herms

The Ohio State University / OARDC, Wooster, OH, United States

Introduction: Emerald ash borer (EAB), *Agrilus planipennis*, has killed millions of ash (*Fraxinus* spp.) trees in the Midwestern United States since its accidental importation from Asia. Congeneric relatives endemic to North America only colonize stressed trees. However, EAB is killing healthy trees on high quality sites, creating a wood-borer outbreak of unprecedented intensity.

Methods: We have 99 forest plots to determine effects of community composition on susceptibility to invasion, and established a common garden to document interspecific variation in ash resistance to EAB.

Results: Once trees began to die in an infested stand, ash mortality progressed rapidly, increasing 30% per year. There was no relationship between ash mortality and ash density, ash basal area, total stand density, or any measure of biodiversity, suggesting that silvicultural approaches hold little potential for reducing ash mortality. In a common garden study, Manchurian ash, which is also native to Asia, was found to be much more resistant to EAB than North American green and white ash, perhaps by virtue of targeted defenses selected via its coevolutionary history with EAB. Phytochemical analysis of phloem revealed the presence of phenolic compounds unique to Manchurian ash that might represent mechanisms of resistance to EAB.

Conclusions: As EAB continues to spread, it clearly has the potential to decimate ash throughout North America with impacts reminiscent of chestnut blight and Dutch elm disease. A hybridization program has been initiated with the objective of breeding resistance genes into North American ash species.

Fitness costs associated with lab-selected Cry1Ac-resistance may help explain the lack of field-evolved resistance in *Helicoverpa zea* to Bt cotton

Konasale Anilkumar, William Moar

Auburn University, Auburn, Alabama, United States

A stable and highly resistant (>100-fold) population of *H. zea* to the *Bt* Cry 1Ac toxin has been established (AR) and maintained in the laboratory for 30 generations. While feeding on toxin-treated diet, AR had significant fitness costs (increased pupal mortality, male sex ratio and male mating costs resulting in a reduction in mating) compared to the unselected parental strain (SC). Similarly, on untreated diet, AR had lower larval and pupal weight, and increased larval, pupal mortality and larval and pupal duration compared to SC. Cry1Ac toxin resistance in AR was reduced significantly within a generation in the absence of selection. When tested for performance on Bt cotton, AR significantly outperformed SC in numbers of survivors, highest number of larval instar reached, and duration of larval survival; however, AR could not complete larval development on *Bt* cotton. Additionally, a significantly lower percentage of AR (25%) larvae reached pupation on non-Bt cotton compared to SC (31%). Therefore, this study demonstrates that fitness costs are strongly linked with selecting for Cry1Ac resistance in *H. zea* in the laboratory, and fitness costs remain, and in some cases, even increase, after selection pressure is removed. These results support the low percentage of success for selecting, and maintaining Cry1Ac-resistant populations of *H. zea* in the laboratory, and may help explain why field-evolved resistance has yet to be observed in this major pest of *Bt* cotton.

Using insects in an integrated, novel approach to land-use planning: A case study of bioenergy crops

Alison J. Haughton[1], David A. Bohan[1], Rufus Sage[2], Mark Mallott[1], Victoria Mallott[1], Mark Cunningham[2], Jon Finch[3], Martin Turner[4], Trudie Dockerty[5]

[1]Rothamsted Research, Harpenden, Hertfordshire, United Kingdom, [2]The Game and Wildlife Conservation Trust, Fordingbridge, Hampshire, United Kingdom, [3]Centre for Ecology and Hydrology, Benson Lane, Crowmarsh Gifford, Wallingford, Oxfordshire. OX10 8BB., United Kingdom, [4]University of Exeter, Amory Building, Rennes Drive, Exeter. Devon. EX4 4RJ, United Kingdom, [5]University of East Anglia, 5School of Environmental Sciences, Norwich, Norfolk. NR4 7TJ, United Kingdom

Introduction: EU and UK Government policies for reducing greenhouse gas emissions present challenging targets. Energy from crops is expected to contribute significantly to reducing CO_2 emissions and, in the UK, it has been predicted that energy crops will occupy some 1.1m ha by 2020. The area of land planted to perennial biomass crops is expected to expand considerably. This will constitute a major land use change since energy crops differ from the annual arable crops typical of UK and northern European farming landscapes. Increasing land-use under these crops could have wide implications for insect biodiversity and the public acceptance, amongst other things.

Methods: Our work in the RELU-Biomass project (www.relu-biomass.org.uk) uniquely integrates the natural and social sciences to aid sustainable land-use planning for energy crops and focuses on the use of insects as biodiversity indicators. We describe a novel approach to land-use planning where we identify and integrate appropriate entomological indicators with social and economic data from a bioenergy crop, *Miscanthus*, in a Sustainability Appraisal Framework (SAF). The SAF, which takes a long-term view of the expected impacts of a proposed plan, is a tool for policy makers. We illustrate how field and extrapolated regional scale entomological data will be used to produce large-scale integrated maps of sustainable biomass crop planting. Thus, we demonstrate how insects can enable i) optimisation of environmental benefits of the location of energy crops; ii) development of best environmental practice guidelines for planting energy crops; and, iii) improvement of SAF indicators used in decision-making.

Old and novel parasitoid-fruit flies association: physiological suitability consideration

Samira Mohamed[1], Sunday Ekesi[1], Rachid Hanna[2], Robert Wharton[3], Fritz Schulthess[1]

[1]International Centre of Insect Physiology and Ecology (ICIPE), Nairobi, Kenya, [2]International Institute of Tropical Agriculture (IITA), Cotonou, Benin, [3]Department of Entomology, Texas A&M University College Station, Texas, United States

Introduction: Africa is generally considered to be the home of the genera *Dacus* and *Ceratitis*. The latter includes, two notorious species: *Ceratitis capitata* (Wiedemann) (Diptera: Tephritidae), one of the most polyphagous, widespread and damaging fruit fly pests and *C. cosyra* (Walker). In addition to the plethora of native fruit fly pests in Africa, several members of the genus *Bactrocera* have also invaded the continent, including the most devastating species *B. invadens*. In an attempt to find a promising parasitoid candidate for biocontrol of these pests two introduced parasitoid species, *Fopius arisanus* (Sonan) (Hymenopera: Braconidae) and *Diachasmimorpha longicaudata* (Ashmead) (Hymenoptera: Braconidae) and one native parasitoid species *Tetrastichus giffardii* Silvestri (Hymenoptera: Eulophidae) were evaluated. Host acceptability for oviposition and suitability for development of two invasive and six native species were evaluated.

Methods: Host acceptability was assessed by exposing the suitable host stage to the parasitoid species. Then the exposed hosts were later dissected and the number of parasitoid host was recorded. Host suitability was evaluated by rearing the exposed hosts until flies and parasitoid emergence. Total number of parasitoid progeny, Sex ratio (proportion of female) and percent parasitism were recorded. Hosts that proved to be unsuitable were further examined for immunological reaction to three parasitoids species.

Results: Females of three parasitoid species accepted all host species tested though at varying degree. Host suitability was also influenced by host quality. With exception of *D. longicaudata*, sex ratio varied across host species. Eggs of the three parasitoids were encapsulated in at least three of the tested host species. The native parasitoid *T. giffardii* and the introduced *F. arisanus* performed best on their old associated hosts, *D. ciliatus* and *B. invadens*, respectively.

Prey location mechanisms in the snail-killing flies, *Dictya montana* and *Sepedon spinipes spinipes* (Diptera: Sciomyzidae)

Rory Mc Donnell[1], Timothy Paine[1], Mike Gormally[2]

[1]University of California, Riverside, United States, [2]National University of Ireland, Galway, Ireland

Introduction: The Family Sciomyzidae is unique amongst insects in that almost all species are exclusively malacophagous. Globally, this feeding behavior has made the family a target for the selection and assessment of biocontrol agents of snail intermediate hosts of trematode diseases and of gastropod pests of agricultural/horticultural systems. Although a wide range of information has been published on the life history of these flies, relatively little is known about prey location mechanisms.

Methods: In this study, the ability of neonate larvae of the aquatic sciomyzids, *Sepedon spinipes spinipes* and *Dictya montana*, to follow snail mucus trails was assessed using filter paper Y-mazes. Mucus from snails within the intermediate host genus, *Lymnaea*, were used for both species. The responses of neonates to fresh and aged (45 minutes) mucus trails was determined

Results: When fresh mucus trails were used, all of the neonates displayed a positive response and followed the mucus trail into the experimental arm. The stimulatory substance(s), however, appears to become inactive with time and after 45 minutes none of the tested larvae reached the trail end.

Conclusions: These results suggest that trail-following behaviour in Sciomyzidae is an innate response and that aquatic species may have the potential to forage for food in shoreline and semi-aquatic areas. Such plasticity in microhabitat specificity also has significance from a biocontrol point of view as released larvae may have the potential to attack aquatic host populations in addition to utilising fresh mucus trails to locate stranded or shoreline host snails.

Importance of male sex pheromones in sexual selection in the African butterfly *Bicyclus anynana*

Caroline Nieberding[1], Klaus Fischer[3], Helene de Vos[1], Maria Schneider[1], Jean-Marc Lassance[4], Natalia Estramil[1], Jimmy Andersson[5], Joaquim Bang[5], Erik Hedenstrom[5], Christer Lofstedt[4], Paul Brakefield[1]

[1]Institute of Biology, Leiden, Netherlands, [2]Zoogeographical Research Unit, Liege, Belgium, [3]Zoological Institute & Museum, Greifswald, Germany, [4]Chemical Ecology and Ecotoxicology, Lund, Sweden, [5]Chemistry laboratory, Sundsvall, Sweden

Introduction: Sex pheromones in female Lepidoptera ensure recognition between conspecific individuals, discrimination between sexes, and mate choice. As such they play key roles in *i)* the reproductive success within species; and *ii*) the reproductive isolation between species. Whilst interest has focused on female pheromones, male Lepidoptera also produce sex pheromones. The role of sex pheromones produced by males in reproductive success and isolation remains largely unknown in insects. Based on the model butterfly *Bicyclus anynana* (Butler, 1879), we aim to assess here experimentally the role of male sex pheromones in the process of sexual selection by females.

Results: We describe the courtship behaviour of male *B. anynana,* and highlight how androconia distribute pheromones during courtship. We identify by GC-MS and GC-EAD the three active male pheromone components. Competition experiments in a field-like environment show that the mating success of males depends on the presence of pheromones. We then quantified the level of pheromone variability and estimated the heritability level of the male pheromone blend and androconia size by a father-sons regression. Finally, the variation of pheromone titres and ratios was compared between outbred and inbred males, which had been shown previously to display a difference in male mating success.

Discussion and conclusions: Results together suggest that the male sex pheromone blend in *B. anynana* is used by the female as an indicator of its fitness or quality. Therefore, this study and model system will allow evaluate the importance of male sex pheromones in driving reproductive isolation through sexual selection.

Available genetic enhancements to the Sterile Insect Technique

Luke Alphey

Oxitec Ltd, Oxford, United Kingdom

The Sterile Insect Technique (SIT) is a species-specific, environmentally friendly method of pest control which depends on the mass-rearing, sterilization and release of large numbers of pest insects. These sterile insects mate with the wild population, thereby reducing its reproductive potential. If a sufficient number of sterile insects can be released for a sufficient period, the target population will decline and collapse. Large-scale SIT programs have been conducted around the world against a range of pest insects, notable the New World Screwworm (*Cochliomyia hominivorax*) and tephritid fruit flies especially the Mediterranean Fruit Fly (Medfly, *Ceratitis capitata*). Genetic methods have provided major improvements to the Sterile Insect Technique (SIT), for example through the introduction of genetic sexing strains. Recombinant DNA 'transgenic' methods have the potential to provide further improvements, with a wider variety of novel traits and on shorter timescales than by classical methods. Many potential uses for recombinant DNA methods have been suggested; I will focus on developments that have already been incorporated into pest insect strains. Specifically, the methods discussed will be those that have been developed and work well in the laboratory and are in various levels of field testing. These include:

i) a heritable, fluorescent genetic marker;

ii) genetic sexing systems, especially for species other than Medfly;

iii) 'genetic sterilization' methods to reduce or eliminate the need for irradiation; and

iv) 'genetic containment' methods to minimize the hazard from non-irradiated releases and thereby allow a wider range of rearing and distribution options.

Introduction of any or all of these improvements into field practice would improve the cost-effectiveness and/or safety of the SIT. We have developed strains incorporating some or all of these features for the mosquitoes *Aedes aegypti* and *Aedes albopictus*, Medfly (*Ceratitis capitata*), Mexfly (*Anastrepha ludens*), and pink bollworm (*Pectinophora gossypiella*). These are currently in trials in several countries, including an extensive series of field trials in the US for pink bollworm, which will be reported.

Geographic variation in phenotypic plasticity and genetic adaptation to climate in the Afrotropical butterfly *Bicyclus anynana*

Maaike de Jong, Paul Brakefield, Fanja Kesbeke, Bas Zwaan

Leiden University, Leiden, Netherlands

Introduction: The East-African butterfly *Bicyclus anynana* shows striking seasonal plasticity for wing patterns and life history traits, which functions as an adaptation to contrasting wet-dry seasonal environments. Temperature is the single most important climatic variable determining *B. anynana* seasonal phenotype for our well-studied population from Malawi, where temperature is highly correlated with rainfall and thus a reliable indicator for the correct seasonal form. However, patterns of temperature-rainfall correlation vary strongly throughout the distribution of *B. anynana,* and different regions therefore pose different selection pressures on the species' plastic responses to temperature. The outcome of past adaptation can be used as a proxy for the potential for future adaptation of this organism to climate change.

Methods: We explored the nature and extent of phenotypic plasticity and genetic adaptation to temperature by comparing two Malawian populations and a South African population at three temperatures in a family design. This set-up allowed for the quantification of the reaction norms and the broad sense genetic variation of traits. The traits analysed at this level were: larval, pupal, and total developmental time, pupal weight, fat content, and wing pattern elements. Moreover, the following adult life history traits were measured at the population level: resting metabolic rate and starvation resistance.

Results: The experiment was carried out successfully, and first analyses indicate that the role of phenotypic plasticity is more important than genetic differentiation in the populations' ability to cope with local climate conditions. We will discuss our results in the light of adaptation to climate change.

Management of Rice Brown Plant Hopper by different modules of pesticide application

Monilal Chatterjee

Bidhan Chandra Agril. University, Mohanpur,West Bengal, India

Introduction: Rice brown plant hopper (*Nilaparvata lugens*) is one of the major key pests in intensive rice growing areas. Farmers of all parts are extensively used various toxic chemicals for the control of brown plant hopper. But in many cases they are unable to control successfully due to frequent resurgence and resistance phenomenon occurs in BPH. Serious outbreaks of plant hoppers have been reported from many parts of India. Nymphs and adults of brown plant hopper suck the plant sap, devitalize the plants and as a result drying and yellowing of leaves results which is often referred to as 'hopper burn'[1, 2.]

Methods: To cope with ever challenging insect pest's problems in Rice, farmer needs to have the latest technological knowledge in pest management. To control brown plant hopper in rice efficiently, some new modules of pesticide combination with novel chemicals were selected. To determine the effectiveness of different modules of application compared with farmer's practice a field experiment was done on rice over two seasons. They compared seven modules of application belongs to the chemicals imidacloprid, clothianidin, novaluron, buprofezin, dadeci, acephate, dichlorvos fenobucarb, fenvalerate and azadirachtin at different intervals and combination. All the agronomic practices were followed and the application was done from mid tillering stage followed by different intervals in different modules.

Results: The results showed that in module-1 -where application of imidacloprid followed by dadeci and clothianidin at 35, 55 &70 days after transplanting - completely checked the BPH population up to harvesting time, that was closely followed by module- 4 (novaluron+acephate and fenobucarb)and module-2(fenobucarb, novaluron & fenobucarb) at same days interval. In module-5, farmers practice, (imidacloprid 2 times and mixed formulation fenvalerate+acephate 2 times) was also effective in reducing the population initially but some resurgence were noted after certain laps of time. The benzophenyl urea groups of insecticide – novaluron and buprofezin when mixed with other insecticide were highly effective in reducing the BPH population up to harvesting that was reflected in yield also. Azadirachtin was however, less effective against BPH compared to other treatments.

Conclusion: The new pesticides with novel modes of action and high selectivity were highly effective against rice brown plant hopper. They are safer to non-target organisms and quickly degrade to non-toxic products.

Novel roles for E75A and Broad during segmentation of the milkweed bug, *Oncopeltus fasciatus*.

Deniz Erezyilmaz, Hans Kelstrup, James Truman, Lynn Riddiford

[1]Princeton University, Princeton, NJ, United States, [2]Janelia Farm Research Campus, Howard Hughes Medical Institute, Ashburn, VA, United States

The E75A and Broad transcription factors play well-established roles during molting and metamorphosis of holometabolous insects. We have examined the role of these two genes during embryonic development of the hemimetabolous milkweed bug, *Oncopeltus fasciatus*. We find that although the postembryonic roles of these genes in the bug are reminiscent of their reported postembryonic functions in the Holometabola, their embryonic functions in this insect are entirely novel. The milkweed bug is described as an intermediate germ insect, since it patterns the anterior segments simultaneously during the blastoderm stage and then switches to an anterior-to posterior progressive mode to pattern the abdominal segments at the germ band stage. We find that *Of'br* is globally expressed at the transition between the blastoderm and germ band stages, and later appears during nymphal differentiation. Loss of *Of'br* through parental RNAi causes posterior truncations. These truncations range from deletions of a few posterior segments to the loss of all but the most anterior head segments. We suggest that *Of'br* is a permissive factor, required for the transition between the blastoderm and germ band stages. *Of'E75A* also plays a role during segmentation. In this case, however, *Of'E75A* is expressed with double segment periodicity in the blastoderm, and in a dynamic pattern in the growing abdomen. Loss of *Of'E75A* results in fusions between adjacent segments. We show that these fusions occur as odd-numbered parasegments are deleted, resulting in an imperfect pair-rule phenotype. The significance of these findings will be discussed. Supported by NSF and NIH.

Genetic control of mosquitoes

Luke Alphey

Oxitec Ltd, Oxford, United Kingdom

Methods for transforming mosquitoes have improved to the point where it is practical to consider using these methods to control mosquito populations and mosquito-borne diseases. The availability of genome sequences has further increased the range of potential genetic options and improved the timescale for delivering them. Much work has focused on the development of strains refractory to transmission of mosquito-borne pathogens, with some notable successes. We have instead focused on controlling mosquito numbers – population suppression rather than population replacement. Our preferred strategy is a variant of the Sterile Insect Technique (SIT) which we call RIDL, in essence a set of genetic improvements to SIT.

SIT is a species-specific, environmentally friendly method of pest control used with great success and on a very large scale against some agricultural pests. However trials in the 1970s and 1980s against various mosquito species were rather equivocal – some significant successes, for example against *Anopheles arabiensis* in El Salvador, but other trials where poor male performance, or inadequate isolation, led to disappointing results. RIDL potentially allows some of the technical difficulties with classical SIT for mosquitoes to be overcome, thereby providing an attractive and sustainable control tool.

We have developed some very promising RIDL strains for the dengue vector *Aedes aegypti*, which appears to be a suitable target for RIDL; our current progress in this area will be discussed.

Spinosad 45 SC-the novel pesticides for the management of chilli pests

Monilal Chatterjee

Department of Agricultural Entomology. Bidhan Chandra Krishi Viswavidyalaya (Agricultural University), West Bengal, India

Introduction: Chilli is an important vegetable as well as spices crop in Indian Agriculture. Though India ranks first in the world with reference to area and production of chilli, however the average productivity is very low in comparison to other countries. A major constraint in chilli production is direct damage to fruit by *Helicoverpa armigera* (H) and *Spodoptera litura* (F) and damage by thrips (*Scirtothrips dorsalis*) at vegetative growth of plants. As chilli is one of the most popular and profitable crop, farmers everywhere feel the need to protect such high value crops from any type of damage caused by insect pests. They often use synthetic insecticides indiscriminately, and insect resistance to insecticides and resurgence are very common in the tropics.

Methods: To control chilli thrips and fruit borers efficiently, a new organic pesticides Spinosad 45 SC with novel mode of action has been developed recently. To determine the effectiveness of this new pesticides at different doses compared with traditional chemicals effect on natural enemies and compatibility to other insecticides, fungicides and urea, two field experiments were done over two seasons. They compared five pesticides (Spinosad 45 Sc @ 45, 56 & 73 g a.i./ha, Imidacloprid 20SL @ 40 g a.i., Chlorpyrifos 20 EC @ 500 g a.i., Endosulfan 35 EC @ 525 g a.i. and Fipronil 5 Sc @ 40 g a.i./ha) with untreated control. All other agronomic practices were standard, and a blanket sprays to control mites was applied when necessary. First spraying was done with the appearance of thrips and thereafter three sprays at fortnightly interval were followed.

Results : The results showed that Spinosad 45 % SC at 56 and 73 gm a.i./ha gave best control of thrips up to 14 days in both seasons. It has also reflected in yield parameter. Similarly the fruit borer infestation was sharply reduced in Spinosad treated plot that was closely followed by Fipronil. In another observations Spinosad showed less hazard to natural enemies viz. *Menochillus* sp., *Syrphus* sp. And *Chrysoperla* sp. at different doses compared to untreated control. The compatibility of Spinosad with Quinalphos, Carbendazim and Urea was well and no phytotoxicity was noted at any stages of the crop growth .

Conclusions :Spinosad is a naturally derived insecticide produced by fermentation of bacterium, *Saccharopolyspora spinosa* and consists of a mixture of related Spinosyn toxins, principally Spinosyn-A and D. It acts as contact and stomach poison (Dow, 1997, Salgado, 1997; Thompson *et al.* 2000). It has novel mode of action, disrupts the functions of GABA receptors of small neurons in the central nervous system. Spinosad is considered to be 'fast-acting' insecticide provides 7 to 14 days of control have practically no odor, moderately strong soil absorption and degrades rapidly in the environment. It offers excellent selectivity to beneficial organisms with low environmental risk to human beings and has potential use in Integrated Pest Management (IPM) systems.

Globins in *Drosophila*: Oxygen carrier, ROS detoxifier or else?

Thomas Hankeln[1], Eva Gleixner[1], Stefan Zimmerling[1], Thorsten Burmester[2]

[1]University of Mainz, Mainz, Germany, [2]University of Hamburg, Hamburg, Germany

Introduction: Respiratory proteins have been considered unnecessary in most insects, which do not dwell in hypoxic habitats. However, our survey has revealed that globins are a natural constituent of the insect gene repertoire. In *Drosophila*, three globin genes of unknown function have been identified.

Methods: Expression patterns of globin genes have been studied by in situ-hybridization and quantitative realtime RT-PCR. Gene expression levels have also been experimentally modified by RNAi and transgenic overexpression to elucidate functional consequences.

Results: *glob1* is the most prominently expressed Drosophila globin, found in the tracheal system and fat body in embryos, larvae and adults. After experimental hypoxia, *glob1* mRNA levels do not change in adult *D. melanogaster*, but are diminished by 50 % in embryos. Increased *glob 1* expression was observed in larvae after hypoxia/normoxia cycles and after hypERoxia. RNAi-induced downregulation of *glob1* leads to elongations in developmental time. In situ hybridization analysis of the phylogenetically closely related *globins 2* and *3* reveals preferential, but weak expression exclusively in the testes.

Conclusions: Gene regulation data suggest that *glob1* preferentially fulfils a role in supplying O_2 or detoxifying reactive oxygen species, or both. Expression patterns for *glob 2* and *3* suggest a redundant function of the duplicates associated with spermatogenesis.

The role of Allee effects in gypsy moth invasions

Patrick C. Tobin and Andrew M. Liebhold

Forest Service, United States Department of Agriculture, Northern Research Station, 180 Canfield Street, Morgantown, WV USA 26505

Allee effects have been historically applied in efforts to understand the low-density population dynamics of rare and endangered species. Many biological invasions likewise experience the phenomenon of decreasing population growth rates at low population densities, mainly because most founding populations of introduced non-native species occur at low densities. In established species, range expansion occurs when new colonies are introduced outside of the organism's current range, and also can be at low densities and thus subject to Allee dynamics. There has been consistent empirical and theoretical evidence demonstrating, and in some cases quantifying, the role of Allee dynamics in the gypsy moth, *Lymantria dispar* (L.), invasion of North America. In this paper, we will examine the potential causes of an Allee effect in the gypsy moth to highlight the importance of mate-finding failure as the primary mechanism behind an Allee effect. We then explore the role of Allee effects in the establishment and spread dynamics of the gypsy moth, which can serve as an appropriate model system for understanding how Allee effects manifest themselves in the dynamics of other biological invasions.

Comparative and functional genomics of disease vector mosquitoes

Geoge Christophides

Imperial College London, London, United Kingdom

Introduction: Mosquitoes are vectors of parasitic and viral diseases of immense importance for global health. Genome sequencing and comparative genomics studies laid down the basis for the establishment of conceptual and technological frameworks towards understanding of the mosquito responses to the various pathogens which could accommodate the observed diversity between different transmission systems.

Results: Comparative genomics analyses revealed a fascinating picture when vector immune responses were disarticulated into sequential phases, beginning with recognition of microbial patterns, producing signals which may undergo modulation and/or transduction before activating effector mechanisms. Each phase is characterized by different evolutionary dynamics, which collectively account for high flexibility that enables adaptation to new challenges, such as malaria parasites or viruses. These findings, in conjunction with transcriptomics analyses and functional genomics, led us to identify numerous genes as involved in the mosquito responses to infection by the malaria parasite *Plasmodium* and disease viruses. Several of these genes are often highly divergent and have no orthologs in other species. Genetics and population genomics data demonstrated that these genes are likely to have played a key role in the vectorial capacity of mosquitoes to transmit human malaria.

Conclusions: Mosquito response to invasion by human pathogens largely determines their competence for disease transmission. This innate capacity of mosquitoes to kill pathogens could be utilized in future integrated efforts to control and ultimately eradicate human diseases.

Influence of landscape features on the establishment and spread of mountain pine beetle populations

Brian Aukema, Honey-Marie Giroday

Canadian Forest Service at University of Northern British Columbia, Prince George, British Columbia, Canada

The current outbreak of mountain pine beetle in western Canada now covers an area approaching 10 million hectares. In the past few years, several aeolian dispersal events have transported large numbers of insects from central British Columbia over the Rocky Mountains into areas without similar historic beetle pressure, including northeastern British Columbia and northwestern Alberta. Many of these dispersal events have deposited sufficient numbers of insects to colonize and kill live trees, raising concern of eventual movement of mountain pine beetle throughout the boreal forests of northern Canadian within jack pine hosts. In this paper, we present recent research on the settlement patterns of new populations in relation to landscape features, the persistence of new populations, and spatial rates of change that may provide insight into the dominance of local vs. long distance dispersal in establishment events.

Physiological adaptations enable American dog tick adults to survive temperature extremes

Glen Needham, Kai-Lun Hwang

The Ohio State University, Columbus, Ohio, United States

Introduction: Physiologically and behaviorally ticks survive adverse environmental conditions for considerable periods of time. Water balance and metabolism have received considerable attention but studies on specific physiological adaptations that facilitate survival at extreme high or low temperatures are few. We report on one of the most important human disease vectors in North American, the American dog tick *Dermacentor variabilis*.

Methods: Adult ticks were exposed to various temperature regimens to determine their physiological responses including survival, and expression of heat shock proteins and polyol production.

Results: Rapid heat and rapid cold hardening provided significant protection from exposure to high and low temperature extremes in the laboratory. Two partial clones of heat-shock 70 proteins (Hsp70) were identified and characterized (one long Hsp70L at 1727 base pairs; one short Hsp70S at 1540), with differences in the 3' ends, 81% nucleic acid identity and 87% amino acid similarity with an Hsp70 of *Ixodes scapularis*, the deer tick. Hsp70S was expressed at a much higher level than Hsp70L in response to high temperature exposure using a Northern blot analysis. Glycerol and sorbitol concentrations increased with rapid hardening (brief exposure to a temperature extreme). Glycerol appears to protect adult ticks from both high and low temperature injury.

Conclusions: Collectively these adaptations of expressing Hsp70 and increasing polyol concentrations augment survival of this ixodid tick and may play a role in the widespread distribution of this species in North America.

Reconstructing social evolution in halictine bees

Sean Brady[1], Bryan Danforth[2]

[1]Smithsonian Institution, Washington, DC, United States, [2]Cornell University, Ithaca, NY, United States

Introduction: Accurately reconstructing the historical patterns of eusocial gains and losses is critical to understanding general processes of social evolution. We investigated this issue in halictine bees (sweat bees) that show a pattern of multiples gains and loses of primitive eusociality.

Methods: We obtained sequence data from multiple gene fragments for a wide range of halictine social and nonsocial taxa, and conducted phylogenetic analyses using parsimony, likelihood, and Bayesian methods. The timing of social evolution was reconstructed using fossil-calibrated, relaxed molecular clock techniques under both penalized likelihood and Bayesian criteria. The pattern of gains and losses of sociality was inferred using both parsimony and model-based likelihood and Bayesian methods for ancestral state reconstruction.

Results: Our molecular data provided robust resolution for most major lineages of halictine bees. Eusociality in halictine bees evolved as recently as 20 million years ago in three independent lineages. These recent origins are consistent with the high levels of social variation observed within this group. We evaluated alternative scenarios for the pattern of social gains and losses in each of the three social halictine lineages.

Conclusions: Phylogenetics provides crucial insights into the timing and patterns of social evolution in halictine bees. We discuss our results within the context of the age of social origins in other eusocial taxa, and especially consider the impact of our results toward hypotheses regarding the canalization of eusocial traits over time.

Cat fleas, dust mites and mold mites are susceptible to a brief exposure of ultraviolet light

Glen Needham[1], Roman Denallo[1], John Needham[1], Leon Fourie[2]

[1]The Ohio State University, Columbus, Ohio, United States, [2]ClinVet International, Bloemfontein,

Introduction: Ultraviolet (UV) exposure is lethal to an array of organisms by damaging nucleic acids. UV-C sterilizes surfaces in air ducts, laboratories and other settings where micro-organisms were the target. The potential for this non-chemical tactic to kill household arthropods such as cat fleas (*Ctenocephalides felis*), American house dust mites (HDM, *Dermatophagoides farinae*) and mold mites (*Tyrophagus putrescentiae*) has received little or no attention. We report that these organisms are very sensitive to UV-C.

Methods: Embryonic and postembryonic life stages of these three arthropods were exposed to a bulb chamber (35 Watts, 11mW/cm^2 of UV-C irradiance, Halo Technologies) for brief periods but generally less than 5 secs then kept at constant RH and temperature that optimize their survival. In some cases food was provided *ad libitum*. Survival was monitored and recorded.

Results: The embryonic (egg) stage for all three species was very sensitive to UV-C exposure, usually 1 sec was sufficient to cause 100% mortality. Flea larvae (L1 & L3) were sensitive to UV-C and their behavior/physiology was impacted (reduced feeding, mobility changed, delayed molting). Dust mites and mold mites perished several days post-exposure, female mites laid fewer eggs, and feeding activity was diminished, thus reducing allergen production.

Conclusions: With pesticide resistance and exposure to non-target organisms always a concern, novel methods are needed for insect and mite control, especially in very sensitive indoor environments. UV-C offers an alternative especially as an adjunct to vacuuming (Halo Technologies).

Probabilistic methods for assessing the risk of the evolution of resistance to transgenic crops

Michael Caprio[1], C. D. Parker[1], Ryan Kurtz[2]

[1]Mississippi State University, Mississippi State, MS, United States, [2]Syngenta Biotechnology Incorporated, Research Triangle Park, NC, United States

We examine methods to incorporate variation due to both stochastic features and parameter uncertainty into spatially-explicit stochastic models. There is always uncertainty involved in estimation of parameters for both simple and complex models. The conventional methods of risk analysis place this uncertainty between different scenarios with little guidance for users to determine the relative likelihood of the scenarios. Probabilistic risk assessment incorporates uncertainty into a probabilistic framework. By using probability functions for uncertain parameters and running thousands of simulations using random draws from those functions, a probability distribution of time to resistance is obtained that incorporates demographic variation as well as variation due to uncertainty in parameters. The more certain one is in model parameters, the less the variance in the final probability distribution. We examine two case scenarios, the removal of mandated refuges for 2-gene cotton and the impact of reducing requirements for non-Bt corn refuges from 50% to 20% in the Mid-southern USA.

Analyses of diversity and composition of the arthropod fauna associated with bromeliads

Anne Zillikens[1], Nivaldo Peroni[2], Josefina Steiner[2]

[1]University of Tuebingen, Tuebingen, Germany, [2]Federal University of Santa Catarina, Florianópolis, SC, Brazil

Introduction: Tank bromeliads provide aquatic and terrestrial microhabitats suitable for a wide array of invertebrates. The purpose of our study was to compare the species richness and composition of the associated fauna between bromeliad species and habitats.

Methods: In Santa Catarina State, southern Brazil, the arthropods of four species of terrestrial and one species of epiphytic bromeliads were collected in Atlantic rain forests, identified to the lowest taxonomic level possible or assigned to morphospecies. For each bromeliad species sample rarefaction curves were plotted and non-parametric species richness estimators were calculated. The arthropod assemblages of were described using Correspondence analyses (CA).

Results: Highest species richness was observed in *Nidularium innocentii*. For this species and for *Aechmea lindenii* rarefaction curves reached a plateau whereas for *Canistrum lindenii* and *A. nudicaulis* they tended to increase. CA demonstrated similarity of the faunal communities between *A. nudicaulis* and *A. lindenii*, and *C. lindenii* and *N. innocentii*, respectively, whereas that of *Vriesea vagans,* the only epiphytic species among the bromeliads studied, was more different from all other species. Detrended CA revealed a good differentiation between the faunal communities of bromeliads from secondary versus primary forest.

Conclusions: Our study documented a high species richness of the bromeliad associated fauna which differed according to bromeliad species. Factors like similar habit, as in the two *Aechmea* species, or the same microhabitat, as in *C. lindenii* and *N. innocentii,* probably contributed to more similar arthropod faunas. Forest type also strongly influenced the arthropod community.

Progress report on the Lepidoptera Tree-of-Life (LepTree) – 2.5 years of facilitating lepidopteran research globally

Jerome C. Regier[1], Joaquin Baxieras-Almela[2], John W. Brown[3], Soowon Cho[4], Michael P. Cummings[5], Donald R. Davis[6], Akito Y. Kawahara[7], Conrad C. Labandeira[8], Charles Mitter[7], Cynthia S. Parr[9], Amanda D. Roe[10], Jae-Cheon Sohn[7], Susan J. Weller[10], Andreas Zwick[1]

The Lepidoptera Tree-of-Life Project, or LepTree, is an international community collaboration which seeks to advance progress on lepidopteran phylogeny. We review our project goals and highlight three areas of accomplishments after 2.5 years of funding: 1. informatics structure (Leptree.net), 2. morphology and molecular workshops, and 3. molecular project progress. Within the first year, the interactive website Leptree.net was launched, and the LepTree Knowledge Project template is now available for community use. Several morphology and molecular workshops have facilitated exchange of ideas and techniques among lepidopterists, and more are planned. A fossil data base is being constructed for dating divergence times. Nearly all superfamilies and many families have been sequenced for several genes, and we present preliminary phylogenetic results.

Agromyzidae (Diptera) leafminer fly-parasitoid relationships in potato agroecosystems of the Peruvian coast

Norma Mujica[1], Jürgen Kroschel[4]

[1]International Potato Center, Lima, Peru [2]Sociedad Peruana de Entomología, Lima, Peru, [3]IOBC-Neotropical Regional Section, Lavras, Brazil [4]University of Hohenheim, Stuttgart, Germany

Introduction: *Liriomyza huidobrensis* is an important potato pest at the coast of Peru, which is mainly controlled by the use of insecticides. *Liriomyza* species are known to have many natural enemies, particularly in the New World. The aim of our study was to assess in potato agroecosystems leafminer fly-parasitoid relationships in arable weeds that could serve as important reservoirs for the augmentation of parasitoids for the natural control of *L. huidobrensis*.

Methods: In field surveys leave of arable weeds around potato fields and infested by leaf miners were collected and flies and parasitoids reared, recorded and identified. Seven samples were made during the potato-growing season from May to October, during the Peruvian winter.

Results: Agromyzidae flies mined 22 weeds belonging to 14 plant families. *L. sabaziae* was the dominant species (58.7%), followed by *L. huidobrensis* (13.6%). *Galinsoga parviflora* (Asteraceae), *Malva parviflora* (Malvaceae) and *Commelina fasciculata* (Commelinaceae) hosted only non-Agromyzidae potato pests and the highest number of common parasitoids with *L. huidobrensis.* Parasitism from collected weed leaves was 48.9% compared to 21.5% in potato. Fifty hymenoptera parasitoids were recorded with *Chrysocharis caribea*, *C. flacilla*, *Halticoptera arduine*, *Diglyphus begini* and *D. websteri* as the most important. The Shannon index showed higher leafminer fly and parasitoid species diversity around potato fields.

Conclusions: Most weeds proved to provide reservoirs for non-economically important Agromyzidae leafminer flies and are important resources for common parasitoids of *L. huidobrensis*. A rational management of arable weeds associated with potato could support the augmentation of parasitoids and the natural control of *L. huidobrensis*.

Functional genomic analysis of appendage development in the red flour beetle, *Tribolium castaneum*

David Angelini, Moto Kikuchi, Elizabeth Jockusch

University of Connecticut, Storrs, CT, United States

We are studying the relationships between changes in developmental regulatory genes, genetic networks, and the evolution of morphology in the context of adult appendage patterning in cosmopolitan pest beetles closely related to the genetic model *Tribolium castaneum* (Coleoptera, Tenebrionidae). Antennae of *Tribolium* possess an annulated flagellum of nine segments divided into two morphologically distinct regions, the funicle and club. The number of funicle vs. club segments varies across species. We used RNA interference to characterize the function of 23 candidate genes hypothesized to play a role in antennal growth or patterning. Our data suggest that the *Tribolium* antenna is patterned in a "gap"-like manner. The club and the funicle require specific genes, while another group of genes functions throughout the antenna. Novel developmental roles were found for several genes in the specification of regions of the flagellum. Relatively few of these genes had conserved functions, compared to *D. melanogaster*. Genes such *Notch* are conserved in the formation of joints, while *spineless* is required for antenna identity in both species. Preliminary data from morphologically distinct species of *Tribolium* suggest that changes in the regulation of *dachshund* and/or the function of *odd-skipped*-like genes may have been involved in evolution of antenna morphology. We are currently constructing *piggyBac* reporters to test these hypotheses of molecular evolution and to identify region-specific drivers for use in future experiments.

Response of two mosquito heat shock proteins to environmental stress

Joshua Benoit, Giancarlo Lopez-Martinez, David Denlinger

Ohio State University, Columbus, Ohio, United States

Heat shock proteins (Hsps) play a vital role in stress survival, but few such studies have focused on mosquitoes. In this study, we will provide a detailed view of the upregulation and downregulation of genes encoding Hsp70 and Hsp90 when the mosquitoes are subjected to various stresses. The primary stresses tested were heat, cold, and desiccation, both individually or combined. To determine if the response varies between mosquito species we tested *Culex pipiens*, *Anopheles gambiae*, and *Aedes aegypti*. We cloned both Hsps from all three species and found high amino acid homology for the portions of the genes used for northern blot hybridization. Overall, we have determined that *Hsp70* and *Hsp90* respond differentially to different stress, but the three mosquitoes respond in much the same way. Our goal is to provide a comprehensive description of how heat shock proteins are regulated in mosquitoes.

Disease resistance and viral epizootics in western tent caterpillars

Judith Myers[1], Jenny Cory[2]

[1]University of British Columbia, Vancouver, BC, Canada, [2]Algoma University, Sault Ste. Marie, Canada

Western tent caterpillars, *Malacosoma californicum pluviale* demonstrate regular population cycles over their range in western North America. An observed relationship between epizootics of nucleopolyhedrovirus and a subsequent reduction in fecundity of tent caterpillar populations led to the formulation of the disease defense hypothesis. This predicts that viral epizootics select for more resistant moths with reduced fecundity reflecting a cost of disease resistance. To test this, we measured variation in larval resistance to NPV infection for families from four spatially distinct populations of western tent caterpillars over years of peak and declining host densities. Susceptibility to disease varied considerably among families and populations, but was not related to egg mass size. Thus we reject the disease defense hypothesis. In 2003 a population that had previously experienced a less intense NPV epizootic over the last outbreak period in 1997 was significantly more susceptible to NPV than 3 other populations for which epizootics had been more severe. In 2004 the single population that experienced an NPV epizootic the previous year was significantly more resistant to virus suggesting that selection for resistance could have occurred. Although viral epizootics are a characteristic of outbreak populations, mortality of larvae from other causes increased in both the years of peak and early decline and indicated a major deterioration in the quality of field populations. Sublethal and covert viral infection may reduce the fecundity of moths in the decline and also be related to the deterioration in overall quality and increased susceptibility of populations to other diseases.

The evolution and development of integrated phenotypes

Goggy Davidowitz[1], Elizabeth Jockusch[2], Lisa Nagy[1]

[1]University of Arizona, Tucson, AZ, United States, [2]University of Connecticut, Storrs, CT, United States

Phenotypic integration - the ability of a large number of genetic, developmental, physiological and functional morphological characters to generate a functional organism, often under different environmental conditions - is an essential attribute of organisms. Without integration, development would lead to functional multicellular organisms less frequently than it does and the potential for evolutionary change would be severely impaired. Without integration, changes in body size would be constrained, as would developmental plasticity.

We discuss the question of how development is structured to produce integrated phenotypes in relation to both morphological and physiological traits. The best examples of phenotypic integration at the morphological level arise from the study of modularity. Modules are identified as sets of traits within which there is a high level of correlation and between which there is a lower level of correlation. We evaluate examples of modularity from arthropod systems, including segmentation, wing patterns, wing shape and appendage morphology. At the physiological level we compare examples from the study of the regulation of body size and development time as well as endocrine regulation of insect polymorphisms. Finally, we analyze how advances in methodology allow for novel approaches to understand how the environment regulates gene expression through the neuroendocrine axis of the organism.

Phylogeny of the fungus-growing ants and the major evolutionary transitions in their symbiosis with fungi

Sean Brady, Ted Schultz

Smithsonian Institution, Washington, D.C., United States

Introduction: All fungus-growing ants (tribe Attini) depend obligately on the cultivation of fungus for food. We present the first fossil-calibrated comprehensive molecular phylogeny of attine ants in order to illuminate the coevolutionary history between the ants and their fungal cultivars.

Methods: We generated data from four nuclear genes from 65 attine taxa incorporating the full range of taxonomic diversity within the group, with special attention given to rarely collected and potentially paraphyletic groups. Phylogenetic analyses were conducted using parsimony, likelihood, and Bayesian methods. We used fossil-calibrated divergence dating to date the origins of the symbiotic systems using penalized likelihood and Bayesian relaxed clock approaches.

Results: The symbiotic relationship between ants and their fungal cultivars originated in the Neotropics a single time ~50 million years ago. Three known additional symbiotic systems (yeast agriculture, coral fungus agriculture, and higher agriculture) have separately evolved from this original symbiosis during the past 30 million years. The attine genera *Cyphomyrmex* and *Trachymyrmex* are both nonmonophyletic, results with important implications regarding the origin and diversification of the higher agricultural symbiosis. Leaf-cutting ants that practice a highly specialized form of higher agriculture evolved remarkably recently, 8-12 million years ago.

Conclusions: We reconstructed the broad evolutionary history between ants and their fungal cultivars. Our results identify species occupying phylogenetic positions that are transitional between these major fungal symbiotic systems. Future study of these key species may help clarify the accretion of behavioural and ecological characteristics that produced these symbioses.

Pre-breeding for resistance to Russian wheat aphid, *Diuraphis noxia*, in wheat and barley in Australia: germplasm characterization against multiple biotypes

[1]Mehmet Cakir, Janine Vitou[2], Scott Haley[3], Owain Edwards[4], Frank Peairs[3], Dolores Mornhinweg[5], Jacob Lage[6], Haydn Kuchel[7], Bertus Jacobs[8], Iain Barclay[9], Ana Maria Castro[10], Joyce Malinga[11]

[1]Murdoch University, Murdoch, WA, Australia, [2]CSIRO European Laboratory, Montpellier, France, [3]Colorado State University, Fort Collins, CO, United States, [4]CSIRO Entomology-Perth, Floreat Park, WA, Australia, [5]USDA, ARS, Western Stillwater, OK, United States, [6]CIMMYT, Mexico, [7]Australian Grain Technologies, Roseworthy, SA, Australia, [8]LongReach, Marleston, SA, Australia, [9]Department of Agriculture and Food WA, South Perth, WA, Australia, [10]University of La Plata, 1900-La Plata, Argentina, [11]KARI-Njoro, Njoro, Kenya

Russian Wheat Aphid (RWA), *Diuraphis noxia*, has been reported to be one of the most damaging pests for wheat and barley. This aphid is not yet present in Australia though the risk of introduction in the future is high. Since the use of resistant varieties, as opposed to using insecticides, has been found to be most economical method of managing this pest, the Australian Cereal Industry has decided to invest in a pre-breeding project that is highly collaborative with other RWA workers around the world. The objectives of the project are to: 1) characterize available RWA resistant germplasm accessions against available RWA biotypes in France, USA and elsewhere 2) identify closely linked molecular markers to resistance genes and validate them in Australian wheat and barley backgrounds, and 3) introgress RWA resistance into Australian wheat and barley backgrounds.

To date, a number of wheat lines that are known to be resistant to USA RWA biotypes 1 and 2 were tested in Montpellier, France, against four RWA biotypes collected from Mexico, Hungary, South Africa, and France. The aphid infestation was conducted at the seedling stage with infestation six days after planting. Leaf chlorosis and biomass was measured at 21 days after planting. Four lines tested thus far have shown good resistance to biotypes from France, Mexico and South Africa. Results from the testing of these lines with RWA biotypes from Kenya, Argentina, and a second biotype from South Africa, and the screening of 99 barley lines from Oklahoma-USA will also be discussed.

Release of alarm pheromone components during feeding increases bed bug encounters with their host and decreases traumatic insemination

Joshua Benoit[1], M. Robert Michaud[1], Jay Yoder[2], David Denlinger[1]

[1]Ohio State University, Columbus, Ohio, United States, [2]Wittenberg University, Springfield, Ohio, United States

Alarm behavior was elicited in nonfed bed bugs *Cimex lectularius* in response to bugs that were feeding or had recently fed. GC/MS analysis of headspace volatiles captured on absorbents indicated that feeding dramatically boosted secretion of (E)-2-hexenal and (E)-2-octenal, two chemicals previously reported as active components of the bed bug alarm pheromone. When nonfed bugs were exposed to extracts from fed individuals, (E)-2-hexenal, (E)-2-octenal, or a mixture of these two chemicals, the time required for the bugs to locate a feeding site was reduced nearly 50%. The amount of fluid consumed during feeding was not affected, suggesting that, once feeding was initiated, there was no stimulatory effect elicited by the feeding of neighboring bugs. These same two chemicals previously implicated in the alarm response and in aggregation (when present in low concentrations) appear to increase the likelihood of host location. Additionally, we documented that traumatic insemination was significantly reduced when exposed to the high levels of alarm pheromones, indicating one purpose of (E)-2-hexenal and (E)-2-octenal release is to repel males from fully engorged females to prevent damage during insemination. We propose that (E)-2-hexenal and (E)-2-octenal, when present in high concentrations, function as general excitants that modify bed bug behavior by stimulating them to increase movement that leads to shorter periods needed to discover a host and may prevent traumatic insemination immediately after feeding.

Differential gene expression due to diet quality during caste determination in honey bees

Diana Wheeler[1], Jay Evans[2]

[1]University of Arizona, Tucson, Arizona, United States, [2]USDA Bee Research Laboratory, Beltsville, Maryland, United States

Introduction: Worker honey bees determine the caste fate of larvae by controlling their diet. Developing queens are fed rich royal jelly and developing workers receive poorer quality worker jelly.

Methods: We studied larvae 16-88 hours old, ages that span determination and early differentiation. Some larvae were exposed to normal queen and worker diets, and others were transferred from one diet to the other. We examined expression patterns of candidate genes involved in the insulin and TOR signaling pathways, in juvenile hormone synthesis and metabolism, and in management of nutrient supplies and stores.

Results: JH titers are known to begin rising in queen larvae after about 48 hours. The mechanism that triggers this rise would need to be activated prior to that time. In larvae 40 hours past hatching, presumptive queens showed higher expression than workers for ILP1, insulin receptor, TOR and TSC1 genes, suggesting that these signaling pathways could link nutrition and JH titers. Response to transfer varied with gene and caste. ILP1, insulin receptor, and Rheb gene expression directly tracked nutritional quality. Decreased diet quality was followed by dramatic upregulation of gene expression of numerous genes relevant to caste determination and differentiation. In stark contrast, the switch to a poorer quality diet provoked little deviation from normal worker patterns of expression.

Conclusion: Numerous genes known or suspected of being involved in caste determination show a pattern of expression that may represent canalization of the effect of diet on caste.

Insect-pathogenic nematodes and their potential for citrus pest control in the Sonoran Desert

S. Patricia Stock

Department of entomology. University of Arizona, Tucson, Arizona, United States

Citrus production in southwestern USA is limited to areas that are relatively frost-free and where sufficient inexpensive water is available. Climate changes and urban expansion have contributed to changes in this crop's insect and pathogen complex. One of the most debilitating pests is the citrus nematode, *Tylenchulus semipenetrans.* At present, 90% of citrus grown in Arizona are infected by this nematode. Given the current lack of successful control measures and the increasing awareness of the detrimental health and environmental effects due to chemical pesticides, new alternatives are deeply needed for management of this nematode. In this respect, one of the choices for substitution of chemical nematicides is the consideration of biological control agents such as entomopathogenic nematodes (EPN). In this study, two commercially available EPN, *Steinernema riobrave* (Biovector) and *Heterorhabditis bacteriophora* (Nemasys) were assessed for their efficacy against the citrus nematode in laboratory assays. Two-month-old rough lemon seedlings were grown in cone-tainers, at 25℃ and 30% humidity. *Tylenchulus semipenetrans*-infected seedlings were inoculated at a concentration of 12,000 J2/seedling. Citrus nematode (J2) root penetration rate and female egg production were assessed in relation to: 1) EPN application time (i.e., simultaneous [EPN simultaneously applied with citrus nematode], after [EPN applied after citrus nematode establishment in the citrus seedlings]), and 2) EPN application method (i.e., aqueous suspension, EPN-infected cadavers). A completely randomized design with two replications (12 citrus-seedlings/treatment) for each evaluated parameter was considered. Data were subjected to analysis of variance (ANOVA). Results from these studies will be presented and discussed. Assessment of this information is critical for understanding EPN-citrus nematode interactions and in making predictions of the various impacts of EPN application for the control of this nematode.

Analysis of the relationship between Pgm (Phosphoglucomutase) heterozygosity and fitness in honeybee, *Apis mellifera* L.

Meral Kence, Zerrin Gulduren

Middle East Technical University, Ankara, Turkey.

Introduction: In honeybee populations of three different geographical regions each representing different subspecies, combination of the long-term analysis of genetic variation at Pgm locus with the characterization of biochemical and functional correlates of this enzyme polymorphism have revealed that seasonal allele and genotype frequency changes have adaptive value.

Methods: Pgm genotypes were determined by starch-gel electrophoresis. Enzyme activity and glycogen content of worker bees measured spectrophotometrically. Goodness-of-fit (G^2), unpaired, two-side *t*-tests, and Spearman correlation tests were used in analyses of the data where appropriate.

Results: Frequency of Pgm-75/100 heterozygotes were significantly high ($P<0.001$) among winter bees. Analysis of enzyme activity of *Pgm-75/100* and *Pgm-75/75* genotypes revealed that enzyme activity is higher in heterozygotes ($P<0.0001$), the mean PGM activity measured as 1.943 and 3.187 units/mg protein in homozygotes and heterozygotes respectively. Summer and winter bees differed also in their glycogen content ($P<0.0001$) being higher in heterozygotes. Strong correlation (Spearman $r = 0.8410$, $P<0.0001$) detected between enzyme activity and glycogen content.

Conclusions: The observation that *Pgm* heterozygotes that predominate in winter colonies independent of geographical location, have both high levels of PGM activity and glycogen content may be the underlying mechanism to the increased life span during winter because increased PGM activity may provide efficient utilization of the glycogen reserves compared to homozygotes.Therefore increased heterozygosity at *Pgm* locus in winter can be an important physiological mechanism that contributes to efficient use of the glycogen for heat production during thermoregulation and longevity of the bees which is important for the winter survival of the colony.

Pest management in organic hazelnut growing in Turkey

Sebahat K. Ozman-Sullivan, Gregory Thomas Sullivan

Ondokuz Mayis University, Samsun, Turkey

Introduction: Organic hazelnut growing has great potential in Turkey, but pest management strategies need further development.

Methods: The demographics, attitudes, behaviours and practices of 50 organic growers were surveyed in the Black Sea region in 2008. Factors such as education level, avenues of learning, reasons for adopting organic growing, pest species and control methods were elucidated. A review of alternative organic pest control techniques was also undertaken to identify additional low-cost strategies to assist growers to more effectively manage a wide spectrum of pests.

Results: Most organic growers were members of grower cooperatives. Growers' ability to identify pests, predators, parasites and entomopathogens was low. They employed a small range of approved chemical, physical, cultural and mechanical treatments. Mixtures of ash, lime and sulphur were used to control the major pests, the hazelnut weevil *Curculio nucum* L. and big bud mites *Phytoptus avellanae* Nal. and *Cecidophyopsis vermiformis* Nal. Sulphur was also used to control the big bud mites. Removal of big buds in winter was one of the mechanical treatments. Red sticky traps were used to control the bark beetles *Xyleborus dispar* (Fabricius) and *Lymantor coryli* (Perris). Cultural practices such as pruning were also employed.

Conclusions: Growers used a limited array of organic methods to control pests. The majority were not aware of the spectrum of options available for improving their pest management.

Plant-mediated effects in insect-virus interactions

Jenny Cory

Algoma University College, Sault Ste. Marie, Canada

Inter and intra-specific differences in plant chemistry and structure can have significant influences on the interactions between insects and their pathogens. This is particularly the case with pathogens, such as baculoviruses, that produce occlusion bodies that are able to persist away from the insect host on the plant surface and are ingested when the insects feed. There is a trade-off between the effect of plant phytochemicals on the insect and the pathogen; insect performance will be reduced on a poor quality host, making it more susceptible to entomopathogens, whereas, plant allelochemicals might also reduce the effectiveness of the virus. Outcomes of these interactions are hard to predict. Whether it is possible for plants to manipulate insect pathogens as 'bodyguards' to increase their own fitness is a possibility, but has yet to be shown. However, it is becoming increasingly clear that plant-mediated effects could have an important role, not only in the efficacy of baculoviruses as insecticides, but also in the ecology and evolution of insect-pathogen relationships.

Genomic approaches in forest entomology – implications for insect ecology and pest control

Jenny Cory

Algoma University College, Sault Ste. Marie, Canada

Genomics and post genomic technologies have tremendous potential in forest entomology, from providing the tools for unravelling the intricacies of insect-plant and insect-pathogen relationships, to exploring the impact of multi-trophic interactions, and investigating the effects of environmental change on trees, insects and their natural enemies at the genomic level. Through these means we can not only provide insight into the mechanisms that underlie the ecology and evolution of these interactions, but also find ways of overcoming potential pest problems through the creation of novel pest control strategies and the selection or manipulation of crop traits. While these insights may move us towards more environmentally sustainable pest control, the potential consequences of any alterations to ecosystem components must also be considered from a risk assessment perspective.

The determination of some behaviours of the Anatolian honeybee and the local honeybee on *Rhododendron luteum* Sweet, a native plant in Turkey

Ulkem Taniker[1], Sebahat K. Ozman-Sullivan[2]

[1]Black Sea Agricultural Research Institute, Samsun, Turkey, [2] Ondokuz Mayis University, Samsun, Turkey

Introduction: Turkey is the world's third highest honey producer. *Rhododendron luteum* Sweet is a common native plant of the Black Sea region of Turkey used by local honeybees. The Anatolian honeybee, *Apis mellifera anatoliaca* Maa has the best characteristics and is the common species in most parts of Turkey.

Methods: Certain behavioral characteristics of Anatolian and local honeybees were examined on the Korgan high plateau of Ordu in the Black Sea region, Turkey. Ten Anatolian and 10 local honeybee hives were brought to the experimental area during the rhododendron's flowering period from the Ankara-Beypazari district and the Ordu-Korgan high plateau, respectively. Aggression, mortality rate, flying activity and pollen collection were measured.

Results: The average aggressiveness scores of Anatolian and local honeybees were 8.04 stings/min. and 5.08 stings/min, respectively. The average number of dead workers for Anatolian honeybee was 11.17 colony/day and for the local honeybee was 6.69 colony/day. The average number of bees taking flight per minute for Anatolian and local honeybee colonies were 30.72 and 29.03, respectively. Average Anatolian honeybee pollen production was 44.51 g/colony/day from various plants and average local honeybee pollen production was 37.28 g/colony/day, predominantly from *R. luteum*.

Conclusions: Although the local honeybee fed on the dominant plant *R. luteum,* the Anatolian honey bee fed minimally on it and instead foraged on other plants. A hybrid of the local and Anatolian honeybee may have the capacity to better utilise the large quantities of nectar available from *R. luteum*.

Adding segments one by one: comparing the regulation of segmental growth between branchiopod crustaceans and insects

Terri Williams[1], Beata Blachuta[2], Thomas Hegna[1], Lisa Nagy[2]

[1]Yale University, New Haven, Connecticut, United States, [2]University of Arizona, Tucson, Arizona, United States

Introduction: Within arthropods, a taxon defined by their body segments, mechanisms of segmentation are well-described only in *Drosophila*. However, *Drosophila* produces segments simultaneously in the embryo, whereas the vast majority of arthropods add their segments sequentially, budding them one by one from an unsegmented posterior region called the "growth zone". It is clear this pattern is both ancestral and wide-spread. Nevertheless, we do not know whether sequential segment addition involves a variety of highly disparate mechanisms or, conversely, reflects a highly conserved set of mechanisms.

Methods: We use the branchiopods *Artemia franciscana*, *Triops longicaudatus* and *Thamnocephalus platurus***.** We inhibited cell division pharmacologically to examine the link between cell division and patterning. We also used chemical inhibition to examine the role of Notch signaling in segmental growth.

Results: Our data in branchiopods show that segmentation diverges from *Drosophila* in two important ways. First, segment patterning within the growth zone of branchiopod crustaceans is causally linked to cell proliferation. Second, pharmacological inhibition of *Notch* signaling arrests or slows segmentation but has no consequence on the overall growth of the larva.

Conclusions: We hypothesize that the growth zone is not comprised of naïve, unspecified cells, but that cells undergo some degree of specification prior to exiting the growth zone. We further hypothesize that *Notch* function within the growth zone is essential for segment patterning and morphogenesis, but is not controlling proliferative growth.

Fipronil treatments for controlling the dectes stem borer in soybeans

Lawrent Buschman, Holly Davis, Terutaka Niide, Phillip Sloderbeck

Dept. Entomology, Kansas State University, Manhattan, United States

The Dectes stem borer, *Dectes texanus* LeConte, is a native North American insect that normally lives on composite weed hosts such as ragweed, *Ambrosia artemisifolia*. However, it is now becoming an important pest of soybean, *Glycine max*, and sunflower, *Helianthus annuus*, in some parts of the United States. Management is difficult because the eggs are laid in the pith of the soybean plant and larvae tunnel in the pith and thus they are not controlled by standard foliar insecticide treatments. We tested 12 systemic insecticides as foliar treatments and 11 as soil treatments at cultivation for control of the Dectes stem borer in soybean. Only one insecticide, fipronil, clearly controlled the Dectes stem borer, either as a soil treatment or as a foliar treatment. In 2006 and 2007 we tested fipronil as a foliar treatment and also as a seed treatment. Foliar treatments gave 55 to 95% control, depending on the insect pressure at three locations. At the low rate (25mg/100kg) seed treatments gave 45 to 92% control, but at the high rate (100 mg/100kg) seed treatments gave 88 to 100% control depending on insect pressure at three locations. Although we observed excellent insect control we were not able to show a clear yield advantage to controlling Dectes stem borer infestations if harvest occurs before the larvae girdle the stems which cause the plants to lodge. This can cause serious crop losses.

The evolution of novel abdominal appendages in sepsid flies: a role for HOX genes?

Julia Bowsher, Lisa Nagy

University of Arizona, Tucson, Arizona, United States

How do evolutionary changes in the molecular processes of development result in changes in morphology? Abdominal appendages in the male sepsid fly *Themira biloba* (Diptera, Sepsidae) are complex novel structures on the fourth abdominal segment that are used during courtship and mating. This family is the only group of insects to have evolved a complex and well-articulated extra-genitalic abdominal appendage. Given the current phylogeny of Sepsidae, abdominal appendages appear to have evolved in a relatively short time period and in more than one instance within the clade. Determining the molecular processes underlying abdominal appendage development will elucidate how complex novel structure can evolve in a relatively short time period. Previous work has established that the abdominal appendages develop during pupation from imaginal histoblast cells on the fourth abdominal segment. We are investigating to what degree the genetic module known to specify thoracic limb development in Drosophila has been co-opted into the regulation of the sepsid abdominal appendages and to what degree their development is controlled by novel gene interactions. Although the appendages develop during pupation, the specification of fourth segment as the location for appendage development occurs earlier. We investigated when the abdominal appendages are first specified by examining the expression of the HOX genes in the Bithorax complex that are known to determine the identities of each abdominal segment.

Conservation biological control to manage pests of crop plants

Stephen Wratten, J Tompkins

Lincoln University, Lincoln, New Zealand

Introduction: Classical biological control has had dramatic successes but also some spectacular failures. Conservation biological control uses "ecological engineering" approaches to enhance efficacy of biological control agents already in the crop. This paper presents results outlining recent successes in this area, including their economic benefits.

Methods: Work in three agricultural sectors involves planting native New Zealand species as well as non-native within or around crops.

Results: A hierarchy of success has been demonstrated, ranging from aggregation of natural enemies on flowers to widespread adoption by growers.

Conclusion: Conservation biocontrol technologies, supported by sound ecological science, are being adopted throughout Australasia. They significantly reduce variable costs and provide novel marketing opportunities.

Insects and ecosystem services: introduction

Stephen Wratten[1], Harpinder Sandhu[2], John Porter[3,] M Jonsson

[1]Lincoln University, Lincoln, New Zealand, [2]CSIRO, Adelaide, Australia, [3]Copenhagen University, Copenhagen, Denmark

Introduction: From the work of Costanza, Daily, Sandhu, among others we know something of the economic value of insects as ecosystem service providers. For the service of biological control, for instance, Costanza *et al.* (1997) estimated it to be worth US$c500 billion per annum worldwide. However, E.O. Wilson points out that current biodiversity loss is at a rate of between 1,000 and 10,000 times higher than all past such events. This impacts on the ability of biodiversity to provide ecosystem function which, when expressed in monetary terms, is called ecosystem services. This presentation will review insects as ecosystem service providers, give examples of their economic value derived from value-transfer and experimental techniques.

Conclusion: Further significant biodiversity loss will increase reliance on "substitution agriculture", which is largely oil-based, with obvious consequences for energy and food security. This session reviews the vital role that insects play in minimising the dependence on substitution agriculture as well as in ecosystem function in non-crop environments.

Impact of selected pesticides on canopy-dwelling predatory guilds on eastern hemlock, *Tsuga canadensis*

Jerome Grant[1], Abdul Hakeem[1], Paris Lambdin[1], Frank Hale[2], James Rhea[3]

[1]University of Tennessee, Knoxville, Tennessee, United States, [2]University of Tennessee, Nashville, Tennessee, United States, [3]USDA Forest Service, Asheville, North Carolina, United States

Introduction: Hemlock woolly adelgid (HWA), *Adelges tsugae*, native to Asia, is found in the eastern United States, where is has caused tremendous losses to eastern hemlock, *Tsuga canadensis*. This tree is an ecologically important component of eastern forests. In the Great Smoky Mountains National Park, ca. 50% of hemlocks have died since this pest was first found in 2002. Insecticides, the primary means of protecting hemlock, are effective at managing HWA in forests; however, little is known about their impact on non-target predators.

Methods: A two-year study was conducted on the Cherokee National Forest in Tennessee. Thirty trees were grouped in three blocks in a 2x5 split plot design (two treatment times: Fall and Spring; and five treatments: horticultural oil, imidacloprid as soil injection/as soil drench/as tree injection, and untreated [control]). Trees were sampled monthly with beat sheets, malaise traps, and direct observations. A bucket truck was used to assess vertical distribution of predators.

Results: Spiders comprised more than 60% of all predators (n=4,917). More predators were collected from control and horticultural oil-treated trees than from any imidacloprid treatments. Predator numbers rebounded 1-1 ½ years after imidacloprid treatment. Treatment time did not affect predator densities.

Conclusions: Predators were distributed throughout the tree canopy regardless of treatment. Imidacloprid, regardless of application method or treatment time, decreased predators in each strata (top, middle and bottom). Further studies are necessary to assess long-term effects of pesticides on predators on hemlock to enable forest managers to better understand these pesticide management tools.

Does successful biological weed control by an insect herbivore improve the plant community?

Judith Myers, Andrea Stephens, Pam Kranitz

University of British Columbia, Vancouver, BC, Canada

The success of biological control of weeds is usually judged by the decline in the density or biomass of the target weed. An important consideration however is whether successful biological control is followed by restoration of the habitat following the decline of the weed. Recently a serious rangeland weed of western North America, diffuse knapweed, *Centaurea diffusa*, has been successfully controlled at many sites following the establishment and spread of an introduced weevil, *Larinus minutus*. Surveys taken over the period of knapweed decline indicate that another introduced weed, Cheat grass, *Bromus tectorum*, has increased in density. I will discuss the biological control program for knapweed which involved the release of 12 insect species, the impacts of knapweed decline on the diversity of the plant community at rangeland sites, and the success biological weed control for rangeland restoration.

Chemical ecology of *Xylosandrus crassiuculus* (Motschulsky) (Coleoptera: Curculionidae) in the southern USA

Eric Ott, Brian Sullivan, Kier Klepzig

University of Montana, Missoula, MT, United States

Introduction: To date no research has used semiochemical analysis in an attempt to develop novel management techniques for angiosperm-infesting ambrosia beetles, despite increasing concern of these non-indigenous beetles in the United States. A novel technique of flooding host trees stimulated ambrosia beetle attacks while quantifying host compounds and behavioral responses.

Methods: *In-situ* host volatile sampling from bole and leaf were collected on Porapak-Q. Gas chromatography mass spectrometry (GC-MS) analysis of these compounds tested for differences in the compounds, amounts, and area of release (leaf or bole) being emitted by the flooded and unflooded trees. Coupled gas chromatography electroantennographic detection aided in testing antennal responses to these aerations. Field trapping assays tested the behavioral responses of the most promising compounds.

Results: Ambrosia beetle attraction to drowning white oak trees peaked on day 4 of flooding and varied by species. Significant differences in the compounds, amounts, and area of release (leaf or bole) being emitted by the flooded and unflooded trees were found using GC-MS. Coupled gas chromatography electroantennographic detection revealed response to 29 host compounds and 12 nonhost compounds, including known bark beetle pheromones. Field trapping assays with these compounds displayed that ethanol and eugenol in combination showed a mean increase in the number of *Xylosandrus crassiusculus* caught over the current standard trapping bait, ethanol.

Conclusion: A novel technique of flooding angiosperm trees was used in combination with semiochemical techniques in bait development. The antennal and behavioral responses to host and nonhost volatiles suggest a complex semiochemical system.

Is decreased generalized immunity a cost of Bt-resistance in cabbage loopers *Trichoplusia ni*?

Jerry Ericsson[1], Alida Janmaat[2], Judith Myers[3]

[1]Simon Fraser University, Burnaby, BC, Canada, [2]University-College of the Fraser Valley, Abbotsford, BC, Canada, [3]University of British Columbia, Vancouver, BC, Canada

Cabbage loopers, *Trichoplusia ni*, are pests in vegetable greenhouses in British Columbia Canada. Heavy use of the microbial control *Bacillus thuringiensis kurstaki, Btk* has resulted in selection for resistance in these moths. We have studied the immune responses following exposure to a low dose of *Btk* in a resistant population derived originally from a greenhouse and compared this to a susceptible strain. To test if a cost of systematic resistance is a reduced ability of the resistant strain to respond to a disease challenge, we measured the levels of resistance following a low dose of *Btk*, the expression profiles of hemolymph proteins, hemolymph phenoloxidase activity, and the differential number of circulating hemocytes. Exposure to *Btk* or injections with *E. coli* increased the hemocyte counts of susceptible larvae but not of resistant larvae. The hemolymph protein composition of larvae varied between populations and treatments. Phenoloxidase activity was not significantly different following challenge in either line, whereas protein levels only declined significantly in the hemolymph of susceptible larvae continually exposed to *Btk*. The data suggest that phenoloxidase is not involved in constitutive resistance to *Btk*. These results suggest that constitutive resistance may reduce the inducible immune responses of cabbage loopers.

Top-down and bottom-up forces shape the evolution of prey alarm signalling

Wolfgang Weisser

Friedrich-Schiller-University, Jena, Germany

Recent advances in chemical ecology have unravelled a vast array of chemical signals in plant-plant, plant-herbivore, herbivore-predator and plant-predator interactions. While most of these infochemicals are investigated in the context of a specific interaction between two particular species, the evolution of such a signal takes place in a network of biotic interactions. Consequently, the same chemical compound can have different roles depending on the organisms involved. The relative costs and benefits of the signal in its different roles will affect not only whether the signal may evolve at all, but will also influence the quantities emitted and its chemical identity.

Using the example of aphid alarm pheromone I will investigate how top-down and and bottom-up forces affect the evolution of this intraspecific signal. When attacked by a predator or parasitoid aphids may emit this alarm pheromone, in most cases (E)- β-Farnesene (EBF), to warn conspecifics of the presence of a natural enemy. In addition to this function as a pheromone, EBF may be perceived by a variety of natural enemies. I will present evidence that the costs associated with EBF's role as a kairomone may be substantial. EBF also alerts ants, and may act as kairomone or synomone depending on the interaction between aphid and ant. Finally, there is increasing evidence that aphids have to counter-act attempts of manipulation by the host plant. Thus, in the network of interactions between plants, aphids, natural enemies and ants, EBF can take all roles as pheromone, allomone, synomone and kairomone which has consequences for alarm pheromone evolution and emission dynamics.

Harmonising approaches to pest risk assessment in Europe: The EFSA Plant Health Panel

Sharon Cheek[1], Jan Schans[2], Elzbieta Ceglarska[1], Giuseppe Stancanelli[1]

[1]EFSA, Parma, Italy, [2]Ministry of Agriculture, Nature Management and Fisheries, Wageningen, Netherlands

The Plant Health (PLH) Panel of the European Food Safety Authority provides independent scientific advice on the risks posed by plant pests which threaten the safety and security of the food chain and the wider environment in the EU. The aim of the Panel is to contribute to development of a harmonised approach for pest risk assessment in the EU, in cooperation with EU Member States and international organizations. The Panel, which started its activity in June 2006, is composed of 21 Members with expertise in various fields of risk analysis and plant health. It operates with the support of the EFSA PLH secretariat and includes a permanent working group on arthropods. Since its start, it has published six scientific opinions on the risk posed by invasive plants, weeds, a citrus bacterial disease and a citrus insect pest. Most recently, it evaluated thirty pest risk assessments, for the French overseas departments of Martinique, Guadeloupe, French Guiana and Réunion, with the aim of harmonizing their phytosanitary rules with EU plant health legislation. Seven of these opinions relate to insect pests of banana and citrus.

The particular challenges faced by the PLH Panel faces include dealing with uncertainties relating to entry pathways and impacts, and developing a harmonised approach to the evaluation of risk assessments in the EU.

Fruit fly pests of horticultural crops in tropical Africa: present knowledge and prospects for management

Rachid Hanna[1], Sunday Ekesi[2], Desire Gnanvossou[1]

[1]International Institute of Tropical Agriculture, Cotonou, Benin, [2]International Centre for Insect Physiology and Ecology, Nairobi, Kenya

Introduction: Tropical Africa is home to at least 10 fruit fly species that are severe pests of fruit-bearing horticultural crops. Successive invasions of 4 Asian *Bactrocera* species have considerably exacerbated exiting fruit fly problems. Until recently detailed knowledge of factors affecting distribution and abundance of fruit flies infesting horticultural crops, and much less the effectiveness of management options developed and used elsewhere, has been minimal. We illustrate these challenges with examples from cucurbits and mango.

Materials and Methods: We reviewed available knowledge on species composition, distribution, temporal dynamics and host-crop/variety-specific levels of fruit fly infestations and natural control with predators and parasitoids. We compared the effectiveness of male lures and female attractants for population monitoring and potential for use in fruit fly control, and tested the effectiveness of GF-120 as bait spray. We also examined the potential of classical biological control against exotic species, and the enhancement of biological control of native fruit fly pests with native and introduced natural enemies.

Results: Generally**,** *Dacus ciliatus*, *D. vertebratus* and *Bactrocera cucurbitae* are the most common species infesting cucurbits, while *Ceratitis cosyra* and *B. invadens* are the dominant species infesting mango. Fruit fly infestations in both crops can reach 75%, depending on geography, season and varieties, with the large majority of fruits being infested by a single species while the rest by two and rarely by more species. Torula yeast was in general most attractive to the spectrum of fruit flies attacking cucurbits and mango, followed by NuLure, waste yeast from local breweries and BioLure – the latter being least attractive to *Dacus* and *Bactrocera* species. Bait sprays of GF-120 was ineffective for cucurbit flies but appear promising for mango-infesting flies. Parasitism rates on native species were low, but classical biological control of the exotic species such as *Bactrocera invadens* with the braconid *Fopius arisanu*s is promising, as are soil and bait applications of *Metarhizium anisopliae* as components of fruit fly IPM in cucurbits and mango.

Conclusions: Future work should determine the feasibility of, and to test and promote the use of multiple tactics and area-wide approach for fruit fly management in horticultural crops in tropical Africa.

Diversity and role of termites in West African savannas: case studies in Burkina Faso and Côte d'Ivoire

Souleymane Konaté, Dorkas Kaiser, Kanvaly Dosso, Eduard K. Linsenmair

[1]University of Abobo-Adjamé, Abidjan, Cote D'Ivoire, [2]University of Würzburg, Würzburg, Germany

Introduction: African savannas are important and very extended ecosystems of great significance for biodiversity and as a human economic area. Termites represent a very important component of soil biodiversity in West African savannas, delivering essential ecosystem services (by e.g. improving soil water content, soil fertility and carbon sequestration). This study aims to analyse the diversity and functional roles of the termites along a climatic and anthropogenic gradient in West African savannas, with two case studies in Burkina Faso and Côte d'Ivoire.

Methods: Rapid assessment protocol of biodiversity, based on standardized transects, was use to record the termite diversity. Termite biogenic structure and soil physico chemical properties were analyses to access their influence on soil water and nutrient dynamics.

Results: Termites species richness and functional diversity broadly decrease with the increasing aridity (from moist savannas to dry savannas) and with the land use intensification. The fungus growing termite of the genus *Odontotermes* plays a key role, as ecosystem engineer, in the dry savannas as well as in the moist one; where they impact the vegetation structure and dynamic. This they achieve in first line by modifying soil physico chemical properties and soil water content.

Conclusions: In West African savannas, the diversity of termite change with the amount of rainfall and the land use type. Fungus growing termite are playing a key role in soil functioning and performs some essential ecosystems services like soil restoration (in arid savannas) and carbon dynamic (in moist savannas).

Diversity and role of termites in West African savannas: case studies in Burkina Faso and Côte d'Ivoire

Effect of hurricanes Katrina and Rita on the ant fauna of South Louisiana, USA

Linda Hooper-Bui, Beverly Wiltz, Kaitlin Baudier, Rachel Strecker

Dept. Entomology, Louisiana State University, Baton Rouge, La, United States

In August of 2005, Hurricane Katrina inundated southeast Louisiana with storm surge and flood waters; three weeks later Hurricane Rita similarly inundated southwest and portions of southeast Louisiana. More than 80% of New Orleans and the surrounding area were flooded for a few days to several weeks. Initial surveys indicated that most ant populations, including those that are flood adapted, were decimated by the salty storm surge. Only islands of ant populations remained in high areas or in areas with trees where some ants dwell. In laboratory experiments, we demonstrated that flood adapted *Solenopsis invicta* are unable to maintain in salt water (3.5%) the characteristic floating raft that colonies typically form in water. In some flooded areas, all ant populations were eradicated for nearly a year. For three years we have monitored the repopulation of the affected area with ants. In most flooded areas, three invasive ants, *Solenopsis invicta*, *Cardiocondyla venustula*, and *Brachymyrmex patagonicus* are the only ants that reinvaded or remain, except for areas where tree-dwelling species survived because they were high in trees. Presently, these invasive ants are present in extremely high numbers, and in many cases have reached pestiferous levels for returning residents. It is possible that high populations of these invasive ants will suppress the natural succession of native ants in this newly disturbed ecosystem.

The weight of predatory mirids in whitefly control

Paolo Casula[1], Paolo Casula[2], Mauro Nannini[3]

[1]Division of Biology, Imperial College London, Ascot, Berkshire, United Kingdom, [2]Ente Foreste della Sardegna, Cagliari, Sardinia, Italy, [3]Agris Sardegna, Cagliari, Sardinia

Introduction: *Nesidiocoris tenuis* and *Macrolophus* spp. are important whitefly predators in Mediterranean crops. In Sardinia, these mirids are among the most abundant enemies present in summer pole tomato fields, where they may become extremely abundant during late summer. When mirids reach adequate numbers whiteflies are generally kept well below damaging densities. However, to what extent mirids affect whitefly population dynamics?

Methodology: to follow population trends in relation to insecticide applications we sampled mirid, whitefly, and other natural enemy populations in 10 and 9 tomato fields, for two consecutive years. Suction samples were collected monthly, from May to September. We also developed a set of models of whitefly-predator-insecticide interactions to understand predator-prey dynamics and determinants of whitefly resurgence. By means of model selection approaches based on information criteria we evaluated a set of hypotheses related to whitefly abundance variations, with particular focus on the role of predatory mirids in whitefly control.

Results: models specifying a direct link between predator abundance and whitefly control had strong support, showing the importance of mirids as effective whitefly biocontrol agents. Moreover, it was evidenced a relation among insecticide applications, decrease of mirid population and whitefly growth, which could explain whitefly resurgence and occasional outbreaks. Also, spiders appeared to be important in whitefly control, whereas parasitoids did not seem to play a relevant role in it.

Conclusion: The models developed and the model selection approaches appear to be valid tools for understanding complex predator-prey population dynamics, weighting the role of mirids in whitefly control.

Developing sanitary and phytosanitary (SPS) capacity in Africa

Marianna Theyse

Department of Agriculture, Pretoria, Gauteng, South Africa

African regulatory institutions are entrusted to facilitate safe agricultural trade with its international trade partners. The development and effective implementation of sanitary and phytosanitary measures, as non-tariff barriers to trade in important export markets and the local market have the potential to put agricultural imports and exports at risk.

The World Trade Organisation Agreement on the Application of Sanitary and Phytosanitary Measures (WTO SPS) concerns itself with the application of SPS measures. It is imperative for WTO members to develop and implement national systems and capacities to ensure effective implementation of the WTO SPS and its standard setting bodies i.e. International Plant Protection Convention (IPPC), International office of Epizootics (OIE) and Codex Alimentarius Commission.

The IPPC has developed a Phytosanitary Capacity Evaluation (PCE) Tool to assist a country to assess its specific capacity needs in relation to its implementation of the IPPC. The PCE tool is a significant component of the Strategic Direction No 4 (The development of the phytosanitary capacity of members by promoting the provision of technical assistance) and Article XX of the IPPC New Revised Text.

Culture-independent identification of gut bacteria in fourth-instar red imported fire ant, *Solenopsis invicta* Buren, larvae

Albert Lee, Linda Hooper-Bui, Claudia Husseneder

Department of Entomology, Louisiana State University, Baton Rouge, La, United States

Solenopsis invicta Buren, are omnivorous medical, urban, and agricultural pests from South America. Fourth-instar larvae are used by the colony to digest solid food and then regurgitate it for consumption by workers and queens. Larvae are an ideal source of investigations of endosymbiotic bacteria possibly involved in nutrient distributions. Obligate endosymbionts have been found in omnivorous carpenter ants, *Camponotus*, so we searched omnivorous fire ant guts for similar symbionts. Our study utilized 16S rDNA sequencing to describe the composition of the bacterial community in fourth-instar ant larvae in order to identify possible endosymbiotic bacteria present therein. The 16S rRNA gene was directly amplified from mixed-population DNA of whole fire ant larval guts and cloned into *Escherichia coli*. Bacterial communities from three geographically separated RIFA colonies were examined. Sequenced bacterial clones from guts were determined to be 66 species predominantly from the phylum *Proteobacteria* and the family *Enterobacteriaceae*. Our results did not detect the presence of endosymbiotic bacteria in the guts of RIFA larvae among the colonies. In addition, minimal species overlap was found when bacterial inventories were compared among colonies. Thus, bacteria coadapted with red imported fire ant larvae were not detected. Identified bacteria were not closely affiliated with endosymbiotic bacteria common in other insect species. Bacteria communities appeared to be unique to each geographical location and were determined by the foods consumed by the ants. It is possible that Camponotus are lacking nutrients that are provided by the obligate symbionts because they act as herbivores in their community because they often feed exclusively on honey dew from Homopterans; whereas fire ants are truly omnivorous in their dietary habits, which offers complete nutrition, and thus *S. invicta* has no need for obligate symbionts in the gut.

A real world examination of Sulfuryl Fluoride as a replacement for Methyl Bromide in midwestern US flour mills

Wan-Tien Tsai, Linda Mason, Klien Ileleji

Purdue University, West Lafayette, IN, United States

As a result of the Montreal Protocol, methyl bromide, a major fumigant for the food industry, is facing a mandatory 100% production and import phase out. Millers, food processors and fumigators are seeking replacements. Sulfuryl fluoride is one replacement strategy that was recently labeled for the food market. This paper summarizes research that is underway to compare the effectiveness of methyl bromide and sulfuryl fluoride under real world conditions. Since 2005, five methyl bromide and nine sulfuryl fluoride fumigations have been completed in four U.S. flour mills. All life stages (eggs, larvae, pupae, and adults) of two major pest species, Indianmeal moth, *Plodia interpunctella* (L) and red flour beetle, *Tribolium castaneum* (Herbst) were used in bioassays exposed during fumigations. Insect monitoring (moth flight traps and flour beetle dome traps) was conducted before and after the fumigations to determine the existing pests population and rebound rates. Bioassay results indicate 100% mortality of larval and adult stages of both species for both fumigants. More than 99% of RFB and 100% of IMM pupae died when exposed to either fumigant. Of the few exposed eggs that hatched, the majority died before the adult stage. Insect populations were usually significantly lower right after fumigation but could increase to pre-population level within 2-8 weeks depending on the facility, sanitation, and population pressure.

Impact of mattress rotation and vacuuming on allergen levels and dust mite populations

Giancarlo Lopez-Martinez, Glen Needham

The Ohio State University, Columbus, Ohio, USA

Introduction: House dust mites (HDM, *Dermatophagoides sp*) are considered to be the most important allergen producer indoors, thus making them the primary target of prevention and remediation efforts for asthmatics and allergic rhinitis sufferers. Novel methods for making the indoor environment safer without use of acaricides are desirable. Mattresses are a key allergen exposure sites. This study examined the impact of mattress rotation and flipping on dust mite populations and allergen production with the rationale being that these acarines require intermittent high relative humidity to thrive. Moving the allergens away from the sensitive individual has added benefits.

Methods: Mini-mattresses were inoculated with mating pairs of American HDM, *D. farinae*. Food was added and the relative humidity and temperature modulated to simulate human occupation. At various intervals mites and allergen were sampled before and after rotation and flipping of the mattresses. In addition mattresses were sampled to determine where mites matriculated over time. Vacuuming was evaluated as an effective means of allergen removal.

Results: Rotation/flipping reduced mite numbers and allergen levels by approximately 50%. After 25 wks most mites were in the polyester layer just beneath the mattress ticking. A HEPA vacuum removed 75% of the dust mites and allergen levels were reduced signficantly.

Conclusions: A combination of mattress vacuuming and rotation/flipping may have a major impact on dust mite and allergen levels, thus reducing exposure to allergens.

Within farm use of GIS technology for spatial management of blueberry insects: the case for blueberry maggot

Dean Polk, Cesar Rodriguez-Saona, Peter Oudemans, Marilyn Hughes

Rutgers University, New Brunswick, NJ, United States

Blueberry maggot (*Rhagoletis mendax*) has a “0” tolerance in fresh market blueberries. While easy to control with labeled insecticides, seasonal treatment for this insect represents the single greatest effort needed for insect control in terms of the number of applications, total amount of active ingredient (a.i.), costs of labor and equipment use, and effort made in observing pre-harvest and re-entry spray intervals. Fruit destined for export is required to undergo a strict spray program, either by a calendar method, or as dictated by trapping. Management practices have led to overuse of insecticides, time and resources, and do not fit well with resistance management practices, especially since some of the most effective insecticides continue to be the older organophosphates and carbamates, and reduced risk materials such as imidacloprid have limits on total use. Key blueberry pests often reside on alternate hosts in bordering woods prior to dispersal into cultivated fields. Objectives of this project are: Identify locations and high-risk areas of BBM activity on a whole farm basis; Demonstrate that these areas can be spatially recognized and individually managed; and Reduce Costs and Insecticide Use. Five growers participated with 737ha, using 1 trap for every 1.1ha. The majority of traps had a “0” capture, and most positive traps were near field edges. Spatial management led to fewer insecticide applications and less active ingredient applied per ha. Spatially managed farms had a total insecticide use ranging from about 70 to 30% of that on grower standard farms.

Progress towards engineering resistance to weevil in sweetpotato in East Africa using Bt gene technology

William Moar[1], Robert Mwanga[2], Benson Odongo[2], Moses Ekobu[3], Maureen Solera[3], Samuel Kyamanywa[3], Marc Ghislain[4]

[1]Auburn University, Auburn, AL, United States, [2]National Crop Resources Research Institute, Namulonge, Uganda, [3]Makerere University, Kampala, Uganda, [4]International Potato Center, Lima, Peru

Introduction: Sweetpotato is grown in Sub-Saharan Africa (SSA) as a staple food for the urban and rural poor. Major producing countries include Uganda, Nigeria, Rwanda, Burundi, Kenya, and Tanzania. Sweetpotato weevils (*Cylas* spp.) constitute the most important threat to crop productivity and sustainability with losses reaching 60% to 100%. Conventional integrated pest management practices are difficult to apply to production throughout the year by small-scale subsistence farmers. Instead, host plant resistance by expression of multiple *Bacillus thuringiensis* (Bt) proteins represents a new strategy for achieving sustainable control of weevils under African conditions.

Results: First, we developed a diet incorporation methodology to test Bt toxicity against weevil larvae. Of the eight Cry toxins test against *C. puncticollis* and *C. brunneus* using this artificial diet, three Cry toxins had LC_{50}'s below 1 ppm; Cry7Aa1, Cry3Ca1, and ET33/34. Therefore, Cry7Aa1, Cry3Ca1, and ET33/34 gene constructs were developed considering reduced cross resistance concerns, sweetpotato codon usage, avoidance of contractual restrictions and property rights, storage root expression and wound-inducible promoters, and combinations of two selection marker genes and Bt genes. A total of 10 Bt gene constructs have been developed and are now available for direct gene transfer into relevant African sweetpotato varieties. Regeneration and genetic transformation protocols were applied to two African cultivars, Tanzania and Wagabolige, and two non-African cultivars, Jewel and Huachano, Transformation and possible toxicity results of transformed plants will be discussed.

Mass spectral analysis of expressed versus predicted peptides (AKHs, PRLamides, FLRF-amides, NVP-like peptide) in the corpus cardiacum of beetles and moths: evolutionary relationships and functional significance

Robert Weaver[1], Heather Marco[2], Neil Audsley[1], Gerd Gaede[2]

[1]Environmental Biology Group, Central Science Laboratory, York, United Kingdom, [2]Zoology Department, University of Cape Town, Rondebosch, South Africa

Introduction: Mass spectrometry, together with genomic and cDNA sequence information, allows predictions to be made in relation to expressed peptides of the corpora cardiaca (CC).

Methods: Pairs of CC or extracts are analysed using MALDI-TOF or ESI mass spectrometry.

Results: Two AKHs (Trica-AKH, Pyrap-AKH) predicted from the genome of the red flour beetle, *Tribolium castaneum*, are confirmed, but an AKH-like peptide was not found. In contrast, *Tribolium brevicornis* and *Tenebrio molitor* contain only one AKH, which differs from the AKHs of *T. castaneum,* and is the same in both species. Other peptides from the CC of *T. brevicornis* (e.g. pyrokinins) also match the complement in *T. molitor*, but differ from those in *T. castaneum*.

Two peptides are always present in the lepidopterans; these are FLRF-amide-I and Arg^7-corazonin. The silk moth, *Bombyx mori* expresses Bommo-AKH (pELTFTPGWGQ-amide) as a newly identified second peptide to Manse-AKH. In comparison, the fall armyworm, *Spodoptera frugiperda* contains two cDNA-predicted AKHs , but a third predicted AKH (pELTFSSGW-amide) and an AKH-L were not present. Two other noctuid species contain a Gly-extended amidated peptide (pELTFTSSWGG-amide) as a potential third AKH. In the lepidopterans, there are similarities and differences between the peptides derived from the PBAN/diapause hormone precursor, including a new analog of Helze-PGN-8 / Bommo-γ-SNP, (Lacol-PK; NMNFSPRL-amide), which is found in the tomato moth, *Lacanobia oleracea.*

Conclusions: The tenebrionid *T. brevicornis* appears more closely related to *T. molitor* than to *T. castaneum*. Similarly, peptidomics of the lepidopteran CC may provide insight into functionality and relatedness within the noctuidae.

Criteria for determining field-evolved resistance in Bt cotton

William Moar

Auburn University, Auburn, AL, United States

Although monitoring for field-evolved resistance by target pests in Bt crops is widely accepted and practiced, the actual procedures involved with monitoring and interpreting results are not standardized in all cases, and reports arising from non-official monitoring have also been used to interpret field-evolved resistance. This presentation will discuss the US monitoring program for Bt cotton and bollworm (*Helicoverpa zea*) addressing specific topics such as deciding on: 1) the appropriate definition(s) of Bt resistance to use for determining field-evolved resistance, 2) the appropriate plants to collect *H. zea* from for use in laboratory bioassays; 3) whether to use discriminating concentrations vs. LC_{50}'s for determining susceptibility; 4) whether to include failure to molt to second instar in the definition of mortality; 5) the appropriate laboratory colony to be used for comparing susceptibilities of field populations and 6) the appropriate form of Bt protein to use for bioassays. Regardless of the conclusions, agreement of a standardized protocol for monitoring for field-evolved resistance should reduce the likelihood for confusion and controversy when reports of putative resistance to Bt crops by target pests occur.

How does alpine moth, *Syngrapha ottolenguii* adapt their life cycle and flight activity rhythm to severe Alpine environment?

Masami Sasaki, Satoshi Yamamura

Tamagawa University, Machida, Tokyo, Japan

Introduction: *Syngrapha ottolenguii* (Noctuidae: Plusiinae) is a typical Japanese alpine moth with adults appearing from mid to late summer. How does the noctuid moth adapt their life cycle and flight activity rhythm to severe Alpine environment?

Method: Both field surveys at Mt. Zao etc. (1800-2600 m asl) and laboratory studies using actographs were done from 2003-2007.

Results and Discussion: The moth was found to have a univoltine life cycle in 1 year, although one generation can be completed as short as 60 days at 16L-8D and 20℃.

We found two strategies—short-day-induced prolongation of 2nd and 3rd instar larval stages for winter, and long-day-induced arrestment of reproductive maturation in adults for summer to enable the life cycle without obligatory diapause. As a result, oviposition is delayed into autumn, and the late-hatched, cold-tolerant larvae overwinter under deep snow. Larvae before and after overwintering develop very slowly due to their unique behavior of hiding from the sun's radiant heat.

It has been known that the adults take flight and visit alpine flowers during day time even in nocturnal moth. We found the evidence from actograph studies that they (especially in mated female) weakened or lost their circadian activity rhythm to get ready to visit flowers at any favorable time under cold, severe alpine weather.

Stochastic spread of *Wolbachia*: drifting through the threshold

H. Charles J. Godfray[1], Vincent A.A Jansen[2], Michael Turelli[3]

[1]University of Oxford, Dept. of Zoology, Oxford, United Kingdom, [2]University of London, Royal Holloway, School of Biological Sciences, Surrey, United Kingdom, [3]University of California, Section of Evolution and Ecology, California, United States

Most *Wolbachia* that cause cytoplasmic incompatibility (CI) only spread when their frequency is higher than a threshold determined by their detailed biology. In finite populations, *Wolbachia* at frequencies lower than this threshold may become fixed through random events, and similarly infections above the threshold may become extinct by chance. We describe the probability of spread as a function of current frequency, population size, and *Wolbachia* biology. The probability of fixation of a near neutral *Wolbachia* with CI scales with the reciprocal of the root of population size (N) which is much higher than a neutral allele where fixation scales with 1/N. We discuss the implication of these results for *Wolbachia* spread in natural populations, and its use in pest and vector management.

Moth migration patterns over the past 40 years: how are they changing and how is climate influencing this change?

Duncan Sivell, Jason Chapman, Ian Woiwod

Rothamsted Research, Harpenden, United Kingdom

A number of moth species employ migration strategies to track the shifting availability of resources across seasons and continents. The UK receives immigrants from continental Europe and Africa each year, but the degree of influx can vary greatly and for some species in certain years may lead to pest outbreaks. To try to explain this variation and understand these migration patterns we examine a long-term dataset provided by the Rothamsted Light Trap Network, a moth monitoring scheme which has been running in the UK for more than four decades. These data hold spatial as well as temporal information on moth abundance and enable us to compare species with different migration strategies and investigate the relationship between migration events and climate. Migration events are obviously mediated by environmental conditions at their source and along their route, but as our moth data is limited to the UK we are lacking information on migrant species when they are abroad. However, historic climate data are available for the probable source areas of migation and these are assessed to speculate on how migrants fare in the other parts of their migratory range.

Mechanisms of host defense and the geography of galling insects

G Wilson Fernandes, Marco A.A Carneiro

Universidade Federal de Minas Gerais, Ecologia Evolutiva & Biodiversidade/DBG, Belo Horizonte, Brazil

Galling species richness increases with decreasing elevation, is higher under more stressful habitats, reaches a peak in habitats or regions dominated by sclerophyllous vegetation, and natural enemies and plant resistance play a major role in their geography. A tight physiological interaction between the galling organism and the host plant is crucial to the success of the galling habit in more nutrient-stressed, harsh, and sclerophyllous environments. Furthermore, the gall inducing organism success is also shaped by the interaction with the community of natural enemies via habitat. We argue that under higher temperatures and water and nutrient deficiency in harsher habitats, such as those found in the latitudes between 25 and 40 degrees and at the canopy of tropical rain forests, induced defenses are weaker, thus favoring the galling habit. Although plants living in dry and warm habitats may respond more slowly to gall initiation, their induced defenses, such as hypersensitivity, may not be efficient and/or quick enough to impair cell and tissue taken over by the inducing larva, therefore increasing the probability of gall development. Weak selective pressure caused by predators, parasites, pathogens, and plant resistance on galling insects in habitats where sclerophyllous plants are abundant, reinforces the pattern of high richness of galling insect species in this vegetation type. We postule that the geography of galling species and their biodiversity may be driven plant nutritional quality and ability to resist to galling, by leaf sclerophylly and consequent effects on meristem dynamics and natural enemies, all mediated by habitat intrinsic quality.

Mechanisms of host defense and the geography of galling insects

G Wilson Fernandes, Marco A.A Carneiro

Universidade Federal de Minas Gerais, Ecologia Evolutiva & Biodiversidade/DBG, Belo Horizonte, Brazil

Galling species richness increases with decreasing elevation, is higher under more stressful habitats, reaches a peak in habitats or regions dominated by sclerophyllous vegetation, and natural enemies and plant resistance play a major role in their geography. A tight physiological interaction between the galling organism and the host plant is crucial to the success of the galling habit in more nutrient-stressed, harsh, and sclerophyllous environments. Furthermore, the gall inducing organism success is also shaped by the interaction with the community of natural enemies via habitat. We argue that under higher temperatures and water and nutrient deficiency in harsher habitats, such as those found in the latitudes between 25 and 40 degrees and at the canopy of tropical rain forests, induced defenses are weaker, thus favoring the galling habit. We postule that the geography of galling species and their biodiversity may be driven plant nutritional quality and ability to resist to galling, by leaf sclerophylly and consequent effects on meristem dynamics and natural enemies, all mediated by habitat intrinsic quality.

Ants on your plants: a meta-analysis of the role of ants as plant biotic defenses

Tatiana Cornelissen, Newton Barbosa, Livia Diniz, Frederico Neves, Yumi Oki, Flavia Pezzini, Felix Rosumek, Fernando Silveira, G W Fernandes

Universidade Federal de Minas Gerais, Ecologia Evolutiva & Biodiversidade, Belo Horizonte, Brazil

We reviewed the evidence for the effects of ants as plant biotic defenses, by conducting separate meta-analyses for the effects of experimental removal of ants on plant herbivory and fitness with data from 86 studies that generated 294 independent comparisons. Effects reviewed were mainly plant herbivory, herbivore abundance, homoptera abundance, predator abundance, plant biomass and reproduction in studies where ants were experimentally removed (90.5%) and studied where there was natural variation in ant presence among individual plants (9.5%). Ant removal exhibited strong effects on herbivory rates, as plants without ants suffered twice more damage than plants with ants and exhibited 70% more herbivores. Ants also influenced several parameters of plant fitness, as plant without ants suffered a reduction in biomass of (-19.8%), leaf production (-48.9%) and reproduction (-20.5%). Effects were much stronger for tropical regions compared to temperate ones as tropical plants suffered almost three-fold higher herbivore damage than plants from temperate regions (Q_B=37.08, P<0.0001) and exhibited almost five times more herbivores (Q_B=12.9, P=0.0003). In relationship to plant reproduction, reduction in the production of flowers, fruits and seeds were much more pronounced in tropical compared to temperate regions. In tropical regions, ant removal resulted in a reduction of plant fitness of about 59% (E++=-0.593, CI=-0.69 to –0.50), whereas in temperate regions this reduction was not statistically significant (E++=-0.012, CI= -0.08 to 0.05) (Q_B=108.8, P<0.0001). Altogether, these results suggest that ants do act as plant biotic defenses, but the effect of their presence is more pronounced in tropical systems.

Hormonal regulation of sequential insect oocyte development

Johannes Leuchtweis, Hans J. Ferenz

Martin-Luther-University, Halle, Germany

Insects sequentially mature a hierarchy of eggs with the terminal oocyte massively storing yolk reserves and the subsequent subterminal oocytes remaining much less developed. In our model insect *Locusta migratoria* terminal oocytes of all ovarioles grow synchronously while development of the subterminal oocytes is arrested at an early previtellogenic stage and induced only after the current terminal oocyte has completed its development. Although it is likely that the terminal oocyte directly or indirectly controls the developmental arrest of the subterminal oocytes proof for such control is lacking. In our locust model system we are examining cellular and molecular events sequentially up- or down-regulated by endocrines in subterminal oocytes and their follicle cells. Previtellogenic oocytes appear to be prepared and equipped for endocytosis of yolk material. However, the vitellogenic arrest is predominantly caused by the lack of patency in the follicle cell sheath. Thus the follicle cells of subterminal oocytes are the target of so far unidentified stimulating or inhibiting endocrine factors. We are studying such regulatory factors possibly induced by ovulation (neural and neurohormonal signals) or originating from follicle cells of terminal oocytes.

This presentation gives an overview on known mechanisms, discusses results of the locust system and outlines research perspectives.

The state and status of studies of insect learning

Brian H Smith

Arizona State University, Tempe, AZ, United States

With the pioneering work of Karl von Frisch over 100 years ago, insects broke through the traditional boundary between vertebrates and invertebrates in studies of learning. Until then, it was thought that learning, in particular, as well as sophisticated sensory processing, was limited to the realm of large brains. Since then a variety of insects, especially fruit flies, have been used in basic research on the neural and molecular bases of learning and sensory processing. The studies have proliferated because of the relatively smaller size and accessibility of insect nervous systems. Furthermore, in the last decade there has been increasing availability of genomic information as well as the ability to manipulate gene expression to test hypotheses about the relationships among between genetic pathways, neural networks and learning. These studies have been invaluable for what they have revealed of fundamental molecular, neural and behavioral mechanisms that underlie these processes in many animal species. There have also been many studies of learning in insects under more natural conditions. Recently these types of studies have begun to apply an understanding of learning to more applied problems in agriculture, medical entomology and bioterrorism. Because of the breadth and importance of all of these studies for basic and applied problems, insects are central to research on learning and memory. Therefore, entomologists who study learning now have an opportunity integrate these areas and make significant interdisciplinary contributions to many different fields of research.

Australian gall-inducing Eulophidae as globally invasive pests

John La Salle

CSIRO Entomology, Canberra, ACT, Australia

Within Australia, a phytophagous radiation from within the mainly parasitoid family Eulophidae is the dominant group of gall inducing organisms on Eucalyptus trees. A number of these gall inducers have achieved invasive pest status on Eucalyptus trees in many regions of the world. The biology, taxonomy, and pest status of these wasps is summarized. Classical biological control options are summarized, with particular reference to currently ongoing programs.

The Atlas of Living Australia

John La Salle, Donald Hobern

CSIRO Entomology, Canberra, ACT, Australia

The *Atlas of Living Australia* is an ambitious initiative to create a single seamless web interface providing access to integrated biodiversity information for the entire Australian biota. Progress on this project will be reported, along with the planned next steps. Path to impact will be discussed, and how the *Atlas* intends to deliver data in such a manner that it can underpin national initiatives towards sustainable bio-management, improved biosecurity, and increased use of Australian biodiversity for biodiscovery

Modelling temperatures and insect succession on cadavers inside a vehicle environment

Ian Dadour, Sasha Voss, Neville Fowkes

University of Western Australia, Western Australia, Australia

Introduction: (1)Differences in rate of decomposition and insect succession between exposed carcasses on the soil surface and those enclosed within a vehicle following carbon monoxide (CO) poisoning was examined. (2)Temperatures inside vehicles were also modelled.

Methods: (1)Nine 45kg pigs were used as models for human decomposition. Animals were sacrificed by CO gas, half were placed within the driver's side of separate enclosed vehicles and half were placed under scavenger proof cages on the soil surface. (2) Vehicles were placed in open areas in a east/west orientation. Temperatures were measured for 10 days inside the vehicle, inside the trunk and the metal skin surface temperature. These parameters were compared with prevailing climatic conditions.

Results: Progression through the physical stages of decomposition was 3-4 days faster in the enclosed vehicle due to higher temperatures inside the vehicle compared to external ambient temperatures. Patterns of insect succession also differed between vehicle and surface treatments. The pattern of insect succession and rate of decomposition was similar between surface carcasses within trials regardless of the mode of death

Conclusion: This study provides baseline data outlining the decomposition patterns of a carcass enclosed within a vehicle following carbon monoxide poisoning in Western Australia. Understanding how variation in decomposition situations impact on the rate of decomposition and patterns of insect succession is essential to obtaining an accurate estimate of post-mortem interval (PMI). How temperatures change inside a vehicle over time has ramifications for not only cadaver decomposition but also the deaths of children and pets, a consequence of negligence by vehicle operators.

Temperature and humidity facilitates competition between native ants and *Pheidole megacephala* (Hymenoptera:Formicidae) on Fraser Island, Australia.

Wayne Robinson

University of the Sunshine Coast, Queenlsand, Australia

Pheidole megacephala is one of the worlds worst invasive ants and can be common in urban areas in coastal Australia and occasionally in native bushland. Anecdotally, there appears to be a few native species that are consistently able to coexist with *P. megacephala*, and this research investigates the mechanisms of their success. I performed a small scale field experiment on Fraser Island, Queensland, Australia where shade cloth was used to adjust the temperature and humidity on a series of baits that were monitored through a 72 hour period. The experiment was fully crossed between areas with low and high native vegetation cover and areas where *P. megacephala* invasions were long established or at the invasion front. *Iridomyrmex bicknelli* and *Monomorium sydneyensis* were able to exist in *P. megacephala* infestations by partitioning foraging to suitable temperature and humidity conditions. *P. megacephala* were dominant however and displace the native ants when environmental conditions suit their foraging. Without shade *P. megacephala* could not forage above 40oC (Ground temperature) or below 20 % humidity. Vegetation that offers more shade and moister conditions can be readily invaded by *P. megacephala*. However *P. megacephala* will forage at cooler times of the day when invading hotter drier areas and hence can still invade or at least cross drier habitats readily. I also present details of a large scale experiment currently in progress that manipulates environmental factors and native ant communities to further investigate the role of biotic resistance in *P. megacephala* invasions.

Insulin signaling and growth control in *Drosophila*

Ernst Hafen, Hugo Stocker

ETH Zurich, Zurich, Switzeralnd

The control of cell and organ size is important for the developing organism. The discovery of the Drosophila homolog of the vertebrate IRS1–4 (CHICO) has shown that manipulating the Drosophila insulin signaling pathway leads to alterations in cell size, proliferation, and cellular metabolism. Systematic genetic screens relying on a tissue-specific recombination system or over-expression led to the identification of new genes whose products are dedicated to the control of cell and organ growth. Some of them constitute components of the insulin signaling pathway (PKB, PDK1, PTEN) and the dTOR pathway. These two pathways are not only important for the regulation of growth during normal development, they are also the target of environmental influences such as nutrients, oxidative stress, and hypoxia all of which regulate growth. Several of the genes whose products connect environmental stress to the regulation of the insulin and TOR pathways are dispensable under normal culture conditions and mutations were only detected in the overexpression screen. I will provide an overview of our recent results from these genetic screens and describe we combine genetic and proteomic analyses towards an understanding of growth control at the systems biology level.

Experiences of a South African company

Mike Morris[1], Mark Laing[2]

[1]Plant Health Products (Pty) Ltd, Nottingham Road Village, South Africa, [2]University of KwaZulu-Natal, Pietermaritzburg, South Africa

Plant Health Products (Pty) Ltd was started 9 years ago, initially to commercialize some research coming out of the University of KwaZulu-Natal, but it has now grown beyond that. During this time some harsh realities have been experienced. The background of key personnel (research versus business or marketing) influenced decision-making and direction during the early years. The early need for a high level of research inputs and capital puts a huge budgetary strain on a small, start-up company. But outside loans or investments need to be very cautiously approached due to the, often slow, returns to investors. The registration process and delays of several years for each new product in each and every country where markets are opened up is a huge constraint that has to be overcome. Other factors that will be discussed include the importance of market research, production scale up constraints, the damage in the marketplace caused by poorly researched, unregistered products and the importance of product quality and formulation development.

The Bt cowpea project – the long road to field trials

Larry L. Murdock

Purdue University, W. Lafayette, IN, United States

The recipe for creating a public-sector project to develop a genetically-modified crop for Africa requires that the cooks start with a mild case of insanity and have skin so thick that the slings and arrows of skeptics, which are legion, bounce off of it. The Bt cowpea project started this way at Purdue University, in 1987. It involved would-be cooks who should have known better, and should have foreseen that it would take enormous energy and time, more than twenty years, plus plenty of money. Much was learned in the still-ongoing project, thanks to errors of commission and omission, but the ultimate lesson is that a band of individuals with dogged determination and patience can achieve things that only well-funded biotechnology companies otherwise could ever achieve. Some of those lessons are: (1) A biotechnology project should focus on a problem that can not be solved any other way; (2) Private sector help must be accessed, for that is where indispensible experience – and intellectual property – reside; (3) A public-sector project depends on volunteers; (4) There is enormous power in people to do big and unselfish things – if you can find ways to unshackle that power; (5) Institutions each have their own personalities, vanities and agendas, but if you grin and bear it they can be indispensible allies; (6) Even short of success and along the way, the rewards are great and there is joy in it all.

Parasitic wasps: succession, development and forensic importance as PMI indicators.

Sasha Voss[1], Helen Spafford[2], Ian Dadour[1]

[1]Centre for Forensic Science, University of Western Australia, Perth, Australia, [2]School of Animal Biology, University of Western Australia, Perth, Australia

Introduction: The presence of parasitic wasp larvae within insect hosts such as fly pupae can be used to provide and extended estimate of time since death. Use of parasitic wasps as tools in criminal investigations requires; baseline data on the temperature-dependant development of both the host and parasitoid species; knowledge of the development stage at which the female wasp parasitizes the host; and an understanding of the factors involved in host location within a decomposition habitat. Currently, there is a paucity of relevant reference data and the research that is available is either geographically specific or is focused on parasitoid species used as biological control agents of filth flies rather than in a forensic context.

Methods: In this study, the species and biology of parasitic wasps associated with decomposing remains in Western Australia and their relevant host species were investigated. A monthly survey of relevant insect fauna frequenting decomposing remains was conducted. Domestic guinea pig carcasses (*Cavea porcellus*) were used as an attractant.

Results: The stage of decomposition at which the observed parasitoid species attended carcasses, species seasonality and rates of parasitization in the field were identified. Base-line reference data on the temperature-dependant development of two important parasitoid species were also established under laboratory conditions.

Conclusions: The biological and developmental data presented will improve the accuracy of PMI estimations in cases where decomposition has advanced beyond the life cycle of flies, the traditional indicators of time since death.

Insect-Wolbachia-WO phage tripartite symbiotic interaction: exploring the role of phage

Panagiotis Sapountzis[1], Haralabia Boleti[2], Seth Bordenstein[3], Kostas Bourtzis[1]

[1]Department of Environmental and Natural Resources Management, University of Ioannina, Agrinio, Greece, [2]Molecular Parasitoloty Unit & Light Microscopy Unit, Hellenic Pasteur Institute, Athens, Greece, [3]Josephine Bay Paul Center for Comparative Molecular Biology and Evolution, The Marine Biological Laboratory, Woods Hole, United States

Wolbachia is a group of obligatory intracellular and maternally transmitted a-Proteobacteria that infect a number of invertebrate species, including mites, spiders, crustaceans, filarial nematodes, and especially insects. This bacterial group has been extremely successful in establishing symbiotic associations ranging from reproductive parasitism to mutualistic symbiosis. Several *Wolbachia* strains carry prophage elements in their genome. Bacteriophages are responsible for the transfer of new functions to a bacterial cell and are recognized as important agents in bacterial evolution. The molecular mechanisms that mediate host-*Wolbachia*-phage symbiotic interactions are currently unknown.

In the present study, we cloned part of the orf7 gene encoding the minor capsid protein of WO-B bacteriophage located in the genome of the *wMe*l strain of *Wolbachia*. The cloned region of the orf7 gene, which is conserved among different Wolbachia strains of the A and B supergroup, was expressed in *E. coli* as recombinant protein and used to produce rabbit polyclonal anti-sera. Expression of the WO-B bacteriophage capsid protein was confirmed in different insect-*Wolbachia* symbiotic associations by Western Blot and in *Wolbachia*-infected *Drosophila* testes and ovaries by immunofluorescence confocal microscopy. Interestingly, sex specific differences were observed.

Malaria vector control : will insecticide resistance be our downfall?

Maureen Coetzee

[1]NRF Chair in Medical Entomology & Vector Control, Schoo of Pathology, University of the Witwatersrand, Johannesburg, South Africa, [2]Vector Control Reference Unit, National Institute for Communicable Diseases, NHLS, Johannesburg, South Africa

Introduction: Since 1911 when Giemsa first discovered that pyrethrum killed flies, the use of chemicals has been the mainstay of both agricultural and public health control of insect pests. Early research in South Africa, published in 1936, demonstrated that: 1) malaria vector mosquitoes like to rest inside human habitations while waiting for their eggs to develop, and 2) weekly administration of pyrethrum space spraying markedly impacted on the mosquito populations, dramatically reducing malaria transmission. This information led directly to the WHO Eradication Campaign of the 1950's when DDT's residual properties made house spraying a feasible option.

The appearance of insecticide resistance: The discovery of DDT and dieldrin, with their highly insecticidal, long-lasting effects, lead to the enthusiastic adoption of wide-scale application of these insecticides to fight every pest that plagued the human population. As a result, it was not long before insecticide resistance appeared, first in fly populations in Italy and Sardinia in 1947 and in African malaria vector mosquitoes in 1956.

The situation today: All three major malaria vector species in Africa now exhibit insecticide resistance over some parts of their distribution. The extent and spread of the resistance, however, is by no means uniform. With the current global efforts directed at malaria vector control, it is imperative that baseline entomological surveys be carried out prior to implementation of control interventions, followed by regular monitoring so that control strategies can changed to protect the use of insecticides for the future. If the resistance is not managed properly through integrated control measures, then indeed, we may well see the current efforts fail with fatal consequences.

The Brazilian experience in the resistance monitoring and control of *Aedes aegypti*

Denise Valle[1], José Lima[1], Isabela Montella[2], Priscila Viana-Medeiros[1], Thiago Belinato[1], Nathalia Giglio[1], Ima Braga[3]

[1]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil, [2]Instituto de Biologia do Exército, Rio de Janeiro, Brazil, [3]Secretaria de Vigilância em Saúde, Ministério da Saúde, Brasília, Brazil

Introduction: In Brazil, dengue is a major public health concern. Brazilian Dengue Control Program coordinates the *Aedes aegypti* Insecticide Resistance Monitoring Network (MoReNAa). This network is also implicated in defining sentinel municipalities, testing alternative insecticides and recommending novel control strategies.

Methods: Epidemiological parameters, including the dengue historical series of cases in each one of the 5,564 Brazilian municipalities, were used to define localities to be continuously monitored. Resistance monitoring includes larvae and adults bioassays and biochemical tests to unravel resistance mechanisms. Alternative insecticides, mainly Insect Growth Regulators (IGR), are tested in laboratory, simulated field and field conditions. Their potential to induce cross resistance in Brazilian mosquito populations is also evaluated.

Results: One-hundred strategic and sentinel municipalities were chosen to be continuously followed. Novel population classification criteria, based on the Brazilian resistance monitoring experience, were defined. These criteria are at the basis of MoReNAa control strategies recommendations to the Brazilian Dengue Control Program. Biochemical assays point to a strong metabolic resistance component in Brazilian *Aedes* populations. The IGRs tested in laboratory conditions were effective against field mosquito populations resistant to chemical insecticides. Potential relation between IGR tolerance and organophosphate resistance is not general. Persistence in the field of some IGRs, mainly chitin synthesis inhibitors, is consistent with the Brazilian dengue control routine.

Conclusions: In Brazil, dengue is a complex problem that transcends health questions. Although we are far from eliminating dengue from the country, the Brazilian experience is a strong example of integrated work between research and public health services.

Assessing the impact of Bt maize pollen on adult green lacewings

Yunhe Li, Michael Meissle, Jörg Romeis

Agroscope Reckenholz-Tänikon Research Station ART, Zurich, Switzerland

Although the application of *Bt* plants can largely reduce the need for conventional insecticides and benefit the environment and human health, concerns about potential effects of *Bt* crops on non-target organisms have been raised due to the high and consistent expression of *Bt* toxin in most plant parts throughout the whole growth period.

Adults of the green lacewing *Chrysoperla carnea* (Stephens) (Neuroptera: Chrysopidae) are prevalent pollen-consumers in maize field. They are therefore exposed to insecticidal proteins expressed in the pollen from certain *Bt* maize events. Laboratory experiments were conducted to evaluate the impact of transgenic *Bt* maize pollen on adult *C. carnea*.

Adult *C. carnea* were fed with pollen from transgenic maize events Event 176 or Mon 88017 (expressing Cry1Ab or Cry3Bb1, respectively) or from their corresponding non-transformed maize varieties together with sucrose solution. Over a period of four weeks, different life-table parameters (fecundity, fertility, survival) were recorded. The results revealed no negative effects on adult *C. carnea*. To confirm that adult lacewings are not sensitive to Cry1Ab or Cry3Bb1, additional studies were conducted where the insects were fed with an elevated dose of the two purified Cry proteins incorporated into artificial diet. The toxin dose was approximately 10 times higher that in the transgenic pollen. Again no effects on the recorded life-table parameters were detected.

This study shows that adult *C. carnea* are not sensitive to Cry1Ab and Cry3Bb1 and that the consumption of *Bt* maize pollen does not pose a risk to this important non-target species.

Modelling the bait control of tsetse flies (*Glossina* spp) in heterogeneous areas of operation

G.A Vale[1], S.J Torr[2]

[1]Southern African Centre for Epidemiological Modelling and Analysis, University of Stellenbosch, Stellenbosch, South Africa, [2]Natural Resources Institute, University of Greenwich, Greenwich, United Kingdom

A deterministic model simulated the bait control of tsetse in operational areas 32km wide, with good and poor habitat, adjacent to an invasion source of good habitat. In good habitat there were 2500 males and 5000 females/km^2. The population expired due to mating-finding difficulties when the male density was <0.1/km^2, associated with female densities of about 1/km^2. Daily displacement averaged 249m for males and 367m for females. Baits were placed in all or parts of the operational. With good habitat near the invasion front, evenly spaced baits killing 2.5% of the population per day reduced the female density to <1/km^2 at 22km from the front after 18 months; compared to 3km after 2 months with a 40% kill. Gaps of 2-3km between bait placements were inconsequential provided the average kill rate was maintained. Gaps 7km wide delayed effective control within the whole operational area by 11 years. Campaign costs were only 30% greater using the 40% kill, as against the 2.5% -- costs offset by the speedier and more extensive opportunities for tsetse-free farming. The annual cost of progressive control can be double that of the static, but involves the prospect of widespread clearance to natural barriers against invasion. The need for vigilance in maintaining invasion barriers is stressed.

Modelling the bait control of tsetse flies (*Glossina* spp) in heterogeneous areas of operation

Interventions for control of beetle pests of staple food crops in Pacific island countries

Sada N Lal

Secretariat of the Pacific Community, Land Resources Division, Suva, Fiji

The beetle pests, rhinoceros beetle (*Oryctes rhinoceros*) and taro beetles (*Papuana* spp.) are a menace to coconut (*Cocos nucifera*) and taro (*Colocasia esculenta*), which are major staple, cash and culturally important crops in the Secretariat of the Pacific Community region.

The first biocontrol attempts for the rhinoceros beetle were in the 1930's, shortly after arrival of the pest, with introduction of several predators and parasitoids from Asia and Africa, but with limited effect. The first pathogen to be introduced, the fungus *Metarhizium anisopliae* (*Ma*), was released in Samoa in 1939 for use in the breeding sites. Most effective biocontrol was achieved after the *Oryctes virus* was introduced to the region in 1967. Within 3 years of the virus release, beetle damage fell from levels of 70% to 90% of palms infected down to 5% to 15%. The beetle populations reappeared after a decade and the virus was re-released to overcome the damage. Regular releases of virus have continued, but in Samoa and some other countries beetle damage has once again increased and the virus releases no longer appear to reduce the damage levels.

Taro beetles have no effective biocontrol agents although several pathogens are present in its centre of origin, the Papuan region. *Oryctes virus* is very infective to taro beetle, but unlike use for control of rhinoceros beetle its use in the field is limited due to lack of transmission. *Ma* on its own does not give required field control of taro beetles, but is a useful organism as it can be used in synergy with low doses of insecticides such as imidacloprid and provide sufficient control of the beetle to yield over 90% of marketable corms.

Comparative approaches to the evolution of a blood-feeding lifestyle in ticks

Ben Mans

[1]Onderstepoort Veterinary Institute, Pretoria, South Africa, [2]National Institutes of Health, Rockville, United States

Introduction: The vector-host interface is a focus area for the understanding of the evolution of blood-feeding behavior in ticks. Hard (long-feeders) and soft (fast-feeders) ticks evolved different strategies to regulate host defences such as the immune and hemostatic systems. Characterization of these strategies in regard to conservation across tick lineages allows us to reconstruct past adaptations to the blood-feeding niche.

Methods: Comparative biochemical, molecular biological and bio-informatical methodologies are employed to determine conserved functions across various tick genera.

Results: Hard and soft ticks possess similar salivary gland protein family repertoires. Few orthologs are, however, shared between hard and soft ticks or even within the major lineages found within the Ixodidae (prostriate and metastriate). Rather, multi-member protein families show lineage specific expansions. In contrast, a wide diversity of conserved functions is present within the Argasidae.

Conclusions: Conservation of function in the Argasidae suggests that these functions existed in the ancestral lineage of the soft ticks. The lack of conservation found within the Ixodidae suggests that their specific lifestyle (prolonged exposure to the host's defences) had a significant impact on their adaptation to a blood-feeding lifestyle.

Insect-plant interactions in a multitrophic world

Louise E.M. Vet

Netherlands Institute of Ecology (NIOO-KNAW), Maarssen, Netherlands

Insects and plants live in a world of love and hate. To fully understand their interactions a multitrophic approach is crucial since relationships between successive trophic levels can be influenced by other trophic levels. Research on multitrophic interactions (MTI) aims at identifying the molecular, physiological, and behavioural mechanisms involved and how these affect higher-level processes such as the structure, dynamics, functioning and evolution of multitrophic communities. Insight in the functioning of ecological communities is more crucial than ever due to the rapid global changes that our planet is experiencing.

MTI research is flourishing and studies are becoming increasingly interdisciplinary, which is also a general development in ecology. Plant defence is central to multitrophic theory. Plants can defend themselves directly against herbivores, but also indirectly by emitting volatiles upon herbivore damage that attract natural enemies. In addition, plant defence links above- and belowground interactions. Rhizosphere processes can thus have significant consequences for interactions between aboveground herbivores and their natural enemies such as parasitoids, as well as for their fitness. Since insect parasitoids are major players in many terrestrial food webs, not only as enemies of herbivores but also as friends of plants, research on MTI must address their responses to dynamical food web processes such as induced plant defence. For both plants and insects in MTI studies it is becoming imperative to connect different levels of biological organization, i.e. to address and link processes operating at levels from the gene to the community. New techniques such as genomics and metabolomics provide exciting opportunities to forward the field of insect plant-interactions. I will discuss some of these challenges and identify novel foci of MTI research.

Bio-diversity, conservation and priorities concerning some families of the orders Coleoptera, Hemiptera and Lepidoptera

Dolly Kumar, Bhumika Naidu

M.S.University of Baroda, Vadodara, Gujarat, India

Introduction: Insect diversity studies from India, are immense but reports on disappearing insect species and their families from the country are sparse. This is the first comprehensive report on the population studies and the reducing numbers of insect species from the families Scarabidae, Belostomatidae and lycaenidae from the western part of the Indian peninsula.

Methods: Study was undertaken for a period of 4 years from Jan. 2004 to Jan. 2008. Collections and sightings were made within the city area. Rank abundance, Species Diversity and percent composition calculations indicated decline in the entomofauna of the said families.

Results : Percentage composition of *Belostoma indica* declined from 36 % to 9 %. From the family Scarabidae *Gymnopleurus cyaneus* declined from 40% to 9.5%. Occurrence of the members of family Lycaenidae was also rare. Only one or two *Zizeeria otis* were sighted in the year 2007.

Discussion: Decline in the population of Belostomatids is due to the increase in the level of pollutants in the water bodies. Dung rollers are becoming rare as the cattle rearing landscapes are undergoing urbanization. The food plants of family Lycaenidae are being destroyed by humans. Caterpillars of *Freyeria trochilus*, thrives on the weed ,*Heliotropium* which is being killed by weedicides.

Over emphasis and excessive collection of insects by insect lovers is also responsible for their imperilled status.

Evolution and development of *Heliconius* wing patterns

Robert Reed

University of California, Irvine, Irvine, CA, United States

Introduction: Neotropical *Heliconius* butterflies are famous for their extreme geographic wing pattern variation and for the convergence of mimetic wing patterns between species within the genus. To better understand how mimetic polymorphism evolved in this group, we are working to identify the genes underlying mimetic wing pattern variation.

Methods: Our lab is part of a collaboration working to map and sequence regions of the *Heliconius erato* genome containing wing pattern variation genes. We are screening candidate genes identified from genomic sequences using a comparative expression approach. Specifically, by applying genomic tiling microarrays, quantitative RT-PCR, and *in situ* hybridization, we are assessing which candidate genes show color-pattern related expression differences during wing development.

Results: We have successfully sequenced across two different genomic intervals containing two respective color pattern genes. From these intervals we have identified several genes that are expressed during wing development. We will present our most recent results concerning the expression of these candidate genes in butterflies showing different mimetic phenotypes.

Conclusions: Through a combination of mapping, targeted genomic sequencing, and gene expression studies we are getting closer to identifying the specific genes that underlie wing pattern variation in *H. erato*. Identifying these genes will allow us to ask fundamental questions about the evolution and development of adaptive polymorphism and convergent evolution.

Impacts of some forest management practices on insects and other taxa in Europe

Allan Watt[1], Adam Vanbergen[1], Patrick Lavelle[2], Jari Niemelä[3], Paulo Sousa[4], Chris Van Swaay[5]

[1]Centre for Ecology and Hydrology, Edinburgh, United Kingdom, [2]Institut de Recherche pour le Développement, Paris, France, [3]University of Helsinki, Helsinki, Finland, [4]Universidade de Coimbra, Coimbra, Portugal, [5]Dutch Butterfly Conservation, Wageningen, Netherlands

Introduction: The BioAssess project considered the diversity of arthropods and other taxa in eight European countries. The main objectives were to quantify the impact of land use and management on a range of taxa and to identify suitable indicators of biodiversity. Managed and unmanaged forests were included in all countries.

Methods: Field sites were established in eight countries representing all the major biogeographic regions of Europe: Boreal – Finland; Atlantic – UK (Scotland) and Ireland; Continental – France; Pannonian – Hungary; Alpine – Switzerland; Mediterranean – Spain and Portugal. The abundance and diversity of soil macrofauna, soil Collembola, carabids, plants, lichens, butterflies and birds was quantified in each country along land-use intensity gradients from unmanaged forest to intensively managed arable sites. The impact of land use and management on each of these components of biodiversity was quantified and the potential of several indicators was evaluated.

Results: Forest management was found to have a marked impact on the diversity and species composition of all taxa but the impact of forest management varied between taxa and in some cases between regions.

Conclusions: The project highlighted the range of forest management practices in Europe and identified some of their impacts of insects and other taxa. The project also demonstrated that some taxa are better indicators of biodiversity than others. Butterflies, for example, predicted the species richness of birds, lichens and plants, but Carabidae (ground beetles) were found to be a poor indicator of other elements of biodiversity, only showing a weak correlation with soil macrofauna.

The evolution of "resin flowers" (Euphorbiaceae, Clusiaceae) and their bees (Apidae, Megachilidae): the roles of exaptation and natural selection in reward diversification

W. Scott Armbruster[1], Mats Gustafsson[2]

[1]University of Portsmouth, Portsmouth, Hants, United Kingdom, [2]University of Aarhus, Aarhus, Denmark

Flowers have evolved resin as a pollinator reward 3-6 times independently: once in the Euphorbiaceae (*Dalechampia*) and up to five times in the Clusiaceae (*Clusia*, *Tovomitopsis, Clusiella*). Resiniferous Clusiaceae appear to be exclusively neotropical, but resiniferous *Dalechampia* are found in the paleotropics as well as neotropics. Floral resins are collected by pollinating (and non-pollinating) bees (Apidae, Megachilidae) that use resin in nest construction. While resin is often brightly coloured, choice of *Dalechampia* blossoms by resin-collecting bees is usually based on the size of the involucral bracts, an honestly correlated advertisement. In the neotropics, resin lineages have given rise to nectar-reward lineages (*Clusia*), pollen-reward lineages (*Clusia, Dalechampia*), and fragrance-reward lineages (*Dalechampia*). While all *Dalechampia* in the continental paleotropics offer resin rewards, those in Madagascar have pollen rewards and are pollinated by pollen-feeding beetles, flies, and bees, or are "buzz" pollinated by bees. In addition to useful waterproofing and mechanical properties (*Dalechampia*), some floral resins have antibiotic properties (*Clusia*), which seem to be valued by bees. Reward resins probably arose by exaptation from floral-defence resin/latex, and reward resins may have, in turn, promoted the evolution of fruit and foliar defences.

Comparing apples and oranges: methodological challenges of temperate - tropical comparisons

Vojtech Novotny

Biology Center, Czech Academy of Sciences, University of South Bohemia, Czech Republic

Latitudinal gradient in species diversity represents one of the major challenges to ecological theory, as well as an excellent opportunity to study processes generating and maintaining species diversity. Rigorous comparisons between tropical and temperate ecosystems are however rare. Temperate and tropical communities tend to be studied by different sets of ecologists, each using distinct sampling protocols. This methodological bias is further complicated by large biological differences between temperate and tropical communities in their phylogenetic composition, species richness and niche structure. The present study analyses these challenges and suggests unified protocols for the study of insect communities and determinants of their species richness along global latitudinal gradients.

Wide area approach to control *Carpophilus* spp. (Coleoptera: Nitidulidae) in stone fruit in Australia

Mofakhar Hossain, David Williams, Mamun Hossain

Department of Primary Industries (DPI), Tatura, Victoria, Australia

A user-friendly Attract and kill (A&K) system using aggregation pheromone and synthetic co-attractant has been developed for control of *Carpophilus* spp without having to spray the orchard. The attract and kill system proved effective in small scale trial (1 ha block). Generally three attract and kill stations per ha were deployed at the up wind corner of each one ha block. We are currently assessing a wide area approach to reduce *Carpophilus* spp populations across a larger area in order to make the system more effective and sustainable. During the fruit growing season of 2005/06 and 2006/07, respectively 70 and 100 ha of T204 peach blocks were treated with the attract and kill system in the Goulburn Valley, northern Victoria. The attract and kill system worked more effectively when a larger area in an orchard was covered and the *Carpophilus* spp population was reduced by more than 100,000 beetles/ha within a year in orchards with high level of populations. To prevent invasion by beetles into target blocks from neighbouring blocks we studied the effects of treating the blocks, surrounding target blocks of T204 peaches with high beetle populations, with either two or three A&K stations/ha. Six target blocks (each with 3 A&K stations/ha) were selected. Three had neighbouring blocks treated with 3 A&K stations/ha and 3 had neighbouring blocks treated with 2 A&K stations/ha. Six control blocks, not treated with A&K stations, were selected for comparison. Fruit damage assessment was done in nine locations in each target and control block. The average fruit damage levels were 0.39%, 0.35% and 4.20% in blocks treated with 3 A&K/ha or 2 A&K/ha and control. Experiments were also conducted with two or three A&K stations/ha in T204 blocks in properties with medium and low beetle population levels. There was no difference in fruit damage between blocks with either two or three A&K stations/ha. This suggests that cost of control may be reduced without sacrificing efficacy.

Ticks and tsetse control in sub-Saharan Africa: particular reference to a 100 years of acaricides use in South Africa

Abdalla A Latif

Onderstepoort Veterinary Institute, Pretoria, South Africa

Ticks and tick-borne diseases TBDs and tsetse and trypanosomosis coexist in many situations in Africa and affect the same population of cattle. Different effective control methods can be planned for TBDs including treatment of cattle with chemical acaricides, presence of natural acquired immunity to most of TBD after initial infection in endemic areas, immunization against TBDs, vaccination against ticks, treatment of clinical cases, and using tick-resistant cattle. However, there are only few control options for tsetse and trypanosomosis in absence of naturally acquired immunity with the exception of the few trypano-tolerant breeds, absence of effective vaccines, and the wide-spread of drug-resistant strains of trypanosomes. Sterile insect technique is deemed to be expensive and aerial spraying is not appealing to environmentalists and conservation authorities. However, both techniques have been implemented and made successes. Many countries which have limited resources relied largely on its control operations on the application of pyrethroid insecticide on cattle and use of traps to control tsetse flies. Pyrethroid-treated cattle are introduced to graze fly-infested areas and tsetse flies are killed after feeding. The reports from different control projects have shown successful reduction in tsetse populations and incidentally, reductions in tick burdens on cattle. However, the regular use of pyrethroid-bait cattle to control tsetse fly populations, with the opportunistic and unplanned killing of ticks has many disadvantages. These arguments and the way forward will be discussed with particular reference to South Africa

Biological control of the *Sirex noctilio* wood wasp in pine plantations in South Africa

Geoff Tribe

ARC-PPRI, Stellenbosch, South Africa

Introduction: The Eurasian wood wasp *Sirex noctilio* was found in South Africa in April 1994 infesting pine plantations within a 90 km radius around Cape Town. A 3.2% mortality of trees was recorded. *Sirex* spread at an annual rate of 48 km within the Western Cape and reached George by 2001. *Sirex* appeared in parts of the Eastern Cape and KwaZulu-Natal in 2002 apparently by human assistance.

Methods: Three biological control agents have been utilized. Inoculations with the Kamona strain of the parasitic nematode *Beddingia (Deladenus) siricidicola* were carried out in 1995 and 1996. The larval parasitoid *Ibalia leucospoides* was imported in 1998 and 456 parasitoids were released from 1998 until 2001. In 1999, 38 mated females of the late-larval parasitoid *Megarhyssa nortoni* were released.

Results: The parasitism rate of *B. siricidicola* increased to 96.1% by 1998 and has since remained effective between 61% (2006) and 90.9% (2007). *Ibalia leucospoides* achieved a parasitism rate of between 33% (2006) and 25.7% (2007). *Megarhyssa nortoni* failed to become established.

Conclusions: Biological control has been highly effective in the Western Cape where *Sirex* is no longer an economic problem. This can be contrasted with KwaZulu-Natal where a reported 2 million trees were killed by *Sirex* in 2006. This appears to be due to: the biological control agents not being moved to the front as *Sirex* dispersed; a reported inoculation success rate of only 2% indicates non-viable nematodes; and the *Sirex* flight period beginning and ending earlier than in winter rainfall areas.

Isolation and toxicity evaluation of bacterial entomopathogens against phytophagous white grubs (Coleoptera: Scarabaeidae) in Indian Himalayan hills

Shahid Sami Siddique, Zubair Ahmad, Mohd Shamim, Parvez Qamar Rizvi

Aligarh Muslim University, Aligarh,uttarpradesh, India

White grubs (Coleoptera: Scarabaeidae) are the cosmopolitan insect pests of agriculture, forest and pasture lands. The western Indian Himalayan hill region has a vast biodiversity of nearly 40 species of phytophagous white grubs. Among them, *Anomala dimidiata* and *Holotrichia seticollis* are the most abundant species and cause serious damage on many crops. Under natural condition, bacterial epizootics on white grubs were observed to the extent of 20.6%. Hence an attempt was made to isolate and characterize a bacterium, which is most potent for the management of white grubs. Out of 27 bacterial isolates tested against 2^{nd} instar grubs of *A. dimidiata*, the isolate WGPSB-2 was found highly toxic. Based on various morphological, physiological and biochemical tests the isolate WGPSB-2 was identified as *Bacillus cereus*. The dose determination bioassay indicated that the 1^{st} instar grubs of *A. dimidiata* and *H. seticollis* were more susceptible than the 2^{nd} instars. Although the LT_{90} values for 2^{nd} instar grubs were more than eight weeks, the grubs stopped feeding after ingestion of spores, mostly after third week. Under micro plot condition, a dose of $1.7x10^{11}$ spores/m^2 in the form of root zone application was found satisfactory to manage both the species of white grubs. In the absence of any other viable and environmentally competitive biological control agents, the *Bacillus cereus* strain WGPSB-2 appears to be a potential bacterial pathogen for the management of white grubs.

Discussion: international themes and challenges in coffee pest management

Nilsa Bosque-Perez, Sanford Eigenbrode

Department of Plant, Soil and Entomological Sciences, University of Idaho, Moscow, Idaho, United Sates

The themes and challenges on integrated management of coffee pests and beneficial insects emerging from the Symposium will be discussed. Special emphasis will be placed on identifying subjects for future research and potential areas of collaboration between diverse institutions.

Effects of insect-resistant transgenic crops on nontarget organisms

Maureen O'Callaghan[1], Louise Malone[2]

[1]AgResearch, Christchurch, New Zealand, [2]Horticulture and Food Research Institute of New Zealand Ltd, Auckland, New Zealand

Introduction: Measuring nontarget impacts is an essential part of the risk assessment process for insect-resistant transgenic crops. While *Bacillus thuringensis* (Bt)-plants currently dominate the market for insect-resistant transgenic crops, plants expressing alternative insecticidal compounds such as lectins, protease inhibitors and biotin-binding proteins, are currently under development.

Testing nontarget impacts: Testing has focussed on measuring impacts on "ecosystem service providers" (e.g. natural enemies and pollinators), and insects of cultural or aesthetic value. The extensive testing on non-target plant-feeding insects and beneficial species that has accompanied the wide-scale and long-term use of Bt-crops has not detected significant adverse effects. There is also growing recognition of the need to determine nontarget impacts on soil ecosystem function; tests to date have shown that Bt-crops have little impact on soil biota such as earthworms, collembolans and general soil microflora. While extensive testing has been carried out with Bt-crops, plants expressing other insect resistant proteins with a broader spectrum of activity and differing modes of action have been tested on a very limited range of nontarget species to date. In addition, with the exception of Bt endotoxins, little is known about the persistence of other transgene-derived proteins in soil.

Conclusions: Major knowledge gaps remain in the nontarget testing of transgenic plants; for example, test species are often not representative of the environment in which the transgenic plants will be grown and detection of nontarget impacts resulting from novel combinations of insecticidal proteins may require a different set of testing methodologies than those used to date.

Biological control of water hyacinth – the Lake Victoria case

James Ogwang

National Crops Resources Research Institute, Kampala, Uganda

Introduction: Biological control of water hyacinth in Lake Victoria using two weevil species *Neochetina bruchi* and *Neochetina eichhorniae* reduced the weed biomass by 90% five years post release in 1995. Cases of resurgence of the weed have been reported in several points of the lake since 2000.

Methods: Samples were taken using a wooden quadrant tossed randomly in weed mats have been taken since 2000. Data taken included weed weight, petiole and root length in addition to weevil numbers, sex and species per plant were recorded

Results: Results showed that the resurgent mats initially had few (0.5 -2 weevils/plant) in the early 2002 but this has gradually built up to14 weevils/plant by December 2007. Additionally evidence of weed wilting due to pressure from weevil population was widespread in the lake

Conclusion: The collapse of water hyacinth mats in late 1990s resulted in a corresponding weevil population collapse. Sinking mats similarly significantly increased water nutrients which became favourable for the rapid germination of water hyacinth seeds deposited below the water surface. A combination of these factors was probably responsible for the weed resurgence. However, with the weevil build up, it is unlikely that water hyacinth biomass will revert to pre-control level

Species diversity and plant resources of stingless bees along a disturbance gradient in western Kenya

Mary Gikungu[1] and Manfred Kraemer[2]

[1]National Museums of Kenya. Zoology Department. P.O. Box 40658-00100 Nairobi, Kenya, [2]Faculty of Biology, Biological Collection, University of Bielefeld, P.O. Box, 100 131, 33501 Bielefeld, Germany

Introduction: Establishing the composition structure of stingless bee community is necessary for understanding the cumulative impact by anthropogenic factors and their resilience in natural habitats. The study aimed at examining the species diversity and food sources of stingless bees along a disturbance gradient in the study area.

Methods: The abundance of bees was sampled monthly using the belt transect method. Bees were sampled with a sweep net at each site three times per month from May 2002 to April 2004.

Results: The results of this study provide the first documentation of the stingless bees and their food sources of Kakamega forest. The recorded stingless bee species included Meliponula *bocandei, Meliponula lendliana, Meliponula ogouensis, Meliponula ferruginea, Pleibena hildebrandti, Hypotrigona gribodoi and Liotrigona bottegoi.* The highest diversity of stingless bees based on Shannon-Wiener index (H') was recorded in the farmland followed by moderate secondary forest and advanced secondary forest, while no significant difference was found along the gradient in terms of bee species richness. The most important plant families were Asteraceae, Acanthaceae, Labiatae, and Malvaceae while the most important plant species were *Maesa lanceolata*, *Tithonia diversifolia* and *Zea mays*. The stingless bee community was found to be highly influenced by the availability of food sources.

Conclusion: The research suggests that at least in some systems, conservation of native bees and the pollination service they provide depends on management of both natural forests and secondary forests together with the surrounding agro-ecosystems. Further, disturbed habitats in low-intensity farming systems may provide suitable resources for many bee species when there are less flowering plants in forested systems.

Baseline surveys of malaria vector mosquitoes from Guinea Conakry, West Africa

Samuel B Vezenegho[1], Samuel B Vezenegho[2], Basil D Brooke[1], , Basil D Brooke[3], Richard H Hunt[1], Richard H Hunt[4], Lizette L Koekemoer[1], Lizette L Koekemoer[3], Maureen Coetzee[1], Maureen Coetzee[3]

[1]Vector Control Reference Unit (VCRU),National Institude for Communicable Diseases, Johannesburg, South Africa, [2]School of Molecular Cell Biology, University of the Witwatersrand, Johannesburg, South Africa, [3]Division of Virology and Communicable Disease Surveillance, School of Pathology of the NHLS and the University of the Witwatersrand, Johannesburg, South Africa, [4]School of Animal, Plant and Environmental Sciences, University of the Witwatersrand, Johannesburg, South Africa

Introduction: Malaria vector resistance to pyrethroid and DDT insecticides has been reported in West Africa. There is only limited information about vector composition and susceptibility status in Guinea Conakry. This study was designed to provide more information from three localities with very different environment.

Methods: *Anopheles* mosquitoes were collected in Mount Nimba, Siguiri and Boffa. Field bioassays using deltamethrin, DDT, dieldrin, malathion and bendiocarb were performed on *An. gambiae* s.l according to the standard WHO protocol. Further species identification by PCR, WHO standard insecticide susceptibility assays, sporozoite ELISA and the two-step PCR method for *kdr* detection were used.

Results: Field bioassays showed high susceptibility to all insecticides in Boffa. Full susceptibility to deltamethrin and malathion was demonstrated in Siguiri and Mount Nimba. Resistance to DDT, dieldrin and bendiocarb was shown in Siguiri and Mount Nimba. PCR assays identified 494 (82.3%) as *An. gambiae* and 2 (0.33%) *An. arabiensis* in a sample of 600 specimens. No amplification was achieved in the remaining 104 (17.33%) specimens. Plasmodium infection rate of 5%, 6% and 21% was obtained for Siguiri, Mount Nimba and Boffa respectively. *Kdr* PCR and sequencing revealed the presence of the leucine to phenyalanine mutation in the S form. Biochemical enzyme analysis in the F_1 progeny of wild *An. gambiae* s.s exposed to pirimiphos methyl indicated esterase and monooxygenase elevation.

Conclusions: The S molecular form of *An. gambiae* is the main malaria vector at these localities in Guinea Conakry and occurs in sympatry with the M form. The involvement of *Kdr* in phenotypic resistance to DDT is unclear but need to be considered when planning control strategies. Metabolic involvement in resistance is likely. *Kdr* detection by Pyrosequencing is being investigated. The use of long-lived pyrethroids and short-lived organophosphates throughout the year is recommended for vector control in Guinea Conakry.

Ethical Issues in the use of forensic entomology evidence

Robert Hall

University of Missouri, Columbia, Missouri, United States

The most frequent medicocriminal use of forensic entomology evidence is the inference of human postmortem interval (PMI) based on the thermal developmental profile of well-studied blow fly species. As criminal cases are litigated, there may exist extreme pressure on the entomologist expert witness to supply an analysis favorable to the retaining party. Aspects of entomological evidence vulnerable to such pressure include 1) use of remote temperatures obtained from a weather recording station where such temperatures produce an insect-estimated PMI most favorable to the desired outcome, 2) speculative explanations on when ovipositing females may have accessed a corpse when any form of “barrier” is present, 3) misuse of accumulated-degree-hour calculations when such are not warranted, 4) speculation regarding unmeasured maggot mass effects, 5) assertion of unique, “one of a kind” circumstances to achieve the desired result, and 6) selective use of blow fly developmental data sets to achieve a result favorable to the retaining party. The duty of the expert witness in U.S. courts is to provide the trier-of-fact with sound science, regardless of the ultimate legal outcome of the case at bar.

Evolution of wingless reproductives in ants: diversity in morphology and social structure

Christian Peeters

UPMC Paris Universitas, Paris, France

Introduction: A majority of ants produce winged queens that disperse by flight and found colonies independently. However many species belonging to all the major subfamilies shifted to obligate colony fission, and there is no longer a solitary founding stage. Hence selective pressures on reproductives are relaxed, and they become completely dependent on workers. Since fission in ants is synonymous with short-range dispersal on foot, because the workers are wingless, the production of flying queens is selected against. Except for about 200 species where workers can mate and reproduce (= 'gamergates'), in other taxa 'ergatoid queens' have evolved.

Methods: Species having either winged queens or wingless reproductives were studied in various genera, both poneroid and formicoid. Their alternative reproductive systems were compared using a variety of data: colonial demographies and caste ratios, behavioural observations, morphology and morphometry, dissection of ovaries.

Results: In *Cerapachys, Odontomachus, Proceratium* and others, a single ergatoid queen reproduces in each colony. The thorax is highly reduced but they are allometrically different from workers.This contrasts with other genera (*Mystrium, Eutetramorium,* ..) in which many ergatoid queens are present throughout the year. A few of these mate and reproduce, while the others remain in the nest to function as labourers. Colonial investment in ergatoid queens is always much reduced compared to congeneric species producing many winged queens annually.

Conclusions: Different solutions evolved to replace winged queens. Changes in the phenotype of reproductives are associated with modifications in colony-level investment, and both these adaptations contribute to the success of fission in ants.

Combining the mirid *Eccritotarsus catarinensis* and the weevils *Neochetina* spp. as biological control agents of water hyacinth *Eichhornia crassipes*.

Obinna Ajuonu[1], Marcus Byrne[2], Martin Hill[3], Peter Neuenschwander[1], Sam Korie [1]

[1]International Institute of Tropical Agriculture, Benin, Abomey, Calavi, Benin [2]University of the Witwatersrand, Johannesburg, South Africa, [3]Rhodes University, Grahamstown, South Africa

Introduction: The mirid *Eccritotarsus catarinensis* was released to complement biological control of water hyacinth *Eichhornia crassipes* by the weevil species *Neochetina eichhorniae* and *N. bruchi*. In two separate experiments, a) the influence of feeding scars by adult weevils on the survival of the mirid and b), the impact of biological control agents as single species and together on growth parameters of the host plant, were studied.

Methods: In the first study, water hyacinth plants with varying amounts of weevil feeding scars were exposed to adult mirids under laboratory conditions for three days, after which adults were counted to determine adult survival. After fifteen days, immatures were counted to determine reproduction and their survival. In the second study, water hyacinth plants grown in the screen house in competition with water lettuce (*Pistia stratiotes*) were inoculated with agents. Impact of agents was assessed by measuring water hyacinth plant growth parameters.

Results: The mirid survived well on plants with recent feeding scars from adult weevils and on leaves with more than 200 old scars. Combining both agents at half the population densities produced the same growth reduction in *E. crassipes* as the weevil *N. eichhorniae* at full density.

Conclusions: The weevil is not likely to prevent the establishment of the mirid and therefore it would be a good complement to the already established biological control agents of water hyacinth particularly on stranded plants where the weevil is prevented from pupation.

Application of *Sycanus collaris* as biocontrol agent for insect pests in plantation forestry

Budi Tjahjono, Abdul Gafur, Aswardi Nasution, G.D. Golani

APRIL Forestry R&D, PT RAPP, Pangkalan Kerinci 28300 Indonesia,

Introduction: The assassin bug *Sycanus collaris* (Hemiptera: Reduviidae) is well recognized as an important predator of numerous insect pests. In Indonesia, this insect has long been used as a predator to reduce the levels of caterpillar populations in oil palm plantations. Here we report on the application of *S. collaris* to manage *Helopeltis* spp. and leaf roller caterpillar populations in acacia, eucalypt, and *Melaleuca* plantations in south Sumatera. This has the advantage of limiting the application of chemical insecticides and it also promotes the economical and ecologically sound forestry.

Methods: For field introduction, *S. collaris* was produced in the laboratory. It was fed on *Corcyra cephalonica* (Lepidoptera: Pyralidae) and *Tenebrio molitor* (Coleoptera: Tenebrionidae). Up to 2007, it was possible to release as many as 4,571 individual insects into plantations in Sumatera, Indonesia.

Life cycle: The eggs of *S. collaris* are laid in clusters and cemented to each other and to the surface of the plastic boxes in which the insects are reared. The nymphs moult five times before they reach imago stage. The duration required from the first to the fifth instar of the nymph is about 12 weeks. Males and females can be distinguished by their body and abdominal sizes with the males being smaller.

Results: Reduction in pest population, plant recovery, and development of the predator after field release were used as indicators of the efficacy of *S. collaris*. Up to the present, *Helopeltis* incidence has dropped from 30 % to 10 % in *A. mangium* plantations and leaf roller incidence has dropped from 60 % to 10 % in *Melaleuca* plantations.

Inter-country collaborative efforts in vector control in Africa

Rajendra Maharaj

Malaria Research Programme, Medical Research Council, Durban, South Africa

Malaria is not a country specific disease but should be seen as a disease of regional importance. Most countries lack the infrastructure and/or the technical expertise to effectively control the disease in their countries. Therefore through close collaboration countries can share resources and technical expertise to implement more co-ordinated intervention strategies in a more sustainable manner

The Lubombo Spatial Development Initiative (LSDI) is one such initiative that aims to implement effective malaria control within a sub-region. Through proper scientific investigation, intervention strategies were designed to have maximum impact. Insecticide resistance studies and household surveys guided the selection of appropriate strategies. Coupled with a malaria health information system, the success of the vector control strategy could be evaluated. This facilitated continuous monitoring and evaluation. The outcome of these interventions was that prevalence at 28 sentinel sites showed an average decrease of 70% in children aged 2 to 15 years.

The success of the LSDI was acknowledged in the recognition that it presented a model upon which further initiatives could be built. This model was implemented on the Island of Bioko in West Africa and similar successes were achieved. In recognition of this success, this initiative was expanded to mainland Equatorial Guinea and Conakry Guinea. The recently established Trans-Zambezi malaria control initiative is to adopt a similar model that will be implemented in 15 contiguous districts in 5 southern African countries.

The face of vector control is changing to ensure that similar multi-country strategies are implemented across national borders to slow the development of resistance and encourage sustained malaria control. This in turn facilitates the implementation of malaria elimination strategies.

VectorBase: a bioinformatics resource for the analysis and display of vector genomes

Frank Collins

University of Notre Dame, Notre Dame, United States

VectorBase is a centralized relational database based on publicly available and supported database management tools that displays through an internet interface all data relating to the genomes of arthropod vectors of human pathogens. The basic 'engine' of VectorBase is the Ensembl genome browser and analysis system developed by the European Bioinformatics Institute. Genomes in VectorBase are displayed through the Ensembl genome browser, which is modified and 'branded' for VectorBase; genome annotations are updated by the EBI subcontract team using the Ensembl tools. VectorBase also displays data that are not managed and displayed by the Ensembl system. This has been done by creating a hybrid system based on two data schemas. All data in the non-normalized Ensembl schema are also mapped into a VectorBase instance of the GMOD Chado schema designed to be consistent with FlyBase Chado. This schema is also used to capture additional types of data, such as physical mapping data, expression data, controlled vocabulary, and other genome metadata that are not part of the core Ensembl data set. Additional data are brought into the Chado schema and then displayed in the Ensembl core of VectorBase through distributed annotation system (DAS) display tracks that are designed into the Ensembl display. This presentation will give an overview of the general structure of VectorBase as well as a summary of the genomes currently in VectorBase and data likely to be managed by VectorBase in the upcoming year.

Exploitation of wild relatives of crops as source of novel genes for resistance to insect pests

Hari Sharma, Venkateswaran Kamala, Stevenson Clement, James Ridsdill-Smith, G Sujana

[1]International Crops Research Institute for the Semi-Arid Tropics, Patancheru, Andhra Pradesh, India, [2]National Bureau of Plant Genetic Resources Regional Station, Patancheru, Andhra Pradesh, India, [3]USDA-ARS, Washington State, Pulman, United States, [4]CSIRO Entomology, Wembley, WA, Australia, [5]International Crops Research Institute for the Semi-Arid Tropics, Patancheru, Andhra pradesh, India

Cultivated germplasm of many crops has only low to moderate levels of resistance to several insect pests such as bollworms, stem/shoot borers, pod borers, aphids, shoot flies, jassids, and white flies. As a result, progress in developing insect-resistant cultivars in several crops against several insect species has been quite slow. However, closely related wild relatives of several crops have high very levels of resistance o insect pests. Wild relatives with different genes and diverse mechanisms of resistance of resistance have been identified against *Heliothis/Helicoverpa* in cotton, pigeonpea, chickpea, and tomato; *Atherigona*, *Chilo*, and *Stenodiplosis* in sorghum; *Maruca* in cowpea; *Orseolia* and *Scirpophaga* in rice; *Amrasca*, *Aproaerema* and *Spodoptera* in groundnut; and *Maytiola* and *Diuraphis* in wheat. Considerable progress has also been made in understanding the physico-chemical mechanisms of resistance, and introgression of resistance genes from the wild relatives into the high yielding cultivars in several crops. Genes for insect resistance from the wild relatives can be utilized through wide hybridization, marker assisted selection, and sequencing and cloning to increase the levels and diversify the bases of resistance to insect pests for sustainable crop production.

Genes for insect resistance from the wild relatives can be utilized through wide hybridization, marker assisted selection, and sequencing and cloning to increase the levels and diversify the bases of resistance to insect pests for sustainable crop production.

Sociality in nocturnal environments

Simon Tierney, Adam Smith, William Wcislo

Smithsonian Tropical Research Institute, Balboa, Panama

Introduction: Like most biologists, the majority of bees are active during the day. However a number of lineages have temporally shifted their foraging activity to low light or nocturnal environments. Dim-light foraging has repeatedly evolved among bees,, and some of these are social. The entry into this temporal niche requires some degree of physiological and morphological specialization, but how do dim-light environments affect social behaviour?

Methods: The origins of dim-light foraging in bees are examined within a phylogenetic context. Phenotypic adaptations postulated to be associated with such lifestyles are also briefly discussed. The social dim-light light taxa are then reviewed, with regard to the influence of low light environments on the ecology and social behaviour of these bees.

Results: Obligate dim-light foraging has independently evolved 18 times, in four of the nine bee families. Facultative dim-light foraging is more widespread, but does not require the same degree of phenotypic specialization. Evolution of dim-light foraging appears to be associated with an escape from competitors, predators and parasites. The Neotropical sweat bee genus *Megalopta* (Halictidae: Augochlorini) is the most intensively studied nocturnal social bee. Sociality is facultative and highly labile, reproductive dominance within social colonies is mediated by body size and recent studies suggest brood parasites significantly influence adult body size. Behaviour in *Megalopta* is contrasted with other social halictids and facultatively social bees generally.

Conclusion: Social dim-light foraging bees inhabit an uncommon niche, which presents excellent opportunities to investigate the role of extrinsic factors on social evolution.

An integrated approach to biosecurity threat identification and prioritization

Darren Kriticos, David Cook, Dean Paini, Shuang Liu, Jo Luck, Paul De Barro

CRC National Plant Biosecurity, Canberra, Australia

Biosecurity prediction is notoriously uncertain, and in planning biosecurity investments agricultural industries need confidence in the process. Most pest risk prediction rely upon some form of regression-based analysis of the habitat preferences of the target species, and application of the inferred relationships to novel environments where the invasion risk is being assessed. Regression-based methods tend to give results that include spurious modelling artifacts. Process-oriented models overcome some of these problems, but require skilled modellers to produce reliable results, take time to develop and currently lack a means of generating meaningful goodness of fit metrics. The outputs generated by habitat modelling software vary in their meaning, and are not provided in terms that are directly usable by pest risk assessors. Our research aims to relate CLIMEX outputs to damage functions that can be applied in economic impact assessments.

To a large extent systems of pest prioritisation depend on expert opinion regarding a number of uncertainties. While valuable, these subjective opinions have a profound impact on threat perception. Objective economic analyses are rarely used to inform prioritisation decisions, and where they are used their scope is generally limited to market impacts ignoring the effects on non-market goods. Our research aims to improve biosecurity planning and pest prioritisation by blending quantitative and qualitative expert-based impact assessment techniques in a structured, deliberative multi-criteria evaluation framework. A combination of neural network analyses estimating entry potential, bioeconomic impact simulation models and deliberative decision-facilitation tools are used to aid the design of appropriate risk mitigation and management strategies.

Tortricid morphology, phylogeny and systematics from a southern perspective

Marianne Horak

CSIRO Entomology, Canberra, ACT, Australia

The lucky constellation of early contact with the southern hemisphere fauna, exposure to Hennig's ideas and several generous and inspiring mentors provided an ideal foundation for my systematic career. A seminar on Hennig's phylogenetic systematics during my Ph. D. studies led to the rash decision to establish a hypothesis for the tortricid groundplan which has remained a crucial reference for all my future work. Trying to make sense of the conspicuously congruent genitalia morphology of many 'unusual' Gondwanan tortricids that defied tribal assignment, I realised that character states rare in the Holarctic fauna were often implicitly regarded as derived. Correction of this blinkered Holarctic viewpoint led to my reversing several tacitly accepted character polarities. Study of the large Australian Lepidoptera fauna, with only 50% of the species named, called for innovative methods, and Ebbe Nielsen initiated a monograph series based at the generic level to provide a stable framework, in a manner accessible to non-specialists. My olethreutine volume follows this model with one important change: two rather than one species are figured for each genus to provide generic rather than specific concepts. Even though the 90 olethreutine genera present in Australia are shared with or derived from the Oriental fauna, my study has provided comprehensive morphological evidence on which to build robust tribal concepts and furthered understanding of olethreutine phylogeny in a world-wide context. I am greatly indebted to Furumi Komai as without his contribution as first author for the very diverse Australian Grapholitini the olethreutine monograph could never have been completed.

Non-taxonomic biochemical tools for enhancing decision making at the border

Ilia Iline[1], Craig Phillips[1], Max Novoselov[1], Alan Flynn[2], Dave Voice[3], Sherly George[2]

[1]AgResearch & Better Border Biosecurity, Christchurch, New Zealand, [2]MAF Biosecurity New Zealand, Auckland, New Zealand, [3]MAF Biosecurity New Zealand, Lincoln, New Zealand

In addition to the daunting task of making taxonomic identifications of organisms that are intercepted at the border, regulatory authorities must also evaluate other characteristics of intercepted organisms such as their viability. When the intercepted organisms are sessile (e.g. eggs, pupae, scale insects) the challenge of rapidly and objectively assessing viability is significant, and the costs of incorrectly interpreting viability can be high. For example, if regulated scale insects associated with a consignment of imported produce were incorrectly assessed as being alive, the consignment may be unnecessarily rejected and either destroyed, fumigated or returned to the exporter. Alternatively, if the scale insects were incorrectly assessed as being dead, they could be allowed to cross the border into a new region or country, thus risking the establishment of a new pest. Viability assessments of sessile organisms are generally made using morphological criteria that demand high levels of user-experience to obtain reliable results. Moreover, morphological observations are often difficult to quantify or otherwise record in an objective manner, and this can cause problems when border authorities need to defend their viability assessments. This presentation describes a series of rapid, sensitive, inexpensive, simple-to-use biochemical tests that have been developed primarily for use by border authorities to make viability assessments of sessile organisms. The tests are also proving useful in other applications such as validating the efficacy of treatments that have been applied to consignments prior to export. The tests perform well across a diverse range of arthropods, and give easily interpreted, contrasting colour reactions depending on the viability of the organism; these can readily be quantified using a spectrophotometer or by measuring pixel values. The biochemical data have also shown that the physical appearance of sessile organisms can sometimes be misleading with respect to their viability. This work illustrates how relatively small research projects can help to increase the speed, reliability, objectivity, transparency, defensibility and overall efficiency of border biosecurity processes.

Bio-safety of insect-resistant genetically modified crops to non-target natural enemies of crop pests

Hari Sharma, Jorg Romeis, Mukesh Dhillon

[1]International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), Patancheru, Andhra Pradesh, India, [2]Agroscope Reckenholz-Tänikon Research Station ART, Reckenholzstr. 191, 8046 Zurich, Switzerland, [3]International Crops Research Institute for the Semi-Arid Tropics (ICRISAT),), Patancheru 502 324, Andhra Pradesh, India

Genes conferring resistance to insect pests have been inserted into several crops, and transgenic cotton and maize expressing *cry* genes from *Bacillus thuringiensis* (*Bt*) have shown considerable potential for pest management. Adoption of *Bt*-transgenic crops has resulted in increased yields and a decreased the pesticide use. However, there is a need for in-depth studies on the effects of genetically modified crops on nontarget natural enemies of crop pests. The effects of transgenic plants on the activity and abundance of natural enemies varies across crops, and the insect species involved. In general, there are no major adverse effects of genetically modified insect-resistant crops on the generalist predators, while some adverse effects have been observed on the host specific parasitoids, which are largely due to early mortality of the host larvae or poor nutritional quality of the inset host, rather than direct toxicity of the insecticidal proteins. Such effects are common for all pest control interventions, and in general, are not regarded as a risk. Highly specific, insect-resistant transgenic crops could play a significant role in integrated pest management in the future, and lead to a major reduction in the number of insecticide sprays, increase the activity of natural enemies. There is a need to harmonize the regulatory requirements to assess the bio-safety of transgenic crops to the non-target organisms for sustainable crop production.

A journal for pollination ecology.

Carolin Mayer

University of Hamburg, Hamburg, Germany

Despite pollination offering a huge, amazingly diverse and fundamental field of research, no ad hoc platform exists to exchange findings and knowledge in this field. Publications on pollination are scattered in various journals. This is due to the subject crossing multiple biological disciplines. This fact creates a few weak points, one being literature on pollination sometimes difficult and laborious to find. Journals find work on pollination inappropriate for publication on the grounds that it is neither botanical nor zoological. Publication, however, remains the mechanism for scientists to communicate their results, to earn a reputation and, finally, to receive funding for further research.

To promote the concept of pollination as an ecosystem service, researchers have to make themselves heard by stakeholders and the public. Bound publications and a forum for lively discussions will help to achieve this aim.

Therefore, a journal for pollination ecology to support the exchange of original knowledge and research in all area of pollination is proposed. Specifically, the journal should focus on evolutionary, ecological or conservational aspects of pollination, abiotic as well as biotic pollination, reproductive strategies of plants, community and population dynamics of plants and their pollinators as well as biodiversity and conservation issues.

The journal should be online and, most important, have open access to guarantee wide distribution. To keep a high standard of publications, all manuscripts and reviews should be based on original descriptive or experimental research worldwide, and should be peer-reviewed.

Molecular characterization of eggplant fruit and shoot borer, *Leucinodes orbonalis*, populations from India based on ISSR analysis

Leela Alamalakala, Girish Kamble, Bharat Char, Srinivas Parimi, Usha Zehr

Maharashtra Hybrid Seeds Co. Ltd., Jalna, Maharashtra. India

Introduction: Eggplant fruit and shoot borer (EFSB), an economically important pest of brinjal, is a species native to India. Understanding the genetic diversity of geographically distinct populations at molecular level prior to the commercialization of transgenic eggplant, helps in determining whether the differential susceptibility of populations to insecticidal proteins translates to significant differences at the molecular level. No reports were found in literature regarding the genetic diversity of EFSB populations. The goal of this study was to assess molecular genetic relationships among and within populations of EFSB from India using ISSR-PCR technique.

Methods: Larval DNA from 18 locations were genotyped individually using ISSR primers. ISSR- PCR products were resolved on 2.5% Tris-Boric Acid- EDTA agarose gels and stained with ethidium bromide. Primers that generated distinct, reproducible bands across three different amplifications were scored as binary data matrix and analysed with the software NTSYS-pc.

Results: ISSR-PCR technique revealed considerable levels of genetic differentiation both within and between EFSB populations. The ISSR fingerprints of individuals belonging to the same geogrpahical location exhibited a number of bands that varied between individuals, thus reflecting individual differences and high genetic diversity within a population. However, there was no correlation between the geographical distances between the population and genetic similarity or distance.

Conclusions: The results reported in this study demonstrate the utlity of ISSRs for assessing the genetic diversity in EFSB populations and for providing quantitative estimates of genetic similarities.

Comparative analysis of natural predation on colorado potato beetle eggmasses in cry-expressing experimental fields

Salvatore Arpaia[1], Grazia M. Di Leo[1], Joerg E.U. Schmidt[2]

[1]ENEA, National Agency for New Technologies, Energy and Environment, Rotondella, MT, Italy, [2]ETH, Federal Institute of Technology, Zurich, Switserland

Generalist predators, mainly egg feeders, are the most relevant natural enemies of the Colorado potato beetle (CPB) in Italy. In genetically modified (GM) fields expressing Cry toxins, some of these species could be exposed to the toxins either directly (e.g. via pollen or plant sap), ore indirectly through their preys. This guild may then be important to study potential environmental impacts of GM plants. CPB shows a “bet hedging” strategy for oviposition which enables the species to minimize the risks of progeny loss due to adverse environmental conditions (Voss & Ferro, 1990, Environ. Entomol. 19: 123-129). CPB is known to be sensitive to Cry3b toxins expressed in plants (Arpaia et al., 1997, Theor. Appl. Genet. 95(3): 329-334) while in the Cry1 class, only the Cry01IA1 is reported to be toxic to the larvae upon ingestion (van Frankenhuyzen and Nystrom "The *Bacillus thuringiensis* toxin specificity database" (2002) http://www.glfc.cfs.nrcan.gc.ca/bacillus). Potato and eggplant fields were setup in Southern Italy using GM plants expressing Cry1Ab and Cry3Bb toxins respectively, for two cropping seasons. Natural infestation was recorded. Eight newly laid eggmasses per plot were marked at the beginning of four following weeks. In daily visual samplings, the number of intact or preyed eggs and neonate larvae were counted. Moreover, on twelve randomly chosen plants, the number of eggmasses laid was recorded weekly. The egg predators observed were Nabidae, Miridae, Chrysopidae, Coccinellidae and Anthocoridae. In potato fields (where CPB represented a non-target herbivore), egg laying was similar between transgenic and control plots both in terms of number of eggmasses and number of eggs per mass. Likewise, predation rate was comparable between treatments. In eggplant fields, which expressed CPB resistance, the same results were obtained in the year of higher infestation. In the second cropping season, when CPB population was less abundant, egg predation in Bt-expressing plots was significantly more relevant. According to these results, the ecological function of natural predation on CPB eggs does not seem to be impaired by GM plants.

A short history of the commercialisaition and the benefits of MON810 Bt maize in South Africa

Hendrik Kruger

Monsanto, Johannesburg, South Africa

Over the past decade Monsanto has developed its YieldGard® technology protecting maize against insects, especially Lepidopterians. MON810 was initially intended to control *Busseola fusca* and *Chilo partellus*. However, it was observed that the technology also suppressed *Helicoverpa armigera*. Later, *Sesamia calamistis* was added to the list of target organisms. Testing on MON810 commenced in 1994, application for commercial release was done in 1996 and it was first sold commercially in 1998. Initial growth of MON810 sales was slow due to limited inclusion in the best maize hybrids and low seed availability. In recent years, sales have grown exponentially as these factors were overcome. In spite of financial and other benefits for small scale farmers, market acceptance for them has been low due to factors that will be explained in the presentation. Monsanto intends to introduce better events in the next years to further improve the performance of MON810. The technology still holds significant financial and other value for South African farmers in 2008.

Field tests of neem oil and neem seed water extract for the management of sucking and chewing pests attacking cotton.

Masood Khattak[2], Mohammad Rashid[2], Khalid Abdullah[1]

[1]Agriculture Research Institute, Dera Ismail Khan, Pakistan, [2]Gomal University, Dera Ismail Khan, Pakistan

Field trials were carried out to evaluate the effect of neem (*Azadirachta indica* A.Juss) oil and neem seed water extract on some economically important insect pests attacking cotton.

Neem oil at 1, 1.5 and 2% and neem seed water extract was applied at 1, 2 and 3% were compared with that of synthetic insecticide (Polytrin C® 440 EC) [profenophos + cypermethrin]. The treatments were administered four times during the cotton season and observation were recorded before and after 1, 3, 7 and fifteen days of treatment application. Data were recorded on incidence of whitefly (*Bemisia tabaci* [Hemiptera: Aleyrodidae]), jassids (*Amrasca devastans* [Hemiptera: Cicadellidae], thrips (*Thrips tabaci* [Thysanoptera: Thripidae]) spotted bollworm (*Earias insulana* [Noctuidae: Lepidoptera]) pink bollworm (*Pectinophora gossypiella* (Gelechiidae|: Lepidoptera)) and American bollworm (*Helicoverpa armigera* [Noctuidae: Lepidoptera]

Results indicated Neem oil at 2% and neem seed water extract at 3%significantly reduced the Whitefly, Jassids and Thrips infestation up to 12 days after spray as compared to that in the control. Similar trend in population reduction of sucking pests of cotton was observed after rest of the three treatment applications. Synthetic insecticide proved to be a better than neem based treatments at any interval.

Neem derivatives at higher concentrations badly affected the attack of pink bollworms and at all concentrations the attack of Spotted bollworm 12 days after spray. Plots treated with 1.5 % and 2 % neem oil and 3 % neem seed water extract resulted in to significantly higher yield as compared to that in the control. Polytrin C® 440 EC [profenophos+cypermethrin] in all cases was highly toxic to the test insects as compared to any other treatment.

Integrated management of fruit flies *Bactrocera* sp. (Diptera: Tephritidae) infesting mango (*Mangifera indica*) in Pakistan

Khalid Abdullah[1], Said Khan[2], Masood Khattak[1]

[1]Agriculture Research Institute, Dera Ismail Khan, NWFP, Pakistan, [2]Gomal University, Dera Ismail Khan, NWFP, Pakistan

In a series of experiments, food and sex lure, and neem oil was tested in comparison with untreated check to devise the IPM model for fruit fly management in mango orchards. The assessment was based on percent infestation in dropped and harvested fruits. All treatments were significantly effective than untreated check in controlling fruit fly. Neem oil at 50 ml and 30 ml/l of water were equally effective. Pheromone traps lured with methyl euginol integrated with intermittent food bait of protein hydrolysate application reduced the fruit fly population by 86.48 and 94.18% in dropped and harvested fruits in year-1 and 87.5 and 89.2 in dropped and harvested fruits in year-2, respectively. On the basis of experiments the IPM models were tested on a sizeable mango orchard. The model comprised of 1) installation of sex lure traps (4/acres), 2) Crop Hygiene (CH) [removal of weed flora and fruit fly resting and sheltering places], 3) twice hoeing under the trees; 4) twice intermittent food bait application during the fruiting season. Data revealed that IPM practices reduced the % infestation dropped to 0.4 and 0.8% in dropped and harvested fruits respectively in comparison with that of farmer's practice where it was 7% in dropped fruits and 10.5% in harvested fruits.

Neural circuits in the insect brain

I.A Meinertzhagen

Life Sciences Centre, Dalhousie University, Halifax, NS, Canada,

A well-entrenched theme in insect neurobiology is to uncover neural circuits that underlie clear behaviours such as locomotion, flight, olfaction, vision, and learning and memory. This theme is re-emerging from studies especially on *Drosophila*, in which genetic and molecular tools can, with new imaging technologies, be brought to bear on these old questions. The list of speakers will represent both the established and emerging aspects of our theme, from the perspectives of both wiring and neuromodulation, drawing evidence from different systems and insect species, and from different stages of their development.

Saline tolerance in mosquito larvae

Timothy J Bradley

Dept. of Ecology and Evolutionary Biology, University of California, Irvine, California, United States

The osmoregulatory strategies of the larvae from various species of mosquitoes can be divided into three categories. The most common strategy is that the larvae are restricted to fresh water and always regulate the osmotic concentration of the hemolymph at values around 250-300 mOsm (stenohaline hyper-regulators). These larvae produce an isosmotic urine in the Malpighian tubules, and remove ions in the rectum to produce a dilute urine. The anal papillae are used to absorb ions, particularly sodium, potassium and chloride. A second strategy is that of osmotic regulation in dilute media and osmotic conformation in media more concentrated than 300mOsm (euryhaline osmoconformers). This strategy has been shown to occur in some larvae in the genera *Culex* and *Culiseta*. In highly concentrated media trehalose is used as an extracellular compatible osmolyte while proline is used as both an extra- and intracellular compatible osmolyte. The third strategy is that of osmoregulation in both hyper and hyposomotic media (euryhaline osmoregulators). This strategy has been well studied in larvae from the genera *Aedes*, *Opifex*. *Ochlerotatus*. In these larvae, there is an additional segment in the hindgut that is not found in freshwater forms. This segment serves as salt gland, secreting a concentrated salt solution. The taxonomic distribution of these three strategies and the evolutionary patterns by which they arose will be discussed.

The impact of *Wasmannia auropunctata* on local ant species in its invasive range

Merav Vonshak, Tamar Dayan, Abraham Hefetz

Department of Zoology, Life Science Faculty, Tel Aviv University, Tel Aviv, Israel

Invasive ant species are a worldwide threat to biodiversity. 15 ant species are listed in the IUCN's list "100 of the World's Worst Invasive Alien Species", among them is the little fire ant, *Wasmannia auropunctata* (LFA). Native to South and Central America, it is now spreading around the world. It arrived to Israel about 10 years ago, and to date it is found at least in 15 localities.

Microsatellite analyses revealed that the Israeli population reproduces clonally, and are descendants of a single introduction of one queen and one male; laboratory aggression tests confirmed that the ants form one supercolony. Using pitfall traps and baits we found that at high densities the LFA displaces almost all the local ant species, and it represents 99.05% of the ants' diversity. They also had a significant impact on spiders' abundance, and to a lower level on beetles.

We compared the LFA foraging behavior in the laboratory with that of two other species that are generally displaced by it in the field. Surprisingly in short term studies the LFA proved to be an inferior forager as well as competitor, whether it was present first at the resource, or arrived to it simultaneously with the other species. However, preliminary, long duration, nest-merging experiments revealed that the LFA invaded the opponent nest within a few days and killed the whole nest. We propose that the LFA high reproduction rate and lack of intraspecific aggression as well as its powerful sting, enable the species to reach high densities and thus to displace other ant species.

Overcoming the taxonomic impediment: automating the generation of taxonomic information

John La Salle

CSIRO Entomology, Canberra, ACT, Australia

Global initiatives are now addressing many aspects of managing and delivering biodiversity information using modern technology. However, they are not addressing the heart of the taxonomic impediment: that we have been naming species for over 200 years, and have named less than 20% of species. We do not have centuries to finish the job; we need to create an “orders of magnitude” paradigm shift in taxonomy by automating the process of species discovery and description.

Role of commercial bee-attractants in the pollination and yield parameters of Niger

V Sivaram, .V. Jayaramappa

Laboratory of Biodiversity and Apiculture, Dept. of Botany, Bangalore University, Bangalore, India

Introduction: Honeybees and flowering plants are interdependent and a good example for mutualism and co evolution. Bees are considered as most efficient pollinators in the ecosystem and utilization bees as pollinators for various entomophilous crops is the cheapest method for increasing crop yield. Niger is the principal oil seed and cross pollinated crop.

Methods: The commercial bee attractants like Bee-Q, Fruit Boost and Tuberose floral scent and sugar solution of different concentrations were sprayed on Niger flowers during the booming period in the experimental plot. The number of honeybees visiting the Niger flowers was recorded from 0600 to 1800 hrs by following standard techniques. Data on number of flowers, flower head, seed weight, seed yield, oil content, seed germination were obtained.

Results: Spraying of Bee-Q @ 12.5 gm /l attracted 7.13 honey bees/10 flowers/ 5min and Fruit boost at 0.75ml/l attracted 8.26 honey bees/10 flowers/5 min up to 5^{th} day after spray in blooming stage. Spraying of Bee-Q @ 12.5gm/l produced 30.33seeds/ flower head and Fruit boost @ 0.75 ml/l produced 30.66seeds/flower head against 23.66seeds/flower head in open pollinated plot. Spraying of Bee-Q @ 12.5gm/l produced higher 1000 seed weight of 3.55gms and Fruit boost @ 0.75 ml/l produced 3.63gms against 3.03gms in open pollinated plot. Spraying of Bee-Q @ 12.5gm/l produced higher seed yield of 4.76q/ha and Fruit boost @ 0.75 ml/l produced 4.95q/ha against 2.70q/ha in open pollinated plots. The spray of honeybee attractants did not increase oil content of Niger. However, spraying of Bee-Q @ 12.5gm/l and Fruit boost @ 0.75ml/l has enhanced the germination percentage to 89.33 and 90.33% against 74.66% in open pollinated crop. Spraying of Bee-Q @ 12.5gm/l has enhanced root length to 8.66%, Tuberose floral scented water to 8.75% and Fruit boost 0.75ml/ to 8.81% against 8.25 % in open pollinated plot. Spraying of Bee-Q @ 12.5gm/l has increased shoot length to 8.63%, Tuberose floral scented water to 8.51% and Fruit boost 0.75ml/ to 8.41% against 6.66 % in open controlled plots.

Conclusion: In all the 10 different concentrations of bee attractants, Bee-Q @ 12.5g/l and Fruit Boost @ 0.75 ml/l found to be very effective in increasing seed productivity in Niger.

Species conservation – a time of crisis and opportunity

Sacha Spector

Center for Biodiversity and Conservation, American Museum of Natural History, New York, United States

By most measures insect conservation has yet to fully join the mainstream of global conservation efforts. In addition, new signals both from the field and in the literature suggest that large numbers of insect species are on a downward trajectory toward extinction raising the urgency for increased conservation action on behalf of insects. Species level conservation can provide an important fine-filter safety net for insect biodiversity, particularly given the small ranges and specific habitat needs that characterize many endemic insect species. Efforts to assess and recognize threatened insect species have recently received boosts across a number of sectors of the global conservation arena. Advances in bioinformatics and cybertaxonomy are increasing access to nomenclatural, natural history and distribution data on hundreds of thousands of insect species. Restructuring of invertebrate conservation efforts at the IUCN-World Conservation Union's Species Survival Commission has led to the creation of the Terrestrial Invertebrate Red List Authority, which now provides a very flexible mechanism for accepting and processing conservation assessments of insect species' status. These and other new developments are providing opportunities to take a broad, synthetic view of the tools needed to deal with the threats to insect species.

The Crop Diagnostic Training and Research Center – the place for in-field "hands-on" training for field crop insect pests

Corey K Gerber

Department of Agronomy, Purdue University, West Lafayette, Indiana, United States,

Introduction: The Purdue University Crop Diagnostic Training and Research Center (DTC) is known across the Midwestern US for its unique "hands-on" approach to teaching the art and science of accurately diagnosing agricultural crop and pest problems. Entomology is one of the six key areas the Center emphasizes during educational programs.

Methods: The DTC employs multiple methodologies to enhance the educational learning experience of its clientele. The Center conducts in-field, "hands-on" diagnostic training workshops. During these workshops, DTC clientele learn how to accurately identify insects associated with field crops, diagnose insect injury, evaluate sampling methods and techniques, and are exposed to threshold levels for managing insect pests. Along with the workshops, the Center also developed two widely utilized training publications; the *Corn and Soybean Field Guide* and the *Forage Field Guide*.**Results:** Since the Center's inception, approximately 15,000 individuals have been trained at nearly 450 workshops, which have included over 2,500 presentations by almost 200 university faculty and staff. From 1988 to 2008, over 383,000 *Corn and Soybean Field Guides* have been sold, and since 2004, 9,000 *Forage Field Guides* have also been sold, with an additional 10,000 guides pre-sold for 2008.

Conclusions: Due to the ever changing dynamics of production agriculture in the US, specifically with more and more individuals moving away from the agriculture industry, it is evident based on the trend of DTC activities that this Center is a valuable resource for diagnostic training and education.

Phenology models from day-degrees to complex simulations: how to increase their benefit for integrated production?

Jörg Samietz

Swiss Federal Research Station Agroscope Changins-Wädenswil ACW, Wädenswil, Switzerland

Especially in perennial cultures, forecasting tools to predict insect phenology assure precise timing of pest monitoring and management particularly under integrated production regimes. The aim of such tools should be to establish reliable and readily available information for growers and consultants. Consequently they have to consist of a technical side to establish phenologies or population dynamics and of an end-user side to communicate the according decision support.

On the technical side, since decades temperature sums above theoretical developmental thresholds are used to predicts certain events in the pest life cycle or decisions to be made on base of phenology. Such simple day-degree models rely on linear relationships between temperature and stage specific development rates. Improvements of the precision can be achieved by calculation of temperature sums by following the diurnal cycle with sinus integration or by using temperature data on hourly basis *a priori*. Also temperature sums can be calculated for different stages of the life cycle which allows for a more complex prediction. More sophisticated mathematical tools like time-varying distributed delays allow to include and manipulate variability in development time and assure overlapping generations. Approximation of habitat- or body temperatures and the use of high temperature cut-offs or non-linear rate functions further help to improve the precision of the modelling basis. Multispecies models even allow to predict predator-prey dynamics, pest outbreaks and complex management decisions.

Several examples of different approaches are presented in the symposium on phenology modelling. The recent discussion as final part of the symposium is intended to discuss which developments – especially on the end-user side – are needed in future and where we should invest to increase the positive influence of phenology models and according decision support systems on integrated production in perennial cultures.

The role of Cadherin protein in the mode of action of Cry1A toxins from *Bacillus thuringiensis* is to induce oligomeric structures responsible of pore formation in insect membranes

Mario Soberon[1], Liliana Pardo-Lopez[1], Nuria Jimenez-Juarez[1], Isabel Gomez[1], Sarjeet S. Gill[3], Bruce E. Tabashnik[2], Alejandro Bravo[1]

[1]Instituto de Biotecnología, Universidad Nacional Autónoma de México., Cuernavaca, Morelos, Mexico, [2]Department of Entomology. University of Arizona, Tucson, Arizona, [3]United States, Department of Cell Biology and Neurosciences, University of California, Riverside, California, United States

Bacillus thuringiensis Cry1Ab and Cry1Ac toxins are produced in transgenic maize and cotton to protect crops from insect attack. Cry1A toxins kill lepidopteran targets by a mechanism that involves the sequential binding to multiple receptors in the larvae midgut. First, the Cry1A toxins bind to a cadherin receptor which facilitates removal of N-terminal helix-1 and induce oligomer formation. The Cry1A oligomers then bind to GPI-anchored receptors as aminopeptidase N or alkaline phosphatase, inserting into membranes of midgut epithelium cells creating pores and causing cell burst and larval death. However, it has been proposed that binding to cadherin triggers a signal transduction pathway that leads to oncotic–like cell death. The binding interaction of Cry with cadherin is complex involving three different binding sites. Cry1Ab and Cry1Ac protoxins lacking the N-terminal helix-1were constructed (Cry1AbMod and Cry1AcMod) and their toxicity and mode of action analyzed. *In vitro* oligomer formation assays showed that Cry1Ab and Cry1Ac protoxins produce a 250 kDa oligomer when activated with trypsin in the presence of cadherin repeats CR7, CR11 or CR12 that contain the Cry1A binding sites, in contrast with the production of the 60 kDa monomer when no cadherin fragments were present in the assay. The Cry1AbMod and Cry1AcMod protoxins produced the 250 kDa oligomer when activated with trypsin without any cadherin fragments. Moreover, Cry1AMod toxins killed cadherin-silenced *M. sexta* and Bt-resistant *Pectinophora gossypiella* that had cadherin deletion mutations. In addition mutant Cry toxins affected in oligomerization are non-toxic to *M.sexta* larvae despite the fact that they retain high affinity to cadherin receptor. Our findings show that cadherin promotes Bt toxicity by facilitating toxin oligomerization and not by triggering a signal transduction pathway. The modified Bt toxins may be useful against pests resistant to standard Bt toxins.

A GPI-anchored alkaline phosphatase is a functional receptor of *Bacillus thuringiensis* Cry11Aa toxin in *Aedes aegypti*

Luisa E. Fernandez[1], Jianwu Chen[2], Erandi Lira[1], Salvador Hernandez-Martinez[1], Humberto Lanz-Mendoza[3], Alejandro Bravo[1], Sarjeet S. Gill[2], Mario Soberon[1]

[1]Instituto de Biotecnología, Universidad Nacional Autónoma de México, Cuernavaca, Morelos, Mexico, [2]Department of Cell Biology and Neurosciences, University of California, Riverside, California, United States, [3]Centro de Investigación sobre enfermedades infecciosas, Instituto Nacional de Salud Publica, Cuernavaca, Morelos, Mexico

Bacillus thuringiensis subs *israelensis* (Bti) produces Cry and Cyt toxins active against mosquitoes that are vectors of human diseases. Previous work identified a GPI-anchored alkaline phosphatase of *Aedes aegypti* as a functional receptor of Cry11Aa toxin produced by Bti. Three ALP cDNA sequences were cloned from *A. aegypti* midgut tissue and expressed in *E. coli*. Among these, ALPAR93 protein bound Cry11Aa and Cry4Ba and also a peptide phage (P1.BBMV) that was previously shown to bind the ALP protein identified in *A. aegypti* BBMV and to lower the toxicity of Cry11Aa in bioassays. Binding analysis of ten overlapping ALPAR93 protein fragments with Cry11Aa identified two Cry11Aa binding sites, one of which interacts with Cry11Aa domain II loop alpha-8. Binding competition of Cry11Aa binding to BBMV's showed that recombinant ALPAR93, the two ALPAR93 fragments comprising the binding sites and an anti-ALPAR93 antibody competed binding, Using *in vitro* cultured living midguts, we showed that Cry11Aa toxin specifically killed caeca and posterior midgut cells. The toxicity of Cry11Aa to cultured midguts was competed by P1.BBMV and the anti-ALPAR93 antibody but not by an anti-V-ATPAse antibody. These results show that the ALPAR93 protein is the functional receptor of Cry11Aa involved in toxicity to *A. aegypti* larvae.

Evaluation of Transgenic Bt cotton under Integrated Pest Management

N.V.V.S.D Prasad, N.H.P Rao

[1]Regional Agricultural Research Station, A. N.G. R Agricultural University, Andhra Pradesh, India, [2]AICRP on Biological Control of crop pests, College of Agriculture, A.N.G. R Agricultural University, Andhra Pradesh, India

Introduction: Bt cotton introduction from 2002 in India has resulted in phenomenal increase in cotton production and more economic returns to the farmers. Bt cotton enabled to tackle major bollworms complex but at the same time experienced surge in sucking insect pests activity. Transgenic Bt cotton has been evaluated under integrated pest management regime with emphasis on sucking insect pests.

Methods: Transgenic Bt cotton hybrid and correspondingly non Bt hybrid were grown with IPM components for managing pest complex of cotton in a holistic approach during 2004-2005 and 2005-06 crop seasons. The impact of IPM regime on pest complex, natural enemies and economics of cotton production were evaluated.

Results: Sucking pests were kept under control in both Bt cotton and non Bt cotton by seed treatment of insecticide, stem application of insecticides - a noval approach for suppressing early season sucking pests and growing of intercrops besides need based chemical interventions. Natural enemies in the cotton ecosystem were conserved during the vegetative stage of the crop. Transgenic Bt cotton as a component of IPM strategies proved effective against *Helicoverpa armigera* and *Pectinophora gossypiella* resulting in negligible fruiting body damage and minimum insecticidal interventions and also observed safe to beneficial insects. IPM strategies to Transgenic Bt cotton involved four eco friendly interventions with higher cost benefit ratio, due to reduction in plant protection cost and high seed cotton yield compared to non Bt cotton which required as many as eight insecticidal interventions.

Conclusions: Transgenic Bt cotton cultivation with eco friendly IPM practices plays a vital role in managing sucking and bollworm pest complex of cotton for sustainable cotton cultivation.

Frequency and characteristics of alleles conferring resistance to the Bt toxin Cry2Ab in populations of the non-profile Australian target pest *Helicoverpa punctigera*

Sharon Downes[1], Tracy Parker[1], Rod Mahon[2]

[1]CSIRO Entomology, Australian Cotton Research Institute, NSW, Australia [2]CSIRO Entomology, Black Mountain Laboratories, Australian Capital Territory, Australia

H. punctigera and *H. armigera* are important pests of numerous field and horticultural crops in Australia. While *H. armigera* has developed resistance to virtually every insecticide employed against it, there has been only one report of resistance to any insecticide in *H. punctigera*. In 1996 the Australian cotton industry adopted Ingard® which expresses the Bt toxin gene *cry1Ac* that is specific to Lepidopterans including *Helicoverpa* species. To date, no field resistance to Cry1Ac has been detected for *H. armigera* or *H. punctigera* in Australia. In 2004/05 Bollgard II® (which expresses Cry1Ac and Cry2Ab) replaced Ingard® in Australia, and now comprises 80% of the area planted to cotton. In 2002, we began F_2 screens of field populations of *H. armigera* and *H. punctigera* to investigate the frequency of alleles that confer resistance to Cry2Ab. In both species, these alleles are more common than expected. The characteristics of the first allele detected in *H. punctigera* (denoted HP4-13) will be described. Our current estimate of the frequency of alleles in field populations is 0.0022 (n = 3064 alleles) with a 95% credibility interval between 0.0009 and 0.0042. We have not yet tested whether the 6 isolated cases are allelic. We will discuss the genetics, resistance levels, cross resistance to Cry1Ac, and dominance associated with Cry2Ab resistance in HP4-13, and the relevance of these findings to managing Bollgard II®.

Light brown apple moth in California: ecology, impact and management of a new invader

Nick Mills

Department of Environmental Science, Policy and Management, University of California, Berkeley, United States

The confirmation of light brown apple moth (*Epiphyas postvittana*) in California in March 2007 posed a new threat to the agricultural and horticultural industries of the state, with the potential to cause millions of dollars in damage. It has subsequently been found in 8 San Francisco Bay Area counties and in Monterey, Santa Cruz and Los Angeles counties, and climate matching models suggest that it may have the potential to spread more widely throughout the North American continent. Light brown apple moth originates from southeastern Australia, where it has been recorded from more than 250 plant species including crops, weeds, and ornamentals and thus California provides ample opportunity for establishment of this new pest. Here I review the ecology and phenology of light brown apple moth, its potential ecological impacts in California, and the management options available for this new invader.

Insect community ecology: the challenge of hyperdiversity

Charles Godfray

Department of Zoology, University of Oxford, Oxford, United Kingdom,

Insects that feed on plants, the predacious and parasitic insects that attack them, and the micro-organisms with which they are associated, are some of the most numerous and diverse groups of organisms on the planet. I will explore current ideas about the biological processes that might structure these insect-based communities, giving examples from work on assemblages based on aphids and leaf-mining insects. I will also discuss the particular challenges faced by community ecologists studying hyper-diverse groups such as phytophagous insects.

Biological control of emerging weeds in South Africa: an effective strategy to counter invasive alien plants at an early stage

Andrew McConnachie

PPRI Weeds Lab, Hilton, South Africa

Biological control of emerging weeds (plants in the early stage of invasion) is internationally an uncommon practice due to restricted research funds being allocated to weeds which have already reached detrimental levels. Previously in South Africa, because of limited funds and, as a result, few opportunities to conduct overseas exploration work, researchers have capitalised on their survey trips by collecting potentially useful biological control agents from as many target plants as possible. Earlier exploration for agents against high-priority weeds thus allowed simultaneous collection of natural enemies of low-priority weeds in the same region. Such opportunistic programmes have been beneficial for South Africa in the management of several emerging weeds. Formal classification systems, however, have since been developed in South Africa for the prioritisation of invasive alien plants. In light of this, the 'Working for Water' Programme, the main funding agency for weed biological control research in South Africa since 1996, officially recognised and awarded funds for five emerging weed projects in 2003. Several new weed projects have since been added to this list. This paper reviews the cases where emerging weeds were opportunistically targeted for biological control in South Africa and where successes were achieved; the use of classification systems to prioritise the management of invasive plants; and the progress achieved with the emerging weed projects currently underway in South Africa.

Biological control of emerging weeds in South Africa: an effective strategy to counter invasive alien plants at an early stage

Beware of bats, beware of birds: the auditory responses of eared moths to bat and bird predation.

David S Jacobs[1], John Ratcliffe[2], James Fullard[3]

[1]Department of Zoology, University of Cape Town, Rondebosch, South Africa, [2]Department of Neurobiology and Behavior, Cornell University, Ithaca, United States, [3]Department of Biology, University of Toronto at Mississauga, Mississauga, Canada

Introduction: The Allotonic Frequency Hypothesis (AFH) proposes that the preponderance of moths in the diets of some bats (e.g. Rhinolophidae) is the result of these bats echolocating at frequencies outside of the typical hearing range of most moths (approx. 20 – 60 kHz). The broader hearing range of African moths (5 – 110 kHz) suggests that their ears may function at frequencies usually considered allotonic. We investigated 1) whether moth ears were functionally audible to the Cape horseshoe bat, *Rhinolophus capensis* (Rhinolophidae) which echolocates at 84 kHz, and 2) whether moth auditory sensitivity below 10 kHz allows them to detect the rustling noises made by bird predators as they pursued moths through vegetation.

Methods: We used standard neurological preparations of the auditory nerves of moths to measure the auditory sensitivity of moths to rhinolophid calls and the rustling sounds that bird predators made. We also observed whether birds preyed upon moths.

Results: Moths responded both neurologically and behaviourally to the calls of *R. capensis* and the rustling sounds made by birds as they pursued moths.

Conclusion: The AFH cannot explain the preponderance of moths in the diets of rhinolophids and we suggest that the constrained spaces in the cluttered habitat in which rhinolophids forage give moths both less time and less space within which to react to an attacking bat. Furthermore, the high sensitivity of moths to frequencies from 5 – 10 kHz allows them to avoid avian attacks by using responses that have traditionally been considered solely anti-bat behaviour.

Insecticide resistance – can we prevent it?

T Perry, P Daborn, C Robin, P Batterham

Department of Genetics, University of Melbourne, Victoria, Australia

While insecticides remain the primary agent used for the control of most insect pests, the evolution of resistance to any given insecticide seems inevitable. Our capacity to stall or prevent the spread of resistance is minimal because our understanding of insecticide targets and metabolism in pests is rudimentary. Taking the example of the nicotinic acetylcholine receptors, targeted by the neonicotinoids and spinosyns, the potential for resistance prediction and rational insecticide design will be discussed. Taking the example of the Cytochrome P450s, the capacity to use the model insect, *Drosophila melanogaster*, to predict metabolic resistance will be considered.

Chromosomal evolution, molecular phylogeny and trophic affiliation in *Chrysolina* (Coleoptera: Chrysomelidae).

E. Petitpierre[1], Y.E Mikhailov[2], J.A Jurado-Rivera[1]

[1]Dept. of Biology, Univ. of Balearic Islands, Palma de Mallorca, Spain, [2]Dept. of Botany and Forest Protection, Urals State Forestry-Engineering Univ., Yekaterinburg, Russian Federation

The diploid numbers and male sex-chromosome systems have been analysed in seven species of *Chrysolina* mostly from the Urals and Siberia. *Ch. (Arctolina) poretzkyi* and *Ch. (Arctolina) tundralis* have 2n = 26 (Xy_p), *Ch. (Timarchoptera) haemochlora* 2n = 27 (XO), *Ch. (Ovosoma) susterai* 2n = 40 (Xy_p), *Ch. (Heliostola) schewyrevi* 2n = 44 (Xy_p), *Ch. (Crositops) pedestris* 2n = 47 (XO), and *Ch. (Sulcicollis) rufoaenea* 2n = 50 (Xy_p). These findings increase up to 70 cytogenetically known taxa, belonging to 35 subgenera, more than a half of the 65 presently described. Their range of chromosome numbers is very wide, from 2n = 22 to 2n = 50, and four types of sex-chromosome systems have been encountered, Xy_p, XY_p, XY and XO, although the first one is clearly prevalent. The modal haploid numbers are n = 12 found in 39% and n = 20 in 21% of the so far studied species. We assumed previously a chromosomal evolution from the most widespread and common number of n = 12, by frequent increases in different adaptive radiations. To substantiate this hypothesis, a combined molecular phylogeny by Bayesian methods was inferred from the sequences of a 550 bp fragment of 16S, another of 760 bp of cox1 mitochondrial DNA, and one of 362 bp of histone-3 nuclear DNA, in 50 species of 33 subgenera. Many current subgenera are well-supported in the cladogram, but a few might be synonymized on these molecular grounds, namely *Chrysolinopsis* and *Taeniochrysea, Arctolina* and *Pleurosticha, Crositops* and *Paraheliostola,* and *Chalcoidea* and *Pezocrosita* (gr. *convexicollis*). Furthermore, five species of the genus *Oreina* are included with three of *Chrysolina* in a supported clade. Most species with 12 haploid chromosomes and having a trophic affiliation on Lamiaceae plants, appear in the plesiomorphous clades, while those of higher chromosome numbers and living on Scrophulariaceae, Apiaceae, Hypericaceae, Plantaginaceae and Asteraceae, are in apomorphous clades. However, the recruitment of a new plant family for the trophic affiliation in *Chrysolina* was not achieved as an unique event but by several independent events of colonisations, except for Hypericaceae, which were presumably selected in a single lineage. Besides this, the cladograms also suggest, that at least some species with low chromosome numbers, arose from others of higher by centric fusions, contrary to the prevalent trend of increases.

