Multifluid Brazed Aluminum Heat Exchangers

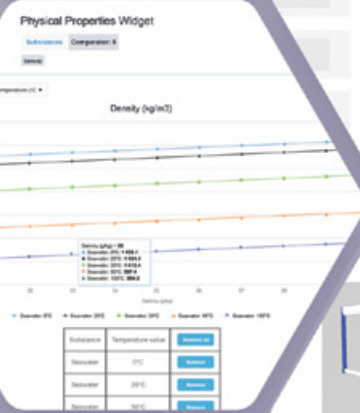

Ralph L. Webb

Large brazed aluminum plate-fin heat exchangers are frequently used in applications involving three or four fluid streams. Typical applications include the liquefaction or separation of gas mixtures. They are used extensively in the production of petrochemicals, natural gas processing (NGL), and liquefied natural gas (LNG). Their compact design yields minimum size and surface area for environmental heat loads.

The brazed aluminum heat exchanger is ideally suited for this service. Applications may involve high heat transfer and pressure drop requirements for each stream are satisfied by varying the tube length and the number of flow channels. Further, bidders can specify a tube length of 1.8 m (6 ft) or more. The number of flow channels is limited by the tube diameter. Header tubes are required to accommodate the flow distribution and to collect the fluid from the tubes. Header tubes are located at the inlet and outlet of the heat exchanger. The size of the header tubes is limited by the vendor's standard sizes. The size of the header tubes is limited by the vendor's standard sizes. **HEAT EXCHANGER
DESIGN HANDBOOK**

**Years of History and
Editorial Influence**

The Heat Exchanger Design Handbook (HEDH) had its origins in the 1970s when, under the leadership of the two founding editors, Professor Ernst Schlünder and Prof. Geoffrey F. Hewitt, a group of leading authorities in the fields of heat transfer and fluid flow began to discuss the possibility of producing a handbook dealing with all aspects of heat exchanger design and operations including the basic design methodology, the associated heat transfer and fluid flow technology and the physical data required for design.

HEDH's first edition, published in 1983 by Hemisphere Publishing Corporation, contained about 1500 pages of original material structured in five parts covering: (i) heat exchanger theory and generic application technology, (ii) fluid mechanics and heat transfer, (iii) thermal and hydraulic design of heat exchangers, (iv) mechanical design of heat exchangers and (v) physical properties. Ever since the first edition was released, the editors strived to keep the content up-to-date which in-

cluded progress on cutting edge fundamental research and progressively add material on applications that were becoming available in the market.

Four major editions followed the first 1983 release. Over the years, HEDH has progressively grown in number of volumes and pages (over 6,000 in the latest 2008 edition) by including detailed information not only on all the major types of heat exchangers (e.g. shell-and-tube, compact, condensers, reboilers, furnaces etc.) but also on special types (e.g. evaporators, heat pipes, waste heat boilers), heat transfer enhancement devices (e.g. tube inserts, dimpled surfaces etc.) and on fundamental theory. Today, HEDH is regarded by many specialists around the world as the standard reference source for design and other information on heat transfer, heat exchangers, and associated technologies.

Heat Exchanger Design > Shell-and-Tube > Mechanical Design > Shell-and-Tube Heat Exchangers: Elements of Construction

Introduction

E. A. D. Saunders

A variety of unfired heat transfer equipment is used in industry, but the most common is the shell-and-tube exchanger. Although it is not especially compact, it has the advantage of being robust and versatile. Except for the special-purpose finned tube air cooler, it is usually the only design that can be considered for large surface areas, pressures greater than 2 MN/m², and temperatures greater than 250° C.

As the name implies, a shell-and-tube heat exchanger consists of a shell (pressure vessel) containing a tube bundle, which is attached to stationary and rear heads. The tubes, which are attached to tube sheets, may be plain or finned, and run parallel to the longitudinal axis of the shell.

An unlinked port can be used to mark the end of a pass, and in Figure 2 it port is left unlinked in each of the two middle plates so that the eight plates form a two-pass/two-pass arrangement. Suitable disposition of these unlinked ports enables any combination and any size of pass to be achieved: the significance of this is discussed in Section 210E.

(c) Effect of impingement plate

There are occasions when it is necessary to fit an impingement plate to the inlet nozzle. The purpose of the impingement plate is to protect the tubes directly in line with the inlet nozzle from the abrading effects of the jet of fluid.

An impingement plate is normally fitted when the value of ρv^2 exceeds

0.00745 bar
745 newton/square meter
745 pascal
5.5879594699674 torr

- Noncorrosive, nonabrasive, single-phase fluids: 2,235 N/m^2
- All other liquids, including a liquid at its boiling point: 745 N/m^2

For all other gases and vapors and two-phase mixtures, impingement protection is required regardless of the value of ρv^2 .