Intrinsic and extrinsic factors in social evolution and the geographical distribution of spider sociality

Leticia Aviles[1], Eric C. Yip[2], Kimberly S. Powers[2], J Guevera[1]

[1]Department of Zoology, University of British Columbia, Vancouver, Canada, [2]Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, United States

Why organisms live in groups and cooperate is one of the central problems in behavioral ecology. Using social spiders as a model system, we illustrate how intrinsic organismal characteristics interact with specific environmental factors to yield social systems in some geographical areas and not in others. We show that social spiders in the genus *Anelosimus* are concentrated in areas where an abundant supply of large insects is available, namely the lowland tropical rain forest up to mid-elevation cloud forests. Field observations further show that as social spider colonies grow in size, prey capture area per spider and thus number of insects caught per capita decline. Where large insects are abundant, the spiders make up for this decline by cooperatively capturing increasingly large insects as colony size increases. The resulting per capita prey biomass intake function is maximal at intermediate colony sizes. Paucity of large insects at high latitudes and elevations, on the other hand, results on biomass per capita being a monotonically declining function of colony size. The varying shapes of the per capita intake functions would explain why *Anelosimus* spiders in the lowland tropical rainforest form large social groups while those at high elevations or latitudes live in small single-family groups that disintegrate prior to reproductive maturity. These findings illustrate the interplay between intrinsic and extrinsic factors---the scaling properties of tri-dimensional spider webs and local insect size distributions, in this case---in shaping social systems and their geographical distribution.

How did the Netherlands handle the risk evaluation of 150 natural enemies in a few months time?

Antoon J.M. Loomans

Senior Scientist, Department of Entomology, National Reference Laboratory, Plant Protection Service, Wageningen, Netherlands,

When designing a general framework for regulation of the import and release of for biological control agents in The Netherlands, we used a so-called quick scan as an initial screening method, based on the available information for known non-target impacts. Except a proper characterization of the agent, evaluation of risks posed to human and animal health this quick scan included an environmental risk assessment as well. Environmental risks posed by introduced species were determined by several ecological factors, such as the potential of the agent to establish, its abilities to disperse, its host range and its direct and indirect effects. We applied the quick scan method, based on the available information of these ecological determinants, to 150 natural enemies currently commercially available in The Netherlands. About 5% of the species were considered too risky for (continuation of) release and 80% were considered safe. For the remaining 15% of the species, information was either still inadequate, inappropriate or lacking to complete the quick scan. However, when no evidence was available on any significant non-target effects, or was not foreseen, it was advised for most species to continue release. As a result, 134 species were placed on a "white list", which will be exempted from further regulatory measures. All other species, BCAs and other beneficial organisms, not exempted or new, need authorization by derogation. For these BCAs a comprehensive full scan method is used as a tool for risk assessment, including all information available or when relevant newly generated information.

Characterization of *Clostridim bifermentans malaysia* that is active to *Anopheline* species.

Supaporn Likitvivatanavong[1], Amy Evans[1], Han Lim Lee[2], Sarjeet S. Gill[1]

[1]Department of Cell Biology and Neuroscience, University of California, Riverside, California, United States, [2]Department of Entomology, Institute for Medical Research, Kuala Lumpur, Malaysia

Formulations of bacterial strains with insecticidal activity have been used for the control of insect pests in public health and agriculture. For example, the dipteran active *Bacillus thuringiensis* subsp. *israelensis* has been used with remarkable success against both *Aedes* and *Culex*, thereby attenuating viral diseases vectored by these mosquito species. Similarly, *B. sphaericus* has been used with remarkable success against *Culex* mosquito vectors. However, the activity of these two bacterial strains against *Anopheles* is not sufficiently high, necessitating the use of recombination technology to develop strains that could be used in the field against anopheline mosquitoes. In contrast, *Clostridium bifermentans* subsp *malaysia* strain has the highest toxicity to *Anopheles* spp. but has no non-target toxicity. We have recently begun characterization of this bacterial strain. Using a variety of approaches we have show the genome of this bacterium is AT rich with a genome of about 4 Mb. No plasmids were identified, indicating the mosquitocidal genes are chromosomally encoded. A number of potentially toxic genes that could be mosquitocidal are present in the genome. The presentation will include a discussion of the genome of this mosquitocidal strain.

Biological study of mealybug, *Nipaecoccus viridis* (Newstead), and possibility of its biological control by *Cryptolaemous montrouzieri* Mulsant in citrus orchards of north Khuzestan

Mohammad Saeed Mossadegh[1], Rahim Eslamizadeh[2], Mehdi Esfandiari[1]

[1]Plant Protection Department, College of Agriculture, Shahid Chamran University, Ahwaz, Islamic Republic of Iran, [2]Safi Abad Agricultural Research Centre, Dezful, Islamic Republic of Iran

Introduction: The mealybug *Nipaecoccus viridis* (Newstead) is one of the major pests of citrus orchards of north Khuzestan province, southwest Iran. Although the pest has many indigenous natural enemies in the region, but it damages the fruits at the early spring due to the low population densities of its natural enemies at this season.

Methods: From November 2005 to March 2007, altogether 1100 ha of citrus orchards were inspected for *N. viridis* infestation. A total of 12000 *Crytolaemous montrouzieri* Mulsant were librated in 5 citrus orchards with 6.7 ha area with heavy infestation from March to July during a period of 2 consecutive years. The developmental period of mealybug and its natural enemies as well as biology and survival of librated Crypt beetles on citrus trees were recorded biweekly in 2 out of 5 citrus orchards. Five citrus trees in each orchard were chosen at random at 5 different locations and sampled at 70, 140 and 210cm above the ground on four different sides of a tree by cutting 15cm branches for further study.

Results: The results indicated that *C. montrouzieri* was able to control *N. viridis* population and produced one spring generation at north of Khuzestan conditions. But, as the temperature increases, its reproduction and activities were suppressed in July.

Conclusion: Apart from the hot summer, the honeydew secreted by *N. viridis* attracts ants and creates a symbiotic behavior between ants and the pest. This symbiotic behavior has a negative influence on biological control by *C. montrouzieri* in citrus orchards of north Khuzestan.

Biological control of *Icerya purchasi* Maskell by *Rodolia cardinalis* Mulsant in citrus orchards of north Khuzestan, southwest Iran

Mohammad Saeed Mossadegh[1], Rahim Eslamizadeh[2], Mehdi Esfandiari[1]

[1]Plant Protection Department, College of Agriculture, Shahid Chamran University, Ahwaz, Islamic Republic of Iran, [2]Safi Abad Agricultural Research Centre, Dezful, Islamic Republic of Iran

Introduction: The cottony cushion scale *Icerya purchasi* Maskell, was observed and identified in June 2003 at severe infestation of citrus trees at Sharaf-Abad in Dezful, north of Khuzestan province and later on a biological control project using *Rodolia cardinalis* Mulsant was worked out from October 2003 to May 2007.

Methods: The Vedalia beetles were reared on mealybug at 27±1°C, 65±5% R.H. and 14:10, L:D. From March to November 2004, beetles were released as adult in groups of 5 or 2-4 larval instars in groups of 10 per tree which was heavily infested with scale. Altogether 1874 adults and larval beetles were librated at 32 times in 21 citrus orchards on area 38 ha. The development and survival of librated Vedalia beetles and larvae on citrus trees as well as adjacent orchards and weeds were recorded weekly. Samples were taken at 70,140 and 210 cm above the ground on four different sides of a tree by cutting 15cm branches for further study.

Results: *R. cardinalis* tolerated the hot summer conditions of Dezful, established at the region, reproduced through all the seasons with its high potential searching capacity (2.5 Km per month) and was able to cleaned 156 ha of very heavily infested of citrus orchards during a period of 9 months. The established Vedalia beetles were appeared in other infested orchards and cleaned up another 1042 ha during 3 years and prevented further infestation by scale to the rest of 4500ha of other citrus orchards.

Conclusion: As *R. cardinalis* has been established in the region, the sever outbreaks of scale in citrus orchards of north Khuzestan is not possible.

Trees or bins? Determining the natal sites of *Rhyzopertha dominica* (F.) using chemical and physical techniques

Rizana M. Mahroof, Thomas W. Phillips

[1]Department of Biological Sciences, South Carolina State University, Orangeburg, S.C, United States [2]Department of Entomology, Kansas State University, Manhattan, K.S, United States,

The relationship between the abundance and occurrence of *Rhyzopertha dominica* (F.), a primary pest of stored grain, in distinctly different habitats is poorly known, and previous work suggests that a primitive wood-boring habit of this bostrchid beetle may persist in natural populations. Movement of insects can be studied using methods of tissue elemental analyses or mark-release-recapture. We used natural stable isotopes and trace elements to track the dietary history of *R. dominica*, as adult insects may retain elemental markers from their larval host plants. Insects collected from the periphery of granaries or inside woodlands in Stillwater, Oklahoma, USA and insects reread on standard diets in the laboratory were used to compare and contrast isotope signatures and trace elements. Insects reared on the C_3 plant-based seeds of wheat or oak showed much depleted $\delta^{13}C$ values (– 23.7 or – 26.2‰, respectively) as opposed to insects reared on seeds of the C_4 corn (– 11.3‰). A majority of the field-collected *R. dominica* showed $\delta^{13}C$ values similar to a C_3 host, however a few insects had $\delta^{13}C$ signatures similar to the C_4 plant-reared insects. Stored grain of C_4 crops were lacking at many of the sample field sites. These results suggest that *R. dominica* occurs on either C_3 or C_4 based hosts in the field, and point to utilization of non-grain C_4 plants as hosts. Trace elemental analyses showed that discriminating trace elements for field collected *R. dominica* were P, Ca, Fe, Zn, and Cu related to different hosts. In this paper we also summarize results on mark-release-recapture studies that suggest variation in dispersal patterns by related to ecologically different field sites.

Breeding systems in social insects: causes and consequences of within colony genetic diversity

Claudia Husseneder[1], Edward L. Vargo[2]

[1]Department of Entomology, Louisiana State University, Agricultural Center, Baton Rouge, L.A, United States, [2]Department of Entomology, North Carolina State University, Raleigh, N.C, United States,

Social insects are one of the most ecologically diverse and successful groups on this planet. The variety and complexity of their colony breeding structures and the causes and consequences of genetic diversity within colonies has been a hot topic in research for many decades. This symposium focuses on the reproductive strategies that determine genetic diversity in colonies and populations as well as on the costs and benefits of genetic diversity. Breeding systems of a wide variety of social insects will be introduced ranging from the social Hymenoptera (bees, ants and wasps) to termites and social spiders.

Insecticidal toxins from *Photorhabdus*: comparative genomics and Rapid Virulence Annotation (RVA).

Richard Ffrench-Constant[1], Andrea Dowling[1], Isabella Vlisidou[2], Maria Sanchez Contreras[2], Nicholas Waterfield[2]

[1]*School of Biological Sciences, University of Exeter in Cornwall, Falmouth, United Kingdom,*
[2]*Department of Biology and Biochemistry, University of Bath, Bath, United Kingdom,*

The genomes of bacteria in the genus *Photorhabdus* encode numerous novel toxins including members of the Toxin complex (Tc) family, Makes Caterpillars Floppy (Mcf) toxins, PirAB toxins and many others. Following the recent completion of two complete genome sequences, one from *P. luminescens* and one from *P. asymbiotica*, we will describe the comparative genomics of toxin encoding genes in these two very different pathogens. We will also discuss what we know about the mode of action of these different toxin classes. Finally, we will describe novel massively parallel screens to perform functional annotation of novel toxin genes in bacteria. We have termed this approach Rapid Virulence Annotation or RVA and its applications to bacteria other than *Photorhabdus* will be discussed.

Invertebrate conservation in British Columbia, Canada

Jennifer Heron

BC Ministry of Environment, Wildlife Science Section, University of British Columbia Campus, Vancouver, B.C, Canada

British Columbia (B.C.) is one of the most biologically diverse provinces in Canada. The province's vast landscapes host approximately 50,000 invertebrate taxa, 40,000 of which are estimated to be insects. Little is known about the life history, distribution and habitat requirements of these invertebrates, thus posing a challenge to conservation planning.

Legislation to protect species at risk has its origins as applied to vertebrates, with conservation assessments made on a species by species basis. Within this current structure, approximately twenty invertebrates from B.C. are federally listed as "at risk", with dozens more to be assessed on the growing list of potentially threatened species. While this approach works for some invertebrate groups, there are other taxa for which this approach is not ideal.

Determining the conservation status of B.C.'s invertebrates and the approaches taken are tasks addressed through multiple levels of government policy and legislation, multi-species and ecosystem approaches through stewardship initiatives, as well as the single species approaches. For example, wildlife habitat features of unique importance to invertebrates at risk (e.g. water springs and rock outcrops) are targeted for protection where the identification of invertebrate taxa is difficult. These features often elude traditional definitions of required habitat, yet may be a key component for a life stage of a species at risk. Ecosystem approaches to conserving invertebrates are addressed through coordinated efforts in the Garry oak and Okanagan desert ecosystems, both areas among the four most endangered ecosystems in Canada. These and other approaches to invertebrate conservation in B.C. are given.

Defining critical habitat for the endangered butterfly Taylor's checkerspot (*Euphydryas editha taylori*), in British Columbia, Canada

Jennifer Heron

BC Ministry of Environment, Wildlife Science Section, University of British Columbia Campus, Vancouver, B.C, Canada

Taylor's Checkerspot is a federally endangered butterfly in Canada, thought to be extirpated until the discovery of a population on Denman Island, British Columbia in 2005. The butterfly is historically known from fifteen locations throughout Garry oak ecosystems in southern British Columbia, and recovery efforts for the Taylor's Checkerspot have focussed on these habitats.

Policy and legislation that protect invertebrate species at risk in British Columbia is relatively new and quickly emerging as a significant challenge to conservation practitioners. A major part of the recovery process involves identifying critical habitat (*habitat necessary for the survival or recovery of a species*) and protection of the species residence (*a dwelling-place occupied or habitually by individuals during all or part of their life cycles*).

There are multiple challenges to defining critical habitat and residence for Taylor's Checkerspot. Legislation for species at risk was designed for the listing of birds and mammals, but each of the four life stages of an insect may have different habitat requirements and habitat may be ephemeral or spatially and temporally difficult to define. Compounding the challenges is a shift in the understanding of what habitat(s) Taylor's Checkerspot requires. Historically, the butterfly was observed within Garry oak and associated ecosystems, including open natural maritime meadows. Yet recent surveys show the adult and larval stages of the butterfly inhabiting young clearcuts, where recent logging activities have created disturbed habitats.

Endocrine and genetic network regulation of social life histories

Gro V. Amdam

Arizona State University, School of Life Sciences, Tempe, Arizona, United States

A mechanistic explanation for the emergence of insect sociality is that regulatory systems present in solitary ancestors are co-opted during social evolution to serve as building blocks for social phenotypes. This hypothesis predicts considerable pleiotropy between physiological and behavioral traits in social species that would mirror trait associations expressed during the life cycle of solitary ancestors. We will review recent results on pleiotropic hormonal- and gene regulatory systems that affect insect life histories, and ask how these systems can contribute to a better understanding of the evolutionary origins and current control of social living.

Return to the little-known planet: species exploration at warp speed

Quentin Wheeler, Virginia M. Ullman

[1]College of Liberal Arts and Sciences, Founding Director of the International Institute for Species Exploration, Arizona, [2]United States, Professor of Natural History and the Environment, Arizona State University, Tempe Arizona, United States

Wake up calls by entomologists Howard Ensign Evans and Edward O. Wilson have not been heeded by the insect taxonomy community. As threats from the biodiversity crisis and an expanding need for reliable taxonomic information for a changing world become clear, so too does the need to take action. A revolution in cyberinfrastructure is taking place that will transform science and engineering. Will insect taxonomy take advantage of this revolution to reinvent and reassert itself as an independent science? Or will it compromise its core theories, missions, and questions under peer pressure to appear modern and compliant with the perspectives of other disciplines? An emerging new field of cybertaxonomy represents a fusion o f the best of taxonomy with cyberinfrastructure and an unprecedented opportunity to reconceive taxonomy for the 21st century. Insect taxonomists need not accept either the constraints of the past nor the compromises of the present in order to advance their science. Decades of compromise by taxonomists, museums and herbaria have failed to advance taxonomy. It is time to set an ambitious insect taxonomy agenda and work together as an international community to design and demand the infrastructure and instrumentation necessary for its success. Outlines of such an agenda are proposed as “Project 2020” with a call to arms.

Identification and population dynamics of mango white scale (*Aulacaspis tubercularis* N. (Hemiptera: Diaspididae) in Tapachula, Chiapas, México

Ricardo Magallanes-Cedeño, Alberto Pérez-Mendoza, Alfonso Pérez-Romero, Javier Paxtián-Hernández, Mario Ernesto Cabrera-Alvarado

Universidad Autonoma de Chiapas, Huehuetan, Chiapas, Mexico

Introduction: To prevent yield losses, many mango growers in Chiapas spray chemicals on the foliage of trees to kill ants, aphids and white scales. Such practice might affect the guild of natural enemies, increasing opportunities of phytophagous insects outbreaks. This study was conducted to acquire fundamental knowledge on taxonomy and population dynamics of mango white scale.

Methods: Weekly samplings were taken during 2005 in a mango orchard without insecticide sprays 9 km NW of Tapachula, Chiapas; the sampling unit was a branch including pre-flowering buds; four of these branches were sampled in each of ten trees to complete a sample size of 40. Alive and dead white scale colonies observed on leaves, stems or fruits were registered; also a record was kept on numbers of predators observed during each inspection.

Results: White scale specimens observed in the field corresponded to description of *Aulacaspis tubercularis* N., (Hemiptera: Diaspididae). Population of white scale increases sharply at beginning of year taking advantage of the dry season, however a guild of predators including syrphids, coccinelids and mostly chrysopids synchronizes well with white scale colonies, preventing outbreaks. Numbers of both white scales and predators drop drastically during the rainy season.

Conclusions: The community of natural enemies in mango plays a major role in the regulation of mango white scale abundance: Considering the biotic potential of white scale, an inadequate use of pesticides might initiate a serious ecological disturbance if numbers of predators are diminished.

Acknowledgments: This research was partially supported by CONACYT and SAGARPA, Mexico.

Digestive enzymes of insects and the insecticidal effect of plant ureases

Celia R. Carlini

Dept. of Biphysics & Center of Biotechnology, Univ. Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil

Ureases (EC 3.5.1.5) are enzymes that hydrolyze urea to ammonia and CO_2, widespread in plants, fungi and bacteria. Little is known about the physiological role of ureases in plants. We have shown that ureases display antifungal and insecticidal properties independent of their ureolytic effect. The kissing bug *R. prolixus,* and crop pests such as the cowpea weevil *C. maculatus,* the green stinkbug *N. viridula* and the cotton stainer bug *D. peruvianus* died after feeding on diets containing jackbean or soybean urease at 0.1 % w/w level. These insects have cathepsins as digestive enzymes, which hydrolyze urease to release an internal entomotoxic peptide of 10 kDa. Changes in the profile of digestive enzymes during life cycle of hemipterans correlate with their susceptibility to ureases. No effect was seen in insects relaying on trypsin-like digestive enzymes, which apparently destroy the proteins. A recombinant urease-derived entomotoxic peptide was produced in *E. coli*. Besides showing toxicity to hemipterans, the recombinant peptide was also lethal to the fall armyworm *S. frugiperda*, which is not affected by intact ureases as it has trypsin as digestive enzyme. Bioassay using leaf discs of transgenic tobacco expressing this peptide were also toxic to *S. frugiperda*. The recombinant peptide showed no toxicity after intraperitoneal injection in mice or given intragastrically to neonate rats. We conclude that ureases probably participate in plant defense against insect predation. The potential use of these proteins and derived peptides as bioinsecticides or a putative transgene to engineering insect resistance into plant is presently under consideration.

Individual reproduction in stingless bees (Meliponini)

Vera Lucia Imperatriz Fonseca, Dirk Koedam

University of S. Paulo, Sao Paulo, Brazil

Stingless bees are eusocial, monandric and feed their brood cells with a liquid larval food before the queen oviposits in them. Since Sakagami & Zucchi (1963), the worker oviposition at the presence of the queen showed that the comb was the main place where interactions and conflicts occur. The provisioning and oviposition processes (POP) were studied for several species, and a special attention was given to the trophic eggs laid by the workers, always in a standard sequence for each species concerned. In these studies sealing of the cells received a few attentions, and reproduction by the workers was confused several times in literature with their ability to lay trophic eggs. To improve our knowledge of maternity of males, molecular studies of the males produced in the colonies and behavioral studies considering individual marked bees working in the combs were developed. Here we will summarize what we know from molecular studies and from studies of individual participation of workers in POP, focusing provisioning and sealing of the cells, as well as individual reproductive behavior by workers of *Melipona bicolor bicolor*, including the dynamics of laying trophic or reproductive eggs.

Collaborating in pollination science

Connal Eardley[1], Lucie Rogo[2], Michael Ruggiero[3], David Schindel[2], Scott Miller[2], Laurence Packer[4], Barbara Herren[5]

[1]Agricultural Research Council, Pretoria, South Africa, [2]The Consortium of the Barcode of Life, Washington, United States, [3]Integrated Taxonomic Information System, Washington, United States, [4]York University, Toronto, Canada, [5]Food and Agricultural Organization of the United Nations, Rome, Italy

A pre-congress workshop was held on July 1-4, 2008 in South Africa to assemble 40 scientists, research managers and postdoctoral graduate students mostly from the United States and Africa. A variety of bee research initiatives were represented. A special emphasis of the workshop was exploring collaborative opportunities with institutions in the USA, with partial support from the US National Science Foundation. Major programs represented were the African Pollinator Initiative, Consortium of the Barcode of Life, GBIF Global Pollinator Species Campaign, Integrated Taxonomic Information System, and the Global Pollination Project of the Food and Agricultural Organization of the United Nations. These initiatives, and others represented, have different but complementary and overlapping goals, stemming from the central role that taxonomy plays in each of them, and their concern for declining bee populations.

The workshop brought together basic and applied scientists, taxonomists and ecologists, bioinformatics specialists, and scientists involved in DNA-based methods and database management. Participants discussed shared goals, challenges and opportunities in bee science. They also developed specific actions and recommendations for a global campaign to create and make available taxonomic data on the world's bees and other pollinator species. One important component of the campaign would be the improvement of bee collections in Africa. Mechanisms to foster interaction and improve pollinator biodiversity conservation were proposed, collaborative research concept papers developed, and training needs identified.

The challenges of commercializing microbial pest control agents in the U.S.

Stefan Jaronski

Northern Plains Agricultural Research Laboratory, Agricultural Research Service of the U.S. Department of Agriculture, Sidney, M.T, United States.

Despite considerable research effort in both public and private sectors in the United States, only a small number of microbial pest control agents, aside from *Bacillus thuringiensis*, have been successfully commercialized. None has had a major impact on American agriculture (I am ignoring Bt-transformed crops because these are not microbial agents). This lack of salient success, despite the ostensibly obvious need for alternatives to chemical pesticides, can be ascribed to numerous causes. A dearth of candidate microbials has not been the problem, nor have insurmountable technical challenges. Rather the main obstacles have been socio economic. The momentum of commercialization has been in the hands of small, venture-capital biotech companies, many of whom have had precarious, often fatal, financial footing, and not with the larger, more stable agricultural companies. My premise for discussion is that two factors – the U.S. regulatory environment and a U.S. economic system heavily dependent on private venture capital and expectations of short-term profitability -- structure the size of commercial microbial enterprises, and, fundamentally force them to a size large enough that high efficiency, low labor input production is necessary. Low-tech, labor intensive systems are not feasible for the size of business needed for long term survival in the U.S. Are there other models for implementation? More fundamentally, microbials have not reached full potential, because historically they have been developed in a chemical rather than an holistic, biological paradigm. This chemical paradigm, the mainstream American agricultural orientation, is often commercially fatal for microbials given their inherent, biological characteristics.

A tool to assist with invasive pest recognition

Glynn Maynard, Ken Walker

Australian Government, Department of Agriculture, Fisheries and Forestry & CRC National Plant Biosecurity, Canberra, Australia

The best biosecurity measures are aimed at keeping invasive species offshore or away from the borders. To do so, invasive species need to be able to accurately and efficiently recognised, both outside and inside a country. Most of this task falls to diagnosticians working within a localised fauna. Also, diagnosticians support surveillance and monitoring programmes, hence need information and images to facilitate reporting on submitted specimens. Added to the complexity of this task are two factors: first, the majority of invasive pests encountered are not local, hence diagnosticians often require a world-wide knowledge of the invasive pests; and second, there is a worldwide decline in the availability of diagnosticians and taxonomists for invasive pests.

To address these issues a virtual Pest and Disease Image Library (PaDIL) has been developed. PADIL (http://www.padil.gov.au/) is a website that provides high quality, colour, diagnostic images and information on invasive pests (ie. taxonomy, distribution, hosts). No software downloads are required to make full use of the site. The software allows the user multiple query points and the ability to build user-defined image tables which combine characters chosen by the user. PaDIL is freely accessibly and the images are available for non commercial use. Currently, it includes 1200 pests. Australia has developed PaDIL to enhance its biosecurity capability with the recognition of invasive species domestically and internationally.. Although the primary user audience is phytosanitary diagnosticians, the image-based website can be easily used by specialists and non-technical persons in all areas of prevention of invasive species.

Identification and population dynamics of mango white scale (*Aulacaspis tubercularis* N. (Hemiptera: Diaspididae) in Tapachula, Chiapas, México

R. Magallanes-Cedeno, A. Perez-Mendoza, A. Perez-Romero, J. Paxtian-Hernandez, M.E. Cabrera-Alvarado

Cuerpo Academico Consolidado de Proteccion Vegetal, Facultad de Ciencias Agricolas Campus IV, Universidad Autonoma de Chiapas, Huehuetan, Chiapas, Mexico,

Introduction: To prevent yield losses, many mango growers in Chiapas spray chemicals on the foliage of trees to kill ants, aphids and white scales. Such practice might affect the guild of natural enemies, increasing opportunities of phytophagous insects outbreaks. This study was conducted to acquire fundamental knowledge on taxonomy and population dynamics of mango white scale.

Methods: Weekly samplings were taken during 2005 in a mango orchard without insecticide sprays 9 km NW of Tapachula, Chiapas; the sampling unit was a branch including pre-flowering buds; four of these branches were sampled in each of ten trees to complete a sample size of 40. Alive and dead white scale colonies observed on leaves, stems or fruits were registered; also a record was kept on numbers of predators observed during each inspection.

Results: White scale specimens observed in the field corresponded to description of *Aulacaspis tubercularis* N., (Hemiptera: Diaspididae). Population of white scale increases sharply at beginning of year taking advantage of the dry season, however a guild of predators including syrphids, coccinelids and mostly chrysopids synchronizes well with white scale colonies, preventing outbreaks. Numbers of both white scales and predators drop drastically during the rainy season.

Conclusions: The community of natural enemies in mango plays a major role in the regulation of mango white scale abundance: Considering the biotic potential of white scale, an inadequate use of pesticides might initiate a serious ecological disturbance if numbers of predators are diminished.

Molecular analysis of predation and parasitism: problems and future directions

William O.C. Symondson

Reader in Invertebrate Molecular Ecology, Cardiff School of Biosciences, Cardiff University, Cardiff, United Kingdom

This Discussion session is designed to give everyone the opportunity to exchange ideas, to highlight problem areas, to cement collaborative links and to discuss future directions and opportunities within this field. Issues raised in the preceding talks can be discussed at greater length, clarifying technical issues of interest to those new to the field. New approaches, particularly those involving quantitative and multiplex PCR, can be evaluated. We can discuss the need for databases of primers of known specificity. The complexity of ecological studies that can be attempted will increase with sequence and primer databases, allowing us to study not just rates of predation on single prey species but also how whole food webs interact. Finally we should identify opportunities for collaborative research projects, exchanges of personnel and training.

The commercialisation of microbial biocontrol agents

Peter Lüth

Prophyta Biologischer Pflanzenschutz GmbH, Malchow/Poel, Germany

Introduction: Many good scientific results do not reach the market. The reason for this unsatisfying situation is that the scientists often completely neglect the economics of a new biocontrol system. For this reason, we find it necessary to release some economic data to the scientific community regarding the development of new microbial biocontrol agents.

Methods: The production, registration and marketing process has been analysed concerning the costs required to bring a microbial biocontrol agent onto the market.

Results: The cost structure of a company is well known. Only one part of the total costs originates from the production process. But all the other costs, such as development costs (including registration costs and licence fees), overhead costs and marketing and distribution costs also need to be considered. Finally, a profit must be added. So, considering all of these positions, the manufacturing of the final product, containing a particular amount of microbial cfu (e.g. fungal spores), may cost EUR 5000 per batch (one fermenter run). The distribution of the product through 2 to 3 distribution levels may cost another EUR 7500 per batch (150 %). Now, the size of the acreage which could be treated with one production batch is very important to calculate the economic feasibility of the product. At a price for the competitive product of EUR 50 per hectare, an area of at least 250 hectares would be necessary to make the product cost efficient. In other words, it makes a big difference whether you can produce 10^{13}, 10^{14} or 10^{15} cfu per batch, and whether you need 10^{11}, 10^{12} or 10^{13} cfu per hectare to ensure reliable pest control. In addition, the market must be large enough. If it is too small, a company will never be able to recoup the development costs. These costs, including the licensing costs for the microbial strain, the costs for the development of an appropriate fermentation and formulation technique, the registration costs, including all efforts needed to prove the efficacy of the new product in different countries, on different crops and under different conditions, may easily amount to EUR 1,000,000. Consequently, it makes no sense to develop a biocontrol agent for only one country, to be used on a minor crop.

Conclusions: When starting a comprehensive and cost-intensive project to develop a new biocontrol agent, 4 important parameters should be ascertained first: The size of the market, the price of the competitive chemical products, the amount of cfu which can be produced per fermenter, and the amount of cfu needed to ensure reliable control. Knowing these parameters, one can easily assess whether a potential new product would be marketable or not.

The entmofauna of Greenland and its zoogeographical status

Jens Bøcher

Natural History Museum of Denmark (Zoology), University of Copenhagen, København, Denmark

Greenland is an arctic area with a comparatively depauperate biota, the origins of which have been a subject of much interest and debate for more than a century. The expectation that the distribution and abundance of insects and arachnids at high latitudes will prove particularly susceptible to global climate change has recently added extra momentum to studies of the Greenland entomofauna, giving an updated stock-taking and continuous inventory of this fauna high priority. As a basis for such work the compilation of an identification manual of this fauna has been undertaken by the Entomology staff of the Natural History Museum of Denmark in collaboration with a large international specialist team. The revision of available museum holdings and new field work carried out in preparation for this publication have provided massive new information about the composition and distribution patterns of the Greenland entomofauna, now known to consist of about 1100 species.

Geological evidence points to a ”tabula rasa” at the height of the last glaciation, so that all Greenland taxa had to immigrate during the only 10.00 years of the Holocene. In spite of the position of the island, close to the North American continent, the Greenland faunas of particularly soil-bound taxa like Coleoptera, Collembola, Oribatida and Mesostigmata have sizable components of species of Palaearctic origin. A number of explanations of this strong Palaearctic element in the Greenland biota have been suggested, and these will be discussed in the light of the extensive new data and evidence from recent palaeo-entomological work.

Globins in *Drosophila*: oxygen carrier, ROS detoxifier or else, contd.

Thomas Hankeln[1], Eva Gleixner[1], Stefan Zimmerling[1], Thorsten Burmester[2]

[1]University of Mainz, Mainz, Germany, [2]University of Hamburg, Hamburg, Germany

Introduction: Respiratory proteins have been considered unnecessary in most insects, which do not dwell in hypoxic habitats. However, our survey has revealed that globins are a natural constituent of the insect gene repertoire. In Drosophila, three globin genes of unknown function have been identified. This presentation continues abstract no. 3243. Methods: see above

Results: see above

Conclusions: see above

Status of the market, commercialization and opportunities for biological insecticides

Pam Marrone

Marrone Organic Innovations, Inc. (MOI), Davis, CA, United States

More than 50% of human pharmaceuticals are derived from natural products from microorganisms and plants, while only 11% of pesticides are derived from natural products. Biopesticides are reduced risk products based on biological or naturally derived chemistry. They are either microbial pesticides or biochemical pesticides (plant extracts, pheromones, etc.). The global chemical pesticide market is approximately $30 billion and is flat to declining, while the market for biological pesticides and organic food is growing at 20% per year. By combining performance and safety, biopesticides offer value through a variety of benefits, some generally not realized by conventional pesticides:

- Better yields and quality when incorporated into the pest management system
- Provide customers the flexibility of minimum application restrictions (spray in the morning and be back in the field in the afternoon)
- Novel and complex modes of action that reduce the risk of pest resistance
- Provide human and environmental safety benefits
- Provide unique solutions for organic crops
- Environmentally friendly and sustainable production processes (use of renewable raw materials vs. fossil-fuel dependent synthetic processes)
- Accelerated time-to-market. (3 years versus ten years for synthetic chemicals)

What new bioinsecticides have come to market since Bt? What market opportunities are there for new insecticides? What new products are on the horizon?

At Marrone Organic Innovations, we are developing two new insecticides, one from plants and one from a new species of bacteria. For our microbial natural product screening, we isolate and screen naturally occurring microorganisms to identify those that may have novel, effective and safe pest management characteristics. We then employ natural product chemistry to analyze and characterize the compound structures of selected microorganisms to identify product candidates for further development and commercialization. We optimize the pesticidal natural product compounds during fermentation of the microorganism, and develop analytical methods to these compounds. We are isolating and testing bacteria (not Bt), fungi and actinomycetes against insects.

Opportunities for biological and biologically-derived insect control products in the global marketplace

Prem Warrior

Bill & Melinda Gates Foundation, Global Development Program, Seattle, WA, United States

The recent spike in food prices is driving millions of poor people around the world deeper into hunger and poverty. The crisis is threatening political and financial security globally. Commercial and non-commercial organizations around the world are attempting to address this crisis using a variety of tools – both short and long term. The need to enhance food production as well as to protect and preserve the produce is urgent. Commercial products of biological origin continue to play a critical role in the management of insect pests and plant diseases. While product formulations based on *Bacillus thuringiensis* dominate the field of biological insect control, efforts at development and commercialization of plant or microbial products continue at various laboratories around the world. The key to development and successful commercial products lies in (a) defining specific niche markets (b) identification of specific agents/organisms capable of affecting critical stages in the life cycle of the insect pest (c) development of commercially viable and sustainable production processes in fermentation and formulation delivery systems and (d) sound understanding and downstream communication all the way to the grower level about the specific mechanisms of action and use methods. This discussion on key attributes of bioinsecticide development will also address some of the critical issues in global agriculture.

Stingless bees and the reproductive ground plan hypothesis

Klaus Hartfelder

Depto. Biologia Celular e Molecular e Bioagentes Patogenicos, Universidade de Sao Paulo, Ribeirao Preto, Brazil

Recent results on the physiology of honey bees have contributed to firmly establish the reproductive ground plan hypothesis as a major explanatory framework for reproduction and division of labor in the castes of eusocial Hymenoptera. Stingless bees, the largest group of eusocial bees, are an excellent resource for comparative studies due to their variability in natural histories and life history strategies. I will provide an overview on what is known about physiological parameters related to reproduction and division of labor in this group. The comparison of vitellogenin expression in three meliponine species suggests divergence in regulatory mechanisms that directly relate to the mode of worker reproduction. Furthermore, juvenile hormone and ecdysteroid titer analyses in adult queens and workers of *Melipona quadrifasciata* indicate a lack of function for these hormones in division of labor. Comparing these data with honey bees and bumble bees may shed light on how evolutionary trajectories in caste physiologies can be viewed under a reproductive ground plan perspective.

Control of the African stalk borer (*Eldana saccharina*) by expression of a truncated *Bacillus thuringiensis cry1Ac* gene in the sugarcane endophyte *Gluconacetobacter diazotrophicus*

Gustav Bouwer

University of the Witwatersrand, School of Molecular and Cell Biology, Wits, South Africa

Introduction: The potential of controlling the sugarcane pest *Eldana saccharina* with a *Gluconacetobacter diazotrophicus* strain expressing a *Bacillus thuringiensis* insecticidal crystal gene (*cry1Ac*) was evaluated.

Methods: A novel truncated *cry1Ac* gene construct was created. The *cry1Ac* construct consisted of a synthetic ribosome recognition site, a truncated *cry1Ac* gene, and a synthetic stop codon. To confirm the functionality of the *cry1Ac* construct, the construct was cloned under control of the T7 promoter of the expression vector pDEST14 and *Escherichia coli* BL21-SI cells were transformed with the resultant plasmid. After evaluating the functionality of the construct in *E. coli* BL21-SI using SDS-PAGE and Western blotting, the *cry1Ac* construct was cloned downstream of the kanamycin resistance promoter of the broad host-range plasmid pKT230 and *G. diazotrophicus* PAl 5 cells were transformed with the resultant plasmid.

Results: SDS-PAGE and Western blot analysis confirmed the functionality of the *cry1Ac* construct in *E. coli* BL21-SI. In contrast to untransformed *G. diazotrophicus* PAl 5 cells, *G. diazotrophicus* PAl 5 cells transformed with pKT230 carrying the *cry1Ac* construct were toxic to *E. saccharina* larvae.

Conclusions: On the basis of the mortality and cessation of feeding observed during bioassays, *G. diazotrophicus* PAl 5 cells expressing a truncated *cry1Ac* gene were toxic to *E. saccharina.* The study suggests that it may be possible to control *E. saccharina* by expression of a truncated *B. thuringiensis cry1Ac* gene in *G. diazotrophicus*.

Recent increase of water hyacinth in Lake Victoria and reduction of lake water level increased breeding habitats for *Anopheles funestus*

Noboru Minakawa[1], Gorge Sonye[2], Gabriel O. Dida[3], Kyoko Futami[1], Satoshi Kaneko[1]

[1]Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan, [2]International Centre for Insect Physiology and Ecology, Mbita, Kenya, [3]School of Public Health, Maseno University, Maseno, Kenya

Introduction: The water level of Lake Victoria has fallen more than 1.5 m since 1998, and a narrow strip of land emerged along the lakeshore. Water hyacinth increased considerably in the lake after the heavy rainfall in 2006. This study examined whether these environmental changes increased habitats for malaria vectors in the lake basin.

Methods: Stagnant water habitats were examined for presence of malaria vectors (the *Anopheles gambiae* complex and *A. funestus*) in the north-eastern part of Suba district in western Kenya in 2008. Masses of water hyacinth along the lakeshore were also examined. House resting malaria mosquitoes were sampled in the villages along the shore. Locations and numbers of breeding habitats were compared with those of 1999. The density of house resting mosquitoes was also compared with that of 1999. Spatial relationships between breeding sites and mosquito densities were examined.

Results: Several breeding habitats for malaria vectors were found in the newly emerged land. It was confirmed that *A. funestus* also inhabits in the lake water with water hyacinth. There were more aquatic habitats in 2008 compared with 1999. The proportion of *A. funestus* to the *A. gambiae* complex in 2008 was significantly higher than that of 1999. The abundance of *A. funestus* in houses was negatively correlated with the distance to the habitats in the newly emerged land and water hyacinth.

Conclusion: The recent increase of water hyacinth in Lake Victoria and reduction in the water level created more breeding habitats for *A. funestus*.

Plant biosecurity capacity to protect national and internal borders against invasive insects

David C. Nowell

IPPC Secretariat, Agriculture and Consumer Protection Department, Food and Agriculture, Organization of the United Nations, Rome, Italy

Invasive insects have had, and still have, a very significant negative economic, social and / or environmental impact. Such impacts in agriculture are usually quantifiable as loss of production or financial losses (incursions can have a major economic impact on market access and trade), many other impacts such as environmental and social impacts are less easily quantified. It is economically and ecologically far more cost effective to prevent pest entry into a country, than trying to manage or eradicate the pest after it has established.

Although national legislative and institutional frameworks, based on the International Plant Protection Convention (IPPC), are necessary for a *Biosecurity* system to function, science provides the foundation for this process. However, the biology, ecology or impacts of many invasive insects are often not completely understood making the accurate assessment of risk and the development of mitigation options difficult. Management tools to support this process are often limited or poorly developed. Anticipated climate changes will ensure that we have to revise all current risk assessments and mitigation measures as the environment changes. Pivotal to managing increasing challenges by invasive insects are international cooperative approaches. The IPPC is developing standards for countries to use in trade, as well as building the capacity to implement these on a worldwide basis.

We need to find new ways of working more efficiently (e.g. risk assessment and emergency response), greater integration and coordination (e.g. public, academic and private research), improved communication and transparency, increased cooperation (e.g. surveillance, diagnostics and reporting), and develop new tools (e.g. diagnostics and treatments).

Diversity patterns of African Galerucinae (Chrysomelidae)

Thomas Wagner

Universität Koblenz-Landau, Institut für Integrierte Naturwissenschaften, Koblenz, Germany

Afrotropical species of the most diverse group of the Galerucinae (Chrysomelidae), that includes taxa which have been traditionally assigned to the “Monoleptites”, were recently revised. Many taxonomic changes became necessary since the generic allocation of many taxa was mainly typological and also the original species descriptions, which were mainly published between 1870 and 1950, based on a typological species concept. After the taxonomic revision, the phylogeny of these leaf-beetles could be studied on base of external and genital characters, as well as molecular data for a better characterization of species and monophyletic groups.

After revision of about 65000 specimens, mainly of species-rich groups such as *Monolepta*, *Candezea, Bonesioides, Galerudophia, Afrocrania, Afromaculepta* and *Afrocandezea* detailed data on distribution patterns are now available for the first time. Centers of diversity are the montane regions along the Albertine and the East African Rift System as well as isolated montane areas in Cameroon, the Eastern Arc Forest in Tanzania and montane regions in southeast South Africa. Speciation processes of the mainly forest dwelling species have been probably strongly influenced by habitat isolation in forest refugees during the quaternary period.

A gene for social parasitism in honeybees

Michael Lattorff

Institut für Zoologie, Martin-Luther-University Halle-Wittenberg, Halle, Germany

Social parasites exploit the social ressources of their hosts. Often, social parasites are close relatives of their hosts, also known as Emery's rule. Hence, social parasites do not differ substantially from their hosts with respect to their genes and genomes.

The Cape honeybee, *Apis mellifera capensis*, is a particularly suitable system to investigate the genetic basis of social parasitism. In contrast to all other subspecies of the honeybee, workers of *A. m. capensis* are able to produce female offspring by thelytokous parthenogenesis. Furthermore, they are able to mimic queens with respect to behaviour and physiology. They show a high potential for fast ovary development and usually are able to produce queen-like pheromone bouquets in large quantities.

We used backcrosses between *A. m. capensis* and *A. m. carnica* to investigate the genetic basis of the type of parthenogenesis as well as the ovary development and the pheromone biosynthesis.

Using more than 500 microsatellite markers we were able to identify a single genomic region, that is highly associated with the type of parthenogenesis. Moreover, the queen-like pheromone production and the speed of ovary activation are linked to the type of parthenogenesis suggesting that the very same gene influences these three different phenotypes. Within the candidate region we could identify 16 genes, of which the transcription factor *gemini* is a very likely candidate for pleiotropically influencing these three phenotypes.

To our knowledge, this is the first report on a single gene that has a high impact on the development of a social parasitic lifestyle.

Dedication to Dr Andrew Spielman

Glen R. Needham

Department of Entomology, Ohio State University, United States

Comments on the contributions of the late Dr Andrew Spielman to research on the biology and control of insect vectors.

How plants use empty flowers to manipulate pollinators

Steven Johnson

School of Biological and Conservation Sciences, University of KwaZulu-Natal, Private Bag X01, Scottsville, Pietermartizburg 3209, South Africa

It has been estimated that one-third of all species in the orchid family have empty (non-rewarding) flowers. Non-rewarding orchids tend to produce fewer fruits per flower than rewarding orchids, thus making it difficult to understand how they gain a fitness advantage from deception of pollinators. In experiments in which we supplemented empty orchid flowers with nectar, bee and fly pollinators visited more flowers per plant. This resulted in increased levels of pollen deposition and removal, and, importantly, an increase in levels of self-pollination. The costs of pollinator-mediated self-pollination for both male and female pollination success can result in selection against rewarding flowers. When pollinators are rare and plant reproductive success is pollen-limited, selection generally favours rewarding flowers despite the costs associated with self-pollination

POSTER PRESENTATION

An experience of using ecological method for Sunn pests' control in Iran

Mehdi Zarabi

University of Tehran, Tehran, Islamic Republic of Iran

Introduction: Sunn pest, *Eurygaster integriceps* (Hemiptera: Pentatomidae) is an endemic serious pest of wheat in Middle East countries. It has been under insecticides pressure since three past decades in Iran. This situation will lead to appearance of resistant populations.

Methods: In this study, some new ecological approaches conducted as control method instead of using insecticides. For, this purpose, a wheat pilot field near 20 ha, selected in Zanjan province (west of Iran). Middle of this field (near one hectare) designed with 12 strips and the rest of it planted as whole-wheat areas, which surrounded the strip plots. Twelve strips were included six wheat rows (each with 6m wide) and six unplanted band (each with 2m wide, which covered with spring weeds). Sunn population density evaluated two times: in early spring when the adults fly from hibernate localities in mountains to wheat fields and then in mid of summer when the new generation appearance in the fields.

Results: Collected data analyzed and the results showed that there was a significant difference between population densities of adults in strip plots in comparison with the whole-wheat areas. In addition, the nymph's population density decreased in the strip plots.

Conclusions: It seems that the strip cultural design can disrupt the migratory adult's vision while they land successfully in whole-wheat area. This method will help growers to decrease insecticides usage in their fields in early season and certainly will prevent the appearance of pest's resistant populations.

POSTER PRESENTATION

Insect fauna (Psocoptera) in the forests of Croatia

Irma Kalinovic, Vlatka Rozman, Anita Liska

Faculty of Agriculture, University of Josip Juraj Strossmayer in Osijek, Osijek, Croatia

Introduction: Insects of order Psocoptera (psocids) with about 4400 species are worldwide known. In the forests they have a good ecological living area. This note is a reviev of Psocoptera fauna fauna in the forests from the eastern part in Republic of Croatia.

Methods: From different forest trees (leaves and barks) psocids have been collected by beating tray methods and by aspirator or fine brush. All specimens (adults, larvae, nymphs) were preserved in 70% alcohol with glycerol and identified using the key, given by Günther, 1974, Smithers, 1990. Representatives of genera Liposcelididae after maceration method and slides making, were identified by the same key.

Results: During 1975-2005 year on forest trees (Salix alba, Populus alba, P. nigra, Quercus robur, Castanea sativa, Ulmus campestris, Morus sp., Robinia pseudoacaccia, Fraxinus americana, F. excelsior, Tillia sp., Fagus sylvatica, Cathalpa cathalpa, Pinus nigra, Abies sp., Picea sp., Cupressus sempervirens) 3766 psocids individuum, from 8 genera and 25 species were identified. The most numerous was genera Ectopsocidae, with 2 species Ectopsocopsis cryptomeriae, E. meridionalis (72%), than generas Lachesillidae 3 species - 14%, Liposcelididae - 4 species with 4%, Peripsocidae with 3 species - 4%, Psocidae 6 species - 3%, Caecillidae 4 species - 1%. Stenopsocidae 2 species - 1% and Trogiidae 1 species with 1% spreading.

Conclusions: All mentioned investigated Psocoptera taxons are new in the forestes of eastern part of Croatia.

POSTER PRESENTATION

Plants' tolerance to insect pest attack, an effectiveness method for decreasing pesticides application

Mehdi Zarabi

University of Tehran, Tehran, Islamic Republic of Iran

Introduction: Colorado beetle, *Leptinotarsa decemlineata* is a serious pest of potato in cold regions of Iran. Resistant pest's populations released because of using of different insecticides throughout of country. Ecological methods are the best way for control of insect's resistant populations. Among these methods, increasing of tolerance rate in host plants is a practical one.

Methods: In this study, some microelements sprayed against Colorado beetle instead of insecticides usage. For this purpose, a potato field pilot (near one ha) was selected in Zanjan province (west of Iran). Three potato varieties planted in a split plot design as main plots and three kinds of microelements; BMX, Sollopotas and Fosamco sprayed one time based on their commercial introduced amounts (three treatments of fertilizers and one treatment as control plot, which sprayed with water) as sub plots. Then population density of adults and larvae evaluated in different treatments after one week.

Results: Results showed that the plots, which sprayed with Sollopotas and BMX, were free of larvae in comparison of Fosamco plots and control ones. In addition, there was not a significant difference between yields of varieties. Only total yields of two varieties Marfona and Agria were increased up to 14 and 8 ton/ha respectively in plots which were treated by BMX.

Conclusions: It seems that some compounds, which included potassium, can increase the rate of potato tolerance to this pest or the stand plants, which sprayed with these microelements, are not desirable for larvae. In any way, this is a success method for controlling of resistant population.

POSTER PRESENTATION

Temporal patterns of some greenhouse pests in the Netherlands

Jan Kaas

Biopre biological pest control, Langeraar, Netherlands

Introduction: Commercial greenhouses in the Netherlands are subject to a limited number of serious pest species. One of the most destructive key pests is the Western Flower Thrips *Frankliniella occidentalis*. Thrips populations in greenhouses are mainly monitored using yellow or blue sticky traps. Several lepidopteran pests in greenhouses are monitored using low frequency light traps. Pest management decisions are based on the result of these generally weekly measurements.

Methods: For a period of eight years, weekly thrips catches on colored sticky traps were recorded. Also weekly light trap counts of *Sufetula* and *Duponchelia* were made.
Results: A graphical representation of statistics is presented. Periodicity and trends in population numbers are indicated.

Discussion: Thrips numbers follow a clear annual cycle with lower numbers near December and a unimodal or bimodal distribution during the rest of the year. The results of weekly light trap collections of two species of Lepidoptera over several years are presented and discussed. Implications for use in pest prediction models are discussed.

POSTER PRESENATION

Predation potency of the predator *Clitostethus arcuatus* (Rossi) on jasmine whitefly *Aleuroclava jasmini*

Mohammed Z. Khalaf*, Ahmed K.Abed*, Huthaifa M.Al-Rubaie* and Hala T. Omran*

**Integrated pest control research center, Ministry of science & technology, P.O.Box; 765, Baghdad, Iraq*

Introduction: Laboratory studies were conducted to evaluated the predation potency of the predator *Clitostethus arcuatus* (Rossi) (Coccinellidae: Coleoptera) on jasmine white fly *Aleuroclava jasmini* on Citrus.

Methods: Establishment of laboratory culture of *C. arcuatus* was achieved by using eggs, movable nymphs and stationary nymphs of *A. jasmini* as food which is considered the main step of mass rearing, the average number of eggs and nymphs consumptive by the larva and adult of predator were recorded.

Results: Results indicated that larvae of *C. arcuatus* consumed an average of 966.2, 1050 and 460 of eggs, movable nymphs and stationary nymphs respectively during one week period.

In addition, Adult predator consumed an average of 1451 eggs, 980 movable nymphs, 367 stationary nymphs and 115 adults during one week period.

Conclusion: Predator potential as apart of pest management was discussed and results of this study can be used in the practical application of biological control to *A. Jasmini* on citrus.

POSTER PRESENTATION

The effects of sex allele homozygote phenomenon on the performance and honey bee production

Abolfazl Asadi Dizaji, Naser Maheri Sis, Hamideh Moeni Alishah, Eynollah Valizadeh

University, Shabestar, Islamic Republic of Iran

Since the homozygote of sex alleles or inbreeding has a great role in the different characteristics of honey bees colony's like the production of honey, this phenomena has been considered in Mianeh. In order to do this %5 of modern hives were chosen and considered in this area. According to the given method by Rotner. The cells which were free of brood were recorded and considered as index of inbreeding. Also the honey production was measured by weighting the hives. Inbreeding studies showed no significant differences between several of Mianeh so that the percent inbreeding was 9.22, 10.93 and 23.48 for Kandowan, Torkmanchai and Kaghazkonan, respectively. The total mean value in Mianeh was estimated as 15.05%. Mean honey production per hive was 11.9 kg. According to this study there were significant negative relationship between inbreeding and honey production (r=-0.57).

POSTER PRESENTATION

Action threshold for controlling pistachio psylla nymphs (Hemiptera: Psyllidae) on *Pistacia vera* cv. Ohadi

Mohammad Reza Hassani, Gadir Nouri Ganbalani, Hamzeh Izadi, Mahmoud Shojai

Islamic Azad University, Rafsanjan, Iran, Rafsanjan, Iran

Introduction: The pistachio psylla, *Agonoscena pistaciae* Burckhardt & Lauterer is a major pest of pistachio in Iran. The economic injury level is an important practical tool for decision-making in IPM programs. Our objective was to determine economic injury level for *A. pistaciae* on pistachio cultivar Ohadi.

Methods: Different density levels of *A. pistaciae* nymphs were maintained on pistachio trees by application different dosages of insecticides. Psyllid nymph densities were monitored weekly by counting psyllid nymphs per terminal leaflet. At harvesting time, yield of every tree was individually harvested and samples of weight of 1000 nuts measured. Regression analysis was used to determine the relationship between psyllid nymph densities and weight of 1000 nuts. The economic injury level was estimated by using pedigo *et al*., (1986) equation.

Results: The infestation levels of psyllid nymphs were different between treatments at different control levels. The weight of 1000 nuts was significantly affected by number of psyllid nymph. Regression equation obtained to describe the relationship between psyllid nymph densities and yield loss is: $Y= -2.89X+841.21$, $R^2=0.96$. The economic injury level estimated for various combinations of management cost and market value. The economic injury level is a function of market value, management costs and efficiency of insecticide. The economic injury level of pistachio psylla nymph on cultivar Ohadi was ranged from 7.7 to 30.7 psyllid nymphal-days per terminal leaflet.

Conclusion: This information may be considered by pistachio plantation for decision-making and help to reduce costs and insecticides application based on economic injury level.

POSTER PRESENTATION

Mating competitiveness value of the blow fly (OWS), *Chrysomya bezziana,* exposed to gamma rays

Ayad Ahmed Al-Taweel, Layla Jabbar Al-Bahadyli, Udo Feldmann

MoST/Directorate of Agricultural Research & Food Technology, Baghdad, Iraq

Introduction: The OWS, *Chrysomya bezziana* is an obligatory parasite of warm blooded animals and human beings. The total cases reported by Iraqi Veterinarian Service from Sept.1996 till Dec.\2004 was 118497 in addition to 23 cases in human beings, while, 414 and 1998 cases were reported during 2005 and 2006, respectively. Chemical insecticides are usually used to control this pest but unfortunately no success has been obtained. Therefore, SIT was suggested as an effective strategy. One of the aspects of this technique which is supposed to be excellent is mating competitiveness value (CV), therefore, this investigation concentrated on studying the effect of gamma rays on CV of OWS irradiated as 4-5 old pupa with either 30 Gy or 60 Gy.

Method and Results: CV of OWS males and females were measured according to the Fried method (1971). Results showed that irradiated males with 30 Gy and released with unirradiated males and females at different ratios had excellent CV in comparison with those irradiated with 60 Gy, while irradiated females with either 30 Gy or 60 Gy and released unirradiated females and males had poor CV. Finally the CV for irradiated males and females irradiated with 30 Gy and released together with unirradiated males & females had excellent CV in comparison with those irradiated with 60 Gy.

Conclusion: These results were encouraging and useful for suggested programs to use SIT for controlling this invasive pest in the near future.

POSTER PRESENTATION

The relationship between the vine mealybug, their parasitoids and ants in South Africa vineyards

Kwaku Akoming Achiano

ARC, Stellenbosch, Western Province, South Africa

Introduction: The mealybug *Planoccocus ficus* infestation is one of the most serious problems for vine growers in South Africa. It is the major vector of grapevine leafroll and causes direct damage by its feeding and honeydew secretions. The presence of mealybug on exported table grapes may lead to rejection of consignments. The study was to establish the relationship that exists between the vine mealybug, their parasitoids and ants.

Methods: Four wine grape vineyards (± 3 ha each) with a history of mealybug infestation were chosen for studies. Female mealybugs and ants were assessed physically every two weeks. For each vine, the presence/absence of vine mealybug on the stem, lateral branches and leaves were noted. Yellow sticky traps Agribiol® (200 mm X 100 mm) were used to sample parasitoids.

Results: There was a progressive upward movement of the female mealybug from the stem onto the lateral branches and finally on the leaves. Later as the season progressed there was a downward movement from the leaves to lateral branches and stem. The predominant parasitoid encountered was *Anagyrus pseudococci* whilst *Leptomastix dactylopii* and *Coccidoxenoides perminutus* were also observed. The low population of parasitoids lagged behind that of the female mealybugs, whilst the increase in ant numbers was in tandem with increase in the female mealybug numbers. Furthermore, low numbers in ant population coincided with high numbers of parasitoids.

Conclusion: Low numbers of ants must be maintained to ensure high numbers of parasitoids. Farmers should consider augmenting existing natural enemies with commercially available parasitoids.

POSTER PRESENTATION

The presence of a forest affects honey yields: One more reason to conserve forests

Susan Sande[1], Sue Nicolson[1], Robin Crewe[1], Ian Gordon[2]

[1]University of Pretoria, Pretoria, South Africa, [2]International Centre of Insect Physiology and Ecology, Nairobi, Kenya

Introduction: To conserve globally threatened tropical forest ecosystems, community-driven conservation projects including beekeeping have been undertaken. Bees, with their specific requirements for nutrition and nesting, are good indicators of landscape structure and overall biodiversity of a forest, provided the ecological and seasonal patterns are taken into consideration. Although some studies worldwide have been carried out on honey quality and pollination services of bees, with others in relation to forests, none has targeted this question; is honey quality and quantity enhanced by the presence of a forest?

Methods: Beehives situated, 0-1 km, 1-2 km, and 2-3 km away from the forest was selected. Bees are known to forage for up to 5km (Hepburn and Radloff, 1998) and only go further if there is acute shortage of pollen and/or nectar. At each distance a fixed number of hives facing North, South, West and East of the forest was selected.

Results: The yield of honey, especially from top bar hives, decreases at a distance of more than 3km from the forest. The moisture content, pH, free acidity, HMF and proline content did not differ significantly among honey collected from various distances away from the forest.

Conclusion: High species diversity and floral density provide a better food base for bees and naturally sustain a higher population per honeybee colony leading to higher honey yields. We suggest that a maintenance of a high Apiflora species diversity and floral density, which happens naturally inside the forest, can be emulated by farmers in order to ensure high yields away from the forest. A catalogue of such species has also been drawn as a result of this study.

POSTER PRESENTATION

Control of maize weevil *Sitophilus zeamais* (Motsch.) using indigenous plants for stored maize protection in Africa

Donald A. Ukeh[1], Michael A. Birkett[2], John A. Pickett[2], A. Jennifer Mordue (Luntz)[1]

[1]School of Biological Sciences, University of Aberdeen, Tillydrone Avenue, AB24 2TZ,, Scotland, United Kingdom, [2]Centre for Sustainable Pest and Disease Management, Biological Chemistry Department, Rothamsted Research, Harpenden, Herts., AL5 2QJ, England, United Kingdom

Introduction: The repellency potential of ginger, *Zingiber officinale*(Zingiberaceae), West African black pepper, *Piper guineense* (Piperaceae) and alligator pepper, *Aframomum melegueta* (Zingiberaceae) were tested against the maize weevil, *Sitophilus zeamais* (Coleoptera: Curculionidae), in laboratory behavioural assays and under field conditions.

Methods: Using a four-arm olfactometer, single choice bioassays were conducted using 2 g of yellow or white maize or winter wheat seeds, and 2 g *Z. officinale* rhizome, *P. guineense* and *A. melegueta* seeds against 3 d old *S. zeamais* adults. In field trials, 10% (w/w) crushed *Z. officinale* rhizomes, *P. guineense* seeds and a combination of *Z. officinale* and *A. melegueta* (5% each) were admixed with shelled and sun dried maize cobs in baskets and sampled weekly for natural infestation for 12 weeks in traditional granaries.

Results: In laboratory assays, both sexes of *S. zeamais* showed strong attraction to maize and wheat seed volatiles but were significantly ($p < 0.001$) repelled by odours emanating from *Z. officinale* rhizomes, *P. guineense* and *A. melegueta* seeds. In field experiments, crushed *Z. officinale* rhizomes, *A. melegueta* seeds and a combination of *Z. officinale* and *A. melegueta*, significantly repelled *S. zeamais* from traditional maize granaries ($p < 0.001$), with maize seeds giving higher germination from untreated cobs.

Conclusions: Thus, under small-scale farmer conditions, protecting grains with indigenous repellent plants could decrease the quantity of toxic insecticides required, and lead to the development of more sustainable crop protection strategies.

POSTER PRESENTATION

Identification and field evaluation of the sex pheromone of an invasive pest, fall webworm *Hyphantria cunea* in China

Zhongning Zhang, Mowen Su, Yuling Fang

Institute of Zoology, Beijing, China

The fall webworm, *Hyphantria cunea* (Lepidoptera: Arctiidae) as an invasive pest insect was found in china in 1979 and had been introduced into four provinces of north of Chins, such as Beijing, Tianjin, Hebei, Shandong and Shaanxi. Currently, pheromone gland extracts of the pest insect were analyzed by gas chromatography and gas chromatography-mass spectrometry. Based on comparison of retention times and mass spectra of synthetic standards, four compounds were identified as (9*Z*, 12*Z*)-octadecadienal, (9*Z*, 12*Z*, 15*Z*)-octadecatrienal, (3*Z*, 6*Z*, 9*S*, 10*R*)-9, 10-epoxy-3, 6-heneicosadiene and (3*Z*, 6*Z*, 9*S*, 10*R*)-9, 10-epoxy-1, 3, 6-henicosatriene with ratio as 2:33.6:58.4: 6 and the ratio was different as 0.6:6.6:27.9:0.1 in New Zealand. Trapping tests showed that quaternary blend of these compounds was highly attractive to male *H. cunea*. Unitraps baited with the quaternary blend loading of 200-300µg on a gray rubber septum were very effective for monitoring *H. cunea* populations.

POSTER PRESENTATION

Influence of rainfall on the occurrence of adult black maize beetles, *Heteronychus arator* (Coleoptera: Scarabaeidae) in the Eastern Cape of South Africa.

Graham Petty

Institute for Tropical and Subtropical Crops, Bathurst, Eastern Cape, South Africa

Introduction: Because pineapple farmers are no longer permitted to apply long residual chlorinated-hydrocarbon insecticides e.g. Aldrin and Dieldrin, as preventative control measures for Black Maize Beetle, *Heteronychus arator* (Fabricius), the species has assumed greater importance. Predicting the incidence of these pests before they cause serious damage to plantations would therefore be useful to the grower.

Methods: Annual field development of Black Maize Beetles was determined by monthly samplings in a pineapple field. Adult beetles were captured in a Robinson light trap, during their flight period, for 13 years and their numbers studied in relation to the rainfall occurring during the different development stadia of this species.

Results and Discussion: The total number of Black Maize Beetles collected in the light trap during January, February and March, was found to be related to the rainfall which occurred during the lifecycle of the parental (P1) generation of beetles and that of their immature offspring (F1). It is thus possible to predict an outbreak of adult Black Maize Beetles thereby permitting a timeous application of control measures. From a review of relevant literature, possible reasons are given for the effects of either wet or dry conditions, during different stages of development on beetle mortality.

POSTER PRESENTATION

Effect of host density (*Ephestia cautella*, larvae) and exposure period on the efficacy of *Bracon hebetor* under field conditions

Ayad Ahmed Al-Taweel[1], Emad Ahmed Mahmmod[2], Alla Abdul-Alhassan Muhsen[2]

[1]MoST/Directorate of Agric. Res. & Food Tech., Baghdad, Iraq, [2]College of Sci. for Woman, Baghdad, Iraq

Introduction: Iraq produces more than 500000, tons of dates annually during its development fill ripening and collecting it form trees it expected to be infested by date moth belong to Ephestia genus specifically *Ephestia cautella* . this infestation cause problem for marketing processes, therefore insecticides usually used to control this pest but unfortunately it is appeared impossible to control this pest biological control using the larval ecto parasite *Bracon hebetar* is suggested.

Materials and Methods: Experiments were carried out under field condition, *E. coutella* larvae at numbers 10 ,20,30,40 and 50 were exposed to five pairs of *B.hebetor* in an cage of 20×20×20 cm after period of exposure which were 24,48 and 72 hrs . the *B.hebeor* was removed from the cages and they kept in the field after the number of paralyzed *E. cautella* larva were counted these cages were examined daily to count the number of *B.hebetor* larvae, pupae and adults produced. Five replicates for each *E.cautella* larval number and for each period of exposure were made.

Results: It is appeared from the results that the B.hebetor females were very active in paralyzing *E.coutella* larvae at all numbers and period of exposure tested this was noticed from the number of eggs, larvae, pupae and adults of *B. hebtor* produced.

Conclusion: The results suggested the possibility of using *B.hebetor* as an biological agent to control E.coutella in the field or date store within an IPM programmed to control *E. cautella* .

POSTER PRESENTATION

Dragonfly (Odonata) phenology and assemblage response to elevation in a sub-tropical region (South Africa)

Augustine Niba, Michael Samways

[1]Walter Sisulu University for Technology & Science, Mthatha, Eastern Cape Province, South Africa, [2]University of Stellenbosch, Stellenbosch, Western Cape Province, South Africa

Little is known of African dragonfly response to elevational gradients. We studied dragonflies and environmental variables over two years (from September 2001 to October 2003) in a series of reservoirs in KwaZulu-Natal, South Africa, and over an elevational gradient of 100 - 1350 m a.s.l.

The aim was to determine how elevation and climate (as regional processes), as well as local factors, influenced species assemblages and phenology. Seven families and 47 species were recorded. Larvae showed positive correlation in species richness and abundance with increasing elevation, while adult did not.

Ordinations of two odonate sub-orders showed that certain measured site variables strongly explained the main variation in species assemblages. These included local factors e.g. pH, marginal grasses, percentage shade, exposed rock, marginal forest and to a lesser extent, marshes and water flow. These conditions varied from one season to another, being optimal in summer, and minimal in winter, and influenced dragonfly species phenologies accordingly.

However, elevation and climate as regional processes had very little influence on dragonfly assemblages over this 1250 m gradient during the study.

Although there were more widespread and elevation-tolerant species (S=44), these sub-tropical odonate species are similar to their tropical counterparts in that they have long flight periods with overlapping generations. Yet they also showed temperate characteristics by over-wintering principally as larvae.

The national endemics: Pseudagrion citricola and Africallagma sapphirinum only occurred at high elevations, while Agriocnemis falcifera was throughout all elevations, suggesting that regional endemism does not necessarily equate to elevational intolerance. This study also offered baseline information for comparing the effects of future global climate change.

POSTER PRESENTATION

Factors influencing population density of bees in Bwindi Impenetrable National Park, Uganda

Robert Kajobe

National Agricultural Research Organisation (NARO), National Livestock Resources Research Institute (NaLIRRI), Tororo, Uganda

Introduction: In the first study of native African honeybees and honey-making stingless bees in the same habitat, humans and chimpanzees are the primary bee nest predators. This study was carried out in Bwindi Impenetrable National Park, Uganda. The park is a UNESCO World heritage site and contains half the world's population of mountain gorillas. The study was undertaken because little is known about bee ecology in Uganda.

Methods: Fieldwork was guided by the local Batwa Pygmies, the indigenous honey-hunters residing near the park. Sometimes, the dwarf honey-guide *Indicator pumilio*, a tiny bird that is endemic to the Albertine Rift Mountains, helped direct the Pygmies to stingless bee nests. Eighty seven plots were established for the study and two parallel 500 m transects were made in each plot, separated by 100 m. Flying bees were searched for in the plots and at nest entrance tubes on tree trunks.

Results: A total of 5 stingless bees (*Meliponula* and subgenera *Axestotrigona* and *Meliplebeia*) and *A. mellifera adansonii* were found. Of the total stingless bee colonies, 15 percent were destroyed by man and 10 percent by chimpanzees. The other predators, civets, gorillas, and baboons destroyed 3 percent of the nests. Sticks used by chimpanzees to harvest brood, honey, and pollen were found on the ground near trees with stingless bee nests. Sticks were missing bark from one or both ends and were peeled or chewed.

Conclusions: The Pygmies were the most important predators. The other agricultural communities neighboring the park mostly kept *A. mellifera* instead of Meliponini.

POSTER PRESENTATION

Relative abundance of *Bactrocera zonata* and *Ceratitis capitata* on fruit hosts in Egypt

S. Elnagar[1], M.A.K. El-Sheikh[1], A.G. Hashem[2], Y.E. Afia[2]

*[1]Department of Economic Entomology and Pesticides, Faculty of Agriculture, Cairo University, Cairo, Egypt, [2]*Horticultural Pests Department, Agricultural Research Centre, Cairo, Egypt*

Ceratitis capitata (Weid) is a highly polyphagous tephritid that was reported in Egypt early last century. In (1990), another harmful tephritid species, *Bactrocera. zonata* (Saunders), was recognized in Egypt causing most of fruit damage. Recently, *B. zonata* has become so widespread that dominating *C. capitata.* The relative abundance of the two fruit flies (Family: Tephritidae): Mediterranean fruit fly, *C. capitata* and the peach fruit fly, *B. zonata* has been compared for three successive seasons on eight different fruit hosts (peach, apricot, mango, guava, navel, balady, mandarin and Valencia) cultivated in three different localities in Egypt . The obtained results revealed that the total captured males of *B. zonata* were, in general higher than that of *C. capitata*. *B. zonata* represented the high majority of fuit flies population in general. The rate of replacement by *B. zonata* over *C. capitata* was evident in all areas under investigation. It is confirmed, that *B. zonata* was abundant throughout the season, except in winter months. On the other hand, *C. capitata* was less abundant during the summer months.

POSTER PRESENTATION

New polar constituents in the pupae of the silkworm *Bombyx mori* L.

Ryuichiro Tanaka

Setsunan University, Hirakata, Osaka, Japan

In addition to serine (L:D = 68:32), a methanol extract of *Bombyx mori* L. pupae contained methionine sulfoxide (MSO), L-methionine sulfone (L-MSO_2), trehalose, and disodium γ-cyclic di-L-glutamate. MSO was isolated as a diastereomeric mixture of L(+)- and D-(+)-MSO in a ratio of 99:1. The presence of these compounds at other developmental stages, including eggs, larvae (1^{st}, 4^{th}, 5^{th}, and mature 5^{th} instar), adults, and excrement (feces and urine) was investigated. The L(+)-isomer of MSO was present in extracts of the 1^{st} and 5^{th} instar larvae, adults, and eggs, but was not detected in feces or urine. The D(+)-isomer was found only in pupal stage extracts, and was excreted into the meconium with the L(+)-isomer. L-MSO_2 and γ-cyclic di-L-glutamate were not detected at other insect life stages or in the insect excrement. γ-Cyclic di-L-glutamate is thought to be produced on blockage of the glutamate synthetic pathway (glutamine synthetase) by L-MSO_2 and Mg^{2+}. During the pupal stage, the quantities of L-MSO_2 and L-MSO increased initially, decreased, and then subsequently increased again, and became maximal the day before emergence; the L-MSO_2 disappeared immediately after emergence. With advancing emergence time, the sugar content (*i.e.*, trehalose) also changed. The biochemical role of L-MSO_2 during the pupal life stage remains unknown, but its stage-specific expression suggests that it is a candidate molecule that induces diapause.

POSTER PRESENTATION

Facilitating learning towards sustainable integrated pest management in organic cocoa production in Ghana

Godwin Ayenor, Daniel Obeng-Ofori, Beatrice Padi, Arnold van Huis, Neils Roling

University of Ghana, Legon, Accra, Greater-Accra, Ghana

Introduction: Cocoa is an important foreign exchange earner for Ghana. However, until recently, production had plummeted due to low producer price and high incidence of pests and diseases. Paradoxically, only 3.5% of cocoa farmers adopt pest management technologies developed by the Cocoa Research Institute of Ghana.

Methods: To improve research uptake and adoption, technographic and diagnostic studies followed by participatory technology development tools were used to address pest and disease constraints of cocoa in the Eastern region of Ghana. Three innovative pest control methods were selected for for field participatory experimentation with key stakeholders including 10 volunteer farmers referred to as Local Agricultural Research Committee (LARC), research scientists, and agricultural extension agents. The pest control methods evaluated were: the use of pheromone traps, crude aqueous neem (*Azadirachta indica* A. Juss) seed extract (ANSE), and the use of the red ants *Oecophylla longinoda* as biological control agents. The temporal distribution of capsids and other insects in the cocoa ecosystem was also investigated to determine the correct timing of the control methods.

Results: Capsid population peak occurred in March contrary to previous findings. Results from the field experiments indicated that where *O. longinoda* occurred in high numbers, the reverse was true for capsids, especially under shady conditions. As a monitoring and control measure, the use of sex pheromone traps did not only confirm March as the peak population period for capsids but it also controlled the capsids by trapping the males. These results contradict previous findings that capsid population increases to a peak in November-January and drops in February-June. The efficacy of ANSE against capsid bugs in both cage and field experiments was encouraging (100% & 80% mortality, respectively), and was even more effective against *Helopeltis* spp (cocoa mosquito) with 100% mortality in the field. Its effect on other insect pests such as cocoa mealy bugs, shield bugs and aphids was also promising.

Conclusion: The three methods investigated might prove to be effective and compatible within the context of an Integrated Pest Management (IPM) strategy for sustainable production of organic cocoa in Ghana.

POSTER PRESENTATION

Action of a biopesticide, Spinosad, and a nonsteroidal ecdisteroid, methoxyfenozide, on *Spodoptera exigua*

Samuel Pineda[1], Aniceto Osorio[1], Ana Mabel Martinez[1], Marcela Ines Schneider[2], Ovidio Diaz[3], Jose Luis Corrales[4], Mayra Crimilda Aviles[5], Guy Samagghe[6]

[1]Instituto de Investigaciones Agropecuarias y Forestales, Universidad Michoacana de San Nicolás de Hidalgo. Km. 9.5 Carr. Morelia-Zinapécuaro., 58880 Tarímbaro, Michoacán, Mexico, [2]Centro de Estudios Parasitológicos y de Vectores CEPAVE., La Plata, Buenos Aires, Mexico, [3]Facultad de Agronomía, Universidad Autónoma de San Luis Potosí., San Luis Potosí, Mexico, [4]Facultad de Agronomía, Universidad Autónoma de Sinaloa., Culiacán, Sinaloa, Mexico, [5]Instituto Nacional de Investigaciones Forestales y Agropecuarias, Campo Experimental del Valle de Culiacán., Culiacán, Sinaloa, Mexico, [6]Laboratory of Agrozoology, Faculty of Bioscience Engineering, Ghent University., Ghent, Belgium

Introduction: Spinosad –a nerve poison biopesticide derived from the soil actinomycete *Saccharopolyspora spinosa* Mertz & Yao- and methoxyfenozide –a nonsteroidal ecdisteroid compound- are considered to be environmentally safer alternatives to broad-spectrum pesticides. Therefore, both biorational insecticides can play an important role in the future as part of beet armyworm, *Spodoptera exigua* (Hübner) (Lepidoptera: Noctuidae), management programs.

Methods: The selection experiments were carried out with a field population (Se-La Floriza) by exposing for 24 h third-instar to corresponding LC_{50} of Spinosad and methoxyfenozide for over six generations (G_2-G_7). Sublethal effects caused by methoxyfenozide were evaluated on insects of the G_7, the final generation subjected to selection procedures. In another experiment, five populations of *S. exigua* were collected from fields of vegetable crops in three states of Mexico (Sinaloa, Guanajuato, and San Luis Potosi) in 2005 and 2006 for susceptibility tests.

Results: Experiments to select insects artificially from a field population revealed no significant loss in susceptibility to both compounds for up to five generations. In G_7, LC_{50} values for insects exposed to Spinosad and methoxyfenozide were 2.75-fold and 1.25-fold greater than G_1 larvae, respectively. Oral treatment with methoxyfenozide also reduced the fecundity and fertility in the adults of G_7, confirming reproductive effects. In susceptibility tests of the five *S. exigua* populations collected from fields, LC_{50} values on third-instar ranged from 0.17 to 2.98, and 0.09 to 0.67 mg per kg diet for spinosad and methoxyfenozide, respectively.

Conclusions: We conclude that resistance management programs should be established, particularly in areas where *S. exigua* has developed resistance to Spinosad.

POSTER PRESENTATION

Goryphus or *Skeatia*?: Genus confirmation using molecular technique

Nur Azura Adam[1], Idris Abd. Ghani[3], Adura Mohd Adnan[2]

[1]Department of Plant Protection, Faculty of Agriculture, Universiti Putra Malaysia, 43400 UPM Serdang, Selangor, Malaysia, [2]School of Environmental and Natural Resource Sciences, Faculty of Science & Technology, Universiti Kebangsaan Malaysia, 43600 UKM Bangi, Selangor, Malaysia, [3]School of Bioscience & Biotechnology, Faculty of Science & Technology, Universiti Kebangsaan Malaysia, 43600 UKM Bangi, Selangor, Malaysia

Introduction: *Gorpyhus* and *Skeatia* are two ichneumonids (Hymenoptera) genera with a very high morphological resemblance. Previous authors separate this two genus only base on the length of the first tergite and the ratio of the postpetiole. Despite these two characters, other morphological characteristics are heterogenous. Therefore, application of molecular technique was conducted to confirm the identity of both genera.

Methods: Samples from both genera were extracted using phenol-chloroform method. The 18s rDNA gene were amplified and purified before sending for sequencing. Sequences obtained were edited and aligned in ClustalX program, Phylogenetic analyses of the sequences were conducted in PAUP program using Maximum Parsimony(MP) and Neighbour-Joining(NJ) methods.

Results: A 550 segment of the 18S gene was successfully sequenced from both genera. The phylogenetic trees constructed from both methods (MP and NJ) showed that *Goryphus* and *Skeatia* are in different clades. The genetic distance (Tamura-Nei Algorithm) between both species of *Skeatia* is very low (0.02), indicating that both species have a very close phylogenetic relationship. The average distance of *S. fuscinervis* and *S. versatilis* with the *Goryphus* species are 0.045 and 0.047 respectively. These values are higher comparing with the average genetic distance within the *Goryphus* species (0.039).

Conclusion: Results from molecular phylogenetic analyses confirmed that *Goryphus* and *Skeatia* are two completely different genera despite their very close morphological resemblance.

POSTER PRESENTATION

Identification and Investigation some of species of Trifinae of Noctuidae in Iran Forests and rangelands.

Nasser Farrar[1], Mahmood Yarmand[2], Helen Alipanah[3], Reza Golestaneh[1], Reza Zahiri[3]

[1]Agricultural & Natural Resources Research Center, Bushehr, Bushehr; [2]Forests & rangelands Research Institute, Tehran; [3]Plant Protection Research Institute, Tehran, Tehran, Islamic Republic of Iran

Introduction: Noctuidae is the largest family in the order, with more than 25000 species. The subfamilies fall broadly into tow groups; The Trifinae (including: Noctuinae, Heliothinae, Hadeninae, Cucullinae, Acronictinae and Amphipyrinae) and Quadrifinae. The design result of this project is identification and investigation fauna of forests and rangeland that were collected in national project. The taxonomic significance of male genitalia is constant. It is most important as a character with high weight.

Methods: The aedeagus or more precisely its tube usually provides good taxonomic character in moths because of sclerotization on the vesica (pars inflabilis) or structure of the outer wall. The structure of the tube is uniform. The abdomen was removed with a small dissecting needle and then cleared in KOH, and the genitalia and aedeagus were dissected out after clearing. They were washed in water with a little acetic acid added. Vesica was averted with small needle. After the study they were mounted with oil clave and xylem and canada balsam on microscope slide.

Results and Conclusions: According with international references the specimens were identified.

Subfamily: Heliothinae: *Heliothis peltigera* (Denis & Schiffermüller), *Heliothis viriplaca* (Hüfnagel, 1766), *Helioverpa armigera* (Hübner, 1808), *Periphanes delphinii* (Linnaeus, 1758). **Subfamily: Acronictinae**: *Acronicta aseris* (Linnaeus,1758), *Acronicta megacephala* (Denis & Schiffermüller). **Sub Family: Amphipyrinae;** *Trachea atriplicis* (Linnaeus, 1758), *Auchmis peterseni* (Chritoph, 1887), *Amphipyra pyramidea* (Linnaeus, 1758), *Amphipyra boursini* Hacker, 1998, *Phlogophora meticulosa* (Linnaeus, 1758), *Dicycla oo* (Linnaeus, 1758), *Spodoptera exigua* (Hübner, 1808). **Subfamily: Hadeninae:** *Mythimna l-album* (Linnaeus, 1767), *Mythimna vitellina* (Hübner,1808), *Acantholeucania loreyi* (Duponchel, 1827), *Polia nebulosa* (Hüfnagel), *Polia serratilinea* (Alpheraky, 1887), *Mamestra persicariae* (Linneus). **Subfamily: Cuculline:** *Cuculia argentina* (Fabricius, 1787), *Cuculia syetana iranica* (Brandt, 1941), *Lithophane furcifera* (Hüfnagel, 1767). **Subfamily: Noctuinae:** *Euxoa basigramma* (F. Wagner,1913), *Amathes triangulum diadochica* Hacker& Ebert, *Agrotis exclamatinis* (Linnaeus, 1758), *Xestia c-niarum (*Linnaeus, 1758*), Ochropleura plecta* (Linnaeus, 1761), (Hübner, 1808), *Euxoa temera* (Hübner, 1808), Hübner,1813*, Euxoa agricola* (Boisduval,1829), *Dichagyris forficula* (Eversmann, 1851).

POSTER PRESENTATION

Population dynamics and on-farm fruit fly integrated pest management in mango orchards in Senegal

Mbaye Ndiaye, Elhadji Omar Dieng, Gilles Delhove

[1]National Plant Protection Service, Dakar, Senegal, [2]PIP/COLEACP/EU, Brussells, Belgium

The trend of the population of fruit flies follows the dynamic of the rains. This tendency is more perceptible on Bactrocera invadens than on *Ceratitis cosyra*. From 350 individuals captured per trap, *B. invadens* seemed to disrupt the presence of C*. cosyra* and the other related Ceratitidae species. This behavior is probably due to an interspecific competition. Such behavior could be due by the fact that *C. cosyra* dominated the emergences from the incubated fruits of alternate host plants up to 87 % even though *B. invadens* was observed. The sex ratio was dominated by females especially at the end of the harvesting period of mangoes, corresponding to the end of the rainy season. Integrated pest management (IPM) package which including 1) male annihilation using wood blocks soaked in insecticide and lure (methyl eugenol and terpinyl acetate), 2) two (2) protein hydrolysate bait applications (Success Appat at 1 liter per ha) and 3) sanitation (mechanical weeding, destroying of the collected fallen fruits in using black plastic bags, digging holes and burning with a barrel transformed into incinerator), were used for the control of the fruit flies in mango orchards in the natural region of Niayes in Senegal. Results showed an inferred improvement in fruit fly (*B. invadens* and *C*. cosyra) infestations in the treated plot up to 83% compared to the untreated. When comparing lures, we found that methyl eugenol attracted significantly *B. invadens* than the home-made baits of grinded nutmeg and NET (beauty cream). Methyl eugenol's half life is also significantly longer (5 weeks) than the grinded nutmeg (less than 1 week) ($P = 0.0109$; $t = 9.4935$; $Df = 2$). There were no capture recorded in the NET based trap.

POSTER PRESENTATION

Long distance dispersal of the island sugarcane planthopper*:* is culture contributing?

Kylie Anderson[1], Mohamed Sallam[2], Bradley Congdon[1]

[1]James Cook University, Cairns, Queensland, Australia, [2]BSES Ltd, Gordonvale, Queensland, Australia

The island sugarcane planthopper, *Eumetopina flavipes*, is the only known vector for Ramu Stunt disease of sugarcane. Ramu Stunt disease appears confined to Papua New Guinea, but disease free populations of the vector are known to occur throughout the Torres Strait archipelago and on the northern tip of Cape York, Australia. The ability of *E. flavipes* to hitch-hike on sugarcane moved by people throughout the region is unknown, but is a process which may explain the initial and subsequent colonisations of the Torres Strait islands and mainland Australia.

We assessed the ability of mobile life stages of *E. flavipes* to survive over time on cut sugarcane stalks. Results indicated that whilst nymphs and adults leave the stalk at different rates over time, almost half of the initial population of nymphs and almost one third of the adults survived six days *in situ* on cut stalks. Therefore, *E. flavipes* is capable of surviving extended periods of time on deteriorating sugarcane. These results imply that human mediated movement may play an important role in the dispersal of *E. flavipes*.

POSTER PRESENTATION

Host location and behavioural response patterns of the parasitoid, *Tachinaephagus zealandicus (*Hymenotpera: Encyrtidae*)*, to host and host-habitat odours

Sasha Voss[1], Helen Spafford[2], Ian Dadour[1]

[1]Centre for Forensic Science, University of Western Australia, Perth, Western Australia, Australia, [2]School of Animal Biology, Perth, Western Australia, Australia

Introduction: To overcome the challenge of host location in patchy and complex environments, many parasitoids exploit host-habitat derived odour cues. This study investigated the role of odour cues used during host location by the generalist parasitoid, *Tachinaephagus zealandicus.*

Methods: A Y-tube olfactometer was used to test aspects of host searching behaviour of *T. zealandicus* females under different choice scenarios. A variety of odour cues were tested: host/liver complex, eaten liver, unwashed host larvae, washed host larvae and liver in six stages of decay. Results were compared to assess the suitability of residency time as opposed to 'first choice' as an indicator of parasitoid attraction to odour stimuli.

Results: *T. zealandicus* females demonstrated an innate response to, and preference for, odours arising from liver substrates following interaction with the host, dependant on the stage of meat decay. Females were not attracted to liver that had never been in contact with a host, regardless of the stage of decay. Analysis of residency time showed discernable differences in parasitoid movement and behaviour under different choice scenarios. The absence of any odour stimulus elicited limited movement about the olfactometer while females remain by an attractive odour source even when denied access to it. Both first choice and residency time were good indicators of parasitoid preference.

Conclusions: Our findings demonstrate that the tritrophic relationship commonly observed in plant-herbivore-parasitoid interactions can also evolve in the absence of selective pressure on the host-habitat.

POSTER PRESENTATION

Life table parameteres of *Hippodamia variegata* (Coleoptera: Coccinellidae) on *Aphis fabae* (Homoptera: Aphididae) under laboratory conditions

Reza Jafari

University Borojerd, Lorestan province- Borojerd, Islamic Republic of Iran

In this study life table parameters of *Hippodamia variegata* (Goeze) as an important predator of *Aphis fabae* Scopoli were studied under laboratory conditions. Ten pairs of male and female adults were released into a cage (6×11×23 cm) set on aphid separately. Experiments were carried out in a growth chamber at 25±1degrees C ,65±5 RH and 16:8(L:D) photoperiod. The most basic life table(survival subtable) parameters were age x,surviving from birth to exact ages x (lx),using these factors for calculation of life table parameters such as number of survival (lx), age specific mortality (qx), and life expectancy (ex), and the curves were prepared. The most basic life table (fecundity subtable) parameters such as number of female produced (mx), intrinsic rate of increase (rm), Net reproductive rate (Ro),mean generation time (T) and doubling time (DT) were calculated . The results of biological parameters studies revealed that proportion of a cohort surviving from birth to exact ages x(Lx) began at 31st day and fell to zero at the 70th day, also age specific mortality (qx) began at the 30th day and reached highest at 69 days. Also life expectancy (ex) was 51.02 at the initiation of development. Total fecundity was 910 eggs, sex ratio was .7, The number of females produced were more than males. Rm =.287, Ro=509, T=21.7 days and DT=2.4 were estimated.

POSTER PRESENTATION

Composition and food properties of red palm weevil *Rhynchophorus ferrugineus* (Curculionidae: Coleoptera)

Ahmed AlJabr

Plant Protection Department, Faculty of Agriculture and Food Sciences, King Faisal University., Hofuf, AlHassa, 31982, Saudi Arabia

Abstract: Red palm weevil *Rhynchophorus ferrugineus* female, male and last instar larva were analyzed for their Nutrient composition and amino acid composition. The data indicate that both sexes and larva are very rich in protein, fat and carbohydrates. Larva contains the highest contents of crud fat (41.8%), protein (25.91%) and ash (3.41%). Male adult contains the highest contents of carbohydrates (50.85%) and fiber (4.36%). Substantial amount of nitrogen, phosphor, potassium, iron, copper and zinc were found in all weevil stages. Traces of iron, copper and zinc were detected in all stages, while there was no detection of manganese in all stages. Larva contains the highest levels of macro and micro elements. It contains the highest contents of nitrogen (4.36%), phosphors (0.43%), potassium (0.85%), calcium (1.45%), sodium (0.22%) and zinc (130 ppm). Female has the highest contents of iron (170 ppm) , while both adult stages are high in copper levels (20 ppm). Hemolymph was rich of many amino acids, especially proline, aspartic and lysine. Adult female contains the highest levels of 15 of the 18 amino acids detected. It is contains the highest levels of aspartic acid (29.91), serinine (13.45), glutamic acid (25.52), praline (45.38), gliycine (11.91), alanine (16.77), valine (10.99), isoleucine (9.80), leucine (16.28), tyrosine (7.88), pheynylalanine (9.18), histidine (9.87), lysine (20.87), NH4 (68.99) and arginine (8.49). These food properties evoke a serious thinking of including such source of food in animal food if not human being.

POSTER PRESENTATION

The impact of *Beauveria bassiana*, *Trichogramma*, *Bt* sprays and Spinosad on the lepidopteran (C*rambidae*) cereal stalk borer - the European corn borer

Rostern N. Tembo[1], Daniel M. Pavuk[2]

Biological Sciences Department, Bowling Green State University, Bowling Green, Ohio 43402. USA.

Introduction: The research examined the effects of microbial control strategies on the European corn borer (ECB). The European corn borer is one of the most devastating pests of field corn in corn-growing regions of the United States.

Method: Our research had 7 Microbial treatments and each treatment had five replications making a total of 35 plots. The treatments included Spinosad, an insect growth regulator from bacteria, the entomopathogenic fungus *Beauveria bassiana*, *Trichogramma pretiosum*, foliar applied *Bt spray,* plus two combinations *Beauveria bassiana* and *Bt* spray, and Spinosad and *Trichogramma pretiosum*.

Results: The infections by the European corn borer larvae on stalks of corn were severe in all the control treatments. The Microbial treatments applied to the corn imposed various degrees of restraints on the European corn borer larvae. In all the parameters there was a significant difference between the control and other treatments with a P value of <0.001. Spinosad emerged as the most effective biological agent in the control of the European corn borer.

Conclusion: The results of the research done on the abundance and composition of the arthropods in the treatment plots showed that different treatments applied to various plots had no effect on the abundance and composition of the arthropods. The P values obtained by one way ANOVA were greater than 0.005.

This research is relevant in boosting alternative control strategies, underutilized control strategies for *Ostrinia nubilalis* and increasing farmers' adoption of integrated pest management practices especially in organic farming thereby reducing the use of conventional insecticides.

POSTER PRESENTATION

Biology of *Hippodamia variegata* (Coleoptera: Coccinellidae) on *Aphis fabae* under laboratory conditions

Reza Jafari, Karim Kamali, Mahmod Shojai

University, Lorestan, Islamic Republic of Iran

The *Hippodamia variegata* is one of the most important predators of *Aphis fabae* In this survey biological characteristic of *H. variegata* including duration of different life stages,feeding capacity, tolerance to starvation , cannibalism and life table parameters were studied under laboratory conditions Experiments were carried out in a growth chamber under 25±1degrees C ,65±5 Rh and 16:8(L:D) photoperiod. Under laboratory condition at 20±1,25±1 and 30±1 degrees C developmental period from egg to adult lasted 27.75±.38,21.35±.39 and 15.40±.33 days respectively.Both adult and 4th. Larvae feed on each stage of growth. Minimum and Maximum of Starvation were 8.1+0.84 and 2.3+0.11 in larvae and female adult respectively. The mean total fecundity was 910 eggs, the number of females produced were more than males. Mean preoviposition, oviposition and postoviposition periods were 6.20,52.8 and 7.4 days respectively. The number of eggs produced by each female was between 0 to 103 in a day, females produced (mx)=7.40±1.01

POSTER PRESENTATION

The faunistic survey of ladybirds (Coleoptera: Coccinellidae) in Lorestan province (Iran)

Reza Jafari

University, Lorestan, Islamic Republic of Iran

In this study species diversity of coccinellids was studied in Lorestan province during 2001-2005. Altogether 28 species from 14 genera, 7 tribes and 4 subfamilies were collected and identified. External characters plus characteristics of the male and female genitalia were used in order to diagnose species. Among coccinellid species collected: two species were new records for Iran. Many species were predacious, preying on various species of aphids, mites and coccids. The scientific names of the species according to their subfamilies and tribes are as follows.Species marked with asterisk (*) are considered as new records from Iran.Some species were also sent to Dr.Helmut Fursch in Germany for identification or confirmation.

1-*Coccinella septempunctata* Linnaeus
2-*Hippodamia variegata* (Goeze)
3-*Oenopia conglobata* (Linnaeus)
4-*Oenopia oncina* (Olivier)
5-*Adalia bipunctata* (Linnaeus)
6-*Adalia decimpunctata* (Linnaeus)
7-*Aphidecta obliterata* (Linnaeus)
8-*Propylaea quatuordecimpunctata* *
9-*Psyllobora vigintiduopunctata* (Linnaeus)
10-*Chilocorus bipustulatus* Linnaeus
11-*Exochomus melanocephalus* Zoubkoff
12-*Exochomus nigromaculatus* (Goeze)
13-*Exochomus quadripustulatus* Linnaeus
14-*Exochomus pubescens* Kuster
15-*Brumus gebleri* (Weise)
16-*Brumus undulatus* (Weise)
17-*Platynaspis luteorubra* (Goeze)
18-*Scymnus apetzi* Mulsant
19-*Scymnus pallipes* Mulsant
20-*Scymnus pallipediformis* Gunther
21-*Scymnys frontalis* Fabricius
22-*Scymnus apetzoides* Capra&Fursh
23-*Scymnus subvillosus* (Goeze)
24-*Scymnus syriacus* (Marseul)
25-*Scymnus mediterraneus* Khnzorian
26-*Scymnus araraticus* Khnzorian*
27-*Stethorus gilvifrons* Mulsant
28-*Pharoscymnus ovoides* Sicard

POSTER PRESENTATION

Concentration and loading of pesticide residues in Gorganrud and Qaresu rivers (Iran)

Mansoreh Shayeghi, Fatemeh Bagheri, Hassan Nasirian, Seyed Mohammad Abtahi

Department of Medical Entomology and Vector Control, School of Public Health and Institute of Public Health Research, Medical Sciences/University of Tehran, P. O. Box 6446-14155, Tehran, Islamic Republic of Iran

Introduction: Pesticide contamination of fresh water, which has emerged as an important environmental problem in the last few decades, is causing concern with respect to the long-term and low dose effects of pesticides on public health. The Qaresu and Gorganrud rivers (Golestan province) are typical rivers flowing through an agricultural area in northern of Iran, which is the natural inlet of Caspian Sea.

Methods: The concentrations and residues rates of two insecticides (azinphous-methyl and diazinon) which are most used for pest control of the agricultural fields and fruit gardens were estimated over a period of 1 year in the Qaresu and Gorganrud rivers by TLC scanner method and CATS-4 software. Water samples were collected from six localities through the rivers flowing in order to near the Caspian Sea.

Results: Azinphous-methyl and diazinon were found at the higher frequencies with maximum concentrations of 14.6, 22.4 and 14.9, 26.8 ppm in the influent of Qaresu and Gorganrud rivers, respectively. These peak concentrations were observed during the application period of pesticides for agricultural pest control by farmers in summer. The concentrations of the total amount of pesticide residues through the different localities of the rivers to the basin in downstream were estimated to be 2.67, 14.6, 0.2, 0 and 3.1, 22.4, 0.5, 0 ppm in Qaresu and 1.8, 14.9, 0.04, 0 and 3.7, 26.8, 0.6, 0 ppm in Gorganrud for azinphous-methyl and diazinon in spring, summer, autumn and winter, respectively.

Conclusions: Pesticides, which may be a potential hazard to humans and the environment, show an effect even in low concentrations. This study provides information on the concentrations of azinphous-methyl and diazinon in Qaresu and Gorganrud rivers in northern of Iran and offers background data on pesticide residues in river water.

POSTER PRESENTATION

Temporal synergism controls highly resistant poultry red mite

Georgina Bingham, Peter Bates, Graham Moores

[1]Rothamsted Research, Harpenden, Hertfordshire, United Kingdom, [2]Veterinary Laboratory Agency, New Haw Surrey, United Kingdom

The poultry red mite (*Dermanyssus gallinae*) is one the most important ectoparasites affecting broiler and egg layers in all types of production system across the UK and Europe. Management regimes continue to rely heavily on the use of chemical control, such as the synthetic pyrethroids. These pesticides have become increasingly less effective at controlling red mites in recent years due to the development of resistance; in some cases no available pesticides confer effective control.

Pesticide resistance is often due to the enhancement of metabolic enzyme systems within the pest, particularly non-specific esterases and microsomal oxidases. If synergists are allowed sufficient time to fully inhibit these enzymes (temporal synergism) then the sensitivity of insect pests to pesticides can be increased by several orders of magnitude.

In this laboratory study a 42-fold increase in the level of susceptibility to α-cypermethrin was found when a 12 hour pre-treatment of 100ppm PBO was applied to a standard laboratory susceptible strain of *D. gallinae* and a 750-fold enhancement was found with resistant field strains under the same treatment.

This demonstrates the exciting potential temporal synergism could have in the area of ectoparasite control.

POSTER PRESENTATION

Repellent bioassay of anti-mosquito mattresses, treated with HealthguardTM PLB Technology, under laboratory conditions, against two Venezuelan strains of *Aedes aegypti* Linnaeus 1762 on the dengue mosquito vector

Matias Reyes-Lugo, Ivan Salvi, Wilmer Gelves, Ana Avilan, Daniel Llavaneras, Carlos Sanchez

[1]*Medical Entomology Section, Tropical Medicine Instituto, Universidad Central de Venezuela, Caracas, Venezuela,* [2]*Confort de Venezuela C.A, Los Teques, Miranda, Venezuela*

Introduction: The repellent efficacy of the mattress anti-mosquitoes® Confort of Venezuela C.A tried with Healthguard™ PLB technology is evaluated against two Venezuelan strains of *Aedes aegypti* dengue mosquito vector, with different susceptibilities to insecticides.

Methods: 50 fasted females of the *Aedes aegypti* with 5 days of age as adults, were placed with a sample of the mattress anti-mosquitoes® of Confort de Venezuela C.A in two experimental glass cages 42 lt. In other cages or controls, the same number of mosquitoes and a sample of another mattress that were not treated. The number of *Ae. aegypti* females on, or biting the arm of a volunteer, counted during the first 30 seconds per minute during 10min. This was repeated in the morning and the afternoon. For each strain of mosquitos i.e. West Africa susceptible international reference, La Candelaria low susceptibility to organophosphate and El Mojan organophosphate and pyrethroid- resistant and susceptible to carbamic (Reyes-Lugo & Neus 1998), were carried out in two replicates, for a total 100 individuals per strain and moment of the day. ANOVA, F and Student Test (α=0.95) applied to frequency distribution of mosquitoes posed or biting evaluated the differences in the repellent from anti-mosquitoes® mattress between the strains.

Results: In order, the West Africa La Candelaria, El Mojan, repellents go from 61.8% to 91%. The temperature and relative humidity registered: 26.5ºC +/- 1.04 and 80.45% +/- 11.67, respectively.

Conclusion: The mattress anti-mosquitoes® with Healthguard™ PLB protects from the bites of the *Aedes aegypti* and possible dengue control transmission.

POSTER PRESENTATION

The association of *Triatoma maculata* Ericsson 1848, with the gecko *Thecadactylus rapicauda* Houttuyn, 1782 (Reptilia: Squamata: Saurian: Gekkonidae): A strategy for the colonization of dwellings for the vector of Chagas diseases in Venezuela?

Matias Reyes-Lugo, Ma. Isabel Reyes-Contreras, Ivan Salvi, Wilmer Gelves, Ana Avilan, Daniel Llavaneras, Alexis Rodriguez-Acosta, Luis Navarrete, Gerardo Cordero

[1]Medical Entomology Section, Tropical Medicine Instituto, Universidad Central de Venezuela, Caracas, Venezuela, [2]Biology School, Universidad Simón Bolívar, Caracas, Venezuela, [3]Immunochemestry Section, Tropical Medicine Institute, Universidad Central de Venezuela, Caracas, Venezuela, [4]Tropical of Zoology Institute, Universidad Central de Venezuela, Caracas, Venezuela

Introduction: In Venezuela, its frequent wild triatomines introducing in the dwelling, some are able to be domiciled. *Triatoma maculata* vector of *Trypanosomas cruzi*, was capture in dwelling, bitten inhabitants and associated with the gecko *Thecadactylus rapicauda.*

Methods: In a building of three floors, next to remnant Tropical Dry Forest, 10º12'23.39N and 66º51'13.26ºW, Miranda State, at 293m high, was carried out triatomines search: direct and manually (10 hours/9 people) and in difficult access places with electric vacuum cleaner (Genie® 1.5 HP). Gecko samples were also taken. For identification of insects and reptiles, used: stereoscopic microscope and keys. The temperature and relative humidity measured. With optic microscopy and culture blood-agar of the intestinal content and feces of *T. maculata* investigated presence of *T. cruzi*, and blood meal origin establish with test-Elisa and microscopically morphological comparison.

Results: The first two floors of the building were inhabited (2Ch and 3A)**.** The discovery of colony of *T. maculata* cohabiting with population of the gecko *T. rapicauda*, was carried out in the roof, in shed (wooden and metallic sheets with abundant rust, earth and trash-from of TDF). 1448 individuals of *T. maculata* collected: 1074H (74.2%), 18NI (1.2%), 40NII (2.8%), 60NIII (4.1%), 49NIV (3.4%), 145NV (10%), 62A (4.3%). The blood meal of *T. maculata* from gecko and human determined, *T. cruzi* was absent. In the place detects feces of *Didelphys marsupialis* (opossum). The temperature was of 29.65 ºC and HR 54.21%.

Conclusion: The association *T. maculata-T. rapicauda*, is effective strategy of colonization of dwellings located in the vicinity of the habitat where are present both species.

POSTER PRESENTATION

Effects of parasitism by the ectoparasitoid *Bracon hebetor* Say (Hymenoptera: Braconidae) on host hemolymph proteins of the Mediterranean flour moth *Ephestia kuehniella* Zeller (Lepidoptera: Pyralidae)

Hülya Altuntas, Yavuz Kilic

Anadolu University, Eskisehir, Turkey

Introduction: Parasitism of lepidopteran larvae by Braconid and Ichneumonid wasps has dramatic effects on host hemolymph proteins and at the aspects of the host insect's physiology. The effects of parasitism by gregarious, idiobiont and ectoparasitoid *B. hebetor* on host hemolymph plasma proteins of the Mediterranean flour moth *E. kuehniella* last instar larvae were investigated in the present study.

Methods: Host *E. kuehniella* were selected a newly-ecydsed last instar larvae and parasitized individually by exposure to a mated *B. hebetor* females. Hemolymph samples were obtained from parasitized larvae after 24 h. and 48 h. parasitizitation as well as unparasitized host larvae on the last instar. Protein concentration of all hemolymph samples were measured to the Bradford method. The protein profiles of plasma from parasitized and unparasitized *E. kuehniella* larvae were analyzed and compared on discontinuous denaturing sodium dodecyl sulfate-polyacrylamide gel (SDS-PAGE). The gel was scanned and analyzed densitometrically in a Gel-Pro Analyzer Version 4 programme.

Results: Total amount of plasma proteins in host hemolymph were reduced gradually on 24 and 48 hours after parasitation treatment. 55.3, 39.4, 37.2, 35.6, 33.9, 29.6, 24.6, 23.1, and 14.5 kDa proteins in total 25 protein bands, which were analyzed as densitometric, reduced over the 50%, on the other hand, four bands as 52.0, 44.6, 19.0 and 24.6 kDa protein bands pointed out related to the parasitism were increased.

Conclusions: Parasitism of *E. kuehniella* by *B. hebetor* was demonstrated to cause quantitative changes in the plasma proteins of host hemolymph.

POSTER PRESENTATION

Effects of some heavy metals on the larval growth rate of *Calliphora vicina* (Diptera)

Ferhat Altunsoy, Yavuz Kilic, Caner Aydinli

Anadolu University, Eskisehir, Turkey

Introduction: Entomotoxicology is relatively new branch of forensic entomology. The potential use of insects for detecting drugs and other toxins in decomposing tissues has widely demonstrated. In death investigations, Diptera and other arthropods can be reliable altemate specimens for toxicological analysis in the absence of tissues and fluids normally taken for such purposes. *C. vicina* is one of the species which is widely used in medico-criminal investigations.

Methods: Larval development of blowfly *C. vicina* in different concentrations (0,12; 0,25; 0,50; 1 and 2 µg/g) of some heavy metals (Cd, Pb, Hg, Fe, Cu) were analyzed in the present study. Fresh *C. vicina* eggs were placed on the toxin-bovine lung mixture and reared at constant 25 ^{0}C, 70% humidity. After every 3 hours maggots and pupal samples were taken from the diets. Maggot's lengths and dry weights were measured periodically. Data entry and analysis were performed by using S.A.S. (Statistical Analysis System).

Results: All concentrations of these toxins had negative effects on larval growth and estimation of PMI (Post Mortem Interval). Growth rates of experiments and controls are significantly different. 0,50; 1 and 2 µg/g cadmium contamination had lethal effect on larvae, but other toxins had not lethal effect. 1 and 2 µg/g lead, mercury, ferric and copper contamination delayed the larval development one-three days.

Conclusions: Heavy metal pollutions in different tissues had negatively effects on the growth of insects. In this case, estimation of PMI in legal investigation is relatively difficult. In this study, effect of five toxins on maggots growth rate were declared.

POSTER PRESENTATION

Effects of some abiotic factors on the population dynamics of Tabanidae (Diptera) species in Eskişehir in Turkey

Ferhat Altunsoy, Yavuz Kilic

Anadolu University, Eskisehir, Turkey

Introduction: Tabanidae consists of about 4300 species of medium to very large biting flies; indeed, it contains some of the largest blood-sucking insects. The sheer size of tabanids and the pain their bite can cause mean they are not easily ignored. Large accumulations of flies do occur in some areas, and with their painful bite tabanids can be pests of both livestock and humans. Livestock worry can reach a level at which economic losses occur. Females of most Tabanidae species attack mammals and human. Like other blood-sucking flies, Tabanids have a negative economic effect on milk production where they commonly live. Moreover, Tabanids are known worldwide as important mechanical vectors to cause of diseases in some wild and domestic animals.

Methods: Population dynamics of the horse flies were monitored for 3 years. Fluctuations in the population were related to abiotic factors, such as maximum and minimum temperatures, rainfall, pressure and relative humidity, using Kendall's correlation coefficient test.

Results: Correlation coefficient data shown that the maximum and minimum temperatures had a significant immediate negative effect on the population ($P = 0,023$ and $P = 0,047$, respectively). Pressure and rainfall had no significant immediate or delayed effects on the population of horseflies ($P = 0,003$ and $P = 0,0025$), but relative humidity had significant immediate and delayed effect ($P = 0,035$).

Conclusions: It will be helpful for humans to know the ecology, seasonal and daily activity and chances in population density of these vector insects. In this study we discuss the yearly chances in population density of Tabanidae species.

POSTER PRESENTATION

Microorganisms isolated and identified from digestive systems of Tabanidae (Insecta: Diptera) species

Yavuz Kilic, Zerrin Tetik

Anadolu University, Eskisehir, Turkey

Introduction: The females of Tabanidae species feed on homoitherm animals and even humans by sucking their blood. For this reason they are the vectors of many diseases such as viruses, bacteria, protozoa and helminthes. In the present study 36 bacteria species were isolated from the digestive systems of 10 Tabanidae species that sucked blood from their hosts around Eskişehir province (Turkey).

Methods: Hemolysis, catalase, oxidase, indole, methyl red, Voges-proskauers, citrat, TSI, movement, DNaz, VITEK (Biomerieux),; (Microbiology reference Manual (Rev 08/2003), BIOLOG (Microstation; Microlog System Release 4.2) systems and antibiotic resistance tests were applied for the identification of bacteria.

Results: *Aeromanas caviae, A. hydrophila, A. Veronii biovar sobria, Achromobacter xylosoxidans, Alliococcus otitis, Bacillus alvei, B. mycoides, B. Pumilis, B. Subtilis, Brevundimonas vesicularis, Burkholderia mallei, Cedecea davisae, Chrysobacterium indolegenes, Enterobacter aerogenes, E. amnigenus biogrup 2, E. asburiae, E. clocea, Enterococus faecalis, E. gallinarum, Klebsiella oxytoca, Micrococcus lylae, Pseudomanas aeroginosa, P. alcaligenes, P. stutzeri, Raoultella terrigena, Serratia maecescens, S.plymuthica, Staphylococus cohnii, S. epidermidis, S. equorum, S. hominis, S. hominis ss novobiosepticus, S. pasteuri, S. saprophyticus, Sphingomonas paucimobilis Stenotrophomonas maltophila* species were identified from the investigated materials.

Conclusions: All these bacterial species have been isolated at first time from the digestive systems of horseflies. Isolation of many bacterial species from the limited number of Tabanidae species, once more indicated the importance of their properties to serve as vectors. These identified bacterial species always have potential risks on human and animal health.

POSTER PRESENTATION

Overview of personal protection measures used by the Australian Defence Force

Stephen Frances

Australian Army Malaria Institute, Enoggera, Qld, Australia

The personal protection measures used against vectors of disease by Australian Defence Force (ADF) personnel is described. Although a repellent formulation containing 35% deet in a gel is recommended, some soldiers use commercially purchased repellents, and studies comparing the protection provided by commercial repellents will be reported. The use of permethrin treated uniforms, bednets and tentage by ADF personnel will be discussed.

POSTER PRESENTATION

A synopsis of *Bracon* Fabricius species of Turkey with a description of a new species (Hymenoptera; Braconidae, Braconinae)

Ahmet Beyarslan, Ozlem Cetin Erdogan, Mitat Aydogdu

Trakya University Faculty of Arts and Science Department of Biology, Edirne, Turkey

Our studies on *Bracon* Fabricius fauna of Turkey started in 1979 and 107 species have been determined so far belonging to the subgenera *Habrobracon* Ashmead*, Asiabracon* Tobias*, Rostrobracon* Tobias *Bracon* Fahringer*, Cyanopterobracon* Tobias, *Glabrobracon* Fahringer and *Lucobracon* Fahringer. 13 new *Bracon* species were published from Turkey. With this present study *Bracon (Lucobracon) achterbergi* Beyarslan sp. nov. is described and its diagnostic characters are illustrated. The distribution of *Bracon* species are discussed according to the Euxin, Subeuxin, Mediterranean, Kseroeuxin, Iran Steppe, Anatolia Steppe, Central Anatolia Steppe and Mesopotamian Steppe phyto-geographical provinces of Turkey.

POSTER PRESENTATION

Calcium regulated fusion of yolk granules is important for yolk degradation during early embryogenesis of insects

Isabela Ramos, Kildare Miranda, Wanderley de Souza, Ana Paula Cabral de Araujo Lima, Ednildo de Alcantara Machado

Laboratório de Entomologia Médica do IBCCF da UFRJ, Rio de Janeiro, Rio de Janeiro,, Brazil

In insects the embryo development occurs totally dissociated from maternal organism. Reserve (yolk) proteins are mainly stored into organelles called yolk granules (YG), that will be degraded by activation of acidic hydrolases also stored within YGs. The hydrolases activation is mediated by proton pumps (Proton pyrophosphatases and Proton ATPases). Several works describe the presence of different YG population with different macromolecule contents. Thus, fusion of YGs could represent an interesting model of macromolecule transfer between different compartments during embryogenesis. We described the YG fusion mechanisms during early embryogenesis of two insects *Periplaneta americana* and *Rhodnius prolixus*. We showed that eggs with 0 and 3 days (in *R. prolixus*) and 0 and 5 days (in *P. americana*) contained a differential size pattern of YGs contain a greater amount of large YG (LYG) at day 3 and day 5, respectively,. Day 3/5 eggs also contain the highest [Ca^{2+}] found during early embryogenesis of these insects. *In vitro* YGs treatment with the [Ca^{2+}] found on day 3/5 eggs resulted in LYG appearance, as observed *in vivo*. We confirmed that calcium dependent LYG formation by observations of fluorescent membrane dye transfer from previously labeled small YGs (SYG) to larger ones. In addition, we showed that YGs incubation in the presence of calcium promotes the vitellins degradation *in vitro*, evidencing that YGs fusion events take part on yolk mobilization machinery. We showed that the membrane fusion of YG regulated by calcium is probably important for yolk degradation during embryogenesis of these insects.

POSTER PRESENTATION

Use of GIS to characterize areas of non-target feeding by biological control agents of invasive weeds: A case study in Tennessee, USA

Greg Wiggins, Jerome Grant, Paris Lambdin

University of Tennessee, Knoxville, Tennessee, United States

Introduction: The efficacy of two weevils (*Rhinocyllus conicus* and *Trichosirocalus horridus*) introduced in the U.S. against the Eurasian musk thistle (*Carduus nutans*) is countered by their impact on a few native *Cirsium* thistles. Non-target feeding of these weevils may impact plant reproduction and plant populations. Because the biologies of these weevils are closely linked with musk thistle, the distribution of musk thistle populations may influence non-target activity. The use of geographic information systems (GIS) could be useful in analyzing the spatial relationships among musk thistle, weevils and native thistles by characterizing suitable habitats for each thistle species over a large spatial scale.

Methods: In Spring 2004, a four-year study was initiated to identify potential areas of non-target feeding using spatial analysis. The study area (ca. 4,800 km^2) consisted of four counties in eastern Tennessee. Four thistles (native: *C. carolinianum* and *C. discolor*; introduced: *C. nutans* and *C. vulgare*) were selected as model species. Mahalanobis distance (D^2) was used to identify suitable habitats for each thistle species.

Results and Discussion: Cumulative frequency analysis indicated that threshold D^2 values of as low as 6.58 correctly classified over 65% of suitable habitats for all thistles observed in this study. Comparatively, random locations would require many more localities and greater D^2 values to correctly classify similar percentages of suitable habitats. The area of overlap of all species occupied ca. 4% of the total study area. These areas should be the focus of future model-testing efforts and non-target studies.

POSTER PRESENTATION

Arthropod abundance and diversity in commercial Bt corn farms and adjacent riparian areas in the Philippines

Edwin Alcantara[1], Maria Dulce Mostoles[2], Barbara Caoili[3], Pio Javier[3]

[1]National Institute of Molecular Biology and Biotechnology, University of the Philippines (Los Baños), College, Laguna, Philippines, [2]Camarines Sur State Colleges, Pili, Camarines Sur, Philippines, [3]Crop Protection Cluster, University of the Philippines (Los Baños), College, Laguna, Philippines

Introduction: Non-target arthropods are important trophic components of the ecosystem because they also affect the sustainability of transgenic crops. The present study would like to test the hypothesis that Bt corn does not adversely affect non-target arthropod abundance and diversity in corn and riparian ecosystems.

Methods: Arthropod abundance data were obtained by sampling plots selected within commercial farmers' fields and adjacent riparian areas. Significant effect of Bt corn MON 818 YieldGard™ on both the non-target predatory insect *Micraspis discolor* abundance and overall arthropod diversity was determined by repeated measures ANOVA. Principal response curve (PRC) analysis was used to determine significant differences in species composition at every sampling date in Bt- and non-Bt corn arthropod communities. Similar studies were conducted in adjacent riparian areas.

Results: There was no significant difference between Bt and non-Bt corn in the abundance of the predatory insect *M. discolor* within the 2006 (P= 0.436) and 2007 (P= 0.254) cropping seasons. Statistical analysis of the calculated Simpson and Shannon indices revealed no significant difference in arthropod diversity within all experimental sites in both the same period. Similarly, PRC analyses indicated no significant difference in species composition in all the arthropod communities.

Conclusion: Bt corn MON 818 YieldGard™ sustains arthropod abundance and diversity in corn and riparian ecosystems.

POSTER PRESENTATION

Effect of behavior on PVY transmission efficiency of *Rhopalosiphum padi*

Yvan Pelletier, Xianzhou Nie

Potato Research Centre, Fredericton, NB, Canada

Potato virus Y is transmitted to potato in a non-persistent manner by many aphid species, some of which do not colonize this crop. The behavior of *Rhopalosiphum padi* (L.) on potato, a plant species that is not colonized by this aphid, was described and compared with that of the potato colonizing aphid, *Myzus persicae* (Sulzer). A higher proportion of winged morph of *R. padi* than *M. persicae* left the plant, but aphids that stayed in contact with the plant took the same mean time to initiate the first probe and it lasted the same mean time compared to *M. persicae*. Electronic Penetration Graph technique was used to study the probing behavior of the aphids during PVY transmission tests. Transmission rate decreased from 29% to 8% when the acquisition time decreased from 5 minutes of continuous probing to one hour with *M. persicae*, but remained low (2% and 1%) with *R. padi*. Most of the difference in transmission rate between acquisition time with *M. persicae* and between aphid species was related to the change in the time and behavior taking place between the last cell puncture of the acquisition phase to the first cell puncture of the inoculation phase. Results presented here clearly demonstrated the importance of host-plant selection and probing behavior in the transmission of non-persistent plant viruses. They also stress the need to consider the behavior of the aphid in the design of laboratory tests of virus vector efficacy.

POSTER PRESENTATION

Environmental stresses induce expression of cuticular protein genes in the Colorado potato beetle

Jianhua Zhang, Claudia Goyer, Yvan Pelletier

Potato Research Centre, Fredericton, NB, Canada

The deposition of cuticular proteins usually occurs during molting process. Three putative glycine-rich proteins, Ld-GRP1 to 3, were identified and characterized from the Colorado potato beetle. The Ld-GRPs contained conserved GXGX and/or GGXG sequence repeats. Ld-GRP1 also contained a conserved AAPA/V motif commonly found in cuticular proteins. The transcripts of Ld-GRP1 and Ld-GRP2 were detected in epidermal cell layer by *in situ* hybridization making them putative cuticular proteins. The Ld-GRPs were highly induced by the insecticide azinphosmethyl (organophosphorous) 2-3 weeks after adult molting. Gene expression level was higher in azinphosmethyl-resistant beetles than in susceptible beetles. Furthermore, Ld-GRP1 and Ld-GRP2 were highly induced by dry environmental conditions. These results suggested that the insect might increase cuticular component deposition in adult stage in response to the environmental stresses. This ability may allow the insect to adapt to new or changing environments.

POSTER PRESENTATION

Notes on mosquito larvae predators in the Riyadh Region, Saudi Arabia

Azzam Alahmed, Suliman Alamr

King Saud University, Riyadh, Saudi Arabia

A survey for mosquito larvae predators in Riyadh Region, Saudi Arabia, was conducted during the period June 2003 -July 2004, in which 9 different mosquito larvae predators were collected from 46 sites. The collected larvae predators consisted of the mosquito-fish *Gambusia affinis*, (Cyprinodontiformes: Poeciliidae) (4.1%), the Odonata nymphs of the families Coenagrionidae (6.6%) and Libellulidae (7.4%), the water bug *Sigara* sp. (Hemiptera: Corixidae) (31.1%), the water beetle *Agabus* sp. (Coleoptera: Dytiscidae) (22.1%), *Triops* sp (Notostraca: Triopsidae) (13.9%), the adult water beetles *Eretes stictus* (Coleoptera: Dytiscidae) (7.4%), the larvae of the beetle *Cybister tripunctatus* (Coleoptera: Dytiscidae) (3.3%) and adult water beetles *Dineutes aereus* (Coleoptera: Gyrinidae) (4.1%). The predatory efficiency of these predators was assessed in the laboratory using fourth larval instars of *Culex quinquefasciatus* (Diptera: Culicidae) as prey. The highest predatory efficiency was shown by *G. affinis*, followed by *Triops* sp., *E. stictus* and Odonata nymphs of the family Libelulidae respectively.

POSTER PRESENTATION

Knockdown resistance (*kdr*) in the malaria vector *Anopheles arabiensis* from Eastern Sudan

Yousif Himeidan[1], Hong Chen[2], Fabrice Chandre[3], Martin Donnelly[4], Guiyun Yan[2]

[1]Faculty of Agriculture and Natural Resources, University of Kassala, Kassala, Sudan, [2]College of Health Sciences, University of California-Irvine, California, Irvine, United States, [3]Institut de Recherche pour le Développement, Cotonou, Benin, [4]Liverpool School of Tropical Medicine, Liverpoool, United Kingdom

Introduction: In Africa, knockdown resistance in malaria vector mosquitoes may become a major problem for malaria interventions because pyrethroids are the mainstay of vector control strategies. Regular surveillance of the susceptibility of vector populations is imperative for implementing effective insecticide resistance management strategies. This study was aim to assess knockdown resistance (*kdr*) in three populations of *Anopheles arabiensis* from eastern Sudan.

Methods: Based on field-collected anopheline larvae, insecticide bioassays for 4% DDT and 1% permethrin were performed on non-blood fed, female 1–3-day old adults using WHO protocols. DNA was extracted individually from the bioassay-tested mosquitoes, which were identified by the rDNA-PCR method. The L1014F and L1014S *kdr* alleles were screened on a Li-Cor 4300 DNA Analyzer. The results were confirmed by DNA sequencing of ~300-baspair fragments amplified by the primers AgD1 and AgD2.

Results: Bioassay mortalities ranged from 96.9-99.6% against 4% DDT and from 98.4-100% against 1% permethrin, respectively. *An. arabiensis* was the only member of *An. gambiae* complex identified in the area. The L1014F and L1014S alleles were detected in 25 out of 498 mosquitoes. L1014F allele was associated with insecticide resistance, while L1014S allele was observed only in four susceptible individuals. The overall *kdr* frequencies ranged from 7.0% in the area where insecticide-treated nets were used to 3.0% in the area with agricultural insecticide use.

Conclusion: The presence of the *kdr* alleles in *An. arabiensis* in Sudan emphasizes the need to develop appropriate resistance monitoring and management strategies for malaria vectors.

POSTER PRESENTATION

Could mosquitoes become resistant to repellents?

Nina M Stanczyk[1], Lin Field[1], James G Logan[1], John F.Y. Brookfield[2]

[1]Centre for Sustainable Pest and Disease Management, Biological Chemistry Department, Rothamsted Research, Hertfordshire, United Kingdom, [2]Institute of Genetics, The University of Nottingham, Queen's Medical Centre, Nottingham, United Kingdom

Introduction: Repellents are utilised worldwide as personal protection against many biting insects including mosquitoes. DEET is one of the most effective and commonly used repellents, however, new research has demonstrated that natural human-derived repellents could also be used to repel mosquitoes. During laboratory repellency trials a small proportion of mosquitoes still respond to human odours despite the presence of DEET or other repellent compounds.

Methods: Preliminary behavioural assays identified *Aedes aegypti* females that were insensitive to a natural human-derived repellent or DEET. The offspring of these repellent-insensitive females were then tested over three generations to determine if there was a genetic component to the trait. A further series of selection experiments using both types of repellent is being performed to obtain pure-breeding insensitive lines.

Results: In the preliminary selection experiments there was an increase in the proportion of mosquitoes that were insensitive to the repellent throughout successive generations, which shows that there is a heritable component to the trait. In future work this will allow genetic crosses to be carried out to determine the mode of inheritance, and electrophysiology and molecular techniques will be used to determine the mechanisms and gene(s) involved.

Conclusion: This research provides an insight into how insensitivity to repellents can arise and spread throughout a population when the trait is selected for, as might naturally occur in the wild. This information will aid control programmes that seek to use repellents. A more detailed understanding of the gene(s) responsible for insensitivity may lead to novel control methods.

POSTER PRESENTATION

Effects of different control programs on the populations of the lettuce aphid *Nasonovia ribisnigri* (Hemiptera: Aphididae) and its natural enemies

Patricia Larraín, Claudio Salas, Carlos Quiroz

[1]Sociedad chilena de Entomología, Santiago, Chile, [2]ESA, Maryland, United States

A study was conducted in 2007 to determine the effect of different control programs of *Nasonovia ribisnigri* on winter head lettuce, var. Cool Green. The statistical design was random bloks, with 6 treatments and four replicates, conducted in field conditions at Pan de Azúcar (30°04' South lat.; 71°55' West long.), Coquimbo Region, Chile. Treatments were: T1, Pirimicarb (pirimor 250g/ha) foliar application; T2, Chemigation withThiametoxam (actara 25 WG, 200g/ha) in seedlings; T3, Thiametoxam (actara 25 WG, 200g/ha) foliar application immediately after plantation; T4, T2 plus Pirimicarb (pirimor 250g/ha) foliar application; T5, T2 plus Thiametoxam (actara WG)foliar application ; and T6 untreated check. With exception of treatment three (T3), all foliar applications were done once *N. ribisnigri* reach an economic injury level of 1 aphid per plant per week.

The number of alive aphids (alate and apterous) and natural enemies was counted weekly in each plot until harvest.

Although at harvest head infestation levels were significant lower in plots treated with chemigation of thiametoxam in seedlings and pirimicarb foliar application, head contamination was more than likely, not commercially acceptable in any of the treatments. *Platycheirus sp.* syrphid larvae appeared as the main natural enemies responsible for aphid suppression. Its numbers were significant higher in the untreated check than in the insecticides treated plots.

POSTER PRESENTATION

Population fluctuation of Diptera Muscidae and Faniidae associated with pork production in central Chile

Claudio Salas, Patricia Larraín, Carlos Quiroz

[1]Sociedad Chilena de Entomología, Santiago, Chile, [2]ESA, Maryland, United States

From November 2006 to October 2007, a study was carried out at Longovilo (33º55' lat. Sur, 71º23' lon. Oeste), Central Chile with the aim to assess the population fluctuation of fly species belonging to the family Muscidae and Fanniidae, in farms that have approximate stock of 660.000 hogs.

Forty four Stickem traps (model BTSTICK flies I-40; BTS Intrade Laboratories) were distributed in different staffs from wean to sale, zones of irrigations with slurry, slurry stabilization lagoons, dead animal transfer units, plants of water processing, zones of composting, and restaurant located in the neighborhood of the zone of production.

After 1 years of studies, the presence of *Musca domestica, Ophyra aenescens, Psilochaeta chalybea and Stomoxys calcitrans* (Diptera: Muscidae) and *Fannia canicularis* and *Fannia femoralis* (Fanniidae) were established.

More than 67.000 specimens were collected in the course of the investigation. *M. domestica* represented 29% of the total capture, while *O. aensecens* was the 61,4%, *P. chalybea* was the 0,018%, *S. calcitrans* was the 8,6%, *F. canicularis* was the 0,02% and *F. femoralis* was the 0,88%.

Regarding captures according to zones, 82% was obtained from pork staff, 2% from zones of irrigation with slurry, 9% from slurry stabilizations lagoons, 0,97% from dead animal transfer units, 2% from plants of water processing, 3,4% from zones of composting, at the restaurant located nearby only 0,1% of the total fly population was captured.

POSTER PRESENTATION

Which island parasitoid faunas are evenly sampled? A case study using the Taxapad database on Ichneumonoidea (Hymenoptera)

Ana M. C. Santos[1], Joaquín Hortal[2], Kostas A. Triantis[3], Owen R. Jones[1], Paulo A. V. Borges[4], Donald L. J. Quicke[1]

[1]Imperial College London, Ascot, United Kingdom, [2]NERC Centre for Population Biology, Imperial College London, Ascot, United Kingdom, [3]Biodiversity Research Group, Oxford University, Oxford, United Kingdom, [4]CITA-A, Universidade dos Açores, Azores, Portugal

Introduction: Available databases of species diversity are generally biased taxonomically, geographically, or both. Several variables have been identified as effective descriptors of the processes of establishing species richness, such as body size, species abundance, geographical range size, taxonomist home range and non-random availability of expertise. Our knowledge of parasitoid species diversity is no exception, despite their importance as key components of nearly all terrestrial ecosystems. We investigated the reliability of a published database on the world ichneumonid wasps (Hymenoptera, "Parasitica") and determined which island parasitoid faunas are evenly sampled, and thus are appropriate to be used in future analysis trying to identify the underlying patterns of parasitoids on islands.

Methods: First, we used the dispersion observed on each island from the richness predicted by the species-area relationship (SAR) to determine if the archipelago falls into the same SAR as islands. After this, we applied two criteria to determine which islands are evenly sampled: a) SAR curves, and b) taxonomic information from each geographical region.

Results: Almost all the archipelagos analysed fell inside the SAR dispersion interval, demonstrating that archipelagos can be analysed as single islands when applying SARs. More islands were excluded with the taxonomic information criterion than with the SAR curves criterion. However, only the last criterion allowed us to exclude oversampled islands.

Conclusions: The method developed here can be useful in biodiversity research since it identifies some types of bias and produces comparable databases.

POSTER PRESENTATION

Effect of acetylsalicylic acid and oxalic acid on *Myzus persicae* and *Aphidius colemani*

Nikolaos Karatolos, Paul Hatcher

University of Reading, Reading, Berkshire, United Kingdom

Introduction: Plants can respond to damage by pests with both induced direct and indirect defences by the attraction of their natural enemies. Foliar application of several plant-derived chemicals, such as salicylic acid and oxalic acid can induce these defence mechanisms.

Methods: The effect of acetylsalicylic acid and oxalic acid on the aphid *Myzus persicae* Sulzer (Homoptera: Aphididae) and its parasitoid *Aphidius colemani* Viereck (Hymenoptera: Aphidiidae) was investigated. Direct application of acetylsalicylic and oxalic acids on those insects, as well as choice and no choice tests with foliar application of both chemicals on Brussels sprouts plants, *Brassica oleracea* var. *gemmifera* L., were carried out.

Results: Both chemicals have a direct effect on aphid development by increasing their mortality. Foliar application of both chemicals does not seem to induce resistance against aphids. Furthermore, foliar application of such compounds has the potential to induce indirect plant defences against aphids, by attracting parasitoids and encouraging the aphid parasitisation. Although the direct application of both chemicals on parasitoids affects negatively their development by reducing their emergence ability, foliar application does not have any negative effect. However, oxalic acid is found to reduce the number of emerged parasitoids in no-choice experiments.

Conclusion: Foliar application of acetylsalicylic and oxalic acids can be used in order to encourage aphid parasitisation, but care is needed as these chemicals can have negative effects on beneficial organisms.

POSTER PRESENTATION

Influence of the formulation matrix on repellency of IR3535® and KBR 3023 against different medically important mosquito species

Rainer Kroepke[1], Gerhard Benner[1], Jens Schulz[1], Klaus-Peter Wittern[1], Nigel Hill[2], Nicole Beyer[3], Ruediger Graf[3]

[1]Beiersdorf AG, Hamburg, Germany, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Merck KGaA, Darmstadt, Germany

The insect repellents, IR3535® (Ethyl Butylacetylaminopropionate, EBAAP) and KBR 3023 (Hydroxyethyl Isobutyl Piperidine Carboxylate, Picaridin, Bayrepel®) were evaluated in a field study at a panel of volunteers (10 male, 1 female). The testings were conducted in the Vaca Diez region, Bolivia, on field populations of medically important mosquitoes. *Anopheles darlingi, An. albitarsus, Aedes aegypti* and *Culex pedroi* were identified as the main species of the population.

Mimicking the realistic application by the consumer five proprietary repellent formulations fully marketable in composition and appearance were tested regarding their efficiency for preventing bites. The substances were applied as hydro-alcoholic spray solution or skin lotion in concentrations of 15 and 20%.

All tested samples provided lasting protection (time to first bite) over several hours with a mean of approximately 6 h. There was no significant difference in protection times between the two active substances.

Remarkably, the efficiency was more affected by the application form than by the concentration of the insect repellent itself. The applied lotion with 15% repellent led to longer protection times compared with the hydro-alcoholic spray formulation with 20%.

POSTER PRESENTATION

Effects of scabies mites on skin endothelial cells

Larry G. Arlian, B. Laurel Elder, Marjorie S. Morgan

Wright State University, Dayton, Ohio, United States

Introduction: The scabies mite, *S. scabiei*, infects millions of people worldwide and induces inflammatory and immune responses in the skin that are delayed the first time a person is infested. Venule endothelial cells of the skin microvasculature play a key role in regulating migration of inflammatory and immune cells into the site of mite infestation. The purpose of this study was to determine if the expression of cell adhesion molecules (CAMs) on endothelial cells induced by scabies mites is altered in the presence of histamine, lipid-mediators and cytokines that likely occur in scabietic lesions.

Methods: Cultured human microvascular endothelial cells were incubated with selected stimulants in the presence or absence of *S. scabiei* extracts for 6 hrs. The expression of adhesion molecules on the cells and secretion of cytokines into the medium were measured by ELISA.

Results: Scabies mite extract induced endothelial cells to express ICAM-1, VCAM-l, and E-selectin above constitutive levels. Co-stimulation with *S. scabiei* extract and histamine, prostaglandin D2, prostaglandin E2, leukotriene B4, and IL-6 did not change the level of secretion of ICAM-1, VCAM-l, and E-selectin that was induced by scabies alone. Scabies extract down regulated the TNFα induced expression of VCAM-1 but not the IL-1α, or IL-1β induced expression.

Conclusion: The expression of CAMs by human endothelial cells of the skin microvasculature in response to bioreactive substances from *S. scabiei* was not co-influenced by histamine, prostaglandins, leukotrienes, and IL-6 that likely are secreted by surrounding cells in response to scabies mites.

POSTER PRESENTATION

Comparison of natural and artificial bloodfeeding in *Anopheles stephensi*

Hassan Nasirian, Hossein Ladonni, Fatemeh Rafii

Department of Medical Entomology and Vector Control, School of Public Health and Institute of Public Health Researches, Medical Sciences/University of Tehran, Tehran, Islamic Republic of Iran

Introduction: The increasing demand for laboratory-reared haematophagous for research and control purposes makes it necessary to develop effective and standardized mosquitoes feeding methods without using live animals as hosts. Live animals have been used successfully to maintain and colonization of haematophagous insects. However, the use of animal for this purpose is expensive, inconvenient, and increasingly unacceptable in terms of animal welfare. The purpose of this study was to comparison of natural and artificial bloodfeeding in *Anopheles stephensi* (Lis.) by Guinea pig and human whole blood in insectary.

Methods: An artificial membrane and natural, bloodfeeding technique was evaluated for *An. Stephensi* using insectarium's strain in Iran. Parafilm "M" and human whole blood were satisfactory as feeding membrane and nourishing source in artificial bloodfeeding and Guinea pig as a natural bloodfeeding, respectively.

Results: Comparison of feeding rates and different ages were fluctuated in *An. stephensi* with human whole blood via membrane Parafilm "M". *An. stephensi*, a mosquito that normally requires a vertebrate blood meal to produce eggs, has been reared successfully for three generations on this substitute blood meal. Comparison between natural and artificial bloodfeeding were not observed significant differences.

Conclusions: Data showed that artificial feeding with this method, especially in the investigating projects were completely efficient and suitable, in numerous rearing and increasing populations of mosquitoes for specified time without any disadvantages include accidental disease transmission and hypersensitivity to mosquito bites that natural bloodfeeding was to have.

POSTER PRESENTATION

Monitoring of German cockroach insecticide resistance in Iran

Hassan Nasirian, Hossein Ladonni, Mansoreh Shayeghi

Department of Medical Entomology and Vector Control, School of Public Health and Institute of Public Health Researches, Medical Sciences/University of Tehran, Tehran, Iran, P.O. Box 6446-14155, Tehran, Islamic Republic of Iran

Introduction: The German cockroach, *Blattella germanica* (L.), is an important household insect pest worldwide. In addition to its economic importance, the German cockroach is a significant health hazard and acts as a mechanical vector and reservoir for pathogenic agents. Increased incidents of asthma caused by German cockroach allergens are associated with relatively high cockroach infestations and have added emphasis to the need for the control of this insect pest. Extensive use of insecticides has led to the development of resistance in German cockroach to a wide range of insecticides including organochlorines, organophosphates, carbamates and pyrethroids.

Methods: The current study was designed to monitoring of German cockroach insecticide resistance in Iran. The susceptibility level and insecticide resistance mechanisms of German cockroach to organochlorated, organophosphate, carbamate and pyrethroid insecticide groups have been studied and resistant to these insecticides.

Results and Conclusions: Since fipronil has not been used previously in Iran, German cockroach ranged from 1.5- to 2.6-fold resistant to fipronil, so this relatively low resistance could be due to cross-resistance to dieldrin. Therefore, based on the data, fipronil could not be recommended a valuable tool in resistance management of German cockroach in Iran. Management of cockroach populations in urban environments has recently shifted from the predominant use of insecticide sprays to the inclusion of baits in management programs. Studies showed that baits especially fipronil and imidacloprid baits appear to have considerable potential as a bait insecticide for insecticide resistant German cockroach infestation in Iran. I propose further studies on toxicity of novel insecticides such as avermectins acting at GABA, gama-aminobutyric acid, and glutamate receptors in proximity to chloride channels, diacylhydrazines mimicking the action of ecdysone, indoxacarb acting at a novel site in sodium channels, and imidacloprid, thiamethoxam, and spinosad acting at novel sites on the nicotinic acetylcholine receptor, several promising products acting at new target sites, which are currently not affected by resistance that will be used for pest control especially against German cockroach in Iran.

POSTER PRESENTATION

Comparison of Fipronil topical application and WHO glass jar methods, time and toxicity in *Blattella germanica* field population strains

Hassan Nasirian, Hossein Ladonni, Kamal Mashhadi Esmaeily

Department of Medical Entomology and Vector Control, School of Public Health and Institute of Public Health Research, Tehran University of Medical Sciences, Tehran, Iran, P.O. Box 6446-14155, Tehran, Islamic Republic of Iran

Introduction: German cockroaches, *Blattella germanica* (L.), are the most common urban environment cockroaches found in houses and restaurants and remain one of the most economically and medically important pest.

Methods: The duration of Fipronil topical application and WHO glass jar methods toxicity against eleven strains of feral German cockroaches, *Blattella germanica* (L.), was determined.

Results: In the topical application bioassay, the average LD_{50} of susceptible strain was 1.8, 1.3 and 0.96 ng per insect after 24 h, 48 h, and 72 h, respectively. As with the susceptible reference strain, where LD_{50} was halved from 24 to 72 h, the LD_{50} of Fipronil decreased with time in the field populations. In the WHO glass jar bioassay, the average LT_{50} of susceptible strain was 16.4, 14.3, 12.4 and 11.3 exposure minutes after 24 h, 48 h, 72 h and 96 h, respectively. As with the susceptible reference strain, where LT_{50} was halved from 24 to 96 h, the LT_{50} of Fipronil decreased with time in the feral German cockroach strains.

Conclusions: These results indicate that the Fipronil was relatively slow-acting in topical application and WHO glass jar method bioassay, with LD_{50} and LT_{50} values decreasing until 72 and 96 h and becoming stable thereafter, respectively.

POSTER PRESENTATION

Human scalp myiasis in Bandar-Abbas, Hormozgan province, south of Iran

Hassan Nasirian[1], Mussa Soleimani Ahmadi[2]

[1]Department of Medical Entomology and Vector Control, School of Public Health and Institute of Public Health Researches, Medical Sciences/University of Tehran, P.O. Box 6446-14155, Tehran, Iran, Tehran; [2]School of Public Health, Hormozgan University of Medical Sciences, Bandar-Abbas, Iran, Bandar-Abbas, Islamic Republic of Iran

Introduction: This is the second report of *Chrysomia bezziana* larvae infection in human in Iran.

Methods: A 5-year-old boy with sever headache and agitation symptoms referred to the Kodekan Hospital in Bandar-Abbas city, Hormozgan province, South of Iran. In the operating room, about 40 larvae of 3rd instar fly larvae were pulled out under the general anesthesia condition. A 30 larvae were preserved in 70% methanol and the rest were reared on ground beef placed on the top of moist soil in a mosquito net case under insectary condition at 30 ± 2 ˚C, 70 ± 5% RH. The full grown larvae crawled into the soil and developed to adult flies later on. The larvae and adult flies were identified by the available keys.

Results and Conclusions: Our precise identification indicated that the flies were the Old World screw-worm (*Chrysomia bezziana*). Physical examination showed sever extensive wound in parietal of the skull that the whole subcutaneous tissues were eaten by larvae. Endoscopy consideration revealed the presence of numerous larvae lodged inside the lateral sub marginal and the depth of the subcutaneous tissues in the wound.

POSTER PRESENTATION

Predacious mite abundance in IPM orchards in southern Quebec, Canada

Noubar J. Bostanian[1], Michael J. Hardman[2], Gaétan Racette[1], Jeffrey L. Franflin[2]

[1]Horic. Dev. Res. Centre, Agriculture and Agri-Food Canada, St. Jean-sur-Richelieu, Qc., Canada, [2]Atlantic Food and Hortic.Res. Centre, Agriculture and Agri-food Canada, Kentville , NS., Canada

Introduction: Following the withdrawal of key pesticides for biocontrol programs, many growers have adopted conservation and augmentation tactics for beneficial mites in their orchards. This evolution of pest management strategies encouraged us to re-visit several orchards to assess the presence of predacious mites in these orchards.

Materials and Methods: The field work was carried out in seven orchards, from 28 June to 28 September 1999 and from 12 July to 13 September 2000. A 5 ha block was sampled weekly in a northeast-southwest diagonal transect. The sampling was done by administering two blows to two outer branches ca. 1.5 m from the ground and collecting the displaced mites in vials. Specimens were mounted and identified according to Chant et al. (1974), Chant and Hansell (1971) and Smith Meyer and Ueckermann (1987). Repeated measures analysis of variance was used to analyze the data.

Results: Predacious mites were present in all the orchards and 13 species were identified. *Amblyseius finlandicus* and *Typhlodromus conspicuous* were identified for the first time in Quebec. *Agistemus fleschneri*, *Amblyseius fallacis* and *Typhlodromus caudiglans* were the most abundant species. Each season a complex of two to eight species per orchard were present. Repeated measures analysis showed that year had a significant effect on the counts of *A. fleschneri*, *A. fallacis* and *T. caudiglans*. It had no effect on *Anystis baccarum* or *Balaustium sp.*

Conclusion: Conservation and augmentation strategy in Quebec apple orchards in the early 1990s has had a positive impact. Prey-predator ratios have been in favour of predators and phytophagous mites have been below the action threshold for acaricide treatment.

POSTER PRESENTATION

Residual toxicity of six novel insecticides to *Anystis baccarum*

Noubar J. Bostanian, Marie-Claude Laurin

Horiculture Dev. Res. Centre, agriculture and Agri-Food Canada, St. Jean-sur-Richelieu, Qc., Canada

Introduction: In Quebec biological control programs for pest mite species in vineyards and orchards is based on the conservation and augmentation of natural enemies. *Anystis baccarun* is the key predator in vineyards. This study reports the effects of several insecticides used in vineyards.

Materials and Methods: Specimens were collected in 5L buckets from an experimental orchard where habitat management tactics are implemented. The mites were brought to the lab. in 30- ml plastic cups. In the lab. the mites were exposed individually to residues of methoxyfenoxide, spinosad, acetamiprid, imidacloprid, thiamethoxam and lambda-cyhalothrin. The label rates were calculated on the premise of applying 540 liters of sprayable material per hectare. The exposure was made in cages made from 50 mm petri dishes with a circular window . The cages were stored in a growth chamber set at 21^0C, 80% RH and a photoperid of 16:8 (L.D). Mortalty counts were made after 48 h.

Results and Discussion: All the insecticides evaluated had no toxic effects on adult *A.baccarum* except lambda-cyhalothrin. Lambda-cyhalothrin is very toxic to this predator under lab. conditions. The Canadian label rate of 0 .0184 g Ai /liter is 26-fold the LC_{50} value of 0.0007g AI / liter.

Conclusion: Imidacloprid, acetamiprid, thiamethoxam, methoxyfenoxide and spinosad are non-toxic to *A. baccarum* adults. Therefore, the effects of these compounds to *A. baccarum* fecundity, egg hatch and juveniles should be evaluated to complete our understanding of their safety. Lambda-cyhalothrin is too toxic to justify additional studies.

POSTER PRESENTATION

Kaffir lime, *Citrus hystrix* as a potential botanical insecticide to control the diamondback moth, *Plutella xylostella*.

Rita Muhamad Awang, Loh Siew Fan

[1]Universiti Putra Malaysia, 43400 UPM, Serdang, Selangor, Malaysia, [2]Universiti Putra Malaysia, 43400 UPM, Serdang, Selangor, Malaysia

Introduction: Botanical insecticides are either simply derived from natural plants parts or purified insecticidal compounds that are isolated from such plants materials. The kaffir lime, *Citrus hystrix (*family Rutaceae) is a Southeast Asian citrus plant with very pungent leaves. This study was conducted to examine the effect of *C. hystrix* dried leaves and fruit peels extracts with ethanol at different concentration on *P. xylostella* mortality

Methods:. Four concentrations of 10%, 20%, 30% and 40% for both ethanol extractions were tested and Permethrin and Neemix were used as comparisons. Cabbage leaves (*Brassica oleracea* L var. capitata) were used as substrates for the experiment. Ten third instars diamondback moth larvae were placed on the cabbage leaf treated with 1 ml extract solution in petri dishes. Eleven treatments were prepared with 10 replications. Dishes were incubated in the laboratory for 3 days. Larvae mortality was recorded every 24 hours.

Results: It was observed that kaffir lime leaves extract have slightly higher insecticidal properties as compared to the fruit peels extract. The number of larvae killed by both of the crude extracts increase over time. Their toxicity may be as good as compared to Neemix at high concentration (30% and 40%).

Conclusions: Both of the leaves and peels extract could be used as a potential botanical insecticide because of their repellent and antifeedant properties observed during the experiment.

POSTER PRESENTATION

Insecticidal action of galectin-transfected Arabidopsis on *Plutella xylostella*

Shiang-Jiuun Chen[1], Siou-Hua Wang[2], Shaw-Jye Wu[2], Ling-Long Kuo-Huang[1], Ju-Chun Hsu[3], Rong-Nan Huang[1]

[1]Department of Life Science, College of Life Science, National Taiwan University, Taipei, Taiwan, 106, Taiwan, Province of China, [2]Department of Life Science, College of Science, National Central University, Taoyuan 32054, Taiwan, Taiwan, Province of China, [3]Department of Entomology, College of Bioresources and Agriculture, National Taiwan University, Taipei 106, Taiwan, Taiwan, Province of China

Galectins (GALs) are a family of mammalian sugar-binding proteins specific for β-galactosides. Our previous studies have shown that the larvae development of diamondback moth (*P. xylostella*) was significantly disturbed when fed with galectin1 (GAL1) extract and/or recombinant GAL1 proteins purified from GAL1 over-expressed *E. coli.* In these studies, we further showed that GAL1 could interact with chitosan and chtin *in vitro*, indicating that chitosan and chitin could be a ligand of GAL1. Chitin is the structural elements of the exoskeletons and peritrophic membranes in various insects, and could be utilised as a potential target for selective bio-insecticide. To further explore the potential of GAL1 as a bio-insecticide, we established a galectin-transfected stable clone of *Arabidopsis* (GAL1-*Arabidopsis*) for further investigation of insecticidal activity. The results showed that GAL1 were successfully expressed in GAL1-*Arabidopsis* clone. The survival and body weight of *P. xylostella* fed on GAL1-*Arabidopsis* clone were significantly decreased in a time-dependent manner. The ultrastructural studies further showed that the midgut of GAL1-*Arabidopsis*-fed insect was distorted. In view of GAL1 having a carbohydrate-recognition domain recognized the structural motif N-acetyllactosamine (Gal β 1-4GlcNAc) that is similar to that of chitin (β-1,4 N-acetyl-D-glucosamine), we proposed that the insecticidal mechanism of GAL1 involves direct binding with chitin, the main component of insect exoskeleton as well as peritrophic matrices lining the gut epithelium.

POSTER PRESENTATION

Occupation of bird-nest-boxes by invertebrates: is there an inter-taxa competition?

José Pablo Veiga[1], Vicente Polo[1], Wanyoike Wamiti[2]

[1]Museo Nacional de Ciencias Naturales, CSIC, Madrid, Spain, [2]National Museums of Kenya, Nairobi, Kenya

Introduction: Little is known about the propensity of insects and other invertebrates to occupy nest-boxes (usually targeted to birds). Competition for these places as suitable breeding sites or shelters may be potentially strong both among invertebrate taxa and between harmful arthropods and birds or other vertebrates that can use the boxes. We investigated the frequency of occupation of wooden nest-boxes by invertebrates and vertebrates in five study sites representing three ecosystem types (savanna, montane forest and tropical rain forest) in Kenya.

Methods: One hundred and eighty wooden-boxes were placed in five different localities in Kenya in Sept and October 2006. The boxes were checked during the long rains (April-June) and the short rains (September-October) in 2007. We did not collect specimens so the identification of invertebrates was made *in situ* and by inspecting photographs. With the exception of honeybees *Apis mellifera*, classification of other invertebrates was only possible at the level of genus, family or even upper.

Results: Hymenoptera species were the most frequent occupant of nest boxes. In 4.1% of the boxes during spring and 14.0% during fall, we found active hives while in 3.0% either the bees had abandoned the boxes or the honey had been harvested by humans. In 9.2% of the checkings, the box had nesting wasps or their old nests. 4.5% of the boxes had ant nests. All these kind of insects, together with some other venomous arthropods (e.g. arachnids) also found occupying boxes, may represent a serious threat for potential competitors. Only in 14 out of 84 boxes occupied by invertebrates, we found two or more different taxa. The proportion of boxes with arthropods increased markedly from spring to fall suggesting that occupation rates is likely going to increase following our last control.

Conclusions: A relatively high proportion of nest boxes were occupied by arthropods, many of them potentially harmful for other holders, either vertebrate or invertebrate. This implies that inter-taxa competition (even invertebrates vs. vertebrates) for suitable nesting places or shelters may be an important factor affecting population density and structure in hole-nesting-sheltering species.

POSTER PRESENTATION

Oviposition preference by the vine weevil (*Otiorhynchus sulcatus*) in relation to raspberry (*Rubus* spp.) cultivars

Katy Clark[1], Scott Johnson[1], Sue Hartley[2]

[1]Scottish Crop Research Institute, Dundee, United Kingdom, [2]University of Sussex, Brighton, United Kingdom

Introduction: The vine weevil (*Otiorhynchus sulcatus*) is a highly polyphagous insect herbivore and a destructive pest in many production systems. The survival and reproductive success of *O. sulcatus* can be influenced by the status of their host plant, but it is unclear how different plant cultivars affect oviposition behaviour of adults living aboveground. We investigated adult feeding and oviposition behaviour on nine raspberry cultivars.

Methods: Nine cultivars were used; Glen Ample, Glen Clova, Glen Rosa, Glen Magna, Glen Moy, Malling Jewel, Octavia, Tulameen and a wild variety. An adult choice experiment was conduced in 20 large arenas that allowed the weevil to move freely between the plants choosing where to eat and oviposit. In the adult no-choice experiment, individual weevils were caged on a single plant of each variety. In both cases, leaf consumption and number of eggs laid were quantified after 21 days.

Results: Egg laying on or around each plant ranged from 0 to 64 and 0 to 148 for the choice and no-choice experiments respectively. There was no statistically significant difference in the number of eggs laid upon the different cultivars for either experiment. However, weevils laid the least number of eggs on Glen Moy and the most on Glen Ample in both experiments. In the choice experiment, less than 1% of the total cultivar leaf area available to the weevils was consumed.

Conclusion: No oviposition preference for adult vine weevils was found between different raspberry cultivars.

POSTER PRESENTATION

First record of the endoparasitoid *Dolichogenidea (Apanteles) anarsiae* (Hymenoptera: Braconidae) in Greece

Petros T. Damos, Matilda Savopoulou-Soultani

Aristotle University of Thessaloniki, Faculty of Agriculture,Laboratory of Applied Zoology and Parasitology, Thessaloniki, Greece

Parasitoids of the family Braconidae are widely distributed and recorded throughout Europe, the Indian subcontinent and parts of Africa. Despite the fact that a number of individuals of the genus *Dolichogenidea* have been recorded around the Mediterranean (mostly France and Italy), this is the first record of the species *Dolichogenidea anarsiae* in the wide Balkan Peninsula and east Mediterranean area. Although usually listed as a species of the genus *Apanteles* (Foerster 1862), following the breaking up of this genus, which is proposed by a number of taxonomists, *A. anarsiae* (Faure and Alabouvette 1924) should be included in the genus *Dolichogenidae*. The species is considered as an important endoparasitoid of the peach twig borer *Anarsia lineatella*, but is also recorded as an endoparasite in a great variety of Tortricidae members. A significant number of *D. anarsiae* individuals were found in overwintering *A. lineatella* larvae. Hibernacula samples, with overwintering larvae, were collected from peach trees in northern Greece (40.32^{o}N). In addition, the presence of *D. anarsiae* was very high throughout the winter and especially in orchards where no pesticides were applied during the previous years. Sampling sites, habits and morphology of the solitary parasitoid wasp *D. anarsiae* are illustrated.

POSTER PRESENTATION

Content of Pb, Cd, Zn, Cu and Mn in bodies of field ground beetles (Coleoptera, Carabidae) with respect to selected ecological factors – case study from Central Europe

Lubos Purchart[1], Emanuel Kula[2], Vladimir Hula[3]

[1]Mendel University of Agriculture and Forestry, Institute of Forest Ecology, Brno, Czech Republic, [2]Mendel University of Agriculture and Forestry, Department of Forest Protection and Game Management, Brno, Czech Republic, [3]Mendel University of Agriculture and Forestry, Department of Zoology, Brno, Czech Republic

The concentration of heavy metals in the bodies of invertebrates is dependent on their physiological equipment and prevalent environmental factors. To verify the effect of some of these factors on the content of metals (Pb, Cd, Zn, Cu, Mn) we analysed and then tested (using RDA, t-test) ten species of field ground beetles (Coleoptera, Carabidae).

A significant effect of Cu and Cd was discovered in terms of the sex; the males accumulated more Cu (27.520 mg kg^{-1}) than females (18.297 mg kg^{-1}) (P<0.01), which, on the contrary, accumulated more Cd (1.495 mg kg^{-1}) than males (0.663 mg kg^{-1}) (P<0.02). The content of all the metals differed significantly (P<0.03) according to the species, unambiguously showing species-specific models of accumulation. The effect of the feeding ecology was evident only on the essential elements; carnivores (Zn – 222.596 mg kg^{-1}, Cu – 27.211 mg kg^{-1}, Mn – 71.929 mg kg^{-1}) had a significantly (P<0.03) higher contents than omnivores (Zn – 168.198 mg kg^{-1}, Cu – 21.116 mg kg^{-1}, Mn – 58.452 mg kg^{-1}). Although there were differences (P<0.01) in the concentrations of Zn and Cu between the spring (Zn –163.749 mg kg^{-1}, Cu – 19.998 mg kg^{-1}) and autumn (Zn – 202.373 mg kg^{-1}, Cu – 25.496 mg kg^{-1}) species, the effect of the type of reproduction is considered to be only partial. At the same time the time of sampling affected the Zn and Mn (P<0.02) content. An important positive correlation was determined between the contents of Cu-Zn, Mn-Zn and Mn-Cu.

Acknowledgement: The project was supported by Research plan of the Czech Ministry of Education MSM 6215648902.

POSTER PRESENTATION

Metagenomics of glassy-winged sharpshooter, *Homalodisca vitripennis* (Hemiptera: Cicadellidae)

Wayne Hunter[1], Scot Dowd[2], Kent Shelby[3], Catherine Katsar[4], Phat Dang[5], Laura Hunnicutt[6]

[1]USDA, ARS, Fort Pierce, FL, 34945, United States, [2]USDA, ARS, Lubbock, TX, 79403, United States, [3]USDA, ARS, Columbia, MO 65203, United States, [4]USDA, APHIS, Fort Lauderdale, FL 33316, United States, [5]USDA, ARS, Dawson, GA 39842, United States, [6]North Carolina State University, Raleigh, NC, United States

The microenvironment of leafhoppers was exposed by using a Metagenomics approach to identify unknown organisms which live in association with the glassy-winged sharpshooter, 'Homalodisca vitripennis' (Hemiptera: Cicadellidae). Metagenomics is described as "the comprehensive study of nucleotide sequence, structure, regulation, and function". The production of cDNA libraries from the GWSS resulted in the identification of multiple organisms associated with these leafhoppers. Three newly discovered single-stranded RNA viruses, along with three bacteria, and one potential fungi and a bacterial phage were identified, along with plant material ingested by the insects. The viruses are undergoing full genome sequencing and may provide new biological control agents against leafhoppers. Species comparison to all available data on NCBI provided insights into the homologous nature of leafhopper genomics. The number of sequences returning a top homology match to other species provide more matches to 'D. melanogaster', (~12,500) followed by 'A. aegypti',(~9,600), 'T. casteum',(~9,000), 'A. gambiae',(~8500), 'N. vitripennis', (~8,000), 'A. mellifera', (6,000) and then 'H. sapiens' (~4,500). The dataset is being further mined for enzymes which may aid in post processing of cellulosic waste materials, or animal waste streams. Ultimately the information can then be applied to solve problems in agriculture to create healthier human populations which will use environmentally friendly technologies. Metagenomics is a new and exciting field of molecular biology that is growing into the standard technique for understanding biological diversity.

POSTER PRESENTATION

Pentatomidae (Hemiptera) associated with rice crops in south-eastern Australia

Mark Stevens[1], Jianhua Mo[1], Fred McDonald[2]

[1]E H Graham Centre for Agricultural Innovation (NSW Department of Primary Industries and Charles Sturt University), Yanco Agricultural Institute, Yanco NSW, Australia, [2]School of Integrative Biology Insect Collections, St Lucia Campus, The University of Queensland, Brisbane Qld, Australia

Introduction: Pentatomid bugs cause reductions in rice crop yield and quality throughout the world, but have not been regarded as pests in south-eastern Australia until relatively recently. We surveyed rice crops to determine the species composition of the fauna, and conducted glasshouse experiments on the most common species, *Anaxilaus vesiculosus* (Herrich-Schaeffer), to confirm its pest status.

Methods: Sweep-net sampling was conducted in 38 rice crops in the Murrumbidgee and Murray Valleys during maturation of the 2005/6 and 2006/7 crops. Adult *A.vesiculosus* were placed on caged rice plants, where reproduction and development were monitored. Grain from exposed and controlled plants was hulled, milled and assessed for damage.

Results: Seven pentatomid species were recorded, however three species accounted for approximately 97% of the bugs collected. The native species *A.vesiculosus* dominated the fauna (84% of captures). Bug densities were too low to fully account for the level of damage observed, suggesting that fungal infections and/or physiological disorders may also be involved in grain damage. Field-collected *A.vesiculosus* adults placed on caged rice plants survived for up to 20 days. Nymphs that emerged from eggs laid on the plants were reared through to adulthood without any alternate food sources, and grain from the exposed plants showed the characteristic blemishes associated with stink bug feeding.

Conclusions: This is the first record of *A.vesiculosus* feeding and developing on rice. Further research is needed to determine the relative contributions of pentatomids, fungal infections, and physiological disorders to rice grain damage in south-eastern Australia.

POSTER PRESENTATION

Which is the most suitable approach to determine the invaded range of Argentine ant at local scales?

Núria Roura Pascual[1], Josep M. Bas[2], Wilfried Thuiller[3], Rainer Krug[1], Lluis Brotons[4]

[1]*Centre for Invasion Biology, University of Stellenbosch, Stellenbosch, South Africa,* [2]*Departament de Ciencies Ambientals, Universitat de Girona, Girona, Catalonia, Spain,* [3]*Laboratoire d'Ecologie Alpine, UMR-CNRS 5553, Université J. Fourier, Grenoble, France,* [4]*Centre Tecnològic Forestal de Catalunya, Solsona, Catalonia, Spain*

Introduction: Determining the geographical extent and ecological suitability range of an invasive species is a challenge for most ecologists concerned about management practices. In the absence of detailed data on the real distribution of species, distributional models offer the opportunity to estimate the geographic extent of an invasion and also to better understand the ecological processes acting at different spatial scales.

Methods: Herein, several modelling approaches (correlative and mechanistic) are used to determine the distribution of the Argentine ant (*Linepithema humile*), a highly widespread invasive species native to South America. Occurrence data mostly obtained from two different sampling strategies were combined with environmental data at different resolutions in order to predict the geographical extent of the ant invasion in Catalonia (NE Iberian Peninsula) across spatial scales.

Results and conclusions: Comparisons between models suggest that the species is still expanding at the northeastern area of the Iberian Peninsula, where the Argentine ant is not in equilibrium with its environment. Special attention should be paid at the Costa Brava, where the species seems to present highly suitable conditions along the whole coast and also in inland areas. In this sense, long-distance jumps are the ultimate responsible for the expansion and should receive special attention in order to establish efficient measures to control the invasion spread.

POSTER PRESENTATION

Semiochemicals involved in termite raiding by the Ponerine ant *Pachycondyla analis*: Observations on raiding behaviour

Abdullahi Ahmed Yusuf[1], Ian Gordon[1], Robin M. Crewe[2], Peter G. N. Njagi[1], Christian W. Pirk[2], Ahmed Hassanali[1]

[1]International Centre of Insect Physiology and Ecology (icipe), Nairobi, Kenya, [2]Department of Zoology and Entomology, University of Pretoria, Pretoria, South Africa

Introduction: The termitophagous ant *Pachycondyla analis* (Latreille) organises coordinated raids on termites. Understanding the cues mediating the raiding behaviour of this ant and its semiochemical interactions with its termite prey could offer potentials in the control of termite pests.

Methods: Thirty four nests of *P. analis* were studied at Mpala central Kenya. Time of raids, duration of different activities during raids, termite species taken, number of ants in the raid and number of ants carrying termites were recorded. Ground temperature and RH at the time of departure for raids were also recorded.

Results: Out of the 330 raids observed, 56% occurred in the morning (0700-1100 hr), 42% in the evening (1600-1930 hr), and 2% entirely nocturnal (2000-2400 hr). The minimum and maximum foraging distances during a raid were 1.5 and 39.8 m respectively, temperatures during raids were between 18.4-36.4 ℃ and 26.6-69.0 % RH. Duration of raids ranged between 4-99 minutes. Foraging parties contained between 22-800 ants with 10-720 ants carrying termites back from raids. Number of termites captured per foraging party increased from the month of April to May, decreasing in June with a further increase in July and decreasing in August and September respectively. Average number of termites carried per ant ranged from 1.0 to 7.0, while predation rates were 1.063 termites per nest per m^2 and 959.1 termites per nest per day, with preferences of *Microtermes* and *Odontotermes* species.

Conclusion: These results will open opportunities for studies directed at understanding the chemical interaction between these ant raiders and the termites.

POSTER PRESENTATION

Why do striders fly? Inferring evolutionary causation from genetic, environmental and geographic variation in wing dimorphism.

Daphne Fairbairn, Elizabeth King

University of California, Riverside, California, United States

Introduction: In this paper, we take advantage of wing dimorphism in the waterstrider, *Aquarius remigis* (Hemiptera-Heteroptera, Gerridae) to measure genetic and phenotypic variation in dispersal capability within and among populations from across a California. We then use these patterns to deduce the evolutionary mechanisms responsible for the unusually high frequency of macropters in this region of North America.

Methods: (1) A half-sib mating design split across two temperatures is used to estimate the heritability of wing morphology and the genetic correlations between sexes and environments. (2) Three populations are reared under two temperature regimes to measure genetic differentiation among populations. (3) Field samples from 37 Californian populations are used to detect correlations between proportion macropterous and environmental and geographic variables.

Results: (1) In both environments, wing morphology is highly heritable and shows very high genetic correlations between males and females. The genetic correlations between environments are significant but somewhat lower than those between sexes. (2) Both mean proportion macropterous and its reaction norm with temperature differ significantly among the three populations, indicating strong genetic differentiation. (3) Patterns of geographic variation reveal no correlation between proportion macropterous and stream size, rainfall or latitude, but a strong positive correlation with altitude.

Conclusions: Wing dimorphism in *A. remigis* has a high potential to respond to selection within populations and has clearly diverged genetically among populations. The geographic pattern of variation suggests that the high proportion macroptery in California is an adaptation to altitudinal gradients rather than to seasonal lowland drought, as previously thought.

POSTER PRESENTATION

Effects of snowdrop lectin (GNA) on the development of beet armyworm, *Spodoptera exigua* (Lepidoptera: Noctuidae)

M Naghdi, Ali R. Bandani, Kh Talebi

Plant Protection Department, Faculty of Agriculture, University of Tehran, Karaj, Islamic Republic of Iran

Introduction: In order to control this pest emphasis has been placed on using pesticides. However, problems associated with pesticide usage have resulted in greater interest in the potential for exploiting plant defensive proteins such as lectin to control insect pest. GNA (*Galanthus nivalis* agglutinin; Snowdrop lectin) is toxic toward a number of insect species including Homopteran, Coleopteran and Lepidopteran species. So, the aim of the current study is to investigate the effects of GNA on beat armyworm larval growth and development.

Materials and Methods: Larvae of the beet armyworm, *Spodoptera exigua*, were collected from the field and reared on a wheat germ-based artificial diet (Bio-Serv) in a growth chamber (16:8 hrs light: dark, 50% relative humidity and 25 ± 1 ℃. GNA incorporated in artificial diet at 0 Control), 0.1, 0.2, 0.5, 1 and 2 % of total dietary protein.

Results: Larvae in the control grew normally while in the GNA treatments percentages of larval mortality varied in the different treatments. Fore example percentages of mortality in the first instar larvae in the 0.1, 0.25, 0.5, 1 and 2% GNA treatment were 16.6, 30, 33, 36 and 50, respectively. Only larvae in the o.1% lectin treatment grew up to adult stage while in the other treatments all larvae died before reaching pupal stage. Also, larvae and pupae in the control weighed consistently more than those in the GNA treatments.

Conclusions: Current study showed that the main effects of the GNA treatment on beet armyworm were reduction in larval survivorship and larval and pupal weight suggesting that GNA can play an important role in reduction of population and damage levels of the pest in the field.

POSTER PRESENTATION

Control of codling moth through post-harvest fruit removal

R.A. Van Steenwyk, C.F. Fouche, S.C. Welter, C.A. Ingels, L.G. Varela, R.B. Elkins

University of California, Berkeley, United States

Pears, *Pyrus communis* (L.) 'Bartlett' are harvested in California from mid-July through mid-August. After commercial pear harvest, it is common to find a large number of unharvested fruit remaining on the trees. Since insecticide use is terminated two or more weeks before the completion of harvest, the unharvested fruit serve as excellent sites for codling moth, *Cydia pomonella* (L.) (CM) oviposition and allow for a rapid increase in the CM population. CM larvae that complete their development in the unharvested fruit before the end of July will enter the pupal stage and emerge as adults. However, CM larvae that complete their development by the end of August will enter the overwintering stage. If the CM population can be controlled before mid-August, then the overwintering population would be largely eliminated. Studies with post-harvest fruit removal or post-harvest insecticide applications have demonstrated that post-harvest control can reduce the overwintering CM population by approximately 75%. During the course of our studies, it was observed that CM larvae that infest ripe pears do not complete their larval development. The pears rot faster than the larvae can complete their development. It was determined that an application of ethephon shortly after harvest promotes early ripening and fruit drop with a resulting reduction in the overwintering CM population. Plant growth regulators can substitute for post-harvest hand stripping of fruit or post-harvest insecticide applications at a reduced cost to the grower and with less environmental impact. Ethephon was registered in California for post-harvest use in 2007.

POSTER PRESENTATION

Studies on different populations of *Aphis gossypii* in transmission of citrus tristeza virus (CTV) to some citrus cultivars in Mazandaran Province

A Hadizadeh[1], Gh. Reza Rassoulian[1], Gh Mosahebi[1], H Rahiamian[2]

[1]Department of Plant Protection, Faculty of Agriculture, University of Tehran, Karaj; [2]Department of Plant Protection, Faculty of Agriculture, University of Mazandaran, Sari, Islamic Republic of Iran

Introduction: Citrus tristeza virus (CTV) is a phloem – limited aphid transmitted pathogen that causes the most economically important disease of citrus worldwide. The virus appears to be steadily spreading to new sites by melon aphids. Sour orange is the only rootstock used in Mazandaran province that seriously affected by citrus tristeza virus.

Methods: Experiments were conducted to investigate the role of different populations of *Aphis gossypii* in transmitting of the virus to the different citrus cultivars. MIS isolate of CTV maintained on Rangpour lime seedlings were used for determination and transmission efficiencies. Populations of *A. gossypii* were collected from different citrus species. Aphid populations were collected from related host plants in the field. Aphid colonies of cotton and citrus trees were reared on the same host plants in greenhouse conditions and were used directly in transmission tests. Apterous aphids were transferred onto different citrus cultivars after acquisition feeding from donor plants. Approximately 20-25 aphids were used per test seedling and 5 seedlings were used for each plant. The results were assessed three months after inoculation by ELIZA tests.

Results: The M1S isolate of CTV in Rangpour lime were transmitted to different citrus cultivars by cotton and euonymus populations of *A. gossypii* at 8 and 13% respectively. CTV in mandarin was transmitted by cotton populations of aphids at 16%. The cotton and weeping fig aphid populations have transmitted the CTV 7.6% and 51.50%, respectively. Mean transmission rate obtained was 19% for this isolate on different citrus cultivars.

Conclusions: Our investigations have shown that all population of melon aphids in Mazandran Province can transmit the CTV. Therefore it seems that the virus in this area spread rapidly.

POSTER PRESENTATION

Resistance of phytophagous mites as an evidence of the unfavourable changes in biocenose of apple orchard

Elena Moontean, Victoria Sumencova, Elena Iordosopol, Mihai Batko, Igor Yazlovetsky

Institute for Plant Protection and Ecological Agriculture, Kishinev, Europe, Republic of Moldova

Introduction: One of the main problems of pest apple orchards control is excessive reliance on chemicals leading to biocenose destabilization. The influence of the insectoacaricide treatment of apple orchard upon the structure of acarifauna and upon the level of resistance in population of phytophagous mites was studied.

Methods: The median lethal concentrations of insecticide were determined by probit analysis and the rates of resistance were calculated.

Results: In the first orchard (7 insectoacaricide treatments per year during 15 seasons) the acarifauna complex was represented by 8 phytophagous and 4 predatory species. *Tetranychus viennensis* and *Aculus schlechtendali* were dominant, with spots of propagation of *Panonychus ulmi*. The mites were resistant more than x 1000 to Dimethoate, Zolone, Malathion, Chlorpyriphos. *P. ulmi* and *T. viennensis* began to develop form resistance to acaricides Brompropylate (x 3,5) and Propargite (x 4,0). In the second orchard (4 treatments) 5 phytophagous and 20 predatory species of mites were detected. *P. ulmi* was not found. *T. urticae* and *T. viennensis* had low resistance to Dimethoate (x 23 and x 2) and to Zolone (x 10 and x 7) respectively.

Conclusions: The reduction of useful acarifauna under the influence of insectoacaricides occurs together with the formation of acaricide resistance by phytophagous mites. Besides, mites present constantly in the agrocenose, slowly migrate and form quickly a high resistance to insectoacaricides. Therefore, the level of phytophagous mites resistance to insectoacaricides can serve as a criterion for evaluation of the current biocenose status of apple orchard.

POSTER PRESENTATION

On South African diversity of Pterophoroidea (Lepidoptera)

Petr UstJuzhanin[1], Vasily Kovtunovich[3], Mike Mostovski[2]

[1]Siberian Zoological Museum, Institute of Animal Systematics and Ecology, Russian Academy of Sciences, Novosibirsk, Russian Federation, [2]Natal Museum and School of Biological & Conservation Sciences, University of KwaZulu-Natal, Pietermaritzburg, South Africa, [3]Moscow Society of Nature Explorers, Moscow, Russian Federation

Introduction: Research of southern African plume moths was commenced in mid-19th century. This region became the best studied part of sub-Saharan Africa, with almost 90 pterophorid species recorded from here (Gielis, 2003). The pterophorid fauna of South Africa is rather specific, with a number of endemic species and certain links with other parts of the world. Recent survey of museum collections and extensive field work demonstrated that the state-of-art is far from being satisfactory.

Results: The family Macropiratidae (genus *Agdistopis*) is recorded in South Africa for the first time; this is also the first record of this hitherto Australasian family in the Afrotropical Region. The following genera represent South African Pterophoridae (with number of species): *Adaina* (4), *Agdistis* (42–47), *Amblyptilia* (2), *Antarches* (1), *Buckleria* (1), *Cosmoclostis* (2), *Eucapperia* (1), *Exelastis* (9–10), *Gypsochares* (4–5), *Hellinsia* (20–25), *Marasmarcha* (5), *Megalorhipida* (3), *Merrifieldia* (1), *Oxyptilus* (6–7), *Paulianilus* (1), *Picardia* (1), *Platyptilia* (16–18), *Pselnophorus* (2–3), *Pterophorus* (7–8), *Sphenarches* (2), *Stenodacma* (2), *Stenoptilia* (6–7), *Titanoptilus* (2), *Trichoptilus* (10), *Walsinghamiella* (4–5). Some 50 to 60 species of South African Pterophoridae can be recognised as new, with over 20 of them belonging to the genus *Agdistis*. Seven genera and over 20 species are recorded as new to the South African fauna; five species were previously known as endemics of Madagascar. With 155–174 pterophoroid species altogether (excluding alucitids), South Africa can be considered a centre of diversity for *Agdistis* (also Mediterranean and Central Asia), *Exelastis* and *Trichoptilus*.

POSTER PRESENTATION

The impact of fungicides on the predatory mite *Anystis baccarum* in apple orchards in Northern Ireland

Andrew Cuthbertson[1], Archie Murchie[2]

[1]Central Science Laboratory, York, United Kingdom, [2]Agri-Food and Biosciences Institute, Belfast, United Kingdom

Introduction: Apple scab (*Venturia inaequalis*) is the most serious disease in Bramley's Seedling apple orchards in Northern Ireland. As a result, as many as 14 fungicide sprays can be applied each season to control the disease. These fungicide sprays have an impact on both pest populations (*Aculus schlechtendali*) and non-target species (*Anystis baccarum*) populations.

Methods: Three commonly used fungicides (captan/penconazole, mancozeb and dithianon) were selected for investigation. Treatments were applied to individual trees arranged in six randomized blocks using an electric Berthoud Vermorel 2000 knap-sac sprayer to each tree at ten-day intervals. Three litres of spray solution were applied at recommended dose rates to each tree. Control trees were sprayed with water.

Results: On mancozeb treated trees there were fewer *A. baccarum* and more *A. schelcthendali* compared to the other treatments. Dithianon had no detrimental effect on *A. baccarum*. Mancozeb treated trees gave satisfactory scab control.

Conclusion: *Anystis baccarum* has shown a level of compatibility with various chemical fungicides commonly used for apple scab control. Therefore, there is potential for its incorporation into IPM programmes for the control of invertebrate pest species. Apple growers should be encouraged to recognise this beneficial mite and work to conserve its populations and apply only chemical applications that are compatible with the mite.

POSTER PRESENTATION

Impact on abundance of surface active non-target arthropods following soil fumigation with 1,3-Dichloropropene

Andrew Cuthbertson[1], Helen Thompson[1], Mark Miles[2]

[1]Central Science Laboratory, York, United Kingdom, [2]Dow AgroSciences, European Development Centre, Abington, United Kingdom

Introduction: The potato cyst nematode, *Globodera pallida*, is a widespread problem throughout England and Wales. A large scale field study was initiated in North Yorkshire with the aim of investigating the effects of soil fumigation with Telone II, 97.5% w/w 1,3-dichloropropene, for nematode control on carabid, spider and collembola populations.

Methods: Treatments were made by soil injection to a depth of 20 cm of 1,3-dichloropropene, in the autumn prior to cultivation of potatoes in the spring of the following year. Pitfall trapping commenced prior to fumigation and continued for 12 months.

Results: A reduction in arthropod numbers was noted immediately post-application. Carabid and linyphiid populations were noted to exceed the levels in the control 8 months after treatment before returning to untreated levels 10 months after treatment. Collembola populations had recovered within 1 year and were the most sensitive arthropods sampled.

Conclusion: The findings indicated that although effects were apparent post-application in the autumn/winter samples all arthropod populations had recovered within an ecologically relevant time scale. Overall effects on each taxa appeared to be related to their position in the field at the time of application (which determined their exposure) and recovery rate related to reproductive and dispersive capacity.

POSTER PRESENTATION

Efficacy of the entomopathogenic nematode, *Steinernema feltiae*, against sweet potato whitefly, *Bemisia tabaci*, under laboratory and glasshouse conditions

Andrew Cuthbertson, Keith Walters, Phil Northing, Weiqi Luo

Central Science Laboratory, York, United Kingdom

Introduction: The potential of using the entomopathogenic nematode *Steinernema feltiae* to control the sweetpotato whitefly, *Bemisia tabaci* has been well established. However, laboratory studies can overestimate the level of control achieved by biocontrol agents in the glasshouse.

Methods: Controlled laboratory and glasshouse trials were undertaken to confirm the efficacy of *S. feltiae* as a control agent against *B. tabaci*. The nematodes were applied using a hand held applicator. Mortality was assessed following 72 hours. The efficacy of the biocontrol agent at various application rates was also investigated.

Results: Under both controlled laboratory and glasshouse conditions high mortality of second instar *B. tabaci* (>90% and >80% respectively) was recorded after application of *S. feltiae*. Halfing the application rate of *S. feltiae* application (5000 IJ/ml) caused no significant reduction in *B. tabaci* mortality on tomato foliage.

Conclusion: *Steinernema feltiae* has shown much potential for incorporation into integrated pest management strategies for the control of *B. tabaci* in UK glasshouses.

POSTER PRESENTATION

Status quo of honeybee (*Apis mellifera* L.) pests and diseases in Sudan

Mogbel El-Niweiri, Abdalla Satti

Environment and Natural Resources Research Institute, National Centre for Research, Khartoum, Sudan

Introduction: Honeybees are found naturally in Sudan since ancient time and traditional beekeepers are present. Recently, modern beekeeping has been flourished using imported colonies, so the threat of spreading exotic pests and diseases was expected. Since few data is available in this field, it was aimed by this work to recognize important pests, predators, diseases and parasites of honeybees and their incidences in different parts of the country.

Methods: Data were collected through intensive surveys and questionnaires covering nine bee areas (States) in Sudan during the period 2003 - 07. Different modern and traditional apiaries and wild colonies were inspected, where the percentages of affected colonies by major pests or diseases were indicated in most areas. Samples taken included 122 local colonies and 350 Carnio-Egyptian colonies plus 30 colonies of *Apis florea*. Detected insects were mostly identified at the Insect Collection of the Agricultural Research Corporation (ARC), Sudan, whereas vertebrate species identified either at the Wild Life Research Centre, ARC or Sudan Institute for Natural Sciences. Suspected diseases were confirmed through laboratory culturing and biochemical tests followed at the Department of Microbiology, Faculty of Veterinary Sciences-University of Khartoum.

Results: Lists of more than 35 pests and predators of honeybees were recorded at variable levels in different areas. They include mainly insect and vertebrate species and few spiders. Among these, twenty species were new records e.g. the hive beetles, bee wolves, squirrel and honey badger. However, many species were found causing serious problems such as *Galleria* moth (86.3% infested colonies), ants and two predatory birds (*Merops* spp.). On the other hand, all areas were found free of most bacterial and fungal diseases, except the bacterial brood disease, *Serratia marcescens*, found in 2.6% of Khartoum colonies. Moreover, the parasitic mite, *Varroa jacobsoni*, was found firstly infecting 75% of colonies in Khartoum State as new record, thenceforth detected in Sennar and Kordofan States.

Conclusions: Various indigenous pests of honeybees were found in Sudan and some exotic pest and disease species were introduced through commercial beekeeping.

POSTER PRESENTATION

Regressive evolution: ontogenetic study on wing reduction in the bagworm moths (Lepidoptera, Psychidae)

Shuhei Niitsu

Tokyo Metropolitan University, Hachioji-shi, Tokyo, Japan

Winglessness has evolved many times in neopteran insects in a response to a change according to ecological conditions. Females of bagworm moths show phased-reduction of wings: Males are winged while females have frequently the vestigial wings or completely wingless form. Studying processes of wing reduction in Psychidae possibly helps understanding the evolution of wing reduction in insects. Using light and electron microscopy, I studied the process of wing development in the period from larval instar to pupal stages. In the study, histological analysis revealed that the females of the bagworm moths express two ontogenetic patterns of wing reduction. The female adults of *Taleporia trichopterella, Bacotia sakabei,* and *Proutia* sp. have atrophied wings. The wingless-legged state of these species (usually called wingless-legged bagworm moths) has been hypothesized as the intermediate condition between two extremities of females with normal wings and those with absolutely no wings. In these species, wing disc degeneration caused by apoptosis occurs in two steps: in the prepupal stages and pupal stages. In contrast to three species described above, *Eumeta variegata* female adults are vermiform lacking wings and legs. This vermiform state of the females has been hypothesized as the most derived condition in the evolution of Psychidae. In this study by using this species, a sac-like wing rudiment was formed by invagination of the epidermis in the last instar. The wing rudiment disappears through apoptosis on the prepupal stages. These processes of wing reduction have probably evolved secondarily during the course of evolution.

POSTER PRESENTATION

Bt crop effects on functional guilds of non-target arthropods: A meta-analysis

L. LaReesa Wolfenbarger[1], Steven Naranjo[2], Jonathan Lundgren[3], Royce Bitzer[4], Lidia Watrud[5]

[1]University of Nebraska at Omaha, Department of Biology, Omaha, NE 68182, United States, [2]USDA-ARS Arid Land Agricultural Research Center, Maricopa, AZ 85238, United States, [3]USDA-ARS North Central Agricultural Research Laboratory, Brookings, SD 57006, United States, [4]Iowa State University, Department of Entomology, Ames, IA 50011, United States, [5]US Environmental Protection Agency, National Health and Environmental Effects Research Laboratory, Western Ecology Division, Corvallis, OR 97333, United States

Uncertainty persists over the environmental effects of genetically-engineered crops producing the insecticidal Cry proteins of *Bacillus thuringiensis* (Bt). We perform meta-analyses to synthesize current knowledge about the effects of Bt cotton, maize and potato on the abundance and interactions of arthropod non-target functional guilds. We compare the abundance of predators, parasitoids, omnivores, detritivores and herbivores under scenarios in which neither, only the Bt crops, or both Bt and non-Bt crops received insecticide treatments. Predators were less abundant in Bt cotton compared to unsprayed non-Bt controls. Fewer specialist parasitoids of the target pest occurred in Bt maize fields compared to unsprayed non-Bt controls, but no general effects on parasitoids existed. Predators and herbivores increased in Bt crops compared to sprayed non-Bt controls. Type of insecticide influenced the magnitude of increases in predators. In maize, higher abundances of detritivores in insecticide-treated controls were associated with reductions of their predators in sprayed non-Bt maize. Predator-to-prey ratios were unchanged by either Bt crops or the use of insecticides; ratios did increase in Bt maize relative to the sprayed non-Bt control.

Overall, we find no systematic effects of Bt crops on the functional guilds of non-target arthropods. Use of and type of insecticides influenced the magnitude and direction of effects; insecticide effects were much larger than those of Bt crops. These meta-analyses underscore the importance of using controls not only to isolate the effects of a Bt crop but also to reflect the replacement of existing agricultural practices.

POSTER PRESENTATION

Evaluating integrated pest management strategies for managing bed bugs

Timothy Gibb, Changlu Wang

Purdue University, W. Lafayette/ IN, United States

A recent surge of bed bug infestations in the USA is posing a major concern to citizens as well as to Professional Pest Managers who are asked to control them. Elimination of bed bugs currently relies heavily upon chemical sprays or dusts. Exclusive reliance upon pesticides alone presents three serious challenges: 1) none of the registered chemicals have the desirable residual efficacy; 2) there is evidence of wide-spread resistance to insecticides; and 3) treatment of bedding materials causes immediate risk of pesticide exposure to humans. These challenges underscore a need to investigate Integrated pest management (IPM) strategies that will decrease dependence upon pesticides alone, reduce the risk of human-insecticide exposure, and at the same time, improve the efficacy of bedbug management programs.

This summary reports the development and implementation of two IPM strategies to manage bed bugs and compares both their cost and effectiveness in actual bedbug infested residences. These strategies include; 1) non-chemical methods only; and 2) non-chemical methods plus a residual insecticide. Both IPM strategies included resident education and cooperation as components in implementation.

POSTER PRESENTATION

Occurrence of storage pests of kolanuts across the kola-growing belt of Nigeria

E.U Asogwa, T.C.N Ndubuaku, I.U Mokwunye

Cocoa research Institute of Nigeria, Ibadan, Oyo, Nigeria

Introduction: In Nigeria, *Cola acuminata* and *Cola nitida* are important economic crops cultivated in the rainforest zones of the South and riverine areas of the savannah region. Kolanuts play a significant role in the culture and ceremonies of the people, but are attacked by the kolanut weevils, which can cause appreciable damage between 30% - 70%. The distribution and frequency of occurrence of these insect pests was studied with a view of developing standard integrated packages for their control.

Methods: Random samples of matured kola pods and cured kolanuts were procured from across the kola belt and assessed using parameters such as percentage nut infestation, total number of emerged larvae and adult weevils; mean number of exit holes and colour change.

Results: The weevil distribution cuts across all the sampled locations but at different levels of infestations. The mean number of weevils (*Balanogastris kolae* and *Sophrorhinus spp*.) sampled at the various locations were not significantly different, however, *B. kolae* was significantly more abundant than *Sophrorhinus spp*. Weevil infestation level of 100% was recorded after 3 months of storage of nuts selected from kola pods from different zones as compared to the highest infestation level of 21.7% recorded for cured nuts.

Conclusions: It is evident that kolanut weevils, especially *B. kolae* are more abundant and widely distributed in Nigeria at varying degrees and such infestation normally starts on the field. The low infestation level on cured kolanuts could be as a result of application of some control measures by the kola vendors.

POSTER PRESENTATION

Geographic variation in the susceptibility of *Thaumatotibia leucotreta* (FCM) populations to a granulovirus (CrleGV-SA)

John Kwadwo Opoku-Debrah, Sean Douglas Moore, Peter Retief Celliers

Nelson Mandela Metropolitan University; Citrus Research International, Port Elizabeth, Eastern Cape, South Africa

Introduction: The false codling moth (FCM), *Thaumatotibia leucotreta* is a serious pest of citrus and other crops in sub-Saharan Africa. The use of biological control agents such as *Cryptophlebia leucotreta* granulovirus (CrelGV–SA, CRYPTOGRAN®) has proven to be very useful in the control of FCM. Markedly lower susceptibility of some codling moth populations to a granulovirus have been reported in Europe. Genetic variation between FCM populations in South Africa has been reported. It is therefore possible that differences in the susceptibility of geographically distinct FCM populations to CrelGV-SA might exist.

Methods: Firstly a benchmark for pathogenicity was established. Surface dose-response bioassays were conducted with laboratory reared FCM larvae of all five instars with CrelGV-SA. Dose-response relationships were calculated. Bioassays were also conducted with FCM larvae collected from infested fruit from a range of geographic regions.

Results: LC_{50} values were calculated to be 4.095×10^3, 4.516×10^4, 1.581×10^5, 2.205×10^6 and 2.678×10^7 OBs/ml, respectively. The LC_{90} values for the five larval instars were also calculated to be 1.185×10^5, 4.287×10^6, 1.113×10^7, 1.661×10^8 and 9.118×10^9 OBs/ml respectively.

Conclusions: A protocol for conducting bioassays with field collected FCM larvae was established. It was therefore possible to compare the susceptibility of larvae from different regions with laboratory reared FCM.

POSTER PRESENTATION

Cameraria ohridella Deschka and Dimic (Lepidoptera: Gracillariidae) host trees and potential host range expansion of the moth in Greece

Nikolaos Avtzis, Dimitrios Avtzis

[1]Technological Education Institute of Kavala - Branch of Drama - Dept. of Forestry and Natural Environment Management, Drama, Greece, [2]Institute of Forest Entomology, Forest Pathology and Forest Protection - BOKU, Vienna, Austria

Introduction: *Cameraria ohridella* is a new pest in Europe, that was first detected near Ohrid-Lake by Deschka & Dimic (1985). In 1998 Skuhravy found the insect in Greece for the first time, whereas in 2001 started its study within the framework of Controcam Project.

Methods: The distribution of the moth was investigated either by on-site observations as well as through the application of pheromone traps made by the Institute of Organic Chemistry and Biochemistry (Czech Republic), which were installed in various places of Greece. Besides distribution, Controcam included the study of host trees and potential host range expansion of the moth in Greece, something that is still being investigated.

Results: The insect is observed until now in 80 different places, both on wild (39) and ornamental (41) *Aesculus hippocastanum* trees.

The observations made by pheromone traps (2001-2004) and leaf sampling (2001-2007) did not report the moth on the following *Acer* species: *Acer sempervirens, Acer platanoides, Acer monspesulanum, Acer campestre, Acer tataricum, Acer pseudoplatanus, Acer creticum, Acer obtusatum, Acer hyrcanum, Acer heldreichii* and *Acer negundo*. These species were not infected by the moth even when growing near heavily infested horse chestnut trees (greater than 86.3% of the total assimilating surface).

Conclusion: The unique host tree attacked by *C. ohridella* in Greece was found to be *Aesculus hippocastanum,* an endemic species of the Balkans (Polutin, 1997). This result is incongruent with the findings of other researchers, which report the complete development of this insect on *Acer* species, f.e. *Acer pseudoplatanus* (Jona, 2001).

POSTER PRESENTATION

Otiorhynchus sulcatus F. – a pest of ornamental plants

Elda Vitanović, Sonja Kačić, Miro Katalinić

Institute for Adriatic Crops and Karst Reclamation, Split, Croatia, Croatia

Introduction: The genus of *Otiorhynchus* is represented in Croatia by 228 species. *Otiorhynchus sulcatus,* as a pest, has been known in Europe for quite a while, while in Croatia it has been causing significant damages since 2004. It attacks ornamental bushes and flowering plants grown indoors, but also those cultivated outdoors. Presence of this destructive species in glasshouses can cause loss of the whole production of flower species under attack.

Methods: The first control measure is mechanical by all means, i.e. hand-collection of adults and their destruction, as well as use of Rincho-trap strips applied in three ways. Further on, larvæ have to be controlled by chemical protective measures. Chemical preparations based on chlorpyrifos-ethyl, dimethoate, imidachlopride, alphacipermetrine, biphentrine and physical preparation have been used in our facilities. Plants in pots were treated with 1.5 dl of prepared solution.

Results: The mechanical measures reduced the number of females, and thus the number of eggs from which destructive larvæ could have emerged. The used preparations chlorpyrifos-ethyl, and dimethoate were 100% effective in destruction of larvæ as early as two to three days after application, while the other preparations were less effective six days later.

Conclusion: Control of *Otiorhynchus sulcatus* is difficult. Namely, larvæ, which cause damage, are resistant to chemical preparations, so that effectiveness of treatments with various preparations is not always satisfactory. Only rapid-action and 100% effective preparations should be used in control of this weevil's larvæ, because a single surviving larva in a pot causes decay of the plant.

POSTER PRESENTATION

Determintion of efficient dosage of Spirodiclofen Sc240 and Emidakavprid pesticides against *Aganoscenae pistasia* in Damghan, Iran

Mohammad Ali Oshaghi, Alireza Amir-Ahmadi, Saeed Seyfi Keshtgar

Islamic Azad University, Damghan Branch, Damghan, Semnan Province, Islamic Republic of Iran

Introduction: Pistachio is one of the most important agricultural products of Damghan, Iran which has been exported extensively to abroad. Pistacho psylla (*Aganoscenae pistasia*) is one of the main pests which has got great influence on the quantity and quality the products. In this study, we try to test the efficiency of two pesticides (Spirodiclofen Sc240 and Emidakavprid) against the psylla.

Methods: The study was carried out in 10 ha. pistachio garden where was heavily infected by the pest. The trees were of Shahpasand and Abasali cultivars, where the former is very susceptible to psylla. A complete random blocks with eight treatments each involved three replicates was designed. Each replicate included two trees. A day prior to spraying, sampling from trees was done and number of the pest was estimated. Spraying was performed by a 300 litter spraying machine in a sunny day without wind blowing. Sampleing was done in first, third, 7^{th}, 14^{th}, and 25^{th} day post spraying. Five leaves from tips of stems was selected randomly and the number of psylla was counted. The data (mean) were analysed by Donken-test.

Results: Results of this study showed that there were a significat differences between the treatments and control, but no significant variation within treatment. It is shown that both Spirodiclofen Sc240 and Emidakavprid pesticides with 0.2 per thousand dosage without oil are efficient to control of the pistachio psylla.

Conclusion: Two pesticides of Spirodiclofen Sc240 and Emidakavprid can be recommend for control of the psylla in the region.

POSTER PRESENTATION

Sweetpotato weevil, *Cylas formicarius elegantulus* (Summers) in North Carolina, USA

Kenneth Sorensen

North Carolina State University, Raleigh, North Carolina, United States

Introduction: Sweetpotato weevils are the most destructive insect pests of sweetpotato, *Ipomoea batatas. Cylas formicarius elegantulus (Summers)* is one of many species of sweetpotato weevils (SPW) which occur worldwide, but is the only one in the United States (US). In North Carolina (NC), SPW is restricted to barrier islands of the southern coast, where it feeds on alternate host, seaside morning glory (*Ipomoea sagitata*). NC ranks first in US production of sweetpotatoes with over 40,000 acres and well over $80,000,000 and the introduced SPW remains a serious threat.

Methods: Literature and media were reviewed and new information resources prepared to increase awareness of SPW impact and to enforce quarantines throughout the US. Sex pheromones evaluated in NC were placed in unitraps and boll weevil traps and monitored at 2 sites in southeastern NC from 1990-2007.

Results: Illustrations of SPW damage and life stages, of traps, and population graphs from 1990-2003 are shown. Populations since 2003 dropped significantly and are not included. US and worldwide SPW distribution are illustrated. Best management practices sheets, pocket guides, and powerpoint and poster presentations were shared with growers and extension workers throughout the US.

Conclusions: SPW monitoring technology, statewide application and preventive education effort has helped keep the weevil in abeyance. Future research using DNA fingerprinting will help understand taxonomic relations of SPW on wild and cultivated hosts and elucidate pathways of movement. Geographical and spatial collections and DNA analysis will help with SPW source identification, movement and introduction.

POSTER PRESENTATION

Integrated pest management (IPM) of *Helicoverpa armigera* using *Helicoverpa* nuclear polyhedrosis virus on chickpea in Bangladesh.

Svetlana Micic, Abu M Musa, Chris J Johansen

[1]*Department of Agriculture and Food, Western Australia, Albany, Western Australia, Australia,* [2]*People's Resource Orientated Voluntary Association, Rajshahi, Bangladesh,* [3]*Independant Consultant, Perth, Western Australia, Australia*

Helicoverpa armigera (Pod borer) is a major yield reducer of chickpea (*Cicer arietinum*) throughout south Asia. The main control technique for this pest has focused on the use of insecticides. However, *H. armigera* has developed resistance to several insecticides and their field efficacy is now greatly reduced. Previous trials have shown that *Helicoverpa* nuclear polyhedrosis virus (HNPV) can be an effective alternative, or at least a supplement to chemical insecticides. Multiplication of HNPV was initially attempted at village level but poor sanitary techniques prevented the production of HNPV of high titre with low contamination. The first stage in the commercialization of HNPV in Bangladesh has been to assess the field efficacy of high titre HNPV produced in India with that produced by Rajshahi University, Bangladesh and compared to conventional chemical controls. Results suggest that applications of HNPV and chemicals provide adequate control of *H. armigera* relative to unsprayed plots. Monitoring crops for *H. armigera* in Bangladesh can be difficult, especially if larvae are 1st or 2nd instars and difficult to see. It is at this stage that HNPV applications are most effective. Hence, early detection of *H. armigera* leads to better control measures. The traditional technique of assessing *H. armigera* numbers infield by counting larvae per square metre was compared to sweep netting. The comparative efficiency of these methods to monitor *H. armigera* numbers is also discussed.

POSTER PRESENTATION

Evaluation of new pyrethrin synergists for use against the cotton bollworm *Helicoverpa armigera* (Hübner) (Lepidoptera: Noctuidae)

Tanya Joffe[1], Geoff Allen[1], Robin Gunning[2], Graham Moores[3], Matthew Greenhill[4]

[1]University of Tasmania, Hobart, Australia, [2]NSW Department of Primary Industries, Tamworth, Australia, [3]Rothamsted Research, Harpenden, United Kingdom, [4]Botanical Resources Australia, Ulverstone, Australia

Introduction: The cotton bollworm, *Helicoverpa armigera* (Hübner) (Lepidoptera: Noctuidae), is a major pest in many agricultural systems, capable of causing great economic damage if not effectively controlled. The use of pyrethrum is being investigated for control of *H. armigera* in field crops in Australia, however, a substantial problem hampering effective control of these insects is the presence of pyrethroid/pyrethrum resistance. Resistance is metabolic and has been shown to be esterase mediated. The use of a synthetic synergist, such as piperonyl butoxide (PBO), inhibits esterase activity sufficiently so as to allow pyrethrum to take effect. This study aims to determine the efficacy of various natural synergists in combination with pyrethrum to enable synthetic PBO to be replaced with a natural synergist suitable for use in agriculture and the organic crop market.

Methods: Efficacy of the various putative pyrethrum synergists were tested in the laboratory using topical application bioassays on *H. armigera*. Biochemical techniques were used to asses the esterase inhibiting potency of these compounds.

Results: Some natural synergists have shown potential in the laboratory for use with pyrethrum by inhibiting esterases in *H. armigera*, thus temporarily lowering resistance in these insects sufficiently to allow death by pyrethrum.

Conclusions: Some natural synergists are potent esterase inhibitors, and pyrethrum synergists, in the laboratory but further work will be required to determine efficacy in the field.

POSTER PRESENTATION

Comparison of residual effects of Lambdacyhalothrin WP10% and Lambdacyhalothrin SC10% at 25 mg/m2 on various surfaces against *Anopheles stephensi* (Diptera: Culicidae), in southeastern Iran, 2006 – 2007

Kamran Akbarzadeh[1], Ahmad Raeisi[2], Mohammad-Reza Abai[1], Abdolghaffar Hassanzehi[3], Mehdi Nateghpour[4]

[1]Department of Medical Entomology, School of Public Health, Tehran University of Medical Sciences, Tehran;, [2]Center of Management of Diseases, Ministry of Health, Tehran; [3]Public Health Center of Sistan and Baluchestan Province, Zahedan; [4]Dept. of Medical Parasitology, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran

Introduction: Indoor residual spraying (IRS) is one of the primary vector control intervention for reducing and interrupting malaria transmission. Lambdacyhalothrin (Icon®) WP 10% has used successfully during 1993 - 2000 for IRS in Iran. The aim of this study was comparison of the residual effects of two formulations of Icon® WP and Icon® SC (as a new formulation introduced in Iran) at 25 mg/m2 on various surfaces in Iranshahr district, where is the endemic area for malaria in the country, during 2006 - 2007.

Methods: The lab-strain of *Anopheles stephensi mysorensis* was used for bioassays. Each formulation was sprayed separately on various surfaces. Spraying process and bioassay tests were carried out according to the method recommended by WHO.

Results: Both tested adulticides, Icon® SC 10% and Icon® WP 10%, showed statistically similar residual activity about 50, 140, 140 and 140 days on cement, plaster, mud and wood surfaces respectively ($p>0.05$). There is a significantly difference between mortality of the mosquitoes between various surfaces ($p<0.05$).

Conclusions: This is the first study on residual effects of SC formulation of Lambdacyhalothrin in Iran. Previous studies on its WP formulation showed residual effects about 90 days on various surfaces in other parts of Iran. The SC formulation simply dissolves in water and doesn't leave any sediment in equipments. Due to noticeable residual duration, this insecticide could be recommended for continuing the study in large village scale trial in southeastern Iran.

POSTER PRESENTATION

Using a new artificial feeding apparatus for infecting *Anopheles stephensi mysorensis* (Diptera: Culicidae) with *Plasmodium vivax*

Kamran Akbarzadeh[1], Hamid Reza Basseri[1], Soghra Doosti[1], Mehdi Nateghpour[2]

[1]Department of Medical Entomology and Vector Control, School of Public Health, Tehran University of Medical Sciences, Tehran;, [2]Dept. of Medical Parasitology, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran

Introduction: The new designed portable artificial feeding apparatus has been made first for routine rearing of mosquitoes in insectry of Tehran University of Medical Sciences. This cylinder shape apparatus has a 2.5 ml. volume feeding chamber. It safely works with an electrical heater (6 - 12 v. 3 - 4 a.) and a thermostat. Based on literature this system can be used for various scientific subjects such as infecting parasites to blood feeding arthropods for biological and physiological studies. This study has conducted with the aim of determining the capability of the apparatus for infecting *An. stephensi mysorensis* with *Plasmodium vivax*.

Methods: The parasites were obtained from malaria patients harboring gametocytes of *P. vivax* which were referring to health centers of Iranshahr County, southeastern of Iran, during Oct. to Dec. 2004. The apparatus equipped with Parafilm "M" as feeding membrane. All experiments have fulfilled in insectry condition with lab-bred Iranshahr strain of *An. stephensi* in Iranshahr Station of Public Health Research. Double walled cages used for preventing the escape of infected mosquitoes.

Results: In this study total numbers of 164 mosquitoes were fed successfully on infected blood. About 10.22 p 2.88% of them had developed oocysts on their midgut and about 9.68 p 4.95% had sporozoite in their salivary glands.

Conclusions: This study demonstrates that this apparatus can be easily employed for infecting the mosquitoes to malaria parasites. Natural infection of *An. stephensi Mysorensis* had recorded in Iran but this experimental infection provides an outline for further studies in laboratory.

POSTER PRESENTATION

Some observations on the distribution, behavior and hosts of the acacia bagworm *Auchmophila kordofensis* R. (Lepidoptera: Psychidae) in Kordofan, Sudan

Yasir G. A. Bashir[1], Mubarak O. Eljepori[2], Mohammed E. Abd Elrahman[2], Abbas A. Elshiekh[1]

[1]Agricultural Research Corporation, Wad Medani, Sudan, [2]University of Kordofan, Elobeid, Sudan

Introduction: The acacia bagworm *Auchmophila kordofensis*, was first identified in the year 1906 based on type specimens collected from Kordofan, Sudan. This pest remained for long time as a pest of no economical importance attacking only *Acacia nubica* trees. Recently, it emerged as a major pest defoliating many shrubs and tree species in western Sudan. This study investigated some aspects of its relative abundance, feeding behavior as well as it host range.

Methodology: Field surveys were conducted during 2001-2003 to determine the relative abundance of *A. kordofensis* larvae on different hosts. The number of larvae was expressed as number per m twig. Observations on feeding, movement as well as occurrence on different host plants were also monitored.

Results: Field surveys indicated that *Acacia nubica* was the most populated host plant followed by *A. seyal* and *A. tortilis*. The mean number of larvae/m twig during season 2001/2002, was 11.6, 5.3 and 1.3 larvae for *A. nubica*, *A. seyal* and *A. tortilis*, respectively. While during season 2002/2003, the number of larvae/m twig was increased to 18.9, 11.4 and 2.6 for the three hosts, respectively. Newly hatched larvae crawl out of the old bag, attach it self to a host branch and start feeding and constructing a cocoon. During feeding, the head and thorax projected from the case and attachment to branches was done by the thoracic legs. As the larva grows, its bag expands to comfortably accommodate the larva while molting takes place inside the bag. The list of host plants includes *A. seyal*, *A. tortilis*, *A. nilotica*, *Zyziphus spina-christi*, *Prosopis chilensis*, *Cassia senna*, baobab beside its principle host *A. nubica*.

POSTER PRESENTATION

Study of the entomofauna and biodiversity in an urban park in Madrid (Spain)

Laura Del Fresno, Luis Castresana, Antonio Vives, Pedro Ros, Antonio Notario

[1]Universidad Politécnica de Madrid, Madrid, Spain, [2]Sociedad Hispano Luso Americana de Lepidopterología, Madrid, Spain, [3]Asociación Española de Entomología, León, Spain, [4]Sociedad de Entomología Aplicada, Madrid, Spain

Introduction: This dissertation is realized in the Vicálvaro Forest Park (Madrid). The overall objective is to provide the necessary information to help make better management of the Vicálvaro Forest Park, as well as serve as a starting point for comparison and possible entomological studies of biodiversity within urban parks.

Methods: It has been in use traps with attractive of light and food.

Results: It is realized an exhaustive list of the species found, establishing its curves and flight detected which of these species are potentially harmful and which are not. At this point it is determined definitively biodiversity in the park, offering values of indices of biodiversity which serve as a reference for comparison in studies of another parks. It has been captured 157 species, belonging to 67genus and 66 Families. 54 of these species have identified accurately. A specimen belonging to the genus *Scythris* (Lepidoptera, Scythrididae) can be treated as a new species. The values of indices of biodiversity at level of Family and level of species are similar, so we recommend realizing, in this kind of works, the study to level family. The observed Species Richness is minor that the estimated Species Richness. The diversity of the Park is lower-middle; the index of Shannon is approximately 40 % of the maximum possible value for our case.

POSTER PRESENTATION

Laboratory and field investigations of pestiferous Chironomidae (Diptera) in man-made wetlands in central Florida, USA

Arshad Ali, Robert Leckel, Naphtali Carandang

Department of Entomology and Nematology and Mid-Florida Research and Education Center, University of Florida, Apopka, Florida, United States

A one-year population survey of pestiferous Chironomidae was conducted in four man-made wetlands in Florida. Benthic samples were randomly collected each month from each habitat. Geocoordinates, water depth, and substrates physical composition at each sample location were noted. Adult midge populations in the area were assessed by using New Jersey light traps monitored weekly. Chironominae and Tanypodinae occurred in the larval and adult samples; a few Orthocladiinae were also noted. Among Chironominae, Chironomini (mostly *Polypedilum* spp., *Cryptochironomus* spp., *Glyptotendipes paripes,* and *Goeldichironomus carus*) and Tanytarsini (mostly *Tanytarsus* spp.), and some other Chironomidae were recorded. Tanypodinae were quantitatively not important. Annual mean larval density and range of total chironomids amounted to 1,128/m^2, range: 0-12,332/m^2. The total larvae were most abundant in May. *Tanytarsus* spp. and *Polypedilum* spp. were the most predominant spatially as well as temporally. Monthly mean number of total adults per trap night ranged from 23 in February to 211 in October. Mean water depth at the sampled locations was 1.83 m; 47% of the total larvae occurred at < 1 m and 53% at > 1 m water depths. Of all the sampled locations, 51, 28, and 22% predominated with sand, mixed, and muck substrates, respectively. The predominance of sand and mixed substrates was conducive to supporting the numerically dominant *Tanytarsus* spp. and *Polypedilum* spp. In laboratory bioassays, *Tanytarsus* spp., *Polypedilum* spp., *G. carus*, and *G. paripes* were highly susceptible to temephos and to *s*-methoprene. *Bacillus thuringiensis israelensis* was most effective against *Tanytarsus* spp. and least against *G. carus*.

POSTER PRESENTATION

Distribution of neuropeptides in the cephalic nervous system of the Mediterranean flour moth, *Ephestia kuehniella*

Silvie Fexova[1], Radka Zavodska[2], Ivo Sauman[3]

[1]Faculty of Science, University of South Bohemia, Branisovska 31, 370 05 Ceske Budejovice, Czech Republic, [2]Pedagogical Faculty, University of South Bohemia, Jeronymova 10, 371 15 Ceske Budejovice, Czech Republic, [3]Biology Centre ASCR, Institute of Entomology, Branisovska 31, 370 05 Ceske Budejovice, Czech Republic

Introduction: Insect neurohormones influence many physiological processes and some have been proved to be associated with circadian timing as well. Both spatial and temporal localization of seven candidate neuropeptides (allatostatin, allatotropin, eclosion hormone, prothoracicotropic hormone, diuretic hormone, pigment-dispersing factor and corazonin) have been determined in the brain of *Ephestia kuehniella* (Pyralidae, Lepidoptera) in order to explore their possible connection to the circadian clock system.

Methods: Immunocytochemical methods on paraplast sections as well as the whole mount preparations were used to investigate the distribution of immunoreactive neurons in the brains of both sexes.

Animals were kept under 12:12 LD regime and brains were dissected at two time points, ZT 4 and ZT 16.

Results: All the antibodies reacted with a restricted population of cells within the cephalic ganglion-retrocerebral complex of *Ephestia kuehniella* and each produced a distinct staining pattern. The number as well as the localization of the immunopositive cells seemed to be the same in both sexes and does not vary between the night and day samples. The immunoreactive material was always confined to the cytoplasm.

Conclusion: The distribution pattern of some of these neuropeptides, particularly that of corazonin and pigment-dispersing factor, indicates their possible connection to the circadian clock system as the immunoreactive cells seem to correspond both in number and position to neurons that were previously recognized as hosting the circadian clocks in other lepidopterans. It seems that the expression of none of the investigated neuropeptides oscillate throughout the day.

POSTER PRESENTATION

The corazonin- and PDF-immunoreactivities in the brain of termites do not differ among the castes and show no circadian fluctuations

Radka Zavodska[1], Chih-Jen Wen[2], Ivo Sauman[3]

[1]Pedagogical Faculty, University of South Bohemia, Jeronymova 10, 371 15 Ceske Budejovice, Czech Republic, [2]Department of Entomology, National Taiwan University, Taipei, Taiwan, [3]Biology Centre AV CR, Institute of Entomology, Branisovska 31, 370 05 Ceske Budejovice, Czech Republic

Introduction: The neuropeptides pigment-dispersing factor (PDF) and corazonin (Crz) are tentative components of the output pathway of circadian clocks in insects.

Methods: Antibodies to [His^7]-corazonin and to the pigment-dispersing factor were used for immunocytochemical detections of neurons in the central nervous systems of workers and soldiers of seven termite species.

Results: Slight variance between workers and soldiers was found in *Coptotermes formosanus* in which the soldiers lacked 4 Crz-immunoreactive (Crz-ir) perikarya in the *pars intercerebralis* and consistently possessed 4 central perikarya in the labial neuromere, whereas some workers had 6 perikarya in this position. Comparison of the pseudergates, soldiers, and replacement reproductives in *Prorhinotermes simplex* also did not disclose any caste-specific differences. The PDF-immunoreactivity (PDF-ir) occurred in all castes in 3 cells at the base of each optic lobe and in a single cell in the soboesophageal ganglion. The Crz-ir was confined to three lateral clusters in each protocerebral hemisphere. Diurnal changes in PDF-ir and Crz-ir were examined in *P. simplex* kept under a long day (18 hr light and 6 hr darkness) or a short day (10:14 hr light: darkness) photoperiods. No circadian fluctuations in the distribution or the intensity of immunostaining were found in the pseudergates that were sacrificed in 4 hr intervals. No differences were also revealed in 6 hr intervals in the male and female replacement reproductives.

Conclusions: The corazonin- and PDF-immunoreactivities in the central nervous system of termites did not revealed differences among the castes and demonstrated no circadian fluctuations

POSTER PRESENTATION

Systematics and co-evolution of insect herbivores on the Casuarinaceae

Gary Taylor[1], Andy Austin[1], John Jennings[1], Matthew Purcell[2], Nancy Schellhorn[3]

[1]Australian Centre for Evolutionary Biology & Biodiversity, The University of Adelaide, Adelaide, South Australia 5005, Australia, [2]USDA-ARS Office of International Research Programs, Australian Biological Control Laboratory, CSIRO Entomology, Indooroopilly, Brisbane, Queensland 4068, Australia, [3]CSIRO Entomology, Indooroopilly, Brisbane, Queensland 4068, Australia

Introduction: The Casuarinaceae are a significant component of the Australian flora that represents a relict lineage of Gondwanan origin. They possess a unique combination of morphological characters dominated by xeromorphic reductions such as drooping twigs with an apical whirl of reduced scale-like leaves, reduced wind-pollinated flowers, woody 'cones' and wind-dispersed 'samaras' as seeds. Three Australian species, *Casuarina equisetifolia, C. glauca* and C. *cunningamiana* have become serious invasive weeds in southern Florida, including the Everglades National Park. With its rapid growth, dense coverage and thick litter accumulation, *Casuarina* dramatically alters the habitat of infested areas inhibiting growth of native plants and associated herbivores.

Methods: In Australia, the Casuarinaceae has a unique complex of associated insect herbivores that are generally poorly documented. Nor are there any comprehensive studies on the evolutionary events that have driven speciation. In this study the molecular phylogenies of selected taxa will be generated, and compared with the phylogeny for the Casuarinaceae, to test whether insect herbivores and their hosts have co-evolved. It will refine the selection process for identifying suitable biological control agents by utilising a molecular basis for assessing host specificity and host range.

Results: Surveys conducted primarily in eastern Australia have yielded a number of herbivores groups amenable to comparative phylogenetic analysis. These include granivorous micro-Hymenoptera (Torymidae), narrowly host-specific psyllids (Triozidae), *Cylindrococcus* and other eriococcid gall and scale insects, and a major radiation of *Misophrice* weevils (Curculionidae).

Conclusions: It is hypothesised that phylogenies synchronous between herbivore and host would indicate a close evolutionary association that would confer considerably safer options as potential biological control agents than in a group that may have radiated on many host taxa.

POSTER PRESENTATION

Mixed cropping and intercropping as cultural means of control for some cucurbit pests

Abdalla A. Satti

Environment and Natural Resources Research Institute, National Centre for Research, Khartoum, Khartoum State, Sudan

Introduction: Both mixed cropping and intercropping can be defined as growing different crops simultaneously on the same land, but intercropping is characterized by having a base crop and one or more associated crops planted within. Apart from their agronomical merits, they sometimes perceived as cultural means of pests and/or diseases control. However, these cropping systems were attempted in this study for the purpose of mitigating damage of some cucurbit pests.

Methods: The study included five field experiments carried out at Shambat, Khartoum-North, Sudan. A mixed cropping of *Cucumis melo*, *Abelmoschus esculentus*, *Solanum melongena*, *Vigna unguiculata* and *Lablab purpureus* was conducted during late autumn (Sep.-Nov.) where the distribution of *Bemisia tabaci* and *Jacobiasca lybica* were studied. Similarly, five cucurbit species were screened against *B. tabaci*, *Aphis gossypii* and *Epilachna elaterii* during winter season (Nov.-Feb.). Moreover, the effects of intercropping either fenugreek or coriander with cucumber on the *E. elaterii* were evaluated, each in a separate winter experiment.

Results: Results of the first experiment showed that the population mean of *B. tabac*i was significantly higher on *L. purpureus*, whereas *J. lybica* was significantly higher on *S. melongena*. Since the two pests were drastically suppressed on muskmelon (*C. melo*), intercropping either of these crops with muskmelon (or other cucurbits) should be emphasized separately depending on each pest infestation. However, comparing cucurbit species muskmelon was almost lied among the highly infested crops by *B. tabaci*, *A. gossypii* and *E. elaterii*. In this sense *Citrullus colocynthis* was detected as the most repellent plant for the two former pests, but attractant for the latter one. On the other hand, fenugreek and coriander significantly reduced infestation and damage by *E. elaterii* on intercropped cucumber.

Conclusions: Mixed cropping and intercropping were proved effective in controlling some important cucurbit pests particularly *B. tabaci*, *J. lybica* and *E. elaterii*. *L. purpureus*, *S. melongena* and *C. colocynthis* showed attractant effect to the three pests, respectively. Hence, they can be checked as trap crops.

POSTER PRESENTATION

Chalcidoid wasps associated with galls on southern African plants: records from a specimen-based database

Ottilie Neser

ARC-Plant Protection Research Institute, Pretoria, South Africa

Databasing of the chalcidoid specimens at the National Collection of Insects, Pretoria, began in 2001 and the database currently contains details of specimens with host data of all the large families (with the exception of some Encyrtidae and Aphelinidae). The more than 11000 records in the database reflect the wealth of taxonomic, biological and distributional information present in the drawers of the collection. Most specimens have been identified to generic level, but a large proportion remains unidentified at species level. The great diversity of chalcidoids associated with (but not necessarily causing) galls on southern African plants is strikingly brought home by the captured data, with over 850 entries reflecting chalcidoids that emerged from galls. The database should greatly aid further collection and study of galls and their associated parasitoid faunas, by making the mostly unpublished information more readily accessible to the research community. A list of the chalcidoid families, genera and species that are associated with or emerged from galls, is provided. Plant families, genera and species as well as plant parts affected by the galls from which chalcidoids emerged, are recorded. Details of insect and other arthropod hosts present in the galls, and a map showing the collection sites in southern Africa are included. Some interesting examples of galls, the possible or known gall formers and their associated parasitiod complexes are highlighted. Unfortunately very little is known about the biology of many species developing inside these galls – 'who does what' often remaining a mystery.

POSTER PRESENTATION

Status quo of honeybee (*Apis mellifera* L.) pests and diseases in Sudan

A. A. Mogbel El-Niweiri, Abdalla A. Satti

Environment and Natural Resources Research Institute, National Centre for Research, Khartoum, Khartoum State, Sudan

Introduction: Honeybees are found naturally in Sudan since ancient time and traditional beekeepers are present. Recently, modern beekeeping has been flourished using imported colonies, so the threat of spreading exotic pests and diseases was expected. Since few data is available in this field, it was aimed by this work to recognize important pests, predators, diseases and parasites of honeybees and their incidences in different parts of the country.

Methods: Data were collected through intensive surveys and questionnaires covering nine bee areas (States) in Sudan during the period 2003 - 07. Different modern and traditional apiaries and wild colonies were inspected, where the percentages of affected colonies by major pests or diseases were indicated in most areas. Samples taken included 122 local colonies and 350 Carnio-Egyptian colonies plus 30 colonies of *Apis florea*. Detected insects were mostly identified at the Insect Collection of the Agricultural Research Corporation(ARC), Sudan, whereas vertebrate species identified either at the Wild Life Research Centre, ARC or Sudan Institute for Natural Sciences. Suspected diseases were confirmed through laboratory culturing and biochemical tests followed at the Department of Microbiology, Faculty of Veterinary Sciences-University of Khartoum.

Results: Lists of more than 35 pests and predators of honeybees were recorded at variable levels in different areas. They include mainly insect and vertebrate species and few spiders. Among these, twenty species were new records e.g. the hive beetles, bee wolves, squirrel and honey badger. However, many species were found causing serious problems such as *Galleria* moth (86.3% infested colonies), ants and two predatory birds (*Merops* spp.). On the other hand, all areas were found free of most bacterial and fungal diseases, except the bacterial brood disease, *Serratia marcescens*, found in 2.6% of Khartoum colonies. Moreover, the parasitic mite, *Varroa jacobsoni*, was found firstly infecting 75% of colonies in Khartoum State as new record, thenceforth detected in Sennar and Kordofan States.

Conclusions: Various indigenous pests of honeybees were found in Sudan and some exotic pest and disease species were introduced through commercial beekeeping.

POSTER PRESENTATION

Comparative analysis of larval developments of *Lucilia sericata* Meigen (Diptera: Calliphoridae) from different geographic populations at constant temperatures

Matthias Gosselin[2], Yves Braet[1]

[1]National institut of Criminology and Criminalistics, Brussels, Belgium, [2]University of Mons-Hainaut, Mons, Belgium

Introduction: *Lucilia sericata* Meigen (Diptera, Calliphoridae) is a very common forensic fly in the temperate area of the northern hemisphere but is also widespread throughout the major zoogeographical regions. Available publications show that its development depends of the geographical origin of the population. This variation could be driven by local adaptation (intrinsic factors).

Methods: Two modelling methods (linear and non-linear) were used to estimate the developmental constants (Development Minimum Threshold, Thermal Constant) for a Belgian population of *L. sericata* at different constant temperatures. The developments periods (in days) of this population and from previously published studies were compared to verify if larval development is subject to geographical variation. The percentage of pupae emerging successfully was counted at the same temperatures.

Results: New development periods were recorded for extreme temperatures and new developmental constants have been estimated. The developmental periods were observed to be longer than those published before. This difference could be caused by variation of development between different populations of blowflies. It emphasizes that there are large variations in developmental data that have been measured across the temperature range between different publications. The minimal, optimal and maximal temperature for survivorship have been calculated and compared with the former publications.

Conclusions: The variation in developmental rates emphasizes the importance of using local developmental data to estimate PMI in forensic cases. Thermal data coming from the same or a nearby population are important to give a best PMI estimation.

POSTER PRESENTATION

Insect growth regulator novaluron to control Nitidulidae sap beetles in strawberries

James Price, Curtis Nagle

University of Florida, Wimauma, Florida, United States

Introduction: Strawberries valued at 210 million USD were produced on 3,200 ha. in Florida, USA during 2006-2007. Main arthropod pests include the twospotted spider mite (*Tetranychus urticae*), cyclamen mite (*Phytonemus pallidus*), southern and fall armyworms (*Spodoptera eridania* and *S. frugiperda*), strawberry root and melon aphids (*Aphis forbesi* and *A. gossypii*), flower thrips (*Frankliniella bispinosa* and *F. occidentalis*), and sap beetles (principally *Lobiopa insularis* and *Haptoncus luteolus*). Sap beetle adults enter fields in late winter, chew holes in ripe fruit and reproduce there. The presence of small numbers of adults or their larvae in fresh fruit can inflict significant economic damage. Growers largely depend on their removing all ripe fruit from the field and applying the pyrethroid insecticides, bifenthrin and fenpropathrin, but find these tools insufficient to manage the problem adequately. The pyrethroids disrupt natural and applied biological control of other arthropods.

Methods: Two experiments were conducted in 2006 and one in 2007 to determine the usefulness of aqueous sprays of novaluron, the benzoylurea inhibitor of chitin biosynthesis insecticide, for management of sap beetles in strawberries. Novaluron was applied at 87 g/ha. with and without bifenthrin applied at 168 g/ha. twice at 1 week intervals.

Results: Novaluron provided excellent control for sap beetles with or without bifenthrin.

Conclusions: The insect growth regulator, novaluron, can be useful to control sap beetles in strawberries and additionally contribute a new mode of action to the control options. The additional mode of action can enhance programs that reduce probabilities of resistance to chemical control measures.

POSTER PRESENTATION

Life-history and phenology of the non-native *Halyomorpha halys* (Stål) (Hemiptera: Pentatomidae) in the United States

Anne Nielsen[1], Gary Bernon[2], George Hamilton[1]

[1]Rutgers University, New Brunswick, NJ, United States, [2]USDA-APHIS CPHST, Cape Cod, MA, United States

The brown marmorated stink bug, *Halyomorpha halys* (Stål) (Hemiptera: Pentatomidae), is an Asian species that was accidentally introduced into the United States in the mid 1990's into Allentown, PA. We conducted weekly beat samples on ornamental trees and shrubs from 2005-2007 to determine its seasonal phenology and population dynamics as well as the relative abundance of native species of stink bugs. Several host plants were identified as being able to support nymphal development, including *Paulownia tomentosa*, one of its known host plants in its native range. However, despite being univoltine, degree-day accumulations and female ovarian development indicate that a proportion of first generation females become reproductively mature. A small increase in temperature could lead to a second generation in the Mid-Atlantic States. On the host plants we sampled, *H. halys* was the most predominant stink bugs species, far outnumbering native species.

POSTER PRESENTATION

Calreticulin expression and endoplasmic reticulum organization during ovulation and early embryogenesis of *Rhodnius prolixus*

Isabela Ramos[1], Claudia Campos[3], Marcos Sorgine[2], Francisco Nobrega[3], Marina Nobrega[3], Kildare Miranda[1], Wanderley Souza[1], Ednildo Machado[1]

[1]IBCCF, UFRJ, Rio de Janeiro, Brazil, [2]IBqM, UFRJ, Rio de Janeiro, Brazil, [3]IPD, UNIVAP, Sao Paulo, Brazil

Endoplasmic reticulum (ER) is the most important intracellular compartment involved in calcium storage and release, and calreticulin is a multifunctional ER resident chaperone that buffers calcium with high capacity. Egg activation is a complex process that triggers events necessary for the egg to support the early development, including extensive transient rises in intracellular free calcium. This work reports calreticulin expression levels and endoplasmic reticulum organization during ovulation, fertilization and early embryogenesis of the bug *Rhodnius prolixus*. Calreticulin was cloned and its coding sequence was obtained. Real time PCR evidenced that during ovulation and fertilization, calreticulin expression remains at low levels when compared to laid fertilized eggs. Immunohistochemistry showed that this protein is mainly located in the periphery of the eggs, and transmission electron microscopy revealed the existence of a thin differential peripheral ooplasm, external to the yolk granules-filled central ooplasm. It was showed that ovulated oocytes present alterations in the peripheral ooplasm, chorion and permeability, thus suggesting that ovulation triggers the initiation of egg activation. Immunoelectron microscopy evidenced that during ovulation and fertilization the ER (calreticulin labeled) is presented as dispersed lamellae and vesicles, and transmission electron microscopy showed that only after oviposition an organized rough ER is found, filling the peripheral ooplasm. Thus, it was reported that ovulation might trigger initiation of the egg activation, and that even though this process is marked by extensive events of Ca^{2+} release it does not involve alterations or organization of the ER.

Parasitoids complex of *Trioza erytreae* (Del Guercio) (Homoptera:Triozidae), african citrus psyllid, in Cameroon.

Tamesse Joseph Lebel

University of Yaounde I, Ecole Normale Supérieure, ; Laboratory of Zoology, P.O Box 047 Yaounde, Cameroon

In Cameroon, citrus is under the permanent attacks of *Trioza erytreae*, african citrus psyllid; this insect is the vector of the greening disease of citrus. In this country, chemical control against *Trioza erytreae*, does not abate the high level of the pest populations in citrus orchards. Biological control would be the most promising way to limit these populations in the country. The psyllid parasitism was studied on attacked citrus plants. Mummified larvae were collected in a citrus orchard in the area of Yaounde (Cameroon), and on isolated citrus trees and *Clausena anisata* trees, one endemic Rutaceae in Cameroon. These mummies were observed in the laboratory and the hymenoptera which emerged were identified. The total parasitism level was approximately 15%. The inventory of the parasitoïd species of *T. erytreae* showed the presence of primary parasitoids: *Psyllaephagus pulvinatus* (36.3%), *Tamarixia dryi* (3.5%), *P. secus* (3.3%), *Psyllaephagus* sp. (0.6%), *P. chiangamus* (0.6), *Dilyta* cf *camerounensis* (0.4%) and *Coccophagus pulvinariae* (0.03%); and hyperparasitoids: *Aphidencyrtus (Syrphophagus) cassatus* (45.3%), *Tamarixia* sp. (6.8%), *Tetrastichus* sp. (1.5%), *Marrieta javensis* (0.2%), *Physcus* sp. (0.2*%), Aphanogmus* sp. (0.2%) and *Cheiloneurus cyanonotus* (0.1%). The parasitoïd fauna of *T. erytreae* is diversified in Cameroon. Certain species are cited on this psyllid for the first time: *Aphanogmus* sp., *Tamarixia* sp., *Psyllaephagus chiangamus*, *Psyllaephagus* sp., *Psyllaephagus secus* and *Dilyta* cf *camerounensis*. The conservation of the biodiversity of these parasitoids of *T. erytreae* is an interesting advantage in initiating biological control against this important citrus pest in the country.

POSTER PRESENTATION

Parasitoids complex of *Trioza erytreae* (Del Guercio) (Homoptera: Triozidae), the African citrus psyllid, in Cameroon

Tamesse Joseph Lebel

University of Yaounde I, Yaounde, Cameroon

Introduction: The position of termites among the Dictyoptera has long been disputed. I present molecular evidence to show conclusively that termites are cockroaches. However, termites have diverged from cockroach traits in many ways, particularly through the greater phenotypic plasticity that eusociality has provided.

Methods: I will present two phylogenetic datasets, one for Dictyoptera (five genes) and a larger one for termites (three genes) as well as data on gut structure and function.

Results:.Termites are eusocial cockroaches. However, termite eusociality has allowed for an extraordinary range of behavioural, anatomical and physiological traits to evolve. One good example is trophic ecology - a wider variety of feeding substrates can be consumed by termites than by other closely related cockroaches. This has been made possible through the development of specialised castes that have freed workers to evolve gut structures not possible, for intrinsic design-cost reasons, in other cockroaches. These changes are not just observed between *Cryptocercus* and other termites, but also found in other parts of the tree: the general trend being from mid-gut detritivory to hind-gut fermenting. I will discuss the evolutionary and ecological consequences of these changes.

Conclusions: Eusociality has allowed termites to become a very sophisticated sort of cockroach.

POSTER PRESENTATION

Development of *Chrysomya marginalis* Wiedemann 1830 (Diptera: Calliphoridae) at different temperatures for the estimation of post mortem interval

Philip S. R. Weyl, Martin H. Villet

[1]Rhodes University, Grahamstown, South Africa, [2]Rhodes University, Grahamstown, South Africa

Chrysomya marginalis is a carrion-breeding fly, which gives it the potential of being important in forensic investigations to determine post mortem interval (PMI). The developmental curves were established for eight different constant temperatures using length and developmental landmarks and actual age. The thermal summation constants (K) and developmental threshold (D_0) were calculated for five developmental landmarks using the method described by Ikemoto & Takai (2000). Isomorphen and isomegalen diagrams were also constructed for the purpose of PMI. *Chrysomya marginalis* had an average developmental threshold (D_0) of 14.04 ºC (SE = 0.70 ºC, n = 4), and the thermal constant (K) was 74.25 hºC (SE = 2.23) at 1st ecdysis, 566.64 hºC (SE = 42.77) at 2nd ecdysis, 1007.66 hºC (SE = 81.71) at the wandering stage, 1489.91 hºC (SE = 128.37) at pupariation and 3299.53 hºC (SE = 183.99) for eclosion. *Chrysomya marginalis* has a preference for larger carcasses, which makes the results from this study valuable for wildlife management and poacher control.

POSTER PRESENTATION

Preliminary molecular phylogenetics and inferred historical biogeography of three African cicada genera of the Platypleurini (Hemiptera: Cicadidae)

Tarryn Goble, Benjamin Price, Nigel Barker, Martin Villet

Rhodes University, Grahamstown, South Africa

Cicadas provide interesting models for mechanistic studies of biogeography because they are often habitat-specific and their present distributions may reflect past geological history. Representatives of 14 African platypleurine genera were included in this study. Of particular interest were the arid-adapted cicada genera, *Munza*, *Severiana*, and *Soudaniella* that all have biogeographic ranges which include the Kalahari Desert system in southern Africa. Separate phylogeographic analyses of these genera using two mitochondrial genes, *Cytochrome oxidase* I (*COI*) and the large ribosomal subunit *16S* rRNA revealed some discrepancy in the resolution of cicada clades. The separate *COI* and *16S* analyses resolved *Munza* as a well-supported monophyletic group with the genus *Severiana* forming its sister group, but in the combined analysis *Munza* was no longer monophyletic. Molecular dating analyses, calibrated using published *COI* and *16S* substitution rates typical for related insects, showed that the *Munza, Severiana*, *Soudaniella* and *Capcicada* lineages probably date back to the late Miocene or early Pliocene (4.4-8.1 MYA) with a second diversification occurring within *Munza* during the Pleistocene (1.0-2.7 MYA). These diversifications coincide with both the development of the Kalahari Desert at about 5 MYA and the subsequent movement of alluvial sands that have been active since the Pliocene-Pleistocene transition.

POSTER PRESENTATION

Implications of a preliminary molecular investigation of four African cicada genera in the tribe Parnisini (Hemiptera: Cicadidae)

Tarryn Goble, Benjamin Price, Nigel Barker, Martin Villet

Rhodes University, Grahamstown, South Africa

The Cicadidae of southern Africa have not been systematically revised since the publication of Distant's *Insecta Transvaalensia* in 1906, leaving a confusing account of their classification, particularly the poorly-studied tribe Parnisini. Approximately 772 base pairs of mitochondrial DNA from the *Cytochrome oxidase* subunit 1 (*CO1*) gene, from 44 samples, representing the parnisine genera *Koranna*, *Masupha*, *Neomuda*, *Oudeboschia*, *Quintilia*, *Zouga*, were sequenced. Analysis of the sequences revealed that the type species of *Quintilia*, *Q. rufiventris*, appeared to be phylogenetically isolated, implying that the genus *Quintilia* was currently not a monophyletic group, but a taxonomic dumping ground for many cicada species and that its revision was required. All analyses provided good evidence that *Quintilia walkeri* and the *Q. carinata* species-group formed a monophyletic clade. The genus *Masupha* was recognised as a distinct clade. The formation of a clade of *Quintilia* species around the type species of *Koranna* was supported by a strong pattern of common biogeographic distribution, suggesting that many *Quintilia* species should be transferred to *Koranna*. The genera *Neomuda*, *Oudeboschia* and *Zouga* appeared to have little in common with the other Parnisini.

POSTER PRESENTATION

In vivo pathogenicity of *Beauveria bassiana* and *Metarhizium anisopliae* on *Chrotogonus trachypterus* (Orthoptera: Pyrgomorphidae)

Ali Mirshekar, Aziz Kharazi-Pakdel

Department of Plant Protection, Faculty of Agriculture, University of Tehran, Karaj, Tehran, Islamic Republic of Iran

Introduction: Concerns over the environmental and human health impacts of chemical control of grasshoppers have led to considerable interest in developing of alternative control methods e.g. using entomopathogenic fungi.

Methods: Effects of two native isolates of the fungus *Beauveria bassiana*, a native isolate of *Metarhizium anisopliae* a long with Green Muscle™, a commercialized formulation of *M. anisopliae* var. *acridum*, were investigated on the sugarcane grasshopper and some other short and long-horned native grasshoppers. LD_{50} and LD_{99} were separately calculated for male and female adults also without regarding their sex.

Results: The results showed the pathogenicity of all isolates of *M. anisopliae* and *B. bassiana* against the studied grasshopper. The lowest LD_{50} obtained as 187 spore/insect for female insects treated with the native isolate of *Metarhizium anisopliae* and the highest was calculated as $2/06\times10^5$ spore/insect for biologically-treated male insects. Comparison between LD_{50} and LD_{95} off all isolates were demonstrated that native isolate of *Metarhizium anisopliae* had the lowest LD_{50} ; Other native isolates had high pathogenicity rather than commercialized product. The results indicated that insect susceptibility was decreased with increasing of age.

Conclusions: These results indicate that more studies is essential in order to isolation of native strains of entomopathogenic fungi and determination of their effectiveness on insect pests.

POSTER PRESENTATION

Stored pests control by cineole essential oil

Vlatka Rozman[1], Zlatko Korunic[2], Irma Kalinovic[1], Anita Liska[1]

Faculty of Agriculture, University of J.J. Strossmayer in Osijek, Osijek, Croatia[1], Diatom Research and Consulting Inc., Guelph, Canada[2]

Introduction: Laboratory research to control *Sitophilus oryzae* L., *Rhyzopertha dominica* F., *Cryptolestes ferrugineus* L. and *Tribolium castaneum* Herbst. by cineole essential oil aimed to find out potential source of new fumigants.

Methods: Three experiments with cineole were done: first, to test efficacy of cineole against different developmental stages of insects; second, to test effective concentration of 50, 100, 150, 200, 250 µl/L; and third, to test effective cineole concentration in spaces differently occupied with wheat (empty space, 50% and 95% filled up).

Results: Developmental stages of *C. ferrugineus* in wheat grain were more sensitive to cineole in comparison to the remaining tested species. By testing 5 concentrations of cineole, 100% mortality of *C. ferrugineus* was obtained with 50 µl/L. However, 100% mortality of *R. dominica* was obtained with concentration of 150 µl/L, with *S. oryzae* and *T. castaneum* at concentration of 250 µl/L.Concentration of cineole of 50µl/L in empty space induced nearly 100% mortality in all four tested insect species, while results of fumigation of space occupied with wheat (50% and 95%) did not prove to be successful and acceptable.

Conclusion: Cineole proved to have fumigant effect *in vitro*, but it would be needed to apply high concentrations relative to phosphine or methyl bromide to gain satisfactory results.

POSTER PRESENTATION

Ecological niche and potential geographic distribution of the invasive fruit fly *Bactrocera invadens* (Diptera: Tephritidae)

Marc De Meyer[1], Mark Robertson[2], Mervyn Mansell[3], Sunday Ekesi[4], Kenji Tsuruta[5], William Mwaiko[6], Jean-François Vayssières[7], A. Townsend Peterson[8]

[1]Royal Museum for Central Africa, Entomology Section, Tervuren, Belgium, [2]Department of Zoology and Entomology, University of Pretoria, Pretoria, South Africa, [3]United States Department of Agriculture, APHIS, Pretoria, South Africa, [4]International Centre of Insect Physiology and Ecology, Nairobi, Kenya, [5]Moji Plant Protection Station, Nishikaigan, Moji-ku, Kitakyushu, Japan, [6]Ministry of Agriculture and Food Security, Plant Health Services, Dar es Salaam, Tanzania, United Republic of, [7]CIRAD, UPR Production Fruitière, Montpellier, France, [8]Natural History Museum and Biodiversity Research Center, University of Kansas, Lawrence, Kansas, United States

Two correlative, evolutionary-computing solutions to the challenge of ecological niche modeling techniques (genetic algorithm GARP, maximum entropy Maxent), were used to predict the potential distribution of the invasive fruit fly, *Bactrocera invadens* based on known occurrence records and a set of environmental predictor variables. The two models yield similar potential ranges, largely corresponding to Equatorial climate classes with high precipitation. Maxent may be more conservative in its evaluation of suitability (depending on the threshold levels taken into account), excluding areas with distinct dry seasons, while GARP models indicate that climate class as partly suitable. Field observations in Benin and Tanzania confirm relationships between seasonal occurrences and the abiotic factors of humidity and temperature.

POSTER PRESENTATION

Host range and partitioning of fruit-infesting pestiferous fruit flies (Diptera: Tephritidae) in Central Tanzania

Maulid Mwatawala[1], Marc De Meyer[2], Rhodes Makundi[3], Amon Maerere[1]

[1]Department of Crop Science and Production, Sokoine University of Agriculture, Morogoro, United Republic of Tanzania, [2]Royal Museum for Central Africa, Entomology Section, Tervuren, Belgium, [3]Pest Management Centre, Sokoine University of Agriculture, Morogoro, United Republic of Tanzania

The host range of major fruit fly pests in Central Tanzania was evaluated from October 2004 to October 2006. Samples of 48 potential hosts were collected and incubated for fruit flies emergence. *Bactrocera invadens* was the dominant species, both in host plant range, incidence expressed as the ratio of infested to total number samples collected, as well as infestation rate expressed as number of flies emerging per unit weight. Nine new host fruits are reported for this invasive species. Infestation by native fruit fly pests, such as *Ceratitis capitata* and *C. cosyra* was minor compared to *B. invadens*. *Ceratitis rosa* was the dominant species in temperate fruits, and Cucurbitaceae were mainly infested by *Bactrocera cucurbitae*, a specialized cucurbit feeder. Among commercial fruits, high infestation incidences were observed in mango and guava, but they decreased throughout the fruiting season. Low infestation incidences were observed in all *Citrus* species sampled and in avocado indicating these fruits as poor hosts for the studied fruit fly pests in this region. Fruit species studied here provide suitable hosts for year-round breeding of *B. invadens*, while this is not apparent for the other fruit fly pests studied. Seasonal infestation differs with mango being the most important host in October to January, while guava being important from February to August. Tropical almond showed very high incidence and infestation rate for *B. invadens* and might act as an important reservoir host bridging the fruiting seasons of mango and guava. Soursop acts as an important host for *C. cosyra* after the mango season. *Ceratitis capitata* is a pest of minor importance of the commercial fruits studied in this region.

POSTER PRESENTATION

Management of *Sitophilus oryzae* and *Tribolium castaneum* in stored rice by traditional parboiling as practiced in Guinea

Aïssata Camara[1], Charles Vincent[2], Michel Raymond[1]

[1]Institut des sciences de l'environnement (ISE), Université du Québec à Montréal (UQAM), C.P. 8888, succursale Centre-Ville, Montréal, Qc, Canada, [2]Horticultural Research and Development Center, Agriculture and Agri-Food Canada, 430 Gouin Blvd., Saint-Jean-sur-Richelieu, Qc, Canada

Introduction: In Guinea, traditional methods are used to manage insect pests of stored grains. However, the entomological effect of such traditional methods is often unknown.

Methods: We quantified the effect of parboiling as a procedure to manage two bruchid pests, *Sitophilus oryzae* L. and *Tribolium castaneum* Herbst, over a period of three months. Three types of rice (i.e. white, red and paddy) were used in two experiments conducted with the collaboration of peasants from the surroundings of Conakry (Guinea). In experiment 1, *S. oryzae* was used as a sole pest to infest the rice. Parboiled paddy rice had the lowest level of infestation after 15 days, as determined by the number of emerged adults.

Results: Oviposition was significantly lower in parboiled paddy, white and red than in respective control rice types. In experiment 2, the lowest levels of infestations were found in parboiled paddy rice and parboiled white rice. Trends similar to those of experiment 1 were determined regarding oviposition.

Conclusions: We conclude that traditional parboiling is efficient to manage the two insect pests in post-harvest situations akin to guinean peasantry. The next challenges are to foster greater usage of this traditional method to the peasants and to verify its effect on other major post-harvest pests.

POSTER PRESENTATION

Educational programs for indoor pest control in the United States

Susan King, James Fredericks

University of Delaware, Newark, Delaware, United States

From September 2006 to September 2007, eight educational workshops for homeowners were delivered in Delaware, USA through the Cooperative Extension System. The workshops were attended by 129 individuals. All attendees received informational packets that included two magnetized color plates for attaching to their refrigerators: “Indoor Pest Control Decisions - Ants” and “Indoor Pest Control Decisions - Pantry Pests.” Post workshop surveys showed that 83% of attendees planned to use Integrated Pest Managements techniques the next time they had pest insects in their homes. In November 2007, Home Paramount Pest Control provided 100 of their customers with the same magnetized color plates. These individuals were not offered educational workshops. Attitude and behavioral comparisons will be made between homeowners who attended workshops and those who did not.

POSTER PRESENTATION

The seasonal occurrence, soil distribution and flight characteristics of the lesser chestnut weevil, *Curculio sayi* (Coleoptera: Curculionidae) in Mid-Missouri

Ian Keesey, Bruce Barrett

Entomology Program Area, Division of Plant Sciences, University of Missouri, Columbia, Missouri, United States

Introduction: Following the chestnut blight in the early 19th century, the overall range of the American chestnut tree (*Castanea dentata*) was greatly reduced. As interest in the restoration of this tree increases, and as commercial production of chestnut fruit is being developed in the Midwest, multiple aspects of commercial production, such as pest management of key chestnut pests, need to be addressed. This study examined some basic biological aspects of the lesser chestnut weevil, *Curculio sayi* (Gyllenhal) in mid-Missouri: adult seasonal occurrence, soil distribution of immature stages, and adult flight characteristics.

Methods: Three trap types were used to monitor adult activity: ground-based cone traps, circle-trunk traps and pyramid (or Tedder's) traps. Soil containers were buried and mature larvae placed in them to ascertain larvae burrowing depth and time spent underground per developmental stage. A laboratory flight mill was used to examine adult flight characteristics.

Results: Adult weevils had distinct spring (usually May) and fall (August-September) emergence periods (not previously reported in the literature). Peak adult activity within the trees occurred during the fall emergence period (which coincided with nut production). Periodic removal of the buried soil containers over a two-year period revealed that the minimum duration of the underground larval stage was 17 months, and that the depth most larvae burrowed to was 7.5 to 15 cm. Preliminary data from the flight-mill study revealed that the average single flight times of adults lasted about 10 minutes, and that the distance was about 0.25 km for both sexes.

POSTER PRESENTATION

Biodiversity and key insect fauna on wheat agro ecosystem in Romania

Ioan Rosca, Rada Istrate, Constantin Popov

[1]*University of Agricultural Sciences and Veterinary Medicine; Bucharest, Bucharest, Romania,*
[2]*University of Agricultural Sciences and Veterinary Medicine; Bucharest, Bucharest, Romania,*
[3]*Agricultural Research and Development Institute - Fundulea, Fundulea, Romania*

Introduction: It is done a comparative study between useful and pest fauna from wheat agrocoenosis, taking into consideration Heteroptera insect from wheat, as an indicator of agro ecosystem biodiversity.

Methods: Researches referring biodiversity of insect fauna from wheat were done in field, by insect collecting from 10 to 10 days in the whole vegetation period, through pitfall traps, pheromone traps, Yellow sticky traps, entomological net and plant analysis for presence of insects on and in stem.

Results: There were registered species of insects from main insect orders (14133 specimens), and spiders (982 specimens) in wheat agro ecosystem, the most numerous insects were Homoptera (8502, especially aphids), followed by Hymenoptera (2138) and Diptera (1935). From order Heteroptera, there were identified representatives from 11 families, the most numerous being species from families Miridae and Nabidae. From raping Heteroptera, in wheat agro ecosystem the most important key species were representative of family Anthocoridae (*Anthocoris nemorum* L., *A. nemoralis* Fabr.) and Nabidae (*Nabis pseudoferus* Rm., *Nabis feroides* Rm., *Nabis rugosus* L. and *Nabis ferus* L.,), with regulating function in ecosystem. It has to underline the role of species *O. niger* as predator. It is discussed role of these insects in wheat agrocoenosis. The data collected allow to conclude that eventualy adverse effects on the biodiversity could be identified through data obtained regarding whole insect fauna from wheat and Heteroptera insect from wheat, as an indicator of agro ecosystem biodiversity, and Carabidae and Staphylinidae fauna captured in pitfall traps, calculating *Sorensen* index.

POSTER PRESENTATION

Studies of heteroptera insects from Romania: A case study of Heteroptera from wheat and corn, as an indicator of agro ecosystem biodiversity

Ioan Rosca, Constantin Popov

[1]*University of Agricultural Sciences and Veterinary Medicine; Bucharest, Bucharest, Romania,*
[2]*Agricultural Research and Development Institute Fundulea, Fundulea, Romania*

Introduction: Interest of more people jointed in actions referring to protect environment conservation, made to increase interest for study of useful fauna from different agrocoenosis. Heteroptera structure could be an indicator of biodiversity.

Methods: Zoogeographic analysis of whole Heteroptera fauna from Romania, was done on basis of Heteroptera species recorded in literature. The Heteroptera fauna from wheat and corn was analysed as an indicator of agro ecosystem biodiversity, being discussed role of these insects in these two agrocoenosis.

Results: There were registered species of insects from main Heteroptera families with 695 species signalled in Romania, 6 species (0,86%) – cosmopolitan; 48 species (6,90%) – Holarctic; 46 species (6,62%) – Palaearctic; 115 species (16,54%) – Euro-Siberian; 158 species (22,73%) – European; 230 species (33,12%) – Mediterranean; 57 species (8,20%) – Ponto-Mediterranean; 25 species (3,59%) – Turanian and only 10 species (1,44%) endemics.

A number of 80 species (11,51%) are useful of human economy because through their feeding way are limiting pest species populations. From order Heteroptera, there were identified representatives from 11 families, the most numerous being species from families Miridae and Nabidae. From raping Heteroptera, in wheat and corn agro ecosystem the most important key species were representative of family Anthocoridae and Nabidae, with regulating function in ecosystem. It is discussed role of these insects in wheat and corn agrocoenosis. The data collected allow to conclude that eventualy adverse effects on the biodiversity could be identified through data obtained regarding Heteroptera insect, as an indicator of agro ecosystem biodiversity.

POSTER PRESENTATION

IRAC International: Approaches to resistance management for insect-protected Biotech crops

Nicholas Storer[1], Graham Head[2], Jonathan Holloway[3], Ryan Kurtz[4], Elizabeth Owens[5]

[1]Dow AgroSciences LLC, Indianapolis, IN, United States, [2]Monsanto Co., St. Louis, MO, United States, [3]Bayer CropScience, Lubbock, TX, United States, [4]Syngenta Seeds, Inc., Research Triangle Park, NC, United States, [5]Pioneer Hi-Bred International, Johnston, IA, United States

In 2006, IRAC (Insecticide Resistance Action Committee; www.irac-online.org) established a Project Team to address resistance management issues with international significance related to insect-protected biotech crops. Maize and cotton varieties containing *cry* genes from *Bacillus thuringiensis* (*Bt*) are being commercially cultivated on 26.3 million hectares across 17 countries (2005 figures). This represents nearly 25% of the global cotton area and 12% of the global maize area. This area of cropland protected by *Bt* is rapidly increasing and the types of crops involved are broadening. It is in the interest of industry, in partnership with growers, universities, and governments, to preserve the long-term benefits of *Bt* crops by taking proactive resistance management measures that maximize the utility of the technology. Bt crops present some unique challenges to insect resistance management (IRM) since many of the measures taken to protect the durability of sprayable chemicals are not applicable to in-plant protection. The IRAC International Biotech Team is charged with globally advancing guidelines for designing locally-workable resistance management measures. We develop and distribute educational materials to help technology providers, seed companies, and growers appreciate the need for IRM and understand how to implement IRM programs. The group also assists country-level organizations develop specific resistance management programs for insect-protected biotech crops geared to local conditions, cultivation practices and pest spectra. We recommend sound scientific principles to be the foundation of these plans while recognizing the commercial and infrastructure realities in each geography.

POSTER PRESENTATION

Olfactory memories acquired during trophallaxis affect the odor choice at the food source in carpenter ants

Yael Provecho, Roxana Josens

Grupo de Estudio de Insectos Sociales, Departamento de Biodiversidad y Biología Experimental. Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, Argentina

Introduction: A few social insect species are known to establish olfactory memories at the food source associating an odour cue with the reward stimuli (nectar). We studied whether the carpenter ant *Camponotus mus* is able to learn an olfactory cue *during the mouth-to-mouth food exchange (trophallaxis)* and tested the role of this memory in a Y-shaped food source.

Methods: Pairs of ants were isolated under controlled conditions. After a given period, one of them (donor ant) was fed with aromatised sucrose solution and then put back again with her partner (receiver ant). After the first trophallaxis, the response of receiver ant was evaluated on a Y-shaped food source without any reward by presenting two different odours: in one branch, the solution odour and in the other, a new scent.

Results: In non-reinforced tests, receiver ants consistently chose the branch with the odour presented in the sucrose solution and spent more time searching therein. Olfactory learning occurred independently of the duration of trophallaxis.

Conclusions: These results thus show for the first time that individual nectivorous ants perceive and learn odours during trophallaxis and that this memory influences the subsequent search behaviour at the food source. These results will be discussed in light of recent evidence of similar olfactory learning patterns in other eusocial insect species.

POSTER PRESENTATION

Insects: friend, foe or fifty-fifty? Density-dependent pollination and fruit predation in a self-incompatible legume

S.R. Simpson, C.L. Gross

University of New England, Armidale, NSW, Australia

Introduction: Populations are often thinned by habitat fragmentation. Processes such as pollination and predation can be influenced by habitat modification. Self-incompatible species that rely on pollen vectors to set seed may be particularly vulnerable to fluctuations in local population density.

Methods: The Australian endemic *Dillwynia sieberi* (Fabaceae) is reliant on insects for seed set, but its seeds are often consumed by coleopteran larvae. To determine the impact of density on this species, focal plants in 5 dense and 5 sparse plots in each of three populations were monitored in 2004 and 2005 for floral visitation, fruit and seed production and fruit predation.

Results: Bee visitors to *D. sieberi* included *Apis mellifera* and species from *Exoneura, Lasioglossum* and *Leioproctus*. Floral visitation, fruit to flower ratios and fruit predation were often higher in dense plots. However, density effects on seed production were less straight-forward. In the absence of predation, seed to fruit ratios were similar between densities, indicating that 1) fruit to flower ratios are not always good indicators of reproductive success and 2) net seed set is moulded by factors other than pollination. When fruit predation was factored into seed to fruit ratios and when percent reduction of seed due to predation was assessed, seed attrition was often higher in dense plots.

Conclusion: Although we detected density-dependent floral visitation, potential benefits are neutralised at the seed interface by density-dependent predation. Thus, plants in sparse populations may experience better fitness outcomes than conspecifics from dense populations.

POSTER PRESENTATION

Repellents and attractants as push-pull strategy for potato moth control

Maria Isabel Gomez[1], Teja Tscharntke[2], Katja Poveda[2]

[1]Universidad Nacional de Colombia, Bogotá, Colombia, [2]Georg-August University, Göttingen, Germany

Introduction: Push-pull strategies are based on the behavioral manipulation of insect pests by the simultaneous use of repellent stimuli that make the crop unattractive (push) and attractive stimuli to areas where direct control is facilitated (pull). One of the main pests in potato crops is the Guatemalan potato moth (T*ecia solanivora*) whose larvae are specialized on potato tuber feeding. This pest is able to destroy up to 100% of a potato crops in Latin America.

Methods: In greenhouse experiments we tested the oviposition deterrency of eight aromatic plants intercropped with potato plants and the trap capacity of eight potato varieties as oviposition stimulants for *T. solanivora* adults. In a 2 x 2 factorial designed field experiment we tested the effectiveness of the combined use of attractive (trap plant) and repellent stimuli (garlic-pepper extract) on the insect community, herbivory, and tuber production of potato plants.

Results: *T. solanivora* had a higher oviposition rate on one of the potato varieties (Roja Nariño) variety, while none of the aromatic plants tested affected the ovipostion rate on neighboring potato plants. In the field experiment, potato plants growing in plots where we combined the application of attractive and repellent stimuli had less damaged tubers and a higher productivity than any other treatment, including the conventional application of insecticides.

Conclusions: Results suggest that the simultaneous use of garlic-pepper extracts and the intercropping with the Roja Nariño potato variety could be used as an effective and ecologically sound push-pull strategy for the management of *T. solanivora* in the Colombian Andes.

POSTER PRESENTATION

Landscape scale diversification of Andean crop systems: enhancing biological control of potato pests

Katja Poveda[2], Eliana Martinez[1], M.A. Bonilla[1], Teja Tscharntke[2]

[1]Universidad Nacional de Colombia, Bogota, Colombia, [2]Georg-August University, Göttingen, Germany

Introduction: Current agricultural practices have caused serious ecological problems that affect agricultural sustainability by reducing ecological functions and biodiversity. There is evidence that the density of natural enemies of crop pests is related to high biodiversity. Although in temperate zones landscape-scale management practices (augmenting landscape complexity) have been studied, results are very controversial, and their applicability to tropical systems is still unknown. In order to contribute to the development of sustainable and ecologically sound management methods for potato cultivation in the Colombian Andes we evaluated landscape complexity on the insect community associated with potato plants and their effect on tuber production.

Methods: We choose potato fields along a gradient of landscape complexity; complex landscapes characterized by a higher percentage of native forest and shrubs while simpler landscapes are dominated by potato crops and pastures. For each of the 17 plots we determined insect composition, foliar and tuber herbivory, as well as final tuber production.

Results: Landscape complexity (less potato production) increased the abundance and family richness of natural enemies of potato pests. Simultaneously the amount of tubers damaged per plant increased with increasing potato abundance in the landscape.

Conclusions: Landscape complexity has a remarkable effect augmenting the natural enemies of potato pests in potato plantations in the Colombian Andes. Furthermore, the positive effect of complex landscape on tuber quality should be considered in landscape wide management practices of future potato cultivation schemes.

POSTER PRESENTATION

Vibratory signals and mating behavior of the predatory stink bug, *Eocanthecona furcellata* (Heteroptera: Pentatomidae)

Hsiao-Yung Ho, Yu-Ting Su, Ding-Hsuan Chang

Institute of Cellular and Organismic Biology, Taipei, Taiwan

Substrate-borne vibrational signals (songs) were recorded from both sexes of the predatory stink bug species, *Eocanthecona furcellata*. Males initiate substrate borne vibrational communication and produce four different songs. Females sing two different songs. A unique rubbing behavior in copulation of *E. furcellata* is reported and the possible function of the behavior is discussed.

POSTER PRESENTATION

Relationships between defoliating insects and predators in some Romanian oak forests

Constantin Ciornei[1], Catalin Rang[2], Constantin Netoiu[1], Roxana Voicu[2]

[1]Forest Research and Management Institute, Bucharest, Romania, [2]University of Bacau, Faculty of Biology, Bacau, Romania

Introduction: The paper deals with oak forests infested with defoliating insects from Southern and Eastern Romania. Defoliating insects and their main predators are assessed (invertebrates of epigean fauna and birds).

Methods: Classic methods of defoliating insect population density assessment were applied. The diversity of the epigean fauna assemblage was assessed using the captures from Barber traps. The bird communities were analyzed from quantitative and qualitative point of view, based on sound emissions and food diet (stomach content) of adults.

Results: During 2000 – 2007 period, the infestation level with defoliating species (*Lymantria dispar*, *Tortrix viridana*, Geometridae, Noctuidae, Tenthredinidae) in oak forests (*Quercus robur*, *Q. petraea, Q. cerris*, *Q. fraineto*, *Q. pedunculiflora*) fluctuated since very low to very high, in some stands treatments with biological products with *Bacillus thuringiensis* or metamorphosis inhibitors were adopted. In these forests, were detected predators from Carabidae (*Carabus coriaceus, Calosoma sp., Molops piceus, Pterostichus oblongopunctatus*), Staphilinidae, Formicidae families. Nesting birds are important in these forests as defoliating insects' predators, because the food of the brood, during the postembryonic development in the nest, consists in defoliating larvae. The most important bird species belong to Paridae, Sitidae, Fringilidae, Corvidae families. The food range depends on the abundance of defoliating insects.

Conclusions: Predator species in epigean fauna and nesting birds in oak forests may contribute to defoliating insect population decrease in forests with adequate structure.

POSTER PRESENTATION

Varietal susceptibility of potato to the black cutworm, *Agrotis ipsilon* (Hfn.)

Faiza E. Salah[1], Abdien M. Zein Elabdien[2], Salah El –Tom[2], A. Azrag[2]

[1]Dept. of Crop Protection, University of Gezira, Medani, Sudan. P.O. Box 20; [2]Dept. of Crop Protection, University of Khartoum, Sudan

The black cut worm (BCW) *Agrotis ipsilon* (HFN) (Lepidoptera: Noctuidae) is a highly polyphagous pest of several wintry crops and became a major potato pest in lighter soils of Khartoum state. BCW inflicted serious damage on the tubers, resulting in drastic yield losses annually. Despite its economic importance, little attention has been directed to this pest in the Sudan.

Field experiments were conducted for two seasons at Karari, Khartoum state, central Sudan, to evaluate 10 potato varieties (lines/accessions) for resistance to BCW damage. The percent damaged tubers numbers (%DTN) and weight (% DTW) as parameters were used for evaluation. Differences in both parameters were very highly significant, due to varieties and seasons ($P < 0.001$ for both parameters). The interaction between the varieties and seasons was also very highly significant ($P < 0.001$). Two parameters were found to correlate strongly and significantly ($r = 0.83$). The 10 potato varieties (lines/accessions) were also subjected to a series of no – choice test in the laboratory for two seasons. The tests included testing the larval and pupal developmental rates on fresh potato foliage, potato tubers and synthetic potato leaf diet. Significant differences were noted in larval weight gains (LWGs), due to differences in potato varieties across the various feeding tests. Alpha, Lesita, Bright varieties showed higher levels of resistance both in the field and in the laboratory, while Desiree and Spunta showed highest level of susceptibility. Factors governing the causes for resistance were discussed.

POSTER PRESENTATION

Transmission of fungal communities by *Tyrophagus putrescentiae*

Wojciech Wakulinski[1], Ewa Szlendak[2], Agata Domoslawska[1]

[1]Department of Plant Pathology, Warsaw University of Life Sciences SGGW, Warsaw, Poland, [2]Department of Applied Entomology, Warsaw University of Life Sciences SGGW, Warsaw, Poland

Introduction: Fungi are principal decomposers of organic matter but for some organisms, including mites, are also food sources**.** Mites ingest fungi sporadically; however, their migration to places previously colonized by fungi is strictly oriented as a result of specific micro conditions created by the fungi**.** By moving to new places, mites may serve as vectors and transmit fungal colonies. The aim of our study was quantitative and qualitative analyses of this process.

Methods: The ability of *Tyrophagus putrescentiae* to transmit fungi commonly occurring on stored grain (*Fusarium culmorum, F.avenaceum, Alternaria alternata, Penicillium verrucosum* and *P. chrysogenum*) was assayed. The test was performed on arenas containing seven small plugs of fungi, cut of from 10-day-old axenic cultures. Mites were left for 24 hours on these arenas, and the assortment and frequencies of fungal species found on their body surface and in whole-body homogenates were determined.

Results: Five fungal species were transmitted by *T.putrescentiae*: *F.culmorum, A.alternata, A. flavus, P.chrysogenum,* and *P.verrucosum*. The last species occurred most frequently and constituted 47% of the total number of fungal cultures derived from mites. It was isolated with higher frequency from the surface than from the inner parts of mite bodies.

Conclusions: Quantitative and qualitative spectra of fungal species isolated from *T. putrescentiae* indicated that their transmission by mites is not random. The dominance of particular fungal species may reflect trophic preferences of *T. putrescentiae* or the existence of specific mechanism(s) for transferring only particular species.

POSTER PRESENTATION

Honeybee (*Apis mellifera*) serotonin receptors – characterization of full length receptors and truncated splice variants

Markus Thamm, Wolfgang Blenau

University of Potsdam - Institute for Biochemistry and Biology, Potsdam, Germany

The honeybee, *Apis mellifera*, is a model organism for studying learning, memory and division of labor. The biogenic amine serotonin (5-hydroxytryptamine, 5-HT) has been implicated in the control and regulation of these phenomena. Pharmacological and functional studies have indicated, that serotonin can activate various receptor subtypes. These receptors belong primarily to the protein family of G protein-coupled receptors (GPCRs), which in turn are coupled to different intracellular second-messenger pathways.

By screening the honey bee genome, we found four candidate genes encoding for putative serotonin receptors. One of them, Am5-HT_7, was already characterized (Schlenstedt et al. 2007). The sequence information was used to generate a PCR-based strategy to isolate the cDNAs encoding for the three remaining receptors. The deduced amino acid sequence of one putative honeybee serotonin receptor shows the highest homology to the 5-HT_1 receptor of the spiny lobster, *Panulirus interruptus.* Two additional receptor sequences likely represent - 5-HT_2 receptor isoforms, whose closest relatives where found in *Drosophila melanogaster* and *Panulirus interruptus*, respectively. Therefore, we tentatively named them Am5-$HT_{2\alpha}$ and Am5-$HT_{2\beta}$.

The genomic structures of the two honeybee 5-HT_2 receptors show interesting details. Both genes have very large introns of several kB in length. Furthermore, we found alternative splice variants of both Am5-$HT_{2\alpha}$ and Am5-$HT_{2\beta}$. In case of Am5-$HT_{2\alpha}$, the truncated mRNA can potentially be translated into a protein, which is similar to the full-length variant but lacks two transmembrane domains. In contrast, the Am5-$HT_{2\beta}$ splice-variant possesses a frameshift that produces an early stop codon.

In order to clarify the functional properties of the cloned receptors and their splice variants, we are currently studying HEK 293 cell lines which heterologously express the receptor proteins. In addition, we are analyzing the tissue distribution of the native receptor proteins.

POSTER PRESENTATION

Food selection preferences of *Tyrophagus putrescentiae* acarid mites among wheat kernels infested by fungi

Ewa Szlendak[1], Wojciech Wakuliński[2]

[1]*Department of Applied Entomology, Warsaw University of Life Sciences, Warsaw, Poland,*
[2]*Department of Plant Pathology, Warsaw University of Life Sciences, Warsaw, Poland*

Introduction: The suitability of mycelium of a particular fungal species for mites grazing on stored products probably depends on its attractiveness or repellence to mites, on the specific mite species, and on the mites' feeding ability. The aim of our study was to determine whether the species of fungus inoculated on wheat kernels, and the duration of kernel pre-infestation by fungi, influence mite choice of these kernels as potential food.

Methods: Wheat kernels inoculated 1, 5 or 10 days previously with *Fusarium culmorum, F. avenaceum, Alternaria alternata, Penicillium cyclopium = verrucosum, P. notatum = chrysogenum, Aspergillus ochraceus, A. flavus* were distributed on Petri dishes, which served as test arenas, to determine the infested kernels' attractiveness to *Tyrophagus putrescentiae* mites. The number of mites attracted by each species of fungus growing on wheat kernels was recorded at 0.5, 1, 4 and 24 hours after their release into the test arenas.

Results: Similar percentages of mites preferentially selected usually more than one (from 1 to 4) types of inoculated wheat kernel. Kernels inoculated with *Fusarium avenaceum* produced volatiles that attracted numerous mites in almost all experimental combinations. Depending on the test combination, large numbers of mites were also attracted by kernels inoculated with *Alternaria alternata, F. culumorum, Penicillium cyclopium* and *P. notatum.*

Conclusions: Our data show that mites select food among wheat kernels inoculated by particular species of fungi, and that both the selection period and the degree of kernel predigestion by fungi have a strong influence on mite choice.

POSTER PRESENTATION

Determining dispersal patterns of *Planococcus ficus* (Hemiptera: Pseudococcidae) among South African vineyards using RAPD markers

Marna Ferreira[1], Gerhard Pietersen[1], Eugenia Barros[2], Kerstin Kruger[1]

[1]University of Pretoria, Pretoria, South Africa, [2]CSIR, Pretoria, South Africa

Introduction: The vine mealybug *Planococcus ficus* is regarded as a key agricultural pest of grapevine (*Vitis vinifera*). It causes damage to vines through direct feeding, honeydew excretion and transmission of plant viruses. Mealybugs can spread rapidly throughout wine growing areas, e.g. through human contact, farming equipment, nursery stock, insects or birds. By understanding how mealybugs disperse specific control strategies can be implemented. We tested randomly amplified polymorphic DNA (RAPD) markers to differentiate amongst individual mealybugs from different vineyards to deduce possible dispersal patterns in South Africa.

Methods: *Planococcus ficus* individuals were collected from six vineyards in the Western Cape. DNA yield and quality from three DNA extraction methods were compared. RAPD - PCR conditions were optimized by varying final concentrations of PCR components including five sources of *Taq* polymerase and comparing the generated fingerprinting profiles. Twenty-seven 10-mer primers from University of British Columbia (UBC) were tested for polymorphisms.

Results: The three extraction methods yielded DNA concentrations ranging from 35 ng/ul (Roche kit) and 425 ng/ul (STE buffer) to 1704 ng/ul (Nylon membrane). The Roche kit consistently yielded high molecular weight DNA and was used for DNA extractions. Different final concentrations of PCR components and different sources of *Taq* polymerase generated different fingerprinting profiles. BIOTAQ™ DNA polymerase was selected and an optimal set of PCR conditions was determined. Four polymorphic primers revealed genetic differences among vineyards in a preliminary RAPD study.

Conclusions: RAPD markers can be used successfully to determine genetic differences among *P. ficus* individuals from South African vineyards.

POSTER PRESENTATION

The first finding of *Wolbachia* in thelytokous seed chalcids (Hymenoptera : Torymidae, *Megastigmus* sp.)

Thomas Boivin[1], Jean-Noël Candau[1], Alain Roques[2], Marie-Anne Auger-Rozenberg[1]

[1]Institut National de la Recherche Agronomique, Avignon, France, [2]Institut National de la Recherche Agronomique, Orléans, France

Introduction: In haplodiploid insect species, thelytokous parthenogenesis may be associated with bacterial endosymbionts that manipulate their host reproduction. Such an association was tested in the highly invasive genus *Megastigmus*, within which thelytokous parthenogenesis is much less frequent than arrhenotoky, which is the classical way of reproduction in chalcid insects.

Methods: Specific primers were used for the screening of *Wolbachia*, *Cardinium*, *Rickettsia* and *Arsenophonus* endosymbionts in three arrhenotokous and seven thelytokous *Megastigmus* species. Both *Wolbachia* infection and progeny sex ratios were compared between non- and antibiotic-treated females of *M. pinsapinis*. The phylogenetic relationships of the different thelytokous *Megastigmus* species and their infecting *Wolbachia* were compared to assess the evolutionary trajectories of such an association.

Results: PCR amplification with *Wolbachia* primers (*wsp*) was successful in all of the seven thelytokous *Megastigmus* species while no reaction occurred using *Cardinium*, *Rickettsia* and *Arsenophonus* primers. None of the three tested arrhenotokous species allowed amplification whatever the primer. Antibiotic treatments of *M. pinsapinis* females resulted in a loss of their *Wolbachia* infection and in a return to an arrhenotokous mode of reproduction. Molecular phylogeny of *Wolbachia* variants paralleled the observed radiation of *Megastigmus* species with respect with host-plant families (Pinaceae, Rosaceae and Anacardiaceae), but no significant divergence in *Wolbachia* sequences was found within host-plant families.
Conclusions: Thelytokous parthenogenesis in *Megastigmus* species may be associated with *Wolbachia* infection. Phylogenetic constructions suggest that horizontal transfers of *Wolbachia* occurred between insect species exploiting closely related host-plants. This may raise critical questions within the context of biological invasions in this insect genus, which frequently generate novel cases of sympatry.

POSTER PRESENTATION

Preliminary identification of P450 genes of the *CYP4*, *CYP6, CYP9* and *CYP12* Families in *Aspidiotus nerii* Bouché (Hemiptera: Diaspididae)

Jin Wu, Benjamin Normark

University of Massachusetts, Amherst, MA, United States

Aspidiotus nerii Bouché (Hemiptera: Coccoidea) is an extraordinarily polyphagous insect species, attacking plants from 110 families. *A. nerii* is an economically important pest and includes both sexual lineages and *Cardinium*-bacteria-infected parthenogenetic lineages. Given that plant allelochemicals are diverse among these hosts, genes involved in allelochemical metabolism in *A. nerii* are expected to play a critical role in adaptation to such a wide host range. Cytochrome P450 monooxygenase (P450) families *CYP4*, *CYP6, CYP9* and *CYP12* are the most studied metabolic enzymes that have been shown to be involved in detoxification of plant xenobiotics in polyphages. To isolate related cytochrome P450s in *A. nerii*, conserved regions in the alignment of insect *CYP4*, *CYP6, CYP9* and *CYP12* proteins served as a guide for the design of degenerate oligonucleotide primers for reverse transcription–polymerase chain reaction (RT-PCR) amplification of mRNA from adult female *A. nerii*. The RT-PCR products were cloned, sequenced, and then used as probes to screen a cDNA library. Full-length cDNA of selected clones from the cDNA library screening were sequenced, aligned and classified according to the nucleotide and amino acid identity with the other insect cytochrome P450s. To further identify and characterize those genes, phylogenetic analysis was conducted including all Cytochrome P450s from Hemiptera and Lepidoptera.

POSTER PRESENTATION

Phylogenetic relationships of Ciidae (Coleoptera: Cucujiformia)

Christin Grossmann, Gerda Buder, Anna Hundsdoerfer, Klaus-Dieter Klass

Museum of Zoology Dresden, Dresden, Saxony, Germany

Introduction: Cucujiformia is the largest coleopteran subgroup (207.000 species), classified into Lymexyloidea, Cleroidea, Cucujoidea, Tenebrionoidea, Chrysomeloidea, and Curculionoidea. Ciidae (Tenebrionoidea) comprise ca. 600 species in 40 genera, have a cylindrical body 0.5–7 mm long, and live in tree-fungus basidiocarps.

Methods: To study relationships in Ciidae, test its monophyly, and resolve its position within Cucujiformia, we sampled 20 species from 11 genera of Ciidae, 27 species from 20 other families of Cucujoidea and Tenebrionoidea, 2 species from the cleroid family Trogossitidae (all Cucujiformia), and *Bostrichus* (Bostrichiformia: Bostrichidae). We analysed 18S, COI, and – for Ciidae – COII sequences according to maximum parsimony (fixed alignment and partial direct optimization), maximum likelihood, and Bayesian methods, applying these to three subsets of the taxon sample.

Results: Ciidae appear as monophyletic. We find non-monophyly for the huge genus *Cis*, *Sulcacis*, and the tribe Orophiini. Different analyses suggest either *Rhopalodontus*, or *Sulcacis fronticornis* + *Xylographus* + *Octotemnus*, or *Sulcacis fronticornis* + *Xylographus* alone as sister group of the remaining Ciidae. Apart from a clade *Sulcacis fronticornis* + *Xylographus* the results for inter-generic relationships in Ciidae vary strongly with analyses and sampling. Different analyses place Ciidae sister to Nitidulidae or far basally and isolated in the cucujoid-tenebrionoid assemblage. Resolution of the phylogeny of the cucujoid-tenebrionoid assemblage is poor and conflicting. Monophyly is supported for Sphindidae, Cryptophagidae, Tenebrionidae, Coccinellidae + Endomychidae, and Tetratomidae + Anthicidae + Monotomidae. Altogether, families from Cucujoidea and Tenebrionoidea are fairly mixed up in our trees, and the cleroid Trogossitidae falls within the cucujoid-tenebrionoid assemblage.

POSTER PRESENTATION

The tentorium and anterior head sulci in Dictyoptera and Mantophasmatodea (Insecta)

Klaus-Dieter Klass, Ute Eulitz

Museum of Zoology Dresden, Dresden, Saxony, Germany

Introduction: The head capsule in insects has a complicated pattern of internal ridges (sulci), which serve for mechanical strengthening. Inside the head there is a cuticular tentorium, which is composed of 2 pairs of tubular invaginations fused in the center of the head. These structures were studied in Mantophasmatodea and various Dictyoptera and explored regarding their phylogenetic information content.

Methods: The tentorium, the anterior head sulci (epistomal, subgenal, subantennal, circumantennal, and circumocular sulci), and the extension of the anterior tentorial pit were studied in 26 species of Blattaria (representing most principal lineages), 4 species of Mantodea (including the basal *Mantoida schraderi*), and 1 species each of Isoptera (the basal *Mastotermes darwiniensis*) and Mantophasmatodea (*Austrophasma caledonense*). The morphology of these head structures was compared with literature data on other insect orders, mainly Phasmatodea, Orthoptera, Dermaptera, Embioptera, and Plecoptera, and partly Odonata and Zygentoma. Characters were defined, presented in a matrix, and evaluated with regard to phylogenetic implications and homoplastic evolution.

Results: The structural relationships of the subantennal sulcus to the subgenal, circumocular, and circumantennal sulci were found highly variable; the patterns are strongly homoplastic and depend much on the size of the compound eyes. Several types of subantennal sulci are defined. The presence of an anterior transverse bridge in the tentorium ("perforated tentorium") of all Dictyoptera here studied confirms the monophyly of this group. Mantophasmatodea lack this element. Various details of the sulci and tentorium confirm the monophyly of Mantodea.

POSTER PRESENTATION

Effects of desiccation and immersion on the third instar larvae of oriental fruit fly

Xinfeng He, Qi Xie

Institute of Entomology, Zhongshan University, Guangzhou, Guangdong Province, China

Introduction: Many studies have focused on the effects of different temperatures on the development, survival, and fertility of oriental fruit fly. Less attention is paid to the effects of humidity on the pupae of this fly. Humidity is expected to be a major limiting factor on the pupation of the mature larvae.

Methods: Prior to experimentation, soils were sifted through a 1-mm-mesh metal sieve and dried at 100℃ for 48h in an oven. Eight durations (2, 4, 6, 8, 10, 12, 14, and 16 h) were set in the desiccation experiment, each with 40 larvae for testing. Forty larvae were weighed on an electronic balance and placed in desiccation conditions as described above. Following a defined desiccation time (2, 4, 6, 8, 10, 12, 14, and 16 h), the larvae were screened from the soils and reweighed rapidly. Healthy and active mature larvae were immersed simultaneously in still water at 25 ± 1℃. Forty larvae were removed randomly from the water and transferred to moist sand after immersion of 0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, and 4.0 d, respectively. All samples were held at 25 ± 1℃ and 75% RH under a 12:12 (L:D) h photoperiod for emergence. The number of newly emerged adults was recorded and removed daily.

Results: Third instar larvae desiccated in dry soils did not survive beyond 12 h, nor submerged under water beyond 3.5 d. The time to 50%, 90%, and 99% mortality (LT_{50}, LT_{90}, and LT_{99}) were 5.67, 8.60, and 10.99 h respectively in desiccation condition, and 1.81, 2.49, and 3.06 d in immersion test. The average eclosion time of survived flies was not significantly affected by the desiccation time, while that increased linearly with increasing immersion time. Cumulative weight loss of larvae increased curvilinearly with desiccation time, and the rate of weight loss was greatest during the first 2 hours. It was estimated that when the percentage of cumulative weight loss was 29.1%, 36.7%, and 43.0% respectively, the mortality rates was 50%, 90%, and 99% correspondingly.

Conclusions: Flooding would be an effective control method in pupa stage of oriental fruit fly.

POSTER PRESENTATION

Arthropod fauna associated with Southern African sugarcane in relation to sugarcane thrips, *Fulmekiola serrata* control

Mike Way

SASRI, Mt Edgecombe, South Africa

Monitoring techniques provided information on faunal complexes within sugarcane leaf spindles in South Africa that might include natural enemies of the serious pest thrips, *Fulmekiola serrata* (Kobus) (Thysanoptera: Thripidae).

During the 2005/06 seasons extensive surveys were carried out. Twenty-eight thysanopteran taxa from 3 families were identified, namely Thripidae, Phlaeothripidae, Aeolothripidae were distinguished. *F. serrata* was clearly predominant. Genera recovered were: *Fulmekiola, Allelothrips, Anaphothrips, Arhipidothrips, Arorathrips, Chirothrips, Elaphrothrips, Exothrips, Frankliniella, Haplothrips, Megalurothrips, Phibalothrips, Podothrips, Stenchaetothrips and Thrips*. Many taxa were scarce.

The following associated arthropod taxa were recovered: Anthocoridae: possibly *Orius* sp.; Staphylinidae: Oxytelinae; Chrysomelidae: Alticinae: *Chaetocnema* sp.; Curculionidae: Scolytinae; Coccinellidae: Scymninae: *Nephus* cf. *voeltzkowi* Weise and *Scymnus* sp.; Corylophidae, Formicidae: *Anoplolepis* sp.; indeterminate Lepidoptera; Cicadellidae: *Cicadulina niger* Ghauri; Laelapidae: Mesostigmata: *Ololaelaps* sp. (soil predatory mite); Araneae: Clubionidae: *Clubiona* sp.; Thomisidae: *Firmicus* sp.

The South African Sugarcane Research Institute (SASRI) is researching an Integrated Pest Management (IPM) strategy against this pest. Cognisance of this faunal complex is paramount to the long-term success of any recommendation.

POSTER PRESENTATION

Acoustic detection of freshwater insects and other invertebrates

Jaroslava Frouzova[1], Jan Kubecka[1], Josef Matena[1], Jan Frouz[2]

[1]Instutute Hydrobiology, Ceske Budejovice, Czech Republic, [2]Institute of Soil Biology, Ceske Budejovice, Czech Republic

Introduction: Observation activity of aquatic insect in open water of large water bodies is difficult task. Hydroacustic may be new valuable tool to solve this problem.

Methods: This contribution reviews the hydroacustic records of freshwater invertebrates from 14 studies using frequencies between 100 and 500 kHz.

Results: The highest target strength (TS) >-52 dB of common freshwater pelagic invertebrates was recorded for water bugs (Hemiptera, Insecta). In the TS interval of –58 to –75 dB, well defined targets of dipteran insects. Larger crustacean like Amphipoda and Mysidiacea fall into the TS range of –74 to –85 dB. Freshwater jellyfish, Craspedacusta sowerbii was found to be acoustically unidentifiable in most situations; despite quite large size 1-2 cm its TS was under of threshold –95 dB.

Conclusion: Invertebrates with gas filled organs in the body are likely to give strong echoes. Also other invertebrate organisms with exoskeleton give relatively stronger echo than completely soft body organisms.

This review show that water insects and other invertebrates as small as 2-3 mm can be successfully detected by hydroacustic techniques which can be powerful approach for study of many aspects of their biology in water column.

POSTER PRESENTATION

Non-intentional inoculation of earthworms during forest reclamation of post mining sites change soil development and arthropod diversity

Jan Frouz

Institute of Soil Biology, Ceske Budejovice, Czech Republic

Introduction: Soil restoration in post mining sites is an important part of ecosystem reconstruction. Here we studied effect of earthworm on development of soil biota in chornosequences of post mining sites.

Method: Two chronosequences of sites, covered by alder plantations and the second unreclaimed, both covering age from 1-41 years were studied.

Results: Macrofauna namely earthworms were abundant in reclaimed sites due to better litter condition and unintentional colonisation by earthworm during tree planting. In non-reclaimed sites macrofauna abundances were lower and appear in higher densities in 25-30 years old sites. In the contrary Meso and macrofauna density and diversity were higher in unreclaimed sites namely Testacea amoebae and oribatid mites, densities were high, similar as in natural forest. Mesofauna and microfauna densities decreased after 30 year of succession when unreclaimed sites were colonised by earthworms, which resulted in more intensive soil mixing, rapid formation of humus layer and fast removal of litter and fermentation layer from soil surface.

Conclusion: Soil macrofauna alter composition of soil meso and microfauna due to modification in topsoil physical structure.

POSTER PRESENTATION

What is the source of CO_2 production in wood ant nests ant or microbial respiration

Jan Frouz

Institute of Soil biology, Ceske Budejovice, Czech Republic

Introduction: Wood ant nests are hotspot of CO_2 production. Here we partionate ant and microbial respiration of the nest.

Methods: In two dry nest, moisture less that 15% and two wet nest with moisture more than 25% were embedded two plastic cylinders one with holes the second closed with net on the top. Both were filled by nest material in closed cylinder the ants were hand sorted out in cylinder with holes ants remain. CO_2 production both cylinders, and surrounding soil was measured by SR1000. In one dry and one wet nest CO_2 production was also measured on longitudinal transect across the nest.

Results: Respiration in wet nets was higher than in dry one. In dry nests higher CO_2 production (7-15µL/m2 min) was found in center of the nest. In wet nest the highest values was also found in the nest center (50 µL/m2 min) but increase from nest periphery was more gradual. In dry nest the respiration values in ant free cylinder was near control soil value. In wet nest ant free cylinder still keep about half of respiration of ant accessible cylinder. Ant based respiration was higher in wet than dry nest due to higher ant density.

Conclusion: both ant and microbial respiration take part on CO_2 production from wood ant nest, its proportion depends on nest moisture.

POSTER PRESENTATION

Metabolic rate of brown locust eggs

Innocent Kambule, Shirley Hanrahan, Frances Duncan

University of the Witwatersrand, Johannesburg, South Africa

The brown locust, *Locustana pardalina* (Walker) (Orthoptera: Acrididae), is found in the semi-arid regions of the central Karoo, South Africa. Diapause contributes to brown locust survival under arid conditions preventing immediate hatching and allowing build-up of eggs in the soil which contributes to swarming. We measured the metabolic rate of diapause and non-diapause eggs and directly linked these to embryonic development. There are two major stages in egg development, namely anatrepsis and catatrepsis. Anatrepsis is the development prior to rotation of the embryo. Diapause eggs remain in anatrepsis between 9 and 40 days. Catatrepsis begins when the embryo turns and the development process is usually completed irrespective of environmental conditions. Eggs were obtained from adult locusts collected in the Karoo and bred in the laboratory. Metabolic rate was determined measuring CO_2 output of eggs in various stages of development using Licor - 6262 analyzer. Embryonic development was examined using light microscopy. The metabolic rate of non-diapause eggs increased steadily from day 0 until hatching at day 10. Diapause eggs maintained a low constant metabolic rate 4½ times lower than that of non-diapause eggs.

POSTER PRESENTATION

Alien versus predator (and other natural enemies): can *Harmonia axyridis* be controlled?

Helen Roy[1], Marc Kenis[2], Renate Zindel[3], Michael Majerus[4]

[1]NERC Centre for Ecology and Hydrology, Cambridgeshire, United Kingdom, [2]CABI Europe-Switzerland, Delémont, Switzerland, [3]University of Fribourg, Fribourg, Switzerland, [4]University of Cambridge, Cambridge, United Kingdom

The harlequin ladybird, *Harmonia axyridis* (Pallas) (Coleoptera: Coccinellidae), is a predatory beetle native to Asia but an invasive alien species in many countries worldwide. It is considered invasive because it is a human nuisance, a grape and wine pest and a threat to native biodiversity. Many methods have been employed to control this beetle with varying degrees of success. These include: mechanically preventing adult beetles from entering buildings in autumn or removal of beetle aggregations inside buildings; the use of insecticides on buildings or in vineyards to prevent aggregation in houses or on grapes; cultivation practices in vineyards to lower the impact of the ladybird on grape production and wine quality and remedial treatments for wine tainted by the ladybird. However, other methods are under development and these include: the use of deterrent or attractant semiochemicals and the manipulation of natural enemies. Candidate natural enemies include: an insect pathogenic fungus, (*Beauveria bassiana*), a predator (the predatory bug *Deraeocoris ruber*), a hymenopteran parasitoid (*Dinocampus coccinellae*), a dipteran parasite (*Phalacrotophora fasciata*), two sexually transmitted ectoparasites (a mite, *Coccipolipus hippodamiae*, and a laboulbenialean fungus, *Hesperomyces virescens*), and a variety of male-killing bacteria (*Wolbachia*, *Spiroplasma*, *Rickettsia*). We consider the potential of these natural enemies as biological control agents of *Harmonia axyridis* and conclude that only the sudden adaptation of a native natural enemy or the, potentially risky, importation of an Asian natural enemy may ultimately lower population densities.

POSTER PRESENTATION

Molecular studies on *Baetis harrisoni* (Ephemeroptera, Baetidae), using two mitochondrial genes, CO1 and 16S, to distinguish species level differences between populations

Lyndall Pereira da Conceicoa[1], Helen James[2], Benjamin Price[1], Nigel Barker[1], Martin Villet[1]

[1]Rhodes University, Grahamstown, South Africa, [2]Albany Museum, Grahamstown, South Africa

Introduction: *Baetis harrisoni* Barnard (1932) is found in fast flowing streams and rivers throughout Africa south of the Sahara. To date, identifications of *B. harrisoni* have relied on external morphological features. These vary subtly with regards to the gill size, abdominal patterns and length of caudal filaments; which has raised the question of whether *B. harrisoni* in South Africa is a single species or a species complex.

Methods: Genetic variation between nymphs from populations from 11 rivers in different areas of South Africa was quantified using statistical molecular analyses of the CO1 and ribosomal 16S rRNA mitochondrial genes.

Results: The preliminary phylogenetic results for *B. harrisoni* strongly indicate the presence of two clades: a south western (winter rainfall) clade and a north eastern (summer rainfall) clade. A brief morphological examination of the two main clades further supports the phylogeny.

Conclusions: This report has highlighted distinct genetic differences that suggest that this African baetid may be comprised of more than one species. This study has set the foundations for a larger, more in-depth project that will finally resolve the true taxonomy of the *Baetis harrisoni* species complex.

POSTER PRESENTATION

Trait-mediated effects of predatory mites on thrips and its host plant

Andreas Walzer, Peter Schausberger

University of Natural Resources and Applied Life Sciences, Institute of Plant Protection, Vienna, Austria

Introduction: The concept of top-down trophic cascades is the fundament of biological control theory. Despite the increasing knowledge that trait-mediated effects are as important in triggering top-down trophic cascades as density-mediated effects, the occurrence of trait-mediated interactions between predators, prey and plant has been largely ignored in biological control. Here we show that trait-mediated interactions in an agro-ecological food chain can generate top-down trophic cascades.

Methods: The study system consisted of the predatory mites *P. persimilis* and *N. californicus*, the herbivorous non-target prey western flower thrips *F. occidentalis* and the host plant bean. Three experiments were conducted on (1) foraging behaviour of larval prey, (2) survival and development of prey larvae and (3) foraging and oviposition behaviour of female prey in the presence and absence of predator cues.

Results: Irrespective of predator species and risk posed to prey, the presence of predator eggs led to increased ambulation, increased mortality and decreased oviposition of thrips. The presence of predator eggs reduced leaf damage caused by thrips. To our knowledge this is the first experimental evidence for a positive trophic cascade triggered by trait-mediated interactions between predators and non-target prey in an augmentative biological control system.

Conclusions: Our study indicates the potential importance and strength of trait-mediated effects of predators on a non-target herbivorous pest and its host plant. It hopefully stimulates further research on this topic to find out how widespread trait-mediated predator effects are in biological or natural control of arthropod pests and how important they are relative to density-mediated predator effects.

POSTER PRESENTATION

Monitoring of anatomical changes within the bird cherry shoots evoked by *Rhopalosiphum padi* L. (Hemiptera: Aphididae)

Hubert Sytykiewicz, Bogumil Leszczynski

University of Podlasie, Siedlce, Poland

Introduction: The bird cherry-oat aphid, *Rhopalosiphum padi* L. (Hemiptera, Aphididae) is a heteroecious species that life-cycle is characterized with occurrence of holocyclic development. Its primary host is a tree or shrub of the bird cherry (*Prunus padus* L.), whereas a wide spectrum of secondary hosts embraces plants belonging to *Cyperaceae*, *Juncaceae, Poaceae* and *Typhaceae*. The purpose of the study was to define the anatomical damages within primary host tissues caused by *R. padi* feeding.

Methods: Plant material was collected during the peak density of *R. padi* occured on bird cherry shrubs in central-eastern Poland. Infested shoots were incubated in FAA solution - 50% ethanol, acetic acid, 40% formaldehyde /18:1:1, *v:v:v*/. Subsequently, series of transverse sections through stems, petioles and midveins of leaf blades were taken and examined under light microscopy.

Results: Salivary exudates of the bird cherry-oat aphid contained enzymes which depolimerised ultrastructural compounds of middle lamella and cellular wall of the primary host tissues. The bird cherry-oat aphid damaged and hydrolysed large areas within mesophyll tissue of stems and leaf stalks. It was also shown that when bird cherry-oat aphid inserted its stylets directly into phloem bundle, disruption of peripheral tissues was more restricted.

Conclusions: The bird cherry-oat aphid penetrated tissues of its primary host mostly intracellularly and the aphid stylets piercing the bird cherry shoots were generally located within phloem bundle and/or parenchyma cells.

POSTER PRESENTATION

Toxic effects of phytohemagglutinin (PHA) on development and fecundity of rose grain aphid, *Metopolophium dirhodum* Walker

Iwona Sprawka, Bogumil Leszczynski

University of Podlasie, Siedlce, Poland

Introduction: Recent progress in plant breeding for insect resistance has increased interest in potential toxicity of plant proteins towards herbivorous insects. Lectins are class of the entomotoxins considered as potential biopesticides that might be used against polyphagous aphids. Hemagglutinin (PHA) the lectin from *Phaseolus vulgaris* is tetrameric protein with a molecular weight of 120 kDa and sugar specificity for D-galactose/ N-acetyl-D-galactosamine residue. The toxic effects of PHA on Lepidoptera is well documented but little is known on its toxicity to aphids.

Methods: Effect of the PHA on survival, development and fecundity of *M. dirhodum*, was studied in laboratory conditions. Several concentrations (10-1500 μg per ml) of the lectin were incorporated into artificial liquid diets. Fifty adult aphids were used for each treatment and control (without PHA).

Results: The obtained results showed that presence of the PHA in the diet decreased fecundity of the adult *apterae* up to 50% compared to aphids fed on the control diet. Aphids exposed to PHA also showed reduction of weight by about 25% and total mortality at concentration 1000 μg per ml incorporated into the sucrose diet.

Conclusions: The data presented here, sugest that PHA showed a high insecticidal activity towards the rose-grain aphid and might be considered as protein biopesticide towards the insect pest.

.

POSTER PRESENTATION

Influence of grain aphid (*Sitobion avenae* F.) feeding on arginase activity within winter triticale seedlings

Cezary Sempruch, Bogumil Leszczynski, Izabela Wojtas

University of Podlasie, Siedlce, Poland

Introduction: Arginase (EC 3.5.3.1) is an enzyme that catalyses biodegradation of L-arginine to L-ornithine and urea. This enzyme is quite important in plant-insect chemical interactions since it reduces nutritive value of plant tissues for herbivorous pests. The aim of the study was to determine changes in arginase activity within seedlings of winter triticale caused by *S. avenae* feeding.

Methods: Seven days old seedlings of winter triticale cultivars: Tornado (susceptible) and Witon (less susceptible) were artificially infested in climatic chamber with five wingless females per seedling. Infested and control (without aphids) seedlings were collected for analysis after 24 h, 48 h, 1 week and 2 weeks. Number of individuals on the studied plants was determined, and all the aphids were discarded from plants. Enzyme activity was measured with use of spectrophotometric method.

Results: The grain aphid feeding during the first 24 h caused an increase in the arginase activity within susceptible Tornado cv. and decrease in less susceptible Witon cv. After 48 h and 1 week of the aphid feeding activity of the enzyme decreased within tissue of the both studied cultivars and was again induced during the second week. Importance of the arginase in the chemical interactions between winter triticale and *S. avenae* is discussed.

Conclusions: Arginase activity was altered under the grain aphid feeding, and the observed variations in its activity was dependent on plant genotype, aphid number and feeding duration.

POSTER PRESENTATION

Formulations of the entomopathogenic fungi *Beauveria bassiana*, an agricultural pest control organism

Irina Urtubia, Andrés France

INIA Quilamapu, Chillán, Chile

The use of entomopathogenic fungi (EPF) is an effective alternative for agriculture pest control and development of sustainable agriculture, preserving natural resources and environment. However it is necessary to count on formulations allowing decrease viability loss and increase permanence on soil.

In this study, granule formulations were elaborated as pellets based on sodium alginate of conidia of EPF *Beauveria bassiana* strain B-323 belonging to the collection of Technological Center of Biological Control, which controlling Fuller's rose weevil (*Asynonychus cervinus*) y South American fruit tree weevil (*Naupactus xanthographus*), using two substrates: Kaolin (aluminum silicate) and plant residues (fiber and nutrients), plus an specific additive. Formulations were evaluated according to viability (expressed as germination index, GI) and incubation time at different temperatures (15, 20, 25, 30 and 35 ºC).

Formulations elaborated with plant residues showed the highest GI, 62.1 vs. 9.17 for kaolin. This value increase to 696 with additive. With respect to stability on time and GI, the best temperatures were 25, 20 and 15 ºC.

Formulates containing fiber and nutrients increase EPF survival and allow its development at different temperatures, allowing a higher success of soil applications and therefore a higher pest control level.

POSTER PRESENTATION

Mating success and mate choice in relation to sex ratio and mating experience in *Nysius huttoni* White (Heteroptera: Lygaeidae)

Qiao Wang, Linghuan Yang

Massey University, Palmerston North, New Zealand

Introduction: In polygamous mating systems males tend to minimize the probability of sperm competition while females encourage it. Theoretically, in the male-biased sex ratio male-male competition is expected to increase resulting in lower mating success while in the female-biased one male mating success should be higher. Here we investigated mating success and mate choice in relation to sex ratio and mating experience in a polygamous seed bug, *Nysius huttoni* White.

Methods: Petri dishes were used experimental arenas. Mating success and mate choice were recorded. Each Patri dish was considered a replicate.

Results: Mean mating success under even sex ratio was significantly lower than under the biased sex ratios. If a mated male had a chance to choose between a female that had mated with him 24 h ago and a female that had mated with another male 24 h ago, the male significantly preferred the female he had mated before to the female that had mated with another male. However, there was no clear preference by the mated female for mating between the male with which she had mated before and the male which had mated with another partner.

Conclusions: Biased sex ratios increase mating success rate in this species. Males can remember their partners for at least 24 h, and to minimize sperm competition they prefer their previous partners to other mated females. For females genetic diversity and fitness appear to be more important and thus do not have preference between their previous partners and other mated males.

POSTER PRESENTATION

Molecular, biochemical and histochemical characterization of two acetylcholinesterases from the German cockroach *Blattella germanica*

Min Kwon, Chan Sik Jung, Young Ho Koh, Si Hyeock Lee

[1]National Institute of Highland Agriculture, RDA, Pyeongchang, Korea, Republic of, [2]Korea Forest Research Institute, Seoul; [3]Ilsong Institute of Life Science, Hallym University, Anyang; [4]Seoul National University, Seoul, Republic of Korea

Introduction: *Blattella germanica*, is one of the major medically important species in most parts of the world and known to have well-characterized nervous system. Therefore, *B. germanica* is a good model insect to study the putative roles of two insect AChEs from evolutionary points of view and to predict fundamental functions of extra or surplus AChE.

Methods: Various methods such as cloning, real-time PCR, native PAGE, fluorescence *in situ* hybridization etc.

Results: Full length cDNAs encoding two AChEs; *Bgace1* and *Bgace2* were cloned and characterized. Ganglia produced distinct two major and two minor AChE bands in native PAGE, indicative of the presence of at least two active AChEs. *B. germanica* AChEs appeared to be mainly localized in the central nervous system as demonstrated by histochemical activity staining along with quantitative analysis of *Bgace* transcripts. Fluorescence *in situ* hybridization of the 1st thoracic ganglion confirmed that *Bgace1* is predominantly transcribed, and further showed that its transcript is found in almost entire region of inter- or motor neurons including the cell bodies and axonal/dendritic branches but *Bgace2* transcript is found only in the subset of neurons, particularly in cell body. In addition, certain neurons were observed to express *Bgace1* alone.

Conclusions: Two *ace* genes were identified from *B. germanica*,

POSTER PRESENTATION

Targeted cue-lure trapping, bait-spray, sanitation, sterile-male and parasitoid releases in an area wide integrated melon fly (Diptera: Tephritidae) control program in Hawaii

Eric B. Jang[1], Grant T. McQuate[1], Donald O. McInnis[1], Renato Bautista[1], Roger I. Vargas[1], Ronald F. L. Mau[2], Lyle Wong[3]

[1]USDA Agric. Research Service, Hilo, HI, United States, [2]Univ. of Hawaii, Honolulu, HI, United States, [3]Hawaii Dept. of Agric., Honolulu, HI, United States

Introduction: An area wide IPM approach to melon fly *Bactrocera cucurbitae* (Diptera:Tephritidae) suppression was undertaken as part of a Hawaii state-wide program funded by USDA-ARS Area Wide Initiative.

Methods: A grid of 1 cuelure trap/ km^2 over 40 km^2 was established in Kamuela, HI to pinpoint areas of infestation. A targeted male trapping array was applied based on the distribution of host plants (mapped using GIS). Monitoring existing traps led to increasing trap density where catch was highest to achieve male annihilation. Sanitation, bait spray, Sterile Insect Technique (SIT), and augmentation of *Psyttalia fletcheri* parasitoids were also applied.

Results: Pre-treatment trapping in the farming area indicated a melon fly population peak of 11.94±9.90 flies/trap/day (f/t/d) in October 2000. By 2003, mean grid trap catch over 16 weeks was 0.016±0.005 f/t/d /km^2, i.e. a 99.87% reduction. During 2000-2001 mean infestation was 50.6± 4.9% in sampled fruit. In 2002, with all suppression activities fully implemented, the infestation rate averaged 8.5±4.8% that is an 83.2% reduction. Between Aug. 2002 and Aug. 2003, infestation in all observed fruits over 40 km^2 averaged 14.3±2.9% after some suppression activities had been suspended. Uncultivated, wild hosts showed 87.5% mean decline in flies per gram of fruit.

Conclusions: A 3-component suppression strategy of sanitation, male annihilation and bait spray effectively suppresses melon fly.

POSTER PRESENTATION

Extension of the use of augmentoria for sanitation in a cropping system susceptible to the alien tephritid fruit flies (Diptera: Tephritidae) in Hawaii

Eric B. Jang, Lester M. Klungness, Grant T. McQuate

USDA-ARS, Hilo HI, United States

Introduction: This study reports efforts to demonstrate to growers of fruiting crops a technique to sequester emerging adult flies while conserving their parasitoid natural enemies. Sequestering infested fruit to prevent progeny survival is often overlooked.

Methods: Demonstration trials were conducted in 4 phases to determine whether growers on the Island of Hawaii would use a tent-like structure (augmentorium) to sequester fruit-fly infested, culled fruit.

Results: In phase one it was shown that 1127 *Bactrocera cucurbitae* (Coquillett) were recovered from cull fruit removed from the augmentorium, and that sanitation in combination with bait spray, and male lure trapping could reduce the level of infestation. Subsequently, phase two confirmed that the three techniques disrupted the breeding cycle and 2 farmers were convinced to use these techniques. In phase three, further expansion to 12 farms, whose 15 augmentoria were monitored, indicated that over 80% of the growers used the tents (22,217 adult flies recovered from the tents over 1260 days). In phase four, success of phases 1 to 3 convinced 30 farms to request 40 augmentoria and an opinion survey of those growers is reported.

Conclusions: The successful introduction of the augmentorium has implications for use of augmentoria to sequester the progeny of other insect pests and release their natural enemies.

POSTER PRESENTATION

Isolation and characterization of the novel antibacterial peptide Coprisin from a dung beetle, *Copris tripartitus*

Jae-Sam Hwang, Yeon-Ju Kim, Hea-Son Bang, Eun-Youn Yun, Seong-Ryul Kim, Kwan-Ho Park

NIAST, Suwon, Republic of Korea

Introduction: *Copris tripartitus* spends a lot of time in dung, which contains an abundance of pathogens. The larvae feed on dispose of fungi, decaying organic matter, dung and other organic materials in dung ball. It can be supposed that *C. tripartitus* must have antimicrobial activity against invading pathogen. Therefore, our purpose of the present study was to isolate and identify immune related genes in dung beetle, *C. tripartitus.*

Methods: Larvae were kept for 24h. cDNA Library from larvae of *C. tripartitus* immunized with *E. coli* was constructed by using a modification of Maruyama and Sugano's method (Maruyama and Sugano, 1994). Antibacterial activities of peptides were tested against *S. aureus,* MRSA, *E. faecalis, E. coli* ML-35*, P. aeruginosa,* MDRPA in a broth microdilution assay.

Results: Thirteen individual cDNA transcripts were expressed differentially in a total 1,862 random cDNA clones. One of up-regulated genes is a novel member of the insect defensin-like peptide(coprisin), a family of antibacterial peptide. Northern blot analysis showed that coprisin was up-regulated at 4hrs and reached the highest point level at 16h after injection of *E.coli*. The deduced amino acid sequence of coprisin was composed of 80 amino acids with predicted molecular weight of 8.6 kDa and PI of 8.72. Comparison of the deduced amino acid mature portion of coprisin with defensin-like peptide of other insect indicated that it has 79.1% and 67.4% identity with *Anomala cuprea* and *Allomyrina dichotoma*, respectively. In order to antibacterial peptides to the development of therapeutic agents, we looked for the active region of coprisin peptide and modified 9-mer peptide, LRCIALRKK-NH2, by changing amino acid sequences.

Conclusions: We isolated a new member of the insect defensin(coprisin) from the beetle, *Copris tripartitus.* Mature *C. tripartitus* defensin consisted of 43 amino acids and 6 cystein residues and showed 79.1% and 67.4% identity with *Anomala cuprea* defensin and *Allomyrina dichotoma* defensin, respectively. We modified oligopeptide and synthesized four 9-mer peptide. Modified 9-mer peptide, LLCIALRKK-NH2, is stronger antibacterial activity than LCAAHCLAIGRR-NH2 (*A.d.*-12De) and LHCIALRKK-NH2 (CopN5(22-30)) peptide against gram-negative and gram-positive bacteria. This peptide showed no haemolytic activity and quite stable at 100□ for several hours of incubation and in a wide pH range.

POSTER PRESENTATION

Identification of cry1-type genes and characterization of a novel cry1-type gene from *Bacillus thuringiensis* subsp. *alesti* strain LY-99

Xu Feng Qi, Ming Shun Li, Jae Young Choi, Ji Zhen Song, Yong Wang, Byung Rae Jin, Yeon Ho Je, Jian Hong Li

Huazhong Agricultural University, Wuhan, China

Bacillus thuringiensis strain LY-99 belonging to subsp. *alesti* (H3a3c), was isolated from Chinese tobacco warehouse and showed significantly high toxicity to *Plutella xylostella*. For the identification of the *cry1*-type genes from *B. thuringiensis* LY-99, an extended multiplex PCR-restriction fragment length polymorphism (PCR-RFLP) method was established by using two pairs of universal primers based on the conserved regions of the *cry1*-type genes to amplify around 2.4 kb *cry1*-type gene fragments. Then the DNA fragment was cloned into pGEM-T Easy vector and digested with *Eco*RI and *Eco*RV enzymes. Through this method, a known *cry1*-type gene was successfully identified from the reference strain, *B. thuringiensis* subsp. *alesti*. In addition, the RFLP patterns revealed that *B. thuringiensis* LY-99 included a novel *cry1A*-type gene in addition to *cry1Aa*, *cry1Ac*, *cry1Be* and *cry1Ea* genes. The novel *cry1A*-type gene was designated *cry1Ah2*(GenBank accession number: DQ269474). An inverse PCR method was used to amplify the flank regions of *cry1Ah2* gene. Finally, 3143 bp *Hin*dIII fragment from *B. thuringiensis* LY-99 plasmid DNA including 5' region and partial ORF was amplified, and sequence analysis revealed that *cry1Ah2* gene from LY-99 showed 89.31% of maximum sequence similarity with *cry1Ac1* crystal protein gene. In addition, the deduced amino acid sequence of Cry1Ah2 protein shared 87.80% of maximum identity with that of Cry1Ac2. This protein therefore belongs to a new class of *B. thuringiensis* crystal proteins.

POSTER PRESENTATION

Field efficacy of insecticides against jassid (*Amrasca biguttula biguttula* Ishida.) on *Abelmoschus esculentus* L. under sub-himalayan region of N-E India

Sunil Ghosh, Koushik Das

Uttar Banga Krishi Viswavidyalaya (University), Coochbehar, West Bengal/Northern, India

Introduction: Lady's finger (*Abelmoschus esculentus* L.) is an annual crop belongs to the family Malvaceae and one of the most important vegetable crops grown in tropical and sub-tropical areas. The crop is very much susceptible to various insect pests of which jassid (*Amrasca biguttula biguttula* Ishida.) is found to cause heavy damage. It is very difficult to control the pest as the fruits are plucked at frequent interval and consumed after little cooking and there is every possibility to retain toxic substances in the fruits which cause health hazards.

Methods: Studies were made to evaluate new insecticides against jassid of lady's finger under field conditions of sub-himalayan region of N-E India during post-kharif season. Nine insecticides including one phytopesticide neem oil(*Azadiracta indica*) were sprayed twice at 15 days interval. Total jassid population per 3 leaves were taken into account at 3,8and14 days after treatment. The data thus obtained were computed on the per cent of insect population suppressed and analyzed statistically.

Results: Variation in relative efficacy of different insecticides and their persistency at different days after treatment (DAT) on suppression of jassid population was significant. From the overall observation it was revealed that all the insecticides gave a satisfactory jassid control, having more than 65% mortality. Chlothianidine was found most effective insecticide to control jassid population. Imidachloprid was found to record best at 3 DAT closely followed by dimethoate. A rapid degradation of persistency was observed in imidachloprid than chlothianidine and dimethoate after 14 DAT. Neem oil also provide a satisfactory results at 3 DAT.

Conclusions: Imidachloprid, having lower persistency, is suitable for jassid control. Phytopesticide neem oil is of biological origin having less hazardous effect on health and so can be incorporated in the IPM programme of pest control in vegetable cultivation.

POSTER PRESENTATION

Parasitism of diamondback moth, *Plutella xylostella* L. by an endo-parasitoid braconid wasp, *Cotesia glomerata* L. at Highland

Min Kwon, Juil Kim, Seunghwan Lee

National Institute of Highland Agriculture, RDA, Pyeongchang, Gangwon; Seoul National University, Seoul, Korea, Republic of Korea

Introduction: *Cotesia glomerata* is well known for attacking larvae of imported cabbageworm (*Artogeia rapae*) in the field, but little information on attacking diamondback moth (DBM, *Plutella xylostella*) has reported. This study aimed to identify if *C. glomerata* can parasitize DBM larvae, and to investigate some biological characteristics of wasps.

Methods: The cocoons of *C. glomerata* collected in cabbage fields at Daegwallyeong area in Korea, asl 800 meter, were placed into acryl cylinder to emerge. Newly-emerged adults were allowed to mate for 2 days before fresh cabbage leaf with 200 second instar larvae was introduced into cylinder. After exposing for 48 h, cabbage leaf with parasitized larvae was removed from cylinder and placed on fresh 6-week-old cabbage.

Results: Parasitism rate of *C. glomerata* to imported cabbageworm was over 15% on average, and over 70% of cocoons emerged into adults. We identified that *C. glomerata* can attack DBM larvae and parasitize them successfully and efficiently. The parasitoids showed solitary type for DBM, not gregarious type. Parasitism rates were at the field sites werevery low, but up to 90% in cages.

Conclusions: As *C. glomerata* is not available commercially at this time, but this parasitoid could be promising to use as bio-control agent of DBM.

POSTER PRESENTATION

Cloning, expression, and sequence analysis of the major structural protein genes of the porcine reproductive and respiratory syndrome virus isolated in Korea

Hyun-Na Koo[1], Jeong-Mi Oh[1], Jae-Kyung Lee[1], Yeon-Ho Je[2], Byung-Rae Jin[3], Soo-Dong Woo[1]

[1]Department of Agricultural Biology, Chungbuk National University, Cheongju, Chungbuk, [2]Department of Agricultural Biotechnology, Seoul National University, Seoul, [3]College of Natural Resources and Life Science, Dong-A University, Busan, Republic of Korea

Introduction: Porcine reproductive and respiratory syndrome (PRRS) is an economically significant viral disease of swine. Each gene of the six major structural proteins (ORF2, ORF3, ORF4, ORF5, ORF6 and ORF7) of PRRSV isolated in Korea was cloned, sequenced, and expressed.

Methods: Each gene was amplified using degenerated PCR primers and cloned into PCR vector. After sequence analysis, each gene was cloned into baculovirus expression vector and expressed in insect cells. Expression of each protein was analyzed by SDS-PAGE and Western blot.

Results: The each gene analysis showed that Korean isolate is an American strain and the homology of amino acid sequence was from 91% to 100% when compared previous reports. ORFs 2 to 7 were inserted into recombinant baculoviruses downstream of the polyhedrin promoter. Insect cells infected with the respective recombinant baculovirus produced each protein. Expression of each protein was identified by RT-PCR and immunoblot with PRRSV-specific antibody, indicating that they were similar to the native proteins.

Conclusions: The ability to produce each protein in the baculovirus system indicate that these could be major candidates for the development of a vaccine against PRRSV.

POSTER PRESENTATION

Characterization of nucleopolyhedrovirus isolated from *Mamestra brassicae* (Lepidoptera: Noctuidae) in Korea

Jae Kyung Lee[1], Jeong-Mi Oh[1], Hyun-Na Koo[1], Yeon-Ho Je[2], Byung-Rae Jin[3], Soo-Dong Woo[1]

[1]Department of Agricultural Biology, Chungbuk National University, Cheongj, [2]Department of Agricultural Biotechnology, Seoul National University, Seoul; [3]College of Natural Resources and Life Science, Dong-A University, Busan, Republic of Korea

Introduction: The cabbage armyworm, *Mamestra brassicae*, is an important insect pest of vegetables and ornamental plants in Asia and Europe. Several nucleopolyhedroviruses (NPVs) have been isolated from *M. brassicae* and considered useful biological-control agents for *M. brassicae*. However, Korean strain of *M. brassicae* NPV (MbNPV) is poorly characterized. For the practical use of NPV as a control agent of noctuid pests, it is necessary to identify and characterize the virus strain in advance. The objective of our study was the pathogenic, morphologic and genetic characterization of a MbNPV isolate (MbNPV-K1) derived from a diseased larva of *M. brassicae* found in Korea.

Methods: The morphology of polyhedra was observed using SEM and TEM. The lethal dose and time were determined using *M. brassicae* larvae by droplet-feeding bioassay. The polyhedrin gene was amplified by PCR and sequenced. All results were compared with those of the previous commercialized MbNPV as a control.

Results: The morphology of polyhedra and the structure of polyhedrin gene did not show any significant difference between two viruses. But the size of polyhedra of MbNPV-K1 was slightly bigger than the control. The value of lethal concentration (LC_{50}) of MbNPV-K1 against 3rd instar larvae of *M. brassicae* was 15 times higher than the control. The lethal time was also shorter than the control.

Conclusions: The higher pathogenicity of MbNPV-K1 provides the possibility of the development of effective viral insecticide using this for the control of *M. brassicae*.

POSTER PRESENTATION

The mason bee *Osmia orientalis* uses the presence of visitors on the flower as resource assessment

Tomoyuki Yokoi, Kenji Fujisaki

Laboratory of Insect Ecology, Graduate School of Agriculture, Kyoto University, Kyoto, Japan

Introduction: If many bees visit the same flower patch, the probability that they meet on the same flower would increase with resource depletion. However, several social bees preferentially visit the flowers on which conspecifics are feeding. It would be beneficial for them to reduce the time spent on detecting rewarding flowers because floral resources are unpredictable. Field experiments were conducted to test whether the mason bee *Osmia orientalis* visits the flower of wild strawberry *Rubus hirsutus* on which heterospecifics are already feeding as a cue for resource assessment.

Methods: The frequency of encounter with other visitors on the same flower was recorded in three bees; *O. orientalis*, *Apis mellifera* and *Micrandrena* spp. We recorded visitation rate to flowers on which the different dead bees were artificially set.

Results: *O. orientalis* was one of the dominant visitors and always acquired the flower where other visitors were feeding. The visitation rate of *O. orientalis* was highest on flower where *Micrandrena* spp. was artificially set. *A. mellifera* and *Micrandrena* spp. rejected the flowers on which dead bees were set.

Conclusion: *O. orientalis* may recognize the presence of *Micrandrena* spp. on the flower as a cue for resource assessment. The visit to these flowers would be profitable because of the low cost to acquire the resources through the competition.

POSTER PRESENTATION

The value of public involvement in an entomological survey: a model from the UK

Peter M.J. Brown[1], Helen E. Roy[1], David B. Roy[1], Michael E.N. Majerus[2]

[1]NERC Centre for Ecology and Hydrology, Monks Wood, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom

The arrival in England of *Harmonia axyridis* Pallas (Coleoptera: Coccinellidae) represented something of a turning point in species recording in the UK. *Harmonia axyridis* is regarded as an alien invasive species in Europe. Concern by some entomologists that the species would have a seriously detrimental impact on native insects led to major national publicity following the insect's arrival. After verification of over 100 records of *H. axyridis* in 2004, the year of arrival, a project was funded for detailed monitoring of the spread of the species in the UK. A key element of the project was the development of a web-based recording system accessible by members of the general public. Increasingly high levels of access to the internet and digital photography made this project possible. Here we outline the recording system and infrastructure used to support the monitoring scheme, and highlight the importance of public involvement. In some respects the scheme is labour intensive, involving the verification of individual specimens by either photograph or specimen. However, there are several wider benefits of the scheme; firstly the model (in terms of the technology and systems used, as well as the biological spread model) is potentially transferable to other taxa, particularly other invasive species; secondly the engagement of the public in wildlife monitoring; thirdly the rejuvenation of a recording scheme for a whole family of insects (the Coccinellidae) alongside a high profile non-native species. We also reflect on the importance of publicity in making such a monitoring scheme effective, and explore the potential for further automation.

POSTER PRESENTATION

Mitochondrial genetic diversity and phylogeography of the Iberian populations of *Mioscirtus wagneri* (Orthoptera: Acrididae), a specialized grasshopper inhabiting highly fragmented hypersaline environments

Joaquin Ortego, Raul Bonal, Jose Miguel Aparicio, Pedro J Cordero

Instituto de Investigación en Recursos Cinegeticos-IREC, Ciudad Real, Spain

Introduction: Mediterranean inland hypersaline areas are globally threatened habitats harbouring many specialized organisms often endemic or constituting relict populations which frequently show disjunct distributions. Contraction of wider original habitats after historical climate changes/geological events and, more recently, human induced habitat loss have led these species to be distributed forming highly fragmented and isolated populations in small-sized patches of favourable habitats. Here, we analyze mitochondrial genetic diversity and phylogeography of *Mioscirtus wagneri*, a specialist orthoptera inhabiting hipersaline low grounds with patches of *Suaeda vera*, a plant on which it depends for food.

Methods: We used a 260 bp of the cytochrome oxidase subunit II and 486 bp of the 16S rRNA genes to study the genetic diversity and phylogeographic structure of *Mioscirtus wagneri* over the entire species distribution range in the Iberian Peninsula. For this purpose, we sampled a total of 227 individuals from 26 Iberian populations.

Results: After combining sequence information from the two mitochondrial genes we determined the presence of 12 unique haplotypes (COII: 9 haplotypes; 16S rRNA: 5 haplotypes) across the 227 specimens examined. Phylogenetic analyses revealed three mitochondrial DNA clades corresponding with northeast, central-southeast, and southwest populations. Populations from these three different geographic areas never shared any haplotype, indicating that gene flow between them is absent.

Conclusions: We conclude that the three *Mioscirtus wagneri* clades correspond with distinct evolutionary entities and such differences should be considered in future conservation programmes of Iberian hypersaline environments.

POSTER PRESENTATION

When umbrellas kill: the case of small reserves in sensitive habitats

Pedro J. Cordero, Joaquín Ortego, Raúl Bonal, Gustau Calabuig, Elena García-Vigón, José M Aparicio

Instituto Investigación en Recursos Cinegéticos (IREC)(UCLM, CSIC, JCCM), Ciudad Real, Castilla-La Mancha, Spain

Inland hyper-saline lagoons are singular and sensitive habitats of Mediterranean arid land often surrounded by dry crops and plugged land. They present a high amount of rare, specialised or endemic species of plants and invertebrates, insects included. Some are typical of saline environments and others from arid lands taking refuge in the vegetation rings around these lagoons. This fauna is poorly known, may present localised distributions, a low ability of dispersal and are submitted to a high risk of local/total extinction. In turn, several emblematic bird species with preferences in arid land or aquatic environments may gather at high densities and often are determinant of the importance given to these micro-reserves for conservationist agents, constitute an essential cultural value for visitors and are considered umbrella species in management decisions. However, local action plans for bird management and conservation or, simply, the increasing of natural populations of some species put at risk the persistence of these habitats and some of its invertebrate species. An over-population of medium/large-sized-omnivorous/insectivorous-birds may reduce prey because of high foraging pressure on insect rarities (i.e. orthopteroids), or because of habitat changes in the soil or vegetation where these endangered insects live. Two action plans are proposed: firstly cultural, by investing more on the knowledge and divulgation of invertebrate species values. Secondly of management, by increasing the area of vegetation ring preserved around these lagoons and by creating new patches in the surroundings. Both actions could ameliorate the harmful effects of birds on rare insects and would reduce the conservation conflict in these particular and sensitive habitats.

POSTER PRESENTATION

The evolutionary ecology of body size in seed parasites: the case of the acorn feeding Curculio

Raul Bonal[1], Tabitha Pearman[2], Josep Maria Espelta[3], Alberto Muñoz[4], Jose Miguel Aparicio[1], Joaquin Ortego[1], Pedro J. Cordero[1], Alfried Vogler[2]

[1]IREC (CSIC-UCLM-JCCM), Ciudad Real, Spain, [2]THE NATURAL HISTORY MUSEUM, London, United Kingdom, [3]CREAF-UAB, Barcelona, Spain, [4]IRN-CCMA-CSIC, Madrid, Spain

Introduction: The larvae of many granivorous insects, like the acorn feeding Curculio, are parasites which complete their development inside a single seed. Comparative interspecific analyses have shown that body size is correlated with the size of the seeds exploited. This suggests that larval growth could be constrained by seed size so that shifts to larger seeds would trigger body size increase due to its fitness benefits (e. g. higher survival). We studied whether seed size may constrain larval growth in *Curculio elephas*. In addition, we carried out an extensive sampling and assessed whether the adaptation to seed size may start at the intraspecific level.

Methods: We collected infested acorns in different localities of the Iberian Peninsula, measured the emerging larvae and finally opened the seeds to find out whether the food (i. e. cotyledons) had been depleted. We sequenced a fragment of mitochondrial DNA cytochrome oxidase subunit I (826 bp long) to consider the effect of neutral gene-flow in the analyses between populations.

Results: Seeds can be depleted and constrain larval growth. There was a correlation between larval size and seed size across populations due to local adaptation; phenotypic effects of seed size were ruled out including only individuals which developed *ad libitum*, unconstrained by food availability. This correlation was independent of neutral gene-flow between populations.

Conclusion: Seed size can constrain larval growth and may be an important factor for species diversification. This process can start at the intraspecific level with different populations locally adapted to seed size.

POSTER PRESENTATION

The simultaneous measurement of juvenile hormones and ecdysteroids in the haemolymph of crickets *Gryllus bimaculatus* (Ensifera: Gryllidae) by liquid chromatography-mass spectrometry (LC-MS)

Klaus H. Hoffmann, Stephanie Westerlund

University of Bayreuth, Animal Ecology I, Bayreuth, Germany

Radioimmunoassays are frequently used for the quantification of ecdysteroids in the haemolymph of insects, whereas for juvenile hormone titers, physicochemical methods such as GC-MS have been considered the most accurate. Unfortunately, extensive sample preparation and organic solvent usage for GC-MS, and the need of radioactivity in radioimmunoassays, are a major disadvantage for routine analyses. Here we use a time- and chemical-saving LC-MS method for the simultaneous detection of juvenile hormone (JH) and free ecdysteroids in the haemolymph of last instar larvae and adult crickets with the same degree of accuracy and precision as can be afforded with GC-MS and radioimmuno-assay, respectively (Westerlund and Hoffmann, 2004: Analyt. Bioanalyt. Chem. 379, 540-543).

Juvenile hormone III was the only JH homology found in last instar larvae and adults of both sexes. Female and male last instar larvae exhibited a rather steady JH III titer (27 $\pm$ 5 pg/µL), whereas in adults a maximum in the JH III was observed on day 4 after ecdysis for females (94 $\pm$ 35 pg/µL) and on day 3 for males (111 $\pm$ 20 pg/µL).

Ecdysone (E) was present in last instar larvae of both sexes as well as in adult females and males, whereas 20-hydroxyecdysone (20E) was only found in the larvae, but not in the haemolymph of adult animals. In last instar larvae, the maximal concentration of 20E on day 5 corresponds to the moulting process, whereas in adult females the titers of ecdysone and JH III are in parallel with ovarian weight gain and egg maturation.

Supported by the Deutsche Forschungsgemeinschaft GK 678/2.

POSTER PRESENTATION

Determining insect pest impact within multi-cropping systems as part of a holistic approach to diverse cropping systems evaluation

William J Weeks, Philippus D R van Heerden

[1]*Southern District and Research, Potchefstroom, North-West Province, South Africa,* [2]*Sugarcane Research Institute, Mount Edgecombe, South Africa*

Introduction: Multi-cropping systems, characterized by an intimate spatial and maximal temporal overlap, rank among the most complex ecological systems. Studies evaluating multi-cropping system impacts on insect pests often do not consider plant density effects.

Aim: To illustrate how information on insect infestation intensity and plant stress along with land use efficiency calculations can be employed to evaluate multi-cropping systems.

Methods: A cabbage/ carrot companion planting field trial with a split-plot experimental design was established. Insecticide applications and no-spraying were whole-plots with five sub-plot treatments *viz.* cabbage monoculture, carrot monoculture, 1:1, 1:3 and 1:5 cropping ratios (cabbage: carrot), replicated five times. Cabbage insects were sampled fortnightly from sub-plots on no-spraying whole-plots over 3 sampling dates. Chlorophyll *a* fluorescence measurements were recorded from cabbage and carrot leaves on all plots. The performance index (PI_{ABS}) was calculated from these measurements as indicator of plant stress. Cabbage head mass and carrot root mass was determined from all plots. Data was subjected to analysis of variance. Treatment means were separated using Fishers' protected t-test at the 5% level of significance (LSD).

Results: Results indicate low insect infestations on cabbage with no significant differences ($P > 0.05$) between sub-plot treatments and PI_{ABS} values. Cabbage PI_{ABS} values on the sprayed whole-plots were significantly ($P \leq 0.05$) lower, indicating a degree of phytotoxicity induced by insecticide applications. This corresponds with a 14% cabbage yield reduction on sprayed plots. Chlorophyll *a* fluorescence appears to be sensitive as an indicator of insecticide phytotoxicity. Future development of this approach will be done under higher insect infestation levels. Use of the Land Equivalent Ratio to evaluate this multi-cropping system will also be explored.

POSTER PRESENTATION

Phylogeography of the temperate bark beetle *Tomicus piniperda* (Coleoptera, Scolytinae): new evidence of a complex past history

Agnes Horn[1], Christian Stauffer[2], François Lieutier[1], Carole Kerdelhué[3]

[1]Université d'Orléans, Laboratoire de Biologie des LBGC UPRES EA 1207, Orléans, France, [2]Boku, University of Natural Ressources and Applied Life Sciences, Vienna, Austria, [3]INRA, UMR BIOGECO 1202, Cestas, France

Introduction: European temperate species have been largely affected by past climatic oscillations, leading to a general genetic pattern of southern richness and northern purity. The temperate and cold-tolerant bark-beetle *Tomicus piniperda* is largely present all over Europe except the Mediterranean Basin, and develops on pine species. We studied the phylogeography of the species in Europe to test (i) if its phylogeographic pattern reflects those of its main hosts; (ii) if classical southern refugia could be identified in spite of the species' sensitivity to dry climates; and (iii) if northern refugia could be found for this cold-tolerant organism.

Methods: A 797 pb part of the Cytochrome Oxydase I and II genes were sequenced for 150 individuals sampled in 34 European populations.

Results: 36 haplotypes were identified and joined in a single haplotype network. One haplotype was dominant in Europe but Iberian Peninsula, while this last region was characterized by numerous endemic haplotypes.

Conclusion: *T. piniperda* showed a phylogeographic pattern similar to that of its main host *Pinus sylvestris*, with genetic richness in Iberian Peninsula and a predominant haplotype in the rest of Europe, reflecting a rapid recolonization of northern regions during warmer periods. In Iberian Peninsula, the species may have survived the interglacials in fragmented refugia localized in high altitude, leading to isolated populations which poorly contributed to postglacial expansions. In the rest of Europe, some glacial refugia were identified in both southern and northern regions. Yet, high dispersal ability led to a weak genetic structure in Europe.

POSTER PRESENTATION

Colonization history of the Neartic leafhopper *Scaphoideus titanus* in Europe based on microsatellite and mitochondrial DNA variability

Daciana Papura[1], Christian Burban[2], Xavier Giresse[1], Carole Kerdelhué[2], François Delmotte[1], Van Helden Martin[1]

[1]INRA-ENITA, UMR Santé Végétale 1065, Bordeaux, France, [2]INRA, UMR BIOGECO 1202, Cestas, France

Introduction: The Nearctic leafhopper *Scaphoideus titanus* was accidentally introduced in Europe during the 20th century and expanded almost throughout the continent in about 60 years. *S. titanus* is the vector of Flavescence dorée phytoplasma, the causal agent of the most important grapevine yellow disease in European vineyards.

Material and methods: Native American *S. titanus* populations were compared to European populations using seven polymorphic nuclear microsatellite loci and a fragment of 623 bp of the mitochondrial cytochrome oxidase II ($tRNA^{LEU}$-COII) gene.

Results and discussion: Consistent with their recent history, invasive European populations showed much lower levels of genetic diversity than American populations, indicative of recent bottlenecks. Population differentiation inferred from microsatellite data was generally lower but significant in European populations (pairwise mean F_{ST} = 0.030) than among American populations (pairwise mean F_{ST} = 0.042). A significant pattern of isolation by distance was detected among American but not among European populations. Concerning mitochondrial data, none of the European haplotypes was found in the American populations from which they are assumed to originate. Clustering analysis on microsatellite data suggest that most European populations have originated from a main invasion event, with one additional introduction into southern Switzerland, where endemic mitotypes were found. After the initial establishment of *S. titanus* populations, the commercial exchanges of grapevine canes and grafts carrying eggs could have played an important role in the insect dispersal across European vineyards.

POSTER PRESENTATION

Insects in southern African rock art

Jeremy Hollmann[1], Mike Mostovski[2]

[1]Natal Museum and School of Anthropology, Gender and Historical Studies, University of KwaZulu-Natal, Pietermaritzburg, South Africa, [2]Natal Museum and School of Biological & Conservation Sciences, University of KwaZulu-Natal, Pietermaritzburg, South Africa

Southern African hunter-gatherers, the ancestors of contemporary Bushman peoples, have a long tradition of making rock art. This art is predominated by depictions of anthropomorphs and a restricted number of antelope species and large herbivores such as giraffe, rhinoceros and elephant. However, images of insects are also an important, if less numerous component of the art. Paintings of termites and bees are the most prominent categories and occur in particular regions. Other images that have been identified as insects, such as moths and locusts, are far less common. Our current understanding of the art is that painted and engraved depictions are supernaturally charged images, not simply depictions of everyday activities and favoured menu items. Insects play an important role in hunter-gatherer economy and cosmology and therefore our interpretations of paintings and engravings of insects are based upon ethnographic sources and analogies in order to interpret depictions of these arthropods.

POSTER PRESENTATION

Correlates between butterfly species richness and landscape composition and structure: a multi-scale analysis

Jean-Pierre Rossi, Inge van Halder

INRA, UMR1202 Biodiversity Genes & Communities, F-33610 Cestas, France

Introduction: Species richness is strongly affected by habitat type and landscape features. Most butterfly species need complementary resources (host-plants for egg laying and larvae development, nectar plants for adults, roosting-, resting- and over wintering-sites) during their life cycle. Therefore, species richness may be favoured in diverse landscapes. The present study aimed at determining to which extent butterfly species richness could be related to landscape features and if yes, at which spatial scales.

Methods: Butterfly species richness was estimated at 83 sampling points distributed among 2 study sites in the Landes de Gascogne (Southwestern France), in pine stands, deciduous woodlands and firebreaks. Around each sampling location, landscape was described within circular areas (buffers) of increasing sizes using a GIS database. For each buffer size, various landscape metrics were calculated in order to quantify important features such as landscape heterogeneity, fragmentation and composition.

Results and discussion: A total of 2750 individuals belonging to 44 species were recorded in the 83 plots. Partial Least Square Regression (PLS) showed the presence of a significant relationships between landscape metrics and species richness ($p=0.002$). Interestingly the strength of the relationship between landscape metrics and butterfly species richness changed dramatically according to the spatial scale (size of the buffer) and the variable considered. This work illustrates the multiscale nature of the relationships between butterflies and landscape and how adequate statistical tools (PLS) can be useful in unravelling such complex patterns. As a consequence, selection of landscape-based biodiversity indicators should be based on multi-scale approaches.

POSTER PRESENTATION

Post-storm study of the spatial distribution of the bark beetle *Ips sexedentatus* in a pine plantation forest (Landes de Gascogne, Southwestern France)

Jean-Pierre Rossi[1], Jean-Charles Samalens[1], Dominique Guyon[2], Inge van Halder[1], Hervé Jactel[1], Pierre Menassieu[1], Dominique Piou[3]

[1]INRA, UMR1202 Biodiversity Genes & Communities, F-33610 Cestas, France, [2]INRA, UR1263 EPHYSE, F-33140, Villenave d'Ornon, France, [3]DSF, Impasse R. Lavigne, F-33150 Cenon, France

Introduction: The bark beetle *Ips sexdentatus* (Boern) (Coleoptera, Scolytidae) is a serious pest of planted and natural pine forests causing important damages during outbreak phases. Outbreaks are triggered or facilitated by climatic events like windstorms that lead to increased amount of breeding material through felled timbers. In December 1999, Southwestern France was struck by a windstorm that felled more that 27 million m^3 of timber. In a forest of 1500 ha, we surveyed the spatial pattern of attacked trees and its relationship with the spatial location of the pine logs that were temporally stored in piles along stand edges during the post-storm process of fallen tree removal.

Methods: A GIS database was developed on the basis of a complete inventory of attacked trees and log piles. A total of 2393 and 3142 attacked trees were identified and mapped in 2001 and 2002. Patches of attacked trees were defined using kernel estimation coupled with Monte Carlo tests. Patches spatial distribution and their relationship with log piles were assessed using a new method designed to account for object shape in point pattern analysis [Wiegand *et al*, 2006, *J. Ecol*. 94, 825-837].

Results: There was a significant relationship between patches of trees attacked during the both years of the study and log piles. These results indicate that *I. sexdentatus* outbreaks exhibited large-scale spatial structure partly explained by forest management (log pile position) and landscape configuration (network of forest tracks). This suggests that log pile spatial distribution should be taken into account to optimize sampling schemes in forest health monitoring programmes.

POSTER PRESENTATION

Geostatistical analysis of pine processionary moth (*Thaumetopoea pityocampa*) spatial distribution at the landscape scale (Landes de Gascogne, Southwestern France)

Jean-Pierre Rossi[1], Jean-Charles Samalens[1], Hervé Jactel[1], Dominique Piou[2]

[1]INRA, UMR1202 Biodiversity Genes & Communities, F-33610 Cestas, France, [2]DSF, Impasse R. Lavigne, F-33150 Cenon, France

Introduction: The pine processionary moth (PPM) (*Thaumetopoea pityocampa* Denis & Schiffermüller: Lepidoptera Notodontidae) is the most important defoliator of pines in Southern Europe. It produces spectacular outbreaks and often displays non random spatial distributions which determinants remain to be fully understood. This survey aimed at describing the population spatial pattern and its variability through time and its relationship with landscape composition and structure.

Methods: We studied the dynamics of the PPM in pine plantations in the Landes de Gascogne (Southwestern France). Population density was estimated on 145 sites scattered on a 16 x 16 km grid with mesh of 2 Km. Data were collected during 3 consecutive years (2005-2007). Geostatistics were used to assess the presence of autocorrelation and to describe the population pattern by kriging. Data collected on different sampling dates were compared by means of Mantel tests.

Results and discussion: The population exhibited a strongly autocorrelated distribution in 2005 with patches of several kilometers. A very high local variability was superimposed on this long-range spatial structure that is likely due to the effects of local landscape features. Data collected in 2006 and 2007 showed no structure and very low population densities. These dates corresponded to the very end of the decline phase or the beginning of the non-outbreak phase. Sampling will be repeated for 4 additional years so as to determine if the spatial structure observed during the beginning and the outbreak phase is stable through time and to gain a better knowledge on how landscape affects population dynamics.

POSTER PRESENTATION

Effect of fire on arthopods in central semi-arid Argentina

F. Rodrigo Tizón[1], Daniel V. peláez[2], Omar Elía[3], Mirta Mayor[4]

[1]CERZOS, CIC, Departamento de Biología. Universidad Nacional del Sur., Bahía Blanca, Buenos Aires, Argentina, [2]CERZOS, CIC, Departamento de Agronomía. Universidad Nacional del Sur., Bahía Blanca, Buenos Aires, Argentina, [3]CERZOS, Departamento de Agronomía. Universidad Nacional del Sur., Bahía Blanca, Buenos Aires, Argentina, [4]Bahía Blanca, Buenos Aires, Argentina

Introduction: Fire plays a vital role in maintaining the communities of the region central semi-arid Argentina. The grasslands are subjected to burns to manage vegetation. Some of the desirable consequences of this practice are the increase of coverage of grass and the decrease of shrub species. However, the consequences of the animal communities are highly variable.

Methods: We studied the effect of the history of controlled fire at different frequencies, 3 (T_1, 2 replicates) y 6 (T_2, 2 replicates) years, and the short-term effects of fire on the epigean arthropods. Sampling was conducted in SE of the province of La Pampa (38º45´S, 63º45´W) in plots burned and unburned ($T_u T_1, T_2$), since 1991. In the fall of 2007, 20 pitfall traps per treatment were activated for a week, and ending winter, after a controlled burn the traps were re-activate ($T_{up} T_{1p}, T_{2p}$). Shannon-Wiener index and confidence intervals (bootstrap) were calculated.

Results: Comparisons of richness, abundance and diversity of arthropods orders response did not show significant differences ($p>0.05$) between treatments ($T_u T_1, T_2$). On the other hand, the diversity decrease significantly ($p <0.05$) in samples collected after two months of controlled burning ($T_{up} T_{1p}, T_{2p}$). In post-fire treatments the total number of individuals decreased with fire frequency increment, but the total number of orders remained relatively stable. Orders more adversely affected by the fires were Acari, Collembola and Homoptera while Hymenoptera and Coleptera were favored.

Conclusions: In the future, would be desirable to incorporate other level *taxa* to improve comprehension of the effect of fire on arthropods assemblages.

POSTER PRESENTATION

How many species of *Stenobasipteron* (Diptera: Nemestrinidae) in South Africa

Musa Mlambo, David Barraclough, Rob Slotow

University of KwaZulu-Natal, Durban, South Africa

Stenobasipteron Lichtwardt is one of three long-proboscid genera of Nemestrinidae (Diptera), which are important in Southern African pollination biology. Numerous endemic plant species with elongate floral tubes are pollinated by these long-proboscid species. *Stenobasipteron* has received virtually no taxonomic attention for the last 80 years, which has resulted in taxonomic confusion, misidentifications and the failure to recognise species complexes. The genus is mainly distributed through the eastern provinces of South Africa, and into Swaziland and Zimbabwe. Currently the genus includes three described species -- two from Zimbabwe (*S. arnoldi* & *S. gracile*) and one from South Africa (*S. wiedemanni*). *S. wiedemanni* is known to be restricted to forest habitats in the south-eastern provinces of KwaZulu-Natal and the Eastern Cape. Extensive morphological examination of more than 250 specimens has revealed that, within South Africa, *Stenobasipteron* now includes six valid species, i.e. *S. wiedemanni* and five new species. All the new species are distributed in the northeastern provinces of Mpumulanga and Limpopo, and occur in a variety of habitats. The fauna of neighbouring Southern African countries also requires taxonomic revision.

POSTER PRESENTATION

Stink bug management for soybeans in the southern United States

Scott Stewart[1], Angus Catchot[2], Gus Lorenz[3]

[1]University of Tennessee, Jackson, TN, United States, [2]Mississippi State University, Mississippi State, MS, United States, [3]University of Arkansas, Fayetteville, AR, United States

Information will be presented on stink bug pests (Hemiptera: Pentatomidae) and their management for soybeans grown in the southern United States. Stink bugs are considered the primary pests of soybeans in most areas of the southern United States. The most common pest species include the green stink bug (*Acrosternum hilare*), brown stink bug (*Euschistus servus*) and the southern green stink bug (*Nezara viridula*). The damage potential for these pests will be addressed. Management considerations, including the impacts of planting date, selection of maturity groups and insecticide selection will also be included.

POSTER PRESENTATION

Identification of host-plant attractants for the cranberry weevil, *Anthonomus musculus* Say (Coleoptera: Curculionidae)

Zsofia Szendrei[1], Edi Malo[2], Cesar Rodriguez-Saona[1]

[1]*Rutgers, The State University of New Jersey, Chatsworth, New Jersey, United States,* [2]*Departamento de Entomologia, El Colegio de la Frontera Sur, Tapachula, Chiapas, Mexico*

Introduction: The cranberry weevil is an oligophagous flower bud feeder native to North America. It causes significant economic injury on cultivated highbush blueberry, *Vaccinium corymbosum* L. (Ericaceae), and on cranberry, *Vaccinium macrocarpon* Ait. (Ericacea). This project was conducted in New Jersey, where the weevil causes major crop losses to blueberry growers. As part of an integrated response to this problem, we investigated the role of plant volatiles as attractants for monitoring or trapping.

Methods: We analyzed volatile compounds from blueberry leaves, buds, and flowers. More than 30 compounds were identified using GC-mass spectrometry and subsequently tested in electro-antennograms (EAG). Y-tube olfactometer assays were conducted to assess the attractiveness of damaged and undamaged buds and flowers.

Results: Weevil antennae were highly responsive to hexyl acetate, cis-3-hexenyl acetate, cis-3-hexenyl butyrate, methyl salicylate, cinnamyl alcohol, linalool oxide, linalool, and α-humulene. Cis-3-hexenyl butyrate and cinnamyl alcohol were emitted only from blueberry flowers. Cinnamyl alcohol was the major blueberry flower volatile. In laboratory assays, flower buds and flowers were attractive to weevils, and damaged buds were more attractive than undamaged buds.

Conclusion: This project has identified several volatile compounds from blueberries that can serve as a potential attractant for the cranberry weevil. In the spring 2008, traps baited with cinnamyl alcohol will be investigated for weevil attraction in the field. Two trap designs will be compared: soil-cone traps and yellow sticky cards at the canopy level. In addition, both Y-tube and field experiments will test whether conspecifics produce behaviorally active compounds.

POSTER PRESENTATION

Yield benefits of Thiamethoxam and Imadacloprid used as insecticide seed treatments in soybean in the mid-south region of the United States

Angus Catchot[1], Gus Lorenz[2], Scott Stewart[3], Roger Leonard[4]

[1]Mississippi State University, Mississippi State, MS, United States, [2]University of Arkansas, Little Rock, AR, United States, [3]The University of Tennessee, Jackson, TN, United States, [4]Louisiana State University, Baton Rouge, LA, United States

From 2003-2007, researchers in the mid-south region of the Unites States have studied the use of thiamethoxam and imadacloprid as insecticide seed treatments in soybean for control of early season pests. Yield summary of 66 university trials with thiamethoxam compared to untreated plots resulted in an average yield increase of 3.5 bu/acre. Yield summary of 34 university trials with imadacloprid compared to untreated plots resulted in an average yield increase of 2.8 bu/acre. Early season incidence of bean leaf beetle, *Cerotoma trifurcata*, thrips, *thrips sp.*, threecornered alfalfa hopper, *Spissistilus festinus*, scarab grubs, and grape colaspis grubs, *Colaspis brunnea* were reduced compared to untreated check plots.

POSTER PRESENTATION

X-ray microCT enables high-resolution 3-D imaging of the internal anatomy of live locusts

Jenan Al-Harib[1], Vicky Hunt[1], Keith Charnley[1], David Heatley[2], Duncan Bell[1], Nick Corps[1]

[1]University of Bath, Bath, United Kingdom, [2]Disect Systems Ltd, Suffolk, United Kingdom, [3]e2v scientific instruments, Buckinghamshire, United Kingdom

Introduction: Micro-CT scanning is widely used, particularly in medicine, but has rarely been applied to insects. The technique has great potential for providing fine-resolution images of the internal organs of living specimens. We have established the technique in an entomological context using young adult male desert locusts, *Schistocerca gregaria*. We chose this insect because it is large, its anatomy is well described and we wish to apply the technique in an on-going investigation of the pathology of a specific Acridid fungal pathogen.

Methods: Ten day old live and dead adult male locusts were used. X-Ray micro-CT scans were performed using either the Skyscan 1174 or 1172 scanner (www.skyscan.be). Each scan generated between 4 and 5 thousand slices at an inter pixel size of 10.6 microns. Using a modified form of the 'disect' software we viewed 8 bit data at 250 X 250, 512 X 512 or 2000 X 2000 resolution allowing us to view 900, 300 or about 40 slices at a time.

Results: The combination of a high resolution X-ray micro-CT scanner and user friendly 3-D viewing software gave excellent 3-D reconstructions of the internal structures of locust and new insights in particular of the configuration of the tracheal system.

Conclusion: Having established parameters for the use of microCT with the locust we will now use the technique to study the impact of the fungal pathogen, *Metarhizium anisopliae*, on the cuticle during host penetration at an improved scan resolution of just 2 microns per voxel.

POSTER PRESENTATION

Behavioral evidence for a long range female produced sex pheromone in C*allisphyris apicicornis* Fairmaire & Germain (Coleoptera: Cerambycidae: Lepturinae)

Tomislav Curkovic, Catalina Ferrera, Javier Munoz

University of Chile, Crop Protection Dept., Santiago, RM, Chile

Callisphyris apicicornis is a widely distributed wood borer in central Chile, that damages several tree fruit (apple), forest (*Betula* spp.), and ornamental (*Cotoneaster franchetti*) species. Adults emerge in spring and lay eggs on the branches of mature trees. The larvae bore through the bottom of the egg directly into the bark, where they feed on the cambium for 1 to 2 years. During this process the larvae regularly cut off pieces of branches, severely affecting the tree's framework. The pupal stage is about 1 month. None of these pre-adult stages are exposed and feasible for conventional insecticide control, nor have any effective biological control agents been found so far. Because this species attacks living trees and can eventually kill them in severe infestations, we have initiated a study of *C. apicicornis* sexual behavior and chemical ecology, to determine whether a pheromone-based control strategy might be feasible to control adults. Studies conducted in 2006 and 2007 strongly suggest that females use a long-range sex pheromone to attract males for mating. If confirmed, this will be the first evidence reproductive behaviors being mediated by female-produced sex attractant pheromones within the Lepturinae subfamily, and only the third report of female-produced attractants for any cerambycid species. The behavioral sequences during the final approach of a male to a pheromone-producing female have been videotaped and characterized for males (n = 36) and females (n = 20) in order to have a behavioral baseline to evaluate responses from adults to synthetic pheromone sources in the future.

POSTER PRESENTATION

Impact and incidence of dectes stem borer, *Dectes texanus texanus* (Coleoptera: Cerambycidae) in soybean in the Southern United States

Gus Lorenz, Scott Stewart, Angus Catchot

University of Arkansas, Lonoke, Arkansas, United States

Dectes stem borer, *Dectes texanus texanus*, also known as the soybean stem borer, is a native species distributed throughout much of the southern half of the United States in soybean producing areas. While traditionally considered a minor pest, in recent years a marked increase in incidence has been observed throughout the midsouthern states. Dectes damages the plant through petiole and mainstem tunneling but the most damage occurs late in the season as the larva moves to the base of plant and girdle the inside of the plant just above the soil line. This often results in lodging of the plant which, if severe enough may result in loss of yield. Studies have been initiated to determine the impact of Dectes in soybean and determine an effective method of control.

POSTER PRESENTATION

Comparison of the leaf litter ant fauna between an Atlantic Forest area and a *Pinus elliottii* stand (Pinaceae) in Rio Claro, SP, Brazil

Daniel Solis[1], Maria Santina Morini[2], Eduardo Fox[1], Carlos Jesus[1], Eduardo Diniz[1], Itamar Reiss[1], Thiago Moretti[3], Odair Bueno[1]

[1]Centro de Estudos de Insetos Sociais, Departamento de Biologia, Instituto de Biociências, UNESP, Rio Claro, São Paulo, Brazil, [2]Laboratório de Mirmecologia, Universidade de Mogi das Cruzes, Mogi das Cruzes, São Paulo, Brazil, [3]Departamento de Parasitologia, Instituto de Biociências, UNESP, Botucatu, São Paulo, Brazil

Introduction: Insects, especially ants, have been successfully used as environmental bioindicators in other studies. Ants possess a set of traits that enable fast local evaluations and make them for use in management programs, like adequate diversity and abundance in practically all terrestrial habitats. The present study surveyed the leaf litter ant fauna present in two different areas: a remanant semideciduous Atlantic Forest and a 100-year-old stand of *Pinus elliottii*. The species found in both areas were compared in terms of richness and similarity. Such data could be useful in Forest Handling Plans.

Methods: Over the warm and rainy period between November and December of 2007, fifty $1m^2$ leaf litter soil samples were taken of each area with Winkler extractors. The collected ants were identified as morphospecies by comparison with the entomological collection of Universidade de Mogi das Cruzes, SP, Brazil.

Results: A total of 71 species of 26 genera from nine subfamilies were collected from the Atlantic Forest, while 40 species of 23 genera from five subfamilies were obtained from the *P. elliottii* stand. The predominant subfamily in both areas was Myrmicinae and *Pheidole* was the most frequently collected genus. The areas had 12 species in common. The obtained species accumulation curve approached the asymptote, thus proving that the sampling was sufficient for the areas.

Conclusions: Our results show that ant fauna is richer in the Atlantic Forest. Moreover, we think they illustrate the *Pinus* stand cannot be regarded as a recovered forest.

POSTER PRESENTATION

Preliminary data about *Fulvius* phylogeny (Heteroptera: Miridae: Cylapinae)

Izabella Sadowska-Woda[1], Frederic Cherot[2], Jacek Gorczyca[3]

[1]Department of Biochemistry and Cell Biology, University of Rzeszow, 35-959 Rzeszow, Poland, [2]Département de Biologie des Organismes, Free University of Brussels,, 1050 Brussels, Belgium, [3]Department of Zoology, Silesian University, 40-007 Katowice, Poland

Introduction: The genus *Fulvius* STÅL, 1862 belongs to the tribe Fulvinii from subfamily Cylapinae. It is the larger genus of its tribe with about 80 species widely spread in the tropical and subtropical areas of all continents. Among other representatives of the tribe Fulviini the *Fulvius* species can be easily distinguished by an elongated black and yellow body, hemelytra with almost parallel margins, only slightly wider than the length of posterior margin of pronotum, tarsi always two-segmented, and second segment usually divided. The phylogenetic relationships of *Fulvius* species and consequently their classification are still bad known. We provide for the first time a cladistic analysis of the genus to test its subdivision in three groups of species, as defined in literature.

Methods: The cladistic analyses were performed under NONA version 2 and WINCLADA version 1.00.08 for WINDOWS 95-2000 or NT (both available on www.cladistics.com) on a matrix including 29 *Fulvius* species representative of the three groups and 31 characters of external anatomy, male and female genital structures (all non additive and informative, several multistate). A Ratchet strategy (1000/5/8) was applied.

Results: The majority compromise tree (L = 115, ci = 40, ri = 71 with unsupported nodes collapsed) of 2213 equally most parsimonious trees (L = 104, ci = 44, ri = 76) is provided.

Conclusions: The monophyly of the genus *Fulvius* as well as its subdivision in three main clades are confirmed by our analysis.

POSTER PRESENTATION

Researches regarding biodiversity in apple orchard ecosystems in the south-western part of Romania

Rada Istrate, Ioan Rosca

University of Agricultural Sciences and Veterinary Medicine – Bucharest, Bucharest, Romania

Introduction: Apple orchards are considered stable ecosystems, with precise interrelations between different food chains in which natural factors play an essential role. The disequilibrium between different populations categories some considered pests, others deemed useful (usually called ”natural enemies of pests”) calls for a change in the pest control strategy, which focuses on maximising natural control factors, and on directing control measures to the less polluted methods.

Methods: The observations and the harvest of the biologically material have been done in the vegetation period of the trees. The collected material was carried to the laboratory, preserved in 70^0 ethylic alcohols and identified.

Results: The fauna captured in apple orchard in sticky traps, was rich and varied most abundant belonging to the classed *Insecta.* The fauna captured, was more numerous with many predator and parasite specimens. The most common predator species were species of *Coccinellidae* and parasites insect species were well represented belonging especially to the order *Hymenoptera*, superfamily *Chalcidoidea*.

POSTER PRESENTATION

Evaluation of some selective materials as larvicides against the cedar leaf moth, *Acleris undulana* Walsingham

Halil Saribasak, Fedai Erler, Huseyin Cetin, Ayhan Serttas

[1]Southwest Anatolia Forestry Research Inst. Forest Protection and Environment Department, Antalya, Turkey, [2]Akdeniz University, Faculty of Agriculture, Department of Plant Protection, Antalya, Turkey, [3]Akdeniz University, Faculty of Arts and Science, Department of Biology, Antalya, Turkey, [4]Southwest Anatolia Forestry Research Inst. Forest Protection and Environment Department, Antalya, Turkey

Introduction: The cedar leaf moth, *Acleris undulana* Walsingham (Lepidoptera: Tortricidae), has recently become an important pest in the cedar forests in Turkey. In this study, the larvicidal activity of four botanical materials (Neemazal-T/S® and Greeneem® oil, and *Origanum onites* L. and *Pimpinella anisum* L. extracts) and a microbial preparation, *Bacillus thuringiensis* subsp. *kurstaki* (Bioinsecticide WP®) were evaluated against the young and older larvae of the pest under laboratory conditions.

Methods: Larval-dip bioassays were conducted to determine the contact toxicity of the test materials to cedar leaf moth larvae and were performed using direct-dip method.

Result: The results showed that all test materials had larvicidal action against the pest. *Btk* and Neemazal were identified as the most active materials for the larvicidal action, causing 100% larval mortality at their highest tested concentration, 3 g/l and 5 ml/l water, respectively. The other two materials, hot water extract of *O. onites* and Greeneem oil, achieved 96% and 95% mortalities, respectively, at their highest tested concentration (50 ml/l and 5 ml/l water, respectively). *P. anisum* extract caused a mortality of 64% against the young instars larvae of the pest at a concentration of 50 ml/l water.

Conclusions: Our overall results suggest that all materials tested are promising as larvicides against *A. undulana*, and hot water extracts from *O. onites* and *P. anisum* could be useful in the search of newer, more selective, and biodegradable larvicidal natural compounds.

POSTER PRESENTATION

The ipmPIPE: Not just soybean rust

James VanKirk, Julie Golod, Scott Isard

[1]Southern Region IPM Center, Raleigh, NC, United States, [2]Pennsylvania State University, State College, PA, United States

Developed originally to address Asian soybean rust in the United States, the *ipm*PIPE represents an approach that will be useful for managing other pests in other systems. Many factors contribute to the utility and success to date of the system. Key stakeholders are included in all project phases including needs assessment, development, implementation, verification, project governance, and evaluation. Critical information of several different types is integrated to produce useful crop, pest and risk predictions. A voluntary and confidential good farming practices tool allows growers to substantiate best management practices. Useful information is arranged and displayed using a map and and calendar-based interface that is intuitive and easy to use. Crop and pest managers are the initial beneficiaries of this system but many others including research scientists, extension educators, agribusiness, insurers, and regulatory agencies clearly benefit.

POSTER PRESENTATION

Side effects of pesticides on *Anystis baccarum* (Anystidae)

Khalil Talebi[1], Farhad Safarpour[2]

[1]College of Agriculture, University of Tehran, Karaj, Tehran, [2]College of Agriculture, University of Tehran, Karaj, Tehran, Islamic Republic of Iran

Introduction: The beneficial mite *Anystis baccarum* is a voracious predator feeding on two-spotted mites, aphids, thrips, scales and other small arthropods. As a result of special behavior, rearing technique of this predator is not developed. This study reports the sublethal effects of recommended concentrations of fenpropathrin, azinphos methyl, phosalone, propargite and heptenophos.

Method: Adults of *Anystis baccarum* were collected from a field with no previously spray of the tested pesticides in Karaj, Iran. Experiments were conducted at 25±1°C, 75±5% RH and photoperiod of 16:8 (L:D). Application of pesticides was carried out using a Potter tower and experimental units were 9 cm Petri dishes.

Results: Fenpropathrin and azinphos methyl were found to be very toxic to the predator. Even 8-day-old residues of these insecticides caused 100% mortality. Heptenophos was considered to be harmless. The hazard class of propargite and phosalone was not assessed in laboratory and semi-field and field tests were found to be necessary for their classification. These results could be useful for pesticide selection and their use in integrated pest management in orchards.

Conclusion: Fenpropathrin and azinphos methyl were harmful to *Anystis baccarum but* heptenophos was harmless. Field and semi-field tests were necessary to find out the hazard class of propargite and phosalone.

POSTER PRESENTATION

Functional diversity in the insect biocenosis of German pine forests – using the example of pest, parasitoids and hosts

Ulrich Schulz[1], Frank Dreger[2], Curt Majunke[1]

[1]University of Applied Sciences Eberswalde, Eberswalde, Brandenburg, Germany, [2]Leibniz-Centre for Agricultural Landscape Research (ZALF), Müncheberg, Brandenburg, Germany

Introduction: Large areas of the Scots pine forests in Germany are regularly attacked by pine defoliating larvae of the pine beauty moth, *Panolis flammea*. Some areas have been turned into mixed forests (*Pinus sylvestris* with *Quercus petraea*) in order to reduce outbreaks of forest pests and to encourage biodiversity.

Methods: Insects were collected in all strata of pure and mixed Scots pine forests in Brandenburg (northern Germany) using different traps. The two-tailed test was used to assess abundance-differences.

Results: Over 400 species of coleoptera were encountered in each pine forest. The deciduous trees which have been introduced into the mixed pine forest attract a higher diversity of phytophagous insects (e.g. 72 Noctuoidea species compared with 56 in the pure stand). A highly successful parasite of *Panolis flammea,* the tachinid species *Panzeria rudis*, had significantly higher population densities in the mixed pine forest than in the pure stand ($\alpha < 0.0022$).

Conclusions: The parasitic fly *Panzeria rudis* appears to benefit from the increased diversity of Lepidoptera in the mixed forest since it is not an obligate monophage on the pine beauty moth, but - as is known from other investigations - also parasitises on other hosts such as *Orthosia stabilis*, *Xestia c-nigrum* and *Xylena vetusta*.

This example of functional diversity shows that the biodiversity of insects in a forest is important not only from the perspective of nature conservation but also from the perspective of forest health.

POSTER PRESENTATION

Host plant preferences in *Sitona* spp. (Coleoptera: Curculionidae) on lupins (*Lupinus* spp.)

Christine Struck[1], Jeannine Lutz[1], Jana Grassel[2], Wolfgang H. Kirchner[2]

[1]University of Rostock, Faculty of Agricultural and Environmental Sciences, Institute for Land Use - Crop Health, Rostock, Germany, [2]Ruhr-University Bochum, Department of Biology and Biotechnology, Bochum, Germany

Introduction: Adults and larvae of the weevil species *Sitona griseus* and *Sitona gressorius* feed on leafs and roots of lupins (*Lupinus* spp.) and cause severe damage not only due to the loss of biomass, but also through secondary infections by soil-borne pathogens. However, the damage reported seems to vary greatly. Aim of the present study was to investigate food preferences of these beetles in the field using a broad spectrum of lupin species and varieties.

Methods: Six varieties of the European Blue Lupin *Lupinus angustifolius* (Boruta, Borlu, Vitabor, Boregine, Probor and Azuro), the Yellow Lupin *Lupinus luteus* (var. Bornal) and the Dwarf Lupin *Lupinus nanus* (var. Bordüre) were planted in randomized plots in 2006 and 2007. Leaf and root damage and the number of adult beetles and larvae of each species were determined.

Results: The results show that *Lupinus luteus* and *Lupinus nanus* are much less affected by the weevils than the varieties of the Blue Lupin. Significant differences were found between *Lupinus angustifolius* varieties.

Conclusions: The results indicate that both, attractiveness and palatability of the lupins are highly dependent on the variety specific spectra of secondary plant metabolites. Ongoing laboratory experiments suggest that both, volatile attractants and alkaloid repellents, affect the food preferences of *Sitona* spp.

POSTER PRESENTATION

An attempt at differentiation of fossil Formicinae species (Hymenoptera: Formicidae) from their wings

Ksenia Perfilieva

Lomonosov Moscow State University, Biologycal Faculty, Moscow, Russian Federation

Introduction: Some fields of myrmecology use wing venation features. These are research in the phylogeny, evolution and paleontology of ants. Many remains of ant wings have been found in Tertiary fossils, such as in the Oligocene Bembridge Marls, UK. However, the variability of ants wing is poorly understood and differentiation of ant species on fossil wings is very difficult.

Methods: Investigations has been made on six recent ant species of Formicinae, and fossil ants of Oecophylla from the Bembridge Marls. Characters of wing venation of the Formicinae species were studied by standard statistic and geometric morphometrics methods.

Results: Intraspecific variability and variations of wing features were studied at recent species of Formicinae. The limits of variability of the wings length are shown. Variability has it's determine structure on intraspecific level. Female's wings are narrower than male ones in Formicinae. However, the local differences across species are identical for various samples (only females, only males, females + males). Thus, there are the species-specific characters of wing venation. The results of our investigations have been used for differentiation of fossil wings remains of Oecophylla. The wings of females and males of two species were identified. Diagnostic characters of wing venation were described for this two extinct species of Oecophylla.

Conclusions: Studies of variability of recent ant wings allow to detect the regularity of wing venation variability, which can be used for differentiation of fossil wings remains.

POSTER PRESENTATION

Long way round: Global dispersal patterns of the invasive psocids *Liposcelis decolor* (Pearman) and *L. bostrychophila* Badonnel (Psocoptera: Liposcelididae)

Katarina Mikac

University of Canberra, Bruce, ACT, Australia

Introduction: *Liposcelis decolor* and *L. bostrychophila* are invasive psocids that are major pests of stored grain and grain storage structures globally. Currently there is limited information on the dispersal patterns and capabilities of *L. decolor* and *L. bostrychophila* despite their pest status. In this paper molecular markers were used to estimate their genetic structure and gene flow to gain an understanding of their global dispersal patterns.

Methods: Microsatellites and randomly amplified polymorphic DNA (RAPDs) were used to investigate the genetic structure, gene flow and dispersal among 21 global populations of *L. bostrychophila* and 5 Australian *L. decolor* populations respectively.

Results: Microsatellites and RAPDs both revealed low to moderate significant genetic structure among pairwise population comparisons for *L. decolor* (F_{ST}= 0.05 - 0.23) and *L. bostrychophila* (G_{ST}= 0.04 –0.54) respectively. Gene flow (N*m*) was mostly low for all pairwise populations comparisons for *L. bostrychophila* (N*m*= 1.13 - 1.57) and moderate for *L. decolor* (N*m*= 0.8 - 4.7). No pattern of isolation by distance was found among global populations of *L. decolor* and *L. bostrychophila*.

Conclusions: Although they are apterous and small in size both *L. bostrychophila* and *L. decolor* are capable of unrestricted geographic dispersal in excess of 15,000 kilometres probably through human facilitated global transport.

POSTER PRESENTATION

The effect of rotation crops, trash retention, weed control and prophylactic sprays on arthropod abundance in canola crops in south Western Australia

Svetlana Micic, Geoff Strickland, Tony Dore

Department of Agriculture and Food, Perth, WA, Australia

Canola (*Brassica napus* L.) is very susceptible to arthropod attack during the crop establishment phase. The earth mite complex, particularly the redlegged earth mite *Halotydeus destructor* (Tucker), is extremely damaging and can cause almost complete crop loss by killing seedlings. Other soil dwelling pests include weevils and beetles that chew on establishing crops. It is likely that the rapid adoption of minimum tillage farming systems has changed the soil environment to increase the abundance of these pests.

In response to increased arthropod abundance in the field, many farmers have resorted to the routine use of prophylactic sprays with synthetic pyrethroids to protect seedlings. Although cost effective and efficacious, the use of several consecutive synthetic pyrethroid sprays may increase the risk of insecticide resistance development in pests and be highly disruptive to beneficial species that could assist in the control of other pests later in the season.

Anecdotal evidence suggests that management practices such as weed control, trash retention and crop rotations may also influence the abundance of pests and beneficial species. These factors were investigated in replicated trials at two sites over two seasons. Our research showed that protecting canola from high populations of redlegged earth mites was essential to preserve yield. However, in low pest density situations the use of prophylactic sprays provided little or no benefit and adversely affected the populations of some beneficial species. These findings are discussed; including their relevance to recently reported high levels of resistance to synthetic pyrethroids in two redlegged mite populations in southern Western Australia.

POSTER PRESENTATION

High elevation emerging geometrid insect pests in the southwestern United States

Bobbe Fitzgibbon, Terry Rogers, Ann Lynch

USDA Forest Service, Flagstaff, Arizona, United States

Introduction: Since 1996, native geometrids have been responsible for 3 separate outbreaks at high elevations in the southwestern United States. Historically these insects were not known to cause damage. Speculation that climate change may be a factor in these outbreaks has led to the current study. Specimens taken at two of the outbreaks have both been identified as *Nepytia janetae;* the third geometrid has been identified as *Enypia griseata.* Adults of *N. janetae* were described in 1967 from collections made in Arizona and New Mexico. The larvae of the two insects identified as *Nepytia janetae* have been observed to have different feeding patterns, different elevational ranges and different host ranges in addition to physical differences. The third outbreak by a geometrid was found in a 2007 in Arizona. Significant tree mortality has been associated with heavy defoliation by the geometrids alone or in conjunction with secondary agents such as bark beetles and other defoliators.

Methods: Permanent plots have been set up at the sites of the first two outbreaks. Temperatures at the locations of outbreaks are being monitored and compared with historical data. Genetic testing will be necessary to determine if the insects identified as *N janetae* are indeed the same species.

Preliminary results: Mortality from the geometrid outbreak 1996-1999 varied by mountain range from 18 to 85%. Mortality due to the New Mexico *Nepytia janetae* outbreak 2005-2007 was already at 15% in the spring. Site factors do not appear to influence host susceptibility.

POSTER PRESENTATION

Biology and distribution of *Reduvius personatus* in two worlds

M. Javahery

McGill, Ste.Anne de Bellevue, Quebec, Canada

This work is a study of the biology of predatory *Reduvius personatus* (L.) from 1997-2008 in southeastern Canada. The distribution of this species was also studied from specimens in numerous collections from the "Old" and "New" worlds. Adults and nymphs were collected indoors and near light fixtures outdoors, in the southwest of Montreal. Breeding and rearing were carried out under variable temperatures from -10ºC in the winter to a maximum of 42ºC in the summer for ten years. Adults and nymphs were provided with flies and other soft-bodied insects or larvae. Nymphs did not feed during the winter and were resistance to cold temperatures. They lived for several weeks without food. The life cycle was completed after two winters of dormancy. Females appear from May to October, and lay 35 -138 eggs. Each egg has about 55 minuet micropilar processes. Embryonic development takes 2-3 weeks and over 90% of eggs hatch in July and August. Most of the first instars molt to second instars in 2-3 weeks in the summer. Cannibalistic behavior was observed in this species both during larval and adult stages. This *Reduvid* is not usually a harmful species towards humans. A comparison of data from biological studies made in Canada and the USA, versus those done in Europe indicates many similarities between populations of the Nearctic and Palearctic environments. Its distribution expands from 35º-55º in latitude north from west Europe to the east of the Caspian sea in the Palearctic, and 30º-50º north in the Nearctic regions.

POSTER PRESENTATION

Post-commercialization monitoring of Asian corn borer, O*strinia furnacalis* (Guenee), (Lepidoptera: Pyralidae)

Bonifacio Cayabyab[1], Edwin Alcantara[2], Augusto Sumalde[1], Wilma Cuaterno[3], Blair Siegried[4], Charisma Malenab[1], Jaynor Dangan[1], Josemari Belen[1]

[1]National Crop Protection Center - Crop Protection Cluster, Up Los Baños, Los Baños, Laguna, Philippines, [2]Institute of Molecular and Biotechnology, Los Baños, Laguna, Philippines, [3]Bureau of Plant Industry, Malate, Manila, Philippines, [4]Institute of Agriculture and Natural Resources, Department of Entomology University of Nebraska, Lincoln, Nebraska, United States

Since its approval for commercial use in 2002, farmer adoption of Bt-corn (Mon 810) had increased. About 300,000 hectares of total corn production area is planted to Bt-corn. Thus the Philippine is now ranked as #10 among 13 Biotech Mega-countries (James 2007). Post-commercialization monitoring of the performance of Bt-corn is required to detect the development of Asian Corn Borer (ACB), *Ostrinia furnacalis* (Guenee) resistance at the earliest possible time. This study attempted to estimate the frequency of Cry1Ab resistance alleles in the ACB using the F_2 screen described by Andow *et al*. (1998).

A total of two thousand twenty four (2,024) field-collected females of ACB were used to establish isofemale lines. Out of the surviving three hundred fifty three (353) isolines, twenty five thousand one hundred ninety seven (25,197) F_2 larvae were produced and found to be susceptible to Cry1Ab protein. Mortality rate for all of the isolines is at its peak during the first seven days of exposure to the toxin. A total of 800 isolines are expected to be tested in the duration of this study.

POSTER PRESENTATION

A SEM study of *Bovicola pelea*, a louse common to the Vaal Rhebuck (*Pelea capreolus*)

Martin Turner

University of Limpopo, Northern Province, South Africa

Introduction: Good morphological scanning electron microscopic (SEM) studies of lice are rare. This study provides new information as regards the micro-morphology of *Bovicola pelea*, a louse found on the Vaal Rhebuck, *Bovicola pelea*.

Methods: Live lice (9 males and 17 females) were collected and processed for electron microscopic viewing. Micromorphological features investigated included aspects of the head, thorax and abdomen and the appendages found on these three major body parts.

Results: A total average length of 1.1 mm was recorded for males and 1.25 for females. In both sexes, the forehead was markedly emarginated. The mandibles were notched and serrated. The medial groove was especially well developed. The antenna showed two large conical setae on a toothed distal segment. The antennal sensillae consisted of 12 apical pegs, 2 tuft organs protruding from 2 pore organs. The distal pore organ plate showed 2 radiate plate organs whilst the proximal plate showed 1. The mandibles were notched on the cutting edges and well serrated on the oral surfaces. Each leg bore an extended claw that closed toward a fixed appositional but shorter claw. Abdominal segments showed 6 pairs of spiracles, tergites and sternites with transverse rows of short setae. The gonopods covering the genital opening of the female displayed mitten-shaped claspers, slightly different to previously described light microscope images. Two large thoracic spiracles with hexagonal type of filtering apparatus were present.

Conclusions: This investigation should facilitate future identifications and morphological comparisons of this louse, by biologists, entomologists and veterinarians.

POSTER PRESENTATION

Identification of diapause-associated genes in the queen bumblebee, *Bombus terrestris*

Kyeong-Yeoll Lee[1], Dong-Woo Kim[1], Baek-Guen Kim[1], Mi-Sun Gong[1], Tae-Young Kwon[2], Yong-Jung Kwon[1]

[1]Kyungpook National University, Daegu, [2]Gyeongbuk Provincial Agricultural Technology Administration, Daegu, Republic of Korea

Introduction: *Bombus terrestris* is an economically important pollinator for greenhouse crops. To determine the mechanism of diapause regulation in adult queens of bumblebee we identified genes that associated with diapause and demonstrated whether those genes are regulated in relation to diapause process.

Methods: Diapause-associated genes were selected in the brains of queens using suppressive subtractive hybridization. In addition, genes that synthesize three heat shock proteins (*shsp, hsc70 and hsp90*) and vitellogenin were identified from queen's ovary and the fat bodies, respectively. Using Northern hybridization expression patterns of those genes were compared from six different stages in relation to diapause; pre-diapause, diapause initiation, chilling for 1, 2 and 3 months, and post-diapause.

Results: At the queen's brain the levels of three genes (*glucocerebrosidase*, *actin* and *glucose oxidase*) were high at pre- and post-diapause stages but downregulated during diapause. Particularly, the expression of both glucocerebrosidase and glucose oxidase were brain-specific when it compared with other tissues. At the queen's ovary both *hsc70* and *hsp90* levels downregulated whereas the *shsp* level was upregulated during diapause, especially chilling period. At the queen's fat bodies the vitellogenin gene was shut down at diapause initiation and upregulated after the completion of diapause.

Conclusions: Our results indicated that queens suppressed biochemical processes regarding metabolism and reproduction in relation to diapause. However, queens activated a unique process in the ovary, such as stress resistance, during diapause. Our results provide information that can be used for the control of diapause mechanism of important pollinator insect.

POSTER PRESENTATION

Fluctuation and population density of *Bemisia tabaci* (Genn.) on different host plants

Muhammad Arshad, Muhammad Shuaib, Yasir Ahmad, Abdul Ghani Lanjar

[1]Agriculture University Tando Jam, Sindh, Pakistan, [2]Community IPM Project, Punjab, Pakistan

Introduction: The population density of *Bemisia tabaci* (Genn.) was studied on different host plants during spring to summer season 2005

Methods: Seeds of sunflower (HO-1 variety), okra (Subz pari variety) and cotton (Hari dost, Reshmi and Niab-78 varieties) were sown. Weekly observations on the occurrences of whitefly were taken after germination till crop harvesting. Pest population was recorded from entire plant of each host plant those were randomly selected from field.

Results: The results indicate that *B. tabaci* appeared on sunflower from 15th March to May. Two peaks in population (5.60 ± 1.02) and (3.80 ± 0.89) per leaf were recorded in 3rd week of March and 1st week of May respectively. On okra highest population (9.04 ± 1.85) and (5.04 ± 1.28) was recorded in 3rd week of April and 4th week of May respectively. NIAB-78 variety of cotton harbored maximum population (9.32 ± 1.45), (7.44 ± 142) and (6.32 ± 1.23) in 2nd week of May, June and July, respectively. The peaks in *B. tabaci* population on Hari dost and Rashmi were also recorded in the same weeks. The population 7.04 ± 1.02, 5.36 ± 1.01 and 4.80 ± 0.86 on Hari dost and 5.68 ± 0.96, 4.52 ± 0.68 and 3.60 ± 0.74 on Rashmi was recorded, respectively.

Conclusions: The analysis of variance showed that there was non-significant difference between crops. However, LSD test showed non-significant difference in population of whitefly appeared on okra, sunflower and cotton variety Hari dost only. No impact of weather conditions was observed on population fluctuation of whitefly except crop stage.

POSTER PRESENTATION

Laboratory test on the response of acorn weevil, *Curculio glandium* (Coleoptera: Curculionidae) last instar larvae against entomopathogenic nematodes *Steinernema bicornutum* and *Heterorbabditis bacteriophora*

Mostafa Nikdel[1], Golamreza Niknam[2], Mahmood Shojaee[1], Hassan Askari[3], S.Abulghasem Mohammadi[2]

[1]Agriculture and Natural Resources Research Center of East-Azarbaijan province, Tabriz, [2]Faculty of Agriculture, University of Tabriz, Tabriz [3]Iranian Research Institute of Plant Protection, Tehran, Islamic Republic of Iran

Introduction: The acorn weevil, *Curculio glandium* Marsham is an important forest pest of oak trees in most of countries as well as Iran. The pest disturbs regeneration of host trees by feeding on their acorn. Need to control the pest and due to the limitations which are imposed by chemical pesticides application in natural resources, indigenous EPNs, *Heterorhabditis bacteriophora* and *Steinernema bicornutum* were tested against fifth instar larvae of acorn weevil of Arasbaran forest under laboratory conditions.

Methods: In the first experiment, penetration assay test was conducted using a suspension of 4000 IJs of the EPNs per 1 ml distilled water in multi–well plates. The plates were incubated for 12 h. at 25ºC and dead larvae dissected. In the second experiment, *H. bacteriophora* and *S. bicornutum* were applied at different concentrations (0, 150, 250, 500, 1000 and 2000 IJs per 1ml of distilled water) to test their ability to parasitize *C. glandium* fifth instar larvae in the 9 cm petri plates lined with filter papers. The experiments were conducted at two temperature ranges (21-24ºC and 25-28ºC).

Results: Penetration percentage was %1.6 and %0.55 for *H. bacteriophora* and *S. bicornutum*, respectively. Maximum mortality caused by *H. bacteriophora* and *S. bicornutum* were %58.3, %25 (at 21-24ºC) and %63.5, %30.5 (at25-28ºC), respectively. Analysis of variance revealed significant nematode specie and concentration as well as temperature effects on larva mortality. With increased concentration of nematode and temperature, larva mortality was increased. Based on probit analysis, LC50 of *H. bacteriophora* under two temperature ranges of 21-24ºC and 25 -28ºC were determined 1331 and 1037 IJs/ml, respectively. Regression analysis showed significant relationship between concentrations and larval mortality in the both of nematodes under two temperature ranges.

Conclusions: The highest penetration in larva and the highest mortality of fifth instar larvae of *C. glandium* was observed for *H. bacteriophora* under the both temperature ranges.

POSTER PRESENTATION

Distribution of Natal fruit fly, *Ceratitis rosa* Karsch (Diptera: Tephritidae), and false codling moth, *Thaumatotibia leucotreta* (Meyrick) (Lepidoptera: Tortricidae), two pests of citrus, in South Africa

Marelize de Villiers[1], Vaughan Hattingh[2]

[1]Department of Conservation Ecology & Entomology, Faculty of AgriSciences, Stellenbosch University, Private Bag X1, Matieland 7602, Stellenbosch, South Africa, [2]Citrus Research International, P.O. Box 2201, Matieland 7602, Stellenbosch, South Africa

Introduction: Natal fruit fly, *Ceratitis rosa* Karsch, and false codling moth, *Thaumatotibia leucotreta* (Meyrick), are pests of some South African fruit. Due to phytosanitary concern, these pests hinder international fruit trade. Knowing their current distribution, their potential global distribution can be modelled and the relevance of associated phytosanitary regulations evaluated.

Methods: Bucket traps baited with three-component BioLure®, and delta traps baited with pheromone, were placed in different South African climatic regions to trap *C. rosa* and *T. leucotreta* respectively. Three traps, serviced monthly, were used per monitoring area. Relative abundance, as a percentage of maximum monthly counts, was determined for months with highest and lowest abundance.

Results: Generally *C. rosa* was absent or had low abundance in regions with hot, dry summers. *Thaumatotibia leucotreta* occurred across all climatic regions, with localised occurrence of both highest abundance and apparent absence within the same climatic regions. Abundance was moderate but consistent across time and space in the south and east coastal regions, and the north-eastern part of the country, with warm or hot, rainy summers but varying winters.

Conclusions: This abundance distribution of *C. rosa* seemingly corresponded with climatic differences, suggesting it is a good candidate for modelling its potential global distribution based on climate. *Thaumatotibia leucotreta* did not show an abundance distribution pattern corresponding with climatic regions, suggesting that relative abundance is probably more sensitive to factors like host availability than to restrictions imposed by the climatic range covered during the study.

POSTER PRESENTATION

Pathogenicity and protease production relationship between three isolates of *Metarhizium anisopliae* Metch. on *Eurygaster integriceps* Puton (Hemiptera: Scutelleridae)

Mehdi Tork, Ali R. Bandani, Marjan Seyedi

Plant Protection Department, Faculty of Agriculture, University of Tehran, Karaj, Islamic Republic of Iran

Introduction: Sunn pest *Eurygaster integriceps* (Hem: Scutelleridae) is the major pest which causes serious damage to wheat and barley in the Middle East and some other countries. To control the pest, each year hectares of crops sprayed with pesticides. Entomopathogenic fungi can be used in the pest management procedures in order to reduce pesticide use. *Metarhizium anisopliae* Metch. is one of the most important fungi which are used in biological control of insect pests. So, the aim of the current study is to investigate virulence and enzyme production of three isolates including 4556, 3297 and M189 of *M.* anisopliae on Sunn pest.

Materials and Methods: Fungi were cultured on SDAY medial culture and maintained at 25 ± 2 ^{o}C and photoperiod of 16: 8 (L:D). After two weeks that sporulation occurred spores were taken and used for dipping bioassays. After determination of pathogenicity, logarithmic doses including 1×10^{4}, 1×10^{5}, 1×10^{6}, 1×10^{7} and 1×10^{8} spore/ml were prepared.

To study enzyme production, spores of these isolates were separately cultured in minimum media with 1% insect cuticle and left in shaker (130 rpm) for 10 days at 25 ± 2 ^{o}C. Protease activity was measured using Suc – Ala –Ala – Pro – Phe – pNA as substrate.

Results: The results showed that LC_{50} of 4556, 3297 and M 189 was 3.38×10^{5}, 5.60×10^{5} and 7.70×10^{5}, respectively. As can be seen 4556 isolate was most virulence than the two other isolates. Enzyme assays showed that enzyme production in 4556 isolate was more than the other two isolates (3297 and M198 isolates).

Conclusions: So, it was shown that there is a relative relationship between enzyme production and pathogen virulence.

POSTER PRESENTATION

Detection of two new species of the genus *Torymus* (Hymenoptera: Torymidae) parasitizing *Celticecis japonica* (Diptera: Cecidomyiidae) in Japan

Kazunori Matsuo

Kyushu University, Fukuoka, Japan

Introduction: Three parasitoid species, *Eupelmus urozonus* (Hymenoptera: Eupelmidae), *Torymus* sp. (Hymenoptera: Torymidae), and an unidentified endoparasitoid, have been known to attack larvae of *Celticecis japonica* Yukawa and Tsuda (Diptera: Cecidomyiidae) that induces galls on leaves and twigs of *Celtis sinensis* var. *japonica* and *C. jessoensis* (Ulmaceae) in Japan. Recently, I reared *Torymus* spp. from the galls induced by *C. japonica* and tried to identify these species.

Methods: I examined specimens obtained from galls of *C. japonica* in Japan by referring to the original descriptions of *T. diabolus* Moser and *T. huberi* (Hoffmeyer) that have been known to attack *Celticecis spiniformis* and an unidentified gall midge inducing galls on *Celtis* sp. in the Nearctic Region. I also compared the *Torymus* spp. from *Celtis* in Japan with 12 known species of *Torymus* attacking hosts other than *C. japonica* in Japan.

Results: I recognized three species of *Torymus* among the specimens reared from the galls of *C. japonica*. Two of them are distinguishable from *T. diabolus*, *T. huberi* and the 12 Japanese species of *Torymus*. The remaining species is not treated in this presentation because of the insufficient number of specimens.

Conclusions: The two species of *Torymus* seem to be new to science. One of them belongs to the *T. ercarum* species group, which was defined by Graham and Gijswijt (1998) and is known to parasitize Cynipidae inducing galls on *Quercus* spp. (Fagaceae) in the Palaearctic Region. The other new species does not belong to any species group in the Palaearctic Region.

POSTER PRESENTATION

Study on spider mites of plum and cherry orchard and biology of brown mite, *Bryobia rubrioculus* (Sheuten) (Acari: Tetranychidae) in Hamedan, Iran

Mohammad Khanjani, Amir Hosein Eghbalian

Bu Ali Sina University, Hamedan, Islamic Republic of Iran

Spider mites are important pests on plum and cherry trees. Study on spider mites associated with plum and cherry trees was carried out during 2005-2006 in west (Hamedan) of Iran。 In this study were collected four pider mites in phytophous role, their scientific names as follow: *Bryobia rurioculus* (Scheuten), *Eutetranychus orientalis* (Klein,, *Tetranychus turkestani* (Ugarov & Nikolski)) and *T. urticae* Koch Amongst them, brown mite was high level of population. At present this pest is one of the most important pests of cherry, plum and cherry trees in west of Iran. This pest was found bluntly on plum and cherry trees It causes considerable damage in some orchards of this area. So, its biology was studied during 2005-2006. The result showed that, this pest over wintered as egg on fruit trees shoots. The larvae of first generation appear early in April; at temperature 10.58 ℃. This pest creates 4-5 generations per year. Its high population was occurred in September in Hamedan orchards.

POSTER PRESENTATION

New observations on temperature increase due to maggot mass effect

Damien Charabidze[1], Didier Gosset[1], Benoit Bourel[2]

[1]Université Lille 2, Lille, France, [2]Faculté Libre des Sciences et Technologies, Lille, France

Introduction: The estimation of *post-mortem* interval in forensic entomology is related to the temperature of the environment in which maggots develop. Nevertheless, the activity of a maggot mass on a body can lead to a local increase in temperature. Difference between ambient and mass temperature range from 10°C to 15°C and temperature up to 45°C inside the maggot mass have been already observed in field experiments. Nevertheless, this complex phenomenon is not easy to characterise and little experimental data under controlled conditions has been documented so far.

Temperature increase seems to be linked to the local maggot density and the mass volume. Some studies indicate that the so-called maggot-mass effect usually begins when the larvae reach the end of the second instar, and continues until the post-feeding stage. Infrared thermometry has shown that larvae can store or generate heat, following a relationship proportional with the number of individuals; however the exact cause and its dynamics are still unknown.

Methods: Our measurements on *Protophormia terraenovae* maggot masses were performed using constant external temperatures and fixed number of larvae.

Results: Results show an important increase of temperature (up to 10°C), also for first second larvae less than 5 mm length, and a strong dependence to external temperature. Furthermore, heat generation increase linearly with the number of larvae, and rapidly extinguished in absence of food. Together, these results suggest that the heat is generated due to metabolic digestive process instead of friction between larvae.

Conclusion: The understanding of this phenomenon is determinant for forensic entomologists. The relationships between external temperature, number of maggots end heat production are used in the laboratory for modelling the development of maggots. The aim of the global project is the creation of a support decision system (SDS) applied in forensic entomology.

POSTER PRESENTATION

The main biotic limiting factors of gypsy moth (*Lymantria dispar* L.) populations in oak stands in southern Romania

Irinel Constantineanu, Raoul Constantineanu, Camil Stefan Lungu-Constantineanu, Romica Tomescu

[1]Biological Research Institute, Iasi, Romania, [2]Forest Research and Management Institute, Bucharest, Romania

Introduction: Researches were proceeded in 37 oak stands in Southern Romania affected by gypsy moth attack, where the authors recorded parasitoids and predators of immature stages of this defoliator and only one case of adult predation. Observations concerning those biotic mortality factors were achieved both in nontreated stands and in stands with integrated and microbiological treatements.

Methods: All observations and collects of immature stages (egg clusters, caterpillars and pupae) were made in the same plots. Each ones was isolated and kept in a climatological chamber. The parasitoid hatching was watched daily. For predators, the authors did field observations and watching the efficiency on their prey.

Results: The analyzed *Lymantria dispar* populations were limited by a complex of 34 primary parasitoids (33 parasitoid insect species and 1 nematod species – *Hexamermis albicans* Sieb.) and by 7 predator insect species and 1 avian species – *Coleus monedula* L. The most efficient parasitoids were *Exorista larvarum* L. and *Compsilura concinnata* Meig. (Diptera), the first one especially for pupae and the second one for larvae, while Hymenoptera species have had a less important role. *Dermestes erichsonii* Gnglb. (oophagous) and *Calosoma sycophanta* L. (for all stages) were the most efficient predators. Researches showed that the parasitization degree on *L. dispar* populations had varied between 16,5 % and 78,6 %, the highest pasitization degrees were achieved in nontreated stands and in those with microbiological treatments. We consider that in the studied oak stands, entomofagi were ones of the main limiting factors of *L. dispar* populations.

POSTER PRESENTATION

Head-shape convergences in lauxaniid flies (Diptera: Acalyptratae: Lauxaniidae): New light from an undescribed southern African taxon of trigonometopine flies?

Gregory Davies[1], Raymond Miller[2]

[1]Department of Natural Sciences, Natal Museum, Pietermaritzburg, KwaZulu-Natal, South Africa, [2]School of Biological and Conservation Sciences, University of KwaZulu-Natal, Pietermaritzburg, KwaZulu-Natal, South Africa

Lauxaniid flies (Diptera: Acalyptratae: Lauxaniidae) are renowned for their morphological diversity relative to other acalyptrate fly families. J.F. McAlpine commented in the landmark *Manual of Nearctic Diptera* on the "extraordinary morphological plasticity" shown by lauxaniids (McAlpine 1989: 1445). One long-standing problem in lauxaniid morphology is the occurrence of what can be termed the "trigonometopine syndrome". This body form is classically shown by the genus *Trigonometopus* Macquart, and comprises a sub-triangular head with elongated postfrons and generally receding prefrons, and to a lesser extent, a narrow thorax and abdomen, and elongated wings. Wheeler (1956) suggested all these flies represented a monophylum, which he even elevated to family status (Trigonometopidae). Future lauxaniid researchers have unanimously rejected such a proposal, suggesting that the similarity is due to convergence, possibly as the result of living amongst upright grass stems (Stuckenberg 1971: 516).

In this poster we highlight an undescribed genus of lauxaniid found in *Protea*-rich montane grassland and fynbos in South Africa that adds another example to the "trigonometopine syndrome". The genus consists of six species, all undescribed, which fall into two distinct clades. Our observations suggest that this genus is not closely related to other "trigonometopine syndrome" genera, adding evidence to multiple derivation of this morphology (i.e. convergence). Interestingly, the new genus includes species that have an unmodified head-shape, potentially throwing light on how a trigonometopine head-form evolves.

POSTER PRESENTATION

Chitinase inhibitors to manage aphids

Philippe Giordanengo, Julien Saguez, Charles Vincent

[1]Université de Picardie Jules Verne, Amiens, France, [2]Agriculture and Agri-Food Canada, Québec, Canada, [3]Agriculture and Agri-Food Canada, Québec, Canada

Introduction: Chitin is the main component of exoskeletton, trachea and peritrophic matrix of insects. Thus chitin metabolism appears an interesting target to manage insect pests. During post-embryonic development, the molting process involves chitinase activities to hydrolyze chitin and degrade the old cuticle. While chitin synthase has been widely used as target by numerous pesticides, chitinase has received much less attention. However, chitinase inhibitors have been reported for their toxic effects against bacteria, fungi and also insects. We investigate the relevance of different chitinase inhibitors in controlling the potato aphids *Myzus persicae* Sulzer and *Macrosiphum euphorbiae* Thomas which are among the main vectors of viruses on potato crop.

Methods: Two cyclic dipeptides, cyclo-(Proline-Tyrosine) and cyclo-(Histidine-Proline), the pseudotrisaccharide allosamidin and psammaplin A, a brominated tyrosine-derived compound, were selected owing to their different structure and mode of action on chitinases.

To evaluate their effects, the 4 chitinase inhibitors were delivered to aphids *M. persicae* and *M. euphorbiae* via a artificial diet. Nymphal survival, prereproductive period ,adult emergence and reproduction were recorded daily. These parameters were used to calculate the intrinsic rate of natural increase of the aphids populations.

Results: Cyclic dipeptides induced no or slight effects on aphids survival and performance. Aphids fed with allosamidin showed significantly reduced nymp survival and daily fecundity. Finally, psammaplin A used as food intake led to the complete death of the nymphs.

Conclusions: The present results demonstrated for the first time differential aphicidal effects of chitinase inhibitors of different nature on the polyphagous aphids *M. persicae* and *M. euphorbiae.* On the basis of observed developmental alterations, a hypothesis of the mode of action of these compounds is proposed. In the context of crop protection, our results highlight the interest of such strategy that has been shown relevant against bacteria and phytopathogenic fungi to control insect populations.

POSTER PRESENTATION

Does insecticide application in oilseed rape affect root fly damage of radish?

Nur Ahmed, Inger Åhman, Mats Lieberg, Eva Johansson

[1]Swedish University of Agricultural Sciences, Department of Agriculture-Farming System, Technology and Product Quality, Box No. 104 Alnarp, SE-230 53, Sweden, [2]Swedish University of Agricultural Sciences, Department of Agriculture-Farming System, Technology and Product Quality, Box No. 104 Alnarp,SE-230 53, Sweden, [3]Swedish University of Agricultural Sciences, Department of Agriculture-Farming System, Technology and Product Quality, Box No. 104 Alnarp, SE-230 53, Sweden, [4]Swedish University of Agricultural Sciences, Department of Landscape Architecture, Box No. 58 Alnarp, SE-230 53, Sweden.

Introduction: A chemical based strategy is most commonly used for pest control in agriculture, contributing to a high agricultural production and productivity. Insecticide side effects have been investigated in several studies. Investigations about influences of insecticide applications in fields on pests in neighbouring crops are more limited, especially so in near-by garden crops. Gardens and neighbouring farmers' fields may exchange pests via migration. The aim of the present investigation was to study influences and interchanges of pests between farmers' fields, sprayed and unsprayed, and neighbouring garden crops.

Methodology: Oilseed rape (*Brassica napus*) was established as a farmers' field crop and radish (*Raphanus sativus*) as a neighbouring garden crop. The field trial was carried out in Southern Sweden. In the corners of a rapeseed field (100 X 150m), three radish plots (2 x 1.5 m; 3.6 m apart) were sown in each direction; with new plots of radishes sown repeatedly during the season. Half of the oilseed rape area (100 X 77.5m) was treated with insecticides against flea beetles (*Phyllotreta* spp.) and pollen beetles (*Meligethes* spp.) according to recommendations by the Swedish Board of Agriculture. Root damage by root flies (*Delia* spp.) was recorded in the radish crop.

Results: In the urban fringe, private gardens are often situated adjacent to farmers' fields. This opens up for opinions on farming activities such as pesticide use. Also, chemical pest control in farmers' fields might affect the pest situation in private gardens. The preliminary results from this study indicate that radish plots closest to the oilseed rape have more root fly damage compared to plots further away from the field. No significant differences between plots nearby the treated versus the untreated side of the field were found.

POSTER PRESENTATION

Resitance of wild *Solanum* species against potato aphids

Vincent Le Roux, Charles Vincent, Sébastien Dugravot, Erick Campan, Philippe Giordanengo

[1]Université de Picardie Jules Verne, Amiens, France, [2]Agriculture and Agri-Food Canada, Québec, Canada, [3]INRA Agrocampus Rennes, Rennes, France, [4]UMR CNRS 5172, Toulouse, France, [5]Université de Picardie Jules Verne, Amiens, France

Introduction: Wild *Solanum* species related to the cultivated potato present a high genetic diversity. These materials are used by breeders to improve potato crop for resistance or tolerance characteristics such as resistance to insect pests. In this context we have determined the nature of resistance of 8 wild *Solanum* accessions (5 species) against aphids, vector of viruses.

Methods: We used three complementary experiments (physiology, olfactometry and electropenetrography) to determine the antixenosis or antibiosis resistance of wild *Solanum* and localization of resistance factors within plant tissues.

Results: None of the wild *Solanum* species had repulsive effects on aphids that precluded involvement of wild *Solanum* volatiles in resistance. We report for the first time at once antibiosis and antixenosis resistance of wild *Solanum* species against *M. euphorbiae*. At the opposite, resistance exhibited by all wild *Solanum* accessions was antixenosis against *M. persicae*.