The impingement plate is normally positioned not less than $D_n/4$ below the lower tip of the nozzle, as shown in Figure 6, which means that there is no change in flow area caused by the impingement plate. Under such circumstances the static pressure change is given approximately by the normal equation for a square right-angled bend:

Figure 6 Position of impingement plate.

Correlation of heat transfer and friction data

Ralph L. Webb

Although performance data are normally presented on a surface-by-surface basis, considerable progress has been made in prediction or correlation of surface performance. Analytical solutions exist for most possible plain fin geometries in laminar flow regions as discussed in Section 3.9.5. In the turbulent flow region, the hydraulic diameter is the significant dimension. One may predict the turbulent region j and f characteristics of plain fin geometries using the hydraulic diameter. This will generally give good results, except for isosceles triangular channels having a very small apex angle. This section gives heat transfer and friction correlations for wavy, offset-strip, and

Wavy and Herringbone Fin

The wavy and herringbone fin geometries are geometrically similar to the herringbone wave form is that of a chevron and the wavy is in the form of a smooth wave. [Dong, J., Chen, Z., Chen, Y., Zhou, and W. Zhang \(2007\)](#) provide an empirical power law correlation for herringbone fins. Their correlation is based on data for 11 herringbone fin geometries. The j and f versus Re_{D_h} correlations are given by

$$j = 0.0836 Re_{D_h} \left(\frac{Pr}{b}\right)^{0.1284} \left(\frac{Pr}{2c_w}\right)^{-0.153} \left(\frac{L}{P_w}\right)^{-0.326} \quad (1)$$

$$f = 1.16 Re_{D_h} \left(\frac{Pr}{b}\right)^{0.3703} \left(\frac{Pr}{2c_w}\right)^{-0.25} \left(\frac{L}{P_w}\right)^{-0.1152} \quad (2)$$

Plate fin surface geometries

Introduction and fundamentals

K. Gersten

A. Equations governing the motion of a fluid

(a) Basic concepts and definitions

A fluid is considered a continuous isotropic substance, the individual elements of which continue the result of applied tangential surface stresses. Fluids comprise both liquids and gases.

Although fluid matter, whether liquid or gaseous, is discrete on a microscopic - i.e., molecular - coarseness - and will be done in the following - to consider small fluid elements to contain many so work with the average statistical properties of such large numbers of molecules, that is, the direct structure is not taken into account but is replaced by a continuous model of the fluid, assuming the relevant length scale considered is still very large compared with the average intermolecular distance of fluids. †

† The continuous model is valid for gases so long as the Knudsen number is small, i.e., $Kn = \lambda / L \ll 1$, where λ is the mean free path, and L is the characteristic length of the flow field, see Schlichting and Gersten (1979), Schlichting (1979).

The physical behavior of a fluid can be described by its thermodynamic and transport properties. The such a continuous property of the fluid, defined by the following limiting process, which is typical in mechanics:

$$\rho = \lim_{\Delta V \rightarrow 0} \frac{\Delta M}{\Delta V}$$

According to this definition, the density is the ratio of mass to volume for the case in which the volume is an extremely small value but remains large enough to contain a large number of molecules.

The continuous local properties describing the behavior of the fluid that may depend on the temperature T and the pressure p are as follows:

Thermodynamic properties:
 Density: ρ
 Speed of sound: $c_{sound} = \sqrt{\frac{\partial p}{\partial \rho}}_{T,s}$
 Heat capacity: $c_p = \frac{\partial h}{\partial T}_{p,c}$, $c_v = \frac{\partial u}{\partial T}_{v,c}$
 Coefficient of expansion: $\beta = -\frac{1}{\rho} \left(\frac{\partial \rho}{\partial T}\right)_{p,c}$

Plate fin surface geometries

Ralph L. Webb

Figure 1 shows typical surface geometries used for heat transfer to gases in compact plate-fin heat exchangers. The figure shows six basic types of surface geometry, and defines the geometric variables associated with each type. By varying the basic geometric variables for each type of surface, it is possible to obtain a wide variety of specific surface geometries. Although typical fin pitches are five to eight fins per centimeter, applications may exist for as many as 1200 fins per meter in automotive applications. Fin thicknesses of 0.1–0.25 mm are common. Fin heights may range from 0.25 to 2 cm. A plate-fin exchanger with 600 fins per meter provides about 1300 m²/m³ of heat transfer surface per cubic meter of volume. Such a heat exchanger would contain 10 times as much heat transfer surface per unit volume as in a typical shell-and-tube heat exchanger having 19 mm diameter tubes. Operated at a frontal velocity of 3 m/s, the heat transfer coefficient based on prime surface area would be on the order of 1800 W/m² K.