Conclusions: Antixenosis against *M. persicae* seems to be widespread in the *Solanum* species when comparing our results with published works. However important variability in localization of antixenosis factors within plant tissues was determined between wild *Solanum* species and even between accessions of the same species, suggesting involvement of several resistance mechanisms. For a given wild *Solanum* accession resistance variability was also observed according to the two aphid species. To explain antixenosis or antibiosis, possible resistance mechanisms are discussed. Determining the nature of resistance of wild *Solanum* is essential to potato breeders to introduce resistant traits in the cultivated potato allowing creation of new resistant cultivars.

POSTER PRESENTATION

Effects of plant age and development on the *Mi-1.2*- mediated resistance of tomato against whitefly *Bemisia tabaci*

Clara I. Rodríguez, Mariano Muñiz, Gloria Nombela

Institute for Agricultural Sciences - Consejo Superior de Investigaciones Científicas (CSIC), Madrid, Spain

The sweetpotato whitefly *Bemisia tabaci* (Gennadius) (Hemiptera: Aleyrodidae) is an important pest of horticultural crops worldwide. This insect causes damage directly through phloem feeding or indirectly by transmission of plant viruses such as Tomato Yellow Leaf Curl Diseases (TYLCDs). The tomato gene *Mi-1.2* is responsible for resistance against the B and Q biotypes of *B. tabaci,* in addition to three species of root-knot nematodes (*Meloidogyne* spp.) and the potato aphid (*Macrosiphum euphorbiae*). It is known that tomato plants carrying *Mi-1.2* are resistant to root-knot nematodes early in development: seedlings inoculated at 24 hours after germination are resistant to nematode infection. In contrast, the *Mi-1.2*-mediated resistance against potato aphid is developmentally regulated, with fully expanded leaves becoming resistant only when plants are 4 to 5 weeks of age. We have observed *Mi-1.2*-regulated resistance to *B. tabaci* in 8-week old tomato plants but not in other experiments with younger plants. However, a definitive study lacked to investigate whether *Mi-1.2*-mediated resistance against *B. tabaci* is developmentally regulated. Two sets of assays have been carried out in the present study, with tomato plants cv. Motelle (with *Mi-1.2*) and Moneymaker (lacking *Mi-1.2*) under free-choice and no-choice conditions, to determine if plant age or development could have any effect on whitefly resistance. In the first set of assays, 3-, 5- and 8-week old plants were compared. In the second set of assays, two groups of 8-week old plants were compared, which had been grown under different temperatures (24 or 19ºC) to obtain different plant developments.

POSTER PRESENTATION

Leaf beetle fauna of the Mecsek Hills (southern Hungary) (Coleoptera: Chrysomelidae)

Károly Vig

Savaria Museum, Szombathely, Hungary

Introduction: The aim of this study was to obtain data on the leaf beetle fauna of the Mecsek Hills (Baranya County, southern Hungary).

Methods: The present account is based on the material preserved mainly in Janus Pannonius Museum (Pécs) and Hungarian Natural History Museum (Budapest) as well as on literature sources.

Results: A total of 352 leaf beetle species are listed from Mecsek Hills. In spite of the fact that Mecsek is one of the most diverse mountainous areas in Hungary, the overwhelming majority of the species is common and widely distributed in the forest steppes and forested hilly and lower mountainous districts of the country. It should be also pointed out, that a considerable number of locality data are very old and sometimes unreliable. From faunistical point of view the most remarkable species are *Oulema rufocyanea, Cheilotoma musciformis, Smaragdina flavicollis, Eupales ulema, Luperus rugifrons, Phyllotreta christinae, Aphthona herbigrada, Longitarsus lateripunctatus personatus, Neocrepidodera nigritula, Apteropeda orbiculata*. Two species (*Smaragdina graeca, Cryptocephalus bameuli*) are new to Hungarian fauna. The presence of *Cryptocephalus bicolor, Chrysolina fimbrialis, C. purpurascens rufocuprea, Chrysomela tremula, Longitarsus curtus, Longitarsus junicola, Longitarsus nanus, Neocrepidodera femorata, Dibolia cynoglossi, Psylliodes cupreatus* needs further confirmation. The occurrence of twenty-four species (i. e. *Pachybrachis hippophaes, P. pallidulus suturalis, Cryptocephalus rufipes, Timarcha corinthia, Chrysolina geminata, Sclerophaedon orbicularis, Longitarsus aeruginosus, L. ferrugineus, L. nigerrimus, L. suturatus, Neocrepidodera impressa, Podagrica fuscipes, Psylliodes marcidus, Hypocassida meridionalis*) is inconceivable in the territory, The identity of *Smaragdina tibialis hungarica* needs further examination.

POSTER PRESENTATION

Biocide effect of essentials oils extracted from *Capsicum annuum* (Solanaceae), *Zingiber officinale* (Zingiberaceae) and *Piper nigrum* (Piperaceae) on *Anopheles gambiae* Giles 1902 Diptera: Culicidae), a vector of malaria

Foko Daji Gisele Aurelie

University of Yaounde I, Yaounde, Cameroon

Malaria remains one of the major causes of morbidity and mortality worldwide. Integration of disease treatment with vector control is considered as the most effective means of disease control. The use of native plants with insecticidal properties is a new approach in the fight against malaria vectors. Volatile oils extracted by hydrodistillation from tree plants species obtained from the Agronomic Research Institute for Development (Yaounde-Cameroun), *Capsicum annuum* (*Solanaceae*) yellow and red varieties, *Zingiber officinale* (*Zingiberaceae*) and *Piper nigrum* (*Piperaceae)* were evaluate toxicity on adults of *Anopheles gambiae* under laboratory conditions using WHO cones covered with volatile oils treated nets. Oils dissolved in acetone, were tested at 7.8 %, 3.9 %, 2 %, 1 % and 0.3 % (w/v). The results showed that: the knockdown effect 3min after contact, with the adults of *An. gambiae* is superior to 95% for the oils extracted from *C. annuum* and *Z. officinale* at concentrations 7.8% and 3.9% this effect is of 70% with the *P. nigrum* oil at concentration 7.8% and 3.9%. 60min after the knockdown effect is superior to 90% for oils extracted from *C. annuum* and *Z. officinale* at concentration 7.8% this effect is of 63% with the *P. nigrum* oil. 60min after the knockdown effect is superior to 80% for oils extracted from *C. annuum* and *Z. officinale* at concentration 3.9% this effect is of 46% with the *P. nigrum* oil. 24 hours after, for the concentrations 7.8% and 3.9%, the mortality rate of adults is in average 90% for the oils extracted from *C. annuum* and *Z. officinale*. This rate is in average 45% with *P. nigrum* oil. *C. annuum* and *Z. officinale* seem this to be very useful for the control of adults of *An. gambiae*. Field trails should be carried out, particularly to evaluate the operational feasibility and dermal toxicity over a long period, especially to infants and children. It is important to determine whether widespread use of one of these biocides would produce an overall reduction of vector biting in a community.

POSTER PRESENTATION

Optimization of carbon:nitrogen ratio for *Beauveria bassiana* and *Metarhizium anisopliae* conidia production for bioassays against larvae of *Anopheles arabiensis*, a major African malaria vector

Luisa Nardini, Vince Gray

University of the Witwatersrand, Johannesburg, Gauteng, South Africa

Introduction: Mycelium and spores of the entomopathogenic Hyphomycetes, *Beauveria bassiana* and *Metarhizium anisopliae*, were produced using a diphasic fermentation process. Conidia produced from optimized diphasic culture were harvested and their pathogenicity tested against *Anopheles arabiensis* larvae. Infection was confirmed by electron microscopy.

Methods: The first phase of the diphasic fermentation involved liquid culture where the influence of different concentrations of sucrose, maltose, glucose and yeast extract, and different ratios of these nutrient sources, on mycelial growth was investigated. The second phase of fermentation (solid substrate) was initiated using fungi that had been cultured in broth solutions that produced optimum conidial yields in sporulation studies. The dried spores were harvested and tested against *An. arabiensis* larvae. For comparative purposes, a commercial preparation of *B. bassiana* was also tested.

Results: High spore yields were obtained for both *B. bassiana* and *M. anisopliae* indicating that liquid phase culture optimization was successful. All preparations were found to be pathogenic to the mosquito larvae and produced acceptable LT_{50} values, where at a spore concentration of 10^7 conidia.cm^{-2} high levels of mortality occurred and LT_{50} values of 43, 89 and 41 hours for *M. anisopliae, B. bassiana* and *B. bassiana* (commercial preparation) respectively, were obtained.

Conclusions: Diphasic fermentation proved to be a successful means for producing infectious spores of *B. bassiana* and *M. anisopliae*. The spores were able to cause infection in *An. arabiensis* larvae, as confirmed by electron microscopy. Furthermore, the spores that we produced by biphasic fermentation produced similar LT_{50} values to that obtained from a commercial preparation of *B. bassiana*.

POSTER PRESENTATION

Dose-dependent effects of Gal4 affects the development of *Drosophila melanogaster*

Fernanda Humann, Klaus Hartfelder, Maria Luisa Paçó-Larson

Universidade de São Paulo, Ribeirão Preto, São Paulo, Brazil

Introduction: The Gal4-upstream activating sequences (UAS) system is the most widely used strategy for achieving spatially restricted gene expression in *Drosophila*. Since UAS sequences are not found in the *D. melanogaster* genome, it is assumed that Gal4 drives the expression of UAS targeted genes without affecting neighboring tissues. We demonstrate here that this assumption has to be viewed with a *caveat* and that the expression of Gal4 may affect viability in ad dose-dependent manner.

Methods: We evaluated the viability of three *Drosophila* lines expressing Gal4. Two of these express Gal4 specifically in the ring gland and oenocytes: the one developed by us carries a 67 bp activator (RG67bp) from a DNA puff gene as a driver, the second is an enhancer-trap (PO206), and in the third line, the driver is an enhancer of an actin gene (Bloomington #3954). As control we used the parental line *yw.*

Results: The RG67bp line was not viable when grown at 25^0C and could only survive at 18^0C, a condition where Gal4 activity levels in *Drosophila* are diminished. In contrast, the PO206 line, which expresses Gal4 in the same tissues as RG67bp, could be maintained at 25^0C, albeit at a much reduced viability (38%) compared to the control. The actin-enhancer line, which ubiquitously expresses Gal4, also showed reduced viability (58%).

Conclusion: Gal4 can have adverse effects on *D. melanogaster* development, especially when expressed at high levels. This should be considered when interpreting results obtained from Gal4 constructs.

POSTER PRESENTATION

A phylogenetic analysis of armoured scale insects, based upon nuclear, mitochondrial, and endosymbiont gene sequences

Jeremy C. Andersen, Jin Wu, Matthew E. Gruwell, Geoffrey E. Morse, Sharlene Santana, Natalie Feliciano, Rodger Gwiazdowski, Benjamin B. Normark

University of Massachusetts Amherst, Amherst, Massachusetts, United States

Armoured scale insects (Diaspididae) are the most species-rich family of scale insects and one of the most economically important. They are promising subjects for the evolutionary study of physiology (no complete gut), genetics (chimerism, paternal genome elimination, frequent parthenogenesis) and coevolution (with host plants, parasitoids, *Septobasidium* fungi, endosymbiotic bacteria). Here we present an expanded molecular-phylogenetic analysis of relationships within this family. Our data matrix consists of fragments of two nuclear genes (elongation factor 1-alpha and the large subunit of ribosomal DNA), a mitochondrial region (cytochrome oxidase I-II), and a gene from the vertically transmitted primary endosymbiont *Uzinura diaspidicola* (small ribosomal subunit), with a combined total of 3523 base pairs. The terminal taxonomic units in the matrix are 256 individuals, representing over 123 species in 6 tribes. We find evidence for no more than two origins of paternal genome elimination.

POSTER PRESENTATION

Eye size in aphids

Thomas Döring[1], Johannes Spaethe[2]

[1]Imperial College London, Ascot, United Kingdom, [2]University of Vienna, Vienna, Austria

Introduction: Aphids lead a risky life when it comes to finding new host plants. Since vision plays a major role in finding suitable hosts, the animal's visual capabilities largely determine the success of locating food sources.

Methods: We measured several eye parameters, including vertical eye length (EL), and diameter of ommatidial lenses in the centre of the eye, as well as other morphological parameters, including total thorax length (TTL), in winged females of 24 aphid species. The animals, mainly from the sub-families Aphidinae and Calaphidinae, were collected from various field sites in the UK and Germany and from laboratory cultures. All measurements were done electronically (on-screen) on live pictures produced by a digital camera connected to a microscope and a PC. Five animals were measured per species on both the left and right eye. In some samples, the number of ommatidia per compound eye could be directly counted.

Results: The largest aphid was *Lachnus roboris* (TTL=1.52±0.03mm, mean±s.e.), the smallest was *Tuberculatus querceus* (TTL=0.51±0.01). Generally, eye size scaled positively with body size (EL vs. TTL: r^2=0.73, n=24). The ommatidial diameter (mean 0.010 mm) ranged from 0.008 mm (in the relatively small *Tinocallis takachihoensis*) to 0.016 mm (in the large *Tuberolachnus salignus*). The number of ommatidia per eye ranged from 127 (in *Rhopalosiphum padi*) to 268 (*Euceraphis betulae*). The mean divergence angle of ommatidia over all species was 7.6 degrees.

Conclusions: Our morphological measurements show that aphids, with their relatively few ommatidia and large interommatidial angles, have presumably a low spatial resolution.

POSTER PRESENTATION

Diversity and distribution of Collembola of Brazil: Relationships between systematics and the biodiversity crisis

Mark Culik

Instituto Capixaba de Pesquisa, Assistência Técnica e Extensão Rural – INCAPER, Vitória, Espírito Santo, Brazil

Collembola, common in soils throughout the world, are little known but important organisms because of their influences on soil fertility. This study provides an update on diversity and distribution of Collembola of Brazil based on a review of the literature and discusses this information and related observations with respect to systematics and the biodiversity crisis. There has been a noticeable increase in research on collembolans in Brazil recently with the number of articles published on Collembola of Brazil increasing from ~2/year prior to 2003 to >3 publications/year during the past 5 years (2003-2008). However, collembolan research in Brazil continues to remain restricted to limited areas, and with few exceptions remains limited to description of new species with studies of communities in specific environments almost nonexistent. The results demonstrate that descriptions of new species alone provide an incomplete knowledge of biodiversity and indicate the importance of faunistic and zoogeographic studies for providing a more accurate understanding of the biodiversity of specific areas. There is a great need for recognition of the importance of, and support for interdisciplinary, taxonomy-based surveys of insect communities, and actual publication of results of such research (such as species lists), i.e. a truly global approach to arthropod systematics, especially for biologically diverse but little known areas such as Brazil, not only to provide information essential for systematics (zoogeographical information etc.) but also to support development of integrated pest management and sustainable development, as well as (and as essential parts of) efforts to address the biodiversity crisis.

POSTER PRESENTATION

Responses of pollen beetles to petal colour: towards habitat management via manipulation of visual signals used in host-plant location

Samantha M. Cook, Matthew P. Skeller, John A. Pickett

Rothamsted Research, Harpenden/Herts, United Kingdom

Habitat manipulation as a means for control of herbivorous insects relies upon a thorough understanding of the host-plant location process. The crop habitat in push-pull strategies is manipulated so that the main crop is made to be as unattractive as possible (push) and pests are diverted to highly attractive traps or trap crops nearby (pull). Many pests use a combination of visual and olfactory cues in host-plant location, but manipulation of visual cues in push-pull strategies has been little explored. It is well known that the pollen beetle (*Meligethes aeneus*), a major pest of oilseed rape (*Brassica napus*) inflorescences, is attracted to the yellow colour of the petals. We investigated the responses of pollen beetles to flowers of a white-petalled oilseed rape cultivar that had been dyed different colours. Red and blue flowers were significantly less attractive than those dyed yellow, and the untreated white flowers. These results suggest that a main crop of oilseed rape with a petal colour other than yellow in combination with a yellow-petalled trap crop could act as an efficient push-pull tactic in the control of this pest.

POSTER PRESENTATION

Computational comparative analysis of insect genomes

Robert Waterhouse

Imperial College, London, United Kingdom

One of the major public health concerns of the new millennium centres on diseases transmitted to humans by blood-feeding insects. Sequencing of the *Anopheles gambiae* genome (Holt *et al*, 2002) drove an unprecedented acceleration in malaria research, particularly in the field of insect innate immunity, together with a growing appreciation of the importance of mosquito-parasite interactions. The second mosquito genome, *Aedes aegypti* (Nene *et al*, 2007), has enabled a comparative phylogenomic analysis of the insect immune repertoire among these two mosquitoes and the fruitfly *Drosophila melanogaster*. Analysis of immune signalling pathways and response modules revealed both conservative and rapidly evolving features associated with different functional gene categories and particular aspects of immune reactions (Waterhouse *et al*, 2007). These dynamics reflect in part the continuous readjustment between accommodation and rejection of pathogens and suggest how innate immunity may have evolved. The sequencing of additional genomes of insects of medical or agricultural importance such as the honeybee (*Apis mellifera*), the silkmoth (*Bombyx mori*), and the red flour beetle (*Tribolium castaneum*), enables informative comparative analyses across insect orders with the integration of data sources, and the employment of a range of methodologies to investigate the patterns of gene ancestry which can reflect the underlying biology.

POSTER PRESENTATION

Effects of kaolin on pear psylla oviposition

Haim Reuveny, Zehev Farkash, Amiram Levi-Shaked, Orna Akunis, Rieke Kedoshim

Migal Northern R&D, IPMC, Kiryat Shmona, Israel

Introduction: Control of pear psylla, *Cacopsylla bidens* (Sulc), in Israel is commonly based on use of Amitraz (in blossom time) and Abamectin (in summer). In a previous study we found that kaolin (Surround, WP) reduced the population level on blossoms when used before "green-tip" (GT). In this study the exact effects of kaolin and of application timing on the winter form of psylla were tested.

Methods: Two experiments were done, one started two months before GT (January) and the second one month before GT (February). In both experiments kaolin (at 3% concentration) was used three times (to reduce rain rinse-off) at one-day intervals. The numbers of eggs on spurs and the percentage of flower clusters bearing psylla nymphs were recorded.

Results: The number of eggs laid on spurs by winter-form females was significantly lower in the kaolin treatment than in the control.

Conclusions: These data explain the results of the previous study, which showed the effect of kaolin on 1st-generation psylla development. The winter form females were prevented from laying eggs on trees that were covered with kaolin. Use of kaolin on dormant trees can replace the use of Amitraz In blossom time and help to delay development of resistance in psylla, and to promote the presence of natural enemies and pollinators in pear orchards.

POSTER PRESENTATION

Rapid recovery of an insect-plant interaction following habitat loss and experimental wetland restoration

Corinne Watts

Landcare Research, Hamilton, New Zealand

Introduction: Restiad peat bogs are threatened ecosystems in northern New Zealand, yet several areas of bogs are still being mined commercially. This study examined whether wetland habitat loss and isolation can alter an insect-plant interaction, and how rapidly the interaction recovers following restoration.

Methods: We compared the damage done by an undescribed stem-mining moth on experimentally placed potted *Sporadanthus ferrugineus* (Restionaceae) plants at various distances (up to 800 m) from an intact habitat (the source population) over 18 weeks. Subsequently, to test the rate of recovery of the interaction we surveyed the damage on naturally regenerated *S. ferrugineus* plants on experimentally restored 'islands'.

Results: The proportion of stems damaged by 'Fred the Thread' (the stem-mining Lepidoptera; referred to in Robert Hoare's presentation, this conference), number of eggs and larvae and average larval size per metre of *S. ferrugineus* stem significantly decreased on the potted plants with increasing distance from the intact habitat. Loss of wetland habitat caused an almost complete 'collapse' of the specialist insect-plant functional interaction on isolated *Sporadanthus* plants at distances of between 400 and 800 m from the undisturbed wetland. However, recovery of the interaction following experimental habitat restoration was rapid. Three years after restoration, there was no significant difference in the frequency of oviposition on host plants at differing distances of isolation from the peatland and after six years restoration, the degree of herbivory damage had returned to pre-habitat loss levels.

POSTER PRESENTATION

Tick infestation rate of sheep and temporal distribution of ticks in Bahar, Hamadan Province, Iran, 2006-2007

Zakkyeh Telmadarraiy[1], Alireza Moradi[2]

[1]School of Public Health, Tehran University of Medical Sciences, P.O.Box6446-14155, Tehran; [2]Hamadan University of Medical Science, Hamadan, Islamic Republic of Iran

Introduction: The ticks are one of the main important ectoparasites of the livestock which cause economic losses, reduce animal products and transmission of pathogens to human and animals. Hamadan province including Bahar city is one of the most important husbandry centers in Iran.This study was conducted to determine tick infestation rate of sheep in Bahar.

Materials and methods: Sampling was performed seasonaly in 33 villages through one year during summer 2006- spring 2007. From each village two animal husbandries and from each animal husbandry 3 sheep were selected and tested for tick infestation. Ticks were identified using valid identification keys.

Findings: Tick infestation was detected in 85 (9.37%) out of 907 sheep. The spatial infestation rate was 20%, 6.9%, 4.3%, and 8.4% in spring, summer, autumn, and winter respectively. The highest infestation rate was seen in 2 year-old sheep and the lowest rate observed in sheep with more than four year-old. infestation rate was 10.20% in male and 8.41% in female sheep.

Totally 424 ticks were collected on the sheep which were classified into two families of Ixodidae(66.7%) and Argasidae(33.2%). They belong to four genera *Rhipicephalus* (45.2%), *Hyalomma* (19.3%), *Ornithodoros*(33.2%), and *Haemaphysalis*(2.1%), and to 11 species of *Rh.bursa*(33.9%), *O.lahorensis*(33.2%), *Rh.sanguineus* (11.3%), *Hy.dromedarii*(8.4%) ,*Hy.marginatum*(6.1%), *Hy.anatolicum*(2.5%), *Hy.detritum*(2.1%), *H.concinna*(0.94%), *H.punctata*(0.7%), *H. sulcata*(0.47%) and *Rh.turanicus*(0.23%). The highest tick seasonal activity was 46.9% in spring.

Conclusion: This study showed that there are a great number of tick species in this region including some important vectors pathogens. These data plus information about spatial and temporal distribution of ticks could help farmers and health authorities to monitor the population dynamic of ticks and to make good strategy for tick control.

POSTER PRESENTATION

Description of the immature stages of *Monomorium floricola* (Jerdon, 1851) (Hymenoptera: Formicidae)

Daniel Solis[1], Luciane Kato[2], Eduardo Fox[1], Carlos Jesus[1], Antonio Yabuki[1], Ana Eugênia Campos-Farinha[2], Odair Bueno[1]

[1]Departamento de Biologia, Instituto de Biociências, UNESP, Rio Claro, São Paulo, Brazil, [2]Laboratório de Sanidade Vegetal, Centro de Sanidade Vegetal, Instituto Biológico, São Paulo, São Paulo, Brazil

Introduction: Wheeler & Wheeler described over 700 larvae of different ant species and emphasized the relevance of certain characters to the systematics of this group. However, their descriptions occasionally ended up incomplete or were based on few specimens. This happened with the species *Monomorium floricola*. The present study aimed at determining the number of larval instars of *M. floricola* along with their growth rates and detailed descriptions of each immature stages were carried out.

Methods: Larval instars were determined by measuring head capsules (n=1785). Immatures of *M. floricola* were collected from laboratory colonies, measured and described through optical and scanning electronic microscopy. All measures are given as mean ± SD.

Results: Eggs (n=159) are ovoid and about 0.29 ± 0.01 x 0.18 ± 0.02 mm. There are three larval instars, with mean growth rate of 1.2276. In all instars, head capsule was subpentagonal and body pheidoloid in shape. Types and distribution of the body setae of the 1st larval instar is different from that of 2nd and 3rd ones. Larvae (n=150 each) of 1st, 2nd and 3rd instar were respectively 0.39 ± 0.05, 0.51 ± 0.06 and 0.86 ± 0.19 mm long, and 0.15 ± 0.01, 0.18 ± 0.02 and 0.35 ± 0.09 mm wide. Pupae (n=50) presented no cocoons and were 1.42 ± 0.07 mm-long.

Conclusions: Our results illustrated some traits of *M. floricola* that had been overlooked, such as details about the body setae, besides registering the number of larval instars and their dimensions.

POSTER PRESENTATION

Effects of *Cleome viscosa* L. (Capparidacae) extract on toxicity and the activity of carboxylesterase and glutathione-s-transferase in *Spodoptera litura* (Lepidoptera: Noctuidae)

Supojjanee Buatippawan[1], Vasakorn Bullangpoti[1], Suraphon Visetson[1], John Milne[2], Manthana Milne[3]

[1]Kasetsart University, Bangkok, Thailand; [2]Mahidol University, Bangkok, Thailand; [3]Department of Agriculture, Bangkok, Thailand

The senescent leaf *Cleome viscosa*, L. (Capparidacae) was investigated extract on second instars *Spodoptera litura* (Lepidoptera: Noctuidae) under the laboratory no-choice assay. The toxicity in terms of LC50 values ca. 34 mg ml^{-1} (r^2 = 0.95) at 24 after exposure by the dipping method. Also, in *in vitro* detoxification enzyme analysis, survival treated instars *S. litura* treated showed a inhibit respond to carboxylesterase and glutathione-s-transferase activities. Results indicate that these botanical pesticides have the potential to be as the alternative control program for *Spodoptera litura*.

POSTER PRESENTATION

Acute toxicity of *Jatropha gossypifolia* L. (Euphorbiaceae) extract to guppies (*Poecilia reticulata*)

Sudatip Siriarcharungroj[1], Vasakorn Bullangpoti[1], Chaiwud Sudthongkong[2]

[1]Kasetsart University, Bangkok, Thailand; [2]Samutsakron Coastal Research Center, Samutsakron, Thailand

Jatropha gossypifolia L. shows the insecticidal activity to control many insect pests in agricultural situations. Adult guppy fish (*Poecilia reticulata* standard test species) were selected for the bioassay experiments. The experiments were performed in four series and the 24-h LC_{50} value was determined for guppies. The acute toxicity experiments were carried out by static method and behavioral changes in guppies were determined for each *Jatropha gossypifolia* L. concentration extract which extracted by Soxhlet's extraction method with ethanol as solvent. Data obtained from the extract investigation were evaluated by the use of probit analysis statistical method and the 24-h LC_{50} value for guppy was estimated as *ca.* 3100 ppm (r^2 = 0.95). However, in this concentration, no mortality was observed at higher concentration for 30 second.

POSTER PRESENTATION

Investigation of acute toxicity of *Cleome viscosa* L. (Capparidacae) extract on guppies *Poecilia reticulata*

Varithron Chuaysuwan[1], Vasakorn Bullangpoti[1], Chaiwud Sudthongkong[2]

[1]Kasetsart University, Bangkok, Thailand; [2]Samutsakron Coastal Research Center, Samutsakron, Thailand

Cleome viscosa, L. (Capparidacae), Thai-plant species, have phytocidal chemical components and responsible for controlling and repelling insects from the host plants. To avoid potential toxic pollutant contaminating aquatic ecosystems, this present study was investigated for acute toxicity. Guppy fish (*Poecilia reticulata*) were selected for the bioassay experiments. The experiments were repeated 3 times and the 24-h LC_{50} was determined for the guppies. The static test method of acute toxicity test was used. Water temperature was regulated at 20 ± 1 ℃. In addition, behavioral changes at each concentration were observed for the individual fish. Data obtained from the acute toxicity tests were evaluated using the probit analysis statistical method. The 24-h LC_{50} value for guppy was estimated as *ca.* 5300 ppm (r^2 = 0.96). However, in this concentration, no mortality was observed at higher concentration for 30 second.

POSTER PRESENTATION

Qualitative analysis of the effect of oxycodone (opioid analgesic) on the development rate of *Chrysomya megacephala* (Diptera: Calliphoridae) and its importance for estimating of the post-mortem interval in Brazil

Maicon Diego Grella[1], Patricia Jacqueline Thyssen[2]

[1]UNICAMP, Campinas, SP, Brazil, [2]UNESP, Botucatu, SP, Brazil

Introduction: Recent research has demonstrated that the presence of drugs in decomposing tissues may alter the insect development rate when they using such tissues as food, thus potentially altering estimates of the post-mortem interval (PMI). The oxycodone, opioid semi-synthetic similar to the morphine, is a drug subject to abuse, resulting in respiratory depression and death. In this study, we investigated the effect of the oxycodone on the development rate of *Chrysomya megacephala* (Diptera: Calliphoridae) immatures.

Methods: Groups of larvae were placed in artificial diet containing Oxycodone in 3 different concentrations: 0.5 x LD (lethal dose), 1 x DL and 2 x DL. The control group was reared on the diet containing no drug. Weights were recorded for groups of 10 larvae at 12 h intervals up to the end of the larval stage.

Results: There was not a significant effect of the drug concentration on larval development as measured by weight ($F = 0.06$; $p = 0.97$). Immatures from all groups reached the developmental total time (egg-adult) at 225 h. The emergence rate was 92%, 94.2%, 90.6% and 95.1%, respectively, for control, 0.5 x LD, 1 x LD and 2 x LD groups.

Conclusion: Studies done with different drugs in several species of Calliphoridae suggest that larval development respond differently to the presence of each drug. Although our results show that oxycodone not cause interference in maggots, the register of this knowledge is important, especially when there is a need to determine the PMI using entomological means

POSTER PRESENTATION

Effects of imidacroprid and fipronil insecticide application on the larvae and adults of *Sympetrum frequens* (Libellulidae: Odonata)

Hiroshi Jinguji, Tetsuyuki Ueda

[1]Miyagi University, Sendai, Miyagi, Japan, [2]Ishikawa Prefectural college, Nonoshi, Ishikawa, Japan

Introduction: The insecticides fipronil and imidacloprid are effectively used against sucking insect pests of rice. Since these agents are absorbed by rice seedlings and stored in their tissues, they are usually applied to nursery boxes before planting. The effects of imidacroprid and fipronil on the life history of *Sympetrum frequens* larvae and adults were monitored using an experimental micro-paddy lysimeter for the duration of the cultivation period.

Methods: Groundwater was added to nine small micro-paddy lysimeters (350mm×500mm×300mm (H)) to a depth of approximately 3cm. Three lysimeters were treated with imidacroprid, three with fiproni, and the remaining three were left untreated and were used as controls. Three hundred eggs were laid on the soil surface of each of the nine lysimeters and the larval populations, larval development, and emergence patterns of *Sympetrum frequens* were observed in each lysimeter.

Results: The absence of *Sympetrum frequens* larvae from fipronil-treated-lysimeters was most remarkable and exuviae were not observed. Imidacroprid-treated-lysimeters had approximately 60% of the larvae observed in control lysimeters. In addition, larvae in the imidacloprid lysimeter had lower mean specific growth rates and the length of adult wings was decreased relative to those observed in the control lysimeter. Emergence in imidacloprid lysimeters was also significantly lower than it was in the control.

Conclusions: The application of fipronil and imidacroprid to seedling in the nursery box, and the subsequent transplanting of these into an experimental lysimeter, was associated with a decrease in the abundance of *Sympetrum frequens* larvae and adults.

POSTER PRESENTATION

Classification of the plant bugs from Korea (Hemitpera: Miridae)

Yong Jung Kwon[1], Kyeong-Yeoll Lee[1], Ohseok Kwon[1], Young Jae Cho[1], Sang Jae Suh[2], Tae Young Kwon[3]

[1]School of Applied Biology & Chemistry, Kyungpook National University, Daegu; [2]Department of Environmental Horticulture, Kyungpook National University, Daegu; [3]Division of Horticultural Research, Gyeongbuk Provincial Agricultural Technology Administration, Daegu Republic of Korea

The Miridae are the most species rich family-level grouping of true bugs, with approximately 10,200 described species recognized as now (Schuh, 1995). Plant bugs are widely distributed all over the zoogeographical regions of the world. Many mirid bugs are associated with herbaceous plants predominantly inhabiting grasslands, bushes of forests and sometimes cultivated areas, while many others are predacious to other insects and mites. Thus most of the species play a key role either in natural system or in agro-ecosystems constituting herbivores as primary consumers as well as predators as secondary ones.

The present work revises all the known species of the family Miridae from Korea. A total of 231 species belonging to 95 genera under 6 subfamilies are arranged herein, of which 1 genus with 2 species are new to science, and 12 species are first recorded in Korea. Keys are given for all the taxa respectively, host plants and distributional data are also provided for each species.

POSTER PRESENTATION

Staphylinini in Australia: phylogenetic and biogeographic review, with revision of some little-known and new taxa (Coleoptera: Staphylinidae)

Alexey Solodovnikov[1], Alfred Newton[2]

[1]Department of Entomology, Natural History Museum of Denmark/University of Copenhagen, Universitetsparken 15, 2100 Copenhagen, Denmark, [2]Zoology Department, Field Museum of Natural History, 1400 South Lake Shore Drive, Chicago, Illinois 60605, United States

Introduction: The Australian fauna of the mega-diverse rove beetle tribe Staphylinini (>210 genera and 5,400 species worldwide) appears depauperate compared to other regions, with only 158 species placed in 24 mostly widespread genera reported so far, but this reflects lack of attention more than reality. Our study, incorporating review of large recent collections, seeks to provide in preliminary fashion a phylogenetic framework and better understanding of the biogeographic origins of the Australian fauna, as background for more detailed studies including much descriptive taxonomic work that will be needed to fully unveil the fauna. The phylogenetic analysis (about 70 taxa and 70 adult morphological characters) extends an earlier analysis of Staphylinini by Solodovnikov by including an extensive sample of Australian taxa.

Results: Viewed in the context of what is known about the world fauna of the tribe, the Australian fauna includes three distinct elements: species of widespread genera that most likely arrived in Australia relatively recently, probably from the north; "ghosts of Gondwana", species of genera (including at least four new genera) that are restricted to southern temperate areas in Australia, New Zealand, southern South America and sometimes nearby areas; and several indigenous genera (including one new) that are phylogenetically isolated, with no known close relatives outside Australia. This last group is partially revised, with description of the new genus (two new species), and revision of Antimerus (five new species) and Lonia. One widespread genus (Tympanophorus) is also recorded from Australia for the first time, based on a new species.

POSTER PRESENTATION

Libnotes immaculipennis Senior-White (Diptera: Limoniidae), a pest of oyster mushroom *Pleurotus ostreatus*: a preliminary study in Bogor, Indonesia

Nina Maryana, Dewi Sartiami

Bogor Agricultural University, Faculty of Agriculture, Department of Plant Protection, Bogor, West Java, Indonesia

Introduction: *Libnotes immaculipennis* (Diptera: Limoniidae) is a pest of oyster mushroom *Pleurotus ostreatus*. It does not directly attack fruit-bodies, but causes loss of mushroom production by damaging bag-logs, substrates for fungus growth. We studied *L. immaculipennis* to obtain fundamental information on its biology.

Methods: Field surveys were performed in 2007 at three different localities in Bogor Regency, Indonesia. We investigated developmental stages in the laboratory of Bogor Agricultural University.

Results: Eggs were oval, 0.25 mm in long-axis and 0.17 mm in short-axis. Egg stage lasted for 3.30 ± 0.46 days. Larval body lengths were about 1.53, 2.76, 4.77, and 9.45 mm, in respective stadia. Larval stage lasted for 9.30 ± 0.57 days. Larvae were found in damped bag-logs. They decreased the density of mycelia and inhibited growth of mycelia on bag-logs. Pupal length was 8.55 ± 0.71 mm and pupal stage lasted for 2 days. Body length was about 0.78 in males and 0.67 cm in females. The longevity of males and females were 3.09 ± 2.08 and 3.64 ± 2.17 days, respectively. Each female laid 104.00 ± 81.20 eggs. The average number of larvae per bag-log varied with localities. Larval population density was lower in Cibuntu Batas than in Cikarawang or on Sukamaju I. Adult density was relatively high in Cibuntu Batas.

Conclusions: Total duration from egg to adult was about 14.6 days, and life cycle was 16.9 days. When the population density becomes high, *L. immaculipennis* would become a serious pest of oyster mushrooms.

POSTER PRESENTATION

Advances in Australian spider wasp systematics (Hymenoptera: Pompilidae)

Lars Krogmann, Michael C. Day, Andrew D. Austin, Steven J.B. Cooper

[1]Staatliches Museum für Naturkunde Stuttgart, Stuttgart, Germany, [2]National Museum Cardiff, Cardiff, United Kingdom, [3]Australian Centre for Evolutionary Biology and Biodiversity, School of Earth and Environmental Sciences, The University of Adelaide, Adelaide, Australia, [4]Evolutionary Biology Unit, South Australian Museum, Adelaide, Australia

Spider-hunting wasps (Hymenoptera, Pompilidae) are a diverse group of parasitic wasps that prey exclusively on spiders. Females search and hunt for spiders, which they paralyse and store in a previously constructed nest as food for their developing larvae. All pompilid species provide a single spider per nest cell on which they lay a single egg. The Australian pompilid fauna is huge with an estimate of 500+ species, about 60% of which are undescribed. The primary aim of the current project is to develop a synopsis of the Australian pompilid genera. Based on extensive morphological and molecular data we will also derive a robust phylogeny and reclassification of the Pompilidae to provide an evolutionary framework for ecological and behavioural research on the family.

POSTER PRESENTATION

Evaluation of farm lands located in urban area and industrial complex using insect diversity indices

Young-Cheol Choi, Jong-Gill Kim, Ji-Young Choi, Won-Tae Kim, Ha-Sik Shim, Beong-Do Park

National Institute of Agricultural Science and Technology, SUWON, Republic of Korea

Introduction: To evaluate environment of farm lands using indicator insects and evaluation indices, the insect abundance of which is one of the major criteria for the evaluation of agricultural environment of farm land in urban areas and industrial complex, three sites (Ansan, Daesan, Suncheon) were designated and monitored.

Methods: For the evaluation of agricultural environment of farm land in urban areas and industrial complex, the flora of agricultural land and the population of insects were surveyed, and the insect diversity indices of farm land were analyzed in three sites.

Results: The flora of agricultural land was more than urban areas and industrial complex of that in three sites. Soil, water and air pollution of urban areas and industrial complex were more serious than those of agricultural land in three sites. Overall population of insects were high from June to August in the surveyed three sites. Collected insects in agricultural land were 12 order, 106 family and 166 species, those in urban areas were 11 order, 102 family and 148 species, and in industrial complex were 11 order, 100 family and 152 species. Species and population belonging to Coleoptera was dominant in the surveyed sites. The insect diversity indices of farm land were 2.36 in agricultural land, 1.92 urban areas and industrial complex.

Conclusions: Agricultural environment of agricultural land was good, urban areas was common and industrial complex was poor. Based on the major criteria of evaluation items, the criteria were selected as diversity index over 2.1, insect indicator *Pheropsophus javanus* in agricultural land, diversity index 1.5-2.0, insect indicator *Nephotettix cincticeps* in urban areas, diversity index below 1.5, insect indicator *Pagria signata* in industrial complex.

POSTER PRESENTATION

Mechanisms of resistance to DNA damage in insect cell Sf9

I-Cheng Cheng, How-Jing Lee, Tsing-Cheng Wang

[1]Department of Entomology, National Taiwan University, Taipei, Taiwan, [2]Institute of Cellular and Organismic Biology, Academia Sinica, Taipei, Taiwan

Insect cells are known to be much more resistant to ionizing radiation (IR) and other DNA-damaged chemicals than mammalian cells in culture. This phenomenon seems to imply that insect cells might possess certain unique mechanisms responsible for resistance to DNA-damaged treatments. For further investigations, a lepidopteran cell line, Sf9, and several cell lines of human origin were included in this study. Insect cells were found to be more resistant to X-irradiation and hydrogen peroxide than human cell lines, and had less DNA damage induced due to the more efficient in DNA repair, which was confirmed by the single cell gel electrophoresis technique (Comet assay). Sf9 also exhibited the higher antioxidant ability to remove reactive oxygen species (ROS) induced by IR and hydrogen peroxide. Insect cells, on the other hand, were found to be equally sensitive to methylating agents as human cells. Methylating agents induce cell death by forming DNA adducts, which later on were cleaved by mismatch repair enzymes thereby generate fatal DNA strand breaks. Methylating agent-induced cytotoxicity consequently is not associated with the intracellular level of ROS. Therefore, the higher efficiency in removing ROS in Sf9 were unable to increase the resistance to methylating agents, as it did to IR, hydrogen peroxide, bleomycin, and streptonigrin in Sf9 cells.

POSTER PRESENTATION

Effect of Gamma Radiation on the Histology of the testis of red date palm weevils: *Rhynchophorus ferrugineus* (Olivier) (Coleoptera: Curculionidae)

Waleed Al-Waneen, Mohammed Al-Kalifah, Hassan Al-Ayedh

[1]Natural Resources and Environmental Research Institute, Riyadh, Saudi Arabia, [2]College of Science, King Saud University, Riyadh, Saudi Arabia

Histological changes in the testis of Red date palm weevils *Rhynchophorus ferrugineus* (Olivier) were investigated by irradiating male weevils with 15-Gy of Gamma radiation at Natural Resources and Environmental Research Institute, King Abdulaziz City for Science and Technology, Riyadh, Saudi Arabia.
Histological slides made with ordinary and electron microscope at various magnifications revealed damaged spermatic tubules, spermatogonia, spermatogonial cysts and a clear breakage at the junction of spermatic tube and vas efferens that disconnected the normal passage of sperm movement toward vas deferens via vas efferens.

POSTER PRESENTATION

Selection of non-target Lepidoptera species for ecological risk assessment of Bt maize in South Africa

Annemie Van Wyk, Johnnie Van den Berg, Huib Van Hamburg

[1]ARC - Grain Crops Institute, Potchefstroom, South Africa, [2]North-West University, Potchefstroom, South Africa

Introduction: It is essential to assess environmental risk that Bt maize may hold and to study its effect on species assemblages fulfilling a variety of ecosystem functions. Environmental risk assessment can be improved through the use of an ecological model. Local species can be classified functionally and prioritized to identify test species. Except for *Busseola fusca* and *Chilo partellus,* the target species of Bt maize in South Africa, other Lepidoptera species are also exposed to Bt toxin.

Methods: An ecological approach was followed for selection of non-target Lepidoptera, using data collected on the biodiversity of Lepidoptera species that are primary consumers of maize. Nine primary non-target lepidopterous consumers were identified. A selection matrix was developed in which species was ranked for its maximum potential exposure to maize. Non-target Lepidoptera most likely to be affected were identified and prioritized for future testing and inclusion in risk assessments. Several non-target species were prioritized for close association with maize, general occurrence in maize growing regions and potential for economic damage if they become secondary pests. In the selection matrix, knowledge gaps were identified for future research.

Results: Non-target species populations with the highest maximum potential exposure to Bt toxin are *Sesamia calamistis*, *Helicoverpa armigera* and *Acantholeucania loreyi*. *Eublemma gayneri* can be considered to be a "value unknown" species. Because of their sporadic occurrence *Agrotis segetum* and *Spodoptera exigua* are of lesser importance, but should be considered during pre- and post-release monitoring.

POSTER PRESENTATION

Detection of iAChE organophosphate resistance in *Bactrocera oleae* from Turkey

George Skavdis, Hanife Genc, John Vontas

[1]Democritus University of Thrace, Department of Molecular Biology and Genetics, Dimitras 19, 68100 Alexandroupolis, Greece, [2]Canakkale Onsekiz Mart University, Faculty of Agriculture, Department of Plant Protection, Terzioglu Campus, 17020 Canakkale, Turkey, [3]Laboratory of Pesticides Science, Agricultural University of Athens, Iera Odos 75, 11855 Athens, Greece

Introduction: The olive fruit fly *Bactrocera oleae* (Gmelin) (Diptera:Tephritidae) is the most important olive pest worldwide. Its control in S.E. Europe has been based on organophosphate insecticides for many decades. However their intensive use has lead to development of iAChE resistance, due to the selection of two resistance mutations (I199V and G488S). The frequency of these mutations in Turkey has not been investigated. Furthermore, a test previously developed to detect the G488S in field populations may not be as robust as originally thought, as revealed by more recent extensive sequencing data.

Methods: We designed a new PCR-RFLP diagnostic assay, for the unequivocal detection of the G488S mutation, based on primer induced mutagenesis, by introducing a point mismatch at the reverse primer, which resulted in the generation of an MbiI restriction site at the PCR product of the resistant allele. The test was applied to insects collected from olive orchards regularly treated with insecticides and no treated with insecticides in Canakkale province, Turkey.

Results: The novel PCR-RFLP allows the safe determination of the G488S resistance mutation. Although the frequency of the G488S resistance mutation was as expected higher in the sprayed areas, a significant percentage of flies from neighboring non sprayed areas also carried the resistance allele.

Conclusions: A novel molecular diagnostic assay able to reliably monitor the frequency of the iAChE G488S resistance mutation was developed. Its application in *B. oleae* populations from Turkey showed the high abundance of this mutation, especially in areas with intense organophosphate spray history.

POSTER PRESENTATION

Occurrence and seasonality of Aphididae and Coccinellidae species associated with lettuce cultivated under variable shade house conditions in the central Free State (South Africa)

Johan Pretorius, Schalk Louw, Pierre Venter

[1]Department of Agriculture, Central University of Technology, Bloemfontein, Free State, South Africa, [2]Department of Zoology and Entomology, University of the Free State, Bloemfontein, Free State, South Africa, [3]Unit for Applied Food Science and Biotechnology, Central University Technology, Bloemfontein, Free State, South Africa

Introduction: Consumer demands have resulted in the year-round production of lettuce in certain areas of Southern Africa. The sequential planting of this crop puts it at risk to attack by several aphid species throughout the year, complicating control strategies.

Methods: Lettuce was planted throughout a one-year period (December 2005 - November 2006) in two different shade house structures (one partially and one fully covered with shade netting) to determine the occurrence and seasonality of different aphid species and their associated coccinellid predatory guilds.

Results: A total of nine aphid species and five coccinellid species were observed. Both structures harboured similar aphid and coccinellid species, with minor exceptions. The aphid species *A. lactucae*, *M. euphorbiae* and *Aphis* sp. 1 showed no seasonality, being present throughout the trial period. By employing Sørensen's coefficient of similarity, it was determined that these species occurred during similar periods in both structures. The aphid, *N. ribisnigri*, also exhibited similar occurrence in both structures, but only during the warmer months of December – March. The coccinellids *H. variegata* and *Scymnus* sp. 1 were the two predatory coccinellid species which showed a significant similar association with *A. lactucae*, *M. euphorbiae* and *Aphis* sp. 1.

Conclusions: *A. lactucae*, *M. euphorbiae* and *Aphis* sp. 1 pose the greatest threat to lettuce producers in the central Free State, while *N. ribisnigri* is a potential threat during the warmer months, and *M. persicae* during the cooler months. *H. variegata* and *Scymnus* sp. 1 have potential as possible biological control agents.

POSTER PRESENTATION

The contribution of biological control to management of an invasive weed, *Acacia cyclops*, in South Africa

Fiona Impson[1], Carien Kleinjan[1], John Hoffmann[1], Judy Post[2], Cliff Moran[1]

[1]University of Cape Town, Rondebosch, South Africa, [2]Plant Protection Research Institute, Stellenbosch, South Africa

Acacia cyclops is a plant of Australian origin, which has become an invasive environmental weed in South Africa. Suitable climatic and edaphic factors combined with high annual seed-yields have contributed to the invasiveness of the plant. Since 1994, two insect biological control agents have been introduced successfully against this weed in South Africa. The first of these, a seed-feeding weevil, *Melanterius servulus*, despite slow dispersal, has made a large contribution towards reducing the annual seed output (and hence the aggressiveness and spread) of *A. cyclops*. The second and more recent introduction, the flower-galling midge, *Dasineura dielsi*, has spread rapidly and has the ability to curb pod production very dramatically. Unlike some of the gall-forming agents used in biological control programmes, the midge does not have any negative impacts on the vegetative growth of its host plant. This is an additional benefit due to the utilization of *A. cyclops* wood as a fuel source. Despite the combined contribution of these insects in limiting the annual seed-production, the success of these two agents in managing populations of *A. cyclops*, ultimately rests on what impacts, if any, they are having on the seed-banks of the host plant. Preliminary investigations demonstrate that due to the relatively short-lived nature of the seed bank, biological control can play an important role in the integrated management of *A. cyclops*.

POSTER PRESENTATION

Developing the sterile insect technique for *Thaumatotibia leucotreta* (Lepidoptera: Tortricidae): Radiation biology and inherited sterility

Stephanie Bloem, James E. Carpenter, J. Hendrik Hofmeyr

[1]USDA APHIS, Raleigh, North Carolina, United States, [2]USDA ARS, Tifton, Georgia, United States, [3]Citrus Research International, Citrusdal, Western Cape, South Africa

False codling moth, *Thaumatotibia leucotreta* (Meyrick), male and female mature pupae and newly emerged adults were treated with increasing doses of gamma radiation and then either inbred or out-crossed with fertile counterparts. For newly emerged adults, there was no significant relationship between dose of radiation and insect fecundity when untreated females were mated to treated males (N♀ by T♂). However, fecundity of treated females mated to either untreated (T♀ by N♂) or treated males (T♀ by T♂) declined as the dose of radiation increased. A similar trend was observed when mature pupae were treated. The dose at which 100% sterility was achieved in treated females mated to untreated males (T♀ by N♂) for both adults and pupae was 200 Gy. In contrast, newly emerged adult males treated with 350 Gy still had a residual fertility of 5.2% when mated to untreated females and newly emerged adult males that were treated as pupae had a residual fertility of 3.3%. Inherited effects resulting from irradiation of parental (P_1) males with selected doses of radiation were recorded for the F_1 generation. Decreased F_1 fecundity and fertility, increased F_1 mortality during development, and a significant shift in the F_1 sex ratio in favor of males was observed when increasing doses of radiation were applied to the P_1 males.

POSTER PRESENTATION

Developing the sterile insect technique for *Thaumatotibia leucotreta* (Lepidoptera: Tortricidae): influence of radiation dose and release ratio on fruit damage and population growth in field cages

J. Hendrik Hofmeyr, James E. Carpenter, Stephanie Bloem

[1]Citrus Research International, Citrusdal, Western Cape, South Africa, [2]USDA ARS, Tifton, Georgia, United States, [3]USDA APHIS, Raleigh, North Carolina, United States

The effect of radiation dose and different release ratios of treated (T) to untreated (U) false codling moth, *Thaumatotibia leucotreta* (Meyrick), on the incidence of fruit damage, the competitiveness of the treated males, and population growth was examined inside field-cages. Navel orange trees were individually enclosed in large nylon mesh cages. Newly emerged adult moths treated with either 150 or 200 Gy of gamma radiation were released into the cages at ratios of 5T:1U or 10T:1U. The fruit was collected after four weeks and the number of damaged fruit and larval entries per cage were recorded for each treatment. Infested fruit was maintained in the laboratory until all emerging F_1 progeny were collected and out-crossed to untreated moths of the opposite gender.

Treatment had a significant effect on the mean number of larval entries and on the number of undamaged fruit per cage. The number of larval entries as well as the number of F_1 progeny per cage decreased as the overflooding ratio increased. A significant reduction in egg hatch was observed in the progeny of crosses between F_1 females or F_1 males originating from the treatment cages when compared to crosses of F_1 moths originating from the control cages. The lowest mean number of fertile F_1 adult females and males was obtained from the 150 Gy and 10T:1U ratio treatment. This treatment also showed the lowest per generation rate of increase (<1 from the P_1 to the F_1 generation), suggesting that growth in the fertile population would have been prevented if releases of treated moths at this dose and ratio were maintained in the field.

POSTER PRESENTATION

Developing the sterile insect technique for *Thaumatotibia leucotreta* (Lepidoptera: Tortricidae): Pilot project and commercialization

J. Hendrik Hofmeyr, James E. Carpenter, Stephanie Bloem

[1]Citrus Research International, Citrusdal, Western Cape, South Africa, [2]USDA ARS, Tifton, Georgia, United States, [3]USDA APHIS, Raleigh, North Carolina, United States

A pilot experiment to determine the potential of the Sterile Insect Technique (SIT) to suppress false codling moth (FCM), *Thaumatotibia leucotreta*, in citrus orchards, was conducted in Citrusdal, Western Cape, South Africa. One thousand mixed gender FCM treated with 150 Gy gamma irradiation were released twice a week for 56 weeks in 35 ha of oranges. The releases were made by hand from an ATV quad bike at 40 m intervals between release rows. Distribution and longevity were monitored with sex pheromone in delta traps. The released moths distributed adequately and fully overlapped between release rows. The desired overflooding ratio of 10 released males to one wild male was exceeded by margins of up to 188:1 and a mean of 43:1 was maintained for the duration of the release period. Fruit drop surveys were conducted once a week in release and control orchards. Fruit drop due to FCM was reduced by 94,4% in the release area compared to an untreated control orchard.

An insectary for the mass rearing of 15 million FCM per week for release in 6000 ha of citrus trees in the Citrusdal region was consequently constructed. The building covers 2000 m^2 and consists of a diet preparation room, aseptic egg inoculation rooms, an egg laying room, 20 larval rearing and pupation rooms, a moth eclosion room, several cold rooms, a 20 kGy gamma irradiation facility and a general cleaning area.

The commercial project is being phased in over three years. Rearing of insects began in September 2007 and moth releases in 1500 ha of citrus commenced in November 2007. Moths were released twice a week from a gyrocopter and were supplemented by ATV releases when necessitated by factors such as orchard topography and adverse weather conditions. The SIT programme is currently a multidisciplinary operation to suppress FCM and consists of strict orchard sanitation to remove infested fruit, moth releases and the selective treatment of problem areas with an environmentally-friendly granulovirus spray product. Results are not yet available.

POSTER PRESENTATION

Diversity and abundance of spiders (Arachnida: Araneae) in the field and tree layers of Erfenis Dam Nature Reserve, Free State Province

René Fourie, Charles Haddad

University of the Free State, Bloemfontein, South Africa

Introduction: The Grassland Biome dominates the central area of South Africa and is dominated by a single layer of grass and an absence of trees, except in a few localised areas.

Methods: From November 2005 to August 2007, spiders (Arachnida: Araneae) were collected every three months from the Erfenis Dam Nature Reserve in the Free State Province, South Africa. Spiders were collected from three tree species (*Acacia karroo*, *Rhus lancea* and *Rhus ciliata*) and four different types of grasslands (uniform *Themeda triandra*, mixed, weedy and woodland grasslands). Beats were used to collect the tree-dwelling spiders and sweeps were used to collect the grass-dwelling spiders.

Results: During the period of two years a total of 496 tree-dwelling spiders were collected, representing 17 families and 54 species, while 1649 grass-dwelling spiders were collected, representing 15 families and 84 species. More spiders were found during the summer months, when the temperature and rainfall are higher, than during the winter months. A bottom-up effect from rainfall might be a reason why there are more spiders in the summer season. The higher rainfall leads to denser vegetation growth, which attracts more insects, providing more prey to spiders. More spider species, as well as individuals, were collected from the grasslands than from the tree layers, but the tree layers had a greater diversity of spider families.

Conclusion: It seems that vegetation complexity and structure, and season of flowering, determine the dominant spider families and species in grassland.

POSTER PRESENTATION

Influence of hemipteran pests on the grain quality of *Sorghum bicolor* (L.) Moenich

Anél Grobler[1], José Parau[2]

[1]University of the Free State, Bloemfontein, South Africa, [2]Chemtura (Pty) Ltd., Kempton Park, South Africa

Introduction: Panicle feeding bugs of the order Hemiptera reduce sorghum grain quality by sucking sap from developing sorghum grains, resulting in shrivelled grains with red-brown feeding punctures. These damaged grains are small, poorly developed and often infected by fungi. The study was aimed at quantifying seed germination and mass of different sorghum cultivars relative to this insect damage.

Methods: The germination rates and mass for 15 red and 15 white sorghum cultivar lines were determined. Damage to field sampled grains of these lines received from the Potchefstroom Grain Crops Institute was scored visually on a scale of 0 to 3.

Results: When mass and germination were compared, it was mostly found that grains with less damage had a higher mass and germination percentage. The red sorghum cultivar lines usually had a higher mass and germination percentage than the white cultivar lines. The white cultivar lines showed higher damage indices than the red cultivar lines.

Conclusions: Damaged sorghum grains have poor germination rates and are more susceptible to grain moulds. Red sorghum lines appear to be more resistant to mould and insect damage because of higher tannin content.

POSTER PRESENTATION

The use of blowfly larvae in entomotoxicology - the influence of gunshot residue on insect succession and the development of *Chrysomya chloropyga* (Diptera: Calliphoridae) larvae

Shaun Hoffman, Theuns van der Linde, Piet van der Merwe

University of the Free State, Bloemfontein, South Africa

Introduction: Entomotoxicology is a specialized field where insects are used as toxicological indicators on decomposing human bodies when poisoning, drug abuse or murder with a fire arm is expected. A number of substances can be detected in necrophilous blowfly larvae. Reliable results in forensic entomology is dependent on the correct calculation of the post-mortem interval (PMI). The development stage of the fly larvae is used to determine the PMI. A foreign substance being ingested by larvae can alter the developmental time as well as the growth rate of the larvae. The importance of the correct calculation of the PMI is vital in suicide, drug overdose and murder investigations.

Methods: Pigs were euthanased, shot and placed in the field to decompose. The hind legs of the pigs were cut off after being shot and used in the laboratory for further assays. Larvae were sampled every six hours from the hind legs in the laboratory. The larvae were measured and weighed.

Results: Preliminary results indicated that gunshot residue GSR had a suppressing effect on larval development. Larvae that fed on the hind legs containing GSR, fed directly in and around the bullet wound and were significantly smaller than the larvae feeding on the control.

The larvae that fed on the hind legs containing GSR, all contained significantly higher concentrations of Lead (Pb) and Barium (Ba) and Calcium (Ca) than the larvae feeding on the control.

Conclusions: This suggests that GSR may initially have a suppressing effect on the development rate of larvae.

POSTER PRESENTATION

Effect of honey and temperature on longevity and fecundity of *Dirhinus himalayanus* and *Spalangia endius*, the parasitoids of *Musca domestica*

Hamdan Ahmad[2], Idris Ghani[1], Ahmad Salleh[2]

[1]Universiti Kebangsaan Malaysia, Bangi, Selangor, Malaysia, [2]Department of Veterinary Services, Putrajaya, W.P., Malaysia

Introduction: Two species of parasitoid namely *Dirhinus himalayanus* and *Splangia endius* commonly found in poultry farms in Malaysia. The study was conducted to determine the optimum honey concentration and temperature for rearing these parasitoids.

Methods: The parasitoids were two experiments; (1) parasitoid treated with different honey concentrations (nothing, water only, 10% honey, 20 % honey, 30% honey, 40% honey, 60% honey, 80% honey and pure honey) at a constant temperature (28 ℃) and (2) parasitoid treated with different temperatures on the 10% honey solution (10% honey). Parasitoid's longevity and fecundity was recorded for 60 days.

Results: Mean longevity and fecundity *D. himalayanus* are significantly ($P<0.05$) higher than *S. endius*. Parasitoid without food, fed with water or honey live 6.1 ± 0.45 days, 10.3 ± 0.70 days and 24.0 ± 2.52 days respectively. Longevity and fecundity of *S. endius* and *D. himalayanus* was significantly ($P< 0.05$) higher when fed on 10 - 30% honey solutions than fed with honey solutions. Means longevity and fecundity parasitoids reared at 28 - 30^{o}C were significantly ($P<0.05$) higher than at other temperatures.

Conclusions: Results indicated that these parasitoids are potentially be used as biological agents of housefly as they could be produced commercially at 28 – 30^{o}C fed with 10 - 30% honey and can survive without food for several days.

POSTER PRESENTATION

Pest control system effects on the arthropod communities in Romanian apple orchards

Sonica Drosu[1], Grigore Margarit[1], Constantina Chireceanu[1], Maria Ciobanu[1], Ioan Rosca[2], Maria Neamtu[3]

[1]Research-development Institute for Plant Protection, Bucharest, Romania, [2]University of Agronomical Sciences and Veterinary Medicine, Bucharest, Romania, [3]Research and Development Station for Fruit Tree Growing, Baneasa, Bucharest, Romania

Introduction: The comparative study on the beneficial fauna and the pests under two treatment systems in apple orchards was carried out. These two variants (low polluting treatment system and conventional system) were observed in 2 orchards with different history of the treatment practice (one with the intensive treatments in the previous years and other with IPM practice) and different climate conditions.

Methods: Three sampling methods were used to catch the arthropods between April – September 2007: (i) beating branches of trees into entomological funnel with 0.5 m^2 opening; (ii) yellow sticky traps; (iii) pitfall trapping. Samples were taken to the laboratory for specimen identification; they were identified to family and to species as well as possible.

Results: Both beneficial fauna and pests registered a lower effective in the first type of orchard (with previous intensive treatment) than those with IPM practice. The beneficial and the pests had total individuals approximately equal in the 2 variants at beating method and at yellow sticky traps; pitfall traps registered higher number of beneficial fauna than pests. During the year the number of the beneficial fauna increased from April to September in the experimental variant (low polluting treatment system).

The beneficial fauna was represented mostly by Heteroptera (Fam. Miridae-*Deraeocoris lutescens* Sch.), Hymenoptera (Fam. Calcididae and Braconidae) and Coleoptera (Fam. Coccinellidae-*Coccinella 7 punctata, Adalia bipunctata* L., Fam. Carabidae-*Bembidion properans* L.). The main pests belong at following: Thysanoptera (Fam. Thripidae-*Thrips spp.*), Homoptera (Fam. Aphididae, Cicadelidae), Coleoptera (Fam. Carabidae-*Harpalus spp.*, Fam. Chrysomelidae-*Phylotreta spp.*). The pheromone traps and the visual observations showed high population of the codling moth (*Cydia pomonella* L.) and summer fruit tortrix moth (*Adoxophyes reticulana* Hb.).

Conclusions: This study shows that the main effect of farming practice is to influence the abundance and structure of the fauna in the apple orchards and the implications in keeping bioecological equilibrium.

POSTER PRESENTATION

Integrated control system of pests and diseases of winter cereals crops by seed treatment in Romania

Popov Constantin, Cana Lidia, Raranciuc Steluta

National Agricultural Research and Development Institute, Fundulea, Romania

Introduction: In Romania, production of winter cereals crops (wheat, rye, triticale and barley) is often conditioned by various pests and pathogens. In order to save production, use of various measures was necessary, sometimes inadequate, to control the harmful organisms.

Methods: Researches took into consideration insect pests, of which particular interest is shown by: *Zabrus tenebrioides*, *Agriotes spp.* and aphid species (*Macrosiphum avenae, Rhopalosiphum maidis, R. padi, Metopolophium dirhodum, Schizaphis graminum*), vectors for *BYD* and *WDV*, also diseases *Tilletia spp., Fusarium spp.* in wheat, rye, triticale and respectively *Ustilago nuda, Pyrenophora spp.* in barley and two-row barley.

Results: Thus, soil pest control was based for a long period, nearly exclusively, on organochoride insecticides, applied as dust, this particularly contributing to environment pollution and destroying beneficial fauna. Likewise, long-term use of ethyl-mercury chlorine for treating wheat seed against the wheat bunt led to onset of pathogen resistance to this chemical. It is worth mentioning as unsuitable the high share of monoculture of spiked cereals and ignorance of optimum seed-time, thus favourizing reproduction of some pests and pathogens. Due to these facts, in the last decades approaching of numerous investigations has been imposed, having to outline the real ecological factors to be considered in developing a system of integrated control of pests and diseases of winter wheat and barley crops.

Conclusions: In the present, for pest control are used insecticides or insect-fungicides for seed treatments: tiametoxam and imidacloprid are the main active ingredients, used on 1.5 mil. ha.

POSTER PRESENTATION

Morphological identification of Chalcidoidea wasps occurring on *Erythrina caffra* and *E. lysistemon* and the impact of nutrient availability and concentration on survival rates

Burgert Muller[1], Schalk Louw[1], Gerhard Prinsloo[2], Stefan Neser[3]

[1]Department of Zoology and Entomology, University of the Free State, Bloemfontein, Free State, South Africa, [2]ARC-PPRI (Biosystematics Division), Pretoria, South Africa, [3]ARC-PPRI (Weeds Research Division), Pretoria, South Africa

Introduction: *Erythrina* species are of cardinal importance in various ecosystems, as well as various social and ornamental viewpoints. Across the Pacific and Asiatic islands, an invasive eulophid wasp, *Quadrastichus erythrinae*, is causing havoc by inducing galls on various species of *Erythrina* trees, which can ultimately lead to mortality. African species of coral tree are also galled by various indigenous Eulophidae wasp species. There are also inquilines and parasitoids present, making the insect-plant interactions much more intricate than in other countries where the insects are invasive. The purpose of the present study is to unravel this *Erythrina* gall wasp complex.

Methods: A key to the sampled insects was compiled, together with illustrations for identification. The survival rates of the wasps were determined by the availability and concentration of different nutrients (sugar water and honey), with water as control.

Results: The wasps sampled to date were two species of *Quadrastichus* spp., two species of *Aprostocetus* spp. (Eulophidae), one species of *Bruchophagus* sp. (Eurytomidae), and currently two unidentified Chalcidoidea species. Nutrient availability greatly influenced and increased the wasps' survival, with concentration influencing feeding time.

Conclusion: The knowledge of which wasps occur in the complex is the first step to unravelling it. Nutrient concentration and availability help with the optimisation of host specificity trials.

POSTER PRESENTATION

IPM of sunn pest (*Eurygaster* spp. and *Aelia* spp.) in Romania

Popov Constantin, Rosca Ioan, Raranciuc Steluta

National Agricultural Research and Development Institute, Fundulea, Romania

Introduction: Sunn pest (*Eurygaster integriceps, E. austriaca, E. maura, E. testudinaria, Aelia acuminata* and *A. rostrata*) is one of the most important pests of wheat in Romania.

Methods: The insect effectives are estimated at the end of control campaign, before leaving crops towards forests and also the attack level is analysed, by establishing the percentage of stung kernels, this representing an early step in evaluation of insect effectives which will infest crops in the next year.

Results: The following elements have been examined: ratio between species and their distribution areas in Romania, size and space distribution of sunn pest populations, study of annual peculiarities of their life cycle, relationships between pest and oophagous parasites and establishing of the economic damage thresholds and the means for their control. Thus, the share of various elements has been established, and namely: prevalence of *Eurygaster integriceps* has been proved, covering a damaging area of account 1,000,000 ha of wheat crops in 24 districts; contribution of oophagous parasites and the economic damage thresholds, as differentially calculated in accordance with crop vegetation stage and harvest destination. Climate conditions and surfaces cropped with wheat and oak forests, differentiate damaging area in a very favourable zone (15 districts) and a less suitable area (9 districts).

Conclusions: Forecast and warning are permanent concerns in the whole country, and they are based on a methodology developed by NARDI Fundulea, and applied across the country by the Department Phytosanitary Quarantine. Chemical control of sunn pest in Romania is supported by Government.

POSTER PRESENTATION

IPM of *Tanymecus dilaticollis* Gyll. : The main pest of maize crops in Romania

Popov Constantin, Raranciuc Steluta, Cana Lidia

National Agricultural Research and Development Institute, Fundulea, Romania

Introduction: The maize is one of the most important crops in Romania, being cultivated on three million ha. Their crop technology involves complex protection measures vs. pests and pathogens.

Methods: The main pest of maize in Romania, which affects more than 1.0 mil. ha is *Tanymecus dilaticollis*. The seed treatment with neonicotinoidic insecticides have been developed by recent researches. In the same time seed treatment was included in an IPM system in which agrotehnic methods play an important role, taking into consideration treatments in vegetation for particular situations.

Results: The greatest damages are produced by *Tanymecus dilaticollis* attack even from the emergence. In order to avoid the damages or total crop compromising, the adoption of a complex measures system based on seed treating is necessary, as follows:

for areas where the preceding crop was a winter spike cereal, vetch-oats mixture, bean, soybean, pea or linseed, the chemical treatments are not indicated, because the density registers low values till 3 individuals/m^2;

if the preceding crop was maize, sunflower, sugar beet or sorghum, the maize seed treating is recommended with the following ingredient: carbofuran, thiamethoxam, imidachloprid, and bensultap;

in the case of favourable climatic conditions for pest appearance, after plant emergence,the application of one correction treatment during vegetation is recommended on seed areas treated with: thiamethoxam, thiachloprid, acetamiprid, fipronil, dimetoat+cipertrin or bensultap.

Conclusions: In the present, for pest control are used insecticides for seed treatments: tiametoxam and imidacloprid are the main active ingredients, used on 0.7 mil. ha.

POSTER PRESENTATION

Evaluation of the arthropod populations in vineyards under different management strategies

Constantina Chireceanu[1], Adrian Serdinescu[2], Loreta Dumitrascu[2], Silvia Cazacu[2], Sonica Drosu[1]

[1]Research-Development Institute for Plant Protection, Bucharest, Romania, [2]Research Institute for Viticulture and Enology, Valea Calugareasca Prahova, Saint Helena

Introduction: A comparative study was undertaken concerning the arthropod populations in vineyard under conventional, biological and integrated pest management strategies and permanent ground cover, herbicide treated and vegetation-free conditions.

The survey was carried out in vineyards of the Research Institute for Viticulture and Enology Valea Calugarească (south-east sub Carpathian region of Romania).

Methods: The beating of vine foliage technique and the pitfall trapping were used for collecting arthropods from May to September in 2006-2007. A specific Romanian pheromone trap was used for capturing the grape berry moths. The arthropods were taxonomically identified and separated into two categories, the pests and beneficial, those where analyzed separately.

Results: The structure and seasonal dynamic of pests and beneficial were appreciated for each experimental blocks. It was established that the pest arthropods were represented mainly by major pest of vineyard, grape berry moths and leaf- and plant-hopers. The useful arthropods were represented by spiders group and generalist predators in the families Coccinellidae, Chrysopidae, Nabidae, and Syrphidae. Arthropod populations were low in the spring and increased during the summer. The vine blocks managed by biological program exhibited a higher abundance of the two fauna categories than in integrated and conventional programmes. Similar trends were observed in ground cover blocks, showing that pest a useful fauna was influenced by presence of vegetation in vineyards.

Conclusions: Our studies showed that the densities of pests and associated natural enemies are influenced by the pest management strategies a ground cover practices in vineyard.

POSTER PRESENTATION

IPM of *Tetranychus urticae* Koch. : The main pest of soybean crops in Romania

Popov Constantin[1], Rosca Ioan[2], Raranciuc Steluta[1]

[1]National Agricultural Research and Development Institut, Fundulea, Romania, [2]University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania

Introduction: In Romania, soybean is considered an important crop, which currently occupies about 130,000 ha, on all over the country. One of limitative pest is *Tetranychus urticae*.

Methods: To establish the life-cycle and number of generations, the occurring of pest mobile stages, species bio-ecology under various conditions on different legumes (soybean, pea, and bean) the attack way and the level of damages, were followed. To perform the control technology, it was tested an assortment of chemicals.

Results: The researches showed that under conditions of Romania, *Tetranychus urticae* wintered as adult into soil, underground or vegetable debris and into tree bark cracks. During a year, it develops six generations. The average duration of a generation was of 27 days, at an air average temperature of 21.6^0C and 38 days at 11.8^0C. During summer, the development is faster than the first and last generations, developed at lower temperatures. For soybean crop, the third and fourth generations are economically important. The occurring and development of these generations coincide with the end of soybean growth and reproductive stage. The warning should be made at the occurring of mobile forms from third and fourth generations. A lot of commercial products with different active ingredient,(*amitraz, bromprop*ilat, *dicofol, dimetoat, fenbutatin oxide, fenpiroximat, propargit, spirodiclofe,* had result effective from trials.

Conclusions: The best results were obtained by the application of two chemical treatments. In this way, the mobile forms of third and fourth generations are controlled.

POSTER PRESENTATION

Storage pests and seed injury in farm storage facilities in Namibia

Vaclav Stejskal

Crop Research Institute, Prague, Czech Republic

Introduction: There is a controversy over the extent of weight loss potential caused by storage pests.

Methods: A survey of stored product pests, their natural enemies, grain storage and pest management approaches in northern Namibia was conducted.

Results and Conclusions: The survey revealed five types of crop commodities (pearl millet, sorghum, cowpea, maize, feed mixture) stored in four types of grain stores (baskets, bag stags-flat stores, concrete bin, metal containers). No synthetic pesticides or plastic sheeting was recorded. Wooden-ash natural pesticide is the only protectant used. Ten insect pest species were found affiliated to the orders of Coleoptera (*Attagenus fasciatus, Callosobruchus subinnotatus, Cryptolestes ferrugineus, Oryzaephilus surinamensis, Rhyzopertha dominica and Tribolium castaneum*), Lepidoptera (*Corcyra cephalonica, Sitotroga cerealella*), Psocoptera (*Liposcelis paeta*) and Blattodea (*Blattella germanica*). Out of these, seven species were recognized as new stored-products pests for Namibia. Although listed for southern Africa region, no storage pest-mites (Acari) and Sitophilus spp., Prostephanus sp. or Trogoderma sp. beetles were traced. We found four new species of natural enemies of storage pests recruiting from insects (*Habrobracon hebetor, Cephalonomia wattersoni, Brachymeria sp.*) and mites (*Blattisocius tarsalis*). There is a controversy over the extent of weight loss potential caused by storage pests. In this work we report unusually high pest related losses (i.e. losses >95%) to stored legumes (*Vigna unguicula, Arachis hypogea* - Leguminosae) in Namibia caused by combined infestation by pyralid moth (*C. cephalonica*) and bruchid beetles (*C. subinnotatus*). This study was supported by the by MZe (project Vyzkumny zamer 0002700603).

POSTER PRESENTATION

The effects of biological-control-agent herbivory on water hyacinth plants: Resource and nutrient allocation; herbivore-induced plant defenses; and photosynthetic mechanisms and outputs

Kate Lorentz, Martin Hill, Marcus Byrne, Bradley Ripley

[1]Rhodes University, Grahamstown, South Africa, [2]University of the Witwatersrand, Johannesburg, South Africa

Six biological control agents have been released since the initiation of the biological control programme against water hyacinth (*Eichhornia crassipes*) in South Africa in 1973. Those agents released are either plant material chewers or sap-suckers. Little is known about the effects of insect herbivory on plant physiology. This involves understanding herbivore stress induced disruptions to photosynthetic mechanisms and outputs; the translocation of nutrient and resources within plant material; and plant defense responses in the form of volatile organic compounds. Furthermore, the impacts of herbivore-induced changes in plant nutrient quality on the herbivore population are poorly understood. Shifts in resources and nutrients from one plant organ to another may make some parts of the plant more prone to attack by biological control agents. Stable isotope ratio analyses at natural abundance levels have been used to track the translocation of carbon and nitrogen from water media throughout plants, in both the presence and absence of agent herbivory. Chlorophyll fluorescence analysis has been used to measure altered potential photosynthetic output as a result of herbivory. Results of headspace sampling of water hyacinth plants exposed to herbivory have been analyzed for volatile compound elucidates (isoprenoids, phenylpropanoids/benzenoids and fatty acid derivatives) by using gas chromatography.

Preliminary results show that whilst low levels of herbivory have little effect on plant growth parameters, they do induce changes in plant physiology. However water hyacinth appears to be capable of compensating fairly high levels of herbivory from both guilds of agents released.

POSTER PRESENTATION

Pest thrips of Bulgaria

Gerald Moritz[1], Vladimir Krumov[2], Olia Karadjova[2]

[1]Martin-Luther University, Halle, Germany, [2]Plant Protection Institute, Kostinbrod, Bulgaria

Introduction: Thrips are among the most damaging insect pests on tomatoes, cucumbers, onions, tobacco, cereals and ornamentals, causing considerable economic losses in Bulgaria. Besides direct damage, caused by feeding, thrips also cause far more serious indirect damages through transmitting plant viruses – agents of diseases, against which there is currently no effective control. An early species determination is necessary to avoid yield losses.

Dichotomous identification keys require good systematic training. The lack of taxonomists brings the need of creation of user-friendly identification software that can be used by anyone – from quarantine workers and economic entomologists, to the virologists and ecologists concerned with crops.

Methods: For creation of the CD-ROM, Lucid 3 software was used. The molecular key is based on the amplification of ribosomal ITS1 and ITS2 regions and restriction fragment length polymorphism (ITS-RFLP). High-quality light microscope and SEM pictures were made.

Results: The interactive key of Pest thrips of Bulgaria was made combining molecular and morphological features for identification. Besides the identification part the CD-ROM includes useful information for the methods used, general information for thrips, their biology, distribution and host-plants. The software will be available in 3 languages – Bulgarian, English and Russian.

Conclusions: The Pest thrips of Bulgaria interactive key allows fast and reliable diagnostics of all stages that can be done even from non-specialist in thrips taxonomy.

POSTER PRESENTATION

Influence of morphological and anatomical characteristics of the leaves on the host selection by *Frankliniella occidentalis* (Pergande) (Thyasanoptera: Thripidae)

Maria Papadaki, Vili Harizanova, Andreas Bournazakis

[1]Technological Education Institute of Crete, Heraklion, Crete, Greece, [2]Agricultural University of Plovdiv, Plovdiv, Bulgaria, [3]University of Crete, Heraklion, Crete, Greece

Introduction: The thrips *Frankliniella occidentalis* is one of the most important insect pests in vegetable crops in greenhouses on the island of Crete (Greece). Leaves features such as trichome length, width as well as thickness of leaves cuticle and waxes can have a profound effect on the acceptability of a plant. We recently showed that the insect's preference for the leaves of several vegetables is variable, ranging from the highest levels for eggplants to a minimum ones for pepper.

Methods: The morphological and anatomical structure of the leaves of different crops – including number, length and shape (original microscope photos) of trichomes, number, length and width of stomata, leaf thickness, thickness of spongy and palisade parenchyma, thickness of upper and lower epidermis- were studied.

Results: Number of trichomes on the lower epidermis is moderately correlated and length of trichomes is significantly correlated (r) with the population density of *F. occidentalis*. Number of stomata is moderately negatively correlated and length of stomata is weakly negatively correlated. Width of stomata is significantly correlated with the preference of *F. occidentalis* to the different crops. Leaf thickness and spongy parenchyma is weakly negatively correlated. Thickness of upper, lower epidermis and palisade parenchyma is moderately negatively correlated.

Conclusions: The leaves of the most preferred crop (eggplant) are densely pubescent and those of the least preferred one (pepper) are glabrous. Morphological and anatomical characteristics play an important role for the preference of *F. occidentalis* for the crop species. Morphology of trichomes is connected to host selection.

POSTER PRESENTATION

Biodiversity of the insect pest fauna from rape crops in Romania

Popov Constantin[1], Rosca Ioan[2], Cana Lidia[1]

[1]National Agricultural Research and Development Institute, Fundulea, Romania, [2]University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania

Introduction: Rape crop for oil in Romania registered an important extension, in 2007 being cultivated on 250,000 ha. In this paper is presented biodiversity of crop's insect pests.

Methods: Researches referring biodiversity of insect fauna from rape were conducted in 5 representative localities, by insect collecting from 10 to 10 days in the whole vegetation period, through pitfall traps, pheromone traps, Yellow sticky traps, entomological net and plant analysis for presence of insects onto and into the stem or seeds.

Results: There were registered species of insects from the main insect orders (*Homoptera* – 3 species; *Heteroptera* – 4; *Coleoptera* – 25; *Lepidoptera* – 9; *Hymenoptera* – 1; *Diptera* - 6). Damage impact was present differentiated in function of plant development stage and pest life cycle in the attack moment. Important damages were registered in different periods of time from case to case. Thus, in autumn, soon after emergency, the plants were attacked by *Athalia colibri, Pieris brassicae, Phyllotreta atra*. In the spring, the attack was done by *Entomoscelis adonidis, Ceuthorrynchus picitarsis* and in late spring, before and after flowering, by *Brevicorynae brassicae, Meligetes aeneus*, *Athalia colibri, Agriotes* spp., *Loxostege stricticalis, Phytomyza rufipes*. During the ripening of pods and seeds maturation the attack is continued by *Eurydema ornata, Dolycoris baccarum, Contarinia nasturtii, Dasineura brassicae, Ceuthorrynchus napi, Lygus pratensis*.

Conclusions: Importance of attack of different species on rape in different plant growth stages impose application of a plant protection technology, which include seed treatment and 1-2 spraying with insecticides during vegetation time.

POSTER PRESENTATION

Fat body influence in the dynamics of the sunn pest (*Eurygaster integriceps* Put.) populations in Romania

Popov Constantin, Cana Lidia, Raranciuc Steluta

National Agricultural Research and Development Institute, Fundulea, Romania

Introduction: The fat body presents a significant role into the life-cycle of *Eurygaster integriceps*, constituting one of the most important factors of perpetuation and numerical blasting with invasion role.

Methods: The prolificacy of populations was studied under field and controlled conditions, by individualized couples, collected at the end of diapause, in spring. The fat analyses were performed on groups of 25 or 100 insects, separately on sexes and weight groups.

Results: The accumulation of reserve matter and the fat body level among this species present a great no uniformity, both individually and from one zone to another or from one generation to another, being the consequence of a complex of factors from which the climatic and agro technical ones are the most important. The mean value of the fat body is different between sexes too. The fat body level influences the mortality during diapause, the sterility and fertility, strongly influencing the bug population multiplication. The insects with low level of fat matter accumulations have a high mortality percentage during diapause as well as a very low fertility. The fat body is consumed in a proportion of 25% for maturation during diapause and 50% for oviposition. The main factor of the formation of a well developed fat body is the complete rearing of adults under the best conditions. This factor is the premise of an optimum development of bug population in a specific area determining an adequate multiplication.

Conclusions: The multiplication index, calculated by fat body, ranges between 0 and 56.47.

POSTER PRESENTATION

Fitness and fertility of interpopulation matings in *Pareuchaetes insulata* (Lepidoptera: Arctiidae): a biocontrol agent of *Chromolaena odorata* (Asteraceae) in South Africa.

Nontembeko Dube[1], Yoseph Assefa[2], Terence Olckers[3], Costas Zachariades[1]

[1]Agricultural Research Council-Plant Protection Research Institute, Hilton, South Africa, [2]North West University, Potchefstroom, South Africa, [3]University of KwaZulu-Natal, Pietermaritzburg, South Africa, [4]Agricultural Research Council-Plant Protection Research Institute, Hilton, South Africa

Introduction: *Pareuchaetes insulata* from Florida and Jamaica were released separately at several sites each in South Africa, but only one (Florida) site was definitely established. It is likely that insects from this established site interbred with insects from the Jamaican population released at nearby sites. The aims of this study were to test whether there were differences in biology between two populations and whether hybridization affected the fitness of either.

Methods: Trials comprising breeding of a Florida population from the only established site in South Africa (SAF) and a Jamaica (J) population from a laboratory culture, crossbreeding and two back-crossing were conducted. The fitness was determined by measuring fecundity, egg viability, longevity, larval development and survival rates. Genetic differences were analysed using mitochondrial DNA.

Results: The SAF population was superior to the J population in fecundity. Hybridization of these populations reduced the fitness of SAF population. It is unknown whether these differences in fitness reflect differences in their native regions, laboratory cultures or response to South African *C. odorata*. No genetic difference between the two populations was evident.

Conclusion: Different populations of the same agent species may have different levels of fitness, and hybridization may negatively affect the fitness of stronger populations. *Pareuchaetes insulata* has proved to be a difficult agent to establish in South African fields, for various possible reasons. The lower fitness of the J population may have reduced its likelihood of establishing successfully, and reduced the fitness of the established SAF population where it came into contact.

POSTER PRESENTATION

Molecular and functional characterization of serotonin receptors in the cockroach *Periplaneta americana*

Britta Troppmann[1], Arnd Baumann[2], Wolfgang Blenau[1]

[1]University of Potsdam, Institute of Biochemistry and Biology, Potsdam, Germany, [2]Research Centre Jülich, Institute of Neurosciences and Biophysics, Jülich, Germany

Biogenic amines are important messenger substances in the central nervous system as well as in the periphery. In invertebrates, the group of classical biogenic amines consists of five members: dopamine, tyramine, octopamine, histamine, and serotonin (5-HT). The indolamine 5-HT is known to function as a neurotransmitter, neuromodulator and neurohormone and affects behaviors as diverse as locomotion, circadian rhythms, and learning. 5-HT mediates these multifaceted effects predominantly by binding to members of the superfamily of G protein–coupled receptors. The identification and functional characterization of these receptors is decisive for the comprehension of the cellular pathways influenced by 5-HT. Here, we focus on our results concerning a serotonin receptor of *P. americana.*

Using a strategy based on PCR with degenerate primers and RACE PCR we achieved a cDNA sequence encoding a putative serotonin receptor. The full length cDNA (Pea*5-ht1*) comprises 2,564 base pairs and encodes a protein of 683 amino acids (Pea5-HT_1) that displays the characteristic heptahelical structure of G protein-coupled receptors. The tissue-specific expression pattern of the receptor mRNA has been investigated by RT-PCR and indicates high levels of expression in samples of brain, salivary glands and midgut. The distribution of the receptor protein was analyzed by immunohistochemistry with a specific affinity-purified antibody. In order to clarify the functional and pharmacological properties of the cloned receptor, we studied a HEK293 cell line, stably expressing the Pea5-HT_1 receptor protein. Stimulation with 5-HT induces a significant decrease in intracellular cAMP levels. This effect can be antagonized by the substances methiothepin and WAY100635.

POSTER PRESENTATION

Evolutionary analysis of *Anopheles minimus* species complex by the molecular markers of ribosomal and mitochondrial genes

CM Ho[1], YH Lin[2], HJ Teng[3], TY Zhao[4], T Toma[5]

[1]National University of Yang Ming University, Taipei, Taiwan, [2]Yuan Pei University, Shinchu, Taiwan, [3]Centre of Disease Control, Department of Health, Taipei, Taiwan, [4]Institute of Microbilology and Epidemiology, Bejing, China, [5]Faculty of Medicine University of Rykyus, Nishihara, Okinawa, Japan

Introduction: *An. minimus* is a primary vector of malaria in Southeast Asia. The taxon *An. minimus* has shown to consist of at least four sibling species. We describe here the sequence of the ribosomal DNA (rDNA) and mitochondrial genes of this species complex that distributed in Taiwan, Mainland china and Rykyu Achipelago, Japan.

Methods: Larvae or adults of *An. minimus* were collected from 12 locations at three counties in Taiwan, southwest parts of Mainland China, and Ishgaki Island, Rykyu Archipelago, Japan. Total DNA was extracted these specimens, and the target genes were amplified by polymerase chain reaction (PCR). Primers used for amplification were designed based on the published data base for *Anopheles*. The PCR products were cloned and sequenced. Finally, the evolutionary relationships of the *An. minimus* were analyzed with the sequences of nucleotide or deduced amino acid in data base using Neighbour-joining methods.

Results: Examining 12 populations of *An. minimus* in Taiwan, the ITS-2 and D region of the 28 S rDNA of *An. minimus* was 496 bp and 375 bp in length, respectively. 2-nucleotide divergence was found between populations, but no intraspecific variation in the D region of 28S. Identical sequence of the whole mitochondrial COII gene was shown in all populations. The similar results were also found in partial sequence of the mitochondrial ND5. The NJ trees derived from these fragments revealed that *An. minimus* in Taiwan was most closed to *An. minimus* species A of southwest parts of Main China. However, the population of *An. minimus* in Ishigaki Island, Rykyu Archipelago had the highest similarity to that of *An. minimus* species E based of the sequences of ITS-2, D-region of 28 S and mitochondrial COII gene.

Conclusion: Get together the molecular evidence of the ribosomal gene and mitochondrial genes suggests that the *An. minimus* A existing in Taiwan and the southwest parts of Mainland China was derived from the ancestor populations with closed lineage before the landscape separation 20,000 years ago. Since then, their progenies are expanded in the ecological environments similar to that of their ancestors. On the other hands, *An. minimus* E in Ishigaki Island appears to be an originally variant species.

POSTER PRESENTATION

Survey and seasonal activity of adult mosquitoes (Diptera: Culicidae) in Riyadh City, Saudi Arabia

Mohammed Al-Kheraiji[1], Azzam Alahmed[2], Salah Kheir[2]

[1]Natural Resources and Environmental Research Institute, King Abdulaziz City for Science & Technology (KACST), Riyadh, Saudi Arabia, [2]Plant Protection Dept., College of Food and Agric. Sciences, King Saud University, Riyadh, Saudi Arabia

A survey for adult mosquitoes (Diptera: Culicidae) in Riyadh City, Saudi Arabia, was undertaken during the period June 2003-July 2004 using light traps; .and the following 15 different species were collected*:*

Aedes. caspius (Pallas)*, Anopheles. stephensi* Liston *, An. coustani* Laveran*, An. dthali* Patton; *An. pretoriensis* (Theobald);*Culex laticinctus, Cx. perexguus* Theobald*, Cx. pipiens* L*; Cx. quinquefasciatus* Say*, Cx. simpsoni* Theobald*, Cx. sinaiticus* Kirkpatrick; *Cx. theileri* Theobald*; Cx. tritaeniorhynchus* Giles*, Cx. univittatus* Theobald and *Culiseta longiareolata* (Macquart)*.*

During the survey, 6646 adult mosquitoes, which represented 4 genera, were collected.. Out of these, 6446 were *Culex* (96.99%), 147 were *Aedes* (2.21%), 39 were *Anopheles* (0.59%) and 14 were *Culiseta* (0.21%). All these species were reported for the time in Riyadh City, except *Cx .molestus pipiens*, which has been reported earlier.

The seasonal activity of adult mosquitoes in Riyadh City was also investigated. The study showed that the adult mosquitoes were present throughout the year, but at different densities depending on the prevailing climatic conditions. The study showed two peaks for the seasonal activity of the adults; in December-January, and in April- May, where temperature and humidity were optimum.

POSTER PRESENTATION

The management of *Scyphophorus acupunctatus* Gyllenhal (Coleoptera: Curculionidae) on *Agave americana* L. (Agavaceae) in South Africa

Franciska Jordaan, Schalk Louw

[1]University of the Free State, Bloemfontein, Free State, South Africa, [2]University of the Free State, Bloemfontein, Free State, South Africa

Introduction: *Agave americana* L. is cultivated by Agava Distillers (Pty) Ltd at Graaf Reinet in the Eastern Cape and used to produce an alcoholic beverage referred to as Agava®. *Scyphophorus acupunctatus* Gyllenhal (Coleoptera: Curculionidae), the *Agave* weevil, is an important pest of *A. tequilana* Weber and *A. americana* L. It feeds on the core of both plants, dispersing through flight once a year.

Methods: Fungal isolates have been done from the cadavers of *S. acupunctatus* and an entomopathogen has been isolated and identified, the weevils were then exposed to the spores of the pathogen in a water suspension. Olfactory tests are also being conducted in the laboratory, using a Y-olfactometer and a variety of lures. These lures include fresh and fermented plant materials from various host species, and the pheromone of the banana weevil, *Cosmopolites sordidus* Germar. The aim is to attain an attractant.

Results: The pathogen was identified as a strain of *Beauveria bassiana* which targets the *Agave* weevil. It grows and feeds on the internal organs of the weevil, killing the weevil, and then growing out of the cadaver and producing spores. If the weevil dies inside the core of the plant, the spores can distribute and infect other weevils, subsequently killing them. A 100% mortality rate and a 50% fungal growth rate were recorded from weevils exposed to the pathogen.

Conclusion: The attractant and entomopathogen will be combined in “attract and infect” traps and deployed as a management tactic. Field application studies will ultimately be conducted.

POSTER PRESENTATION

In situ identification of powdery stinkbug egg package status as a management practice in pistachio orchards in South Africa.

Schalk Louw

University of the Free State, Bloemfontein, South Africa

Introduction: Pistachio, *Pistacia vera* (Anacardiaceae), is an important new nut crop to South Africa. Presently, large orchards of these trees are under cultivation at IDC-Green Valley Nuts (GVN) near Prieska in the Northern Cape Province. The powdery stinkbug, *Atelocera raptoria* (Hemiptera: Pentatomidae), is a primary pest on this crop, attacking nut clusters and causing severe tissue necrosis to individual nuts.

Method: Initially, identification of *A. raptoria* egg packages through visual scouting was cumbersome and problematic, largely due to the lack of bio-ecological data regarding the species. Subsequently, several studies were conducted on the life-cycle and general ecology of *A. raptoria* in the GVN orchards.

Results: As a result it was determined that an egg-parasitoid, *Trissolcus basalis* (Hymenoptera: Sceleonidae), successfully parasitizes a significant number of *A. raptoria* egg packages in the orchards, showing promise as a possible biological control agent. Furthermore, continuous scouting in the orchards revealed that the status of *A. raptoria* egg packages could be determined *in situ* and that a pictorial guide could be compiled that could be used as an efficient scouting tool.

Conclusion: The simplicity of this tactic is believed to encourage a continuation of scouting GVN management in the orchards. Continued orchard scouting is of crucial importance when considering pest management strategies towards the management of *A. raptoria* (and other stink bugs) on pistachio in South Africa.

POSTER PRESENTATION

Adult experiences influence foraging and oviposition behaviour of *Lysiphlebus fabarum* (Hymenoptera: Aphidiidae) females

Arash Rasekh[1], A. Kharazi Pakdel[1], J.P. Michaud[2], H. Allahyari[1]

[1]University of Tehran, Karaj, Tehran, Islamic Republic of Iran; [2]Kansas State University, Hays, Kansas, United States

In Iran, the black bean aphid (*Aphis fabae* Scop.) is heavily parasitized by the aphid parasitoid *Lysiphlebus fabarum*, both on agricultural crops and associated weeds. The influence of adult experience on foraging behavior was examined in *L. fabarum*. Three-Day-old females of a thelytokous population were each provided with two sequential host patches consisting of 20 2nd instar *A. fabae* that were either healthy or previously parasitized (24 h prior to the experiment), Each female was subsequently transferred to a patch containing 15 healthy 2nd instars. Another experiment, parasitoids were grown under three different daylength conditions; parasitized aphids were grown under short daylength (L10:D14) and subjected the adults to the same conditions, parasitized aphids were reared under long day conditions (L16:D8) and subjected the adults to short days, both parasitized aphids and adults were grown under long day conditions. Females exposed to previously parasitized aphids displayed longer residence times in the 2nd patch and encountered and attacked a larger of aphids before leaving, including aphids probed more than 25 seconds, the threshold time required for oviposition. More aphids were either killed or parasitized in the second patch when the first patch contained previously parasitized hosts, but there was no difference in the rate of superparasitism. Daylength results showed, parasitoids under short day's conditions displayed longer residence times and parasitized more aphids than two other treatments. Short days indicate the end of the aphid season and previously parasitized aphids indicate competition with other females for hosts. Thus exposure to short days and low value hosts raised the value of subsequently encountered host patches.

POSTER PRESENTATION

The species composition and bio-ecology of *Culicoides* spp. frequenting livestock in the Bloemfontein district

Julian Liebenberg[1], Theuns Van der Linde[1], Gert Venter[2], Anne-Marie Pretorius[1]

[1]University of the Free State, Bloemfontein, South Africa, [2]ARC-Onderstepoort Veterinary Institute, Pretoria, South Africa

Introduction: *Culicoides* midges are known to be some of the most important vectors of viral diseases of livestock, such as bluetongue (BT) disease of sheep, African horse sickness (AHS) and bovine ephemeral fever (BEF) in South Africa. Therefore a study on the *Culicoides* midges and vector potential is being undertaken to aid in the control of these diseases and minimize losses.

Methods: Midges were collected from February 2007 to date, using 220V and 12V down draught light traps set up at horse stables in order to determine the species composition, relative abundance and seasonality of the midges. The following surveys are also planned for the future namely, the host preference and abundance of the midge species at horses, sheep, cattle and pigs respectively. Potential breeding habitats of *Culicoides* midges will be explored, to identify possible control strategies. The optimal development temperature and optimal preferred relative humidity (RH) for *C. imicola* and *C. bolitinos* will be determined to aid in the development of an early warning system against periods of high risk for disease spread. Both biological and chemical control of the midges and midge breeding sites will be evaluated.

Results: Preliminary results have shown that *Culicoides* numbers have been very low during 2007 with more midges emerging early in 2008 due to favourable environmental conditions.

Conclusions: The obtained results following these experiments will hopefully lead to more efficient control of *Culicoides* borne disease in Southern Africa.

POSTER PRESENTATION

Insect transferrin functions as an antioxidant protein in a beetle larva

Bo Yeon Kim[1], Kwang Sik Lee[1], Young Moo Choo[1], Iksoo Kim[2], Yeon Ho Je[3], Soo Dong Woo[4], Sang Mong Lee[5], Hyun Cheol Park[5], Hung Dae Sohn[1], Byung Rae Jin[1]

[1]Dong-A University, Busan, Republic of Korea, [2]Chonnam National University, Chonnam, Republic of Korea, [3]Seoul National University, Seoul, Republic of Korea, [4]Chungbuk National University, Chunbbuk, Republic of Korea, [5]Pusan National University, Busan, Republic of Korea

Introduction: In insects transferrin is known as an iron transporter, an antibiotic agent, a vitellogenin, and a juvenile hormone regulated protein. Here, a novel functional role for insect transferrin as an antioxidant protein is demonstrated.

Results: Stressors, such as heat shock, fungal challenge, and H_2O_2 exposure, cause upregulation of the white-spotted flower chafer *Protaetia brevitarsis* (Coleoptera: Scarabaeidae) transferrin (*PbTf*) mRNA in the fat body and increases PbTf protein levels in the hemolymph. RNA interference (RNAi) treated *PbTf* reduction causes increased iron and H_2O_2 levels in the hemolymph and results in induction of apoptotic cell death in the fat body during exposure to stress. The observed effects of *PbTf* RNAi suggest that PbTf inhibits stress-induced apoptosis by diminishing the Fenton reaction via the binding of iron.

Conclusion: Based on these results, we concluded that insect transferrin may be part of the antioxidative defenses and is an antioxidant protein.

POSTER PRESENTATION

Diversity of herbivorous and predatory Hemiptera on sorghum panicles in South Africa

Marlene Kruger[1], Johnnie Van Den Berg[1], Hannelene Du Plessis[2]

[1]North-West University, Potchefstroom, South Africa, [2]ARC-Grain Crop Institute, Potchefstroom, South Africa

Introduction: During the past two decades, panicle-feeding Hemiptera became serious pests of sorghum in West and Central Africa. Prior to this study, no research had been done on these insects in South Africa. Objectives of this study were to determine the abundance and diversity of panicle-feeding Hemiptera on sorghum.
Methods: Collection was done using a plastic bag method and a D-Vac. A check list was compiled and the temporal distribution of different Hemiptera species determined during panicle development.
Results: The total number of adults and nymphs collected during this study was 23 798. Forty herbivorous Hemiptera species were collected. The most abundant family was the Miridae followed by the Lygaeidae which made up 41 % and 17 % respectively of the total number of individuals. *Eurystylus bellevoyi*, *Campylomma* sp., *Creontiades pallidus*, *Nysius natalensis*, *Nezara viridula* and *Sthenaridea suturalis* were the most abundant species and also occurred widely in the sorghum production area. Infestation levels of these species were generally low compared to that in other parts of Africa but comparatively high infestation levels were observed at some sites. There was no clear distinction between insect numbers during different panicle development. The general tendency was that nearly all species were present from the flowering stage onwards and that numbers declined when grain hardened. The predatory Hemiptera, *Orius* sp. and *Deraeocoris* sp., were recorded at all sampling sites.
Conclusion: Future research should be directed at establishing the relationship between the incidence of Hemiptera infestation and yield or quality loss of sorghum.

POSTER PRESENTATION

Water mite fauna in the Sakha Republic, Russia

Hiroshi Abe, Semenchenko Ksenia, Gennady Boeskorov

[1]Nihon University, Fujisawa, Kanagawa, Japan, [2]Institute of Biology and Soil Sciences, Vladivostok, Russian Federation, [3]Institute of Applied Ecology of the North Academy of Sciences of the Sakha Republic, Yakutsk, Russian Federation

A faunal survey of water mites was executed from 10 August 2006 to 27 August 2006 in Yakutsk and Tiksi, the north-eastern Siberia. During the survey four species (*Unionicola* (*Unionicola*) *gracilipalpis, Neumania* (*Neumania*) *vernalis, Arrenurus* (*Arrenurus*) *cf. cuspidifer, Midea orbiculata*) and three unidentified species (*Tiphys* sp., *Limnesia* sp., *Arrenurus* sp.) in Hydrachnellae and two species (*Porohalacarus alpinus*, *Porolohmannella violacea*) in Halacaridae were recorded from Yakutsk. Two species (*Tiphys* (*Tiphys*) *scaurus, Lebertia* (*Pilolebertia*) *porosa*) and two unidentified species (*Lebertia* sp*., Feltria* sp.) in Hydrachnellae were found in Tiksi. Among the water mites mentioned above, only one species, *Lebertia* (*Pilolebertia*) *porosa,* has been recorded from Yakutia, the other five species in Hydrachnellae and two species in Halacaridae were collected in Yakutia for the first time. All these species have a wide distribution in Eurasian continent and typical for the fauna in Europe.

POSTER PRESENTATION

The organosilicone, Break-Thru S240 and its effect on increased movement of a spray application into maize plant whorls and the efficacy of insecticides applied against stem borers in maize

Olivier Slabbert, Johnnie van den Berg, Dave Viljoen

North-West University, Potchefstroom, South Africa

Introduction: Chemical control of the maize stem borers *Busseola fusca* and *Chilo partellus* is often uneconomical or ineffective. Conventional insecticide applications often do not reach larvae inside whorl leaves. Thorough coverage of the target area is an important factor affecting the efficacy of insecticides. Organosilicones reduce the surface tension of water in spray solutions thus improving spreading of droplets on waxy, hydrophobic surfaces of the target plant's leaf surface. The aims of this study were to determine the effect of different dosages of the organosilicone, Break-Thru S240, on the depth of water movement into whorls of maize plants as well as the efficacy of different insecticides applied with the organosilicone Break-Thru S240.

Methods: In one experiment a colorant dye was added to indicate movement of the spray into plant whorls. In the other experiment insecticides were applied together with Break-Thru S240. All treatments were applied by using a CO_2-pressurised knapsack sprayer. Five plants of each replicate were sampled and dissected to determine the distance of movement of the spray application into plant whorls. The number of surviving larvae (*Chilo partellus*) on ten plants per replicate was counted to determine insecticide efficacy.

Results: The addition of Break-Thru S240 resulted in an increased distance of movement of water applications into plant whorls as well as an increase in insecticide efficacy.

Conclusion: This study provides information about the increased movement of organosilicones, water and insecticide applications on maize plants, which may lead to improved stem borer control measures.

POSTER PRESENTATION

Pr-lynx1, a modulator of nicotinic acetylcholine receptors in the insect

Young Moo Choo[1], Kwang Sik Lee[1], Bo Yeon Kim[1], Jianhong Li[2], Jong Gill Kim[3], Jae Heon Lee[1], Hung Dae Sohn[1], Byung Rae Jin[1]

[1]Dong-A University, Busan, Republic of Korea, [2]Huazhong Agricultural University, Wuhan, China, [3]National Institute of Agricultural Science and Technology, Suwon, Republic of Korea

Introduction: Insect nicotinic acetylcholine receptors (nAChRs) are targets for insecticides. Despite the importance of the nAChR as a major target for insecticide action, modulators of nAChRs in insects remain unidentified. Here we describe the cloning and identification of a nAChR modulator gene in an insect.

Results: A nAChR modulator gene was isolated by searching the firefly *Pyrocoelia rufa* cDNA library, and the gene itself encodes a protein 120 amino acids in length, named *Pr-lynx1*. *Pr-lynx1* shares all the features, including a cysteine-rich consensus motif and common gene structure, of the *Ly-6*/*neurotoxin* superfamily. The recombinant Pr-lynx1, which is expressed as a 12-kDa polypeptide in baculovirus-infected insect Sf9 cells, is normally present at the cell surface as a GPI-anchored protein. Northern and Western blot analyses revealed that Pr-lynx1 is expressed in various tissues, such as the ganglion, brain, mandibular muscle, proventriculus, leg muscle, and epidermis. This expression pattern is similar to the distribution of nAChRs as assayed by α3 nAChR immunoreactivity. Co-expression of Pr-lynx1 in *Xenopus* oocytes expressing α3β4 nAChRs results in an increase in acetylcholine-evoked macroscopic currents

Conclusion: Our results indicate a functional role of Pr-lynx1 as a protein modulator for nAChRs. This study on *Pr-lynx1* is the first report of a modulator of nAChRs in an insect species.

POSTER PRESENTATION

Biochemical characterization of venom from the endoparasitoid wasp *Pteromalus puparum* (Hymenoptera: Pteromalidae)

Jia-Ying Zhu, Gong-Yin Ye, Zhong Zhang, Cui Hu

Institute of Insect Sciences, College of Agriculture and Biotechnology, Zhejiang University, Hangzhou 310029, China

Introduction: *Pteromalus puparum* is a predominant pupal endoparasitoid of *Pieris rapae*, which has evolved a unique means to adapt to the hosts immune system, as there are no other parasitoid-associated factors other than venom are found in the female reproductive organ. The biochemical characters of its crude venom were preliminary investigated.

Methods: SDS-PAGE and two-dimensional (2-D) PAGE were used to explore the venom protein components. Cytotoxicity to hemocytes *in vitro* assay was performed to examine the effects of physical and chemical factors on the venom physiological functions. Different enzymatic methods were used for measuring the enzyme categories and its dynamic activity in the venom.

Results: SDS-PAGE profile revealed many bands of a broad of molecular weight range from 14.4 to higher than 116.0 kDa demonstrating the presence of numerous proteins in the venom. 2-D PAGE resulted in 56 evident protein spots with pI range from 4-7. With regard to the hemocytes cytotoxicity, the venom was sensitive to pH, temperature, host's larvae salivary secretion and mid-gut fluid incubation and some organic solution such as hexane, chloroform and methanol, while this was not the case for salt concentration (NaCl), proteinase K and the detergents such as SDS, Tween 20, Triton-X 100, NP 40 and CHAPS. Enzymatic assays indicated that acid phosphatase, alkaline phosphatase, phosphodiesterase, phospholipase, and esterase were present in the venom and their enzyme activities were time-course related to the parasitoid development.

POSTER PRESENTATION

Molecular cloning and characterization of a glycosyl hydrolase family 9 cellulase expressed throughout the digestive tract of the emma field cricket, Teleogryllus emma

Namjung Kim[2], Young Moo Choo[1], Kwang Sik Lee[1], Seong Jin Hong[2], Kwang Youl Seol[2], Yeon Ho Je[3], Hung Dae Sohn[1], Byung Rae Jin[1]

[1]Dong-A University, Busan, Republic of Korea, [2]National Institute of Agricultural Science and Technology, Suwon, Republic of Korea, [3]Seoul National University, Seoul, Republic of Korea

Introduction: A novel endogenous β-1,4-endoglucanase (EG) gene belonging to the glycosyl hydrolase family 9 (GHF 9) that is expressed throughout the digestive tract of the emma field cricket, *Teleogryllus emma*, was cloned and characterized.

Results: A novel EG gene, named *TeEG-I,* consists of eight exons encoding 453 amino acid residues and exists as a single copy in the *T. emma* genome. *TeEG-I* possesses all the features, including signature motifs and catalytic domains, of GHF 9 members, sharing high levels of identity with the termite, *Mastotermes darwiniensis* (64% protein sequence identity), and the cockroach, *Panesthia cribrata* (62%), GHF 9 cellulases. Recombinant TeEG-I, which is expressed as a 47-kDa polypeptide in baculovirus-infected insect Sf9 cells, showed an optimal pH and temperature of pH 5.0 and 40 ℃. The K_m and V_{max} values for digestion of carboxymethyl cellulose were 5.4 mg/ml and 3118.4 units/mg, respectively. Northern and Western blot analyses revealed that TeEG-I was expressed throughout the digestive tract, which correlated with the TeEG-I distribution and cellulase activity in the digestive tract as assayed by immunofluorescence staining and enzyme activity assay, respectively. These results indicate that TeEG-I is expressed throughout the entire digestive tract of *T. emma*, suggesting a functional role of endogenous TeEG-I in a sequential cellulose digestion process throughout the *T. emma* digestion tract.

Conclusion: Based on these results, we suggest that endogenous TeEG-I could be involved in sequential cellulose digestion throughout the *T. emma* digestive tract.

POSTER PRESENTATION

Selection of host plants for nest building by the Japanese foliage spider, *Cheiracanthium japonicum* (Araneae: Miturgidae)

Yutaka Hironaka, Hiroshi Abe

[1]Nihon University College of Bioresource Sciences, Fujisawa, Kanagawa, Japan, [2]Nihon University College of Bioresource Sciences, Fujisawa, Kanagawa, Japan

Introduction: The purpose of the present study is to elucidate the relationship between host plants and nest-types of *Cheiracanthium japonicum* in the developmental stages of the spider. The spider builds a nest mainly with a monocotyledonous plant leaf. Its nest forms vary not only according to the developmental stages of the spider but according to their use for molting, mating and breeding.

Materials and Methods: We examined the developmental stages of the spider and the plant species used to build a nest by the spider. The vegetation cover of the study area was fully investigated and the numbers of the nests and the host plant species were recorded. In addition, the leaf toughness and leaf width of each host plant were also recoded to examine physical factors relating to the spider's selection of host plant species.

Results and Discussion: As the developmental stages of the spider proceeded, the frequency of use of the two host plant species, *Miscanthus sinensis* and *Phragmites australis,* increased. Especially these two plants were typically used for breeding-nests. There was no significant relationship between the composition of the host plant species and that of the entire flora in the study area. Leaf toughness and leaf width of the host plants were correlated positively with the nest-type in the developmental stages. These results showed that *C. japonicum* recognizes the leaf toughness and leaf width and selects the preferable host plant according to the nest-types relating to the developmental stages.

POSTER PRESENTATION

Effect of the superparasitism and multiparasitism in the Biological Control of the "Pine Shoot Moth", Rhyacionia buoliana (Schiff.) (Lepidoptera: Tortricidae) in Chile.

Mar Ramos, Cecilia Ruiz, Dolly Lanfranco

Faculty of Forest Sciences, Universidad Austral de Chile, Valdivia, XIV region, Chile

Introduction: The superparasitism is a parasitoid strategy that supposes the presence of two or more larvae competing for the same host, resulting in the death of the less competitive larvae. This strategy takes place when the same host is attacked several times by the same female parasitoid species.

The multiparasitism or interespecífic superparasitism take place when the same host is attacked by two different species of female parasitoids.

Both strategies occur in the biological control of one of the pest species on the Chilean pine forest plantations, *Rhyacionia buoliana* (Schiff.) (Lepidoptera: Tortricidae).

The superparasitism produced by the introduced parasitoid *Orgilus obscurator* (Ness.) (Hymenoptera: Braconidae) and the multiparasitism given by a second parasitoid without specific determination yet, *Temelucha sp*. (Hymenoptera: Ichneumonidae), can be affecting the effectiveness of the biological control of this pest species.

Methods: A total of 268 larvae of *R. buoliana* were extracted of a field of the VIII region of South Chile and reared during four months under controlled conditions of laboratory. Every week, 10 larvae were dissected. The data obtained during the rearing were used in a model of population dynamics, to quantify the incidence of superparasitism and multiparasitism.

Results: The obtained results show a loss of effectiveness of the introduced parasitoid *O. obscurator* and a significant increase of larvae not parasitized, raising the population density of the pest species.

Conclusions: The competition resultant of the superparasitism and the multiparasitism between these two species is affecting the biological control of *R. buoliana* negatively.

POSTER PRESENTATION

Developing a predictive degree day model for field sand fly vector of visceral leishmaniasis in the Northwest of Iran

Mohammad Ali Oshaghi, Naseh Maleki, Ezat-aldin Javadian, Yavar Rassi, Zabiholah Zarei, Fatemeh Mohtarami

Tehran University of Medical Sciences, School of Public Health, Tehran, Islamic Republic of Iran

Introduction: Temperature plays a significant role in insect development where a rise in temperature accelerates the insect's metabolic rate, increases egg production and makes blood feeding more frequents. It also shortens and speeds up pathogen development within insects. Visceral leishmaniasis is one of the most important diseases which transmit by different sandfly species.

Methods: A phenological model was used to estimate number of generation, peak activity and temporal variability of the most important vector of VL, *Phlebotomus perfiliewi* in one of the main VL foci in northwest Iran. The development zero and the thermal requirements of *P.papatasi* were measured under laboratory conditions and were used as a model for *P.perfiliewi* under field condition.

Results: The complete life cycle (egg to egg) development of *P.papatasi* required 273 degree day (DD) and developmental zero (Dz) values were 12.99℃ for egg, 23.07℃ for larvae, and 21.23℃ for pupa. Field samplings of adult *P. perfiliewi* determined that the first adult population occurred in mid-to-end June. The highest population density was observed in early August, but that in early September the population density decreased rapidly, with the adult population disappearing completely in late September. Matching the population dynamics with the development data revealed that in Germi region, *P.perfiliewi* has only one generation per year.

Conclusion: This is the first phenological study about vectors of VL in Iran. The phenological data could be used in constructing effective control programs against the diseases and their vectors.

POSTER PRESENTATION

Life cycle traits of *Cheiracanthium lascivum* examined by a breeding experiment

Haruhiro Rokuta, Yutaka Hironaka, Hiroshi Abe

[1]Department of Animal Science and Resources, College of Bioresource Sciences, Nihon University, Fujisawa, Kanagawa, Japan, [2]Graduate School of Bioresouce Sciences, Nihon University, Fujisawa, Kanagawa, Japan, [3]Biological Laboratory, College of Bioresource Sciences, Nihon University, Fujisawa, Kanagawa, Japan

Up to date, detailed studies on the life cycle and the ecology of *Cheiracanthium lascivum* have been quite limited. The purpose of the present study is to elucidate the hatching period, disperse time, molting period, and mortality rate of the spiderlings, and to study the female's behavior from reproduction till death under the laboratory conditions. The reproduction occurred only once a year and the females' reproduction period was about a month long. The post-reproduction period was estimated to be less than a month long. The females didn't eat anything during their maternal care — like spiders of the family Salticidae, Antrodiaetidae, etc. Hatchings took place during about two weeks, and then the spiderlings molted into the second instar in the cocoon. The spiderlings dispersed seven days after their hatching. The intervals between instars correlated positively with the age development. The mortality rate was the highest in the second instar after dispersing.

POSTER PRESENTATION

Evaluation of some selective preparations for the control of the mushroom phorid fly, Megaselia halterata (Wood)

Fedai Erler[1], Ersin Polat[2], Halil Demir[2], Huseyin Cetin[3], Tugba Erdemir[1]

[1]Akdeniz University, Faculty of Agriculture, Department of Plant Protection, Antalya, Turkey,
[2]Akdeniz Universit, Faculty of Agriculture, Department of Horticulture, Antalya, Turkey,
[3]Akdeniz University, Faculty of Arts and Science, Department of Biology, Antalya, Turkey

Introduction: Over the last decade, cecidomyiid, sciarid and phorid flies have become one of most damaging pest groups of mushroom in the Antalya-Korkuteli district (southwestern Turkey) where about 45% of the total mushroom production and more than 50% of the total compost production of the country are produced.

Methods: Three commercial microbial preparations [a bacterial larvicide, *Bacillus thuringiensis* var. israelensis (*Bti* for short) - Gnatrol®; a granulavirus - Madex®; and an entomopathogenic nematode, *Steinernema feltiae* - Entonem®)] and a biologically derived insecticide, spinosad - Laser® were evaluated for the control of *Megaselia halterata* (Wood) (Diptera: Phoridae), the most common species in the district, by soil drench to sufficiently wet the top 10-cm soil surface layer where larvae are found. The effect of the test materials were evaluated by measuring larval damage (mean number of mushroom fruits damaged by the larvae per bag) and counting the emerging adults of the pest (mean number of emerging adults per bag) in each treatment.

Results: *Bti* and spinosad were found the most active materials, but had a short-term efficacy. Although *S. feltiae* was less active than *Bti* and spinosad, it had a long-lasting activity which lasted until the growing period was completed. The granulavirus (Madex) was found the least active preparation used in the study.

Conclusions: Our overall results suggest that *Bti*, spinosad and *S. feltiae* can be used as alternatives to conventional insecticides used in the control of mushroom phorid fly.

POSTER PRESENTATION

Spectral sensitivity in two winged forms of the black bean aphid

Thomas Döring, Sayako Arai, Jim Hardie

Imperial College London, Ascot, United Kingdom

Introduction: Although the visual sense is of considerable importance for host finding in herbivorous insects, only little is known about their colour vision. Therefore, electroretinogram measurements were conducted to measure spectral sensitivity of the compound eye in winged female gynoparae and virginoparae of *Aphis fabae*.

Methods: Light flashes (0.5 s), varied in wavelength (320 to 640 nm, 10 nm steps) and in light intensity were produced with a Xenon lamp and monochromatic and grey filters. The flashes were applied to the eye either after dark adaptation or after adaptation in yellow light, (5 animals per adaptation condition and per morph). The summed response from light sensitive cells was recorded with a tungsten electrode inserted into the eye, while an indifferent electrode rested in the abdomen. The amplified signal was displayed on a PC.
Results: The overall shape of the sensitivity curve was similar in gynoparae and virginoparae. Pooled data from both morphs revealed maximal spectral sensitivity at 550 nm after dark adaptation and at 530 nm after yellow adaptation. Sensitivity to blue light was significantly increased after yellow adaptation compared to dark adaptation. Sensitivity sharply decreased with increasing wavelengths >550 nm and was very low (<2.5%) in the red domain (640 nm).

Conclusions: The results suggest that *A. fabae* at least possesses a green receptor and possibly also a blue receptor, but that the presence of a red receptor is unlikely.

POSTER PRESENTATION

Life stage composition of growing cultures of the house dust mite, Dermatophagoides farinae

Swetha Poola, Larry Arlian, Marjorie Morgan

Wright State University, Dayton, OH, United States

Background: House dust mites are a major source of indoor allergens in homes worldwide. Commercially grown dust mites are used to make extracts for diagnostic testing and immunotherapy. The life stage composition and allergen content of mite populations in developing cultures used to make extracts is relatively undefined. The purpose of this study was to define the population growth rate, life stage profile and allergen content of growing cultures of *Dermatophagoides farinae*.

Methods: *Dermatophagoides farinae* was cultured and the mite and allergen characteristic of the culture determined at 2-week interval for up to 10 weeks.

Results: The mite population grew exponentially for the first 6 weeks and then remained relatively stable at 8 and 10 wks as the growth medium was depleted. Larvae were the most numerous developing life stage at all times but were particularly abundant during the early 4-6 week growth period. Among all life stages, adults (females and males) were the most abundant stages at all times and comprised the highest percentage of the population during weeks 8 and 10 when the population size had plateaued. Protonymphs were the least numerous life stage during the entire 10-week culture period and comprised <5% of all active life stages. Egg density in the cultures increased during weeks 2, 4, and 6 and peaked at week 8 and declined at week 10.

Conclusion: The life stage composition of a developing culture changes as the mite population increases in size and this may effect the allergen composition of the culture.

POSTER PRESENTATION

Field responses of *Halyomorpha halys* to methyl 2,4,6-decatrienoate

George Hamilton[1], Ashot Khrimian[2], Peter Shearer[3]

[1]Rutgers University, New Brunswick, NJ, United States, [2]USDA ARS, Beltville, MD, United States, [3]Rutgers University Agricultural Research and Extension Center, Bridgeton, NJ, United States

In the United States, *Halyomorpha halys* (Stål) (Hemiptera: Pentatomidae)is a polyphagous, introduced Asian pest that damages various trees, vegetables, and leguminous crops. In its native range, it is reported to be attracted to methyl (2*E*,4*E*,6*Z*)-decatrienoate, the aggregation pheromone of the brown-winged green bug, *Plautia stali*. In 2003 and 2004, we conducted studies to evaluate the attractiveness of this compound and its isomers, methyl (2*Z*,4*E*,6*Z*)-decatrienoate and methyl (2*E*,4*Z*,6*Z*)-decatrienoate, to late fall individuals. In 2005 and 2006, we conducted additional field trials in late fall to evaluate the attractiveness of traps baited with 0, 0.5, 2.5, 7.5 and 25 mg of methyl (2*E*,4*E*,6*Z*)-decatrienoate per trap and placed in different plant systems. We found that methyl (2*E*,4*E*,6*Z*)-decatrienoate and its isomers, as well as mixtures of geometric isomers, were attractive to *H. halys* males, females and nymphs. The data suggest that the presence of the *EEZ* but not *ZEZ* isomer is essential for attracting *H. halys* and other isomers do not appear to be antagonistic and may be needed for maximum attraction. We also found, regardless of plant system tested, that traps baited with high amounts of pheromone (7.5 and 25mg) caught significantly more individuals than traps baited with lesser amounts.

POSTER PRESENTATION

Age and reproduction in the parental burying beetle, *Nicrophorus orbicollis*

Stephen Trumbo

University of Connecticut-Waterbury, Connecticut, United States

Introduction: Three hypotheses have been proposed to explain enhanced reproductive performance with age: the restraint hypothesis (young individuals restrain current reproductive effort because a high level of current effort might put future reproductive opportunities at risk), the constraint hypothesis (young individuals are constrained because of a lack of skills or accumulated resources), and the selection hypothesis (there is more time for less fit individuals to be selected out of an older cohort). Burying beetles are a favorable group with which to examine these hypotheses because they have short but discrete reproductive/parental cycles during which they prepare a small vertebrate carcass as a food source for young.

Methods: Using a laboratory population of *Nicrophorus orbicollis*, we reduced adult mortality to zero, and equalized social experience during the pre-reproductive period across age groups, thereby eliminating consideration of the selection or constraint hypotheses. We then tested the restraint hypothesis by providing young (20-25 days) or old (52-58 days) single females with a breeding resource and later introducing a potentially infanticidal female (young or old).

Results: In Experiment 1, older parents were more likely to produce a brood and were faster to oviposit, and older intruders were more likely to take over a carcass. Age was not related to any measure of performance once a parent had a brood (probability of successful defense against infanticide, number and mass of larvae in original broods, number and mass of larvae in replacement broods by intruders). In a follow-up experiment using smaller carcasses (Experiment 2), age of the parent, again, was not related to successful defense of the brood, or to number and mass of larvae, suggesting that the high level of reproductive success of young females in Experiment 1 was not due to the large potential reward.

Conclusion: In *Nicrophorus orbicollis* the reproductive restraint observed in younger individuals appears to occur in a step-wise manner, inhibiting the initiation but not the continuance of reproductive attempts.

POSTER PRESENTATION

Colour learning in honeybees using a classical conditioning paradigm

Claudia Niggebrügge[1], Gérard Leboulle[1], Bernhard Komischke[1], Randolf Menzel[1], Natalie Hempel de Ibarra[2]

[1]Free University of Berlin, Berlin, Germany, [2]University of Exeter, Exeter, United Kingdom

Introduction: Bees learn colours quickly under free-flight conditions. Here we report about our success to train fixed bees to colours in a classical conditioning paradigm.

Methods: Harnessed bees with cut antennae were exposed during 10 conditioning trials to a sugar reward preceded and paired with a coloured stimulus. They learned to extend their proboscis (PER) towards the colour stimulus prior to reward and in unrewarded tests.

Results: After an absolute conditioning, accompanied by a response increase of 50-60%, bees learned the hue of the rewarded colour and showed broad colour generalisation. Differential conditioning resulted in different acquisition performances for rewarded and unrewarded stimuli, i.e. discrimination learning, only when colours were very dissimilar. Brightness contrast did not contribute to discrimination learning. Decline in responses in unrewarded trials after a training of either three or seven conditioning trials indicates that the conditioned PER is prone to extinction.

Conclusions: We conclude that colour learning occurred and memory was established within a few pairings of colour and sugar reward, similarly to free-flight conditions. We aim to implement this behavioural paradigm in the study of visual mechanisms in bees using electrophysiological and molecular-biological techniques.

POSTER PRESENTATION

Vertebrates that are victimized by an insect parasitoid: a remarkable host shift by the burying beetle, *Nicrophorus pustulatus*

Garrison Smith[2], Stephen Trumbo[1], Derek Sikes[3], Michelle Scott[4], Robert Smith[2]

[1]University of Connecticut-Waterbury, Waterbury, CT, United States, [2]University of Arizona, Tucson, AZ, United States, [3]University of Alaska Museum, Fairbanks, AK, United States, [4]University of New Hampshire, Durham, NH, United States

Introduction: Insects are well known to be parasitoids of other insects. An insect parasitoid of a vertebrate, however, is all but unknown. Recent work [Ecoscience (2000) vol. 7, 395-397] suggests that the burying beetle *Nicrophorus pustulatus* may have undergone a remarkable host shift, exploiting live reptile eggs rather than carrion as resources for breeding. We conducted behavioral and physiological experiments to test the hypothesis of a host shift and to formulate hypotheses on its origin.

Methods: From 1-5 snake or turtle eggs were provided to *N. pustulatus*, as well as to two congeners, *N. orbicollis* and *N. defodiens*, to measure the ability to produce offspring and to regulate brood size. In addition, *N. pustulatus* use of mouse carcasses vs. snake eggs was compared.

Results: Two congeners of *N. pustulatus*, *N. orbicollis* and *N. defodiens*, did not respond to snake eggs with typical breeding behavior. When *N. pustulatus* male-female pairs were presented with clutches of snake eggs the number of offspring but not the mean size of offspring varied with snake egg mass, indicating effective regulation of brood size. Turtle eggs were also utilized by *N. pustulatus*, but not as readily. *Nicrophorus pustulatus* presented with both snake eggs and a mouse carcass combined and exploited the two resources within the same nest (10 of 12 trials). Mouse carcasses and snake eggs were treated differently. Carcasses were moved, buried, and stripped of hair in a manner characteristic of burying beetles while snake eggs were not moved or buried. Females that discovered a mouse carcass also had a significantly greater juvenile hormone increase than did females discovering snake eggs. Some responses to the two resources, however, were similar. Female *N. pustulatus* oviposited rapidly in response to either a mouse carcass or snake eggs, and males elevated sex pheromone emission in response to either resource.

Conclusion: The efficient use of snake eggs, the ability to regulate brood size, and the different responses to snake eggs and to carrion suggest that *N. pustulatus* is well adapted to exploiting snake eggs for breeding. The use of eggs of vertebrates by *N. pustulatus* has potential implications for conservation of oviparous reptiles in North America.

POSTER PRESENTATION

Appearance, spreading, current status and risk assessment of invasive mosquito species of *Aedes albopictus* (Diptera, Culicidae) in Croatia

Enrih Merdić[1], Toni Žitko[2], Nediljko Landeka[3] and Sanja Merdić[1]

[1]Department of Biology, University of J.J. Strossmayer in Osijek, Croatia, [2]Health Public Institute of Split-Dalmatia county, Split, Croatia, [3]Health Public institute of Istria county, Pula, Croatia

Introduction: The invasive mosquito species of *Aedes albopictus* has been introduced in several European countries since 1975. In 2007 the species was recorded in Albania, Bosnia and Herzegovina, Croatia, Greece, France, Italy, the Netherlands, Serbia and Montenegro, Slovenia, Spain and Switzerland. It was proved that this species had the vector rule in Chicungunya virus transmission in Italy in 2007.

Methods: No European standard is currently available for vector surveillance methods, which influences the comparability of data between countries. Different surveillance methods currently used in Europe include ovitraps, carbon dioxide-baited CDC traps and larval surveys, we used them too.

Results: The first record of *Aedes albopictus* in Croatia was made in the capital city of Zagreb, in continental Croatia. The arrival is connected with companies dealing with the import of used tires. The following year, in 2005 the species appeared on the Adriatic coast: several sites on the Istria peninsula, and big cities of Zadar, Split and Dubrovnik, Findings of this species on the islands of Cres, Lošinj, Hvar and Vis, in 2007 (very attractive tourist destinations), prove that the spreading was done by yachts.

Conclusions: The risk assessment is dependent on four environmental conditions: winter temperature ≥0˚C; rainfall is at least 500mm; there is sufficient amount of summer rainfall and optimal summer temperatures (25˚C-30˚C). Local characteristics and microclimates should be considered for both establishment and abundance. The vector surveillance in Croatia must be conducted in those areas of high risk for establishment (Istria), because this species is known as high vector competence species.

POSTER PRESENTATION

Insect pests on urban greenery in Croatia

Aleksandar Mešić[1], Josip Barčić[2] and Jasminka Igrc Barčić[1]

[1]*Department for Agricultural Zoology, Faculty of Agriculture, University of Zagreb, Zagreb, Croatia,*
[2]*Department for Agricultural Engineering, Faculty of Agriculture, University of Zagreb, Zagreb, Croatia*

Introduction: Urban greenery in is attacked by different insects species. Large population of those pests usually provoke important damages on urban greenery and decrease their ecological, esthetical and other functions.

Methods: The pests of the most importance Croatia (*Aesculus hippocastanum*, *Platanus spp., Rosa spp., Acer spp., Buxus spp., Quercus spp.* and *Robinia pseudoacacia*) were researched in Zagreb and Sisak in period 2004-2007. The plant parts with symptoms of attack were evaluated in the laboratories where the pests were identified. The damages provoked by those insects were recorded and systematized.

Results: Damages on those plants were present each year. High populations of *Cameraria ohridella* were recorded each year on leaves of horse chestnuts and high populations of *Corythuca ciliata* and *Phyllonorycter platani* on plane trees. Aphids and some other insects attacked different species of roses and maple. Since 2005, total damages on leaves made by *Apethymus abdominalis* were recorded on many oaks. Small popultions of *Monarthoplpus buxi* ususaly attack *Buxus spp.*Two diffrent *Gracilariidae* species (*Phyllonorycter robiniella* and *Parectopa robiniella*) harms the black locust.

Conclusions: Each year high population of different insects provoke large damages on urban greenery. Such large populations must to be controlled by different insecticides.

POSTER PRESENTATION

Beauveria bassiana (Deuteromycotina) as a management agent for free-living ixodid ticks

Kenwyn Cradock[1], Glen Needham[2]

[1]Eastern New Mexico University, Portales, NM, United States, [2]The Ohio State University, Columbus, OH, United States

Introduction: Ticks, important disease vectors, spend much of their lives off-host. Various entomopathogenic fungi have shown potential as management agents under controlled laboratory conditions. Few studies have tested their effectiveness in the field. Unfed adult *Amblyomma americanum* were challenged with *Beauveria bassiana* GHA and placed in a field setting. The mortality of exposed ticks was compared with ticks not exposed to the fungus.

Methods: Unfed adult *Amblyomma americanum* were exposed to the entomopathogenic fungus *Beauveria bassiana* and placed in the field enclosed in BugDorm™ enclosures. Hobo data loggers were used to monitor environmental conditions both inside and outside the enclosures.

Results: Ticks exposed to the fungus experienced higher mortality than those in the control group ($p = 0.001$). The BugDorm™ enclosures did not have a biologically significant impact on environmental conditions, increased the recovery rate of study organisms, and successfully prevented unwanted organisms from removing ticks from the study.

Conclusions: *Beauveria bassiana* has potential as a useful component of tick management programs targeting off-host ixodid ticks such as *Amblyomma americanum*. It is recommended that for inclusion in a tick management program, the fungus be applied in the late evening when conditions suitable for fungal activity occur.

POSTER PRESENTATION

Physiological effects of infection with *Beauveria bassiana* (Deuteromycotina) in A*mblyomma americanum* (Ixodidae).

Kenwyn Cradock[1], Glen Needham[2]

[1]Eastern New Mexico University, Portales, NM, United States, [2]The Ohio State University, Columbus, OH, United States

Introduction: Fungal infection can result in altered behavior and physiology of infected arthropods. Although mortality may require an extended time of infection, changes in behavior due to altered physiology may still make microbial control agents effective. *Amblyomma americanum* were infected with *Beauveria bassiana* GHA to determine the effect of infection on water balance and survival relative to uninfected ticks.

Methods: Unfed adult *Amblyomma americanum* were exposed to *Beauveria bassiana*. All ticks were placed in desiccation chambers at 80%RH just below the critical equilibrium activity for the species. Change in weight was used to indicate water loss.

Results: Treated ticks survived an average of 7.2 ± 0.22 days. Control ticks survived 17.88 ± 0.73 days on average ($p = 0.01$; $df = 57$). At death, ticks exposed to the fungus had lost 25.2% ± 0.84 of their starting weight. Control ticks had lost 14.08% ± 0.85 of their starting weight (p 0.01; df = 96). Water loss was highest immediately following inoculation and then declined, although losses continued to be higher in exposed ticks.

Conclusions: This suggests that the penetration of the fungus causes sufficient damage to the cuticle to cause desiccation. Alternatively, infection may negatively impact the ticks' ability to rehydrate using water extracted from sub-saturated atmospheres, or infection increases the rate of spiracular opening resulting in increased water loss. Any or all of the impacts may cause alteration in behavior and reduce survival.

POSTER PRESENTATION

Intra- and interspecific bacterial diversity within the gut microbiota of fungus-growing termites (Macrotermitinae) from Kenya

Andreas Marten[1], Hamadi I. Boga[2], Janet Andert[2], Manfred Kaib[3], Andreas Brune[2], Roland Brandl[1]

[1]Department of Animal Ecology, University of Marburg, Marburg, Germany, [2]Max Planck Institute of Terrestrial Microbiology, Marburg, Germany, [3]Department of Animal Physiology, University of Bayreuth, Bayreuth, Germany

Termites are important decomposers in tropical ecosystem. The guts of termites harbour diverse communities of bacteria responsible for degradation of plant material. So far we have little knowledge about the variability of the gut microbiota with space as well as between closely related species.

Major workers from colonies of *Macrotermes michaelseni (*27 colonies*)*, *M. subhyalinus* (5) and *M. herus* (3) were sampled across Kenya. We constructed a clone library of the 16S rRNA gene for the gut microbiota of *M. michaelseni*. The clone library was dominated by Firmicutes (42%), Bacteroidetes (38%) and Proteobacteria (11%). Almost all clones were related to sequences isolated from guts of other termite species. Obviously the microbiota in the guts of *Macrotermes* are assemblages of bacteria specific to termites. Further, we calculated Morisita-Horn-similarity-indices and run a correspondence analysis (CA) based on t-RFLP profiles of the 16S rRNA gene to compare intra- and interspecific bacterial diversity. The CA shows no differentiation of the bacterial communities between the three termite species. Similarity-indices between communities within host species were similar to the similarity between hosts. Focussing on the similarity between colonies of *M. michaelseni* we found no consistent pattern of community composition in microbiota with space. High turnover between bacterial communities were found even between neighbouring colonies as well as low turnover between distant colonies (> 400km).

We conclude that on the limited level of taxonomic resolution of the t-RFLP method the bacterial communities of the gut within the Macrotermitinae show no species-specific differences and no spatial structure.

POSTER PRESENTATION

Foraging behaviour and reproductive strategy of *Callonychium chilense* (Apoidea: Andrenidae: Calliopsini) on *Eryngium paniculatum* (Umbrelliferae) in central Chile

Víctor Hugo Monzon[1], Luisa Ruz[2]

Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile[1]
Universidad Católica del Maule, Talca, Maule, Chile[2]

Callonychium chilense (Friese, 1906) is a solitary bee that belongs to the tribe Calliopsini, within which it belongs to the most phylogenetically derived genus. The species of *Callonychium* are mostly oligolectic. Behavioural observations of *C. chilense* were made at Cobquecura, a coastal area of central Chile, (36°08'00''S - 72°47'00''W) in January, in 1991 and 1992, before the invasion of *Bombus ruderatus*. The abiotic conditions were also evaluated. The study site was sandy with medium-sized vegetation of shrubs, herbs and grasses. *C. chilense* prefers *Eryngium paniculatum* for its daily foraging and mating activities which take place from 09:00 to 18:00 h. The females arrived first at the flowers to forage. They take a position at less than 45° to the stamens, grasp the anthers with their mandibles and extract the pollen with the forelegs, which is then transferred to the posterior legs. The males patrol the inflorescences and mate with the females while foraging, but use special strategies to grasp them necessitated by their smaller size. The mating peak occurred at 11:30 to12:30 h. Mating lasted for a maximum of 20 minutes, after which the couple fly together to a different plant far away. The abundance of females at the beginning of the reproductive period did not necessarily determine short matings. The males of *C. chilense* perform only one of the known mating strategies, like *C. coquimbense* also from Chile, but not three strategies as happens in *C. petuniae* from Brasil.

POSTER PRESENTATION

The influence of temperature and aphid host at development time and parasitoid size of *Aphidius colemani* Viereck and *Aphidius transcaspicus* Telenga (Hymenoptera: Aphidiidae)

Nikolaos Garantonakis, Dionyssios Lykouressis and Dionyssios Perdikis

Laboratory of Agricultural Zoology and Entomology, Agricultural University of Athens, Iera Odos 75, 11855 Athens, Greece.

Introduction: *Aphidius colemani* Viereck and *Aphidius transcaspicus* Telenga are koinobiont solitary oligophagous aphid parasitoids. The influence of temperature and aphid host on the development time and at the size of the parasitoids *A. colemani* and *A. transcaspicus* was studied. As aphid host, *Aphis gossypii* and *Myzus persicae* was used.

Methods: On an eggplant leaf 30 individuals of second instar of *M. persicae* or *A. gossypii* were placed using a fine paintbrush and left for 1 h to settle down. Then, a female parasitoid (*A. colemani* or *A. transcaspicus*) was released in each petri dish. After the first attack on an aphid, the dish was transferred in a growth cabinet at 15, 20, 25, 27,5 or 30 ^{o}C, 65±5% R.H. and 16L:8D photoperiod. The parasitoid was allowed to forage in the dish for 30 minutes. The development time and the size of the emerged parasitoids was estimated by body length and length of the right hind tibia.

Results: The development time was found to be longer in parasitoids which developed at 15^{o}C. Longer body size was found in parasitoids which developed at 15 ^{o}C having as host the aphid *M. persicae*.

Conclusions: Both factors temperature and aphid host were found to affect the development time and size of the progeny.

POSTER PRESENTATION

Predation rate of *Macrolophus pygmaeus* (Hemiptera: Miridae) on aphid prey species

Dionyssios Lykouressis, Dionyssios Perdikis and Ioannis Mandarakas

Laboratory of Agricultural Zoology and Entomology, Agricultural University of Athens, Iera Odos 75, 118 55 Athens, Greece

Introduction: The predation rate of the polyphagous predator *Macrolophus pygmaeus* was investigated on all instar nymphs of *Aphis gossypi* when offered alone and together with nymphs of the aphids *Myzus persicae* or *Macrosiphum euphorbiae*.

Methods: Equal (10 nymphs of each instar, 40 in total) or unequal numbers (18, 13, 7 and 2 nymphs from each of 1st, 2nd, 3rd and 4th instars of *A. gossypii* alone or together with 18, 11, 8 and 3 nymphs from each instar of *M. persicae* or 19, 11, 7 and 3 nymphs from each instar of *M. euphorbiae*) were used. The aphids were placed on an eggplant leaf in a plastic Petri dish. In each dish one unstarved 5th instar nymph of the predator was introduced. The dishes were kept in a growth cabinet at 25°C, and the predation rate was recorded 24h after the introduction of the predator.

Results: Predation rates on *A. gpossypii* were similar to those on *M. persicae* but higher than *M. euphorbiae*. When equal number of nymphs of each instar of *A. gossypii* were offered alone, predation rate was similar among the instars but preference was highest for the 2nd and the 3rd instar and biomass consumption when feeding on the 3rd and 4th instars.

Conclusions: If other conditions have equal effect, *M. pygmaeus* can be more efficient in reducing *A. gossypii* numbers than *M. persicae* and *M. euphorbiae* on plants such as eggplants, where all these aphid species can occur.

POSTER PRESENTATION

Area-wide suppression of *Ceritidis capitata* and *Bactrocera dorsalis* in Kamuela Hawaii.

Roger I. Vargas[1], Eric B. Jang[1], Donald O. McInnis[1], Ernest B. Harris[1], Grant T. McQuate[1], Renato C. Bautista[3], Ronald F. L. Mau[2], Lyle Wong[3], Lester M. Klungness[1]

[1]USDA-ARS Pacific Basin Agric. Research Center, Hilo, Hawaii, United States, [2]University of Hawaii, College of Tropical Agric. & Human Resources, Honolulu, Hawaii, United States, [3]Hawaii Dept. of Agric., Honolulu, Hawaii, United States

Introduction: USDA Agricultural Research Service initiated a fruit fly suppression program for the State of Hawaii in 1999. The first suppression demonstration site was implemented in Kamuela, Hawaii in 2000.

Methods: *B. dorsalis* was suppressed with sanitation, bait spray, male annihilation using methyl eugenol, augmentation of parasitism using *F. arisanus* and the release of male sterile *B. dorsalis* in a 48 km^2 area containing urban, rural and agricultural zones. *C. capitata* females were suppressed with sanitation, bait spray and Biolure® traps.

Results: *C. capitata*: suppression techniques produced an 88.3% reduction in flies/trap/day (f/t/d) while fruit infestation declined 88.3%. *B. dorsalis*: reduction in fly captures over the 6 yrs of the treatments averaged 44.9%, but maximum reduction was 99.5% (comparing highest and lowest periods). Fruit infestation declined 60.67% over the period of bait spray application, and parasitoid augmentation, but began to increase after those treatments were suspended. The reduction in *B. dorsalis* from peak to lowest infestation was 98.1%. The 48 km^2 treatment area was compared to 3 control sites at 1, 9 and 10 km from Kamuela, over 4.64 years. The *C. Capitata* f/t/d at Kamuela was 94.7% lower and *B. dorsalis* f/t/d at Kamuela was 81.2% lower than the mean of the three control sites.

Conclusions: Combining suppression techniques in an area wide approach was effective in reducing tephritid flies below the economic threshold for crop production.

POSTER PRESENTATION

Genetic speciation of *Lutzomyia pseudolongipalpis* and *Lutzomyia longipalpis* s. l (species C2) and its vector biological- ecological implications in Venezuela.

Jazzmin Arrivillaga, Patricia Salerno

Universidad Simon Bolivar, Caracas,DF/SArtenejas, Venezuela

Reproductive isolation of two monophyletics vector species of visceral Leishmaniasis, *L. pseudolongipalpis* and *L. longipalpis* (species C2), from a sympatric area in Northwestern Venezuela was studied by mean of cross-mating experiments (homo and hetero-specific no selective cross) and isozymes diagnostic markers profile (AK and HK). The mating whereas the reciprocal mating (*L. pseudolongipalpis* females x *L. longipalpis* males) produced viable progeny (F1) and the detection of enzymatic markers codominance in the hybrids. However, fecundity and fertility were lower in comparison with co-specific mating. Asymmetric gene exchange between species (*L. pseudolongipalpis* males x *L. longipalpis* females= no eggs) and the lower production of offspring could suggest the occurrence of prezygotic and post zygotic isolation mechanisms, with re-forcing by sexual preference. In addition, the lack of natural hybrid would suggest a stronger isolation that keeps apart these species in nature than in experimental colonies.

Project S1 DID-USB to J. Arrivillaga

POSTER PRESENTATION

Oral trophallaxis between workers in the carpenter ant *Camponotus mus.*

Sarah Knish[1], Roxana Josens[2]

[1]Department of Biology, Georgia Institute of Technology, Atlanta, GA, United States, [2]Fac. of Exact and Natural Science, University of Buenos Aires, Buenos Aires, Argentina

Introduction: Sugar baits are commonly used in pest-control programs for nectivorous ants. Bait success depends on high food distribution among colony members, through mouth-to-mouth food exchanges (trophallaxis). The sugar concentration affects individual behaviours and sharing within the nest. This work analyses trophallaxis between pairs of workers as a function of the sugar concentration.

Methods: Pairs of foraging ants were isolated under controlled conditions. After an acclimation period, one ant (donor) was allowed to feed on a sucrose solution (from 10 to 60%w/w) and then returned to her partner (recipient). Time, volume, and rate were recorded for ingestion and trophallaxis.

Results: Time of both ingestion and trophallaxis, as well as volumes ingested and transferred, increased with increasing sucrose concentrations; however, 40%w/w tended to present the great proportion of load transferred. Both intake and transfer rates decreased with the concentration, but the ingestion rate decrease is more pronounced beyond 40%w/w. There is a direct relationship between intake rate and transfer rate, partially due to the effect of the viscosity on fluid dynamics (slower flow for more viscous solutions); however, this relationship is maintained within solutions of similar concentration.

Conclusions: Solution concentration affects both feeding and trophallaxis behaviours. Moreover, the correlations between crop load as well as intake rate with the transfer rate – independent of solution viscosity and the worker size – suggest that other factors must also affect transfer dynamics. Ants that fed faster demonstrated faster transfer rates. The same threshold involved in feeding responsiveness probably also affects solution-sharing behaviour.

This study was supported by CONICET PIP 5986.

POSTER PRESENTATION

Chemical ecology of the bedbug *Cimex lectularius* (Cimicidae)

Emma Weeks[1], Mike Birkett[1], Mary Cameron[2], James Logan[1], John Pickett[1]

[1]Rothamsted Research, Harpenden, Hertfordshire, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

Introduction: The common bedbug, *Cimex lectularius* (Hemiptera: Cimicidae) is a major public health problem due to the biting nuisance caused when it feeds upon the blood of human hosts. Although little is known about bedbug behaviour, they are gregarious, and aggregate in response to semiochemicals. These semiochemicals could be exploited to develop monitoring tools to detect bedbug infestations. However, in order to study the response of bedbugs to semiochemicals, a suitable bioassay needs to be developed. A still air Petri-dish olfactometer, previously used to study aphid behaviour will be adapted for use with bedbugs.

Methods: A preliminary trial was completed using a volatile stimulus from intraspecific faecal material, a known aggregation signal for other Hemiptera. The stimulus was introduced into the arena, the behavioural response was observed, and the time spent active was recorded for 15 minutes per replicate. Twenty randomised replicates of experiments (stimulus present) and controls (no stimulus present), to test for bias in experimental design, were completed.

Results: Results of experiments indicated that the presence of faecal volatiles in the olfactometer caused a significant increase in time spent active when compared with controls.

Conclusions: The Petri-dish olfactometer is suitable to study the response of bedbugs to semiochemicals. The presence of faecal volatiles in the arena caused a three fold increase in bedbug activity. Further work with air entrainments, gas chromatography, electrophysiology and mass spectrometry will enable the identification of behaviourally active compounds which could be used to develop tools for bedbug monitoring and control.

POSTER PRESENTATION

Chemical ecology of the bedbug Cimex lectularius (Cimicidae).

Emma Weeks[1], Mike Birkett[1], Mary Cameron[2], James Logan[1], John Pickett[1]

[1]Rothamsted Research, Harpenden, Hertfordshire, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

Results: Results of experiments indicated that the presence of faecal volatiles in the olfactometer caused a significant increase in time spent active when compared with controls.

Conclusions: The Petri-dish olfactometer is suitable to study the response of bedbugs to semiochemicals. The presence of faecal volatiles in the arena caused a three fold increase in bedbug activity. Further work with air entrainments, gas chromatography, electrophysiology and mass spectrometry will enable the identification of behaviourally active compounds which could be used to develop tools for bedbug monitoring and control.

POSTER PRESENTATION

DNA in support of tachinid taxonomy: matching the females with males in ancient described genera of Chilean Dexiini (Diptera: Tachinidae)

Antonio Rodríguez, Jose Núñez

Universidad Austral de Chile, Valdivia, XIV Region, Chile

Introduction: Tachinid taxonomy is plagued with incorrect identifications, in part due to early (s.XIX and beginning of s.XX) descriptions of species based mostly on combinations of characters too variable to be used in a classification. Furthermore, the descriptions based in more stable genitalic characters are mainly based in males, with absence of paratypes for many of the species described. The latter is the case of the related Patagonian Dexiini *Psecacera* Bigot, 1880; *Dasyuromyia* Bigot, 1885 and *Morphodexia* Townsend, 1931, after the revision of them by J. M. Aldrich in 1934.

Methods: In the course of a biodiversity inventory in the Chilean temperate valdivian forest, nine species belonging to the three genera were identified based in genitalic and first-instar larvae characters. For each of the individuals collected, total genomic DNA was extracted and COI was amplified and sequenced. A phylogeny of haplotypes was inferred to cluster together the males and females of the same species.

Results: The haplotype phylogeny shows strongly supported clades as assessed by bootstrapping, clustering together both sexes of the same species. Furthermore, allow to redescribe the species based in female genitalia and first-instar larvae, adding diagnostic characters to the description.

Conclusion: The used methodology allows us to test hypothesis about the conspecifity of the sexes inferred by the resemblance of the exemplars, and provides a powerful tool for the descriptive taxonomy.

POSTER PRESENTATION

Biology of a hyperparasitoid that disrupts biological control in New Zealand

Tara J. Murray[1,2], Sarah Mansfield[3]

[1]Scion (New Zealand Forest Research Institute Ltd), Rotorua, New Zealand, [2]Lincoln University, BioProtection & Ecology Division, Lincoln, New Zealand, [3]Faculty of Agriculture, Food & Natural Resources, University of Sydney, Sydney, Australia

The Australian hyperparasitoid *Baeoanusia albifunicle* (Hymenoptera: Encyrtidae) was discovered in the Central North Island of New Zealand in 2001. It's only known host in New Zealand is the biological control agent *Enoggera nassaui* (Hymenoptera: Pteromalidae), introduced in 1987 against the Eucalypt feeding pest *Paropsis charybdis* (Coleoptera: Chrysomelidae). In Australia, hyperparasitoids exert considerable regulatory pressure on the parasitoids of Eucalypt defoliators. There was concern therefore that in New Zealand *B. albifunicle* could disrupt the control of *P. charybdis* through its attack of *E. nassaui*. There was also some hope however that another recently arrived Pteromalid parasitoid of *P. charybdis* eggs, *Neopolycystus insectifurax*, could compensate for any decline in *E. nassaui*, as it was thought to be immune to hyperparasitoid attack.

We conducted laboratory research to determine basic biological characteristics of the hyperparasitoid to reveal its potential impact on *E. nassaui*. Data indicate that females are long lived and highly fecund with a high rate of parasitism success in the laboratory. Obligatory hyperparasitoid status was confirmed as *B. albifunicle* only developed successfully when oviposition followed parasitism by *E. nassaui*. *P. charybdis* eggs parasitised by *N. insectifurax* were occasionally accepted for oviposition but did not support hyperparasitoid development. Prior to this study it was thought that *E. nassaui* may find some refuge from the hyperparasitoid in southern New Zealand. We discuss the implications of field survey results which have indicated that *E. nassaui* has become more difficult to find and that *B. albifunicle* is now also established in the South Island.

POSTER PRESENTATION

A long-term experimental study of saproxylic beetle succession in Tasmanian *Eucalyptus obliqua* logs

Simon Grove, Dick Bashford, Marie Yee

Forestry Tasmania, Hobart, Tasmania, Australia

Concern over the conservation implications of declining availability of large logs in Tasmania's wet eucalypt production forests led to a long-term experiment examining succession of saproxylic (dead wood-dependent) beetles. This paper reports on the first sampling cycle, which spanned the first five years following the felling of six mature-aged and six regrowth-aged *Eucalyptus obliqua* trees growing in a multi-aged forest. These were felled over three seasons from May 1999 to February 2000. Five emergence traps were progressively fitted to each resultant log at roughly three-monthly intervals; and each was left in place for about three years. At total of 11546 individuals and 311 species of saproxylic beetles were sampled from the twelve logs. Twenty species made up 75% of the individuals, while 66 were represented by singletons. Seasonal patterns in abundance, species richness and assemblage composition were evident. The sampling cycle coincided with an initial pulse in abundance; the time-lag between felling and trap fitting did not noticeably influence this pattern. However, the height of the summer abundance peaks was weakly related to the date of felling. Different species showed different patterns in their annual peaks over this period. Obligately saproxylic species were more numerous than facultatively saproxylic species; species able to disperse by flight were much more numerous than crawlers; predators comprised the most abundant feeding guild; and there were roughly equal numbers of litter/surface dwelling and log interior-dwelling species. The lower collecting bottles tended to preferentially sample 'crawlers' and the upper collecting bottles 'fliers'. This paper documents the findings from merely the first sampling cycle of many that will be undertaken as the logs decay over coming decades or centuries. It provides a baseline assessment of the fauna, and gives the context for future studies, including those assessing relationships of this fauna with log size.

POSTER PRESENTATION

The effectiveness of wildlife habitat strips in maintaining mature forest carabid beetle assemblages

Simon Grove[1], Belinda Yaxley[3], Robert Taylor[2]

[1]Forestry Tasmania, Hobart, Tasmania, Australia, [2]Dept of Environment and Climate Change, Dubbo, NSW, Australia, [3]University of Tasmania, Hobart, Tasmania, Australia

A long-term research project was established in wet eucalypt forest at Tarraleah in Tasmania's central highlands, to assess the effectiveness of wildlife habitat strips (WHS) in maintaining the fauna of intact mature native forest. The present study examined carabid beetles sampled by means of pitfall traps. Samples were collected at multiple locations at one control site and two treatment sites, firstly before harvesting and then again five to six years after harvesting and regeneration and the establishment of WHS. Areas that had been logged showed decreases in abundance of carabid beetles, but great increases in species richness as pioneer or open-country species colonised. Assemblages in the control site remained essentially unchanged. Assemblages in the WHS areas remained little changed overall compared to their pre-harvest condition, but some sampling locations showed some degree of perturbation, though not always in a way comparable to the logged areas. It seems that for carabid beetles at least, WHS are largely fulfilling one of their functions of maintaining the fauna of mature native forest in a production forest landscape dominated by younger forest age-classes. Further monitoring will be required in coming decades to assess the long-term viability of WHS as a conservation strategy for these and other species of mature native forest. For instance, it is not yet apparent whether WHS can act as sources for recolonisation of surrounding regenerating forest as it matures, nor whether they can maintain their structural and functional integrity over time.

POSTER PRESENTATION

Seasonal occurrence of oriental beetle, Exomala orientalis (Coleoptera: Scarabaeidae) in Korean golf courses

Dong Woon Lee[1], Ho Yul Choo[2], Sang Myeong Lee[3], Jae Ho Kim[4], and Jong Chang Shin[5]

[1]Department of Applied Biology, Kyungpook National University, Sangju, Gyeongguk, Korea, [2]Department of Applied Biology and Environmental Sciences, Institute of Agricultural and Life Sciences, Gyeongsang National University, Jinju, Gyeongnam, Korea, [3]Southern Forest Research Center, Korea Forest Research Institute, Jinju, Gyeongnam, Korea. [4]Gimpo Seaside Country Club, Gimpo, Gyeonggii, Korea, [5]Dongrae Benest Golf Club, Gemjung, Busan, Korea.

Introduction: Oriental beetle, *Exomala*(=Blitopertha) *orientalis* is serious insect pest of turfgrasses in golf courses in Korea. Although adults of these beetles are active at night, their activity is questionable in the daytime. Therefore, monitoring of this beetle is difficult in golf courses. This study was conducted using pheromone trap to clarify seasonal occurrence of oriental beetle in Korean golf courses.

Methods: Seasonal occurrence of oriental beetle was surveyed at Gimpo Seaside Golf Club in Gimpo, Anyang Benest Golf Club in Gunpo, Gapyeong Benest Golf Club in Gapyeong, Gyeonggii province and Dongrae Benest Golf Club in Gumjung, Busan using oriental beetle sex pheromone from late May to late August. In addition, daily activity was surveyed every 2 hours on 20 June 2007 in Dongrae Benest Golf Club using pheromone trap. Soil sample was made every month with standard hole cutter from April to September in fairway and rough of Dongrae Benest Golf Club.

Results: The number of oriental beetles to pheromone trap was different depending on golf courses and holes. High numbers of oriental beetles were captured from Anyang Benest Golf Club and Dong Benest Golf Club, but none from Gapyeong Benest Golf Club. Oriental beetle was attracted to the pheromone traps from early June to middle August. The peak time was late June in Dongrae Benest Golf Club and Anyang Benest Golf Club. Oriental beetle was highly captured in pheromone trap from 20:00 to 22:00. Overwintered 3rd instar of oriental beetle pupated in May and Ist instar larva was observed at Dongrae Benest Golf Club in June. 2nd and 3rd instars were observed in July.

Conclusions: Oriental beetle adult occurred from early June to middle August and peak time was late June in Korean Golf courses. Adult was highly captured in pheromone trap from 20:00 to 22:00.

POSTER PRESENTATION

Molecular characterizations of a novel P450 gene encoding CYP6CE1 overexpressed in Phosphine and Dichlovos resistant strains of *Liposcelis bostrychophila* Badonnel (Psocoptera: Liposcelididae)

Hong-Bo Jiang, Jin-Jun Wang, Pei-An Tang, Yong-Qiang Xu, Feng-Ming An

Southwest University, Chongqing, China

Introduction: In China, *Liposcelis bostrychophila* Badonnel (Psocoptera: Liposcelididae) is a dominant species in stored products and the resistance to PH_3 and other insecticide has been a severe problem. In order to reveal whether P450 enzymes were involved in the resistance to PH_3 and DDVP or not, a novel P450 gene encoding CYP6CE1 was isolated. And the mRNA expression levels in different strains were determined.

Methods: The degenerate primers derived from the conserved domain of CYP6 family: 5'-CGGARACNHYNMGNAARTAYCC-3' and 5'-CGGGNCCNKCNCCRAANGG-3' were used to amplify the P450 fragments. The 5'-RACE and 3'-RACE were applied to obtain the full-length cDNA. Searching of similar sequences was performed using BlastP on the NCBI website. Deduced protein sequence was analyzed by the ProtParam program and a phylogenetic tree was constructed by DNAMAN. The mRNA expression levels were determined by Real-time PCR using the $\Delta\Delta CT$ method and the data was statistical analyzed.

Results: The complete CYP6CE1 (GenBank accession number, EF421245) cDNA sequence are comprised of 2025 bp with an open reading frame of 1581 bp encoding 527 amino acid residues, 215 bp 5' untranslation regions and 226 bp 3' untranslation regions, respectively. Putative cytochrome P450 CYP6CE1 is highly similar to several insect CYP6s that are responsible for increased detoxification to pyrethroid insecticides. The mRNA levels in DDVP- and PH_3-resistant strains were 1.74 and 1.41 folds higher than susceptible strain, respectively.

Conclusions: The results implied that overexpression of cytochrome P450 probably contributed to the resistance to PH_3 and DDVP in psocids.

POSTER PRESENTATION

Establishment of new insect cultured cell lines and insect cell bank in NIAS

Shigeo Imanishi

National Institute of Agobiological Sciences, Tsukuba, Ibaraki, Japan

Introduction: Cultural technique is not adequately established for all kind of insect species and their tissues. However, cell lines derived from Lepidoptera, Coleoptera, Hemiptera, and Diptera can be tool for analyzing molecular biological phenomena.

Methods: Materials for the primary culture are derived from the tissues of embryo, ovary, testis and fatty body of these species' insects. MX medium is being registered in the USA'Patent. Primary culture was done for approximately three months by exchanging half medium on every two weeks under 25C temperature. The established cell lines were registered at NIAS Genebank.

Results: MX30, including 30% volume of FBS in the MX medium, could accelerate a migration and multiplication of the cells from testis tissues of *Bombyx mori*, and could shorten the primary culture period in several months. I established the *Plautia stali* cells derived from embryo, of *Anomala cuprea* cells from fatty body, of *Agrius convolvuli* cells from fatty body, of *Bombyx mandarina* cells from fatty body, of *Bombyx mori* cells from fatty body, ovary, and embryo and of *Culicoides oxystoma* cells from embryo. One cell line is being used as a large scale culture *in vitro*. The other cell lines are confirmed that *Bombyx* cell line can keep *Wolbachia*, some *Bombyx* cell lines maintain a certain kind of plant disease viruses, and one cell line reacts typically to insect hormone.

Conclusions: These cell lines are promoting the development of insect molecular research. Cell lines registered as "active collection" can be distributed under BIOLOGICAL MATERIAL TRANSFER AGREEMENT (MTA).

POSTER PRESENTATION

Life history strategies of the armored Rambutan scale insect, *Aulacaspis alisiana* (Hemiptera: Diaspididae) on the Japanese silver tree in Fukuoka, Japan

Charles Midega, Keiji Takasu

Kyushu University, Fukuoka, Japan

Introduction: *Aulacaspis alisiana* is a pest species host-specific to the Japanese silver tree. We studied its life history strategies at Ino and Nakakubara forests in Fukuoka Japan.

Methods: Fecundity was determined by counting the number of crawlers that emerged from female scales twice a week for three weeks from twenty trees at both sites. Generation time was determined by weekly observing *A. alisiana* at the initial crawler stages on randomly selected leaves until adults emerged. Physical characteristics of the trees such as height, branch, leaf position and predator abundance were recorded and infestation rates by the pest assessed for any relationships. Impact of natural enemies was determined by natural enemy exclusion procedures using nets and insect trap adhesive.

Results: Each *A. alisiana* female produced an average of 55.8 eggs at Ino and 67.4 eggs at Nakakubara. The generation time ranged from 64 to 76 days, and the generations were overlapped. The potential natural enemy guild in both forests comprised mainly ants, spiders and beetles (coccinelids), with an average of 28.6 and 19.8 individuals per tree at Ino and Nakakubara respectively. Disappearance of *A. alisiana* nymphs was significantly higher on control than on exclusion branches at both sites (Ino: Exclusion 15.1%, control 26.1%. Nakakubara: Exclusion 11.5%, control 21.0%). Infestation rates of *A. alisiana* were not influenced by physical characteristics of trees and natural enemy presence or absence.

Conclusion: *A. alisiana* has three overlapping generations in Fukuoka with relatively high female fecundity and moderate natural mortality.

POSTER PRESENTATION

Good-bye Scydmaenidae: fully resolved phylogeny of the Staphylinine Group, or why the ant-like stone beetles should become Staphylinidae *sensu latissimo* (Coleoptera)

Vasily Grebennikov[1], Alfred Newton[2]

[1]Entomology Research Laboratory, Ontario Plant Laboratories, Canadian Food Inspection Agency, K.W. Neatby Bldg., 960 Carling Avenue, Ottawa, Ontario K1A 0C6, Canada, [2]Zoology Department, Field Museum of Natural History, 1400 South Lake Shore Drive, Chicago, Illinois 60605, United States

Ant-like stone beetles (Coleoptera: Scydmaenidae) include more than 4850 described species in about 90 genera maintained as a separate cosmopolitan family since 1815. Recent authors have hypothesised that Scydmaenidae might be rooted deep inside rove-beetles (Staphylinidae). To test this hypothesis we analysed 206 parsimoniously informative larval and adult morphological characters scored for 38 taxa: Leiodidae (1 terminal), Agyrtidae (1), Silphidae (3), Scydmaenidae (6), Omaliinae (1), Tachyporinae (1), Piestinae (1), Apateticinae (1), Trigonurinae (1), Oxyporinae (1), Megalopsidiinae (1), Solieriinae (1; larva unknown), Leptotyphlinae (3), Steninae (2), Euaesthetinae (4), Pseudopsinae (3), Paederinae (3) and Staphylininae (4).

Twelve analyses utilised three datasets (larval, adult and combined) each treated under four sets of assumptions (successively weighted/unweighted and multistate characters ordered/unordered). Strict consensus topologies from the shortest trees in all 12 analyses consistently placed Scydmaenidae as sister to (Steninae + Euaesthetinae) in a monophyletic Staphylinine Group (with or without Oxyporinae). The single fully resolved and most consistently supported topology maintains a monophyletic Staphylinine Group consisting of Oxyporinae + (Megalopsidiinae + ("Scydmaenidae" + (Steninae + Euaesthetinae)) + (Leptotyphlinae + (Pseudopsinae + (Paederinae + Staphylininae))))); Solierius lacks larval data and is ambiguously placed within the Group.

Preliminary analyses of 18S rDNA data for 93 members of Staphylinoidea under parsimony, neighbour-joining and Bayesian approaches were inconclusive, and largely conflicting with the morphological results.

Our results strongly suggest that ant-like stone beetles do not form an independent family, but are morphologically modified members of Staphylinidae and, consequently, should be treated as a 32nd subfamily within the megadiverse Staphylinidae sensu latissimo.

POSTER PRESENTATION

Beetle-Bits 101: Imaging Staphyliniformia & Scarabaeiformia for the Beetle Tree of Life project

Margaret Thayer, José-Cristian Martínez

Field Museum of Natural History, Chicago, Illinois, United States

Introduction: The Staphyliniformia TWiG (Taxonomic Working Group) of the multi-investigator, multi-institutional project BToL (Assembling the Beetle Tree of Life) is producing digital images of whole-body habitus and structural features of both adults and larvae of 32 exemplar taxa belonging to the series Staphyliniformia (Hydrophiloidea, sensu lato, plus Staphylinoidea) and 16 taxa of Scarabaeiformia. The images consist of 66 standard views selected by all participants in the project to document for each taxon the states of approximately 600 morphological characters of adults and larvae. These data will be combined with extensive DNA sequence data to perform phylogenetic analyses of the entire order Coleoptera.

Methods: We use primarily a Microptics ML Macro XLT digital imaging system incorporating a Canon EOS 1D Mark II camera. Some images of smaller specimens require using a compound microscope (Leitz Dialux 20 with a Spot Insight Color digital camera) or a scanning electron microscope (LEO EVO 60®). Most final images are composites of a series of up to 26 individual images taken in multiple focal planes, combined using either CombineZM (public domain) or Auto-Montage (©Syncroscopy) software. Imaging specimens ca. 1 to 35 mm long and parts thereof presents a variety of logistical challenges, our solutions to some of which we present here.

POSTER PRESENTATION

Managing Bt-resistance development in maize: Are stem borer populations in refugia still susceptible?

Johnnie Van den Berg, Marlene Kruger

North-West University, Potchefstroom, South Africa

Introduction: Genetically modified (Bt) maize is used for control of *Busseola fusca* (Lepidoptera: Noctuidae) and *Chilo partellus* (Lepidoptera: Crambidae) in South Africa. Resistance of this species to Bt maize has recently been reported in South Africa. The high dose/refuge strategy for resistance management is prescribed is South Africa. The aim of this study was to investigate whether *B. fusca* populations in "refugia" were still susceptible to Bt maize.

Methods: *B. fusca* larvae were collected from the resistant population and on conventional maize at several sites. Larvae were reared on Bt- or conventional maize until moths appeared. Eggs were collected from these rearing colonies and, after hatching, neonate larvae were inoculated onto conventional and Bt maize plants. Larval survival and mass were determined until the pupal stage was reached.

Results: When larvae originating from susceptible colonies were put on Bt plants 100% mortality was observed within 12 days while normal development occurred on conventional maize. Larvae collected from the reportedly resistant population survived on Bt and susceptible plants, all be it at a lower percentage. Larvae originating from the "refugia" associated with the resistant stem borer population survived on Bt maize up to the pupal stage but at low levels.

Conclusion: Stem borer populations in conventional maize refugia in the area where resistant populations have been reported is less susceptible to Bt than populations from conventional maize in other areas.

POSTER PRESENTATION

Morphological studies of *Cissococcus fulleri* (Hemiptera: Coccidae), a unique gall-inducing soft scale insect in South Africa, and evidence of a closely related new species

Ian Millar[1], Penny Gullan[2], Chris Hodgson[3]

[1]ARC Plant Protection Research Institute, Pretoria, South Africa, [2]University of California, Davis, United States, [3]The National Museum of Wales, Cardiff, United Kingdom

Cissococcus fulleri Cockerell is an unusual South African scale insect species that induces galls on species of *Rhoicissus* (Vitaceae). It was described by Cockerell in 1902, and *Cissococcus* has remained a monotypic genus ever since. It has very unusual morphology and its familial placement has been uncertain. Cockerell considered *Cissococcus* to belong to the Eriococcidae when he described it. However, Hodgson believed it was a soft scale (Coccidae), in his overview of world Coccidae genera, and the present studies of male and crawler morphology support the view that *Cissococcus* is a soft scale, although it is the only known member of this family to induce complex coverings or enclosed galls.

Studies on the adult female stage by Hodgson in 1994 revealed the existence of a separate "form" which differed morphologically from *C. fulleri*, and which could represent an undescribed species. Observations on recently-collected samples of *Cissococcus* show that two different types of galls are induced by *Cissococcus*; and the available material indicates that each of the two morphological "forms" lives inside its own characteristically-shaped gall. So far, samples of the "typical form", representing *C. fulleri*, have been found on *Rhoicissus tridentata*, whereas the "non-typical form" occurs on *R. digitata*. Our samples show that the geographical ranges of the two morphological "forms" of *Cissococcus* overlap but molecular data from each of the two different "forms" strongly support the hypothesis that they are separate species.

POSTER PRESENTATION

Developmental changes in cholorplast of three cecidomyiid galls indicated by confocal imagery

Meng-Yuan Huang[1], Yung-Ta Chang[1], Man-Miao Yang[2], Chi-Ming Yang[3]

[1]Department of Life science, National Taiwan Normal University, Taipei, Taiwan, [2]Department of Entomology, National Chung-Hsing University, Taichung, Taiwan, [3]Research Center for Biodiversity, Academia Sinica, Taipei, Taiwan

Introduction: Multiple changes in response to gall inducers have been found in host plant tissues. While much attention has been focused on the morphology and anatomy of insects or their induced galls, relatively little work has been done on the chloroplast of galls and its photosynthesis. Therefore, the aim of this research was to test a hypothesis that leaf-derived cecidomyiid galls alter the distribution of chloroplast.

Methods: Confocal laser-scanning microscopy was applied to investigate the distribution of chloroplast in three cecidomyiid galls derived from *Machilus thunbergii* and *Litsea acuminata* leaves.

Results: Stronger characteristics of chloroplasts are found in host leaves than in leaf-derived galls in terms of number, size, and fluorenscence intensity for all the types of gall tested. While the three characteristics of chloroplasts are homogeneously throughout the tissues of all host leaves, in contrast, these features in all gall tissues gradually decrease from outside toward the larval chamber direction. In other words, the deeper center the gall tissue is, the less the number, the smaller the size and the weaker the fluorescence intensity will be found.

Conclusions: The results indicate that different species of herbivorous insect dramatically alter the photosynthetic characteristics of chloroplast in their host leaves. The galls are life time deficient in some biophysical and biochemical characteristics of chloroplasts which are normally found in host leaves.

POSTER PRESENTATION

Phylogenetic patterns of brachyptery in the cicada Tribe Tettigomyiini (Hemiptera: Cicadidae) in the Eastern Cape.

Benjamin Price, Terence Bellingan, Martin Villet, Nigel Barker

Rhodes University, Grahamstown, South Africa

The Tettigomyiini is endemic to Africa, having diversified predominantly within East and South Africa and particularly within the Eastern Cape. The tribe currently consists of nine genera, of which six have not been reviewed since description (1904 – 1980). In addition, the phenomenon of female brachyptery (rudimentary wings rendering the organism flightless) occurs in some species within the tribe. This female-only brachyptery may be a result of two factors: 1) obligate inheritance from a recent common ancestor; 2) recurrent adaptation through brachyptery in stable habitats, allowing the partition of greater resources to egg production. A phylogenetic study of the tribe was conducted using two mitochondrial genes (CO1 & 16S) from sixteen species, representing six of the seven genera to test the monophyly of the described genera with respect to the brachypterous trait. Furthermore the phylogenetic estimation was related to the biogeography of the tribe and patterns of diversification within the Eastern Cape. It was found that the monophyly of *Paectira*, *Stagea* and *Stagira* was well supported whereas the genera *Xosopsaltria*, *Bavea* and *Tettigomyia* formed a paraphyletic group. Brachyptery was demonstrated to have no particular orientation within the tree, and to occur independently in *Xosopsaltria, Tettigomyia* and *Stagira*. This result suggests that brachyptery evolved more than once in association with savanna grassland, possibly as a result of decreasing habitat heterogeneity. It is suggested that the generic taxonomy of the Tettigomyiini be reviewed.

POSTER PRESENTATION

Effects of neo-nicotinoid insecticides on feeding behaviour of *Myzus persicae* (Homoptera: Aphididae) with EPGs

M.K. Kang, M.J. Seo, E.J. Kang, H.B. Seok, D.H. Lee, H.J. Lee, Y.M. Yu, Y.N. Youn

Chungnam National University, Daejon, Republic of Korea

The green peach aphid, *Myzus persicae* is a pest which has been found on more than hundreds of host plants in over 40 plant families all over the world. *M. persicae* causes wilting and reducing growth rate of plant and it's honeydew causes sooty mold at plant. It is difficult to control with contact insecticides because aphids often positioned under the leaves and less volatilization under 20℃. For these reasons, systemic insecticides are much effective at cool temperatures. Neo-nicotinoid insecticide class is one of the new insecticides. Three neonicotinoid insecticides were used, imidacloprid, thiamethoxam and dinotefuran. After 1 hour of feeding behaviour recording, each insecticide were treated by 1/5, 1, and 5 fold of recommended concentration by manufacturer. EPGs were recorded for 7 hours and recorded aphids were regularly checked feeding or not. In order to compare with feeding behaviour and inflow concentration of insecticide, HPLC analyze was used. Total time could not suggest specific data, but result showed that high concentration showed a long non-penetration and a short feeding pattern compare with lower concentration. Also, different feeding time in same concentration categories was shown. It might due to different traits of each insecticide. Each insecticide and each concentration was seemed to similar feeding behaviour, but inflow concentrations were considered, each insecticide may have different characteristic. Specifically, inflow concentration of imidacloprid was drastically lower than other insecticides but strong anti-feeding or repellent phenomenon was showed.

POSTER PRESENTATION

Control methods for agricultural insect pests in Japan during the Edo period (17th - 19th century)

Taro Adati, Takuya Kawase

Department of International Agricultural Development, Faculty of International Agriculture and Food Studies, Tokyo University of Agriculture, Sakuragaoka 1-1-1, Setagaya-ku, Tokyo 156-8502, Japan

The control of agricultural insect pests was economically important in Japan in the Edo period as it is today, and there are many descriptions of old methods of pest control. Some of those control methods, including use of plant-derived insecticides and insect repellents, are both biorational and environmentally friendly from the viewpoint of modern entomology. Here, we review three remarkable pest control methodologies described during the Edo period, and reassess their effects on pests in light of the latest knowledge in entomology and pest management science:

Pouring oil into rice paddies: To control leaf- and plant-hoppers, farmers poured oil on the water surface of rice paddies. Rice plants were submerged by a bamboo stick so that hoppers drop on the surface of water and are smothered because the oil chokes their spiracles. The oils were both of animal and plant origin, but whale oil was used primarily after the remarkable insecticidal effect of whale oil was discovered.

Plant-derived insecticides and insect repellents: More than twenty plant species were claimed to be effective against insect pests if the plants were under-ploughed or their extracts were poured into the paddy water. Among those plants, about ten species have not yet been analyzed for their active components.

Bonfires: During the Edo period, Japanese farmers knew that bonfires could attract and kill insect pests. The latest knowledge suggests that temporary lighting causes behavioural suppression for nocturnal insect pests, thus disrupting their reproduction.

POSTER PRESENTATION

Differences in gene expression level of endogenous cellulase in young xylophagus cockroaches and termites

Keisuke Shimada, Kiyoto Maekawa

University of Toyama, Toyama, Japan

Introduction: Xylophagy is an important trait for the evolution of sociality in termites and cockroaches. Recent phylogenetic studies strongly suggest that the xylophagous and subsocial cockroach genus *Cryptocercus* is a sister group to termites. There are many similarities, including symbiotic protozoa and long-lasting biparental care which includes parental feeding. Sociality in *Cryptocercus* and termites thus seems to have a common origin. However, the blaberid genus *Salganea* (Panesthiinae) is also xylophagous, with biparental subsociality that includes parental feeding; their social structure, parental behavior, and ecology are convergent with those of *Cryptocercus*. The xylophagous blaberid *Panesthia angustipennis* (Panesthiinae), however, has a gregarious social structure, without parental care. Because the cellulose based diet of these taxa may be difficult for young nymphs to process, wood-digestion abilities of first instars may vary with social structure in these cockroaches and termites.

Methods: We compared the wood-digesting ability of first-instar nymphs among four xylophagous and three non-xylophagous species by analyses of endogenous cellulase gene expression using real-time quantitative PCR.

Results: The results showed that first-instar nymphal expression levels are strikingly low in relation to adults in biparental species (termites: *Zootermopsis nevadensis*, cockroaches: *Cryptocercus punctulatus*, *Salganea esakii*), expression levels in gregarious *Panesthia angustipennis* are quite high. In non-xylophagous, gregarious cockroaches (*Periplaneta fuliginosa*, *Elliptorhina* sp., *Blattella germanica*), first-instar nymphal expression levels are low, but higher than those of biparental species.

Conclusions: These results suggest that there is a clear correlation between first-instar nymphal wood-digesting ability and social structure in xylophagous cockroaches and termites.

POSTER PRESENTATION

Species composition and population dynamics of spider mites on Kudzu vine, *Pueraria lobata* (Fabaceae)

Tetsuo Gotoh

Ibaraki University, Ami, Ibaraki 300-0393, Japan

Introduction: Identification of spider mites based on morphological characters is often difficult because differences can be subtle. Therefore, I developed a method based on the enzymes, esterase and phosphoglucomutase (PGM), to tell apart the 13 known *Tetranychus* species in Japan [Gotoh et al. (2007) Appl. Entomol. Zool. 42: 579-585 and 685-692]. Using this method, I describe the composition and population dynamics of the tetranychid mites on Kudzu vine.

Methods: At two sites a ground area of 10 x 10 m was subdivided into 100 1 x 1 m plots each. Kudzu vine leaves are composed of three leaflets, one of these was sampled from each plot at 10-day intervals from April to November during the three successive years. All adult female mites sampled were placed individually onto leaf discs of common bean (*Phaseolus vulgaris*) and allowed to lay eggs for three days (for using morphological study), and then females were used for electrophoresis.

Results: Five *Tetranychus* species were sampled on Kudzu vine: *Tetranychus puerariсola, T. ludeni, T. parakanzawai, T. kanzawai* and *T. piercei*. Most abundant in each of the three years was *T. puerariсola* (76-97% of mites). Populations peaked in June and/or September-October. Most colonies (defined as areas surrounded by silky spider-mite threads) consisted of only one species, but some (10%) had two or three species.

Conclusions: Isozyme analysis proved a useful tool to elucidate population development of the five Japanese *Tetranychus* species on Kudzu vine.

POSTER PRESENTATION

Phylogenetics and biogeography of the Australian Colletidae

Pelin Kayaalp, Michael Schwarz

Flinders University, Adelaide, South Australia, Australia

Introduction: Colletid bees are most prevalent in the southern hemisphere, in particular in Australia and South America. Preliminary results looking at the patterns and timings of biogeographical events will be presented, with emphasis on diversification of the Australian colletids.

Methods: One mitochondrial (CO1), and two nuclear genes, (EF1α and LW Rhodopsin) are used to analyse phylogenetic relationships among the southern hemisphere colletids via Bayesian and maximum parsimony methods, and r8s and DIVA are used to examine biogeographical scenarios and divergence times within Australia.

Results: Previous work by Eduardo Almeida has suggested a sister-group relationship between the Australian subfamily Euryglossinae and the southern African Scrapterinae, and the mainly Australian Hylaeinae with the South American Xeromelissinae. Molecular analyses of the Australian Hylaeinae and Euryglossinae infer times and patterns of radiation of the Australian components of these groups and divergence times from the non-Australian groups.

Conclusion: The richness of the Hylaeinae and Euryglossinae in Australia, and the restriction of Euryglossines to Australia, is probably due to both recency of origin and to the abundance and diversity of Myrtaceae. Because these two bee groups are short-tongued they are easily able to access the nectar in the shallow cups presented by the Myrtaceae. This may be indicative of two clades that have undergone a recent radiation with the rise of Myrtaceae in Australia. While earlier studies suggested that the dominance of colletid bees in Australia may reflect retention of an ancient Gondwana bee fauna, our results suggest a more recent explanation for this abundance and diversity.

POSTER PRESENTATION

Biotic communities in *Protea infructescences*: Examples of mutualism, commensalism and antagonism

Francois Roets[1], Michael Wingfield[1], Brenda Wingfield[1], Léanne Dreyer[2]

[1]Forestry and Agricultural Biotechnology Institute (FABI) University of Pretoria, Gouteng Province, South Africa, [2]Department of Botany and Zoology, Stellenbosch University, Western Cape Province, South Africa

Introduction: The flowers of the African endemic plant genus *Protea* mature into infructescences that remain on the plants for several years. During this period, they are colonized by numerous arthropods and fungi. We investigated the interactions between these organisms focusing on the ophiostomatoid fungi (*Ophiostoma* and *Gondwanamyces*) and their associated arthropods.

Materials and methods: *Protea*-fungus interactions were investigated using fungal competition studies. Mite-fungus interactions were assessed using food preference studies, microscopy, molecular methods and direct isolations. Mite-arthropod interactions were assessed using scanning and light microscopy.

Results: The ophiostomatoid fungi from *Protea* are saprophytic and dominate fungal communities in infructescences. They appear to exclude fungal decomposers that break down the internal tissues of infructescences, leading to premature release and consequent predation of the seeds. *Protea*-associated *Ophiostoma* serve as a food source for various mites. E.g., when *Trichouropoda* mites were fed these fungi, they had significantly higher reproductive rates that when their diet was composed of other fungi. Mites were shown to disperse ophiostomatoid spores between infructescences. These mutualistic interactions resulted in evolutionary adaptations in both the mites (specialized spore-carrying structures) and the fungi (sticky spore-drop for attachment to arthropods). Long-distance dispersal of the mites and the ophiostomatoid fungal spores that they carry was shown to be achieved through phoresy on beetles (e.g. *Genuchus hottentottus*) that feed on *Protea* seeds.

Conclusions: The interactions between biotic communities within *Protea* infructescences are complex and they include examples of mutualism, commensalism and antagonism. *Protea* infructescences clearly represent mini-ecosystems including various trophic levels and feeding guilds.

POSTER PRESENTATION

Mapping and distribution modeling of individual flea species (Siphonaptera) and flea's species diversity in the Negev Desert

Georgy Shenbrot, Boris Krasnov, Sergey Burdelov

Mitrani Department of Desert Ecology, Jacob Blaustein Institutes for Desert Research, Ben-Gurion University of the Negev, Midreshet Ben-Gurion, Israel

Introduction: Detailed knowledge on distribution and abundances of blood-sucking ectoparasites is essential for understanding processes in the natural foci of zoonotic diseases. However, such a data are scarce and irregularly distributed spatially. Distribution modeling is increasingly in use for evaluation of distribution patterns of free-living organisms but rarely used for ectoparasites whose distribution depend on hosts and abiotic environment.

Methods: Rodents and fleas were randomly sampled in the area of 9,200 sq km of the north-central part of the Negev Desert with sampling intensity of one sampling point per 100 sq. km. For each rodent species and for each flea species within each host rodent species we composed distribution model based on environmental (climate, topography, soil and vegetation) and presence/absence and abundance data using MAXENT and step-wise multiple regression analysis. Individual species models were projected into the geographic space and presented as the maps of distribution and abundances. Maps of individual species were overlaid to get the map of species diversity.

Results: Distributional models were constructed for 18 rodent host species and 12 flea species. Based on these models, we compiled the maps of distribution and abundances for each flea species and integral maps of general abundance and species diversity of fleas.

Conclusions: Modeling of ectoparasite distribution can be used as a powerful tool for estimation of areas of high epidemiological risk.

POSTER PRESENTATION

Malaria vector control and insecticide resistance

Maureen Coetzee[3], Richard Hunt[2], Lizette Koekemoer[1], Basil Brooke[1]

[1]Vector Control Reference Unit, National Institute for Communicable Diseases, School of Pathology, Division of Microbiology, University of the Witwatersrand, Johannesburg, South Africa, [2]School of Animal, Plant & Environmental Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]NRF Chair in Medical Entomology & Vector Control, University of the Witwatersrand, Johannesburg, South Africa

Introduction: Effective malaria vector control interventions have been available for over 60 years but are seldom applied efficiently or appropriately. Research across Africa has shown that the vectors are not homogeneous, they adapt to different environments in various ways and respond differently to insecticidal pressure. Control programmes must be tailored to address the specific needs of each situation and to do this, entomological surveys are required. We present data from three African countries where vector control is being implemented and discuss the problems faced by these programmes.

Methods: Mosquito surveys were carried out in Sudan, Ghana and South Africa. Specimens were identified by PCR, examined for parasite infectivity, assessed for susceptibility to insecticides approved for vector control by WHO and where applicable, processed for the *kdr* mutation.

Results: Sudan: *Anopheles arabiensis* was 1% parasite positive, resistant to pyrethroids, DDT and organophosphates and susceptible to carbamates. The West African *kdr* mutation was found at a high frequency and did not correlated with the bioassay data.

Ghana: *Anopheles gambiae* 'S' form was 5% parasite positive, susceptible to organophosphates and resistant to pyrethroids, carbamates and DDT. *An. funestus* was 2% parasite positive, susceptible to pyrethroids and organophosphates but resistant to carbamates and DDT. The West African *kdr* mutation was found at low frequencies in *An. gambiae*.

South Africa: *An. funestus* was 5% parasite positive, susceptible to DDT and organophosphates, and resistant to pyrethroids and carbamates. *An. arabiensis* was resistant to DDT but susceptible to pyrethroids.

Discussion: All three localities are using indoor residual house spraying (IRS) for vector control. South Africa implements a mosaic resistance management strategy using DDT and pyrethroids. Ghana is using organophosphates in an integrated vector management (IVM) programme. Sudan uses a carbamate for IRS as well as ITNs. Each programme has tailored its strategy in the light of the above results.

POSTER PRESENTATION

The possible mechanisms of Spinosad resistance in *Bactrocera dorsalis*

Ju-Chun Hsu[1], Guo-Cih Lin[1], Chin-Gi Huang[2], Hai-Tung Feng[1]

[1]*Taiwan Agricultural Chemicals and Toxic Substances Research Institute, Taichung, Taiwan,* [2]*Department of Entomology, Taipei, Taiwan*

Introduction: The oriental fruit fly (*Bactrocera dorsalis*), disturbed throughout Southeast Asia and the Pacific, is a major pest in orchard crops and one of the most prominent quarantine pests in the world. Currently, spinosad is considered an effective insecticide for control of various fruit flies, however, the oriental fruit fly could be highly resistant to spinosad after successive selections. The purpose of this study is to find out the possible mechanisms evolved in spinosad resistance of *B. dorsalis*.

Methods: Bioassays were carried out by using synergists, S,S,S-tributyl phosphorotrithioate (DEF), piperonyl butoxide (PBO) and diethyl maleate (DEM) with spinosad in spinosad-resistant and susceptible lines. The activities of metabolic enzymes including esterases (ESTs), glutathione-S-transferase (GSTs), and mixed function oxidases (MFOs) were assayed and compared between these two lines. Finally, to elucidate the possible target site alteration, the susceptibilities to other neurotoxic insecticides, fipronil and imidacloprid, were assayed and compared between the two lines.

Results: DEF showed significant synergistic effect toward spinosad in susceptible flies. In resistant flies, the synergism was not conclusive because the highest dose of spinosad (100 mg/mL) in use only caused less than 10% mortality. The resistant line exhibited a slightly higher ESTs activity than in susceptible flies and appeared to be cross-resistant to imidacloprid but not to fipronil.

Conclusions: In *B. dorsalis,* both esterases and imidacloprid-related nicotinic acetylcholine receptors might have mild influences in the resistance to spinosad. The major resistance mechanism of spinosad, probably altered target site, needs to be ascertained in the future.

POSTER PRESENTATION

Initial assessment of *Trichogrammatoidea lutea* (Hymentopera: Trichogrammatidae) as a biological control agent of codling moth (*Cydia pomonella*, Lepidoptera: Tortricidae) in apple and pear orchards under sterile insect release (SIR)

Nadine Wahner, Matthew F. Addison, Alicia Timm

University of Stellenbosch, Stellenbosch, WC, South Africa

Codling moth, *Cydia pomonella*, is the major pest of apples and pears in the Western Cape, South Africa. *Trichogrammatoidea lutea* (Hymentopera: Trichogrammatidae) is an indigenous egg parasitoid of False Codling Moth as well as Codling Moth that has previously been found to have considerable parasitism potential.

For secure identification of *Trichogrammatoidea lutea* and its distinction from the morphologically similar local species *T. cryptophlebiae* (an indigenous False Codling Moth parasitoid on citrus) the ITS 2 sequences of both species have been determined and species specific primers have been developed. The efficacy and population sustainability of released *T. lutea* were investigated in several field studies. Trials took place in apple and pear orchards that formed part of an area-wide sterile Codling Moth release program. Inoculative, as well as inundative releases were carried out within blocks of up to 1 ha. The square grid of up to 36 monitoring trees per block allowed spatial distribution analysis, as well as population density estimation throughout the season. Toxicity studies, concerning some of the most often sprayed pesticides in the Western Cape elucidated the potential effects of chemical sprays in orchards on released parasitoids. Life table studies of *T. lutea* gave an indication of how population cycling and reproduction in the field is influenced by the ambient temperatures.

According to the results of above studies, *T. lutea* shows potential for broad-scale releases against Codling Moth, within a broader integrated pest management program.

POSTER PRESENTATION

Seasonal abundance of fleas on stray dogs and cats in Taipei, Taiwan

Chin-Gi Huang, Mauricio E. Alarcón, Wen-Jer Wu

National Taiwan University, Taipei, Taiwan

Introduction: Flea is the most abundant and problem-causing ectoparasite of cats and dogs especially in stray animals. Although the pet owner can treat fleas at home, fleas always infect and attack animals from outdoor. Surveying flea from stray animals may help us more clearly in control programs.

Methods: From March 2006 to February 2008, we surveyed fleas monthly from stray dogs and cats collected in different administrative division of Taipei city. Animals were checked for 10 minutes using flea comb. Fleas were examined and identified under microscope.

Results: In last two years, fleas were detected on 519 (44.4%) out of the 1169 dogs (976) and cats (193) surveyed. A total of 5490 fleas was sampled and only one species, *Ctenocephalides felis* (Bouché), was found. *Ctenocephalides canis* (Curtis) was not found in our survey. The male to female cat flea ratio is 1:2.9. In spite of seasonal fluctuation in flea prevalence, the trend line of flea index in current survey was lower than that of in 1990. There were 2 peaks of the flea index in the year. In addition, we found that 14.4% (792/5490) of flea midgut were infected with trophozoites of a gregarine (Apicomplexa).

Conclusions: Only one flea species *Ctenocephalides felis* (Bouché) was found in dogs and cats in Taipei City, and there are 2 peaks of flea prevalence.

POSTER PRESENTATION

Damage evaluation of the olive insect pest *Rhynchites cribripennis* (Coleoptera: Attelabidae)

Dionyssios Perdikis[1], Nikolaos Garantonakis[1], Antonios Paraskevopoulos[2], Dionyssios Lykouressis[1], Athanassios Giatropoulos[1]

[1]Laboratory of Agricultural Zoology and Entomology, Agricultural University of Athens, Athens, Greece, [2]Directorate of Rural Development, Trifylia, Kyparissia, Greece

Introduction: *Rhynchites cribripennis* (Desbr.) has a wide distribution in the Mediterranean region and has been reported to cause significant yield losses on olive orchards.

Methods: The damage potential of this pest was investigated in an olive groove of var. "Koroneiki" in the area of Kyparissia, near Kalamata, western Greece, in 2007. Shoots with fruits were enclosed in mouslin cages (25cm diameter and 70cm length) along with adult weevils at the end of the flowering period (May 22, 2007). In each cage 2 or 4 adults introduced and cages without any weevil were used as controls. All the treatments were situated on shoots developed from a single main twig. In each cage the number of olives on the shoots, the dropped olives and the feeding holes on olive fruits were recorded on June 18, August 4 and September 4.

Results: The total percentage of the dropped fruits was highest (53%) in the cages with the high pest density (i.e. 4 adults) followed by that observed in the cages of the low pest density (i.e. 2 adults) (37%) whereas in the controls it was 16%. The damage severity (feeding holes) on the fruits was proved to depend on the time and the pest density, being significantly higher at the highest pest density.

Conclusions: These results indicate that *R. cribripennis* can create significant damage mainly due to the drop of a high percentage of the fruits. In addition, the damage level on the fruits that are harvested can be serious.

POSTER PRESENTATION

Fumigant toxicity of essential oil from *Tanacetum balsamita* L. against *Callosobruchus maculatus* (F.) (Coleoptera:Bruchidae)

Nouraddin Shayesteh[1], Farzaneh Attighi[2], Shahram Aramide[2], Adel Khashaveh[2]

[1]Islamic Azad University, Branch of Mahabad, mahabad/West Azarbaijan,, [2]Urmia University, Urmia/West Azarbaijan, Islamic Republic of Iran

Introduction: The fumigant activity of essential oil vapors distilled from *Tanacetum balsamita* (Compositae) was tested against adults and eggs of *Callosobruchus maculatus*. *T. balsamita* growing wild in North Iran. (Elburz area, near Kandovan Tonel).

Methods: A sufficient quantity of *T. balsamita*, extracted by water steam method, was obtained from Golbahar Co. Urmia, Iran. Experiments were carried out at 27±2°C and 65±5% R.H. adopting a factorial design. Essential oil at 5.12, 7.23, 10.19, 14.36 and 20.24 µl/lair for adults and 5.3, 8.5, 10.8, 13.7 and 17.4 µl/lair for eggs of *C. maculatus* was used. For each concentration four replications that each replication including thirty one day old adult**s** or thirty 0-24 h eggs. Different concentrations of the essential oil applied on filter paper, were kept in 0.5-liter glass jars with the insects kept in the fumigation jars. Mortality was recorded after 24, 48 and 72 h. The percent mortality was corrected using Abbot's formula (1925). Data were subjected to Duncan's multiple range test.

Results: Increasing the essential oil concentrations increased the effects of essential oil on mortality of adults and eggs of *C. maculatus*. The percentage mortality after 72 h, received to 75.20 % of adults at higher dose (20.24 µl/lair), and 49.06 % of eggs at higher dose (17.4 µl/lair) of T. *balsamita.* The LC50 values after 72 h, on adults and eggs of *C. maculatus*, were observed (1.96 µl/lair), and (21.29 µl/lair), respectively.

Conclusions: Fumigant activity of this essential oil was more effective against adults of *C. maculatus*.

POSTER PRESENTATION

Displacement among exotic herbivorous insects on introduced tall goldenrods

Yoshino Ando[1], Shunsuke Utsumi[1], Timothy Craig[2], Takayuki Ohgushi[1]

[1]Center for Ecological Research, Kyoto University, Otsu, Shiga, Japan, [2]Department of Biology, University of Minnesota, Duluth, Minnesoa, United States

Introduction: The exotic aphid *Uroleucon nigrotuberculatum* was one of most dominant species on introduced tall goldenrods at a common field in Japan. Recently, the aphid markedly decreased on tall goldenrods at the field. In the same year, the exotic lacebug *Corythucha marmorata* was frequently observed on tall goldenrods. We hypothesized that lacebug colonization decreased the formally established aphid.

Methods: We set lacebug-attacked plants and lacebug-free plants in greenhouse and then inoculated the aphids. Behavior, colonization density, and survival of the aphid were compared between treatment plants. Distribution and density of both exotic herbivorous insects on tall goldenrods were recorded in five local areas. Also, we took census of their natural enemies found on tall goldenrods.

Results: There was no direct interference between these herbivorous species. Also, the aphid density and survival did not differ between treatments. However, the alate type of the aphids repelled leaves attacked by the lacebug, suggesting that the lacebug affected host selection of alate aphids through plants. On the other hand, predators decreased survival of the aphid. There were many kinds of predators of the aphids in the field, although there were few predators of the lacebug. The lacebugs occurred on most of tall goldenrods at high density, while the aphids locally distributed on tall goldenrods in a small colony size.

Conclusion: Not only colonization of the exotic lacebugs but also predation decreased the exotic aphids on tall goldenrods.

POSTER PRESENTATION

Nestmate discrimination in the harvester termite *Hodotermes mossambicus* in the Namib desert

Felix Hager[1], Joh Henschel[2], Wolfgang H. Kirchner[1]

[1]Ruhr-University, Department of Biology and Biotechnology, Bochum, Germany, [2]Gobabeb Training and Research Centre, Gobabeb, Namibia, [3]University of the Witwatersrand, School of Animal, Plant and Environmental Sciences, Johannesburg, South Africa

Nestmate and kin recognition in social insects have been studied extensively in social hymenopterans. Much less is known about nestmate recognition and the underlying mechanisms in termites. In the African harvester termite *Hodotermes mossambicus* it has been recently shown in laboratory experiments that they are able to discriminate between nestmates and non-nestmates using cues provided by the colony-specific composition of the intestinal flora. Aim of the present study was to investigate nestmate discrimination in this species under natural conditions.

Termites were collected close to the Gobabeb Training and Research Centre in the Namib-Naukluft Park, Namibia. Pairs of nestmate or non-nestmate termites taken from colonies which were up to 2 km apart were observed in Plexiglass arenas. All interactions were recorded for two minutes.

Discrimination between nestmates and non-nestmates was significant at all distances between nests tested ranging from 13m to 2100m. The probability of agonistic behaviour was significantly distance dependent. The reactions to non-nestmates were generally much more aggressive than in previous laboratory studies.

The results confirm previous laboratory studies on nestmate discrimination in *Hodotermes mossambicus.*

POSTER PRESENTATION

A peripheral circadian clock controls the cuticle deposition rhythm in *Drosophila melanogaster*.

Chihiro Ito[1], Shin Goto[1], Sakiko Shiga[1], Kenji Tomioka[2], Hideharu Numata[1]

[1]Graduate School of Science, Osaka City University, Osaka, Japan, [2]Graduate School of Natural Science and Technology, Okayama University, Okayama, Japan

Introduction: Insect endocuticle thickens after adult emergence by daily alternating deposition of two chitin layers with different orientation. Although the cuticle deposition rhythm is known to be controlled by a circadian clock in many insects, the site of the driving clock, the photoreceptor for entrainment, and the oscillatory mechanism remain elusive. In the present study, we investigated them in *Drosophila melanogaster*.

Method: The cuticle growth layers in the furca, which is the thoracic apodeme attached to inner muscles, were observed. Wild type (Canton-S) and clock mutant flies (per^{01}, tim^{01}, cyc^{01}, Clk^{Jrk} and cry^{b}) were used.

Results: The cuticle deposition rhythm in wild-type fly free-ran in constant darkness and was entrained to light-dark cycles. The cuticle deposition rhythm also free-ran and was entrained to light-dark cycles when the whole thorax was cultured *in vitro*. These results suggest that it is controlled by a peripheral circadian oscillator. In most per^{01}, tim^{01}, cyc^{01} and Clk^{Jrk} flies, the endocuticle was thickened without distinct growth layers under constant darkness. In cry^{b} flies, the cuticle deposition rhythm free-ran but was not entrained to light-dark cycles. Entrainment ability of cry^{b} was restored by *act-Gal4*-mediated *cry* expression.

Conclusions: The circadian clock for the cuticle deposition rhythm is in the peripheral tissues and composed of the same clock genes as the central clock regulating locomotor activity rhythm. Unlike other peripheral circadian rhythms of *Drosophila*, CRYPTOCHROME is not involved in generation of the circadian oscillation for the cuticle deposition rhythm.

POSTER PRESENTATION

Immunological challenge promotes dispersal in a territorial damselfly *Calopteryx virgo*

Suhonen Jukka, Honkavaara Johanna, Rantala Markus J.

University of Turku, Turku, Finland

Introduction: Dispersal is an important determinant of gene flow, and thus subject to strong natural selection. Parasites can also have important fitness consequences, and increased rates of dispersal from areas with high infection risk could reflect parasite avoidance behaviour.

Methods: We tested whether experimental activation of immune system has an effect on dispersal behaviour of *Calopteryx virgo* males collected from three populations in southern Finland. For immune-challeged group, we inserted a nylon monofilament in an abdominal segment, for sham-manipulated group a puncture was made in the same segment, and the control group was captured and handled without a puncture or an implant. The damselflies were released back to nature, and their dispersal behaviour was monitored.

Results: Immune-challenged males exhibited increased levels of dispersal rate and dispersal distance. Sham-manipulate males also dispersed more readily compared to control males, but for shorter distances than males with implants.

Conclusions: Activation of the immune system enhances dispersal behaviour in *C. virgo* males. Dispersal might reduce risk of further infections if activation of the immune system indicates high infection risk in the present habitat. Further, increased risk of parasites might incur an increased infection risk also to offspring and dispersal might reduce this risk, too. Moreover, immune defence might deplete energy reserves, amount of which is an important determinant of territory holding capacity in these insects. If a male cannot defend a territory due to activation of immune system, it might be more prone to disperse in order to find a non-vacant territory elsewhere.

POSTER PRESENTATION

Influence of feeding frequency on a life cycle of the antlion, *Myrmeleon formicarius* (Neuroptera: Myrmeleontidae)

Toshiaki Matsura

Kyoto University of Education, Kyoto, Japan

Larvae of *Myrmeleon formicarius* are common antlions that make a conical pit on the dry sand. Since antlion larvae seldom relocate their pits, prey consumption of them possibly varies among individuals. To clarify how the variation of prey consumption affects their life cycles, third instar larvae of *M. formicarius* were reared under various feeding conditions using chironomid larvae as a prey. All larvae reached adult stage in the second year from their egg-hatching, although it has been said that *M. formicarius* needs at least two years to complete one generation because the third instar larva must experience a short day length after having experienced a long day length in order to form a cocoon. This experiment demonstrated that *M. formicarius* can potentially become univoltine if the larva has grown under a rich feeding condition. Moreover it was shown that the difference of feeding rate caused a variation in adult size but their periods of the final instar stage were nearly constant. As a result the adult eclosion was synchronous.

POSTER PRESENTATION

An investigation into the potential of entomopathogenic nematodes for control of banded fruit weevil, *Phlyctinus callosus* (Schoenherr) (Coleoptera: Curculionidae)

Tiarin Ferreira, Antoinette Malan

University of Stellenbosch, Stellenbosch, South Africa

Introduction: The banded fruit weevil, *Phlyctinus callosus* (Schoenherr), is the most important weevil pest on apples and nectarines in South Africa. Control of weevils is important due to damage caused to fruits, leaves and roots and also regarding export because of phytosanitary regulations. Current control of weevils in orchards is mainly targeted at the above ground adult. The use of South African species of entomopathogenic nematodes (EPN) against different life stages of the weevil were investigated in laboratory assays.

Methods: In this study *Steinernema khoisanae*, *Heterorhabditis zealandica* and *H. bacteriophora* were used to test the efficacy of the nematodes against adults and larvae of weevils in the laboratory. The nematodes were cultured on *Tenebrio molitor* and used within one week of harvesting. Adult weevils were collected from cardboard bands around the trunks of apple trees. Eggs were collected from adults that oviposited on wet cotton wool. Larvae used were either sieved from soil or reared on an artificial diet. The insects were inoculated with infective juveniles in 24 well plates and kept in a growth chamber at 25 ºC. Insect adults and larvae were individually dissected to determine infection with nematodes.

Results: After a period of 14 days all adults in the controls and inoculated wells were dead. Up to 75% of inoculated adults were infected with nematodes. All weevil larvae were found to be infected by the three nematodes species used.

Conclusion: Two stages of the banded fruit weevil, the adult and larvae, have been shown to be susceptible to three EPN species in laboratory conditions.

Assessment of termite biodiversity in Kakamega forest (Kenya) using DNA barcodes

Zipporah B. Osiemo[1], Godfrey H. Kagezi[2], Johanna P.E.C. Darlington[3], Andreas Marten[1], Manfred Kaib[4], Linus M. Gitonga[5], Hamadi I. Boga[6], Roland Brandl[1]

[1]Department of Animal Ecology, University of Marburg, Marburg, Germany, [2]Kawanda Agricultural Research Institute, Kampala, Uganda, [3]Zoology Department, University of Cambridge, Cambridge, United Kingdom, [4]Department of Animal Physiology, University of Bayreuth, Bayreuth, Germany, [5]Department of Zoology, Jomo Kenyatta University of Agriculture & Technology, Nairobi, Kenya, [6]Department of Botany, Jomo Kenyatta University, Nairobi, Kenya

Termites are among the most important decomposer in tropical ecosystems, where they can make up to 95% of the insect biomass in soil. The taxonomy as well as the determination of termites to the species level mostly relies on characters of soldiers. However, workers are the most frequently sampled caste during ecological surveys. Therefore, the diversity of termites is poorly understood, especially in tropical forests. Recently it was suggested to use DNA-sequences (barcoding) for inventories of hyper-divers taxa as well as taxa, which are difficult to determine. Here we present a first approach towards establishing a DNA barcode library to termite species identification and biodiversity assessment using sequences of the mitochondrial COII gene.

Kakamega Forest is the most eastern extension of the Kongolian forest block reaching western Kenya. This isolated forest is a hotspot of biodiversity in Kenya, however, threatened by the increasing human population. We sampled termites across a gradient from primary forests to farmland to assess the regional pool of termite species. A first morphological assessment of almost 250 samples suggested that at least 16 morphospecies occur along the gradient. A first analysis of 100 sequences suggested that more than 20 termite species may occur along the habitat gradient. Furthermore, the assignment of samples to morphotypes corresponded not always to the sequence analysis. Obviously barcoding provides a more comprehensive picture of the diversity of termites. We will use barcoding to estimate the total richness of termites in the Kakamega forest.

POSTER PRESENTATION

Assessment of on-farm stored maize losses in the highland areas of Bungoma district, Kenya

Kimondo Mutambuki, Christopher N. Ngatia

National Agricultural Research Laboratories, Nairobi, Kenya

Introduction: A simulation trial to assess losses in crib and in-house maize storage practices was conducted.

Methods: Three cribs were constructed and 180kg maize in two bags treated with 1.6% pirimiphos methyl and 0.3% permethrin stored in one. In the other, a similar quantity of untreated maize in two bags was stored while in the third crib, 4 bags of cob maize were placed. Another 4 bags, two treated and two untreated were placed on dunnage separated by a 2-meter path in the living house. Samples were analysed at 4-week interval for 24 weeks and pest damage was used to calculate percent weight loss. Grain from selected farmers was also analysed for comparison.

Results: Crib trial had 53% and 20% pest damage in untreated and treated maize compared with 56% and 16% for in-house storage after six months. Cumulative weight loss averaged 20.6% and 9.7% for untreated and treated maize. The figures are markedly higher than 5% criterion for effective pest control measures. Weight loss on farmer stocks compared well with untreated maize and grain damage varied from 5.4% to 27%, translating to 0.5% and 16.8% cumulative loss.

Conclusion: These results suggest ineffective pest control measures by Bungoma farmers. The results contrast with Kitui ones in an earlier study where *Prostephanus truncatus* is endemic and contributed to 10% cumulative loss above the Bungoma level. Efforts should be made to reduce grain damage to below 5% to realise food security at farm level.

POSTER PRESENTATION

Biological and ecological studies of the leucaena bruchid (*Acanthoscelides macrophthalmus*)

Li-Hsin Wu, Wen-Jer Wu, Chiao-Pin Wang

Department of Entomology, National Taiwan University, Taipei, Taiwan

Introduction: *Leucaena leucocephala* (Lam.) de Wit is a powerful invasive weed plant can cause serious ecological problems such as destruction on local vegetation diversity. A new recorded bruchid beetle (*Acanthoscelides macrophthalmus*) attacking the seeds of leucaena was found in Taiwan in 2004.

Method: We studied the effect of temperature on developmental rate of each life stage and the influences of food supplement and mating on the population growth rate. In addition, the shelter and other host plant surveys were proceeded simultaneously in the field.

Results: The developmental zero temperature is 8.769□, the effective cumulative temperature is 706.471 DD (degree days), their developmental rate gradually increased with the temperature, while maximum survival rate reached 66% in 27□ and further population growth rate parameters were also described. In the field, leucaena bruchid can complete their life cycle on pods that we manipulated underground or within canopy, and their population number fluctuates with the phenology of mature leucaena pods; we also found leucaena bruchid can feed on *Albizzia falcataria*, a new host plant in 9 legume species surveyed.

Conclusion: Our study provides several developmental parameters of leucaena bruchid which can help us to evaluate the feasibility for using them as a biocontrol agent of *Leucaena leucocephala*.

POSTER PRESENTATION

Influence of temperature on some developmental stages of *Culex quinquefasciatus* Say.

Vijaylakshmi Swain

University of Delhi, Delhi, India

Introduction: Temperature is an intrinsic factor of the environment which exhibits variations and fluctuations. It influences all living organisms and alters certain physiological characteristics. Vector mosquitoes pose a threat to mankind due to their capacity to transmit disease, genetically inherited trait of development of resistance against common insecticides and their observed adaptability to varied ecological changes including thermal adaptation. An attempt has been made to evaluate the effect of temperature on insecticide susceptible and resistant strains of some developmental stages *of* the filarial vector, *Culex quinquefasciatus*.

Methods: Malathion resistant (RR) and susceptible (SS) laboratory strains of *Culex quinquefasciatus* were exposed to a range of temperatures (35-42℃) to determine sub-lethality. Replicates of 4^{th} instar larvae were pooled and subjected to sub-lethal temperature, then allowed to recover and proceed with their life cycles. Rate of pupation, adult emergence and longevity were closely monitored along with the control.

Results: In malathion (RR) strain there was increased longevity in adult females but a substantial decrease in case of males. The males were more sensitive and succumb to stress and hence there is increased mortality. There was late onset of pupation, higher larval mortality and diminished adult eclosion in the thermal adapted strains.

Conclusions: The ability to tolerate thermal exposure and get adapted is reported to be a homeostatic response to protect the insect and confers adaptive thermotolerance.

POSTER PRESENTATION

Role of the salicylic acid signalling pathway in the *Mi-1*-mediated resistance of tomato to whitefly *Bemisia tabaci*.

Gloria Nombela[1], Clara I. Rodríguez[1], Isgouhi Kaloshian[2], Mariano Muñiz[1]

[1]Institute for Agricultural Sciences - Spanish National Research Council (CSIC), Madrid, Spain, [2]Department of Nematology (University of California, Riverside), Riverside, United States

Plant defense responses to pests, pathogens or wounding are usually dependent on either the salicylic acid (SA) pathway or jasmonic acid (JA) and ethylene-dependent pathways. In Arabidopsis, the B-biotype of *Bemisia tabaci* (Gennadius) (Hemiptera: Aleyrodidae) induced SA defenses and suppressed JA defenses. In tomato, resistance to *B. tabaci* is mediated by the *Mi-1* gene, which also regulates resistance to potato aphid *Macrosiphum euphorbiae* and 3 species of root-knot nematodes (*Meloidogyne* spp.). A role for the SA signaling pathway in *Mi-1*-mediated resistances to root-knot nematodes and aphids has been previously identified.

In the present work, the *NahG* transgene that eliminates endogenous salicylic acid (by degradation to catechol) was used to test the role of the SA pathway in the resistance mediated by *Mi-1 gene* to *B. tabaci* (B and Q biotypes). The tomato genotypes used were VFN (*Mi-1/Mi-1*), Moneymaker (*mi-1/mi-1*), the transgenic tomato expressing *NahG* in Moneymaker background, and the cross VFN x *NahG* to introduce *NahG* in the *Mi-1* background. In no-choice assays under controlled conditions, 5 female whiteflies were confined in a clip-cage attached to the abaxial surface of a leaflet per plant. Females were allowed to oviposit for 6 days. Then, females and clip-cages were removed and the number of eggs was counted. Twenty one days later, the numbers of L3, L4 and new adults on each plant were recorded. The resistance was lost in the cross VFN x *NahG*, which indicates that SA signaling pathway is required for the *Mi-1*-mediated resistance to *B. tabaci* in tomato.

POSTER PRESENTATION

Effects of host plant and temperature on *Aphidius colemani* (Hymenoptera: Braconidae) intrinsic rate of population increase

Rostislav Zemek[1], Vojtech Jarosik[2], Jan Havelka[1], Fernando Chihale[1]

[1]Biology Centre of Academy of Sciences of the Czech Republic, Institute of Entomology, Ceske Budejovice, Czech Republic, [2]Charles University, Faculty of Natural Sciences, Prague, Czech Republic

Introduction: *Aphidius colemani* is a generalist aphid endoparasitoid commonly used in augmentative biological control of *Myzus persicae* in vegetable greenhouses. The aim of this paper was to investigate the aphid-mediated effects of plant on *A. colemani* life-history characteristics.

Methods: *A. colemani* was reared on *Myzus persicae* using either *Nicotiana tabacum* or *Vicia faba* as a host plant for aphids. The experiments were carried out at four constant temperatures 18, 22, 26 and 29 °C. The intrinsic rate of increase as well as other derived parameters, were estimated from the life table data by means of the computer program. The standard error of the parameters was estimated using a Jackknife sub-sampling method.

Results: The highest mean total number of offsprings per female was found when parasitoids were offered to *M. persicae* grown on bean at 22 °C. The lowest mean total number of offsprings was found at 29 °C when tobacco was used as a host plant. Survivorship of females was significantly higher on tobacco than bean at 26 °C while at the other temperatures no differences were found. The intrinsic rate of increase was higher for *A. colemani* parasitizing aphids on bean than tobacco although significant differences were found only at optimal temperature 22 °C.

Conclusions: The obtained results corroborated our hypothesis that the host plant is important factor in an aphid-parasitoid relationship. Plant toxins are probably the cause of lower rate of population increase in *A. colemani* developed on tobacco-reared aphids.

Acknowledgments: This work was supported by MSMT grants No. 2B06005, 21620828 and LC06073.

POSTER PRESENTATION

Grapevine leafroll-associated virus 3 (GLRaV-3) extraction from grapevine and mealybugs (Hemiptera: Pseudococcidae) for quantitative real-time PCR

Nicoleen Douglas, Glen P. Malherbe, Kerstin Krüger

Department of Zoology and Entomology, University of Pretoria, Pretoria, South Africa

Introduction: The integrity of purified RNA is critical for reliable diagnostic use in quantitative real-time reverse transcription polymerase chain reaction (real-time RT-PCR). Sampling, storage and extraction method affect the integrity and purity of extracted RNA. *Grapevine leafroll-associated virus 3* (GLRaV-3) has been associated with one of the most economically important viral diseases of grapevines. An important vector is the vine mealybug *Planococcus ficus*. For the development of a quantitative real-time RT-PCR for GLRaV-3, the efficiency of different extraction methods was evaluated using plant material and mealybugs.

Methods: Initially five extraction methods were compared: Qiagen RNeasy Mini, Promega SV total RNA Isolation System, Gentra Purescript RNA Isolation Kit, Phenol-chloroform method and QiaZol extraction method. Of the five extraction techniques tested, the Gentra, QiaZol and Phenol-chloroform techniques were selected based on cost involved. Extractions were tested for GLRaV-3 presence using nested reverse transcription PCR (nested RT-PCR) and efficiency was compared using real-time RT-PCR to determine relative concentrations of GLRaV-3.

Results: The PCR results showed 60-70% of the Phenol-chloroform, 80-90% of the Gentra and 90-100% of the QiaZol plant material samples to be positive for GLRaV-3. The number of GLRaV-3 - positive mealybug samples was 60-70% for Phenol-chloroform, 60-90% for Gentra and 79-100% for QiaZol extractions.

Conclusion: Overall, the QiaZol technique was selected as the preferred method, based on cost and time involved. The Phenol-chloroform and Gentra techniques also produced good results. However, the former is time-consuming and the latter is no longer commercially available.

POSTER PRESENTATION

Integrated production and durable management of a reproduction sericultural family farm

Matei Alexandra[1], Popescu Agatha[2], Sladescu Viorica[3], Talpes Marilena[4], Dan Mioara[5], Androne Magda[1]

[1]Commercial Society Sericarom-Research department, Bucharest, Romania, [2]University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania, [3]National University of Fine Arts Bucharest – Textiles Arts Department, Bucharest, Romania, [4]Institute of Research and Development for Aquatical Ecology, Fishing and Aquaculture, Galati, Romania, [5]National Institute of Research and Development for Textiles and Leather Goods, Bucharest, Romania

Introduction: The paper presents a management system of the sericultural activities in family farms based on the principle of integration between the main activities, respective the production of reproduction biological material, with the processing of the waste products and the production of secondary products obtained from the main activity. The project is based on the long experience existing in sericulture in the country, on the high value silkworm races and hybrids, mulberry varieties and on the tradition in the domestic silkworm rearing and cocoon processing.

Methods: Techniques and methods: specific for producing biological reproduction biological reproduction material (selection based on biological and technological criteria, pure breed reproduction or inbreeding), for achieving new textile structures of natural silk and other fibres (mohair, wool), for processing unreeling cocoons, for determining the nutritive value of the forage recipes and food conversion in body weight at fishes.

Results: The project can be applied in family farms, more exactly in households having at least 1 ha arable land (0.5 ha mulberry plantation and 0.5 ha mulberry nursery), 150 s.m. buildings as silkworm rearing houses and 2-3 family members dealing with the activities stipulated in the project. The main product is represented by silk cocoons. The yearly production capacity of the family farm is 400 kg cocoons. The cocoons can be partially used for obtaining silkworm eggs (1000 boxes)) or can be sold to specialized reproduction units. Other cocoons could be processed in silk fibres and traditional handy-crafts. The expectations for the average technical performances are the following ones: 6000 kg leaf yield production/0.5 ha plantation, 35 kg raw cocoon production/box, 400 kg raw cocoon production/0.5 ha mulberry plantation, 15 kg leaf consumption/kg cocoons, 80% pupation rate, 2.0 g raw cocoon weight, 0.400 g shell weight and 1200 m filament length.

Conclusions: The major project objective is to establish the scientific and economic fundamentals for setting up a family sericultural reproduction farm under the conditions of integrated production and management.

POSTER PRESENTATION

Molecular tools for improving insecticide resistance management in the whitefly *Bemisia tabaci* (Homoptera: Aleyrodidae)

John Vontas[1], Emmanouel Roditakis[2], Ralf Nauen[3], Mark Paine[4], Shai Morin[5], Anastasia Tsagkarakou[2]

[1]Laboratory of Pesticides Science, Agricultural University of Athens, Iera Odos 75, 11855 Athens, Greece, Greece, [2]Laboratory of Entomology and Agricultural Zoology, National Agricultural Research Foundation, Heraklion (N.AG.RE.F.),, Kastorias 32A Katsampas, 71003 Heraklio, Greece, Greece, [3]Bayer CropScience AG Research Insecticides, Insect Toxicology and Resistance Building 6220 Alfred Nobel Str. 50 D-40789 Monheim, Germany, [4]Vector Group, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, United Kingdom, [5]Department of Entomology, Faculty of Agricultural, Food and Environmental Quality Sciences, Hebrew University of Jerusalem, P.O.Box 12, Rehovot 76100, Israel

Introduction: The whitefly *Bemisia tabaci* is responsible for significant yield losses in numerous protected and field crops. Growers rely on insecticides, however many of those no longer effectively control these pests, due to the appearance of insecticide-resistant populations. Early detection and monitoring of insecticide resistance and knowledge of the population genetic structure are crucial for the implementation of insecticide management tactics.

Methods: Insecticide resistant strains and field populations are collected from the island of Crete (Greece). Simple PCR based detection assays, appropriate for low tech laboratories, are being designed for the detection of characterised markers, such as those associated with target site insecticide resistance (MACE, kdr) and *B. tabaci* biotypes. Antibody detection assays, based on artificially synthesized specific peptides are used for the diagnosis of metabolic resistance.

Results: We developed simple PCR–RFLP and PASA agarose gel visualization based assays for monitoring the L125I, T129V pyrethroid resistance mutations in the IIS4-IIS6 region of the para sodium channel gene and a MACE organophosphate resistance mutation of the Ace gene. A PCR-RFLP and a diagnostic PCR based on mitochondrial DNA differences were developed for the reliable discrimination between different biotypes, while higher resolution gene flow analysis is performed using microsatellite markers. Finally, a specific antibody assay was produced for the detection of a CYP6 cytochrome P450 which is associated with Imidacloprid resistance in both B and Q biotypes of *B. tabaci*. The assay is being simplified into a diagnostic format.

Conclusions: A number of applicable simple molecular tools have been developed, which can be used to improve insecticide resistance management in the whitefly *B. tabaci.*

POSTER PRESENTATION

Changes of mosquito diversity: Vectors of pathogenic agents in relationship to weather changeability in inundated areas of the Czech rivers Morava and Dyje

Ivan Gelbic, Jiri Halouzka

[1]Biological Centre AS CR, Ceske Budejovice, Czech Republic, [2]Institute of Vertebrate Biology, Brno, Czech Republic

Introduction: The global climate change is well known phenomenon for several years. The annual mean temperature in the last decade is 1-2°C higher than long-term normal and rain-falls are less regular. Temperature is sizeable fluctuated, especially in spring and summer and dry and hot weeks are changed by rainstorms causing local and sometimes catastrophic floods, practically in all European countries during the last decades.

Methods: This phenomenon together with increased temperature in spring and summer months causes changes in biodiversity of mosquito communities as well as in the density of mosquito species connected with calamitous situations. The study is dealing with mosquito populations and their changes in an inundated area of the Morava and Dyje rivers after flood in 1997.

Results: Rainstorms and following floods dramatically increased mosquito density. However, subsequent year showed rapid decrease of species biodiversity but on the contrary multiple growth of only some mosquito species density including the known main vector of *West Nile* virus – *Culex pipiens*. The global change is also probably responsible for emergence of new arboviruses in Europe, for example originally African *Usutu* virus. Species with seasonal regular overcrowding having epidemiological importance are *Aedes vexans*, *Ochlerotatus sticticus*, Oc*. cinereus* and Oc*. cantans*. During the last year also more numerous populations of *Anopheles claviger* and *Culex modestus* species on some Moravian localities were observed.

Conclusions: In the past decade the changes in the number and species composition of the mosquito fauna were observed. The species preferring lower temperature subsequently disappear and species developing in higher temperature occurs.

POSTER PRESENTATION

Spectral sensitivity and colour choice in the pollen beetle, *Meligethes aeneus*

Thomas Döring[1], Samantha Cook[2]

[1]Imperial College London, Ascot, United Kingdom, [2]Rothamsted Research, Harpenden, United Kingdom

Introduction: The pollen beetle, *Meligethes aeneus* is a serious pest of oilseed rape (OSR, *Brassica napus*) in Europe. Resistance levels to insecticides have increased dramatically over the last few years and the OSR acreage is rapidly expanding. Alternative control methods are therefore urgently needed. As a first step towards exploring the potential use of coloured traps for monitoring and the use of cultivars with petal colours other than yellow for pollen beetle control, physiological and behavioural experiments were conducted to elucidate their response to colours.

Methods: Spectral sensitivity was measured in 6 animals using the electroretinogram technique: light flashes (100 ms) at varied wavelengths (340-660 nm, 10 nm steps) and at different light intensities were applied to the eye after dark adaptation. Water traps of 140 colours (from yellow to green to blue with varying amounts of white and black added) were set out in the field in May 2007.

Results: The mean spectral sensitivity curve peaked at 520 nm; however, a model template fitted to the long wavelength tail of the observed curve revealed a peak around 535-540 nm. A secondary sensitivity peak was observed in the UV (370 nm). In the coloured traps, a total of 159 pollen beetles were found. Yellow traps with small amounts of white added caught the most, while the second highest catch was observed in pure yellow traps.

Conclusions: Our results confirm that pollen beetles prefer yellow over other colours, however more trap experiments are needed that include varied reflectance in the UV.

POSTER PRESENTATION

Frequency patterns in empty and occupied ovipositional patches in blowflies

Luciane Galindo, José Passos, Liciana Silveira, Wesley Godoy

Universidade Estadual Paulista, Botucatu, São Paulo, Brazil

Introduction: In this study, the ovipositional behavior in blowflies was investigated focusing the patches occupation, with the purpose of verifying whether the previously occupied patches influence the ovipositional habit by females.

Methods: The collections were done by using suspended traps in trees during four days. Each trap had ground meat and 100 larvae of *C. albiceps*, *C. megacephala* and *C. putoria*. As the control, a container without larvae was included.

Results: 34.561 dipterous were obtained with Accumulated Frequency, estimated inside and among treatments. *Chrysomya megacephala* was the most numerous species, followed by *Lucilia* ssp., *Chrysomya albiceps* and *Ophyra chalcogaster*. The control traps were the most attractive, accordingly to the results of a previous study in the laboratory.

Conclusions: The high number of *C. megacephala* suggests that the species might not carry influence from the occupation and it indicates good larval performance under competition for food in the previously occupied patches. *Lucilia* ssp., showed a larger ovipositional inhibition due to the occupation, and *C. albiceps* did not inhibit the oviposition in general. The preference for not occupied patches suggests that the insects choose to lay eggs under this condition, but the mechanism by which the females are able to detect other species is still unknown. A more complete analysis, including results obtained in the following months, might indicate clearer trends for the confirmation of the suggested result.

POSTER PRESENTATION

‘Exite’-like structures on the thoracic appendicular bases of the mayfly *Bleptus fasciatus* Eaton (Ephemeroptera: Heptageniidae)

Koji Tojo, Ken Miyairi

Shinshu University, Matsumoto, Nagano, Japan

Insects account for three quarters of all animal species, and more than 99 percent of them are wing-acquired insects. Pterygotans have achieved spectacular prosperity and radiation, and elucidating their evolution and groundplans is a most interesting subject. With regard to the ‘origin of wings’, which has been argued over for a long period, various hypotheses have been proposed. Of these hypotheses, presently, the ‘epicoxal exite (outer lobe or podite of the most basal leg segment) theory’ is the most widely accepted. Furthermore, the epicoxal exite hypothesis for the origin of wings can be reconciled readily with other theories on related topics. That is to say thatwings derive from tracheal gills of an ancestral aquatic “protopterygote”. According to this theory, the abdominal winglets (or gills) of the protopterygote are serially homologous with thoracic wings, and also the gill itself is a modified epicoxal exite of a hypothetical, basal leg podite.

When verifying the direct homology of the wing to the epicoxal exite, it becomes important to compare the serial homology between wings with other proximal exites (e.g., subcoxal, coxal, trochanteral and prefemural). Recently, we could find the remaining structures of subcoxal and coxal exites in a heptageniid mayfly. Furthermore, in these exites, tracheation can be clearly observed. The remnants of these structures are a new discovery amongst present Pterygotans. This discovery amongst present Pterygotans, provides long required research opportunities to verify the serial homology discussed above using various newly available techniques.

POSTER PRESENTATION

Biology and feeding capacity of anthocorid predator, *Orius maxidentex* Ghauri (Hemiptera: Anthocoridae) as a biological control agent of thrips

Oraphan Kernasa, Athitiya Kaewpradit, Wiwat Suasa-Ard

[1]NBCRC CRC, Nakhon Pathom, Thailand, [2]Kasetsart University, Nakhon Pathom, Thailand

Introduction: Anthocorid predator, *Orius maxidentex* Ghauri (Hemiptera: Anthocoridae) was a new recorded as biological control agent of thrips and sap-sucking insects in chili plantations in Thailand, during 2006. Biology and feeding capacity of *O. maxidentex* were since then investigated in laboratory condition at National Biological Control Research Center, Central Regional Center, Kasetsart University, Kamphaeng Saen Campus, Nakhon Pathom.

Methods: Investigation of biology and efficiency of *O. maxidentex* against thrips were conducted by individually reared first instar nymphs in petri dishes on small piece of egg plant leaf, 3x3 cm that was infected by thrips. Daily observation of developmental growth in each stage and number of thrips feeding were recorded.

Results: This assessment revealed that female adult laid the eggs singly in tissue of leaf vein of eggplant leaf. The egg translucent and looked like jar. The incubation period was 3.83 ± 0.38 days. The nymphal stage consisted of 4 instars. The developmental period of nymphal stage was 12.73 ± 0.74 days. The longevity of adult male and female were 10.36 ± 1.96 and 19.05 ± 4.36 days, respectively. Feeding capacity of *O. maxidentex* nymphs on thrips revealed that the total nymphal stage fed about 27.56 ± 2.82 thrips. Male and female fed about 40.73 ± 8.17 and 87.16 ± 14.31 thrips, respectively.

Conclusion: *Orius maxidentex* should be an promising natural enemy as biological control agent of thrips in Thailand.

POSTER PRESENTATION

Diversity of insecticide resistance profiles in pyrethroid-resistant *Triatoma infestans* (Hemiptera: Reduviidae) from Argentina and Bolivia

Mónica Germano, Claudia Vasssena, Pablo Santo Orihuela, Eduardo Zerba, María Inés Picollo

Centro de Investigaciones en Plagas e Insecticidas (CONICET-CITEFA), Buenos Aires, Argentina

Introduction: *Triatoma infestans* is the main vector of Chagas Disease in South América. Chemical control by insecticides has been successful for the elimination of domestic infestation and consequently the reduction of vectorial transmission. Recently, high resistance to pyrethroids was reported in northern Argentina and southern Bolivia. Additionally a decrease in the effectiveness of field treatments was found in two Andean areas of Bolivia. In this work we studied the susceptibility profile to non-pyrethroid insecticides in resistant populations from Salta (Argentina) and Yacuiba, Sucre and Mataral (Bolivia)

Methods: Toxicity test were done by topical application of insecticides (0,2 µl) on first nymphs (3- 5 days old). Activity of cytochrome P-450 mono-oxygenase was measured in individual first nymphs through ethoxycoumarine-o-deethylase.

Results: Resistant ratios (RRs) demonstrated lower deltamethrin resistance for Andean populations (RR Sucre 31.3; RR Mataral 17.4) than Salta (RR 133.1) and Yacuiba (RR 154.4). Moreover, remarkable differences were found in resistance profile to fipronil in Andean and non-andean populations. Sucre and mataral showed very high RRs (585.5 and 386.9 respectively) to fipronil, while Salta and Yacuiba were susceptible to this insecticide. Additional studies demonstrated that all populations were susceptible to the organophosphorus fenithrotion. Activity of mono-oxygenases showed noticeable differences in the distribution of activities between susceptible and resistant populations. The total percentage of insects below 0.48 pmol of 7-OH coumarine/m/l was lower for susceptible strain (36%) than for resistant populations

Conclusions: The differential pattern of susceptibility to insecticides and the relative contribution of mono-oxygenases, suggest an independent evolution of resistance in the studied populations of *T. infestans.*

POSTER PRESENTATION

Phenotypic characterization of races from native genetical stock of the silkmoth *Bombyx mori* L.

Matei Alexandra[1], Androne Magda[1], Popescu Agatha[2]

[1]Commercial Society Sericarom-Research department, Bucharest, Romania, [2]University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania

Introduction: The importance of gene bank existence as an essential condition for breeding programs elaboration is unanimously known for every plant and animal species, from which the permanent concern for its diversification and maintaining by appropriate preservation procedures "in situ" or "ex situ". This way, the loss of biological material, especially of the local races resisting to diseases and adapted to environmental conditions is avoided. This study aims the analysis of phenotypic characters variability within the genetic stock of *B. mori,* in accordance with its biological development stages (egg, larva and pupa). Native genetic stock of silkmoth *B. mori* resulted from the identification of gene sources from local populations, bilateral exchange of biologic material with similar foreign institutes, creation of new genotypes using specific breeding methods. Within its structure, the genetical stock of silkmoth includes 72 races.

Methods: The silkworm specific experimental technique has been applied, differentiated by technological and biological development stages (Grekov D., 2005). The sample size used as the base for phenotypic parameters determination as well as the working methods correspond to sericulture technical standards.

Results: The main phenotypical and quantitative parameters of the races that represent the gene stock of *B. mori* have the following values: fecundity (230-710 eggs/laying), hatchability (80.6-100%), larval stage duration (26-32 days), larvae weight (4.2-5.7 g), larvae pupation (80.8-96.6%), raw cocoon weight (1.445-2.361 g), cocoon shell weight (0.240-0.520 g), fiber length (746-1356 m), metric number of fiber (2917-3764 m/g).

Conclusions: Depending on the quantitative parameters value, the silkworm races are differently used, the entire genetic stock being destined for various technological levels, as follows: 4 active races (parents of hybrids), 4 candidate races for parents of hybrids, 64 races in preservation.

POSTER PRESENTATION

Ovicidal effect of monoterpenoids against permethrin-resistant human head louse (Phthiraptera: Pediculidae)

Ariel Toloza, Claudia Vassena, María Inés Picollo

Centro de Investigaciones en Plagas e Insecticidas, CONICET-CITEFA, Buenos Aires, Argentina

Introduction: The human head louse *Pediculus humanus capitis* De Geer is an important cosmopolitan pest affecting school-aged children. Previous works of our laboratory have detected populations in Buenos Aires with high resistance levels to pyrethroids in both adult and egg stages (RR>80). In the search of new insecticides, monoterpenoids seem to be good control alternative candidates because they are environmental friendly and not acutely toxic to mammals. The purposes of this work were to develop a methodology employed to detect the ovicidal effect of 23 monoterpenoids against *P.humanus capitis* from Buenos Aires, and to compare it with the activity previously reported on adults.

Methods: Eggs were collected from heads of children 5-12 yr old, using an anti-louse comb. Groups of 15-20 late development eggs were exposed to the vapours of the evaluated monoterpenoids in an enclosed chamber. The number of emerged nymphs was counted, and those with incomplete emergence were considered as dead.

Results: There were highly significant differences among the evaluated monoterpenoids ($p<0.0001$). Ten of the monoterpenoids produced mortality above 80%. The most effective monoterpenoids were hydrocarbons and ethers, followed by ketones, alcohols, phenols and esters. Regression analysis revealed a statistically significant relationship between ovicidal mortality and adulticidal knockdown of the same evaluated monoterpenoids at the 99% confidence level.

Conclusion: This study demonstrated the ovicidal activity of monoterpenoids in concordance with their effectiveness on nymphs and adults. The potential use of mono-terpenoides as ovicides and adulticides in novel pediculicide formulations is discussed

POSTER PRESENTATION

Developing a laboratory rearing technique for the litchi moth*, Cryptophlebia peltastica* (Lepidoptera: Tortricidae).

Willem P. Steyn, Pieter S. Schoeman

Agricultural Research Council, Institute for Tropical and Subtropical Crops, Nelspruit, Mpumalanga, South Africa

Introduction: The litchi moth, *Cryptophlebia peltastica* (Meyrick) (Lepidoptera: Tortricidae) is a quarantine pest of litchi, *Litchi chinensis* Sonnerat in South Africa. Litchis are exported from South Africa but countries such as the USA, which is climatically suitable for litchi moth establishment, impose quarantine restrictions against countries likely to carry new pest species across their boundaries. The female moth lays her eggs on the skin of the fruit and newly hatched larvae eat through the skin and into the fruit flesh and seed. The aim of the present study was to rear high numbers of the litchi moth in captivity for future research, to establish quarantine measures that will prevent the accidental distribution of this pest to foreign countries.

Methods: Infested litchi fruit was collected in the Nelspruit area of the Mpumalanga province in South Africa during the growing season. Final instar larvae found in the fruit were placed in plastic containers with sand at the bottom for the larvae to pupate in. Pupae found were placed in gauze cages to emerge and adult moths were kept in these cages at room temperature to reproduce. Eggs laid were placed into honey flasks with a steam sterilized maize meal medium and kept at room temperature.

Results: The eggs hatched and the first generation of *C. peltastica* was successfully reared through all life stages. Currently eggs of the second generation are on medium.

Conclusions: From these results, it would appear that a viable technique for the rearing of litchi moth has been developed and that a laboratory colony of this quarantine pest can now be established.

POSTER PRESENTATION

The fate of the clock protein PERIOD in the *Drosophila melanogaster* ovary

Joanna Kotwica[1], Maureen Larson[2], Piotr Bebas[1], Jadwiga M. Giebultowicz[2]

[1]Univeristy of Warsaw, Department of Animal Physiology, Warsaw, Poland, [2]Oregon State University, Department of Zoology, Corvallis, United States

Introduction: The clock protein PER undergoes cycles of accumulation, phosphorylation, nuclear translocation and degradation in *Drosophila melanogaster* clock cells. One exception to this pattern is in follicular cells enclosing previtellogenic ovarian follicles. In these cells, PER remains high and cytoplasmic at all times of day. Here, we studied PER levels and subcellular localization in older vitellogenic follicles. We also investigated whether DBT, a kinase known to affect PER in clock cells, interacts with PER in ovarian follicular cells.

Methods: Levels of PER and DBT proteins were assessed by Western blotting and immunocytochemistry. Expression of *dbt* was driven into wild type ovarian follicular cells using the *tim*-Gal4/UAS-*dbt* system.

Results: In wild type flies, PER levels decreased in follicular cells of vitellogenic follicles compared to younger follicles. Nuclear PER was detected in stage 9 follicles, while PER was completely absent in stage 10 follicles. DBT was absent in previtellogenic follicular cells, but present in stage 9 follicular cells. Surprisingly, overexpression of DBT led to higher levels of ovarian PER than in control ovaries. Experiments are under way to verify these data using different GAL4 lines, directing expression of *dbt* into specific follicle stages.

Conclusions: The absence of *dbt* expression in the follicular cells of previtellogenic follicles is the likely reason for stable and cytoplasmic expression of PER in these cells. Onset of *dbt* expression in vitellogenic follicles coincides with nuclear localization and subsequent decline in PER protein. The functional significance of the interplay between ovarian PER and DBT levels is under investigation.

POSTER PRESENTATION

Mapping the cellular network of the circadian clock in two cockroach species

Chih-Jen Wen, How-Jing Lee

Department of Entomology, National Taiwan University, Taipei, Taiwan

Introduction: *Blattella germanica* and *B. bisignata* are sibling species with similar *period* sequence but distinctive circadian rhythm in locomotion. Period (PER), Pigment Dispersing Factor (PDF), and Corazonin (CRZ) are three clock-related proteins whose antibodies are used to map the cellular network of the circadian clock.

Methods: The cell distribution and connection of immunoreactivity (ir) against PER, PDF and CRZ were compared between the two cockroach species.

Results: Three major PER-ir cell groups are located in the optic lobes, which are the sites of the major circadian clock. The output signal, PDF, is co-localized with PER in all groups of cells. Only two CRZ-ir cells and their axons are found in the optic lobes and they are not co-localized with PER-ir or PDF-ir cells and axons. A group of 3-4 PER-ir cells in the protocerebrum display typical characteristics of neurosecretary cells. In addition, there are numerous, small PER-ir and PDF-ir co-localized cells in the pars intercerebralis, which have direct connections with CC through PER-ir and PDF-ir axons.

Conclusions: Since the overall distribution pattern of the clock cells are the same for *B. germanica* and *B. bisignata*, the possible explanation for the differential expression of locomotor circadian rhythm between the species depends on downstream genes of *per, pdf*, and *crz*.

POSTER PRESENTATION

Differential testing laboratory conditions for *Pediculus humanus humanus* and *Pediculus humanus capitis (*Phthiraptera: Pediculidae)

Anabella Gallardo, Gastón Mougabure cueto, María Inés Picollo

Centro de Investigaciones en Plagas e Insecticidas, CONICET-CITEFA, Buenos Aires, Argentina

Introduction: Human pediculosis is a prevalent parasitic infestation occurring in both developed and underdeveloped nations. It is produced by *Pediculus humanus humanus* and *Pediculus humanus capitis*, two obligate ecto-parasites who affect the body or the head of the host. A laboratory strain of the body lice was adapted to a rabbit host in the 1940s and was maintained without feeding on humans in laboratories from different countries. Experimental evidence has proved that body lice are an appropriate test organism for testing products for the control of its sub-species, the head lice. This study compared the optimal environmental conditions for females and males of *P humanus humanus* and *P humanus capitis* at laboratory level.

Methods: For the tests, we used separately females or males of body or head lice. Insects were kept for 24 h in closed chamber at different measured temperatures (18, 24 and 28 ºC) and humidities (50-60 and 95- 100 % RH). Mortality of lice was recorded at 18 and 24 h.

Results: There was a significant differential response to changes in temperature and humidity between body and head lice. All *P humanus humannus* exposed to different combinations of temperature and humidity, showed high survival (90- 100%). In contrast, survival of *P humanus capitis* was clearly dependant on temperature and humidity. Mortality of males and females increased as the temperature increased or the humidity decreased. The optimal laboratory conditions for head lice were 18ºC and 95- 99% RH, where average survival of males was 90% and females 85%.

Conclusions: At laboratory, head lice required more special conditions of temperature and humidity than body lice for the survival of control insects. Thus, optimal head lice conditions (18ºC and 95- 99% RH) can be used for both sub-species in comparative toxicological tests for evaluating pediculicide activity

POSTER PRESENTATION

Bioecology of the fruit gall system in strawberry guava

Anamaria DalMolin[1], Gabriel Melo[2], Rosy M. S. Isaias[3], Jose Henrique Pedrosa-Macedo[2]

[1]Texas A&M University, Department of Entomology, College Station, TX, United States, [2]Universidade Federal do Parana, Curitiba, PR, Brazil, [3]Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil

Introduction: This work presents basic biological aspects of the gall-maker – plant interaction in fruit galls induced by the chalcid wasp *Prodecatoma carpophaga* in the weedy tree strawberry guava (*Psidium cattleianum*).

Methods: We characterized the gall as to the associated wasp species and their ecological roles, gall ontogeny, fruit infestation at different localities in Southern Brazil (Parana State First Plateau and littoral), and resistance of a possible alternative host, *Psidium longipetiolatum*. The morphoanatomic alterations were described through anatomical staining and histochemical tests. The comparison of fruit infestation levels were made with quantitative parasitological indicators such as prevalence (number of galled fruits), intensity (number of galls per infested fruit) and aggregation. *P. longipetiolatum* resistance was compared to *P. cattleianum* by testing plant acceptability as oviposition site and suitability for gall development.

Results: The gall results from modified cells from ovary, placenta and funicle internal epiderm in the early stages and from tissue reorganization induced in the fruit by larvae. There is a greater prevalence of infested fruit in the plateau localities, in the comparison to the coastal ones. Infested fruits produce less seeds than non-infested ones. Although both *P. cattleianum* and *P. longipetiolatum* were accepted by the ovipositing females, the latter tends to abort the infested buds and shows a practically null level of infestation.

Conclusions: The gall has a significant impact in the reproductive potential of the host plant and should be further investigated for its use in biocontrol for specificity and the causes of differential infestation levels.

POSTER PRESENTATION

The effects of rapid phase-shifting on adult lifespan and reproduction of the German cockroach

Shu-Chi Tsao, How-Jing Lee

Department of Entomology, National Taiwan University, Taipei, Taiwan

Introduction: Desynchronization between internal clocks and environment time signals can affect the well-being of organisms. Longevity and reproduction of the German cockroach are investigated as the long term effect of circadian timing desynchronization by rapid phase-shifting schedules.

Method: With a 12 hours light-dark reversal in every 3 or 7 days schedules were used to monitor the adult lifespan and fecundity.

Result: The longevity of male cockroaches was significantly reduced by rapid phase-shifting. Furthermore, the shorter interval between phase-shifting enhanced the effect of lifespan reduction. The females did not show lifespan and offspring reduction under the 7 days phase-shifting schedule. However, the 3 days phase-shifting schedule did cause lifespan and offspring reduction, even though the effect was significantly smaller than that of males.

Conclusion: Rapid phase-shifting causes detrimental effects on longevity and reproduction of the German cockroach. But it induced different level of impact between males and females, suggesting the existence of sexual dimorphism in circadian regulation.

POSTER PRESENTATION

Preliminary study: The analyses of blowfly larval crops for the presence of host genomic DNA

Theo Viljoen, Theuns van der Linde, Karen Ehlers

University of the Free State, Bloemfontein, South Africa

Introduction: The DNA technology subsection of forensic entomology is primarily emphasized in cases where there are insects present at a crime scene but no decedent. DNA typing can also be used to test if the larvae on the decedent are related to the crime scene or to rule out an alternative food source. The aim of this study is to determine if DNA from the food source can be extracted from the larval crops.

Methods: Three extraction methods were tested for efficiency namely the QIAamp mini kit tissue extraction protocol (Qiagen®), the phenol-chloroform extraction protocol and the salt-chloroform extraction protocol. *Calliphora vicinia* Robineau-Desvoidy, *Chrysomya albiceps* (Wiedemann), *Lucilia cuprina* (Wiedemann) and *Lucilia sericata* (Meigen) larvae were fed on fresh bovine liver (*Bos taurus*) and the alimentary canal removed. The bovine primers INRA023, SPS115 and ETH225 were used to test whether the DNA extraction was successful.

Results: The salt-chloroform extraction proved to be the most effective extraction method due to the amount of DNA delivered. The bovine DNA from the larval crops showed a decrease in peak size relative to the standard. This could be contributed to the quality of the extracted DNA due to activity of digestive enzymes. The bovine DNA extracted from the larval crop was successfully amplified at locus ETH225 in both the third instar and post-feeding larvae.

Conclusions: The genomic DNA from the larval crops was successfully extracted using the salt-chloroform extraction, but the quality of the DNA was only sufficient enough to produce a partial DNA profile.

POSTER PRESENTATION

Study of embryogenesis's abnormalities for *Morus* sp. plants cultivated for sericulture

Tanase Doina, Nicolae Toma, Motoc Rozalia

[1]Commercial Society Sericarom-Research department, Bucharest, Romania, [2]National Institute of Biology, Bucharest, Romania

Introduction: The present paper work presents modifications within *Morus* sp. plants' embryogenesis (the only nutritional source for *Bombyx mori* L. silkworms) made by traffic air-l pollution with Pb and surpass of the heavy metals content (Pb, Ni, Cr, Co)**.**

Methods: The distinguish of mineral elements translocation from soil and environment to Morus sp plants was made by soil profile method. The biological samples were roots, leaves and fruits from different development stages, of plants belonging to M. alba and M. multicaulis varieties. The samples for photonic microscopy were realised through paraffin technology and analysis with Fluowal microscope and a microphotographic system. The electron microscopy was made by syntetic resins including technology, and the ultra sections grills were analysis with a TEM Philips 2001, details from photonic samples drew on a clear room for jugal embryogenesis.

Results: The heavy metals Pb, Ni, Cr, Co content from traffic pollution site, are over the reference value, for fruits samples (5,0 ppm, 7,2 ppm, 1.5 ppm and 2,7 ppm) and leaves samples (9.1 ppm, 10.6 ppm, 2.1 ppm and 10.1 ppm). The photonic microscopy data, distinguished the anomalies apparition during the zygotic embryogenesis process for the fruits samples within traffical pollution (some processes unsynchronization, atypical endosperogenesis, uncomplet development, polyembryony). Electron microscope researches for leaves samples, distinguish anomalies upon ultrastructure organisation of chromatine, cloroplasts and mitocondries (decrease of cellular components volume and decrease of membranes electronic density)

Conclusions: The traffic pollution may affect in a visible way the embryogenesis for Morus sp. fruits and determine the appariton of some anomalies upon the ultrastructural organisation of different cells and cellular components types for the Morus sp leaves.

POSTER PRESENTATION

Microsatellite DNA markers to study genetic differentiation and dispersion capacities in three Calliptaminae species (Orthoptera, Acrididae)

Elodie Blanchet, Alex Franc, Christine Pages, Laurence Blondin, Antoine Foucart, Jean-Michel Vassal, Michel Lecoq

CIRAD, Montpellier, France

Introduction: Global changes have an impact on the habitat of endangered species as well as pests. Some grasshopper pests, like the *Calliptaminae* species, in the North Mediterranean Basin, can be affected. In certain regions such as Languedoc (France), landscape has undergone modifications for a long time, particularly an important fall of agricultural practices which has closed landscapes. The present study expects to verify if alterations of vegetation cover have an impact on genetic diversity and dispersion capacities of three *Calliptaminae* species, with different habitats and dispersion capacities, observed in this region: *Calliptamus barbarus*, *C. italicus* and *C. wattenwylianus*.

Method: We sampled 1200 specimens from the three species, on two sites (72 km²) that were 40 kilometres apart. For each specimen, we took geographic coordinates (GPS point) so having possibility to cross individual sample site and spatial data of landscape structure on these sites. To develop microsatellite bank, DNA were extracted with CTAB protocol and an enriched method was used.

Results: In total, we isolated 11 polymorphic markers, among which three amplified on the three species, five on *C. barbarus* and three on *C. italicus*. Hitherto we observed more than four alleles for each primer, but genotyping and analysis are in progress.

Conclusion: Associated with spatial characterisation of the environment, these new markers may allow us to develop spatial genetic studies on this genus and to have a better evaluation of their dangerousness. This method already used in conservation could be applied on different locusts.

POSTER PRESENTATION

Multiplex ITS1 PCR for identification of two species of the genus *Phorbia* (Anthomyiidae: Diptera), pests on wheat

Ventsislav Ventsislavov, Hristina Krasteva, Olia Karadjova

Plant Protection Institute, Kostinbrod, Bulgaria

Introduction: *Phorbia fumigata* (Meigen, 1826) and *Phorbia haberlandti* (Schiner, 1865) are economically important pests on wheat in Bulgaria. Because of their similar morphology, the correct identification of both species is of great importance for the pest management. Currently these pests are being identified using morphological differences, which is suitable for the adult, but is very difficult or even impossible for the eggs and larvae.

Methods: The abdomens of collected male specimens were treated with KOH and species were determined following Hennig (1976) using stereomicroscope. DNA extraction was performed with High Pure PCR Template Preparation Kit (Roche, Germany), according to the protocol of the manufacturer. PCR with universal and specific primers was performed (annealing temperature - 50 ^{o}C). *Opomyza florum* (Fabricius, 1794) was used as a control for primer specificity.

Results: Total DNA from the two species was extracted and subjected to amplification of Internal Transcribed Spacer 1 (ITS1), 5.8S rRNA gene and Internal Transcribed Spacer 2 (ITS2) with universal primers ITS1 and ITS4. The amplicons were cloned and sequenced in both directions. Sequences were analyzed and three specific primers (two forward and one reverse) annealing on ITS1 region, differentiating the two species were designed. The performed Multiplex PCR showed clear differentiation of the two species, resulting in specific bands of 350 bp for *Ph. fumigata* and 610 bp for *Ph. haberlandti*.

Conclusions: For the first time new specific primers are developed, which are very reliable for identification of all stages of *Ph. fumigata* and *Ph. haberlandti*.

POSTER PRESENTATION

Possible function of norharmane in egg-laying by ergatoids and nymphoids of the lower termite, *Reticulitermes speratus* (Kolbe)

Shuji Itakura, Satoshi Kawabata, Hiromi Tanaka, Akio Enoki

Kinki University, Nara, Japan

The aromatic ß-carboline norharmane, which is located in the fat body of *Reticulitermes speratus*, stimulated the activity of juvenile hormone epoxide hydrolase (JHEH) of larva, ergatoid, and nymphoid homogenates. JHEH activity of ergatoid (16.67 ± 1.30 µU/termite) and nymphoid (20.94 ± 1.64 µU/termite) homogenates fortified with 0.1 mM norharmane was significantly higher than that of ergatoid (9.84 ± 1.69 µU/termite) and nymphoid (16.99 ± 0.60 µU/termite) homogenates to which no norharmane was added. Egg-laying by ergatoids and nymphoids, which ingested norharmane by feeding on norharmane-treated filter paper, was observed in 3 weeks. During rearing on filter paper without norharmane, egg-laying by ergatoids was observed in 5 weeks, whereas no egg-laying by nymphoids was observed throughout the incubation period of 8 weeks. Norharmane seems to be involved in egg development of ergatoids and nymphoids of *R. speratus*.

POSTER PRESENTATION

Host plants of the genus *Mussidia* (Lepidoptera: Pyralidae) in Kenya

Benjamin Muli[1], Johnnie van den Berg[2], Schulthess Fritz[1]

[1]International Centre of Insect Physiology and Ecology, Nairobi, Kenya, [2]North West University, Potchefstroom, South Africa

Introduction: The ear-borer, *Mussidia nigrivenella*, is one of the most important pests of maize in West Africa. Several species of the genus *Mussidia* have been reported from different regions of the world attacking different host plants. In east Africa, for example Kenya, the *Mussidia* spp. diversity and their hosts have not been explored hence little is known about them. Consequently, as part of the efforts to fill this knowledge gap, and probably explain why *Mussidia* spp. have not acquired pest status in the region.

Materials: Fruits were sampled in an attempt to investigate the diversity of *Mussidia* spp. and associated host plants in Kenya. Mature fruits were collected from trees, shrubs and vines suspected to harbor *Mussidia* spp. and were kept in the laboratory until insects in them emerged. The spatial distribution of *Mussidia spp.* was done on selected host plants during the study.

Results: Eight plant spp. (*Kigelia africana, Adansonia digitata, Afzelia quanzensis, Tamarindus indica, Strychnos spinosa, Strychnos madagascariensis, Canavalia cathartica* and *Canavalia ensiformes*) were found to host *Mussidia* spp. *Mussidia* spp were aggregated on *C. cathartica* and *S. madagascariensis* respectively while it was regular distribution on *K. africana*.

Conclusion: Different *Mussidia* spp. exist in Kenya and attack a variety of host plants. However, maize has not been exploited by the borer as a host as it is in west Africa.

POSTER PRESENTATION

Leptocybe invasa (Hymenoptera: Eulophidae) now in South Africa

Gudrun Dittrich-Schröder[1], Bernard Slippers[1], Stefan Neser[1], Zvi mendel[2], Michael J. Wingfield[1]

[1]Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, Gauteng, South Africa, [2]Department of Entomology, Agricultural Research Organization, 50250 Bet Dagan, Israel

The *Eucalyptus* gall wasp, *Leptocybe invasa* (Hymenoptera: Eulophidae) was initially discovered on species of *Eucalyptus* in the Middle East and Mediterranean region in 2000. This wasp is native to Australia although its discovery there was only noted after infestations in introduced environments. Although *L. invasa* is not problematic in Australia, *Eucalyptus* plantations in other countries have experienced significant damage. Since the initial reports, the wasp has spread extremely fast and today it covers the eucalyptus planting areas of the Mediterranean basin, southern Europe, northern and eastern Africa, and southern Asia from Iraq to India and Vietnam. Most recently it has also been reported from South Africa. Adults of *Leptocybe invasa* are small, ranging from 1.1 –1.4 mm, and are thus not easily seen in the field. Symptoms of *L. invasa* are, however, easily recognizable as galls present on the midrib, petiole and twigs of trees. After oviposition, five stages of gall development can be identified. As the gall matures its colour changes from green to a dark pink with slight variations depending on whether the gall is on the midrib, petiole or shoot and the exposure to the sun. The wasp attacks new growth of all age ranges of the tree, including nursery stock. Heavy galling causes the leaves to warp and in extreme cases may stunt the growth of the tree. A number of *Eucalyptus* species have shown susceptibility to *L. invasa*, including *E. botryoides, E. bridgesiana, E. robusta, E. saligna, E. tereticornis and E. viminalis. Eucalyptus camaldulensis* (and other members of the Exsertaria section), however, seems to be the most susceptible. Preliminary work suggests that control of this wasp will have to rely mainly on biological control of the galler and on an integrated approach of sylvicultural measures and breeding for resistance.

POSTER PRESENTATION

Effect of wavelengths on the *N*-acetyltransferase activity in *Dianemobius nigrofasciatus* (Orthoptera: Grillidae)

Norimitsu Izawa, Takeshi Suzuki, Makio Takeda

Kobe University, Kobe city, Japan

N-acetyltransferase (NAT) is known as the output system of the circadian rhythms and constitutes a large family of enzymes, found in a variety of organisms, which catalyze the transfer of an acetyl moiety from acetyl-CoA to monoamine substrates. Most of NAT family shows a feature whose activity is inhibited by light from. NAT is involved in many physiological functions in insects: inactivation of biological amines, formation of *N*-acetyldopamine and *N*-acetyloctopamine, an agent important for sclerotization of the cuticle, formation of puparium, tanning of oviposited eggs and synthesis of melatonin.

Deguchi (1981) showed effect of various intensities of monochromatic light on the night-time increase of NAT activity in organ cultures of chicken pineal organ. It was reported that NAT has a high sensitivity to light of around 500 nm wavelength. Later, Okano et al., (1994) clarified that there were two kinds of photoreceptors, pinopsin and iodopsin. Pinopsin was sensitive to blue light and iodopsin was sensitive to red light. Pinopsin had higher expression level than iodopsin. Hence, it was clarified that the highest NAT sensitivity shifted to middle wave length light.

It was clarified that NAT activity depended on light in *D.nigrofasciatus* head. NAT activity in nighttime was higher than daytime as in mammals and birds. Effect of wavelengths on NAT activity was measured in *D. nigrofasciatus*. The following monochromatic light was employed; 350, 400, 450, 500, 550, 600 and 650 nm. *D.nigrofasciatus* had the highest sensitivity to light of around 450 nm and 550 nm wavelengths. 450 nm Wavelength light had higher sensitivity level than 550 nm wavelength light. Hence, it was clarified that the most important light affecting NAT activity was blue light. Blue wave sensitive photoreceptors, blue wave (BW) opsin and cryptochrome which were therefore the candidates of photoreceptor that had the highest effects on NAT activity. Next plan is immunohistochemistry of BW opsin and cryptochrome to compare the expression position of NAT.

This study aims at developing human and eco-friendly pest control systems by targeting insect NAT.

POSTER PRESENTATION

The effects of different temperature conditions on the colony characteristics of *Bombus terrestris* L.

Fehmi I Gurel, Ayhan Gosterit

Akdeniz University Department of Animal Science, Antalya, Turkey

Introduction: In this work our aims were to compare the effects of three temperature regimes (24°C, 27°C and 30°C) on the colony development characteristics of *B. terrestris* and to find out optimal temperature condition for mass rearing of bumblebee.

Methods: A total of 300 queens which had been over wintered in artificial conditions were used. Queens were subjected to one of three temperature treatments at 24±0.5 °C, 27±0.5 °C or 30±0.5°C under constant humidity of 60 ± 5 %. All queens and colonies were furnished with unlimited amounts of sugar solution and fresh pollen collected from honeybee colonies.

Results: There were significant differences among treatments in terms of egg laying, colony production, saleable colony production and progeny queen production ratios, the colony initiation time, the number of egg cells in first brood, and the first worker emergence time. The highest egg laying, colony production and saleable colony production ratios were found at the 30°C treatment (86, 48, 34 %) followed by 27°C (42, 19, 13 %) and 24°C (43, 14, 12 %) treatments respectively. Similarly, at the 30°C queens developed more egg cells (4.72±0.22) in the first brood and started egg laying (12.47 ± 0.78 days) earlier than in the other treatments.

Conclusions: The results show that 30°C is the best temperature condition for colony development of *B. terrestris.*

POSTER PRESENTATION

Biology of *Trichogrammatoidea lutea* (Hymenoptera: Trichogrammatidae), a potential biological control agent for *Helicoverpa armigera* (Lepidoptera: Noctuidae)

Khethani V. Mawela[1], Kerstin Krüger[2], Rami Kfir[3]

[1]University of Pretoria, ARC-Plant Protection Research Institute, Pretoria, South Africa, [2]University of Pretoria, Pretoria, South Africa, [3]ARC-Plant Protection Research Institute, Pretoria, South Africa

Introduction: The African cotton bollworm *Helicoverpa armigera* is a major pest in many parts of the Old World. The egg parasitoid, *Trichogrammatoidea lutea,* is indigenous to South Africa and an important natural enemy of *H. armigera*. We assessed the life-history parameters of *T. lutea* on *H. armigera* to determine its potential as a biological control agent.

Methods: Forty pairs of *T. lutea* were each supplied daily with 20 UV-radiated *H. armigera* eggs. These were collected daily and incubated at 25°C. Age-specific fecundity and longevity of parents, and sex ratio of offspring were recorded. In addition, percent parasitism, development time and sex ratio on *H. armigera* eggs at five different constant temperatures (18–30°C) were determined.

Results: Mean longevity of male and female *T. lutea* was 5.6 and 8.6 days, respectively. *Trichogrammatoidea lutea* did not show a pre-oviposition period. The reproduction period lasted for up to 14 days. Females produced on average 52 offspring. Daily fecundity and parasitism per female were highest on the day of eclosion; both parameters decreased with age of females. The sex ratio changed with age of females from female- to male-biased after 3 days. The overall sex ratio of *T. lutea* progeny was 1:1. Parasitism and rate of development of *T. lutea* were highest at 27°C. The sex ratio was similar at all temperatures.

Conclusion: The study provides important information on the biology of *T. lutea* on *H. armigera* eggs as well as for mass rearing of this potentially promising biological control agent.

POSTER PRESENTATION

Stingless bees (Meliponini) and their nests in the Balsas savannah ("cerrado"), Ma, Brazil

Marcia Rego[1], Patricia Albuquerque[1], Giorgio Venturieri[2]

[1]Federal University of Maranhaonhão, Sao Luis,MA, Brazil, [2]EMBRAPA Amazonia Oriental, Belem, PA, Brazil

Introducion: The majority of stingless bees nest in hollows of trees, alive or dead.

Methods: The Meliponini nests were looked for from July/2006 to November/2007 in a cerrado area (07° 42' 58.5" S and 46° 11' 19.8" W), numbered and mapped with the aid of a GPS receiver. Nest characteristics like its height above the ground, stem diameters at breast height (DBH) of the trees and or branches diameters were annotated, as soon as the popular name of floral species, where the nests were found.

Results: A total of 110 stingless bee nests of 21 species were located. Among those, *Scaptotrigona* was the most abundant genus (36.4% of nests), followed by *Oxytrigona* (15.5%) and *Frieseomellita* (12.7%). The bees known as "tubi" (two belonging to *Scaptotrigona* genus), "tataíra" (2 *Oxytrigona*), "mané-de-abreu" (*Frieseomellita flavicornis*), "borá" (*Tetragona quadrangula*) and "jataí" (*Tetragonisca angustula*) were the most common species. The nests were found mainly in main trunks and branches of "sucupira-amarela" (*Pterodon aff. polygalaeflorus* - Fabaceae), "piqui" (*Caryocar brasiliense* - Caryocaraceae) and "puçá" (*Mouriri grandiflora* - Melastomataceae). Trees with larger diameter of the main trunk and bigger hollows were preferentially selected by bigger bees, like "uruçu" species (*Melipona flavolineata*) and "tiúba" (*Melipona fasciculata*), both not so abundant in the Maranhao cerrado anymore.

Conclusion: The stingless bees from Maranhão cerrado nest in some tree species with hollows in their trunks, but the environment destroyed by human action has been slowing down the nesting places and threatening these important insects.

POSTER PRESENTATION

Are females attracted by wound volatiles to cane splits? Early stages in the development of a plant derived attractant for raspberry cane midge

Carolyn Mitchell[1], Tom Shepherd[1], Nick Birch[1], Stuart Gordon[1], Jerry Cross[2], David Hall[3]

[1]SCRI, Dundee, United Kingdom, [2]East Malling Research, East Malling, Kent, United Kingdom, [3]Natural Resources Institute, Chatham Maritime, Kent, United Kingdom

Introduction: The raspberry cane midge, *Resseliella theobaldi,* is an important pest of red raspberry (*Rubus idaeus*) in the UK and much of north and central Europe. The adult midge lays eggs in the splits of young canes, either caused by natural splitting or by mechanical injury. The larvae feed on the pith causing lesions which allow entry of a range of diseases such as cane blight fungus and midge blight. There has already been a great deal of research into the development of female sex pheromone traps for local monitoring of male midges. However, advancement of this monitoring and mass trapping technology to aid the control of midge numbers requires an attractant to lure the females as they emerge from the soil in early spring (first generation) and during the second generation (coinciding with fruit harvest and the main time of fungal colonisation). The early stages in the identification of a plant volatiles released from cane wounds are discussed.

Materials and methods: Two separate methods are currently being used to identify possible attractants. (1) Behavioural assays observing the females preferences over split and unsplit canes. (2) Entrainment of volatiles from the cane splits and identification of these volatiles.

Results: Preliminary observations indicate that the presence of a split affects the behaviour of the female midge prior to oviposition. Entrainment shows variation in the wound volatiles released from the split and unsplit canes.

Discussion: The preliminary results are encouraging and provide ideas on how this will shape future work.

POSTER PRESENTATION

Selective antennal receptors for pheromone, non-host, and host compounds govern behavioural responses in a bark beetle

Martin N. Andersson, Mattias C. Larsson, Fredrik Schlyter

Department of Plant Protection Biology, Swedish University of Agricultural Sciences, Alnarp, Sweden

Host selection by conifer-inhabiting bark beetles is mediated by pheromones from conspecifics and kairomones from host trees. The response to attractive odours is modulated by non-host volatiles (NHV), originating from angiosperm trees. The spruce bark beetle, *Ips typographus*, uses aggregation pheromone and NHV in host location, but the role of kairomones in host attraction is unclear. Several repellent NHV are known, some with redundant, others with synergistic effects.

By means of single-sensillum recordings, we investigate the proportions of olfactory receptor neurons (ORNs) that respond to pheromones, host, and non-host volatiles, respectively, and we study if the behavioural pattern of redundancy and synergism among NHV could be explained by ORN response specificity.

We have recorded from 150 sensilla and obtained powerful responses to synthetic chemicals from more than 100 ORNs. Most receptor neurons respond specifically to one or a few compounds and dose-response trials show that specificity is highest at low doses. Four ORN classes responding to NHV have been characterised and these neurons occupy a surprisingly large proportion of sensilla. The response specificities of these neurons explain much of the behavioural redundancy and synergism observed among NHV. One neuron does not distinguish between three redundant GLV alcohols while synergizing compounds (verbenone and *trans*-conophthorin) are perceived by different ORNs. Six ORN classes that respond to host compounds have been characterised, suggesting that kairomone might be relevant in host tree location. Our results provide a basis for how different attractive and inhibitory signals are encoded by the insects' peripheral olfactory system.

POSTER PRESENTATION

Pathogenicity of *Metarhizium anisopliae* and *Beauveria bassiana* to the pea leafminer *Liriomyza huidobrensis*

Lorna N. Migiro[1], Nguya K. Maniania[1], Johnnie Van den Berg[2], Adenirin Chabi-Olaye[1]

[1]International Centre of Insect Physiology and Ecology (ICIPE), Nairobi, Kenya, [2]North West University, Potchefstroom, South Africa

Introduction: The pea leafminer, *Liriomyza huidobrensis*, is a polyphagus pest of vegetable and ornamental crops. Chemical control has shown to be ineffective. Entomopathogenic fungi are being considered as an alternative for its control.

Methods: Twenty 1-2 day-old adult *L. huidobrensis* were contaminated through a velvet cloth placed inside of a cylindrical plastic tube. They were allowed to walk for one minute, after which they were transferred to Perspex cages and fed on 10% sugar solution. The number of conidia picked by a single fly was determined by selecting 5 flies at random and vortexed to dislodge the conidia. Control insects were exposed to fungus-free velvet cloth. Mortality was recorded daily for 11 days.

Results: The number of conidia picked by single fly varied between 2.3-2.8 x 10^5 conidia ml^{-1}. All the fungal isolates tested were pathogenic to adult *L. huidobrensis*. However, there were significant differences in mortality between the fungal isolates, with the least pathogenic isolate causing mortality of 39.9% and 100% with the most virulent isolate. The lethal time to 50% mortality (LT_{50}) values varied between 5.5 days for the less virulent isolates, and 2.6 days for the most virulent isolates.

Conclusions: *Beauveria bassiana* and *M. anisopliae* are pathogenic to *L. huidobrensis*. However, the challenge is how to apply the fungus in the field. Studies are underway to design and test different contamination devices that could be used in the field.

POSTER PRESENTATION

Biological control of *Plutella xylostella*: role of generalist predators and enemy-enemy interactions

Freddy Miranda[2], Christer Bjorkman[1], Helena Bylund[1], Riccardo Bommarco[1]

[1]*Department of Ecology, Swedish University of Agricultural Sciences, Uppsala, Sweden,* [2]*Universidad Nacional Agraria, Managua, Nicaragua*

Introduction: The diamondback moth (*Plutella xylostella*) is a major pest in large parts of the world. It has developed resistance against almost all known insecticides, including Bt. Efforts to develop biological control have mainly focused on parasitoids. Less emphasis has been on the role of generalist predators.

Methods: The density of natural enemies (predators and parasitoids) and level of parasitism was estimated on farms using or not using insecticides in Nicaragua. The level of damage by *P. xylostella* on cabbage plants was estimated on the same farms. An exclosure experiment was performed, on semi-organic farms, to estimate the relative importance of different nataurel enemy types (flying vs. ground-dwelling).

Results: The density of generalist predators and parasitoids was higher on farms not using insecticides than on farms using insecticides. This difference translated into a lower damage of cabbage on farms not using insecticides. The exclosure experiment showed that flying and ground-dwelling natural enemies predated upon *P. xylostella* larvae to a similar extent, when either of them was excluded. However, when both types were allowed to act as enemies, there was a significant negative interaction between them.

Conclusions: Generalist predators, especially wolf spiders (Lyocsidae), but also rove beetles (Col.; Staphylinidae), jumping spiders (Salticidae) and damsel bugs (Heteropt.: Nabidae), are important natural enemies of *P. xylostella* and should be considered when developing biological control programs. The possible negative interaction between different types of natural enemies needs to be explored further to reduce the risk of counterproductive efforts when developing biological control methods.

POSTER PRESENTATION

Vibrational communication in the predaceous spined soldier bug *Podisus maculiventris* (Say) (Pentatomidae: Asopinae)

Alenka Zunic[1], Andrej Cokl[1], Meta Virant Doberlet[1], Jocelyn G. Millar[2]

[1]Department of Entomology, National Institute of Biology, Ljubljana, Slovenia, [2]Department of Entomology, University of California, Riverside, United States

Introduction: The predatory bug *Podisus maculiventris* has received extensive attention as a potential biological control agent. Numerous studies have examined predator-prey interactions but little is known about vibrational communication in this species. Mating behaviour of *P. maculiventris* was observed, and vibrational signals used in intraspecific communication were recorded and analyzed.

Methods: Vibrational signals were recorded from adults placed on a non-resonant loudspeaker membrane, and by laser vibrometry of bugs placed on a plant cutting. Behaviour was observed on a freshly cut plumbago shoot. In playback experiments, bugs were stimulated by pre-recorded males' signals, or by pre-recorded vibrations produced by a female walking on a plant.

Results: Males produced vibrational signals by different mechanisms: vibration of the abdomen (MS-V), percussion with the front legs (MS-P), or tremulation of the body (MS-T). Observations of mating behaviour and playback experiments showed that MS-V signals had long range calling and short range recognition functions. MS-T signals were emitted at close range and were essential for copulation to occur. In the courtship phase of mating behaviour, males emitted combined pulse trains composed of a MS-V pulse following a MS-T pulse. MS-P signals were not emitted in a particular behavioural context; they were emitted during both calling and courtship phases. In male-male interactions, signals were produced by only one male, and no regular alternation of signalling was recorded.

Conclusions: Compared to phytophagous Pentatomidae, *P. maculiventris* produce vibratory signals by three different modes. The signals are emitted only by males, and females search for the calling male.

POSTER PRESENTATION

Molecular phylogeny of Apoidea (Hymenoptera) with special emphasis on sphecid wasps

Volker Lohrmann[1], Michael Ohl[1], Lars Podsiadlowski[2], Christoph Bleidorn[3]

[1]Museum für Naturkunde der Humboldt-Universität zu Berlin, Berlin, Germany, [2]Freie Universität Berlin, Institut für Biologie, Chemie, Pharmazie – AG Evolution und Systematik der Tiere, Berlin, Germany, [3]Universität Potsdam, Institut für Biochemie & Biologie – AG Evolutionsbiologie / Spezielle Zoologie, Golm, Germany

Introduction: Within the aculeate Hymenoptera the monophyly of the Apoidea [bees and digger wasps (=Sphecidae sensu lato)] is well supported but its basal phylogeny is still controversial discussed.

Methods: Sequences from the nuclear long-wavelength-rhodopsin and the mitochondrial cytochrom-c-oxidase (subunit I) from different representatives of the aculeate Hymenoptera, with special emphasis on digger wasps, were analysed using maximum parsimony, maximum likelihood and Baysian inference methods.

Results & Discussion: Compared with previous phylogenetic studies based on morphology, the results of the molecular analyses are controversial but correspond in the absence of support for the Sphecidae s. l (sensu BOHART & MENKE). The relationships within the Sphecidae sensu stricto correspond largely with recent morphological studies. There is circumstantial evidence that the Ampulicidae and Sphecidae s. str. together form a monophyletic group, whereas the relationships within this taxon are still uncertain. Although there is no evidence for a definitive phylogenetic position of the Heterogynaidae; it can be excluded that they are the sistertaxon to all other Apoidea. Instead, they are probably a derived group within the Crabronidae. In conflict to the majority of current morphological studies, the molecular analyses provide no support for the Crabronidae and Bembicinae. Some molecular analyses imply a close relationship between Philanthinae and the monophyletic bees.

Since the phylogeny of the Crabronidae as the phylogenetic position of the Heterogynaidae (and other questions) remain uncertain, further studies should be made including more taxa and using more genes.

POSTER PRESENTATION

Insecticidal and plant growth regulator effects of some botanical materials

Ersin Polat[1], Fedai Erler[2], Halil Demir[1], Huseyin Cetin[3], Tugba Erdemir[2]

[1]Akdeniz University, Department of Horticulture, Antalya, Turkey, [2]Akdeniz University, Department of Plant Protection, Antalya, Turkey, [3]Akdeniz University, Department of Horticulture, Antalya, Turkey, [4]Akdeniz University, Department of Biology, Antalya, Turkey, [5]Akdeniz University, Department of Plant Protection, Antalya, Turkey

Introduction: The major pests of mushroom are cecidomyiid, sciarid and phorid flies; *Megaselia halterata* (Wood) (Diptera: Phoridae) being the most common species in Turkey. In the present study, five hot water plant extracts, namely; *Origanum onites* L., *Inula viscosa* (L.), *Melisa officinalis* L., *Ononis natrix* L., *Teucrium divericatum* Sieber, and two commercial neem-based products, Neemazal-T/S® and Greeneem® oil, were tested for insecticidal activity against *M. halterata* and for plant growth regulator (PGR) effect on the white button mushroom (*Agaricus bisporus* L.).

Methods: Experiments were conducted in a mushroom house in the campus of Akdeniz University (Antalya, Turkey) in three successive growing periods. The concentrations were 50 g/l water for all hot water plant extracts, and 5 ml/l water for both neem-based products. Only one application was made by soil drench at the spawn-runned stage in each growing period. The insecticidal activity of test materials was evaluated by measuring larval damage and counting the emerging adults of the pest in each treatment. Their PGR effects were evaluated by measuring cap and stalk size (cm), yield per bag (kg) and stalk length (cm).

Results: All test materials caused significantly reduction in mean number of emerging adults and larval damage compared to water-treated controls. All botanical material treatments significantly increased yield and were better in visual quality parameters.

Conclusion: Overall results suggest that all botanical materials can be used for the control of mushroom phorid fly and may also be used to enhance the yield and other quality parameter of white button mushroom.

POSTER PRESENTATION

Character displacement of calling songs in *Euterpnosia varicolor* and *Euterpnosia alpine* (Hemiptera: Cicadidae) from Taiwan

Chen-Hsiang Chen, Shiuh-Feng Shiao

Department of Entomology, National Taiwan University, Taipei, Taiwan

Introduction: Calling songs of most *Euterpnosia* species don't share a common general pattern, and it is considered as a good character for species identification. *Euterpnosia varicolor* and *Euterpnosia alpina* are two closely-related species; evidences show the character displacement of calling songs between these two species may play an important role in reinforcement of reproductive isolation in sympatric area (Guanwu, Hsinchu County, Taiwan).

Methods: Calling songs were recorded in the field using a digital recorder with a shotgun microphone. The microphone was placed as close to the insects as possible, generally not far away from 5 M, The calling song were analyzed using BatSound Pro and Avisoft-SASLab Pro. Molecular analysis using mitochondrial cytochrome oxidase subunit I (COI) sequences was performed to further compare the population differences.

Results: The dominant call pitch (frequency) is approximately at 5.1-5.8 kHz in *E. varicolor*, and at about 10.3 kHz in allopatric *E. alpine.* The dominant call pitch of *E. varicolor* increases from 5.1-5.8 kHz to 11.9 kHz; meanwhile, the frequency increases from 10.3 kHz to 12.3 kHz in sympatric populations of *E. alpina* (overlapping zone). The group of pulses in *E. varicolor* increases from 1-1.5 per sec to 2.5 per sec, and decreases from 29 per sec to 22 per sec in sympatric *E. alpina* population.

Conclusion: The increase of call pitch and the changes of pulse group for *E. varicolor* and *E. alpina* in sympatric area meet the criteria for reproductive character displacement. And the molecular data also reveal that two sympatric *Euternosia* species have not yet evolved to new species from their conspecific but allopatric populations based on their genetic distances.

POSTER PRESENTATION

Integrated control of *Lobesia botrana* by using IGRs, *Bacillus thuringiensis* products and neonicotinoid; relationship between the insect infestation and development of *Botrytis cinerea*

Thomas Thomidis, Emmanouel Navrozidis, Zisis Michailides

A.T.E.I. Thessaloniki, Sindos Thessaloniki, Greece

Introduction: *Lobesia botrana* (Denis & Schiffermueller) (Lepidoptera: Tortricidae) is the major grape berry moth in vineyards of southern Europe. IThe caterpillars gnaw the almost ripe fruits and various moulds, in particular *Botrytis*, develop very rapidly on the wounds. The main aim of this study was to investigate the effectiveness of two insect growth regulators Lufox 105EC (lufenuron + fenoxycarb) and Cascade 10WDC (flufenoxuron), two commercial products of *Bacillus thuringiensis* (XenTari DF, Dipel 150 Dust) and thiamethoxam (Actara 25WC) in managing *L. botrana*.

Methods: The growth regulators were applied in the beginning of the second flight, *B. thuringiensis* products were applied one week after the beginning of the second flight, while deltamethrin was applied in the peek of the second flight.

Results: The results showed that the insect growth regulators were the most effective. There was no significant difference between flufenoxuron and lufenuron+fenoxucarb. Less effective were *B. thuringiensis* and the insecticide thiamethoxam.

In addition, the relationship between the percentage of attacked fruits from *L. botrana* and rotted berries from *B. cinerea* was examined in the experimental field where the above insectices were applied. In all treatments, a relationship between the percentage of attacked berries from *L. botrana* and the rotted berries from *B. cinerea* was found. Also, it was noticed that larvae were grown, pupated and adult-emerged independent from the percentage of fungal infection.

Discussion: This study showed the possible use of the insect growth regulators against *L. botrana* and the relationship between the insect infestation and development of *B. cinerea.*

POSTER PRESENTATION

Scots pine felling debris as a substrate for development of saproxylic beetles

Jiri Foit

Faculty of Forestry and Wood Technology, Mendel University of Agriculture and Forestry in Brno, Brno, Czech Republic

It is widely known, that felling debris is potential substrate for many species of saproxylic beetles. The aim of this study was to find out, which species of saproxylic beetles use different types of Scots pine (*Pinus sylvestris* L.) felling debris for their development, how do the season of felling and the different ways of treatment of felling debris (concentrating to the mounds and cross-cutting) affect species composition, abundance, and success of development. The research was carried out in planned mature cutting, thinning in stands older than 40 years, and in juvenile thinning. In chosen stands many elaborately designed felling measures took place to produce required felling debris. From 2006 to 2008 colonization of this felling debris by saproxylic beetles and their development were thoroughly studied. The season of felling and the way of treatment of the felling debris has significant impact on species composition, abundance and success of development of saproxylic beetles. Felling debris produced during winter and spring supports development of high abundances of important insect pests, above all *Pityogenes chalcographus* (L.), and *Ips acuminatus* (Gyll.). On the contrary felling debris produced in later summer (August and/or September) does not allow above mentioned insect pests to develop there. The felling debris situated in the inner parts of the felling debris mounds is significantly less attractive for the most species of saproxylic beetles than felling debris left dispersed or situated on the surface of the mounds.

This study was supported by the project VaV MZP CR TARMAG SP/2D4/59/07

POSTER PRESENTATION

Extinction of the genus *Neurohelea* (Diptera: Ceratopogonidae) in Europe?

Andrea Tóthová

Masaryk University, Brno, Czech Republic

Introduction: The species *Neurohelea luteitarsis* (Waltl, 1837) is the only representative of the genus *Neurohelea* Kieffer in Europe. So far it has been reported from 4 EU countries - Great Britain, Belgium, Ireland and Germany; however in Germany was lately proclaimed extinct.

Material and Methods: About 40 specimens of *Neurohelea* were collected during years 2005-06 in PLA Jizerské hory (Czech Republic) using Malaise traps. The chosen specimens were mounted into microscope slides, measured and examined.

Results: While processing the collected specimens of *N. luteitarsis*, we observed some morphological features that have not been described before. We observed 3 fully developped spermathecae in all female specimens. There is an indication that the number of spermathecae not an abberation and this fact might support the potential phylogenetic relation of *Neurohelea* to *Physohelea.* We have also found in females abdominal saccules of unknown function; puffy, pale but clearly visible formations turn to residuals after the slides are mounted. These structures are known only within Palpomyiini+Stenoxenini tribes and their presence in Heteromyiini might show new relations between these tribes. The other unique morphological feature we observed is the interruption of the vein r-m observed in both sexes of all specimens of our collection.

Conclusions: We consider the report of *N. luteitarsis* and its new features an important reference of a species that has been proclaimed extinct in the neighbouring Germany. The study has been supported by the Ministry of Education grant MSM No. 0021622416.

POSTER PRESENTATION

Mushrooms appearing from insects in Japan

Hiroki Sato[1], Sayaka Ban[2], Hayato Masuya[3], Tsuyoshi Hosoya[4]

[1]Forestry and Forest Products Research Institute, Kumamoto, Japan, [2]NITE-NBRC, Kazusa, Japan, [3]Forestry and Forest Products Research Institute, Tsukuba, Japan, [4]National Museum of Nature and Science, Tsukuba, Japan

Insects are killed by several kinds of microorganisms. Some fungal groups make infection to insects, kill them, and produce curious mushroom on the cadavers. Dr. Kobayasi was one of the most active mycologists who studied entomopathogenic fungi in Japan and described more than 150 species mainly in *Cordyceps* and *Torrubiella,* showing approximately 30% of species in those genera were by his description. Japan is rich in entomopathogenic fungal flora that may have wide source for controlling insect pests. Insect cadavers showing mushrooms collected in the field must be identified, and should be compared with type specimen in detail for identification. However, the information of preservation is obscure about specimens of Dr. Kobayasi. During the total re-arrangement of the fungal specimens in National museum of nature and science in the last two years, many specimens of entomopathogenic fungi, both registered and non-registered, including *Cordyceps, Torrubiella* were found out mainly immersed in liquid formalin. We evaluated those specimens for their type status referring to their original descriptions and their current condition under preservation. More than one hundred specimens were found out for the candidates of holotype specimens, and to date, we judged nineteen specimens of *Torrubiella* as holotype: *Torrubiella alboglobosa, T. aurantia, T. corniformis, T. ellipsoidea, T. formosana, T. fusiformis, T. globosostipitata, T. longissima, T. mammillata, T. minutissima, T. miyagiana, T.neofusiformis, T. oblonga, T. ooaniensis, T. pallida, T. rosea, T. ryogamimontana, T. ryukyuensis, T. superficialis.* Most of all the specimens found out very good condition.

POSTER PRESENTATION

Agronomic techniques to control *Lobesia botrana*

Zisis Michailides, Aikaterini Vartholomeou, Emmanouel Navrozidis, Christopher Payne, Georgios Salpiggidis

A.T.E.I. Thessaloniki, Sindos, Thessaloniki, Greece

Introduction: The grapevine moth *Lobesia botrana* (Denis & Schiffermuller) (Lepidoptera: Tortricidae) is a key pest of grapevines in Greece. As part of a broader study on integrated pest management, we investigated the effects of different cultural methods on the establishment and survival of *L. Botrana*.

Methods: Application of different nitrogen levels (30 and 100 N units applied as Ammonium Sulphate or 70 N units applied as Agrobiosol); summer leaf and shoot pruning; application of growth regulators (Regalis, prohexadione-calcium or Falgro, gibberellic acid).

Results: The results showed that there were significant differences among the three levels of N application. The lowest *L. botrana* infestation rates were found in plots treated with 30 units of N applied as Ammonium Sulphate and plots that received some summer pruning. Following the application of plant growth regulators, the lowest *L. botrana* infestation levels were found in the plots treated with Regalis or Falgro at manufacturers recommended concentrations. On vines where growth regulators had been applied, the clusters had fewer berries than those not treated with growth regulators.

Discussion: This study suggests the use of the growth regulators Regalis and Falgro reduced the *L. botrana* infestation. Reduction of the *L. botrana* infestation is also possible by application 30 units' ammonium sulfate. Summer pruning is recommended in reducing *L. botrana*'s infestation.

POSTER PRESENTATION

Chemical characterization of the pheromone trail in *Reticulitermes lucifugus.*

Valeria Tubiolo[1], Claudio de Pasquale[2], Giuseppe Alonzo[2], Ezio Peri[1], Alfonso Agrò[1], Stefano Colazza[1]

[1]Department S.EN.FI.MI.ZO, Università di Palermo, Palermo, Sicilia, Italy, [2]Department ITAF, Università di Palermo, Palermo, Sicilia, Italy

Reticulitermes lucifugus (Rossi) is a subterranean termite present in Italy where is a serious pest of wooden human structures, historic buildings and cultural heritage. *Reticulitermes spp* , in the search for food, react to chemical trail pheromones laid from abdominal sternal glands. Here we report the results of behavioural tests and the chemical investigations of trail pheromone in workers of *R. lucifugus.* Experiments were conducted in an open arena. A video tracking and motion analysis system was used to evaluate the behaviour of *R. lucifugus* in the presence of naturally laid trails, or in the presence of trails prepared with hexane extracts of the sternal glands (4°-6° abdominal segment), and, as a control, hexane extracts of the 6°-8° abdominal segment. Termites followed either naturally laid trails and trails made by solvent extracts of the sternal glands. While, they did not reacted to trails made by control solvent extracts. Hexane extracts of the sternal glands were then analyzed by GC-MS. The mass spectra of sternal gland hexane extracts were recorded from 42 to 550 m/z. Commercial NIST 98 mass spectra library search on the diagnostic of relative intense ions, and the determination of Kovats indices according to the linear long chain hydrocarbon standard compounds, allowed to identify alcoholic, aldehydic and linear and branched hydrocarbon in the solvent extracts.

POSTER PRESENTATION

Soybean rust protection using the Integrated Pest Management Pest Information Platform for Extension and Education (ipmPIPE)

Kitty Cardwell, Martin Draper, Dennis Kopp, Elizabeth Li

USDA, Washington, DC, United States

Introduction: In late 2004, aerobiological models predicted that Asian soybean rust (SBR) might be introduced to the continental U.S. from South America. Soon after Hurricane Ivan's landfall, SBR was reported in nine states. No damage resulted from SBR in 2004, but uncertainty about 2005 weighed on producers. The pathogen was expected to survive along the US southern coast on kudzu, potentially compromising 75 million acres of soybeans in 2005. To avoid unnecessary spraying of fungicides in 2005, an education and extension system was launched to provide timely, web-based information about SBR risk to soybean producers. The system is now known as *ipm*PIPE.

Methods: Field observers in every soybean producing state monitor sentinel plots and submit weekly data on disease presence/absence and management recommendations in their respective states. The information system, a partnership of private and public sector agricultural scientists and grower organizations, maps field observations and visualizes the movement of soybean rust throughout the year, apprising soybean producers of risk and management options.

Results: In `05 and `06, *ipm*PIPE saved soybean producers an estimated $299 million/year in fungicides not applied. By 2007, 74% of fungicide application decisions to manage SBR were based on *ipm*PIPE advisories, valued at $100 million dollars in decision support.

Conclusions: The *ipm*PIPE is a coordinated effort of agricultural industry, scientists, extension specialists, and educators. In addition to SBR, the *ipm*PIPE facilitates pest risk management by monitoring movement and delivering timely expert advice to growers for other invasive and migratory pests across Mexico, the U.S. and Canada.

POSTER PRESENTATION

Differentiation of follicular cells in panoistic ovarioles of *Gryllus bimaculatus* (Insecta: Orthoptera)

Janusz Kubrakiewicz

Zoological Institute, University of Wroclaw, Wroclaw, Poland

In *Gryllus* ovarioles three distinct zones can be recognized along their anterior-posterior axis: terminal filament, germarium and vitellarium. Germarium houses oogonia and early meiotic oocytes, while vitellarium is formed by a linear array of ovarian follicles (oocytes covered by somatic follicular epithelium) in progressively advanced stages of oogenesis. Germ cells in the germarium are accompanied by few somatic prefollicular cells (pFCs). Some of the pFCs are located peripherally and adhere to the ovariole basal lamina, while others can be found inside the ovariole, among the germ cells. In the previtellogenic follicles somatic cells stretch over the surface of the growing oocytes to form follicular epithelium. Single follicular cells (FCs) can be found inside the ovariole, at the border of neighboring ovarian follicles. FCs proliferate intensively until the advanced stages of previtellogenesis. Those on the surface of the oocyte (main body FCs) become cuboidal with bilobate nuclei. The “excess” of FCs crowd in between the ovarian follicles thus forming interfollicular stalks. During vitellogenesis main body FCs change their shape, become rounded and not tightly apposed to each other so that the follicular epithelium becomes patent. In the late stages of vitellogenesis a few, single FCs located on the ventral side of the ovarian follicle form short processes towards the oocyte surface. These processes mould canals of the micropyles. FCs in panoistic ovarioles of *Gryllus* do not exhibit any migratory activity. Changes in their positions and shape result exclusively from their proliferative activity and reorganization of the cytoskeleton.

POSTER PRESENTATION

Cuticular hydrocarbon profiles of inquiline–host pairs of ants: a search for patterns

Kari Vepsäläinen[1], Riitta Savolainen[1], Toshiharu Akino[2], Pekka Punttila[3]

[1]University of Helsinki, Helsinki, Finland, [2]National Institute of Agrobiological Sciences, Tsukuba, Japan, [3]Finnish Environment Insitute, Helsinki, Finland

Introduction: Social-parasitic ant species must trespass the semiochemical defence of their host. This may be achieved if the host and parasite ants are related chemically, or if callow parasites are odourless and acquire the host-colony odour when invading the nest. Here we test the alternative hypotheses.

Methods: We assessed cuticular hydrocarbon (CHC) profiles of *Myrmica* species: three inquiline–host pairs, *karavajevi–scabrinodis*, *hirsuta–sabuleti* and *microrubra–rubra* (inquiline recently synonymized with its host), and six additional *Myrmica* species. We collected ten virgin queens from one nest per species (of two *hirsuta* nests). Additionally, we included established, old *hirsuta* queens found in the nest, and lab-mated queens; virgin queens from two nests were cross-mated with males from the opposite nest. We analysed the samples using non-metric multidimensional scaling (NMDS).

Results: NMDS ordinated the samples to species-specific clusters, such that each inquiline and its host grouped as neighbours. The *hirsuta* samples mostly clustered by queen status and age, with lab-mated nests at opposite ends of the NMDS space.

Conclusions: The semiochemical similarity of inquiline and host concur with phylogenetic studies suggesting sympatric speciation of some inquilines within their host colonies. Distinctiveness between *rubra* and its inquiline agrees with population-genetic studies implying that *microrubra* is a good species at least *in statu nascendi*. To understand better the role of semiochemicals in inquiline–host relationships, analyses of details of CHC profiles are needed to find possible key compounds—and their origins— that enable the inquiline to integrate with the host colony.

POSTER PRESENTATION

Artificial diet with tomato juice for larvae of *Bactrocera oleae* (Diptera: Tephritidae)

Emmanouel Navrozidis, Minos Tzanakakis

A.T.E.I. Thessaloniki, Sindos, Thessaloniki, Greece

Introduction: In nature, oviposition and larval growth of the olive fruit fly *Bactrocera oleae* (Rossi) (Diptera: Tephritidae) occur only in the mesocarp of fruits of the genus Olea, including the cultivated olive.

Methods: Larvae of *B. oleae* were reared on Rey's (1970) reference artificial diet in which the water was replaced by canned tomato juice, and the nutritive components were gradually reduced or omitted altogether one by one maintaining the pH at 4. The criteria for comparison and selection of diets were the duration of the larval stage, pupal weight, yield in adults and adult fecundity and fertility.

Results: The diet finally selected was consisted of: tomato juice (Sekove) 51.5 ml, cellulose powder 21.5 g, brewer yeast (Schwechat, Vienna) 8 g, chickpeas seedlings (*Cicer arietinum*) 15 g, potassium sorbate (Merc) 0.05 g, methyl-p-hydroxybenzoate (Merc) 0.1 g and HCL 2N 3 ml to a pH of 4.The yield of this diet in adults over neonate larvae was 69.7 %, the mean pupal weight 6.4 mg and larval development was completed in 9.6 days at 25 ± 1^{o} C. The female in F_3 generation produced 15.3 eggs per day from 7^{th} until 17^{th} day of their lives and the eclosion was 94.1 %.

Discussion: The suggested solid artificial diet was simpler and contained 25% less chickpea seedlings and 20% less brewer yeast than Rey's reference artificial diet.

POSTER PRESENTATION

Distribution of saproxylic insects on standing Scots pine trees with the relation to diameter, thickness of the bark, and height above the ground

Jiri Foit

Faculty of Forestry and Wood Technology, Mendel University of Agriculture and Forestry in Brno, Brno, Czech Republic

The aim of this study was to examine the composition of coenosis of saproxylic insects developing on the standing Scots pine trees (*Pinus sylvestris* L.), to evaluate home ranges of particular species, and to assess impact of the basic factors (section of the tree, thickness of the bark, diameter of the trunk/branch, and height above ground) on the composition of insect communities. Eighty randomly chosen freshly dead standing pine trees were thoroughly analyzed during the spring 2006 in the area of Drahanska Highlands. Thirty-five species of saproxylic insects were found. Preferred home ranges for the development of all abundant species were evaluated along the transect from the tree base to the thinnest branches. At least four well separated guilds of species were found by means of the Correspondence Analysis. Three of these guilds can be described as typical for the specific part of the tree. All examined environmental factors (see above) have significant impact on the composition of studied communities. Factor “section of the tree” explains almost all explained variance of the species data itself. However, this factor can be largely substituted by combination of pure metrical parameters (thickness of the bark, diameter of the trunk/branch, and height above ground). The most significant of these parameters is thickness of the bark. Although examined factors have undisputed impact on the composition of studied communities, major part of the variance of the species data must be attributed to other factors.

This study was supported by the project VaV MZP CR TARMAG SP/2D4/59/07

POSTER PRESENTATION

Evaluation of mini-barcodes for the identification of tephritid fruit flies (Diptera, Tephritidae)

Jeroen Van Houdt[2], Floris Breman[2], Massimiliano Virgilio[1], Thierry Backeljau[3], Marc De Meyer[1]

[1]Entomology Section, Royal Museum for Central Africa, Tervuren, Belgium, [2]Joint Experimental Molecular Unit, Brussels/Tervuren, Belgium, [3]Dept Recent Invertebrates, Royal Belgian Institute of Natural Sciences, Brussels, Belgium

The family of Tephritidae is composed of more than 4,000 species and more than 350 are of economic importance (EI). Because of the user interest and the reasonable taxonomic knowledge the Tephritid Barcoding Initiative (TBI) was initiated in 2006. TBI aims at obtaining DNA barcodes for all EI species and the majority of their congeners. Most of the source material originates from museum collections and is often not suitable for the generation of full DNA barcodes (650bp). The full length barcode could be amplified for most specimens (88%) collected after 2001. However, this success rate dropped dramatically to less than 50% for older specimens. Therefore we evaluated the applicability of mini-barcodes for the identification of tephritid fruit flies in 88 specimens collected between 1961 and 2007. We developed DNA barcodes of different lengths, being 450 bp, 340 bp and 220 bp. The 450 bp marker had a slightly higher success rate compared to the full DNA barcode. However, the amplification success of the 340 bp marker was substantially higher. A 100% success rate for specimens collected after 1990 was obtained, but this decreased to 40% for specimens collected between 1990 and 1980. More than 95% of the latter specimens and almost 60% of the oldest specimens (before 1980) rendered a PCR product for the 220 bp marker. The power of these mini-barcodes to discriminate tephritid fruit fly species is evaluated and discussed.

POSTER PRESENTATION

Synopsis of the genus *Chloropepla* Stål with a phylogenetic analysis of the species (Hemiptera: Heteroptera: Pentatomidae)

Jocelia Grazia, Caroline Greve, Cristiano Schwertner

Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil

Introduction: In this paper, a cladistic analysis based on morphological data of the genus *Chloropepla* is presented. Redescription of the genus and a key for all species are also done. *Chloropepla* was first described to include *Loxa vigens* Stål, 1860 (Stål 1867). Currently the taxon is composed by nine species, distributed exclusively on South America.

Methods: The data matrix comprised ten species: nine of *Chloropepla* and *Mayrinia curvidens* (Mayr, 1864), defined as outgroup based on literature. Only adult general and genitalia morphology characters were included.

Results: The analysis of 20 informative characters, seven of general morphology, two of female and eleven of male genitalia morphology resulted in one most parsimonious tree that shows *Chloropepla* as a monophyletic taxon. The monophyly were sustained by six synapomorphies: 1) jugae slightly overlapping clypeus at apex, 2) mesosternal carina strongly developed, 3) long evanescent ostiolar rugae, 4) marginal process of dorsal rim of pygophore present, 5) reduced membranous conjuntiva, almost totally obscured by phallotheca and 6) collar process on base of vesica. The relationships found among the species are: (*C. aurea*, *C. pirani*) (*C. vigens*, *C. paveli*) (*C. lenti C. stysi C. rolstoni C. tucuruiensis*, *C. dollingi*). The clade formed by *C. stysi + C. rosltoni + C. dollingi + C. tucuruiensis* is the best supported one, all characters corresponding to morphology of male and female genitalia. This group includes species distributed on Amazonian region only, revealing probably a congruence between the area and taxon history.

POSTER PRESENTATION

Dynamics of intraspecific interactions in blowflies under the influence of phenobarbital: Ecological applications in the forensic context

Juliana Gião, Wesley Godoy

Universidade Estadual Paulista; Julio de Mesquita Filho;- UNESP, Botucatu, São Paulo, Brazil

Introduction: We evaluated the effect of phenobarbital on the population dynamics of *Chrysomya albiceps*, in an attempt to compare behaviour patterns in species of forensic importance by using a population growth model.

Methods: An oligidic diet containing powdered milk, agar, yeast, nipagin, casein and chicken hearts was used as a rearing medium. Scramble larval competition was established in the laboratory by setting up six larval densities. A larval setting was maintained in 50 g of the oligidic diet as a control, and another in the same diet including phenobarbital (150 mg/Kg). Fecundity was estimated by counting the number of eggs per female, and survival by recording the emergent adults in each larval density. A population growth mathematical model was used to analyse the dynamic behaviour of flies, comparing the control diet with the diet containing the drug.

Results: The population dynamics of *C. albiceps* was slightly changed as a response to addition of phenobarbital to the artificial diet. Apparently, this drug produced destabilising effects, anticipating bifurcations and consequently the occurrence of cycles and chaos. No qualitative change in dynamic behaviour was found after the introduction of the drug, but quantitative changes were observed.

Conclusions: Studies such as this are important in terms of forensic entomology because they characterise patterns of dynamic behaviour inherent to different taxonomic groups, by mixing empiricism and population theory.

POSTER PRESENTATION

Presence of cytokinin-producing *Wolbachia* in different plant-leafminer systems and associated plant physiological alterations

Wilfried Kaiser[1], Elisabeth Huguet[1], Céline Commin[1], Carlos Lopez-Vaamonde[2], Jérôme Casas[1], David Giron[1]

[1]*Institut de Recherche sur la Biologie de l'Insecte, CNRS- University of Tours, Tours, France,* [2]*National Institute of Agronomic Research (INRA), Orléans, France*

Introduction: The nutrition hypothesis states that galling or mining, two major forms of endophytophagy in insects, provide enhanced nutrition over other external-feeding modes, and allow endophagous organisms to avoid major plant defences. This behaviour can also be reinforced by manipulating the plant physiology and leafminer insects have been shown to create an "optimal" nutritional micro-environment through cytokinin production by their endosymbiotic partners. This study aims to explore the presence of cytokinin-producing *Wolbachia* in different plant-leafminer systems and associated plant physiological alterations.

Methods: Using ELISA assays and colorimetric techniques the amount of phytohormones and nutrients in mined areas were recorded. Isopentenyl transferase gene expression (key enzyme of the cytokinin biosynthetic pathway) was investigated by RT-PCR. Using the Wolbachia specific *wsp* and *ftsz* genes and the 'green-island' phenotype we investigated the simultaneous presence of *Wolbachia* and visible altered host-plant physiology.

Results: Our results clearly show that leafminer insects trigger host plant physiology modification through an unexpected association with cytokinin-producing endosymbiotic bacteria. This plant physiology manipulation induced by a large accumulation of cytokinins in the mined tissues is responsible for the preservation of functional nutrient-rich green tissues at a time when leaves are otherwise turning yellow.

Conclusions: The primary role played by *Wolbachia* in the synthesis of cytokinins and in the induction of nutrient-rich tissues is of considerable ecological value to the development of the leafminer larvae as it allows the insect to maintain a favourable nutritional environment in an otherwise degenerating context.

POSTER PRESENTATION

Isolation and characterization of circadian clock genes *period* and *timeless* in Mediterranean flour moth, *Ephestia kuehniella*

Alena Kobelková[1], David Doležel[3], Radka Závodská[2], Ivo Šauman[3]

[1]*Faculty of Science, University of South Bohemia, Ceske Budejovice, Czech Republic,*
[2]*Pedagogical Faculty, University of South Bohemia, Ceske Budejovice, Czech Republic,*
[3]*Biology Center ASCR, Institute of Entomology, Ceske Budejovice, Czech Republic*

Introduction: Although homologous circadian genes are found in insect clocks, their contribution to circadian timing system may be different. Striking differences in the clock gene regulation were found between master clocks of the fruitly, *Drosophila melanogaster* (Diptera) and the silkmoth, *Antheraea pernyi* (Lepidoptera) (Sauman and Hashimi, 1999). Therefore we have extended our research to relatively primitive lepidopteran species, the Mediterranean flour moth (*Ephestia kuehniella*), in order to explore how well the *Antheraea* model is conserved within Lepidoptera.

Methods: Gene walking strategy supplemented with 3´and 5´ RACE were employed to clone full-length *per* and *tim* cDNA sequences. Northern and Southern analyses were used for further characterization of both genes. *per* and *tim* expressing neurons in *Ephestia* brain were localized using *in-situ* hybridization with digoxigenin-labeled RNA probes.

Results: *Ephestia kuehniella* has been used for the first time as a model organism for circadian rhythm studies. Full-length cDNA sequences encoding the circadian clock genes *period* and *timeless* in *E. kuehniella* were cloned. Southern analyses confirm one copy of *per* and *tim* gene, respectively, within both sexes. *In situ* hybridization revealed expression of *per* and *tim* RNAs in nuclei of most neurons throughout the brain and optic lobes. Strong cytoplasmic signal with antisense probe to *tim* RNA was detected in four neurons in the *pars intercerebralis* of each hemisphere. In addition, characterization of circadian controlled egg hatching behavior and locomotor activity of *E. kuehniella* adults is presented.

Conclusions: *Ephestia kuehniella* was established as a convenient non-drosophilid species for circadian rhytm studies.

POSTER PRESENTATION

A local outbreak of the northern pine processionary moth *Thaumetopoea pinivora* on Gotland, south Sweden

Stig Larsson[1], Cecilia Ronnås[1], Andrea Battisti[2]

[1]Swedish University of Agricultural Sciences, Uppsala, Sweden, [2]University of Padova, Padova, Italy

An outbreak of the northern pine processionary moth *Thaumetopoea pinivora* is currently occurring on *Pinus sylvestris* in an area of about 3,000 ha at the northern limit of its distribution on the Baltic island of Gotland, south Sweden. It is not clear how long the population has been present on Gotland, but from observations made by the local residents it appears that it has been present at least since the 1930s. *Thaumetopoea pinivora* has a two-year development cycle on Gotland, with discrete year classes; high larval densities occur in even years and much lower densities in odd years. The larvae feed between April and July on mature pine needles, and release microscopic hairs that can cause severe allergic reactions in humans. Presumably, the population escaped from controlling factors, but no strong control agent has been identified. A tachinid fly (*Blondelia nigripes*) is present in the population, but no precise data on degree of parasitism are available. Present research aims at understanding the local nature of the outbreak.

POSTER PRESENTATION

Influence of climate factors on biology and behavior of vine moth (*Lobesia botrana* Den & Schiff) in the "dealu bujorului" vineyards of Romania

Tabaranu Gabriel, Enache Viorica, Simion Cristina, Donici Alina

Research and development center for viticulture and wine –Bujoru, Targu Bujor Galati, Romania

The paper presents the researches carried out at the Research and development center for viticulture and wine –Bujoru (SCDVV) in the period 1996-2006 highlighting some climate factors (temperature, precipitation) which influence the biology and virulent behavior (F,I and G A%) of the vine moth -Lobesia botrana-Den &Schiff) in the South Moldavian vineyards In the past few years it has been noted a change in the average climate factors (high temperatures, more frequent droughts , aridity) which may induce changers of both biology and behavior of the major vine pest in the vineyard Dealu Bujorului (vine moth or eudemis) with consequences difficult to evaluate for the integrity of the entire vine eco-system.

POSTER PRESENTATION

Monitoring obscure mealybug, *Pseudococcus viburni* (Signoret), in pome fruit orchards in the Western Cape Province, South Africa

Pride Mudavanhu, Pia Addison

Stellenbosch University, Stellenbosch, South Africa

Morphological identification of various mealybug species infesting pome fruits is difficult; therefore mealybugs are still phytosanitary pests. This has led to rejections of export fruit to various markets. Chemical control options are becoming increasingly limited. Little is known about the efficacy of naturally occurring biological control agents and this was therefore investigated between December 2006 and March 2007. The seasonal movement of *P. viburni* was monitored in three pome fruit growing areas. A survey of the identity and incidence of natural enemies attacking mealybugs in pome fruits was conducted to determine the status of potential biocontrol agents. Natural enemies and male mealybugs were sampled on sticky bottoms of yellow delta traps. Correlations between percentage fruit infestation and mealybug trap counts were done. Preliminary results showed similar trends in mealybug populations on the two kinds of fruit, with much variation occurring on apples. Populations on pears remained more even and lower throughout the season. Most mealybugs were found on the main trunk and crutch, while few were found moving to other plant parts. 48% of parasitic wasps caught on yellow delta traps were identified as *Coccidoxenoides perminutus*, 12% were *Leptomastix* spp., 4% were *Anagyrus* spp., while 36% were unidentified. Some predatory beetles found could possibly belong to the genus *Cryptolaemus*. There was a positive relationship between average number of male mealybugs caught on pheromone traps and percentage fruit infestation but increasing male mealybug trap counts did not correlate well with increasing fruit infestation levels. The survey for biological control agents continues.

POSTER PRESENTATION

Metagenomic analysis of the microbiota hindgut of *Reticulitermes lucifugus* (Rossi) (Isoptera: Rhinotermitidae).

Paola Quatrini[1], Gabriella Butera[1], Giovanna Varrica[2], Giuseppe Alonzo[3], Stefano Colazza[2]

[1]Department of Cellular and Developmental Biology DBCS, University of Palermo, Palermo, Sicilia, Italy, [2]Department S.EN.FI.MI.ZO, Università di Palermo, Palermo, Sicilia, Italy, [3]Department ITAF, Università di Palermo, Palermo, Sicilia, Italy

Termites' hindguts host a microbial community consisting of anaerobic flagellates and bacteria. This gut microflora is responsible for the degradation of lignocellulosic material. Here we report the data concerning the analysis of the hindgut microbial community of *Reticulitermes lucifugus* (Rossi), a termite commonly present in Italy, based on a metagenomic approach. Metagenomic DNA was extracted from the gut content of termites and the SSU rDNA was polymerase chain reaction (PCR) - amplified using universal primers for prokaryotes and eukaryotes. Two clone libraries were constructed and clones were grouped into Operational Taxonomic Units (OTU) by RFLP analysis. One representative clone was sequenced for each OTU and sequences were compared to the database. In order to isolate the cellulolytic bacterial fraction from the gut of *R. lucifugus* enrichment cultures were set up on different substrates. The isolates obtained were characterized. A large and diverse population of microbial symbionts was found in the *R. lucifugus* hindgut. Comparisons with other termites communities are presented.

POSTER PRESENTATION

Evolutionary genetics of the invasive harlequin ladybird (*Harmonia axyridis*)

Cathleen Thomas[1], Lori Lawson Handley[1], Michael Majerus[2], Remy Ware[2]

[1]University of Hull, Hull, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom

Introduction: Biological invasions are currently the second largest cause of biodiversity loss after habitat destruction, and have important economical and ecological consequences. It is still not fully understood why certain species become invasive, what factors determine their success, and what impacts they have on the native species with which they interact.

The genetic composition of the founding population is crucial in determining how a species will adapt to a novel environment and its capacity for range expansion. Genetic data are therefore essential to develop our understanding of the evolutionary processes underlying species invasions, and to determine how genetic factors contribute to invasion success. However, to date, only a few studies have addressed the evolutionary genetics of invasive species. Knowledge of source populations could also be advantageous when developing methods of biological control for invasive species.

The initial aim of this project is to investigate the genetic structure of harlequin ladybird populations in the UK, where the species is invasive and spreading rapidly. Comparing this with native Asian populations and other invasive populations in Europe and North America should then allow identification of source populations and quantification of the number of founders of invasive UK populations. Further work to assess whether the genetic composition of the source population has influenced invasion success can then be done by comparing levels of genetic diversity within native and invasive populations.

Methods: Harlequin ladybirds were sampled from the species' native range in Asia, and invasive ranges in the UK, continental Europe and North America. Selected regions of mitochondrial and nuclear DNA are currently being amplified by polymerase chain reaction and then sequenced to create a phylogeny, and individuals are being genotyped at microsatellite loci.

Results: This work is ongoing, and we therefore present our preliminary results.

POSTER PRESENTATION

Evolutionary genetics of the invasive harlequin ladybird (*Harmonia axyridis*)

POSTER PRESENTATION

Potential for natural regulation of codling moth populations by natural enemies

Benoit Sauphanor, Emmanuel Cuenot, Jean François Toubon, Sylvaine Simon

INRA, Avignon, France

Introduction: The control of codling moth, *Cydia pomonella*, using chemical or microbiological insecticides was made difficult in southern Europe by the widespread of resistance phenomena. Environmental parameters which could affect the presence and distribution of *C. pomonella* predators and parasitoids were analyzed in two insecticide free experimental orchards.

Results: The field exposure of egg batches revealed a low egg parasitism by two *Trichogramma* species, similar in apple and pear orchards and increasing in late season. The egg predation was significant, and reduced from 30% to 7% and from 41% to 10% in pear and apple orchard, respectively, when the eggs batches were protected using exclusion cages giving only access to micro-predators. The use of tanglefoot rings designed to prevent the access of ants, earwigs or running spiders did not reduce the rate of egg predation, which was not affected by the distance to the hedgerow. The parasitism of late instar larvae and pupae of the first generation collected in corrugated band traps reached 12.9% and 3.4% in apple and pear orchards, respectively. The ovo-larval parasitoid *Ascogaster quadridentata,* and later in the season the larval parasitoid *Pristomerus vulnerator,* were the most frequent species. Their prevalence was not related to the distance to the hedgerow nor to the density of their host inside the orchard.

Conclusion: The addition of these predation and parasitism-based mortalities at different stages in the life cycle of the pest may reduce the intrinsic rate of increase of codling moth populations in environmentally friendly production systems.

POSTER PRESENTATION

Parasitoids' efficiency in controlling the population size of *Ceutorhynchus assimilis* (Payk.) (Coleoptera: Curculionidae) on winter oilseed rape

Eve Veromann, Anne Luik

Estonian University of Life Sciences, Tartu, Estonia

Introduction: *Ceutorhynchus assimilis* (Paykull) (Coleoptera: Curculionidae) (cabbage seed weevil) is widely distributed and major pest of oilseed rape in Europe. In Estonia, they are generally more abundant on winter oilseed rape and little is known about the occurrence, importance and efficiency of their parasitoids as biocontrol agents.

Methods: In this four year study, the damage of *C. assimilis* and their larval parasitization rates were assessed in winter oilseed rape. Pod samples were collected from oilseed rape plants in 2004–2007 from three commercially grown unsprayed winter oilseed rape crops at the pods maturing stage (BBCH 81–83) and incubated in emergence traps. Thereafter emerged larvae, their exit holes and parasitoids were counted, identified and the percentage of damaged pods and parasitism rate were calculated.

Results: Although, the number of damaged pods by larvae of *C. assimilis* was quite low it increased continuously during study years. The parasitization level showed generally a strong linear increase over the four years and reached noticeable 96% in 2007. The number of parasitizised larvae was the lowest in 2005 and this was the only year when parasitism rate decreased compared to the previous year. The most abundant parasitoid was *Trichomalus perfectus* (Walker) (Hymenoptera: Pteromalidae).

Conclusions: This study showed that parasitoids of *C. assimilis* were establishing a viable population during four years in suitable conditions. We conclude, therefore, that parasitoids of *C. assimilis* can efficiently control the population size of their host and that these natural enemies have a significant value for environmentally friendly crop protection.

POSTER PRESENTATION

Peach-*Myzus persicae* interactions as controlled by winter pruning and nitrogen fertilization: From experimental analysis to modeling.

Isabelle Grechi, Benoit Sauphanor, Marie Hélène Sauge, Jean-Philippe Lacroze, Nadine Hilgert, Françoise Lescourret

[1]INRA, Avignon, France, [2]INRA, Montpellier, France

Introduction: The research purpose is the management of the peach–*Myzus persicae* system, by integration of chemical, biological and cultural pest control methods. We used a modeling approach to address it. To assist model development, we first aim to experimentally characterize peach–aphid interactions driven by winter pruning and nitrogen (N) fertilization, proposed as potential cultural control methods.

Methods: We artificially infested peach trees with aphids and applied various levels of pruning intensity (from 0 to 80%) and N treatments (from shortage to overdose). Aphid dynamics, foliar growth, fruit yield and quality were monitored.

Results: Aphid infestation of peach trees increased with increasing pruning intensity because of an exponential increase of the proportion of growing shoots at the expense of short shoots, aphids having developed better on growing shoots. According to the N gradient, plant vigor increased then leveled off while aphid abundance increased then decreased. Plant vigor partially explained aphid performance that exhibited a significant nonlinear response to leaf N content. Preliminary analyses of foliar chemistry (free amino-acids, phenolic and cyanogenic compounds) gave elements to explain this response at N shortage but not at N overdose. Aphids induced premature defoliation on growing shoots and reduced their growth. Following infestation, trees had compensatory growth. Aphids did not significantly reduce fruit mass and refractometric index.

Conclusions: Winter pruning and N fertilization can be used to control aphids; application in production orchards is discussed. We illustrate the potential of a simulation model, incorporating these results, to investigate alternative strategies for crop-pest management.

POSTER PRESENTATION

Phylogenetic analysis of the tribe Pyrophorini (Coleoptera: Elateridae: Agrypninae)

Simone Policena Rosa

Museu de Zoologia da Universidade de São Paulo, São Paulo, SP, Brazil

Introduction: Pyrophorini comprises 144 species and 20 genera which occur in Southern Neartic, Neotropical and Australian Regions. They have been traditionally recognized as a monophyletic group, sharing as presumed synapomorphy the bioluminescent organs. A cladistic analysis of the tribe was conducted to test its monophyly and investigate the evolution of bioluminescence.

Methods: 140 species were examined and included in 36 in-group clades, representing all Pyrophorini species groups and genera. One species of Pityobiinae and 17 of several Agrypninae tribes, including the supposed sister-group Heligmini, were included as out-groups. Maximum parsimony analysis of 77 adult morphological characters was conducted on TNT traditional search.

Results: The eighteen most parsimonious cladograms show Pyrophorini as paraphyletic because it includes three Heligmini genera. Presence of bioluminescence is corroborated as synapomorphy, but this condition was lost in at least 4 clades. Several genera resulted as polyphyletic. The consensus cladogram shows the following relationships for Pyrophorini: (*Pyrearinus basalis* ((*Agnostelater* + *Coctilelater* + *Pyrearinus lampyris group*) (Pyrophorus + Genus A) (*Pyrearinus cinnameus* ((*Phanophorus* + *Hypsiophthalmus*) (*Noxlumenes* (*Nyctophyxis* + *Cryptolampros*) (*Pyrearinus major part*)) (*Meroplinthus* + *Hapsodrilus* + *Ptesimopsia* major part + *Ptesimopsia paralella* (*Pyroptesis* + *Sooporanga*) (*Fulgeochlizus*) (*Hifo* (*Opselater melanurus* group (*Lygelater bifossulatus* (*Deilelater physoderus* group (*Lygelater* major part (*Photophorus* + *Ignelater*) (*Deilelater sirius* group (*Vesperelater gemmiferus* + *Vesperelater* major part) (*Deilelater atlanticus* group).

Conclusion: Pyrophorini and several genera of this tribe are not monophyletic and their classification should be revised. The bioluminescent pronotal and abdominal organs are independant synapomorphies which were lost at least 4 times independently.

POSTER PRESENTATION

Host-preference of the parasitoid wasp *Sinarachna pallipes* (Holmgren, 1860) (Hymenoptera: Ichneumonidae: Pimplinae) in apple orchards

Stanislav Korenko, Stano Pekar, Veronika Michalkova

Masaryk University, Brno, Czech Republic

Introduction: The population of ectoparasitoid ichneumonid wasp *Sinarachna pallipes* (Holmgren, 1860) that was observed to attack araneid and linyphiid spiders (Gauld, Dubois 2006) was investigated in a commercial apple orchard in the central Europe. Aim of the study was to assess the host-preference and the rate of parasitation.

Methods: Arboreal spider population was observed by beating technique and incidence of parasitized spiders was recorded. Parasitized spiders were reared in laboratory conditions until hatching of the parasitoids.

Results: *S. pallipes* attacked 5 species of theridiid spiders: *Theridion varians* Hahn 1833, *Theridion pinastri* L. K. 1872, *Theridion impressum* L. K. 1881, *Neottiura bimaculata* (L. 1767), and *Paidiscura pallens* (Bl. 1834); and one species of araneid spiders: *Araniella* sp. Theridiid spiders were markedly preferred to araneid spiders. In total, about 2.75 % of theridiid spider population was parasitized. The highest incidence of parasitism was observed among medium sized spiders (prosoma length = 0.7 mm).

Conclusions: Contrary to expectation, *S. pallipes* was found to attack theridiid spiders.

POSTER PRESENTATION

Spatial distribution of aphid and scale populations

Isabel Borges[1], António O. Soares[1], Jean-Louis Hemptinne[2]

[1]University of the Azores, Ponta Delgada, Azores, Portugal, [2]École Nationale de Formation Agronomique, Castanet-Tolosan, France

Introduction: Spatial distribution of aphid and scale populations was assessed in July 2004 and in May, June, July and August of 2006 and 2007 using three distinct methods: Taylor's power law, Iwao's patchiness regression and Spatial Analysis by Distance IndicEs (SADIE).

Methods: Spatial distribution was assessed by three different approaches. Both Taylor's and Iwao's models use a regression to determine the spatial distribution. In the former the sample mean is regressed against the sample variance while in the latter the mean density and Lloyd's mean crowding are the parameters regressed. SADIE, on the other hand, uses the distance to regularity and compares the value observed with the value expected by random assignment of counts.

Results: For every sampling Taylor's power law indicated that both aphid and scale populations were aggregated. Iwao's patchiness regression indicated that aphids and scales formed colonies but differently distributed in space: aphids predominantly presented random colonies while scales' colonies were aggregated in space. According to SADIE, aphid spatial distribution varied between aggregated and random with significant aggregation in some samplings while scales' spatial distribution varied between aggregated and regular but never at a significant level. Additional information on clustering was provided by SADIE with significant patches and gaps identified only for aphids.

Conclusions: Aphid and scale populations seem to occupy differently the habitat. The method that provided the most consistent results was Iwao's patchiness regression. It is noteworthy that, in general, the methods did not provide conflicting results.

POSTER PRESENTATION

Time course of colonization of the glassy-winged sharpshooter precibarium by *Xylella fastidiosa* suggests two types of egestion during inoculation

Elaine Backus[1], David Morgan[2]

[1]USDA Agricultural Research Service, Parlier, CA, United States, [2]California Dept. of Food & Agriculture, Riverside, CA, United States

Introduction: Establishment of the invasive glassy-winged sharpshooter (GWSS), *Homalodisca vitripennis,* in California has caused an increase in incidence of Pierce's Disease bacterium, *Xylella fastidiosa* (*Xf*), in grape-growing regions. Although host plant resistance to the pathogen and its vector is being sought, research is hampered by lack of understanding of acquisition and inoculation mechanisms.

Methods: The anatomical location of acquisition (from which inoculation occurs) was studied using a confocal microscopy method to visualize *in situ* green fluorescent protein (GFP)-transformed *Xf* within the undissected precibarium and cibarium of the vector. We performed a time course study of GFP-*Xf* acquisition by GWSS, across acquisition access periods (AAP) ranging from 1 to 14 days.

Results: Bacterial colonies form in the cibarium within the first 24 hr AAP; at the same time, they begin to move forward from this cibarial reservoir into the precibarium. By AAP day 3, bacteria line the length of the precibarium except the area of the D-sensilla field (below the precibarial valve), which is almost nearly always free of bacteria. By AAP day 5, this large accumulation of bacteria has disappeared, and evidence suggests that the precibarium was physically swept clear of biofilm. After day 5, this cycle of loading above the valve then discharging starts again.

Conclusions: We hypothesize that there are two types of egestion (injection of material from the anterior foregut back into the plant): rinsing egestion (continuously occurring from below the precibarial valve) and discharging egestion (sporadically [every 3 to 5 days] occurring from above the precibarial valve).

POSTER PRESENTATION

The effects of two different biotypes (SA-1 and SA-2) of Russian wheat aphid, *Diuraphis noxia* (Kurdjumov) (Homoptera: Aphididae) on non-resistant and resistant wheat cultivars Tugela and Tugela-Dn (*Triticum aestivum*)

Shaun Walton, Ted Botha

Rhodes University, Grahamstown, South Africa

Introduction: The negative effect aphids such as the Russian Wheat Aphid (RWA) *Diurpahis noxia* have on commercially important crops such as wheat, *Triticum aestivum*, has in recent years received increasing attention due to the suspected evolution of aphid biotypes that are capable of inducing severe crop yield loss in modern day resistant wheat cultivars.

Methods: The effects of two different biotypes (SA-1 and SA-2) of Russian wheat aphid on non-resistant and resistant wheat cultivars, Tugela and Tugela-Dn *Triticum aestivum,* was investigated using both fluorescence microscopy and population studies.

Results: The new biotype Russian Wheat Aphid SA-2 (RWA SA-2) was found to be more damaging to both the non-resistant and resistant cultivars of wheat in both short term and long term feeding experiments. The results of the population experiment showed that the new biotype RWA SA-2 also has a significantly faster breeding rate than the old biotype RWA SA-1 on both the non-resistant and resistant cultivars ($P = 0.013$).

Conclusions: The suspected evolution of a new resistant and more virulent biotype of RWA is in fact true and that this new biotype poses a severe threat to the commercial wheat industry of South Africa.

POSTER PRESENTATION

The molecular phylogeny of oestroid Diptera, with special emphasis on the taxonomic position of the genus *Bengalia* (Robineau-Desvoidy, 1830)

Shaun Walton, Doug Downie, Martin Villet, Ashley Kirk-Spriggs

Rhodes University, Grahamstown, South Africa

Introduction: The taxonomic placement of the genus *Bengalia* has recently come under scrutiny. To resolve the current disparity, the taxonomic placement of *Bengalia* and phylogenetic relationships of the oestroid Diptera were investigated using molecular methods.

Methods: To test the hypothesis, 43 species of calyptrate fly including two *Bengalia* specimens; representative members of six of the currently recognized calliphorid subfamilies (Bengaliinae, Auchmeromyiinae, Rhiniinae, Luciliinae, Calliphorinae, Chrysomyiinae); and a range of suitable out-group taxa representing three families within the Oestroidea (Sarcophagidae, Oestridae, Tachinidae); and two other superfamilies (Muscoidea and Tephritoidea) were used. Phylogenies were constructed using sequences derived primarily from published data in combination with sequences obtained from seven additional species. Portions of both the large ribosomal subunit RNA gene (28S rDNA) and mitochondrial cytochrome oxidase subunit I were used. Analysis used Parsimony and Bayesian Inference methods.

Results: *Bengalia* placed well within the main calliphorid clade, however the placement was weakly supported.

Conclusions: Support for the placement of *Bengalia* within the Calliphoridae was obtained from three sources: 1) previous morphological studies; 2) similar biology and common termite mound association amongst closely related taxa; and 3) common taxonomic placement of the group well within the main calliphorid clade. The well supported placement of the Rhiniinae as well as the strange placement of a number of other out-group taxa within the main calliphorid clade [Calliphoridae (Tachinidae (Oestridae (Muscidae))) Calliphoridae]; suggest that the Calliphoridae, as it is currently recognized, does not appear to be a monophyletic group or that the genes are saturated.

POSTER PRESENTATION

The sharpshooter X-wave: Correlation of xylem penetration by *Homalodisca* spp. with an Electrical Penetration Graph (EPG) waveform

Elaine Backus[1], Wendy Holmes[2], Brendon Reardon[3], Fred Schreiber[2], Gregory Walker[3]

[1]USDA Agricultural Research Service, Parlier, CA, United States, [2]California State Univ., Fresno, Fresno, CA, United States, [3]Univ. of California, Riverside, Riverside, CA, United States

Introduction: Electrical penetration graph (EPG) monitoring is a rigorous means of observing and quantifying the feeding of piercing-sucking insects. Previous studies with aphids and leafhoppers have demonstrated the value of what is termed the X wave, i.e. the waveform that represents first penetration of the insect's piercing-sucking mouth parts, the stylets, into a preferred vascular tissue for ingestion, usually a phloem sieve element or xylem tracheary element.

Methods: Salivary sheath termini of smoke tree sharpshooters, *Homalodisca liturata*, were correlated with successive events of X wave components.

Results: We observed the consistent association of the X wave with salivary sheath termini in a xylem cell, especially mature (lignified), secondary xylem cells. The sharpshooter X wave is a complex, multi-component waveform family that is composed of waveform types B1s (previously shown to represent precibarial valve movement and possible egestion), B1w (salivation), proto-C (possible micro-ingestion) and C (macro-ingestion/ cibarial pumping). The X wave is a pathway- and interruption-phase waveform that is best visualized using the AC-DC EPG monitor, with input impedance set at 10E7 Ohms, to balance emf and R components.

Conclusions: The sharpshooter X wave is correlated with first penetration of xylem, and represents a suite of behaviors that we propose function to: 1) physically seal stylet tips into the cell via sheath salivation, 2) taste constituents of the cell to determine acceptability, and 3) mechanically test strength of the stylet seal via trial cibarial pumping. We hypothesize that the X wave is associated with behaviors that control inoculation of *Xylella fastidiosa*.

POSTER PRESENTATION

Calesidae, a potential new family of Hymenoptera

Jason Mottern, John Heraty, Emily Hartop

University of California, Riverside, Riverside, CA, United States

Although the monophyly of some groups of Chalcidoidea is strongly supported by morphological and/or molecular synapomorphies, higher-level relationships within the superfamily remain uncertain. Several families are regarded as either paraphyletic or even polyphyletic. This uncertainty regarding sister-group relationships, combined with hyperdiversity of form and function, has left some chalcid groups unplaced into higher taxonomic categories Establishing relationships within Chalcidoidea is further hindered by a dearth of comprehensive morphological studies, either across character systems or across taxa. Calesinae (Howard) is a small group of Australian and Neotropical parasitoids of whiteflies, comprising a single genus, *Cales*. Historically, the Calesinae have been included within the Trichogrammatidae and Mymaridae, though they are most often associated with the Aphelinidae. In addition, they share some features with the Eulophidae. The subfamily is currently unplaced within the superfamily Chalcidoidea. Here we present a detailed morphological examination of the three described species in addition to a newly discovered species from New Zealand. The apparently apomorphic characteristics of the head, mouthparts, antennae, wings, mesosoma and genitalia, are weighed against characteristics suggesting affinities with established chalcidoid families. We suggest that the Calesinae are sufficiently unique to warrant family-level status, the Calesidae.

POSTER PRESENTATION

Thoracic vibrations in stingless bees: is body size important for an efficient buzz pollination?

Patrícia Nunes-Silva, Michael Hncir, Vera Lucia Imperatriz-Fonseca

Faculty of Philosophy, Science and Letters of Ribeirão Preto, University of Sao Paulo, Ribeirão Preto/São Paulo, Brazil

Various morphological and behavioral characters determine the efficiency of an animal as pollinator. Many bee species vibrate their thorax when in contact with poricid anthers, thereby inducing a rapid pollen release. This so called buzz pollination occurs in many angiosperms. Here, the most important physical aspects for an efficient pollen release are the vibrations' velocity and acceleration. These two parameters putatively depend on the size of the bees' thorax, since this character correlates with the mass of the flight muscles, which, further, determines the strength of the vibration. The annoyance buzzing, which is similar to the vibrations produced during buzz pollination, of seven stingless bee species (*Melipona scutellaris*, *M. seminigra*, *M. quadrifasciata anthidioides*, *M. rufiventris*, *Schwarziana bipunctata*, *Scaptotrigona* aff. *depilis* and *Nannotrigona testaceicornis*) was measured using a laser vibrometer. The thorax size was described by the area of the scutellum. This measure was used as an estimate for the bees' size and the mass of their flight muscles. The seven analyzed bee species differed significantly in their size. Moreover, the thoracic displacement amplitude during annoyance buzzing strongly depended on the thorax size of the respective species. However, there was no significant difference between the fundamental frequencies and the velocity amplitudes among most species. Therefore, since the vibration velocity does not necessarily depend of the bees' size, small bees might be as efficient as big ones during buzz pollen collection. Thus, the behavior of stingless bees while collecting pollen might be the main determinant of their efficiency as buzz pollinators.

POSTER PRESENTATION

Geographical distribution of mutant carboxylesterase gene involved with insecticide resistance in New World screwworm fly (NSW) *Cochliomyia hominivorax* (Diptera: Calliphoridae).

Renato Assis Carvalho, Norma Machado Silva, Ana Maria Lima Azeredo-Espin

[1]Centro de Biologia Molecular e Engenharia Genética. Instituto de Biologia. Universidade Estadual de Campinas, Campinas, São Paulo, Brazil, [2]Centro de Biologia Molecular e Engenharia Genética. Instituto de Biologia.Universidade Estadual de Campinas, Campinas, São Paulo, Brazil, [3]Centro de Biologia Molecular e Engenharia Genética. Depto. Genética e Evolução. Instituo de Biologia. Universidade Estadual de Campinas, Campinas, São Paulo, Brazil

Introduction: The New World screwworm (NWS) *Cochliomyia hominivorax* Coquerel is one of the most important myiasis-causing flies in Central and South America. It is responsible for severe economic losses in livestock. The improper and continuous use of insecticides can lead to the selection of resistant strains. Mutations in carboxylesterase E3 gene associated with organophosphate and pyrethroids resistance (Gly137/Asp and Trp251/Ser) have been recently characterized in this species.

Methods: Part of the *C. hominivorax* E3 gene was sequenced, by direct sequencing of PCR products, from several localities of Central and South America. The mutations were analyzed and their frequencies were recorded.

Results: The sequences were analyzed in a total of 10 individuals for each of 8 populations. Three possible genotypes were found: mutant Gly137/Asp, mutant Trp251/Ser and wild types. The mutation Gly137/Asp (a general form of OP resistance) was mainly found at the regions with intense use of OP insecticide in Brazil (33-55%). The mutation Trp251/Ser (dimethil OP and pyrethroid resistance) was found in high frequency in regions with intense use of OP (Brazil) and pyrethroids insecticides for *C. hominivorax* control (Uruguay: 80% and Venezuela: 100%). However, in Cuba, where another class of insecticide (a GABA inhibitor) was used for long time, no mutant individuals were found.

Conclusions: The data obtained indicates a correlation between the mutations in the *C. hominivorax* carboxylesterase and the class of insecticide used throughout its current geographic distribution. This characterization will provide information for the selection and for the implementation of more effective pest management programs.

POSTER PRESENTATION

New, Universal AC-DC Electrical Penetration Graph (EPG) monitor reveals detailed R- and emf-component waveforms for any piercing-sucking insect

Elaine Backus[1], Murugesan Rangasamy[2], Heather McAuslane[2], Margaret Redinbaugh[3], Astri Wayadande[4], William Bennett[5]

[1]USDA Agricultural Research Service, Parlier, CA, United States, [2]Univ. of Florida, Gainesville, FL, United States, [3]USDA Agricultural Research Service, Wooster, OH, United States, [4]Oklahoma State Univ., Stillwater, OK, United States, [5] private consultant, Otterville, MO, United States

Introduction: Electrical Penetration Graph (EPG) monitoring is the most rigorous means of observing and quantifying the feeding of any piercing-sucking arthropod. However, until now, most studies have emphasized relatively few insects, mostly small-bodied hemipterans such as aphids (Aphididae) and leafhoppers (Cicadellidae). Virtually no heteropterans or blood-sucking arthropods have been studied.

Methods: A recently designed Universal AC-DC EPG monitor provides updated, high-quality amplifiers with a wider range of user-selectable adjustments, to tailor the monitor to each new species.

Results: The instrument is briefly described. Then, examples are provided of representative waveforms from the following insects: cotton aphid, *Aphis gossypii* (Aphididae), smoke tree sharpshooter, *Homalodisca liturata* (Cicadellidae: Cicadellinae), black-faced leafhopper, *Graminella nigrifrons* (Cicadellidae: Deltocephalinae), chinch bug, *Blissus insularis* (Heteroptera: Lygaeidae), and squash bug, *Anasa tristis* (Heteroptera: Coreidae). These insects range in size from 0.3 mm to 18 mm in length, a wider array of insect sizes than has been recordable in the past. For aphids and leafhoppers, comparisons are made with the same species' waveforms from older monitors, to show that waveform detail and resolution are highly improved with the new monitor. In addition, examples from chinch bug waveforms demonstrate how simple switches of input resistor values can distinguish between emf-component and R-component waveforms.

Conclusions: EPG holds the potential to significantly improve research on a wide array of species, such as heteropterans and blood-sucking vectors of medical/veterinary pathogens. The key to broadening the applicability of EPG has been improving the electronic design and flexibility of the instrument.

POSTER PRESENTATION

Temporal dynamics of insecticide aerosols in a small experimental store

Jan Plachy, Vladimir Kocourek, Vaclav Stejskal, Radek Aulicky, Jana Hajslova

DDD servis sro, Prague, Czech Republic

Introduction: In mill industry there is an urgent need for replacement toxic fumigants. One viable option is the use of insecticide aerosols. The prerequisite for their efficient use is the knowledge of their temporal dynamic in the air. The objective of the presented study was to assess the dynamics of insecticides when applied as aerosols in an experimental store (simulated by a small experimental room) under two different regimes of sealing using plastic sheets and strips.

Methods: In the experiments, aerosol sm.oke generator (Ultimate super SG, TransChem s.r.o) was employed. The tested pesticide preparation contained two types of active ingredients: pirimiphos-methyl (71, 3g/1 kg) and cypermethrin (13, 1 g/kg). Air sampling was carried out by the Escort Elf sampler (Mine Safety Appliances Co., Pittsburg, PA, USA) 3, 6 and 12 hours after application. The temporal dynamics was estimated on the basis of data obtained by gas chromatographic analysis (GC) of trapping filters; conventional (EGO or NPO) and mass spectrometric (MSO) detectors were used for detection of target compounds. Blattella germanica was used as a model insect to evaluate biological efficacy of insecticide aerosols.

Results and Conclusions: The obtained data document distinct effect of sealing quality on the temporal dynamics of air residues in both types of insecticides. The full biological activity was achieved in the sealed room only where losses of active ingredients due to air circulation were avoided. This study was supported by the MSMT (project NVP2-CHEMKONTAM-2B06099) and partly by MZe (project Vyzkumny zamer 0002700603).

POSTER PRESENTATION

Complex food web created by a biological control agent – the case of *Dasineura dielsi* on *Acacia cyclops*

Carien Kleinjan

University of Cape Town, Cape Town, South Africa

The Australian midge, *Dasineura dielsi* (Cecidomyiidae) induces gall formation within the flowers of *Acacia cyclops* thereby preventing pod formation. Following its introduction into South Africa for biological control of *A. cyclops, D. dielsi* dispersed rapidly and occurred throughout the range of the weed within four years. The incidence of galling everywhere is consistently high and most flower-heads now develop into complex, convoluted gall clusters rather than seed pods. Details of the organisms associated with the galls induced by *D. dielsi* were obtained by observation, dissection of gall material and by rearing immature stages in galls through to adulthood. Parasitoids developing within afflicted hosts were reared, where possible, to determine host associations. The study has revealed that galls created by *D. dielsi* are utilized, either as a resource or as a refuge, by a variety of other organisms. In conjunction with *D. dielsi,* they support a complex web of predators and parasitoids.

POSTER PRESENTATION

Oviposition site selection in natural populations of *Ramosiana insignis* and *Vulcirea violaceae* (Hemiptera: Pentatomidae) involve a trade-off in the survival of progeny.

Maurilio López[1], Francisco Díaz-Fleischer[1], Trevor Williams[2]

[1]Laboratorio de Biotecnología y Ecología Aplicada, Universidad Veracruzana, Xalapa, Veracruz, Mexico, [2]Instituto de Ecología A.C.,, Xalapa, Veracruz, Mexico

Introduction: The selection of oviposition sites of natural populations of two species of pentatomid bugs *Ramosiana insignis* and *Vulcirea violaceae* (Hemiptera: Pentatomidae) were studied on and around focal trees of *Schoepfia schreberi* J.F. Gmel (Olacaceae) in Veracruz State, Mexico.

Methods: Observations were performed at approximately weekly intervals at Tejerias and natural area Ejido Monte Blanco from Teocelo, Veracruz Mexico, from September to April, 2005-2007. The numbers of eggs laid by each species, percentage of parasitism, type of vegetation and distance from the focal host tree were noted.

Results: One species, *V. violaceae* reproduced and fed exclusively on the fruits of *S. schreberi* during the entire lifecycle. In contrast, *R. insignis* was found in association with *S. schreberi* and on 40 other species from 23 families of plants that surrounded focal trees. These plants were used as oviposition sites and appeared to represent natural enemy free space around each focal tree. Two species of egg parasitoids, *Telenomus* spp. (Hymenoptera: Scelionidae), an unidentified parasitoid and two species of tachinids, one of which was *Trichopoda pennipes* F. (Diptera: Tachinidae) attacked pentatomid egg masses and nymphs on *S. schreberi.* Predators included ants, salticid spiders and *Eutyrhinchus floridanus* (L.) (Hemiptera: Asopinae). Maternal care was observed in both species from oviposition to the first nymphal instar. The mean (±S.D.) number of eggs laid per female on *S. schreberi* was 343.8 ± 91.1, of which 28.4% were parasitized. In contrast, the mean number of eggs laid per female on the vegetation surrounding focal trees was 400.3 ± 69.6 (*R. insignis*) of which 15.2% suffered parasitism. The average distance between the focal tree and egg masses laid on surrounding vegetation was 3.1 ± 1.8 m. Nymphs of *R. insignis* had to migrate this distance to locate the fruits of *S. schreberi*, with associated risks of predation.

Conclusions: The two species adopt differing oviposition site selection that appears to represent a trade-off between the higher prevalence of parasitism of their progeny on *S. schreberi* and the risks associated with migration from surrounding vegetation to the focal host tree for feeding.

POSTER PRESENTATION

Assessment of containerized insecticide baits for the control of ants (Hymenoptera: Formicidae) in South African vineyards

Casper Nyamukondiwa, Pia Addison

Stellenbosch University, Stellenbosch, South Africa

Ant infestations comprising the Argentine ant, *Linepithema humile* (Mayr); common pugnacious ant, *Anoplolepis custodiens* (Smith); and cocktail ant, *Crematogaster peringueyi* (Emery) are a widespread pest problem in South African vineyards. Integrated Pest management (IPM) programmes aimed at suppressing problematic honeydew excreting mealybug pests on grapes must include ant control in order to optimize the effectiveness and efficacy of mealybug natural enemies. If ants are eliminated, natural enemies are capable of keeping these Homopteran pests below the Economic Threshold Level (ETL). Current strategies for ant control are limited and generally include the application of long term residual insecticides that are detrimental to the environment, labour intensive to apply and can disrupt natural biological control. A more practical method of ant control using low toxic baits was therefore investigated. Bait preference assessments and bait acceptance assessments were carried out in three different vineyards during the 2007/08 season. Five low toxic insecticide baits comprising 0.5% Gourmet ant bait, 0.5% boric acid, 0.0001% fipronil, 0.001% fenoxycarb and 0.5% spinosad were tested against a 25% sucrose solution control. Preliminary results showed that low toxic ant baits were equally preferred and accepted by the three ant species compared to the 25% sucrose solution control. Thus, use of low toxic baits can offer producers with a more practical, economical and environmentally friendly method of ant control which is compatible with vineyard IPM programmes.

POSTER PRESENTATION

Gene expression pattern of caste and life-stage specific EST libraries in the termite, *Reticulitermes flavipes*, utilizing bioinformatic tools

Matthew Steller, Srini Kambhampati

Kansas State University, Manhattan, KS, United States

Introduction: Termites (Isoptera) are separated into morphologically and behaviorally distinct castes of sterile workers and soldiers, and reproductive alates. Previous research has implicated that caste differentiation is controlled genetically. We compared the gene expression patterns of each caste and two larval life stages of *R. flavipes* in an attempt to better understand caste-specific gene expression.

Methods: Five caste- and life stage-specific cDNA libraries were constructed , cloned, and sequenced to generate an EST library of almost thirteen thousand sequences. All sequences were trimmed and arranged into contiguous sequences using Sequencher 4.7. Putative gene functions were assigned based on a tblastx swissprot search. Expressed gene patterns for each library were compared using Blast2GO.

Results: Seventy to ninety percent of sequences had no significant (e-value<1E-10) homology to sequences in existing databases. ESTs of workers and soldiers were from the widest array of functional classes. All libraries showed sequences with putative functions assigned to reproduction, which is unexpected in the non-reproductive soldier and worker castes. The biological process ontology was most variable for the worker caste with three unique terms (reproductive process, biological adhesion, and growth), however soldiers did have 10% of the ontology terms represented as sequences that made up less than 1% of the total, while workers consisted of 8% indicating increased functional variability in the soldier ESTs.

Conclusions: As expected, each caste appears to have unique expression patterns; of special interest are genes associated with transcriptional control and reproduction. We plan on performing fine-scale analysis of caste-specific expression patterns using a microarray of over 2,000 ESTs.

POSTER PRESENTATION

Efficacy of five selected acaricides against *Tetranychus urticae* (Acari: Tetranychidae) and their side-effects on relevant natural enemies occurring in citrus orchards

Alberto Urbaneja[1], Sara Pascual-Ruiz[1], Tatiana Pina[1], Raquel Abad-Moyano[1], Pilar Vanaclocha[1], Helga Montón[1], Pedro Castañera[3], Josep A. Jacas[2]

[1]Centro de Protección Vegetal y Biotecnología. Instituto Valenciano de Investigaciones Agrarias (IVIA), E-46113-Moncada. Valencia, Spain, [2]Departament de Ciències Agràries i del Medi Natural. Universitat Jaume I (UJI); Campus del Riu Sec, E-12071-Castelló de la Plana, Spain, [3]Departamento Biología de Plantas. Centro de Investigaciones Biológicas CIB, Consejo Superior de Investigaciones Científicas (CSIC), C/ Ramiro de Maetzu, 9, E-28040. Madrid, Spain

Introduction: Three groups of natural enemies are fundamental in citrus IPM in Spain: coccinellid and phytoseiid predators and hymenopteran parasitoids. *Tetranychus urticae* is an important pest affecting citrus, for which biological control has not yet been achieved; therefore, acaricides are commonly used to control it.

Methods. The aims of this study were to assess the efficacy of five acaricides widely used in citrus against *T. urticae,* and their acute side-effects on the adult stage of three selected natural enemies present in Spanish citrus orchards, which represent the key groups mentioned: the coccinelid *Cryptolaemus montrouzieri* Mulsant, a mealybug predator, the phytoseiid *Neoseiulus californicus* McGregor, a spider mite predator, and the braconid *Aphidius colemani* Viereck, an aphid parasitoid. Furthermore, sublethal effects were also considered for *C. montrouzieri* adults and immature stages.

Results: Some products proved highly effective against *T. urticae* and harmless to *A. colemani* (mineral oil, tebufenpyrad, clofentezin and fenazaquin). However, almost all products tested were slightly harmful for both predators considered. Fenazaquin was even moderately harmful for *N. californicus*.

Conclusions: Further studies, like the one presented here, are necessary to gain a better understanding of integrating biological and chemical controls. When considering both efficacy and side-effects on beneficial arthropods, the best options would seem to be mineral oil, tebufenpyrad and clofentezin. However, it is urgent to complete testing the side-effects of the acaricides used in citrus. This question is crucial if we consider that two recently introduced Tetranychidae are being controlled in citrus by chemical means exclusively.

POSTER PRESENTATION

Reparation of heat and cold injury in the bug *Pyrrhocoris apterus*: Does it require the expression of inducible *hsp70* gene?

Michaela Tollarová[1], Alena Kobelková[1], Vladimír Košťál[2]

[1]*Faculty of Science, University of South Bohemia, Ceske Budejovice, Czech Republic,* [2]*Biology Center ASCR, Institute of Entomology, Ceske Budejovice, Czech Republic*

Introduction: The expression of Heat Shock Proteins (Hsps) is known to be induced by diverse stresses, including heat and cold shocks, desiccation, anoxia, and exposure to a wide range of chemicals. Hsps function as molecular chaperones binding to partially denatured proteins and promoting their return to native conformation. Although it has been well established that Hsps are developmentally up-regulated in various diapausing insects, their exact physiological roles during diapause are not completely clear (Rinehart et al., 2007: PNAS USA 104, 11130-11137).

Methods: We have cloned structural homologs of inducible *hsp70* and cognate *hsc70* genes in the heteropteran *Pyrrhocoris apterus*, and quantified the abundance of their mRNA transcripts after the exposures to high (+45ºC) and low (-5ºC) temperature shocks using qRT-PCR technique.

Results: While the levels of *hsp70* mRNA increased by about three orders (1 000 – 4 000-fold) after the shocks, the levels of *hsc70* mRNA remained constant. After the injection of synthetic *hsp70* dsRNA (RNAi technique), we managed to diminish the shock-induced *hsp70* response to approximately 30 – 60-fold increase. Such a suppression of *hsp70* expression was sufficient to completely prevent the recovery from heat-injury. While more than 95 % of the control bugs (treated by injection buffer only) recovered and were fit 3d after the exposure, none of the *hsp70* dsRNA-treated bugs survived after the exposure to +45/5h.

Conclusion: The results of ongoing experiments will be presented, in which we asked whether the recovery of *P. apterus* bugs after cold shock also requires the up-regulated expression of inducible *hsp70* gene.

POSTER PRESENTATION

Suitability of the tomato borer *Tuta absoluta* as prey for *Macrolophus caliginosus* and *Nesidiocoris tenuis*

Alberto Urbaneja[1], Helga Montón[1], Óscar Mollá[1], Josep Anton Jacas[2]

[1]Centro de Protección Vegetal y Biotecnología. Instituto Valenciano de Investigaciones Agrarias (IVIA), E-46113 Moncada/Valencia, Spain, [2]Departament de Ciències Agràries i del Medi Natural. Universitat Jaume I (UJI); Campus del Riu Sec;, E-12071-Castelló de la Plana, Spain

Introduction: The tomato borer, *Tuta absoluta* (Meyrick) (Lepidoptera: Gelechiidae) is an important tomato pest native to South America which appeared in eastern Spain at the end of 2006. As a first step to discovering the extent to which two indigenous predators, *Macrolophus caliginosus* Wagner and *Nesidiocoris tenuis* Reuter (Hemiptera: Miridae) can adapt to this invasive pest, the prey suitability of eggs and larval instars of *T. absoluta* was evaluated.

Methods: Both predators and both sexes were exposed separately to different *T. absoluta* egg densities (10, 20, 40 and 60) whereas the capacity of both predators to feed on *T. absoluta* larval instars was evaluated in a no-choice experiment.

Results: Both predators preyed actively on *T. absoluta* eggs. Females of both species consumed more *T. absoluta* eggs than males. Both mirid predators were able to prey on the four *T. absoluta* larval instars. However, the number of preyed larvae varied significantly with prey instar for both mirid predators. The first larval instar was the most frequently preyed followed by the second instar larvae, for *M. caliginosus* and *N. tenuis*, respectively.

Conclusions: Our results again demonstrate the adaptability of both mirids to different environmental conditions, in this case an invasive pest, which contributes to their value as a biological control agent in tomato crops. A challenge for future studies will be to clarify how both predators can be used in the biological control of *T. absoluta*.

POSTER PRESENTATION

A comparison of decomposition and succession process on pig carcass: preliminary study of forensic entomology in the Western São Paulo State, Brazil

Juliana Alves Neves, Patricia Jacqueline Thyssen, Helton Otsuka, Carolina G. P. Lima, Wesley A. C. Godoy

UNESP, BOTUCATU, SP, Brazil

Introduction: This is the first report of an ongoing study of insect succession on carrion carried out in the Western of São Paulo State, Brazil, using pigs (*Sus scrofa* L.) as a model to determine the insect sequence over 14 days. The main objective was setting up a preliminary data-base for medicolegal purposes in this region.

Methods: Invertebrates were collected daily in a field investigation and identified in laboratory.

Results: During this period, 16,493 insects belonging to the following orders and families were collected: Diptera: Calliphoridae, Muscidae, Piophilidae, Sarcophagidae, Syrphidae, Otitidae; Micropezidae; Tachinidae; Asilidae; Faniidae; Tephritidae; Richardidae; Lauxaniidae; Hymenoptera: Formicidae, Vespidae; Coleoptera: Histeridae, Scarabaeidae, Dermestidae; Lepidoptera and Hemiptera. Four decomposition stages were observed (fresh, bloated, active decay and dry remains) and four insect ecological categories (necrophagous, predators, omnivorous and incidental). The first insects that appeared and oviposited were flies of the family Calliphoridae, *Lucilia eximia* (Wiedemann), but the predominant species were *Chrysomya albiceps* (Wiedemann) during almost all decomposition process. During the second and third stages, the most abundant families were Calliphoridae and Sarcophagidae. During the last stage, the dominant family was Formicidae followed by Histeridae with a large number of immature insects.

Conclusions: The fauna collected in the course of this work contained fewer species than were previously recorded as occurring in corpses in other regions from Brazil, due to the strong competition and predation by *C. albiceps* on other species. We understand that these community level approaches must be considered of potential forensic interest for estimating the post-mortem interval.

POSTER PRESENTATION

Prevalence of microsporidian infection of the European corn borer, *Ostrinia nubilalis* Hbn. (Lepidoptera: Pyralidae) at the Krasnodar Territory

Yury Tokarev, Julia Malysh, Dmitry Serapionov, Andrei Frolov

All-Russian Institute for Plant Protection, St. Petersburg, Russian Federation

Introduction: Incidence of microsporidia infecting of the European corn borer (ECB), *Ostrinia nubilalis* in Eurasia has been studied not enough. Only few reports are known from Italy, France, Poland, Czech Republic and Slovakia. In present work we compare prevalence rates of different geographic insect populations inhabiting different host-plants at the Krasnodar Territory.

Methods: Microscopic analysis of larvae, collected in field and perished under lab conditions was carried out with the use of fluorescent microscopy. Preparations of spores fixed by absolute methanol were stained with DAPI. Spore sizes were evaluated using Carl Zeiss Axiovision 4.6.

Results: Microsporidian infection of ECB in Russia was revealed for the first time. DAPI staining confirmed presence of *Nosema*-like spores with markedly stained diplocarya and weakly stained cytoplasm and exospore, as well as unstained zone of endospore. Prevalence rates of last instar larvae varied from 4.8 to 12.5%. We have compared prevalence rates for larvae collected i) near west vs east borders of the Krasnodar Territory, ii) during 2005 vs 2006, iii) from dicotyledonous (cocklebur, mugwort) vs monocotyledonous (maize) hosts. Microsporidia prevalence rates failed to differ significantly in all cases compared.

Conclusions: Microsporidia are widespread parasites in ECB populations inhabiting the south of Russia. Since *Nosema pyrausta* shows high efficiency as controlling ECB in North America, further research of microsporidia of ECB in Russia should be of importance. Supported by RFBR grants 06-04-48265, 07-04-92170, and a grant of the President of Russian Federation MK-653.2007.4.

POSTER PRESENTATION

Outbreak dynamics and natural enemies of the pine bark beetle *Ips acuminatus*

Fernanda Colombari, Massimo Faccoli, Andrea Battisti

University of Padova Dep. Environmental Agronomy, Padova, Italy

Introduction: Since 2004, many Scots pine (*Pinus sylvestris*) stands growing in the South-Eastern Italian Alps are severely attacked by the bark beetle *Ips acuminatus*. The investigated forests show dozens of infestation spots having size ranging from about 20-30 trees (small spots) up to 300 trees (large spots). The spots show up and extinguish quickly, while new ones appear within a radius of hundreds of meters. We hypothesize that natural enemies may drive the spot dynamics.

Methods: During 2007 we sampled branches from small and large spots and lodged them into emergence cages. Adults of *I. acuminatus* as well as natural enemies were collected weekly, identified and counted. At the same time, a monitoring of the examined pine stands was carried out to check the enlargement of old spots and the appearance of new ones. Voltinism and phenology of *I. acuminatus* were investigated by pheromone traps.

Results: In the surveyed areas *I. acuminatus* is bivoltine, with the first generation showing the highest density. Twentythree species of natural enemies (7 predators and 16 parasitoids) emerged from the branches, with *Metacolus unifasciatus* (Pteromalidae), *Dendrosoter hartigii* and *D. middendorfi* (Braconidae) being the most common.

Conclusions: The parasitism may have a role in outbreak dynamics as it was significantly higher (about 75%) during the second host generation, in both small and large spots. The number of both *I. acuminatus* and its natural enemies was not affected by spot size.

POSTER PRESENTATION

Expression and localization of cadherins in the honey bees (*Apis mellifera* L.) ovary

Mônica Florecki, Klaus Hartfelder

University of São Paulo, Ribeirão Preto, São Paulo, Brazil

Background: Cadherins constitute a superfamily of transmembrane glycoproteins involved in intercellular adhesion and signaling pathways. Classical cadherins (e.g. E-cadherin and N-cadherin) are the best studied members of this family. The role of cadherins in insect oogenesis has been investigated in *Drosophila* showing the importance of E-cadherin in (i) anchoring germline stem cells to their niche at the top of the germarium and (ii) in organizing follicles. The differences in ovary function between the female castes stimulated us to study the expression and localization of cadherins in honey bee oogenesis.

Materials and Methods: Indirect immunofluorescence analyses were performed with a polyclonal primary antibody against pan-cadherin. Nuclear DNA was labeled with Hoechst 33252. The expression of classical cadherins and of some protocadherins in honey bee ovaries was investigated by RT-PCR.

Results: Cadherins were visualized in the cytoplasm of trophocytes, oocytes and follicle cells and concentrated in focal points inside the nuclei of trophocytes and follicle cells. The immunolabeling results indicate additional functions for cadherins in somatic and germline cells, besides intercellular adhesion, such as a possible role in a signaling pathway between the plasma membrane and the nucleus. The expression of honey bee orthologs for E-cadherin and N-cadherin and of the protocadherins Fat, Fat-like and Starry Night was confirmed by RT-PCR and verified by sequencing of the amplification products. To our knowledge, this is the first report on a nuclear localization of classical cadherins in insects and of the expression of protocadherins in the context of gametogenesis.

POSTER PRESENTATION

Biology and determination of temperature requirements in *Tamarixia radiata* (Hymenoptera: Eulophidae)

José Roberto Parra, Mariuxi Torres

University of Sao Paulo, ESALQ, Piracicaba, Brazil

Introduction: The objective of this study was to determine ideal conditions for *T. radiata* development under laboratory conditions, allowing its effectiveness to be evaluated in the citrus-growing regions of the State of São Paulo.

Methods: Fifth-instar *D. citri* nymphs were offered for parasitism by *T. radiata* during a 24-hour period at 25 ± 1°C. After that period, the nymphs were transferred to incubators adjusted to 18, 20, 22, 25, 28, 30, and 32°C, RH: 70 ± 10%, and a 14-hour photophase. Three hundred nymphs were observed at each temperature, divided into 10 replicates containing 30 nymphs per plant.

Results: Parasitism by *T. radiata* had values ranging between 56.6 and 90%. In the various treatments, emergence remained between 55.6 and 80.2%; temperature did not have a significant effect on sex ratio, with values of 0.8±0.10. Based on development velocity at the temperatures studied for the egg-adult period of the parasitoid, the lower temperature development threshold (Tb) and thermal constant (K) were determined, with values of 7.13°C and 188.7GDD, respectively, and a coefficient of determination (R^2) of 94.7, which attests to the reliability of the results obtained.

Conclusions: By observing aspects of the interaction between *T. radiata* and *D. citri*, the data obtained can be useful to support mass production and estimate the number of generations of the parasitoid in order to implement a biological control program within *D. citri* management in ecologically distinct regions under our conditions.

POSTER PRESENTATION

Field validation of a temperature requirements model obtained in the laboratory for *Diaphorina citri* Kuwayama (Hemiptera: Psyllidae).

José Roberto Parra[1], Dori Nava[2], Mariuxi Torres[1]

[1]University of Sao Paulo, ESALQ, Piracicaba-SP, Brazil, [2]Embrapa Clima Temperado, Pelotas-RS, Brazil

Introduction: The confirmation that *Diaphorina citri* transmits the bacterium that causes greening has been a reason for concern among professionals involved in the citrus production chain in Brazil, since this is considered one of the most important citrus diseases worldwide. The objective of this study was to validate a laboratory temperature requirements model under field conditions.

Methods: Air temperature was used in the growing degree-day linear model determined for the insect under laboratory conditions. The number of growing degree-days accumulated for *D. citri* development was determined by the daily sum of thermal units above the base temperature (13.5ºC), using *Citrus limonia* (rangpur lime) and *Murraya paniculata* (orange jessamine) plantlets as food. The thermal constant value (K) was used to predict the occurrence of the insect, based on the mean air temperature values recorded during the experimental period. The data were compared by the overlapping confidence intervals technique at 0.05 probability.

Results: The sum of growing degree-days (GDD) obtained in the field from the mean daily temperature for the biological cycle (egg-adult) of *D. citri* was lower than the quantity of degree-days determined in the laboratory. The degree-day totals obtained in the field for *D. citri* reared on *C. limonia* (rangpur lime) and *M. paniculata* (orange jessamine) were 167.8 and 171.1, amounting to differences of 43.2 GDD (20.5%) and 39.8 GDD (18.9%), respectively, in relation to the laboratory-estimated value of 210.9 GDD. In both citrus and orange jessamine, the confidence intervals calculated for the field model did not overlap the laboratory model, indicating an apparent inadequacy.

Conclusions: The temperature requirements model obtained in the laboratory using constant temperatures (linear model $y = 0.004741x - 0.064134$) was not adequate to predict the occurrence of *D. citri* in the field.

POSTER PRESENTATION

Climate change alters phenology and abundance in butterflies and dragonflies

Luc De Bruyn, Geert De Knijf, Dirk Maes

Research Institute for Nature and Forest, Brussels, Belgium

Phenology refers to the study of seasonal appearances and timing of life-cycle events. Phenological activities of ectotherm animals are influenced by environmental temperatures. It is hypothesised that, due to increasing temperatures, spring activities will shift forward in time while autumn activities will occur later in the year. In the scope of the Flemish Nature Report, we analyse flight periods of butterflies and dragonflies. To assess flight periods, we used the data collected between 1980 and 2006 by volunteers of the Flemish butterfly and Flemish dragonfly working groups. These data were related to temperature data collected over the same period by the Belgian Royal Meteorological Institute. Overall, the flight period in most butterfly species changed over 26 years. Early generations generally shifted forward in spring; late generations occur later. Some species did not change. In dragonflies, the flight period did not change over time for most species. Annual flight period is correlated with temperature in 20 of the 23 species tested in butterflies and in 18 of the 22 tested dragonflies. Species where the flight period extended also showed an increased abundance over the same time span.

POSTER PRESENTATION

Activity of *Cordulegaster erronea* (Odonata: Cordulegastridae) studied using Radio-Tracking and Mark-Resighting techniques

David Moskowitz, Michael May

Rutgers University, New Brunswick, New Jersey, United States

Cordulegaster erronea is a large dragonfly confined to small forested streams in temperate eastern North America. Males patrol along the streams, apparently seeking females, while females fly in briefly to oviposit. We placed miniature radio-transmitters on 5 males and 1 female during July and August 2006 and relocated them 2-4 times per day for up to 15 days. Individuals apparently spent the great majority of their time in the tree canopy within an area of about 75 Ha centered on the study stream. During these intermittent observations, only one radio-tagged male was observed to return to the stream. During July and August of 2007, we and several assistants individually marked males using a coded pattern of paint dots on the wings. Up to 17 separate individuals per hour were resighted from a single station during peak activity. Despite frequent but very brief aggressive interactions, males gave no indication of territoriality. The apparent tenure of individual males was commonly less than ½ hour, at any given stream reach that we monitored, although some males did reappear at different reaches or even on another small stream about 800 m away. Females were observed very rarely and successful tandem formation only once on the stream in 2007. Given the brief tenure of both males and females at the stream and the long periods spent in the canopy, we consider the existence of alternate mating strategies by both sexes deserves investigation.

POSTER PRESENTATION

Predators associated with citrus blackfly *Aleurocanthus woglumi* Ashby (Hemiptera: Aleyrodidae), in the area of Manaus, Am

Maiara Gonçalves, Márcia Pena, Neliton Marques

Universidade Federal do Amazonas, Manaus, Brazil

Introduction: The citrus blackfly (*Aleurocanthus woglumi* Ashby) is an important citrus plague of Asian origin. Recently introduced in Brazil, was detected for the first time in Belem/PA in 2001. In Manaus this plague was detected in 2004. In various parts of the world biological control has been most efficient than chemical control; with the use of parasitoids, predators and entomopathogenic fungus.

Methods: The collects were realized fortnightly. Were sampled 20 plants of citrus (4 quadrants per plant). For the survey of parasitoids, were collected citrus leaves infested with blackflies. These were conditioned in Petri dishes, covered with pierced plastic and conditioned in B.O.D. (26±2℃; 80% UR) until the emergency of adults. The predators were collected manually.

Results: Were registered 11 specimens of predators from the Neuroptera order associated to nymphs colonies of citrus blackfly. The species identified were: *Ceraeochrysa ubana, Ceraeochrysa cincta, Ceraeochrysa claveri, Ceraeochrysa sanchezi, Leucochrysa (Nodita) sp,* mainly during the raining season, and two specimens of parasitoids from the Hymenoptera order, Signiphoridae family.

Conclusions: It is possible that the low rates of natural enemies are due to the relationship, not established yet, between the blackfly and its predators and parasitoids.

POSTER PRESENTATION

Ficus trees and shrubs under attack – thrips, scales, and whiteflies

Catharine Mannion

University of Florida, Homestead, Florida, United States

The genus, *Ficus*, consists of over 800 species, several of which are desirable interior foliage plants. Although most ornamental figs are trees, a few are shrubs or vines. Ficus are native throughout the tropics with a few species extending into the warm temperate zone. The ornamental industry in Florida produces numerous species and cultivars of ficus which are sold in a wide range of sizes. Ficus trees and shrubs are also a common landscape plant in south Florida. In Florida, insect pest problems on ficus have been relatively few, however, recent pest introductions and outbreaks of previously introduced pests are causing much concern to the industry. Most recently a whitefly, *Singhiella simplex*, was identified attacking many of the ficus species in south Florida, causing massive defoliation and branch dieback. This whitefly in conjunction with other introduced pests such as *Gynaikothrips uzeli*, *Ceroplastes rusci* (ficus wax scale), *Pulvinaria psidii* (green shield scale) and most recently, *Horidiplosis ficifolii* (gall midge), are causing severe damage and potential plant loss in the landscape as well as to the nursery industry. Investigations on the presence and impact of natural enemies have been conducted for the whitefly and thrips. The distribution, biology and management of these pests in Florida will be presented.

POSTER PRESENTATION

Oviposition sites of three generalist predators in non-crop vegetation adjacent to cotton fields

Ingrid Rencken[1], Letitia Silberbauer[2]

Department of Primary Industries & Fisheries, Toowoomba, Queensland, Australia

Introduction: Non-crop vegetation which provides oviposition sites for generalist predators is an important resource, particularly in ephemeral cropping systems. The oviposition sites of three generalist predators were identified through sampling the non-crop vegetation surrounding cotton fields.

Method: Dry-land pastures, a travelling stock route, dry-land lucerne and a planted native windbreak were sampled using a suction sampler. The presence of immature and larval stages of generalist predators was used as indication of oviposition sites.

Results: Larval stages of generalist predators were collected in the non-crop vegetation during winter and early spring before planting of the cotton crop. There appeared to be a correlation between plant species and capture of different species of juvenile generalist predators.

Conclusion: Non-crop vegetation adjacent to crops is an important resource providing oviposition sites for generalist predators, particularly in ephemeral cropping systems. A range of vegetation types is needed to support a suite of generalist predator species.

POSTER PRESENTATION

Using differential responses to light spectra as a push-pull control strategy for wood borers and bark beetles

Stephen Pawson, Michael Watt

Scion, Christchurch, New Zealand

Wood borers and bark beetles are globally significant quarantine pests of export timber. Insect are known to have strong responses to ultra-violet light and weak responses to other regions of the visible spectra. In a two part experiment we ascertained the least attractive light spectra to wood borers and then tested a push-pull strategy that takes advantage of these differential spectral responses to control unwanted insect species at wood processing or transfer facilities.

Yellow light was the least attractive spectrum to wood borers with more than an order of magnitude fewer individuals caught than ultra-violet light. The push-pull strategy was implemented to test the effect of commercially available lamps and was simulated in recent clearfells rather than manipulating light at processing facilities. Metal halide (white light) and both high and low-pressure sodium (two yellow lamps) were tested to determine which attracted the fewest individuals thus representing a 'push' component and ultra-violet lamps were used to attract unwanted insects to kill traps. Both high and low-pressure sodium lamps attracted fewer individuals than the metal halide lamps for the *Prionoplus reticularis* (Cerambycidae), however the results for *Arhopalus ferus* were less clear and we propose a behavioural interaction between the two species as the cause. Ultra-violet pull traps were successful in reducing the catch of beetles in adjacent non-illuminated control traps.

The results show that visual cues can be used successfully in a push-pull strategy for controlling insect populations; additional trials are required on a greater range of quarantine insects.

POSTER PRESENTATION

Insecticidal activities of basil oil, *trans*-anethole, estragole, and linalool to adults of *Ceratitis capitata*, *Bactrocera dorsalis*, and *B. cucurbitae*

Chiou Ling Chang[1], Il Kyu Cho[2], Qing Xiao Li[2]

[1]USDA-ARS, Honolulu, Hawaii, United States, [2]Department of Molecular Biosciences and Bioengineering, University of Hawaii, Honolulu, Hawaii, United States

Basil oil, *Ocimum basilicum* Linn, and its three major active constituents, trans-anethole, estragole, and linalool, were tested on three tephritid fruit fly species for insecticidal activities. The insecticidal action of basil oil, linalool, *trans*-anethole, and estragole is very fast and follows a very steep dose-response relation. The 90% lethal times (LT_{90}) of the three tephritid fruit fly species under 10% of these test chemicals were 8-38 min. The action of basil oil is faster to *C. capitata* than to *B. dorsalis* and *B. cucurbitae;* estragole is faster to *B. dorsalis* than to *C. capitata* and *B. cucurbitae;* linalool is faster to *B. dorsalis* and *C. capitata* than to *B. cucurbitae;* and *trans*-anethole is similar to all three species. When linalool was mixed with cuelure (attractant to *B. cucurbitae* male), its potency to the three fly species decreased as the concentration of cuelure increased, which was confirmed by chemical analysis, due to linalool hydrolysis catalyzed by acetic acid from cuelure degradation. When methyl eugenol (*B. dorsalis* male attractant) was mixed with basil oil, *trans*-anethole, estragole or linalool, it did not apparently reduce the mortality of *B. dorsalis* from both basil oil and linalool, but did significantly decrease the mortality from *trans*-anethole and estragole. Structural similarity between methyl eugenol and *trans*-anethole and estragole suggests that methyl eugenol might compete with *trans*-anethole and estragole at the same action site and serve as an antagonist if a distinct action site would exist. Methyl eugenol may also play a significant physiological role on the toxicity reduction.

POSTER PRESENTATION

Santocellus, a new genus of green lacewings (Neuroptera: Chrysopidae: Leucochrysini) from South America

Catherine Tauber[1], Maurice Tauber[1], Gilberto Albuquerque[2]

[1]Cornell University, Ithaca, NY, United States, [2]Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, RJ, Brazil

Introduction: Among the six previously recognized genera of Leucochrysini, five are very small and well defined. However, the sixth, *Leucochrysa*, encompasses a large array of species (approx. 200 described and several more undescribed) that are united only by the lack of features that distinguish the other genera. As an initial step towards revising and subdividing *Leucochrysa*, here we used a broad approach, including characters from both the adult and larval stages, to describe a new genus with three species.

Results: *Santocellus atlanticis* gen. et sp. nov. and *Santocellus riodoce* (Tauber) comb. nov. are from the Atlantic Forest of Brazil; *Santocellus bullata* (Tauber) comb. nov. is from Peru. The adults of the three species, as well as the larvae of the first two (the third is unknown), share a distinguishing suite of features: wings with dark (sometimes pustulate) markings; males with an elongate, cylindrical mediuncus and stiff membrane below; females with round, doughnut-shaped spermatheca having a shallow invagination and a sail-shaped velum that extends anteriorly; larvae with discrete, longitudinal head markings, short mandibles, broad labial palpi, and short, stubby, ventrally projecting terminal palpomeres.

Conclusion: recent descriptions of the larvae of several genera of Leucochrysini have demonstrated the value of larval characteristics in deciphering generic relationships within this tribe. Without such knowledge, the three species that now comprise the new genus *Santocellus* would have fallen within *Gonzaga* Navás or *Leucochrysa* (subgenus *Leucochrysa*) McLachlan.

POSTER PRESENTATION

Influence of ants on arthropod communities in vineyard

Chee Seng Chong, Linda J. Thomson, Ary A. Hoffmann

Centre for Environmental Stress and Adaptation Research, Department of Zoology, University of Melbourne, Parkville 3010, Australia

Introduction: Ants are highly dominant and have a significant role in structuring arthropod communities in many agroecosystems. They are often implicated in interfering in control of pests by natural enemies. Manipulative experiments were conducted to determine the impact of ants on arthropod diversity in canopy and ground within a vineyard.

Methods: Ants were excluded from vine canopy in randomly assigned row sections with Tacgel. Arthropods were sampled in treatment (ant-excluded) and control vines with beat-and-collect method, yellow sticky and pitfall traps over several occasions. Egg cards of light brown apple moth, the dominant insect pest in vineyards in southeastern Australia, were also placed to determine that effect of ants on egg parasitism and mortality.

Results: A higher ground ant foraging activity was present in ant-excluded vines. There were more spiders in ant-excluded vines. Differences were also detected for other groups but these were complex and depended on the month of sampling.

Conclusions: Preliminary findings indicate ant effects on other arthropods but these are complex and change over time.

POSTER PRESENTATION

Vegetation effect on spatial distribution of ants in vineyards

Chee Seng Chong, Linda J. Thomson, Ary A. Hoffmann

Centre for Environmental Stress and Adaptation Research, Department of Zoology, University of Melbourne, Parkville 3010, Australia

Introduction: The spatial distribution of ants within a landscape is influenced by interplay of many factors including competition, habitat preferences, environment heterogeneity and stochastic processes. Here, we investigate the influence of adjacent vegetation on the spatial distribution of ground-dwelling ants within vineyards.

Methods: Ants were sampled with pitfall trappings that were placed in either random or systematic arrangements in several vineyards that had adjacent vegetation (remnant forest patches or complex shelterbelts). The x- and y-coordinates at each sampling point, ant species and their abundance were recorded. Data were analysed using Spatial Analysis by Distances IndicEs (SADIE) to determine dispersal or aggregation of ant species and spatial maps were generated.

Results: Ant richness was relatively high (30-50 species within a hectare) in vineyards surveyed with several species only found close to adjacent vegetation. Spatial maps showed that the distribution of ant genera and species were significantly aggregated and ants occupied spatially-exclusive patches with dominant *Iridomyrmex* ants being negatively associated with other ant genera. In particular, *Rhytidoponera* species were found to be closely associated with adjacent vegetation suggesting the role of adjacent vegetation in modifying habitats that are suitable for particular ant species and thus modifying competitiveness.

Conclusions: The presence of significant patches and gaps demonstrated the role of interspecific competition in structuring ants' spatial distribution. However, the distribution of some ants especially *Rhytidoponera* species close to vegetation clearly suggested the importance of adjacent vegetation in enhancing a species advantage over another.

POSTER PRESENTATION

Analysis of the sex pheromone composition of the variegated cutworm (*Peridroma saucia*) in Korea

Kyung San Choi, Jum Rae Cho, Jeong Heub Song, Doon Soon Kim, Kyung Saeng Boo

National Institute of Subtropical Agriculture, Jeju, Republic of Korea

Introduction: In Korea, the variegated cutworm, classified as a quarantine pest insect by Korean National Plant Quarantine Service, was first discovered at Mudeung Mountain and in Jeju Island in 1996. Since then, the damage by *P. saucia* was found in carrot, corn, cabbage, and citrus in Jeju. The goal of this study was identifying the sex pheromone composition and applying it to monitor the population fluctuation of *P. saucia* in Korea.

Method: Calling and mating behavior of female *P.saucia* was investigated during scotophase under 16L:8D photoperiod and 25□±1 temperature. The extract of female sex pheromone glands was analyzed with GC-MS and then GC-EAD test was conducted. EAG test of male antennae was investigated on sex pheromone analogues and a series of dose of their own sex pheromone components. Changes of amount of sex pheromone components biosynthesized in a sex pheromone gland were analyzed with GC. Field attraction test was conducted with a series of sex pheromone blend at Milyang and Snaggui.

POSTER PRESENTATION

Isolations of new *Bacillus thuringiensis* strains with high toxicity to *Spodoptera litura* (Lepidoptera: Noctuidae)

Da-A Kim, Mi-Ra Kil, Seung-Kyoung Baik, Jin-Su Kim, Su-Yeon Choi, Da-Yong Jin, Jang Hyun Hur, Yong-Man Yu

[1]Chungnam National. Uni., Daejon, [2]Kangwon Nat'l Univ., Chuncheon, Republic of Korea

New strains of *Bacillus thuringiensis* with high toxicities against the tobacco cutworm, *Spodoptera litura* (Lepidoptera: Noctuidae), were isolated and selected from several kinds of domestic soils. Sixteen *B. thuringiensis* strains were isolated from 12 among 142 soil samples. Among 16 *B. thuringiensis* isolated strains, 11 strains have toxical activities against *Plutella xylostella* (Lepidoptera: Yponomeutidae), 7 strains on *Spodoptera litura* (Lepidoptera: Noctuidae), 5 strains on *Spodoptera exigua* (Lepidoptera: Noctuidae), 5 strains on *Arcte coerulea* (Lepidoptera: Noctuidae), and 5 strains on *Culex pipiens pallens* (Diptera: Culicidae). When being examined with a phase-contrast microscope, the insecticidal crystal proteins were observed. These crystal proteins were produced from selected strains; 13 strains showed bipyramidal crystal protein shapes and other 3 strains showed spherical shapes. As results of identifying by H serotype, 13 strains separated among 16 strains, 1 strain was showed *ostriniae* (8ac), 8 strains were *kurstaki* (3abc), 3 strains were *aizawai* (7) and 1 strain was *colmeri* (21). On the other hands, insecticidal activities were examined against 3rd larva of *S. litura* with new strains and existing ready-made products. CAB109 strain of *B. thuringiensis aizawai* showed 100% mortality with 1.3×10^7 spore concentration (cfu/ml). LC_{50} values of CAB109 strain of *B. t. aizawai* were 9.78×10^5, 6.87×10^6 and 1.83×10^7 spore concentration (cfu/ml) against 2nd, 3rd and 4th larva of *S. litura*, respectively. It was a very high insecticidal activity compared with existing ready-made *B. thuringiensis* products. Unlike *P. xylostella, S. litura* was slowly died up to 7 days after application at same concentration.

POSTER PRESENTATION

Electronic noses for the detection of flystrike in sheep

Andrew Cramp[1], Jae Ho Sohn[2], Peter James[1]

[1]Animal Research Institute, Department of Primary Industries and Fisheries, Yeerongpilly, Queensland, Australia, [2]Sustainable Intensive Systems, Department of Primary Industries and Fisheries, Toowoomba, Queensland, Australia

Introduction: Cutaneous myiasis (flystrike) is a debilitating, painful and potentially lethal disease of sheep. In Australia, South Africa and New Zealand the principal agent of myiasis is *Lucilia cuprina* (Wiedemann). Early detection of flystrike is difficult and continual flock surveillance is required to enable timely treatment of struck sheep. Electronic nose technology offers the potential for the early and remote detection of flystrike.

Methods: Two electronic noses were evaluated, one an array with six metal oxide semiconductor sensors chosen on the basis of GC-MS flystrike odour profiles and the other, a non-specific gas sensor array of 24 metal oxide semiconductor sensors. Odour samples were collected by dynamic headspace sampling from the sheep's back before and during flystrike development and from urine- and faeces-stained fleece. Conventional statistical analyses and chemometrics were used for data pre-processing and model development to discriminate strike and excrement odours from dry fleece.

Results: Both electronic noses accurately discriminated the odours of day 1, 2 and 3 flystrike from that of dry wool. Both successfully distinguished urine staining from dry wool and strike and faeces staining from strike, but not dry wool. The accuracy of prediction of the best sensor array was 96.8%, 100%, 98.3%, and 98.4%, for strike on days 0 (day of implant), 1, 2 and 3 respectively.

Conclusion: This study provides proof of concept for the detection of flystrike using electronic nose technology. Suitable detection algorithms and methods for collection of odour in the field will be required for development to practical application.

POSTER PRESENTATION

Pathogenicity of entomopathogenic nematodes to sheep lice (*Bovicola ovis* Schrank)

Peter James, Stacey Hook, Andrew Cramp

Animal Research Institute, Department of Primary Industries and Fisheries, Yeeronpilly, Queensland, Australia

Introduction: Alternatives to chemical methods for controlling sheep lice are required to address resistance in sheep louse populations and increasing 'eco-consciousness' amongst consumers and sheep producers worldwide. Entomopathogenic nematodes (ENs) have been referred to as 'pesticides with the power of search' and have particular advantages against pests in cryptic habitats, such as the fleeces of sheep, where it is difficult to directly contact the target pest with conventional pesticides.

Methods: Laboratory assays were conducted with *Steinernema carpocapsae* (ALL strain), *S. feltiae* (NJ), *Heterorhabditis bacteriophora* (Otio) and *S. riobrave* to test their pathogenicity to lice at different temperatures and confirm their ability to infect *B. ovis* when applied to wool. Preliminary studies with *S. carpocapsae* applied to sheep were carried out to test their longevity in the fleece and effectiveness in reducing louse numbers.

Results: Infective juvenile nematodes of all species were able to move along wool fibres to infect and kill lice when applied to wool in solution with Tween80 at 25°C. At temperatures above 30°C only *S. carpocapsae* and *S. riobrave* caused significant mortality. Treatment of louse-infested sheep with *S. carpocapsae* reduced louse numbers by 89.8% at 11 days after treatment. Live nematodes were recovered from the fleeces of treated sheep for up to 20 days, but baiting studies suggested significant infectivity for only 6 days.

Conclusion: To our knowledge this is the first report of the use of direct animal application of ENs to control ectoparasites and the first report of pathogenicity of ENs to chewing lice.

POSTER PRESENTATION

The arthropod fauna of Bt corn, hybrid corn, and sweet corn

Bonifacio Cayabyab[1], Wilma Cuaterno[2], Edwin Alcantara[3], Pablito Gonzales[1], Josemari Belen[1]

[1]National Crop Protection Center-Crop Protection Cluster, Los Baños, College, Laguna, Philippines, [2]Crop Protection Division, Bureau of Plant Industry, San Andres, Manila, Philippines, [3]Institute of Biotechnology, UP Los Baños, Los Baños, College, Laguna, Philippines

The information on the arthropods fauna of Bt corn and other varieties of corn in the Philippines is not updated. There are very few studies conducted on this subject matter recently. This study was conducted at Lubao, Pampanga, Philippines from February 2008 – May 2008. The study aims to generate data on the arthropods fauna on the three most common varieties planted in the locality and these are Bt corn (Pioneer 30b80YG), sweet corn (SG 75) and hybrid corn (Bioseed 900). It will elucidate the pest and natural enemies and damages on these varieties during the various growth stages.

A randomized complete block design on a one thousand two hundred square meters field was used. Each variety was planted on a 120 sq m area replicated three times. Standard agronomic practices were done. Monitoring of arthropods was thru sticky traps, pitfall traps and sweep net. Damages were recorded on plants within the 50 sq m plot located at the middle of its replicate. There were very few arthropods at three leaves stage and no damages were recorded. The study is on-going and the results with statistical analysis will be presented.

POSTER PRESENTATION

Climate change and its effect on the migratory locust, *Locusta migratroria manilensis* Meyen (Orthptera: Acrididae), population in the Philippines

Bonifacio Cayabyab, Pablito Gonzales, Melvin Ebuenga

Plant and Environmental Health Division Crop Protection Cluster, UP Los Baños, College, Laguna, Philippines

Climate change particularly elevated temperature or increased warming due to El Niño can greatly affect the population of the migratory locust, *Locusta migratoria manilensis* Meyen in the Philippines. This phenomenon causes prolonged dry spell and widespread drought resulting to the formation of patches of green vegetation in certain areas wherein the migratory locust congregate and multiply. Gregarization follows that eventually lead to migration.

Migratory locusts devastated rice, corn and sugarcane in Central Luzon (1996-2000), it threatened the sugarcane growing areas of Negros Island (2000-2002) while population build-up in various islands of the archipelago were observed from 2003-2006. Just recently, a prolonged dried spell in the Fuga Island, the located at the tip of Northern Luzon from October 2006 resulted to the population build-up and destruction of rice crops in the island in December 2006 – January 2007. It is now imperative to do a risk assessment of the various islands by using climate change models. The temperatures during the last 50-100 years could be used in developing population simulation models. The result can be used to issue early warning pest advisories. Technicians and farmers must be trained to monitor population build-up and massive information campaign for community efforts to control outbreaks should be done. The government must allocate funds for information campaign and community based locust management. ASEAN member countries should be forewarned since the *Locusta migratoria manilensis* has the ability to fly long distances.

POSTER PRESENTATION

Impact of glyphosate-resistant soybean weed management on abundance and taxonomic composition of arthropods in Missouri soybeans

Clinton Meinhardt[1], Wayne Bailey[1], Thomas Clark[2]

[1]University of Missouri, Columbia, Missouri, United States, [2]Monsanto Corporation, St. Louis, Missouri, United States

Introduction: Glyphosate-resistant soybeans, *Glycine max* (L.) Merr., enables flexibility in the timing of weed removal from the soybean agroecosystem. The wide adoption of this weed management technology in the USA has the potential to alter the occurrence and timing of winter annual and spring germinating weeds. Changes in weed dynamics may result in changes in the abundance and taxonomic composition of arthropods in the soybean agroecosystem

Methods: Field studies were conducted in Missouri to investigate how arthropods are affected by glyphosate-resistant soybean weed management when exposed to four different weed removal times and four weed species compositions. Sweep net and pitfall collection methods were used to estimate numbers of foliar and soil surface dwelling arthropods, respectively.

Results: Sixty percent of arthropod groups investigated were affected by weed management. Arthropods were most influenced by weed removal timing and exhibited preferences for either weedy soybean habitats with delayed weed removal or soybean habitats with reduced weed density from early weed removal. Ground-dwelling arthropod populations, were supported by increased weediness. Carabidae were 1.5 – 2 times more abundant in the weediest treatment (season-long mixed grass and broadleaf weeds) than in the weed-free control treatment. Soybean habitats with prolonged weediness supported 10 of the 15 foliage-dwelling arthropod groups with significant weed removal timing effect results, including the total natural enemy and phytophagous arthropod groups.

Conclusion: Glyphosate-resistant soybean weed management impacts the taxonomic composition and abundance of arthropods in soybean agroecosystems; however yield disadvantages associated with increase arthropod numbers have yet to be elucidated.

POSTER PRESENTATION

Effects of sugar availability on the mating behaviour of *Anopheles gambiae* (Diptera: Culicidae)

Chris Stone, Robin Taylor, Woodbridge Foster

The Ohio State University, Columbus, Ohio, United States

Sugar is the only source of energy for adult male mosquitoes, but the extent to which the lack of opportunities to sugar feed impacts a cohort of males' ability to inseminate female mosquitoes is unknown. We report here on an investigation on the impact of sugar availability on the mating performance of male *Anopheles gambiae* in both mesocosms and in cages.

Over a ten day period, each day twenty male and female mosquitoes were allowed to emerge into mesocosms; enclosures with simulated natural conditions, and cages. Sugar was either absent or present in the form of 10% sucrose solutions. Every night female mosquitoes were given the chance to blood feed. After 10 days all surviving mosquitoes were inspected for insemination.

In the mesocosms 10.9% of the females were inseminated when sugar was not available, against 49.7% when sugar was present. Enclosure size also influenced insemination rates; in the cages 23.5% of the females were inseminated in the absence of sugar, whereas 76% were inseminated in the presence of sugar. No significant differences in biting activity were discovered. Survival of females after ten days was 51.6% with sugar, and 25.6% with water only in the mesocosms. In the cages female survival was 95% with sugar and 73% without.

We conclude that insemination capability of males in the absence of sugar sources is greatly diminished but not completely absent under semi-field conditions, and stress the importance of using an appropriately scaled experimental system for behavioural studies of this medically important species

POSTER PRESENTATION

Phylogeny analysis of Thripidae based on 28S rDNA

Wen-Bin Yeh, Mei-Rong Tseng

National Chung Hsing University, Taichung, Taiwan, Taiwan

The nuclear 28S rDNA sequence has been widely used in higher phylogenetics of Insecta, but has seldom been applied to thrips. In this study, ~3000 bp of 28S rDNA sequences from 45 Thripinae and three Panchaetothripinae were used to probe the essence of this gene and its applicability to the delineation of phylogenetic relationship of these species. Sequences of 28S rDNA across thrips, though with variable region, were not randomly distributed, with the expansion segments being more variable than the core regions and with an increasing sequence divergence with taxonomic distances. Scatter plots of total substitutions (Tvs) against transversions (Tv) or transitions (Ts) in 28S region revealed similar and linear evolving processes for both Tv and Ts. Sequence divergence of the 28S rDNA region of 30 species among 48 individuals was less than 1.2% within species, and that among species in a given genus was 0.7-15 %, that among genera in the same subfamily was 5-20 %, and that between subfamilies was 14-20%. Phylogenetic inferences from both parsimony and clustering methods suggested members of the same subfamily and genus were grouped together except *Thrips* genus. Analyses of the nearly complete sequences of thrips 28S rDNA have shown that its expansion region may be more useful in the resolution of lower taxonomic relationship, and its core region may be more reliable for that of higher category.

POSTER PRESENTATION

Indo-Australian Aleyrodidae (Whiteflies): A molecular analysis of phylogenetic relationships

Paul DeBarro[1], Rosemarie C. Rosell[2], Heather S. Costa[2], Donald R. Frohlich[3]

[1]CSIRO, Brisbane, Queensland, Australia, [2]University of St. Thomas, Houston, Texas, United States, [3]University of California, Riverside, California, United States

Two nuclear DNA sequences (D2 and 18S) were used to reconstruct the phylogeny of 89 species of whiteflies in over 40 Indo-Australian Aleyrodid genera. Four methods were applied: distance, parsimony, maximum likelihood, and a bayesian technique. Herein we discuss relationships between the genera and compare the utility and differences of the four analytic approaches with relationships based on morphological characteristics of puparia.

POSTER PRESENTATION

Nutritional factors influencing whitefly development in a hydroponic system

Jacquelyn Blackmer, Lynn Forlow Jech

US ALARC-ARS-USDA, Maricopa, Arizona, United States

Introduction: Whiteflies are phloem feeders and encounter some of the lowest levels of N found; however, they manage to excel due to behavioral and physiological modifications. Understanding how fluctuations in their diet influence their life-history traits could provide us with novel means of controlling this major pest.

Methods: We used hydroponic units to deliver known quantities of macronutrients or macro- and micronutrients at three concentrations. Bollguard II® cotton was grown in rockwool media, and nutrients were supplied via a drip system. The influence of different nutrient regimes on plant attributes (height, basal diameter, and petiole NPK) and whitefly life-history traits (oviposition preference, developmental time, emergence rates, and adult weights) were measured. Whiteflies were placed on the 3rd (vegetative), 6th (pinhead square) and 9th (flowering) true leaf and allowed to oviposit for 48-h. Subsequent development was monitored.

Results: Plants provided with macronutrients were taller and had larger basal circumferences under the medium and high nutrient regimes, but when macro- and micronutrients were supplied, no differences relative to nutrient levels were observed. Petiole analysis indicated fluctuations in NPK were correlated with plant phenology and nutrient levels. Whiteflies deposited twice as many eggs on plants that were supplied with both macro- and micronutrients, and female weights decreased with leaf age; however, few other parameters showed a response to nutrient regime or nutrient levels.

Conclusions: Plant attributes and whitefly oviposition were influenced by nutrient regimes and levels, but few other whitefly life-history parameters showed a clear response. Additional studies are underway to better define these relationships.

POSTER PRESENTATION

Superoxide dismutase activity in temperature stressed viruliferous whiteflies (Hemiptera: Aleyrodidae)

Rosemarie C. Rosell[1], Arsalan Shah[1], Mudasser Khan[1], Niloufar Aghakasiri[1], Robert S. Jr. Shatters[2], Cindy L. McKenzie[1]

[1]University of St. Thomas, Houston, Texas, United States, [2]USDA, ARS, Horticultural Research Laboratory, Ft. Pierce, Florida, United States

Whiteflies' remarkable ability to transmit and spread begomovirus diseases has had an immense impact on global food production and thus they have become one of the most serious crop pests throughout much of the world. Our hypothesis is that the ability of the whitefly to survive under extreme temperature conditions is related to the regulation of the enzyme, superoxide dismutase (SOD). The purpose of our study is to determine the relationship between stress, virus infection and SOD activity. SOD functions in the conversion of O_2^- free radicals to less toxic products. Superoxide free radicals bind to macromolecules in cells and may lead to breakdown of cellular membranes. Previously, we have shown under normal metabolic conditions the presence of superoxide dismutase in *Bemisia tabaci* whole body extracts. In this study, we determined the effects of temperature stress on whiteflies fed on either begomovirus-infected tomato or healthy tomato plants. Two begomoviruses, tomato mottle virus (ToMoV) and tomato yellow leaf curl virus (TYLCV) were used in the study. We characterized and quantified SOD activity using an electrophoretic assay combined with. a commercially available spectrophotometric assay. Our data showed that SOD activity was directly proportional to an increase in temperature in non-viruliferous whiteflies. However, the SOD activity in whiteflies reared on virus-infected plants was varied. These data were supported by the SOD isozymes observed in the electrophoretic assay. The roles of SOD activity and temperature stress in relation to whitefly interactions with begomovirus in whitefly are discussed.

POSTER PRESENTATION

Dynamic population density of the coconut hispine beetle, *Brontispa longissima* Gestro (Coleoptera: Chrysomelidae)

Sopon Uraichuen, Kittiya Suksen, Wiwat Suasa-ard

National Biological Control Research Center, Central Regional Center, Nakhon Pathom, Thailand

Introduction: The coconut hispine beetle, *Brontispa longissima* Gestro was accidentally introduced into continental Southeast Asian countries, presumably in the early 2000's, with ornamental palms. Since then it become one of the most serious insect pest of coconut in Thailand.

Methods: Dynamic population density study of *B. longissima* was taken place by using 3 coconut fields at Kamphaeng Saen, Nakhon Pathom province in the Central Region of Thailand. Data collection was done twice a month. The sampling program was set by using 5 leaves as a sample unit and 16 samples per location. The number of eggs, larvae, pupae and adults of the beetle were recorded from August 2006 to December 2007. All data were subsequently analyzed and considered with density independent (DI) factors.

Results: Analysis results of the combinative DI factors affected to dynamic population of *B. longissima* indicated that rain volume, temperature and relative humidity caused change of the beetle population. The result revealed that the more rain volume and the less relative humidity, the greater number of egg pest. Meanwhile, temperature was a negative additional effect to the survival beetle larvae. Regard to adult population, the DI factors did not directly make a change in its population. Nevertheless, they could substantially give the lower egg laying rate of the female adult as well as the lesser hatch percentage.

Conclusions: The DI factors, rain volume, temperature and relative humidity which seasonal alter through the year round were the combinative effect to the dynamic change of *B. longissima* population.

POSTER PRESENTATION

Malaria transmission risk and the potential role of microbial larviciding in irrigated rice agroecosystems

Simon Muriu[1], Josephat Shililu[1], John Githure[1], Robert Novak[2]

[1]I.C.I.P.E., Nairobi, Kenya, [2]UAB, Birmingham, AL, United States

Introduction: Irrigated rice agro-ecosystems are associated with high densities of malaria vectors due to expansive open water surfaces conducive for *Anopheles* mosquito breeding. These habitats are amenable to larval control. The use of biological control agents in malaria vector control is becoming popular in Africa with use of two microbial larvicides, *Bacillus thuringiensis* var *israelensis* (Bti) and *B. sphaericus* (Bs). The study evaluated the potential of a new combined Bti/ Bsph microbicide formulation for larval control in rice agroecosystems in Mwea, Kenya.

Methods: Data on *Anopheles* mosquito breeding habitat types and their productivity in space and time in Mwea irrigated rice scheme was collected. Anopheline species abundance and diversity was evaluated based on larval and adult collections. The effect of Bti/ Bs on vector populations was evaluated at village level.

Results: Eleven habitat types were identified with differential mosquito productivity potential during the year. Rice paddies and drainage canals were the most productive especially during the early vegetative stages of rice growth while the other habitats provided ideal breeding areas during rainy seasons. The peak adult vector density expressed as the human biting rates (10.4 bites per person per night) occurred shortly after rice planting. The application of the microbial larvicides significantly reduced larval densities in the study sites confirming its potential for control of the immature stages of anopheline mosquitoes.

Conclusions: *Anopheles* habitats in irrigated systems are differentially productive and application of larval interventions using microbial insecticides has to be time and habitat specific. The new combined Bti/Bsph formulation has shown a potential in reducing malaria vector populations and transmission risk in the irrigated rice agroecosystems.

POSTER PRESENTATION

Insecticide resistance in a major malaria vector from South Africa, *Anopheles arabiensis*

Lizette Koekemoer[1], Joel Mouatcho[1], Basil Brooke[1], Givemore Munhenga[2], Ron Masendu[2], Keith Hargreaves[3], Richard Hunt[4], Maureen Coetzee[1]

[1]NICD, Johannesburg, South Africa, [2]University of Zimbabwe, Harare, Zimbabwe, [3]Malaria Control Programme, KwaZulu/Natal, South Africa, [4]University of the Witwatersrand, Johannesburg, South Africa

Introduction: *Anopheles arabiensis* is a major vector of malaria in South Africa in addition to *An. funestus* and is responsible for seasonal malaria transmission. DDT resistance in a population of *An. arabiensis* in the Mamfene region of Kwazulu/Natal was recorded in 2003. There was no pyrethroid resistance observed in this population at that time.

Methods: *Anopheles arabiensis* originating from Mamfene in 2003 was colonized and a DDT resistant line selected. Wild females were collected during 2005 using exit traps in sprayed houses. Two-day-old adult progeny obtained from these wild females and from the colony were exposed to permethrin, bendiocarb and deltamethrin according to the standard WHO bioassay procedures followed by biochemical and target site analysis.

Results: The DDT resistant strain of *An. arabiensis* showed 25% mortality after 1 hr exposure to DDT. Susceptibility assays on field collected material revealed 63-73% mortality against permethrin. All F1 families tested showed full susceptibility to bendiocarb and deltamethrin. Biochemical analysis showed elevated levels of monooxygenase correlating with the permethrin bioassay data. Although elevated levels of non specific esterases were found in some families, these did not show any correlation to the permethrin bioassay data. F1 progeny were also used to select a pyrethroid resistant laboratory strain in order to characterize the pyrethroid resistance mechanism. Parallel to these studies a bendiocarb resistant line was selected in order to characterize the bendiocarb resistance observed in the *An. arabiensis* strain colonised in 2003. Both these selected lines were analysed using biochemical assays as well as synergists. Molecular analysis revealed no mutations associated with target site insensitivity to insecticide.

Conclusions: Biochemical analyses suggest that the insecticide resistance found in *An. arabiensis* from South Africa is most likely metabolic and does not involve target site insensitivity mutations.

POSTER PRESENTATION

Insecticidal properties of bistrifluron against sycamore lace bug, *Corythucha ciliata* (Hemiptera: Tingidae)

Changmann Yoon, Jeong-Oh Yang, Shin-Ho Kang, Gil-Hah Kim

Chungbuk National University, Cheongju, Chungbuk, Republic of Korea

Bistrifluron, a member of the benzoylphenylurea (BPU) class, was developed in the Republic of Korea as an inhibitor of chitin synthesis. This study examined the effect of bistrifluron on insecticidal activity, adult longevity, fecundity and ovarian development in the sycamore lace bug, *Corythucha ciliata*. The results showed that bistrifluron had no direct effect on the egg, but produced 100% mortality in larvae hatched within 24 hr with a similar effect regardless of the instars of the larvae (LC50_0.01–0.06 ppm). When the final instar was treated with bistrifluron, the emergence rate, adult longevity and reproduction decreased with increasing concentration (up to 100 ppm). With the passage of time after the final larvae had emerged, chemical treatment delayed the preoviposition period of the adults at high concentrations, and decreased adult longevity, fecundity and the hatching rate. Ovarian development of the adult was also inhibited.

POSTER PRESENTATION

On the interactions of whitefly, *Bemisia tabaci* and its natural enemies on different chilli cultivars

Khalid Saeed Aqlan Naser[1], Idris Ghani[2], Mohamad Roff Mohd Noor[3]

[1]Sana'a University, Sana'a, Yemen, [2]Universiti Kebangsaan Malaysia, Bangi, Selangor, Malaysia, [3]Malaysian Agricultural Research and Development Institute, Serdang, Selangor, Malaysia

Introduction: Whitefly (WF) is causing a significant damage to chilli crops in Malaysia. Nevertheless, presence of natural enemies are expected to control their populations but their interactions are yet to be resolved. Temporal and vertical distributions of WF and its natural enemies were assessed on four cultivars of chillies.

Methods: Yellow sticky traps on poles were placed in plots of chilli cultivars in a randomized block design. Trapped WF adults were counted weekly and infested leaves were examined for WF of other life stages and natural enemies.

Results: Infestation rates among cultivars varied periodically with plant maturity causing adult population to tremendously increased through time. Concentration of eggs and larvae were obviously varied, being higher at 63 DAT, whilst lower at 35 DAT. Differences were also observed amongst chilli plant strata of cultivars with upper stratum more infested than the lower stratum. A strong correlation was found between plant height and the WF population. In terms of natural enemies, number of predatory coccinellid viz. *Menochilus sexmaculatus* Fabricius, was significantly higher on infested cultivars. However, the other important coccinellids, *Coccinella transversalis* F. and *Coelophora inaequialis* F. per plant remain lower. The percentage of lacewing and of *Encarsia* sp. were also significantly higher among infested plants. Strong correlations were evident between different life stages of WF and its natural enemies with multilevel interactions.

Conclusion: The study provides a base line data for the interactions of WF with their natural enemies which can be useful in developing the IPM strategies for chilli crops.

POSTER PRESENTATION

Relationship between dehydration rate and success of anhydrobiosis in the sleeping chironomid, *Polypedilum vanderplanki*

Yuichi Nakahara, Gusev Oleg, Masahiko Watanabe, Daisuke Tanaka, Ken-ichi Iwata, Yasushi Kanamori, Cornette Richard, Takahiro Kikawada, Takashi Okuda

National Institute of Agrobiological Sciences, Tsukuba, Ibaraki, Japan

Introduction: Aquatic larvae of the sleeping chironomid, *Polypedilum vanderplanki*, can enter anhydrobiosis, a latent life (ametabolism) without free water. In general, for successful anhydrobiosis, slow dehydration is required to form biological glasses which can provide effective protections against threats such as oxidative stress. It is assumed that degree of damages sustained during desiccation affects survivorship of the larvae.

Methods: *P. vanderplanki* larvae were desiccated by exposing them to different drying regimes, each progressing from high to low relative humidity, and we examined the cell damage and survival rate after rehydration. DNA damages were detected by comet assay.

Results: Without preconditioning at high relative humidities, rapid desiccation caused an immediate death. Exposure to RH 100% for at least 12 h assured to revive after rehydration. Even after the preconditioning, if dehydration rate exceeded 0.7 mg water/day, most of the rehydrated larvae died before reaching the adult form. However, differential scanning calorimetry showed that such larvae formed glasses during desiccation, indicating that vitrification is insufficient for successful anhydrobiosis. To our surprise, considerable DNA-damages occurred even in the larvae dehydrated by an adequate regime. However, number of cells with broken DNA decreased with the course of time after rehydration. Gene expression analysis showed upregulation of proteins involved in reducing oxidative stress and enzymes involved in DNA damage repair.

Conclusion: *P. vanderplanki* larvae suppress accumulation of damages during desiccation to a repairable level for entering successful anhydrobiosis. Unrepairable damages probably cause delayed death.

POSTER PRESENTATION

Susceptibility of ussur brown katydid, *Paratlanticus ussuriensis* (Orthoptera: Tettigoniidae) to commercially registered insecticides

Doo-Jin Noh, Jeong-Oh Yang, Changmann Yoon, Gil-Hah Kim

Chungbuk National University, Cheongju, Chungbuk, Republic of Korea

Insecticidal activity of 33 registered insecticides was tested against last nymphal instars and adults of ussur brown katydid, *Paratlanticus ussuriensis*. All experiments were tested at the recommended concentration of each insecticides by producer. Acephate, chlorpyrifos, diazinon, EPN and fenitrothion which were organophosphates, and a mixture combined with chlorpyrifos+α-cypermethrin showed 100% mortality of *P. ussuriensis*. But fipronil showed only 100% mortality in leaf-dipping method. Carbamates insecticidal groups, benfuracarb and furathiocarb were showed over 80% and phenthoate was 60~80% in mortality of *P. ussuriensis*. Among the mixture, etofenprox+diazinon and esfenvalerate+fenitrothion were showed 60~80% against last nymphal instars of *P. ussuriensis*. Otherwise, acephate, chlorphyrifos, diazinon, EPN and fenitrothion were showed 100% mortality of *P. ussuriensis* within only 24 hours after treatment, but there was no effective after then in residual tests with leaves.

POSTER PRESENTATION

Pathogenicity of the entomopathogenic fungi *Paecilomyces fumosoroseus* and *Lecanicillium* (= *Verticillium lecanii*) against *Trialeurodes vaporariorum*

Samuel Pineda, Marcela-Inés Schneider, Ana-Mabel Martínez

[1]Instituto de Investigaciones Agropecuarias y Forestales. Universidad Michoacana de San Nicolás de Hidalgo., Tarímbaro, Michoacán., Mexico, [2]Centro de Estudios Parasitológicos y de Vectores CEPAVE, La Plata, Buenos Aires., Argentina

Introduction: Entomopatogenic fungi are a promising alternative for the control of agricultural pests. We evaluated the pathogenicity of three isolates of *Paecilomyces fumosoroseus* (Pf_1, Pf_2, and Pf_3) and six isolates of *Lecanicillium* (= *Verticillium lecanii*) (Vl_1, Vl_2, Vl_3, Vl_4, Vl_5, and Vl_{10}) on eggs, second, third, and fourth nymphal instars of the greenhouse whitefly, *Trialeurodes vaporariorum*.

Methods: Pathogenicity tests were performed in the laboratory. For this, fungal applications were made on tomato leaves infested with *T. vaporariorum.* After three days post-treatment, eggs and nymphs were observed daily for eight days to register and confirm mortality caused by fungi. Two field trials were conducted independently with the most infective isolate (Pf_2) on zucchini squash plants. Five fully expanded middle leaves were randomly selected at different times from each replicate and were transported to the laboratory to count all living *T. vaporariorum* nymphs.

Results: Three of the nine isolates (Pf_1, Vl_3, and Vl_5) produced 11-26% infections on eggs, while the remaining isolates had no significant effect. All three *P. fumosoroseus* isolates caused homogeneous pathogenicity in all nymphal instars, while *L. lecanii* isolates showed high variability. In field conditions, survival of whitefly nymphs decreased by 19 and 28% after the first and second fugal applications, respectively, in one trial, and by 62 and 71% in the another trial.

Conclusions: We concluded that the use of fungal preparations based on the Pf_2 isolate could be feasible for controlling *T. vaporariorum*.

This work was supported by the Coordinación de la Investigación Científica, Universidad Michoacana de San Nicolás de Hidalgo and the Programa de Mejoramiento al Profesorado (PTC-110).

POSTER PRESENTATION

Expressed Sequence Tags from cDNA library of the sleeping chironomid (*Polypedilum vanderplanki*) and analysis of mRNAs expression patterns during the induction of anhydrobiosis.

Richard Cornette, Yasushi Kanamori, Kanako Mitsumasu, Oleg Gusev, Takahiro Kikawada, Takashi Okuda

National Institute of Agrobiological Sciences, Tsukuba, Ibaraki, Japan

In the semiarid regions of central Africa, larvae of the sleeping chironomid (*Polypedilum vanderplanki*) are able to survive in a completely desiccated state without any metabolic activity throughout the dry season, which may last for 8 months. This phenomenon is known as anhydrobiosis or cryptobiosis. During anhydrobiosis, trehalose represents ca. 20% of the dry mass of the larva. Loss of free water, accumulation of trehalose and the subsequent vitrification phenomenon are thought to play an important role in the protection and stabilization of cells in anhydrobiotic individuals.

In the laboratory, induction of anhydrobiosis was triggered artificially by slow desiccation for 48 hours and individuals dehydrated in such conditions successfully recovered normal activity after immersion into water.

In order to identify genes involved in the anhydrobiosis of *P. vanderplanki*, cDNA libraries were constructed from normally active larvae (0h of desiccation), larvae during early stage of anhydrobiosis induction (desiccation for 12h) and advanced induction of anhydrobiosis (desiccation for 36h). After sequencing, a total of 15,054 clones were incorporated into an anhydrobiosis-related EST database. Analysis of this EST database allowed the identification of genes up- or down-regulated during the induction of anhydrobiosis. General expression patterns were inferred for important functions such as signal transduction, ion transport or regulation of transcription.

Actual expression patterns were investigated by real-time quantitative PCR for some genes involved in anhydrobiosis such as enzymes from the trehalose synthesis pathway, Late Embryogenesis Abundant (LEA) proteins and aquaporins. The general mechanism of successful induction of anhydrobiosis was finally discussed, on the basis of these data.

POSTER PRESENTATION

Comparison of feeding behavior of biotype B and Q of *Bemisia tabaci* (Homoptera: Aleyrodidae) against red pepper and tomato varieties

Jeong-Oh Yang, Eun-Hee Kim, Changmann Yoon, Gil-Hah Kim

Chungbuk National University, Cheongju, Chungbuk, Republic of Korea

This study was performed to investigate the feeding behavior of *Bemisia tabaci* B- and Q-biotypes using EPG technique against nine red peppers and seven tomatoes commercial varieties. EPG waveforms was recorded during three hours compare to the characteristic patterns of feeding behaviors between two biotypes such as total non penetration times, the time taken until stylet activities changed after reaction, frequencies of stylet pathway pattern, and total duration of phloem feeding. In comparing the effect of the pepper varieties between the two biotypes, biotype Q showed the feeding behavior against all pepper varieties in the total duration of phloem feeding. Daeshin variety has the longest feeding time. However in total duration of phloem feeding, biotype B was observed in hanyeoreumbigarim and Daeshin varieties, but feeding time was very short. Biotype B was longer time in non-probing pattern, and showed lower frequencies of stylet pathway pattern, and probing time. However biotype Q was shorter time in non-probing time than biotype B, but showed more aggressive probing and stylet pathway pattern. These results suggest that biotype Q are more preferred the pepper host than biotype B. However, tomato varieties between the two biotypes did not show the difference.

POSTER PRESENTATION

Novel alpha-amylase inhibitor mutant genes and their potential use for insect-pests control

Maria Fatima Grossi de Sa, Rafael P. Del Sarto, Cesar C. Cruz, Osmundo B. Oliveira Neto, Marise V. Coutinho, Thales L. Rocha, Maria Cristina M. Silva

Embrapa Recursos Genéticos e Biotecnologia, Brasília -DF, Brazil

The cotton boll weevil *Anthonomus grandis* is an important insect-pest in South America. It causes severe damage in cotton floral buds and fruits. The *A. grandis* larvae development is difficult to control because it occurs inside the floral structures. Starch granules from cotton structure are digested by α-amylases in the intestinal lumen. Alpha-amylase inhibitors (α-AIs) are attractive candidates to control seed weevils. However *A. grandis* α-amylases (AGA) showed no significant inhibition by α-AI-1 and α-AI-2, two α-AIs isoforms isolated from common and wild bean, respectively.

In this work, a large combinatorial library of 10^7 inhibitor variants, obtained by DNA shuffling of *αAI-1* and *αAI-2* genes, was used to select α-amylase inhibitor mutant genes for novel α-AIs with potential to inhibit cotton boll weevil α-amylases. Twenty-six αAIs mutants were selected by Phage display technique showing different mutation patterns. Five of these mutants were expressed in *Arabidopsis thaliana* and their α-amylase inhibitory activity assayed. Two of these AI mutants, denominated C3 and A11 were active against AGA *in vitro* assay at nM range. Molecular modeling studies of the C3 and A11 inhibitors in complex with AGA revealed residues probably involved in the stabilization of the enzyme-inhibitor complex. Our results demonstrate the potential of α-AI mutants in controlling cotton boll weevil, which put them as candidates to generate insect-pest resistant cotton transgenic plants.

POSTER PRESENTATION

Contribution to the knowledge of predatory mites and insects associated with brown mite in Hamedan, Iran

Mohammad Khanjani, Amir Hosein Eeghbalian

Bu Ali Sina University, Hamedan, Islamic Republic of Iran

Introduction: Brown mite *Bryobia rubrioculus* (Scheuten) is one of the most important pests of cherry and plum trees in west of Iran. This pest was found abundantly on fruit trees in Hamedan (west of Iran). It causes considerable damage in some orchards of this area. Some predatory of insects and mites were found to the associated with this pest.

Methods: The collecting of natural enemies which are associated with brown mite was carried out during 2005 – 2006. In this study infested leaves were transferred to laboratory and have been shaken on white tray then brushes into Petri dish The Petri dish which containing the samples were examined by stereomicroscope. Also some specimens were mounted as slides microscope.

Results: In this study were collected and identified 11 species associated with brown mite. Their scientific name as follows: O*rius niger* Wolff., *Coccinella septempunctata* L., *Adalia bipunctatus* G., *Stethorus gilviferons* (M.). C*hrysoperla carnea* (S.), *Scolothrips longicornis* (P) *Deraeocoris* sp., *Anystis baccarum* (L.) *Zetzellia pourmirzai* Khanjani & Ueckermann, *Amblyseius iraniensis* Daneshvar & Danmark and *Eupalopsellus hamedaniensis* Khanjani, *et al*. were found from this pest. They feed on different stages of brown mite and causing considerable decease its population.

Conclusion: Among the mutual enemies *O. niger, S. longicorni* and *A. baccarum* were high level of population and abundant.

POSTER PRESENTATION

Transgenic Bt-potato in South Africa: Effect on non-target organisms

Thembisa Majola, Diedrich Visser, David Sehlola, Sakhi Sambo

ARC-Vegetable and Ornamental Plant Institute, Pretoria, South Africa

Introduction: A genetically modified potato containing the *Bacillus thuringiensis* gene (*Bt-Cry1Ia1*) to control potato tuber moth (*Phthorimaea operculella*) (PTM) was evaluated for six consecutive years in South Africa. The first three years comprised of efficacy studies and the last three years were environmental impact studies relating to the effect on non-target organisms.

Methods: Field trials comprising randomized block designs were conducted in three provinces, namely, Gauteng (Pretoria), Free State (Petrus Steyn) and the Western Cape (Ceres). Non-target arthropods and nematodes were monitored regularly during the growing season using various techniques and traps, e.g. soil samples, pitfall traps, sticky traps, sweep net catches and monitoring of natural enemies and non-target pests. All arthropods were divided into orders or lower guilds for comparisons between the GMO potato and non-GMO potato lines. Nematodes were divided into plant parasitic and free-living guilds.

Results: The results showed no differences between the GMO potato and non-GMO potato lines except that no PTM or PTM damage was observed on the GMO potato compared to the non-GMO potato lines where PTM and damage was found. All micro- and macro arthropods, nematodes, natural enemies and other non-target pests were equally represented in all treatments.

Conclusion: Bt-potato containing the *Bacillus thuringiensis* gene (*Bt-Cry1Ia1*) provided complete control of PTM and had no effect on non-target organisms under field conditions in South Africa.

POSTER PRESENTATION

The role of litter decomposition, fertility, and litter-dwelling animals in the carbon cycle of a tropical rain forest

Evan Poirson, Terry McGlynn

[1]Occidental College, Los Angeles, CA, United States, [2]California State University - Dominguez Hills, Carson, CA, United States

Understanding the global carbon cycle is a crucial step in confronting one of the foremost concerns of our era: the unprecedented rate of worldwide climate change. Tropical rainforests, which process more carbon than any other terrestrial ecosystem, are an unparalleled research location in the effort to comprehend the implications of environmental variation on the cycling of carbon in food webs. As the continuation of a larger study begun in 2007, this research project completed measurements of decomposition and animal density across a fertility gradient. Our results show that decomposition rate was independent of nutrients, but that detritivore communities responded to decomposition rate and a nutrient gradient.

POSTER PRESENTATION

Investigation of the effects of different doses of chloropryfos-methyl against *Phyllocnistis citrella* Stainton (Lepidptera: Gracillariidae)

Behnam Amiri-Besheli

University of Mazandaran, Sari/Mazandaran, Islamic Republic of Iran

The object of this experiment was to determine the potential poison of the five doses (1, 0.5, 0.1, 0.05 & 0.01 ml per liters) of chemical insecticidal Chloropryfos methyl which is used Emulcifiable furmolation on after 24, 48, 72 and 96 hours post treatments against *phylocnistis citrella* Stainton in laboratory. In all experiments, leaves of citrus with second and third instars of leafminer larvae were used and the mortality was monitored. The analysis of variance has shown that there were significantly difference between treatments and control ($p<0.01$) and also significant differences were found among treatments and among days. The mortality of the leafminer with Chloropryfos-methyl was dose dependent. The analysis of variance has shown that there were significantly different among post test periods. LSD & Tukey-Test with different dose of the Chloropryfos methyl have shown that 1 & 0.5 ml per liters of Chloropryfos methyl with 80.62% and 62.33% mortality were more effective than the other doses ($p<0.01$). LSD & Tukey-Test among post test period has shown that 72 and 96 h post treatments with 52.6±7.7 and 47±7.4 percentage mortality are more effective than 24 and 48 h post treatments with 21±5.6 and 40.9±7.2 percentage mortality respectively. Based on the composite response of this assay with the probit analysis, the predicted LC_{50} of toxin was 0.10 ml per liters with confident interval 0.04-4.17 ml per liters respectively. The results showed that Chloropryfos methyl provided very good control of CLM larvae and would greatly reduce adult emergence.

POSTER PRESENTATION

The potential use of plant extracts as control option for Russian wheat aphid

J.M. Richter[1], G.J. Prinsloo[2], T.C. van der Linde[3]

[1]Department of Agriculture, Glen Research Institute, Bloemfontein, South Africa, [2]ARC Small Grain Institute, Bethlehem, South Africa, [3]Department of Zoology & Entomolgy, University of the Free State, Bloemfontein, South Africa

Introduction: Traditional, subsistence and resource-limited farmers remain poorly served by the top-down-transfer of technologies. In these low input agriculture systems where financing, necessary equipment, and know-how is not readily available, the use of insecticides are very limited. The presence of Russian wheat aphid in some of these production areas therefore causes severe yield loss. Plants are known to have insect repellent properties and extracts of such plants are used to control insects. The purpose of this study was to test repelling properties of three plants commonly found in the area where subsistence farmers grow wheat.

Methods: Water and light mineral oil extracts were made from three different plants, *Tagetes minuta*, *Artemisia afra* and *Tulbachia violaceae*. The behavioural response of alate Russian wheat aphid to these abstracts was tested with a four-arm olfactometer in the laboratory.

Results: The results of the different tests will be discussed.

Conclusion: Extracts from plants with aphid repellent properties may be a more user-friendly method of pest control for subsistence and resource limited-farmers, which can save them costs and is easy to use.

POSTER PRESENTATION

Fungal biopesticides for sheep lice (*Bovicola ovis*) control?

Diana Leemon, Peter James, Jacinta McMahon

Animal Research Institute, Department of Primary Industries and Fisheries, Yeerongpilly, Queensland, Australia

Introduction: Biological control of sheep lice (*Bovicola ovis* Schrank) is an attractive option to address concerns associated with the use of chemicals and the development of resistance to some currently available products.

Methods: Isolates of the fungi *Metarhizium anisopliae* and *Beauveria bassiana* collected in Queensland Australia were screened for ability to grow and infect *B. ovis* at high temperatures, a high sporulation rate suitable for mass production and virulence to different stages of *B. ovis* in wool-based assays. The best strains from the laboratory investigations were selected and tested in live animal studies.

Results: *S*everal isolates caused 100% mortality to all stages of lice within 7 days in wool based bioassays. Scanning electron and light microscope examination showed a large number of spores in the gut within 48 hours of exposure and extensive hyphal growth in louse tissues within 72 hours, suggesting ingestion as the main route of infection. The lipophilic spores adhered well to wool grease and were still viable and highly virulent to lice in laboratory tests after 14 weeks. Formulated *Metarhizium* spores applied to the fleece of lousy sheep by immersion dipping caused a 98% reduction in louse numbers in comparison to controls at 14 weeks post treatment.

Conclusions: This research demonstrates the potential for the use of appropriate strains of *Metarhizium* in the control of sheep lice. Further trials towards the registration of a commercial product are currently in progress.

POSTER PRESENTATION

Differentiation between forensic important Central South African Calliphoridae and Sarcophagidae puparia, using puparium specific characteristics

Sonja Brink, Theuns Van der Linde, Linda Basson, Pieter Van Wyk

University of the Free State, Bloemfontein, South Africa

Introduction: Viable puparia or empty puparial cases can be utilised as forensic evidence from after a week up to years post-mortem. The correct identification of puparia is crucial if it is to be used as forensic entomological evidence.

Methods: Dehydration and critical point drying was not required as the puparium was cut in half to remove the soft, hydrated inner pupa in preparation to examine the hardened, dehydrated puparium with a JSM 6400 WINSEM at 5 kV.

Results: The bubble membrane, present in early puparia, was investigated for the number of bubbles, the shape and size of the bubbles as well as the arrangement. Consideration was given to the general shape of the puparia, examining specifically the angle of its anterior end. Furthermore, the prominence of the lateral ridge varied and was therefore also of diagnostic use. Due to pupariation, the surface characteristics of puparia, namely reflectivity and striations, varied and had diagnostic value. The caudal segment was assessed for (i) being flat, bulging or recessed and (ii) the prominence of the perispiracular tubercles. However, the newly introduced diagnostic characteristic of the frontal field yielded the most significant puparium characteristic. The retraction of the head capsule during pupariation caused unique folding patterns in each of the species.

Conclusion: Puparia of forensic important Calliphoridae and Sarcophagidae can be identified, using only the frontal field characteristic. Identification can be backed-up using a range of other puparium specific characteristics as well as third instar characteristics.

POSTER PRESENTATION

Comparisons of the toxicity of different doses of methoxyfenozide against *Phyllocnistis citrella* Stainton (Lepidptera: Gracillariidae)

Behnam Amiri-Besheli

Faculty of Agricultural Science, Sari/ Mazandaran, Islamic Republic of Iran

The purpose of this study was to determine the toxicity of chemical insecticidal Methoxyfenozide which is apply on the control of *Phyllocnistis citrella* Stainton in lab conditions. In this experiment five dose of Methoxyfenozide (1, 0.5, 0.1, 0.05 & 0.01 ml per liter) have been tested. Leaves of citrus with second and third instar of citrus leafminer (CLM) larvae were used in all tests. The mortality was monitored after 24, 48, 72 and 96 hours post treatments. The analysis of variance (ANOVA) has shown that there were significantly different between treatments and control ($p<0.01$) but ANOVA has shown that there were not significant differences among post treatment periods. The mortality of the leafminer with Methoxyfenozide was dose dependent. LSD and Tukey-Test with different dose of the Methoxyfenozide have shown that 1 & 0.5 ml per liter of Methoxyfenozide with 85.10% and 77.97 % mortality were more effective than the other doses ($p<0.01$). LSD & Tukey-Test among post test period has shown that after 72 and 96 hours post treatments with 52.1±7.2and 59±6.9 percentage mortality are more effective than 24 and 48 hours post treatments with 44.1±6.9and 49.1±7 percentage mortality respectively. Based on the composite response of this assay with the probit analysis, the predicted LC_{50} of the Methoxyfenozide was 0.04 ml per liter with confident interval 0.08-2.57 ml per liter respectively. The results showed that Methoxyfenozide provided good control of CLM larvae and would greatly reduce adult emergence.

POSTER PRESENTATION

Egg parasitism rates of the invasive Australian eucalyptus weevil, *Gonipterus sp.*, in its home range

Jane Elek[1], Nita Ramsden[1], Vinu Patel[2], Geoff Allen[2]

[1]Forestry Tasmania, Hobart, Tasmania, Australia, [2]CRC for Forestry, Hobart, Tasmania, Australia

Gonipterus scutellatus (Coleoptera: Curculionidae) is native to Tasmania, Australia, as are the plantation tree species, *Eucalyptus globulus*. This weevil has invaded and become a serious pests of eucalypt plantations around the world. In the past, the weevils were not considered a pest in their home range because their populations were generally well controlled by egg parasitism. However, they have become serious pests that require management in *E. globulus* plantations in Western Australia. More recently, they also appear to be achieving pest status in Tasmanian *E. globulus* plantations.

Field surveys were conducted over two consecutive egg-laying seasons to collect weevil egg pods that were held in the laboratory until they hatched. Fresh pods were collected fortnightly in early spring, during October and November, from adult-phase foliage three 4-year-old (in 2004) and three 2-year-old (in 2005) *E. globulus* plantations in southern Tasmania that had had notable weevil populations in the previous year. In 2004, up to 50 egg pods were collected from 20 random plots per site per collection date. One collection was made in early November at six other sites around Tasmania. At each collection date in 2005, 4 egg pods were collected at 25 m intervals along four transects from the edge of the plantation bordering native eucalypt forest, for 100 m towards the centre (a total of 80 pods). Pods were held in the laboratory at 20^0 C, and all emerged larvae and parasitoid wasps counted. After three weeks all pods were dissected and unhatched larvae and wasps scored. The numbers of eggs per pod averaged seven.

In 2004, the percentage of pods parasitised ranged from zero early in October to 86%, and the percentage of eggs parasitised increased from zero to 72% by the end of November. In 2005, the levels of parasitism fell from a high of 46% in early October to a low of 5% at the end of November. The levels of parasitism remained relatively constant from the plantation edge for 100 m into the plantation for the first three sample dates, but declined sharply away from the edge for the last sample date, when the parasitism rates were lowest.

The parasitoid wasps most likely comprise a species complex of *Anaphes nitens* and its hyperparasitoids that are native to the area.

POSTER PRESENTATION

Resistance mechanism and inheritance of two-spotted spider mite, *Tetranychus urticae* (Tetranychidae), to Chlorfenapyr

Choi Byeong-Ryeol, Lee Si-Woo, Park Hyung-Man, Kwon Deok-Ho, Lee Si-Hyeock

[1]National Institute of Agricultural Science and Technology, RDA, Suwon, Gyeonggi, [2]Entomology Program, School of Agricultural Biotechnology, Seoul National University, Seoul, Republic of Korea

Field populations of *T. urticae* collected from apple trees in 2002 and strawberries in 2003 appeared to be highly resistant to chlorfenapyr in spite of its short-term use. A strain of *T. urticae* collected from apple orchard was further selected with chlorfenapyr 10% SC for 27 times at a selection pressure of 30-50% mortality (CR-27 strain). Resistance and cross-resistance levels of the CR-27 strain to 16 acaricides were determined by spray method. The CR-27 strain was extremely resistant to chlorfenapyr (Resistance ratio (RR) was 2,600-fold). The strain exhibited high cross-resistance to chlorfenpyr. pyridaben(RR 56.1), fenpyroximate(RR 38.8). But, showed low cross-resistance to tebufenpyrad(RR 2.8), abamectin(RR 2.5), and nearly no cross-resistance to benfenthrin, bifenazote, etc. Synergist experiments with specific metabolic inhibitors revealed that piperonyl butoxide known as inhibitor of P450 oxidase, had synergistic effect of **164.4**-fold on the efficacy of chlorfenapyr. Iprobenfos rolling as inhibitor of carboxylesterase showed **41.1**-fold inhibition to CR-27 mite. It was proposed that metabolic detoxification by esterase and P450 oxidase might play an important role in resistance *T. urticae* to chlorfenapyr. Degrees of dominance were 0.48 and 0.34 in F_1 progenies of CR×S, S×CR, respectively. Inheritance of chlorfenapyr resistance was incomplete dominant in TSSM.

POSTER PRESENTATION

Ovary structure and development in *Stomaphis quercus* (Hemiptera, Aphidinea: Lachnidae)

Teresa Szklarzewicz, Grazyna Pyka-Fosciak

Jagiellonian University, Krakow, Poland

Introduction: The aphid, *Stomaphis quercus*, like other aphids, has a complex life cycle that includes four viviparous generations and one oviparous generation.

Methods: The ovaries of *Stomaphis quercus* were examined using light and electron microscopes.

Results: The ovaries of young embryos of *S. quercus* contain a limited number of oogonial cells. The last generation of oogonia (cystoblasts), enters the cycles of incomplete mitotic divisions that lead to the formation of clusters of interconnected cells (cystocytes). In the ovaries of viviparous generations arise 6-9 clusters, in the ovaries of oviparous generation - 5 clusters. Clusters of viviparous females consist of 32 cystocytes. In oviparous females the number of cystocytes is larger and variable (i.e. 45-60). Each rosette-shaped cluster is surrounded by a single layer of follicular cells. During further development, cystocytes differentiate into oocytes and trophocytes. Subsequently, rosettes of cystocytes transform into ovarioles. The anterior region of the ovariole enclosing trophocytes becomes the tropharium, whereas its posterior region containing oocytes becomes the vitellarium. In the vitellaria of viviparous generations two oocytes develop, while in oviparous females only one. The oocytes of viviparous females do not accumulate yolk and are not covered by eggshells. Immediately after previtellogenesis, the oocyte nuclei start to divide forming embryos. In oviparous females, the only oocyte develops through three stages: previtellogenesis, vitellogenesis and choriogenesis.

Conclusions: There are significant differences between viviparous and oviparous females regarding: (1) the number of germ cell clusters per ovary, (2) the number of germ cells per cluster, (3) the course of oogenesis.

POSTER PRESENTATION

A comparison of the toxicity of different doses of Spinosad against *Phyllocnistis citrella* Stainton (Lepidoptera: Gracillariidae)

Behnam Amiri-Besheli

Faculty of Agric. Univ. of Mazandaran, Sari/ Mazandaran, Islamic Republic of Iran

The purpose of this experiment was to examine the efficacy of Spinosyn that is used on the control of *phylocnistis citrella* Stainton (Lepidoptera: Gracillariidae) in lab condition. In this experiment five doses of Spinosyn (1, 0.5, 0.1, 0.05 & 0.01 ml per liter) have been tested. Leaves of Citrus with the second and third instar larvae of the citrus leaf miner (CLM) larvae were used in all tests. The mortality was monitored after 24, 48, 72 and 96 hours post treatments. The analysis of variance (ANOVA) has shown that there were significantly different between treatments and control ($p<0.01$) and also the ANOVA has shown that there were significantly different among post treatment periods. The mortality of the leafminer with Spinosyn was dose dependent. LSD and Tukey-Test with different dose of the Spinosyn have shown that 1 & 0.5 ml per liter of the Spinosyn with 100% and 98.95% mortality were more effective than the other doses ($p<0.01$). LSD & Tukay-Test among post test period has shown that after 72 and 96 hours post treatments with 58.2±8.4 and 63.8±7.9 total percentage mortality are more effective than 24 and 48 hours post treatments with 41.2±8.9 and 52.7±8.6 total percentage mortality respectively. Based on the composite response of this assay with the probit analysis, the predicted LC_{50} of the Spinosad was 0.05 ml per liter with confident interval 0.01-0.17_ml per litre respectively. The results showed that Spinosad provided good control of CLM larvae and would greatly reduce adult emergence.

POSTER PRESENTATION

Systematics and evolution of weevils of the genus *Wagnerinus* Korotyaev (Coleoptera: Curculionidae)

Hiraku Yoshitake, Toshihide Kato, Utsugi Jinbo, Nozomu Utsuki, Motomi Ito

University of Tokyo, Tokyo, Japan

The weevil genus *Wagnerinus* Korotyaev in the tribe Ceutorhynchini, subfamily Ceutorhynchinae is revised systematically. A phylogenetic study combined with ecological field surveys is conducted to elucidate the evolution of host plant utilization pattern within this genus.

Presently, *Wagnerinus* comprises four species from Northeast Asia, but species identification is often very difficult in this genus due to the presence of morphologically similar undescribed species. Ecological information on *Wagnerinus* weevils is extremely limited, except that *W. costatus* (Hustache) is known to be associated exclusively with galls on the axillary buds of *Weigela hortensis* (Caprifoliaceae) induced by the gall midge *Asphondylia baca* Monzen (Diptera).

As the result of our systematic revision of *Wagnerinus*, this genus is classified into two species groups and 16 species from the Russian Far East, Northeast China, Korea, and Japan, including twelve undescribed species. Our field surveys revealed that *Wagnerinus* weevils are associated with *Weigela* or *Abelia* species (Caprifoliaceae) and their host plant utilization can be divided into four types: 1) flower-bud feeding, 2) facultative cecidophagy (gall and flower-bud feeding), 3) obligatory cecidophagy (obligate gall-feeding), and 4) seed-capsule feeding.

Results of molecular phylogenetic analyses based on sequences of the mitochondrial COI and 16S rRNA genes agree well with classification based on morphological traits. The ancestral state reconstruction of host plant utilization on the molecular phylogeny suggests that the ancestral state for *Wagnerinus* was flower-bud feeding and that cecidophagy occurred once within one of the species groups, with subsequent diversification in the host plant utilization.

POSTER PRESENTATION

Reference and image databases TABR and TAB based on tropical Asian bees

Osamu Tadauchi, Katsushi Mitai, Ryuki Murao, Hitoshi Inoue

Kyushu University, Fukuoka, Japan

Since Fabricius (1775) described some bees, including *Apis cerana* and *Apis dorsata* from tropical Asia, many investigators have reported bees from this area. The most comprehensive works of bees in tropical Asia were published as the Fauna of British India including Ceylon and Burma by Bingham (1897). Europeans were the main researchers who then studied tropical Asian bees in the first half of the 20th century. But on the whole it may be said that studies of bees in this area are inadequate at the present time, compared with those of Africa and South America. Michener (1965) presented a monograph of bees in the neighboring areas of Australia and the Pacific Islands. But a comprehensive work on bees in tropical Asia absent. It is, therefore, necessary for investigators in this area to search sporadic references. Furthermore, it is important to construct a database of bees in tropical Asia for future studies. We have constructed two files, representing image and reference databases of tropical Asian bees. One of the files, reference database TABR is based on main articles related to tropical Asian bees and is open to the public via the Internet. The other is an image database TAB. The files are written in English and is administered by a SIGMA text database management system working at a workstation in the Entomological Laboratory at Kyushu University, Fukuoaka. A user can presently access the TAB database files by visiting the following URL: http://konchudb.agr.agr.kyushu-u.ac.jp/tabr/.

POSTER PRESENTATION

Trachelas L. Koch, 1872 (Araneae: Corinnidae), with emphasis on southern Africa

Robin Lyle, Charles Haddad

Department of Zoology & Entomology, University of the Free State, Bloemfontein, South Africa

The dark sac spider subfamily Trachelinae (Araneae: Corinnidae) is currently represented in the Afrotropical region by seven genera, *Austrachelas* Lawrence, 1938, *Cetonana* Strand 1929, *Paccius* Simon, 1898, *Pronophaea* Simon, 1897, *Spinotrachelas* Haddad, 2006, *Thysanina* Simon, 1910 and *Trachelas* L. Koch, 1872. The genus *Trachelas*, with a worldwide distribution in the tropical and temperate regions, is revised in the Afrotropical region. The species *T. chubbi* Lessert, 1921, *T. minor* O. P. –Cambridge, 1872, *T. punctatus* Simon, 1885, *T. pusillus* Lessert, 1923, *T. roeweri* Lawrence, 1938, *T. schenkeli* Lessert, 1923, *T. scopulifer* Simon, 1896 and *T. sylvae* Caporiacco, 1949 are redescribed. Based on its redescription, *T. scopulifer* is misplaced and is transferred to the genus *Thysanina*. Thus far more than 20 new species are described from the Afrotropical region, with the majority of these distributed in southern and eastern Africa.

POSTER PRESENTATION

Effect of sugarcane varieties on performance of *Telenomus busseolae* Gahan (Hymenoptera: Scelionidae) an egg parasitoid of sugarcane stem borers *Sesamia* spp. (Lepidoptera: Noctuidae) in Iran

Arsalan Jamshidnia[1], Aziz Kharrazi-Pakdel[1], Hossein Allahyari[1], Ebrahim Soleymannejadian[2]

[1]Tehran University, Karaj, Tehran, [2]Chamran university, Ahwaz, Khuzestan, Islamic Republic of Iran

Introduction: The sugarcane stem borers *Sesamia cretica* and *S. nonagrioides* are the most important pest of sugarcane in Iran. The egg clusters of *Sesamia* spp. are attacted by *T. busseolae*. A field experiment was conducted to evaluate the performance of T. busseolae on sugarcane commercial varieties in Khuzestan province (southwest of Iran).

Methods: This study evaluated in a split plot design on 4 sugarcane commercial varieties (CP69-1062, CP48-103, CP57-614 and SP70-1143) with 5 fields per variety in Khuzestan in 2007. Sampling of egg masses were carried out in tillering stage of sugarcane (5-15 June) and final stage of sugarcane growing (10-20 October). All percentage data were arcsine-transformed before being subjected to analysis of variance using the GLM procedure.

Results: Our results of a two-way ANOVA indicated both growth stage and variety of sugarcane had a significant effect on the egg batch density, discovery efficiency and percent parasitism. The interaction between growth stage and variety on percent parasitism and discovery efficiency were statistically significant. There was no effect on parasitism efficiency, adult emergence and F1 progeny sex ratio of growth stage , variety, or any interaction between them. The highest egg batch density, discovery efficiency and percent parasitism was observed in CP48-103 variety.

Conclusion: *T. busseolae* in CP48-103 variety is more efficient than the other sugarcane commercial varieties.

POSTER PRESENTATION

Repellency effect of cyphenothrin against *Aedes aegypti* in field tests in Thailand

Piti Mongkalangoon, John P. Grieco, Nicole L. Achee, Wannapa Suwonkerd, Theeraphap Chareonviriyaphap

[1]Department of Entomology, Kasetsart University, Bangkok, 10900, Thailand, [2]Department of Preventive Medicine and Biometrics, Uniformed Services University of the Health Sciences, Bethesda, MD. 20891, United States, [3]Office of Disease Prevention and Control No.10, Ministry of Public Health, Chaing Mai, 50200, Thailand, [4]Corresponding Author, Department of Entomology, Kasetsart University, Bangkok, 10900, Thailand

The main objective of this study was to find the optimal dosage of cyphenothrin to use for field collected *Aedes aegypti*. Such dosage was further utilized in the experimental hut study for testing the excito-repellency effect. All of dosages were first tested in the excito-repellency system. It was found that cyphenothrin had both repellency effect and contact irritancy effect. The LC50 was selected as the appropriate dosage for testing in the field. Two identical experimental huts were used for evaluation the efficacy of cyphenothrin to *Ae. aegypti*. The results indicated that cyphenothrin at LC50 level could protect the mosquitoes to fly into the treatment hut and chase the mosquitoes out of the treatment hut as compared to the controls.

Culturally Significant Insects in Blouberg, Limpopo Province, South Africa

Bronwyn Egan[1], Rob Toms[2], Piet Olivier[1], Dr Abe Addo-Bediako[1]

[1]University of Limpopo, Polokwane, South Africa, [2]Transvaal Museum, Pretoria, South Africa

Introduction: Blouberg has a rich culture of entomophagy, resulting in a valuable body of indigenous knowledge around edible insects and their associated food plants. To date, this data has been available only to the local inhabitants through the oral traditions of the area. Younger generations do not have the time for and/or interest in sustaining this culture. This study documents the use of the insects and the attitudes of the inhabitants of the area to entomophagy.

Methods: Fieldworkers from nine villages collected specimens of and information on the insects eaten. Structured questionnaire surveys were conducted amongst households and competition questionnaires were conducted amongst school going youth. Data were also collected during harvesting trips.

Results: There is a strong culture of entomophagy across the Blouberg, with more than 23 different insect species eaten. They are considered a delicacy and eaten in large numbers during the harvesting season, although most are unavailable in winter despite effective preservation methods. Certain insects are sold but most are collected for own consumption. The older generation has a deeper understanding of the insects than the younger generation and collect and utilise them more frequently than the youth. Most residents feel that edible insect numbers have declined over the years due to a lack of rain. There is concern amongst older people at the loss of this culture of entomophagy and of the decline of the insects themselves.

Conclusions: Linking available indigenous knowledge around these insects, to ecological data collected through conventional scientific methods and simultaneously involving the local community in the process, will give valuable insights into insect conservation management and into that of the associated plant species.

POSTER PRESENTATION

New and rare Hemigasterini and Euryproctini (Hymenoptera: Ichneumonidae) for the Romanian fauna in protected areae

Irinel Constantineanu, Raoul Constantineanu, Camil Stefan Lungu-Constantineanu

Biological Research Institute, Iasi, Romania

Introduction: The authors did their researches in the following protected areae in Romania: Retezat National Park, natural reservations “Slatioara Secular Forest” and ”Todirescu Alpine Clearing”, situated in the Carpathians mountains, with a rich and varied biodiversity. In the first two protected areae there are a mixture of beech with coniferous forests and many clearings with a rich herbaceous vegetation and ”Todirescu Alpine Clearing” only with alpine lawn.

Methods: The ichneumonids were collected in June and July during the period 2001 – 2007 with entomological net, many of them in clearings upon some species of Apiaceae, especially *Angelica archangelica, Laserpitium latifolium* and *Angelica sylvestris*. For the identification of the ichneumonid species we used the Olympus stereomicroscope.

Results: The authors present 14 species of Ichneumonidae. Of these, 4 species belong to three genera of the tribe Euryproctini (subfamily Ctenopelmatinae) and 10 species belong to 7 genera of the tribe Hemigasterini (subfamily Cryptinae). The following 3 species: *Euryproctus plantator* Thunb., *Mesoleptidea hohenwartensis* Schm. and *Hadrodactylus rectinervis* (Rom.) are new for the Romanian fauna and the other ones are rare for the Romanian fauna and for the European fauna, too. About geographycal distribution, *Parmortha parvula* (Grav.) and *P. pleuralis* Thoms. are holarctic species and the others are palaearctic, majority of them being European species.

POSTER PRESENTATION

Leaf insect *Galerucella nipponensis* as a useful bioindicator for heavy metal pollution

Heungtae Kim, Jihyun Yoon, Jae Geun Kim

Seoul National University, Seoul, Republic of Korea

Introduction: Heavy metals flowed into a wetland ecosystem threaten organisms in higher trophic level through biomagnification. *Galerucella nipponensis* (Coleoptera: Chrysomelidae) feeds on mainly *Trapa japonica* in wetland. They might be a prey to predators such as spiders. The purpose of this study was to identify the transfer of heavy metals through the beetle-centered food chain and to certify the potential of the beetle as bioindicator for heavy metal pollution.

Methods: The heavy metals (Cd, Cr, Cu, Mn, Pb, Zn) in the beetle, spiders, the aquatic plant leaf, and sediments were analyzed with ICP-MS. Stable isotope was also analyzed for trophic level analysis. The superficial sediments were characterized for physico-chemical properties.

Results: The heavy metals excluding Pb and Mn showed higher contents in the beetle than in the plant. Although higher contents of most heavy metal were found in the spiders, Cr and Pb showed a decreasing phase through the beetle-centered food chain. The beetle-centered food chain reflected the difference of Cd, Cu and Pb contents in the study sites. The beetle showed marked differences of Cd, Cu and Pb contents among the sites, while the spiders indicated the difference of Cd and Cu; the plant for Cu, Pb and Zn.

Conclusions: *G. nipponensis* as an herbivorous insect and a prey for predator might play an important role in the transfer of heavy metals (Cd, Cu, Mn, Zn) through the food chain. The beetle can be a useful bioindicator for heavy metal pollution.

POSTER PRESENTATION

Field monitoring of Mediterranean fruit fly (C*eratitis capitata*) (Diptera: Tephritidae) populations on cherry peppers (C*apsicum baccatum*) (Solanaceae) in the Belmont Valley, Eastern Cape

Jessica Cockburn, Colleen Hepburn, Martin Hill

Rhodes University, Grahamstown, South Africa

Introduction: The cherry pepper, *Capsicum baccatum*, is an export crop new to the Eastern Cape. Little is known about pest insects associated with the crop in this region. The Mediterranean fruit fly, *Ceratitis capitata*, has been identified as a potential key pest of the crop.

Methods: *C. capitata* field populations were monitored in a crop of *C. baccatum* over a 20-week period in the Eastern Cape. Adult *C. capitata* numbers were measured weekly using pheromone traps. Larvae and pupae were collected from pod and soil samples respectively on a fortnightly basis. An analysis of edge effects and a vegetation survey of alternate hosts in natural vegetation adjacent to the crop were carried out to determine the effect of these on movements of *C. capitata* populations.

Results: Populations fluctuated during the growing season, starting out low, reaching a number of peaks and tailing off at the end of the season. The highest peaks occurred during periods of higher temperatures and low rainfall and when the pepper crop was at its ripest, reaching a maximum of over 2000 individuals per plot. Edge effect analyses indicated that edge vegetation had an effect on *C. capitata* movements into the pepper plots. The vegetation survey revealed numerous alternate hosts in close proximity to the crop.

Conclusions: Temperature, rainfall, edge vegetation and availability of alternate hosts affect movements of *C. capitata* populations in the *C. baccatum* crop in the Eastern Cape. These factors have important implications for IPM-based control measures including population monitoring and cultural control.

POSTER PRESENTATION

Wireworms (Coleoptera: Elateridae) faunal-structure evaluation on Romanian sugar-beet crops

Maria Iamandei[1], Grigore Margarit[1], Gheorghe Solcan[2], Gheorghe Ciubuc[2]

[1]Department of Entomology, Research-Development Institute for Plant Protection, Bucharest, Romania, [2]Department of Plant Protection, S.C. AdminDate & Inf S.R.L., Bucharest, Romania

Introduction: Between the sowing time and the appearance of the first real leaves, the sugar beet crop might be attacked by a group of insects generically named “soil pests”, among which the most important are the species of the *Bothynoderes, Tanymecus* (Coleoptera: Curculionidae) and *Agriotes* (Coleoptera: Elateridae) genera. This research aims to also evaluate the presence in the sugar beet crops and other three crops recommended in the crop rotation of the wireworms species collected all over Romania, in over 25 years.

Methods: The material analyzed was obtained by two methods: (I)Surveys on soils with areas of 25/25/25 cm (3 for each crop) were used for collecting the larvae; (II)The adults were collected either by threading or by direct collecting from the plants.

Results: The analyzed material includes a number of 2904 specimens belonging to 7 sub-families, 8 genera, 19 species and one variety. Two species were exclusively found in the sugar beet crop, while the species of the *Agriotes* genus were frequently found in all four crops. The wireworms are practically represented in all soils, but the specific composition changes, as each type of soil is characterized by a faunal complex that is in close connection with the ecological elements.

Conclusions: The results will be the starting point for realizing a data base concerning the sugar beet pests and they will be useful for developing experimental models for the remote detection of the sugar beet pest agents, which will constitute a support for the management decision.

POSTER PRESENTATION

Development of group-specific primers for prey DNA detection in the predator gut

Anna-Karin Kuusk[1], Nuria Agustí[2]

[1]Department of Ecology, Swedish University of Agricultural Sciences, 750 07 Uppsala, Sweden, [2]IRTA, Plant Protection, E-08348 Cabrils (Barcelona), Spain

Introduction: The development of molecular techniques to analyze the gut content of polyphagous predators allows understanding how the diversity and the availability of alternative preys (non-pest) contribute to the maintenance of the predator populations in the crops. The Order of the springtails (Hexapoda: Collembola), covers a whole range of species present in the soil of agricultural ecosystems, and represents one of the most abundant alternative preys. Some arthropod species have been described as major predators of springtails in unfavorable periods (no pest species present). In these periods the springtails represent in many cases the alternative prey numerically dominant.

Methods: Group-specific primers were designed for the first time in order to detect springtails within predator gut contents. Degenerate primers were developed based on the sequences of 17 species of springtails collected in agricultural ecosystems. 18S rDNA was the region used to be a multi-copy and semi-conserved genomic region.

Results: Primers designed amplified DNA fragments of 272 and 177 bp. Specificity analysis demonstrated that these markers were not detecting DNA of 41 other species of arthropods. The use of these group-specific primers is advantageous when trying to study a broad spectrum of species close phylogenetically and/or potentially ingested by a polyphagous predator.

Conclusions: These group-specific markers can greatly facilitate the study of trophic relationships between springtails and generalists predators.

POSTER PRESENTATION

Proteomic analysis of the parasitized host (*Plutella xylostella*) fat body

Min Kyo Jung, Kyung Han Song, Sung Sik Han

School of Life Sciences and Biotechnology, Seoul, Republic of Korea

Introduction: Insect fat body has been considered as a principal organ that performs with multiple and diverse metabolic functions. In the parasitized Diamondback moth (*Plutella xylostella*) by *Cotesia Plutellae* showed hypertrophied structures in fat body compared with non-parasitized larvae.

Methods: To investigation, we used a proteomic approach to obtain the proteomic profiles of the parasitized larva fat body. We used a total of 300 μg of protein of fat bodies and detected about 100 protein spots on specially chosen area by 2-DE.

Results: Amount of the parasitized *P. xylostella* fat body was decreased in posterior part and the residual lipid droplets in the parasitized host fat cells were smaller than non-parasitized host fat cell. Total 4 proteins were identified as a TIM (Triose-phosphate isomerase), FKBP (FK506-binding protein), TCTP (Translationally-controlled tumor protein homolog) and Hypothetical protein (from *Cotesia plutellae* polydnavirus) by quadrupole time-of-flight tandem mass spectrometry (QTOF-MS/MS) analysis.

Discussion: Hypothetical protein was newly synthesized in parasitized host and came from *Cotesia plutellae* polydnavirus. Probably up-regulation of Tim is involved in gluconeogenesis of lipid. Down-regulated FKBP and TCTP might be involved in immune response by parasitism.

POSTER PRESENTATION

Long-term aphid monitoring in seed potatoes in South Africa

Mark Robertson, Kerstin Kruger, Lezel Muller, Michelle Fourie

Department of Zoology & Entomology, University of Pretoria, Pretoria, South Africa

Introduction: Accurate prediction of the spread of aphid-transmitted viruses and the risk they pose depends amongst others on reliable estimation of aphid numbers. Several aphid species are known to transmit viruses that reduce the profitability of seed potato production. Populations have to be monitored to determine overall vector pressure and manage virus vectors. Monitoring is usually done using a combination of yellow bucket traps and suction traps. The aim of this study is to correlate yellow bucket and suction trap counts to assess the efficiency of suction traps as a monitoring tool in a seed potato producing region in South Africa.

Methods: Long-term monitoring trials were conducted in the Christiana region (Free State). For each trial, six yellow bucket traps were placed evenly around a circular potato field at each of six sites. A 12 m high suction trap was placed north of the potato fields, the furthest from the fields distance being 25 km. Yellow bucket and suction trap samples were collected weekly. Pearson correlations were calculated between the weekly aphid counts of yellow bucket and suction trap samples.

Results: Initial results suggest that total aphid abundance between the weekly yellow bucket and suction trap samples is poorly correlated.

Conclusions: Total aphid counts are of limited use. Although the correlation of aphid abundance between the two types of traps was poor, for some aphid species the suction trap may provide a good surrogate for the yellow bucket traps.

POSTER PRESENTATION

Species diversity of plants and insects in the Mokolodi Nature Reserve and Gaborone Game Reserve

Ntebaleng Makate, Moffat Setshogo

University of Botswana, Gaborone, Botswana

Two game reserves, Gaborone Game Reserve (GGR) and Mokolodi Nature Reserve (MNR) were used for the one-year study to compare plant and insect diversity during the dry and wet seasons. GGR is located within the city of Gaborone, i.e., in an urban setting, while MNR is about 15km to the south west out of the city. Vegetation composition and topography of the two reserves differ. The vegetation type for both is tree savanna but it is the species composition that varies. The vegetation in MNR was found to be predominantly of *Combretum* / *Acacia* association with hilly and undulating topography; while that of GGR was *Acacia* dominated with the topography being mainly flat. There was a significant difference in the insect species densities between the two reserves.

POSTER PRESENTATION

Possible function of the soybean stink bug, *Piezodorus hybneri* (Heteroptera: Pentatomidae) male pheromone

Nobuyuki Endo[1], Tetsuya Yasuda[2], Takashi Wada[1], Keiichiro Matsukura[1], Shin-etsu Muto[3], Rikiya Sasaki[3]

[1]National Agricultural Research Center for Kyushu Okinawa Region, Koshi, Japan, [2]National Agricultural Research Center, Tsukuba, Japan, [3]Fuji Flavor Co., Ltd., Hamura, Japan

Introduction: Male-produced pheromone system of *P. hybneri* has been reported to be a mixture of three components. However, the function or role of the pheromone still remains unknown. Thus, we investigated the relationship between sexual maturity and pheromone production in males of the bug. We also evaluated the attractiveness of the synthetic *P. hybneri* pheromone in soybean fields.

Methods: Copulation and the development of ectodermal accessory gland (EAG) were checked as an indicator of male sexual maturity. Males at particular ages were extracted individually with hexane to quantify each pheromone production. The hexane extracts were concentrated and further analyzed by GC-MS. Attractiveness of the synthetic pheromone was evaluated with water-pan traps baited with the synthetic pheromone (30 mg). The numbers of adults and nymphs of *P. hybneri* captured in the traps were counted everyday.

Results: The male pheromone was produced simultaneously with the beginning of mating behavior and EAG development. No pheromone components were detected in any of diapause males which were reared under short-day condition (12L:12D). Both sexes of adults were attracted to the synthetic pheromone, but the sex ratio was significantly female-biased particularly in non-diapaused period (summer). Nymphs and diapausing adults were also attracted to the synthetic pheromone in autumn.

Conclusions: The pheromone system of *P. hybneri* has a sex-related function but seems to play multifunctional roles.

POSTER PRESENTATION

Cabbage looper, *Trichoplusia ni* (Lepidpotera: Noctuidae) is now common pest in Japan

Masashi Nomura[1], Takako Itoh[1], Yutaka Minagawa[1], Jun-ya Yase[2]

[1]Chiba University, Chiba, Japan, [2]Hyogo Prefectural Agricultural Experiment Station, Hyogo, Japan

Introduction: Cabbage looper (CL), *Trichoplusia ni* (Lepidoptera: Noctuidae) is a notorious pest species of vegetables in North America. While CL was known to occur in Japan, the species was previously considered to be rare and not a pest species in Japan. However, in 2000, CL was observed in a cabbage field in Kagoshima and Hyogo Prefecture in western Japan, and then in the east of Japan shortly thereafter. The objectives of our study were thus to (1) clearly define the distribution of CL in Japan, especially in cabbage fields, and (2) determine the why the distribution of the species has extended into agricultural areas in Japan.

Materials and Methods: We determined the (1) distribution of CL in cabbage fields throughout Japan, (2) assessed the seasonal population dynamics of CL at several locations in Japan using sex pheromone traps, (3) examined resistance to insecticides, and (4) maximum and minimum temperature tolerance of the species. The data collected in each of the experiments was compared with those obtained for another plusiine moth, *Autographa nigrisigna*, a common cabbage pest species in Japan.

Results and Discussion: Our investigations showed that CL is widely distributed in western Japan, and that it has spread to the eastern and northern parts of the country. As CL populations increase with the approach of fall this species becomes the dominant pest in cabbage fields in western Japan. CL did not exhibit resistance to insecticides or extremes in temperature. However, recent increases in temperature due to global warming have facilitated the survival in Japan, where it is becoming a major pest on a variety of vegetables.

POSTER PRESENTATION

The characteristics of the populations of five *Agriotes* (Coleoptera: Elateridae) species in three regions in Croatia

Reneta Bažok, Antonela Kozina, Jasminka Igrc Barčić, Tomislav Kos

Faculty of Agriculture, Zagreb, Croatia

Introduction: The literature data reported that the most abundant species in eastern regions of Croatia are *A.ustulatus* and *A.sputator. A.lineatus* together with *A.obscurus* were reported as the most abundant species in western regions. *A.brevis* was not mentioned. Our investigations indicated the changes in the distribution and abundance of these species.

Methods: The abundance of the five species was examined on sex pheromone traps (Csalomon) in 15 fields (corn, soybean, barley and alfalfa) located in three different regions in Croatia in 2007. Pheromones were operated from April to September, checked weakly and changed every 6 weeks.

Results: The total number of collected beetles varied between 181 and 1482 per field. No significant differences between the total numbers of adults among different crops were registered. The average number of collected adults per field per region varied between 419 and 868 without any significant difference among the regions. The most abundant species in all regions was *A.ustulatus* with dominance index between 52 and 80%. *A.lineatus* had significantly higher dominance index in the west region (28.72%) while *A.obscurus* had significantly higher dominance index in east region than in other 2 regions. The abundances of *A.brevis* and *A sputator* were between 1.42 and 13.08% depending on the species and region without significant differences.

Conclusions: The most dangerous species *A.ustulatus* has been spread toward west and is eudominant species in all regions. *A.lineatus* is eudominant in the west region but *A.obscurus* is eudominant in east region and these species do not appear together.

POSTER PRESENTATION

Ecological divergence within a population of the bladder grasshopper *Bullacris discolor*

Vanessa Couldridge

University of the Western Cape, Bellville, South Africa

Bullacris discolor (Orthoptera: Pneumoridae) is a species of bladder grasshopper endemic to South Africa. A single population of this species has been found to exhibit two distinct colour morphs, each of which feeds and lives on a different species of host plant. Morphological measurements and sound recordings of male advertisement calls were compared between the two types to determine to what extent they differ from each other. Morphology was found to be fairly similar for the two colour morphs, with pronotum length being the only characteristic that differed significantly between them. Male calls differed significantly in three of the seven characteristics measured, including carrier frequency, total length and length of the introductory syllables. These results suggest that ecological differentiation may be taking place within this population, which may be the first step towards speciation in sympatry. Host switching may provide the initial catalyst for population divergence that is then reinforced through natural or sexual selection.

POSTER PRESENTATION

Long-lasting repellents for treatment of mosquito nets against insecticide resistant and susceptible malaria vectors

Raphael N'Guessan, Carnevale Pierre, Bart GJ Knols, Pelagie Boko, Abibathou Odjo, Mark Rowland

[1]Centre de Recherche Entomologique de Cotonou (CREC), Cotonou, Benin, [2]Institut de Recherche pour le Developement (IRD), Montpellier, France, [3]University of Wageningen, The Netherlands, Wageningen, Netherlands

Owing to the development of pyrethroid resistance in malaria vectors, it is of paramount importance to identify chemical alternatives, which if necessary could be used to replace or supplement the pyrethroids for use on bed nets. Synthetic insect repellent are widely used for personal protection as skin or clothing applications. The efficacy of conventional repellent treated nets (RTNs) was evaluated in experimental huts against insecticide-resistant *Anopheles gambiae* and *Culex quinquefasciatus*. The repellents tested were DEET (N,N-diethyl-3-methylbenzamide) at 7.9g/m^2 and two formulations of ethyl butylacetylaminopropionate (IR3535) at 7.6 and 7.3 mg/m^2. Over 45 nights the RTNs reduced by 74-82% the number of *An. gambiae* entering the huts but had no impact on *Cx. quinquefasciatus* entry to huts.

There was a 62-64% reduction in the proportion of *An. gambiae* blood-feeding in huts with RTNs but no reduction in the proportion of *Cx. quinquefasciatus* blood-feeding. An unexpected result was a 69-76% mortality of *An. gambiae* and 58%-61% mortality of *Cx. quinquefasciatus* in huts containing RTNs. Tunnel tests conducted in the laboratory to assess the residual activity of RTNs indicated that mortality and bloodfeeding inhibition were still apparent 6 weeks after treatment though a rapid decline in residual activity over time was observed. A more rapid decline in toxicity was noticed with the IR3535 brands than with DEET. The conventional repellent being inherently volatile, further tests of a Microcapsule suspension of DEET on nets in which the active ingredient slowly diffuses from a capsule that binds the repellent, strongly enhanced the residual efficacy of the net. The formulation repelled, inhibited bloodfeeding and killed mosquitoes for a period of at least 6 months. The high mortality of wild mosquitoes bearing multiple insecticide resistance mechanisms indicates that application of repellent to nets might constitute a useful tool to overcome insecticide resistant mosquitoes and have potential for use on clothing, bedding materials distributed in disasters, emergencies and refugee camp settings.

POSTER PRESENTATION

Eusocial beetle revealed as diploid

Shannon Smith[1], Andrew Beattie[1], Adam Stow[1], Deborah Kent[2]

[1]Department of Biological Sciences, Macquarie University, New South Wales, Australia, [2]New South Wales Department of Primary Industries Science and Research, New South Wales, Australia

The ambrosia beetle, *Austroplatypus incompertus* (Schedl), is the only known Coleopteran that exhibits eusocial behaviour. It lives in a multi-branched gallery system excavated in living trees of the genus *Eucalyptus* and is distributed across the east coast of New South Wales, Australia. Gallery systems are initiated by solitary fertilised females. Mature colonies are composed of overlapping generations, with morphologically distinct females undertaking tunnel maintenance and predator control. Despite the economic importance and unique characteristics of *A. incompertus*, this study is the first to apply molecular techniques to investigate their demography and mating system.

We developed a highly polymorphic and informative microsatellite marker for *A. incompertus*, and used this marker to reveal their diplo-diploid nature. Our finding supports the notion that collateral kin selection as a result of genetic relatedness has not played a significant role in the evolution of eusocialty in the beetle. In this case, eusociality could be attributed to factors such as: relatively easily defended gallery systems, stability of their habitat and food source, and the risk and difficulty associated with new gallery establishment. Current research has been designed to consider this premise. Examination of spatio-temporal molecular variation within *A. incompertus* will reveal details of their mating system, colony composition and persistence, illuminating historical and current dispersal patterns. These specifics will also provide the basis of practical advice for hardwood forest management.

POSTER PRESENTATION

Side-effects of bait formulated insecticides with potential use against *Bactrocera oleae* on *Chrysoperla carnea*

Pilar Medina, Gladis Contreras, Angeles Adán, Flor Budia, Pedro Del Estal, Manuel González, Pedro Luis Aguado, Elisa Viñuela

[1]Technical University of Madrid (UPM), Madrid, Spain, [2]Dpto. Protección Vegetal, INIA, Madrid, Spain

Introduction: *Bactrocera oleae* (Gmelin) (Diptera: Tephritidae) is one of the key pests on olives in the Mediterranean area, representing 97% of world production. Olive fly larvae feed on olive fruits, causing premature drop of attacked fruits and direct pulp destruction as well as an increase on oil acidity, which renders the oil unmarketable.

Methods: The main method usually used to control this pest in Spain, is the application of aerial or terrestrial bait spraying of hydrolysate attactants with conventional insecticides (currently dimethoate) targeting adults. One disadvantage of these treatments is the negative impact on non-target insects such as *Chrysoperla carnea* (Stephens), the major oophagous predator of the olive moth *Prays oleae* (Bernard), the second pest on importance on Mediterranean basin on olive groves. In this work, some candidate insecticides for the control of the olive fruit fly were investigated: fipronil (Regente®), imidacloprid (Confidor®), natural pyrethrins+piperonyl butoxide (Pelitre Hort®) and spinosad (Spintor Cebo®) and compared with the standard dimethoate (Perfeckthion®). The maximum field recommended rate was tested on *C. carnea* larvae following the IOBC (International Organization of Biological Control) guidelines for extended laboratory and persistence tests.

Results: Fipronil was the most toxic insecticide on extended laboratory test, followed by dimethoate, imidacloprid, natural pyrethrins+piperonyl butoxide and, finally, spinosad, which was harmless. Regarding persistence, fipronil was the most persistant, followed by dimethoate and imidacloprid, whereas natural pyrethrins+piperonyl butoxide resulted innocuous.

Conclusions: Our results show that out of the studied pesticides, spinosad is compatible with the studied natural enemy while fipronil is clearly harmful.

POSTER PRESENTATION

Epicuticular lipids as caste-recognition cues in the termite *Prorhinotermes simplex* (Isoptera: Rhinotermitidae)

Robert Hanus, Rafal Piskorski, Jan Šobotník, Irena Valterová

Institute of Organic Chemistry and Biochemistry AS CR, v.v.i., Prague, Czech Republic, Prague, Czech Republic

Introduction: The recognition of nestmates in eusocial animals is a prerequisite for the maintenance of integrity of societies. It allows an exchange of altruistic behaviour with related individuals and reduces social parasitism. Another level of recognition in eusocial communities is the recognition of particular castes. In termites the epicuticular lipids are involved at both levels. We compare the chemical diversity of epicuticular lipids in imaginal and neotenic reproductives, soldiers, and pseudergates from related and unrelated populations of *Prorhinotermes simplex* from Cuba and Florida with emphasis on a) discrimination among castes and its dynamics, b) chemical phenotype distances between populations.

Methods: Individuals were removed from laboratory colonies, their body washes were analysed by means of gas chromatography with flame ionisation and mass spectrometric detection. Multivariate statistical comparison allowed us to compare the similarities between samples and draw conclusion about chemical diversity of epicuticular lipids.

Results: In each colony, a clear distinction could be made among castes, often based not only on quantitative but also on qualitative differences. However, the chemical pattern of castes was not identical in all colonies and revealed to be variable in time. Nevertheless, these variations were not as profound as the geographical differences.

Conclusions: The results indicate that the chemical composition of epicuticular lipids varies among related colonies and in time, and suggest thus that also the caste recognition system is subjected to dynamic changes at a short-term scale.

POSTER PRESENTATION

Impact of UV-absorbing greenhouse nets in the population increase and spatial distribution of *Macrosiphum euphorbiae* Thomas on lettuce crops

Saioa Legarrea, Beatriz M. Diaz, Ignacio Morales, Elisa Viñuela, Alberto Fereres

[1]Dpto Preotección Vegetal, CCMA-CSIC, Madrid, Spain, [2]Technical University of Madrid (UPM), Madrid, Spain

Introduction: The presence of *Macrosiphum euphorbiae* Thomas in lettuce involves cosmetic damage and high economic losses that forces to develop new control strategies.

Methods: In this context, UV-absorbing nets were tested under field conditions under two tunnels divided in four sealed identical compartments. The greenhouses were covered by 50 mesh nets, one of which had no UV-absorbing additives (Standard) while the other (BioNet®) filtered most of the UV incident light. Four lettuce plants were artificially infested with a density of 8 adult aphids/plant at the entrance of each tunnel compartment. Every plant in the tunnel was sampled twice or once a week by visual inspection in order to describe aphid population dynamics and their spatial distribution.

Results: The results show that the population increase of *M. euphorbiae* was significantly larger under the Standard net that under BioNet® from three weeks after infestation onward. In addition, the total number of aphids and the percentage of aphid-infested plants were significantly higher under the tunnel coverted by the standard net. The spatial distribution of aphids for each sampling date was analized using the SADIE and FOCI methodology. When the crop was half developed aphids were established in a more aggregated pattern under the BioNet cover. We also calculated the Shannon' entropia index as a measure of the degree of hetereogenity of population counts which was found to be highest for the Bionet tunnels. Marketable yield was also higher under the UV-absorbing nets.

Conclusion: Our results suggest that the reproduction rate and the dispersion of *M. euphorbiae* is significantly reduced under the UV-absorbing nets, which should be considered as a promising alternative pest-control strategy.

POSTER PRESENTATION

Geographical patterns, biodiversity hotspots and gaps in knowledge: Species-area relationships for moths and butterflies of Russia

Mikhail Kozlov[1], Sergey Sinev[2]

[1]University of Turku, Turku, Finland, [2]Zoological Institute, St. Petersburg, Russian Federation

Introduction: Until very recently, only scattered information was available on species richness of moths and butterflies of Russia. Publication of the first comprehensive catalogue in 2008 allowed biogeographical analysis aimed at exploration of large-scale geographical patterns.

Methods: We based our analysis on the numbers of species of different taxa calculated for 40 regions covering the entire territory of Russia, and compared species-area relationships with those in well-studied countries of Europe.

Results: The analysis demonstrated that fauna of moths and butterflies of Russia is explored much worse than in the rest of the Europe; only few regions of Russia (e.g. Murmansk district) fit species-area relationships based on data from European countries. The knowledge is generally biased, and 'microlepidoptera' are underrepresented in the majority of the regions. The most obvious shortage of information was detected for north-eastern parts of both Siberia (especially from territories adjacent to the Okhotsk sea) and the European Russia. Correction for these geographical and taxonomic biases allowed discovering both latitudinal and longitudinal trends in species richness and species-area relationships and identifying several biodiversity hotspots. We also estimated the numbers of species that are not yet reported but are likely to be found in each region of Russia and in the country as a whole.

Conclusions: Although information on local faunas of moths and butterflies of Russia is still incomplete, analysis of the data summarized in recently published catalogue has important ecological implications, including suggestion of tentative conservation targets for different regions.

POSTER PRESENTATION

Bt Cotton expressing the Cry1F and Cry1Ac protein in the management of *Alabama argillacea* Hueb, *Heliothis virescens* Fabr. and *Spodoptera frugiperda* Smith

Renan Gravena[1], Santos Antonio[2], Santin Gravena[1], Marcelo Batistela[1], Sergio Benvenga[1], Adriana Gravena[1]

[1]Gravena Ltd., Jaboticabal, SP, Brazil, [2]Dow Agro Sciences, São Paulo, SP, Brazil

Introduction: The insertion of genes of *Bacillus thuringiensis* in cotton crop promotes healthy crop and beneficial entomofauna. The efficiency of Bt Cotton, expressing Cry1F and Cry1Ac, was compared to the conventional, treated or not with spinosad to control *Alabama argillacea*, *Heliothis virescens* and *Spodoptera frugiperda*.

Methods: Randomized complete block design with 4 treatments and 5 replicates was used. Ten small larvae of *Spodoptera* and 5 of *Heliothis* larvae/plant were released natural ocurrence of *Alabama* was considered for evaluations. Percent of defoliation, number of eggs and larvae, and reproductive structures were evaluated. The application of spinosad on Bt-plot and the conventional plot was made from 2 to 5 days after the larvae release.

Results: *Heliothis* small larvae in Bt Cotton (with or without insecticide) presented infestations from 0 to 0.4 in contrast to the control, from 0.8 to 10.6/plant. The conventional plots showed from 0.2 to 3 larvae/plant with no difference with Bt and control plots. No large larvae were found in Bt Cotton. The oviposition of *Heliothis* was even less in control than the treatments. The average of damaged reproductive structures was less in Bt than in conventional and control plots. The density of *Spodoptera* was low even with larvae releases, with no statistical difference. The number of reprodoctive structures damaged by *Spodoptera*, in Bt Cotton (both systems) was less than in conventional and control plots statiscally.

Conclusion: The Cry1F/Cry1Ac Cotton is effective in the management of *Alabama*, *Spodoptera* and *Heliothis*, showing no damage to their reproductive structures.

POSTER PRESENTATION

Identification of a natural source of resistance to leaf miner species in melon (*Cucumis melo* L.)

Faiza E.E.Salah[1], M. T. Yousif[2], Y. G. Unis[2] , A. A. Gesmella[2]

[1]Faculty of Agriculture, Gezira University, Sudan; [2]National Institute for Promotion Horticultural Exports, Gezira University, Sudan

Melon (*Cucumis melo* L.) considered one of the most important vegetable crop. It is production facing the problem of insect infestation. Mainly white flies (*Bemisia tabac*i), aphids (*Aphis gossypyii*), leaf miners *(Liriomyza* spp.), beetles and fruit flies.

Objective of this study to identify natural source(s) for resistance to leaf miner. Surveys and collection missions carried out in some states in Central Sudan, to estimate damage caused and to collect promising accessions for resistance. Infestation found high in all visited areas. It observed leaf miners infestation is drastically decreased as you go north from Duem city in the White Nile State. The collected accessions with some introduced lines, kindly provided by the Plant Genetic Resource Unit of the Agricultural Research Corporation, were evaluated for resistance to leaf miner under field conditions of the Gezira University Research Farm, Medani, Sudan. The Complete randomized Block Design with four replications used in this study. Among the 102 screened accessions and lines only nine accessions, 7 indigenous accessions and 2 introduced lines, were found to be promising for leaf miner resistance under field conditions. The top resistant genotypes were HSD 2445, collected in Gezira State, with a general mean of infestation of 0.18% and HSD 1923, collected in the White Nile State, with a general mean of 1.77%, followed by the introduced lines Nantais Oblong (France) with a general mean of 24.7% and PI 313970 with a general mean of 36. 7%.

Optimization of methods for monitoring of *Oscinella frit* (L.) (Diptera: Chloropidae) on winter and spring barley

Hristina Krasteva, Olia Karadjova, Ventsislav Ventsislavov

Plant Protection Institute, Kostinbrod, Bulgaria

Introduction: *Oscinella frit* is the most damaging pest on winter and spring barley grains in Bulgaria. Yield reductions ranging from 3% to 35% have resulted from larvae feeding. The relationships between percent of damaged grains and density of flies in relations to barley growth stage and daily fly activity of adults were studied to formulate efficient sampling procedures.

Methods: Studies were conducted in winter and spring barley fields at the Plant Protection Institute in Kostinbrod during 1997-2007. Density dynamics of flies was observed by sweep-net using samples of 10 and 20 sweeps. Grain injury was presented in percentage of the total amount of grains per ear. Data were analyzed with program "Statistica 6" at $P \leq 0.05$. The relative standard error was used to compute the accuracy of estimations (Southwood, 1978).

Results: Significant positive correlations were found between per cent of damaged winter and spring barley grains and density of flies registered at the beginning of ear emergence stage (50-55 on Zadoks scale). Adult observation accuracy below 25 % was achieved in treatments in which the observation was carried out between one and four o'clock in the afternoon for the first generation and between ten and twelve o'clock in the morning for the second generation of *O. frit* by using samples of 10 sweeps.

Conclusion: The barley growth stage 50-55 is an optimum for sampling of frit fly adult density to make a decision for chemical control. For adult density observation accuracy below 25% is achieved by using samples of 10 sweeps.

POSTER PRESENTATION

Interspecific competition rather than predation explains host plant shift of a leaf beetle *Chrysomela lapponica*

Elena Zvereva[1], Mikhail Kozlov[1], Oksana Kruglova[2]

[1]University of Turku, Turku, Finland, [2]University of Belarus, Minsk, Belarus

Introduction: Leaf beetle *Chrysomela lapponica* sequesters major component of larval defensive secretion, salicylaldehyde, from salicyl glucosides (SGs) of host plant. However, some populations have shifted to SG-poor hosts; their defensive secretion does not contain salicylaldehyde. We tested whether these shifts allowed to escape from (i) specialist natural enemies and/or (ii) interspecific competition.

Methods: We compared field mortality in four populations of the leaf beetle feeding on SG-rich (in Kola Peninsula and Finnish Lapland) and SG-poor host plant species (in Ural and Belarus).

Results: Mortality from generalist enemies was highest in Belarus population, but mortality from specialists did not differ among four populations. Experiments showed that *C. lapponica* failed to escape from specialists by shift to SG-poor hosts because specialist enemies developed ability to use secretion of prey from SG-poor hosts as a search cue as effectively as salicylaldehyde.

Foliar damage of host imposed both by leaf puncturing and by feeding larvae of *Chrysomela vigintipunctata* decreased performance of *C. lapponica* indicating that indirect (host plant mediated) competition with early season specialist herbivores may have forced *C. lapponica* to escape from SG-rich host. Direct exploitative competition may also be strong during outbreaks of *C. vigintipunctata*. Moreover, populations of *C. lapponica* switched to SG-poor hosts are found mostly in the localities where distributions of these two leaf beetle species overlap.

Conclusions: Interspecific competition rather than escape from specialist enemies is the most plausible selection force that have caused host plant shift at least in some populations of *C. lapponica*.

POSTER PRESENTATION

Digestive proteaeses of the banana weevil, *Cosmopolites sordidus* Germar (Coleoptera: Curculionidae) and their response to protease inhibitors

Miguel Montesdeoca, Gloria Lobo, Félix Ortego, Aurelio Carnero, Pedro Castañera

ICIA, La Laguna,Canary Islands, Spain

Introduction: "Dwarf Cavendish" cv. banana is widely grown in Canary Islands with a production of approximately 400000 tons/year distributed in 8000 Ha. As the banana weevil larvae, *Cosmopolites sordidus* Germar (Coleoptera: Curculionidae) grows inside the rhizome, common practices as insecticide treatments and pheromones are poor effective in the control of this pest being an alternative the development of pest resistant banana expressing genes proteinase inhibitor. Thus, it is necessary to gain a comprehensive knowledge of the major digestive enzymes present in the banana weevil gut and their interaction with appropriate inhibitors.

Material and methods: Digestive protease activities of the banana weevil were characterized based on the ability of gut extracts to hydrolyze specific synthetic substrates, optimal pH and hydrolysis sensitivity to protease inhibitors.

Results: Adults of this species were found to use a complex proteolytic system for protein digestion that includes cathepsin D-, cathepsin B-, trypsin-, chymotrypsin-, aminopeptidase-, carboxypeptidase A- and carboxypeptidase B-like activities. According to this proteolytic profile, several serine and cysteine proteinase inhibitors were tested in vitro to establish their potential as resistance factors.

Ovary structure and oogenesis in Dermaptera – New evidence for relationship within an order

Szczepan M. Bilinski[1], Fabian Haas[2], Waclaw Tworzydlo[1]

[1]Department of Systematic Zoology, Institute of Zoology, Jagiellonian University, Krakow, Poland, [2]icipe - African Insect Science for Food and Health, Nairobi, Kenya

Introduction: Dermaptera (earwigs) is an insect order comprising about 2200 extant described species classified in 11 families and 3 suborders. Some research has been conducted on phylogenic relationship within this group, including characters of the wing and male genitalia as well as molecular data. However, the studies still did not answer all the question about their relationships. It has been shown that representatives of various subgroups of earwigs may significantly differ in structure of ovaries and process of oogenesis.

Methods: The ovaries of earwigs were analysed using light and electron microscopy.

Results: In all cases, the ovaries were of meroistic – polytrophic type which means that developing oocytes are accompanied by the nurse cells. An individual ovary from representatives of more basal taxa (e.g. Labiduridae) comprises five long ovarioles, whereas in more derived taxa (e.g. Forficulidae) there are about 30-40 short ovarioles per ovary. In all studies species, ovarian follicles are composed of two cells only: an oocyte and a polyploid nurse cell that are connected by a simple intercellular bridge. Although, the final number of cells constituting the ovarian follicle is constant in Dermaptera, the processes that lead to their formation in various earwig subgroups are apparently different. In derived taxa, the cystoblast divides only once, whereas in more basic families, the cystoblast undergoes three mitotic divisions leading to the formation of 8-cell clusters that are secondarily split into 2-cell clusters. We also found that in taxa except the Pygidicranidae, the nurse cell nucleus is of an ameboid shape. In the Pygidicranidae its shape is rather discoidal.

Conclusions: We consider the ovaries and the oogenesis to be useful characters for phylogenic studies.

POSTER PRESENTATION

Structure and functioning of the ovarian follicles in forficuloid dermapterans

Szczepan M. Bilinski, Waclaw Tworzydlo

Department of Systematic Zoology, Institute of Zoology, Jagiellonian University, Krakow, Poland

Introduction: The ovaries of the studied forficuloid earwig species (*Forficula auricularia, Chelidurella acanthopygia, Doru lineare* and *Opisthocosmia silvestris*) are meroistic-polytrophic and composed of numerous short ovarioles that consist of a terminal filament, germarium and vitellarium.

Methods: The ovaries of earwigs were analysed using light, fluorescence and electron microscopy.

Results: The germaria of adult females comprise meiotic (pachytene) and postmeiotic (differentiating) germ cell clusters, as well as small prefollicular cells. All germ cell clusters consist of two cells that are connected by a single intercellular bridge. In the vitellarium there are usually 2 ovarian follicles only. The individual follicle consists of a synthetically dormant oocyte and a single, polyploid nurse cell and is surrounded by a layer of somatic follicular cells (FCs). During previtellogenesis the nurse cell enlarges and becomes highly active. Concurrently its nucleus attains characteristic, irregular shape. In the nurse cell nucleus of one studied species, *F. auricularia* in addition to chromatin aggregations and RNA- and Ag-NOR-positive nucleoli, a single compact DNA- and Ag-NOR-positive body is present.Immunocytochemical tests showed that the body coantains snoRNAs. During advanced vitellogenesis the molecules synthesized in the nurse cells (RNAs, proteins, as well as nurse cell ogranelles) are transferred to the ooplasm *via* the intercellular bridge. During this transfer the nurse cell nucleus is retained in the cell center and does not occlude the intercellular bridge.

Conclusions: The results of hictochemical and immunocytochemical analyses indicate that the DNA-positive body is involved in the formation of the nucleoli.

POSTER PRESENTATION

Insect identification using Artificial Neural Networks (ANN)

Jaromir Vanhara, Peter Fedor, Igor Malenovský, Natália Murárikova, Josef Havel

[1]Masaryk University, Brno, Czech Republic, [2]Comenius University, Bratislava, Slovakia, [3]Moravian Museum, Brno, Czech Republic, [4]Masaryk University, Brno, Czech Republic, [5]Masaryk University, Brno, Czech Republic

Introduction: Entomology, as well as its application in many fields, such as agriculture, forestry, human and veterinary medicine, relies heavily on the accurate identification of species. Besides molecular diagnostic techniques, the progress in information technology has opened opportunities for the computer-assisted taxonomy. Artificial Neural Networks (ANN) seem to have been one of the most promising tools for the basis of such systems. The advantages of ANN include an ability to learn from examples and to generalize observed patterns.

Methods: The use of ANN requires a training database in which specimens, correctly identified by experts, are included. Each specimen has to be characterized by diagnostic variables (characters). For ANN inputs can be used digital images, optically sensed wing beat frequency spectra, near-infrared reflectance spectra, bioacoustic recordings, chemotaxonomy or morphometry. An ANN model is designed to find a relationship between the characters (=*input*) and species (=*output*). The quality of the training set is an essential prerequisite to obtaining reliable identifications.

Results: Our case studies on thrips and diptera used morphometric data mostly. The high percentage of correctly identified specimens (about 97 %) is promising for a wider use of ANN for insect identification in practice.

Conclusions: ANN is cheap and non-destructive suitable also for type material or permanently mounted slides. ANN have the potential to enhance the practice of routine identification with a non-expert as technical help. High reliability of classification is promising for a wider application of ANN in the practice of insect identification.

POSTER PRESENTATION

Efficiency of Cyflumetofen to manage the leprosis mite *Brevipalpus phoenicis* (Geijskes) (Acari: Tenuipalpidae) in a Brazilian citrus orchard (*Citrus sinensis* Osbeck).

Jose Silva[1], Toshiaki Shitara[2], Santin Gravena[1], Marcelo Batistela[1], Sergio Benvenga[1], Adriana Gravena[1], Renan Gravena[1]

[1]Gravena Ltd., Jaboticabal, SP, Brazil, [2]Iharabras, Sorocaba, SP, Brazil

Introduction: The citrus plantations in Brazil has as key pest the Citrus Leprosis (Flat) Mite (CLM), *Brevipalpus phoenicis (*Geijskes). This pest has also a high tendency to become resistant against acaricides needing to alternate the mode of actions of several compounds to monitor it. This paper deals with the study of the effect of the new compound Cyflumetofen to manage the CLM.

Methods: Cyflumetofen (OK-5101), in several doses, was compared with espirodiclofen and cyhexatin, spraying in citrus (*Citrus sinensis)* orchards, S. Paulo, Brazil. The trials were a semi-field to determine the Cyflumetofen residual effect and two field trials being one using plants 7 years old, variety Pera and the other with 3 years old. The Cyflumetofen dosages tested were 30, 35, 37.5 e 40 mL/hL. The field trials had as experimental design the randomized blocks and the semi-field design was complete randomized blocks. For this test, after application with a ground sprayer fruits were collected at 1, 3, 5, 7, 10, 12 and 15 after for mite exposition and mortality evaluation.

Results: The residual effect of Cyflumetofen (OK-5101) against CLM, in all dosages, was 7 days on citrus fruits. By the results of both field trials, all dosages of the new acaricide Cyflumetofen (OK-5101) were efficient to control the CLM, *B. phoenicis*, in fruits and branches, either in percent of population reduction or in number o mites per sample.

Conclusions: All dosages of the new acaricide Cyflumetofen were efficient to control the CLM with residual effect of 7 days.

POSTER PRESENTATION

Tecia solanivora (Povolny 1973) (Lepidoptera: Gelechiidae) a new pest in Canary Islands

Aurelio Carnero, Angeles Padilla, Santiago Perera, Elena Trujillo, Estrella Hernández

ICIA, La Laguna,Canary Islands, Spain

Distribution: First reports in the Canary Islands of damage to potatoes by the Guatemalan moth *Tecia solanivora* were made in 1999, on the island of Tenerife. Although continental Europe is currently still free of *T. solanivora*, it is an important quarantine pest elsewhere and its spread to other islands posed a serious threat to the local staple potato crop. Initial incidence was established by placing pheromone traps in several field localities and in wholesale seed-potato warehouses throughout Tenerife. Data from December 2006 showed that the entire northern side of the island is affected, while infestations in the south remain restricted. Some evidences reports also cite its presence on the islands of Gomera, Grand Canary and La Palma.

Damages and losses: To date, the consequences of this pest are reductions in yield and in growing surface, and increased crop costs. Failure to adequately contain the moth could lead to the collapse of the local potato industry as well as the possibility of losing historically important cultivars, and the ever present threat of its spread to Mainland Spain and from there to the rest of Europe.

Control alternatives: Although most research to date has focussed on integrated management of the potato crop, ongoing research on fumigating harvested tubers with gases such as CO_2, O_2, and N_2 (alone or combined) appears promising: provisional results show a 100% mortality rate for larvae and adults in potatoes exposed to subjected to CO_2 (20%) Meanwhile the pupae were unaffected: pupal mortality was not significant.

POSTER PRESENTATION

The effect of vernalization on host plant resistance of wheat to Russian wheat aphid, *Diuraphis noxia*, biotype RWASA2

Robbie Lindeque[1], Vicki Tolmay[1], Maryke Labuschagne[2]

[1]ARC-Small Grain Institute, Bethlehem, Free State, South Africa, [2]University of the Free State, Bloemfontein, Free State, South Africa

Above-average late winter- and early spring temperatures during 2005 linked vernalization requirement of winter- and facultative varieties to field susceptibility of commercial varieties to RWA. The alternative hypothesis suggested that RWA damage of wheat varieties resulted from biotype development. In 2005 82% of winter and intermediate dryland wheat varieties available in South Africa contained host plant resistance through the dominant single genes, *Dn1* or *Dn2* from donor accessions PI 137739 and PI 262660. Although donors such as PI 294994 (*Dn-5, Dn-8 and Dn-9*) were also introduced into some varieties loss of *Dn-1* and *Dn-2* resistance in the field was greatly anticipated. Implications of lost host plant resistance to wheat breeding and seed production would however be significant and warranted investigations of both hypotheses. Mass screening of seedlings for RWA resistance under controlled conditions would also not be objective if vernalization is important in expression of RWA host plant resistance. Seedlings of Betta (susceptible check), CItr2401 (resistant check), Molen, Hugenoot, Limpopo, Gariep and Elands were subjected to 0-, 2-, 4-, and 6-weeks vernalization at 3°C (± 2°C) with a 10:14 hour light:dark photoperiod regime. Seedlings were removed simultaneously after vernalization and cultured at 18°C/ 12°C day/ night (± 2°C) - and 26°C/ 18°C day/ night temperatures (± 3°C) for four weeks. After a week seedlings were infested with 5 aphids per plant and visual damage rating (1 – 10) and fresh plant biomass (grams 2 plants^{-1}) was determined three weeks later. Main effects of variety on visual damage ratings and fresh biomass confirm susceptibility of Gariep, Limpopo and Elands to RWASA2. Application of the 2-week vernalization period in our experiment resulted in the best resistance by Elands to RWASA2, measured in percentage fresh biomass and corresponded with the vernalization recommendation for this variety. Our findings consequently also suggest that CItr2401 benefited from extended vernalization periods as the 6-weeks period produced significantly higher percentage biomass than 0-weeks, 2-weeks and 4-weeks periods. Results from our research however support findings in literature reporting no effect of non-vernalized or vernalized plants on RWA plant resistance ranking.

POSTER PRESENTATION

Thiamethoxam in the management of insect vectors of virus diseases and benefits to the tomato crop

Sergio Benvenga, Marcelo Batistela, Santin Gravena, Renan Gravena, Jose Silva, NIlton Araujo Jr, Luis Amorim

Gravena Ltd., Jaboticabal, Brazil

Introduction: *Frankliniella schultzei* (Trybom), *Thrips palmi* (Karny) (Thysanoptera: Thripidae), *Myzus persicae* (Sulzer) (Homoptera: Aphididae) and *Bemisia* spp. (Homoptera: Aleyrodidae) are key pests in tomato crops. The management is based on the treatment of plants in the pre-transplanting, followed by the population monitoring for new decision-makings according to the levels of action. The efficiency of thiamethoxam (Actara 250 WG at 600 g/ha), applied in plants by the transplanting date and complemented with eight weekly foliar applications of thiamethoxam + lambdacyhalothin (Engeo Pleno at 25, 50 and 75 mL/100 L), was evaluated in the management of insect vectors and beneficial aspects on a tomato crop.

Methods: The test was installed in staked tomato, *Lycopersicon esculentum*, hybrid Debora Max, County of Cravinhos, State of Sao Paulo, Brazil, with plots of 20 plants, in randomized blocks with 4 replications. The evaluation of insects density was made weekly through shaking the terminal branches on a plastic container, using 5 useful plants, complemented with a visual assessment. The benefits of the compounds on the crop were evaluated by the index of non-infected plants by viruses and productivity.

Results: The reduction rate of vectors with Thiamethoxan (Actara 250 WG) applied by the transplanting and complemented with foliar applications (Engeo Pleno; 25, 50 and 75 mL/100 L) was of 71, 73 and 81%, respectively.

Conclusions: Thiamethoxam (Actara 250 WG) and (Engeo Pleno) was efficient in the management of vectors and protected the plants against viruses, increasing the productivity related to the check.

POSTER PRESENTATION

Effect of rainfall and temperature on host plant resistance of wheat to Russian wheat aphid, *Diuraphis noxia*; biotype RWASA2

Robbie Lindeque[1], Vicki Tolmay[1], Maryke Labuschagne[2]

[1]ARC-Small Grain Institute, Bethlehem, Free State, South Africa, [2]University of the Free State, Bloemfontein, Free State, South Africa

Widespread reports of RWA virulence on commercial wheat varieties (containing *Dn-1*) were received from the eastern Free State in 2005. Virulence was confirmed by mass screening seedlings of all commercial varieties under controlled conditions and the new biotype was designated as RWASA2. In South Africa fluctuations from long-term average temperatures and rainfall coincided with lost resistance in the eastern Free State during 2005. This study firstly investigated changes in temperature and rainfall in the eastern Free State during 2005. The second objective was to determine visual damage of seedlings at 18°C/12°C, 22°C /16°C and 26°C /22°C by RWASA1 and RWASA2 and the relation with climatic variations in the eastern Free State. Thirdly, effects of RWASA2 on plant variables of Komati, Matlabas, SST 966 and SST 399 were determined at 26°C/ 20°C (± 3°C). High temperatures and soil-moisture stress occurred in the eastern Free State in 2005 during early developmental stages of dryland-wheat. A possible implication would have been reduced plant growth vigour and increased RWA population growth ultimately increasing virulence on wheat. Higher rainfall during the off–season ensured alternative host plant availability and increased over-wintering survival rate of RWA. In the second experiment resistance ratings to RWASA1 of Halt, Komati and Matlabas shifted to a less resistant- or susceptible category as developmental temperature increased and changed ranking of SST 966 substantially. RWASA2 was highly virulent on seedlings of all varieties except Halt regardless of temperature regimen. Komati, Matlabas, SST 966 or SST 399 did not express any significant resistance to RWASA2 through leaf area, leaf roll and chlorosis and support results obtained for the same varieties in the visual screening test.

POSTER PRESENTATION

Phylogeny of the tribe Athetini Casey, 1910 and its position in the subfamily Aleocharinae (Coleoptera: Staphylinidae)

Hallvard Elven, Vladimir Gusarov

Natural History Museum, University of Oslo, Oslo, Norway

Introduction: The staphylinid tribe Athetini has never been subjected to a thorough phylogenetic study. In our study molecular markers are used to infer the phylogeny of the tribe and its position within Aleocharinae.

Methods: Sequences were obtained from representative taxa of most subtribes of Athetini and several tribes related to Athetini. Sequenced regions include both mitochondrial (COI, COII, Leu1, Leu2, NADH1, 16S) and nuclear (18S) markers. RNA coding sequences were aligned manually using secondary structure information inferred by comparison with published structures. Data were analysed using maximum parsimony (PAUP) and bayesian inference (Phase). For the protein coding genes, both nucleotide and amino acid sequences were used in different analyses. For the RNA genes, secondary structure information was included in the analyses where possible.

Results: Our study supports the monophyly of a clade consisting of the tribes Athetini and Lomechusini, and a sister group relationship between that clade and the tribe Placusini. Lomechusini, together with the athetine genera *Geostiba* and *Earota*, forms a sister group to the remaining Athetini.

Conclusions: The monophyly of Athetini + Lomechusini is supported. Additional markers are needed to study relationships within Athetini in detail.

POSTER PRESENTATION

Insecticides against cone and seed insects in Norway spruce (*Picea abies*) seed orchards

Olle Rosenberg[1], Tiina Ylioja[2], Paal Krokene[3]

[1]Forestry Research Institute of Sweden, Uppsala, Sweden, [2]Finnish Forest Research Institute, Suonenjoki, Finland, [3]Norwegian Forest and Landscape Institute, Ås, Norway

Introduction: Seed production in Norway spruce (*Picea abies*) seed orchards may be severely reduced by insects attacking cones and seeds. Insects in several orders and genera are responsible for the damage, and at present there are no effective and environmentally acceptable control options. Studies in Sweden have shown promising results with spraying Bt (*Bacillus thuringiensis* var. *kurstaki* x *aizawai*) against species of Lepidoptera, but for other pests other control methods must be developed.

Methods: Tests with several insecticides were carried out in seed orchards in Sweden, Finland and Norway in 2006 and 2007. Insecticides were either conventionally applied by spraying cones (s) or injected into the lower stems (i). The following active ingredients were used: diflubenzuron (s), spinosad (s), esfenvalerate (s), imidacloprid (s), abamectin (i), acetamiprid (s) and azadirachtine (s).

Results: The efficacy of the insecticides ranged from low to negligible. Spinosad and abamectin showed most potential. Weather conditions, the fact that insecticides were applied only once during flowering and low infestation rates in some of the test sites in 2006 may explain the low efficacy of the applications. In 2007, very high infestation rates in the cones and early insect flight relative to insecticide applications may have contributed to the low efficacy.

Conclusions: The low efficacy was probably not only due to inefficient insecticides, but also due to problems with timing of insecticide application, weather conditions and insect density. To solve these problems more experimentation is called for in the future, including the use of semiochemicals for population monitoring.

POSTER PRESENTATION

Generalist fly pollination in *Ceropegia ampliata* and the role of trapping hairs

Gareth Coombs, Craig Peter, Tony Dold

Rhodes University, Grahamstown, South Africa

Introduction: Many species in the genus *Ceropegia* (Apocynaceae - Asclepiadoideae) have flowers with elaborate tubular corollas that are thought to mimic brood sites or food for pollinating flies. Pollinators are attracted to the unpleasant scent of the flowers where they are thought to be trapped by erect hairs lining the constriction of the bulbous base of the corolla tube, "forcing" prolonged visits and increasing pollen export and deposition. Pollinators are then released once the hairs have wilted.

Methods: Pollinators were collected and flowering phenology determined in a natural population of *C. ampliata* E.Mey. in the Eastern Cape, South Africa. Natural levels of pollination success were determined and the state of the hairs within the tube recorded. Histochemical stains where used to detect areas that emit scent and produce nectar.

Results: *C. ampliata* is visited by small, mainly female flies from at least 6 families but only flies of the Tachinidae (8 flies), Muscidae (2 flies) and Sarcophagidae (1 fly) bore pollinaria. Although the hairs may function to prolong pollinator visits, our data shows that pollinators can escape before hairs become flaccid and pollen transfer efficiency is generally very low. The flowers appear to accumulate small amounts of nectar in the nectaries located at the base of the gynostegium although the volumes are too small too accurately measure. Histochemical staining confirms metabolically active cells here as well as in the adaxial basal region of the petals which appears to be the site of scent of production.

Conclusion: This is the one of the first detailed studies to examine the pollination biology of a wild-growing population of *Ceropegia* and suggests generalist fly pollination in this species. Flies detained within the flowers may still escape, questioning the advantage of the trapping mechanism given the low pollination success.

POSTER PRESENTATION

Grooming behavior in the ant, *Lasius japonicus*, against entomopathogenic fungi

Masaki Okuno[1], Kazuki Tsuji[2], Kenji Fujisaki[1]

[1]Kyoto University, Kyoto, Japan, [2]University of the Ryukyus, Okinawa, Japan

Introduction: In social insects, grooming behavior is known not only for nestmate recognition, but also for immune defense system. Grooming behaviors have been indirectly studied in terms of survival rate or infection rate, under the vulnerable condition. We directly analyzed self-grooming and allogrooming to reveal the behavioral alteration as a measure of frequency of each behavior.

Methods: We tested 20 individuals in each Petri dish that was exposed to 1 of 3 fungal spore concentrations: low (10^4 spores/ml), high (10^7 spores/ml) and control (0 spore/ml). During 48h of exposure, we recorded grooming behaviors 7 times (30 min each time).The frequency of 2 types of behavior was calculated as the total number of observed behavioral events divided by the number of survival individuals. It was then converted into the mean frequency of grooming behavior and the percentage of self-grooming. Thus, we analyzed the total frequency of grooming behavior as a sum of self-grooming and allogrooming. We also observed the survival time as an indirect parameter.1

Results: When spore concentration increased from control (0 spore/ml) to high concentration (10^7 spores/ml), the mean frequency of self-grooming decreased, the mean frequency of allogrooming increased, the frequency of total grooming did not change and the percentage of self-grooming increased.

Conclusions: Frequency of self-grooming and allogrooming behaviors changes depending on spore concentration, indicating that it is an “allocation behavior”. Allogrooming behavior may play a role in the hygiene of nest, although we could not identify the significance of self-grooming.

POSTER PRESENTATION

Pathogenicity of blastospores and conidia of *Isaria fumosorosea* against pupae of the horse chestnut leaf-miner, *Cameraria ohridella*

Eva Prenerova[1], Rostislav Zemek[2], Frantisek Weyda[2]

[1]Laboratory of Plant Protection Olesna, Bernartice u Milevska, Czech Republic, [2]Biology Centre of Academy of Sciences of the Czech Republic, Institute of Entomology, Ceske Budejovice, Czech Republic

Introduction: The objective of this paper is testing the insecticidal activity of entomopathogenic fungus *Isaria fumosorosea* (Deuteromycetes) against the horse chestnut leaf-miner, a serious invasive pest spreading in Europe.

Methods: The experiments were carried out using strain of *I. fumosorosea* isolated from spontaneously infected hibernating pupa of *C. ohridella* (strain CCEFO.010.IFR) discovered in horse chestnut leaf samples. Blastospores were produced in an originally developed liquid medium, whereas conidia were produced on a Sabouraud agar. Toxicity of both types of spores was tested using a single-dosage dip assay. Diapausing pupae of *C. ohridella* were treated with a concentration of 6×10^7 conidia or blastospores/ml and incubated in Petri dishes at 23±1 °C and RH approx. 95 %. Pupae treated with destilled water served as control. Totally, 200 pupae were used in each treatment.

Results: Blastospores, conidia, and no-fungus control treatments averaged 100%, 88%, and 5% mortality of *C. ohridella* pupae, respectively, after a 3-day continuous exposure. The difference between blastospores and conidia treatments was statistically significant. Development of mycosis on pupae treated with blastospores was also faster compared to pupae treated with conidia (83 % versus 14%).

Conclusions: Our results demonstrate a high insecticidal activity of I. fumosorosea on C. ohridella pupae. It also show that blastospores kill the host faster than conidia.

Acknowledgments: This work was supported by MSMT grant No. 2B06005. The authors thank Ms. M. Krivanova for her help with experiments.

POSTER PRESENTATION

Molecular identification and characterization of two adipokinetic hormones in *Aedes aegypti* and *Culex pipiens*

Gerd Gaede[2], Christian Kaufmann[1], Hans Merzendorfer[1]

[1]University of Osnabrueck, Osnabrueck, Germany, [2]University of Cape Town, Rondebosch, South Africa

Introduction: Adipokinetic hormones (AKHs) are peptides that induce the mobilization of metabolites which are used to provide energy for such intense activities as, for example, flight in mosquitoes. We have cloned two AKH genes in each of two mosquito species under investigation, viz. *Aedes aegypti* and *Culex pipiens*.

Methods and Results: In each species one gene encodes for a novel "classical" AKH octapeptide, named Aedae/Culpi-AKH-I with the sequence (pELTFTPSWa), while the other gene in each species encodes for a "non-classical" AKH decapeptide which has the same sequence (pEVTFSRDWNAa) as the equivalent from *Anopheles gambiae* and is called Anoga-AKH-II. We investigated gene expression during the life cycle of *A. aegypti*. Northern blot analyses show expression of both AKHs in head and thorax but not in the abdomen of female mosquitoes, while males have, additionally, a significant AKH-I-mRNA amount in the abdomen. Immunocytochemistry performed with a polyclonal AKH antibody shows immunoreactivity in lateral neurosecretory cells of the brain, the corpora cardiaca, the x-cells, and in axons along the anterior midgut.

Conclusions: Comparing the translated coding sequences, *Aedes*-prepro-AKH-I has strikingly high similarity with *Culex*-prepro-AKH-I; the same is true for the prepro-AKH-II in the two species. This may point to conserved functions in the different mosquitoes. However, the classical and non-classical AKH preprohormones in any of the two mosquito species differ significantly, favouring the hypothesis of ancient gene duplication. Further studies using *in-situ* hybridization and bioassays will shed light on the localization of AKH synthesis and the functions of classical and non-classical AKHs.

POSTER PRESENTATION

Molecular identification and characterization of two adipokinetic hormones in *Aedes aegypti* and *Culex pipiens*

Gerd Gaede[2], Christian kaufmann[1], Hans Merzendorfer[1]

[1]*University of Osnabrueck, Osnabrueck, Germany,* [2]*University of Cape Town, Rondebosch, South Africa*

Introduction: Adipokinetic hormones (AKHs) are peptides that induce the mobilization of metabolites which are used to provide energy for such intense activities as, for example, flight in mosquitoes. We have cloned two AKH genes in each of two mosquito species under investigation, viz. *Aedes aegypti* and *Culex pipiens*.

Methods and Results: In each species one gene encodes for a novel "classical" AKH octapeptide, named Aedae/Culpi-AKH-I with the sequence (pELTFTPSWa), while the other gene in each species encodes for a "non-classical" AKH decapeptide which has the same sequence (pEVTFSRDWNAa) as the equivalent from *Anopheles gambiae* and is called Anoga-AKH-II. We investigated gene expression during the life cycle of *A. aegypti*. However, the classical and non-classical AKH preprohormones in any of the two mosquito species differ significantly, favouring the hypothesis of ancient gene duplication. Further studies using *in-situ* hybridization and bioassays will shed light on the localization of AKH synthesis and the functions of classical and non-classical AKHs.

POSTER PRESENTATION

A comparative study on the life cycles of *Liriomyza trifolii* (Burgess) and *Liriomyza sativae* (Blanchard)

Faiza Salah[1], Elamin M Elamin[2], Elameen Eltoum[1], Dominique Bordat[3]

[1]Dept. Crop Protection, Faculty of Agricultues, Gezira University, Medani, Sudan; [2]Agricultural Research, Medani, Sudan; [3]CIRAD, Montpellier, France

The life cycles of the leaf miners, *Liriomyza trifolii* (Burgess) and *Liriomyza sativae* (Blanchard), were studied in a growth chamber (25 ± 1°C; 75 ± 5% R.H.; 12 hL/12 LD and 3000 – 4000 LUX) at CIRAD, Montpellier, France. The host plant used was haricot bean, (*Phaseolus vulgaris)*. The egg incubation period of both species lasted for two days. Larval instars durations for both species was almost 6 days with no significant differences between the means. Regarding the pupal stage duration ranged between 9.14 and 10.66 days; the differences between the species were significant. The percentage of adult emergence for *trifolii* ranged between 62 to 76%, whereas that for *sativae* ranged was narrow 67.3 -68.8%; differences between the species were significant. Adult longevity was not studied. The total of the life cycle for the former was 16.6 – 18.0 days and for the latter was 17.7 -18.8 days; the difference was significant. Highly significant differences ($P<0.01$) were recorded between the number of feeding punctures caused by *L. trifolii* and *L. sativae.* Differences between the larval periods and number of emerging adults were not significant. Upon hatching, during 1996, the number of larvae of *L. trifolii* was significantly higher than that of *L. sativae,* but the total life span of *L. sativae* was significantly longer than that of *L. trifolii*.

POSTER PRESENTATION

A new species of the genus *Chionea* Dalman from Korea (Diptera: Limoniidae)

Sang Jae Suh, Yong Jung Kwon

Kyungpook National University, Sangju, Gyeongbuk, Republic of Korea

Snow crane flies, the *Chionea* species are characterized by the complete reduction of their wings and by the winter activity of adults. They are distributed over the whole Holarctic region. Only five species are known from Palaearctic Asian region: *Chionea araneoides* Dalman, *C. kanenoi* Sasakawa, *C. crassipes* Boheman, *C. nipponica* Alexander *and C. pusilla* Savchenko.

This new species is similar to *C. kanenoi* Sasakawa having 11 antennal segments which is differences from the other Palaeractic Asian species. But this species is distinctly differed from the known species by tibiae with a small node at apex respectively, conical outer gonostylus lobe, and the shape of gonostylus.

POSTER PRESENTATION

Spatial distribution pattern of cryptus mealybug and its optimal sample size for development of sampling plan in citrus groves, Korea

Jeong-Heub Song, Soon-Young Hong, Ki-Tek Kim

Jeju Agricultural Research and Extension Services, Jeju, Republic of Korea

Introduction: Cryptus mealybug, *Pseudococcus cryptus* is a serious scale pest of citrus in Jeju, Korea. To develop its sampling plan, it should take precedence over the others for its spatial distribution pattern in citrus orchard and determined the optimal sample size.

Methods: 14 datasets collected from a commercial citrus orchard were used for spatial pattern analysis by mean-variance relationship, probability distribution model, indices of dispersion and spatial autocorrelation. The linear strength of bivariate relations by season was summarized using covariance and correlation coefficients. The optimal sample size was determined by estimates of variability among primary (tree) and secondary (twig) sample units.

Results: The frequency distribution of cryptus mealybug follows a negative binomial distribution and iterative individual *k* was better fitted than others by χ^2 –test. The spatial continuity for 0° and 45° direction were 4 and 6m and for 90°, 135° and omnidirection was 12m. Morista's index and index of dispersion were shown the clumped distribution. Consider the bivariate scatterplot and summary statistics among March (after overwintering), May (1^{st} generation), June (2^{nd} generation), September (3^{rd} generation) collections. There was a positive and linear relationship between series seasons. The optimal sample size was determined as 7 twigs per tree and 8 trees per block.

Conclusions: The sampling plan for cryptus mealybug can be developed by the negative binomial probabilities and estimate the density precisely.

POSTER PRESENTATION

Comparative analysis of genes expressed from different castes of the termite *Coptotermes gestroi* (Isoptera: Rhinotermitidae).

Flávia Costa Leonardo[1], Anderson Ferreira da Cunha[2], Marcelo Falsarella Carazzolle[1], Fernando Ferreira Costa[2], Gonçalo Amarante Guimarães Pereira[1]

[1]Laboratory of Genomics and Expression, Department of Genetics and Evolution, Institute of Biology, State University at Campinas, Campinas, São Paulo, Brazil, [2]Center of Hematology and Hemotherapy, State University at Campinas, Campinas, São Paulo, Brazil

Introduction: Social insects such as termites present differential gene expression during development. Although *Coptotermes gestroi* has an important economic impact and is relevant from a biological point of view, to date only a few sequences have been produced from this species. The main objective of this study was to survey the gene composition of *C. gestroi*, comparing the gene expression between castes and find genes with biotechnological relevance.

Methods: To accomplish this study, we sequenced and analyzed expressed sequence tags (ESTs) isolated from libraries of workers' heads. Subtractive suppressive libraries using larvae, workers and soldiers were also constructed. Real time PCR was performed to confirm gene expression.

Results: From the workers' library, we obtained 2,332 sequences of appropriate standard quality that were clustered and assembled into contigs and singletons, revealing important biotechnology genes involved in cellulose degradation (endo-β-1,4-glucanase and β-glucosidase). Through the suppressive method we generated 529 ESTs that revealed genes involved in protein biosynthesis, digestive enzymes, iron and calcium transport, structural proteins, chitin catabolism and a variety of metabolic pathways.

Conclusions: These results provide novel insights into previously uncharacterized aspects of *C. gestroi* polyphenism and caste-associated biology.

POSTER PRESENTATION

Ecology of groundnut storage pests in Burkina Faso

Ouedraogo Issoufou, Traore N. Seydou, Dakouo Dona, Guenda Wendgoundi

INERA, Bobo-dioulasso, Burkina Faso

Introduction: In Burkina Faso, several groundnut varieties with good yield potential were developed and released. This leads to a significant development of groundnut production. Groundnut production increased from 180,532 tons in 1995 to 323,642 tons in 2003 (FAO, 2003). Despite this effort of production, groundnut is available only during a short period of the year due to damage caused by *Caryedon serratus* Olivier (Coleoptera: Bruchidae). It has been reported that in groundnut producing zones, about 70% of pods were damaged after four months of storage. This poster review aims at giving a better knowledge of the bio-ecology of the insect pest and at making some suggestions for managing groundnut storage in Burkina Faso.

Methods: In 2005 and 2007, pods from wild plants were sampled in groundnut production zones and belonging to the families of Mimosaceae, Papillionaceae and Cesalpiniacea. Adults emergence from these sampled pods and females egg laying were monitored in laboratory conditions.

Results: A total of 20 sites were visited and 64 samples were collected. Fruits were collected on 8 host plants belonging to four families (Caesalpiniacea, Mimosaceae, Papillionnaceae and Meliaceae). About 102 insects emerged from the harvested fruits. The majority of these insects were from three plant hosts (*Tamarindus indica*, *Piliostigma reticulatum* and *P.thonningii*). The identification of adults revealed that beetles emerged from the pods of *A. hypogea, P. reticulatum, P. thonningii* and *T. indica* all belong to the species of *C.serratus.* In laboratory, results on the behaviour of egg laying of *C. serratus* showed a significant difference between the number of eggs laid on groundnut varieties and those laid on other host plants.

Conclusions: Investigations carried out in different groundnut growing locations showed that *C. serratus* is the main insect pest during groundnut storage. The groundnut pods seem to the most suitable food support for this species of beetle.

POSTER PRESENTATION

1-Octen-3-ol as an important cue in fungal host finding of *Cis boleti*

Prodpran Thakeow, Sergio Angeli, Bernhard Weißbecker, Stefan Schütz

Forest Zoology and Forest Conservation, Goettingen, Lower Saxony, Germany

Introduction: The fungivorous insect *Cis boleti* (Coleoptera: Ciidae) belongs to a group of insects which colonize bracket fungi (Basidiomycetes: Polyporaceae) growing on tree trunks and wood logs. *C. boleti* is a host-specific species, selectively colonizing fruiting bodies of the genus *Trametes* generally known as important wood-rotting fungi. Fungal host volatiles were proposed to play an important role in its host finding.

Method: The electroantennographic responses of *C. boleti* antenna to *Trametes gibbosa* fruiting body volatiles and standard compounds (which are present in the fruiting body volatiles) were recorded by using gas chromatography-mass spectrometry, with parallel electroantennographic detection (GC-MS/EAD). In addition, the perception of *C. boleti* antenna to the standard compounds was carried out by electroantennography (EAG).

Results: *C. boleti* antenna responded consistently to 1-octen-3-ol, a major compound of *T. gibbosa* fruiting body volatiles. The GC-MS/EAD and EAG to pure standard compounds demonstrated that *C. boleti* antenna was additionally elicited by other host-fungal volatiles in different intensity.

Conclusion: Our discovery is the first evidence that 1-octen-3-ol is an important cue in fungal host finding of ciid beetles.

POSTER PRESENTATION

Males inhibit female remating using substances from accessory gland in the seed bug *Togo hemipterus* (Heteroptera: Lygaeidae)

Chihiro Himuro, Kenji Fujisaki

Kyoto University, Kyoto, Japan

Introduction: Females of many insect species mate repeatedly throughout their life. However, multiple mating by females increases both the risk and intensity of sperm competition for males. Thus males adopt various strategies to reduce the risk of sperm competition from future males. In Heteropteran species, many studies have reported that males guard females after ejaculation to reduce the risk of sperm competition. The seed bug *Togo hemipterus* males do not guard females. On the other hand, females show long refractory period. We hypothesized that *T. hemipterus* males inhibit female remating using some kind of seminal fluid, as in the case of *Drosophila melanogaster*.

Methods: Firstly, to examine the relationship between the mating duration and the refractory period, we adjusted mating duration artificially and examined the refractory period. Secondly, we injected each of three kinds of extracts from accessory gland (A and B) or seminal vesicle to virgin females. Then, we examined the effect of those solutions on the duration from the injection to the mating in females.

Results: There was a significantly positive relationship between the mating duration and the refractory period. The duration from injection to mating in females was significantly longer in females which was injected the solution from accessory gland B than in females which was injected the solution from seminal vesicle, accessory gland A and control (only saline).

Conclusions: We showed that *T. hemipterus* males inhibit female remating using substances from accessory gland B, and the seminal fluid has dose-dependent inhibition effect. This is the first report showing that substances from male reproductive tract reduce female mating receptivity in Heteropteran species.

POSTER PRESENTATION

Ecology of the Salticid spider *Afraflacilla epiblimoides*; Implications for conservation of central European low-land forests

Vladimír Hula, Martin Jarab

Agronomical Faculty of Mendel university of Agriculture and, Brno, Czech Republic

Introduction: Salticid spider *Afraflacilla epiblimoides* is one from endangered species of spiders in the Czech Republic. Only one male was recorded at 2001 and population was found in Lednice Castle Park in 2006. This species strictly inhabits old oak (*Qurcus robur*) trees with population of basically Pannonian ant *Liometopum microcephalum*.

Methods: So far we know only the distribution across Europe, furthermore it was known that this species mimics *Liometopum* ants and that it prefers old oak trees. We studied the species' life history, phenology, prey, protection strategy again ants, spider species composition and preferences for particular trees (by ordination analyses).

Results: It was theorised that the spiders prey on *Liometopum* ants. However, we found, that the spider must protect itself against the ants and that it has special strategies against the aggressive ant species. As a prey *A. epiblimoides* uses everything that they can to overpower the ants. The species prefers mainly solitary trees about 100 cm in diameter, with insulated bark, inhabited by rich population of *Liometopum* ants. For survival of the spider it is necessary to conserve all alive oak trees in Lednice Castle Park. However, as all trees are old and the majority of them are, in reality, dead, there are no available younger trees for the future. In the area there is a lack of trees in age category about 70 years.

Conclusions: Management of protected areas must help by making new possible habitats in surrounding forests, where there exist some threes of a suitable age. This study was supported by the project VaV-MZP-CR-SP/2D4/59/07.

POSTER PRESENTATION

The effect of thiopentone sodium on the development rate of *Chrysomya megacephala* (Diptera: Calliphoridae) and its importance for the post-mortem interval estimate in Brazil

Dora Amparo Estrada[1], Patricia Jacqueline Thyssen[2], Aricio Xavier Linhares[1]

[1]Department of Parasitology, Institute of Biology, State University of Campinas, Campinas/SP, Brazil, [2]Department of Parasitology, Institute of Biosciences, UNESP, Botucatu/SP, Brazil

Introduction: Recent research has demonstrated that the presence of drugs in decomposing tissues may affect the insect development rate when they using such tissues as food, thus potentially altering estimates of the post-mortem interval (PMI). The thiopentone sodium is a short-acting barbiturate and is most commonly used in the induction phase of general anesthesia in veterinary medicine. In this study, we investigated the effect of the thiopentone sodium on the development rate of *Chrysomya megacephala* (Diptera: Calliphoridae) immatures.

Methods: Groups of larvae were placed in artificial diet containing thiopentone sodium in 3 different concentrations: 0.5 x LD (lethal dose), 1 x LD and 2 x LD. The control group was reared on the diet without any drug. Weights were recorded for groups of 10 larvae at 12 h intervals up to the end of the larval stage.

Results: There was a significant effect of the drug concentration on larval development as measured by weight ($F = 1154.20$; $p < 0.0001$). Immatures from the 2 x LD and 1 x LD groups died in the third instar (96 h). The survivorship rates up to the pupae stage were 70.7% and 34% at control and 0.5 x LD groups, respectively.

Conclusion: Studies done with different drugs in several species of Calliphoridae suggest that larval development respond differently to the presence of each drug. These results evidenced that the effects of thiopentone sodium on maggots development may lead to errors in estimating the PMI, especially when is necessary to use entomological means.

POSTER PRESENTATION

Atlas of the burnets of the Iberian Peninsula (Lepidoptera: Zygaenidae)

José Martin, Juan M. Jambrina, M. Pilar Gurrea

Universidad Autónoma de Madrid, Madrid, Spain

Introduction: Here is presented the atlas of burnets in the Iberian Peninsula based on the10 x 10 km UTM grid. This atlas consists of 22 maps with all 22 *Zygaena* species present in the Iberian Peninsula. One of these species, *Zygaena ignifera*, is endemic, while all the others can be found in other regions of Europe.

Material and Methods: The atlas has been built up from a database specifically created to this end. The database consists of almost 4000 records from two main sources of information, the MNCN (Museo Nacional de Ciencias Naturales de Madrid) collection and the references in SHILAP Revta lepid. The MNCN which collection has 3969 iberian specimens of *Zygaena*, is the most important zoological and entomological museum of Spain and one of the most in Europe. Both of these sources contribute with about 3200 records. In addition to this, other periodical journals and books related to Lepidoptera in the Iberian Peninsula have been checked as well.

Results: The results show that all the Iberian species except *Z. ignifera* live en the Pyrenees. There are 2 groups rather differenced attending to their geographic distribution. On one side we have a group of 9 species that have a very restricted distribution, taking up just a few number of 10 x 10 km squares, 4 of these species are completely included in the Pyrenees. The rest of them have a wider distribution, they also live in the Pyrenees but also in other regions of the Iberian Peninsula.

POSTER PRESENTATION

Artificial Neural Network in forensic entomology: Contribution to PMI estimates

Lucila Maria L Carvalho[1], Fernando J von Zuben[2], Aricio Xavier Linhares[3], Cláudio J von Zuben[1]

[1]Departamento de Zoologia, UNESP, Rio Claro/SP, Brazil, [2]Faculdade de Engenharia Elétrica, laboratório de Bioinformática e Computação Bioinspirada, State University of Campinas, Campinas/SP, Brazil, [3]Departamento de Parasitologia, State University of Campinas, Campinas/SP, Brazil

Introduction: In forensic entomology the knowledge of fly life cycle and environmental conditions taken on the death scene is crucial. With the new perspectives of FE in Brazil a computer-based database is important to get quick results during an investigation. In order to attend this necessity a computational program was developed using artificial neural networks (ANN). The key element of this paradigm is the novel structure of the information processing system, composed of a large number of highly interconnected processing elements working together to solve specific problems. ANNs learn by example and training and is configured for a specific application, such as pattern recognition or data classification, through a learning process.

Methods: Dynamic phenomena such as weight of insect, developmental time, threshold and temperature (environmental and controlled) were used to elaborate the model. After data simulation, they were divided in groups of training, validation and tests. The Matlab program was used to train the different situations.

Results: The relation among the studied factors showed non-linear associations between the independent variable (input pattern) and dependent variable (output pattern). A non linear performance of input/output was determined with available data on insects. The model using ANN is recommended when time of larval development is required, whereas a table is indicated to determine the pupation time,

Conclusions: ANN is an alternative methodology to estimate the PMI once neural networks, with their ability to derive meaning from complicated or imprecise data, can be used to extract patterns and detect trends that are too complex to be noticed by either humans or other computer techniques.

POSTER PRESENTATION

Geographical variation in the susceptibility of the African cotton bollworm to a baculovirus

Michelle Grant, Gustav Bouwer

University of the Witwatersrand, Johannesburg, South Africa

Introduction: The susceptibility of *Helicoverpa armigera* (Hübner) (Lepidoptera: Noctuidae) populations of varying geographical origin in South Africa to a baculovirus, *Helicoverpa armigera* single nucleopolyhedrovirus (*Hear*SNPV), was examined.

Methods: Field-collected *H. armigera* populations from Brits and Groblersdal were compared to a laboratory reared population (ARC). The volumes imbibed by the larvae from each *H. armigera* population was determined by fluorescent spectrophotometry. The droplet feeding assay was used to determine a lethal dose range and the survival time for each *H. armigera* population in order to compare their susceptibility to *Hear*SNPV.

Results: The fluorescent spectrophotometry showed that there was no significant difference in the volume imbibed by larvae from the different populations. Bioassays showed that in comparison to the ARC population, the Brits and Groblersdal populations were 1.9 and 1.3 times respectively, more susceptible to *Hear*SNPV. At the calculated population-specific LD_{90} values, the median survival time (ST_{50}) of each population was compared. On the basis of the ST_{50} values, the Brits and Groblersdal populations were 0.74 and 0.81 times as susceptible to *Hear*SNPV as the ARC population.

Conclusion: These findings have significant implications for the future use of baculoviruses as biopesticides, because a dose that is adequate to control *H. armigera* populations in one geographical area may not be adequate in another area. It also implies that lethal dose studies using a *H. armigera* population from one geographical area are not comparable to studies done using populations from another geographical area.

POSTER PRESENTATION

Phylogeny, historical biogeography, and evolution of parasitic myrmecophily in the Glaucopsyche-section (Lepidoptera: Lycaenidae)

Pavel Pech[1], Zdenek Fric[1], Jan Zrzavy[2]

[1]Institute of Entomology, BC CAS, Ceske Budejovice, Czech Republic, [2]Faculty of Sciences, University of South Bohemia, Ceske Budejovice, Czech Republic

Introduction: The vast majority of lycaenid butterflies exhibits some kind of relationship with ants. The obligate parasitic blues of *Phengaris* Doherty, 1891 belong to the most intensively studied butterflies in Eurasia. Although several studies concerning their phylogeny, population biology, and evolution have been published recently, a more complete phylogenetic study including a wider taxon sampling of putatively related taxa has not yet been done. At present, we can reliably reconstruct ecology of the *Phengaris* ancestor; however, more comprehensive analyses are required to reconstruct evolutionary processes that have constrained deeper origins of the obligate parasitism.

Methods: We used morphological and molecular data for 77 analysed taxa. We used the maximum parsimony program NONA (Goloboff, 1999), with bootstrap and Bremer values. Historical biogeographical analyses were computed for combined all-species trees using the dispersal-vicariance analysis (DIVA).

Results: The combined morphological-molecular analysis showed that *Glaucopsyche*-section was monophyletic, with the exception of *Lachides*. Within the *Glaucopsyche*-section, several clades could be recognised, with the basalmost *Iolana-Turanana* group (including *Iolana*, *Turanana*, *Otnjukovia*, *Micropsyche*), followed by *Palaeophilotes* and two major clades, namely, “Glaucopsychiti” (= *Phengaris* s.lat., *Glaucopsyche*, *Praephilotes*, *Philotiella*, *Shijimiaeoides*, and *Caerulea*) and “Scolitantiditi” (= *Sinia*, *Scolitantides*, *Philotes*, *Euphilotes*, *Pseudophilotes*). Several genera seemed to be nonmonophyletic: they included *Glaucopsyche* (paraphyletic in respect of *Shijimiaeoides* and *Caerulea*), *Sinia* (polyphyletic), and *Turanana* (paraphyletic in respect of *Micropsyche*). Obligate myrmecophily developed in the common ancestor of *Phengaris*. The origin was also connected with change of host plant family and the origin was situated in Manjuria.

POSTER PRESENTATION

The effect of alpha-cypermethrin on the cyclic gas exchange of bumblebee *Bombus terrestris* L. foragers

Reet Karise, Marika Mänd, Anne Luik

Estonian University of Life Sciences, Institute of Agricultural and Environmental Sciences, Tartu, Estonia

Introduction: Minor effects of pesticides may remain unnoticeable in adult bees because of no visible changes in their behaviour throughout several days after coming into contact with pesticides. The hypothesis of this work is that changes which are not observable through the behaviour of the bee can be seen through physiological patterns. The aim of the present research was to study the effect of a low concentration of alpha-cypermethrin on discontinuous gas exchange cycles of bumblebee *Bombus terrestris* foragers.

Methods: Using a system of flow-through CO_2 respirometry, the effect of low concentration of alpha-cypermethrin on bumblebee *Bombus terrestris* foragers was studied.

Results: We found an increase in CO_2 emission rate at high relative humidity (RH = 95%) (0.130 ± 0.01 ml h^{-1}), compared to low relative humidity (RH = 2%) (0.074 ± 0.01 ml h^{-1}). Treatment with alpha-cypermethrin decreased significantly the frequency of bursts of CO_2 release during discontinuous gas exchange (DGC) in dry conditions. In humid conditions no significant differences were found.

Conclusions: Alpha-cypermethrin caused changes in the respiration patterns of *B. terrestris* foragers although not seen through the behaviour. These changes could potentially lead to the decreasing individual and colony survival.

POSTER PRESENTATION

Susceptibility of some varieties and breeding lines of tomato to *Liriomyza* spp. infestation in Central Sudan

Faiza Salah[1], Elamin Elamin[2], Elameen Eltoum[1] , Dominique Bordat[3]

[1]Dept. Crop Protection, Faculty of Agriculture, Gezira University, Medani, Sudan; Agricultural [2]Research, Medani, Sudan; [3] CIRAD, Montpellier, France.

Tomato crop in the central Sudan is liable to heavy infestation by the leaf miners (LM). Field experiments indicated significant differences between susceptibilities of varieties and breeding lines of tomato to the damage in terms of infestation percentages caused by Liriomyza spp. The variety Flora Dade and the breeding lines Omdurman, UG Fireset A3 36L and UG Fireset A6 30R were the most infested (susceptible). The breeding line Trop G 9–18 and the varieties, Alfa, Peto 86 and Strain B were the least infested (resistant). Moderate susceptibility was exhibited by the breeding lines, Hillo, UG 46 and UG Fireset A4 20R and the variety Red Star.

The laboratory tests revealed that Flora dade was more susceptible to sativae than Trop-G, whereas the latter was absolutely resistant to trifolii. The mean number of larvae/leaf and the larval period were tahen as parameters to evaluate the susceptibilities of two breeding lines and two varieties. Omdurman harbored the highest number and Trop-G was not attacked. The two varieties showed moderate resistance. No differences were found in larval duration of the varieties and Omdurman breeding line. Resistance is attributed to antiffedents and associated with the glandular trichomes on the leaves.

POSTER PRESENTATION

Dispersal abilities in marsh fritillary, *Euphydryas aurinia* (Lepidoptera: Nymphalidae): A large scale study

Kamil Zimmermann[2], Martin Konvicka[1], Vladimir Hula[3], Petr Jiskra[4], Michala Kopeckova[5], David Novotny[1], Petr Vlasanek[1], Michal Zapletal[1], Zdenek Fric[2]

[1]University of South Bohemia, Ceske Budejovice, Czech Republic, [2]Institute of Entomology, Czech Academy of Sciences, Ceske Budejovice, Czech Republic, [3]Mendel Agricultural University, Brno, Czech Republic, [4]Czech Conservation Authority, Karlovy Vary, Czech Republic, [5]Ametyst o.s., Plzen, Czech Republic

Introduction: *Euphydryas aurinia* is a continentally endangered butterfly, depending on nutrient-poor seminatural meadows in Central Europe. While it has been subject to intensive research in many countries, there was a spectacular lack of large-scale mark-recapture projects that would assess status of populations on large scale.

Methods: We carried out mark-recapture study of all known colonies in W Bohemia, Czech Republic. It encompassed 100 local colonies in seven regional clusters, studied by 24 persons for entire 2007 flight period. In total, we marked 9,466 individuals and recaptured 5,212 individuals in 14,678 capture events.

Results: We found a high degree of interconnection among seemingly isolated local populations. Out of the 5,212 individuals recaptured at least once, 69 (56 males, 13 females) moved over 5 km, and 20 (18 males, 2 females) moved over 10 km, the longest flights being 23.1 km (a male) and 15.2 km (female). The populations thus form a superpopulation distributed across over 1000 km^2 of land area – however, the actual summed area of occupation is just 300 hectares. The total population size in the Czech Republic, estimated using constrained linear models, approaches 30,000 adults, and various estimation methods converged at this number.

POSTER PRESENTATION

Investigation of *Myzus persicae* salivary proteome and potential role in plant defence mechanisms following aphid infestation

Nicolas Harmel[1], Frederic Francis[1], Edwin De Pauw[2], Eric Haubruge[1]

[1]Gembloux Agricultural University, Functional and Evolutionary Entomology, Gembloux, Belgium, [2]University of Liege, Mass Spectrometry Laboratory, Liege, Belgium

Introduction: Salivary secretions are a key component in plant-aphid interactions and constitute the first contact between insect and plant. Proteic and non-proteic elicitors have been discovered in saliva of some chewing insects but no aphid elicitor is known to date although some enzymatic activities have been detected. Moreover aphid induces plant volatiles emission and plant phloem proteins modification.

Method: We investigate salivary proteome of the green peach aphid, *Myzus persicae*, in search of an elicitor. Proteins were isolated from artificial diets and salivary glands. Proteins were either directly in-solution digested or separated by 2D SDS-PAGE before being digested. Resulting peptides were then identified by mass spectrometry coupled with data bank investigations constituted with ESTs from the pea aphid *Acyrtosiphon pisum* and *M. persicae*. These specific databases were used to identify proteins related to this organism with non-sequenced genome.

Results: This procedure allowed us to discover glucose oxidase, glucose dehydrogenase, NADH dehydrogenase, α-glucosidase and α-amylase in *M. persicae* saliva. Implication of these enzymes was discussed in term of plant-aphid interactions.

POSTER PRESENTATION

A fluorescent sperm-specific marker for the medfly, *Ceratitis capitata*

Francesca Scolari[1], Marc Schetelig[2], Sabrina Bertin[1], Anna Malacrida[1], Giuliano Gasperi[1], Ernst Wimmer[2]

[1]University of Pavia, Pavia, Italy, [2]Georg-August-University Göttingen,, Göttingen, Germany

The medfly, *Ceratitis capitata* (Diptera: Tephritidae) is an invasive pest species of agricultural importance. Its polyphagous behavior and its high reproductive capacity are responsible for the spread of this species in the last two centuries from sub-Saharan Africa to several tropical and sub-tropical regions worldwide.

The environmental-friendly Sterile Insect Technique (SIT) has been effectively applied as a component of area-wide integrated pest management (AW-IPM) for *C. capitata* since the 1970s. Effective monitoring to assess the number and mating success of the released medflies is essential.

Using a transgenic approach we developed a direct sperm visualization system which makes it possible to follow the fate of sperm from different males in the female reproductive tract of the medfly.

For this purpose, we generated a sperm-specific marking system based on the spermatogenesis-specific *C. capitata beta2-tubulin* (*Ccbeta2t)* promoter driving the expression of the reporter genes GFP or DsRed.

Monitoring of the mating success of sterile released males by trapping females and examining their spermathecae is possible with these strains.

Moreover, the availability of differently sperm-marked lines will help us to understand the relationship between sperm allocation, remating frequency and sperm displacement in the medfly, given that in wild populations females can remate with a strong paternity skew.

In preliminary laboratory competitiveness assays we determined that the marker does not cause general fitness disadvantages. Therefore, such harmless transgenic markers represent an ideal springboard to transfer insect transgenesis technology from the laboratory to field applications.

POSTER PRESENTATION

Surveys of Chilean indigenous entomopathogenic fungi and nematodes and studies on their pathogenicity against pests of economic importance

Loreto Merino, Steve Edgington, Dave Moore, Marcos Gerding, Andrés France

INIA Quilamapu, Chillan Bio bio zone, Chile

The Insect Pathology Program of the Institute of Agricultural Research (INIA) Quilamapu, Chile, is working in collaboration with CABI (Commonwealth Agricultural Bureaux International, UK) on a Darwin Initiative (DEFRA, UK) to conserve and use Chilean entomopathogenic microorganisms. The aim was to collect entomopathogenic fungi and nematodes from some of the major ecological habitats in Chile. Six survey transects were chosen: 1) Latitude 20^{o}, with sections of Altiplano and on the periphery of the Atacama Desert; 2) Latitude 30^{o}, desert with remnants of ancient tropical forests; 3) Latitude 33^{o}, an area of Mediterranean vegetation; 4) Latitude 37^{o}, a transitional zone from dryland to wetland; 5) Latitude 46^{o}, heavy rainfall, relatively cold, with humid forests and areas of pampas, 6) Latitude 52^{o}, Tierra del Fuego, with almost Antarctic conditions and flora and fauna adapted to low temperatures. The first two transects have been surveyed, revealing 157 isolates of entomopathogenic fungi, predominately *Metarhizium* and *Beauveria* spp. and 14 isolates of nematodes *Heterorhabditis* and *Steinernema* spp. The isolates will be maintained in the Genetic Resource Collection of INIA, significantly enhancing the bank of indigenous germplasm already present. It is likely that indigenous isolates will show stronger adaptations to Chilean conditions compared to exotic isolates and could be important pest control alternatives

POSTER PRESENTATION

Sublethal effects of entomopathogenous fungus B*eauveria bassiana* (Bals.) Vuill. on European paper wasp *Polistes dominulus* (Hymenoptera: Vespidae)

Merino Loreto, Gerding Marcos, France Andres

Inia Quilamapu, Chillan, Bio Bio zone, Chile

The sublethal effects of an infection is an aspect of entomopathogenic fungi efficacy that not include insect mortality but affect or decrease various aspects of its biology. The objective of this research was evaluating sublethal effect of Qu-B933 isolates of *Beauveria bassiana* over *Polistes dominulus* wasps. A matrix was build to establish activities and distribution of time on healthy wasp colonies, comparing with wasps belonging to colonies receiving a liquid bait with a dose of 10^8 espores mL^{-1} using The Observer™ software and grouping activities in active and inactive times.

The test results showed significant decreases ($P<0,05$) in total active time of inoculated wasps, reaching 79.89% decrease at day 11 of test, isolate application caused a progressive reduction in activities as drinking, washing, nest expansion, larva feeding, flying, walking, and interaction with other individuals, also increasing inactive time in inoculated wasps, finally causing insect death since 10^{th} day and collapse of inoculated colonies due to a lack of defense work, cleaning and nest maintenance.

POSTER PRESENTATION

The isoprenoid pathway in aphids: Focus on geranyl/farnesyl diphosphate synthase

Sophie Vandermoten[1], Stephanie Sen[2], Frederic Francis[1], Michel Cusson[3], Eric Haubruge[1]

[1]Gembloux Agricultural University, Functional and Evolutionary Entomology, Gembloux, Belgium, [2]Indiana University-Purdue University at Indianapolis, Department of Chemistry, Indianapolis, United States, [3]Natural Resources Canada, Laurentian Forestry Centre, Quebec, Canada

Introduction: Short-chain isoprenyl diphosphate synthases (scIPPSs) catalyse condensation of an allylic diphosphate substrate with isopentenyl diphosphate to generate C10, C15 or C20 products.

Methods: We report on the cloning of two scIPPS cDNA isoforms from the aphid *Myzus persicae* (MpIPPS-S and MpIPPS-L), including one with an N-terminal extension containing a putative mitochondrial targeting peptide. Expression in *Escherichia coli* of each *M. persicae* cDNA were performed

Results: Active prenyltransferase activities were obtained from both *M. persicae* cDNA.. However, although the cloned *M. persicae* enzymes were predicted to be farnesyl diphosphate synthases by BLASTP analysis, the rMpIPPS-S, when supplied isopentenyl diphosphate and dimethylallyl diphosphate as substrates, typically generated geranyl diphosphate (C10) as its main product, along with significant quantities of farnesyl diphosphate (C15), suggesting that it is a bifunctional enzyme. Analysis of an MpIPPS-S homology model pointed to some aphid-specific substitutions that could confer bifunctionality to the *M. persicae* enzyme.

POSTER PRESENTATION

Development of a biopesticide from proteic waste issued from pea processing

Gaetan Cuartero Diaz, Frederic Francis, Eric Haubruge

Gembloux Agricultural University, Functional and Evolutionary Entomology, Gembloux, Belgium

Introduction: Some components of the pea seed are known as antinutritional factors. During the industrial process aiming to valorize proteic isolate from pea, some of those factors are removed by clarification. Among them are the proteins from the albumin class. Very often those antinutritional factors can act also against insect.

Methods: To evaluate the potential for the crop protection of the waste issued from the clarification, active components have been detected through their enzymatic activity. Then the proteins present in this sample have been separated by gel filtration with a Sephadex® G-75 media. Lectins are collected with an affinity chromatography with the same media. Each fraction issued from the chromatography has been identified by MSMS. Toxical assays have been performed on the aphid *Myzus persicae*.

Results: Several toxic components have been highlighted and caracterized in these waste. Among them: the pea lectin, trypsin inhibtors and the pea albumin 1b (PA1b). Those substances showed toxicity activity against *Myzus persicae* feeded with an artifical diet.

Conclusion: The waste issued from clarification contains insecticidal components. The challenge now is to valorize such substances in the crop protection. It would allow in the same time to increase the yield of pea's industry by reducing the wastes and to reduce pressure on environment by the use of a natural product in crop protection.

POSTER PRESENTATION

Control of *Dysaphis plantaginea* in IPM orchards: Effect of cultivar and predatory arthropods

Sylvaine Simon, Emilie Durand, Karine Morel, Hubert Defrance, Benoit Sauphanor

[1]INRA, St Marcel les Valence, France, [2]INRA, Avignon, France

Introduction: The rosy apple aphid *Dysaphis plantaginea* is a major pest in European apple orchards. Its treatment threshold is very low, due to the detrimental effect of spring infestation on trees and fruits. The development of sustainable and relevant new strategies for aphid control is thus a challenge in IPM orchards.

Results: We investigated the effect of cultivar and predatory arthropods within the apple tree-rosy aphid-natural enemies system in three organic apple orchards. Shoot growth was reduced during aphid infestation, but more leaves were emitted after the migration of the aphid towards its secondary host in late spring, compared to uninfested shoots. The Golden and Ariane cultivars were always affected whereas the Melrose cultivar was not affected for low levels of infestation. For all cultivars, fruit growth and nitrogen leaf content were not significantly different within low-infested trees compared with uninfested ones. Beneficial arthropods that were assessed within infested shoots mainly comprised Syrphidae, Cecidomyiidae and Coccinellidae, but the predator/prey ratio remained the same along the period of infestation and only increased when the migration of *D. plantaginea* occurred.

Conclusion: A moderate infestation in orchards can be tolerated by some cultivars such as Melrose, without effect on yield, calibre or shoot growth. A higher treatment threshold can be recommended for these cultivars, which should contribute to more sustainable control strategies. From this study, it seems that the plant tolerance to infestation rather than the control by natural enemies may contribute to the management of the apple rosy aphid in orchards.

POSTER PRESENTATION

Bringing biological control to the heartland: A South Dakota PPQ 526 story

Kelley Tilmon

South Dakota State University, Brookings, SD, United States

There are many obstacles to overcome when instituting a classical biological control program for the management of a given pest. Apart from the logistic, scientific, and regulatory aspects of the process, there are also frequently social and political forces involved. This poster details the unusual political circumstances surrounding the issuance of a regulatory permit to ship and release the soybean aphid parasitoid *Binodoxys communis* in South Dakota, USA.

POSTER PRESENTATION

IMGD: An integrated platform for dissecting insect mitochondrial gene sequences

Wonhoon Lee[1], Jongsun Park[1], Jaeyoung Choi[1], Bongsoo Park[2], Kyongyong Jung[1], Seogchan Kang[2], Yong-Hwan Lee[1], Seung-Hwan Lee[1]

[1]Seoul National University, Seoul, Korea, Republic of, [2]Penn State University, University Park, United States

Introduction: Two databases, AMIGA and MITOME, provide web-based useful tools for analyzing mitochondrial genome sequences used for phlylogenetic studies. Because two databases archived only completely sequenced mitochondrial genomes, comparative analyses across broad ranges of insect species in these databases are limitated. In addition, they do not support comprehensive phylogenetic tools on the web, so that phylogenetic analyses of mitochondrial genes are not conducted efficiently in one place.

Methods: For collecting both completely and partially sequenced mitochondrial genomes, standardized genome database structure implemented in Comparative Fungal Genomeics Platform (CFGP; http://cfgp.snu.ac.kr/) were used in IMGD. Components of Phyloviewer (http://www.phyloviewer.org/) support three different methods, such as neighbor-joining, maximum parsimony, and maximum likelihood for drawing phylogenetic trees via user-friendly interface of the web.

Results: IMGD archives fully sequenced mitochondrial genomes of 113 species and 86,214 genes in partially sequenced mitochondrial genomes covering 17,839 insect species. For manipulating large species, Species-driven User Interface (SUI) was developed in IMGD, providing an interface similar to on-line shopping site. In SUI, eight analysis functions were supported including downloading sequences with various options, drawing phylogenetic tress with three methods, and BLAST search.

Conclusions: The IMGD will serve as a versatile informatics platform not only for archiving rapidly increasing insect mitochondrial genes but also for conducting efficient phylogenetic and comparative analyses.

POSTER PRESENTATION

Molecular analysis of trophic links within an autumn- and winter-active invertebrate community

Bernhard Eitzinger, Michael Traugott

University of Innsbruck, Innsbruck, Austria

Many arthropods, such as linyphiid spiders and beetle larvae, are active during the cold months of the year; some of them are important natural enemies of pests during summer. A better understanding of the feeding ecology of these autumn- and winter-active predators is essential to promote these species in agroecosystems and maximize natural pest control.

Within this project we address two main objectives: (1) recording species spectrum, activity-densities and abundance of winter-active epigeic invertebrates in an organically cultivated spelt field and a bordering meadow near Innsbruck, Austria, and (2) assessing trophic links within this invertebrate community.

Throughout the winter catches were dominated by larval *Cantharis* and carabid beetles as well as linyphiid spiders. Collembolans and earthworms were also abundant, possibly representing important food sources. As the predators are fluid feeders, a PCR-based approach was used to screen the predators' guts for DNA of specific prey taxa. Using group-specific markers, the importance of collembolan and earthworm prey will be assessed for the different predator groups. First results indicate that cantharid- and carabid beetle larvae regularly feed on collembolans and earthworms. Newly designed markers - targeting cantharids, carabids and linyphiid spiders - will be used to determine the levels of intraguild predation.

POSTER PRESENTATION

Dispersal abilities of adult click beetles in arable land revealed by analysis of carbon stable isotopes

Nikolaus Schallhart, Corinna Wallinger, Anita Juen, Michael Traugott

University of Innsbruck, Innsbruck, Austria

Larvae of the genus *Agriotes* feed on roots and tubers of plants and are serious pests on a variety of crops. Albeit highly relevant for the control of agrioted beetles, their dispersal abilities are poorly known, as it is difficult to track the movements of the beetles in the field. Here we used, for the first time, a stable isotope approach to assess the dispersal abilities of these insects in arable land.

Pheromone traps, lured for *Agriotes* sp., were installed at two study sites in Western Austria, each comprising a maize field and adjacent grassland. Traps were installed in the centre of each maize field and along transects into the grassland.

The different $\delta^{13}C$ signatures of grassland and maize habitats are reflected in the herbivorous larvae. During metamorphosis, the $\delta^{13}C$ signature of the larval diet is translocated to the adult beetle, allowing the identification of the beetles' larval habitat (maize or grassland). By measuring the $\delta^{13}C$ signatures of wing covers from adults, we were able to estimate the dispersal by *Agriotes* beetles developing in maize fields into the adjacent grasslands.

Beetles covered distances of at least 80 m beeline and up to 13 % of individuals caught in traps at 80 m distance from the maize field emigrated from the maize habitat. These findings show that *Agriotes* beetles are capable to migrate over larger distances than previously assumed. Moreover, the stable isotope approach has been proven to be a useful tool to assess migration in arthropods.

POSTER PRESENTATION

Impact of wildflower strips and companion plants on pest control in organic cabbage crops

Johannes Schied[1], Andrea Leimgruber[3], Martin Willareth[3], Peter Nagl[3], Lukas Pfiffner[2], Henryk Luka[2], Eric Wyss[2], Christian Schlatter[2], Michael Traugott[1]

[1]University of Innsbruck, Innsbruck, Austria, [2]Research Institute of Organic Agriculture, Frick, Switzerland, [3]University of Basel, Basel, Switzerland

The promotion of natural antagonists is an important strategy of pest management in organic agriculture. In organic cabbage cultures the lepidopterans *Plutella xylostella, Mamestra brassicae* and *Pieris rapae* are the main pests, under attack by a guild of insect natural enemies, including parasitoids and generalist predators.

Within this project we assess whether wildflower strips and companion plants increase the level of pest control exerted by (i) natural enemies and (ii) mass-released *Trichogramma* egg parasitoids.

At Alten (Switzerland), two organic cabbage fields were used for this project: adjacent to each field a wildflower strip was sown and cornflowers (*Centaurea cyanus*) used as companion plants, sown intermixed within the crop. Within each field ~15,000 *M. brassicae* eggs were placed out to determine the parasitism rates by mass-released *Trichogramma brassicae* and assess the levels of egg predation. Over 1,000 lepidopteran larvae were collected and screened for hymenopteran and tachinid parasitoid DNA using am multiplex PCR assay. Invertebrate generalist predators (n=1,063) were collected for DNA-based gut content analysis to assess predation on healthy and parasitized lepidopteran pests. The epigaeic and plant dwelling invertebrate community was recorded by the use of pitfall traps, yellow bowls and sweep nets.

Currently the extensive sample set is being analysed: first results indicate that the wildflower strips increase egg parasitism rates and that companion plants enhance invertebrate predation on *M. brassicae* eggs suggesting that both wildflower strips and companion plants provide a effective measure to enhance pest control.

POSTER PRESENTATION

DNA-based identification of *Agriotes* wireworms

Karin Staudacher[1], Lorenzo Furlan[2], Michael Traugott[1]

[1]University of Innsbruck, Innsbruck, Austria, [2]University of Padova, Padova, Italy

This study focuses on larvae of European *Agriotes* species (Coleoptera: Elateridae), which are abundant below-ground living herbivores and cause considerable damage to field crops. There are up to 20 species occurring in arable land, which differ in regard to ecology, abundance and pest status. The basis of any wireworm risk assessment is the correct identification of the larvae; however, this is considerably hampered when morphological features are being used: current identification keys do allow identifying just eight of the 20 species in larval stage. Moreover, some morphological characters used for identification look very similar among some of the described species and their intraspecific variability has yet not been assessed.

Here we used a DNA-based approach to identify the different Agriotes species in larval stage. Within each species adult beetles, which are readily identifiable, were collected from different locations all over Europe. From these beetles, part of the mitochondrial cytochrome oxidase subunit I gene was sequenced to estimate the genetic variation within and between species. A non-destructive DNA-extraction method was used to gain DNA of rare specimens from insect collections. Species-specific markers were designed and applied in a multiplex-PCR approach, allowing to discriminate between the different *Agriotes* species within a single-step reaction.

Once the feasibility of this molecular identification system has been evaluated, it can easily be used by other researchers to routinely and securely differentiate between *Agriotes* wireworms, which will improve our ability to determine subtle differences in their specific ecology.

POSTER PRESENTATION

Detecting prey-DNA in invertebrate predators: The influence of predator taxon and storage method

Thomas Waldner, Michael Traugott

University of Innsbruck, Innsbruck, Austria

Molecular gut content allows studying the trophic connections of predatory invertebrates under natural conditions, often not accessible by conventional approaches. However, our knowledge on predator-specific prey DNA digestions rates, important to correctly interpret field data, still is scarce. Moreover, the influence of different storage methods on the quality of prey DNA within invertebrate predators has not been evaluated yet.

Were we compare DNA digestion rates between several ground-living predator groups including adult carabid and histerid beetles, cantharid and elaterid beetle larvae, and centipedes (Geophilidae and Lithobiidae). Predators were fed with larvae of the summer chafer, *Amphimallon solstitiale*, and frozen after several time points (0 - 60 h) post feeding. Using summer chafer-specific markers and diagnostic PCR, prey DNA detection rates for three differently sized mitochondrial DNA fragments (127 bp, 463 bp and 856 bp) are being compared among the different predator groups.

Within another experiment we assess how different storage conditions – freezing at -28°C or -80°C, storage in 80% ethanol - affect prey DNA detection success in carabid beetles fed with *A. solstitiale*.

The outcomes of these experiments will provide new insights into prey DNA digestion rates across a wide range of soil-dwelling invertebrate predators and guide us on how to store field-collected predators to preserve high-quality prey DNA.

POSTER PRESENTATION

Exploitation of plant biodiversity by below-ground herbivores: Tracking dietary choice in elaterid larvae using a molecular approach

Corinna Wallinger, Nikolaus Schallhart, Karin Staudacher, Michael Traugott

University of Innsbruck, Innsbruck, Austria

In the last decades the importance of biodiversity in ecosystem functioning has been increasingly acknowledged. To understand the structure of floral and faunal communities and the interactions within them, the investigation of trophic relationships is crucial. Upon now, research on trophic interactions in natural and agricultural ecosystems focussed mainly on above-ground relationships, whereas our knowledge on below-ground trophic interactions is limited.

This project, started in spring 2008, focuses on the trophic links within a plant-soil insect system. As soil-insects wireworms, the larvae of click-beetles (Coleoptera: Elateridae), have been selected. They are highly abundant herbivores in grassland and arable land and can cause considerable damage to crops. Additionally, weeds are known to be regularly fed on by wireworms. We will use stable isotope and molecular gut content analysis combined with an analysis of plant assemblage structure to assess the wireworms' feeding preferences under field conditions. Moreover, the affects of plant diversity on the insects' dietary choices will investigated experimentally. Besides addressing functional biodiversity in a below-ground food web, our research aims at providing a better understanding of plant biodiversity–wireworm trophic interactions, creating new ways of sustainable control strategies for these pests.

POSTER PRESENTATION

Arthropods associated with commercial Proteaceae in the Western Cape, South Africa: Preliminary results

Archbold Sasa, Michael. J. Samways, Melodie. A. McGeoch

Stellenbosch University, Western Cape, South Africa

Introduction: Commercial Proteaceae industry is growing in South Africa but the greatest problem is that of insect pests. Research on insects associated with plant species in the family Proteaceae in South Africa over the past three decades shows that these plants have a rich and diverse insect fauna. However, the data are insufficient for a number of reasons: (a) confirmation of insect identification requires expert advice and a comprehensive reference collection, (b) the list of insects covered is incomplete and (c) most of the studies were carried out on wild Proteaceae species and this is a ground breaking study on commercial Proteaceae.

Methods: Infructescences and leaves of commercial Proteaceae are being sampled for arthropods seasonally for a period of 12 months through use of active collection and active searching (spot check) methods.

Results: These plants have a rich and diverse insect fauna, which includes insects across a full range of plant-feeding guilds: leaf miners, leaf chewers, flowers bud borers, sap suckers and seed feeders. In addition to phytophages, there is a large suit of insect predators and parasitoids. A large percentage of the arthropods are indigenous and have pest status, in that they cause significant damage to the protea plants. Arthropods such as *Capys alphaeus* (Protea butterfly) and *Phyllocnistis* sp. (Channel leaf miner) appear to be specialist pests, as they only attack *Protea cynaroides* and Susara cultivar (*P. magnifica* x P. sussane) respectively.

Conclusions: A large percentage of arthropods associated with commercial protea plants are of economic importance.

POSTER PRESENTATION

Insecticidal activity of some wood-oils against the large pine weevil, *Hylobius abietis* L. (Coleoptera: Curculionidae)

Ivar Sibul, Linnar Pärn, Angela Ploomi

Estonian University of Life Sciences, Tartu, Estonia

Introduction: *H. abietis* is the major damaging pest in conifer reforestation areas in Northern and Eastern Europe. Weevil feeds on the bark causing newly planted trees mortality. The effect of some wood-oils was tested on the large pine weevils feeding.

Methods: Wood-oils extracted from native tree species (*Alnus incana*, *A. glutinosa*, *Populus tremula*, *Betula pendula*, *Picea abies*, *Tilia cordata*) by pyrolysis were studied in laboratory and field conditions. In laboratory tests the preferences and feeding activity of *H. abietis* for treated and untreated food (*Pinus sylvestris* branches) were assayed in simple choice and no-choice tests in spring 2007. Field experiment assayed the repellent or deterrent effect of wood-oils on weevil feeding activity in different conifer transplants over a 4-month period during 2007.

Results: Weevils feeding activity was depressed and wood-oils toxic effect caused many insects death in laboratory tests. The results from field tests indicated that wood-oils had deterrent influence to weevils. There was revealed a phytotoxic influence, a part of treated seedlings died. Although the wood-oils had only some weeks persistent effect nevertheless in autumn were the treated conifer trees less damaged than control plants.

Conclusions: The results indicate that wood-oils may have a role to play in protecting transplanted conifers from attack by pine weevil.

This research is supported by ETF grant no 6781.

POSTER PRESENTATION

Effects of isolation and landscape fragmentation on dispersal abilities of butterflies

Martina Klimova, Zdenek Fric

[1]Czech Conservation Authority, Zlin, Czech Republic, [2]School of Sciences, University of South Bohemia, Ceske Budejovice, Czech Republic, [3]Institute of Entomology, Czech Academy of Sciences, Ceske Budejovice, Czech Republic

Introduction: Biomechanical design of butterflies (allocation of flight muscles, shape and area of wings, wing loading) is directly related to flight abilities of species and individuals. We compared the changes in design of several butterflies differing in habitat requirements and both increasing and decreasing during the 20th century. We hypothesized that in decreasing species, traits associated with good dispersal should prevail in samples from early-20th century, when the habitats were less fragmented than in present.

Methods: We used specimens from large public and private collections, and recent material from identical sites. We then digitized the material and measured it using ScionImage (ScionCorp). Using discriminant function analyses, we compared changes of body design in time.

Results: We found significant changes in dispersal-related biomechanical traits in time in all studied species, indicating a shift in dispersal with changing landscape structure.

POSTER PRESENTATION

Chemical ecology in forensic entomology: Investigation of volatile infochemicals from pig cadaver on necrophagous insect behaviour

Jessica Dekeirsshieter, Francois Verheggen, Frederic Francis, Eric Haubruge

Gembloux Agricultural University, Functional & Evolutionary Entomology, Gembloux, Belgium

Introduction: The « chemistry of death » is poorly studied and information regarding the volatile organic compounds (VOCs) released after death is limited. Nevertheless, the VOCs from cadaver may attract a wide range of insects. These necrophagous insects, mainly Diptera and Coleoptera, may easily detect a dead body sometimes at long distances. Insects perceive chemical cues, the cadaveric odorant molecules or VOCs, that contribute to the dispersal and reproductive behaviour. Chemical ecology is a particular branch of ecology that focuses on the chemical communications between "living" organisms, such as the necrophagous insects and the dead body.

Methods: The chemical ecology approach is divided in three steps: (1) the volatile collection from a dead body (from pig's carcasses) and their identification by analytical techniques (GC-MS). (2) The study of the perception of these volatile organic compounds by a selected necrophagous insect (e.g. blowflies and Silphidae such as Silpha sinuata F.) with electrophysiological techniques (EAG). Third, the behavioural approach that study the insect behaviour to an odorant stimuli.

Results: Volatile compounds from pig cadaver were identified according to increasing durations of decomposition. Most interesting molecules were tested in both EAG and behavioural assays using olfactometry. Results from these experiments will be discussed in relation to the use of necrophagous insects and VOCs as bio-indicators or bio-sensors in the environment of a corpse.

POSTER PRESENTATION

Variation of the arthropod communities associated with repopulated plots with native shrub species at the micro-basin of Santa Helena–Suesca (Cundinamarca, Colombia)

María Catalina Cotes-Bravo[2], Giovanny Fagua[1], José Ignacio Barrera[1]

[1]Pontificia Universidad Javeriana, Bogotá, D.C., Colombia, [2]AKÁSIHA, Fundación para la Conservación y Biodiversidad Tropical, Bogotá, D.C., Colombia

Introduction: The change of both composition and structure of the arthropod community associated to native shrubs along the establishment of a riparian corridor in a micro-basin was studied.

Methods: The study was made in two zones of the micro-basin, one at 3000 m of altitude, and the other at 2800 m. Five samplings were made every two months from June 2004 to April 2005. The captures were made using the following traps: pitfall, Malaise, net transects, and Berlesse funnels, in twelve plots of 100 m² (10x10 m), six per zone.

Results: 108 families, 351 morph species and 30.900 individuals were colleted. Collembola and Diptera were the orders with the highest number of morph species and individuals. In both zones the abundance between the plots tending to increase and for the richness, which tends to diminish during the sampling time. It was found a tendency to increase of the diversity during the sampling time and the dominance diminished in both type plots. The Bray-Curtis analysis for the four capture methods showed that the similitude was higher between every sampling for the two types of plots that between each plot for the total sampling.

Conclusions: the composition of the arthropods community was associated to the complex structure of plants that is formed with the time of succession. The comparisons between communities of the two zones showed an increment of the diversity and a low dominance in the time, associated with an incipient succession at planted shrubs.

POSTER PRESENTATION

Understanding the role of symbionts in *Diaphorina citri* Kuwayama (Hemiptera: Psyllidae) by developing symbiont free lines

Izabela Salvador, Fernando Cônsoli

ESALQ-University of São Paulo, Piracicaba, São Paulo, Brazil

Introduction: Many insects harbour primary symbionts within specialized cells or structures for their growth and maintenance, while secondary symbionts may infect other tissues. These symbionts, mainly bacteria, may affect the host physiology and its interactions with the trophic levels, besides being necessary for the production of required nutrients. Because symbionts play a major role in determining host fitness, their use in developing new technologies for pest and disease control has been investigated. However, a candidate symbiont with a known effect on host biology has to be selected for the development of such technologies. The citrus psyllid *Diaphorima citri* vectos greening disease in Brazil, and is known to harbor the symbionts *Carsonella*, *Wolbachia* and the syncitium symbiont.

Methods: We proposed to develop symbiont lines of the citrus psyllid to understand the role symbionts play on *D. citri* development and reproduction as a step forward to develop strategies to control the disease it vectors. Ten-days old adults were fed antibiotic solutions (tetracycline, streptomycin, ampicillin, cefotaxime and rifampicin) for three days, and transferred to mating cages for egg collection and immature development.

Results: The syncitium symbiont was the most affected, followed by *Wolbachia.* Streptomycin and tetracycline were the most effective antibiotics in eliminating or reducing the symbiont load associated with the citrus psyllid, resulting in lower egg and nymphal survivorship, respectively. *Carsonella* was not affected by any of the antibiotics tested.

Conclusion: The secondary symbiont associated with the syncitium of the bacteriome holds a mutualistic association with the citrus psyllid.

POSTER PRESENTATION

Emission of alarm pheromone in aphids: A contagious phenomenon?

Francois Verheggen[1], Mark Mescher[2], Frederic Francis[1], Eric Haubruge[1], Consuelo de Moraes[2], Ezra Schwartzberg[2]

[1]Gembloux Agricultural University, Functional and Evolutionary Entomology, Gembloux, Belgium, [2]The Pennsylvania State University, Department of Entomology, State College, United States

Introduction: In response to attack by natural enemies, most aphid species release an alarm pheromone that causes nearby conspecifics to cease feeding and disperse. The primary component of the alarm pheromone of most studied aphid species is (E)-ß-farnesene. We recently demonstrated that the production and accumulation of (E)-ß-farnesene during development by juvenile aphids is stimulated by exposure to odor cues, most likely (E)-ß-farnesene itself, emitted by other colony members.

Methods: Volatiles from aphids were determined by gas chromatography – mass spectrometry. Here we examined whether the release of (E)-ß-farnesene can be triggered by exposure to the alarm pheromone of other individuals and thereby amplify the signal. Such contagious emission might be adaptive under some conditions because the amount of (E)-ß-farnesene released by a single aphid may not be sufficient to alert an appropriate number of individuals of the colony to the presence of a potential threat. Using a push-pull headspace collection system, we quantified the (E)-ß-farnesene released from aphids exposed to conspecific alarm signals.

Results: Typical avoidance behavior in aphids was observed with exposure to (E)-ß-farnesene (i.e., they ceased feeding and dropped from host-plant); however, no additional alarm pheromone was detected, suggesting that contagious release of (E)-ß-farnesene does not occur.

POSTER PRESENTATION

Microsatellite loci analysis in population of *Melipona marginata*

Alisson Roberto Campos Moresco, Maria Cristina Arias

USP, São Paulo, SP, Brazil

Introduction: *Melipona marginata* is a species of Meliponini found in eight Brazilian states, RS, SC, PR, SP, RJ, ES, MG, BA. This specie is considered the most ancestral from the genus, and like others species from this genus, makes nests in tree hollows. Due to the forest devastation, this species is considered endanger in some states. Also the uncontrolled transportation of colonies mediated by humans can increase the genetic drift among natural and isolated populations.

Methods: To study the population structure of *M. marginata* we collected specimens from 54 colonies along the geographical distribution of *M. marginata*, and we tested the amplification via PCR of 3 microsatellite loci (Mbi 201, Mbi 215 and Mbi 278), characterized originally in *M. bicolor*.

Results: The loci Mbi 278 and Mbi 201 presented a high number of alleles (6 each) and high level of heterozygosity, however the locus Mbi 215 presented only two alleles, being one of them extremely rare.

Conclusion: The use of heterospecific primers in order to amplify microsatellite loci in *M. marginata* was not so promising. It is necessary a survey of more loci, including others characterized in *M. bicolor* and *Scaptotrigona postica*.

POSTER PRESENTATION

Plutella xylostella (L.) (Lepidoptera: Plutellidae): strategies for integrated pest management

Sergio De Bortoli, Robson Thuler

FCAV-UNESP, Jaboticabal, São Paulo, Brazil

Introduction: This work was developed to evaluate the effect of the interaction between resistance of cabbage cultivars, insecticides and *Trichogramma* on the *Plutella xylostella* control.

Methods: The biology of *P. xylostella* was evaluated in the following cabbage cultivars: Chato de Quintal (CQ), Midori (MD), Roxo Precoce (RP) and Roxo Hybrid (RH), and kale cultivars: Geórgia (CM) and Geórgia Hybrid HS20 (HS20), in laboratory. The toxicity of the insecticides lufenuron and deltamethrin and, the vegetal products neem oil and pyroligneous extract, were evaluated for the adequacy of the lethal concentrations (LC50) of the products. With those products, the effect on *Trichogramma* was also evaluated. Finally, it was evaluated the association of the methods tested, using cabbage cultivars, chemical insecticides and vegetal products, and the effect on *Trichogramma*.

Results: The cultivar CQ was classified as moderately resistant; RP and MD as susceptible, and CM, HS20 and HR as highly susceptible, being also observed, that the cultivars tested did not present sinigrin. Lufenuron, Neem oil and pyroligneous extract caused up to 100% of *P. xylostella* mortality and deltamethrin was not efficient. Deltamethrin was most harmful product to the parasitoids *T. exiguum* and *T. pretiosum*, while neem oil and lufenuron were less harmful.

Conclusion: The interaction of chemical and plant resistance methods, increased the potential to *P. xylostella* control, but this strategy must be well evaluated, as it can affect negativity the parasitoid performance, reducing its control potential.

POSTER PRESENTATION

Resistance of citrus varieties and hybrids to the citrus psyllid *Diaphorina citri* Kuwayama (Hemiptera: Psyllidae)

Paulo Bogorni, José Vendramim, André Lourenção, Marcos Machado, Cristina Vasconcelos

ESALQ/USP, Piracicaba, São Paulo, Brazil

Introduction: The *greening* disease was detected in Brazil only in 2004, where it is vectored by the citrus psyllid *Diaphorina citri*, which is commonly found all over the country.

Methods: As a possible strategy to control the vector of this disease, was evaluate the resistance of Citrus varieties and hybrids and three related genera to the citrus psyllid. Twenty-two genotypes were evaluated. They were distributed in three groups of three genotypes each, and sweet orange (Pêra) was used as control. Each group was caged and 30 psyllid adults were released inside. Each group was replicated 8 times. Data was analyzed by applying the resistance index R.I.= [(A – B) / (A + B)] x 100, where: A = number of psyllid eggs, nymphs or adults in the tested genotype; B = number of psyllid eggs, nymphs or adults in the control. The number of insects was assessed from the 18^{th} to the 21^{st} day after adult release into the cages.

Results: *Poncirus trifoliata* was the most resistant genotype, and none of the psyllid stages of development evaluated were found associated to this plant. Other genotypes, such as grapefruit, *Fortunella margarita*, sweet orange (Natal), hybrid (*Poncirus trifoliata* x *C. sinensis*) and hybrid (*Citrus paradisi* x *Poncirus trifoliata*) were also resistant to the citrus psyllid, while the genotypes pummelo, citron, sweet orange (Hamlin), *Murraya paniculata*, sweet orange (Valência), lemon, hybrid mandarin x sweet orange (*C. reticulata* x *C. sinensis*), mandarin and hybrid (*C. reticulata* x *Poncirus trifoliata*) were the most susceptible.

POSTER PRESENTATION

Aphid - ant mutualism : How do aphids focus ant foraging?

Francois Verheggen[1], Lise Diez[1], Claire Detrain[2], Bernard Wathelet[3], Frederic Francis[1], Eric Haubruge[1]

[1]Gembloux Agricultural University, Functional and Evolutionary Entomology, Gembloux, Belgium, [2]Free University of Brussels, Department of Social Ecology, Brussels, Belgium, [3]Gembloux Agricultural University, Department of Biological Chemistry, Gembloux, Belgium

Introduction: The mutualistic relationships that occur between myrmecophilous aphids and ants are based on the rich food supply that honeydew represents for ants and on the protection they provide against aphid natural enemies. Scouts of aphid-tending ant species would benefit from locating honeydew ressources by orienting toward aphid pheromone sources. The present study aims to identify the chemical factors that attract ants and that maintain their mutualistic relationships with aphids.

Methods: The perception and behavioral impact of *Aphis fabae* alarm pheromone, namely (E)-β-farnesene, on *Lasius niger* were firstly investigated using electroantennography and a four-arm olfactometer. *Aphis fabae* honeydew sugar composition was subsequently analyzed and the preference and recruitment operated by individual *L. niger* scouts for each of the identified sugars was studied.

Results: Clear electrical depolarisations were observed from *L. niger* scout antennae to stimulations of *A. fabae* alarm pheromone. Scouts were significantly attracted toward (E)-β-farnesene in the four-arm olfactometer, suggesting for the first time that the latter compound is a key chemical in the establishment of the mutualism. *Aphis fabae* honeydew composition consisted of 9 identified mono-, di- and tri-saccharides and 8 hydrocarbons that could not be identified. Individual *L. niger* scouts showed the following preferences for the tested sugars: melezitose = sucrose = raffinose > glucose = fructose > maltose = trehalose = melibiose = xylose. Ant scouts are therefore presumed to use aphid semiochemicals to locate at distance an aphid colony and subsequently to estimate honeydew quality by tasting it before recruiting conspecifics and establishing mutualistic relationship.

POSTER PRESENTATION

Mixed forests – a strategy to avoid pest outbreaks? How euryphages and stenophages could react: A case study of temperate forests

Julian Heiermann, Stefan Schütz

Büsgeninstitute, Georg-August-University Göttingen, Göttingen, Germany

Introduction: Mixed forests are assumed to be less prone to insect outbreaks than monocultures. This common thesis was tested by observing two Lepidoptera pests with various diet widths. *Lymantria monacha* L. (Nun moth) as a euryphagous pest on coniferous and deciduous tree species, and *Calliteara pudibunda* L. (Pale tussock moth) as stenophaguous pest on broad-leaved trees.

Methods: The relative abundances and species dominance of both target pests were investigated in six forest types (with five replications): pure spruce (Norway spruce (*Picea abies* (L.) Karst.), pure beech European beech (*Fagus sylvatica* L.) and four mixed stands with different ratios of both tree species. Light traps were used for catching the moths.

Results: Both target species react different. The relative abundances of *C. pudibunda* appear to be linked to the tree species compositions of the test forests. Both the number of individuals and the dominance of the pest species increased from pure spruce forests to above mixed forests with rising beech ratio towards pure beech stands. Remarkable is that beech forests with a small portion of spruce (25 %) show a strong effect of decreasing number of individuals. No significant effects were observed concerning to *L. monacha* and beech/spruce ratio of forests. The only clear trend was that the dominance of this pest decreased with rising beech ratio in forests.

Conclusions: Overall, our findings confirm the assumption that mixed forests are less prone to insect outbreaks in comparison to monocultures.

POSTER PRESENTATION

Selectivity of pesticides for two species of *Trichogramma* (Hymenoptera: Trichogrammatidae) in different hosts

Sergio De Bortoli, Roberto Goulart, Robson Thuler

FCAV-UNESP, Jaboticabal, SP, Brazil

Introduction: The aim of this work was to evaluate the selectivity of pesticides triflumurom, etofenprox and endosulfan for two species of *Trichogramma*; *T. pretiosum* and *T. exiguum*, in different hosts: *A. kuehniella*, *S. frugiperda* and *P. xylostella*, under laboratory conditions.

Methods: This research was conducted at Faculdade de Ciências Agrárias e Veterinárias de Jaboticabal (FCAV-UNESP), in the Laboratório de Biologia e Criação de Insetos. The tests were based on two methodologies: a new methodology for selectivity tests which was developed in LBCI and the IOBC/WPRS methodology. Using LBCI methodology parasitized eggs, percentage of emergence, percentage of parasitism, longevity and sex ratio were evaluated for generations F_1 and F_2. Using IOBC methodology were evaluated parasitized eggs, percentage of emergence, percentage of parasitism and parasitism reduction.

Results: The endosulfan and etofenprox were harmful to parasitoids inhibiting the parasitism in all hosts or killing the insects by two methodologies. Triflumurom was selective to parasitoids just in natural host eggs when the new methodology was applied. When the IOBC methodology was applied triflumurom showed selectivity for both species of parasitoids.

Conclusion: The use of these methodologies influenced the results of insect selectivity.

POSTER PRESENTATION

Traps used in different European countries for the monitoring of vectors of Bluetongue (BT) and African Horse Sickness (AHS)

Ricardo del Rio Lopez[1], Miriam Monerris Mascaró[1], Miguel Angel Miranda Chueca[1], Carlos Calvete[2], David Borras[3], Margalida Miquel[1], Rosa Estrada[4], Javier Lucientes[4]

[1]University of Balearic Islands, Palma de Mallorca, Spain, [2]CITA, Aragon, Spain, [3]IBABSA, Palma de Mallorca, Spain, [4]University of Zaragoza, Palma de Mallorca, Spain

Bluetongue is a disease of ruminants caused by a virus transmitted by the bites of midges species from genus *Culicoides* (Diptera; Ceratopogonidae).Several types of light traps are being used in different European countries for capturing the major vector species of BTV. The four different traps used for the study were: i) OVI-Ondestepoort trap, black light trap provided with 8W U.V. light tube, used in UK and Italy ii) Mini CDC, black light model 912 provided with 4W U.V. light tube, John Hock Company, used in Spain and Portugal iii) Rieb trap, white light model provided with 4W U.V. light tube, used from 2000-2006 in France iv) UK trap, provided by 4W standard incandescent bulb, used in the past in UK and other European countries for AHS surveillance. All traps are provided with a draught back suction fan. Here we have compared the performance of the four types of traps used for the surveillance of the *Culicoides* vector species. The Comparison consisted on a randomized block design. During nine non-consecutive nights the traps were placed in four different positions in a cattle farm located in the island of Mallorca (Balearic Islands, Spain). Results showed important differences in collecting *Culicoides*. The catches were less abundant compared with previous years because of heavy rains and strong winds during the sampling OVI trap showed the best performance in terms of total amount of *Culicoides* captured. However, all four traps captured a similar range of species making non difference in specificity when comparing traps.

POSTER PRESENTATION

Phylogenetics relationships among species of genus *Scaura* (Hymenoptera: Meliponini) inferred from mtDNA sequences

Alayne Domingues, Maria Cristina Arias

USP, São Paulo, SP, Brazil

Introduction: The genus *Scaura* contains species of stingless bees of small size and dark color pattern. The group presents variation in the nesting behavior including several types of cavities as tree hollows or within active termite nests. Currently, four species are recognized: *Scaura latitarsis*, *S. atlantica*, *S. longula* e *S. tenuis*. This genus is of particular interest in terms of taxonomy and phylogenetic relationships. However all the literature are based on morphology and behavior data. The present work aim at to establish the pattern phylogenetic in the genus *Scaura* by using molecular approaches as a new contribution to this bee group.

Methods: Samples were collected from nests in different regions of Brazil. Five mitochondrial genes (12S, 16S, CO I, CO II and Cyt *b*) were amplified and sequenced for *Scaura* species and *Schwarzula timida* and *Schwarziana quadripunctata* (outgroups). Phylogenetic relationships among the included taxa were inferred using neighbor-joining and maximum parsimony methods.

Results: The results show high A+T content. The tree obtain allowed discrimination of species closely related, making part the same monophyletic group.

Conclusion: Further studies using more molecular techniques will contribute to a better understanding of the mechanisms involved in the evolution and to contribute to the correct taxonomic classification of the genus.

POSTER PRESENTATION

A survey of ticks in sheep in the Serra de Tramontana in Mallorca (Balearic Islands, Spain)

Miriam Monerris[1], Ricardo Del Rio[1], Marga Miquel[1], David Borràs[2], Cristina Rincón[1], Miguel Angel Miranda[1], Agustín Estrada-Peña[3]

[1]University of Balearic Island, Palma de Mallorca, Baleares, Spain, [2]IBABSA, Palma de Mallorca, Baleares, Spain, [3]Universidad de Zaragoza, Zaragoza, Aragón, Spain

Ticks are ectoparasites of vertebrates, being identified as highly competent vectors. In fact, ticks have a great medical and veterinary importance, because of its capacity for transmitting a large number of pathogens, including viruses, bacteria and protozoa.

The objective of this work was to survey the species of ticks found on sheep in the island of Mallorca (Balearic Islands). The study took place in the Serra de Tramontana, located in the north of the island. Six farms were chosen and 15 to 30 sheep were sampled in each one. The ticks were directly collected from the head and perianal area of the animals and preserved in ethanol 70 % until identification.

A total of 558 ticks were collected. The farm with a higher abundance of ticks was Sollerich (212 ticks), followed by Son Sales (136), Sòller (82), Son Alzines (49), Es Clot (45) and finally Es Pujol (24). The species of ticks found were *Rhiphicephalus turanicus* (64.3%) and *Rhipicephalus sanguineus* (31.7%). Only one specimen of *Haemophysalis punctata* was collected.

Results showed a high infestation of animals by ticks. From the total of sheep sampled (171 animals), a 77.7 % were infested with ticks. The average of infestation per animal was 5 ± 2,74 ticks. The free range management of the sheep herds in the mountains of Mallorca seems to be directly related with the high abundance of ticks found in the animals.

POSTER PRESENTATION

Genetic variability of a small population of *Frieseomelitta varia* (Hymenoptera, Apidae: Meliponini) through RFLP of mitochondrial DNA

Paulo Henrique Pereira Gonçalves, Maria Cristina Arias

Universidade de São Paulo, São Paulo/SP, Brazil

Introduction: The stingless bees present great ecological importance because they are the main pollinators of several ecosystems. Some species are threatened due to forest fragmentation and devastation; such human actions are decreasing directly the bee population in special the ones that nest in hollow of trees, like *Frieseomelitta varia*. This species is characterized by the production of honey quite viscous. Its distribution covers the Brazilian states of BA, MG and SP. The objective of this study was to verify the genetic variability of a small population of *F. varia* living at the campus of the University of São Paulo, Ribeirão Preto-SP with subsequent inferences about the colonization of new areas by this species and also test Kerr and Vencovsky's hypothesis, which postulates a minimum of 44 nests per area to prevent the loss of genetic variability in a population.

Methods: The DNA was extracted from workers collected in 22 nests. Five mitochondrial regions were amplified: [ND2/COI], [COII], [8 and ATPase 6/COIII], [ND1/16S], [16S/12S], and digested by the following restriction enzymes, *Eco*R I, Bcl I, *Dra* I, *Ase* I *Eco*R V, *Bgl* II, *Hind* III, *Pst* I, *Hinf* I, *Cla* I *Ssp* I and *Bam* HI.

Results: The results obtained so far, allow us to delineate mitochondrial regions that have accumulated more replacements of bases and the enzymes more effective in detecting them. Among the nest sampled only two haplotypes were identified. This fact indicates that this small population was presumably founded by at least two colonies, considering that the mtDNA has maternal inheritance.

POSTER PRESENTATION

Overwintering of *Culicoides* spp. in the western Mediterranean Basin

Miguel Angel Miranda[1], Ricardo Del RIo[1], Miriam Monerris[1], Marga Miquel[1], Carlos Calvete[3], Rosa Estrada[4], Javier Lucientes[4], David Borràs[2]

[1]University of Balearic Island, Palma de Mallorca, Baleares, Spain, [2]IBABSA, Palma de Mallorca, Baleares, Spain, [3]CITA, Aragón, Spain, [4]Universidad de Zaragoza, Zaragoza, Aragón, Spain

Since the declaration of an outbreak of Bluetongue (BT) in the Balearic Islands (Spain) in 2000 (BTV2) a survey, that was intensified in late 2003 (BTV4), was conduced for the *Culicoides* spp. species involved in the transmission of BTV. Collections were made every week in 21 farms distributed in Majorca, Minorca and Ibiza using 6V U.V. miniCDC light - traps. During the last four years (2004 - 2007) a total of 3.862 samples were analysed and 15.262 were identified as *C.imicola* Kieffer, 1913, 66.935 belonging to the Complex Obsoletus, 43 specimens as *C. pulicaris* Linnaeus, 1758, and 115.876 as other *Culiciodes* species. Annual capture of midges is required to better establish the seasonal vector free period in a given area. In the Balearics, the first detection of *C.imicola* occurs in April and remains active up to December, being the maximum period of risk during the vector population peak in late autumn. The introduction of BTV8 (2008) in the Iberian Peninsula and the presence of BTV4 and 1 has changed the situation. The *C. obsoletus* complex has been recently related with the transmission of BTV8 and BTV1 in northern Iberia. This species complex is active during the whole year and peaks in May-June. Tree species belonging to this complex are present in the Balearics: *C. obsoletus* “sensu stricto” Meigen, 1818, *C.scoticus* Downes and Kettle, 1952, and *C.dewulfi* Goetghebuer, 1936. The current epidemiological situation in Europe makes necessary to maintain a well developed entomological and virus surveillance system in an annual basis.

POSTER PRESENTATION

Cuticular hydrocarbons variability, as a potential taxonomic tool for *Anacroneuria* spp. (Perlidae: Plecoptera)

Maribet Gamboa, Jose Vicente Hernández, Jazzmín Arrivillaga

Universidad Simon Bolivar, Caracas, Miranda, Venezuela

Introduction: Cuticular hydrocarbons play a significant role in the regulation of permeability and the insect chemical communication system. We report here the variability in composition on the cuticular hydrocarbons in four Plecoptera species (*Anacroneuria chorrera*, *A. cacute*, *A. tachira* and *A. paleta)*, considered as bioindicators of the lotic system contamination.

Methods: Solid Sample of individual pronotum of naiads were prepared. Gas chromatography/mass spectroscopy was used to determine the presence or absence of cuticular hydrocarbons.

Results and conclusion: Cuticular composition indicate that four species represented two species groups, Group 1 (*A. chorrera* and *A. paleta)* and Group 2 (*A. tachira* and *A. cacute*). These results agreed with our naiads morphological revision performed previously.

POSTER PRESENTATION

Biology and behavior of the cocoa borer, *Carmenta foraseminis* (Eichlin, 1995) (Lepidoptera: Sesiidae)

Beatriz Herrera-Malaver[1], Carmen V. Liendo-Barandiaran[1], Cristina Sainz-Borgo[1], José Vicente Hernández[1], Franklin Morillo[2]

[1]Universidad Simón Bolívar, Caracas, Estado Miranda, Venezuela, [2]Instituto Nacional de Investigaciones Agrícolas, Estación Experimental Miranda, Calle El Placer, Caucagua, Estado Miranda, Venezuela

Introduction: In Venezuela, one of the most important cocoa pest insect is *C. foraseminis* Eichlin (1995). Larvae of this sesiid feed within the fruit and seed of *Theobroma cacao* L., cause serious damage on commercial products.

Methods: *C. foraseminis* larvae and pupae were collected from cocoa fruit in Choroní, Aragua State, Venezuela. Larvae were reared individually in clear plastic container, and feed with a small cocoa piece. Pupae were removed from their cocoons and kept on wed adsorbent paper until its emergence. Room conditions were 25℃, 63% relative humidity and 12:12 L/D. Male and female adult number of *C. foraseminis* that emerged during an hour intervals on different colect period were recorded by observers. Observation chambers wereprovided with a source of 10% sucrose solution and an unripe cocoa pod. Newly emerged female and male moth were place individually into the chamber. Female moth were observed for calling behavior by one hour intervals during ≥48h after emergence.

Result and Conclusions: Males and females of *C. foraseminis* moths showed an emergence peak within 14:00 to 15:00 hours. Pupal period was 15 ± 2 days and adult longevity was 7 ± 4 days. The onset of calling behavior occurs on the day after emergence and was observed during crepuscular period. Calling female of *C. foraseminis* assume a posture that includes abdominal hairs displayed and abdomen ventrally curved.

POSTER PRESENTATION

Phylogenetic relationships among Brazilian bumblebees (Hymenoptera: Apidae) inferred from mitochondrial DNA sequence data and gene organization

Elaine Françoso, Maria Cristina Arias

Universidade de São Paulo, São Paulo, SP, Brazil

Introduction: In Brazil, are found only six species from the genus *Bombus: Bombus morio, B. atratus*, *B. brevivillus*, *B. brasiliensis*, *B. transversalis and B. bellicosus,* a low number comparing to the Northern hemisphere. Molecular markers are widely used in biology, and molecular markers from mtDNA analyses were applied to stingless bee species and the data obtained has proving useful to infer hypotheses about phylogeny, population dynamics, species validity and evolution. The objectives of this research are: to understand the phylogenetic relationship among the Brazilian species through mitochondrial genes analysis; to correlate the present biogeography with past paleoclimatics and geological events; and to propose an alternative hypothesis for the evolution and speciation within the genus. To achieve our goals we analyzed sequences from three mitochondrial regions and also the gene order of two mitochondrial tRNAs clusters, which in previous studies showed translocations and presence of pseudogene in *Bombus morio.*

Methods: Mitochondrial DNA was extracted from ethanol preserved thoracic or dry leg from museum specimens. The genes 16S and COI, and tRNAs cluster 1 and 4 were amplified by PCR, cloned into vector and sequenced from both strands.

Results: A molecular phylogenetic relationships was inferred from mitochondrial DNA sequences data and the secondary tRNA structure was obtained showing the presence of $tRNA^{lys}$ pseudogene within cluster IV.

Conclusion: The six Brazilian bumblebee species consist a monophyletic group and the presence of the $tRNA^{lys}$ pseudogene seems to be a unique characteristic of this South American group.

POSTER PRESENTATION

Tephritide of economic importance in the Balearic Islands (Spain)

Miguel Angel Miranda, Marga Miquel, Jaume Terrassa, Maria del Mar Leza, Antònia Romero, Ricardo Del Rio, Miriam Monerris, Ana Alemany

University of Balearic Island, Palma de Mallorca, Baleares, Spain

The Balearic Islands are located in the western area of the Mediterranean Basin. Olive, citrus and stone orchards are the main crops in the islands. Several species of Tephritidae of economic importance are present in the Balearics. The Mediterranean fruit fly, *Ceratitis capitata* and the Olive fly, *Bactrocera oleae,* are well known species which cause important damages and losses to the agriculture. The current control strategies for these species are mainly based in the use of a wide range of insecticides. However, in the last year 10 years, a great effort in the use of alternatives, such as mass trapping and sterilization by chemical means, has been carried out in the Balearics. The combination of the three synthetic attractants Trimethylamine, Putrescine and Ammonium Acetate are the main lures used for the monitoring and mass trapping of the females of *C. capitata.* In the case of the Olive fly, the monitoring is still mainly based in the synthetic pheromones for capturing females and the use of ammonium phosphate for capturing females. Two news species of economic importance have been recently recorded in the Balearic. In August 2007 several specimens of *Carpomyia incompleta* and *Capparimyia savastani* were captured in traps that were deployed for capturing C. capitata and B. oleae respectively. The larvae of *C. incompleta* develop in the fruits of *Ziziphus* spp., meanwhile the larvae of *C. savastani* develop in the edible bud flowers of *Capparis spinosa*. Both species has been recorded as a potential pest species of their respective hosts.

POSTER PRESENTATION

Morphometric analysis of the antennal sensilla of the adult female blackfly, *S. chutteri* Lewis (Diptera: Simuliidae)

Vuyisile Hobololo[1], Alan Hall[3], Chris van der Merwe[3]

[1]ARC-Onderstepoort Veterinary Institute, Onderstepoort, Pretoria, South Africa, [2]University of Pretoria, Faculty of Veterinary Science, Onderstepoort, Pretoria, South Africa, [3]University of Pretoria,Laboratory for Microscopy and Microanalysis, Hatfield, Pretoria, South Africa

Introduction: A thorough understanding of blackfly behavioural patterns exhibited during host location cannot be fully understood unless detailed information on the structural dimensions, relative abundance and distribution of antennal sensilla of female *S.chutteri* is available.

Methods: Live populations of wild female *S. chutteri* were sweep-netted from sheep grazing in open fields in two localities of proven blackfly challenge along the Vaal River, South Africa. Specimens were prepared for scanning electron microscopy using standard techniques. The antennal hair-types were observed, micrographed and measured. All numerical measurements of all the antennal hair-types are averages of at least 20 observations. Statistical significance was determined using unpaired student's t-test at the 5% level.

Results: The antennal flagellum of female *S. chutteri* is divided into nine flagellomeres ranging from 183 to 311μm (average = 257 μm) in length. The overall length of the most prominent Type 1 sensilla chaetica (T1) ranges from 8.41 to 18.00 μm (average = 14 μm) with the mean basal diameter of 1.96 μm and 1.6 μm at midpoint. Type 2 sensilla chaetica (T2) have an average length of 9.38 μm (range = 7.75 – 9.80 μm) with the average base diameter of 1.45 μm and midpoint diameter of 1.05 μm. Sensilla trichodea (ST) have an average length of 15.9 μm (range = 12.90 – 20.42 μm), average basal diameter of 2.00 µm (1.92 – 2.17 μm). The elongate, cylindrical subtype of sensilla basiconica (SB) have an average length of 9.68 μm (range = 6.88 – 12.25 μm), while the club-shaped subtype have an average length of 3.9 μm, basal diameter of 1.58μm and midpoint diameter of 1.51μm. Grooved sensilla basiconica (GSB) average length is 5.90 μm (range = 4.81 – 7.00 μm), while basal diameter is 1.49 μm (range = 1.19 – 1.83 μm) and midpoint diameter of 1.05 μm (range = 0.75 – 1.13 μm).

Conclusions: The most numerous (>1000 sensilla), smooth-walled, olfactory ST are the longest sensilla occurring in all flagellomeres while the least abundant (2-5 sensilla) T1 are the most prominent contact chemoreceptors found only in the distal flagellomere. Although structurally similar to T1's, T2 are almost half the length of T1's, occurring in all flagellomeres. Club-shaped SB's are almost 2/5 the size of cylindrical SB's in length. GSB are the smallest sensilla in all dimensions.

POSTER PRESENTATION

Natural Products Based Pesticide Development Centre (BOPAM) in Turkey

Nezhun Goren[1], Neset Kilincer[2], M.Oktay Gurkan[2], Ayhan Gokce[3], Mark Wholan[4]

[1]Yildiz Teknik Univ., Istanbul, Turkey, [2]Ankara University, Ankara, Turkey, [3]Gaziosmanpasa Univ., Tokat, Turkey, [4]Michigan State Univ, Michigan, United States

This project aims to develop natural products that are compatible with other control strategies, are safe for non-target organisms and the environment, and will decrease residue issues at harvest. In order to achieve these aims, natural products extracted from plant species endemic to Turkey were tested against various important pest species e.g. *Spodoptera littoralis*, *Leptinotarsa decemlineata*, *Bemisia tabaci* under laboratory conditions.

Initial data has suggested that natural products are highly effective against insects, particularly those with a broad history of potential resistance. The unique mode of action of natural products e.g. antifeedant, repellent promises potential for their use in rotation with other pesticides with a decreased chance of development of resistance.

POSTER PRESENTATION

Ecological and biological investigations on emergent bluetongue vectors, the biting midges *Culicoides*, in Belgium

Jean-Yves Zimmer, Frederic Francis, Eric Haubruge

Gembloux Agricultural University, Functional and Evolutionary Entomology, Gembloux, Belgium

Introduction: Bluetongue is a non-contagious disease coming from South Africa that affects domestic and wild ruminants. This viral epizooty – of which there are 24 different serotypes – causes considerable economical losses on its passage. In 2006, bluetongue appeared in the North of Europe including Belgium. *Culicoides* are biting midges counting about 1400 species but only some of them seem to act in the transmission of the bluetongue virus. We aimed to identify the bluetongue adult vector species and determine the particular larval habitat.

Methods: A field study was performed in animal production farms in Belgium. A Culicoides adult trapping was realised using light trap to collect and identify the potential flying vector species. Also, knowing the ecological requirement of biting midge larvae, frequently observed in the upper layer of the wet and rich organic matter environment, an investigation of several potential ecological habitats of larvae were sampled and the larvae were reared in the laboratory until adult emergence to be identified.

Results: After adult Culicoides identifications, the relations between the characteristics of the investigated habitats, the presence of cattle, the distance to the farm and the identified biting midges species were studied. The survival and activity of adults were strongly influenced by the weather factors. Higher adult Culicoides populations were observed nearby farming than in the neighbouring meadows. The *C.obsoletus / scoticus* complex was the most abundant. The main potential bluetongue fly vectors privileged at the larval stage the anthropogenic areas close to livestock.

POSTER PRESENTATION

Effective sampling range of food-based attractants for pest Tephritidae

Nancy Epsky, Paul Kendra, Robert Heath

USDA/ARS, SHRS, Miami, Florida, United States

Introduction: Semiochemical-based detection and monitoring systems are critical components of tephritid fruit fly trapping programs. Trapping efficacy is dependent upon the attractant's effective sampling range, defined as the maximum distance from which an insect can reach an attractive source in a given period of time. Mark-release-recapture studies were conducted with sterile *Anastrepha suspensa* females to determine effective sampling range for a female-targeted synthetic food-based lure and for liquid protein bait.

Methods: Sexually immature and mature sterile females, marked with different pigments, were released from a centrally-located point source. 25 Multilure traps were placed in concentric circles between 9 and 46 m from the release point. Recapture was determined after 0.5, 1, 2, 3 and 6 d. Separate tests were conducted with Multilure traps baited with a two component synthetic lure (ammonium acetate and putrescine) or with liquid protein bait (torula yeast/borax).

Results: In all tests, recapture of immature females was higher than recapture of mature females. Most of the flies were recaptured within the first 24 h of release in traps located within 17-27 m of the release point. Results were similar for immature and mature flies, and for traps baited with synthetic lures or liquid protein. Few females were recaptured by 6 d of release.

Conclusions: Additional studies will be conducted to compare response of wild flies with sterile flies. This information is needed to determine coverage of traps used for population delimitation or for mass trapping control strategies, or to pin-point areas of infestation for precision targeting of control measures.

POSTER PRESENTATION

Fluctuations in abundance of green lacewings (Neuroptera: Chrysopidae) in guava orchards in southeastern Brazil

Jatinder Multani, Gilberto Albuquerque

Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, RJ, Brazil

Introduction: Green lacewings are predominantly arboreal and play a key role in biological control. Despite the high diversity of these predators in the Neotropics (> 300 species), little is known about their population dynamics in this region. An understanding of their seasonal patterns of activity has implications for pest management in guava, an important cash crop in southeastern Brazil.

Methods: All stages of lacewings were sampled weekly, for two years, in three guava orchards in Campos dos Goytacazes, state of Rio de Janeiro. Tree branches were inspected thoroughly for immatures, whereas adults were collected with attractive traps. The influence of prey availability and climatic factors on the predators' abundance was evaluated.

Results: Adults of 17 species, from *Leucochrysa*, *Ceraeochrysa*, *Chrysopodes*, *Chrysoperla* and *Plesiochrysa*, were captured, with high abundance in July-August and a long period of low numbers between October and May. Six of these species, however, do not occur on guava trees, as demonstrated by their absence in the immature samplings, and were probably attracted from the surrounding vegetation. Of the 11 guava-inhabiting species, most individuals belonged to *Ceraeochrysa* spp. Considering only the species found in guava, there was no clear seasonality, i.e., all stages were present throughout the year, with alternating short periods of high and low numbers.

Conclusion: The year-round occurrence of green lacewings in guava orchards shows that there is no interruption in their life cycle in southeastern Brazil. Consequently, they show potential for use in conservative and augmentative programs to control guava pests during all seasons.

POSTER PRESENTATION

New developments in food-based synthetic attractants for pest Tephritidae

Robert Heath, Paul Kendra, Nancy Epsky

USDA/ARS, SHRS, Miami, Florida, United States

Introduction: Optimal capture of several species of *Anastrepha* and *Bactrocera* spp. tephritid fruit flies is in traps baited with the aqueous protein bait Nulure combined with borax. Nulure is produced by acid hydrolysis of corn and has an acidic pH. Addition of borax makes the solution more alkaline and more attractive to several fruit fly species. We report herein research on chemical modifications of Nulure to identify volatiles responsible for attraction and also to improve stability of Nulure-based baits for these species.

Methods: The pH of Nulure solutions was modified by addition of borax or sodium hydroxide (NaOH) at a range of pH4 to pH10. Stability was monitored and ammonia release rate was quantified over a 14 d period. Electroantenography (EAG) was used to determine antennal sensitivity for *Anastrepha suspensa* females, and field tests were conducted to determine effect on trapping efficacy.

Results: It was observed that the zwitter ion effect plays a critical and confounded role on pH stability in aqueous solutions. Stabilization of pH was noted when propylene glycol was added at a 10% (vol:vol) concentration. EAG analysis indicated that female antennal response to Nulure increased as pH shifted from acidic to neutral. Highest field capture of females was in traps baited with synthetic lures ammonium acetate and putrescine in combination with Nulure at pH7 with NaOH and 10% propylene glycol.

Conclusions: Chemical analysis will be used to identify additional attractant chemicals from modified Nulure bait solutions for use in food-based synthetic lures.

POSTER PRESENTATION

Decrease of vertical transmission rate of a spiroplasma in *Drosophila hydei* at low temperatures

Ryu Osaka[1], Masashi Nomura[1], Masayoshi Watada[2], Daisuke Kageyama[3]

[1]Graduate School of Horticulture, Chiba University, Matsudo, Chiba, Japan, [2]Faculty of Science, Ehime University, Matsuyama, Ehime, Japan, [3]National Institute of Agrobiological Sciences (NIAS), Tsukuba, Ibaraki, Japan

Introduction: In Japanese populations of *Drosophila hydei* infected endosymbionts belonging genus *Spiroplasma*. The infection rate of spiroplasma has been shown middle frequencies (23 to 66 %). But the spiroplasma did not cause male killing. In natural population of *D. hydei*, the frequency of spiroplasma is high in summer, but low in spring. Why the frequency is decrease with the approach of next spring?

Method: We used an iso-female line of spiroplasma–infected *D. hydei* that was established from collecting in Japan. New emerged adult flies were reared, and females were oviposited at various temperatures (28, 25, 18 and 15ºC). The frequency of infected spiroplasma in flies of next generation was investigated by using a diagnostic PCR method. Additionally, the titers of spiroplasma in flies of parental and next generation were quantified by using a real-time PCR method.

Results: In low temperatures (18 and 15ºC), the frequencies of infected spiroplasma in next generation were decreased dramatically. Especially at 15ºC, there was no transmission of infected spiroplasma. In parental generation, the titer of spiroplasma at 25ºC was higher than the titer at 18 and 15ºC, but the level of the titer of spiroplasma was equivalence. On the other hand, in next generation, the titer of spiroplasma at 18ºC was tithe as much as the titer at 28 and 25ºC.

Conclusion: Low temperatures restrict the frequency of spiroprasma in a natural population of *D. hydei*.

POSTER PRESENTATION

Mitochondrial gene order and the evolution of bees (Hymenoptera: Apidae)

Daniela Silvestre, Maria Arias

USP, São Paulo, SP, Brazil

Introduction: The classification of bees and their phylogenetic relationships are controversial questions still. Mitochondrial gene order is cited by several authors as a promising molecular marker to study the phylogeny of major groups, like Insecta orders. Thus comparative analyses of mtDNA may constitute a good character source to infer the phylogeny among tribes, subfamilies and families of bees.

Methods: mtDNA regions of 13 bee species from 11 different tribes were amplified with primers derived from other insects. All fragments were cloned and sequenced from both directions. Sequences were analyzed to determine gene order and compared among species.

Results: A large amount of rearrangements was found. Unfortunately, comparing all species of this work, gene translocations had not generated sufficient data to obtain a phylogenetic tree. It is common, in cases like that, to use a previous proposed phylogenetic tree to "apply" the rearrangements and try to get more data about them. Michener (2000) presents a tree to relate subfamilies and families of bees, splitting the group between short tongued and long-tongued taxa. Gene rearrangements of some clusters were plotted over that tree to infer some new hypotheses about the evolution of the group.

Conclusions: It is clear that bees have an accelerated rate of mitochondrial genome evolution, including base substitution and also gene order rearrangement. Data are congruent to previous studies on wasps. More investigations on that insect order can lead to a better understanding of molecular evolution.

POSTER PRESENTATION

Evolutionary and ecological events that influenced the population structure in *Plebeia remota*, a stingless bee from Brazil

Flavio O. Francisco, Maria C. Arias

Departamento de Genética e Biologia Evolutiva, Instituto de Biociências, Universidade de São Paulo, São Paulo, SP, Brazil

Introduction: Multidisciplinary studies have demonstrated that the stingless bee *Plebeia remota* have distinct behavior, morphometry, chemistry, and genetic characteristics according to the geographic distribution. In order to evaluate which evolutionary and ecological processes may have contributed to this scenario, the genetic structure of *P. remota*, from four distinct geographic areas in Brazil, was studied through mtDNA and microsatellite data.

Methods: Seventy nests were sampled and mtDNA was analyzed with 15 restriction enzymes. Microsatellite analysis was performed in 72 individuals from 72 nests, by screening 7 heterospecific loci.

Results: Fifteen composite haplotypes were found and a strong mtDNA population structure was detected among all populations. Analysis of microsatellite polymorphism indicated that the four populations are characterized by a low genetic diversity. We believe that vegetation shifts caused by climatic changes and uplift of Brazilian coastal ranges since Tertiary, and also female philopatry were responsible for population isolation. Recent habitat fragmentation caused by human occupation may be the reason for the low nuclear genetic diversity. Microsatellite and mtDNA data showed high genetic distance and isolation between one geographic distinct population and the other 3 ones.

Conclusions: Our work and the data already published in literature present evidences that one population might constitute a new species. This information plus the current habitat fragmentation between the populations studied constitute relevant data to conservation strategies.

POSTER PRESENTATION

Population analysis of *Partamona mulata* and *Partamona helleri* (Hymenoptera: Apidae: Meliponini) in Brazil

Rute M. Brito, Maria C. Arias

Departamento de Genética e Biologia Evolutiva, Instituto de Biociências, Universidade de São Paulo, São Paulo, SP, Brazil

Introduction: The *Partamona* genus comprises 33 species distributed from south Mexico to southern Brazil. Molecular approaches were developed to characterize populations of two species presenting a distinct geographic distribution: *P. mulata* has a small geographic range, found only in central Brazil (savanna); and *P. helleri*, which ranges largely in eastern Brazil (Atlantic forest).

Methods: Individuals of *P. mulata* and *P. helleri* were collected from 58 and 47 nests, respectively. Both samples were divided into 5 geographic sub-samples or populations following their endemic range. Four PCR amplified mtDNA regions were analyzed by 6 restriction enzymes, and 9 microsatellite loci were amplified by using heterospecific primers.

Results: *P. mulata* presented only 2 haplotypes which differed by presence/absence of one single restriction site. Analyses indicated no differentiation among the populations. Conversely, *P. helleri* presented 10 haplotypes, being some exclusive and others shared among populations. The microsatellite analysis showed low genetic variability in both species and discrete population structuring, not related to the geographic distribution.

Conclusions: The data indicates that *P. mulata* may have passed through a recent populational bottleneck or recent speciation process. However *P. helleri* seems to an ancient species that have suffered a recent isolation probably due Atlantic Forest fragmentation during the Pleistocene. In both species, the low nuclear variability is an evidence of migration of males, since the queens are highly phylopatric; also habitat fragmentation (degradation of savanna and Atlantic forest areas) should be taken in account to explain the current genetic scenario.

POSTER PRESENTATION

How much do eucalyptus leaf beetles eat?

Jane Elek, Natasha Beveridge

Forestry Tasmania, Hobart, Tasmania, Australia

Tasmanian leaf beetles, *Paropsisterna bimaculata* (formerly *Chrysophtharta* sp.; Coleoptera: Chrysomelidae), are native insects that cause economic loses of wood volume as a result of defoliation to commercial eucalypt plantations in Tasmania, Australia. The integrated pest management system used to prevent economic losses is based on damage thresholds from larval feeding alone. The amount of *Eucalyptus nitens* foliage lost due to feeding by adult beetles was assessed in a field trial during eight weeks at the end of summer, between eclosion and cessation of feeding prior to overwintering. Changes in area of matched control shoots were used to correct for leaf expansion of the treatment shoots on which feeding beetles were caged.

After eight weeks of feeding, half the beetles had changed elytra colour from green to red in preparation for overwintering and all had ceased feeding. During this period, each adult beetle caused an average loss (included potential expanded leaf area) of 16 $\pm$ 2.6 cm^2 of foliage, which was almost 9% of the total shoot leaf area. Feeding caused an average loss of 63 $\pm$ 17 mm^2 foliage per beetle per day.

Using data from this trial and other sources, the total amount of foliage lost due to one pair of beetles and one generation of their offspring during one summer was estimated to be about 13 leaves or almost 2 shoots. Adult beetles, both parent and first generation, would be expected to remove 195.5 cm^2 of foliage, which is 36% of the total estimated defoliation by both adults and larvae. One sixth of the damage was caused by the first generation adults at the end of summer. However, eucalypt trees are less able to refoliate at the end of summer so spend winter with lower crown volumes, resulting in greater relative growth impact on wood volume from late-summer defoliation.

These results demonstrate that it is important to incorporate both larval and adult defoliation into damage thresholds for IPM.

POSTER PRESENTATION

Reconstruction of Pterygota ancestral wing morphology

Diego Griffon

Universidad Bolivariana de Venezuela, Caracas, Venezuela

Introduction: The Devonian was likely the scenery where an insect flew for the first time. Unfortunately, there are no winged insects fossils found from this early time, so we have no direct information of the morphological characteristics of these ancient flying animals. This lack of information in the fossil record has led to the proposal of various hypothetical Pterygota archetypical wings. Between these proposals highlights the radically different models of Hamilton (1972) and Kukalova-Peck (1982)

Methods: In this work we use for the first time techniques of the Comparative Method (Harvey and Pagel, 1991) to build a hypothetical model of the wing morphology of the most recent common ancestor of Pterygota. These techniques allow the assignment of states to characters in ancestral nodes of a phylogenetic tree. In this case, we reconstruct the wing's longitudinal veins morphology for the node that represent the most recent common ancestor of all winged insects. We made the reconstructions based on morphological information of all extant insect's orders.

Results: The results of this work are consistent with the model of Hamilton (1972), differing only in our proposal of a basal union between Radius Posterior (RP) vein with Media Anterior (MA) vein.

Conclusions: We support the Hamilton archetypical model, in accordance with this author we name our wing type Archaeoptera, name that we propose as genus taxonomic rank name for the Pterygota most resent common ancestor.

POSTER PRESENTATION

Division of labor during the organization of open-air foraging of *Syntermes molestus* (Termitidae: Nasutitermitinae)

Dayaleth Alfonzo[1], Solange Issa[2]

[1]Universidad Bolivariana de Venezuela, Caracas, Dtto Capital, Venezuela, [2]Universidad Simón Bolívar, Caracas, Dtto Capital, Venezuela

Introduction: Foraging behavior is often a collective activity composed of integrated actions of individuals. The polytheism could be based upon sex, size, morphological characteristic, and age. The role of the castes in the division of labor on Isopteran is difficult to study because the majority of the termites foraging under covered galleries. *Syntermes* is a Neotropical genus distributed from Venezuela until Argentina. The specie, *S. molestus*, forms big epigeal nest and foraging on open air over grass.

Methods: By filming the foraging behavior, we determined if this specie present polytheism between castes. The data was analyzed by 2 x 2 Contingency Tables to establish the main activity of each caste involucres foraging behavior. In addition, a biometric study was made to establish differences between workers and soldiers (widest and longest head capsule, WH and LH, respectively); these were analyzed with ANOVA and Tukey Multiple Means.

Results: The observation over 9 nests show that *S. molestus* foragers caste has a sociometric trimorphism among workers and a monomorphic soldier. The three castes of workers can be distinguished as minor (LH:2.18±0.04cm; WH:1.94 ± 0.04cm), medium (LH:2.68±0.11cm; WH:2.15±0.04cm) and major (LH:3.17±0.14cm; WH:2.56±0.06cm). We, also observed three kind of basic tasks: Worker carrying soil particles from inside nest to outside; foragers looking and carrying grass to inside nest and soldiers as guardians of the foragers.

Conclusions: Polytheism between workers was clear, while minor and medium workers carrying soil particles; major workers were cutting and carrying grass from foraging site to the nest.

POSTER PRESENTATION

Behavior and chemical communication in *Carmenta theobromae* (Busck) (Lepidoptera: Sesiidae)

F Morillo[1], Beatriz Herrera[2], Carmen Virginia Liendo[2], Wilfredo Muñoz[2], Pedro Sánchez[2], Jose Vcente Hernández[2]

[1]Instituto Nacional de Investigaciones Agrícolas, Estación Experimental del Estado Miranda (INIA-Miranda), Caucagua, Miranda state, Venezuela, [2]Universidad Simón Bolívar (USB), Biología de Organismos, Laboratorio de Comportamiento, Caracas, Dtto. Capital, Venezuela

Introduction: *Carmenta theobromae* (Busck) is one of the main entomologic problems of cocoa plantations in Venezuela. In this work the behavior of adults was studied and the main compound involved as sexual pheromone in this insect was determined.

Methods: Larvae in the bark of perforated cocoa pods were collected, in Curiepe, Miranda State, Venezuela. They were individualized and placed in pieces of healthy pod bark, in containers of 350 ml. Each formed pupae was placed on plastic trays, on a piece foam rubber with humidified absorbent paper and covered with a container of 30 ml, under controlled environmental conditions. The emergence and the daily activity of adults were recorded in observation chambers. The chromatographic and spectrometric analyses were carried out on abdominal tip extracts of males and females.

Results: Adults emergences begin between 07:30-08:00 hours, and was extends from 14:00 to 15:30 hours, in females and males respectively. The emergence peaks occur in the first hour during the day for both sexes. The duration of the female calling behavior was 4 hours, with the calling peak at 17:30 hours. Female keep this behavior until the third day of life. The time of calling behaviour coincided with the higher flight activity, walk or flapping of the males. The female chromatograms showed an exclusive peak, not observed in males. It correspond to (*Z*,*E*)-3,13-octadecadienyl acetate.

Conclusion: *C. theobromae* females emit a sexual pheromone in sunset. Probably, the main component of the pheromone is the octadecadienil acetate or their isomeric ones.

POSTER PRESENTATION

High bluestain fungus (*Ophiostoma minus*) abundance negatively affects outbreaks of the southern pine beetle, *Dendroctonus frontalis*

Stephen Taerum[1], Kier Klepzig[2], Matt Ayres[1]

[1]Dartmouth College, Hanover, NH, United States, [2]Southern Research Station, USDA Forest Service, Pineville, LA, United States

Introduction: Feedbacks help shape multispecies interactions. One example is the southern pine beetle–mite–fungus symbiosis, which involves positive, negative, and commensal interactions between the southern pine beetle (*Dendroctonus frontalis*) and its symbionts. We examined how the abundance of the bluestain fungus (*Ophiostoma minus*), which depends on *D. frontalis* for transportation between pine trees and frequently outcompetes fungal mutualists of *D. frontalis* in trees, affects the population dynamics of *D. frontalis*.

Methods: Between 2001 and 2008, we estimated *O. minus* abundances at *D. frontalis* infestations, or "spots," in different forests in the United States (forests at different years are herein referred to as forest-years). Using USDA data on *D. frontalis* trap captures and spot formation, we determined how *O. minus* abundance affected *D. frontalis* populations in subsequent years.

Results: Forest-years with high *O. minus* abundances had significantly fewer *D. frontalis* infestations in subsequent years than forest-years with low *O. minus* abundances. In addition, forest-years with high *O. minus* abundances tended to have lower *D. frontalis* trap captures in following years than forest-years with low *O. minus* abundances.

Conclusions: High *O. minus* abundance had a negative effect on the number of *D. frontalis* infestations produced in following years, suggesting that *O. minus* abundance might predict *D. frontalis* outbreak dynamics.

POSTER PRESENTATION

Molecular intra-specific phylogeny of *Hylesia metabus* (Saturnidae: Hemileuciinae)

Cristina Sainz-Borgo, Maribet Gamboa, Beatriz Herrera-Malaver, Carmen V. Liendo-Barandiaran, José Vicente Hernández, Jazzmin Arrivillaga

Universidad Simón Bolívar, Caracas, Estado Miranda, Venezuela

Introduction: In Venezuela, *Hylesia metabus* has been reported as a "single species" with phenotypic differences based on adults coloration and female sexual pheromone composition that suggest genetic variability among populations with possible implications on the differentiation and divergence, if the female sexual pheromone produce partial or complete reproductive isolation.

Methods: The present work study the genetic variation on adults samples (males) from different geographical locations belong to Venezuela North east, and three different population peak cycles using molecular data (12S and COI mitochondrial regions) and cladistic analysis.

Results and Conclusions: The results indicate that *Hylesia metabus* is a single species without phylogenetic structure, which are not congruent with pheromone or coloration patterns based on the adults sampled.

POSTER PRESENTATION

Overexpression of c-type lysozyme from *Agrius convolvuli* using prokaryotic expression system

Sung Moon Yoe, Soon Ik Park, Jong-Wan Kim, Hong Sun An

Dankook University, Cheonan, Republic of Korea

We have isolated and characterized the *Agrius convolvuli* cDNA encoding a c-type lysozyme. The cDNA sequence encodes a processed protein of 139 amino acid residues with 19 signal sequence and 120 mature sequence.

Recombinant *A. convolvuli* lysozyme was expressed in *Escherichia coli* BL21 (DE3) pLysS cells for pGEX 4T-1 vector. Their optimal conditions for the fusion protein expression and purification were screened. Lysozyme gene amplified with primers ACLyz *Bam*HI and ACLyz *Xho*I was ligated into the pGEX 4T-1 vector, which contained the glutathione S-transferase (GST) gene for fusion partner. The anti sense primer has additional sequence (Gly) for protection of mature sequence from various stressful circumstances and increasing solubility.

After transformation, the bacteria cell was incubated and inoculated IPTG for 2h. The cell lysate was analyzed by SDS-PAGE, where the appearance of a ~45kDa band indicates the synthesis of GST fused lysozyme. Recombinant lysozyme, fused to GST, was purified by glutathion-Sepharose 4B affinity chromatography.

Western blot analysis of this protein revealed an immunoreactivity with the anti-*Agrius* lysozyme. Thrombin digestion of GST-lysozyme fusion protein, 15, 29 and 45 kDa fragments were detected by SDS-PAGE. From the size of fragments, it seems that 29 kDa fragment represents the GST fusion partner and 15 kDa fragment represents the recombinant lysozyme while 45 kDa fragment represents uncut GST-lysozyme.

POSTER PRESENTATION

Overexpression of a cecropin-like peptide from *Agrius convolvuli* in *Escherichia coli*

Sung Moon Yoe, Hong Sun An, Soon Ik Park, Jong-Wan Kim

Dankook University, Cheonan, Republic of Korea

Insects have developed efficient immune responses that protect them against the damaging effects of microbial and eukaryotic invader. Antibacterial peptides are one of the most important humoral immune system in insects. Cecropin is a well-studied group of insects antibacterial peptides and widespread in a variety of organisms.

A cDNA encoding cecropin like peptide from *Agrius convolvuli* (named ACcec) was isolated from total RNA using RT-PCR and was expressed in *Escherichia coli.* The DNA fragment encoding mature ACcec was amplified with primers ACcec *Eco*RI and ACcec *Xho*I was ligated into the pGEX 4T-1 expression vector. These recombinant ACcec was highly expressed in *E.coli* BL21 (DE3) pLysS by fusing glutathione S-transferase (GST) and optimal induction concentration of IPTG. The expressed proteins, fused to GST, were purified by glutathione-Sepharose 4B affinity chromatography. After purification, the GST fusion partner was cleaved by thrombin. After thrombin digestion of GST-ACcec fusion protein were detected by SDS-PAGE.

POSTER PRESENTATION

A molecular phylogeny of the tribe Aphidini (Insecta: Hemiptera: Aphididae) based on the mitochondrial tRNA/COII, 12S/16S, and the nuclear EF1α genes

Hyojoong Kim, Seunghwan Lee

Seoul National University, Seoul, Republic of Korea

A phylogeny of the tribe Aphidini (Hemiptera: Aphididae) was reconstructed from three gene fragments: two mitochondrial regions, partial tRNA-leucine + cytochrome oxidase II (tRNA/COII), partial 12S rRNA + tRNA-valine + 16S rRNA (12S/16S), and one nuclear gene, the elongation factor-1 alpha (EF1α). Three minimum evolution phylogenetic analyses were performed on each individual dataset of tRNA/COII, 12S/16S, and EF1α, and maximum parsimony, Bremer support test, maximum likelihood, and Bayesian phylogenetic analyses were performed on the combined dataset. After comparing our molecular phylogenetic results with the classical classification based on morphological and ecological data, we analyzed three main issues: the monophyletic relationships among tribes and subtribes, the validities of the latest taxonomic positions of genera and species, and the status of certain *Aphis* species groups. Our results indicate that 36 of the species analyzed, with the exception of *Cryptosiphum artemisiae*, are clustered within the monophyletic clade of Aphidini. Also, the 28 species selected in the subtribe Aphidina were separated from the 8 species selected in Rhopalosiphina; each monophyletic subtribe was supported by significant *P* values in the combined analysis. According to our results, *Cryptosiphum* should be moved to Macrosiphini because it is more closely related to the genera *Lipaphis* and *Brevicoryne*. The genus *Toxoptera* was recovered as non-monophyletic. In Rhopalosiphina, three genera, *Hyalopterus*, *Rhopalosiphum*, and *Schizaphis* were relatively closer to each other and than to the genus *Melanaphis*. In the relationships between species-groups among *Aphis*, most species were separated to the two main lineages; the *fabae* group seemed to be more closely related to the *spiraecola* and *craccivora* group rather than to the *gossypii* group.

POSTER PRESENTATION

Difference in aphid and fly host-driven divergence of *Entomophthora*

Annette Bruun Jensen[1], Jørgen Eilenberg[1], Claudia Lopéz Lastra[2]

[1]University of Copenhagen, Copenhagen, Denmark, [2]Universidad Nacional de La Plata, La Plata, Argentina

Several species of the fungal genus *Entomophthora* infect higher dipterans (Cyclorrhapha): *E. fernandii*, *E. grandis*, *E. muscae*, *E. scathophagae*, *E. schizophorae* and *E. syrphi*. In comparison, only two aphid pathogenic *Entomophthora* species, *E. chromaphidis* and *E. planchoniana* have been described. Recently molecular analyses have confirmed the species status of most of the fly pathogenic *Entomophthora*, while it has been questioned whether the two aphid pathogenic *Entomophthora* species are distinct species, since they cannot be distinguished molecularly. In addition, molecular analyses have revealed high intra-specific variation within *E. muscae* showing that each host species harbor its own fungus genotype.

In the current study we sequenced several DNA regions of *Entomophthora* originating from different fly and aphid host taxa. The results documented a huge genetic divergence of the fly pathogenic *Entomophthora* in comparison to the aphid pathogenic *Entomophthora*, where only minor differences in the sequences where detected. The evolutionary time of divergence of the fly and the aphis host taxa included in this study cannot account for this difference. The host driven divergence of *Entomophthora*, therefore, is much higher in flies compared to aphids. A recent host shift of *Entomophthora* to become pathogens of aphids is an alternative hypothesis explaining the lack of differentiation seen in aphid pathogenic *Entomophthora*.

POSTER PRESENTATION

Novel insecticidal alkaloids from *Alstonia boonei* De Wild (Apocynaceae)

Nathaniel Oigiangbe, Benjamin Igbinosa, Manuele Tamo, Osayande Eguavoen

Ambrose Alli University, Ekpoma, Edo State, Nigeria

Alstonia boonei De Wild (Apocynaceae) is an important medicinal plant in the rain forest regions of West and Central Africa. Bioactive compounds found in this plant include alkaloids, saponins, tannins, cardiac glycosides and flavonoids. In some preliminary bioassays, the crude water and methanol extracts of the leaves and stem bark were effective against *Maruca vitrata* Fabricius and *Sesamia calamistis* Hampson. Several indole alkaloids have been reported from *A. boonei*. We tested the mixture of crude alkaloids from *A. boonei* against *M. vitrata* in a bioassay. There were significant differences in the survival, growth, and duration of development of the insect when reared on artificial diet incorporated with 0.0 ppm (control), 1.0 ppm, 2.5 ppm and 5.0 ppm of the alkaloids. At ten days after introduction (10 DAI) the survival of the larvae ranged from 70.83 % in the 5.0 ppm treatment to 91.67 % in the control. Similarly, larval weight ranged from 18.59 mg in the 5.0 ppm treatment to 40.09 mg in the control. Fifteen days after introduction, 62.5 % of the larvae in the control diet were at the pupal stage and 20.83 % at the pre-pupa stage. The percentage pupation was 0.0, 25.00 and 33.33 in the 5.0 ppm, 2.5 ppm and 1.0 ppm treatments, respectively at 15 DAI. The bioactivity of each of the individual alkaloids against *M. vitrata* and *S. calamistis* will be evaluated within the next four months. The potential of each alkaloid in the management of these insects will be discussed.

POSTER PRESENTATION

Early Jurassic trace fossils of possible termite origin

Adam Bumby[1], Emese Bordy[2], Christian Pirk[3], PW (Bill) Bateman[3]

[1]Department of Geology, University of Pretoria, Pretoria 0002, South Africa, [2]Department of Geology, Rhodes University, Grahamstown 6140, South Africa, [3]Department of Zoology and Entomology, University of Pretoria, Pretoria 0002, South Africa

Bioturbated sandstone pillars at Mapungubwe (South Africa), at the confluence of the Limpopo and Shashe rivers, and in western Lesotho are preserved in aeolian sandstone of the Lower Jurassic Clarens Formation. Preserved pillars are up to 3.3 m high, often elliptical in plan, and are orientated N-S. Typically the pillars have bent apices, and are inclined towards the east. Pillar walls are characterised by an anastomosing network of approximately 5 mm diameter sandstone tubes, some of which have preserved meniscate back-filling. Other pillars have smooth outer walls, which may surround an empty space.

The pillars resemble termite nests, which were coeval with the Clarens Formation. The eastward-inclined apices are thought to reflect nest construction within dominantly westerly palaeowinds, derived from the dip-direction of aeolian dune foresets. Tube networks with rare backfilling are interpreted as galleries within the termite nest, and empty spaces are thought to be preserved paracaie structures. The elliptical shapes of nests may be to enhance diurnal cooling of nests, or to enhance nest respiration by build-up of a pressure gradient, as nests appear to be constructed perpendicular to the prevailing palaeowind.

Although the state of preservation of the pillars does not allow for a fully conclusive interpretation, the similarity of these trace fossils to structures constructed by modern-day termites is striking, and the possibility of eusocial termite-like colonies having evolved in semi-arid environments by the Early Jurassic should be bourn in mind.

POSTER PRESENTATION

Altitudinal variation of dung beetle communities in Sierra Nevada Mountains (Southeast Spain)

Rocío Márquez-Ferrando[1], Adela González-Megías[1], Rosa Menéndez[2]

[1]Universidad de Granada, Granada, Spain, [2]Lancaster University, Lancaster, United Kingdom

We studied dung beetle communities of the Sierra Nevada Mountains (southeast of Spain) a region of high animal and plant diversity in Europe. We examined changes in species richness, abundances and community composition along altitudinal gradients (from 800m to 2500m) on both northern and southern facing slopes. Beetles were collected using dung-baited pitfall traps during three months (May to July) and in two consecutive year (2006 & 2007). We recorded 47 dung beetles species (21 Scarabaeidae, 2 Geotrupidae and 24 Aphodiidae). Total species richness increased with altitude as well as the species richness of the two dominant families (Scarabaeidae and Aphodiidae). Although Scarabaeidae was the richest taxa at all altitudes, the proportion Scarabaeidae species decreased with altitude and the opposite was observed for Aphodiidae. The number of individuals collected was not significantly related to altitude when considering all species together or when considering only Scarabaeidae species, but did increase with altitude for Aphodiidae species. Aspect did not have an effect on the relationship between species richness and altitude for any of the studied groups but it affected the relationship between altitude and number of individuals. Species composition was also related to both aspect and altitude. We discuss our results in relation to those found in other mountain areas in Europe and the implications of our findings for the conservation of mountain dung beetle communities in view of future climate change.

POSTER PRESENTATION

Inhibition of esterases by synergists in the western flower thrips, *Frankliniella occidentalis* (Pergande)

Neus López-Soler, Amelia Cervera, Ana C. Maymó, Rafael Martínez-Pardo, María Dolores Garcerá

Universitat de València, Burjassot, Valencia, Spain

Introduction: Synergists are frequently utilized as indicators of the possible biochemical mechanisms involved in insecticide resistance. The fact that piperonyl butoxide (PBO), a known inhibitor of oxidases, also inhibits esterase activity, and that some insecticides act as synergists, points out the necessity to investigate the direct effect of synergists on enzyme activity, in order to corroborate the resistance mechanisms of insects to insecticides. In this sense, we have investigated the effects, both *in vivo* and *in vitro*, of two synergists (PBO and *S*,*S*,*S*-tributyl phosphorotrithioate (DEF)) and one insecticide (metiocarb) on total esterase activity of one susceptible and three laboratory selected resistant strains to acrinathrin, formetanate and metiocarb of the western flower thrips *Frankliniella occidentalis* (Pergande). At the same time *in vitro* inhibition of esterase isoenzymes by sinergysts has been analyzed.

Methods: α-naphthyl acetate esterase activity was measured with a Tecan Spectrafluor microplate reader. *In vitro* determinations were performed incubating homogenates from each individual strain with the synergists. For *in vivo* bioassays insects were treated with the synergists and after 10, 20, 30, 60 or 90 min, freeze at -80ºC until use. *In vitro* inhibition of esterase isoenzymes was performed in native conditions polyacrilamide gel electrophoresis.

Results: DEF is the compound with major esterase inhibitory capability independently of the studied strain. On the other hand electrophoretic study of esterase isoenzymes reveals that DEF inhibition points to a specific group of three isoenzymes previously described by our group as related to insecticide resistance. PBO inhibition was greater after 90 min of treatment.

POSTER PRESENTATION

P450 activity in *F. occidentalis* (Pergande)susceptible and resistant strains strains

Ana C. Maymó, Amelia Cervera, Neus López-Soler, Rafael Martínez-Pardo, María Dolores Garcerá

Universitat de València, Burjassot, Valencia, Spain

Introduction: The western flower thrips (WFT), *Frankliniella occidentalis* is one of the main pests of horticultural crops in Southern Spain and has become an economic problem. Recently this species has been reported with the highest number of control failures in Spain, due to its ability to develop resistance under high insecticide pressure, as is the case of greenhouse cultures of the SE of Spain. MFOs have been reported as enzymes responsible for resistance mainly based in bioassays with synergists (PBO). On the other hand, it has been indicated the difficulty to measure directly P450 oxidase related activities in *F. occidentalis* extracts. So, we have tried to quantify and to compare P450 activity in one susceptible and three laboratory selected resistant strains to acrinathrin, formetanate and metiocarb of the western flower thrips *Frankliniella occidentalis* (Pergande).

Methods: 7-ethoxycoumarin (ECOD) P450 activity was measured with a Victor 1420 multilabel HTS counter (Wallac) using the kinetic mode for 10 min. An aliquot of 20µL of extract from a pool of insects was used as enzyme source.

Results: Preliminary results indicate that selected resistant strains have higher ECOD activity than the susceptible one. The study of the Michaelis Menten constant calculated for each strain seems to indicate that the higher activities found in the resistant strains are due to a higher proportion of enzyme present in the sample, rather than to a better efficiency of it.

POSTER PRESENTATION

Biological control of *Oligonychus perseae* (Acari: Tetranychidae) on avocado in the Canary Islands (Spain)

Estrella Hernandez-Suarez, Eduardo Torres, Yiselle Velazquez, Aurelio Carnero, Francisco Ferragut

ICIA, La Laguna, Canary Islands, Spain

Introduction: *Oligonychus perseae* Tuttle, Baker and Abbatiello is a pest of avocado that has reached the Mediterranean Basin and the Canary Islands in recent years. This species has become a major pest of avocados in the Canarian archipelago, causing defoliation of trees that indirectly produce important yield looses due to sunburn damage and premature fruit drop. The aims of this study were to (1) identify the indigenous predatory fauna on avocado, (2) understand the population dynamics of *O. perseae* and their main predators and (3) study the effect of inundative releases of *Neoseiulus californicus* (McGregor) to improve biological control.

Methods: In 2006-2007, avocado production areas were surveyed to identify the predatory fauna of *O.perseae* and two commercial avocado orchards were selected to study fluctuations in mite populations. Two field trials were conducted in early spring and late summer 2007 to evaluate the effects on *O.perseae* populations of releases of *N. californicus* at two rates of 1000 and 2000 per tree.

Results: Ten phytoseiid species were found associated with *O.perseae*, being *Euseius stipulatus* (Athias-Henriot) the dominant species, followed by *Iphiseius degenerans* (Berlese) and *N. californicus*. Two population peaks of the persea mite occurred in summer (June-July) and autumn (October-November). Phytoseiid mite populations (mostly *E. stipulatus*) peaked in summer (August) and autumn (November), following spider mite increases, but *O. persea* leaf damage still not admissible by growers. *N. californicus* releases did not improve *O. persea*e control in any of both field trials.

POSTER PRESENTATION

Scale-dependent responses in cabbage herbivores affect attack rates in spatially heterogenous systems

Peter Hambäck[1], Maria Björkman[1], Birgitta Rämert[2]

[1]Dept Botany, Stockholm University, Stockholm, Sweden, [2]Dept of Plant Protection Biology, Swedish University of Agricultural Sciences, Alnarp, Sweden, [3]Dept of Ecology, Swedish University of Agricultural Sciences, Uppsala, Sweden

Herbivorous insects face a dilemma when selecting suitable hosts in a complex environment, and their sensory capability may often reduce the female capacity for proper selection. This has the consequence that eggs are often deposited on inferior hosts, affecting both on insect and host plant fitness. We examined the attack rates of three cabbage herbivores in monocultures and bicultures plots, of different *Brassica oleracea* genotypes, with different spatial heterogeneity. The main goals of the study were to improve our understanding of the spatial scales involved in herbivore search processes and to examine the possibility of using spatial heterogeneity for manipulating pest attack rates in cabbage cropping systems. The results showed that the host selection behavior of the small white butterfly (*Pieris rapae*) was strongly dependent on spatial heterogeneity. The difference in egg density between plant genotypes was larger when contrasting plants were growing in close proximity than among monoculture plots This suggests that *P. rapae* is able to compare among genotypes from a small distance, while selection is compromised at larger spatial scales. The two other herbivores in the study (*Mamestra brassicae* and *Delia radicum*) did not respond to heterogeneity at any spatial scale, but showed a constant preference hierarchy. This suggests that host selection for these species occurs on direct plant contact. The difference in species responses to spatial heterogeneity has consequences both for selection gradients in natural communities and for the potential to reduce pest attack in polyculture systems.

POSTER PRESENTATION

Diocalandra frumentii (Coleoptera: Curculionidae), a new pest for palms in the Canary Islands

Aurelio Carnero, Antonio Gonzalez, Jose Esteban, Nuria Casañas, Angeles Padilla

ICIA, La Laguna, Canary Islands, Spain

Introduction: This species is a plague known only in the islands located in the Pacific and Indian oceans, introduced into the Canary Islands in an unknown way. Now it strongly attacks Canarian palms and palm-like species in Tenerife and Gran Canaria. *D. frumentii* is a small curculionid. During its larval stage it digs in the base of the leaves and in the crown, producing desiccation and plant death. The pest is a problem very difficult to control. Furthermore it could spread to the European mainland. There are no known natural enemies, and its vital cycle in the field is poorly known.

Methods: At present, breeding is taking place in chambers, under artificial conditions. Improved artificial diet or natural (based on sugarcane) are taking place, in order to know the biology and development of *D. frumentii*, and also to compare with results obtained by other authors (González-Nuñez et al, 2002). Then, the biology in field and semi-field conditions are going to be studied. Also, control assays using native strains of entomopathogenic nematodes and fungi from our collections will be developed.

Results: It is known that, with sugarcane, it takes 7,8 days for eggs, 76,2 days for the larval stage and 10,2 for the pupa (González-Nuñez el al, 2002). Survival was very low in normal artificial diet conditions. Results regarding to entomopathogenic organisms are not finished.

POSTER PRESENTATION

Semi-field assay using a strain of *Metarhizium anisopliae* (Metschn.) for the control of *Cosmopolites sordidus* (Germar, 1824) (Coleoptera: Dryophthoridae)

Angeles Padilla, Aurelio Carnero, Dulce Molina, Luis Lopez, Carolina Fernandez

ICIA, La Laguna, Canary Islands, Spain

Introduction: The potential use of a strain of *M. anisopliae* isolated in the Canary Islands was assayed in semi-field conditions. The bioformulation of this organism was developed by FuturEco S.L.

Methods: The assay was performed in greenhouse conditions, using Nemacur® 10G, a commercial bioformulated bioformulation (Botanigard®) based on *Beauveria bassiana*, the strain of *M. anisopliae*, and the control. The plague development was tested 35, 77 and 120 days after transplanting. Along the experiments, the following variables were taken in account: situation and number of *C. sordidus*, abundance and stages of *C. sordidus*, infestation coefficient at the border level, base and transversal cut. Two methods (Guzmán, 1994 y Vilardebó, 1973) were used to evaluate damage produced by larvae in the rhizome.

Results: According to the obtained results, both the commercial formula and the strain of *M. anisopliae*, act as control agents against adult *C. sordidus*. *M. anisopliae* can be an effective alternative to the chemical control of this insect.

POSTER PRESENTATION

Elucidation of defence pathways activated in Betta near isogenic wheat lines upon infestation by *Diuraphis noxia*

Thia Schultz, Anna-Maria Botah-Oberholster

Department of Genetics & FABI, University of Pretoria, Hillcrest, Pretoria, Gauteng, South Africa

Russian Wheat Aphid (*Diuraphis noxia*, Kurdjumov) has yet again become a focal point to research and commercial fields after the recent development of new RWA biotypes. The mechanism of defense, conveyed by each *Diuraphis noxia* (*Dn*) gene differ i.e. *Dn1* confers an antibiotic resistance, while *Dn2* confers a tolerance for aphid infestation. We aimed to investigate the systemic changes and biological pathways activated due to systemic acquired resistance (SAR) conferred by *Dn1* and *Dn2*. For this propose, we used susceptible 'Betta' and two resistant near isogenic lines 'BettaDN' and Betta *Dn2*, in cDNA-AFLPs to identify transcripts affected by RWA infestation. 146 transcript derived fragments (TDFs) where sequenced characterized for putative identification with BLASTn and BLASTx. Transcripts where grouped into the following cellular processes: Amino acid metabolism, nucleic acid processing, fatty acid and lipid metabolism, starch and sucrose metabolism, protein folding, cell cycle, cell maintenance, membrane proteins, chloroplast or photosynthesis related, defense or stress related, unknown proteins and proteins with no homology. TDFs carrying material from 'BettaDN' had identities such as; defence F-box protein, Zinc finger-like protein, chaperone proteins, annexin-like protein, WAP2 kinase, Zn-dependant protease and ubiquitin specific protease; while TDFs from material from Betta *Dn2* showed; Na+/H+ antiporters, P-type ATPase transporter, Zinc transporter, Integral membrane protein NRAMP, Cytochrome p450, ATP dependent Clp protease- chloroplast precursor and non-phototrophic hypocotyls 1b.

POSTER PRESENTATION

How sensitive are insects compared to other aquatic organisms for the presence of cyanobacterial biotoxins in drinking water?

Paul Johan Oberholster, Bongiwe LS Mthethwa, M Callies Selala

Department of Genetics & FABI, University of Pretoria, Hillcrest Pretoria, South Africa

Bloom-forming cyanobacteria in eutrophic surface waters have caused increasing concern over the last decade in South Africa due to their toxic potential. Due to a lack of toxin standards and resource limitations for wide scale use of analytical methods (i.e. high-performance liquid chromatography and enzyme-linked immunosorbent assay) in cyanobacterial toxin monitoring, it is necessary to assess and develop additional methods that is rapid yet realistic and cheap for the detection of cyanobacterial toxins in rural water treatment plants of South Africa. A well-known cyanobacterial secondary metabolite, microcystin-LR and dominant cyanotoxin in South Africa, was tested for its effect on insects, i.e. *Periplaneta americana* (American cockroach); *Tenebrio molitar* (yellow mealworm) and *Gryllus bimaculatus* (common cricket) and the macrophyte *Spirodela punctata* (duckweed); as well as the crustacean zooplankton (*Artemia salina*). LD_{50} values calculated for *Gryllus bimaculatus* and *Artemia salina* body weight were respectively 0.45 µg/animal and 0.1 µg/animal within 48 h, making these organisms as sensitive to low concentrations of microcystin-LR as the mouse bioassay. No 48 h LD_{50} was established for any of the pure microcystin-LR (0.5, 1.0, 5.0 $\mu g l^{-1}$) concentrations in the conducted *Periplaneta americana* and *Tenebrio molitar* bioassays. DNA laddering was also detected in *Periplaneta americana*, *Tenebrio molitar*, *Artemia salina* and *Gryllus bimaculatus* within the first 48 hours. Although ease of culturing the American cockroach and yellow mealworm make them the ideal organisms to include in a battery of bioassays, their 48h LD_{50} non response to low levels of microcystin exclude them from a rapid sensitive bioassay.

POSTER PRESENTATION

Understanding potential effects of climate change on dung beetle communities in subtropical rainforests of Australia

Rosa Menéndez[1], Geoff Monteith[2]

[1]Lancaster University, Lancaster, United Kingdom, [2]Queensland Museum, Brisbane, Australia

We investigated changes in dung beetle communities along an altitudinal gradient in a subtropical rainforest in order to asses the sensitivity of different species to changes in temperature and to identify potential bio-indicators for future climate change. The work took place in Lamington National Park, Queensland, Australia. The sampling protocol consisted of using four baited pitfall traps and one flight intercept trap to collect the dung beetles in four replicate (1ha plots) positioned at five altitudes: 300m, 500m, 700m, 900m and 1100m. A total of 33 species of native dung beetles (Coleoptera, Scarabaeinae) were collected along the altitudinal gradient; all of them exclusives to the rainforest. Examination of individual species distributions along the altitudinal transect showed a highly stratified fauna, and that no single species occurs at all elevations. The lowest zone (300m) has not only the most diverse fauna (22 species), but also 41% of species which occur there do not occur any higher than 500m. The highest zone (1100m) has a small fauna of 9 species but 78% of those are restricted to high elevations extending downwards only as far as the 900m. These results suggest that species altitudinal distributions are probably constrained by climatic conditions, and they are likely to be affected by global warming. We discuss the potential effects of climate change on individual species based on their occurrence along the altitudinal gradient as well as their geographic distribution in Australia.

POSTER PRESENTATION

How persistent are the dorsal abdominal scent glands in the Heteroptera adults?

Jitka Vilimova, Katka Kutalova

Charles University, Faculty of Science, Department of Zoology, Prague, Czech Republic

Introduction: The specific scent gland system represents the autapomorphy of the Heteroptera. The dorsal abdominal scent glands (DAGs) were originally supposed to be the unique nymphal structure. However, recently the persistence of DAGs in adult stage has been proved for more and more heteropteran taxa.

Methods: The material of Central European representatives was analysed. The dissected heteropteran adults were studied using standard optical and scanning electron microscopes.

Results: The following diversity of morphological traces of DAGs in heteropteran adults was found: Neither any part of scent system, nor its remnant maintained (e.g., representatives of Notonectidae, Nepidae, Naucoridae, most of Gerridae, Cimicidae). Differently conspicuous scars in location of nymphal DAGs developed (e.g., representatives of Lygaeidae, numerous Pentatomoidea). Small, probably partly full, variable conspicuous gland reservoirs developed (e.g., Corixidae, Aphelocheiridae, Saldidae, Tingidae, Aradidae, numerous Pentatomoidea). Apparently full, one to three reservoirs developed, sometime sexually dimorphic (e.g., Pyrrhocoridae, Rhopalidae, many Pentatomoidea - most frequently predacious Asopinae). The largest number of full reservoirs, four, developed in representatives of Dipsocoromorpha.

Conclusions: DAGs are very probably persistent, and functional?, in heteropteran adults in larger extent than was believed. DAGs are not almost generally maintained in the adults of Nepomorpha and Gerromorpha. On the contrary, DAGs are very often persistent in all the other heteropteran infraorders. The only one conclusive evidence for the adult functional DAG is the full gland reservoir and functional ostiole.

POSTER PRESENTATION

Mate number and paternity in *Plebeia remota*

André Ramos Vaquero, Maria Cristina Arias

São Paulo University, São Paulo/São Paulo, Brazil

Introduction: The stingless bees present large distribution, great diversity, very significant contribution as pollinator agents, and economic and medical value. Despite their biological and economic importance, basic aspects about their biology and evolution are still not elucidated. The multiple mate in Hymenoptera is relatively common, however in stingless bees only few studies on this subject have been published. To increase our understanding on this behavior the species *Plebeia remota* was choosen as experimental model. This species has a small body size and small number of individuals per nest. The literature has postulated that queens of *P. remota* mate once, However all these studies are based on just one temporal sample and one nest. The knowledge of queen mate number and the relationship degree among workers allows inferences on social evolution and conflict between queen and workers in the male production.

Methods: Workers and males from two colonies were collected monthly during one year, totalizing 123 individuals. Total DNA was extracted and used to PCR amplify microsatellite loci. Four loci were screening by using heterologous primers derived from *Melipona bicolor* (Mbi33, Mbi 215, Mbi 259 and Mbi278).

Results: The loci Mbi215, Mbi259 and Mbi278 presented two alleles each. By analyzing the males we could infer the queens genotypes, which were heterozygous for the three loci. Also most of the workers were heterozygous, however in different temporal samples we found workers homozygous for either alleles.

Conclusion: The data indicated that the queens likely were mated by at least two males.

POSTER PRESENTATION

The effect of nematicide vapors on the spiraling whitefly, *Aleurodicus dispersus* Russell (Homoptera: Aleyrodidae) population and its natural enemies.

Helga Blanco-Metzler[1], Sergio Laparade Coto[2]

[1]University of Costa Rica, San Jose, Costa Rica, [2]CORBANA, San Jose, Costa Rica

Introduction: Side effect of pesticides on natural enemies has been widely documented; phytophagous organisms previously innocuous can become frequent and serious pests due to beneficial organism destruction. This study was conducted to determine if nematicide vapors were responsible for the spiraling whitefly outbreaks and the reduction of their natural enemies in banana plantations of Costa Rica.

Methods: The effect of terbufos (Counter®), terbufos (Bioquím®), carbofuran (Furadan®), cadusafos (Rugby®) and fenamifos (Nemacur®) on the spiralling whitefly and its parasitoid, *Encarsiella* spp. population was evaluated. The number of live and parasityzed nymphs of *A. dispersus* were evaluated prior to nematicide application as at 15, 30, 45 and 60 days after pesticide application.

Results: The total number of nymphs was greater when Counter and Bioquim were applied, while parasitoid population was greater in the control and the lesser *Encarsiella* population was found when Bioquim was applied. The study showed that organophosphates affected the pest-parasitoid equilibrium. Since nematicides are of obligatory use in banana production, there is a need to understand the timing of pesticide application.

POSTER PRESENTATION

Phoretic behavior of a scelionid egg parasitoid on its reduviid host

Walker Jones[1], William Warfield[2]

[1]*European Biological Control Laboratory, ARS, USDA, CS90013 Montferrier sur Lez, France,*
[2]*Beneficial Insects Research Unit, ARS, USDA, Weslaco, TX, United States*

Introduction: Although telenomine parasitoids of Heteroptera eggs may use adult-produced cues to locate host eggs, few are known to search for and mount adult female hosts to await an oviposition bout. A new such association has been discovered between an undescribed *Telenomus* sp. and the assassin bug, *Sinea coronata* (Reduviidae) in Texas.

Methods: A field survey was conducted to record the frequency of male and female hosts bearing *Telenomus* sp. individuals. Laboratory observations were recorded on Host defensive behaviors, and parasitoid mounting and positioning behaviors were recorded in the laboratory.

Results: Twenty-three of 33 mating pairs observed in the field had at least one parasitoid mounted; only once was a parasitoid observed on the male. Of 113 solitary males observed, 33 (29%) had at least one parasitoid mounted; 14 had more than one parasitoid (2-4). Of 115 females observed, 67 (58%) possessed phoretic parasitoids; 40 were carrying from 2 up to 13 individual parasitoids. All parasitoids observed on adult hosts were female. Host females resisted mounting of stalking parasitoids by kicking. Immediately upon mounting, the host frequently released its grip on the substrate. Other defensive behaviors included wing-buzzing and leg-rubbing. Solitary parasitoids preferred to position themselves on the dorsum of host females along the midline of the pronotum, mesonotum or scutellum, sometimes with movement among these sites during the day. Multiple parasitoids on a single host usually distributed themselves over the same areas that solitary parasitoids preferred. No evident competition was observed among parasitoid individuals.

Conclusions: A new phoretic relationship is described between an egg parasitoid and its predaceous host. It is unclear what the attractant cues may be, but are clearly different from the *Telenomus calvus* - *Podisus maculiventris* (Pentatomidae) system.

POSTER PRESENTATION

The French Quarter program: A pilot program for area-wide integrated pest management of formosan subterranean termites in New Orleans, Louisiana, USA

Dennis Ring[1], Alan Morgan[1], Frank Guillot[2], Alan Lax[2]

[1]LSU agCenter, Baton Rouge, Louisiana, United States, [2]USDA, ARS, Southern Regional Research Center, New Orleans, Louisiana, United States

The Formosan subterranean termite, *Coptotermes formosanus*, is a serious pest where it has become established and is one of the most destructive insects in Louisiana. A pilot test was begun in 1998 in the French Quarter to demonstrate the effectiveness of using area-wide management. All properties in a contiguous 15 block area were treated using commercially available baits or non-repellent termiticides. The treatment zone was expanded in 2002, 2003, 2006, and 2007. Glue boards were used to estimate alate numbers and in-ground monitors for foraging activity. Alates were sampled once a week in April and two to three times weekly from May to July 15 in 1998 through 2008. Monthly monitoring of foraging activity began in January, 1999. These data showed that area-wide management reduced termite activity by 50 % within two years after initial treatment and overall by 75 % in the first area treated. Isolated areas of "high" termite activity remain inside the test area. Thorough inspections of properties assisted by infrared videography are being conducted to allow discovery and treatment of colonies which have, so far, escaped treatment. Such treatments are expected to further reduce termite numbers. Continued treatment, expansion, and monitoring are required to assess the long-term effects of the area-wide management program.

POSTER PRESENTATION

Effect of habitat and trap depth on pitfall trap catches of ground dwelling invertebrates

Colin Bergeron, Evan Esch, Jaime Pinzon, John Spence

University of Alberta, Edmonton,Alberta, Canada

Introduction: Biases of the long used pitfall trap sampling method in assessing ground dwelling invertebrate communities are well acknowledged. However, the effects of the depth at which the opening of the trap is located in the ground profile (potentially arising from installation irregularity) remains unknown. The goal is to quantify the combined effect of trap depth and habitat on pitfall trap catches of Coleoptera (Carabidae and Staphylinidae) and Araneae.

Methods: Three nested replicate of six pitfall traps were installed in White spruce dominated, Aspen dominated and Black spruce dominated habitats of the Boreal Mixedwood forest of Western Canada. In each site, three randomly selected traps were installed with the opening at the level of mineral soil (15 to 25 cm below the forest floor) and three other with the opening at the level of the forest floor.

Results: More specimens and species were caught in the surface traps than in the deep traps. Few species characteristic of deep traps are known to be underestimated when comparing pitfall traps to litter washing. The effect of trap depth and habitat is more obvious on beetles than on spiders. Habitat overrides the effect of trap depth in multivariate analysis.

Conclusions: The trap to trap depth variation in pitfall trap studies is of minimal importance when analyzing composition data using multivariate analysis. However, the use of pitfall traps by itself to evaluate the density of certain species is erroneous as some species crawl in the litter and their density is not adequately estimated.

POSTER PRESENTATION

Efficacy of YieldGard® corn borer and VT PROTM Bt corn hybrids against key lepidopteran insect pests in the United States and South America: The reduction of Aflatoxin in grain produced from Bt corn hybrids under insect infestation

Isaac Oyediran, Oscar Heredia, Guillermo Videla, Claudio Robredo, Juan De Santa Eduviges, Paula Bodrone, Ricardo Miranda

Monsanto Company, St. Louis, MO, United States

Introduction: Monsanto developed YieldGard® Corn Borer hybrids expressing the Cry1Ab protein. These hybrids have provided excellent control of corn borers; European corn borer (*Ostrinia nubilalis*), southwestern corn borer (*Diatraea grandiosella*), and sugarcane borer (*Diatraea saccharalis*). New corn hybrids, YieldGard VT PRO™ expressing Cry1A.105 and Cry2Ab2, two lepidopteran insecticidal proteins, are effective for controlling these key lepidopteran stalk-borers, as well as corn earworm (*Helicoverpa zea*), and fall armyworm (*Spodoptera frugiperda*). These lepidopteran insects can cause significant damage to corn resulting in grain and yield reduction. Damaged grains have high fungal infestation, leading to unacceptably high levels of aflatoxin in the grains.

Methods: Trials were conducted in the United States and South America to test the efficacy of YieldGard®, YieldGard VT PRO™ and Non-Bt corn against key lepidopteran pests. Aflotoxin concentration in grains under insect infestation was determined only in the U S.

Experimental design was randomized complete block (RCB) with four replications. Data were collected on leaf feeding, stalk tunneling, ear damage, and aflatoxin concentrations in grains. Data were analyzed using SAS statistical software (SAS Institute Inc. 2003) and subjected to analysis of variance (ANOVA). Means were separated by LSD test at $\alpha = 0.05$.

Results: Insect damage and aflatoxin concentrations varied significantly. Compared to the YieldGard® and YieldGard VT PRO™ hybrids, insect damage and aflatoxin concentrations in the Non-Bt hybrids was significantly higher.

Conclusion: YieldGard® and YieldGard VT PRO™ hybrids provided excellent control against key lepidopteran insect pests. Aflatoxin levels were very low in the grains of these hybrids under insect infestation.

POSTER PRESENTATION

Evaluation of bagging materials for the control of the fruit fly *Anastrepha* sp. (Diptera:Tephritidae) in Taiwaneese guava fruits (*Psidium guajava* L.) variety Tai-kuo bar in Carrillos Bajos de Alajuela, Costa Rica.

Helga Blanco-Betzler[1], Rossy Morera[1], Carlos Loria[2]

[1]University of Costa Rica, San Jose, Costa Rica, [2]University of Costa Rica, Alajuela, Costa Rica

Introduction: The main problem in guava production is fruit fly damage; this insect feeds inside the fruit and facilitates the entrance of pathogens and fruit drop.

Methods: This study evaluated different materials used for making protective bags for guava fruits in order to reduce fruit fly damage and pathogen presence, as well as to extend their life expectancy in the field. The study took place during the dry and rainy seasons. During the first phase four different bagging materials were evaluated: waxed paper, nylon fabric, Taiwan bag and telephone guide paper, the latter normally used by local farmers; for the second phase only Taiwan and nylon bags were used.

Results: Highly significant differences were found during the first bagging period in terms of percentage of protected fruit where nylon > Taiwan > waxed paper > telephone guide paper. For the second period nylon bags protected more fruits than Taiwan bags. The longest duration of the bag in the field was obtained with nylon followed by telephone guide paper, Taiwan and waxed paper bags. For the second phase Taiwan outlasted nylon. Telephone guide paper and nylon yielded the highest amount of infected fruit during the first and second periods respectively. The highest number of fallen fruit was obtained in the control during the first phase. The results of this research show that the use of the nylon bag offers the highest protection against the fruit fly; however it doesn't protect against pathogens which also affect guava production.

POSTER PRESENTATION

Durivo (Thiamethoxam plus Clorantraniliprole) to control Asian citrus psyllid *Diaphorina citri*, citrus leafminer *Phyllocnistis citrella* and brown citrus aphid *Toxoptera citricida* in citrus drench application

Santin Gravena[1], Renan Gravena[1], Sergio Benvenga[1], Jose Silva[1], Adriana Gravena[1], Paulo Aramaki[2]

[1]Gravena Ltd., Jaboticabal, SP, Brazil, [2]Syngenta Crop Protection, São Paulo, SP, Brazil

Introduction: *Diaphorina citri* (Hemiptera: Psyllidae), *Phyllocnistis citrella* (Lepidoptera: Gracillariidae), *Toxoptera citricida* (Hemiptera: Aphididae) are associated to important diseases in Brazilian citriculture. This research was to test the ecological selective use of a new formulation mixture of Thiamethoxam + Clorantraniliprole, in drench application, to control those pests.

Methods: The trial was conducted in a citrus orchard, Matão, São Paulo, Brazil, var. Valencia, rootstock of lemon volkameriano, 2 years old and height of 2.0 m. The statistical design was the complete randomized blocks with 7 treatments, 4 repplications and the mean comparison was made under Tukey's test. The application of Durivo at dosages of 1.0, 1.5, 2.0, and 3.0 mL/plant were done in November 26, 2007, being Thiamethoxam in drench (Actara 250WG) and Imidacloprid on trunck spray (Winner) as standards treatments. The evaluations were made at 0, 7, 10, 14, 17, 21, 25 and 30 days after the applications. The number of nymphs anda adults of psyllids and aphids, and number of leafminer larvae were counted in 15 young terminals as well as the percet of presence on terminals was calculated.

Results: The directly application of systemic insecticides in soil or on trunk is a way to preserve natural enemies in citriculture as found by the results. Leafminers and sucking insects like aphids and psyllids are controlled by thiamethoxam, clorantraniliprole, as compared with imidacloprid and thiamethoxam sprayed on the citrus canopy.

Conclusions: Durivo was efficient at all dosages in drench application to control the psyllid, the leafminer and the aphid.

POSTER PRESENTATION

Mass production of entomopathogenic fungi for aerial use as mycoinsecticide

Buba Ahmed, Tariq Butt

Abubakar Tafawa Balewa University, Bauchi, Bauchi, Bauchi State, Nigeria

The development of resistance to chemical pesticides by insect pests as well as the public concern over their high cost and deleterious effects on environmental and human safety is at increasing rate. These concerns which are today compounded by perceived risks associated with genetic modification of plants have provided strong impetus and desire for the development of sustainable and environmentally friendly strategies for the control of insect pests. Interestingly, there have been increasing interests in exploitation of naturally occurring microorganisms (Bacteria, Fungi, Protozoa and Viruses) for use in the control of insect pests. Of the entire microorganisms, fungi have demonstrated high considerable potentials in providing environmentally friendly alternative to the use of chemical pesticides. Normally, the fungus will come into contact with the cuticle/body of the insect. The spore will germinate and penetrate into the body of the insect as a result of physical pressure and enzymatic degradation of the cuticle. The fungus will then invade the internal organs of the insects and starts to feed on the liquid content and at the same time secreting toxin until the insect finally died. The technology for the mass production of the fungus is accomplished by producing conidia of *Metarhizium anisopilae* on rice substrate. The first step was the preparation of a Sabouraud Dextrose Agar (SDA) broth media followed by formation of 3-day-old mycelium as shown in the figures. Thereafter, about 500g of rice was prepared (step 3) and transferred into an autoclaving bag (step 4) and autoclaved at 120 ºC for 20 minutes. After cooling, the rice was inoculated with 15ml of 3-day mycelium as shown in step 6. They were then inflated with sterile air, tied at the top and incubated at 25 ºC for 14 days (step7). Rice grains highly and fully colonized by fungus (inoculum) capable of controlling insect pests were harvested and obtained as shown in step 8. This was later transferred into commercial containers for distribution to farmers at a price lower than the conventional insecticides with a view to reduce poverty among our local farmers (step 9).

POSTER PRESENTATION

Occurrence of Mediterranean and Natal fruit flies (Diptera: Tephritidae) in the Western Cape Province, South Africa: Differences between orchards and home gardens

Nonto Mfeka, Aruna Manrakhan, Pia Addison

University of Stellenbosch, Stellenbosch,Western Cape, South Africa

Introduction: Mediterannean fruit fly, *Ceratitis capitata* (Wiedemann) and Natal fruit fly *C. rosa* Karsch are important pests of commercial fruits in the Western Cape Province of South Africa. Homegardens that contain multiple host species throughout the year are claimed to be potential breeding grounds for these pests and could be sources of infestation in orchards for the first ripening fruits. The aim of this study was to compare the abundance of these two species in orchards and homegardens and to determine the patterns of host use for each species.

Methods: Traps baited with a food attractant (Biolure, 3 component lure) were placed in commercial orchards and homegardens in five localities in Western Cape to monitor for adult fly activities. Various fruit species were sampled in orchards and homegardens on a monthly basis. Fruits were collected, brought to laboratory and incubated in plastic containers filled with sand for 6 weeks. Emerged flies were fed on protein and sugar for four days before being killed for identification.

Results & Discussion: In most of the study areas, adult fly activity was observed in homegardens throughout the year whilst in orchards very few or zero fly catch was recorded during winter, Fruit fly population in homegardens tended to be higher compared to orchards. Relative abundance of the two species was a function of locality and host species. Both Medfly and Natal fly were found to have a number of bridging hosts across the year. Practical implications of these results are discussed.

POSTER PRESENTATION

Sarcopromusca pruna (Shannon & Del Ponte, 1926): Not only a cattle dung breeding muscid fly

Thiago Moretti[1], Patrícia Thyssen[1], Daniel Solis[2]

[1]*São Paulo State University; Júlio de Mesquita Filhot; - UNESP, Botucatu, São Paulo, Brazil,*
[2]*São Paulo State University; Júlio de Mesquita Filhot; - UNESP, Rio Claro, São Paulo, Brazil*

Introduction: Despite taxonomic and morphological studies, and also investigations regarding to the adult development and to the role of the muscid fly *Sarcopromusca pruna* as the most important egg vector of *Dermatobia hominis* (Linnaeus Jr., 1781) in the Neotropical region, life history studies of *S. pruna* are still very scarce, particularly considering its immature stages.

Methods: During a field investigation conducted in a secondary forest (ca. 3,500 m^2) in the city of Campinas, Brazil (22°49'15''S, 47°04'08''W), from August 2003 to June 2004, aiming to analyze the composition of the local carrion invertebrate fauna, four carcasses were left inside iron cages in sunlit and shady areas twice a season for four seasons (n=16 carcasses of mouse and n=16 carcasses of rat). The visiting invertebrates were collected daily and identified. Immature forms were also collected and grown in laboratory for further identification.

Results: During the spring trial, we collected 2,749 dipteran larvae, belonging to the families Muscidae, Sarcophagidae, Calliphoridae and Fanniidae. From these, 20 larvae of *S. pruna* were collected from one mouse carcass (45,31 grams) exposed in the shady area.

Conclusions: The unexpected finding of juvenile forms of *S. pruna*, which has rarely been observed displaying a necrophagous behavior, may contribute to a better understanding of the biology of *S. pruna* immature stages. Moreover, due to its breeding in vertebrate carrion, we understand that this species can now be considered of potential forensic interest, and should not only be regarded as a cattle dung breeding dipteran.

POSTER PRESENTATION

A preliminary checklist of necrophagous insects associated to different environments in Southeastern Brazil: implications for forensic entomology

Thiago Moretti, Patrícia Thyssen, Wesley Godoy

São Paulo State University; Júlio de Mesquita Filho; - UNESP, Botucatu, São Paulo, Brazil

Introduction: Forensic entomology investigations have shown that the post mortem interval (PMI) may be estimated in two ways: by the age of the insect or by analyzing the succession and faunistic composition of the insects associated to carcasses.

Methods: The collections of insects were carried out monthly from September 2006 to March 2007 using as baits fish, cow liver and poultry viscera in appropriate bottle-traps in three different environments (rural, urban and forest area) in five municipalities in Southeastern Brazil.

Results: We collected adult members of the following species: Diptera: Calliphoridae: *Lucilia eximia* (n=110), *Lucilia cuprina* (n=4), *Chrysomya albiceps* (n=34), *Chrysomya megacephala* (n=22), *Chrysomya putoria* (n=9), *Mesembrinella bellardiana* (n=5) and *Cochliomyia macellaria* (n=16); Muscidae: *Musca domestica* (n=4); Otitidae: *Euxesta* sp. (n=4); Phoridae: *Megaselia scalaris* (n=16); Drosophilidae: *Drosophila* sp. (n=1); Piophilidae: *Piophila casei* (n=1); Lepidoptera: Nymphalidae: *Paryphthimoides poltys* (n=3), *Paryphthimoides prhonius* (n=1), *Fountainea ryphea* (n=3) and *Hermeuptychia hermes* (n=2); Riodinidae**:** *Cremna thasus* (n=1); Hymenoptera: Vespidae: *Agelaia pallipes* (n=62); Orthoptera: Tettigoniidae: Copiphorinae (n=1); Gryllidae: Nemobiinae (n=2). Interestingly, all the lepidopterans and all the specimens of *M. bellardiana* were caught in the forest area of the analized cities, which may be important to analize possible forensic indicators for this specific environment.

Conclusions: Information on the presence of insects from groups that are usually neglected as cadaveric fauna, associated to the knowledge on their biology and ecology, may provide important tools to increase the accuracy in the estimation of the post-mortem interval, when it is based on the succession patterns or faunistic composition.

POSTER PRESENTATION

Female sex pheromone of the sorghum plant bug, S*tenotus rubrovittatus* (Miridae)

Msasashi Kakizaki, Takeshi Teramoto

Hokkaido Dohnan Agricultural Experiment Station, Hokuto, Hokkaido, Japan

The sorghum plant bug, *Stenotus rubrovittatus* (Matsumura), is distributed in Japan, Korea, China, and eastern part of Russia and injures various gramineous crops and forage grasses, is one of important species causing a pecky rice in Japan. The female sex pheromone of this bug was analyzed by the GC-EAD method and GC-MS. Eleven EAD-active peaks by male antennae were found in hexane extracts of the female whole body. *n*-Hexyl *n*-butyrate were major components in female extracts. *n*-Hexyl *n*-butyrate, (*E*)-2-hexenyl *n*-butyrate, *n*-hexyl acetate, *n*-hexyl *n*-hexanoate, and *n*-hexyl (*E*)-2-hexenoate, and (*E*)-2-hexenyl acetate in the ratio of 1000 : 76-136 : trace–3.2: 21–35 : 6.3 : trace were contained in the female extracts, esters of *n*-hexan-1-ol were dominated in female extracts. On the other hand, esters of (*E*)-2-hexen-1-ol were dominated in male extracts, the relation of amounts of *n*-hexyl esters and (*E*)-2-hexenyl esters in the extracts were contrary between female and male. Field trapping tests using these synthetic compounds indicated that a mixture of *n*-hexyl *n*-butyrate, (*E*)-2-hexenyl *n*-butyrate, *n*-hexyl acetate, *n*-hexyl *n*-hexanoate, and (*E*)-2-hexenyl acetate are sex pheromone components. Optimum ratio of the 5-components for male attraction is narrow range, males were attracted to the mixtures of *n*-hexyl *n*-butyrate, (*E*)-2-hexenyl *n*-butyrate, *n*-hexyl acetate, *n*-hexyl *n*-hexanoate, and (*E*)-2-hexenyl acetate in the ratio of 100 : 10 : 1.5 : 2.5 : 0.03–1.0. The optimum doses on gray rubber septum are ranging from 100 μg to 300 μg *n*-hexyl *n*-butyrate in the 5-component mixture in this ratio for male attraction.

POSTER PRESENTATION

A preliminary screening of candidacy materials for development of monitoring tools of pumpkin fruit fly, *Bactrocera depressus* (Tephritidae: Diptera)

Kim Dong-Soon, Seo Yon- Dong, Choi Kyung San, Kang Taek Joon, Jeon Heung-Yong

Cheju National University, Jeju-si, Republic of Korea

Introduction: In Korea, total 85 species of Tephritid fly in 45 genera are recorded. Among them, the pumpkin fruit fly, *Bactrocera depressus*, is one of the most important pests in Cucurbitaceae plants, and this fly is considered a serious quarantine pest in foreign countries. Development of a monitoring tool is needed to control the flies successfully.

Methods: The attraction ability of various candidacy materials for *B. depressus* were evaluated in the field and laboratory. Materials included were methyl eugenol, cue-lure, protein sources, and volatiles from pumpkin fruits. Also, GC-EAD analysis was conducted for Orbo trap extracts of pumpkin odors.

Results: *B. depressus* showed no response to methyl eugenol and cue-lure in the field and laboratory. The protein sources of brewer hydrolysate and torula yeast attracted well *B. depressus* in the laboratory. However, a few adult flies were caught in the protein-baited traps in the field. The crude extracts from three varieties of pumpkin induced a behavioral response to *B. depressus* adults such as highly attraction and oviposition. Orbo trap extracts of the pumpkin odors had 8 to 10 common components. Some of them elicited significant EAG response from antennae of female flies.

Conclusions: Methyl eugenol, cue-lure, protein-baited traps were not appropriate as a monitoring tools of *B. depressus.* Adult flies showed significant behavioral and EAG responses to the crude extracts or odors of pumpkins. The odors of pumpkin should be useful for attraction chemicals of *B. depressus*, and further studies were required.

POSTER PRESENTATION

Effects of saline intake until the second mating on the spermatophore mass and sperm number in male swallowtail butterfly, *Papilio xuthus*

Sunao Niihara, Mamoru Watanabe

University of Tsukuba, Tsukuba city, Ibaraki prefecture, Japan

Introduction: Although sodium ions induce puddling behavior in males of some butterfly species, the role of sodium ions in male life history is unclear.

Materials and Methods: Effects of saline intake until the second mating on the spermatophore mass and sperm number were examined in male swallowtail butterfly, *Papilio xuthus*.

Results and Discussion: A virgin male transferred a spermatophore of 6mg with 40 eupyrene sperm bundles to a virgin female during the copulation. Although every spermatophore of the second mating of the mated males the day after the first copulation was too small, the mated males that fed on 0.01mol/L saline solution for the day produced a relatively large one than the mated males fed on the distilled water. The mated males fed on 0.01mol/L saline solution during five days until the second copulation increased the spermatophore size rather than that fed on distilled water. However, It was not a full size. The number of eupyrene sperm bundles included in the second spermatophore transferred by the mated males fed on 0.01mol/L saline solution for a day was around 45, which was greater than that in the first spermatophore. Thus, saline intake affected the number of eupyrene sperm bundles rather than the spermatophore size.

POSTER PRESENTATION

Synergistic behavioral responses of female moths to synthetic plant-derived mixtures are mirrored by odor-evoked calcium activity in their antennal lobes

Jaime Pinero[2], Giovanni Galizia[1], Silvia Dorn[2]

[1]University of Konstanz, Konstanz, Germany, [2]ETH-Zurich, Zurich, Switzerland, [3]University of Hawaii at Manoa, Honolulu, United States

Introduction: Synergism among constituents of odor mixtures can underlie attraction of insect herbivores to their host plants. Yet, practically nothing is known about the representation of synergistic odor-mixture effects in the antennal lobes. We combined behavior with optical imaging to characterize the response of female Oriental fruit moths, *Cydia (Grapholita) molesta* (Lepidoptera: Tortricidae), to synergistic odor mixtures.

Material. Behavioral and neurophysiological experiments were conducted to (1) quantify, in dual choice bioassays, the olfactory response of females to synthetic mixtures, and (2) characterize, using calcium imaging, the pattern of glomeruli activated by odor mixtures and their individual constituents in the antennal lobes of the female moths.

Results Behaviorally, trace amounts of benzonitrile synergized the behavioral response of female moths to a synthetic mixture. Physiologically, the addition of trace amounts of benzonitrile to an unattractive mixture led to more complex patterns of activated glomeruli in the antennal lobes. A new type of olfactory receptor functioning as a mixture detector was discovered.

Conclusions: Synergistic interactions documented at the level of behavior were mirrored by calcium activity in the antennal lobes of female moths. The mixture-sensitive glomerulus discovered offers excellent physiological evidence for a complex pattern extractor of behaviorally relevant mixtures already occurring at the level of odor representation in the antennal lobes of this moth species. The synergistic effect elicited by benzonitrile seems to be central, when present in a mixture that contains other key constituents, for adequate coding (at the physiological level) and discrimination (at the behavioral level) of odor mixtures.

POSTER PRESENTATION

Managing Oriental fruit fly, *Bactrocera dorsalis* (Diptera: Tephritidae) using Spinosad-based protein sprays in papaya orchards in Hawai'i

Jaime Piñero[1], Ronald Mau[1], Roger Vargas[2]

[1]University of Hawaii at Manoa, Honolulu, Hawaii, United States, [2]USDA-ARS, Hilo, Hawaii, United States

Introduction: Management of tephritid flies in many areas of the world has traditionally relied on frequent applications of broad spectrum insecticides. We evaluated the efficacy of sprays of GF-120 Fruit Fly Bait, in combination with two additional environmentally friendly fruit fly management methods, in reducing populations of oriental fruit fly in papaya orchards in Hawai'i. Our main goal is to develop and implement environmentally acceptable and sustainable pest management strategies that reduce use of broad spectrum insecticides while suppressing fruit flies to economically manageable levels.

Material Study was conducted in the Puna district of the island of Hawai'i in an area comprising 60 hectares currently in production. Fruit fly management tactics used included field sanitation (by growers), use of the highly attractive male-specific lure methyl eugenol and weekly sprays of GF-120 Fruit Fly Bait to papaya tree foliage and bordering plants. Results were assessed weekly using traps that monitored local populations of females and every 6 week by sampling fruit to determine level of infestation.

Results Weekly applications of GF-120 Fruit Fly Bait, when combined with field sanitation and mass trapping of males, led to a significant reduction in the number of females captured in monitoring traps in the treated plots compared to the control plots and a substantial reduction in levels of fruit infestation of papaya fruit.

Conclusions: An environmentally-friendly approach to managing oriental fruit flies was evaluated with high success. With additional research currently being conducted, this technology will be transferred shortly to papaya growers in Hawai'i.

POSTER PRESENTATION

Effects of cold winter microenvironments on overwintering survival and potential fecundity of sunn bug pest (*Eurygaster integriceps* Put.)

Ahmad Baghdadi, Sedigheh Salemimoez

Tehran university, Tehran, Islamic Republic of Iran

The effects of two overwintering microenvironments on survival and potential fecundity of sunn bug pest (*E. integriceps* put.) was studied during 2006-2007 in ghara-aghaj altitudes of Varamin located in central part of Iran. Freeze-tolerant adults overwinter on dry or moist microenvironments under different plants on mountains. When plant covered by snow, adults insect and plants freeze together. There is some dry microenvironment too. By winter's end, the mortality rate in the dry and moist microenvironments were 68% and 23% respectively that showed significant difference and reduced potential fecundity of pest (21±2 eggs/female for dry microenvironment and 37±3 eggs/female for moist microenvironments), probably due higher metabolic rates in dry microenvironment which reduced the energy available for development and egg production in spring.

We conclude that, freezing winter microenvironments, had a positive effect on survival and potential fecundity of sunn bug pest, particularly those that stored his energy for produce eggs in future spring. The enhanced reproductive output of insects overwintering in freeze microenvironments may be a selective effect promoting the evolution of increased cold-hardiness.

POSTER PRESENTATION

Improved performance of Abamectin insecticide by Volk oil for chemical control of the leaf miner, *Liriomyza trifolii* (Burgess)

Ahmad Baghdadi, Fatemeh zeshti, Aziz Sheikhi

Tehran University, Tehran, Islamic Republic of Iran

The leaf miner, *Liriomyza trifolii* (Burgess), has become the most serious pest in greenhouses of vegetable crops through out the world because of its short generation time, high reproductive rate, conspicuous damage, and ability to develop resistance to currently registered insecticides. Abamectin recommend to control *L. trifolii* ,the use of plant oil might help to reduce the required rate to achieve acceptable control of this pest. In conclusion, the effectiveness of Abamectin applied alone or mixed with plant oil on leaf miner fly (LMF) *L. trifolii* , was evaluated on cucumber plants under laboratory conditions The addition of plant oil (25%) to Abamectin concentration increased the effectiveness of the insecticide to the extent that the active ingredient of the insecticide could be reduced of the normal dosage. The synergistic effect shown by the mixture of Abamectin and plant oil allows a reduction in the commercially recommended concentration of Abamectin without any loss in effectiveness. For determine the relationship of different affective of Abamectin alone and the mixture of plant oil a randomized complete design with six treatment and three replication in each experimental, for determine to the LC_{50}. In the laboratory to evaluate the effects of various concentrations of insecticide and determine LC_{50}, leaf miner (*L. trifolii*) were collected from cucumber greenhouse in the Varamin area and rearing. A leaf dip bioassay of leaves of *cucumber sp.* infested with different extract solutions Abamectin applied singly or in combination with plant oil. Analysis data was calculated with POLO-PC , SAS software indicate significantly different characterization were found on the mixture of Abamectin produced lower LC_{50} in the compared to the mixture and plant oil. (LC_{50} of Abamectin alone = 82/31ml , LC_{50} of Abamectin and oil = 32/3 ml). Laboratory bioassay showed that, residual efficacy was significantly reduced when Abamectin was applied in an oil spray environment.

POSTER PRESENTATION

Below and aboveground multitrophic interactions in tropical and temperate regions

Hironori Yasuda[1], Keitaro Tawaraya[1], Hideki Murayama[1], Satoru Sato[1], Takashi Nisizawa[1], Testuya Murayama[1], Tomonobu Tomoyasu[1], S Suhardi[2], Andi Trisyono[3], Erry Purnomo[4], S Suputa[3], W Witjaksono[3]

[1]Faculty of Agriculture, Yamagata University, Tsuruoka, Japan, [2]Faculty of Forestry, Gadjah Mada University, Yogyakarta, Indonesia, [3]Faculty of Agriculture, Gadjah Mada University, Yogyakarta, Indonesia, [4]Faculty of Agriculture, Lambung Mangkurat University, Banjarbaru, Indonesia

Introduction: Understanding of the linkages between below and aboveground organisms is important issue in ecology since they influence each other, which in turn would produce biological diversity, although our understanding of the interactions is still incomplete, tropical regions in particular. Here, we reveal that the effect of arbuscular mycorrhizal (AM) colonization on diversity of arthropods through plant diversity at Java islands in Indonesia in addition to at Tsuruoka in Japan.

Methods: Vegetation at the experimental plot (5 m x 5 m) was removed by herbicide, then fungicide (benomyl) was applied on soil surface at each plot every two weeks as a treatment, while water was applied to the plot as a control through a year in 2004 at the three sites mentioned above. In general, plant and insect samplings were obtained every two months except for the sampling in Japan, while AM colonization was measured twice through the year.

Results: Fungicide application decreased the AM colonization of three plant species, while the effect of fungicide application tended to be smaller in other species. In contrast, in general, plant biomass tended to increase after fungicide application.

Conclusions: Belowground organisms are likely to influence differently on the functional groups of arthropods through plant diversity across spatial and temporal scales, and possible mechanism of this will be discussed.

POSTER PRESENTATION

Genetic variation and prevalence rule of *Bursaphelenchus xylophilus* in China

Hong Yang Pan

General Station of Forest Pest Management, State Forest Administration, Shenyang, China

Genetic diversities existed in not only inter-population but also inner-population between *B. xylophilus* and *B. mucronatus*. Genetic diversities of inter-population (86.6%) were higher than that of inner-population (13.4%). Under the condition of genetic distance <0.01, 173 strains of *B. xylophilus* from 13 provinces could be divided into 86 colonies. Relationship between Chinese and Japanese populations was closer than that of Chinese and American. Under the condition of genetic distance <0.197, 173 strains were divided into 3 groups.
In temporal pattern, development of pine wilt disease in local area could be divided into 3 phases. According to occurrence area, temporal phases were 1^{st}~3^{rd} y, 4^{th}~7^{th} y and time after 7 years. According to quantity of dead trees, temporal phases were 1^{st}~4^{th} y, 5^{th}~8^{th} y and time after 8 years. In whole China, damage process of pine wilt disease could be divided into 4 phases.

The spatial pattern and distribution of pine wilt disease were conducted with geostatistics. The results indicated that semivariogram of pine wilt disease could be described by spherical model in the whole country and provinces of Jiangsu, Anhui, Guangdong and Zhejiang, showing an aggregated spatial arrangement. Ranges of spatial dependence were 10.19°, 3.45°, 2.16°, 3.08° and 2.44°, and degrees of spatial dependence were 79.60%, 87.43%, 95.88%, 94.98% and 94.54% respectively. There were two main aggregated areas of pine wilt disease in China, the first one was E113°~114.5°, N22.5°~24° in Guangdong area. The second one was E22.5°~24°, N30.5°~32.5°, which centered with Nanjing.

POSTER PRESENTATION

Interspecific variation of male ejaculates on monandrous and polyandrous swallowtail butterflies (Lepidoptera: Papilionidae) in successive copulation

Nayuta Sasaki, Mamoru Watanabe

University of Tsukuba, Tsukuba, Ibaraki, Japan

Introduction: In Japanese swallowtail butterflies, lifetime mating frequency of females in *Papilio xuthus*, *P. protenor* and *P. machaon* has been reported to 3, 2.5 and 1.2, respectively. To clarify the quantity and quality of male ejaculate in relation to the mating frequency, laboratory reared butterflies were mated by hand-pairing method.

Results and Discussion: For *P. xuthus*, copula duration was 1 hour and the weight of a spermatophore transferred was 6 mg, including 40 eupyrene sperm bundles and 170,000 apyrene spermatozoa. The length of an eupyrene and an apyrene spermatozoon was 0.7 mm and 0.4 mm, respectively. On the second day after the first mating, the mated males transferred a smaller spermatophore (3.6 mg) with significantly more eupyrene sperm bundles (60), but not significantly different number of apyrene spermatozoa (180,000) than those in the first mating. For *P. protenor* and *P. machaon*, the copula duration, the spermatophore weight and the number of apyrene spermatozoa at the first mating were similar to those of *P. xuthus*. However, the number of eupyrene sperm bundles in both species was higher than that of *P. xuthus*. The eupyrene and apyrene spermatozoon sizes in *P. protenor* were as half as those of *P. xuthus*. A smaller spermatophore in the second mating with the same number of apyrene spermatozoa was also found in the mated males of both species, though no increase in the number of eupyrene sperm bundles at the second mating was found. The lifetime mating strategy of male swallowtail butterflies was discussed in relation to female polyandry.

POSTER PRESENTATION

Electron beam treatment as a phytosanitary measure for stored product pests

Nouraddin Shayesteh, Abbas Hosseinzadeh, Mohammad Reza Ardakani, Hamid Reza Zolfagharieh, Mohammad Babaii, Hadi Fatollahi, Hasan Zareshahi, Shahram Aramideh

Islamic Azad University, Branch of Mahabad, Mahabad, Islamic Republic of Iran

Introduction: Grains and pulses infested with insects such as *Tribolum castaneum* and *Plodia interponctella* may be disinfested with methyl bromide. Despite low residues, however, fumigation with MeBr may not to be desirable from the viewpoint of human health. More importantly, MeBr can deplet the ozon layer and on this basis it will be phased out for most uses. Development of an alternative treatment is urgently needed.

Methods: Developmental stages of two stored-product insect pests **viz.** *Tribolum castaneum* and *Plodia interponctella* were exposed directly to electrons using Rhodetron accelerator(tt200). Exposure doses on all stages were 0, 270, 380, 520, 700, 840, 1640, 2020, 2400, 2750 and 3130 Gy.

Results: The results of these studies indicate that inhibiting doses for eggs, larval, pupal and adults of *Tribolum castaneum* were 840, 380, 2020 and 3130Gy respectively. These criteria for *Plodia interponctella* were 840, 520, 1640 and 3130 respectively. Due to results eggs, larval and adults of *Tribolum castaneum* were sensitive than *Plodia interponctella*.

Conclusions: We suggest that it is possible to disinfest grains contaminated with these insects using high energy electrons at 3130Gy.

POSTER PRESENTATION

Programmed cell death in intestinal cells of *Bombyx mori* during the metamorphosis: morphological observation of autophagy and apoptosis and expression of the ecdysone-regulated genes

Zhi-Jun Huang[1], Qing-Rong Li[1], Yan-Xia Shi[1], Xiao-Juan Deng[1], Wan-Ying Yang[1], Ya-dong Huang[2], Qili Feng[3], Yang Cao[1]

[1]Department of Sericulture science, College of Animal Science, South China Agricultural University, Guangzhou, Guangdong, China, [2]Biopharmaceutical Research and Development Center, Jinan University, Guangzhou, Guangdong, China, [3]Guangdong Provincial Key Lab of Biotechnology for Plant Development, School of Life Sciences, South China Normal University, Guangzhou, Guangdong, China

During metamorphosis in insect, degeneration and dissolution of the larval tissues, which is triggered by ecdysone hormone (EH), require programmed cell death, such as autophagy and apoptosis. Morphological observation on autophagy and apoptosis and analysis of ecdysone-regulated gene expression in the epithelium cells of *Bombyx mori* gut indicated that the Cvt, autophagy, mitophagy and reticulophagy pathwayes of autophagy occurred in intestinal epithelium cells during the larval to pupal metamorphosis. The typical DNA ladder of apoptosis was also detected in the degenerating epithelium cells. The expression peaks of transcripts of the EH receptor gene BmEcR and earlier transcriptional genes BmHR39□BmE74A appeared before pupation, but BmFTZ-F 1 expressed later. All the data together suggested that the early expression of BmEcR□BmHR39□BmE74A might initiate autophagy and apoptosis, and autophagy pathway occurred dominantly and earlier than apoptosis pathway. This work was supported by the “863 project” (2006AA10A119), the “973 Project) (2005CB121000), NNSF (30370716, 30570938) of China.

POSTER PRESENTATION

Functional divergence and inductive expression patterns of three multi-gene families of antimicrobial peptides in *Bombyx mori*

Ming-qiang Ye[1], Wan-ying Yang[1], Ya-dong Huang[2], Xiao-juan Deng[1], Shuo-yang Wen[3], Qing-you Xia[4], Yang Cao[1]

[1]Department of Sericulture Science, College of Animal Science, South China Agricultural University, Guangzhou, Guangdong, China, [2]Biopharmaceutical Research and Development Center, Jinan University, Guangzhou, Guangdong, China, [3]Department of Entomology, College of Natural Resource of Environment, SCAU, Guangzhou, Guangdong, China, [4]The Key Sericultural Laboratory of Agricultural Ministry, College of Sericulture and Biotechnology, Southwest University, Chongqing, China

Three multi-gene families of the antimicrobial peptides, Cecropins, Moricins and Attacins, in *Bombyx mori* were investigated for their inductive expression and functional divergence. Fifteen genes were cloned and expressed *in vitro*. Antimicrobial activity of the peptides was assayed by agar diffusion and minimum inhibitory concentration. Gene expression of the four Cecropin subfamilies was examined by quantitative RT-PCR. Strong antibacterial activity in Cecropin D and BmcecB1 and high transcriptional levels in Cecropin D and BmcecB1-B5 were found, whereas BmcecD1 transcripts were not detected, indicating that dominant inducible genes are present in this family. Antibacterial activity and high transcription levels were detected in the Moricins A, but not Moricins B subfamily, suggesting that Moricins A subfamily is dominant in the Moricins family. Antibacterial activity of Bmatt1 and Nuecin in the Attacins family displayed similar antibacterial spectrum. This study was supported by the “973 Program” (2005CB121000), the “863 Program” (2006AA10A119) and the NNSF of Guangdong Province of China (032256, 04020553).

POSTER PRESENTATION

Selection of mutants for resistance to leaf miner (*Liriomyza cicerina* Rond.) and iron deficiency chlorosis in chickpea (*Cicer arietinum* L.)

Cengiz Toker[1], Huseyin Canci[1], Nisa Ertoy Inci[1], Fatma Ceylan[1], Dilek Uras[2], Fedai Erler[3]

[1]Department of Field Crops, Akdeniz University, Antalya, Turkey, [2]Department of Soil Science, Akdeniz University, Antalya, Turkey, [3]Department of Plant Protection, Akdeniz University, Antalya, Turkey

Introduction: Yield loss due to leaf miner in chickpea may reach up to 40% in the Mediterranean region. Also, considerable yield losses due to iron (Fe) deficiency chlorosis in chickpea may occur when susceptible genotypes are grown in calcareous soils with high pH. The only practical and economical solution to overcome leaf miner damage and Fe deficiency chlorosis is through the utilization of genetic resistance.

Methods: The chickpea accessions ICC 6119 was irradiated with 200, 300 and 400 Gy gamma rays. Mutated populations were screened for resistance to leaf miner using a 1–9 scale, where 1 = free from any damage and 9 = maximum damage, and evaluated for Fe-deficiency chlorosis using a scale 1-2, where 1 corresponds to plants free of any Fe-deficiency symptoms and 2 corresponds to the youngest leaflets of plant show in chlorosis.

Results: In the M_3 generation, five mutants were selected for resistance to leaf miner and Fe-deficiency chlorosis from a single seed descent set. Maximum viable mutations were obtained from 200 Gy treatments.

Conclusions: According to literature available, this is the first report on selection of mutants for resistance to leaf miner and Fe-deficiency chlorosis in chickpea. Resistance to leaf miner and Fe-deficiency chlorosis was induced by gamma rays in a short time by altering previously unknown genes. The identified Fe-efficient and leaf miner-resistant mutants may be useful in chickpea breeding programs to develop cultivars suitable for a niche environment.

POSTER PRESENTATION

Phytophagous insects associated with *Chromolaena odorata* in continental and island habitats within its native range

Lorraine Strathie, Costas Zachariades

Agricultural Research Council - Plant Protection Research Institute, Hilton, KwaZulu-Natal, South Africa

Introduction: *Chromolaena odorata* (Asteraceae) is native to most of the Neotropics, and has invaded the Old World tropics and subtropics. Surveys of natural enemies associated with chromolaena in its native range were first conducted in Trinidad in the 1960's, for potential utilization in biological control. Since 1988, the South African chromolaena biocontrol research programme has undertaken survey and collecting expeditions in many neotropical countries.

Methods: Field surveys of phytophagous insects on chromolaena were conducted during the wet season from 1996 until 2006 in Venezuela and Jamaica, at localities up to 1500m in altitude. Insects were collected, identified, and their distribution, damage, and host range investigated. Literature records were consulted for parts of the neotropical distribution of chromolaena.

Results: The phytophagous insect community associated with chromolaena in the island habitat (Jamaica) was poor compared to that on the mainland (Venezuela). Candidate agents such as *Melanagromyza eupatoriella, Calycomyza eupatorivora* (Agromyzidae), and *Phestinia costella* (Pyralidae) were widespread throughout the entire distribution of chromolaena, but relative abundance varied: *C. eupatorivora* was common in Jamaica but rare in Venezuela. Several species, including *Carmenta* sp. nov. (Sesiidae), *Longitarsus* sp. (Chrysomelidae), *Lixus aemulus*, *Conotrachelus reticulatus* and *C. curabilis* (Curculionidae) were found only on the mainland (including Trinidad). Conversely, *Polymorphomyia basilica* (Tephritidae) and *Dichrorampha odorata* (Tortricidae) were restricted to Jamaica and neighbouring islands.

Conclusions: The geographic distributions of phytophagous insect communities on chromolaena are discussed; some species were ubiquitous while several others were restricted to either only parts of the mainland or islands in the neotropics.

POSTER PRESENTATION

Biology of the clothes moth, *Tinea translucens* Meyrick (Lepidoptera: Tineidae) and the preference analysis of their case-making materials

Po-Yen Chen, Shiuh-Feng Shiao

National Taiwan University, Taipei, Taiwan

Introduction: *Tinea translucens* is the most common household clothes moth species in Taiwan. After the general survey around Taiwan, we found there are at least two other species which also lived in our surroundings; they have similar behavior of building the portable cases, but could be differentiated by their different case shapes. Due to the fact that the different instar larvae have different size of mouthpart, the older larvae could also enlarge their outer cases. In order to further understand their case-making behavior, we focus on their casings which have the phenomenon of concentric circles, and also the different materials the larvae could choose to see their preference of case-making materials.

Methods: To understand the biology and case-making behavior of clothes moths, a field collection in Taiwan was conducted, the related environmental parameters, such as humidity, illumination, wind velocity and elevation in the collecting sites were recorded. In addition, their case shapes, male genitalia, case-building behavior and the nature enemies were also described for further references. We offered some different materials and design experiments to understand their larval case-building behavior in lab; the preference of case-making materials were then recorded and analyzed.

Results: In this study, at least there different species of clothes moths were found in Taiwan. Experiments showed there is no particular preference in their case-making materials. Although sand is the most common material the clothes moth adopted for their casing, yet if different material offered in their living environment, such as feather or hair, they could randomly use those materials around them for their case-making material.

Conclusions: Clothes moth has high tolerance to the environmental changes; they can use many different kinds of material to build their nest. On the other hand, previous studies have recorded some Tineidae larvae could be found on mammal corpses of the late dry decay stages. Thus, connecting their high tolerance to the environment and their case-making behavior to forensic entomology may be a possible way to provide some other evidences in further describing the environment of crime scene.

POSTER PRESENTATION

Behavioral syndrome, antipredator-behavior and immune defence in field crickets

Raine Kortet[1], Markus Rantala[2], Ann Hedrick[3]

[1]Department of Biology, University of Oulu, Oulu, Finland, [2]Section of Ecology, Department of Biology, University of Turku, Turku, Finland, [3]Section of Neurobiology, Physiology & Behavior, University of California, Davis, Davis, CA, United States

Introduction: Behavioral syndromes have recently drawn attention from evolutionary biologists. In the field cricket *Gryllus integer*, males are aggressive with one another and fight vigorously over females and territories. This aggressiveness is likely associated with other behavioral traits that are potentially costly in terms of resistance against parasites and pathogens.

Methods: We examined whether aggressiveness was correlated with activity in a potentially dangerous context (a novel environment,) and if anti-predator-associated behavioral traits were related to immune defence.

Results: More aggressive males, who won more fights, had shorter latencies to become active and shorter latencies to emerge from a safe refuge. Encapsulation response was positively correlated with the latency to become active and latency to emerge from a safe refuge in the high-predation-risk population, but not in the low- predation-risk population.

Conclusions: These results suggest that a behavioral syndrome exists in G. integer, in which more aggressive males are also more active in general, and possibly less cautious towards predation risk. Moreover, predation and parasitoids may increase the cricket's investment in parasite resistance, despite the potential costs of anti-predator behavior.

POSTER PRESENTATION

Subgenus Meloehelea (Diptera: Ceratopogonidae) in the Neotropical Region?

Andrea Tóthová

Masaryk University, Brno, Czech Republic

Introduction: The diverse biting midge genus, *Atrichopogon* Kieffer, contains 476 species worldwide. The subgenus *Meloehelea* Wirth includes ectoparasitic species that feed on the haemolymph of blister beetles (Meloidae) and other related coleopteran families. There are 16 species of this subgenus, 10 of which occur in the Palaearctic, 3 in the Nearctic, 2 in the Holarctic and 1 in the Afrotropical Region. Hitherto the subgenus *Meloehelea* has not previously been reported from the Neotropical Region.

Material and Methods: A slide-mounted adult males and females of *Meloehelea* (CNCI) from the Neotropical and Nearctic Regions have been examined, described and photographed with a Leica DM5500 compound microscope with Leica DFC320 digital camera. The specimens have been also compared to other Palaearctic and Nearctic *Meloehelea* species.

Results: The genus *Atrichopogon* is diverse but most species usually cannot be accurately identified and the subgeneric classification of *Atrichopogon* is poorly understood, particularly in the Neotropical region. The record of the subgenus *Meloehelea* from the Neotropical region is therefore noteworthy. The record of *A.* (*M.*) *oedemerarum* and two additional new species of the sg. *Meloehelea* from the Neotropical Region deposited at the CNCI increases our knowledge of the diverse Neotropical biting midge fauna.

Conclusions: A more thorough focus on generic and subgeneric characters of *Atrichopogon* as well as the construction of workable keys for the Holarctic and Neotropical Regions are badly needed.

The study has been supported by the Ministry of Education grant MSM No. 0021622416 and by the 6th Framework Program – The Mobility Program of Masaryk University.

POSTER PRESENTATION

Effects of Soil Fertilization on Surface Active Arachnids at Toolik Lake, Alaska

Karl Wyant[1], Paula Cushing[4], Boris Kondratieff[3], John Moore[2]

[1]Graduate Degree Program in Ecology, Colorado State University., Fort Collins, CO, United States, [2]Natural Resource Ecology Laboratory, Colorado State University, Fort Collins, CO, United States, [3]Bioagricultural Science and Pest Management, Colorado State University, Fort Collins, CO, United States, [4]Denver Museum of Nature and Science, Denver, CO, United States

Introduction: Arctic soils are nutrient limited because organic matter contained in permafrost is not available to the soil food web. Climate change models suggest that as the Arctic becomes warmer the permafrost will melt, making labile nutrients (N & P) available to microbes. This may prompt higher rates of net primary productivity, changes in plant community structure, and alteration of soil food web structure and dynamics. We initiated a study to assess changes of a major soil predator group as a result of simulated climate change.

Methods:1,758 spiders were collected from pitfall traps in moist acidic (MAT) and dry heath (DH) tundra from the Toolik Lake LTER, AK during the 2004 growing season. The field site is arranged into four (MAT) and three (DH) blocks, each with factorially-arranged nitrogen-phosphorus addition and grazing treatments.

Results: Fertilization treatments show significant increase of spider populations ($p=.003$). Diversity and richness measurements yielded contrasting results for the two study sites ($p=0.274$), and ($p=0.003$), respectively.

Discussion: We attribute these results to differences in plant cover on the fertilized plots and unique response characteristics for distinct tundra habitat types.

POSTER PRESENTATION

EMEND Entomology: Arthropod conservation and sustainable forest management

John Spence[1], Jason Edwards[1], Colin Bergeron[1], Esther Kamunya[1], Jaime Pinzon[1], Jan Volney[2], David Langor[2], Joshua Jacobs[3], Timothy Work[3]

[1]University of Alberta, Edmonton, Alberta, Canada, [2]Canadian Forest Service, Edmonton, Alberta, Canada, [3]Université du Québec à Montréal, Montréal, Québec, Canada

Introduction: EMEND is a large-scale (c. 1000 ha) forest experiment in northern Alberta, Canada initiated in 1998 to compare ecosystem effects of several approaches to retention harvest with the effects of wildfire. The objective is to illuminate harvest and regeneration methods that contribute most significantly to forest sustainability in the Canadian boreal region.

Methods: Replicated 10-ha blocks of forest, representing each of four successionally arranged cover-types were harvested (1999) to several green-tree retention (2%, 10%, 20%, 50% and 75%) prescriptions, burned in two ways or held as un-manipulated checks, after a pre-treatment year (1998). Arthropods populations representing many taxa (moths, epigaeics and saproxylics are featured here) have been monitored since.

Results: Distributed retention provided no significant 'life-boating' for any arthropod taxon, but even very small (0.2-0.4 ha) patches provided a significant degree of habitat reserve for arthropods, especially species characteristic of mature forest. Early effects, which were largely explained by cover-type, are misleading with respect to emerging long-term patterns which are driven mainly by type and degree of disturbance. Faunal recovery after harvest travels on a different trajectory of that after wildfire and certain pyrophillous faunal elements go missing on harvest-origin blocks.

Conclusions: Retention harvesting leaves important legacy elements and has conservation advantages over clear-cutting, but it is not a full substitute for fire in these boreal forest systems. Biodiversity will be best conserved by a combination of green-tree retention harvest, silvicultural methods that encourage regeneration of habitats and the use of fire as a regeneration tool.

POSTER PRESENTATION

Electroantennography for development of food-based attractants for pest Tephritidae

Paul E. Kendra, Wayne S. Montgomery, Nancy D. Epsky, Robert R. Heath

USDA-ARS, Subtropical Horticulture Research Station, Miami, Florida, United States

Introduction: *Anastrepha* fruit flies (Diptera: Tephritidae) are serious pests of vegetable and fruit crops throughout the American tropics and subtropics. Current trapping systems utilize synthetic lures which emit ammonia and other attractant chemicals that function as protein feeding cues. However, field captures are variable with synthetic lures, and this variability does not appear to be related solely to ammonia release rate. The need for improved attractants prompted research using electroantennography (EAG), a technique which measures response of antennal olfactory receptors to volatile chemical stimuli.

Methods: *Anastrepha suspensa* of known age and physiological state were used for EAG analyses. Antennae were presented with quantified chemical samples in vapor form. Upon binding with specific olfactory receptors, test chemicals evoked a measurable electrical response (an EAG spike) which represents summation of multiple receptor potentials. Analysis of the amplitude of EAG spikes provided information on appropriate doses and combinations of chemicals needed to elicit optimal antennal response.

Results: EAG response of *A. suspensa* was quantified for ammonia, carbon dioxide, putrescine, and a series of diamines homologous to putrescine. Quantitative EAG identified factors which contribute to the variability in fly response to food-based attractants, including sex, age, nutritional requirements, and reproductive status. EAG also identified potential new fruit fly attractants.

Conclusions: Information from EAG analysis will be used to determine the relationship between antennal sensitivity to fruit fly attractants and efficacy of those compounds when deployed in traps for pest *Anastrepha* species.

POSTER PRESENTATION

Comparative morphological study of three Brazilian Physodactylinae species (Coleoptera: Elateridae)

Simone Policena Rosa

Museu de Zoologia da Universidade de São Paulo, São Paulo, SP, Brazil

Introduction: Physodactylinae comprises 7 genera and 28 species distributed in South America, Africa and Southeast Asia. Eighteen species occur in Brazil. Their supposed synapomorphies are: fossorial legs, large mandibles and chin peace absent. The objective of this study was compare the morphology of the type-species of the three Brazilian genera *Physodactylus, Dactylophysus* and *Teslasena* and two *Heterocrepidius* species (Dicrepidiini, Elaterinae), in which the *Dactylophysus* species were described.

Material and methods: Since females of the majority of species are unknown only males were examined. One specimen of each species were whole disarticulated, they were dissected through traditional techniques using NaOH.

Results: *Physodactylus henningi*, *Dactylophysus mendax*, *Heterocrepidius gilvellus* and *H. depressus* share several characters as the carina on mandibular dorsal face, two long setae on mentum, basiestipe elongated with several long setae, transversal carina on mesepisternun, general shapes of mesosternum and mesoscutum, lamellate tarsomeres, sternite VIII partially sclerotized and basal piece longer than paremeres. *Teslasena femoralis* is the most conspicuous species, among its unique characters are: hind wing without wedge cell and CuA_1, mentum without setae, basiestipe short with one strong long seta and simple tarsomeres.

Conclusion: The similarities among *Physodactylus*, *Dactylophysus* and *Heterocrepidius* species suggest that should be a phylogenetic relationship between Physodactylinae and Dicrepidiini. The unique characters of *Teslasena* could be either autapomorphies or synapomorphies shared with other group does not studied here. A phylogenetic study should be carry out, including all Physodactylinae and traditionally related species, to test the monophyly of this subfamily and elucidate its position in Elateridae.

POSTER PRESENTATION

Insect importance on exhume cases and human remains in forensic investigation in Brazil

Lucila Maria Lopes de Carvalho[1], Patricia Jacqueline Thyssen[2], Fortunato Badan Palhares[3]

[1]UNESP, Rio Claro, SP, Brazil, [2]UNESP, Botucatu, SP, Brazil, [3]Instituto de patologia, Campinas, SP, Brazil

Introduction: In recent years, arthropod evidence has made its way into routine use in forensic and medico-legal investigation specially to contribute on estimating PMI. The advantage in using insects is they can be collected in any stage of investigation such as at the death scene, necropsy as well during the exhumation, besides it is possible to use them death or alive. Necropsy usually offers information regarding the manner and cause of death, stage of decomposition and location. Besides these factors, the presence of insects can be helpful to estimate the PMI, however, it is important an expert in entomology to collect all necessary samples and information. Two exhume cases of forensic interest are presented.

Methods: After exhumation, immature and adult insects were collect from bodies and taken to the laboratory to complete their development in an artificial diet or be identified.

Results: It was found only remains in both cases. It was collected dead and alive insects. There were empty puparium and adults of *Megaselia scalaris* (Phoridae) in the case 1 and maggots of *Piophila casei* (Piophilidae) in the case 2. These insects played an important role in the decomposition process.

Conclusions: In forensic investigation to obtain an accurate result it is important the participation of a diverse group of professionals such as pathologists, chemists, police officers and entomologists. Insects can contribute as evidence in an investigation especially when dead is up 72 hours. Then, a professional trained is indicated to avoid any lost of sample and minimize the error.

POSTER PRESENTATION

Pest species of Orthoptera of the central part of the Volga-Kama region (Russia)

Nikolay Shulaev, Inessa Karmazina

Kazan State University, Kazan, Russian Federation

Introduction: Orthoptera are an integral part of the fauna of natural and agrarian biocenoses- of Volga-Kama region. The central position of the Volga-Kama province took Tatarstan Republic (Popov, 1960).

Methods: The research was carried from 2005 to 2007 year in various parts of Tatarstan Republic. Research covered various biotopes and habitats. Charges were standard method.

Results: In Tatarstan at the moment orthoptera recorded 64 species belonging to 34 genera and 6 families. The family Tettigoniidae - 19 species, Gryllotalpidae - 1 species, Gryllidae - 3 species, Acrididae - 43 species, Tetrigidae - 3 species Tridactylidae - 1 species (Karmazina, Shulaev, 2008). We exhibited 4 pest species of family Acrididae (Locusta migratoria L., Calliptamus italicus L., Pararcyptera microptera F.-W., Oedaleus decorus Germ.). Two species of pests Aelopus sibiricus L. and Dociostaurus brevicollis Ev. were marked by literary date (Aleinikova, 1950).

Conclusion: We have found pest species are rare or small populations. These species do not formed large swarms. Hereby, they do not cause significant damage to agriculture of the republic.

POSTER PRESENTATION

Historical development of the suborder Heteroptera (Hemiptera)

Yuri Popov

Paleontological Institute, Russian Academy of Sciences, Moscow, Russian Federation

Heteroptera include ca. 1000 fossil (mostly Cainozoic) species in about 500 genera and 50 families. The earliest Heteroptera are known from the Late Triassic of Australia, North America, China, France, and Ukraine. They are mainly represented by aquatic Naucoridae, Triassocoridae, Belostomatidae, and Notonectidae. The oldest extinct terrestrial lygaeoid Pachymeridiidae is recorded from the Late British Triassic. A rapid radiation of Heteroptera started in the Early Jurassic in Western Europe (aquatic Belostomatidae and Corixidae, amphibious gerromorphan Mesoveliidae, littoral Ochteridae, saldoid Archegocimicidae, terrestrial Cimicomorpha and Pentatomomorpha) and in Central Asia and China (Corixidae and Shurabellidae). It is significant that diverse nepomorphan bugs widespread in Early Jurassic Laurasian deposits are represented by extant families. The extinct corixoid Shurabellidae were very common during the first half of the Jurassic in Central Asia, Eastern Siberia and Mongolia, but practically absent from the Upper Jurassic. During the Middle and Late Jurassic, Heteroptera diverged into many families, some of them being extinct, e.g. water pleoid Scaphocoridae, terrestrial pentatomoid Mesopentacoridae from the Upper Jurassic of Kazakhstan. At that time first extant Miridae, Coreidae, and Alydidae appeared among terrestrial bugs. Being quite numerous in the Upper Jurassic, cimicomorphan Miridae are not recorded in the Lower Cretaceous, but found in the Upper Cretaceous of North Siberia. The Early Cretaceous Heteroptera (mainly known from Eurasia and South America) are quite similar to the Late Jurassic assemblages. The transition from the Jurassic to Cretaceous was accompanied by the appearance of still very rare Hydrometridae, Tingidae, Reduviidae, and Aradidae. Some terrestrial groups became abundant, e.g. Archegocimicidae, Pachymeridiidae or Cydnidae. Aquatic bugs are also abundant during the Upper Jurassic and Lower Cretaceous. They are mainly represented by Corixidae (mostly Velocorixinae and Diaprepocorinae), Naucoridae, Notonectidae, and Belostomatidae. By mid-Cretaceous, the remaining Mesozoic families like water pleoid Mesotrephidae, Pachymeridiidae and Mesopentacoridae became extinct. Extant Gerroidea (Gerridae) and Coreoidea (Lygaeidae) became more numerous. The first Vianaididae and Thaumastocoridae (both Tingoidea) are found in the Turonian New Jersey amber. During the Cainozoic, the number of the still living (sub)families further increased, representing almost all main taxonomic groups.

POSTER PRESENTATION

The role of active host defensive reactions on host-instar selection by *Cotesia plutellae* (Hymenoptera: Braconidae), a larval parasitoid of *Plutella xylostella* (Lepidoptera: Plutellidae)

Robert S. Nofemela, Rami Kfir

ARC-Plant Protection Research Institute, Private Bag X134,, Pretoria 0001, South Africa

Introduction: Parasitoid fitness depends on resources provided by their hosts, and as a consequence host selection behaviour of female parasitoids is assumed to be influenced by host quality only. However, parasitoid host selection behaviour may also be influenced by differences in ability to subdue different host instars. This aspect was investigated with *Cotesia plutellae* on *Plutella xylostella* larvae.

Methods: The host-instar selection behaviour of newly emerged, mated and naïve female *C. plutellae* was investigated in no-choice, choice and preference test by observation experiments. Fitness traits such as developmental rate and survival of immature stages as well as female proportion in the offspring were also investigated.

Results: In a no-choice test, a significant preference for 3^{rd} instars followed by 2^{nd} then 4^{th} instar hosts was observed. The developmental rate of the progeny was shorter for parasitoids that started their development in 4^{th} instars than in either 2^{nd} or 3^{rd} instars. However, significantly more parasitoids completed their development in 3^{rd} instars than either 2^{nd} or 4^{th} instars. The younger the host was at the time of oviposition, the higher was female parasitoid proportion in progeny. In a choice test, a significant preference for 2^{nd} instars followed by 3^{rd} then 4^{th} instar hosts was observed. These results were validated with direct observations. The females were unable to subdue the aggressive 4^{th} instars, but preference for 2^{nd} than 3^{rd} instars in choice tests was not clear as both were subdued easily.

Conclusion: The defensive host reactions influenced the host selection behaviour in *C. plutellae.*

POSTER PRESENTATION

The infection process of *Beauveria bassiana* to *Apriona germari* larvae and defense response of the host to the pathogen

Huang Dazhuang, Li Huiping, Wang zhigang

Forestry College of Hebei Agricultural University, Baoding, China

The infection process of *Beauveria bassiana* to *Apriona germari* larvae and defense response of the host to the pathogen were studied. The results showed that the penetration process of *B.bassiana* include adherence, germination, appressoria and penetration. The conidia on the cuticle of *A.germari* larvae germinated in 16h after inoculation. The hyphae penetrated the cuticle and propagated in the coelom. Then it infected and destroyed the cutex, hemloymph lipoid and muscles, alimentary tract and malpighian tubule, etc. The phenoloxidase activity in hemolymph of *A.germari* larvae infected by *B.bassiana* increased within the early days of infection, but followed by decreasing because of the adaptability of *B.bassiana*. The phenoloxidase activity in hemolymph of *A.germari* larvae infected by successive reisolates obtained by repeatedly passing through the Czapek medium was higher than that by repeatedly passing through the *A.germari* larvae. There was some correlation between the maximal time producing phenoloxidase activity and LT_{50} of different reisolates. At the same time, a high relationship between the maximal activity and the LC_{50} was also found. All this indicated that the phenoloxidase activity can not only weigh the immunity ability of the host, but also act as an important reference index of pathogen. The hemocytes of *A.germari* larvae can resist the invasion of *B.bassiana*. The immune response mainly include adhesion, phagocytosis, aggregation, encapsulation and nodule formation. The peak response times were 2~2.5d after invasion of *B.bassiana*. The defense responses were just temporarily inhibition for the pathogen but could not clear them completely.

POSTER PRESENTATION

Life History of *Aleochara nigra* and *Aleochara formosanorum* (Coleoptera: Staphylinidae)

Shou-Wang Lin

National Taiwan University, Taipei, Taiwan

Introduction:, Researches of forensic entomology were so far mostly focused on the flies (Diptera) which appearing at the earlier stages of carrion decomposition, especially the blow flies (Diptera, Calliphoridae). Other insects also come to the carrions, like hymenopterans and coleopterans, but their biology and behavior are otherwise not well studied. Two common species of necrophagous *Aleochara* in Taiwan, *A. nigra* and *A. formosanorum*, were collected and reared in lab to study their life history and the time they arrive at the rat carrion in the field. It helps us to determine the ecological roles which they play in the carrion insect succession.

Methods: Adult beetles and their arriving time on carcasses were collected and recorded by using the pitfall traps once a day. Life history data was recorded from the lab colony which the larvae were reared in a plastic box and the pupae of their possible host species of *Hemipyrellia pulchra* and *Chrysomya megacephala* were provided.

Results: Larvae of *A. nigra* and *A. formosanorum* occurred on the carrions were observed almost at every succession stages, but mostly during the bloated to the advanced decay stage. At 28 ℃, eggs take about 3.5 and 4.3 days to hatch in *A. nigra* and *A. formosanorum,* respectively. Larvae of both species of *A. nigra* and *A. formosanorum* could use pupae of *Hemipyrellia pulchra* as hosts, and the 3rd instar larva comes out of the host's puparium, makes cocoon and then pupates inside the cocoon in the soil. Adults emerge after the pupal stages of 13.5 and 12 days in *A. nigra* and *A. formosanorum*, respectively.

Conclusions: *A. nigra* and *A. formosanorum* are necrophagous and their larvae are ectoparasitoids of *Hemipyrellia pulchra*, adult predation on maggots and larva being a parasitoid of pupae may affect the fly population and further change the composition of carrion insect fauna.

POSTER PRESENTATION

Genetic differentiation of *Rhyzopertha dominica* among geographical populations with different resistance level to PH_3

Hongyu Zhang, Xuhong Song, Yongshun Zhao, Xiaoxue Li

Institute of Urban Pests, College of Plant Science and Technology, Huazhong Agricultural University, Wuhan, China

The LC_{50} values to phosphine (PH_3) of *Rhyzopertha dominica* (Fabricius) different geographical populations were detected by a method recommended by FAO. Results showed that the LC_{50} values of populations from Banan, Chengdu, Shayang, Zhucheng, Yangchun, Xuchang was 0.04948mg/L, 0.04981mg/L, 0.58510mg/L, 3.18523mg/L, 3.2933mg/L and 3.25482mg/L respectively, their *Rf* values were 1, 1.01, 11.82, 64.37, 65.78, 66.55 times, respectively, and the resistance in order was Banan, Chengdu, Shayang, Zhucheng, Yangchun, Xuchang. Genetic differentiation among those populations was investigated using amplified fragment length polymorphism. Results showed that a genetic differentiation was found among geographical populations with different resistant level to PH_3, and the six geographical populations were clustered as 4 branches at 4.6904, the low-resistance populations such as Chengdu and Banan were clustered into one group firstly. Then they were clustered with Shayang and Yangchun which were medial-resistance populations at 4.6904. Finally, all of four were clustered with higher-resistance populations of Xuchang and Zhucheng at 3.3166. The result showed the higher resistance was, the bigger variation was. Additionally, 8 characteristic DNA bands, which may be helpful for surveying the *R. dominica* resistance to PH_3 as a molecular marker, were found using EcoRI +ATA/HpaII +TAC and EcoRI +AAC/ MspI +TAC primers. Moreover, Genetic differentiation among geographical populations of *R. dominica* was also investigated using COI, COII genes of mitochondrial DNA as molecular markers.

POSTER PRESENTATION

Synergistic effect of *Bacillus thuringiensis* on *Habrobracon hebetor* during combine biological control of *Plodia interpunctella*

Rotimi Akinkurolere, Hongyu Zhang

Institute of Urban Pests, College of Plant Science and Technology, Huazhong Agricultural University, Wuhan, China

The potential of combining microbial pesticides and natural enemies for integrated pest management of stored cereal was carried out using the interactions between *Bacillus thuringiensis* (Bt), Bt-intoxicated host larvae and *Habrobracon hebetor* (Hymenoptera: Braconidae) during the control of *Plodia interpunctella* (Lepidoptera: Pyralidae). Application of Bt or *H. hebetor* alone caused 41.67% and 35.35% *P. interpunctella* larval mortality respectively. However, Bt-*H. hebetor* combination treatment significantly evoked more *P. interpunctella* mortality (86%) than other treatments. Host mortality in controls was negligible. Progeny development of parasitoid wasp was dependent upon its susceptibility to Bt contaminated host. *H. hebetor* was able to successfully complete its development on the hosts though, fewer wasps emerged from Bt-parasitoid combined treatment than in none Bt treatments. The present study suggest that since Bt did not prevent parasitoid development, a combine treatment with Bt and parasitoid release, would produce better protection against *P. interpunctella* than either treatments when used singly.

POSTER PRESENTATION

Studies on the susceptibility of Colorado potato beetle eggs (Coleoptera: Chrysomelidae) to Calypso and Diflubenzuron

Ghazaleh Mohitazar, Mohammad.H Safaralizadeh, Ali.A Pourmirza, Nouaddin Shayesteh

[1]Urmia university, Urmia, Iran, Islamic Republic of, [2]Islamic Azad University, Branch of Mahabad, Mahabad, Islamic Republic of Iran

Introduction: The Colorado potato beetle *Leptinotarsa decemlineata* (Say) is one of the important pest of potato throughout the world. Control of CPB is a challenge for crop-producers because of its overlapping generations. The pest has developed resistance almost to all conventional insecticides. Therefore to delay resistance manifestation to chemical agents control of this pest warranted application of new class of control methods. At peresnt time the majority of control measure are forced on larval stage. At this research the susceptibility of eggs of CPB to Calypso and Diflubenzuron was determined.

Methods: Experimental design was CRD with 6 treatments and 3 replications. Bioassays were conducted with dipping and leaf disk methods. Percentage mortality was recorded 5 days initiation of trials and result were analyzed using probit procedur of SPSS software.

Results: The percentage of unhatched eggs showed significant difference between the chemicals. The maximum mortality rate was observed for Calypso and Diflubenzuron with 1.2 and 5600 ppm respectively. Based on the collected data LC_{50} values and confidence limits were 0.59(0.8021 – 0.4728) and 1491.05(1722.756 – 1269.191) ppm respectively.

Conclusions: The results revealed that Calypso have formidable effects on suppression of CPB eggs hatch.

POSTER PRESENTATION

Evaluation the level of resistance to diflubenzuron in house flies (*Musca domestica* L.) from different areas in Antalya, Turkey

Huseyin Cetin[1], Fedai Erler[2], Atila Yanikoglu[1]

[1]Akdeniz University, Department of Biology, Antalya, Turkey, [2]Akdeniz University, Department of Plant Protection, Antalya, Turkey

Introduction: The house fly, *Musca domestica* L. is a well-known cosmopolitan pest of both farm and home. This species is always found in association with humans or activities of humans and it is an important vector in transmitting various bacterial, viral and protozoal infections. Because of its importance as a public health pest, many insecticides have been used by man directly or indirectly in the control of *M. domestica*.

Methods: Field strains of *M. domestica* were collected between June 2006 and June 2007 from Antalya province, southwest of Turkey (Serik, Kumluca, Manavgat and Center). In the feeding tests, diflubenzuron was applied to larval breeding jars. Twenty grams of medium were put in a jar, and then 2.5 ml of water containing diflubenzuron or water alone was added and mixed into the medium. First instar larvae of the test species, 0–6 h old, were used in the assays. Four replicates of twenty-five larvae were used for each concentration level. The number of emerging flies was recorded during the 3 week-test period. The resistance ratios determined by comparing LC_{50} values of of the test populations and sensitive strain of SRS/WHO were compared.

Results: The resistance ratios ranged from 0,1 to 11.8 in test period (June 2006-June 2007). The highest ratios were determined in the Kumluca populations (4.7-11.8).

Conclusions: As the levels of insecticide resistance continue to increase, it is more important monitoring of resistance for effectively control of housefly populations.

POSTER PRESENTATION

Taxonomy, phylogeny and distribution of *Necrophila* sensu lato (Coleoptera: Silphidae) from south-eastern Asia

Jan Ruzicka

Czech University of Life Sciences, Prague, Czech Republic

Introduction: Eastern Palaearctic and Oriental carrion beetles of the subfamily Silphinae are only poorly known. Their taxonomy was strongly influences by the work of G. Portevin (papers published 1903-1943), and is in a need of recent revision. Taxonomy and species diversity of *Necrophila* Kirby et Spence sensu lato in south-eastern Asia is revised here.

Methods: External morphology characters of the adults are used for cladistic analysis. Distribution was tracked from museum specimens and recently collected material.

Results: The preliminary results present phylogenetic analysis of the following taxa (treated as separate genera or as subgenera of *Necrophila* by different recent authors): *Calosilpha* Portevin, *Chrysosilpha* Portevin, *Deutosilpha* Portevin and *Eusilpha* Semenov-Tian-Shanskiy. In total, 14 valid species/subspecies from this region are reported, and their distributional pattern is summarized.

POSTER PRESENTATION

Impact of herbivory by the mite, *Orthogalumna terebrantis* (Acarina: Galumnidae) on water hyacinth (*Eichhornia crassipes*) growth parameters and leaf chlorophyll content

Danica Lukac[1], Marcus Byrne[2], Martin Hill[1]

[1]*Department of Zoology and Entomology, Rhodes University, Grahamstown, South Africa,* [2]*School of Animal, Plant and Environmental Sciences, University of the Witwatersrand, Johannesburg, South Africa*

Introduction: *Orthogalumna terebrantis* is a biological control agent of water hyacinth. Very little is known about its impact on the growth of the plant. Here we determined what numbers of mites per plant are needed to cause significant damage to the plants and how mite herbivory on the plants was affected by the nutrient status of the water in which plants were grown.

Methods: 1) Density trial – mites were placed onto plants at four different densities (120, 80, 40 and 0 mites per plant). 2) Nutrient trial – plants were grown at three different nutrient concentrations (high, medium and low) and 100 mites were placed onto each plant. Plant growth parameters (*i.e.* wet weight, number of leaves, number of ramets, petiole lengths, root length and plant turn-over rate) were measured weekly on each plant for both trials. Leaf surface area damaged by mite galleries was recorded. Additionally, the chlorophyll content of leaves was measured in the nutrient trial.

Results: The density trial showed that the plant growth rate of certain parameters (*e.g.* wet weight) was slower at high mite densities, but not significantly. High mite densities did, however, cause significantly more damage to the leaf surface area than lower densities. It appears that mite herbivory reduces the photosynthetic ability of leaves.

Conclusion: Water hyacinth growth is not impacted negatively at the mite densities used in this experiment, however, damage to the leaf surface area caused by mite herbivory increases as mite numbers increase. Mite herbivory, at the populations tested here, does not have significant impacts on plant growth. Under high nutrient conditions, the mites are less effective against the plant.

POSTER PRESENTATION

Field Efficacy of *Melia azedarach* L. Fruit Extracts on the Survival of *Ommatissus lybicus* DeBerg.(Homoptera : Tropiduchidae).

Hussain F. M.Ali[2], Ahmed .Al-Dhamin[1], Mohammed Al-Rawy[1]

[1]Univ. of Baghdad, College of Science, Dept. of Biology, Jadhrya, Baghdad, Baghdad, Iraq,
[2]Ministry of Sci. & Tech., IPC Res.Ctr., P.O.Box 765, Baghdad, Iraq

Introduction: Dubas bug *Ommatissus lybicus* DeBerg. is consider the most serious insect pest of date palms in North Africa and the Near East.). In Iraq and since the thirties, the only control method used is spraying synthetic chemical insecticides . Presently, botanical insecticides offer a promising alternative to synthetic insecticides . In this article, we investigate the effects of *M. azedarach* fruit crude extracts on the survival of the dubas bug, *Ommatissus lybicus* infesting date palm offsets under field conditions.

Methods: Ripe fruits of *M. azedarach*, of Baghdad origin were used for preparing water and organic (hexane followed by methanol)crud extracts using Soxhelt extracts. Bioefficacy of different concentrations of extracts as well as two commercial insecticides were tested on naturally infested offsets with eggs and nymph instars (1^{st}, 3^{rd} and 5^{th}).

Results: A negative correlation between egg hatchability and increase in any extract type concentrations were depicted. The results also showed the death of first nymphal instar hatched from eggs treated with alcoholic extract. Treated first nymphal instar, fed on the leaflet was found to be more susceptible than older instars at both generations. Mortalities were directly correlated with concentrations, regardless the type of crude extract used. In general it was found that methanol extract was more effective, followed by hexane. Meanwhile, synthetic insecticides used showed the highest efficacies.

Conclusions: the results obtained clearly indicated the feasibility of integrating crude extracts of *M. azedarach* fruit in the control programme of dubas bug, *Ommatissus lybicus*.

POSTER PRESENTATION

The sign stimulus for virgin queen execution in the stingless bee *Melipona beecheii*

Stefan Jarau[1], Johan W. van Veen[2], Ingrid Aguilar[2], Manfred Ayasse[1]

[1]Institute for Experimental Ecology, University of Ulm, Ulm, Germany, [2]Centre for Tropical Bee Research, National University, Heredia, Costa Rica

Introduction: Stingless bee colonies generally contain one physogastric- and several virgin queens, which are produced all year round and subsequently killed by the workers unless the old queen has to be replaced or a filial colony is founded. Nothing is known how workers recognize virgin queens in the nest, or which stimulus induces the execution behaviour. We studied this question in *Melipona beecheii*.

Methods: We observed the interactions between virgin queens and workers in small orphan observation boxes containing one brood comb and about 30 adult bees. To investigate the potential role of chemical- and behavioural stimuli emitted by virgin queens we conducted (i) experiments with small cages containing living individuals of either caste, and (ii) bioassays with attacked virgin queens, which we killed (2min at –82°C) and subsequently put back on the comb.

Results: Virgins were only attacked when they quickly moved inside the observation boxes. The workers' aggression significantly decreased (Wilcoxon signed-ranks test, P=0.008, N=9) from 15.0 (median) to 0.0 attacks per 10min before and after a virgin queen was killed by freezing, respectively. The workers' behaviour towards an empty cage or a cage with another worker or a virgin queen inside was the same. Neither the number nor the duration of contacts with these cages differed significantly (one-way ANOVA, P>0.05, N=12).

Conclusions: Our results show that workers only attack virgin queens when they are alive and actively moving. We conclude that the sign stimulus for queen execution is the queens' behaviour rather than a specific chemical cue.

POSTER PRESENTATION

Bio-ecological comparative studies of greenhouse whitefly, *Trialeurodes vaporariorum* (Westwood) (Homoptera: Aleyrodidae) on cucumber and tomato

Shadi Movasaghi, Mehdi Zarabi, Neda Asemany, Bahare Salehi

University of Tehran, Tehran, Islamic Republic of Iran

Introduction: Greenhouse whitefly, *Trialeurodes vaporariorum* (Westwood), is a major pest of greenhouse crops. This study was conducted to investigate some bio-ecological aspects of pest on two glasshouse crops, cucumber and tomato.

Methods: In this study, a 24-h old pair released in plant cages with 4-leaves tomato and 2-leaves cucumber separately (in 15 replicates) in controlled conditions (25±2^{o}C, 60±5% RH and L-D: 16-8) and then related data about all developmental stages and population densities collected daily.

Results: Results showed no significant difference between longevity of immature forms (egg, 1-3rd larval stages, pre pupa and pupa) on hosts. Its life cycle duration was 25.6± 0.7 and 25.5± 0.5 on cucumber and tomato respectively which did not show significant differences. Population density results showed: 2.8± 0.5 and 4± 0.6 for eggs/female/day and 2.7± 0.5, 3.7±0.7; 2.3±0.7, 2±0.5; 2.2±0.5, 1.8±0.4; 2.2±0.6, 1.6±0.2 for (1-4th) larval stages, pre pupa, pupa and adults densities/day on cucumber and tomato respectively. All densities did not show significant differences but death rate of adults was 50% and 28% for population on tomato and cucumber respectively. There found no pupal death in the population of cucumber but it showed the average of 11% in tomato. The new generation sex ratio was 85.5% and 80% in the population of cucumber and tomato respectively. There was no significant difference between males and females densities on hosts but, the female's density was 59.6% on cucumber and 40.4% on tomato.

Conclusions: Lower death rate of adults and higher female's density in the colony of pest on cucumber indicate that this crop is a better host for continuing pest generations. Thus the pest's population will increase highly on cucumber in compare with tomato.

POSTER PRESENTATION

The novel function of apolipophorin-III in *Hyphantria cunea*

Hong Ja Kim[1], Young Jin Kang[2], Yong Min Kwon[1], Yong Il Kim[1], In Hee Lee[3], Byung Rae Jin[4], Yeon Soo Han[5], Hyang Mi Cheon[6], Sook Jae Seo[1]

[1]Gyeongsang National University, Jinju, Gyeongnam, [2]Yeungnam University, Daegu, [3]Hoseo University, Asan, Chungnam, [4]Dong-A University, Busan, [5]Chonnam National University, Gwangju, [6]Korea Forest Research Institute, Jinju, Gyeongnam, Republic of Korea

Introduction: Apolipophorin-III (apoLp-III) is a hemolymph protein whose function is to facilitate lipid transport in an aqueous medium in insects. Recently, apolipophorin-III in *Galleria mellonella* and *Hyphantria cunea* was shown to play an unexpected role in insect immune activation. We show here a novel possible function/role of the apoLp-III in insects.

Methods: To investigate the genes which have a relationship with apoLp-III in fall webworm larvae, we reduced endogenous *Hc* apoLp-III mRNA levels in larvae via RNA interference (RNAi). We performed DD-PCR to identify down-regulated genes during the knock-down of *Hc* apoLp-III cDNA. DNA fragmentation from the fat body cells, with or without RNAi, was assayed using an Apoptotic DNA-Ladder Kit. Visualization and localization of apoLp-III, antioxidants and ROS (or apoptosis) in the three tissues were performed using a confocal microscope.

Results: We cloned and sequenced a total of 179 cDNAs which disappeared or decreased by *Hc* apoLp-III knockdown. The RNAi-mediated *Hc* apoLp-III reduction resulted in the reduction of antioxidants, like MnSOD, catalase, and glutathione S transferase as well as immune proteins. In particular, expression of MnSOD commonly decreased in fat body, midgut, and hemocytes following the knockdown of *Hc* apoLp-III, which induced an elevated level of superoxide anion in *Hyphantria cunea* larvae.

Conclusions: The observed effect of *Hc* apoLp- RNAi suggests that *Hc* apoLp- is related to the action/expression of antioxidants.

POSTER PRESENTATION

POSTER PRESENTATION

Characterization of hemocyte STAT gene in *Hyphantria cunea*

Hong Ja Kim[1], Young Jin Kang[2], Yong Min Kwon[1], Yong Il Kim[1], In Hee Lee[3], Byung Rae Jin[4], Yeon Soo Han[5], Hyang Mi Cheon[6], Sook Jae Seo[1]

[1]Gyeongsang National University, Jinju, Gyeongnam, [2]Yeungnam University, Daegu, [3]Hoseo University, Asan, [4]Dong-A University, Busan, [5]Chonnam National University, Gwangju, [6]Korea Forest Research Institute, Jinju, Gyeongnam, Republic of Korea

Introduction: Innate immunity responses are triggered by the immune challenge and therefore involve signaling processes. The cellular response is initiated by hemocytes and mainly involves phagocytosis and encapsulation of intruders by these cells. First report about the lepidopteran hemocytic STAT is discussed in regard to its induction and translocation into nucleus in hemocyte upon bacterial and fungal challenge.

Methods: The mRNA expression level of Hc-STAT at the embryonic, larval, pupal, and adult stages was analyzed by RT-PCR. Last instar larvae were injected with *E. coli, E. faecalis, C, albican* and total RNA was extracted from various organs at 12 h post-injection of bacteria and fungi for RT-PCR. We next investigated whether Hc-STAT can bind STAT binding motif using EMSA. To address whether Hc-STAT is activated upon bacterial challenge, we examined the subcellular location of STAT protein in hemocyte by immunostaining.

Results: A new insect member of the STAT family of transcription factors (Hc-STAT) has been cloned from the lepidopteran, *Hyphantria cunea*. The domain involved in DNA interaction and the SH2 domain are well conserved. The gene is transcribed at a low level during all stages of development, and the protein is present in hemocytes, fat body, midgut, epidermis, and Malphigian tuble. Especially, the organs showed transcriptional activation of Hc-STAT upon Gram (-) bacteria and fungal challenge. Gram (-) bacteria and fungal challenge specifically results in nuclear translocation of Hc-STAT protein and induction of DNA-binding activity that recognizes a STAT target site in *H. cunea* hemocyte. *In vitro* treatment with pervanadate translocates Hc-STAT to the nucleus in hemocyte cells.

Conclusions: Here we report the first evidence for the involvement hemocyte JAK/STAT pathway upon microbial infection in lepidopteran insect.

POSTER PRESENTATION

Comparative analysis of two attacin genes from *Hyphantria cunea*

Yong Min Kwon[1], Young Jin Kang[2], Hong Ja Kim[1], Yong Il Kim[1], In Hee Lee[3], Byung Rae Jin[4], Yeon Soo Han[5], Hyang Mi Cheon[6], Nam Gyu Ha[7], Sook Jae Seo[1]

[1]Gyeongsang National University, Jinju, Gyeongnam, [2]Yeungnam University, Daegu, [3]Hoseo University, Asan, Chungnam, [4]Dong-A University, Busan, [5]Chonnam National University, Gwagju, [6]Korea Forest Research Institute, Jinju, Gyeongnam, [7]Gyeongnam Agricultural Research and Extension Services, Jinju, Gyeongnam, Republic of Korea

Introduction: In lepidopteran insects, attacin is one of the major antibacterial proteins secreted into the hemolymph upon infection with bacteria. We describe the characterization of cDNA clones for two types of attacin A and B from *H. cunea*.

Methods: To investigate the biological activity of *H. cunea* attacin, two attacin cDNAs were introduced into a baculovirus expression system and purified using HisTrap and HiTrap desalting columns. Antimicrobial activity of two attacins was determined by a radial diffusion assay. The induction of two attacins against various kinds of microorganism was investigated by Northern blot.

Results: The two attacin cDNAs encode precursor proteins of 233 and 248 amino acid residues, respectively, and 45.9% identity at the amino acid level. Attacin B is a typical glycine-rich protein (13.8%), while attacin A is leucin-rich (13.4%). Attacin B is expressed from last instar larvae to adult, while attacin A showed stage-specific expression during the prepupal and pupal stages. Attacin A and B showed similar hydrophilicity patterns while both proteins showed different secondary structures. Attacin A shows no induction in infected larvae, while attacin B is strongly induced against Gram-positive and -negative bacteria, fungi, and viruse. Recombinant attacin A showed no antibacterial activity, while recombinant attacin B showed strong antibacterial activity in proportion to the amount of the protein applied.

Conclusions: Hyphantria attacin A and B showed low identity (49.9%) each other, different amino acid composition, and different secondary structures. Our work focused the characterization of attacin A and B in which they showed stage-specific expression and different induction activity against various microorganisms.

POSTER PRESENTATION

Life table and age-dependant reproduction of *Chrysoperla carnea* on eggs of *Ephestia kuehniella* and *Helicoverpa armigera* under laboratory conditions

Mehdi Hassanpour, Gadir Nouri-Ganbalani, Jafar Mohaghegh, Shahzad Iranipour

[1]University of Tabriz, Tabriz, [2]University of Mohaghegh Ardabili, Ardabil, [3]Irainan Research Institute of Plant Protection, Tehran, Islamic Republic of Iran

Introduction: *Chrysoperla carnea* is a widely distributed predator of soft-bodied arthropods throughout the world. Due to the importance of this predator in biocontrol programs, life table studies of this predator on different preys give the most comprehensive description of the survivorship, development, and reproduction of the predator.

Methods: Life table of *C. carnea* were studied on eggs of *Ephestia kuehniella* and *Helicoverpa armigera* at 26±1℃, a photoperiod of 16:8 (L:D) h and 70±5% RH. Newly emerged larvae of predator were reared singly with an ample supply of eggs of both prey separately (n=100). When adults emerged, the females and males were paired in a plastic cup (400 ml) with screen top and were fed on artificial diet and distilled water. The fecundity and survival were recorded daily until all of females were dead.

Results: The intrinsic rates of increase (r_m) on two prey were 0.1816 and 0.2238 female/female/day respectively. Net reproduction rates (R_0), finite rate of increase (λ), intrinsic birth (b) and death (d) rates, doubling time (DT) and mean generation time (T) of the predator feeding on two prey were 352.6777 and 579.78424 (female /female), 1.1991 and 1.2508 (day^{-1}), 0.1823 and 0.2271 (day^{-1}), 0.0007 and 0.0033 (day^{-1}), 3.8176 and 3.0974 (days), and 32.2728 and 28.4185 (days), respectively.

Conclusion: The higher values of r_m, R_0, and λ and shorter T and DT were achieved with rearing predator on eggs of *H. armigera.* This result revealed that the egg of *H. armigera* is a suitable prey for *C. carnea* than that of *E. kuehniella*.

POSTER PRESENTATION

Toxicity appraisement of Methaldehyde, Biopesticide, repellent bands and repellent colors against the land snails, X*eropicta derbentina*, *Xeropicta krynickii* (Stylommatophora: Hygromiidae)

Behnam Amiri-Besheli, Fatemeh Asgharnejad

Faculty of Agric. Univ. of Mazandaran, Sari, Islamic Republic of Iran

Different methods have been applied to control the land snail (*Xeropicta derbentina*) and (*Xeropicta krynickii*) but the chemical are realized to be the best and effective methods to control this pest. The main goal of this work was to determine the efficacy of Methaldehyde، Biological toxin, repellent band and repellent color on this pest. Methaldehyde, Biological toxin were used as bait around citrus trees and repellent band and repellent color rolled up around main stem of the citrus trees. The live snails on citrus trees were monitored at 2, 15, 29, 36, 68 and 98 days after treatments. Analysis of variance showed that there were significant differences between treatments and control, and also significant differences were found among treatments ($p<0.01$). LSD & Tukay-Test among above treatments has shown that repellent band and Methaldehyde with 5± 1.3 and 10.6± 0.9 percentage of the alive snail on trees were more effective than repellent color and Biological toxin with 14.2 ± 2.6 and 31.3±3.9 percentage alive snail on citrus trees and significant differences with control respectively. The control efficacies of the Methaldehyde and Biologic toxin were 91.87%, 82.63% respectively, also the control efficacies of the repellent band and the repellent color were 95.22% and 82.26 % respectively after 2, 15, 29, 36, 68 and 98 days of post treatment. Therefore the repellent band and methaldehyde were better than the other treatments for the management of land snail population.

POSTER PRESENTATION

Ixodid tick species infesting sheep and cattle in Kelardasht (Chloos), Iran

Mohamad Yossef Asnaashari, Mohamad Reza Yoeefi, Zohreh Saltanatpour, Afsaneh Amoei, Fatemeh Asgarian, Saeid Salehi

Mazandaran University, Sari, Islamic Republic of Iran

Introduction: Ticks are features which are of metastigmata order. All of these features are parasite of animals which only feed on them. Ticks and disease related, causes economical damages which in some case these damages reaches to million dollars each year. Because of the importance of recognition ticks, particularly Ixodidae,this research has been done on Ixodidae ticks on domestic animals at Kelardasht in Mazandaran Northern Iran.

Methods: The used method in this research it was cross-section and ticks were studied on, were collected samples,798numbers of them departed in genus and species and the rest were eliminated.

Conclusion: In this study 6 groups species. In *Ixodes* the only observed species was *ricinus*, in *Boophilus* only *anulatus* species, in *Dermacentor* only *marginatus* was identified. But in *Haemaphisalis* two different species were observed *punktata* and *inermis*. In *Hyalloma* and *Ripicephalus bursa* was observed. in these study samples the most percentages was seen in *Ixodes* (26.8%) and the minimum was in *Haemaphisalis* (0.2%).

POSTER PRESENTATION

Natural occurrence and characteristics of entomopathogenic fungi isolated from red palm weevil in Sicily (Italy)

Barbara Manachini[1], Stefano Colazza[2], Franco Palla[3]

[1]Department of Animal Biology, University of Palermo, Palermo, Italy, [2]Department of S.En.Fi.Mi.Zo., section of Entomology, Acarology and Zoology,University of Palermo, Palermo, Italy, [3]Molecular Biology Laboratory, Department of Botanical Sciences,University of Palermo, Palermo, Italy

Introduction: Originally from tropical Asia, the red palm weevil (*Rhynchophorus ferrugineus* (Olivier)) is the most dangerous and deadly pest of date, coconut, oil, sago and other palms. It has spread to Africa and Europe, reaching the Mediterranean in the 1980s, and was first recorded in Sicily (Italy) in 2005. Due to its recent introduction and the difficulty of its control, to known the natural pathogens of RPW in the introduced areas is very important.

Methods: Pupae from infested palms *Phoenix canariensis* Hort. were collected. The entomopathogenic fungi were isolated and growth. Because of it is possible to growth only the 1% of the known fungi, the identification of entomopathogens is done also using specific molecular markers (e.g. microsatellites and ITS) and microscopical analysis (SEM, CLSM).

Results and conclusion: This is the first report of a native fungal pathogen affecting the pupa of *R. ferrugineus* in Italy. About 30% of pupae collected in Palermo (Sicily) were infected with the entomopathogens. Symptoms of fungal infection included rapid pupal tissue atrophy and failure of adults to emerge, death. Dissections of infected pupae revealed dense hyphal growth inside pupae, thus suggesting fungal penetration and pathogenicity.

A GIS method for assessing different Malagasy migratory locust risks

Aurelia Decherf[1], Alex Franc[1], Tsito Andriamaroahina[2], Jean-François Duranton[1]

[1]CIRAD, Montpellier, France, [2]National Locust Centre (CNA), Tuléar, Madagascar

Introduction: The Malagasy migratory locust, *Locusta migratoria capito* (Saussure, 1884) is the most important agricultural pest in Madagascar. When solitary individuals group together, they become gregarious then causes swarm outbreaks. As rainfall discriminates annual locust population dynamics, by monitoring the eco-meteorological conditions, it is possible to locate and assess locust risk. A forecasting system is the main goal of the Malagasy National Locust Centre in running national preventive controls and establishing three levels of risk: local upsurge, major outbreak with phase transformation, and invasion.

Method: A Geographical Information System (GIS) had been created to delimit locust risks in a pilot study area (the Ejeda zone) 15% of the outbreak area (100 000 km²). This system combines first locust habitats, mapped using remote sensing data, along with rainfall data to evaluate ecological potential. Second, this ecological potential is compiled spatially in a database which includes locust data (density and phase) collected in the field. From this point, several levels of locust risk can be evaluated: 1) local upsurge risk; 2) phase transformation risk; and 3) invasion risk. These locust risks are evaluated and mapped monthly. Risk localisation can guide survey and control operations in the field to be quick and more efficient.

Results: The risk maps were validated for the pilot zone using archived data. A generalisation to the entire outbreak area is now in progress.

POSTER PRESENTATION

Citrus whitefly, *Dialeurodes citri* (Ashmead) (Homoptera: Aleyrodidae), life cycle and population fluctuation studies in Iran

Maede Kordrostami, Mehdi Zarabi, Mohamad Fazel Halaji Sani

University of Tehran, Tehran, Ministry of Jihad-Agril., Research and Teaching Organization, Citrus research Centre, Ramsar, Islamic Republic of Iran

Introduction: The citrus whitefly, *Dialeurodes citri* (Ashmead) is one of the most important pests of citrus plants in north regions of Iran. It has a high population density on citrus plants in greenhouses and gardens. In this study its life cycle and population fluctuation was studied on young Tompson Navel variety.

Methods: For this purpose five trees were selected randomly and ten leaves of each plant sampled every 3 days during early April until late December. The population of adults, nymphs and eggs evaluated on 4 ^{cm2} of these leaves area. Biological studies carried out with the field and incubation experiments by releasing one pair in leaf cages on young trees.

Results: Results showed that this pest has three generations which the early generation start at mid of May and complete its life cycle until late June. The second one observed from early August and the third one at mid of Sep. According to its population fluctuation, the nymphal density increase in early Sep. and the adult's density at June, July and October. The biological data showed that the longevity of egg, nymphs(three stages), pupa and adults was 10-13, 21-32, 10-12 and 12-15 days respectively in controlled condition (25±2^{ºC}, 75±5% RH and L-D:14-10). This data was near to fields experiments too.

Conclusions: It seems that the 2nd generation has the highest density and cause serious damage. Thus duration of its life cycle was near 65 days. Each female can oviposit up to 120 eggs in his life. The 3rd nymphal stage is the over wintering form of pest which remain on diapauses.

POSTER PRESENTATION

Changes in development of male germinal cells of Egyptian cotton leaf worm *Spodoptera littoralis* (Boisd) caused by selected compound with activity of insect hormones.

Ivan Gelbic

Biological Centre AS CR, Institute of Entomologz, Ceske Budejovice, Czech Republic

Introduction: The role of insects hormones in the process of reproduction is studied by many authors. Present paper deals with the effects of selected compounds with activity of insect hormones on the development and maturation of male germinal cells in *Spodoptera littoralis* (Boisd.).

Methods: Morphological and histological changes of testis caused by methoprene, 20-hydroxyecdysone, RH-2485 and RH-5992 were studied.

Results: Spermatogenesis begins early in the postembryonic development. Formation of spermatogonia occurs in larval instars 1-3. Meiotic division starts in instar4 and in the last larval instar all developmental stages of spermatozoa can be found. The first bundles of mature spermatozoa occurs in prepupae. In 5 day-old-pupa more than 90 % of the spermatozoa are mature. Application of juvenoids or ecdysterone caused some disorders in the development of spermatozoa. After application of different concentration of methoprene on the different developmental stages reduction of the reproductive ability of males was observed. This reduction is caused by numerous disorders in development of spermatozoa. Numerous pycnosis appear in spermatogonia, inhibition of spermatocytes and their gradual disintegration and disorders of spermateliosis take place. On the other hand, pathological changes were not found after application of 20-hydroxyecdysone or RH compounds and the spermateliosis started earlier in comparison with controls.

Conclusions: All compounds tested caused dose dependent changes in development and growth – prolongation of larval intermoult periods, formation of different larval pupal intermediates. Sterility of males was induced only by application of methoprene.

This work was supported by the grant GA CR 522/08/1407 of the Grant Agency of the Czech Republic and AV0Z50070508.

POSTER PRESENTATION

A phylogenetic study of the subtribe Dicrepidiina (Coleoptera: Elateridae: Elaterinae: Ampedini)

Sônia Casari

Museu de Zoologia da Universidade de São Paulo, São Paulo- SP, Brazil

Introduction: The subtribe Dicrepidiina is composed by 36 genera and about 1,520 species. The purpose of the present cladistic analysis is to test the monophyletism of the subtribe and to verify the relationships among the genera. All genera, except Asebis, Lamononia, Neopsephus, Semiotopsis and Spilomorphus were studied. For each genus at least the type-species was analysed**.**

Methods: Seventy eight characters of fifty two taxa were selected; multistate characters were used, always being treated as unordered. The analyses were conducted using the TNT program, based on 20000 random addition sequences with 2 trees save per replication. The swapping algorithm used was tree bisection reconnection (TBR). The characters were initially treated as unweighted. In a second analysis, they were weighted using successive weighting, and fits 5, 10, 15, 20, 25, 30, 40 and 50 were tested.

Results: The first analysis, using equally weighted characters produced 11 equally most-parsimonious trees. The second analysis was conducted after aplication of the sucessive weighting option according to the maximum value of the fitness. Using fit 5 resulted in four trees and fits from 10-50 produced one tree.

Conclusions: It was concluded that Ovipalpus Solier, 1851, does not belong to Dicrepidiina and even to Ampedini. It appears to be closely related to Prosternini (Prosterninae). The subtribe Dicrepidiina (excluding Ovipalpus) is monophyletic, defined especially by tarsomeres 2 and 3 lamellate. It is the sister group of Physorhinina. Besides, it is demonstrated that the genera Achrestus, Anoplischius, Dipropus and Propsephus are not monophyletic.

POSTER PRESENTATION

Biology of saprophagous hoverflies (Diptera, Syrphidae) and its role in degrading of pig slurry

Pilar Hurtado, Celeste Pérez-Bañón, Thomas Gladis, Berta Pastor, Santos Rojo

Instituto Universitario CIBIO. Universidad de Alicante, Alicante, Spain

Introduction: One of the most important trophic habits of syrphid larvae is the saprophagy. In fact, some species are very common in the huge volume of pig manure derived from intensive production model in Spain. We will analyze several aspects of larvae and adult biology including mass-rearing production.

Methods: Adults and larvae were collected in pig farms. Larval stages were reared in the laboratory with different media as pig slurry, oat with water and barley with water, in order to know the best media for their development. Mass-rearing included also, permanent adult colonies under controlled conditions. Different types of pollen, sugar and water were used to mature adults. Biotic interactions with parasitoids were also studied.

Results: The most common syrphid species in pig farms was *Eristalis tenax*. This species can develop its larval cycle on pig slurry. Artificial media based on oat or wheat can be used satisfactory. Four species of eristalines can be artificially reared with this technology. These results have been applied in the frame of ECODIPTERA project (LIFE-environment EU project).

Conclusions: Mass rearing of saprophagous hoverflies is possible. This fact let us use these insects as biodegrading agents or pollinators.

POSTER PRESENTATION

Is the diversity of jumping-spider mimicry in micromoths driven by jumping spider's diversity?

Mu-Yung Wang, Shen-Horn Yen

Department of Biological Sciences, National Sun Yat-Sen University, Kaohsiung, Taiwan

Biological mimicry comprises a wide range of relationships among predators and preys. If the predator is mimicked by the prey and perceptionally confused by the signals exhibited by the prey, the mimicry scenario is called "predator mimicry". It has been proved that several phylogenetically distant clades of microlepidoptera, that demonstrate distinct wing patterns and wing display behaviours, participate in this peculiar mimicry system with jumping spiders (Salticidae), and several types of visual signal, e.g. UV and fluorescence, may play important roles in promoting the mimicry. In the present study, we aim to answer the following questions using multiple approaches: (1) Do different types (and combinations) of wing patterns and display behaviours micromoths create discrete effects on this putative mimicry? (2) Is there any key feature in moths' colour pattern that promotes mimicry, which can be referred to the so-called "imperfect mimicry"? (3) If there is discrete effectiveness between different wing pattern and display behaviours, is the diversity of moths' mimetic pattern correlated with spider's diversity in responding moth's behaviour? and (4) if any moth clade that exhibits specific type of jumping spider-mimicking wing pattern has greater species richness due to the relative success in defending jumping spiders in respect to its sistergroup that does not own the colour patterns and photonic features? The results of the present study are expected to explore the unresolved mystery of this peculiar mimicry system and contribute to both behavioural and evolutionary ecology of this phenomenon which is commonly seen but being ignored for long.

POSTER PRESENTATION

Did the model obtain mimetic colouration earlier than the mimics? A preliminary analysis using the mimicry complex displaying the "*Euploea mulciber*" syndrome as a case study

Chia-Hsuan Wei[1], Li-Wei Wu[2], Yu-Feng Hsu[2], Shen-Horn Yen[1]

[1]National Sun Yat-Sen University, Kaohsiung, Taiwan, [2]National Taiwan Normal University, Taipei, Taiwan

Defensive mimicry among organisms has attracted attention from biologists for centuries and has been investigated in various areas such as psychology, ethology, visual ecology, genetics and development. In the general prediction, the model, which displays stronger secondary defence and aposematism, is expected to have evolved earlier than the co-mimic species. The less protected species, which are usually called mimics, may have participated in the mimicry sequentially. Previous studies have shown the evolutionary trend of formation of a particular mimetic syndrome within a single evolutionary lineage, but the evolutionary dynamics among multiple independent lineages that involve in one co-mimicry system has never been investigated. In the present study we focus on a mimicry complex, of which the species involved all demonstrate the sexually dimorphic "*Euploea mulciber*" syndrome. At least seven lepidopteran genera belonging to the Nymphalidae, Papilionidae and Zygaenidae and predominantly distributed in Sundaland and Indochina have been found to involve in the mimicry complex. We first inferred the individual phylogenies of the *Euploea mulciber* complex and the *Papilio* subgenus *Chilasa* based on multiple gene sequence information, and then estimated the divergence time of the lineages that are sympatric in distribution and participate in the mimicry complex. We wish to use this preliminary study case to address two questions: (1) if the putative model, which is always considered more unpalatable and abundant, has evolved earlier than the palatable mimics? and (2) if diversification of the model and mimic lineage has been driven by one of each or each other.

POSTER PRESENTATION

Use of infochemicals to attract burying beetles (Coleoptera: Silphidae) into pitfall traps

Hana Podskalska[1], Jan Ruzicka[1], Michal Hoskovec[2]

[1]Czech University of Life Sciences, Prague, Czech Republic, [2]Institute of Organic Chemistry and Biochemistry, Prague, Czech Republic

Introduction: Our team is focused on ethological and chemo-ecological research of burying beetles (Silphidae: Nicrophorinae), which are attracted by small vertebrate carrion, and are well-known for their biparental care.

Methods: In previous study, we identified the following volatile substances (infochemicals) from small vertebrate carcass using 2D-GC/MS-TOF method: methanethiol (MSH), dimethylsulfide (DMS), dimethyldisulfide (DMDS), dimethyltrisulfide (DMTS) and methylthiolacetate (MTA). Three of these infochemicals were tested in a field (220 baited pitfall traps with DMTS or blank, combined with DMS or DMDS).

Results: In a field experiment in southern Bohemia (Czech Republic) we collected a total of 362 adults of *Nicrophorus vespillo* (Linnaeus). We conclude that DMTS attracts burying beetles form a long distance, and for short distance DMDS has proven to be significantly more effective than the more volatile DMS molecules. DMTS volatility is low, compared to DMDS and DMS.

POSTER PRESENTATION

Pesticide-induced metabolism in *Caenorhabditis elegans*

Samantha Broad[2], Anthony Flemming[1], Peter Urwin[2]

[1]Syngenta, Berkshire, United Kingdom, [2]University of Leeds, Leeds, United Kingdom

We are interested in the inducible metabolic defences of organisms to applied chemicals. We used the nematode *C. elegans* to uncover genes up-regulated in response to pesticides and other toxic compounds. We identified using microarrays a number of such genes including members of classes known to be involved in xenobiotic chemical metabolism (Cytochrome P450s, Glutathione S transferases etc). Many of these genes were specific to chemical stress, though some were also induced by other forms of stress (osmotic and thermal). Strikingly we found that different compounds often induced different metabolic genes. In some cases the genes induced by one compound were almost entirely mutually exclusive to those induced by another. This implies a complex regulatory process, allowing specific metabolic responses to specific chemicals. Thus far only one regulator of metabolic gene expression has been demonstrated in *C. elegans*, the conserved nuclear hormone receptor NHR-8. Our data suggest that inducible metabolism is more complex than an all-or-nothing-response mediated by a single 'switch' and so additional regulators, acting in parallel or downstream of NHR-8 are likely to exist. Understanding how metabolism is regulated in *C. elegans* will allow us to ask framed questions about how it is regulated in pests. This, in turn, can be used for a variety of applications: to better understand metabolic field resistance to pesticides, to design small molecule pesticides that 'avoid' pest metabolism, or to discover chemical synergists that target metabolism directly.

POSTER PRESENTATION

Understanding and improving the residual efficacy of the *Cryptophlebia leucotreta* granulovirus

Wayne Kirkman, Sean Moore

Citrus Research International, Port Elizabeth, South Africa

Introduction: False codling moth (FCM), *Thaumatotibia* (=*Cryptophlebia*) *leucotreta* (Meyr) (Lepidoptera: Tortricidae), is one of the most important pests on citrus. The *Cryptophlebia leucotreta* granulovirus (CrleGV) has been developed into a successful biological control agent, registered as Cryptogran for the control of FCM on citrus in South Africa. A study was conducted to investigate biotic and abiotic factors affecting field persistence of the virus, and how to improve it.

Methods: Laboratory bioassays were conducted to determine the effect of UV-irradiation on the virus. Various products were tested as UV protectants for the virus, both in laboratory bioassays and in orchard trials. Laboratory trials were conducted to determine rainfastness of Cryptogran. The effect of the timing of applications was determined in orchard trials. The effect of the navel end of a navel orange on the efficacy of the virus was also investigated.

Results: The addition of lignin improved FCM control by up to 93%, although results were variable. Cryptogran was shown to be rainfast. Cryptogran applied early in the season was effective for up to 16 weeks compared to 6 weeks for sprays applied closer to harvest. Daytime applications were less effective than evening sprays. Sprays applied coinciding with peaks in pheromone moth trap catches were more effective than those applied between peaks. Control lasted for 17 weeks where treatments were applied to blocks as opposed to 8 weeks for single tree treatments.

Conclusion: Lignin enhanced the activity of the virus, but results were variable and the lignin product is expensive. Timing of applications and the use of effective application equipment are more important than the addition of UV-protectants.

POSTER PRESENTATION

Analysis and functional annotation of 15,000 expressed sequence tags from the gut of European corn borer (*Ostrinia nubilalis* Hübner) larvae.

Chitvan Khajuria[1], Yu Cheng Zhu[2], Ming Shun Chen[1], Lawrent L. Buschman[1], Muthukrishnan Subbaratnam[1], Kun Yan Zhu[1]

[1]Kansas State University, Manhattan, KS, United States, [2]USDA-ARS-JWDSRC, Stoneville, MS, United States

Introduction: The European corn borer (ECB) is an important lepidopteran pest of corn in the United States. Large sets of expressed sequence tags (ESTs) were sequenced from the gut of the ECB larvae. The identification of these genes will allow a better understanding of the mechanisms of Bt toxicity/ Bt resistance in insects.

Methods: A cDNA library was constructed using ZAP-cDNA synthesis kit and ZAP-cDNA Gigapack III gold cloning kit (Stratagene). Recombinant plasmid DNA was isolated with Qiagen Bio Robot- 3000 and sequenced using an ABI 3700 DNA analyzer. ESTs were analyzed using online softwares EG assembler and Blast2go.

Results: A total of 15,000 random clones were sequenced from the cDNA library constructed from the gut of ECB larvae. These sequences were assembled into 4,451 unique sequences, including 2,787 singletons and 1,664 contigs. Among these sequences, 78% encoded for putative proteins which shared significant sequence similarity with known sequences in GenBank with E-values ≤ 10^{-5}. These sequences include genes encoding various digestive enzymes such as chymotrypsin-like proteases, trypsin like-proteases, elastases, cysteine proteases, carboxypeptidases, and aminopeptidases. These putative proteins were further analyzed and sorted into different categories of molecular functions, biological processes and cellular components.

Conclusions: Our EST analysis has putatively identified many different genes expressed in the digestive system of ECB. These results provide foundation to use microarray technology for analyzing the global changes of gene expression in response to Bt protoxins/toxins between Bt-resistant and -susceptible strains of ECB.

POSTER PRESENTATION

Molecular mechanisms of proximodistal patterning during leg regeneration in the cricket, *Gryllus bimaculatus*

Taro Nakamura[1], Taro Mito[1], Tetsuya Bando[2], Ohuchi Hideyo[1], Sumihare Noji[1]

[1]Department of life system, Institute of Technology and Science, The Univ. of Tokushima, Tokushima City, Japan, [2]Tokushima Intellectual Cluster, The Univ. of Tokushima, Tokushima City, Japan

Introduction: Nymphs of hemimetabolous insects such as cockroaches and crickets possess functional legs with a remarkable capacity for regenerating epimorphically. To elucidate the mechanism of leg regeneration, we have focused on the role of *Distal-less* (*Dll*), *Epidermal growth factor receptor* (*Egfr*), and *dachshund* (*dac*), which are involved in subdivision of the leg disc along the proximal-distal (PD) axis in *Drosophila* leg development.

Methods: For loss-of-function analyses of these genes, we injected double-stranded RNA of *Gb'Egfr*, *Gb'Dll*, and *Gb'dac* in the third instar nymph and then amputated a leg at the distal or proximal tibia.

Results: We found the followings: (1) EGFR signaling are involved in re-patterning of the most distal region, the third tarsal segment and pretarsus, through the regulation of *Gb'aristaless* (*al*) and *Gb'dac* with a gradient of activity; (2) *Gb'dac* controls the tibial length and re-patterning of proximal tarsus, through the functional relationship between *Gb'Dll* and *Gb'dac*, and also act as a leg gap gene; and (3) *Gb'Dll* activity is not required for regeneration of the tibia, while in the distal blastema, high activity of *Gb'Dll* is required for re-patterning of tarsal and pretarsal segments through repression of *Gb'dac* expression and regulation of *Gb'al* and *Gb'BarH*.

Conclusions: These results suggest that EGFR signaling and Dll activity are used for providing positional information along the PD axis in the distal leg patterning in insects regardless of the mode of leg formation (leg development and regeneration).

POSTER PRESENTATION

Investigation on developmental stages and host range of *Clitostethus arcuatus* (Coleoptera: Coccinellidae)

Mehdi Zarabi[1], Maryam Yazdani[1], Abas Yazdani[2]

[1]Unive of Tehran, Tehran, Islamic Republic of Iran, [2]Plant Protection offices, Organization of Jihad- Agril., Kerman, Islamic Republic of Iran

Introduction: *Clitostethus arcuatus*, has recorded as whitefly predator in Mediterranean, Russia, North African, Asia minor, Europe and Iran. This research was carried out to study its life cycle and host range in Iran.

Methods: Newly emerged ladybirds collected from ash whiteflies colonies in early spring then reared in controlled conditions (25±2ºC, 65±5% RH and L-D: 16-8). They fed daily with different life stages of Ash whitefly and related data collected daily. In the other hand, its host rang was evaluated by random sampling of ladybirds from whiteflies host plants throughout of central parts of country (Kerman province).

Results: Results showed that, mean of longevity of egg, 1-4th larvae, pupa, female and male were 3/5±0/93, 3/5±0/53, 4/63±0/92, 5/38±1/41, 10/75±1/16, 4/5±0/53, 77/3±6/9 and 67/5±7/2 days respectively. Consequently, it has 4 generations annually that the entire life cycle from egg to adult takes an average of 32/9±3/11days. Adults remain in diapauses for 5 months in the last generation. 2nd and 3rd generations fall on aestivation in hot summer. Females laid an average of 3/89±1/76 eggs/day. Host range studies showed that the matured adults appeared in late May on Ash Whitefly, *Siphoninus phillyreae* but its larval stages were found on another whitefly colony, *Bulgariodes cotessii*. Also in late June they are seen on pomegranate trees too.

Conclusions: This predator can control all life stages of Ash whitefly on different hosts specially the Ash and pomegranate trees. In addition the *Bulgariodes cotessii* is a suitable host for predator in absent of main prey, Ash whitefly.

POSTER PRESENTATION

Investigation on developmental stages and host range of *Clitostethus arcuatus* (Coleoptera: Coccinellidae)

Mehdi Zarabi[1], Maryam Yazdani[1], Abas Yazdani[2]

Adults remain in diapauses for 5 months in the last generation. 2nd and 3rd generations fall on aestivation in hot summer. Females laid an average of 3/89±1/76 eggs/day. Host range studies showed that the matured adults appeared in late May on Ash Whitefly, *Siphoninus phillyreae* but its larval stages were found on another whitefly colony, *Bulgariodes cotessii*. Also in late June they are seen on pomegranate trees too.

Conclusions: This predator can control all life stages of Ash whitefly on different hosts specially the Ash and pomegranate trees. In addition the *Bulgariodes cotessii* is a suitable host for predator in absent of main prey, Ash whitefly.

POSTER PRESENTATION

The effects of herbivore induced plant volatiles on tritrophic interactions among host plants, spider mites, peach aphids and a predatory mirid bug

Hamisd R. S. Moayeri, Annie Enkegaard, Ahmad Ashouri

University of Tehran, Karaj, Tehran, Islamic Republic of Iran

Herbivore induced plant volatiles (HIPVs) are produced by herbivores attack that affects on ecology and behavioural responses of heterospecefics/conspecific herbivores and natural enemies. This study was conducted to investigate the effect of HIPVs on interaction among plants (pepper and green bean), herbivores (*Tetranychus urticae* and *Myzus persicae*) and a predatory bug (*Macrolophus caliginosus*) by using a Y-tube olfactometer and gas chromatography-mass spectrometry (GC-MS) technique. Our results show that *M. caliginosus* preferred plants infested by herbivores rather than un infested plants. The mirids did, however, not seem to exploit odours emitted directly from the prey themselves.

Furthermore, the olfactory responses of male and female *M. caliginosus* adults towards volatiles from green bean plants previously exposed to feeding by conspecifics and to direct odours from conspecifics were tested. Female *M. caliginosus* did not respond to volatiles from plants exposed to mirid feeding or to odours emitted directly by adult mirids. In contrast, male mirid bugs were attracted both to volatiles from plants previously exposed to feeding by conspecific females and to direct conspecific odours. The results suggest that female-specific HIPVs are used at least partially as mate-finding cues by the male mirids. These results suggest that female-specific herbivoreinduced plant volatiles play a role as mate-finding cues by the male mirids. The ecological implications of the findings are discussed, and the term 'sexual synomone' is introduced.

POSTER PRESENTATION

Plant host and insecticide effects on some bio-ecological parameters of Greenhouse whitefly, *Trialeurodes vaporariorum* (Westwood) (Homoptera: Aleyrodidae)

Bahare Salehi, Mehdi Zarabi, Neda Asemany, Shadi Movasaghi

University of Tehran, Tehran, Islamic Republic of Iran

Introduction: Greenhouse whitefly, *Trialeurodes vaporariorum* (Westwood), is a major pest of glass house crops. It shows resistant to different common Insecticides. In the other hand, different compounds may show special effects on host plants or vice versa. This study was conducted to evaluate effect of hosts and insecticide, Abamectin on amount of female's oviposition.

Methods: For this purpose, two leaves stand plants of cucumber and tomato dipped by dosages 50,100,150 and 200_{PPM} of Abamectin (1/8% EC). Then three 24-h old pairs released on plants under cages separately which located in controlled conditions ($25\pm2^{\circ C}$, 60±5% RH and L-D: 16-8). Number of eggs/day/female counted after 1, 3 and 5 days. Collected data were analyzed based on a Factorial design with SAS software. This experience repeated for 3 times.

Results: Results showed significant difference (level 5%) between mean of eggs/day/female in two hosts. Averages of amount of oviposition were 7.71±1.2 and 4.2 ±0.9 for cucumber and tomato respectively. There were no significant differences between times and dosages. But the mean of eggs/day/female at the dosage 200 $_{PPM}$ (average of 2.3±0.7) showed a high decreasing in comparing with the control plots (average of 8.9±1.8). In the other hand, amount of oviposition decreased in fifth day in comparing to first day after dipping.

Conclusions: Amount of oviposition on tomato showed this is not a preferred host in comparing with cucumber while it dipped with Abamectin. However, it seems that 200_{PPM} dosage of Abamectin can decrease the amount of oviposition especially after 3-5 days of pesticide usage on these hosts.

POSTER PRESENTATION

Production of queens and males in inbred and outbred population of a stingless bee species, *Melipona scutellaris* (Hymenoptera: Apidae)

Denise de Araujo Alves, Vera Lucia Imperatriz-Fonseca, Pérsio de Souza Santos-Filho

[1]São Paulo University, São Paulo, Brazil, [2]São Paulo University, São Paulo, Brazil, [3]São Paulo University, São Paulo, Brazil

Due to the high potential use of stingless bees in sustainable activities, as meliponiculture and as pollinators of crops, the production of their nests in large scale has an important role for human purposes. Our objective was to evaluate the inbreeding effects on the queens and male production in *Melipona scutellaris*, a species with high value for meliponiculture in Northeast Brazil.

We evaluated 53 brood combs (18,929 bees) from different colonies in an inbred population located at São Simão, Southeast Brazil, and 44 combs (16,812 bees) from colonies in their natural habitat (Northeast Brazil), an exogamic population. The inbred population began with two nests 12 years ago, and 30 nests were reached through successive splitting.

At the population level, the outbred population produced fewer reproductives (5.25% of queens and 10.33% of males) than the inbred population (11.52% of queens and 21.81% of males). The relative frequency of males and queens differed when we compared the populations ($p<0.001$). The colonies produce the reproductives during the whole year, but there is an asynchrony among the nests. Some of them can produce higher frequencies of males than others, due to orphanage or reproductive workers. Besides these within-nest conditions, the inbred population probably produced high number of diploid males; this hypothesis will be tested with molecular tools. The higher queen production in inbred population may be a result of the high frequency of replacement due to matched matings, which is considered a problem for insect societies, due the potential production of diploid males.

POSTER PRESENTATION

The importance of permanent monitoring of vector mosquito populations for their control in Romania

Octavian Ciolpan[1], Gabriela Nicolescu[2], Elena Claudia Coipan[2], Alexandru Filip Vladimirescu[2]

[1]University of Bucharest, Bucharest, Romania, [2]National Institute of Research-Development for Microbiology and Immunology; Cantacuzino, Bucharest, Romania

Introduction: Mosquitoes, the most important insect vectors, transmit West Nile virus infections and maintain the high risk of malaria re-emergence in Romania. The mosquito fauna (56 species) is widely distributed in the country both in urban and rural areas. The control of mosquito populations is needed to eliminate the disease transmission and the nuisance produced by them. The integrated application of control methods in appropriate areas and moments has to be in correlation with the dynamics of mosquito population in various environmental conditions.

Methods: The larvae and adult mosquitoes in Cernica forest (tourism area near Bucharest, south Romania) were investigated for five years by different collecting techniques to detect the number and succession of species, and the structure of populations in correlation with the changing environmental factors.

Results: 18 mosquito species and their qualitative and quantitative dynamics in correlation with the variation of the climatic factors were registered. The main factors favouring the development of high density mosquito populations have been detected. The results showed that the permanent monitoring of the parameters characterizing the mosquito populations under control in correlation with the environmental factors will lead to the efficient application of the adequate control measures in adequate areas and moments.

Conclusions: The mosquito control programme in a territory includes the permanent monitoring of the mosquito population as a main component of the programme which has the aim to reduce the risk of disease transmission and avoid the negative impact upon the environment and human population.

POSTER PRESENTATION

Ecdysteroids affect the expression of ftz-f1, a candidate to regulate vitellogenin in honeybee development

Tathyana Mello, Angel Barchuk, Márcia Bitondi, Michelle Soares, Zilá Simões

FFCLRP of University of São Paulo, Ribeirão Preto, Brazil

Introduction: FTZ-F1 is an orphan member of the nuclear hormone receptor superfamily. In *Drosophila melanogaster ftz-f1* encodes two protein isoforms, α and β. The latter acts as a competence factor for ecdysteroid hormones function. In *Apis mellifera*, knockdown of *vitellogenin*, a major yolk protein which also influences immune response and longevity, results in a decreased expression of *ftz-f1*. The aims of this study were to analyze the characteristics, expression profiles and functions of *ftz-f1* during honeybee development.

Results: The predicted *Amftz-f1* gene comprises 15,612bp and six exons. 1,196bp of the cDNA were sequenced. Expression profiles were determined by sqPCR and qPCR. The profiles are similar in workers and queens. As found in other insects, peaks of *Amftz-f1* expression occur during periods of low ecdysteroids titers - at the fifth larval instar (S3) and at pre-pupae (PP3) - and analyses of pupal integument samples incubated in 1µg of 20-hydroxyecdysone confirmed that this hormone inhibits *ftz-f1* transcription. The highest expression level occurs at the last pupal stage (Pbd) and is 9.4 times higher in queen fat bodies than in workers. A peak of *vitellogenin* expression is also observed at Pbd.

Conclusion: Our results suggest that also in the honeybee, FTZ-F1 has an important role as a competence factor for ecdysteroids, as its gene expression is repressed by ecdysone and occurs during periods of low hormone titer. Moreover, it is a candidate to regulate *vitellogenin* expression. Knockdown experiments are in progress in order to answer these questions about FTZ-F1 functions in honeybee development.

POSTER PRESENTATION

Bumblebee importations into Ireland: growers' understanding of rewards and risks

Finbarr Horgan, Tomas Murray, Eamonn Kehoe

Teagasc Oak Park R.S., Carlow, Ireland

Introduction: Bumblebees (*Bombus terrestris*) are imported into Ireland each year for fruit pollination. The imported subspecies, *B. t. terrestris* and *B. t. dalmatinus*, are non-native. Despite risks of hybridization and competition between these and the native *B. t. audax*, importation remains unregulated. We assessed the extent of the trade in Ireland, growers' use of bees, their understanding of potential risks, and the benefits of bee importation.

Methods: Using advisory networks, a questionnaire was posted to all registered fruit growers in Ireland in 2007. Bee pollination in polytunnels was quantified and fruit/seed production monitored.

Results: We estimate that ≈ 1350 colonies entered Ireland in 2007 marking a steady increase since the late 1980s. Bee-pollination improved fruit/seed production when compared to hand-pollination. Over 50% of hives are used in strawberry pollination, mainly in glasshouses and polytunnels. Over 50% of hives are used in 'open-cultivation' systems including Spanish/French tunnels and open fields. There is a significant overlap in the occurrence of exotic and native reproductives indicating a high potential for hybridization. Growers generally do not destroy hives, but prefer to leave hives in situ or release bees to the wild. Even informed growers were unaware of how to avoid potential risks.

Conclusions: Improved fruit production is noted by growers; however, growers are generally unaware of potential importation risks and few make attempts to properly dispose of hives during periods of bee-reproductive activity. As part of this program, we are conducting a directed education campaign to improve hive management among growers.

POSTER PRESENTATION

Differential hind leg development in *Apis mellifera* castes

Ana Bomtorin, Angel Barchuk, Zilá Simões

FFCLRP of University of São Paulo, Ribeirão Preto, Brazil

The diphenism in the honeybee *Apis mellifera* results from differential feeding offered to females during larval development. Among the morphological differences between workers and queens are structures related to pollen and propolis collecting in workers hind legs, one of them is the pollen-basket. Queens hind legs have no those structures. Previous work (Barchuk *et al*., *BMC Dev Biol*, 2007) using microarray analysis showed that four out 240 differentially expressed genes in developing castes are related to leg development (*ataxin-2*, *cryptocephal*, *grunge* and *dachshund*). By using qPCR *abdominal-A*, *ataxin-2*, *cryptocephal*, *grunge* and *ultrabithorax* expression was analyzed. *cryptocephal*, *ataxin-2* and *grunge,* genes related to bristles formation and discs elongation, were not found differentially expressed. *ultrabithorax* and *abdominal-A* are expressed in the honeybee hind leg imaginal discs, and both genes are over-expressed in workers in early pupal stage. Similar pattern of *ultrabithorax* and *abdominal-A* expression can be found in hind legs of ninphal development in grasshoppers and crickets. *Drosophila* leg (with naked cuticle) also over-expresses *ultrabithorax* in this region during pupal stages. Using Scanning Electronic Microscopy we observed that leg structures and bristles are already formed in brown eyed pupa, and pollen-basket is a region deprived of bristles, containing a unique bristle in it middle that seems to be a sensorial bristle. Our results suggest *ubx* as a key player in pollen-basket formation and caste differentiation in *Apis mellifera*. Gene expression silencing using iRNA assays are underway in order to get more information on *ubx* function during leg development of honeybees.

POSTER PRESENTATION

Anopheline malaria vectors in Venezuela: Two cases of morphological diagnostic characters invalidation using molecular phylogenetic analyses

Juan-Carlos Navarro[1], Monica Prado[1], Camila Hernandez[1], Gabriela Rangel-Diaz[1], Edmundo Guerrero[1], Jazzmin Arrivillaga[2]

[1]Universidad Central de Venezuela, Caracas, Venezuela, [2]Universidad Simon Bolivar, Caracas, Venezuela

Introduction: Putative diagnostic characters can be proved autapomorphic characters or instead part of the morphological intra-specific variation into a genetic pool of a mosquito population. Two different studies with females *Anopheles* in Venezuela have been addressed to prove by mean of cladistic and molecular analyses the taxonomic value of some characters used in descriptions and keys to identify similar morphological species.

Methods: At Northeastern Venezuela malaria focus, in the *An aquasalis* (main vector) studies we found several specimens identified also as *An benarrochi* (proved vector in Peru) agree with the Cova-Garcia, Rubio-Palis and Laurenço de Oliveira keys, using the scales on Medial vein, while in the *subgenus Kerteszia* studies in Venezuelan Andes, we sorted three species: *gonzalezrinconesi, rollai* and *boliviensis* by mean of scales patterns on the Anal vein *sensu* the original descriptions. We have contrast the putative morphological diagnostic characters against the PCR-COI and ND5 (mtDNA) sequences amplified and analysed by cladistic methods using PAUP4.0b10.

Results: The COI and ND5 mtDNA parsimony analyses shown a large politomy, few genetic distance and no phylogenetic structure among sequences from putative different species, suggesting the occurrence of a single species and demonstrating that the putative morphological diagnostic characters used should be considered as intra-specific variation. The *aquasalis* analysis are agree with the Faran's key and assumptions where he pointed out there are no morphological diagnostic characters in the females of *aquasalis* Vs *benarrochi* . By the other hand, the *Kerteszia* analyses suggest two possible synonymies for *An boliviensis*.

POSTER PRESENTATION

Hexamerin genes in *Apis mellifera*: sequence, developmental expression, function and evolution

Juliana Martins, Francis Nunes, Alexandre Cristino, Zilá Simões, Márcia Bitondi

[1]FMRP - University of São Paulo, Ribeirão Preto, Brazil, [2]FMRP - University of São Paulo, Ribeirão Preto, Brazil, [3]IFSC - University of São Paulo, São Carlos, Brazil, [4]FFCLRP - University of São Paulo, Ribeirão Preto, Brazil

Introduction: Hexamerins are hemocyanin-related storage proteins massively synthesized in insect larval fat body. Here we describe the structure of the four honeybee hexamerin genes, and their putative functions, as deduced from expression patterns in fat body and gonads of developing and adult workers, queens and drones. The molecular relationship among these hexamerins and related proteins from other insects was also investigated.

Methods: Hexamerin cDNAs were isolated and sequenced using conventional methods. Semiquantitative and real-time RT-PCR were used to characterize expression profiles. For a phylogenetic analysis, hexamerin sequences were aligned using ClustalW. Neighbor-joining method was used for tree construction.

Results: Except for the conserved hemocyanin domains, the honeybee hexamerin genes (*hex*) are structurally very diverse and display distinct developmental expression profiles. *hex 70a* and *hex 110* genes are expressed in the fat body of developing and adult honeybees, whereas expression of *hex 70c* and *hex 70a* is limited to different periods of larval development. Levels of *hex 70a* and *hex 110* transcripts are significantly higher in the fat body of reproductive than non-reproductive females. Ovaries and testes express *hex 70a* and *hex 110,* but not the other two hexamerin genes.

Conclusion: In the honeybee, hexamerin genes display significant differences in sequence and structure. The function of the respective proteins is not exclusively limited to metamorphosis, but is extended to other aspects of honeybee life-cycle. Phylogenetic analysis revealed that HEX 110 is ancestral to HEX 70a, b and c.

POSTER PRESENTATION

Life history of *Euptychia* sp. (Nymphalidae: Satyrinae) feeding on *Selaginella* (Selaginellaceae)

José Enrique Piñango Bustamante[1], Ángel Luis Viloria Petit[2]

[1]Insectario Zoológico El Pinar, Caracas, DC, Venezuela, [2]Centro de Ecología, Instituto Venezolano de Investigaciones Científicas, Altos de Pipe, Edo Miranda, Venezuela

Satyrine larvae commonly feed on monocotyledoneous plants. *Euptychia* has been traditionally used as a blanket genus for most small neotropical Satyrinae that have rounded wings with small ocelli. However, only a small, distinctive number of species within this group feeds on Selaginellaceae, a group of non-vascular plants (Lycopsida). The relationship between butterflies and spike mosses of the genus *Selaginella* is only known for three satyrine genera in the world, and it has been poorly studied in the Neotropics. Adults and immatures of *Euptychia* sp. collected at 650 m in the Guatopo National Park, Venezuela, were found feeding on two species of *Selaginella.* Eggs and larvae were observed in the field at different stages, collected, and later transferred to glass containers to be reared at El Pinar Zoo Insectarium, Caracas (905 m). Morphological observations, measurements, and development times were recorded for all life stages. Eggs are laid singly; they are green, round, smooth, and lack reticulation in the chorion surface. Larvae are also green and bear fleshy tubercles (scoli), which is an unusual feature for the Satyrinae; the head is dark. The general aspect of the larvae mimics that of their hostplants. Dry head capsules and exuviae were kept for ulterior studies. A chalcidid wasp emerged from one of the pupae collected in the wild. Further study of the morphology of the immature stages and the comparative biology of this genus and others with similar hostplant relationships might provide the basis to establish the natural affinities of the *Euptychia* butterflies, whose systematic position is still uncertain.

POSTER PRESENTATION

Studies on population dynamic of dipteran species (Calliphoridae) from Brazil: A new approach for forensic purpose

Patricia Jacqueline Thyssen, Wesley A. C. Godoy

UNESP, Botucatu, SP, Brazil

Introduction: The insects can be useful to understand the cases in which there is body displacement after the death associated to the knowledge of their geographical distribution and, in some cases, to describe the suspects' movement. None of the population censuses nor the works on entomological succession on carcass accomplished in our study area considered the hypothetical space migrations in a given place among different environments as urban, rural and forest area.

Methods: This study investigated through monthly collection, for one year, in different environments and by using mathematical models, the dynamic behavior of ten dipteran species (Calliphoridae) of forensic importance.

Results: The great majority of the collected caliphorids presented certain predominance in relation to the different types of environments, such as Hemilucilia semidiaphana, found only in forest area. Correlation calculations between species and population growth rate could demonstrate, as observed for *Cochliomyia macellaria* and *Lucilia eximia*, that some species can have more potential to explore a habitat than others, modulated by the competition or by the search for a specific resource. Thus, the discrepancy between the insect composition on a body and the insect composition from the local where the body was discovered could provide evidences that the victim was displaced.

Conclusions: The non observation of the possibility of population oscillation of certain species associated to an environment may lead to mistakes in the determination of the death place.

POSTER PRESENTATION

DNA barcodes for invasive species identification

Shelley Ball, Karen Armstrong

Lincoln University, Canterbury, New Zealand

The movement of species around the world has increased exponentially in recent years due to increased global trade and travel. The economic cost of species establishment in non-native ranges can be enormous. Consequently, the ability to accurately identify exotic and potentially invasive species is crucial towards minimising the risk. We have developed DNA barcodes for identification of exotic and pest insects. DNA barcoding involves using a small fragment (~ 650bp) of the COI mitochondrial gene as a species-specific genetic identification tag. Here we present data demonstrating that DNA barcodes have enormous potential as standardized tool for biosecurity and phytosanitary application. For example, COI barcodes were 100% successful in discriminating over 30 species of lymantriid moths and exactly the same approach was effective at distinguishing over 60 tephritid fruit fly species outside of known species complexes. As with other barcode studies, we found that mean interspecific genetic distances were an order of magnitude greater than mean intraspecific divergences, indicating that many species are easily distinguishable with COI barcodes. Furthermore, DNA barcodes are playing an important role in species discovery. For example, *Lymantria mathura* populations that had distinct COI barcode sequences also displayed inconsistencies in pheromone lure attraction; the species has subsequently been revised as two species, *L. mathura* and *L. flavida*. International collaborations are now beginning to assemble open access COI sequence libraries for a diversity of invasive and pest species, with the goal of developing an internationally standardized species identification tool for biosecurity and phytosanitary application.

POSTER PRESENTATION

larvicidal activity of magnolia officinalis root cortex compounds toward two mosquito species

Nam-Jin Kim, Tae-Kyun Hong, Young-Joon Ahn

Seoul National University, Seoul, Republic of Korea

Introduction: The toxicity of materials derived from the root cortex of *Magnolia officinalis* Rehd. Et Wils (Magnoliaceae; Houpo in Chinese), toward third instar larvae from laboratory-reared *Aedes aegypti* and *Culex pipiens pallens* were examined.

Methods: Insecticidal toxicity of materials was evaluated by paper cup direct contact bioassay. The active principle was identified as the lignin magnolol by spectroscopic analysis.

Results: Based on 24 h LC_{50} values, *Cx. pipiens pallens* larvae were slightly more susceptible than *Ae. aegypti* larvae to the magnolol tested. The LC_{50} value of *Cx. pipiens pallens* was 25.7ppm (21.03 – 30.93) and the LC_{50} value of *Ae. aegypti* was 33.4ppm (27.82 – 38.72).

Conclusions: *M. officinalis* root cortex-derived materials, particularly manolol, merit further study as potential mosquito larvicidal agents or as a lead for the control of mosquitoes for protection from humans and domestic animals form vector-borne diseases and nuisance caused by mosquitoes because of their good activity as a larvicide.

POSTER PRESENTATION

Genetic analysis of Romanian autochtonous and allochtonous silkworm (*Bombyx mori*) strains by means of RAPD technique

Alexandru Filip Vladimirescu[1], Elena Claudia Coipan[1], Daniela Usurelu[2], Alexandra Matei[3], Dan Dezmirean[4], Cristina Bojan[4], Lucian Gavrila[2], Ioan Pasca[4]

[1]National Institute of Research-Development for Microbiology and Immunology Cantacuzino, Bucharest, Romania, [2]Institute of Genetics, University of Bucharest, Bucharest, Romania, [3]SERICAROM S.A., Bucharest, Romania, [4]Apiculture Department, University of Agricultural Sciences and Veterinary Medicine, Cluj-Napoca, Romania

Introduction: Romania has 65 strains of silkworms, of which 6 are commercial hybrids, with very high productivity. Of the total number of genetic resources maintained in Romania, 12 are autochtonous. A recently started national project (COSERISTECH) aims to develop an experimental model for the conservation of the genetic potential and of the autochtonous sericultural resources, in which genetic techniques play an important role.

Methods: In this study the random amplified polymorphic DNA (RAPD) technique was used to analyze the DNA profile of 10 silkworm strains. The strains used were five autochtonous and five allochtonous. The starting material was represented by whole silkworms that were grinded after immersion in liquid nitrogen. DNA was isolated using a Qiagen kit. For the amplification we used one primer pair. The annealing temperature was lowered to 35.5 ℃ to favor the primers unspecific binding to the template DNA.

Results: Following electrophoresis homologous and specific bands were observed for the analyzed strains.

Conclusions: The resulting profiles indicate that RAPD technique can be used to discriminate between some of the important silkworm strains maintained in Romania.

POSTER PRESENTATION

Coupled spatio-temporal dynamics of the bruchid beetle *Acanthoscelides schrankiae* and its parasitoids

Ligia M.S. Rodrigues[1], Marcelo N. Rossi[2]

[1]*Universidade Estadual Paulista (Unesp), Instituto de Biociências, Botucatu, SP, Brazil,* [2]*Universidade Federal de São Paulo (Unifesp), Campus de Diadema, São Paulo, SP, Brazil*

Introduction: Using a spatially explicit approach, we investigated the spatio-temporal dynamics of the bruchid *Acanthoscelides schrankiae* and its parasitoids occurring on a *Mimosa bimucronata* population. We firstly used the Spatial Analysis by Distance Indices (SADIE) approach to investigate patterns of spatial distribution of bruchids and parasitoids. Secondly, we used an extension of the SADIE method (overall spatial association) to compare coincidences of patch and gap clusters of host and parasitoids.

Methods: Coupled dynamics between parasitoids and bruchids were evaluated within (unlagged) and between (lagged) all different sampling occasions in order to understand temporal patterns of spatial associations. Fifty branches were selected on plants and fruits were collected at 2-weekly intervals. Six and three collections were carried out on years 2006 and 2007, respectively. Each branch was mapped and positioned in a Cartesian plane with coordinates. After collection, fruits were individualized and the number of emerging adult bruchids and parasitoids was recorded for each branch.

Results: Most significant results were found for unlagged spatial associations. However, for the year 2007, significant lagged spatial associations were found. The most important significant lagged associations were found between the following sampling occasions: sampling two for parasitoids with sampling one for bruchids, sampling three for parasitoids with sampling one for bruchids, and sampling three for parasitoids with sampling two for bruchids. Therefore, the parasitoid-bruchid populations were dynamically coupled because lagged and unlagged spatial associations were observed.

Conclusions: We provided evidences that the parasitoids responded positively to the spatial distribution of bruchids shown in earlier occasions.

POSTER PRESENTATION

Evaluation of white khomein and some other Iranian onion cultivars for resistance to thrips (*Thrips tabaci* Lindeman)

Mazaher Yousefi, Ahmadreza Abasifar

Agricultural and Natural Resources Research Center, Markazi Province , Arak, Islamic Republic of Iran

Thrips tabaci L. is one of the most important pests on onion in Iran, and can make a serioues damage on onion. In this research, Khomein breeded cultivar compared with seven cultivars of onoin (Azarshahr Red, Kashan White, Native White Khomain, Qom White, Kordestan White, Shahrood Red) in a RCB design in four replications in the Agricultural & Natural Resources Research Center of Markazi Province, during 2001-2003. The numbers of thrips on five plants were recorded each two weeks. The symptom of pest feeding including chlorosis, necrosis, and curling of leaves was evaluated and recorded based on a ten scale for damaging and a six scale for leaves curling. The field of control also planted around and sprayed with current insecticide on the eight time due to decreasing thrips damage. The data was analyzed using a SAS system, and the means compared with Duncan's test. In this study, the highest number of thrips observed on Azarshar Red, breeded Khomein and Shahroud White (27.7, 25.7 and 25.3 respectively) and the lowest number recorded on Shahroud Red, Kordestan (16.01 and 15.8 respectively).Amount of damage on Azarshahr Red was the highest and Kordestan and Qom white was the lowest. In nonsprayed plots, the highest yield recorded for Kashan and Qom White cultivars (79.2 and 75.2 T/h respectively) and the lowest yield for Kordestan cultivar (61.1 T/ha). The results of the study over the three years showed that breeded onion of Khomein compare with other cultivars in Iran due to high density of thrips (an avarage of 25.7 thrips per plant) on medium of curling and damage, and intermediate yield in both spraying and nonspraying plots known as tolerant genotype. No different variation yield observed across of spraying (Average: 67.6 Tha^{-1}) and nospraying (Averag; 68.6 Tha^{-1}) blocks.

POSTER PRESENTATION

Dispersal of the broad mite, *Polyphagotarsonem*us *latus* (Banks) (Acari: Tarsonemidae), by greenhouse pests

Huseyin Gocmen, Utku Yukselbaba

Department of Plant Protection, Faculty of Agriculture, University of Akdeniz, Antalya, Turkey

Introduction: Broad mite*, Polyphagotarsonemus latus* (Banks), is an economically important pests of greenhouse grown plants and its presence in Turkey first discovered in 1992. In this study, the interaction between broad mite and other important greenhouse pests was studied to understand the dispersal process of broad mite in greenhouse vicinity.

Methods: The study was undertaken on 2 cm diameter leaf disks exposing 2400 lux light intensity at 26 ^{o}C under 16:8 L:D regime. Groups of live and dead greenhouse pests, *Bemisia tabaci* (Genn.), *Frankliniella occidentalis* (Pergande) and *Liriomyza trifolii* (Burgess) were co-located at varying times of 1, 2, 4 and 8 hours and broad mite carrying capability of each pest were evaluated.

Results: The results shown that broad mite attachment to any pest tested was minimum at 1 hour treatment whereas maximum numbers obtained in 8- hour treatment. At 20 broad mite/leaf disk density, 7.2 broad mites attached to individual *B. tabaci* adult whereas none observed on *F. occidentalis* at the end of 8 hour treatment. With dead pests at 20 broad mite/leaf disk density, the num*bers* on individual *B. tabaci* were 15.4 whereas only 3.12 were attached to *F. occidentalis.* The results further showed that *L. trifolii* was not capable of carrying broad mite.

Conclusions: Overall results indicate that *B. tabaci* has a central role in dispersal of broad mite, hence should be given consideration in management of the pests in greenhouses.

POSTER PRESENTATION

Dispersal of the broad mite, *Polyphagotarsonem*us *latus* (Banks) (Acari: Tarsonemidae), by greenhouse pests

Huseyin Gocmen, Utku Yukselbaba

Department of Plant Protection, Faculty of Agriculture, University of Akdeniz, Antalya, Turkey

Introduction: *Broad mite, Polyphagotarsonemus latus* (Banks), is an economically important pests of greenhouse grown plants and its presence in Turkey first discovered in 1992. In this study, the interaction between broad mite and other important greenhouse pests was studied to understand the dispersal process of broad mite in greenhouse vicinity.

Results: The results shown that broad mite attachment to any pest tested was minimum at 1 hour treatment whereas maximum numbers obtained in 8- hour treatment. At 20 broad mite/leaf disk density, 7.2 broad mites attached to individual *B. tabaci* adult whereas none observed on *F. occidentalis* at the end of 8 hour treatment. With dead pests at 20 broad mite/leaf disk density, the num*bers* on individual *B. tabaci* were 15.4 whereas only 3.12 were attached to *F. occidentalis.* The results further showed that *L. trifolii* was not capable of carrying broad mite.

Conclusions: Overall results indicate that *B. tabaci* has a central role in dispersal of broad mite, hence should be given consideration in management of the pests in greenhouses.

POSTER PRESENTATION

New management tools against the European pine sawfly *Neodiprion sertifer*

Paal Krokene[1], Svein Solberg[1], Andreas Bostad Thause[2]

[1]Norwegian Forest and Landscape Institute, Ås, Norway, [2]Norwegian University of Life Sciences, Ås, Norway

The European pine sawfly *Neodiprion sertifer* is a widely distributed defoliator of pines that can cause substantial growth losses over extensive areas. It attacks most species of two-needle pines in its distribution area, and have occasional short-lived outbreaks that may cover up to 200.000 ha. In Norway we have had outbreak populations in the eastern part of the country since 2004, and in an ongoing research project we are evaluating aerial application of the *Neodiprion sertifer* nuclear polyhedrosis virus (NsNPV) to control *Neodiprion sertifer*. Defoliation levels at the landscape level were measured using airborne laser scanning. Laser scanning was performed twice during the growth season; once in May, before the sawfly larvae had started feeding, and once in August, after pupation. Defoliation level was calculated as the difference in estimated leaf area index (LAI) between the two scans. Virus application significantly reduced defoliation levels in sprayed areas relative to unsprayed control areas, but since defoliation levels remained low throughout the study area the differences were small. At the end of the summer virus levels were significantly higher in sprayed areas than in unsprayed control areas, as demonstrated by a newly developed PCR-based detection method. This method is much more reliable, sensitive and flexible than the presently available microscopy-based method for virus visualization. Defoliation levels after *Neodiprion sertifer* attack was also compared with stand characteristics, such as stand age, productivity and exposure, to identify stands that were highly susceptible to attack.

POSTER PRESENTATION

Genetic mapping of CpGV resistance loci in the codling moth *Cydia pomonella*

Nadine A. Gund[1], Annette Reineke[1], Claus P. W. Zebitz[2], David G. Heckel[3], Sabine Asser-Kaiser[4], Johannes A. Jehle[1]

[1]Research Center Geisenheim, Section Phytomedicine, 65366 Geisenheim, Germany, [2]University of Hohenheim, Institute of Phytomedicine, Department Entomology, 70599 Stuttgart, Germany, [3]Max Plank Institute for Chemical Ecology, Department Entomology, 07745 Jena, Germany, [4]Agricultural Service Center Palatinate (DLR Rheinpfalz), Department of Phytopathology, 67435 Neustadt an der Weinstrasse, Germany

The codling moth, *Cydia pomonella* (L.) (Lep., Tortricidae), is a major pest in apple growing regions worldwide. Without control, infestations can result in severe damage and complete loss of marketable fruits. One of the cornerstones of codling moth control in organic and integrated apple production is the use of biocontrol agents based on the *Cydia pomonella* granulovirus (CpGV). In many countries CpGV products are among the very few codling moth control measures allowed in organic apple production. Neonates ingest the virus through feeding and die after 4-7 days. In 2004, field observations in organic apple orchards in Germany and France suggested a failure of CpGV products in controlling codling moth populations. Rearing and resistance testing of these populations revealed an up to 1,000-fold decrease in CpGV susceptibility.

For future management of CpGV resistance it is pivotal to know the resistance mechanism(s) and to identify the respective gene(s). Mass crossing experiments as well as single-pair crosses have revealed that resistance loci are located on the sex-chromosome, i.e. the Z-chromosome. To further identify and isolate the respective gene(s), linkage mapping on *C. pomonella* backcross populations is being performed. Markers located on the sex-chromosome are identified through SNP (single nucleotide polymorphism) analysis. Furthermore AFLP (amplified fragment length polymorphism) markers were generated that are located on the Z-chromosome and are putatively linked to the CpGV-resistance loci. These markers are the fundament for further linkage mapping and thus for the identification of resistance genes.

POSTER PRESENTATION

The haemocytes of *Eldana saccharina* Walker (Lepidoptera: Pyralidae): structural characteristics and proportions of subtypes

Irene Ketseoglou, Gustav Bouwer

University of the Witwatersrand, Johannesburg, South Africa

Introduction: Lepidoptera are capable of mounting a variety of immune responses to foreign bodies. The importance of haemocytes in insect immunity prompted the characterisation of the haemograms of the African sugarcane stalkborer, *Eldana saccharina* Walker (Lepidoptera: Pyralidae).

Methods: Differential and total haemocyte counts were performed on fifth instar *E. saccharina* larvae. Haemolymph was extracted from anaesthetized larvae. Differential haemocyte counts were performed by light microscopy and total haemocyte counts were obtained by haemocytometer counts. Haemolymph volume was estimated by injecting red amaranth into anaesthetized larvae and the absorbance of the cell-free haemolymph was compared against a red amaranth standard curve. Transmission electron microscopy was used to characterize haemocytes.

Results: Five haemocyte subtypes were identified and characterised in *E. saccharina* larvae by light and transmission electron microscopy. Plasmatocytes and granular haemocytes comprised the largest percentage of haemocytes in *E. saccharina*. The spherule cells, oenocytoids and the prohaemocytes made up less than 2% of the total haemocyte population. Two distinct plasmatocyte populations, spherical and spindle-shaped, were present in *E. saccharina* larvae. The granular haemocytes had lipid droplets in their cytoplasm, an uncommon occurrence in most lepidopteran species. The total haemocyte count of *E. saccharina* was generally lower than other lepidopteran species. Fifth instar *E. saccharina* larvae had slightly higher haemolymph volumes than other lepidopteran species.

Conclusions: This study provides valuable information on the haemocytes, the effectors of the cellular immune response, of *E. saccharina* and should aid in the understanding of the immune system of *E. saccharina*.

POSTER PRESENTATION

Blow fly (Diptera: Calliphoridae) early larval colonization of pig carcasses, in semi-arid Mediterranean areas (SE. Spain)

Yelitza Velasquez, Anabel Martinez, Berta Pastor, Santos Rojo

CIBIO, Alicante, Spain

Introduction: The southeast coast of the Iberian Peninsula is characterized by an important human activity. Some habitat shows adverse environmental conditions imposed by low-quality soils. Annual average temperatures range from 13-19 ºC, and the minimum average temperature of the coldest month ranges from 1-10 ºC. Annual rainfall ranges are very low.

Methods: In this study, we compare Diptera colonization in early stage of decomposition in two seasons of the year: fall (November 2007) and winter (February 2008). For each season, a domestic pig (*Sus scrofa*) was exposed in the antrophic area at University of Alicante, Spain, during ten days. On the 10th day, the pig was covered with a net in order to avoid colonization, but allowed the development of species which had already been breeding. A sample of immature stages were collected daily and reared under controlled conditions (23ºC, 70% and 14:10 photoperiod).

Results and Conclusions: The results showed there were different species breeding in two seasons. In fall season, we found *Lucilia sericata*, *Chrysomya albiceps*, *Chrysomya megacephala*, *Calliphora vicina* and *Calliphora vomitoria*. However, in winter, only *Calliphora vicina* and *Calliphora vomitoria* emerged. We also discussed the abundance of species in each season and their presence in different parts of the body.

POSTER PRESENTATION

Evaluating the phylogenetic relationships of tribe Toxomerini and *Ocyptamus* (Diptera, Syrphidae)

Ximo Mengual, Gunilla Stahls, Santos Rojo, Berta Pastor

[1]CIBIO, Alicante, Spain, [2]Finnish Museum of Natural History, Helsinki, Finland

Introduction: *Toxomerus* and *Ocyptamus* (Diptera, Syrphidae) are the New World members of the subfamily Syrphinae more diverse and abundant. *Toxomerus* constitutes the monogeneric tribe Toxomerini with more than 150 described species, while *Ocyptamus* is a very diverse genus with some subgenera and species groups.

Methods: The phylogenetic relationships between both genera were analyzed based on sequence data from three gene regions, i.e. the mitochondrial protein-coding gene cytochrome c oxidase subunit I (COI) and the nuclear 28S and 18S ribosomal RNA genes. We analyzed the data under direct optimization using parsimony as optimality criterion, under six different parameter cost schemes in a sensitivity analysis. An implied aligment resulting from the direct optimization analysis was subsequently utilized to perform a Bayesian analysis.

Results: The monophyly of Toxomerini was recovered in all the analyses, and some species groups were consistently found. Results obtained indicated paraphyly of the genus *Ocyptamus* with respect to *Toxomerus*. Several species groups were found consistently in *Ocyptamus*, indicating probably the necessity of subdivisions. Paraphyly of the genus *Salpingogaster* was proposed because subgenus *Eosalpingogaster* was always recovered embedded in *Ocyptamus*, whereas *Salpingogaster* s. str. was never placed inside this genus. Most of Syrphinae are predatory species. Comments about predation habits in the frame of the phylogenetic results are also indicated.

POSTER PRESENTATION

Molecular phylogeny of *Lasius* ants in Korea

Byung-Jin Kim, Ki-Gyoung Kim

Wonkwang University, Iksan, Jeonbuk, Republic of Korea

Introduction: Systematic study of *Lasius* ants in Korea was made using both morphological analysis and RAPD-PCR for 9 species and 2 ssp. in *Lasius*.

Methods: The molecular phylogeny of 11 species of *L.* ants in Korea was examined using random amplified polymorphic DNA markers as inputs for an analysis of molecular variance and cluster analysis to describe the relationships between species. For comparison, morphometric data were also gathered for phylogenetic analysis. Assessments of similarity between species were made, and the results of these assessments are compared for the molecular and morphological data sets.

Result: In the morphometric analysis, the following groups were identified: (i) *L. alienus*, *L.* sp.2*, L.* sp.1, *L. niger* and *L. hayashi* (87% similarity); (ii) *L. flavus* and *L. talpa* (97%); (iii) *L. crispus* and *L. spatepus* (97%); (iv) *L. meridionalis* and *L. teranishii* (90%). *Paratrechina sakurae* was 38% similar to the 11 *Lasius* species studied here. the group comprising *L. flvus* and *L. talpa*, and comprising *L. crispus* and *L. spatepus* had the highest similarity index (97%), followed by the group comprising *L. meridionalis* and *L. teranishii* (90%), and then *L. alienus*, *L.* sp.2 and *L.* sp.1 (95%). In the molecular analysis the following groups were identified: (i) *L. meridionalis* and *L. teranishii* (70%); (ii) *L. hayashi* and *L.* sp.1 (47%); (iii) *L.* sp.2, *L. crispus* and *L. talpa* (35%); and (iv) *L. flavus* and *L. alienus* (15% similarity).

Key words: *Lasius*, Korea

POSTER PRESENTATION

Predictions of range expansion of an invasive gall wasp (*Quadrastichus erythrinae*) under the double pre-industrial CO_2 concentration scenario

Tung Gene-Sheng, Hsu Chia-Chun, Hsu Chia-Chin, Yang Man-Miao

TFRI, Taipei, Taiwan

Introduction: Events of species invasion were becoming more frequent as a consequence of intensifying intercontinental transportations. However, global climate change even worsens the situation. Global warming is likely to allow range expansion of many invasive species from tropics, such as the erythrina gall wasp (EGW), which forms galls and causes severe damages on coral trees (*Erythrina* spp.) in the past few years.

Methods: The species distribution model was used to predicted range-size change of EGW and five species of host trees (*Erythrina* spp.) under the double pre-industrial CO_2 concentration scenario. Changes on the species' range size were calculated and compared.

Results: Models indicated an overall invasion risk of EGW for tropical areas and a trend of polarward expansion under the climate change scenario. Furthermore, results suggest that there are different abilities of range expansion between EGW and their host tress.

Conclusions: Our results suggest that risks associated with invasive EGW will likely become more intense under further impacts of climate change, not only for areas where EGW were reported but also regions where it has opportunities to establish populations.

POSTER PRESENTATION

Evaluation of the re-emergence risk of mosquito-borne diseases in Romania

Gabriela Nicolescu[1], Valeria Purcarea-Ciulacu[1], Alexandru Vladimirescu[1], Liviu Prioteasa[1], Elena Falcuta[1], Claudia Coipan[1], Gabriela Dumitrescu[2], Diana Popescu[2], Aurora Alexse[1]

[1]Cantacuzino Institute, Bucharest, Romania, [2]Army Centre of Medical Research, Bucharest, Romania

Introduction: The climatic and other environmental changes in the last years induced the intensifying of the circulation and transmission of West Nile virus to humans and the increased risk of malaria re-emergence in Romania.

Methods: The multidisciplinary investigations using entomological, immunological, viral and molecular biology techniques were performed for the ecological surveillance of the re-emergence risk of mosquito-borne diseases in the country.

Results: Investigation of WNV circulation showed the significant values of the seroprevalence of the antibodies against WNV in domestic birds (mean value – 10.8 %), wild birds (16.4 %) and horses (19.9 %), and their variations in correlation with the environmental factors. The virus was detected in *Coquillettidia richiardii* and *Culex pipiens* mosquitoes and was isolated from *Culex pipiens* females. The investigation of the anophelism in the former malaria endemic areas put in evidence the high abundance of the *maculipennis* group anophelines (*Anopheles atroparvus*, *A. maculipennis*, *A. messeae* and *A. daciae*), the species dominance and the main elements of their vectorial capacity in correlation with the environmental factors.

Conclusions: The investigations demonstrate the presence of the intensive and permanent enzootic circulation of WNV on extended territories in Romania and the possibility of its transmission to humans. The risk of malaria re-emergence is given by the presence of abundant populations of the potential anopheline vectors in the former endemic areas simultaneously with the constant increase of the number of imported malaria cases. The permanent surveillance of mosquitoes and implementation of integrated control programmes are adequate decisions in the risk areas in Romania.

POSTER PRESENTATION

Effect of temperature on feeding and development rates of a potential biocontrol agent, *Cornops aquaticum* Brüner (Orthoptera: Acrididae) for water hyacinth, *Eichhornia crassipes* Mart. Solms-Laubach (Pontederiaceae) in South Africa

Angela Bownes[1], Martin Hill[2], Marcus Byrne[3]

[1]Agricultural Research Council, Pretoria, South Africa, [2]Rhodes University, Grahamstown, South Africa, [3]University of the Witwatersrand, Johannesburg, South Africa

Water hyacinth remains South Africa's most problematic invasive aquatic plant, despite more than 40 years of an active biological control programme against the weed. One of the major factors identified to be constraining success of the agents currently established in South Africa is climate. Populations of the insects which are of tropical/subtropical origin decline dramatically in regions with cold winter temperatures and are slow to pick up at the start of the growing season, whereas plants bounce back quickly. Due to the limited success, an additional agent is currently under consideration for release, the grasshopper, *Cornops aquaticum*. Its distribution in South America, which extends from central Argentina around Buenos Aires as far north as Mexico suggest that it has a wide thermal tolerance, however, it would be valuable to make predictions about its potential efficacy based on its thermal physiology. Feeding trials at temperatures from 10°C to 30°C at 5 degree intervals showed that temperature had significant effects on adult ($F_{1;37}$ = 17.44; P = 0.0002) and 3rd ($F_{4;42}$ = 64.69; P = 0.0000) and 1st nymphal instar ($F_{4;42}$ = 24.30; P = 0.0000) feeding rates. No feeding took place at 10°C and in some cases 15°C. Temperature also had significant effects on development rates. These results suggest that our current culture in quarantine has a low thermal tolerance and collection and release of a strain of the insect from its southern-most distribution may need to be considered to improve chances of establishment and success in the temperate regions of South Africa.

POSTER PRESENTATION

Nectar guide removal dramatically decreases long-tongued fly visitation in *Lapeirousia oreogena*

Timotheüs van der Niet, Dennis Hansen, Steven Johnson

University of KwaZulu-Natal, Scottsville, South Africa

Flowers pollinated by insects often have contrasting colour patterns, referred to as nectar guides. These are thought to facilitate efficient feeding by the insect and thereby enhance pollination. This suggests that the presence of nectar guides has implications for plant fitness. A group of about 30 plant species in Namaqualand of diverse phylogenetic origin, all exclusively pollinated by two species of long-tongued fly (Prosoeca), is characterized by flowers with marked nectar guides. The role of nectar guides in long-tongued fly pollinated plants is currently poorly understood. We investigated the effect of nectar guide removal on plant visitation by flies using *Lapeirousia oreogena*, an actinomorphic Iridaceae with six conspicuous nectar guides with a radially symmetrical configuration. We erased the cream-coloured nectar guides of the plant using black ink so as to resemble the black colour of the tissue surrounding the nectar guide. Choice tests reveal that a decrease in number of nectar guides decreases plant visitation. Flowers with nectar guides removed receive significantly less visits than control plants. We also recorded visitation of isolated flowers with and without nectar guides. The number of approaches to plants with nectar guides was equal to plants without nectar guides. Approached plants without nectar guides were, however, never probed for nectar whereas approached plants with nectar guides were also always probed. We suggest that nectar guides in long-tongued fly pollinated plants serve for short distance orientation and that they probably are a necessary element in the evolution towards fly pollination.

POSTER PRESENTATION

Fungal associates of the conifer-infesting bark beetle, *Hylastes brunneus*

Riikka Linnakoski[1], Z. Wilhelm de Beer[2], Pekka Niemelä[1], Ari Pappinen[1], Michael J. Wingfield[2]

[1]Faculty of Forest Sciences, University of Joensuu, P.O. Box 111, FIN-80101 Joensuu, Finland, [2]Department of Microbiology and Plant Pathology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, 0002, South Africa

Introduction: *Hylastes* bark beetles (Coleoptera: Scolytinae) are considered to be less aggressive beetles, infesting roots of declining conifers. Several *Hylastes* spp. are known to vector Ophiostomatoid fungi. However, nothing is known regarding the fungal associates of *Hylastes brunneus*, a common species infesting spruce (*Picea abies*) and pine (*Pinus sylvestris*) in the boreal forests of Finland. The aim of this study was to isolate and identify fungal associates of *Hylastes brunneus*.

Methods: Fungi were isolated from beetles and their galleries collected at two different sites in eastern Finland. Resulting fungal cultures were grouped based on morphology. ITS, β-tubulin, LSU and elongation factor 1-α sequences were obtained for isolates representing the various groups identified based on morphology. Phylogenetic analyses were done to confirm the identity the fungal species.

Results: Both spruce and pine were infested with *Hylastes brunneus*. Based on morphology and phylogenetic analyses, at least nine fungal species were found to be associated with *H. brunneus*. These included *Ophiostoma canum*, *O. piliferum*, *Grosmannia cucullata*, *G. galeiforme*, *Leptographium lundbergii*, and at least three undescribed *Ophiostoma* and one undescribed *Leptographium* species. None of the fungi were consistently isolated from *H. brunneus*, only *O. canum* was found at both collection sites.

Conclusions: The results of this study show that *Hylastes brunneus* is a casual vector of Ophiostomatoid fungi, but apparently lacks fixed fungal associates. The ecological relationships between the fungi and the beetle need further investigation. The novel species will be characterized and described as new species.

POSTER PRESENTATION

Biological control of *Sirex noctilio* with *Beddingia siricidicola*: Current status in the *Pinus radiata* plantations of the Arauco companies

Miguel Angel Poisson, Alvaro Duran, Rodrigo Ahumada

[1]BIOFOREST S.A., Concepcion, Chile, [2]Department of Microbiology and Plant Pathology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa

Sirex noctilio is a siricid wood wasp native to Eurasia and northern Africa and it has become a significant pest of exotic *Pinus* plantations in the Southern Hemisphere. In Chile, *S. noctilio* was detected at the beginning of 2001, after which the insect has been monitored under a quarantine control system regulated by the government plant health agency (SAG). The government sector and private companies now implemented a strategy for *Sirex* control, based on early detection, biological control and improvement of plantation management. A model was developed that categorized about 90,000 ha at different risk levels to *Sirex* attack, based in silvicultural management, site index, age, average diameter, density, and distance of declared focus,. This model, supported by GIS analysis, was used to direct the monitoring and trap tree plot placement in Arauco company plantations. A total of 674 plots of trap trees (6,740 trees) were established, during the 2006-2007 season, based on this system. Of these, 267 trap tree plots (2,598 trees) distributed in 88 different fields, were inoculated with the parasitic nematode, *Beddingia siricidicola.* The first result of the parasitism levels of *S. noctilio*, following this inoculation, showed an average of approximately 10%. Future research is aiming to optimize the period of inoculation.

POSTER PRESENTATION

Sublethal effects of crop protection on honey bee pollination: foraging behaviour and flower visits

Bruno Gobin[1], Kevin Heylen[2], Roger Huybrechts[2], Johan Billen[2], Lutgarde Arckens[2]

[1]Zoology department Pc Fruit, Sint-Truiden B-3800, Belgium, [2]Zoological Institute K.U.Leuven, Leuven B-3000, Belgium

Many fruit crops depend on availability of honey bee hives for sufficient pollination to ensure maximal fruit quality (shape and size) and quantity (yield weight). In Belgium, non-commercial beekeepers and commercial fruit growers have mutual benefits from this cooperation as both honey and fruit yield increase. Fruits can however not be grown commercially without the use of crop protection agents, either from organic or chemical origin. The use of products with toxic effects is banned during flowering, and precise pre-flowering intervals have to be respected in Good Agricultural Practice. In those European countries with a monitoring scheme, acute bee poisoning incidents have decreased considerably and hardly cause problems at present.

In recent years, some concerns arose over sublethal effects (ie behavioural changes) of chemical crop protection on bees. Even though short-term effects can indeed be induced in individually exposed bees, studies that exposed complete colonies did not reveal any long-term consequences at colony level. However, from the fruit growers' viewpoint, potential short-term effects on foraging behaviour are relevant as they can bear on pollination efficacy. We observed effects of either maximal bee exposure (feeding) or in-crop exposure (treatments at flowering) of a selection of chemicals with various degrees of bee toxicity. To characterize specific behavioural changes, we chose specifically high risk levels of exposure (greater than normal agronomic use), more practically relevant exposure remains to be tested. Both changes in quantitative (food retrieval, number of visits) and qualitative (food source location) foraging parameters were observed in greenhouse and field settings. Repellent effects were minimal in both lab and field, parameters of foraging and nestbuilding behaviour were –at maximal sublethal exposure- affected by some products but not others.

POSTER PRESENTATION

A new species of *Ceresa* Amyot & Serville, 1843 (Hemiptera: Membracidae) associated with the soy culture in Brazil

Gabriel Andrade

Universidade Estadual do Oeste do Paraná, Cascavel, Paraná, Brazil

Introduction: *Ceresa* is one of the most speciose genera within the Membracidae, and was reviewed by ANDRADE (2004). This work provides a foundation for naming undescribed taxa, and also trying new data from their host plants and distribution.

Methods: Dried specimens are being examined, from the most representative collections of the Neotropical fauna, and also recent data from the literature that refers to species of this group. The usual routines in systematics and morphological taxonomy are applied, and all new data on undescribed taxa and host plants are now being compiled.

Results: Some species were already formally associated to host plants, and in recent divulgation in events, *C. brunnicornis* (Germar, 1835) was verified causing damages in soy in south Brazil. There is another, probably new species was recently found in Brazil (ZANELLA, 2007: Cultivar Grandes Culturas 97: 24-26) causing damage to soy culture in the states of Piauí, Maranhão, Tocantins and probably Rio Grande do Sul. It has distribution along the east coast, within the main domain of the Atlantic forest. It is similar to *C. fasciatithorax* Remes-Lenicov, 1973 described from Bolivia, differing mostly in color pattern, but also in the male genitalia features.

Conclusions: Although reviewed and with 34 described species, new species of this genus remain to be described. Some have been previously associated with different hosts, but all species are potential pests invasive to soy and other culture in Brazil, due to the polyphagism detected by collection data.

POSTER PRESENTATION

A new unusual, ornate species of *Ilithucia* Stål, 1867 from Costa Rica, with some considerations on other ornate Ceresini (Hemiptera: Membracidae)

Gabriel Andrade

Universidade Estadual do Oeste do Paraná, Cascavel, Paraná, Brazil

Introduction: *Ilithucia* was reviewed by SAKAKIBARA (2002), with several taxonomic changes within it and allied genera, and was the last comprehensive work on this group. Additional efforts are now being directed to all ornate genera of the tribe Ceresini. These studies are continuations of the work started by KOPP & YONKE (1979).

Methods: The specimens examined as a part of the present study are from the most representative collections of Membracoidea of the New World fauna, and specimens of a new species are from the collection of the The Natural History Museum, London, England. The usual techniques of systematics and morphological taxonomy are applied, and a manuscript is being submitted for publication.

Results: This new species conforms with the general features of *Ilithucia*, but has lateral spines on the posterior pronotal process. The three-spined posterior pronotal process is characteristic of *Poppea* Stål, 1867, *Cyphonia* Laporte, 1832 and *Eucyphonia* Sakakibara, 1968 (all Ceresini). Outside the Ceresini we find this condition in *Smilidarnis* Andrade, 1989, which appears to be a basal group for Smiliinae and Darninae, according to DIETRICH *et al.* (2001). The male genitalia features of the new species agree with both *Ilithucia* and *Poppea*, and also of *Antonae* Stål, 1867, although very different to that of *Cyphonia* and *Eucyphonia*.

Conclusions: Several features used formerly for the characterization the ornate Ceresini genera are labile and need reappraisal, and also investigation to define the reliable limits within these genera to understand the relationship between the ornate and the inornate genera of this tribe.

POSTER PRESENTATION

Genitalia description of *Hylesia metabus* (Lepidoptera: Saturniidae: Hemileucinae)

José Enrique Piñango Bustamante[1], Beatriz Herrera-Malaver[2], Carmen V. Liendo-Barandiaran[2], Cristina Sainz-Borgo[2], José Vicente Hernández[2]

[1]Insectario, Zoológico El Pinar, Caracas, DC, Venezuela, [2]Universidad Simón Bolívar, Caracas, Estado Miranda, Venezuela

Introduction *Hylesia* is a Neotropical moth genus, widely distributed from Mexico to Argentina. In Venezuela North-eastern, *Hylesia metabus* is an insect of importance in Public Health because it causes contact dermatitis with the abdominal setae released by females of this species. In general, adults and larvae present different patterns of coloration. These observations could suggest more than one species of *H. metabus* the presence in that area.

Methods Pupae and larvae were collected in different localities of Monagas, Sucre and Delta Amacuro States- Venezuela. The genitalia of females and males were extracted and observed under a binocular microscope. The material was preserved and labelled.

Results Differences in males and females genitalia were not found among compared samples.

Conclusions These results are congruent with DNA molecular analysis of *H. metabus.* Both evidences suggest that *H. metabus* is a single species.

POSTER PRESENTATION

Effects of ace inhibitors and TMOF on growth, development and trypsin activity of larval *Spodoptera littoralis*

Els Lemeire[1], Dov Borovsky[2], John Van Camp[3], Guy Smagghe[1]

[1]Laboratory of Agrozoology, Department of Crop Protection, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium, Ghent, Belgium, [2]University of Florida, Institute of Food and Agricultural Sciences, Florida Medical Entomology Laboratory, 200 9th St SE, Vero Beach, FL 32962, Vero Beach, United States, [3]Research Group of Food Chemistry and Human Nutrition, Department of Food Safety and Food Quality, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium, Ghent, Belgium

Angiotensin converting enzyme (ACE) is a zinc metallopeptidase capable of cleaving dipeptide or dipeptideamide moieties at the C-terminal end of peptides. ACE is present in the hemolymph and reproductive tissues. The presence of ACE in the hemolymph and its broad substrate specificity suggests an important role in processing of bioactive peptides. After molecular cloning and characterization of *SlACE*, this study reports the effects of ACE inhibitors on larval growth in the cotton leafworm *Spodoptera littoralis*. Feeding ACE inhibitors *ad lib* decreased the growth rate, inhibited ACE activity in the larval hemolymph and down regulated trypsin activity in the larval gut. These results indicate that *S. littoralis* ACE may influence trypsin biosynthesis in the larval gut by interacting with a trypsin modulating oostatic factor (TMOF). Injecting third instar larvae with a combination of Aea-TMOF and the ACE inhibitor captopril, down regulated trypsin biosynthesis in the larval gut indicating that an Aea-TMOF gut receptor analogue could be present. Whereas, injecting captopril and enalapril into newly molted fifth instar larvae stopped larval feeding and decreased weight gain. Together, these results indicate that ACE inhibitors are efficacious in stunting larval growth and ACE plays an important role in larval growth and development.

This work was supported by the Fund for Scientific Research (FWO-Vlaanderen, Belgium) and the Special Research Council of Ghent University (BOF-UGent).

POSTER PRESENTATION

Expression of *Sambucus nigra* agglutinin (SNA-I') from elderberry bark in transgenic tobacco plants results in enhanced resistance to different insect species

Shahnaz Shahidi-Noghabi[1], Els JM Van Damme[2], Guy Smagghe[1]

[1]Laboratory of Agrozoology, Department of Crop Protection, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium, Ghent, Belgium, [2]Laboratory of Biochemistry and Glycobiology, Department of Department of Molecular Biotechnology, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium, Ghent, Belgium

Tobacco plants (*Nicotiana tabacum* cv Samsun NN) have been transformed with the gene encoding the type-2 ribosome-inactivating protein (RIP) SNA-I′ from elderberry (*Sambucus nigra*) under the control of the cauliflower mosaic virus 35S promoter. Previous research confirmed that these plants synthesize, correctly process and assemble a fully active RIP. Variability in protein expression was observed within the transgenic lines. The effects of the type-2 RIP SNA-I′ delivered through a leaf feeding assay were evaluated in the laboratory on two economically important pest insects belonging to the orders of Hemiptera, the tobacco aphid (*Myzus nicotianae*) and Lepidoptera, the beet armyworm (*Spodoptera exigua*). In the experiment with aphids, significant effects were observed on the life parameters, such as survival, intrinsic rate of increase, net reproductive rate, mean generation time and mean daily offspring, whereas with caterpillars significant reduction in fresh weight as well as retardation in development were observed. In addition, significant increases in mortality were noted for insects fed on the transgenic lines as compared to wild type plants. This information provides further support for RIPs having a role in plant resistance to insect pest species.

This work was supported by the Fund for Scientific Research (FWO-Vlaanderen, Belgium) and the Special Research Council of Ghent University (BOF-UGent).

POSTER PRESENTATION

Ferritin and α-amylase act as putative target sites for the insecticidal snowdrop lectin (*Galanthus nivalis* agglutinin; GNA) in the cotton leafworm *Spodoptera littoralis*

Amin Sadeghi[1], Els JM Van Damme[2], Guy Smagghe[1]

[1]Laboratory of Agrozoology, Department of Crop Protection, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium, Ghent, Belgium, [2]Laboratory of Biochemistry and Glycobiology, Department of Molecular Biotechnology, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium, Ghent, Belgium

Despite numerous efforts that have been made to evaluate the toxicity of plant lectins against insects, their mechanism of action is not clearly understood. Therefore the aim of this project was to identify putative target receptor protein(s) in the midgut of larvae of the cotton leafworm (*Spodoptera littoralis*) that are responsible for binding of the insecticidal lectin from snowdrop (*Galanthus nivalis* L.; GNA). After dissection and homogenization of 800 larval midguts, the water soluble and membrane proteins were fractionated and chromatographed on an affinity column with immobilized GNA. SDS-PAGE analysis revealed many different GNA-binding proteins among which 4 soluble proteins with polypeptides of approximately 26, 42, 50 and 72 kDa, and 6 membrane proteins composed of 26, 34, 42, 50, 74 and 78 kDa subunits. N-terminal sequencing identified the 26 kDa soluble protein band (TQXHVNPVDIQDXVTG) as secreted ferritin and the 50 kDa band (YKNPYYAANRSVNVHLF) as α–amylase. The 32 and 26 kDa polypeptides from the membrane protein fraction (ADTAYQDVSGDXXAXT and TQXHVNPVTIXXEXXM) revealed sequence homology to ferritin from the midgut of the tobacco hornworm (*Manduca sexta*) and the silkmoth (*Bombyx mori*), respectively. In conclusion, we hope that with this new information we can sustain the use and exploitation of insecticidal lectins to enhance the resistance of crops against pest insects into an IPM strategy.

This work was supported by Ministry of Science, Research and Technology of Iran and Kurdistan University to AS, and Fund for Scientific Research (FWO-Vlaanderen, Belgium) to GS and EJMVD.

POSTER PRESENTATION

Ground beetle community response to commercial and alternative silviculture in Eastern boreal forests of Canada

Kit O'Connor, Timothy Work

Université du Québec à Montréal, Montréal, Québec, Canada

Introduction: Emulating natural forest structure is seen as one of the keys to maintaining biodiversity and natural ecosystem function in managed forests. Inclusion of structural components such as standing snags and large diameter downed deadwood is being considered in forest management plans as a way to buffer managed stands against major ecosystem shifts. We used carabid communities to evaluate the efficacy of a series of experimental silvicultural treatments for maintaining beetle biodiversity over a 270-year successional gradient in the mixedwood boreal zone of western Quebec.

Methods: Beetles were collected over 2004-2007 using pitfall traps from a series of replicated whole-stand treatments including, partial cutting (both dispersed and aggregated), clearcutting, prescribed burning, whole-tree harvesting and a series of treatments that altered quantities of standing and fallen deadwood. We used naturally burned and uncut stands from three successional cohorts as controls. We used multivariate regression trees to quantify compositional differences.

Results: We collected more than 22,400 carabids representing 52 species. Aspen and mixedwood clear-cuts most closely resembled natural wildfire while conifer-dominated clear-cuts contained distinct insect assemblages. Gap-cut mosaic communities were similar to those found in clear-cuts while dispersed cuts removing equivalent basal area hosted communities similar to uncut control stands. Deciduous stands were tolerant of up to 2/3 stem removal without detectable community change. Jack pine thinning treatments emphasized the role of downed dead-wood in determining carabid communities.

Conclusion: These findings underscore the need to adapt coarse-filter management to stand-level characteristics such as successional stage and structural components to maintain biodiversity.

POSTER PRESENTATION

On the polymorphism of Membracoidea (Hemiptera), with emphasis on *Phormophora maura* (Fabricius, 1803) (Membracidae)

Gabriel Andrade

Universidade Estadual do Oeste do Paraná, Cascavel, Paraná, Brazil

Introduction: Morphology is the main base for systematics, and new features for interpretation can still be discovered. The observations found are presented to call attention to special features in studies on groups that are gregarious and on polymorphic, especially Membracoidea.

Methods: Dried specimens were borrowed from the most representative collections of the Neotropical fauna, along with field observations of species of Membracidae that aggregate in family groups. Of special note is *Phormophora maura* in Minas Gerais State, Brazil, of which we found adults and immatures attacking *Piptocarpha* sp. (Asteraceae) and associated with the ant *Cephalotes atratus* (Linné,1758).

Results: Within this species we found polymorphism and sexual dimorphism, in both adults and immatures, and a polychromism within the females. The males differ from females in their smaller size, brown groundcolor, and in pronotal and forewing sculpture. Within the females, the general color black can be thoughout or can be ornate, with a variable green spot on the sides of the pronotum. This peculiarity was used to distinguish the *P. maura* from *P. dorsata* by FABRICIUS. The immatures presents also dimorphism, in size and most by color. These observations agree with that all gregarious Membracoidea presents polymorphism, as noted here and some authors.

Conclusions: Studies within gregarious species of Membracoidea show that the polymorphism are quite common, and requires caution in the interpretations of characters. It is very important to examining specimens from the same aggregation, and the male genitalia features are generally the reliable apomorphies.

POSTER PRESENTATION

Pathogenicity of *Beauvaria bassiana* against the plum curculio

Daniel Cormier[1], Claude Guertin[2], Gérald Chouinard[1]

[1]Institut de recherche et de développement en agroenvironnement, St-Hyacinthe, Québec, Canada, [2]INRS-Institut Armand-Frappier, Laval, Québec, Canada

Introduction: The plum curculio, *Conotrachelus nenuphar* (Herbst), is one of the most destructive insects of pome and stone fruit in North America and control is achieved mainly by insecticide applications. Laboratory bioassays were conducted to evaluate the pathogenicity of two isolates of the microbial agent *Beauveria bassiana*, (Balsamo) Vuillemin against this pest and also on the predatory lady beetles, *Coleomegilla maculata lengi* Timberlake.

Methods: Suspensions of the *B. bassiana* isolates *INRS-CFL* and *INRS-IP* were prepared to a concentration of 0,10^4, 10^6, 10^7 and10^8 conidia/ml. Thirty plum curculio adults from both the hibernating and summer populations were soaked during five seconds into each solution, then placed in Petri dishes in an environmental chamber. The pest mortality was recorded every 48h for 14d, to determine the $LC_{10, 50, 90}$. Twenty lady beetles were soaked in 0 and 10^7 conidia/ml and predator mortality was recorded daily for 14d. Each bioassay was repeated 3-5 times.

Results: A significant difference was observed between the lethal concentrations of the *INRS-CFL* and *INRS-IP* isolates for both the hibernating and summer populations of the plum curculio. However, using a dose of 10^7conidia/ml, the survival time of this insect was not significantly different when treated with either isolates suggesting that both isolates had similar virulence against this insect pest. Moreover, both *B. bassiana* isolates had low toxicity on the lady beetles.

Conclusion: The two isolates of the entomopathogen *B. bassiana* are promising as microbial agent to control the plum curculio while having little negative impact on lady beetle.

POSTER PRESENTATION

Assessing lethal and sublethal effects of insecticides with different modes of action in bumblebees *Bombus terrestris*

Veerle Mommaerts[1], Xavier Cuvelier[1], Sofie Reynders[1], Guido Sterk[2], Guy Smagghe[3]

[1]Laboratory of Cellular Genetics, Department of Biology, Faculty of Sciences, Free University of Brussels, Brussels, Belgium, Brussels, Belgium, [2]Biobest NV, Westerlo, Belgium, Westerlo, Belgium, [3]Laboratory of Agrozoology, Department of Crop Protection, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium, Ghent, Belgium

Nowadays bumblebees are widely used in greenhouses for the pollination of several crops like tomatoes, sweet peppers and eggplants. Moreover due to Integrated Pest Management (IPM) programs cultivators are spraying less broad-spectrum pesticides in order to control pest insects and mites. Although it remains important to determine possible negative effects of pesticides on bumblebees as pollination must be guaranteed. This study examined the adverse effects of several classes of pesticides on the survival and on the reproduction of the beneficial organisms *Bombus terrestris*. In total nine commercial insecticides/acaricides were tested: three neonicotinoids (imidacloprid, thiacloprid, flonicamid), three acaricides (bifenthrin, milbectine, spirodiclofen) and three insect growth regulators (chitin synthesis inhibitor: flucycloxuron, juvenile hormone analogue: pyriproxyfen, ecdysone agonist: tebufenozide). The bumblebees were exposed in in-house made artificial nests (Mommaerts *et al.,* 2006) to the compounds via three different routes of exposure: topically via dermal contact, and orally via the drinking of treated sugar water and via eating treated pollen. The compounds were tested at their respective maximum field recommended concentrations (MFRC). In general, these risk hazard tests showed that only few of the tested pesticides showed acute worker toxicity. In addition, during 11 weeks the numbers of drones were scored at weekly basis as endpoint of sublethal effects against reproduction. The compatibility of each compound to be used in combination with *B. terrestris* within an IPM approach is discussed in relation to routes of uptake and effects.

Mommaerts, V., Sterk, G., Smagghe, G. (2006). Hazards and uptake of chitin synthesis inhibitors in bumblebees Bombus terrestris. Pest Management Science, 62, 752-758.

POSTER PRESENTATION

Changes in integument structure during the imaginal molt of the honeybee, *Apis mellifera*

Moysés Elias-Neto, Michelle Soares, Márcia Bitondi

São Paulo University, Ribeirão Preto/SP, Brazil

Introduction: The sequencing of the honeybee genome brought a new dimension to the study of the integument (cuticle and associated epidermis) in social insects. Information on the structural changes that the integument undergoes during molting cycles is of interest for the characterization of differential expression and regulation of cuticle protein genes in the context of metamorphosis. In the present work we combined information on the external morphology of the honeybee with a description of the changes taking place in the integument during the pupal-imaginal molt.

Methods: Thoracic and abdominal integuments were dissected and prepared for light microscopy. Cross sections were stained with methylene blue and basic fucsin. Whole mounts were also examined.

Results: The temporal sequence of integument sections and whole mounts revealed considerable changes in epidermis and cuticle structure during the pupal-imaginal molt. In the sequential morphological patterns, the periods of deposition and differentiation of the adult cuticle were clearly distinguished. Apolysis and the subsequent deposition of the adult cuticle were marked by an increase in the thickness of epidermal cells, which also changed their shapes. But epidermis becomes thin as cuticle differentiation advances. We also observed that thoracic cuticle was deposited earlier and showed to be thicker than the abdominal.

Conclusions: It is hoped that data presented here will be of help in studies on functional genomics on the context of metamorphosis and adult exoskeleton formation.

POSTER PRESENTATION

Use of bumblebees and microbiological antagonists in the battle against plant pathogens

Veerle Mommaerts[1], Guido Sterk[2], Guy Smagghe[3]

[1]Laboratory of Cellular Genetics, Department of Biology, Faculty of Sciences, Free University of Brussels, Brussels, Belgium, [2]Biobest NV, Westerlo, Belgium, [3]Laboratory of Agrozoology, Department of Crop Protection, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium

A promising alternative for fungicides are microbiological control agents (MCAs). Although in the field the ability of these MCAs to control plant pathogen infections is limited. The success of MCAs is depending on several factors but the most important one is being present at the site of infection. Here bumblebees that are already used in modern greenhouses may play an important role as they can transport by use of a dispenser system the MCAs directly to the flowers which are the main entry point of many plant pathogens. In a first part of this study the effect of MCAs was evaluated on the pollinator *Bombus terrestris*. The bumblebees were exposed to a powder formulation of each antagonist via walking through a miniature dispenser. In this work we tested three commercial MCAs: Binab T-vector, Prestop Mix and Serenade, containing *Trichoderma atroviride* and *Hypocrea parapilulifera*, *Gliocladium catenulatum* J1446 and *Bacillus subtilis* QST713, respectively. These tests showed that the Binab T-vector, Prestop Mix and Serenade did not cause acute worker toxicity nor caused an adverse effect on the reproduction (production of drones). In a second part of the study, bumblebee hives were mounted with a dispenser and the efficiency of bumblebee workers to carry MCAs was evaluated. In this test we compared an existing system, the side by side passageway (SSP), and an own developed system, the Funnel-dispenser. In both systems the bumblebees workers needed to walk through a 0.5 cm layer of commercial MCA product. Then the amounts of CFU present on the head, the thorax, the abdomen and the legs were determined in order to get more insight in the transport capacity of the two systems. The results showed that the whole body of the bumblebees was treated after walking through the dispensers, and that the F-dispenser showed higher CFUs per tissue than the SSP dispenser.

Overall, the results indicated that the Binab T-vector, Prestop Mix and Serenade are safe to be used in a vectoring system of flying doctors. Here the F-dispenser is a promising system, although further optimizations are necessary.

POSTER PRESENTATION

Analysis of testes in the production of ecdysteroids in Lepidoptera (*Spodoptera littoralis*)

Masatoshi Iga, Tim Vleugels, Guy Smagghe

Laboratory of Agrozoology, Department of Crop Protection, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium

Over the last decade there have been some reports on production of ecdysteroids and a testis ecdysiotropin by testes from *Lymantria dispar* and *Rhodnius prolixus* (Loeb *et al*., 2001; Vafopoulou & Steel, 2005) In this project we tested the potency of the testes from the cotton leafworm, *Spodoptera littoralis* (Lepidoptera: Noctuidae), to produce ecdysteroids at different levels. In our approach, we measured the *in vivo* ecdysteroid titers of the hemolymph and the testes at different moments in the last larval stage to see the relationship between them by using an enzyme immunoassay (EIA). Then testes were cultured in Grace's insect medium and tested the effect of insulins and peptides as these are reported as inducers of ecdysteroid biosynthesis. The ecdysteroid amounts in the cultured testes and the culture medium were followed. In addition, the expression of the Halloween genes such as *spook*, *phantom*, *disembodied* and *shadow* were evaluated as criterion of *de novo* ecdysteroid biosynthesis. For this study we compared to the situation of the prothoracic glands. Finally the results are discussed in relation to potential different resources of ecdysteroids and developmental stages.

This work was supported by the Fund for Scientific Research (FWO-Vlaanderen, Belgium)

POSTER PRESENTATION

Ecdysteroid-resistance mechanism independent from ecdysteroid receptor function in cell lines from the polyphagous noctuid pest *Spodoptera exigua*

Luc Swevers[1], Thomas Soin[2], Hadi Mosallanejad[2], Kostas Iatrou[1], Guy Smagghe[2]

[1]Insect Molecular Genetics and Biotechnology, Institute of Biology, National Centre for Scientific Research "Demokritos", Aghia Paraskevi Attikis, Athens, Greece, [2]Laboratory of Agrozoology, Department of Crop Protection, Faculty of Bioscience Engineering, Ghent University, Ghent, Belgium

In this project we describe an analysis of the ecdysteroid receptor signaling pathway in ecdysteroid-resistant Se4 cell lines resistant towards the insect molting hormone 20-hydroxyecdysone (20E) or a non-steroidal ecdysone agonist (methoxyfenozide). In contrast to other ecdysteroid-resistant cell lines described in literature, our data support the existence of a normal functioning ecdysteroid receptor complex in the resistant Se4 cell lines: (1) using a recombinant BmNPV baculovirus as a transduction tool, activation of an ecdysone-responsive luciferase cassette was demonstrated; (2) the early gene *HR3* is constitutively expressed in the resistant cell lines that are grown in the presence of 20E or methoxyfenozide. Quantitative RT-PCR indicated that expression levels of *SeEcR* mRNA were comparable among sensitive and resistant cell lines. Sequencing revealed the presence of *SeEcR* mRNA with a wild-type ligand-binding domain in resistant cells. Finally, a possible role for the gene *FTZ-F1*, whose expression correlates with the absence of circulating ecdysteroids during insect development, in the resistance mechanism was investigated. However, it was observed that *FTZ-F1*, in contrast to what is observed during insect development, is constitutively expressed in Se4 cells and that its expression is not regulated by the addition of ecdysteroid. It is proposed that the resistance mechanism in Se4 cells resides at the coupling between the conserved hierarchical cascade of early and early-late gene expression and the differentiation program in the Se4 cell line.

This work is supported by General Secretariat for Research and Technology, Ministry of Development in Greece, a doctoral grant from the Ministry of Science, Research and Technology (SRT) and Agricultural Research Organization of Iran (Plant Pest and Disease Research Institute, the Institute for the Promotion of Innovation by science and Technology in Flanders (IWT, Belgium) and the Fund for Scientific Research (FWO, Belgium).

POSTER PRESENTATION

Response of weevil assemblages (Coleoptera: Curculionidae) to edge effects in tropical lowland forests adjacent to different matrix habitats.

Alida Mercado Cárdenas[1], Christopher Buddle[1], Héctor Barrios[3]

[1]Department of Natural Resource Sciences, McGill University, Ste-Anne-de-Bellevue, Quebec, Canada, [2]Smithsonian Tropical Research Institute, Panama, Panama, [3]Programa Centroamericano de Maestría en Entomología, Universidad de Panamá, Panama, Panama

Introduction: Deforestation and fragmentation in tropical regions is increasing the proportion of edges between forests and modified adjacent habitats. The contrast between adjoining habitats are expected to influence the effects created by edges. Few consistent patterns have been determined on the response of insects to edge effects as different species show opposite responses.

Methods: The response of insect species to edge effects is being studied in tropical lowland forests in Panama using weevils (*Coleoptera: Curculionidae*) as focal taxon. The influence of the adjacent habitat to the forest is being assessed by sampling at three transects located adjacent to coffee plantations and three to pastures (July and October 2007). Insects are collected sifting leaf-litter at five distance points from the edge into the forest (0, 10, 50, 100 and 250 m).

Results: A total of 2001 beetles were collected, of which 248 are weevils of 14 species. The highest number of species is found further away from the edges. 13 species (111 specimens) have been collected from the coffee plantation transects and 9 species (137 specimens) from the pasture transects. The number of species found at and near the edge is lower in pasture sites than in coffee plantation sites.

Conclusion: Forest edges have a negative effect on species richness of leaf-litter weevils. The results show a trend of a higher extent of edge effects between sites with a higher contrast. However, we have yet to find supporting evidence to state that weevil assemblages differ between pasture sites and coffee sites.

POSTER PRESENTATION

Evaluation of resistance mechanism to two spotted spider mite on some chiti bean genotype in greenhouse condition

Mazaher Yousefi, Hamidreza Dori

Agricultural and Natural Resources Research Center of Markazi Province, Arak, , Islamic Republic of Iran

Tetranychus urticae (Koch) is one of the most important pest on bean field in our country , according to its high economical damage in the area of our country , this investigation carried out in order to recognize new resistance resource . in this study , resistance and its mechanism evaluated to related of *Tetranychus urticae* , that including : Antixenosis (number of placed *Tetranychus urticae* after 24 and 48 hours in genotype of chiti bean) , Tolerance (evaluated amount of damage in genotypes based on 1 – 6 scale) and Antibiosis (average of nymph in every genotype) by using greenhouse standard test in 12 chiti bean genotype (screened of 300 chiti bean genotype in field condition)and 24 genotype (resulted from same genotype in greenhouse condition). The result of mean comparison by Douncans test showed that genotypes with numbers Ks-21184, Ks-21479 and local Khomein chiti have high symptom of damage for *Tetranychus urticae* and the lowest amount of toleration to pest observed in genotypes Ks-21104, Ks-21201, Ks-31163, Ks-41235 and Ks-21343. The highest amount of antibiosis counted and recorded from genotypes with numbers Ks-41144, Ks-21246, Ks-21365 and Ks-21184 and the lowest recorded from genotypes with numbers Ks-21102, Ks-21112, Ks-21429, Ks-21156, Ks-21360, Ks-31163and Ks-41235. The highest amount of antixenosis counted and recorded from genotypes with numbers Ks-21320, Ks-21343, Ks-21390, Ks-31144 and Ks-21429 and the lowest recorded from genotypes with numbers Talash, Ks-21283, Ks-41144, Ks-21143, Ks-21189, Ks-21102 and Ks-21178. The highest amount of Plant Resistance Index observed in Ks-21178 and Ks-21235 with amount (104.8 and 63.4) and the lowest amount of PRI from genotypes with numbers Ks-21320, Ks-21324 and Ks-31144. The result of this study showed that different and desired mechanism resistance or tolerance in chiti bean genotype on combination with their yield and its component could be suitable base for recognizing genetic resources of *Tetranychus urticae.* The resistance genotype of this research could be recommend to farmers after succefull experiment in to culture on extend area.

POSTER PRESENTATION

Novel mosquito traps in the fight against urban dengue – from monitoring to control

Andreas Rose[1], Martin Geier[1], Alvaro E. Eiras[2], Maria da Gloria Teixeira[3], Maria das Gracas Vale Barbosa[4], Maria Paula Gomes Mourao[4]

[1]BioGents AG / University of Regensburg, Regensburg, Germany, [2]Federal University of Minas Gerais, Belo Horizonte, Brazil, [3]Federal University of Bahia, Salvador, Brazil, [4]Tropical Medicine Foundation of the Amazon, Manaus, Brazil

Dengue vector surveillance relies on the identification and analysis of larval habitats, on ovitraps, and also on sticky traps that catch ovipositing females. A recent addition to the arsenal is the BG-Sentinel trap for host-seeking females. This trap is very efficient for *Aedes aegypti*, *Ae. albopictus* and also *Ae. polynesiensis*. Due to its efficacy, it allows for a quick and meaningful population assessment in vector control programs and also for a better evaluation of the dengue transmission risk.

Still, a sustainable *Aedes* control remains a challenging task. Even combinations of adulticidal fogging, the reduction of oviposition sites in clean-up campaigns, and treating larval habitats with insecticides have only lead to limited success, especially over longer periods of time.

Recent field and laboratory tests have shown that the BG-Sentinel is not only a highly sensitive trap for dengue vector surveillance, but also that its trapping efficacy should be large enough for the trap to be used as an actual suppression tool against dengue. The data suggest that an area-wide use would significantly shorten the average life expectancy in the vector population and reduce vector density. This would lower the vectorial capacity and reduce the risk of dengue transmission.

To evaluate the impact of this strategy in the real world and with support from the World Bank and the Gates Foundation, we are currently beginning a pilot project involving several hundred households in Manaus, Brazil. In our presentation, we will introduce this project, presenting the underlying data and further explaining the concept.

POSTER PRESENTATION

Three new Hymenoptera species obtained from important agricultural pests

Helena Onody, Ágatha Gil, Ivy Melo, Manoel Dias, Angélica Penteado-Dias

Universidade Federal de São Carlos, São Carlos, SP, Brazil

Introduction: The parasitoids are one of the most important agents in the control of agricultural pests, either by their natural occurrence in the environment or for their use in biological control programs. The Hymenoptera predominate among insects entomophagous. Despite its importance, there is major insufficiency knowledge of their biology and taxonomy especially in neotropical region. This paper records the occurrence of new Hymenoptera species occurring on important agricultural pests.

Material and Methods: The collects of the lepidopterous caterpillars were made in organic crops São Carlos, SP, Brazil region. The caterpillars were transferred to the laboratory, aiming to verify the emergence of natural enemies.

Results: It was observed the occurrence of three new Hymenoptera species parasitizing important agricultural pests. From a *Diaphania hyalinata* Linnaeus, 1758 caterpillar, a new *Eiphosoma* Cresson, 1865 (Ichneumonidae; Cremastinae) species was obtained. A specimen of *Colpotrochia* Holmgren, 1855 (Ichneumonidae, Metopiinae) emerged from the pupae of *S. eridania* (Cramer, 1782). A new species of *Hypomycrogaster* Ashmead, 1898 (Braconidae, Microgastrinae) was obtained from *Hellula phidialis* (Walker, 1859) caterpillar. There was no previous register of some *Colpotrochia* and *Hypomicrogaster* species parasitizing the hosts cited above.

Conclusion: The data gathered here point out the necessity for more studies about the Hymenoptera parasitoids in the neotropical region. The increase in taxonomic and biology knowledge of the group can offer more possibilities for its use in biological control programs.

POSTER PRESENTATION

The Campopleginae (Hymenoptera: Ichneumonidae) fauna of Brazilian savannah

Diogo Sandonato, Helena Onody, Angélica Penteado-Dias

Universidade Federal de São Carlos, São Carlos, SP, Brazil

Introduction: In Brazil, the savannah occupies about 20% of its territory. It can be found in plain regions that have dry climate with tortuous trees which grow in poor and acid soil. Considered as a "hot spots", it´s one of the most rich, endemic and threatened areas of the planet. Only 3% of its original extension is protected in parks and reserves. The Campopleginae (Hymenoptera, Ichneumonidae) are endoparasitoids cenobiontes mainly of Lepidoptera larvae. They are a cosmopolitan subfamily with 19 genera occurring in the neotropical region.

Methods: The analyzed material was collected with Malaise and Moericke traps, "sweeping" the vegetation and at light in 9 places in the Southeast and Center-west of Brazil.

Results: A total of 4002 specimens were identified in 14 different genera. *Microcharops* (38, 1 %), *Casinaria* (27, 4 %) and *Venturia* (18, 8 %) were the most common genera collected; the rarest genera were *Campoplex, Diadegma, Xanthocampoplex* and *Prochas*. The results obtained here differ from a similar study realized in another important Brazilian ecosystem, the Atlantic forest, where more than 60% of the material collected belonged to the genus *Dusona*.

Conclusions: The studied material revealed a large number of morphospecies, which points out the necessity of taxonomic studies to be conducted for the group. A higher knowledge of the biodiversity of this Brazilian biome can be useful in the management and conservation plans of the extremely threatened areas.

POSTER PRESENTATION

Integrated genomic and gene expression data for insect vectors of disease at VectorBase

Robert M. MacCallum, Seth Redmond, Fotis C. Kafatos, George K. Christophides

Imperial College London, London, United Kingdom

Introduction: VectorBase provides genomic bioinformatics resources for mosquito species and other insect vectors of disease. In addition to the annotation and visualisation of genomic data, a core role for VectorBase is to make gene expression data available to the community in an easily digested form for non-microarray experts.

Methods: It is vital to establish the relationship between each reporter (a.k.a. probe) on a microarray and its corresponding gene(s) or genomic region(s). This is usually done through alignment of reporter sequence to the genome. Since genome assemblies and gene sets go through many revision cycles, we have to have a robust method which is easy to apply to each new assembly/gene build. Since VectorBase uses the Ensembl genome annotation system, we can add the reporter alignment and gene assignment to the gene build process to ensure timely and reliable updating.

The experimental data is loaded into an open-source microarray management system called BASE. Each experiment is put through a standard processing pipeline, including normalisation. One or more statistical tests are then applied to the expression data with respect to the experimental factors being tested (e.g. developmental stage). The biologist is presented with a simple web page for their gene of interest. This page highlights the experiments that show differential expression and describes their results with a short text summary, which is searchable. More detailed plots and tables are also available to view or download, and access to the BASE analysis platform is available for experts.

Results: For *Anopheles gambiae*, experiments submitted by the community include developmental series, blood meal time-courses, tissue and organ comparisons, insecticide resistant strain comparisons. For *Aedes aegypti* we have developmental series, strain comparisons, viral infection and xenobiotic exposure. We welcome data from all VectorBase organisms.

Availability: The VectorBase website can be found at http://vectorbase.org

POSTER PRESENTATION

Genetic patterns of *Phyllonorycter platani* - an invasive leaf miner moth with Mediterranean origin

Ferenc Lakatos[1], Sylvie Augustin[2], Carlos Lopez-Vaamonde[2]

[1]University of West-Hungary, Sopron, Hungary, [2]INRA, Orleans, France

Introduction: *Phyllonorycter platani* (Staudinger) belongs to the family Gracillariidae, a large lepidopteran family having a high number of invasive species (e.g. *Cameraria ohridella*, *Phyllonorycter robiniella*). The species have invaded several parts of Europe in the last decades, however the expansion of the species range can be traced back to the 19th century. Its current distribution ranges from Denmark and South-Sweden in the north, to Great Britain and Spain in the west. Fortunately the colonization history of *P. platani* is well known (for review see Sefrova, 2001). The endemic area of the species is thought to be in the southern part of the Balkans, and to be aligned with the natural distribution of its main host *Platanus orientalis*. Due to wide cultivation of different *Platanus* species - mainly in urban areas - *P. platani* has now potential hosts throughout all of Europe. The aim of our study was to look at the pattern of genetic variation of *P. platani* to find possible colonization patterns within the present distribution of the species.

Methods: We used sequences of a 570bp long fragment of the mitochondrial COI gene to study the genetic variability of *P. platani* across its present distribution in Europe.

Results: Our results show moderate genetic variation in Europe with a reduction in genetic diversity of *P. platani* populations from east-to-west and from south-to-north across Europe.

Conclusions: Our findings confirms the hypothesis that *P. platani* have invaded the central and western part of Europe from the Balkans.

POSTER PRESENTATION

Detritivorous hairstreak butterflies (Lycaenidae: Theclinae: Eumaeini): phylogenetic analysis of the *Lamprospilus* Section

Marcelo Duarte[1], Robert Robbins[2]

[1]Museu de Zoologia, Universidade de São Paulo, São Paulo, SP, Brazil, [2]National Museum of Natural History, Smithsonian Institution, Washington, DC, United States

Introduction: Recent fieldwork indicates that facultative or obligate detritivory is more widespread in Lycaenidae than previously reported, occurring in *Lamprospilus*, *Arumecla*, *Camissecla*, *Ziegleria*, *Electrostrymon* and *Calycopis*, which were preliminary grouped in the *Lamprospilus* Section of the Eumaeini. The purpose of this contribution is to establish a phylogenetic basis for this section and its component genera. It is intended to be used to study the evolution of detritivory in Lycaenidae.

Methods: Adult morphology were used to infer phylogenetic relations. The ingroup included species (82) for which both sexes were available for study species. Equal-weight most parsimonious trees were searched in NONA 2.0. To test the assumption of equally weighed characters, implied weighting option of TNT was used. A variety of fit functions (k=3, 10, 50, 100, 1000) was tested.

Results: There were 50,000 equal-weight most parsimonious trees retained with 166 steps. There were either 594 or 1188 implied weight most parsimonious trees with k=10, 50, 100, 1000. The implied weight tree with k=3 rooted the ingroup in the middle of *Electrostrymon* and were not among the equal-weight most parsimonious trees. A new genus was erected and thirteen new combinations were established.

Conclusions: *Lamprospilus* Section was monophyletic in all analyses. Phylogenetic relations among genera were resolved and identical in the set of 594 or 1,188 trees that were most parsimonious with equal weights and with implied weights ranging from k=10 to 1,000. For this reason, we consider it to be the best estimate, albeit provisional, of relations among the *Lamprospilus* Section genera.

POSTER PRESENTATION

Orientation flights in bumblebees, *Bombus terrestris*

Andrew O. Philippides[1], Natalie Hempel de Ibarra[2], Olena Riabinina[1], Thomas S. Collett[1]

[1]University of Sussex, Brighton, United Kingdom, [2]University of Exeter, Exeter, United Kingdom

Introduction: When bees and wasps leave the nest to forage they perform learning flights. Several components of the flights seem to be adapted for the active acquisition of visual information allowing the animals to find their nests at return. Here we present an analysis of the learning flights of bumblebees when they are close to their nest in the ground.

Methods: Single, individually marked bumblebees were video-recorded when leaving their colony that was located under an artificial ground covered with a textured white carpet in a semi-open outdoor area. Two or four conspicuous landmarks, i.e. upright black cylinders, were set 15 cm from the nest hole.

Results: Flights start with a phase in which the bee flies in tight circles close to the nest hole and low on the ground. This component seems to be less prominent in the learning flights of other insects that have been recorded. It leads into the more usual semi-circular arcs backing away from the nest which resemble those of solitary wasps. These arcs appear to consist of a number of linked phases with behaviour consistent across arcs.

Conclusions: Bees tend to look at the landmarks from similar locations during learning and return flights possibly for learning and retrieving snapshots of landmarks and surrounding visual background.

POSTER PRESENTATION

Influence of clothianidin-based seed treatments on maize yield in North America.

Billy Fuller[1], Bradley McManus[1], Larry Bledsoe[2], Mark Boetel[3], Eileen Cullen[4], Chris DeFonzo[5], Bruce Eisley[6], Lance Meinke[7], James Oleson[8], Kenneth Ostlie[9], Mark Sears[10], Jon Tollefson[8], Roger Youngman[11]

[1]South Dakota State University, Brookings, SD, United States, [2]Purdue University, West Lafayette, IN, United States, [3]North Dakota State University, Fargo, ND, United States, [4]University of Wisconsin-Madison, Madison, WI, United States, [5]Michigan State University, Lansing, MI, United States, [6]The Ohio State University, Columbus, OH, United States, [7]University of Nebraska-Lincoln, Lincoln, NE, United States, [8]Iowa State University, Ames, IA, United States, [9]University of Minnesota, St. Paul, MN, United States, [10]University of Guelph, Guelph, Ontario, Canada, [11]Virginia Tech University, Blacksburg, VA, United States

Anecdotal reports suggest the possibility of increased yield in corn fields where clothianidin (Poncho) insecticide-treated seeds are planted. Higher yield would be expected in cases where this treatment might provide protection from feeding injury by corn rootworms and other soil-dwelling insect pests. However, some reports indicate higher yields from these seed treatments when rootworm densities were very low. Preliminary data from several states in did little to support or rule out clothianidin-related yield enhancements. Therefore, a 3-yr study was begun in 2004 by a multi-state/national corn rootworm committee (NCCC46) to more fully investigate this issue. Evaluations were designed to evaluate clothianidin-treated seed in comparison with conventional granular insecticides, transgenic hybrids, and untreated control plots. Combined results from this investigation indicated that occasionally higher yields were obtained in clothianidin-treated plots than would have been expected for corn fields with moderate to high corn rootworm infestations. In other instances, clothianidin-treated seed produced no yield enhancements, even where no rootworms were present. This mixed response could relate to the wide geographical range (10 U. S. states and one Canadian province) and variety of environmental conditions among research sites used for this project.

POSTER PRESENTATION

Seed treatment insecticide technology for managing soil insect pests of sugarbeet

Mark A. Boetel[1], Robert J. Dregseth[1], Allen J. Schroeder[1], Ayanava Majumdar[2]

[1]Department of Entomology, North Dakota State University, Fargo, North Dakota, United States, [2]North Dakota State University Extension Service, Finley, North Dakota, United States

Introduction: North American sugarbeet fields are often at risk of infestation by one or more soil-dwelling arthropod pests that can cause major yield losses. Granular and liquid insecticide formulations have been used to manage soil insect pests for decades. Insecticidal seed treatments, if found efficacious against these pests, would be attractive control alternatives because they are simple and relatively safe to deploy.

Methods: Four years of field trials (2004 to 2007) were carried out to compare experimental seed treatments and conventional insecticides for efficacy against the following: 1) sugarbeet root maggot (SBRM), *Tetanops myopaeformis* Röder; 2) wireworms (*Limonius* spp.); and 3) subterranean springtails (Collembola).

Results: Poncho (clothianidin) + cyfluthrin at 60:16 g active ingredient (a.i.) per unit (100,000 seeds) provided similar levels of SBRM control to the conventional insecticide (terbufos 15G applied at 2 kg a.i./ha]). Excellent wireworm control was provided by Poncho+betacyfluthrin (60:8 g a.i./unit seed), Cruiser 5FS (thiamethoxam; 60 g a.i./unit), and terbufos 15G (1.7 kg a.i./ha). Springtail trials demonstrated that seed treatments (V-10170, V-10170+danitol, and Poncho+betacyfluthrin) were comparable in performance to low and moderate rates (1 to 1.7 kg a.i./ha) of terbufos 15G.

Conclusions: Seed treatments appear to be less likely than conventional insecticides to cause phytotoxicity and associated yield losses. The experimental seed treatments we evaluated are likely to provide similar efficacy as moderate rates of currently labeled conventional soil insecticides for controlling SBRM, wireworms, and subterranean springtails; however, they should not be relied on as the sole control tactic in areas heavily infested by SBRM002E

POSTER PRESENTATION

New predator of redgum lerp psyllid in *Eucalyptus* plantations in Brazil

Carlos Wilcken[1], Thaise Dias[1], Pedro Ferreira Filho[1], Luiz Alexandre Sá[2], Hélcio Gil-Santana[3]

[1]UNESP - campus of Botucatu, Botucatu, SP, Brazil, [2]Embrapa Meio Ambiente, Jaguariuna, SP, Brazil, [3]Fiocruz, Rio de Janeiro, RJ, Brazil

Introduction: In 2003 Redgum Lerp Psyllid (RLP), *Glycaspis brimblecombei* (Hemiptera: Psyllidae) was detected in eucalyptus forests in State of São Paulo, Brazil and it spread quickly by central and south regions, reaching other countries including Uruguay and Argentina. This pest causes defoliation, sooty mold and dieback in *Eucalyptus camaldulensis* and in *E. grandis x E. urophylla* clonal plantations. In 2004 it was started a biological control program using an exotic parasitoid, *Psyllaephagus bliteus* (Hymenoptera: Encyrtidae), with partial success of control. The most common predators, like ladybirds, lacewings and hover flies are not effective in control of this pest until now.

Methods: In August, 2007 a new predator, identified as *Atopozelus opsimus* Elkins, 1954 (Hemiptera: Reduviidae) was discovered during a pest survey in *E. camaldulensis* plantation at Luiz Antonio, SP, Brazil**.**

Results: *A. opsimus* is the first Brazilian native predator that specialized in attacking RLP. The adults of this reduviid look for the pest in leaves and branches of eucalyptus, predating adults and nymphs. About the lerp protection, predators place their stylets under the lerp until released it and after rises it with the front legs to eat the nymph. Predator can capture adults of psyllid in fly. Bioecology and predatory capacity studies of *A. opsimus* are in development and this predator has demonstrated to be an important agent in biological control of RLP in Brazil, mainly in cerrado region, where the parasitoid is not effective during the outbreaks in dryer periods.

POSTER PRESENTATION

Seasonal changes in dietary preferences of the European red ant in its invasive range.

Eleanor Groden, H. Alejandro Arevalo-Rodriquez, F. A. Drummond

University of Maine, Orono, ME, United States

Introduction: *Myrmica rubra*, the European red ant, a common northern temperate ant in Europe, has been introduced and become invasive in coastal areas in the northeastern US and parts of Maritime Canada. In addition to its pestiferous stinging behavior, high density populations of *M. rubra* are also impacting native North American flora and fauna. This study on the feeding ecology of *M. rubra* was initiated to assess how this ant sustains the large populations observed in the invasive range and its impact on native species, and to provide information about potential baits for management.

Methods: We evaluated preferences of different nutrients types using a standard diet matrix to which set concentrations of the nutrients were added. Diets were presented to ants in choice experiments in the field throughout the field season. Colonies were also collected regularly and the rate at which different nutrient-based diets were transferred throughout the colony was measured using flourescent tracers.

Results: As ant activity increased post diapause, a strong initial preference for sugars was seen, with the combined sucrose and honeydew diet accounting for greater than 53% of the diets consumed in the first month. Sugar preference declined in mid season as a stronger preference for protein was exhibited. However, as populations approached pre-diapause conditions, sugar consumption increased again.

Conclusions: Diet preferences corresponded to changing needs associated phenology of the colonies. Transitions in preference from sugars to proteins and back to sugars tracked the needs of the maturing colonies.

POSTER PRESENTATION

Effect of a new insecticide of the diamides chemical class(chlorantraniliprole) for control of: whitefly, *Bemisia tabaci* Biotype B; thrips, *Frankliniella schultzei*; leafminer, *Liriomyza huidobrensis*; and tomato pinworm, *Tuta absoluta*, on tomato

Geraldo Papa, Mario Sergio Oliveira, Dhiego Duvaresch, Fernando Celoto, Shizuo Seno

Sao Paulo State University -Unesp, Ilha Solteira/SP, Brazil

Introduction: The new insecticide (chlorantraniliprole) of the diamides chemical class has activity on a broad spectrum of economically important pest species. The mode of action is activation of insect ryanodine receptors. The objective of this work was to evaluate the performance of this insecticide on the control of the early pests in tomato.

Methods: The experiment was installed in greenhouse conditions, in Ilha Solteira/SP/Brazil, in tomato. The design was randomized blocks, whit 4 replicates. The treatments consisted: chlorantraniliprole 350 WG (at 20, 40 and 80 g a.i./ha), imidacloprid 700 WG (at 210 g a.i./ha) and thiamethoxam 250 WG (at 50 g a.i./ha) at 3 applications through chemigation by drip irrigation (15 days interval between each application, being the first application accomplish just after the transplant of the seedlings). The evaluations were accomplished until 25 days after the last application, by counting the number of insects in 5 plants per plot.

Results: In the evaluations after the second and third applications, all the treatments were differences significantly of the untreated treatment. The insecticide chlorantraniliprole 350 WG, at the doses of 40 and 80 g i.a./ha showed efficiency on control of the early pests (up to 85%) in tomato crop.

Conclusions: The insecticide chlorantraniliprole after 3 application by drip irrigation, at 40 and 80 g a.i./ha, were efficient on control of the *Bemisia tabaci* Biotype B, *Frankliniella schultzei, Liriomyza huidobrensis* and *Tuta absoluta,* in tomato, being a new tool for IPM in tomato crop.

POSTER PRESENTATION

Activity of a new insecticide of the diamides chemical class (chlorantraniliprole) for control of the stem borer, *Diatraea saccharalis* (Lepidoptera: Pyralidae), in sugarcane

Dhiego Duvaresch, Mario Sergio Oliveira, Willian Takao, Mauricio Rotundo, Geraldo Papa

Sao Paulo State University, Ilha Solteira/SP, Brazil

Introduction: The sugarcane is an important crop in Brazil, your produce are linked with the ethanol and sugar production. The stem borer, *Diatraea saccharalis,* is the most important insect pest in sugarcane in Brazil. The new insecticide (chlorantraniliprole) of the diamides chemistry class has activity on a broad spectrum of economically important pest species. The mode of action is activation of insect ryanodine receptors. The objective of this work was to evaluate the performance of this insecticide on the control of stem borer in sugarcane.

Methods: The experiment was carried out at field conditions in São Paulo/Brazil. The two foliar applications (interval of 14 days) was accomplished being used pressurized backsprayer. The design was randomized blocks. The treatments were: chloroantraniliprole 350 WG (10.50; 15.75 and 21.00 g a.i/ha) and novaluron 100 EC (10.00; 15.00 and 20.00 g a.i/ha). The evaluations were accomplished to the 13, 28 and 45 days after the second application, by counted the percentage of damaged plants by stem borer.

Results: In the evaluations of 13 and 28 days after second application all the treatments were differences significantly of the untreated treatment. The insecticide chlorantraniliprole 350 WG, at the dose starting from 15.75 g i.a./ha showed efficiency on control of the stem borer, up to 83%. Novaluron at the dose of 20.00 g i.a/ha showed 75% of efficiency.

Conclusions: The insecticide chlorantraniliprole and novaluron were efficient on control of the *Diatraea saccharalis*, being a new tool for IPM in sugarcane in Brazil.

POSTER PRESENTATION

Activity of a new insecticide of the diamides chemical class (chlorantraniliprole) for control of soybean looper, *Psedoplusia includens* (Lepidoptera: Noctuidae), in soybean

Mario Sergio Oliveira, Dhiego Duvaresch, Willian Takao, Fernando Celoto, Geraldo Papa

Sao Paulo State University - Unesp, Ilha Solteira/SP, Brazil

Introduction: The caterpillars represent a constant problem to the soybean growers in Brazil. The most important species are velvetbean caterpillar, *Anticarsia gemmatalis,* and soybean looper, *Pseudoplusia includens*. The current technological progress in the chemical area has been providing the introduction of new molecules that are safer and more appropriate for use in the agriculture. Chlorantraniliprole (diamides chemical class) is a new insecticide with a novel mode of action: activation of insect ryanodine receptors. The objective of this work was to evaluate the performance of this insecticide on the control of soybean looper in soybean crop.

Methods: The experiment was carried out at field conditions in Mato Grosso do Sul/Brazil. The one foliar application was accomplished, being used pressurized backsprayer. The statistic design was randomized blocks with 4 replicates. The treatments were: chloroantraniliprole 200 SC (2.5; 5.0; 7.5 and 10.0 g a.i/ha), permethrin 384 EC (25 g a.i./ha) and methomyl 215 sac (215 g a.i./ha). The evaluations were accomplished to the 0, 2, 5 and 10 days after the application, by counted the number of caterpillars by plot.

Results: In the evaluations of 5 and 10 days after application, the insecticide chlorantraniliprole 200 SC, at the doses of 7.5 and 10.0 g i.a./ha showed efficiency on control of the soybean looper, up to 85%, overcoming the insecticides permethrin and methomyl, whose control efficiencies were inferior to 80%.

Conclusions: The insecticide chlorantraniliprole was efficient on control of the *Pseudoplusia includens*, being a new tool for IPM in soybean crop in Brazil.

POSTER PRESENTATION

Testing the monophyly of the Australian leaf beetle genus *Paropsis* (Chrysomelidae: Chrysomelinae)

Gunter Maywald[1], Lyn Cook[1], Chris Reid[2]

[1]The University of Queensland, Brisbane, Australia, [2]Australian Museum, Sydney, Australia

The leaf beetle genus *Paropsis* Olivier (Chrysomelidae) comprises 78 described species and is endemic to Australia and New Guinea, where its members feed mainly on eucalypts (Myrtaceae). The genus is part of a larger group of more than 400 species (the paropsine beetles), a group that has not been taxonomically revised for over 100 years. Affiliations within this group and relationships to the rest of the Chrysomelinae are unclear. A recent revision of the genera of Chrysomelinae of Australia (Reid, 2006, *Zootaxa* 1292) has redefined the genus *Paropsis*, assigning to it those species previously placed into *Procrisina* Aslam.

In order to test the monophyly of *Paropsis*, a 750bp segment of the D2 region of the 28S nuclear gene for a range of species in the genus has been sequenced. The same gene fragment has also been sequenced from representative species of most of the other paropsine genera. A number of outgroup species from the Chrysomelidae have also been included. The results were analysed using PAUP* and MrBayes, and seem to be consistent with a monophyletic *Paropsis* as defined in Reid (2006). Relationships within the paropsine genera are also discussed.

POSTER PRESENTATION

Perspectives of entomopathogenic fungi to control scale pests in Georgia

Ekaterine Tabatadze

L. Kanchaveli Institute of Plant Protection, Tbilisi, Georgia

Introduction: Fauna of scale insects (*Homoptera, Coccoidea*) in Georgia have been mainly formed by the adventive's species introduced together with plants. Many species of them have very important economical significance for agriculture of Georgia. 23 species of scale insets have constantly registrated on citrus : *Diaspidida*e – 10 species, *Coccidae* -9 species, *Pseudococcidae* – 3 species, *Monophlebidae* – 1 species. Biological control agents – entomopathogenic fungi play important role in number regulation of insects and successfully used as alternative for chemical control.

Material and Methods: The investigation and study of scales infectious pathology have been conducted in West Georgia (Adjara,Guria) during 1989 - 2007 according the established methods.

Results :Fungal epizootics of different scale insects in subtropical zones of Georgia (Adjara, Guria) were discovered. Among 33 species of entomopathogenic fungi detected in citrus orchards at present the most important are: *Aschersonia rubra* Tabatadze&koval (a recently identified species in Caucasus), *Lecanicillium lecanii* (Zimm.) Zare et W. Gams., *Fusarium larvorum* (Fask.) Bilai and *F.* sp.. Infestation of armored (*Diaspididae)* scales : Japanese scale –*Lopholeucaspis japonica* Ckll., by *A.. rubra* and *Fusarium* varied from 20,5 up to 94,0%; Dictiospermum scale – *Chrysomphalus dictyospermi* (Morg.) 6,0 -65,5%, Yellow scale – *Aonidiella citrine* (Craw.) – 4,1 -57,1%. Infestation of Coccids (*Coccoidae)* - *Coccus hesperidum* L., by the *L. lecanii* varied from 8 up to 72,2 %, Japanese wax scale – *Ceroplastes japonicus* Green 6,3-31,8% and citrus wax scale – *Ceroplastes sinensis* Guerchio - 9.0 -28,6%.

POSTER PRESENTATION

Natural Enemies of Scale Insects *(Homoptera, Coccoidea)* in Citrus Plantings of West Georgia

Ekaterine Tabatadze

L.Kanchaveli Institute of Plant Protection, Tbilisi, Georgia

Introduction: 23 species of scale insects registrated in citrus plantings of Georgia, but 8-10 species may achieve presently high density and would damage the plants: *Chrysomphalus dictyospermi* Morg., *Lopholeucaspis japonica* Ckll., *Aonidiella citrina* (Craw.), *Coccus hesperidum* L., *Ceroplastes sinensis* Green. The complex of natural enemies of scales includes: parasitoids, predators and entomopathogenic fungi.

Materials and Methods: The observation have been conducted in West Georgia (Adjara,Guria) during 1989-2007. The fluctuation of scales population and efficacy of fungi were determined by monitoring in citrus orchards.

Results: Twenty two species of parasitoids (*Hymenoptera,Chalcidoidea*) are recorded as entomophagous of scale insects in citrus groves. The list includes: *Aphelinidae* – 14 species, *Encyrtidae* - 5 species, *Pteromalidae* – 2 species, *Signiforidae* – 1 specie. *Encarsia citrina* (Craw.)(=*Aspidiotiphagus citrinus*) as oligophagous species is the major effective parasitoids of armored scales (*Homoptera, Diaspididae*). Parasitism's often reaches up to 40%. From 2 up to 90% of coccids (*Homoptera, Coccidae*) are destroyed by *Coccophagus lycimnia* (Walker.). In citrus orchards of Georgia on coccids recorded 10 species of predators: 8 species of *Coleoptera, Coccinellidae* and 2 - *Acari. Chilocorus bipustulatus* L. is more common and effective then *Ch. renipustulatus* Scriba and *Exochomus guadripustulatus* L. The scale mortality varied between 0, 2 -16, 6 %. At present on coccids detected 33 species of entomopathogenic fungi. More effective are: *Aschersonia rubra* Tabatadze&Koval, *Lecanicillium lecanii* (Zimm.) Zare et W.Gams, *Fusarium larvorum* (Fask) Bilai and *Fusarium* sp. Efficacy of *A. rubra* varied from 4, 1 up to 94, o and *L. lecanii* 6, 3-72, and 2%.

POSTER PRESENTATION

Maximizing student learning through active learning in entomology: service learning, case studies, and wikis

Linda Hooper-Bui, Albert Lee, Rachel Strecker, Kaitlin Baudier

Dept. Entomology, Louisiana State University, Baton Rouge, La, United States

Students maximize their learning through the constructing of their own knowledge structure rather than listening to lectures and viewing Power Point. Service learning requires students to take course concepts and identify a community need that addresses those concepts and meet that need through a service project. Entomological examples of service-learning projects include: donation of insect collections to schools, libraries and service clubs (general entomology or taxonomy class), creation of butterfly gardens in area needy schools (insect ecology), and suppression of urban pests in community centers or public swimming pool areas (urban entomology). Case studies can be used to measure student knowledge before a topic is taught and can be continued and expanded through the course. These case studies allow student "judgement of learning" in a formative manner rather than a summative manner (tests) and allows the students to find out what they know and fill in the gaps in their knowledge. Case studies are especially useful in courses where theory is extensively taught such as Insect Ecology. Lastly, wikis can be useful in helping students self-construct knowledge and can replace the classic term paper. Students often use wikis for their personal interests, and this shows them an academic way of using Web 2.0 interfaces. If the wiki information is placed on Wikipedia, then the students are creating something useful while their learning is maximized. Examples from LSU Insect Ecology wikis will be used. Students respond positively to these techniques when they see that their learning is maximized.

POSTER PRESENTATION

Pnigalio agraules-*P. mediterraneus* (Hymenoptera: Eulophidae): a true synonymy?

Gennaro Viggiani

Dipartimento di Entomologia e Zoologia Agraria; Università di Napoli, Portici, Italy

Introduction: Several species of the genus *Pnigalio* are still poorly characterized and difficult to identify due to the variations of features considered diagnostic in the known keys. In the framework of a biosystematic study of the group, we tried to evaluate the status of two described species, namely, *Pnigalio agraules* (Walker, 1839) and *P. mediterraneus* Ferrière & Delucchi (1957). They were synonymized by Askew (1984). The first species, originally described on one collected female in England, subsequently keyed (Graham, 1959) and partially redescribed (Graham, 1963), was recorded from several hosts, particularly *Tischeria ekebladella* (Bjerkander) (Lepidoptera: Tischeriidae) and congeneric species. *P. mediterraneus* was originally described as parasitoid of *Bactrocera oleae* (Rossi) (Diptera: Tephritidae) and then recorded also from other hosts. The proposed synonymy influenced some views on the biocenotic relationships in the olive agroecosystem, where the olive fly is the key pest, and the measures to increase the functional biodiversity.

Methods: To verify the validity of the synonymy of *P. mediterraneus* under *P. agraules*, we compared populations of the mentioned species obtained from their typical hosts, respectively *B. oleae* and *T. ekebladella*, but also from other ones. We used an integrative approach, combining morphological (dimension of new laid eggs), biological (mating tests) and molecular (nuclear and mitochondrial DNA sequences).

Results: 28S-D2 and COI sequences, along with the mating tests and the dimension of the eggs, clearly show that *P. agraules* and *P. mediterraneus* represent two valid species.

Conclusions: Our results allow a more rational management of the biodiversity in several agroecosystems.

POSTER PRESENTATION

Determination of midgut pH of sun pest, *Eurygaster integriceps*, using the color changing of chemical materials

Majid Kazzazi, Vahid Hoseini Naveh

Bu Ali sina University, Hamedan, Islamic Republic of Iran

Introduction: Sun pest *Eurygaster integriceps* is one of the most important pests of wheat and barley in most parts of Iran. This pest was found abundantly on wheat in all over the country, spatially western. It causes considerable damage in most wheat farms of Iran. Enzymatic study of digestive system of bugs on midgut pH is important characters in physiological studies.

Methods: In this study midgut of *Eurygaster integriceps* is divided into four sections (V1-V4) respectively. A universal buffer pH 3-8 was made by mixing equal portions of 0.02 M for each one of Succinate, Mes and Glycine and adusting the pH with NaOH 1 normal. To obtain standard color changing, various chemical materials:Thymol Blue, Bromophenol Blue, Bromothymol Blue, Methyl Orange, Bromocrosol Purple, m- Crosol purple and Nutral Red were put into buffer tubes. The effects these materials on midgut sections (V1- V4) and color variations were compared with standard color.

Results: In this study pH V1=6.5 , V2= 6.3, V3= 6 V4= 5.8 were determined respectively. The acetic slope of midgut sections were increased from V1 to V4. This study showed that midgut of sun pest has acetic property.

POSTER PRESENTATION

Relationship of body size and egg maturity in *Culex pipiens pallens* depending on population densities

Jong-Jin Lee, Yeon-Kook Kim, Eun-Mi Park

Chonbuk National University, Chonju, Chonbuk, Korea

In most mosquitoes, female require additional protein after emergence to initiate vitellogenesis. In general, seeking sugar solutions is a common behavior for most of them and for both sexes. Feeding on sugar solutions as an energy source extends their life span and improves their reserve energies, mainly in lipids. On the other hand, there has been much interest in using mathematical models or correlates of the intrinsic rate of increase to identify factors affecting population growth in the female mosquitoes. However, use of these models requires date relating morphological factors such as body size with population growth factors such as egg maturity. Recent use of correlates of the intrinsic rate of increase and models to study population dynamics in mosquitoes has emphasized the need for species specific data on the relationship of morphological factors such as body size to life history parameters such as egg maturity. *Culex pipiens pallens* is of concern because of its continued spread and population growth in Korea and the potential for Japanese encephalitis every year. This study had examined the relationships between pupal weight and adult female wing length and between female wing length and egg maturity in the first reproductive cycle of *Culex pipiens pallens.* There was a significant positive relationship between pupal weight and adult wing length. The relationship between wing length and egg maturity was also significant and positive, but with lower correlation coefficients and higher variance indicating that other factors also affect egg maturity.

POSTER PRESENTATION

Insecticidal activities of the outer seed coat of gingko against *Ochlerotatus togoi* (Diptera: Culicidae) larvae

Jong-Jin Lee, Se-Won Oh, Chung-Un Lee

Chonbuk National University, Chonju, Chonbuk, Republic of Korea

Potent insecticidal components against *Ochlerotatus togoi* larvae were isolated from the *Ginkgo biloba* (L.) leaves and outer seed coats through organic solvent extraction method, and various chromatographic techniques. Molecular weights of these compo-nents extracted from the leaves and seed coats were measured by gas chromatography mass spectrum. The insecticidal activity of the extracts from *Ginkgo biloba* outer seed coat was higher than that of leaves. LC_{50} of methanol extracts of *Ginko biloba* leaves was 272.90 ppm and that of outer seed coats was 171.74 ppm, respectively. Methanol extract of *Ginko biloba* outer seed coats was sequentially partitioned into n-hexane, chloroform, ethyl acetate, and water-soluble portions. Chloroform fraction purified was 43g, and was shown to have a strong insecticidal activity against *Ochlerotatus togoi* larvae. Chloroform fraction was further isolated by column chromatography and 8 fractions eluted were collected. Amongst 8 fractions, C_2 amounted to 3.07g, and was highly active for mortality tests, against *Ochlerotatus togoi* larvae. C_2 was further isolated repeatedly by the same method as above, yielding C_{222} fraction, which was very active against *A. togoi* larvae. C_{222} produced five fractions after being purified by HPLC. Fractions purified as C_{2223} and C_{2224} with molecular weights of 220 and 279 respectively were shown to have high insecticidal activities against *Ochlerotatus togoi* larvae.

POSTER PRESENTATION

Economic threshold for diamondback moth, *Plutella xylostella* (L.) (Lepidoptera: Plutellidae), on leaf broccoli (*Brassica oleracea* var. *botrytis italiana*)

Seon-U Choi[1], Ki-Kwon Lee[2], Ju-Rak Lim[2], Ju-Hee Kim[2], Dae-Hyang Kim[2], Jeong-Sik Choi[2], Yeong-Geun Choi[2], Chang-Yeon Hwang[3]

[1]Floriculture Resources Research Institute, Namwon sity Jeollabuk-do, Republic of Korea, [2]Jeonllabuk-do Agricultural Research and Extension Service, Iksan sity Jeollabuk-do, Republic of Korea, [3]Chonbuk National University, Jeonju city Jeollabuk-do, Republic of Korea

Introduction: This study was conducted to develop the economic threshold for the diamondback moth (*Plutella xylostella* (L.) on Leaf Broccoli(leaf vegetable) in 2007.

Methods: To investigate the relationship between initial density of diamondback moth larvae and broccoli leaf yield, experimental plots with five treatments(0, 0.5, 1.0, 2.0, 4.0 larvae per plant) as initial density were established. We inoculated larvae in chesses cloth covering to survey larvae density change.

Results: When grown to eat, leaves of broccoli were harvested by periods. 60-70% of larvae were removed whenever we picked the leaves. High levels of larvae were associated with significant reductions in leaf yield. There were 85%, 64%, 58%, and 56% yield reductions from the diamond back moth larvae density in 0, 0.5, 1,0, 1.5, 2.0 per plant, respectively 25days after larvae inoculation. The regression equation used to predict leaf yield based on the number of initial larvae density per a plant was $y=1635-393x(R^2=0.79)$.

Conclusions: The economic injury level of diamondback moth on leaf broccoli was 2-3 larvae per 10 plants for a damage level of 5%. The economic thresholds was 1-2 larvae per 10 plants. Thus, the diamond back moth management should be initiated 1-2 larvae occurrence per plant.

POSTER PRESENTATION

Intraguild predation: molecular detection of carabid-spider interactions within cereal crops

Jeffrey Davey[2], King Andrew[2], James Bell[1], Michael Bruford[2], David Bohan[1], William Symondson[2]

[1]Rothamsted Research, Harpenden, Hertfordshire, United Kingdom, [2]Cardiff School of Biosciences, Cardiff, Wales

Carabid beetles and spiders dominate the generalist predator community in arable crops in Europe and elsewhere. Both help to control crops pests, such as aphids and slugs, yet very little is known about interactions between these predators. Although positive synergistic interactions are known (for example where aphids are dislodged, fall to the ground and are eaten by the carabids) little is known about the negative interactions that may arise from direct predation on the spiders by the carabids. We report the first use of molecular analyses to quantify this trophic interaction.

Species- and group-specific primers were developed for the analysis of predation on the major species of spider found at our field sites. Feeding trials were conducted with each pair of primers to determine the mean detection period following ingestion. This information was then used to adjust recorded rates of predation in the field so that direct comparisons could be made between predation by the carabid *Pterostichus melanarius* on each spider species. Around 650 beetles were collected from the field and analysed. We demonstrated, for example, that ~20% of the beetles had been consuming the spider *Tenuiphantes tenuis* but only 0.32% had consumed *Bathyphantes gracilis*. Rates of predation were related to prey density and location in the crop in relation to ground-hunting carabids. We also report the development of multiplex PCRs that allowed simultaneous detection of predation on different spider species. The plan is to use these primers to quantify the effects of intraguild predation on aphid numbers.

Varying glucosinolate profiles in *Arabidopsis* influence plant defense against generalist and specialist caterpillars differently

I. Mewis[1], J.G. Tokuhisa[2], J. Gershenzon[3], H.E. Hummel[4], Ch. Ulrichs[1]

[1]Humboldt University Berlin, Institute for Horticultural Science, Urban Horticulture, Berlin, Germany, [2]Virginia Tech University, Horticulture Department, Blacksburg, VA, United States, [3]Max Planck Institute for Chemical Ecology, 07745 Jena, Germany, [4]Justus-Liebig-University Giessen, Organic Agriculture, Giessen, Germany

Glucosinolates (GS) are characteristic secondary defense compounds in Brassicaceae and other families in the order Brassicales. To date more than 120 different GS are described sharing a common chemical core structure with varying side chain. Depending on the chemical nature of the side chain they are classified as aliphatic, aromatic or indolyl GS. All GS containing plants store in different compartments and cells GS hydrolyzing enzymes, so called myrosinases. After tissue damage such as herbivory the actual biologically active compounds are released. The GS-myrosinase system is an effective defense system especially against generalist insects, pathogen and other herbivores. But many specialists are using these compounds in host-recognition.

The aliphatic GS profiles of the model plant *Arabidopsis thaliana* L. and other members of *Brassicaceae* are highly variable, but indolyl GS are widely distributed in this plant family. Indeed studies are missing to discover the function of GS classes and the effect of different GS side chains on insect resistance. To study the effect of GS classes on different insects, the host plant suitability of two *A. thaliana* mutants with altered GS profile compared to Columbia wild type (WT) for three lepidopteran species was tested. The performance of the generalist caterpillar *Spodoptera exigua* (Hübner) was better on *mam3*$^{+}$, lower aliphatic GS content, followed by *cyp79B2*$^{-}$*cyp79B3*$^{-}$, absence of indolyl GS, when compared to WT. No significant differences within weight gain and herbivory on genotypes was found for the specialist lepidopteran *Pieris rapae* L. and *P. brassicae* L. The impact of different GS within plant defense response is discussed.

POSTER PRESENTATION

Possible factors affecting bark beetle outbreaks after forest fires

Maria Lombardero

University of Santiago, Lugo, Spain

Fires are one of most important threats to forest, not just because of the direct effects but also because of the later consequences, including increased risks of insect outbreaks, especially bark beetles. How forest fires may facilitate insect outbreaks is not well known. We tested three general hypotheses that included the three main factors that regulate insect populations: (1) Fire may compromise tree defenses; (2) Burned trees may be more nutritionally suitable for bark beetle; (3) Natural enemies may be less abundant in burned forest. In support of hypothesis 1, the flow of defensive oleoresin from pines was reduced by fire. However, the recovery depended on crown damage. Resin defenses never recovered in trees with scorched crowns and most of those trees were attacked and killed by bark beetles. But burned trees with undamaged crowns recovered their resin defenses and actually produced twice as much resin after 24 days compared to control trees; none of these trees were attacked by beetles. Therefore, bark beetle outbreaks probably depend on time of year when the fire occurs relative to the abundance of adult bark beetles in the area during the period of low resin immediately after the fire. Contrary to hypothesis 2, burned trees were no more nutritionally suitable for bark beetles; in fact, beetles in burned trees survived less well, had to excavate longer galleries, and laid fewer eggs compared to control trees. Hypothesis 3 was supported in that natural enemies were less abundant and with lower specific richness in burned forests. Therefore, forest fires facilitate tree colonization by bark beetles by decreasing tree defences and providing vulnerable host trees for the beetles. In addition the pressure of natural enemies is lower in burned forest which may affect positively bark beetle population even if burned trees have lower nutrient contents.

POSTER PRESENTATION

Stable isotope analyses to determine plant host origins of mating *Helicoverpa armigera* (Lepidoptera: Noctuidae) within Bt cotton crops in Australia

Colin Tann, Geoff Baker

[1]CSIRO Entomology, Narrabri, NSW, Australia [2]CSIRO Entomology, Canberra, ACT, Australia

In Australia, as in many other parts of the world, the noctuid moth *Helicoverpa armigera* represents a serious pest problem to a large number of agricultural crops including cotton. The introduction of genetically modified (Bt) cotton in Australia has been very successful in reducing the pest status of *H. armigera*, but the potential for this moth to develop resistance to the two insecticidal Bt proteins (Cry1Ac and Cry2Ab) contained within the BOLLGARD 11® cotton product is a serious threat, particularly given that the Australian cotton industry is so reliant on the technology (approximately 90% of cotton grown is Bt-based).

Refuge crops (selected for high attractiveness to *Helicoverpa spp*.) and which have the capacity to produce large numbers of Bt susceptible *H.armigera* moths, are grown in conjunction with the Bt cotton, with the aim of reducing the chances of resistance developing.

One of the key assumptions within this strategy is the notion of random mating occurring between moths emerging from different crop origins. However, little research has thus far tested this assumption. The work described in this paper involved a series of studies aimed at understanding *H. armigera*'s movements and breeding within landscapes containing Bt cotton and refuge crops. It utilised stable isotope analyses of moths, captured whilst mating within Bt cotton crops, to provide signatures of plant host origins. Carbon isotope analyses suggested that moths from both C3 and C4 plant origins mated at random within the Bt cotton crops. We had anticipated that additional analyses of nitrogen isotope signatures would further separate the C3 plant host origins (e.g. separate cotton from legumes such as pigeon pea) but this has not yet proven possible, probably due to poor N fixation by pigeon pea.

POSTER PRESENTATION

Regulation of protocatechuic acid synthesis in female *Periplaneta americana*.

David Whitehead

Oxford University, Oxford, United Kingdom

Introduction: The sclerotin oothecal walls are formed by combining the secretion of both colleterial glands. The left gland secretes 3,4-dihydroxybenzoicacid glucoside, proteins (oothecins) and a phenoloxidase enzyme (1) The resulting quinone formed from the 3,4-diphenol cross-links the oothecins to form the oothecal walls (2a, 2b). JH (juvenile hormone) regulates the synthesis of oothecins in the left colleterial gland of cockroaches. (3,4,5)

Methods: Plasmatocytes washed with saline from colleterial glands were isolated and incubated with [14C] L-p-Tyrosine or [14C]-tyramine. Resulting metabolites were separated by paper chromatography (BAW 4:1:1) and HV electrophoresis (pH 1.9 or 4.2). 1 cm strips were counted in a scintillation counter.

Results: Plasmatocytes show an enhanced ability to decarboxylate and deaminate tyrosine if treated with JH whereas α-ecdysone has no effect. By contrast, injecting α-ecdysone into newly emerged adult females significantly ($p \leq 0.001$) inhibited synthesis of the phenolic 4-o-β-D-glucoside in the developing left gland but not of the β-glucosidase produced by the right gland (7). p-Hydroxyphenylacetic acid is derived from tyrosine via tyramine (6) when incubated with the gland plasmatocytes but is not synthesized in the gland itself (6) .

Conclusion: It is proposed that in adult female cockroaches, tyramine is oxidized in plasmatocytes and then hydroxylated in the gland to give 3,4-dihydroxyphenylacetate (8). Regulation of the synthesis of the oothecal sclerotizing agent is possibly controlled by JH acting directly on plasmatocytes adhering to the left colleterial gland. Scanning and thin section EM show their presence on the gland but significantly they are absent on the right colleterial gland.

POSTER PRESENTATION

Organic insecticides and nematicides for small-scale cotton farmers

Lawrence Malinga, Eugen Eulitz

ARC-IIC, Rustenburg, South Africa

A study was conducted at Vaalharts and Rustenburg in South Africa to test different plant extracts with insecticide and nematicide possibilities for the use by small-scale cotton farmers. Five organic nematicides, khaki weed (*Tagetes minuta*), Marigold (*Tagetes erecta*), tobacco (*Nicotinia tabacum*), thorn-apple (*Datura sp.)* and caster oil (*Ricinus communis*) were compared with Temik®. Four organic insecticides, tobacco (*Nicotiana tabacum*), khaki weed (*Tagetes minuta*), thorn-apple (*Datura sp.)* and garlic (*Allium sativum*) were compared with Mospilan® (*Acetamiprid*) and Decis® (*Deltamethrin*). Khaki weed, castor oil plant and the control had more *Meloidogyne* species nematodes. Castor oil and thorn apple had more *Pratylenchus* nematodes. Ring nematodes (*Criconematidae*) were higher in khaki weed, tobacco and marigold treatments. Temik® gave the highest yield. Castor oil and marigold gave the lowest yield. Tobacco, khaki weed and thorn apple shown promise in seed yield. The four organic insecticides did not give a good control of bollworms (*Helicoverpa armigera, Diparopsis castanea, and Earias insulana*). Mospilan®, Decis® and the tobacco treatments exhibited significantly less leafhopper (*Amrasca terraereginae*) damage on the cotton leaves. There was no significant difference on aphid (*Aphis gossypii*) population in all the treatments with the exception of the Decis® which exhibited a significantly higher aphid population. There were no significant differences in the whitefly (*Bemisia argentifolii*) numbers in all the treatments. Garlic, Mospilan® and Decis® exhibited significantly higher spider mite numbers. The seed yields of Mospilan® and Decis® were significantly higher than the yields of the control and the four organic treatments.

POSTER PRESENTATION

The distribution of Trichoptera and Ephemeroptera in the tributary rivers of the Doring and mainstream Olifants Rivers, South West Cape, South Africa and implications for conservation planning

Ferdinand C. de Moor, Helen M. Barber-James

[1]Albany Museum, Grahamstown, South Africa, [2]Rhodes University, Grahamstown, South Africa,

Introduction: Research on freshwater invertebrates in the southern and south Western Cape has revealed a diverse fauna, largely endemic to the Cape Floral Kingdom. Phylogenetic relationships suggest that some lineages are relict survivors of a once widespread temperate southern fauna dating back about 140 million years prior to the breakup of Gondwana. The aquatic pre-imaginal stages of invertebrates representing this Gondwana fauna in rivers flowing off the Cedarberg need further study. Firstly the relationship between this Cedarberg group and the rest of the southern and south-western Cape must be confirmed. Secondly, can a broader-based approach incorporating more aquatic faunal groups for conservation of aquatic ecosystems be developed? The first aspect needs the collection of adult insects to confirm species identification. For the second, the use of diverse assemblages of species to identify distinct river signatures, will help evaluate uniqueness. This provides a broader approach to biodiversity conservation of rivers than the use of only rare or endangered species.

Methods: Based on distribution patterns of rare endemic fish, a selection of eleven rivers, tributaries of the Olifants River in the Cederberg, Western Cape were surveyed for aquatic macroinvertebrates. The study focused on Trichoptera, Ephemeroptera and Diptera (Simuliidae). Diverse collecting techniques ensured maximum species representation.

Results: Analysis of fauna from 52 biotopes surveyed, recorded Ephemeroptera (32 species), Trichoptera (45 species) and Simuliidae (8 species). The species distribution pattern between the tributaries of the Doring and Olifants Rivers was significantly different. The survey of these rivers revealed 14 undescribed species. More survey work covering more rivers and sampling selected rivers over several seasons is recommended.

POSTER PRESENTATION

Action threshold for controling pistachio psylla nymphs (Hemiptera: Psyllidae) on *Pistacia vera* cv. Ohadi

Mohammad Reza hassani, Gadir Nouri-Ganbalani, Hamzeh Izadi, Mahmoud Shojai

Islamic Azad University, Rafsanjan, Islamic republic of Iran

Introduction: The pistachio psylla, *Agonoscena pistaciae* Burckhardt & Lauterer is a major pest of pistachio trees in Iran. The economic injury level is an important practical tool for decision-making in IPM programs. Our objective was to determine economic injury level for *A. pistaciae* on pistachio cultivar Ohadi.

Methods: Different density levels of *A. pistaciae* nymphs were maintained on pistachio trees by application different dosages of insecticides. Nymph densities were monitored weekly by counting nymphs per terminal leaflet. At harvesting time, yield of every tree was individually harvested and samples of weight of 1000 nuts measured. Regression analysis was used to determine the relationship between nymph densities and weight of 1000 nuts. The economic injury level was estimated by using pedigo *et al*., (1986) equation.

Results: The infestation levels of psylla nymphs were different between treatments at different control levels. The weight of 1000 nuts was significantly affected by number of nymph. Regression equation obtained to describe the relationship between nymph densities and yield loss is: $Y= -2.89X+841.21$, $R^2=0.96$. The economic injury level estimated for various combinations of management cost and market value. The economic injury level is a function of market value, management costs and efficiency of insecticide. The economic injury level for pistachio psylla nymph on cultivar Ohadi ranged from 7.7 to 30.7 nymphal-days per terminal leaflet.

Conclusion: This information may be considered by pistachio plantation for decision-making and help to reduce costs and insecticides application based on economic injury level.

POSTER PRESENTATION

Development of organic certification for honeybee products in Mwingi District, Kenya

Esther Kioko, Suresh Raina, Elliud Muli, Ken Fening Okwae

[1]ICIPE, Nairobi, Kenya, [2]National Museums of Kenya, Nairobi, Kenya

Introduction: Mwingi, a district situated in a semi-arid region of Kenya, has limited distribution of modern agricultural systems. Bee keeping is a traditional activity in the district. This project undertook steps to develop organic certification for honeybee products in the district.

Methods: A Survey was undertaken in the district to identify the key divisions. suitable for organic certification. This was followed by training at different levels, nomination of internal group inspectors, writing of the internal control system (ICS) manual, registration of farmers and certification of the honey-processing center.

Results: Seven divisions, Kyuso, Mumoni, Nguni, Nuu, Ngomeni, Central and Mui were identified for the organic certification process. Training was done for forty-five group secretaries and seven field officers to lead as community trainers in producer group preparation for certification and to participate in the making of the internal control system (ICS) manual. A total of 1013 beekeepers owning 27,331 traditional beehives were registered in the seven divisions. The processing center has set up the required procedures and opened an ICS office at the Mwingi honey marketplace.

Conclusion: The process has advanced and the first external inspection was undertaken by the Institute for marketecology (IMO) in November 2007.

POSTER PRESENTATION

Variation of the local populations of the Asian corn borer, *Ostrinia furnacalis* (Guenee), in the Philippines: some preliminary results

Merdelyn Lit, Adelina Barrion, Gelyn Sapin, Roberta Garcia, Ayn Kristina Beltran, May Flor Cuaresma, Cleotilde Caldo

UP Los Baños, College, Laguna, Philippines

Variation exists among the Asian corn borer populations in the Philippines. This was first reported by Barrion in 1988 using morphometric differences and cytological studies. Later, Mendoza *et al* (1994) using isozyme analysis had found variation in the local populations. Recent study by Caasi Lit et al (2006) also showed variation in larval duration. This paper presents some preliminary results on the variation of the local populations of the ACB.

Samples were collected from six regional sites and the life history (F2 generations) were studied using IPB modified diet. For cytogenetic study, ACB populations were mass-reared and ten adult male were fixed in Carnoy's solution and stained with lacto-aceto orcein. For isozyme analysis, midgut of the fifth instar larvae was removed and homogenized in cold distilled water, the resulting slurry was centrifuged and the supernatant was collected.

Results revealed that populations from Laguna and Leyte, respectively, underwent six and five larval instars which suggest that there could be mixed populations of ACB. The meiotic indices were highest on Leyte and lowest on Bukidnon. Being a bisexual species, such meiotic indices suggest variation in the reproductive potentials of the local populations. Based on the behavior of the meiotic chromosomes, ACB possesses small and holokinetic chromosomes. Differences in esterase banding patterns were observed by the presence of both slow and fast moving bands in the first zone of activity. For acid phosphatase, the two samples from Camarines Sur and Bukidnon also showed a fast moving band and a slow moving band.

POSTER PRESENTATION

LC-MS/MS analysis of the *Diachasmimorpha longicaudata* entomopoxvirus (DlEPV) proteins and their expression in host haemocytes

Pauline Lawrence

University of Florida, Gainesville, Florida, United States

Introduction: The *Diachasmimorpha longicaudata entomopoxvirus* (DlEPV) is injected into *Anastrepha suspensa* (Diptera: Tephritidae) larval hosts during oviposition by the female wasp (Hymenoptera: Braconidae). DlEPV replicates in the host's haemocytes and inhibits encapsulation. The objectives were to identify major DlEPV proteins, haemocyte classes of host larvae, and their differential/temporal expression of DlEPV proteins.

Methods: DlEPV proteins, fractionated by 1-D SDS-PAGE, were excised from the gel and component proteins reduced, alkylated, and trypsinized and separated by HPLC on a PepMap C18 column. Inline MS/MS analysis was carried out on a hybrid quadrupole- time-of-flight (TOF) mass spectrometer and the peptides identified against the available database (http://www.ncbi.nlm.nih.gov/; NCBInr_20061201) using the Mascot 2.0.01 search engine and the Scaffold (version -01_06_03) software. Hemocytes from 3rd instar unparasitized (control) *A. suspensa* and larvae 24-124 h post parasitism (hpp), were analyzed by flow cytometry then measured under a confocal microscope and sorted by size. Mouse polyclonal and monoclonal DlEPV antibodies were used in immunoconfocal microscopy to identify temporal and/or differential expression in haemocytes. TEM of haemocytes was also performed to identify onset of virus infection.

Results: Over 10 DlEPV proteins were identified including homologues of the poxvirus major virion core proteins P4a and P4b, early transcription factor, nucleoside triphosphate phosphohydrolase I (NPH I) and II (NPH II), and DNA-directed RNA polymerase. Virions invaded haemocytes via elongated protein spikes within 6-12 hpp. DlEPV proteins were expressed in three (5-8, 11-18, and 20-28 μm) haemocyte classes but not in the fourth (30-35 μm), a highly vacuolated type. Proteins of ~46 kD and ~ 70 kD were seen by 24 hpp and ~127 kD and 208 kD by 48-72 hpp. These were homologues of NPHI, early transcription factor, and DNA polymerase and an unknown protein respectively. By 124 hpp, the P4 major core proteins (~70-75 kD and 127 kD) were expressed.

Conclusion: The DlEPV proteins and their temporal (but non-sequential) expression are consistent with known poxvirus replication and morphogenesis. Infection induces granularity and blebbing in all three cell types that are involved in encapsulation inhibition.

POSTER PRESENTATION

Molecular phylogeny of the banana weevil, *Cosmopolites sordidus* (Germar) (Coleoptera: Curculionidae), based on AFLP analysis

J De Graaf[1], P Govender[2], A.S. Schoeman[2], A. Viljoen[3]

[1]Westfalia Technological Services, Tzaneen, South Africa, [2]Department of Zoology and Entomology, University of Pretoria, Pretoria, South Africa, [3]Department of Plant Pathology, University of Stellenbosch, Matieland, South Africa

Introduction: The banana weevil, *Cosmopolites sordidus*, is a serious pest of banana and plantain (*Musa*) and has been distributed to most areas where the crops are grown. Pest status is variable around the world, and may be influenced by genetically distinct populations of weevil. The aim of the study was to quantify the genetic relatedness within and among geographically separated populations of *C. sordidus*.

Methods: Six populations from four countries were sampled: Australia, Costa Rica, South Africa (South Coast, North Coast and Tzaneen) and Uganda. DNA was isolated and subjected to amplified fragment length polymorphism (AFLP) analysis using five selective primer sets.

Results: Empirical analysis of the AFLP fingerprints showed that, within populations, genetic diversity varied from 16-53%, with the South Coast and Tzaneen/Australian populations the least and most variable, respectively. The coefficient of gene differentiation showed that the Tzaneen population were the most differentiated from the South Coast population, while the South and North Coast populations were the most similar. All the populations showed statistically distinct marker frequencies, except for the Costa Rican and South and North Coast populations, which were similar. A neighbour-joining tree showed the Australian, Ugandan and South African coastal populations produced monophyletic groups, while the South African Tzaneen population were removed from the other populations and presented an ancestral state.

Conclusion: The data suggested that the South African coastal, Australian, Ugandan, and Tzaneen populations could be classified as separate taxonomic units.

POSTER PRESENTATION

Phylogenetic analysis of recent giant water scavenger beetles allows the character-based study of fossil record of the group (Coleoptera: Hydrophilidae: Hydrophilina)

M. Fikacek[1], A. E. Z. Short[3], S. Wedmann[4], J Prokop[2]

[1]National Museum, Department of Entomology, Praha, Czech Republic, [2]Charles University in Prague, Faculty of Science, Department of Zoology, Praha, Czech Republic, [3]University of Kansas, Natural History Museum & Biodiversity Research Center, Division of Entomology, Kansas, United States, [4]Senckenberg Research Institute, Research Station Grube Messel, Messel, Germany

The majority of the Tertiary hydrophiloid fossils is represented by large and strongly sclerotized aquatic forms of the subtribe Hydrophilina. Five recent genera are recognized (*Hydrophilus*, *Hydrobiomorpha*, *Hydrochara*, *Tropisternus* and *Sternolophus*) and two additional are to be described or up-graded to generic level based on the phylogenetic revision using 80 morphological characters of adults. The analysis supports the monophyly of the subtribe Hydrophilina and all recent genera except of *Hydrochara* and defines synapomorphies of the clades allowing a character-based study of fossil record of the subtribe. Based on this phylogenetic background, fossil material of the subtribe Hydrophilina was studied on selected Tertiary localities in Germany (Grube Messel, Enspel, Seifhennersdorf) and Czech Republic (Bílina mine). Three genera were recorded: *Hydrophilus* from most localities examined, recent pan-tropical genus *Hydrobiomorpha* from all Eocene to Oligocene localities, and the genus *Hydrochara*, which is reliably recorded only from the Eocene locality of Grube Messel so far. All recorded genera belong to the monophyletic “greater hydrophilines clade” characterized by the seventh antennomere divided into lobes, disorganized field of clypeal systematic punctures, ultimate maxillary palpomere shorter than penultimate and two characters of ventral morphology not seen in fossil material.. Simultaneous occurrence of all three mentioned genera in locality of Grube Messel proves that the diversification of the clade had to pre-date middle Eocene and took place most probably during the Paleocene.

POSTER PRESENTATION

Virosoft^{CP4} field trials in an organic apple orchard

Caroline Provost[1], Harnaivo Rasamimanana[2], Charles Vincent[3], Jose Valero[1]

[1]Biotepp Inc., Mont St-Hilaire, Quebec, Canada, [2]Biotepp Inc., Cap Chat, Quebec, Canada, [3]Horticultural Research and Dvelopment Center, Agriculture and Agri-Food Canada, Saint-Jean-sur-Richelieu, Quebec, Canada

Introduction: The codling moth, *Cydia pomonella* L (Tortricidae), is a major pest of several orchard crops throughout major apple-producing areas of the world. Its management requires several insecticidal treatments per year. However, several populations of codling moth recently developed resistance to insecticides, notably in Europe, so that the treatments are less effective. Some alternative methods are available to control this insect, among them Baculovirus-based insecticides.

Methods: The viral insecticide Virosoft^{CP4} was evaluated in field trials in an organic apple orchard located in souththern Quebec, where codling moth populations were historically very high. The experimental protocol varied during these years to address different questions. In 2003 and 2004, we evaluated the impact of the frequency of treatment (4 vs 7 treatments) and the presence or not of additives (Surround and Soya oil) on the product efficacy. In 2006, we used different Virosoft^{CP4} concentrations to determine an optimal dose in organic orchards.

Results : In 2003, 7 treatments of Virosoft^{CP4} reduced significantly codling moth damage. The presence of Surround did not increase efficacy of Virosoft^{CP4}. In 2004, 4 and 7 treatments significantly reduced codling moth damage. The presence of Soya oil did not increase efficacy of the CpGv-based insecticide. In 2006, no significant difference was observed between the different concentrations.

Conclusions : In an agricultural context where very high codling moth populations exerted considerable and recurrent pressures on insect management programs, Virosoft^{CP4} caused significant and important reductions of the percentage of codling moth damage at harvest. It is a valuable alternative to chemical insecticides in organic orchards.

POSTER PRESENTATION

Measuring the economic value of biological control of the maize stemborer *Busseola fusca* Fuller (Lepidoptera: Noctuidae) in the Kenyan highlands

Anderson Kipruto Kipkoech[1], Fritz Schulthess[1], Wilson K Yabann[2], Henry K Maritim[2], Dagmar Mithofer[1]

[1]International Centre of Insect Physiology and Ecology, Nairobi, Kenya, [2]Moi University, Eldoret, Kenya

The scelionid egg parasitoid *Telenomus isis* Polaszek from West Africa and a virulent strain of the braconid larval parasitoid *Cotesia sesamiae* Cameron from western Kenya were introduced to control the noctuid maize stemborer *Busseola fusca* Fuller in the Taita Hills, in coastal Kenya. While *T. isis* is absent in Kenya, the virulent strain of *C. sesamiae*, which, unlike the avirulent strain, successfully develops in *B. fusca*, is common in some parts of the Kenyan highlands but absent in the Taita Hills. This study assesses the *ex-ante* economic impact of the establishment of the two parasitoids in the Taita Hills. The results are then extrapolated to assess the economic impact of the establishment of the parasitoids in their entire potential niche in Kenya. The output loss due to stemborers before the releases of parasitoid was estimated at 28.5%. Yield losses could fall to less than 10% in ten years, if pest reduction by each of the parasitoids grows to at least 20% or if one parasitoid only established but achieved a pest reduction of 40% by year 10. This study demonstrates the economic potential of redistributing parasitoids indigenous to Africa for the control of African stemborers. Because the benefits of biological control are positively scale-dependent while the costs are generally scale irresponsive, biological control programs would accrue more benefits when parasitoids are released to a wider area.

POSTER PRESENTATION

Monitoring populations of *Scyphophorus acupunctatus* Gyllenhal (Coleoptera: Curculionidae) with sexual pheromone in *Polianthes tuberosa* L.

Georgina Torres-Jimenez[1], Victor Lopez-Martinez[1], Iran Alia-Tejacal[1], Ramon Cuellar-Valdes[2], Jorge Vargas-Barrena[2], Armando Burgos-Solorio[3]

[1]Universidad Autonoma del Estado de Morelos, Facultad de Ciencias Agropecuarias, Cuernavaca Morelos, Mexico, [2]Feromonas y Compuestos Sinteticos de Uso Agricola de Mexico, D.F, Mexico, [3]Universidad Autonoma del Estado de Morelos, Centro de Investigaciones Biologicas, Cuernavaca Morelos, Mexico

Introduction: The black weevil is an important pest in *Polianthes tuberosa* (Liliales: Agavaceae) in Morelos, Mexico. Natural baits (agave, pineapple) have been employed to monitoring adult pupulations, but captures are too low. The sexual pheromone was synthesized recently, but no exist evaluations in natural conditions.

Methods: In a *P. tuberosa* plot (18°39'4.25'' N, 99°22'6.78'', 3 ha, 991 msnm) were ubicated the following treatments: Pheromone, Pheromone and pineapple, Pheromone and agave, pineapple, agave, water, all disposed inside yellow plastic traps. Each treatment has four repetitions completely randomized. The period of collect was 2008 January 26th to March 28th; the period of revision was 8.

Results: 366 adults have been collected in the experiment. Combination of pheromone and pineapple were the best treatment with 158 black weevils (43.17 % of captures). When the natural baits are only employed, the number of insects detected is reduced (18 adults in agave, 18 in pineapple). The pheromone capture 8.11 weevils/trap/week, but the cost and time to check it, is minor in comparison with the rest of treatments, the attraction in natural conditions losses after four weeks.

Conclusions: Is possible to increase effectiveness of black weevil traps using a combination of pheromones and pineapple.

POSTER PRESENTATION

Sticky traps and sexual pheromone to collect thrips in chrysanthemum (*Dendranthema grandiflorum* Kitam.)

Victor Lopez-Martinez[1], Ramon Cuellar-Valdes[2], Jorge Vargas-Barrena[2], Iran Alia-Tejacal[1], Maria De Jesus Garcia-Ramirez[3], Armando Burgos-Solorio[4]

[1]Universidad Autonoma del Estado de Morelos, Facultad de Ciencias Agropecuarias, Cuernavaca Morelos, Mexico, [2]Feromonas y Compuestos Sinteticos de Uso Agricola de Mexico, D.F, Mexico, [3]Universidad Autonoma de Campeche, Escuela Superior de Ciencias Agropecuarias, Campeche, Mexico, [4]Universidad Autonoma del Estado de Morelos, Centro de Investigaciones Biologicas, Cuernavaca Morelos, Mexico

Introduction: Sticky blue traps are used to monitoring thrips pupulations in ornamental species in Morelos, Mexico. But until now, none thrips pheromones has been employed to increase sticky trap´s captures.

Methods: Two doses (60 and 300 mg) of the sexual pheromone Tripslure ® were ubicated in sticky blue traps (60 x 20.5 cm) suspended 10 cm above chrysanthemum (*D. grandiflorum*) in Coatlán del Río, Morelos (18° 44' 30.71'' N, 99° 26' 7.00'' W, 0.15 ha). The sampling period was from 2008 January 26th to April 8th, each 8 days the traps were sampled and transported to laboratory for thrips counting. Each treatment has five repetitions and a completely random distribution, sticky blue traps without pheromone were used to compare our results.

Results: Using pheromone as bait, increase in 40% effectiveness of sticky traps, doses of 300 mg captures 500 thrips/trap/week, in comparison with 300 thrips/trap/week when no pheromone is used. The pheromone attraction is maintained in a month as a maximum period of collect.

Conclusions: Tripslure® as a complement for sticky blue traps improvement number of thrips collected in chrysanthemum plots.

POSTER PRESENTATION

Thrips (Insecta: Thysanoptera) in Sapotaceae flowers in Morelos, Mexico

Victor Lopez-Martinez[1], Iran Alia-Tejacal[1], Roberto M. Johansen-Naime[2], Aurea Mojica-Guzman[2], Maria De Jesus Garcia-Ramirez[3], Armando Burgos-Solorio[4]

[1]Universidad Autónoma del Estado de Morelos, Facultad de Ciencias Agropecuarias, Cuernavaca Morelos, Mexico, [2]Departamento de Zoología, Instituto de Biología, Distrito Federal, Mexico, [3]Universidad Autónoma de Campeche, Escuela Superior de Ciencias Agropecuarias, Campeche, Mexico, [4]Universidad Autónoma del Estado de Morelos, Centro de Investigaciones Biológicas, Cuernavaca Morelos, Mexico

Introduction: In Morelos three Sapotaceae have commercial valor: mamey sapote (*Pouteria sapota*), caimito (*Chrysophyllum cainito*) and chicozapote (*Manilkara zapota*). Thrips are common insects associated to Sapotaceae flowers, but their identities are largely unknown.

Methods: Flowers of three Sapotaceae species were collected in 2005 (August to November) in commercial and house orchards in Morelos, México. Specimens were extracted and maintained in alcohol at 70% for conservation. The preparation and identification process follows standard procedures. The material is deposited in UNAM Insect Collection.

Results: 1200 specimens were collected. The genus determined was *Frankliniella*. *Frankliniella curiosa* is the principal species determined until now, and was collected in mamey sapote and caimito. Other species collected were *F. albacuriosa* (mamey sapote), *F. aureauriosa* (chicozapote and mamey sapote) and *F. difficilis* (chicozapote). All host records are reported for the first time for all *Frankliniella* species determined. Four new species of *Frankliniella curiosa* group are detected.

Conclusions: Eight species of Frankliniella are reported for the first time associated to Sapotaceae flowers in Mexico.

POSTER PRESENTATION

Some aspects of the preliminary biology of *Leptinotarsa lacerata* Stål (Coleoptera: Chrysomelidae)

Jose Manuel Pineda-Uriostegui[1], Armando Burgos-Solorio[2]

[1]*Laboratorio de Parasitologia Vegetal, Centro de Investigaciones Biologicas, Mexico,* [2]*Universidad Autónoma del Estado de Morelos, Mexico*

The family Chrysomelids or leaf beetles constitute one of the most abundant and diverse insects, however, there is little information about the biology of this rate with the exception of species of economic importance. It provides information on aspects of the biology of *Leptinotarsa lacerata*, the result of 10 years of research on this beetle on tropical deciduous forest distributed in the state of Morelos, Mexico. *L. Lacerata* is distinguished from the rest by presenting a crisomelids oval body height of 14 mm, black with irregular rows, flavous bands at base cross zigzagging, flavous color or white. The life cycle includes several important events among these is the emergency teneral adults which emerge from the soil; courtship takes place on the host plant, it has been observed that precopule is that the male rubbing the elytra from the female, copulation, the male mounts and inmobilize the female with his forefeet, and put in a position to carry out after the sexual act. The female selects carefully oviposition site usually located on the lower side of leaves. Eggs are yellow, oval-cylindrical with an average length of 0.30 mm and 0.18 mm wide, up positions in masses of 40 and 60 eggs per mass. Larvae are cifisomatic, yellowish in its early stages of development, with transverse black stripes on the back and whitish in later stages features four stages of development and can reach a maximum size of 15 mm in length. Legs are dark brown. The pupa exarata is white with dark shades, with a long of 18 mm in length. This state starts at the moment when the larvae stops feeding and is buried in the soil and usually makes near the host plant. Teneral adults are clumsy in their slow movements, these are uploaded to the host plant and remain still. His body is soft and the color is opaque, a little active. After five days, they are sexually mature and active. The species is bivoltine and life cycle lasts about 30 to ± 40 days on average. *L. Lacerata* usually associated with *Montanoa grandiflora* (Asteraceae) and is prey to a bird and bug *Oplomus* sp (Hemiptera: Pentatomidae).

POSTER PRESENTATION

The bark and ambrosial beetles from state Morelos, México

Armando Burgos-Solorio[1], Armando Equihua-Martinez[2]

[1]Laboratorio de Parasitología Vegetal Universidad Autónoma del estado de Morelos, C.P, Mexico, [2]Entomología Forestal Instituto de Fitosanidad Colegio de Postgraduados Montecillo, C.P, Mexico

The bark and ambrosia beetles of the family Scolytidae and Platypodidae and are commonly known as "bark and ambrosia beetle" "borers in the wood." The tunnels constructed in ways adults subcortical on their host plants and through a series of processes of specialization, have diversified their feeding habits, so that almost any plant is susceptible to insect infestation, which has resulted in the success the same, this feature makes them distinctive from the rest of the beetles. We present a checklist of species of the families Platypodidae and Scolytidae associated to seven kind of forest in the state of Morelos, México. The state is located in the south central part of the Mexican republic, has a territorial extension of 4598 km^2 and presents seven types of vegetation; the most important thing is tropical deciduous forest and pine-oak forest. Little it is known about the distribution that they present these coleopters in this type of community.

As many as eight species within two genera belonging to platypodidae and 213 species were collected within 31 genera to Scolytidae. The tribe was more diverse with Corthylini genera 8 and 86 species. It has been reported in 19 species of bark beetles for the state. Concerning the different types of vegetation in the which these insects are established 75 % of the species live in tropical deciduous forests, 25 % in the pine and oak forests. This outstanding difference remarks the richness of the species in the vegetation plant associations. In this sense, as many as 101 plants species were determined included in 33 families. The Fabaceae and Pinaceae was frequent host for these coleopterans. Considering feedings habits, we found seven feeding habits, the phloeofagy was the most habit (56.3 % of all beetles) being the Scolytidae the most represented. In terms of specificity to a host plant, monophagy was the predominating category (62.9 %) in 30 genera of both families. Biogeographic affinity of these insects group is remarkable among the species, being the neotropical the most relevant (74.5 % of all species), followed by the circumtropical distribution (3.2 %), the Mexican (1 %), the neartic (20.6 %) and the worldwide (0.7 %).

POSTER PRESENTATION

Implication of exotic volatiles as a new strategy for management of *Coleophora obducta* (Meyrick)

Shan-Chun Yan, Hui Yang, Lu-Lu Gao

Forest Entomology Division, College of Forestry, Northeast Forestry University, Harbin, China

Coleophora obducta (Meyrick) (Lepidoptera: Coleophoridae), a kind of larch defoliators that exclusively latent in leaves. We tested the EAG and behavioral responses of *C. obducta* to nine kinds of larch volatile compositions, namely *R*-α-pinene, *S*-α-pinene, β-pinene, ocimene, phellandrene, 3-carene, myrcene, camphene and phytol by EAG and Y-tube olfactometer. The results showed that, in concentration of 0.4 mol·L^{-1}, most volatile compositions had significant EAG responses compared with the blank ($P<0.05$), except females to *R*-α-pinene, males to *R*-α-pinene and phellandrene; Besides, EAG responses between males and females also existed differences. Observations of behavioral responses of *C. obducta* to nine kinds volatile compositions in a series of concentrations of 0.0004, 0.004, 0.04, 0.4, 0.8 mol·L^{-1} had been carried out with the application of Y-tube olfactometer. Females were inclined to *S*-α-pinene, *S*-ß-pinene, phellandrene, 3-carene, and phytol to some extent ($P<0.05$), and males were inclined to ocimene, myrcene, camphene and phytol to some extent ($P<0.05$). In order to explore insect-control agent using exotic host plant volatile components dueing to larva's special habit of feeding latently, we further adopted volatile compositions that activated to females, then sprayed them singly to healthy larch seedlings, most larvae that feeding on twigs sprayed with volatile compositions were dead compared to the blank ($P<0.01$) with exception of myrcene 0.004 mol·L^{-1} which had no significance ($P>0.05$), Thereinto, *S*-α-pinene 0.04 mol·L^{-1} caused most larvae dead, which accounted for 86.677% of total number. The result suggested that volatile compositions have some influences on larvae developing and feeding, and may be implicated as a new strategy for forest health and pest management.

POSTER PRESENTATION

Biology of Wolbachia and its interaction with insects

A.R. Bandani, M. Mehrabadi

Department of plant protection, university of Tehran, College of Horticultural Science and Plant Protection, Karaj, Islamic Republic of Iran

Genera of *Wolbachia* are a group of bacteria that have closely related with Rickettsia and similar to them ,are obligate intracellular and mainly be in reproductive tissue of arthropods. *Wolbachia* can transmit to next generation through egg cytoplasm. *Wolbachia* was first observed by Herting and Wolbach in the ovaries of the mosquito *Culex pipiens* and since then, have been detected in most order of insects and are believed to be the most widespread genera between endoparasitic bacteria. This distribution is due to presence of *Wolbachia* in reproductive tissue and manipulation of reproductive system in hosts. Our study was documented- analyzed research include of library, books, papers and internet sources. The most importance of this manipulation is cytoplasmic incompatibility (CI). This situation happened when an infected male coupled with an uninfected female.CI has different types including of monodirectional (infected with one strain of *Wolbachia*), bidirectional (infected with tow strain of *Wolbachia*) and even infected with different strain of *Wolbachia*. The propose models for the mechanism of CI are, Lock and Key model, Titration – Restitution and Slow motion. At last concluded that the lock and key model is the most parsimonious and realistic one.

POSTER PRESENTATION

Queenless *Apis mellifera* and *A. cerana* colonies do not reject more non-nestmate workers than queenright colonies

Nadine C. Chapman[1], Piyamas Nanork[2], M. Shankar Reddy[3], N. Shankar Bhat[4], Madeleine Beekman[1], Benjamin P. Oldroyd[1]

[1]Behaviour and Genetics of Social Insects Laboratory, School of Biological Sciences A12, University of Sydney, NSW, Australia, [2]Department of Biology, Mahasarakham University, Mahasarakham, Thailand [3]Center for Apiculture Studies, Department of Zoology, Bangalore University, Bangalore, India, [4]Department of Apiculture, University of Agricultural Sciences, Bangalore, India

When a honey bee (*Apis*) colony becomes queenless and broodless its only reproductive option is for some of its workers to produce sons before the colony perishes. However, for this to be possible the policing of worker-laid eggs must cease. This makes queenless colonies vulnerable to reproductive parasitism by workers from other nests. Such reproductive parasitism is known to occur in *A. florea* and *A. cerana* and sometimes occurs in *A. mellifera*. Genetic analysis of worker populations has demonstrated that the proportion of non-natal workers present in *A. mellifera* and *A. cerana* colonies declines after a colony is made queenless. This suggests that queenless colonies may be more vigilant in repelling potentially parasitic non-natal workers than queenright colonies. We compared rates of nestmate and non-nestmate acceptance in both queenright and queenless *A. mellifera* and *A. cerana* colonies using standard assays. We showed that colonies of *A. mellifera* and *A. cerana* reject more non-nestmate workers than nestmates and that queenless colonies are no more likely to reject non-nestmate workers than queenright colonies.

POSTER PRESENTATION

Queenless *Apis mellifera* and *A. cerana* colonies do not reject more non-nestmate workers than queenright colonies

POSTER PRESENTATION

Utility of the DNA barcoding gene for phylogeographic inference in black flies (Diptera: Simuliidae)

Julio Rivera[1], Douglas C. Currie[2]

[1]Department of Ecology & Evolutionary Biology, University of Toronto, Toronto, Canada, [2]Department of Natural History, Royal Ontario Museum, Toronto, Canada

The COI barcoding gene provides accurate species-level identification in many groups of insects. As a mitochondrial marker, the barcoding gene also has potential for elucidating intraspecific processes at the population level. This latter aspect has so far received little attention in the literature. In this study we use the barcoding gene to infer phylogeographic patterns within the cordilleran black fly species *Prosimulium travisi* and *Prosimulium neomacropyga.* Whereas *P. travisi* is widely distributed in western North America (from Yukon to California), *P. neomacropyga* exhibits a markedly disjunct distribution (Alaska/Yukon and Colorado). The present-day ranges of both species include areas that were affected by glacial oscillations during the Pliocene-Pleistocene epochs. Our analyses reveal that these events had a marked impact on the distribution and population genetics of these two species, as considerable population structure was observed. Glacial refugia, post-glacial migratory routes and areas of secondary contact were all identified in our analyses. Furthermore, cryptic diversity, presumably the result of these historical events, was also revealed. The phylogeographic patterns observed in *P. travisi* and *P. neomacropyga* were largely congruent with those observed in numerous other western Cordilleran organisms. These findings suggest that the COI barcoding gene has potential to reveal both interspecific and intraspecific patterns, giving 'valued added' information for species sampled throughout their geographical range.

POSTER PRESENTATION

Ant morphological traits and assemblage structure: patterns in remnant and pasture habitats along an environmental gradient.

Michelle Yates[1], Saul Cunningham[2], Heloise Gibb[2], Nigel R. Andrew[1]

[1]Discipline of Zoology, School of Environmental and Rural Science, University of New England, Armidale, NSW, [2]Australia, CSIRO Entomology, Canberra, Australia

Assessing how insect assemblages change along environmental gradients today enables predictions to be made about how animals may respond to climate change and other environmental disturbances.

This study used three techniques to try to understand what influences ant assemblages in two differing habitat types (pastures and native remnant forest) across a regional environmental gradient encompassing 296.5 km distance gradient, a 7.3°C temperature gradient and a 285.1mm rainfall gradient. Measures to assess changes in assemblage structure along the environmental gradient included (1) species diversity and composition; (2) ant functional groups; and (3) a range of morphological traits.

Within three regions of Northern NSW (Australia), three properties containing pasture and remnant sites were selected. Three sets of five pitfall traps were left open for seven days and data were then recorded.

Ant communities were more similar in pastures than in remnants across the gradient. This may be because pastures have an inherently similar structure (more than 80% grass cover) which is most suitable to grazing. Remnants are grazed to a lesser extent due to the high density of trees (more than 80% tree cover). Ant communities differed more between regions than between habitats. as a result of high variation in climate, elevation and geography between regions.

Results examining the effects of the environmental gradient on Species diversity, showed that there is a significant difference between regions. Results also showed that there is a significant difference between habitat types, however the difference between regions is much more significant.

POSTER PRESENTATION

Biology of *Allobaccha sapphirina* (Wiedemann)(Diptera: Syrphidae) with feeding on *Diaphorina citri* in Baluchestan

Nia B. Motamedi

Natural Resources & Agricultural Research Center of Baluchestan, Iranshahr, Islamic Republic of Iran

Diaphorina citri is one of the major pest in Baluchestan. In natural enemies, *Allobaccha sapphirina* is the predator of *Diaphorina citri* . adults and nymphal were collected from Sarbaz(Baluchestan). The biology of *A.sapphirina* was studied under laboratory conditions at 22±2 ℃ , 70-75% R.H and 14:10 L.D. The oviposition mean for each female was 101.8±44.1 eggs in cage(60*60*100 cm). The mean duration of development times of *A.sapphirina* from egg to adult were 14.1 ± 0.9 days feeding on *Diaphorina citri* in petri dishes(6 * 1.5 cm). The mean longevity of adult males and females were 3 ±0.5 and 3.5±0.5 days without feeding. Nutrition had not effects on male and female. Feeding capacity was increased with age of larvae and mean total larval feeding on *Diaphorina citri* was 98.2 ±16.2 .

POSTER PRESENTATION

Study of insect growth regulators (Hexaflumuron and Pyriproxyfen) and Fipronil on vegetative and conidia germination of *Beauveria bassiana*.

Ahmad Baghdadi[1], Marzieh Rashid[1], Aziz Sheikhi[2], Mehran Ghazavi[2]

[1]*Department, College of Abouraihan, Tehran University, Tehran, Islamic Republic of Iran*
[2]*Pests and Plant Diseases Institute, Tehran, Islamic Republic of Iran*

Use of pesticides with entomopathogenic fungi can decrease the pest resistance to pesticides. Effects of Fipronil (20, 80, 1600 ppm), Pyriproxyfen (10, 500, 1500 ppm) and Hexaflumuron (15, 45, 80 ppm) with *Beauveria bassiana* was studied on vegetative growth and sporulation at SDA medium. For determining the conidia germination of *B. bassiana* malt agar (as control) and mixed with pesticides at 500, 100, 400 ppm concentrations used. Mean comparison of inhibitory vegetative growth at different concentrations of insecticides, indicated that inhibitory percent for Pyriproxyfen (1500 ppm) and Hexaflumuron (80 ppm) is %100 and for Fipronial (1600PPm) is %76.6. At lowest concentrations of all insecticides, inhibitory percents are %10-20.For all insecticides conidia production inhibitory of fungi has not significantly different among highest concentration of all insecticides and conidia production inhibitory was %80-100.At different concentrations of insecticides mean comparison of conidia germination indicated that there was no significant difference at different concentrations of Hexaflumuron and Pyriproxyfen. The results showed that,Hexaflumuron decrease significantly conidia germination of *B. bassiana*, therefore could not use with fungus for control of any pest.

POSTER PRESENTATION

Biology of *Scolothrips longicornis* Priesner (Thysanoptera: Thripidae), as a predator of two-spotted spider mite *Tetranychus turkestani* Ugarov & Nikolski (Acari: Tetranychidae)

Mehdi Gheibi[1], Ebrahim Soleymannejadian[2], Parviz Shishebor[1]

[1]Department of Plant Protection, College of Agiculture, Islamic Azad University, Shiraz, Shiraz, Islamic Republic of Iran, [2]Department of Plant Protection, College of Agriculture, shahid Chamran University, Ahvaz, Islamic Republic of Iran

Introduction: The two spider mite, *Tetranychus turkestani* U. & N. is a major agricultural pest in Iran. Many natural enemies of the pest have been known but *Scolothrips longicornis* P. has been recognized as a promising predator of tetranychid mites.

Methods: The biology, feeding activity, development, fecundity as well as some ecological aspects of *S. longicornis* P. on *T. turkestani* were investigated under laboratory conditions (27±1 ℃, 70±5% R.H. and 16L : 8D). A stockculture of *S. longicornis* and the two-spotted spider mite was provided on cowpea. In all experiments, each predator was held on leaf discs cut from cowpea leaves infested with different stages of *T. turkestani*.

Results: *S. longicornis* females required a mean of 14.26 and10.38 days at 26 and 35ºC respectively, to complete development from egg to adult. The immature stages of thrips consumed a mean of 86.9 and 12.8 spider mite eggs and females, respectively. Females thrips killed a mean of 49.1 eggs and 11.7 female mites per day and a mean of 1861 and 453 eggs and females respectively during adult stage. The rate of predation was influenced by temperature. The thrips ate an average of 0.3 *T. turkestani* females/day at 5ºC compared with 17.1 females/day at 40ºC. Eggs of *S. longicornis* were inserted into the leaf tissue. Mating was not necessary to induce oviposition. Unmated females produced only male progeny. Mated females produced a mean of 226 eggs on cowpea during oviposition period of 37.5 days. The mean age mortality of adult female thrips was 21-25 days which was nearly equal to the life expectancy (e_x) at the time of adult eclosion. The highest sex ratio for females was 0.88 on first day of egg laying and it decreased gradually and reached to less than 0.46 after day 26. It is suggested that in mass rearing of predatory thrips, the culture should be renewed after 26th days of the beginning egg-laying. Leaves of cowpea were more suitable than sugarcane for oviposition by *S. longicornis*.

Conclusions: the results of the study suggest that *S. longicornis*, in comparison with other predators of tetranychid mites especially predatory mites, shows promising qualities as a predator of spider mites.

POSTER PRESENTATION

The effect of different vineyard management systems on the epigaeic arthropod assemblages in the Cape Floristic Region, South Africa

Rene Gaigher, Michael Samways

Department of Conservation Ecology and Entomology, Faculty of AgriSciences, Stellenbosch University, Stellenbosch, South Africa

Introduction: In the Cape Floristic Region of South Africa, where wine grape production and biodiversity conservation are of major importance, innovative management of the landscape is necessary to integrate the two activities. This study assessed the potential of alternative vineyard management i.e. organic and biodynamic vineyard management, to conserve epigaeic arthropod diversity, relative to the more widespread integrated vineyard management in the CFR.

Methods: A hierarchical design was used, consisting of three localities, each including an alternative vineyard, an integrated vineyard and a natural vegetation site as reference habitat. Arthropods were sampled using pitfall traps. Nested ANOVAs were used to test for differences in abundance and species richness of total assemblages and selected predatory taxa. Canonical correspondence analyses were used to evaluate the effects of environmental variables, management practices and landscape variables on community composition.

Results: Alternative vineyards supported a higher overall arthropod abundance and species richness, and more abundant and speciose spider and staphylinid assemblages than the integrated vineyards. Results for carabid beetles were variable. The differences could be explained in part by higher non-crop vegetation complexity and reduced management intensity of the alternative vineyards. Community composition was influenced by a combination of management practices, the surrounding landscape and geographic locality.

Conclusions: Alternative vineyard management seems to be a promising option for reducing the impact of agriculture on arthropod diversity. Because of the complex nature of these agroecosystems, it is recommended that multi-scale and site-specific studies should precede efforts to integrate it into conservation strategies.

POSTER PRESENTATION

Locust Control Support Project, a tool for a sustainable management of desert locust and trans-boundaries pests

Amadou Bocar Bal

Projet d'Appui à la Lutte Anti-acridienne, Niamey, Niger

Introduction: The objective of the Locust control Support Project is to reduce the economic impact of the Desert Locust (DL) damages and to minimiser/prevent the harmful effects on the environment of the control operations. It is funded by USAID for 2 and ½ years duration and is carried out by AGRHYMET Regional Centre since April 2006.

Methods: The project invoves the members countries of the Permanent Inster states Committee for Drought control in the Sahel (CILSS). It is carried out in Burkina Faso, in Cape Verde, in Gambia, in Guinea Bissau, in Niger (national and regional levels) and in Chad.

Results: Mass rearings of DL are developed and maintained in Niamey and Agadez. Research activities are going on, on the use of Phényl-Acéto-Nitrile (PAN)and Green Muscle®, a biopesticide which active ingredient is *Metarhizium anisopliae* var. *acridum*, in the management of the DL populations. Data-processing equipment was provided to the countries. Visits of exchange were organized in Alger (Algeria), Agadir (Morocco) and Akjoujt and Nouakchott (Mauritania) for the reinforcement of the sub-regional collaboration. One thousand six hundred and sixty sixteen (1676) staff members of the national services of agriculture, phytosanitary brigades and producers were trained into 2007 on the safety use of pesticides and on transboundary pests.

Coclusion: The execution of the project proceeds as planned and will continue with the farmers trainings on the transboundary pests and research on the PAN and Green Muscle®.

POSTER PRESENTATION

Role of topoclimatic and land cover factors predicting butterfly distributions at fine scales: a case study in central Spain.

Javier Gutierrez[1], David Gutierrez[1], Robert J Wilson[2]

[1]Biodiversity & Conservation Area, ESCET, University Rey Juan Carlos, Mostoles, Spain, [2]Centre for Ecology and Conservation, University of Exeter, Cornwall Campus, Penryn, United Kingdom

Species distribution modelling is a potentially useful tool to evaluate global change effects on biodiversity, but there is debate over whether habitat or topoclimatic models offer higher prediction accuracy.

In this study, we tested the ability of land cover and topoclimatic variables to predict the abundance and distribution of 48 butterfly species in the Sierra de Guadarrama (central Spain). This mountain region of c. 100 x 80 km has a pronounced elevational gradient (500-2430 m), and widespread, clearly-defined areas of grassland, scrub and woodland habitat.

Butterflies were sampled on transects at independent locations stratified by altitude and landcover type in 2004 and 2005. Distribution and abundance models were developed for each year using generalized linear models based on topoclimatic or habitat variables sampled at 100 m resolution in GIS, or a combination of the two,. Models from each year were then used to predict occupancy and abundance at the independent sites sampled the alternate year, and the accuracy of models was evaluated using AUC (distribution models) or correlation coefficients (abundance models).

Even at this relatively fine scale, topoclimate models gave more accurate predictions of distribution and abundance for most species, across a range of species abundances, distribution sizes and elevational associations. For relatively few species land cover variables outperformed topoclimatic models, or improved model performance when combined with topoclimatic variables in the model.

The results raise concerns about the capacity of landcover variables to predict species distributions, and of habitat management to buffer species against climate change in mountainous regions.

POSTER PRESENTATION

Development of a light emitting diode (LED) system for effective attraction of stored product insects

Me-Chi Yao[1], Chi-Yang Lee[1], En-Cheng Yang[2], Kuang-Hui Lu[3]

[1]Applied Zoology Division, Agricultural Research Institute, Council of Agriculture, Taichung, Taiwan, [2]Department of Entomology, National Taiwan University, Taipei, [3]Taiwan, Department of Entomology, National Chung Hsing University, Taichung, Taiwan

Introduction: To maintain the quality of stored rice by reducing the damage from stored-product insect pests, a new apparatus with LED to attract the pests has been developed for this purpose. In this study, we evaluated the efficacy of different monochromatic lights on attracting four dominant stored-product insects, including *Rhyzopertha dominica*, *Sitophilus oryzae*, *Sitotroga cerealella*, and *Cadra cautella*.

Methods: A dodecagon maze with 12 inside-chambers, which a light emitting diode (LED) was installed in each chamber, was used to detect the efficacy of insect attraction under different wavelengths. Eleven LEDs with peak wavelengths at 373, 398, 408, 465, 472, 517, 570, 610, 634, 677 and 715 nm, respectively, were used for producing monochromatic light. Fifty insects were put in the center of the maze and dark adapted for 20 min before the LEDs were turned on to elicit phototactic behavior for 30 min. The number of the insects in each chamber was counted after the test. Each test was 30 replicates. All experimental data were subjected to analysis of variance using SAS and Fisher's protected least significant difference (LSD) at the 5% level of probability.

Results: The most attractive wavelength to *R. dominica* and *C. cautella* was 373 nm; to *S. oryzae* was 408 nm; and to *S. cerealella* was 398 nm.

Conclusions: Attractive wavelengths have been identified for the four dominant species of stored-product insects. The active wavelengths are useful for developing an apparatus which applies phototactic behavior of the insect pests.

POSTER PRESENTATION

Cascading effects of moose browsing on galling insects and their associates on balsam fir

Ken Tabuchi[1], Dan Quiring[1], Kenichi Ozaki[2]

[1]Faculty of Forestry and Environmental Management, University of New Brunswick, Fredericton, N.B, Canada, [2]Hokkaido Research Center, Forestry and Forest Products Research Institute, Sapporo, Japan

Introduction: Mammal browsing influences plant growth and development, which may indirectly affect the abundance and species diversity of insect herbivores. Most previous studies of indirect effects of mammal browsing only examined the abundance of herbivorous insects and did not examine their performance, though effects on performance are important to predict the long term effect of mammal browsing on the herbivorous insect community. We examined the indirect effects of moose browsing on the abundance and performance (survivorship and size of survivors) of P. tumifex and its inquiline.

Methods: We investigated the number of galls per shoot, larval survival rate and the weight of mature larvae of P. tumifex and its inquiline on balsam fir saplings inside and outside of moose exclosures in Newfoundland, Canada.

Results: Moose browsing had a strong, negative impact on the abundance of P. tumifex and its inquiline, presumably by decreasing the number of current year shoots on each sapling outside exclosures. The rate of inquilinism was lower on browsed than on non-browsed plants. In contrast, the weight of mature larvae of both of P. tumifex and the inquiline was weakly but positively related to browsing, due perhaps to the longer needles on browsed plants. There was no effect of browsing on the survival rate of P. tumifex.

Conclusions: Moose browsing caused contrasting indirect effects on abundance and performance of both P. tumifex and its inquiline.

POSTER PRESENTATION

Rapid development of microsatellite markers for *Deladenus siricidicola*, a biological control agent of *Sirex notilio*, using FIASCO enrichment and pyrosequencing

Osmond X.M. Mlonyeni[1], Bernard Slippers[1], Brett P. Hurley[1], Rodrigo J. Ahumada[2], Paula Klasmer[3], Brenda D. Wingfield[1], Michael J. Wingfield[1]

[1]Department of Genetics, Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa, [2]Bioforest S.A, Concepción, [3]Chile, Campo Forestal General San Martín, Estación Experimental Bariloche, Instituto Nacional de Technología Agropecuaria, Negro, Argentina

The woodwasp *Sirex noctilio* and its symbiotic Basidiomycetes fungus, *Amylostereum areolatum*, are invasive pests that cause the most significant damage to *Pinus* spp. in the Southern Hemisphere. The nematode, *Deladenus siricidicola* parasitizes *S. noctilio* and is one of the most important biological control agents of the woodwasp. Currently, nothing is known about the genetic diversity of *D. siricidicola* populations even though such information can be valuable for biological control programs. The aim of this study was to develop microsatellite markers for future use in population studies of *D. siricidicola*. In addition, we test pyrosequencing as a tool to shorten the time needed for microsatellite development. Genomic DNA was enriched for microsatellites using the Fast Isolation by AFLP of Sequences Containing repeats (FIASCO) protocol and products were sequenced using pyrosequencing (Genome Sequencer FLX System™, Roche Diagnostics). The obtained sequences were used to design primers via the webbased program Primer 3 (http://frodo.wi.mit.edu). The pyosequencing data yielded 94 microsatellite containing contigs from which 26 primer pairs were designed. Preliminary analysis indicates extremely little variation amongst the Southern Hemisphere strains. This study demonstrated that pyrosequencing is an effective and fast tool to characterize fragments of microsatellite enriched gDNA, and produced potential markers for population studies of *D. siricidicola*.

POSTER PRESENTATION

Natural enemies associated with *Nipaecoccus viridis* (Newstead) in Khuzestan Province, southwest Iran

Mohammad Saeed Mossadegh, Mehdi Esfandiari, Gholamali Asadeh, Abdolreza Khodaman, Mandana Novin, Valiollah Baniameri

Plant Protection Department, College of Agriculture, Shahid Chamran Univeristy, Ahwaz, Islamic Republic of Iran

Introduction: The mealybug *Nipaecoccus viridis* (Newstead) is one of the major pests of citrus orchards of north Khuzestan, southwest Iran. This pest was first recorded on a sweet lemon tree in 1985 in Ahwaz south of Khuzestan, and then spread rapidly in many citrus orchards in the province.

Methods: A survey for biology as well as natural enemies associated with the mealybug was conducted from 1989 to March 2007 in seven different consecutive projects.

Results: The species recorded belong to the following orders and families: Coccinellidae, Col.: *Hyperaspis polita* Weise, *Nephus includens* (Kirsh), *N.* sp. near *fenestratus* (Sahberg). Encyrtidae, Hym.: *Anagyrus dactylopii* (Howard), *A. agraensis* Sara., *A. diversicornis* Mercet, *A. mirzai* Agarwal & Alam. Cecidomyiidae, Dip.: *Dicrodiplosis manihoti* Harris. The following hyperparasitoids were also recorded: Encyrtidae, Hym.: *Homalotylus quaylei* Timberlake; Signiphoridae, Hym.: *Chartocerus* (*Matritia*) sp. Near *kurdjumovi* (Nikolskaya) and *Pteromalidae*, Hym.: *Pachyneuron muscarum* L.

Conclusion: Although the pest has many natural enemies in the region, but it damages the fruits at early spring due to the low population densities of its natural enemies at this time of the year.

POSTER PRESENTATION

Aquatic bugs (Hemiptera, Heteroptera) of the "Lago Municipal de Cascavel", Paraná, Brazil, as indicators of environmental pollution

Gabriel Simoes de Andrade

Universidade Estadual do Oeste do Paraná, Centro de Ciências Biológicas e da Saúde, Parana, Brazil

Introduction: Aquatic insects are of great environmental interest, both those with only immature stages in this habitat, as those who live there permanently. Some of them are characteristic of lakes or rivers, or both, and in all cases there are species that may be biological indicators of water quality. The first step is the knowledge of representatives from different regions and environments.

Methods: The specimens are being collected in all parts of the lake, which is located in a large area of leisure of the city, with woods and gardens. Usual methods of collection has been used, and the fixing and conservation are made in plastic bottles with alcohol 70%. The identifications are made by the general literature and in some cases, with the help of specialists.

Results: The following species have been found frequently: in Nepomorpha *Belostoma micantulum* Stål, 1858 and *B. oxyurum* (Dufour, 1863) (Belostomatidae), *Notonecta polystolisma* Fieber, 1851 and *Buenoa paranaensis* Jaczewski, 1928 (Notonectidae), *Heterocorixa nigra* Hungerford, 1928 and *Sigara chrostowskii* Jaczewski, 1927 (Corixidae), and in Gerromorpha *Platyvelia brachialis* (Stål, 1860) (Veliidae), *Limnogonus aduncus* Drake & Harris, 1933 and *Halobatopsis platensis* (Berg, 1879) (Gerridae).

Conclusions: All these species were found in large series, showing a good adaptation to local conditions and can be characterized as synantropics. These taxa, specially of Belostomatidae, already have been identified in other Brazilian and South America lakes with features of the present, and can be used as indicators of pollution. The study is being continued with the identification of species of minor occurrence.

POSTER PRESENTATION

The extracts of house dust mite, *Dermatophagoides pteronissinus* (DpE), induce MCP-1, IL-6 and IL-8 in human monocytic THP-1 cells and eosinophilic EoL-1 cells

Ji-Sook Lee[1], Ji-Sun Ryu[1], Joo-Hwan Kim[1], Sang Kyun Koh[2], In Sik Kim[3], Chi-Young Yun[1], Sang-Ho Nam[1]

[1]Department of Biology, Daejeon University, Daejeon, Korea, [2]Republic of, Department of Biology and Department of Microbiology and Biotechnology, Daejeon University, Daejeon, Korea, [3]Department of Biomedical Laboratory Science, School of Medicine, Eulji University, Daejeon, Republic of Korea

Introduction: The house dust mite, *Dermatophagoides pteronissinus* (Pyroglyphidae), is a cosmopolitan guest in human habitation. Dust mites are the most common cause of asthma and allergic symptoms worldwide. In mediating the infiltration of various cells into the skin of patients with atopic dermatitis and psoriasis, pro-inflammatory cytokines such as monocyte chemotactic protein-1 (MCP-1/CCL2), IL-6, and IL-8 (CXCL8) play pivotal roles.

Methods: We investigated the effect of *D. pteronissinus* extract (DpE) on expression of MCP-1/IL-6/IL-8 in the level of both mRNA and protein, and the signal transduction in the human monocytic THP-1 and human eosinophilic EoL-1 cells.

Results: The mRNA and protein expression of MCP-1, IL-6 and IL-8 were elevated by DpE in a time and dose-dependent manner in THP-1 and EoL-1 cells. In addition, the concentration of MCP-1, IL-6 and IL-8 increased in serum of patients with atopic dermatitis, compared with those in normal serum.

Conclusions: These results indicate that DpE can trigger allergic response by increasing the expression of pro-inflammatory cytokines, and may be used as a helpful screening system in drug development for the treatment of atopic dermatitis and other allergic diseases by measuring the effect to inhibit cytokines.

POSTER PRESENTATION

Expression of *Bacillus thuringiensis* subsp. *aizawai* Cry1D toxins in *Escherichia coli*

Hamzah Abdul Aziz[1], Wei Hong Lau[1], Yee How Tan[1], Ahmad Said Sajap[2], Khatijah Yusoff[3]

[1]Department of Plant Protection, Faculty of Agriculture, Universiti Putra Malaysia, Serdang, Selangor, Malaysia, [2]Department of Forest Management, Faculty of Forestry, Universiti Putra Malaysia, Serdang, Selangor, Malaysia, [3]Department of Microbiology, Faculty of Biotechnology and Biomolecular Sciences, Universiti Putra Malaysia, Serdang, Selangor, Malaysia

Introduction: The most widely used microbial insecticide to date is a product based on *Bacillus thuringiensis,* a spore-forming soil bacterium that produces highly specific insecticidal proteins called Bt toxins during sporulation. In this study, expression of protoxin and active-truncated Cry1D toxin, respectively, *B. thuringiensis* subsp. *aizawai* was carried out in *Escherichia coli*.

Methods: The active and full-length *cry1D* genes were amplified from the genomic DNA of *B. thuringiensis* subsp. *aizawai* and cloned into a TA cloning vector for sequencing. The expression of recombinant Cry1D proteins was carried out in *E. coli* and the proteins were assayed against the larvae of *Spodoptera litura*.

Results: The active and full-length *cry1D* gene were successfully amplified from the genomic DNA of *B. thuringiensis* subsp. *aizawai* and their size was about 1 878 bp and 3 495 bp, respectively. The nucleotide sequence of the *cry1D* genes is very similar to the sequence of *cry1Da1* (accession no.: X54160) and *cry1Da2* gene (accession no.: I76415), with a homology of 100%. In SDS-PAGE analysis, both genes were expressed and their size was about 130 kDa (full-length *cry1D* gene) and 53 kDa (active *cry1D* gene), respectively. The Cry1D protoxin caused 100% mortality to the larvae of *S. litura* after 4 days postinoculation. It induced mortality at a faster rate when compared to the commercial Bt product (Flobac FC*, Denmark), which induced 100% larval mortality after 6 days postinoculation. The active-truncated Cry1D toxin only induced 100% larval mortality after 8 days postinoculation.

Conclusion: We succeeded in expressing active Cry1D toxins in a prokaryotic expression system. It may be useful as an alternative Bt product for insect pest control.

POSTER PRESENTATION

Overwintering and cold hardiness of western flower thrips, *Frankliniella occidentalis* (Pergande)

Zhong-ren Lei, Ming-juan Bi

State Key Laboratory for Biology of Plant Diseases and Insect Pests, Institute of Plant Protection, Chinese Academy of Agricultural Science, Beijing, China

Introduction: Discovering of *Frankliniella occidentalis* (Pergande) is not long in China, so cold hardiness of *Frankliniella occidentalis* (Pergande) in China and how they can overwinter safely in North of China should be testified through some experiments.

Methods: Put the probe in the type of VM04/100 super-high-low temperature vegetal box , then cooled at 1□/min using a thermoelectric cooling unit until an exotherm corresponding to the release of the latent heat of fusion was registered. The temperature change of insects was gathered□noted and analysed through TC-20 analysis system.

Results: The supercooling point(SCP),freezing point(FP) were tested on western flower thrips, *Frankliniella occidentalis (*Pergande).The lowest temperature of SCP was -23.36±0.93℃ of prophase pupae.The SCP of other stages is pupae < adult < second instar larval < first instar larval < egg. So we can conclude that the fitted overwintering instar of western flower thrips is prophase pupae in Beijing. In certain range SCP gradually lowing through the advanced freezing time extend. But SCP rise if advanced freezing time too long. Pupae can not survive in the winter, estimated by field trials in Beijing with pupae buring. It is suggested that western flower thrips died rapidly near the temperature of SCP. In a word ,the range of cold tolerance ability is prophase pupae > pupae > adult > second instar > first instar > egg.

POSTER PRESENTATION

Developmental changes according to gamma irradiation on the different stages of *Harmonia axyridis* (Coleoptera: Coccinellidae)

Hee Jin Lee[1], Me Ja Seo[1], Eun Jin Kang[1], Hee Bong Seok[1], Dae Hong Lee[1], Chang Wook Jo[1], Cho Rong Park[1], Si Yong Kang[2], Yong Man Yu[1], Young Nam Youn[1]

[1]Dept. of Applied Biology, College of Agriculture & Life Sciences, Chungnam National University, Daejeon, Republic of Korea, [2]Korea Atomic Energy Research Institute, Daejeon, Republic of Korea

The multicolored Asian ladybird beetle, *Harmonia axyridis* (Pallas) (Coleoptera: Coccinellidae), is common to a wide range of natural and agricultural habitats. Applications of gamma irradiation minimized the losses of stored food and the death or failure of emergence in larval and pupal stages. On the other hand, degrade toxin waste as one of alternative to chemical pesticide for both quarantine and sprout control purposes of storage crop pest. So, we have investigated whether gamma irradiation exposed to eggs, lava, pupa and adults of *H. axyridis*. It may be affected the emergence, fertility, fecundity, development period and sex ratio of *H. axyridis*. Some changes of physiological characteristics may be applied to more efficient agents as biological control of several aphids. Insects were exposed to gamma irradiation from 0 to 500 Gy of ^{60}Co depended on their developmental stages. The results showed that the first instar, eggs, third instar, pupae, and adults were more sensitive in order of irradiation dose. And fecundity and fertility of female adults were significantly decreased with increasing gamma irradiation dose at all tested individuals.

POSTER PRESENTATION

Analyses of different elytra color patterns using AFLP in *Harmonia axyridis*

Dae Hong Lee, Eun Jin Kang, Hee Jin Lee, Hee Bong Seok, Chang Wook Jo, Cho Rong Park, Myoung Gi Kang, Mi Ja Seo, Yong Man Yu, Young Nam Youn

Dept. of Applied Biology, College of Agriculture & Life Sciences, Chungnam National University, Daejeon, Republic of Korea

The multicolored Asian ladybird beetle, *Harmonia axyridis*, which demonstrates typical genetic polymorphism in its elytra color patterns. Early studies have color polymorphism in terms of geographical clines while a few investigated temporal populations in Coccinellidae. Nevertheless, note that geographical and temporal morph variation does not always correspond to what is expected from thermal and industrial adaption theories. A recent study of transformation and RNAi of the ladybird beetle, however, there is yet no evidence to indicate the variation is genetic or environmental factors. Here we describe a relatively new molecular fingerprinting technique, amplified fragment length polymorphism (AFLP). Because we think that color polymorphism in Coccinellidae is affected by genetic polymorphism. In total 38 markers were scored from which some markers were polymorphic. Supsequent UPGMA cluster analysis revealed 3 major group of *Harmonia axyridis* populations. But for strains that are more genetically similar, different primer combinations may be need to generate enough polymorphic marker.

POSTER PRESENTATION

Variation of elytra color patterns according to temperatures and photoperiods in *Harmonia axyridis* (Coleoptera: Coccinellidae)

Eun Jin Kang, Hee Jin Lee, Hee Bong Seok, Dae Hong Lee, Chang Wook Jo, Cho Rong Park, Mi Ja Seo, Young Man Yu, Young Nam Youn

Dept. of Applied Biology, College of Agriculture & Life Sciences, Chungnam National University, Daejeon, Republic of Korea

The surface of most coccinellids (particularly the elytra) has characteristic color patterns, which show great variability within many species. Individuals of a species of ladybird often differ from one another in color and pattern. In case of *Harmonia axyridis*, environmental factors, such as temperature or food, can probably influence color and pattern. However, virtually no work has been carried out in the influence of such factor. Therefore, in this study, according to rearing temperature, photoperiod and diet, variation of elytra color patterns were investigated. First instar larva on each color pattern were reared in an incubator at one of two temperatures; 25 and 30℃, under the following photoperiod; L16: D8, L12: D12 and L8: D16 and were provided three species of aphids. And their color patterns of adults were estimated.

POSTER PRESENTATION

Assay of α-amylase in gut and salivary glands of *Eurygaster maura* (Hemiptera: Scutelleridae)

Mohammad Mehrabadi, Ali R Bandani

Department of Plant Protection, University of Tehran, Karaj, Islamic Republic of Iran

Introduction: Among the wheat pest in Iran, genera of *Eurygaster* sp. (Hemiptera: Scutelleridae) is the most economic pest. It's major injury is feeding of wheat seeds. This insect introduces its salivary enzymes into seed and after partially digestion, sucking digested material, therefore identification and assessing of its enzymes is very important.

Methods: The insects were collected from Gorgan wheat farm of Golestan Province, Iran, and maintained on wheat plants in the laboratory at 27 ± 2°C with 14L:10D. Voucher specimens are kept in the Entomological Laboratory, Plant Protection Department, Tehran University Adults were randomly selected and midgut and salivary glands from these individuals were removed by dissection under a light microscope in ice-cold saline buffer (0.006 M NaCl). After dissecting the insects and exploiting of its salivary glands in NaCl, 10 pair of salivary glands were floating in 1000 µl Phosphate buffer and homogenized After hemogenation in standard condition, each sample were separately transferred to 1.5 ml centrifuge tubes and centrifuged at 15000 ×g for 20 min at 4˚C. The supernatants were pooled and stored at -20˚C for subsequent analyses. Amylase activity was measured by dinitrosalicilic acid (DNS) procedures, using soluble starch as substrate. The effect of different ions on α-amylase activity surveyed in the presence of different concentration of chloride salts of Na^+ (5,10,20,40 m mol/L) and K^+,Ca^{2+},Mg^{2+} and ethylenediamine tetraacetic acid (EDTA),sodium dodecyl sulfate (SDS) in concentration (0.5,1,2,4 m mol/L)and urea (0.5,1,2,4 mol/L). Determination of activity in all assessing measured by spectrophotometer based on light absorbent in λ_{max} (OD/min).

Results: Results showed that enzyme activity in salivary glands and guts of adult insects were 0.022 and 0.036 OD/min degrees, respectively. The temperature optimum for enzyme activity was 30-35 c^o, the optimum PH was 6-7. Studying the effect of various ions on α-amylase activity was showed that Na^+ and K^+ ions increased activity only a little. Mg^{2+} decreased amylase activity alittle.Ca^{2+} increased amylase activity. SDS , EDTA a and urea decreased amylase activity.

Conclusions: There were some differences between α-amylase in gut and salivary glands of *Eurygaster maura*, activity of mentioned enzyme in gut is more than salivary glands that could be due to differences of organ's activity.

POSTER PRESENTATION

Assay of α-amylase in gut and salivary glands of *Eurygaster maura* (Hemiptera: Scutelleridae)

Mohammad Mehrabadi, Ali R Bandani

Republic of, Department of Plant Protection, University of Tehran, Karaj, Islamic Republic of Iran

Introduction: Among the wheat pest in Iran, genera of *Eurygaster* sp. (Hemiptera: Scutelleridae) is the most economic pest. It's major injury is feeding of wheat seeds. Conclusions: There were some differences between α-amylase in gut and salivary glands of *Eurygaster maura*, activity of mentioned enzyme in gut is more than salivary glands that could be due to differences of organ's activity.

POSTER PRESENTATION

Determination of gut & salivary pH and comparing of α-Amylase activity in various nymphal stages and adult of *Eurygaster maura* (Hemiptera: Scutelleridae)

Mohammad Mehrabadi, Ali R Bandani

Department of Plant Protection, University of Tehran, Karaj, Islamic Republic of Iran

Introduction: Isolation, studying and identification of insect enzymes and the organs that are resource of them, would be useful to us for more understanding of digestive process in insects. Knowing of this information about economic pests is very valuable and applicable in order to their control. Salivary enzyme entrance of mentioned bugs into the feeding seeds In addition to its direct injury to wheat seeds,causes decreasing of feeding seeds quality, has harmful medicine effects on consumers involved humans.

Methods: The insects were collected from Gorgan wheat farm of Golestan Province, Iran, and maintained on wheat plants in the laboratory at 27 ± 2°C with 14L:10D. Voucher specimens are kept in the Entomological Laboratory, Plant Protection Department, Tehran University. Adults were randomly selected and midgut and salivary glands from these individuals were removed by dissection under a light microscope in ice-cold saline buffer (0.006 M NaCl). Whole *E. maura* nymphs were homogenized in the above mentioned universal buffer and centrifugation carried out as before. The supernatants were pooled and stored at -20˚C for later use. After hemogenation in standard condition, each sample was separately transferred to 1.5 ml centrifuge tubes and centrifuged at 15000 ×g for 20 min at 4˚C. The supernatants were pooled and stored at -20˚C for subsequent analyses. Amylase activity was measured by dinitrosalicilic acid (DNS) procedures, using soluble starch as substrate. Determination of activity measured by spectrophotometer based on light absorbent in λ_{max} (OD/min). PH determinations of salivary glands and midgut were assayed by indicator staining reagent separately.

Results: Studies showed that first part of midgut was slightly alkaline and other three parts were some acidic. α- amylase activity is present in midgut and salivary glands of adult *E. intergriceps* and in whole body of nymphs. Only trace amounts of enzyme activity were detected in the first-nymphal stage (0.008 OD/min), whereas α- amylase activity in second-nymphal stage was 0.025degree of OD/min. In other stages (third to fifth-nymphal stage) reached its highest value (0.036 OD/min). Result determined that the highest activity observed in third to fifth- nymphal stage and the lowest activity in the first nymphal stage.

Conclusions: Because of being the lowest feeding and movement activities in first nymphal stage of *E. maura* against other stages, hence, it is common to be the lowest amylase activity in this stage. After this stage, feeding causes activity of amylase and continues in higher stages. On the other words, these results showed that α-amylase specific activity in the immature stages increased constantly up to third-instar nymph.

POSTER PRESENTATION

Arthropod biodiversity on transgenic cotton in single gene traits, expressing either herbicide tolerance or bollworm resistance (*Cry1Ac*), and in a double gene trait, expressing both herbicide tolerance and bollworm resistance, in South Africa

Tanya Joffe[1], Annette Bennett[2], Neethling Du Toit[3], Erica Du Toit[3], Walter M. Green[4]

[1]School of Agricultural Science/TIAR, University of Tasmania, Hobart, Australia, [2]Inselele Training CC, Centurion, South Africa, [3]Agri-Biotech Research Consultancies CC, Nelspruit, [4]South Africa, Crop and Plant Biotechnology Services CC, Kempton Park, South Africa

This study was aimed at establishing the baseline for insect biodiversity in genetically altered cotton containing single and double gene traits, in Groblersdal (South Africa), over two cotton growing seasons (2003/04 and 2004/05). The purpose was to collect data on arthropod species during the fruiting phase of cotton on a commercial cotton farm, under common management practices for each cotton type (conventional cotton - DeltaOPAL), Bollgard™ (NuOPAL), Roundup Ready™ (DeltaOPAL RR) and Stack gene (NuOPAL RR). Arthropod biodiversity was compared within genetically modified (GM) and non-GM cotton fields after normal spray programs aimed at controlling bollworm populations, to populations found in unsprayed fields. Scouting data from 2003/04 showed that species diversity and richness occurring on GM cotton was similar to that found on conventional cotton, with higher species diversity appearing to be present on Stack gene cotton when monitored by means of sweeping. Pest management strategies differed for each of the GM cotton varieties (Stack gene, Bollgard™ and Roundup Ready™) and this had an effect on the pest and predator populations found during each count. The GM cotton varieties had no obvious negative environmental effect when comparing the arthropod diversity within each field with unsprayed conventional cotton. The results from 2004/05 statistically confirmed that of the previous season. Overall, the highest total number of predators was found on NuOPAL RR during the 2004/05 season. NuOPAL and NuOPAL RR tended to have higher numbers of predators than the sprayed DeltaOPAL and DeltaOPAL RR varieties. The total number of arthropods found on the unsprayed cotton types was similar. In the case of Roundup Ready cotton, fewer arthropods at any specific time was the result of chemical application. A large variety of arthropod species was present on all cotton types evaluated and no trend could be established that these particular species were more prevalent on any particular cotton type. This data could be useful for decision makers interested in developing biosafety regulations for transgenic cotton.

POSTER PRESENTATION

Expression of *Bacillus thuringiensis* subsp. *aizawai* Cry1D toxins in *Escherichia coli*

Abdul Aziz Hamzah[1], Wei Hong Lau[1], Tan Yee How[1], Ahmad Said Sajap[2], Yusoff Khatijah[3]

[1]Department of Plant Protection, Faculty of Agriculture, Universiti Putra Malaysia, Selangor, Malaysia, [2]Department of Forest Management, Faculty of Forestry, Universiti Putra Malaysia, Selangor, Malaysia, [3]Department of Microbiology, Faculty of Biotechnology and Biomolecular Sciences, Universiti Putra Malaysia, Selangor, Malaysia

Introduction: The most widely used microbial insecticide to date is a product based on *Bacillus thuringiensis,* a spore-forming soil bacterium that produces highly specific insecticidal proteins called Bt toxins during sporulation. In this study, expression of protoxin and active-truncated Cry1D toxin, respectively, *B. thuringiensis* subsp. *aizawai* was carried out in *Escherichia coli*.

Methods: The active and full-length *cry1D* genes were amplified from the genomic DNA of *B. thuringiensis* subsp. *aizawai* and cloned into a TA cloning vector for sequencing. The expression of recombinant Cry1D proteins was carried out in *E. coli* and the proteins were assayed against the larvae of *Spodoptera litura*.

Results: The active and full-length *cry1D* gene were successfully amplified from the genomic DNA of *B. thuringiensis* subsp. *aizawai* and their size was about 1 878 bp and 3 495 bp, respectively. The nucleotide sequence of the *cry1D* genes is very similar to the sequence of *cry1Da1* (accession no.: X54160) and *cry1Da2* gene (accession no.: I76415), with a homology of 100%. In SDS-PAGE analysis, both genes were expressed and their size was about 130 kDa (full-length *cry1D* gene) and 53 kDa (active *cry1D* gene), respectively. The Cry1D protoxin caused 100% mortality to the larvae of *S. litura* after 4 days postinoculation. It induced mortality at a faster rate when compared to the commercial Bt product (Flobac FC*, Denmark), which induced 100% larval mortality after 6 days postinoculation. The active-truncated Cry1D toxin only induced 100% larval mortality after 8 days postinoculation.

Conclusion: We succeeded in expressing active Cry1D toxins in a prokaryotic expression system. It may be useful as an alternative Bt product for insect pest control.

POSTER PRESENTATION

Characterization of nucleopolyhedrovirus and granulovirus of armyworm *Spodoptera litura* (Lepidoptera: Noctuidae) in Malaysia

Wei Hong Lau[1], Said Sajap Ahmad[2], Yusoff Khatijah[3], Manaf Ali Abdul[4], Abdul Samad Noraini[3]

[1]Department of Plant Protection, Faculty of Agriculture, Universiti Putra Malaysia, Selangor, Malaysia, [2]Department of Forest Management, Faculty of Forestry, Universiti Putra Malaysia, Selangor, Malaysia, [3]Department of Microbiology, Faculty of Biotechnology and Biomolecular Sciences, Universiti Putra Malaysia, Selangor, Malaysia, [4]Department of Cell and Molecular Biology, Faculty of Biotechnology and Biomolecular Sciences, Universiti Putra Malaysia, Selangor, Malaysia

Introduction: Diseased larvae of *Spodoptera litura* collected from MARDI Research Station in Kelantan, Malaysia exhibited *Wipfelkrankheit* symptom with combinations of whitish and pinkish body colour. Preliminary electron microscopic study conducted on the diseased *S. litura* larvae revealed the presence of two distinct forms of viral occlusion body in the infected tissues of the larvae. In the present study, we attempted to isolate and characterize the different forms of occlusion body (OBs) in the diseased *S. litura* larvae.

Methods: The OBs, virus particles, nucleocapsids and virions were extracted and purified by ultra-centrifugation in a 40-80% (w/w) sucrose gradient. The purified virus components were examined under a TEM. The polyhedrin and granulin genes of both OBs were amplified and sequenced.

Results: The TEM micrograph of isolated preparation revealed two types of OBs that have morphology typical of nucleopolyhedrovirus (NPV) and granulovirus (GV). The NPV is composed of multiple virus particles while the GV is composed of only single virus particle per capsule. Based on the variable number of nucleocapsids enclosed within a virus particle, we confirmed that the NPV belonged to multiple nucleocapsids NPV. The nucleotide sequence analysis of the polyhedrin gene of NPV and granulin gene of GV showed 98% and 81% sequence identity to SpltNPV (accession number: AF037262) and XcGV (accession number: U70069), respectively. Based on the sequence analysis, the local isolates of NPV and GV are placed as a taxon of Group II NPV and Group GV, respectively.

Conclusion: The results presented in this study revealed that the viruses isolated from the diseased larvae of *S. litura* belong to the group of baculoviruses.

POSTER PRESENTATION

Spatio-temporal dynamics of the redlegged earth mite in Western Australia

Robert Smith[1], John Read[2], James Ridsdill-Smith[3]

[1]University of Huddersfield, Huddersfield, United Kingdom, [2]University of Warwick, Warwick, [3]United Kingdom, CSIRO Entomology, W.A, Australia,

The Redlegged Earth Mite (RLEM) *Halotydeus destructor* is an introduced pest of clover pasture in parts of South and Western Australia. RLEM feeds on subterranean clover, a major component of grazing pasture, and causes substantial loss of yield. A long-term study was established at Waroona, south of Perth, during the 1950s. Numbers of RLEM and a competing herbivore, the Lucerne 'Flea' (LF) *Sminthurus viridis*, were sampled on a regular grid of 252 sampling points every three weeks during autumn and winter over a 3-year period to establish baseline dynamics. Numbers of a predator were also counted.

It is known that RLEM form feeding aggregations on plant leaves. Individual mites move only a few metres in their lifetime, yet there are large-scale aggregations of mites over tens of metres. These aggregations must result from population dynamics rather than individual behaviour. The typical aggregation was found by hierarchical mean square analysis to be around 80m x 160m. The locations of aggregations changed between sampling dates.

A non-parametric test of temporal density dependence demonstrated both direct (within generation) and delayed (lag of three generations) density dependence, suggesting a trophic interaction with the predator, modulated by interaction with the competitor.

We tested the hypothesis that the aggregations represent travelling waves of high density moving across the landscape. A U-shaped Mantel correlation plot supported the travelling-wave hypothesis.

- Delayed density dependence suggests that the travelling waves in part result from ecological interactions affecting rates of population increase
- There is some evidence of competition between Redlegged Earth Mite and Lucerne Flea, both of which are predated by another mite (Bdellid).
- High, potential reproductive rate interacts with delayed density dependence and low rates of dispersal to produce travelling waves ('spatial cycles').

POSTER PRESENTATION

Sublethal effects of *Beauveria bassiana* (Balsamo) Vuillemin (Deuteromycotina: Hyphomycetes) on the whitefly *Bemisia tabaci* (Gennadius) (Hemiptera: Aleyrodidae) under laboratory conditions

Edison Torrado-Leon[1], James Montoya-Lerma[2], Edison Valencia-Pizo[3]

[1]Universidad Nacional de Colombia, Facultad de Agronomía, Cali, Colombia, [2] Universidad del Valle, Departamento Biología, Cali, [3]Colombia, Bayer CropScience, Cali, Colombia

Sublethal effects were evaluated in subsequent generations of whiteflies *Bemisia tabaci* (Gennadius) after exposure of each of the four nymphal stages of the parental generation to the fungus *Beauveria bassiana* (Balsamo) Vuillemin. Examples of such effects include impaired fertility and production of malformations or external variations as well as non-immediate mortality, that is, premature death of later generations. Malformations of the head, legs, wings or abdomen were not observed in adults derived from treated nymphs, nor were negative effects observed in the fecundity and fertility of the descendants of the whiteflies treated with the fungus. However, moulting problems were observed in insects descended from *B. bassiana*-treated whiteflies, the first time this has been reported. Almost 30% of the imagoes resulting from treated nymphs were unable to detach completely from the exuvia. Corrected mortality rates showed a gradual dilution over time.The importance of these findings is analysed in the light of other similar results.

POSTER PRESENTATION

Implementation of an IPM model in tobacco based on the use of a systemic insecticide and the protection of *Nesidiocoris tenuis* as the key predator of the *Traleurodes vaporariorum* white fly

Edison Valencia-Pizo[1], Katerine Valderrama[2], Jaime Granobles[2]

[1]Corporacion Colombiana de Investigacion Agropecuaria, CORPOICA., Research Centre Tibaitata, Bogota, Colombia, [2]Bayer CropScience, Bogota, Colombia

The tobacco is one of the main labour-intensive crops in Colombia, which promotes more than 50,000 direct employments and near to 70,000 indirect employments during the production season, in the optimal producing zones of Huila and Santander departments. The whitefly *Trialeurodes vaporariorum,* definitely is the most limiting pest of tobacco in several producing zones of Colombia, because of its capacity to produce mechanical damage and physiological stress to the tobacco plants. But probably, the most limiting damage caused by whiteflies to the tobacco crop, is related to their capacity to transmit plant viruses, especially of the Geminiviridae familiy, which can produce losses higher than 60%, with whitefly infestations lower than 5% under field conditions. Farmer usually rely on chemical control for the management of the *T. vaporariorum* whitefly, being the pyrethroid, the chloronicotinilic and the growth regulator insecticides the main groups of chemical compounds used against this pest. Normally the control of the whitefly is satisfactory during the early phases of the season (in the seedling trays and during the first 30 days after transplanting). However, as the season progresses, the whitefly control becomes increasingly difficult and very often, growers have to perform more than eight applications until harvest, in order to achieve control and avoid losses. This situation implies an intrinsic risk of development of resistance of the whitefly, especially because there is a limited number of chemical groups with different mechanism of action, suitable for its control under commercial conditions. Regardless of this negative aspect of tobacco production, the crop is also rich in a diversity of beneficial insects (predators and parasitoids), that make a contribution to the crop protection as natural enemies of the main pests. However, the individual contribution of key natural enemies had not being determined. Among insects recognized as predators of *Bemisia* whiteflies, a small group of Hemiptera: Heteroptera belonging to the Anthocoridae, Lygaeidae and Miridae families, represent a significant functional group, suitable for the control of immature as well adult whiteflies in tobacco and other important crops in Colombia. One of the species confirmed in the present study as responsible for an outstanding control of *T. vaporariorum* in tobacco fields in Colombia, is the predatory chinch bug *Nesidiocoris tenuis* (Heteroptera: iridae). This insect represents an extremely interesting study case of applied biological control, considering that the youngest developmental stages of the insect (first and second instar nymphs or N1 and N2) are referred as a pest by some farmers (because of their phytophagous habits). Experiments performed under laboratory conditions, made possible to confirm that the Functional Response of *N. tenuis* feeding on *T. vaporariorum* reached up to 100 first-to-second instar nymphs per day, while consuming up to 60 adult whitefly in the same period of time. Usually foliar application of broad spectrum chemical insecticides, maintain the population of *N. tenuis* far below the average population of its prey, the *T. vaporariorum* whitefly, thus being the predator completely unable to control the pest under the level of the action threshold. Under commercial conditions of pest management, the population relationship between the predator and its prey is of about 2 to 10, expressed as a ratium of 0,2., which implies a high potential of population increase of the whitefly and therefore, a big chance of chemical applications by the farmer. Interestingly, within the IPM model presented here, two applications by drench of the chemical systemic insecticide imidachloprid in the seedling trays (at 1 cc/liter/m2) and to the field between 5 and 8 days after transplanting (at 600 cc/Ha), are enough for maintaining the sucking pest below the action threshold, while allowing a significant population increase of many beneficial insects, as well as the Heteropteran predator, reaching a ratium of 5.0 (a predator/prey relation of 10 to 2, around 50 days after transplanting). As a result of the combined efficacy and control achieved by the chemical systemic insecticide and the predatory Mirid chinch bug, the total number of applications was reduced from an average of 8 in the region to 3 in the experimental fields, including one general treatment of a *Bacillus thuringiensis*-based

bioinsecticide required for the control of the Lepidopteran pest *Heliothis tergemina*. Experiments performed under laboratory conditions with induced-high populations of first and second instar nymphs of *N. tenuis*, were unable to produce a significant damage to the plants exposed, thus posing a serious question to the real potential of this species as pest of tobacco crop. This study represents an important case of an insect with an ambiguous role of herbivore in its initial developmental stages and predator in its latest ones, a characteristic also observed in the case of other predatory Heteropteran chinch bugs, as for example in the family Pentatomidae. The presence of high natural populations of *N. tenuis* in the high land tropical forests surrounding the tobacco producing zones in Santander, suggests that a promising Environmental Service in terms of pest predation might be provided by these forest to the crops. These observations suggest that it may be necessary to develop a more comprehensive and integrated model of pest management, involving not only the crop, but also the periagricultural areas, so far connecting the cultivated lands with the existing natural environments in the main producer regions of Colombia. A model that once validated, could provide a more sustainable approach for IPM, by a rational utilization of natural resources, including the management of arthropod biodiversity in agricultural landscapes.

POSTER PRESENTATION

Studies on comparative feed efficacy of MR_2 variety mulberry leaves treated with vitamin B_6 on *Bombyx mori* (L.) (Lepidopetera: Bombycidae) in relation to cocoon weight and silk traits.

D. Balasundaram, . Selvisabhanayakam, V. Mathivanan

Department of Zoology, Annamalai University, Tamil-Nadu, India

Mulberry leaf (*Morus alba L*) is an exclusive food for silkworm rearing and contributes about 100% of the material for biosynthesis of protein. An experiment was conducted to find out the feed efficacy of *Bombyx mori*. (L.) on control MR_2 leaves treated with vitamin B_6 in order to know the cocoon weight, silk traits, silk quality and quantity. It has been revealed from the present study that the MR_2 varity with vitamin B_6 treated is considered as the most effective feed for silk production rather than the control MR_2 variety. The results are discussed in detail.

POSTER PRESENTATION

Forced copulation in four taxa of Alpine bushcrickets (*Anonconotus* spp).

K. Vahed[1], G. Carron[2]

[1]*Biological Sciences Research Group, University of Derby, Derby, United Kingdom,* [2]*Freshwater Ecology Laboratory (LEBA), University of Geneva, Geneva, Switzerland*

Forced or coercive copulation is known to occur in a variety of insect taxa, but until recently this behaviour had not been recorded in crickets and bushcrickets (Orthoptera: Ensifera). The aim of the present study was to compare the recently documented forced mating behaviour in the Alpine bushcricket *Anonconotus alpinus ghilianii* with that of *A. alpinus alpinus*, *A. pusillus* and *A. baracunensis occidentalis* in both lab. and semi-natural field conditions. In all four taxa, males did not sing to attract females, but instead initiated copulation by "stalking" the female before leaping onto her and using their sharply pointed cercal spurs to maintain a hold on the female's abdomen. In *A. a. ghilianii* and *A. a. alpinus*, the positioning of the male's hind legs appeared to impede the movement of the female's hind legs during copulation. In *A. baracunensis*, the duration of copulation following spermatophore transfer was considerably longer than in the other species. This longer duration of copulation is interpreted as functioning to prolong ejaculate transfer by preventing the female from eating the external portions of the spermatophore. In support of this, male *A. baracunensis* were found to produce a significantly greater ejaculate mass than males of the other *Anonconotus* taxa. Males of all four taxa appeared to be highly unselective when it came to mating and, in the lab., would readily attempt to copulate with other males and nymphs of either sex.

POSTER PRESENTATION

An adapted economic threshold level for the management of bollworm larvae on transgenic cotton in South Africa

Annette Bennett[1], Tanya Joffe[2]

[1]Inselele Training CC., Centurion, South Africa, [2]School of Agricultural Science/TIAR, University of Tasmania, Hobart, Australia

Insect-resistant transgenic cotton (Bt cotton) has been available commercially in South Africa since 1998. Cotton SA has since been continuously involved in the dissemination of information on the benefits for farmers of planting Bt cotton. Besides the environmental benefits from reduced spraying, the associated decreased cost of production, together with improved yield result in greater financial benefits for farmers. Due to a variety of reasons, such as drought and the poor price of cotton on the international market, the production of cotton in South Africa has fallen, however, for many small-scale farmers and dryland commercial farmers, cotton is a preferred choice since it can be cultivated under dryland conditions when few other crops can be planted. The major pest problem on cotton in South Africa is the bollworm complex, made up of the African bollworm *Helicoverpa armigera*, Red bollworm *Diparopsis castanea* and spiny bollworms *Earias biplaga* and *E. insulana*, but with the introduction of Bt cotton, this has been largely eliminated. However, it is vital that farmers continue to scout their cotton and take note of the adapted threshold value for the number of bollworms present on Bt cotton, which is considered to be five or more plants with one or more bollworm larvae present per 24 plants scouted, as opposed to the threshold on conventional cotton of five or more bollworm larvae present per 24 plants scouted. This threshold has been introduced since stress conditions, such as drought, flooding or excessive weeds, can cause some Bt plants to exhibit a lower expression of the Bt gene, resulting in the survival of some larger bollworm larvae on those plants, or larvae may originate from neighbouring weeds or other host plants. Scouting techniques therefore remain essential in both commercial and small-scale farmer setups, with the use of the pegboard system encouraged for illiterate scouts.

POSTER PRESENTATION

Evaluation of the novel insecticide, chlorantraniliprole, applied to the soil for systemic control of lepidopteran pests of vegetables

Thomas P. Kuhar, Helene Doughty

Dept. of Entomology, Virginia Tech Eastern Shore Agricultural Research and Extension Center, Painter, Virginia, United States

Introduction: Application of systemic insecticides through trickle irrigation systems offers several potential advantages over foliar applications, including reduced worker exposure to pesticides, reduced risk to beneficial arthropods, and longer residual control. Chlorantraniliprole (= Rynaxypyr™, Dupont) is a novel systemic insecticide from a new class, the anthranilic diamides. This new class of insecticides activates the insect ryanodine receptors that play a critical role in muscle function. The insecticide has extremely low mammalian toxicity and is a promising new tool for use in food crops such as vegetables.

Methods: Field efficacy experiments and bioassays were conducted in Virginia (USA) on tomatoes, cabbage, and peppers for control of a variety of lepidopteran pests.

Results: Soil-applied chlorantraniliprole provided excellent control of tomato fruitworm (*Helicoverpa zea*) on tomato, European corn borer (Ostrinia nubilalis) on pepper, and a variety of lepidopteran pests on cabbage.

Conclusion: Chlorantraniliprole offers a novel and versatile new insecticide tool for control of lepidopteran pests on vegetable crops.

POSTER PRESENTATION

Reducing food miles: an investigation of gardening by a sedentary caddisfly.

N.L Ings, A.G Hildrew, J. Grey

School of Biological and Chemical Sciences, Queen Mary, University of London, London, United Kingdom

Sedentary macroinvertebrates face a trade-off between the benefits gained from defending food close to their homes and the costs of defence. Therefore, sedentary organisms are likely to be most successful at sites with intermediate food levels and replenishment rates. However, it has been suggested that sedentary grazers such as the caseless caddis larva *Tinodes waeneri* (Trichoptera), which can form a dominant component of the stony littoral community of lakes, may overcome this restriction through manipulating food resources within its feeding territory, *i.e.* gardening.

T. waeneri build galleries of silk bound sediment which were assumed simply to provide protection for the larva. However, it has been postulated that nutrients secreted by larvae might fertilize algae growing on gallery walls providing the larvae with a better quality or quantity of food. We tested this hypothesis by analysing the carbon and nitrogen stable isotope ratios of larvae, their galleries and the biofilm on rocks collected from six lakes spread across a natural nutrient gradient.

We found evidence of nutrient recycling within the *Tinodes* gallery community. Galleries were ^{15}N-depleted compared to the rock biofilm, suggesting that algae on the gallery walls preferentially assimilated ^{14}N from larval excretions that would themselves have been ^{15}N-depleted relative to the larval food source. In addition, mixing models suggest that galleries formed an important carbon and nitrogen source for the larvae. These results provide evidence that *T. waeneri* galleries can act as a garden. This has important implications for community structure and ecosystem function within the littoral of lakes.

POSTER PRESENTATION

Butterflies as environmental indicators for Argentinean Semiarid Chaco

Liliana Didato[1], José Martín-Cano[2] & Andrea Fuster[1]

[1]Facultad de Ciencias Forestales, Univ. Nacional de Santiago del Estero. Sgo. del Estero. Argentina, [2]Departamento de Biología, Universidad Autónoma de Madrid, Spain

Introduction. Semiarid Chaco is a vast region from North Argentina that enlarges until bordering zones. This region is undergoing important transformations during the last years. Forests are being overexploited and great part of these forests is being deforested and replaced by intensive crops. In order to find a balance and a sustainable exploitation it's imperative to have knowledge of the biodiversity and so be able to measure the loss caused by these changes.

Butterflies, due to their colourful look and their well known taxonomy, are one of the easiest animals to watch. On the other hand, butterflies have a high number of species and their high ability to move and ecological requirements get them to be excellent indicators of ecosystem conservation und habitat destruction. This is why they have been chosen as indicators of Chaco Semiarid's modifications.

Material and Methods. Sampling took place during the summertime in the location of Santos Lugares in Alberdi's Department. The method used has been a periodic cover across transects with entomological net and Malaise traps.

Results. Between the most important observed species we emphasize *Ascia manuste* (Pieridae), *Junonia varete hilaris* and *Anartia jatrophae jatrophae* (Nymphalidae), *Libytheana carinenta, Strimon argona* (Lycaenidae) and *Pyrgus alleus* (Hesperiidae).

POSTER PRESENTATION

Cape Ground Squirrel (*Xerus inauris*) influence on invertebrate biodiversity

Corris M. Kaapehi[1], Tharina L. Bird[2], Jim Roth[3] And Jane M Waterman[3]

[1]Department of Agriculture and Nature Conservation, Faculty of Natural Resource Management, Polytechnic of Namibia, Namibia, [2]National Museum of Namibia, Department of Arachnida and Myriapoda, Namibia, [3]Department of Biology, University of Central Florida, Florida, USA

Introduction: The two concepts 'keystone species' and 'ecosystem engineers' are interrelated in that they both refer to the concept of a single or multiple species, having disproportionately large affects on the organization and functioning of ecosystems. Keystone species include species whose effects are direct for example through predator/prey relationships, or indirect through ecosystem engineering by altering succession and composition of ecosystems. Squirrels dig extensive burrow systems that persist year-round. Grass is also removed in the immediate burrow area. We wanted to determine whether Cape ground squirrels (*X. inauris*) are keystone species in terms of their burrowing modifying the habitat to shelter provision and habitat improvement for invertebrates.

Methods: The abundance (how many individuals were trapped) and diversity (number of species) of four invertebrate groups (spiders, beetles, Orthoptera and ants) were compared inside and outside (control) areas occupied by squirrel colonies. Data was collected over two seasons, winter 2007 and summer 2008 in the pro-Namib region of Namibia. Here the winter data is presented.

Results: The four invertebrate groups sampled showed no significant differences in terms of abundance between the colony and control areas. Beetles showed a significantly lower number of species and Orthoptera a significantly higher number of species in the colony areas.

Conclusions: Cape ground squirrels appear to influence the biodiversity of invertebrates at their colonies, but more data is required to make firm conclusions, specifically with regards to seasonal variations.

Morphological dimorphism in carabid beetles living on land snails

Junji Konuma[1], Satoshi Chiba[2]

[1]Department of Zoology, Graduate School of Science, Kyoto University, Sakyo, Kyoto, Japan, [2]Department of Ecology and Evolutionary Biology, Graduate School of Life Sciences, University of Tohoku, Aobayama, Sendai, Japan

Introduction: Morphological dimorphism, known as macrocephalism and stenocephalism, is observed in carabid beetles living on land snails. Macrocephalic type is the beetles whose head is wide enlarged, while stenocephalic type is the beetles whose head is slender elongated. Such dimorphism is not found in the carabid beetles living on insect larvae and earth worms. Why did this dimorphism evolve in the carabid beetles living on land snails?

Methods: We examined the feeding behavior of representative malacophagous carabid beetles, *Damaster blaptoides*. This species is composed of large-headed subspecies and small-headed subspecies, and no intermediate beetle exists in the wild. We developed hybrids between large-headed and small-headed beetles, and intermediate lines in the laboratory. The feeding performance of these beetles was examined experimentally.

Results: Large-headed beetles could readily crush snail shells with their powerful biting, but could not insert their oversized heads into the shells. In contrast, small-headed beetles could insert their heads into the shells for direct predation on snail bodies, but poorly crushed the shells because of their frugal biting. Intermediate beetles had lower performance than large-headed beetles in crushing snail shells, and had lower performance than small-headed beetles in inserting their head into snail shells.

Conclusions: Intermediate beetles had lower performance than large-headed and small-headed beetles in each feeding behavior. This result implies that disruptive selection could occur in the beetle head size. The functional trade-off in feeding behavior would result in morphological dimorphism in carabid beetles living on land snails.

Effects of Break-thru® and an oil emulsion on the efficacy of *Beauveria bassiana* for the control of red spider mite, *Tetranychus urticae* Koch

Celestin M. Gatarayiha, Mark D. Laing, Brendon Neumann, Mike Morris, Ray Miller

[1]University of KwaZulu Natal, School of Biochemistry, Genetics, Microbilogy and Plant Pathology, Pietermaritburg, South Africa, [2]Plant Healty Products (Pty) Ltd., Pietermaritzburg, South Africa, [3]University of KwaZulu Natal, School of Biological and Conservation Sciences, Pietermaritzburg, South Africa

Introduction: The fungus *Beauveria bassiana* has potential use in controlling red spider mite, *Tetranychus urticae*. In this study, Isolate R444 of *B. bassiana* was used to control the pest on cucumbers. Effects of two carriers (Break-thru® and oil emulsion) on the efficacy of the isolate were compared.

Methods: Pure conidia at different concentrations ($5x10^8$; $5x10^7$; $5x10^6$ and $5x10^5$ conidia ml^{-1}) were suspended either in Break-thru® (0.01%) or an oil-based emulsion and sprayed on leaves 2wk after pest inoculation. Two sprays were performed at the interval of 1wk and counts of dead individuals (both motile and egg stages) were made 7d after every spray.

Results: High rate ($5x10^8$ spores ml^{-1}) resulted in the best control where, in average, 85.7 and 59.7 % of adult population were killed in Break-thru® and oil emulsion respectively; similarly 39.8 and 35% of juveniles were killed. In general, there was less mortality of juveniles compared to adults; and no mortality was observed on egg stage for the tested treatments. Break-thru® and oil applied alone did not significantly differ from the untreated control. And when *B. bassiana* was applied in water only the mortality of adult mites was <40%, suggesting that the two surfactants increased the efficacy of the fungus. However, *Beauveria* conidia applied in Break-thru® solution were more efficacious than the mineral oil as measured by greater mortality of mites observed.

Conclusion: Use of Break-thru® as a carrier can be one of the strategies for the efficiency of *B. bassiana* in the management of *T. urticae*.
